and $\langle F_\alpha|F_\alpha\rangle=1$ exactly. As for the off-diagonal elements, the semiclassical Darboux–Christoffel formula, Eq. (2.25), predicts that $\Delta_\alpha(x_\beta)=O(\hbar)$, and Eq. (3.4) predicts that $K_\alpha=O(1/\hbar)$. Thus, if the semiclassical expressions we have derived are correct, we expect

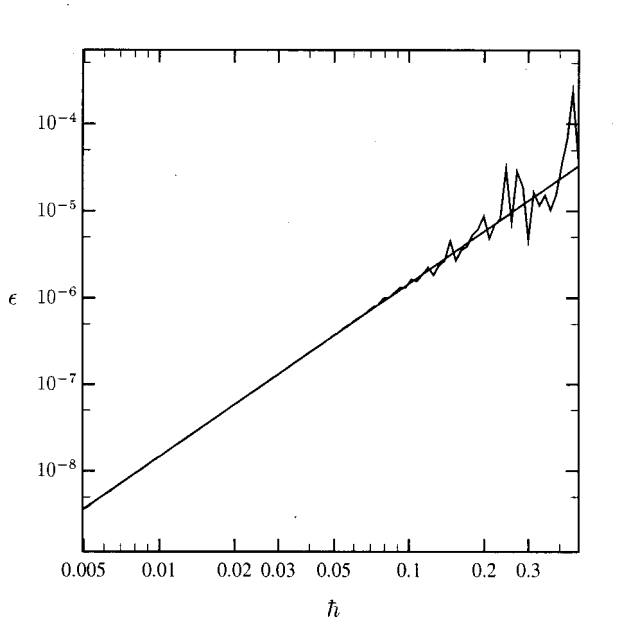

FIG. 1. The rms off-diagonal element in one column of the matrix $\langle F_\alpha|F_\beta\rangle$ is plotted as a function of $\hbar$. The column chosen was the one for which the root x_α was closest to $x=0$. Also plotted is a straight line of slope 2, passing through the data point at the smallest value of $\hbar$. The theory predicts a slope of 2, which is well verified by the data.

$$\langle F_\alpha | F_\beta \rangle = \begin{cases} 1, & \alpha = \beta \\ O(\hbar^2), & \alpha \neq \beta. \end{cases} \tag{3.14}$$

We tested these predictions for the off-diagonal elements by computing the matrix $\langle F_\alpha | F_\beta \rangle$ for various values of $\hbar$. We found that the off-diagonal elements were all approximately of the same order of magnitude, and all much less than the diagonal elements (which are exactly unity) when $\hbar$ is small. Figure 1 contains a log–log plot of the rms value of the off-diagonal elements of this matrix in a central column (near $x=0$), as a function of $\hbar$. According to Eq. (3.14), this value should scale as $\hbar^2$, that is, the curve should be a straight line with a slope of 2 on the plot. Also shown in Fig. 1 is a straight line passing through the point at the smallest value of $\hbar$ with a slope of exactly 2. It will be seen that this straight line provides a good fit to the data, confirming the predicted dependence of the off-diagonal elements of the matix on $\hbar$.

There is the question of whether the approximate LM/DVR functions that are constructed by the methods we have described can be useful in practice. In this regard we point out the work of Lado,[45] Johnson,[46] and Lemoine,[26] in which approximate LM/DVR functions are constructed from the radial eigenfunctions of a particle in a spherical box. These eigenfunctions are not orthogonal polynomials (times the square root of any weighting function), so LM/DVR functions in the usual sense do not exist. But these authors note that a certain matrix, which in the language of this paper is $U_{n\alpha} = \langle \psi_n | F_\alpha \rangle$, is approximately orthogonal, a fact that is equivalent to the approximate orthonormality of the functions $F_\alpha(x)$ as indicated by Eq. (3.14). The functions $F_\alpha(x)$ then turn out to be useful in an approximately unitary, discretized version of the Hankel transform.

IV. CONCLUSIONS

In summary, we have explained the importance of the Darboux–Christoffel formula for the theory of ''Lagrangian mesh'' or ''discrete variable representation'' (LM/DVR) basis sets and we have outlined a semiclassical area rule that suggests that a semiclassical generalization of the Darboux–Christoffel formula should exist. We have then used Green's functions and semiclassical techniques to derive that generalization, which involves the eigenfunctions of one-dimensional, time-reversal invariant systems for which tunneling can be ignored. The result differs in part from the exact Darboux–Christoffel formula by replacing the $x-y$ denominator by $\cos\theta(x) - \cos\theta(y)$, in which θ is the classical angle variable, measured with respect to the left turning point. We have shown how semiclassical approximations to LM/DVR basis functions can be created. We have also taken the continuum limit of the semiclassical Darboux–Christoffel formula, and outlined how it is equivalent to certain exact relations that hold for Bessel and Airy functions. Finally, we have carried out numerical calculations that confirm the expected $\hbar$ dependence of certain quantities (the off-diagonal elements of the overlap matrix of the approximate LM/DVR functions).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 10 OCTOBER 2002

The two-dimensional hydrogen atom revisited

D. G. W. Parfitt and M. E. Portnoi[a)]
School of Physics, University of Exeter, Stocker Road, Exeter EX4 4QL, United Kingdom

(Received 20 May 2002; accepted for publication 2 June 2002)

The bound-state energy eigenvalues for the two-dimensional Kepler problem are found to be degenerate. This ''accidental'' degeneracy is due to the existence of a two-dimensional analog of the quantum-mechanical Runge–Lenz vector. Reformulating the problem in momentum space leads to an integral form of the Schrödinger equation. This equation is solved by projecting the two-dimensional momentum space onto the surface of a three-dimensional sphere. The eigenfunctions are then expanded in terms of spherical harmonics, and this leads to an integral relation in terms of special functions which has not previously been tabulated. The dynamical symmetry of the problem is also considered, and it is shown that the two components of the Runge–Lenz vector in real space correspond to the generators of infinitesimal rotations about the respective coordinate axes in momentum space.

I. INTRODUCTION

A semiconductor quantum well under illumination is a quasi-two-dimensional system, in which photoexcited electrons and holes are essentially confined to a plane. The mutual Coulomb interaction leads to electron–hole bound states known as excitons, which are extremely important for the optical properties of the quantum well. The relative in-plane motion of the electron and hole can be described by a two-dimensional Schrödinger equation for a single particle with a reduced mass. This is a physical realization of the two-dimensional hydrogenic problem, which originated as a purely theoretical construction.[1] An important similarity with the three-dimensional hydrogen atom is the ''accidental'' degeneracy of the bound-state energy levels. This degeneracy is due to the existence of the quantum-mechanical Runge–Lenz vector, first introduced by Pauli[2] in three dimensions, and indicates the presence of a dynamical symmetry of the system.

The most important study relating to the hidden symmetry of the hydrogen atom was that by Fock in 1935.[3] He considered the Schrödinger equation in momentum space, which led to an integral equation. Considering negative-energy (bound-state) solutions, he projected the three-dimensional momentum space onto the surface of a four-dimensional hypersphere. After a suitable transformation of the wavefunction, the resulting integral equation was seen to be invariant under rotations in four-dimensional momentum space. Fock deduced that the dynamical symmetry of the hydrogen atom is described by the four-dimensional rotation group SO(4), which contains the geometrical symmetry SO(3) as a subgroup. He related this hidden symmetry to the observed degeneracy of the energy eigenvalues.

Shortly afterwards, Bargmann[4] made the connection between Pauli's quantum mechanical Runge–Lenz vector and Fock's discovery of invariance under rotations in four-dimensional momentum space. Fock's method was also extended by Alliluev[5] to the case of d dimensions ($d \geqslant 2$). A comprehensive review concerning the symmetry of the hydrogen atom was later given by Bander and Itzykson,[6,7] including a detailed group-theoretical treatment and extension to scattering states.

Improvements in semiconductor growth techniques over the subsequent decades, which enabled the manufacture of effectively two-dimensional structures, led to a resurgence of interest in

[a)]Also at A.F. Ioffe Physico-Technical Institute, St. Petersburg, Russia. Electronic mail: m.e.portnoi@ex.ac.uk

the two-dimensional hydrogen atom. The Runge–Lenz vector for this case was defined for the first time,[8] and real-space solutions of the Schrödinger equation were applied to problems of atomic physics in two dimensions.[9]

Recent studies have focused on diverse aspects of the hydrogenic problem. The *d*-dimensional case has been reconsidered, leading to a generalized Runge–Lenz vector (see Ref. 10 and references therein). The algebraic basis of the dynamical symmetry has also been given a thorough mathematical treatment.[11,12]

In the present work we return to the two-dimensional problem, and use the method of Fock to obtain a new integral relation in terms of special functions. The dynamical symmetry of the system is also considered, and a new interpretation of the two-dimensional Runge–Lenz vector is presented.

II. PROBLEM FORMULATION

A. Preliminaries

The relative in-plane motion of an electron and hole, with effective masses m_e and m_h, respectively, may be treated as that of a single particle with reduced mass $\mu = m_e m_h/(m_e+m_h)$ and energy E, moving in a Coulomb potential $V(\rho)$. The wavefunction of the particle satisfies the stationary Schrödinger equation

$$\hat{H}\Psi(\boldsymbol{\rho}) = \left[-\frac{1}{\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial}{\partial\rho}\right) - \frac{1}{\rho^2}\frac{\partial^2}{\partial\phi^2} + V(\rho)\right]\Psi(\boldsymbol{\rho}) = E\Psi(\boldsymbol{\rho}), \tag{1}$$

where (ρ,ϕ) are plane polar coordinates. Note that excitonic Rydberg units are used throughout this article, which leads to a potential of the form $V(\rho) = -2/\rho$.

The eigenfunctions of Eq. (1) are derived in Appendix A. It is well known that the bound-state energy levels are of the form[1]

$$E = -\frac{1}{(n+\frac{1}{2})^2}, \quad n = 0,1,2,..., \tag{2}$$

where n is the principal quantum number. Notably, Eq. (2) does not contain explicitly the azimuthal quantum number m, which enters the radial equation [see Appendix A, Eq. (A4)]. Each energy level is $(2n+1)$-fold degenerate, the so-called accidental degeneracy.

It is convenient to introduce a vector operator corresponding to the z-projection of the angular momentum, $\hat{\mathbf{L}}_z = \mathbf{e}_z\hat{L}_z$, where $\mathbf{e}_z$ is a unit vector normal to the plane of motion of the electron and hole. We now introduce the two-dimensional analog of the quantum-mechanical Runge–Lenz vector as the dimensionless operator

$$\hat{\mathbf{A}} = (\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z - \hat{\mathbf{L}}_z\times\hat{\mathbf{q}}) - \frac{2}{\rho}\boldsymbol{\rho}, \tag{3}$$

where $\hat{\mathbf{q}} = -i\nabla$ is the momentum operator. Note that $\hat{\mathbf{A}}$ lies in the plane and has Cartesian components $\hat{A}_x$ and $\hat{A}_y$.

$\hat{L}_z$, $\hat{A}_x$, and $\hat{A}_y$ represent conserved quantities and therefore commute with the Hamiltonian:

$$[\hat{H},\hat{L}_z] = [\hat{H},\hat{A}_x] = [\hat{H},\hat{A}_y] = 0. \tag{4}$$

They also satisfy the following commutation relations:

$$[\hat{L}_z,\hat{A}_x] = i\hat{A}_y, \tag{5}$$

$$[\hat{L}_z,\hat{A}_y] = -i\hat{A}_x, \tag{6}$$

$$[\hat{A}_x,\hat{A}_y]=-4i\hat{L}_z\hat{H}. \tag{7}$$

B. Derivation of energy eigenvalues from $\hat{A}$

The existence of the noncommuting operators $\hat{A}_x$ and $\hat{A}_y$, representing conserved physical quantities, implies that the Runge–Lenz vector is related to the accidental degeneracy of the energy levels in two dimensions.[13] We now present a simple interpretation of the hidden symmetry underlying this degeneracy.

For eigenfunctions of the Hamiltonian we can replace $\hat{H}$ by the energy E, and defining

$$\hat{\mathbf{A}}'=\frac{\hat{\mathbf{A}}}{2\sqrt{-E}}, \tag{8}$$

we obtain the new commutation relations:

$$[\hat{L}_z,\hat{A}'_x]=i\hat{A}'_y, \tag{9}$$

$$[\hat{L}_z,\hat{A}'_y]=-i\hat{A}'_x, \tag{10}$$

$$[\hat{A}'_x,\hat{A}'_y]=i\hat{L}_z. \tag{11}$$

If we now construct a three-dimensional vector operator

$$\hat{\mathbf{J}}=\hat{\mathbf{A}}'+\hat{\mathbf{L}}_z, \tag{12}$$

then the components of $\hat{\mathbf{J}}$ satisfy the commutation rules of ordinary angular momentum:

$$[\hat{J}_j,\hat{J}_k]=i\epsilon_{jkl}\hat{J}_l, \tag{13}$$

where ϵ_{jkl} is the Levi-Civita symbol.

Noting that $\hat{\mathbf{A}}'\cdot\hat{\mathbf{L}}_z=\hat{\mathbf{L}}_z\cdot\hat{\mathbf{A}}'=0$, we have

$$\hat{\mathbf{J}}^2=(\hat{\mathbf{A}}'+\hat{\mathbf{L}}_z)^2=\hat{\mathbf{A}}'^2+\hat{\mathbf{L}}_z^2, \tag{14}$$

where the operator $\hat{\mathbf{J}}^2$ has eigenvalues $j(j+1)$ and commutes with the Hamiltonian.

We now make use of a special expression relating $\hat{\mathbf{A}}^2$ and $\hat{\mathbf{L}}_z^2$, the derivation of which is given in Appendix B:

$$\hat{\mathbf{A}}^2=\hat{H}(4\hat{\mathbf{L}}_z^2+1)+4. \tag{15}$$

Substituting in Eq. (14) and again replacing $\hat{H}$ with E, we obtain

$$\hat{\mathbf{J}}^2=-\frac{1}{4E}[E(4\hat{\mathbf{L}}_z^2+1)+4]+\hat{\mathbf{L}}_z^2. \tag{16}$$

Because $[\hat{H},\hat{\mathbf{J}}^2]=0$, an eigenfunction of the Hamiltonian will also be an eigenfunction of $\hat{\mathbf{J}}^2$. Operating with both sides of Eq. (16) on an eigenfunction of the Hamiltonian, we obtain for the eigenvalues of $\hat{\mathbf{J}}^2$:

$$j(j+1)=-\left(\frac{1}{4}+\frac{1}{E}\right). \tag{17}$$

Rearranging, and identifying j with the principal quantum number n, we obtain the correct expression for the energy eigenvalues:

$$E=-\frac{1}{(n+\frac{1}{2})^2}, \quad n=0,1,2,\ldots. \tag{18}$$

Note that the z-component of $\hat{\mathbf{J}}$ is simply $\hat{L}_z$. Recalling that the eigenvalues of $\hat{L}_z$ are denoted by m, there are $(2j+1)$ values of m for a given j. However, as $j=n$, we see that there are $(2n+1)$ values of m for a given energy, which corresponds to the observed $(2n+1)$-fold degeneracy.

III. FOCK'S METHOD IN TWO DIMENSIONS

A. Stereographic projection

The method of Fock,[3] in which a three-dimensional momentum space is projected onto the surface of a four-dimensional hypersphere, may be applied to our two-dimensional problem. We begin by defining a pair of two-dimensional Fourier transforms between real space and momentum space:

$$\Phi(\mathbf{q})=\int \Psi(\boldsymbol{\rho})e^{i\mathbf{q}\cdot\boldsymbol{\rho}}\,d\boldsymbol{\rho}, \tag{19}$$

$$\Psi(\boldsymbol{\rho})=\frac{1}{(2\pi)^2}\int \Phi(\mathbf{q})e^{-i\mathbf{q}\cdot\boldsymbol{\rho}}\,d\mathbf{q}. \tag{20}$$

We shall restrict our interest to bound states, and hence the energy $E=-q_0^2$ will be negative.

Substitution of Eq. (20) in Eq. (1) yields the following integral equation for $\Phi(\mathbf{q})$:

$$(q^2+q_0^2)\Phi(\mathbf{q})=\frac{1}{\pi}\int \frac{\Phi(\mathbf{q}')\,d\mathbf{q}'}{|\mathbf{q}-\mathbf{q}'|}. \tag{21}$$

The two-dimensional momentum space is now projected onto the surface of a three-dimensional unit sphere centered at the origin, and so it is natural to scale the in-plane momentum by q_0. Each point on a unit sphere is completely defined by two polar angles, θ and ϕ, and the Cartesian coordinates of a point on the unit sphere are given by

$$u_x=\sin\theta\cos\phi=\frac{2q_0q_x}{q^2+q_0^2}, \tag{22}$$

$$u_y=\sin\theta\sin\phi=\frac{2q_0q_y}{q^2+q_0^2}, \tag{23}$$

$$u_z=\cos\theta=\frac{q^2-q_0^2}{q^2+q_0^2}. \tag{24}$$

An element of surface area on the unit sphere is given by

$$d\Omega=\sin\theta\;d\theta\;d\phi=\left(\frac{2q_0}{q^2+q_0^2}\right)^2 d\mathbf{q}, \tag{25}$$

and the distance between two points transforms as

$$|\mathbf{u}-\mathbf{u}'|=\frac{2q_0}{(q^2+q_0^2)^{1/2}(q'^2+q_0^2)^{1/2}}|\mathbf{q}-\mathbf{q}'|. \tag{26}$$

If the wavefunction on the sphere is expressed as

$$\chi(\mathbf{u})=\frac{1}{\sqrt{q_0}}\left(\frac{q^2+q_0^2}{2q_0}\right)^{3/2}\Phi(\mathbf{q}), \tag{27}$$

then Eq. (21) reduces to the simple form

$$\chi(\mathbf{u})=\frac{1}{2\pi q_0}\int\frac{\chi(\mathbf{u}')\,d\Omega'}{|\mathbf{u}-\mathbf{u}'|}. \tag{28}$$

B. Expansion in spherical harmonics

Any function on a sphere can be expressed in terms of spherical harmonics, so for $\chi(\mathbf{u})$ we have

$$\chi(\mathbf{u})=\sum_{l=0}^{\infty}\sum_{m=-l}^{l}A_{lm}Y_l^m(\theta,\phi), \tag{29}$$

where $Y_l^m(\theta,\phi)$ are basically defined as in Ref. 14:

$$Y_l^m(\theta,\phi)=c_{lm}\sqrt{\frac{2l+1}{4\pi}\frac{(l-|m|)!}{(l+|m|)!}}P_l^{|m|}(\cos\theta)e^{im\phi}, \tag{30}$$

where $P_n^{|m|}(\cos\theta)$ is an associated Legendre function as defined in Ref. 15. The constant c_{lm} is an arbitrary "phase factor." As long as $|c_{lm}|^2=1$ we are free to choose c_{lm}, and for reasons which will become clear we set

$$c_{lm}=(-i)^{|m|}. \tag{31}$$

The kernel of the integral in Eq. (28) can also be expanded in this basis as[16]

$$\frac{1}{|\mathbf{u}-\mathbf{u}'|}=\sum_{\lambda=0}^{\infty}\sum_{\mu=-\lambda}^{\lambda}\frac{4\pi}{2\lambda+1}Y_\lambda^\mu(\theta,\phi)Y_\lambda^{\mu*}(\theta',\phi'). \tag{32}$$

Substituting Eqs. (29) and (32) into Eq. (28) we have

$$\sum_{l=0}^{\infty}\sum_{m=-l}^{l}A_{lm}Y_l^m(\theta,\phi)=\frac{2}{q_0}\sum_{l_1=0}^{\infty}\sum_{l_2=0}^{\infty}\sum_{m_1=-l_1}^{l_1}\sum_{m_2=-l_2}^{l_2}\int\frac{1}{2l_2+1}A_{l_1m_1}Y_{l_1}^{m_1}(\theta',\phi')\times Y_{l_2}^{m_2}(\theta,\phi)Y_{l_2}^{m_2*}(\theta',\phi')\,d\Omega'. \tag{33}$$

We now make use of the orthogonality property of spherical harmonics to reduce Eq. (33) to the following:

$$\sum_{l=0}^{\infty}\sum_{m=-l}^{l}A_{lm}Y_l^m(\theta,\phi)=\frac{2}{q_0}\sum_{l_1=0}^{\infty}\sum_{m_1=-l_1}^{l_1}\frac{1}{2l_1+1}A_{l_1m_1}Y_{l_1}^{m_1}(\theta,\phi). \tag{34}$$

Multiplying both sides of Eq. (34) by $Y_n^{m'*}(\theta,\phi)$ and integrating over $d\Omega$ gives

$$A_{nm'}=\frac{2}{q_0(2n+1)}A_{nm'}, \tag{35}$$

where we have again used the orthogonality relation for spherical harmonics. The final step is to rearrange for q_0 and identify the index n with the principal quantum number. This enables us to find an expression for the energy in excitonic Rydbergs:

$$E=-q_0^2=-\frac{1}{(n+\frac{1}{2})^2},\quad n=0,1,2,\ldots. \tag{36}$$

This is seen to be identical to Eq. (2).

For a particular value of n, the general solution of Eq. (28) can be expressed as

$$\chi_n(\mathbf{u})=\sum_{m=-n}^{n} A_{nm}Y_n^m(\theta,\phi). \tag{37}$$

Each of the functions entering the sum in Eq. (37) satisfies Eq. (28) separately. So, for each value of n we have $(2n+1)$ linearly independent solutions, and this explains the observed $(2n+1)$-fold degeneracy.

We are free to choose any linear combination of spherical harmonics for our eigenfunctions, but for convenience we simply choose

$$\chi_{nm}(\mathbf{u})=A_{nm}Y_n^m(\theta,\phi). \tag{38}$$

If we also require our eigenfunctions to be normalized as follows:

$$\frac{1}{(2\pi)^2}\int |\chi(\mathbf{u})|^2\,d\Omega=\frac{1}{(2\pi)^2}\int \frac{q^2+q_0^2}{2q_0^2}|\Phi(\mathbf{q})|^2\,d\mathbf{q}=\int |\Psi(\boldsymbol{\rho})|^2\,d\boldsymbol{\rho}=1, \tag{39}$$

then Eq. (38) reduces to

$$\chi_{nm}(\mathbf{u})=2\pi Y_n^m(\theta,\phi). \tag{40}$$

Applying the transformation in Eq. (27), we can obtain an explicit expression for the orthonormal eigenfunctions of Eq. (21):

$$\Phi_{nm}(\mathbf{q})=c_{nm}\sqrt{2\pi\frac{(n-|m|)!}{(n+|m|)!}}\left(\frac{2q_0}{q^2+q_0^2}\right)^{3/2}P_n^{|m|}(\cos\theta)e^{im\phi}, \tag{41}$$

where we have used the fact that $q_0=(n+\frac{1}{2})^{-1}$, and θ and ϕ are defined by Eqs. (22)–(24).

C. New integral relations

To obtain the real-space eigenfunctions $\Psi(\boldsymbol{\rho})$ we make an inverse Fourier transform:

$$\Psi(\boldsymbol{\rho})=\frac{1}{(2\pi)^2}\int \Phi(\mathbf{q})e^{-i\mathbf{q}\cdot\boldsymbol{\rho}}\,d\mathbf{q}=\frac{1}{(2\pi)^2}\int_0^{2\pi}\int_0^{\infty}\Phi(\mathbf{q})e^{-iq\rho\cos\phi'}q\,dq\,d\phi', \tag{42}$$

where ϕ' is the azimuthal angle between the vectors $\boldsymbol{\rho}$ and $\mathbf{q}$. However, if we now substitute Eq. (41) into this expression, we have to be careful with our notation. The angle labeled ϕ in Eq. (41) is actually related to ϕ' via

$$\phi=\phi'+\phi_\rho, \tag{43}$$

where ϕ_ρ is the azimuthal angle of the vector $\boldsymbol{\rho}$, which can be treated as constant for the purposes of our integration.

Taking this into account, the substitution of Eq. (41) into Eq. (42) yields

$$\Psi(\boldsymbol{\rho})=\frac{c_{nm}}{(2\pi)^{3/2}}\sqrt{\frac{(n-|m|)!}{(n+|m|)!}}e^{im\phi_\rho}\int_0^{2\pi}\int_0^{\infty}\left(\frac{2q_0}{q^2+q_0^2}\right)^{3/2}P_n^{|m|}(\cos\theta)e^{i(m\phi'-q\rho\cos\phi')}q\,dq\,d\phi'. \tag{44}$$

From Eq. (24) we obtain

$$P_n^{|m|}(\cos\theta)=P_n^{|m|}\left(\frac{q^2-q_0^2}{q^2+q_0^2}\right), \tag{45}$$

and we use the following form of Bessel's integral:[16]

$$\int_0^{2\pi} e^{i(m\phi'-q\rho\cos\phi')}\,d\phi'=2\pi(-i)^m J_m(q\rho), \tag{46}$$

where $J_m(q\rho)$ is a Bessel function of the first kind of order m. Substituting Eqs. (45) and (46) into Eq. (44) leads to

$$\Psi(\boldsymbol{\rho})=\frac{c_{nm}(-i)^m}{\sqrt{2\pi}}\sqrt{\frac{(n-|m|)!}{(n+|m|)!}}e^{im\phi_\rho}\int_0^\infty\left(\frac{2q_0}{q^2+q_0^2}\right)^{3/2}P_n^{|m|}\left(\frac{q^2-q_0^2}{q^2+q_0^2}\right)J_m(q\rho)q\,dq. \tag{47}$$

We now make a change of variables, $x=q_0\rho$ and $y=q^2/q_0^2$, so that Eq. (47) becomes

$$\Psi(\boldsymbol{\rho})=c_{nm}(-1)^{n+m}(-i)^m\sqrt{\frac{q_0(n-|m|)!}{\pi(n+|m|)!}}e^{im\phi_\rho}\int_0^\infty P_n^{|m|}\left(\frac{1-y}{1+y}\right)\frac{J_m(x\sqrt{y})}{(1+y)^{3/2}}dy, \tag{48}$$

where we have used the fact that[16]

$$P_n^{|m|}\left(\frac{y-1}{y+1}\right)=(-1)^{n+m}P_n^{|m|}\left(\frac{1-y}{1+y}\right). \tag{49}$$

If we now equate the expression for $\Psi(\boldsymbol{\rho})$ in Eq. (48) with that derived in Appendix A, we obtain the following:

$$c_{nm}(-1)^{n+m}(-i)^m\int_0^\infty P_n^{|m|}\left(\frac{1-y}{1+y}\right)\frac{J_m(x\sqrt{y})}{(1+y)^{3/2}}dy=\frac{(2x)^{|m|}e^{-x}}{n+1/2}L_{n-|m|}^{2|m|}(2x). \tag{50}$$

The value of c_{nm} chosen earlier in Eq. (31) ensures that both sides of Eq. (50) are numerically equal. If we restrict our interest to $m\geqslant 0$, then the relation simplifies to

$$\int_0^\infty P_n^m\left(\frac{1-y}{1+y}\right)\frac{J_m(x\sqrt{y})}{(1+y)^{3/2}}dy=\frac{(-1)^n(2x)^m e^{-x}}{n+1/2}L_{n-m}^{2m}(2x),\quad n,m=0,1,2,\ldots;\ \ m\leqslant n. \tag{51}$$

As far as we can ascertain, this integral relation between special functions has not previously been tabulated. For $n,m=0$ we recover the known integral relation[15]

$$\int_0^\infty\frac{J_0(x\sqrt{y})}{(1+y)^{3/2}}dy=2e^{-x}. \tag{52}$$

IV. DYNAMICAL SYMMETRY

A. Infinitesimal generators

Consider now a vector $\mathbf{u}$ from the origin to a point on the three-dimensional unit sphere defined in Sec. III A. If this vector is rotated through an infinitesimal angle α in the $(u_x u_z)$ plane, we have a new vector

$$\mathbf{u}'=\mathbf{u}+\delta\mathbf{u}, \tag{53}$$

where the components of **u** are given in Eqs. (22)–(24), and

$$\delta\mathbf{u}=\alpha\mathbf{e}_y\times\mathbf{u}. \tag{54}$$

This rotation on the sphere corresponds to a change in the two-dimensional momentum from **q** to **q**′. The Cartesian components of Eq. (53) are then found to be

$$u_x'=\frac{2q_0q_x'}{q'^2+q_0^2}=\frac{2q_0q_x}{q^2+q_0^2}+\alpha\frac{q^2-q_0^2}{q^2+q_0^2}, \tag{55}$$

$$u_y'=\frac{2q_0q_y'}{q'^2+q_0^2}=\frac{2q_0q_y}{q^2+q_0^2}, \tag{56}$$

$$u_z'=\frac{q'^2-q_0^2}{q'^2+q_0^2}=\frac{q^2-q_0^2}{q^2+q_0^2}-\alpha\frac{2q_0q_x}{q^2+q_0^2}, \tag{57}$$

where $q^2=q_x^2+q_y^2$.

After some manipulation we can also find the components of $\delta\mathbf{q}=\mathbf{q}'-\mathbf{q}$:

$$\delta q_x=\alpha\frac{q^2-q_0^2-2q_x^2}{2q_0}, \tag{58}$$

$$\delta q_y=-\alpha\frac{q_xq_y}{q_0}. \tag{59}$$

The corresponding change in $\Phi(\mathbf{q})$ is given by

$$\delta\Phi(\mathbf{q})=\frac{\alpha}{(q^2+q_0^2)^{3/2}}\left(\frac{q^2-q_0^2-2q_x^2}{2q_0}\frac{\partial}{\partial q_x}-\frac{q_xq_y}{q_0}\frac{\partial}{\partial q_y}\right)[(q^2+q_0^2)^{3/2}\Phi(\mathbf{q})]. \tag{60}$$

We can write this as

$$\delta\Phi(\mathbf{q})=-\frac{i}{2q_0}\alpha\hat{\mathcal{A}}_x\Phi(\mathbf{q}), \tag{61}$$

where the infinitesimal generator is given by

$$\hat{\mathcal{A}}_x=\frac{i}{(q^2+q_0^2)^{3/2}}\left[(q^2-q_0^2-2q_x^2)\frac{\partial}{\partial q_x}-2q_xq_y\frac{\partial}{\partial q_y}\right](q^2+q_0^2)^{3/2}. \tag{62}$$

We now make use of the following operator expression in the momentum representation:

$$\hat{\boldsymbol{\rho}}=\mathbf{e}_x\hat{x}+\mathbf{e}_y\hat{y}=i\nabla_q, \tag{63}$$

and the commutation relation

$$[\hat{\boldsymbol{\rho}},f(\mathbf{q})]=i\nabla_q f, \tag{64}$$

to derive a more compact expression for $\hat{\mathcal{A}}_x$:

$$\hat{\mathcal{A}}_x=(q^2-q_0^2)\hat{x}-2q_x(\mathbf{q}\cdot\hat{\boldsymbol{\rho}})-3iq_x. \tag{65}$$

By considering an infinitesimal rotation in the (u_yu_z) plane we can obtain a similar expression for $\hat{\mathcal{A}}_y$:

$$\hat{\mathcal{A}}_y=(q^2-q_0^2)\hat{y}-2q_y(\mathbf{q}\cdot\hat{\boldsymbol{\rho}})-3iq_y. \tag{66}$$

These expressions operate on a particular energy eigenfunction with eigenvalue $-q_0^2$. If we move the constant $-q_0^2$ to the right and replace it with the Hamiltonian in momentum space, $\hat{\mathcal{H}}$,

$$\hat{\mathcal{A}}_x=q^2\hat{x}+\hat{x}\hat{\mathcal{H}}-2q_x(\mathbf{q}\cdot\hat{\boldsymbol{\rho}})-3iq_x, \tag{67}$$

$$\hat{\mathcal{A}}_y=q^2\hat{y}+\hat{y}\hat{\mathcal{H}}-2q_y(\mathbf{q}\cdot\hat{\boldsymbol{\rho}})-3iq_y, \tag{68}$$

then $\hat{\mathcal{A}}_x$ and $\hat{\mathcal{A}}_y$ can operate on any linear combination of eigenfunctions.

B. Relation to Runge–Lenz vector

Recall the definition of the two-dimensional Runge–Lenz vector in real space:

$$\hat{\mathbf{A}}=(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z-\hat{\mathbf{L}}_z\times\hat{\mathbf{q}})-\frac{2}{\rho}\boldsymbol{\rho}. \tag{69}$$

Using $\hat{\mathbf{L}}_z=\boldsymbol{\rho}\times\hat{\mathbf{q}}$, and the following identity for the triple product of three vectors:

$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c})=(\mathbf{a}\cdot\mathbf{c})\mathbf{b}-(\mathbf{a}\cdot\mathbf{b})\mathbf{c}, \tag{70}$$

we can apply the commutation relation $[\boldsymbol{\rho},\hat{\mathbf{q}}]=i$ to rewrite Eq. (69) in the form:

$$\hat{\mathbf{A}}=\hat{\mathbf{q}}^2\boldsymbol{\rho}+\boldsymbol{\rho}\left(\hat{\mathbf{q}}^2-\frac{2}{\rho}\right)-2\hat{\mathbf{q}}(\hat{\mathbf{q}}\cdot\boldsymbol{\rho})-3i\hat{\mathbf{q}}. \tag{71}$$

If we now return to the expression for the real-space Hamiltonian in Eq. (1), it is apparent that we may substitute

$$\hat{\mathbf{q}}^2-\frac{2}{\rho}=\hat{H} \tag{72}$$

in Eq. (71) to yield

$$\hat{\mathbf{A}}=\hat{\mathbf{q}}^2\boldsymbol{\rho}+\boldsymbol{\rho}\hat{H}-2\hat{\mathbf{q}}(\hat{\mathbf{q}}\cdot\boldsymbol{\rho})-3i\hat{\mathbf{q}}. \tag{73}$$

Comparing this with Eqs. (67) and (68), it is evident that the two components of the Runge–Lenz vector in real space correspond to the generators of infinitesimal rotations in the (u_xu_z) and (u_yu_z) planes.

V. CONCLUSION

We have shown that the accidental degeneracy in the energy eigenvalues of the two-dimensional Kepler problem may be explained by the existence of a planar analog of the familiar three-dimensional Runge–Lenz vector. By moving into momentum space and making a stereographic projection onto a three-dimensional sphere, a new integral relation in terms of special functions has been obtained, which to our knowledge has not previously been tabulated. We have also demonstrated explicitly that the components of the two-dimensional Runge–Lenz vector in real space are intimately related to infinitesimal rotations in three-dimensional momentum space.

APPENDIX A: SOLUTION OF REAL-SPACE SCHRÖDINGER EQUATION

We apply the method of separation of variables to Eq. (1), making the substitution

$$\Psi(\boldsymbol{\rho})=R(\rho)\Phi(\phi). \tag{A1}$$

Introducing a separation constant m^2, we can obtain the angular equation

$$\frac{d^2\Phi}{d\phi^2}+m^2\Phi=0, \tag{A2}$$

with the solution

$$\Phi(\phi)=\frac{1}{\sqrt{2\pi}}e^{im\phi}. \tag{A3}$$

The corresponding radial equation (with $E=-q_0^2$) is

$$\frac{d^2R}{d\rho^2}+\frac{1}{\rho}\frac{dR}{d\rho}+\left(\frac{2}{\rho}-q_0^2-\frac{m^2}{\rho^2}\right)R=0. \tag{A4}$$

We make the substitution

$$R(\rho)=C\rho^{|m|}e^{-q_0\rho}w(\rho), \tag{A5}$$

where C is a normalization constant. This leads to the equation

$$\rho\frac{d^2w}{d\rho^2}+(2|m|+1-2q_0\rho)\frac{dw}{d\rho}+(2-2|m|q_0-q_0)w=0. \tag{A6}$$

Making a final change of variables $\beta=2q_0\rho$, we obtain

$$\beta\frac{d^2w}{d\beta^2}+(2|m|+1-\beta)\frac{dw}{d\beta}+\left(\frac{1}{q_0}-|m|-\frac{1}{2}\right)w=0. \tag{A7}$$

This is the confluent hypergeometric equation,[15] which has two linearly independent solutions. If we choose the solution which is regular at the origin, then this becomes a polynomial of finite degree if $q_0=(n+\frac{1}{2})^{-1}$ with $n=0,1,2,\ldots$. Equation (A7) then becomes the associated Laguerre equation,[16] the solutions of which are the associated Laguerre polynomials:

$$w=L_{n-|m|}^{2|m|}(\beta)=L_{n-|m|}^{2|m|}(2q_0\rho). \tag{A8}$$

We can now write the real-space wavefunction in the form

$$\Psi_{nm}(\boldsymbol{\rho})=\frac{C}{2\pi}\rho^{|m|}e^{-q_0\rho}L_{n-|m|}^{2|m|}(2q_0\rho)e^{im\phi_\rho}, \tag{A9}$$

where the reason for the subscript on ϕ is explained in Sec. III C.

To normalize this wavefunction we need to make use of the integral[16]

$$\int_0^\infty e^{-2q_0\rho}(2q_0\rho)^{2|m|+1}L_{n-|m|}^{2|m|}(2q_0\rho)L_{n-|m|}^{2|m|}(2q_0\rho)\,d(2q_0\rho)=\frac{(n+|m|)!}{(n-|m|)!}(2n+1). \tag{A10}$$

The normalized wavefunctions are therefore

$$\Psi_{nm}(\boldsymbol{\rho})=\sqrt{\frac{q_0^3(n-|m|)!}{\pi(n+|m|)!}}(2q_0\rho)^{|m|}e^{-q_0\rho}L_{n-|m|}^{2|m|}(2q_0\rho)e^{im\phi_\rho}, \tag{A11}$$

satisfying the following orthogonality condition:

$$\int \Psi^*_{n_1 m_1}(\boldsymbol{\rho})\Psi_{n_2 m_2}(\boldsymbol{\rho})\, d\boldsymbol{\rho} = \delta_{n_1 n_2}\delta_{m_1 m_2}. \tag{A12}$$

APPENDIX B: DERIVATION OF EQ. (15)

From Eq. (3) we have

$$\hat{\mathbf{A}}^2 = \left[(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z - \hat{\mathbf{L}}_z\times\hat{\mathbf{q}}) - \frac{2}{\rho}\boldsymbol{\rho} \right]^2 = [2(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z) - i\hat{\mathbf{q}}]^2 - \frac{2}{\rho}\boldsymbol{\rho}\cdot[2(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z) - i\hat{\mathbf{q}}] - \frac{2}{\rho}[2(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z) - i\hat{\mathbf{q}}]\cdot\boldsymbol{\rho} + 4. \tag{B1}$$

We further expand as follows:

$$\begin{aligned}[2(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z) - i\hat{\mathbf{q}}]^2 &= 4(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z)^2 - 2i\hat{\mathbf{q}}\cdot(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z) - 2i(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z)\cdot\hat{\mathbf{q}} - \hat{\mathbf{q}}^2 \\ &= 4\hat{\mathbf{q}}^2\hat{\mathbf{L}}_z^2 + 2\hat{\mathbf{q}}^2 - \hat{\mathbf{q}}^2 = \hat{\mathbf{q}}^2(4\hat{\mathbf{L}}_z^2 + 1),\end{aligned} \tag{B2}$$

and

$$-\frac{2}{\rho}\boldsymbol{\rho}\cdot[2(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z) - i\hat{\mathbf{q}}] - \frac{2}{\rho}[2(\hat{\mathbf{q}}\times\hat{\mathbf{L}}_z) - i\hat{\mathbf{q}}]\cdot\boldsymbol{\rho} = -\frac{2}{\rho}(4\hat{\mathbf{L}}_z^2 + 1). \tag{B3}$$

Substituting Eqs. (B2) and (B3) into Eq. (B1) gives

$$\hat{\mathbf{A}}^2 = \hat{\mathbf{q}}^2(4\hat{\mathbf{L}}_z^2 + 1) - \frac{2}{\rho}(4\hat{\mathbf{L}}_z^2 + 1) + 4, \tag{B4}$$

which, from Eq. (72), is just

$$\hat{\mathbf{A}}^2 = \hat{H}(4\hat{\mathbf{L}}_z^2 + 1) + 4. \tag{B5}$$

(Received 15 March 2002; accepted for publication 29 May 2002)

By combining iterative methods with Laplace transformation, we construct the solution of a dissipative Jaynes–Cummings model. The dissipative part of the model is based on the standard Markovian master equation for a harmonic oscillator that is coupled to a heat bath of nonzero temperature. Besides photon loss, we also take into account frequency detuning between atom and field. Before commencing the iteration, we subject the matrix elements of the density operator to a transformation that depends on temperature. As a result, the pole structure of all Laplace transformed matrix elements is improved. It becomes manifest which poles do not contribute to the asymptotic behavior of the density operator. In proving that our iterative process yields convergent results, we assume upper bounds on: the matrix elements of the density operator, the matrix elements of the initial density operator, the damping parameter of the heat bath, and the temperature of the heat bath. All of these bounds are physically acceptable. The photon field may start from a coherent state or a number state. For experiments in a microwave cavity, temperatures of the order of 0.1 [K] are allowed. As an application, the evolution of the atomic density matrix is studied. We propose a limit for which this matrix converges to the state of maximum von Neumann entropy. The time, the cubed initial energy density, and the inverse of the damping parameter must tend to infinity equally fast. The photon field is assumed to be in a number state at time zero, whereas the initial state of the atom can be chosen freely. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1504503]

I. INTRODUCTION

A. Motivation

Some 20 years ago, the field of quantum optics witnessed fast developments. Owing to the arrival of new laser sources, atomic states of high quantum number became experimentally accessible.[1] Transitions between these Rydberg states are accompanied by large electric dipole moments, so couplings to the electromagnetic radiation field are quite strong. Being also long-lived, the Rydberg states could be successfully exploited to perform experimental tests on the Jaynes–Cummings model.[2]

Proposed back in 1963,[3] this analytically solvable model describes the interaction between a two-level atom and a single privileged mode of the quantized electromagnetic radiation field. The model relies on various simplifications, for instance, the electric-dipole and rotating-wave approximations. Its dynamics[4] exhibits such challenging features as collapse and revival of Rabi oscillations.[5] In various disciplines, especially quantum statistical mechanics[6,7] and quantum computing,[8] the model is a prime reference.

a)Electronic mail: vanwonderen@planet.nl

In an experimental setup the mode selector is a microwave cavity of high quality. Eventually, all of the initial energy leaks away from the cavity. Hence, the Jaynes–Cummings interaction cannot be observed for an unlimited amount of time. To deal properly with the damping phenomena, further theoretical efforts are indispensable. Such efforts were indeed made,[9] although exact extensions of the Jaynes–Cummings model became available only after some delay.[10,11] The cavity temperature was always set equal to zero. The attempt[12] to capture the effects of finite temperature on the basis of matrix continued fractions has a strictly formal character.

In this paper we intend to solve an extended version of the Jaynes–Cummings model that respects Planck's law for large times. Use is made of a Markovian master equation, which emanates from a weak-coupling procedure.[13] As the temperature of the cavity is nonzero, one may expect good agreement with experiment for all evolutionary stages. We allow for frequency detuning of atom and field, but ignore the possibility that the atom may spontaneously emit a photon into electromagnetic modes other than the privileged one.

A sound mathematical treatment of the temperature effects requires considerable vigilance. If one plainly mimicks techniques from the zero-temperature case, then one quickly runs into unpleasant surprises. For example, the evolution of the photon field toward the thermal state must be safeguarded from the very outset. Before constructing any solutions, one should perform a temperature transformation of the master equation. Omission of this preparatory step confronts us with summations that do not converge uniformly in time. Their asymptotic behavior cannot be found by making the time infinitely large behind a summation sign.

The temperature transformation ensures that our solution converges uniformly in time. As we shall prove, all summations are dominated by a geometric series. The latter is convergent if the average number of thermal photons inside the cavity is sufficiently small. Consequently, we must set a bound on the temperature. In a strict sense, this paper is silent about the case of arbitrarily high temperature.

In Sec. I B we review the Jaynes–Cummings model with cavity damping, whereas in Sec. I C we introduce some handy notations. A summary can be found in Sec. II. It serves the reader who wishes to get a good impression of this paper through a modest effort. We present our four assumptions (i)–(iv), as well as the two limits that will be proved. All material can be easily understood by anyone having some experience in iterative techniques.

In Sec. III we construct our solution. We only perform a finite number of iterations. Hence, the ensuing identities are equivalent to our point of departure, the master equation for the density operator. The issue of convergence turns up in Sec. IV, as the order of iteration is taken to infinity. Sections IV A, IV B, IV C, and IV D each contain one building block of the convergence proof. Use is made of basic linear algebra and function theory.

As an application of the newly established solution, we propose in Sec. V a limit for which the atom reaches the state of maximum entropy. A similar limit was already presented for the zero-temperature case.[11] In contrast to Secs. III and IV, we do not pursue mathematical rigor in Sec. V. Our conclusions appear in Sec. VI. Finally, this paper includes four appendices. In each of the Appendices B, C, and D we prove a result, which is needed in the main text. Appendix A does not include any proofs, but describes a possible approach for extending our mathematical framework to the case of weak damping.

B. The model

The Jaynes–Cummings interaction between a two-level atom A and a single privileged mode of the quantized electromagnetic radiation field F is described by the Hamiltonian $H_0+\hbar g H_1$. The constituents H_0 and H_1, which act on the product Hilbert space $\mathsf{C}^2\otimes\mathcal{H}_F$, are given by

$$H_0=\hbar\omega_F[\tfrac{1}{2}(i_+-i_-)\otimes\mathbf{1}+\mathbf{1}_2\otimes a^\dagger a],$$

$$H_1=\Delta(i_+-i_-)\otimes\mathbf{1}+\sigma_+\otimes a+\sigma_-\otimes a^\dagger.$$

The excited state $\hat{\mathbf{b}}_1=(1,0)^T$ of energy ϵ_2 and the ground state $\hat{\mathbf{b}}_2=(0,1)^T$ of energy ϵ_1 span the atomic Hilbert space C^2. Hence, all atomic operators linearly depend on the matrices

$$i_+=\begin{pmatrix}1&0\\0&0\end{pmatrix},\quad i_-=\begin{pmatrix}0&0\\0&1\end{pmatrix},\quad \sigma_+=\begin{pmatrix}0&1\\0&0\end{pmatrix},\quad \sigma_-=\begin{pmatrix}0&0\\1&0\end{pmatrix}.$$

The privileged mode of frequency ω_F has ladder operators a and $a^\dagger$, the commutator $[a,a^\dagger]$ being equal to unity. They act on the Hilbert space $\mathcal{H}_F$, which is spanned by the orthonormal photon-number states $\{|n\rangle\}_{n=0}^{\infty}$, with $|n\rangle=(n!)^{-1/2}(a^\dagger)^n|0\rangle$ and $a|0\rangle$ identical to the zero element. The detuning parameter $\Delta=(\epsilon_2-\epsilon_1-\hbar\omega_F)/(2\hbar g)$ measures the difference between the atomic and field frequencies in units of the interaction strength g.

To account for photon loss, we couple the field mode to a thermal reservoir of inverse temperature β. Then the evolution of the density operator $\rho(t)$ for atom and field is governed by the master equation

$$\frac{\mathrm{d}}{\mathrm{d}t}\rho(t)=-i[H_1,\rho(t)]+\frac{\kappa}{1+\bar{n}}\mathcal{L}[\rho(t)]. \tag{1}$$

We have moved to the interaction picture, and divided by g, so the time t and the damping constant κ are dimensionless. Although general expressions for the damping operator $\mathcal{L}$ are available,[14] we assume that the damping process is driven by a quantum dynamical semigroup. The standard[13] weak-coupling procedure leads to

$$\begin{aligned}\mathcal{L}[\rho]=&2(\mathbf{1}_2\otimes a)\rho(\mathbf{1}_2\otimes a^\dagger)-(\mathbf{1}_2\otimes a^\dagger a)\rho-\rho(\mathbf{1}_2\otimes a^\dagger a)+2\bar{n}[(\mathbf{1}_2\otimes a^\dagger)\rho(\mathbf{1}_2\otimes a)\\&+(\mathbf{1}_2\otimes a)\rho(\mathbf{1}_2\otimes a^\dagger)-(\mathbf{1}_2\otimes a^\dagger a)\rho-\rho(\mathbf{1}_2\otimes aa^\dagger)],\end{aligned} \tag{2}$$

where $\bar{n}$ stands for the average number of thermal photons in the privileged mode. Trace, self-adjointness, and positivity of the density operator are conserved.

As t becomes large, the density operator is expected to converge to a thermal state

$$\lim_{t\to\infty}\|\rho(t)-\exp(-\beta H_0)/\mathrm{Tr}[\exp(-\beta H_0)]\|=0, \tag{3}$$

in trace norm. This state is a fixed point of the dynamics (1) if the condition

$$\exp(-\beta\hbar\omega_F)=\frac{\bar{n}}{1+\bar{n}}\equiv\lambda$$

is satisfied. Simply stated, Planck's radiation law must be valid. Finally, note that (3) is invariant under backtransformation to the Schrödinger picture.

C. Notation

The direct product $\otimes$ of two matrices, sometimes called the right Kronecker product, is defined as usual.[15] To avoid heavily burdened formulas, we introduce for any integer n the theta symbol

$$\theta_n=\begin{cases}0 & \text{if } n\leqslant -1\\ 1 & \text{if } n\geqslant 0,\end{cases}$$

and for any integer $k\geqslant -1$ the matrix product

$$\left\{\prod_{s=0}^{k}M(s)\right\}=M(0)M(1)\cdots M(k),\quad \left\{\prod_{s=0}^{-1}M(s)\right\}=\mathbf{1}.$$

We shall stick to the use of curly braces. Our Laplace transform reads

$$\tilde{f}(z) = -i \int_0^\infty \mathrm{d}t\, e^{izt} f(t),$$

with $\mathrm{Im}\, z$ positive. In the sequel, we shall work for n integer with the function

$$\psi(a,b;n) = a^n + (b/n)^n,$$

where a and b are positive. We shall also need the matrices

$$I(n) = \begin{pmatrix} \theta_n & 0 \\ 0 & \theta_{n+1} \end{pmatrix}, \quad W(n) = \begin{pmatrix} n^{1/2}\theta_{n-1} & 0 \\ 0 & (n+1)^{1/2}\theta_n \end{pmatrix},$$

$$B(n) = \begin{pmatrix} (-\kappa n - \kappa\lambda n - \kappa\lambda)\,\theta_n & -i(n+1)^{1/2}\theta_n \\ -i(n+1)^{1/2}\theta_n & (-\kappa n - \kappa - \kappa\lambda n - 2\kappa\lambda + 2i\Delta)\,\theta_{n+1} \end{pmatrix}.$$

The eigenvalues and normalized eigenvectors of the matrix $B(n;\lambda=0)$ are found as

$$\mu_\eta(n) = [-\kappa(n+1/2) + i\Delta - i\,\eta u(n)]\,\theta_n + 2i\Delta\,\delta_{n,-1},$$

$$\hat{\mathbf{q}}_\eta(n) = \nu_\eta^{-1}(n) \begin{pmatrix} (n+1)^{1/2} \\ \eta u(n) - i\kappa/2 - \Delta \end{pmatrix} \theta_n + \begin{pmatrix} 0 \\ 1 \end{pmatrix} \delta_{n,-1}.$$

We have abbreviated

$$\nu_\eta(n) = [n+1+|\eta u(n) - i\kappa/2 - \Delta|^2]^{1/2},$$

$$u(n) = (n+1+\Delta^2 - \kappa^2/4 + i\kappa\Delta)^{1/2}\theta_n,$$

with $\eta = \pm 1$. We shall derive bounds on matrices and vectors by making use of the sup norm and the Euclidean norm, respectively. The dyadic product $\hat{\mathbf{e}}_i\hat{\mathbf{e}}_j$ represents the (4×4) matrix, the ij element of which equals unity; all other matrix elements equal zero. The set $\{\hat{\mathbf{e}}_j\}_{j=1}^4$ contains the Cartesian unit vectors in four dimensions.

II. SOLUTION IN SHORT

In Sec. III we get the iterative process going, but keep the order of iteration finite. Section IV is devoted to our convergence proofs.

Section III A shows in three steps how the primal master equation (1) can be converted to an algebraic c-number equation in four dimensions. As a first step, we take matrix elements of $\rho(t)$ with the help of the product states $\{|\hat{\mathbf{b}}_1\otimes n\rangle, |\hat{\mathbf{b}}_2\otimes n\rangle\}_{n=0}^\infty$, and group these in the following way:

$$\mathbf{v}'(t;m,n) = [\langle\hat{\mathbf{b}}_1\otimes m|\rho(t)|\hat{\mathbf{b}}_1\otimes n\rangle,\ \langle\hat{\mathbf{b}}_2\otimes(m+1)|\rho(t)|\hat{\mathbf{b}}_1\otimes n\rangle,$$
$$\langle\hat{\mathbf{b}}_1\otimes m|\rho(t)|\hat{\mathbf{b}}_2\otimes(n+1)\rangle,\ \langle\hat{\mathbf{b}}_2\otimes(m+1)|\rho(t)|\hat{\mathbf{b}}_2\otimes(n+1)\rangle]^T, \tag{4}$$

with $m,n = -1,0,1,2,\ldots$. We use the convention that a matrix element $\langle\hat{\mathbf{b}}_i\otimes m|\rho(t)|\hat{\mathbf{b}}_j\otimes n\rangle$ be identical to zero for negative photon number m or n. The choice (4) ensures that in the c-number equation for $\mathbf{v}'$ the photon numbers (m,n) only couple to their neighbors $(m+1,n+1)$ and $(m-1,n-1)$.

The second step is made up by the transformation

$$\begin{aligned} \mathbf{v}(t;m,n) &= \mathbf{v}'(t;m,n), \\ \mathbf{v}(t;n,n) &= (\theta_n Q_1 + \delta_{n,-1}Q_2)\mathbf{v}'(t;n,n) - \lambda\,\theta_n Q_2 \mathbf{v}'(t;n-1,n-1), \end{aligned} \tag{5}$$

with $m,n\geqslant -1$ and $m\neq n$. The matrices Q_1 and Q_2 are chosen such that, in case limit (3) holds true, the new vector $\mathbf{v}(t;n,n)$ vanishes for $n\geqslant 0$ and $t\to\infty$. Consequently, the fixed point in (3) is mapped to its zero-temperature counterpart.

A further constraint on Q_1 and Q_2 is that no new couplings between photon numbers be introduced. One then arrives at the equation of motion

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{v}(t;m,n)=A(m,n)\mathbf{v}(t;m,n)+2\kappa S(m,n)\mathbf{v}(t;m+1,n+1)+2\kappa\lambda T(m,n)\mathbf{v}(t;m-1,n-1), \tag{6}$$

with $m,n\geqslant -1$. The matrices A, S, and T are defined in Sec. III A. We emphasize the equivalence between the master equation (1) and the differential equation (6).

Laplace transformation of (6) constitutes the third and final step of the conversion. The transformed vector $\tilde{\mathbf{v}}(z;m,n)$ satisfies an algebraic equation. By carrying out a matrix inversion, we arrive at a recursion relation of second order in the photon numbers (m,n).

In Sec. III B the Nth-order iterative solution of (6) is constructed. Upon iterating our recursion relation N times and performing inverse Laplace transformation, we obtain

$$\mathbf{v}(t;m,n)=\mathbf{v}(t;N;m,n)+\mathbf{r}(t;N;m,n), \tag{7}$$

$$\mathbf{v}(t;N;m,n)=\sum_{p=0}^{N-1}\sum_{k=-\min(m,n)-1}^{N-p-1}\lambda^p K(t;k,p;m,n)\mathbf{v}(t=0;m+k,n+k) \tag{8}$$

for $m,n\geqslant -1$ and $N\geqslant 1$. The term $\mathbf{r}(t;N;m,n)$ is a remainder, which still depends on $\mathbf{v}(t;m,n)$. The kernel $K(t;k,p;m,n)$ is a (4×4) matrix, which possesses the properties

$$\begin{aligned} K(t=0;k,p;m,n)&=I(n)\otimes I(m)\,\delta_{k,0}\delta_{p,0},\\ K(t=0;k,p;-1,-1)&=\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2\delta_{k,0}\delta_{p,0}, \end{aligned} \tag{9}$$

with $m,n\geqslant -1$, and the choice $m=n=-1$ forbidden. We have taken care to arrange the iteration such that the temperature makes its appearance through a power series in λ.

In Sec. IV we investigate what happens to identity (7) if the order of iteration N is taken to infinity. The treatment rests on the following four assumptions.

(i) For all non-negative times one may employ the inequalities

$$\begin{aligned} \|\mathbf{v}(t;m,n)\|&\leqslant c_1 e^{-c_2\kappa t}(m/2+n/2+2)^3\psi(c_3\lambda/\kappa,c_4;m/2+n/2+1),\\ \|\mathbf{v}(t;-1,-1)-(1-\lambda)(1+\lambda)^{-1}\hat{\mathbf{e}}_2\|&\leqslant c_1 e^{-c_2\kappa t}. \end{aligned} \tag{10}$$

In the upper line the choice $m=n=-1$ is forbidden. The function ψ is defined in Sec. I C. The positive constants $\{c_i\}$ are specified in Sec. IV.

As $\mathbf{v}(t;m,n)$ is composed of matrix elements of $\rho(t)$, the inequalities (10) determine the class of density operators to which we confine ourselves. This class does not include density operators that do not comply with the thermal limit (3).

(ii) The initial density operator $\rho(t=0)$ is chosen such that for all m and n the inequality

$$\|\mathbf{v}(t=0;m,n)\|\leqslant c_5\left[\frac{(m+2)(n+2)}{(m+1)!(n+1)!}\right]^{1/2}c_6^{m+n+2}\theta_{m+1}\theta_{n+1} \tag{11}$$

holds true. The constants c_5 and c_6 are positive. Note that for $t=0$ and $\lambda>0$ the constraint (10) is weaker than (11).

The bound (11) is physically acceptable, because it is possible to make two familiar choices for the initial density operator, namely

$$\rho(t=0)=\rho_A\otimes|\alpha\rangle\langle\alpha|, \quad \rho(t=0)=\rho_A\otimes|q\rangle\langle q|, \tag{12}$$

where ρ_A denotes any density operator in two dimensions, $|\alpha\rangle=\exp(-|\alpha|^2/2+\alpha a^\dagger)|0\rangle$ stands for a coherent state, with α complex, and $|q\rangle$ stands for a photon-number state, with q a non-negative integer. The constant c_6 must be set equal to $\max(1,|\alpha|)$ if one works with the coherent state.

(iii) On the damping parameter the restriction

$$0<\kappa<2$$

is imposed. Earlier findings for a reservoir of zero temperature[7] tell us that the overdamped case $\kappa\geqslant 2$ is of no physical interest at all. The same goes for the choice $\kappa=0$, which decouples the reservoir from the Jaynes–Cummings interaction.

(iv) The inequality

$$0\leqslant\lambda<\lambda_0<1$$

is indispensable. The temperature of the reservoir is assumed to stay below a certain level, prescribed by the constant λ_0. In Sec. VI we calculate what order of magnitude the temperature may have for experiments in a microwave cavity.

Making use of assumptions (ii)–(iv), we prove in Sec. IV the existence of a vector $\mathbf{v}(t;\infty;m,n)$ such that

$$\lim_{N\to\infty}\ \sup_{0\leqslant t<\infty}\|\mathbf{v}(t;\infty;m,n)-\mathbf{v}(t;N;m,n)\|=0 \tag{13}$$

for $m,n\geqslant -1$. The properties (9) guarantee that for small t the new vector $\mathbf{v}(t;\infty;m,n)$ converges to the initial vector $\mathbf{v}(t=0;m,n)$.

The proof of (13) consists of three steps. In Sec. IV A we derive bounds on the matrices from which the kernel K is built up. This task being accomplished, we can derive in Sec. IV B a bound on K itself. Last, by invoking the Cauchy theorem on the existence of a limit, we prove in Sec. IV C the statement (13). We also check that the limiting vector $\mathbf{v}(t;\infty;m,n)$ fulfills the conditions (10). It thus respects the thermal limit (3).

Assumptions (i)–(iv), with the bound λ_0 replaced by $\lambda_0'<\lambda_0$, allow us to prove in Sec. IV D the limit

$$\lim_{N\to\infty}\ \sup_{0\leqslant t<\infty}\|\mathbf{v}(t;m,n)-\mathbf{v}(t;N;m,n)\|=0 \tag{14}$$

for $m,n\geqslant -1$. The proof starts by employing (7) on the left-hand side of (14). To cope with the dependence of the remainder $\mathbf{r}(t;N;m,n)$ on the vector $\mathbf{v}(t;m,n)$, we must estimate the norm of the latter. At this point assumption (i) comes in.

By means of a triangle inequality we deduce from (13) and (14) the identity

$$\mathbf{v}(t;m,n)=\mathbf{v}(t;\infty;m,n), \tag{15}$$

with $m,n\geqslant -1$. Therefore, the limiting vector $\mathbf{v}(t;\infty;m,n)$ may be viewed as the solution of the dissipative Jaynes–Cummings model. In principle, λ must remain smaller than λ_0'. However, we can exchange the bound λ_0' for λ_0 by applying analytic continuation in λ to the limiting vector.

In Sec. V we utilize our solution to examine the evolution of $\rho_A(t)$, the density matrix describing the two-level atom. We argue that, besides the thermal state, the state of maximum entropy may also be operative as an attractor in atomic phase space. This observation is based on the limit

$$\lim_{t\to\infty,\kappa\to 0,q\to\infty}\rho_A(t)=\tfrac{1}{2}\mathbf{1}_2. \tag{16}$$

The tilde denotes that the products κt and κq^3 must be kept constant. The full density operator starts from the state $\rho(0)=\rho_A\otimes|q\rangle\langle q|$, with ρ_A free and $|q\rangle$ a photon-number state. The temperature may have any fixed value within its interval of convergence. A completely rigorous proof of (16) falls outside the scope of our treatment, because it forces us to tighten the bound (10) on the limiting vector $\mathbf{v}(t;\infty;m,n)$. The factor of κ^{-1} should be removed from the first argument of ψ. In Appendix A we outline a possible method to achieve this.

III. CONSTRUCTION OF THE SOLUTION

We now take on the job of devising the iterative process that generates the solution of the dissipative Jaynes–Cummings model. Convergence proofs are not yet required, because the order of iteration is kept finite. In Sec. III A we replace the master equation (1) by a c-number recursion relation in four dimensions. In Sec. III B we construct the Nth-order iterative solution of this recursion relation.

A. Toward an algebraic equation

We employ the product states $\{|\hat{\mathbf{b}}_1\otimes n\rangle,|\hat{\mathbf{b}}_2\otimes n\rangle\}_{n=0}^{\infty}$ to cast the master equation (1) into c-number shape. For negative photon number m or n the matrix element $\langle\hat{\mathbf{b}}_i\otimes m|\rho(t)|\hat{\mathbf{b}}_j\otimes n\rangle$ vanishes by definition. In terms of vector (4) the c-number equation can be represented as

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{v}'(t;m,n)=A'(m,n)\mathbf{v}'(t;m,n)+2\kappa S'(m,n)\mathbf{v}'(t;m+1,n+1)$$
$$+2\kappa\lambda T'(m,n)\mathbf{v}'(t;m-1,n-1), \tag{17}$$

with $m,n\geqslant -1$. For the matrices we find

$$A'(m,n)=I(n)\otimes B(m)+B(n)^{\dagger}\otimes I(m),$$

$$S'(m,n)=T'(m+1,n+1),\quad T'(m,n)=W(n)\otimes W(m),$$

where we refer to the notation of Sec. I C.

According to (3), the vector (4) is expected to behave for large times as

$$\lim_{t\to\infty}\mathbf{v}'(t;m,n)=\delta_{m,n}(1-\lambda)(1+\lambda)^{-1}\lambda^{n+1}(\hat{\mathbf{e}}_1\theta_n+\hat{\mathbf{e}}_4\theta_{n+1}).$$

We want to set up a one-to-one transformation that maps the limiting vector on the right-hand side to zero, for $m=n$ non-negative. Moreover, the transformed equation (17) should not contain any additional couplings between photon numbers. A transformation meeting these constraints is given by (5), with the matrices

$$Q_1=\begin{pmatrix}1&0&0&-1\\0&0&0&1\\0&1&-1&0\\0&1&1&0\end{pmatrix},\quad Q_2=\hat{\mathbf{e}}_2\hat{\mathbf{e}}_4.$$

The inverse reads

$$\mathbf{v}'(t;n,n)=[\theta_nQ_1^{-1}+\delta_{n,-1}\hat{\mathbf{e}}_4\hat{\mathbf{e}}_2]\mathbf{v}(t;n,n)+\theta_n\sum_{k=1}^{n+1}\lambda^kQ_1^{-1}Q_2Q_1^{-1}\mathbf{v}(t;n-k,n-k).$$

Transformation of (17) brings us to (6). The transformed matrices come out as

$$A(n,n)=Q_1A'(n,n)Q_1^{-1}+2\kappa\lambda(-\hat{\mathbf{e}}_1\hat{\mathbf{e}}_2+\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2),$$

$$S(n,n)=Q_1S'(n,n)Q_1^{-1},$$

$$T(n,n)=Q_1T'(n,n)Q_1^{-1}+\hat{\mathbf{e}}_1\hat{\mathbf{e}}_2-\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2-in^{1/2}(2\kappa)^{-1}\hat{\mathbf{e}}_2\hat{\mathbf{e}}_3,$$

$$A(-1,-1)=T(-1,-1)=0,\quad S(-1,-1)=\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2,$$

with n non-negative. Note that $T(0,0)$ equals zero. Of course, for $m\neq n$ the transformed matrices are identical to their primed counterparts.

To stay in complete control of temperature dependencies, we head for a power series in the parameter λ. We make the split

$$A(m,n)=A_0(m,n)+2\kappa\lambda A_1(m,n),$$

with

$$A_0(n,n)=Q_1A'(n,n;\lambda=0)Q_1^{-1}\theta_n,\quad A_0(m,n)=A'(m,n;\lambda=0) \tag{18}$$

for $m\neq n$, and

$$A_1(m,n)=-\tfrac{1}{2}[I(n)\otimes W^2(m+1)+W^2(n+1)\otimes I(m)]+\hat{\mathbf{e}}_4\hat{\mathbf{e}}_4\delta_{m,-1}\delta_{n,-1}+\tfrac{1}{2}(\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2+\hat{\mathbf{e}}_4\hat{\mathbf{e}}_4)\delta_{m,n}\theta_n,$$

for all $m,n\geqslant -1$. The matrix $A_1(-1,-1)$ equals zero.

Laplace transformation of (6) yields

$$\begin{aligned}\tilde{\mathbf{v}}(z;m,n)=R(z;m,n)[&\mathbf{v}(t=0;m,n)+2i\kappa S(m,n)\tilde{\mathbf{v}}(z;m+1,n+1)\\&+2i\kappa\lambda T(m,n)\tilde{\mathbf{v}}(z;m-1,n-1)+2i\kappa\lambda A_1(m,n)\tilde{\mathbf{v}}(z;m,n)],\end{aligned} \tag{19}$$

with $m,n\geqslant -1$. The resolvents are given by

$$R(z;-1,-1)=\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2/z,\quad R(z;n,n)=[z\mathbf{1}_4-iA_0(n,n)]^{-1},$$

for $n\geqslant 0$, and

$$R(z;m,n)=I(n)\otimes I(m)[z\mathbf{1}_4-iA_0(m,n)]^{-1}I(n)\otimes I(m),$$

for $m,n\geqslant -1$ and $m=n$ forbidden. The projector $I(n)\otimes I(m)$ comes in because of the property

$$I(n)\otimes I(m)\mathbf{v}'(t;m,n)=\mathbf{v}'(t;m,n).$$

It reflects the convention that matrix elements of the density operator disappear if a photon number becomes negative.

The simple pole $z=0$ of $R(z;-1,-1)$ determines the asymptotic behavior of our solution, because the poles of all other resolvents lie below the real axis of the complex z plane. Their location can be deduced from the eigenvalue equation

$$A'(m,n;\lambda=0)\hat{\mathbf{q}}^*_{\eta_2}(n)\otimes\hat{\mathbf{q}}_{\eta_1}(m)=[\mu_{\eta_1}(m)+\mu^*_{\eta_2}(n)]\hat{\mathbf{q}}^*_{\eta_2}(n)\otimes\hat{\mathbf{q}}_{\eta_1}(m), \tag{20}$$

with $\eta_1,\eta_2=\pm 1$. Definitions of eigenvectors and eigenvalues appear in Sec. I C. Note that for either $m=-1$, $n\geqslant 0$ or $m\geqslant 0$, $n=-1$ the resolvent $R(z;m,n)$ has two instead of four poles.

B. Iteration

The recursion (19) is solved in two steps. First, we iterate in the parameter κ, and subsequently, in the parameter $\kappa\lambda$. This route leads to a power series in λ, as planned.

The outcome of the first iteration can be expressed as

$$\tilde{\mathbf{v}}(z;m,n)=R(z;m,n)\sum_{k=0}^{N-1}(2i\kappa)^k D_1(z;k;m,n)\mathbf{v}(t=0;m+k,n+k)$$
$$+\lambda R(z;m,n)\sum_{k=0}^{N}(2i\kappa)^k D_2(z;N;k;m,n)\tilde{\mathbf{v}}(z;m+k-1,n+k-1)+\tilde{\mathbf{r}}_1(z;N;m,n), \tag{21}$$

with $N\geqslant 1$ and the remainder

$$\tilde{\mathbf{r}}_1(z;N;m,n)=(2i\kappa)^N R(z;m,n)D_1(z;N-1;m,n)S(m+N-1,n+N-1)\tilde{\mathbf{v}}(z;m+N,n+N).$$

We have introduced the matrices

$$D_1(z;k;m,n)=\left\{\prod_{s=0}^{k-1}S(m+s,n+s)R(z;m+s+1,n+s+1)\right\},$$

$$D_2(z;N;k;m,n)=\theta_{N-k-1}2i\kappa D_1(z;k;m,n)T(m+k,n+k)$$
$$+\theta_{k-1}D_1(z;k-1;m,n)A_1(m+k-1,n+k-1),$$

where for D_1 the notation of Sec. I C has been employed.

Next, we iterate (21) to arrive at the following schematic result:

$$\tilde{\mathbf{v}}(z;m,n)=\sum_{p=0}^{N-1}\sum_{k=-\min(m,n)-1}^{N-p-1}\lambda^p\tilde{K}(z;k,p;m,n)\mathbf{v}(t=0;m+k,n+k)+\sum_{j=1}^{4}\tilde{\mathbf{r}}_j(z;N;m,n), \tag{22}$$

with $m,n\geqslant -1$ and $N\geqslant 1$. The kernel can be written as

$$\tilde{K}(z;k,p;m,n)=\theta_{k+p}(2i\kappa)^{k+p}\sum_{l_0=0}^{k+p-1}\sum_{l_1=l_0-1}^{k+p-2}\cdots\sum_{l_p=l_{p-1}-1}^{k}R(z;m,n)$$
$$\times\left\{\prod_{s=1}^{p}D_2(z;\infty;l_s-l_{s-1}+1;m+l_{s-1},n+l_{s-1})R(z;m+l_s,n+l_s)\right\}$$
$$\times D_1(z;k-l_p;m+l_p,n+l_p).$$

It is essential to be aware of the condition

$$l_s\geqslant -\min(m,n)-1+\delta_{m,n} \tag{23}$$

for $1\leqslant s\leqslant p$. It is imposed on the summand of $\tilde{K}$ by the matrices A_1 and T figuring in D_2. Note that the above-given summation over l_0 consists of one term only, for which l_0 equals zero.

The remainders in (22) are byproducts of the iteration process. As shown in Sec. IV D, they can be made small by making N large. We thus need the precise expressions for the second remainder

$$\tilde{\mathbf{r}}_2(z;N;m,n)=\sum_{p=1}^{N-1}\sum_{l_0=0}^{N+l_0-1}\sum_{l_1=l_0-1}^{N+l_1-1}\sum_{l_2=l_1-1}^{N+l_{p-1}-1}\cdots\sum_{l_p=l_{p-1}-1}^{N+l_{p-1}-1}\lambda^p(2i\kappa)^{l_p+p}R(z;m,n)$$
$$\times\left\{\prod_{s=1}^{p-1}D_2(z;N;l_s-l_{s-1}+1;m+l_{s-1},n+l_{s-1})R(z;m+l_s,n+l_s)\right\}$$
$$\times D_2(z;N;l_p-l_{p-1}+1;m+l_{p-1},n+l_{p-1})\tilde{\mathbf{r}}_1(z;N;m+l_p,n+l_p),$$

the third remainder

$$\tilde{\mathbf{r}}_3(z;N;m,n)=\sum_{l_0=0}^{N+l_0-1}\sum_{l_1=l_0-1}^{N+l_1-1}\sum_{l_2=l_1-1}^{}\cdots\sum_{l_N=l_{N-1}-1}^{N+l_{N-1}-1}\lambda^N(2i\kappa)^{l_N+N}R(z;m,n)$$
$$\times\left\{\prod_{s=1}^{N-1}D_2(z;N;l_s-l_{s-1}+1;m+l_{s-1},n+l_{s-1})R(z;m+l_s,n+l_s)\right\}$$
$$\times D_2(z;N;l_N-l_{N-1}+1;m+l_{N-1},n+l_{N-1})\tilde{\mathbf{v}}(z;m+l_N,n+l_N),$$

and, finally, the fourth remainder,

$$\tilde{\mathbf{r}}_4(z;N;m,n)=\sum_{p=1}^{N-1}\sum_{k=N-p}^{(p+1)(N-1)}\sum_{l_0=0}^{}\sum_{l_1=l_0-1}^{k+p-1}\sum_{l_2=l_1-1}^{k+p-2}\cdots\sum_{l_p=l_{p-1}-1}^{k}\lambda^p(2i\kappa)^{k+p}R(z;m,n)$$
$$\times\left\{\prod_{s=1}^{p}D_2(z;N;l_s-l_{s-1}+1;m+l_{s-1},n+l_{s-1})R(z;m+l_s,n+l_s)\right\}$$
$$\times D_1(z;k-l_p;m+l_p,n+l_p)\mathbf{v}(t=0;m+k,n+k)$$
$$\times\prod_{s=1}^{p}\theta_{N+l_{s-1}-l_s-1}\theta_{l_s-k+(N-1)(p-s+1)}.$$

With these expressions in hand, we can readily verify that the identity (22) is equivalent to the recursion (19).

Inverse Laplace transformation of (22) confirms Eqs. (7) and (8). Moreover, it gives rise to the following correspondences:

$$K(t;k,p;m,n)=\oint\frac{\mathrm{d}z}{2\pi i}e^{-izt}\tilde{K}(z;k,p;m,n),\tag{24}$$

$$\mathbf{r}(t;N;m,n)=i\sum_{j=1}^{4}\int_C\frac{dz}{2\pi}e^{-izt}\,\tilde{\mathbf{r}}_j(z;N;m,n).\tag{25}$$

The kernel $\tilde{K}$ is meromorphic in z, so in (24) the contour has been closed on account of Jordan's lemma. It encircles all poles of the integrand counterclockwise. In (25) the contour C is a straight line with $\mathrm{Im}\,z$ fixed and positive, and $\mathrm{Re}\,z$ running from $-\infty$ to $+\infty$.

The initial conditions (9) directly relate to the structure of (24), as can be demonstrated with the help of a standard technique.[16] For $t=0$ the contour (24) can be deformed into a circle $|z|=R$. The radius R is chosen sufficiently large, so that each resolvent may be expanded into a Neumann series. Since these uniformly converge on the deformed contour, one may integrate term by term, and hence, invoke the identity

$$\oint\frac{\mathrm{d}z}{2\pi i}z^{-n}=\delta_{n,1},\tag{26}$$

for any integer n. One immediately recovers the right-hand sides of (9).

IV. CONVERGENCE OF THE SOLUTION

We set out to prove statements (13) and (14). Making use of assumption (iii), we derive in Sec. IV A bounds on the matrices that generate the kernel K. In Sec. IV B we prove the inequality (40), which provides us with a bound on the kernel itself. The proof of (13) is presented in Sec. IV C. The bound (40) is needed, as well as assumptions (ii) and (iv). In Sec. IV D we turn to the

proof of the key result (14). We appeal to all assumptions (i)–(iv), with λ_0 replaced by $\lambda_0' < \lambda_0$. In view of the possibility of analytic continuation, we do not bother about the precise value of λ_0'.

A. Basic bounds

Consider a complex $(d\times d)$ matrix M and assume that it satisfies the eigenvalue equation $M\hat{\mathbf{v}}^{(j)}=\lambda_j\hat{\mathbf{v}}^{(j)}$, where the right eigenvectors $\{\hat{\mathbf{v}}^{(j)}\}_{j=1}^d$ are normalized and linearly independent. The set of eigenvalues $\{\lambda_j\}_{j=1}^d$ may contain degeneracies. An arbitrary vector $\mathbf{v}$ can be decomposed as $\mathbf{v}=\Sigma_{j=1}^d c_j(\mathbf{v})\hat{\mathbf{v}}^{(j)}$, where the objects $\{c_j(\mathbf{v})\}_{j=1}^d$ are complex coefficients. They can be expressed as $c_j(\mathbf{v})=\Sigma_{k=1}^d c_j(\hat{\mathbf{w}}^{(k)})\hat{\mathbf{w}}^{(k)}\cdot\mathbf{v}$, if the set $\{\hat{\mathbf{w}}^{(j)}\}_{j=1}^d$ is orthonormal. Hence, we have the inequality $|c_j(\mathbf{v})|\leqslant\|\mathbf{v}\|[\Sigma_{k=1}^d|c_j(\hat{\mathbf{w}}^{(k)})|^2]^{1/2}$ at our disposal. For the sup norm of M we can put forth the bound

$$\|M\|\leqslant\sum_{j=1}^d|\lambda_j|\left(\sum_{k=1}^d|c_j(\hat{\mathbf{w}}^{(k)})|^2\right)^{1/2}. \tag{27}$$

The coefficients on the right-hand side can be evaluated by means of matrix inversion

$$\hat{\mathbf{w}}^{(j)}\cdot\hat{\mathbf{v}}^{(k)}\equiv D_{jk},\quad c_k(\hat{\mathbf{w}}^{(j)})=D_{kj}^{-1}, \tag{28}$$

with $j,k=1,2,3,\ldots,d$.

We apply (27) to our resolvents. The eigenvalues and eigenvectors $\{\lambda_j,\hat{\mathbf{v}}^{(j)}\}_{j=1}^4$ are those of Eq. (20). As orthonormal basis $\{\hat{\mathbf{w}}^{(j)}\}_{j=1}^4$ we take

$$\{\hat{\mathbf{q}}_{\eta_2}^*(n;\kappa=0)\otimes\hat{\mathbf{q}}_{\eta_1}(m;\kappa=0)\}_{\eta_1,\eta_2=\pm1}.$$

Solution of (28) comes down to inversion of a direct product of (2×2) matrices for $m,n\geqslant0$, and a single (2×2) matrix otherwise. The root in (27) can be elaborated with the help of the identity

$$\nu_+^2(n)\nu_-^2(n)=(n+1)[\nu_+^2(n)+\nu_-^2(n)].$$

The result is smaller than the constant

$$\xi=\|Q_1\|\|Q_1^{-1}\|(1-\kappa^2/4)^{-1}.$$

We thus obtain the estimate

$$\|R(z;m,n)\|\leqslant\xi\sum_{\eta_1,\eta_2=\pm1}|z-i\mu_{\eta_1}(m)-i\mu_{\eta_2}^*(n)|^{-1}, \tag{29}$$

for $m,n\geqslant-1$. By assumption (iii), the right-hand side is positive and finite.

For the other matrices figuring in the kernel one derives the bounds

$$\begin{aligned}\|S(m,n)\|&\leqslant2(m+2)^{1/2}(n+2)^{1/2}\theta_{m+1}\theta_{n+1},\\ \|T(m,n)\|&\leqslant5\kappa^{-1}[(m+1)^{1/2}(n+1)^{1/2}-\delta_{m,0}\delta_{n,0}]\theta_m\theta_n,\\ \|A_1(m,n)\|&\leqslant2(m+n+4-2\delta_{m,-1}\delta_{n,-1})\theta_{m+1}\theta_{n+1}.\end{aligned} \tag{30}$$

The factor of κ^{-1}, contained in the bound for T, is due to transformation (5). This factor lives on all the way to the first argument of ψ in the estimate (10) for the limiting vector. No problems arise as long as κ is kept fixed and finite. In Appendix A we sketch what measures must be taken in order to create estimates that do not blow up for small damping parameter.

B. Bound on the kernel

We are now in a position to construct a bound on the kernel. Let us start by fixing the contour on the right-hand side of (24). From the auxiliary inequalities

$$c_2 \equiv \tfrac{1}{4}[1-|\Delta|/|\mathrm{Re}\,u(0)|]>0, \quad |\mathrm{Re}\,u(m)|>|\mathrm{Re}\,u(n)|, \tag{31}$$

valid for $m>n\geqslant 0$, one learns that the poles of the integrand of (24) are contained within the following rectangle:

$$-|\mathrm{Re}\,u(m+k+p)|-|\mathrm{Re}\,u(n+k+p)|-|\Delta|\leqslant \mathrm{Re}\,z\leqslant |\mathrm{Re}\,u(m+k+p)|+|\mathrm{Re}\,u(n+k+p)|+|\Delta|,$$

$$-\kappa(m+n+2k+2p+2)\leqslant \mathrm{Im}\,z\leqslant -2\kappa c_2,$$

the pole at $z=0$ excepted. The latter pertains to the case $m=n=-1$, which will be handled later on.

The contour of our choice is specified by

$$\begin{gathered} z=\kappa w-i\kappa c_2, \\ w=x, \quad -\rho\leqslant x\leqslant \rho \quad (C_1), \\ w=\rho\exp(i\phi), \quad -\pi\leqslant\phi\leqslant 0 \quad (C_2). \end{gathered} \tag{32}$$

If the radius of the closing arc C_2 is taken as $\rho(m/2+n/2+k+p)$, with the definition

$$\rho(l)=12\kappa^{-1}(l+2+|\Delta|+\Delta^2),$$

then surely all of the poles are covered.

Having fixed the contour (32), we can refine the bounds on resolvents. From (29) and (31) we infer the inequalities

$$\begin{gathered} \|R(\kappa w-i\kappa y;m,n)\|\leqslant 4\xi\kappa^{-1}(m\theta_m+n\theta_n+c_2)^{-1}, \\ \|R(\kappa w-i\kappa y;m,n)\|\leqslant \xi\kappa^{-1}\sum_{\eta_1,\eta_2=\pm 1}|x+\mathrm{Im}[\mu_{\eta_1}(m)-\mu_{\eta_2}(n)]/\kappa+ic_2|^{-1}, \end{gathered} \tag{33}$$

with $w\in C_1$, and

$$\|R(\kappa w-i\kappa y;m+s,n+s)\|\leqslant 8\xi[\kappa\rho(m/2+n/2+k+p)]^{-1}, \tag{34}$$

with $w\in C_2$. The conditions $y\leqslant c_2$ and $-\min(m,n)-1\leqslant s\leqslant k+p$ must be satisfied, whereas the choice $m=n=-1$ is forbidden. Combination of (30) with (33) and (34) brings us for $-\min(m,n)-1\leqslant s\leqslant k+p-1$ and $y\leqslant c_2$ to the comfortable estimate

$$\|S(m+s,n+s)\|\|R(\kappa w-i\kappa y;m+s+1,n+s+1)\|\leqslant 8\xi(\kappa c_2)^{-1}, \tag{35}$$

which is valid for $w\in C_1\cup C_2$. Use has been made of the fact that the geometric mean $(mn)^{1/2}$ is smaller than the arithmetic mean $(m+n)/2$.

Special attention must be paid to the zero-temperature case $p=0$, because one must distinguish between the choices $k=0$ and $k\geqslant 1$. For $k=0$ the kernel has one resolvent only. The inequality

$$\left\| \oint \frac{\mathrm{d}z}{2\pi i} e^{-izt}R(z;m,n)\right\|\leqslant 4\xi e^{-c_2\kappa t},$$

can be applied. For the proof, one evaluates all residues on the left-hand side. The result can be estimated with the help of (29).

The choice $k \geqslant 1$ allows for employment of (32), because one meets two resolvents at least. For the contours C_1 and C_2 we control the two resolvents with photon numbers (m,n) and $(m+1,n+1)$ through (33) and (34), respectively. The other $k-1$ resolvents are estimated with the help of (35). Upon extending the boundaries of the integral over x to infinity, we arrive at

$$\|K(t;k,p=0;m,n)\| \leqslant 4\xi e^{-c_2\kappa t}\delta_{k,0} + \xi^2 (16\xi/c_2)^{k-1} e^{-c_2\kappa t} \|S(m,n)\| \times \left[\left(\sum_{\eta_1,\eta_2,\eta_3,\eta_4=\pm 1} \mathcal{J}(a,b)/\pi \right) + 64[\rho(m/2+n/2+k)]^{-1} \right] \theta_{k-1},$$

where the integral

$$\mathcal{J}(a,b) = \int_{-\infty}^{\infty} \mathrm{d}x |x+a+ic_2|^{-1} |x+b+ic_2|^{-1} < 10/c_2$$

appears. The inequality is valid for all real a and b. These parameters must be taken as $\mathrm{Im}[\mu_{\eta_1}(m) - \mu_{\eta_2}(n)]/\kappa$ and $\mathrm{Im}[\mu_{\eta_3}(m+1) - \mu_{\eta_4}(n+1)]/\kappa$, respectively.

Insertion of the bound on $\mathcal{J}$ gives $160/(\pi c_2)$, which is larger than the form containing ρ, at least, if $\kappa < 2$. Therefore, by adding an overall factor of 2, we can drop the latter term. We use (30) to finalize the bound as follows:

$$\|K(t;k,p=0;m,n)\| \leqslant 16\xi (16\xi/c_2)^k (m+2)^{1/2} (n+2)^{1/2} e^{-c_2\kappa t} \theta_k, \tag{36}$$

where the choice $m=n=-1$ is forbidden.

Next, we consider the kernel for $p \geqslant 1$, making use of (32) for all k. From the resolvents with photon numbers (m,n) and $(m+l_p, n+l_p)$ we create an integral $\mathcal{J}$ in the same vein as previously. Owing to condition (23) on the summation indices $\{l_s\}$, the inequality (35) can furnish bounds on the D_1 matrices. Processing the resolvents that are left with the aid of (33) and (34), we find

$$\begin{aligned} \|K(t;k,p;m,n)\| \leqslant{}& \frac{1}{2} (2\kappa)^k (8\xi)^{p+1} e^{-c_2\kappa t} \theta_{k+p} \\ & \times \sum_{l_0=0} \sum_{l_1=l_0-1}^{k+p-1} \sum_{l_2=l_1-1}^{k+p-2} \cdots \sum_{l_p=l_{p-1}-1}^{k} \left[\left(\sum_{\eta_1,\eta_2,\eta_3,\eta_4=\pm 1} \mathcal{J}(a,b)/(32\pi) \right) \right. \\ & \left. \times \prod_{s=1}^{p-1} [(m+l_s)\theta_{m+l_s} + (n+l_s)\theta_{n+l_s} + c_2]^{-1} + [\rho(m/2+n/2+k+p)/2]^{-p} \right] \\ & \times \prod_{s=1}^{p} [\|T(m+l_s+1,n+l_s+1)\| + \|A_1(m+l_s,n+l_s)\|] \left(\frac{8\xi}{\kappa c_2} \right)^{k-l_p} \\ & \times \prod_{s=1}^{p} \left[2\kappa \left(\frac{8\xi}{\kappa c_2} \right)^{l_s - l_{s-1}+1} + \theta_{l_s-l_{s-1}} \left(\frac{8\xi}{\kappa c_2} \right)^{l_s-l_{s-1}} \right], \end{aligned}$$

with $p \geqslant 1$. The parameter a need not be modified, but b must be chosen now as $\mathrm{Im}[\mu_{\eta_3}(m+l_p) - \mu_{\eta_4}(n+l_p)]/\kappa$.

Again, we replace $\mathcal{J}$ by its upper bound, and omit the term containing ρ in exchange for an overall factor of 2. This enables us to appeal to the inequality

$$\frac{\|T(m+1,n+1)\| + \|A_1(m,n)\|}{m\theta_m + n\theta_n + c_2} \leqslant 2c_2^{-1}(4+5/\kappa), \tag{37}$$

which follows from (30). For $s=p$ the denominator of (37) lacks, so that another inequality must be employed, namely

$$\|T(m+l_p+1,n+l_p+1)\|+\|A_1(m+l_p,n+l_p)\|\leqslant(4+5/\kappa)(m/2+n/2+l_p+2), \tag{38}$$

where l_p is put equal to its maximum value of k.

Having disposed of all dependencies on the dummies $\{l_s\}$, we can perform the corresponding summations by the rule

$$\sum_{l_1=0}^{p}\sum_{l_2=l_1}^{p}\sum_{l_3=l_2}^{p}\cdots\sum_{l_q=l_{q-1}}^{p}=\binom{p+q}{q}, \tag{39}$$

with $p\geqslant 0$ and $q\geqslant 1$. In final form, the bound on the kernel reads

$$\|K(t;k,p;m,n)\|\leqslant 16\xi\left(\frac{16\xi}{c_2}\right)^{k+p}\left(1+\frac{16\xi}{c_2}\right)^{p}\left(4+\frac{5}{\kappa}\right)^{p}\binom{2p+k}{p}(m/2+n/2+k+2)e^{-c_2\kappa t}\theta_{k+p}, \tag{40}$$

with $m,n\geqslant -1$, the choice $m=n=-1$ forbidden, and $p\geqslant 0$; note that for $p=0$ the above-mentioned bound exceeds (36). As pointed out already, the factor of κ^{-1} stems from (30). In Appendix A we discuss how this factor can be suppressed.

C. Taking the order of iteration to infinity

Assumption (ii) and Eq. (40) supply us with bounds on the components generating the solution vector. Hence, we are ready to examine the distance $\|\mathbf{v}(t;N;m,n)-\mathbf{v}(t;N';m,n)\|$ for large iteration orders. The involved sums can be rearranged as

$$\begin{aligned}\sum_{p=0}^{N-1}\sum_{k=-\min(m,n)-1}^{N-p-1}-\sum_{p=0}^{N'-1}\sum_{k=-\min(m,n)-1}^{N'-p-1}&=\sum_{p=0}^{N-1}\sum_{k=N'-p}^{N-p-1}\theta_{\min(m,n)+N'-p}\\&+\sum_{p=N'}^{N-1}\sum_{k=-\min(m,n)-1}^{N'-p-1}\theta_{\min(m,n)+N'-p}\\&+\sum_{p=0}^{N-1}\sum_{k=-\min(m,n)-1}^{N-p-1}\theta_{p-\min(m,n)-N'-1},\end{aligned}$$

with $N\geqslant N'\geqslant 1$. We shift $k\to k-p$, and interchange the sums over k and p.

Next, we use assumption (ii) and Eq. (40), as well as the inequalities

$$\frac{(k+p)!}{k!}\leqslant(k+p_{\max})^p,\quad \frac{([m/2+n/2+1])!}{[(m+1)!(n+1)!]^{1/2}}\leqslant 1,$$

where $m,n\geqslant -1$ and $p_{\max}$ denotes the maximum of p in a given sum. By (11), we may set $p_{\max}$ equal to $k+\min(m,n)+1$. This paves the way for applying the binomial theorem. One encounters the factors

$$\left[1+\frac{2\lambda}{c_6^2}\left(1+\frac{16\xi}{c_2}\right)\left(4+\frac{5}{\kappa}\right)[k+\min(m,n)+1]\right]^{k+m/2+n/2+1},$$

and $1/([m/2+n/2+1]+k)!$, the entire function $[\cdots]$ rendering the argument of the factorial integer. To modify these factors, we let us be guided by the inequalities $(a+b)^k\leqslant(2a)^k+(2b)^k$ and $1/k!\leqslant\exp(k+1)/(k+1)^k$. We then obtain the result

$$\|\mathbf{v}(t;N;m,n)-\mathbf{v}(t;N';m,n)\|\leqslant c_1(N,N')e^{-c_2\kappa t}(m/2+n/2+2)^3\psi(c_3\lambda/\kappa,c_4;m/2+n/2+1), \tag{41}$$

with $N\geqslant N'\geqslant \min(m,n)+2$ and the choice $m=n=-1$ forbidden. The constants are found as

$$c_1(N,N')=256e\xi c_5\sum_{k=N'-\min(m,n)-1}^{N-1}\theta_{k-1}k^3\left(\frac{16\xi}{c_2}\right)^k\psi(c_3\lambda/\kappa,c_4;k),$$

$$c_3=4e(4\kappa+5)(1+16\xi/c_2),\quad c_4=2ec_6^2.$$

The constants c_2, c_5, and c_6 appear in (11) and (31).

From (41) we conclude that $\mathbf{v}(t;N;m,n)$ may be regarded as a Cauchy sequence in N. Consequently, a vector $\mathbf{v}(t;\infty;m,n)$ exists such that (13) is true. The upper bound belonging to assumption (iv) comes out as

$$0\leqslant\lambda<\lambda_0=\frac{c_2\kappa}{16\xi c_3}. \tag{42}$$

Repetition of the foregoing proof for $N'=0$ shows that for $c_1=c_1(\infty,0)$ the limiting vector $\mathbf{v}(t;\infty,m,n)$ satisfies the inequality (10). Note that the choice $m=n=-1$ is still forbidden.

Hence, the proof must be repeated for the case $m=n=-1$ as well. By severing the pole at $z=0$ from the contour (24), we can cast (8) into the form

$$\mathbf{v}(t;N;-1,-1)=\mathbf{v}_{\rm ss}(N)+e^{-c_2\kappa t}\mathbf{v}_{\rm fl}(t;N).$$

The steady-state (ss) term and fluctuating (fl) term are given by

$$\mathbf{v}_{\rm ss}(N)=\sum_{p=0}^{N-1}\sum_{k=0}^{N-p-1}\lambda^p\lim_{z\to0}z\tilde{K}(z;k,p;-1,-1)\mathbf{v}(t=0;k-1,k-1),$$

$$\mathbf{v}_{\rm fl}(t;N)=\kappa\sum_{p=0}^{N-1}\sum_{k=0}^{N-p-1}\lambda^p\oint\frac{dw}{2\pi i}e^{-i\kappa tw}\tilde{K}(\kappa w-i\kappa c_2;k,p;-1,-1)\mathbf{v}(t=0;k-1,k-1).$$

In the lower line one may work with contour (32), so for $k=p=0$ the result is vanishing. The radius of C_2 is taken as $\rho(k+p)$.

For the fluctuating term we can establish a counterpart of (41) along the same lines as before. The factor of $|x-ic_2|^{-1}$ pertaining to C_1 is included in the integral $\mathcal{J}$. Owing to condition (23), employment of (33)–(35) is permitted. One is led to the assertion

$$\|\mathbf{v}_{\rm fl}(t;N)-\mathbf{v}_{\rm fl}(t;N')\|\leqslant 8ec_5\sum_{k=N'}^{N-1}k^2\left(\frac{16\xi}{c_2}\right)^k\psi(c_3\lambda/\kappa,c_4;k), \tag{43}$$

for $N\geqslant N'\geqslant 1$.

To deal with the steady-state term, one should recognize that the matrix

$$K_0(k,p)=\lim_{z\to0}z\tilde{K}(z;k,p;-1,-1)$$

obeys the recursion

$$K_0(k+1,p+1)=-2\kappa[K_0(k,p+1)S(k-1,k-1)+K_0(k+2,p)T(k+1,k+1)$$
$$+K_0(k+1,p)A_1(k,k)]A_0^{-1}(k,k),$$

with $k \geqslant 0$, $p \geqslant -1$, and $K_0(k,-1)=0$ by definition. The initial condition $K_0(0,p)=\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2\delta_{p,0}$ gives the solution

$$K_0(k,p)=\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2\delta_{k,0}\delta_{p,0}-\hat{\mathbf{e}}_2\hat{\mathbf{e}}_1\theta_{k-1}\delta_{p,0}+2(-1)^p(\hat{\mathbf{e}}_2\hat{\mathbf{e}}_1+\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2)\theta_{k-1}.$$

The constraint $\mathrm{Tr}\,\rho(t=0)=1$ is equivalent to

$$\sum_{k=-1}^{\infty}\left(\theta_k,\frac{2}{1-\lambda}-\delta_{k,-1},0,0\right)\cdot\mathbf{v}(t=0;k,k)=1.$$

Combination of the last two results yields

$$\|\mathbf{v}_{\mathrm{ss}}(N)-(1-\lambda)(1+\lambda)^{-1}\hat{\mathbf{e}}_2\|\leqslant 14c_5\sum_{k=N-2}^{\infty}\frac{c_6^{2k+2}}{k!}+8c_5\sum_{k=0}^{N-3}\lambda^{N-k-1}\frac{c_6^{2k+2}}{k!}.$$

Together with (43), this statement completes the proof of (13) and shows that the limiting vector $\mathbf{v}(t;\infty;-1,-1)$ satisfies the inequality (10).

D. Controlling the remainders

We aim at proving that all of our remainders tend to zero for large iteration order. Again, the case $m=n=-1$ asks for a separate effort. The argument makes use of assumption (i). Hence, the Laplace transform of the unknown vector $\mathbf{v}(t;m,n)$ can be estimated as

$$\|\tilde{\mathbf{v}}(z;m,n)\|\leqslant\frac{c_1(m/2+n/2+2)^3}{\mathrm{Im}\,z+c_2\kappa}\psi(c_3\lambda/\kappa,c_4;m/2+n/2+1),$$

with $\mathrm{Im}\,z>-c_2\kappa$ and the choice $m=n=-1$ forbidden. The inequality fixes the half space on which the Laplace transform is analytic.

For the first remainder of (25) we may shift the contour downward to the level $\mathrm{Im}\,z=-c_2\kappa/2$. Next, we call upon the inequalities (33) and (35), with y set equal to $c_2/2$. By copying previously explained techniques, we reach the result

$$\left\|\int_C \mathrm{d}z\, e^{-izt}\,\tilde{\mathbf{r}}_1(z;N;m,n)\right\|\leqslant c_1(10N)^4(16\xi/c_2)^N(m/2+n/2+1)^5\times\psi(c_3\lambda/\kappa,c_4;m/2+n/2+N+1).$$

By assumption (iv), the right-hand side tends to zero for large N.

As they do not differ much, the second and third remainders can be treated on a par. The contour is laid out as above. In building integral $\mathcal{J}$, we select the resolvents with photon numbers $(m,n),(m+l_p,n+l_p)$ and $(m,n),(m+l_{N-1},n+l_{N-1})$ for the second and third remainder, respectively. We employ (30) for the matrix $S(m+N+l_p-1,n+N+l_p-1)$ of the second remainder. We also make use of (38); for the second remainder as it stands, for the third one with the replacements $p\to N$ and $p\to N-1$ made. All other matrix norms are taken care of by (35) and (37). We now arrive at the intermediate inequalities

$$\left\| \int_C \mathrm{d}z\, e^{-izt}\, \tilde{\mathbf{r}}_2(z;N;m,n) \right\| \leqslant 20 c_1 \sum_{p=1}^{N-1} \sum_{l_0=0} \sum_{l_1=l_0-1}^{N+l_0-1} \sum_{l_2=l_1-1}^{N+l_1-1} \cdots \sum_{l_p=l_{p-1}-1}^{N+l_{p-1}-1} \left(\frac{16\xi}{c_2}\right)^{N+l_p+p} \left(\frac{c_3\lambda}{4e\kappa}\right)^p$$
$$\times (m/2+n/2+N+l_p+2)^5 \psi(c_3\lambda/\kappa, c_4; m/2+n/2+N+l_p+1)$$
$$\times \prod_{s=1}^{p} \theta_{l_s+\min(m,n)+1},$$

and

$$\left\| \int_C \mathrm{d}z\, e^{-izt} \tilde{\mathbf{r}}_3(z;N;m,n) \right\| \leqslant 10 c_1 \sum_{l_0=0} \sum_{l_1=l_0-1}^{N+l_0-1} \sum_{l_2=l_1-1}^{N+l_1-1} \cdots \sum_{l_N=l_{N-1}-1}^{N+l_{N-1}-1} \left(\frac{16\xi}{c_2}\right)^{N+l_N} \left(\frac{c_3\lambda}{4e\kappa}\right)^N$$
$$\times (m/2+n/2+l_N+3)^5 \psi(c_3\lambda/\kappa, c_4; m/2+n/2+l_N+1)$$
$$\times \prod_{s=1}^{N} \theta_{l_s+\min(m,n)+1}.$$

As for (23), the conditions on the dummies $\{l_s\}$ originate from (30).

In elaborating the bound on the second remainder, we take N such that $c_4/N \leqslant c_3\lambda/\kappa$; consequently, the c_4 term in ψ can be dropped at the cost of a factor of 2. In treating the factor $(m/2+n/2+N+l_p+1)^5$, the inequality $l_p \leqslant N^2$ is helpful. Upon omitting the conditions on $\{l_s\}$, transforming these dummies as $l_s - l_{s-1} + 1 \to l_s$, and extending their upper boundaries to infinity, we meet a product of p identical sums. Problems with convergence do not occur as long as λ stays sufficiently small.

In elaborating the bound on the third remainder, we once more use the inequality $l_N \leqslant N^2$, and subsequently extend the upper boundaries of all sums to infinity. We then must face the following form:

$$\chi(x_1,x_2;p,q) = \sum_{l_0=p} \sum_{l_1=l_0-1}^{\infty} \sum_{l_2=l_1-1}^{\infty} \cdots \sum_{l_q=l_{q-1}-1}^{\infty} \left(x_1^{l_q} + \frac{x_2^{l_q}}{l_q!}\right) \prod_{s=1}^{q} \theta_{l_s},$$

with $x_1 = 16\xi c_3\lambda/(\kappa c_2) < 1$, $x_2 = 16\xi c_4/c_2$, $p = \min(m,n)+1$, and $q = N$. In Appendix B it is demonstrated that

$$\chi(x_1,x_2;p,q) \leqslant [4/(1-x_1)]^q + 4^q \exp[x_2(p+q)], \tag{44}$$

for $0 \leqslant x_1 < 1$, $x_2 \geqslant 0$, and $p,q \geqslant 0$. We can finish the treatment of the second and third remainders through the estimate

$$\sum_{j=2,3} \left\| \int_C \mathrm{d}z\, e^{-izt}\, \tilde{\mathbf{r}}_j(z;N;m,n) \right\| \leqslant c_1 (m/2+n/2+2)^5 c_7^{m/2+n/2+1} (10N)^{11} \left(\frac{16\xi c_3\lambda}{c_2\kappa}\right)^N$$
$$\times \left[\left(1 - \frac{16\xi c_3\lambda}{c_2\kappa}\right)^{-N} + \exp\left(\frac{16\xi c_4 N}{c_2}\right) \right],$$

where constant c_7 need not be specified.

The right-hand side of the above-given inequality tends to zero for $N \to \infty$ and $\lambda < \lambda_0'$, with λ_0' sufficiently small. The new condition on λ does not have any physical significance. The replacement of λ_0 by λ_0', necessary for eliminating the remainders, can be annulled. For the solution vector one should perform analytic continuation in λ.

The fourth remainder does not pose any new difficulties. The integral $\mathcal{J}$ is constructed on the basis of the resolvents with photon numbers (m,n) and $(m+l_p, n+l_p)$. All matrix norms can be dealt with through use of (33), (35), (37), and (38). Of course, for the initial vector the bound (11)

must be substituted. Rule (39) can be applied to the $\{l_s\}$ sums. Upon performing the shift $k \to k - p$, and computing the sum over p by the binomial theorem, we end up with

$$\left\| \int_C \mathrm{d}z\, e^{-izt}\, \tilde{\mathbf{r}}_4(z;N;m,n) \right\| \leqslant 10^4 c_5 \xi (m/2+n/2+2)^3 c_7^{m/2+n/2+1} \times \sum_{k=N}^{\infty} k^3 (16\xi/c_2)^k \psi(c_3 \lambda/\kappa, c_4; k).$$

Again, the right-hand side does not survive the limit $N \to \infty$.

With the above-noted material available, it is straightforward to prove that also for the case $m=n=-1$ one can get rid of the remainders by making the iteration order large. As before, the pole at $z=0$ must be severed from the contour. The ensuing residues must be handled separately. Altogether, we reach the satisfactory conclusion that the important limit (14) holds true.

V. A LIMIT OF MAXIMUM ENTROPY

From here onwards, we adopt as the initial density operator the factorized form (12), with the field in a photon-number state $|q\rangle$, and q positive. We are going to take a closer look at the evolution of the (2×2) density matrix $\rho_A(t) = \mathrm{Tr}_F[\rho(t)]$ describing the atom. A limit will be proposed, for which this matrix converges to the so-called central state $\mathbf{1}_2/2$. Then the von Neumann entropy of the atom, which is proportional to the trace $-\mathrm{Tr}(\rho_A \log \rho_A)$, attains its maximum value.

For the given initial condition the atomic density matrix can be computed from

$$\rho_A(t)_{22} = 1 - \rho_A(t)_{11} = \mathbf{d}(t;q)\cdot(\hat{\mathbf{e}}_1 \rho_{A,11} - \hat{\mathbf{e}}_2 \lambda \rho_{A,22}) + \mathbf{d}(t;q-1)\cdot(\hat{\mathbf{e}}_2 - \hat{\mathbf{e}}_1)\rho_{A,22},$$

$$\rho_A(t)_{12} = \rho_A(t)^*_{21} = \sum_{p=0}^{\infty} \sum_{n=0}^{q+p} \lambda^p \hat{\mathbf{e}}_3 \cdot K(t;q-n,p;n,n-1)\cdot \hat{\mathbf{e}}_3 \rho_{A,12}, \tag{45}$$

$$\mathbf{d}(t;q) = (1-\lambda)^{-1} \sum_{p=0}^{\infty} \sum_{n=-1}^{p+q} \lambda^p \hat{\mathbf{e}}_2 \cdot K(t;q-n,p;n,n)\cdot(\hat{\mathbf{e}}_1 \hat{\mathbf{e}}_1 + \hat{\mathbf{e}}_2 \hat{\mathbf{e}}_2), \tag{46}$$

where the notations $\rho_A(t)_{ij} = \hat{\mathbf{b}}_i \cdot \rho_A(t) \cdot \hat{\mathbf{b}}_j$ and $\rho_A = \rho_A(t=0)$ appear.

In contrast to Sec. IV, we do not conduct the argument in a completely rigorous manner. While working out (45) and (46) for small κ, we operate directly in the summands, without investigating whether the interchange of limit and sum is allowed. Unfortunately, completion of this job is far from immediate, because it necessitates us to strengthen the bounds (10) on the limiting vector $\mathbf{v}(t;\infty,m,n)$. In the first argument of ψ the factor of κ^{-1} must be removed. Appendix A presents a possible strategy. Still, in Appendix D we carry out an important consistency check. We make sure that for large times the weak-damping version of $\rho_A(t)$ neatly converges to the thermal state. Other behavior would be physically unacceptable.

Let us set the detuning Δ equal to zero, and investigate the atomic density matrix in the limit of $\kappa \to 0$, $t \to \infty$, $q \to \infty$, under the constraint that κt and κq^3 be constant. Thus the time scales of the Jaynes–Cummings interaction and the process of photon loss become separated. On top of that, during the time lag of κ^{-1} that photon losses are modest, the field can maximally fuel the atom. Indeed, for the undamped Jaynes–Cummings model one already observes that a field of high energy drives the atom toward the central state.[7] But perpetual oscillations of $\rho_A(t)$ inhibit convergence.

We examine the behavior of (24) for $m=n$ positive. The kernel falls apart into two terms: one pertaining to the poles of order κ, and another to those of order unity. If z remains finite, a resolvent $R(z;n,n)$ cannot diverge, so the latter term is of order κ^{k+p} for κ small. Consequently, only the case $k+p=0$ contributes. Condition (23) causes the closed contour of K to be confined

to the half space $\mathrm{Im}\, z<-\kappa(2n-2p+1)\theta_{n-p}$. Hence, in each residue a factor of $\exp[-\kappa t(2n-2p+1)\theta_{n-p}]$ is contained. It explicitly appears if the transformation $z=y-i\kappa(2n-2p+1)\theta_{n-p}$ is made.

Altogether, for small κ and $n\geqslant 0$ we can write

$$K(t;k,p;n,n)=K_1(t;k,p;n,n)+K_2(t;k,p;n,n),$$

$$K_1(t;k,p;n,n)=\oint\frac{\mathrm{d}y}{2\pi}e^{\kappa t y}\kappa\tilde{K}(i\kappa y;k,p;n,n),$$

$$K_2(t;k,p;n,n)=\delta_{k+p,0}e^{-\kappa t(2n-2p+1)}\oint\frac{\mathrm{d}y}{2\pi i}e^{-iyt}\tilde{K}(y-i\kappa(2n-2p+1);k,p;n,n). \quad (47)$$

In K_1 we have transformed $z=i\kappa y$, so that for small κ all poles are of order unity. One can further simplify the term K_2 by recognizing that for $p\geqslant 2$ and y finite, the product

$$\left\{\prod_{s=1}^{p}2i\kappa T(n-s+1,n-s+1)R(y;n-s,n-s)\right\}$$

is of order κ at least. Therefore, K_2 makes a contribution to (46) that decays as $\exp(-2\kappa tq)$ for q large.

In working out K_1, we must realize that now factors of κ^{-1} are generated by the resolvents. For all $k+p\geqslant 0$ finite contributions occur. On the other hand, we still may neglect terms of order κ against terms of order unity. This offers us the possibility to replace matrices as

$$2i\kappa R(i\kappa y;n,n)=(\hat{\mathbf{e}}_2\hat{\mathbf{e}}_1+2\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2+2\hat{\mathbf{e}}_4\hat{\mathbf{e}}_4)(y+2n+1)^{-1},$$

$$\begin{aligned}2i\kappa T(n+1,n+1)R(i\kappa y;n,n)=&[-y\hat{\mathbf{e}}_2\hat{\mathbf{e}}_1/2+\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2(2n+1)](y+2n+1)^{-1}\\&+2\hat{\mathbf{e}}_4\hat{\mathbf{e}}_4(n+1)^{1/2}(n+2)^{1/2}(y+2n+1)^{-1},\end{aligned}$$

for κ small, $n\geqslant 0$, and y finite. From inspection of the left-hand sides one sees that contributions of order $\kappa n^{5/2}$ have been dropped. Surely n can become of order q, so as soon as q tends to infinity the constraint $\kappa q^3=$constant becomes important. Note that the product with T has the structure

$$(\kappa^{-1}T_0+T_1)(R_0+\kappa R_1)=T_1R_0+T_0R_1+\cdots,$$

where T_0R_0 vanishes. Generally speaking, if the leading term of a matrix expansion is noninvertible, then the next-to-leading term may contribute to the final result. In the present case T_1 indeed does so.

In view of (46), the above-given replacements, and the blocked shape of $A_1(n,n)$ and $S(n,n)$, we can retreat to the subspace spanned by $(1,0)^T$ and $(0,1)^T$. Accordingly, for each (4×4) matrix we only retain the upper left block by carrying out the substitution

$$M\rightarrow\begin{pmatrix}M_{11}&M_{12}\\M_{21}&M_{22}\end{pmatrix}. \quad (48)$$

This gives rise for example to the identity

$$\left\{\prod_{s=0}^{m} S(n+s,n+s)\begin{pmatrix}0 & 0\\ 1 & 2\end{pmatrix}\right\}=(2n+3)^{-1}\prod_{s=1}^{m+1}(2n+2s+1)$$
$$\times\left[\begin{pmatrix}2(n+2) & 2\\ -(n+2) & -1\end{pmatrix}\delta_{m,-1}+\begin{pmatrix}-1 & -2\\ n+2 & 2(n+2)\end{pmatrix}\right],$$

with $m\geqslant -1$ and $n\geqslant 0$. In the sequel, the correction term with the Kronecker delta plays an important role.

The foregoing material safely guides us through the evaluation of the K_1 kernel for weak damping. The final expression reads

$$K_1(t;k,p;n,n)=\theta_{k+p}\oint\frac{\mathrm{d}y}{4\pi i(2n+1)(2n+3)}e^{\kappa t y}\prod_{s=0}^{k+n}\frac{2s+1}{y+2s+1}\prod_{s=0}^{n-1}\frac{y+2s+1}{2s+1}$$
$$\times\begin{pmatrix}0 & 0\\ 1 & 2\end{pmatrix}D_3(y;k+n,p;n). \tag{49}$$

We have imposed $n\geqslant 0$, $p\geqslant 0$, κ small, and κt constant. We have defined the matrix

$$D_3(y;q,p;n)=\sum_{l_0=n}\sum_{l_1=l_0-1}^{q+p-1}\sum_{l_2=l_1-1}^{q+p-2}\cdots\sum_{l_p=l_{p-1}-1}^{q}\prod_{s=1}^{p}\theta_{l_s}\prod_{s=1}^{p}[(y+2l_s+1)(y+2l_s+3)(2l_s+3)]^{-1}$$
$$\times\left\{\prod_{s=1}^{p}V(y;l_s,l_{s-1})\right\}\left[\begin{pmatrix}2(q+2) & 2\\ -(q+2) & -1\end{pmatrix}\delta_{l_p,q}+\begin{pmatrix}-1 & -2\\ l_p+2 & 2(l_p+2)\end{pmatrix}\theta_{q-l_p}\right],$$

where V stands for

$$V(y;k,l)=(2k+3)(2k+5)\begin{pmatrix}0 & 0\\ -y/2 & 2k+1\end{pmatrix}\delta_{k,l-1}-(k+1)(y+2k+3)\begin{pmatrix}2 & 4\\ -1 & -2\end{pmatrix}\delta_{k,l}$$
$$-2\begin{pmatrix}-1 & -1\\ l+2 & l+2\end{pmatrix}\begin{pmatrix}0 & 0\\ y(4k+5)/2+(2k+3)(k+1) & 2y(k+1)+2k+3\end{pmatrix}\theta_{k-l}.$$

One should remember that (48) has been practiced, so K_1 is indeed a (2×2) matrix.

For a full computation of (46) the kernel must be specified for $n=-1$ as well. The K_2 part disappears, because for $k=p=0$ there are no finite poles. In elaborating the K_1 part, the identity $R(z;-1,-1)=\hat{\mathbf{e}}_2\hat{\mathbf{e}}_2/z$ must be employed. For small κ one ends up with

$$K_1(t;k,p;-1,-1)=\oint\frac{\mathrm{d}y}{2\pi i}\frac{e^{\kappa t y}}{y}\prod_{s=0}^{k-1}\frac{2s+1}{y+2s+1}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix}D_3(y;k-1,p;-1), \tag{50}$$

where $k\geqslant 1$ and $p\geqslant 0$ must be respected.

We are ready to calculate (46) for κ small, κt constant, and κq^3 constant. As pointed out, the K_2 term may be completely ignored. In K_1 the power series $\Sigma_{j=0}^{\infty}(\kappa t y)^j/j!$ is inserted for the exponential factor. By invoking (26), we can readily find out how the $j=0$ term contributes to (46). In Appendix C we show that the terms with $1\leqslant j\leqslant p+q$ do not produce anything at all. These findings bring us to the relation

$$\mathbf{d}(t;q)-\frac{1}{2}\left(1,\frac{2}{1-\lambda}\right)=\frac{1}{1-\lambda}\sum_{p=0}^{\infty}\lambda^p\oint\frac{dy}{2\pi i}\sum_{j=p+q+1}^{\infty}\frac{(\kappa t y)^j}{j!}\prod_{s=0}^{q}\frac{2s+1}{y+2s+1}$$
$$\times\left[\frac{1}{2}\sum_{n=0}^{p+q}\prod_{s=0}^{n-1}\frac{y+2s+1}{2s+1}\frac{(1,2)\cdot D_3(y;q,p;n)}{(2n+1)(2n+3)}\right.$$
$$\left.+y^{-1}(0,1)\cdot D_3(y;q,p;-1)\right], \tag{51}$$

with κ small, κt constant, and $q\geqslant 1$. For large q the product κq^3 must remain constant.

The only task left consists of investigating how (51) behaves as q tends to infinity. To that end, the contour $y=4(p+q+1)\exp(i\phi)$, with $0\leqslant\phi\leqslant 2\pi$, is employed. Combination of the estimate

$$\|V(y;k,l)\|\leqslant 16(2k+3)(l+3)(|y|+k+1)$$

with (39) leads to

$$\|D_3(y;q,p;n)\|\leqslant 6(n+3)40^p\binom{q+2p-n}{p},$$

for $n\geqslant -1$. In setting a bound on (51), the term containing y^{-1} may be dropped in exchange for an overall factor of 2.

Next, we can profit from the assertions

$$\prod_{s=n}^{p+q}\left|\frac{2s+1}{y+2s+1}\right|\leqslant 1,\quad \prod_{s=q+1}^{p+q}\left|\frac{y+2s+1}{2s+1}\right|\leqslant\frac{3^p(p+q+1)^p q!}{(p+q)!},$$

and substitute for the sum over n the largest term, which is the one with $n=0$, multiplied by the number of terms, which amounts to $p+q+1$. We can finalize the bound on (51) with the help of the results

$$\frac{(2p+q)!q!}{[(p+q)!]^2}\leqslant 4^p,\quad \sum_{j=n}^{\infty}\frac{(\alpha n)^j}{j!}\leqslant\frac{\exp[n(1+\log\alpha)]}{1-\alpha},$$

where $0\leqslant\alpha<1$ must be valid. The desired inequality reads

$$\left\|\mathbf{d}(t;q)-\frac{1}{2}\left(1,\frac{2}{1-\lambda}\right)\right\|\leqslant c_8 q^2\exp\{[1+960\lambda+\log(4\kappa t)]q\}, \tag{52}$$

where c_8 does not depend on q. For $\lambda<1/(960e)$ the constant c_8 is finite. Moreover, if we take $\kappa t<[4\exp(1+1/e)]^{-1}$, then for large q the right-hand side falls off exponentially.

To learn what becomes of the matrix element $\rho_A(t)_{12}$, one has to analyze the kernel $K(t;k,p;n,n-1)$ for κ small. All poles turn out to be of order unity. Hence, only for $k+p=0$ nonzero contributions occur. As the matrix $T(n,n-1)$ is regular for small κ, the choice $p=0$ is also necessary. The contour is confined to the half space $\mathrm{Im}\,z<-2\kappa n$, so in each residue a factor of $\exp(-2\kappa tn)$ is contained. It causes exponential decay for large q, because in (45) only the $q=n$ term differs from zero. Together with (52), this recognition directly implies the validity of the limit (16).

VI. CONCLUSION

The Jaynes–Cummings model owes much of its popularity to the experimental progress in quantum optics that dates back to the early 1980s.[1,2] Remarkable predictions, such as collapse and revival of Rabi oscillations,[5] were experimentally confirmed.[2] Nevertheless, the predictive power

of the Jaynes–Cummings model is limited. For sufficiently large times one is confronted with a departure from experimental reality. Due to contact with the outside world, the photon field evolves to a thermal state, slowly but irreversibly. Planck's radiation law gains control over the dynamics.

In this paper we solve an extended Jaynes–Cummings model, for which the photon field is coupled to a large thermal reservoir. This modification secures the validity of Planck's law for large times. Although the Hilbert space is of infinite dimension, the mathematical problem at hand can be posed in terms of a four-dimensional vector. The composition of this solution vector reflects the fact that energy is conserved in absence of the reservoir.

Our method for evaluating the solution vector is based on Laplace transformation, followed by iteration. To settle the question of convergence, we make use of four assumptions. They are discussed in Sec. II. Assumptions (i) and (ii) impose confinement to a certain class of density operators. Besides this standard measure, there is a second and more subtle point to pay attention to.

For the extended Jaynes–Cummings model, the thermal state $\exp(-\beta H_0)/\mathrm{Tr}[\exp(-\beta H_0)]$ is a fixed point of the dynamics. A transformation can be devised that maps the thermal state to its zero-temperature counterpart. If the solution vector is subjected to the same transformation, then the analytical properties of its Laplace transform change in an advantageous manner. Before transformation, all of the poles generate damped residues. Ambiguity arises if it comes to selecting the poles that describe the evolution to the thermal state. After transformation, one simple pole emerges at the origin. The corresponding residue, which of course does not depend on time, produces the transformed thermal state, as desired.

In spite of the above-noted precautions, the temperature keeps causing problems. The solution vector is constructed as a perturbative series in the Boltzmann factor that determines the average number of thermal photons inside the microwave cavity. In proving convergence, we are forced to set the bound (42) on this factor. It is uncertain whether assumption (iv) can be eliminated by means of analytic continuation of the solution.

If our method of solution is applied to the case of a cold resonator, i.e., no atom present, then a temperature constraint is also necessary. However, it has no physical meaning; by starting from a partial differential equation for a characteristic function, one can represent the solution as a finite sum.[17] Unfortunately, ordering problems for matrices make it improbable that the same can be achieved for the present model.

In Appendix A our bounds on vectors and matrices are judged to be rather crude. At the same time, assumption (iv) is physically acceptable. Let us take $\kappa=0.1$ and $\Delta=0$. For higher values of κ the Rabi oscillations scarcely exhibit any revivals.[7] With the help of the identity $\|Q_1\|\|Q_1^{-1}\| = (3+5^{1/2})/2$,[16] one finds that the bound λ_0 amounts to 6×10^{-8}. One may set the Boltzmann factor $\exp(-\beta\hbar\omega_F)$ equal to this number. In experiments, the atomic transition has a wavelength of the order of 1 [cm].[2] We thus arrive at a cavity temperature of the order of 0.1 [K], which is feasible.

The unification of the Jaynes–Cummings model and Planck's radiation law has one important drawback: the mathematical structure of the solution becomes much less transparent. An in-depth exploration of the dynamics surely demands a numerical effort. For the case of zero temperature such an effort was already made.[7] In preparation for the numerical work, all contour integrals were expressed as sums of residues. If one chooses the same approach for finite temperature, then one should carefully handle the poles of higher order. One may employ the identity

$$\prod_{j=1}^{M}[z+a(n_j)]^{-1}=\prod_{s=\min_j n_j}^{\max_j n_j}[z+a(s)]^{-\nu(s)},$$

where the integer

$$\nu(s)=\sum_{j=1}^{M}\delta_{s,n_j}$$

has been defined.

Owing to the numerical work for zero temperature, the central state $\mathbf{1}_2/2$ can be identified as an attractor in atomic phase space.[7] For weak damping, preferably κ smaller than 10^{-3}, and high average photon number, initially not less than 25, all trajectories in atomic phase space convene at the central state. There they stay for a time of at least 10^3 $[g^{-1}]$, whereafter they all take the Markovian path to i_-, the atomic ground state. If κ is increased, the central state abandons its special role; the trajectories meet each other at the ground state. This course of events was analytically confirmed by a limit of maximum entropy,[11] still for zero temperature.

For the standard configuration of an atom in contact with a heat bath, the thermal state is the attractor in phase space. This immediately follows from the principle of maximum entropy.[18] The von Neumann entropy is maximized under the conditions that $\mathrm{Tr}\,\rho_A$ and $\mathrm{Tr}\,\rho_A H_A$ be constant, where H_A denotes the atomic Hamiltonian. Apparently, for the present configuration we can deactivate the latter condition by making suitable parameter choices. In other words, the extended Jaynes–Cummings model allows us to manipulate the conditions accompanying the principle of maximum entropy. The thermal state can be exchanged for the central state.

The foregoing interpretation supposes that the limit of maximum entropy, proposed in Ref. 11, is not a zero-temperature artifact. The limit should persist as the temperature becomes finite. In Sec. V we utilize our solution of the extended Jaynes–Cummings model to argue that this indeed happens. To evade a great amount of technical work, we assume that the field starts from a photon-number state. For the same reason, we do not present a rigorous proof. The extended limit is given in (16), where the conditions $\kappa t<[4\exp(1+1/e)]^{-1}$ and $\lambda<1/(960e)$ have been omitted. The first one is not violated for the times that are of interest. The second condition is weaker than (42), because κ takes on low values.

The main message of this paper can be phrased as follows: the dissipative Jaynes–Cummings model displays an unexpectedly rich dynamics, which is worthy of further examination. For instance, one may wonder what the consequences are of modifying the damping mechanism, or assuming entanglement of atom and field at time zero. These questions will be addressed in a forthcoming publication.

APPENDIX A: BOUNDS FOR WEAK DAMPING

For small κ the bound (10) on the limiting vector $\mathbf{v}(t;\infty;m,n)$ diverges. This can be ascribed to the fact that in the 23 element of $T(n,n)$ a factor of κ^{-1} figures. Our rescuing move is inspired by the material of Sec. V, where all divergencies were mastered. One should recognize that in products such as $T(n+1,n+1)R(z;n,n)$, the divergency of T ceases to exist. In reconsidering (24), we concentrate on the C_1 part of the contour. The C_2 part causes no problems for small κ; the radius $\rho(l)$ includes a factor of κ^{-1}, which compensates the divergency in T.

Explicit evaluation of the third row of the resolvent cannot be avoided. One has

$$\hat{\mathbf{e}}_3\cdot R(\kappa x-i\kappa c_2;n,n)=\kappa^2\prod_{\eta_1,\eta_2=\pm 1}[\kappa x-i\kappa c_2-i\mu_{\eta_1}(n)-i\mu^*_{\eta_2}(n)]^{-1}(2(n+1)^{1/2}[x+ia(n)]$$
$$\times[x+ia(n)+i],\ 4i(n+1)^{1/2}[x+ia(n)],$$
$$\kappa[x+ia(n)]^3+\kappa[x+ia(n)],\ -2\Delta[x+ia(n)]^2-2\Delta),$$

with $n\geqslant 0$ and $a(n)=2n+1-c_2$. Employment of the inequalities

$$(n+1)^{1/2}|\mathrm{Re}\,u(n)|^{-1}\leqslant(1-\kappa^2/4)^{-1/2},\quad |\Delta|<|\mathrm{Re}\,u(n)|,$$

and

$$\prod_{\eta_1,\eta_2=\pm 1} |\kappa x - i\kappa c_2 - i\mu_{\eta_1}(n) - i\mu^*_{\eta_2}(n)|^{-1} \leqslant \kappa^{-2} |2\,\mathrm{Re}\,u(n)|^{-1} |x + ia(n)|^{-1} |x + ia(n) + i(4c_2 - 1)|^{-1} |\kappa|x| + 2|\mathrm{Re}\,u(n)| + i\kappa a(n)|^{-1} \times \left[1 + \left|\frac{x}{|x| - 2|\mathrm{Re}\,u(n)|/\kappa + ia(n)}\right|\right],$$

leads to the proposition

$$\|T(n+1,n+1)R(\kappa x - i\kappa c_2; n,n)\| \leqslant \frac{10\xi}{\kappa c_2}\left[1 + \left|\frac{x}{|x| - 2|\mathrm{Re}\,u(n)|/\kappa + ia(n)}\right|\right], \tag{A1}$$

with $n \geqslant 0$. The right-hand side is of order κ^{-1}, but compensation is available in the kernel. Therefore, we can lift the singularity in (10) at the cost of a space-dependent factor. It is well-behaved under extension of the contour to the interval $-\infty < x < \infty$. After replacement of $T(n+1,n+1)$ by $A_1(n,n)$, the result (A1) may still be employed.

In (24) we utilize (33) for controlling the resolvents with photon numbers (n,n) and (h,h). The integer h will not be specified. In principle, h depends on all summation dummies, so that its bounds are merely given by $1 \leqslant h \leqslant k+n+p$. The accompanying matrix $S(h-1,h-1)$ is dominated by $2(k+n+p+1)$. Use of (35) and (A1) now gives

$$\|K(t;k,p;n,n)\| \leqslant \frac{c_2\xi}{8\pi} e^{-c_2\kappa t}(k+n+p+1)(16\xi/c_2)^k (20\xi/c_2)^p (1+16\xi/c_2)^p \times \theta_{k+p} \sum_{l_0=n}^{k+n+p-1} \sum_{l_1=l_0-1}^{k+n+p-2} \cdots \sum_{l_p=l_{p-1}-1}^{k+n} \prod_{s=1}^{p} \theta_{l_s}\, \mathcal{I}(n,p;\{l_s\},h) + B_2,$$

with the integral

$$\mathcal{I}(n,p;\{l_s\},h) = \int_{-\infty}^{\infty} dx \sum_{\eta_1,\eta_2,\eta_3,\eta_4=\pm 1} |x + \mathrm{Im}\,\mu_{\eta_1}(n)/\kappa - \mathrm{Im}\,\mu_{\eta_2}(n)/\kappa + ic_2|^{-1} |x + \mathrm{Im}\,\mu_{\eta_3}(h)/\kappa - \mathrm{Im}\,\mu_{\eta_4}(h)/\kappa + ic_2|^{-1} \prod_{s=1}^{p} \left[1 + \left|\frac{x}{|x| - 2|\mathrm{Re}\,u(l_s)|/\kappa + ia(l_s)}\right|\right].$$

We have assumed that both $k+n$ and p are greater than zero. We remark once more that the behavior of B_2, which denotes the contribution from the arc C_2, is regular for κ small.

It is possible to establish for integral $\mathcal{I}$ a bound that does not depend on κ. The integration axis must be divided into intervals, which are centered around the singular points. These are determined by setting the real parts of all denominators equal to zero. However, one cannot circumvent the restriction that all of the dummies $\{l_s\}$ must differ from each other. To treat the terms that remain, one is obliged to extend (A1) to larger matrix products. The new bounds must furnish additional factors of κ, so as to cancel the higher-order singularities that are brought about by the coincidences among the dummies $\{l_s\}$. Inevitably, the derivation of an improved bound (10) on the limiting vector $\mathbf{v}(t;\infty;m,n)$ degenerates into a rather technical affair.

APPENDIX B: CONTROLLING THE SUM χ

We set out to prove inequality (44) for the sum $\chi(x_1,x_2;p,q)$, with $0 \leqslant x_1 < 1$, $x_2 \geqslant 0$, and p,q non-negative. The proof relies on the following auxiliary result:

$$\chi(x_1,x_2;p,q)\leqslant\sum_{l=0}^{q-1}\alpha(l,q)\left[\frac{x_1^{\max(p-q+l,0)}}{(1-x_1)^{l+1}}+\frac{e^{x_2(l+1)}x_2^{\max(p-q+l,0)}}{\max(p-q+l,0)!}\right], \tag{B1}$$

where the choice of the coefficients $\alpha(l,q)$ is postponed. Verification of the inequality happens by applying induction in q to the recursion relation

$$\chi(x_1,x_2;p,q+1)=\sum_{k=\max(p-1,0)}^{\infty}\chi(x_1,x_2;k,q).$$

On the right we employ the induction assumption (B1). The sum over k can be done on the basis of the results

$$\sum_{k=\max(p-1,0)}^{\infty}x_1^{\max(k+l-q,0)}=\sum_{k=l}^{q-1}x_1^{\max(k+p-q-1,0)}+\frac{x_1^{\max(p-1,0)}}{1-x_1},$$

$$\sum_{k=\max(p-1,0)}^{\infty}\frac{x_2^{\max(k+l-q,0)}}{\max(k+l-q,0)!}\leqslant\sum_{k=l}^{q-1}\frac{x_2^{\max(k+p-q-1,0)}}{\max(k+p-q-1,0)!}+\frac{e^{x_2}x_2^{\max(p-1,0)}}{\max(p-1,0)!},$$

with $q\geqslant l\geqslant 0$. We interchange summations, and reproduce the induction assumption for $q+1$ by operating with the inequalities $(1-x_1)^{-1}\geqslant 1$ and $\exp(x_2)\geqslant 1$ in a suitable manner. It turns out that the coefficients $\alpha(l,q)$ are determined by the recursion

$$\alpha(l,q+1)=\sum_{k=0}^{l}\alpha(k,q)\,\theta_{q-k-1},$$

for $0\leqslant l\leqslant q$. The initial condition is given by $\alpha(l,q=1)=1$.

From our auxiliary result we deduce

$$\chi(x_1,x_2;p,q)\leqslant[(1-x_1)^{-q}+e^{x_2(p+q)}]\sum_{l=0}^{q-1}\alpha(l,q),$$

whereas from an identity similar to (39) we infer

$$\sum_{l=0}^{q-1}\alpha(l,q)\leqslant\binom{2q-1}{q}\leqslant 4^q.$$

This completes the proof.

APPENDIX C: CUT-OFF FOR THE κt EXPANSION

In deriving representation (51) for vector $\mathbf{d}(t;q)$, we expanded the exponential factor $\exp(\kappa t y)$ into a power series. The expansion yields a sum over j running from zero to infinity. For $j=0$ the summand can be evaluated on the basis of (26). The answer is given by the time-independent vector on the left-hand side of (51). We intend to show that for $1\leqslant j\leqslant p+q$ the summand is identical to zero. As far as the term including $D_3(y;q,p;-1)$ is concerned, this claim is an immediate consequence of (26). We thus focus on the term including $D_3(y;q,p;n)$.

Upon exploiting the identities

$$(1,\ 2)M\begin{pmatrix}2\alpha & 2\\ -\alpha & -1\end{pmatrix}=(1,\ 2)\cdot M\cdot\begin{pmatrix}2\\ -1\end{pmatrix}(\alpha,\ 1),$$

$$(1,\ 2)M\begin{pmatrix} -1 & -2 \\ \beta & 2\beta \end{pmatrix} = (1,\ 2)\cdot M \cdot \begin{pmatrix} -1 \\ \beta \end{pmatrix}(1,\ 2),$$

with M any (2×2) matrix, we see that the jth expansion coefficient is proportional to the form

$$\frac{1}{j!}\left[\mathbf{f}(j,p,q)\cdot\begin{pmatrix} 2 \\ -1 \end{pmatrix}(q+2,\ 1)+g(j,p,q)(1,\ 2)\right].$$

We have defined the vector

$$\begin{aligned}\mathbf{f}(j,p,q)=&\sum_{n=0}^{q+p}\sum_{l_0=n}\sum_{l_1=l_0-1}^{q+p-1}\sum_{l_2=l_1-1}^{q+p-2}\cdots\sum_{l_p=l_{p-1}-1}^{q}\prod_{s=1}^{p}\theta_{l_s}\oint\frac{\mathrm{d}y}{2\pi i}\frac{y^j}{(2n+1)(2n+3)}\\ &\times\prod_{s=0}^{q}\frac{2s+1}{y+2s+1}\prod_{s=0}^{n-1}\frac{y+2s+1}{2s+1}\prod_{s=1}^{p}\left[(y+2l_s+1)(y+2l_s+3)(2l_s+3)\right]^{-1}\\ &\times(1,2)\cdot\left\{\prod_{s=1}^{p}V(y;l_s,l_{s-1})\right\}\delta_{l_p,q},\end{aligned}$$

and the scalar

$$\begin{aligned}g(j,p,q)=&\sum_{n=0}^{q+p}\sum_{l_0=n}\sum_{l_1=l_0-1}^{q+p-1}\sum_{l_2=l_1-1}^{q+p-2}\cdots\sum_{l_p=l_{p-1}-1}^{q}\prod_{s=1}^{p}\theta_{l_s}\oint\frac{\mathrm{d}y}{2\pi i}\frac{y^j}{(2n+1)(2n+3)}\\ &\times\prod_{s=0}^{q}\frac{2s+1}{y+2s+1}\prod_{s=0}^{n-1}\frac{y+2s+1}{2s+1}\prod_{s=1}^{p}\left[(y+2l_s+1)(y+2l_s+3)(2l_s+3)\right]^{-1}\\ &\times(1,2)\cdot\left\{\prod_{s=1}^{p}V(y;l_s,l_{s-1})\right\}\cdot\begin{pmatrix} -1 \\ l_p+2 \end{pmatrix}\theta_{q-l_p},\end{aligned}$$

for j, p, and q non-negative.

The following recursion relations will be of service to us

$$g(j+1,p,q)=(2q+1)\left[g(j,p,q-1)\,\theta_{q-1}-g(j,p,q)+\mathbf{f}(j,p,q)\cdot\begin{pmatrix} -1 \\ q+2 \end{pmatrix}\right]+\mathbf{f}(j+1,p,q)\cdot\begin{pmatrix} -1 \\ q+2 \end{pmatrix},$$

$$\begin{aligned}&(2q+3)[\mathbf{f}(j+1,p+1,q)+(2q+1)\mathbf{f}(j,p+1,q)]\\ &\quad=(2q+1)(2q+5)\mathbf{f}(j,p,q+1)\cdot\begin{pmatrix} 0 \\ 1 \end{pmatrix}(0,1)-\frac{1}{2}(2q+5)\mathbf{f}(j+1,p,q+1)\\ &\qquad\cdot\begin{pmatrix} 0 \\ 1 \end{pmatrix}(1,0)-(q+1)\mathbf{f}(j,p,q)\cdot\begin{pmatrix} 2 \\ -1 \end{pmatrix}(1,2)-(2q+3)^{-1}g(j+1,p,q+1)(4q+5,4q+4)\\ &\qquad-2g(j,p,q+1)(q+1,1)+(2q+3)^{-1}\mathbf{f}(j+1,p,q+1)\cdot\begin{pmatrix} -1 \\ q+3 \end{pmatrix}(4q+5,4q+4)\\ &\qquad+2\mathbf{f}(j,p,q+1)\cdot\begin{pmatrix} -1 \\ q+3 \end{pmatrix}(q+1,1),\end{aligned}$$

with j, p, and q non-negative again. To check the first recursion, one should perform for $g(j+1,p,q)$ the reduction $j+1\to j$ by writing $y=y+2q+1-(2q+1)$. The cases $l_p=q$ and $l_p\leqslant q-1$ must be processed separately. To check the second recursion, one should perform for $\mathbf{f}(j+1,p+1,q)+(2q+1)\mathbf{f}(j,p+1,q)$ the reduction $p+1\to p$ by substituting for $V(y;q,l_p)$ the rep-

resentation out of Sec. V. In the second contribution of V the Kronecker delta δ_{q,l_p} is contained. It causes the upper boundaries of all sums to decrease by one, and hence, generates the reduction $q+1\to q$. To reshape the third contribution of V, the above-mentioned identities for matrix M should be employed. The sum over l_p must be extended to $l_p=q+1$; the ensuing correction term can be converted to two vectors of type **f**.

We first solve the above-mentioned recursions for $p=0$. From (26) we learn that $\mathbf{f}(j=0,p=0,q)=(2q+3)^{-1}(1,2)$ and $g(j=0,p=0,q)=1$ make up the initial conditions. Furthermore, one has $\mathbf{f}(j+1,p=0,q)+(2q+1)\mathbf{f}(j,p=0,q)=0$, because the left-hand side gives rise to an analytic integrand. From the first recursion we now infer

$$\mathbf{f}(j,p=0,q)=(-1)^j(2q+3)^{-1}(2q+1)^j(1,2),\quad g(j,p=0,q)=\delta_{j,0}.$$

On the result for g the constraint $0\leqslant j\leqslant q$ must be imposed. For $p=0$ and $1\leqslant j\leqslant q$ the jth coefficient of the κt expansion is indeed identical to zero.

Moving on to the case $p\geqslant 1$, we deduce from the representation of V and (26)

$$\mathbf{f}(j=0,p,q)=-\delta_{p,1}(2q+3)^{-1}(1,0),\quad g(j=0,p,q)=\delta_{p,1}(2q+3)^{-1},$$

with $p\geqslant 1$ and $q\geqslant 0$. Let us make in the first and second recursion the choice $p=1$ and $p=0$, respectively. With the help of the findings for the case $p=0$ the solutions come out as

$$\mathbf{f}(j,p=1,q)=(-1)^j(2q+3)^{-1}(2q+1)^{j-1}(1,2),\quad g(j,p=1,q)=0,$$

where the inequality $1\leqslant j\leqslant q+1$ must be respected. Also for $p=1$ our truncation of the κt expansion is permitted.

Next, we set in the first and second recursion $p=2$ and $p=1$, respectively. The above-mentioned results for the case $p=1$ provide us with the following solutions:

$$\mathbf{f}(j,p=2,q)=g(j,p=2,q)=0,$$

with q non-negative and the condition $0\leqslant j\leqslant q+2$ to be fulfilled. Induction in p shows that the last statement is true for all $p\geqslant 2$ and $0\leqslant j\leqslant p+q$. This completes our proof.

APPENDIX D: CONVERGENCE TO THE THERMAL STATE FOR WEAK DAMPING

We are going to carry out the consistency check that was announced in the main text. The idea is to demonstrate that the interchange of limit and sum, as practiced in Sec. V, does not harm the limit (3). The atomic density operator still converges to the thermal state for large times.

It is sufficient to prove that

$$\lim_{t\to\infty}K(t;q-n,p;n,n)=\left[\begin{pmatrix}0&0\\1&2\end{pmatrix}\delta_{p,0}+2(-1)^p\begin{pmatrix}0&0\\1&1\end{pmatrix}\theta_{p-1}\right]\delta_{n,-1},$$

with $q\geqslant 0$, $p\geqslant 0$, $n\geqslant -1$, and $p+q\geqslant n$. Owing to (48), we can work in two dimensions. For the kernel on the left-hand side the weak-damping expression of Sec. V must be substituted.

For n positive the foregoing statement is a consequence of (47) and (49), whereas for $n=-1$ it reduces to

$$\mathbf{f}'(p,q)\cdot\begin{pmatrix}2\\-1\end{pmatrix}(q+2,1)+g'(p,q)(1,2)=\left(\frac{1}{2},1\right)\delta_{p,0}+(1,1)\,\theta_{p-1},\tag{D1}$$

where p and q are non-negative, and (50) has been used. We have introduced a vector

$$\mathbf{f}'(p,q)=\frac{1}{2}\sum_{l_0=-1}\sum_{l_1=l_0-1}^{q+p-1}\sum_{l_2=l_1-1}^{q+p-2}\cdots\sum_{l_p=l_{p-1}-1}^{q}\prod_{s=1}^{p}\theta_{l_s}\delta_{l_p,q}(0,\ 1)\cdot\left\{\prod_{s=1}^{p}V'(l_s,l_{s-1})\right\},$$

a scalar

$$g'(p,q)=\frac{1}{2}\sum_{l_0=-1}\sum_{l_1=l_0-1}^{q+p-1}\sum_{l_2=l_1-1}^{q+p-2}\cdots\sum_{l_p=l_{p-1}-1}^{q}\prod_{s=1}^{p}\theta_{l_s}(0,1)\cdot\left\{\prod_{s=1}^{p}V'(l_s,l_{s-1})\right\}\cdot\begin{pmatrix}-1\\ l_p+2\end{pmatrix},$$

and a matrix

$$V'(k,l)=(2k+1)^{-1}(2k+3)^{-1}\left[-(2k+1)(2k+5)\begin{pmatrix}0&0\\0&1\end{pmatrix}\delta_{k,l-1}\right.$$
$$\left.+(k+1)\begin{pmatrix}2&4\\-1&-2\end{pmatrix}\delta_{k,l}+2\begin{pmatrix}-1&-1\\l+2&l+2\end{pmatrix}\begin{pmatrix}0&0\\k+1&1\end{pmatrix}\theta_{k-l}\right].$$

From these expressions we see that for $p=0$ the condition (D1) is trivial.

To cope with the case $p\geqslant 1$, one should exploit the recursions

$$\mathbf{f}'(p+1,q)=-\frac{2q+5}{2q+3}\mathbf{f}'(p,q+1)\cdot\begin{pmatrix}0\\1\end{pmatrix}(0,1)+\frac{q+1}{(2q+1)(2q+3)}\mathbf{f}'(p.q)\cdot\begin{pmatrix}2\\-1\end{pmatrix}(1,2)$$
$$+\frac{2g'(p,q)}{(2q+1)(2q+3)}(q+1,1),$$

$$g'(p+1,q)=-\frac{(q+2)(2q+5)}{(2q+3)}\mathbf{f}'(p,q+1)\cdot\begin{pmatrix}0\\1\end{pmatrix}+3\mathbf{f}'(p,0)\cdot\begin{pmatrix}0\\1\end{pmatrix}-\frac{2(q+2)}{2q+3}g'(p,q),$$

with $p\geqslant 1$ and $q\geqslant 0$. In deriving these, one must use the identity

$$\sum_{l=1}^{m}(2l-1)^{-1}(2l+1)^{-1}=m(2m+1)^{-1},$$

with m non-negative. For $p=1$ the solution for $\mathbf{f}'$ and g' can be calculated from the defining expressions. For $p\geqslant 2$ the above-given recursions come into play. One is led to

$$\mathbf{f}'(p,q)=\frac{(q+1,1)}{(2q+1)(2q+3)},\quad g'(p,q)=\frac{q+1}{2q+3},$$

for $p\geqslant 1$. Constraint (D1) turns out to be true, so our consistency check is successful.

(Received 29 November 2001; accepted for publication 28 May 2002)

We use simple iterated one-loop graphs in massless Yukawa theory and QED to pose the following question: what are the symmetries of the residues of a graph under a permutation of places to insert subdivergences. The investigation confirms partial invariance of the residue under such permutations: the highest weight transcendental is invariant under such a permutation. For QED this result is gauge invariant, i.e., the permutation invariance holds for any gauge. Computations are done making use of the Hopf algebra structure of graphs and employing GiNaC to automate the calculations. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1502926]

I. INTRODUCTION

This paper serves three purposes: (i) it employs GiNaC[1] in Feynman diagram calculations and provides algorithms which automate the renormalization process, very much in the spirit of Ref. 2; (ii) it investigates symmetries of short distance singularities under permutations of places where to insert subdivergences in a graph; (iii) it once more confirms the presence or absence of transcendental coefficients of short-distance singularity in accordance with the topology of a graph.

Our laboratory of investigation are simple one-loop Feynman graphs in massless Yukawa theory or QED, inserted into each other in tree-like hierarchies. Thus, the combinatorics of renormalization boils down to the Hopf algebra of decorated rooted trees with only a small number of decorations and the analytical challenge posed by those decorations reduces to expansions of Γ-functions near unit argument. The question we can ask is for the distribution of the Riemann ζ-function over the various poles in the Laurent series of graphs of that form.

In contrast to Ref. 2 and subsequent papers,[3] where the renormalization problem was automated in a similar context optimized for speed and efficiency, we have developed algorithms which allow for nontrivial spin-structures and an easy generalization to arbitrary decorations: the primitive decorations can be inserted as arguments so that the algorithm can handle arbitrary primitive graphs when their analytic structure becomes known.

We work in the context of dimensional regularization, so that any Feynman graph becomes a Laurent series in $\epsilon=(4-D)/2$, the deviation of the dimension from its integer value four, and the pole terms reflect the short distance singularities in the theory. The first-order pole is denoted as the residue of a graph. Its significance lies in the fact that higher pole terms can be reduced to polynomials in residues,[4] and in the fact that the residue of a primitive graph is an invariant under diffeomorphisms of external parameters of the graph (diffeomorphisms of external momenta and masses) as well as an invariant under variations of renormalization schemes. Such a residue is a motivic number then in some modern mathematic parlance. The question as to which class of such numbers is sufficient to describe the residues of a given quantum field theory is open and fascinating.[5]

We only study two much more basic questions, motivated by previous and ongoing investi-

gations into the analytic structure of pole terms and residues in particular.

The first is the independence of the appearance of transcendentals under variations of the quantum field theory which realizes a graph with a given topology. To specify the topology of a one-particle irreducible Feynman graph Γ, let us consider the adjacency matrix $M(\Gamma)$ of Γ. If Γ has n vertices, this matrix is an $n\times n$ matrix. We take for its nonzero entries pairs (`propagator type, powercounting weight`), i.e., each nonzero entry $M(\Gamma)_{ij}$ specifies that vertex i is connected to vertex j by a propagator of some type, which has a certain powercounting weight. In the cases studied here, the possible entries are

$$(\texttt{fermion,1}),\ (\texttt{photon,2}),\ (\texttt{scalar boson,2}).$$

The listing of the powercounting weight is redundant, as it is determined by the type of the propagator. We list it just for easy reference. Additionally, we can state the types of the vertices in the diagonal entries of the matrix (no vertex is connected to itself by a propagator).

The graphs of QED and Yukawa theory which we will compare always have adjacency matrices which agree in all their zero entries,

$$M(\Gamma_{\mathrm{QED}})_{ij}=0\Leftrightarrow M(\Gamma_{\mathrm{Yuk}})_{ij}=0$$

and agree for each nonzero entry in the powercounting degree of the corresponding edge. It is only the nature of the edges which changes from the spin one vector boson propagator—the QED photon—to the spin zero scalar boson propagator in Yukawa theory. Note that the structure of short distance singularity then remains fixed in the transition of one theory to the other. We then expect and confirm that rational numbers can vary in the transition from one theory to the other, while the transcendentals we see remain invariant and specific for the chosen topology. Here, a topology is uniquely described by considering in such an adjacency matrix all nonzero entries as equal. So it just gives information about how vertices are connected, but forgets about the nature of the propagators establishing that connection. To find nonrational numbers, we have to go up to four loops at least in the simple class of Feynman graphs which we consider. There it is the swiss cheese topology of Fig. 1(a) in which we expect to see a residue $\sim\zeta(3)$, while the ladder topology of Fig. 1(b) is known to have only rational residues.[6]

The second question is of different nature: for a log-divergent vertex graph which is primitive under the coproduct, it is evident that its residue has the above-mentioned invariances. The Hopf algebra structure immediately allows one to prove that in a vertex graph which is not primitive under the coproduct such that the graph contains divergent subgraphs, the coefficient of the highest order pole still has these symmetries and is given by an easy calculable product of residues with a combinatorial factor, determined by the scattering type formula of Ref. 4, which incorporates the 't Hooft relations between higher pole terms in graphs.

What we call here the 't Hooft relations in accordance with Ref. 4 is the simple fact that higher order poles in a graph Γ with UV-divergent subgraphs γ can be calculated from products of lower order poles of these subgraphs γ and their complements Γ/γ. This is well known and a necessary requirement to make the renormalization group work: the Z-factor for a given physical quantity is an invertible (it starts with 1) formal series over counterterms of graphs such that its logarithmic derivative with respect to the variation of the renormalization scale ν, $\mathrm{d}\log(Z)/\mathrm{d}\nu^2$, is finite. This finiteness establishes relations between pole terms which, for the case of dimensional

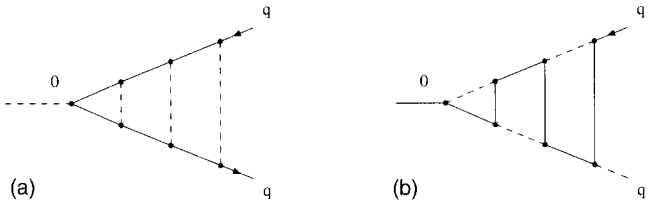

FIG. 2. The two types of vertex corrections. (a) Vertex correction of type one. (b) Vertex correction of type two.

regularization, were, it seems, first explored by 't Hooft. These relations are a direct consequence of the mathematical structure of the Hopf algebra underlying renormalization, and its one-parameter group of automorphisms.[4]

Let us now consider the residue of such a graph which does have divergent subgraphs. Typically, this residue will be a number which can be decomposed in terms of transcendental weight: it will contain contributions ranging from rational numbers to monomials in $\zeta(j)$ of up to transcendental weight $\ell-1$, where ℓ is the bidegree of the graph, calculated from its coproduct.[7] For all graphs considered here, this bidegree simply agrees with the number of loops in Yukawa theory, or can be shifted in the case of QED as explained later in the text. We cannot expect the whole residue to be invariant under the above-mentioned symmetries, as rational numbers can and will vary freely. But here we report a remarkable partial symmetry observed in our rather restricted lab of iterated one-loop graphs: the highest weight transcendental in the residue is invariant under permutations of external momentum as described in the following. We confirm this by empirical calculation to high loop orders. We finally prove the result in the context of the simple iterated one-loop graphs considered here. One has an almost elementary proof in this context and we will discuss the difficulties which arise in the general case. The nature of this result fits nicely with a structural investigation of Dyson–Schwinger equations.[8] Note again that changing the momentum flow but maintaining the topology corresponds to alterations of the type of nonzero entries in a suitable adjacency matrix, as Fig. 2 clearly exhibits. Again, the degree of powercounting and hence the structure of short distance singularities, as well as the topology, remain unchanged.

To understand the type of symmetry we want to investigate, let us consider the one-loop vertex function. If $\Gamma(p_1,p_2,p_3)$ is a vertex correction with momentum p_1 for the external boson, p_2 for the incoming fermion, and $p_3=p_1+p_2$ for the outgoing fermion, then we will compare $\Gamma^1:=\Gamma(0,p,p)$ with $\Gamma^2:=\Gamma(p,p,0)$ at the one-loop level. It is a single permutation of the flow of an external momentum for a vertex function at zero momentum transfer, which distinguishes the two one-loop functions. Locality of counterterms ensures that the counterterm for a vertex correction graph is invariant under this permutation for any graph. So nothing exciting can be learned from just changing the momentum flow in a given vertex graph. Now let us start with such one-loop vertex corrections and let us insert more one-loop vertex corrections always at the vertex of zero momentum transfer (zmt), which indeed changes under the above-mentioned permutation. This gives the topological equivalent Feynman graphs Γ^1, Γ^2, with permuted types of propagators, of Fig. 2. They indeed have adjacency matrices such that again

$$M(\Gamma^1)_{ij}=0\Leftrightarrow M(\Gamma^2)_{ij}=0.$$

Note that it is the requirement to maintain the same topology which forces us to consider quite different looking graphs. For them, the usual field theoretic requirements only demand that the coefficients of the highest order poles are identical. All nonleading pole terms in ϵ do not have to and indeed do not agree.

But a closer investigation will establish a remaining partial symmetry between those graphs, such that the highest weight transcendental in the residue is invariant. Such symmetries are of great interest. Feynman graphs with subdivergences can be built by using the pre-Lie structure of graphs, which results from underlying insertion operads.[5] The question to what extent the permutation group acts trivially under such insertions is a natural question in operad theory which needs

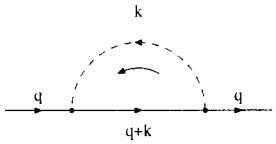
to be answered to understand these operads. It directly leads to the questions studied here in a simplified context. We regard the results reported here as a first step in a detailed analysis of actions of the permutation group in this context.

With regard to the first question, we remind the reader that for a massless Yukawa theory represented as a Laurent-series in ϵ, it was already shown in Ref. 9 that graphs with the swiss cheese topology of Fig. 1(a) possess a $\zeta(n)$ in their counterterm, whereas graphs with a ladder topology like in Fig. 1(b) just evaluate to rational coefficients. Similar results were obtained in QED and other theories for vertex functions of type $\Gamma(0,p,p)$ and self-energies, in Refs. 2, 3, and 6.

Our first aim is now to find out if this remains true in massless QED for both types of momentum flow and if there are any symmetries in the coefficients of the ζ-functions in both theories, under the permutation between the two types of vertex functions Γ^1 and Γ^2. Therefore we will rebuild the scheme given in Ref. 9 for the massless Yukawa theory with an extension to vertex corrections that carry a different flow of momentum in the above-described sense, and similarly for QED using the matrix calculus of Ref. 10. The resulting algorithm is implemented using the GiNaC library and will be described in Sec. V. With the help of this program, we will calculate the antipode of graphs that represent the different topologies given previously and compare them.

II. CALCULATIONS

Consider a one-loop contribution to the fermionic propagator:



$$\equiv \quad \Sigma_{[0,0]}(q^2) = \int d^D k \, \frac{1}{(\not{q}+\not{k})} \frac{1}{k^2}$$

where the subscript "[0, 0]" will soon serve to give the number of one-loop subdivergences to be inserted inside the diagram at the fermionic or bosonic line. All integrals considered in this paper can be reduced to integrals $F_{a,b}$ (Ref. 11) in D-dimensional Euclidean space:

$$\begin{aligned} I(q;a,b) &\equiv \frac{1}{(\nu^2)^{-\varepsilon}} \int d^D k \, \frac{1}{[k^2]^a [(q-k)^2]^b} \\ &=: \frac{1}{(\nu^2)^{-\varepsilon}} [q^2]^{(2-(a+b)-\varepsilon)} F_{a,b} \end{aligned} \tag{1}$$

with

$$F_{a,b} \equiv F_{b,a} := \frac{\Gamma(2-a-\varepsilon)\Gamma(2-b-\varepsilon)\Gamma(a+b-2+\varepsilon)}{\Gamma(a)\Gamma(b)\Gamma(4-a-b-2\varepsilon)}, \tag{2}$$

and $D=4-2\varepsilon$. ν is the renormalization scale that we set equal to "1" in the following. We typically need these integrals for $a=n_1+n_2\varepsilon$, $b=m_1+m_2\varepsilon$, for integers n_1, n_2, m_1, m_2. Note that

$$F_{a,-n} = F_{-n,b} = 0, \quad n \in \mathbb{N}^0. \tag{3}$$

Accordingly, in our conventions

$$\Sigma_{[0,0]}(q^2) = [q^2]^{-\varepsilon} \tfrac{1}{2} F_{1,1} \not{q} =: [q^2]^{-\varepsilon} \Sigma_{0,0} \not{q}. \tag{4}$$

This reduces the identification of nonrationals (transcendentals, we dare say in the following) to an expansion of the Γ-function near unit argument, as promised, given by the formula:

$$\Gamma(1+\varepsilon)=\exp(-\gamma\varepsilon)\exp\left(\sum_{n=2}^{\infty}\frac{\zeta(n)}{n}(-\varepsilon)^n\right),\quad |\varepsilon|<1.$$

Internally, GiNaC follows a different approach. It computes the derivatives $\Gamma'(x)=\Gamma(x)\psi(x)$ and $(\mathrm{d}^n/\mathrm{d}x^n)\psi(x)=\psi_n(x)$ in terms of polygamma functions $\psi_m(x)$ and "knows" how to evaluate polygamma functions at integer arguments, e.g., $\psi(1)=-\gamma$ and $\psi_n(1)=(-)^{n+1}n!\zeta(n+1)$.

A. Yukawa theory

The study of iterated one-loop integrals reduces to the study of the following elementary functions, which we will call *characterizing functions*: The one-loop fermion self-energy with insertions at its two internal propagators demands knowledge of

$$\Sigma_{i,j}:=\tfrac{1}{2}[F_{i\varepsilon,1+j\varepsilon}+F_{1+i\varepsilon,1+j\varepsilon}-F_{1+i\varepsilon,j\varepsilon}]. \tag{5}$$

The one-loop boson self-energy with insertions at its two internal edges is given by $\Pi_{i,j}$ and the two one-loop vertex functions at zero momentum transfer with insertions at either the zero momentum vertex, or internal lines, need knowledge of functions $\Gamma_{i,j}$ for the vertex corrections,

$$\Pi_{i,j}/[\mathrm{tr}(\mathbb{1})]:=-\tfrac{1}{2}[F_{i\varepsilon,1+j\varepsilon}-F_{1+i\varepsilon,1+j\varepsilon}+F_{1+i\varepsilon,j\varepsilon}], \tag{6}$$

$$\Gamma^1_{i,j}:=F_{1+i\varepsilon,1+j\varepsilon}, \tag{7}$$

$$\Gamma^2_{i,j}:=\tfrac{1}{2}[F_{2+i\varepsilon,j\varepsilon}-F_{2+i\varepsilon,1+j\varepsilon}+F_{1+i\varepsilon,1+j\varepsilon}]. \tag{8}$$

Here, we have divided the boson self-energy by the trace of the unit matrix $\mathrm{tr}(\mathbb{1})$ (trace over spinorial indices) for easier comparison of insertions of subgraphs into boson and fermion lines.

The functions Γ^1 and Γ^2 represent the two types of vertex corrections shown in Fig. 2.

The indices i and j give the number of subdivergences at different lines:

$\Sigma_{i,j}$: i = number of subdivergences at the fermion line,
j = number of subdivergences at the boson line.

$\Pi_{i,j}$: i = number of subdivergences at the lower fermion line,
j = number of subdivergences at the upper fermion line.

$\Gamma^1_{i,j}$: i = number of fermion self-energies and vertex corrections plugged into the zmt vertex and the internal edges connected to it,
j = number of subdivergences at the boson line not connected to this vertex.

$\Gamma^2_{i,j}$: i = number of fermion or boson self-energies and vertex corrections plugged into the zmt vertex and the internal edges connected to it,
j = number of fermion self-energies at the fermion line not connected to the vertex of zmt.

To denote complete graphs, we introduce additional functions $\Sigma_{[i,j]}$, $\Pi_{[i,j]}$, and $\Gamma_{[i,j,k]}$ which state the different kinds of subdivergences [cf. $\Sigma_{[0,0]}$ in (4)]. The indices count for $\Sigma_{[i,j]}$ and $\Pi_{[i,j]}$ as the indices in their corresponding characterizing functions given earlier. For vertex corrections of type one and two, the notation $\Gamma_{[i,j,k]}$ denotes the three types of insertions in the following way: i insertions of self-energies at the edges connected to the zero momentum vertex, j insertions of self-energies at the edge not connected to that vertex, and k insertions of vertex corrections at the zmt vertex. Table I gives examples.

B. QED

The main difference stems from the presence of a gauge parameter ξ in the photon propagator and from the $-ie\gamma_\mu$ vertex which make the calculations more difficult. In fact, as we will see, we

TABLE I. Some examples how self-energy and vacuum polarization graphs are built up in Yukawa theory.

	$\Sigma_{[0,0]}(q^2) = (-ig)^2\,\Sigma_{0,0}[q^2]^{-\epsilon}\not{q}$
	$\Sigma_{[1,0]}(q^2) = (-ig)^4\Sigma_{1,0}\Sigma_{0,0}[q^2]^{-2\epsilon}\not{q}$
	$\Sigma_{[2,1]}(q^2) = (-ig)^8\,\Sigma_{2,1}\Pi_{0,0}(\Sigma_{0,0})^2[q^2]^{-4\epsilon}\not{q}$
	$\Pi_{[0,0]}(q^2) = (-ig)^2\,\Pi_{0,0}[q^2]^{-\epsilon}q^2$
	$\Pi_{[2,1]}(q^2) = (-ig)^8\,\Pi_{2,1}\Sigma_{1,0}(\Sigma_{0,0})^2[q^2]^{-4\epsilon}q^2$
	$\Gamma^1_{[0,0,0]}(q^2) = (-ig)^3\,\Gamma^1_{0,0}[q^2]^{-\epsilon}$
	$\Gamma^1_{[0,0,2]}(q^2) = (-ig)^7\,\Gamma^1_{2,0}\Gamma^1_{1,0}\Gamma^1_{0,0}[q^2]^{-3\epsilon}$
	$\Gamma^1_{[2,0,0]}(q^2) = (-ig)^7\,\Gamma^1_{2,0}\Sigma_{1,0}\Sigma_{0,0}[q^2]^{-3\epsilon}$
	$\Gamma^1_{[0,1,0]}(q^2) = (-ig)^5\,\Gamma^1_{0,1}\Pi_{0,0}[q^2]^{-2\epsilon}$
	$\Gamma^2_{[0,0,0]}(q^2) = (-ig)^3\,\Gamma^2_{0,0}[q^2]^{-\epsilon}$
	$\Gamma^2_{[0,0,2]}(q^2) = (-ig)^7\,\Gamma^2_{2,0}\Gamma^2_{1,0}\Gamma^2_{0,0}[q^2]^{-3\epsilon}$
	$\Gamma^2_{[1,1,1]}(q^2) = (-ig)^9\Gamma^2_{3,0}\Gamma^2_{1,1}(\Sigma_{0,0})^2[q^2]^{-4\epsilon}$

will have to deal with matrices for the vertex corrections.[10] Nevertheless, the structure for the translation of a graph to an analytical result will be similar to what we had in Yukawa theory. Hence we will mainly give the results and just list the relevant changes.

1. Vacuum polarization

We will only consider one-loop photon self-energies, vacuum polarizations, as in our restricted class of Feynman graphs we cannot construct a gauge invariant set of vacuum polarizations at higher loop orders.

2. Fermion self-energy

The fermionic propagator in QED with insertions at the fermionic and photonic lines demands $\widetilde{\Sigma}$:

$$\begin{aligned}\widetilde{\Sigma}_{i,j} = \tfrac{1}{2}[&(2-D)F_{1+i\varepsilon,j\varepsilon} - (3-D)F_{i\varepsilon,1+j\varepsilon} - (3-D)F_{1+i\varepsilon,1+j\varepsilon}\\ &+ F_{-1+i\varepsilon,2+j\varepsilon} - 2F_{i\varepsilon,2+j\varepsilon} + F_{1+i\varepsilon,2+j\varepsilon}](1-\delta_{0,j})\\ &+ [(2-D)\Sigma_{i,0} + \xi\Sigma'_{i,0}]\delta_{0,j}\,, \end{aligned} \tag{9}$$

with

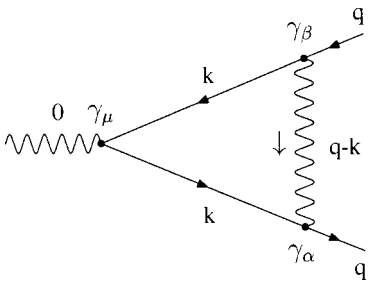


FIG. 3. One-loop contribution to the vertex correction.

$$\Sigma_{i,0}=\tfrac{1}{2}[F_{1+i\varepsilon,1}+F_{i\varepsilon,1}], \tag{10}$$

$$\Sigma'_{i,0}=\tfrac{1}{2}[F_{-1+i\varepsilon,2}-2F_{i\varepsilon,2}-F_{i\varepsilon,1}+F_{1+i\varepsilon,2}-F_{1+i\varepsilon,1}]. \tag{11}$$

The appearance of the Kronecker $\delta_{0,j}$ is obvious from the fact that the presence of one-loop vacuum polarizations in the internal photon line forces transversality of that propagation.

3. Vertex corrections

The most important difference to the Yukawa theory occurs in this part of the calculation. Consider the one-loop vertex correction in QED for vertex graphs as shown in Fig. 3.

The external structure of the vertex consists of two form factors: One for γ_μ and one for $q_\mu \not{q}/q^2$, as $\Gamma_\mu(0,q,q)=F_1(q^2)\gamma_\mu+F_2(q^2)(q_\mu \not{q}/q^2)$. In the previous calculations, every subdivergence just caused a change in the exponent of various momenta in denominators of the integrals, resulting in nonintegral exponents in Eq. (1). Now the result has two form factors F_1, F_2 that emerge through the evaluation of a subgraph in a ''bigger'' graph. We will administer the two form factors in a matrix notation in accordance with Ref. 10. We will need two-by-two matrices. The four entries determine four functions $\Delta^{(i,j)}_{a,b}$. Here, a, $b\in\{1,2\}$ and (i, j) count the number of internal insertions as before. The case $b=1$ corresponds to an internal vertex γ_μ, the case $b=2$ corresponds to an internal vertex $q_\mu \not{q}/q^2$ (where q, say, is the momentum flowing through this zero-momentum transfer vertex), while the index a enumerates the two possible form factors in the result. The result for the one-loop graph of Fig. 3 is then

$$\left[\Delta^{(0,0)}_{1,1}\gamma_\mu+\Delta^{(0,0)}_{2,1}\frac{q_\mu \not{q}}{q^2}\right][q^2]^{-\varepsilon}.$$

For the two-loop graph shown in Fig. 4 we find

$$\Gamma_{[0,0,1]}=\left[(\Delta^{(0,0)}_{11}\Delta^{(1,0)}_{11}+\Delta^{(0,0)}_{21}\Delta^{(1,0)}_{12})\gamma_\mu+(\Delta^{(0,0)}_{11}\Delta^{(1,0)}_{21}+\Delta^{(0,0)}_{21}\Delta^{(1,0)}_{22})\frac{q_\mu \not{q}}{q^2}\right][q^2]^{-2\varepsilon}. \tag{12}$$

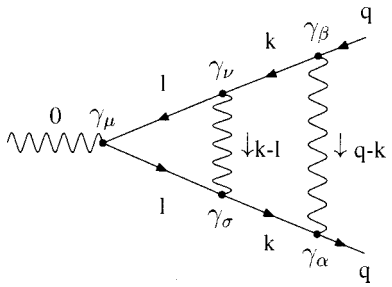

FIG. 4. Two-loop contribution to the vertex correction.

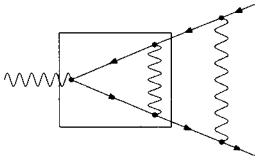
The multiplication of the $\Delta_{kl}^{(i,j)}$ can be reformulated as a matrix multiplication. We define the general matrix (the upper index refers to the two cases of vertex corrections which we consider, we omit that index for simplicity in the matrix entries):

$$M_{i,j}^{1} := \begin{pmatrix} \Delta_{11}^{(i,j)} & \Delta_{12}^{(i,j)} \\ \Delta_{21}^{(i,j)} & \Delta_{22}^{(i,j)} \end{pmatrix}.$$

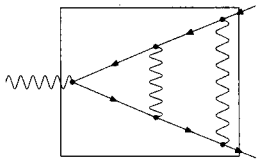
To each part of a graph which has the form of a vertex correction we assign a matrix. In this case of vertex corrections of type one, as in Fig. 2(a), the index i is the total number of subdivergences at the fermionic line (with no difference if it is of the form Σ or Γ) and j the number of subdivergences at the photon line, as in Yukawa theory. One multiplies the matrices for the different divergent parts of a graph, starting from the innermost vertex correction which contains the vertex of zmt, and the corresponding matrix has zero entries in the second column obviously.

Let us make this clear with the help of our example of the two-loop vertex correction again. For the graph of Fig. 4 this means that we begin with the inner vertex correction marked with a box:



$$\equiv M_{0,0}^{1} = \begin{pmatrix} \Delta_{11}^{(0,0)} & 0 \\ \Delta_{21}^{(0,0)} & 0 \end{pmatrix}$$

and then multiply this with the matrix for the outer vertex correction, which has one vertex correction as a subdivergence:



$$\equiv M_{1,0}^{1} = \begin{pmatrix} \Delta_{11}^{(1,0)} & \Delta_{12}^{(1,0)} \\ \Delta_{21}^{(1,0)} & \Delta_{22}^{(1,0)} \end{pmatrix}$$

$$\Rightarrow \quad \begin{pmatrix} \Delta_{11}^{(1,0)} & \Delta_{12}^{(1,0)} \\ \Delta_{21}^{(1,0)} & \Delta_{22}^{(1,0)} \end{pmatrix} \begin{pmatrix} \Delta_{11}^{(0,0)} & 0 \\ \Delta_{21}^{(0,0)} & 0 \end{pmatrix} = \begin{pmatrix} \Delta_{11}^{(1,0)}\Delta_{11}^{(0,0)} + \Delta_{12}^{(1,0)}\Delta_{21}^{(0,0)} & 0 \\ \Delta_{21}^{(1,0)}\Delta_{11}^{(0,0)} + \Delta_{22}^{(1,0)}\Delta_{21}^{(0,0)} & 0 \end{pmatrix}. \tag{13}$$

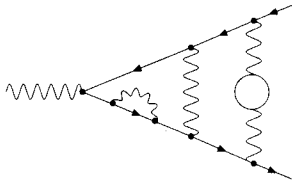
Multiplying (13) with $(1,0)^T[q^2]^{-2\epsilon}$, we get the result as the column vector

$$\begin{pmatrix} (\Delta_{11}^{(1,0)}\Delta_{11}^{(0,0)} + \Delta_{12}^{(1,0)}\Delta_{21}^{(0,0)})[q^2]^{-2\epsilon} \\ (\Delta_{21}^{(1,0)}\Delta_{11}^{(0,0)} + \Delta_{22}^{(1,0)}\Delta_{21}^{(0,0)})[q^2]^{-2\epsilon} \end{pmatrix},$$

where in general the ''upper'' entry of this vector is the form factor $F_1(q^2)$ belonging to γ_μ and the ''lower'' one the form factor $F_2(q^2)$ belonging to $q^\mu \not{q}/q^2$.

Subdivergences that are *not* vertex corrections given by $\Sigma_{i,j}$ and $\Pi_{i,j}$ are multiplied with a unit matrix and inserted in the string of matrices in front of the matrix of the vertex correction which they are part of. They increase subscripts *i,j* accordingly in that matrix.

As an example we get for the following graph:



$$\equiv \begin{pmatrix} \Delta_{11}^{(2,1)} & \Delta_{12}^{(2,1)} \\ \Delta_{21}^{(2,1)} & \Delta_{22}^{(2,1)} \end{pmatrix} \begin{pmatrix} \Pi_{0,0} & 0 \\ 0 & \Pi_{0,0} \end{pmatrix} \begin{pmatrix} \Delta_{11}^{(1,0)} & \Delta_{12}^{(1,0)} \\ \Delta_{21}^{(1,0)} & \Delta_{22}^{(1,0)} \end{pmatrix} \begin{pmatrix} \tilde{\Sigma}_{0,0} & 0 \\ 0 & \tilde{\Sigma}_{0,0} \end{pmatrix}$$

$$\equiv M_{2,1}^{1} \Pi_{0,0} M_{1,0}^{1} \tilde{\Sigma}_{0,0}.$$

As already mentioned, the indices i and j count for QED vertex corrections of type one, $\Gamma^{1}_{[i,j,k]}$, analogous to the ones defined for Yukawa vertex corrections of this type. Similarly, the indices for the type two vertex corrections $\Gamma^{2}_{[i,j,k]}$ in QED count as in Yukawa type two. And the above-described matrix multiplication stays the same apart from different entries for the matrices, which can be readily calculated in terms of functions $F_{a,b}$. We do not list the two sets of four functions $\Delta_{a,b}^{(i,j)}$ in terms of $F_{c,d}$ functions explicitly, but the interested reader can find them from our publicly available programs.[12] Table II shows some examples of how graphs are built in QED.

III. RENORMALIZATION

Renormalization employs a simple principle of multiplicative subtraction, making use of the underlying Hopf algebra structure of Feynman graphs:[14,4] the coproduct

$$\Delta(\Gamma) = \Gamma \otimes 1 + 1 \otimes \Gamma + \sum_{\gamma \subset \Gamma} \gamma \otimes \Gamma / \gamma$$

and antipode

$$S(\Gamma) = -\Gamma - \sum_{\gamma \subset \Gamma} \gamma \Gamma / \gamma$$

are the structure maps which allow the construction of counterterms and renormalized quantities. One employs Feynman rules $\phi: H \to V$ as an element in the group of characters of the Hopf algebra H, with target space V (a suitable ring or algebra) and makes the target space into a Baxter algebra (V,R) by choosing a renormalization map R such that $R(ab)+R(a)R(b)=R(aR(b))+R(R(a)b)$. One then has the counterterm

$$S_R^{\phi}(\Gamma) = -R\left[\phi(\Gamma) + \sum_{\gamma \subset \Gamma} S_R^{\phi}(\gamma) \phi(\Gamma/\gamma) \right]$$

and a further recursion delivers the renormalized result

$$S_R^{\phi} \star \phi(\Gamma) = S_R^{\phi}(\Gamma) + \phi(\Gamma) + \sum_{\gamma \subset \Gamma} S_R^{\phi}(\gamma) \phi(\Gamma/\gamma).$$

TABLE II. Some examples of how self-energy and vacuum polarization graphs are built up in QED.

	$\Sigma_{[0,0]}(q^2) = (-ig)^2\,\Sigma_{0,0}[q^2]^{-\epsilon}\not{q}$
	$\Sigma_{[1,0]}(q^2) = (-ig)^4\Sigma_{1,0}\Sigma_{0,0}[q^2]^{-2\epsilon}\not{q}$
	$\Sigma_{[2,1]}(q^2) = (-ig)^8\,\Sigma_{2,1}\Pi_{0,0}(\Sigma_{0,0})^2[q^2]^{-4\epsilon}\not{q}$
	$\Pi_{[0,0]}(q^2) = (-ig)^2\,\Pi_{0,0}[q^2]^{-\epsilon}q^2$
	$\Pi_{[2,1]}(q^2) = (-ig)^8\,\Pi_{2,1}\Sigma_{1,0}(\Sigma_{0,0})^2[q^2]^{-4\epsilon}q^2$
	$\Gamma^1_{[0,0,0]}(q^2) = (-ig)^3\,\Gamma^1_{0,0}[q^2]^{-\epsilon}$
	$\Gamma^1_{[0,0,2]}(q^2) = (-ig)^7\,\Gamma^1_{2,0}\Gamma^1_{1,0}\Gamma^1_{0,0}[q^2]^{-3\epsilon}$
	$\Gamma^1_{[2,0,0]}(q^2) = (-ig)^7\,\Gamma^1_{2,0}\Sigma_{1,0}\Sigma_{0,0}[q^2]^{-3\epsilon}$
	$\Gamma^1_{[0,1,0]}(q^2) = (-ig)^5\,\Gamma^1_{0,1}\Pi_{0,0}[q^2]^{-2\epsilon}$
	$\Gamma^2_{[0,0,0]}(q^2) = (-ig)^3\,\Gamma^2_{0,0}[q^2]^{-\epsilon}$
	$\Gamma^2_{[0,0,2]}(q^2) = (-ig)^7\,\Gamma^2_{2,0}\Gamma^2_{1,0}\Gamma^2_{0,0}[q^2]^{-3\epsilon}$
	$\Gamma^2_{[1,1,1]}(q^2) = (-ig)^9\Gamma^2_{3,0}\Gamma^2_{1,1}(\Sigma_{0,0})^2[q^2]^{-4\epsilon}$

The counterterm S_R^ϕ is in the image of R, while $\phi(\Gamma)+\Sigma_{\gamma\subset\Gamma}S_R^\phi(\gamma)\phi(\Gamma/\gamma)$ is the result of Bogoliubov's famous $\overline{R}(\Gamma)$ operation on Γ which eliminates subdivergences in Γ.[13]

Under suitable conditions on the behavior of R, in this ratio of characters short distance singularities drop out.[14,15]

Before we comment on the renormalization scheme chosen for our calculations, let us introduce the bidegree of a Feynman graph. This standard notion can be introduced for any Hopf algebra which is reduced to scalars[7,4] by the counit $\overline{e}$ with

$$\overline{e}(q1)=q,\quad \overline{e}(X)=0,\quad \text{else.}$$

If we decompose $H=H_0\oplus H_{\text{aug}}$, with H_{aug} being the augmentation ideal as the kernel of $\overline{e}$ we can investigate, for any positive integer k and Hopf algebra element X,

$$X_k := \Delta^{k-1}(X)\cap H_{\text{aug}}^{\otimes k}.$$

For sufficiently large k this will necessarily vanish. We define the bidegree bid(X) as the largest k such that $X_k \neq 0$. Elements in H_0 have bidegree zero. Note that Hopf algebra elements of unit bidegree are precisely the primitive elements $X \in H_{\text{aug}}$ in the Hopf algebra, with

$$\Delta(X) = X \otimes 1 + 1 \otimes X \notin H_{\text{aug}} \otimes H_{\text{aug}}.$$

Having introduced this standard notion we introduce the renormalization scheme for which we choose minimal subtraction (MS). Each application of the scheme is given by a projection onto the pole-part of the considered Laurent series and is symbolized with brackets "$\langle\,\rangle$:"

$$\left\langle \sum_{j=-r}^{+\infty} c_j \epsilon^j \right\rangle = \sum_{j=-r}^{-1} c_j \epsilon^j.$$

The reader should convince him/herself that this map makes the ring of Laurent series with poles of finite order into a Baxter algebra,

$$\langle ab \rangle + \langle a \rangle \langle b \rangle = \langle a \langle b \rangle \rangle + \langle \langle a \rangle b \rangle.$$

Note that the degree r of the pole terms in a Laurent series assigned to a graph by the Feynman rules in dimensional regularization is in general majorized by the bidegree $r \leqslant \text{bid}(\Gamma)$ and equals the bidegree in our simple applications.

We expect to encounter $\zeta(n)$ inside the coefficients of the Laurent series in the regularization parameter ϵ emerging from a series expansion of the functions $F_{a,b}$.

In QED we have to take our matrix-calculus into account. The renormalization of such matrix expressions is now given by inserting a diagonal matrix R, which consists of the renormalization map as entries:

$$R := \begin{pmatrix} R_{\text{MS}} & 0 \\ 0 & R_{\text{MS}} \end{pmatrix}.$$

Inside a string of matrices, this matrix has to be inserted wherever the renormalization map is applied. It acts on expressions on the right.

IV. ROOTED TREES

Before we build up graphs and calculate their counterterms, i.e., their antipodes, let us first mention that in our simplified context, the Hopf algebra of Feynman graphs is isomorphic to a Hopf algebra of rooted trees with a very small set of decorations given by our one-loop graphs.

In the class of graphs to which we have restricted ourselves one-particle irreducible subgraphs are either nested in each other, or disjoint. They hence form tree-like hierarchies, and one easily translates graphs in rooted trees,[15] with a one-to-one correspondence between one-particle irreducible subgraphs and vertices in the rooted tree (the map from graphs to rooted trees is one-to-many for overlapping divergent graphs, and can be systematically constructed):[16]

The translation from a Feynman diagram to a rooted tree has to be done in the following way: *Set a box around the subdivergences of a Feynman graph* Γ *and mark the upper horizontal line with a dot (≃ vertex). Dots of nested boxes, that is boxes where one of them is contained inside the other, are connected with a line (≃ edge) (see Fig. 5).*

Each vertex of a tree then represents a divergent subgraph of the diagram. The antipode of such a tree is a sum over all *full cuts* or, recursively, iterates over admissible cuts using the coproduct. This easy-to-implement[2] coproduct

$$\Delta(T) = T \otimes 1 + 1 \otimes T + \sum_{\text{admissible cuts } c} P^c(T) \otimes R^c(T)$$

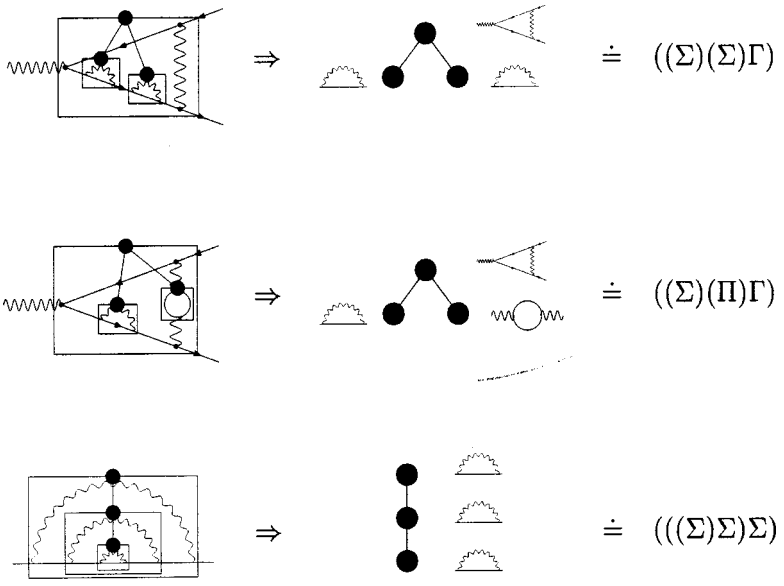


FIG. 5. Translation of Feynman diagrams into rooted trees. Here we are dealing with decorated rooted trees, where the subdivergences are written next to the vertex to which they belong. In the last column one can see another way to encode the structure of the trees in the form of nested lists (Ref. 14): The entries are again the divergent parts of a Feynman diagram and the formation of the parentheses gives the structure of the tree, beginning with the vertices ''at the end'' of a tree up to the root.

is by now a standard combinatorial tool (see, e.g., Ref. 15). Using it, the counterterm is a recursive construct

$$S_{\mathrm{MS}}(T) = -\left\langle T(\Gamma) + \sum_{\text{admissible cuts } c} S_{\mathrm{MS}}(P^c(T)) R^c(T) \right\rangle,$$

where an evaluation of the graph corresponding to the tree using the Feynman rules is understood before applying the projection $\langle\,\rangle$ for minimal subtraction (MS), in accordance with the general formula given for graphs.

V. IMPLEMENTATION

We briefly describe an implementation of our scheme in a computer program. This implementation is not entirely self-contained in the sense that given a Feynman diagram, it would compute the antipode. Instead, its input is a decorated rooted tree in list notation such as $(\Gamma(\Pi)(\Sigma))$. The actual construction of that rooted tree from the diagram, as described in Sec. IV, is left to the user (see also Fig. 5).

Our implementation uses the GiNaC system for symbolic computation in the C++ programming language.[1] GiNaC provides efficient implementations for handling Laurent series as needed in dimensional regularization. From C++, all the linguistic instruments for object-oriented programming are borrowed and available to us. We follow a traditional approach for representation of our rooted trees where there exists a container class called `node` that may or may not have several children of the same class. In addition, each vertex in an object of class `node` contains an object of the abstract and polymorphic class `decoration`. From the abstract `decoration` class a number of concrete classes like `Sigma`, `Gamma` and `Vacuum` are derived, corresponding to primitive Feynman diagrams Σ, Γ, and Π, as well as some additional classes that allow us to distinguish between the position of a subgraph inside its supergraph.

The trees under consideration are not ordered with respect to their children, i.e., the trees $(\Gamma(\Sigma)(\Pi))$ and $(\Gamma(\Pi)(\Sigma))$ are equivalent. Therefore the children form a multiset where only the multiplicity of occurrences is relevant.

A template class `multiset` is part of the C++ Standard Template Library (STL). It has the additional advantage that the elements are always automatically sorted with respect to some specified ordering. This turns out to be useful for convenient identification of equivalent nodes and also to establish an order relation on them. The state of the edges leading to the children of a node (either ''cut'' or ''uncut'') needs to be taken into account as well, so the multiset is really one of pairs of nodes and boolean variables. We chose to delegate methods from class `node` to the corresponding class derived from `decoration` using dynamic type-dispatch. Hence, the decoration must be stored as a pointer, calling for some hand-made memory management in class `node`. A completely realistic layout of our class `node` is then:

```
1 class node {
2 public:
3  // constructors, destructors, delegators,
4  // etc...
5 private:
6 decoration *deco;
7 multiset< pair< node, bool > > children;
8 };
```

Note that a `node` can be either the entire tree, or a subtree or a single (atomic) leaf. The layout of class `decoration` holds a pair of indices and in the case of QED a GiNaC expression (class `ex`) for the gauge. An object of class `ex` is entirely sufficient, since it may contain either a numerical value (integer or fractional) or a symbol (like ξ) (or even more complex expressions, if need should arise).

Knowledge of how to manipulate the indices i and j, depending on the type of decoration and on the state of the edges, is built into the classes of type `decoration`. They are automatically adjusted when the tree is constructed. Furthermore, the state of the edges is also irrelevant for the user of the program since we need all possible combinations of cuts. If there are n vertices inside a tree, then there are $n-1$ edges and we have to construct all possible 2^{n-1} combinations.

Once all the trees have been created we call a method called `evaluate` in each of them that traverses the tree in a top-down fashion: In each node, the expression in terms of $F_{a+i\varepsilon,b+j\varepsilon}$ is dispatched and expanded as a series in the regularization parameter ε before `evaluate` is called on the multiset of children. The resulting 2^{n-1} Laurent series are then added together and the coefficients are expanded. This procedure yields the antipode.

Here is an example how the programs are used in practice:

```
1 $ ./qed1 "(((Sigma[0])(Sigma[xi])Gamma[-1])Gamma[xi])"
2 After decoration the tree has these indices:
3 (Gamma[3,0][xi](Gamma[2,0][-1](Sigma[0,0] [0])(Sigma[0,0][xi])))
4  - - -+- - -#- - -+- - -#- - -+- - -#- - -+- - -#- - -+- - -#- - -
   +- - -#
5 The antipode of this tree is:
6
7 (-1/4-1/4*xi^2-1/2*xi)*x^(-3)
8 +(7/24+1/24*xi^2+1/3*xi)*x^(-2)
9 +(-5/16-13/48*xi^2-7/12*xi)*x^(-1)
```

The graph to be computed is passed in tree form as a string on the command line, together with the gauge parameter. Note how the indices i and j are then set up automatically in line 3. The next line is a simple progress bar, useful when computations become longer. The result is then printed as a power series in the regularization parameter, called `x` instead of ε in order to please the computer.

Computationally, the results are always quite small (cf. Sec. VI) but there is a huge swell of intermediate expressions. After all, the Laurent series arise from expanding products and sums of

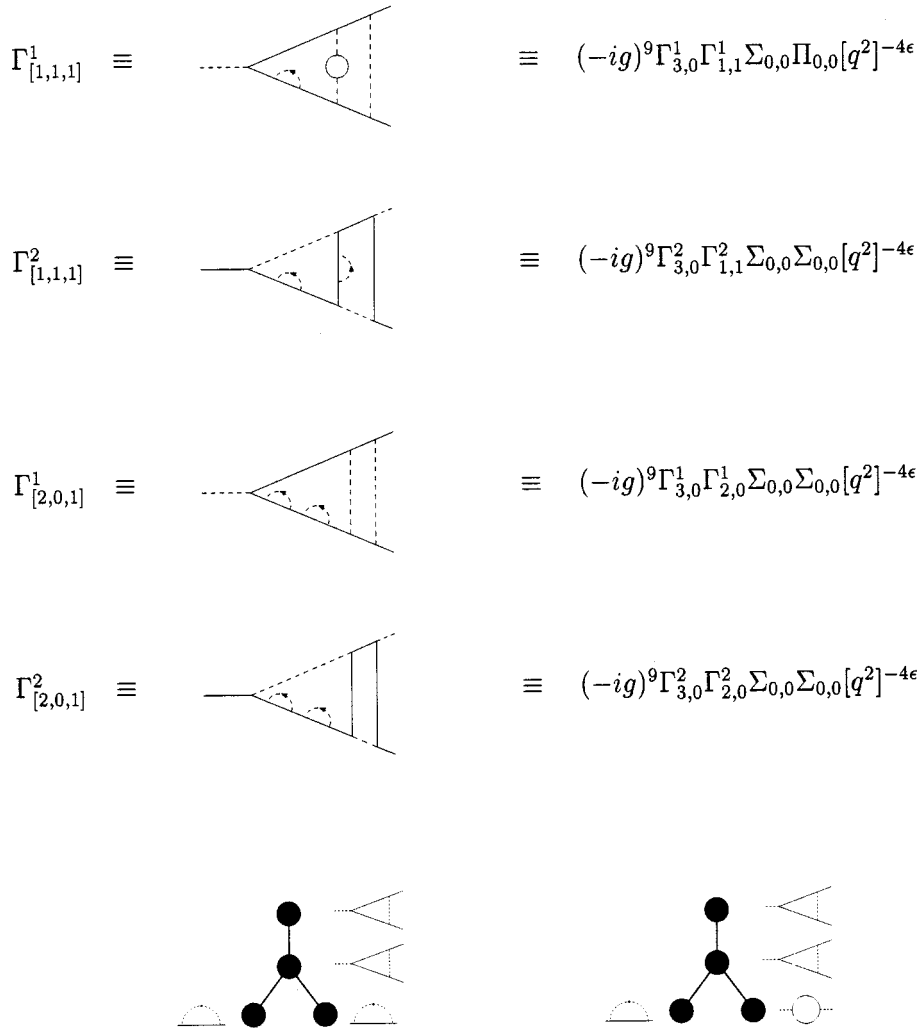

FIG. 6. Graphs in Yukawa theory and their decorated rooted trees.

lots of Γ-functions and so carry Euler–Mascheroni constants. But these have to vanish by cancellations, a fact that is conveniently used as a consistency check for the result. In practice, antipodes of nine-loop graphs in massless QED are still computationally feasible but may require several hours and hundreds of megabytes memory. This emphasizes the drastic loss of efficiency in comparison with Refs. 2 and 3, which is compensated by a gain in flexibility to handle different decorations at any step in the recursion.

The programs developed herein are written in plain ISO C++ (Ref. 17) and will run on any system where the GiNaC library has been ported to. Note that porting to a new platform will require porting CLN[18] to that platform first, since GiNaC depends on CLN for its arbitrary precision arithmetic.

VI. COMPUTATIONAL RESULTS

In a first step, to examine the appearance of ζ-functions, we will now calculate the antipode of different graphs given in Figs. 6 and 7 that represent the two topologies of Fig. 1. In Yukawa theory the graphs $\Gamma^1_{[1,1,1]}$ and $\Gamma^2_{[1,1,1]}$ of Fig. 6 are representations of the ladder topology of Fig. 1(b), the graphs $\Gamma^1_{[2,0,1]}$ and $\Gamma^2_{[2,0,1]}$ of the swiss cheese topology in Fig. 1(a). The same holds for QED with [1,1,1] replaced by [1,1,2] and [2,0,1] by [2,0,2].

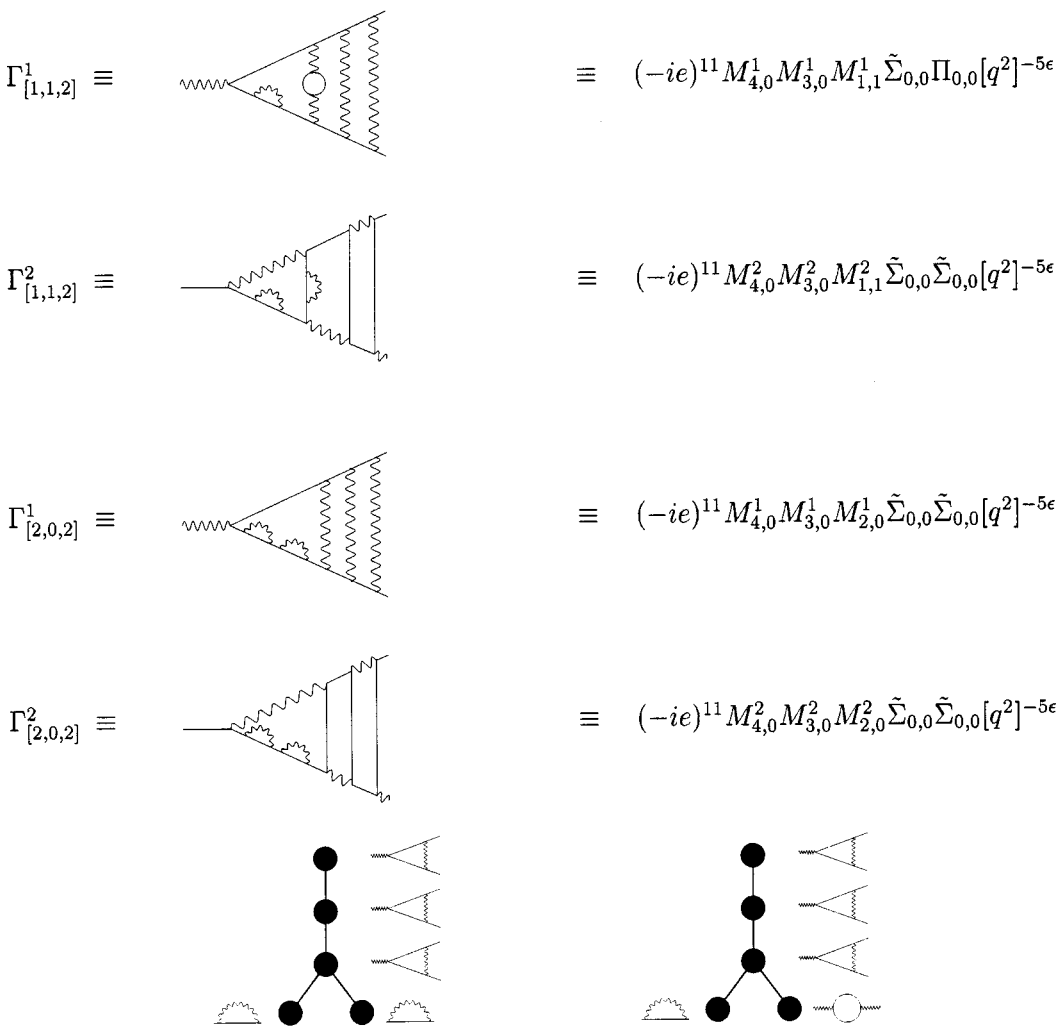

FIG. 7. Graphs in QED and their decorated rooted trees.

The graphs for the Yukawa theory, together with their expressions in characterizing functions, are given in Fig. 6. Figure 6 also contains the decorated rooted trees we get from them to calculate the antipode. One can see that except for the decorations they all belong to the same rooted tree, and hence have the same structure as far as their short distance singularities go, as advertised in Sec. I.

In QED, the considered graphs in Fig. 7 possess one more vertex correction compared to the graphs in Yukawa theory. This additional photon line is necessary because the short distance singularity structure is actually determined by the bidegree, i.e., the number of subdivergent graphs. It so happens in QED that the one-loop fermion self-energy and one-loop vertex corrections (with divergent subgraphs) are overall finite if the internal photon is transversal. In our case, we thus find that the insertion of a one-loop vacuum polarization into the internal photon line in a vertex results in a convergent vertex correction. We have to plug the whole function into one more vertex corrections to get to the next level in the bidegree. And indeed, we need an additional vertex correction, compared to Yukawa theory, to obtain the $\zeta(3)$ in the pole-terms: gauge symmetry delays the appearance of transcendentals.[19] Also let us mention that we can easily compare graphs which have an internal vacuum polarization with graphs which have an internal fermion

self-energy by using the before-mentioned elimination of the trace in the vacuum polarization, using

$$\Pi_{0,0}=\mathrm{tr}(\mathbb{1})\tfrac{1}{2}F_{1,1}=\mathrm{tr}(\mathbb{1})\Sigma_{0,0}.$$

Furthermore, $\Gamma^2_{[1,1,2]}$ and $\Gamma^2_{[2,0,2]}$ in QED do not have this extra shift between loop number and bidegree by themselves, as there the desire to maintain the same topology never forces us to use a vacuum polarization as a subgraph: all one-loop subdivergences are fermion self-energies and vertex corrections. However, we use the same gauges in these graphs as in the graphs $\Gamma^1_{[1,1,2]}$ and $\Gamma^1_{[2,0,2]}$ to compare the results directly (see the following), and therefore obtain the same difference between loop-number and bidegree.

Finally, in our results, we are only interested in residues of counterterms, poles of first order. All interesting relations between transcendental degree and topology will appear there. The scattering type formula[4] will make sure that parts of these relations will then resurface in the poles of higher order in the counterterm, but they contain no new information. So in the following we solely exhibit the residues of the counterterms for our selected class of graphs. We denote by res(Γ) this coefficient of the pole of first order in the MS counterterm in dimensional regularization of a graph Γ. Assorted results for these residues are as follows.

Yukawa theory:

$$\mathrm{res}(\Gamma^1_{[1,1,1]})=\tfrac{5}{48},$$

$$\mathrm{res}(\Gamma^2_{[1,1,1]})=\tfrac{1}{24},$$

$$\mathrm{res}(\Gamma^1_{[2,0,1]})=(\tfrac{5}{48}-\tfrac{1}{8}\zeta(3)),$$

$$\mathrm{res}(\Gamma^2_{[2,0,1]})=(\tfrac{1}{12}-\tfrac{1}{8}\zeta(3)).$$

QED:

$$\mathrm{res}(\Gamma^1_{[1,1,2]})=-(\tfrac{1}{480}(301+143\xi-170\xi^2),)$$

$$\mathrm{res}(\Gamma^2_{[1,1,2]})=-(\tfrac{1}{960}(584+659\xi+59\xi^2)),$$

$$\mathrm{res}(\Gamma^1_{[2,0,2]})=-(\tfrac{1}{480}(521+309\xi-236\xi^2)+\tfrac{3}{10}\zeta(3)(1+\xi)^2),$$

$$\mathrm{res}(\Gamma^2_{[2,0,2]})=-(\tfrac{1}{960}(832+879\xi+31\xi^2)+\tfrac{3}{10}\zeta(3)(1+\xi)^2).$$

We see that in Yukawa theory the graphs $\Gamma^1_{[2,0,1]}$ and $\Gamma^2_{[2,0,1]}$ with the swiss cheese topology have a residue involving $\zeta(3)$, while $\Gamma^1_{[1,1,1]}$ and $\Gamma^2_{[1,1,1]}$ realizing the ladder topology just have a rational residue, as expected. A similar result holds in QED: the graphs $\Gamma^1_{[2,0,2]}$ and $\Gamma^2_{[2,0,2]}$ with the swiss cheese topology again have a residue involving $\zeta(3)$, while $\Gamma^1_{[1,1,2]}$ and $\Gamma^2_{[1,1,2]}$ realizing the ladder topology just have a rational residue.

Those residues are in general a linear combination of terms of varying transcendental weight. This weight vanishes for a rational number, and in accordance with standard practice in the study of multiple zeta values the transcendental weight w of a monomial $\Pi_i\zeta(j_i)$ is

$$w\left(\prod_i \zeta(j_i)\right)=\sum_i j_i.$$

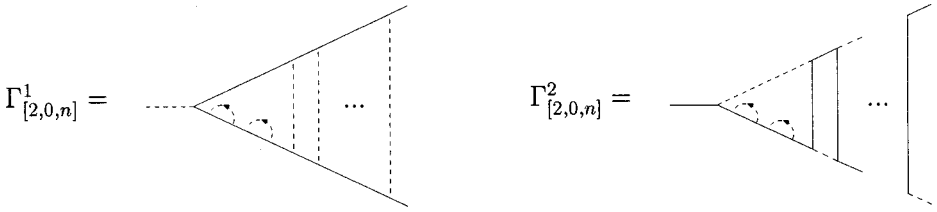

FIG. 8. Iterated vertex corrections.

Then, the above-given results confirm that the coefficient of the highest weight transcendental in the transition from $\mathrm{res}(\Gamma^1_{[2,0,1]})$ to $\mathrm{res}(\Gamma^2_{[2,0,1]})$ ($\mathrm{res}(\Gamma^1_{[2,0,2]})$ to $\mathrm{res}(\Gamma^2_{[2,0,2]})$ for QED) is invariant. This is the partial symmetry announced in Sec. I. It holds for any gauge in the QED case and holds in general, if we increase the loop number as for example in Fig. 8.

In Yukawa theory we get:

$$\mathrm{res}(\Gamma^1_{[2,0,1]})=(\tfrac{5}{48}-\tfrac{1}{8}\zeta(3)),$$

$$\mathrm{res}(\Gamma^2_{[2,0,1]})=(\tfrac{1}{12}-\tfrac{1}{8}\zeta(3)),$$

$$\mathrm{res}(\Gamma^1_{[2,0,2]})=(\tfrac{1}{20}-\tfrac{9}{40}\zeta(3)-\tfrac{3}{80}\zeta(4)),$$

$$\mathrm{res}(\Gamma^2_{[2,0,2]})=(\tfrac{1}{240}-\tfrac{1}{20}\zeta(3)-\tfrac{3}{80}\zeta(4)),$$

$$\mathrm{res}(\Gamma^1_{[2,0,3]})=-(\tfrac{23}{90}+\tfrac{9}{20}\zeta(3)+\tfrac{7}{80}\zeta(3)+\tfrac{7}{240}\zeta(5)),$$

$$\mathrm{res}(\Gamma^2_{[2,0,3]})=-(-\tfrac{1}{240}+\tfrac{1}{6}\zeta(3)+\tfrac{1}{80}\zeta(4)+\tfrac{7}{240}\zeta(5)),$$

$$\mathrm{res}(\Gamma^1_{[2,0,4]})=-(\tfrac{919}{630}+\tfrac{71}{70}\zeta(3)+\tfrac{111}{560}\zeta(4)+\tfrac{1}{12}\zeta(5)+\tfrac{1}{560}\zeta(3)^2+\tfrac{1}{112}\zeta(6)),$$

$$\mathrm{res}(\Gamma^2_{[2,0,4]})=-(\tfrac{65}{224}+\tfrac{11}{140}\zeta(3)+\tfrac{1}{16}\zeta(4)+\tfrac{1}{120}\zeta(5)+\tfrac{1}{560}\zeta(3)^2+\tfrac{1}{112}\zeta(6)),$$

$$\begin{aligned}\mathrm{res}(\Gamma^1_{[2,0,5]})=-(&\tfrac{6481}{1120}+\tfrac{33\,613}{13\,440}\zeta(3)+\tfrac{2133}{4480}\zeta(4)+\tfrac{101}{480}\zeta(5)\\&+\tfrac{27}{4480}\zeta(3)^2+\tfrac{27}{896}\zeta(6)+\tfrac{3}{4480}\zeta(3)\zeta(4)+\tfrac{7}{1920}\zeta(7)),\end{aligned}$$

$$\begin{aligned}\mathrm{res}(\Gamma^2_{[2,0,5]})=-(&\tfrac{863}{3360}+\tfrac{61}{160}\zeta(3)+\tfrac{27}{1120}\zeta(4)+\tfrac{7}{120}\zeta(5)+\tfrac{1}{2240}\zeta(3)^2\\&+\tfrac{1}{448}\zeta(6)+\tfrac{3}{4480}\zeta(3)\zeta(4)+\tfrac{7}{1920}\zeta(7)).\end{aligned}$$

Similarly, for QED we find:

$$\mathrm{res}(\Gamma^1_{[2,0,2]})=-\tfrac{1}{480}(521+309\xi-236\xi^2)-\tfrac{3}{10}(1+\xi)^2\zeta(3),$$

$$\mathrm{res}(\Gamma^2_{[2,0,2]})=-\tfrac{1}{960}(832+879+31\xi^2)-\tfrac{3}{10}(1+\xi)^2\zeta(3),$$

$$\begin{aligned}\mathrm{res}(\Gamma^1_{[2,0,3]})=&-\tfrac{1}{5760}(13\,377+16\,773\xi+12\,091\xi^2+9463\xi^3)\\&+\tfrac{1}{30}(1+\xi)^2(-38+7\xi)\zeta(3)-\tfrac{3}{40}(1+\xi)^3\zeta(4),\end{aligned}$$

$$\begin{aligned}\mathrm{res}(\Gamma^2_{[2,0,3]})=&-\tfrac{1}{5760}(13\,327+32\,578\xi+26\,038\xi^2+6811\xi^3)\\&-\tfrac{1}{60}(1+\xi)^2(31+4\xi)\zeta(3)-\tfrac{3}{40}(1+\xi)^3\zeta(4),\end{aligned}$$

$$\begin{aligned}\mathrm{res}(\Gamma^1_{[2,0,4]}) = &-\tfrac{1}{40\,320}(427\,681+1\,048\,812\xi+889\,375\xi^2+130\,774\xi^3-145\,630\xi^4)\\ &-\tfrac{1}{840}(1+\xi)^2(2551+425\xi+736\xi^2)\zeta(3)\\ &+\tfrac{1}{280}(1+\xi)^3(-121+23\xi)\zeta(4)-\tfrac{1}{20}(1+\xi)^4\zeta(5),\end{aligned}$$

$$\begin{aligned}\mathrm{res}(\Gamma^2_{[2,0,4]}) = &-\tfrac{1}{161\,280}(1\,357\,764+4\,016\,396\xi+4\,028\,301\xi^2+1\,438\,370\xi^3+68\,749\xi^4)\\ &-\tfrac{1}{1680}(1+\xi)^2(1448+2365\xi+836\xi^2)\zeta(3)\\ &-\tfrac{1}{140}(1+\xi)^3(29+2\xi)\zeta(4)-\tfrac{1}{20}(1+\xi)^4\zeta(5),\end{aligned}$$

$$\begin{aligned}\mathrm{res}(\Gamma^1_{[2,0,5]}) = &\tfrac{1}{430\,295\,040}(-19\,150\,607\,852-5\,5087\,254\,529\xi-55\,376\,777\,218\xi^2\\ &-24\,306\,202\,368\xi^3-10\,014\,576\,786\xi^4-5\,440\,770\,359\xi^5)\\ &+\tfrac{1}{4480}(1+\xi)^2(-39\,057-40\,975\xi-19\,389\xi^2+6061\xi^3)\zeta(3)\\ &-\tfrac{3}{4480}(1+\xi)^3(2031+11\xi+446\xi^2)\zeta(4)+\tfrac{1}{960}(1+\xi)^4(-347+67\xi)\zeta(5)\\ &-\tfrac{3}{1120}(1+\xi)^5\zeta(3)^2-\tfrac{3}{224}(1+\xi)^5\zeta(6),\end{aligned}$$

$$\begin{aligned}\mathrm{res}(\Gamma^2_{[2,0,5]}) = &-\tfrac{1}{1290240}(29\,658\,556+111\,493\,999\xi+161\,539\,373\xi^2+112\,812\,993\xi^3\\ &+38\,688\,379\xi^4+5\,579\,364\xi^5)-\tfrac{1}{26\,880}(1+\xi)^2(80\,770+155\,550\xi+79\,521\xi^2\\ &+3472\xi^3)\zeta(3)-\tfrac{1}{8960}(1+\xi)^3(3254+3919\xi+1340\xi^2)\zeta(4)-\tfrac{1}{960}(1+\xi)^4(179\\ &+8\xi)\zeta(5)-\tfrac{3}{1120}(1+\xi)^5\zeta(3)^2-\tfrac{3}{224}(1+\xi)^5\zeta(6).\end{aligned}$$

The reader will note that in QED our residues are polynomials in the gauge parameter of a degree reduced by two steps from what one might expect, to enable comparison between configurations with insertions of self-energies into photon or fermion lines. The corresponding fermion self-energy was for that purpose evaluated in the Feynman gauge, and in the Landau gauge for the affected photon propagator. If one only compares cases with self-energy insertions at fermionic lines, one can abandon these restrictions and we did confirm that the reported invariance holds as expected with coefficients which are polynomials in the gauge parameter of degree equal to the number of photon lines.

VII. DISCUSSION AND PROOF

Actually, results of the form reported in the previous sections can be derived from the analytic structure of the functions $F_{a,b}$ and some basic field theoretic arguments.

Let us reconsider the situation. The simplicity of Feynman graphs considered here manifests itself computationally by the fact that they factorize in a unique manner. Each divergent subgraph γ depends only on a single external momentum q say (that is the reason why we only consider vertex subgraphs at zmt), such that its evaluation in dimensional regularization gives a result of the form

$$\phi(\gamma)(\varepsilon)=[q^2]^{-n(\gamma)\varepsilon}\sum_i F_i(\varepsilon)c_i(q).$$

Here, $n(\gamma)$ is the number of loops in γ, and $F_i(\varepsilon)$ are q-independent form factors, and the dimensionless $c_i(q)$ are

$c_1(q)=\gamma_\mu$, $c_2(q)=q_\mu \not{q}/q^2$ for the QED vertex (the only case here in which the sum has more than one term),
$c_1(q)=1$ for the vertex correction in Yukawa theory,
$c_1(q)=\not{q}$ for any fermion self-energy,
$c_1(q)=(g_{\mu\nu}-q_\mu q_\nu/q^2)\cdot q^2$ for the photon,
$c_1(q)=q^2$ for the scalar boson.

Insertions of such graphs γ in another graph Γ only raises powers of the scalar part of some propagator of Γ:

$$\frac{1}{q^2}\rightarrow\frac{1}{[q^2]^{1+n(\gamma)\varepsilon}}.$$

We can keep track of this by notating these loop numbers $n(\gamma)$ in the entries $M(\Gamma)_{ij}$ for the corresponding propagator in the adjacency matrix $M(\Gamma)$.

Let us now assume that Γ is some primitive vertex correction, i.e., free of divergent subgraphs, and let us write as before Γ^1 and Γ^2 for two distinct choices of zmt.

Consider a bunch of 1PI graphs $X=\Pi_{i=1}^k \gamma_i$ each dependent on a sole external momentum as described previously. Let $k=\mathrm{bid}(X)$ be the bidegree of X, so that X has a highest pole in ε of degree k with coefficient c_k^X. Let now G_X be chosen gluing data such that $\Gamma_X:=\Gamma\star_{G_X} X$ is obtained from inserting X at specified vertices and propagators into Γ, with $\mathrm{bid}(\Gamma)=1$ without loss of generality. (Any 1PI graph can be written in the form $\Gamma\star_{G_X} X$ for such appropriate Γ, X,[14,16,4] in generalization of the closed Hochschild one cocycle B_+ of undecorated rooted trees). Further, each X allows for an expansion

$$\phi(X)=\frac{c_k^X}{\varepsilon^k}(1+T(X)(\varepsilon))$$

and similarly, let

$$\phi(\Gamma)=\frac{\mathrm{res}(\Gamma)}{\varepsilon}(1+T(\Gamma)(\varepsilon)).$$

Now assume that the Taylor series $[1+T(X)(\varepsilon)][1+T(\Gamma)(\varepsilon)]=1+\Sigma_{j=1}^\infty c_j\varepsilon^j$ is such that the transcendental weight $w(c_j)$ of c_j increases with j:

$$w(c_j)<w(c_{j+1}),$$

$\forall j\geqslant k-1$. Here, we define the transcendental weight of an expression which is a sum of terms as the highest transcendental weight appearing in its terms. The question as to how to define the transcendental weight in a context which exceeds the Riemann ζ-functions or MZVs[19] we do not have to answer here. Also, the attentive reader might have noticed that we set the transcendental weight of the gauge parameter to be zero for the QED results, treating it as an independent variable.

Proposition 1: The counterterm is the same for Γ_X^1 and Γ_X^2, and hence their residues are equal.

Proof: Elementary, as $\Gamma^1-\Gamma^2$ is UV convergent, and hence Γ_X^1 and Γ_X^2 generate the same counterterm. □

In particular, we also note that in the above, $\Gamma_X^1-\Gamma_X^2$, when inserted into another graph, produces a result with a bidegree reduced by one unit compared to the insertion of either Γ_X^1 or Γ_X^2 alone.

This is not yet the desired result, as in our case we have to compare $\Gamma^1_{X_1}$ with $\Gamma^2_{X_2}$, where X_1 is a collection of subgraphs in which all vertex subgraphs are of type Γ^1, and X_2 is the same collection of subgraphs apart from the replacement $\Gamma^1 \to \Gamma^2$ for all vertex subgraphs.

Any graph of type $\Gamma^1_{X_1}$ or $\Gamma^2_{X_2}$, which itself can contain subgraphs X_i of these varying types of vertex corrections plus self-energy subgraphs, can now be expressed in terms of the other. Similarly, this holds for these vertex subgraphs of either type, at the expense of generating extra terms of reduced bidegree

$$\mathrm{bid}(\Gamma^1_{X_1} - \Gamma^2_{X_2}) < \mathrm{bid}(\Gamma^1_{X_1}) = \mathrm{bid}(\Gamma^2_{X_2}),$$

which involve differences $\Gamma^1_{X_i} - \Gamma^2_{X_i}$ for appropriate X_i. Hence, under the above-noted assumption of monotonic increase of the transcendental weight with the bidegree, we get upon iterating such insertions

Proposition 2: The coefficient of the term of maximal transcendental weight is the same for $\mathrm{res}(\Gamma^1_{X_1})$ *and* $\mathrm{res}(\Gamma^2_{X_2})$.

Here, X_1, X_2 are related, as above.

This immediately explains our results as a look at the functions $F_{a,b}$, and hence the corresponding evaluations of our subdivergent graphs show that they fulfill the required assumptions of monotonic increase of transcendental weight, which was completely determined from the appearance of the Riemann ζ-function in our simple examples. Note that the factorizations into two-point functions and the absence of all other primitive graphs apart from one-loop functions were the two main simplifications which enabled us to satisfy the assumption.

The study to what extent a sensible transcendental weight can be established in general will be a topic of future work. Any sensible answer we will expect to deliver the same permutation invariance of the residue as reported here.

Chronon corrections to the Dirac equation

Andrei A. Galiautdinov[a] and David R. Finkelstein
School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332-0430

(Received 31 July 2001; accepted for publication 1 July 2002)

The Dirac equation is not semisimple. We therefore regard it as a contraction of a simpler decontracted theory. The decontracted theory is necessarily purely algebraic and nonlocal. In one simple model the algebra is a Clifford algebra with $6N$ generators. The quantum imaginary $\hbar i$ is the contraction of a dynamical variable whose backreaction provides the Dirac mass. The simplified Dirac equation is exactly Lorentz invariant but its symmetry group is SO(3, 3), a decontraction of the Poincaré group, and it has a slight but fundamental nonlocality beyond that of the usual Dirac equation. On operational grounds the nonlocality is $\sim 10^{-25}$ s in size and the associated mass is about the Higgs mass. There is a nonstandard small but unique spin–orbit coupling $\sim 1/N$, whose observation would be some evidence for the simpler theory. All the fields of the standard model call for similar nonlocal simplification. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1505666]

I. INTRODUCTION

We begin with basic concepts.

A *simple* theory is one with simple (irreducible) dynamical and symmetry groups. What is not simple or semisimple we call *compound*. A *contraction* of a theory is a deformation of the theory in which some physical scale parameter, called the *simplifier*, approaches a singular limit, taken to be 0 with no loss of generality. The contraction of a simple theory is in general compound.[1–3] By *simplification* we mean the more creative, nonunique inverse process, finding a simple theory that contracts to a given compound theory and agrees better with experiment. The main revolutions in physics of the 20th century were simplifications with simplifiers c, G, $\hbar$.

One sign of a compound theory is a breakdown of reciprocity, the principle that every coupling works both ways. The classic example is Galilean relativity. There reciprocity between space and time breaks down; boosts couple time into space and there is no reciprocal coupling. Special relativity established reciprocity by replacing the compound Galilean bundle of space fibers over the time base by the simple Minkowski space–time. Had Galileo insisted on simplicity and reciprocity he could have formulated special relativity in the 17th century [unless he were to choose SO(4) instead of SO(1, 3)]. Every bundle theory violates reciprocity as much as Galileo's. The bundle group couples the base to the fiber but not conversely. Every bundle theory cries out for simplification.

This now requires us to establish reciprocity between space–time (base coordinates) x^μ and energy-momenta (fiber coordinates) p_μ. (Segal[1] postulated $x \leftrightarrow p$ symmetry exactly on grounds of algebraic simplicity; his work stimulated that of Inönü and Wigner, and ours. Born[4] postulated $x \leftrightarrow p$ reciprocity, on the grounds that it is impossible in principle to measure the usual four-dimensional interval of two events within an atom. We see no law against measuring space–time coordinates and intervals at that gross scale. We use his term ''reciprocity'' in a broader sense that includes his.)

Einstein's gravity theory and the standard model of the other forces are bundle theories, with field space as fiber and space–time as base. Therefore these theories are ripe for simplification.[5] Here we simplify a spinor theory, guided by criteria of experimental adequacy, operationality, causality, and finity.

[a]Electronic mail: gt1570a@prism.gatech.edu

Classical field theory is but a singular limit of quantum field theory; it suffices to simplify the quantum field theory. Quantum field theory in turn we regard as many-quantum theory. Its field variables all arise from spin variables of single quanta. By *quantification* we mean the transition from the one-body to the many-body theory, converting yes-or-no predicates about an individual into how-many predicates about an aggregate of isomorphic individuals; as distinct from quantization. For example, a spinor field theory arises by quantifying the theory of a single quantum of spin 1/2.

To unify field with space–time in quantum field theory, it suffices to unify spin with space–time in the one-quantum theory, and to quantify the resulting theory. We unify in this paper and quantify in a sequel.

Some unification programs concern themselves with simplifying just the internal symmetry group of the elementary particles, ignoring the fracture between the internal and external variables. They attempt to unify (say) the hypercharge, isospin and color variables, separate from the space–time variables. Here we close the greatest wound first, expecting that the internal variables will unite with each other when they unite with the external variables; as uniting space with time incidentally unified the electric and magnetic fields. We represent space–time variables x^μ and p_μ as approximate descriptions of many spin variables, in one quantum-spin-space–time structure described in a higher-dimensional spin algebra. This relativizes the split between field and space–time, as Einstein relativized the split between space and time.

The resulting quantum atomistic space–time consists of many small exactly Lorentz-invariant isomorphic quantum bits, qubits which we call *chronons*. [Feynman, Penrose, and Weizsäcker attempted to atomize space or space–time into quantum spins. Feynman wrote a space–time vector as the sum of a great many Dirac spin-operator vectors,[6] $x^\mu \sim \Sigma_n\ \gamma^\mu(n)$, Penrose dissected the sphere S^2 into a spin network;[7] his work inspired this program. Weizsäcker[8] attempted a cosmology of spin-1/2 urs. The respective groups are Feynman's SO(3, 1), Penrose's SO(3), Weizsäckers SU(2), and our SO($3N$,$3N$) ($N \gg 1$).]

Simplifying a physical theory generally detaches us from a supporting condensate. (For Galileo and Kepler, the condensate was the Earth's crust, and to detach from it they moved in thought to a ship or the moon, respectively.[9,10]) In the present situation of physics the prime condensate is the ambient vacuum. Atomizing space–time enables us to present the vacuum as a condensate of a simple system, and to detach from it in thought by a phase transition, a space–time melt-down.

Chronons carry a fundamental time-unit χ, one of our simplifiers. We have argued that χ is much greater than the Planck time and is on the order of the Higgs time $\hbar/M_H c^2$. (In an earlier effort to dissect space–time, assuming multiple Fermi–Dirac statistics for the elements.[11,12] This false start led us eventually to the Clifford–Wilczek statistics;[13–17] an example of Clifford–Wilczek statistics is unwittingly developed in chap. 16 of Ref. 12.) We now replace the classical Maxwell–Boltzmann statistics of space–time events with the simple Clifford–Wilczek statistics appropriate for distinguishable isomorphic units. This enormously reduces the problem of forming a theory.

We single out two main quantifications in field theories like gravitation and the standard model:

A classical quantification assembles a space–time from individual space–time points.

A separate quantification constructs a many-quantum theory or quantum field theory from a one-quantum theory on that space-time.

In the standard physics the space–time quantification tacitly assumes Maxwell–Boltzmann statistics for the elements of space–time, and the field quantification uses Fermi–Dirac or Bose–Einstein statistics. The simplified theory we propose uses one Clifford quantification for all of these purposes.

In this paper we work only with one-quantum processes of $N \gg 1$ chronons. To describe several quanta and their interactions, getting closer to field theory and experiment, will require no further quantification, but only additional internal combinatory structure that is readily accommodated within the one Clifford–Wilczek quantification.

Each physical theory defines at least three algebras that should be simple: the associative

operator algebra of the system,[12,18] the kinematical Lie algebra consisting of possible Hamiltonians, and the symmetry Lie algebra of one preferred Hamiltonian.

There is no second quantization. But there is a second simplification; and a third, and so on, all of different kinds with different simplifiers. Each of the historic revolutions that guide us now introduced a simplifier, small on the scale of previous experience and therefore long overlooked, into the multiplication table and basis elements of one or more of these algebras, and so deformed a compound algebra into a simpler algebra that works better. Among these simplifiers are c, G, and $\hbar$.

Here we simplify the free Dirac equation and its underlying *Dirac–Heisenberg* (real unital associative) algebra

$$A_{\mathrm{DH}}=A_D\otimes A_H, \tag{1}$$

the tensor product of the Dirac and the relativistic Heisenberg algebras, in turn defined as follows.

Relativistic Heisenberg algebra. $A_H=A[i,\hat{p},\hat{x}]$ is generated by the imaginary unit i and the space–time and energy–momentum translation generators $\hat{p}_\nu:=ip_\nu\equiv-\hbar\partial/\partial x^\nu$ and $\hat{x}^\mu:=ix^\mu$, subject to the relations

$$\begin{gathered}[\hat{p}^\mu,\hat{x}^\nu]=-i\hbar g^{\mu\nu},\\ [\hat{p}^\mu,\hat{p}^\nu]=0,\\ [\hat{x}^\mu,\hat{x}^\nu]=0,\\ [i,\hat{p}^\mu]=0,\\ [i,\hat{x}^\mu]=0,\\ i^2=-1.\end{gathered} \tag{2}$$

Here $g^{\mu\nu}$ is the Minkowski metric, held fixed in this paper. The carets (on $\hat{p}$, for example) indicate that a factor i has been absorbed to make the operator anti-Hermitian.[19] The algebra A_H has both the usual associative product and the Lie commutator product. As a real Lie algebra A_H is compound, Segal emphasized, containing the nontrivial ideal generated by the unit i.

The orbital Lorentz-group generators are

$$\hat{\mathcal{O}}^{\mu\nu}:=i\mathcal{O}^{\mu\nu}=-i(\hat{x}^\mu\hat{p}^\nu-\hat{x}^\nu\hat{p}^\mu). \tag{3}$$

These automatically obey the usual relations

$$\begin{gathered}[\hat{\mathcal{O}}^{\mu\nu},\hat{\mathcal{O}}^{\lambda\kappa}]=\hbar(g^{\mu\lambda}\hat{\mathcal{O}}^{\nu\kappa}-g^{\nu\lambda}\hat{\mathcal{O}}^{\mu\kappa}-g^{\mu\kappa}\hat{\mathcal{O}}^{\nu\lambda}+g^{\nu\kappa}\hat{\mathcal{O}}^{\mu\lambda}),\\ [\hat{x}^\mu,\hat{\mathcal{O}}^{\nu\lambda}]=\hbar(g^{\mu\nu}\hat{x}^\lambda-g^{\mu\lambda}\hat{x}^\nu),\\ [\hat{p}^\mu,\hat{\mathcal{O}}^{\nu\lambda}]=\hbar(g^{\mu\nu}\hat{p}^\lambda-g^{\mu\lambda}\hat{p}^\nu),\\ [i,\hat{\mathcal{O}}^{\mu\nu}]=0.\end{gathered} \tag{4}$$

Dirac algebra. $A_D=A[\gamma_\mu]$ is generated by Dirac–Clifford units γ_μ subject to the familiar relations

$$\{\gamma_\nu,\gamma_\mu\}=2g_{\nu\mu}. \tag{5}$$

As usual we write $\gamma_{\mu\nu\cdots}$ for the antisymmetric part of the tensor $\gamma_\mu\gamma_\nu\cdots$.

Statistics. One may define the *statistics* of an (actual, not virtual) aggregate by defining how the aggregate transforms under permutations of its units. That is, to describe N units with given unit mode space V_1 (Refs. 12 and 18) we give, first, the mode space V_N of the aggregate quantum system and, second, a simple representation $R_N : S_N \to \mathrm{End}\, V_N$ of the permutation group S_N on the given N units by linear operators on V_N. This also defines the quantification that converts yes-or-no questions about the individual into how-many questions about a crowd.

In *Clifford statistics* $\mathrm{End}\, V_N$ is a Clifford algebra $C = \mathrm{Cliff}(V_1)$, and so V_N is a spinor space for that Clifford algebra, with $C = \mathrm{End}\, V_N$. We write C_1 for the first-degree subspace of C. A Clifford statistics is defined by a projective (double-valued) representation $R_C : S_N \to C_1 \subset C$ of the permutation group S_N by first-grade Clifford elements over the unit mode space V_1.[17] To define R_C we associate with the nth unit (for all $n = 1,...,N$) a Clifford unit γ_n, and we represent every swap (transposition or two-cycle) (mn) of two distinct units by the difference $\pm(\gamma_n - \gamma_m) \in C_1$ of the associated Clifford units.

For a free Clifford statistics the units γ_n are independent and the metric g_{mn} is Euclidean. This representation has dimension $2^{N/2}$ and is reducible. The irreducible representations have dimension[20]

$$2^{[N-1/2]} = 1,1,2,2,4,4,8,8,16,...$$

$$\text{for } \mathrm{Dim}\, V_1 = N = 0,1,2,3,4,5,6,7,8,.... \tag{6}$$

Some useful terms:

A *cliffordon* is a quantum with Clifford statistics.

A *squadron* is a quantum aggregate of cliffordons.

A *sib* is a quantum aggregate of bosons.

A *set* of quanta is an aggregate of fermions.

A *sequence* of quanta is an aggregate of Maxwell–Boltzmann quanta with a given sequential order.[11]

R_C can be extended to a spinor representation of $\mathrm{SO}(N) \supset \mathrm{S}_N$ on the same spinor space $\Sigma(N)$.

The symmetry group G_U of the quantum kinematics for a universe U of N_U chronons is an orthogonal group

$$G_U = \mathrm{SO}(N_{U+}, N_{U-}),$$
$$N_U = N_{U+} + N_{U-}. \tag{7}$$

The algebra of observables of U is the simple finite-dimensional real Clifford algebra

$$C_U = \mathrm{Cliff}(V_1) = \mathrm{Cliff}[1, \gamma(1), \ldots, \gamma(N_U)] \tag{8}$$

generated by the N_U Clifford units $\gamma(n)$, $n = 1,...,N_U$ representing exchanges. The Clifford units $\gamma(n)$ span a vector space $V_1 \cong C_1$ of first-grade elements of C_U.

Within C_U we shall construct a simplified Dirac–Heisenberg algebra

$$\check{A}_{\mathrm{DH}} = A[\check{i}, \check{p}, \check{x}, \tilde{\gamma}] \subset C(V_1) \tag{9}$$

whose commutator Lie algebra is simple and which contracts to the usual Dirac–Heisenberg algebra A_{DH} in the continuum limit. We factor $\check{A}_{\mathrm{DH}}$ into the Clifford product

$$\check{A}_{\mathrm{DH}} = \mathrm{Cliff}(N\mathbf{6_0}) = \mathrm{Cliff}((N-1)\mathbf{6_0}) \amalg \mathrm{Cliff}(\mathbf{6_0}) \tag{10}$$

of two Clifford algebras, an ''internal'' algebra from the last hexad and an ''external'' algebra from all the others.

We designate our proposed simplifications of γ and i, $\hat{p}$, $\hat{x}$, and $\hat{O}$ by $\tilde{\gamma}$ and $\breve{i}$, $\breve{p}$, $\breve{x}$, and $\breve{O}$. In the limit $\chi\to 0$ the tildes ($\tilde{}$) disappear and the breves ($\breve{}$) become hats ($\hat{}$).

We use the following quadratic spaces:

$N\mathbb{R}:=\mathbb{R}\oplus\ldots\oplus\mathbb{R}$ (with N terms) $=\oplus_1^N\mathbb{R}$ is the positive-definite N-dimensional real quantum-mode space.

$-N\mathbb{R}$ is the corresponding negative-definite space.

$\mathbb{M}$ is Minkowski space with signature $1-3$.

$-\mathbb{M}$ is the same space with the opposite signature $3-1$.

Also,

$$\begin{gathered} X\Theta Y:=X\oplus(-Y),\\ \mathbf{1}:=\mathbb{R},\\ -\mathbf{1}:=-\mathbb{R},\\ \mathbf{3}:=3\mathbb{R},\\ -\mathbf{3}:=-3\mathbb{R},\\ \mathbb{M}:=\mathbf{1}\Theta\mathbf{3},\\ -\mathbb{M}:=\mathbf{3}\Theta\mathbf{1},\\ \mathbf{6_0}:=\mathbf{3}\Theta\mathbf{3}. \end{gathered} \tag{11}$$

$\mathbb{M}$ and $-\mathbb{M}$ are tangent spaces to Minkowski space–times and support natural representations of the Lorentz group.

II. SIMPLIFICATION OF THE RELATIVISTIC HEISENBERG ALGEBRA

As already mentioned, field theory employs a compound field-space–time bundle with space–time for base and field space for fiber; just as Galilean space–time is a four-dimensional bundle with $\mathbb{R}^3$ for base and $\mathbb{R}^1$ for fiber. The prototype is the covector field, where the fiber is the cotangent space to space–time, with coordinates that we designate by p_μ.

We assume that in experiments of sufficiently high resolution the space–time tangent bundle (or the Dirac–Heisenberg algebra) manifests itself as a simple quantum-field-space–time synthesis. The space–time variables x^μ and the tangent space variables p_μ unite into one simple construct, as space and time have already united. Now, however, the simplification requires an atomization, because the field variable actually derives from an atomic spin.

We first split the space–time tangent bundle into quantum cells. The minimum number of elements in a cell for our simplification is six: four for space–time and two for a complex or symplectic plane. We provisionally adopt the hexadic cell. Earlier work, done before our present stringent simplicity standard, assumed a pentadic cell.[16] This provided no natural correspondent for the energy–momentum operators.

N hexads define a unit mode space $V_1=N\mathbf{6_0}$. Each term $\mathbf{6_0}$ has a Clifford algebra Cliff(3, 3) whose spinors have eight real components, forming an $\mathbf{8}_0$. [Eight-component spinors have also been used in physics by Penrose,[7] Robson and Staudte,[21] and Lunsford;[22] though not to unify spin with space–time.] The spinors of V form the spinor space

$$\bigotimes_1^N \mathbf{8}_0=\mathbf{8}_0^N.$$

We do not deal with empty space–time. We explore space–time with one relativistic quantum spin-$\frac{1}{2}$ probe of rest mass $m\sim 1/\chi$. We express the usual spin operators γ^μ, space–time position operators x^μ, and energy–momentum operators p_μ of this probe as contractions of operators in the Clifford algebra Cliff$(3N,3N)$.

We write the dynamics of the usual contracted, compound Dirac theory in manifestly covariant form, with a Poincaré-scalar Dirac operator

$$D=\gamma^\mu p_\mu - mc. \tag{12}$$

D belongs to the algebra of operators on spinor-valued functions $\psi(x^\mu)$ on space–time. Any physical spinor $\psi(x^\mu)$ is to obey the dynamical equation

$$D\psi=0. \tag{13}$$

We simplify the dynamical operator D, preserving the form of the dynamical equation (13).

The compound symmetry group for the Dirac equation is the covering group of the Poincaré group ISO($\mathbb{M}$). We represent this as the contraction of a simple group SO(3, 3) acting on the spinor pseudo-Hilbert (ket) space of $6N$ Clifford generators $\gamma^\omega(n)$ ($\omega=0,...,5$; $n=1,...,N$) of the orthogonal group SO$(3N,3N)$. The size of the experiment fixes the parameter N.

We first simplify the anti-Hermitian space–time and energy–momentum translation generators $\hat{p}_\mu$ and $\hat{x}^\nu$, not the associated Hermitian observables p_μ, x^ν. Then we simplify the Hermitian operators by multiplying the anti-Hermitian ones by a suitably simplified i and symmetrizing the product.

As in Dirac one-electron theory, we use the spinor representation Spin($\mathbb{M}$) of SO($\mathbb{M}$) to describe the contracted generators $\hat{S}^{\mu\nu}$ of rotations and boosts. The spin generators are represented by second-degree elements

$$\hat{S}^{\mu\nu}:=\frac{\hbar}{4}[\gamma^\mu,\gamma^\nu]\equiv\frac{\hbar}{2}\gamma^{\mu\nu},\quad \mu,\nu=0,...,3 \tag{14}$$

of the Clifford algebra Cliff(1, 3).

We simplify ISO($\mathbb{M}$) within Spin($N\mathbf{6_0}$) by representing the simplified space–time symmetry generators of the probe by second degree elements of Cliff V_1. We associate the position and momentum axes with the γ^4 and γ^5 elements of the hexad, respectively, so that an infinitesimal orthogonal transformation in the 45-plane couples momentum into position. This accounts for the symplectic symmetry of classical mechanics and the i of quantum mechanics.

We therefore define the simplified $\breve{i}$, $\breve{x}^\mu$, and $\breve{p}^\nu$ of the probe by

$$\begin{aligned}
\breve{i}&\equiv\frac{1}{N-1}\sum_{n=1}^{N-1}\breve{i}(n):=\frac{1}{N-1}\sum_{n=1}^{N-1}\gamma^{45}(n),\\
\breve{x}^\mu&\equiv\sum_{n=1}^{N-1}\breve{x}^\mu(n):=-\chi\sum_{n=1}^{N-1}\gamma^{\mu 4}(n),\\
\breve{p}^\nu&\equiv\sum_{n=1}^{N-1}\breve{p}^\nu(n):=\phi\sum_{n=1}^{N-1}\gamma^{\nu 5}(n),
\end{aligned} \tag{15}$$

where χ, ϕ, and N are simplifiers of our theory, and

$$\gamma^{\rho\sigma}(n):=\tfrac{1}{2}[\gamma^\rho(n),\gamma^\sigma(n)]. \tag{16}$$

To support this choice for the expanded generators we form the following commutation relations among them (cf. Refs. 23, 1, and 24):

$$
\begin{aligned}
[\check{p}^{\mu},\check{x}^{\nu}] &= -2\phi\chi(N-1)g^{\mu\nu}\check{i},\\
[\check{p}^{\mu},\check{p}^{\nu}] &= -\frac{4\phi^{2}}{\hbar}\check{L}^{\mu\nu},\\
[\check{x},\check{x}^{\nu}] &= -\frac{4\chi^{2}}{\hbar}\check{L}^{\mu\nu},\\
[\check{i},\check{p}^{\mu}] &= -\frac{2\phi}{\chi(N-1)}\check{x}^{\nu},\\
[\check{i},\check{x}^{\mu}] &= +\frac{2\chi}{\phi(N-1)}\check{p}^{\mu}.
\end{aligned}
\tag{17}
$$

In (17),

$$
\begin{aligned}
\check{L}^{\mu\nu} &:= \frac{\hbar}{2}\sum_{n=1}^{N-1}\gamma^{\mu\nu}(n),\\
\check{J}^{\mu\nu} &:= \frac{\hbar}{2}\sum_{n=1}^{N}\gamma^{\mu\nu}(n) \equiv L^{\mu\nu}+S^{\mu\nu}.
\end{aligned}
\tag{18}
$$

where $\check{S}^{\mu\nu}$ is the Dirac spin operator [cf. (29)].

Equation (17) incorporates two decontractions: one leading to finite commutators between coordinates of the Snyder type, and one leading to finite commutators between $\hbar i$ and the coordinates and momenta of the Segal type. Both are necessary for simplicity.

The Snyder decontraction makes the theory more nonlocal than the Dirac equation. In the contracted theory, the coordinates *x,y,z* commute. This means that in principle one can produce the single quantum at a definite place and register it at a definite place. To be sure, to do so will mix positive and negative energy levels. In the more physical many-quantum theory, a pair will be created in these processes. Nevertheless, in the standard interpretation of the quantum theory it is still possible in principle to precisely determine the operators *x,y,z* with arbitrary precision at one instant, before the pair separates.

In the decontracted theory, any one of the operators *x,y,z* can be determined with arbitrary precision, say *z*. Its spectrum will then be discrete. The operators *x,y* will then have fundamental indeterminacies, depending on the magnitude of L_z and the constant χ. Thus the single quantum can no longer be localized in principle. This nonlocality is intrinsic to the space–time–momentum–energy–spin unification that makes the theory simpler.

$J^{\mu\nu}$ obeys the Lorentz-group commutation relations:

$$
[\check{J}^{\mu\nu},\check{J}^{\lambda\kappa}] = \hbar(g^{\mu\lambda}\check{J}^{\nu\kappa}-g^{\nu\lambda}\check{J}^{\mu\kappa}-g^{\mu\kappa}\check{J}^{\nu\lambda}+g^{\nu\kappa}\check{J}^{\mu\lambda}),
\tag{19}
$$

and generates a total Lorentz transformation of the variables x^{μ}, p_{μ}, i and $S^{\mu\nu}$:

$$
\begin{aligned}
[\check{x}^{\mu},\check{J}^{\nu\lambda}] &= \hbar(g^{\mu\nu}\check{x}^{\lambda}-g^{\mu\lambda}\check{x}^{\nu}),\\
[\check{p}^{\mu},\check{J}^{\nu\lambda}] &= \hbar(g^{\mu\nu}\check{p}^{\lambda}-g^{\mu\lambda}\check{p}^{\nu}),\\
[\check{i},\check{J}^{\mu\nu}] &= 0,\\
[\check{S}^{\mu\nu},\check{J}^{\lambda\kappa}] &= 0.
\end{aligned}
\tag{20}
$$

There is a mock orbital angular momentum generator of familiar appearance,

$$\check{O}^{\mu\nu} := -\check{i}(\check{x}^{\mu}\check{p}^{\nu} - \check{x}^{\nu}\check{p}^{\mu}). \tag{21}$$

$\check{O}$ too obeys the Lorent group commutation relations. We relate $\check{L}^{\mu\nu}$ and $\check{O}^{\mu\nu}$ in Sec. III.

Since the usual complex unit i is central and the simplified $\check{i}$ is not, we suppose that the contraction process includes a projection that restricts the probe to one of the two-dimensional invariant subspaces of $\check{i}$, associated with the maximum negative eigenvalue -1 of $\check{i}^2$. This represents a condensation that aligns all the mutually commuting hexad spins $\gamma^{45}(n)$ with each other, so that

$$\gamma^{45}(n)\,\gamma^{45}(n') \to -1 \tag{22}$$

for any n and n'. We call this the condensation of i.

Projection onto a sharp value of i kills i-changing variables like x^{μ} and p_{μ}. Only SO(2)-invariant combinations like $\chi^2 p^2 + \phi^2 x^2$ should survive. Nonetheless one observes position and momentum separately. This is a spontaneous symmetry-breaking by the vacuum condensate, analogous to the fact that a crystal in its ground state, with spherically symmetric Hamiltonian, can have a nonzero internal magnetization.

Under Wigner time-reversal, $t \to -t$ and $i \to -i$. Since the variable t is chosen by the experimenter, not the system, we must suppose that i too is mainly fixed by the experimenter, not the system. But since the boundary between system and experimenter is somewhat arbitrary, we must therefore suppose that the entire universe contributes uniformly to i; it is simply that the system is much smaller than the experimenter, and influences i less. This fits with an earlier theory of i as a Stückelberg–Higgs variable that imparts mass to some otherwise massless gauge vector bosons.[25–28]

Then the momentum variables p_{μ} that we usually attribute to the system, for example, are actually i-invariant bilinear combinations $P^{\rho\sigma}_{[\mu]} J_{\rho\sigma}$ of experimenter standards $P^{\rho\sigma}_{[\mu]}$ and the system tensor $J_{\rho\sigma}$. As creatures of the space–time condensate we do not experience the symmetry of the dynamics that produced it, but only its residual symmetries. The spontaneously broken symmetries reappear when the condensate melts down.

To recover the canonical commutation relations for $\check{x}^{\mu}$ and $\check{p}_{\mu}$ we must impose

$$\chi\phi(N-1) \equiv \frac{\hbar}{2} \tag{23}$$

and assume that

$$\begin{aligned} \chi &\to 0, \\ \phi &\to 0, \\ N &\to \infty. \end{aligned} \tag{24}$$

Then the relations (17) reduce to the commutation relations (2) of the relativistic Heisenberg algebra A_H as required.

The three parameters χ, ϕ, $1/N$ are subject to one constraint $\chi\phi(N-1) = \hbar/2$ leaving two independent simplifiers. N is not a physical constant like $\hbar$ and c, but depends on the scope of the experiment, and is under the experimenter's control. N-dependent effects might appear as curious boundary effects. We set a cosmological limit $N \lesssim N_{\mathrm{Max}}$ in the following.

This leaves one N-independent physical constant with the dimensions of time. We can consider two contractions, $\chi \to 0$ with N constant, and $N \to \infty$ with χ constant. They combine into the continuum limit $\chi \to 0$, $N \to \infty$. We fix one simplifier χ in Sec. IV by supposing that the mass of a probe approaches a finite limit as $N \to \infty$.

III. ORBITAL, SPIN, AND TOTAL ANGULAR MOMENTUM

As was shown in Sec. II, three sets of operators obeying Lorentz-group commutation relations appear in our theory. $\check{L}^{\mu\nu}$ represents the simplified *orbital angular momentum* generators, $\check{S}^{\mu\nu}$ represents the *spin* angular momentum, and $\check{J}^{\mu\nu}$ represents the simplified *total angular momentum* generators. There is a mock orbital angular momentum $\check{O}^{\mu\nu}$ (21).

In this section we show that $\hat{O}\to\hat{L}$ in the contraction limit.

Consider $\check{O}^{\mu\nu}$. By definition,

$$
\begin{aligned}
\check{O}^{\mu\nu} &= -(\check{x}^{\mu}\check{p}^{\nu}-\check{x}^{\nu}\check{p}^{\mu})\check{i} \\
&= +\frac{\chi\phi}{N-1}\left(\sum_{n=1}^{N-1}\gamma^{\mu 4}(n)\sum_{n'=1}^{N-1}\gamma^{\mu 5}(n')-\sum_{n=1}^{N-1}\gamma^{\nu 4}(n)\sum_{n'=1}^{N-1}\gamma^{\mu 5}(n')\right)\sum_{m=1}^{N-1}\gamma^{45}(m) \\
&= +\frac{\chi\phi}{N-1}\sum_{n}\left(\gamma^{\mu 4}(n)\gamma^{\nu 5}(n)-\gamma^{\nu 4}(n)\gamma^{\mu 5}(n)\right)\sum_{m}\gamma^{45}(m) \\
&\quad +\frac{\chi\phi}{N-1}\sum_{n\neq n'}\left(\gamma^{\mu 4}(n)\gamma^{\nu 5}(n')-\gamma^{\nu 4}(n)\gamma^{\mu 5}(n')\right. \\
&\quad \left.+\gamma^{\mu 4}(n')\gamma^{\nu 5}(n)-\gamma^{\nu 4}(n')\gamma^{\mu 5}(n)\right)\left(\gamma^{45}(n)+\gamma^{45}(n')\right) \\
&\quad +\frac{\chi\phi}{N-1}\sum_{n\neq n'}\left(\gamma^{\mu 4}(n)\gamma^{\nu 5}(n')-\gamma^{\nu 4}(n)\gamma^{\mu 5}(n')+\gamma^{\mu 4}(n')\gamma^{\nu 5}(n)\right. \\
&\quad \left.-\gamma^{\nu 4}(n')\gamma^{\mu 5}(n)\right)\sum_{m\neq n,m\neq n'}\gamma^{45}(m) \\
&= -\frac{2\chi\phi}{N-1}\sum_{n}\gamma^{\mu\nu}(n)\gamma^{45}(n)\sum_{m}\gamma^{45}(m) \\
&\quad +\frac{\chi\phi}{N-1}\sum_{n\neq n'}\left(\gamma^{\mu 4}(n)\gamma^{\nu 5}(n')-\gamma^{\nu 4}(n)\gamma^{\mu 5}(n')\right. \\
&\quad \left.+\gamma^{\mu 4}(n')\gamma^{\nu 5}(n)-\gamma^{\nu 4}(n')\gamma^{\mu 5}(n)\right)\sum_{m\neq n,m\neq n'}\gamma^{45}(m). \qquad (25)
\end{aligned}
$$

Thus, in the contraction limit (22)–(24) when condensation singles out the eigenspace of $\gamma^{45}(n)\gamma^{45}(n')$ with eigenvalue -1,

$$\hat{O}^{\mu\nu}\to\hat{J}^{\mu\nu}-\hat{S}^{\mu\nu}\equiv\hat{L}^{\mu\nu}, \qquad (26)$$

as asserted.

IV. SIMPLIFIED DIRAC DYNAMICS

Dirac's *one-body* theory in real (Majorana) form uses the operator algebra A_{DH} acting on a vector space

$$V_1 := \Sigma^{-\mathbb{M}} \qquad (27)$$

of spinor-valued wave functions, mapping the space–time to the spinor space $\Sigma=\Sigma(-\mathbb{M})$ over the Minkowski space–time $-\mathbb{M}$. This exhibits part of the compound structure we must simplify by

decontraction, the split between spin space Σ and space–time $\mathbb{M}$. We construct the new space entirely from spins, replacing the infinite-dimensional function space V_1 by a spinor space of high but finite dimensionality.

To simplify Dirac's spin-$\frac{1}{2}$ dynamics, we regard the position of the probe as the resultant of N quantum steps, each represented by one hexad of chronons. We identify the spin variables of the probe with those of the last hexad in (10), the growing tip of the world line of the probe.

We thereby simplify the Dirac–Heisenberg algebra A_{DH} to $\check{A}_{\mathrm{DH}} := \mathrm{Cliff}(N\mathbf{6_0})$, the Clifford algebra of a large squadron of cliffordons.

To construct the contraction from $\check{A}_{\mathrm{DH}}$ to A_{DH}, we group the generators of Cliff($3N$,$3N$) into N hexads $\gamma^{\omega}(n)$ ($\omega=0,...,5$; $n=1,...,N$). Each hexad algebra acts on eight-component real spinors in $\mathbf{8}_0$. Hexad N will be used for the spin of the quantum. The remaining $N-1$ hexads provide the space–time variables.

We identify the usual Dirac gammas γ^{μ} for $\mu=0,...,3$ of Cliff($-\mathbb{M}$) with second-degree elements of the last hexad:

$$\gamma^{\mu} \cong \tilde{\gamma}^{\mu} := \gamma^{\mu 5}(N). \tag{28}$$

Dirac's spin generators $\hat{S}^{\mu\nu}$ (14) simplify to the corresponding 16 components of the tensor

$$\check{S}^{\omega\rho} := \frac{\hbar}{2}\gamma^{\omega\rho}(N), \tag{29}$$

where ω, $\rho=0,...,5$ and μ, $\nu=0,...,3$.

It is now straightforward to simplify the Dirac equation $D\psi=0$ of (13). The internal degrees of freedom will be seen to contribute a rest mass term $m_{\chi}=\hbar/2\chi c$, and for simplicity we take this to be the entire rest mass of the Dirac equation, omitting any bare mass term in $\tilde{D}$. We simplify $D\rightarrow\tilde{D}$ and extend the internal symmetry group from SO(1, 3) to the group SO(3, 3) of a hexad by setting

$$\tilde{D} := \frac{2\phi}{\hbar^2}\check{S}^{\omega\rho}\check{L}_{\omega\rho}, \tag{30}$$

where [cf. (18)]

$$\check{L}_{\omega\rho} := \frac{\hbar}{2}\sum_{n=1}^{N-1}\gamma_{\omega\rho}(n). \tag{31}$$

Our proposed dynamical operator is invariant under a conformal group SO(3, 3) whose contraction includes the Poincaré group. [Our symmetry group SO(3, 3) incorporates and extends the SO(3, 2) symmetry possessed by Dirac's dynamics for an electron in de-Sitter space–time.[29] That dynamics has the form

$$D' = \frac{1}{\hbar R}\hat{S}^{\omega\rho}\hat{O}_{\omega\rho} - mc,$$

where $\hat{S}^{\omega\rho}$ and $\hat{O}_{\omega\rho}$ are the five-dimensional spinorial and orbital angular momentum generators and R is the radius of the de-Sitter universe. Its group is still compound, not simple, unifying translations, rotations, and boosts, but not symplectic transformations.]

A complete set of commuting generators for the Poincaré group ISO(1, 3) consists of the time translation generator $\hat{p}_0$, the rotation generator $\hat{L}_{12}$, and the boost generator $\hat{L}_{03}$. In the present context, we adjoin the imaginary unit i. In the proposed simplification ISO(1, 3)$\times$SO(2) $\leftarrow$SO(3, 3) these simplify according to $\hat{p}_0\leftarrow\check{L}_{04}$, $\hat{L}_{12}\leftarrow\check{L}_{12}$, $\hat{L}_{03}\leftarrow\check{L}_{03}$, $i\leftarrow\check{L}_{45}$. A commuting set

cannot contain both $\check{L}_{04}$ and $\check{L}_{45}$. Since varying energy is more familiar than varying i, in a first treatment we hold $\check{L}_{45}$ constant and couple different masses in one representation.

V. REDUCTION TO THE POINCARÉ GROUP

We now assume a condensation that reduces SO(3, 3) to its subgroup $\mathrm{SO}(1,3)\times\mathrm{SO}(2)$. Relative to this reduction, the $\tilde{D}$ of (30) breaks up into

$$\tilde{D}=\frac{\phi}{2}\gamma^{\omega\rho}(N)\sum_n\ \gamma_{\omega\rho}(n)\quad(\omega,\rho=0,1,...,5)$$

$$=\phi\gamma^{\mu 5}(N)\sum_n\ \gamma_{\mu 5}(n)+\phi\gamma^{\mu 4}(N)\sum_n\ \gamma_{\mu 4}(n)+\phi\gamma^{\mu\nu}(N)\sum_n\ \gamma_{\mu\nu}(n)+\phi\gamma^{45}(N)\sum_n\ \gamma_{45}(n)$$

$$=\gamma^{\mu 5}\check{p}_\mu-\frac{\phi}{\chi}\gamma^{\mu 4}\check{x}_\mu+\frac{2\phi}{\hbar}\gamma^{\mu\nu}\check{L}_{\mu\nu}+(N-1)\phi\gamma^{45}\check{i}. \tag{32}$$

In the condensate all the operators $\gamma^{45}(n)\gamma_{45}(n')$ attain their minimum eigenvalue -1. Then

$$(N-1)\phi\gamma^{45}\check{i}\to-\frac{\hbar}{2\chi} \tag{33}$$

and the dynamics becomes

$$\tilde{D}=\gamma^{\mu 5}\check{p}_\mu-\frac{\phi}{\chi}\gamma^{\mu 4}\check{x}_\mu+\frac{2\phi}{\hbar}\gamma^{\mu\nu}\check{L}_{\mu\nu}-m_\chi c, \tag{34}$$

with rest mass

$$m_\chi=\frac{\hbar}{2\chi c}. \tag{35}$$

For sufficiently large N this reduces to the usual Dirac dynamics.

We identify the mass m_χ with the N-independent mass m of the Dirac equation for the most massive individual quanta that the condensate can propagate without melt-down, on the order of the top quark or Higgs masses:

$$m_\chi\sim 10^2\ \mathrm{GeV},\quad \chi\sim 10^{-25}\ \mathrm{s}. \tag{36}$$

The universe is $\sim 10^{10}$ years old. This leads to an upper bound

$$N_{\max}\sim 10^{41}. \tag{37}$$

This implies that χ is independent of N as $N\to\infty$ and that $\phi\sim 1/N\to 0$ as $N\to\infty$ even for finite χ. In experiments near the Higgs energy, $p\sim\hbar/\chi$. If we also determine N by setting $x\sim N\chi$ then all four terms in (34) are of the same order of magnitude.

To estimate experimental effects, however, we must take gauge transformations into account. These transform the second term away in the continuum limit. This refinement of the theory is still in progress.

VI. CONCLUSIONS

Like classical Newtonian mechanics, the Dirac equation has a compound (nonsemisimple) invariance group. Its variables break up into three mutually commuting sets: the space–time–energy–momentum variables (x^μ,p_μ), the spin variables γ^μ, and the imaginary unit i.

To unify them we replace the space–time continuum by an aggregate of $M<\infty$ finite elements, chronons, described by spinors with $\sim 2^{M/2}$ components. Chronons have Clifford–Wilczek statistics, whose simple operator algebra is generated by units γ^m, $m=1,...,M$. We express all the variables x^μ, p_μ, γ^μ and i as polynomials in the γ^m. We group the $M=6N$ chronons into N hexads for this purpose, corresponding to tangent spaces; the hexad is the least cell that suffices for this simplification. There are three simplifiers χ, ϕ, $1/N$, all approaching 0 in the continuum limit, subject to the constraint $\chi\phi(N-1)=\hbar/2$ for all N.

In the continuum limit the Dirac mass becomes infinite. In our theory, the finite Dirac masses in nature are consequences of a finite atomistic quantum space–time structure with $\chi>0$.

The theory predicts a certain spin–orbit coupling $\gamma^{\mu\nu}L_{\mu\nu}$ not found in the standard model, and vanishing only in the continuum limit. The experimental observation of this spin–orbit coupling would further indicate the existence of a chronon.

In this theory, the spin we see in nature is a manifestation of the (Clifford) statistics of atomic elements of space-time, as Brownian motion is of the atomic elements of matter. As we improve our theory we will interpret better other indications of chronon structure that we already have, and as we improve our measuring techniques we shall meet more such signs.

Complex velocity transformations and the Bisognano–Wichmann theorem for quantum fields acting on Krein spaces

Hanno Gottschalk[a)]
Institut für angewandte Mathematik, Rheinische Friedrich-Wilhelms-Universität, Wegelerstr. 6, D-53115 Bonn, Germany

(Received 21 December 2001; accepted for publication 23 May 2002)

It is proven that in indefinite metric quantum field theory there exists a dense set of analytic vectors for the generator of the one parameter group of x^0-x^1 velocity transformations. This makes it possible to define complex velocity transformations also for the indefinite metric case. In combination with the results of Bros, Epstein, and Moschella [Commun. Math. Phys. **196**, 535–570 (1998)], proving Bisognano–Wichmann (BW) analyticity within the linear program, one then obtains a suitable generalization of the BW theorem for local, relativistic quantum fields acting on Krein spaces (''quantum fields with indefinite metric''). © *2002 American Institute of Physics.* [DOI: 10.1063/1.1503151]

I. INTRODUCTION

The connection of the Unruh effect[39] describing the Hawking radiation seen by a uniformly accelerated observer in local quantum field theory (QFT) with the Tomita–Takesaki modular theory[11,38] of v. Neumann algebras has been one of the most fascinating achievements in the study of the general structure of QFT, cf. Refs. 10 and 18 for an overview. In the Wightmanian formulation of QFT this connection is given by the Bisognano–Wichmann theorem[6] which, under a few additional assumptions, can then be extended to localized v. Neumann algebras associated with the algebras of unbounded Wightman fields, see, e.g., Refs. 5, 6, and 24.

The present work attempts to adapt the Bisognano–Wichmann theorem[6] to the case of quantum fields with indefinite metric in the framework of Morchio and Strocchi.[26,34,36] That this should in fact be possible was proven by J. Bros, H. Epstein and U. Moschella in Ref. 12. In this reference the authors show that the KMS condition for the algebra localized in the right wedge $\mathcal{W}_R=\{x\in\mathbb{R}^d: x^1>|x^0|\}$ w.r.t. the one parameter group of Lorentz boosts in the x^0-x^1 direction follows from the analyticity properties of Wightman functions from solely the linear program, i.e., without using positivity. In contrast to this, the original proof of Ref. 6 uses functional calculus for the generators of the Lorentz boosts, and thus positivity, to establish that property.

Quantum fields with indefinite metric have been introduced in the Wightmanian formulation of QFT in order to deal also with gauge fields in local and covariant gauges. Such fields can not be fields with positive metric.[35–37] Quantum fields with indefinite metric surely have to be considered to be artificial and ''nonphysical'' (at least as long as the related physical Hilbert space with positive metric and the algebra of gauge invariant fields acting on that space have not been constructed), but still some motivation can be found to consider the BW theorem also in this framework:

(i) QFT with indefinite metric is close to perturbation theory where local and covariant gauges are needed for technical reasons (see Refs. 32 and 36).
(ii) There are nontrivial examples in arbitrary space–time dimension.[1–3,29,30,31,32]

a)Electronic mail: gottscha@wiener.iam.uni-bonn.de

(iii) The BW theorem might be important to develop a bounded operator approach for quantum fields with indefinite metric defining wedge algebras as weak commutants in the style of Refs. 6 and 24.
(iv) The BW theorem can be seen as a first step towards studying the influence of constraints (gauge) to wedge-duality.
(v) It is an interesting technical exercise to develop a suitable substitute for functional calculus in the case of quantum fields with indefinite metric.

This article is organized as follows: In Sec. II we collect the basic tools for the formulation of QFT with indefinite metric.

In Sec. III we prove a crucial continuity property for GNS-like representations on maximal inner product spaces (Krein spaces[4,7]) and we recall basic properties of the field algebra as the Reeh–Schlieder property. As the vacuum plays a special role in modular theory, we clarify the status of the vacuum as the only translation invariant state for QFTs with indefinite metric and a mass gap—this then also implies the irreducibility of the field algebra (see also Ref. 26). In particular we show that the occurrence of theta-vacua, in the description of G. Morchio and F. Strocchi,[26] and reducibility of the field algebra due to classical long range fluctuations[13] are strictly linked to mass zero phenomena, as of course suggested by these references.

In Sec. IV we define the complex velocity transformations for the case of quantum fields with indefinite metric using the continuity properties established in Sec. III in connection with functional calculus on the Borchers algebra. Rather than using functional calculus for η-symmetric operators, see, e.g., Refs. 4 and 19 and references therein, we follow a ''pedestian's approach'' and prove the existence of a dense set of entire analytic vectors for the generator of the Lorentz boosts.

In Sect. V we recall the result of Bisognano–Wichmann (BW) analyticity within the linear program as proven by Bros–Epstein–Moschella[12] and derive a version of the BW theorem for quantum fields with indefinite metric. In particular, we identify the ''modular objects:'' The antiunitary implementation of the reflection $\Theta_{0,1}:(x^0,x^1,x^2,\ldots,x^{d-1})\to(-x^0,-x^1,x^2,\ldots,x^{d-1})$ is the ''modular conjugation'' and velocity transformations at imaginary boost parameter $i\pi$ are Tomita's modular operator $\Delta^{1/2}$. For space–time dimension $d=4$ the modular conjugation thus coincides with the rotation around $e_1=(0,1,0,\ldots,0)$ by an angle π times the PCT-operator $\Theta:x\to -x$, which is the description given in Ref. 6. Here, of course, no answer is given to what extent Tomita–Takesaki theory can be generalized to η- v.Neumann algebras acting on Krein spaces and thus to what extent the ''modular objects'' defined here really can be related to some extension of Tomita–Takesaki theory. This might, however, be an interesting question for the future. At least Tomita–Takesaki theory on the Pontryagin space Π_1 has been established in Ref. 25.

II. QFT WITH INDEFINITE METRIC

Here some notation is introduced and basic results on the GNS construction on maximal inner product spaces (Krein spaces) are recalled (see, however, Refs. 21, 26 and 40 for more details). We only consider Bosonic, scalar and chargeless QFTs over a d-dimensional Minkowski space–time $(\mathbb{R}^d,\cdot)$. Generalization to arbitrary spin, charge and statistics is straightforward. The associated Borchers algebra[8,9] is the free, unital, involutive, topological tensor algebra over $\mathcal{S}_1=\mathcal{S}(\mathbb{R}^d,\mathbb{C})$, the space of complex Schwartz test functions over $\mathbb{R}^d$. In more explicit terms, we set

$$\underline{\mathcal{S}}=\oplus_{n=0}^{\infty}\mathcal{S}_n,\quad \mathcal{S}_n=\mathcal{S}(\mathbb{R}^{dn},\mathbb{C}),\quad \mathcal{S}_0=\mathbb{C}, \tag{1}$$

with $\underline{f}+\underline{h}=(f_0+h_0,f_1+h_1,\ldots)$, $\underline{f}\otimes\underline{h}$ given by $(\underline{f}\otimes\underline{h})_n=\Sigma_{j+l=n}^{\infty,l=0}f_j\otimes h_l\ \forall n\in\mathbb{N}_0$, $\mathbf{1}=(1,0,\ldots)$ and $\underline{f}^*=(f_0^*,\ldots,f_n^*,0\ldots)$ with $f_l^*(x_1,\ldots,x_l)=\overline{f_l(x_l,\ldots,x_1)}$. Here the bar denotes complex conjugation and the product always exists as for $\underline{f}\in\underline{\mathcal{S}}$ only finitely many $f_l\in\mathcal{S}_l$ are different from zero.

The canonic action $\alpha:P_+^{\uparrow}\to\mathrm{Aut}(\mathcal{S}_l)$ of the orthochronous, proper Poincaré group on $\mathcal{S}_l$, $l\in\mathbb{N}$, induces a representation $\underline{\alpha}:P_+^{\uparrow}\to\mathrm{Aut}(\underline{\mathcal{S}})$ by continuous $*$-algebra homomorphisms on $\underline{\mathcal{S}}$.

The spectral ideal $I_{\mathrm{sp}}\subset\underline{\mathcal{S}}$ is the left-ideal generated by elements of the form

$$\underline{g}=\underline{g}(\underline{f},h)=\int_{\mathbb{R}^d}\underline{\alpha}_{\{1,a\}}(\underline{f})h(a)da\in\underline{\mathcal{S}} \tag{2}$$

for supp $\hat{h}\cap\overline{V}_0^+=\varnothing$ where $h\in\mathcal{S}_1$, $\hat{h}(k)=\int_{\mathbb{R}^d}e^{ik\cdot a}h(a)da$ and $\overline{V}_0^+=\{k\in\mathbb{R}^d,k^0\geqslant 0,k\cdot k\geqslant 0\}$ is the closed forward light cone. The related left-ideal I_{sp}^m where in the definition of I_{sp} $\overline{V}_0^+$ is replaced by $\{0\}\cup\overline{V}_m^+=\{0\}\cup\{k\in\mathbb{R}^d,k^0\geqslant 0,k\cdot k\geqslant m^2\}$, $m>0$, is called spectral ideal with mass-gap m.

A further useful ideal in $\underline{\mathcal{S}}$ is the two-sided ideal generated by $(0,0,[f_1,h_1],0,\ldots)$ with $f_1,h_1\in\mathcal{S}_1$ and supp f_1, supp h_1 space-like separated, i.e., $(x-y)\cdot(x-y)<0\ \forall x\in\text{supp } f_1, y\in\text{supp } h_1$. It is called the ideal of locality.

We recall that $\underline{\mathcal{S}}$ is endowed with the strongest topology, such that the relative topology of $\mathcal{S}_n$ in $\underline{\mathcal{S}}$ is the Schwartz topology (direct sum topology). Let $\underline{\mathcal{S}}'=\underline{\mathcal{S}}'(\mathbb{R}^d,\mathbb{C})$ be the topological dual space of $\underline{\mathcal{S}}$. Then $\underline{R}\in\underline{\mathcal{S}}'$ is of the form $\underline{R}=(R_0,R_1,R_2,\ldots)$ with $R_0\in\mathbb{C},R_n\in\mathcal{S}_n',n\in\mathbb{N}$. Furthermore, any such sequence defines uniquely an element of $\underline{\mathcal{S}}'$. An element $\underline{W}\in\underline{\mathcal{S}}'$ is called a Wightman functional if it fulfills the following set of conditions, which are also called the modified Wightman axioms, cf. Refs. 26 and 40:

Axioms 2.1: (A1) Temperedness and normalization: $\underline{W}\in\underline{\mathcal{S}}'$ and $W_0=1$.

(A2) Poincaré invariance: $\underline{W}(\underline{\alpha}_{\{\Lambda,a\}}(\underline{f}))=\underline{W}(\underline{f})\ \forall\{\Lambda,a\}\in\tilde{P}_+^{\uparrow}$, $\underline{f}\in\underline{\mathcal{S}}$.

(A3) Spectral property: Let I_{sp} be the spectral (left) ideal in $\underline{\mathcal{S}}$. Then $I_{\mathrm{sp}}\subseteq$kernel $\underline{W}$.

(A4) Locality: Let I_{loc} be the (two-sided) ideal of locality in $\underline{\mathcal{S}}$. Then $I_{\mathrm{loc}}\subseteq$kernel $\underline{W}$.

(A5) Hilbert space structure condition (HSSC): There exists a Hilbert seminorm $\underline{p}$ on $\underline{\mathcal{S}}$ s.t. $|\underline{W}(\underline{f}^*\otimes\underline{g})|\leqslant\underline{p}(\underline{f})\underline{p}(\underline{g})\forall\underline{f},\underline{g}\in\underline{\mathcal{S}}$.

(A6) Cluster property: $\lim_{t\to\infty}\underline{W}(\underline{f}\otimes\underline{\alpha}_{\{1,ta\}}(\underline{g}))=\underline{W}(\underline{f})\ \underline{W}(\underline{h})\ \forall\underline{f},\underline{g}\in\underline{\mathcal{S}},a\in\mathbb{R}^d$ space like.

(A7) Hermiticity: $\underline{W}(\underline{f}^*)=\overline{\underline{W}(\underline{f})}\ \forall\underline{f}\in\underline{\mathcal{S}}$.

We say that the Hilbert seminorm $\underline{p}$ in (A5) is of Sobolev type, if

$$\underline{p}(\underline{f})=\sum_{l=0}^{\infty}p_n(f_n)\forall\underline{f}\in\underline{\mathcal{S}} \tag{3}$$

s.t. p_n defined on $\mathcal{S}_n$ up to multiplication with a positive constant is given by a Hilbert norm of Sobolev type,[17]

$$p_n(f_n)^2=c^2\int_{\mathbb{R}^{dn}}\left|\prod_{l=1}^{n}(1+|x_l|^2)^{N/2}(1-\Delta_{x_l})^{L/2}f_n(x_1,\ldots,x_n)\right|^2dx_1\cdots dx_n, \tag{4}$$

for some possibly n-dependent $L,N\in\mathbb{N}_0$ and $c>0$ with $\Delta_{x_l}=\Sigma_{l=1}^n\partial^2/(\partial x_l)^2$. $\underline{p}$ is called Sobolev dominated, if there exists a Hilbert norm $\underline{p}'$ of Sobolev type s.t. $\underline{p}\leqslant\underline{p}'$ or, in other words, if $\underline{p}$ is continuous with respect to (w.r.t.) the $\underline{\mathcal{S}}$-topology.

If I_{sp} in (A3) can be replaced with some bigger I_{sp}^m, $m>0$, then we say that $\underline{W}$ fulfills the strong spectral condition. One can show by explicit calculations that the axioms (A1)–(A4), (A6) and (A7) are equivalent to the usual Wightman axioms,[33] whereas positivity has been replaced by the weaker assumption (A5). Nevertheless, (A5) is enough to get an analog of the Wightman reconstruction theorem on maximal, non degenerate inner product spaces as follows:

A metric operator $\eta:\mathcal{H}\to\mathcal{H}$ by definition is a self-adjoint operator on a complex separable Hilbert space $(\mathcal{H},(.,.))$ with $\eta^2=1$. η induces a second, in general indefinite, inner product on $\mathcal{H}$ via $\langle .,.\rangle=(.,\eta.)$ and η then gives a fundamental decomposition of $\mathcal{H}$ into intrinsically complete subspaces $\mathcal{H}=\mathcal{H}^+\oplus\mathcal{H}^-$ s.t. $\langle .,.\rangle$ restricted to $\mathcal{H}^{\pm}$ is positive/negative definite. Hence $(\mathcal{H},\langle .,.\rangle)$ is a Krein space.[4,7] It should be mentioned that $(.,.)$, η and the fundamental decomposition $\mathcal{H}^{\pm}$ are not unique given $(\mathcal{H},\langle .,.\rangle)$; η, for example, can be replaced by $\eta_C=\mathrm{sign}(|C|^{-2}\eta)$ for a bounded, continuously invertible operator on $\mathcal{H}$ leading to an in general different, but topologically equivalent, $(.,.)_C=(.,|C|^2||C|^{-2}\eta|.)$ and also a new fundamental decomposition according to η_C.

Let $\mathcal{D}$ be a dense and linear subspace of $\mathcal{H}$. The set of (possibly unbounded) Hilbert space operators $\mathsf{L}:\mathcal{D}\to\mathcal{D}$ with (restricted) η-adjoint $\mathsf{L}^{[*]}=\eta\mathsf{L}^*\eta|_{\mathcal{D}}:\mathcal{D}\to\mathcal{D}$ is denoted with $\mathsf{O}_\eta(\mathcal{D})$. Clearly, $\mathsf{O}_\eta(\mathcal{D})$ is an unital algebra with involution $[*]$. The canonical topology on $\mathsf{O}_\eta(\mathcal{D})$ is generated by the seminorms $\mathsf{L}\to|\langle\Psi_1,\mathsf{L}\Psi_2\rangle|$, $\Psi_1,\Psi_2\in\mathcal{D}$. We then have the following theorem:

Theorem 2.2: *Let $\underline{W}\in\underline{\mathcal{S}}$ be a Wightman functional which fulfills Axioms 2.1. Then we have the following.*

(i) *There is a Hilbert space $(\mathcal{H},(.,.))$ with a distinguished normalized vector $\Omega\in\mathcal{H}$ called the vacuum, a metric operator η with $\eta\Omega=\Omega$ inducing a nondegenerate inner product $\langle.,.\rangle=(.,\eta.)$ and a continuous $*$-algebra representation $\phi:\underline{\mathcal{S}}\to\mathsf{O}_\eta(\mathcal{D})$ with $\mathcal{D}=\phi(\underline{\mathcal{S}})\Omega$ which is connected to the Wightman functional $\underline{W}$ via $\underline{W}(\underline{f})=\langle\Omega,\phi(\underline{f})\Omega\rangle\forall\underline{f}\in\underline{\mathcal{S}}$.*

(ii) *There is a η-unitary continuous representation $\mathsf{U}:\widetilde{P}^\uparrow_+\to\mathsf{O}_\eta(\mathcal{D})$ $(\mathsf{U}^{[*]}=\mathsf{U}^{-1})$ such that $\mathsf{U}(\Lambda,a)\phi(\underline{f})\mathsf{U}(\Lambda,a)^{-1}=\phi(\underline{\alpha}_{\{\Lambda,a\}}(\underline{f}))\forall\underline{f}\in\underline{\mathcal{S}},\{\Lambda,a\}\in\widetilde{P}^\uparrow_+$ and Ω is invariant under the action of U.*

(iii) *ϕ fulfills the spectral condition $\phi(I_{\mathrm{sp}})\Omega=0$.*

(iv) *ϕ is a local representation in the sense that $I_{\mathrm{loc}}\subseteq\mathrm{kernel}\ \phi$.*

(v) *For $\Psi_1,\Psi_2\in\mathcal{D}$ and $a\in\mathbb{R}^d$ space like, we get $\lim_{t\to\infty}\langle\Psi_1,\mathsf{U}(1,ta)\Psi_2\rangle=\langle\Psi_1,\Omega\rangle\langle\Omega,\Psi_2\rangle$.*

A quadruple $((\mathcal{H},\langle.,.\rangle,\Omega),\eta,\mathsf{U},\phi)$ is called a local relativistic QFT in indefinite metric.

Conversely, let $((\mathcal{H},\langle.,.\rangle,\Omega),\eta,\mathsf{U},\phi)$ be a local relativistic QFT in indefinite metric. Then $\underline{W}(\underline{f})=\langle\Omega,\phi(\underline{f})\Omega\rangle\ \forall\ \underline{f}\in\underline{\mathcal{S}}$ defines a Wightman functional $\underline{W}\in\underline{\mathcal{S}}'$ which fulfills Axioms 2.1.

As we will come back to some details of the proof of Theorem 2.2 in the next section, we recall these points here while for the rest of the proof we refer to Refs. 26, 40 and 21.

Sketch of Proof: Without loss of generality one can assume that $\underline{p}$ is a Hilbert norm. If $\underline{p}$ is only a Hilbert seminorm we can replace it by the Hilbert norm $\underline{p}'=\sqrt{\underline{p}^2+\underline{p}_1^2}$ where $\underline{p}_1$ is a Hilbert norm on $\underline{\mathcal{S}}$ which not necessarily dominates $\underline{W}$. Such $\underline{p}_1$ can, e.g., be chosen as a direct sum of Sobolev norms on $\mathcal{S}_n$.

Then, $\mathcal{H}_1=\overline{\underline{\mathcal{S}}}^{\underline{p}}$ defines the Hilbert space completion of $\mathcal{D}_1=\underline{\mathcal{S}}$ w.r.t. $\underline{p}$. The Hermitian inner product $\langle\underline{f},\underline{g}\rangle=\underline{W}(\underline{f}^*\otimes\underline{g})$ defined for $\underline{f},\underline{g}\in\mathcal{D}_1$ is continuous and thus extends uniquely to $\mathcal{H}_1$. By the Riesz representation theorem there exists a self-adjoint operator η_1 bounded by one s.t. $\langle.,.\rangle=(.,\eta_1.)_1$. The algebra $\underline{\mathcal{S}}$ acts via the identical representation ϕ_1 by multiplication from the left on $\mathcal{D}_1\subseteq\mathcal{H}_1$. Likewise, a η_1-unitary continuous representation $\mathsf{U}_1:P^\uparrow_+\to\mathsf{O}_{\eta_1}(\mathcal{D}_1)$ is defined by the action of $\underline{\alpha}$ on $\mathcal{D}_1$.

Let $\mathcal{K}_0=\{v\in\mathcal{H}_1:\langle w,v\rangle=0\forall w\in\mathcal{H}_1\}$ and $\underline{\mathcal{S}}_0=\{\underline{f}:\underline{W}(\underline{g}\otimes\underline{f})=0\forall\underline{g}\in\underline{\mathcal{S}}\}$. Then, $\mathcal{K}_0$ is a closed subspace of $\mathcal{H}_1$. Let $\mathcal{H}_2=\mathcal{H}_1/\mathcal{K}_0$ be quotient Hilbert space of $\mathcal{H}_1$ and $\mathcal{K}_0$ with scalar product $(.,.)_2$. By Hermiticity, linearity and definition of $\mathcal{K}_0$, $\langle.,.\rangle$ is also defined on the quotient space $\mathcal{H}_2$. Let $\pi:\mathcal{H}_1\to\mathcal{H}_2$ be the quotient map. Then, by the definition of $\mathcal{K}_0$, $(\pi(\underline{f}),\pi(\underline{g}))_2$ still dominates $\langle.,.\rangle$. Thus, there exists a self-adjoint operator η_2 bounded by one s.t. $\langle.,.\rangle=(.,\eta_2.)_2$. Furthermore, we set $\mathcal{D}=\pi(\mathcal{D}_1)\cong\underline{\mathcal{S}}/\underline{\mathcal{S}}_0$ as $\mathcal{D}_1\cap\mathcal{K}_0=\phi_1(\underline{\mathcal{S}}_0)$. As $\underline{\mathcal{S}}_0$ is a left ideal and is taken into itself by the action of $\underline{\alpha}$, $\phi=\pi\circ\phi_1$ and $\mathsf{U}=\pi\circ\mathsf{U}_1$ define a left-representation of $\underline{\mathcal{S}}$ and $\widetilde{P}^\uparrow_+$, respectively, in $\mathsf{O}_{\eta_2}(\mathcal{D})$.

Let $(.,.)=(.,|\eta_2|.)_2$. Then, the metric operator η defined by $\langle.,.\rangle=(.,\eta.)$ is $\eta=\mathrm{sign}(\eta_2)$. Thus, also $(.,.)$ dominates $\langle.,.\rangle$ and obviously $\|.\|\leqslant\|.\|_2$. We can now set $\mathcal{H}$ to be the completion of $\mathcal{D}$ w.r.t. $\|.\|$, and extend η and $\langle.,.\rangle$ to $\mathcal{H}$ in order to obtain a Krein space representation, as described by the assertion of the theorem. The representations ϕ and U in $\mathsf{O}_\eta(\mathcal{D})$ then fulfill the requirements $(i)-(v)$, as proven in Refs. 26, 21, 33, 40 (see also Ref. 16). For the fact that η can be chosen s.t. $\eta\Omega=\Omega$, $\Omega=\pi(1,0,\ldots)$, cf. Ref. 21. ∎

Let $\Theta_{0,1}$ be the antilinear PCT-like transformation given by the action $\alpha_{\{\Theta_{0,1},0\}}(f_n)\times(x_1,\ldots,x_n)=\overline{f_n(\Theta_{0,1}x_1,\ldots,\Theta_{0,1}x_n)}$ for $f_n\in\mathcal{S}_n$, $\Theta_{0,1}x$ as in the Introduction, and $\underline{\alpha}_{\{\Theta_{0,1},0\}}$ the related action on $\underline{\mathcal{S}}$. From the proof of Theorem 2.2 one immediately (cf. Ref. 36) obtains the following.

Corollary 2.3: Let $\underline{p}$ in (A5) be such that $\underline{p}(\underline{\alpha}_{\{\Lambda,0\}}(\underline{f}))=\underline{p}(\underline{f})\ \forall\underline{f}\in\underline{\mathcal{S}}$ and $\Lambda\in G\subseteq L$, with G

generated by rotations (in a given frame of reference) and the PCT-like transformation $\Theta_{0,1}$. *Then,* U *extends to all* G *and* $\mathsf{U}(G)$ *commutes with the metric operator* η *constructed in the Proof of Theorem 2.2. In particular,* $\mathsf{U}(G)$ *is represented by (anti-) unitary, and hence bounded, operators on* $\mathcal{H}$.

Proof: By the PCT-theorem in d space–time dimensions, which does not require positivity (here we assumed the standard connection of spin and statistics, which is required for the PCT theorem—in theories with indefinite metric where also ghost fields are included, the results of this article on the BW theorem do not apply), $\underline{W}$ is invariant under the antilinear PCT-like transformation $\Theta_{0,1}$,[12,33] and thus $\mathsf{U}(G)$ is (anti-)η-unitarily represented. As $\underline{p}$ is invariant under the action of G, η_1 commutes with $\mathsf{U}_1(G)$. Since the construction of $\mathcal{H}$ consists of twice changing the operators η_1 and η_2 by functions of these operators, $\mathsf{U}(G)$ also commutes with η. (Anti-) unitarity of $\mathsf{U}(G)$ now follows from $\eta^2=1$. ■

It is demonstrated in Ref. 28, Theorem 3.1, that Sobolev dominated Hilbert norms which do not fulfill the condition of Corollary 2.3 can be replaced by equivalent norms which fulfill that condition. It is automatically fulfilled by Hilbert norms of Sobolev type.

To close this section we would like to address two points concerning the usefulness of Theorem 2.2 to describe the physics of quantum fields with indefinite metric. The first point is that the construction of $\mathcal{H}$ depends not only on $\underline{W}$ but possibly depends also on the auxilary Hilbert seminorm $\underline{p}$. In fact, unless the fundamental decomposition $\mathcal{H}^{\pm}$ of $\mathcal{H}$ given by η has either $\mathcal{H}^{+}$ or $\mathcal{H}^{-}$ intrinsically complete, i.e., complete w.r.t. the topology generated by the restriction of $\langle .,. \rangle$ to $\mathcal{H}^{\pm}$, recent results prove that there are infinitely many topologically inequivalent maximal Hilbert space structures.[15,22,23] In the generic situation in QFT the fundamental decomposition $\mathcal{H}^{\pm}$ can not be expected to have an intrinsically complete component. On the other hand it is argued in Refs. 27 and 28 that exactly this nonuniqueness can be exploited for the construction of charged states in certain infrared representations (depending on the space–time splitting) and thus is a necessary feature of gauge QFT. Another application involving an adequate choice of the closure of local states is, e.g., bosonization in low-dimensional QFT, cf. Ref. 36. The present article deals with this issue in the way that we prove our results for *all* such maximal Hilbert space structures which originate from Sobolev dominated $\underline{p}$.

The second point, which has recently been expressed by O. Steinmann, is that maximal Hilbert topologies on the space(s) $\mathcal{H}$ might have little to do with the topology on the space of physical states, as in the case of quantum electrodynamics it is not possible to construct charged states for the Maxwell (Gauss) charge in a physical Hilbert space constructed from $\mathcal{H}$ with the help of an abstract Gupta–Bleuler formalism in the spirit of Ref. 26, cf. Theorem 7.3 of Ref. 32. Instead, Steinmann proposes to work with the inner product space $\mathcal{D}=\underline{\mathcal{S}}/\underline{\mathcal{S}}_0$ and to avoid a (possibly nonunique) maximal Hilbert closure. Endowing $\mathcal{D}$ with a suitable quotient topology, the arguments of the present article can also be formulated without reference to maximal Hilbert space closures of $\mathcal{D}$. This will in fact be the main strategy of this article. As the results which take reference to Hilbert space structures are mathematically slightly stronger and it might be of interest to compare them with results on functional calculus on Krein spaces,[4,19] here we use the language of Krein spaces and do not restrict the analysis to $\mathcal{D}$.

Remark 2.4: Section 5 of Ref. 27 states that charged, physical states *can be* constructed in a closure of the local states. Theorem 7.3 of Ref. 32 is just the opposite of this statement. As far as I can see, this contradiction can be traced back to different assumptions in Refs. 27 and 32. In Ref. 32 it is assumed that the local states are in the domain of definition of the Maxwell charge Q. This assumption leaves open a kind of loophole as Q resulting from a closure of the Maxwell charge defined on states of the type of Eq. (86) of Ref. 27 might not contain all local states in its domain.

On the other hand, the construction of the metric operator in Ref. 27 according to conditions $\mathbf{A}_2$) for the ''in''-field and Eq. (70), leading to the construction of charged physical states, could also be problematic: The vacuum expectation values of local and ''in''-fields, which can be calculated from the local theory, partially fix the action of the metric operator on the ''in''-fields, as, e.g., sequences of states converging in the ''in''-space must have finite inner product with the local states. In a hypothetic, nonperturbative QED $\mathbf{A}_2$) and Eq. (70) of Ref. 27 might not match

with this *a priori* requirement on the metric operator. In a related situation (again not exactly the same as in Ref. 27), Steinmann gives evidence from perturbation theory that there could in fact be a problem, cf. Chap. 12.4 of Ref. 32. But the Hilbert space of an interacting theory usually is singular to the Hilbert space of the free theory, on which perturbation theory is carried out, thus perturbative arguments on the states of the interacting theory are not fully conclusive. ■

III. SOME PROPERTIES OF THE FIELD ALGEBRA

The reason why we went through the well-known construction in the proof of Theorem 2.2 is that the continuity $\phi:\underline{\mathcal{S}}\to\mathsf{O}_\eta(\mathcal{D})$ for most applications is insufficient, as the topology on $\mathsf{O}_\eta(\mathcal{D})$ is very weak. From the above construction we get, however, that

$$\|\phi(\underline{f})\Omega\|\leqslant \underline{p}(\underline{f})-\forall\,\underline{f}\in\underline{\mathcal{S}}, \tag{5}$$

and we thus get the following lemma, which gives sufficient continuity properties of the representation ϕ to effectively control certain constructions on $\mathcal{H}$.

Lemma 3.1: Suppose $\underline{W}$ fulfills the HSSC (A5) with $\underline{p}$ Sobolev dominated. Then, ϕ is strongly continuous in the sense $\underline{f}_n\to\underline{f}$ in $\underline{\mathcal{S}}\Rightarrow\phi(\underline{f}_n)\Omega\to\phi(\underline{f})\Omega$ strongly in $\mathcal{H}$.

Proof: As $\underline{\mathcal{S}}$ carries the direct sum topology, $\underline{f}_n\to\underline{f}$ implies the convergence of any component in $\mathcal{S}_n$ and the existence of a maximal N s.t. the components of $\underline{f}_n$ in $\mathcal{S}_l$, $l>N$, are equal to zero $\forall n\in\mathbb{N}$. As the topology on $\mathcal{S}_n$ is generated by Sobolev dominated norms and convergence in $\mathcal{S}_n$ thus implies the convergence in any specific Sobolev norm, we get $0\leqslant\underline{p}(\underline{f}_n-\underline{f})\leqslant\underline{p}'(\underline{f}_n-\underline{f})\to 0$, as $n\to\infty$, for $\underline{p}'$ a seminorm of Sobolev type dominating $\underline{p}$. Together with (5) this gives $\|\phi(\underline{f}_n)\Omega-\phi(\underline{f})\Omega\|=\|\phi(\underline{f}_n-\underline{f})\Omega\|\to 0$. ■

From now on we assume that the maximal Hilbert space $\mathcal{H}$ with metric operator η has been constructed from a Sobolev dominated Hilbert norm $\underline{p}$. That such a $\underline{p}$ exists can be checked explicitly using the following sufficient condition, which has been verified in Refs. 1 and 3 for models of QFT with indefinite metric and nontrivial scattering matrix. It should be no major problem to verify the condition of Theorem 3.2 also for the truncated Wightman functions of nth order perturbation theory of Refs. 30–32 and the conformally invariant Wightman functions as classified by Nikolov and Todorov.[29]

Theorem 3.2: *Let $\|.\|$ be a Schwartz norm on $\mathcal{S}_1$. If the truncated Wightman functions W_n^T associated with $\underline{W}$ [cf. (8) below] are continuous w.r.t. $\|.\|^{\otimes n}$ $\forall n\in\mathbb{N}$, then $\underline{W}$ fulfills the HSSC with respect to a Hilbert norm $\underline{p}$ of Sobolev type. (As $\mathcal{S}_1$ is a nuclear space, the tensor product of norms exists, cf. e.g., Ref. 20.)*

For the proof see Refs. 3 and 20. Here we only recall that the Schwarz norms $\|.\|=\|.\|_{L,N}$, $L,N\in\mathbb{N}_0$, on $\mathcal{S}_1$ are given by

$$\|f\|_{L,N}=\sup_{x\in\mathbb{R}^d,|\beta|\leqslant L}|(1+|x|^2)^{N/2}\partial^\beta f(x)|, \tag{6}$$

where β is a multiindex and $\partial^\beta=\Pi_{l=0}^{d-1}\partial^{|\beta^l|}/(\partial x^l)^{\beta_l}$. The topology generated by the family of Schwartz norms is equivalent to the topology generated by the Sobolev norms, which also generate the Schwartz topology. For concrete estimates it is often more convenient to work with Schwartz norms, therefore Theorem 3.2 is formulated for such norms.

For $\mathcal{A}\subseteq\mathsf{O}_\eta(\mathcal{D})$ the weak commutant of $\mathcal{A}$ is given by

$$\mathcal{A}'=\{C\in\mathcal{B}(\mathcal{H}):\langle\Psi_1,C\mathsf{L}\Psi_2\rangle=\langle\mathsf{L}^{[*]}\Psi_1,C\Psi_2\rangle\ \ \forall\Psi_1,\Psi_2\in\mathcal{D},\mathsf{L}\in\mathcal{A}\}. \tag{7}$$

Here $\mathcal{B}(\mathcal{H})$ is the set of bounded operators on $\mathcal{H}$. $\mathcal{A}$ is called irreducible if $\mathcal{A}'=\mathbb{C}1_{\mathcal{H}}$.

For $\mathcal{O}\subseteq\mathbb{R}^d$ we define $\underline{\mathcal{S}}(\mathcal{O})$ to be the unital*-algebra of those $\underline{f}\in\underline{\mathcal{S}}$ which have components f_n, $\mathrm{supp}f_n\subseteq\mathcal{O}^{\times n}$. We set $\mathcal{P}(\mathcal{O})=\phi(\underline{\mathcal{S}}(\mathcal{O}))$ and we call this set the polynomial field algebra localized in $\mathcal{O}$. Furthermore, we let $\mathsf{E}_0=(\Omega,.)\Omega\in\mathsf{O}_\eta(\mathcal{D})$ be the projection operator onto the vacuum. One then gets the Reeh–Schlieder property of the field in analogy to the positive metric case (the proof essentially is due to Refs. 26 and 34):

Theorem 3.3:

(i) For $\mathcal{O}\subseteq\mathbb{R}^d$ *open and not empty,* Ω *is cyclic w.r.t.* $\mathcal{P}(\mathcal{O})$
(ii) For $\mathcal{O}$ *as in (i), the set of operators* $\{\mathcal{P}(\mathcal{O}),\mathsf{E}_0\}$ *is irreducible.*
(iii) For $\mathcal{O}$ *as in* (i) *s.t.* $\mathcal{O}'=\{x\in\mathbb{R}^d,(x-y)\cdot(x-y)<0\,\forall y\in\mathcal{O}\}$ *has nonempty open interior,* Ω *is standard (i.e., cyclic and separating) for* $\mathcal{P}(\mathcal{O})$.

Proof: (i) By Lemma 3.1, $\underline{\mathcal{S}}\ni\underline{f}\to\langle\Psi_1,\phi(\underline{f})\Omega\rangle$ defines a functional in $\underline{\mathcal{S}}'$ for arbitrary $\Psi_1\in\mathcal{H}$. This step has been used also in Refs. 34 and 26 without being explicitly mentioned. For the standard Wightman axioms it follows from positivity, cf. Ref. 33. As in Ref. 33 we may now conclude that the n-point functions associated to such Wightman functionals are boundary values of analytic functions and thus vanish everywhere, if they vanish in $\mathcal{O}$. Now suppose that Ψ is perpendicular (w.r.t. $(.,.)$) to $\mathcal{P}(\mathcal{O})\Omega$. This implies for $\Psi_1=\eta\Psi$, using the above argument, that $\langle\Psi_1,\phi(\underline{f})\Omega\rangle=0\,\forall\underline{f}\in\underline{\mathcal{S}}$. Thus $\Psi_1=0$ and $\Psi=\eta\Psi_1=0$.

(ii) We have to show that for any $C\in\mathcal{B}(\mathcal{H})$

$$\langle\Psi_1,C\phi(\underline{f})\Psi_2\rangle=\langle\phi(\underline{f}^*)\Psi_1,C\Psi_2\rangle\quad\forall\underline{f}\in\underline{\mathcal{S}}(\mathcal{O}),\quad\Psi_1,\Psi_2\in\mathcal{D},$$

and $C\mathsf{E}_0=\mathsf{E}_0C$ implies $C=c1_{\mathcal{H}}$ for some $c\in\mathbb{C}$. Let $\Psi_1\in\mathcal{D}$ and $\Psi_2\in\mathcal{P}(\mathcal{O})\Omega$, i.e., $\Psi_2=\phi(\underline{f})\Omega$ for some $\underline{f}\in\underline{\mathcal{S}}(\mathcal{O})$. We get in analogy to Eqs. (4–16) of Ref. 33:

$$\langle\Psi_1,C\Psi_2\rangle=\langle\phi(\underline{f}^*)\Psi_1,C\Omega\rangle=\langle\phi(\underline{f}^*)\Psi_1,C\mathsf{E}_0\Omega\rangle=(\phi(\underline{f}^*)\Psi_1,\eta\mathsf{E}_0C\Omega)=(\phi(\underline{f}^*)\Psi_1,\eta\Omega)$$
$$\times(\Omega,C\Omega)=\langle\phi(\underline{f}^*)\Psi_1,\Omega\rangle(\Omega,C\Omega)=\langle\Psi_1,\Psi_2\rangle(\Omega,C\Omega).$$

Since $\mathcal{P}(\mathcal{O})\Omega$ is dense in $\mathcal{H}$ by (i), this implies $C=(\Omega,C\Omega)1_{\mathcal{H}}$.

(iii) Follows from property (i) for $\mathcal{P}(\mathcal{O})$ and $\mathcal{P}(\mathcal{O}')$ since locality implies that these algebras commute and thus cyclicity of Ω for $\mathcal{P}(\mathcal{O}')$ implies separability of Ω for $\mathcal{P}(\mathcal{O})$. ■

We want to adapt further results of positive metric QFT to the case of indefinite metric QFT, namely the irreducibility of the field algebra and the uniqueness of the vacuum. The proofs in the positive metric case use the spectral resolution of the translation group—something which is not at disposal in ''indefinite metric.'' Instead we use a smooth cut-off function to separate the vacuum from the remaining states and we have to restrict ourselves to the case of QFTs with a mass-gap $m>0$.

Since U is only densely defined, one calls $\tilde{\Omega}\in\mathcal{H}$ invariant under the action of the translation group $\mathsf{U}(1,a)$ if $\langle\tilde{\Omega},\mathsf{U}(1,a)\Psi_1\rangle=\langle\tilde{\Omega},\Psi_1\rangle\forall a\in\mathbb{R}^d,\Psi_1\in\mathcal{D}$, cf. Ref. 36.

Theorem 3.4: *Suppose that* $\underline{W}$ *fulfills the strong spectral condition with mass gap* $m>0$. *Then*

(i) $\mathcal{P}(\mathbb{R}^d)$ *is irreducible, and*
(ii) the vacuum Ω *is the unique translation invariant state in* $\mathcal{H}$ *(up to multiplication with a constant).*

Related results have been proven by Morchio and Strocchi:[26] (ii) has been verified for nonmaximal Hilbert spaces of Sobolev type and (i) has been deduced from the assumption of (essential) uniqueness of the vacuum. Here we extend these results also to maximal Hilbert closures originating from a Sobolev dominated HSSC and we prove that such closures do not contain any theta-vacua,[26] provided the strong spectral condition holds. That this statement can not be obtained in the mass-zero case is proven in Ref. 26 by explicit examples. These examples, however, do not fulfill the cluster property, which in Ref. 26 is not included in the modified Wightman axioms. Such a statement fits nicely into the picture that there is a connection of symmetry breaking and the presence of massless fields.[14] Also, (i) shows that a potential reducibility of the algebra of local fields can occur in the mass-zero case only. For massless gauge theories reducibility of the representation can be expected resulting from classical long range fluctuations, see Ref. 13 for the example of QED. For nontrivial examples of massive theories, see Ref. 1.

The proof of Theorem 3.4 starts with some technical preparations: Let $\underline{f}\in\underline{\mathcal{S}}$ and $h\in\mathcal{S}_1$ and $\underline{g}=\underline{g}(\underline{f},h)$ be defined as in (2). We assume that supp $\hat{f}_n$ is compact $\forall n\in\mathbb{N}$ with $\hat{f}_n$ the Fourier

transform of f_n in all arguments, supp $\hat{h} \subseteq (m/3,\infty) \times \mathbb{R}^{d-1}$ and $\hat{h}=1$ on the set $\{k=k_1+\cdots+k_n : (k_1,\ldots,k_n) \in \text{supp } \hat{f}_n, n \in \mathbb{N}\} \cap \overline{V}^+_{m/2}$. We denote the vector space of all such $\underline{g}$ which are obtained in this way by $\underline{\mathcal{S}}^+$.

Let $\lambda_l=(\lambda_l^1,\ldots,\lambda_l^j) \subseteq (1,\ldots,n)$ where the inclusion means that λ_l is a subset of $\{1,\ldots,n\}$ and the natural order of $(1,\ldots,n)$ is preserved. Let $\mathcal{P}(1,\ldots,n)$ denote the collection of all partitions of $(1,\ldots,n)$ into disjoint sets λ_l, i.e., for $\lambda \in \mathcal{P}(1,\ldots,n)$ we have $\lambda=\{\lambda_1,\ldots,\lambda_r\}$ for some r where $\lambda_l \subseteq (1,\ldots,n)$, $\lambda_l \cap \lambda_{l'}=\emptyset$ for $l \neq l'$ and $\cup_{l=1}^r \lambda_l=\{1,\ldots,n\}$. Given a Wightman functional $\underline{W} \in \underline{\mathcal{S}}'$ and $\lambda_l=(\lambda_l^1,\ldots,\lambda_l^j)$, we set $W(\lambda_l)=W_j(x_{\lambda_l^1},\ldots,x_{\lambda_l^j})$.

With this definition at hand we can recursively define the truncated Wightman functional $\underline{W}^T \in \underline{\mathcal{S}}'$ associated to $\underline{W} \in \underline{\mathcal{S}}'$ via $W_0^T=0$ and

$$W(1,\ldots,n)=\sum_{\lambda \in \mathcal{P}(1,\ldots,n)} \prod_{l=1}^{|\lambda|} W^T(\lambda_l), n \in \mathbb{N}, \tag{8}$$

where $|\lambda|$ is the number of sets λ_l in λ. We also recall that the translation invariance of $\underline{W}$, clustering and the strong spectral property imply supp $\hat{W}_n^T(k_1,\ldots,k_n) \subseteq \{(k_1,\ldots,k_n) \in \mathbb{R}^{dn} : \Sigma_{l=1}^n k_l=0, \Sigma_{l=j}^n k_l \in \overline{V}_m^+, j=2,\ldots,n\}$.

Lemma 3.5: In a QFT with indefinite metric which fulfills the strong spectral condition, $\phi(\underline{\mathcal{S}}^+)\Omega$ is orthogonal [w.r.t. $(.,.)$] to Ω and is dense in the orthogonal complement of Ω.

Proof: We consider the following equation for $\underline{g} \in \underline{\mathcal{S}}^+$ with $\underline{f}$ and h as above:

$$0=\hat{h}(0)\langle \Omega, \phi(\underline{f})\Omega\rangle=\int_{\mathbb{R}^d} \langle \Omega, \phi(\underline{\alpha}_{\{1,a\}}(\underline{f}))\Omega\rangle h(a)da=\langle \Omega, \phi(\underline{g})\Omega\rangle=(\Omega, \eta\phi(\underline{g})\Omega). \tag{9}$$

Thus, $\eta\phi(\underline{g})\Omega$ is perpendicular to Ω w.r.t. $(.,.)$. Since $\eta\Omega=\Omega$ and η is self adjoint, the same applies to $\eta^2\phi(\underline{g})\Omega=\phi(\underline{g})\Omega$.

It remains to show that vectors of the form $\phi(\underline{g})\Omega$ are dense in the orthogonal complement [w.r.t. $(.,.)$] of Ω in $\mathcal{H}$. By Lemma 3.1, the span of states of the form $(1-\mathsf{E}_0)\phi(\underline{f})\Omega$ with $\underline{f}=(0,0,\ldots,f_r,0\ldots)$, with supp $\hat{f}_r$ compact, is dense in the orthogonal complement of Ω. We want to show that for such states

$$(1-\mathsf{E}_0)\phi(\underline{f})\Omega=\phi(\underline{g})\Omega \tag{10}$$

for some $\underline{g}=\underline{g}(\underline{f},h) \in \underline{\mathcal{S}}^+$, h as above. To prove this, it is sufficient to show that the expectation values (w.r.t. $\langle .,. \rangle$) of both sides coincide for a set of vectors which span a dense set in $\mathcal{H}$, namely $\phi(\underline{q})\Omega$ with $\underline{q}=(0,0,\ldots,q_j,0,\ldots)$. Taking this expectation value for the left hand side of (10) we get

$$\langle \phi(\underline{q})\Omega, (1-\mathsf{E}_0)\phi(\underline{f})\Omega\rangle=\langle \Omega, \phi(\underline{q}^* \otimes \underline{f})\Omega\rangle-\langle \Omega, \phi(\underline{q}^*)\Omega\rangle\langle \Omega, \phi(\underline{f})\Omega\rangle,$$

where we used that $\eta\Omega=\Omega$. Expanding the right hand side into truncated Wightman functions according to Eq. (8) and Fourier transforming we get for $n=r+j$

$$\ldots=(2\pi)^{-dn}\int_{\mathbb{R}^{dn}} \sum_{\lambda \in \mathcal{P}(1,\ldots,n)}{}' \prod_{l=1}^{|\lambda|} \hat{W}^T_{|\lambda_l|}(k_{\lambda_l^1},\ldots,k_{\lambda_l^{|\lambda_l|}}) \hat{q}^*(k_1,\ldots,k_j)\hat{f}(k_{j+1},\ldots,k_n)dk_1\cdots dk_n,$$

where the reduced sum Σ' runs over all partitions λ s.t. there is at least one set $\lambda_l \in \lambda$ with $\lambda_l \cap (1,\ldots,j) \neq \emptyset$ and $\lambda_l \cap (j+1,\ldots,n) \neq \emptyset$.

For $(k_1,\ldots,k_n) \in \text{supp } \Pi_{l=1}^{|\lambda|} \hat{W}^T(\lambda_l)$ with λ in the range of the sum, we obtain that $k=k_{j+1}+\cdots+k_n \in \overline{V}_m^+$ by the strong spectral condition fulfilled by $\hat{W}^T_{|\lambda|}$. [In fact, k is a sum of zero vectors and vectors from $\overline{V}_m^+$. Since λ is in the range of the reduced sum, there must be at least one vector from $\overline{V}_m^+$ due to the support properties of $\hat{W}^T(\lambda_l)$.] Thus, we can replace

$\hat{f}_r(k_{j+1},\ldots,k_n)$ by $\hat{h}(k)\hat{f}_r(k_{j+1},\ldots,k_n)$ which does not change $\hat{f}_r$ on the support of $\Pi_{l=1}^{|\lambda|}\hat{W}^T(\lambda_l)$. Furthermore, we can then drop the restriction of the sum and sum up over all partitions, since the terms which do not belong to the restricted sum give zero contribution if evaluated on $\hat{q}^*(k_1,\ldots,k_j)\hat{h}(k)\hat{f}(k_{j+1},\ldots,k_n)$ (on the support of such terms we have $k=0$).

If we now Fourier transform back, we get the $\langle .,. \rangle$-inner product of $\phi(q)\Omega$ with right hand side of Eq. (10). ■

Proof of Theorem 3.4: (i) We have to make sure that for $C \in \mathcal{B}(\mathcal{H})$

$$\langle \Psi_1, C\phi(\underline{f})\Psi_2 \rangle = \langle \phi(\underline{f}^*)\Psi_1, C\Psi_2 \rangle \forall \underline{f} \in \mathcal{S}, \Psi_1, \Psi_2 \in \mathcal{D}$$

implies $C = c1_{\mathcal{H}}$. Applying the above equation to $\underline{g}^*$ where $\underline{g} \in \mathcal{S}^+$ and $\Psi_1 = \Psi_2 = \Omega$ we get that

$$\langle \phi(\underline{g})\Omega, C\Omega \rangle = \langle \Omega, C\phi(\underline{g}^*)\Omega \rangle = 0$$

since $\underline{g}^* = \int_{\mathbb{R}^d} \underline{\alpha}_{\{1,a\}}(\underline{f}^*)\overline{h}(a)da \in I_{\text{sp}}$ by the support properties of $\hat{h}$.

Since $\phi(\mathcal{S}^+)\Omega$ is dense in the orthogonal complement of Ω, we have thus obtained $C\Omega = c\Omega$. For $\Psi_1, \Psi_2 \in \mathcal{D}, \Psi_2 = \phi(\underline{f})\Omega$ for some $\underline{f} \in \mathcal{S}$ we obtain

$$\langle \Psi_1, C\Psi_2 \rangle = \langle \phi(\underline{f}^*)\Psi_1, C\Omega \rangle = c\langle \Psi_1, \Psi_2 \rangle$$

and thus $C = c1_{\mathcal{H}}$.

(ii) Suppose $\tilde{\Omega}$ is translation invariant. We note that in Eq. (9) we can replace the vector Ω in the first argument of $\langle .,. \rangle$ and $(.,.)$ respectively by $\tilde{\Omega}$ without changing the rest of the calculation. Thus, $\tilde{\Omega}$ is perpendicular [w.r.t. $(.,.)$] to $\eta\phi(\mathcal{S}^+)\Omega$. By Lemma 3.5 $\phi(\mathcal{S}^+)\Omega$ is dense in the orthogonal complement of Ω. Since η self-adjoint and $\eta\Omega = \Omega$, this is also true for $\eta\phi(\mathcal{S}^+)\Omega$. Thus $\tilde{\Omega} = c\Omega$. ■

IV. COMPLEX VELOCITY TRANSFORMATIONS FOR THE INDEFINITE METRIC CASE

In this section we prove the existence of a dense set of entire analytic vectors for the generator of the velocity transformations (Lorentz boosts) in $x^0 - x^1$ direction. This will then allow us to define the complex velocity transformations, which are needed in the BW theorem to express the ''modular operator,'' on this domain. In this way we avoid the use of functional calculus which in general is not available on Krein spaces. The strategy is as follows: One first defines ''Gaussian spectral cut-offs'' for the Lorentz boosts on the Borchers algebra and thereby obtains an analytic action of the velocity transformations on a dense sub-*-algebra $\mathcal{S}^{\text{anal}}$ of the Borchers algebra. Then one uses Lemma 3.1 to derive the existence of a dense set of analytic vectors $\mathcal{D}^{\text{anal}} \supseteq \phi(\mathcal{S}^{\text{anal}})\Omega$.

We start with the definition of Gaussian mollifiers and their complex extension. Let, for $z \in \mathbb{C}$,

$$c_\epsilon(z) = (\sqrt{2\pi\epsilon})^{-1} e^{-z^2/2\epsilon}, \quad \epsilon > 0, \tag{11}$$

such that $c_\epsilon(t)$ for $t \in \mathbb{R}$ is the centered Gaussian bell curve with (variation) parameter $\epsilon > 0$. We also note that $c_\epsilon * c_{\epsilon'}(t) = c_{\epsilon+\epsilon'}(t)$ where $*$ means convolution in t, i.e., the c_ϵ form a convolution semigroup. As $\epsilon \downarrow 0$, $c_\epsilon(t) \to \delta(t)$ in the following sense:

Lemma 4.1: Let $F(t)$ be a continuous and exponentially bounded function, i.e., $\exists\ C, M > 0$ s.t. $|F(t)| \leq Ce^{M|t|}\ \forall t \in \mathbb{R}$. Then $\int_{\mathbb{R}} F(t)c_\epsilon(t)dt \to F(0)$ as $\epsilon \downarrow 0$.

Proof: If F is continuous and has compact support, the statement is well-known. Using a partition of unity we can represent $F = F_1 + F_2$ as a sum of a function F_1 with compact support and a function F_2 which is zero on $[-1,1]$, thus $F(0) = F_1(0)$. It remains to show that the integral $\int_{\mathbb{R}} F_2(t)c_\epsilon(t)dt$ vanishes as $\epsilon \downarrow 0$. This is true by the theorem of dominated convergence as $F_2(t)c_\epsilon(t)$ converge to zero pointwisely $\forall t \in \mathbb{R}$ and this function, for $\epsilon < 1$, is dominated by the integrable function $|F_2(t)|c_1(t)$. ■

Let $\alpha_t = \alpha_{\{\Lambda(t),0\}}$ with

$$\Lambda(t)=\Lambda_{0,1}(t)=\begin{pmatrix}\cosh t & \sinh t & 0 & \cdots & 0\\ \sinh t & \cosh t & 0 & \cdots & 0\\ 0 & 0 & 1 & \ddots & \vdots\\ \vdots & & \ddots & \ddots & 0\\ 0 & \cdots & & 0 & 1\end{pmatrix}, \tag{12}$$

the velocity transformation in x^0-x^1 direction. By $|\Lambda(t)|$ we denote the maximum norm of the matrix $\Lambda(t)$ and we note that this is an exponentially bounded function.

For $f\in\mathcal{S}_1$ and $\epsilon>0$ we set

$$f_\epsilon=\int_{\mathbb{R}}\alpha_t(f)c_\epsilon(t)dt \tag{13}$$

and we obtain the following lemma:

Lemma 4.2: Let $f\in S_1$. Then

(i) $f_\epsilon\in\mathcal{S}_1\ \forall\epsilon>0$, *and*
(ii) $f_\epsilon\to f$ *in* $\mathcal{S}_1$ *as* $\epsilon\downarrow 0$.

Proof: (i) Recall that $\mathcal{S}_1$ is the projective limit $\cap_{L,N\geqslant 0}\mathcal{S}_{L,N}$ of L-time continuously differentiable functions on $\mathbb{R}^d$ with finite Schwartz norm $\|.\|_{L,N}$. It is thus sufficient to prove that f_ϵ for all $\epsilon>0$ and $L,N\geqslant 0$ has finite $\|.\|_{L,N}$ norm:

$$\|f_\epsilon\|_{L,N}\leqslant\int_{\mathbb{R}}\|\alpha_t(f)\|_{L,N}c_\epsilon(t)dt\leqslant\int_{\mathbb{R}}(1+|\Lambda(t)|^2)^{(N+L)/2}c_\epsilon(t)dt\|f\|_{L,N}, \tag{14}$$

and we note that the integral on the right hand side is finite due to the Gaussian decay of $c_\epsilon(t)$ and the only exponential increase of $|\Lambda(t)|$. Here we used the estimate

$$\|\alpha_t(f)\|_{L,N}\leqslant\sup_{x\in\mathbb{R}^d,|\beta|<L}|(1+|\Lambda(-t)x|^2)^{N/2}|\Lambda(t)|^{|\beta|}\partial^\beta f(x)|\leqslant(1+|\Lambda(t)|^2)^{(L+N)/2}\|f\|_{L,N}. \tag{15}$$

(ii) As $\int_{\mathbb{R}}c_\epsilon(t)dt=1$,

$$\|f_\epsilon-f\|_{L,N}\leqslant\int_{\mathbb{R}}\|\alpha_t(f)-f\|_{L,N}c_\epsilon(t)dt.$$

Note that by (15) $F(t)=\|\alpha_t(f)-f\|_{L,N}$ is exponentially bounded in t. $F(t)$ is also continuous. Thus, by Lemma 4.1, we get for arbitrary $L,N\in\mathbb{N}_0$ that the right hand side of the above estimate converges to $F(0)=0$ for $\epsilon\downarrow 0$. As the family of Schwartz norms $\{\|.\|_{L,N}\}_{L,N\in\mathbb{N}_0}$ generates the Schwartz topology, the statement follows. ■

Remark 4.3: If we do not deal with a scalar theory, Lemma 4.2 and all other constructions of this work can be generalized to representations $\alpha_{\{\Lambda,0\}}$ where Λ acts on the spin components via a finite-dimensional linear representation τ s.t. the matrix elements of $\tau(\Lambda(t))$ are exponentially bounded. This follows from $\tau(\Lambda(t))$ being additive and continuous in $t\in\mathbb{R}$. ■

Clearly, (13) can be interpreted as a Gaussian cut-off $\hat{c}_\epsilon(q)=e^{-\epsilon|q|^2}$ of the spectrum of the generator of the velocity transformations on $\mathcal{S}_1\subseteq L^2(\mathbb{R}^d,\mathbb{C})$. Lemma 4.2 then proves that such cut-offs (in contrast to a simple L^2-projection to a compact spectral set) take $\mathcal{S}_1$ to itself and can also be removed without leaving $\mathcal{S}_1$. We next show that such cut-offs give the required analyticity on $\mathcal{S}_1$:

Proposition 4.4: Let $f\in\mathcal{S}_1$ and $\epsilon>0$. The function $\alpha_t(f_\epsilon)$ from $\mathbb{R}$ to $\mathcal{S}_1$ has an entire analytic continuation $\alpha_z(f_\epsilon)$ from $\mathbb{C}$ to $\mathcal{S}_1$.

Proof: We first note that for $f\in\mathcal{S}_1$, $\epsilon>0$, $\alpha_t(f_\epsilon)=\int_{\mathbb{R}}\alpha_s(f)c_\epsilon(s-t)ds$ and thus the natural extention of α_t, $t\in\mathbb{R}$, to complex parameters is given by

$$\alpha_z(f_\epsilon)=\int_{\mathbb{R}}\alpha_s(f)c_\epsilon(s-z)ds,\quad z\in\mathbb{C}. \tag{16}$$

Since $c_\epsilon(z-s)=e^{-(z^2-2sz)/2\epsilon}c_\epsilon(s)$ and $e^{-(z^2-2sz)/2\epsilon}$ for $z\in\mathbb{C}$ fixed is exponentially bounded in s, one can show that $\alpha_z(f_\epsilon)\in\mathcal{S}_1$ $\forall z\in\mathbb{C}$ in analogy to the proof of Lemma 4.2 (i).

Next we have to prove that $\alpha_z(f_\epsilon)$ is entire analytic in z, hence $\alpha_z(f_\epsilon)=\Sigma_{l=0}^{\infty}z^l f_l$ for $z\in\mathbb{C}$. Complex differentiability of $\alpha_z(f_\epsilon)$ then holds automatically and we get $f_l=(1/l!)d^l\alpha_z(f_\epsilon)/dz^l|_{z=0}$. For notational convenience we prove this statement for $\tilde{\alpha}_z(f_\epsilon)=e^{z^2/2\epsilon}\alpha_z(f_\epsilon)$ which is equivalent. Note that by an argument as in the proof of Lemma 4.2 (i) $\int_{\mathbb{R}}\alpha_s(f)c_\epsilon(s)s^l ds\in\mathcal{S}_1$. What we have to show is thus that for $L,N\in\mathbb{N}_0$

$$\left\|\tilde{\alpha}_z(f_\epsilon)-\sum_{l=0}^{n}\frac{(z/\epsilon)^l}{l!}\int_{\mathbb{R}}\alpha_s(f)c_\epsilon(s)s^l ds\right\|_{L,N}\leqslant\sum_{l=n+1}^{\infty}\frac{(|z|/\epsilon)^l}{l!}\int_{\mathbb{R}}\|\alpha_s(f)\|_{L,N}c_\epsilon(s)|s|^l ds$$
$$\to 0\ \text{ as }\ n\to\infty. \tag{17}$$

We also note that by a calculation as (15) for l even

$$\int_{\mathbb{R}}\|\alpha_s(f)\|_{L,N}c_\epsilon(s)|s|^l ds\leqslant\int_{\mathbb{R}}c_\epsilon(s)|s|^l(1+|\Lambda(s)|^2)^{(N+L)/2}ds\|f\|_{L,N}.$$

Let $0<\epsilon<\epsilon'$. Then there exists a constant $C>0$ depending on L,N and ϵ,ϵ' such that the integral on the right hand side of the above estimate is smaller than $C\int_{\mathbb{R}}c_{\epsilon'}(s)|s|^l ds$. Since

$$\sum_{l=0}^{\infty}\frac{R^l}{l!}\int_{\mathbb{R}}c_{\epsilon'}(s)|s|^l ds=\int_{\mathbb{R}}c_{\epsilon'}(s)e^{R|s|}ds<\infty$$

for all $R>0$, (17) follows. ■

We now define $\mathcal{S}_1^{\text{anal}}$ to be the $\mathbb{C}$-linear span of $\{\alpha_z(f_\epsilon): f\in\mathcal{S}_1,\epsilon>0,z\in\mathbb{C}\}$. Some properties of this space are listed in the following lemma:

Lemma 4.5:

(i) $\mathcal{S}_1^{\text{anal}}$ *is a vector space which is closed under taking the complex conjugate.*
(ii) $\mathcal{S}_1^{\text{anal}}\subseteq\mathcal{S}_1$ *is dense in* $\mathcal{S}_1$.
(iii) The mapping $\alpha_z:\mathcal{S}_1^{\text{anal}}\to\mathcal{S}_1^{\text{anal}}$ *is well-defined for* $z\in\mathbb{C}$.
(iv) $\mathbb{C}\ni z\to\alpha_z(f)\in\mathcal{S}_1^{\text{anal}}$, $f\in\mathcal{S}_1^{\text{anal}}$, *is additive in* z, *i.e.,* $\alpha_{z_1}(\alpha_{z_2}(f))=\alpha_{z_1+z_2}(f)$ $\forall z_1,z_2\in\mathbb{C}$, *and* $\alpha_z(f)^*=\alpha_{\bar{z}}(f^*)$.
(v) The mapping $\mathbb{C}\ni z\to\alpha_z(f)\in\mathcal{S}_1^{\text{anal}}$ *for* $f\in\mathcal{S}_1^{\text{anal}}$ *is entire analytic [here we admit the coefficients for the expansion of* $\alpha_z(f)$, $f\in\mathcal{S}_1^{\text{anal}}$, *in* z *to be in* $\mathcal{S}_1$, *not necessarily in* $\mathcal{S}_1^{\text{anal}}$*] in* z.

Proof:

(i) Closedness under taking the complex conjugation is obvious, cf. (13).
(ii) This follows from Lemma 4.2 *(i)* and *(ii).*
(iii) We first have to show that for $g\in\mathcal{S}_1^{\text{anal}}$, $g=\alpha_{z_1}(f_{\epsilon_1})=\alpha_{z_2}(h_{\epsilon_2})$, $f,h\in\mathcal{S}_1$, $\epsilon_1,\epsilon_2>0$, $z_1,z_2\in\mathbb{C}$, $\alpha_z(g)=\alpha_z(\alpha_{z_1}(f_{\epsilon_1}))=\alpha_{z+z_1}(f_{\epsilon_1})=\alpha_{z+z_2}(h_{\epsilon_2})=\alpha_z(\alpha_{z_2}(h_{\epsilon_2}))$ is not ambiguous. Note that this holds for real z. By entire analyticity in z, cf. Proposition 4.4, $\alpha_z(\alpha_{z_2}(f_{\epsilon_1}))=\alpha_z(\alpha_{z_2}(h_{\epsilon_2}))$ then extends to all $z\in\mathbb{C}$.
(iv) That α_z is additive in z and $\alpha_z(f)^*=\alpha_{\bar{z}}(f^*)$ follows from Eq. (16).
(v) is an immediate consequence of (iii) and Proposition 4.4. ■

Let $\underline{\mathcal{S}}^{\mathrm{anal}}$ be the free, unital,*-algebra generated by $\mathcal{S}_1^{\mathrm{anal}}$, i.e.,

$$\underline{\mathcal{S}}^{\mathrm{anal}}=\oplus_{n=1}^{\infty}\mathcal{S}_n^{\mathrm{anal}},\ \ \mathcal{S}_n^{\mathrm{anal}}=\mathcal{S}_1^{\mathrm{anal}\otimes n},\ \ n\geqslant 1,\ \ \mathcal{S}_0^{\mathrm{anal}}=\mathbb{C}. \tag{18}$$

By Lemma 4.5 (i) this is well defined. Then $\mathcal{S}_1^{\mathrm{anal}}$ is a dense, unital sub-*-algebra of $\underline{\mathcal{S}}$, cf. Lemma 4.5 (ii).

Proposition 4.6:

(i) $\underline{\alpha}_z:\underline{\mathcal{S}}^{\mathrm{anal}}\to\underline{\mathcal{S}}^{\mathrm{anal}}$ *is a well defined unital algebra automorphism for* $z\in\mathbb{C}$. *It behaves under taking the involution as* $\underline{\alpha}_z(\underline{f})^*=\underline{\alpha}_{\overline{z}}(\underline{f}^*)$ *and is entire analytic and additive in* $z\in\mathbb{C}$.

(ii) Let $\underline{W}\in\underline{\mathcal{S}}'$ *be Poincaré invariant [cf. (A2)] and* $\underline{\mathcal{S}}_0^{\mathrm{anal}}=\{\underline{f}\in\underline{\mathcal{S}}^{\mathrm{anal}}:\underline{W}(\underline{g}\otimes\underline{f})=0\ \forall\,\underline{g}\in\underline{\mathcal{S}}\}$. *Then* $\underline{\alpha}_z(\underline{\mathcal{S}}_0^{\mathrm{anal}})\subseteq\underline{\mathcal{S}}_0^{\mathrm{anal}}$.

Proof: (i) It is sufficient to prove this for the restriction of $\underline{\alpha}_z$ to $\mathcal{S}_n^{\mathrm{anal}}$. By Lemma 4.5, the statement holds for elements $\alpha_{z_1}(f_1)\otimes\cdots\otimes\alpha_{z_n}(f_n)$, $f_l\in\mathcal{S}_1^{\mathrm{anal}}$, $z_l\in\mathbb{C}$, $l=1,\ldots,n$ in each of the components $\alpha_{z_l}(f_l)$. The claim now follows from going to the diagonal $z=z_1=\cdots=z_n$.

(ii) Let $\underline{f}\in\underline{\mathcal{S}}_0^{\mathrm{anal}}$. Then $\underline{W}(\underline{g}\otimes\underline{\alpha}_z(\underline{f}))=0$ for all real z. By (i) and $\underline{W}\in\underline{\mathcal{S}}'$, $\underline{W}(\underline{g}\otimes\underline{\alpha}_z(\underline{f}))$ is an analytic function in z and thus vanishes identically. ■

We now want to use Lemma 3.1 in order to show that the results of Proposition 4.6 carry over to the Krein space representation on $\mathcal{H}$. We first give some definitions:

Definition 4.7: Let $(\mathcal{H},\eta)$ *be a Krein space with fundamental decomposition* η *and let* $\mathsf{U}:\mathbb{R}\to\mathsf{O}_\eta(\mathcal{D})$ *be a one parameter group of* η*-unitary operators* $\mathsf{U}(t):\mathcal{D}\to\mathcal{D}$.

(i) *Let*

$$\mathcal{D}(\mathsf{A})=\left\{\Psi\in\mathcal{D}:\ \lim_{t\to 0,t\neq 0}\frac{\mathsf{U}(t)-1}{it}\Psi\ \text{ converges strongly in }\ \mathcal{H}\right\}.$$

Then $\mathsf{A}=(\mathsf{A},\mathcal{D}(\mathsf{A}))$, $\mathsf{A}\Psi=\lim_{t\to 0,t\neq 0}(it)^{-1}(\mathsf{U}(t)-1)\Psi$, $\Psi\in\mathcal{D}(\mathsf{A})$, is called the generator of $\{\mathsf{U}(t)\}_{t\in\mathbb{R}}$.

(ii) A vector $\Psi\in\mathcal{D}(\mathsf{A})$ is called analytic for A if $\forall n\in\mathbb{N}\ \mathsf{A}^n\Psi\in\mathcal{D}(\mathsf{A})$ and $\exists R>0$ such that $\forall z\in\mathbb{C}$, $|z|<R$, $\Sigma_{n=0}^{\infty}(z^n/n!)\mathsf{A}^n\Psi$ converges strongly in $\mathcal{H}$. If this holds for all $R>0$, Ψ is called entire analytic.

(iii) By $\mathcal{D}^{\mathrm{anal}}=\mathcal{D}^{\mathrm{anal}}(\mathsf{A})$ we denote the set of all entire analytic vectors of A. ■

By standard methods one shows that A is η-symmetric on $\mathcal{D}(\mathsf{A})$. By these very definitions we get $\mathsf{U}(z)=\Sigma_{n=0}^{\infty}((iz)^n/n!)\mathsf{A}^n:\mathcal{D}^{\mathrm{anal}}\to\mathcal{H}$ is well-defined and additive for $z\in\mathbb{C}$ and $\mathsf{U}(z)\Psi$, $\Psi\in\mathcal{D}^{\mathrm{anal}}$, is entire analytic in $z\in\mathbb{C}$ in the strong topology on $\mathcal{H}$.

We now get as the main theorem of this section:

Theorem 4.8: *Let* $\underline{W}\in\underline{\mathcal{S}}'$ *fulfill the Axioms 2.1 with Sobolev dominated Hilbert seminorm* $\underline{p}$ *and let* $((\mathcal{H},\langle .,.\rangle,\Omega),\eta,\mathsf{U},\phi)$ *be the associated QFT with indefinite metric, cf. Theorem 2.2. Let, furthermore,* $\mathsf{U}(t)=\mathsf{U}(\{\Lambda(t),0\})$, $t\in\mathbb{R}$ *and* A *be the generator of the one parameter* η*-unitary group* $\{\mathsf{U}(t)\}_{t\in\mathbb{R}}$.

Then A *has a dense domain* $\mathcal{D}^{\mathrm{anal}}$ *of entire analytic vectors. In particular,* $\{\mathsf{U}(t)\}_{t\in\mathbb{R}}$ on $\mathcal{D}^{\mathrm{anal}}$ *has a well-defined additive extension to* $\mathsf{U}(z)$, $z\in\mathbb{C}$, *given by* $\mathsf{U}(z)=\Sigma_{n=0}^{\infty}((iz)^n/n!)\mathsf{A}^n$ *and* $\mathsf{U}(z)^{[*]}=\mathsf{U}(-\overline{z})$ *holds on this domain.*

Proof: As $\underline{\mathcal{S}}^{\mathrm{anal}}$ is dense in $\underline{\mathcal{S}}$, it follows from Lemma 3.1 and the fact that $\phi(\underline{\mathcal{S}})\Omega$ is dense in $\mathcal{H}$ that also $\phi(\underline{\mathcal{S}}^{\mathrm{anal}})\Omega$ is dense in $\mathcal{H}$.

It therefore suffices to show that $\phi(\underline{\mathcal{S}}^{\mathrm{anal}})\Omega\subseteq\mathcal{D}^{\mathrm{anal}}$. Let $\Psi\in\phi(\underline{\mathcal{S}}^{\mathrm{anal}})\Omega$, $\Psi=\phi(\underline{f})\Omega$, $\underline{f}\in\underline{\mathcal{S}}^{\mathrm{anal}}$. By Proposition 4.6 (ii), $\mathsf{U}(z)\Psi=\phi(\underline{\alpha}_z(\underline{f}))\Omega$ is well-defined. Furthermore, by Proposition 4.6 $\exists\ \underline{f}_n\in\underline{\mathcal{S}}$ such that $\underline{\alpha}_z(\underline{f})=\Sigma_{l=0}^{\infty}((iz)^n/n!)\underline{f}_n$. Hence, $\lim_{t\to 0,t\neq 0}(it)^{-1}(\underline{\alpha}_t(\underline{f})-\underline{f})=\underline{f}_1$ in $\underline{\mathcal{S}}$. By Lemma 3.1 this implies

$$\phi(\underline{f}_1)\Omega=\phi\left(\lim_{t\to 0,t\neq 0}\frac{\underline{\alpha}_t(\underline{f})-\underline{f}}{it}\right)\Omega=\lim_{t\to 0,t\neq 0}\frac{\mathsf{U}(t)-1}{it}\Psi.$$

Thus $\Psi \in \mathcal{D}(\mathsf{A})$ and $\mathsf{A}\Psi = \phi(\underline{f}_1)\Omega$. Repeating this argument n times we get that $\mathsf{A}^{n-1}\Psi \in \mathcal{D}(\mathsf{A})$ and $\mathsf{A}^n\Psi = \phi(\underline{f}_n)\Omega$. Again by Lemma 3.1 we get that the following chain of equation holds:

$$\mathsf{U}(z)\Psi = \phi(\underline{\alpha}_z(\underline{f}))\Omega = \phi\left(\lim_{N\to\infty}\sum_{n=0}^{N}\frac{(iz)^n}{n!}\underline{f}_n\right)\Omega = \lim_{N\to\infty}\phi\left(\sum_{n=0}^{N}\frac{(iz)^n}{n!}\underline{f}_n\right)\Omega = \lim_{N\to\infty}\sum_{n=0}^{N}\frac{(iz)^n}{n!}\mathsf{A}^n\Psi,$$

where the convergence is strong convergence in $\mathcal{H}$ and $z \in \mathbb{C}$ is arbitrary. This, by definition of $\mathcal{D}^{\text{anal}}$, just means that $\Psi \in \mathcal{D}^{\text{anal}}$. ■

Let us briefly discuss the relation of Therorem 4.8 with functional calculus on Krein spaces: Setting $\mathcal{C} = \{\xi: \mathbb{C} \to \mathbb{C}, \xi(z) = \Sigma_{l=1}^{\infty} a_l z^l \ a_l \in \mathbb{C} \text{ s.t. } \exists R > 0, C > 0, |a_l| < CR^l/l! \forall l \in \mathbb{N}\}$, we get by the same methods as in the proof of Proposition 4.4 and Theorem 4.8 that $(F(\mathsf{A}), \phi(\underline{\mathcal{S}}^{\text{anal}})\Omega)$ is well-defined for all F in the algebra $\mathcal{C}$. This defines a restricted functional calculus for A. But this algebra of entire analytic functions of course does not contain any characteristic sets (''spectral projections'').

If one would try to use the approach of this article to define spectral projections, one essentially has to continuously extend the Wightman functional $\underline{W}$ to a bigger algebra generated by elements

$$\int_{\mathbb{R}} \alpha_t(f) c_{[a,b]}(t)\,dt, \quad f \in \mathcal{S}_1, \tag{19}$$

where $c_{[a,b]}$ is the inverse Fourier transform of the characteristic function of the set $[a,b]$. While it is easy to show that this defines a function on $\mathbb{R}^d - \{x \in \mathbb{R}^d : |x^0| = |x^1|\}$, the estimates of the proof of Lemma 4.2 obviously fail as $c_{[a,b]}(t)$ falls to zero no faster than $1/t$ as $t \to \infty$. One thus would have to restrict to Wightman functionals $\underline{W}$ with Wightman functions being rather functions of sufficiently fast decay than just distributions. This, however, is not a physical assumption, as, e.g., the two-point function of a scalar field in the physical space–time $d=4$ has singularities on the light cone $\sim 1/x^2$ and thus is not a locally integrable function and due to Lorentz invariance is constant along the orbits of the Lorentz group. This forced us in (13) to work with the Gaussian cut-offs giving a less sharp localization of the spectrum. Of course, spectral projections in some cases could be defined using different methods.

Remark 4.9: On an informal level, spectral calculus can also be defined using Gaussian localization of the spectrum $\hat{c}_{a,\epsilon}(\mathsf{A}) = \sqrt{\epsilon/\pi}\, e^{-\epsilon|a-\mathsf{A}|^2}$, $a \in \mathbb{R}, \epsilon > 0$. Informally, $\lim_{\epsilon\uparrow\infty}\hat{c}_{a,\epsilon}(\mathsf{A}) = d\mathsf{E}_{(-\infty,a]}/da$ where $\mathsf{E}_{(-\infty,a]} = \hat{c}_{(-\infty,a]}(\mathsf{A})$ is the spectral projection of A on $(-\infty, a]$. Thus one gets the following heuristic formula,

$$F(\mathsf{A}) = ''\int_{\mathbb{R}} F(a)\,d\mathsf{E}_{(-\infty,a]}'' = \lim_{\epsilon\uparrow\infty}\int_{\mathbb{R}} F(a)\hat{c}_{a,\epsilon}(\mathsf{A})\,da, \tag{20}$$

and one could study the existence of this limit depending on the choice of F and suitable domains in order to extend the choice of admissible F beyond $\mathcal{C}$. ■

V. ON THE BW THEOREM FOR QFTs WITH INDEFINITE METRIC

In this section we combine the existence of complex velocity transformations established in the previous section with a theorem of J. Bros, H. Epstein, and U. Moschella which shows that Bisognano–Wichmann analyticity (in particular, the KMS condition) does not depend on positivity. We first recall this result, which is the crucial step towards the BW theorem for QFT with indefinite metric. Here $\mathcal{W}_R = \{x \in \mathbb{R}^d : x^1 > |x^0|\}$, $\mathcal{W}_L = -\mathcal{W}_R$. We also note that $\underline{\alpha}_t$ takes the $*$-algebras $\underline{\mathcal{S}}(\mathcal{W}_{R/L})$ into themselves. We only formulate our statements for the right wedge—the related statement for the left wedge can be derived analogously.

Theorem 5.1:[12] *Let $\underline{W} \in \underline{\mathcal{S}}'$ fulfill temperedness, locality and the spectral condition [cf. (A1), (A3) and (A4) of Axioms 2.1]. Then we have the following.*

(i) The "dynamical system" $(\underline{\mathcal{S}}(\mathcal{W}_R), \underline{\alpha}_t, \underline{W})$ fulfills the KMS condition with temperature $1/2\pi$, i.e., $\forall \underline{f}, \underline{g} \in \underline{\mathcal{S}}(\mathcal{W}_R)$ $\exists$ a holomorphic function $F(z)$ on the strip $\mathbb{R}+i(0,2\pi)$ which continuously extends to $\mathbb{R}+i[0,2\pi]$ such that

$$F(t) = \underline{W}(\underline{f} \otimes \underline{\alpha}_t(\underline{g})), \quad \text{and} \quad F(t+i2\pi) = \underline{W}(\underline{\alpha}_t(\underline{g}) \otimes \underline{f}), \quad t \in \mathbb{R}.$$

(ii) For *F as in (i), the Bisognano–Wichmann relation is fulfilled:*

$$F(i\pi) = \underline{W}(\underline{f} \otimes \underline{\alpha}_{\{\Theta_{0,1},0\}}(\underline{g}^*)).$$

Remark 5.2: The proof for this theorem, based on analytic completion along the orbits of the group of complex Lorentz boosts, has been formulated for the case of de Sitter space–time, but the same proof also holds for Minkowski space–time, cf. Ref. 12. Here, up to different notation, *(i)* corresponds to Eq. (45) of Ref. 12 and (ii) is the special case $\lambda = -1$ of Eq. (46) of that reference where $\lambda = e^z$, z being the argument of F.

It should also be remarked that the statement of Ref. 12 has been formulated for the case of test functions with compact support. Nevertheless, the proof of the crucial Lemma 2 of that reference is based on the estimate (67) which guarantees in (69) of Ref. 12 boundary values in $\mathcal{S}'$, see Theorem 2-10 of Ref. 33. But in the Minkowski case, (67) follows automatically from the assumption of temperedness Theorem 2-10 of Ref. 33 [see also (17) of Ref. 12]. Hence the statement of Theorem 5.1 also holds for Schwartz test functions. ■

If we re-write (ii) of Theorem 5.1 for a Wightman functional $\underline{W}$ associated to some quantum field theory with indefinite metric, cf. Theorem 2.2, we find

$$\langle \phi(\underline{f}^*)\Omega, \mathsf{U}(i\pi)\phi(\underline{g})\Omega \rangle = \langle \phi(\underline{f}^*)\Omega, \mathsf{J}\phi(\underline{g}^*)\Omega \rangle, \quad \mathsf{J} = \mathsf{U}(\{\Theta_{0,1},0\}), \tag{21}$$

where $\underline{f}, \underline{g} \in \underline{\mathcal{S}}(\mathcal{W}_R)$. J is a η-antiunitary and antiunitary (cf. Corollary 2.3) operator and $\mathsf{J}^2 = 1$. Equation (21) is, however, only symbolic as it is not clear whether one can make sense out of the expression $\mathsf{U}(i\pi)\phi(\underline{g})\Omega$ for all $\underline{g} \in \underline{\mathcal{S}}(\mathcal{W}_R)$. We therefore have to consider a wedge algebra which is smaller than $\mathcal{P}_R = \phi(\underline{\mathcal{S}}(\mathcal{W}_R))$ and maps Ω to $\mathcal{D}^{\text{anal}}$. At the same time, such a smaller wedge algebra must not be too small as important properties, e.g., the Reeh–Schlieder property, have to be preserved and the weak commutant should coincide with the wedge algebra. Here we suggest the following solution:

Let $\underline{\mathcal{S}}^{\text{anal}}(\mathcal{W}_{R/L}) = \underline{\mathcal{S}}^{\text{anal}} \cap \underline{\mathcal{S}}(\mathcal{W}_{R/L})$ and $\mathcal{P}^{\text{anal}}_{R/L} = \phi(\underline{\mathcal{S}}^{\text{anal}}(\mathcal{W}_{R/L}))$. By definition $\mathcal{P}^{\text{anal}}_{R/L} \subseteq \mathsf{O}_\eta(\mathcal{D})$ and $\mathcal{P}^{\text{anal}}_{R/L}\Omega \subseteq \mathcal{D}^{\text{anal}}$.

The following properties of $\mathcal{P}^{\text{anal}}_{R/L}$ show that these algebras can be seen as legitimate substitutes for the wedge algebras $\mathcal{P}_{R/L}$:

Proposition 5.3: Let $\mathcal{P}^{\text{anal}}_{L/R}$ be defined as above. Then,

(i) Ω is standard (cyclic and separating) for $\mathcal{P}^{\text{anal}}_{R/L}$;

(ii) $\mathcal{P}^{\text{anal}}_{R/L}$ is dense in $\mathcal{P}_{R/L}$ w.r.t. the separating norm $\mathcal{P}_{R/L} \ni \mathsf{L} \to \|\mathsf{L}\Omega\|$; and

(iii) the weak commutants of $\mathcal{P}_{R/L}$ and $\mathcal{P}^{\text{anal}}_{R/L}$ coincide.

Proof:

(i) By Theorem 3.3 Ω is cyclic and separating for $\mathcal{P}_{R/L}$. As $\mathcal{P}^{\text{anal}}_{R/L} \subseteq \mathcal{P}_{R/L}$, Ω is separating for $\mathcal{P}^{\text{anal}}_{R/L}$. It remains to show that Ω is also cyclic. Note that $\mathcal{S}_1(\mathcal{W}_{L/R})$ is mapped into itself by the action of α_t. Thus, as in Lemma 4.2 (ii), one can show that $\mathcal{S}_1^{\text{anal}}(\mathcal{W}_{R/L}) = \mathcal{S}_1^{\text{anal}} \cap \mathcal{S}_1(\mathcal{W}_{R/L})$ is dense in $\mathcal{S}_1(\mathcal{W}_{R/L})$. Thus, $\underline{\mathcal{S}}^{\text{anal}}(\mathcal{W}_{R/L})$ is dense in $\underline{\mathcal{S}}(\mathcal{W}_{R/L})$. Consequently, by Lemma 3.1, any vector $\Psi = \phi(\underline{f})\Omega$, $\underline{f} \in \underline{\mathcal{S}}(\mathcal{W}_{R/L})$, can be approximated in the strong sense by a sequence of vectors $\Psi_n = \phi(\underline{f}_n)\Omega$, $\underline{f}_n \in \underline{\mathcal{S}}^{\text{anal}}(\mathcal{W}_{R/L})$.

(ii) As we only have to show that any vector $\Psi = \mathsf{L}\Omega$, $\mathsf{L} \in \mathcal{P}_{R/L}$, can be approximated in the strong topology by vectors in $\{\mathsf{L}\Omega : \mathsf{L} \in \mathcal{P}^{\text{anal}}_{R/L}\}$, the same argument as in (i) can be used.

(iii) Obviously $\mathcal{P}'_{R/L} \subseteq \mathcal{P}_{R/L}^{\text{anal}\,\prime}$. We have to show the opposite inclusion. Let $C \in \mathcal{P}_{R/L}^{\text{anal}\,\prime}$. Then, by Lemma 3.1, we get for $\Psi_1, \Psi_2 \in \mathcal{D}$, $\Psi_1 = \phi(\underline{f})\Omega$, $\Psi_2 = \phi(\underline{h})\Omega$, $\underline{f}, \underline{h} \in \underline{\mathcal{S}}$ and $\mathsf{L} \in \mathcal{P}_{R/L}$, $\mathsf{L} = \phi(\underline{g})$, $\underline{g} \in \underline{\mathcal{S}}(\mathcal{W}_{R/L})$,

$$\langle \Psi_1, C\mathsf{L}\Psi_2 \rangle = \langle \phi(\underline{f})\Omega, C\phi(\underline{g})\phi(\underline{h})\Omega \rangle = \langle \phi(\underline{f})\Omega, C\phi(\underline{g} \otimes \underline{h})\Omega \rangle = \lim_{n\to\infty} \langle \phi(\underline{f})\Omega, C\phi(\underline{g}_n \otimes \underline{h})\Omega \rangle$$

$$= \lim_{n\to\infty} \langle \Psi_1, C\mathsf{L}_n\Psi_2 \rangle = \lim_{n\to\infty} \langle \mathsf{L}_n^{[*]}\Psi_1, C\Psi_2 \rangle = \langle \mathsf{L}^{[*]}\Psi_1, C\Psi_2 \rangle,$$

where in the last step one has to repeat the argument of the first four steps in reverse order to see that the equality follows from Lemma 3.1. Here we used that there exists a sequence $\underline{g}_n \in \underline{\mathcal{S}}^{\text{anal}}(\mathcal{W}_{R/L})$ such that $\underline{g}_n \to \underline{g}$ in $\underline{\mathcal{S}}$ as $n \to \infty$ [cf. the proof of (i)] and $\mathsf{L}_n = \phi(\underline{g}_n) \in \mathcal{P}_{R/L}^{\text{anal}}$. ■

We define the domain $\mathcal{D}_R^{\text{anal}} = \mathcal{P}_R^{\text{anal}}\Omega$. By Proposition 5.3, $\mathcal{D}_R^{\text{anal}}$ is dense in $\mathcal{H}$ and

$$\mathsf{S}_R : \mathcal{D}_R^{\text{anal}} \to \mathcal{D}_R^{\text{anal}} \subseteq \mathcal{H}, \quad \mathsf{S}_R : \mathsf{L}\Omega \mapsto \mathsf{L}^{[*]}\Omega, \quad \mathsf{L} \in \mathcal{P}_R^{\text{anal}} \tag{22}$$

densely defines an antilinear operator S_R. Note that Ω is separating for $\mathcal{P}_R^{\text{anal}}$, hence (22) is not ambiguous. Also, $(\mathsf{S}_R^{[*]}, \mathcal{D}_R^{\text{anal}[*]}) \supseteq (\mathsf{S}_L, \mathcal{D}_L^{\text{anal}})$, with S_L defined in analogy to (22) for the right wedge replaced by the left wedge. This implies that S_R is closable.

We can now collect the pieces and formulate a version of the Bisognano–Wichmann theorem for quantum fields acting on Krein spaces:

Theorem 5.4: *Let $\mathcal{P}_{R/L}^{\text{anal}}$ be the analytic right/left wedge algebras associated with some quantum field theory with indefinite metric and let J and S_R be defined as in Eqs.* (21) *and* (22). *Then,*

(i) $[\mathcal{P}_R^{\text{anal}}, \mathcal{P}_L^{\text{anal}}] = 0$ *on* $\mathcal{D}$;
(ii) $\mathsf{J}\mathcal{P}_R^{\text{anal}}\mathsf{J} = \mathcal{P}_L^{\text{anal}}$ *and* $\mathsf{J}\mathcal{P}_L^{\text{anal}}\mathsf{J} = \mathcal{P}_R^{\text{anal}}$;
(iii) $\mathsf{U}(t)\mathcal{P}_{R/L}^{\text{anal}}\mathsf{U}(t)^{-1} = \mathcal{P}_{R/L}^{\text{anal}}$;
(iv) $\mathsf{S}_R = \mathsf{J}\mathsf{U}(i\pi)|_{\mathcal{D}_R^{\text{anal}}}$;
(v) $(\mathcal{P}_R^{\text{anal}}, \mathsf{U}(t), \Omega)$ *fulfill the KMS condition (w.r.t.* $\langle .,. \rangle$).

Proof: (i) holds by locality. (ii) This is a simple consequence of

$$\underline{\alpha}_{\{\Theta_{0,1},0\}}(\underline{\mathcal{S}}^{\text{anal}}) = \underline{\mathcal{S}}^{\text{anal}} \quad \text{and} \quad \underline{\alpha}_{\{\Theta_{0,1},0\}}(\underline{\mathcal{S}}(\mathcal{W}_{R/L})) = \underline{\mathcal{S}}(\mathcal{W}_{L/R}).$$

(iii) Similar as in *(ii)*, this point follows from

$$\underline{\alpha}_t(\underline{\mathcal{S}}^{\text{anal}}) = \underline{\mathcal{S}}^{\text{anal}} \quad \text{and} \quad \underline{\alpha}_t(\underline{\mathcal{S}}(\mathcal{W}_{R/L})) = \underline{\mathcal{S}}(\mathcal{W}_{R/L}).$$

(iv) We note that for $\underline{f}, \underline{g} \in \underline{\mathcal{S}}^{\text{anal}}(\mathcal{W}_R)$, $\tilde{F}(z) = \langle \phi(\underline{f}^*)\Omega, \mathsf{U}(z)\phi(\underline{g})\Omega \rangle$ defines an entire analytic function in z, cf. Theorem 4.8. This function $\tilde{F}(z)$ coincides for real z with the continuation of the analytic function $F(z)$ of Theorem 5.1 (i). By the edge of the wedge theorem, $\tilde{F}(z)$ is thus an analytic continuation of $F(z)$ to all $\mathbb{C}$. We identify these two functions. For $z = i\pi$ we then get by Theorem 5.1 (ii) that (21) holds rigorously. Thus,

$$\langle \Psi_1, \mathsf{U}(i\pi)\mathsf{L}\Omega \rangle = \langle \Psi_1, \mathsf{J}\mathsf{L}^{[*]}\Omega \rangle, \quad \forall \Psi_1 \in \mathcal{D}_R^{\text{anal}}, \ \mathsf{L} \in \mathcal{P}_R^{\text{anal}}.$$

Ω is cyclic for $\mathcal{P}_R^{\text{anal}}$, cf. Proposition 5.3 (i), hence $\mathcal{D}_R^{\text{anal}}$ is dense in $\mathcal{H}$ and one gets from the above equation that $\mathsf{U}(i\pi)\Psi = \mathsf{J}\mathsf{S}_R\Psi \ \forall \Psi \in \mathcal{D}_R^{\text{anal}}$. The assertion now follows by multiplication of both sides with J using $\mathsf{J}^2 = 1$.

(v) Like in (iv) one shows that the function $F(z)$ for suitable choice of $\underline{f}, \underline{g} \in \underline{\mathcal{S}}^{\text{anal}}(\mathcal{W}_R)$ coincides with $\langle \Omega, \mathsf{L}_1\mathsf{U}(z)\mathsf{L}_2\Omega \rangle$, $\mathsf{L}_1, \mathsf{L}_2 \in \mathcal{P}_R^{\text{anal}}$ and one then gets the KMS condition

$$\langle \Omega, \mathsf{L}_1\mathsf{U}(t + i2\pi)\mathsf{L}_2\Omega \rangle = \langle \Omega, \mathsf{L}_2\mathsf{U}(-t)\mathsf{L}_1\Omega \rangle$$

from Theorem 5.1 (i). ■

Twistor representation of null two-surfaces

Kostyantin Ilyenko[a)]

(Received 9 November 2001; accepted for publication 3 May 2002)

We present a twistor description for null two-surfaces (null strings) in four-dimensional Minkowski space–time. The Lagrangian density for a variational principle is taken as a surface-forming null bivector. The proposed formulation is reparametrization invariant and free of any algebraic and differential constraints. The spinor formalism of Cartan–Penrose allows us to derive a nonlinear evolution equation for the world-sheet coordinate $x^a(\tau,\sigma)$. An example of null two-surface given by the two-dimensional self-intersection (caustic) of a null hypersurface is studied. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1501166]

I. INTRODUCTION

The study of massless (null) objects in four-dimensional (4D) Minkowski and curved space–times has drawn considerable attention in recent years.[1–8] These investigations are concerned not only with physical implications stemming from the theory of massless particles and string theory but also with the geometrical entities which found a convenient representation as extended null objects. The research is mainly confined to one-dimensional null objects (massless particles and superparticles)[1,9–12] and to the null hypersurfaces because of their relevance in relativity.[8,13–16] It is surprising that a study of generic null two-dimensional surfaces is quite rare (see, however, Refs. 17 and 18). This situation is rather unfortunate because a generic null two-surface corresponds to the notion of a tensionless string, which plays an important role in the current research on the string theory.[5,6,19,20] Besides, null two-surfaces can naturally arise as two-dimensional caustics of null hypersurfaces and the availability of such a description could provide additional insights into the geometry of the latter ones. Finally, our understanding of the geometry of the null submanifolds in space–times of special and general relativity is certainly incomplete without a satisfactory description of the null two-surfaces.

Initially, the notion of a null two-surface was put forward by Schild[21] in the form of a geodesic null string, i.e., a two-dimensional degenerate submanifold of 4D Minkowski or curved space–time ruled by null geodesics. The degenerate property of the induced metric can be written in the form

$$\dot{x}^2 x'^2 - (\dot{x}x')^2 = 0. \tag{1.1}$$

Here $x^a(\tau,\sigma)$ is the world-sheet coordinate, $\dot{x}x'$ stands for $\dot{x}^a x'_a$, etc. The dots and primes denote differentiation with respect to τ and σ, respectively. It is worth noting that the degenerate property (1.1) is manifestly reparametrization invariant while the Schild's variational principle does not possess this feature.

In Ref. 3 Bandos and Zheltukhin proposed a spinor version of the null string action functional. A study of null string dynamics in external fields in three-dimensional and 4D Minkowski space–times was undertaken in Refs. 22–25. In Refs. 23 and 24 Ilyenko and Zheltukhin showed that interaction with antisymmetric tensor gauge field may lead to the violation of the geodesic property of the resulting null two-dimensional submanifold of the 4D Minkowski space–time.

a)Electronic mail: kost@ire.kharkov.ua

A different approach was employed in Refs. 5 and 26. The idea was to use an algebraically special differential two-form obeying certain integrability conditions. In Ref. 26 Stächel took a null bivector field $p_{ab}(x)$ ($p_{ab}=-p_{ba}$, $p_{ab}{}^*p^{ab}=0$, $p_{ab}p^{ab}=0$ and $p_{a[b}\nabla_c p_{de]}=0$; the asterisk denotes dualization) as the Lagrangian density and showed that Schild's null string could be treated in this way. Recently, Gusev and Zheltukhin[5] have used a fundamental result of spinor calculus on the representation of a real null bivector in 4D Minkowski space–time to cast the variational principle in the form

$$S=\int (\bar{\pi}_A\bar{\pi}_B\epsilon_{A'B'}+\pi_{A'}\pi_{B'}\epsilon_{AB})dx^{AA'}\wedge dx^{BB'}.$$

They proved the degenerate property of the resulting two-dimensional manifold and treated the case of geodesic null string.

In the present article we show that the above-mentioned variational principle admits a natural twistor form. The corresponding Euler–Lagrange equations possess solutions not only in the form of ruled null two-surfaces (geodesic null strings) but also generic (i.e., nongeodesic, cf. Ref. 24) null strings. A nonlinear counterpart of the geodesic evolution equation for a generic null string is derived.

An outline of the paper is as follows. In Sec. II we propose a twistor variational principle for null two-surfaces in 4D Minkowski space–time. Section III is devoted to a study of the corresponding equations of motion. An evolution equation for a generic nongeodesic null two-surface is derived in Sec. IV. Section V contains an example of nongeodesic null two-surface as a two-dimensional caustic of a wave front. Discussion and outlook are presented in Sec. VI.

The conventions are those of Penrose–Rindler.[13]

II. VARIATIONAL PRINCIPLE

We begin with the Stächel's variational principle. By definition, a bivector $p_{ab}(x)=-p_{ba}(x)$ is simple if the condition $\det(p_{ab})=0$ holds. In 4D Minkowski space–time one can show that $\det(p_{ab})=(1/16)(p_{ab}{}^*p^{ab})^2$ [see Ref. 13, Vol. 1], where ${}^*p^{ab}=(1/2!)\varepsilon^{abcd}p_{cd}$ ($\varepsilon_{0123}=-\varepsilon^{0123}=1$) is the dual of p_{ab}. This means that there exists a pair of vector fields $u_a(x)$ and $v_b(x)$ which obey the identity $p_{ab}=u_{[a}v_{b]}$. The null property $p_{ab}p^{ab}=0$ gives

$$u_a u^a=0,\quad v_a v^a<0$$

and without loss of generality we will assume that they are normalized by the conditions

$$u_a v^a=0,\quad v_a v^a=-2. \tag{2.1}$$

Let the spinors $\bar{\pi}^A$ and $\bar{\eta}^A$ constitute a normalized Newman–Penrose dyad (spin-frame) and spinor $\bar{\pi}^A$ be chosen so as to represent the coincident principal null directions of the null bivector p_{ab}. Then, one can write the following representation for u_a and v_b:

$$u_a=\bar{\pi}_A\pi_{A'},\quad v_b=\bar{\pi}_B\eta_{B'}+\pi_{B'}\bar{\eta}_B. \tag{2.2}$$

Introducing a null twistor $Z^\alpha=^{\text{def}}(\bar{\omega}^A,\pi_{A'})$ and its complex conjugate $\bar{Z}_\alpha=(\bar{\pi}_A,\omega^{A'})$, where $\bar{\omega}^A$ is given by the usual definition $\bar{\omega}^A=ix^{AA'}\pi_{A'}$, we obtain

$$iu_a\,dx^a=i\bar{\pi}_A\pi_{A'}dx^{AA'}=\bar{Z}_\alpha dZ^\alpha.$$

The null property of the twistor Z^α corresponds to the Hermitian property of $x^{AA'}$ and reflects the reality condition imposed on the points of 4D Minkowski space–time.

Next we consider another one-form

$$iv_b\mathrm{d}x^b = i(\overline{\pi}_B\eta_{B'} + \pi_{B'}\overline{\eta}_B)\mathrm{d}x^{BB'} = \frac{i}{2}[(\overline{\pi}_B + \overline{\eta}_B)(\pi_{B'} + \eta_{B'}) - (\overline{\pi}_B - \overline{\eta}_B)(\pi_{B'} - \eta_{B'})]\mathrm{d}x^{BB'} \tag{2.3}$$

and introduce a second null twistor $W^\beta = {}^{\mathrm{def}}(\overline{\xi}^B, \eta_{B'})$ and its complex conjugate $\overline{W}_\beta = (\overline{\eta}_B, \xi^{B'})$. Calculating $\mathrm{d}(\overline{\xi}^B \pm \overline{\omega}^B) = i(\pi_{B'} \pm \eta_{B'})\mathrm{d}x^{BB'} + ix^{BB'}\mathrm{d}(\pi_{B'} \pm \eta_{B'})$, we find

$$i(\overline{\pi}_B + \overline{\eta}_B)(\pi_{B'} + \eta_{B'})\mathrm{d}x^{BB'} = (\overline{\pi}_B + \overline{\eta}_B)d(\overline{\xi}^B + \overline{\omega}^B) + (\xi^{B'} + \omega^{B'})d(\pi_{B'} + \eta_{B'}),$$

$$i(\overline{\pi}_B - \overline{\eta}_B)(\pi_{B'} - \eta_{B'})\mathrm{d}x^{BB'} = -(\overline{\pi}_B - \overline{\eta}_B)d(\overline{\xi}^B - \overline{\omega}^B) - (\xi^{B'} - \omega^{B'})\mathrm{d}(\pi_{B'} - \eta_{B'}).$$

Subtracting these two equations and using (2.3) we obtain

$$iv_b\mathrm{d}x^b = \overline{Z}_\beta\mathrm{d}W^\beta + \overline{W}_\beta\mathrm{d}Z^\beta.$$

Since

$$p_{ab}\mathrm{d}x^a \wedge \mathrm{d}x^b = u_{[a}v_{b]}\mathrm{d}x^a \wedge \mathrm{d}x^b = u_a\mathrm{d}x^a \wedge v_b\mathrm{d}x^b, \tag{2.4}$$

we can take the following expression:

$$S = \int \overline{Z}_\alpha\mathrm{d}Z^\alpha \wedge (\overline{Z}_\beta\mathrm{d}W^\beta + \overline{W}_\beta\mathrm{d}Z^\beta) \tag{2.5}$$

as a twistor variational principle for the null two-surfaces. The two-form in (2.5) is understood to be restricted to a two-dimensional submanifold of 4D Minkowski space–time parametrized by τ and σ. The null property of the twistors Z^α and W^α leads to the following identities:

$$\overline{Z}_\alpha Z^\alpha = \overline{W}_\alpha W^\alpha = \overline{Z}_\alpha W^\alpha = \overline{W}_\alpha Z^\alpha = 0.$$

The Lagrangian density of the twistor action functional (2.5) is multiplied by the factor q^2 under the gauge transformations of the form

$$Z^\alpha \to qZ^\alpha, \quad W^\alpha \to q^{-1}W^\alpha + pZ^\alpha.$$

Here $q(\tau,\sigma)$ is a nowhere-vanishing real-valued function and $p(\tau,\sigma)$ is an arbitrary complex-valued function. This is an admissible freedom for a differential form representing a surface.[27] It gives rise to the invariance of the Euler–Lagrange equations under the above-mentioned transformations. The invariance corresponds to the possibility of rescaling with real multiples of the extent of the null direction tangent to the null two-surface and to addition of any real multiple of the null direction to the space-like tangent direction

$$\overline{\pi}^A \to q\overline{\pi}^A, \quad \overline{\eta}^A \to q^{-1}\overline{\eta}^A + p\overline{\pi}^A. \tag{2.6}$$

These transformations comprise the null-rotations and boost-rotations (cf. Ref. 28).

III. EQUATIONS OF MOTION

A. Euler–Lagrange equations

The Lagrangian of the twistor variational principle derived in Sec. II has the form

$$\mathcal{L} = \varepsilon^{\mu\nu}\partial_\mu Z^\alpha \overline{Z}_\alpha(\overline{Z}_\beta\partial_\nu W^\beta + \overline{W}_\beta\partial_\nu Z^\beta), \tag{3.1}$$

where the indices μ,ν run over τ, σ and $\varepsilon^{\tau\sigma}=-\varepsilon^{\sigma\tau}=1$. We also write $\partial_\mu=\partial/\partial\xi^\mu=(\partial/\partial\tau,\partial/\partial\sigma)$ and extensively use the shorthand notations $`````=\partial_\tau$ and $```'''=\partial_\sigma$. The Euler–Lagrange equations are

$$\frac{\partial\mathcal{L}}{\partial\Upsilon^u}-\frac{\partial}{\partial\xi^\mu}\left[\frac{\partial\mathcal{L}}{\partial(\partial_\mu\Upsilon^u)}\right]=0.$$

Here $\Upsilon^u=\{Z^\alpha,W^\alpha,\overline{Z}_\alpha,\overline{W}_\alpha\}$ are the dynamical quantities. The substitution of the Lagrangian density (3.1) into the equations yields

$$\begin{aligned}&\varepsilon^{\mu\nu}(\overline{Z}_\alpha\partial_\mu\overline{Z}_\beta\partial_\nu W^\beta+\partial_\mu\overline{Z}_\alpha\overline{Z}_\beta\partial_\nu W^\beta+\overline{Z}_\alpha\partial_\mu\overline{W}_\beta\partial_\nu Z^\beta+\partial_\mu\overline{Z}_\alpha\overline{W}_\beta\partial_\nu Z^\beta-\overline{W}_\alpha\partial_\mu\overline{Z}_\beta\partial_\nu Z^\beta\\&\quad-\partial_\mu\overline{W}_\alpha\overline{Z}_\beta\partial_\nu Z^\beta)=0,\\&\varepsilon^{\mu\nu}(\partial_\mu Z^\alpha\overline{Z}_\beta\partial_\nu W^\beta+\partial_\mu Z^\alpha\overline{W}_\beta\partial_\nu Z^\beta-\partial_\mu W^\alpha\overline{Z}_\beta\partial_\nu Z^\beta)=0,\\&\varepsilon^{\mu\nu}(\overline{Z}_\alpha\partial_\mu\overline{Z}_\beta+\partial_\mu\overline{Z}_\alpha\overline{Z}_\beta)\partial_\nu Z^\beta=0,\quad\varepsilon^{\mu\nu}\partial_\mu Z^\alpha\overline{Z}_\beta\partial_\nu Z^\beta=0.\end{aligned}\tag{3.2}$$

We can rewrite these equations in terms of the spinor fields $\overline{\pi}^A$ and $\overline{\eta}^A$ and the world-sheet derivatives of $x^{AA'}$ employing the definitions of the null twistors Z^α and W^α. In what follows it will be also convenient to take advantage of the identities

$$\begin{aligned}&\overline{\pi}^A\pi^{A'}\overline{\eta}^B-(\overline{\pi}^A\eta^{A'}+\pi^{A'}\overline{\eta}^A)\overline{\pi}^B=\pi^{A'}\epsilon^{AB}-\eta^{A'}\overline{\pi}^A\overline{\pi}^B,\\&\dot{x}^{AA'}\acute{x}^{BB'}-\acute{x}^{AA'}\dot{x}^{BB'}=\phi^{AB}\epsilon^{A'B'}+\overline{\phi}^{A'B'}\epsilon^{AB}.\end{aligned}\tag{3.3}$$

Here we use the normalization condition

$$\varepsilon_{AB}=\overline{\pi}_A\overline{\eta}_B-\overline{\eta}_A\overline{\pi}_B\tag{3.4}$$

and the symmetric spin-tensor ϕ^{AB} is given by the expression $\phi^{AB}=\dot{x}^{(A}{}_{C'}\acute{x}^{B)C'}$.

Let us consider the first equation in the system (3.2). Utilizing the above-presented formulas, we obtain that this equation is equivalent to the following system:

$$\begin{aligned}&\dot{x}^{BB'}[x^{AA'}(\pi_{B'}\epsilon_{AB}+\eta_{B'}\overline{\pi}_A\overline{\pi}_B)]'-\acute{x}^{BB'}[x^{AA'}(\pi_{B'}\epsilon_{AB}+\eta_{B'}\overline{\pi}_A\overline{\pi}_B)]^{\cdot}=0,\\&\dot{x}^{BB'}(\pi_{B'}\epsilon_{AB}+\eta_{B'}\overline{\pi}_A\overline{\pi}_B)'-\acute{x}(\pi_{B'}\epsilon_{AB}+\eta_{B'}\overline{\pi}_A\overline{\pi}_B)^{\cdot}=0.\end{aligned}\tag{3.5}$$

Substituting the second equation in (3.5) into the first one and using the second identity in (3.3), we can represent the first equation in (3.2) in the form

$$\begin{aligned}&\dot{x}^{BB'}[\overline{\eta}_A\overline{\pi}_B\pi_{B'}-\overline{\pi}_A(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]'-\acute{x}^{BB'}[\overline{\eta}_A\overline{\pi}_B\pi_{B'}-\overline{\pi}_A(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]^{\cdot}=0,\\&2\overline{\phi}^{A'B'}\pi_{B'}+\eta^{A'}(\phi^{AB}\overline{\pi}_A\overline{\pi}_B)=0.\end{aligned}\tag{3.6}$$

The second equation in the system (3.2) yields

$$\begin{aligned}&\dot{x}^{BB'}[(x^{AA'}\eta_{A'})'\overline{\pi}_B\pi_{B'}-(x^{AA'}\pi_{A'})'(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]-\acute{x}^{BB'}[(x^{AA'}\eta_{A'})^{\cdot}\overline{\pi}_B\pi_{B'}\\&\quad-(x^{AA'}\pi_{A'})^{\cdot}(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]=0,\\&\dot{x}^{BB'}[\acute{\eta}_{A'}\overline{\pi}_B\pi_{B'}-\acute{\pi}_{A'}(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]-\acute{x}^{BB'}[\dot{\eta}_{A'}\overline{\pi}_B\pi_{B'}-\dot{\pi}_{A'}(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]=0.\end{aligned}$$

Substituting the second equation in this system into the first and using (3.3) again, we find that the second equation in (3.2) results in

$$\dot{x}^{BB'}[\acute{\eta}_{A'}\overline{\pi}_B\pi_{B'}-\acute{\pi}_{A'}(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]-\acute{x}^{BB'}[\dot{\eta}_{A'}\overline{\pi}_B\pi_{B'}-\dot{\pi}_{A'}(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})]=0,$$
$$2\phi^{AB}\overline{\pi}_B+\overline{\eta}^A(\overline{\phi}^{A'B'}\pi_{A'}\pi_{B'})=0. \tag{3.7}$$

We incidentally observe that the second equations in the systems (3.6) and (3.7) are complex conjugates of one another. We next consider the third equation of the system (3.2). It can be represented as follows:

$$\dot{x}^{BB'}(x^{AA'}\overline{\pi}_A\overline{\pi}_B\pi_{B'})'-\acute{x}^{BB'}(x^{AA'}\overline{\pi}_A\overline{\pi}_B\pi_{B'})^{\cdot}=0,$$
$$\dot{x}^{BB'}(\overline{\pi}_A\overline{\pi}_B\pi_{B'})'-\acute{x}^{BB'}(\overline{\pi}_A\overline{\pi}_B\pi_{B'})^{\cdot}=0.$$

The substitution of the second equation above into the first and the use of (3.3) allow us to write this pair of equations in the form

$$\dot{x}^{BB'}(\overline{\pi}_A\overline{\pi}_B\pi_{B'})'-\acute{x}^{BB'}(\overline{\pi}_A\overline{\pi}_B\pi_{B'})^{\cdot}=0,$$
$$\phi^{AB}\overline{\pi}_A\overline{\pi}_B=0. \tag{3.8}$$

The fourth equation in (3.2) gives

$$[\dot{x}^{BB'}(x^{AA'}\pi_{A'})'-\acute{x}^{BB'}(x^{AA'}\pi_{A'})^{\cdot}]\overline{\pi}_B\pi_{B'}=0,$$
$$(\dot{x}^{BB'}\acute{\pi}_{A'}-\acute{x}^{BB'}\dot{\pi}_{A'})\overline{\pi}_B\pi_{B'}=0. \tag{3.9}$$

The second equation in (3.9) can be used to rewrite the two equations (3.8) as follows:

$$(\dot{x}^{BB'}\acute{\pi}_{A'}-\acute{x}^{BB'}\dot{\pi}_{A'})\overline{\pi}_B\pi_{B'}=0,$$
$$\overline{\phi}^{A'B'}\pi_{A'}\pi_{B'}=0. \tag{3.10}$$

We also find that the second equation in (3.8) is a complex conjugate of the second equation in (3.10).

Let us use the first equation in (3.7) to simplify the first equation in the system (3.6). The calculation gives

$$[\dot{x}^{BB'}(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})'-\acute{x}^{BB'}(\overline{\pi}_B\eta_{B'}+\overline{\eta}_B\pi_{B'})^{\cdot}]\overline{\pi}_A-[\dot{x}^{BB'}(\overline{\pi}_B\pi_{B'})'-\acute{x}^{BB'}(\overline{\pi}_B\pi_{B'})^{\cdot}]\overline{\eta}_A=0. \tag{3.11}$$

Since $\overline{\pi}^A$ and $\overline{\eta}^A$ constitute a normalized basis for the two-dimensional vector space $\mathbb{C}^2$, Eq. (3.11) is equivalent to the following pair:

$$\dot{x}^{AA'}(\overline{\pi}_A\eta_{A'}+\overline{\eta}_A\pi_{A'})'-\acute{x}^{AA'}(\overline{\pi}_A\eta_{A'}+\overline{\eta}_A\pi_{A'})^{\cdot}=0,$$
$$\dot{x}^{AA'}(\overline{\pi}_A\pi_{A'})'-\acute{x}^{AA'}(\overline{\pi}_A\pi_{A'})^{\cdot}=0. \tag{3.12}$$

Performing the same procedure with the first equations in (3.8) and (3.10), we derive

$$\dot{x}^{AA'}(\overline{\pi}_A\pi_{A'})'-\acute{x}^{AA'}(\overline{\pi}_A\pi_{A'})^{\cdot}=0.$$

It coincides with the second equation in the system (3.12).

Finally, for the purposes of the future analysis, we divide the independent Euler–Lagrange equations in the following three pairs:

$$(\dot{x}^{AA'}\overleftarrow{\overline{\pi}}_B-\acute{x}^{AA'}\dot{\overline{\pi}}_B)(\overline{\pi}_A\eta_{A'}+\pi_{A'}\overline{\eta}_A)-(\dot{x}^{AA'}\overleftarrow{\overline{\eta}}_B-\acute{x}^{AA'}\dot{\overline{\eta}}_B)\overline{\pi}_A\pi_{A'}=0,$$
$$\dot{x}^{AA'}(\overline{\pi}_A\eta_{A'}+\pi_{A'}\overline{\eta}_A)'-\acute{x}^{AA'}(\overline{\pi}_A\eta_{A'}+\pi_{A'}\overline{\eta}_A)^{\cdot}=0; \tag{3.13}$$

$$\dot{x}^{AA'}(\overline{\pi}_A\pi_{A'})'-\acute{x}^{AA'}(\overline{\pi}_A\pi_{A'})^{\cdot}=0,$$
$$(\dot{x}^{AA'}\overleftarrow{\overline{\pi}}_B-\acute{x}^{AA'}\dot{\overline{\pi}}_B)\overline{\pi}_A\pi_{A'}=0; \tag{3.14}$$

$$2\overline{\phi}^{A'B'}\pi_{A'}+(\phi^{AB}\overline{\pi}_A\overline{\pi}_B)\eta^{B'}=0,$$
$$\phi^{AB}\overline{\pi}_A\overline{\pi}_B=0. \tag{3.15}$$

Here we made substitutions of dummy indices, where appropriate, and presented complex conjugate versions of some equations.

B. Preliminary analysis

Now we will establish a few auxiliary results.

The third pair of the equations of motion (3.15) gives $\phi^{AB}\overline{\pi}_B=0$, which means that

$$2\phi^{AB}=v\,\overline{\pi}^A\overline{\pi}^B \tag{3.16}$$

for some complex-valued function $v(\tau,\sigma)$.

Let us substitute the representation (3.16) into the second equation of (3.3),

$$2(\dot{x}^{AA'}\acute{x}^{BB'}-\acute{x}^{AA'}\dot{x}^{BB'})=v\,\overline{\pi}^A\overline{\pi}^B\epsilon^{A'B'}+\overline{v}\,\overline{\pi}^{A'}\pi^{B'}\epsilon^{AB}.$$

Multiplying both sides of this equation by $\dot{x}_{BB'}$ we obtain

$$2[\dot{x}^2\acute{x}^{AA'}-(\dot{x}\acute{x})\dot{x}^{AA'}]=v\,\overline{\pi}^A\overline{\pi}_B\dot{x}^{BA'}+\overline{v}\,\overline{\pi}^{A'}\pi_{B'}\dot{x}^{AB'}. \tag{3.17}$$

Following Ref. 5 we calculate

$$2\dot{x}^A{}_{C'}\acute{x}^{BC'}=2\dot{x}^{(A}{}_{C'}\acute{x}^{B)C'}+2\dot{x}^{[A}{}_{C'}\acute{x}^{B]C'}=2\phi^{AB}+(\dot{x}\acute{x})\epsilon^{AB}=v\,\overline{\pi}^A\overline{\pi}^B+(\dot{x}\acute{x})\epsilon^{AB}.$$

Using this result one obtains

$$2\dot{x}^A{}_{C'}\acute{x}^{BC'}\dot{x}_{AD'}\acute{x}_B{}^{D'}=(\dot{x}\acute{x})^2. \tag{3.18}$$

On the other hand,

$$\dot{x}^A{}_{D'}\acute{x}^{BC'}\dot{x}_{AC'}\acute{x}_B{}^{D'}=-\dot{x}^A{}_{C'}\dot{x}_{AD'}\acute{x}^{BC'}\acute{x}_B{}^{D'}$$

and this fact can be used to show that the left-hand side of Eq. (3.18) is also given by

$$2\dot{x}^A{}_{C'}\acute{x}^{BC'}\dot{x}_{AD'}\acute{x}_B{}^{D'}=(\dot{x}^A{}_{C'}\dot{x}_{AD'}-\dot{x}^A{}_{D'}\dot{x}_{AC'})\acute{x}^{BC'}\acute{x}_B{}^{D'}=2\dot{x}^A{}_{[C'}\dot{x}_{|A|D']}\acute{x}^{BC'}\acute{x}_B{}^{D'}=\dot{x}^2\acute{x}^2. \tag{3.19}$$

Equations (3.18) and (3.19) result in identity (1.1). The left-hand side of (1.1) is the determinant of the induced metric on the null string world-sheet, or equivalently, on a two-dimensional real

null submanifold of 4D Minkowski space–time, and this equation shows that it vanishes identically. The vanishing property of the determinant of the induced metric is invariant under the group of nondegenerate diffeomorphisms of the null string world-sheet

$$\tau \to f(\tau,\sigma), \quad \sigma \to \varphi(\tau,\sigma). \tag{3.20}$$

According to the second Noether theorem,[29,30] the reparametrization invariance (3.20) of the twistor action functional implies that the equations of motion contain two arbitrary real-valued functions. Then, without loss of generality, we can choose one of them in such a way as to ensure that $\dot{x}^2=0$. Taking into account (1.1), this entails

$$\dot{x}^2=0, \quad \dot{x}\acute{x}=0. \tag{3.21}$$

Having fixed the orthogonal gauge (3.21), we restrict the group of diffeomorphisms of the null string world-sheet to the following subgroup of transformations:

$$\tau \to f(\tau,\sigma), \quad \sigma \to \varphi(\sigma). \tag{3.22}$$

It, therefore, follows from (3.17) and (3.21) that

$$v\,\overline{\pi}^A \dot{x}^{BA'}\,\overline{\pi}_B + \overline{v}\,\overline{\pi}_{B'}\dot{x}^{AB'}\pi^{A'}=0,$$

and projection of this equation on the elements of the spin-tensor basis $\overline{\pi}_A\pi_{A'}$, $\overline{\pi}_A\eta_{A'}$, $\pi_{A'}\overline{\eta}_{A'}$ and $\overline{\eta}_A\eta_{A'}$ yields

$$\begin{gathered} v\dot{x}^{AA'}\overline{\pi}_A\eta_{A'} + \overline{v}\dot{x}^{AA'}\overline{\eta}_A\pi_{A'}=0, \\ \dot{x}^{AA'}\overline{\pi}_A\pi_{A'}=0. \end{gathered} \tag{3.23}$$

The second equation in the system (3.23), together with the null property (3.21) of the vector field $\dot{x}^a$, gives rise to the representation for this vector field in the form

$$\dot{x}^{AA'} = r\,\overline{\pi}^A\pi^{A'}, \tag{3.24}$$

where $r(\tau,\sigma)$ is a real-valued function. This representation for one of the two vector fields tangent to the null string world-sheet automatically solves the first equation of the system (3.23). The result (3.24) and the second equation in (3.21) imply

$$\acute{x}^{AA'}\overline{\pi}_A\pi_{A'}=0.$$

Now $\acute{x}^{AA'}$ can be written as

$$\acute{x}^{AA'} = \overline{\zeta}\,\overline{\pi}^A\eta^{A'} + \zeta\,\overline{\eta}^A\pi^{A'} + g\,\overline{\pi}^A\pi^{A'},$$

where $\zeta(\tau,\sigma)$ and $g(\tau,\sigma)$ are complex- and real-valued functions, respectively. Therefore, the representation for two linearly independent vector fields tangent to the null string world-sheet which obey constraints (3.21) is

$$\dot{x}^{AA'} = r\,\overline{\pi}^A\pi^{A'}, \quad \acute{x}^{AA'} = \overline{\zeta}\,\overline{\pi}^A\eta^{A'} + \zeta\,\overline{\eta}^A\pi^{A'} + g\,\overline{\pi}^A\pi^{A'}. \tag{3.25}$$

The substitution of the representation (3.25) into the first equation of the system (3.13) gives

$$\dot{\overline{\pi}}^A(\zeta+\overline{\zeta})=0. \tag{3.26}$$

The situation in which $\dot{\bar{\pi}}^A$ vanishes corresponds to the geodesic property of the null string world-sheets and it has been considered in Ref. 5. Unfortunately, the authors of that article had overlooked the other possibility, given by the vanishing of the expression in parentheses in Eq. (3.26), and had not paid any attention to nongeodesic null strings. The remainder of this paper will be devoted to the analysis of the nongeodesic case, which corresponds, as we will see, to the situation where the function $\zeta(\tau,\sigma)$ is purely imaginary.

It is convenient to redefine the function ζ to be a real-valued function in the null string motion equations and in the representations for the vector fields $\dot{x}^{AA'}$ and $\acute{x}^{AA'}$ by means of the substitution $\zeta \to -i\zeta$. Taking into account (3.25), we can reduce the remainder of the motion equations (3.13)–(3.14) to the system

$$r(\bar{\pi}^A \overleftarrow{\bar{\pi}}_A + \pi^{A'} \acute{\pi}_{A'}) = 2i\zeta(\pi^{A'} \dot{\eta}_{A'} - \bar{\pi}^A \dot{\bar{\eta}}_A) + g(\bar{\pi}^A \dot{\bar{\pi}}_A + \pi^{A'} \dot{\pi}_{A'}),$$

$$\bar{\pi}^A \dot{\bar{\pi}}_A - \pi^{A'} \dot{\pi}_{A'} = 0.$$

Finally, we obtain the motion equations of the null string in the form

$$\begin{gathered} \dot{x}^{AA'} = r\bar{\pi}^A \pi^{A'}, \quad \acute{x}^{AA'} = i\zeta(\bar{\pi}^A \eta^{A'} - \bar{\eta}^A \pi^{A'}) + g\bar{\pi}^A \pi^{A'}, \quad \bar{\pi}^A \dot{\bar{\pi}}_A - \pi^{A'} \dot{\pi}_{A'} = 0, \\ r(\bar{\pi}^A \overleftarrow{\bar{\pi}}_A + \pi^{A'} \acute{\pi}_{A'}) = 2i\zeta(\pi^{A'} \dot{\eta}_{A'} - \bar{\pi}^A \dot{\bar{\eta}}_A) + g(\bar{\pi}^A \dot{\bar{\pi}}_A + \pi^{A'} \dot{\pi}_{A'}), \end{gathered} \tag{3.27}$$

where $r(\tau,\sigma)$ and $\zeta(\tau,\sigma)$ are arbitrary real-valued functions.

Let us briefly explore the effects of the gauge transformations (2.6) and the null string world-sheet reparametrizations (3.22) on the equations of motion. The gauge transformations (2.6) leave the null string motion equations (3.27) invariant and result in simple redefinitions of the functions r and g,

$$r \to q^2 r, \quad g \to q^2 g - iq(p - \bar{p})\zeta.$$

Under the world-sheet reparametrizations (3.22)

$$\dot{x}^a \to \dot{f}^{-1} \dot{x}^a, \quad \acute{x}^a \to \acute{\varphi}^{-1} \acute{x}^a - (\acute{\varphi}\dot{f})^{-1} \acute{f} \dot{x}^a.$$

We then observe that the reparametrizations (3.22) preserve the form of the null string motion equations (3.27) while leading to the following redifinitions of the functions r, g, and ζ:

$$r \to \dot{f}^{-1} r, \quad g \to \acute{\varphi}^{-1} g - (\acute{\varphi}\dot{f})^{-1} \acute{f} r, \quad \zeta \to \acute{\varphi}^{-1} \zeta.$$

One can make sure that the null property of the vector field $\dot{x}^a$ and the orthogonal character of the vector fields $\dot{x}^a$ and $\acute{x}^a$ are preserved with respect to both transformations.

The invariant property of the twistor action functional with respect to either of those transformations can be used in order to eliminate the null component, $g\bar{\pi}^A \pi^{A'}$, of the space-like vector field $\acute{x}^{AA'}$ from the null string equations of motion (3.27). This can be achieved by performing the transformations (2.6) with the parameters

$$q = 1, \quad i(p - \bar{p}) = \zeta^{-1} g,$$

where the real part of the function p may remain arbitrary. Then, the null string equations of motion take the reduced form

$$\begin{gathered} \dot{x}^{AA'} = r\bar{\pi}^A \pi^{A'}, \quad \acute{x}^{AA'} = i\zeta(\bar{\pi}^A \eta^{A'} - \bar{\eta}^A \pi^{A'}), \quad \bar{\pi}^A \dot{\bar{\pi}}_A - \pi^{A'} \dot{\pi}_{A'} = 0, \\ r(\bar{\pi}^A \overleftarrow{\bar{\pi}}_A + \pi^{A'} \acute{\pi}_{A'}) = 2i\zeta(\pi^{A'} \dot{\eta}_{A'} - \bar{\pi}^A \dot{\bar{\eta}}_A). \end{gathered} \tag{3.28}$$

They are invariant under the gauge transformations (2.6) with real functions $p(\tau,\sigma)$. These restricted gauge transformations result in trivial rescaling of the function $r(\tau,\sigma)$ in the null string motion equations (3.28),

$$r \to q^2 r,$$

and reflect the freedom inherent in the choice of the extent of the null direction represented by the vector field $\dot{x}^a$. This restriction of the admissible gauge transformations to those with real p's further reduces the reparametrization freedom of the null string world-sheet. The invariance of the null string equations of motion in the form (3.28) requires that the function f entering the reparametrization transformations (3.22) is a function of τ alone, thereby restricting the reparametrization freedom to the following transformations:

$$\tau \to f(\tau), \quad \sigma \to \varphi(\sigma). \tag{3.29}$$

In the above-given equations the function r defines the extent of the flagpole direction $l^a \equiv \overline{\pi}^A \pi^{A'}$ tangent to the null string world-sheet. We also note that unrestricted gauge transformations (2.6) preserve the associated flag plane represented by the space-like vector field $\mu^a \equiv \overline{\pi}^A \eta^{A'} + \pi^{A'} \overline{\eta}^A$. This vector is orthogonal to the space-like vector field $q^a \equiv i(\overline{\pi}^A \eta^{A'} - \overline{\eta}^A \pi^{A'})$ tangent to the null string world-sheet. The vector fields l^a, μ^a, and q^a together with the second null vector field $n^a \equiv \overline{\eta}^A \eta^{A'}$ define a (non-normalized) Newman–Penrose tetrad for 4D Minkowski space–time. Here the vector fields μ^a and q^a can be expressed in terms of the usual complex elements of the tetrad as follows:

$$\mu^a = m^a + \overline{m}^a, \quad q^a = i(m^a - \overline{m}^a).$$

C. Integrability conditions

The representations for $\dot{x}^{AA'}$ and $\acute{x}^{AA'}$ in (3.28) must satisfy the compatibility conditions

$$(\dot{x}^{AA'})' = (\acute{x}^{AA'})^{\cdot}. \tag{3.30}$$

In turn, this leads to some compatibility conditions on the τ- and σ-derivatives of the basis spinor fields $\overline{\pi}^A$ and $\overline{\eta}^A$. It will have proven to be interesting to explore the geometrical significance of the compatibility conditions (3.30).

Using the definitions of the vector fields l^a and q^a we find

$$\begin{aligned} \frac{\partial}{\partial \tau} &= \frac{\partial x^a}{\partial \tau} \frac{\partial}{\partial x^a} \equiv \dot{x}^a \nabla_a = r l^a \nabla_a, \\ \frac{\partial}{\partial \sigma} &= \frac{\partial x^a}{\partial \sigma} \frac{\partial}{\partial x^a} \equiv \acute{x}^a \nabla_a = \zeta q^a \nabla_a. \end{aligned} \tag{3.31}$$

We next calculate the Lie derivative of the vector field ∂_σ along ∂_τ,

$$\pounds_{rl}(\zeta q^a) = \tilde{a} l^a + \tilde{b} q^a + r\zeta \pounds_l \eta^a,$$

where we have defined $\tilde{a} = -\zeta q^a \nabla_a r$ and $\tilde{b} = r l^a \nabla_a \zeta$. In the derivation we have used the fact that in 4D Minkowski space–time the derivatives ∇_a commute. Now, the geometrical meaning of the condition (3.30) becomes apparent, it requires the Lie derivative of the connecting vector field q^a along the vector field l^a to be contained in the subspace spanned by those vector fields

$$\pounds_l \eta^a = a l^a + b q^a. \tag{3.32}$$

Here $a=-r^{-1}q^a\nabla_a r$ and $b=\zeta^{-1}l^a\nabla_a\zeta$ are some real-valued functions of τ and σ. This equation can be recognized as the Frobenius integrability condition applied to the vector fields l^a and q^a. We note in passing that the vector field ζq^a plays the role of the Jacobi field along the null congruence given by the vector field rl^a and, therefore, is simply a Lie-dragged vector field. This condition can be phrased in a yet another form by observing that (3.32) entails that the projections of the vector field $\pounds_l\eta^a$ on the elements l^a and μ^a of the Newman–Penrose tetrad must vanish

$$l_a\pounds_l q^a=0, \quad \mu_a\pounds_l q^a=0. \tag{3.33}$$

Having established the geometrical meaning of the compatibility conditions (3.30), or equivalently (3.33), we can proceed with their analysis. The first equation in (3.33) gives

$$l^a l^b\nabla_b q_a - l^a q^b\nabla_b l_a=0.$$

Noting that the second term on the left-hand side vanishes identically and using the orthogonal property of the vector fields l^a and q^a we obtain

$$q^a l^b\nabla_b l_a=0 \tag{3.34}$$

as the first integrability condition. The second equation in (3.33) yields

$$\mu^a q^b\nabla_b l_a - \mu^a l^b\nabla_b q_a=0. \tag{3.35}$$

Summarizing, the Frobenius integrability conditions for the two-dimensional submanifold of 4D Minkowski space–time representing the null string world-sheet are given by the formulas (3.34) and (3.35). A straightforward calculation shows that these equations are invariant under the restricted to real q's and p's gauge transformations of the form (2.6).

At this point we can compare the different forms of the integrability conditions, namely, the differential condition for the null bivector $p_{ab}(x)$ stated in Sec. I and (3.32). For this purpose, we note that the null bivector can be written in the form

$$2p_{ab}=\overline{\pi}_A\overline{\pi}_B\epsilon_{A'B'}+\pi_{A'}\pi_{B'}\epsilon_{AB}. \tag{3.36}$$

Here we have used the definitions (2.4) and (2.2) for the null bivector and the vector fields u^a and v^a, the normalization conditions (2.1) and identity (3.4). The above-mentioned integrability condition is equivalent to

$$p_{ab}\nabla_c p_{de}\boldsymbol{\epsilon}^{bcde}=0, \tag{3.37}$$

where the totally antisymmetric tensor density $\boldsymbol{\epsilon}^{bcde}$ is given by the expression[13] (Vol. 1),

$$\boldsymbol{\epsilon}^{bcde}=i(\boldsymbol{\epsilon}^{BD}\boldsymbol{\epsilon}^{CE}\boldsymbol{\epsilon}^{B'E'}\boldsymbol{\epsilon}^{C'D'}-\boldsymbol{\epsilon}^{BE}\boldsymbol{\epsilon}^{CD}\boldsymbol{\epsilon}^{B'D'}\boldsymbol{\epsilon}^{C'E'}).$$

First, we write

$$2\nabla_c p_{de}=\overline{\pi}_E\epsilon_{D'E'}\nabla_{CC'}\overline{\pi}_D+\overline{\pi}_D\epsilon_{D'E'}\nabla_{CC'}\overline{\pi}_E+\pi_{E'}\epsilon_{DE}\nabla_{CC'}\pi_{D'}+\pi_{D'}\epsilon_{DE}\nabla_{CC'}\pi_{E'}.$$

Second, we calculate

$$\boldsymbol{\epsilon}^{bcde}\nabla_c p_{de}=i(\overline{\pi}^B\nabla^{CB'}\overline{\pi}_C-\pi^{B'}\nabla^{BC'}\pi_{C'}+\overline{\pi}_C\nabla^{CB'}\overline{\pi}^B-\pi_{C'}\nabla^{BC'}\pi^{B'}).$$

Finally, we obtain

$$\begin{aligned}2p_{ab}\nabla_c p_{de}\boldsymbol{\epsilon}^{bcde}=i[&\overline{\pi}_A\overline{\pi}^B\pi^{B'}\nabla_{BB'}\pi_{A'}-\pi_{A'}\overline{\pi}^B\pi^{B'}\nabla_{BB'}\overline{\pi}_A+\pi_{A'}\pi^{B'}\pi^{C'}\nabla_{AC'}\pi_{B'}\\&-\overline{\pi}_A\overline{\pi}^B\overline{\pi}^C\nabla_{CA'}\overline{\pi}_B+\overline{\pi}_A\pi_{A'}(\overline{\pi}^B\nabla_{BB'}\pi^{B'}-\pi^{B'}\nabla_{BB'}\overline{\pi}_B)].\end{aligned} \tag{3.38}$$

Then, the desired result follows from equating the right-hand side of the formula (3.38) to zero. Since Eq. (3.37) is equivalent to its projections on the spin-tensor basis elements $\bar{\pi}^A\pi^{A'}$, $\bar{\pi}^A\eta^{A'}$, $\bar{\eta}^A\pi^{A'}$, and $\bar{\eta}^A\eta^{A'}$, we derive the results which are presented in the following. First, the projection of Eq. (3.37) on $\bar{\pi}^A\pi^{A'}$ vanishes identically. Second, its projections on the spin–tensor basis elements $\bar{\pi}^A\eta^{A'}$ and $\bar{\eta}^A\pi^{A'}$ are the complex conjugates of one another and can be represented in the form

$$\bar{\pi}^A\bar{\pi}^B\pi^{B'}\nabla_{BB'}\bar{\pi}_A-\pi^{A'}\bar{\pi}^B\pi^{B'}\nabla_{BB'}\pi_{A'}=0. \tag{3.39}$$

Finally, the projection of (3.37) on the remaining element of the spin-tensor basis, $\bar{\eta}^A\eta^{A'}$, is given by

$$\begin{aligned}2(\bar{\pi}^A\bar{\pi}^B\pi^{B'}\nabla_{BB'}\bar{\eta}_A-\pi^{A'}\bar{\pi}^B\pi^{B'}\nabla_{BB'}\eta_{A'})+\pi^{A'}\bar{\pi}^B\eta^{B'}\nabla_{BB'}\pi_{A'}-\pi^{A'}\bar{\eta}^B\pi^{B'}\nabla_{BB'}\pi_{A'}\\ -\bar{\pi}^A\bar{\eta}^B\pi^{B'}\nabla_{BB'}\bar{\pi}_A+\bar{\pi}^A\bar{\pi}^B\eta^{B'}\nabla_{BB'}\bar{\pi}_A=0.\end{aligned} \tag{3.40}$$

The substitution of the definitions for the vector fields l^a, q^a and μ^a through the spinors $\bar{\pi}^A$ and $\bar{\eta}^A$ into (3.39) and (3.40) reduces those equations to the system (3.34) and (3.35). This concludes our demonstration of the equivalence of the integrability conditions (3.37) and (3.32).

Using (3.31) we can rewrite formulas (3.39) and (3.40) as

$$\begin{gathered}r(\bar{\pi}^A\overleftarrow{\bar{\pi}}_A+\pi^{A'}\acute{\pi}_{A'})=2i\zeta(\pi^{A'}\dot{\eta}_{A'}-\bar{\pi}^A\dot{\bar{\eta}}_A),\\ \bar{\pi}^A\dot{\bar{\pi}}_A-\pi^{A'}\dot{\pi}_{A'}=0.\end{gathered} \tag{3.41}$$

We find that the integrability conditions (3.41) coincide with the null string equations of motion in the system (3.28).

The conclusion of the subsection is that the integrability conditions do not contribute additional constraints to the null string equations of motion (3.28). Moreover, the complete system of the null string equations of motion consists of the spinor representations for $\dot{x}^a$ and $\acute{x}^a$ in (3.28) together with their compatibility conditions (3.30).

It is easy to show that nongeodesic null string equations of motion derived in Ref. 24 can be cast into the form (3.28). This proves that the two variational formulations are equivalent on the classical level. All the results on the properties of those equations also hold in our case. For more details we refer an interested reader to that paper. It is also remarkable that the present formulation is free of the pair of artificial auxiliary world-sheet quantities, ρ^μ, in the action principle, which was proposed by Bandos and Zheltukhin in Ref. 3 and studied by Zheltukhin and Ilyenko in Refs. 22–25. The action principle of Ref. 24 contains eight arbitrary functions of τ and σ, namely, two ρ^μ's and six components of the external antisymmetric gauge field $B_{ab}(x)$. Nevertheless, as we showed there, only two gauge invariant combinations of the field strength components of $B_{ab}(x)$ enter the equations of motion. This means that only four functions define generic null string dynamics in 4D Minkowski space–time, as is the case with the present formulation.

To summarize, in this section we have shown that the twistor action functional (2.5) describes a two-dimensional submanifold of 4D Minkowski space–time with a degenerate induced metric. The twistor action also gives the equations of motion for a generic null string in 4D Minkowski space–time.

IV. EVOLUTION EQUATION

A. Preliminary results

The invariance of the null string equations of motion under the restricted gauge transformations of the form (2.6) with real functions q and p enables us to impose one more gauge condition

on the functions entering the complete equations of motion of a null string. It will prove convenient in the nongeodesic case to fix the extents of the null directions tangent to the null string world-sheet by imposing the so-called natural parametrization

$$\dot{\bar{\pi}}_A \bar{\pi}^A = 1. \tag{4.1}$$

This amounts to taking $r = \kappa^{-1}$, where κ is the spin-coefficient, whose nonvanishing property shows that a null congruence is non-geodesic [cf. Ref. 13 (Vol. 2)]. The resulting equations are invariant under the residual gauge transformations

$$\bar{\pi}^A \to \bar{\pi}^A, \quad \bar{\eta}^A \to \bar{\eta}^A + p\,\bar{\pi}^A. \tag{4.2}$$

Here p is a real-valued function of τ and σ. The gauge transformations of the form (4.2) correspond to the freedom inherent in the definition of the flag planes, which are associated with the flagpole directions l^a tangent to the null string world-sheet. The condition (4.1) fixes natural parameter, τ, along the integral curves of the vector field l^a, thus restricting the reparametrization invariance (3.29) to trivial transformations

$$\tau \to \tau, \quad \sigma \to \varphi(\sigma).$$

Under these transformations the flagpole extent, κ^{-1}, remains invariant, whereas ζ changes to $\acute{\varphi}^{-1}\zeta$.

The condition for the natural parametrization (4.1) leads to the identity

$$\ddot{\bar{\pi}}_A \bar{\pi}^A = 0.$$

It follows that $\ddot{\bar{\pi}}^A$ is proportional to $\bar{\pi}^A$. Using the definition of the spin-coefficients κ, ε, and τ' and noting that $D \equiv l^a \nabla_a$, we obtain

$$\ddot{\bar{\pi}}^A = [\kappa^{-1} D(\varepsilon \kappa^{-1}) + \kappa^{-2}(\varepsilon^2 + \kappa\tau')]\,\bar{\pi}^A. \tag{4.3}$$

In what follows, we will denote the expression in square brackets in Eq. (4.3) as U. The natural parametrization (4.1) also gives that

$$\bar{\eta}^A = -\dot{\bar{\pi}}^A \tag{4.4}$$

up to addition of real multiples of $\bar{\pi}^A$.

B. Derivation of equation

We use the spinor representations in (3.28) for the vector fields $\dot{x}^a$ and $\acute{x}^a$ to find a nonlinear evolution equation satisfied by the coordinate, $x^a(\tau, \sigma)$, of the null string world-sheet. Since the analysis here is applicable only to the nongeodesic case, we will restrict our derivation to the situation in which the natural parametrization is applied.

Let us substitute (4.4) and $r = \kappa^{-1}$ into the definitions of $\dot{x}^a$ and $\acute{x}^a$ in (3.28), the result reads

$$\dot{x}^a = \kappa^{-1}\bar{\pi}^A \pi^{A'}, \quad \acute{x}^a = i\zeta(\dot{\bar{\pi}}^A \pi^{A'} - \bar{\pi}^A \dot{\bar{\pi}}^{A'}). \tag{4.5}$$

First, taking the τ-derivative of $\acute{x}^a$, we calculate with the aid of (4.3):

$$\dot{x}'^a = i\dot{\zeta}(\dot{\bar{\pi}}^A \pi^{A'} - \bar{\pi}^A \dot{\bar{\pi}}^{A'}) + i\zeta(U - \bar{U})\,\bar{\pi}^A \pi^{A'}. \tag{4.6}$$

Second, taking the τ-derivative of $\dot{x}^a$, we obtain

$$\ddot{x}^a = -\kappa^{-2}\dot{\kappa}\bar{\pi}^A \pi^{A'} + \kappa^{-1}(\dot{\bar{\pi}}^A \pi^{A'} + \bar{\pi}^A \dot{\bar{\pi}}^{A'}), \quad \ddot{x}^2 = -2\kappa^{-2}. \tag{4.7}$$

One can also find that

$$\acute{x}^2=-2\zeta^2,\quad \acute{x}\dot{x}'=-2\zeta\dot{\zeta},\quad \ddot{x}\ddot{x}'=2\kappa^{-3}\acute{\kappa}. \tag{4.8}$$

Here we have made use of the identity $(\ddot{x}^2)'=2\ddot{x}\ddot{x}'$. In order to obtain the σ derivative of κ we can employ the compatibility conditions of Sec. III C with the necessary substitution $\overline{\eta}^A\mapsto -\dot{\bar{\pi}}^A$. Taking the σ-derivative of $\dot{x}^a$ and using (4.5), we derive

$$\dot{x}'^A=-\kappa^{-2}\acute{\kappa}\overline{\pi}^A\pi^{A'}+\kappa^{-1}(\acute{\overline{\pi}}^A\pi^{A'}+\overline{\pi}^A\acute{\pi}^{A'}).$$

Since $(\dot{x}^a)'$ equals to $(\acute{x}^a)^{\cdot}$, we must also have $\dot{\bar{\pi}}_A\dot{\pi}_{A'}(\acute{x}^{AA'})^{\cdot}=\dot{\bar{\pi}}_A\dot{\pi}_{A'}(\dot{x}^{AA'})'$. This entails

$$-\kappa^{-2}\acute{\kappa}+\kappa^{-1}(\dot{\bar{\pi}}_A\acute{\overline{\pi}}^A+\dot{\pi}_{A'}\acute{\pi}^{A'})=i\zeta(U-\overline{U}), \tag{4.9}$$

where we used the normalization condition (4.1). Employing the same normalization condition again we find

$$\dot{\bar{\pi}}_A\acute{\overline{\pi}}^A-\overline{\pi}_A\dot{\overline{\pi}}'^A=0. \tag{4.10}$$

On the other hand, taking into account (4.3), the first motion equation in (3.28) gives

$$\overline{\pi}_A\acute{\overline{\pi}}^A+\pi_{A'}\acute{\pi}^{A'}=0.$$

Differentiating this equation with respect to τ and making the use of (4.10) we obtain

$$2(\dot{\bar{\pi}}_A\acute{\overline{\pi}}^A+\dot{\pi}_{A'}\acute{\pi}^{A'})=(\overline{\pi}_A\acute{\overline{\pi}}^A+\pi_{A'}\acute{\pi}^{A'})^{\cdot}=0.$$

The substitution of this result into Eq. (4.9) finally yields

$$\acute{\kappa}=-i\kappa^2\zeta(U-\overline{U}). \tag{4.11}$$

In a generic situation of a nongeodesic case neither κ nor ζ are equal to zero. Let us then multiply Eq. (4.6) by $\kappa^{-2}\zeta^2$; the results (4.5), (4.7), (4.8), and (4.11) can be used to show that the evolution equation has the form

$$\ddot{x}^2[\acute{x}^2\dot{x}'^a-(\acute{x}\dot{x}')\acute{x}^a]-\acute{x}^2(\ddot{x}\ddot{x}')\dot{x}^a=0. \tag{4.12}$$

This equation is accompanied by the two constraints (3.21). A straightforward but tedious calculation shows that the evolution equation and the constraints are invariant under the world-sheet reparametrizations of the form (3.29).

The evolution equation (4.12), satisfied by the coordinate $x^a(\tau,\sigma)$ of the nongeodesic null string world-sheet, is a nonlinear counterpart of the free (geodesic) null string evolution equation

$$\ddot{x}^a=0.$$

V. WAVE-FRONT CAUSTIC

Here we present an example of a nongeodesic null two-surface and explore its connections with the null string interpretation of such surfaces in 4D Minkowski space–time and the evolution equation derived for the nongeodesic null two-surfaces in Sec. IV. We will construct this example as a two-dimensional caustic of a suitable null hypersurface in 4D Minkowski space–time.

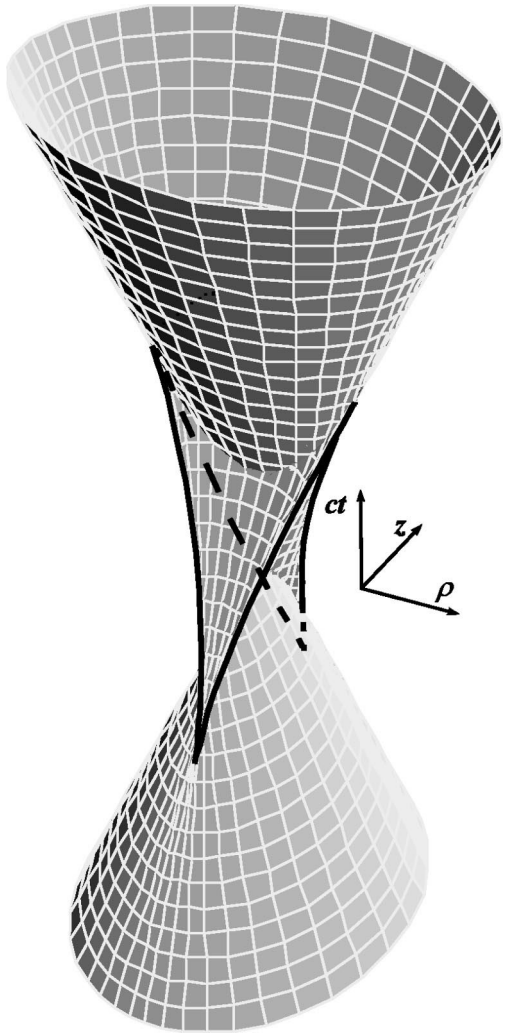

FIG. 1. The null hypersurface (5.1). One dimension is suppressed. The dark solid and dashed lines show its two-dimensional null caustic surface.

A. Null hypersurface

Let us start with considering the hypersurface given parametrically:

$$x^a(u,v,w)=\frac{a}{4}\begin{bmatrix} u \\ (1+2\sin^2 v+u)\cos v\cos w \\ (1+2\sin^2 v+u)\cos v\sin w \\ (3-2\sin^2 v-u)\sin v \end{bmatrix}. \tag{5.1}$$

Here a is a constant with the dimension of length. Taking advantage of an axial symmetry present in our example, we schematically draw the hypersurface using coordinates $(\rho=\sqrt{x^2+y^2},z,ct)$ in Fig. 1. Denoting $x^a_u=\partial x^a/\partial u$, $x^a_v=\partial x^a/\partial v$, and $x^a_w=\partial x^a/\partial w$, we can calculate the vector fields spanning the tangent space to this hypersurface. The result reads

$$x^a_u=\frac{a}{4}[1,\cos v\cos w,\cos v\sin w,-\sin v],$$

$$x^a_v=\frac{a}{4}(3\cos 2v-u)[0,\sin v\cos w,\sin v\sin w,\cos v], \tag{5.2}$$

$$x^a_w=\frac{a}{4}(u+2-\cos 2v)\cos v[0,-\sin w,\cos w,0].$$

For the Lorentz norms of the vector fields we have

$$x^2_u=0,\quad x^2_v=-\frac{a^2}{16}(u-3\cos 2v)^2,\quad x^2_w=-\frac{a^2}{16}\cos^2 v(u+2-\cos 2v)^2.$$

One can also check the orthogonal property of these vector fields in the Lorentz norm $x_u x_v=x_u x_w=x_v x_w=0$. The above-mentioned equations show that the hypersurface (5.1) is null. We can also write the necessarily degenerate induced metric, $G_{\mu\nu}$. Here the subscript indices μ and ν run over u, v, and w. By definition, it is given by $G_{\mu\nu}=\partial_\mu x^a\partial_\nu x_a$. Writing $G_{\mu\nu}$ as a three by three matrix we obtain

$$G_{\mu\nu}=-\frac{a^2}{16}\mathrm{diag}[0,(u-3\cos 2v)^2,\cos^2 v(u+2-\cos 2v)^2].$$

This matrix has the rank of two everywhere with the exception of the following parameter values:

$$u=3\cos 2v,\quad \cos v=0\ \text{ or }\ u=\cos 2v-2. \tag{5.3}$$

It is of rank one matrix there excluding two points $x^a=(-3a/4,0,0,\pm a)$, where the induced metric is of zero rank. One can show that parameter values $\cos v=0$ determine two null straight lines

$$ct=\frac{a}{4}\pm z,\quad x=y=0$$

and the parameter values given by the last equality in (5.3) correspond to the segment $|z|\leqslant a$ contained by the null plain curve

$$ct=-\frac{1}{4a}(2z^2+a^2).$$

On the contrary, the first equality in (5.3) defines a two-dimensional surface. Substituting $u=3\cos 2v$ into (5.1), we find for the space–time points belonging to it:

$$\tilde{x}^a=a[\tfrac{3}{4}\cos 2v,\cos^3 v\cos w,\cos^3 v\sin w,\sin^3 v]. \tag{5.4}$$

By construction, this is a caustic two-surface for the null hypersurface (5.1) and the tangent plains to the two-surface span the null hypersurface. Accounting to the axial symmetry of our example, the caustic null two-surface is shown by thick solid and dashed lines in Fig. 1.

The new tangent fields at the two-surface are

$$\tilde{x}^a_v=-\tfrac{3}{2}a\sin 2v[1,\cos v\cos w,\cos v\sin w,-\sin v],\quad \tilde{x}^a_w=a\cos^3 v[0,-\sin w,\cos w,0].$$

The latter new tangent field coincides with the field obtained as a result of substitution $u=3\cos 2v$ in the expression for x^a_w in (5.2), while the former one is only a multiple of the null vector field x^a_u in (5.2). For this reason and to simplify subsequent calculations, we can equally use the null vector field x^a_u in order to find the spinor corresponding to the null direction tangent to the two-surface. Since the first tangent vector field $\tilde{x}^a_v$ has a zero Lorentz norm and the second tangent

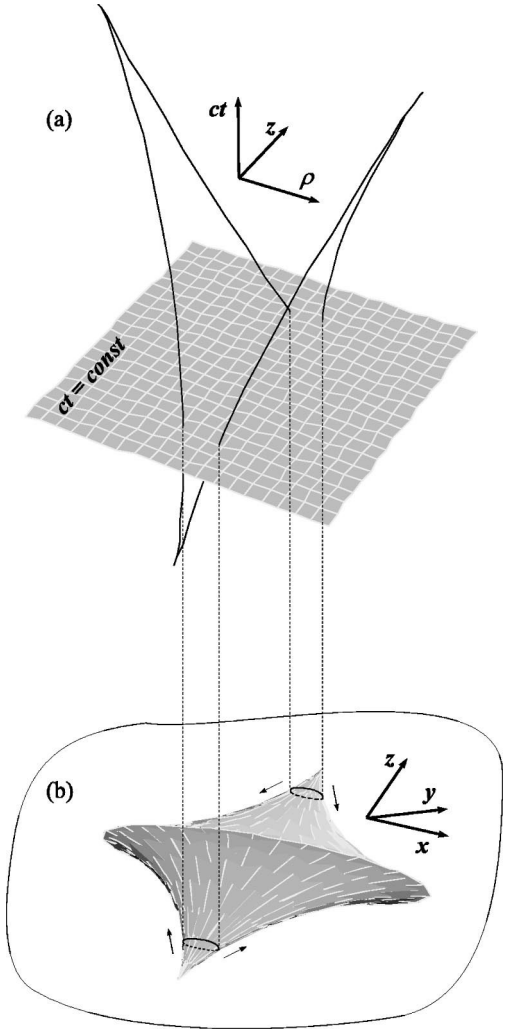

FIG. 2. Null string interpretation of the two-dimensional caustic surface. (a) A section of the two-surface by a hyperplane of constant time (one space dimension is not shown). (b) The space picture of the null strings dynamics.

vector field $\tilde{x}^a_w$ is space-like at the points given by Eq. (5.4), we infer that the two-surface is a null two-surface in 4D Minkowski space–time. The parametric representation (5.4) also provides a representation for this surface as an intersection of two hypersurfaces:

$$x^2+y^2+z^2=\frac{a^2}{4}\left[1+3\left(\frac{4ct}{3a}\right)^2\right], \quad x^2+y^2-z^2=\frac{a^2}{4}\left(\frac{4ct}{3a}\right)\left[3+\left(\frac{4ct}{3a}\right)^2\right]. \tag{5.5}$$

Here $|4ct/3a|\leqslant 1$. Eliminating $4ct/3a$ from the equations in (5.5), we observe that in a particular reference frame the projection of this null two-surface in a hyperplane of constant time is an astroid of revolution with the parameter a given by

$$[x^2+y^2+z^2-a^2]^3+27a^2[x^2+y^2]z^2=0$$

(see Fig. 2).

As is well known, a compact space-like two-surface in 4D Minkowski space–time can be represented as an intersection of two null hypersurfaces. Somewhat analogous to that situation, two-dimensional self-intersections (caustics) of null hypersurfaces provide examples of nongeodesic null two-surfaces in 4D Minkowski space–time.

In order to make a connection with the description of the previous sections, we need the spin-tensor expressions of various vector field quantities. As mentioned previously, the null vector field x_u^a can be employed to obtain the spinor field describing the null directions tangent to the null two-surface. First, we explicitly calculate

$$x_u^{AA'} = x_u^a (\sigma_a)^{AA'} = \frac{a}{4\sqrt{2}} \begin{bmatrix} 1-\sin v & \cos v\, e^{iw} \\ \cos v\, e^{-iw} & 1+\sin v \end{bmatrix}. \tag{5.6}$$

Here $(\sigma_a)^{AA'}$ are the Pauli matrices. Since the vector field x_u^a is real-valued and null, the determinant of the matrix in (5.6) vanishes and we must have $x_u^{AA'} \propto \overline{\pi}^A \pi^{A'}$. The components of the spinor $\overline{\pi}_A$ can be taken as follows:

$$\overline{\pi}_A = -i\sqrt{2} \begin{bmatrix} \cos\left(\frac{v}{2}-\frac{\pi}{4}\right) e^{-iw/2} \\ \sin\left(\frac{v}{2}-\frac{\pi}{4}\right) e^{iw/2} \end{bmatrix}. \tag{5.7}$$

B. Nongeodesic null string

Now we are in a position to explore connections between the example null two-surface and a nongeodesic null string world-sheet in 4D Minkowski space–time.[24] Changing the parameters (v,w) to (τ, σ) we can rewrite the parametric representation (5.4) for the null two-surface as $x^a = a[(3/4)\cos 2\tau, \cos^3\tau\cos\sigma, \cos^3\tau\sin\sigma, \sin^3\tau]$. The range of the parameters is $\tau \in [\pi/2, \pi]$ and $\sigma \in [0, 2\pi]$. This corresponds to a closed null string with the parameter τ playing the role of a time variable. The results (5.6) and (5.7) allow us to write

$$\dot{x}^{AA'} = \frac{3a}{2\sqrt{2}} \sin 2\tau\, \overline{\pi}^A \pi^{A'}. \tag{5.8}$$

Here $\overline{\pi}_A$ is given by formula (5.7) with the necessary change of (v,w) to (τ, σ). Next, we introduce a second spinor field $\overline{\eta}^A$:

$$\overline{\eta}^A = \frac{i}{\sqrt{2}} \begin{bmatrix} \cos\left(\frac{\tau}{2}-\frac{\pi}{4}\right) e^{i\sigma/2} \\ \sin\left(\frac{\tau}{2}-\frac{\pi}{4}\right) e^{-i\sigma/2} \end{bmatrix}. \tag{5.9}$$

which, together with $\overline{\pi}_A$, constitutes a normalized Newman–Penrose dyad (spin-frame) for all admissible values of the parameters τ and σ. Making use of (5.7) and (5.9) we obtain

$$\acute{x}^{AA'} = -i\frac{a}{\sqrt{2}} \cos^3\tau\, (\overline{\pi}^A \eta^{A'} - \overline{\eta}^A \pi^{A'}). \tag{5.10}$$

The vector fields $\dot{x}^a$ and $\acute{x}^a$ tangent to the null two-surface vanish at two space–time points

$$ct = -\frac{3a}{4}, \quad x = y = 0, \quad z = \pm a \tag{5.11}$$

and, in addition, the vector field $\dot{x}^a$ vanishes on the circle

$$ct=\frac{3a}{4},\quad x^2+y^2=a^2,\quad z=0. \tag{5.12}$$

Comparing the results (5.8) and (5.10) with the first two equations in the system (3.28), we can identify the functions r and ζ as follows:

$$r=\frac{3a}{2\sqrt{2}}\sin 2\tau,\quad \zeta=-\frac{a}{\sqrt{2}}\cos^3\tau.$$

The expressions for $\overline{\pi}^A$ and $\overline{\eta}^A$ can be used to obtain the functions $(\omega-\ln|\zeta|)^{\cdot}$ and ψ of the Ref. 24 directly. The result reads:

$$(\omega-\ln|\zeta|)^{\cdot}=0,\quad \psi=\frac{a}{4\sqrt{2}}. \tag{5.13}$$

This knowledge is important for relating $\mathrm{Re}\,\dot{\omega}$ and ψ with the quantities which represent the field strength of the gauge field $B_{ab}(x)$ of Ref. 24 Thus, we obtain

$$\begin{gathered}\psi=-\tfrac{3}{4}\text{æ}a^2\sin 2\tau\cos^3\tau(\rho^{\tau})^{-1}\phi,\\ 2\,\mathrm{Re}\,\dot{\omega}=-\tfrac{3}{2}\text{æ}a^2\sin 2\tau\cos^3\tau(\rho^{\tau})^{-1}\,\mathrm{Re}\,\nu+(\ln|\cos^6\tau(\rho^{\tau})^{-1}|)^{\cdot}.\end{gathered} \tag{5.14}$$

Substituting the result (5.13) in these equations we have

$$\phi=-\rho^{\tau}[3\sqrt{2}\text{æ}a\sin 2\tau\cos^3\tau]^{-1},\quad \mathrm{Re}\,\nu=-\rho^{\tau}[\tfrac{3}{2}\text{æ}a^2\sin 2\tau\cos^3\tau]^{-1}(\ln|\cos^6\tau(\rho^{\tau})^{-1}|)^{\cdot}.$$

The above-mentioned formulas show that the quantity ϕ, which represents the only physical degree of freedom of the field strength, diverges at the space–time points (5.11) and on the circle (5.12).

Therefore, in a particular reference frame, Fig. 2, one can interpret the null two-surface of this section as a pair of circular null strings which appear with zero radius at $t=-3a/4c$ at spatial points $(x,y,z)=(0,0,\pm a)$. They then expand until the time $t=3a/4c$, when they disappear having the circumference of $2\pi a$. The null strings are the sections of the caustic two-surface in Fig. 1 by the hyperplanes of constant time. Projection of the world-sheets of the null strings into a particular reference frame constitutes the astroid of revolution described earlier in this section.

C. Evolution equation

It is also interesting to make connections of this example with the evolution equation for nongeodesic null strings derived in the previous section. The parametric expressions for $\overline{\pi}^A$ and $\overline{\eta}^A$, together with the results (5.8) and (5.10), can be utilized to verify the equality (4.4). Noting that $\kappa=r^{-1}$, we find

$$\acute{\kappa}=0,\quad \dot{\zeta}=\frac{3a}{2\sqrt{2}}\sin 2\tau\cos\tau,\quad \text{and}\quad U-\overline{U}=0.$$

Then, we have $\dot{x}'^a=\zeta^{-1}\dot{\zeta}\acute{x}^a$. Next, the formulas (4.7) and (4.8) yield

$$\acute{x}^2=-a^2\cos^6\tau,\quad \ddot{x}\ddot{x}'=0,$$

$$\acute{x}\dot{x}'=\tfrac{3}{2}a^2\sin 2\tau\cos^4\tau,\quad \ddot{x}^2=-\tfrac{9}{4}a^2\sin^2 2\tau.$$

Finally, with the aid of the above-obtained results, we observe that the evolution equation (4.12) holds.

VI. DISCUSSION AND OUTLOOK

First, the method employed in this paper to obtain a variational principle, (2.5), for a null two-surface can be, in principle, used to design a twistor variational principle for time-like two-surfaces (conventional strings) and space-like two-surfaces. The idea is to take a simple bivector field $p_{ab}(x)$ and impose one of the algebraic conditions $p_{ab}p^{ab}=1$ or $p_{ab}p^{ab}=-1$. The latter condition would single out the string (compare with the last part of Ref. 5), while the former would correspond to a space-like two-surface. It is easy to see that such a procedure uniquely fixes the symmetric second rank spin-tensor field $\phi_{AB}(x)$ in the standard decomposition of an antisymmetric 4D Minkowski space–time tensor field $p_{ab}(x)=\phi_{AB}(x)\varepsilon_{A'B'}+\overline{\phi}_{A'B'}(x)\varepsilon_{AB}$. Then, the variational principle

$$S=\frac{1}{2!}\int [\phi_{AB}(x)\varepsilon_{A'B'}+\overline{\phi}_{A'B'}(x)\varepsilon_{AB}]\mathrm{d}x^{AA'}\wedge\mathrm{d}x^{BB'}$$

would define a two-surface subject to the differential constraint stated in Sec. I [see Eq. (3.36)]. It is hoped that the use of spinor decomposition for $p_{ab}(x)$, consistent with either of the formulated algebraic constraints, would provide equations of motion, which automatically incorporate the differential constraints formulated in Sec. I. Such an assertion is supported by the success of this procedure for the null two-surfaces (null strings) presented in the current contribution. It may well be possible to derive the analogs of the evolution equation (4.12) for generic (interacting) strings in 4D Minkowski space–time and curved space–times of general relativity, where exist explicit spinor and twistor constructions [cf. Ref. 31—Eq. (16) and Ref. 32—Eqs. (3.6)–(3.11)]. In the same way it should be possible to build twistor action functionals in the both cases for generic time-like and space-like two-surfaces of 4D Minkowski space–time.

Second, if one employs Feber's definition of a $\mathrm{SU}(2,2|N)$ supertwistor,[33] (s)he could construct a description of null strings with spin in the physical dimensions of space-time. Its analysis presumably would follow the standard pass outlined in the works of Shirafuji[10] and Bengtsson *et al.*[34]

ACKNOWLEDGMENTS

I acknowledge an early conversation with A.A. Zheltukhin on the matters of Ref. 5. I am very grateful to R. Penrose and Yu.P. Stepanovsky for their interest in this work. Special thanks go to T.Yu. Yatsenko for the help with the production of pictures.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 10 OCTOBER 2002

The peculiarity of a negative coordinate axis in dyonic solutions of noncommutative $\mathcal{N}=4$ super Yang–Mills

Aalok Misra[a)]
Harish Chandra Research Institute, Jhusi, Allahabad-211 019, India

(Received 1 February 2002; accepted for publication 16 April 2002)

We show that in the neighborhood of a negative coordinate axis, the U(1) sector of the static dyonic solutions to the noncommutative U(4) $\mathcal{N}=4$ super Yang–Mills (SYM) can be consistently decoupled from the SU(4) to *all orders in the noncommutativity parameter*. We show the above decoupling in two ways. First, we show the noncommutative dyon being the same as the commutative dyon, is a consistent solution to noncommutative equations of motion in the abovementioned region of noncommutative space. Second, as an example of decoupling of a non-null U(1) sector, we also obtain a family of solutions with nontrivial U(1) components for all components of the gauge field in the same region of noncommutative space. In both cases, the SU(4) and U(1) components separately satisfy the equations of motion. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1500773]

I. INTRODUCTION

Nonperturbative solutions in super Yang–Mills (SYM) theories have been an important area of work. More recently, static dyonic solutions in SU(N), $N\geqslant 3$, 4 $\mathcal{N}=4$ SYM corresponding to planar and nonplanar (respectively) string junctions have been obtained in Refs. 1 and 2 (see also references therein). Also, solitonic solutions in noncommutative SYM have been considered by others before (see Refs. 3, 4, and references therein). Now, the gauge group SU(N), in general is not allowed in noncommutative gauge theories.[5] [See Ref. 6 though, where the gauge parameter in noncommutative gauge tranformations is allowed to depend on the usual SU(N) gauge paramater and gauge fields. The explicit form of the map to all orders in the noncommutativity parameter (which is what we are interested in, in this paper) is quite involved and has not been worked out.] One of the questions that we address in this work is whether it is possible to construct solutions to the equations of motion of a noncommutative supersymmetric gauge theory in which one can decouple the U(1) components from the SU components of the fields at least in some region of the noncommutative space, *to all orders in the noncommutativity parameter*. There are the following two additional motivations for this work. The equality of the angular momentum and (null) quadrupole moment of the commutative and noncommutative monopoles of (S)U(2) $N=2$ SYM up to O(θ^2) was shown in Ref. 13 and in all of space. This makes it natural to pose the following question: Is it possible to construct solutions of a noncommutative supersymmetric gauge theory that are characterized by quantities that receive no noncommutativity corrections *to all orders in the noncommutativity parameter*? Finally, it is of obvious interest to construct solutions that are valid up to all orders in the noncommutativity paramater.

In this paper, we show that for noncommutative U(4) $\mathcal{N}=4$ SYM, the static dyonic solutions in the neighborhood of a negative coordinate axis of the noncommutative space, are such that one can decouple the U(1) from the SU(4), and construct a 6-parameter family of noncommutative dyonic solutions [for a non-null U(1) decoupling]. Even though, the decoupling has been shown for a very limited region of the noncommutative space, the reason the solutions are of interest is because they have the same electric and magnetic charges as and energy differing infinitesimally from the commutative dyonic solutions of Ref. 1, *to all orders in the noncommutativity parameter*.

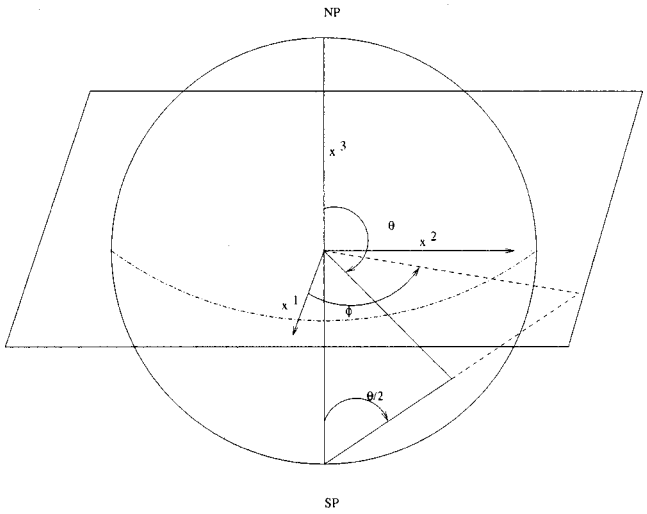

FIG. 1. The stereographic coordinate system.

This points to the peculiar nature of the negative x^3 axis when constructing dyonic solutions to noncommutative $\mathcal{N}=4$ SYM, which requires further investigation.

The paper is organized as follows: In Sec. II, we discuss the basics needed for getting static dyonic solutions in commutative $\mathcal{N}=4$ super Yang–Mills (SYM). In Sec. III, we discuss the modifications in the techniques of Sec. II to get static dyonic solutions of noncommutative $\mathcal{N}=4$ SYM. It has two subsections: (a short) 3.1 on decoupling of a null U(1) from the SU(4), and 3.2 on decoupling of a non-null U(1) from the SU(4). In Sec. IV, we give a summary of and a discussion on the results obtained in the paper, and indicate possible future directions for work.

II. BASICS

In this section, we give a brief review of the techniques given in Ref. 1 to obtain dyonic solutions in commutative SU(4) $\mathcal{N}=4$ SYM.

It is advisable to write the equations of motion as if one were working in curved space–time. The reason is that for solutions of the equations of motion, it is convenient to go to the stereographic coordinate system (see Fig. 1, $z=e^{i\phi}\tan\theta/2$) in which the metric is not constant. The equations of motion for commutative SU(4) $\mathcal{N}=4$ SYM are given by

$$D_i(\sqrt{g}g^{ii_1}g^{jj_1}F_{i_1j_1})=i\sqrt{g}\sum_J [D^j\Phi^J,\Phi^J],$$

$$D_i(\sqrt{g}g^{ij}D_j\Phi^J)=\sqrt{g}[\Phi^I,[\Phi^I,\Phi^J]]. \tag{1}$$

The component-form of the above equations is given in Ref. 1 which we will not be repeating here. Following the close parallel with Skyrme models,[7] one uses the harmonic-map anzatz to solve the equations of motion; the Higgs and gauge fields are assumed to have the following form:

$$\begin{aligned} A_z=A_z^aT^a=&-(1+c_1-c_2-c_0)(r)(\partial P_0)P_0\\ &+(c_2-c_1)(r)[P_1,\partial P_1]+(1-c_2(r))[P_2,\partial P_2], \quad A_r=0,\\ \Phi^I=\Phi^{I,a}T^a=&(b_2^I+b_0^I+b_1^I)(r)(P_0-\tfrac{1}{4}\mathbf{1}_4)\\ &+(b_2^I+b_1^I)(r)(P_1-\tfrac{1}{4}\mathbf{1}_4)+b_2^I(r)(P_2-\tfrac{1}{4}\mathbf{1}_4), \end{aligned} \tag{2}$$

T^a being the generators of SU(4), I indexing the number of scalars that are turned on, and for this paper taking values 1, 2, and 3, $c_{0,1,2}(r)$ and $b^I_{0,1,2}(r)$ being the "profile functions" of the gauge field and Higgs, respectively, and P_i the orthogonal set of $\mathbf{CP}^3$ sigma model projectors defined as

$$P_0=\frac{ff^\dagger}{f^\dagger f},$$

$$P_j=\frac{(\Delta^j f)(\Delta^j f)^\dagger}{|\Delta^j f|^2},\quad j=1,2, \tag{3}$$

where

$$\Delta f\equiv\partial f-f\frac{f^\dagger\partial f}{|f|^2},$$

$$f\equiv(1,\sqrt{3}z,\sqrt{3}z^2,z^3)^t, \tag{4}$$

and $\Delta^2 f=\Delta(\Delta f)$. They can be thought of as Hermitian maps from S^2 to $\mathbf{CP}^3$. The explicit forms of the projectors P_is can be worked out using Mathematica or Maple.

The substitution of the harmonic map anzatz into the equations of motion (written in components) either results in an equation of motion being identically satisfied, or a system of nonlinear second-order coupled differential equations involving the Higgs and gauge field profile functions that can be solved using techniques referred to in Ref. 1. The solutions corresponding to (non-)planar string networks (for nonplanar, assuming an infinitesimal nonplanarity corresponding to an infinitesimal deformation from the BPS nature of the planar solution) were then obtained in Ref. 1.

III. NONCOMMUTATIVE DYONIC SOLUTIONS

In this section we derive a class of static noncommutative dyonic solutions assuming $r-z$ and $r-\overline{z}$ noncommutativity only. Thus, the star product of two functions $f(r,z,\overline{z})$ and $h(r,z,\overline{z})$ will be

$$\begin{aligned}&f(r,z,\overline{z})*h(r,z,\overline{z})\\&\quad=e^{(i/2)[\Theta^{rz}(\partial_r^1\partial^2-\partial_r^2\partial^1)+\Theta^{r\overline{z}}(\partial_r^1\overline{\partial^2}-\partial_r^2\overline{\partial^1})]}f(r_1,z_1,\overline{z_1})h(r_2,z_2,\overline{z_2})\big|_{1=2}.\end{aligned} \tag{5}$$

We show that using stereogrpahic coordinates, in the neighborhood of the South Pole, or equivalently the neighborhood of the negative x^3 axis, one can consistently decouple in the equations of motion, the U(1) from the SU(4) components of the Higgs and the gauge fields.

The noncommutative equations of motion are given by

$$\hat{D}_i*(\sqrt{g}*g^{ii_1}*g^{jj_1}*\hat{F}_{i_1j_1})=i\sqrt{g}*\sum_J[\hat{D}^j*\hat{\Phi}^J,\hat{\Phi}^J]_*,$$

$$\hat{D}_i*(\sqrt{g}*g^{ij}*\hat{D}_j*\hat{\Phi}^J)=\sqrt{g}*[\hat{\Phi}^I,[\hat{\Phi}^I,\hat{\Phi}^J]_*]_*. \tag{6}$$

As we are considering only $r-z,r-\overline{z}$-noncommutativity, the projectors of Ref. 1 are still valid here. We assume the following anzatz for the gauge field $\hat{A}_z$, $\hat{A}_r$, and the Higgs field $\hat{\Phi}^I$,

$$\hat{A}_z=\hat{A}_z^aT^a+i\epsilon F_z(\Theta)g_z(r)\hat{\mathcal{A}}_z^0\mathbf{1}_4,$$

$$\hat{A}_r=i\epsilon F_r(\Theta)g_r(r)\hat{\mathcal{A}}_r^0\mathbf{1}_4,$$

$$\hat{\Phi}^I=\hat{\Phi}^{I,a}T^a+i\epsilon F_\Phi(\Theta)g^I_\Phi(r)\hat{\phi}^0\mathbf{1}_4, \tag{7}$$

where $F_{z,r,\Phi}(\Theta)$ are functions of the noncommutativity parameter Θ which vanish as Θ is set to zero and are bounded as $\Theta\to\infty$, and

$$\hat{A}_z^a T^a = -(1+c_1-c_2-c_0)(r)*(\partial P_0)P_0 + (c_2-c_1)(r)*[P_1,\partial P_1]+(1-c_2(r))*[P_2,\partial P_2],$$

$$\hat{\Phi}^{I,a}T^a=(b_2^I+b_0^I+b_1^I)(r)*(P_0-\tfrac{1}{4}\mathbf{1}_4)+(b_2^I+b_1^I)(r)*(P_1-\tfrac{1}{4}\mathbf{1}_4)+b_2^I(r)*(P_2-\tfrac{1}{4}\mathbf{1}_4), \quad (8)$$

$c_{0,1,2}(r)$ and $b^I_{0,1,2}(r)$ being the ''profile functions'' of the gauge field and Higgs, respectively, as in (2). We have thus taken an anzatz in which the U(4) fields have infinitesimal U(1) components. We will work up to $O(\epsilon)$. Hence, the noncommutative U(1) field strengths are the same as the commutative U(1) field strengths. There is no star product in the anzatz (7) in the U(1) components of the fields because as argued below, the star products can be dropped in the neighborhood of the South Pole in the SU(4)-components of the fields, and we assume similar behavior for the U(1) and SU(4) components. The anzatz for the U(1) components that we choose in (10) below, is such that if one were to put in a star product between the radial and angular functions, then it (the star product) cannot be dropped in the neighborhood of the South Pole.

As *expanding the star product in (8) will involve taking derivatives of* $(\partial)P_i$, using the explicit forms of the projectors that can be worked out using Mathematica or Maple, one sees that *one can drop* $(\partial)\partial P_i$ *relative to* $(\partial)P_i$ *as one approaches the neighborhood of the South Pole*, as the former is suppressed relative to the latter by terms of $O(1/|z|^m), m>0$ that vanish as $|z|\to\infty$ (i.e., in the neighborhood of the South Pole). *One thus has for the SU part of* $\hat{A}_z,\hat{\Phi}$ *the same expression as in Ref. 1*. One can argue similarly that the $*$ products in (6) can also be dropped (in the neighborhood of the South Pole). We now discuss the decoupling from SU(4), of a null U(1) in Sec. III A and non-null U(1) in Sec. III B.

A. Decoupling of null U(1)

Using (7), for null U(1) components, one can require consistently that the SU(4) and U(1) components, separately, satisfy the equations of motion, and one can show there is no mixing between the SU(4) and U(1) sectors. Hence, one can consistently set the U(1) components to zero. The entire analysis of Ref. 1 to show the connection between (non-)planar stable (non-)BPS string junctions and dyon solutions, then goes through even in the neighborhood of the South Pole of the abovementioned noncommutative space if one notices and uses the following transformation that takes one from the North Pole to the South Pole [and is also a symmetry of the equations of motion of the SU(4) part of the solutions, as given in Ref. 2 of Ref. 1],

$$c_0\leftrightarrow c_2;\ \ b_0^I\leftrightarrow b_2^I. \quad (9)$$

One also uses the fact that if $\hat{\Phi}$ is a solution then $-\hat{\Phi}$ is also a solution to the equations of motion.

B. Decoupling of non-null U(1)

Here we discuss in detail, the decoupling of non-null U(1) components of the Higgs and the gauge fields from their SU(4) components in the neighborhood of the South Pole of the noncommutative space. To show the decoupling of a non-null U(1) from SU(4), we choose the following anzatz for the U(1) components (of the Higgs and gauge fields):

$$\hat{\phi}^0,\hat{\mathcal{A}}_z^0=\det[(P_0-a_{\Phi,z}\mathbf{1}_4)(P_1-M_{\Phi,z})(P_2-M_{\Phi,z})]+\text{c.c.},$$

$$\hat{A}_r^0=z\det[(P_0-a_r\mathbf{1}_4)(P_1-M_r)(P_2-M_r)]+\text{c.c.}, \quad (10)$$

where

$$M_i=\begin{pmatrix} 0 & b_i & 0 & 0 \\ c_i & 0 & 0 & 0 \\ 0 & 0 & 0 & e_i \\ 0 & 0 & f_i & 0 \end{pmatrix}, \tag{11}$$

where $i\equiv r,z,\Phi$, and the parameters a_i,b_i,c_i,e_i, and f_i have been introduced to get nonzero determinants using the projectors and some constant matrices; the parameters get constrained later. We now assume that one approaches the South Pole along any path very close to ϕ ($\equiv$azimuthal angle)$=\pi/2$. This implies that $\mathrm{Re}\, z$ is finite, but $\mathrm{Im}\, z$ approaches infinity. Hence, one sees that $\partial\overline{\partial}\hat{\mathcal{A}}_r^0$ [as shown in (A5)] and $(\partial-\overline{\partial})(\hat{\phi}^0,\hat{\mathcal{A}}_z^0)$ [as shown in (A8)] are real. If

$$b_i=f_i,\ \ c_i=e_i, \tag{12}$$

then $\partial((1+|z|^2)^2(\partial+\overline{\partial})(\hat{\phi}^0,\hat{\mathcal{A}}_z^0))$ [as shown in (A9)] will be finite and real as $\mathrm{Im}\, z\to\infty$. These considerations become useful when one solves the equations of motion for the U(1) components as done in (19) and (20) in the neighborhood of the South Pole.

From power (of $|z|$ or $\mathrm{Im}\, z$) counting arguments using expressions given in the Appendix, one can require consistently that the SU(4) and U(1) components, separately, satisfy the equations of motion, and one can show there is no mixing between the SU(4) and U(1) sectors. As the decoupling for non-null U(1) is nontrivial, to illustrate the point, we consider the example of $\hat{F}_{rz}$. We see that up to $\mathrm{O}(\epsilon)$,

$$\hat{F}_{rz}^{\mathrm{U}(4)}=\hat{F}_{rz}^{\mathrm{SU}(4)}+\hat{F}_{rz}^{\mathrm{U}(1)}-i[\hat{A}_r^{\mathrm{U}(1)},\hat{A}_z^{\mathrm{SU}(4)}]_*. \tag{13}$$

Now,

$$\begin{aligned}[\hat{A}_r^{\mathrm{U}(1)},\hat{A}_z^{\mathrm{SU}(4)}]_*=&\,i\Theta^{rz}(\partial_r\hat{A}_r^{\mathrm{U}(1)}\partial\hat{A}_z^{\mathrm{SU}(4)}-\partial\hat{A}_r^{\mathrm{U}(1)}\partial_r\hat{A}_z^{\mathrm{SU}(4)})+i\Theta^{r\overline{z}}(\partial_r\hat{A}_r^{\mathrm{U}(1)}\overline{\partial}\hat{A}_z^{\mathrm{SU}(4)}\\ &-\overline{\partial}\hat{A}_r^{\mathrm{U}(1)}\partial_r\hat{A}_z^{\mathrm{SU}(4)})+\mathrm{O}(\Theta^2).\end{aligned} \tag{14}$$

Using expressions in the Appendix, one sees that

$$\begin{gathered}\partial_r\hat{A}_r^{\mathrm{U}(1)}\equiv\mathrm{O}(1),\ \ \partial\hat{A}_r^{\mathrm{U}(1)},\overline{\partial}\hat{A}_r^{\mathrm{U}(1)}\equiv\mathrm{O}(1),\\ \partial\hat{A}_z^{\mathrm{SU}(4)}\equiv\mathrm{O}\left(\frac{1}{|z|^3}\right)\times M,\ \ \overline{\partial}\hat{A}_z^{\mathrm{SU}(4)}\equiv\mathrm{O}\left(\frac{1}{|z|^4}\right)\times\mathbf{1}_4,\\ \partial_r\hat{A}_z^{\mathrm{SU}(4)}\equiv\mathrm{O}\left(\frac{1}{|z|^2}\right)\times M,\\ \partial_r\hat{A}_z^{\mathrm{U}(1)}\equiv\mathrm{O}(1),\ \ \partial\hat{A}_z^{\mathrm{U}(1)},\\ \overline{\partial}\hat{A}_z^{\mathrm{U}(1)}\equiv\mathrm{O}\left(\frac{1}{|z|^2}\right)\{\text{relevant for } [\hat{A}_r^{\mathrm{U}(1)},\hat{A}_z^{\mathrm{U}(1)}]_*\},\end{gathered} \tag{15}$$

where

$$M\equiv\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{16}$$

TABLE I. Consequences of power counting done in (15).

Term that can be dropped	Relative to
$\partial_r \hat{A}_r^{\mathrm{U}(1)} \partial \hat{A}_z^{\mathrm{SU}(4)}$	$\hat{F}_{rz}^{\mathrm{SU}(4)}$
$\partial \hat{A}_r^{\mathrm{U}(1)} \partial_r \hat{A}_z^{\mathrm{SU}(4)}$	$\hat{F}_{rz}^{\mathrm{SU}(4)}$
$\partial_r \hat{A}_r^{\mathrm{U}(1)} \bar{\partial} \hat{A}_z^{\mathrm{SU}(4)}$	$\hat{F}_{rz}^{\mathrm{U}(1)}$
$\bar{\partial} \hat{A}_r^{\mathrm{U}(1)} \partial_r \hat{A}_z^{\mathrm{SU}(4)}$	$\hat{F}_{rz}^{\mathrm{SU}(4)}$

Thus

$$\hat{F}_{rz}^{\mathrm{U}(1)} \equiv \mathrm{O}(1); \quad \hat{F}_{rz}^{\mathrm{SU}(4)} \equiv \mathrm{O}\left(\frac{1}{|z|^2}\right) \times M, \tag{17}$$

and in Table I, we show which terms can be dropped relative to which terms as $\mathrm{Im}\, z \to \infty$. Similar reasoning can be used to argue that terms of higher order in Θ, can also be dropped relative to the commutative counterparts. Hence, as $\mathrm{Im}\, z \to \infty$,

$$\hat{F}_{rz}^{\mathrm{U}(4)} \sim \hat{F}_{rz}^{\mathrm{SU}(4)} + \hat{F}_{rz}^{\mathrm{U}(1)}, \tag{18}$$

showing the stated decoupling.

By requiring that the SU components of the Higgs and gauge fields still satisfy the commutative equations of motion (having dropped the star product at the South pole), the U(1) components should satisfy these equations,

$$\frac{dg_z}{dr}(\partial - \bar{\partial}) \hat{\mathcal{A}}_z^0 - 2 g_r \partial \bar{\partial} \hat{\mathcal{A}}_r^0 = 0,$$

$$\frac{d^2 g_z}{dr^2} \hat{\mathcal{A}}_z^0 - g_r \partial \hat{\mathcal{A}}_r^0 + \frac{g_z}{2r^2} \partial ((1+|z|^2)^2 (\partial + \bar{\partial}) \hat{A}_z) = 0,$$

$$\frac{1}{r^2} \frac{d}{dr}\left(r^2 \frac{dg_\Phi^I}{dr} \right) \hat{\phi}^0 + \frac{(1+|z|^2)^2}{r^2} g_\Phi^I \partial \bar{\partial} \hat{\phi}^0 = 0. \tag{19}$$

The $*$ product has been dropped as it will generate $\mathrm{O}(1/|z|^m)$-corrections [relative to O(1)], which can be dropped in the neighborhood of the South Pole. We now discuss a family of dyonic solutions to (19).

One gets (setting $c_r = e_r$ and $b_r = f_r$ for convenience),

$$\frac{dg_z}{dr} + 2 g_r \frac{[(b_r c_r)^3 (2c_r - b_r)]}{(b_z c_z)^3 (c_z - b_z)} = 0,$$

$$2 \frac{d^2 g_z}{dr^2} (-1 + a_z) a_z^3 (b_z c_z)^4 - g_r (-1 + a_r) a_r^3 (b_r c_r)^4$$

$$+ \frac{g_z}{r^2} (3(-1 + a_z) a_z^3 b_z^2 c_z^2 (b_z - c_z)^2) = 0,$$

$$2 \frac{1}{r^2} \frac{d}{dr}\left(r^2 \frac{dg_\Phi^I}{dr} \right) (-1 + a_\Phi) a_\Phi^3 (b_\Phi c_\Phi)^4,$$

$$- \frac{6}{r^2} |z|^2 g_\Phi^I (-1 + a_{\Phi,z}) a_\Phi^3 (c_\Phi^4 b_\Phi^2 + b_\Phi^4 c_\Phi^2) = 0. \tag{20}$$

By eliminating $\hat{\mathcal{A}}_r^0$ from the first two equations, one gets the following differential equation for g_z:

$$\frac{d^2g_z}{dr^2}+\frac{dg_r}{dr}\frac{(-1+a_r)a_r^3(b_rc_r)^4\sqrt{3}(-1+a_z)a_z^3[(b_zc_z)^3(c_z-b_z)]}{4(-1+a_z)^2a_z^6(b_zc_z)^4[b_r^3c_r^3\sqrt{3}(2c_r-b_r)]}$$
$$+\frac{g_z}{r^2}\left(3(-1+a_z)a_z^3\frac{(b_z-c_z)^2}{2b_z^2c_z^2}\right)=0. \tag{21}$$

Equation (21) is of the form,

$$r^2y''(r)+\alpha r^2y'(r)+\beta y(r)=0, \tag{22}$$

the solution to which (using maple) is given by

$$y(r)=C_1\sqrt{r}I_{1/2\sqrt{1-4\beta}}(\tfrac{1}{2}\alpha r)e^{-(1/2)\alpha r}+C_2\sqrt{r}I_{-1/2\sqrt{1-4\beta}}(\tfrac{1}{2}\alpha r)e^{-(1/2)\alpha r}, \tag{23}$$

for $\frac{1}{2}\sqrt{1-4\beta}\notin\mathbf{Z}$ and

$$y(r)=C_1'\sqrt{r}I_{1/2\sqrt{1-4\beta}}(\tfrac{1}{2}\alpha r)e^{-(1/2)\alpha r}+C_2'\sqrt{r}K_{1/2\sqrt{1-4\beta}}(\tfrac{1}{2}\alpha r)e^{-(1/2)\alpha r}, \tag{24}$$

for $\frac{1}{2}\sqrt{1-4\beta}\in\mathbf{Z}$. Let us consider the two cases separately.

For the former, to make sure that the solution goes to zero as $r\to\infty$, one sets

$$C_1=-C_2. \tag{25}$$

Even though this is a singular solution (at $r=0$), as we shall see, it is a finite energy solution.

The derivative of the solution involving $I_{\pm\nu}(\alpha r)$ is given by

$$\frac{d}{dr}\left(e^{-\alpha r/2}\sqrt{r}\left(I_{1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-I_{-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)\right)\right)$$
$$=\frac{e^{(-\alpha r/2)}}{4\sqrt{r}}\left(\alpha rI_{-1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)+\alpha rI_{1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)\right.$$
$$+2(-1+\alpha r)I_{-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)$$
$$\left.-\alpha rI_{-1-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-\alpha rI_{1-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-2(-1+\alpha r)I_{1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)\right). \tag{26}$$

For the purpose of getting finite energy, as we will very shortly see, one is required to impose that $r^2(dy(r)/dr)^2\to0$ as $r\to\infty$, and that it is finite at $r=0$. Using the series expansions around $r=0$ and the asymptotic expansions for $I_\nu(r)$, the former is satisfied identically, and the latter is satisfied if one imposes

$$\sqrt{1-4\beta}<1\Leftrightarrow0<\beta<\tfrac{1}{4}. \tag{27}$$

The solution for $g_\Phi^I(r)$ that one gets is

$$g_\Phi^I(r)=0. \tag{28}$$

Hence, the final result for the U(1) components of the Higgs and gauge fields, in the neighborhood of the South Pole (approaching it along ϕ close to $\pi/2$) are

$$\hat{A}_z^0(r,z)=i\epsilon f_z(\Theta)\sqrt{r}e^{-(1/2)\,\alpha r}(I_{1/2\sqrt{1-4\beta}}(\tfrac{1}{2}\alpha r)-I_{-1/2\sqrt{1-4\beta}}(\tfrac{1}{2}\alpha r))$$
$$\times\det[(P_0-a_z\mathbf{1}_4)(P_1-M_r)(P_2-M_r)]+\text{c.c.});$$

$$\hat{A}_r^0=i\epsilon f_r(\Theta)\frac{e^{(-\alpha r/2)}}{4\sqrt{r}}\Bigg(\alpha r I_{-1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)+\alpha r I_{1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)$$
$$+2(-1+\alpha r)I_{-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-\alpha r I_{-1-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-\alpha r I_{1-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)$$
$$-2(-1+\alpha r)I_{1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)\Bigg)(z\,\det[(P_0-a_z\mathbf{1}_4)(P_1-M_r)(P_2-M_r)]+\text{c.c.});$$

$$\hat{\Phi}^0=0, \tag{29}$$

where

$$\beta\equiv\left(3(-1+a_z)a_z^3\frac{(b_z-c_z)^2}{2b_z^2c_z^2}\right)<0;$$

$$\alpha\equiv\frac{(-1+a_r)a_r^3(b_rc_r)^4\sqrt{3}(-1+a_z)a_z^3[(b_ze_z)^3(c_z-b_z)]}{4(-1+a_z)^2a_z^6(b_zc_z)^4[b_r^3c_r^3\sqrt{3}(2c_r-b_r)]};$$

$$0<a_z<1;\quad c_{z,r}=e_{z,r};\quad b_{z,r}=f_{z,r}. \tag{30}$$

Let us consider the energy of the above solution. It is given by (we follow the conventions of Ref. 1),

$$E=-\frac{1}{4\pi}\int r^2dr\frac{dzd\bar{z}}{(1+|z|^2)^2}\text{Tr}\left[(\hat{D}_i*\hat{\Phi})^2+\frac{1}{2}(\hat{F}_{ij})^2{}_*\right]=E_{\text{SU}(4)}+E_{\text{U}(1)}. \tag{31}$$

But, in the neighborhood of the South Pole, where one can drop the $*$ product,

$$E_{\text{U}(1)}=-\int r^2dr\frac{dzd\bar{z}}{(1+|z|^2)^2}[(\partial_r\hat{\mathcal{A}}_z^0-\partial\hat{\mathcal{A}}_r^0)^2+(\partial_r\hat{\mathcal{A}}_z^0+\bar{\partial}\hat{\mathcal{A}}_r^0)^2+((\partial+\bar{\partial})\hat{\mathcal{A}}_z^0)^2]\geqslant 0. \tag{32}$$

Hence, in the neighborhood of the South Pole, even though one is dealing with non-BPS solutions, one gets the following inequality:

$$E_{\text{U}(4)}\geqslant E_{\text{SU}(4)}, \tag{33}$$

with saturation of the inequality occuring for the null U(1) component. Substituting (29) in the $\text{Im}\,z\to\infty$ limit into (32), and integrating in the neighborhood of the South Pole as described earlier, i.e., around $\phi=\pi/2$ and $\theta\in[\pi-\epsilon,\pi]$, $\lim_{\epsilon\to 0}$, one gets an infinitesimal result, provided one gets a finite result from the r integration. The r-integral should converge to get a finite-energy solution. One sees that one has to evaluate

$$E_{\mathrm{U}(1)}\sim\int_0^\infty dr r^2\frac{e^{-\alpha r}}{16r}\Bigg(\alpha r I_{-1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)+\alpha r I_{1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)$$
$$+2(-1+\alpha r)I_{-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-\alpha r I_{-1-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-\alpha r I_{1-1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)$$
$$-2(-1+\alpha r)I_{1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)\Bigg)^2. \tag{34}$$

We have not been able to evaluate the above integral. But the integrand for $0<\beta<\frac{1}{4}$ is analytic for all values of $r\in[0,\infty)$, and it vanishes at $r=0$ and $r\to\infty$. We hence assume that it is convergent corresponding to a finite energy solution. We have verified the same numerically using Mathematica for several values of $\beta<\frac{1}{4}$.

Let us now consider the case $\frac{1}{2}\sqrt{1-4\beta}\in\mathbf{Z}$. In that case in order to get a solution that vanishes as $r\to\infty$, one sets $C_1'=0$ in (24).

One then requires

$$E_{\mathrm{U}(1)}\sim\int_0^\infty dr r^2\frac{e^{-\alpha r}}{16r}\Bigg(-\alpha r K_{-1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)$$
$$-2(-1+\alpha r)K_{1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)-\alpha r K_{1+1/2\sqrt{1-4\beta}}\left(\frac{\alpha r}{2}\right)\Bigg)^2$$
$$<\infty. \tag{35}$$

By using the series expansion of $K_\nu(x)$ about $x=0$ (see Ref. 8), one sees that one cannot find a β: $\frac{1}{2}\sqrt{1-4\beta}\in\mathbf{Z}$ that will satisfy (35) because of the singular nature of the integrand at $r=0$.

Now, let us turn to calculating the commutative Higgs and gauge field: $\Phi^I, A_{r,z,\bar{z}}$. As we have thus far continued working to all orders in the noncommutativity parameter Θ, one hence requires an all-order (in Θ) Seiberg–Witten map.[9–11] There is a conjecture for that as given in Ref. 10. We will not explicitly construct the SW map, but conjecture that in the neighborhood of the negative x^3 axis (or the neighborhood of the South Pole of the Riemann Sphere, approaching it the way described in the paper), the noncommutative hatted fields are the same as the commutative unhatted fields. Noting that as $\mathrm{Im}\,z\to\infty$, $\hat{A}^{\mathrm{SU}(4)}_{z,\bar{z}},\partial,\bar{\partial}\hat{\Phi}^{\mathrm{SU}(4)},\partial\hat{A}^{\mathrm{U}(1)}_z$, $\partial^2\hat{A}^{\mathrm{U}(1)}_r\to 0$, and dropping terms of $\mathrm{O}(\epsilon^2)$ in $\hat{A}^{\mathrm{U}(1)}_{r,\bar{z}}$ in Eqs. (3.3), (3.4), and (3.7) for the Higgs and Eqs. (A3), (A6), and (A8) for the gauge field of Ref. 12, the conjecture can be explicitly verified to $\mathrm{O}(\Theta^2)$. Hence, in the neighborhood of the South Pole, approaching it along an azimuthal angle close to $\pi/2$,

$$\hat{\Phi}=\hat{\Phi}^a T^a=\Phi^a T^a;$$

$$\hat{A}_i=\hat{A}^a_i T^a+\hat{A}^0_i\mathbf{1}_4=A^a_i T^a+A^0_i\mathbf{1}_4. \tag{36}$$

The electric charge is then the same as that given in Ref. 1. The magnetic charge will receive a U(1) contribution proportional to $(\partial+\bar{\partial})A_z(z,\bar{z},r\to\infty)$, which using (29), vanishes. Hence, the noncommutative dyon in the neighborhood of the South Pole, carries the same electric and magnetic charges as the commutative dyon of Ref. 1. Their energy will be more than that of the commutative dyons in the neighborhood of the South Pole, though by an infinitesimal amount. As the equality of the commutative and noncommutative electric and magnetic charges is valid only in the neighborhood of the South Pole, these noncommutative dyonic solutions are likely to be stable.

IV. SUMMARY AND DISCUSSION

To summarize, we have shown that noncommutative (with $r-z$ and $r-\overline{z}$ noncommutativity) U(4) SYM possesses static dyonic solutions in the neighborhood of the South Pole of the Riemann sphere or equivalently the negative x^3 axis, that either are the same as the static commutative SU(4) dyonic solutions of Ref. 1 [corresponding to *decoupling of a null U(1) from the SU(4)*] or, have the same electric and magnetic charges as the commutative dyons and differ infinitesimally in their energy [corresponding to *decoupling of a non-null U(1) from the SU(4)*], to *all orders in the noncommutativity parameter*. We have thus shown the decoupling of the U(1) sector, both for null and infinitesimal U(1) components in the neighborhood of the negative x^3 axis. This decoupling to $O(\Theta)$ for the whole of space, was also seen in the context of noncommutative monopole solutions in SYM in Ref. 3. The noncommutative hatted fields are the same as the commutative unhatted fields [we conjecture to all orders in the noncommutativity parameter and show explicitly up to $O(\Theta^2)$]. Thus, we see that the neighborhood of the negative x^3 axis, acts as "denoncommutatifier." It will be interesting to study the same problem using noncommutative ADHMN construction (see Ref. 14 and references therein), and to be able to establish the existence of such solutions using techniques of Ref. 15 using Morse theory. Also, finding similar solutions with $z-\overline{z}$ noncommutativity will be nice.

ACKNOWLEDGMENTS

We thank A. Kumar for useful discussions. We also thank K. L. Panigrahi, R. R. Nayak, S. S. Pal, and G. Bhattacharya for bringing to our notice Refs. 1, 10, and 5.

APPENDIX

In this Appendix, we summarize the asymptotic (w.r.t. to z) expressions for $A^{\mathrm{U}(1)}_{r,z}$ and some expressions involving them necessary to obtain the U(1) components of the gauge field and Higgs. We have used mathematica for arriving at the expressions given in this Appendix.

Using (10), one can explicity write out the expressions for $\hat{\phi}^0$, $\hat{A}^0_z = \det[(P_0 - a_{\Phi,z}\mathbf{1}_4)(P_1 - M_{\Phi,z})\cdot(P_2 - M_{\Phi,z})] + \text{c.c.}$ and $\hat{A}^0_r = z\det[(P_0 - a_r\mathbf{1}_4)(P_1 - M_r)\cdot(P_2 - M_r)] + \text{c.c.}$, using Mathematica, but because of the length of the expressions, we will give only their asymptotic forms.

One gets as $\mathrm{Im}\, z \to \infty$,

$$\hat{\phi}^0, \hat{A}^0_z \sim 2(-1 + a_{\Phi,z}) a^3_{\Phi,z} (b_{\Phi,z} c_{\Phi,z} e_{\Phi,z} f_{\Phi,z})^2. \tag{A1}$$

Simlarly, as $z \to \infty$, one gets

$$\hat{A}^0_r \sim 2(-1 + a_r) a^3_r (b_r c_r e_r f_r)^2 \,\mathrm{Re}\, z. \tag{A2}$$

Hence, we see that if $z \to \infty$ as $z = (\mathrm{Re}\, z)_0 + i\infty$, where $(\mathrm{Re}\, z)_0$ is finite, then $\hat{A}_r$ is nonsingular, else it is singular.

One sees that as $z \to \infty$,

$$\partial \hat{\mathcal{A}}^0_r \sim (-1 + a_r) a^3_r (b_r e_r c_r f_r)^2. \tag{A3}$$

For the purpose of calculation of energy and imposing it to be finite, one requires to calculate $\overline{\partial}\hat{\mathcal{A}}^0_r$, and its asymptotic expression is given by

$$\overline{\partial}\hat{\mathcal{A}}^0_r \sim (-1 + a_r) a^3_r b^2_r c^2_r e^2_r f^2_r. \tag{A4}$$

One also needs to evaluate $\partial\overline{\partial}\hat{\mathcal{A}}^0_r$ as $z \to \infty$, and is given by

$$\partial\overline{\partial}\hat{\mathcal{A}}^0_r \sim (-1 + a_r) a^3_r \frac{b^2_r c_r e^2_r f_r (\sqrt{3} c_r - \sqrt{3} f_r)\overline{z}^2 + \sqrt{3}(b_r e_r c_r)^2 f_r z^2}{|z|^4}. \tag{A5}$$

Also, one one sees that

$$\partial\overline{\partial}(\hat{\phi}^0,A_z^{\hat{0}})\sim -6(-1+a_{\Phi,z})a_{\Phi,z}^3 \times\frac{((c_{\Phi,z}e_{\Phi,z})^2b_{\Phi,z}f_{\Phi,z}+(b_{\Phi,z}f_{\Phi,z})^2c_{\Phi,z}e_{\Phi,z})}{|z|^2}. \tag{A6}$$

For the purpose of solving for the U(1) components of the gauge field, and for getting the magnetic charge of the dyon, one needs to evaluate $(\partial+\overline{\partial})\mathcal{A}_z^0$, and as $z\to\infty$, one gets

$$(\partial+\overline{\partial})\hat{\mathcal{A}}_z^0\sim\frac{b_zc_z^2e_zf_z^2(\sqrt{3}b_z-\sqrt{3}e_z)\overline{z}^2+(c_zf_zb_z^2(-e_zf_z\sqrt{3}e_z+c_ze_z\sqrt{3}e_z)-3c_zf_zb_ze_zc_ze_z)z^2}{|z|^4}. \tag{A7}$$

Two other quantities that one needs to calculate are $(\partial-\overline{\partial})(\hat{\Phi},\hat{A}_z)$ and $\partial((1+|z|^2)^2(\partial+\overline{\partial})\times(\hat{\Phi},\hat{A}_z))$. The former as $z\to\infty$, is given by

$$(\partial-\overline{\partial})(\hat{\phi}^0,\hat{\mathcal{A}}_z^0) \sim\frac{\sqrt{3}(-1+a_i)a_i^3[(b_ie_i)^2c_if_i(c_i-f_i)\overline{z}+(-b_ic_i^2e_i^2f_i(f_i-b_i)+e_ib_i^2c_if_i^2(c_i-e_i))z](z-\overline{z})}{|z|^4}, \tag{A8}$$

The latter as $z\to\infty$ is given by

$$\begin{aligned}\partial((1+|z|^2)^2(\partial+\overline{\partial})(\hat{\phi}^0,\hat{\mathcal{A}}_z^0))&\\ \sim -2(-1+a_i)a_i^3\Bigg(&\sqrt{3}[c_i^2e_i^2b_if_i(-f_i+b_i)+b_i^2f_i^2c_ie_i(c_i-e_i)]z\\ &-(3b_if_i(c_ie_i)^2+3c_ie_i(b_if_i)^2)+\frac{3b_ic_ie_if_i(b_ie_i+c_if_i)\overline{z}^4}{|z|^4}\Bigg).\end{aligned} \tag{A9}$$

Becchi–Rouet–Stora–Tyutin quantization of histories electrodynamics

Duncan Noltingk[a)]
Blackett Laboratory, Imperial College,
Prince Consort Road, London SW7 2BZ, United Kingdom

(Received 3 January 2002; accepted for publication 5 April 2002)

This article is a continuation of earlier work where a classical history theory of pure electrodynamics was developed in which the history fields have *five* components. The extra component is associated with an extra constraint, thus enlarging the gauge group of histories electrodynamics. In this article we quantize the classical theory developed previously by two methods. First we quantize the reduced classical history space to obtain a reduced quantum history theory. Second we quantize the classical BRST-extended history space, and use the Becchi–Rouet–Stora–Tyutin charge to define a ''cohomological'' quantum history theory. Finally, we show that the reduced history theory is isomorphic (as a history theory) to the cohomological history theory. © *2002 American Institute of Physics.*

I. INTRODUCTION

The history projection operator (HPO) approach to consistent histories was inspired by Isham,[1] and developed by Isham and collaborators.[2,3] An HPO theory is concerned with projection operators on the quantum history Hilbert space $\mathcal{E}$ which represent propositions about the entire *history* of the system under consideration. This should be contrasted with standard quantum logic which is concerned with propositions about the system at a particular instant of time. The quantum history theories with which this article will be concerned are described by a pair $(P(\mathcal{E}),\mathcal{D})$ where $P(\mathcal{E})$ is the lattice of projection operators on the Hilbert space $\mathcal{E}$, and $\mathcal{D}$ is the space of decoherence functionals. A decoherence functional is a map $d:P(\mathcal{E})\times P(\mathcal{E})\rightarrow\mathbb{C}$ that satisfies the following conditions:

(1) *Hermiticity:* $d(\alpha,\beta)=d(\beta,\alpha)^*$ for all $\alpha,\beta\in P(\mathcal{E})$.
(2) *Positivity:* $d(\alpha,\alpha)\geqslant 0$ for all $\alpha\in P(\mathcal{E})$.
(3) *Null triviality:* $d(0,\alpha)=0$ for all $\alpha\in P(\mathcal{E})$.
(4) *Additivity:* if $\alpha\perp\beta$, then $d(\alpha\oplus\beta,\gamma)=d(\alpha,\gamma)+d(\beta,\gamma)$, for all $\gamma\in P(\mathcal{E})$.
(5) *Normalization:* $d(1,1)=1$.

The off-diagonal components of the decoherence functional represent the ''quantum interference'' between histories, while the diagonal components are interpreted as the probability that a particular history ''occurs.''

In this article we construct a quantum history theory of pure electrodynamics by two methods. In Sec. II we quantize the reduced classical history space to obtain a reduced history theory $(P(\mathcal{E}^{red}),d^{red})$. In Sec. III we augment the history fields with ghost fields and quantize the extended theory to obtain a representation of the extended algebra on the Becchi–Rouet–Stora–Tyutin- (BRST) extended history space $\mathcal{E}$. We then define $H^*(\Omega)$, the projection operator cohomology, and show that it has a natural lattice structure. In Sec. IV we define $\mathcal{D}_{gf}$, the space of gauge-fixed decoherence functionals, and show that each gauge-fixed decoherence functional in-

a)Electronic mail: d.noltingk@ic.ac.uk

duces a functional $\tilde{d}$ on $H^*(\Omega)$. Our main result is to show that the cohomological history theory $(H^*(\Omega),\tilde{d})$ is isomorphic (as a history theory) to the reduced history theory $(P(\mathcal{E}^{red}),d^{red})$.

II. RADIATION GAUGE QUANTIZATION

A. Preliminaries

The quantum history space arises as the representation space of a certain Lie group, the *history group*, and the associated Lie algebra is the histories analog of the canonical commutation relations. In the histories approach to scalar field theory proposed by Savvidou,[4] there is an inequivalent representation of the history group for each Lorentzian foliation of space–time. By a Lorentzian foliation of space–time we mean a foliation in which each leaf is a spacelike hyperplane. The *Schrödinger* picture fields satisfy the *covariant* history algebra

$$[\hat{\phi}_n(X),\hat{\phi}_n(X')]=0, \tag{1}$$

$$[\hat{\pi}_n(X),\hat{\pi}_n(X')]=0, \tag{2}$$

$$[\hat{\phi}_n(X),\hat{\pi}_n(X')]=i\hbar\,\delta^{(4)}(X-X'), \tag{3}$$

where n is a future pointing timelike unit vector labeling a particular Lorentzian foliation. The fields are genuine space–time fields under the action of a representation of the Poincare group.[4] This Poincare group acts as

$$\hat{\phi}_n(X)\mapsto\hat{\phi}_{\Lambda n}(\Lambda X) \tag{4}$$

and generates changes in the space–time foliation. Heisenberg picture fields can be defined using the time-averaged Hamiltonian which is also foliation dependent. These Heisenberg picture fields are of the form $\hat{\phi}_n(X,s)$, and there is a second representation of the Poincare group in which the boosts act in the ''internal'' time direction s, and leave the foliation fixed.

In a previous paper[5] we considered the extension of the classical analog of the above theory to the case of electrodynamics. It was argued that in order to preserve the two representations of the Poincare group, the history fields should have *five* components as opposed to the usual four. The extra component is associated with the internal time direction. It is important to note that the theory is not covariant under the action of the SO(3,2) isometry group of the space–time manifold $\mathcal{M}\times\mathbb{R}$, but only under the internal and external SO(3,1) subgroups. It was also shown in Ref. 5 how the extra component leads to an extra constraint, and thus to an enlarged gauge group.

The theory in Ref. 5 is concerned with history configuration fields $A^n_M(X)$, and their canonical momenta $E^M_n(X)$. The index M runs from 0 to 4, X is a four-vector and n is a future-pointing timelike unit vector which labels a particular foliation of space–time. These fields can be considered as vectors tangent to the space of embeddings of $\mathcal{M}$ into $\mathcal{N}\simeq\mathcal{M}\times\mathbb{R}$. The history fields satisfy the Poisson algebra

$$\{A^n_M(X),A^n_N(Y)\}=0, \tag{5}$$

$$\{E^M_n(X),E^N_n(Y)\}=0, \tag{6}$$

$$\{A^n_M(X),E^N_n(Y)\}=\delta^N_M\delta^{(4)}(X-Y). \tag{7}$$

The four-vector n can be embedded in $\mathcal{N}$, resulting in a five-vector $\tilde{n}^M$ given in coordinates by $(n,0)$. We also have the five-vector $\tilde{e}^M$ given by (0,1), and we use these vectors to decompose the fields into their temporal components

$$A^n_t(X):=\tilde{n}^MA^n_M(X),\quad A^n_s(X):=\tilde{e}^MA^n_M(X), \tag{8}$$

and similarly for the momentum field. The n-spatial projection tensor is defined as

$$ {}^{n}P^{M}_{N} = \delta^{M}_{N} - \tilde{e}^{M}\tilde{e}_{N} - \tilde{n}^{M}\tilde{n}_{N}, \tag{9} $$

and can be used to decompose fields on the five-dimensional space-time into their "n-spatial" components

$$ {}^{n}A_{M}(X) := {}^{n}P^{N}_{M}A^{n}_{N}(X). \tag{10} $$

We define "n-spatial tensors" in a similar way, e.g.,

$$ {}^{n}F_{MN}(X) := {}^{n}P^{R}_{M}\,{}^{n}P^{S}_{N}F^{n}_{RS}(X). \tag{11} $$

The first-class constraints can now be written as

$$ E^{s}_{n}(X) \approx 0, \tag{12} $$

$$ E^{t}_{n}(X) \approx 0, \tag{13} $$

$$ {}^{n}E^{M}_{\parallel}(X) \approx 0, \tag{14} $$

where the longitudinal component of the electric field is defined by

$$ {}^{n}E_{\parallel}(X) := {}^{n}\partial_{M}\,{}^{n}E^{M}(X). \tag{15} $$

B. Reduced state space

We now augment the constraints with the histories radiation gauge conditions:

$$ A^{n}_{s}(X) = 0, \tag{16} $$

$$ A^{n}_{t}(X) = 0, \tag{17} $$

$$ {}^{n}A_{\parallel}(X) = 0, \tag{18} $$

where

$$ {}^{n}A_{\parallel}(X) := \frac{{}^{n}\partial^{M}\,{}^{n}A_{M}(X)}{\Delta_{n}} \tag{19} $$

and $\Delta_{n} = {}^{n}\partial_{M}\,{}^{n}\partial^{M}$. The six equations (12)–(14) and (16)–(18) form a second class set of constraints and we can follow the usual procedure to find the Dirac brackets of the reduced history space $\mathcal{C}_{n}$. In terms of the transverse fields

$$ {}^{n}A^{\perp}_{M}(X) := {}^{n}A_{M}(X) - {}^{n}\partial_{M}\,{}^{n}A^{\parallel}(X), \tag{20} $$

$$ {}^{n}E^{M}_{\perp}(X) := {}^{n}E^{M}(X) - {}^{n}\partial^{M}\frac{{}^{n}E_{\parallel}(X)}{\Delta_{n}}, \tag{21} $$

they turn out to be

$$ \{{}^{n}A^{\perp}_{M}(X), {}^{n}A^{\perp}_{N}(Y)\}_{D} = 0, \tag{22} $$

$$ \{{}^{n}E^{M}_{\perp}(X), {}^{n}E^{N}_{\perp}(Y)\}_{D} = 0, \tag{23} $$

$$ \{{}^{n}A^{\perp}_{M}(X), {}^{n}E^{N}_{\perp}(Y)\}_{D} = ({}^{n}P^{N}_{M} - \Delta_{n}^{-1}\,{}^{n}\partial_{M}\,{}^{n}\partial^{N})\,\delta^{(4)}(X-Y). \tag{24} $$

The right hand side of this algebra has become explicitly foliation dependent with the non-covariant gauge choice. In the radiation gauge the time-averaged Hamiltonian is

$$H_n^0 = \int d^4X \left(\frac{1}{2} {}^nE_M^\perp \, {}^nE_\perp^M + \frac{1}{4} {}^nF_{MN} \, {}^nF^{MN} \right), \tag{25}$$

where $F_{MN}^n = 2\partial_{[M} A_{N]}^n$ and ${}^nF_{MN}$ is the corresponding n-spatial tensor [cf. Eq. (11)].

C. Quantization

We wish to find an irreducible representation of the commutator algebra

$$[{}^n\hat{A}_M^\perp(X), {}^n\hat{A}_N^\perp(Y)] = 0, \tag{26}$$

$$[{}^n\hat{E}_\perp^M(X), {}^n\hat{E}_\perp^N(Y)] = 0, \tag{27}$$

$$[{}^n\hat{A}_M^\perp(X), {}^n\hat{E}_\perp^N(Y)] = i\hbar ({}^nP_M^N - \Delta_n^{-1} \, {}^n\partial_M \, {}^n\partial^N) \delta^{(4)}(X-Y) \tag{28}$$

on a Hilbert space such that the radiation gauge quantum Hamiltonian is represented by a *self-adjoint* operator. The self-adjointness condition is required to select one of the infinitely many unitarily inequivalent representations of the infinite dimensional algebra (26)–(28). Such a representation exists on the bosonic Fock space $\mathcal{E}^{red} := \mathcal{F}_B[L^2(\mathbb{R}^4)] \otimes \mathcal{F}_B[L^2(\mathbb{R}^4)]$. This space is associated with annihilation and creation operators which obey the following algebra

$$[\hat{a}_a(X), \hat{a}_b(X')] = 0, \tag{29}$$

$$[\hat{a}_a(X), \hat{a}_b^\dagger(X')] = \hbar \, \delta_{ab} \delta^{(4)}(X-X'), \tag{30}$$

for $a = 1,2$. Using the Fourier transformed operators

$$\hat{a}_a^\dagger(K) = \frac{1}{(2\pi)^2} \int d^4X \hat{a}_a^\dagger(X) e^{iK\cdot X}, \tag{31}$$

$$\hat{a}_a(K) = \frac{1}{(2\pi)^2} \int d^4X \hat{a}_a(X) e^{-iK\cdot X}, \tag{32}$$

we define field operators satisfying the algebra (26)–(28) in the following way:

$${}^n\hat{A}_M^\perp(X) = \frac{1}{(2\pi)^2} \sum_{a=1}^2 \int \frac{d^4K}{\sqrt{2\omega_n(K)}} \, {}^n\epsilon_M^a(K) [\hat{a}_a(K) e^{-iK\cdot X} + \hat{a}_a^\dagger(K) e^{iK\cdot X}], \tag{33}$$

$${}^n\hat{E}_\perp^M(X) = \frac{1}{i(2\pi)^2} \sum_{a=1}^2 \int d^4K \sqrt{\frac{\omega_n(K)}{2}} \, {}^n\epsilon_a^M(K) [\hat{a}_a(K) e^{-iK\cdot X} - \hat{a}_a^\dagger(K) e^{iK\cdot X}]. \tag{34}$$

In the above expressions, K is a four-vector representing the four-momentum of a photon and $\omega_n(K)$ is the modulus of the n-spatial four vector $(\delta_\nu^\mu - n^\mu n_\nu) K^\nu$ with respect to the Minkowski metric. For each K, we define the five-vector $\tilde{K}$ to be the embedding of K into the five-dimensional space–time $\mathcal{N}$. In coordinates (X,s) the vector $\tilde{K}$ can be written as $(K,0)$. The five-vectors ${}^n\epsilon_a^M(K)$ are a pair of mutually orthogonal, n-spatial unit vectors which are in addition orthogonal to the vector ${}^n\tilde{K}^M = {}^nP_N^M \tilde{K}^N$. These vectors satisfy the following completeness relation:

$$\sum_{a=1}^2 {}^n\epsilon_M^a(K) \, {}^n\epsilon_a^N(K) = {}^nP_M^N - \frac{{}^n\tilde{K}_M \, {}^n\tilde{K}^N}{\omega_n(K)^2}. \tag{35}$$

This property ensures that the algebra defined by Eqs. (26)–(28) is satisfied. Using the fact that the polarization vectors are orthonormal,

$$ {}^{n}\epsilon_a^M(K)\,{}^{n}\epsilon_M^b(K)=\delta_a^b, \tag{36}$$

the normal-ordered time-averaged Hamiltonian can be written

$$\hat{H}_n^0=\sum_{a=1}^{2}\int d^4K\,\omega_n(K)\hat{a}_a^\dagger(K)\hat{a}_a(K). \tag{37}$$

This Hamiltonian generates translations in internal time, and it is easy to see that

$$e^{-is\hat{H}_n^0/\hbar}\hat{a}_a(K)e^{is\hat{H}_n^0/\hbar}=e^{is\omega_n(K)}\hat{a}_a(K). \tag{38}$$

Following the argument in Ref. 3, these transformations are unitarily implementable and we conclude that $\hat{H}_n^R$ exists as a self-adjoint operator in this representation. Therefore, for each n, there exists a unitarily inequivalent representation of the radiation gauge history algebra on the Fock space $\mathcal{E}^{red}$.

D. The decoherence functional

In the case when history propositions are realized as the lattice of projection operators on a Hilbert space $\mathcal{V}$, every decoherence functional d can be written in the form[6]

$$d(\alpha,\beta)=Tr_{\mathcal{V}\otimes\mathcal{V}}(\alpha\otimes\beta\Theta_d), \tag{39}$$

where Θ_d is an operator on $\mathcal{V}\otimes\mathcal{V}$. In fact Θ_d must satisfy certain conditions for d to be a decoherence functional.[6] In the case of the scalar field, the operator Θ is dependent on the foliation, and can be written[4,12]

$$\Theta_n=\langle 0|\rho_{-\infty}|0\rangle(\mathcal{SU})_n^\dagger\otimes(\mathcal{SU})_n. \tag{40}$$

The quantum history space for the scalar field is the bosonic Fock space $\mathcal{F}_B[L^2(\mathbb{R}^4)]$. To each operator O, on the base space $L^2(\mathbb{R}^4)$, there is an associated operator on $\mathcal{F}_B[L^2(\mathbb{R}^4)]$ defined by

$$\Gamma(O)=O\oplus(O\otimes O)\oplus\cdots. \tag{41}$$

Using this construction, the operator $(\mathcal{SU})_n$ can be written

$$(\mathcal{SU})_n=\Gamma(1+i\sigma_n), \tag{42}$$

where $\sigma_n=n^\mu\partial_\mu+(-\Delta_n+m^2)^{1/2}$ is an operator on the base Hilbert space $L^2(\mathbb{R}^4)$. The operator σ_n is related to the canonical history action S_n in the following simple way:[4]

$$e^{isS_n}=\Gamma(e^{is\sigma_n}). \tag{43}$$

Equation (43) can be used to *define* the decoherence functional corresponding to a given action operator S on a Fock space $\mathcal{F}=\mathcal{F}_B[\mathcal{H}]$. First S defines σ, the "generator" of the decoherence functional, which is the operator on $\mathcal{H}$ given by

$$e^{isS}=\Gamma(e^{is\sigma}). \tag{44}$$

Now the decoherence functional is defined by the operator on $\mathcal{F}\otimes\mathcal{F}$ given by

$$\Theta_S=\langle 0|\rho_{-\infty}|0\rangle\Gamma(1+i\sigma)^\dagger\otimes\Gamma(1+i\sigma). \tag{45}$$

The reduced canonical history action of electrodynamics in the radiation gauge is

$$S_n^{red} = \int d^4X ({}^n\hat{E}_\perp^M \partial_n^t {}^n\hat{A}_M^\perp - \hat{H}_n^0), \tag{46}$$

where $\partial_n^t := \tilde{n}^M \partial_M$. The corresponding generator of the decoherence functional is the operator σ_n^{red}, defined on vectors of the form $f \otimes g$ in the base Hilbert space $\mathcal{H}^{red} = L^2(\mathbb{R}^4) \otimes L^2(\mathbb{R}^4)$ by

$$\sigma_n^{red}(f \otimes g) = (n^\mu \partial_\mu - \Delta_n^{1/2}) f \otimes (n^\mu \partial_\mu - \Delta_n^{1/2}) g, \tag{47}$$

and extended to an operator on $\mathcal{H}^{red}$ by linearity. The associated decoherence functional is denoted d_n^{red}. The pair $(P(\mathcal{E}^{red}), d_n^{red})$ is the reduced history theory of pure quantum electrodynamics with respect to the foliation n.

III. BRST COHOMOLOGY

As shown in the previous section, electrodynamics can be quantized starting from the reduced state space. This is because the reduced state space has a simple structure, in particular it is a linear space. This is not the case for other constrained field theories such as Yang–Mills theory and gravity. For such theories another, more general, approach is needed. The BRST formalism[7] is a powerful approach to the quantization of constrained systems, and can be formulated using rigorous operator methods. Motivated by these considerations we develop the BRST approach to the quantum theory of histories electrodynamics. In this section we follow closely the notation of Ref. 7.

A. Classical BRST cohomology

The central idea in the BRST formalism is to extend the state space by including fermionic ''ghost'' fields. The extended state space maintains manifest covariance and locality, unlike the reduced state space approach. The BRST charge is constructed from the ghost fields and the constraints and, in the classical case, is a functional on the extended state space. The BRST charge generates *nilpotent* canonical transformations on the extended state space. The physical degrees of freedom are identified with the corresponding set of cohomology classes. The idea is that the ghost fields cancel out the gauge fields in the cohomology.

We begin by briefly recalling the BRST approach to the standard classical theory of electrodynamics as given in Chap. 19 of Ref. 7. We have fields $E^\mu(\underline{x})$ and $A_\mu(\underline{x})$ satisfying the algebra

$$\{A_\mu(\underline{x}), E^\nu(\underline{x}')\} = \delta_\mu^\nu \delta^{(3)}(\underline{x} - \underline{x}'), \tag{48}$$

and a pair of constraints $E^0(\underline{x}) \approx 0$ and $\partial_i E^i(\underline{x}) \approx 0$. Corresponding to the first constraint we add a ghost pair $\eta(\underline{x}), \mathcal{P}(\underline{x})$ with

$$\{\mathcal{P}(\underline{x}), \eta(\underline{x}')\} = -\delta^{(3)}(\underline{x} - \underline{x}'), \tag{49}$$

where the bracket is *symmetric* representing the fact that the ghost fields are fermionic. The Lagrange multiplier field $A_0(\underline{x})$ and its conjugate momentum are associated with an antighost field $\overline{C}(\underline{x})$ and conjugate momentum $\rho(\underline{x})$ satisfying

$$\{\rho(\underline{x}), \overline{C}(\underline{x}')\} = -\delta^{(3)}(\underline{x} - \underline{x}'). \tag{50}$$

The BRST charge is

$$\Omega = \int d^3\underline{x} [-i\rho E^0 + \eta \partial_i E^i], \tag{51}$$

and Ω generates *nilpotent* canonical transformations which are explicitly given in Ref. 7, and we denote by τ, that is $\tau(F) := \{\Omega, F\}$. A functional F is said to be BRST-closed if and only if

$$\tau(F)=0, \tag{52}$$

and a functional G is said to be BRST-exact if and only if

$$G=\tau(G'), \tag{53}$$

for some functional G'. By the nilpotency of τ closed functionals are exact, but the converse is not necessarily true, and the set of functionals which are closed but not exact is isomorphic to the set of functionals on the reduced state space. In addition,[7] there is a natural Poisson algebra defined on the set of cohomology classes which is a Poisson subalgebra of the extended Poisson algebra, and is isomorphic to the Poisson algebra of the reduced classical history space.

This analysis is easy to extend to the classical history theory of electrodynamics. Corresponding to the constraint ${}^nE_{\|}(X)\approx 0$ we introduce a pair of fermionic, scalar ghost history fields $\eta_n^1(X)$ and $\mathcal{P}_n^1(X)$ which satisfy the algebra

$$\{\mathcal{P}_n^1(X),\eta_n^1(X')\}=-\delta^{(4)}(X-X'). \tag{54}$$

In addition we have two Lagrange multipliers in the history theory so we add two antighost fields $C_a^n(X)$ $(a\in\{1,2\})$, along with their conjugate momenta $\rho_n^a(X)$. These fields satisfy

$$\{\rho_n^a(X),C_b^n(X')\}=-\delta_b^a\delta^{(4)}(X-X'). \tag{55}$$

In this way the ring of functions on the extended classical history space is given the structure of a graded Lie algebra. The history BRST charge Ω_n' is defined as

$$\Omega_n'=\int d^4X[-i\rho_n^1E_n^t-i\rho_n^2E_n^s+\eta_n^1\,{}^nE_{\|}], \tag{56}$$

and generates canonical transformations denoted by τ^n. The transformations are

$$\tau^n({}^nA^{\|})=\eta_n^1,\quad \tau^n(\eta_n^1)=0,\quad \tau^n(\mathcal{P}_n^1)={}^nE^{\|},\quad \tau^n({}^nE^{\|})=0, \tag{57}$$

$$\tau^n(A_s^n)=-i\rho_n^1,\quad \tau^n(A_t^n)=-i\rho_n^2,\quad \tau^n(\rho_n^1)=0,\quad \tau^n(\rho_n^2)=0, \tag{58}$$

$$\tau^n(C_n^1)=iE_n^s,\quad \tau^n(C_n^2)=iE_n^t,\quad \tau^n(E_n^s)=0,\quad \tau^n(E_n^t)=0, \tag{59}$$

$$\tau^n({}^nA^{\perp})=0,\quad \tau^n({}^nE_{\perp})=0. \tag{60}$$

From these transformations it is clear that τ^n is nilpotent, and thus defines a cohomology on the space of functionals on the BRST-extended classical history space. The classical history BRST cohomology, $H_{cl}^*(\Omega_n')$, is defined to be the space of equivalence classes of BRST-closed functionals modulo BRST-exact ones. The only fields which are closed but not exact are ${}^nA^{\perp}$ and ${}^nE_{\perp}$, and so the cohomology classes are in bijective correspondence with functionals of the transverse fields. Thus $H_{cl}^*(\Omega_n')$ is isomorphic to the space of functionals on the reduced classical history space.

B. Operator quantization

The BRST operator quantization of standard electrodynamics proceeds by expanding the quantum fields in terms of operators which satisfy the algebra of creation and annihilation operators, thus defining a representation of the field algebra on a Fock space. Then, using the quantum BRST charge $\hat{\Omega}$, which is the operator corresponding to the functional in Eq. (51), a cohomology can be defined on operators on the quantum Hilbert space as follows. An operator $\hat{O}$ is defined to be *BRST-closed* if and only if

$$[\hat{\Omega},\hat{O}]=0, \tag{61}$$

and an operator $\hat{Q}$ is *BRST-exact* if and only if

$$\hat{Q}=[\hat{\Omega},\hat{W}] \tag{62}$$

for some operator $\hat{W}$. Because $\hat{\Omega}$ generates nilpotent transformations and the commutator satisfies the graded Jacobi identity, a BRST-exact operator is necessarily BRST-closed. However, the converse is not true and two BRST-closed operators $\hat{O}$ and $\hat{O}'$ are defined to be BRST-equivalent if $\hat{O}'=\hat{O}+\hat{Q}$ for some BRST-exact operator $\hat{Q}$. The *operator cohomology* of $\hat{\Omega}$, $H^{*}_{op}(\hat{\Omega})$, is defined to be the set of equivalence classes of closed operators modulo this equivalence relation. The expansion of the fields in terms of creation and annihilation operators is given in Ref. 7, and it follows that the quantum BRST charge can be written in the form

$$\hat{\Omega}=\int d^3\underline{k}[\hat{c}^{\dagger}(\underline{k})\hat{a}(\underline{k})+\hat{a}^{\dagger}(\underline{k})\hat{c}(\underline{k})]. \tag{63}$$

Now the nonphysical field modes ''cancel out'' the ghost modes in the cohomology or, more precisely, the operator cohomology is isomorphic to the set of operators on the reduced quantum Hilbert space. This is a consequence of a general result known as the ''quartet mechanism'' [7] which applies to any quantum theory in which the BRST operator is the sum of terms of the form (63).

C. Quantum history theory in quartet form

For the Fock space quantization of a BRST-extended theory it is necessary that the constraints come in pairs allowing the definition of creation and annihilation operators as complex linear combinations of pairs of fields. In the history theory there are three constraints which cannot be grouped in pairs for the Fock space quantization. To proceed we include an extra Lagrange multiplier along with the associated momenta and ghosts. More precisely, we introduce a bosonic scalar field $\hat{\lambda}_n(X)$, the Lagrange multiplier corresponding to the constraint $\hat{E}^s_n(X)\approx 0$. Its canonical momentum is denoted $\hat{B}_n(X)$ and is constrained to vanish

$$\hat{B}_n(X)\approx 0. \tag{64}$$

The associated ghost pair is $(\hat{\eta}^2_n,\hat{\mathcal{P}}^2_n)$. Now the fields do form ''quartets,'' and the results of Ref. 7 can be applied. The detailed transformations of the fields into the ''quartet'' form have been relegated to the Appendix. The important result is that the bosonic fields can be defined in terms of six pairs of bosonic creation and annihilation operators:

$$[\hat{a}_a(K),\hat{b}^{\dagger}_b(K')]=-\hbar\,\delta_{ab}\delta^{(4)}(K-K'), \tag{65}$$

$$[\hat{b}_a(K),\hat{a}^{\dagger}_b(K')]=-\hbar\,\delta_{ab}\delta^{(4)}(K-K'), \tag{66}$$

$$[{}^{\perp}\hat{a}_a(K),{}^{\perp}\hat{a}^{\dagger}_b(K')]=\hbar\,\delta_{ab}\delta^{(4)}(K-K'), \tag{67}$$

for $a,b\in\{1,2\}$. So we have a representation of the bosonic part of the BRST-extended history algebra on the Fock space $\mathcal{E}^B$ which is defined as the tensor product of six copies of the bosonic Fock space $\mathcal{F}_B[L^2(\mathbb{R}^4)]$. Similarly, the fermionic fields can be expanded in terms of four pairs of fermionic creation and annihilation operators, which satisfy the anti-commutators

$$[\hat{c}_a(K),\hat{e}^{\dagger}_b(K')]=-\hbar\,\delta_{ab}\delta^{(4)}(K-K'), \tag{68}$$

$$[\hat{e}_a(K),\hat{c}^{\dagger}_b(K')]=-\hbar\,\delta_{ab}\delta^{(4)}(K-K'), \tag{69}$$

where $a,b\in\{1,2\}$. In this way we have a representation of the fermionic part of the BRST-extended history algebra on the Fock space $\mathcal{E}^F$, which is defined as the tensor product of four copies of the fermionic Fock space $\mathcal{F}_F[L^2(\mathbb{R}^4)]$. The whole algebra is represented on the space $\mathcal{E}=\mathcal{E}^B\otimes\mathcal{E}^F$, which we call the BRST-extended quantum history space.

D. Quantum operator cohomology

The extended BRST charge is

$$\hat{\Omega}_n=\int d^4X[-i\hat{\rho}^1_n\hat{E}^s_n+\hat{\eta}^1_n\,{}^n\hat{E}_\parallel-i\hat{\rho}^2_n\hat{E}^t_n+\hat{\eta}^2_n\hat{B}_n], \tag{70}$$

and in terms of oscillators it takes the n-independent form

$$\hat{\Omega}=\sum_{a=1}^{2}\int d^4K[\hat{c}^\dagger_a(K)\hat{a}_a(K)+\hat{a}^\dagger_a(K)\hat{c}_a(K)]. \tag{71}$$

The anti-Hermitian ghost number operator $\hat{\mathcal{G}}$ is defined in terms of oscillators as

$$\hat{\mathcal{G}}=\sum_a\int d^4K(\hat{c}^\dagger_a(K)\hat{e}_a(K)-\hat{e}_a(K)^\dagger\hat{c}_a(K)). \tag{72}$$

Any operator $\hat{O}$ on $\mathcal{E}$ can be decomposed in components of definite ghost number

$$\hat{O}=\sum_g\hat{O}_g,\quad [\hat{\mathcal{G}},\hat{O}_g]=g\hat{O}_g,\quad g\in\mathbb{Z}. \tag{73}$$

It follows from these definitions that all bosonic fields are of ghost number zero, the fields $\hat{\eta}^a$ and $\hat{\rho}^a$ are of ghost number $+1$, and $\hat{\mathcal{P}}^a$ and $\hat{C}^a$ are of ghost number -1. Vectors in the nonzero eigenspaces of $\hat{\mathcal{G}}$ have an ill-defined scalar product, therefore a ghost number zero condition is often imposed on the physical states. However, in the Fock space quantization the ghost number zero condition is automatically satisfied in the cohomology classes.

From Eq. (70) it is clear that for the case of histories electrodynamics the operators $\hat{\eta}^a_n,\hat{\rho}^a_n,{}^n\hat{E}_\parallel,\hat{E}^s_n,\hat{E}^t_n,\hat{B}_n,{}^n\hat{A}^\perp,{}^n\hat{E}_\perp$ are closed. Similarly, the operators $\hat{\eta}^a_n,\hat{\rho}^a_n,{}^n\hat{E}_\parallel,\hat{E}^s_n,\hat{E}^t_n,\hat{B}_n$ are exact; for example, the smeared ghost field can be written

$$\hat{\eta}^1_n(f)=[\hat{\Omega},\hat{A}^\parallel_n(f)]. \tag{74}$$

The transverse field operators are closed but not exact.

E. Projection operator cohomology

In a history theory it is projection operators that appear in the decoherence functional, and operators which are not projectors lack a direct physical interpretation. In the equivalence classes of $H^*_{op}(\hat{\Omega})$, projection operators are identified with operators which are not projection operators. This identification is unnatural from the histories perspective, so in this subsection we define an equivalence relation directly on the lattice of projectors. We then use this equivalence relation to define $H^*(\hat{\Omega})$, the *projection operator cohomology* associated with $\hat{\Omega}$. Finally we show that $H^*(\hat{\Omega})$ can be given the structure of a lattice, and that this lattice is isomorphic to the lattice of projection operators on the reduced quantum history space.

Definition 3.5.1: Given two closed projectors α and β, we say that "α is an exact fine-graining of β," written $\alpha\preccurlyeq\beta$, if and only if $\beta=\alpha+\gamma$ for some projection operator γ which is exact (i.e., $\gamma=[\hat{\Omega},\hat{Q}]$ for some operator $\hat{Q}$) and disjoint to α.

The relation $\preccurlyeq$ is a partial order. The *primitive* part of α is denoted α_0 and is defined as the limit of exact fine-grainings of α. A unique α_0 exists for each closed α because $\preccurlyeq$ is a partial order. If α is exact, then α_0 is the zero projector. If α is closed but not exact, then α_0 projects onto the spectrum of a closed but not exact field operator. For histories electrodynamics we have seen that the closed but not exact field operators are the transverse field operators, and so closed primitive projectors are in bijective correspondence with elements of $P(\mathcal{E}^{red})$.

Definition 3.5.2: Two BRST-closed projection operators α and β are said to be BRST-equivalent *if and only if $\alpha_0=\beta_0$.*

The projection operator cohomology $H^*(\hat{\Omega})$ is defined as the space of closed projection operators modulo this equivalence relation, and elements of $H^*(\hat{\Omega})$ are identified with *physical* propositions. Given a primitive projection operator α_0, the equivalence class containing α_0 is the collection of all exact coarse-grainings of α_0. The statement "α is an *exact fine-graining* of β" is equivalent to the statement "β is an *exact coarse-graining* of α." Let $[\alpha]$ denote the equivalence class containing the closed projector α. The map $\pi:[\alpha]\mapsto\alpha_0$ is well-defined on $H^*(\hat{\Omega})$, and is in fact an isomorphism between $H^*(\hat{\Omega})$ and $P(\mathcal{E}^{red})$; the inverse is given by $\pi^{-1}:\alpha_0\mapsto[\alpha_0]$. In order to give $H^*(\hat{\Omega})$ the structure of a lattice, we need to examine the geometry of the linear subspaces associated to closed and exact projection operators.

Definition 3.5.3: A BRST-closed subspace $L\subset\mathcal{E}$ is a topologically closed linear subspace of $Ker(\hat{\Omega})$.

Proposition 3.5.4: BRST-closed projection operators are in bijective correspondence with BRST-closed subspaces of $\mathcal{E}$.

Proof: Each projection operator α is associated with a topologically closed linear subspace $L_\alpha\subset\mathcal{E}$. If α is a BRST-closed projection operator, i.e., $[\hat{\Omega},\alpha]=0$, then by writing α in Dirac notation as

$$\alpha=\sum_i |l_i\rangle\langle l_i|, \tag{75}$$

where $|l_i\rangle$ is a basis of L_α, it follows from the independence of the basis vectors and the Hermiticity of $\hat{\Omega}$ that $\hat{\Omega}|l\rangle=0$ for all $|l\rangle\in L_\alpha$. Therefore $L_\alpha\subset\mathrm{Ker}(\hat{\Omega})$.

Conversely, each BRST-closed subspace is associated with a BRST-closed projection operator because $\hat{\Omega}$ is self-adjoint. □

In the case of histories electrodynamics BRST-closed subspaces are spanned by vectors created by the operators ${}^{\perp}\hat{a}_a^\dagger,\hat{a}_a^\dagger,\hat{c}_a^\dagger$ acting on the cyclic vacuum state.

Definition 3.5.5: A BRST-exact subspace $M\subset\mathcal{E}$ is a topologically closed linear subspace of $\mathrm{Im}(\hat{\Omega})$.

Proposition 3.5.6: BRST-exact projection operators are in bijective correspondence with BRST-exact subspaces of $\mathcal{E}$.

Proof: A BRST-exact projection operator can be written in the form $\gamma=[\hat{\Omega},\hat{Q}]$ for some operator $\hat{Q}$. γ is closed, and so is associated with a BRST-closed subspace $M_\gamma\subset\mathcal{E}$. Now

$$\gamma|m\rangle=[\hat{\Omega},\hat{Q}]|m\rangle=\hat{\Omega}(\hat{Q}|m\rangle)\quad\forall|m\rangle\in M_\gamma \tag{76}$$

because $\hat{\Omega}|m\rangle=0$. However, $\gamma|m\rangle=|m\rangle$ for any $|m\rangle\in M_\gamma$ so

$$|m\rangle=\hat{\Omega}(\hat{Q}|m\rangle)\quad\forall|m\rangle\in M_\gamma, \tag{77}$$

and hence $M_\gamma\subset\mathrm{Im}(\hat{\Omega})$.

Conversely, each BRST-exact subspace M with basis $|m_i\rangle$ is associated with an exact projection operator γ,

$$\gamma=\sum_i |m_i\rangle\langle m_i|=\left[\hat{\Omega},\sum_i |u_{m_i}\rangle\langle m_i|\right], \tag{78}$$

where $|u_{m_i}\rangle$ is any vector such that $\hat{\Omega}|u_{m_i}\rangle=|m_i\rangle$. □

In the case of histories electrodynamics BRST-exact subspaces are spanned by vectors created by the operators $\hat{a}_a^\dagger,\hat{c}_a^\dagger$ on the vacuum state.

Definition 3.5.7: A primitive subspace $R\subset\mathcal{E}$ is a BRST-closed subspace with no BRST-exact proper subspaces. The closure of the union of all primitive subspaces is denoted $\mathcal{E}_0$.

Proposition 3.5.8: Primitive projection operators are in bijective correspondence with primitive subspaces of $\mathcal{E}$.

Proof: Let α_0 be a primitive projector. Then the only exact fine graining of α_0 is α_0 itself. This implies that the linear subspace associated with α_0 has no BRST-exact proper subspaces.

Conversely, because a primitive subspace has no BRST-exact proper subspaces it follows that the corresponding projection operator must be a limit of exact fine-grainings, and thus primitive.□

In the case of histories electrodynamics primitive subspaces are spanned by vectors created by the action of the transverse creation operators ${}^\perp\hat{a}_a^\dagger$ on the vacuum state.

From the above discussion it follows that $\mathcal{E}_0$ and $\mathrm{Im}(\hat{\Omega})$ are disjoint, and that the closure of $\mathcal{E}_0\cup\mathrm{Im}(\hat{\Omega})$ is $\mathrm{Ker}(\hat{\Omega})$. Therefore every exact projector is disjoint to every primitive projector, and $\mathrm{id}_0+\mathrm{id}_{\mathrm{Im}}=\mathrm{id}_{Ker}$, where $\mathrm{id}_0,\mathrm{id}_{\mathrm{Im}}$ and id_{Ker} are the identity operators on $\mathcal{E}_0,\mathrm{Im}(\hat{\Omega})$ and $\mathrm{Ker}(\hat{\Omega})$, respectively. These results can be used to prove the following theorem.

Theorem 3.5.9: *(i) The lattice $P(Ker(\hat{\Omega}))$ induces a lattice structure on $H^*(\hat{\Omega})$ by*

$$[\alpha]\wedge[\beta]:=[\alpha\wedge\beta], \tag{79}$$

$$[\alpha]\vee[\beta]:=[\alpha\vee\beta], \tag{80}$$

$$\neg[\alpha]:=[\neg\alpha]. \tag{81}$$

(ii) The map π is a lattice isomorphism of $H^*(\hat{\Omega})$ and $P(\mathcal{E}^{red})$.

Proof:

(i) We have to show that the definitions give the same results when evaluated on different members of an equivalence class. We define the maximal exact part of α to be the unique exact projector γ_α such that $\alpha=\alpha_0+\gamma_\alpha$. Every exact subspace is orthogonal to every primitive subspace so $\alpha\wedge\beta=\alpha_0\wedge\beta_0+\gamma_\alpha\wedge\gamma_\beta$. The intersection of two exact subspaces is exact so $\gamma_\alpha\wedge\gamma_\beta$ is exact, and $[\alpha\wedge\beta]=[\alpha_0\wedge\beta_0]$. In a similar way we have $[\alpha\vee\beta]=[\alpha_0\vee\beta_0]$. Finally, consider $\neg\alpha=\mathrm{id}_{Ker}-(\alpha_0+\gamma_\alpha)$ which can be written $\neg\alpha=(\mathrm{id}_0-\alpha_0)+(\mathrm{id}_{\mathrm{Im}}-\gamma_\alpha)$. Now $\mathrm{id}_{\mathrm{Im}}-\gamma_\alpha$ is exact, so $[\neg\alpha]=[\mathrm{id}_0-\alpha_0]$. Similarly we have $\neg\alpha_0=(\mathrm{id}_0-\alpha_0)+\mathrm{id}_{\mathrm{Im}}$ so $[\neg\alpha_0]=[\mathrm{id}_0-\alpha_0]=[\neg\alpha]$.

(ii) It is straightforward to check that
(a) $\pi([\alpha]\wedge[\beta])=\pi[\alpha]\wedge\pi[\beta]$,
(b) $\pi([\alpha]\vee[\beta])=\pi[\alpha]\vee\pi[\beta]$, and
(c) $\pi(\neg[\alpha])=\neg\pi[\alpha]$,
where the lattice operations on the right hand side of the above equations are defined in $P(\mathcal{E}^{red})$. □

Thus the projection operator cohomology is isomorphic to the lattice of projection operators on the reduced history space. In order to show that the corresponding history theories are ''the same'' we first investigate the space of decoherence functionals on the BRST-extended quantum history space.

IV. GAUGE-FIXED DECOHERENCE FUNCTIONALS

To each gauge-fixed action operator on $\mathcal{E}$, there corresponds a gauge-fixed decoherence functional. The gauge-fixed decoherence functionals assign nontrivial values to propositions regarding the gauge and ghost fields. However, as we shall see, each gauge-fixed decoherence functional induces a well-defined functional on $H^*(\hat{\Omega})$ in such a way that the resulting history theory is equivalent to the reduced quantum history theory.

A. Radiation and Feynman gauges

We begin by giving two explicit examples of gauge-fixed decoherence functionals. The radiation gauge corresponds to the following canonical action

$$\hat{S}_n^R = \hat{V}_n - \hat{H}_n^0, \tag{82}$$

where the Louiville operator is the sum of three parts:

(1) a gauge-invariant part $\hat{V}_n^0$,

$$\hat{V}_n^0 = \int d^4X \, {}^n\hat{E}_\perp^M \partial_n^t \, {}^n\hat{A}_M^\perp, \tag{83}$$

(2) a ghost part

$$\hat{V}_n^{gh} = \int d^4X \sum_{a=1}^{2} (\hat{\mathcal{P}}_n^a \partial_n^t \hat{\eta}_n^a + \hat{\rho}_n^a \partial_n^t \hat{C}_n^a), \tag{84}$$

(3) a gauge part

$$\hat{V}_n^{ga} = \int d^4X (\hat{E}_n^t \partial_n^t \hat{A}_t^n + \hat{E}_n^s \partial_n^t \hat{A}_s^n + {}^n\hat{E}_\parallel^M \partial_n^t \, {}^n\hat{A}_M^\parallel + \hat{B}_n \partial_n^t \hat{\lambda}_n). \tag{85}$$

The gauge-invariant Hamiltonian $\hat{H}_n^0$ is given by

$$\hat{H}_n^0 = \int d^4X \left(\frac{1}{2} \, {}^n\hat{E}_M^\perp \, {}^n\hat{E}_\perp^M + \frac{1}{4} \, {}^n\hat{F}_{MN} \, {}^n\hat{F}^{MN} \right). \tag{86}$$

Using an argument similar to that in Sec. II, it follows that the normal ordered Hamiltonian exists as a self-adjoint operator on $\mathcal{E}$. The Louiville operator also exists, and therefore so does the radiation gauge action $\hat{S}_n^R$. If the gauge and ghost fields vanish initially, then they vanish identically on the extrema of this action. However, note that the extrema of this action satisfy the constraints if and only if the constraints are satisfied initially.

Let $\mathcal{H}_0 \simeq L^2(\mathbb{R}^4) \otimes L^2(\mathbb{R}^4)$ denote the base Hilbert space of the primitive Fock space $\mathcal{E}_0$, i.e., $\mathcal{E}_0 = \mathcal{F}_B[\mathcal{H}_0]$. Then the generator of the decoherence functional associated with the radiation gauge action acts on vectors $f \otimes g \in \mathcal{H}_0$ as

$$\sigma_n^R(f \otimes g) = \left(n^\mu \partial_\mu - \Delta_n^{1/2} \right) f \otimes \left(n^\mu \partial_\mu - \Delta_n^{1/2} \right) g, \tag{87}$$

and is extended to an operator on $\mathcal{H}_0$ by linearity. The radiation gauge Hamiltonian commutes with the gauge and ghost fields. Therefore, as argued in Ref. 9, projectors onto the gauge and ghost fields form a canonical consistent set and the probabilities assigned to these projectors are just the probability in the initial state. This implies that if either ϵ or κ is a projector onto subspaces of the orthogonal complement of $\mathcal{E}_0$, and the initial density matrix contains no gauge or ghost modes, then

$$d^R(\epsilon, \kappa) = 0. \tag{88}$$

This completes the definition of d^R.

In the "Feynman gauge" all fields satisfy the wave equation internally. Let $\mathcal{H}$ denote the base Hilbert space of the BRST-extended quantum history space $\mathcal{E}$. A vector in $\mathcal{H}$ is a linear combination of homogeneous vectors of the form

$$v = \otimes_{i=1}^{10} v_i, \tag{89}$$

where $v_i \in L^2(\mathbb{R}^4)$. The generator of the Feynman gauge decoherence functional is defined on homogeneous vectors by

$$\sigma_n^F v = \otimes_{i=1}^{10} (n^\mu \partial_\mu - \Delta_n^{1/2}) v_i, \tag{90}$$

and is extended to an operator on $\mathcal{H}$ by linearity.

B. Gauge transformations

In this subsection we investigate gauge transformations. For simplicity we consider the constraint $\hat{E}_n^t \approx 0$, but analogous remarks apply to the other three constraints.

In the operator cohomology, the constraint $\hat{E}_n^t \approx 0$ is identified with operators of the form

$$\hat{D}_n^t = \hat{E}_n^t + [\hat{\Omega}, \hat{Q}]. \tag{91}$$

The operator $\hat{D}_n^t$ generates gauge transformations in the gauge field $\hat{A}_t^n$, and also in the ghost fields. We require that the the ghost number zero eigenspace of $\hat{\mathcal{G}}$ is mapped into itself under gauge transformations, which implies that $[\hat{\mathcal{G}}, \hat{D}_n^t] = 0$. As $\hat{\Omega}$ is a ghost number 1 operator, the operator $\hat{Q}$ must be of ghost number -1. In addition we choose $\hat{Q}$ to be self-adjoint, so that $\hat{D}_n^t$ generates unitary transformations.

$\hat{D}_n^t$ is exact, and can be written as $[\hat{\Omega}, \hat{G}_n]$ where $\hat{G}_n = \hat{C}_n^1 + \hat{Q}$. It follows from the Jacobi identity that

$$[\hat{D}_n^t, \hat{O}] = [[\hat{\Omega}, \hat{G}_n], \hat{O}] = [[\hat{G}_n, \hat{O}], \hat{\Omega}], \tag{92}$$

if $\hat{O}$ is a closed operator. Thus closed operators are mapped into exact operators by infinitesimal gauge transformations. Under finite gauge transformations, closed operators transform as

$$\hat{O} \mapsto \hat{U} \hat{O} \hat{U}^\dagger = \hat{O} + [\hat{\Omega}, \hat{W}], \tag{93}$$

where $\hat{W}$ is a ghost number -1 operator. Therefore, gauge transformations act trivially on the equivalence classes of the operator cohomology.

As the gauge transformations are unitary, they map projection operators onto projection operators and, because $\mathcal{E}_0$ and $\mathrm{Im}(\hat{\Omega})$ are disjoint, exact self-adjoint operators commute with primitive projectors. Therefore, the action of a gauge transformation on a BRST-closed projector, $\alpha = \alpha_0 + \gamma_\alpha$, is

$$\alpha \mapsto \hat{U} \alpha \hat{U}^\dagger = \alpha_0 + \hat{U} \gamma_\alpha \hat{U}^\dagger. \tag{94}$$

This shows that the gauge group acts trivially on $H^*(\hat{\Omega})$, and that primitive projectors are *gauge invariant*.

There is also a natural unitary action of the gauge transformations on the space of decoherence functionals. The decoherence functional d is associated with an operator on $\mathcal{E} \otimes \mathcal{E}$, denoted Θ_d. Gauge transformations act on Θ_d as $\Theta_d \mapsto \Theta_{d'}$ where $\Theta_{d'} = U \otimes U \Theta_d U^\dagger \otimes U^\dagger$. As shown in Ref. 8, the operator $\Theta_{d'}$ is indeed associated with a *bone fide* decoherence functional d'. We say that the decoherence functionals d and d' are *related by the gauge transformation* U.

Definition 4.2.1: The collection of all decoherence functionals related to the radiation gauge decoherence functional, d^R, by a gauge transformation is denoted $\mathcal{D}_{gf}$ and called the space of gauge-fixed decoherence functionals.

V. GAUGE INVARIANCE

We now fix a particular foliation, drop the n-label, and use coordinates adapted to the foliation. Let $\mathcal{D}$ denote the space of decoherence functionals associated with the quantum history space $\mathcal{E}$. A physical symmetry of a *history* quantum theory (PSHQT) realized on the Hilbert space $\mathcal{E}$ is defined in Ref. 8 as an affine one-to-one map

$$P(\mathcal{E})\otimes P(\mathcal{E})\times\mathcal{D}\rightarrow P(\mathcal{E})\otimes P(\mathcal{E})\times\mathcal{D}, \tag{95}$$

$$([\alpha\otimes\beta],\Theta)\mapsto([\alpha\otimes\beta]',\Theta'), \tag{96}$$

that preserves the pairing between history propositions and operators associated with decoherence functionals, i.e.,

$$tr_{\mathcal{E}\otimes\mathcal{E}}([\alpha\otimes\beta]\Theta)=tr_{\mathcal{E}\otimes\mathcal{E}}([\alpha\otimes\beta]'\Theta'). \tag{97}$$

Schreckenberg[8] proved the following histories analogue of Wigners theorem:

Theorem 5.0.1: *Every PSHQT can be induced by a unitary or antiunitary operator $\hat{U}$ on $\mathcal{E}$ in the sense that each PSHQT can be written as*

$$[\alpha\otimes\beta]\mapsto\hat{U}\otimes\hat{U}[\alpha\otimes\beta]\hat{U}^\dagger\otimes\hat{U}^\dagger, \tag{98}$$

$$\Theta\mapsto\hat{U}\otimes\hat{U}\Theta\hat{U}^\dagger\otimes\hat{U}^\dagger, \tag{99}$$

for some unitary or antiunitary operator $\hat{U}$. Conversely, every transformation of the form (98) and (99) for unitary or antiunitary $\hat{U}$ induces a PSHQT.

We have seen that gauge transformations act unitarily on projection operators and on the space of decoherence functionals. Therefore gauge transformations induce a PSHQT and we can use the histories analog of Wigner's theorem. The following is an immediate consequence:

Proposition 5.0.2.: For any gauge-fixed decoherence functional $d\in\mathcal{D}_{gf}$, and any two primitive projectors $\alpha_0,\beta_0\in P(\mathcal{E}_0)$,

$$d(\alpha_0,\beta_0)=d^{red}(\alpha_0,\beta_0). \tag{100}$$

Proof: Since $d\in\mathcal{D}_{gf}$, it is related to d^R by a gauge transformation. We denote the unitary operator associated with this gauge transformation by $\hat{U}_d$. The primitive projectors α_0 and β_0 satisfy $\hat{U}_d\alpha_0\hat{U}_d^\dagger=\alpha_0$ and $\hat{U}_d\beta_0\hat{U}_d^\dagger=\beta_0$. Now Eq. (97) implies $d(\alpha_0,\beta_0)=d^R(\alpha_0,\beta_0)$. Finally, from the definition of d^R it follows that $d^R(\alpha_0,\beta_0)=d^{red}(\alpha_0,\beta_0)$. □

This shows that gauge-fixed decoherence functionals ensure the following.

(i) The *probabilities* assigned to gauge-invariant propositions are gauge invariant.
(ii) The *quantum interference* between gauge-invariant propositions is gauge invariant.

We have the following lemma:

Lemma 5.0.3: For any gauge-fixed decoherence functional $d\in\mathcal{D}_{gf}$, any projector $\alpha\in P(\mathcal{E})$, and any exact projector γ,

$$d(\alpha,\gamma)=0. \tag{101}$$

Proof: We act on $d(\alpha,\gamma)$ with $\hat{U}_d$, the gauge transformation that maps d into d^R. Under the action of $\hat{U}_d$, α and γ transform to $\alpha_d:=\hat{U}_d\alpha\hat{U}_d^\dagger$ and $\gamma_d:=\hat{U}_d\gamma\hat{U}_d^\dagger$. Now using Eq. (97) we have

$$d(\alpha,\gamma)=d^R(\alpha_d,\gamma_d), \tag{102}$$

which is equal to zero by Eq. (88) because γ_d is exact. □

Corollary 5.0.4: Let γ and δ be exact propositions. Then $d(\gamma,\delta)=0$ for any gauge-fixed decoherence functional $d\in\mathcal{D}_{gf}$.

Proof: Immediate. □

This implies that there is no interference between exact projectors, and that exact propositions are assigned a probability of zero by any gauge-fixed decoherence functional. Projectors onto the spectrum of the constraint fields are exact, so a special case of this result is that any gauge-fixed decoherence functional assigns a probability of zero to any propositions that are not compatible with the constraints.

Theorem 5.0.5: *Any gauge-fixed decoherence functional $d\in\mathcal{D}_{gf}$ reduces to a well-defined functional $\tilde{d}:H^*(\hat{\Omega})\times H^*(\hat{\Omega})\to\mathbb{C}$ defined by*

$$\tilde{d}([\alpha],[\beta]):=d(\alpha,\beta). \tag{103}$$

In addition,

$$\tilde{d}([\alpha],[\beta])=d^{red}(\alpha_0,\beta_0), \tag{104}$$

for all $[\alpha],[\beta]\in H^*(\hat{\Omega})$, where α_0 and β_0 are the primitive parts of α and β, respectively.

Proof: We use the additivity axiom of the space of decoherence functionals,

$$d(\alpha,\beta)=d(\alpha_0+\gamma_\alpha,\beta)=d(\alpha_0,\beta)+d(\gamma_\alpha,\beta), \tag{105}$$

because α_0 and γ_α are disjoint. Now because γ_α is exact, Lemma (5.0.3) along with the Hermiticity of d implies that $d(\gamma_\alpha,\beta)=0$. This means that

$$d(\alpha,\beta)=d(\alpha_0,\beta). \tag{106}$$

Repeating this for the other argument of d, we have

$$d(\alpha,\beta)=d(\alpha_0,\beta_0), \tag{107}$$

for any gauge-fixed decoherence functional d. This shows that every gauge-fixed decoherence functional reduces to a well-defined functional $\tilde{d}:H^*(\hat{\Omega})\times H^*(\hat{\Omega})\to\mathbb{C}$ defined by $\tilde{d}([\alpha],[\beta]):=d(\alpha,\beta)$. Now Proposition (5.0.2) proves the theorem. □

Theorem (5.0.5) shows that the cohomological history theory $(H^*(\hat{\Omega}),\tilde{d})$ is "the same" as the reduced history theory $(P(\mathcal{E}^{red}),d^{red})$. More precisely, we have the following.

Definition 5.0.6: Two quantum history theories $(P_1,\mathcal{D}_1)$ and $(P_2,\mathcal{D}_2)$ are defined to be isomorphic *if there exists (i) an isomorphism of lattices $\lambda:P_1\to P_2$, and (ii) a bijective map $\vartheta:\mathcal{D}_1\to\mathcal{D}_2$, such that*

$$d(\alpha,\beta)=\vartheta(d)(\lambda(\alpha),\lambda(\beta)), \tag{108}$$

for all $\alpha,\beta\in P_1$ and all $d\in\mathcal{D}_1$.

Proposition 5.0.7: $(H^*(\hat{\Omega}),\tilde{d})$ is isomorphic to $(P(\mathcal{E}^{red}),d^{red})$.

Proof: The map $\pi:[\alpha]\mapsto\alpha_0$ provides the required lattice isomorphism between $H^*(\hat{\Omega})$ and $P(\mathcal{E}^{red})$. Now define ϑ by $\vartheta(\tilde{d})=d^{red}$, and Eq. (104) states precisely that the two history theories are isomorphic. □

VI. CONCLUSION

We have constructed two concrete models of history quantum electrodynamics on Fock space. First, we quantized the classical reduced history space by finding an inequivalent representation of

the reduced history algebra on $\mathcal{E}^{red}$ for each foliation. We then defined the decoherence functional using the canonical history action on the reduced history space. This results in the reduced history theory $(P(\mathcal{E}^{red}),d^{red})$.

Second, we extended the history algebra by including ghost fields, and found representations of the extended history algebra on the extended quantum history space $\mathcal{E}$. Using the BRST charge Ω, we defined $H^*(\Omega)$, the projection operator cohomology of Ω, and showed that $H^*(\Omega)$ is isomorphic (as a lattice) to $P(\mathcal{E}^{red})$. Finally, we defined the space of gauge-fixed decoherence functionals and showed that, for each gauge-fixed decoherence functional d, $(H^*(\Omega),\tilde{d})$ is isomorphic to $(P(\mathcal{E}^{red}),d^{red})$.

Although the construction of quantum history electrodynamics is interesting in itself, it is hoped that the results obtained here will be useful in a wider context. Given a general BRST-extended quantum history space and a nilpotent BRST charge, Sec. III provides a definition of the corresponding projection operator cohomology, and shows that it is isomorphic to the lattice of projection operators on the reduced history space. In addition, the discussion of the space of gauge-fixed decoherence functionals is relevant to any gauge theory. It would be interesting to apply the histories BRST formalism developed here to mini-superspace models, or to topological quantum field theory. These examples are of particular importance in light of the recent interest in diffeomorphism invariance in history theories.[10,11]

ACKNOWLEDGMENTS

I would like to thank Professor Isham for suggesting this research and for his comments on a draft of this article. I am also grateful to Dr. N. Linden and Professor B. Hiley for their comments. Financial support in the form of a PPARC studentship is gratefully acknowledged.

APPENDIX

First, we consider the bosonic part of the BRST-extended commutator algebra:

$$[\hat{\lambda}_n(X),\hat{B}_n(X')]=i\hbar\,\delta^{(4)}(X-X'), \tag{A1}$$

$$[\hat{A}^n_M(X),\hat{E}^N_n(X')]=i\hbar\,\delta^N_M\delta^{(4)}(X-X'), \tag{A2}$$

where all unwritten commutators vanish. We expand the configuration fields as

$$\hat{\lambda}_n(X)=\frac{1}{(2\pi)^2}\int\frac{d^4K}{\sqrt{2\omega_n(K)}}[\hat{d}(K)e^{iK\cdot X}+\hat{d}^\dagger(K)e^{-iK\cdot X}], \tag{A3}$$

$$\hat{A}^n_s(X)=\frac{1}{(2\pi)^2}\int\frac{d^4K}{\sqrt{2\omega_n(K)}}[\hat{d}_s(K)e^{iK\cdot X}+\hat{d}^\dagger_s(K)e^{-iK\cdot X}], \tag{A4}$$

$$\hat{A}^n_t(X)=\frac{1}{(2\pi)^2}\int\frac{d^4K}{\sqrt{2\omega_n(K)}}[\hat{d}_t(K)e^{iK\cdot X}+\hat{d}^\dagger_t(K)e^{-iK\cdot X}], \tag{A5}$$

$${}^n\hat{A}_M(X)=\frac{1}{(2\pi)^2}\sum_{i=1}^{3}\int\frac{d^4K}{\sqrt{2\omega_n(K)}}, \tag{A6}$$

$$[\hat{d}_i(K){}^n\epsilon^i_M(K)e^{iK\cdot X}+\hat{d}^\dagger_i(K){}^n\epsilon^i_M(K)e^{-iK\cdot X}]. \tag{A7}$$

The five-vectors ${}^n\epsilon^a_M(K)$ for $a=1,2$ are defined as in Sec. II, and ${}^n\epsilon^3_M(K)$ is the unit vector pointing in the direction of ${}^n\tilde{K}$. Now the momentum fields are expanded as

$$\hat{B}_n(X)=\frac{1}{i(2\pi)^2}\int d^4K\sqrt{\frac{\omega_n(K)}{2}} \tag{A8}$$

$$[(\hat{d}(K)+\hat{d}_s(K))e^{iK\cdot X}-(\hat{d}^\dagger(K)+\hat{d}_s^\dagger(K))e^{-iK\cdot X}], \tag{A9}$$

$$\hat{E}_n^s(X)=\frac{1}{i(2\pi)^2}\int d^4K\sqrt{\frac{\omega_n(K)}{2}}[(\hat{d}_s(K)+\hat{d}(K))e^{iK\cdot X} \tag{A10}$$

$$-(\hat{d}_s^\dagger(K)+\hat{d}^\dagger(K))e^{-iK\cdot X}], \tag{A11}$$

$$\hat{E}_n^t(X)=\frac{1}{i(2\pi)^2}\int d^4K\sqrt{\frac{\omega_n(K)}{2}}[(\hat{d}_t(K)+\hat{d}_3(K))e^{iK\cdot X} \tag{A12}$$

$$-(\hat{d}_t^\dagger(K)+\hat{d}_3^\dagger(K))e^{-iK\cdot X}], \tag{A13}$$

$${}^n\hat{E}^M(X)=\frac{1}{i(2\pi)^2}\sum_{i=1}^{3}\int d^4K\sqrt{\frac{\omega_n(K)}{2}} \tag{A14}$$

$$[(\hat{d}_i(K){}^n\epsilon_M^i(K)+\hat{d}_t(K){}^n\epsilon_3^M(K))e^{iK\cdot X} \tag{A15}$$

$$-(\hat{d}_i^\dagger(K){}^n\epsilon_i^M(K)+\hat{d}_t^\dagger(K){}^n\epsilon_3^M(K))e^{-iK\cdot X}]. \tag{A16}$$

Defining

$$\hat{a}_1(K)=\frac{1}{\sqrt{2}}(\hat{d}_t(K)+\hat{d}_3(K)), \tag{A17}$$

$$\hat{b}_1(K)=\frac{1}{\sqrt{2}}(\hat{d}_t(K)-\hat{d}_3(K)), \tag{A18}$$

$$\hat{a}_2(K)=\frac{1}{\sqrt{2}}(\hat{d}_s(K)+\hat{d}(K)), \tag{A19}$$

$$\hat{b}_2(K)=\frac{1}{\sqrt{2}}(\hat{d}_s(K)-\hat{d}(K)), \tag{A20}$$

we obtain the commutators (65)–(67) in which $\hat{d}_a$ has been written ${}^\perp\hat{a}_a$ for $a\in\{1,2\}$.

The fermionic part of the BRST-extended quantum history algebra is

$$[\hat{\eta}_n^a(X),\hat{\mathcal{P}}_n^b(X')]=\hbar\,\delta^{ab}\delta^{(4)}(X-X'), \tag{A21}$$

$$[\overline{C}_n^a(X),\hat{\rho}_n^b(X')]=\hbar\,\delta^{ab}\delta^{(4)}(X-X'), \tag{A22}$$

where on fermionic fields square brackets represent anti-commutators. We write the ghost fields as

$$\hat{\eta}_n^1(X)=-\frac{1}{(2\pi)^2}\int\frac{d^4K}{2\,\omega_n(K)^{3/2}}[c_1(K)e^{iK\cdot X}+c_1^\dagger(K)e^{-iK\cdot X}], \tag{A23}$$

$$\hat{\mathcal{P}}_n^1(X) = \frac{i}{(2\pi)^2}\int d^4K\,\omega_n(K)^{3/2}[\overline{c_1}(K)e^{iK\cdot X} + \overline{c}_1^{\dagger}(K)e^{-iK\cdot X}], \tag{A24}$$

$$\hat{\rho}_n^1(X) = -\frac{1}{(2\pi)^2}\int \frac{d^4K}{2\omega_n(K)^{1/2}}[c_1(K)e^{iK\cdot X} - c_1^{\dagger}(K)e^{-iK\cdot X}], \tag{A25}$$

$$\overline{C_n^1}(X) = \frac{1}{i(2\pi)^2}\int d^4K\,\omega_n(K)^{1/2}[\overline{c_1}(K)e^{iK\cdot X} + \overline{c}_1^{\dagger}(K)e^{-iK\cdot X}], \tag{A26}$$

$$\hat{\eta}_n^2(X) = -\frac{1}{(2\pi)^2}\int \frac{d^4K}{2\omega_n(K)^{1/2}}[c_2(K)e^{iK\cdot X} + c_2^{\dagger}(K)e^{-iK\cdot X}], \tag{A27}$$

$$\hat{\mathcal{P}}_n^2(X) = \frac{i}{(2\pi)^2}\int d^4K\,\omega_n(K)^{1/2}[\overline{c_2}(K)e^{iK\cdot X} + \overline{c}_2^{\dagger}(K)e^{-iK\cdot X}], \tag{A28}$$

$$\hat{\rho}_n^2(X) = -\frac{1}{(2\pi)^2}\int \frac{d^4K}{2\omega_n(K)^{1/2}}[c_2(K)e^{iK\cdot X} - c_2^{\dagger}(K)e^{-iK\cdot X}], \tag{A29}$$

$$\overline{C_n^2}(X) = \frac{1}{i(2\pi)^2}\int d^4K\,\omega_n(K)^{1/2}[\overline{c_2}(K)e^{iK\cdot X} + \overline{c}_2^{\dagger}(K)e^{-iK\cdot X}], \tag{A30}$$

and the algebra (A21) and (A22) implies the anti-commutators in Eqs. (68) and (69).

Chiral superconducting strings and Nambu–Goto strings in arbitrary dimensions

Xavier Siemens[a] and Ken D. Olum
Institute of Cosmology, Department of Physics and Astronomy, Tufts University, Medford, Massachusetts 02155

(Received 22 April 2002; accepted for publication 3 May 2002)

We present general solutions to the equations of motion for a superconducting relativistic chiral string that satisfy the unit magnitude constraint in terms of products of rotations. From this result we show how to construct a general family of odd harmonic superconducting chiral loops. We further generalize the product of rotations to an arbitrary number of dimensions. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1501169]

I. PRELIMINARIES

Particle physics models where symmetry breaking is involved predict, in many cases, the existence of topological defects, which are formed when the topology of the vacuum manifold of the low energy theory is nontrivial.[1] Cosmic strings, in particular, are linelike objects that are formed when the the vacuum manifold contains unshrinkable loops. For a review, see Ref. 2.

In Ref. 3 it was shown that cosmic strings can be superconducting. In the case when the charge carriers on the string are not coupled to a gauge field, the action for the string and the current can be taken to be

$$S=\int d^2\xi\sqrt{-\gamma}\left(-\mu+\frac{1}{2}\gamma^{ab}\phi_{,a}\phi_{,b}\right), \tag{1}$$

where μ is the mass per unit length of the string, γ^{ab} is the induced metric on the string worldsheet and ϕ is the field of the charge carriers living on the string. These strings were shown in Refs. 4 and 5 to have solutions in the case when $\gamma^{ab}\phi_{,a}\phi_{,b}=0$ of the form

$$\mathbf{x}=\tfrac{1}{2}[\mathbf{a}(u)+\mathbf{b}(v)] \tag{2}$$

for the string position and

$$\phi=\tfrac{1}{2}f(v) \tag{3}$$

for the field living on the string with the constraints

$$\mathbf{a}'^2=1 \tag{4}$$

and

$$\mathbf{b}'^2+f'^2=1, \tag{5}$$

where $u=\sigma-\tau$ and $v=\sigma+\tau$ and σ and τ are spacelike and timelike parameters, respectively, that parametrize the string world-sheet. These strings are called chiral because the current only moves in one direction on the string.

[a]Electronic mail: siemens@cosmos.phy.tufts.edu

Comparing this to the usual Nambu–Goto case, one can see that $f(v)$ acts like a fourth component of the three-vector $\mathbf{b}(v)$, making chiral superconducting strings behave like Nambu–Goto ones with chiral excitations in an extra fifth dimension. Indeed, this property was used in Ref. 6 in an investigation of the properties of superconducting cosmic string cusps.

The right- and left-moving excitations, $\mathbf{a}'$ and $\mathbf{b}'$, on a regular Nambu–Goto string in Minkowski space–time are arbitrary functions that satisfy the unit magnitude constraint, $|\mathbf{a}'| = |\mathbf{b}'| = 1$. Expressions for these functions are often given as Fourier sums and the unit magnitude constraint generally gives a nonlinear set of equations involving the vector coefficients of the Fourier expansion. As a result, parametrizing strings beyond the first few harmonics proves to be a difficult task. Fortunately, in that case, there exists a method to generate strings involving products of rotation matrices[7] that act on a starting unit vector so that the unit magnitude constraint is satisfied trivially.

In a recent study of the properties of chiral cosmic strings[8] it was assumed that the current is constant. The work in Ref. 9 assumed that the current takes a very simple nonconstant form. As was pointed out in the latter work, one could expect to have loops with varying currents if the loops are formed by intersections involving different strings or if different segments of the loop or string were at some point in causally disconnected regions. For long strings this is always the case and we therefore expect varying chiral currents to be generic.

The purpose of this work is to generalize the work in Ref. 7 for generating three-dimensional unit vectors to four-dimensional ones that include the current as a fourth component of $\mathbf{b}(\sigma + \tau)$. We start by casting the method somewhat differently and generalize it to four dimensions. From this result we construct a family of chiral superconducting odd-harmonic loops. We further generalize the product of rotations to an arbitrary number of dimensions.

In Sec. II we show how to construct an arbitrary N harmonic unit vector in four and three dimensions. In Sec. III we use these results to construct arbitrary chiral current carrying superconducting odd harmonic loops. In Sec. IV we generalize the arguments in Sec. II to an arbitrary number of dimensions and we conclude in Sec. V.

II. SOLUTION TO THE UNIT MAGNITUDE CONSTRAINT IN TERMS OF PRODUCTS OF ROTATIONS

We can think of the Euclidean four-vector

$$\tilde{\mathbf{b}}' = \begin{pmatrix} b'_w \\ b'_x \\ b'_y \\ b'_z \end{pmatrix} \tag{6}$$

as having unit magnitude according to (5) with $b_w = f$. Consider the vector $\tilde{\mathbf{b}}'_N$, which can be constructed from a finite sum of Fourier components,

$$\tilde{\mathbf{b}}'_N(v) = \mathbf{Z} + \sum_{n=1}^{N} \{\mathbf{A}_n \cos nv + \mathbf{B}_n \sin nv\}. \tag{7}$$

The Fourier coefficients satisfy the set of $4N+1$ nonlinear relations derived in Ref. 7,

$$\sum_{n=m-N}^{N} (\alpha_n \cdot \alpha_{m-n} - \beta_n \cdot \beta_{m-n}) = 4\delta_{m0} \tag{8}$$

with $m = 0,1,\ldots,2N$,

$$\sum_{n=m-N}^{N} (\alpha_n \cdot \beta_{m-n} - \beta_n \cdot \alpha_{m-n}) = 0 \tag{9}$$

with $m=1,\ldots,2N$,

$$\alpha_n=\alpha_{-n}=\mathbf{A}_n, \quad \beta_n=-\beta_{-n}=\mathbf{B}_n, \quad n\neq 0, \tag{10}$$

and

$$\alpha_0=2\mathbf{Z}, \quad \beta_0=0. \tag{11}$$

These equations can be obtained from the constraint equation (5). The total number of degrees of freedom in the coefficients in (7) is $8N+4$, so the remaining number of degrees of freedom after satisfying the constraint is $4N+3$. Below we show how to construct (7) from a product of rotation matrices by generalizing a modified version of the three-dimensional method presented in Ref. 7 to four dimensions.

The constraint equations (8) and (9) for $m=2N$ and $m=2N-1$ are

$$\mathbf{A}_N^2=\mathbf{B}_N^2, \quad \mathbf{A}_N\cdot\mathbf{B}_N=0, \tag{12}$$

and

$$\begin{aligned}\mathbf{A}_N\cdot\mathbf{A}_{N-1}-\mathbf{B}_N\cdot\mathbf{B}_{N-1}&=0,\\ \mathbf{A}_N\cdot\mathbf{B}_{N-1}+\mathbf{B}_N\cdot\mathbf{A}_{N-1}&=0,\end{aligned} \tag{13}$$

respectively. It follows from (12) that the highest harmonic is a circle that lives on some arbitrary plane. Clearly, we can introduce coordinates such that $\mathbf{A}_N$ and $\mathbf{B}_N$ lie on the w and x axes,

$$\mathbf{A}_N=a\hat{w}, \quad \mathbf{B}_N=a\hat{x}, \tag{14}$$

making the highest harmonic a circle of radius a on the w-x plane. This puts the vector $\tilde{\mathbf{b}}_N'$ into the so-called standard form.[7] Let $R_{wx}(\theta)$ be a matrix that rotates the w-x plane by an angle θ. Acting on $\tilde{\mathbf{b}}_N'$ with $R_{wx}(-v)$ in these coordinates lowers the highest harmonic term of (7),

$$R_{wx}(-v)\begin{pmatrix} a\cos Nv\\ a\sin Nv\\ 0\\ 0\end{pmatrix}=\begin{pmatrix} a\cos(N-1)v\\ a\sin(N-1)v\\ 0\\ 0\end{pmatrix}. \tag{15}$$

This is not sufficient to verify that the overall harmonic content has been lowered because the $N-1$ terms of (7) could still give us an N harmonic through trigonometric identities. We now show, however, that this is not the case.

The constraint equations for $m=2N-1$ in (13) give us, using (14), the conditions on the coefficients,

$$(\mathbf{A}_{N-1})_w=(\mathbf{B}_{N-1})_x, \quad (\mathbf{A}_{N-1})_x=-(\mathbf{B}_{N-1})_w. \tag{16}$$

It is not too difficult to see that using the conditions (16) when acting with $R_{wx}(-v)$ on the $N-1$ terms of (7) does not lead to the creation of N harmonic terms,

$$\begin{aligned}&R_{wx}(-v)[\mathbf{A}_{N-1}\cos(N-1)v+\mathbf{B}_{N-1}\sin(N-1)v]\\ &=\begin{pmatrix}(\mathbf{A}_{N-1})_w\cos(N-2)v-(\mathbf{A}_{N-1})_x\sin(N-2)v\\ (\mathbf{A}_{N-1})_x\cos(N-2)v+(\mathbf{A}_{N-1})_w\sin(N-2)v\\ (\mathbf{A}_{N-1})_y\cos(N-1)v+(\mathbf{B}_{N-1})_y\sin(N-1)v\\ (\mathbf{A}_{N-1})_z\cos(N-1)v+(\mathbf{B}_{N-1})_z\sin(N-1)v\end{pmatrix}.\end{aligned} \tag{17}$$

Clearly, the $N-2$ terms will not yield an N harmonic term when acted on by $R_{wx}(-v)$.

We now have a string in the form of (7) with $N \to N-1$. Its highest harmonic is therefore also a circle of some other radius living on some other arbitrary plane. Armed with this knowledge, we can see that the unit magnitude constraints are such that, in general, we can write

$$\tilde{\mathbf{b}}'_N = R_{P_N}(v)\tilde{\mathbf{b}}'_{N-1}, \tag{18}$$

where $R_{P_N}(v)$ is a rotation by an angle v on the plane P_N where the highest harmonic lives. By induction it must be that

$$\tilde{\mathbf{b}}'_N = \prod_{i=N}^{1} R_{P_i}(v)\tilde{\mathbf{b}}'_0, \tag{19}$$

where the $R_{P_i}(v)$ are rotations by an angle v on arbitrary planes P_i and $\tilde{\mathbf{b}}'_0$ is an arbitrary constant unit vector in four dimensions.

To specify a plane in four dimensions one needs to specify a direction on the plane (three angles), a linearly independent direction (two angles), but now the plane is overspecified by internal rotations (-1 angle), giving a total of four degrees of freedom for the matrices $R_{P_i}(v)$. For an N harmonic vector, one therefore has $4N$ parameters in the rotators and three parameters in the constant unit vector $\tilde{\mathbf{b}}'_0$ giving a total of $4N+3$ parameters which checks perfectly with $8N+4$ vector coefficients in (7) minus the $4N+1$ constraints (8) and (9).

The form of the $R_{P_i}(v)$ matrices is quite simple. Generally, if we want to transform, say, a rotation by an angle v on the w-x plane to one on an arbitrary plane, we will need to perform a transformation of the type

$$R_{P_i}(v) = E_i R_{wx}(v) E_i^T. \tag{20}$$

For the purpose of finding the form of the rotators E_i it is easiest to envision the inverse process to the one we are seeking, namely the rotation of an arbitrary oriented plane to lie on the w-x plane. Let us consider first the projection of the four-dimensional arbitrary plane onto the (x,y,z) subspace. We can perform a rotation by some angle α about the z axis $[R_{xy}(\alpha)]$ until the vector perpendicular to the projected plane lies on the y-z plane and perform a further rotation by an angle β about the x axis $[R_{yz}(\beta)]$ until that vector lies on the z axis. At this stage the projected plane lies wholly on the x-y plane. The ranges of both α and β from 0 to π are sufficient to perform these transformations. After performing these two rotations, our original four dimensional plane lies entirely in the (w,x,y) subspace and we can repeat an analogous process to the one above to rotate it into the w-x plane. A rotation by an angle γ about the y axis $[R_{wx}(\gamma)]$ puts the vector perpendicular to the plane on the x-y plane and a rotation by an angle δ about w $[R_{xy}(\delta)]$ makes that vector parallel with the y axis. For the first of these rotations a range of γ from 0 to π is sufficient, for the second rotation, however, matters are slightly different. If the plane we were trying to rotate was featureless, it would be enough for the range of δ to be from 0 to π. In fact, this is not the case. The plane contains a circle in v which can be oriented clockwise or counterclockwise on the w-x plane and therefore the final rotation on the x-y plane in general requires an angle that ranges from 0 to 2π.

Keeping in mind these considerations, we can quite generally write

$$E_i = R_{xy}(\alpha_i)R_{yz}(\beta_i)R_{wx}(\gamma_i)R_{xy}(\delta_i), \tag{21}$$

where α_i, β_i, γ_i range from 0 to π and δ_i ranges from 0 to 2π. Then

$$\tilde{\mathbf{b}}'_N(v) = \prod_{i=N}^{1} E_i R_{wx}(v) E_i^T \tilde{\mathbf{b}}'_0. \tag{22}$$

In order to construct the entire chiral string, we also need to find the form of $\mathbf{a}(u)$ in (2). The constraints (4) can be satisfied using a product of rotations that can be found from analogous arguments to the ones in the preceding section. For M harmonics this yields

$$\mathbf{a}'_M(u)=\prod_{i=M}^{1} D_i R_{xy}(u) D_i^T \mathbf{a}'_0 \tag{23}$$

with the rotator

$$D_i=R_{xy}(\phi_i)R_{yz}(\theta_i) \tag{24}$$

where the angles θ_i range from 0 to π, the angles ϕ_i from 0 to 2π and R are the three dimensional rotation matrices.

III. AN APPLICATION: A FAMILY OF ODD HARMONIC SUPERCONDUCTING CHIRAL LOOPS

A. Overall orientation freedom

Both expressions for the oppositely moving excitations on the string (22) and (23) include overall orientation freedom. In some applications, for instance self-intersection or gravitational radiation analyses, only the shape of a loop, and not its orientation, is important. In this case the inclusion of overall orientation freedom of the right- and left-moving excitations separately is unnecessary: All that matters is the relative orientation between $\mathbf{a}'$ and the spatial part of $\tilde{\mathbf{b}}'$.

Overall orientation freedom of the loop is set by an Euler matrix Q that acts only on $\mathbf{a}'$ and the spatial components of $\tilde{\mathbf{b}}'$ and contains three angles. We can use this freedom to standardize the vectors in some way. We will choose the plane of the last rotation in $\mathbf{a}'$ and $\tilde{\mathbf{b}}'$ to contain some coordinate axis (this will enable us in the following subsection to use the arbitrariness in the origin of u and v to eliminate more parameters).

The four-dimensional circle that constitutes the highest harmonic of $\tilde{\mathbf{b}}'$ projected onto three-dimensional space typically looks like an ellipse. We can perform ordinary three-dimensional rotations on it to put it in some convenient form. In particular, we can rotate the ellipse on the x-y plane until its major axis, say, lies on the y-z plane and further rotate on the y-z plane until it lies entirely on the z axis. We still have one more rotation left in Q which we choose to be a rotation on the x-y plane. This leaves the major axis of the ellipse on the z-axis but orients the circle of the highest harmonic in $\mathbf{a}'$ such that it contains the x-axis.

We now construct a four-dimensional planar rotator that contains the z-axis but is otherwise arbitrary. Starting with $R_{wz}(v)$, we see that we can perform an arbitrary planar rotation on it in the (w,x,y) subspace that preserves the z-axis. This requires only two rotations. Therefore, to rotate about a plane that contains the z-axis but is otherwise arbitrary we can use

$$R_{xy}(\gamma)R_{wx}(\delta)R_{wz}(v)R_{wx}(-\delta)R_{xy}(-\gamma) \tag{25}$$

where δ ranges from 0 to π and γ from 0 to 2π. This procedure eliminates two of the parameters in the last planar rotation of $\tilde{\mathbf{b}}'$.

In three dimensions, to rotate by an angle u on a plane that contains the x-axis, but is otherwise arbitrary, we may use

$$R_{yz}(\theta)R_{xy}(u)R_{yz}(-\theta) \tag{26}$$

where θ ranges from 0 to 2π. This procedure eliminates one of the parameters in the last planar rotation of $\mathbf{a}'$.

This leaves $\mathbf{a}'$ and $\tilde{\mathbf{b}}'$ in the form

$$\tilde{\mathbf{b}}'_N(v)=\tilde{R}^b_{P_N}(v)\prod_{i=N-1}^{1}E_iR_{wx}(v)E_i^T\tilde{\mathbf{b}}'_0 \tag{27}$$

with

$$\tilde{R}^b_{P_N}(v)=R_{wx}(\gamma)R_{xy}(\delta)R_{wz}(v)R_{xy}(-\delta)R_{wx}(-\gamma) \tag{28}$$

and

$$\mathbf{a}'_M(u)=\tilde{R}^a_{P_M}(u)\prod_{i=M-1}^{1}D_iR_{xy}(u)D_i^T\mathbf{a}'_0 \tag{29}$$

with

$$\tilde{R}^a_{P_M}(u)=R_{yz}(\theta)R_{xy}(u)R_{yz}(-\theta). \tag{30}$$

B. The origin of *u* and *v*

The conditions on the coefficients of the highest harmonics (12) only specify the planar rotation up to a phase so that generally we can take $\tilde{R}^b_N(v+\beta)$ and $\tilde{R}^a_M(u+\alpha)$ in (27) and (29).

We consider the action of this extra planar rotation matrix on $\tilde{\mathbf{b}}'_N(v)$. It can be verified to be

$$\tilde{\mathbf{b}}'_N(v)=\tilde{R}^b_{P_N}(v)\prod_{i=N-1}^{1}R_{P'_i}(v)\tilde{R}^b_{P_N}(\beta)\tilde{\mathbf{b}}'_0, \tag{31}$$

where

$$R_{P'_i}(v)=\tilde{R}^b_{P_N}(\beta)R_{P_i}(v)\tilde{R}^b_{P_N}(-\beta) \tag{32}$$

with analogous expressions for $\mathbf{a}'_M(u)$. It is important to note that the effect of replacing $R_{P_i}(v)$ with $R_{P'_i}(v)$ is to make the same transformation on each of the planes of rotation, in other words, to rotate on some other set of planes. Since we can express any rotation on a plane using (21), however, the effect of the matrices $\tilde{R}^b_{P_N}(\beta)$ and $\tilde{R}^a_{P_M}(\alpha)$ on the rotators can be ignored.

Since the planar rotations $\tilde{R}^b_{P_N}$ and $\tilde{R}^a_{P_M}$ both contain one of the coordinate axes we can choose β and α so that the z component of $\tilde{\mathbf{b}}'_0$ and the x component $\mathbf{a}'_0$ vanish. This leaves them in the form

$$\tilde{R}^b_{P_N}(\beta)\tilde{\mathbf{b}}'_0=\begin{pmatrix}\cos\theta_b\\ \cos\phi_b\sin\theta_b\\ \sin\phi_b\sin\theta_b\\ 0\end{pmatrix}=R_{xy}(\phi_b)R_{wx}(\theta_b)\hat{w} \tag{33}$$

and

$$\tilde{R}^a_{P_M}(\alpha)\mathbf{a}'_0=\begin{pmatrix}0\\ \cos\theta_a\\ \sin\theta_a\end{pmatrix}=R_{yz}(\theta_a)\hat{y}, \tag{34}$$

where ϕ_b and θ_a range from 0 to 2π and θ_b ranges from 0 to π. This means we can write $\mathbf{a}'$ and $\tilde{\mathbf{b}}'$ as

$$\mathbf{a}'_M(u)=\tilde{R}^a_{P_M}(u)\prod_{i=M-1}^{1}R_{P_i}(u)R_{yz}(\theta_a)\hat{y} \tag{35}$$

and

$$\tilde{\mathbf{b}}'_N(v)=\tilde{R}^b_{P_N}(v)\prod_{i=N-1}^{1}R_{P_i}(v)R_{xy}(\phi_b)R_{wx}(\theta_b)\hat{w}. \tag{36}$$

C. The center of mass constraint

In order to construct string loops, apart from solving the unit magnitude constraint, we need to satisfy the center of mass constraint, namely that the loop should be closed and that we want to work in the rest frame of the loop. These constraints imply that the center of mass term must vanish, $\mathbf{Z}=0$ in (7), for both $\mathbf{a}'$ and $\tilde{\mathbf{b}}'$. In general this is an intractable problem because the center of mass term $\mathbf{Z}$ is a nonlinear function of the angles in the rotation matrices. We can, however, solve this problem in an analogous way to that introduced in Ref. 10. The guiding principle behind such a construction is to set the starting center of mass terms to zero, and to apply further rotation matrices in such a way as to ensure that trigonometric identities never lead to the production of a zero harmonic. In practice this was done by using odd harmonics only and choosing some parameters so that the starting center of mass term is zero. Here we will proceed along similar lines.

Generally, if the starting unit vector lies somewhere on the plane of the first rotation, $i=1$ in (35) and (36), no center of mass term will be generated. Since our starting unit vectors are given by (33) and (34) we need to choose the first planes of rotation appropriately.

Earlier we established that if we want a rotation by an angle u on a plane that contains the x-axis, we can use (26). If we want an arbitrary rotation that contains the y-axis, instead we may use

$$R_{xz}(\phi)R_{xy}(u)R_{xz}(-\phi). \tag{37}$$

If we now decide we want a rotation by u on a plane that contains a vector lying somewhere on the y-z plane, it is sufficient rotate this last matrix (37) on the y-z plane by whatever angle the vector makes with the y-axis. This is precisely the situation in (34). We therefore write the first rotation, $i=1$ in (35), as

$$R_{P_1}(u)=R_{yz}(\theta_a)R_{xz}(\phi_1)R_{xy}(u)R_{xz}(-\phi_1)R_{yz}(-\theta_a) \tag{38}$$

where ϕ_1 ranges from 0 to 2π.

To find the first rotator in (35) we proceed analogously. We want to find a rotation by an angle v on a plane that contains a vector lying somewhere in the (w,x,y) subspace, but is otherwise arbitrary, because this is the situation of (33). If we start with a rotator that contains the w-axis but is otherwise arbitrary, taking say,

$$R_{yz}(\gamma_1)R_{xy}(\delta_1)R_{wx}(v)R_{xy}(-\delta_1)R_{yz}(-\gamma_1), \tag{39}$$

where δ_1 ranges from 0 to π and γ_1 ranges from 0 to 2π, it is not hard to see that the first rotator in (35) must be

$$R_{P_1}(v)=R_{xy}(\theta_b)R_{wx}(\phi_b)R_{yz}(\gamma_1)R_{xy}(\delta_1)R_{wx}(v)R_{xy}(-\delta_1)R_{yz}(-\gamma_1)R_{wx}(-\phi_b)R_{xy}(-\theta_b). \tag{40}$$

Further rotations should be by $2u$ and $2v$ to avoid the production of center of mass terms through trigonometric identities. These considerations yield

$$\tilde{\mathbf{b}}'_{2N-1}(v)=\tilde{R}^{b}_{P_N}(2v)\prod_{i=N-1}^{2}E_iR_{wx}(2v)E_i^TR_{xy}(\theta_b)R_{wx}(\phi_b)R_{xz}(\gamma_1)R_{xy}(\delta_1)R_{wx}(v)\hat{w} \quad (41)$$

and

$$\mathbf{a}'_{2M-1}(u)=\tilde{R}^{a}_{P_M}(2u)\prod_{i=M}^{2}D_iR_{xy}(2u)D_i^TR_{xy}(\theta_a)R_{yz}(\phi_1)R_{xy}(u)\hat{y}. \quad (42)$$

IV. GENERALIZATION TO HIGHER DIMENSIONS

Here we show the straightforward generalization of our four-dimensional argument in Sec. II to a unit vector living in arbitrary dimensions. The constraint equations (8) and (9) as well as the argument leading to (19) and (20) are independent of the number of dimensions the vector lives in. The only thing that changes with the number of dimensions is the parametrization of E, the rotator that takes an arbitrary oriented plane to the plane of the first two coordinates. In the following, we label our spatial coordinates by the numbers 1 through d.

If we consider the projection of the plane onto the subspace given by the last three coordinates $(d-2,d-1,d)$, one can see that a rotation by α_d about the d axis $[R_{d-2,d-1}(\alpha_d)]$ until the vector perpendicular to the projected plane lies in the d-$d-1$ plane followed by a rotation by an angle β_d about the $d-2$ axis $[R_{d-1,d}(\beta_d)]$ is sufficient to rotate the projected plane out of the d axis. To perform these transformations it is sufficient for the angles to range from 0 to π. We can repeat this procedure by moving up $d-2$ times in the coordinates until the plane lies entirely in the 1-2 plane as desired, ensuring that the range of the angle in the very last rotation $R_{2,3}(\beta_3)$ is from 0 to 2π to account for the fact that we are dealing with an oriented plane. We can then write the rotator as

$$E=R_{d-2,d-1}(\alpha_d)R_{d-1,d}(\beta_d)\cdots R_{1,2}(\alpha_3)R_{2,3}(\beta_3). \quad (43)$$

The number of parameters introduced by such a product is $2(d-2)$ per harmonic plus $(d-1)$ parameters to specify the initial unit vector, giving a total of $2N(d-2)+d-1$ which checks with $d(2N+1)$ degrees of freedom in the vector coefficients of the Fourier series minus $4N+1$ constraints.

In the case of Nambu–Goto strings in an arbitrary number of dimensions d one would span both right- and left-moving excitations according to

$$\mathbf{a}'_N(u)=\prod_{i=N}^{1}E_iR_{1,2}(u)E_i^T\mathbf{a}'_0 \quad (44)$$

and

$$\mathbf{b}'_N(v)=\prod_{i=N}^{1}E_iR_{1,2}(v)E_i^T\mathbf{b}'_0 \quad (45)$$

with the E_i given by the choice of (43) appropriate to the desired number of dimensions.

V. CONCLUSIONS

We have generalized the solution to the unit magnitude constraint presented in Ref. 7 from three to four dimensions, casting it somewhat differently, in an effort to arrive at a general parametrization of chiral superconducting strings with a finite number of harmonics. We have further shown how to construct loop solutions that satisfy the center of mass constraint and exclude overall orientation freedom. This result is useful because in studies of the properties of chiral loops, such as self-intersection and gravitational radiation properties, overall orientation of the loop is unimportant.

Studies of chiral cosmic string loops with constant currents[8] and simple varying currents[9] have been performed. Generally, however, we expect the current to be arbitrarily varying when loops are formed by intersections involving different strings or if different segments of the loop or string were at some point in causally disconnected regions. This is a fairly generic situation and a study of the properties of more general chiral loops should account for these variations.

Along the way, we have found that our modification of the method lends itself readily to a generalization to arbitrary dimensions. We use such a generalization to present solutions that could be useful in the investigation of classical relativistic strings in higher dimensions as well as strings in $3+1$ Minkowski space with currents and charges induced by Kaluza–Klein compactification[11] when the back-reaction from the gauge fields can be considered negligible.

(Received 18 January 2002; accepted for publication 6 May 2002)

In this work we study two complex scalar fields coupled through a quadratic interaction in $2+1$ dimensions using the method of bilinears as suggested by Rajeev [Int. J. Mod. Phys. A **9**, 5583 (1994)]. The resulting theory can be formulated as a classical theory. We study the linear approximation, and show that there is a possible bound state in a range of coupling constants. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1501167]

I. INTRODUCTION

Quantum field theory has been an essential tool for the modeling of various physical phenomena. One of the major problems in field theory is the understanding of relativistic bound states. The standard way to look at field theories is via perturbation theory around the free theory, and bound state problems are difficult to formulate in this approach. The most common way is to use a Bethe–Salpeter approach for the four-point function (for two particle bound states) and find a self-consistency condition for the bound state solution. Typically this requires various approximations which may break down in the highly relativistic cases.

One of the most successful applications of this approach is within the large-N_c approximation: In his classic paper, 't Hooft obtained a bound state equation for mesons in two dimensions in the large-N_c where N_c refers to the color for the non-Abelian SU(N_c) gauge theory.[1] This leads to a singular integral equation for the possible masses of the mesonic excitations. This equation is expressed in terms of the wave function of the meson given as a function of the fractional light-cone momentum. The analysis of this integral equation in Ref. 2 shows that there are only bound states corresponding to positive eigenvalues with finite multiplicity, and these eigenvalues tend to infinity. The scalar version of this model is worked out in Ref. 3 using the original approach of 't Hooft and in Ref. 4 via a Hamiltonian approach to the large-N_c limit. These relativistic equations behave in a very similar way to the standard 't Hooft equation. In two dimensions we can generalize the Yang–Mills Lagrangian, since the gauge fields are not dynamical, by means of a nondynamical scalar field. The large-N_c limit meson bound state equation of these models have some other interesting features.[5] In Ref. 6, Aoki has generalized these bound state equations for bosons and fermions coupled via SU(N_c) gauge theory. A good presentation of many two-dimensional models using the bilocal fields in the path integral formalism within the large-N_c limit is given in Ref. 7. In this article several interesting bound state equations are derived, and further references are given.

In Ref. 8 Rajeev has formulated the large-N_c model as a classical field theory using color invariant bilinears, and he has shown that the phase space of the theory is the restricted Grassmannian. The knowledge of the phase space allows one to make a variational ansatz for the baryons in this theory, which correspond to the large fluctuations of the field (see Ref. 9). Further details of this approach are given in Ref. 10. Toprak and the author of this paper have extended this work to SO(N_c) gauge theory of bosons and fermions and obtained variants of the 't Hooft equation for these cases.[11,12] The adjoint matter fields in the large-N_c limit yields again singular integral equations for possible mesonic strings, they exhibit a very similar bound state structure as

a)Electronic mail: turgutte@boun.edu.tr

the original model, but these equations are more complicated due to the fact that mesons are now color invariant strings of operators.[13–16]

The two-dimensional Yukawa model is analyzed within the light-cone method in Refs. 17–19. These models are more complicated due to nonlocal renormalization effects; it is possible to get an integral equation for bound states using some further approximations. A four-dimensional extension of these ideas is given in Ref. 20. The common feature of all these bound state equations is that they are singular integral equations. In the gauge theory cases these singular integral equations are rather restrictive in that they only allow for a discrete spectrum. In the other cases this is not necessarily true. There is usually a finite number (typically one) bound state. There are investigations in three dimensional QCD for the bound state equations of mesons (see the recent article—Ref. 21). Four-dimensional realistic theories are very complicated since one has to deal with renormalization. The author is not knowledgeable enough about these realistic bound state equations, however some information can be found in Ref. 22 (see also Ref. 23 for a review of renormalization in the light-front point of view and some nonperturbative applications in this formalism).

In this article we will apply a certain kind of mean field theory, which is a large-N_f limit to two coupled complex bosons (we call it flavor symmetry to emphasize that it is not gauged). This theory is simple since it does not require coupling constant and wave function renormalization in the perturbation theory. Defining the scalar field around the free field theory may not be so interesting from a physical point of view, but we regard this as an interesting toy model. The linear approximation yields a bound state for the composite of two bosons. We will apply the methods of Rajeev[10] and formulate it as a classical field theory of bilinears. In this case (unlike the gauge theory case) this is only an approximation since the theory does not have to be restricted to this flavor invariant sector. To avoid repetitions we sometimes refer to our work on complex bosons in Ref. 24. There is an interesting Bethe–Salpeter treatment of bound states in the broken phase of ϕ^4 theory in Ref. 25, in some sense this is similar to the model we work with.

II. THE MODEL IN THE LIGHT-CONE AND LARGE-N_f LIMIT

We write down a $U(N_f)$ invariant action for two complex scalars ϕ_a and ϕ_b,

$$S=\int \mathrm{d}^3x\Big(\partial^\mu\phi_a^\dagger\partial_\mu\phi_a+\partial^\mu\phi_b^\dagger\partial_\mu\phi_b-m_a^2\phi_a^\dagger\phi_a-m_b^2\phi_b^\dagger\phi_b$$
$$-\frac{\lambda}{4}[(\phi_a^\dagger\phi_a)^2+(\phi_b^\dagger\phi_b)^2-2(\phi_a^\dagger\phi_b)(\phi_b^\dagger\phi_a)]\Big). \tag{1}$$

We introduced a common coupling λ, for the two complex fields $\phi_{a\alpha}$ and $\phi_{b\alpha}$. We assume that the internal index α takes the values 1,...,N_f. If we do not have the last term which couples the two fields the action would have a $U(N_f)\times U(N_f)$ symmetry, and the interaction term explicitly breaks this. The interaction may look discomforting, but it is easy to see that it is always positive. The classical ground state of the massive theory is when both fields are set to zero. This means that we can quantize the theory around its classical minimum by introducing creation–annihilation operators for the Fourier modes, as we will see in the following. Note that this theory in three dimensions is super-renormalizable from a perturbative point of view, so we do not expect any multiplicative renormalizations (when $\lambda<0$ the theory is unstable, it can be defined by a perturbation theory analysis, but we restrict ourselves to positive values).

Perturbatively, there is only one type of divergence after normal ordering which we will comment on later.[26] To apply the methods developed by Rajeev, we will use the light-cone coordinates, introduce $x^+=(1/\sqrt{2})(x^0+x^2)$ and $x^-=(1/\sqrt{2})(x^0-x^2)$, and x^1 remains as the transverse coordinate. We choose x^+ as time (that is our evolution variable). A good review of light-front methods is given in Ref. 27; a good discussion of the scalar field in the light-front is also given in Refs. 28 and 29. The three-dimensional scalar field theory has been investigated from different points of view in Refs. 26, 30–32.

We basically use the same conventions as in our previous work,[24,33]

$$S=\int \mathrm{d}x^+\,\mathrm{d}x^-\mathrm{d}x^1\Big(\frac{1}{2}\phi_a^\dagger(-2\partial_-)\partial_+\phi_a+\frac{1}{2}\phi_b^\dagger(-2\partial_-)\partial_+\phi_b-\phi_a^\dagger(m_a^2-\partial_1^2)\phi_a-\phi_b^\dagger(m_b^2-\partial_1^2)\phi_b$$
$$-\frac{\lambda}{4}[(\phi_a^\dagger\phi_a)^2+(\phi_b^\dagger\phi_b)^2-2(\phi_a^\dagger\phi_b)(\phi_b^\dagger\phi_a)]\Big).$$

The action is first order in time x^+, which means that we are already in the Hamiltonian formalism. The Hamiltonian can be read off directly,

$$H=\int \mathrm{d}x^-\,\mathrm{d}x^1\Big(\phi_a^\dagger(-\partial_1^2+m_a^2)\phi_a+\phi_b^\dagger(-\partial_1^2+m_b^2)\phi_b$$
$$+\frac{\lambda}{4}[(\phi_a^\dagger\phi_a)^2+(\phi_b^\dagger\phi_b)^2-2(\phi_a^\dagger\phi_b)(\phi_b^\dagger\phi_a)]\Big). \tag{2}$$

The quantization at equal time following Dirac gives

$$[\hat{\phi}_a^{\alpha\dagger}(x^-,x^1),\hat{\phi}_{a\beta}(y^-,y^1)]=-\frac{i}{4}\delta_\beta^\alpha\,\mathrm{sgn}(x^--y^-)\,\delta(x^1-y^1), \tag{3}$$

and the same rule applies for ϕ_b. We recall that the field can be expanded in terms of creation–annihilation operators at initial light-front time (since the classical minimum is the zero configuration for the fields),

$$\hat{\phi}_{a\alpha}(x^-,x^1)=\int\frac{[\mathrm{d}p_-\,\mathrm{d}p_1]}{\sqrt{2|p_-|}}a_\alpha(p_-,p_1)e^{-ip_-x^--p_1x^1},$$

$$\hat{\phi}_{b\alpha}(x^-,x^1)=\int\frac{[\mathrm{d}p_-\,\mathrm{d}p_1]}{\sqrt{2|p_-|}}b_\alpha(p_-,p_1)e^{-ip_-x^--p_1x^1},$$

where we use $[\mathrm{d}p]=\mathrm{d}p/2\pi$. (To properly define everything we should assume that this expansion is given for $(-\infty,-\epsilon_0]\cup[\epsilon_0,\infty)$ at the end we take $\epsilon_0\to 0$ limit.)

The creation and annihilation operators now satisfy

$$[a_\alpha(p_-,p_1),a^{\beta\dagger}(q_-,q_1)]=\mathrm{sgn}(p_-)\,\delta_\alpha^\beta\delta[p_--q_-]\delta[p_1-q_1],$$

$$[b_\alpha(p_-,p_1),b^{\beta\dagger}(q_-,q_1)]=\mathrm{sgn}(p_-)\,\delta_\alpha^\beta\delta[p_--q_-]\delta[p_1-q_1].$$

Since the fields are complex valued, annihilation and creation operators are not related. We introduce a vacuum state $|0\rangle$ for the Fock space construction,

$$a_\alpha(p_-,p_1)|0\rangle=0\quad\text{for } p_->0,\quad a^{\alpha\dagger}(p_-,p_1)|0\rangle=0\quad\text{for } p_-<0,$$

$$b_\alpha(p_-,p_1)|0\rangle=0\quad\text{for } p_->0,\quad b^{\alpha\dagger}(p_-,p_1)|0\rangle=0\quad\text{for } p_-<0.$$

It is important to keep in mind that the operator $a_\alpha(p_-,p_1)$ for $p_-<0$, *creates an antiparticle of momentum* $(-p_-,-p_1)$ and similarly for b_α (which one can see by rewriting the above-given expansions in a more conventional way, by separating particle and antiparticle operators). We define normal ordering rules with respect to this vacuum as usual and denote it by a colon $:\phi_a\ldots\phi_a:$, for the computations we will use the following relation:

$$:a^{\alpha\dagger}(p_-,p_1)a_\beta(q_-,q_1):=a^{\alpha\dagger}(p_-,p_1)a_\beta(q_-,q_1)-\frac{\delta^\alpha_\beta}{2}(1-\mathrm{sgn}(p_-))\,\delta[p_--q_-]\,\delta[p_1-q_1], \tag{4}$$

and exactly the same for b quanta.

We have the following Hamiltonian in the quantized theory:

$$\hat{H}=\int \mathrm{d}x^1\,\mathrm{d}x^-\Big(:\hat{\phi}_a^\dagger(m_a^2-\partial_1^2)\hat{\phi}_a:+:\hat{\phi}_b^\dagger(m_b^2-\partial_1^2)\hat{\phi}_b:$$
$$+\frac{\lambda}{4}[:(\hat{\phi}_a^\dagger\hat{\phi}_a)^2:+:(\hat{\phi}_b^\dagger\hat{\phi}_b)^2:-2:(\hat{\phi}_a^\dagger\hat{\phi}_b)(\hat{\phi}_b^\dagger\hat{\phi}_a):]\Big).$$

As it stands the Hamiltonian would not be a well-defined operator for finite N_f theory. We need to introduce mass renormalization terms which correspond in the diagramatic language to the setting-sun diagrams.[26,30,31] When we take the large-N_f limit these counterterms become of smaller order, therefore the Hamiltonian as written will have a well-defined limit.

We now define as an approximation a large-N_f limit and restrict the theory to the flavor invariant sector. This is to be taken as an approximation to the full quantum theory. We introduce a set of flavor invariant operators, which are directly written in the momentum representation, and to simplify notation we write p to denote p_-,p_1 collectively, and $\delta[p-q]=\delta[p_--q_-]\times\delta[p_1-q_1]$,

$$\hat{N}_a(p,q)=\frac{2}{N_f}:a^{\alpha\dagger}(p_-,p_1)a_\alpha(q_-,q_1):,$$

$$\hat{N}_b(p,q)=\frac{2}{N_f}:b^{\alpha\dagger}(p_-,p_1)b_\alpha(q_-,q_1):,$$

$$\hat{C}(p,q)=\frac{2}{N_f}a^{\alpha\dagger}(p_-,p_1)b_\alpha(q_-,q_1),$$

$$\hat{\bar{C}}(p,q)=\frac{2}{N_f}b^{\alpha\dagger}(p_-,p_1)a_\alpha(q_-,q_1). \tag{5}$$

Note that $\hat{C}$ and $\hat{\bar{C}}$ are just Hermitian conjugates of each other.

The idea behind Refs. 8 and 10 is that when we take the large-N_f limit the flavor invariant operators have smaller and smaller fluctuations, and if we compute their commutator, for example, for N_a with itself, we get

$$[\hat{N}_a(p,q),\hat{N}_a(s,t)]=\frac{2}{N_f}(\hat{N}_a(p,s)\mathrm{sgn}(p_-)\,\delta[q-r]-\hat{N}_a(r,q)\mathrm{sgn}(p_-)\,\delta[p-s]-(\mathrm{sgn}(p_-)$$
$$-\mathrm{sgn}(q_-))\,\delta[p-s]\,\delta[q-r]).$$

We assume that when we let $N_f\to\infty$ there are proper large-N_f limits for these bilinears restricted to the flavor invariant states. As a result the theory becomes classical, and the expectation values of flavor invariant operators factorize as $N_f\to\infty$.[10,34] Thus we may postulate a set of Poisson brackets for these *classical* variables:

$$\{N_a(p,q),N_a(s,t)\}=-2i(N_a(p,s)\mathrm{sgn}(p_-)\,\delta[q-r]-N_a(r,q)\mathrm{sgn}(p_-)\,\delta[p-s]-(\mathrm{sgn}(p_-)$$
$$-\mathrm{sgn}(q_-))\,\delta[p-s]\,\delta[q-r]),$$

$$\{N_b(p,q),N_b(s,t)\}=-2i(N_b(p,s)\mathrm{sgn}(p_-)\delta[q-r]-N_b(r,q)\mathrm{sgn}(p_-)\delta[p-s]$$
$$-(\mathrm{sgn}(p_-)-\mathrm{sgn}(q_-))\delta[p-s]\delta[q-r]),$$

$$\{C(p,q),\overline{C}(s,t)\}=-2i(N_a(p,t)\mathrm{sgn}(q_-)\delta[q-s]-N_b(s,q)\mathrm{sgn}(t_-)\delta[p-t]$$
$$-(\mathrm{sgn}(p_-)-\mathrm{sgn}(q_-))\delta[p-t]\delta[q-s]),$$

$$\{N_a(p,q),C(s,t)\}=-2i\,\mathrm{sgn}(q_-)\delta[q-s]C(p,t),$$

$$\{N_b(p,q),C(s,t)\}=2i\,\mathrm{sgn}(q_-)\delta[p-t]C(s,q),$$

$$\{N_a(p,q),\overline{C}(s,t)\}=2i\,\mathrm{sgn}(p_-)\delta[p-t]\overline{C}(s,q),$$

$$\{N_b(p,q),\overline{C}(s,t)\}=-2i\,\mathrm{sgn}(q_-)\delta[q-s]\overline{C}(p,t),$$

all other Poisson brackets being zero.

There are constraints coming from the $U(N_f)$ invariance, if we restrict the theory to the flavor invariant sector. They are very similar to the ones found in Ref. 24,

$$(\epsilon N_a+\epsilon)^2+\epsilon C\epsilon C^\dagger=1,$$

$$(\epsilon N_b+\epsilon)^2+\epsilon C^\dagger\epsilon C=1,$$

$$N_a\epsilon C+C\epsilon N_b+\epsilon C+C\epsilon=0,$$

and the Hermitian conjugate of the last equation. These conditions are derived using techniques similar to Refs. 33 and 24. Here we are using $\epsilon(p,q)=\mathrm{sgn}(p_-)\delta[p_--q_-]\delta[p_1-q_1]$, $1(p,q)=\delta[p-q]$, and a shorthand for the operator products, for example, N_aC means

$$(N_aC)(p,s)=\int[\mathrm{d}q_-\mathrm{d}q_1]N_a(p_-,p_1;q_-,q_1)C(q_-,q_1;s_-,s_1), \tag{6}$$

and similarly for the others.

We will have further convergence conditions coming from the super-renormalizability. These should be regarded as sufficiently restrictive conditions to keep the system's evolution in phase space. The Hamiltonian puts more stringent conditions on the admissible class of observables—we believe its domain should be dense inside the phase space. Correct normalization should then be found using the Hamiltonian as a quadratic form on the space of these variables and demanding this form to be finite for all physical states. To state our conditions we recall that the one-particle Hilbert spaces of bosons are divided into positive and negative energy subspaces according to $\mathrm{sgn}(p_-)$. We assume that the operators which act between positive and negative energy subspaces will be Hilbert–Schmidt, whereas the operators acting between the same subspaces will be trace class.[35] We write explicitly the one for C: $C(u_-,u_1;v_-,v_1)$ is trace class for $u_-v_->0$, and Hilbert–Schmidt for $u_-v_-<0$, and the same for the other variables. Note that these are consistent with the constraints on the system, which defines the geometry of the phase space. The constraints and the convergence conditions can be cast into a coherent geometric picture: it defines a homogeneous manifold of $U_1((\mathcal{H}_a\oplus\mathcal{H}_b)_+,(\mathcal{H}_a\oplus\mathcal{H}_b)_-)$, but we will not use it in this work.

We can rewrite the large-N_f Hamiltonian in terms of these variables,

$$H=\frac{1}{4}\int [\mathrm{d}p]\frac{m_a^2+p_1^2}{|p_-|}N_a(p,p)+\frac{1}{4}\int [\mathrm{d}p]\frac{m_b^2+p_1^2}{|p_-|}N_b(p,p)$$
$$+\frac{\lambda}{64}\int [\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]\frac{\delta[p-q+s-t]}{\sqrt{|p_-q_-s_-t_-|}}[N_a(p,q)N_a(s,t)+N_b(p,q)N_b(s,t)$$
$$-2C(p,q)\overline{C}(s,t)].$$

This defines our large-N_f approximation, and in principle we can calculate the equations of motion of the basic observables by

$$\frac{\partial O(u,v)}{\partial x^+}=\{O(u,v),H\}, \tag{7}$$

where O refers to any one of N_a, N_b, C, $\overline{C}$. The resulting equations are nonlinear integral equations and we also have the constraint to satisfy. It would be interesting to study this system using a variational ansatz. We will leave the analysis of the full system to a future work and look at a linearized version.

III. LINEARIZATION AND A POSSIBLE BOUND STATE

To get a better feeling about the system we can start with a linear approximation. This means we should linearize the constraint as well as the equations of motion. The linearization of the constraint gives us, for our basic variables,

$$(1+\mathrm{sgn}(u_-)\mathrm{sgn}(v_-))N_a(u_-,u_1;v_-,v_1)=0,\quad (1+\mathrm{sgn}(u_-)\mathrm{sgn}(v_-))N_b(u_-,u_1;v_-,v_1)=0,$$
$$(\mathrm{sgn}(u_-)+\mathrm{sgn}(v_-))C(u_-,u_1,v_-,v_1)=0. \tag{8}$$

We will be using the last one in our computations, it says that the light-cone momenta should be opposite to each other: $C(u_-,u_1;v_-,v_1)=0$ if $u_-v_->0$, and nonzero if $u_-v_-<0$. The same conditions hold for N_a and N_b as well. In the linear approximation we will search for a possible bound state of a and b particles. In principle we can compute the linearized equations for all the other variables, but they will not lead to a solution for the bound state or a solution for a resonance: they only have scattering states. Therefore we work only with the composite $C(u,v)$, let us choose $u_->0$, $v_-<0$. The equations of motion of $C(u,v)$ for $u_->0$, $v_-<0$, in the linear approximation become

$$\frac{\partial C(u,v)}{\partial x^+}=\{C(u,v),H\}$$
$$=\frac{i}{2}\left[\frac{m_a^2+u_1^2}{u_-}-\frac{m_b^2+v_1^2}{v_-}\right]C(u,v)$$
$$-i\frac{\lambda}{8\pi}\int\frac{[\mathrm{d}p\,\mathrm{d}q]}{\sqrt{|p_-q_-u_-v_-|}}\delta[p_--q_-+v_--u_-]\delta[p_1-q_1+v_1-u_1]C(u,v).$$

Let us make an ansatz, in the light-front direction we make a 't Hooft-like choice with respect to the relative momentum variable $\zeta=u_-/(u_--v_-)$. This variable now satisfies $0<\zeta<1$, and we set $C(u_-,u_1;v_-,v_1)=\tilde{f}(\zeta;u_1,v_1)e^{iP_+x^+}$. Notice that $P_-=u_--v_->0$, and we introduce a relativistically invariant mass variable $\mu^2=2P_+|u_--v_-|-(u_1+(-v_1))^2$, which will be the mass of the bound state [recall that the momentum v_1 denotes an antiparticle with momentum

$-v_1$, thus $u_1+(-v_1)$ is the total transversal momentum of the two particle state]. After some manipulations, similar to the ones in Refs. 8 and 11, this gives us an eigenvalue equation for the invariant mass:

$$\mu^2\tilde{f}(\zeta;u_1,v_1)=\left[\frac{m_a^2+(u_1-\zeta(u_1+(-v_1)))^2}{\zeta}+\frac{m_b^2+(v_1-(1-\zeta)(u_1+(-v_1)))^2}{1-\zeta}\right]\tilde{f}(\zeta;u_1,v_1)$$
$$-\frac{\lambda}{8\pi}\int_0^1 d\eta\int_{-\infty}^{\infty}\frac{[dp_1dq_1]\tilde{f}(\eta;p_1,q_1)}{\sqrt{\eta(1-\eta)\zeta(1-\zeta)}}\delta[p_1-q_1-(u_1+(-v_1))].$$

(Note that this form reduces to $\mu=m_a+m_b$ if we set $\lambda=0$, and choose the function $\tilde{f}$ properly.) We may equivalently use a new set of variables, $R=u_1-\zeta(u_1+(-v_1))$ and $u_1+(-v_1)$, relative transversal light-front momentum and transversal total momentum, respectively, instead of the above-mentioned variables. If we write everything in terms of these new set of variables we get

$$\mu^2\tilde{f}(\zeta;R,u_1+(-v_1))=\left[\frac{m_a^2+R^2}{\zeta}+\frac{m_b^2+(-R)^2}{1-\zeta}\right]\tilde{f}(\zeta;R,u_1+(-v_1))$$
$$-\frac{\lambda}{8\pi}\int_0^1 d\eta\int_{-\infty}^{\infty}\frac{[dQ][d(p_1-q_1)]\tilde{f}(\eta;Q,p_1+(-q_1))}{\sqrt{\eta(1-\eta)\zeta(1-\zeta)}}$$
$$\times\delta[p_1-q_1-(u_1+(-v_1))].$$

(The Jacobian of this transformation in the integral is one.) The total momentum integral can be done due to the delta function and we end up with

$$\mu^2\tilde{f}(\zeta;R,u_1+(-v_1))=\left[\frac{m_a^2+R^2}{\zeta}+\frac{m_b^2+(-R)^2}{1-\zeta}\right]\tilde{f}(\zeta;R,u_1+(-v_1))$$
$$-\frac{\lambda}{8\pi}\int_0^1 d\eta\int_{-\infty}^{\infty}\frac{[dQ]\tilde{f}(\eta;Q,u_1+(-v_1))}{\sqrt{\eta(1-\eta)\zeta(1-\zeta)}}.$$

We see that the total momentum $u_1+(-v_1)$ is conserved, thus we can factor out the transversal center of mass motion by assuming $\tilde{f}(\zeta;u_1,v_1)=f(\zeta,R)g(u_1+(-v_1))$:

$$\mu^2 f(\zeta,R)=\left[\frac{m_a^2+R^2}{\zeta}+\frac{m_b^2+R^2}{1-\zeta}\right]f(\zeta,R)-\frac{\lambda}{16\pi^2}\int_{-\infty}^{\infty}dQ\int_0^1 d\eta\frac{f(\eta,Q)}{\sqrt{\eta(1-\eta)\zeta(1-\zeta)}}. \tag{9}$$

We can reduce this again to a functional equation for the unknown eigenvalue, by using the standard techniques,

$$\frac{\lambda}{16\pi^2}\int_{-\infty}^{\infty}\int_0^1\frac{d\eta\,dQ}{Q^2+m_a^2+\mu^2\eta^2+(m_b^2-m_a^2-\mu^2)\eta}=1. \tag{10}$$

The integrand will have no poles if the quadratic expression involving η has no real roots, or if it has a double root. This is the case if we can assume that $|m_a-m_b|\leqslant\mu\leqslant m_a+m_b$. The last inequality is clear, the bound state mass cannot be bigger than the sum of its constituent's masses. The other inequality says that the fundamental quanta should be stable against decay if, for example, $m_a>m_b$, then it would be favorable to have m_a decaying into μ and m_b. Then we can evaluate the integral in any way we want. First we take the Q integral, this gives us

$$\int_0^1 \frac{d\eta}{\sqrt{\mu^2\eta^2+(m_b^2-m_a^2-\mu^2)\eta+m_a^2}}=\frac{16\pi}{\lambda}. \tag{11}$$

The next integral can be done and simplified into

$$\frac{1}{\mu}\ln\left[\frac{m_a+m_b+\mu}{m_a+m_b-\mu}\right]=\frac{16\pi}{\lambda}, \tag{12}$$

which is valid when $|m_a-m_b|\leqslant\mu\leqslant m_a+m_b$. We may study the small coupling limit of this expression. In this case we expect that the bound state mass becomes very close to the two mass treshold, then we can write

$$\frac{m_a+m_b-\mu}{m_a+m_b+\mu}\approx e^{-16\pi(m_a+m_b)/\lambda}, \quad \mu\approx(m_a+m_b)(1-2e^{-16\pi(m_a+m_b)/\lambda}), \tag{13}$$

which is consistent if we take $\lambda/(m_a+m_b)\ll 1$. The other extreme is interesting as well, $\mu\approx m_a-m_b$ (assuming a is the heavier particle). This implies a critical coupling λ_c beyond which our methods break down, due to the appearance of a tachyon,

$$\frac{16\pi}{\lambda_c}=\frac{1}{m_a-m_b}\ln\left[\frac{m_a}{m_b}\right]$$

or

$$\lambda_c=\frac{16\pi}{\ln\left[\frac{m_a}{m_b}\right]}(m_a-m_b). \tag{14}$$

This critical coupling is pushed to higher and higher values if b becomes lighter and lighter with respect to the a particle. For any given value of the coupling constant in the interval $(0,\lambda_c]$, there is a solution for the bound state energy. Hence we see that there is a composite bound state for these values of the coupling constants. It is not clear what happens beyond this value. It is possible that the linear approximation breaks down. It is also possible that the large-N_f limit is not a good approximation beyond a certain value. The other possibility is that the naive vacuum is not a true vacuum of the quantum theory and we should redefine the vacuum of the system. We are not able to analyze these possiblities at the moment.

Let us compare this with the results we would have found if we looked at a $1+1$-dimensional version of the same model. Then the bound state equation could be written in terms of the fractional light-cone momentum ζ only. There is no transversal component and we have only one integral to compute. As a result we find the equation that should be satisfied by the eigenvalue μ (with the condition $|m_a-m_b|\leqslant\mu\leqslant m_a+m_b$),

$$\frac{1}{\sqrt{4m_a^2m_b^2-z^2}}\left[\arctan\left(\frac{2m_b^2+z}{\sqrt{4m_a^2m_b^2-z^2}}\right)+\arctan\left(\frac{2m_a^2+z}{\sqrt{4m_a^2m_b^2-z^2}}\right)\right]=\frac{8\pi}{\lambda^2}, \tag{15}$$

where $\mu^2=m_a^2+m_b^2+z$ and we wrote λ^2 for the coupling constant since it has dimensions mass-squared. To analyze the behavior it is more natural to define the dimensionless variables, $\tilde{z}=z/2m_am_b$, and $\sigma=m_a/m_b$, and rescale the coupling $\tilde{\lambda}^2=\lambda^2/m_am_b$,

$$\frac{1}{\sqrt{1-\tilde{z}^2}}\left[\arctan\left(\frac{\sigma+\tilde{z}}{\sqrt{1-\tilde{z}^2}}\right)+\arctan\left(\frac{1/\sigma+\tilde{z}}{\sqrt{1-\tilde{z}^2}}\right)\right]=\frac{16\pi}{\tilde{\lambda}^2}. \tag{16}$$

Note that now $\tilde{z}$ satisfies $-1<\tilde{z}<1$. If we take the limit $\tilde{z}\to -1^{+}$, this corresponds to $\mu\to|m_a-m_b|^{+}$ and the other limit $\tilde{z}\to 1^{-}$ corresponds to $\mu\to(m_a+m_b)^{-}$. If we assume $\tilde{z}\approx 1^{-}$ we see that the bound states satisfy the relation

$$\tilde{z}\approx 1-\frac{\tilde{\lambda}^4}{128}$$

or

$$\mu\approx(m_a+m_b)\left[1-\frac{\lambda^4}{128m_am_b(m_a+m_b)^2}\right], \tag{17}$$

and if we take $\tilde{\lambda}$ sufficiently small this is consistent. Notice that in $2+1$ dimensions we have an exponential behavior in the inverse coupling, which is nonanalytic in the coupling constant (around zero), as opposed to this power law change. If we look at the other extreme we see that there is a finite limit for $\tilde{z}\to -1^{+}$, in fact it is equal to 1. This implies a critical coupling again, beyond which our methods predict a tachyonic state,

$$\tilde{\lambda}_c^2=16\pi$$

or

$$\lambda_c^2=16\pi m_am_b\,. \tag{18}$$

This is to be compared with the result in Eq. (14), which is sensitive to the mass difference.

Let us comment on the convergence conditions in this context. Since we are looking for a normalizable solution it looks natural to demand

$$\int_0^1 d\zeta\int_{-\infty}^{\infty}[dR]|f(\zeta,R)|^2<\infty. \tag{19}$$

In fact this is right, and we could see this from our Hilbert–Schmidt condition,

$$\int_{u_-v_-<0}[du_-dv_-][du_1dv_1]|C(u_-,u_1;v_-,v_1)|^2<\infty. \tag{20}$$

If we now make the above change of variables by calling $u_--v_-=P_-$ we have

$$\frac{1}{\pi}\int_0^1 d\zeta\int_{0^+}^{\infty}P_-[dP_-]\int[d(u_1+(-v_1))dR]|C(P_-,\zeta;R,(u_1+(-v_1)))|^2<\infty. \tag{21}$$

In our case we are restricting P_- to the surface $2P_-P_+=\mu^2+(u_1+(-v_1))^2$ (for fixed μ,P_+), this means we should reinterpret the above-mentioned normalization as

$$\int_0^1 d\zeta\int[dR]|f(\zeta,R)|^2\int\frac{\mu^2+(u_1+(-v_1))^2}{2P_+}|g(u_1+(-v_1))|^2[d(u_1+(-v_1))]<\infty \tag{22}$$

(notice that P_+ is not allowed to be zero), which means two separate conditions,

$$\int_0^1 d\zeta\int[dR]|f(\zeta,R)|^2<\infty\quad\int\frac{\mu^2+(u_1+(-v_1))^2}{2P_+}|g(u_1+(-v_1))|^2[d(u_1+(-v_1))]<\infty. \tag{23}$$

The second one simply is a Sobolev-type condition, which states that the energy of the transversal center of momentum component should also be finite. We see that our solution actually satisfies a stronger condition for equations of motion to make sense.

ACKNOWLEDGMENTS

The author would like to thank S. G. Rajeev for several ideas related to the scalar field theory and large-N_f limits and acknowledges E. Langmann for pointing out the Bethe–Salpeter treatment of bound states in the broken phase of ϕ^4 theory in Ref. 25. The author gratefully acknowledges discussions with M. Arik, E. Langmann, J. Mickelsson, C. Saclioglu, and E. Toprak. The author's stay in KTH is made possible by the Gustafsson Fellowship, and he would like to thank to J. Mickelsson for this great opportunity.

(Received 7 September 2000; accepted for publication 8 January 2001)

In order to get geodesically complete Reißner–Nordstrøm space–times, it is necessary to identify pairs of singular points. This can be done in such a way that ''wormholes'' are created which generate electric field lines without any charge. Finally, it is shown that it is possible to glue this space–time not in the singularities $r=0$, but at some $r>0$. The surface energy generated by this gluing is exotic, but tends to zero in the limit $r\to 0$. © *2002 American Institute of Physics.*

I. INTRODUCTION

More than 40 years ago, Archibald Wheeler realized[1,2] that nontrivial electric fields can be generated whose field lines do not end in electric charges. Instead some domain of the space is cut out, in which the charge would be expected. To this ''hole,'' a channel (''wormhole'') is attached, through which the field lines pass to some other place such that the divergence of the field lines vanishes. So no charges are needed—they are replaced by special topological structures.

For the realization of this idea, one starts from the Reißner–Nordstrøm solution[3,4] to Einstein's equations. It contains an electric field proportional to $1/r^2$. Visser has cut out the regions $r<\epsilon$ from two Reißner–Nordstrøm space–times and has glued together the remaining parts along the subspaces $r=\epsilon$.[5,6] He wanted to obtain a ''transversable'' wormhole. Therefore he chose ϵ larger than the outer horizon r_+. But this causes some problems.

The geodesics passing through the subspace $r=\epsilon$ are not C^2. (Trivially, they can be made continuously differentiable everywhere.) This means that freely falling particles get a δ-like kick at $r=\epsilon$. Second, the Ricci tensor contains a singularity proportional to $\delta(r-\epsilon)$. Therefore the energy-momentum tensor T has surface terms. They violate the ''average null energy condition'' [6,7]

$$g_{ij}\dot{\gamma}^i(\tau)\dot{\gamma}^j(\tau)=0\Rightarrow\int T_{ij}\dot{\gamma}^i(\tau)\dot{\gamma}^j(\tau)d\tau\geqslant 0, \qquad (1)$$

τ: generalized affine parameter

for some curves $\tau\to\gamma(\tau)$, i.e., the surface matter is ''exotic.'' This is true for all spherically symmetric transversable wormholes, whatever the specific assumptions are. A good survey of the literature on this subject is given in Ref. 6.

In the present work, we want to develop a model for the topological generation of charge via wormholes. This is done for the specific example of electric charge, but, of course, the idea applies to all kinds of charge. For this purpose, it is not necessary to have transversable wormholes: We do not need information from the ''other part of the world.'' In addition, we cannot even expect to get transversable wormholes, because in the Reißner–Nordstrøm solution with $M^2>Q^2$, the mass and charge are hidden by two horizons. So it would be very surprising, if one could avoid all horizons by introducing wormholes and leave the rest of physics unchanged.

The most natural way to reach our goal is to identify singularities $r=0$ in the maximal analytic extension of the Reißner–Nordstrøm solution. Then in the case $M^2>Q^2$, no changes of

a)Electronic mail: buchner@mathematik.tu-muenchen.de

space–time outside the horizons are needed. By this identification, the topology becomes nontrivial—a fact which is to be expected: Einstein's equations determine only the local geometry, but in most cases give little information about the global structure of space–time. It has to be determined by other requirements.

In order that this identification makes sense, one needs a precise definition of singularities. This is still an open problem. But here, we are not interested in the most general situation. Instead, one can start from the maximal analytical extension and use some theory defining the necessary geometric quantities in the singularity. The details of such a theory are irrelevant in this connection, because all functions are uniquely determined by their behavior near the singularity. In the present work, the Reißner–Nordstrøm solution together with its singularities is considered as a d-space.[8,9] This is almost identical to the differential space of Refs. 10 and 11. For the discussion of differential equations on these spaces, the results of Ref. 12 are used. But as remarked above, most other generalizations of differential manifolds will lead to the same results. This is true in particular for the differential spaces described in Refs. 10 and 11.

In addition, gluing of two Reißner–Nordstrøm solutions at some $r=\epsilon>0$ will be discussed. Here, exotic surface matter appears. But the energy of the electromagnetic field rises as $1/r$, whereas the contribution of the surface matter tends to zero for $\epsilon\to 0$. Therefore, by an appropriate choice of ϵ, the ratio of the surface energy to the electric energy can be made arbitrarily small.

Gluing at $r=0$ has the advantage that all geodesics are everywhere C^3. On the other hand, gluing at some $\epsilon>0$ avoids the singularities in the metric and the electric field, but entails surface matter.

II. THE GLOBAL STRUCTURE OF THE REIßNER–NORDSTRØM SOLUTION

The Reißner–Nordstrøm solution[3,4] to Einstein's equations

$$R_{ik}-\frac{1}{2}Rg_{ik}=\frac{8\pi G}{c^2}T_{ik}, \quad G\text{: Newton's gravitational constant,}$$

describes a static spherically symmetric object with electric and magnetic fields. It is given by the metric

$$ds^2=\frac{\Delta}{r^2}dt^2-\frac{r^2}{\Delta}dr^2-r^2d\Omega^2 \tag{2}$$

with the abbreviations

$$\Delta=r^2-2Mr+Q^2$$

and

$$d\Omega^2=d\vartheta^2+\sin^2\vartheta\, d\varphi^2.$$

Here M and Q are constants determined by the mass m, the electric charge q and the magnetic charge q_m, respectively, of the object:

$$M=\frac{2Gm}{c^2}; \quad Q^2=\frac{G}{4\pi\epsilon_0 c^4}(q^2+q_m^2).$$

So, the Reißner–Nordstrøm solution may also contain a magnetic monopole. But in the following, we will set $q_m=0$, unless the contrary is stated explicitly.

We shall restrict ourselves to the case $M^2>Q^2$. For elementary particles, this condition is violated by many orders of magnitude. On the other hand, all ''elementary'' objects, i.e., quarks and leptons, have spin. Therefore the Reißner–Nordstrøm solution does not apply to them, no matter whether $M^2>Q^2$ or $M^2<Q^2$.

The construction of the maximal analytic extention starts from the three regions

$$A:\ 0<r<r_-,$$

$$B:\ r_-<r<r_+,$$

$$C:\ r_+<r<\infty.$$

Here r_+ and r_- are the zeros of Δ:

$$r_+ := M+\sqrt{M^2-Q^2}, \tag{3}$$

$$r_- := M-\sqrt{M^2-Q^2}. \tag{4}$$

It is convenient to introduce new coordinates u,v by

$$A \text{ and } C: \quad u := t-r_*, \quad v := t+r_*, \tag{5}$$

$$B: \quad u := t+r_*, \quad v := r_*-t, \tag{6}$$

with the abbreviation

$$r_* := \int \frac{r^2}{\Delta}\,dr = r+\frac{r_+^2}{r_+-r_-}\ln|r-r_+|-\frac{r_-^2}{r_+-r_-}\ln|r-r_-|. \tag{7}$$

Next, one constructs the new regions A', B' and C' from A, B and C, respectively, by replacing $u\mapsto -u$; $u\mapsto -v$ in (5) and (6). These six regions are composed to a periodic ''ladder'' according to Fig. 1 (see, e.g., Refs. 7 and 13). The transformations

$$A_n: U := \operatorname{arctg}(-e^{-\alpha u})+(n+1)\pi,$$

$$V := \operatorname{arctg}(e^{\alpha v})+n\pi,$$

$$B_n: U := \operatorname{arctg}(e^{\alpha u})+n\pi,$$

$$V := \operatorname{arctg}(e^{\alpha v})+n\pi,$$

$$C_n: U := \operatorname{arctg}(-e^{-\alpha u})+n\pi,$$

$$V := \operatorname{arctg}(e^{\alpha v})+n\pi,$$

$$A'_n: U := \operatorname{arctg}(-e^{-\alpha u})+(n-\tfrac{1}{2})\pi,$$

$$V := \operatorname{arctg}(e^{\alpha v})+(n-\tfrac{1}{2})\pi,$$

$$B'_n: U := \operatorname{arctg}(e^{\alpha u})+(n-\tfrac{1}{2})\pi,$$

$$V := \operatorname{arctg}(e^{\alpha v})+(n-\tfrac{1}{2})\pi,$$

$$C'_n: U := \operatorname{arctg}(-e^{-\alpha u})+(n+\tfrac{1}{2})\pi,$$

$$V := \operatorname{arctg}(e^{\alpha v})+(n-\tfrac{1}{2})\pi,$$

$$\alpha := (r_+-r_-)/(2r_+^2) \tag{8}$$

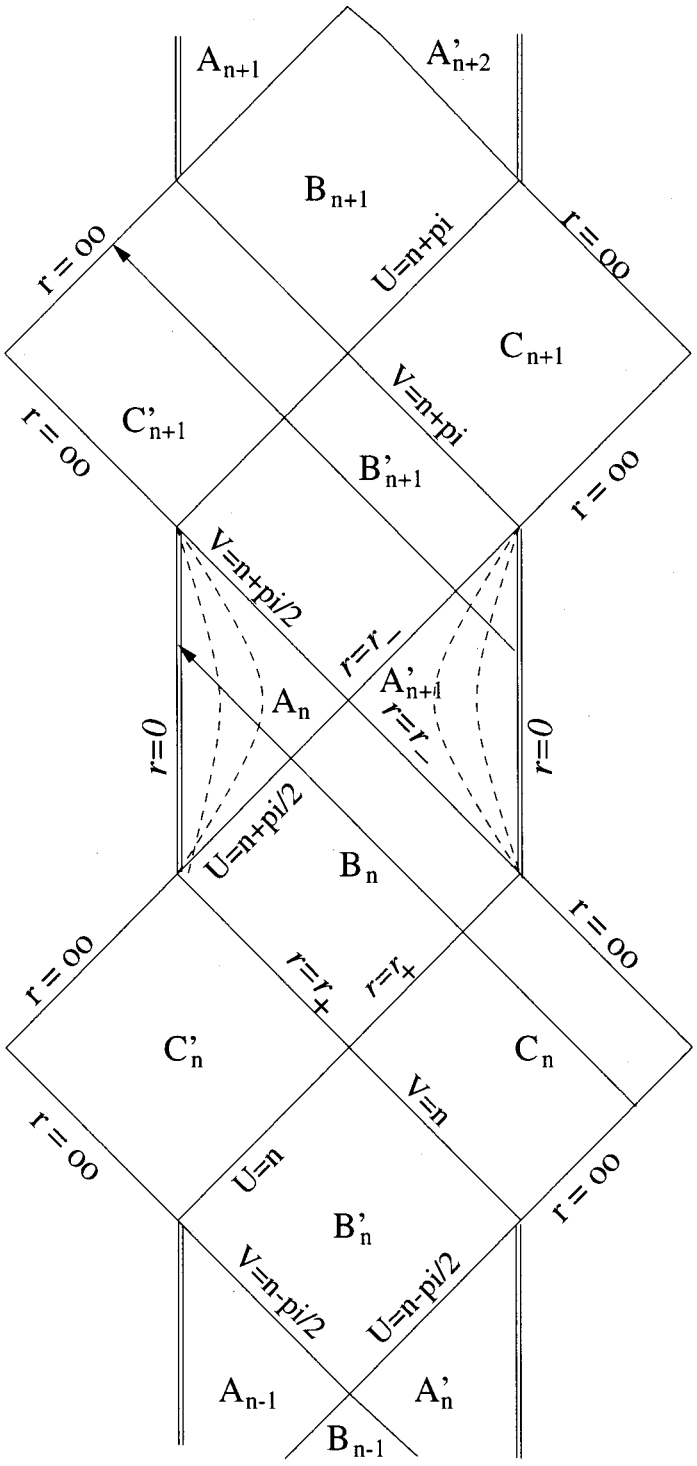

FIG. 1. Maximal analytic extension of the Reißner–Nordstrøm space–time. Dashed lines: $r=\text{const}$. The solid line with arrows shows a photon starting in C_n and passing to C'_{n+1} through a singularity.

define global parameters (U,V,ϑ,φ). Here $U+V$ may be interpreted as ''time,'' and $U-V$ as ''radius.'' With these coordinates, the line element (2) becomes

$$ds^2=-\frac{4}{\alpha^2 r^2}\frac{|r-r_+||r-r_-|}{\sin(2U)\sin(2V)}dUdV-r^2d\Omega^2. \tag{9}$$

It can be seen from Fig. 1 that this maximal analytic extension is not geodesically complete, because all radial spacelike and lightlike geodesics end in the singularities. This suggests to identify the singularities in A_n with those in A'_m for suitable pairs *m, n*. But, of course, the metric (9) and its derivatives are not defined in $r=0$. So it is not possible to apply here the usual rules[14,15] for gluing spaces in general relativity, i.e., to require that the metric (9) is at least C^2 in the tangential directions and C^1 in the normal direction. Instead, one considers the geodesics passing through the singularities. By definition, they need to be C^2-functions of their parameters. And in order to define ''geodesic'' coordinates, it is necessary,[16] that their limits for $r\to 0$ are at least C^3 in $A_n\cup A'_m$. But in general it is not possible to work with affine parameters, as the metric is singular at $r=0$.

The first step is to generalize differential manifolds in such a way that the singularities can be included. For this, the d-spaces of Refs. 8 and 9 will be used, which have been very useful in the discussion of Schwarzschild's metric, the radiation filled Friedmann universe and some more exotic space–times.[17,18] The basic idea is to replace the coordinate functions in the definition of differential manifolds by a more general set *C* of functions. In particular, no compatibility conditions between different charts are needed. The only requirement is that one can add, substract and multiply the functions in *C*. This leads to the following definition:

Let *M* be a topological space. The pair (*M, C*) is called d-space, if *C* is a sheaf of continuous real-valued functions on *M* which form an algebra w.r.t. pointwise operation.

For these d-spaces, it is simple to construct the tangent vectors as ''directional derivatives:''

Let (*M, C*) be a d-space and C_x the stalk at $x\in M$. A map

$$V:C_x\to\mathbb{R}$$

is called tangent vector to (*M, C*) in *x*, if for all $n\in\mathbb{N}$, all $f_1,\ldots,f_n\in C_x$, and all germs α of $C^1(\mathbb{R}^n,\mathbb{R})$ at $y:=(f_1(x),\ldots,f_n(x))\in\mathbb{R}^n$, the equation

$$V(\alpha\circ(f_1(x),\ldots,f_n(x)))=\sum_{i=1}^{n}(\partial_i\alpha)\cdot V(f_i)$$

holds, provided $\alpha\circ(f_1,\ldots,f_n)\in C_x$. Here $\partial_i\alpha$ denotes the partial derivative of α w.r.t. the *i*th argument.

For the construction of geodesics, it is necessary to have some theory of differential equations. In general, such a theory does not exist. But in the case under discussion, the regular points are dense in the d-space. Here the results of Ref. 12 guarantee existence and uniqueness of the solutions.

In such a theory it is possible to glue the singular points in A_n to those in A'_m. It is natural to require $m=n+1$ and to identify points with equal ''local times'' *t* or with equal ''global times'' $U+V$. We choose the latter possibility: If the points $(r=0,\,t)\in A_n$ are identified with the points $(r=0,\,t)\in A'_{n+1}$, there exist causal geodesics, which come arbitrarily close to themselves. To see this, regard the lines in Fig. 1 with $U=n+\pi/2$ or $V=n+\pi/2$. A lightlike geodesic just below such a line would be continued to a geodesic just above that line.

Gluing points with $r=0$ and equal values of $U+V$ entails a time reflexion, i.e., an identification of the points $(r=0,\,t)$ in A_n with the points $(r=0,\,-t)$ in A'_{n+1}.

III. THE GEODESICS IN $r=0$

The geodesics are most easily computed in the local coordinates (r,ϑ,φ,t). The method is similar to that used for Schwarzschild's solution: Because of spherical symmetry, it is possible to put $\vartheta=\pi/2=\text{const}$. In this way, the equations are considerably simplified, and the first integrals are easily obtained. The results for spacelike geodesics are[13]

$$\frac{d\varphi}{d\tau}=\frac{L}{r^2}, \tag{10}$$

$$\frac{dt}{d\tau}=E\frac{r^2}{\Delta}, \tag{11}$$

$$\left(\frac{dr}{d\tau}\right)^2=E^2+\frac{\Delta}{r^2}\left(1-\frac{L^2}{r^2}\right). \tag{12}$$

Here E and L are constants of integration. It can be seen from (12) that spacelike geodesics in A_n and in A'_m reach the value $r=0$, if and only if $L=0$ (radial geodesics). In the limit $r\to 0$, Eqs. (10)–(12) yield for $L=0$

$$\frac{d}{d\tau}(r(\tau),\vartheta(\tau),\varphi(\tau),t(\tau))\to\left(\pm\frac{Q}{r},0,0,E\frac{r^2}{Q^2}\right) \tag{13}$$

or

$$(r(\tau),\vartheta(\tau),\varphi(\tau),t(\tau))\to\left(\pm\sqrt{2|Q\tau|},\frac{\pi}{2},\varphi_0,\text{sign}(\tau)\frac{E}{|Q|}\tau^2+t_0\right). \tag{14}$$

These equations show that the radial spacelike geodesics can be continued through the singularities such that they are (at least) C^3 in the sense of d-spaces. This includes the fact that they are three times continuously differentiable on $A_n\cup A'_{n+1}-\{(r=0,\ t)|t\in\mathbb{R}\}$. But this is only true, if suitable curve parameters σ (not the arc length τ, but, e.g., $\sigma:=\tau/r$) and appropriate constants of integration are chosen [positive sign in (14) and positive (resp. negative) sign in (13) for $Q\tau>0$ (resp. <0); E and t_0 change their sign in $\tau=0$]. Notice that in $\sigma=0$ both $dr/d\sigma$ and $t(\sigma)$ have to change sign. Otherwise, the geodesics are not C^3. A general discussion of the gluing conditions can be found in Ref. 16.

Of course, the arc length τ is not a good parameter near $r=0$, because the metric is singular and τ is not well defined. If the tangent points in the r-direction, i.e., if $E=0$, Eq. (12) yields

$$\frac{dr}{d\tau}=\pm\sqrt{\frac{\Delta}{r^2}} \tag{15}$$

with the solution (remember that $\Delta\geqslant 0$ holds in A and A')

$$\sqrt{\Delta}+M\ln(M-r-\sqrt{\Delta})=\pm\tau+\tau_0.$$

Here τ_0 is a constant of integration. This implicit equation for $r(\tau)$ shows that the r-lines are geodesics which can be continued through the singularities.

In addition to the spacelike geodesics, also the radial lightlike geodesics reach the singulatity. Their equations can be derived as in the spacelike case.[13] With an affine parameter τ they read

$$\frac{dr}{d\tau}=\pm E,$$

$$\frac{dt}{d\tau}=\frac{Er^2}{\Delta}, \tag{16}$$

$$\frac{d\vartheta}{d\tau}=\frac{d\varphi}{d\tau}=0.$$

This yields

$$\frac{dr}{dt}=\pm\frac{\Delta}{r^2}$$

with the solution

$$t=\pm r_*+\text{const}$$

[cf. (7)]. It is convenient to choose the parameter τ such that $r(0)=0$ holds. If in addition the constant E changes sign in $r=0$, then these geodesics are of class C^∞ in $r=0$ [in the local coordinates U and V modulo $\pi/2$; cf. (8) and Ref. 19].

IV. THE CHARGE IN THE REIßNER–NORDSTRØM SOLUTION

The electromagnetic field tensor of the Reißner–Nordstrøm solution is[6]

$$F=\frac{1}{4\pi\epsilon_0}\left(\frac{q}{r^2}\frac{\partial}{\partial t}\wedge\frac{\partial}{\partial r}+\frac{q_m}{r^4\sin\vartheta}\frac{\partial}{\partial\vartheta}\wedge\frac{\partial}{\partial\varphi}\right). \tag{17}$$

From this, the components j^i of the four current can be computed:

$$j^i=F^{ik}_{;k}. \tag{18}$$

Here the semicolon denotes the covariant derivative. For $r>0$, it follows immediately from (20) that the components j^1 and j^2 vanish. The other components are

$$j^3=\frac{-1}{4\pi\epsilon_0}\left[\frac{d}{d\vartheta}\left(\frac{q_m}{r^4\sin\vartheta}\right)+\frac{q_m}{r^4\sin\vartheta}\cot\vartheta\right]=0$$

and

$$j^4=\frac{q}{4\pi\epsilon_0}\left(\frac{2}{r^3}-\frac{2}{r^3}\right)=0.$$

At $r=0$, Eq. (18) cannot be used, as F diverges. But it is possible to compute the exterior derivative by Gauß's theorem. This means to discuss the electric field lines near $r=0$. In our coordinates, these are the r-lines. It has been shown in the last section that they pass through the singularities. Therefore the divergence of the electric field vanishes: After gluing the space–time, the ϵ-neighborhood V of the points $r=0$ consists of two balls with center at $r=0$: one in A_n, and one in A'_{n+1}. Consider

$$\int_V J=\int_V dF^*=\int_V d(\epsilon_{ijkl}F^{kl}dx^i\wedge dx^j)=\int_{\partial V}\epsilon_{ijkl}F^{kl}dx^i\wedge dx^j \tag{19}$$

with $q_m=0$. Then only the components $(k,l)=(1,4)$ contribute. As the field lines crossing the sphere in A_n pass it from outside to inside, while they pass the sphere in A'_{n+1} in the opposite direction, the total surface integral over ∂V vanishes. This is even true, if $q_m\neq 0$: The term F^{23} in

(19) is present only in integrals in the x^1- and x^4-directions. But in the x^1-integration, the contribution from A_n cancels that from A'_{n+1}. So also this integral vanishes, and we finally get

$$\int_V J = 0.$$

V. ENERGY AND MOMENTUM

In this section, we glue the space–time not in the singularity $r=0$, but at finite values of r. For this, we choose some ϵ satisfying $0<\epsilon<r_-$ [see (4)] and delete all points with $r<\epsilon$. Then we identify the points $(r=\epsilon,\ t)$ in A_n with the points $(r=\epsilon,\ -t)$ in A'_{n+1} in a similar way as we did before. The stability of such surfaces $r=\epsilon$ between two parts of Reißner–Nordstrøm space–times has been discussed by Visser.[5,6]

The r-lines are geodesics perpendicular to the boundary $r=\epsilon$. If one follows such a line, the r-values first decrease, until the boundary $r=\epsilon$ is reached. Then they increase again. But, of course, at the boundary $dr/d\tau \neq 0$ [cf. (15)]. Therefore the derivatives of the metric in the direction of τ are discontinuous and the Einstein tensor gets additional terms proportional to $\delta(r-\epsilon)$.[14,15] The existence of such terms can also be seen from a simple consideration: If they would be absent, the radial lightlike geodesics would go on to the singularity $r=0$. But at $r=\epsilon$, they have to change their direction towards increasing r-values. Therefore some interaction is needed which forces them to do this.

In the coordinates (r,ϑ,φ,t), the only nonvanishing Christoffel symbols are

$$\Gamma^1_{11} = \frac{1}{2}\,\frac{-2M/r^2+2Q^2/r^3}{1-2M/r+Q^2/r^2},$$

$$\Gamma^1_{22} = -\left(1-\frac{2M}{r}+\frac{Q^2}{r^2}\right)\cdot r,$$

$$\Gamma^1_{33} = -\left(1-\frac{2M}{r}+\frac{Q^2}{r^2}\right)\cdot r\sin^2\vartheta,$$

$$\Gamma^1_{44} = -\frac{1}{2}\left(1-\frac{2M}{r}+\frac{Q^2}{r^2}\right)\left(-\frac{2M}{r^2}+\frac{2Q^2}{r^3}\right),$$

$$\Gamma^2_{12} = \Gamma^2_{21} = \frac{1}{r}, \tag{20}$$

$$\Gamma^2_{33} = -\sin\vartheta\cos\vartheta,$$

$$\Gamma^3_{13} = \Gamma^3_{31} = \frac{1}{r},$$

$$\Gamma^3_{23} = \Gamma^3_{32} = \cot\vartheta,$$

$$\Gamma^4_{14} = \Gamma^4_{41} = -\frac{1}{2}\,\frac{-2M/r^2+2Q^2/r^3}{1-2M/r+Q^2/r^2}.$$

The normal to the boundary, pointing away from the region A, resp. A', has the components

$$(n_i) = \left(\frac{-1}{\sqrt{1-2M/\epsilon+Q^2/\epsilon^2}},0,0,0\right);\quad n^i n_i = -1. \tag{21}$$

The second fundamental form K of the boundary is defined by

$$K_{ij}=-\tfrac{1}{2}((\nabla_i\, n)_j+(\nabla_j\, n)_i);\quad i,j=2,3,4.$$

Together with (20), this yields in the limit $r\to\epsilon,\ r<\epsilon$,

$$K_{22}=\epsilon\sqrt{1-2M/\epsilon+Q^2/\epsilon^2},$$

$$K_{33}=\epsilon\sin^2\vartheta\sqrt{1-2M/\epsilon+Q^2/\epsilon^2}, \tag{22}$$

$$K_{44}=-(M/\epsilon^2-Q^2/\epsilon^3)\sqrt{1-2M/\epsilon+Q^2/\epsilon^2}.$$

All other components of K vanish. Therefore the energy-momentum tensor T gets the additional terms from the boundary[6]

$$Z_{ij}=\frac{c^2}{4\pi G}\,\delta(r-\epsilon)(-K_{ij}+K^r_r g_{ij});\quad i,j,r=2,3,4.$$

For K^r_r, (22) yields

$$K^r_r=\frac{-2+3M/\epsilon-Q^2/\epsilon^2}{\epsilon\sqrt{1-2M/\epsilon+Q^2/\epsilon^2}}.$$

In the limit $\epsilon\to 0$, the leading terms in K^r_r are $-|Q|/\epsilon^2$. So one obtains

$$Z_{44}\to\frac{-c^2\delta(r-\epsilon)}{4\pi G}\,\frac{2|Q|^3}{\epsilon^4}. \tag{23}$$

The additional energy due to the gluing is

$$E=\frac{1}{6}\int u^r Z^i_r\epsilon_{ijkl}dx^j dx^k dx^l,$$

where ϵ_{ijkl} is defined as

$$\epsilon_{ijkl}=\sqrt{|\det g|}\begin{cases}+1\\0\\-1\end{cases}$$

and u is the four-velocity of an observer at rest:

$$(u^r)=\left(0,0,0,\frac{1}{\sqrt{1-2M/\epsilon+Q^2/\epsilon^2}}\right).$$

Equation (23) shows that the additional energy E is negative and tends to zero, if ϵ goes to zero. Therefore there is exotic matter (i.e., matter violating the average null energy condition) on the surface $r=\epsilon$, but its contribution to the total energy can be made arbitrarily small: Remember that the components $T^{(em)i}_j$ of the electromagnetic energy-momentum tensor are proportional to $1/\epsilon^4$ [see (17)]. So we obtain the well-known result that the electromagnetic energy E' is proportional to $1/\epsilon$, i.e., the ratio between the electromagnetic energy and the surface energy becomes arbitrarily large. Therefore also the stability of the system is completely determined by the electromagnetic self-energy.

To sum up, we have the following results: Gluing the two parts of the Reißner–Nordstrøm solution at some small $r=\epsilon>0$ avoids the infinite self-energy of a point charge and the singu-

larities in the metric. Furthermore, although there exists exotic surface matter, its contribution to the total energy can be made arbitrarily small, if ϵ tends to zero. On the other hand, if the two parts of the Reißner–Nordstrøm solution are glued together in the singularity $r=0$, there is no surface energy.

(Received 10 January 2002; accepted for publication 22 May 2002)

We study a class of inhomogeneous and anisotropic G_2 string cosmological models. In the case of separable G_2 models we show that the governing equations reduce to a system of ordinary differential equations. We focus on a class of separable G_2 M-theory cosmological models, and study their qualitative behavior (a class of models with time-reversed dynamics is also possible). We find that generically these inhomogeneous M-theory cosmologies evolve from a spatially inhomogeneous and negatively curved model with a nontrivial form field toward spatially flat and spatially homogeneous dilaton-moduli-vacuum solutions with trivial form fields. The late time behavior is the same as that of spatially homogeneous models previously studied. However, the inhomogeneities are not dynamically insignificant at early times in these models. © *2002 American Institute of Physics.*

I. STRING COSMOLOGY

Nonperturbative M-theory encompasses and unifies all five anomaly free, perturbative superstring theories[1] and corresponds to eleven-dimensional supergravity in the low-energy limit.[2] In particular, the compactification of M-theory on a circle, S^1, leads to the type IIA superstring. A study of the qualitative cosmological effects that can arise in M-theory is therefore of considerable importance. To lowest order (in the inverse string tension), the tree-level effective action for massless fields contains a dilaton, a form field (which in four-dimensions is dynamically dual to pseudoscalar axion field) and (a) stringy cosmological constant(s). Even in this approximation the one-loop string equations of motion for inhomogeneous backgrounds are very difficult to solve, and it is a useful first step to consider models in which the homogeneity is broken only in one spatial direction. Metrics that admit two commuting (orthogonally transitive) space-like Killing vectors are referred to as G_2 space–times.

String models admitting an Abelian group, G_2, of isometries have a number of important physical applications. The spatially homogeneous Bianchi types I–VII$_h$ and locally rotationally symmetric (LRS) types VIII and IX admit a G_2 group of isometries[3] and so the G_2 cosmologies can be considered as inhomogeneous generalizations of these Bianchi models. Nonlinear inhomogeneities in the dilaton and axion fields can be investigated and, in principle, this allows density perturbations in string-inspired inflationary models such as the pre-big bang scenario to be studied.[4,5] Given the potential importance of this scenario it is important to study its generality with respect to inhomogeneities as well with respect to anisotropies. The general effects of small inhomogeneities and anisotropies have been studied by Veneziano.[4]

In general relativity (GR) the generic singularity is neither spatially homogeneous nor isotropic. Hence it is of interest to study more general models. In particular, it has been conjectured that G_2 metrics represent a first approximation to the general solution of Einstein gravity in the vicinity

[a)]Electronic mail: aac@mscs.dal.ca
[b)]Electronic mail: rvandenh@stfx.ca

of a curvature singularity.[6–9] The high curvature regime is precisely the regime where stringy deviations from GR are expected to be significant. The G_2 models studied here may therefore provide insight into the generic behavior of cosmologies at very early times.

A number of exact inhomogeneous and anisotropic G_2 string cosmologies have been found. Barrow and Kunze studied an inhomogeneous generalization of the Bianchi type I string cosmology[10] and Feinstein, Lazkoz, and Vazquez-Mozo derived a closed, inhomogeneous model by applying duality transformations on the LRS Bianchi type IX cosmology.[11] Clancy *et al.* have found inhomogeneous generalizations of the Bianchi type VI_h universe and have studied their asymptotic behavior.[12]

In general, the field equations reduce to a system of coupled, partial differential equations in two variables when spatial homogeneity is broken along a single direction. Unfortunately, these equations are still very complicated. However, solutions can be found due to the noncompact global symmetries of the string effective action. When the metric admits two commuting spacelike Killing vectors, there exists an infinite-dimensional symmetry on the space of solutions that may be identified infinitesimally with the O(2,2) current algebra.[13–15] This symmetry reduces to the Geroch group, corresponding to the SL(2,R) current algebra, when the dilaton and two-form potential are trivial,[16] and includes the global SL(2,R) S-duality of the action.

New inhomogeneous G_2 string cosmologies containing a nontrivial two-form potential may be generated by an application of both the S- and T-duality symmetries from simpler (dilaton-vacuum) seed solutions. Lidsey *et al.*[17] discuss the noncompact, global symmetries of the string effective action in a variety of settings and review various methods for solving the Einstein-scalar field equations utilizing generating techniques (from solutions with a minimally coupled, massless scalar field from a vacuum, G_2 cosmology). In particular, Feinstein, Lazkoz, and Vázquez-Mozo[11] present an algorithm which permits the construction of inhomogeneous string solutions by employing a Buscher transformation, inverse scattering techniques,[7,8] followed by the generating technique of Wainwright, Ince, and Marshman.[18] Feinstein *et al.* employ this algorithm to generate a closed, inhomogeneous string cosmology with S^3 topology from a LRS Bianchi type IX solution.[11,19] However, this algorithm involves a number of nontrivial operations, and an alternative and more straightforward approach is to apply an O(2,2) transformation directly to the seed cosmology.[17]

In this paper we shall consider a class of separable string cosmological models whose governing equations reduce to ordinary differential equations (ODE) which can be studied by qualitative methods. In particular, we shall focus on a class of M-theory cosmological models.

II. STRING ACTION

We consider the general string action in the form[20]

$$S=\int \mathrm{d}^4x\sqrt{-g}\left\{e^{-\Phi}\left[R+(\nabla\Phi)^2-6(\nabla\beta)^2-\frac{1}{2}e^{2\Phi}(\nabla\sigma)^2-2\Lambda\right]-\frac{1}{2}Q^2e^{-6\beta}-\Lambda_M\right\}, \quad (2.1)$$

in terms of the pseudoscalar axion field, σ, the four-dimensional dilaton field Φ, and the modulus field β, where Λ and Λ_M represent cosmological constant terms and Q^2 may be interpreted as a zero-form field strength. This is a phenomenological action representing the bosonic sector of the effective supergravity action for the low-energy limit of M-theory and encompasses other string theories.[20] We are particularly interested in the class of four-dimensional cosmologies derived from the type IIA string and M-theory effective actions and which include a nontrivial Ramond–Ramond (RR) sector.[21] In these models a specific compactification from eleven to four dimensions was considered, where the topology of the internal dimensions was assumed to be a product space consisting of a circle and an isotropic six-torus;[21] this is dynamically equivalent to compactifications on a Calabi–Yau threefold.[22] The FRW models in this class of cosmologies was studied in Ref. 21.

Defining

$$\mathcal{L}_M=-3e^{-\Phi}(\nabla\beta)^2-\frac{1}{4}e^{\Phi}(\nabla\sigma)^2-\Lambda e^{-\Phi}-\frac{1}{4}Q^2e^{-6\beta}-\frac{1}{2}\Lambda_M;\quad T_{\alpha\beta}\equiv g_{\alpha\beta}\mathcal{L}_M-2\frac{\partial\mathcal{L}_M}{\partial g^{\alpha\beta}},$$

the Euler–Lagrange equations then lead to the field equations (FE)[23]

$$G_{\mu\nu}=-\nabla_\mu\nabla_\nu\Phi+6\nabla_\mu\beta\nabla_\nu\beta+\tfrac{1}{2}e^{2\Phi}\nabla_\mu\sigma\nabla_\nu\sigma-\tfrac{1}{2}g_{\mu\nu}[(\nabla\Phi)^2+6(\nabla\beta)^2+\tfrac{1}{2}e^{2\Phi}(\nabla\sigma)^2+2\Lambda$$
$$+\tfrac{1}{2}Q^2e^{\Phi-6\beta}+\Lambda_Me^{\Phi}-2\Box\Phi],\tag{2.2a}$$

$$\Box\Phi=\tfrac{1}{2}(\nabla\Phi)^2+3(\nabla\beta)^2-\tfrac{1}{4}e^{2\Phi}(\nabla\sigma)^2+\Lambda-\tfrac{1}{2}R,\tag{2.2b}$$

$$\Box\beta=\nabla_\mu\Phi\nabla^\mu\beta-\tfrac{1}{4}Q^2e^{\Phi-6\beta},\tag{2.2c}$$

$$\Box\sigma=-\nabla_\mu\Phi\nabla^\mu\sigma.\tag{2.2d}$$

In Eqs. (2.2a)–(2.2d), greek indices take on values 0, 1, 2, 3, and units are chosen so that $16\pi\hat{G}=1$.

III. G_2 COSMOLOGIES

Let us examine (2.2) within the context of G_2 cosmological models described by the line element

$$ds^2=e^{2F}(-dt^2+dz^2)+e^{G}(e^{q}\,dx^2+e^{-q}\,dy^2),\tag{3.1}$$

where the metric functions $\{F,G,q\}$ and the string functions $\{\Phi,\beta,\sigma\}$ are all functions of t and z only. For any $q(t,z)$, we define $\dot{q}\equiv\partial q/\partial t$, $q'\equiv\partial q/\partial z$, and $\Delta^2q\equiv\ddot{q}-q''$. The local behavior of these models is determined by the gradient $B_\mu\equiv\partial_\mu G$, and cosmological solutions arise if B_μ is globally time-like.

Also, the Ricci scalar is given by

$$R=\tfrac{1}{2}e^{-2F}[4\Delta^2G+4\Delta^2F+3(\dot{G}^2-G'^2)+(\dot{q}^2-q'^2)].\tag{3.2}$$

Using these expressions, and defining the modified dilaton field,

$$\varphi\equiv\Phi-F-G,\tag{3.3}$$

the field equations become

$$\Delta^2\varphi=\tfrac{1}{2}[(\dot{\varphi}+\dot{F})^2-(\varphi'+F')^2]+\tfrac{1}{4}(\dot{G}^2-G'^2)+\tfrac{1}{4}(\dot{q}^2-q'^2)+3(\dot{\beta}^2-\beta'^2)$$
$$-\tfrac{1}{4}e^{2\varphi+2F+2G}(\dot{\sigma}^2-\sigma'^2)-\Lambda e^{2F},\tag{3.4a}$$

$$\Delta^2\beta=[(\dot{\varphi}+\dot{F})\dot{\beta}-(\varphi'+F')\beta']+\tfrac{1}{4}Q^2e^{\varphi+3F+G-6\beta},\tag{3.4b}$$

$$\Delta^2\sigma=-[(\dot{\varphi}+\dot{F}+2\dot{G})\dot{\sigma}-(\varphi'+F'+2G')\sigma'],\tag{3.4c}$$

$$\Delta^2q=[(\dot{\varphi}+\dot{F})\dot{q}-(\varphi'+F')q'],\tag{3.4d}$$

$$\Delta^2F=\tfrac{1}{2}(\dot{\varphi}+\dot{F})^2-\tfrac{1}{2}(\varphi'+F')^2-\tfrac{1}{4}(\dot{G}^2-G'^2)-\tfrac{1}{4}(\dot{q}^2-q'^2)-3(\dot{\beta}^2-\beta'^2)$$
$$+\tfrac{1}{4}e^{2\varphi+2F+2G}(\dot{\sigma}^2-\sigma'^2)-\Lambda e^{2F}-\tfrac{1}{2}Q^2e^{\varphi+3F+G-6\beta}-\Lambda_Me^{\varphi+3F+G},\tag{3.4e}$$

$$\Delta^2 G=[(\dot{\varphi}+\dot{F})\dot{G}-(\varphi'+F')G']+(\dot{\sigma}^2-\sigma'^2)e^{2\varphi+2F+2G}-\tfrac{1}{2}Q^2e^{\varphi+3F+G-6\beta}-\Lambda_M e^{\varphi+3F+G}, \tag{3.4f}$$

$$(\dot{\varphi}+\dot{F})^{\cdot}+(\varphi'+F')'=2(\dot{\varphi}+\dot{F})\dot{F}+2(\varphi'+F')F'+\tfrac{1}{2}(\dot{G}^2+G'^2)+\tfrac{1}{2}(\dot{q}^2+q'^2)+6(\dot{\beta}^2+\beta'^2)$$
$$+\tfrac{1}{2}(\dot{\sigma}^2+\sigma'^2)e^{2\varphi+2F+2G}, \tag{3.4g}$$

$$(\dot{\varphi}+\dot{F})'=\tfrac{1}{2}\dot{G}G'+\tfrac{1}{2}\dot{q}q'+6\dot{\beta}\beta'+F'(\dot{\varphi}+\dot{F})+\dot{F}(\varphi'+F')+\tfrac{1}{2}e^{2\varphi+2F+2G}\dot{\sigma}\sigma'. \tag{3.4h}$$

These equations reduce to those in Refs. 20 and 21 in the appropriate limits.

IV. SEPARABLE G_2 STRING COSMOLOGIES

A. General case

Let us assume separability of the metric functions of the form

$$F(t,z)\equiv F(t)+f(z),\quad G(t,z)\equiv G(t)+g(z),\quad q(t,z)\equiv q(t)+\nu(z),$$

and appropriate separability conditions on the matter fields $\Phi(t,z)$, $\beta(t,z)$, $\sigma(t,z)$. Then the Ricci scalar is given by

$$R=\tfrac{1}{2}e^{-2F-2f}[4\ddot{G}+4\ddot{F}+3\dot{G}^2+\dot{q}^2-(4g''+4f''+3g'^2+\nu'^2)].$$

If

$$4g''+4f''+3g'^2+\nu'^2=C, \tag{4.1}$$

where C is a constant, then we obtain a condition which constrains the spatial dependence of the metric. The Ricci scalar is then given by

$$R=\tfrac{1}{2}e^{-2F-2f}[4\ddot{G}+4\ddot{F}+3\dot{G}^2+\dot{q}^2-C].$$

Putting this expression for the Ricci scalar into the action (2.1), the spatial dependence of the geometrical terms can be eliminated (by integration over the spatial coordinates in the action). After applying any further separability conditions (on the matter fields), the resulting FE will be a system of ODEs. Note that the effect of the spatial dependence is to add a further contribution (C) to the cosmological constant Λ in the action.

B. Specific example: Linear dependence in z

In an attempt to remove the z dependence, let us assume separability of the form

$$F(t,z)\equiv F(t)+\tfrac{1}{2}cz,\quad G(t,z)\equiv G(t),\quad q(t,z)\equiv q(t)+az,$$

$$\Phi(t,z)\equiv\Phi(t)+mz,\quad \beta(t,z)\equiv\beta(t)+nz,$$

$$\sigma(t,z)\equiv\sigma(t)+lz,$$

where a, c, l, m, n are constants [a^2 is equivalent to the constant C in Eq. (4.1)], and therefore

$$\varphi(t,z)=\Phi(t)-F(t)-G(t)+(m-\tfrac{1}{2}c)z\equiv\varphi(t)+(m-\tfrac{1}{2}c)z.$$

With the above-given assumptions, the metric becomes an extension of the inhomogeneous scalar-field G_2 solutions found by Feinstein and Ibanez[24] to M-theoretical models. In addition, for particular values of the parameters, the metric reduces to spatially homogeneous Bianchi I, III, and VI_0 models. Hence,

$$\ddot{\varphi}=\tfrac{1}{2}(\dot{\varphi}+\dot{F})^2+\tfrac{1}{4}\dot{G}^2+\tfrac{1}{4}\dot{q}^2+3\dot{\beta}^2-\tfrac{1}{4}e^{2\varphi+2F+2G+2mz}(\dot{\sigma}^2-l^2)-\Lambda e^{2F+cz}-\tfrac{1}{4}(a^2+2m^2+12n^2), \tag{4.2a}$$

$$\ddot{\beta}=(\dot{\varphi}+\dot{F})\dot{\beta}+\tfrac{1}{4}Q^2e^{[\varphi+3F+G-6\beta+(c+m-6n)z]}-mn, \tag{4.2b}$$

$$\ddot{\sigma}=-(\dot{\varphi}+\dot{F}+2\dot{G})\dot{\sigma}+ml, \tag{4.2c}$$

$$\ddot{q}=(\dot{\varphi}+\dot{F})\dot{q}-ma, \tag{4.2d}$$

$$\ddot{F}=\tfrac{1}{2}(\dot{\varphi}+\dot{F})^2-\tfrac{1}{4}\dot{G}^2-\tfrac{1}{4}\dot{q}^2-3\dot{\beta}^2+\tfrac{1}{4}e^{2\varphi+2F+2G+2mz}(\dot{\sigma}^2-l)-\Lambda e^{2F+cz}$$
$$-\tfrac{1}{2}Q^2e^{[\varphi+3F+G-6\beta+(c+m-6n)z]}-\Lambda_M e^{\varphi+3F+G+(c+m)z}+\tfrac{1}{4}(a^2-2m^2+12n^2), \tag{4.2e}$$

$$\ddot{G}=(\dot{\varphi}+\dot{F})\dot{G}+(\dot{\sigma}^2-l^2)e^{2\varphi+2F+2G+2mz}-\tfrac{1}{2}Q^2e^{[\varphi+3F+G-6\beta+(c+m-6n)z]}-\Lambda_M e^{\varphi+3F+G+(c+m)z}, \tag{4.2f}$$

$$(\ddot{F}+\ddot{\varphi})=2(\dot{F}+\dot{\varphi}+m)(\dot{F}+\tfrac{1}{2}c)+\tfrac{1}{2}\dot{G}^2+\tfrac{1}{2}(\dot{q}+a)^2+6(\dot{\beta}+n)^2+\tfrac{1}{2}(\dot{\sigma}+l)^2e^{2\varphi+2F+2G+2mz}. \tag{4.2g}$$

Note that the constraint equation can be rewritten as

$$0=(\dot{F}+m)^2-\dot{\varphi}^2+c(\dot{F}+\dot{\varphi}+m)+\tfrac{1}{2}\dot{G}^2+\tfrac{1}{2}(\dot{q}+a)^2+6(\dot{\beta}+n)^2+\tfrac{1}{2}(\dot{\sigma}+l)^2e^{2\varphi+2F+2G+2mz}$$
$$+\Lambda e^{2F+cz}+\tfrac{1}{2}Q^2e^{[\varphi+3F+G-6\beta+(c+m-6n)z]}+\Lambda_M e^{\varphi+3F+G+(c+m)z}. \tag{4.3}$$

In order for the FE to be independent of z, it is necessary that $m=0$ and that either $c=0$ or $c=6n$. Furthermore if $c=0$ then we have that either $n=0$ or $Q=0$. In the $c=6n$ case, we have that $\Lambda=\Lambda_M=0$. It is the latter case that is of interest to us here. From here forth we shall assume that $c=6n$ and that $\Lambda=\Lambda_M=0$. This particular subcase, which is of relevence in M-theory cosmology, is of special physical interest. (The resulting FE in the remaining cases are displayed in Ref. 23.)

V. INHOMOGENEOUS M-THEORY COSMOLOGICAL MODELS

Substituting $c=6n$, $m=0$, $\Lambda=0$, $\Lambda_M=0$ into (3.4), (4.3) (and taking the linear combination [(4.2g)–(4.2e)–(4.2a)]) we obtain the following system of ODE with two constraints:

$$\ddot{\varphi}=\tfrac{1}{4}(\dot{q}^2+\dot{G}^2-a^2+2(\dot{\varphi}+\dot{F})^2+12\dot{\beta}^2-12n^2+e^{2\varphi+2F+2G}(l^2-\dot{\sigma}^2)), \tag{5.1a}$$

$$\ddot{\beta}=\dot{\beta}(\dot{\varphi}+\dot{F})+\tfrac{1}{4}Q^2e^{-6\beta+\varphi+3F+G}, \tag{5.1b}$$

$$\ddot{\sigma}=-\dot{\sigma}(\dot{\varphi}+\dot{F}+2\dot{G}), \tag{5.1c}$$

$$\ddot{q}=\dot{q}(\dot{\varphi}+\dot{F}), \tag{5.1d}$$

$$\ddot{F}=\tfrac{1}{4}(3a^2+\dot{q}^2+\dot{G}^2+36n^2+12\dot{\beta}^2+e^{2\varphi+2F+2G}(l^2+3\dot{\sigma}^2)-2(\dot{\varphi}-\dot{F})^2+8\dot{F}^2), \tag{5.1e}$$

$$\ddot{G}=\dot{G}(\dot{\varphi}+\dot{F})-e^{2\varphi+2F+2G}(l^2-\dot{\sigma}^2)-\tfrac{1}{2}Q^2e^{-6\beta+\varphi+3F+G}, \tag{5.1f}$$

$$0=2\dot{\varphi}^2-\dot{G}^2-\dot{q}^2-12\dot{\beta}^2-2\dot{F}^2-12n^2-a^2-e^{2\varphi+2F+2G}(l^2+\dot{\sigma}^2)-Q^2e^{-6\beta+\varphi+3F+G}, \tag{5.1g}$$

$$0=a\dot{q}+le^{2\varphi+2F+2G}\dot{\sigma}+6n(\dot{\varphi}+\dot{F}+2\dot{\beta}). \tag{5.1h}$$

From Eq. (5.1g) we are able solve for and make a global substitution for the quantity $Q^2e^{-6\beta+\varphi+3F+G}$. Making this substitution we have the following system of ODEs:

$$\ddot{\varphi}=\tfrac{1}{4}(\dot{q}^2+\dot{G}^2-a^2+2(\dot{\varphi}+\dot{F})^2+12\dot{\beta}^2-12n^2+e^{2\varphi+2F+2G}(l^2-\dot{\sigma}^2)), \tag{5.2a}$$

$$\ddot{\beta}=\tfrac{1}{4}(2\dot{\varphi}^2-\dot{G}^2-\dot{q}^2-12\dot{\beta}^2-2\dot{F}^2-12n^2-a^2-e^{2\varphi+2F+2G}(l^2+\dot{\sigma}^2))+\dot{\beta}(\dot{\varphi}+\dot{F}), \tag{5.2b}$$

$$\ddot{\sigma}=-\dot{\sigma}(\dot{\varphi}+\dot{F}+2\dot{G}), \tag{5.2c}$$

$$\ddot{q}=\dot{q}(\dot{\varphi}+\dot{F}), \tag{5.2d}$$

$$\ddot{F}=\tfrac{1}{4}(3a^2+\dot{q}^2+\dot{G}^2+36n^2+12\dot{\beta}^2+e^{2\varphi+2F+2G}(l^2+3\dot{\sigma}^2)-2(\dot{\varphi}-\dot{F})^2+8\dot{F}^2), \tag{5.2e}$$

$$\ddot{G}=\dot{G}(\dot{\varphi}+\dot{F})-e^{2\varphi+2F+2G}(l^2-\dot{\sigma}^2)-\tfrac{1}{2}(2\dot{\varphi}^2-\dot{G}^2-\dot{q}^2-12\dot{\beta}^2-2\dot{F}^2-12n^2-a^2 -e^{2\varphi+2F+2G}(l^2+\dot{\sigma}^2)), \tag{5.2f}$$

$$0=a\dot{q}+le^{2\varphi+2F+2G}\dot{\sigma}+6n(\dot{\varphi}+\dot{F}+2\dot{\beta}). \tag{5.2g}$$

From the constraint (5.1g) we see that if $\dot{\varphi}=0$, then all of the other state variables must be simultaneously zero, which can only occur at an equilibrium point of the system. Hence $\dot{\varphi}$ must be positive (or negative) throughout the physical phase space. Here we shall assume $\dot{\varphi}>0$ (the case $\dot{\varphi}<0$ can be obtained by a time reversal—see the following).

We define new variables of the form

$$\tilde{F}=\frac{\dot{F}}{\dot{\varphi}},\quad \tilde{G}=\frac{1}{\sqrt{2}}\frac{\dot{G}}{\dot{\varphi}},\quad \tilde{q}=\frac{1}{\sqrt{2}}\frac{\dot{q}}{\dot{\varphi}},\quad \tilde{\sigma}=\frac{1}{\sqrt{2}}e^{\varphi+F+G}\frac{\dot{\sigma}}{\dot{\varphi}},$$

$$\tilde{\beta}=\sqrt{6}\,\frac{\dot{\beta}}{\dot{\varphi}},\quad \tilde{\Psi}_1=\sqrt{\frac{a^2+12n^2}{2}}\frac{1}{\dot{\varphi}},\quad \tilde{\Psi}_2=\frac{1}{\sqrt{2}}e^{\varphi+F+G}\frac{l}{\dot{\varphi}}$$

and a new time variable

$$\frac{\mathrm{d}t}{\mathrm{d}\tau}=\frac{1}{\dot{\varphi}}. \tag{5.3}$$

The variables are chosen so that the transformed dynamical system has a compactified phase space. This property comes from the fact that $Q^2e^{-6\beta+\varphi+3F+G}\geqslant 0$ which implies that Eq. (5.1g) yields

$$1\geqslant\tilde{F}^2+\tilde{G}^2+\tilde{q}^2+\tilde{\sigma}^2+\tilde{\beta}^2+\tilde{\Psi}_1^2+\tilde{\Psi}_2^2. \tag{5.4}$$

The dynamical system (5.2) becomes

$$\frac{\mathrm{d}\tilde{F}}{d\tau}=\tilde{F}(2\tilde{F}-\tilde{r})+\frac{1}{2}(\tilde{q}^2+\tilde{G}^2+\tilde{\beta}^2+3\tilde{\sigma}^2+3\tilde{\Psi}_1^2+\tilde{\Psi}_2^2-(1-\tilde{F})^2), \tag{5.5a}$$

$$\frac{d\tilde{G}}{d\tau}=\tilde{G}(1+\tilde{F}-\tilde{r})-\frac{1}{\sqrt{2}}(1-\tilde{F}^2-\tilde{G}^2-\tilde{q}^2-3\tilde{\sigma}^2-\tilde{\beta}^2-\tilde{\Psi}_1^2+\tilde{\Psi}_2^2), \tag{5.5b}$$

$$\frac{d\tilde{q}}{d\tau}=\tilde{q}(1+\tilde{F}-\tilde{r}), \tag{5.5c}$$

$$\frac{d\tilde{\sigma}}{d\tau}=-\tilde{\sigma}(\sqrt{2}\tilde{G}+\tilde{r}), \tag{5.5d}$$

$$\frac{d\tilde{\beta}}{d\tau}=\tilde{\beta}(1+\tilde{F}-\tilde{r})+\frac{\sqrt{6}}{2}(1-\tilde{F}^2-\tilde{G}^2-\tilde{q}^2-\tilde{\sigma}^2-\tilde{\beta}^2-\tilde{\Psi}_1^2-\tilde{\Psi}_2^2), \tag{5.5e}$$

$$\frac{d\tilde{\Psi}_1}{d\tau}=-\tilde{\Psi}_1\tilde{r}, \tag{5.5f}$$

$$\frac{d\tilde{\Psi}_2}{d\tau}=\tilde{\Psi}_2(1+\tilde{F}+\sqrt{2}\tilde{G}-\tilde{r}), \tag{5.5g}$$

and

$$\tilde{r}=\tfrac{1}{2}[(1+\tilde{F})^2+\tilde{G}^2+\tilde{q}^2+\tilde{\beta}^2+\tilde{\Psi}_2^2-\tilde{\Psi}_1^2-\tilde{\sigma}^2],$$

where the constraint equation becomes

$$0=\sqrt{\frac{2}{a^2+12n^2}}\tilde{\Psi}_1\left[\sqrt{2}a\tilde{q}+6n\left(1+\tilde{F}+\frac{2}{\sqrt{6}}\tilde{\beta}\right)\right]+2\tilde{\Psi}_2\tilde{\sigma}. \tag{5.6}$$

There exists a first integral in the physical phase space $(\tilde{q}\neq 0,\tilde{\Psi}_1\neq 0)$ for this system. The function

$$M=\frac{\tilde{\sigma}\tilde{\Psi}_2}{\tilde{q}\tilde{\Psi}_1}$$

is constant, i.e., $M'=0$. This implies a first integral for the original system of ordinary differential equations (5.2)

$$\dot{q}=C\dot{\sigma}e^{2\varphi+2F+2G},$$

where C is a constant.

A. Invariant sets, monotonic functions

We first recall that the phase space for this dynamical system is the interior and boundary of the compact set given by

$$1\geqslant\tilde{F}^2+\tilde{G}^2+\tilde{q}^2+\tilde{\sigma}^2+\tilde{\beta}^2+\tilde{\Psi}_1^2+\tilde{\Psi}_2^2. \tag{5.7}$$

Various hyperplanes divide the phase space into a number of different regions, they are $\tilde{q}=0$, $\tilde{\sigma}=0$, $\tilde{\Psi}_1=0$, and $\tilde{\Psi}_2=0$ hyperplanes. We note that $\tilde{\Psi}_1=0$ divides the phase space into two distinct regions $\tilde{\Psi}_1<0$ and $\tilde{\Psi}_1>0$. The dynamics in the invariant set $\tilde{\Psi}_1<0$ is the time reversal of the dynamics in the invariant set $\tilde{\Psi}_1>0$ [see (5.3)].

Consider the function

$$M_1=\frac{\tilde{\sigma}^2\tilde{\Psi}_2^2}{\tilde{q}^4}$$

and its derivative

$$\frac{dM_1}{d\tau}=-2M_1(1+\tilde{F}).$$

We easily see that this function is monotonically decreasing in the invariant set $\tilde{q}\neq 0,\tilde{\sigma}\neq 0$, $\tilde{\Psi}_2\neq 0$. Therefore, we can conclude that there are no closed or periodic orbits in the seven-dimensional phase space, except possibly on the lower dimensional boundaries of this seven-dimensional invariant set.

We restrict ourselves now to the invariant set $\tilde{\sigma}=0$. Consider the function

$$M_2=\frac{\tilde{\Psi}_1^2}{\tilde{q}^2}$$

and its derivative

$$\frac{dM_2}{d\tau}=-2M_2(1+\tilde{F}).$$

We easily see that this function is monotonically decreasing in the invariant set $\tilde{q}\neq 0,\tilde{\Psi}_1\neq 0$. Therefore, we can conclude that there are no closed or periodic orbits in this six-dimensional phase space, except possibly on the lower dimensional boundaries of this six-dimensional invariant set.

In the six-dimensional invariant set $\tilde{\Psi}_2=0$, the function

$$M_3=\frac{\tilde{\Psi}_1^2}{\tilde{q}^2}$$

has the derivative

$$\frac{dM_3}{d\tau}=-2M_3(1+\tilde{F})$$

which is monotonically decreasing in the set $\tilde{\Psi}_2=0,\tilde{q}\neq 0,\tilde{\Psi}_1\neq 0$. Therefore we conclude that there are no closed or periodic orbits in this six-dimensional invariant set.

In the six-dimensional invariant set $\tilde{q}=0$, the function

$$M_4=\frac{\tilde{\sigma}^2\tilde{\Psi}_2^2}{\tilde{\Psi}_1^4}$$

has the derivative

$$\frac{dM_4}{d\tau}=2M_4(1+\tilde{F}),$$

which is monotonically increasing in the set $\tilde{q}=0,\tilde{\sigma}\neq 0,\tilde{\Psi}_2\neq 0$. Therefore we can conclude that there are no closed or periodic orbits in this six-dimensional set.

With the existence of these monotonic functions M_1, M_2, M_3, and M_4, we can conclude that there are no closed or periodic orbits in the physical six-dimensional phase space [except possibly on lower dimensional (less than 5) invariant sets].

The zero-curvature spatially homogeneous and isotropic space–times are contained in the set $\tilde{q}=\tilde{\Psi}_1=\tilde{\Psi}_2=\tilde{G}-\sqrt{2}\tilde{F}=0$ union $\tilde{q}=\tilde{\Psi}_1=\tilde{\sigma}=\widetilde{G-\sqrt{2}F}=0$.

The matter fields in (2.1) satisfy various energy conditions. For example, the positivity of the kinetic energy of the pseudoaxion scalar field, σ, demands that $\dot{\sigma}^2-l^2\geqslant 0$ (i.e., $\tilde{\sigma}^2-\tilde{\Psi}_2^2\geqslant 0$). However, we note that $\tilde{\sigma}^2-\tilde{\Psi}_2^2=0$ is not an invariant set.

B. Equilibrium points and exact solutions

There are two equilibrium points and one three-dimensional equilibrium set.

The three-dimensional equilibrium set is given by

$$\{\tilde{F}^2+\tilde{G}^2+\tilde{q}^2+\tilde{\beta}^2=1,\tilde{\sigma}=0,\tilde{\Psi}_1=0,\tilde{\Psi}_2=0\}.$$

Note that since both $\tilde{\Psi}_1=0$ and $\tilde{\Psi}_2=0$ we necessarily have that $a=n=l=0$. At this point the value of $\tilde{r}=1+\tilde{F}_0$. The exact solution is then

$$\varphi(t)=h_1-\frac{1}{\tilde{r}}\ln(\tilde{r}t+h_0),$$

$$F(t)=F_0\left(h_1-\frac{1}{\tilde{r}}\ln(\tilde{r}t+h_0)\right)+F_1,$$

$$G(t)=\sqrt{2}G_0\left(h_1-\frac{1}{\tilde{r}}\ln(\tilde{r}t+h_0)\right)+G_1,$$

$$q(t)=\sqrt{2}q_0\left(h_1-\frac{1}{\tilde{r}}\ln(\tilde{r}t+h_0)\right)+q_1,$$

$$\sigma(t)=\sigma_1,$$

$$\beta(t)=\frac{1}{\sqrt{6}}\beta_0\left(h_1-\frac{1}{\tilde{r}}\ln(\tilde{r}t+h_0)\right)+\beta_1,$$

where $F_0^2+G_0^2+q_0^2+\beta_0^2=1$ and where F_1, G_1, q_1, σ_1, β_1, h_1, and h_0 are integration constants.

Since $a=n=l=0$, this metric is spatially homogeneous (and flat). Since $\tilde{\sigma}=0$ and $Q=0$ (which follows from the other conditions), this equilibrium set represents spatially flat solutions where the form-fields (the axion field and the four-form field strength) are trivial and only the dilaton and moduli fields are dynamically important. These solutions are known as the ''dilaton-moduli-vacuum'' solutions (and their analytical form is given in Ref. 25).

Recall that the dynamics of these models is restricted by the constraint given by Eq. (5.6). At these equilibrium points we are able to locally solve for the value of $\tilde{\Psi}_1$ and substitute into the remaining equations. The eigenvalues in the six-dimensional constraint surface are

$$0,0,0,\sqrt{2}\tilde{G},-\sqrt{2}\tilde{G}-1-\tilde{F},-1+\tilde{F}+\sqrt{2}\tilde{G}-\sqrt{6}\tilde{\beta}.$$

The three zero eigenvalues correspond to the fact that this equilibrium set is three-dimensional. It is clear that a subset of this equilibrium set will act as saddles of varying degree of stability, while

another subset will act as sinks. Consequently, a subset of these dilaton-moduli-vacuum solutions with trivial form fields are sinks in the physical phase space, even in the presence of (negative) spatial curvature, and are thus generic attracting solutions.

A second equilibrium point is

$$\left\{\tilde{F}=-\frac{2}{3},\tilde{G}=0,\tilde{q}=0,\tilde{\beta}=-\frac{1}{\sqrt{6}},\tilde{\sigma}=\pm\frac{\sqrt{2}}{6},\tilde{\Psi}_1=\frac{\sqrt{2}}{3},\tilde{\Psi}_2=0\right\}.$$

Note that since $\tilde{\Psi}_2=0$ we necessarily have that $l=0$. At this point the value of $\tilde{r}=0$. [Note, since the dynamical system (5.5) is invariant under the transformation $(\tilde{\Psi}_1,\tilde{\Psi}_2)\rightarrow(-\tilde{\Psi}_1,-\tilde{\Psi}_2)$ there exists a corresponding equilibrium point with a $\tilde{\Psi}_1=-\sqrt{2}/3$.] The exact solution is then

$$\varphi(t)=h_0t+h_1,\quad F(t)=-\tfrac{2}{3}(h_0t+h_1)+F_1,\quad G(t)=G_1,$$

$$q(t)=q_1,\quad \sigma(t)=\mp e^{-1/3(h_0t+h_1)-(F_1+G_1)}+\sigma_1,\quad \beta(t)=-\tfrac{1}{6}(h_0t+h_1)+\beta_1,$$

where $h_0=\frac{3}{2}\sqrt{a^2+12n^2}$, $Q^2=\frac{1}{2}(a^2+12n^2)e^{6\beta_1-3F_1-G_1}$, and F_1, G_1, q_1, σ_1, β_1, h_1 are all constants. In this situation the variable $\tilde{q}$ can be eliminated. The eigenvalues restricted to the constraint surface are

$$\tfrac{1}{3},\tfrac{1}{3},\tfrac{1}{6}(1\pm\sqrt{15+8\sqrt{2}i}),\tfrac{1}{6}(1\pm\sqrt{15-8\sqrt{2}i}).$$

This point represents a past attractor or a source. This corresponds to a spatially nonvacuum inhomogeneous model with a diagonal Einstein tensor, having negative curvature.

The line element corresponding to this solution (after a few coordinate redefinitions) is

$$ds^2=C^2e^{-2\sqrt{a^2+12n^2}t+6nz}(-dt^2+dz^2)+(e^{az}dx^2+e^{-az}dy^2). \tag{5.8}$$

The third equilibrium point is

$$\left\{\tilde{F}=-\frac{5}{7},\tilde{G}=\frac{\sqrt{2}}{7},\tilde{q}=0,\tilde{\beta}=-\frac{\sqrt{6}}{7},\tilde{\sigma}=0,\tilde{\Psi}_1=\frac{2\sqrt{3}}{7},\tilde{\Psi}_2=0\right\}.$$

Note that since $\tilde{\Psi}_2=0$ we necessarily have that $l=0$. At this point the value of $\tilde{r}=0$. [Note, since the dynamical system (5.5) is invariant under the transformation $(\tilde{\Psi}_1,\tilde{\Psi}_2)\rightarrow(-\tilde{\Psi}_1,-\tilde{\Psi}_2)$ there exists a corresponding equilibrium point with a $\tilde{\Psi}_1=-2\sqrt{3}/7$.] The exact solution is then

$$\varphi(t)=h_0t+h_1,\quad F(t)=-\tfrac{5}{7}(h_0t+h_1)+F_1,\quad G(t)=\tfrac{2}{7}(h_0t+h_1)+G_1,$$

$$q(t)=q_1,\quad \sigma(t)=\sigma_1,\quad \beta(t)=-\tfrac{1}{2}(h_0t+h_1)+\beta_1,$$

where $h_0=(7/2\sqrt{3})\sqrt{a^2+12n^2}$, $Q^2=\frac{1}{3}(a^2+12n^2)e^{6\beta_1-3F_1-G_1}$, and F_1, G_1, q_1, σ_1, β_1, h_1 are all constants. This solution is a curved inhomogeneous model with a trivial axion field. In this situation the variable $\tilde{q}$ can be eliminated. The eigenvalues restricted to the constraint surface are

$$\tfrac{2}{7},\tfrac{2}{7},\tfrac{4}{7},-\tfrac{2}{7},\tfrac{1}{7}(1\pm\sqrt{23}i).$$

This point is always a saddle.

VI. DISCUSSION

We have studied several classes of inhomogeneous string models whose governing equations reduce to ODE. In particular, we have found that generically solutions of the class of separable G_2

inhomogeneous M-theory cosmologies studied evolve from a spatially inhomogeneous and negatively curved model with a nontrivial form fields toward (a subset) of spatially flat and spatially homogeneous dilaton-moduli-vacuum solutions where the form-fields (the axion field and the four-form field strength) are trivial and only the dilaton and moduli fields are dynamically important. This late time behavior is the same as that of the spatially homogeneous models studied previously. However, in these models the inhomogeneities are not dynamically insignificant at early times, and the models asymptote (in the past) toward a new class of inhomogeneous cosmological models.

As noted earlier, the time-reversed dynamics of the $\dot{\varphi}>0$ models we have considered thus far is equivalent to the dynamics of the case where $\dot{\varphi}<0$. This follows by redefining the time variable according to $dt/d\tau = -1/\dot{\varphi}$ and appropriate definitions of the other state variables. The evolution equations will have an ''overall'' change in sign, and hence the equilibrium points are identical in both cases, but the eigenvalues have opposite signs. Consequently, the dynamics of the $\dot{\varphi}<0$ models is the time reversal of the $\dot{\varphi}>0$ models and the time-reversed dynamics of the above class of models is deduced by interchanging the sources and sinks and reinterpreting expanding solutions in terms of contracting ones, and vice versa.

Although at late times (in the $\dot{\varphi}>0$ models) the inhomogeneities decay, the inhomogeneities are important at intermediate times and, in particular, at early times. Thus the qualitative features of the models are quite different to those of spatially homogeneous models studied previously. For example, in a study of FRW models[21] it was found that all negatively curved FRW models evolve from the solution corresponding to a global source in which the curvature is (negative and) dynamically important (but with a trivial axion field) toward the dilaton-moduli-vacuum solutions,[25] even in the presence of spatial curvature. The physical interpretation of these models, where both the NS–NS two-form potential and RR three-form potential are dynamically significant, was discussed in Ref. 21, with particular emphasis on the fact that the RR field causes the universe to collapse, but the NS–NS field has the opposite effect, whereby the interplay between these two fields leads to the models undergoing bounces. In the models under investigation here, orbits in the full phase space (with $\dot{\varphi}$ monotone) approach the dilaton-moduli-vacuum solution on the zero-curvature boundary (at late times) and again exhibit a ''bouncing'' behavior; this bouncing behavior is the result of the orbits shadowing orbits in the boundary that are constantly being redirected to saddle points of the same or higher stability until it reaches a stable equilibrium.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 10 OCTOBER 2002

A topological method for geodesic connectedness of space–times: Outer Kerr space–time

José Luis Flores[a] and Miguel Sánchez[b]
Departamento Geometría y Topología, Facultad de Ciencias, Universidad de Granada, Avenida Fuentenueva s/n, 18071-Granada, Spain

(Received 14 January 2002; accepted for publication 24 June 2002)

The geodesic connectedness of outer Kerr space–time is proven by using a topological method. The proof is based on arguments about Brouwer's degree for the solutions of functional equations. The applicability of these topological arguments for dealing with geodesics in space–times is stressed. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1506403]

I. INTRODUCTION

For a space–time, the question whether two causally related points can be joined by means of a causal geodesic has a clear physical meaning. More geometrically, geodesic connectedness (the possibility of joining any two points by a geodesic of any causal type) is a basic property. Some techniques introduced to study geodesic connectedness are appliable to related problems of physical interest, such as the gravitational lensing effect, or the connectedness of two submanifolds by a causal geodesic (see, e.g., Refs. 1–5).

Different tools have been introduced to study geodesic connectedness of Lorentzian manifolds. The first nontrivial examples were spaceforms, which become specially relevant from the geometrical viewpoint.[6] A complete positive Lorentzian spaceform is geodesically connected if and only if it is not time-orientable. In particular, de Sitter space–time S_1^n is not geodesically connected; this happens in spite of the fact that it is globally hyperbolic and, thus, each two causally related points in S_1^n can be joined by a causal geodesic.[7,8] The results about geodesic connectedness of manifolds endowed with an affine connection[9] (see also Refs. 10–12) are potentially appliable to any manifold endowed with a nondegenerate metric. Geodesics of Lorentzian tori provide interesting examples related to connectedness.[13–15]

But the systematic study of the geodesic connectedness of physically relevant space–times was carried out after the introduction of some variational methods in Lorentzian geometry.[16] These methods permit one to prove the geodesic connectedness of stationary and splitting type manifolds under reasonable conditions (see the book—Ref. 17 or the survey—Ref. 18). Moreover, with different improvements, they ensure the connectedness of outer Schwarzschild space–time,[19] intermediate Reissner–Nordström,[20] Gödel type,[21] and other space–times. Recently, the authors have obtained the necessary and sufficient condition for the connectedness of generalized Robertson–Walker space–times.[22] Moreover, topological arguments have been developed which prove the connectedness of multiwarped space–times, under sufficient conditions which are close to necessary conditions[23] (see also Refs. 24 and 25). In particular, not only space–times as Schwarzschild black hole are shown to be geodesically connected,[23] but also new proofs of the geodesic connectedness of space–times such as intermediate Reissner–Nördstrom[23] and outer Schwarzschild[26] are obtained.

Significantly, geodesic connectedness of outer Kerr space–time has not been studied yet.[27] It is not difficult to prove that the stationary part of Kerr space–time is not geodesically connected; moreover, fast rotating Kerr space–time (i.e., Kerr space–time with parameters $a^2 > m^2$) is not geodesically connected.[26] On the other hand, for values of the parameter a close to 0, the hyper-

[a]Electronic mail: jflores@ugr.es
[b]Electronic mail: sanchezm@ugr.es

surface between the stationary part and the ergosphere has some good properties from a variational viewpoint (it is time and light-*convex*, essentially). This ensures some properties of causal geodesics, such as the multiplicity of connecting timelike or lightlike geodesics for big time-separation (Ref. 17, Theorem 7.2.4).

Nevertheless, the inexistence of a privileged time function or timelike Killing vector field on the ergosphere introduces difficulties for its study. In fact, the following result holds.[26] *Let r_+ be the outer radius which determines the first event horizon of Kerr space–time. For any $\nu>0$ the region $r>r_+ + \nu$ is not geodesically connected*. In this article, we show that the topological arguments introduced by the authors in Ref. 23 are applicable to study geodesic connectedness of Kerr space–time, and prove that the whole region $r>r_+$ is geodesically connected. Even though our study is restricted to Kerr space–time for simplicity, the method would work for some different generalizations of this space–time.

This article is organized as follows.

In Sec. II Kerr space–time is briefly recalled. In Sec. III we give a general overview of our proof, which may serve as a guide for the following sections. The importance of the topological arguments first introduced in Ref. 23 (for the rather different class of multiwarped space–times) is stressed. In Sec. IV general properties of the geodesics of Kerr space–time are recalled, and those geodesics relevant under our approach are selected. Then, we reduce the problem of geodesic connectedness to an analytic problem (Lemma 4.3), among other technical results.

In Secs. V and VI geodesic connectedness is proven for the slow rotating Kerr $a^2<m^2$. In Sec. V the case when one of the two points to be connected lies in the symmetry axis z, is solved. Otherwise, the problem is technically more complicated, and solved in Sec. VI. Some concluding remarks are given in Sec. VII.[28]

II. KERR SPACE–TIME

Kerr space–time is the standard relativistic model of the gravitational field of a rotating massive object. The simplest description of the Kerr metric tensor is in terms of the time coordinate t on $\mathbb{R}$ and spherical coordinates r, θ, φ on $\mathbb{R}^3$ (θ denotes colatitude and φ longitude), which are called Boyer–Lindquist coordinates. Following Ref. 31, Sec. 1.1 we treat the coordinate φ as circular, so the coordinate system θ, φ covers all of the sphere except its north and south poles $(0,0,\pm 1)$. The coordinate function φ is undefined at the poles, but its coordinate vector field ∂_φ is well-defined and smooth on the entire sphere and is zero at the poles. Defining $\theta(0,0,+1)=0$ and $\theta(0,0,-1)=\pi$ extends the function θ to the entire sphere with $0\leqslant\theta\leqslant\pi$. At the poles, θ is only continuous, but $\cos\theta$ and $\sin\theta$ are smooth (indeed, analytic) everywhere.

Let $m>0$ and a be two constants, such that m represents the mass of the object and ma the angular momentum as measured from infinity. In previous coordinates, Kerr metric takes the form

$$\mathrm{d}s^2 = g_{t,t}\mathrm{d}t^2 + g_{r,r}\mathrm{d}r^2 + g_{\theta,\theta}\mathrm{d}\theta^2 + g_{\varphi,\varphi}\mathrm{d}\varphi^2 + 2g_{\varphi,t}\mathrm{d}\varphi\,\mathrm{d}t \tag{2.1}$$

with

$$g_{r,r}=\frac{\lambda(r,\theta)}{\Delta(r)},\quad g_{\varphi,\varphi}=\left[r^2+a^2+\frac{2mra^2\sin^2\theta}{\lambda(r,\theta)}\right]\sin^2\theta,\quad g_{t,t}=-1+\frac{2mr}{\lambda(r,\theta)},$$

$$g_{\theta,\theta}=\lambda(r,\theta),\quad g_{\varphi,t}=-\frac{2mra\sin^2\theta}{\lambda(r,\theta)}$$

and using

$$\lambda(r,\theta)=r^2+a^2\cos^2\theta,\quad \Delta(r)=r^2-2mr+a^2.$$

Halting the rotation by setting $a=0$, Kerr space–time becomes Schwarzschild space–time; if, then, the mass is removed ($m=0$) only (empty) Minkowski space–time remains.

In this article we only consider the case $0<a^2<m^2$, we mean, *slow rotating Kerr space–time*. Fast Kerr space–time is simpler; its (non)geodesic connectedness is studied in Ref. 26. Note that the above-given formulas show that Kerr metric fails when either $\lambda(r,\theta)=0$ or $\Delta(r)=0$. The function $\Delta(r)$ has the zeroes $r_+=m+\sqrt{m^2-a^2}$ and $r_-=m-\sqrt{m^2-a^2}$ and

$$\Delta(r)=(r-r_-)(r-r_+). \tag{2.2}$$

So the hypersurfaces $\mathbb{R}\times\{x\in\mathbb{R}^3: r=r_+\}$ and $\mathbb{R}\times\{x\in\mathbb{R}^3: r=r_-\}$ are singular for (2.1) and are *event horizons*. From now on, we will consider the *exterior Kerr space–time* $\mathbb{K}$, we mean the region without singularities in the metric tensor defined by imposing $r>r_+$. Recall that the region between the two event horizons has a strange physical behavior: matter might disappear in finite proper time, or suddenly appear from nowhere. Beyond the second event horizon, the ring singularity appears with its associated time machine.

III. OVERVIEW

The relation between geodesic connectedness and our topological arguments can be seen intuitively as follows. Consider two points $p_0\neq p_1$ of a Lorentzian manifold M, and fix a topological sphere of the tangent space to p_0, $S\subset T_{p_0}M$, such that the vector 0 is included in the interior of S. Consider now the subset $\exp_{p_0}sS, s\in\mathbb{R}$, yielded by the geodesics emanating at p_0 ($\exp_{p_0}$ is the exponential map at p_0). Initially, for small s, p_1 is outside $\exp_{p_0}sS$, but for some bigger s, p_1 may lie inside $\exp_{p_0}sS$. This topological change (from being outside to being inside the exponential of a sphere) reflects that p_0 and p_1 can be connected by a geodesic.

In order to be more precise mathematically, let us see a variation of this idea. Assume that M is an open subset of $\mathbb{R}^k$, and consider the function

$$F:\mathcal{D}\subset T_{p_0}M\equiv\mathbb{R}^k\to\mathbb{R}^k,\quad F(v)=\gamma_v(1)-p_1, \tag{3.1}$$

where γ_v is the unique geodesic starting at p_0 satisfying $\gamma_v'(0)=v$, for any $v\in T_{p_0}M$, and γ_v is defined at 1 for all v in the domain $\mathcal{D}$. Now, the zeroes of the function F correspond with geodesics connecting p_0 and p_1. If F satisfies certain conditions at the boundary of $\mathcal{D}$ then topological arguments may imply the existence of a zero. In dimension $k=1$ these conditions will be quite trivial: if $[a,b]\subset\mathcal{D}$ and $F(a)\cdot F(b)<0$ then F will have a zero. For $k=2$, and, say, $[a,b]\times[a',b']\subset\mathcal{D}$, $F=(F^1(x,y),F^2(x,y))$, if $F^1(a,y)\cdot F^1(b,y)<0,\forall y\in[a',b']$, $F^2(x,a')\cdot F^2(x,b')<0,\forall x\in[a,b]$, then the degree of F will be $\neq 0$, and F will have a zero; natural extensions of these conditions will be needed for $k\geqslant 3$. More exactly, we will need a variation of this argument. We will consider a sequence of increasing intervals $[a_n,b_n]$, $[a_n',b_n']$. Under the condition for F^1, $F^1(a_n,y)\cdot F^1(b_n,y)<0,\forall y\in[a_n',b_n']$, a connected set $\mathcal{C}_n$ of zeroes of F^1 which joins the horizontal lines $y=a_n', y=b_n'$ can be found. Then, we will look for a zero of F^2 in $\mathcal{C}_n$ for n big enough.

Clearly, a crucial step in this procedure is to ensure the boundary conditions on F. Thus, it is important to have a partial integration of the geodesic equations, as in most classical space–times.

For Kerr space–time $\mathbb{K}$, the geodesic equations admit four independent first integrals [see (4.1)]. But the problem is still complicated, and previous arguments will be used by including some subtleties and technical computations. Our approach can be summarized in the following steps.

(1) In order to connect two given points $p_0=(t_0,r_0,\theta_0,\varphi_0), p_1=(t_1,r_1,\theta_1,\varphi_1)$, we will consider all the geodesics emanating from p_0. Each geodesic $\gamma(s)$ is determined by its initial velocity $\gamma'(s_0)$. In Kerr space–time, this initial velocity is essentially characterized by *the constants of motion* q,K,L,E (see Sec. IV). More precisely, $\gamma'(s_0)$ yields naturally q,K,L,E, and fixing the values of q,K,L,E, one obtains $t'(s_0), r'(s_0)^2, \theta'(s_0)^2, \varphi'(s_0)$ [see Eq. (4.1)]. The sign

of $r'(s_0), \theta'(s_0)$ will be canonically fixed ($r'(s_0) \leqslant 0, \theta'(s_0) \geqslant 0$) for the geodesics which are relevant under our approach. Recall that there are restrictions for the possible values of q, K, L, E because $r'(s_0)^2, \theta'(s_0)^2$ calculated from (4.1) cannot be negative.

Geodesics with $L=0, E=0$ will be used to connect points in the simple case $t_0=t_1$ and either p_0 or p_1 lying in the z axis. In what follows we will consider geodesics with $E^2+L^2>0$. Moreover, we will also assume for simplicity $r_0 \leqslant r_1$, $t_0 \leqslant t_1$ (see Remark 4.5). Among geodesics with $L \neq 0$ those normalized with $L=1$ will always be chosen; if $L=0$ the chosen normalization will be $E=1$. These last geodesics will be useful when at least one of the points p_0, p_1 lies in the z axis; otherwise, geodesics with $L=1$ will be enough.

Summing up, we have *three degrees of freedom* for geodesics starting at p_0, corresponding to the set of directions in the tangent space to p_0, which will be described either by parameters $(q, K, L=1, E)$ or by $(q, K, L=0, E=1)$.

(2) The dimension of the manifold is four and, thus, there are four geodesic equations; nevertheless, the reparametrization of the geodesics is not relevant for geodesic connectedness and *one of the equations will be dropped*.

Concretely, we will prove that p_0, p_1 can be geodesically connected by using geodesics with $r'(s) \neq 0$ for all s in the domain of γ except at a point s^* such that $r^*=r(s^*)$ satisfies $r_+ < r^* < r_0$. Thus, taking into account this singular point r^*, any such geodesic $\gamma(s) = (t(s), r(s), \theta(s), \varphi(s))$ [characterized by its initial conditions as explained in step (1)] *will be reparametrized with* r, that is, as $\gamma(r) \equiv \gamma(s(r)) = (t(r), r, \theta(r), \varphi(r))$ for $r > r^*$.

The other two steps depend on if at least one of the points p_0, p_1 lies in the z axis or not. The first case is simpler; assume that, say, p_1 lies in the z axis.

(3^A) Because of the importance of the returning point r^* *the initial parameters* q, K ($L=0, E=1$) *will be changed by other parameters*, (r^*, S) in a domain $\hat{\mathcal{D}} \equiv (r_+, r_0) \times (0, \infty)$ [parameter S will also be related with properties of r^*, see formula (5.2)].

Given a value $(r^*, S) \in \hat{\mathcal{D}}$ we can recover the values of q and K [Eq. (5.3)]. Nevertheless, the domain $\hat{\mathcal{D}}$ will be restricted to a subset $\mathcal{D} = (r_+, r_L^*] \times (0, \infty) \subset \hat{\mathcal{D}}$. The value of $r_L^* (\in (r_+, r_0))$, which characterizes $\mathcal{D}$, is calculated to ensure the following properties:

($3^A I$) As commented in step (1), the values of q, K have some restrictions to characterize $\gamma'(s_0)$. When (r^*, S) belongs to $\mathcal{D}$, these restrictions are satisfied for the corresponding q, K. [In fact, $h(r_0)$ in Eq. (5.1) will be positive, and Eq. (5.6) will hold; thus, from (4.1) we will be able to choose $r'(s_0) < 0$, $\theta'(s_0) > 0$].

($3^A II$) As commented in step (2), the behavior of $r(s)$ for the relevant geodesics will be: first $r(s_0)=r_0$ then $r(s)$ decreases until $r=r^*$ and finally $r(s)$ increases until r_1. This behavior is ensured in $\mathcal{D}$ by the characterization of r_L^* in (5.4). [This can be checked because Eq. (4.10) with (5.1) will be satisfied when $r^* \in (r_+, r_L^*]$.]

($3^A III$) The component $\theta(s)$ of any geodesic γ in $\mathcal{D}$ will satisfy $\theta'(s) \neq 0$ out of the z-axis (see (4.1), (5.6)); in particular, from (1), $\theta'(s) > 0$ initially.

Only geodesics with $(r^*, S) \in \mathcal{D}$ will be used for connectedness.

(4^A) Now, for each $(r^*, S) \in \mathcal{D}$ we have a reparametrized geodesic $\gamma(r)$ with the parameter r going from r_0 to r^* and, finally, to r_1. When this parameter arrives at r_1, the coordinates t, θ, and φ will have increments $\Delta t, \Delta\theta$, and $\Delta\varphi$ on γ. The increment $\Delta\varphi$ will not be relevant in this case, because p_1 lies in the z axis. But, in order to connect p_0 and p_1, we have to find one of such geodesics with $\Delta t = t_1 - t_0$ and $\Delta\theta = \theta_1 - \theta_0$. Moreover, for the increment of θ the following trick will be useful. Let $\Delta|\theta|$ be the increment in the coordinate θ where it is regarded as a "circular coordinate," that is, as if θ increased even after crossing the z axis. Then, it is enough for θ: $\Delta|\theta| = \theta_1 - \theta_0 + 2n\pi$, for some integer $n \geqslant 0$.

Topological arguments will be relevant now. If we study how Δt varies with parameter S, we will find that (5.7) holds (see Fig. 1). Thus, applications of Brouwer's topological degree yield connected sets $\mathcal{C}_m$, $m \in \mathbb{N}$ of values of the parameters (r^*, S) such that:

(i) for all $(r^*, S) \in \mathcal{C}_m$, $\Delta t = t_1 - t_0$, and

(ii) the projection of the points in $\mathcal{C}_m$ on the r^* axis [that is, the image of the map (r^*, S)

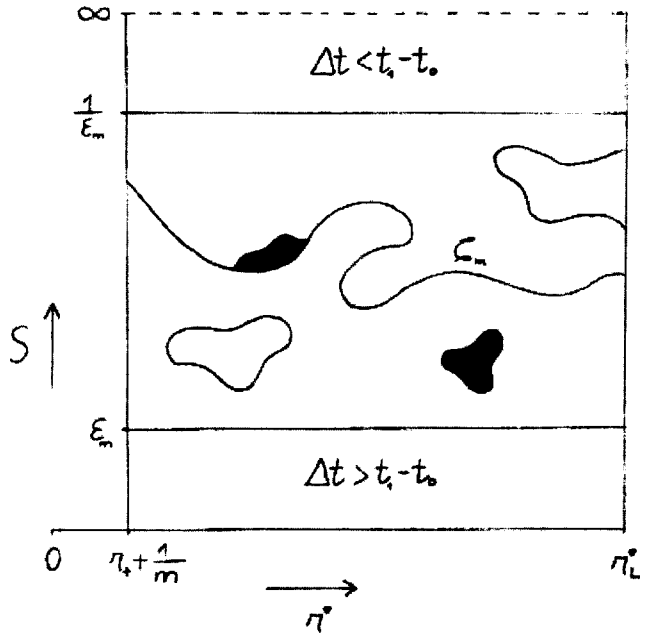

FIG. 1. When the behavior of $\Delta t(r^*,S)$ is as in formulas (5.7) then a connected set $\mathcal{C}_m$ of zeros of $\Delta t - t_1 + t_0$ which connect $r^* = r_+ + 1/m$ and $r^* = r_L^*$ can be found.

$\to r^*$ for $(r^*,S) \in \mathcal{C}_m$] is equal to the whole interval $[r_+ + 1/m, r_L^*]$. Now, the behavior of $\Delta|\theta|$ on $\mathcal{C}_m$ can be studied, finding: (a) the value of $\Delta|\theta|$ on the points of $\mathcal{C}_m$ in the line $r^* = r_L^*$ admit an upper bound independent of m, and (b) the value of $\Delta|\theta|$ on the points of $\mathcal{C}_m$ in the line $r^* = r_+ + 1/m$ becomes arbitrarily big. Thus, obviously, there exists at least one point in some $\mathcal{C}_m$ such that $\Delta|\theta| = \theta_1 - \theta_0 + 2n\pi$, for some integer $n \geqslant 0$ [in addition to $\Delta t = t_1 - t_0$, satisfied by (i)]. So, the required geodesic is found.

Let us see what happens if neither p_0 nor p_1 belongs to the z axis. Now, we will consider always geodesics with $L = 1$ (in particular, they do not cross the z axis).

(3^B) Analogously to case (3^A), *parameters* (q,K,E) *will be changed by parameters* $(r^*,S,E) \in \hat{\mathcal{D}} \equiv (r_+, r_0) \times (0,\infty)^2$, more closely related to the "returning point" of the geodesic. Analogously, the domain $\hat{\mathcal{D}}$ of (r^*,S,E) will be restricted to a subset $\mathcal{D}$ to solve the following similar problems to ($3^A I$), ($3^A II$), ($3^A III$):

($3^B I$) The values of q,K,E have some restrictions to characterize $\gamma'(s_0)$. Given (r^*,S,E), parameters q,K,E are directly computed [formula (6.1)], but perhaps the restrictions are not satisfied and, thus, they are not associated with any geodesic.

($3^B II$) Again, the behavior of $r(s)$ must be as in ($3^A II$). First, $r(s_0) = r_0$ then $r(s)$ decrease until $r = r^*$ and finally $r(s)$ increase until r_1. To achieve this, Eq. (4.10) [with (4.5)] must be satisfied.

($3^B III$) In ($3^A III$) the found connecting geodesic might cross the z axis many times [because of (5.6)]. But now, we are considering geodesics which do not cross the z axis. In fact, for any geodesic with $L = 1$, an angle $\theta_L \in (0, \pi/2]$ will exist such that if $\theta_L \leqslant \theta_0 \leqslant \pi - \theta_L$ then the component $\theta(s)$ of the geodesic varies between θ_L and $\pi - \theta_L$. Thus, θ_L can be regarded as a limit angle for $\theta(s)$ (see Definition 4.1 and Remark 4.2). Recall that, if also $\theta_L \leqslant \theta_1 \leqslant \pi - \theta_L$, $\theta(s)$ will find no obstruction to cross θ_0 and θ_1.

($3^B IV$) Technical conditions [Eq. (6.4), Remark 6.4] will be required for $\mathcal{D}$ in order to apply topological arguments.

In case 3^A a value of r_L^* is found such that the corresponding problems $3^A I$–$3^A III$ for the parameters (r^*,S) are solved if $r^* \in (r_+, r_L^*]$. Unfortunately, this is not sufficient now. The best

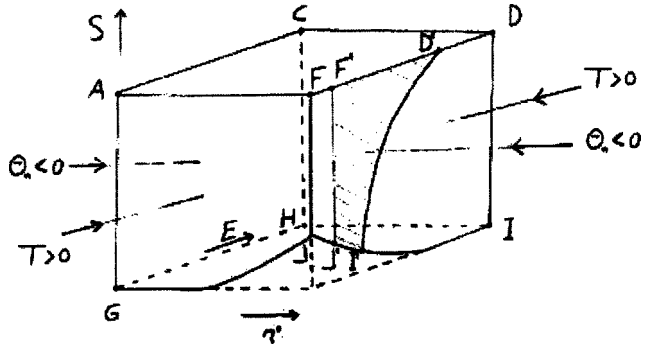

FIG. 2. Domain $\mathcal{D}_n$ in (6.32): $A=(r_+ + \epsilon_n, \overline{S}_n, \delta_n)$, $C=(r_+ + \epsilon_n, \overline{S}_n, 1/\delta_n)$, $D=(r_L^*, \overline{S}_n, 1/\delta_n)$, $G=(r_+ + \epsilon_n, S(r_+ + \epsilon_n, \delta_n), \delta_n)$, Behavior of T, Θ_n from Lemma 6.3 and (6.34) in Proposition 6.7: $T<0$ on $(AFJG)\cup(FF'J'J)$; $T>0$ on $(CHID)\cup(D'DII')$; $\Theta_n>0$ on $(ACHG)$; $\Theta_n<0$ on $(F'D'I'J')$. Lower face: graph of $S=S(r^*,E)(\geq 0)$.

we can find is some domain $\mathcal{D}$, with restrictions not only for r^* but also for S, such that restrictions $3^B I - 3^B IV$ are satisfied when $(r^*,S,E)\in\mathcal{D}$ (see Lemma 6.2 and Remark 6.4). More precisely, fixed $\overline{\theta}>0$ let $S(r^*,E)\geqslant 0$ be the minimum non-negative number such that $\theta_L(r^*,S,E)\leqslant\overline{\theta}$ if $S>S(r^*,E)$ (see Definition 4.1 and Lemma 6.3). $S(r^*,E)$ is a continuous function with finite supremum $\mathcal{S}$, but it will vanish for some (r^*,E) (this must be taken into account noticing that $S>0$ for the elements of $\hat{\mathcal{D}}$). Then there exist $r_L^*\in(r_+,r_0)$ and $\overline{\theta}\in(0,\pi/2)$ such that $\mathcal{D}\equiv\{(r^*,S,E)\in\hat{\mathcal{D}}: r^*\in(r_+,r_L^*], E\in(0,\infty), S\in[S(r^*,E),\infty)\}$ is the required domain.

(4^B) Now, for each $(r^*,S,E)\in\mathcal{D}$ we have a reparametrized geodesic $\gamma(r)$ with the parameter r going from r_0 to r^* and, finally, to r_1. As in case (4^A), when this parameter arrives at r_1, the coordinates t,θ, and φ will have increments $\Delta t,\Delta\theta$, and $\Delta\varphi$ on γ, but now the increment $\Delta\varphi$ is also relevant. In order to connect p_0 and p_1, it is sufficient to find one of such geodesics with $\Delta t=t_1-t_0$, $\Delta\theta=\theta_1-\theta_0$, and $\Delta\varphi=\varphi_1-\varphi_0$. Moreover, we will denote by $\Delta|\theta|$ the increment in the coordinate θ computed as if it were positive beyond any rebound of $\theta(s)$ at θ_L or $\pi-\theta_L$; for example, if $\theta(s)$ increases from $\theta(s_0)$ to $\pi-\theta_L$ and then decreases to $\theta(s_1)$ we define $\Delta|\theta| = |(\pi-\theta_L)-\theta(s_0)|+|(\pi-\theta_L)-\theta(s_1)|$. Thus, it is sufficient for θ: $\Delta|\theta|=\theta_1-\theta_0+2n(\pi-2\theta_L)$, for some integer $n\geqslant 0$. Finally, as φ will be regarded as a circular coordinate it is enough $\Delta\varphi=\varphi_1-\varphi_0+2n'\pi$, for some integer $n'\geqslant 0$. The *topological arguments* are now subtler.

First we will find connected sets $\mathcal{C}_n$ of parameters such that the associated geodesics have exactly $\Delta t=t_1-t_0$, $\Delta|\theta|=\theta_1-\theta_0+2n(\pi-2\theta_L)$.

$(4^B I)$ Consider the functions $T=\Delta t-(t_1-t_0)$ and $\Theta_n=\Delta|\theta|-(\theta_1-\theta_0)-2n(\pi-2\theta_L)$ with domain $\mathcal{D}$, for some integer $n\geqslant 0$. Given $\{\overline{S}_n\}_n$ diverging, there exist $\{\epsilon_n\}_n$, $\epsilon_n>0$, $\epsilon_n\searrow 0$, and $\{\delta_n\}_n$, $\delta_n>0$, $\delta_n\searrow 0$ such that functions T and Θ_n satisfy the boundary conditions (6.34) in a domain $\mathcal{D}_n$ (Fig. 2), for n big enough (Proposition 6.7).

$(4^B II)$ Taking into account that in some points $S(r^*,E)$ vanishes, a natural compact subset $\mathcal{D}_n^m\subset\mathcal{D}$ can be defined [see (6.35)] where connected sets $\mathcal{C}_n^m$ of simultaneous zeroes of T and Θ_n will be found. In order to obtain $\mathcal{C}_n^m$, recall that a homeomorphism z_n^m maps $\mathcal{D}_n^m$ to a cube as in Fig. 3. Thus, topological arguments imply the existence of a connected set $z_n^m(\mathcal{C}_n^m)$ of zeroes of the two functions $T\circ(z_n^m)^{-1}$, $\Theta_n\circ(z_n^m)^{-1}$ connecting the upper and the lower faces of the cube (Lemma 6.9).

$(4^B III)$ Using Whyburn arguments on the sets $\mathcal{C}_n^m$ we construct a new connected set $\mathcal{C}_n\subset\overline{\mathcal{D}}_n$ (depicted in Fig. 4). We will prove:

(i) $\mathcal{C}_n\subset\mathcal{D}_n$ and thus, points in $\mathcal{C}_n$ are zeroes of T and Θ_n, and

(ii) each $\mathcal{C}_n$ has a point with $S=\overline{S}_n$ and a point with $S=S(r^*,E)>0$ (and, thus $\theta_L=\overline{\theta}$) for all n (Lemma 6.10 and comments above).

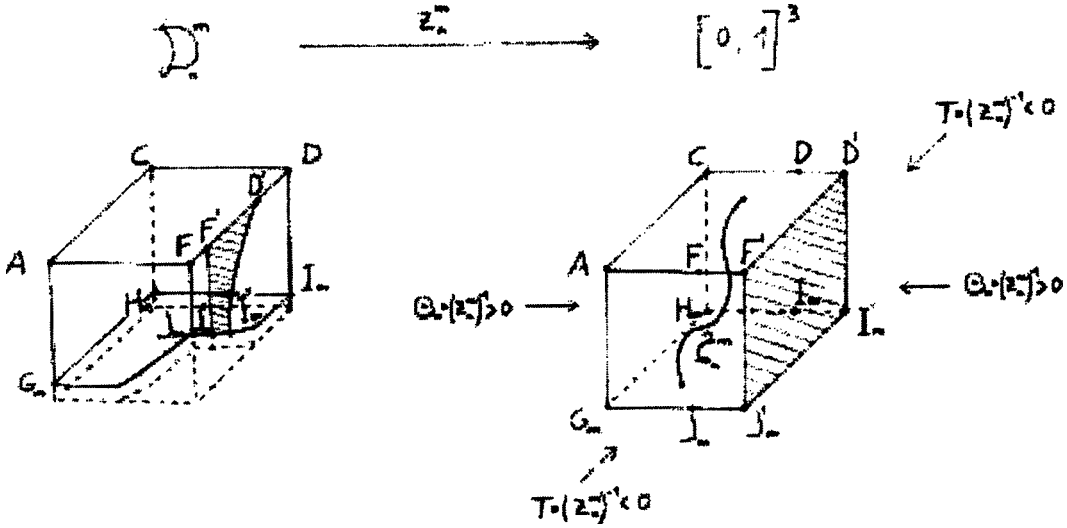

FIG. 3. (1) Homeomorphism z_n^m between $\mathcal{D}_n^m$ in (6.35) and the cube $[0,1]^3$. The dashed region ($F'D'I'_mJ'_m$) corresponds by the homeomorphism. (2) Brouwer's topological degree applied to $T\circ(z_n^m)^{-1}$ and $\Theta\circ(z_n^m)^{-1}$ yields a simultaneous connected set of zeroes $\hat{\mathcal{C}}_n^m = z_n^m(\mathcal{C}_n^m)$ joining the upper and lower faces of the cube $[0,1]^3$.

Now, geodesics associated to each $(r^*,S,E)\in\mathcal{C}_n$ have the required value of Δt, $\Delta|\theta|$, but we have not controlled the value of $\Delta\varphi$ yet. Our aim will be to find two points in a connected set $\mathcal{C}_n$ for some (big) n, whose difference in $\Delta\varphi$ is greater than 2π. Thus, some point in $\mathcal{C}_n$ will satisfy $\Delta\varphi=\varphi_1-\varphi_0+2\pi n'$, $n'\geqslant 0$, which concludes the proof. In fact, we prove the existence of a

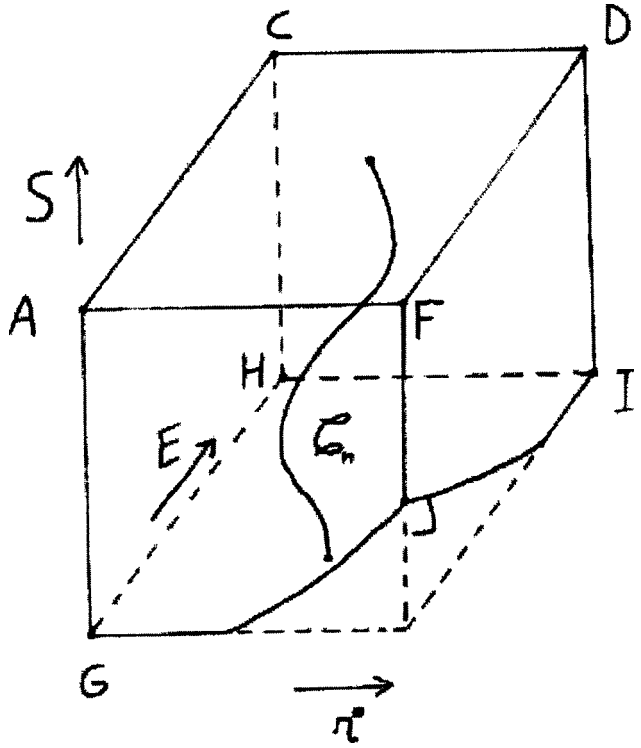

FIG. 4. Taking $\limsup_m$ on $\mathcal{C}_n^m$ a connected set $\mathcal{C}_n$ is obtained, satisfying: (a) all the points in $\mathcal{D}_n\cap\mathcal{C}_n$ are zeroes of T and Θ_n, (b) $\mathcal{C}_n$ touches the upper and the lower faces, the latter in a point with $S>0$ (Lemma 6.10; in particular, $\mathcal{C}_n\subset\mathcal{D}_n$), and (c) for big n, function $\Delta\varphi|_{\mathcal{C}_n}$ covers an interval of length greater than 2π (Lemmas 6.11 and 6.12).

choice of $\{\overline{S_n}\}_n$ such that points $(r_n^*,\overline{S_n},E_n)\in\mathcal{C}_n$ obtained in (ii) satisfy:

$$2n\pi-(\Delta\varphi)(r_n^*,\overline{S_n},E_n)<n\cdot\epsilon \tag{3.2}$$

for every $\epsilon>0$ and n big enough (Lemma 6.11). On the other hand, again from (ii) we can take a sequence of points $(r_n^{*\prime},S_n',E_n')\in\mathcal{C}_n$ with $\theta_L(r_n^{*\prime},S_n',E_n')=\overline{\theta}>0$ for all n which, from Lemma 6.12, implies

$$2n\pi-(\Delta\varphi)(r_n^{*\prime},S_n',E_n')>n\cdot\epsilon_0 \tag{3.3}$$

for some $\epsilon_0>0$. The result follows then from (3.2) and (3.3).

IV. GENERAL BEHAVIOR OF THE GEODESICS

Let $\gamma:\mathcal{J}\to\mathbb{R}^4$, $\gamma(s)=(t(s),r(s),\theta(s),\varphi(s))$ be a (smooth) curve on the interval $\mathcal{J}$. The first integrals of the geodesics equations of Kerr space–time are

$$\begin{aligned}
\lambda(r,\theta)t' &= a\mathbb{D}(\theta)+(r^2+a^2)\frac{\mathbb{P}(r)}{\Delta(r)},\\
\lambda(r,\theta)^2r'^2 &= \Delta(r)(qr^2-K)+\mathbb{P}^2(r),\\
\lambda(r,\theta)^2\theta'^2 &= K+qa^2\cos^2\theta-\frac{\mathbb{D}^2(\theta)}{\sin^2\theta},\\
\lambda(r,\theta)\varphi' &= \frac{\mathbb{D}(\theta)}{\sin^2\theta}+a\frac{\mathbb{P}(r)}{\Delta(r)},
\end{aligned} \tag{4.1}$$

where

$$\begin{aligned}
\mathbb{D}(\theta) &= L-Ea\sin^2\theta,\\
\mathbb{P}(r) &= (r^2+a^2)E-La
\end{aligned} \tag{4.2}$$

and q (normalization of the geodesic; rest mass), K (Carter constant), L (angular momentum), and E (energy measured by observers in ∂_t) are constants; we follow essentially the notation in Ref. 31, Chap. 4. So, if we assume $r'(s_0)\leqslant 0$, $\theta'(s_0)\geqslant 0$ every geodesic is fixed by an initial point p_0 [i.e., $\gamma(s_0)=p_0$] and the constants q, K, L, and E. Moreover, from the third equation in (4.1), if γ reaches the z axis then, necessarily $L=0$; recall that when $L\neq 0$ we can normalize $L=1$.

Let $s(r)$ be the inverse function (where it exists) of $r(s)$ in (4.1); using r as the parameter in the other three equations in (4.1):

$$\begin{aligned}
\frac{dt}{dr} &= \epsilon\frac{a\mathbb{D}(\theta)+(r^2+a^2)\dfrac{\mathbb{P}(r)}{\Delta(r)}}{\sqrt{\Delta(r)(qr^2-K)+\mathbb{P}^2(r)}},\\
\frac{d\theta}{dr} &= \epsilon'\frac{\sqrt{K+qa^2\cos^2\theta-\dfrac{\mathbb{D}^2(\theta)}{\sin^2\theta}}}{\sqrt{\Delta(r)(qr^2-K)+\mathbb{P}^2(r)}},\\
\frac{d\varphi}{dr} &= \epsilon\frac{\dfrac{\mathbb{D}(\theta)}{\sin^2\theta}+a\dfrac{\mathbb{P}(r)}{\Delta(r)}}{\sqrt{\Delta(r)(qr^2-K)+\mathbb{P}^2(r)}}
\end{aligned} \tag{4.3}$$

on a certain domain, being $\epsilon,\epsilon' \in \{\pm 1\}$. Equation (4.3) will be used to prove the geodesic connectedness of outer Kerr space–time $\mathbb{K}$. But, previously, we need the following definition related to the expression of θ'.

Definition 4.1: For any $(q,K,L,E) \in \mathbb{R}^4$ *we define* $\theta_L \equiv \theta_L(q,K,L,E)$ *as the smaller angle in* $[0,\pi/2]$ *satisfying*

$$K + qa^2 \cos^2\theta - \frac{\mathbb{D}^2(\theta)}{\sin^2\theta} > 0, \quad \forall\, \theta \in \left(\theta_L, \frac{\pi}{2}\right], \tag{4.4}$$

with $\mathbb{D}(\theta) \equiv \mathbb{D}(\theta,L,E)$ *given in (4.2).*

[Recall that if for some (q,K,L,E) the left-hand side of inequality (4.4) is nonpositive at $\theta = \pi/2$ then $\theta_L = \pi/2$].

Remark 4.2: Assume that (q,K,L,E) corresponds to a geodesic with $\gamma(s_0) = p_0 \equiv (t_0, r_0, \theta_0, \varphi_0)$ and $\theta_L \leqslant \theta_0 \leqslant \pi - \theta_L$. If $L = 1$ then θ_L can be seen as a limit angle for $\theta(s)$ as explained in $(3^{B}III)$; in fact, it is clear from (4.1) that $\theta(s)$ takes values in $[\theta_L, \pi - \theta_L]$ being $\theta'(s) = 0$ only when $\theta(s) \in \{\theta_L, \pi - \theta_L\}$.

If one consider geodesics with $r' \neq 0$ at any point, then the geodesic can be reparametrized by[29] r and the increments Δt, $\Delta\theta$, and $\Delta\varphi$ can be calculated integrating in (4.3). Nevertheless, in this article we are going to see that two arbitrary points $p_0 = (t_0, r_0, \theta_0, \varphi_0)$, $p_1 = (t_1, r_1, \theta_1, \varphi_1)$ in $\mathbb{K}$ with $r_0 \leqslant r_1$ can be always joined with a geodesic such that $r'(s)$ vanishes exactly at one point s^*, and $r^* = r(s^*)$ satisfies $r_+ < r^* < r_0$. Recall that, for these geodesics the denominator in formula (4.3), that is

$$h(r) = \Delta(r)(qr^2 - K) + \mathbb{P}^2(r), \tag{4.5}$$

will vanish at r^*. As $r(s)$ will go from r_0 to r^* then necessarily $h'(r^*) > 0$; in fact, this implies $|s(r^*) - s(r_0)| < \infty$ (see Ref. 29). As later on $r(s)$ will go from r^* to r_1, then $h(r) > 0$ if $r^* < r < r_1$; we will consider geodesics with $h(r_1) > 0$ too. Thus, the increment in the variable t will be

$$\Delta t = \int_{r^*}^{r_0} \frac{a\mathbb{D}(\theta) + (r^2 + a^2)\dfrac{\mathbb{P}(r)}{\Delta(r)}}{\sqrt{h(r)}}\,\mathrm{d}r + \int_{r^*}^{r_1} \frac{a\mathbb{D}(\theta) + (r^2 + a^2)\dfrac{\mathbb{P}(r)}{\Delta(r)}}{\sqrt{h(r)}}\,\mathrm{d}r. \tag{4.6}$$

For the coordinate θ, if $L = 1$ we will assume that $\theta(s)$ will go from θ_0 to θ_1 with $\theta'(s)$ only vanishing at an even number of points s_i, $i = 1,\ldots,2n$, such that $\theta(s_i)$ is equal either to the limit angle θ_L or to $\pi - \theta_L$, Remark 4.2. If $L = 0$, we will choose always geodesics such that q, K, E make the left-hand side of (4.4) positive for all θ and thus, $\theta_L = 0$; that is, $\theta'(s) \neq 0$ always except at the points s_i, $i = 1,\ldots,2n$, where γ reaches the z axis [at these points $\theta(s)$ is not differentiable and the sign of $\theta'(s)$ changes]. In particular,

$$\begin{gathered} \theta_L \leqslant \theta_0, \quad \theta_1 \leqslant \pi - \theta_L \ \text{ if } \ L = 1, \\ \theta_L = 0 \quad \text{and} \quad (4.4) \ \text{holds strictly at} \ \theta_L \ \text{if} \ L = 0. \end{gathered} \tag{4.7}$$

As explained in (4^{A}) and (4^{B}) we will define $\Delta|\theta|$ considering the increments as positive beyond the points s_i. That is, we define

$$\Delta|\theta| = \int_{r^*}^{r_0} \frac{\sqrt{K + qa^2\cos^2\theta - \dfrac{\mathbb{D}^2(\theta)}{\sin^2\theta}}}{\sqrt{h(r)}}\,\mathrm{d}r + \int_{r^*}^{r_1} \frac{\sqrt{K + qa^2\cos^2\theta - \dfrac{\mathbb{D}^2(\theta)}{\sin^2\theta}}}{\sqrt{h(r)}}\,\mathrm{d}r. \tag{4.8}$$

Finally, the circular coordinate φ will have an increment

$$\Delta\varphi=\int_{r^*}^{r_0}\frac{\frac{\mathbb{D}(\theta)}{\sin^2\theta}+a\frac{\mathbb{P}(r)}{\Delta(r)}}{\sqrt{h(r)}}\mathrm{d}r+\int_{r^*}^{r_1}\frac{\frac{\mathbb{D}(\theta)}{\sin^2\theta}+a\frac{\mathbb{P}(r)}{\Delta(r)}}{\sqrt{h(r)}}\mathrm{d}r. \tag{4.9}$$

Recall that this increment also represents a certain number n' of turns around the z axis (if $2n'\pi\leqslant\Delta\varphi<2(n'+1)\pi$). Summing up:

Lemma 4.3: Let $p_0=(t_0,r_0,\theta_0,\varphi_0)$, $p_1=(t_1,r_1,\theta_1,\varphi_1)$ be two points in $\mathbb{K}$ with $r_0\leqslant r_1$, such that $\sin\theta_0\neq 0\neq\sin\theta_1$ (*respectively, one or both points in the z axis*). *Assume that there exist q, K, and E as well as $r^*\in(r_+,r_0)$ such that (4.7) and the following relations (4.10) and (4.11) hold with $L=1$ (respectively, $L=0$):*

$$h(r^*)=0,\quad h'(r^*)>0,\quad h(r)>0\quad on\quad (r^*,r_1]; \tag{4.10}$$

$$\begin{cases}\Delta t=t_1-t_0,\\ \Delta|\theta|=\theta_1-\theta_0+2n(\pi-2\theta_L),\\ \Delta\varphi=\varphi_1-\varphi_0+2\pi n'\end{cases} \tag{4.11}$$

for some integers $n,n'\geqslant 0$ [for the case $L=0$, without the restriction on $\Delta\varphi$ in (4.11)]. Then, there exists $s_1>s_0$ such that the geodesic $\gamma:[s_0,s_1]\to\mathbb{K}$, $\gamma(s_0)=p_0$ with constants $L=1$ (respectively, $L=0$), q, K and E, satisfies $\gamma(s_1)=p_1$.

Remark 4.4: Recall that the restriction on $\Delta\varphi$ in (4.11) is not imposed when $L=0$ because if $\sin\theta_1=0$ (as we assumed in the overview) then the coordinate φ becomes irrelevant. If $\sin\theta_0=0\neq\sin\theta_1$ then Lemma 4.3 yields a geodesic $\gamma(s)=(t(s),r(s),\theta(s),\varphi(s))$ with the appropiate values of Δt, $\Delta|\theta|$. Then $\overline{\gamma}(s)=(t(s),r(s),\theta(s),\varphi(s)+\overline{\varphi})$ with $\overline{\varphi}=\varphi_1-\varphi(s_1)$ is the required geodesic.

Remark 4.5: In order to prove the connectedness of two arbitrary points $p_0=(t_0,r_0,\theta_0,\varphi_0)$, $p_1=(t_1,r_1,\theta_1,\varphi_1)$ we will assume $t_0\leqslant t_1$ and $r_0\leqslant r_1$. In fact, if this last inequality does not hold, Lemma 4.3 can be obviously modified taking $r^*\in(r_+,r_1)$.

The following simple technical result will be useful in the following sections (see Ref. 26 for a detailed proof):

Lemma 4.6: Let $\{f_n(x)\}_n$ be a sequence of continuous functions on $[a_n,b_n]\subset\mathbb{R}$, $a_n\to a$, $b_n\to b$, $a<b$ satisfying $0<c\leqslant f_n(x)\leqslant C$ for all n, and let $\{p_n(x)\}_n$ be a sequence of polynomials with degree bounded in n satisfying for all n: $p_n(a_n)=0$, $p_n'(a_n)=R_n>0$ and $p_n^{(k)}(a_n)\geqslant 0$ for $k\geqslant 2$.

(i) If $R_n\to\infty$, then

$$\int_{a_n}^{b_n}\frac{f_n(x)}{\sqrt{p_n(x)}}\mathrm{d}x\to 0.$$

(ii) If $R_n\to 0$ and $p_n^{(k)}(a_n)$ admits an upper bound for $k\geqslant 2$ and for all n, then

$$\int_{a_n}^{b_n}\frac{f_n(x)}{\sqrt{p_n(x)}}\mathrm{d}x\to\infty.$$

V. GEODESIC CONNECTEDNESS WITH THE *z* AXIS

In this section we prove that there exists a geodesic joining two arbitrary points when, at least, one of them lies in the z axis. From Remark 4.5, it suffices:

Theorem 5.1: *Given two points $p_0=(t_0,r_0,\theta_0,\varphi_0)$, $p_1=(t_1,r_1,\theta_1,\varphi_1)$ in $\mathbb{K}$, at least one of them in the z axis, with $r_0\leqslant r_1$, $t_0\leqslant t_1$, there exists a geodesic $\gamma:[s_0,s_1]\to\mathbb{K}$ such that $\gamma(s_0)=p_0$, $\gamma(s_1)=p_1$.*

Proof: Taking into account Lemma 4.3 it is sufficient to prove that there exist constants q, K, and E as well as $r^*\in(r_+,r_0)$ satisfying (4.7), (4.10), and (4.11) for $L=0$.

First, consider the case $t_0<t_1$ and choose $E=1$; so (4.5) becomes

$$h(r)=(r-r_-)(r-r_+)(qr^2-K)+(r^2+a^2)^2. \tag{5.1}$$

If we look for r^* such that

$$h(r^*)=0, \quad h'(r^*)=S>0 \tag{5.2}$$

then the following two relations for the constants q and K are obtained:

$$\begin{aligned} qr^{*2}-K&=-\frac{(r^{*2}+a^2)^2}{(r^*-r_-)(r^*-r_+)},\\ q&=\frac{(r^{*2}+a^2)^2}{2r^*(r^*-r_-)^2(r^*-r_+)}+\frac{(r^{*2}+a^2)^2}{2r^*(r^*-r_-)(r^*-r_+)^2}\\ &\quad-\frac{2(r^{*2}+a^2)}{(r^*-r_-)(r^*-r_+)}+\frac{S}{2r^*(r^*-r_-)(r^*-r_+)}. \end{aligned} \tag{5.3}$$

Taking into account the dependencies of q on (r^*-r_+) in the second equation in (5.3), there exists $r_L^*\in(r_+,r_0)$ near enough to r_+ such that if $r^*\in(r_+,r_L^*]$ then

$$r_+^2 q(r^*,S)>a^2, \quad \forall S>0 \quad (\Rightarrow K(r^*,S)>a^2, \quad \forall S>0). \tag{5.4}$$

Moreover, derivating in (5.1) in order to apply Lemma 4.6,

$$\begin{aligned} h^{(2)}(r^*)&=4qr^*(r^*-r_+)+4qr^*(r^*-r_-)+2(qr^{*2}-K)+2q(r^*-r_-)(r^*-r_+)+12r^{*2}+4a^2,\\ h^{(3)}(r^*)&=6q(r^*-r_+)+6q(r^*-r_-)+(12q+24)r^*,\\ h^{(4)}(r^*)&=24q+24. \end{aligned} \tag{5.5}$$

Clearly $h^{(3)}(r^*)$, $h^{(4)}(r^*)>0$. Moreover, r_L^* can be chosen such that the sum of the second plus third terms in the expression of q in (5.3) is positive and thus, $h^{(2)}(r^*)>0$. In particular, $h(r)>0$ if $r>r^*$. On the other hand, from (5.4)

$$K+qa^2\cos^2\theta-\frac{\mathbb{D}^2(\theta)}{\sin^2\theta}=K+(qa^2+a^2)\cos^2\theta-a^2>0 \tag{5.6}$$

for all θ [in particular, (4.7) is satisfied with $L=0$]. Summing up, because of Lemma 4.3 it is sufficient to find an element of $\mathcal{D}\equiv\{(r^*,S):r^*\in(r_+,r_L^*],S\in(0,\infty)\}$ such that the corresponding (q,K) given from (5.3) and the function $h(r)\equiv h(r,q,K)$ in (5.1) satisfy the first two equalities (4.11) with Δt, $\Delta|\theta|$ as in (4.6) and (4.8) (and $L=0$, $E=1$).

Fix sequences $\{S_n\}_n\to\infty$, $\{r_n^*\}_n\to r^*\in(r_+,r_L^*]$, and put

$$f_n(r)\equiv a\mathbb{D}(\theta_n(r))+(r^2+a^2)\frac{\mathbb{P}(r)}{\Delta(r)}, \quad p_n(r)\equiv h_n(r)$$

with $h_n(r)\equiv h(r,q(r_n^*,S_n),K(r_n^*,S_n))$ and $\theta_n(r)$ computed with (r_n^*,S_n) from the second equation in (4.3) [recall (5.6)]. Using (5.2) and the positiveness of (5.5), hypotheses of Lemma 4.6 (i) clearly hold on the interval $[a_n,b_n]=[r_n^*,r_1]$. Therefore,

$$(\Delta t)_n=\int_{r_n^*}^{r_0}\frac{f_n(r)}{\sqrt{p_n(r)}}\mathrm{d}r+\int_{r_n^*}^{r_1}\frac{f_n(r)}{\sqrt{p_n(r)}}\mathrm{d}r\to 0.$$

Analogously, if we consider $\{S_n\}_n \to 0$ then, from (5.5) and (5.3), $h_n^{(k)}(r_n^*)$ admits an upper bound for $k \geqslant 2$ and all n thus, from Lemma 4.6(ii), $(\Delta t)_n \to \infty$. In conclusion, there exists $\{\epsilon_m\}_m$, $\epsilon_m > 0$, $\epsilon_m \searrow 0$, such that

$$\Delta t(r^*,S) < t_1 - t_0 \quad \text{when} \quad (r^*,S) \in \left[r_+ + \frac{1}{m}, r_L^* \right] \times \left[\frac{1}{\epsilon_m}, \infty \right),$$
$$\Delta t(r^*,S) > t_1 - t_0 \quad \text{when} \quad (r^*,S) \in \left[r_+ + \frac{1}{m}, r_L^* \right] \times (0, \epsilon_m] \tag{5.7}$$

(see Fig. 1). This is a typical situation where Brouwer's topological degree ensures, for each m, the existence of a connected set $\mathcal{C}_m$ of zeroes of $\Delta t - t_1 + t_0$ connecting the extreme vertical lines. More precisely,

Lemma 5.2: There exists a connected subset $\mathcal{C}_m$ of zeroes of $T(r^*,S) = \Delta t - t_1 + t_0$ such that

$$\mathcal{C}_m \cap \left(\left\{ r_+ + \frac{1}{m} \right\} \times \left(\epsilon_m, \frac{1}{\epsilon_m} \right) \right) \neq \varnothing \quad \textit{and} \quad \mathcal{C}_m \cap \left(\{ r_L^* \} \times \left(\epsilon_m, \frac{1}{\epsilon_m} \right) \right) \neq \varnothing$$

for every $m \in \mathbb{N}$.

(For a detailed proof, see Ref. 26 Lemma 2.) Therefore, for these subsets (i) and (ii) in (4^A) holds. So, we only need to prove that among the found zeroes of T there is a $(r^*,S) \in \mathcal{D}$ such that $\Delta|\theta|$ satisfies (4.11), for some n.

Let $(r_m^*, S_m) \in \mathcal{C}_m$ be with $r_m^* = r_+ + 1/m$, and take in Lemma 4.6(ii)

$$f_m(r) \equiv \frac{\sqrt{K_m + q_m a^2 \cos^2 \theta_m(r) - a^2 \sin^2 \theta_m(r)}}{\sqrt{q_m}} \quad \text{and} \quad p_m(r) \equiv \frac{h_m(r)}{q_m}$$

with K_m, q_m obtained from (5.3), $\theta_m(r)$ from (4.3). From (5.3), q_m will grow at least as m^2 and, from (5.4) and (5.5) one checks that the hypotheses of this lemma hold on the intervals $[a_m, b_m] = [r_m^*, r_1]$, obtaining

$$(\Delta|\theta|)_m = \int_{r_m^*}^{r_0} \frac{f_m(r)}{\sqrt{p_m(r)}} \mathrm{d}r + \int_{r_m^*}^{r_1} \frac{f_m(r)}{\sqrt{p_m(r)}} \mathrm{d}r \to \infty. \tag{5.8}$$

On the other hand, from (5.7) the points in $\mathcal{C}_m$ with $r^* = r_L^*$ have $S \in (\epsilon_1, 1/\epsilon_1)$, thus q, K is upper bounded for these points and all m [see (5.3)] and so is $\Delta|\theta|$. This fact, (5.8) and the connectedness of each $\mathcal{C}_m$ imply for some big m the existence of $(r^*,S) \in \mathcal{C}_m$ such that the second equality (4.11) also holds, as required.

Finally, consider the case $t_0 = t_1$. Choose $E = 0$ and, thus, $T = 0$ automatically. Now (4.5) becomes

$$h(r) \equiv (r - r_-)(r - r_+)(qr^2 - K).$$

By imposing $h(r^*) = 0$ and $h'(r^*) = 1$ we obtain the following values for the constants q and K:

$$qr^{*2}-K=0,$$
$$q=\frac{1}{2r^*(r^*-r_-)(r^*-r_+)}. \tag{5.9}$$

If we take $\{r_m^*\}_m\to r_+$, (5.9) and formulas analogous to (5.5) imply that Lemma 4.6(ii) can be applied to the functions

$$f_m(r)\equiv\frac{\sqrt{K_m+q_m a^2\cos^2\theta_m(r)}}{\sqrt{q_m}},\quad p_m(r)\equiv\frac{h_m(r)}{q_m},$$

on the intervals $[a_m,b_m]=[r_m^*,r_1]$. Thus, we obtain (5.8) and, so, $(\Delta|\theta|)_m\equiv\Delta|\theta|(r_m^*)\to\infty$. Therefore, a required value for r^* can be found in $[r_m^*,r_L^*]$ for some big m. □

VI. GEODESIC CONNECTEDNESS BETWEEN POINTS OUT OF THE *z* AXIS

In this section we conclude the proof of the geodesic connectedness of $\mathbb{K}$ by proving that there exists a geodesic joining two arbitrary points out of the z axis. Recalling again Remark 4.5, we will prove:

Theorem 6.1: *Given two points* $p_0=(t_0,r_0,\theta_0,\varphi_0)$, $p_1=(t_1,r_1,\theta_1,\varphi_1)$ *in* $\mathbb{K}$, $\sin\theta_0\neq 0\neq\sin\theta_1$, $r_0\leqslant r_1$, $t_0\leqslant t_1$, *there exists a geodesic* $\gamma:[s_0,s_1]\to\mathbb{K}$ *such that* $\gamma(s_0)=p_0$, $\gamma(s_1)=p_1$.

Taking into account Lemma 4.3, it is sufficient to prove that there exist constants q, K, and E as well as $r^*\in(r_+,r_0)$ satisfying (4.7), (4.10), and (4.11) with $L=1$.

We will again use r^* such that (5.2) holds. Then the following two relations for the constants q and K are obtained from (4.5):

$$qr^{*2}-K=-\frac{[(r^{*2}+a^2)E-a]^2}{(r^*-r_-)(r^*-r_+)},$$
$$q=\frac{[(r^{*2}+a^2)E-a]^2}{2r^*(r^*-r_-)^2(r^*-r_+)}+\frac{[(r^{*2}+a^2)E-a]^2}{2r^*(r^*-r_-)(r^*-r_+)^2}$$
$$-\frac{2[(r^{*2}+a^2)E-a]E}{(r^*-r_-)(r^*-r_+)}+\frac{S}{2r^*(r^*-r_-)(r^*-r_+)}. \tag{6.1}$$

Moreover,

$$h^{(2)}(r^*)=4qr^*(r^*-r_+)+4qr^*(r^*-r_-)+2(qr^{*2}-K)$$
$$+2q(r^*-r_-)(r^*-r_+)+4E[(r^{*2}+a^2)E-a]+8r^{*2}E^2,$$
$$h^{(3)}(r^*)=12qr^*+6q(r^*-r_+)+6q(r^*-r_-)+24E^2r^*, \tag{6.2}$$
$$h^{(4)}(r^*)=24q+24E^2.$$

From (6.1), given $(r^*,S,E)\in\hat{\mathcal{D}}\equiv(r_+,r_0)\times(0,\infty)^2$ we obtain $(q(r^*,S,E),K(r^*,S,E),E)$. So, we can define $\theta_L\equiv\theta_L(r^*,S,E)(\equiv\theta_L(q,K,E))$, Definition 4.1, and write the following result:

Lemma 6.2: There exist $r_L^*\in(r_+,r_0)$ *close to* r_+ *and* $\overline{\theta}\in(0,\pi/2)$ *close to 0 with* $\overline{\theta}<\theta_0,\theta_1<\pi-\overline{\theta}$ *such that for all* (r^*,S,E) *with* $r_+<r^*\leqslant r_L^*$ *and* $\theta_L(r^*,S,E)\leqslant\overline{\theta}$ *we have*:

(i)

$$q\geqslant\mu_1>0\quad \textit{for some}\ \ \mu_1, \tag{6.3}$$

(ii) derivatives in (6.2) are greater than 0 [*in particular,* $h(r)>0$ *if* $r>r^*$], *and*

(iii)

$$\int_{\theta_L}^{\pi/2} \frac{1}{\sqrt{\dfrac{K}{q}+a^2\cos^2\theta-\dfrac{\mathbb{D}^2(\theta)}{q\sin^2\theta}}}\,d\theta \tag{6.4}$$

is upper bounded.

Proof of Lemma 6.2: From Definition 4.1 and formula (4.2),

$$\frac{1}{\sin^2\theta_L}=K+2Ea-E^2a^2+(qa^2+E^2a^2)\cos^2\theta_L\leqslant K+2Ea+qa^2\cos^2\theta_L\,; \tag{6.5}$$

thus taking into account the different terms in (6.1), there exist $a_i,b_i,c_i>0$, $i=1,\ldots,4$ and $\nu>0$ such that:

$$\frac{1}{\sin^2\theta_L}<\left[a_1\frac{((r^{*2}+a^2)E-a)^2}{(r^*-r_+)^2}-a_2\frac{|(r^{*2}+a^2)E-a|E}{(r^*-r_+)}\right]+a_3\frac{S}{(r^*-r_+)}+a_4, \tag{6.6}$$

$$\begin{aligned}\nu q&>4qr^*(r^*-r_-)>4qr^*(r^*-r_-)+2(qr^{*2}-K)\\&>\left[b_1\frac{((r^{*2}+a^2)E-a)^2}{(r^*-r_+)^2}-b_2\frac{|(r^{*2}+a^2)E-a|E}{(r^*-r_+)}\right]+b_3\frac{S}{(r^*-r_+)},\end{aligned} \tag{6.7}$$

$$\frac{K}{2}-E^2a^2>\left[c_1\frac{((r^{*2}+a^2)E-a)^2}{(r^*-r_+)^2}-c_2\frac{|(r^{*2}+a^2)E-a|E}{(r^*-r_+)}\right]+c_3\frac{S}{(r^*-r_+)}-c_4 \tag{6.8}$$

for any $(r^*,S,E)\in\hat{\mathcal{D}}$.

Now, we claim that for some $r_L^*\in(r_+,r_0)$ and $\overline{\theta}>0$ small, if $r^*\in(r_+,r_L^*]$ and $\theta_L(r^*,S,E)\leqslant\overline{\theta}$ then

$$4qr^*(r^*-r_-)+2(qr^{*2}-K)>\mu_0, \tag{6.9}$$

$$\frac{K}{2}-E^2a^2>0 \tag{6.10}$$

for some $\mu_0>0$; in particular, from (6.7) and (6.9), we obtain (i) with $\mu_1=\mu_0/\nu$. In fact, if $E>1/a$ then for some $r_L^*>r_+$ if $r^*\in(r_+,r_L^*]$:

$$\frac{(r^{*2}+a^2)E-a}{(r^*-r_+)}>d\cdot E,\quad d=\max\left\{\frac{a_2}{a_1},\frac{b_2}{b_1},\frac{c_2}{c_1}\right\}+1. \tag{6.11}$$

Therefore, the square brackets in (6.6), (6.7), and (6.8) are positive. Thus, from (6.6) if $\overline{\theta}$ is small, then either $[(r^{*2}+a^2)E-a]/(r^*-r_+)$ or $S/(r^*-r_+)$ are big, and (6.9), (6.10) are a consequence of (6.7), (6.8), respectively. If $E\leqslant 1/a$, some square brackets in (6.6), (6.7), (6.8) might be negative. But if this happens, then instead of (6.11) one has

$$\frac{|(r^{*2}+a^2)E-a|}{(r^*-r_+)}\leqslant\frac{d}{a}. \tag{6.12}$$

As a consequence, if $\overline{\theta}$ is chosen small enough then, from (6.6), $S/(r^*-r_+)$ is big. Thus, (6.9) and (6.10) are again a consequence of (6.7) and (6.8). Moreover, we can also prove:

$$\forall M>0 \quad \exists \overline{\theta}>0: \quad q(r^*,S,E)>M \ \text{ if } \ \theta_L(r^*,S,E)\leqslant\overline{\theta}, \quad r^*\in(r_+,r_L^*]. \tag{6.13}$$

From (6.3), $h^{(3)}(r^*),h^{(4)}(r^*)>0$ and, from (6.9), $h^{(2)}(r^*)>0$ too and, thus, (ii) is obtained. In order to prove (iii), put

$$\Lambda_{q,K,E}(\theta)=\frac{K}{q}+a^2\cos^2\theta-\frac{\mathbb{D}^2(\theta)}{q\sin^2\theta}, \quad \theta\in\left[\theta_L,\frac{\pi}{2}\right]. \tag{6.14}$$

When the integral (6.4) is carried out, $\Lambda_{q,K,E}(\theta)$ vanishes just in θ_L. It is sufficient to prove that, when $\Lambda_{q,K,E}(\theta)$ is smaller than, say, $r_+^2/4$ the contribution to the integral (6.4) is bounded. So, we need just to find $\overline{\theta}$ such that, for the corresponding q,K,E with $\theta_L\leqslant\overline{\theta}$:

$$\text{if} \quad \Lambda_{q,K,E}(\theta)\leqslant\frac{r_+^2}{4} \ \text{ with } \ \theta\in\left[\theta_L,\frac{\pi}{2}\right] \quad \text{then} \quad \frac{\mathrm{d}}{\mathrm{d}\theta}\Lambda_{q,K,E}(\theta)\geqslant 1. \tag{6.15}$$

Using (6.3) and (6.10) it is easy to check:

$$\Lambda_{q,K,E}(\theta)>\frac{K}{2q}-\frac{1}{q\sin^2\theta}. \tag{6.16}$$

Therefore, as $K/q>r_+^2$ [from the first Eq. (6.1)], we have

$$\text{if} \quad \Lambda_{q,K,E}(\theta)\leqslant\frac{r_+^2}{4} \quad \text{then} \quad \frac{1}{q\sin^2\theta}>\frac{K}{4q} \tag{6.17}$$

and, again using (6.10), we obtain

$$\frac{1}{q\sin^2\theta}>\mathcal{M}(E,q):=\max\left\{\frac{r_+^2}{4},\frac{E^2a^2}{2q}\right\}. \tag{6.18}$$

On the other hand, from (6.14)

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\Lambda_{q,K,E}(\theta)=-\left(1+\frac{E^2}{q}\right)a^2\sin 2\theta+\frac{2\cos\theta}{q\sin^3\theta} \tag{6.19}$$

which, from (6.18), imply

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\Lambda_{q,K,E}(\theta)>-a^2\sin 2\theta+2\mathcal{M}(E,q)\left(-\sin 2\theta+\frac{\cos\theta}{\sin\theta}\right). \tag{6.20}$$

In conclusion, from (6.13) if $\overline{\theta}$ is small the angles θ satisfying (6.18) are small too and, thus, the right-hand side in (6.20) is greater than 1. □

From (6.1), $\lim_{S\to\infty}q(r^*,S,E)=\lim_{S\to\infty}K(r^*,S,E)=\infty$ and, thus, using (6.5): $\lim_{S\to\infty}\theta_L(r^*,S,E)=0$. So, fixed $\overline{\theta}$ and r_L^* in Lemma 6.2 we can define $S(r^*,E)=\mathrm{Inf}\{S>0:\theta_L(r^*,\overline{S},E)\leqslant\overline{\theta},\forall\overline{S}>S\}\geqslant 0$ for all $(r^*,E)\in(r_+,r_L^*]\times(0,\infty)$. Recall that $\theta_L(r^*,S,E)$ is differentiable [use $(\mathrm{d}/\mathrm{d}\theta)\,\Lambda_{q,K,E}(\theta_L)\neq 0$ because of (6.15) and, thus $\theta_L(q,K,E)$ is differentiable]; moreover, $S(r^*,E)$ is continuous [when $\theta_L(r^*,S,E)=\overline{\theta}$ from (6.5) and (6.1) $\partial\theta_L/\partial S>0$]. Recall also that $S(r^*,E)$ has a finite supremum $\mathcal{S}$. In fact, from (6.11) and (6.12) the square brackets in (6.8) are lower bounded. So, for some big value S_0 of S, the expression $K/2-E^2a^2$ can be made arbitrarily big. Thus, from (6.5) and (6.3), $\theta_L(r^*,S,E)$ will be less than $\overline{\theta}$, independently of (r^*,E), and $S(r^*,E)<S_0$ as required. Define now:

$$\mathcal{D}=\{(r^*,S,E)\in\hat{\mathcal{D}}:r^*\in(r_+,r_L^*],S\in[S(r^*,E),\infty),E\in(0,\infty)\}. \tag{6.21}$$

Lemma 6.3: Consider the continuous function $T(r^*,S,E)=\Delta t-(t_1-t_0)$ *defined on* $\mathcal{D}$. *There exist positive constants* $M_1(r^*)$, $M_2(r^*)$ *and* $m(r^*)$ *such that*

$$\begin{gathered} E\leqslant m(r^*)\Rightarrow T(r^*,S,E)<0,\\ M_1(r^*)\cdot\sqrt{S}+M_2(r^*)\leqslant E\Rightarrow T(r^*,S,E)>0. \end{gathered} \tag{6.22}$$

Moreover, these constants can be chosen such that if either $m(r_n^*)\to 0$ *or* $M_1(r_n^*)\to\infty$ *or* $M_2(r_n^*)\to\infty$ *for some sequence* $\{r_n^*\}_n$ *then, necessarily,* $r_n^*\to r_+$.

Proof of Lemma 6.3: Fix $(r^*,S,E)\in\mathcal{D}$, recalling the expression of Δt in (4.6) put:

$$a\mathbb{D}(\theta(r))+(r^2+a^2)\frac{\mathbb{P}(r)}{\Delta(r)}=\left[\frac{(r^2+a^2)^2}{(r-r_-)(r-r_+)}-a^2\sin^2\theta(r)\right]E-\left[\frac{a(r^2+a^2)}{(r-r_-)(r-r_+)}-a\right] \tag{6.23}$$

being $\theta(r)$ computed from the second equation in (4.3) with constants $(q(r^*,S,E),K(r^*,S,E),E)$. But each term on the right-hand side of (6.23) will be bounded, say:

$$0<r_+^2<\frac{(r^2+a^2)^2}{(r-r_-)(r-r_+)}-a^2\sin^2\theta(r)<\frac{(r_1^2+a^2)^2}{(r^*-r_+)^2},\quad r\in[r^*,r_1], \tag{6.24}$$

and

$$0<\frac{a^3}{r_1^2}<\frac{a(r^2+a^2)}{(r-r_-)(r-r_+)}-a<\frac{a(r_1^2+a^2)}{(r^*-r_+)^2},\quad r\in[r^*,r_1]. \tag{6.25}$$

Now, put:

$$m(r^*)=\frac{1}{2}\cdot\frac{a^3(r^*-r_+)^2}{r_1^2(r_1^2+a^2)^2}. \tag{6.26}$$

Thus, if $E\leqslant m(r^*)$ then (6.23) is less than 0 and $(\Delta t)(r^*,S,E)<0\leqslant t_1-t_0$, thus $T(r^*,S,E)<0$ [see (4.6)]. Let

$$M_1(r^*)=\sup_{\mathcal{D}}\left\{\frac{E}{\sqrt{S}}:T(r^*,S,E)\leqslant 0,S\geqslant 1\right\},$$

$$M_2(r^*)=\sup_{\mathcal{D}}\{E:T(r^*,S,E)\leqslant 0,S(r^*,E)\leqslant S<1\}+1.$$

To prove (6.22) it is sufficient to prove $M_1(r^*)<\infty$, $M_2(r^*)<\infty$. But, if some of these inequalities do not hold then there exists a sequence of points $\{(r^*,S_n,E_n)\}_n\subset\mathcal{D}$ satisfying hypotheses of Lemma 4.6(ii) for the functions

$$f_n(r)=\frac{1}{E_n}\left[a\mathbb{D}_n(\theta_n(r))+(r^2+a^2)\frac{\mathbb{P}_n(r)}{\Delta(r)}\right],\quad p_n(r)=\frac{h_n(r)}{E_n^2} \tag{6.27}$$

with $h_n(r)\equiv h(r,q(r^*,S_n,E_n),K(r^*,S_n,E_n),E_n)$ in $[r^*,r_1]$ and thus $R_n=S_n/E_n^2$ [see (6.24), (6.25), (6.1), and (6.2)]. Thus, the conclusion of Lemma 4.6(ii) contradicts $T(r^*,S_n,E_n)\leqslant 0$ for all n [see (4.6)].

For the last assertion, it is clear that $m(r_n^*)\to 0$ implies $r_n^*\to r_+$ [see (6.26)]. Even more, if either $M_1(r_n^*)$ or $M_2(r_n^*)$ go to ∞ and, up to a subsequence, $r_n^*\geqslant r_++\epsilon_0$, $\epsilon_0>0$ then there exists a sequence of points $\{(r_n^*,S_n,E_n)\}_n\subset\mathcal{D}$ with $T(r_n^*,S_n,E_n)\leqslant 0$ and either $S_n/E_n^2\to 0$ and $S_n\geqslant 1$ or $1/E_n^2\to 0$ and $S(r_n^*,E_n)\leqslant S_n\leqslant 1$. Then, by applying Lemma 4.6(ii) to (6.27) as before but, now, with the sequence $\{(r_n^*,S_n,E_n)\}_n\subset\mathcal{D}$ we obtain a contradiction again. □

Remark 6.4: Notice that we can choose $\overline{\theta}$ in Lemma 6.2 small enough such that $\mathcal{D}$ in (6.21) satisfies, additionally:

(i) the component S of the points $(r^*,S,E)\in\mathcal{D}$ with $r^*=r_L^*$ and $m(r_L^*)\leqslant E\leqslant M_1(r_L^*)+M_2(r_L^*)$ admits a positive lower bound [from (6.5) if θ_L is small then either q or K is big and, from (6.1) S will be big too], and

(ii) if $(r^*,S,E)\in\mathcal{D}$ and $S/(r^*-r_+)\leqslant 1$ then

$$\left|\frac{(r^{*2}+a^2)E-a}{(r^*-r_-)(r^*-r_+)}\right|>\frac{2a}{r_+^2+a^2}$$

[use (6.6)].

From now on we will assume that $\mathcal{D}$ is the domain fixed by this new value of $\overline{\theta}$, and Lemma 6.2 with Remark 6.4 will ensure that none of the problems 3^BI–3^BIV explained in Sec. III. Summing up, it is sufficient to find an element of $\mathcal{D}$ such that the corresponding (q,K,E) given from (6.1) and the function $h(r)\equiv h(r,q,K,E)$ in (4.5) satisfy the equalities (4.11) with Δt, $\Delta|\theta|$ and $\Delta\varphi$ as in (4.6), (4.8), and (4.9), and with $L=1$. For this aim, we establish the next two technical Lemmas. First, taking into account Lemma 6.3 define the subset

$$B=\{(r_L^*,S,E)\in\mathcal{D}:0<m(r_L^*)\leqslant E\leqslant M_1(r_L^*)\cdot\sqrt{S}+M_2(r_L^*)\}. \tag{6.28}$$

Lemma 6.5: (*i*) *For* $(r^*,S,E)\in\mathcal{D}$ *then* $((r^{*2}+a^2)E-a)^2/q$ *and* E^2/q *are upper bounded.* (*ii*) *If also* $(r_L^*,S,E)\in B$ *then*

$$(\Delta|\theta|)(r_L^*,S,E)=\int_{r_L^*}^{r_0}\frac{\sqrt{\Lambda_{q,K,E}(\theta(r))}}{\sqrt{\dfrac{h(r)}{q}}}\mathrm{d}r+\int_{r_L^*}^{r_1}\frac{\sqrt{\Lambda_{q,K,E}(\theta(r))}}{\sqrt{\dfrac{h(r)}{q}}}\mathrm{d}r$$

is upper bounded too.

Proof of Lemma 6.5: (i) If $E\leqslant 1/a$ these terms are obviously bounded from (6.3); otherwise, first use (6.7) and (6.11) to prove

$$\nu q>b_1\frac{E((r^{*2}+a^2)E-a)}{(r^*-r_+)}.$$

(ii) From Remark 6.4(i) the component S of the points in B admits a positive lower bound (see points J', I' in Fig. 2). Then, there exists $L_0>0$ such that

$$\frac{h'(r_L^*)}{q}=\frac{S}{q}>L_0 \tag{6.29}$$

for all $(r_L^*,S,E)\in B$ [see (6.1)]. But taking into account (6.1), (6.14) and (i) there exists $C_0>0$ such that

$$\sqrt{\Lambda_{q,K,E}(\theta(s))}<C_0 \tag{6.30}$$

along the geodesic $\gamma(s)$ corresponding to each $(r_L^*,S,E)\in B$. Summing up, inequalities (6.29), (6.30) joined with $h^{(k)}(r_L^*)/q\geqslant 0$ for $k\geqslant 2$ (see Lemma 6.2) imply that

$$(\Delta|\theta|)(r_L^*,S,E)=\int_{r_L^*}^{r_0}\frac{\sqrt{\Lambda_{q,K,E}(\theta(r))}}{\sqrt{\frac{h(r)}{q}}}\mathrm{d}r+\int_{r_L^*}^{r_1}\frac{\sqrt{\Lambda_{q,K,E}(\theta(r))}}{\sqrt{\frac{h(r)}{q}}}\mathrm{d}r$$

is upper bounded on B. □

Lemma 6.6: For any sequence $\{(r_n^*,S_n,E_n)\}_n\subset\mathcal{D}$ *satisfying either* $r_n^*\searrow r_+$ *or* $S_n\searrow 0$ *then* $(\Delta|\theta|)(r_n^*,S_n,E_n)\to\infty$.

Proof of Lemma 6.6: This result is a consequence of the following two steps:

Step 1. For any such sequence $\{(r_n^*,S_n,E_n)\}_n\subset\mathcal{D}$, the polynomials $p_n(r)=h_n(r)/q_n$ satisfy hypotheses in Lemma 4.6(ii) in $[r_n^*,r_1]$. In fact, $p_n'(r_n^*)=S_n/q_n\to 0$ [use that the square brackets in (6.7) is lower bounded and (6.3)] and, from (6.2) and Lemma 6.5(i), derivatives $p_n^{(k)}(r_n^*)$ $(\geqslant 0)$ admit an upper bound for $k\geqslant 2$.

Step 2. For any sequence $\{(r_n^*,S_n,E_n)\}_n\subset\mathcal{D}$ such that the polynomials $p_n(r)=h_n(r)/q_n$ satisfy hypotheses in Lemma 4.6(ii) in $[r_n^*,r_1]$ then $(\Delta|\theta|)(r_n^*,S_n,E_n)\to\infty$. Otherwise, $(\Delta|\theta|)$ (r_n^*,S_n,E_n) is bounded up to a subsequence. Using (6.14) and (4.5), the second equation in (4.3) is rewritten as

$$\epsilon'\frac{\sqrt{q_n}\mathrm{d}r}{\sqrt{h_n(r)}}=\frac{\mathrm{d}\theta}{\sqrt{\Lambda_{q_n,K_n,E_n}(\theta)}},$$

and using that $(\Delta|\theta|)(r_n^*,S_n,E_n)$ is bounded:

$$\int_{r_n^*}^{r_0}\frac{\sqrt{q_n}}{\sqrt{h_n(r)}}\mathrm{d}r+\int_{r_n^*}^{r_1}\frac{\sqrt{q_n}}{\sqrt{h_n(r)}}\mathrm{d}r\leqslant\int_{\theta_0}^{\theta_1}\frac{1}{\sqrt{\Lambda_{q_n,K_n,E_n}(\theta)}}\mathrm{d}\theta+2n_0\int_{\theta_{L,n}}^{\pi-\theta_{L,n}}\frac{1}{\sqrt{\Lambda_{q_n,K_n,E_n}(\theta)}}\mathrm{d}\theta \tag{6.31}$$

for some integer $n_0>0$. As $\{(r_n^*,S_n,E_n)\}_n\subset\mathcal{D}$ for all n, Lemma 6.2 implies that the second member of (6.31) is upper bounded. This contradicts Lemma 4.6(ii) applied to the functions $f_n(r)\equiv 1$ and $p_n(r)=h_n(r)/q_n$ in $[r_n^*,r_1]$. □

Next, consider the continuous functions on $\mathcal{D}$, $\Theta_n=\Delta|\theta|-(\theta_1-\theta_0)-2n(\pi-2\theta_L)$, $n\geqslant 0$. Then, the following result on boundary conditions of T and Θ_n on $\mathcal{D}$ holds.

Proposition 6.7: Let $\{\overline{S_n}\}_n$ *be a sequence with* $\overline{S_n}>\mathcal{S}(\equiv\mathrm{Sup}\{S(r^*,E):(r^*,E)\in(r_+,r_0)\times(0,\infty)\})$ *for all* n. *There exists* $\{\epsilon_n\}_n$, $\epsilon_n>0$, $\epsilon_n\searrow 0$ *and* $\{\delta_n\}_n$, $\delta_n>0$, $\delta_n\searrow 0$, *such that if*

$$\mathcal{D}_n=\left\{(r^*,S,E)\in\hat{\mathcal{D}}:r^*\in[r_+\!+\epsilon_n,r_L^*],S\in[S(r^*,E),\overline{S_n}],E\in\left[\delta_n,\frac{1}{\delta_n}\right]\right\} \tag{6.32}$$

then

$$B\cap\{(r^*,S,E)\in\mathcal{D}_n:r^*=r_L^*\}\subseteq\left\{(r^*,S,E)\in\mathcal{D}_n:r^*=r_L^*,E\in\left(\delta_n,\frac{1}{\delta_n}\right)\right\} \tag{6.33}$$

[*for B in* (6.28)], *and*

$$\begin{gathered}T>0\quad on\quad\left(r^*,S,\frac{1}{\delta_n}\right)\in\mathcal{D}_n,\\ T<0\quad on\quad(r^*,S,\delta_n)\in\mathcal{D}_n,\\ \Theta_n>0\quad on\quad(r_+\!+\epsilon_n,S,E)\in\mathcal{D}_n,\end{gathered} \tag{6.34}$$

$$\Theta_n<0 \quad on \quad (r^*,S,E)\in B\cap\{(r^*,S,E)\in\mathcal{D}_n : r^*=r_L^*\}$$

for n big enough (see Fig. 2).

Proof of Proposition 6.7: From Lemma 6.5(ii), $\Delta|\theta|$ is upper bounded on B and, thus, $\Theta_n<0$ on B for n big enough.

On the other hand, there exists a sequence $\{\epsilon_n\}_n$, $\epsilon_n>0$, $\epsilon_n\searrow 0$ such that $\Theta_n>0$ when $r^*=r_+ +\epsilon_n$. In fact, otherwise we obtain a sequence of points $\{(r_l^*,S_l,E_l)\}_l\subset\mathcal{D}$, $r_l^*<r_+ +1/l$ with $\Theta_n(r_l^*,S_l,E_l)\leqslant 0$ for all l. But these last inequalities contradict the conclusion of Lemma 6.6.

Finally, the sequence $\{\delta_n\}_n$ is obtained from Lemma 6.3 applied to $r^*\in[r_+ +\epsilon_n,r_L^*]$. □

Remark 6.8: The choice of $\{\epsilon_n\}_n$ in Proposition 6.7 does not depend on the sequence $\{\overline{S_n}\}_n$. Nevertheless, $\{\delta_n\}_n$ does depend on $\{\epsilon_n\}_n$ and $\{\overline{S_n}\}_n$.

Following step $(4^B II)$ (Sec. III), if we define the sequence of homeomorphisms $\{z_n^m\}_m$, $z_n^m:\mathcal{D}_n^m\to[0,1]^3$ with

$$\mathcal{D}_n^m=\left\{(r^*,S,E)\in\mathcal{D}_n : S\geqslant S(r^*,E)+\frac{1}{m}\right\} \tag{6.35}$$

as depicted in Fig. 3 then, from (6.34) and Lemma 6.3, the functions $T\circ(z_n^m)^{-1}$, $\Theta_n\circ(z_n^m)^{-1}$ satisfy

$$\begin{aligned}
&T\circ(z_n^m)^{-1}>0 \quad on \quad (r^*,S,E)\in[0,1]^2\times\{1\},\\
&T\circ(z_n^m)^{-1}<0 \quad on \quad (r^*,S,E)\in[0,1]^2\times\{0\},\\
&\Theta_n\circ(z_n^m)^{-1}>0 \quad on \quad (r^*,S,E)\in\{0\}\times[0,1]^2,\\
&\Theta_n\circ(z_n^m)^{-1}<0 \quad on \quad (r^*,S,E)\in\{1\}\times[0,1]^2.
\end{aligned} \tag{6.36}$$

Now, we are in conditions to apply topological arguments based on Brouwer's degree. In fact,

Lemma 6.9: There exists a connected subset $z_n^m(\mathcal{C}_n^m)$ of zeroes of $T\circ(z_n^m)^{-1}$ and $\Theta_n\circ(z_n^m)^{-1}$ such that

$$z_n^m(\mathcal{C}_n^m)\cap([0,1]\times\{0\}\times[0,1])\neq\varnothing \quad and \quad z_n^m(\mathcal{C}_n^m)\cap([0,1]\times\{1\}\times[0,1])\neq\varnothing$$

for every $m\in\mathbb{N}$.

Proof of Lemma 6.9: Consider the function

$$\mathcal{F}_n^m: \quad (0,1)\times[0,1]\times(0,1)\to X\equiv\mathbb{R}^2,$$

$$(r^*,S,E)\mapsto(\Theta_n\circ(z_n^m)^{-1}(r^*,S,E),T\circ(z_n^m)^{-1}(r^*,S,E))+(r^*,E)$$

and put $\mathcal{F}_{n,0}^m(r^*,E)=\mathcal{F}_n^m(r^*,0,E)$, $G=(0,1)^2$. By Ref. 32, Lemma 3.4 it is sufficient to prove that, because of (6.36):

$$\deg(\mathrm{Id}-\mathcal{F}_{n,0}^m,G,0)\neq 0,$$

where $\deg(Id-\mathcal{F}_{n,0}^m,G,0)$ is the degree of the function $\mathrm{Id}-\mathcal{F}_{n,0}^m$ in the open subset G with respect to the value 0.[30] But the affine map

$$\hat{\mathcal{F}}^m: \quad (0,1)^2\to\mathbb{R}^2,$$

$$(r^*,E)\mapsto(1-2r^*,-1+2E)+(r^*,E)$$

has obviously $\deg(\mathrm{Id}-\hat{\mathcal{F}}^m,G,0)\neq 0$, and $\deg(\mathrm{Id}-\mathcal{F}^m_{n,0},G,0)=\deg(\mathrm{Id}-\hat{\mathcal{F}}^m,G,0)$ [the map $\lambda\mapsto \mathrm{Id}-\mathcal{F}^m_{n,0}+\lambda(\mathcal{F}^m_{n,0}-\hat{\mathcal{F}}^m)$, $\lambda\in[0,1]$ is a homotopy from $\mathrm{Id}-\mathcal{F}^m_{n,0}$ to $\mathrm{Id}-\hat{\mathcal{F}}^m$ without zeroes on the boundary from (6.36)] which concludes the proof. □

Up to a subsequence, $\lim_m f_m\mathcal{C}^m_n\neq\varnothing$ and, thus, $\mathcal{C}_n=\limsup_m\mathcal{C}^m_n\subset\overline{\mathcal{D}}_n$ is connected (see Ref. 33 Chap. I, Theorem 9.1). By continuity $T=\Theta_n=0$ in $\mathcal{C}_n\cap\mathcal{D}_n$ and

$$\mathcal{C}_n\cap\{(r^*,S,E)\in\overline{\mathcal{D}}_n : S=S(r^*,E)\}\neq\varnothing \quad\text{and}\quad \mathcal{C}_n\cap\{(r^*,S,E)\in\mathcal{D}_n : S=\overline{S}_n\}\neq\varnothing.$$

(see Fig. 4). This joined with the following result implies (i) and (ii) in ($4^B III$):

Lemma 6.10: If $(r^*,S,E)\in\mathcal{C}_n$ *then* $S>0$ (*in particular,* $\mathcal{C}_n\subset\mathcal{D}_n$).

Proof of Lemma 6.10: Otherwise, there exists a sequence $\{(r^*_l,S_l,E_l)\}_l\subset\mathcal{D}_n\subset\mathcal{D}$ in $\mathcal{C}_n$ such that $S_l\to 0$. Then, from Lemma 6.6, we obtain a contradiction with $\Theta_n=0$ in $\mathcal{C}_n\cap\mathcal{D}_n$. □

Finally, as Δt and $\Delta|\theta|$ satisfy (4.11) for geodesics in each $\mathcal{C}_n$ we only have to prove that one of such geodesics satisfies the required value for $\Delta\varphi$. This will be straightforward from the following two lemmas:

Lemma 6.11: *There exists a choice of the sequence* $\{\overline{S}_n\}_n$ *in Proposition 6.7 such that for any* $\epsilon>0$ *points* $(r^*_n,\overline{S}_n,E_n)\in\mathcal{C}_n$ *satisfy*:

$$2n\pi-(\Delta\varphi)(r^*_n,\overline{S}_n,E_n)<n\cdot\epsilon \tag{6.37}$$

for n big enough.

Proof of Lemma 6.11: First, we will prove that for any sequence $\{\overline{S}_n\}_n$ diverging fast enough there exists a constant $\delta>0$ such that

$$(\Delta\varphi)(r^*_n,\overline{S}_n,E_n)+\delta>\int_{r^*_n}^{r_0}\frac{1}{\sqrt{\sin^2\theta_n(r)}}\frac{1}{\sqrt{h_n(r)}}\mathrm{d}r+\int_{r^*_n}^{r_1}\frac{1}{\sqrt{\sin^2\theta_n(r)}}\frac{1}{\sqrt{h_n(r)}}\mathrm{d}r. \tag{6.38}$$

Thus, the right-hand side in (6.38) can replace $(\Delta\varphi)(r^*_n,\overline{S}_n,E_n)$ in order to prove (6.37). To prove (6.38) note, taking into account (4.9):

$$\mathcal{P}_n(r)\equiv\frac{\mathbb{D}_n(\theta_n(r))}{\sin^2\theta_n(r)}+a\,\frac{\mathbb{P}_n(r)}{\Delta(r)}-\frac{1}{\sin^2\theta_n(r)}=E_n\left(\frac{a(r^2+a^2)}{(r-r_-)(r-r_+)}-a\right)-\frac{a^2}{(r-r_-)(r-r_+)}. \tag{6.39}$$

If $E_n>1/a$ then (6.39) is positive. In the case $E_n\leqslant 1/a$ note first that, from Remark 6.8, points $(r^*_n,\overline{S}_n,E_n)\in\mathcal{C}_n$ satisfy $r^*_n>r_++\epsilon_n$, independently of $\overline{S}_n$. Thus, for every n there exists $\overline{S}_n$ big enough such that

$$\int_{r^*_n}^{r_0}\frac{\mathcal{P}_n(r)}{\sqrt{h_n(r)}}\mathrm{d}r+\int_{r^*_n}^{r_1}\frac{\mathcal{P}_n(r)}{\sqrt{h_n(r)}}\mathrm{d}r>-\delta,$$

and (6.38) is obtained.

Using the second equation in (4.3), the variable of integration r in (6.38) can be substituted by θ. Then, as $(\Delta|\theta|)_n=\theta_1-\theta_0+2n(\pi-2\theta_{L,n})$, (6.38) can be written

$$(\Delta\varphi)_n+\delta>\int_{\theta_0}^{\theta_1}\Omega_n(\theta)\mathrm{d}\theta+2n\cdot\int_{\theta_{L,n}}^{\pi-\theta_{L,n}}\Omega_n(\theta)\mathrm{d}\theta, \tag{6.40}$$

where

$$\Omega_n(\theta)=\frac{\dfrac{1}{\sin^2\theta}}{\sqrt{K_n+q_n a^2\cos^2\theta-\dfrac{\mathbb{D}_n^2(\theta)}{\sin^2\theta}}}. \tag{6.41}$$

Therefore, from (6.40) and the symmetry of the integrals

$$\int_{\theta_{L,n}}^{\pi/2}\Omega_n(\theta)\mathrm{d}\theta,\quad \int_{\pi/2}^{\pi-\Theta_{L,n}}\Omega_n(\theta)\mathrm{d}\theta$$

it is sufficient to prove

$$\lim\ \inf_{n\to\infty}\int_{\theta_{L,n}}^{\pi/2}\Omega_n(\theta)\mathrm{d}\theta\geqslant\frac{\pi}{2}. \tag{6.42}$$

In fact, from an elemental integration:

$$\int_{\theta_{L,n}}^{\pi/2}\frac{\dfrac{1}{\sin^2\theta}}{\sqrt{\dfrac{1}{\sin^2\theta_{L,n}}-\dfrac{1}{\sin^2\theta}}}\mathrm{d}\theta=\frac{\pi}{2}, \tag{6.43}$$

for all n. But from the equality in (6.5)

$$\begin{aligned}\frac{1}{\sin^2\theta_{L,n}}&=K_n+2E_n a-E_n^2a^2+(q_na^2+E_n^2a^2)\cos^2\theta_{L,n}\\&\geqslant K_n+2E_n a-E_n^2a^2+(q_na^2+E_n^2a^2)\cos^2\theta\\&=\frac{1}{\sin^2\theta}+K_n+q_na^2\cos^2\theta-\frac{\mathbb{D}_n^2(\theta)}{\sin^2\theta}\end{aligned} \tag{6.44}$$

if $\theta\in[\theta_{L,n},\pi/2]$. Thus (6.42) is a consequence of (6.43) and (6.44). □

As explained in ($4^B III$), each $\mathcal{C}_n$ contains a point with $\theta_L=\overline{\theta}$. Thus, the following result will be appliable:

Lemma 6.12: Let $\{(r_n^{*\prime},S_n',E_n')\}_n$ *be a sequence of points, each one in the corresponding* $\mathcal{C}_n$ *with* $\theta_{L,n}=\theta_L(r_n^{*\prime},S_n',E_n')=\overline{\theta}>0$. *Then, there exists* $\epsilon_0>0$ *such that*

$$2n\pi-(\Delta\varphi)(r_n^{*\prime},S_n',E_n')>n\cdot\epsilon_0 \tag{6.45}$$

for n big enough.

Proof of Lemma 6.12: First, we will prove

$$h_n'(r_n^{*\prime})=S_n'\to 0 \tag{6.46}$$

and then the limits:

$$r_n^{*\prime}\to r_+,\quad E_n'\to\frac{a}{r_+^2+a^2},\quad q_n'\to q',\quad K_n'\to q'r_+^2, \tag{6.47}$$

where

$$q' = \frac{r_+^2 + a^2 \cos^2 \overline{\theta}}{(r_+^2 + a^2)^2 \sin^2 \overline{\theta}}.$$

In order to prove (6.46) and taking into account that $\Theta_n = 0$ on $\mathcal{C}_n$ we have that

$$(\Delta|\theta|)(r_n^{*\prime}, S_n', E_n') = \theta_1 - \theta_0 + 2n(\pi - 2\overline{\theta}) \to \infty \quad \text{when} \quad n \to \infty. \tag{6.48}$$

By using (6.44) with $\theta_{L,n} \equiv \overline{\theta}$ the numerator in (4.8) is upper bounded by $1/\sin \overline{\theta}$ in our sequence, thus from (6.48)

$$\int_{r_n^{*\prime}}^{r_0} \frac{1}{\sqrt{h_n(r)}} \mathrm{d}r + \int_{r_n^{*\prime}}^{r_1} \frac{1}{\sqrt{h_n(r)}} \mathrm{d}r \to \infty, \tag{6.49}$$

which implies (6.46) (recall that from Lemma 6.2 the remainder of the derivatives of h_n are positive). Notice that we also obtain $E_n' \leqslant 1/a$ for big n. In fact, otherwise computing directly from (4.2):

$$a\mathbb{D}_n(\theta_n(r)) + (r^2 + a^2)\frac{\mathbb{P}_n(r)}{\Delta(r)} \geqslant a + \frac{r_+^2}{a} > 0,$$

thus, from (4.6) and (6.49) we have $(\Delta t)_n \to \infty > t_1 - t_0$, in contradiction with $(r_n^{*\prime}, S_n', E_n') \in \mathcal{C}_n$. In order to prove the first limit in (6.47) assume, by contradiction, $r_n^{*\prime} \geqslant r_+ + \delta_0$ for some $\delta_0 > 0$ up to a subsequence. Then, from (6.46) we have

$$\frac{S_n'}{(r_n^{*\prime} - r_+)} \to 0.$$

This joined with Remark 6.4(ii) allows us to assume

$$\left| \frac{(r_n^{*\prime 2} + a^2)E_n' - a}{(r_n^{*\prime} - r_-)(r_n^{*\prime} - r_+)} \right| > \frac{2a}{r_+^2 + a^2} \tag{6.50}$$

for n big enough. Even more, we can extend the lower bound in (6.50) through $r_n^{*\prime}$. More precisely, for $E_n' \in (0, 1/a]$ and $r \in [r_+ + \delta_0, r_0]$ function

$$r \mapsto \frac{(r^2 + a^2)E_n' - a}{(r - r_-)(r - r_+)}$$

has a derivative which admits a bound independent of E_n'. Thus, there exists $\overline{\delta_0} > 0$ such that

$$\left| \frac{(r^2 + a^2)E_n' - a}{(r - r_-)(r - r_+)} \right| > \frac{3a}{2(r_+^2 + a^2)}, \quad \forall r \in [r_n^{*\prime}, r_n^{*\prime} + \overline{\delta_0}];$$

therefore

$$\left| a\mathbb{D}_n(\theta_n(r)) + (r^2 + a^2)\frac{\mathbb{P}_n(r)}{\Delta(r)} \right| \geqslant \frac{a}{2}, \quad \forall r \in [r_n^{*\prime}, r_n^{*\prime} + \overline{\delta_0}]. \tag{6.51}$$

We will prove that (6.51) implies the contradiction $|(\Delta t)_n| \to \infty > |t_1 - t_0|$ and, thus, $r_n^{*\prime} \to r_+$. In fact, assuming $\overline{\delta_0} < r_0 - r_L^*$ Lemma 4.6(ii) is applicable to the expression of $|\Delta t(r_n^{*\prime}, S_n', E_n')|$ in (4.6) when the integrals are carried out in $[r_n^{*\prime}, r_n^{*\prime} + \overline{\delta_0}]$ [use (6.51), (6.46), and the facts that

$E_n' \leqslant 1/a$ and $r_n^{*\prime} \geqslant r_+ + \delta_0$, with (6.2), (6.1)]. As the integrals of the expression of $\Delta t(r_n^{*\prime}, S_n', E_n')$ in $[r_n^{*\prime}+\delta_0, r_0]$ and $[r_n^{*\prime}+\delta_0, r_1]$ are bounded [the numerator is bounded and the derivatives $h^{(k)}(r_n^{*\prime})$ are positive with $h^{(4)}(r_n^{*\prime}) > 24\mu_1 > 0$], the contradiction is obtained, and $r_n^{*\prime} \to r_+$.

For the convergence of E_n' in (6.47), recall that

$$\left| \frac{(r_n^{*\prime 2} + a^2)E_n' - a}{(r_n^{*\prime} - r_+)} \right| \tag{6.52}$$

is bounded. In fact, otherwise q_n' and $K_n'/2 - E_n'^2 a^2$ go to ∞, up to a subsequence [see (6.7) and (6.8)]; this and (6.5) contradict that $\theta_{L,n} = \overline{\theta}$ for all n. Therefore, as $r_n^{*\prime} \to r_+$, the second limit in (6.47) is obtained. Finally, for the other two limits, the boundedness of (6.52) and the convergence of E_n' imply that $q_n' r_n^{*\prime 2} - K_n' \to 0$ [see the first equation in (6.1)] which, joined to the fact that $\theta_{L,n} = \overline{\theta}$ for all n, implies the two required limits [use the equality in (6.5)].

In order to prove (6.45) notice that the second limit in (6.47) implies

$$\int_{r_n^{*\prime}}^{r_0} \frac{1 - E_n' a \sin^2 \theta_n(r)}{\sqrt{h_n(r)}} \mathrm{d}r + \int_{r_n^{*\prime}}^{r_1} \frac{1 - E_n' a \sin^2 \theta_n(r)}{\sqrt{h_n(r)}} \mathrm{d}r$$
$$\geqslant \frac{r_+^2}{2(r_+^2 + a^2)} \left(\int_{r_n^{*\prime}}^{r_0} \frac{1}{\sqrt{h_n(r)}} \mathrm{d}r + \int_{r_n^{*\prime}}^{r_1} \frac{1}{\sqrt{h_n(r)}} \mathrm{d}r \right), \tag{6.53}$$

which goes to ∞ by (6.49). But $(\Delta t)_n = t_1 - t_0$ for all n, thus from (6.53), (4.6) and the expression of $\mathbb{D}(\theta)$ [formula (4.2) with $L = 1$]

$$\int_{r_n^{*\prime}}^{r_0} \frac{(r^2 + a^2) \dfrac{\mathbb{P}_n(r)}{\Delta(r)}}{\sqrt{h_n(r)}} \mathrm{d}r + \int_{r_n^{*\prime}}^{r_1} \frac{(r^2 + a^2) \dfrac{\mathbb{P}_n(r)}{\Delta(r)}}{\sqrt{h_n(r)}} \mathrm{d}r \to -\infty. \tag{6.54}$$

Obviously, from (6.54) and (4.9)

$$(\Delta\varphi)_n < \int_{r_n^{*\prime}}^{r_0} \frac{\dfrac{1 - E_n' a \sin^2 \theta_n(r)}{\sin^2 \theta_n(r)}}{\sqrt{h_n(r)}} \mathrm{d}r + \int_{r_n^{*\prime}}^{r_1} \frac{\dfrac{1 - E_n' a \sin^2 \theta_n(r)}{\sin^2 \theta_n(r)}}{\sqrt{h_n(r)}} \mathrm{d}r. \tag{6.55}$$

If the variable of integration r in (6.55) is changed by θ (as in Lemma 6.11) and taking into account that now $(\Delta|\theta|)_n = \theta_1 - \theta_0 + 2n(\pi - 2\overline{\theta})$, (6.55) can be written

$$(\Delta\varphi)_n < \int_{\theta_0}^{\theta_1} W_n(\theta) \mathrm{d}\theta + 2n \cdot \int_{\overline{\theta}}^{\pi - \overline{\theta}} W_n(\theta) \mathrm{d}\theta, \tag{6.56}$$

where

$$W_n(\theta) = \frac{\dfrac{1}{\sin^2 \theta}}{\sqrt{\dfrac{K_n' + q_n' a^2 \cos^2 \theta}{(1 - E_n' a \sin^2 \theta)^2} - \dfrac{1}{\sin^2 \theta}}}.$$

Then, taking the limit $W(\theta)$ of $\{W_n(\theta)\}_n$ we have from (6.47):

$$W(\theta)=\lim_{n\to\infty} W_n(\theta)=\frac{\dfrac{1}{\sin^2\theta}}{\sqrt{q'\dfrac{(r_+^2+a^2)^2}{r_+^2+a^2\cos^2\theta}-\dfrac{1}{\sin^2\theta}}}. \tag{6.57}$$

Notice that

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\frac{(r_+^2+a^2)^2}{r_+^2+a^2\cos^2\theta}=\frac{a^2(r_+^2+a^2)^2\sin 2\theta}{(r_+^2+a^2\cos^2\theta)^2}\begin{cases}\geqslant 0, & \theta\in\left(0,\dfrac{\pi}{2}\right]\\ \leqslant 0, & \theta\in\left[\dfrac{\pi}{2},\pi\right).\end{cases} \tag{6.58}$$

and the denominator of (6.57) vanishes just in $\overline{\theta}$, $\pi-\overline{\theta}$. As $\{W_n\}_n$ is a sequence of dominated functions, $\lim_n\int_{\overline{\theta}}^{\pi-\overline{\theta}} W_n(\theta)d\theta=\int_{\overline{\theta}}^{\pi-\overline{\theta}}W(\theta)\mathrm{d}\theta$, and from (6.56):

$$(\Delta\varphi)_n<(2n+1)\int_{\overline{\theta}}^{\pi-\overline{\theta}}W(\theta)\mathrm{d}\theta, \tag{6.59}$$

for n big enough. But from (6.58), if $\cos\theta$ is replaced by $\cos\overline{\theta}$ in (6.57):

$$\int_{\overline{\theta}}^{\pi-\overline{\theta}}W(\theta)\mathrm{d}\theta<\int_{\overline{\theta}}^{\pi-\overline{\theta}}\frac{\dfrac{1}{\sin^2\theta}}{\sqrt{q'\dfrac{(r_+^2+a^2)^2}{r_+^2+a^2\cos^2\overline{\theta}}-\dfrac{1}{\sin^2\theta}}}\mathrm{d}\theta=\pi.$$

Thus, the proof concludes putting $\int_{\overline{\theta}}^{\pi-\overline{\theta}}W(\theta)\mathrm{d}\theta=\pi-\epsilon_0$ in (6.59). □

From Lemmas 6.11 and 6.12, there exist two points in a $\mathcal{C}_n$ for some (big) n whose difference in $\Delta\varphi$ is greater than 2π, which implies the existence of $(r^*,S,E)\in\mathcal{C}_n$ such that (4.11) holds, as required.

VII. CONCLUSION

We have proven a relevant geometric property of outer Kerr space–time $\mathbb{K}$ ($a^2<m^2$), the geodesic connectedness. The proof uses essentially topological arguments. These arguments are appliable to most of the classical relativistic space–times (Schwarzschild, Robertson–Walker, Reissner–Nordström, etc.).

The difficulty to study $\mathbb{K}$ seems to arise from the following facts:

(1) No Killing vector field of $\mathbb{K}$ is timelike; otherwise, the problem would be reducible to a ''Riemannian'' problem, where variational methods yields very precise results.

(2) $\mathbb{K}$ can be seen as a splitting type manifold such as those studied by using variational methods and Rabinowitz's saddle point theorem in Ref. 34. These results are especially appropiate to study globally hyperbolic space–times under a splitting with complete Cauchy hypersurfaces $t=$constant. But no clear choice of the time function t seems to be natural to apply such techniques for $\mathbb{K}$.

(3) At any case, the role of the event horizon $r=r_+$ seems to be unavoidable (recall that, under our approach, geodesics approaching the event horizon play an essential role). It is known that the convexity of the boundary of a semi-Riemannian manifold sometimes yields the geodesic connectedness of the manifold, especially in the Riemannian case.[18] The boundary $r=r_+$ of $\mathbb{K}$ is singular, and the approaching hypersurfaces $r=r_++\nu, \nu>0$, are not convex (regions $r>r_++\nu$

are not geodesically connected). In the Riemannian case, there are techniques to measure if the lack of convexity goes to zero, when $\nu \to 0$, yielding geodesic connectedness.[35] In the static case, some of these techniques are translatable,[36] and geodesic connectedness of some space–times with singular boundary, including outer Schwarzschild, have been proven.[19] But none of these techniques seem applicable to a nonstationary situation.

Thus, our method circumvents previous difficulties.

Embedding of the brane into six dimensions

Merab Gogberashvili[a)]
Andronikashvili Institute of Physics, 6 Tamarashvili Str., Tbilisi 380077, Georgia

(Received 18 February 2002; accepted for publication 6 May 2002)

Embedding of the brane metric into Euclidean $(2+4)$-space is found. Brane geometry can be visualized as the surface of the hypersphere in six dimensions which ''radius'' is governed by the cosmological constant. Minkowski space in this picture is placed on the intersection of this surface with the plane formed by the extra space-like and time-like coordinates. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1505650]

There has been great interest in recent years in models with extended extra dimensions. Ordinary gravity can be recovered if the observable universe is represented by a brane embedded in a higher-dimensional space with a nonfactorizable geometry.[1]

A useful method to study brane models can be the embedding theory.[2] It is well known that n-dimensional space–time can be embedded into N-dimensional pseudo-Euclidean space with $n \leqslant N \leqslant n(n+1)/2$.[2,3] Thus, no more than ten dimensions are required to embed any four-dimensional solution of Einstein's equations with arbitrary energy–momentum tensor. There also exists Campbell's theorem,[4] which implies that any solution of n-dimensional Einstein's equations can be embedded, at least locally, in a space–time that is itself a solution of $(n+1)$-dimensional, vacuum Einstein's equations.[5] Several authors tried to interpret the embedding as producing an effective stress–energy tensor in low dimensions.[6]

The embedding procedure is also interesting from a purely mathematical point of view. It allows invariant classification of known solutions of Einstein's equations to be made.[7] Furthermore, the embedding method may lead to new solutions. For example, the maximal analytic extension of Schwarzschild's solution was independently found in this way.[8]

Embedding of the space–time with the coordinates x^α and metric $g_{\alpha\nu}$ into pseudo-Euclidean space with the coordinates X^A and with the flat metric η_{AB} is given by

$$ds^2 = g_{\alpha\nu} dx^\alpha dx^\nu = \eta_{AB} \partial_\alpha X^A \partial_\nu X^B dx^\alpha dx^\nu = \eta_{AB} dX^A dX^B. \tag{1}$$

For example, it is well known[9] that the Schwarzschild metric

$$ds^2 = \left(1 - \frac{2m}{r}\right) dt^2 - \frac{dr^2}{(1-2m/r)} - r^2 d\Omega^2 \tag{2}$$

admits isometric embedding of class 2 into Euclidean $(2+4)$-space. Embedding functions in this case are

$$\begin{gathered} X^1 = \sqrt{1 - \frac{2m}{r}} \cos t, \quad X^2 = \sqrt{1 - \frac{2m}{r}} \sin t, \quad X^3 = f(r), \\ X^4 = r \sin\theta \cos\varphi, \quad X^5 = r \sin\theta \sin\varphi, \quad X^6 = r \cos\theta, \end{gathered} \tag{3}$$

where $f(r)$ is solution of

$$f'^2 = (m^2/r^4 + 2m/r)/(1-2m/r). \tag{4}$$

a)Electronic mail: gogber@hotmail.com

In this paper we consider embedding of the brane metric (which was introduced in Ref. 1) into six-dimensional pseudo-Euclidean space with the same signature $(2+4)$ as for the Schwarzschild case. The necessity of two time directions for embedding of P- and M-branes was shown in Ref. 10.

We are looking for the functions X^A which fulfill the relation

$$ds^2 = e^{2a\xi} dl^2 - d\xi^2 = dX_0^2 - dX_1^2 - dX_2^2 - dX_3^2 + dX_\tau^2 - dX_\kappa^2. \tag{5}$$

Here

$$l = \sqrt{t^2 - x^2 - y^2 - z^2} \tag{6}$$

is the length in four-dimensional Minkowski space–time, ξ is the fifth coordinate orthogonal to the brane, and a is the parameter connected with the five-dimensional cosmological constant $\pm\Lambda$. For simplicity on the brane we consider the Minkowski metric. The Ricci tensor of the five-dimensional space–time where the cosmological constant Λ appears is not zero,[1] while we assume bulk $(2+4)$-space to be pseudo-Euclidean again. This can be interpreted as a kind of geometrical introduction of the cosmological constant.

It can be checked that the embedding (5) is done by the functions

$$X_\alpha = e^{a\xi} x_\alpha, \quad X_\tau = \left(l^2 - \frac{1}{4} \right) e^{a\xi} - \frac{1}{a^2} e^{-a\xi}, \quad X_\kappa = \left(l^2 + \frac{1}{4} \right) e^{a\xi} - \frac{1}{a^2} e^{-a\xi}, \tag{7}$$

where x^α are coordinates of Minkowski space–time and the index α runs over 0, 1, 2, 3.

The inverse expression of five-dimensional coordinates by the embedding functions has the form

$$x_\alpha = \frac{X_\alpha}{2(X_\kappa - X_\tau)}, \quad \xi = \frac{1}{a} \ln[2(X_\kappa - X_\tau)]. \tag{8}$$

The geometry of the five-dimensional metric (5) can be visualized as the surface of the hypersphere in six dimensions, since

$$X_0^2 - X_1^2 - X_2^2 - X_3^2 + X_\tau^2 - X_\kappa^2 = \frac{1}{a^2}. \tag{9}$$

The radius of this ''sphere'' is $1/|a|$ and thus governed by the value of the five-dimensional cosmological constant $\pm\Lambda$. In this picture four-dimensional Minkowski space–time is the intersection of this hypersphere with the plane

$$X_\kappa - X_\tau = \tfrac{1}{2}, \tag{10}$$

where X_κ and X_τ are, respectively, extra space-like and time-like coordinates of the six-dimensional space–time.

Possibly here we have correlations with the situation of the linearization of conformal group, the symmetry group of the main equations of physics in zero-mass limit. A long time ago it was discovered that the nonlinear 15-parameter conformal transformations can be written as a linear Lorentz-type transformation in a $(2+4)$-space. For this case the intersection of the null six-cone with the null five-plane formed by the extra time-like and space-like coordinates has induced metric of the Minkowski form (for these subjects see, e.g., Ref. 11) and formulas of this embedding are similar to (8)–(10) we have in the branes case.

At the end of the paper we want to note that $(2+4)$-space is the object of interest for Kaluza–Klein models. For compact extra dimensions this space was studied in Ref. 12 and in the context of brane models with nonfactorizable geometry in Ref. 13.

Anisotropic geodesic fluid spheres in general relativity

L. Herrera[a)]
Escuela de Física, Facultad de Ciencias, Universidad Central de Venezuela, Caracas, Venezuela

J. Martin[b)] and J. Ospino
Area de Física Teórica, Facultad de Ciencias, Universidad de Salamanca, 37008 Salamanca, España

(Received 5 April 2002; accepted for publication 2 July 2002)

It is shown that unlike the perfect fluid case, anisotropic fluids (principal stresses unequal) may be geodesic, without this implying the vanishing of (spatial) pressure gradients. Then the condition of vanishing four acceleration is integrated in noncomoving coordinates. The resulting models are necessarily dynamic, and the mass function is expressed in terms of the fluid velocity as measured by a locally Minkowskian observer. An explicit example is worked out. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1505985]

I. INTRODUCTION

As is well known, the vanishing of four acceleration (geodesic condition) implies for a perfect fluid that pressure gradients vanish. In the case of spherical bounded (nondissipative) configuration, the vanishing of pressure at the boundary surface implies in turn the vanishing of pressure everywhere within the distribution (dust).

Indeed, for a perfect fluid the equation of motion reads

$$(\rho+p)a^{\alpha}=h^{\alpha\nu}p_{,\nu} \tag{1}$$

with

$$h^{\alpha}_{\mu}\equiv\delta^{\alpha}_{\mu}-u^{\alpha}u_{\mu}, \tag{2}$$

$$a^{\mu}=u^{\nu}u^{\mu}_{;\nu}, \tag{3}$$

where the colon and semicolon denote partial and covariant derivatives, and as usual a^{μ}, u^{μ}, ρ, and p stand for the four acceleration, the four velocity, the energy density, and the pressure, respectively.

From the above it becomes evident that the geodesic condition implies the vanishing of pressure gradients. From purely physics considerations this conclusion is also obvious: the vanishing of four-acceleration means that only gravitational forces are acting on any fluid element, thereby implying that pressure gradients (the only hydrodynamic force in a perfect fluid) vanish. However in the case of anisotropic fluids, an additional force term appears besides the pressure gradient (see Sec. II). Therefore it is in principle possible to have a fluid distribution, such that both terms cancel each other, leading to a geodesic fluid with nonvanishing pressure gradients.

Since the original Lemaitre paper[1] and particularly since the work of Bowers and Liang[2] anisotropic fluids have attracted the attention of many researchers in relativity and relativistic astrophysics (see Ref. 3, and references therein), due to the conspicuous role played by local anisotropy of pressure in the structure and evolution of self–gravitating objects. It is the purpose

[a)]Postal address: Apartado 80793, Caracas 1080 A, Venezuela; electronic mail: laherrera@telcet.net.ve
[b)]Electronic mail: chmm@usal.es

of this work to present further models of anisotropic spheres, based on the geodesic condition. Besides the natural interest of such models in general relativity, the presented models are interesting because they represent the generalization of Tolman–Bondi[4] models to anisotropic fluids, in noncomoving coordinates. Incidentally, it is worth noticing that in the classical paper by Oppenheimer and Snyder on dust collapse,[5] they start their study, using the same kind of coordinates we use here, and then switch to comoving ones, in order to integrate the field equations.

The plan of the paper is as follows. In Sec. II we define the conventions and give the field equations and expressions for the kinematic variables we shall need, in noncomoving coordinates. The geodesic condition is explicitly integrated in Sec. III. In Sec. IV we work out an example. Finally a discussion of results is presented in Sec. V.

II. RELEVANT EQUATIONS AND CONVENTIONS

We consider spherically symmetric distributions of collapsing anisotropic fluid, which we assume to evolve adiabatically (without dissipation), bounded by a spherical surface Σ. The line element is given in Schwarzschild-type coordinates by

$$ds^2 = e^{\nu}dt^2 - e^{\lambda}dr^2 - r^2(d\theta^2 + \sin^2\theta\, d\phi^2), \tag{4}$$

where $\nu(t,r)$ and $\lambda(t,r)$ are functions of their arguments. We number the coordinates: $x^0 = t$; $x^1 = r$; $x^2 = \theta$; $x^3 = \phi$.

The metric (4) has to satisfy Einstein field equations

$$G^{\nu}_{\mu} = -8\pi T^{\nu}_{\mu}, \tag{5}$$

which in our case read:[6]

$$-8\pi T^0_0 = -\frac{1}{r^2} + e^{-\lambda}\left(\frac{1}{r^2} - \frac{\lambda'}{r}\right), \tag{6}$$

$$-8\pi T^1_1 = -\frac{1}{r^2} + e^{-\lambda}\left(\frac{1}{r^2} + \frac{\nu'}{r}\right), \tag{7}$$

$$-8\pi T^2_2 = -8\pi T^3_3 = -\frac{e^{-\nu}}{4}(2\ddot{\lambda} + \dot{\lambda}(\dot{\lambda} - \dot{\nu})) + \frac{e^{-\lambda}}{4}\left(2\nu'' + \nu'^2 - \lambda'\nu' + 2\frac{\nu' - \lambda'}{r}\right), \tag{8}$$

$$-8\pi T_{01} = -\frac{\dot{\lambda}}{r}, \tag{9}$$

where dots and primes stand for partial differentiation with respect to t and r, respectively.

In order to give physical significance to the T^{μ}_{ν} components we apply the Bondi approach.[6]

Thus, following Bondi, let us introduce purely locally Minkowski coordinates (τ,x,y,z) (alternatively one may introduce a tetrad field associated with locally Minkowskian observers):

$$d\tau = e^{\nu/2}dt, \quad dx = e^{\lambda/2}dr, \quad dy = r\,d\theta, \quad dz = r\sin\theta\, d\phi.$$

Then, denoting the Minkowski components of the energy tensor by a bar, we have

$$\overline{T^0_0} = T^0_0, \quad \overline{T^1_1} = T^1_1, \quad \overline{T^2_2} = T^2_2, \quad \overline{T^3_3} = T^3_3, \quad \overline{T_{01}} = e^{-(\nu+\lambda)/2}T_{01}.$$

Next, we suppose that when viewed by an observer moving relative to these coordinates with proper velocity $\omega(t,r)$ in the radial direction, the physical content of space consists of an anisotropic fluid of energy density ρ, radial pressure P_r, and tangential pressure $P_{\perp}$. Thus, when viewed by this moving observer the covariant tensor in Minkowski coordinates is

$$\begin{pmatrix} \rho & 0 & 0 & 0 \\ 0 & P_r & 0 & 0 \\ 0 & 0 & P_\perp & 0 \\ 0 & 0 & 0 & P_\perp \end{pmatrix}.$$

Then a Lorentz transformation readily shows that

$$T_0^0 = \overline{T}_0^0 = \frac{\rho + P_r\omega^2}{1-\omega^2}, \tag{10}$$

$$T_1^1 = \overline{T}_1^1 = -\frac{P_r + \rho\omega^2}{1-\omega^2}, \tag{11}$$

$$T_2^2 = T_3^3 = \overline{T}_2^2 = \overline{T}_3^3 = -P_\perp, \tag{12}$$

$$T_{01} = e^{(\nu+\lambda)/2}\overline{T}_{01} = -\frac{(\rho + P_r)\omega e^{(\nu+\lambda)/2}}{1-\omega^2}. \tag{13}$$

Note that the coordinate velocity in the (t, r, θ, ϕ) system, $\mathrm{d}r/\mathrm{d}t$, is related to ω by

$$\omega(t,r) = \frac{\mathrm{d}r}{\mathrm{d}t} e^{(\lambda-\nu)/2}. \tag{14}$$

Feeding back (10)–(13) into (6)–(9), we get the field equations in the form

$$\frac{\rho + P_r\omega^2}{1-\omega^2} = -\frac{1}{8\pi}\left\{ -\frac{1}{r^2} + e^{-\lambda}\left(\frac{1}{r^2} - \frac{\lambda'}{r}\right)\right\}, \tag{15}$$

$$\frac{P_r + \rho\omega^2}{1-\omega^2} = -\frac{1}{8\pi}\left\{ \frac{1}{r^2} - e^{-\lambda}\left(\frac{1}{r^2} + \frac{\nu'}{r}\right)\right\}, \tag{16}$$

$$P_\perp = -\frac{1}{8\pi}\left\{ \frac{e^{-\nu}}{4}(2\ddot{\lambda} + \dot{\lambda}(\dot{\lambda} - \dot{\nu})) - \frac{e^{-\lambda}}{4}\left(2\nu'' + \nu'^2 - \lambda'\nu' + 2\frac{\nu' - \lambda'}{r}\right)\right\}, \tag{17}$$

$$\frac{(\rho + P_r)\omega e^{(\nu+\lambda)/2}}{1-\omega^2} = -\frac{\dot{\lambda}}{8\pi r}. \tag{18}$$

At the outside of the fluid distribution, the space–time is that of Schwarzschild, given by

$$\mathrm{d}s^2 = \left(1 - \frac{2M}{r}\right)\mathrm{d}t^2 - \left(1 - \frac{2M}{r}\right)^{-1}\mathrm{d}r^2 - r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\phi^2), \tag{19}$$

As is well known, in order to match smoothly the two metrics above on the boundary surface $r = r_\Sigma(t)$, we must require the continuity of the first and the second fundamental form across that surface. In our notation this implies

$$e^{\nu_\Sigma} = 1 - \frac{2M}{r_\Sigma}, \tag{20}$$

$$e^{-\lambda_\Sigma} = 1 - \frac{2M}{r_\Sigma}. \tag{21}$$

and

$$[P_r]_\Sigma = 0, \tag{22}$$

where, from now on, subscript Σ indicates that the quantity is evaluated at the boundary surface Σ.

Equations (20)–(22) are the necessary and sufficient conditions for a smooth matching of the two metrics (4) and (19) on Σ.

Next, let us write the energy momentum tensor in the form

$$T_{\mu\nu} = (\rho + P_\perp)u_\mu u_\nu - P_\perp g_{\mu\nu} + (P_r - P_\perp)s_\mu s_\nu \tag{23}$$

with

$$u^\mu = \left(\frac{e^{-\nu/2}}{(1-\omega^2)^{1/2}}, \frac{\omega e^{-\lambda/2}}{(1-\omega^2)^{1/2}}, 0, 0 \right), \tag{24}$$

$$s^\mu = \left(\frac{\omega e^{-\nu/2}}{(1-\omega^2)^{1/2}}, \frac{e^{-\lambda/2}}{(1-\omega^2)^{1/2}}, 0, 0 \right), \tag{25}$$

where u^μ denotes the four velocity of the fluid and s^μ is a radially directed space-like vector orthogonal to u^μ. Then the radial component of the conservation law

$$T^\mu_{\nu;\mu} = 0 \tag{26}$$

may be written as

$$(-8\pi T_1^1)' = \frac{16\pi}{r}(T_1^1 - T_2^2) + 4\pi\nu'(T_1^1 - T_0^0) + \frac{e^{-\nu}}{r}\left(\ddot{\lambda} + \frac{\dot{\lambda}^2}{2} - \frac{\dot{\lambda}\dot{\nu}}{2} \right), \tag{27}$$

which in the static case becomes

$$P_r' = -\frac{\nu'}{2}(\rho + P_r) + \frac{2(P_\perp - P_r)}{r}, \tag{28}$$

representing the generalization of the Tolman–Oppenheimer–Volkof equation for anisotropic fluids.[2] Thus, as mentioned before, local anisotropy introduces an extra term in this ''force'' equation, besides the usual pressure gradient term.

Finally, for the two nonvanishing components of the four acceleration, we easily find

$$a_0 = \frac{1}{1-\omega^2}\left[\left(\frac{\omega\dot{\omega}}{1-\omega^2} + \frac{\omega^2\dot{\lambda}}{2} \right) + e^{\nu/2}e^{-\lambda/2}\left(\frac{\omega\nu'}{2} + \frac{\omega^2\omega'}{1-\omega^2} \right) \right], \tag{29}$$

$$a_1 = -\frac{1}{1-\omega^2}\left[\left(\frac{\omega\omega'}{1-\omega^2} + \frac{\nu'}{2} \right) + e^{-\nu/2}e^{\lambda/2}\left(\frac{\omega\dot{\lambda}}{2} + \frac{\dot{\omega}}{1-\omega^2} \right) \right]. \tag{30}$$

III. INTEGRATING THE GEODESIC CONDITION

Let us now integrate the geodesic condition. First, observe that from the field equations (15), (16), and (18), one obtains after simple manipulations

$$\omega e^{(\nu-\lambda)/2}(\lambda' + \nu') + (1+\omega^2)\dot{\lambda} = 0. \tag{31}$$

Next, it follows at once from (29) and (30) that

$$\omega a_1 = -a_0 e^{(\lambda-\nu)/2}. \tag{32}$$

Therefore the vanishing four-acceleration condition amounts to

$$\left(\frac{\omega\omega'}{1-\omega^2}+\frac{\nu'}{2}\right)+e^{-\nu/2}e^{\lambda/2}\left(\frac{\omega\dot{\lambda}}{2}+\frac{\dot{\omega}}{1-\omega^2}\right)=0. \tag{33}$$

Then, replacing ν' by its expression from (31), into (33), this last equation becomes

$$\omega e^{(\nu-\lambda)/2}\left(\lambda'-\frac{2\omega\omega'}{1-\omega^2}\right)+\dot{\lambda}-\frac{2\omega\dot{\omega}}{1-\omega^2}=0, \tag{34}$$

or, using (14)

$$\dot{\phi}\,\mathrm{d}t+\phi'\,\mathrm{d}r=0, \tag{35}$$

whose solution is

$$\phi=\ln(1-\omega^2)+\lambda=\text{constant}. \tag{36}$$

Finally, from the fact that $\omega(t,0)=0$ we obtain

$$e^{-\lambda}=1-\omega^2. \tag{37}$$

Introducing the mass function as usual,

$$e^{-\lambda}=1-\frac{2m}{r}, \tag{38}$$

we have

$$m=\frac{\omega^2 r}{2}. \tag{39}$$

In all the above we have assumed $\omega\neq 0$, since from simple physical considerations we should not expect static solutions to exist.

Indeed, if we assume staticity ($\omega=0$) then the geodesic condition implies $\nu'=0$, which in turn, using (16) and (38), leads to

$$8\pi P_r=-\frac{2m}{r^3}. \tag{40}$$

Then junction condition (22) would lead to $m_\Sigma=M=0$.

There is however one possible case of static geodesic solution, which appears if we relax the condition of continuity of the second fundamental form (implying the continuity of radial pressure) across the boundary surface, and assume the existence of a surface layer.[7]

In this specific case, it follows from (40), the geodesic condition and field equations (15) and (17) that

$$\rho+P_r+2P_\perp=0, \tag{41}$$

implying that the active gravitational mass (Tolman[8]) defined for any $r<r_\Sigma$ as

$$m_T=4\pi\int_0^r r^2 e^{(\nu+\lambda)/2}(T_0^0-T_1^1-2T_2^2)\mathrm{d}r, \tag{42}$$

vanishes inside the sphere.

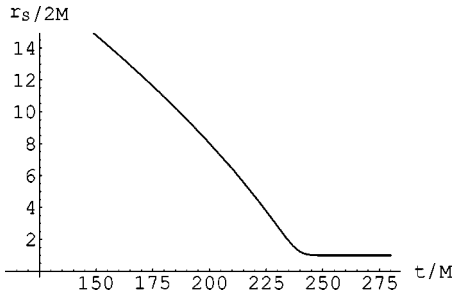

FIG. 1. $y=r_\Sigma/2M$ as function of t/M for the inital value $y(0)=30$.

We shall not consider here these kinds of solutions and accordingly all our models will be dynamic ($\omega\neq 0$) and satisfy all junction conditions.

Now, from (14) evaluated at the boundary surface, and (20) and (21), we obtain

$$\omega_\Sigma=\frac{\dot r_\Sigma}{1-2M/r_\Sigma}. \tag{43}$$

On the other hand, from (39) evaluated at the boundary surface, we have

$$\omega_\Sigma=\pm\sqrt{\frac{2M}{r_\Sigma}}, \tag{44}$$

where the $+$ $(-)$ refers to the expansion (contraction) of the surface (from now on we shall only consider the contracting case). Feeding back (44) into (43), we get

$$\omega_\Sigma=\frac{\dot r_\Sigma}{1-\omega_\Sigma^2}. \tag{45}$$

Then equating (45) and (44) we have

$$\dot r_\Sigma=\left(\frac{2M}{r_\Sigma}\right)^{3/2}-\left(\frac{2M}{r_\Sigma}\right)^{1/2}. \tag{46}$$

This equation may be integrated to give

$$\frac{t}{2M}=2\tanh^{-1}\sqrt{\frac{2M}{r_\Sigma}}-\frac{2[1+6M/r_\Sigma]}{3(2M/r_\Sigma)^{3/2}} \tag{47}$$

giving the evolution of the boundary surface. Unfortunately Eq. (47) cannot be inverted (at least we were unable to do that) to obtain the explicit form $r=r_\Sigma(t)$. Accordingly we have also integrated (46) numerically, in order to exhibit the evolution of r_Σ, see Fig. 1.

So far we have found all consequences derived from the geodesic condition which, obviously, are valid in the pure dust case as well as in the anisotropic case. In Sec. IV we shall work out an explicit example by imposing an ''equation of state'' for the physical variables.

IV. A MODEL

The purpose of this section is not to model any specific physical system, but just to illustrate the consequences derived from the geodesic condition. Thus, somehow inspired by the incompressible fluid model, let us assume

$$T_0^0=f(t). \tag{48}$$

Then from (39) and the fact that

$$m' = 4\pi r^2 T_0^0 \tag{49}$$

one obtains

$$\omega = -r\sqrt{\frac{8\pi}{3} f(t)}, \tag{50}$$

where

$$f(t) = \frac{3M}{4\pi r_\Sigma^3}. \tag{51}$$

Observe from (50) that the evolution in this model is homologous.

Next, introducing the dimensionless variables

$$x \equiv \frac{r}{r_\Sigma}, \quad y \equiv \frac{r_\Sigma}{2M}, \tag{52}$$

we have

$$e^{-\lambda} = 1 - \frac{x^2}{y}, \tag{53}$$

$$\omega = -\frac{x}{\sqrt{y}}. \tag{54}$$

Finally, from the field equations the following relations follow:

$$\rho y + P_r x^2 = \frac{3(y - x^2)}{32\pi M^2 y^3}, \tag{55}$$

$$P_r y + \rho x^2 = \frac{(y - x^2)}{8\pi}\left[\left(1 - \frac{x^2}{y}\right)\left(\frac{1}{4M^2x^2y^2} + \frac{\partial \nu}{\partial x}\frac{1}{4M^2xy^2}\right) - \frac{1}{4M^2x^2y^2}\right], \tag{56}$$

$$\rho + P_r = -\frac{3\dot{y}(y - x^2)^{1/2} e^{-\nu/2}}{8\pi(2My^3)}. \tag{57}$$

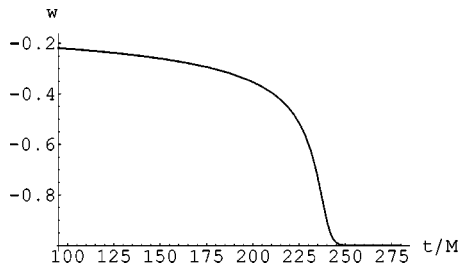

FIG. 2. ω_Σ as function of t/M for the same initial data as in Fig. 1.

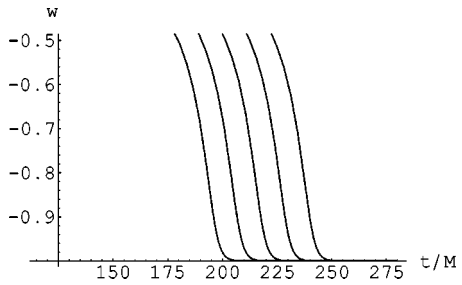

FIG. 3. ω_Σ as function of t/M for $y(0)=30,29,28,27,26$ curves from right to left, respectively.

Then from (55) and (56) we obtain $\rho+P_r$ as function of $\partial\nu/\partial x$, x and y. Feeding back this expression into (57), this equation may be solved for ν, which in turn allows one to express all physical variables (ρ, P_r, and $P_\perp$) in terms of x and y which are given by (47) or alternatively by the numerical solution of (46).

V. CONCLUSIONS

We have seen that the geodesic condition, which for anisotropic fluids is compatible with the presence of pressure gradients, can be integrated, giving the explicit form of the evolution of the boundary surface. Resulting models may be regarded as generalizations of Tolman–Bondi solutions, to anisotropic fluids. In order to obtain the evolution of all physical variables for different pieces of matter, additional information has to be given. In the above-presented model we have assumed condition (48), which in turn leads to the homology condition (50). Parenthetically, this last condition is widely used by astrophysicists in their modeling of stellar structure and evolution.[9]

Figures 1 and 2 display the behavior of the radius and the evolution of ω_Σ in the contracting case. As expected, as the boundary surface approaches the horizon, its coordinate velocity ($\dot{r}_\Sigma$) stalls, whereas the velocity ω_Σ measured by the locally Minkowskian observer, tends to light velocity. Figure 3 shows the sensitivity of the pattern evolution with respect to the compactness of the initial configuration. As expected more compact configurations collapse faster. The good behavior of ρ and p_r is easily deduced from (55) to (57).

(Received 6 May 2002; accepted for publication 17 June 2002)

We compute the Schwinger term in the gravitational constraints in two dimensions, starting from the path integral in Hamiltonian form and the Einstein anomaly. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1505127]

I. INTRODUCTION

A Yang–Mills theory with a non-Abelian anomaly (gauge anomaly) leads to Schwinger terms (central charges) in the constraint algebra (the Gauss law operators) as well as in the algebra of currents (see, e.g., Refs. 1 and 2). Theories of gravitation and matter that have a gravitational anomaly (Einstein or Lorentz) also lead to Schwinger terms in the constraints and currents (energy-momentum tensors). As we will see later, in the tensor theory of Einstein in two dimensions, the gravitational constraints reduce to the energy-momentum tensor and therefore the two Schwinger terms are equivalent. This case has been considered in Refs. 3–6. The Schwinger terms in the constraints of a scalar-tensor theory are discussed in Refs. 7–10.

In Ref. 11, Faddeev *et al.* found the following method to compute the Schwinger term in the algebra of the Gauss law operators in a Yang–Mills theory: starting with the path integral in Hamiltonian form, they make a gauge transformation and include the non-Abelian anomaly. From the Ward identity in second order in the gauge parameter, one can then extract the Schwinger term by acting with a suitable operator. Our goal is to generalize this to gravitation.

II. GRAVITATION AS A CONSTRAINED HAMILTONIAN SYSTEM

We start with Einstein's theory of gravitation and a massless chiral fermion, which are described by the action [we have either $P_+\psi=0$ or $P_-\psi=0$ with $P_\pm=\frac{1}{2}(1\pm\gamma_5)$]

$$S=\int dx\ \ e\left[R+\frac{i}{2}e^{a\mu}\overline{\psi}\gamma_a\overleftrightarrow{\nabla}_\mu\psi\right]. \tag{1}$$

This action can also be written as a constrained Hamiltonian system (see, e.g., Refs. 12–14) (in d-dimensions i runs from 1 to $d-1$):

$$S=\int dx\left[\pi_a^i\dot{e}_i^a+i^{(3)}g^{1/2}\overline{\psi}\Gamma^\perp\dot{\psi}-N\tilde{\mathcal{H}}_\perp-N^i\tilde{\mathcal{H}}_i-\frac{1}{2}\omega_0^{ab}J_{ab}\right], \tag{2}$$

where ${}^{(3)}g^{ij}$ is the induced metric and π_a^i is the canonical momentum to e_i^a defined by $p^{ij}=\frac{1}{4}(\pi_a^i\ {}^{(3)}e^{aj}+\pi_a^j\ {}^{(3)}e^{ai})$, where the canonical momentum to g_{ij} is expressed in terms of the extrinsic curvature K_{ij},

$$p^{ij}={}^{(3)}g^{1/2}(K^{ij}-K^{(3)}g^{ij}). \tag{3}$$

The Lagrangian multipliers are the lapse N, the shift N_i, $N^i={}^{(3)}g^{ij}N_j$, and the 0-component of the spin connection ω_0^{ab}. The constraints are

a)Electronic-mail address: emmanuel.kohlprath@cern.ch

$$\tilde{\mathcal{H}}_\perp = \mathcal{H}_\perp + \partial_k J^{\perp k} - i^{(3)}g^{1/2}\overline{\psi}\Gamma^i D_i\psi, \tag{4}$$

$$\tilde{\mathcal{H}}_i = \mathcal{H}_i + \tfrac{1}{2}g_{ij}\partial_k J^{kj} + K_{ik}J^{\perp k} + i[{}^{(3)}g^{1/2}\overline{\psi}\Gamma^\perp D_i\psi - \tfrac{1}{4}\partial_k({}^{(3)}g^{1/2}\overline{\psi}[\Gamma_i,\Gamma^k]\Gamma^\perp\psi)], \tag{5}$$

$$J_{ab} = \pi^i_a e_{bi} - \pi^i_b e_{ai} - \frac{i}{4}{}^{(3)}g^{1/2}\overline{\psi}(\Gamma^\perp\gamma_a\Gamma^i - \Gamma^i\gamma_a\Gamma^\perp)e_{bi} + \frac{i}{4}{}^{(3)}g^{1/2}\overline{\psi}(\Gamma^\perp\gamma_b\Gamma^i - \Gamma^i\gamma_b\Gamma^\perp)e_{ai}, \tag{6}$$

$$\Gamma^i = {}^{(3)}g^{ij}e^a_j\gamma_a = {}^{(3)}e^{ai}\gamma_a, \quad \Gamma^\perp = -n^a\gamma_a. \tag{7}$$

Remember that the gravitational Hamiltonian is vanishing.

III. THE GRAVITATIONAL PATH INTEGRAL

The general coordinate transformations are the gauge transformations of gravitation. To define a well behaved path integral, we choose the gauge fixing $e^a_0 = \delta^a_0$ and introduce the coordinate ghosts using the Faddeev–Popov method. Under infinitesimal active coordinate transformations (Einstein transformations) the vielbein transforms as

$$\delta^c_\xi e^a_\mu(x) = e'^a_\mu(x) - e^a_\mu(x) = \xi^\nu\partial_\nu e^a_\mu(x) + e^a_\nu(x)\partial_\mu\xi^\nu. \tag{8}$$

This leads to the ghost action

$$\begin{aligned} S_{GH} &= \int dxdy e(x)\overline{v}^\nu(x)e_{a\nu}(x)\left.\frac{\delta^c_\xi(e^a_0 - \delta^a_0)}{\delta\xi_\mu(y)}\right|_{\xi=0} v_\mu(y) \\ &= \int dx e(x)\overline{v}_\nu(x)(e^\nu_a(x)\partial_\mu e^a_0(x)v^\mu(x) + \partial_0 v^\nu(x)). \end{aligned} \tag{9}$$

We find the path integral in Hamiltonian form for gravitation and a chiral fermion:

$$\begin{aligned} Z = \frac{1}{N}\int d\pi^i_a de^a_i de^a_0 d\overline{\psi}d\psi d\overline{v}_\alpha dv^\alpha \delta(e^a_0 - \delta^a_0) \\ \times\exp\left\{ i\int dx\left[\pi^i_a\dot{e}^a_i + i^{(3)}g^{1/2}\overline{\psi}\Gamma^\perp\dot{\psi} - N^\mu\tilde{\mathcal{H}}_\mu - \frac{1}{2}\omega^{ab}_0 J_{ab} + e\overline{v}_\nu(e^\nu_a\partial_\mu e^a_0 v^\mu + \partial_0 v^\nu)\right]\right\}. \end{aligned} \tag{10}$$

The inclusion of powers of e as weights in the fermionic measure, as it is explained in Refs. 15 and 16, would be no problem but we will not need it.

IV. SCHWINGER TERMS IN GRAVITATION IN TWO DIMENSIONS

In two dimensions the Einstein–Hilbert action is proportional to the Euler number of the two-dimensional manifold (see, e.g., Ref 17). We choose a manifold where the Euler number vanishes. So in two dimensions there are no dynamical degrees of freedom for gravity in Einstein's theory. From (3) we see that the conjugate momenta π^1_a identically vanish. Using $e^a_1 e^b_1[\gamma_a,\gamma_b] = 0$ and $\gamma_b\gamma_0\gamma_a - \gamma_a\gamma_0\gamma_b = 0$ the constraints reduce to

$$\tilde{\mathcal{H}}_\perp = -i^{(1)}g^{1/2}\overline{\psi}\Gamma^1\partial_1\psi, \tag{11}$$

$$\tilde{\mathcal{H}}_1 = i^{(1)}g^{1/2}\overline{\psi}\Gamma^\perp\partial_1\psi, \tag{12}$$

$$J_{ab} = 0. \tag{13}$$

We have

$$\Gamma^1 = {}^{(1)}e^{a1}\gamma_a = (g_{11})^{-1}e_1^a\gamma_a = e^{a1}\gamma_a - \frac{N^1}{N}n^a\gamma_a, \tag{14}$$

$$\Gamma^\perp = N^\perp e^{a0}\gamma_a = -n^a\gamma_a, \tag{15}$$

$$e = |g|^{1/2} = {}^{(1)}g^{1/2}N, \tag{16}$$

so that

$$N^\mu\mathcal{H}_\mu = -ie\,\overline{\psi}e^{a1}\gamma_a\partial_1\psi. \tag{17}$$

The path integral (10) reduces to

$$Z = \frac{1}{N}\int d\pi_a^1 de_1^a de_0^a d\overline{\psi}d\psi d\overline{v}_\alpha dv^\alpha \delta(e_0^a - \delta_0^a) \times \exp\left\{ i\int dx[\pi_a^1\dot{e}_1^a + ie\,\overline{\psi}e^{a0}\gamma_a\partial_0\psi + ie\,\overline{\psi}e^{a1}\gamma_a\partial_1\psi + e\overline{v}_\nu(e_a^\nu\partial_\mu e_0^a v^\mu + \partial_0 v^\nu)]\right\}. \tag{18}$$

We relabel all fields, $e_\mu^a(x)\to e'^a_\mu(x)$, as for the other fields. We interpret this as an active coordinate transformation and use the invariance of the classical action and the bosonic measure under coordinate transformations. The fermionic measure gives us the Einstein anomaly $G[\Lambda,\Gamma]$, and we are left with

$$Z = \frac{1}{N}\int d\pi_a^1 de_1^a de'^a_0 d\overline{\psi}d\psi d\overline{v}_\alpha dv^\alpha \delta(e'^a_0 - \delta_0^a) \times \exp\left\{ i\int dx[\pi_a^1\dot{e}_1^a + ie\,\overline{\psi}e^{a0}\gamma_a\partial_0\psi + ie\,\overline{\psi}e^{a1}\gamma_a\partial_1\psi + e\overline{v}_\nu(e_a^\nu\partial_\mu e_0^a v^\mu + \partial_0 v^\nu)]\right\} G[\Lambda,\Gamma] \tag{19}$$

with the explicit expression (see, e.g., Ref. 18)

$$G[\Lambda,\Gamma] = \exp\left\{ \pm\frac{i}{96\pi}\left[\frac{1}{3}\int_{\Gamma^+}\mathrm{tr}(d\Lambda\Lambda^{-1})^3 + \int_{M_2}\mathrm{tr}(d\Lambda\Lambda^{-1}\Gamma)\right]\right\}, \tag{20}$$

where Γ_b^a is the Christoffel connexion one-form, Λ_b^a is the "gauge" element and $\partial\Gamma^+ = M_2$. For a general coordinate transformation $x' = x'(x)$ we define the "gauge" parameter ξ by

$$x'^\alpha = x^\alpha - \xi^\alpha(x), \tag{21}$$

$$(\Lambda^{-1})_\beta^\alpha = \frac{\partial x'^\alpha}{\partial x^\beta} = \delta_\beta^\alpha - \partial_\beta\xi^\alpha(x), \tag{22}$$

so that, in second order in ξ, we have

$$x^\alpha = x'^\alpha + \xi^\alpha(x') + \xi^\lambda\partial_\lambda\xi^\alpha(x') + O(\xi^3), \tag{23}$$

$$\Lambda_\beta^\alpha = \frac{\partial x^\alpha}{\partial x'^\beta} = \delta_\beta^\alpha + \partial_\beta\xi^\alpha(x) + \partial_\beta\xi^\lambda\partial_\lambda\xi^\alpha(x) + O(\xi^3). \tag{24}$$

The zweibein transforms under passive coordinate transformations as

$$e'^a_\mu(x') = \Lambda_\mu^\nu e_\nu^a(x) = e_\mu^a(x) + \partial_\mu\xi^\nu e_\nu^a(x) + \partial_\mu\xi^\lambda\partial_\lambda\xi^\nu e_\nu^a(x) + O(\xi^3) \tag{25}$$

and under active coordinate tranformations (Einstein transformations) as

$$e'^{a}_{\mu}(x)=e^{a}_{\mu}(x)+\partial_\mu\xi^\nu e^{a}_{\nu}(x)+\xi^\alpha\partial_\alpha e^{a}_{\mu}(x)+\partial_\mu\xi^\lambda\partial_\lambda\xi^\nu e^{a}_{\nu}(x)+\xi^\alpha\partial_\alpha\partial_\mu\xi^\nu e^{a}_{\nu}(x)$$
$$+\xi^\alpha\partial_\mu\xi^\nu\partial_\alpha e^{a}_{\nu}(x)+\xi^\alpha\partial_\alpha\xi^\beta\partial_\beta e^{a}_{\mu}(x)+\tfrac{1}{2}\xi^\alpha\xi^\beta\partial_\alpha\partial_\beta e^{a}_{\mu}(x)+O(\xi^3). \tag{26}$$

The gauge fixing $e'^{a}_{0}(x)=\delta^a_0$ leads to a second order differential equation for e^a_0. If we are in two dimensions and choose $\xi^1=0$, then we find

$$\delta^a_0=[1+\partial_0\xi^0+\xi^0\partial_0+\partial_0\xi^0\partial_0\xi^0+\xi^0\partial_0\partial_0\xi^0+2\xi^0\partial_0\xi^0\partial_0+\tfrac{1}{2}\xi^0\xi^0\partial_0\partial_0]e^a_0. \tag{27}$$

Its solution is

$$e^a_0=(1-\partial_0\xi^0)\,\delta^a_0+O(\xi^3). \tag{28}$$

Using (28) we express everything up to second order in ξ, in terms of e^0_1 and e^1_1. For the Einstein anomaly (20) we find

$$G[\xi,\Gamma]=\exp\left\{\pm\frac{i}{48\pi}\int dx[\partial_0\partial_0\xi^0\partial_1\partial_0\xi^0(e^0_1)^2(e^1_1)^{-2}+\partial_1\partial_0\xi^0\partial_1\partial_1\xi^0(e^1_1)^{-2}\right.$$
$$-2\partial_1\partial_0\xi^0\partial_1\partial_0\xi^0e^0_1(e^1_1)^{-2}+[(\partial_0\partial_0\xi^0+2\partial_0\partial_0\xi^0\partial_0\xi^0)(e^0_1)^2(e^1_1)^{-2}-2(\partial_1\partial_0\xi^0$$
$$+\partial_1\partial_0\xi^0\partial_0\xi^0)e^0_1(e^1_1)^{-2}+\partial_1\partial_1\xi^0(e^1_1)^{-2}]\partial_0e^0_1+[-(\partial_0\partial_0\xi^0+2\partial_0\partial_0\xi^0\partial_0\xi^0)e^0_1(e^1_1)^{-1}$$
$$\left.+(\partial_1\partial_0\xi^0+\partial_1\partial_0\xi^0\partial_0\xi^0)(e^1_1)^{-1}]\partial_0e^1_1]\right\}+O(\xi^3), \tag{29}$$

where we use the convention $\varepsilon^{01}=1$. As can be seen from (19), the momentum π^1_a is no longer conjugate to e^a_1, since there are terms in (29) proportional to $\partial_0e^0_1$ and $\partial_0e^1_1$. Therefore we make a shift in π^1_a to absorb these terms. The functional determinant is simply 1 and its effect is to kill all terms proportional to $\partial_0e^0_1$ and $\partial_0e^1_1$ in (29). Using

$$\mathcal{L}_{GH}=e\overline{v}_\nu(e^\nu_a\partial_\mu e^a_0v^\mu+\partial_0v^\nu)=e\overline{v}_\nu\partial_0v^\nu+e^1_1\partial_\mu e^0_0\overline{v}_0v^\mu, \tag{30}$$

$$ee^{a0}\gamma_a=-(e^1_1\gamma_0+e^0_1\gamma_1),\quad ee^{a1}\gamma_a=e(e^1_1)^{-1}\gamma_1, \tag{31}$$

we find the generating functional in second order in the gauge parameter

$$Z=\frac{1}{N}\int d\pi^1_ade^a_1d\overline{\psi}d\psi d\overline{v}_\alpha dv^\alpha\exp\left\{i\int dx\left[\pi^1_a\dot{e}^a_1-i\overline{\psi}(e^1_1\gamma_0+e^0_1\gamma_1)\partial_0\psi+(1-\partial_0\xi^0)i\overline{\psi}\gamma_1\partial_1\psi\right.\right.$$
$$+(1-\partial_0\xi^0)e^1_1\overline{v}_\nu\partial_0v^\nu-\partial_\mu\partial_0\xi^0e^1_1\overline{v}_0v^\mu\pm\frac{1}{48\pi}[\partial_0\partial_0\xi^0\partial_1\partial_0\xi^0(e^0_1)^2(e^1_1)^{-2}$$
$$\left.\left.-2\partial_1\partial_0\xi^0\partial_1\partial_0\xi^0e^0_1(e^1_1)^{-2}+\partial_1\partial_0\xi^0\partial_1\partial_1\xi^0(e^1_1)^{-2}]\right]\right\}+O(\xi^3). \tag{32}$$

In $O((\xi^0)^2)$ we find the following Ward identity:

$$0=\left\langle\pm\frac{i}{48\pi}\int dx[\partial_0\partial_0\xi^0\partial_1\partial_0\xi^0(e^0_1)^2(e^1_1)^{-2}-2\partial_1\partial_0\xi^0\partial_1\partial_0\xi^0e^0_1(e^1_1)^{-2}+\partial_1\partial_0\xi^0\partial_1\partial_1\xi^0(e^1_1)^{-2}]\right.$$
$$\left.+\frac{1}{2}\left[\int dx[\partial_0\xi^0\overline{\psi}\gamma_1\partial_1\psi-i\partial_0\xi^0e^1_1v_\nu\partial_0v^\nu-i\partial_\mu\partial_0\xi^0e^1_1\overline{v}_0v^\mu]\right]^2\right\rangle. \tag{33}$$

Acting with $\delta^2/\delta\xi^0(x)\,\delta\xi^0(y)$ on (33) we arrive at

$$0=\Big\langle \pm\frac{i}{48\pi}[(2\partial_1^y\partial_0^y\partial_0^y\partial_0^y\delta(x-y)+3\partial_1^y\partial_0^y\partial_0^y\delta(x-y)\partial_0^y+\partial_0^y\partial_0^y\partial_0^y\delta(x-y)\partial_1^y+\partial_0^y\partial_0^y\delta(x-y)\partial_1^y\partial_0^y$$
$$+\partial_1^y\partial_0^y\delta(x-y)\partial_0^y\partial_0^y)((e_1^0)^2(e_1^1)^{-2})-4(\partial_1^y\partial_1^y\partial_0^y\partial_0^y\delta(x-y)+\partial_1^y\partial_1^y\partial_0^y\delta(x-y)\partial_0^y$$
$$+\partial_1^y\partial_0^y\partial_0^y\delta(x-y)\partial_1^y+\partial_1^y\partial_0^y\delta(x-y)\partial_1^y\partial_0^y)(e_1^0(e_1^1)^{-2})+(2\partial_1^y\partial_1^y\partial_1^y\partial_0^y\delta(x-y)+\partial_1^y\partial_1^y\partial_1^y\delta(x-y)\partial_0^y$$
$$+3\partial_1^y\partial_1^y\partial_0^y\delta(x-y)\partial_1^y+\partial_1^y\partial_1^y\delta(x-y)\partial_1^y\partial_0^y+\partial_1^y\partial_0^y\delta(x-y)\partial_1^y\partial_1^y)(e_1^1)^{-2}]\rangle+\partial_0^x\partial_0^y\langle(-\overline{\psi}\gamma_1\partial_1\psi(x)$$
$$+ie_1^1\overline{v}_\nu\partial_0 v^\nu(x)+i\partial_\mu^x(e_1^1\overline{v}_0 v^\mu(x)))\times(-\overline{\psi}\gamma_1\partial_1\psi(y)+ie_1^1\overline{v}_\nu\partial_0 v^\nu(y)+i\partial_\mu^y(e_1^1\overline{v}_0 v^\mu(y)))\Big\rangle. \tag{34}$$

The last two lines give the commutator times $\partial_0^y\delta(x^0-y^0)$:

$$\partial_0^y\delta(x-y)[\overline{\psi}\gamma_1\partial_1\psi(x),\overline{\psi}\gamma_1\partial_1\psi(y)], \tag{35}$$

plus terms that are proportional to $\delta(x^0-y^0)$ or regular as $y^0\to x^0$. Next we apply

$$\lim_{(p_0-q_0)\to\infty}\frac{p_0-q_0}{p_0q_0^3}\int dx^0dy^0e^{ip_0x^0+iq_0y^0} \tag{36}$$

on (34) to project onto terms proportional to $\partial_0^y\partial_0^y\partial_0^y\delta(x-y)$ and we find

$$0=\pm\frac{i}{48\pi}\langle(2\partial_1^y\delta(x^1-y^1)+\delta(x^1-y^1)\partial_1^y)((e_1^0)^2(e_1^1)^{-2})\rangle. \tag{37}$$

Using this, we apply

$$\lim_{(p_0-q_0)\to\infty}\frac{p_0-q_0}{p_0q_0^2}\int dx^0dy^0e^{ip_0x^0+iq_0y^0} \tag{38}$$

on (34) to project onto terms proportional to $\partial_0^y\partial_0^y\delta(x-y)$. We obtain

$$0=\Big\langle \pm\frac{i}{48\pi}[\partial_1^y\delta(x^1-y^1)\partial_0^y((e_1^0)^2(e_1^1)^{-2})-4(\partial_1^y\partial_1^y\delta(x^1-y^1)+\partial_1^y\delta(x^1-y^1)\partial_1^y)(e_1^0(e_1^1)^{-2})]\Big\rangle. \tag{39}$$

Using this and finally applying

$$\lim_{(p_0-q_0)\to\infty}\frac{p_0-q_0}{p_0q_0}\int dx^0dy^0e^{ip_0x^0+iq_0y^0} \tag{40}$$

on (34) to project onto terms proportional to $\partial_0^y\delta(x-y)$, we arrive at

$$\langle[-i\overline{\psi}\gamma_1\partial_1\psi(x),-i\overline{\psi}\gamma_1\partial_1\psi(y)]\rangle$$
$$=\pm\frac{i}{48\pi}\langle[2\partial_1^y\partial_1^y\partial_1^y\delta(x^1-y^1)+3\partial_1^y\partial_1^y\delta(x^1-y^1)\partial_1^y+\partial_1^y\delta(x^1-y^1)\partial_1^y\partial_1^y](e_1^1)^{-2}\rangle. \tag{41}$$

From the fermionic part of the action (1) we find the energy-momentum tensor

$$T_{\mu\nu} = -\frac{i}{4}[\bar{\psi}\gamma_\mu \overleftrightarrow{\nabla}_\nu \psi + \bar{\psi}\gamma_\nu \overleftrightarrow{\nabla}_\mu \psi] + g_{\mu\nu}\frac{i}{2}\bar{\psi}\gamma^\lambda \overleftrightarrow{\nabla}_\lambda \psi. \tag{42}$$

For flat space, we have $e_1^0 = 0, e_1^1 = 1$, and we find the Schwinger term in the energy–momentum tensor

$$\langle [T_{00}(x), T_{00}(y)]_{ET} \rangle = \pm \frac{i}{24\pi} \partial_1^y \partial_1^y \partial_1^y \delta(x^1 - y^1). \tag{43}$$

This indeed agrees with Refs. 3–6.

V. CONCLUSION

From (17) we see that we found an elegant way to compute the Schwinger term in the gravitational constraints in two dimensions, which emphasizes its relation to the gravitational anomaly. The gravitational anomaly contributes in $4k+2 = 2,6,10,\ldots$ dimensions, and we expect that this method could be generalized to these higher dimensions. However, the calculation will become more complicated there.

Time-dependent solution for a star immersed in a background radiation

Hongya Liu[a] and Qiuyang Zhang
Department of Physics, Dalian University of Technology, Dalian, 116024, People's Republic of China

(Received 17 April 2002; accepted for publication 31 May 2002)

We study a time-dependent and spherically symmetric solution with a starlike source. We show that this solution can be interpreted as an exterior solution of a contracting star which has a decreasing temperature and is immersed in a homogenous and isotropic background radiation. Distribution of the temperature in the fields and close-to-Schwarzschild approximation of the solution are studied. By identifying the radiation with the cosmic background one, we find that the close-to-Schwarzschild approximate solution is valid in a wide range in our solar system. Possible experimental tests of the solution are discussed briefly. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1503147]

I. INTRODUCTION

It is well known that spherically symmetric sources such as stars can be modeled in the simplest way by the interior and exterior Schwarzschild solutions. But to include the radiation outside a star, more complicated solutions are required.[1] These include the Vaidya metric which uses a retarded time coordinate to describe a radiating atmosphere,[2] the metrics of Herrera and co-workers wherein spheres of matter are matched to exterior space–times,[3–5] and the metrics of Glass and Krisch which extend the Vaidya solution to include both a radiation field and a string fluid.[6] Recently, Liu and Wesson presented a new kind of solution in which the metric is time-dependent (but not of the Vaidya form) and the energy-momentum tensor is of the form of a perfect fluid for radiation plus a radial heat flow.[7] Clearly, this solution describes sources which are time-dependent and spherically symmetric. However, we wish to know specifically what kind of sources the solution represents. In this article we will show that it can describe **exterior** fields of a contracting (or expanding) star immersed in a homogenous and isotropic background radiation.

II. 4D SOLUTION DERIVED FROM 5D SOLUTIONS

Campbell's theorem says that any 4D Einstein solution with a source can be locally embedded in a 5D manifold *without* sources whose field equations in terms of the Ricci tensor are $R_{AB}=0$.[8] (Here and elsewhere lower case Greek letter run 0,123 and uppercase Latin letters run 0, 123, 4, and we use units $c=1$.) A major application of Campbell's theorem is to study embeddings of known 4D Einstein solutions in 5D Ricci flat manifolds.[9] Another application of the theorem is to generate new 4D solutions from known 5D Ricci flat solutions.[7,10] In the following we will show briefly how a new 4D solution is generated in Ref. 7. For the purpose of convenience, some of the equations and notations in Ref. 7 will be reexpressed.

In Ref. 7, Liu and Wesson presented a class of 5D solutions. This class of solutions is time-dependent in 5D and spherically symmetric in 3D with the 5D metric being

$$dS^2=B(r)dt^2-(1-\lambda t)^2[A(r)dr^2+r^2(d\theta^2+\sin^2\theta d\varphi^2)]-(1-\lambda t)^{-4}dy^2, \tag{1}$$

[a]Electronic mail: hyliu@dlut.edu.cn

where λ is a constant and the two functions B and A are determined by

$$\frac{B'}{B}=3\lambda^2 r\frac{A}{B}+\frac{A-1}{r}, \tag{2}$$

$$\frac{A'}{A}=3\lambda^2 r\frac{A}{B}-\frac{A-1}{r}, \tag{3}$$

where a prime denotes derivative with respect to r. Clearly, (2) and (3) can be solved, at least numerically, by imposing boundary conditions on $B(r)$ and $A(r)$. This 5D solution satisfies the 5D equations $R_{AB}=0$ and therefore is 5D empty. However, the 4D part of the 5D metric (1), together with the two equations (2) and (3), defines a 4D solution as shown in the following:[7]

$$ds^2=B(r)dt^2-(1-\lambda t)^2[A(r)dr^2+r^2(d\theta^2+\sin^2\theta d\varphi^2)] \quad , \tag{4}$$

$$\frac{B'}{B}=3\lambda^2 r\frac{A}{B}+\frac{A-1}{r}, \tag{5}$$

$$\frac{A'}{A}=3\lambda^2 r\frac{A}{B}-\frac{A-1}{r}, \tag{6}$$

$$8\pi G T_{\alpha\beta}\equiv G_{\alpha\beta}, \tag{7}$$

where $T_{\alpha\beta}$ is an effective or induced energy-momentum tensor with

$$8\pi G T_0^0=\frac{6\lambda^2}{B(1-\lambda t)^2}, \tag{8}$$

$$8\pi G T_1^1=8\pi G T_2^2=8\pi G T_3^3=-\frac{2\lambda^2}{B(1-\lambda t)^2}, \tag{9}$$

$$8\pi G T_0^1=\frac{\lambda B'}{AB(1-\lambda t)^3}. \tag{10}$$

It was also shown in Ref. 7 that this $T_{\alpha\beta}$ can be modeled as a perfect fluid plus a radial heat flow,

$$T_{\alpha\beta}=(\rho+p)u_\alpha u_\beta-pg_{\alpha\beta}+q_\alpha u_\beta+u_\alpha q_\beta, \tag{11}$$

where ρ is the mass density, p is the pressure, $u^\alpha=(u^0,0,0,0)$ is the four-velocity, $q^\alpha=(0,q^1,0,0)$ is the heat-flux vector, and u_α and q_α obey the orthogonality condition $q_\alpha u^\alpha=0$. Then Eqs. (8)–(10) yield

$$\rho=3p=\frac{3\lambda^2}{4\pi GB(1-\lambda t)^2}, \tag{12}$$

$$q^1=\frac{\lambda B'}{8\pi GAB^{3/2}(1-\lambda t)^3}. \tag{13}$$

Equations (4)–(13) constitute a complete set of the 4D solution, from which we see that the equation of state of the 4D fluid is $\rho=3p$, so it represents a radiation or extra-relativistic particles accompanied by a radial heat flow.

III. HEAT FLOW AND TEMPERATURE OF THE FIELDS

The induced 4D energy-momentum tensor (11) describes a thermodynamical system in which the radial heat current q_α implies a radial temperature gradient. Now we wish to calculate this temperature distribution over the fields. The generalized relativistic relation between heat current and temperature gradient can be found in Refs. 11 and 12 with

$$q^\alpha = -\kappa(T_{,\mu} - \dot{u}_\mu T)h^{\alpha\mu}, \quad \dot{u}_\mu \equiv u_{\mu;\nu}u^\nu, \tag{14}$$

where κ is the coefficient of the thermal conductivity and $h^{\alpha\mu}$ is the projection tensor,

$$h^{\alpha\beta} = u^\alpha u^\beta - g^{\alpha\beta}. \tag{15}$$

To calculate Eqs. (14), we calculate $\dot{u}_\mu$ first. With use of (4), we find the only nonvanishing $\dot{u}_\mu$ being $\dot{u}_1 = -B'/(2B)$. Furthermore, we assume $T = T(t,r)$. Then Eqs. (14) reduce to $q^0 = q^2 = q^3 = 0$ and

$$q^1 = -\frac{\kappa}{A(1-\lambda t)^2}\left(T_{,1} + \frac{B'}{2B}T\right). \tag{16}$$

Combining (13) and (16), we get

$$-\kappa\left(T_{,1} + \frac{B'}{2B}T\right) = \frac{\lambda B'}{8\pi G(1-\lambda t)B^{3/2}}. \tag{17}$$

We find that this equation can be integrated, giving an exact solution

$$\sqrt{B(r)}T(t,r) = \sqrt{B_R}T_R(t) + \frac{\lambda}{8\pi G\kappa(1-\lambda t)}\ln\frac{B_R}{B(r)}, \tag{18}$$

where R is a constant radius, and B_R and $T_R(t)$ are values of $B(r)$ and $T(t,r)$ at $r = R$, respectively. From (13) we see that $\lambda = 0$ corresponds to thermal equilibrium $q^\alpha = 0$. Then, from (18), if $\lambda = 0$, we get $\sqrt{B}T = \text{const}$. Thus we recover the conclusion that thermal equilibrium corresponds not to constant temperature, but to the redshifted temperature distribution $\sqrt{g_{00}}T = \text{const}$.[11] Generally we have $\lambda \neq 0$ and the exact solution (18) determines both the space distribution and the time variation of the temperature T over the fields.

IV. CLOSE-TO-SCHWARZSCHILD APPROXIMATION

The close-to-Schwarzschild approximation of the solution (4) was given in Ref. 7. We find that it can be reexpressed in the following form:

$$ds^2 = B(r)dt^2 - (1-\lambda t)^2[A(r)dr^2 + r^2(d\theta^2 + \sin^2\theta d\varphi^2)], \tag{19}$$

$$B = 1 - \frac{2GM}{r} + 2\lambda^2 r^2 + O(\varepsilon^3), \tag{20}$$

$$A^{-1} = 1 - \frac{2GM}{r} - \lambda^2 r^2 + O(\varepsilon^3). \tag{21}$$

Here ε is a small quantity of the order of the Newtonian potential GM/r, $O(\varepsilon^3)$ are terms of the order of ε^3 or higher, and we have assumed, for practical usage, that λr is also a small quantity of the order ε, i.e.,

$$|\lambda|r \sim GM/r \sim \varepsilon \ll 1. \tag{22}$$

To verify the accuracy of this solution, one can calculate B'/B and A'/A first, and then substitute them into the two equations (2) and (3). Thus the approximate solutions (19)–(21) are correct in the range (22), or, equivalently, in

$$GM \ll r \ll |\lambda|^{-1}. \tag{23}$$

We also conclude that (19)–(21) are accurate up to the second order of ε and give back to the Schwarzschild solution if $\lambda = 0$. So generally we can interpret the solution as an exterior solution of a starlike source. We will show, in the next section, that in a wide range in our solar system the condition (22), or, equivalently, (23), is satisfied.

Consider now the equation (12), which, by (20), reduces to

$$\rho = 3p = \frac{3\lambda^2}{4\pi G(1-\lambda t)^2}\left[1 + \frac{2GM}{r} + O(\varepsilon^2)\right]. \tag{24}$$

Here ρ and p constitute a perfect fluid with the equation of state $\rho = 3p$, implying a property for radiation or ultra-relativistic particles. From (24) we see that neglecting higher-order terms in the square bracket on the rhs of (24), the densities ρ and p are homogenous and isotropic. Thus we find that one can not interpret the fluid as a radiating atmosphere of a star such as in the Vaidya metric.[2] Apparently, we can interpret it as to describe a star immersed in a homogenous and isotropic background radiation.

The existence of the heat flow term in the energy-momentum tensor (11) implies that there must be a temperature gradient in the field and a heat interchanges between the star and the background radiation. Using (20) and (21) in (18) gives

$$\sqrt{B(r)}T(t,r) - \sqrt{B_R}T_R(t) = \frac{\lambda M}{4\pi\kappa(1-\lambda t)}\left\langle \frac{1}{r} - \frac{1}{R}\right\rangle [1 + O(\varepsilon)]. \tag{25}$$

If we choose R as the radius of the star, then in the exterior $r > R$, Eq. (25) implies that if $\lambda > 0$, then $\sqrt{B(r)}T(t,r) < \sqrt{B_R}T_R(t)$. Be aware that the thermal equilibrium corresponds to $\sqrt{B(r)}T(t,r) = \sqrt{B_R}T_R(t)$ for which there is no heat flow.[11] So we conclude that the heat flows outwards if $\lambda > 0$ and inwards if $\lambda < 0$. This agrees with the original relation (13) in which $q^1 > 0$ for $\lambda > 0$ and $q^1 < 0$ for $\lambda < 0$ since $B' > 0$ according to (20). Meanwhile, from the metric (19) and the result (24) we also see that if $\lambda > 0$, then as the time t increases, the 3D space contracts and the energy density of the outside fluid increases. All these properties are physically reasonable.

V. DISCUSSION

We have concluded in Sec. IV that the 4D solution discussed in this article can be interpreted as an exterior solution of a spherical source such as a star which has a nonzero temperature and is immersed in a homogenous and isotropic background radiation. A natural candidate for this kind of radiation is the cosmic background radiation, for which the temperature is about $T_0 \approx 2.7$ K at present days with an energy density around $\rho_b \approx 4.0 \times 10^{-13}$ erg cm^{-3}. Thus, by using (12), we determine the constant λ as

$$|\lambda|^{-1} \approx \sqrt{\frac{3c^4}{4\pi G\rho_b}} \approx 2.7 \times 10^{30} \text{ cm} \approx 1.8 \times 10^{17} \text{ AU}. \tag{26}$$

So, λ is of the order of the Hubble constant. Now we wish to know if the close-to-Schwarzschild solution given in (19)–(21) can describe our solar system. That is, we need to calculate and compare orders of the two terms GM/r and $\lambda^2 r^2$ appearing in (20) and (21). The average distance between the Sun and the nearest planet Mercury is about 0.387 AU. So, we have

$$\frac{GM_\odot}{R_{\rm Merc}c^2}\approx 2.55\times 10^{-8},\quad |\lambda|R_{\rm Merc}\approx 2\times 10^{-18}. \tag{27}$$

The average distance between the Sun and the Pluto is about 39.53 AU. So,

$$\frac{GM_\odot}{R_{\rm Pluto}c^2}\approx 2.5\times 10^{-10},\quad |\lambda|R_{\rm Pluto}\approx 2\times 10^{-16}. \tag{28}$$

Therefore, we conclude that in a wide range in our solar system, we have $|\lambda|r\ll GM/r$. So, $\lambda^2 r^2$ is of an order higher than the post-Newtonian order. This implies that the contributions of the cosmic background radiation to all of the known solar system experiments[13] are negligible. However, there may be other ways to detect possible new effects of the solution. For example, according to the time-dependent metric (19) and the value of λ in (26), the radius of the central star should be contracting or expanding, depending on whether λ is positive or negative, with a relative rate at present time being

$$\left(\frac{\dot R}{R}\right)_0 = -\lambda c\approx -3.5\times 10^{-13}\ \ {\rm yer}^{-1}\quad \text{for}\ \ \lambda>0. \tag{29}$$

It is worthwhile to study whether this kind of effect is observable.

We solve the Klein–Gordon and Dirac equations in an open cosmological universe with a partially horn topology in the presence of a time dependent magnetic field. Since the exact solution cannot be obtained explicitly for arbitrary time dependence of the field, we discuss the asymptotic behavior of the solutions with the help of the relativistic Hamilton–Jacobi equation. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1501445]

I. INTRODUCTION

During the last years a large amount of observational data has been reported showing that our universe is almost isotropic and homogeneous. The study of the structure of the cosmic microwave radiation leads us to conclude that the ratio of the total density to the critical density of the universe Ω_0 is likely to be close to one,[1–3] favoring a spatially flat Robertson–Walker metric over other topologies.

It is well known that general relativity is a local metrical theory and, therefore, the corresponding Einstein field equations do not fix the global topology of space–time and, consequently, the universe may have compact spatial sections with a nontrivial topology.[4,5] Then the observational data does not rule out the possibility that our universe possesses a hyperbolic topology.[4,6–8]

The study of cosmological models with nonstandard topologies is not new and goes back to the works by Zelmanov,[9,10] showing that, upon different coordinate transformations, spatially closed or flat sections can be transformed into hyperbolic sections and vice versa.

The line element associated with a spatially open Friedman universe has the form

$$ds^2 = a^2(\eta)[-d\eta^2 + dr^2 + \sinh^2(d\theta^2 + \sin^2\theta d\phi^2)]. \tag{1}$$

Making the coordinate transformation[5]

$$e^{-z} = \cosh r - \sinh r \cos\theta, \quad e^{-z}x = \sin\theta\cos\phi\sinh r, \quad e^{-z}y = \sin\theta\sin\phi\sinh r, \tag{2}$$

the metric (1) becomes

$$a^{-2}(\eta)ds^2 = -d\eta^2 + dz^2 + e^{-2z}(dx^2 + dy^2). \tag{3}$$

The topology is induced by identifying points periodically along x and y by $(x,y) = (x+b, y+h)$, where b and h are constant, to create a two dimensional torus. The torus is stretched by the factor e^{-2z} along the z axis to create a toroidal horn. The comoving proper area of the torus is $e^{-2z}bh$ and depends on location along the z axis. The global topology induces global inhomogeneity as well as global anisotropy.[4]

The study of quantum effects in cosmological universes with a nontrivial topology allows us a deeper understanding of the properties of different scenarios and which of them can describe our universe. In this direction the metric (3) represents a very interesting scenario in order to discuss particle production and propagation of perturbations in cosmology.

After the publication of the pioneering article by Schrödinger,[11] discussing particle production in a deSitter universe, many articles have been published on the problem of quantum effects in cosmological scenarios,[12–14] most of them dealing with a Robertson–Walker line element with spatially flat topology. This particularly simple line element, which is the most used in inflationary models, permits one to compute the Green function as well as to solve the relativistic wave equations.[15–17]

In order to study quantum processes in curved space–times one has to fulfill a preliminary step which consists in having a description of the single-mode solution of the relativistic particles or perturbations in those background fields, i.e., exact solution of the relativistic scalar and spinor wave equations. In the literature we have at our disposal different methods for solving relativistic wave equations in curved spaces and in curvilinear coordinates; among them, the method of separation of variables is one of the most widely used.[18–21]

It is the purpose of the present article to solve the Klein–Gordon and Dirac equations in the Friedman universe associated with the metric (3) in the presence of a time dependent magnetic field. In order to solve the Dirac equation we apply the algebraic method of separation of variables.[20–24] We compare the solutions with those of obtained after solving the relativistic Hamilton Jacobi equation. The article is structured as follows: In Sec. II we solve the relativistic Hamilton–Jacobi equation in an open cosmological universe with a horn topology. In Sec. III we separate variables and solve the Klein–Gordon equation. In Sec IV, using the algebraic method of separation of variables, we reduce the Dirac equation to a system of first order coupled differential equations that we solve in terms of special functions. Finally, in Sec. V we briefly discuss the results reported in this article.

II. SOLUTION OF THE HAMILTON–JACOBI EQUATION

The covariant generalization of the Hamilton–Jacobi equation has the form[25]

$$g^{\alpha\beta}\left(\frac{\partial S}{\partial x^{\alpha}}-eA_{\alpha}\right)\left(\frac{\partial S}{\partial x^{\beta}}-eA_{\beta}\right)+M^{2}=0, \tag{4}$$

where $g^{\alpha\beta}$ is the contravariant metric, A_{α} is the vector potential and M is the mass of the particle. Here and elsewhere we adopt the convention $c=\hbar=1$.

Let us introduce an electromagnetic field associated with the vector potential

$$A^{\mu}=A_{1}(y)\,\delta_{1}^{\mu}, \tag{5}$$

where the index $\mu=0$ is associated with the evolution parameter η and $\mu=1,2,3$ correspond to the space coordinates x,y,z, respectively. Looking at the relativistic invariants

$$\frac{1}{2}F^{\mu\nu}F_{\mu\nu}=B^{2}-E^{2}=\frac{e^{4z}}{\alpha(\eta)^{4}}\left(\frac{dA_{1}(y)}{dy}\right)^{2}, \tag{6}$$

$$F^{\mu\nu}F^{*}_{\mu\nu}=0, \tag{7}$$

and taking into account that only F_{23} is different from zero, we notice that (5) corresponds to a nonconstant magnetic field B, directed along the z axis, with strength

$$B=\frac{e^{2z}}{\alpha(\eta)^{2}}\left|\frac{dA_{1}(y)}{dy}\right|, \tag{8}$$

whose value is inversely proportional to the expansion factor $\alpha(\eta)^2$.

The line element (3) is a Stäckel space,[26] and the Hamilton–Jacobi equation (4) is completely separable in (3) in the presence of the vector potential (5), therefore we can look for a solution in the form

$$S=k_x+S_y(y)+S_z(z)+S_\eta(\eta). \tag{9}$$

Substituting (9) into Eq. (4) we obtain

$$\frac{(k_x-A_1(y))^2}{e^{-2z}}+\frac{1}{e^{-2z}}\left(\frac{dS_y}{dy}\right)^2+\left(\frac{dS_z}{dz}\right)^2-\left(\frac{dS_\eta}{d\eta}\right)^2-M^2\alpha(\eta)^2=0. \tag{10}$$

Equation (10) reduces to the following system of differential equations:

$$\left(\frac{dS_z}{dz}\right)^2+k_{xy}^2e^{2z}=k_z^2, \tag{11}$$

$$\left(\frac{dS_\eta}{d\eta}\right)^2+M^2\alpha(\eta)^2=k_z^2, \tag{12}$$

$$(k_x-A_1(y))^2+\left(\frac{dS_y}{dy}\right)^2=k_{xy}^2, \tag{13}$$

where k_{xy}^2 and k_z^2 are separation constants.

In the absence of electromagnetic interaction, we have that $A_1(y)=0$ and the solution of Eq. (13) takes the form

$$S_y=\pm\sqrt{k_{xy}^2-k_x^2}y=\pm k_y y, \tag{14}$$

where we have introduced the constant k_y. Equation (14) can also be derived looking at the symmetry between the torus coordinates x and y in the line element (3) and Eq. (10) when $A_1(y)=0$.

When the vector potential has the simple form $A_1(y)=A_1y$, the magnetic field reads $B=[e^{2z}/\alpha(\eta)^2]|A_1|$ and the function $S_y(y)$ is

$$S_y(y)=-\frac{k_x-A_1y}{2A_1}\sqrt{k_{xy}^2-(k_x-A_1y)^2}+\frac{k_{xy}^2}{2A_1}\arctan\frac{A_yy-k_x}{\sqrt{k_{xy}^2-(k_x-A_1y)^2}}. \tag{15}$$

The solution of Eq. (11) can be expressed in terms of elementary functions as follows:

$$S_z=\sqrt{k_z^2-k_{xy}^2\exp(2z)}-k_z\tanh^{-1}\sqrt{\frac{k_z^2-k_{xy}^2\exp(2z)}{k_z^2}}. \tag{16}$$

The solution of Eq. (12) can be written as

$$S_\eta=\pm\int\sqrt{k_z^2-M^2\alpha(\eta)^2}d\eta, \tag{17}$$

whose explicit form in terms of elementary functions will depend on a particular choice of the expansion function $\alpha(\eta)$.

Since we have been able to solve the Hamilton–Jacobi equation in the Stäckel space given by (4), we can construct the quasiclassical modes of the relativistic wave equations through the identification

$$\Phi \to e^{iS} = e^{\pm i\int \sqrt{k_z^2 - M^2\alpha(\eta)^2}\, d\eta} e^{ik_x x} e^{iS_y} e^{iS_z}, \tag{18}$$

where S_z and S_y take the following values at the asymptotes:

$$S_{z(\infty)} \to ik_{xy}e^z, \quad S_{z(-\infty)} \to k_z z, \tag{19}$$

$$S_{y(\infty)} \to \mp i \frac{(k_x - A_1 y)^2}{2A_1}. \tag{20}$$

When the electromagnetic interaction is not present we have that $S_y = \exp(ik_y y)$.

III. SOLUTION OF THE KLEIN–GORDON EQUATION

The covariant generalization of the Klein–Gordon equation in curved space–time has the form[12]

$$g^{\alpha\beta}(\nabla_\alpha - ieA_\alpha)(\nabla_\beta - ieA_\beta)\Phi - (M^2 + \xi R)\Phi = 0, \tag{21}$$

where ∇_α is the covariant derivative, R is the curvature scalar and ξ is a scalar dimensionless coupling constant which takes the value $\xi = \frac{1}{6}$ in the conformal case and $\xi = 0$ when a minimal coupling is considered. The value of the R for the metric (3) is

$$R = 6\frac{-a(\eta) + (d^2a(\eta)/d\eta^2)}{a(\eta)^3}. \tag{22}$$

Substituting the metric associated with the line element (3) into the Klein–Gordon equation (21) one obtains

$$e^{2z}\frac{\partial^2\Phi}{\partial x^2} + e^{2z}\frac{\partial^2\Phi}{\partial y^2} - 2\frac{\partial\Phi}{\partial z} + \frac{\partial^2\Phi}{\partial z^2} - 2\frac{\partial\Phi}{\partial\eta}\frac{d\alpha}{d\eta}\frac{1}{\alpha^3} - e^{2z}A_1(y)^2\Phi - 2ie^{2z}\frac{\partial\Phi}{\partial x}A_1(y) - M^2\alpha^2\Phi = 0, \tag{23}$$

where we have chosen to work with a minimal coupling $\xi = 0$. The Klein–Gordon equation (21) is completely separable in (3), therefore we look for its solution in the form

$$\Phi = H(\eta)Z(z)Y(y)e^{ik_x x}. \tag{24}$$

Substituting (24) into Eq. (21) we reduce the problem of solving the Klein–Gordon equation to that of finding solutions of the following set of ordinary differential equations

$$\frac{d^2Y}{dy^2} - ((k_x - A_1(y))^2 - k^2)Y = 0, \tag{25}$$

$$\frac{d^2Z}{dz^2} - 2\frac{dZ}{dz} - (\lambda^2 + k^2e^{2z})Z = 0, \tag{26}$$

$$\frac{d^2H}{d\eta^2} + 2\frac{dH}{d\eta}\frac{d\alpha}{d\eta} + (\alpha^2(\eta)M^2 - \lambda^2)H = 0, \tag{27}$$

with λ^2 and k^2 as separation constants. For $A(y) = A_1 y$ the solution of Eq. (25) can be expressed in terms of Whittaker functions[27] as follows:

$$Y = C_1 v^{-1/2} M_{k^2/4A_1,\,1/4}(v^2) + C_2 v^{-1/2} W_{k^2/4A_1,\,1/4}(v^2), \tag{28}$$

where

$$v=\frac{A_1 y-k_x}{\sqrt{A_1}}, \tag{29}$$

and C_1 and C_2 are arbitrary constants. In the absence of electromagnetic field the solution of Eq. (25) reduces to

$$Y=C_1 e^{\pm i\sqrt{k^2-k_x^2}y}=C_1 e^{\pm ik_y y}. \tag{30}$$

The solution of Eq. (26) is[28]

$$Z=C_3 e^z H^{(1)}_{\sqrt{1+\lambda^2}}(ike^z)+C_4 e^z H^{(2)}_{\sqrt{1+\lambda^2}}(ike^z), \tag{31}$$

where $H^{(1)}_\nu(z)$ and $H^{(2)}_\nu(z)$ are the Hankel functions and C_3 and C_4 are arbitrary constants. We can also express the solution of (26) in terms of Bessel functions $J_\nu(z)$ as

$$Z=D_3 e^z J_{\sqrt{1+\lambda^2}}(ike^z)+D_4 e^z J_{-\sqrt{1+\lambda^2}}(ike^z), \tag{32}$$

where D_3 and D_4 are arbitrary constants.

After introducing the function $h(\eta)$,

$$H(\eta)=\frac{h(\eta)}{\alpha(\eta)}, \tag{33}$$

Eq. (27) reduces to

$$\frac{d^2h}{d\eta^2}+\left(\alpha^2(\eta)M^2-\lambda^2-\frac{d^2\alpha(\eta)}{d\eta^2}\right)h=0. \tag{34}$$

In order to analyze the asymptotic behavior of the solutions of the Klein–Gordon equation (21) we make use of the asymptotic behavior of the Hankel functions,[27]

$$H^{(1)}_\nu(z)\to\left(\frac{2}{\pi z}\right)^{1/2}e^{i(z-\pi\nu/2-\pi/4)},\quad H^{(2)}_\nu(z)\to\left(\frac{2}{\pi z}\right)^{1/2}e^{-i(z-\pi\nu/2-\pi/4)}, \tag{35}$$

as $z\to\infty$, and the behavior of $J_\nu(z)$ as $z\to 0$ (Ref. 28),

$$J_\nu(z)\to\frac{\left(\frac{z}{2}\right)^\nu}{\Gamma(1+\nu)} \tag{36}$$

The asymptotic behavior of the Whittaker function $W_{k,\mu}(z)$ for large values of z is[28]

$$W_{k,\mu}(z)\to e^{-z/2}z^k, \tag{37}$$

and the function $M_{k,\mu}(z)$ has the following asymptotic behavior as $z\to 0$:

$$M_{k,\mu}(z)\to e^{-z/2}z^{\mu+(1/2)}. \tag{38}$$

An approximate solution of Eq. (34) can be obtained provided that the expansion parameter $\alpha(\eta)$ satisfies the conditions of validity of the adiabatic approximation. In this case one has that $h(\eta)$ has the form[29–31]

$$h(\eta)=\frac{1}{\sqrt{2W(\eta)}}\exp\left(\pm i\int^\eta W(\eta')d\eta'\right), \tag{39}$$

with

$$W(\eta)^2=\omega(\eta)^2[1+\delta_2(\eta)\omega^{-2}+\cdots], \tag{40}$$

where the function $\omega(\eta)$ has the form

$$\omega(\eta)^2=\alpha^2(\eta)M^2-\lambda^2-\frac{d^2\alpha(\eta)}{d\eta^2}, \tag{41}$$

$\delta_n(\eta)$ is a function of $\omega(\eta)$ and its derivatives at η up through $\omega^{(n)}(\eta)$ and $\delta_n(\eta)$ is bounded as $\omega\to\infty$. The solution of the Klein–Gordon equation (21) can be written as

$$\Phi=\frac{\exp(\pm i\int\sqrt{\alpha^2(\eta)M^2-\lambda^2-(d^2\alpha(\eta)/d\eta^2)}\,d\eta}{\sqrt{2}a(\eta)^{3/2}}Z(z)Y(y)e^{ik_xx}. \tag{42}$$

Let us analyze the asymptotic behavior of (42) as $y\to\infty$ and $z\to-\infty$. Using (19) and (36) we obtain that, when the electromagnetic interaction is switched off, the mode solutions of Eq. (21) take the asymptotic form

$$\Phi\to\frac{\exp(\pm i\int\sqrt{\alpha^2(\eta)M^2-\lambda^2-(d^2\alpha(\eta)/d\eta^2)}\,d\eta}{\sqrt{2}a(\eta)^{3/2}}e^{\mp ik_yy}e^{ik_xx}e^{(\mp\sqrt{1+\lambda^2}+1)z}. \tag{43}$$

Analogously, we have that in the presence of the electromagnetic potential the mode solutions of Eq. (21) take the following asymptotic form:

$$\Phi\to\frac{\exp(\pm i\int\sqrt{\alpha^2(\eta)M^2-\lambda^2-(d^2\alpha(\eta)/d\eta^2)}\,d\eta}{\sqrt{2}a(\eta)^{3/2}}e^{(\pm\sqrt{1+\lambda^2}+1)z}\nu^{k^2/2A_1}e^{-\nu^2/2}e^{ik_xx}. \tag{44}$$

For large positive values of z we have that the asymptotic behavior of Φ is

$$\Phi\to\frac{\exp(\pm i\int\sqrt{\alpha^2(\eta)M^2-\lambda^2-(d^2\alpha(\eta)/d\eta^2)}\,d\eta}{\sqrt{2}a(\eta)^{3/2}}e^{\mp e^{-ke^z}}e^{z/2}\nu^{k^2/2A_1}e^{-\nu^2/2}e^{ik_xx}. \tag{45}$$

From Eq. (44) we can identify the quasiclassical modes as $y\to\infty$ and $z\to-\infty$ as

$$\Phi_{\text{class}(z\to-\infty)}=\frac{h(\eta)}{\alpha(\eta)}e^zJ_{\pm\sqrt{1+\lambda^2}}(ike^z)v^{-1/2}W_{k^2/4A_1,\,1/4}(v^2)e^{ik_xx}. \tag{46}$$

Analogously, from Eq. (45) we have that the quasiclassical modes as $y\to\infty$ and $z\to\infty$ are

$$\Phi_{\text{class}(z\to\infty)}=\frac{h(\eta)}{\alpha(\eta)}e^zH^{(1,2)}_{\pm\sqrt{1+\lambda^2}}(ike^z)v^{-1/2}W_{k^2/4A_1,\,1/4}(v^2)e^{ik_xx}. \tag{47}$$

IV. SOLUTION OF THE DIRAC EQUATION

The Dirac equation is a system of coupled partial differential equations which is separable in a very restricted set of metrics. Among the space–times where the separability of the Klein–Gordon and Dirac equations has been studied one can mention the Stäckel spaces,[26] which are those metrics where the Hamilton–Jacobi equation is separable. Nevertheless, recently it has been shown that this condition is neither necessary nor sufficient in order to guarantee a complete separability of variables in the Dirac equation (see Ref. 32 and references therein). A systematic

classification of the gravitational backgrounds where the Dirac equation is separable with the help of the algebraic method is presented in Ref. 20 The line element (3) belongs to this family and, consequently, one can apply the algebraic method of separation.

The covariant generalization of the Dirac equation in curved space–time is[12,33]

$$\tilde{\gamma}^{\alpha}(\partial_{\alpha}-\Gamma_{\alpha}-ieA_{\alpha})\tilde{\Psi}+M\tilde{\Psi}=0, \tag{48}$$

where the curved Dirac matrices $\tilde{\gamma}^{\alpha}$ satisfy the commutation relation

$$\{\tilde{\gamma}^{\alpha},\tilde{\gamma}^{\beta}\}=2g^{\alpha\beta}, \tag{49}$$

and Γ_{α} are the spin connections[33]

$$\Gamma_{\alpha}=\frac{1}{4}g_{\mu\lambda}\left[\left(\frac{\partial b_{\nu}^{\beta}}{\partial x^{\alpha}}\right)a_{\beta}^{\lambda}-\Gamma_{\nu\alpha}^{\lambda}\right]s^{\mu\nu}, \tag{50}$$

where

$$s^{\mu\nu}=\tfrac{1}{2}(\tilde{\gamma}^{\mu}\tilde{\gamma}^{\nu}-\tilde{\gamma}^{\nu}\tilde{\gamma}^{\mu}), \tag{51}$$

and the matrices b_{μ}^{α}, a_{β}^{μ} establish the connection between the Dirac matrices $\tilde{\gamma}^{\mu}$ on a curved space–time and the flat Dirac matrices γ^{μ} as follows:

$$\tilde{\gamma}_{\mu}=b_{\mu}^{\alpha}\gamma_{\alpha}, \quad \tilde{\gamma}^{\mu}=a_{\beta}^{\mu}\gamma^{\beta}. \tag{52}$$

Since the line element (3) is associated with a diagonal metric, we can work in the diagonal tetrad gauge for $\tilde{\gamma}^{\mu}$:

$$\tilde{\gamma}^{0}=\frac{\gamma^{0}}{a(\eta)}, \quad \tilde{\gamma}^{1}=\frac{\gamma^{1}}{a(\eta)e^{-z}}, \quad \tilde{\gamma}^{2}=\frac{\gamma^{2}}{a(\eta)e^{-z}}, \quad \tilde{\gamma}^{3}=\frac{\gamma^{0}}{a(\eta)}. \tag{53}$$

Substituting (53) into (50) we obtain that the spinor connections are

$$\Gamma_{1}=-\frac{1}{2}\frac{e^{-z}}{\alpha(\eta)}\left\{-\alpha(\eta)\gamma^{1}\gamma^{3}+\frac{d\alpha(\eta)}{d\eta}\gamma^{1}\gamma^{4}\right\}, \tag{54}$$

$$\Gamma_{2}=-\frac{1}{2}\frac{e^{-z}}{\alpha(\eta)}\left\{-\alpha(\eta)\gamma^{2}\gamma^{3}+\frac{d\alpha(\eta)}{d\eta}\gamma^{2}\gamma^{4}\right\}, \tag{55}$$

$$\Gamma_{3}=-\frac{1}{2}\frac{d\alpha(\eta)}{d\eta}\frac{1}{\alpha(\eta)}\gamma^{3}\gamma^{4}, \quad \Gamma_{4}=0. \tag{56}$$

Substituting (53)–(56) into (48) we find that the Dirac equation takes the simple form

$$\left\{\gamma^{0}\frac{\partial}{\partial\eta}+\gamma^{1}e^{z}\left(\frac{\partial}{\partial x}-A_{1}(y)\right)+\gamma^{2}e^{z}\frac{\partial}{\partial y}+\gamma^{3}\frac{\partial}{\partial z}+M\alpha(\eta)\right\}\Psi=0, \tag{57}$$

where we have introduced the spinor Ψ,

$$\tilde{\Psi}=a(\eta)^{-3/2}e^{z}\Psi. \tag{58}$$

Regarding Eq. (57), we should mention that it does exhibit a nonfactorizable structure.[22,34] In order to solve Eq. (57) we apply the algebraic method of separation of variables.[20–24] The method consists in rewriting the Dirac equation (57) as a sum of two first order differential operators $\hat{K}_{1}$, $\hat{K}_{2}$ satisfying the relation

$$[\hat{K}_1,\hat{K}_2]_-=0, \quad \{\hat{K}_1+\hat{K}_2\}\Phi=0, \tag{59}$$

with

$$\gamma^3\gamma^0\Psi=\Phi \tag{60}$$

and

$$\hat{K}_1(x,y)\Phi=\left\{\gamma^2\frac{\partial}{\partial y}+\gamma^1\left(\frac{\partial}{\partial x}-iA_1(y)\right)\right\}\gamma^3\gamma^0\Phi=ik\Phi, \tag{61}$$

$$\hat{K}_2(z,\eta)\Phi=e^z\left\{\gamma^0\frac{\partial}{\partial\eta}+\gamma^3\frac{\partial}{\partial z}+M\alpha(\eta)\right\}\gamma^3\gamma^0\Phi=-ik\Phi. \tag{62}$$

It should be noticed that, using the pairwise scheme of separation, one has been able to reduce the problem of solving the Dirac equation to finding solutions of the decoupled system of Eqs. (61) and (62). A further problem arises when we try to separate variables in Eq. (62). Here it is not possible to reduce the problem to a set of two commuting first order differential operators. In order to separate variables in Eq. (62), we rewrite it in the following form:[22,35]

$$(\hat{L}_1\gamma^3\gamma^0+\hat{L}_2)\Phi=0, \tag{63}$$

where $\hat{L}_1$ and $\hat{L}_2$ are two commuting differential operators given by the expressions

$$\hat{L}_1=\gamma^0\frac{\partial}{\partial\eta}+M\alpha(\eta), \tag{64}$$

$$\hat{L}_2=\gamma^0\frac{\partial}{\partial z}+ike^z. \tag{65}$$

In order to separate variables in Eq. (63), we introduce the auxiliary spinor $\mathcal{Y}$,

$$(\hat{L}_1\gamma^3\gamma^0+\tilde{L}_2)\mathcal{Y}=\Phi, \tag{66}$$

where the differential operator $\tilde{L}_2$ is given by the expression

$$\tilde{L}_2=\gamma^0\frac{\partial}{\partial z}-ike^z. \tag{67}$$

Substituting (66) into (63) we obtain that $\mathcal{Y}$ satisfies the following equation:

$$\{\hat{M}_1+\hat{M}_2\}\mathcal{Y}=0, \tag{68}$$

with $[\hat{M}_1,\hat{M}_2]=0$, and

$$(\hat{M}_1+\tilde{\lambda})\mathcal{Y}=\left(-\frac{\partial^2}{\partial z^2}-i\gamma^0ke^z+k^2e^{2z}+\tilde{\lambda}\right)\mathcal{Y}=0, \tag{69}$$

$$(\hat{M}_2-\tilde{\lambda})\mathcal{Y}=\left(\frac{\partial^2}{\partial\eta^2}+\gamma^0M\frac{d\alpha(\eta)}{d\eta}+M^2\alpha^2(\eta)-\tilde{\lambda}\right)\mathcal{Y}=0, \tag{70}$$

where $\tilde{\lambda}$ is a separation constant. Introducing the new variable $u=2ke^z$, we have that Eq. (69) can be written as

$$\left(\frac{\partial^2}{\partial u^2}+\frac{i}{2u}\gamma^0-\frac{1}{4}+\left(\frac{1}{4}-\lambda\right)\frac{1}{u^2}\right)\mathcal{S}=0, \tag{71}$$

where

$$u^{-1/2}\mathcal{S}=\mathcal{Y}. \tag{72}$$

Choosing the following representation of the Dirac matrices,[36]

$$\gamma^0=\begin{pmatrix}-i & 0\\ 0 & i\end{pmatrix},\quad \gamma^j=\begin{pmatrix}0 & \sigma^j\\ \sigma^j & 0\end{pmatrix},\quad 1\leqslant j\leqslant 3, \tag{73}$$

we readily obtain that the spinor Φ has the following structure:

$$\left[\sigma_1\frac{\partial}{\partial y}-i\sigma_2(k_x-A_1(y))\right]\Phi_1=ik\Phi_2, \tag{74}$$

$$\left[-\sigma_1\frac{\partial}{\partial y}+i\sigma_2(k_x-A_1(y))\right]\Phi_2=ik\Phi_1, \tag{75}$$

$$\Phi=\begin{pmatrix}\Phi_1\\ \Phi_2\end{pmatrix}=\begin{pmatrix}\phi(y)\\ F\sigma^3\phi(y)\end{pmatrix}\exp(ik_x x), \tag{76}$$

where

$$\phi(y)=\begin{pmatrix}A(y)\\ B(y)\end{pmatrix}. \tag{77}$$

Using the representation (73) we obtain that the solution of Eq. (71) can be written in terms of Whittaker functions

$$S_{1,2}=D_1W_{-1/2,\sqrt{\lambda}}(u)+D_2M_{-1/2,\sqrt{\lambda}}(u),\quad S_{3,4}=D_3W_{1/2,\sqrt{\lambda}}(u)+D_4M_{1/2,\sqrt{\lambda}}(u), \tag{78}$$

where D_1, D_2, D_3, D_4 do not depend on the variable u. Looking at (70) and (71), we have that, for regular solutions at $u=0$, the spinor $\mathcal{Y}$ has the following structure:

$$\mathcal{Y}=\begin{pmatrix}a(y)c_1(\eta)u^{-1/2}M_{+1/2,\sqrt{\lambda}}(u)\\ b(y)c_1(\eta)u^{-1/2}M_{+1/2,\sqrt{\lambda}}(u)\\ c(y)c_2(\eta)u^{-1/2}M_{-1/2,\sqrt{\lambda}}(u)\\ d(y)c_2(\eta)u^{-1/2}M_{-1/2,\sqrt{\lambda}}(u)\end{pmatrix}\exp(ik_x x). \tag{79}$$

Substituting (79) into (66) and noticing that Eq. (70) is equivalent to the following system of equations,

$$\left(\frac{\partial}{\partial\eta}-iM\alpha(\eta)\right)c_1(\eta)=\sqrt{\tilde{\lambda}}c_2(\eta), \tag{80}$$

$$\left(\frac{\partial}{\partial\eta}+iM\alpha(\eta)\right)c_2(\eta)=\sqrt{\tilde{\lambda}}c_1(\eta), \tag{81}$$

we obtain that the spinor Φ has the following structure

$$\Phi=\begin{pmatrix} A(v)c_1(\eta)e^{-z/2}M_{-1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \\ B(v)c_1(\eta)e^{-z/2}M_{-1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \\ iA(v)c_2(\eta)e^{-z/2}M_{1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \\ -iB(v)c_2(\eta)e^{-z/2}M_{1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \end{pmatrix}\exp(ik_x x), \tag{82}$$

where $A(v)$ and $B(v)$ satisfy the system coupled system of equations

$$\left(\frac{d}{dy}-(k_x-A_1(y))\right)B=ikA, \tag{83}$$

$$\left(\frac{d}{dy}+(k_x-A_1(y))\right)A=ikB, \tag{84}$$

where v was defined in Eq. (29).

The corresponding solution of Eq. (59) in terms of the Whittaker functions $W_{k,\mu}(z)$ has the form

$$\Phi=\begin{pmatrix} \sqrt{\tilde{\lambda}}iA(v)c_1(\eta)e^{-z/2}W_{-1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \\ -i\sqrt{\tilde{\lambda}}B(v)c_1(\eta)e^{-z/2}W_{-1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \\ A(v)c_2(\eta)e^{-z/2}W_{1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \\ B(v)c_2(\eta)e^{-z/2}W_{1/2,\sqrt{\tilde{\lambda}}}(2ke^z) \end{pmatrix}\exp(ik_x x). \tag{85}$$

Let us look for solutions of the system (83) and (84) when the electromagnetic potential has the simple functional dependence $A_1(y)=A_1 y$. In this case one can obtain exact solutions for $A(v)$ and $B(v)$ in terms of hypergeometric functions. After making the change of variable (29) and using the recurrence relations[27]

$$(b-1)M(a,b-1,z)=(b-1)M(a,b,z)+z\frac{dM(a,b,z)}{dz}, \tag{86}$$

$$\frac{1}{a}\frac{dM(a,b,z)}{dz}+M(a,b,z)=M(a+1,b,z), \tag{87}$$

$$\frac{dU(a,b,z)}{dz}-U(a,b,z)=-U(a,b+1,z), \tag{88}$$

we find that the general solution of the system of equations (83) and (84) reads

$$A=\frac{\sqrt{2A_1}}{ik}e^{-(1/2)v^2}\left(C_1M\left(-\frac{k^2}{4A_1}+\frac{1}{2},\frac{1}{2},v^2\right)+C_2U\left(-\frac{k^2}{4A_1}+\frac{1}{2},\frac{1}{2},v^2\right)\right), \tag{89}$$

$$B=e^{-(1/2)v^2}v\left(C_1M\left(-\frac{k^2}{4A_1}+\frac{1}{2},\frac{3}{2},v^2\right)-C_2U\left(-\frac{k^2}{4A_1}+\frac{1}{2},\frac{3}{2},v^2\right)\right). \tag{90}$$

The exact solution of the system of equations (83) and (84) in the absence of electromagnetic interaction has the form

$$A=C_1e^{i\sqrt{k^2-k_x^2}y}+C_2e^{-i\sqrt{k^2-k_x^2}y}, \tag{91}$$

$$B=\frac{\sqrt{k^2-k_x^2}-ik_x}{k}C_1e^{i\sqrt{k^2-k_x^2}y}-\frac{\sqrt{k^2-k_x^2}+ik_x}{k}C_2e^{-i\sqrt{k^2-k_x^2}y}, \tag{92}$$

where C_1 and C_2 are arbitrary constants. The solutions of the Dirac equations (82) and (85) exhibit an asymptotic behavior which can be identified with the quasiclassical solutions of the Hamilton–Jacobi equation (4). With the help of the asymptotic expressions (38), we find that the Dirac spinor Φ as $z\to-\infty$, and $y\to\infty$ takes the form

$$\Phi_{z\to-\infty}=\begin{pmatrix} \frac{\sqrt{2A_1}}{ik}c_1(\eta) \\ -vc_1(\eta) \\ -\frac{\sqrt{2A_1}}{k}c_2(\eta) \\ ivc_2(\eta) \end{pmatrix} e^{-ke^z}e^{\sqrt{\tilde{\lambda}}z}e^{-v^2/2}v^{(k^2/2A_1)-1}\exp(ik_x x), \tag{93}$$

where the functions $c_1(\eta)$ and $c_2(\eta)$ satisfy the system of equations (80) and (81). For asymptotically large values of z we have that the spinor Φ takes the form

$$\Phi_{z\to\infty}=\begin{pmatrix} \sqrt{\tilde{\lambda}}\frac{\sqrt{2A_1}}{k}c_1(\eta)e^{-z} \\ i\sqrt{\tilde{\lambda}}vc_1(\eta)e^{-z} \\ -i2\sqrt{2A_1}c_2(\eta) \\ -2kvc_2(\eta) \end{pmatrix} e^{-ke^z}e^{-v^2/2}v^{k^2/2A_1}\exp(ik_x x). \tag{94}$$

Looking at the solution of the Hamilton–Jacobi equation, we can identify (82) and (85) as the corresponding quasiclassical modes as $z\to-\infty$ and $z\to\infty$, respectively. An approximate expression for the time dependence of the spinor Φ can be obtained with the help of the WKB approximation. In this case we obtain

$$c_2(\eta)\sim c_{10}\exp(i\omega(\eta)), \tag{95}$$

$$c_1(\eta)\sim -i\frac{c_{10}}{\omega(\eta)+M\alpha(\eta)}\exp(i\omega(\eta)), \tag{96}$$

where c_{10} is a normalization constant and $\omega(\eta)=\sqrt{iM(d\alpha/d\eta)+M^2\alpha^2-\tilde{\lambda}}$. Looking at (95), (96) and (93) we readily see that, for large values of η we obtain $c_1(\eta)\to -i[c_{10}/2M\alpha(\eta)]\exp(i\omega(\eta))$. Analytic solutions of the system of equations (95) and (96) can be obtained for some particular expansion parameter $\alpha(\eta)$.[22,35]

V. CONCLUDING REMARKS

In this article, we have solved the Klein–Gordon and Dirac equations in an open cosmological universe with partially horn topology. The solutions of the relativistic wave equations are expressed in terms of special functions. In Sec. IV we have shown that the algebraic method of separation[22–24,35] permits one a complete separation of variables of the Dirac equation in the line element associated with a horn topology. The identification of the quasiclassical modes with the help of the relativistic Hamilton–Jacobi equation shows that this method is a very useful tool in the study of quantum effects in curved spaces.

As a final remark, we should mention that the introduction of nonstandard topologies in order to describe the large scale structure of the space–time also opens new possibilities to discuss quantum effects in globally inhomogeneous and anisotropic backgrounds in the presence of nontrivial electromagnetic interactions.

A bidirectional Kaup–Kupershmidt equation and directionally dependent solitons

J. M. Dye and A. Parker[a)]
School of Mathematics and Statistics, University of Newcastle upon Tyne, NE1 7RU, United Kingdom

(Received 18 December 2001; accepted for publication 31 May 2002)

Exact multisoliton solutions are obtained for the bidirectional Kaup–Kupershmidt equation that was reported in a recent paper [J. Math. Phys. **42**, 2567 (2001)]—this fills the gap that was left in the prior study. These solutions are found to possess the same remarkable, and unusual, property as the solitary-wave solution; namely, *their wave profiles are directionally dependent*. In particular, solitons are presented which describe multiple ''head-on'' collisions between *single*- and *double*-humped solitary waves. Explicit expressions are given for the first few multisoliton solutions and a procedure is described for constucting the general N-soliton by iteration on the solitons of lower order. © *2002 American Institute of Physics.*

I. INTRODUCTION

In a recent paper,[1] we constructed two fifth-order nonlinear evolution equations (NEEs) of ''Boussinesq''-type which govern wave propagation in two opposite directions. The first of these equations can be written in the nonlocal form

$$5\partial_x^{-1}u_{tt}+5u_{xxt}-15uu_t-15u_x\partial_x^{-1}u_t-45u^2u_x+\frac{75}{2}u_xu_{xx}+15uu_{3x}-u_{5x}=0, \tag{1}$$

and may be considered a *bidirectional* version of the well-known Kaup–Kupershmidt (KK) equation[2,3]

$$u_t+45u^2u_x-\frac{75}{2}u_xu_{xx}-15uu_{3x}+u_{5x}=0. \tag{2}$$

In Ref. 1, we designated Eq. (1) the *bidirectional Kaup–Kupershmidt* (or bKK) equation—it is the main interest of the present study.

The second equation studied in Ref. 1—and of equal relevance here—is

$$5\partial_x^{-1}u_{tt}+5u_{xxt}-15uu_t-15u_x\partial_x^{-1}u_t-45u^2u_x+15u_xu_{xx}+15uu_{3x}-u_{5x}=0; \tag{3}$$

it was formulated there as a bidirectional generalization of the Sawada–Kotera (SK) equation[4,5]

$$u_t+45u^2u_x-15u_xu_{xx}-15uu_{3x}+u_{5x}=0. \tag{4}$$

By constructing its bilinear form,[1] we were able to identify the *bidirectional Sawada–Kotera* (bSK) equation (3) with the well-known Ramani equation[6] [Eq. (9)]. In this study, we shall refer to Eq. (3) as the ''bSK-Ramani'' equation so as to emphasize its *bi*directional character and genealogy with the SK equation (4) while, at the same time, signaling its equivalence to Ramani's bilinear equation (9).

The KK and SK equations (2) and (4) have been studied extensively in the literature and their complete integrability is now firmly established (see, e.g., Refs. 2 and 6–11 and Refs. 2, 4, 5, 12,

a)Author to whom correspondence should be addressed; electronic mail: allen.parker@newcastle.ac.uk

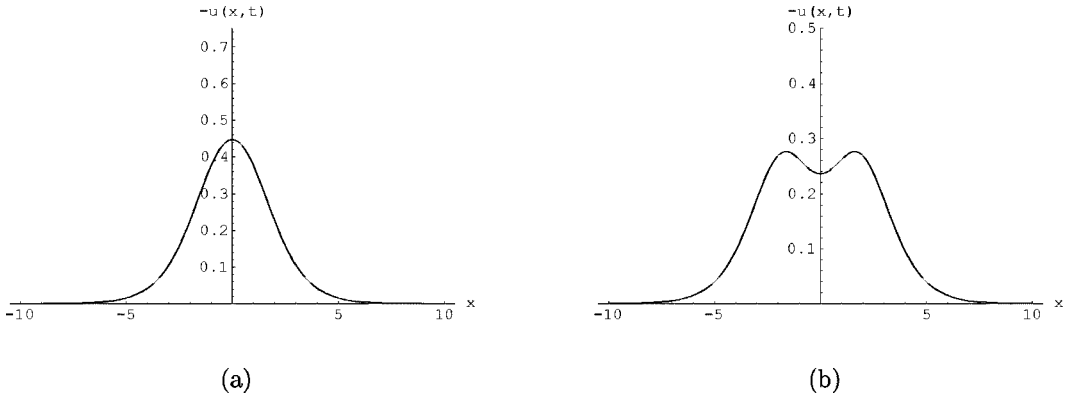

FIG. 1. Solitary-wave solutions of the bKK equation: (a) a right-traveling single-humped wave, (b) a left-traveling double-humped pulse.

and 13, respectively). Further, the intimate connection between these two *uni*directional NEEs has long been known;[2,10–12,14,15] nevertheless, Eqs. (2) and (4) are fundamentally different.[14] Indeed, the equations belong to quite distinct integrable hierarchies;[7,16] the KK Eq. (2) appears as a reduction in the so-called CKP system (KP hierarchy of C-type), while the SK Eq. (4) can be found in the BKP hierarchy.

The bSK-Ramani equation, Eq. (3), has likewise received considerable attention over the last two decades,[6,17–19] though it should be said, primarily in the guise of the bilinear form Eq. (9). However, we recently pointed to its bidirectional nature and relation to the SK Eq. (4) through the normal form (3).[1] The mathematical properties that assure the complete integrability of the bSK-Ramani equation have largely been established.[6,7,16–19] In Ref. 1 we were able to construct a Lax pair directly, along with an infinite number of conserved densities; we remark that the former associates Eq. (3) with a *fifth*-order scattering problem. In view of its connection with the SK equation, we might anticipate that the bSK-Ramani equation will also belong to the BKP hierarchy. This is indeed the case; yet, the equation appears in Ref. 16 neither in its normal form (3) nor in the form of Ramani's Eq. (9), but, rather, as the coupled bilinear form (8).

In contrast to the bSK-Ramani equation, it appears that very little of detail is known about the bKK Eq. (1). In Ref. 1 we formulated this NEE specifically as a bidirectional counterpart of the KK Eq. (2). Not surprisingly, then, the bKK equation is listed in Ref. 16 as a reduction of the CKP hierarchy and is given there in the normal form (1). The Lax pair reported by us in Ref. 1—together with an infinity of conservation laws—would seem to confirm its integrable status and, moreover, associates the bKK equation with a *fifth*-order spectral operator. Yet, arguably, the chief distinguishing property of any completely integrable equation is the existence of an infinite sequence of soliton solutions which describe the ''elastic'' interaction of multiple solitary waves.[20–23] In the previous study[1] we were able to derive the solitary wave of the bKK Eq. (1), but no further soliton solutions. This ''anomalous'' solitary wave possesses a remarkable property; namely, *its profile is dependent on the direction of travel* (see Fig. 1). This type of soliton behavior would seem to be quite unusual and, to our knowledge, had not been reported before then.

The aim of the present article is to obtain explicit multisoliton solutions of the bidirectional Kaup–Kupershmidt equation (1), and so fill the gap that was left in Ref. 1. To do so, we shall build on the results of our prior work;[1] we showed there that the ''anomalous'' character of these solitons arises quite naturally within Hirota's bilinear formalism.[24,25] Consequently, we were able to predict the structure—though not the precise analytical form—of the N-soliton solution of the bKK Eq. (1). In this regard, we will follow the strategy pursued by one of us (AP) to obtain the soliton solutions of its unidirectional cousin, the KK Eq. (2).[11] However, the current problem differs from that for the KK equation in one important respect—for the bKK equation we must additionally take account of its bidirectionality. Thus, in the case of the KK Eq. (2), one is able to

take advantage of its unidirectional character; this endows the solitons with a large measure of symmetry that facilitates the analysis greatly.[11] But, as we shall see, the soliton solutions of the bKK equation inherit the property of *directional dependence* from their constituent ''solitary'' waves. As a result, much, though by no means all, of the symmetry possessed by their unidirectional counterparts of the KK equation is lost. This makes the results for the bKK equation that much more complicated, though, by the same token, that much more interesting. This scenario differs markedly from that for its near relative, the bSK-Ramani Eq. (3). It too admits solitons which describe counter-propagating solitary waves, but its purely left- and right-traveling solitons are simply mirror images of one another! In short—and to the best of our knowledge—the directional dependence of the multisoliton solutions presented here distinguishes the bKK Eq. (1) from other bidirectional NEEs and makes it worthy of study.

Notwithstanding our comments above regarding the extra complications encountered here, the parallels with the solution procedure adopted in Ref. 11 for deriving soliton solutions of the KK equation are evident and illuminating. For example, we shall find that the analytic description of the N-soliton of the bKK equation requires the introduction of a ''new'' parameter at each order N; computing this parameter may be considered the central problem of the present work. This is quite unlike the bSK-Ramani equation whose N-soliton solution is given by Hirota's well-known *ansatz* [24] and is described by essentially a single parameter [see Eq. (10)]. We will also exploit the duality between the bKK and bSK-Ramani equations that is evident from Eqs. (1) and (3). This mirrors the deep connection between their unidirectional cousins, the KK and SK Eqs. (2) and (4), which was used to good effect in Ref. 11. We formulate the first three multisolitons of the bKK equation explicitly, and describe an iterative procedure for generating its soliton solutions to any order.

II. BILINEAR FORMS AND DIRECTIONALLY DEPENDENT SOLITARY WAVES

In the earlier study,[1] we introduced the change of dependent variable

$$u(x,t)=\alpha\partial_x^2 \ln f(x,t), \tag{5}$$

where α is a constant (and ∂_x^n denoted the nth partial derivative with respect to x). Then, following Hirota's direct method,[24,25] we showed that, under the transformation (5), the bKK Eq. (1) admits *two* possible bilinear forms:[1] with $\alpha=-1$, we obtain

$$(80\mathrm{D}_t^2+20\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f-120\mathrm{D}_x\mathrm{D}_t f\cdot g+30\mathrm{D}_x^2 f\cdot h=0, \tag{6a}$$

$$\mathrm{D}_x^2 f\cdot f+2\,f\cdot g=0, \tag{6b}$$

$$\mathrm{D}_x^4 f\cdot f+2\,f\cdot h=0, \tag{6c}$$

where the Hirota derivatives $\mathrm{D}_x,\mathrm{D}_t$ are defined by[25]

$$\mathrm{D}_x\mathrm{D}_t a(x,t)\cdot b(x,t)=(\partial_x-\partial_{x'})(\partial_t-\partial_{t'})a(x,t)b(x',t')\big|_{x'=x,\ t'=t}.$$

The second bilinear form has $\alpha=-2$ and reads

$$\begin{aligned}&4(5\mathrm{D}_t^2+5\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f-15\mathrm{D}_x^4 f\cdot g+15\mathrm{D}_x^2 f\cdot h=0,\\ &\mathrm{D}_x^2 f\cdot f+2\,f\cdot g=0,\\ &\mathrm{D}_x^4 f\cdot f+2\,f\cdot h=0.\end{aligned} \tag{7}$$

The derivations of Eqs. (6) and (7), in which $g(x,t)$ and $h(x,t)$ are auxiliary functions, can be found in Ref. 1.

Similarly, with u and f related by Eq. (5), the bSK-Ramani Eq. (3) has precisely two bilinear representations:[1] with $\alpha=-1$, we get

$$(80\mathrm{D}_t^2+20\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f+30(4\mathrm{D}_x\mathrm{D}_t-\mathrm{D}_x^4)f\cdot g=0, \tag{8a}$$

$$\mathrm{D}_x^2 f\cdot f-2\,f\cdot g=0, \tag{8b}$$

where $g(x,t)$ is again some auxiliary function. On the other hand, when $\alpha=-2$ we obtain the single bilinear equation

$$(5\mathrm{D}_t^2+5\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f=0, \tag{9}$$

which identifies the bidirectional Sawada–Kotera Eq. (3) with the eponymous Ramani equation.[6] A cursory comparison of the bilinear forms (6) and (8) (with $u=-\partial_x^2\ln f$), and, more particularly, Eqs. (7) and (9) (for which $u=-2\partial_x^2\ln f$), underlines the duality of the bKK and bSK-Ramani equations that is apparent from Eqs. (1) and (3), and will be of some importance to the analysis that follows. [We remark that the choice of transformation (5) and the admissible values $\alpha=-1$ or -2 are no accident, but derive from the deeper structural form of the solutions to Eqs. (1) and (3); see the Appendix and the further comments at the end of this section.]

Obtaining multisoliton solutions of the bSK-Ramani equation is relatively straightforward since we can choose to solve the single (Ramani) bilinear form (9), rather than the coupled system (8a) and (8b). The N-soliton solution of Eq. (9) is given by Hirota's celebrated formula[24]

$$f(x,t)=\sum_{\mu=0,1}\exp\left[\sum_{i=1}^{N}\mu_i\theta_i+\sum_{1\leqslant i<j\leqslant N}\mu_i\mu_j\ln A_{ij}\right], \tag{10}$$

where $\theta_i=p_ix+\omega_it+\eta_i$ $(i=1,\ldots,N)$ and p_i, ω_i, η_i are constant (possibly complex) parameters. In the remainder of this article we will refer to the generic expression (10) as simply the *regular* N-soliton. Significantly, it is described by essentially a single interaction coefficient, A_{ij}, that measures the mutual phase shift following the collision of the ith and jth "solitary" waves. For the bSK-Ramani equation, one easily shows that

$$A_{ij}=-\frac{5(\omega_i-\omega_j)^2+5(\omega_i-\omega_j)(p_i-p_j)^3-(p_i-p_j)^6}{5(\omega_i+\omega_j)^2+5(\omega_i+\omega_j)(p_i+p_j)^3-(p_i+p_j)^6},\quad 1\leqslant i<j\leqslant N, \tag{11}$$

where $\omega_i(p_i)$ is given by the quadratic dispersion law

$$5\omega_i^2+5\omega_ip_i^3-p_i^6=0,\quad i=1,\ldots,N. \tag{12}$$

The explicit N-soliton solution $u(x,t)$ of the bSK-Ramani Eq. (3) is then obtained from (10) and the relation $u=-2\partial_x^2\ln f$: we will say more about this solution later. For now, we note that the solitary wave is given by setting $N=1$ in Eq. (10) and leads to the familiar sech^2 pulse[1]

$$u(x,t)=-\frac{1}{2}\,p^2\,\mathrm{sech}^2\frac{1}{2}(px+\omega t+\eta). \tag{13}$$

For our part, the important feature of this solitary wave is that it propagates either to the left or right with the *same* bell-shaped profile.

For the bKK equation, however, things are not quite so simple. Neither of the two alternative bilinear forms (6) and (7) can be reduced to a single bilinear equation of the type $F(\mathrm{D}_x,\mathrm{D}_t)f\cdot f=0$, akin to Ramani's Eq. (9). We therefore have to solve one or the other of the *coupled* bilinear systems (6) or (7) for which no prescribed solution is available analagous to the Hirota ansatz (10)! In fact, we will later formulate and work with a simpler version of the bilinear form (6); but, for now, we pursue the argument set down in Ref. 1. There we were able to exploit the close connection between the bKK and bSK-Ramani equations and argued as follows: Because the

bilinear forms (8) and (9) of the bSK-Ramani equation are equivalent under the mapping $f^2 \leftrightarrow f$,[1] we can immediately infer that the N-soliton solution of the coupled system (8a) and (8b) is given by *squaring* the regular N-soliton (10). But, then, the duality of the bilinear forms (6) and (8) strongly suggests that the N-soliton solution of the bKK equation will mimic its bSK-Ramani counterpart. Applying this argument to the regular solitary wave [set $N=1$ in (10)], we find that[1]

$$f(x,t)=1+\mathrm{e}^{\theta}+\tfrac{1}{16}a^2\mathrm{e}^{2\theta}, \quad \theta=px+\omega t+\eta, \tag{14}$$

solves Eq. (6) if

$$a^2=\frac{4\omega-p^3}{\omega-p^3} \quad (a>0) \tag{15}$$

and $\omega(p)$ satisfies the (bSK-Ramani) dispersion law [Eq. (12)]

$$5\omega^2+5\omega p^3-p^6=0. \tag{16}$$

Then, using $u=-\partial_x^2 \ln f$, we obtain the ''anomalous'' solitary wave of the bKK Eq. (1),

$$u(x,t)=-ap^2\frac{a+2\cosh\theta}{(a\cosh\theta+2)^2}; \tag{17}$$

this solution was first reported by us in Ref. 1. (The detailed computations, along with the expressions for the auxiliary functions g and h, are given in Ref. 1.) The most compelling feature of the bKK solitary wave (17) is that *its profile depends on the direction of propagation*. The right-traveling solitary wave is a single-humped pulse shown in Fig. 1(a), while the left-going solitary wave has the symmetrical double-humped shape in Fig. 1(b). The left $(-)$ and right $(+)$ running waves are distinguished by solving the dispersion relation (16) for its two (real) roots

$$\omega=-\Omega_{\pm}p^3, \quad \Omega_{\pm}=\frac{1}{2}\left(1\pm\frac{3}{\sqrt{5}}\right), \tag{18}$$

which, in turn, give $a(\Omega_{\pm})=\frac{1}{2}(\sqrt{5}\pm 1)$.

Extending this reasoning to the N-soliton of the bKK Eq. (6), we postulate that it has the structure—though not the exact analytical form—of a *squared* regular soliton (10). We shall exploit this duality argument—which was formulated in Ref. 1 , but used there only to derive the solitary wave (17)—to obtain higher-order soliton solutions of the bKK equation. In short, we elect to solve the coupled bilinear form (6) rather than the alternative Eq. (7). This makes good sense for, as we show in the Appendix, the Hirota ansatz f of Eq. (6) is an *entire* function, whereas that for Eq. (7) is *not* entire.

Before proceeding, there is a further preliminary consideration which will assist our analysis. Were we to employ the bKK bilinear form (6) as it stands—as we did in the previous study[1]—the calculations very soon become prohibitively complex and unwieldy (as the order of the N-soliton increases). The reason for this is simple: just as for the solitary wave,[1] the auxiliary functions g and h in Eqs. (6b) and (6c) turn out to be irreducible quotients [and this makes the subsequent solution of the third bilinear Eq. (6a) extremely difficult, even for lower-order solitons]. More precisely, Eq. (6) is not a ''good'' bilinear form in the sense that g and h are *not* in general entire functions, notwithstanding that the ansatz f is entire (see the Appendix). This suggests that we should first recast the bilinear form (6) so that any auxiliary function is also entire. To this end, we first substitute for g and h from Eqs. (6b) and (6c) into Eq. (6a) to obtain

$$(80\mathrm{D}_t^2+20\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f+15\mathrm{D}_x^2\left[f\cdot\frac{(4\mathrm{D}_x\mathrm{D}_t-\mathrm{D}_x^4)f\cdot f}{f}\right]=0.$$

We now introduce a ''new'' auxiliary variable $\tilde{g}(x,t)$ so as to obtain the coupled equations

$$(80\mathrm{D}_t^2+20\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f+30\mathrm{D}_x^2 f\cdot\tilde{g}=0, \tag{19a}$$

$$(4\mathrm{D}_x\mathrm{D}_t-\mathrm{D}_x^4)f\cdot f-2\,f\cdot\tilde{g}=0. \tag{19b}$$

A singularity analysis of the solutions to the bKK Eq. (1) shows that the auxiliary function $\tilde{g}$ in the simplified bilinear form (19) *is* entire. (A brief outline of this Painlevé analysis is presented in the Appendix). Henceforth, we will use this ''good'' bilinear form of the bKK equation in preference to Eq. (6) as it justifies expanding $\tilde{g}$ in terms of exponentials [Eq. (27)] and leads to considerable computational simplification. The similarity of the bilinear forms (8) and (19) is striking, and provides further evidence of the duality between the bSK-Ramani and bKK equations.

III. TWO-SOLITON SOLUTION OF THE BIDIRECTIONAL KAUP–KUPERSHMIDT EQUATION

To generate the regular two-soliton solution of the bSK-Ramani equation, Eq. (9), we set $N=2$ in Eqs. (10)–(12): this gives

$$f(x,t)=1+\mathrm{e}^{\theta_1}+\mathrm{e}^{\theta_2}+A_{12}\mathrm{e}^{\theta_1+\theta_2},\quad \theta_i=p_ix+\omega_it+\eta_i,\quad i=1,2, \tag{20}$$

with ω_i satisfying the the dispersion law (12) and

$$A_{12}=-\frac{5(\omega_1-\omega_2)^2+5(\omega_1-\omega_2)(p_1-p_2)^3-(p_1-p_2)^6}{5(\omega_1+\omega_2)^2+5(\omega_1+\omega_2)(p_1+p_2)^3-(p_1+p_2)^6}. \tag{21}$$

The two-soliton solution of the bSK-Ramani Eq. (3) is then obtained via the relation $u=-2\partial_x^2\ln f$. Now, following our argument in Sec. II, the two-soliton solution of the bKK Eq. (19) mimics the structure of f^2. Accordingly, we seek a two-soliton solution of the bilinear equations (19a) and (19b) in the form

$$f(x,t)=1+\mathrm{e}^{\theta_1}+\mathrm{e}^{\theta_2}+\alpha_1\mathrm{e}^{2\theta_1}+\alpha_2\mathrm{e}^{2\theta_2}+b_{12}\mathrm{e}^{\theta_1+\theta_2}+c_1\mathrm{e}^{2\theta_1+\theta_2}+c_2\mathrm{e}^{\theta_1+2\theta_2}+B\mathrm{e}^{2(\theta_1+\theta_2)}, \tag{22}$$

where $\theta_i=p_ix+\omega_it+\eta_i$, $i=1,2$, and α_1, α_2, b_{12}, c_1, c_2 and B are constants. The expression (22) warrants further comment: to begin with, it has been *normalized* by setting the coefficients of the terms e^{θ_1} and e^{θ_2} to unity (which is always possible since η_1, η_2 are arbitrary). Further, f must be a symmetrical function of the two phase variables θ_1 and θ_2. This means that, in effect, there are just four unknown coefficients which are either symmetrical (b_{12},B) or invertible (α_i,c_i) under the transformation $(p_1,\omega_1)\leftrightarrow(p_2,\omega_2)$.

Although we could proceed to solve Eqs. (19a) and (19b) with f given by (22), some further simplification is possible. Since the bKK Eq. (1) is deemed to be completely integrable,[1] its soliton solutions should exhibit the characteristic ''elastic'' interaction property of colliding solitary waves.[21,22] If we apply this principle to (22)—which (asymptotically) separates into a pair of ''solitary'' waves—and compare the results to the bKK solitary wave (14), we find that

$$f(x,t)=1+\mathrm{e}^{\theta_1}+\mathrm{e}^{\theta_2}+\frac{1}{16}a_1^2\mathrm{e}^{2\theta_1}+\frac{1}{16}a_2^2\mathrm{e}^{2\theta_2}+b_{12}\mathrm{e}^{\theta_1+\theta_2}+\frac{A}{16}(a_1^2\mathrm{e}^{2\theta_1+\theta_2}+a_2^2\mathrm{e}^{\theta_1+2\theta_2})$$
$$+\left(\frac{A}{16}\right)^2 a_1^2a_2^2\mathrm{e}^{2(\theta_1+\theta_2)}, \tag{23}$$

where [cf. Eq. (15)]

$$a_i^2=\frac{4\omega_i-p_i^3}{\omega_i-p_i^3},\quad i=1,2, \tag{24}$$

and ω_i satisfies the (bSK-Ramani) dispersion law (12). The parameter "A" in Eq. (23) arises quite naturally in the asymptotic analysis as a measure of the post-interaction phase shifts. It therefore plays the same role in the putative bKK two-soliton (23) as the interaction coefficient "A_{12}" in the bSK-Ramani two-soliton (20). Thus, it only remains to determine the unknown parameters b_{12} and A in Eq. (23).

To proceed, we shall make use of the fundamental result[25]

$$F(\mathrm{D}_x,\mathrm{D}_t)\mathrm{e}^{\theta_1}\cdot\mathrm{e}^{\theta_2}=F(\mathbf{p}_1-\mathbf{p}_2)\mathrm{e}^{\theta_1+\theta_2},\quad \theta_i=p_ix+\omega_it+\eta_i,\quad i=1,2, \tag{25}$$

where $F(\mathrm{D}_x,\mathrm{D}_t)$is a general bilinear operator, and we write $F(\mathbf{p})=F(p,\omega)$. Then, with f given by Eq. (23), it is straightforward to show that

$$\begin{aligned}
F(\mathrm{D}_x,\mathrm{D}_t)f\cdot f=2\Bigg\{&F(\mathbf{p}_1)\mathrm{e}^{\theta_1}+F(\mathbf{p}_2)\mathrm{e}^{\theta_2}+\frac{1}{16}a_1^2F(2\mathbf{p}_1)\mathrm{e}^{2\theta_1}+\frac{1}{16}a_2^2F(2\mathbf{p}_2)\mathrm{e}^{2\theta_2}+[b_{12}F(\mathbf{p}_1+\mathbf{p}_2)\\
&+F(\mathbf{p}_1-\mathbf{p}_2)]\mathrm{e}^{\theta_1+\theta_2}+\left[\frac{1}{16}a_1^2[AF(2\mathbf{p}_1+\mathbf{p}_2)+F(2\mathbf{p}_1-\mathbf{p}_2)]+b_{12}F(\mathbf{p}_2)\right]\mathrm{e}^{2\theta_1+\theta_2}\\
&+\left[\frac{1}{16}a_2^2[AF(\mathbf{p}_1+2\mathbf{p}_2)+F(\mathbf{p}_1-2\mathbf{p}_2)]+b_{12}F(\mathbf{p}_1)\right]\mathrm{e}^{\theta_1+2\theta_2}+\frac{1}{16}a_1^2F(\mathbf{p}_1)\mathrm{e}^{3\theta_1}\\
&+\frac{1}{16}a_2^2F(\mathbf{p}_2)\mathrm{e}^{3\theta_2}+\left[\frac{1}{16}A[a_1^2F(2\mathbf{p}_1)+a_2^2F(2\mathbf{p}_2)]+\frac{1}{16^2}a_1^2a_2^2[A^2F(2\mathbf{p}_1+2\mathbf{p}_2)\right.\\
&\left.+F(2\mathbf{p}_1-2\mathbf{p}_2)]\right]\mathrm{e}^{2(\theta_1+\theta_2)}+\frac{1}{16}[AF(\mathbf{p}_1+\mathbf{p}_2)+b_{12}F(\mathbf{p}_1-\mathbf{p}_2)]\\
&\times(a_1^2\mathrm{e}^{3\theta_1+\theta_2}+a_2^2\mathrm{e}^{\theta_1+3\theta_2})+\frac{1}{16^2}a_1^4AF(\mathbf{p}_2)\mathrm{e}^{4\theta_1+\theta_2}+\frac{1}{16^2}a_2^4AF(\mathbf{p}_1)\mathrm{e}^{\theta_1+4\theta_2}\\
&+\frac{1}{16}a_1^2A\left[\frac{1}{16}a_2^2[AF(\mathbf{p}_1+2\mathbf{p}_2)+F(\mathbf{p}_1-2\mathbf{p}_2)]+b_{12}F(\mathbf{p}_1)\right]\mathrm{e}^{3\theta_1+2\theta_2}\\
&+\frac{1}{16}a_2^2A\left[\frac{1}{16}a_1^2[AF(2\mathbf{p}_1+\mathbf{p}_2)+F(2\mathbf{p}_1-\mathbf{p}_2)]+b_{12}F(\mathbf{p}_2)\right]\mathrm{e}^{2\theta_1+3\theta_2}\\
&+\frac{1}{16^3}a_1^2a_2^2A^2[a_1^2F(2\mathbf{p}_2)\mathrm{e}^{4\theta_1+2\theta_2}+a_2^2F(2\mathbf{p}_1)\mathrm{e}^{2\theta_1+4\theta_2}]\\
&+\frac{1}{16^2}a_1^2a_2^2A^2[b_{12}F(\mathbf{p}_1+\mathbf{p}_2)+F(\mathbf{p}_1-\mathbf{p}_2)]\mathrm{e}^{3(\theta_1+\theta_2)}\\
&+\frac{1}{16^3}a_1^2a_2^2A^3[a_1^2F(\mathbf{p}_2)\mathrm{e}^{4\theta_1+3\theta_2}+a_2^2F(\mathbf{p}_1)\mathrm{e}^{3\theta_1+4\theta_2}]\Bigg\}
\end{aligned} \tag{26}$$

whenever the bilinear operator F is even and $F(\mathbf{0})=0$. With the aid of (26), we are now in a position to solve the bKK bilinear form (19).

We begin by rewriting Eq. (19b) as $F_2f\cdot f=2\,f\tilde{g}$, with $F_2(\mathrm{D}_x,\mathrm{D}_t)=4\mathrm{D}_x\mathrm{D}_t-\mathrm{D}_x^4$. Now, in view of (23) and (26)—and recalling that $\tilde{g}$ is *entire*—the left and right sides of this equation will be consistent if the auxiliary function $\tilde{g}$ has the form

$$\tilde{g}=\beta_1\mathrm{e}^{\theta_1}+\beta_2\,\mathrm{e}^{\theta_2}+\mu\,\mathrm{e}^{\theta_1+\theta_2}+\nu_1\mathrm{e}^{2\theta_1+\theta_2}+\nu_2\,\mathrm{e}^{\theta_1+2\theta_2} \tag{27}$$

for some constants β_1, β_2, μ, ν_1, ν_2 [with the implied symmetry in $\mathbf{p}_1=(p_1,\omega_1)$ and $\mathbf{p}_2=(p_2,\omega_2)$]. Substituting (23), (26) (with $F\to F_2$) and (27) into Eq. (19b), and equating terms on both sides, we obtain

$$\beta_i=F_2(\mathbf{p}_i)=p_i(4\omega_i-p_i^3), \tag{28a}$$

$$\nu_1=\frac{1}{16}\,a_1^2\beta_2 A, \tag{28b}$$

$$\nu_2=\frac{1}{16}\,a_2^2\beta_1 A, \tag{28c}$$

and

$$\mu+\beta_1+\beta_2=b_{12}F_2(\mathbf{p}_1+\mathbf{p}_2)+F_2(\mathbf{p}_1-\mathbf{p}_2), \tag{29a}$$

$$\mu+A(\beta_1+\beta_2)=A\,F_2(\mathbf{p}_1+\mathbf{p}_2)+b_{12}F_2(\mathbf{p}_1-\mathbf{p}_2), \tag{29b}$$

$$\mu+\frac{1}{16}\,a_1^2\beta_2(A+1)=\frac{1}{16}\,a_1^2[AF_2(2\mathbf{p}_1+\mathbf{p}_2)+F_2(2\mathbf{p}_1-\mathbf{p}_2)]-b_{12}(\beta_1-\beta_2), \tag{29c}$$

$$\mu+\frac{1}{16}\,a_2^2\beta_1(A+1)=\frac{1}{16}\,a_2^2[AF_2(\mathbf{p}_1+2\mathbf{p}_2)+F_2(\mathbf{p}_1-2\mathbf{p}_2)]+b_{12}(\beta_1-\beta_2), \tag{29d}$$

$$\mu b_{12}+\frac{1}{8}\,A(a_1^2\beta_2+a_2^2\beta_1)=\frac{1}{16^2}\,a_1^2a_2^2[A^2F_2(2\mathbf{p}_1+2\mathbf{p}_2)+F_2(2\mathbf{p}_1-2\mathbf{p}_2)]+A(\beta_1+\beta_2), \tag{29e}$$

where a_i^2, $i=1,2$, is given in Eq. (24). Equations (29a)–(29e) are an overdetermining set of equations for the unknowns A, b_{12}, and μ which bear comparison with the corresponding set of equations obtained in[11] for the KK Eq. (2). However, rather than solve these equations directly and, at the same time, ensure their compatibility—which was the path taken in Ref. 11—we will follow a different route here and consider next the bilinear equation (19a).

We substitute for f and $\tilde{g}$, Eqs. (23) and (27), into (19a) and once again use the basic results (25) (with $F=\mathrm{D}_x^2$) and (26) with $F\to F_1=80\mathrm{D}_t^2+20\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6$. This yields the further set of equations [the routine calculations—which additionally make use of the dispersion relations (12)—are omitted]

$$b_{12}F_1(\mathbf{p}_1+\mathbf{p}_2)+F_1(\mathbf{p}_1-\mathbf{p}_2)+15[\mu(p_1+p_2)^2+(\beta_1+\beta_2)(p_1-p_2)^2]=0, \tag{30a}$$

$$AF_1(\mathbf{p}_1+\mathbf{p}_2)+b_{12}F_1(\mathbf{p}_1-\mathbf{p}_2)+15[\mu(p_1-p_2)^2+A(\beta_1+\beta_2)(p_1+p_2)^2]=0, \tag{30b}$$

$$\begin{aligned}&\frac{1}{16}\,a_1^2[AF_1(2\mathbf{p}_1+\mathbf{p}_2)+F_1(2\mathbf{p}_1-\mathbf{p}_2)]+15b_{12}p_2^2(\beta_1-\beta_2)\\&\quad+15\left[\mu p_2^2+\frac{1}{16}\,a_1^2\beta_2[A(2p_1+p_2)^2+(2p_1-p_2)^2]\right]=0,\end{aligned} \tag{30c}$$

$$\begin{aligned}&\frac{1}{16}\,a_2^2[AF_1(\mathbf{p}_1+2\mathbf{p}_2)+F_1(\mathbf{p}_1-2\mathbf{p}_2)]-15b_{12}p_1^2(\beta_1-\beta_2)\\&\quad+15\left[\mu p_1^2+\frac{1}{16}\,a_2^2\beta_1[A(p_1+2p_2)^2+(p_1-2p_2)^2]\right]=0,\end{aligned} \tag{30d}$$

$$\frac{1}{16^2}a_1^2a_2^2[A^2F_1(2\mathbf{p}_1+2\mathbf{p}_2)+F_1(2\mathbf{p}_1-2\mathbf{p}_2)]+\frac{15}{2}A(a_1^2\beta_2p_1^2+a_2^2\beta_1p_2^2)=0. \tag{30e}$$

We notice that these last equations bear more than a passing resemblance to Eqs. (29a)–(29e). Ostensibly, we have ten equations for just three unknowns—they should therefore conceal a large measure of redundancy. For example, it is evident that Eqs. (29c) and (29d)—and, similarly, Eqs. (30c) and (30d)—are essentially the same equation under the symmetry requirement $\mathbf{p}_1\leftrightarrow\mathbf{p}_2$. To make further progress, we need some additional notation and results.

The key to solving the bKK equation is its duality with the bSK-Ramani equation: this intimacy is already apparent through the shared dispersion law (12) (both for the solitary wave[1] and now the two-soliton solution). To reinforce this connection, we introduce the bSK-Ramani (strictly Ramani) bilinear operator [see Eq. (9)]

$$F_{\mathrm{R}}(\mathrm{D}_x,\mathrm{D}_t)=5\mathrm{D}_t^2+5\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6, \tag{31}$$

so that the dispersion law (12) reads $F_{\mathrm{R}}(\mathbf{p}_i)=0$. The equally important interaction coefficient A_{ij}, Eq. (11), can now be written as

$$A_{ij}=-\frac{F_{\mathrm{R}}(\mathbf{p}_i-\mathbf{p}_j)}{F_{\mathrm{R}}(\mathbf{p}_i+\mathbf{p}_j)}=-\frac{D_{ij}^-}{D_{ij}},\quad 1\leqslant i<j\leqslant N, \tag{32}$$

where $D_{ij}^-(\mathbf{p}_i,\mathbf{p}_j)=D_{ij}(\mathbf{p}_i,-\mathbf{p}_j)$ and

$$D_{ij}(\mathbf{p}_i,\mathbf{p}_j)=F_{\mathrm{R}}(\mathbf{p}_i+\mathbf{p}_j)=5(\omega_i+\omega_j)^2+5(\omega_i+\omega_j)(p_i+p_j)^3-(p_i+p_j)^6. \tag{33}$$

However, with the help of the dispersion law (12), we may recast D_{ij} as

$$\begin{aligned}D_{ij}=&10\omega_i\omega_j+5\omega_ip_j(3p_i^2+3p_ip_j+p_j^2)+5\omega_jp_i(p_i^2+3p_ip_j+3p_j^2)-p_ip_j(6p_i^4+15p_i^3p_j\\&+20p_i^2p_j^2+15p_ip_j^3+6p_j^4).\end{aligned} \tag{34}$$

The dispersion relation (12)—which here effects the replacement of the terms ω_i^2 in (33)—will become indispensable to our development as it will be used repeatedly to remove powers of ω_i.

Now, since the wave numbers $p_i(i=1,2)$are entirely arbitrary—and bearing in mind the dispersion formula (18)—all our equations must remain valid under the parity transformation $\mathbf{p}_i\rightarrow-\mathbf{p}_i$. But, if we let $\mathbf{p}_2\rightarrow-\mathbf{p}_2$ in Eqs. (29a) and (30a), and combine the resulting equations with (29b) and (30b), then we readily deduce the following useful transformations:

$$\left.\begin{aligned}A&\rightarrow\frac{1}{A},&(35a)\\ b_{12}&\rightarrow\frac{1}{A}b_{12},&(35b)\\ \mu&\rightarrow\frac{1}{A}\mu,&(35c)\end{aligned}\right\}\quad\text{if}\quad\mathbf{p}_2\rightarrow-\mathbf{p}_2.$$

One immediate consequence of these results is to show that Eqs. (29a) and (29b), and also (30a) and (30b), are equivalent. This means that we have effectively reduced each of the systems (29a)–(29e) and (30a)–(30e) to three equations. We could, of course, elect to solve one of these two sets of equations for A, b_{12} and μ, and then ensure the compatibility of the other set (the approach, incidentally, adopted in Ref. 11). However, as our intention is to solve these equations as efficiently as posssible, we will solve Eqs. (29) and (30) simultaneously. Before doing so, we wish to emphasize our use of the vector argument $(\mathbf{p}_1,\mathbf{p}_2)$ for all parameters: this is essential if we are to capture the bidirectionality of the solutions that stems from the choice of ω in Eq. (18).

Eliminating μ between Eqs. (29a) and (30a), we get

$$b_{12}=\frac{60p_1p_2(\beta_1+\beta_2)-[F_1(\mathbf{p}_1-\mathbf{p}_2)+15(p_1+p_2)^2F_2(\mathbf{p}_1-\mathbf{p}_2)]}{[F_1(\mathbf{p}_1+\mathbf{p}_2)+15(p_1+p_2)^2F_2(\mathbf{p}_1+\mathbf{p}_2)]}.$$

But, if we substitute for β_i from (28a)—and note the identity $F_1(\mathbf{p})+15p^2F_2(\mathbf{p})=16F_{\mathrm{R}}(\mathbf{p})$—then we obtain the compact result

$$b_{12}=\frac{\Delta_{12}}{2D_{12}}, \tag{36}$$

where

$$\Delta_{12}=20\omega_1\omega_2+10\omega_1p_2(3p_1^2+p_2^2)+10\omega_2p_1(p_1^2+3p_2^2)-p_1p_2(12p_1^4-5p_1^2p_2^2+12p_2^4) \tag{37}$$

and D_{12} is defined in Eq. (33). The similarity between Δ_{12} and D_{12}, Eq. (34), is striking. Both are homogeneous polynomials in p_1,p_2 of total degree six [since $\omega_i\propto p_i^3$; see Eq. (18)], which implies that b_{12} is a parameter of, effectively, degree zero. The key difference is that the numerator Δ_{12} is of *odd* degree in each of the wave numbers p_i, so that $\Delta_{12}(\mathbf{p}_1,-\mathbf{p}_2)=-\Delta_{12}(\mathbf{p}_1,\mathbf{p}_2)$. Combining this with the parity transformation for b_{12}, Eq. (35b), and Eq. (36), yields [by way of Eq. (32)]

$$A=\frac{b_{12}(\mathbf{p}_1,\mathbf{p}_2)}{b_{12}(\mathbf{p}_1,-\mathbf{p}_2)}=-\frac{D_{12}^-}{D_{12}}=A_{12}. \tag{38}$$

Although it is not needed to compute f, Eq. (23), for completeness, we easily calculate the remaining unknown quantity μ: using Eqs. (28a), (29a) and (36), we find that

$$\mu=\frac{C_{12}}{2D_{12}},\quad C_{12}=\Delta_{12}F_2(\mathbf{p}_1+\mathbf{p}_2)+2D_{12}[F_2(\mathbf{p}_1-\mathbf{p}_2)-F_2(\mathbf{p}_1)-F_2(\mathbf{p}_2)]. \tag{39}$$

The numerator C_{12} is readily expanded in terms of p_1, p_2 and is (homogeneous) of total degree ten (so that μ has net degree four). Bearing in mind our earlier comments, it only remains to check that Eqs. (29c), (29e), (30c) and (30e) are satisfied identically. This is a routine exercise, although, in view of the lengthy expressions involved, it is best carried out using a symbolic manipulation program (we used Mathematica).

Combining these results with Eq. (23), we finally obtain the solution of the bKK bilinear form (19a) and (19b),

$$f(x,t)=1+\mathrm{e}^{\theta_1}+\mathrm{e}^{\theta_2}+\frac{1}{16}a_1^2\mathrm{e}^{2\theta_1}+\frac{1}{16}a_2^2\mathrm{e}^{2\theta_2}+b_{12}\mathrm{e}^{\theta_1+\theta_2}+\frac{A_{12}}{16}(a_1^2\mathrm{e}^{2\theta_1+\theta_2}+a_2^2\mathrm{e}^{\theta_1+2\theta_2})$$
$$+\left(\frac{A_{12}}{16}\right)^2a_1^2a_2^2\mathrm{e}^{2(\theta_1+\theta_2)}, \tag{40}$$

with the auxiliary function $\tilde{g}$ given by inserting (28a)–(28c), (38) and (39) into (27). The explicit two-soliton solution $u(x,t)$ of the bKK Eq. (1) follows immediately from (40) and the relation $u=-\partial_x^2\ln f$ [Eq. (5) with $\alpha=-1$]. Figures 2–4 illustrate various two-soliton interactions [where here, and in all subsequent figures, we graph the physical wave $-u(x,t)$]. Figure 2 pictures a two-soliton comprising a pair of double-humped ''solitary'' waves propagating to the left: typically, it shows the taller, faster pulse catching and then colliding with the shorter, slower solitary wave, only for each wave to emerge unscathed from the interaction (except for a phase shift). Figure 3 shows perhaps the most interesting of the bKK two-soliton interactions, the head-on collision of a pair of counter-propagating ''solitary'' waves. Here, we illustrate the case in which the right-going single-peaked pulse is taller than the left-running twin-peaked wave. Figure 4 is a perspective view (in time) of the same two-soliton solutions in which the phase shifts are clearly visible.

It is important to emphasize the difference between the two-soliton solutions of the bKK and bSK-Ramani equations. The bKK two-soliton is *directionally dependent*, a property that it inherits from the solitary wave (17). This means that there are *three* quite distinct versions of this two-

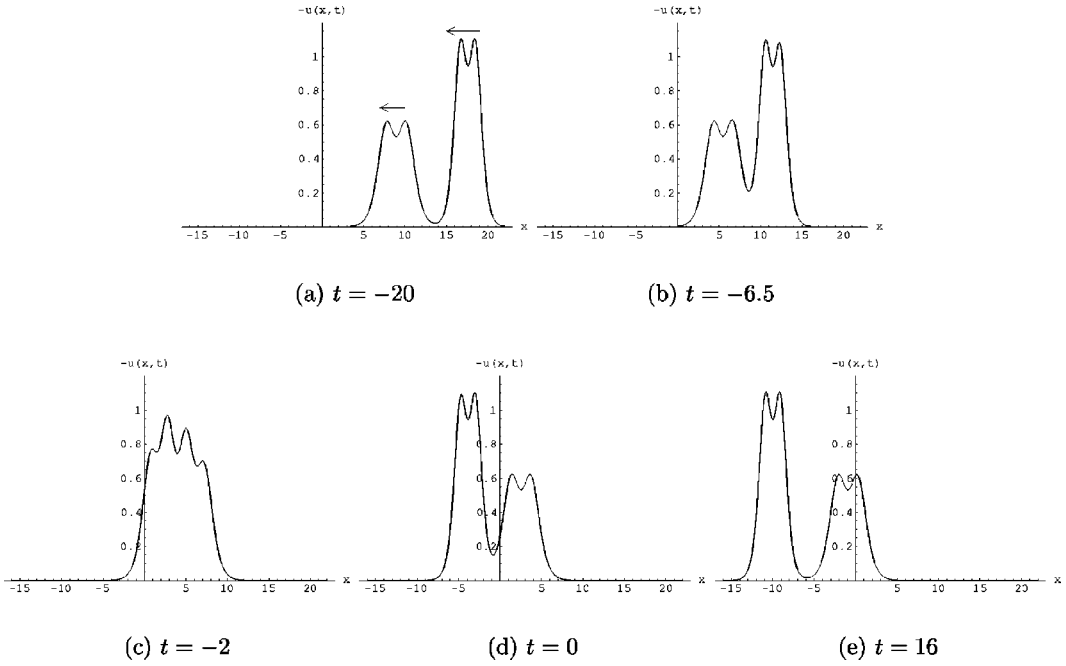

FIG. 2. A two-soliton solution of the bKK equation comprising two left-traveling double-humped solitary waves: $p_1=1.5$, $p_2=2.0$.

soliton interaction. On the other hand, the bSK-Ramani solitary wave (13) has the same sech^2 profile irrespective of its direction of travel. Consequently, the bSK-Ramani equation admits only *two* variants of the two-soliton solution because those comprised of two left-running or two right-running solitary waves are essentially mirror images of one another. To our knowledge, the

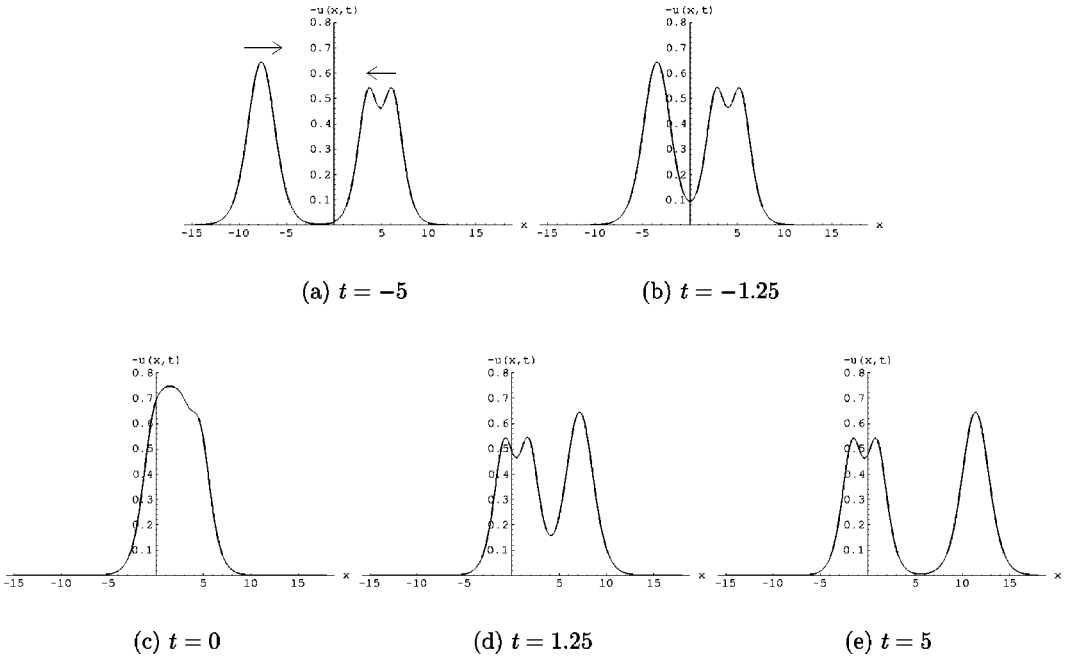

FIG. 3. A bKK two-soliton solution showing the head-on collision of a right-going single-peaked solitary wave ($p_1=1.2$) and a left-running double-peaked pulse ($p_2=1.4$).

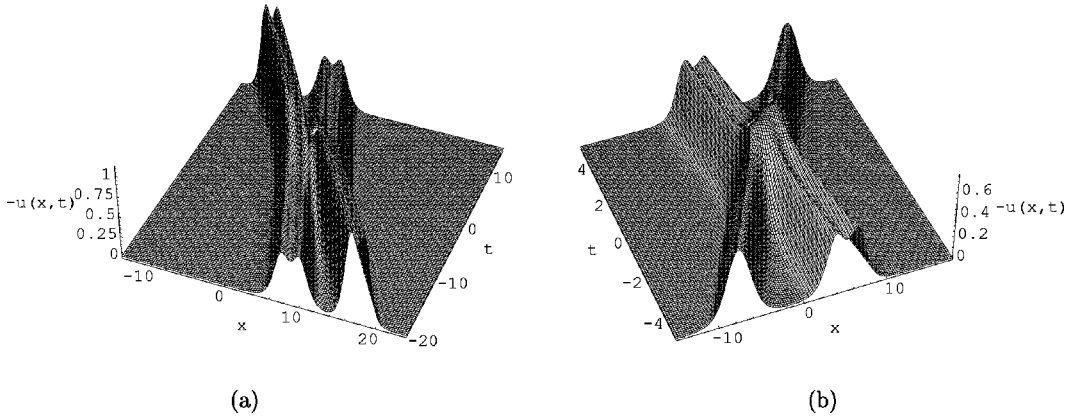

FIG. 4. Perspective views of the bKK two-soliton: (a) the interaction of two left-traveling twin-peaked solitary waves ($p_1=1.5,\ p_2=2.0$), (b) the head-on collision of a single-humped ($p_2=1.2$) and double-humped pulse ($p_2=1.4$).

directional dependence that is exhibited here by the bKK two-soliton solution has not been observed before now, and sets it apart from previously known multisoliton interactions.

The expression for f, Eq. (40), deserves further scrutiny. Equation (38) shows that the bKK and bSK-Ramani two-solitons have a common interaction coefficient, A_{12}, which underlines the duality between the equations. Thus, in spite of appearances, the solutions (20) and (40) share the same wave dynamics; in particular, their colliding solitary waves undergo identical phase shifts after separation that are completely determined by A_{12}, Eq. (21). Another notable feature of (40) is the additional parameter b_{12}, Eq. (36), that is required to formulate f explicitly (although, unlike A_{12}, it would appear to have no obvious dynamical interpretation). We stress that b_{12} is a "new" parameter in the sense that it cannot be expressed solely in terms of A_{12} [cf. the bSK-Ramani two-soliton solution (20)]. Furthermore, b_{12} is given in Eq. (36) in its simplest possible form; even so, this expression is far more complicated than its counterpart for the two-soliton of the unidirectional KK Eq. (2) (see Ref. 11). Finally, if one uses Eqs. (35a) and (35b) (with $A \to A_{12}$), it is easy to show that the two-soliton solution $u(x,t)$ is invariant under the parity transformation $\mathbf{p}_i \to -\mathbf{p}_i$ $(i=1,2)$. It follows that, without loss of generality, we need only consider wave numbers $p_i>0$.

Before we continue, it is instructive to examine the key parameter b_{12} a little more carefully. In view of the duality argument that led to the putative bKK two-soliton (22), we might conjecture that b_{12} will mimic the corresponding coefficient (of $e^{\theta_1+\theta_2}$) in the squared regular two-soliton solution of the bSK-Ramani equation. This is, in fact, the case: squaring f in Eq. (20), and normalizing, leads to

$$b_{12}^{\mathrm{R}}=\frac{1}{2}(A_{12}+1)=\frac{\Delta_{12}^{\mathrm{R}}}{2D_{12}},$$

with

$$\Delta_{12}^{\mathrm{R}}=20\omega_1\omega_2+10\omega_1 p_2(3p_1^2+p_2^2)+10\omega_2 p_1(p_1^2+3p_2^2)-p_1p_2(12p_1^4+40p_1^2p_2^2+12p_2^4).$$

Hence, the parameter b_{12} differs from b_{12}^{R} in just the $p_1^3p_2^3$ term of its numerator Δ_{12}, Eq. (37). With hindsight, we may extend the duality argument—which at present provides only the general structure of the bKK solitons—to include a more precise formulation of this key coefficient. This further insight will prove helpful when we seek bKK solitons of higher order.

IV. FURTHER SOLITON SOLUTIONS OF THE BIDIRECTIONAL KAUP–KUPERSHMIDT EQUATION

It is apparent from the results of the preceding section that we cannot write down the explicit three-soliton solution of the bKK equation—much less any higher-order solitons—based on prior knowledge of the two-soliton (40). For, unlike the (regular) N-soliton solution of the bSK-Ramani equation—which depends on a single generic parameter and is entirely predictable [Eqs. (10)–(12)]—we can expect its bKK counterpart to include an additional parameter (akin to b_{12}) at every order N. [Coincidentally, this is analogous to the structure that was found for the N-soliton solution of the related KK Eq. (2).[11]] The remainder of this study is bound up with computing this extra parameter.

A. The three-soliton solution

Our starting point is the regular three-soliton [put $N=3$ in Eq. (10)] which, after squaring and normalizing, yields the putative three-soliton solution of the bKK equation

$$\begin{aligned} f(x,t) = 1 &+ e^{\theta_1} + e^{\theta_2} + e^{\theta_3} + \frac{1}{16}(a_1^2 e^{2\theta_1} + a_2^2 e^{2\theta_2} + a_3^2 e^{2\theta_3}) + b_1 e^{\theta_1+\theta_2} + b_2 e^{\theta_1+\theta_3} + b_3 e^{\theta_2+\theta_3} \\ &+ c_1 e^{2\theta_1+\theta_2} + c_2 e^{\theta_1+2\theta_2} + c_3 e^{2\theta_1+\theta_3} + c_4 e^{\theta_1+2\theta_3} + c_5 e^{2\theta_2+\theta_3} + c_6 e^{\theta_2+2\theta_3} + b_{123} e^{\theta_1+\theta_2+\theta_3} \\ &+ d_1 e^{2(\theta_1+\theta_2)} + d_2 e^{2(\theta_1+\theta_3)} + d_3 e^{2(\theta_2+\theta_3)} + k_1 e^{2\theta_1+\theta_2+\theta_3} + k_2 e^{\theta_1+2\theta_2+\theta_3} + k_3 e^{\theta_1+\theta_2+2\theta_3} \\ &+ m_1 e^{2(\theta_1+\theta_2)+\theta_3} + m_2 e^{2\theta_1+\theta_2+2\theta_3} + m_3 e^{\theta_1+2(\theta_2+\theta_3)} + K e^{2(\theta_1+\theta_2+\theta_3)}, \end{aligned} \tag{41}$$

in which the undetermined coefficients are consonant with the symmetry in the phase variables $\theta_i = p_i x + \omega_i t + \eta_i$, $i=1, 2, 3$. Once again, we have used the requirement that (41) separates (asymptotically) into three "solitary" waves to fix the coefficients of the terms $e^{2\theta_i}$ and the dispersion laws $\omega_i(p_i)$, Eq. (12).

There are two ways we can proceed. We could attempt to solve the coupled bilinear form (19a) and (19b) for the auxiliary variable $\tilde{g}$ and the unknown coefficients in (41), just as we did for the two-soliton solution in the previous section. But this avenue will more than likely involve some extremely lengthy, possibly intractable, algebraic computation (and almost certainly prove impossible for higher-order solitons); moreover, we do not need $\tilde{g}$ in order to compute $u(x,t)$. Instead, we adopt the alternative route which proceeds by iteration on the solitons of lower order [a technique that was first presented in Ref. 11 to solve the related KK Eq. (2)]. Thus, after reducing f to a two-soliton solution—which arises (asymptotically as $t \to \pm\infty$) when the third solitary wave is well-separated from the remaining two—and comparing the results to the bKK two-soliton (40), the three-soliton (41) becomes

$$\begin{aligned} f = 1 &+ \sum_{i=1}^{3} e^{\theta_i} + \frac{1}{16}\sum_{i=1}^{3} a_i^2 e^{2\theta_i} + \sum_{1\leqslant i<j\leqslant 3} b_{ij} e^{\theta_i+\theta_j} + \frac{1}{16}\sum_{1\leqslant i<j\leqslant 3} A_{ij}(a_i^2 e^{2\theta_i+\theta_j} + a_j^2 e^{\theta_i+2\theta_j}) \\ &+ b_{123} e^{\theta_1+\theta_2+\theta_3} + \frac{1}{16^2}\sum_{1\leqslant i<j\leqslant 3} a_i^2 a_j^2 A_{ij}^2 e^{2(\theta_i+\theta_j)} + \frac{1}{16}[a_1^2 b_{23} A_{12} A_{13} e^{2\theta_1+\theta_2+\theta_3} \\ &+ a_2^2 b_{13} A_{12} A_{23} e^{\theta_1+2\theta_2+\theta_3} + a_3^2 b_{12} A_{13} A_{23} e^{\theta_1+\theta_2+2\theta_3}] + \frac{1}{16^2} A_{12} A_{13} A_{23}[a_1^2 a_2^2 A_{12} e^{2(\theta_1+\theta_2)+\theta_3} \\ &+ a_1^2 a_3^2 A_{13} e^{2\theta_1+\theta_2+2\theta_3} + a_2^2 a_3^2 A_{23} e^{\theta_1+2(\theta_2+\theta_3)}] + \frac{1}{16^3} a_1^2 a_2^2 a_3^2 A_{12}^2 A_{13}^2 A_{23}^2 e^{2(\theta_1+\theta_2+\theta_3)}, \end{aligned} \tag{42}$$

in which all but one of the coefficients have been determined [and b_{13}, b_{23} generalize b_{12}, Eq. (36), in the obvious way]. The remaining unknown coefficient b_{123} is a "new" parameter that cannot be found by reducing f to a lower-order soliton. Nevertheless, we are still able to deduce three useful reductions of b_{123} in this way:

$$b_{123}(\mathbf{p}_1,\mathbf{p}_2,\mathbf{0})=b_{12}(\mathbf{p}_1,\mathbf{p}_2), \tag{43a}$$

$$b_{123}(\mathbf{p}_1,\mathbf{0},\mathbf{0})=b_{23}(\mathbf{0},\mathbf{0}), \tag{43b}$$

$$b_{123}(\mathbf{p}_1,\mathbf{p}_2,\mathbf{p}_2)=\frac{1}{18}a_2^2A_{12}. \tag{43c}$$

Some care is required when using the first two reductions which must be interpreted in the limiting sense $\mathbf{p}_i=(p_i,\omega_i)\to\mathbf{0}$.

We now invoke the further premise that the parameter b_{123} will mimic its counterpart b_{123}^{R} in the three-soliton solution of the bSK-Ramani equation. After squaring and normalizing the regular three-soliton, Eq. (10), and extracting the coefficient of $\mathrm{e}^{\theta_1+\theta_2+\theta_3}$, we discover that

$$b_{123}^{\mathrm{R}}=\frac{1}{4}(A_{12}A_{13}A_{23}+A_{12}+A_{13}+A_{23})=\frac{\Delta_{123}^{\mathrm{R}}}{4D_{12}D_{13}D_{23}} \tag{44}$$

with

$$\begin{aligned}\Delta_{123}^{\mathrm{R}}=&-108[18\langle\langle p_i^{10}p_j^6p_k^2\rangle\rangle+60\langle\langle p_i^{10}p_j^4p_k^4\rangle\rangle+30\langle\langle p_i^8p_j^8p_k^2\rangle\rangle-20\langle\langle p_i^8p_j^6p_k^4\rangle\rangle+72\,p_1^6p_2^6p_3^6\\&-90\langle\langle\omega_ip_i^7p_j^6p_k^2\rangle\rangle-75\langle\langle\omega_ip_i^5p_j^8p_k^2\rangle\rangle-45\langle\langle\omega_ip_i^3p_j^{10}p_k^2\rangle\rangle-300\langle\langle\omega_ip_i^7p_j^4p_k^4\rangle\rangle-10\langle\langle\omega_ip_i^5p_j^6p_k^4\rangle\rangle\\&+50\langle\langle\omega_ip_i^3p_j^8p_k^4\rangle\rangle+60\langle\langle\omega_ip_i^3p_j^6p_k^6\rangle\rangle-15\langle\langle\omega_ip_ip_j^{10}p_k^4\rangle\rangle-25\langle\langle\omega_ip_ip_j^8p_k^6\rangle\rangle+225\langle\langle\omega_i\omega_jp_i^7p_j^3p_k^2\rangle\rangle\\&+75\langle\langle\omega_i\omega_jp_i^7p_jp_k^4\rangle\rangle+120\langle\langle\omega_i\omega_jp_i^5p_j^5p_k^2\rangle\rangle-200\langle\langle\omega_i\omega_jp_i^5p_j^3p_k^4\rangle\rangle+55\langle\langle\omega_i\omega_jp_i^5p_jp_k^6\rangle\rangle\\&-300\langle\langle\omega_i\omega_jp_i^3p_j^3p_k^6\rangle\rangle-50\langle\langle\omega_i\omega_jp_i^3p_jp_k^8\rangle\rangle-30\langle\langle\omega_i\omega_jp_ip_jp_k^{10}\rangle\rangle+150\langle\langle\omega_i\omega_j\omega_kp_i^7p_jp_k\rangle\rangle\\&+200\langle\langle\omega_i\omega_j\omega_kp_i^5p_j^3p_k\rangle\rangle].\end{aligned} \tag{45}$$

The symbol $\langle\langle\ \rangle\rangle$ in (45) denotes the sum over all distinct permutations of (1,2,3) assigned to the subscripts (i,j,k) of the enclosed product. The expression (45) has been simplified by using the dispersion laws (12) to remove any powers of ω_i; this is essential if we are to use b_{123}^{R} as a template for the parameter b_{123}. The derivation of $\Delta_{123}^{\mathrm{R}}$ from Eq. (44)—and its subsequent simplification—requires some lengthy (albeit routine) algebraic manipulation that is best carried out using symbolic computation. (Henceforth, we shall make use of Mathematica to perform algebraic computations whenever it is necessary or convenient, and without further mention.) We observe that [modulo the dispersion relations $\omega_i\propto p_i^3$, Eq. (18)] $\Delta_{123}^{\mathrm{R}}$ is homogeneous of total degree 18 and *even* in each of the wave numbers $p_i(i=1,2,3)$.

We therefore write

$$b_{123}=\frac{\Delta_{123}}{4D_{123}},\quad D_{123}=\prod_{1\leqslant i<j\leqslant 3}D_{ij}, \tag{46}$$

analogous to Eq. (44), and take

$$\Delta_{123}=18\langle\langle p_i^2p_j^2p_k^2(5\omega_i-2p_i^3)(5\omega_j-2p_j^3)\Delta_{ij}\rangle\rangle+H_{123}, \tag{47}$$

where

$$\begin{aligned}H_{123}=&\alpha_1\langle\langle p_i^{10}p_j^4p_k^4\rangle\rangle+\alpha_2\langle\langle p_i^8p_j^6p_k^4\rangle\rangle+\alpha_3p_1^6p_2^6p_3^6+\beta_1\langle\langle\omega_ip_i^7p_j^4p_k^4\rangle\rangle+\beta_2\langle\langle\omega_ip_i^5p_j^6p_k^4\rangle\rangle\\&+\beta_3\langle\langle\omega_ip_i^3p_j^8p_k^4\rangle\rangle+\beta_4\langle\langle\omega_ip_i^3p_j^6p_k^6\rangle\rangle+\beta_5\langle\langle\omega_ip_ip_j^{10}p_k^4\rangle\rangle+\beta_6\langle\langle\omega_ip_ip_j^8p_k^6\rangle\rangle+\gamma_1\langle\langle\omega_i\omega_jp_i^7p_jp_k^4\rangle\rangle\\&+\gamma_2\langle\langle\omega_i\omega_jp_i^5p_j^3p_k^4\rangle\rangle+\gamma_3\langle\langle\omega_i\omega_jp_i^5p_jp_k^6\rangle\rangle+\gamma_4\langle\langle\omega_i\omega_jp_i^3p_j^3p_k^6\rangle\rangle+\gamma_5\langle\langle\omega_i\omega_jp_i^3p_jp_k^8\rangle\rangle\end{aligned}$$

$$+\gamma_6\langle\!\langle \omega_i\omega_j p_i p_j p_k^{10}\rangle\!\rangle+\delta_1\langle\!\langle \omega_i\omega_j\omega_k p_i^7 p_j p_k\rangle\!\rangle+\delta_2\langle\!\langle \omega_i\omega_j\omega_k p_i^5 p_j^3 p_k\rangle\!\rangle+\delta_3\omega_1\omega_2\omega_3 p_1^3 p_2^3 p_3^3 \tag{48}$$

and Δ_{13}, Δ_{23} generalize Δ_{12}, Eq. (37). The formulation of Δ_{123} requires some further explanation. Like its counterpart $\Delta_{123}^{\mathrm{R}}$, every term in the expression (47) is *even* in each p_i and is of (total) degree 18 (recall that Δ_{ij} is odd and of degree six). This means that, just like a_i^2, A_{ij} and b_{ij}, the parameter b_{123} has effectively degree *zero*. The coefficients in the first term of Eq. (47) are fixed by virtue of the reduction (43a) (and symmetry). To see this, we let $\mathbf{p}_3\to\mathbf{0}$ in Eq. (46) and substitute the result into Eq. (43a): this shows that

$$\Delta_{123}=18p_1^2p_2^2p_3^2(5\omega_1-p_1^3)(5\omega_2-p_2^3)\Delta_{12}+O(p_3^4)\quad \text{as}\quad p_3\to 0\,, \tag{49}$$

(where we use $\omega_3\propto p_3^3$). In other words, the $\langle\!\langle\ \rangle\!\rangle$ term in (47) contains the leading order terms as $p_i\to 0$ $(i=1,2,3)$—these correspond to the terms in $\Delta_{123}^{\mathrm{R}}$, Eq. (45), of lowest degree (p_i^2) in any one of the wave numbers. [Of course, it now makes no sense to remove the ω_i^2 terms from this sum, as we did in (45).] The remaining terms in H_{123}, Eq. (48), follow directly: each term is even and of minimum degree four in each wave number, and of (total) degree 18. However, we must be sure to include in H_{123} *all* possible combinations of such product terms; these have been conveniently grouped according to type by the four sets of coefficients (α_i), (β_j), (γ_k) and (δ_m). Significantly, these terms do not duplicate exactly the terms in $\Delta_{123}^{\mathrm{R}}$ of the same type—observe that the final symmetrical term in (48) is absent from (45)! Hence, notwithstanding that we have used $\Delta_{123}^{\mathrm{R}}$ as a template, we cannot rely on it to provide all the terms that are needed to construct Δ_{123}. We shall return to the formulation of the parameter Δ_{123} later.

To determine the 18 unknown constants in (48), we proceed as follows. We first let $\mathbf{p}_2$, $\mathbf{p}_3\to\mathbf{0}$ in b_{123} and b_{23}, and make use of the second reduction (43b): to leading order, this yields

$$\alpha_1=810,\ \ \beta_1=-4050,\ \ \beta_5=1620,\ \ \gamma_1=-8100,\ \ \gamma_6=3240,\ \ \delta_1=-16200. \tag{50}$$

We now substitute the constants (50) into (47) and set $\mathbf{p}_3=\mathbf{p}_2$ in b_{123}, Eq. (46). Then, inserting the result in the final reduction (43c)—taking care to remove any powers of ω_i via the dispersion relation (12)—we obtain just ten independent equations for the remaining 12 coefficients. These can be solved in terms of two of the coefficients (we chose γ_5 and δ_3) to give

$$\begin{gathered}\alpha_2=-\frac{1}{5}\,\gamma_5,\quad \alpha_3=\frac{6}{5}\,\gamma_5+324,\quad \beta_2=\frac{1}{30}\,\delta_3+3105,\quad \beta_3=\gamma_5-\frac{1}{30}\,\delta_3-2700,\\ \beta_4=-2\,\gamma_5-\frac{1}{15}\,\delta_3-7830,\quad \beta_6=\frac{1}{30}\,\delta_3+2700,\quad \gamma_2=\gamma_5-4050,\\ \gamma_3=-\gamma_5-\frac{1}{6}\,\delta_3-12\,690,\quad \gamma_4=-2\,\gamma_5+\frac{1}{3}\,\delta_3+43\,200,\quad \delta_2=-\frac{1}{6}\,\delta_3-21\,600.\end{gathered} \tag{51}$$

Unfortunately, the reductions (43a)–(43c) are insufficient to fix all the coefficients in Δ_{123}. This scenario differs markedly from that for the sister KK Eq. (2). There, the soliton solutions possess a greater degree of symmetry so that just two reductions [comparable to Eqs. (43a) and (43c)] are needed to compute the equivalent KK parameter.[11] But for the bKK Eq. (1), much of this symmetry is lost because of the bidirectional nature of its solitons. We are therefore obliged to introduce a larger number of unknown coefficients in Δ_{123} to allow for the directional dependence of the constituent ''solitary'' waves. Regrettably, the additional unknowns cannot be matched by further soliton reductions that capture the *head-on* collisions of solitary waves. Put another way, information is wanting because we are unable to reduce a bKK soliton to one of lower order by coalescing a single-humped pulse with a double-humped solitary wave (because the latter wave profile is immutable [1]).

To complete the derivation of the three-soliton, we revert back to the bilinear form of the bKK equation, Eqs. (19a) and (19b). Fortunately, for this final step we need only take a truncated form of the ansatz (42),

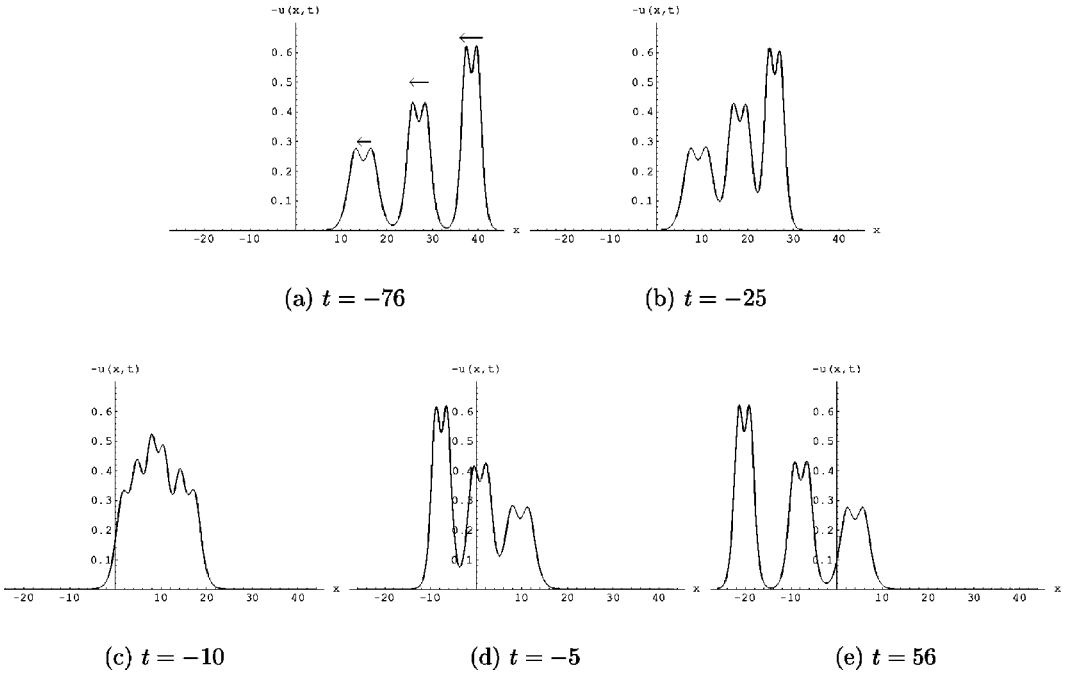

FIG. 5. A bKK three-soliton solution comprised of three left-traveling double-humped solitary waves: $p_1=1.0$, $p_2=1.25$, $p_3=1.5$.

$$\hat{f}=1+\sum_{i=1}^{3} e^{\theta_i}+\sum_{1\leqslant i<j\leqslant 3} b_{ij}e^{\theta_i+\theta_j}+b_{123}e^{\theta_1+\theta_2+\theta_3}, \tag{52}$$

since no other terms of f contribute to the $e^{\theta_1+\theta_2+\theta_3}$ terms in which the desired parameter b_{123} first appears. We substitute $\hat{f}$, and a similarly truncated expansion for $\tilde{g}$ [cf. Eq. (27)],

$$\hat{g}=\sum_{i=1}^{3} \rho_i e^{\theta_i}+\sum_{1\leqslant i<j\leqslant 3} \mu_{ij}e^{\theta_i+\theta_j}+\lambda e^{\theta_1+\theta_2+\theta_3}, \tag{53}$$

into the bilinear equations (19a) and (19b) (retaining terms only as far as $e^{\theta_1+\theta_2+\theta_3}$). The resulting equations (omitted here) are solved for b_{123} which is then equated with (46). This leads to an equation for Δ_{123} which, after substituting the expression (47) along with the known coefficients (50) and (51), is satisfied identically if

$$\gamma_5=0, \quad \delta_3=-81\,000. \tag{54}$$

Then, using Eq. (51), we get

$$\begin{gathered}\alpha_2=0, \quad \alpha_3=324, \quad \beta_2=405, \quad \beta_3=0, \quad \beta_4=-2430,\\ \beta_6=0, \quad \gamma_2=-4050, \quad \gamma_3=810, \quad \gamma_4=16\,200, \quad \delta_2=-8100,\end{gathered} \tag{55}$$

so that Δ_{123}, and hence b_{123}, is fully determined.

The derivation of f, Eq. (42), is now complete: the explicit three-soliton solution of the bKK Eq. (1) is given by $u=-\partial_x^2 \ln f$. The additional parameter b_{123} in Eq. (42) is essential to the formulation of the three-soliton solution, but it cannot be expressed solely in terms of the interaction parameters A_{12}, A_{13}, A_{23} that characterize the pairwise collisions between the three constituent ''solitary'' waves. Figures 5–7 illustrate two of the *four* possible versions of the three-

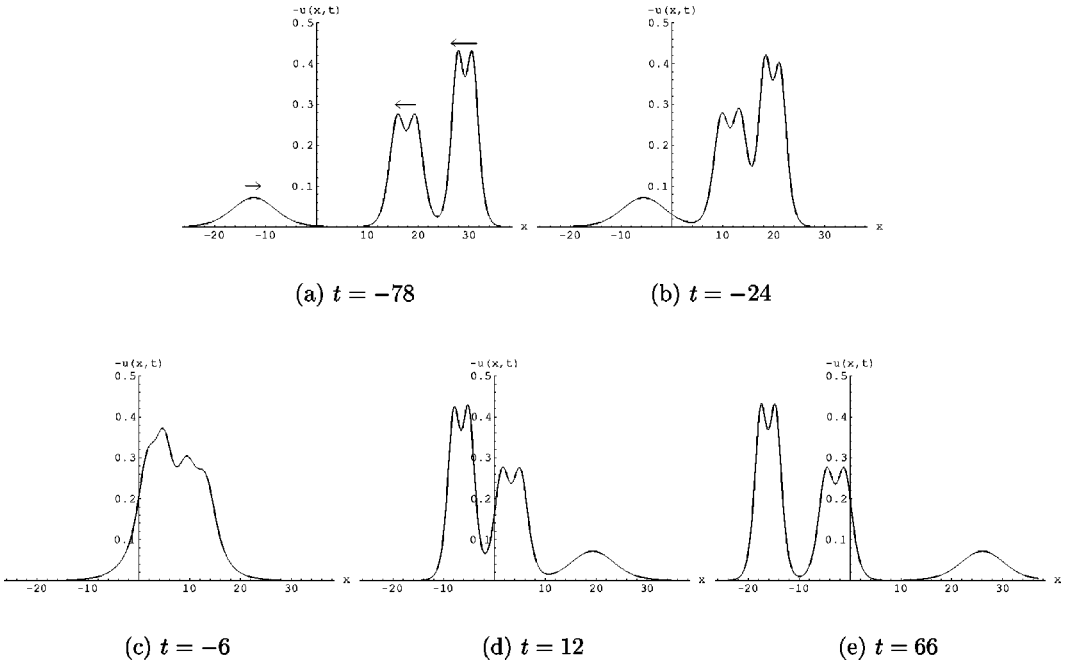

FIG. 6. A bKK three-soliton showing the head-on collision of a right-going single-peaked solitary wave ($p_1=0.4$) with a pair of left-running double-humped pulses ($p_2=1.0,\ p_3=1.25$).

soliton in both transverse and perspective views (this compares with just *two* for the bSK-Ramani equation). Figure 5 pictures a typical bKK three-soliton that consists of a triplet of double-humped ''solitary'' waves all propagating to the left. Figure 6 shows a three-soliton solution depicting the head-on interaction of a right-traveling single-peaked soliton with a counter-propagating pair of twin-peaked pulses. Figure 7 shows these same two three-solitons in perspective view—they exhibit the familiar ''elastic'' interaction property whereby the three individual solitons retain their identities, save for a cumulative phase shift.

Before we move on, let us return to the formulation of the key parameter Δ_{123}. We recall that Δ_{123} is of even degree in each $p_i\,(i=1,2,3)$, whereas Δ_{12} is odd: this is no coincidence. If we let $\mathbf{p}_3\rightarrow-\mathbf{p}_3$ in Eq. (46), and use Eq. (32), then we obtain the parity transformation

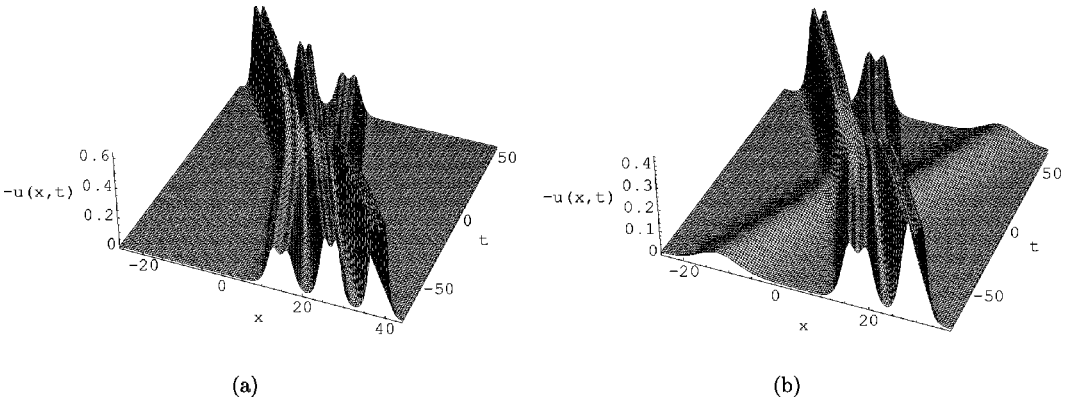

FIG. 7. Perspective views of the bKK three-soliton: (a) three left-travelling twin-peaked pulses ($p_1=1.0,\ p_2=1.25,\ p_3=1.5$), (b) the head-on interaction of a right-running single-peaked wave ($p_1=0.4$) with a pair of counter-propagating double-humped pulses ($p_2=1.0,\ p_3=1.25$).

$$b_{123}\to\frac{1}{A_{13}A_{23}}b_{123}\quad\text{if }\mathbf{p}_3\to-\mathbf{p}_3,\tag{56}$$

which should be compared with Eq. (35b) (with $A\to A_{12}$). This result ensures that, like the lower-order solitons (14) and (40), the bKK three-soliton solution $u(x,t)$ is invariant under the parity transformation $\mathbf{p}_i\to-\mathbf{p}_i(i=1,2,3)$ and we may assume that $p_i>0$, without loss of generality. But the even parity of Δ_{123} has yet a further important consequence. Barring the first (and quantifiable) term of Δ_{123}, Eq. (47), it is evident that the key term is $\langle\langle p_i^{10}p_j^4p_k^4\rangle\rangle$ in the expression for H_{123}, Eq. (48): it can be fixed by the degree and parity property of Δ_{123}. Once this *principal term* is known, the remaining terms of H_{123} follow immediately by cascading down the (even) powers of p_i and successively replacing $p_i^3\to\omega_i$ [according to the dispersion relation (18)]. It follows that we may formulate Δ_{123} without relying on its bSK-Ramani counterpart $\Delta_{123}^{\mathrm{R}}$: these observations will assist us when we seek solitons of higher order.

B. The four-soliton solution

We follow the solution strategy of the preceding section, except that now we iterate on the first three bKK solitons. Starting with a squared regular four-soliton [set $N=4$ in (10)], and applying the soliton reduction procedure (we omit the routine details), we arrive at the bKK four-soliton solution

$$\begin{aligned}
f(x,t)=1&+\sum_{i=1}^{4}\mathrm{e}^{\theta_i}+\frac{1}{16}\sum_{i=1}^{4}a_i^2\mathrm{e}^{2\theta_i}+\sum_{1\leqslant i<j\leqslant 4}b_{ij}\mathrm{e}^{\theta_i+\theta_j}+\frac{1}{16}\sum_{1\leqslant i<j\leqslant 4}A_{ij}[a_i^2\mathrm{e}^{2\theta_i+\theta_j}+a_j^2\mathrm{e}^{\theta_i+2\theta_j}]\\
&+\sum_{1\leqslant i<j<k\leqslant 4}b_{ijk}\mathrm{e}^{\theta_i+\theta_j+\theta_k}+\frac{1}{16^2}\sum_{1\leqslant i<j\leqslant 4}a_i^2a_j^2A_{ij}^2\mathrm{e}^{2(\theta_i+\theta_j)}+b_{1234}\mathrm{e}^{\theta_1+\theta_2+\theta_3+\theta_4}\\
&+\frac{1}{16}\sum_{1\leqslant i<j<k\leqslant 4}[a_i^2b_{jk}A_{ij}A_{ik}\mathrm{e}^{2\theta_i+\theta_j+\theta_k}+a_j^2b_{ik}A_{ij}A_{jk}\mathrm{e}^{\theta_i+2\theta_j+\theta_k}\\
&+a_k^2b_{ij}A_{ik}A_{jk}\mathrm{e}^{\theta_i+\theta_j+2\theta_k}]+\frac{1}{16}[a_1^2b_{234}A_{12}A_{13}A_{14}\mathrm{e}^{2\theta_1+\theta_2+\theta_3+\theta_4}\\
&+a_2^2b_{134}A_{12}A_{23}A_{24}\mathrm{e}^{\theta_1+2\theta_2+\theta_3+\theta_4}+a_3^2b_{124}A_{13}A_{23}A_{34}\mathrm{e}^{\theta_1+\theta_2+2\theta_3+\theta_4}\\
&+a_4^2b_{123}A_{14}A_{24}A_{34}\mathrm{e}^{\theta_1+\theta_2+\theta_3+2\theta_4}]+\frac{1}{16^2}\sum_{1\leqslant i<j<k\leqslant 4}A_{ij}A_{ik}A_{jk}[a_i^2a_j^2A_{ij}\mathrm{e}^{2(\theta_i+\theta_j)+\theta_k}\\
&+a_i^2a_k^2A_{ik}\mathrm{e}^{2\theta_i+\theta_j+2\theta_k}+a_j^2a_k^2A_{jk}\mathrm{e}^{\theta_i+2(\theta_j+\theta_k)}]\\
&+\frac{1}{16^2}[a_1^2a_2^2b_{34}A_{12}^2A_{13}A_{14}A_{23}A_{24}\mathrm{e}^{2(\theta_1+\theta_2)+\theta_3+\theta_4}\\
&+a_1^2a_3^2b_{24}A_{12}A_{13}^2A_{14}A_{23}A_{34}\mathrm{e}^{2\theta_1+\theta_2+2\theta_3+\theta_4}+a_1^2a_4^2b_{23}A_{12}A_{13}A_{14}^2A_{24}A_{34}\mathrm{e}^{2\theta_1+\theta_2+\theta_3+2\theta_4}\\
&+a_2^2a_3^2b_{14}A_{12}A_{13}A_{23}^2A_{24}A_{34}\mathrm{e}^{\theta_1+2(\theta_2+\theta_3)+\theta_4}+a_2^2a_4^2b_{13}A_{12}A_{14}A_{23}A_{24}^2A_{34}\mathrm{e}^{\theta_1+2\theta_2+\theta_3+2\theta_4}\\
&+a_3^2a_4^2b_{12}A_{13}A_{14}A_{23}A_{24}A_{34}^2\mathrm{e}^{\theta_1+\theta_2+2(\theta_3+\theta_4)}]\\
&+\frac{1}{16^3}\sum_{1\leqslant i<j<k\leqslant 4}a_i^2a_j^2a_k^2A_{ij}^2A_{ik}^2A_{jk}^2\mathrm{e}^{2(\theta_i+\theta_j+\theta_k)}+\frac{1}{16^3}A_{12}A_{13}A_{14}A_{23}A_{24}A_{34}\\
&\times[a_1^2a_2^2a_3^2A_{12}A_{13}A_{23}\mathrm{e}^{2(\theta_1+\theta_2+\theta_3)+\theta_4}+a_1^2a_2^2a_4^2A_{12}A_{14}A_{24}\mathrm{e}^{2(\theta_1+\theta_2)+\theta_3+2\theta_4}\\
&+a_1^2a_3^2a_4^2A_{13}A_{14}A_{34}\mathrm{e}^{2\theta_1+\theta_2+2(\theta_3+\theta_4)}+a_2^2a_3^2a_4^2A_{23}A_{24}A_{34}\mathrm{e}^{\theta_1+2(\theta_2+\theta_3+\theta_4)}]\\
&+\frac{1}{16^4}a_1^2a_2^2a_3^2a_4^2A_{12}^2A_{13}^2A_{14}^2A_{23}^2A_{24}^2A_{34}^2\mathrm{e}^{2(\theta_1+\theta_2+\theta_3+\theta_4)},
\end{aligned}\tag{57}$$

where $\theta_i = p_i x + \omega_i t + \eta_i$, $i=1,2,3,4$, and $\omega_i(p_i)$ are the usual (bSK-Ramani) dispersion laws, Eq. (12). The parameters b_{124}, b_{134}, b_{234} in (57) generalize b_{123}, Eq. (46), in the obvious manner. All but one of the coefficients in (57) have been obtained by reducing f to a three-soliton solution of the form (42)—the only remaining unknown is the "new" parameter b_{1234}. Although b_{1234} cannot be determined completely by further reducing (57) to solitons of lower order, we do obtain the reductions

$$b_{1234}(\mathbf{p}_1,\mathbf{p}_2,\mathbf{p}_3,\mathbf{0}) = b_{123}(\mathbf{p}_1,\mathbf{p}_2,\mathbf{p}_3), \tag{58a}$$

$$b_{1234}(\mathbf{p}_1,\mathbf{p}_2,\mathbf{0},\mathbf{0}) = b_{12}(\mathbf{p}_1,\mathbf{p}_2)\,b_{34}(\mathbf{0},\mathbf{0}), \tag{58b}$$

$$b_{1234}(\mathbf{p}_1,\mathbf{0},\mathbf{0},\mathbf{0}) = b_{234}(\mathbf{0},\mathbf{0},\mathbf{0}), \tag{58c}$$

$$b_{1234}(\mathbf{p}_1,\mathbf{p}_2,\mathbf{p}_3,\mathbf{p}_3) = \frac{1}{8}\,a_3^2 b_{12} A_{13} A_{23}; \tag{58d}$$

once again, the reductions (58a)–(58c) must be treated as limits ($\mathbf{p}_i \to \mathbf{0}$). In addition, we have the parity transformation [cf. Eq. (56)]

$$b_{1234} \to \frac{1}{A_{14}A_{24}A_{34}}\, b_{1234} \quad \text{if } \mathbf{p}_4 \to -\mathbf{p}_4, \tag{59}$$

which follows by virtue of the fact that p_i is arbitrary in (57) and by noting the gauge invariance of the solution $u = -\partial_x^2 \ln f$. As before, this last result ensures that the four-soliton u is parity invariant under $\mathbf{p}_i \to -\mathbf{p}_i$.

Following our observations in Sec. IV A, we can now formulate b_{1234} *without* reference to the bSK-Ramani equation. Thus, Eqs. (36) and (46) generalize to

$$b_{1234} = \frac{\Delta_{1234}}{8 D_{1234}}, \quad D_{1234} = \prod_{1 \le i < j \le 4} D_{ij}, \tag{60}$$

with D_{ij} defined in Eq. (34). It only remains to find the numerator Δ_{1234} which is homogeneous in p_i [modulo $\omega_i \propto p_i^3$, Eq. (18)] of total degree 36 (equal to that of the denominator D_{1234}). But, if we make use of the parity transformation (59), one easily shows that Δ_{1234} is of *odd* degree in each of the wave numbers p_i (as expected). From this we immediately infer that

$$\Delta_{1234} = 54 \langle\!\langle p_i^2 p_j^2 p_k^2 p_l^3 (5\omega_i - 2p_i^3)(5\omega_j - 2p_j^3)(5\omega_k - 2p_k^3)\Delta_{ijk} \rangle\!\rangle + H_{1234} \tag{61}$$

with

$$\begin{aligned}
H_{1234} = {} & \alpha_1 \langle\!\langle p_i^{15} p_j^{11} p_k^5 p_l^5 \rangle\!\rangle + \alpha_2 \langle\!\langle p_i^{15} p_j^9 p_k^7 p_l^5 \rangle\!\rangle + \alpha_3 \langle\!\langle p_i^{15} p_j^7 p_k^7 p_l^7 \rangle\!\rangle + \alpha_4 \langle\!\langle p_i^{13} p_j^{13} p_k^5 p_l^5 \rangle\!\rangle \\
& + \alpha_5 \langle\!\langle p_i^{13} p_j^{11} p_k^7 p_l^5 \rangle\!\rangle + \alpha_6 \langle\!\langle p_i^{13} p_j^9 p_k^9 p_l^5 \rangle\!\rangle + \alpha_7 \langle\!\langle p_i^{13} p_j^9 p_k^7 p_l^7 \rangle\!\rangle + \alpha_8 \langle\!\langle p_i^{11} p_j^{11} p_k^9 p_l^5 \rangle\!\rangle \\
& + \alpha_9 \langle\!\langle p_i^{11} p_j^{11} p_k^7 p_l^7 \rangle\!\rangle + \alpha_{10} \langle\!\langle p_i^{11} p_j^9 p_k^9 p_l^7 \rangle\!\rangle + \alpha_{11} p_1^9 p_2^9 p_3^9 p_4^9 + \beta_1 \langle\!\langle \omega_i p_i^{12} p_j^{11} p_k^5 p_l^5 \rangle\!\rangle \\
& + \beta_2 \langle\!\langle \omega_i p_i^{12} p_j^9 p_k^7 p_l^5 \rangle\!\rangle + \beta_3 \langle\!\langle \omega_i p_i^{12} p_j^7 p_k^7 p_l^7 \rangle\!\rangle + \beta_4 \langle\!\langle \omega_i p_i^{10} p_j^{13} p_k^5 p_l^5 \rangle\!\rangle + \beta_5 \langle\!\langle \omega_i p_i^{10} p_j^{11} p_k^7 p_l^5 \rangle\!\rangle \\
& + \beta_6 \langle\!\langle \omega_i p_i^{10} p_j^9 p_k^9 p_l^5 \rangle\!\rangle + \beta_7 \langle\!\langle \omega_i p_i^{10} p_j^9 p_k^7 p_l^7 \rangle\!\rangle + \beta_8 \langle\!\langle \omega_i p_i^8 p_j^{15} p_k^5 p_l^5 \rangle\!\rangle + \beta_9 \langle\!\langle \omega_i p_i^8 p_j^{13} p_k^7 p_l^5 \rangle\!\rangle \\
& + \beta_{10} \langle\!\langle \omega_i p_i^8 p_j^{11} p_k^9 p_l^5 \rangle\!\rangle + \beta_{11} \langle\!\langle \omega_i p_i^8 p_j^{11} p_k^7 p_l^7 \rangle\!\rangle + \beta_{12} \langle\!\langle \omega_i p_i^8 p_j^9 p_k^9 p_l^7 \rangle\!\rangle + \beta_{13} \langle\!\langle \omega_i p_i^6 p_j^{15} p_k^7 p_l^5 \rangle\!\rangle \\
& + \beta_{14} \langle\!\langle \omega_i p_i^6 p_j^{13} p_k^9 p_l^5 \rangle\!\rangle + \beta_{15} \langle\!\langle \omega_i p_i^6 p_j^{13} p_k^7 p_l^7 \rangle\!\rangle + \beta_{16} \langle\!\langle \omega_i p_i^6 p_j^{11} p_k^{11} p_l^5 \rangle\!\rangle + \beta_{17} \langle\!\langle \omega_i p_i^6 p_j^{11} p_k^9 p_l^7 \rangle\!\rangle
\end{aligned}$$

$$

\end{aligned}
$$

where the symbol $\langle\langle\ \rangle\rangle$ now denotes the sum over all distinct permutations of (1,2,3,4). The increased complexity in stepping from $N=3$ to $N=4$ is evident: the expression H_{1234} contains 123 unknown coefficients and a total of 2000 terms (whereas H_{123} has just 18 and 80, respectively). The first term of Δ_{1234}, Eq. (61), is fixed by the reduction (58a) and symmetry [in just the same way as for the three-soliton; cf. Eq. (49)]. It contains the leading order terms p_l^3 as $p_l \to 0$ ($l=1,2,3,4$); this implies that H_{1234} is comprised of products of *at least* degree five in each of the wave numbers. To determine the principal term of H_{1234} we argue as follows: Setting $\mathbf{p}_4=\mathbf{p}_3$ in Eq. (60), and using the reduction (58d), we find that

$$\Delta_{1234}\big|_{\mathbf{p}_4=\mathbf{p}_3} = 30\,p_3^3(4\omega_3 - p_3^3)\Delta_{12}D_{13}D_{23}D_{13}^{-}D_{23}^{-}. \tag{63}$$

We see that the right-hand side of Eq. (63) has a maximum degree of 15 in p_1 [refer to Eqs. (34) and (37), and recall that $D_{ij}^{-}=D_{ij}(\mathbf{p}_i,-\mathbf{p}_j)$]. But since this reduction leaves the wave number p_1 untouched, it follows that the maximum degree of *any* one of the wave numbers p_i in Δ_{1234}, and hence in H_{1234}, must also be 15. Combining this with the total degree of 36—and a minimum degree of five in each p_i—yields the principal term $\langle\langle p_i^{15}p_j^{11}p_k^5p_l^5\rangle\rangle$ (and not $\langle\langle p_i^{21}p_j^5p_k^5p_l^5\rangle\rangle$!). The remaining terms in (62) are then obtained by systematically reducing the (odd) powers of p_i and successively replacing $p_i^3 \to \omega_i$ [via the dispersion relation (18)] to accommodate the bidirectionality.

Now, letting $\mathbf{p}_3$, $\mathbf{p}_4 \to \mathbf{0}$ in b_{1234} and making use of the reduction (58b), we obtain (to leading order) the 21 coefficients

$$\begin{gathered}
\alpha_1=-2\,755\,620,\quad \alpha_4=328\,050,\quad \beta_1=15\,746\,400,\quad \beta_4=-2\,296\,350,\\
\beta_8=13\,778\,100,\quad \beta_{25}=-5\,511\,240,\quad \beta_{27}=656\,100,\quad \gamma_1=-78\,732\,000,\\
\gamma_5=31\,492\,800,\quad \gamma_7=16\,074\,450,\quad \gamma_{13}=-4\,592\,700,\quad \gamma_{23}=27\,556\,200,\\
\gamma_{40}=-11\,022\,480,\quad \gamma_{41}=1\,312\,200,\quad \delta_1=-157\,464\,000,\quad \delta_6=62\,985\,600,\\
\delta_7=32\,148\,900,\quad \delta_{15}=-9\,185\,400,\quad \delta_{24}=55\,112\,400,\\
\epsilon_1=-314\,928\,000,\quad \epsilon_4=64\,297\,800.
\end{gathered} \tag{64}$$

Next, we invoke the reduction (58c): balancing the leading order terms as p_2, p_3, $p_4 \to 0$ leads to the further 24 coefficients:

$$\begin{gathered}
\alpha_2=0,\quad \alpha_3=-1\,102\,248,\quad \beta_2=0,\quad \beta_3=6\,298\,560,\quad \beta_{13}=-1\,377\,810,\\
\beta_{19}=0,\quad \beta_{20}=8\,266\,860,\quad \beta_{26}=0,\quad \gamma_2=7\,873\,200,\quad \gamma_3=0,\\
\gamma_4=-47\,239\,200,\quad \gamma_6=0,\quad \gamma_{29}=13\,778\,100,\quad \gamma_{32}=-2\,755\,620,\\
\gamma_{35}=-55\,112\,400,\quad \gamma_{38}=0,\quad \delta_2=-78\,732\,000,\quad \delta_3=15\,746\,400,\\
\delta_4=314\,928\,000,\quad \delta_5=0,\quad \delta_{29}=27\,556\,200,\quad \delta_{30}=275\,562\,000,\\
\epsilon_2=-157\,464\,000,\quad \epsilon_3=-1\,574\,640\,000.
\end{gathered} \tag{65}$$

To obtain the remaining coefficients in H_{1234}, we first use the reduction (58d). After substituting the constants (64) and (65) into Δ_{1234}, Eq. (61), and setting $\mathbf{p}_4=\mathbf{p}_3$, we insert the result into Eq. (63) (being sure to remove any powers of ω_i as usual). This gives 69 equations (we do not list them here) which may be solved in terms of any nine of the remaining 78 unknown coefficients

(we chose β_6, β_7, β_9, β_{18}, β_{24}, β_{29}, β_{30}, γ_9 and ϵ_8). As anticipated, the reductions (58a)–(58d) are not sufficient to fix all the coefficients in H_{1234} and we therefore return to the bilinear form (19) to complete the derivation of the bKK four-soliton.

We substitute truncated expansions for f and $\tilde{g}$ [cf. Eqs. (52) and (53)]—consistent with extracting just the terms in $e^{\theta_1+\theta_2+\theta_3+\theta_4}$—into the bilinear equations (19a) and (19b). Solving for b_{1234} and equating with Eq. (60), we obtain an equation for Δ_{1234} which, after inserting (61) along with all the coefficients so far determined, is satisfied identically if

\end{gathered}
\tag{66}
$$

We reiterate that the routine (but lengthy) algebra needed to extract these coefficients has been performed with the assistance of Mathematica.

With the formulation of b_{1234}, and hence f, now complete, the four-soliton solution $u(x,t)$ of the bKK Eq. (1) follows directly from Eq. (57) and $u=-\partial_x^2 \ln f$. There are *five* variants of the four-soliton interaction, dependent on the direction of propagation of the constituent solitary waves (compared with just *three* for the bSK-Ramani equation). Several of these are illustrated in Figs. 8–11; in each case, we see that the four solitons emerge from the mutual collisions in

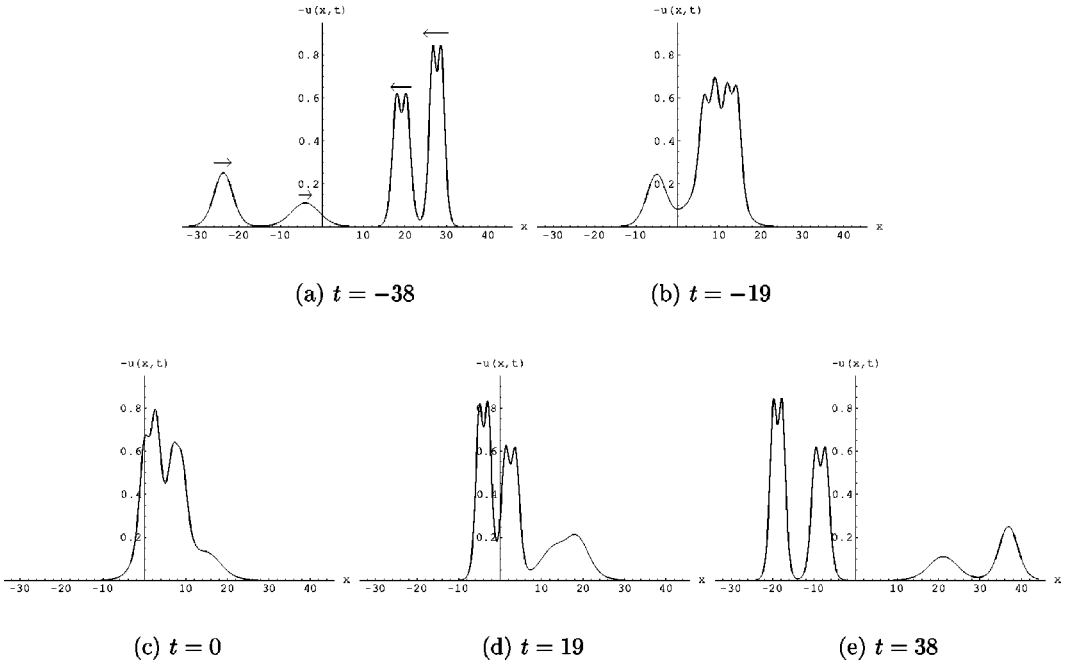

FIG. 8. A four-soliton solution of the bKK equation comprised of two right-running single-humped solitary waves ($p_1=0.5$, $p_2=0.75$) and a pair of left-going double-humped pulses ($p_3=1.5$, $p_4=1.75$).

characteristic fashion with their profiles unchanged. [Note that, because of the scaling, in Fig. 9(a) the incoming single-peaked soliton lies far to the left and so is absent; similarly in Fig. 9(e) where it is now far to the right.] Particularly noteworthy are the unusually large, almost resonantlike amplitude spikes that can be seen in Figs. 9(c) and 10(c) when at least three left-traveling double-

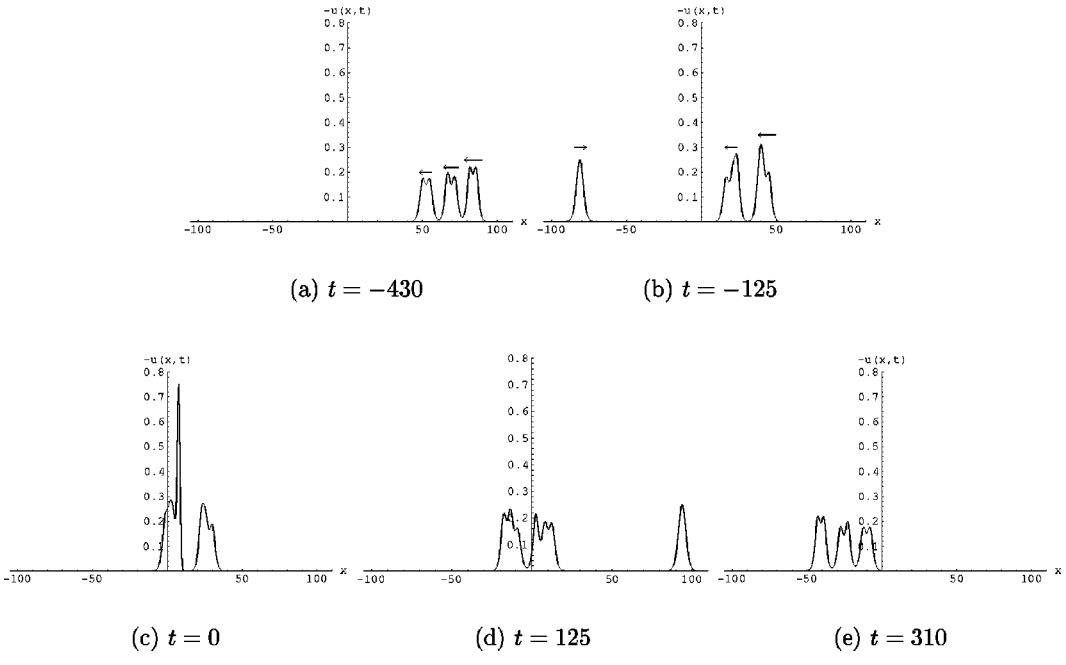

FIG. 9. A bKK four-soliton showing the head-on collision of a right-moving single-peaked pulse ($p_1=0.75$) with a triplet of left-traveling twin-peaked pulses ($p_2=0.8$, $p_3=0.85$, $p_4=0.9$).

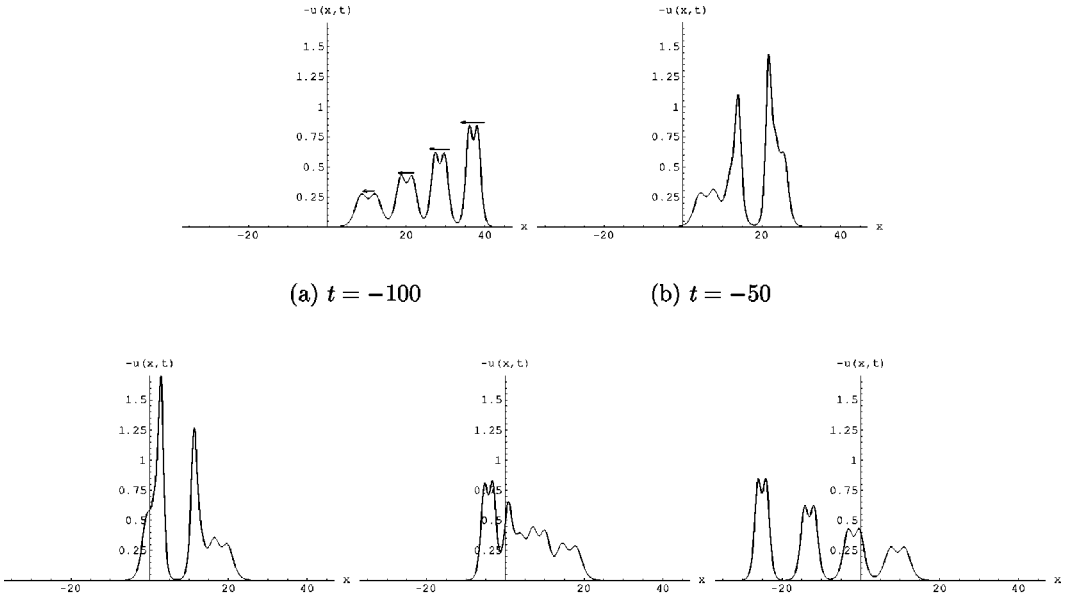

FIG. 10. A bKK four-soliton interaction comprised of four leftward propagating double-peaked solitary waves ($p_1=1.0$, $p_2=1.25$, $p_3=1.5$, $p_4=1.75$).

peaked ''solitary'' waves are present. Here we content ourselves with just two perspective views of the bKK four-soliton, Figs. 11(a) and 11(b). Bearing in mind the length and complexity of the expressions for f, Eq. (57), and its coefficients—particularly that of b_{1234}—it is clear that the computational demands of plotting these last two figures are considerable.

C. An iteration procedure for higher-order solitons

We are now in a position to outline an iterative method for constructing—at least in principle—the general N-soliton solution of the bKK equation by generalising the procedure of the preceding section for the four-soliton. Following our now well-rehearsed argument, we begin by writing down the general form of the solution. Accordingly, we square and normalize the regular

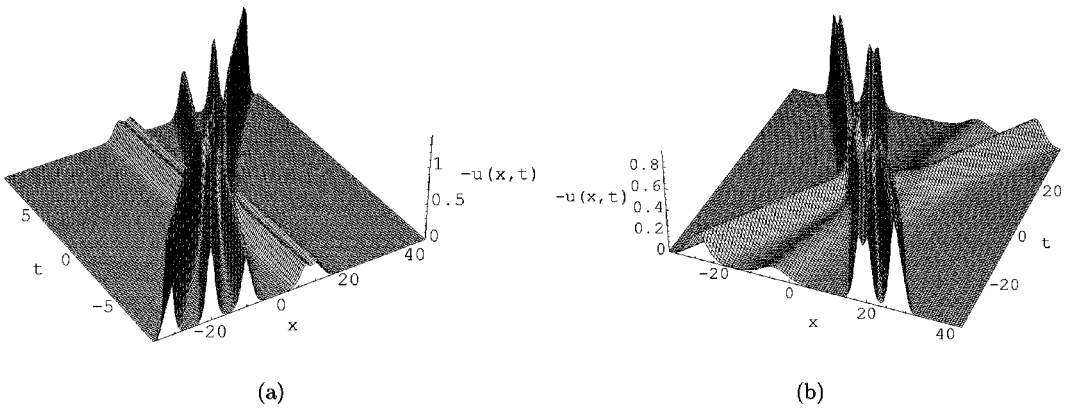

FIG. 11. Perspective views of the bKK four-soliton: (a) three single-peaked pulses ($p_1=1.25$, $p_2=1.5$, $p_3=1.75$) colliding head-on with a double-humped solitary wave ($p_4=1.0$), (b) head-on collision of a pair of single-humped ($p_1=0.5$, $p_2=0.75$) and a doublet of twin-peaked ($p_3=1.5$, $p_4=1.75$) pulses.

N-soliton (10), introducing arbitrary coefficients consonant with the symmetry in the phase variables $\theta_i = p_i x + \omega_i t + \eta_i$, $i = 1, \ldots, N$. This gives the putative N-soliton solution $f(x,t)$ of the bKK bilinear form (19a) and (19b).

We now use the soliton reduction procedure,[11] to reduce $f(x,t)$ to a soliton of order $N-1$ (in the limits $t \to \pm\infty$). Then comparison with the *known* bKK $(N-1)$-soliton fixes the dispersion relations $\omega_i(p_i)$, Eq. (12), and all but one of the coefficients in the expression for f. The only unknown is the coefficient $b_{12\ldots N}$ of the term $e^{\theta_1+\theta_2+\cdots+\theta_N}$, a "new" parameter that cannot be determined by reducing f to lower order. Nevertheless, we can deduce reductions of $b_{12\ldots N}$ of the type (58) in this way: this gives N conditions of which we note the two key results (for $N \geqslant 4$)

$$b_{12\ldots N}(\mathbf{p}_1, \ldots, \mathbf{p}_{N-1}, \mathbf{0}) = b_{12\ldots N-1}(\mathbf{p}_1, \ldots, \mathbf{p}_{N-1}); \tag{67}$$

$$b_{12\ldots N}(\mathbf{p}_1, \ldots, \mathbf{p}_{N-1}, \mathbf{p}_{N-1}) = \frac{1}{8} a_{N-1}^2 b_{12\ldots N-2} \prod_{i=1}^{N-2} A_{i,N-1}. \tag{68}$$

Now, generalizing the expressions (36), (46) and (60), we have

$$b_{12\ldots N} = \frac{1}{2^{N-1}} \frac{\Delta_{12\ldots N}}{D_{12\ldots N}}, \quad D_{12\ldots N} = \prod_{1 \leqslant i < j \leqslant N} D_{ij}, \tag{69}$$

with D_{ij} given in Eq. (34). It only remains to determine the numerator $\Delta_{12\ldots N}$ in Eq. (69) which is a homogeneous polynomial in p_i [modulo the dispersion relations $\omega_i \propto p_i^3$, Eq. (18)] of total degree $3N(N-1)$, equal to that of $D_{12\ldots N}$. Further, one easily verifies the parity transformation

$$b_{12\ldots N}(\mathbf{p}_1, \ldots, \mathbf{p}_{N-1}, -\mathbf{p}_N) = \frac{b_{12\ldots N}(\mathbf{p}_1, \ldots, \mathbf{p}_N)}{A_{1N} A_{2N} \cdots A_{N-1,N}},$$

which implies that $\Delta_{12\ldots N}$ is of even/odd degree in each of the wave numbers if N is odd/even.

To deduce the functional form of $\Delta_{12\ldots N}$, we first make use of the reduction (67) which shows that

$$\Delta_{12\ldots N} \sim 2.3^{N-1} p_1^2 p_2^2 \cdots p_{N-1}^2 p_N^{N-1} \Delta_{12\ldots N-1} \prod_{i=1}^{N-1} (5\omega_i - 2p_i^3) \quad \text{as} \quad p_N \to 0.$$

Allowing for symmetry, we may therefore write [cf. Eqs. (47) and (61)]

$$\Delta_{12\ldots N} = 2.3^{N-1} \left\langle\!\!\left\langle p_{i_1}^2 p_{i_2}^2 \cdots p_{i_{N-1}}^2 p_{i_N}^{N-1} \Delta_{i_1 i_2 \ldots i_{N-1}} \prod_{k=1}^{N-1} (5\omega_{i_k} - 2p_{i_k}^3) \right\rangle\!\!\right\rangle + H_{12\ldots N}, \tag{70}$$

where $\langle\!\langle\ \rangle\!\rangle$ denotes the sum over all distinct permutations of $(1,2,\ldots,N)$ assigned to the subscripts $(i_1, i_2, \ldots, i_N)$ of the enclosed product. Thus, the $\langle\!\langle\ \rangle\!\rangle$ term in (70) contains the terms of lowest degree p_i^{N-1} in any of the wave numbers; but then the even/odd parity of $\Delta_{12\ldots N}$ implies that $H_{12\ldots N}$ is comprised of terms having minimum degree $N+1$ in each wave number. To obtain the *principal term* of $H_{12\ldots N}$ we use the reduction (68) and maximum degree argument. Putting $\mathbf{p}_N = \mathbf{p}_{N-1}$ in Eq. (69) and equating with (68), we find that [cf. Eq. (63)]

$$\Delta_{12\ldots N}\big|_{\mathbf{p}_N = \mathbf{p}_{N-1}} = (-1)^{N-2} 30 p_{N-1}^3 (4\omega_{N-1} - p_{N-1}^3) \Delta_{12\ldots N-2} \prod_{i=1}^{N-2} D_{i,N-1} D_{i,N-1}^{-}. \tag{71}$$

We note that the right-hand side of Eq. (71) has maximum degree $T_N = T_{N-2} + 10$ in p_1 with $T_2 = 5$ and $T_3 = 10$, whereupon $T_N = 5(N-1)$, $N \geqslant 2$. But since this reduction leaves p_1 untouched,

the maximum degree of *any* p_i in $\Delta_{12\ldots N}$, and hence in $H_{12\ldots N}$, must also be $5(N-1)$. If we combine this result with the total degree $3N(N-1)$, and minimum degree $N+1$ in each p_i, we are able to formulate the principal term of $H_{12\ldots N}$ as

$$\langle\!\langle p_{i_1}^{5(N-1)} p_{i_2}^{5(N-1)} \cdots p_{i_k}^{5(N-1)} \cdots p_{i_{N-l+1}}^{N+1} \cdots p_{i_{N-1}}^{N+1} p_{i_N}^{N+1} \rangle\!\rangle.$$

The precise number k and l of terms with maximum and minimum degree, respectively—and the consequent intermediary terms of decreasing degree—will depend on N [cf. Eqs. (48) and (62)]. The remaining terms that make up $H_{12\ldots N}$ follow by systematically cascading the powers of p_i and successively replacing $p_i^3 \to \omega_i$ [via the dispersion relation (18)], just as we did in Eq. (62) for $N=4$. We can now formulate $H_{12\ldots N}$ as a linear combination of these terms, fixing as many of the coefficients as possible by using the other $N-2$ reductions of the type (67), $b_{12\ldots N}(\mathbf{p}_1,\ldots,\mathbf{p}_k,\mathbf{0},\ldots,\mathbf{0})$, $1 \leqslant k \leqslant N-2$, and the reduction (68). However, these reductions will not be sufficient to determine all the coefficients in $H_{12\ldots N}$ and we return to bilinear form (19) to complete the derivation of the N-soliton. We substitute *truncated* versions of f and $\tilde{g}$ [cf. Eqs. (52) and (53)]—consistent with extracting only the terms in $e^{\theta_1+\theta_2+\cdots+\theta_N}$—into the bilinear equations (19a) and (19b). This yields an equation for $\Delta_{12\ldots N}$ which is equated with (70) to find the remaining unknown coefficients in $H_{12\ldots N}$. With $\Delta_{12\ldots N}$, and hence $b_{12\ldots N}$ and $f(x,t)$, now completely determined, we obtain the explicit N-soliton solution of the bKK Eq. (1) using $u=-\partial_x^2 \ln f$.

V. DISCUSSION

In this sequel to a recent study,[1] we have presented a direct method for obtaining explicit multisoliton solutions of the bidirectional Kaup–Kupershmidt equation (1). Not surprisingly, these solitons possess the remarkable property that their wave profiles are *directionally dependent*, a property that is inherited from the constituent solitary waves.[1] To our knowledge, this type of soliton interaction is quite unusual and is reported here for the first time. In particular, soliton solutions are presented that describe multiple head-on collisions of *single*- and *double*-humped "solitary" waves.

The "anomalous" character of the bKK solitons arises quite naturally within Hirota's bilinear formalism[24,25] in the guise of a *squared* regular N-soliton.[1] This canonical form, which derives from the duality of the bKK and bSK-Ramani equations, provides the basis for the iterative procedure that we have developed to obtain higher-order solitons. Significantly, the expression for the bKK N-soliton—like its unidirectional counterpart for the sister KK Eq. (2)[11]—requires the introduction of a new parameter $b_{12\ldots N}$, Eq. (69), at every order N; we therefore cannot write down an explicit formula for this solution akin to Hirota's generic form (10). This is in marked contrast to the bSK–Ramani equation whose N-soliton solution (10) is described by the single parameter A_{ij}, Eq. (11). Nevertheless, our formulation of the bKK solitons—couched in terms of the common interaction parameter A_{ij} and shared dispersion laws (12)—would seem to be a natural one, for it makes explicit the dynamical duality of the soliton solutions of the bKK and bSK-Ramani equations and points to the deep connection between these two fundamentally different integrable bidirectional equations. This mirrors the intimacy between their better known unidirectional cousins, the KK Eq. (2) and SK Eq. (4), respectively.[2,11,14]

Although we have sought to describe the iterative procedure in some detail (Sec. IV C), a few salutary remarks are in order. Compared with the iteration method that was used to obtain the multisoliton solutions of the sister KK Eq. (2),[11] the procedure given here for the bKK equation is less definitive. The reason for this is clear. The unidirectional KK solitons possess a high degree of symmetry which permits a precise description of the iterative steps.[11] For the bKK equation, much, though by no means all, of this symmetry is lost due to the need to account for the bidirectionality. In particular, there is insufficient *a priori* information available to completely determine the "new" parameter $b_{12\ldots N}$ that is pivotal to formulating the bKK N-soliton [whereas just two reductions, comparable to Eqs. (67) and (68), were required to compute the equivalent KK parameter]. This lack of information stems from the fact that a bKK soliton cannot be reduced

to one of lower order by coalescing a single- and a double-humped solitary wave (the reason for this is given in Ref. 11). Consequently, it is necessary to revert to the bilinear form of the bKK equation to complete the derivation of $b_{12\ldots N}$ and, thereby, the N-soliton solution. Notwithstanding this ''extra'' step, we stress that the above iteration procedure yields the key parameter $b_{12\ldots N}$ in its simplest possible form since the quotient expression (69) is irreducible. Indeed, it is this simple and repetitive structure that makes an iterative approach viable. Were we to attempt to obtain this parameter by solving the bilinear equations directly, the algebraic demands would soon become intractable (as the order N increases) and lie beyond the competence of symbolic software (even with the necessary computational resources). To give a measure of the complexity one faces, even for $N=4$, direct substitution into the bilinear form yields a coefficient of $e^{\theta_1+\theta_2+\theta_3+\theta_4}$ with in excess of *half a million* terms. Moreover, it is extremely unlikely that the compact expression (69) could be obtained in this way. In part, this is because of the immense difficulty in identifying the ''correct'' factors that are needed to effect the simplification. But here the task is compounded by the option of using the dispersion relations (12) which enable us to recast an expression by removing (or inserting) powers of ω_i (a facility that has been been crucial to our analysis).

The simplification that derives from our direct approach—and from the structured procedure described in Sec. IV C—makes the computations manageable and should not be underestimated. Nevertheless, at some point, the length and complexity of the algebraic expressions involved will still be such that they will almost certainly breach the limit of available computational resource (though not the competence of algebraic software such as Mathematica). That said, the synergy between mathematical analysis and the power of symbolic computation to manage lengthy, but otherwise routine, algebraic manipulation is evident in this study. We have been able to exploit this synergy to elicit—and display—multisoliton solutions of the bKK equation which might otherwise be inaccessible. Naturally, it is interesting to speculate whether there are other bidirectional nonlinear evolution equations that possess directionally dependent solitons: to date, they appear to be unique to the bKK Eq. (1).

APPENDIX: SINGULARITY ANALYSIS FOR THE BKK EQUATION

We briefly describe a singularity analysis for solutions of the bidirectional Kaup–Kupershmidt (bKK) equation (1). The results show that the bKK equation passes the Painlevé test for partial differential equations due to Weiss, Tabor and Carnevale (WTC).[26] [The full analysis for both this equation and the bSK-Ramani Eq. (3) will be presented elsewhere.] Using the results of the WTC analysis, we then examine the singularity properties of the functions that appear in the various bilinear forms of the bKK equation given in Sec. II. Judged from this perspective, we conclude that the coupled system (19) is a ''good'' Hirota bilinear form whereas the alternative bilinear equations (6) and (7) are not.

1. Painlevé analysis

To proceed with the singularity analysis, it is convenient to write the bKK Eq. (1) in its conservative form with $u=v_x$:

$$5v_{tt}+5v_{xxxt}-15v_xv_{xt}-15v_{xx}v_t-45v_x^2v_{xx}+\frac{75}{2}v_{xx}v_{3x}+15v_xv_{4x}-v_{6x}=0. \tag{A1}$$

Following the WTC method,[26] we seek a Laurent expansion

$$v(x,t)=\phi^{-\rho}\sum_{k=0}^{\infty}v_k(x,t)\phi^k \quad (v_0\not\equiv 0), \tag{A2}$$

where $\phi(x,t)$, $v_k(x,t)$ are analytic functions in the neighborhood of an arbitrary (noncharacteristic) singular manifold $\phi(x,t)=0$ (ϕ_x, $\phi_t\neq 0$). Substituting the series (A2) into (A1), the balance of leading order terms in ϕ^{-7} yields $\rho=1$ and the two choices

$$v_0=-\phi_x, \quad v_0=-8\phi_x. \tag{A3}$$

Inserting the series (A2) with $\rho=1$ into (A1), and collecting terms in ϕ^{k-7}, we obtain a recurrence relation for v_k ($k\geqslant 1$):

$$(k-1)(k-6)\phi_x^4[(k-2)(k-3)(k-4)(k-5)\phi_x^2+15(k^2-8k+18)\phi_x v_0+45v_0^2]v_k=F_k, \tag{A4}$$

with $F_k=F_k(v_0,v_1,\ldots,v_{k-1};\phi_x,\phi_t,\ldots)$. The choices (A3) lead to the resonance families

$$k=-1, 1, 3, 5, 6, 7; \tag{A5}$$

$$k=-7,-1, 1, 6, 10, 12, \tag{A6}$$

respectively. To simplify the succeeding analysis, we introduce the Kruskal manifold ansatz[27]

$$\phi(x,t)=x-x_0(t), \tag{A7}$$

where $x_0(t)$ and $v_k(t)$ are analytic functions of t only. It can be shown that all compatibility conditions are satisfied for both resonant sets (A5) and (A6). It follows that Eq. (A1), and hence the bKK Eq. (1), has the Painlevé property.[26,28]

We observe that only the first family (A5) has a full complement of positive resonances and, for our purposes, we need consider only this principal branch. In this case, the Laurent series (A2) provides a local representation of the general solution of Eq. (A1) in which x_0, v_1, v_3, v_5, v_6, v_7 are arbitrary functions of t. Using the recurrence relation (A4) with $v_0=-\phi_x=-1$, one finds that

$$v(x,t)=-\frac{1}{x-x_0}+v_1+\frac{1}{3}x_0'(x-x_0)+v_3(x-x_0)^2+\frac{1}{9}(2x_0'^2-3v_1')(x-x_0)^3+\cdots, \tag{A8}$$

where a prime denotes the derivative with respect to t. Hence, $v(x,t)$ has a simple pole on the movable singular manifold path $x=x_0(t)$. The Laurent expansion for $u=v_x$ follows directly from (A8) as

$$u(x,t)=\frac{1}{(x-x_0)^2}+\frac{1}{3}x_0'+2v_3(x-x_0)+\frac{1}{3}(2x_0'^2-3v_1')(x-x_0)^2+\cdots. \tag{A9}$$

Thus, solutions of the bKK Eq. (1) have, at worst, a polelike behavior of order 2 in the neighborhood of the singular manifold $x=x_0(t)$.

2. Hirota bilinear transform

We consider the consequences of the Painlevé analysis for the bilinearization of the bKK equation. From Eq. (5) we have $v=\alpha\partial_x \ln f$: after equating this with (A8) and integrating with respect to x, we have

$$f(x,t)=(x-x_0)^{-1/\alpha}\exp\left\{\frac{1}{\alpha}\left[c+v_1(x-x_0)+\frac{1}{6}x_0'(x-x_0)^2+\frac{1}{3}v_3(x-x_0)^3+\cdots\right]\right\}, \tag{A10}$$

where $c=c(t)$ is an arbitrary function. Equation (A10) shows that, for the bKK Eq. (1), the appropriate choice is $\alpha=-1$ since it leads to an Hirota function $f(x,t)$ which is *entire*. This accords with our choice of dependent variable transformation $u=-\partial_x^2 \ln f$ and justifies expanding

f as a finite polynomial of exponentials. We note that the alternative choice $\alpha=-2$ in (A10) yields an ansatz f in the bilinear form (7) having a square-root branch singularity—it does not therefore lead to a "good" Hirota form. [Incidentally, a similar Painlevé analysis for the bSK-Ramnai Eq. (3) shows that the choice $\alpha=-2$ in (5) leads to entire f in the Ramani bilinear form (9) as expected.]

We are left to consider the two possible bilinear forms (6) and (19) of the bKK equation corresponding to $\alpha=-1$ (with f entire). Then (A10) shows that $f\sim(x-x_0)$ near a pole singularity of $v(x,t)$. Now, substituting the Laurent expansion (A8) into Eq. (6b), one readily obtains

$$g(x,t)=\frac{1}{x-x_0}+O(x-x_0),$$

while Eq. (6c) gives

$$h(x,t)=-\frac{4x_0'}{x-x_0}+O(1),$$

near $x_0(t)$. Hence, the auxiliary functions g and h in the bilinear form (6) are *not* entire since each has a simple pole singularity in the vicinity of a zero of f. On the other hand, from (19b) we deduce that

$$\tilde{g}(x,t)=-24v_3+6(v_1'-x_0'^2)(x-x_0)+O(x-x_0)^2,$$

which shows that $\tilde{g}$ *is* an entire function. We conclude that (19) is a "good" Hirota bilinear form and should therefore be used instead of the alternate bilinear system (6) which is not.

(Received 12 November 2001; accepted for publication 5 June 2002)

By symmetry constraints, new finite-dimensional integrable systems are deduced from a Lax representation of the MKdV_ equation, whose two terms containing spatial derivatives have the same sign. Lax representations are presented for the resulting finite-dimensional integrable systems and an r-matrix formulation is established for the corresponding Lax operator. From the Lax operator, a nonconfocal involutive system of functionally independent polynomial functions is constructed. Solutions of the MKdV_ can be obtained by the method of separation of variables. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1506202]

I. INTRODUCTION

The technique of symmetry constraints of soliton equations is a powerful tool to generate $1+1$ dimensional soliton equations from $2+1$ dimensional soliton equations[1,2] and finite-dimensional integrable systems (FDISs) from $1+1$ dimensional soliton equations.[3] Various FDISs have been presented starting from the Lax representations (or zero curvature equation representations) of $1+1$ dimensional soliton equations,[3–13] by using that symmetry constraint technique (or direct nonlinearization of Lax systems[4–8]). The resulting FDISs have many nice mathematical properties. For example, they possess Lax representations and their Lax operators satisfy r-matrix relations. Following a procedure of Sklyanin,[15] one can define separated variables for most of the resulting FDISs, which serve for constructing the Jacobi inversion problems.

In recent years, the study of separation of variables of soliton equations in $1+1$ dimensions (or $2+1$ dimensions) has attracted an increasing attention.[15–20] It has been shown that soliton equations in $1+1$ dimensions possessing Lax representations can be separated into two commuting FDISs (x-part and t-part of constrained flows) by symmetry constraints. Then, one can get solutions of soliton equations by solving the corresponding x-part and t-part of constrained flows. This process together with separating variables for the constrained flows constitutes separation of variables for soliton equations.[18]

The method of separation of variables has been used to construct solutions of soliton equations associated with the ZS-AKNS spectral problem.[18,21] It is well known that from the ZS-AKNS spectral problem, under the potential reductions $r=+q$ and $r=-q$, one obtains the MKdV equations

$$q_t-q_{xxx}+6q^2q_x=0$$

and

$$q_t+q_{xxx}+6q^2q_x=0,$$

a)Electronic mail: ysli@ustc.edu.cn
b)Electronic mail: mawx@math.usf.edu

respectively. They are called the MKdV_+ and MKdV_- equations, respectively. The MKdV_+ equation has different signs but the MKdV_- equation has the same sign for the two terms containing spatial derivatives of the dependent variable q. Starting from other two specific spectral problems, the FDISs associated with the MKdV_+ equation have been obtained by symmetry constraints (Bargmann type),[22–25] and the associated r-matrices are different from the r-matrix in the case of the ZS-AKNS spectral problem.[24,25] However, there is no result on symmetry constraints of the MKdV_- equation, although there exists some analysis on symmetry constraints of the MKdV_+ equation.[23,24]

In this paper, we would like to start from a new, convenient spectral problem to derive the MKdV_- hierarchy and consider the corresponding problem of symmetry constraints for the MKdV_- equation. It is known that all important 2×2 matrix spectral problems associated with soliton equations are exhausted. However, the classification task of constrained flows always presents problems. To our surprise, the resulting r-matrices in the case of the MKdV_- equation are very different from the existing r-matrices in the case of the MKdV_+ equation,[24,25] and the type of the Lie algebra generated from the Lax operator associated with the resulting constrained flows has not been seen so far in the study of constrained flows. More importantly, an involutive system being nonconfocal can be presented. It is absolutely not easy to get nonconfocal involutive systems of polynomial functions, starting from 2×2 matrix spectral problems. Almost all examples established in the theory of constrained flows are confocal. Moreover, through the difference between two Lie algebras associated with two Lax operators, we will see different solution types for the MKdV_+ equations and the MKdV_- equation.

The paper is organized as follows. In Sec. II, starting from a new, specific spectral problem, we derive a soliton hierarchy of the MKdV_- equations. In Sec. III, we construct the constrained flows of the MKdV_- equation by the Bargmann symmetry constraints and decompose the MKdV_- equation into two FDISs, the x-part and t-part of the constrained flows. In Sec. IV, we deduce the r-matrix formulation, present a nonconfocal involutive system of functionally independent polynomial functions and show the Liouville integrability of the constrained flows. In Sec. V, we construct action-angle variables and the Jacobi inversion problems for the resulting constrained flows of the MKdV_- equation. Some concluding remarks are given in Sec. VI. Finally, in the Appendix, we show that the different spectral problems appearing in the literature associated with the MKdV_+ equation and the MKdV_- equation are gauge equivalent to each other, respectively.

II. MKdV_- SOLITON HIERARCHY

Let us consider a specific spectral problem

$$\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}_x = U(q,\lambda)\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}, \quad U(q,\lambda)=\begin{pmatrix}0 & \lambda+q\\ \lambda-q & 0\end{pmatrix}, \tag{1}$$

where λ is a spectral parameter and $q=q(x,t)$ is the potential. We solve the adjoint equation

$$V_x=[U,V]\equiv UV-VU, \tag{2}$$

by assuming

$$V=\begin{pmatrix}A & B\\ C & -A\end{pmatrix}=\sum_{j=0}^{\infty}\begin{pmatrix}a_j & b_j\\ c_j & -a_j\end{pmatrix}\lambda^{-j}. \tag{3}$$

The components of the adjoint equation (2) read as

$$A_x=(\lambda+q)C-B(\lambda-q), \quad B_x=-2A(\lambda+q), \quad C_x=2A(\lambda-q). \tag{4}$$

Upon introducing

$$E=B+C, \quad F=C-B, \quad \text{or} \quad C=\frac{E+F}{2}, \quad B=\frac{E-F}{2}, \tag{5}$$

the conditions (4) can be written as follows:

$$A_x=\lambda F+qE, \quad E_x=-4Aq, \quad F_x=4\lambda A.$$

It is direct to obtain the recursion relation

$$LF=\lambda^2 F, \quad L=\frac{1}{4}\partial_x^2+q\partial_x^{-1}q\partial_x, \quad \partial_x=\frac{\partial}{\partial x}. \tag{6}$$

Assuming that

$$E=\sum_{j=0}^{\infty} e_j\lambda^{-j}, \quad F=\sum_{j=0}^{\infty} f_j\lambda^{-j}, \tag{7}$$

if we take $a_0=f_0=a_1=0$, $e_0=-1$, then we find

$$f_{2n}=a_{2n+1}=e_{2n+1}=0, \quad n=1,2,\ldots$$

and

$$f_1=q, \quad f_{2n+1}=Lf_{2n-1}, \quad a_{2n}=\tfrac{1}{4}f_{2n-1,x}, \quad e_{2n}=-\partial_x^{-1}q\partial_x f_{2n-1}, \quad n=1,2,\ldots. \tag{8}$$

The first few of the above functions read as

$$f_3=\tfrac{1}{4}q_{xx}+\tfrac{1}{2}q^3, \quad a_2=\tfrac{1}{4}q_x, \quad e_2=-\tfrac{1}{2}q^2;$$

$$f_5=\tfrac{1}{16}q_{xxxx}+\tfrac{5}{8}q^2q_{xx}+\tfrac{5}{8}qq_x^2+\tfrac{3}{8}q^5, \quad a_4=\tfrac{1}{8}q_{xxx}+\tfrac{3}{4}q^2q_x, \quad e_4=-\tfrac{1}{4}q^2q_{xx}+\tfrac{1}{8}qq_x^2-\tfrac{3}{8}q^5.$$

Let us associate the spectral problem (1) with the auxiliary spectral problem

$$\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}_{t_n}=V^{(n)}(q,\lambda)\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}=V^{(n)}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}, \tag{9}$$

with $V^{(n)}$ being chosen as

$$V^{(n)}=V^{(n)}(q,\lambda)=(\lambda^{2n-1}V)_+, \quad n\geqslant 0, \tag{10}$$

where the plus symbol $_+$ denotes taking the terms of non-negative powers of λ. The zero curvature equations

$$U_{t_n}-V_x^{(n)}+[U,V^{(n)}]=0, \quad n\geqslant 1, \tag{11}$$

lead to the following soliton hierarchy of MKdV$_-$ equations

$$q_{t_n}+\tfrac{1}{2}\partial_x f_{2n-1}=0, \quad n=1,2,\ldots, \tag{12}$$

which when $n=2$, gives the MKdV$_-$ equation

$$q_{t_2}+\tfrac{1}{8}q_{xxx}+\tfrac{3}{4}q^2q_x=0, \tag{13}$$

where the constants can be rescaled to the previous one in the introduction.

III. CONSTRAINED MKdV_ FLOWS

It is direct to find that for the spectral problem (1), we have

$$\int_{-\infty}^{\infty}[\lambda'[K](\phi_1^2-\phi_2^2)-K(\phi_1^2+\phi_2^2)]dx=0,$$

and thus we obtain the variatial derivative of the spectral parameter λ (up to a constant factor)

$$\frac{\delta\lambda}{\delta q}=\phi_1^2+\phi_2^2. \tag{14}$$

There are also the following relations for the spectral problem (1):

$$(\phi_1^2+\phi_2^2)_x=4\lambda\phi_1\phi_2,\ \ (\phi_1^2+\phi_2^2)_{xx}=4\lambda(\phi_2^2+\phi_1^2)+4\lambda(\phi_2^2-\phi_1^2),\ \ (\phi_2^2-\phi_1^2)_x=-4\phi_1\phi_2 q, \tag{15}$$

and thus under zero boundary conditions of ϕ_1 and ϕ_2, we can show that

$$L\frac{\delta\lambda}{\delta q}=\lambda^2\frac{\delta\lambda}{\delta q}, \tag{16}$$

which implies that the operator L has an eigenvalue λ^2.

We take N copies of the spectral problem (1) with N distinct λ_j

$$\begin{pmatrix}\phi_{1j}\\ \phi_{2j}\end{pmatrix}_x=U(q,\lambda_j)\begin{pmatrix}\phi_{1j}\\ \phi_{2j}\end{pmatrix},\quad j=1,2,\ldots,N. \tag{17}$$

From (14), we have (up to a constant factor)

$$\frac{\delta\lambda_j}{\delta q}=\phi_{1j}^2+\phi_{2j}^2,\quad j=1,2,\ldots,N.$$

Now, we take the Bargmann symmetry constraint[3]

$$a_2=\sum_{j=1}^{N}\frac{1}{4}\partial_x\frac{\delta\lambda_j}{\delta q},\quad \text{i.e.,}\quad q=\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle, \tag{18}$$

where $\langle .,. \rangle$ denotes the standard inner product in $\mathbb{R}^N$ and

$$\Phi_j=(\phi_{j1},\ldots,\phi_{jN})^T,\quad j=1,2. \tag{19}$$

From (8), (15), and (16), we have

$$\begin{aligned}&\tilde{f}_1=\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle,\quad \tilde{f}_{2n+1}=\langle\Lambda^{2n}\Phi_1,\Phi_1\rangle+\langle\Lambda^{2n}\Phi_2,\Phi_2\rangle,\\ &\tilde{a}_{2n}=\langle\Lambda^{2n-1}\Phi_1,\Phi_2\rangle,\quad \tilde{e}_{2n}=\langle\Lambda^{2n-1}\Phi_2,\Phi_2\rangle-\langle\Lambda^{2n-1}\Phi_1,\Phi_1\rangle,\end{aligned} \tag{20}$$

where $\tilde{a}_i$, $\tilde{e}_i$, and $\tilde{f}_i$ denote the constrained expressions under the constraint (18) and zero boundary conditions of ϕ_{ij}, and the matrix Λ is defined by

$$\Lambda=\mathrm{diag}(\lambda_1,\ldots,\lambda_N). \tag{21}$$

Under the symmetry constraint (18), the N copies of the spectral problem (1) are nonlinearized into a system of ordinary differential equations

$$\Phi_{1x}=(\Lambda+\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle)\Phi_2,\quad \Phi_{2x}=(\Lambda-\langle\Phi_1,\Phi_1\rangle-\langle\Phi_2,\Phi_2\rangle)\Phi_1, \tag{22}$$

which can be transformed into a Hamiltonian system in the symplectic space $(R^{2n}, d\Phi_2 \wedge d\Phi_1)$

$$\Phi_{1x} = \frac{\partial H_1}{\partial \Phi_2}, \quad \Phi_{2x} = -\frac{\partial H_1}{\partial \Phi_1}, \tag{23}$$

with the Hamiltonian H_1 being defined by

$$H_1 = \tfrac{1}{4}(\langle \Phi_1, \Phi_1 \rangle + \langle \Phi_2, \Phi_2 \rangle)^2 + \tfrac{1}{2}\langle \Lambda \Phi_2, \Phi_2 \rangle - \tfrac{1}{2}\langle \Lambda \Phi_1, \Phi_1 \rangle.$$

From (5) and (20), we have

$$A(\lambda) = \sum_{j=1}^{N} \frac{\lambda_j \phi_{1j} \phi_{2j}}{\lambda^2 - \lambda_j^2}, \quad F(\lambda) = \sum_{j=1}^{N} \frac{\lambda(\phi_{1j}^2 + \phi_{2j}^2)}{\lambda^2 - \lambda_j^2}, \quad E(\lambda) = -1 + \sum_{j=1}^{N} \frac{\lambda_j(\phi_{2j}^2 - \phi_{1j}^2)}{\lambda^2 - \lambda_j^2}, \tag{24}$$

and then we define a Lax operator as

$$\begin{aligned} L(\lambda) &\equiv \begin{pmatrix} A(\lambda) & B(\lambda) \\ C(\lambda) & -A(\lambda) \end{pmatrix} \\ &\equiv \begin{pmatrix} A(\lambda) & \dfrac{E(\lambda) - F(\lambda)}{2} \\ \dfrac{E(\lambda) + F(\lambda)}{2} & -A(\lambda) \end{pmatrix} \\ &= \frac{1}{2}\begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix} + \frac{1}{2}\sum_{j=1}^{N} \begin{pmatrix} \dfrac{2\lambda_j \phi_{1j} \phi_{2j}}{\lambda^2 - \lambda_j^2} & \dfrac{\lambda_j(\phi_{2j}^2 - \phi_{1j}^2) - \lambda(\phi_{1j}^2 + \phi_{2j}^2)}{\lambda^2 - \lambda_j^2} \\ \dfrac{\lambda_j(\phi_{2j}^2 - \phi_{1j}^2) + \lambda(\phi_{1j}^2 + \phi_{2j}^2)}{\lambda^2 - \lambda_j^2} & \dfrac{-2\lambda_j \phi_{1j} \phi_{2j}}{\lambda^2 - \lambda_j^2} \end{pmatrix}. \end{aligned} \tag{25}$$

Now, by a direct computation, we have the following theorem.

Theorem 1. *The spectral constrained MKdV$_-$ flow (23) admits the Lax representation*

$$(L(\lambda))_x = [\tilde{U}, L(\lambda)], \tag{26}$$

where $\tilde{U}$ is given by

$$\tilde{U} = \begin{pmatrix} 0 & \lambda + \langle \Phi_1, \Phi_1 \rangle + \langle \Phi_2, \Phi_2 \rangle \\ \lambda - \langle \Phi_1, \Phi_1 \rangle - \langle \Phi_2, \Phi_2 \rangle & 0 \end{pmatrix}. \tag{27}$$

Under the symmetry constraint (18) and the control of the x-constrained flow (22), the t_2-constrained flow obtained from N copies of the temporal spectral problem (9) and (10) for N distinct λ_j reads as follows:

$$\begin{aligned} \Phi_{1j,t_2} &= \lambda_j \overline{A} \phi_{1j} + \tfrac{1}{2}(-\lambda_j^3 - \overline{B}\lambda_j^2 + \overline{C}\lambda_j - \overline{D})\phi_{2j}, \\ \phi_{2j,t_2} &= \tfrac{1}{2}(-\lambda_j^3 + \overline{B}\lambda_j^2 + \overline{C}\lambda_j + \overline{D})\phi_{1j} - \lambda_j \overline{A} \phi_{2j}, \end{aligned} \tag{28}$$

where $j = 1, 2, \ldots, N$, and

$$\begin{aligned}&\overline{A}=\langle\Lambda\Phi_1,\Phi_2\rangle,\ \ \overline{B}=\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle,\ \ \overline{C}=-\tfrac{1}{2}(\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle)^2,\\&\overline{D}=\langle\Lambda^2\Phi_1,\Phi_1\rangle+\langle\Lambda^2\Phi_2,\Phi_2\rangle+(\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle)(\langle\Lambda\Phi_2,\Phi_2\rangle-\langle\Lambda\Phi_1,\Phi_1\rangle)\\&\quad+\tfrac{1}{2}(\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle)^3.\end{aligned}\tag{29}$$

By a direct computation, this system can be rewritten in Hamiltonian form

$$\Phi_{1,t_2}=\frac{\partial H_2}{\partial\Phi_2},\quad \Phi_{2,t_2}=-\frac{\partial H_2}{\partial\Phi_1},\tag{30}$$

with H_2 being defined by

$$\begin{aligned}H_2=&\tfrac{1}{2}\langle\Lambda\Phi_1,\Phi_2\rangle^2-\tfrac{1}{4}(\langle\Lambda^3\Phi_2,\Phi_2\rangle-\langle\Lambda^3\Phi_1,\Phi_1\rangle)-\tfrac{1}{4}(\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle)(\langle\Lambda^2\Phi_1,\Phi_1\rangle\\&+\langle\Lambda^2\Phi_2,\Phi_2\rangle)-\tfrac{1}{8}(\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle)^2(\langle\Lambda\Phi_2,\Phi_2\rangle-\langle\Lambda\Phi_1,\Phi_1\rangle)\\&-\tfrac{1}{16}(\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle)^4.\end{aligned}$$

Therefore, we have the following theorem.

Theorem 2. *The temporal constrained MKdV$_-$ flow (30) admits the Lax representation*

$$L_{t_2}=[\tilde{V}^{(2)},L],\tag{31}$$

where $\tilde{V}^{(2)}$ is given by

$$\tilde{V}^{(2)}=\frac{1}{2}\begin{pmatrix}2\overline{A}\lambda & -\lambda^3-\overline{B}\lambda^2+\overline{C}\lambda-\overline{D}\\ -\lambda^3+\overline{B}\lambda^2+\overline{C}\lambda+\overline{D} & -2\overline{A}\lambda\end{pmatrix},\tag{32}$$

with $\overline{A}$, $\overline{B}$, $\overline{C}$, and $\overline{D}$ being defined by (29).

Proof. By using (26), the zero curvature equation and the Jacobi identity,

$$\tilde{U}_{t_n}-\tilde{V}^{(2)}_x+[\tilde{U},\tilde{V}^{(2)}]=0,$$

$$[[\tilde{V}^{(2)},\tilde{U}],L]+[[L,\tilde{V}^{(2)}],\tilde{U}]+[[\tilde{U},L],\tilde{V}^{(2)}]=0,$$

we can prove $\tilde{V}_x=[\tilde{U},\tilde{V}]$, where $\tilde{V}=L_{t_2}-[\tilde{V}^{(2)},L]$. Note that $\tilde{V}|_{\phi_{ij}=0}=0$ ($i=1,2$, $j=1,\ldots,N$). It follows from $\tilde{V}_x=[\tilde{U},\tilde{V}]$ that $\tilde{V}\equiv 0$. Thus we have the Lax representation (31). The Theorem is proved.

IV. A NONCONFOCAL INVOLUTIVE SYSTEM AND COMPLETE INTEGRABILITY OF THE CONSTRAINED FLOWS

In this section, we use the r-matrix theory to prove that the constrained MKdV$_-$ flows (23) and (30) are completely integrable Hamiltonian systems in the sense of Liouville.[14]

Under the standard Poisson bracket in $\mathbb{R}^{2n}$

$$\{f,g\}=\sum_{j=1}^{N}\left(\frac{\partial f}{\partial\phi_{1j}}\frac{\partial g}{\partial\phi_{2j}}-\frac{\partial f}{\partial\phi_{2j}}\frac{\partial g}{\partial\phi_{1j}}\right),\tag{33}$$

a direct computation can give rise to

$$\begin{aligned}
&\{A(\lambda),A(\mu)\}=\{E(\lambda),E(\mu)\}=\{F(\lambda),F(\mu)\}=0,\\
&\{A(\lambda),E(\mu)\}=\frac{2(\lambda F(\lambda)-\mu F(\mu))}{\mu^2-\lambda^2},\\
&\{A(\lambda),F(\mu)\}=\frac{2\mu(E(\lambda)-E(\mu))}{\mu^2-\lambda^2},\\
&\{E(\lambda),F(\mu)\}=\frac{-8\mu(A(\lambda)-A(\mu))}{\mu^2-\lambda^2}.
\end{aligned} \tag{34}$$

Therefore, we can obtain an important Lie algebra

$$\begin{aligned}
&\{A(\lambda),A(\mu)\}=0,\\
&\{B(\lambda),B(\mu)\}=\frac{2}{\lambda+\mu}(A(\lambda)-A(\mu)),\\
&\{C(\lambda),C(\mu)\}=\frac{2}{\lambda+\mu}(A(\lambda)-A(\mu)),\\
&\{A(\lambda),B(\mu)\}=\frac{1}{\lambda-\mu}B(\lambda)-\frac{1}{\lambda+\mu}C(\lambda)-\frac{2\mu}{\lambda^2-\mu^2}B(\mu),\\
&\{A(\lambda),C(\mu)\}=\frac{1}{\lambda+\mu}B(\lambda)-\frac{1}{\lambda-\mu}C(\lambda)+\frac{2\mu}{\lambda^2-\mu^2}C(\mu),\\
&\{B(\lambda),C(\mu)\}=\frac{2}{\lambda-\mu}(A(\lambda)-A(\mu)).
\end{aligned} \tag{35}$$

These commutator relations show us a specific characteristic for the resulting MKdV$_-$ hierarchy. Usually, $\{A(\lambda),B(\mu)\}$ is a linear combination of A and B, and $\{A(\lambda),C(\mu)\}$ is a linear combination of A and C. But in (35), the situation is different. The commutator relations (35) are of new type among examples of Lax operators appearing in the study of constrained flows.

Now as usual, assume that

$$L_1(\lambda)=L(\lambda)\otimes I,\quad L_2(\mu)=I\otimes L(\mu), \tag{36}$$

and $\{L_1(\lambda)\overset{\otimes}{,}L_2(\mu)\}$ is the fundamental Poisson bracket. A tactful search can present the following r-matrix formulation for the Lax operator $L(\lambda)$.

Theorem 3. *Let $L(\lambda)$ be defined by (25). Then we have the r-matrix formulation*

$$\{L_1(\lambda)\overset{\otimes}{,}L_2(\mu)\}=[L_1(\lambda),r_{12}(\lambda,\mu)]+[r_{21}(\lambda,\mu),L_2(\mu)], \tag{37}$$

where the r matrices are given by

$$r_{12}(\lambda,\mu)=\begin{pmatrix}
\frac{\lambda}{\lambda^2-\mu^2} & 0 & 0 & \frac{1}{\lambda+\mu}\\
0 & \frac{\lambda}{\mu^2-\lambda^2} & \frac{1}{\lambda-\mu} & 0\\
0 & \frac{1}{\lambda-\mu} & \frac{\lambda}{\mu^2-\lambda^2} & 0\\
\frac{1}{\lambda+\mu} & 0 & 0 & \frac{\lambda}{\lambda^2-\mu^2}
\end{pmatrix},\quad r_{21}(\lambda,\mu)=r_{12}(\mu,\lambda). \tag{38}$$

The integrals of motion of two constrained flows can be obtained from expanding $\frac{1}{2}trL^2(\lambda) = -\det L(\lambda)$. We observe that

$$-\det L(\lambda)=A^2(\lambda)+B(\lambda)C(\lambda)=A^2(\lambda)+\frac{1}{4}(E^2(\lambda)-F^2(\lambda))=\frac{1}{4}+\sum_{j=1}^{N}\frac{\lambda_j I_j}{\lambda^2-\lambda_j^2},$$

where the I_j are defined by

$$I_j=-\frac{1}{2}(\phi_{2j}^2-\phi_{1j}^2)-\frac{1}{4\lambda_j}(\phi_{2j}^2+\phi_{1j}^2)^2+\sum_{k\neq j,k=1}^{N}\frac{\lambda_k B_{jk}-\lambda_j A_{jk}}{\lambda_j^2-\lambda_k^2}, \tag{39}$$

with A_{ij} and B_{ij} being defined by

$$A_{ij}=A_{ji}=(\phi_{2j}^2+\phi_{1j}^2)(\phi_{2i}^2+\phi_{1i}^2), \quad B_{ij}=B_{ji}=(\phi_{1i}\phi_{1j}+\phi_{2i}\phi_{2j})^2-(\phi_{1i}\phi_{2j}-\phi_{1j}\phi_{2i})^2.$$

Alternatively, expanding $-\det(A)$ in powers of λ^{-2}, based on (20) and (24), we have

$$\begin{aligned}\sum_{n=0}^{\infty}F_n\lambda^{-2n}:=A^2+\frac{1}{4}(E^2-F^2)&=\left(\sum_{j=1}^{\infty}\frac{\tilde{a}_{2j}}{\lambda^{2j}}\right)^2+\frac{1}{4}\left[\left(-1+\sum_{j=1}^{\infty}\frac{\tilde{e}_{2j}}{\lambda^{2j}}\right)^2-\left(\sum_{j=1}^{\infty}\frac{\tilde{f}_{2j-1}}{\lambda^{2j-1}}\right)^2\right]\\&=\frac{1}{4}+\left(-\frac{1}{2}\tilde{e}_2+\frac{1}{4}\tilde{f}_1^2\right)\frac{1}{\lambda^2}+\sum_{n=2}^{\infty}\left(\sum_{k+l=n}\tilde{a}_{2l}\tilde{a}_{2n}-\frac{1}{2}\tilde{e}_{2n}\right.\\&\quad\left.+\frac{1}{4}\sum_{k+l=n}\tilde{e}_{2k}\tilde{e}_{2l}-\frac{1}{4}\sum_{l+k=n-1}\tilde{f}_{2l+1}\tilde{f}_{2k+1}\right)\frac{1}{\lambda^{2n}}.\end{aligned}$$

Therefore, the integrals of motion F_n read as

$$F_0=\frac{1}{4},\quad F_1=-\frac{1}{2}\tilde{e}_2-\frac{1}{4}\tilde{f}_1^2=-H_1,$$

$$F_n=\sum_{k+l=n}\tilde{a}_{2l}\tilde{a}_{2n}-\frac{1}{2}\tilde{e}_{2n}+\frac{1}{4}\sum_{k+l=n}\tilde{e}_{2k}\tilde{e}_{2l}-\frac{1}{4}\sum_{k+l=n-1}\tilde{f}_{2l+1}\tilde{f}_{2k+1},\quad n\geqslant 2. \tag{40}$$

From the r-matrix formulation (37) or a direct computation of

$$\{A^2(\lambda)+B(\lambda)C(\lambda),A^2(\mu)+B(\mu)C(\mu)\}=0,$$

it follows that:

$$\{I_i(\lambda),I_j(\mu)\}=0 \ \text{ or } \ \{F_i(\lambda),F_j(\mu)\}=0. \tag{41}$$

This means that the integrals of motion are involution in pair. The involutive system of the polynomial functions I_j, $j=1,2,\ldots,N$, is completely different from the confocal system,[7] and actually it is nonconfocal.

To show the complete integrability of the constrained flows (23) and (30) we need only to prove that the integrals of motion F_n, $n=1,2,\ldots,N$, are functionally independent over some open subset of $\mathbb{R}^{2N}$.

To the end, we use the ϵ-technique proposed in Ref. 26. Let $p_0=(\phi_{11},\ldots,\phi_{1N},\phi_{21},\ldots,\phi_{2N})$ be a point of $\mathbb{R}^{2N}$ satisfying $\phi_{jl}=\epsilon$, $j=1,2$, $l=1,2,\ldots,N$, where ϵ is a small parameter. From the expressions of F_n defined by (40) and (20), it follows that:

$$\left.\frac{\partial F_n}{\partial\phi_{jl}}\right|_{p_0}=-(-1)^j\lambda_l^{2n-1}\epsilon+O(\epsilon^3).$$

Therefore,

$$\left.\begin{pmatrix} \frac{\partial F_1}{\partial \phi_{11}} & \frac{\partial F_2}{\partial \phi_{11}} & \cdots & \frac{\partial F_N}{\partial \phi_{11}} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial F_1}{\partial \phi_{1N}} & \frac{\partial F_2}{\partial \phi_{1N}} & \cdots & \frac{\partial F_N}{\partial \phi_{1N}} \end{pmatrix}\right|_{p_0} = \begin{pmatrix} \lambda_1 & \lambda_1^3 & \cdots & \lambda_1^{2N-1} \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_N & \lambda_N^3 & \cdots & \lambda_N^{2N-1} \end{pmatrix} \epsilon^N + O(\epsilon^{3N})$$

$$= \epsilon^N \prod_{j=1}^{N} \lambda_j \prod_{1 \leqslant i < j \leqslant N} (\lambda_j^2 - \lambda_i^2) + O(\epsilon^{3N}).$$

This implies that when

$$\lambda_j \neq 0, \quad j = 1,2,\ldots,N, \quad \lambda_i^2 - \lambda_j^2 \neq 0, \quad 1 \leqslant i \neq j \leqslant N, \tag{42}$$

the functions F_n, $n=1,2,\ldots,N$, are functionally independent over some dense open subset of $\mathbb{R}^{2N}$ and so are the functions I_j, $j=1,2,\ldots,N$.

Theorem 4. *Assume that (42) holds. Then the Hamiltonian systems (23) and (30) have N functionally independent integrals of motion F_n, $n=1,2,\ldots,N$, which are in involution in pair, and thus the systems (23) and (30) are completely integrable systems in the sense of Liouville.*

V. ACTION-ANGLE VARIABLES AND THE JACOB INVERSION PROBLEMS

We present action-angle variables for the finite-dimensional integrable systems (23) and (30). Let us introduce

$$\tilde{A}(\lambda) = \frac{iF(\lambda)}{2}, \quad \tilde{B}(\lambda) = A(\lambda) + \frac{iE(\lambda)}{2}, \quad \tilde{C}(\lambda) = A(\lambda) - \frac{iE(\lambda)}{2}. \tag{43}$$

By using the relations (34), we have

$$\begin{gathered} \{\tilde{A}(\lambda), \tilde{A}(\mu)\} = 0, \ \{\tilde{B}(\lambda), \tilde{B}(\mu)\} = 0, \ \{\tilde{C}(\lambda), \tilde{C}(\mu)\} = 0, \\ \{\tilde{A}(\lambda), \tilde{B}(\mu)\} = \frac{\lambda}{\mu^2 - \lambda^2}(\tilde{B}(\mu) - \tilde{B}(\lambda)), \\ \{\tilde{A}(\lambda), \tilde{C}(\mu)\} = \frac{\lambda}{\mu^2 - \lambda^2}(\tilde{C}(\lambda) - \tilde{C}(\mu)), \\ \{\tilde{B}(\lambda), \tilde{C}(\mu)\} = \frac{2}{\mu^2 - \lambda^2}(\mu\tilde{A}(\mu) - \lambda\tilde{A}(\lambda)). \end{gathered} \tag{44}$$

These relations are just the same as the relations (33) in Ref. 25, and thus we can use the same process as that in Ref. 25 to present action-angle variables as follows. Note that if u_k is a zero point of $\tilde{B}(\lambda)$, then so is $-u_k$, and thus we have

$$\tilde{B}(\pm u_k) = 0, \quad k = 1,2,\ldots,N. \tag{45}$$

We assume that the choice of $\lambda_1,\ldots,\lambda_N$, makes all zero points of $B(\lambda)$ simple. But note that not all these zero points are real, since $\tilde{B}(\lambda)$ is complex. In the case of the MKdV$_+$ equation, $\tilde{B}(\lambda)$ is real.

The other N variables are chosen to be

$$v_k=\tilde{A}(u_k)=\sum_{j=1}^{N}\frac{u_k(i\phi_{1j}^2+i\phi_{2j}^2)}{u_k^2-\lambda_j^2},\quad k=1,2,\ldots,N. \tag{46}$$

A similar deduction as in Ref. 25 yields that u_k and v_k, $k=1,2,\ldots,N$, are canonically conjugated variables, i.e.,

$$\{u_i,u_j\}=\{v_i,v_j\}=0,\quad \{u_i,v_j\}=\delta_{ij},\quad i,j=1,2,\ldots,N. \tag{47}$$

We denote

$$\det L(\lambda)=\frac{P(\lambda)}{K(\lambda)},\quad K(\lambda)=\prod_{j=1}^{N}(\lambda^2-\lambda_j^2), \tag{48}$$

and $P(\lambda)$ is a $2N$th-order polynomial of λ:

$$P(\lambda)=P_N\lambda^{2N}+P_{N-1}\lambda^{2N-2}+\cdots+P_0=\sum_{j=0}^{N}P_j\lambda^{2j},$$

$$P_N=\tfrac{1}{4},\quad P_{N-1}=-H_1-\tfrac{1}{4}\alpha_1,\quad P_{N-2}=2H_2+\alpha_1(-P_{N-1}-\tfrac{1}{4}\alpha_1)+\tfrac{1}{4}\alpha_2, \tag{49}$$

$$\alpha_1=\sum_{j=1}^{N}\lambda_j^2,\quad \alpha_2=\sum_{1\leqslant j<l\leqslant N}\lambda_j^2\lambda_l^2.$$

All P_j can be expressed by $I_1,\ldots,I_N$ or $F_1,\ldots,F_N$, and thus the P_i's are integrals of motion of (23) and (30), and we have

$$\{P_i,P_j\}=0,\quad i,j=1,2,\ldots,N. \tag{50}$$

We observe that

$$\det L(u_k)=-\tfrac{1}{4}F^2(u_k)=\tilde{A}^2(u_k)=v_k^2,$$

which leads to

$$P(u_k)=K(u_k)v_k^2,\quad k=1,2,\ldots,N. \tag{51}$$

Therefore, u_k and v_k, $k=1,2,\ldots,N$, constitute a set of separated variables for (23) and (30). To obtain the Hamilton–Jacobi equation, we replace the canonical momentum components v_k in (51) by the partial derivatives $v_k=\partial S/\partial u_k$. The function S can be separated as $S(u_1,\ldots,u_N)=\Sigma_{k=1}^{N}S_k(u_k)$, where

$$\left[\frac{\partial S_k(u_k)}{\partial u_k}\right]^2=\frac{P(u_k)}{K(u_k)},\quad k=1,2,\ldots,N. \tag{52}$$

Therefore, we have

$$S(u_1,\ldots,u_N)=\sum_{k=1}^{N}\int^{u_k}\frac{P(\lambda)}{\sqrt{P(\lambda)K(\lambda)}}d\lambda,$$

which gives rise to the linearization coordinates

$$Q_k=\frac{\partial S}{\partial P_k}=\frac{1}{2}\sum_{k=1}^{N}\int^{u_k}\frac{\lambda^{2k}d\lambda}{\sqrt{P(\lambda)K(\lambda)}},\quad k=0,\ldots,N-1. \tag{53}$$

These angle variables Q_k, $k=1,2,\ldots,N$, constitute the whole set of action-angle variables together with the action variables P_k, $k=1,2\ldots,N$.

Now based on (49), the linear flow defined by (23) is then given by

$$Q_i=c_i+\frac{\partial H_1}{\partial P_i}x=c_i-x\delta_{i,N-1}, \quad i=0,1,\ldots,N-1, \tag{54}$$

where the c_i's are independent of t_2, and the linear flow defined by (30) is then given by

$$Q_i=\overline{c}_i+\frac{\partial H_2}{\partial P_i}t_2=\overline{c}_i+\frac{1}{2}(\delta_{i,N-2}+\alpha_i\delta_{i,N-1})t_2, \quad i=0,1,\ldots,N-1, \tag{55}$$

where the $\overline{c}_i$'s are independent of x. These two linear flows together with (53) yield the Jacobi inversion problems for (23) and (30)

$$\frac{1}{2}\sum_{k=1}^{N}\int^{u_k}\frac{\lambda^{2k}d\lambda}{\sqrt{P(\lambda)K(\lambda)}}=c_i-x\delta_{i,N-1}, \quad k=0,\ldots,N-1,$$

$$\frac{1}{2}\sum_{k=1}^{N}\int^{u_k}\frac{\lambda^{2k}d\lambda}{\sqrt{P(\lambda)K(\lambda)}}=\overline{c}_i+\frac{1}{2}(\delta_{i,N-2}+\alpha_i\delta_{i,N-1})t_2, \quad k=0,\ldots,N-1,$$

respectively. Then by using the Jacobi inversion technique, one can find solutions of the MKdV$_-$ equation (13) in terms of Riemann theta functions.

VI. CONCLUSIONS AND REMARKS

By the Bargmann symmetry constraints, two commuting finite-dimensional integrable Hamiltonian systems were presented from the constrained flows of a specific spectral problem for the MKdV$_-$ equation. The Lax pairs of those two finite-dimensional systems were given, and the r-matrix formulation was established for the corresponding common Lax operator. We point up that the resulting r-matrices are of new type and the Lax operator leads to a nonconfocal involutive system of polynomial functions, which is a good supplement to the existing theory of symmetry constraints.

Moreover, we presented action-angle variables and the Jacobi inversion problems for those two finite-dimensional integrable systems. Then the solutions of the MKdV$_-$ equation can be obtained by the method of separation of variables and solving the resulting Jacobi inversion problems. The difference from the deduction in the case of the MKdV$_+$ equation[25] is that not all the separated variables are real. Therefore, the MKdV$_+$ equation and the MKdV$_-$ equation have different type solutions. This is also reflected by a Bäcklund transformation $q_+(ix,it)=q_-(x,t)$, where $q_\pm$ are solutions of the MKdV$_+$ equation and the MKdV$_-$ equation, respectively.

Finally in the Appendix, we show that a couple of different spectral problems appearing in the literature associated with the MKdV$_+$ equation and the MKdV$_-$ equation are gauge equivalent to each other, respectively.

APPENDIX A

By the reductions $r=\pm q$, the ZS-AKNS spectral problem (1) becomes

$$\mathrm{MKdV}_+: \quad \Psi_x=\begin{pmatrix} -\lambda & q \\ q & \lambda \end{pmatrix}\Psi \equiv U_+\Psi, \tag{A1}$$

$$\mathrm{MKdV}_-: \quad \Psi_x=\begin{pmatrix} -\lambda & q \\ -q & \lambda \end{pmatrix}\Psi \equiv U_-\Psi, \tag{A2}$$

which generate the MKdV_+ and MKdV_- hierarchies, respectively. The MKdV_+ equation also can be associated with the spectral problem[22]

$$\bar{\Phi}_x=\begin{pmatrix} -q & \lambda^2 \\ 1 & q \end{pmatrix}\bar{\Phi} \equiv \bar{M}\bar{\Phi}, \tag{A3}$$

and the spectral problem[22,25]

$$\Phi_x=\begin{pmatrix} -q & \lambda \\ \lambda & q \end{pmatrix}\Phi \equiv M\Phi. \tag{A4}$$

By using the gauge transformations

$$\bar{\Phi}=T_1\Phi, \quad T_1=\begin{pmatrix} \lambda & 0 \\ 0 & 1 \end{pmatrix},$$

we have

$$\bar{M}=T_1MT_1^{-1}.$$

By using the gauge transformation

$$\Phi=T_3\Psi, \quad T_3=\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix},$$

and noting

$$T_3^{-1}=\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix},$$

we have

$$M=T_3U_+T_3^{-1}$$

and

$$U=T_3U_-T_3^{-1},$$

where U is defined by (1). Therefore, for the MKdV_+ equation, the spectral problems (A1), (A3) and (A4) are gauge equivalent to each other, and for the MKdV_- equation, the spectral problem (1) is gauge equivalent to the spectral problem (A2).

The MKdV_+ equation discussed here is also related to the spectral problem[23,24]

$$\hat{\Phi}_x = \begin{pmatrix} q & \lambda^2 \\ -1 & -q \end{pmatrix} \hat{\Phi} = \hat{M}\hat{\Phi}. \tag{A5}$$

We take $i\lambda$ to replace λ, then $\hat{M}$ is transformed into

$$\begin{pmatrix} q & -\lambda^2 \\ -1 & -q \end{pmatrix} = -\overline{M}.$$

The zero curvature equation associated with (A3) reads as

$$\overline{M}_{t_n} - V_x + \overline{M}V - V\overline{M} = 0, \tag{A6}$$

and the zero curvature equation associated with (A5)

$$-\overline{M}_{t_n} - W_x - \overline{M}W + W\overline{M} = 0. \tag{A7}$$

Interestingly, if we take $-x$ to replace x, then (A6) and (A7) are transformed into each other. Therefore, the MKdV$_+$ equation obtained in Refs. 23 and 24 is equivalent to the MKdV$_+$ equation discussed in this paper.

(Received 13 December 2001; accepted for publication 28 May 2002)

For a given differentiable map $(x,y)\to(X(x,y),Y(x,y))$, which has an inverse, we show that there exists a Hamiltonian flow in which x plays the role of the time variable while y is fixed. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1503150]

Let us consider a differentiable map

$$(x,y)\to(X(x,y),Y(x,y)), \tag{1}$$

and assume that it has an inverse

$$(X,Y)\to(x,y). \tag{2}$$

A small change of (x,y) causes a variation of (X,Y). They are governed by

$$\begin{pmatrix}\partial_x\\ \partial_y\end{pmatrix}=J\begin{pmatrix}\partial_X\\ \partial_Y\end{pmatrix},\quad J:=\begin{pmatrix}J_{xX} & J_{xY}\\ J_{yX} & J_{yY}\end{pmatrix}, \tag{3}$$

where $\partial_x:=\partial/\partial x$, $J_{xX}:=\partial X/\partial x$, etc., or

$$\begin{pmatrix}\partial_X\\ \partial_Y\end{pmatrix}=J^{-1}\begin{pmatrix}\partial_x\\ \partial_y\end{pmatrix}. \tag{4}$$

To be specific we consider the case in which y is fixed while x is changed. We introduce the notation

$$Q(x):=X(x,y),\quad P(x):=Y(x,y).$$

Then from (3) the variations of (Q,P) are given by

[a)]Electronic mail: saito@phys.metro-u.ac.jp
[b)]Electronic mail: shudo@phys.metro-u.ac.jp
[c)]Electronic mail: yjunichi@phys.metro-u.ac.jp
[d)]Electronic mail: yoshida@kiso.phys.metro-u.ac.jp

$$\frac{dQ}{dx}=J_{xX},\quad \frac{dP}{dx}=J_{xY}. \tag{5}$$

We can prove the following:

Proposition 1: Let H be a function of (Q,P) which is given by

$$H(Q,P)=\int^{y(Q,P)}(\det J)dy, \tag{6}$$

and satisfies

$$\frac{\partial H}{\partial x}=0.$$

Then the following system of Hamilton's equations holds:

$$\frac{dQ}{dx}=\frac{\partial H}{\partial P},\quad \frac{dP}{dx}=-\frac{\partial H}{\partial Q}. \tag{7}$$

Conversely, if $H(Q,P)$ satisfies Hamilton's equations, then it must be of the above form.

Note that the value x plays the role of time variable of this system. The proof is straightforward. Applying (4) to H yields

$$\begin{pmatrix}\partial_Q H\\ \partial_P H\end{pmatrix}=J^{-1}\begin{pmatrix}\partial_x H\\ \partial_y H\end{pmatrix}. \tag{8}$$

If we impose the condition that H satisfies

$$J^{-1}\begin{pmatrix}\partial_x H\\ \partial_y H\end{pmatrix}=\begin{pmatrix}-J_{xY}\\ J_{xX}\end{pmatrix}, \tag{9}$$

and compare with (5), the Hamilton equations (7) follow. To solve (9) for H, we multiply J from the left and obtain

$$\begin{pmatrix}\partial_x H\\ \partial_y H\end{pmatrix}=J\begin{pmatrix}-J_{xY}\\ J_{xX}\end{pmatrix}=\begin{pmatrix}0\\ \dfrac{\partial X}{\partial x}\dfrac{\partial Y}{\partial y}-\dfrac{\partial X}{\partial y}\dfrac{\partial Y}{\partial x}\end{pmatrix},$$

hence

$$\partial_x H=0,\quad \partial_y H=\frac{\partial X}{\partial x}\frac{\partial Y}{\partial y}-\frac{\partial X}{\partial y}\frac{\partial Y}{\partial x}=\det J.$$

Therefore (6) is obtained. (*QED*)

This article is motivated by an observation found by one of the authors (AS) during the study of the quantized Hénon map,[1] and generalizes the result to a wide class of maps. Before closing let us present the case of the Hénon map, which is defined by

$$\begin{pmatrix}X\\ Y\end{pmatrix}=\begin{pmatrix}x^2-y+c\\ x\end{pmatrix},\quad \begin{pmatrix}x\\ y\end{pmatrix}=\begin{pmatrix}Y\\ Y^2-X+c\end{pmatrix},\quad J=\begin{pmatrix}2x & 1\\ -1 & 0\end{pmatrix}. \tag{10}$$

Since $\det J=1$, we have simply $H=y+\text{const}$, hence

$$H(Q,P)=P^2-Q+c. \tag{11}$$

Hamiltonian structures on foliations

Izu Vaisman[a)]
Department of Mathematics, University of Haifa, Haifa, Israel

(Received 30 April 2002; accepted for publication 26 May 2002)

We discuss Hamiltonian structures of the Gelfand–Dorfman complex of projectable vector fields and differential forms on a foliated manifold. Such a structure defines a Poisson structure on the algebra of foliated functions, and embeds the given foliation into a larger, generalized foliation with presymplectic leaves. In a so-called tame case, the structure is induced by a Poisson structure of the manifold. Cohomology spaces and classes relevant to geometric quantization are also considered. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1502928]

I. PRELIMINARIES

Let $\mathcal{S}$ be a moving body with supplementary physical characteristics, expressed by scalar parameters, which have no impact on the motion but depend on the latter. For instance, the temperature of a rigid body which moves with high friction.

The mathematical model of such a system will consist of a *configuration space* which is an s-dimensional differentiable manifold N endowed with a p-dimensional foliation $\mathcal{G}$ such that the supplementary parameters are the coordinates along the leaves of $\mathcal{G}$, and the position coordinates are constant along these leaves. Then, the *phase space* of $\mathcal{S}$ will be the total space M of the annihilator bundle $\nu^*\mathcal{G}\subseteq T^*N$ of the tangent bundle $T\mathcal{G}$, and M is endowed with the natural lift $\mathcal{F}$ of $\mathcal{G}$, which is such that the leaves of $\mathcal{F}$ are covering spaces of the leaves of $\mathcal{G}$ (see, e.g., see Ref. 7).

Since the motion does not depend on the supplementary parameters, the Hamiltonian function H of the system will be an *$\mathcal{F}$-foliated function* on M, i.e., a function which is constant along the leaves of $\mathcal{F}$. On the other hand, since we want the motion to determine the time evolution of the supplementary parameters, we should be able to define the Hamiltonian vector field of H as a foliated vector field on the phase space of $\mathcal{S}$.

Therefore, $(M,\mathcal{F})$ should be endowed with a *generalized Hamiltonian structure* that prescribes foliated Hamiltonian vector fields to foliated functions. The aim of this paper is to initiate the study of such Hamiltonian structures.

The generalized Hamiltonian structures we need may be defined within the general Gelfand–Dorfman scheme of Hamiltonian structures on complexes over a Lie algebra.[1,2] For convenience, we refer to such complexes as *Gelfand–Dorfman complexes*,[13] and recall their definition in the following.

Definition 1.1: A *Gelfand–Dorfman complex* consists of:
(i) a real Lie algebra $(\chi,[\ ,\ ])$;
(ii) a cochain complex of real vector spaces

$$\mathcal{C}=\left(\bigoplus_{k=0}^{\infty}\Omega^k,\ \ d:\Omega^k\to\Omega^{k+1},\ \ d^2=0\right);$$

(iii) mappings $X\mapsto i(X)\in L_{\mathbf{R}}(\Omega^k,\Omega^{k-1})$, $(\Omega^{-1}:=0;\ :=$ denotes a definition), defined for all X

a)Electronic mail: vaisman@math.haifa.ac.il

$\in\chi$ and $k=0,1,2,\ldots$, such that
(a) if $\alpha\in\Omega^1$ and $i(X)\alpha=0$ for all $X\in\chi$ then $\alpha=0$;
(b) if $L_X:=di(X)+i(X)d$ then

$$i(X)i(Y)+i(Y)i(X)=0,\ \ i([X,Y])=L_Xi(Y)-i(Y)L_X. \tag{1}$$

Usually, one says that $\mathcal{C}$ is a *complex over* χ, and the mapping $X\mapsto i(X)$ encountered in Definition 1.1 may be seen as a *representation of* χ *on* $\mathcal{C}$. This mapping also defines a pairing

$$\langle\alpha,X\rangle=\langle X,\alpha\rangle:=i(X)\alpha,\quad X\in\chi,\alpha\in\Omega^1,$$

and, in particular, one denotes $Xf:=\langle \mathrm{d}f,X\rangle,\ f\in\Omega^0,X\in\chi$.

A linear mapping $H\in L_{\mathbf{R}}(\Omega^1,\chi)$ is said to be *skew symmetric* if

$$\langle\alpha,H\beta\rangle=-\langle\beta,H\alpha\rangle,\quad \forall\alpha,\beta\in\Omega^1. \tag{2}$$

The Hamiltonian structures of a Gelfand–Dorfman complex are defined by generalizing the notion of a Poisson bivector (e.g., Ref. 11). For this purpose, one notices that the formula[1,2]

$$[H,K](\alpha,\beta,\gamma):=\sum_{\mathrm{Cycl}(\alpha,\beta,\gamma)}\{\langle KL_{H\alpha}\beta,\gamma\rangle+\langle HL_{K\alpha}\beta,\gamma\rangle\}, \tag{3}$$

where $H,\ K\in L_{\mathbf{R}}(\Omega^1,\chi)$ are skew symmetric and $\alpha,\ \beta,\ \gamma\in\Omega^1$, may be seen as defining a bracket

$$[H,K]\in L_{\mathrm{alt},\mathbf{R}}((\Omega^1)^3,\Omega^0),$$

which is a generalization of the Schouten–Nijenhuis bracket of bivector fields on manifolds. We call bracket (3) the *Gelfand–Dorfman bracket*. Then, one defines

Definition 1.2: A skew-symmetric homomorphism $H\in L_{\mathbf{R}}(\Omega^1,\chi)$ which satisfies the *Poisson condition* $[H,H]=0$ is called a *Hamiltonian structure* on the Gelfand–Dorfman complex $(\chi,\mathcal{C})$.

For a Hamiltonian structure one defines the following generalizations of classical notions:
(i) $\forall f\in\Omega^0,\ X_f:=H(\mathrm{d}f)\in\chi$ is the *Hamiltonian vector* of f;
(ii) $\forall f,g\in\Omega^0,\ \{f,g\}:=X_fg$ is the *Poisson bracket*; this bracket is skew-symmetric because of (2), and it satisfies the Jacobi identity because (3) yields

$$[H,H](\mathrm{d}f,\mathrm{d}g,\mathrm{d}h)=2\sum_{\mathrm{Cycl}(f,g,h)}\{\{f,g\},h\};$$

(iii) $\forall\alpha,\beta\in\Omega^1$, one has a Ω^1-*bracket*

$$\{\alpha,\beta\}:=L_{H\alpha}\beta-L_{H\beta}\alpha-d\langle H\alpha,\beta\rangle, \tag{4}$$

with the particular case

$$\{\mathrm{d}f,\mathrm{d}g\}=\mathrm{d}\{f,g\}. \tag{5}$$

The Ω^1-bracket (4) may be defined for any skew-symmetric mapping $H\in L_{\mathbf{R}}(\Omega^1,\chi)$, and it satisfies the following fundamental identities:[4,12]

$$\langle\gamma,H\{\alpha,\beta\}\rangle=\langle\gamma,[H\alpha,H\beta]\rangle+\tfrac{1}{2}[H,H](\alpha,\beta,\gamma), \tag{6}$$

$$\sum_{\mathrm{Cycl}(\alpha,\beta,\gamma)}\langle\{\{\alpha,\beta\},\gamma\},X\rangle=[H,L_XH](\alpha,\beta,\gamma)+\frac{1}{2}\sum_{\mathrm{Cycl}(\alpha,\beta,\gamma)}[H,H](\alpha,\beta,d\langle\gamma,X\rangle), \tag{7}$$

where $\alpha,\ \beta,\ \gamma\in\Omega^1,\ X\in\chi$, and

$$L_X H(\alpha) := [X, H\alpha] - H(L_X \alpha). \tag{8}$$

In the Hamiltonian case $[H,H]=0$, it follows from (7) that the Ω^1-bracket is a Lie algebra bracket. Furthermore, under the supplementary *regularity hypothesis*: if $\forall\, \alpha \in \Omega^1\ \langle \alpha, X\rangle = 0$ then $X=0$ $(X \in \chi)$, H is a homomorphism of Lie algebras, i.e.,

$$H\{\alpha,\beta\} = [H\alpha, H\beta]. \tag{9}$$

On the other hand, even without the regularity hypothesis, (6) shows that if we ask $H \in L_{\mathbf{R}}(\Omega^1, \chi)$ to be skew symmetric and satisfy (9), H is a Hamiltonian structure.

II. HAMILTONIAN STRUCTURES OF FOLIATIONS

With the motivation of Sec. I in mind, let us consider an arbitrary n-dimensional differentiable manifold M (in the present paper "everything" is of differentiability class C^∞) endowed with a p-dimensional foliation $\mathcal{F}$. An object of M that projects to the space of the leaves of $\mathcal{F}$ is called either *projectable* or *foliated*. We refer the reader to Ref. 7 for all the notions of foliation theory which we are going to use.

The Lie algebra $\chi_{\mathcal{F}}$ of the $\mathcal{F}$-foliated vector fields and the complex of projectable differential forms $\Omega_{\mathcal{F}} = \oplus_{k=1}^{q} \Omega^k_{\mathcal{F}}$ $(q := n-p)$, with the usual exterior differential and contraction operators $i(X)$, $X \in \chi_{\mathcal{F}}$, define a Gelfand–Dorfman complex associated with the pair $(M,\mathcal{F})$. One might consider general Hamiltonian structures on this complex, but, such a structure may have a nonlocal character. We avoid nonlocality by

Definition 2.1: A *Hamiltonian structure* on (or of) the foliation $\mathcal{F}$ is a vector bundle morphism $h: \nu^*\mathcal{F} \to TM$ ($\nu\mathcal{F} = TM/T\mathcal{F}$ is the transversal bundle of $\mathcal{F}$) such that the induced map of cross sections $H: \Omega^1_{\mathcal{F}} \to \chi(M)$ [$\chi(M)$ is the space of all the tangent vector fields of M] is a Hamiltonian structure of the Gelfand–Dorfman complex of $(M,\mathcal{F})$.

In particular, Definition 2.1 implies that the morphism h is skew symmetric [i.e., it satisfies (2) pointwisely], and that the values of the mapping H are in $\chi_{\mathcal{F}}$.

Example 2.1: Any skew symmetric $h \in L_{\mathbf{R}}(\nu^*\mathcal{F}, T\mathcal{F})$ may be seen as a trivial Hamiltonian structure of the foliation $\mathcal{F}$. Indeed, formula (3) shows that $[H,H]=0$ if the values of H are vector fields tangent to $\mathcal{F}$

Example 2.2: Let P be a Poisson bivector field on the foliated manifold $(M,\mathcal{F})$, such that for any foliated function $f \in \Omega^0_{\mathcal{F}}$ the Hamiltonian vector field X^P_f is a foliated vector field. Define $\sharp_P : T^*M \to TM$ by $\langle \sharp_P \alpha, \beta\rangle := P(\alpha,\beta)$. Then, $h := \sharp_P|_{\nu^*\mathcal{F}}$ defines a Hamiltonian structure of the foliation $\mathcal{F}$.

Example 2.3: A bivector field P is called a *transversal Poisson structure* of $\mathcal{F}$ if the bracket

$$\{f,g\} := P(\mathrm{d}f, \mathrm{d}g) \quad (f,g \in C^\infty(M))$$

makes $\Omega^0_{\mathcal{F}}$ a Poisson algebra.[6] In this case, again, $h := \sharp_P|_{\nu^*\mathcal{F}}$ is a Hamiltonian structure of $\mathcal{F}$. Moreover, for any Hamiltonian structure h of $\mathcal{F}$ and any choice of a decomposition $TM = E \oplus T\mathcal{F}$, the bivector field P defined by

$$\sharp_P|_{E^* \approx \nu^*\mathcal{F}} = h, \quad \sharp_P|_{T^*\mathcal{F}} = 0$$

is a transversal Poisson structure of $\mathcal{F}$.

We also show how to express Hamiltonian structures of a foliation $\mathcal{F}$ by means of *adapted local coordinates* (x^a, y^u), where $a = 1,\ldots,q$; $u = q+1,\ldots,n$, and $x^a = \text{const}$ are the local equations of $\mathcal{F}$. In order to get an expression by tensors, we fix a decomposition $TM = E \oplus T\mathcal{F}$ where[8]

$$E = \mathrm{span}\left\{ X_a := \frac{\partial}{\partial x^a} - t^u_a \frac{\partial}{\partial y^u} \right\}, \quad T\mathcal{F} = \mathrm{span}\left\{ \frac{\partial}{\partial y^u} \right\}, \tag{10}$$

for some local coefficients t_a^u and with the Einstein summation convention. The local bases of TM defined by (10) have the dual co-bases

$$dx^a, \quad \theta^u := dy^u + t_a^u\, dx^a, \tag{11}$$

and $\nu^*\mathcal{F} = \mathrm{span}\{dx^a\}$.

Then, a skew-symmetric morphism $h: \nu^*\mathcal{F} \to TM$ has local equations

$$h(dx^a) = h^{ab} X_b + k^{au} \frac{\partial}{\partial y^u}. \tag{12}$$

The components h^{ab} define a global cross section W of $\wedge^2 E$, therefore, a global cross section of $\wedge^2 \nu\mathcal{F}$, which is independent of the choice of E, and the components k^{au} define a global cross section of $E \otimes T\mathcal{F}$. The following assertion is obvious.

Proposition 2.1: The morphism h defined by (12) is a Hamiltonian structure of $\mathcal{F}$ iff the cross section W with local components h^{ab} is foliated and defines a structure of Poisson algebra on $\Omega^0_{\mathcal{F}}$.

The Poisson bracket defined by W on $\Omega^0_{\mathcal{F}}$ is of the local type, and it has the following interpretation. Let U be an open neighborhood of M such that the manifold N of the slices of $\mathcal{F}$ in U exists, and let $p: U \to N$ be the natural projection (constant along the slices of $\mathcal{F}$ in U). Then $h_N(p(x)) := p_*(x) \circ (h|_U(x)) \circ p^*(p(x))$, $x \in U$, is the morphism $\sharp_{P_N}$ of a well-defined Poisson bivector field P_N on N, which defines the same local Poisson brackets as W. (h_N is well defined since the values of the mapping H defined by h are foliated vector fields.)

Furthermore, any Poisson algebra structure of local type on $\Omega^0_{\mathcal{F}}$ is defined by a family of Hamiltonian structures on $\mathcal{F}$. Indeed, the required structure is equivalent to a foliated section W of $\wedge^2 \nu(\mathcal{F})$, which satisfies the Poisson condition $[W,W] = 0$. Choose a decomposition $TM = E \oplus T\mathcal{F}$, and, $\forall \alpha \in \nu^*\mathcal{F}$, define $h(\alpha)$ to be the unique vector of E with projection $\sharp_W \alpha$ on $\nu\mathcal{F}$. Since by (3)

$$[H,H](\alpha,\beta,\gamma) = [W,W](\alpha,\beta,\gamma) \quad (\alpha,\beta,\gamma \in \Omega^1_{\mathcal{F}}),$$

h is a Hamiltonian structure of $\mathcal{F}$, and h induces W.

More exactly, if h_0 is one of the Hamiltonian structures which define W, the whole family which defines W is $h_0 + k$, where $k \in L_{\mathbf{R}}(\nu^*\mathcal{F}, T\mathcal{F})$ is skew symmetric. This holds since for any Hamiltonian structure h of $\mathcal{F}$ and any skew symmetric $k \in L_{\mathbf{R}}(\nu^*\mathcal{F}, T\mathcal{F})$, the corresponding morphisms H, K of global cross sections satisfy the relation $[H,K] = 0$ [see (3)].

Proposition 2.2: For any Hamiltonian structure h on a foliation $\mathcal{F}$, the generalized distribution $\mathcal{H} := T\mathcal{F} + \mathcal{H}_0$ ($\mathcal{H}_0 :=$ im h) is a projectable, completely integrable distribution, and its leaves are presymplectic manifolds with kernel $T\mathcal{F}$. Furthermore, $h(\mathrm{ann}\,\mathcal{H}) = \mathcal{H}_0 \cap T\mathcal{F}$ (ann *denotes the annihilator of a vector space or bundle*).

Proof: We continue to use the previous notation. Let $x_0 \in U \subseteq M$ where U is a neighborhood such that $\mathcal{F}|_U$ has a q-dimensional, transversal submanifold N. Since the projection p is a submersion, if $L_{p(x_0)}$ is the symplectic leaf of the Poisson structure P_N through $p(x_0) \in N$, $\tilde{L}_{x_0} := p^{-1}(L_{x_0})$ is an integral submanifold of $\mathcal{H}$ through x_0. The existence of these integral submanifolds shows the complete integrability of $\mathcal{H}$. Projectability follows from the fact that $\mathcal{H}_0$ is spanned by the projectable vector fields $H(\alpha)$, $\alpha \in \Omega^1_{\mathcal{F}}$, and $\mathcal{H}$ projects onto the symplectic distribution of P_N. The lift of the symplectic form of $L_{p(x_0)}$ by p^* yields the required presymplectic form of the corresponding leaf of $\mathcal{H}$. Finally, notice that $\alpha \in \mathrm{ann}\,\mathcal{H}$ iff $\alpha = p^*(\lambda)$ for some $\lambda \in \ker \sharp_{P_N}$, and then $p_* h(\alpha) = 0$. This implies $h(\mathrm{ann}\,\mathcal{H}) \subseteq \mathcal{H}_0 \cap T\mathcal{F}$. On the other hand, if $h(\alpha) \in T\mathcal{F}$, we must have $\alpha = p^*(\lambda)$ where $\lambda \in \ker \sharp_{P_N}$, and this justifies the converse inclusion. (All these also follow immediately from the local equations (12) of h.) Q.E.D.

The distribution $\mathcal{H}$ will be called the *characteristic distribution* of the Hamiltonian structure h, and its leaves constitute the *presymplectic foliation*. The Hamiltonian structure h of the foliation $\mathcal{F}$ on M will be called *transitive* if the characteristic distribution is $\mathcal{H} = TM$. In this case,

Proposition 2.2 tells us that M is a presymplectic manifold with the kernel foliation $\mathcal{F}$, and that $TM=\mathcal{H}_0\oplus T\mathcal{F}$. The latter equality also shows that the corresponding local Poisson structures P_N are the symplectic reduction of the presymplectic form of M. Conversely, if M is a presymplectic manifold with the presymplectic two-form σ, and if E is a complementary distribution of the kernel foliation $\mathcal{F}$ of σ, there exists a well-defined, transitive, Hamiltonian structure h of $\mathcal{F}$ such that $\mathcal{H}_0=E$ and the local Poisson structures P_N are the symplectic reductions of σ.

Example 2.4: Let $\mathcal{H}$ be a coisotropic foliation of dimension $n+k(k\leqslant n)$ of a symplectic manifold M of dimension $2n$, with the symplectic form ω. It is well known that the ω-orthogonal distribution of $\mathcal{H}$ is tangent to a foliation $\mathcal{F}$, and that, $\forall x\in M$, there exist local coordinates (x^a,x^u,y^i) around x such that $a=1,\ldots,p:=n-k$, $u=p+1,\ldots,n$, $i=1,\ldots,n$, $x^a=\text{const}$ are the local equations of $\mathcal{H}$, and the symplectic form has the canonical expression

$$\omega=\sum_{a=1}^{p}\mathrm{d}x^a\wedge\mathrm{d}y^a+\sum_{u=p+1}^{n}\mathrm{d}x^u\wedge\mathrm{d}y^u. \tag{13}$$

(This result is a theorem due to Lie.[5]) The local equations of the foliation $\mathcal{F}$ are $x^a=\text{const}$, $x^u=\text{const}$, $y^u=\text{const}$, and the computation of the Hamiltonian vector field X_f^ω of an $\mathcal{F}$-foliated function [via (13)] shows that X_f^ω is an $\mathcal{F}$-foliated vector field tangent to the leaves of $\mathcal{H}$. Therefore, $h:=-\flat_\omega^{-1}|_{\nu^*\mathcal{F}}$ is a Hamiltonian structure of the foliation $\mathcal{F}$ with the presymplectic foliation $\mathcal{H}$. Moreover, in this case we have $T\mathcal{F}\subseteq\mathcal{H}_0$.

Example 2.5: Example 2.4 can be generalized as follows. Let (M,ω) be an almost symplectic manifold (i.e., we ask ω to be nondegenerate but not necessarily closed), and let $\mathcal{H}$ be a coisotropic foliation such that the pullback of ω to every leaf of $\mathcal{H}$ is closed on the leaf. Then formula (13) is to be replaced by

$$\omega=\sum_{a=1}^{p}\mathrm{d}x^a\wedge\varpi^a+\sum_{u=p+1}^{n}\mathrm{d}x^u\wedge\mathrm{d}y^u, \tag{14}$$

where ϖ^a are linearly independent, local, one-forms which contain only the differentials $\mathrm{d}y^a$. Now, we obtain the foliation $\mathcal{F}$ and its Hamiltonian structure h in the same way as in the symplectic case.

We finish this section with a remark about the chosen definition of the notion of a Hamiltonian structure on a foliation.

If we start with the physical motivation of Sec. I, and do not think of Gelfand–Dorfman complexes *a priori*, the natural definition of a generalized Hamiltonian structure (ghs) that suites the problem is that of an **R**-linear morphism of sheaves

$$\Phi:\underline{\Omega^0_{\mathcal{F}}}\to\underline{\chi},\quad f\mapsto X_f, \tag{15}$$

(underlining means passing to germs of the corresponding type of objects), such that the bracket defined by

$$\{f,g\}=X_fg,\quad f,g\in\underline{\Omega^0_{\mathcal{F}}}, \tag{16}$$

makes $\Omega^0_{\mathcal{F}}$ a Poisson algebra sheaf.

In particular, the action of a Hamiltonian vector field X_f on foliated functions $g\in\Omega^0_{\mathcal{F}}$ depends only on the first jet j^1f. This is not enough to ensure that the ghs has local type. A natural condition for the latter property is to ask $X_f=0$ for all $f\in\Omega^0_{\mathcal{F}}$ such that $j^1_xf=0$ at each point $x\in M$. If the ghs structure Φ satisfies this locality condition, Φ is completely defined by local vector fields

$$X_{x^a}=h^{ab}X_b+k^{au}\frac{\partial}{\partial y^u}, \tag{17}$$

that satisfy the conditions of Proposition 2.1.

Therefore, the generalized Hamiltonian structures of local type are exactly the Hamiltonian structures of foliations which we defined earlier.

III. TAME HAMILTONIAN STRUCTURES

The Gelfand–Dorfman complex of a foliation does not satisfy the regularity hypothesis formulated at the end of Sec. I. The equality $\langle \alpha, X\rangle = 0$, $\forall \alpha \in \Omega^1_{\mathcal{F}}$, only implies $X \in \Gamma T\mathcal{F}$ (Γ denotes the space of global cross sections). Therefore, (9), or the equivalent property

$$X_{\{f,g\}} = [X_f, X_g], \quad \forall f, g \in \Omega^0_{\mathcal{F}}, \tag{18}$$

obtained by taking $\alpha = \mathrm{d}f$, $\beta = \mathrm{d}g$, f, $g \in \Omega^0_{\mathcal{F}}$ in (9), may not hold, and we shall define

Definition 3.1: A skew symmetric morphism $h: \nu^*\mathcal{F} \to TM$ which satisfies condition (18) is a *strong Hamiltonian structure* on $\mathcal{F}$.

Remark 3.1: If h is a strong Hamiltonian structure, the sheaf $\nu^*\mathcal{F}$ has a natural structure of a sheaf of twisted Lie algebras[3] over $(\mathbf{R}, \underline{\Omega^0_{\mathcal{F}}})$, with the action of $\underline{\text{germs}}$ $\alpha \in \underline{\nu^*\mathcal{F}}$ defined as the action of $H(\alpha)$.

Formula (6) shows that a strong Hamiltonian structure is Hamiltonian. The Hamiltonian structures indicated in Examples 2.2 and 2.4 are strong but this is not necessarily true for Examples 2.3 and 2.5. If h is a strong Hamiltonian structure, the generalized distribution $\mathcal{H}_0 = \mathrm{im}\, h$ is involutive. Conversely, if $\mathcal{H}_0$ is involutive and if $\mathcal{H}_0 \cap T\mathcal{F} = 0$, h is a strong Hamiltonian structure [use (6)]. These facts suggest

Definition 3.2: A Hamiltonian structure h of a foliation $\mathcal{F}$ is *transversal* (to $\mathcal{F}$) if there exists a differentiable complementary distribution E of $T\mathcal{F}$ ($E \oplus T\mathcal{F} = TM$) such that $\mathcal{H}_0 \subseteq E$. The distribution E will be called an *image extension* of h. (It is possible to have more than one image extension.) A transversal Hamiltonian structure of $\mathcal{F}$ is a *tame* structure if all the brackets of differentiable vector fields that belong to $\mathcal{H}_0$ are contained in an image extension E. (In the tame case, only such image extensions will be used.)

A tame Hamiltonian structure is strong [see (6)], and a transversal, strong Hamiltonian structure is tame. The condition $\mathcal{H}_0 \cap T\mathcal{F} = 0$, which is implicit in the definition of transversality, is equivalent to $h(\mathrm{ann}\,\mathcal{H}) = 0$ and also to the fact that the rank of the morphism h is equal to the rank of the Poisson structures induced by h on the manifolds of local slices of $\mathcal{F}$. [See Proposition 2.2 and formula (12)] This condition is not enough for transversality. Indeed, there always exists a smallest regular distribution $\overline{\mathcal{H}_0}$ which contains the generalized distribution $\mathcal{H}_0$ but, we may have $\overline{\mathcal{H}_0} \cap T\mathcal{F} \neq 0$.

Example 3.1: Let $TM = F \oplus F'$ be a locally product structure on the manifold M, and $\mathcal{F}$ the foliation tangent to F. Assume that one has a Poisson algebra structure of the local type on $\Omega^0_{\mathcal{F}}$. Then, the Hamiltonian structure h which induces the former and has its Hamiltonian vector field in F' is tame. Indeed, F' is an image extension of h of the kind required for tame structures. Notice also that a transitive, tame, Hamiltonian structure must be of the locally product type shown in the example.

Proposition 3.1: Let h be a transversal Hamiltonian structure of the foliation $\mathcal{F}$ with image extension E. Then h is tame with image extension E iff the Nijenhuis tensor N_E of the projection $p_E: TM \to TM$ of $TM = E \oplus T\mathcal{F}$ onto E satisfies the condition

$$N_E(h\alpha, h\beta) = 0, \quad \forall \alpha, \beta \in \nu^*_x\mathcal{F}, \quad \forall x \in M. \tag{19}$$

Proof: Following the general definition of a Nijenhuis tensor, e.g., Refs. 4 and 13 and since $p_E^2 = p_E$, for $X, Y \in \Gamma TM$, one has

$$N_E(X,Y) = [p_E X, p_E Y] - p_E[p_E X, Y] - p_E[X, p_E Y] + p_E[X,Y]. \tag{20}$$

Consider the local equations (12) of h using an image extension E, which implies that $k^{au}=0$. Then, h is tame iff

$$H(\mathrm{d}h^{ab})=[H(\mathrm{d}x^a),H(\mathrm{d}x^b)],$$

which is equivalent to

$$h^{ac}h^{be}\tau^u_{ce}=0,\quad \tau^u_{ce}:=\frac{\partial t^u_c}{\partial x^e}-\frac{\partial t^u_e}{\partial x^c}+t^v_c\frac{\partial t^u_e}{\partial y^v}-t^v_e\frac{\partial t^u_c}{\partial y^v}. \tag{21}$$

The invariant meaning of (21) is exactly (19). Q.e.d.

In the case of a transversal Hamiltonian structure h on a foliated manifold $(M,\mathcal{F})$ it is possible to extend the Hamiltonian formalism in a way similar to what was done for presymplectic manifolds in Ref. 9.

Let us recall that, if $(M,\mathcal{F})$ is a foliated manifold and if E is a complementary distribution of $T\mathcal{F}$, the use of the local bases (10), (11) yields a bigrading of tensor fields and differential forms, with the convention that the first degree is the E-degree and the second is the $T\mathcal{F}$-degree.[8] For instance, a differential k-form is of bidegree (s,t) if its local expressions contain s forms $\mathrm{d}x^a$ and t forms θ^u $(s+t=k)$. Then, one has a decomposition

$$d=d'_{(1,0)}+d''_{(0,1)}+\partial_{(2,-1)}, \tag{22}$$

and $d^2=0$ is equivalent to

$$\begin{gathered} d''^2=0,\quad \partial^2=0,\quad d'^2+d''\partial+\partial d''=0,\\ d'd''+d''d'=0,\quad \partial d'+d'\partial=0. \end{gathered} \tag{23}$$

Now, we return to the transversal Hamiltonian structure h of $\mathcal{F}$, and fix an image extension E of h. Then the corresponding section mapping H is well defined for any differential form $\alpha\in\Omega^{(1,0)}(M)$ of bidegree (1,0), and $H\alpha\in\Gamma E$. For any differentiable function $f\in C^\infty(M)$, we can define the Hamiltonian vector field $X'_f\in\Gamma E$ by

$$X'_f=H(d'f) \tag{24}$$

and $\forall f,g\in C^\infty(M)$ we get an *extended Poisson bracket*

$$\{f,g\}':=X'_fg=\langle Hd'f,dg\rangle=\langle Hd'f,d'g\rangle=-\{g,f\}'. \tag{25}$$

Furthermore, if $X\in\Gamma E$ and $\alpha\in\Omega^{(1,0)}(M)$, (22) leads to

$$L_X\alpha=L'_X\alpha+L''_X\alpha, \tag{26}$$

where

$$L'_X=i(X)d'+d'i(X),\quad L''_X=i(X)d''+d''i(X). \tag{27}$$

Accordingly, it is possible to extend the Gelfand–Dorfman bracket (3) to arbitrary (1,0)-forms α,β,γ by

$$[H,K]'(\alpha,\beta,\gamma):=\sum_{\mathrm{Cycl}(\alpha,\beta,\gamma)}\{\langle KL'_{H\alpha}\beta,\gamma\rangle+\langle HL'_{K\alpha}\beta,\gamma\rangle\}, \tag{28}$$

where H,K are defined by skew symmetric morphisms $h,k:\nu^*\mathcal{F}\to E$. A straightforward computation shows that the extended bracket is trilinear over $C^\infty(M)$, and for a Hamiltonian structure h we have $[H,H]'(\alpha,\beta,\gamma)=0$ for any $\alpha,\beta,\gamma\in\Omega^{(1,0)}(M)$.

In particular, using (25) and (27), one gets

$$[H,H]'(d'f,d'g,d'k)=2\sum_{\mathrm{Cycl}(f,g,k)}[\{\{f,g\}',k\}'+d'^2f(X'_g,X'_k)]=0. \tag{29}$$

Proposition 3.2: If h is a tame Hamiltonian structure on $(M,\mathcal{F})$ the Poisson bracket $\{,\}'$ defines a Poisson structure on the manifold M.

Proof: For any foliation and any choice of a complementary distribution E one gets

$$d'^2f(X,Y)=\langle d''f,N_E(X,Y)\rangle,\quad \forall f\in C^\infty(M),\ \forall X,Y\in\Gamma E, \tag{30}$$

where N_E is the Nijenhuis tensor (20). Indeed, if $X,Y\in\Gamma E$, (20) yields

$$N_E(X,Y)=p_{T\mathcal{F}}[X,Y], \tag{31}$$

where $p_{T\mathcal{F}}$ denotes the projection onto the second term of the decomposition $TM=E\oplus T\mathcal{F}$. On the other hand,

$$\begin{aligned}d'^2f(X,Y)&=d(d'f)(X,Y)=XYf-YXf-\langle d'f,[X,Y]\rangle=[X,Y]f-(p_E[X,Y])f\\&=\langle df,p_{T\mathcal{F}}[X,Y]\rangle=\langle d''f,p_{T\mathcal{F}}[X,Y]\rangle.\end{aligned}$$

Thus, (30) is justified, and the conclusion follows from the characterization (19) of the tame Hamiltonian structures and formula (29). Q.E.D.

Proposition 3.2 tells us that a tame Hamiltonian structure h is defined by a usual Poisson structure P on the foliated manifold $(M,\mathcal{F})$. The Hamiltonian vector fields of foliated functions with respect to h coincide with those with respect to P, $\sharp_P|_{E^*}=h$ and $\sharp_P|_{T^*\mathcal{F}}=0$. Thus, the tame Hamiltonian structures are included in Example 2.2. But, not all the structures of Example 2.2 are tame.

Similarly, it is possible to extend the bracket (4) of foliated one-forms to any $\alpha,\beta\in\Omega^{(1,0)}(M)$ by

$$\{\alpha,\beta\}':=L'_{H\alpha}\beta-L'_{H\beta}\alpha-d'\langle H\alpha,\beta\rangle. \tag{32}$$

From (32), it follows that $\forall f,g\in C^\infty(M)$ one has

$$\{f\alpha,g\beta\}'=fg\{\alpha,\beta\}'+f(H(\alpha)g)\beta-g(H(\beta)f)\alpha. \tag{33}$$

In particular, we see that the bracket (32) is skew symmetric because it is such for foliated one-forms, where it reduces to (4).

Let us also evaluate the bracket (32) on an argument $X\in\Gamma E$. First we define $L'_XH\in L_{\mathbf{R}}(\Omega^{(1,0)}(M),\Gamma E)$ by

$$L'_XH(\alpha):=p_E[X,H(\alpha)]-H(L'_X\alpha). \tag{34}$$

Taking the derivative of (2) in direction X, and with the decomposition (26), we see that L'_XH is skew symmetric. Then, if the derivatives L' of (32) are replaced by $L-L''$ one gets

$$\{\alpha,\beta\}'(X)=H(\alpha)i(X)\beta-H(\beta)i(X)\alpha-\langle\alpha,L'_XH(\beta)\rangle. \tag{35}$$

In particular, if $\alpha=d'f$, $\beta=d'g$, (35) yields

$$\{d'f,d'g\}'=d'\{f,g\}'+L_{X'_g}d''f-L_{X'_f}d''g. \tag{36}$$

The result follows by an easy computation which takes into account the fact that the space of (1,0)-forms is the annihilator of E.

We will say that $f\in C^\infty(M)$ is a *distinguished function*[9] if (a) $d'f$ is a foliated one-form, and (b) $\mathcal{H}\subseteq\ker d'^2 f$, and we will denote by Ω^0_d the space of distinguished functions. Any foliated function is distinguished, but not conversely. Formula (29) shows that the extended Poisson bracket of distinguished functions satisfies the Jacobi identity, and (a) implies that $\{f,g\}'\in\Omega^0_{\mathcal{F}}$, $\forall f,\ g\in\Omega^0_d$. Therefore, Ω^0_d is a Poisson algebra and $\Omega^0_{\mathcal{F}}$ is an ideal of the former. Furthermore, if $f,g\in\Omega^0_{\mathcal{F}}$, one gets $L_{X'_g}d''f=0$, and (36) implies

$$\{d'f,d'g\}'=d'\{f,g\}',\quad \forall f,g\in\Omega^0_d. \tag{37}$$

Then, if we take $f,g\in\Omega^0_d, k\in C^\infty(M)$ in (29) and use (31), we get

$$X'_{\{f,g\}'}=p_E[X'_f,X'_g],\quad f,g\in\Omega^0_d. \tag{38}$$

Proposition 3.3: Let h be a tame Hamiltonian structure of the foliation $\mathcal{F}$, E an image extension of h, and P the Poisson structure defined by the brackets $\{,\}'$. Then, the triple $(\nu^*\mathcal{F},\{,\}',h)$, with the bracket (32)*, is a Lie subalgebroid of the cotangent Lie algebroid $(T^*M,\{,\}_P,\sharp_P)$.*

Proof: The bracket $\{,\}_P$ is given by (4) with H replaced by $\sharp_P$, and, since $\sharp_P|_{E^*}=h$, we have $\forall\alpha,\beta\in\Omega^1_{\mathcal{F}}$,

$$\{\alpha,\beta\}_P=\{\alpha,\beta\}=\{\alpha,\beta\}'.$$

Then, (33) implies

$$\{f\alpha,g\beta\}_P=\{f\alpha,g\beta\}',\quad \forall f,g\in C^\infty(M),\forall\alpha,\beta\in\Omega^1_{\mathcal{F}}.$$

Q.E.D.

Now, let us notice that there exist an inclusion and a splitting morphism of Lie algebroids

$$\iota:\nu^*\mathcal{F}\hookrightarrow T^*M,\pi=p_{E^*}:T^*M\to\nu^*\mathcal{F}\quad(\pi\circ\iota=id), \tag{39}$$

where p_{E^*} is the projection onto E^* in the decomposition $T^*M=E^*\oplus T^*\mathcal{F}$.

Proposition 3.4: Under the hypotheses of Proposition 3.3, the projection π induces an injection π^* of the de Rham cohomology of the Lie subalgebroid $\nu^*\mathcal{F}$ into the Lichnerowicz–Poisson cohomology of (M,P). For any complex vector bundle S over M, the Lichnerowicz–Poisson Chern classes $c_k^{LP}(S)$ belong to the image of the injection π^*.

Proof: For the definition of the de Rham cohomology of Lie algebroids, see Ref. 4; the Lichnerowicz–Poisson cohomology is the de Rham cohomology of the cotangent Lie algebroid T^*M of the Poisson manifold (M,P) (e.g., Ref. 11). These definitions show the existence of homomorphisms

$$H^*_{\text{de Rham}}(M)\xrightarrow{j_1^*}H^*_{\text{LP}}(M,P)\xrightarrow{\iota^*}H^*(\nu^*\mathcal{F}),$$

$$H^*_{\text{de Rham}}(M)\xrightarrow{j_2^*}H^*(\nu^*\mathcal{F})\xrightarrow{\pi^*}H^*_{\text{LP}}(M,P),$$

where the morphisms are naturally induced by $j_1=\sharp_P, j_2=h,\iota,\pi$. [For instance, at the level of cochains we define

$$(j_2^*\lambda)(\alpha_1,\ldots,\alpha_k)=\lambda(H\alpha_1,\ldots,H\alpha_k),(\lambda\in\Omega^k(M),\alpha_1,\ldots,\alpha_k\in\Gamma E^*),$$

etc.] The following relations are obvious: $\iota^*\circ j_1^*=j_2^*$, $\pi^*\circ j_2^*=j_1^*$, $\iota^*\circ\pi^*=id$. The last one shows that π^* is injective; the others were mentioned for a later utilization.

Now, we recall that the Lichnerowicz–Poisson Chern classes are the j_1^*-image of the real Chern classes. Representatives of $c_k^{\text{LP}}(S)$ are obtained by evaluating Chern–Weil polynomials on

the curvature of an arbitrary contravariant derivative ${}^{P}D$ on S (i.e., a connection of the Lie algebroid T^*M on S) like in the usual Chern–Weil theory.[11] In particular, if ${}^{h}D$ is a connection of the Lie algebroid $\nu^*\mathcal{F}$ on S then

$$ {}^{P}D_{\alpha}s = {}^{h}D_{\pi\alpha}s \tag{40}$$

is a contravariant derivative on S, and, if C denotes curvatures, one has

$$ C_{P_D} = \pi^* C_{h_D}, \tag{41}$$

where π^* is used at the level of cochains. Now, the same procedure of evaluating Chern–Weil polynomials on curvature applied to C_{h_D} yields Chern classes $c_k^h(S) \in H^{2k}(\nu^*\mathcal{F})$, which are the j_2^*-images of the real Chern classes. Furthermore, (41) shows that $c_k^{\mathrm{LP}}(S) = \pi^* c_k^h(S)$. Q.E.D.

Corollary 3.1: Let h be a tame Hamiltonian structure and let P be the bivector field of the Poisson brackets $\{,\}'$. Then, there exists a prequantization bundle of the h-Poisson bracket iff $\iota^*[P] \in j_2^*(H^2(M,\mathbf{Z}))$.

Proof: $[P] \in H^2_{\mathrm{LP}}(M,P)$ is the cohomology class defined by the cocycle P. We refer the reader to Ref. 11 for the geometric quantization theory involved in the corollary. Since P defines the same Poisson brackets as h, the existence of a prequantization bundle implies $[P] = j_1^*(\zeta)$ for some $\zeta \in H^2(M,\mathbf{Z})$, which implies $\iota^*[P] = j_2^*(\zeta)$. Conversely, if this condition is satisfied, and if [as a consequence of (40)] we see the Kostant–Souriau prequantization formula as

$$ \hat{f}(s) = {}^{h}D_{d'f}s + 2\pi\sqrt{-1}fs, \quad s \in \Gamma K, \tag{42}$$

where K is the required prequantization bundle, the Dirac quantization principle implies that $c_1^h(K) = \iota^*[P]$. Since we assumed that $\iota^*[P]$ is an integral cohomology class, K exists. Q.e.d.

Now, let us consider the case of a transversal Hamiltonian structure h on $(M,\mathcal{F})$, and fix an image extension E. In this case, we may still see the cross sections of $\wedge^k E$ as a kind of generalized cochains with a coboundary $\delta^{(k)} = \delta$ defined by

$$\begin{aligned}(\delta Q)(\alpha_0,\ldots,\alpha_k) = &\sum_{i=0}^{k} (-1)^i H(\alpha_i)(Q(\alpha_0,\ldots,\hat{\alpha}_i,\ldots,\alpha_k)) \\ &+ \sum_{i<j=1}^{k} (-1)^{i+j} Q(\{\alpha_i,\alpha_j\}',\alpha_0,\ldots,\hat{\alpha}_i,\ldots,\hat{\alpha}_j,\ldots,\alpha_k),\end{aligned} \tag{43}$$

where $Q \in \wedge^k E$, $\alpha_i \in \Gamma E^*$ $(i = 0,\ldots,k)$, and the caret denotes the absence of the corresponding argument.

If we denote $\delta^2 = \delta^{(k+1)} \circ \delta^{(k)}$, a straightforward computation yields

$$\begin{aligned}&(\delta^2 Q)(\alpha_0,\ldots,\alpha_{k+1}) \\ &= \sum_{i<j=1}^{k+1} (-1)^{i+j} \Delta_h(\alpha_i,\alpha_j)(Q(\alpha_0,\ldots,\hat{\alpha}_i,\ldots,\hat{\alpha}_j,\ldots,\alpha_{k+1})) \\ &\quad + \sum_{i<j<k=2}^{k+1} (-1)^{i+j+k} Q\left(\sum_{\mathrm{Cycl}(i,j,k)} \{\alpha_k,\{\alpha_i,\alpha_j\}'\}',\alpha_0,\ldots,\hat{\alpha}_i,\ldots,\hat{\alpha}_j,\ldots,\hat{\alpha}_k,\ldots,\alpha_{k+1}\right),\end{aligned} \tag{44}$$

where

$$ \Delta_h(\alpha_i,\alpha_j) := H(\{\alpha_i,\alpha_j\}') - [H(\alpha_i),H(\alpha_j)]. \tag{45}$$

Since $\delta^2 \neq 0$, we can only define the *twisted cohomology spaces* (e.g., Ref. 10)

$$H^k_{tw}(h) := \frac{\ker \delta^{(k)}}{\mathrm{Im}\, \delta^{(k-1)} \cap \ker \delta^{(k)}}. \tag{46}$$

For instance, by straightforward computations one gets

$$H^0_{tw}(h) = \{f \in C^\infty(M)/X'_f = 0\}, \quad H^1_{tw}(h) = \frac{\{Q \in \Gamma E/L'_Q H = 0\}}{\{X'_f/f \in C^\infty(M), L'_{X'_f} = 0\}}.$$

But, if we define $W' \in \Gamma \wedge^2 E$ by $W'(d'f, d'g) = \{f,g\}'$, we do not get a cocycle since

$$(\delta W')(d'f, d'g, d'k) = -2 \sum_{\mathrm{Cycl}(i,j,k)} \{\{f,g\}', k\}',$$

and the Jacobi identity may not hold.

Several interpretations of twisted cohomology as a usual cohomology exist (e.g., Ref. 10). For instance, the subspaces $\tilde{\mathcal{C}}^k(h) = \ker(\delta^{(k+1)} \circ \delta^{(k)})$ with the coboundary δ constitute a usual cochain complex $\tilde{\mathcal{C}}(h)$, and $H^k_{tw}(h)$ are the usual cohomology spaces of $\tilde{\mathcal{C}}(h)$.

On the other hand, since the Poisson bracket $\{,\}'$ defines a representation of the Lie–Poisson algebra Ω^0_d of distinguished functions on the space $\Omega^0_{\mathcal{F}}$ of foliated functions, we get corresponding cohomology spaces $H^*_d(h) := H^*(\Omega^0_d, \Omega^0_{\mathcal{F}})$. Then, the cochains

$$c(f_1, \ldots, f_k) = Q(d'f_1, \ldots, d'f_k), \quad Q \in \Gamma \wedge^k E, \quad f_1, \ldots, f_k \in \Omega^0_{\mathcal{F}},$$

with values in $\Omega^0_{\mathcal{F}}$ and the coboundary (43) define the cochain complex of projectable cross sections of $\wedge E$ with the Lichnerowicz-like coboundary (see Ref. 11) $\delta Q = -p_{\Gamma \wedge^{k+1} E}[W, Q]$ (p denotes the projection), where W defines the h-Poisson bracket of foliated functions, and $[,]$ is the Schouten–Nijenhuis bracket. We may say that the cohomology spaces, say $H^*_{\mathrm{LPb}}(h)$, of this complex are the *basic Lichnerowicz–Poisson cohomology spaces* of h. The restriction of the cochain W' to distinguished functions is W, and we have a *fundamental class* $[W] \in H^2_{\mathrm{LPb}}(h)$.

Now, remember that a foliated manifold also has *basic de Rham cohomology spaces* $H^*_b(M, \mathcal{F})$,[7] defined as the cohomology spaces of the complex $(\Omega^*_{\mathcal{F}}, d)$, and there exist natural homomorphisms

$$\varphi : H^*_b(M, \mathcal{F}) \to H^*_{\mathrm{de\ Rham}}(M), \psi : H^*_b(M, \mathcal{F}) \to H^*_{\mathrm{LPb}}(h),$$

induced by inclusion and h, respectively.

These facts have the following consequences for geometric quantization. Assume that $[W] = \psi[\Phi]$ where $\varphi[\Phi]$ is an integral de Rham cohomology class. Then $\Phi \in \Omega^2_{\mathcal{F}}$ is a closed two-form with integral periods, such that

$$\{f,g\}' = \Phi(X'_f, X'_g), \quad \forall f, g \in \Omega^0_d. \tag{47}$$

Accordingly, there exists a Hermitian line bundle K over M with a connection ∇ of curvature $2\pi\sqrt{-1}\Phi$, and the Kostant–Souriau formula

$$\hat{f}s = \nabla_{X'_f} s + 2\pi\sqrt{-1} f s \tag{48}$$

provides a prequantization such that the Dirac principle holds for distinguished functions but, generally, not for arbitrary functions [use (47)]. The transitive case, i.e., presymplectic manifolds, was discussed in Ref. 9.

Seeking new integrable couplings of the known integrable hierarchies of evolution equations is a quite new interesting aspect and is of great significance in soliton theory. In this paper, a loop algebra $\tilde{P}$ and its basis are first presented. Second, a new isospectral problem with four potentials in the loop algebra $\tilde{P}$ is considered to construct integrable couplings of the well-known TC hierarchy by the zero-curvature equation such that a family of new integrable couplings including two arbitrary functions are obtained. In particular, when we set two arbitrary functions to be zero, a special integrable couplings of the generalized Korteweg–de Vries equation is also given. © *2002 American Institute of Physics.*

I. INTRODUCTION

It is of important significance in the field of soliton theory and dynamical integrable system to find more new hierarchies evolution equations and to further consider their algebraic properties and geometrical structures, such as Hamiltonian structure, conserved density, symmetry, and Liouville integrable property.[1–7] In 1989, Tu[5] presented a so-called loop algebra scheme to generate a hierarchy of Lax integrable evolution equations and used a trace identity to construct their Hamiltonian structures from an eigenvalue problem. This approach has been applied to find many new important nonlinear evolution equations hierarchies (AKNS, TA, TB, TC, BTP, Kaup-Newell, WKI, etc.) and the corresponding Hamiltonian structures.

A natural problem is how to extend these known integrable systems from small to large and from simple to complicated. Recently, Fuchssteiner[8] presented the notion of ''integrable couplings.'' It originates from an investigation on centerless Virasoro symmetry algebras of integrable systems or soliton equations. Some papers about integrable couplings have been published.[8–13]

Mathematically, a system of integrable coupling means that it is a nontrivial system of evolution equations which is still integrable and includes the known integrable system of evolution equations $u_t=F(u)$ as a subsystem. Simply, for a given integrable system of evolution equations

$$u_t=F(u)=F(u,u_x,u_{xx},\ldots) \tag{1}$$

if we can find the following new bigger integrable system of evolution equations:

$$\begin{aligned} u_t&=F(u),\\ w_t&=C(u,w), \end{aligned} \tag{2}$$

a)Electronic mail: zhenya_yan@yahoo.com

with the condition $\partial C/\partial[u]\neq 0$, then system (2) is called the system of integrable couplings of system (1), where $[u]$ denotes a vector consisting of all derivatives of u with respect to a space variable.[13]

The symmetry approach,[8] the perturbation system method,[9–11] and a direct method[12] have been used to construct integrable couplings of evolution equations. Recently, Ma[13] presented the general theory by perturbations and was used to study the problems of integrable couplings of the Korteweg–de Vries (KdV) hierarchy, but the approach is complex to calculate. Finding a more powerful approach to construct integrable couplings of evolution equations is still an important subject.

In this paper, based on the idea in Ref. 12, we would like to present a loop algebra $\tilde{P}$ and construct its basis $\{h_1(n),h_2(n),h_3(n),h_4(n),h_5(n)\}$ such that by using the zero-curvature equation a new isospectral problem in loop algebra $\tilde{P}$ is used to construct integrable couplings of the known TC hierarchy,[5,14]

$$u_{t_n}=\begin{pmatrix} q \\ r \end{pmatrix}_{t_n}=JL^{n-1}\begin{pmatrix} 0 \\ \frac{1}{2}\beta r \end{pmatrix}, \quad J=\begin{pmatrix} \partial & \partial\frac{q}{r} \\ \frac{q}{r}\partial & \partial \end{pmatrix}, \quad L=-\frac{1}{4}\begin{pmatrix} 2\partial^{-1}q\partial & 2\partial^{-1}r\partial \\ 2r-\partial\frac{q}{r}\partial & 2q-\partial^2 \end{pmatrix}, \tag{3}$$

whose associated isospectral problem is

$$\phi_x=U\phi, \quad U=\begin{pmatrix} 0 & 1+\frac{q+r}{2\lambda} \\ \lambda+\frac{q-r}{2} & 0 \end{pmatrix}, \quad \phi=\begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix}, \quad u=\begin{pmatrix} q \\ r \end{pmatrix}, \tag{4}$$

where q and r are two scalar potentials, λ being a constant spectral parameter.

This paper is organized as follows. In Sec. II, we give a simply general approach to construct integrable couplings by use of a loop algebra and some properties of its basis. In Sec. III, we first give a loop algebra $\tilde{P}$ and its new basis $\{h_i(n)|i=1,2,3,4,5\}$. And then the TC hierarchy is chosen to illustrate the general theory determined by the loop algebra $\tilde{P}$ by using a new isopsectral problem such that a new integrable coupling with two arbitrary functions of TC hierarchy is obtained. In addition, a special integrable coupling of the generalized KdV equation is also given. Finally, some summaries and conclusions are given in Sec. IV.

II. A SIMPLY GENERAL THEORY TO CONSTRUCT INTEGRABLE COUPLINGS

For the given isospectral problem (4), taking a basis of loop algebra $\tilde{A}_1$ as

$$h(n)=\begin{pmatrix} \frac{1}{2}\lambda^n & 0 \\ 0 & -\frac{1}{2}\lambda^n \end{pmatrix}, \quad e_+(n)=\begin{pmatrix} 0 & \frac{1}{2}\lambda^{n-1}, \\ \frac{1}{2}\lambda^n & 0 \end{pmatrix}, \quad e_-(n)=\begin{pmatrix} 0 & \frac{1}{2}\lambda^{n-1} \\ -\frac{1}{2}\lambda^n & 0 \end{pmatrix},$$

$$\deg e_\pm(n)=2n-1, \quad \deg h(n)=2n, \tag{5}$$

which has the relations

$$[h(m),e_\pm(n)]=e_\mp(m+n), \quad [e_-(m),e_+(n)]=h(m+n-1), \tag{6}$$

Eq. (1) becomes

$$\phi_x=U\phi, \quad U=2e_+(1)+qe_+(0)+re_-(0). \tag{7}$$

In order to deduce TC hierarchy of evolution equations from (1), we consider the auxiliary problem of (1), namely

$$\phi_{t_n}=V^{(n)}\phi=V^{(n)}(\lambda,u)\phi, \tag{8}$$

$$V^{(n)}=(\lambda^n V)_+ +\Delta_n=\sum_{i=0}^{n}(a_i h(n-i)+b_i e_+(n-i)+c_i e_-(n-i))+\left[\frac{q}{r}c_n-b_n\right]e_+(0).$$

Therefore it is easy to prove that the compatibility condition $\phi_{xt}=\phi_{tx}$ of (7) and (8) generates the zero curvature equation $U_{t_n}-V_x^{(n)}+[U,V^{(n)}]=0$, namely,

$$u_t=\begin{pmatrix} q_{t_n} \\ r_{t_n}\end{pmatrix}=J_0\begin{pmatrix} -b_n \\ c_n\end{pmatrix}=J_0 L_0^{n-1}\begin{pmatrix} 0 \\ \frac{1}{2}\beta r\end{pmatrix} \tag{9}$$

with β as a constant and

$$J_0=\begin{pmatrix} \partial & \partial\frac{q}{r} \\ \frac{q}{r}\partial & \partial\end{pmatrix},\quad L_0=-\frac{1}{4}\begin{pmatrix} 2\partial^{-1}q\partial & 2\partial^{-1}r\partial \\ 2r-\partial\frac{q}{r}\partial & 2q-\partial^2\end{pmatrix}. \tag{10}$$

In order to use the zero curvature equation to consider the integrable couplings of TC hierarchy (9), we need to seek a bigger loop algebra $\tilde{P}$ and to construct its basis $\{h_i(n)(i=1,2,..,m)\}$.[12]

If $\tilde{P}_1=\{h_1(n),h_2(n),h_3(n)\}$ and $\tilde{P}_2=\{h_4(n),h_5(n),\ldots,h_m(n)\}$ satisfy

$$[\tilde{P}_1,\tilde{P}_1]\subset\tilde{P}_1,\quad [\tilde{P}_1,\tilde{P}_2]\subset\tilde{P}_2,\quad [\tilde{P}_2,\tilde{P}_2]\subset\tilde{P}_2 \tag{11}$$

and $\tilde{P}_1$ is isomorphic to $\tilde{A}_1$, then for the isospectral problem

$$\phi_x=U\phi,\quad U=2h_2(1)+qh_2(0)+rh_3(0)+\sum_{i=3}^{m-1}u_i h_{i+1}(0)$$

and its properly chosen auxiliary problem

$$\phi_{t_n}=V^{(n)}\phi=V^{(n)}(\lambda,u)\phi,\quad V^{(n)}\in\tilde{P}.$$

It is easy to prove that the compatibility condition $\phi_{xt}=\phi_{tx}$ of the above two equations, i.e.,

$$\phi_{xt}=U_t\phi+U\phi_t=U_t\phi+UV^{(n)}\phi=\phi_{tx}=V_x^{(n)}\phi+V^{(n)}\phi_x=V_x^{(n)}\phi+V^{(n)}U\phi_x,$$

gives rise to the zero curvature equation

$$U_{t_n}-V_x^{(n)}+[U,V^{(n)}]=0,$$

which will be the integrable couplings of TC hierarchy we would like to obtain.

III. APPLICATIONS AND INTEGRABLE COUPLINGS OF TC HIERARCHY

According to the above-mentioned simply general theory, in order to deduce integrable couplings of TC hierarchy (9), we need introduce a new loop algebra $\tilde{P}$ and its basis.

We easily know that when $m=3$ only trivial integrable couplings of TC hierarchy are obtained. More recently we find that when $m=4$, we can also obtain some nontrivial integrable couplings of TC hierarchy.[15] But the obtained integrable couplings of TC hierarchy are simpler than the integrable couplings (25) obtained under the case $m=5$. We guess that when $m>5$, we may find some more complex integrable couplings of TC hierarchy. In what follows we choose a more complex case, i.e., $m=5$, to illustrate the theory. We take its basis, say, $\{h_1(n),h_2(n),h_3(n),h_4(n),h_5(n)\}$, which is different from the one in Ref. 12 and satisfies the commutative relation

$$\begin{gathered}
[h_1(m),h_2(n)]=h_3(m+n), \quad [h_1(m),h_3(n)]=h_2(m+n),\\
[h_1(m),h_4(n)]=0, \quad [h_1(m),h_5(n)]=0,\\
[h_2(m),h_3(n)]=-h_1(m+n-1), \quad [h_2(m),h_4(n)]=h_5(m+n),\\
[h_2(m),h_5(n)]=h_4(m+n), \quad [h_3(m),h_4(n)]=h_5(m+n),\\
[h_3(m),h_5(n)]=h_4(m+n), \quad [h_4(m),h_5(n)]=0,\\
\deg h_1(n)=2n, \quad \deg h_2(n)=\deg h_3(n)=\deg h_4(n)=\deg h_5(n)=2n-1
\end{gathered} \tag{12}$$

and set

$$\tilde{P}_1=\{h_1(n),h_2(n),h_3(n)\}, \quad \tilde{P}_2=\{h_4(n),h_5(n)\}, \tag{13}$$

and we easily know that $\tilde{P}_1$ is isomorphic to $\tilde{A}_1$ and $[\tilde{P},\tilde{P}_2]\subset\tilde{P}_2$.

Remark 1: For a give basis of a loop algebra $\tilde{P}$ with $m=5$, the corresponding commutative relation can be determined, which is similar to the loop algebra $\tilde{A}_1$ used by Tu.[5] To seek integrable couplings of TC hierarchy (9), we choose one of all possible bases of $\tilde{P}$ with $m=5$ and its corresponding commutative relation (12) here. Of course we can also choose other bases and the corresponding commutation relation. But one key condition is that the basis must satisfy (11), (13) and $\tilde{P}_1$ is isomorphic to $\tilde{A}_1$.

In what follows, we would like to choose an isospectral problem in the loop algebra $\tilde{P}$ with $m=5$ in order to construct integrable couplings of TC hierarchy (9).

Choose the following proper isospectral problem ($\lambda_t=0$):

$$\phi_x=U\phi, \quad U=2h_2(1)+u_1h_2(0)+u_2h_3(0)+u_3h_4(0)+u_4h_5(0). \tag{14}$$

It is clear that the adjoint equation of (14) can be written as

$$V_x=[U,V]\equiv UV-VU, \tag{15}$$

where

$$V=V(\lambda,u)=\sum_{m=0}^{\infty}[a_mh_1(-m)+b_mh_2(-m)+c_mh_3(-m)+d_mh_4(-m)+e_mh_5(-m),$$

where a_m, b_m, c_m, d_m, $e_m(m=0,1,2,\dots)$ are all functions of $u_i(i=1,2,3,4,5)$ to be determined later. Equation (15) leads to

$$\begin{aligned} a_{m,x}&=-u_1c_{m-1}+u_2b_{m-1}-2c_m,\\ b_{m,x}&=-u_2a_m,\\ c_{m,x}&=-u_1a_m-2a_{m+1},\\ d_{m,x}&=2e_{m+1}+(u_1+u_2)e_m-u_4(b_m+c_m),\\ e_{m,x}&=2d_{m+1}+(u_1+u_2)d_m-u_3(b_m+c_m). \end{aligned} \tag{16}$$

The following recursion formulas are obtained from (16):

$$\begin{pmatrix} -b_{n+1}\\ c_{n+1}\\ d_{n+1}\\ e_{n+1} \end{pmatrix}=L\begin{pmatrix} -b_n\\ c_n\\ d_n\\ e_n \end{pmatrix}, \tag{17}$$

$$L=\begin{pmatrix} -\frac{1}{2}\partial^{-1}u_1\partial & -\frac{1}{2}\partial^{-1}u_2\partial & 0 & 0\\ -\frac{1}{2}u_2+\frac{1}{4}\partial\dfrac{u_1}{u_2}\partial & -\frac{1}{2}u_1+\frac{1}{4}\partial^2 & 0 & 0\\ -\frac{1}{2}u_3 & \frac{1}{2}u_3 & -\frac{1}{2}(u_1+u_2) & \frac{1}{2}\partial\\ -\frac{1}{2}u_4 & \frac{1}{2}u_4 & \frac{1}{2}\partial & -\frac{1}{2}(u_1+u_2) \end{pmatrix}, \tag{18}$$

where $\partial=\partial/\partial x$, $\partial\partial^{-1}=\partial^{-1}\partial=1$. If we take the initial values $a_0=0$, $b_0=\beta=\text{const}$, $c_0=d_0=e_0=0$. Then, (17) and (18) imply the following results:

$$a_1=0,\quad b_1=0,\quad c_1=\tfrac{1}{2}\beta u_2,\quad d_1=\tfrac{1}{2}\beta u_3,\quad e_1=\tfrac{1}{2}\beta u_4,$$

$$a_2=-\tfrac{1}{4}\beta u_{2x},\quad b_2=\tfrac{1}{8}\beta u_2^2,\quad c_2=\tfrac{1}{8}(u_{2,xx}-2u_1u_2),$$

$$d_2=\tfrac{1}{4}\beta u_{4x}-\tfrac{1}{4}\beta u_1u_3,\quad e_2=\tfrac{1}{4}\beta u_{3x}-\tfrac{1}{4}\beta u_1u_4,\cdots.$$

Set

$$\begin{aligned} (\lambda^nV)_+&=\sum_{m=0}^{n}[a_mh_1(n-m)+b_mh_2(n-m)+c_mh_3(n-m)+d_mh_4(n-m)+e_mh_5(n-m),\\ (\lambda^nV)_-&=\lambda^nV-(\lambda^nV)_+. \end{aligned} \tag{19}$$

Therefore we from (15) and (19) have

$$-(\lambda^nV)_{+,x}+[U,(\lambda^nV)_+]=(\lambda^nV)_{-,x}-[U,(\lambda^nV)_-]. \tag{20}$$

It is clear to know that the terms on the left-hand side of (20) are of degree $\leqslant -2$, while the terms on the right-hand side of (20) are of degree $\geqslant -1$. Therefore both sides of (20) are of degree -1 and -2, that is

$$\begin{aligned} -(\lambda^nV)_{+,x}+[U,(\lambda^nV)_+]&=(u_2b_n-u_1c_n)h_1(-1)-(b_{n,x}+u_2a_n)h_2(0)-(c_{nx}+u_1a_n)h_3(0)\\ &\quad+[-d_{nx}+u_1e_n+u_2e_n-u_4(b_n+c_n)]h_4(0)\\ &\quad+[-e_{nx}+u_1d_n+u_2d_n-u_3(b_n+c_n)]h_5(0). \end{aligned} \tag{21}$$

In order to cancel the term $(u_2b_n-u_1c_n)h_1(-1)$, we introduce the term

$$\Delta_n=\left[\frac{u_1}{u_2}c_n-b_n\right]h_2(0)+\delta_{1n}h_4(0)+\delta_{2n}h_5(0), \tag{22}$$

where δ_{1n} and δ_{2n} are arbitrary functions of $u_i(i=1,2,3,4,5)$ Thus it is clear to know that if we set

$$V^{(n)}=(\lambda^nV)_+ +\Delta_n, \tag{23}$$

then we get

$$\begin{aligned}-(\lambda^nV)_{+,x}+[U,(\lambda^nV)_+]=&\left(b_n-\frac{u_1}{u_2}c_n\right)_x h_2(0)-\left(c_{nx}-\frac{u_1}{u_2}b_{nx}\right)h_3(0)\\&+\left[-d_{nx}-\delta_{1nx}+(u_1+u_2)(e_n+\delta_{2n})-u_4\left(1+\frac{u_1}{u_2}\right)c_n\right]h_4(0)\\&+\left[-e_{nx}-\delta_{2nx}+(u_1+u_2)(d_n+\delta_{1n})-u_3\left(1+\frac{u_1}{u_2}\right)c_n\right]h_5(0).\end{aligned} \tag{24}$$

Therefore according to the zero curvature equation, we have the following Lax integrable hierarchy of evolution equations with two arbitrary functions:

$$u_{t_n}=\begin{pmatrix}u_1\\u_2\\u_3\\u_4\end{pmatrix}_{t_n}=-\begin{pmatrix}\left(b_n-\frac{u_1}{u_2}c_n\right)_x\\-\left(c_{nx}-\frac{u_1}{u_2}b_{nx}\right)\\-d_{nx}-\delta_{1nx}+(u_1+u_2)(e_n+\delta_{2n})-u_4\left(1+\frac{u_1}{u_2}\right)c_n\\-e_{nx}-\delta_{2nx}+(u_1+u_2)(d_n+\delta_{1n})-u_3\left(1+\frac{u_1}{u_2}\right)c_n\end{pmatrix}, \tag{25}$$

which has the Lax pair

$$\phi_x=U\phi,\quad \phi_{t_n}=V^{(n)}\phi, \tag{26}$$

where U and $V^{(n)}$ satisfy (14) and (23), respectively.

Remark 2: In particular, when taking $\delta_{1n}=\delta_{2n}=0$, from (17) and (25), we have

$$u_{t_n}=\begin{pmatrix}u_1\\u_2\\u_3\\u_4\end{pmatrix}_{t_n}=-\begin{pmatrix}\left(b_n-\dfrac{u_1}{u_2}c_n\right)_x\\-\left(c_{nx}-\dfrac{u_1}{u_2}b_{nx}\right)\\-d_{nx}+(u_1+u_2)e_n-u_4\left(1+\dfrac{u_1}{u_2}\right)c_n\\-e_{nx}+(u_1+u_2)d_n-u_3\left(1+\dfrac{u_1}{u_2}\right)c_n\end{pmatrix}$$

$$=\begin{pmatrix}\partial & \partial\dfrac{u_1}{u_2} & 0 & 0\\ \dfrac{u_1}{u_2}\partial & \partial & 0 & 0\\ 0 & u_4+\dfrac{u_1u_4}{u_2} & \partial & -(u_1+u_2)\\ 0 & u_3+\dfrac{u_1u_3}{u_2} & -(u_1+u_2) & \partial\end{pmatrix}\begin{pmatrix}-b_n\\c_n\\d_n\\e_n\end{pmatrix}$$

$$=J\begin{pmatrix}-b_n\\c_n\\d_n\\e_n\end{pmatrix}=JL^{n-1}\begin{pmatrix}-b_1\\c_1\\d_n\\e_1\end{pmatrix}=JL^{n-1}\begin{pmatrix}0\\\frac{1}{2}\beta u_2\\\frac{1}{2}\beta u_3\\\frac{1}{2}\beta u_4\end{pmatrix}. \tag{27}$$

Set

$$w_{t_n}=\begin{pmatrix}u_1\\u_2\end{pmatrix}_{t_n},\quad v_{t_n}=\begin{pmatrix}u_3\\u_4\end{pmatrix}_{t_n}.$$

Then the hierarchy of evolution equations (27) can be rewritten as

$$w_{t_n}=\begin{pmatrix}u_1\\u_2\end{pmatrix}_{t_n}=F_n(w)=\begin{pmatrix}\partial & \partial\dfrac{u_1}{u_2} & 0 & 0\\ \dfrac{u_1}{u_2}\partial & \partial & 0 & 0\end{pmatrix}\begin{pmatrix}-b_n\\c_n\\d_n\\e_n\end{pmatrix}$$

$$=J_0\begin{pmatrix}-b_n\\c_n\end{pmatrix}=J_0L_0^{n-1}\begin{pmatrix}0\\\frac{1}{2}\beta u_2\end{pmatrix}, \tag{28}$$

$$v_{t_n}=\begin{pmatrix}u_3\\u_4\end{pmatrix}_{t_n}=C_n(w,v)=\begin{pmatrix}0 & u_4+\dfrac{u_1u_4}{u_2} & \partial & -(u_1+u_2)\\ 0 & u_3+\dfrac{u_1u_3}{u_2} & -(u_1+u_2) & \partial\end{pmatrix}\begin{pmatrix}-b_n\\c_n\\d_n\\e_n\end{pmatrix}.$$

If we set $u_1=q$, $u_2=r$, then it is clear to see that the first one of system (28) is just the TC hierarchy (9).

Remark 3: In particular, when $n=2$, $\beta=8$, system (28) becomes

$$w_{t_2}=\begin{pmatrix}u_1\\u_2\end{pmatrix}_{t_2}=F_2(w)=\begin{pmatrix}\left(\dfrac{u_1}{u_2}u_{2,xx}-2u_1^2-u_2^2\right)_x\\ u_{2,xxx}-2u_{1x}u_2-4u_1u_{2x}\end{pmatrix},$$

$$v_{t_2}=\begin{pmatrix}u_3\\u_4\end{pmatrix}_{t_2}=C_2(w,v) \tag{29}$$

$$=\begin{pmatrix}2u_{4,xx}-2u_{1x}u_3-2u_2u_{3x}+u_4\left(1+\dfrac{u_1}{u_2}\right)(u_{2xx}-2u_1u_2)+u_1u_4(u_1+u_2)\\ 2u_{3,xx}-2u_{1x}u_4-2u_2u_{4x}+u_3\left(1+\dfrac{u_1}{u_2}\right)(u_{2,xx}-2u_1u_2)+u_1u_3(u_1+u_2)\end{pmatrix}.$$

If we set $u_1=q$, $u_2=r$, then the first system of (29) is just (20) in Ref. 5. When $q=\pm r$, the system of equations reduces to the celebrated KdV equation. It is clear to know that $\partial C_2(w,v)/\partial[w]\neq 0$. In addition because the hierarchy (28) possesses Lax pair, it is Lax integrable. Therefore according to the notion of integrable couplings,[8] we know that the hierarchy of evolution equations (28) is the integrable couplings of TC hierarchy (9).

IV. SUMMARY AND CONCLUSIONS

In summary, we have obtained integrable couplings of the well-known TC hierarchy by considering a new isospectral problem in a new loop algebra $\tilde{P}$. This denotes that the approach is powerful to obtain new integrable couplings. The obtained integrable couplings contain two arbitrary functions of old potentials (u_1,u_2) and new potentials (u_3,u_4) which are different from the results which do not contain arbitrary functions.[8–13] In the loop algebra $\tilde{P}$, other new isopsectral problems may be used to construct many integrable couplings of other many known hierarchies of evolution equations. As is well known, there exist two integrable forms: (1) Lax integrable; (2) Liouville integrable. In this paper, we use the zero curvature equation (Lax pair) to construct integrable couplings. It is clear to see that TC hierarchy is both Lax integrable and Liouville integrable. Recently many authors have devoted efforts to seeking symplectic structures of some Lax pair systems(seem Ref. 16, and references therein).

Therefore some natural open problems are as follows: (1) whether the integrable couplings (28) are shown also to be Liouville integrable according to the methods used in Ref. 16 and therein? (2) Can Backlund transformation of the hierarchy (28) be obtained? (3) Can the hierarchy (28) pass the Painleve test?, etc. These need to be further studied.

In this article we characterize all the exponential factors and the Darbouxian first integrals for the Lorenz system $\dot{x}=s(y-x)$, $\dot{y}=rx-y-xz$, $\dot{z}=-bz+xy$. In the proofs, we use the weight homogeneous polynomials and the method of characteristic curves for solving linear partial differential equations. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1503152]

I. INTRODUCTION AND DEFINITIONS

We consider the Lorenz system

$$\begin{aligned}\dot{x}&=s(y-x)=\xi(x,y,z),\\ \dot{y}&=rx-y-xz=\eta(x,y,z),\\ \dot{z}&=-bz+xy=\zeta(x,y,z),\end{aligned}\tag{1}$$

where x,y and z are real variables, and s,r and b are real parameters. This system is a famous dynamic model [see, for instance, Lorenz (1963) and Sparrow (1982)]. From the point of view of integrability, it was intensively studied using different theory of integrability (for example, Cairó and Hua, 1993; Giacomini *et al.*, 1991, 1997; Gupta, 1993; Kús, 1983; Segur, 1982; Strelcyn and Wojciechowski, 1988). Recently, using the weight homogeneous polynomials and the method of characteristic curves, Llibre and Zhang (2002) characterized all the irreducible invariant algebraic surfaces, the invariants, the rational first integrals and the algebraic integrability for the Lorenz system. In this article, applying the method given in Llibre and Zhang (2002) to the Lorenz system, we obtain all the exponential factors and provide the necessary and sufficient conditions for the Lorenz system to have a Darbouxian first integral.

The Darboux theory of integrability is classical. It mainly received contributions from Darboux (1878), who gave a link between the algebraic geometry and the search of first integrals, and showed how to construct the first integral of a planar polynomial vector field having sufficient number of Darboux polynomials. Poincaré (1891) noticed the difficulty in obtaining an algorithm to compute Darboux polynomials. Singer (1992) proved that a polynomial differential system has a Liouvillian first integral if and only if it has a Darbouxian integrating factor (see also Camacho and Scárdua, 2001). For three dimensional dynamic systems, Labrunie (1996) and Moulin Ollagnier (1997) characterized independently all the polynomial first integrals of the (a,b,c) Lotka-Volterra systems, and Moulin Ollagnier (1999) investigated its rational first integrals. Llibre and Zhang (2000) obtained all the Darboux polynomials, the polynomial first integrals, the rational first integrals and the algebraic integrability for the Rikitake system.

For presenting our main results, we first recall some definitions.

A polynomial $f(x,y,z)\in\mathbb{C}[x,y,z]$ is called a *Darboux polynomial* of the Lorenz system if

a)Electronic mail: xzhang@mail.sjtu.edu.cn

$$\xi(x,y,z)\frac{\partial f}{\partial x}+\eta(x,y,z)\frac{\partial f}{\partial y}+\zeta(x,y,z)\frac{\partial f}{\partial z}=k(x,y,z)f, \tag{2}$$

for some polynomial $k(x,y,z)\in\mathbb{C}[x,y,z]$, which is called a *cofactor* of f. As usual, $\mathbb{C}[x,y,z]$ denotes the ring of polynomials with complex coefficients in the variables x,y and z.

An *exponential factor* $F(x,y,z)$ of the Lorenz system is an exponential function of the form $\exp(g/h)$ with $g,h\in\mathbb{C}[x,y,z]$ coprime, denoted by $(g,h)=1$, and satisfying

$$\xi(x,y,z)\frac{\partial F}{\partial x}+\eta(x,y,z)\frac{\partial F}{\partial y}+\zeta(x,y,z)\frac{\partial F}{\partial z}=l(x,y,z)F, \tag{3}$$

for some $l(x,y,z)\in\mathbb{C}[x,y,z]$ a polynomial of degree at most one. The polynomial l is called a *cofactor* of F.

We say that a real function $H(x,y,z,t):\mathbb{R}^3\times\mathbb{R}\to\mathbb{R}$, is a *first integral* of the Lorenz system, if $H(x(t),y(t),z(t),t)\equiv$const for all values of t for which the solution $(x(t),y(t),z(t))$ of the Lorenz system is defined. A first integral H of the Lorenz system is called *Darbouxian* if it has the form

$$H=f_1^{\lambda_1}\cdots f_p^{\lambda_p}\left(\exp\left(\frac{h_1}{g_1^{n_1}}\right)\right)^{\mu_1}\cdots\left(\exp\left(\frac{h_q}{g_q^{n_q}}\right)\right)^{\mu_q},$$

where f_i, g_j and h_j are polynomials in $\mathbb{C}[x,y,z]$, f_i and g_j are irreducible, the polynomials g_j and h_j are coprime, and λ_i and μ_j are real or complex numbers appearing together with their conjugates. Obviously, polynomial first integrals and rational first integrals are Darboux first integrals.

A polynomial $g(x,y,z)$ is said to be *weight homogeneous* if there exist $\mathbf{s}=(s_1,s_2,s_3)$ with s_i natural numbers for $i=1,2,3$, and $m\in\mathbb{N}$ such that for all $\alpha\in\mathbb{R}\backslash\{0\}$ we have

$$g(\alpha^{s_1}x,\alpha^{s_2}y,\alpha^{s_3}z)=\alpha^m g(x,y,z),$$

where $\mathbb{N}$ is the set of natural numbers. We shall refer to $\mathbf{s}$ as the *weight* of g, and m as the *weight degree*.

This article is organized as follows. In Sec. II we state our main result. Its proof is given in Sec. III.

II. STATEMENT OF THE MAIN RESULT

Theorem 1: For *the Lorenz system, if* $s\neq 0$, *then the following statements hold*.

(a) *The generator of exponential factors of the Lorenz system is* $F=\exp(x/s)$ *with the cofactor* $l=y-x$.

(b) *The Lorenz system has a Darbouxian first integral if and only if* $b=1$, $s=\frac{1}{2}$ *and* $r=0$. *In this case the first integral is* $(y^2+z^2)/(x^2-z)^2$.

We remark that when $s=0$, the Lorenz system has always the Darbouxian first integral $H=x$, and then on each plane $x=$const the system becomes linear.

For proving this theorem, we need the following two results. The first one is given in Llibre and Zhang (2002).

Theorem 2: *When* $s\neq 0$, *a set of generators for the set of all Darboux polynomials of the Lorenz system consists of the following six ones:*

Darboux polynomial	Cofactor	Parameters
x^2-2sz	$-2s$	$b=2s$
$x^4+\frac{4}{3}x^2z-\frac{4}{9}y^2-\frac{8}{9}xy+\frac{4}{3}rx^2$	$-\frac{4}{3}$	$b=0,\ s=\frac{1}{3}$
y^2+z^2	-2	$b=1,\ r=0$
$x^4-4x^2z-4y^2+8xy-4rx^2-16(1-r)z$	-4	$b=4,\ s=1$
$y^2+z^2-rx^2$	-2	$b=1,\ s=1$
$x^4-4sx^2z-4s^2y^2+4s(4s-2)xy-(4s-2)^2x^2$	$-4s$	$b=6s-2,\ r=2s-1$

The next result is related to the Darboux theory of integrability (see for instance, Darboux, 1878; Joualonou, 1979; Chavarriga *et al.*, 1997, Christopher and Llibre, 1999, 2000).

Theorem 3: *(Darboux theory of integrability) Suppose that a polynomial vector field X defined in $\mathbb{R}^n$ admits p Darboux polynomials f_i with cofactors K_i for $i=1,\ldots,p$, and q exponential factors $F_j=\exp(g_j/h_j)$ with cofactors L_j for $j=1,\ldots,q$. If there exist $\lambda_i,\mu_j\in\mathbb{C}$ not all zero such that*

$$\sum_{i=1}^{p}\lambda_i K_i+\sum_{j=1}^{q}\mu_j L_j=0, \tag{4}$$

then the following real (multi-valued) function of Darbouxian type

$$f_1^{\lambda_1}\cdots f_p^{\lambda_p}F_1^{\mu_1}\cdots F_q^{\mu_q}, \tag{5}$$

substituting $f_i^{\lambda_i}$ by $|f_i|^{\lambda_i}$ if $\lambda_i\in\mathbb{R}$, is a first integral of the vector field $\mathcal{X}$.

It is clear that condition (4) is also necessary for function (5) to be a Darbouxian first integral of the vector field $\mathcal{X}$.

In Theorem 3 we said that function (5) is real. It follows from the following fact. Since the vector field $\mathcal{X}$ is real, it is well known that if a complex Darboux polynomial or exponential factor appears, then its conjugate must appear simultaneously. If among the Darboux polynomials of $\mathcal{X}$ a complex conjugate pair f and $\overline{f}$ occur, the first integral (5) has a real factor of the form $f^{\lambda}\overline{f}^{\overline{\lambda}}$, which is the multi-valued real function

$$[(\mathrm{Re}\,f)^2+(\mathrm{Im}\,f)^2]^{\mathrm{Re}\,\lambda}\exp\left(-2\,\mathrm{Im}\,\lambda\arctan\left(\frac{\mathrm{Im}\,f}{\mathrm{Re}\,f}\right)\right),$$

if $\mathrm{Im}\,\lambda\,\mathrm{Im}\,f\not\equiv 0$. If among the exponential factors of $\mathcal{X}$ a complex conjugate pair $F=\exp(h/g)$ and $\overline{F}=\exp(\overline{h}/\overline{g})$ occur, the first integral (5) has a real factor of the form

$$\left(\exp\left(\frac{h}{g}\right)\right)^{\mu}\left(\exp\left(\frac{\overline{h}}{\overline{g}}\right)\right)^{\overline{\mu}}=\exp\left(2\,\mathrm{Re}\left(\mu\frac{h}{g}\right)\right).$$

III. PROOF OF THEOREM I

Proof of statement (a): Let $F=\exp(g/h)$ be an exponential factor of the Lorenz system with a cofactor l, where $g,\ h\in\mathbb{C}[x,y,z]$ with $(g,h)=1$. Then from the definition of the exponential factor we get that

$$h\left(\xi\frac{\partial g}{\partial x}+\eta\frac{\partial g}{\partial y}+\zeta\frac{\partial g}{\partial z}\right)-g\left(\xi\frac{\partial h}{\partial x}+\eta\frac{\partial h}{\partial y}+\zeta\frac{\partial h}{\partial z}\right)=lh^2. \tag{6}$$

If $h\equiv\mathrm{const}$, without loss of generality we set $h=1$. Then Eq. (6) becomes

$$\xi(x,y,z)\frac{\partial g}{\partial x}+\eta(x,y,z)\frac{\partial g}{\partial y}+\zeta(x,y,z)\frac{\partial g}{\partial z}=l(x,y,z). \tag{7}$$

If $h\not\equiv$const, since $(g,h)=1$, there exists a polynomial $k\in\mathbb{C}[x,y,z]$ such that

$$\xi(x,y,z)\frac{\partial h}{\partial x}+\eta(x,y,z)\frac{\partial h}{\partial y}+\zeta(x,y,z)\frac{\partial h}{\partial z}=kh, \tag{8}$$

i.e., h is a Darboux polynomial with the cofactor k. Then Eq. (6) becomes

$$\xi(x,y,z)\frac{\partial g}{\partial x}+\eta(x,y,z)\frac{\partial g}{\partial y}+\zeta(x,y,z)\frac{\partial g}{\partial z}=kg+lh. \tag{9}$$

In order to simplify the computations we introduce the weight change of the variables

$$x=\alpha^{-1}X,\quad y=\alpha^{-2}Y,\quad z=\alpha^{-2}Z,\quad t=\alpha T. \tag{10}$$

The Lorenz system is transformed to

$$\begin{aligned} X'&=s(Y-\alpha X)=P(X,Y,Z),\\ Y'&=-XZ-\alpha Y+\alpha^2 rX=Q(X,Y,Z),\\ Z'&=XY-\alpha bZ=R(X,Y,Z), \end{aligned} \tag{11}$$

where the prime denotes the derivative of the dependent variables with respect to T. Set

$$l(x,y,z)=l_0+l_1x+l_2y+l_3z,$$

$$G(X,Y,Z)=\alpha^m g(\alpha^{-1}X,\alpha^{-2}Y,\alpha^{-2}Z)=G_0(X,Y,Z)+\alpha G_1(X,Y,Z)+\cdots+\alpha^m G_m(X,Y,Z),$$

where m is the highest weight degree in the weight homogeneous components of g associated with the weight $\mathbf{s}=(1,2,2)$, and G_i has the weight degree $m-i$. Obviously, we have $g=G|_{\alpha=1}$.

Depending on whether h is constant or not, we separate the following proofs into two parts.

A. *g* satisfies Eq. (7)

Since an exponential factor multiplicative with a constant is also an exponential factor, without loss of generality, we assume that $G_m=0$. Using the weight change (10), we get from (7) and (11) that G satisfies

$$P(X,Y,Z)\frac{\partial G}{\partial X}+Q(X,Y,Z)\frac{\partial G}{\partial Y}+R(X,Y,Z)\frac{\partial G}{\partial Z}=\alpha^{m+1}l(x,y,z).$$

It can be written as

$$\begin{aligned} &(sy-\alpha sx)\sum_{i=0}^{m-1}\alpha^i\frac{\partial G_i}{\partial x}+(-xz-\alpha y+\alpha^2 rx)\sum_{i=0}^{m-1}\alpha^i\frac{\partial G_i}{\partial y}+(xy-\alpha bz)\sum_{i=0}^{m-1}\alpha^i\frac{\partial G_i}{\partial z}\\ &\quad=\alpha^{m-1}(l_2y+l_3z)+\alpha^m l_1x+\alpha^{m+1}l_0, \end{aligned} \tag{12}$$

where we use x,y,z to denote X,Y,Z.

Case 1: $m=1$. Then we can assume that $G=G_0=ax$. An easy computation shows that $l_0=l_3=0$, $l_2+l_1=0$ and $a=l_2/s$. So, we have $g=(l_2/s)x$ and $l=l_2(y-x)$. This verifies that the Lorenz system has always the exponential factor $F=\exp((l_2/s)x)$ with the cofactor $l=l_2(y-x)$, where l_2 is an arbitrary nonzero constant.

Case 2: $m=2$. Comparing the terms with the same degree in α of (12), we get that

$$\begin{aligned} L[G_0]&=0,\\ L[G_1]&=sx\frac{\partial G_0}{\partial x}+y\frac{\partial G_0}{\partial y}+bz\frac{\partial G_0}{\partial z}+l_2y+l_3z, \end{aligned} \tag{13}$$

where L is the linear partial differential operator

$$L=sy\frac{\partial}{\partial x}-xz\frac{\partial}{\partial y}+xy\frac{\partial}{\partial z}.$$

We now use the method of characteristic curves for solving linear partial differential equations to solve Eqs. (13) (see for instance, Bleecker and Csordas, 1992). The characteristic equation associated with the linear operator L is

$$\frac{dx}{dz}=\frac{sy}{xy},\quad \frac{dy}{dz}=-\frac{xz}{xy}.$$

It has general solutions

$$x^2-2sz=d_1,\quad y^2+z^2=d_2,$$

where d_1 and d_2 are arbitrary constants. We make the change of the variables

$$u=x^2-2sz,\quad v=y^2+z^2,\quad w=z. \tag{14}$$

Its inverse change is

$$x=\pm\sqrt{u+2sw},\quad y=\pm\sqrt{v-w^2},\quad z=w. \tag{15}$$

In the following we only consider the positive case. The negative one can be proved similarly.

From the last two transformations, and applying the method of characteristic curves to the first equation of (13), we obtain the following ordinary differential equation (for fixed u and v).

$$\frac{d\overline{G}_0}{dw}=0.$$

Here and after, we always use $\overline{A}(u,v,w)$ to denote $A(x,y,z)$ written in terms of u,v and w. The above equation has a general solution $\overline{G}_0(u,v,w)=G_0^*(u,v)$, where G_0^* is an arbitrary function in u and v. Since G_0 is a weight homogeneous polynomial of weight degree 2, we should have $G_0(x,y,z)=G_0^*(u,v)=a_0(x^2-2sz)$ with $a_0\in\mathbb{C}$.

Substituting G_0 into the second equation of (13) and using the changes (14) and (15), we obtain the following ordinary differential equation:

$$\sqrt{u+2sw}\sqrt{v-w^2}\frac{d\overline{G}_1}{dw}=2su+l_2\sqrt{v-w^2}+(4s^2-2sb+l_3)w.$$

It has a general solution

$$\overline{G}_1=\frac{l_2}{s}\sqrt{u+2sw}+2su\int\frac{dw}{\sqrt{u+2sw}\sqrt{v-w^2}}+(4s^2-2sb+l_3)\int\frac{wdw}{\sqrt{u+2sw}\sqrt{v-w^2}}.$$

From integrating formulas (A1) to (A3) of the Appendix, in order that $G_1(x,y,z)=\overline{G}_1(u,v,w)$ is a polynomial, we should have $s=0$. It is in contradiction with the assumption $s\neq 0$. So, the Lorenz system does not have exponential factors of the given form.

Case 3: $m\geqslant 3$. Then from (12) we get that $L[G_0]=0$ and

$$L[G_1]=sx\frac{\partial G_0}{\partial x}+y\frac{\partial G_0}{\partial y}+bz\frac{\partial G_0}{\partial z}. \tag{16}$$

Working in a similar way to the proof of case 2, we can prove that $G_0(x,y,z)=\overline{G}_1(u,v,w)=G_0^*(u,v)=G_0^*(x^2-2sz,y^2+z^2)$. Since G_0 is a weight homogeneous polynomial with the weight degree m, we must have $m=4n$ or $m=4n-2$ for $n\in\mathbb{N}$. Hence, G_0 has the form

$$G_0=\sum_{i=0}^{n} a_i(x^2-2sz)^{2i}(y^2+z^2)^{n-i},\quad m=4n, \tag{17}$$

or

$$G_0=\sum_{i=1}^{n} a_i(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i},\quad m=4n-2. \tag{18}$$

If G_0 has form (17), then from Eq. (16) and using the method of characteristic curves, we can prove that

$$\begin{aligned}\overline{G}_1(u,v,w)=&\sum_{i=0}^{n}\frac{1}{s}[4si+2(n-i)]a_iu^{2i}v^{n-i-1}\sqrt{u+2sw}\sqrt{v-w^2}\\&+\sum_{i=0}^{n-1}\left\{\frac{1}{s}[4si+2(n-i)]a_i+4s(2s-b)(i+1)a_{i+1}\right\}\\&\times u^{2i+1}v^{n-i-1}\int\frac{wdw}{\sqrt{u+2sw}\sqrt{v-w^2}}+4na_nu^{2n+1}v^{-1}\\&+\sum_{i=0}^{n-1}[12si+2(b+2)(n-i)]a_iu^{2i}v^{n-i-1}\int\frac{w^2dw}{\sqrt{u+2sw}\sqrt{v-w^2}}.\end{aligned}$$

Using formulas (A2) and (A3) of the Appendix and the fact that G_1 is a polynomial, we get that $na_n=0$, and

$$[4si+2(n-i)]a_i+4s^2(2s-b)(i+1)a_{i+1}=0,$$

$$[6si+(b+2)(n-i)]a_i=0,$$

for $i=0,1,\ldots,n-1$. It implies that $a_i=0$ for $i=0,1,\ldots,n$. So, we have $G_0(x,y,z)\equiv 0$.

If G_0 has form (18), we can prove that

$$\overline{G}_1(u,v,w)=\sum_{i=1}^{n}\frac{1}{s}[2(2i-1)s+2(n-i)]a_i u^{2i-1}v^{n-i-1}\sqrt{u+2sw}\sqrt{v-w^2}$$
$$+\sum_{i=0}^{n}\left\{\frac{1}{s}[2(2i-1)s+2(n-i)]a_i+(4s^2-2sb)(2i+1)a_{i+1}\right\}$$
$$\times u^{2i}v^{n-i-1}\int\frac{wdw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+\sum_{i=1}^{n}[6(2i-1)s+(2b+4)(n-i)]a_i u^{2i-1}v^{n-i-1}\int\frac{w^2dw}{\sqrt{u+2sw}\sqrt{v-w^2}}.$$

Hence, we have

$$(2s^2-sb)(2i+1)a_{i+1}+\frac{1}{s}[(2i-1)s+(n-i)]a_i=0,\quad i=0,1,\ldots,n,$$

$$[3(2i-1)s+(b+2)(n-i)]a_i=0,\quad i=1,\ldots,n.$$

This verifies that $a_i=0$ for $i=1,\cdots,n$. So, we also have $G_0(x,y,z)\equiv 0$.

This proves that the Lorenz system does not have the exponential factors of the given form.

B. *g* satisfies Eq. (9)

Using the weight change (10), we get from (11) that G satisfies

$$P(X,Y,Z)\frac{\partial G}{\partial X}+Q(X,Y,Z)\frac{\partial G}{\partial Y}+R(X,Y,Z)\frac{\partial G}{\partial Z}=\alpha kG+\alpha^{m+1}l(x,y,z)h(x,y,z),$$

i.e.,

$$(sY-\alpha sX)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial X}+(-XZ-\alpha Y+\alpha^2 rX)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial Y}+(XY-\alpha bZ)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial Z}$$
$$=\alpha k\sum_{i=0}^{m}\alpha^i G_i+\alpha^{m-1}(l_2Y+l_3Z+\alpha l_1X+\alpha^2 l_0)h(x,y,z). \tag{19}$$

In what follows we need the following result [for a proof, see, for instance Christopher and Llibre (2000)].

Lemma 4: Assume that f is a polynomial and that $f=f_1^{m_1}\cdots f_l^{m_l}$ is the irreducible factorization with $(f_i,f_j)=1$ for $i\neq j$. Then f is a Darboux polynomial of a polynomial vector filed $\mathcal{X}$ with a cofactor k if and only if $f_1,\ldots,f_l$ are Darboux polynomials of the vector filed $\mathcal{X}$ with cofactors $k_1,\ldots,k_l$. Moreover, we have $k=m_1k_1+\cdots+m_lk_l$.

Since h is a Darboux polynomial, by Theorem 2, depending on the different conditions for the Lorenz system to have a Darboux polynomial, we separate the following proofs into five cases.

Case 1. $b=2s$. Then $f=x^2-2sz$ is the generator of Darboux polynomials of the Lorenz system. The corresponding cofactor is $-2s$. From Lemma 4 we assume that $h=(x^2-2sz)^\mu$ with the cofactor $k=-2s\mu$, where $\mu\in\mathbb{N}$. Now Eq. (19) becomes

$$(sy-\alpha sx)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial x}+(-xz-\alpha y+\alpha^2 rx)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial y}+(xy-\alpha bz)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial z}$$
$$=\alpha(-2s\mu)\sum_{i=0}^{m}\alpha^i G_i+\alpha^{m-1-2\mu}(l_2y++l_3z+\alpha l_1x+\alpha^2 l_0)(x^2-2sz)^\mu, \tag{20}$$

where we first use the weight change (10), and then use x,y,z to denote X,Y,Z.

We claim that $m \geqslant 2\mu+1$. Otherwise, in what follows we can prove that $l=0$. So g is a Darboux polynomial with the cofactor $-2s\mu$. From the proof of Llibre and Zhang (2002), we obtain that $g=a(x^2-2sz)^\mu$, where a is an arbitrary constant. Hence, we have $(g,h)=(x^2-2sz)^\mu$. It is in contradiction with the assumption $(g,h)=1$.

We now prove the claim. If $m-1-2\mu<-2$, from (20) it is easy to check that $l_2=l_3=l_1=l_0=0$. Hence we have $l=0$.

If $m-1-2\mu=-2$, Eq. (20) shows that $l_2=l_3=l_1=0$ and

$$L[G_0]=l_0(x^2-2sz)^\mu.$$

Applying the method of characteristic curves to this equation, we obtain that

$$G_0(x,y,z)=\overline{G}_0(u,v,w)=l_0u^\mu\int\frac{dw}{\sqrt{u+2sw}\sqrt{v-w^2}}.$$

Since G_0 is a polynomial, from integrating formulas (A1)–(A3) of the Appendix we should have $l_0=0$. This verifies that $l=0$.

If $m-1-2\mu=-1$, then from (20) we get that $l_2=l_3=0$, and

$$\begin{aligned} L[G_0]&=l_1x(x^2-2sz)^\mu,\\ L[G_1]&=D_1[G_0]+l_0(x^2-2sz)^\mu, \end{aligned} \tag{21}$$

where D_1 is the linear partial differential operator

$$D_1=sx\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}+bz\frac{\partial}{\partial z}-2s\mu.$$

Since the operators L and D_1 are linear, we separate G_i into $G_i=G_i^{(0)}+G_i^{(1)}$ for $i=0,1$. Then Eq. (21) can be written as

$$L[G_0^{(0)}]=0,\quad L[G_0^{(1)}]=l_1x(x^2-2sz)^\mu, \tag{22}$$

$$L[G_1^{(0)}]=D_1[G_0^{(0)}],\quad L[G_1^{(1)}]=D_1[G_0^{(1)}]+l_0(x^2-2sz)^\mu, \tag{23}$$

where we require that in the process to solve the above equations, $G_i^{(1)}$, for $i=0,1$, do not contain integrating constants.

From the proof of Llibre and Zhang (2002) we get that $L[G_0^{(0)}]=0$ and $L[G_1^{(0)}]=D_1[G_0^{(0)}]$ always have polynomial solutions. The second equation of (22) has the solution

$$G_0^{(1)}(x,y,z)=\overline{G}_0^{(1)}(u,v,w)=l_1u^\mu\arcsin\frac{w}{\sqrt{v}}.$$

So we must have $l_1=0$, and hence $G_0^{(1)}=0$. Solving the second equation of (23) we get that

$$G_1^{(1)}(x,y,z)=\overline{G}_1^{(1)}(u,v,w)=l_0u^\mu\int\frac{dw}{\sqrt{u+2sw}\sqrt{v-w^2}}.$$

This verifies that $l_0=0$, and so we have $l=0$. This proves the claim.

We assume that $m=2\mu+1+\nu$ for some $\nu\in\mathbb{N}\cup\{0\}$. Then from (20) we obtain that

$$L[G_{\nu-i}]=D_1[G_{\nu-i-1}]-rx\frac{\partial G_{\nu-i-2}}{\partial y},\quad i=1,\ldots,\nu,$$

$$L[G_{\nu}]=D_1[G_{\nu-1}]-rx\frac{\partial G_{\nu-2}}{\partial y}+(l_2y+l_3z)(x^2-2sz)^{\mu},$$

$$L[G_{\nu+1}]=D_1[G_{\nu}]-rx\frac{\partial G_{\nu-1}}{\partial y}+l_1x(x^2-2sz)^{\mu},\tag{24}$$

$$L[G_{\nu+2}]=D_1[G_{\nu+1}]-rx\frac{\partial G_{\nu}}{\partial y}+l_0(x^2-2sz)^{\mu},$$

$$L[G_j]=D_1[G_{j-1}]-rx\frac{\partial G_{j-2}}{\partial y},\quad j=\nu+3,\ldots,2\mu+\nu+3,$$

where $G_i=0$ for $i<0$ or $i>2\mu+1+\nu$.

We write $G_i=G_i^{(0)}+G_i^{(1)}$ such that

$$L[G_i^{(0)}]=D_1[G_{i-1}^{(0)}]-rx\frac{\partial G_{i-2}^{(0)}}{\partial y},\quad i=0,1,\ldots,2\mu+\nu+3,\tag{25}$$

$$L[G_{\nu-i}^{(1)}]=0,\quad i=1,\ldots,\nu,\tag{26}$$

$$L[G_{\nu}^{(1)}]=(l_2y+l_3z)(x^2-2sz)^{\mu},\tag{27}$$

$$L[G_{\nu+1}^{(1)}]=D_1[G_{\nu}^{(1)}]-rx\frac{\partial G_{\nu-1}^{(1)}}{\partial y}+l_1x(x^2-2sz)^{\mu},\tag{28}$$

$$L[G_{\nu+2}^{(1)}]=D_1[G_{\nu+1}^{(1)}]-rx\frac{\partial G_{\nu}^{(1)}}{\partial y}+l_0(x^2-2sz)^{\mu},\tag{29}$$

$$L[G_j^{(1)}]=D_1[G_{j-1}^{(1)}]-rx\frac{\partial G_{j-2}^{(1)}}{\partial y},\quad j=\nu+3,\ldots,2\mu+\nu+3.\tag{30}$$

Moreover, we require that in the process to solve $G_i^{(l)}$ for $i=0,1,\ldots,m$ and $l=0,1$, the polynomials $G_i^{(1)}$ do not contain integrating constants. Set $G^{(0)}=\Sigma_{i=0}^{m}\alpha^iG_i^{(0)}$ and $G^{(1)}=\Sigma_{i=0}^{m}\alpha^iG_i^{(1)}$. Then we have $G=G^{(0)}+G^{(1)}$.

From (25) and working in a similar way to the proof of Llibre and Zhang (2002), we obtain that $g^{(0)}=G^{(0)}|_{\alpha=1}=\Sigma_{i=0}^{m}G_i^{(0)}$ is a Darboux polynomial of the Lorenz system with the cofactor $-2s\mu$. So, we should have $g^{(0)}=a(x^2-2sz)^{\mu}$, where a is an arbitrary constant.

Under the assumptions on $G_i^{(1)}$, we obtain that Eqs. (26) have the unique solutions $G_{\nu-i}^{(1)}=0$ for $i=1,\ldots,\nu$. From Eq. (27) we get that

$$G_{\nu}^{(1)}(x,y,z)=\overline{G}_{\nu}^{(1)}(u,v,w)=\frac{l_2}{s}u^{\mu}\sqrt{u+2sw}+l_3u^{\mu}\int\frac{wdw}{\sqrt{u+2sw}\sqrt{v-w^2}}.$$

Since $G_{\nu}^{(1)}$ is a polynomial, using formula (A2) we obtain that $l_3=0$ and

$$G_{\nu}^{(1)}=\frac{l_2}{s}x(x^2-2sz)^{\mu}.$$

This implies that $m=2\mu+1$, i.e., $\nu=0$.

Substituting $G_\nu^{(1)}$ into Eq. (28), we can prove that

$$G_{\nu+1}^{(1)}(x,y,z)=\overline{G}_{\nu+1}^{(1)}(u,v,w)=(l_1+l_2)u^\mu \arcsin\frac{w}{\sqrt{v}}.$$

Hence, we should have $l_1+l_2=0$ and $G_{\nu+1}^{(1)}=0$.

Introducing $G_\nu^{(1)}$ and $G_{\nu+1}^{(1)}$ into (29) and in a similar way to the proof of the case $m-2\mu=-1$, we get that $l_0=0$ and $G_{\nu+2}^{(1)}=0$. Furthermore, using the assumptions on $G_i^{(1)}$ we can prove that Eqs. (30) have only the solutions $G_j^{(1)}=0$ for $j=\nu+3,\ldots,m$. This proves that

$$g=(G^{(0)}+G^{(1)})|_{\alpha=1}=\frac{l_2}{s}x(x^2-2sz)^\mu+a(x^2-2sz)^\mu,$$

with $l=l_2(y-x)$. But $(g,h)=(x^2-2sz)^\mu$. It is in contradiction with the assumption $(g,h)=1$.

Case 2. $b=1$ and $r=0$. The Darboux polynomial is $h=(y^2+z^2)^\mu$ with the cofactor $k=-2\mu$, where $\mu\in\mathbb{N}$. Working in a similar way to the proof of case 1, we can prove that

$$g=\frac{l_2}{s}x(y^2+z^2)^\mu+a(y^2+z^2)^\mu,$$

with $l=l_2(y-x)$.

Case 3. $b=1$ and $s=1$. Then the Darboux polynomial is $h=(y^2+z^2-rx^2)^\mu$ with the cofactor $k=-2\mu$. Equation (19) becomes

$$\begin{aligned}&(y-\alpha x)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial x}+(-xz-\alpha y+\alpha^2 rx)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial y}+(xy-\alpha z)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial z}\\&\quad=-2\alpha\mu\sum_{i=0}^{m}\alpha^i G_i+\alpha^{m-1-4\mu}(l_2y+l_3z+\alpha l_1x+\alpha^2 l_0)(y^2+z^2-\alpha^2 rx)^\mu,\end{aligned}\tag{31}$$

where we first use the weight change (10), and then use x,y,z to denote X,Y,Z. Similar to the proof of case 1, we can assume that $m=4\mu+1+\nu$ for some $\nu\in\mathbb{N}\cup\{0\}$.

Consider the following equations:

$$L[G_i^{(0)}]=D_2[G_{i-1}^{(0)}]-rx\frac{\partial G_{i-2}^{(0)}}{\partial y},\quad i=0,1,\ldots,m+2,\tag{32}$$

$$L[G_{\nu-i}^{(1)}]=0,\quad i=1,\ldots,\nu\tag{33}$$

$$\begin{aligned}L[G_{\nu+2k}^{(1)}]&=D_2[G_{\nu+2k-1}^{(1)}]-rx\frac{\partial G_{\nu+2k-2}^{(1)}}{\partial y}+(l_2y+l_3z)\binom{\mu}{k}(y^2+z^2)^{\mu-k}(-rx^2)^k\\&\quad+l_0\binom{\mu}{k-1}(y^2+z^2)^{\mu-k+1}(-rx^2)^{k-1},\quad k=0,\ldots,\mu+1,\end{aligned}\tag{34}$$

$$L[G_{\nu+2k+1}^{(1)}]=D_2[G_{\nu+2k}^{(1)}]-rx\frac{\partial G_{\nu+2k-1}^{(1)}}{\partial y}+l_1x\binom{\mu}{k}(y^2+z^2)^{\mu-k}(-rx^2)^k,\quad k=0,\ldots,\mu,\tag{35}$$

$$L[G_{\nu+j}^{(1)}]=D_2[G_{\nu+j-1}^{(1)}]-rx\frac{\partial G_{\nu+j-2}^{(1)}}{\partial y},\quad j=2\mu+3,\ldots,4\mu+1,\tag{36}$$

where $G_i^{(l)}=0$ with $l=0,1$ for $i<0$ or $i>m$, $\binom{\mu}{k}=0$ for $k<0$ or $k>\mu$, and

$$D_2=x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}+z\frac{\partial}{\partial z}-2\mu.$$

We can prove that $G=\Sigma_{i=0}^{m}\alpha^i G_i$ satisfies (31) if and only if there exists a decomposition of G_i into $G_i=G_i^{(0)}+G_i^{(1)}$ such that $G_i^{(0)}$ and $G_i^{(1)}$ are weight homogeneous polynomials of the weight degrees same as those of G_i, and that $G_i^{(0)}$ satisfy (32), and $G_i^{(1)}$ satisfy (33)–(36). As before, we require that in the process to solve $G_i^{(1)}$, the integration constants are always equal to zero.

From Eqs. (32) and using the method given in Llibre and Zhang (2002), we can prove that $g^{(0)}=G^{(0)}|_{\alpha=1}=\Sigma_{i=0}^{m}G_i^{(0)}=a(y^2+z^2-rx^2)^{\mu}$, where a is an arbitrary constant. Using the assumptions on $G_i^{(1)}$, we obtain that Eqs. (33) have only the solutions $G_{\nu-i}^{(1)}=0$ for $i=1,\ldots,\nu$. Then Eq. (34) with $k=0$ becomes

$$L[G_\nu^{(1)}]=(l_2y+l_3z)(y^2+z^2)^{\mu}.$$

Working in a similar way to solve (27) we can prove that $l_3=0$ and

$$G_\nu^{(1)}=l_2x(y^2+z^2)^{\mu}.$$

Moreover, from Eq. (35) with $k=0$, we get that $l_2+l_1=0$ and $G_{\nu+1}^{(1)}=0$.

Now, Eq. (34) with $k=1$ becomes

$$L[G_{\nu+2}^{(1)}]=l_0(y^2+z^2)^{\mu}-3rl_2\mu x^2y(y^2+z^2)^{\mu-1}.$$

Solving this equation gives $l_0=0$ and

$$G_{\nu+2}^{(1)}=l_2x\binom{\mu}{1}(y^2+z^2)^{\mu-1}(-rx^2).$$

Introducing $G_{\nu+1}^{(1)}$ and $G_{\nu+2}^{(1)}$ into (35) with $k=1$, we obtain that $L[G_{\nu+3}^{(1)}]=0$. So, we have $G_{\nu+3}^{(1)}=0$.

By induction we assume that

$$G_{\nu+2k-1}^{(1)}=0,\quad G_{\nu+2k}^{(1)}=l_2x\binom{\mu}{k}(y^2+z^2)^{\mu-k}(-rx^2)^k.$$

Then, Eq. (35) can be simplified to

$$L[G_{\nu+2k+1}^{(1)}]=(l_2+l_1)x\binom{\mu}{k}(y^2+z^2)^{\mu-k}(-rx^2)^k=0.$$

Hence, we have $G_{\nu+2k+1}^{(1)}=0$. Now Eq. (34) becomes

$$L[G_{\nu+2k+2}^{(1)}]=(-r)^{k+1}l_2\binom{\mu}{k+1}(2k+3)(y^2+z^2)^{\mu-k-1}x^{2k+2}y.$$

Applying the method of characteristic curves to this equation, we obtain that

$$G_{\nu+2k+2}^{(1)}=l_2x\binom{\mu}{k+1}(y^2+z^2)^{\mu-k-1}(-rx^2)^{k+1}.$$

Therefore, we have

$$g^{(1)}=G^{(1)}|_{\alpha=1}=\sum_{i=0}^{m} G_i^{(1)}=l_2x\sum_{i=0}^{\mu}\binom{\mu}{i}(y^2+z^2)^{\mu-i}(-rx^2)^i=l_2x(y^2+z^2-rx^2)^{\mu}.$$

Moreover, from the above proof we get that $m=4\mu+1$, and

$$g=g^{(0)}+g^{(1)}=l_2x(y^2+z^2-rx^2)^{\mu}+a(y^2+z^2-rx^2)^{\mu}.$$

It is in contradiction with the assumption $(g,h)=1$.

Case 4. $b=6s-2$ and $r=2s-1$. The Darboux polynomial is $h=[x^4-4sx^2z-4s^2y^2+4s(4s-2)xy-(4s-2)^2x^2]^{\mu}$ with the cofactor $k=-4s\mu$. Equation (19) becomes

$$\begin{aligned}&(sy-\alpha sx)\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial x}+[-xz-\alpha y+\alpha^2(2s-1)x)]\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial y}+[xy-\alpha(6s-2)z]\sum_{i=0}^{m}\alpha^i\frac{\partial G_i}{\partial z}\\&=-4\alpha s\mu\sum_{i=0}^{m}\alpha^iG_i+\alpha^{m-1-4\mu}(l_2y+l_3z+\alpha l_1x+\alpha^2l_0)\\&\quad\times[x^4-4sx^2z-4s^2y^2+4\alpha s(4s-2)xy-\alpha^2(4s-2)^2x^2]^{\mu}.\end{aligned}\tag{37}$$

Working in a similar way to the proof of cases 1 and 3, we can prove that $m=4\mu+1$ and $G=G^{(0)}+G^{(1)}$ with $G^{(0)}|_{\alpha=1}=ah(x,y,z)$, and $G^{(1)}=\Sigma_{i=0}^{m}\alpha^iG_i^{(1)}$, where $G_i^{(1)}$ satisfy

$$L[G_0^{(1)}]=(l_2y+l_3z)(x^4-4sx^2z-4s^2y^2)^{\mu},\tag{38}$$

$$\begin{aligned}L[G_1^{(1)}]=&sx\frac{\partial G_0^{(1)}}{\partial x}+y\frac{\partial G_0^{(1)}}{\partial y}+(6s-2)z\frac{\partial G_0^{(1)}}{\partial z}-4s\mu G_0+(l_2y+l_3z)\binom{\mu}{1}\\&\times(x^4-4sx^2z-4s^2y^2)^{\mu-1}4s(4s-2)xy+l_1x(x^4-4sx^2z-4s^2y^2)^{\mu}.\end{aligned}\tag{39}$$

We still assume that the solutions $G_0^{(1)}$ and $G_1^{(1)}$ of (38) and (39) do not contain integrating constants.

Solving Eq. (38), we obtain that $l_3=0$ and

$$G_0^{(1)}=\frac{l_2}{s}x(x^4-4sx^2z-4s^2y^2)^{\mu}.$$

Then Eq. (39) becomes

$$\begin{aligned}L[G_1^{(1)}]=&(l_2+l_1)x(x^4-4sx^2z-4s^2y^2)^{\mu}+\mu l_2x(x^4-4sx^2z-4s^2y^2)^{\mu-1}\\&\times[-4(4s-2)(x^2-2sz)z-16s(4s-2)z^2+8s(4s-2)(y^2+z^2)].\end{aligned}$$

Applying the method of characteristic curves to this equation, we obtain that

$$\begin{aligned}G_1^{(1)}=\bar{G}_1^{(1)}=&(l_2+l_1)(u^2-4s^2v)^{\mu}\arcsin\frac{w}{\sqrt{v}}+\mu l_2(u^2-4s^2v)^{\mu-1}\\&\times\left[4(4s-2)u\sqrt{v-w^2}+16s(4s-2)\int\sqrt{v-w^2}dw-8s(4s-2)v\arcsin\frac{w}{\sqrt{v}}\right].\end{aligned}$$

If $s\neq\frac{1}{2}$, we must have $l_2+l_1=0$ and $l_2=0$. So, we get that $G_0^{(1)}=G_0^{(2)}=0$. Moreover, we have

$$L[G_2^{(1)}]=l_0(x^4-4sx^2z-4s^2y^2)^{\mu}.$$

Solving this equation yields $l_0=0$ and $G_2^{(1)}=0$. This proves that $l=0$. Hence, we have $g=g^{(0)}=ah(x,y,z)$. This means that the Lorenz system does not have exponential factors of the given form.

If $s=\frac{1}{2}$, then $b=1$ and $r=0$. The function $H=(x^2-z)^2/(y^2+z^2)$ is a rational first integral of the Lorenz system. The Darboux polynomial of the Lorenz system has a general form

$$h(x,y,z)=\prod_{i=1}^{m_1} f_i^{\mu_i}\prod_{j=1}^{m_2} g_j^{\nu_j},$$

where $f_i=(x^2-z)^2-c_i^{(1)}(y^2+z^2)$ and $g_j=(y^2+z^2)-c_j^{(2)}(x^2-z)^2$, with $c_i^{(1)}$ and $c_j^{(2)}$ arbitrary constants, are Darboux polynomials. The polynomial h has the weight degree $4(\Sigma_{i=1}^{m_1}\mu_i+\Sigma_{j=1}^{m_2}\nu_j)$. Working in a similar way to the proof of case 1 of this section, we can prove that $g=((l_2/s)x+a)h(x,y,z)$, where a is an arbitrary constant. It is also in contradiction with the assumption $(g,h)=1$.

Case 5. $b=0$, $s=\frac{1}{3}$; or $b=4$, $s=1$. The Darboux polynomial of the Lorenz system is $h=(x^4-\frac{4}{3}x^2z-\frac{4}{9}y^2-\frac{8}{9}xy+\frac{4}{3}rx^2)^\mu$ with the cofactor $k=-\frac{4}{3}\mu$, or $h=[x^4-4x^2z-4y^2+8xy-4rx^2-16(1-r)z]^\mu$ with the cofactor $k=-4\mu$, where $\mu\in\mathbb{N}$. Doing some similar computations as those in case 4, we may obtain that $g=ah(x,y,z)$, where a is an arbitrary constant. So, the Lorenz system does not have the exponential factor of the given form.

Summing up the above five cases, we have proved that the Lorenz system does not have exponential factors of the form $\exp(g(x,y,z)/h(x,y,z))$ with $(g,h)=1$. This proves statement (a).

Proof of statement (b): From Theorem 3 the Lorenz system has a Darbouxian first integral if and only if there exist $\mu_i,\nu_j\in\mathbb{C}$ not all zero such that

$$\sum_{i=1}^{m_1}\mu_i k_i+\sum_{j=1}^{m_2}\nu_j l_j=0, \tag{40}$$

where m_1 and m_2 are the numbers of Darboux polynomials and exponential factors, respectively; and k_i and l_j are the cofactors of Darboux polynomials and exponential factors, respectively. Theorem 2 shows that the cofactors of Darboux polynomials are constants. Statement (a) of Theorem 1 gives that the cofactors of exponential factors are of the form $l_j=c_j(y-x)$, where c_j are constants. So, Eq. (40) is equivalent to $\Sigma_{i=1}^{m_1}\mu_i k_i=0$ and $\Sigma_{j=1}^{m_2}\nu_j l_j=0$. This last equation is equivalent to $\Sigma_{j=1}^{m_2}\nu_j c_j=0$. Corresponding to the cofactor l_j, the exponential factor is $F_j=\exp((c_j/s)x)$. Hence, we have $\Pi_{j=1}^{m_2}F_j^{\nu_j}=\exp(\Sigma_{j=1}^{m_2}(\nu_j c_j/s)x)=1$. Thus, from Theorem 3 we obtain that the Lorenz system has a Darbouxian first integral H if and only if $H(x,y,z)=\Pi_{i=1}^{m_1}f_i^{\mu_i}$ with

$$\sum_{i=1}^{m_1}\mu_i k_i=0, \tag{41}$$

where $\mu_i\in\mathbb{C}$ are not all equal to zero, and each f_i is a Darboux polynomial with the cofactor k_i.

From Theorem 2 we get that the Lorenz system has Darboux polynomials such that their cofactors k_i satisfy (41) if and only if $b=1$, $r=0$ and $s=\frac{1}{2}$. Under these conditions the Lorenz system has the two independent Darboux polynomials $f_1=x^2-z$ and $f_2=y^2+z^2$ with the cofactors $k_1=-1$ and $k_2=-2$, respectively. Hence, the Lorenz system has a Darbouxian first integral

$$H=(x^2-z)^{-2\mu}(y^2+z^2)^\mu.$$

Of course, the Lorenz system may have other forms of Darbouxian first integrals, but they are dependent on H. This proves statement (b).

We have finished the proof of the theorem.

Liouville integrability of the finite dimensional Hamiltonian systems derived from principal chiral field

Zixiang Zhou[a)]
Institute of Mathematics, Fudan University, Shanghai 200433, People's Republic of China

(Received 29 January 2002; accepted for publication 13 May 2002)

For finite dimensional Hamiltonian systems derived from $1+1$ dimensional integrable systems, if they have Lax representations, then the Lax operator creates a set of conserved integrals. When these conserved integrals are in involution, it is believed quite popularly that there will be enough functionally independent ones among them to guarantee the Liouville integrability of the Hamiltonian systems, at least for those derived from physical problems. In this article, we give a counterexample based on the $U(2)$ principal chiral field. It is proved that the finite dimensional Hamiltonian systems derived from the $U(2)$ principal chiral field are Liouville integrable. Moreover, their Lax operator gives a set of involutive conserved integrals, but they are not enough to guarantee the integrability of the Hamiltonian systems. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1501446]

I. INTRODUCTION

For many $1+1$ dimensional integrable systems, the nonlinearization method can be applied to get finite dimensional ($1+0$ dimensional) Hamiltonian systems.[1] Usually these Hamiltonian systems have Lax representations so that the involutive conserved integrals can be obtained. In this way the original nonlinear partial differential equations are changed to systems of nonlinear ordinary differential equations.[2–8] Many interesting exact solutions, especially quasi-periodic solutions, were obtained in this way.

For a finite dimensional Hamiltonian system, if it can be written in the Lax form as

$$\frac{\mathrm{d}}{\mathrm{d}t}L(\lambda)=[M(\lambda),L(\lambda)], \tag{1.1}$$

then the conserved integrals are easily derived from the coefficients of $\mathrm{tr}(L^k(\lambda))$'s ($k\geqslant 1$) when they are expanded as Laurent series of λ. Usually the number of these coefficients is infinite. It is believed quite popularly that when these conserved integrals are in involution, there will be enough functionally independent ones among them to guarantee the Liouville integrability of the Hamiltonian systems. Indeed, this is the case for most known physically interesting systems, such as the equations in the AKNS system, Kaup–Newell system and many other examples including those derived from $2+1$ dimensional integrable systems.[3,4,7,9–11]

However, we will give a counterexample in this article to show that this is not always true.

This counterexample is based on a well-known physical model–the $U(n)$ principal chiral field [or, mathematically, the harmonic map from $\mathbf{R}^{1,1}$ to $U(n)$].[12–16] In this article, the equation of $U(n)$ principal chiral field can be first reduced to a set of Hamiltonian systems by the standard procedure of the nonlinearization method. This will be done in Secs. II and III. Then, in Sec. IV, we show that there are not enough conserved integrals in those given by $\mathrm{tr}(L^k(\lambda))$'s to guarantee the Liouville integrability of the systems. In Sec. V, it is proved that these Hamiltonian systems are actually Liouville integrable for $n=2$. That is, they still have a full set of involutive and independent conserved integrals. These conserved integrals are obtained from $\mathrm{tr}L^k(\lambda)$ and other obvious

a)Electronic mail: zxzhou@guomai.sh.cn

conserved integrals. When $n>2$, it is still open whether one can find enough involutive and independent conserved integrals by adding some obvious ones to $\mathrm{tr}L^k(\lambda)$'s. Therefore, at least for $n=2$, the Hamiltonian systems derived from the $U(2)$ principal chiral field are Liouville integrable, but their conserved integrals for Liouville integrability can not be fully obtained from $\mathrm{tr}L^k(\lambda)$.

II. HAMILTONIAN SYSTEMS DERIVED FROM $U(n)$ PRINCIPAL CHIRAL FIELD

The equation for the $U(n)$ principal chiral field is

$$(g_x g^{-1})_t+(g_t g^{-1})_x=0, \tag{2.1}$$

where the field $g(x,t)\in U(n)$. Write

$$P=g_x g^{-1}, \quad Q=g_t g^{-1}. \tag{2.2}$$

Then $P,Q\in u(n)$ (i.e., $P^*+P=0$, $Q^*+Q=0$) and (2.1) becomes

$$P_t+Q_x=0, \quad P_t-Q_x+[P,Q]=0. \tag{2.3}$$

Here the second equation is the integrability condition of (2.2).

It is known that (2.3) has a Lax pair

$$\Phi_x=\frac{1}{1-\lambda}P\Phi, \quad \Phi_t=\frac{1}{1+\lambda}Q\Phi, \tag{2.4}$$

where λ is a complex spectral parameter.

Now we write down the corresponding finite dimensional Hamiltonian systems and their Lax operators.

Let $\lambda_1,\ldots,\lambda_N$ be N distinct real constants with $\lambda_j\neq\pm1$ $(j=1,\ldots,N)$, and let $(\phi_{1\alpha},\ldots,\phi_{n\alpha})^T$ be an arbitrary solution of the Lax pair (2.4) with $\lambda=\lambda_\alpha$, $\Lambda=\mathrm{diag}(\lambda_1,\ldots,\lambda_N)$, $\Phi_j=(\phi_{j1},\ldots,\phi_{jN})^T$. Let

$$L=\sum_{\alpha=1}^{N}\frac{1}{\lambda-\lambda_\alpha}\begin{pmatrix}\bar{\phi}_{1\alpha}\phi_{1\alpha} & \bar{\phi}_{2\alpha}\phi_{1\alpha} & \cdots & \bar{\phi}_{n\alpha}\phi_{1\alpha}\\ \vdots & \vdots & \ddots & \vdots\\ \bar{\phi}_{1\alpha}\phi_{n\alpha} & \bar{\phi}_{2\alpha}\phi_{n\alpha} & \cdots & \bar{\phi}_{n\alpha}\phi_{n\alpha}\end{pmatrix}. \tag{2.5}$$

Expand L to power series of $1-\lambda$ and $1+\lambda$, respectively:

$$\begin{aligned}L=L^{(1)}&=\sum_{k=1}^{\infty}(1-\lambda)^{k-1}\begin{pmatrix}\langle\Phi_1,(1-\Lambda)^{-k}\Phi_1\rangle & \cdots & \langle\Phi_n,(1-\Lambda)^{-k}\Phi_1\rangle\\ \vdots & \ddots & \vdots\\ \langle\Phi_1,(1-\Lambda)^{-k}\Phi_n\rangle & \cdots & \langle\Phi_n,(1-\Lambda)^{-k}\Phi_n\rangle\end{pmatrix},\\ L=L^{(2)}&=-\sum_{k=1}^{\infty}(1+\lambda)^{k-1}\begin{pmatrix}\langle\Phi_1,(1+\Lambda)^{-k}\Phi_1\rangle & \cdots & \langle\Phi_n,(1+\Lambda)^{-k}\Phi_1\rangle\\ \vdots & \ddots & \vdots\\ \langle\Phi_1,(1+\Lambda)^{-k}\Phi_n\rangle & \cdots & \langle\Phi_n,(1+\Lambda)^{-k}\Phi_n\rangle\end{pmatrix},\end{aligned} \tag{2.6}$$

where the inner product $\langle V_1,V_2\rangle$ of two vectors is defined as $V_1^*V_2$. The first series converges when $|\lambda-1|<\min_{1\leq\alpha\leq N}|\lambda_\alpha-1|$ and the second one converges when $|\lambda+1|<\min_{1\leq\alpha\leq N}|\lambda_\alpha+1|$.

Lemma 1: If

$$P_{jk}=\mathrm{i}\langle\Phi_k,(1-\Lambda)^{-1}\Phi_j\rangle, \quad Q_{jk}=\mathrm{i}\langle\Phi_k,(1+\Lambda)^{-1}\Phi_j\rangle, \tag{2.7}$$

then

$$L_x=\frac{1}{1-\lambda}[P,L],\quad L_t=\frac{1}{1+\lambda}[Q,L], \tag{2.8}$$

and (P,Q) *gives a solution of (2.3).*

Proof: Let $\phi_\alpha=(\phi_{1\alpha},\ldots,\phi_{n\alpha})^T$. Then

$$L=\sum_{\alpha=1}^{N}\frac{1}{\lambda-\lambda_\alpha}\phi_\alpha\phi_\alpha^*. \tag{2.9}$$

Since $P^*=-P$ and λ_α's are real,

$$\begin{aligned}L_x&=\sum_{\alpha=1}^{N}\frac{1}{\lambda-\lambda_\alpha}\left(\phi_\alpha\frac{1}{1-\lambda_\alpha}\phi_\alpha^*P^*+\frac{1}{1-\lambda_\alpha}P\phi_\alpha\phi_\alpha^*\right)\\&=\sum_{\alpha=1}^{N}\frac{1}{\lambda-\lambda_\alpha}\frac{1}{1-\lambda_\alpha}[P,\phi_\alpha\phi_\alpha^*]\\&=\sum_{\alpha=1}^{N}\left(\frac{1}{\lambda-\lambda_\alpha}\frac{1}{1-\lambda}-\frac{1}{1-\lambda_\alpha}\frac{1}{1-\lambda}\right)[P,\phi_\alpha\phi_\alpha^*]=\frac{1}{1-\lambda}[P,L].\end{aligned} \tag{2.10}$$

The last equality holds due to (2.7). The equation for L_t in (2.8) is derived similarly. Finally, by computing the integrability condition $L_{xt}=L_{tx}$ from (2.8) or substituting (2.7) into (2.3) directly, we know that (P,Q) satisfies (2.3). The lemma is proved.

Now we always suppose (2.7) holds for the $U(n)$ principal chiral field, which gives the nonlinear constraints. Substituting (2.7) into (2.4), we get a system of partial differential equations

$$\begin{aligned}\Phi_{j,x}&=\mathrm{i}(1-\Lambda)^{-1}\sum_{k=1}^{n}\langle\Phi_k,(1-\Lambda)^{-1}\Phi_j\rangle\Phi_k,\\\Phi_{j,t}&=\mathrm{i}(1+\Lambda)^{-1}\sum_{k=1}^{n}\langle\Phi_k,(1+\Lambda)^{-1}\Phi_j\rangle\Phi_k,\end{aligned} \tag{2.11}$$

which can be studied as two systems of ordinary differential equations when t and x are considered as constants, respectively.

Now $\phi_{11},\phi_{12},\ldots,\phi_{1N},\ldots,\phi_{n1},\phi_{n2},\ldots,\phi_{nN}$ and their complex conjugations form the complex coordinates of $\mathbf{R}^{2nN}$. In this $\mathbf{R}^{2nN}$, let ω be the standard symplectic form

$$\omega=2\sum_{j=1}^{n}\sum_{\alpha=1}^{N}\mathrm{d}\,\mathrm{Im}(\phi_{j\alpha})\wedge\mathrm{d}\,\mathrm{Re}(\phi_{j\alpha})=\mathrm{i}\sum_{j=1}^{n}\sum_{\alpha=1}^{N}\mathrm{d}\bar{\phi}_{j\alpha}\wedge\mathrm{d}\phi_{j\alpha}. \tag{2.12}$$

Then the corresponding Poisson bracket for two functions f and g is

$$\{f,g\}=\frac{1}{\mathrm{i}}\sum_{j=1}^{n}\sum_{\alpha=1}^{N}\left(\frac{\partial f}{\partial\phi_{j\alpha}}\frac{\partial g}{\partial\bar{\phi}_{j\alpha}}-\frac{\partial g}{\partial\phi_{j\alpha}}\frac{\partial f}{\partial\bar{\phi}_{j\alpha}}\right). \tag{2.13}$$

From (2.8), the coefficients of $(1-\lambda)^j$ $(j=0,1,2,\ldots)$ in $\mathrm{tr}(L^{(1)})^k$ $(k=1,2,\ldots)$ and the coefficients of $(1+\lambda)^j$ $(j=0,1,2,\ldots)$ in $\mathrm{tr}(L^{(2)})^k$ $(k=1,2,\ldots)$ are all conserved. Suppose

$$\mathrm{tr}(L^{(1)})^m=\sum_{k=1}^{\infty}(1-\lambda)^{k-1}\mathcal{E}_{mk}^{(1)},\quad \mathrm{tr}(L^{(2)})^m=(-1)^m\sum_{k=1}^{\infty}(1+\lambda)^{k-1}\mathcal{E}_{mk}^{(2)}. \tag{2.14}$$

Since $\mathrm{tr}P=\mathrm{i}\mathcal{E}_{11}^{(1)}$ and $\mathrm{tr}Q=\mathrm{i}\mathcal{E}_{11}^{(2)}$, both $\mathrm{tr}P$ and $\mathrm{tr}Q$ are conserved. On the other hand, the Hamiltonians for Eqs. (2.11) are given by $\mathcal{E}_{21}^{(1)}$ and $\mathcal{E}_{21}^{(2)}$ according to the following lemma.

Moreover, direct computation shows that they commute with each other under the Poisson bracket (2.13) (this can also be derived directly from Lemma 3 in Sec. III).

Lemma 2: The Hamiltonians for the x-equation and the t-equation of (2.11) are given by

$$H^x=-\tfrac{1}{2}\mathcal{E}_{21}^{(1)}=-\tfrac{1}{2}\sum_{j,k=1}^{n}\langle\Phi_k,(1-\Lambda)^{-1}\Phi_j\rangle\langle\Phi_j,(1-\Lambda)^{-1}\Phi_k\rangle,$$
$$H^t=-\tfrac{1}{2}\mathcal{E}_{21}^{(2)}=-\tfrac{1}{2}\sum_{j,k=1}^{n}\langle\Phi_k,(1+\Lambda)^{-1}\Phi_j\rangle\langle\Phi_j,(1+\Lambda)^{-1}\Phi_k\rangle, \tag{2.15}$$

respectively. That is, (2.11) is equivalent to the Hamiltonian equations

$$\mathrm{i}\phi_{j\alpha,x}=\frac{\partial H^x}{\partial\bar{\phi}_{j\alpha}},\quad -\mathrm{i}\bar{\phi}_{j\alpha,x}=\frac{\partial H^x}{\partial\phi_{j\alpha}},\quad \mathrm{i}\phi_{j\alpha,t}=\frac{\partial H^t}{\partial\bar{\phi}_{j\alpha}},\quad -\mathrm{i}\bar{\phi}_{j\alpha,t}=\frac{\partial H^t}{\partial\phi_{j\alpha}}. \tag{2.16}$$

Moreover, $\{H^x,H^t\}=0$.

Remark 1: The above procedure can also be used for the harmonic map from $\mathbf{R}^2$ *to* $U(n)$. *In this case, the equation is*

$$(g_zg^{-1})_{\bar{z}}+(g_{\bar{z}}g^{-1})_z=0, \tag{2.17}$$

where z *is the complex coordinate of* $\mathbf{R}^2$, $g(z,\bar{z})\in U(n)$. *The Lax pair is*

$$\Phi_z=\frac{1}{1-\mathrm{i}\lambda}g_zg^{-1}\Phi,\quad \Phi_{\bar{z}}=\frac{1}{1+\mathrm{i}\lambda}g_{\bar{z}}g^{-1}\Phi, \tag{2.18}$$

where λ *is a complex spectral parameter. Using the same method in this section, we can also get finite dimensional Hamiltonian systems whose Lax operator is completely the same as (2.5).*

III. CONSERVED INTEGRALS

Lemma 3: With the Poisson bracket (2.13), the following two conclusions hold.
(1) For any two complex numbers λ, μ *and two positive integers* k, l,

$$\{\mathrm{tr}L^k(\lambda),\mathrm{tr}L^l(\mu)\}=0. \tag{3.1}$$

(2) For any complex number λ *and integers* j, k, l *with* $1\leqslant j,k\leqslant n$,

$$\{\langle\Phi_j,\Phi_k\rangle,\mathrm{tr}L^l(\lambda)\}=0. \tag{3.2}$$

This can be verified by direct computation of the Poisson brackets and was given in Ref. 11. Suppose the eigenvalues of $L(\lambda)$ are $\nu_1(\lambda)$, $\nu_2(\lambda),\ldots,\nu_n(\lambda)$. Then

$$\mathrm{tr}L^k(\lambda)=\nu_1^k(\lambda)+\cdots+\nu_n^k(\lambda),\quad (k=1,2,\ldots),$$
$$\det(\mu-L(\lambda))=\mu^n-p_1(\lambda)\mu^{n-1}+\cdots+(-1)^np_n(\lambda), \tag{3.3}$$

for any complex number μ where

$$p_k(\lambda)=\sum_{1\leqslant j_1<\cdots<j_k\leqslant n}\nu_{j_1}(\lambda)\cdots\nu_{j_k}(\lambda) \tag{3.4}$$

is the sum of all the determinants of the principal submatrices of $L(\lambda)$ of order k. Hence $\mathrm{tr}L^k(\lambda)$ $(k=1,2,\ldots)$ are uniquely determined by $p_k(\lambda)$ $(k=1,2,\ldots,n)$ and vise versa. Moreover, $\mathrm{tr}(L^{(1)})^k$ and $\mathrm{tr}(L^{(2)})^k$ in (2.14) can all be uniquely determined by $p_k(\lambda)$ $(k=1,2,\ldots,n)$.

Each $p_k(\lambda)$ is a holomorphic function of λ near $\lambda=\infty$. Let

$$p_m(\lambda)=\sum_{k=0}^{\infty} E_k^{(m)}\lambda^{-k-m}. \tag{3.5}$$

Then

$$\begin{aligned} E_k^{(m)} &= \sum_{1\leqslant i_1<\cdots<i_m\leqslant n}\ \sum_{\substack{r_1+\cdots+r_m=k\\ r_1,\cdots,r_m\geqslant 0}} \begin{vmatrix} \langle\Phi_{i_1},\Lambda^{r_1}\Phi_{i_1}\rangle & \langle\Phi_{i_2},\Lambda^{r_2}\Phi_{i_1}\rangle & \cdots & \langle\Phi_{i_m},\Lambda^{r_m}\Phi_{i_1}\rangle \\ \langle\Phi_{i_1},\Lambda^{r_1}\Phi_{i_2}\rangle & \langle\Phi_{i_2},\Lambda^{r_2}\Phi_{i_2}\rangle & \cdots & \langle\Phi_{i_m},\Lambda^{r_m}\Phi_{i_2}\rangle \\ \vdots & \vdots & \ddots & \vdots \\ \langle\Phi_{i_1},\Lambda^{r_1}\Phi_{i_m}\rangle & \langle\Phi_{i_2},\Lambda^{r_2}\Phi_{i_m}\rangle & \cdots & \langle\Phi_{i_m},\Lambda^{r_m}\Phi_{i_m}\rangle \end{vmatrix} \\ &= \sum_{1\leqslant i_1<\cdots<i_m\leqslant n}\ \sum_{\substack{r_1+\cdots+r_m=k\\ r_1,\cdots,r_m\geqslant 0}}\ \sum_{\substack{\alpha_1,\cdots,\alpha_m=1\\ \alpha_a\neq\alpha_b \text{ for } a\neq b}}^{N} \lambda_{\alpha_1}^{r_1}\cdots\lambda_{\alpha_m}^{r_m} \\ &\quad\times \begin{vmatrix} \overline{\phi}_{i_1\alpha_1}\phi_{i_1\alpha_1} & \overline{\phi}_{i_2\alpha_2}\phi_{i_1\alpha_2} & \cdots & \overline{\phi}_{i_m\alpha_m}\phi_{i_1\alpha_m} \\ \overline{\phi}_{i_1\alpha_1}\phi_{i_2\alpha_1} & \overline{\phi}_{i_2\alpha_2}\phi_{i_2\alpha_2} & \cdots & \overline{\phi}_{i_m\alpha_m}\phi_{i_2\alpha_m} \\ \vdots & \vdots & \ddots & \vdots \\ \overline{\phi}_{i_1\alpha_1}\phi_{i_m\alpha_1} & \overline{\phi}_{i_2\alpha_2}\phi_{i_m\alpha_2} & \cdots & \overline{\phi}_{i_m\alpha_m}\phi_{i_m\alpha_m} \end{vmatrix}. \end{aligned} \tag{3.6}$$

In the last summation, the condition "$\alpha_a\neq\alpha_b$ for $a\neq b$" is added since the determinants with $\alpha_a=\alpha_b$ $(a\neq b)$ are all zero.

Remark 2: When $m\geqslant N+1$, the last summation in (3.6) for "$1\leqslant\alpha_1,\ldots,\alpha_m\leqslant N$ with $\alpha_a\neq\alpha_b$ for $a\neq b$" is empty. This means that $E_k^{(m)}\equiv 0$ for $m\geqslant N+1$.

According to (2.8), all $E_k^{(m)}$'s are conserved.

From the first part of Lemma 3, all $E_k^{(m)}$'s are in involution. The second part of Lemma 3 implies that all $\langle\Phi_j,\Phi_k\rangle$'s commute with $E_k^{(m)}$'s. However, these $\langle\Phi_j,\Phi_k\rangle$'s may not commute with each other.

Remark 3: For the Heisenberg ferromagnetic equation, the x-equation of its Lax pair is similar to that of the $U(2)$ principal chiral field. The nonlinearization for this equation was dealt with in Ref. 2 and a set of involutive conserved integrals was obtained there.

Remark 4: Since tr$P$, tr$Q$ *are conserved, if (P,Q) is a solution of (2.3) in $u(n)$, then*

$$P'=P-\frac{1}{n}\mathrm{tr}P,\quad Q'=Q-\frac{1}{n}\mathrm{tr}Q \tag{3.7}$$

gives a solution of the same equation (2.3) in $su(n)$.

IV. DEPENDENCE OF CONSERVED INTEGRALS

In order to consider the integrability of the Hamiltonian systems, we should find a full set of involutive and independent conserved integrals. Unlike many other cases, here we cannot get a full set of independent conserved integrals simply from tr$L^k(\lambda)$'s.

For further discussion, we need the following lemma.

Lemma 4: Suppose k, m are two integers with $k\geqslant 0$ and $m\geqslant 2$, and $\mu_1,\ldots,\mu_m$ are distinct complex numbers. Then

$$\sum_{j=1}^{m} \mu_j^k \prod_{\substack{r=1 \\ r\neq j}}^{m} (\mu_j-\mu_r)^{-1} = \begin{cases} 0 & \text{if } k<m-1, \\ \displaystyle\sum_{\substack{p_1+\cdots+p_m=k-m+1 \\ p_1,\cdots,p_m\geqslant 0}} \mu_1^{p_1}\cdots\mu_m^{p_m} & \text{if } k\geqslant m-1. \end{cases} \tag{4.1}$$

Proof: Let

$$f(\zeta)=\zeta^k \prod_{r=1}^{m} (\zeta-\mu_r)^{-1}. \tag{4.2}$$

Then $f(\zeta)$ is a meromorphic function of ζ with poles $\mu_1,\ldots,\mu_m$. Let C_R be a circle with radius R, center 0 and positive orientation. Then, when $R>\max_{1\leqslant j\leqslant m}|\mu_j|$,

$$\frac{1}{2\pi \mathrm{i}} \int_{C_R} f(\zeta)\mathrm{d}\zeta = \sum_{j=1}^{m} \operatorname*{Res}_{\zeta=\mu_j} f(\zeta) = \sum_{j=1}^{m} \mu_j^k \prod_{\substack{r=1 \\ r\neq j}}^{m} (\mu_j-\mu_r)^{-1}. \tag{4.3}$$

On the other hand, let $\xi=\zeta^{-1}$. Then

$$\begin{aligned} \frac{1}{2\pi \mathrm{i}} \int_{C_R} f(\zeta)\mathrm{d}\zeta &= \lim_{R\to\infty} \frac{1}{2\pi \mathrm{i}} \int_{C_{1/R}} \xi^{m-k-2} \prod_{r=1}^{m} (1-\mu_r\xi)^{-1}\mathrm{d}\xi \\ &= \begin{cases} 0 & \text{if } k-m+1<0, \\ \displaystyle\sum_{\substack{p_1+\cdots+p_m=k-m+1 \\ p_1,\cdots,p_m\geqslant 0}} \mu_1^{p_1}\cdots\mu_m^{p_m} & \text{if } k-m+1\geqslant 0 \end{cases} \end{aligned} \tag{4.4}$$

by expanding all the terms $(1-\mu_j\xi)^{-1}$ at $\xi=0$. The lemma is proved.

Theorem 1: *For* $1\leqslant m\leqslant n$, *there are at most* $\max(0,N-m+1)$ *linearly independent functions in* $E_k^{(m)}$ $(k=0,1,2,\ldots)$. *Therefore, the number of linearly independent functions in* $E_k^{(m)}$ $(m=1,2,\ldots,n;\ k=0,1,2,\ldots)$ *cannot exceed* $nN-\frac{1}{2}n(n-1)$ *if* $N\geqslant n$ *or* $\frac{1}{2}N(N+1)$ *if* $N<n$.

Proof: According to Remark 2, $E_k^{(m)}\equiv 0$ for $m\geqslant N+1$. Hence we always suppose $m\leqslant N$.

By definition, $\Lambda=\mathrm{diag}(\lambda_1,\ldots,\lambda_N)$, $\lambda_j\neq\lambda_k$ $(j\neq k)$. Clearly, for any non-negative integers $(k_1,\ldots,k_l)$ with $k_i\neq k_j$ $(i\neq j)$ and $l\geqslant N+1$, $E_{k_1}^{(1)},\ldots,E_{k_l}^{(1)}$ are linearly dependent. On the other hand, since the Van de Monde determinant of $\lambda_1,\ldots,\lambda_N$ is not zero, there are exactly N independent functions in $E_k^{(1)}$ $(k=0,1,2,\ldots)$.

For $m\geqslant 2$, we show that there are at most $N-m+1$ independent functions in $E_k^{(m)}$ $(k=0,1,2,\ldots)$ for fixed m.

Let $k_1,\ldots,k_N$ be N arbitrary distinct non-negative integers. For fixed s with $0\leqslant s\leqslant m-2$, let $(\gamma_1^{(s)},\ldots,\gamma_N^{(s)})$ be a solution of the linear algebraic system

$$\sum_{j=1}^{N} \lambda_\alpha^{k_j+m-1}\gamma_j^{(s)}=\lambda_\alpha^s \quad (\alpha=1,2,\ldots,N). \tag{4.5}$$

Since the coefficient matrix in (4.5) is $(\lambda_\alpha^{k_j+m+1})_{\alpha,j=1,\ldots,N}$ which is invertible, $(\gamma_1^{(s)},\ldots,\gamma_N^{(s)})$ exists uniquely.

Let

$$F_s^{(m)}=\sum_{j=1}^{N} \gamma_j^{(s)} E_{k_j}^{(m)} \quad (s=0,1,\ldots,m-2). \tag{4.6}$$

Then

$$F_s^{(m)}=\sum_{j=1}^{N}\sum_{1\leqslant i_1<\cdots<i_m\leqslant n}\ \sum_{\substack{r_1+\cdots+r_m=k_j\\ r_1,\cdots,r_m\geqslant 0}}\ \sum_{\substack{\alpha_1,\cdots,\alpha_m=1\\ \alpha_a\neq\alpha_b \text{ for } a\neq b}}^{N}\gamma_j^{(s)}\lambda_{\alpha_1}^{r_1}\cdots\lambda_{\alpha_m}^{r_m}$$
$$\times\begin{vmatrix}\overline{\phi}_{i_1\alpha_1}\phi_{i_1\alpha_1} & \overline{\phi}_{i_2\alpha_2}\phi_{i_1\alpha_2} & \cdots & \overline{\phi}_{i_m\alpha_m}\phi_{i_1\alpha_m}\\ \overline{\phi}_{i_1\alpha_1}\phi_{i_2\alpha_1} & \overline{\phi}_{i_2\alpha_2}\phi_{i_2\alpha_2} & \cdots & \overline{\phi}_{i_m\alpha_m}\phi_{i_2\alpha_m}\\ \vdots & \vdots & \ddots & \vdots\\ \overline{\phi}_{i_1\alpha_1}\phi_{i_m\alpha_1} & \overline{\phi}_{i_2\alpha_2}\phi_{i_m\alpha_2} & \cdots & \overline{\phi}_{i_m\alpha_m}\phi_{i_m\alpha_m}\end{vmatrix}. \tag{4.7}$$

For fixed $i_1,\ldots,i_m$, $\alpha_1,\ldots,\alpha_m$ and s with $0\leqslant s\leqslant m-2$, let

$$\Delta=\sum_{j=1}^{N}\sum_{\substack{r_1+\ldots+r_m=k_j\\ r_1,\ldots,r_m\geqslant 0}}\gamma_j^{(s)}\lambda_{\alpha_1}^{r_1}\cdots\lambda_{\alpha_m}^{r_m}. \tag{4.8}$$

Then

$$\Delta=\sum_{j=1}^{N}\gamma_j^{(s)}\sum_{a=1}^{m}\lambda_{\alpha_a}^{k_j+m-1}\prod_{\substack{r=1\\ r\neq a}}^{m}(\lambda_{\alpha_a}-\lambda_{\alpha_r})^{-1} \tag{4.9}$$

by Lemma 4. The relations (4.5) imply

$$\Delta=\sum_{a=1}^{m}\lambda_{\alpha_a}^{s}\prod_{\substack{r=1\\ r\neq a}}^{m}(\lambda_{\alpha_a}-\lambda_{\alpha_r})^{-1}. \tag{4.10}$$

Using Lemma 4 again, we get $\Delta=0$ for $s=0,1,2,\ldots,m-2$. Hence

$$F_0^{(m)}=F_1^{(m)}=\cdots=F_{m-2}^{(m)}=0. \tag{4.11}$$

By (4.5), the matrix $(\gamma_j^{(s)})_{1\leqslant j\leqslant N;\ 0\leqslant s\leqslant m-2}$ has rank $m-1$. Hence $E_{k_j}^{(m)}$ $(j=1,2,\ldots,N)$ satisfy $m-1$ independent linear relations for fixed m. This means that there are at most $N-m+1$ independent functions in N functions $E_{k_j}^{(m)}$ for fixed m.

Since $k_1,\ldots,k_N$ are arbitrary, there are at most $N-m+1$ independent functions in $E_k^{(m)}$ $(k=0,1,2,\ldots)$.

The total number of possible linearly independent functions in $E_k^{(m)}$ $(m=1,2,\ldots,n;\ k=0,1,2,\ldots)$ is

$$\sum_{m=1}^{n}(N-m+1)=nN-\tfrac{1}{2}n(n-1) \tag{4.12}$$

for $N\geqslant n$ and

$$\sum_{m=1}^{N}(N-m+1)=\tfrac{1}{2}N(N+1) \tag{4.13}$$

for $N<n$. The theorem is proved.

A completely integrable Hamiltonian system in $\mathbf{R}^{2nN}$ needs nN independent involutive conserved integrals. Hence the above theorem shows that it is not possible to find enough conserved integrals only from $E_k^{(m)}$'s for Liouville integrability.

V. LIOUVILLE INTEGRABILITY OF THE HAMILTONIAN SYSTEMS

In general, we have not been able to determine whether the Hamiltonian systems for the $U(n)$ principal chiral field are Liouville integrable or not. However, when $n=2$, the answer is positive.

Hereafter, we suppose $n=2$. Therefore, we want to find $2N$ independent conserved integrals for the Hamiltonian systems in $\mathbf{R}^{4N}$.

If $N=1$, let

$$\begin{aligned}\tilde{E}_0^{(1)}&=E_0^{(1)}=\langle\Phi_1,\Phi_1\rangle+\langle\Phi_2,\Phi_2\rangle,\\ \tilde{E}_0^{(2)}&=\langle\Phi_1,\Phi_2\rangle+\langle\Phi_2,\Phi_1\rangle.\end{aligned}\tag{5.1}$$

If $N\geqslant 2$, let

$$\begin{aligned}\tilde{E}_k^{(1)}&=E_k^{(1)}=\langle\Phi_1,\Lambda^k\Phi_1\rangle+\langle\Phi_2,\Lambda^k\Phi_2\rangle \quad (k=0,1,\ldots,N-1),\\ \tilde{E}_k^{(2)}&=E_k^{(2)}=\sum_{j=0}^{k}\begin{vmatrix}\langle\Phi_1,\Lambda^j\Phi_1\rangle & \langle\Phi_2,\Lambda^{k-j}\Phi_1\rangle\\ \langle\Phi_1,\Lambda^j\Phi_2\rangle & \langle\Phi_2,\Lambda^{k-j}\Phi_2\rangle\end{vmatrix} \quad (k=0,1,\ldots,N-2),\\ \tilde{E}_{N-1}^{(2)}&=\langle\Phi_1,\Phi_2\rangle+\langle\Phi_2,\Phi_1\rangle.\end{aligned}\tag{5.2}$$

Here the last one is chosen to be $\langle\Phi_1,\Phi_2\rangle+\langle\Phi_2,\Phi_1\rangle$ because all the conserved integrals should take real value.

Theorem 2: *When $n=2$, $\tilde{E}_k^{(m)}$ $(m=1,2;\ k=0,1,\ldots,N-1)$ are in involution and are functionally independent in a dense open subset of $\mathbf{R}^{4N}$.*

Proof: By Lemma 3, $\tilde{E}_k^{(m)}$ $(m=1,2;\ k=0,1,\ldots,N-1)$ are in involution.

It is obvious that they are independent for $N=1$. Hence we suppose $N\geqslant 2$. Let $a_{1\alpha}$ $(\alpha=1,2,\ldots,N)$ be N nonzero real numbers,

$$a_{2\alpha}=a_{1\alpha}^{-1}\prod_{\substack{\beta=1\\ \beta\neq\alpha}}^{N}(\lambda_\alpha-\lambda_\beta)^{-1} \quad (\alpha=1,2,\ldots,N).\tag{5.3}$$

Then Lemma 4 implies

$$\begin{aligned}\sum_{\beta=1}^{N}\lambda_\beta^k\overline{a}_{2\beta}a_{1\beta}&=0 \quad (k=0,1,\ldots,N-2),\\ \sum_{\beta=1}^{N}\lambda_\beta^{N-1}\overline{a}_{2\beta}a_{1\beta}&=1.\end{aligned}\tag{5.4}$$

Let $P_0\in\mathbf{R}^{4N}$ be given by $\phi_{1\beta}=a_{1\beta}$, $\phi_{2\beta}=\epsilon a_{2\beta}$ $(\beta=1,2,\ldots,N)$. Here ϵ is a nonzero small real constant to be determined. Then, at P_0,

$$\begin{aligned}&\frac{\partial\tilde{E}_k^{(1)}}{\partial\overline{\phi}_{1\alpha}}=\lambda_\alpha^k\phi_{1\alpha}, \quad \frac{\partial\tilde{E}_k^{(1)}}{\partial\overline{\phi}_{2\alpha}}=\lambda_\alpha^k\phi_{2\alpha} \quad (k=0,1,\ldots,N-1),\\ &\frac{\partial\tilde{E}_k^{(2)}}{\partial\overline{\phi}_{1\alpha}}=\sum_{j=0}^{k}\begin{vmatrix}\lambda_\alpha^j\phi_{1\alpha} & \displaystyle\sum_{\beta=1}^{N}\lambda_\beta^{k-j}\overline{\phi}_{2\beta}\phi_{1\beta}\\ \lambda_\alpha^j\phi_{2\alpha} & \displaystyle\sum_{\beta=1}^{N}\lambda_\beta^{k-j}|\phi_{2\beta}|^2\end{vmatrix}=\sum_{j=0}^{k}r_{2,k-j}\lambda_\alpha^j\phi_{1\alpha},\end{aligned}\tag{5.5}$$

$$\frac{\partial \tilde{E}_k^{(2)}}{\partial \overline{\phi}_{2\alpha}} = \sum_{j=0}^{k} \begin{vmatrix} \sum_{\beta=1}^{N} \lambda_\beta^{k-j} |\phi_{1\beta}|^2 & \lambda_\alpha^j \phi_{1\alpha} \\ \sum_{\beta=1}^{N} \lambda_\beta^{k-j} \overline{\phi}_{1\beta} \phi_{2\beta} & \lambda_\alpha^j \phi_{2\alpha} \end{vmatrix} = \sum_{j=0}^{k} r_{1,k-j} \lambda_\alpha^j \phi_{2\alpha} \qquad (k=0,1,\ldots,N-2),$$

$$\frac{\partial \tilde{E}_{N-1}^{(2)}}{\partial \overline{\phi}_{1\alpha}} = \phi_{2\alpha}, \quad \frac{\partial \tilde{E}_{N-1}^{(2)}}{\partial \overline{\phi}_{2\alpha}} = \phi_{1\alpha}$$

by using (5.4) where

$$r_{jk} = \sum_{\beta=1}^{N} \lambda_\beta^k |\phi_{j\beta}|^2. \tag{5.6}$$

Let J be the Jacobian matrix

$$J = \left. \frac{\partial(\tilde{E}_0^{(1)},\ldots,\tilde{E}_{N-1}^{(1)},\tilde{E}_0^{(2)},\ldots,\tilde{E}_{N-1}^{(2)})}{\partial(\overline{\phi}_{11},\ldots,\overline{\phi}_{1N},\overline{\phi}_{21},\ldots,\overline{\phi}_{2N})} \right|_{P_0}. \tag{5.7}$$

Denote ROW_j to be the jth row of J. Take the elementary transformations for the rows of J as follows:

(1) k from 1 to $N-1$:

$$\mathrm{ROW}_{N+k} - \sum_{j=0}^{k-1} r_{2,k-1-j} \mathrm{ROW}_{j+1} \to \mathrm{ROW}_{N+k},$$

(2) k from 2 to $N-1$:

$$\mathrm{ROW}_{N+k} - \sum_{j=1}^{k-1} \frac{r_{1j}-r_{2j}}{r_{10}-r_{20}} \mathrm{ROW}_{N+k-j} \to \mathrm{ROW}_{N+k}, \tag{5.8}$$

(3) k from 1 to $N-1$:

$$(r_{10}-r_{20})^{-1} \mathrm{ROW}_{N+k} \to \mathrm{ROW}_{N+k},$$

(4) k from 1 to $N-1$:

$$\mathrm{ROW}_k - \mathrm{ROW}_{N+k} \to \mathrm{ROW}_k.$$

Then J is transformed to

$$\tilde{J}=\begin{pmatrix} \phi_{11} & \phi_{12} & \cdots & \phi_{1N} & 0 & 0 & \cdots & 0 \\ \lambda_1\phi_{11} & \lambda_2\phi_{12} & \cdots & \lambda_N\phi_{1N} & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \lambda_1^{N-2}\phi_{11} & \lambda_2^{N-2}\phi_{12} & \cdots & \lambda_N^{N-2}\phi_{1N} & 0 & 0 & \cdots & 0 \\ \lambda_1^{N-1}\phi_{11} & \lambda_2^{N-1}\phi_{12} & \cdots & \lambda_N^{N-1}\phi_{1N} & \lambda_1^{N-1}\phi_{21} & \lambda_2^{N-1}\phi_{22} & \cdots & \lambda_N^{N-1}\phi_{2N} \\ 0 & 0 & \cdots & 0 & \phi_{21} & \phi_{22} & \cdots & \phi_{2N} \\ 0 & 0 & \cdots & 0 & \lambda_1\phi_{21} & \lambda_2\phi_{22} & \cdots & \lambda_N\phi_{2N} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & \lambda_1^{N-2}\phi_{21} & \lambda_2^{N-2}\phi_{22} & \cdots & \lambda_N^{N-2}\phi_{2N} \\ \phi_{21} & \phi_{22} & \cdots & \phi_{2N} & \phi_{11} & \phi_{12} & \cdots & \phi_{1N} \end{pmatrix}. \tag{5.9}$$

Let

$$T=\begin{pmatrix} T_2 & \\ & T_1 \end{pmatrix}, \tag{5.10}$$

where

$$T_j=\begin{pmatrix} \lambda_1^{N-1}\overline{\phi}_{j1} & \lambda_1^{N-2}\overline{\phi}_{j1} & \cdots & \overline{\phi}_{j1} \\ \lambda_2^{N-1}\overline{\phi}_{j2} & \lambda_2^{N-2}\overline{\phi}_{j2} & \cdots & \overline{\phi}_{j2} \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_N^{N-1}\overline{\phi}_{jN} & \lambda_N^{N-2}\overline{\phi}_{jN} & \cdots & \overline{\phi}_{jN} \end{pmatrix}\Bigg|_{P_0} \qquad (j=1,2). \tag{5.11}$$

Then

$$\det T=\prod_{1\leqslant\alpha<\beta\leqslant N}(\lambda_\alpha-\lambda_\beta)^2\prod_{\gamma=1}^{N}\overline{\phi}_{1\gamma}\overline{\phi}_{2\gamma}|_{P_0}\neq 0. \tag{5.12}$$

Using the relations (5.4), we have, at P_0,

$$\tilde{J}T=\begin{pmatrix} \rho & 0 & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\ * & \rho & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & & \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots \\ * & * & \cdots & \rho & 0 & 0 & 0 & \cdots & 0 & 0 \\ * & * & \cdots & * & \rho & * & * & \cdots & * & \overline{\rho} \\ 0 & 0 & \cdots & 0 & 0 & \rho & 0 & \cdots & 0 & 0 \\ 0 & 0 & \cdots & 0 & 0 & * & \rho & \cdots & 0 & 0 \\ \vdots & \vdots & & \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & 0 & * & * & \cdots & \rho & 0 \\ * & * & \cdots & * & \sum_{j=1}^{N}|\phi_{2j}|^2 & * & * & \cdots & * & \sum_{j=1}^{N}|\phi_{1j}|^2 \end{pmatrix}, \tag{5.13}$$

where

$$\rho=\sum_{\beta=1}^{N}\lambda_{\beta}^{N-1}\overline{\phi}_{2\beta}\phi_{1\beta}\Big|_{P_0}=\epsilon\neq 0 \tag{5.14}$$

and $*$ represents the entries which may not be zero.

Hence, at P_0,

$$\begin{aligned}(r_{10}-r_{20})^{-N+1}\det(JT)=\det(\tilde{J}T)&=\rho^{2N-2}\left(\rho\sum_{j=1}^{N}|\phi_{1j}|^2-\overline{\rho}\sum_{j=1}^{N}|\phi_{2j}|^2\right)\\&=\epsilon^{2N-1}\left(\sum_{j=1}^{N}a_{1j}^2-\epsilon^2\sum_{j=1}^{N}a_{2j}^2\right).\end{aligned} \tag{5.15}$$

It is not zero when ϵ is small enough. Since $\det J$ is a real analytical function on $\mathbf{R}^{4N}$, $\det J$ is not zero in a dense open subset of $\mathbf{R}^{4N}$. The theorem is proved.

Remark 5: Although the constraint here is of Bargmann type, the proof of the independence of the conserved integrals is not so simple as in the AKNS system. In that case, P_0 is simply chosen as a point near 0. *However, here $L(\lambda)$ is homogeneous to all Φ_j's so the choice of P_0 near* 0 *does not have any effect on the simplification of the computation on J.*

The Liouville integrability of the $U(2)$ principal chiral field follows from Lemma 2 and Theorem 2. It is given by the following theorem.

Theorem 3: *When $n=2$, the Hamiltonian systems given by* (2.15) *are completely integrable in the Liouville sense. Each solution of the Hamiltonian systems* (2.15) *gives a solution (P,Q) of* (2.3), *the equation of the $U(2)$ principal chiral field, and $(P-\frac{1}{2}\mathrm{tr}P, Q-\frac{1}{2}\mathrm{tr}Q)$ is a solution of the $SU(2)$ principal chiral field.*

Remark 6: Theorem 1 implies that one needs at least $n(n+1)/2$ extra conserved integrals together with $E_k^{(m)}$'s to form a full set of conserved integrals for the complete integrability of the Hamiltonian systems. According to Lemma 3, all $\langle\Phi_k,\Phi_j\rangle$'s commute with $E_k^{(m)}$. However, two elements in $\{\langle\Phi_k,\Phi_j\rangle\}$ may not commute with each other. Therefore, it is not obvious how to add at least $n(n+1)/2$ extra conserved integrals to $E_k^{(m)}$ in general.

A time-dependent completely integrable Hamiltonian system is quantized with respect to time-dependent action-angle variables near an instantly compact regular invariant manifold. Its Hamiltonian depends only on action variables, and has a time-independent countable energy spectrum. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1502927]

I. INTRODUCTION

A time-dependent Hamiltonian system of m degrees of freedom is called a completely integrable system (CIS) if it admits m independent first integrals in involution. Choosing appropriate dynamic variables, one may hope to quantize a time-dependent CIS so that its quantum Hamiltonian and first integral operators possess time-independent spectra.[1] The time-dependent action-angle variables introduced in the following are of this type. Written relative to these variables, a Hamiltonian of a time-dependent CIS is a function only of the action coordinates. It follows that, if time-dependent action-angle coordinates hold fixed, a time-dependent CIS can be quantized just as an autonomous one, and its energy spectrum is time-independent.

In order to introduce time-dependent action-angle variables, we use the fact that a time-dependent CIS of m degrees of freedom can be extended to an autonomous one of $m+1$ degrees of freedom where the time is regarded as a dynamic variable.[2–4] By virtue of the classical Arnold–Liouville theorem,[5,6] an autonomous CIS admits the action-angle coordinates around a regular connected compact invariant manifold. The problem is that invariant manifolds of a time-dependent CIS are not compact because of the time axis. Therefore, we first generalize the above-mentioned theorem to noncompact invariant manifolds. Then we show that, if a regular connected invariant manifold N of a time-dependent CIS is compact at each instant, it admits an open neighborhood in the ambient momentum phase space which is isomorphic to the product

$$W=\mathbb{R}\times T^m\times V \tag{1}$$

of the time axis $\mathbb{R}$, an m-dimensional torus T^m, and an open domain $V\subset\mathbb{R}^m$. This product is equipped with the coordinates

$$(t,\phi^i,I_i), \quad i=1,\ldots,m, \tag{2}$$

[b)]Electronic mail: giachetta@campus.unicam.it
[c)]Electronic mail: sard@grav.phys.msu.su; URL: http://webcenter.ru/~sardan/

where t is the Cartesian coordinate on $\mathbb{R}$ and ϕ^i are cyclic coordinates on T^m. Written with respect to these coordinates, a Hamiltonian and first integrals of a time-dependent CIS are functions only of action coordinates I_i. The corresponding Hamilton equation on W reads

$$\dot{I}_i = 0, \quad \dot{\phi}^i = \partial^i \mathcal{H}(I_j).$$

A glance at this equation shows that, given action-angle coordinates (2), a time-dependent CIS can be seen as an autonomous CIS on the symplectic annulus

$$P = V \times T^m, \tag{3}$$

equipped with the action-angle coordinates (ϕ^i, I_i) and provided with the symplectic form

$$\Omega_P = \mathrm{d}I_i \wedge \mathrm{d}\phi^i. \tag{4}$$

Therefore, we can quantize a time-dependent CIS with respect to action-angle variables similarly to that of an autonomous CIS. Of course, the choice of time-dependent action-angle coordinates by no means is unique. They are changed by canonical transformations. Therefore, we employ the geometric quantization technique[7–9] which remains equivalent under such kind transformations. At the same time, geometric quantization essentially depends on the choice of polarization.[10,11]

Geometric quantization of an autonomous CIS has been studied with respect to polarization spanned by Hamiltonian vector fields of first integrals.[12] In fact, the Simms quantization of the harmonic oscillator[9] is also of this type. The problem is that the associated quantum algebra includes functions which are not defined on the whole momentum phase space, and elements of the carrier space fail to be smooth sections of the quantum bundle. Indeed, written with respect to the action-angle variables, this quantum algebra consists of functions which are affine in angle coordinates.

We choose a different polarization spanned by almost-Hamiltonian vector fields ∂^k of angle variables. The associated quantum algebra $\mathcal{A}$ consists of smooth functions which are affine in action variables. Note that this quantization of the symplectic annulus P (3) is equivalent to geometric quantization of the cotangent bundle T^*T^m of the torus T^m with respect to the familiar vertical polarization. As is well known, the vertical polarization of a cotangent bundle leads to its Schrödinger quantization. We show that $\mathcal{A}$ possesses a set of nonequivalent representations in the separable pre-Hilbert space $\mathbb{C}^\infty(T^m)$ of smooth complex functions on T^m. In particular, the action operators read

$$\hat{I}_k = -i\partial_k - \lambda_k, \tag{5}$$

where λ_k are real numbers which specify different representations of $\mathcal{A}$. By virtue of the multidimensional Fourier theorem, an orthonormal basis for $\mathbb{C}^\infty(T^m)$ consists of functions

$$\psi_{(n_r)} = \exp[i(n_r\phi^r)], \quad (n_r) = (n_1, \ldots, n_m) \in \mathbb{Z}^m. \tag{6}$$

With respect to this basis, the action operators (5) are countable diagonal matrices

$$\hat{I}_k \psi_{(n_r)} = (n_k - \lambda_k)\psi_{(n_r)}. \tag{7}$$

Given the representation (5), any polynomial Hamiltonian $\mathcal{H}(I_k)$ of a CIS is uniquely quantized as a Hermitian element $\hat{\mathcal{H}}(I_k) = \mathcal{H}(\hat{I}_k)$ of the enveloping algebra $\overline{\mathcal{A}}$ of $\mathcal{A}$. It has the countable time-independent spectrum

$$\hat{\mathcal{H}}(I_k)\psi_{(n_r)} = E_{(n_r)}\psi_{(n_r)}, \quad E_{(n_r)} = \mathcal{H}(n_k - \lambda_k), \quad n_k \in (n_r). \tag{8}$$

Similarly, polynomial first integrals are quantized. Since $\hat{I}_k$ are diagonal, one can also quantize Hamiltonians $\mathcal{H}(I_j)$ and first integrals $F(I_j)$ which are analytic functions on $\mathbb{R}^m$.

Note that, because geometric quantization is equivalent under canonical transformations, quantization of a time-dependent CIS with respect to action-angle variables induces its quantization with respect to initial variables near an invariant manifold in the ambient momentum phase space. However, its Hamiltonian need not be represented in terms of first integrals and need not belong to the quantum algebra $\overline{\mathcal{A}}$ because it fails to be a scalar under time-dependent transformations. Moreover, this induced quantization cannot be in general extended to the whole momentum phase space because of the topological obstructions to the existence of global action-angle coordinates.[13,14]

For instance, one usually mentions a harmonic oscillator as the simplest CIS whose quantization in the action-angle variables looks notoriously difficult.[15] However, a harmonic oscillator written relative to action-angle coordinates (ϕ,I) is located in the momentum phase space $\mathbb{R}^2\backslash\{0\}$, but it is not the standard oscillator on $\mathbb{R}^2$. Namely, there is a monomorphism, but not an isomorphism of the Poisson algebra of smooth complex functions on $\mathbb{R}^2$ to that on $\mathbb{R}^2\backslash\{0\}$. In particular, the angle polarization on $\mathbb{R}^2\backslash\{0\}$ is not extended to $\mathbb{R}^2$. As a consequence, the quantum algebra associated with this polarization is not extended to $\mathbb{R}^2$, and so is its carrier space $\mathbb{C}^\infty(T^m)$.

In conclusion, let us remark that, since Hamiltonians depend only on action variables and possess time-independent countable spectra, quantum CISs look especially promising for holonomic quantum computation, based on driving degenerate eigenstates of a Hamiltonian over a parameter space.[16–18] We will construct the corresponding quantum control operator.

II. CLASSICAL COMPLETELY INTEGRABLE SYSTEMS

Recall that the configuration space of time-dependent mechanics is a fiber bundle $Q\to\mathbb{R}$ over the time axis $\mathbb{R}$ equipped with the bundle coordinates (t,q^k), $k=1,\ldots,m$. The corresponding momentum phase space is the vertical cotangent bundle V^*Q of $Q\to\mathbb{R}$ endowed with holonomic coordinates (t,q^k,p_k).[19,20] The cotangent bundle T^*Q, coordinated by $(q^\lambda,p_\lambda)=(t,q^k,p_0,p_k)$, plays a role of the homogeneous momentum phase space. It is provided with the canonical Liouville form $\Xi=p_\lambda dq^\lambda$, the symplectic form $\Omega=d\Xi$, and the corresponding Poisson bracket

$$\{f,f'\}_T=\partial^\lambda f\partial_\lambda f'-\partial_\lambda f\partial^\lambda f', \quad f,f'\in C^\infty(T^*Q). \tag{9}$$

There is the one-dimensional trivial affine bundle

$$\zeta: T^*Q\to V^*Q. \tag{10}$$

Given its global section h, one can equip T^*Q with the global bundle coordinate $r=p_0-h$.

The fiber bundle (10) provides the vertical cotangent bundle V^*Q with the canonical Poisson structure $\{,\}_V$ such that

$$\zeta^*\{f,f'\}_V=\{\zeta^*f,\zeta^*f'\}_T, \quad \forall f,f'\in C^\infty(V^*Q), \tag{11}$$

$$\{f,f'\}_V=\partial^k f\partial_k f'-\partial_k f\partial^k f'. \tag{12}$$

Its characteristic symplectic foliation coincides with the fibration $V^*Q\to\mathbb{R}$. However, the Poisson structure (12) fails to set any dynamic equation on the momentum phase space V^*Q because Hamiltonian vector fields

$$\vartheta_f=\partial^k f\partial_k-\partial_k f\partial^k, \quad \vartheta_f\rfloor df'=\{f,f'\}_V, \quad f,f'\in C^\infty(V^*Q),$$

of functions on V^*Q are vertical.

A Hamiltonian of time-dependent mechanics is defined as a global section

$$h: V^*Q\to T^*Q, \quad p_0\circ h=-\mathcal{H}(t,q^j,p_j),$$

of the affine bundle ζ (10).[19,20] It yields the pull-back Hamiltonian form

$$H = h^*\Xi = p_k \mathrm{d}q^k - \mathcal{H}\,\mathrm{d}t \tag{13}$$

on V^*Q. Then there exists a unique vector field γ_H on V^*Q such that

$$\begin{gathered} \gamma_H \rfloor \mathrm{d}t = 1, \quad \gamma_H \rfloor \mathrm{d}H = 0, \\ \gamma_H = \partial_t + \partial^k \mathcal{H} \partial_k - \partial_k \mathcal{H} \partial^k. \end{gathered} \tag{14}$$

Its trajectories obey the Hamilton equation

$$\dot{q}^k = \partial^k \mathcal{H}, \quad \dot{p}_k = -\partial_k \mathcal{H}. \tag{15}$$

A first integral of the Hamilton equation (15) is a smooth real function F on V^*Q whose Lie derivative

$$L_{\gamma_H} F = \gamma_H \rfloor \mathrm{d}F = \partial_t F + \{\mathcal{H}, F\}_V$$

along the vector field γ_H (14) vanishes, i.e., F is constant on trajectories of γ_H. A time-dependent Hamiltonian system (V^*Q, H) is said to be completely integrable if the Hamilton equation (15) admits m first integrals F_k which are in involution with respect to the Poisson bracket $\{,\}_V$ (12) and whose differentials $\mathrm{d}F_k$ are linearly independent almost everywhere, i.e., the set of points where this condition fails is nowhere dense in V^*Q. One can associate to this system an autonomous CIS on T^*Q as follows.

Let us consider the pull-back $\zeta^* H$ of the Hamiltonian form H (13) onto the cotangent bundle T^*Q. It is readily observed that

$$\mathcal{H}^* = \partial_t \rfloor (\Xi - \zeta^* h^* \Xi) = p_0 + \mathcal{H} \tag{16}$$

is a function on T^*Q. Let us regard $\mathcal{H}^*$ as a Hamiltonian of an autonomous Hamiltonian system on the symplectic manifold (T^*Q, Ω). Its Hamiltonian vector field

$$\gamma_T = \partial_t - \partial_t \mathcal{H} \partial^0 + \partial^k \mathcal{H} \partial_k - \partial_k \mathcal{H} \partial^k \tag{17}$$

is projected onto the vector field γ_H (14) on V^*Q so that

$$\zeta^*(L_{\gamma_H} f) = \{\mathcal{H}^*, \zeta^* f\}_T, \quad \forall f \in C^\infty(V^*Q).$$

An immediate consequence of this relation is the following:

Proposition 1: (i) Given a time-dependent CIS $(V^*Q, H; F_k)$ on V^*Q, the Hamiltonian system $(T^*Q; \mathcal{H}^*, \zeta^* F_k)$ on T^*Q is completely integrable. (ii) Let N be a connected regular invariant manifold of $(V^*Q, H; F_k)$. Then $h(N) \subset T^*Q$ is a connected regular invariant manifold of the autonomous CIS $(T^*Q; \mathcal{H}^*, \zeta^* F_k)$.

Hereafter, the vector field γ_H (14) is assumed to be complete. In this case, the Hamilton equation (15) admits a unique global solution through each point of the momentum phase space V^*Q, and trajectories of γ_H define a trivial bundle $V^*Q \to V_t^*Q$ over any fiber V_t^*Q of $V^*Q \to \mathbb{R}$. Without loss of generality, one can choose the fiber $i_0 : V_0^*Q \to V^*Q$ at $t = 0$. Since N is an invariant manifold, the fibration

$$\xi : V^*Q \to V_0^*Q \tag{18}$$

also yields the fibration of N onto $N_0 = N \cap V_0^*Q$ such that $N \cong \mathbb{R} \times N_0$ is a trivial bundle.

III. TIME-DEPENDENT ACTION-ANGLE COORDINATES

Let us introduce the action-angle coordinates around an invariant manifold N of a time-dependent CIS on V^*Q by use of the action-angle coordinates around the invariant manifold $h(N)$ of the autonomous CIS on T^*Q in Proposition 1. Since N and, consequently, $h(N)$ are noncompact, we first prove the following:

Proposition 2: Let M be a connected invariant manifold of an autonomous CIS $\{F_\lambda\}$, $\lambda=1,\ldots,n$, on a symplectic manifold (Z,Ω_Z), and let the Hamiltonian vector fields of the first integrals F_α on M be complete. Let U be a neighborhood of M such that $\{F_\lambda\}$ have no critical points in U and the submersion $\times F_\lambda: U\to\mathbb{R}^n$ is a trivial bundle of Lagrangian invariant manifolds over a domain $V'\subset\mathbb{R}^n$. Then U is isomorphic to the symplectic annulus

$$W'=\mathbb{R}^{n-m}\times T^m\times V' \tag{19}$$

provided with the generalized action-angle coordinates

$$(x^1,\ldots,x^{n-m},\phi^{n-m+1},\ldots,\phi^n,I_1,\ldots,I_n) \tag{20}$$

such that the symplectic form on W' reads

$$\Omega_Z=\mathrm{d}I_a\wedge\mathrm{d}x^a+\mathrm{d}I_k\wedge\mathrm{d}\phi^k,$$

and the first integrals F_λ depend only on the action coordinates (I_α).

Proof: In accordance with the well-known theorem,[5,21] the invariant manifold M is diffeomorphic to the product $\mathbb{R}^{n-m}\times T^m$, provided with coordinates $(y^\lambda)=(s^a,\varphi^i)$, where φ^i are linear functions of parameters s^λ along the integral curves of Hamiltonian vector fields of first integrals F_λ on M. Let (J_λ) be coordinates on V' which are values of first integrals F_λ. Since $W'\to V'$ is a trivial bundle, (y^λ,J_λ) are bundle coordinates on the annulus W' (19). It should be emphasized that, since group parameters are given up to a shift, the coordinates y^λ on W' are determined up to a shift by functions of coordinates J_λ. Written relative to these coordinates, the symplectic form Ω_Z on W' reads

$$\Omega_Z=\Omega^{\alpha\beta}\mathrm{d}J_\alpha\wedge\mathrm{d}J_\beta+\Omega^\alpha_\beta\mathrm{d}J_\alpha\wedge\mathrm{d}y^\beta. \tag{21}$$

By the definition of coordinates (y^λ), the Hamiltonian vector fields ϑ_λ of first integrals take the coordinate form $\vartheta_\lambda=\vartheta^\alpha_\lambda(J_\mu)\partial_\alpha$ where

$$\vartheta_a=\partial_a+\vartheta^i_a(J_\lambda)\partial_i,\quad \vartheta_i=\vartheta^k_i(J_\lambda)\partial_k, \tag{22}$$

and they obey the relations

$$\vartheta_\lambda\rfloor\Omega_Z=-\mathrm{d}J_\lambda,\quad \Omega^\alpha_\beta\vartheta^\beta_\lambda=\delta^\alpha_\lambda. \tag{23}$$

It follows that Ω^α_β is a nondegenerate matrix and $\vartheta^\alpha_\lambda=(\Omega^{-1})^\alpha_\lambda$, i.e., the matrix functions Ω^α_β depend only on coordinates J_λ. In Appendix A, we obtain the desired coordinates

$$x^a=s^a,\quad \phi^a(s^b,\varphi^i,J_\lambda),\quad I_a=J_a,\quad I_i(J_k). \tag{24}$$

Note that, if M is a compact invariant manifold, the conditions of Proposition 2 always hold.[6]

Of course, the generalized action-angle coordinates (20) by no means are unique. For instance, let $\mathcal{F}_a$, $a=1,\ldots,n-m$ be an arbitrary smooth function on $\mathbb{R}^m$. Let us consider the canonical coordinate transformation

$$x'^a=x^a,\quad \phi'^i=\phi^i+x^a\partial^i\mathcal{F}_a(I_j),\quad I'_a=I_a-\mathcal{F}_a(I_j),\quad I'_k=I_k. \tag{25}$$

Then (x'^a,ϕ'^k,I'_a,I'_k) also generalized action-angle coordinates on the symplectic annulus which differs from W' (19) in another trivialization.

Now, we apply Proposition 2 to the CISs in Proposition 1.

Proposition 3: Let N be a connected regular invariant manifold of a time-dependent CIS $(V^*Q,H;F_k)$, and let the image N_0 of its projection ξ (18) be compact. Then the invariant manifold $h(N)$ of the autonomous CIS $(T^*Q;\mathcal{H}^*,\zeta^*F_k)$ has an open neighborhood U obeying the condition of Proposition 2.

The proof is in Appendix B. In accordance with Proposition 2, the open neighborhood U of the invariant manifold $h(N)$ in Proposition 3 is isomorphic to the symplectic annulus

$$W'=\mathbb{R}\times T^m\times V', \tag{26}$$

provided with the generalized action-angle coordinates $(t,\phi^1,\ldots,\phi^m,I_0,\ldots,I_m)$ such that the symplectic form on W' reads

$$\Omega'=\mathrm{d}I_0\wedge\mathrm{d}t+\mathrm{d}I_k\wedge\mathrm{d}\phi^k.$$

A glance at the Hamiltonian vector field $\vartheta_0=\gamma_T$ (17) and relations (23) and (24) shows that $I_0=J_0=\mathcal{H}^*$ and the corresponding generalized angle coordinate is $x^0=t$, while the first integrals $J_k=\zeta^*F_k$ depend only on the action coordinates I_i.

Since the action coordinates I_i are independent of the coordinate J_0, the symplectic annulus W' (26) inherits the fibration (10) which reads

$$\zeta: W'\ni(t,\phi^i,I_0,I_i)\to(t,\phi^i,I_i)\in W=\mathbb{R}\times T^m\times V.$$

By the relation similar to (11), the product W is provided with the Poisson structure

$$\{f,f'\}_W=\partial^i f\partial_i f'-\partial_i f\partial^i f',\quad f,f'\in C^\infty(W). \tag{27}$$

Therefore, one can regard W with coordinates (t,ϕ^i,I_i) as the momentum phase space of the time-dependent CIS in question around its invariant manifold N.

It is readily observed that the Hamiltonian vector field γ_T of the autonomous Hamiltonian $\mathcal{H}^*=I_0$ is $\gamma_T=\partial_t$, and so is its projection γ_H (14) on W. Consequently, the Hamilton equation (15) with respect to the action-angle coordinates takes the form $\dot I_i=0$, $\dot\phi^i=0$. Hence, (t,ϕ^i,I_i) are the initial date coordinates. One can introduce such coordinates as follows. Given the fibration ξ (18), let us provide $N_0\times V\subset V_0^*Q$ in Proposition 3 with action-angle coordinates $(\overline{\phi^i},\overline{I_i})$ for the CIS $\{i_0^*F_k\}$ on the symplectic leaf V_0^*Q. Then, it is readily observed that $(t,\overline{\phi^i},\overline{I_i})$ are time-dependent action-angle coordinates on W (1) such that the Hamiltonian $\mathcal{H}(\overline{I_j})$ of a time-dependent CIS relative to these coordinates vanishes, i.e., $\mathcal{H}^*=\overline{I_0}$. Using the canonical transformations (25), one can consider time-dependent action-angle coordinates besides the initial date ones. Given a smooth function $\mathcal{H}$ on $\mathbb{R}^m$, let us further provide W with the action-angle coordinates

$$\phi^i=\overline{\phi^i}+t\partial^i\mathcal{H}(\overline{I_j}),\quad I_0=\overline{I_0}-\mathcal{H}(\overline{I_j}),\quad I_i=\overline{I_i}$$

such that $\mathcal{H}(I_i)$ is the Hamiltonian.

Thus, action-angle coordinates for a time-dependent CIS provide a particular solution of the problem of a representation of its Hamiltonian in terms of first integrals.[22,23] However, this representation need not hold with respect to the initial bundle coordinates on V^*Q because a Hamiltonian fails to be a scalar under time-dependent transformations.

IV. QUANTUM COMPLETELY INTEGRABLE SYSTEMS

In order to quantize a time-dependent CIS on the Poisson manifold $(W,\{,\}_W)$, one may follow the general procedure of instantwise geometric quantization of time-dependent Hamiltonian sys-

tems in Ref. 24. As was mentioned previously, it however can be quantized as an autonomous CIS on the symplectic annulus (P,Ω_P) (3) with respect to fixed time-dependent action-angle coordinates.

In accordance with the standard geometric quantization procedure,[7,8] since the symplectic form Ω_P (4) is exact, the prequantum bundle is defined as a trivial complex line bundle C over P. Since the action-angle coordinates are canonical for the symplectic form (4), the prequantum bundle C needs no metaplectic correction. Let its trivialization

$$C\cong P\times\mathbb{C} \tag{28}$$

hold fixed. Any other trivialization leads to equivalent quantization of P. Given the associated bundle coordinates (ϕ^k,I_k,c), $c\in\mathbb{C}$, on C (28), one can treat its sections as smooth complex functions on P.

The Konstant–Souriau prequantization formula associates to each smooth real function $f\in C^\infty(P)$ on P the first-order differential operator

$$\hat{f}=-i\nabla_{\vartheta_f}+f \tag{29}$$

on sections of C, where $\vartheta_f=\partial^k f\partial_k-\partial_k f\partial^k$ is the Hamiltonian vector field of f and ∇ is the covariant differential with respect to a suitable $U(1)$-principal connection on C. This connection preserves the Hermitian metric $g(c,c')=c\overline{c'}$ on C, and its curvature form obeys the prequantization condition $R=i\Omega_P$. It reads

$$A=A_0+icI_k d\phi^k\otimes\partial_c, \tag{30}$$

where A_0 is a flat $U(1)$-principal connection on $C\to P$. The equivalence classes of flat principal connections on C are indexed by the set $\mathbb{R}^m/\mathbb{Z}^m$ of homomorphisms of the de Rham cohomology group

$$H^1(P)=H^1(T^m)=\mathbb{R}^m$$

of P to the cycle group $U(1)$.[9] We choose their representatives of the form

$$A_0[(\lambda_k)]=\mathrm{d}I_k\otimes\partial^k+\mathrm{d}\phi^k\otimes(\partial_k+i\lambda_k c\partial_c),\quad \lambda_k\in[0,1).$$

Then the connection (30) up to gauge transformations reads

$$A[(\lambda_k)]=\mathrm{d}I_k\otimes\partial^k+\mathrm{d}\phi^k\otimes(\partial_k+i(I_k+\lambda_k)c\partial_c). \tag{31}$$

For the sake of simplicity, we will assume that the numbers λ_k in expression (31) belong to $\mathbb{R}$, but will bear in mind that connections $A[(\lambda_k)]$ and $A[(\lambda'_k)]$ with $\lambda_k-\lambda'_k\in\mathbb{Z}$ are gauge conjugated. Given a connection (31), the prequantization operators (29) read

$$\hat{f}=-i\vartheta_f+(f-(I_k+\lambda_k)\partial^k f). \tag{32}$$

Let us choose the above-mentioned angle polarization $V\pi$ which is the vertical tangent bundle of the fibration $\pi:P\to T^m$, and is spanned by the vectors ∂^k. It is readily observed that the corresponding quantum algebra $\mathcal{A}\subset C^\infty(P)$ consists of affine functions

$$f=a^k(\phi^j)I_k+b(\phi^j) \tag{33}$$

of action coordinates I_k. The carrier space of its representation by operators (32) is defined as the space E of sections ρ of the prequantum bundle C of compact support which obey the condition $\nabla_\vartheta\rho=0$ for any Hamiltonian vector field ϑ subordinate to the distribution $V\pi$. This condition reads

$$\partial_k f \partial^k \rho = 0, \quad \forall f \in C^\infty(T^m).$$

It follows that elements of E are independent of action variables and, consequently, fail to be of compact support, unless $\rho = 0$. This well-known problem of Schrödinger geometric quantization is solved as follows:[24,25]

Fix a slice $i_T : T^m \to T^m \times V$. Let $C_T = i_T^* C$ be the pull-back of the prequantum bundle C (28) over the torus T^m. It is a trivial complex line bundle $C_T = T^m \times \mathbb{C}$ provided with the pull-back Hermitian metric $g(c,c') = c\overline{c'}$. Its sections are smooth complex functions on T^m. Let

$$\overline{A} = i_T^* A = \mathrm{d}\phi^k \otimes (\partial_k + i(I_k + \lambda_k) c \partial_c)$$

be the pull-back of the connection A (31) onto C_T. Let $\mathcal{D}$ be a metalinear bundle of complex half-forms on the torus T^m. It admits the canonical lift of any vector field τ on T^m, and the corresponding Lie derivative of its sections reads

$$\mathbf{L}_\tau = \tau^k \partial_k + \tfrac{1}{2} \partial_k \tau^k.$$

Let us consider the tensor product

$$Y = C_T \otimes \mathcal{D} \to T^m. \tag{34}$$

Since the Hamiltonian vector fields

$$\vartheta_f = a^k \partial_k - (I_r \partial_k a^r + \partial_k b) \partial^k$$

of functions f (33) are projectable onto T^m, one can associate to each element f of the quantum algebra $\mathcal{A}$ the first-order differential operator

$$\hat{f} = (-i\overline{\nabla}_{\pi\vartheta_f} + f) \otimes \mathrm{Id} + \mathrm{Id} \otimes \mathbf{L}_{\pi\vartheta_f} = -ia^k \partial_k - \frac{i}{2} \partial_k a^k - a^k \lambda_k + b \tag{35}$$

on sections of Y. A direct computation shows that the operators (35) obey the Dirac condition

$$[\hat{f}, \hat{f}'] = -i\widehat{\{f, f'\}}.$$

Sections ρ_T of the quantum bundle $Y \to T^m$ (34) constitute a pre-Hilbert space E_T with respect to the nondegenerate Hermitian form

$$\langle \rho_T | \rho_T' \rangle = \left(\frac{1}{2\pi} \right)^m \int_{T^m} \rho_T \overline{\rho_T'}, \quad \rho_T, \rho_T' \in E_T.$$

Then it is readily observed that $\hat{f}$ (35) are Hermitian operators in E_T. In particular, the action operators take the form (5).

Of course, the above-noted quantization depends on the choice of a connection $A[(\lambda_k)]$ (31) and a metalinear bundle $\mathcal{D}$. The latter need not be trivial. If $\mathcal{D}$ is trivial, sections of the quantum bundle $Y \to T^m$ (34) obey the transformation rule

$$\rho_T(\phi^k + 2\pi) = \rho_T(\phi^k)$$

for all indices k. They are naturally complex smooth functions on T^m. In this case, E_T is the above-mentioned pre-Hilbert space $\mathcal{C}^\infty(T^m)$ of complex smooth functions on T^m whose basis consists of functions (6). The action operators $\hat{I}$ (5) with respect to this basis are represented by countable diagonal matrices (7), while functions $a(\phi)$ are decomposed into the pull-back functions $\psi_{(n_r)}$ which act on $\mathbb{C}^\infty(T^m)$ by multiplications

$$\psi_{(n_r)}\psi_{(n'_r)}=\psi_{(n_r)}\psi_{(n'_r)}=\psi_{(n_r+n'_r)}. \tag{36}$$

If $\mathcal{D}$ is a nontrivial metalinear bundle, sections of the quantum bundle $Y\to T^m$ (34) obey the transformation rule

$$\rho_T(\phi^j+2\pi)=-\rho_T(\phi^j) \tag{37}$$

for some indices j. In this case, the orthonormal basis of the pre-Hilbert space E_T can be represented by double-valued complex functions

$$\psi_{(n_i,n_j)}=\exp[i(n_i\phi^i+(n_j+\tfrac{1}{2})\phi^j)] \tag{38}$$

on T^m. They are eigenvectors

$$\hat{I}_i\psi_{(n_i,n_j)}=(n_i-\lambda_i)\psi_{(n_i,n_j)}, \quad \hat{I}_j\psi_{(n_i,n_j)}=(n_j-\lambda_j+\tfrac{1}{2})\psi_{(n_i,n_j)}$$

of the operators $\hat{I}_k$ (5), and the functions $a(\phi)$ act on the basis (38) by the above-given law (36). It follows that the representation of $\mathcal{A}$ determined by the connection $A[(\lambda_k)]$ (31) in the space of sections (37) of a nontrivial quantum bundle Y (34) is equivalent to its representation determined by the connection $A[(\lambda_i,\lambda_j-\frac{1}{2})]$ in the space $\mathbb{C}^\infty(T^m)$ of smooth complex functions on T^m.

Therefore, one can restrict the study of representations of the quantum algebra $\mathcal{A}$ to its representations in $\mathbb{C}^\infty(\mathbb{T}^m)$ associated to different connections (31). These representations are nonequivalent, unless $\lambda_k-\lambda'_k\in\mathbb{Z}$ for all indices k.

Now, in order to quantize the Poisson manifold $(W,\{,\}_W)$, one can simply replace functions on T^m with those on $\mathbb{R}\times T^m$.[7,24] Let us choose the angle polarization of W spanned by the vectors ∂^k. The corresponding quantum algebra $\mathcal{A}_W\subset C^\infty(W)$ consists of affine functions

$$f=a^k(t,\phi^j)I_k+b(t,\phi^j) \tag{39}$$

of action coordinates I_k, represented by the operators (35) in the space $\mathbb{C}^\infty(\mathbb{R}\times T^m)$ of smooth complex functions on $\mathbb{R}\times T^m$. This space is provided with the structure of the pre-Hilbert $\mathbb{C}^\infty(\mathbb{R})$-module with respect to the nondegenerate $\mathbb{C}^\infty(\mathbb{R})$-bilinear form

$$\langle\psi|\psi'\rangle=\left(\frac{1}{2\pi}\right)^m\int_{T^m}\psi\overline{\psi'}, \quad \psi,\psi'\in\mathbb{C}^\infty(\mathbb{R}\times T^m).$$

Its basis consists of the pull-backs onto $\mathbb{R}\times T^m$ of the functions $\psi_{(n_r)}$ (6).

Since the Poisson structure (27) defines no dynamics on the momentum phase space W (1), we should quantize the homogeneous momentum phase space W' (26) in order to describe evolution of a quantum time-dependent CIS. Following the general scheme in Refs. 25 and 26, one can provide the relevant geometric quantization of the symplectic annulus (W',Ω'). The corresponding quantum algebra $\mathcal{A}_{W'}\subset C^\infty(W')$ consists of affine functions

$$f=a^\lambda(t,\phi^j)I_\lambda+b(t,\phi^j)$$

of action coordinates I_λ. It suffices to consider its subalgebra consisting of the elements f and I_0+f for all $f\in\mathcal{A}_W$ (39). They are represented by the operators $\hat{f}$ (35) and $I_0=-i\partial_t$ in the pre-Hilbert module $\mathbb{C}^\infty(\mathbb{R}\times T^m)$. If a Hamiltonian $\mathcal{H}(I_j)$ of the time-dependent CIS is a polynomial (or analytic) function in action variables, the Hamiltonian $\mathcal{H}^*$ of the associated autonomous CIS is quantized as

$$\hat{\mathcal{H}}^*=-i\partial_t+\mathcal{H}(\hat{I}_j).$$

Then we obtain the Schrödinger equation

$$\hat{\mathcal{H}}^*\psi = -i\partial_t\psi + \mathcal{H}(-i\partial_k - \lambda_k)\psi = 0, \quad \psi \in \mathbf{C}^\infty(\mathbb{R}\times T^m).$$

Its solutions are the series

$$\psi = \sum_{(n_r)} B_{(n_r)} \exp[-iE_{(n_r)}t]\psi_{(n_r)}, \quad B_{(n_r)} \in \mathbb{C},$$

where $E_{(n_r)}$ are the eigenvalues (8) of the Hamiltonian $\hat{\mathcal{H}}$.

In conclusion, bearing in mind applications to holonomic quantum computation, let us choose action-angle coordinates such that a Hamiltonian $\mathcal{H}$ of a CIS is independent of action variables I_a $(a,b,c=1,\ldots,l)$. Then its eigenvalues are countably degenerate. Let us consider the perturbed Hamiltonian

$$\mathcal{H}' = \Delta(s^\mu, \phi^b, I_a) + \mathcal{H}(I_j),$$

where the perturbation term Δ depends on the action-angle coordinates with the above-mentioned indices $a,b,c,\ldots$ and on some time-dependent parameters $s^\mu(t)$ by the law

$$\Delta = \Lambda^a_\beta(s^\mu, \phi^b)\partial_t s^\beta I_a. \tag{40}$$

The Hamiltonian $\mathcal{H}'$ characterizes a CIS with time-dependent parameters.[20,26,27] Being affine in action variables, the perturbation term Δ (40) is represented by the operator

$$\hat{\Delta} = -\left(i\Lambda^a_\beta\partial_a + \frac{i}{2}\partial_a\Lambda^a_\beta + \lambda_a\Lambda^a_\beta\right)\partial_t s^\beta.$$

Since the operators $\hat{\Delta}$ and $\hat{\mathcal{H}}$ mutually commute, the total quantum evolution operator falls into the product

$$T\exp\left[-i\int_0^t \hat{\mathcal{H}}'\,dt'\right] = T\exp\left[-i\int_0^t \hat{\mathcal{H}}\,dt'\right]\circ T\exp\left[-i\int_0^t \hat{\Delta}\,dt'\right].$$

The first factor in this product is the dynamic evolution operator of the quantum CIS. The second one acts in the eigenspaces of the dynamic Hamiltonian $\hat{\mathcal{H}}$ and reads

$$T\exp\left[\int_0^t \{-\Lambda^a_\beta(\phi^b, s^\mu(t'))\partial_a - \tfrac{1}{2}\partial_a\Lambda^a_\beta(\phi^b, s^\mu(t')) + i\lambda_a\Lambda^a_\beta(\phi^b, s^\mu(t'))\}\partial_t s^\beta\,dt'\right]$$
$$= T\exp\left[\int_{s([0,t])} \{-\Lambda^a_\beta(\phi^b, \sigma^\mu)\partial_a - \tfrac{1}{2}\partial_a\Lambda^a_\beta(\phi^b, \sigma^\mu) + i\lambda_a\Lambda^a_\beta(\phi^b, \sigma^\mu)\}d\sigma^\beta\right]. \tag{41}$$

It is readily observed that this operator depends on the curve $s([0,1])\subset S$ in the parameter space S. One can treat it as an operator of parallel displacement along the curve s.[26–28] For instance, if $s([0,1])$ is a loop in S, the operator (41) is the geometric Berry factor, and it can be treated as a holonomy control operator.[26,29]

APPENDIX A

In order to complete the proof of Proposition 2, let us first apply relation (23) to the Hamiltonian vector fields ϑ_a and ϑ_i (22). We obtain

$$\Omega^a_b = \delta^a_b, \quad \vartheta^\lambda_a\Omega^i_\lambda = 0, \tag{A1}$$

$$\vartheta^k_i\Omega^j_k = \delta^j_i, \quad \vartheta^k_i\Omega^a_k = 0. \tag{A2}$$

The first of the equalities (A2) shows that the matrix Ω^j_k is nondegenerate, and so is ϑ^k_i. Then the second one results in $\Omega^a_k=0$.

Using the well-known Künneth formula for the de Rham cohomology of a product, one can easily justify that the closed form Ω_Z on W' (19) is exact. Moreover, $\Omega_Z=\mathrm{d}\Xi$ where Ξ takes the form

$$\Xi=\Xi^\alpha(J_\lambda,y^\lambda)\mathrm{d}J_\alpha+\Xi_i(J_\lambda)\mathrm{d}\varphi^i.$$

Of course, Ξ is determined up to an exact form. Using the fact that components of $\mathrm{d}\Xi=\Omega_Z$ are independent of y^λ and obey equalities (A1) and (A2), we obtain the following.

(i) $\Omega^a_i=-\partial_i\Xi^a+\partial^a\Xi_i=0$. It follows that $\partial_i\Xi^a$ is independent of φ, i.e., Ξ^a is affine in φ and, consequently, is independent of φ since φ is a cyclic coordinate. Hence, $\partial^a\Xi_i=0$, i.e., Ξ_i is a function only of coordinates J_j.

(ii) $\Omega^k_i=-\partial_i\Xi^k+\partial^k\Xi_i$. Similarly, one shows that Ξ^k is independent of φ and $\Omega^k_i=\partial^k\Xi_i$, i.e., $\partial^k\Xi_i$ is a nondegenerate matrix.

(iii) $\Omega^a_b=-\partial_b\Xi^a=\delta^a_b$. Hence, $\Xi^a=D^a(J_\lambda)+s^a$.

(iv) $\Omega^i_b=-\partial_b\Xi^i$, i.e., Ξ^i is affine in s^a.

In view of items (i)–(iv), the Liouville form Ξ reads

$$\Xi=x^a\,\mathrm{d}J_a+[D^i(J_\lambda)+B^i_a(J_\lambda)s^a]\mathrm{d}J_i+\Xi_i(J_j)\mathrm{d}\varphi^i,$$

where $x^a=s^a+D^a(J_\lambda)$. Since the matrix $\partial^k\Xi_i$ is nondegenerate, one can introduce new coordinates $I_i=\Xi_i(J_j)$, $I_a=J_a$. We obtain

$$\Xi=x^a\,\mathrm{d}I_a+[D'^i(I_\lambda)+B'^i_a(I_\lambda)s^a]\mathrm{d}I_i+I_i\mathrm{d}\varphi^i.$$

Finally, put

$$\phi^i=\varphi^i-[D'^i(I_\lambda)+B'^i_a(I_\lambda)s^a]$$

in order to obtain the desired coordinates (24).

APPENDIX B

In order to prove Proposition 3, we first show that functions $i_0^*F_k$ make up a CIS on the symplectic leaf (V_0^*Q,Ω_0) and N_0 is its invariant manifold without critical points. Clearly, the functions $i_0^*F_k$ are in involution, and N_0 is their connected invariant manifold. Let us show that the set of critical points of $\{i_0^*F_k\}$ is nowhere dense in V_0^*Q and N_0 has none of these points. Let V_0^*Q be equipped with some coordinates $(\overline{q}^k,\overline{p}_k)$. Then the trivial bundle ξ (18) is provided with the bundle coordinates $(t,\overline{q}^k,\overline{p}_k)$ which play a role of the initial date coordinates on the momentum phase space V^*Q. Written with respect to these coordinates, the first integrals F_k become time-independent. It follows that

$$\mathrm{d}F_k(y)=\mathrm{d}i_0^*F_k(\xi(y)) \tag{B1}$$

for any point $y\in V^*Q$. In particular, if $y_0\in V_0^*Q$ is a critical point of $\{i_0^*F_k\}$, then the trajectory $\xi^{-1}(y_0)$ is a critical set for the first integrals $\{F_k\}$. The desired statement at once follows from this result.

Since N_0 is compact and regular, there is an open neighborhood of N_0 in V_0^*Q isomorphic to $N_0\times V$ where $V\subset\mathbb{R}^m$ is a domain, and $N_0\times\{v\}$, $v\in V$, are also invariant manifolds in V_0^*Q.[6] Then

$$W''=\xi^{-1}(N_0\times V)\cong N\times V \tag{B2}$$

is an open neighborhood in V^*Q of the invariant manifold N foliated by invariant manifolds $\xi^{-1}(N_0\times\{v\})$, $v\in V$, of the time-dependent CIS on V^*Q. By virtue of the equality (B1), the first integrals $\{F_k\}$ have no critical points in W''. For any real number $r\in(-\varepsilon,\varepsilon)$, let us consider a section

$$h_r: V^*Q\to T^*Q, \quad p_0\circ h_r=-\mathcal{H}(t,q^j,p_j)+r,$$

of the affine bundle ζ (10). Then the images $h_r(W'')$ of W'' (B2) make up an open neighborhood U of $h(N)$ in T^*Q. Because $\zeta(U)=W''$, the pull-backs ζ^*F_k of first integrals F_k are free from critical points in U, and so is the function $\mathcal{H}^*$ (16). Since the coordinate $r=p_0-h$ provides a trivialization of the affine bundle ζ, the open neighborhood U of $h(N)$ is diffeomorphic to the product

$$h(W'')\times(-\varepsilon,\varepsilon)\cong h(N)\times V\times(-\varepsilon,\varepsilon),$$

which is a trivialization of the fibration

$$\mathcal{H}^*\times(\times\zeta^*F_k): U\to V\times(-\varepsilon,\varepsilon).$$

It remains to prove that the Hamiltonian vector fields of $\mathcal{H}^*$ and ζ^*F_k on U are complete. It is readily observed that the Hamiltonian vector field γ_T (17) of $\mathcal{H}^*$ is tangent to the manifolds $h_r(W'')$, and is the image $\gamma_T=Th_r\circ\gamma_H\circ\zeta$ of the vector field γ_H (14). The latter is complete on W'', and so is γ_T on U. Similarly, the Hamiltonian vector field

$$\gamma_k=-\partial_t F_k\partial^0+\partial^i F_k\partial_i-\partial_i F_k\partial^i$$

of the function ζ^*F_k on T^*Q with respect to the Poisson bracket $\{,\}_T$ (9) is tangent to the manifolds $h_r(W'')$, and is the image $\gamma_k=Th_r\circ\vartheta_k\circ\zeta$ of the Hamiltonian vector field ϑ_k of the first integral F_k on W'' with respect to the Poisson bracket $\{,\}_V$ (12). The vector fields ϑ_k on W'' are vertical relative to the fibration $W''\to\mathbb{R}$, and are tangent to compact manifolds. Therefore, they are complete, and so are the vector fields γ_k on U. Thus, U is the desired open neighborhood of the invariant manifold $h(N)$.

(Received 4 December 2001; accepted for publication 7 May 2002)

A family of solutions of the Lorentz–Dirac equation is constructed. It consists in the motion of two charges e_1 and e_2 of masses m_1 and m_2 in two coplanar and concentric circles of radii a and b. The charges rotate with constant angular velocity, and have an angular separation ψ. The radiation reaction forces and the retarded interactions between the charges are taken into account. The external electromagnetic field that allows the motion consists of a tangential time-independent electric field that takes a fixed value on each orbit, and a homogeneous time-independent magnetic field perpendicular to the plane of the motion. For all the solutions energy conservation is rigorously demonstrated by evaluating the energy radiated, with independence of the equation of motion, through the calculation of the instantaneous energy flux across a sphere of an infinitely large radius. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1500792]

I. INTRODUCTION

Classical electrodynamics is one of the most fundamental and successful frameworks of physics. However, one of its most fundamental aspects, namely, the equation of motion of a point charge that takes into account the effect of radiation reaction, still remains in an unsatisfactory state. The equation of motion, derived by Dirac[1] in 1938 and known as the Lorentz–Dirac equation, has been objected because it presents some inconsistencies such as runaway solutions and violation of causality.

Although electromagnetic phenomena are properly described by quantum theory, classical electrodynamics is of interest not only because of its wide range of applicability and the large variety of physical phenomena it successfully describes, but also because both theories have common basic problems, not completely understood yet, as for instance the electron mass renormalization. The mass renormalization procedure was introduced by Dirac[1] in his derivation of the equation of motion in order to deal with the infinite self-energy associated to the electromagnetic field of a point electron. In spite of the fact that the derivation of the Lorentz–Dirac equation is based on the conservation equation of the energy-momentum tensor, the manipulation of the infinite self-energy of the electron makes obscure the conservation of the energy in the equation of motion. The existence of runaway solutions, where the electron accelerates even in the absence of an external field, is a clear illustration of this aspect.

The energy radiated away by a system of charges plays a fundamental role in the study of the consistency of the equation of motion with the energy conservation law. This problem is completely solved, in the case of only one charge, by Rohrlich's radiation criterion,[2] since with its help it is easy to identify the term in the Lorentz–Dirac equation that describes the radiation that escapes to infinity. Unfortunately, in the case of more than one charge it is in general impossible, mainly due to the complications introduced by the retarded effects, to identify the rate of radiation that escapes to infinity starting from the equations of motion of the charges. In this context let us

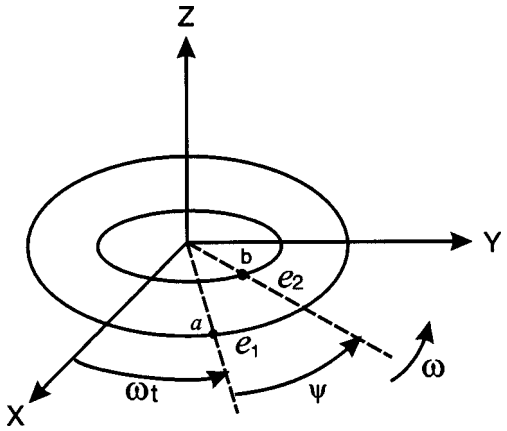

FIG. 1. The positions at time t of charges e_1 and e_2 moving with constant angular velocity ω in concentric circles of radius a and b, respectively.

recall that in Dirac's derivation of the equations of motion the retarded field includes both the near and the far fields, whereas the energy radiated that escapes to infinity is determined exclusively by the far fields. Therefore the connection between these two ways of describing the radiation is by no means immediate, a point that was first emphasized by Comay.[3]

The construction of exact solutions of the equation of motion for more than one charge is of interest both from a mathematical and from a physical point of view. In fact, the equations of motion for several charges have a rich mathematical structure, since they constitute a set of nonlinear third order differential equations that are coupled by means of the retarded interactions between the different charges. On the other hand, the construction of exact solutions constitutes a powerful tool in order to clarify the description of the radiation by the equations of motion and the consistence of them with the conservation of the energy.

Recently, the first exact solution of the Lorentz–Dirac equation for more than one charge[4] was constructed. It corresponds to the motion of two identical charges that rotate at constant angular velocity at opposite ends of a diameter. The external fields that make possible this motion consist of a static homogeneous magnetic field perpendicular to the plane of the motion and a time-independent electric field of fixed magnitude over the orbit and tangent to it. In this case it was demonstrated that the Lorentz–Dirac equation satisfies energy conservation, since the energy supplied by the external electric field to the two charges turns out to be exactly equal to the energy that escapes to infinity. In this article a family of solutions of the Lorentz–Dirac equations with the same external fields is constructed in the case of two electrical charges e_1 and e_2 of masses m_1 and m_2 that move in a plane in two concentric circumferences of radii a and b with constant angular velocity, and where the angular separation of charge e_2 with respect to charge e_1 is ψ, as shown in Fig. 1. The Lorentz–Dirac equation imposes, of course, restrictions in the values of the different parameters that make possible the motion, that is, the charges, masses, radii, angular velocity and angular separation ψ; but in general continuous ranges are admissible for the variation of those parameters. The exact solution of Ref. 4 constitutes a very special case within the family of solutions that we present in this article.

The simple mathematical structure of the external fields plays a determinant role in the construction of the analytical solution of the Lorentz–Dirac equation given below. However, in order to obtain an external field that is an exact analytical solution of Maxwell's equations and that also has a simple mathematical structure it is necessary to use idealized sources. The case of a flat, unbounded sheet in which a current flows with constant density and direction everywhere, and which gives rise to an homogeneous magnetic field, is a well-known example.[5] Our source for the electric field is also an idealized one, and consists of an infinitely long solenoid fed with a density of current that increases linearly with time. Of course, from a practical point of view, an idealized source like this can be implemented only in an approximate way; but this work is focused on the

study of the solutions of the Lorentz–Dirac equation from a fundamental point of view, and practical or experimental aspects are out of the scope of this article.

The radiation that escapes to infinity is studied independently of the equation of motion, by calculating explicitly the energy flux across the surface of a sphere of infinite radius that encloses the charges' orbit. The result splits into the Larmor formulas for the radiation rate of each charge and an interference rate of radiation that mixes the fields of the particles. The calculation is somewhat elaborate due to the complications that the retardation condition introduces. Fortunately, the equation that defines the retarded times is formally equal to the one that appears in Kepler's problem, and therefore the formalism developed by Bessel and Watson for Kepler's problem can be applied here. This technique conducts to a Fourier series in angle ψ for the interference rate of radiation, series that turns out to be identical to the one that is obtained from the solution of the Lorentz–Dirac equation, where the fields appear evaluated not at infinity, but at the retarded positions of the charges.

The family of solutions found here expands considerably the set of solutions of the Lorentz–Dirac equation and corroborates its consistency with the basic principle of energy conservation.

II. THE SOLUTIONS

Figure 1 shows the motion under consideration, which consists in charges e_1 and e_2 moving in the x-y plane with constant angular velocity ω in concentric circular orbits of radii a and b, respectively. The angular separation of charge e_2 with respect to e_1, measured in the direction of the motion, is denoted by ψ. The charges move in the electric field generated by an infinitely long solenoid whose axis is the z-axis and whose radius is $\rho_0<b$. The current density that flows around the solenoid is given, for any time t, by

$$\mathbf{J}=-\alpha t\,\delta(\rho-\rho_0)\,\hat{\boldsymbol{\varphi}}, \tag{1}$$

where α is a positive number, δ is the usual Dirac delta function, ρ is the radial cylindrical coordinate and $\hat{\boldsymbol{\varphi}}$ is the unit vector associated with the cylindrical coordinate φ. The current density (1), together with a charge density that vanishes everywhere, gives rise to the following electric and magnetic fields, expressed in terms of their Cartesian coordinates:

$$\begin{aligned} E_x&=-(2\pi\alpha\rho_0^2/c^2)\,\frac{y}{x^2+y^2},\\ E_y&=+(2\pi\alpha\rho_0^2/c^2)\,\frac{x}{x^2+y^2},\\ E_z&=0,\\ B_x&=B_y=B_z=0 \end{aligned} \tag{2}$$

outside the solenoid, and

$$\begin{aligned} E_x&=-(2\pi\alpha/c^2)y,\\ E_y&=+(2\pi\alpha/c^2)x,\\ E_z&=0,\\ B_x&=B_y=0,\quad B_z=-4\pi\alpha t/c \end{aligned} \tag{3}$$

inside it. The fields (2) and (3) satisfy the source-free Maxwell equations, and since they also satisfy the corresponding boundary conditions at the solenoid's surface, they are indeed an exact solution of Maxwell's equations. We will need these fields only in the region $\rho>\rho_0$, where their values in cylindrical coordinates are given by

$$\mathbf{E}=\frac{2\pi\alpha\rho_0^2}{c^2}\,\frac{1}{\rho}\,\hat{\boldsymbol{\varphi}}, \tag{4}$$

$$\mathbf{B}=0. \tag{5}$$

The magnitude of the electric field (4) can be adjusted by choosing an appropriate value of the parameter α. In order for the motion of Fig. 1 to be a solution of the Lorentz–Dirac equation, an external homogeneous time-independent magnetic field $\mathbf{B}^{\text{ext}}$ will be also necessary.

The Lorentz–Dirac equation for particle 1 is

$$m_1 a_1^\mu=(e_1/c)F_{\text{ext}}^{\mu\alpha}v_{1\alpha}+(e_1/c)(F_{2\text{ret}}^{\mu\alpha})v_{1\alpha}+(2e_1^2/3c^3)(\dot{a}_1^\mu-(1/c^2)a_1^\lambda a_\lambda^1 v_1^\mu), \tag{6}$$

where v_1^μ and a_1^μ denote the four-velocity and four-acceleration of charge e_1, respectively, c is the velocity of light and $\dot{a}_1^\mu$ is the proper time derivative of a_1^μ. Greek indices range from 0 to 3 and the diagonal metric of Minkowski space is $(-1,+1,+1,+1)$. The equation for particle 2 can be obtained from Eq. (6) by interchanging the indices 1 and 2.

The tensor $F_{\text{ext}}^{\mu\alpha}$ in the first term of Eq. (6) contains the external fields in which particle 1 moves, and gives rise to the associated Lorentz-force term. In a similar way, the tensor $F_{2\text{ret}}^{\mu\alpha}$ contains the retarded fields exerted by particle 2 at the position of particle 1, and gives rise to the retarded Lorentz force. Finally, the last term in Eq. (6) arises from the self-field of the charge and is known as the Abraham four-vector. For the circular motion under consideration, it gives rise to a radiation reaction force that is tangential to the particle's orbit.

As it is usually done, we will study the solutions of Eq. (6) in a specific Lorentz frame, namely the ''laboratory frame,'' where the infinitely long solenoid is at rest. Because of the relativistic invariance of both the Maxwell equations and the Lorentz–Dirac equation, the solutions of Eq. (6) in any Lorentz frame can be obtained by simply carrying out the corresponding Lorentz transformation.

We will study solutions of the equations of motion for the external fields

$$\begin{aligned}\mathbf{E}^{\text{ext}}&=E_t^{\text{ext}}\hat{\boldsymbol{\varphi}}=\frac{D}{\rho}\hat{\boldsymbol{\varphi}},\\ \mathbf{B}^{\text{ext}}&=-B_{\text{ext}}\hat{\mathbf{z}}.\end{aligned} \tag{7}$$

The orientation of the coordinate axes will be chosen such that particle 1 is on the x-axis at $t=0$. Thus, the trajectory of particle 1 is given by $x_1=a\cos(\omega t)$, $y_1=a\sin(\omega t)$, $z_1=0$, and similar equations hold for the trajectory of particle 2. From these equations it follows that the components with $\mu=3$ of the equations of motion of both particles are identically satisfied by the external fields (7). On the other hand, the equations with $\mu=1$ and $\mu=2$ can be combined into one tangential and one radial equation for each particle. These equations can be simultaneously satisfied only for certain range of values of the parameters of the system. It is convenient to introduce the following ones:

$$\begin{aligned}\chi&=b/a<1,\\ \beta_1&=\omega a/c<1,\\ \beta_2&=\omega b/c=\chi\beta_1,\\ \lambda&=e_2/e_1,\\ \sigma&=m_2/m_1,\end{aligned} \tag{8}$$

which make it possible to obtain the orbit's radius, speed, charge and mass of particle 2 if the corresponding values of particle 1 are known.

The retarded fields that appear in the equations of motion can be computed by using the Liénard–Wiechert formula[6]

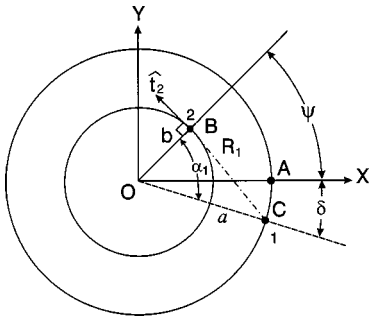

FIG. 2. The locations at time $t=0$ of charges e_1 (position A) and e_2 (position B) and the retarded position of charge e_1 (position C) associated to the actual position of charge e_2. We also show the retarded angle α_1, the retarded distance R_1, the tangential unit vector $\hat{\mathbf{t}}_2$ at the actual position of charge e_2 and the angle δ that particle 1 travels from its retarded time to the actual time.

$$\mathbf{E}(\mathbf{x},t)=e\left[\frac{(\hat{\mathbf{n}}-\boldsymbol{\beta})(1-\beta^2)}{\kappa^3R^2}\right]+\frac{e}{c}\left[\frac{\hat{\mathbf{n}}\times\{(\hat{\mathbf{n}}-\boldsymbol{\beta})\times\dot{\boldsymbol{\beta}}\}}{\kappa^3R}\right],$$
$$\mathbf{B}(\mathbf{x},t)=\hat{\mathbf{n}}\times\mathbf{E}(\mathbf{x},t), \tag{9}$$

where $\hat{\mathbf{n}}$ is the unit vector that points from the retarded position $\mathbf{r}(t')$ of the charge that produces the field to the point $\mathbf{x}$ where the field is being considered at time t; R is the distance from the retarded position of the charge to point $\mathbf{x}$, that is, $R=|\mathbf{x}-\mathbf{r}(t')|$; $\boldsymbol{\beta}$ and $\dot{\boldsymbol{\beta}}$ are defined by $(1/c)\times(d\mathbf{r}(t')/dt')$ and $d\boldsymbol{\beta}/dt'$, respectively, and are both evaluated at the retarded time t', which is implicitly defined by $t-t'=|\mathbf{x}-\mathbf{r}(t')|/c$; and κ is the positive number

$$\kappa=1-\boldsymbol{\beta}\cdot\hat{\mathbf{n}}. \tag{10}$$

In these formulas the observation point $\mathbf{x}$ will be the position at time t of one of the charges. Then, the retarded electromagnetic fields produced by particle k ($k=1,2$) result to be a function of the retarded angle α_k, which is defined as the angle between the retarded position of the particle that generates the field and the actual position of the particle that experiences the retarded force. The retarded angle is measured starting from the retarded position of particle k in the sense of motion in the case $k=1$, and opposite to the sense of motion in the case $k=2$. In Fig. 2 we show the actual position of particle 2 and the retarded position of particle 1. We also show the retarded distance R_1 between those positions, the tangential unit vector $\hat{\mathbf{t}}_2$ at the actual position of particle 2 and the angle δ that particle 1 travels from its retarded time to the laboratory time.

These quantities are related by

$$\alpha_1=\psi+\delta,$$
$$R_1=a\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}, \tag{11}$$

and therefore the retardation condition $R_1/c=\delta/\omega$ is

$$\alpha_1-\beta_1\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}=\psi. \tag{12}$$

By using Eq. (9) the following result for the tangential component of the retarded electric field exerted by particle 1 on particle 2 is obtained:

$$E_{12t}=\mathbf{E}_{12}\cdot\hat{\mathbf{t}}_2=\frac{e_1}{\kappa_1^3R_1^2}\left\{(1-\beta_1^2)\left(\frac{\sin\alpha_1}{\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}}-\beta_1\cos\alpha_1\right)+\beta_1^2(\cos\alpha_1-\chi)\right.$$
$$\left.\times\left(\frac{\chi\sin\alpha_1}{\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}}-\beta_1\right)\right\}, \tag{13}$$

where, according to Eq. (10), κ_1 is given by

$$\kappa_1=1-\frac{\beta_1\chi\sin\alpha_1}{\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}}. \tag{14}$$

In the same way, in the case of the field exerted by particle 2 on particle 1, we have

$$R_2=a\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}, \tag{15}$$

and angle α_2 satisfies now the retardation condition

$$\alpha_2+\beta_1\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}=\psi. \tag{16}$$

The factor κ_2 is given by

$$\kappa_2=1+\frac{\beta_2\sin\alpha_2}{\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}}, \tag{17}$$

and the tangential component of the retarded electric field exerted by particle 2 on particle 1 is

$$E_{21t}=\frac{e_2}{\kappa_2^3R_2^2}\left\{-(1-\beta_2^2)\left(\frac{\chi\sin\alpha_2}{\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}}+\beta_2\cos\alpha_2\right)+\frac{\beta_2^2}{\chi}(1-\chi\cos\alpha_2)\right.$$
$$\left.\times\left(\frac{\sin\alpha_2}{\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}}+\beta_2\right)\right\}. \tag{18}$$

The tangential equations of motion for particles 1 and 2 obtained from the Lorentz–Dirac equation are given by

$$\begin{aligned} e_1E_t^{\mathrm{ext}}(\rho=a)+e_1E_{21t}&=\frac{2e_1^2\beta_1^3\gamma_1^4}{3a^2},\\ e_2E_t^{\mathrm{ext}}(\rho=b)+e_2E_{12t}&=\frac{2e_2^2\beta_2^3\gamma_2^4}{3b^2}, \end{aligned} \tag{19}$$

where γ is the usual relativistic parameter $\gamma=(1-\beta^2)^{-1/2}$. These equations can be simultaneously solved for the constant D in the external electric field of Eq. (7) and for the parameter $\lambda=e_2/e_1$. The following results are obtained:

$$\lambda=\frac{2\beta_1^3\gamma_1^4/3+\chi(a^2/e_1)E_{12t}}{2\chi^2\beta_1^3\gamma_2^4/3+(a^2/e_2)E_{21t}}, \tag{20}$$

$$D=\rho E_t^{\mathrm{ext}}=\left(\frac{e_1}{a}\right)\left\{\frac{4\chi^2\beta_1^6\gamma_1^4\gamma_2^4/9-\chi(a^2/e_1)(a^2/e_2)E_{12t}E_{21t}}{2\chi^2\beta_1^3\gamma_2^4/3+(a^2/e_2)E_{21t}}\right\}. \tag{21}$$

Thus, for a given value of the charge e_1, Eq. (20) determines the value of the charge e_2 for which it is possible to simultaneously balance the radiation reaction and retarded interactions acting on each charge, while Eq. (21) fixes the magnitude of the external electric field that makes

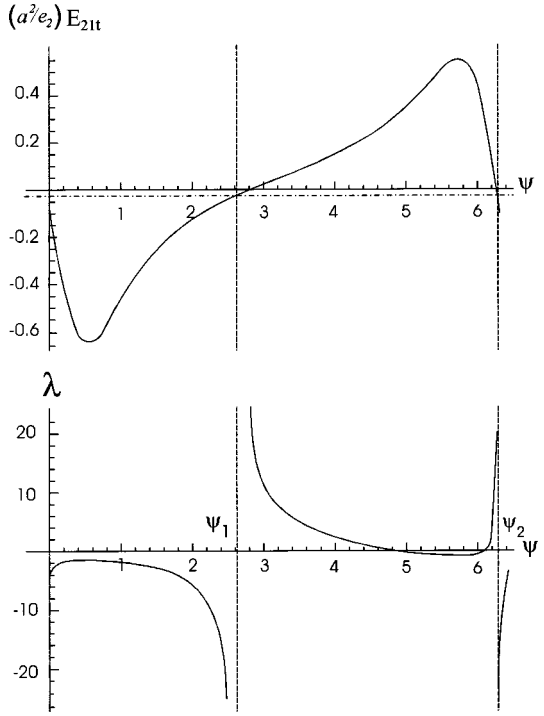

FIG. 3. The dimensionless quantity $(a^2/e_2)E_{21t}$ and the ratio of charges $\lambda = e_2/e_1$ as a function of the angle ψ in the case $\beta_1 = 0.6$ and $\chi = 0.4$. The dot-dashed line in the first graph corresponds to the value $-2\chi^2\beta_1^3\gamma_2^4/3$ for which the denominator of Eq. (20) vanishes.

this possible. From Eqs. (11), (13), (15) and (18) it follows that $(a^2/e_1)E_{12t}$ and $(a^2/e_2)E_{21t}$ are independent of the orbit's radius a for given values of β_1 and χ, and therefore λ is also independent of a. On the other hand, the constant D does depend on a, and therefore a given value of a fixes the value of the parameter α in Eq. (4).

Equations (20) and (21) depend implicitly on the angular separation ψ, since from the retardation conditions (12) and (16) we obtain $\partial\alpha_1/\partial\psi = 1/\kappa_1 > 0$ and $\partial\alpha_2/\partial\psi = 1/\kappa_2 > 0$, and therefore for fixed values of β_1 and χ the retarded angles α_1 and α_2 are uniquely determined as functions of ψ. In Fig. 3 we illustrate the dependence on ψ of the dimensionless combination $(a^2/e_2)E_{21t}$ and of λ, in the case $\beta_1 = 0.6$ and $\chi = 0.4$.

The dimensionless quantity $(a^2/e_2)E_{21t}$, associated to the retarded field exerted by particle 2 on particle 1, depends qualitatively on ψ as one expects. Note in particular that $(a^2/e_2)E_{21t}$ takes positive and negative values in two ranges of values of ψ which correspond roughly to $\pi < \psi < 2\pi$ and $0 < \psi < \pi$, with one maximum absolute value in each zone.

The behavior of $(a^2/e_1)E_{12t}$ is similar to the one sketched above, and since $2\beta_1^3\gamma_1^4/3$ is usually smaller than the maximum absolute value of $\chi(a^2/e_1)E_{12t}$, due to the factor β_1^3, there exist two values of ψ for which the numerator in Eq. (20) vanishes. In this case we have $e_2 = 0$ and the only solution of the Lorentz–Dirac equation corresponds to the one-particle solution in which particle 1 moves in a circular orbit of radius a with velocity β_1. Similarly, there exist two values of ψ, which we will denote by ψ_1 and ψ_2, located near $\psi = \pi$ and $\psi = 2\pi$, for which the denominator of Eq. (20) vanishes. Since the equations of motion only determine the ratio of charges λ, this is the same situation as above and it means that for a given value of e_2 the only solution of the Lorentz–Dirac equations when $\psi = \psi_1$ or $\psi = \psi_2$ is the one-particle solution in which particle 2 moves in a circular orbit of radius $b = \chi a$ and velocity $\beta_2 = \chi\beta_1$. Finally, from Eq. (20) it follows that for any given value of χ there exists a threshold value β_0 such that λ does not vanish if $\beta_1 > \beta_0$.

Of course, the details of the general behavior that we have sketched above depend on the

specific values of β_1 and χ chosen. Thus, the value ψ_1, which is a little less than π for $\beta_1 \to 0$, shifts to lower values with increasing β_1 for a fixed χ. For instance, for the case $\chi = 0.4$, ψ_1 is approximately 1.4 for $\beta_1 \to 1$. On the other hand, ψ_2 is a little less than 2π for $\beta_1 \to 0$ and shifts only very slightly to lower values when $\beta_1 \to 1$ for any fixed value of χ.

The above discussion shows that for any given values of β_1 and χ it is always possible (with exception of at most four values of ψ for which one of the charges vanishes) to adjust the external electric field in Eq. (7) and the charge of particle 2 so that the tangential equations of motion of both particles are satisfied. We will see below that the radial equations of motion obtained from the Lorentz–Dirac equation determine the mass of particle 2 in a more restrictive way. They are given by

$$\begin{aligned} -m_1\beta_1^2 c^2 \gamma_1 / a &= e_1 E_{21r} + e_1 \beta_1 B_{21z} - e_1 \beta_1 B_{\text{ext}}, \\ -m_2\beta_2^2 c^2 \gamma_2 / b &= e_2 E_{12r} + e_2 \beta_2 B_{12z} - e_2 \beta_2 B_{\text{ext}}, \end{aligned} \tag{22}$$

where E_{ijr} denotes the radial component of the retarded electric field exerted by particle i on particle j, and B_{ijz} denotes the z component of the retarded magnetic field exerted by particle i on particle j. By using Eq. (9) the following expressions follow:

$$\begin{aligned} E_{12r} = \frac{e_1}{\kappa_1^3 R_1^2} \Bigg\{ (1-\beta_1^2) \Bigg(\frac{\chi - \cos\alpha_1}{\{1+\chi^2 - 2\chi\cos\alpha_1\}^{1/2}} - \beta_1 \sin\alpha_1 \Bigg) \\ + \beta_1^2 \sin\alpha_1 \Bigg(\frac{\chi \sin\alpha_1}{\{1+\chi^2 - 2\chi\cos\alpha_1\}^{1/2}} - \beta_1 \Bigg) \Bigg\}, \end{aligned} \tag{23}$$

$$\begin{aligned} E_{21r} = \frac{e_2}{\kappa_2^3 R_2^2} \Bigg\{ (1-\beta_2^2) \Bigg(\frac{1 - \chi\cos\alpha_2}{\{1+\chi^2 - 2\chi\cos\alpha_2\}^{1/2}} + \beta_2 \sin\alpha_2 \Bigg) \\ + \beta_2^2 \sin\alpha_2 \Bigg(\frac{\sin\alpha_2}{\{1+\chi^2 - 2\chi\cos\alpha_2\}^{1/2}} + \beta_2 \Bigg) \Bigg\}, \end{aligned} \tag{24}$$

$$B_{12z} = \frac{\chi - \cos\alpha_1}{\{1+\chi^2 - 2\chi\cos\alpha_1\}^{1/2}} E_{12t} - \frac{\sin\alpha_1}{\{1+\chi^2 - 2\chi\cos\alpha_1\}^{1/2}} E_{12r}, \tag{25}$$

$$B_{21z} = \frac{1 - \chi\cos\alpha_2}{\{1+\chi^2 - 2\chi\cos\alpha_2\}^{1/2}} E_{21t} + \frac{\chi \sin\alpha_2}{\{1+\chi^2 - 2\chi\cos\alpha_2\}^{1/2}} E_{21r}. \tag{26}$$

Equations (22) can be simultaneously solved for the ratio of masses $\sigma = m_2/m_1$ and for the external magnetic field B_{ext} in Eq. (7). We obtain

$$\sigma = \frac{\lambda}{\gamma_2} \Bigg\{ \gamma_1 + \frac{(r_1/a)F}{\beta_1} \Bigg\} := \frac{\lambda}{\gamma_2} \sigma_r, \tag{27}$$

$$B_{\text{ext}} = \Bigg(\frac{e_1 \beta_1 \gamma_1}{r_1 a} \Bigg) + \frac{1 - \chi\cos\alpha_2}{\{1+\chi^2 - 2\chi\cos\alpha_2\}^{1/2}} E_{21t} + \Bigg(\frac{1}{\beta_1} + \frac{\chi \sin\alpha_2}{\{1+\chi^2 - 2\chi\cos\alpha_2\}^{1/2}} \Bigg) E_{21r}, \tag{28}$$

where r_1 is the classical radius of particle 1, $r_1 = e_1^2/(m_1 c^2)$, and F is the combination of retarded fields:

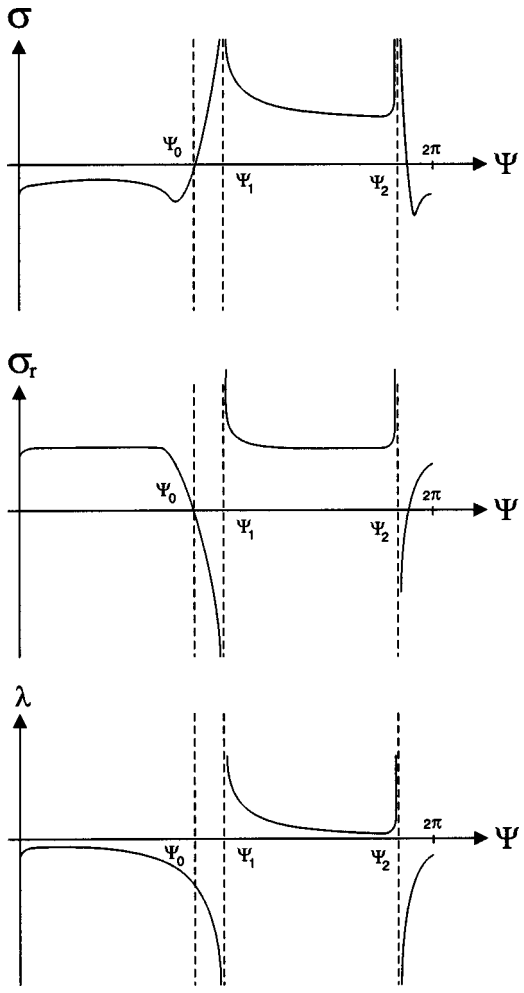

FIG. 4. Schematic behavior of the ratio of masses $\sigma=m_2/m_1$ as a function of angular separation ψ. We also show the behavior of σ_r defined in Eq. (27) and of the ratio of charges λ.

$$F=\lambda\left\{\frac{(1-\chi\cos\alpha_2)(a^2/e_2)E_{21t}}{\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}}+\left(\frac{1}{\beta_1}+\frac{\chi\sin\alpha_2}{\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}}\right)(a^2/e_2)E_{21r}\right\}$$
$$-\frac{(\chi-\cos\alpha_1)(a^2/e_1)E_{12t}}{\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}}-\left(\frac{1}{\beta_2}-\frac{\sin\alpha_1}{\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}}\right)(a^2/e_1)E_{12r}. \tag{29}$$

The first terms on the right hand sides of Eqs. (27) and (28) correspond to the results that would have been obtained if there were no retarded interactions between the charges. The term that depends on the retarded fields in Eq. (27) is proportional to the dimensionless number r_1/a, which is usually a very small number. However, it will be shown below that this term has qualitative implications.

The physical solutions of the Lorentz–Dirac equations are those with $\sigma>0$. The behavior of σ as a function of ψ arises from the behavior of both λ and the quantity in curly brackets in Eq. (27), which we have called σ_r. The typical behavior of these quantities is sketched in Fig. 4, where for simplicity we have chosen the case in which λ does not become zero for any value of ψ.

The behavior of σ_r in Fig. 4 follows from Eq. (27), since the smallness of r_1/a implies that σ_r does not differ appreciably from γ_1 for most values of ψ. However, Eq. (29) shows that the first

two terms of F are proportional to λ, and therefore σ_r is singular at points $\psi=\psi_1$ and $\psi=\psi_2$. A detailed analysis shows that the expression inside the curly brackets in Eq. (29) is positive for any β and χ, and therefore $\sigma_r\to\pm\infty$ when $\lambda\to\pm\infty$. Therefore, since σ_r has the same sign that λ near $\psi=\psi_1$ and $\psi=\psi_2$, σ in Eq. (27) is positive at both sides of those points. Besides, σ_r must take the value zero for some $\psi=\psi_0<\psi_1$ as it goes down towards $-\infty$, thus making $\sigma=0$ at that point. Therefore the physical solutions around $\psi=\psi_1$ consist of a narrow interval $\psi_0<\psi<\psi_1$ for which $\lambda<0$, followed by a range of solutions with $\lambda>0$ which extends up to $\psi=\psi_2$ in Fig. 4. The pattern of solutions around $\psi=\psi_2$ is similar.

The features sketched in Fig. 4 are valid in general, except of course when β_1 is very small, of the order of r_1/a, case in which the behavior of F as a function of ψ is relevant. A similar analysis can be performed in this case and it shows that again ranges of solutions exist around $\psi=\psi_1$ and $\psi=\psi_2$ with both $\lambda>0$ and $\lambda<0$, but this time the solutions that exist in a small angular interval are the ones with $\lambda>0$.

III. STUDY OF ENERGY CONSERVATION

For all the solutions that we have built it is possible to obtain an energy balance equation starting directly from the tangential equations of motion. By multiplying the first equation in (19) by $v_1=\beta_1 c$ and the second one by $v_2=\beta_2 c$ and adding the results, it follows that

$$e_1\mathbf{E}^{\mathbf{ext}}\cdot\mathbf{v_1}+e_2\mathbf{E}^{\mathbf{ext}}\cdot\mathbf{v_2}=\frac{2e_1^2c}{3a^2}\beta_1^4\gamma_1^4+\frac{2e_2^2c}{3b^2}\beta_2^4\gamma_2^4-e_1\mathbf{E_{21}}\cdot\mathbf{v_1}-e_2\mathbf{E_{12}}\cdot\mathbf{v_2}. \tag{30}$$

The left hand side of Eq. (30) corresponds to the energy provided by the external field to the charges. Since the kinetic energy of the charges and the total energy stored in the fields are time-independent, consistency with energy conservation demands the right hand side of Eq. (30) to be equal to the energy that escapes to infinity. Thus, in order to have a conclusive proof of energy conservation, it is necessary to calculate with independence of the equations of motion the energy that escapes to infinity, using only the far fields of the charges. To this end the total power of radiation at time t will be evaluated by computing the surface integral

$$\frac{c}{4\pi}\int_{\Sigma_r}(\mathbf{E}\times\mathbf{B})\cdot d\boldsymbol{\Sigma}, \tag{31}$$

where Σ_r is the surface of a sphere of very large radius, centered at the orbit's center, and $\mathbf{E}$, $\mathbf{B}$ are the retarded electric and magnetic fields generated by the charges, which are evaluated over Σ_r at time t.

The fields in (31) correspond to the superposition of the retarded electric fields $\mathbf{E}_1$ and $\mathbf{E}_2$ and retarded magnetic fields $\mathbf{B}_1$ and $\mathbf{B}_2$ generated by charges e_1 and e_2, respectively. Therefore the integral in (31) splits into three parts:

$$\frac{c}{4\pi}\int_{\Sigma_r}(\mathbf{E}_1\times\mathbf{B}_1)\cdot d\boldsymbol{\Sigma}+\frac{c}{4\pi}\int_{\Sigma_r}(\mathbf{E}_2\times\mathbf{B}_2)\cdot d\boldsymbol{\Sigma}+\frac{c}{4\pi}\int_{\Sigma_r}(\mathbf{E}_1\times\mathbf{B}_2+\mathbf{E}_2\times\mathbf{B}_1)\cdot d\boldsymbol{\Sigma}. \tag{32}$$

Each of the first two integrals in (32) deals with the fields of only one of the charges, and its evaluation gives the total power of radiation of a monoenergetic electron in circular motion, namely[7] $(\frac{2}{3})(e_1^2c/a^2)\beta_1^4\gamma_1^4$ for charge e_1 and $(\frac{2}{3})(e_2^2c/b^2)\beta_2^4\gamma_2^4$ for charge e_2. Therefore, from the comparison of (32) and the right hand side of (30) it is seen that energy conservation requires the equality of the last term in (32) and the negative of the retarded interaction power W, defined by

$$W=e_1E_{21t}\beta_1c+e_2E_{12t}\beta_2c, \tag{33}$$

where E_{21t} and E_{12t} are given by Eqs. (13) and (18), respectively.

The last integral in (32) represents the radiation rate associated with the interference of the fields of the two charges, and involves only the far fields of both charges. This situation contrasts with the definition of W in Eq. (33), where the exact fields are involved, that is, both the far and the near fields. In what follows the explicit calculation of the interference rate of radiation and of W will be performed.

A. The interference rate of radiation

If we denote by (θ,φ) the usual spherical angles, the last integral in Eq. (32) can be performed by considering first the contribution of the ribbon parallel to the orbit plane defined between the angles θ and $\theta+d\theta$. Even though the electric and magnetic fields at a fixed point of the ribbon are changing with time, the instantaneous energy flux across the ribbon is time-independent. This is so because of the symmetry of the charge's motion, which makes different positions of the system of charges to appear as completely equivalent for the ribbon as a whole. This property of time-independence of the instantaneous energy flux across the ribbon is of course valid for any ribbon of Σ_r, and therefore the instantaneous energy flux over Σ_r is time-independent.

The surface element on the sphere Σ_r is $d\boldsymbol{\Sigma}=r^2\sin\theta d\theta d\varphi\hat{\mathbf{r}}$, where the unit normal to the sphere, $\hat{\mathbf{r}}$, is given by $\hat{\mathbf{r}}=\sin\theta\cos\varphi\hat{\mathbf{x}}+\sin\theta\sin\varphi\hat{\mathbf{y}}+\cos\theta\hat{\mathbf{z}}$. The detection point $\mathbf{x}$ on the surface of the sphere is $\mathbf{x}=r\sin\theta\cos\varphi\hat{\mathbf{x}}+r\sin\theta\sin\varphi\hat{\mathbf{y}}+r\cos\theta\hat{\mathbf{z}}$, and therefore the retarded times t_1' and t_2' of charges e_1 and e_2 associated to the point $\mathbf{x}$ at time t satisfy

$$t-t_1'=\frac{1}{c}\{r^2+a^2-2ar\sin\theta\cos(\varphi-\omega t_1')\}^{1/2}, \tag{34}$$

$$t-t_2'=\frac{1}{c}\{r^2+b^2-2br\sin\theta\cos(\varphi-\omega t_2'-\psi)\}^{1/2}. \tag{35}$$

It turns out convenient to introduce the variables x and y defined by

$$x=\varphi-\omega t_1', \tag{36}$$

$$y=\varphi-\omega t_2'-\psi, \tag{37}$$

which, according to Eqs. (34) and (35), are linked by

$$y-x+\psi=\frac{\omega r}{c}[\{1+(a/r)^2-2(a/r)\sin\theta\cos x\}^{1/2}-\{1+(b/r)^2-2(b/r)\sin\theta\cos y\}^{1/2}]. \tag{38}$$

This equation defines a one-to-one correspondence between variables x and y for any ribbon on the sphere of radius r. In fact, from Eq. (38) it follows that

$$\frac{dy}{dx}=\frac{\kappa_1}{\kappa_2}>0, \tag{39}$$

where, according to (10), we have

$$\kappa_1=1-\frac{\beta_1\sin\theta\sin x}{\{1+(a/r)^2-2(a/r)\sin\theta\cos x\}^{1/2}}, \tag{40}$$

$$\kappa_2=1-\frac{\beta_2\sin\theta\sin y}{\{1+(b/r)^2-2(b/r)\sin\theta\cos y\}^{1/2}}. \tag{41}$$

In a similar way, Eq. (34) determines t_1' as a function of the angle φ over the ribbon and therefore variable x defined by Eq. (36) has a unique value for each φ in the interval $0<\varphi \leqslant 2\pi$. In fact, taking the derivative with respect to φ of Eqs. (34) and (36) and combining them we obtain

$$\frac{d\varphi}{dx}=\kappa_1>0,$$

and therefore the surface integral over the ribbon

$$\frac{c}{4\pi}\int_0^{2\pi}(\mathbf{E}_1\times\mathbf{B}_2+\mathbf{E}_2\times\mathbf{B}_1)\cdot\hat{\mathbf{r}}d\varphi \tag{42}$$

can be written as an integral over variable x,

$$\frac{c}{4\pi}\int_\alpha^{2\pi+\alpha}(\mathbf{E}_1\times\mathbf{B}_2+\mathbf{E}_2\times\mathbf{B}_1)\cdot\hat{\mathbf{r}}\kappa_1 dx, \tag{43}$$

where variable y is determined as a function of x through Eq. (38), and where parameter α is given by $\alpha=-\omega t_2'(\varphi=0)=-\omega t_2'(\varphi=2\pi)$. When we explicitly evaluate the integrand of (43), it turns out that it depends on x and y only through the functions $\cos x$, $\cos y$, $\sin x$ and $\sin y$. Moreover, from Eq. (38) it follows that y is a periodic function of x of period 2π, and therefore the integrand of (43) is a periodic function of x, of period 2π. Thus, (43) does not depend on the value of α and we can set $\alpha=0$. The instantaneous energy flux over the sphere Σ_r is therefore

$$P=\frac{c}{4\pi}r^2\int_0^{\pi}\sin\theta d\theta\int_0^{2\pi}(\mathbf{E}_1\times\mathbf{B}_2+\mathbf{E}_2\times\mathbf{B}_1)\cdot\hat{\mathbf{r}}\kappa_1 dx. \tag{44}$$

In the limit when the radius of the sphere r tends to infinity we obtain the following explicit expression,

$$P=\frac{e_1e_2c\beta_1^2\beta_2^2}{2\pi ab}\int_0^{\pi}\sin\theta d\theta\int\frac{\{\}}{\kappa_1^2\kappa_2^3}dx, \tag{45}$$

where

$$\{\}=\cos^2\theta\cos x\cos y+\sin x\sin y-\beta_1\sin\theta\sin y-\beta_2\sin\theta\sin x+\beta_1\beta_2\sin^2\theta, \tag{46}$$

and where Eqs. (40) and (41) simplify to

$$\kappa_1=1-\beta_1\sin\theta\sin x, \tag{47}$$

$$\kappa_2=1-\beta_2\sin\theta\sin y. \tag{48}$$

Similarly, the retardation condition (38) becomes

$$y-x+\psi=\sin\theta\{\beta_1\cos x-\beta_2\cos y\}. \tag{49}$$

The expression (45) is an exact formula for the part of the radiation rate associated with the interference between the charge's fields.

The retardation condition (49) is a functional relation similar to that studied by Watson in his well known book,[8] and it makes it possible to perform the x-integration. To this end it is useful to shift the x and y variables to

$$\overline{x}=x-\pi/2,$$

$$\overline{y}=y-\pi/2$$

to write $\varepsilon_1=\beta_1\sin\theta$, $\varepsilon_2=\beta_2\sin\theta$ and to introduce the combination

$$u=\overline{x}-\varepsilon_1\sin\overline{x}-\psi, \tag{50}$$

in terms of which Eq. (49) becomes

$$\overline{y}-\varepsilon_2\sin\overline{y}=u, \tag{51}$$

which is essentially the same relation studied by Watson. Equations (50) and (51) determine $\overline{x}$ and $\overline{y}$ respectively as functions of the independent variables u,ψ,ε_1 and ε_2. For fixed values of ψ,ε_1 and ε_2, both $\overline{x}$ and $\overline{y}$ are uniquely determined by u, since $d\overline{x}/du=1/(1-\varepsilon_1\cos\overline{x})>0$ and $d\overline{y}/du=1/(1-\varepsilon_2\cos\overline{y})>0$. Besides, if $\overline{x}\to\overline{x}+2\pi$ in Eq. (50) or $\overline{y}\to\overline{y}+2\pi$ in Eq. (51), we have $u\to u+2\pi$, and therefore $\overline{x}$ and $\overline{y}$ are periodic functions of u of period 2π. Also, it can be seen that $\overline{y}$ is an odd function of u.

In terms of the new variables, (45) can be written

$$P=\frac{e_1e_2c\beta_1^2\beta_2^2}{2\pi ab}\int_0^{\pi}\sin\theta d\theta\int_0^{2\pi}\frac{\cos^2\theta\sin\overline{x}\sin\overline{y}+(\cos\overline{x}-\varepsilon_1)(\cos\overline{y}-\varepsilon_2)}{(1-\varepsilon_1\cos\overline{x})^3(1-\varepsilon_2\cos\overline{y})^3}du. \tag{52}$$

The integrand of (52) can be rewritten by using the following identities,

$$\begin{aligned}
\frac{\sin\overline{x}}{(1-\varepsilon_1\cos\overline{x})^3}&=-\frac{1}{\varepsilon_1}\frac{\partial}{\partial u}\left(\frac{1}{\kappa_1}\right),\\
\frac{\sin\overline{y}}{(1-\varepsilon_2\cos\overline{y})^3}&=-\frac{1}{\varepsilon_2}\frac{\partial}{\partial u}\left(\frac{1}{\kappa_2}\right),\\
\frac{(\cos\overline{x}-\varepsilon_1)}{(1-\varepsilon_1\cos\overline{x})^3}&=\frac{\partial}{\partial\varepsilon_1}\left(\frac{1}{\kappa_1}\right),\\
\frac{\cos\overline{y}-\varepsilon_2}{(1-\varepsilon_2\cos\overline{y})^3}&=\frac{\partial}{\partial\varepsilon_2}\left(\frac{1}{\kappa_2}\right),
\end{aligned} \tag{53}$$

where $1/\kappa_1$ and $1/\kappa_2$ are periodic functions of u, and therefore can be expanded in Fourier series by using the techniques developed by Watson.[8] The results are

$$\begin{aligned}
\frac{1}{\kappa_1}&=\frac{1}{1-\varepsilon_1\cos\overline{x}}=1+2\sum_{n=1}\{-\sin(n\psi)J_n(n\varepsilon_1)\sin(nu)+\cos(n\psi)J_n(n\varepsilon_1)\cos(nu)\},\\
\frac{1}{\kappa_2}&=\frac{1}{1-\varepsilon_2\cos\overline{y}}=1+2\sum_{n=1}J_n(n\varepsilon_2)\cdot\cos(nu).
\end{aligned} \tag{54}$$

Replacing Eqs. (53) and (54) in (52) and performing the u-integration, which now is trivial, (52) becomes

$$P=\frac{e_1e_2c\beta_1^2\beta_2^2}{2ab}\int_0^{\pi}\sin\theta\sum_{n=1}^{\infty}\cos(n\psi)\left\{\frac{n^2\cos^2\theta J_n(n\varepsilon_1)J_n(n\varepsilon_2)}{\varepsilon_1\varepsilon_2}+n^2J_n'(n\varepsilon_1)J_n'(n\varepsilon_2)\right\}d\theta. \tag{55}$$

The angular integration in (55) is performed by using the series representation of the Bessel function

$$J_n(z)=\sum_{p=0}^{\infty}\frac{(-1)^p z^{n+2p}}{2^{n+2p}p!(n+p)!}$$

and its derivative, evaluated at $z_1=n\varepsilon_1=n\beta_1\sin\theta$ and $z_2=n\varepsilon_2=n\beta_2\sin\theta$, and by using the result

$$\int_0^{\pi}(\sin\theta)^{2j-1}d\theta=\frac{\pi^{1/2}\Gamma(j)}{\Gamma(j+\frac{1}{2})},$$

where $\Gamma(z)$ is the Gamma function. Then, the interference rate of radiation can be written as

$$P=\frac{2e_1e_2c\beta_1^2}{a^2}\sum_{n=1}^{\infty}\cos(n\psi)(n^2\beta_1\beta_2)^n\sum_{p,q=0}^{\infty}\frac{(-1)^{p+q}n^{2p+2q}(n+p+q)!(n+p+q-1)!}{p!q!(n+p)!(n+q)!(2n+2p+2q)!}$$
$$\times\left\{\frac{n^2}{(2n+2p+2q+1)}+(n+2p)(n+2q)\right\}\beta_1^{2p}\beta_2^{2q}. \tag{56}$$

According to the discussion after Eq. (32), Eq. (56) for the interference rate of radiation should equal the negative of the rate of work W defined in Eq. (33). In order to compare P and $-W$, in what follows we will explicitly calculate the right hand side of (33), expressing it as a double series in β_1 and β_2.

B. The rate of work

The retardation conditions (12) and (16) determine implicitly α_1 and α_2 as functions of β_1,χ and ψ, which will be chosen as independent parameters. For fixed χ and β_1, α_1 and α_2 are uniquely determined as functions of ψ, since

$$\partial\alpha_1/\partial\psi=1/\kappa_1>0, \tag{57}$$

$$\partial\alpha_2/\partial\psi=1/\kappa_2>0, \tag{58}$$

where κ_1 and κ_2 are given by Eqs. (14) and (17). Besides, if $\alpha_1\to\alpha_1+2\pi$ in Eq. (12) or $\alpha_2\to\alpha_2+2\pi$ in Eq. (16), we have $\psi\to\psi+2\pi$, and therefore α_1 and α_2 are periodic functions of ψ of period 2π.

From Eqs. (12) and (16) it follows that

$$\frac{\partial\alpha_1}{\partial\beta_1}=\frac{\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2}}{\kappa_1}>0,$$
$$\frac{\partial\alpha_2}{\partial\beta_1}=-\frac{\{1+\chi^2-2\chi\cos\alpha_2\}^{1/2}}{\kappa_2}<0. \tag{59}$$

By using these results it is easily verified that expressions (13) and (18) for the tangential components of the retarded electric fields can be written as

$$E_{12t}/e_1=-\frac{1}{\chi}\left(1-\frac{\beta_1^2}{2}-\frac{\beta_1^2\chi^2}{2}\right)\frac{\partial}{\partial\beta_1}\left(\frac{1}{\kappa_1R_1^2}\right)-\frac{\beta_1^2}{2a^2\chi}\frac{\partial}{\partial\beta_1}\left(\frac{1}{\kappa_1}\right),$$
$$E_{21t}/e_2=\left(-1+\frac{\beta_1^2}{2}+\frac{\beta_1^2\chi^2}{2}\right)\frac{\partial}{\partial\beta_1}\left(\frac{1}{\kappa_2R_2^2}\right)-\frac{\beta_1^2}{2a^2}\frac{\partial}{\partial\beta_1}\left(\frac{1}{\kappa_2}\right), \tag{60}$$

and therefore the retarded interaction power W in Eq. (33) can be expressed as

$$W=e_1e_2c\left\{\left(-1+\frac{\beta_1^2}{2}+\frac{\beta_1^2\chi^2}{2}\right)\beta_1\frac{\partial}{\partial\beta_1}\left(\frac{1}{\kappa_1R_1^2}+\frac{1}{\kappa_2R_2^2}\right)-\frac{\beta_1^3}{2a^2}\frac{\partial}{\partial\beta_1}\left(\frac{1}{\kappa_1}+\frac{1}{\kappa_2}\right)\right\}. \tag{61}$$

W will be now expanded as a Fourier series in angle ψ, by doing the corresponding expansions of the factors containing κ_1 and κ_2 in Eq. (61). These factors are even functions of ψ, as can be seen from the following symmetry of the retardation conditions, Eqs. (12) and (16). If α_2 satisfies Eq. (16) for the angle ψ, then $\alpha_1=-\alpha_2$ satisfies Eq. (12) for the angle $-\psi$. Also, if α_1 satisfies Eq. (12) for the angle ψ, then $\alpha_2=-\alpha_1$ satisfies Eq. (16) for the angle $-\psi$. That is, when $\psi\rightarrow-\psi$, $\alpha_1\rightarrow-\alpha_2$ and $\alpha_2\rightarrow-\alpha_1$, which in turn implies that $\kappa_1\rightarrow\kappa_2$, $\kappa_2\rightarrow\kappa_1$, $R_1\rightarrow R_2$ and $R_2\rightarrow R_1$. Therefore, $1/\kappa_1+1/\kappa_2$ and $1/(\kappa_1R_1^2)+1/(\kappa_2R_2^2)$ remain unchanged when $\psi\rightarrow-\psi$. Thus, it follows

$$\frac{1}{\kappa_1}+\frac{1}{\kappa_2}=\sum_n A_n\cos n\psi,$$

where

$$A_n=\frac{1}{\pi}\int_{-\pi}^{\pi}\frac{\cos n\psi}{\kappa_1}d\psi+\frac{1}{\pi}\int_{-\pi}^{\pi}\frac{\cos n\psi}{\kappa_2}d\psi. \tag{62}$$

Using Eqs. (57) and (58) to change the variable of integration, we have

$$A_n=\frac{1}{\pi}\int_{-\pi}^{\pi}\cos(n\alpha_1-n\beta_1\{1+\chi^2-2\chi\cos\alpha_1\}^{1/2})d\alpha_1+\frac{1}{\pi}\int_{-\pi}^{\pi}\cos(n\alpha_2+n\beta_1\{1+\chi^2$$

$$-2\chi\cos\alpha_2\}^{1/2})d\alpha_2=\frac{4}{\pi}\int_0^{\pi}\cos(n\alpha)\cos(n\beta_1\{1+\chi^2-2\chi\cos\alpha\}^{1/2})d\alpha. \tag{63}$$

In the same way we obtain

$$\frac{1}{\kappa_1R_1^2}+\frac{1}{\kappa_2R_2^2}=\frac{1}{a^2}\sum_n B_n\cos n\psi, \tag{64}$$

where

$$B_n=\frac{4}{\pi}\int_0^{\pi}\frac{\cos(n\alpha)\cos(n\beta_1\{1+\chi^2-2\chi\cos\alpha\}^{1/2})}{1+\chi^2-2\chi\cos\alpha}d\alpha. \tag{65}$$

Replacing Eqs. (62)–(65) in Eq. (61), we obtain

$$W=-\frac{e_1e_2c\beta_1}{2a^2}\sum_n\cos n\psi\left\{(2-\beta_1^2-\chi^2\beta_1^2)\frac{\partial B_n}{\partial\beta_1}+\beta_1^2\frac{\partial A_n}{\partial\beta_1}\right\}. \tag{66}$$

The coefficients A_n and B_n can be expressed as power series in β_1 by expanding the factor $\cos(n\beta_1\{1+\chi^2-2\chi\cos\alpha\}^{1/2})$ in Eqs. (63) and (65). For instance,

$$A_n=\frac{4}{\pi}\sum_{m=0}^{\infty}\frac{(-1)^m(n\beta_1)^{2m}}{(2m)!}\int_0^{\pi}\cos(n\alpha)(1+\chi^2-2\chi\cos\alpha)^m d\alpha. \tag{67}$$

Writing $1+\chi^2-2\chi\cos\alpha=c-d\cos\alpha$, with parameters c and d given by

$$\begin{aligned}c&=1+\chi^2,\\ d&=2\chi,\end{aligned} \tag{68}$$

and using the binomial theorem, Eq. (67) becomes

$$A_n=\frac{4}{\pi}\sum_{m=0}^{\infty}\frac{(-1)^m(n\beta_1)^{2m}}{(2m)!}\sum_{k=0}^{m}\binom{m}{k}(-1)^k c^{m-k}d^k\int_0^{\pi}\cos(n\alpha)(\cos\alpha)^k d\alpha. \tag{69}$$

The result of the integration is[9]

$$\int_0^{\pi}\cos n\alpha(\cos\alpha)^k d\alpha=\begin{cases}0 & \text{if } k<n \quad \text{or} \quad k=n+2i-1, \quad i>0,\\ \dfrac{\pi}{2^k}\binom{k}{i} & \text{if } k=n+2i, \quad i>0.\end{cases} \tag{70}$$

Therefore, the terms with $m<n$ on the right hand side of Eq. (69) vanish. Putting $m=n+j$, and since only $k=n+2i$ gives a nonvanishing result, Eq. (69) becomes

$$\begin{aligned}A_n&=4\sum_{j=0}^{\infty}\frac{(-1)^{n+j}(n\beta_1)^{2n+2j}}{(2n+2j)!}\sum_{k=n}^{n+j}\binom{n+j}{k}\binom{k}{i}(-1)^k\frac{c^{n+j-k}d^k}{2^k}\\ &=4\sum_{j=0}^{\infty}\frac{(-1)^{n+j}(n\beta_1)^{2n+2j}}{(2n+2j)!}\sum_{i=0}^{[j/2]}\binom{n+j}{n+2i}\binom{n+2i}{i}(-1)^{n+2i}\frac{c^{j-2i}d^{n+2i}}{2^{n+2i}},\end{aligned} \tag{71}$$

where $[x]$ represents the integer part of x. From Eq. (71) it is immediate that

$$\frac{\partial A_n}{\partial\beta_1}=4\sum_{j=0}^{\infty}(-1)^j\frac{n^{2n+2j}\beta_1^{2n+2j-1}}{(2n+2j-1)!}\sum_{i=0}^{[j/2]}\binom{n+j}{n+2i}\binom{n+2i}{i}\frac{c^{j-2i}d^{n+2i}}{2^{n+2i}}. \tag{72}$$

The dependence of Eq. (72) on χ and β_1 can be changed to a dependence on $\beta_2=\chi\beta_1$ and β_1 by using Eq. (68) and by regrouping factors as follows:

$$\frac{d^{n+2i}}{2^{n+2i}}\beta_1^{n+2i}=(\beta_1^2\chi)^{n+2i}=(\beta_1\beta_2)^{n+2i},$$

$$c^{j-2i}\beta_1^{2j-4i}=(\beta_1^2(1+\chi^2))^{j-2i}=(\beta_1^2+\beta_2^2)^{j-2i}=\sum_{\ell=0}^{j-2i}\binom{j-2i}{\ell}\beta_1^{2j-4i-2\ell}\beta_2^{2\ell},$$

which, when replaced in Eq. (72), give

$$\frac{\partial A_n}{\partial\beta_1}=4\sum_{j=0}^{\infty}\frac{(-1)^j n^{2j+2n}(\beta_1\beta_2)^n\beta_1^{-1}}{(2n+2j-1)!}\times\sum_{i=0}^{[j/2]}\sum_{\ell=0}^{j-2i}\binom{n+j}{n+2i}\binom{n+2i}{i}\binom{j-2i}{\ell}\beta_1^{2j-2i-2\ell}\beta_2^{2i+2\ell}. \tag{73}$$

In the same way, it is readily obtained that

$$\frac{\partial B_n}{\partial\beta_1}=4\sum_{j=0}^{\infty}\frac{(-1)^{j+1}n^{2n+2j+2}(\beta_1\beta_2)^n\beta_1}{(2n+2j+1)!}\times\sum_{i=0}^{[j/2]}\sum_{\ell=0}^{j-2i}\binom{n+j}{n+2i}\binom{n+2i}{i}\binom{j-2i}{\ell}\beta_1^{2j-2i-2\ell}\beta_2^{2i+2\ell}. \tag{74}$$

Replacing Eqs. (73) and (74) in Eq. (66) we obtain

$$\begin{aligned}W=&-\frac{2e_1e_2c\beta_1^2}{a^2}\sum_{n=0}^{\infty}\cos(n\psi)(n^2\beta_1\beta_2)^n\sum_{j=0}^{\infty}\frac{n^{2j}(-1)^{j+1}}{(2n+2j+1)!}\times\{n^2(2-\beta_1^2-\beta_2^2)\\ &-(2n+2j)(2n+2j+1)\}S(n,j),\end{aligned} \tag{75}$$

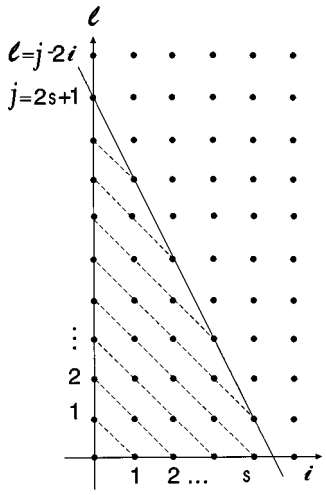

FIG. 5. The values of ℓ and i that occur in the double sum S are located inside the triangular region delimited by the straight line $\ell=j-2i$ and the coordinate axes. The points located on the segmented lines have a constant value of $q=\ell+i$.

where

$$S(n,j)=\sum_{i=0}^{[j/2]}\sum_{\ell=0}^{j-2i}\binom{n+j}{n+2i}\binom{n+2i}{i}\binom{j-2i}{\ell}\beta_1^{2j-2i-2\ell}\beta_2^{2i+2\ell}. \tag{76}$$

Equation (75) would have the same structure as the retarded interference rate P in Eq. (56) if one of the sums in Eq. (76) could be performed. To this end, it turns out convenient to collect terms in (76) with a fixed value of $\ell+i:=q$. In order to see more clearly how to arrange the terms of the double sum in Eq. (76) according to the new variables q and i, it is useful to plot in the $\ell-i$ plane the values that ℓ and i take in Eq. (76).

In Fig. 5 we assume for simplicity that j is odd, that is, $j=2s+1$. From Eq. (76) it follows that the possible values of i and ℓ are located inside the triangular region delimited by the positive coordinate axes and the slope -2 straight line $\ell=j-2i$. In this plot the combinations of values of ℓ and i that have a constant value of $q=\ell+i$ are located on straight lines of slope -1. Therefore, q takes values in the range $0\rightarrow j$. From Fig. 5 we see that the values taken by i for a given value of q depend on whether $q\leqslant s$ or $q>s$. If $q\leqslant s$, then the straight line $i+\ell=q$ joins both catets of the triangular allowed region, and therefore i takes values $0,1,\ldots,q$. On the other hand, if $q>s$, the straight line $i+\ell=q$ joins the $i=0$ axis with the straight line $\ell=j-2i$. In this case the maximum value that i takes is the one corresponding to the intersection point of both straight lines, that is, $i=j-q$. Therefore, the value of S in the case $j=2s+1$ is

$$\begin{aligned}S(n,j)=&\sum_{q=0}^{s}\sum_{i=0}^{q}\binom{n+j}{n+2i}\binom{n+2i}{i}\binom{j-2i}{q-i}\beta_1^{2j-2q}\beta_2^{2q}+\sum_{q=s+1}^{j}\sum_{i=0}^{j-q}\binom{n+j}{n+2i}\binom{n+2i}{i}\\&\times\binom{j-2i}{q-i}\beta_1^{2j-2q}\beta_2^{2q}.\end{aligned} \tag{77}$$

Making the change of dummy index $q=j-v$ in the second term of Eq. (77), and using the symmetry of the binomial coefficient

$$\binom{j-2i}{j-v-i}=\binom{j-2i}{v-i},$$

Eq. (77) can be rewritten as

$$S(n,j)=\sum_{q=0}^{s}\sum_{i=0}^{q}\binom{n+j}{n+2i}\binom{n+2i}{i}\binom{j-2i}{q-i}(\beta_1^{2j-2q}\beta_2^{2q}+\beta_1^{2q}\beta_2^{2j-2q}). \tag{78}$$

The sum over the index i in Eq. (78) can be carried out by noting that it corresponds to a hypergeometric series. In effect, the ratio of consecutive terms of the sum is

$$\frac{a_{i+1}}{a_i}=\frac{(i-q)(i-(j-q))}{(i+n+1)(i+1)},$$

and, therefore, from the definition of the hypergeometric series we have

$$A(n,j,q):=\sum_{i=0}^{q}\binom{n+j}{n+2i}\binom{n+2i}{i}\binom{j-2i}{q-i}=\frac{(j+n)!}{n!q!(j-q)!}\,{}_2F_1(-q,-(j-q),n+1;1). \tag{79}$$

Using the well known relation

$${}_2F_1(a,b,c;1)=\frac{\Gamma(c-a-b)\Gamma(c)}{\Gamma(c-a)\Gamma(c-b)},$$

it follows that

$$A(n,j,q)=\frac{[(j+n)!]^2}{q!(j-q)!(j+n-q)!(q+n)!}, \tag{80}$$

a result that is invariant under the interchange of q and $j-q$.

The analysis can be repeated for the case of even j, that is, for $j=2s$, and the final result is exactly the same. Thus, for any j we have

$$S(n,j)=\sum_{q=0}^{j}A(n,j,q)\beta_1^{2j-2q}\beta_2^{2q}, \tag{81}$$

where $A(n,j,q)$ is given by Eq. (80). Replacing Eqs. (81) and (80) in Eq. (75), changing the index j in the sums for the new dummy index $p=j-q$, and using the identity for absolutely convergent series

$$\sum_{j=0}^{\infty}\sum_{q=0}^{j}a_{q,j}=\sum_{q=0}^{\infty}\sum_{p=0}^{\infty}a_{q,p+q}, \tag{82}$$

the following expression for W is obtained:

$$W=\frac{2e_1e_2c\beta_1^2}{a^2}\sum_{n=0}^{\infty}\cos(n\psi)(n^2\beta_1\beta_2)^n\sum_{p=0}^{\infty}\sum_{q=0}^{\infty}\{a_{p,q}(2-\beta_1^2-\beta_2^2)-b_{p,q}\}\beta_1^{2p}\beta_2^{2q}, \tag{83}$$

where the coefficients $a_{p,q}$ and $b_{p,q}$ are given by

$$\begin{aligned}a_{p,q}&=\frac{(-1)^{p+q}n^{2p+2q+2}[(n+p+q)!]^2}{(2n+2p+2q+1)!p!q!(n+p)!(n+q)!},\\ b_{p,q}&=\frac{(-1)^{p+q}n^{2p+2q}(2n+2p+2q)(2n+2p+2q+1)[(n+p+q)!]^2}{(2n+2p+2q+1)!p!q!(n+p)!(n+q)!}.\end{aligned} \tag{84}$$

Note that Eq. (56) for the interference rate of radiation P can be written in terms of the coefficient $a_{p,q}$ in (84). The resulting expression is

$$P=\frac{2e_1e_2c\beta_1^2}{a^2}\sum_{n=0}^{\infty}\cos(n\psi)(n^2\beta_1\beta_2)^n\sum_{p,q=0}^{\infty}\frac{a_{p,q}}{n^2(n+p+q)}$$
$$\times\{n^2+(2n+2p+2q+1)(n+2p)(n+2q)\}\beta_1^{2p}\beta_2^{2q}. \tag{85}$$

On the other hand, Eq. (83) for the rate of retarded work W is not still in its final form as a double power series in β_1 and β_2, due to the factor $(2-\beta_1^2-\beta_2^2)$ in the numerator. Equation (83) can be rewritten in the form

$$W=\frac{2e_1e_2c\beta_1^2}{a^2}\sum_{n=0}^{\infty}\cos(n\psi)(n^2\beta_1\beta_2)^n\sum_{p,q=0}^{\infty}\{2a_{p,q}-b_{p,q}-a_{p-1,q}-a_{p,q-1}\}\beta_1^{2p}\beta_2^{2q}, \tag{86}$$

where the coefficients $a_{p=-1,q}$ and $a_{p,q=-1}$ are defined to be zero. Introducing in (86) the following relations between the different coefficients,

$$b_{p,q}=\frac{(2n+2p+2q)(2n+2p+2q+1)}{n^2}a_{p,q},$$
$$a_{p-1,q}=-\frac{2p(n+p)(2n+2p+2q+1)}{n^2(n+p+q)}a_{p,q}, \tag{87}$$
$$a_{p,q-1}=-\frac{2q(n+q)(2n+2p+2q+1)}{n^2(n+p+q)}a_{p,q},$$

and comparing with Eq. (85) it is readily seen that $-W$ reduces to the interference rate of radiation P, thus showing the consistency of the Lorentz–Dirac equation with energy conservation.

(Received 29 September 2000; accepted for publication 5 June 2002)

The inverse problem involving a point pulse source exterior to a scattering medium, where the velocity $c(x)$ is continuous, is considered. The layer stripping approach is applied to thin curvilinear layers whose surfaces are the primary wave fronts [with $c(x)$ continuous, the reflected wave fronts will be secondary, i.e., of lower order singularity]. It is shown that the layer stripping approach can be used in the time-domain inverse problem without employing the added complexity of having to perform wave splitting. Furthermore the procedure to determine the normal derivative of c from the asymptotic short time behavior of the field quantities on an adjacent wave front surface has been simplified compared to earlier wave splitting methods. Uniqueness results are given. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1504502]

I. INTRODUCTION

Wave splitting in the time domain for one-dimensional inverse problems involving the wave equation was employed by Corones and Kreuger[1,2] and subsequently extended to more complicated one-dimensional equations, like viscoelastic equations, Karlsson,[3] etc. In three dimensions, Fishman,[4,5] used the pseudodifferential operator resulting from the planar splitting to obtain one-way propagation in the frequency domain. Planar wave splitting was formulated for the three-dimensional wave equation in the time domain by Weston,[6,7] and applied to the inverse problem for the telegraph equation by Weston and He.[8] Working in a sector of the complex Laplace transform plane of the wave equation, de Hoop[9,10] was able to get rigorous results for planar wave splitting and the resulting Bremmer series, etc. A comprehensive review and bibliography of time-domain wave splitting for the wave equation and Maxwells equation is given in the book by He, Ström, and Weston.[11]

Nonplanar wave splitting in time-domain was introduced by Weston[12] for the three-dimensional wave equation. This formulation proved useful in obtaining the appropriate absorbing boundary condition for the wave equation. Here the procedure of the layer stripping process on curved surfaces is given for the case when the curved surfaces are the wave fronts associated with a particular scattering problem.

An alternative approach to inverse scattering in an inhomogeneous medium is to use the Bremmer series. In this connection, some very fast algorithms have been developed for the calculation of the Bremmer series. They are the Generalized Screen method[13] and the rational approximation method.[14]

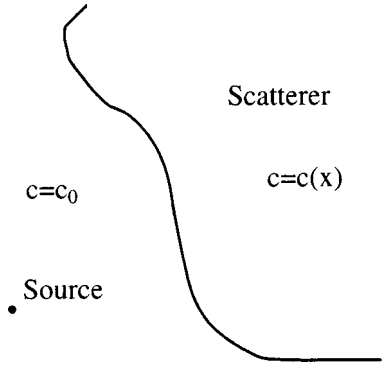

FIG. 1. Scattering geometry.

II. OVERVIEW OF THE WAVE FRONT CONNECTION TO THE INVERSE PROBLEM

Consider the scattering problem where there is a point impulse source at x^0, which is exterior to a scatterer whose domain is characterized by the support of $(c(x)-c_0)$ where c_0 is the free space value of the velocity $c(x)$ (see Fig. 1). The total field $u(x,t)$ satisfies the wave equation

$$\frac{1}{c^2(x)}\frac{\partial^2 u}{\partial t^2}-\Delta u=\delta(x-x^0)H(t), \quad x^0,x\in\mathbb{R}^3, \tag{1}$$

where, initially, it will be assumed that $c(x)$ is a continuous function of x.

The incident field portion, $u^i(x,t)$, in free space, of $u(x,t)$ will have the form

$$u^i(x,t)=\frac{1}{4\pi R}H\left(t-\frac{R}{c_0}\right), \quad R=|x-x^0|. \tag{2}$$

Let $\tau(x,x^0)$ be the travel time from the source point x^0 to the observation point x, then the wave front surface at time t is given by

$$\tau(x,x^0)=t, \tag{3}$$

with $\tau(x,x^0)$ satisfying the Eikonal equation

$$|\nabla\tau|^2=\frac{1}{|c(x)|^2}. \tag{4}$$

The rays (the trajectories orthogonal to the wave front surfaces) emanating from the source point in the direction of the unit vector

$$\nu=(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta), \tag{5}$$

can be represented in terms of the two parameter family of curves

$$x_j=X_j(\tau,\theta,\phi), \quad 0\leqslant\theta\leqslant\pi, \quad 0\leqslant\phi<2\pi, \quad 0\leqslant\tau, \quad j=1,2,3, \tag{6}$$

with the parameters θ and ϕ being the angles associated with a local spherical coordinate system centered at the source point x^0. The rays satisfy the following differential equation.[15]

$$\frac{\partial}{\partial\tau}\left(\frac{1}{c^2}\frac{\partial X}{\partial\tau}\right)=c\nabla\left(\frac{1}{c}\right). \tag{7}$$

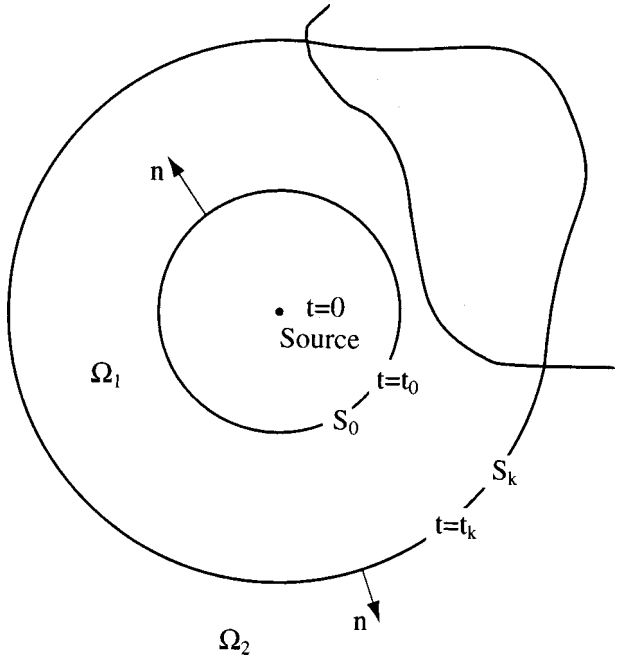

FIG. 2. Wave front geometry.

Note that the ray coordinate system (τ,θ,ϕ), is an orthogonal system which maps, in an 1:1 fashion, the domain $0\leqslant\tau\leqslant\tau^*$, $0\leqslant\theta\leqslant\pi$, $0\leqslant\phi<2\pi$ into a simply connected domain containing the source point x^0, provided that τ^* is restricted so that no caustics appear.

Let the time $t=t_0>0$ be such that the incident wave front has not impinged on the scatterer, and let S_0 be the wave front surface at that time. S_0 will then be a spherical surface with a radius c_0t_0 and centered at x^0; see Fig. 2. At a later time $t_k<T$, when the incident wave has impinged on the scatterer, let the corresponding wave front surface be S_k where

$$S_k=\{x\in\mathbb{R}^3:\tau(x,x^0)=t_k\}. \tag{8}$$

Let the open domain between the two surfaces S_0 and S_k be denoted Ω_1, and the region exterior to S_k be denoted Ω_2; see Fig. 2. Then it follows that the total field satisfies the following initial conditions in the domains Ω_1 and Ω_2, respectively:

$$u=u_t=0, \quad x\in\Omega_1, \quad t=t_0, \tag{9}$$

$$u=u_t=0, \quad x\in\Omega_2, \quad t=t_k. \tag{10}$$

The inverse problem can now be stated. Assume that the total field u and its normal derivative $\partial_n u$ are known on S_0, for $0\leqslant t\leqslant T$, either through direct measurements or through indirect measurements and calculations. For the latter case if the incident field is known and the scattered field u^r (which vanishes on S_0 for $t<t_0$) is measured on S_0 for times $0\leqslant t\leqslant T$, one can compute the normal component of each, especially that of the scattered wave component by using the ingoing and outgoing wave conditions on the spherical surface S_0,[12] and identifying the outgoing and incoming wave components, respectively, with u^i and u^r.

In the layer stripping process as applied to wave front surfaces, one has a set of nested (wave front) surfaces $S_0\subset S_1\subset S_2\subset\cdots\subset S_k$, each corresponding to the wave fronts at times $t_0,t_1,t_2,\ldots,t_k$, where $t_k=t_0+k\Delta_t$, and where Δ_t is a very small time interval.

When the initial wave front surface S_0 is known, one can compute in succession each wave front surface $\{S_n\}_{n=0}^k$, using the ray equation (7). If $x_k=X_k(\tau,\theta_0,\phi_0)$ is a point on the surface S_k

associated with the ray (θ_0,ϕ_0) then, upon integrating Eq. (7), one can show that the point x_{k+1}, on the wave front surface S_{k+1} associated with the same ray (θ_0,ϕ_0), is given by

$$x_{k+1}=x_k+\Delta_t c_k n_k+(\Delta_t)^2(-\tfrac{1}{2}c_k(\nabla c)_k+c_k(n\cdot\nabla c)_k n_k)+\cdots, \tag{11}$$

where n_k is the unit normal to the wave front surface S_k at the point x_k and c_k, $(\nabla c)_k$ are evaluated at the point x_k. Thus to determine the wave front surface S_{k+1} from the wave front surface S_k to order $(\Delta_t)^2$, one needs only the values of c and its normal derivative $\partial_n c$ on S_k.

On the surface S_0, as mentioned previously, u and $\partial_n u$ are known for $0\leqslant t\leqslant T$ as well as c and $\partial_n c$ ($c=c_0$ and $\partial_n c=0$). From knowledge of c and $\partial_n c$ on S_0, one can find the wave front surface S_1 by using expression (11) and also obtain an estimate for the value of c on S_1. Using this value of c in the first layer and knowledge of u and $\partial_n u$ on S_0 one wants to obtain the values of u and $\partial_n u$ on S_0 for $0\leqslant t\leqslant T$. This is discussed in Sec. III. Then from the asymptotic (leading time) behavior of u and $\partial_n u$ on S_1, one wants to obtain $\partial_n c$ on S_k. This is investigated in Sec. IV. Finally these steps are repeated, layer by layer. The above-mentioned analysis holds for a time period where there are no caustics. The effect of caustics is discussed in Sec. V.

To investigate the mathematics behind the layer stripping process, the kth step will be considered starting with the knowledge or estimate of $c(x)$ in the kth layer bounded by S_{k-1} and S_k, but instead of working with the knowledge of u and $\partial_n u$ on S_{k-1} for $0\leqslant t\leqslant T$, and working in the kth layer, the domain Ω_1 bounded by the surfaces S_0 and S_k will be used together with the knowledge of u and $\partial_n u$ on S_0. This will then shed light on the influence of the *data* u and $\partial_n u$ on S_0 upon the determination of u and $\partial_n u$ on S_k.

Note that although $c(x)$ is assumed to be continuous throughout, its derivatives may or may not be continuous. In the typical numerical procedure for layer stripping, $c(x)$ and its first derivatives are continuous in each layer, but the normal derivative may have a jump discontinuity across each surface of the layer.

III. DETERMINATION OF u AND $\partial_n u$ ON S_k FROM KNOWLEDGE OF u AND $\partial_n u$ ON S_0

Given, the continuous velocity, $c(x)$, in $\overline{\Omega}_1$, the problem is to determine u and $\partial_n u$ on S_k for an appropriate time interval (to be determined) from knowledge of u and $\partial_n u$ on S_0 for $0\leqslant t\leqslant T$. Both quantities vanish on S_0 for $0\leqslant t\leqslant t_0$.

The problem of determining $u(x,t)$ in Ω_1 for $0\leqslant t\leqslant t_k$, from knowledge of either $u(x,t)$ or $\partial_n u(x,t)$ on S_0, is well-posed, and can be found in many ways. This fact will be used to first determine the leading (short time) term for $u(x,t)$ and $\partial_n u(x,t)$ on S_k as follows. Since the data on S_0 [the surface $|x-x^0|=c_0 t_0$, where c_0 is the free space value of $c(x)$] have the leading asymptotic terms

$$u(x,t)=\frac{1}{4\pi|x-x^0|}H\left(t-\frac{|x-x^0|}{c_0}\right)+\cdots,\quad x\in S_0, \tag{12}$$

$$\frac{\partial u(x,t)}{\partial n}=-\frac{1}{4\pi c_0|x-x^0|}\delta\left(t-\frac{|x-x^0|}{c_0}\right)+\ldots,\quad x\in S_0, \tag{13}$$

the leading term of $u(x,t)$ in $\overline{\Omega}_1$ for $0\leqslant t\leqslant t_k$ is given by

$$u(x,t)=U_0(x)H(t-\tau(x,x^0))+\cdots. \tag{14}$$

The surfaces S_0 and S_k are given by the wave front surfaces $\tau(x,x^0)=|x-x^0|/c_0=t_0$ and $\tau(x,x^0)=t_k$, respectively. Thus, since the problem is well-posed for $0\leqslant t\leqslant t_k$, and $c(x)$ is continuous, the value of $U_0(x)$ on the surface can be determined. Since the normal to the wave front is in the direction of the gradient of $\tau(x,x^0)$, it follows that the leading form $V_0(x)$ to $\partial_n u$ on S_k as given in the following:

$$\frac{\partial u(x,t)}{\partial n} = V_0(x)\,\delta(t-t_k)+\cdots, \quad t_k=\tau(x,x^0) \tag{15}$$

is given in terms of $U_0(x)$ by

$$V_0(x) = -\frac{\partial \tau}{\partial n} U_0(x) = -\frac{1}{c(x)} U_0(x). \tag{16}$$

Hence the leading term $V_0(x)$ can be found.

The problem now is to determine the remaining portion of $u(x,t)$ and $\partial_n u(x,t)$ on S_k for a time interval (to be specified).

The fundamental solution (or Green's function) $\mathcal{E}(x,y,t)$ of the wave equation will be introduced. It satisfies the system for fixed x,

$$\frac{1}{c^2(y)}\frac{\partial^2 \mathcal{E}}{\partial t^2} - \Delta \mathcal{E} = \delta(x-y)\,\delta(t), \quad x,y\in\mathbb{R}^3, \tag{17}$$

$$\mathcal{E}(x,y,t)=0 \quad \text{for } t<0. \tag{18}$$

Since $c(x)$ is continuous, the fundamental solution will have the leading asymptotic behavior

$$\mathcal{E}(x,y,t)\sim \frac{1}{\rho(x,y)}\,\delta(t-\tau(x,y))+\cdots, \tag{19}$$

where $\tau(x,y)$ is the travel time from point x to point y and vice verse. If $c(x)$ is differentiable, the amplitude factor $\rho(x,y)$ can be found by solving the transport equation. Further details are given in Sec. IV, but are not needed here, other than that $\rho(x,y)$ has the asymptotic value $\rho(x,y)\sim 4\pi|x-y|$ as $y\to x$.

Let $\mathcal{E}_{\mathcal{N}}(x,y,t)$ be the Neumann Green's function for the domain Ω_1, satisfying the Neumann boundary conditions

$$\frac{\partial \mathcal{E}_{\mathcal{N}}(x,y,t)}{\partial n_y}=0, \quad \text{for } x\in\Omega_1 \quad \text{and } y\in S_0\cup S_k. \tag{20}$$

Using this Green's function one can write down the solution $u(x,t)$ to the scattering problem, which satisfies initial conditions $u(x,0)=u_t(x,0)=0$ in $\overline{\Omega}_1$, and Neumann data on S_0 and S_k. We have

$$u(x,t)=\int_0^t \mathrm{d}s\int_{S_k}\mathrm{d}\sigma_y \mathcal{E}_{\mathcal{N}}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y} - \int_0^t \mathrm{d}s\int_{S_0}\mathrm{d}\sigma_y \mathcal{E}_{\mathcal{N}}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y}, \quad x\in\Omega_1, \tag{21}$$

where the normal derivative on both surfaces is taken in the direction of wave front propagation, see Fig. 2. Note that $\partial_n u$ on S_0 vanishes for $0\leqslant t<t_0$, and on S_k for $0\leqslant t<t_k$.

An alternative to expression (21) can be obtained by the usual approach for solving a homogeneous partial differential equation with nonhomogeneous boundary conditions, and that is to replace the solution $u(x,t)$ by the sum $w(x,t)+q(x,t)$ where $q(x,t)$ is a known function that satisfies the initial conditions $q(x,0)=q_t(x,0)=0$, and nonhomogeneous Neumann boundary conditions $\partial_n u=\partial_n q$ on S_0 and S_k. Then $w(x,t)$ satisfies homogeneous boundary and initial conditions and the nonhomogeneous equation

$$\frac{1}{c^2(x)}\frac{\partial^2 w}{\partial t^2} - \nabla^2 w = \nabla^2 q - \frac{1}{c^2(x)}\frac{\partial^2 q}{\partial t^2} = F(x,t). \tag{22}$$

The solution[16] for $w(x,t)$ can then be found in terms of the orthonormal set of eigenfunctions $\{\phi_m\}_{m=0}^{\infty}$ satisfying

$$-c^2(x)\nabla^2\phi_m = w_m^2\phi_m, \quad x\in\Omega_1,$$
$$\frac{\partial\phi_m}{\partial n}=0, \quad x\in S_0 \text{ and } S_k, \tag{23}$$

where w_0 is the zero eigenvalue, and the inner product is given by

$$(\phi_n,\phi_m)=\int_{\Omega_1}\frac{\phi_n(x)\phi_m(y)}{c^2(x)}\,dx. \tag{24}$$

Using this approach, one can show that the resulting solution can be expressed in the form given by Eq. (21) with

$$\mathcal{E}_{\mathcal{N}}(x,y,t)=\sum_{m=0}^{\infty}\frac{\sin(w_m t)}{w_m}\phi_m(x)\phi_m(y), \tag{25}$$

where the convergence of the series (25) is in the sense of distributions. The eigenfunction representation is useful when $\partial_n u$ is known. For the present case $\partial_n u$ on S_k is unknown. To obtain an equation to determine $\partial_n u$ on S_k (apart from the leading term which is already determined), let the $x\in\Omega_1$ in expression (21) approach a point on the surface S_0. One obtains the following integral equation of the first kind for $\partial_n u$ on S_k:

$$u(x,t)=\int_0^t ds\int_{S_k} d\sigma_y\,\mathcal{E}_{\mathcal{N}}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y}-\int_0^t ds\int_{S_0} d\sigma_y\,\mathcal{E}_{\mathcal{N}}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y},$$
$$x\in S_0, \quad 2t_k-t_0\leqslant x\leqslant T. \tag{26}$$

In taking the limit of the second integral on the right-hand side of Eq. (26), one uses the local behavior of $\mathcal{E}_{\mathcal{N}}(x,y,t)$,

$$\mathcal{E}_{\mathcal{N}}(x,y,t)\sim\frac{\delta(t-|x-y|/c(x))}{2\pi|x-y|}, \tag{27}$$

for y on the smooth surface S_0 and x on S_0, very close to y.

From Eq. (26) it is seen that the values of the measured data $u(x,t)$ where $x\in S_0$, $2t_k-t_0\leqslant t\leqslant T$ and $\partial_n u(x,t)$, $x\in S_0$ for $t_0\leqslant t\leqslant T$, can be used to obtain the values of $\partial_n u$ (apart from the leading term which is already known) on S_k for $t_k<t\leqslant T-t_k-t_0$. This implies that when $t_k>(T-t_0)/2$, the nonzero values of $\partial_n u$ cannot be deduced, hence in the inverse problem one cannot obtain the value of $c(x)$ in the region beyond the surface $\tau(x,x_0)=(T-t_0)/2$.

The problem of obtaining $\partial_n u$ on S_k, for $t_k<t\leqslant T-t_k-t_0$, from Eq. (26) is not well-posed. It will require some regularization method or an optimization approach. This will not be pursued here. The question of uniqueness will be examined next.

Let $\mathcal{M}$ be the class of functions $w(y,t)$, $y\in S_k$, $0\leqslant t\leqslant T-t_k-t_0$, such that

(i) $w(y,0)=0$, $0\leqslant t<t_k$;

and if K is the operator

$$u(x,t)=Kw=\int_0^t\int_{S_k}\mathcal{E}_{\mathcal{N}}(x,y,t-s)w(y,s)\,d\sigma_y\,ds, \tag{28}$$

then:

(ii) $u(x,t)\in C(\overline{\Omega}_1)$;

(iii) $u(x,t)$ is a generalized solution of the system

$$\frac{1}{c^2(x)}\frac{\partial^2 u}{\partial t^2}-\nabla^2 u=0, \quad x\in\Omega_1, \quad 0<t,$$
$$u(x,t)=0, \quad x\in\overline{\Omega}_1, \quad 0\leqslant t<t_k. \tag{29}$$

(iv) If n_1 is the unit normal (pointing into Ω_1) at $x^1\in S_k$, the normal derivative of u at x^1 is given by

$$\frac{\partial u(x^1,t)}{\partial n_1}=\lim_{x\in\Omega_1\to x^1} n_1\cdot\nabla_x Kw$$
$$=w(x^1,t)+\int_0^t\int_{S_k}\frac{\partial\mathcal{E}_{\mathcal{N}}}{\partial n_1}(x^1,y,t-s)w(y,s)\,d\sigma_y ds=w(x^1,t), \quad x^1\in S_k, \tag{30}$$

where use is made of the fact that the normal derivative of the Green's function vanishes on the surface.

(v) If n_1 is the unit normal to (pointing into Ω_1) at a point x^1, on S_0, then

$$\frac{\partial u(x^1,t)}{\partial n_1}=\lim_{x\in\Omega_1\to x^1} n_1\cdot\nabla_x u=0, \quad x^1\in S_0. \tag{31}$$

Remark: For condition (30) to hold the surface S_k must be sufficiently smooth and $w(y,t)$ must be at least Hölder continuous. [A similar result involving the Green's function $\mathcal{E}(x,y,t)$ is examined in detail in Sec. IV, where sharper results are required.]

One can now examine the uniqueness of the solution to Eq. (26). If $\partial_n u^1$ and $\partial_n u^2$ are two solutions, let $v(y,t)$ be their difference. It follows from Eq. (26) that

$$Kv=0, \quad x\in S_0, \quad 0\leqslant t\leqslant T. \tag{32}$$

Hence if $v(y,t)$ belongs to class $\mathcal{M}$, then it follows that $u=Kv$ satisfies system (iv), and boundary conditions

$$u+Kv=0, \quad \frac{\partial u}{\partial n}=v, \quad x\in S_k, \quad 0\leqslant t\leqslant T-t_k-t_0, \tag{33}$$

$$u=0, \quad \frac{\partial u}{\partial n}=0, \quad x\in S_0, \quad 0\leqslant t\leqslant T. \tag{34}$$

Conditions (33) imply that $v(y,t)$ generates an incoming wave across the surface S_k (produced by sources in Ω_2). Conditions (34) imply that the surface S_0 is both a hard and soft surface, which in general are incompatible, unless $v\equiv 0$. This suggests that Eq. (26) is unique in the class of functions $\mathcal{M}$.

Once $\partial_n u$ is known on S_k, then $u(x,t)$ for $x\in S_k$ and $0\leqslant t\leqslant T-t_k-t_0$ can be obtained from the following:

$$u(x,t)=\int_0^t ds\int_{S_k} d\sigma_y\,\mathcal{E}_{\mathcal{N}}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y}-\int_0^t\int_{S_0} d\sigma_y\,\mathcal{E}_{\mathcal{N}}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y},$$
$$x\in S_k, \quad t_k\leqslant t\leqslant T-t_k-t_0, \tag{35}$$

which is derived from Eq. (21) by letting $x\in\Omega_1$ approach the surface S_k. As a result, $u(x,t)$ and $\partial_n u(x,t)$ on the surface S_k can be found from Eqs. (26) and (35).

IV. OUTGOING WAVE CONDITION AND DETERMINATION OF $\partial_n c$ ON S_k

Once the values of u and $\partial_n u$ (or at least the leading asymptotic short-time behavior) are known on S_k, the next step is to develop a condition that utilizes this information on S_k, to infer values of $c(x)$, in particular $\partial_n c$.

The leading asymptotic terms for u and $\partial_n u$ on S_k will be given as follows:

$$u(x,t)=H(t-t_k)[U_0(x)+(t-t_k)U_1(x)+\cdots], \quad x\in S_k, \tag{36}$$

$$\frac{\partial u(x,t)}{\partial n}=\delta(t-t_k)V_0(x)+H(t-t_k)[V_1(x)+\cdots], \quad x\in S_k, \tag{37}$$

where, as will be seen, $U_0(x)$ and $V_0(x)$ are not independent, since S_k is the wave front at time $t=t_k$. For the present purposes it will be assumed that $U_0(x)$, $U_1(x)$ and $V_1(x)$ are at least Hölder continuous, and $V_0(x)$ is a Hölder differentiable function of x on S_k.

It will be assumed that the surface is C^2. In particular, if x^1 is a point on the surface and (y_1,y_2,y_3) is a local Cartesian coordinate system centered at x^1 so that $x^1=(0,0,0)$, with the y_3 pointing into the domain Ω_2 in a direction normal to the surface at x^1, then the surface will be described locally by

$$y_3=a_1y_1^2+a_3y_2^2+\cdots, \tag{38}$$

where the y_1 and y_2 axes are along the directions of principal curvature.

Let $\mathcal{E}(x,y,t)$ be the fundamental solution of the wave equation for points $x,y\in\overline{\Omega}_2$. Hence if $x\in\Omega_2$, the solution $u(x,t)$ of the wave equation in Ω_2, which satisfies the initial condition $u(x,0)=u_t(x,0)=0$ in Ω_2, can be expressed in terms of the Dirichlet and Neumann data on S_k by the relation

$$u(x,t)=-\int_0^t\int_{S_k}\mathcal{E}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y}\mathrm{d}\sigma_y\,\mathrm{d}s+\int_0^t\int_{S_k}\frac{\partial\mathcal{E}(x,y,t-s)}{\partial n_y}u(y,s)\mathrm{d}\sigma_y\,\mathrm{d}s, \tag{39}$$

where the normal to S_k points into Ω_2.

Next, the resulting equation obtained from (39) when $x\in\Omega_2$ approaches a point x (say x^1) on S_k will be sought. Then, this will be used to obtain the relationship between the coefficients of the short-time behavior of u and $\partial_n u$ as expressed by Eqs. (36) and (37). This means that the short-time behavior of $\mathcal{E}(x,y,t)$ for a point x in Ω_2 close to or on S_k, and point a y on S_k close to x will be needed.

Since in the derivation of Eq. (39) only the domain Ω_2 (but not Ω_1) is involved, the value of $c(x)$ in Ω_1 is not specified and is free to be chosen. With this in mind, it will be assumed that in order to get the short-time behavior of $\mathcal{E}(x,y,t)$ with x close to $y\in S_k$, that $c(x)$ is defined to be locally extended into Ω_1 as a C^2 function.

The Green's function will take the form

$$\mathcal{E}(x,y,t)=\frac{\delta(t-\tau(x,y))}{\rho(x,y)}+p(x,y,t), \tag{40}$$

where $\tau(x,y)$ satisfies the Eikonal equation

$$|\nabla\tau(x,y)|^2=1/|c(x)|^2. \tag{41}$$

It can be shown that it has the form for small (x,y),

$$\tau(x,y)=\frac{|x-y|}{\sqrt{c(x)c(y)}}[1-q(x,y)+O(|x-y|)^3], \tag{42}$$

$$q(x,y)=-\frac{|x-y|^2}{12}\left(\frac{|\nabla c(x)|}{c(x)}\right)^2+\frac{1}{6}\sum_{j=k=1}^{3}(y_j-x_j)(y_k-x_k)\left(\frac{1}{c}\frac{\partial^2 c}{\partial x_j \partial x_k}\right). \tag{43}$$

The amplitude factor $(1/\rho)$ satisfies the transport equation

$$2\nabla\tau\cdot\nabla\rho-\rho\nabla^2\tau=0, \tag{44}$$

and is given for small $|x-y|$, by

$$\rho(x,y)=4\pi|x-y|[1+Q|x-y|^2+\cdots], \tag{45}$$

where Q, the term of order $|x-y|^2$ in expression (45), depends upon the first and second partial derivatives of $c(x)$, as well as the direction cosines of the vector $y-x$.

The second term in expression (40) satisfies the system

$$\frac{1}{c^2(y)}\frac{\partial^2 p}{\partial t^2}-\nabla^2 p=\delta(t-\tau(x,y))\nabla^2\left(\frac{1}{\rho}-\frac{1}{4\pi|x-y|}\right), \tag{46}$$

$$p(x,y,t)=0, \quad t<0. \tag{47}$$

Since the term in the Laplacian on the right-hand side of (46) behaves like

$$\left(\frac{1}{\rho}-\frac{1}{4\pi|x-y|}\right)\sim-\frac{1}{4\pi}Q|x-y|+\cdots, \tag{48}$$

for $|x-y|$ small, the Laplacian of this quantity has at most a singularity of order $|x-y|^{-1}$ as $y\to x$. From this it can be deduced that, besides vanishing for $t>\tau(x,y)$, $p(x,y,t)$ is bounded as y approaches x.

For y a point on S_k, it follows from (40) that

$$\frac{\partial\mathcal{E}(x,y,t)}{\partial n_y}=-\frac{\delta'(t-\tau(x,y))}{\rho(x,y)}\frac{\partial\tau(x,y)}{\partial n_y}-\frac{\delta(t-\tau(x,y))}{[\rho(x,y)]^2}\frac{\partial\rho(x,y)}{\partial n_y}+\frac{\partial p(x,y,t)}{\partial n_y}. \tag{49}$$

In terms of local coordinates centered at $x^1=(0,0,0)$ on S_k and with $x=(0,0,x_3)$ and $y=(y_1,y_2,y_3)$ a point on S_k where y_3 is given by Eq. (38), it can be shown that

$$\frac{1}{\rho(x,y)}\frac{\partial\tau(x,y)}{\partial n_y}\mathrm{d}\sigma_y=-\frac{\left[\Sigma_{j=1}^2 y_j^2\left(a_j+\frac{1}{2}\alpha_3\right)+x_3\left(1-\frac{1}{2}\Sigma_{j=1}^2\alpha_j y_j+\alpha_3 x_3\right)\right]}{4\pi c(x)[y_1^2+y_2^2+(x_3-a_1y_1^2-a_2y_2^2)^2]}\mathrm{d}y_1\mathrm{d}y_2, \tag{50}$$

where cubic and higher order terms are neglected in the numerator, and

$$\alpha_j=\frac{1}{c(x)}\frac{\partial c(x)}{\partial x_j}, \quad j=1,2,3. \tag{51}$$

Similarly it can be shown to the same order that

$$\frac{1}{[\rho(x,y)]^2}\frac{\partial\rho(x,y)}{\partial n_y}\mathrm{d}\sigma_y=-\frac{[a_1y_1^2+a_2y_2^2+x_3]\mathrm{d}y_1\mathrm{d}y_2}{4\pi[y_1^2+y_2^2+(x_3-a_1y_1^2-a_2y_2^2)^2]^{3/2}}. \tag{52}$$

One is now in a position to let x_3 approach zero, and thus obtain the equation corresponding to (39), when x is now on S_k. The approach that is employed is the usual procedure that is used

for a double layer potential.[16] Because of this, the only modification that is needed is due to the leading step function behavior of $u(x,t)$ when t approaches t_k, as is indicated by Eq. (36). The critical term in Eq. (39) is the integral

$$-\int_{S_k}\frac{u(x,t-\tau(x,y))}{[\rho(x,y)]^2}\frac{\partial\rho(x,y)}{\partial n_y}\mathrm{d}\sigma_y, \tag{53}$$

which arises when expression (49) is inserted into (39). In particular, the portion of $\partial_{n_y}\rho$ that is critical is the component in Eq. (52) involving x_3 in the numerator. One first integrates this portion over a small disk of radius ϵ and centered at (0,0) in the (y_1,y_2) plane, and then lets x_3 approach zero (through positive values). Finally the limit $\epsilon\to 0$ is taken. The integral under consideration is thus

$$x_3\int_0^{2\pi}\int_0^{\epsilon}\frac{H(t-t_k-\tau(x,y))U_0(y)}{4\pi(r^2+x_3^2)^{3/2}}r\,\mathrm{d}r\,\mathrm{d}\theta, \tag{54}$$

where the leading term of $u(y,t)$ is taken, and polar coordinates (r,θ)

$$y_1=r\cos\theta,\quad y_2=r\sin\theta, \tag{55}$$

are introduced. One needs to consider the integral (54) in the time interval $0<c(x)(t-t_k)\leqslant\epsilon$. With $\tau(x,y)$ given approximately by $\sqrt{r^2+x_3^2}/c(x)$, $U_0(y)H(t-t_k-\tau(x,y))$ is expanded about the point $x^1=(0,0,0)$ as follows:

$$[H(t-t_k-\tau(x,y))-H(t-t_k)]U_0(x^1)+H(t-t_k-\tau(x,y))[U_0(y)-U_0(x^1)]+H(t-t_k)U_0(x^1). \tag{56}$$

Since $U_0(y)$ is differentiable $|U_0(y)-U_0(x^1)|\leqslant$ constant $\cdot r$, so that the second term in (56) poses no problem. The last term in (56) inserted into (54) yields, on letting $x_3\to 0$,

$$\int_0^{2\pi}\int_0^{\epsilon}\frac{x_3H(t-t_k)U_0(x^1)}{4\pi(r^2+x_3^2)^{3/2}}r\,\mathrm{d}r\,\mathrm{d}\theta=\frac{H(t-t_k)U_0(x^1)}{2}\left[1-\frac{x_3}{\sqrt{\epsilon^2+x_3^2}}\right]\to\frac{1}{2}H(t-t_k)U_0(x^1), \tag{57}$$

as is expected. Insertion of the first term of (56) into (54) yields the limit, as $x_3\to 0$,

$$-\frac{1}{4\pi}\int_0^{2\pi}\int_{r_0}^{\epsilon}\frac{x_3U_0(x^1)}{(r^2+x_3^2)^{3/2}}r\,\mathrm{d}r\,\mathrm{d}\theta\to 0,\quad 0<c(x)(t-t_k)\leqslant\epsilon, \tag{58}$$

where $r_0^2+x_3^2=(t-t_k)^2c^2(x)$ and the approximation $\tau(x,y)=(r^2+x_3^2)^{1/2}/c(x)$ is used.

Thus one obtains the usual result as $x\in\Omega_2\to x^1$ on S_k, namely that the limit of expression (53) as $x\to x^1$ is given by

$$\frac{1}{2}u(x^1,t)-\int_{S_k}\frac{u(y,t-\tau(x^1,y))}{[\rho(x^1,y)]^2}\frac{\partial\rho(x^1,y)}{\partial n_y}\mathrm{d}y,\quad t>t_k. \tag{59}$$

Henceforth the superscript one for x on S_k will be dropped. The resulting equation corresponding to Eq. (39) when $x\in S_k$ is

$$u(x,t)=-2\int_0^t\int_{S_k}\mathcal{E}(x,y,t-s)\frac{\partial u(y,s)}{\partial n_y}\mathrm{d}\sigma_y\,\mathrm{d}s+2\int_0^t\int_{S_k}\frac{\partial\mathcal{E}(x,y,t-s)}{\partial n_y}u(y,s)\mathrm{d}\sigma_y\,\mathrm{d}s \tag{60}$$

for $t>t_k$. When $t<t_k$, both sides are zero. When both $u(x,t)$ and $\partial_n u(x,t)$ are known on S_k for $t_k \leqslant t \leqslant T-t_k-t_0$, Eq. (60) constitutes a nonlinear equation to determine $c(x)$ in Ω_2. A numerical method could be used to solve this nonlinear equation for $c(x)$.

As an example of how Eq. (60) can be used to determine the normal derivative of $c(x)$, we will use an asymptotic expansion approach here. We assume that $c(x)$ has sufficient smoothness in a small neighborhood of the boundary, such that the asymptotic expansion of the Green's function in the form (40) is valid. We notice that Eq. (60) only uses the exterior values of the Green's function, and hence is independent of the velocity in the interior region Ω_1, and hence we can assume that $c(x)$ is sufficiently smooth over the boundary. We assume that only the leading coefficients, U_0, U_1, V_0, and V_1 of $u(x,t)$ and $\partial_n u(x,t)$ [as given by Eqs. (36) and (37)] are known.

Let x be the point $(0,0,0)$ on S_k and y the point $(r\cos\theta, r\sin\theta, r^2(a_1\cos^2\theta + a_2\cos^2\theta)+\cdots)$ on S_k, where the polar coordinates Eq. (55) are used. It then follows from Eqs. (42), (45), (50), and (51) with $x_3=0$, that

$$c(x)\tau(x,y) = r\left[1 - \frac{r}{2}(\alpha_1\cos\theta + \alpha_2\sin\theta)+\cdots\right], \tag{61}$$

$$\frac{1}{\rho(x,y)}\,d\sigma_y = \frac{1}{4\pi}[1+O(r^2)]\,dr\,d\theta, \tag{62}$$

$$\frac{1}{\left(\dfrac{\partial\tau}{\partial\rho}\right)} = c(x)[1 + r(\alpha_1\cos\theta + \alpha_2\sin\theta)+\cdots], \tag{63}$$

$$\frac{1}{\rho(x,y)}\,\frac{\partial\tau(x,y)}{\partial n_y}\,d\sigma_y = -\frac{[(a_1+\frac{1}{2}\alpha_3)\cos^2\theta + (a_2+\frac{1}{2}\alpha_3)\sin^2\theta]r\,dr\,d\theta}{4\pi c(x)}, \tag{64}$$

$$\frac{1}{[\rho(x,y)]^2}\,\frac{\partial\rho(x,y)}{\partial n_y}\,d\sigma_y = -\frac{1}{4\pi}(a_1\cos^2\theta + a_2\sin^2\theta)\,dr\,d\theta\,. \tag{65}$$

To obtain the asymptotic results the following result,

$$\begin{aligned}\int_0^\infty \delta(t-\tau(x,y))r^n dr &= H(t)\left(r^n\left(\frac{\partial\tau}{\partial r}\right)^{-1}_{\tau=t}\right)\\ &= c(x)H(t)[c(x)t]^n\left[1+\left(\frac{n}{2}+1\right)c(x)t(\alpha_1\cos\theta+\alpha_2\sin\theta)+O(t^2)\right],\end{aligned} \tag{66}$$

will be used.

The leading asymptotic form (for small $t-t_k$) of the integral

$$-2\int_0^t\int_{S_k}\mathcal{E}(x,y,t-s)\,\frac{\partial u(y,s)}{\partial n_y}\,d\sigma_y\,ds \tag{67}$$

is obtained by replacing $\partial_n u$ in Eq. (67) by the asymptotic expression (for small $s-t_k$)

$$\frac{\partial u(y,s)}{\partial n_y} = \delta(s-t_k)\left[V_0(x) + r\left(\frac{\partial V_0}{\partial x_1}\cos\theta + \frac{\partial V_0}{\partial x_2}\sin\theta\right)+O(r^2)\right] + H(s-t_k)[V_1(x)+\cdots, \tag{68}$$

and neglecting the contribution to $\mathcal{E}(x,y,t-s)$ of $p(x,y,t-s)$ which, since it is bounded and vanishes for $t-s<\tau(x,y)$, produces a term of $O(t-t_k)^2$ in the resulting expression for the integral (67). Thus the leading terms of the integral (67) is given by

$$-\frac{1}{2\pi}\int_0^t\int_0^{2\pi}\int_0^\infty \delta(t-s-\tau(x,y))\,\delta(s-t_k)\left[V_0(x)+r\left(\frac{\partial V_0}{\partial x_1}\cos\theta+\frac{\partial V_0}{\partial x_2}\cos\theta\right)+\cdots\right] r\,dr\,d\theta\,ds$$

$$-\frac{1}{2\pi}\int_0^t\int_0^{2\pi}\int_0^\infty \delta(t-s-\tau(x,y))H(s-t_k)[V_1(x)+\cdots]\,dr\,d\theta\,ds. \tag{69}$$

This can be evaluated using (66), to give

$$-c(x)H(t-t_k)[V_0(x)+(t-t_k)V_1(x)+O(t-t_k)^2]. \tag{70}$$

The second integral on the right-hand side of Eq. (60) [on using Eq. (49)] has the explicit form

$$-2\frac{\partial}{\partial t}\int_0^t\int_{S_k}\frac{\delta(t-s-\tau(x,y)}{\rho(x,y)}\frac{\partial\tau}{\partial n_y}(x,y)u(y,s)\,d\sigma_y\,ds$$

$$-2\int_0^t\int_{S_k}\left\{\frac{\delta(t-s-\tau(x,y))}{[\rho(x,y)]^2}\frac{\partial\rho(x,y)}{\partial n_y}-\frac{\partial p(x,y,t-s)}{\partial n_y}\right\}u(y,s)\,d\sigma_y\,ds\,. \tag{71}$$

Replacing $u(y,s)$ by $H(s-t_k)[U_0(x)+O(s-t_k)]$ the leading terms of expression (71) are given by

$$\frac{1}{2\pi c(x)}\frac{\partial}{\partial t}\int_{t_k}^t\int_0^{2\pi}\int_0^\infty \delta(t-s-\tau(x,y))\left[\left(a_1+\frac{1}{2}\alpha_3\right)\cos^2\theta+\left(a_2+\frac{1}{2}\alpha_3\right)\sin^2\theta\right]U_0(x)r\,dr\,d\theta\,ds$$

$$+\frac{1}{2\pi}\int_{t_k}^t\int_0^{2\pi}\int_0^\infty \delta(t-s-\tau(x,y))[a_1\cos^2\theta+a_2\sin^2\theta]U_0(x)\,dr\,d\theta\,ds$$

which, on using relation (66), reduces to

$$\frac{c(x)}{4}\frac{\partial}{\partial t}\{H(t-t_k)(t-t_k)^2[U_0(x)(a_1+a_2+\alpha_3)+O(t-t_k)^3]\}$$

$$+\frac{1}{2}c(x)H(t-t_k)[(t-t_k)U_0(x)(a_1+a_2)+O(t-t_k)^2]$$

$$=H(t-t_k)\left[(t-t_k)c(x)\left(a_1+a_2+\frac{1}{2}\alpha_3\right)U_0(x)+O(t-t_k)^2\right]. \tag{72}$$

Thus inserting the results of Eqs. (70) and (72) into the right-hand side of Eq. (60) and Eq. (36) into the left-hand side of Eq. (60), one has the following asymptotic result:

$$H(t-t_k)[U_0(x)+(t-t_k)U_1(x)+\cdots]=-H(t-t_k)[c(x)V_0(x)+(t-t_k)c(x)(V_1(x)$$

$$-(a_1+a_2+\tfrac{1}{2}\alpha_3)U_0(x))]. \tag{73}$$

Equating coefficients of $t-t_k$, one obtains

$$U_0(x)=-c(x)V_0(x), \tag{74}$$

which is to be expected since S_k is a wave front at $t=t_k$. Equating the coefficients of $(t-t_k)H(t-t_k)$ one obtains

$$U_1(x) = -c(x)[V_1(x) - (a_1 + a_2 + \tfrac{1}{2}\alpha_3)U_0(x)], \tag{75}$$

where $U_1(x)$, $U_0(x)$, $V_1(x)$, $c(x)$, a_1, and a_2 are known at the point x on S_k. Since

$$\alpha_3 = \lim_{x \in \Omega_2 \to x \in S_k} \frac{1}{c(x)} \frac{\partial c}{\partial x_3}, \tag{76}$$

it follows that from Eq. (75) one can determine

$$\lim_{x \in \Omega_2 \to x \in S_k} \frac{\partial c}{\partial n}, \tag{77}$$

at the point x on S_k. In the practical use of layer stripping one assumes that $c(x)$, $\partial_n c$ are known at the bottom of each layer and using a model of $c(x)$ which is linear in the direction normal to the bottom surface, one uses the results of condition (75) to determine $\partial_n c$ at the bottom of the next layer [i.e., $c(x)$ is piecewise differentiable in the direction normal to the wave front].

The process is strongly dependent on good estimates of the wave front surfaces S_k, $k = 1,2,\ldots$, which depend upon the value of c, $\partial_n c$ on each surface S_{k-1}. However one can use an iterative Newton process to improve the value of c, $\partial_n c$ on S_k by using both the values of c, $\partial_n c$ on S_{k-1} and the derived values of c, $\partial_n c$ on S_k.

V. EFFECT OF CAUSTICS

The procedure developed in the previous sections has to be modified considerably when caustics appear. The approach in these sections stresses the formulation of the problem primarily in terms of wave fronts at the expense of the rays. However when rays intersect to form caustics, the rays must be emphazised instead of the wave fronts. Thus one has to use the Hamilton–Jacobi system for the bicharacteristics [the rays being the projection onto $x = (x_1, x_2, x_3)$] given as follows:

$$\frac{\partial x_j}{\partial s} = p_j, \quad \frac{\partial p_j}{\partial s} = \frac{1}{c} \frac{\partial c^{-1}}{\partial x_j}, \quad j = 1,2,3, \tag{78}$$

where the ray parameter s is related to the travel time parameter τ by the relation

$$c^2 \, \mathrm{d}\tau = \mathrm{d}s. \tag{79}$$

Even though global ray coordinates (s, θ, ϕ) can be used to specify points on the rays, also at caustics and beyond, the local coordinates (x_1, x_2, x_3) cannot be used to specify the rays at caustics and instead one must use one of the sets (x_i, x_j, p_k), (x_i, p_j, p_k), or (p_1, p_2, p_3), where i, j, k are distinct numbers belonging to the set 1,2,3, choosing the set of local coordinates that yield a unique point for the rays. This choice depends upon the local structure of the caustics. Thus, at a caustic and beyond, one cannot use the asymptotic formulation (36) of the wave equation that was used in Sec. IV. In addition, once the initial wave front has passed through the caustic one may end up with multiple wave fronts. This means that the simple formulation of global nested wave front layers cannot be used at caustics and beyond and has to be modified.

Because the procedure in Sec. IV involves local analysis in time and space, the basic idea behind the method used in Sec. IV to determine the value of the normal derivative of c, namely $\partial_n c$, on a local portion of an adjacent wave front surface, can still be employed. A possible approach is to use the Maslov Lagrangian formulation,[17,18] to determine the asymptotic nature of the field in a neighborhood of the caustic. To get the short-time behavior of the field, one could take the Fourier transform with respect to the time variable, (mapping the t-line into the ω-line) and on setting

$$k=\omega/c_0, \quad \frac{\omega^2}{c^2}=k^2\epsilon(x), \tag{80}$$

reducing the wave equation to the form

$$\nabla^2 u+k^2\epsilon(x)u=0. \tag{81}$$

Then one can look for asymptotic solutions of Eq. (81) for large ω or k, using the Maslov precanonical operator K. In the neighborhood of a caustic point, taken as origin, the asymptotic form of the solution $u(x,k)$ of Eq. (81) will have the various forms

$$u(x,k)=\int_{\mathbb{R}}\phi(x_2,x_3,p_1)e^{ik(\pm p_1^3-x_1p_1)}\mathrm{d}p_1,$$

$$u(x,k)=\int_{\mathbb{R}}\phi(x_2,x_3,p_1)e^{ik(\pm p_1^4+x_2p_1^2-x_1p_1)}\mathrm{d}p_1,$$

$$u(x,k)=\int_{\mathbb{R}}\phi(x_2,x_3,p_1)e^{ik(\pm p_1^5+x_3p_1^3+x_2p_1^2-x_1p_1)}\mathrm{d}p_1,$$

$$u(x,k)=\int_{\mathbb{R}^2}\phi(x_3,p_1,p_2)e^{ik(\pm p_1^2p_2\pm p_2^3+x_3p_2^2-x_2p_2-x_1p_1)}\mathrm{d}p_1\,\mathrm{d}p_2,$$

the choice of which depends upon which local coordinate system that can be used to specify the rays in the neighborhood of the caustic. By Fourier transforming back to the time domain and using the result that the near wave front time behavior t can be obtained from the asymptotic behavior for large ω or k, one can obtain the proper local small time asymptotic behavior of the wave field $u(x,t)$ that can be used in Eq. (60) of Sec. IV. As can be seen there will be a considerable amount of analysis to estimate the integrals in these expressions. The details and hard analysis will be pursued in future work.

VI. SUMMARY

It has been demonstrated in the inverse problem that one can do layer stripping following the wave front until caustics appear, without resorting to wave splitting. The procedure for obtaining the values of u and $\partial_n u$ on the surface S_k (wave front at time $t=t_k$) from knowledge of the corresponding values on the surface S_{k-1} (wave front at time $t=t_{k-1}$), has been examined from a theoretical viewpoint in Sec. III, in order to determine what limitations there are. In order to investigate how far into the interior of the scattering object one can determine $c(x)$ when the initial data were measured on the surface S_0 for a restricted time T, the actual analysis was performed for the region S_0 and S_k instead of the curvilinear slab between S_{k-1} and S_k. By using the value of c and $\partial_n c$ on the bottom surface S_{k-1} of the curvilinear slab, one can obtain an estimate for the value of $c(x)$ for the top surface S_k of the curvilinear slab. Then the results of Sec. IV can be used to obtain the value of $\partial_n c$ on the top surface S_k.

In Sec. V an approach is briefly outlined as how to extend the method to the region in and beyond a neighborhood of a caustic. This will require future work to pursue.

One of the advantages of wave-front layer stripping as opposed to planar wave stripping is that it is a more natural numerical procedure in that rays are used to follow the propagation of singularities (the wave front). Also the procedure to determine the normal derivative of c from the asymptotic short-time behavior of the field quantities on an adjacent wave front surface is much simpler.

The procedure to determine u and $\partial_n u$ on the top surface S_k from the data on the bottom surfaces S_{k-1} of the curvilinear slabs needs to be examined further to develop a better numerical

approach to the problem. First, Eqs. (26) and (25) must be modified by taking as the spatial domain of the second integrals, the surface S_{k-1} (instead of S_0) and by replacing t_0 by t_{k-1} in the corresponding time intervals. In addition x in Eq. (26) must lie on S_{k-1} (instead of S_0). The normal derivative of the Green's function $\partial_n \mathcal{E}$ vanishes on S_k and S_{k-1}. [Note that the latter condition can be relaxed by requiring that the normal derivative only vanishes on S_k. In this case, Eqs. (26) and (25) would have to be modified accordingly.] Since the equation corresponding to Eq. (26) is an integral equation of the first kind for the unknown $\partial_n u$, it should be replaced by a regularized version for numerical stability.

As a first step in determining u and $\partial_n u$ on the surface S_k from knowledge of their values on the surface S_{k-1}, together with knowledge of $c(x)$ between the two surfaces S_k and S_{k-1}, it should be noted that their leading terms U_0 and V_0 in expansions (36) and (37) are immediately obtained through ray theory.

In order to determine the remaining portions of the unknowns u and $\partial_n u$ on S_k, it should be noted that the layer between the surfaces S_k and S_{k-1} is very thin, and this allows some approximations to be made to simplify the calculations. For a short-time interval beginning with time t_k (the time the wave front inpinges on the surface S_k), a local parallel plane approximation to the domain between the two surfaces, and hence, a local expansion for the Green's function can be used. (An even simpler representation is achieved if one uses the formulation where the normal derivative of the Green's function vanishes on S_k only, as mentioned previously). It may be possible to extend the results for a longer time interval by including the local curvature of the surfaces.

Even for times much greater than t_k the local approximation may give a good approximation to u and $\partial_n u$ at a point x on S_k, provided that the values of the data u and $\partial_n u$ on S_{k-1} are not too small in a small neighborhood of x, and at the same time their values outside the neighborhood are not too large. All this has to be quantized by the appropiate analysis. For cases where this approach is invalid, other methods have to be investigated and employed.

Direct calculation of thermodynamic quantities for the Heisenberg model

Go Kato[a] and Miki Wadati[b]
Department of Physics, Graduate School of Science, University of Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113-0033, Japan

(Received 11 September 2001; accepted for publication 15 May 2002)

The XXX Heisenberg model is studied at finite temperature. The free energy is derived without recourse to thermal Bethe ansatz method and quantum transfer matrix method. The result perfectly agrees with the free energy derived by thermal Bethe ansatz method. An explicit expression of the cluster expansion coefficient in arbitrary order is presented for the first time. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1501444]

I. INTRODUCTION

In a pioneer work,[1] Bethe solved the XXX Heisenberg model. The Hamiltonian of the model is written as

$$H(J,h)=-J\sum_{j=1}^{N}(S_j^xS_{j+1}^x+S_j^yS_{j+1}^y+S_j^zS_{j+1}^z)+2h\sum_{j=1}^{N}S_j^x+\text{constant}, \tag{1.1}$$

where J is the coupling constant and h is the external field. The energy of the system is given by

$$E_M=2hM+\sum_{j=1}^{M}\frac{2J}{x_j^2+1}, \tag{1.2}$$

where M is the number of up-spins and the variables x_j are required to satisfy the Bethe ansatz (BA) equation,

$$\left(\frac{x_j+i}{x_j-i}\right)^N=\prod_{j'\neq j}\frac{x_j-x_{j'}+2i}{x_j-x_{j'}-2i}. \tag{1.3}$$

It was shown[1] that every eigenstate of this model corresponds to a solution of this simultaneous equation.

The XXX Heisenberg model is the quantum integrable system. The thermal Bethe ansatz method (TBA)[2] and quantum transfer matrix method (QTM)[3–7] are the well-known methods to derive thermodynamic quantities for quantum integrable systems. TBA was originated by Yang and Yang,[2] who derived the thermodynamics of repulsive δ-function Bose gas system. Then, on the assumption of the so-called string hypothesis, Takahashi[8] applied TBA to the Heisenberg model. Recently, some analytical results of thermodynamic quantities using QTM were presented by Klümper.[9,10] Many pieces of the concept with respect to QTM had been introduced before then. The equivalence of the results using TBA and QTM was proved by several researchers.[9,11–13]

Our purpose is to derive the free energy of this system independent of TBA and QTM. In this paper, we use a method which we call a direct method. We start from the string hypothesis. There are no other mathematical assumptions except for the string hypothesis. In other words, using the

[a]Electronic mail: kato@monet.phys.s.u-tokyo.ac.jp
[b]Electronic mail: wadati@phys.s.u-tokyo.ac.jp

direct method, a problem based on the string hypothesis is solved. On the other hand, TBA is a method to solve the problem using a definition of nonequilibrium state entropy. As a main result of this paper, the direct method justifies TBA.

The direct method was used for the δ-function Bose system.[14–17] We apply the method to the Heisenberg model here. We define z and β as $z \equiv e^{-2\beta h}$ and $\beta \equiv 1/k_B T$. The direct method enables us to express the cluster expansion coefficients b_n in arbitrary order explicitly,

$$\log[z^{N/2}\mathrm{Tr}\, e^{-\beta H(J,h)}] \equiv \sum_{n=1}^{\infty} b_n z^n, \tag{1.4}$$

and, the free energy,

$$\frac{1}{N}\log[\mathrm{Tr}\, e^{-\beta H(J,h)}], \tag{1.5}$$

by use of a function which is a solution of a nonlinear integral equation. Thus, we can show that the expression of the free energy perfectly agrees with the results of TBA.[11]

The outline of this paper is the following. In Sec. II, we derive an explicit expression of cluster expansion coefficients in all orders. In Sec. III, we prove that the free energy can be expressed in terms of a solution of a nonlinear integral equation. Section IV is devoted to the concluding remarks. Technical details of calculations are summarized in Appendices A–H.

II. THE CLUSTER EXPANSION

The string hypothesis is formulated as follows. In the thermodynamic limit, the energy of the Heisenberg model (1.1) can be written as

$$E_M(J,h) = 2hM + \sum_{n,\alpha} \frac{2Jn}{(x_\alpha^n)^2 + n^2}. \tag{2.1}$$

Here, the variables x_α^n are determined by

$$\left(\frac{x_\alpha^n + ni}{x_\alpha^n - ni}\right)^N = \prod_{(m,\beta)\neq(n,\alpha)} E_{nm}(x_\alpha^n - x_\beta^m), \tag{2.2}$$

where

$$E_{nm}(x) = \frac{(x-(n+m)i)(x-|n-m|i)}{(x+(n+m)i)(x+|n-m|i)} \prod_{l=0}^{\min(n,m)} \left(\frac{x+(n+m-2l)i}{x-(n+m-2l)i}\right)^2. \tag{2.3}$$

Equation (2.2) is referred to as string center equation. Every eigenstate corresponds to a solution of these simultaneous equations. Taking a logarithm of both sides of (2.2), we obtain

$$2N\tan^{-1}\left(\frac{x_\alpha^n}{n}\right) = 2\pi I_\alpha^n + \sum_{(m,\beta)\neq(n,\alpha)} \Delta_{n,m}(x_\alpha^n - x_\beta^m), \tag{2.4}$$

where

$$\Delta_{n,m}(x) = -2\tan^{-1}\left(\frac{x}{n+m}\right) - 2(1+\delta_{nm})\tan^{-1}\left(\frac{x}{|n-m|}\right) + \sum_{l=0}^{\min(n,m)} 4\tan^{-1}\left(\frac{x}{n+m-2l}\right). \tag{2.5}$$

From now on, we call (2.4) modified Bethe ansatz (mBA) equation.

The string hypothesis indicates that the partition function is a sum of the Boltzmann weights with respect to integers (or half integers) $\{I_\alpha^n\}$ which define the energy of the system,

$$z^{N/2}\mathrm{Tr}\, e^{-\beta H(J,h)}=\sum_M \sum_{\{I_\alpha^n\}} e^{-\beta E_M(J,h)}. \tag{2.6}$$

When we take the thermodynamic limit, we can replace the summations over discrete variables by integral,

$$\sum_M \int e^{-\beta E_M(J,h)} \prod dI_\alpha^n. \tag{2.7}$$

There are some points which we have to consider carefully. The Fermi statistics must be taken into account in this integral. In this case, the exclusion property leads to the conditions that $x_\alpha^n \neq x_\beta^n$ and that a state specified by $\{x_\alpha^n\}$ and a state specified by $\{x_\alpha'^n\}$ which satisfies $x_\alpha'^n = x_{p(\alpha)}^n$ are the same, where p is a permutation.

To express a concrete form of (2.7), we prepare three symbols.

Definition 1: N_A denotes the number of elements in a set A.

Definition 2: $\Theta(A)$ denotes all the patterns of division of a set A. A pattern of division is represented as a set having elements each of which is a cluster. The cluster is one of the pieces into which a set A is divided, and the cluster is regarded as a set. For example, for $A=\{a,b,c\}$, $\Theta(A)$ means

$$\Theta(\{a,b,c\})=\{\{a\},\{b\},\{c\}\},\{\{a\},\{b,c\}\},$$
$$\{\{b\},\{c,a\}\},\{\{c\},\{a,b\}\},\{\{a,b,c\}\}. \tag{2.8}$$

On condition that the domain of $\Theta(n)$ is the natural number, $n\in\mathbb{N}$, $\Theta(n)$ is interpreted as $\Theta(\{1,2,...,n\})$.

Definition 3: $\overline{\Theta}(B)$ denotes all the patterns of division of a set B, when each element of B is a set and each pattern of division satisfies the following condition—all the sets which are included in each cluster have the same number of elements. For example, we can show for $\sigma_1=\{a,b\}$, $\sigma_2=\{c\}$, $\sigma_3=\{d\}$,

$$\overline{\Theta}(\{\sigma_1,\sigma_2,\sigma_3\})=\{\{\sigma_1\},\{\sigma_2\},\{\sigma_3\}\},\{\{\sigma_1\},\{\sigma_2,\sigma_3\}\}. \tag{2.9}$$

Using the above given symbols, the integral (2.7) can be written explicitly in the following form:

$$z^{N/2}\mathrm{Tr}\, e^{-\beta H(J,h)}=1+\sum_{n=1}^{\infty}\frac{z^n}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\overline{\Theta}(\theta)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}(N_{\theta'}-1)!\right]$$
$$\times\int\left|\frac{\partial I}{\partial x}\right|_{N,\zeta} e^{-\beta E(\zeta)}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'}. \tag{2.10}$$

We explain functions, $|\partial I/\partial x|_{N,\zeta}$ and $E(\zeta)$ used in this equation, where $\zeta\in\overline{\Theta}(\theta)$ and $\theta\in\Theta(n)$. The Jacobian $|\partial I/\partial x|_{N,\zeta}$ is constructed as follows. First, we consider θ uniquely determined by the condition $\zeta\in\overline{\Theta}(\theta)$. Second, we make correspondence between each element σ of θ and two suffixes (n,α) for the variables I_α^n and x_α^n introduced in the string hypothesis. In this case, the condition $N_\sigma=n$ is required. Third, we consider the mBA equation for the variables $\{I_\alpha^n\}$, $\{x_\alpha^n\}$, which are constructed out of θ. Fourth, we introduce $x_{\theta'}$, $I_{\theta'}$, where θ' is an element of ζ. Here, we have constraining conditions; $x_{\theta'}=x_\alpha^n$ and $I_{\theta'}=I_\alpha^n$, where (n,α) corresponds to $\sigma\in\theta'$. Finally, $|\partial I/\partial x|_{N,\zeta}$ is the Jacobian between $\{x_{\theta'}\}$ and $\{I_{\theta'}\}$ which satisfy, respectively, the mBA

equation made from θ and the constraining conditions made from ζ. Explicit expression of such Jacobian matrix is given in Eq. (A1). We show the above-given procedure by an example. For the case,

$$\zeta=\{\theta_1,\theta_2\},\quad \theta_1=\{\{1,2\}\},\quad \theta_2=\{\{3\},\{4\}\},\tag{2.11}$$

we have

$$\theta=\{\{1,2\},\{3\},\{4\}\},\quad \zeta\in\overline{\Theta}(\theta),$$

$$2N\tan^{-1}\left(\frac{x_{\theta_1}}{2}\right)=2\pi I_{\theta_1}+2\Delta_{2,1}(x_{\theta_1}-x_{\theta_2}),$$

$$2N\tan^{-1}(x_{\theta_2})=2\pi I_{\theta_2}+\Delta_{1,2}(x_{\theta_2}-x_{\theta_1}),$$

$$\begin{aligned}(2\pi)^2\left|\frac{\partial I}{\partial x}\right|_{N,\zeta}=&\frac{4N}{x_{\theta_1}^2+4}\,\frac{2N}{x_{\theta_2}^2+1}-\frac{4N}{x_{\theta_1}^2+4}\left(\frac{2}{(x_{\theta_1}-x_{\theta_2})^2+1}+\frac{6}{(x_{\theta_1}-x_{\theta_2})^2+9}\right)\\&-2\,\frac{2N}{x_{\theta_2}^2+1}\left(\frac{2}{(x_{\theta_2}-x_{\theta_1})^2+1}+\frac{6}{(x_{\theta_2}-x_{\theta_1})^2+9}\right).\end{aligned}\tag{2.12}$$

The energy $E(\zeta)$ is expressed in terms of $\{x_\alpha^n\}$ made from θ,

$$E(\zeta)=\sum_{n,\alpha}\frac{2Jn}{(x_\alpha^n)^2+n^2}.\tag{2.13}$$

For the case (2.11), $E(\zeta)$ is given by

$$E(\zeta)=\frac{2J\times 2}{x_{\theta_1}^2+4}+2\,\frac{2J}{x_{\theta_2}^2+1}.\tag{2.14}$$

Note that the constraining conditions made from ζ have been used.

Now, we show how (2.10) is derived. We notice two important facts. One is that we must exclude unphysical states from the sum, when the sum is represented as the integral in (2.7). The unphysical state means the state corresponding to $\{x_\alpha^n\}$ where some two elements of $\{x_\alpha^n\}$ coincide, $x_\alpha^n=x_\beta^n$. Those states should be excluded because the norm of the state constructed out of $\{x_\alpha^n\}$ satisfying such a condition is zero. In Eq. (2.10),

$$\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}(N_{\theta'}-1)!\tag{2.15}$$

are factors which exclude the unphysical states. In expression (2.10), we add unphysical states in some terms of series and subtract them in some other terms. Then, the sum of positive terms and negative terms is zero with respect to unphysical states. This mathematical manipulation enables us to write the free energy explicitly like (2.10). Let us explain this manipulation for the case of ζ in (2.11) in detail. The states corresponding to ζ in (2.11) are unphysical states. We define $\zeta'=\{\{1,2\}\},\{\{3\}\},\{\{4\}\}$. ζ' corresponds to the results of a string center equation (2.2) which defines one two-string $x_{1,2}$ and two one-strings x_3 x_4. On the other hand, $\zeta=\{\{1,2\}\},\{\{3\},\{4\}\}$ in (2.11) corresponds to the results of the string center equation which satisfy $x_3=x_4$. Therefore, the results corresponding to ζ are part of the results corresponding to ζ'. Here, in the sum with respect to elements in $\overline{\Theta}$ (2.10), both ζ and ζ' are summed up. And, the sum of coordinates (2.15) of terms corresponding to both ζ and ζ' is zero. Therefore, unphysical states corresponding to ζ do not affect the sum in (2.10). The other important fact is that we must divide the sum by the number of

the symmetry. Here, the symmetry means that when $\{x_\alpha^n\}$ is a solution of the mBA equation, $\{x_\alpha'^n\}$ which satisfies the relation $x_\alpha'^n = x_{p(\alpha)}^n$ is also a solution of the mBA equation. In this case, it is necessary to divide the sum by the number of the symmetry because $\{x_\alpha^n\}$ and $\{x_\alpha'^n\}$ correspond to the same state. In Eq. (2.10),

$$\left[\prod_{\sigma\in\theta} N_\sigma!\right] \Big/ n! \tag{2.16}$$

is a factor for the correction of the sum which takes such symmetry into account.

We have met similar correction factors in the analysis of the δ-function Bose gas system. The reason for the appearance of the correction factors is common. A detailed proof for the δ-function bose gas system case is given in Sec. 3.1 of Ref. 15.

In order to express the Jacobian $|\partial I/\partial x|_{N,\zeta}$ explicitly, we further define three symbols.

Definition 4: M_B denotes a number of elements in one of the sets. Here, all the elements of a set B are sets, and all sets in B have the same number of elements. Then, M_B is defined as the number of elements in one of the sets,

$$M_\theta = N_\sigma, \tag{2.17}$$

where $\sigma\in\theta\in\zeta\in\overline{\Theta}(\theta')$ and $\theta'\in\Theta(n)$.

Definition 5: $\Lambda(A)$ denotes all the patterns of connection of a set A. Here, what we call a pattern of connection satisfies the following two conditions. (1) Any two elements of A are connected or not. In other words, there is no multiple connection. (2) There is no closed path in the connections. Then, a pattern of connection is represented as a set of elements each of which corresponds to a connection. Here, an element corresponding to a connection is a set which consists of two elements connected by the connection. For example, we have

$$\begin{aligned}\Lambda(\{a,b,c\}) = \varnothing, &\{\{b,c\}\},\{\{c,a\}\},\{\{a,b\}\},\\ &\{\{a,b\},\{a,c\}\},\{\{b,a\},\{b,c\}\},\{\{c,a\},\{c,b\}\}.\end{aligned} \tag{2.18}$$

Definition 6: $G([\lambda,A])$ is an element of $\Theta(A)$, where $\lambda\in\Lambda(A)$. In other words, $G([\lambda,A])$ is a pattern of division of A. The pattern of division θ satisfies the following conditions; (1) any two connected elements are in the same set in θ, and (2) elements of θ are larger in number than elements of any other $\theta'\in\Theta(A)$ satisfying (1). For example, we can show that

$$G([\{\{a,b\}\},\{a,b,c\}]) = \{\{a,b\},\{c\}\}. \tag{2.19}$$

By use of the above three symbols, the Jacobian can be expressed as

$$\begin{aligned}(2\pi)^{N_\zeta}\left|\frac{\partial I}{\partial x}\right|_{N,\zeta} = &\left[\prod_{\theta\in\zeta} N_\theta\right]^{-1} \sum_{\lambda\in\Lambda(\zeta)} \left[\prod_{\{\theta,\theta'\}\in\lambda} -N_\theta N_{\theta'} K_{M_\theta,M_{\theta'}}(x_\theta - x_{\theta'})\right]\\ &\times \prod_{\zeta'\in G([\lambda,\zeta])} \left[\sum_{\theta\in\zeta'} \frac{2N_\theta M_\theta N}{M_\theta^2 + x_\theta^2}\right],\end{aligned} \tag{2.20}$$

where $K_{n,m}(x) \equiv \mathrm{d}\Delta_{n,m}(x)/\mathrm{d}x$. A proof of Eq. (2.20) is given in Appendix A.

At last, we show the explicit expression of the cluster expansion. Taking a logarithm of both sides of (2.10) and rewriting the right-hand side, we get

$$\log[z^{N/2}\mathrm{Tr}\,e^{-\beta H(J,h)}]=\sum_{n=1}^{\infty}\frac{z^n}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\Theta(\theta)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}(N_{\theta'}-1)!\right]$$
$$\times\int\left|\frac{\partial I}{\partial x}\right|_{cN,\zeta}e^{-\beta E(\zeta)}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'}. \tag{2.21}$$

A proof is given in Appendix B. Here, $|\partial I/\partial x|_{cN,\zeta}$ is the first-order term of $|\partial I/\partial x|_{N,\zeta}$ regarded as a polynomial with respect to the number of spins, N. From expression (2.21), the cluster expansion coefficient b_n is given by

$$b_n=\frac{1}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\Theta(\theta)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}(N_{\theta'}-1)!\right]\int\left|\frac{\partial I}{\partial x}\right|_{cN,\zeta}e^{-\beta E(\zeta)}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'}, \tag{2.22}$$

where the explicit form of $|\partial I/\partial x|_{cN,\zeta}$ is

$$(2\pi)^{N_\zeta}\left|\frac{\partial I}{\partial x}\right|_{cN,\zeta}=\left[\prod_{\theta\in\zeta}N_\theta\right]^{-1}\sum_{\lambda\in\Lambda_c(\zeta)}\left[\prod_{\{\theta,\theta'\}\in\lambda}-N_\theta N_{\theta'}K_{M_\theta,M_{\theta'}}(x_\theta-x_{\theta'})\right]\sum_{\theta\in\zeta}\frac{2N_\theta M_\theta N}{M_\theta^2+x_\theta^2}. \tag{2.23}$$

The symbol $\Lambda_c(A)$ is defined as follows.

Definition 7: $\Lambda_c(A)$ is a subset of $\Lambda(A)$, where any element $\lambda\in\Lambda_c(A)$ satisfies the condition $N_{G[\lambda,A]}=1$. For example, we can show that

$$\Lambda_c(\{a,b,c\})=\{\{a,b\},\{a,c\}\},\{\{b,a\},\{b,c\}\},\{\{c,a\},\{c,b\}\}. \tag{2.24}$$

A derivation of the expression $|\partial I/\partial x|_{cN,\zeta}$ in (2.23) is given in Appendix C.

III. THE FREE ENERGY

From Eqs. (2.10) and (2.21), we can easily show that

$$z^{1/2}[\mathrm{Tr}\,e^{-\beta H(J,h)}]^{1/N}=1+\sum_{n=1}^{\infty}\frac{z^n}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\Theta(\theta)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}(N_{\theta'}-1)!\right]$$
$$\times\int\left|\frac{\partial I}{\partial x}\right|_{1,\zeta}e^{-\beta E(\zeta)}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'}, \tag{3.1}$$

where $|\partial I/\partial x|_{1,\zeta}$ means $|\partial I/\partial x|_{N,\zeta}$ in which N is replaced with 1.

Now, we introduce a function $u(x)$,

$$u(x)\equiv 1+\sum_{n=1}^{\infty}z^n u_n(x), \tag{3.2}$$

where $u_n(x)$ is given by

$$u_n(x)\equiv\frac{1}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\Theta(\theta)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}(N_{\theta'}-1)!\right]$$
$$\times\int\left|\frac{\partial I}{\partial x}\right|_{1,\zeta}(x)e^{-\beta E(\zeta)}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'} \tag{3.3}$$

with the modified Jacobian $|\partial I/\partial x|_{1,\zeta}(y)$ defined as

$$(2\pi)^{N_\zeta}\left|\frac{\partial I}{\partial x}\right|_{1,\zeta}(y)\equiv\left[\prod_{\theta\in\zeta}N_\theta\right]^{-1}\sum_{\lambda\in\Lambda(\zeta)}\left[\prod_{\{\theta,\theta'\}\in\lambda}-N_\theta N_{\theta'}K_{M_\theta,M_{\theta'}}(x_\theta-x_{\theta'})\right]$$
$$\times\prod_{\zeta'\in G([\lambda,\zeta])}\left[\sum_{\theta\in\zeta'}\frac{2N_\theta M_\theta}{M_\theta^2+(x_\theta-y)^2}\right]. \tag{3.4}$$

Comparing this definition with (2.20), it is readily seen that $|\partial I/\partial x|_{1,\zeta}=|\partial I/\partial x|_{1,\zeta}(0)$. Then, it is clear that we can get a relation

$$[\mathrm{Tr}\,e^{-\beta H(J,h)}]^{1/N}=u(0)z^{-1/2}. \tag{3.5}$$

It can be shown (see Appendix D for a proof) that the function $u_n(x)$ satisfies the following recursion relation;

$$u_{n+1}(x)=\oint_{0+}\left[\frac{\exp\left(-\frac{2J\beta}{(y+i)^2+1}\right)}{x-y-2i}+\frac{\exp\left(-\frac{2J\beta}{(y-i)^2+1}\right)}{x-y+2i}\right]$$
$$\times\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\left[\prod_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y)\right]\frac{dy}{2\pi i}, \tag{3.6}$$

$$u_1(x)=1+\oint_{0+}\left[\frac{\exp\left(-\frac{2J\beta}{(y+i)^2+1}\right)}{x-y-2i}+\frac{\exp\left(-\frac{2J\beta}{(y-i)^2+1}\right)}{x-y+2i}\right]\frac{dy}{2\pi i}, \tag{3.7}$$

where n is the natural number. Using this recursion relation we obtain a relation

$$u(x)=z+1+\oint_{0+}\left[\frac{\exp\left(-\frac{2J\beta}{(y+i)^2+1}\right)}{x-y-2i}+\frac{\exp\left(-\frac{2J\beta}{(y-i)^2+1}\right)}{x-y+2i}\right]\frac{z}{u(y)}\frac{dy}{2\pi i}. \tag{3.8}$$

These results, (3.5) and (3.8), are the same as those of Ref. 11 in the XXX Heisenberg model limit.

IV. CONCLUSION

We have shown a method, which we call the direct method, to derive the free energy of the XXX Heisenberg model using the BA equation. The cluster expansion coefficient in arbitrary order is given for the first time. The expression of the free energy perfectly agrees with that by TBA. It is remarkable that the free energy is obtained without recourse to TBA and QTM. On the other hand, there remains a problem. We have started from the string hypothesis in this paper. Therefore, it is still a challenging problem to derive each cluster expansion coefficient only from the BA equation. This problem is under investigation.

We think, however, that these results have theoretical significance. What we have done here is calculate a certain summation using combinatorial argument with mathematical justification. The summation may contain a problem which comes from the string hypothesis. On the contrary, TBA solves this problem as follows. We define a nonequilibrium entropy, and minimize the free energy using such entropy. Then, the condition of minimization gives the summation. In other words, TBA entirely relies on the physical definition of the entropy. In this paper, it is proved that the two results by TBA and by the direct method are the same. Therefore, in addition to the δ-function Bose gas, for the XXX Heisenberg model, the direct method gives the mathematical justification of TBA. To summarize, it is suggested that TBA can be systematically proved for many other integrable systems using the combinatorial argument presented here.

APPENDIX A: EXPLICIT FORM OF JACOBIAN $|\partial I/\partial x|_{N,\zeta}$

In this appendix, we prove (2.20). Recall that $|\partial I/\partial x|_{N,\zeta}$ is the Jacobian defined for $\zeta \in \overline{\Theta}(\theta)$, where $\theta \in \Theta(n)$. The Jacobian matrix can be rewritten as follows: the Jacobian matrix has the order $N_\zeta \times N_\zeta$, and each element of the matrix is

$$2\pi \frac{\partial I_{\theta'}}{\partial x_\theta} = \begin{cases} \dfrac{2M_\theta N}{M_\theta^2 + x_\theta^2} - \displaystyle\sum_{\theta'' \neq \theta} N_{\theta''} K_{M_\theta, M_{\theta''}}(x_\theta - x_{\theta''}) & \text{if } \theta = \theta' \\ N_\theta K_{M_\theta M_{\theta'}}(x_\theta - x_{\theta'}) & \text{if } \theta \neq \theta', \end{cases} \tag{A1}$$

where θ, θ', $\theta'' \in \zeta$ and $K_{n,m}(x) \equiv \mathrm{d}\Delta_{n,m}(x)/\mathrm{d}x$.

Here, we generalize the setting of the problem. We define $N \times N$ matrix

$$A_{n,m} = \begin{cases} e_n - \displaystyle\sum_{k \neq n} c_k a_{n,k} & \text{if } n = m \\ c_n a_{n,m} & \text{if } n \neq m, \end{cases} \tag{A2}$$

where $\{a_{n,m}\}$, $\{c_n\}$, and $\{e_n\}$ are arbitrary series and $a_{n,m}$ is symmetric, $a_{n,m} = a_{m,n}$. This matrix is a generalized form of the Jacobian matrix (A1). Therefore, what we have to prove becomes that the determinant of $A_{n,m}$ is

$$|A_{n,m}| = \left[\prod_{n=1}^{N} c_n\right]^{-1} \sum_{\lambda \in \Lambda(\{1,\ldots,N\})} \left[\prod_{\{n,m\} \in \lambda} -c_n c_m a_{n,m}\right] \prod_{\sigma \in G([\lambda, \{1,\ldots,N\}])} \left[\sum_{n \in \sigma} c_n e_n\right]. \tag{A3}$$

First, we prove that each term of the determinant $|A_{n,m}|$ can be considered as a pattern of connection $\lambda \in \Lambda(\{1,\ldots,N\})$. When we regard the determinant as a multi-variable polynomial with respect to $\{a_{n,m}\}$ and regard $a_{n,m}$ as a connection between n and m, we can consider each term of the polynomial as a pattern of connection λ. In other words, we can prove the following two facts. First, there is no multiple connection. That is to say, there is no $a_{n,m}$ to the power of 2 or more in any term of the polynomial. Second, there is no closed path made from connections. That is to say, there is no product $a_{p(1),p(2)} a_{p(2),p(3)} \cdots a_{p(M-1),p(M)} a_{p(M),p(1)}$ in any term, where p is a permutation.

To prove these two facts, we use the method of false position. We assume there is a term that has at least one closed path through M connections. Without loss of generality, the above-mentioned assumption can be rewritten that there is a product $a_{1,2} a_{2,3} \cdots a_{M-1,M} a_{M,1}$ in any term. Then, we introduce a matrix $A'_{n,m}$ such that

$$A'_{n,m} = \begin{cases} -\displaystyle\sum_{k \neq n} c_k a_{n,k} & \text{if } n = m \leqslant M \\ e_n - \displaystyle\sum_{k \neq n} c_k a_{n,k} & \text{if } n = m > M \\ 0 & \text{if } n \leqslant M < m \text{ or } m \leqslant M < n \\ c_n a_{n,m} & \text{other.} \end{cases} \tag{A4}$$

Now, we regard $|A'_{n,m}|$ as a multi-variable polynomial with respect to $\{a_{n,m}\}$. From the definition of determinant, it is easily shown that the term with a product $a_{1,2} a_{2,3} \cdots a_{M-1,M} a_{M,1}$ in $|A_{n,m}|$ has the same coefficient as a term with such product in $|A'_{n,m}|$. However, $|A'_{n,m}|$ is identically 0 because the matrix $A'_{n,m}$ is linearly dependent. Therefore, there is no term containing a product $a_{1,2} a_{2,3} \cdots a_{M-1,M} a_{M,1}$. Substituting 2 for M, we can prove that there is no $a_{n,m}$ to the power of 2 or more in any term of the polynomial. Then, we can consider each term of the matrix $|A_{n,m}|$ as a pattern of connection λ.

Second, we find where a term considered as a pattern of connection is formed. From the definition, we can write the determinant $|A_{n,m}|$ as

$$|A_{n,m}| = \sum_{p \in P_N} \operatorname{sgn} p \cdot \prod_{n=1}^{N} A_{n,p(n)}, \tag{A5}$$

where P_N is a permutation group with respect to $\{1,...,N\}$. It can be shown that any term considered as a pattern of connection is in an expansion of a product only in the case where p is the identity permutation. The following is a proof of the fact by the method of false position. If there is such term in the case where p is not the identity permutation, there exist n_0 and l_0 which satisfy $p^{l_0}(n_0)=n_0$, $p^{l}(n_0)\neq n_0$ and $l_0 \neq 0$, where $l_0 > l$ and $p^m(n)$ means that p operates on n for m times, $p(p(\cdots p(n)\cdots))$. Therefore, we can rewrite $\Pi_{n=1}^{N} A_{n,p(n)}$ as

$$\left[\prod_{l=0}^{l_0-1} c_{p^l(n_0)} a_{p^l(n_0),p^{l+1}(n_0)} \right] \prod_{n \neq p^l(n_0)} A_{n,p(n)}. \tag{A6}$$

This term clearly has a closed path, and conflict with the definition of the p.

Finally, we can rewrite $|A_{n,m}|$ as follows. We expand

$$\prod_{n=1}^{N} A_{n,n}, \tag{A7}$$

and regard it as a multivariable polynomial with respect to $\{a_{n,m}\}$. $|A_{n,m}|$ is a sum of terms which are in this polynomial and can be considered as a pattern of connection. This means that the term has no multiple connection and no closed path. This sum means the right-hand side of (A3).

APPENDIX B: A PROOF OF (2.21)

In this appendix, we prove (2.21) from (2.10).

We define Z_n by

$$z^{N/2} \operatorname{Tr} e^{-\beta H(J,h)} \equiv 1 + \sum_{n=1}^{\infty} Z_n z^n. \tag{B1}$$

From (2.10) we get

$$Z_n = \frac{1}{n!} \sum_{\theta \in \Theta(n)} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'}-1} (N_{\theta'}-1)! \right] \int \left| \frac{\partial I}{\partial x} \right|_{N,\zeta} e^{-\beta E(\zeta)} \prod_{\theta' \in \zeta} \mathrm{d}x_{\theta'}, \tag{B2}$$

where $|\partial I/\partial x|_{N,\zeta}$ is the Jacobian defined for ζ. It is convenient to introduce $f(\zeta)$ as

$$f(\zeta) \equiv \int \left| \frac{\partial I}{\partial x} \right|_{cN,\zeta} e^{-\beta E(\zeta)} \prod_{\theta' \in \zeta} \mathrm{d}x_{\theta'}. \tag{B3}$$

Using this function and relation (C1) proved in Appendix C, we can rewrite Z_n as

$$Z_n = \frac{1}{n!} \sum_{\theta \in \Theta(n)} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'}-1} (N_{\theta'}-1)! \right] \sum_{\xi \in \Theta(\zeta)} \prod_{\zeta' \in \xi} f(\zeta'). \tag{B4}$$

We also define b_n by

$$\log\left[1+\sum_{n=1}^{\infty} Z_n z^n\right] \equiv \sum_{n=1}^{\infty} b_n z^n. \tag{B5}$$

We can easily show the following relation between b_n and Z_n:

$$b_n = \frac{1}{n!} \sum_{\theta \in \Theta(n)} (N_\theta - 1)!(-1)^{N_\theta - 1} \sum_{\sigma \in \theta} N_\sigma! Z_{N_\sigma}. \tag{B6}$$

Substituting (B4) for Z_n in (B6), we get

$$\begin{aligned} b_n &= \frac{1}{n!} \sum_{\theta \in \Theta(n)} (N_\theta - 1)!(-1)^{N_\theta - 1} \prod_{\sigma \in \theta} \left[\sum_{\theta' \in \Theta(\sigma)} \left[\prod_{\sigma' \in \theta'} N_{\sigma'}! \right] \right. \\ &\quad \left. \times \sum_{\zeta \in \Theta(\theta')} \left[\prod_{\theta'' \in \zeta} (-1)^{N_{\theta''} - 1} (N_{\theta''} - 1)! \right] \sum_{\xi \in \Theta(\zeta)} \prod_{\zeta' \in \xi} f(\zeta') \right] \\ &= \frac{1}{n!} \sum_{\theta \in \Theta(n)} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'} - 1} (N_{\theta'} - 1)! \right] \\ &\quad \times \sum_{\xi \in \Theta(\zeta)} \left[\prod_{\zeta' \in \xi} f(\zeta') \right] \sum_{\eta \in \Theta(\xi)} (N_\eta - 1)!(-1)^{N_\eta - 1} \\ &= \frac{1}{n!} \sum_{\theta \in \Theta(n)} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'} - 1} (N_{\theta'} - 1)! \right] f(\zeta). \end{aligned} \tag{B7}$$

In the first equality, we have only performed the substitution. In the second equality, we have done the following manipulation. We regard each side of the equality as the sum with respect to elements in a set which satisfies some conditions. Therefore, we may change the order of the sums. Here, we show a simple example of ''change of order,''

$$\sum_{n=1}^{N} \sum_{m=1}^{n} f(\{n,m\}) = \sum_{m=1}^{N} \sum_{n=m}^{N} f(\{n,m\}). \tag{B8}$$

Similar to this example, both sides of the second equality are the sum of the same function with respect to elements in the same set. In the third equality, we have simplified the last term of the left-hand side using a relation,

$$\sum_{\theta \in \Theta(\sigma)} (N_\theta - 1)!(-1)^{N_\theta - 1} = \delta_{N_\sigma, 1}. \tag{B9}$$

Finally, combining (B1), (B3), (B5), and (B7) we arrive at Eq. (2.21).

APPENDIX C: THE STRUCTURE OF THE JACOBIAN $|\partial I/\partial x|_{N,\zeta}$

In this appendix, we prove

$$\left|\frac{\partial I}{\partial x}\right|_{N,\zeta} = \sum_{\xi \in \Theta(\zeta)} \prod_{\zeta' \in \xi} \left|\frac{\partial I}{\partial x}\right|_{cN,\zeta'} \tag{C1}$$

and Eq. (2.23) from Eq. (2.20). We here repeat that $|\partial I/\partial x|_{cN,\zeta}$ is the first-order term of $|\partial I/\partial x|_{N,\zeta}$ with respect to N.

Equation (2.20) can be rewritten as

$$(2\pi)^{N_\zeta}\left|\frac{\partial I}{\partial x}\right|_{N,\zeta}=\sum_{\xi\in\Theta(\zeta)}\prod_{\zeta'\in\xi}\left[\left[\prod_{\theta\in\zeta'}N_\theta\right]^{-1}\right.$$
$$\left.\times\sum_{\lambda\in\Lambda_c(\zeta')}\left[\prod_{\{\theta,\theta'\}\in\lambda}-N_\theta N_{\theta'}K_{M_\theta,M_{\theta'}}(x_\theta-x_{\theta'})\right]\sum_{\theta\in\zeta' N}\frac{2N_\theta M_\theta}{M_\theta^2+x_\theta^2}\right]. \quad \text{(C2)}$$

In this equality, we have changed the order of the sums. We can easily show the relation (2.23) from this expression. Then, Eqs. (C2) and (2.23) prove (C1).

APPENDIX D: A PROOF OF (3.6) AND (3.7)

In this appendix, using the mathematical induction we prove the relations with respect to $u_n(x)$, (3.6) and (3.7). The definition of $u_n(x)$ is given in Eq. (3.3).

We can change the right-hand side of (3.7) into

$$\int\frac{2}{1+(x-y)^2}\exp\left(-\frac{2J\beta}{y^2+1}\right)\frac{dy}{2\pi i}. \quad \text{(D1)}$$

This is the same as the definition of $u_1(x)$. Thus, we have shown the relation (3.7).

We suppose (3.6) and (3.7) hold for $1\leqslant n<n_0$, where n_0 is a natural number. For simplicity, n_0 is merely written as n in what follows. Then, the function $u_m(x)$ has poles only at $x=\pm 2i$, and satisfies $\lim_{|x|\to\infty}u_m(x)=\delta_{m,1}$, where $1\leqslant m\leqslant n$. By use of these two properties, the right-hand side of (3.6) becomes

$$\oint_{0+}\left[\frac{\exp\left(-\frac{2J\beta}{(y+i)^2+1}\right)}{x-y-2i}+\frac{\exp\left(-\frac{2J\beta}{(y-i)^2+1}\right)}{x-y+2i}\right]\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\left[\prod_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y)\right]\frac{dy}{2\pi i}$$
$$=\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\int_{-\infty}^{\infty}\left[\frac{\Pi_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y-i)}{x-y-i}-\frac{\Pi_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y+i)}{x-y+i}\right]\exp\left(-\frac{2J\beta}{y^2+1}\right)\frac{dy}{2\pi i}$$
$$-\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\int_{C_+}\frac{\Pi_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y)}{x-y-2i}\exp\left(-\frac{2J\beta}{(y+i)^2+1}\right)\frac{dy}{2\pi i}$$
$$+\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\int_{C_-}\frac{\Pi_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y)}{x-y+2i}\exp\left(-\frac{2J\beta}{(y-i)^2+1}\right)\frac{dy}{2\pi i}. \quad \text{(D2)}$$

In this equality we have changed the path of integration. Both C_+ and C_- are the paths of integration which counterclockwise surround the region $\Im y>0$. When these paths are in the neighborhood of real axis, C_+ passes above the real axis and C_- passes below the real axis. We separate (D2) into two parts, and calculate them separately.

First, we consider the first term of (D2) which is rewritten as

$$\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\int_{-\infty}^{\infty}\sum_{s=\pm 1}\frac{s\Pi_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y-si)}{s-(y-x)i}\exp\left(-\frac{2J\beta}{y^2+1}\right)\frac{dy}{2\pi}. \quad \text{(D3)}$$

The integral diverges in cases that we do not sum up with respect to s. However, the sum turns out not to play an important role in the following calculation. Hence, to shorten the expression, the symbol $\Sigma_{s=\pm 1}$ is omitted for a while. Now, by use of relation (E1) proved in Appendix E, Eq. (D3) is rewritten as

$$\frac{1}{n!}\int_{-\infty+s\delta i}^{\infty+s\delta i}\frac{dy}{2\pi}\sum_{\theta\in\Theta(n)}\prod_{\sigma\in\theta}\left[-\sum_{\theta'\in\Theta(\sigma)}\left[\prod_{\sigma'\in\theta'}N_{\sigma'}!\right]\sum_{\zeta\in\Theta(\theta')}\left[\prod_{\theta''\in\zeta}(-1)^{N_{\theta''}-1}\frac{(N_{\theta''}-1)!}{N_{\theta''}}\right]\right.$$
$$\times\left[\prod_{\theta''\in\zeta}\int_{-\infty}^{\infty}\frac{dx_{\theta''}}{2\pi}\right]\sum_{\lambda\in\Lambda_c(\zeta)}\left[\prod_{\{\theta'',\theta'''\}\in\lambda}-N_{\theta''}N_{\theta'''}K_{M_{\theta''},M_{\theta'''}}(x_{\theta''}-x_{\theta'''})\right]$$
$$\left.\times\sum_{\theta''\in\zeta}\frac{2N_{\theta''}M_{\theta''}}{M_{\theta''}^2+(x_{\theta''}-y+si)^2}\frac{s\exp\left(-\beta\left(\frac{2J}{y^2+1}+E(\zeta)\right)\right)}{s-(y-x)i}\right]. \tag{D4}$$

On condition that we take a limit $\delta\to 0$ and $M_\theta=1$, $1/(M_\theta^2+(x_\theta-y+si)^2)$ yields a pole on the real axis with respect to the variable y. To detour the pole on the real axis and symmetrize the integral paths, we use the relation (F1) proved in Appendix F. Then, (D4) becomes

$$\frac{1}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\bar{\Theta}(\theta+\{n+1\})}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}\frac{(N_{\theta'}-1)!}{N_{\theta'}}\right]\frac{N_{\theta_{n+1}}}{(N_{\theta_{n+1}}-1)!}$$
$$\times\left[\sum_{\zeta'\in\Theta(N_{\theta_{n+1}}-1)}B_{N_{\zeta'}}\prod_{\theta'\in\zeta'}(N_{\theta'}-1)!\right]\int_{\mathrm{sym}}\left[\prod_{\theta'\in\zeta}\frac{dx_{\theta'}}{2\pi}\right]\sum_{\lambda\in\Lambda_c(\zeta)}\frac{se^{-\beta E(\zeta)}}{s-(x_{\theta_{n+1}}-x)i}$$
$$\times\left[\prod_{\{\theta',\theta''\}\in\lambda,\ \theta',\theta''\neq\theta_{n+1}}C(\theta',\theta'')\right]\left[\prod_{\{\theta_{n+1},\theta'\}\in\lambda}E(\theta_{n+1},\theta')\right]. \tag{D5}$$

Here, we assume the relation $\{n+1\}\in\sigma_{n+1}\in\theta_{n+1}\in\zeta$. We also use this symbol in the same sense as in (D12), (D19), and (D20). The constant B_n in (D5) is known as the Bernoulli number and is determined by

$$\sum_{n=0}^{\infty}\frac{B_n}{n!}x^n\equiv\frac{x}{1-e^{-x}}. \tag{D6}$$

For example, the first few B_n's are

$$B_0=1,\quad B_1=\tfrac{1}{2},\quad B_2=\tfrac{1}{6},\quad B_3=0,\quad B_4=-\tfrac{1}{30},\quad \cdots. \tag{D7}$$

The symbol $\int_{\mathrm{sym}}$ in (D5) indicates that each path of integration symmetrically avoids poles on the real axis. Because all the poles on the real axis have the form $1/(x_\theta-x_{\theta'})$, we can explicitly write $\int_{\mathrm{sym}}$ as

$$\int_{\mathrm{sym}}\prod_{n=1}^{N}dx_n\equiv\frac{1}{N!}\sum_{\{p\in P_N\}}\prod_{n=1}^{N}\left[\int_{-\infty+n\delta i}^{\infty+n\delta i}dx_{p(n)}\right]. \tag{D8}$$

The functions $C(\theta,\theta')$ and $E(\theta,\theta')$ are defined by

$$C(\theta,\theta')\equiv -N_\theta,N_{\theta'}K_{M_\theta,M_{\theta'}}(x_\theta-x_{\theta'}), \tag{D9}$$

$$E(\theta,\theta')\equiv-(N_\theta-1)N_{\theta'}K_{M_\theta,M_{\theta'}}(x_\theta-x_{\theta'})-N_{\theta'}K_{M_\theta-1,M_{\theta'}}(x_\theta-x_{\theta'}-si)$$
$$-\frac{2N_{\theta'}M_{\theta'}}{M_{\theta'}^2+(x_\theta-x_{\theta'}+s(M_\theta-2)i)^2}. \tag{D10}$$

Note here that the second term of (D10) is 0 for $E(\theta,\theta')$ used in (D5) because of the relation $M_{\theta_{n+1}}=1$. Then, by use of the relation

$$\sum_{\theta\in\Theta(n)} B_{N_\theta}\prod_{\sigma\in\theta}(N_\sigma-1)!=\frac{n!}{n+1}, \tag{D11}$$

which is easily shown, (D5) becomes

$$\frac{1}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\overline{\Theta}(\theta+\{n+1\})}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}\frac{(N_{\theta'}-1)!}{N_{\theta'}}\right]\frac{1}{N_{\theta_{n+1}}}\int_{\mathrm{sym}}\left[\prod_{\theta'\in\zeta}\frac{dx_{\theta'}}{2\pi}\right]$$
$$\times\sum_{\lambda\in\Lambda_c(\zeta)}\frac{sN_{\theta_{n+1}}e^{-\beta E(\zeta)}}{s-(x_{\theta_{n+1}}-x)i}\left[\prod_{\{\theta',\theta''\}\in\lambda,\theta',\theta''\neq\theta_{n+1}}C(\theta',\theta'')\right]\left[\prod_{\{\theta_{n+1},\theta'\}\in\lambda}E(\theta_{n+1},\theta')\right]. \tag{D12}$$

Changing the order of the sums, this expression becomes

$$\frac{1}{(n+1)!}\sum_{\theta\in\Theta(n+1)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\Theta(\theta)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}\frac{(N_{\theta'}-1)!}{N_{\theta'}}\right]\int_{\mathrm{sym}}\left[\prod_{\theta'\in\zeta}\frac{dx_{\theta'}}{2\pi}\right]$$
$$\times\sum_{\lambda\in\Lambda_c(\zeta)}\sum_{\theta_0\in\zeta,M_{\theta_0}=1}\frac{sN_{\theta_0}e^{-\beta E(\zeta)}}{s-(x_{\theta_0}-x)i}\left[\prod_{\{\theta',\theta''\}\in\lambda,\theta',\theta''\neq\theta_0}C(\theta',\theta'')\right]\left[\prod_{\{\theta_0,\theta'\}\in\lambda}E(\theta_0,\theta')\right]. \tag{D13}$$

Thus, using the above-given relations we have shown that (D3) is expressed as (D13).

Second, we write the sum of the second and third terms of (D2),

$$-\sum_{s=\pm1}s\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\int_{C_s}\frac{\Pi_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y)}{2s-(y-x)i}\exp\left(-\frac{2J\beta}{(y+si)^2+1}\right)\frac{dy}{2\pi}, \tag{D14}$$

where $C_{\pm1}$ means $C_\pm$. In the following change of the expressions, the sum with respect to s does not play an important role. This situation is similar to the one for (D3). Then, the symbol $\Sigma_{s=\pm1}$ will be also omitted for a while. Using relation (E1), we have from (D14),

$$-\frac{1}{n!}\int_{C_s}\frac{dy}{2\pi}\sum_{\theta\in\Theta(n)}\prod_{\sigma\in\theta}\left[-\sum_{\theta'\in\Theta(\sigma)}\left[\prod_{\sigma\in\theta'}N_{\sigma'}!\right]\sum_{\zeta\in\overline{\Theta}(\theta)'}\left[\prod_{\theta''\in\zeta}(-1)^{N_{\theta''}-1}\frac{(N_{\theta''}-1)!}{N_{\theta''}}\right]\right.$$
$$\times\left[\prod_{\theta''\in\zeta}\int_{-\infty}^{\infty}\frac{dx_{\theta''}}{2\pi}\right]\sum_{\lambda\in\Lambda_c(\zeta)}\left[\prod_{\{\theta'',\theta'''\}\in\lambda}-N_{\theta''}N_{\theta'''}K_{M_{\theta''},M_{\theta'''}}(x_{\theta''}-x_{\theta'''})\right]$$
$$\left.\times\sum_{\theta''\in\zeta}\frac{2N_{\theta''}M_{\theta''}}{M_{\theta''}^2+(x_{\theta''}-y)^2}\frac{s\exp\left(-\beta\left(\frac{2J}{(y+si)^2+1}+E(\zeta)\right)\right)}{2s-(y-x)i}\right]. \tag{D15}$$

We use a relation,

$$\int_{C_s} dy\, f(y) \prod_{\sigma\in\theta}\left[\int_{-\infty}^{\infty}\frac{dx_\sigma}{2\pi}\frac{2N_\sigma f_\sigma(x_\sigma)}{N_\sigma^2+(y-x_\sigma)^2}\right]$$
$$= \int_{C_s} dy\, f(y+msi)\prod_{\sigma\in\theta}\left[\int_{-\infty}^{\infty}\frac{dx_\sigma}{2\pi}\frac{2N_\sigma f_\sigma(x_\sigma)}{N_\sigma^2+(y-x_\sigma+msi)^2}\right]+\sum_{n=1}^{m-1}\int_{C_s} dy\, f(y+nsi)$$
$$\times\left[\prod_{\sigma\in\theta}\int_{-\infty}^{\infty}\frac{dx_\sigma}{2\pi}\frac{f_\sigma(x_\sigma)}{N_\sigma^2+(y-x_\sigma+nsi)^2}-\prod_{\sigma\in\theta}\left[\int_{-\infty}^{\infty}\frac{dx_\sigma}{2\pi}\frac{2N_\sigma f_\sigma(x_\sigma)}{N_\sigma^2+(y-x_\sigma+nsi)^2}\right.\right.$$
$$\left.\left.-\delta(n+1,N_\sigma)f_\sigma(y-si)\right]\right], \tag{D16}$$

where $f_\sigma(x)$ and $f(x)$ are analytic functions in the regions $-1<\Im x\leqslant 0$ and $0<\Im x\leqslant m$ in case of $s=1$ ($0\leqslant\Im x<1$ and $-m\leqslant\Im x<0$ in case of $s=-1$) respectively, and $\max_{\sigma\in\theta}N_\sigma=m$. Then, (D15) becomes

$$\frac{1}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\bar{\Theta}(\theta)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}\frac{(N_{\theta'}-1)!}{N'_\theta}\right]\sum_{\theta'\in\zeta}\frac{N_{\theta'}(-1)^{N_{\theta'}-1}}{(N_{\theta'}-1)!}$$
$$\times\left[\sum_{\theta''\in\Theta(N_{\theta'})}\prod_{\sigma''\in\theta''}(-1)^{N_{\sigma''}-1}(N_{\sigma''}-1)!\right]\int_{C_s}\frac{dx_{\theta'}}{2\pi}\left[\prod_{\theta''\in\zeta,\theta''\neq\theta'}\int_{-\infty}^{\infty}\frac{dx_{\theta''}}{2\pi}\right]$$
$$\times\sum_{\lambda\in\Lambda_c(\zeta)}\frac{s\exp\left[-\beta\left(E(\zeta)+\frac{2J}{(x_{\theta'}+sM_{\theta'}i)^2+1}+\frac{2JM_{\theta'}}{(x_{\theta'}-si)^2+M_{\theta'}^2}-\frac{2JM_{\theta'}}{x_{\theta'}^2+M_{\theta'}^2}\right)\right]}{(M_{\theta'}+1)s-(x_{\theta'}-x)i}$$
$$\times\left[\prod_{\{\theta'',\theta'''\}\in\lambda,\theta'',\theta'''\neq\theta'}C(\theta'',\theta''')\right]\prod_{\{\theta',\theta''\}\in\lambda}\left[-N_{\theta'}N_{\theta''}K_{M_{\theta'},M_{\theta''}}(x_{\theta'}-x_{\theta''}-si)\right.$$
$$\left.-\frac{2N_{\theta''}M_{\theta''}}{M_{\theta''}^2+(x_{\theta'}-x_{\theta''}+s(M_{\theta'}-1)i)^2}\right]. \tag{D17}$$

We point out that in this case the first term of the right-hand side in (D16) is 0 because there is no pole inside (outside) the path of integration C_+ (C_-) with respect to y including the point $|y|=\infty$. Then, using a simple relation $\Sigma_{\theta\in\Theta_n}\Pi_{\sigma\in\theta}(-)^{N_\sigma-1}(N_\sigma-1)!=\delta_{n,1}$, we get from (D17),

$$\frac{1}{n!}\sum_{\theta\in\Theta(n)}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\sigma_0\in\theta}\sum_{\zeta\in\bar{\Theta}(\theta-\sigma_0)}\left[\prod_{\theta'\in\zeta}(-1)^{N_{\theta'}-1}\frac{(N_{\theta'}-1)!}{N_{\theta'}}\right]\int_{-\infty+s\delta i}^{\infty+s\delta i}\frac{dx_{\theta_0}}{2\pi}$$
$$\times\left[\prod_{\theta'\in\zeta}\int_{-\infty}^{\infty}\frac{dx_{\theta'}}{2\pi}\right]\sum_{\lambda\in\Lambda_c(\zeta+\theta_0)}+\frac{s\exp\left[-\beta\left(E(\zeta)+\frac{2J(M_{\theta_0}+1)}{x_{\sigma_0}^2+(M_{\theta_0}+1)^2}-\frac{2JM_{\theta_0}}{x_{\sigma_0}^2+M_{\theta_0}^2}\right)\right]}{(M_{\theta_0}+1)s-(x_{\sigma_0}-x)i}$$
$$\times\left[\prod_{\{\theta',\theta''\}\in\lambda,\theta',\theta''\neq\theta_0}C(\theta',\theta'')\right]$$
$$\times\prod_{\{\theta_0,\theta'\}\in\lambda}\left[-N_{\theta'}K_{M_{\theta_0},M_{\theta'}}(x_{\theta_0}-x_{\theta'}-si)-\frac{2N_{\theta'}M_{\theta'}}{M_{\theta'}^2+(x_{\theta_0}-x_{\theta'}+s(M_{\theta_0}-1)i)^2}\right]. \tag{D18}$$

where $\theta_0 \equiv \{\sigma_0\}$. Here, we have changed the path of integration from C_s to $-\infty + s\delta i \to \infty + s\delta i$, because there is no pole at $|x_{\theta_0}| \to \infty$. In Eq. (D18), when we take a limit $\delta \to 0$ and $M_\theta = M_{\theta_0} + 1$, the last term contains a pole on the real axis with respect to x_θ. Symmetrizing by use of (F1) the integral paths which avoid the pole on the real axis, we obtain from (D18),

$$\frac{1}{n!} \sum_{\theta \in \Theta(n+1), N_{\sigma_{n+1}} \neq 1} \left[\prod_{\sigma \in \sigma} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'}-1} \frac{(N_{\theta'}-1)!}{N_{\theta'}} \right] \frac{N_{\theta_{n+1}}}{N_{\sigma_{n+1}} (N_{\theta_{n+1}}-1)!}$$
$$\times \left[\sum_{\theta' \in \Theta(N_{\theta_{n+1}}-1)} B_{N_{\theta'}} \prod_{\sigma' \in \theta'} (N_{\sigma'}-1)! \right] \int_{\mathrm{sym}} \left[\prod_{\theta' \in \zeta} \frac{dx_{\theta'}}{2\pi} \right] \sum_{\lambda \in \Lambda_c(\zeta)} \frac{s e^{E(\zeta)}}{M_{\theta_{n+1}} s - (x_{\theta_{n+1}} - x) i}$$
$$\times \left[\prod_{\{\theta', \theta''\} \in \lambda, \ \theta', \theta'' \neq \theta_{n+1}} C(\theta', \theta'') \right] \left[\prod_{\{\theta_{n+1}, \theta'\} \in \lambda} E(\theta_{n+1}, \theta') \right]. \tag{D19}$$

By use of (D11), (D19) is written as

$$\frac{1}{n!} \sum_{\theta \in \Theta(n+1), N_{\sigma_{n+1}} \neq 1} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'}-1} \frac{(N_{\theta'}-1)!}{N_{\theta'}} \right] \frac{1}{N_{\sigma_{n+1}} N_{\theta_{n+1}}}$$
$$\times \int_{\mathrm{sym}} \left[\prod_{\theta' \in \zeta} \frac{dx_{\theta'}}{2\pi} \right] \sum_{\lambda \in \Lambda_c(\zeta)} \frac{s N_{\theta_{n+1}} e^{E(\zeta)}}{M_{\theta_{n+1}} s - (x_{\theta_{n+1}} - x) i}$$
$$\times \left[\prod_{\{\theta', \theta''\} \in \lambda, \theta', \theta'' \neq \theta_{n+1}} C(\theta', \theta'') \right] \left[\prod_{\{\theta_{n+1}, \theta'\} \in \lambda} E(\theta_{n+1}, \theta') \right]. \tag{D20}$$

Changing the order of the summations, this expression becomes

$$\frac{1}{(n+1)!} \sum_{\theta \in \Theta(n+1)} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'}-1} \frac{(N_{\theta'}-1)!}{N_{\theta'}} \right] \int_{\mathrm{sym}} \left[\prod_{\theta' \in \zeta} \frac{dx_{\theta'}}{2\pi} \right]$$
$$\times \sum_{\lambda \in \Lambda_c(\zeta)} \sum_{\theta_0 \in \zeta, M_{\theta_0} \neq 1} \frac{s N_{\theta_0} e^{E(\zeta)}}{M_{\theta_0} s - (x_{\theta_0} - x) i} \left[\prod_{\{\theta', \theta''\} \in \lambda, \theta', \theta'' \neq \theta_0} C(\theta', \theta'') \right] \left[\prod_{\{\theta_0 \theta'\} \in \lambda} E(\theta_0, \theta') \right]. \tag{D21}$$

From the above-mentioned relations we see that (D14) is equal to (D21).

Both parts of the right-hand side of (D2) are replaced with (D12) and (D21). Then, the right-hand side of (D2) is expressed as

$$\frac{1}{(n+1)!} \sum_{\theta \in \Theta(n+1)} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \Theta(\theta)} \left[\prod_{\theta' \in \zeta} (-1)^{N_{\theta'}-1} \frac{(N_{\theta'}-1)!}{N_{\theta'}} \right] \int_{\mathrm{sym}} \left[\prod_{\theta' \in \zeta} \frac{dx_{\theta'}}{2\pi} \right]$$
$$\times \sum_{\lambda \in \Lambda_c(\zeta)} \sum_{\theta_0 \in \zeta} \sum_{s = \pm 1} \frac{s N_{\theta_0} e^{E(\zeta)}}{M_{\theta_0} s - (x_{\theta_0} - x) i} \left[\prod_{\{\theta' \theta''\} \in \lambda, \theta', \theta'' \neq \theta_0} C(\theta', \theta'') \right] \left[\prod_{\{\theta_0 \theta'\} \in \lambda} E(\theta_0, \theta') \right]. \tag{D22}$$

Using Eq. (G1) proved in Appendix G, we can confirm the definition of $u_{n+1}(x)$, which is the right-hand side of (3.6).

APPENDIX E: AN EXPRESSION OF $u_n(x)$

In this appendix, we prove the following expression of $u_n(x)$,

$$\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\prod_{\sigma\in\theta}-N_\sigma!u_{N_\sigma}(y)$$
$$=\frac{1}{n!}\sum_{\theta\in\Theta(n)}\prod_{\sigma\in\theta}\left[-\sum_{\theta'\in\Theta(\sigma)}\left[\prod_{\sigma'\in\theta'}N_{\sigma'}!\right]\sum_{\zeta\in\Theta(\theta')}\left[\prod_{\theta''\in\zeta}(-1)^{N_{\theta''}-1}(N_{\theta''}-1)!\right]\right.$$
$$\left.\times\int\left|\frac{\partial I}{\partial x}\right|_{c1,\zeta}(y)e^{-\beta E(\zeta)}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'}\right]. \tag{E1}$$

Here, the definition of $u_n(x)$ is (3.3), and the definition of $|\partial I/\partial x|_{c1,\zeta}(y)$ is

$$(2\pi)^{N_\zeta}\left|\frac{\partial I}{\partial x}\right|_{c1,\zeta}(y)\equiv\left[\prod_{\theta\in\zeta}N_\theta\right]^{-1}\sum_{\lambda\in\Lambda_c(\zeta)}\left[\prod_{\{\theta,\theta'\}\in\lambda}-N_\theta N_{\theta'}K_{M_\theta,M_{\theta'}}(x_\theta-x_{\theta'})\right]$$
$$\times\sum_{\theta\in\zeta}\frac{2N_\theta M_\theta}{M_\theta^2+(x_\theta-y)^2}. \tag{E2}$$

Substituting (3.3) for $u_{N\sigma}(y)$ on the left-hand side of (E1) and using a relation

$$\left|\frac{\partial I}{\partial x}\right|_{1,\zeta}(y)=\sum_{\xi\in\Theta(\zeta)}\prod_{\zeta'\in\xi}\left|\frac{\partial I}{\partial x}\right|_{c1,\zeta'}(y), \tag{E3}$$

which is proved in the same way as (C1), we can show that the left-hand side of (E1) is calculated as

$$\sum_{\theta\in\Theta(n)}\frac{N_\theta!}{n!}\prod_{\sigma\in\theta}\left[-\sum_{\theta'\in\Theta(\sigma)}\left[\prod_{\sigma'\in\theta'}N_{\sigma'}!\right]\sum_{\zeta\in\Theta(\theta')}\left[\prod_{\theta''\in\zeta}(-1)^{N_{\theta''}-1}(N_{\sigma''}-1)!\right]\right.$$
$$\left.\times\sum_{\xi\in\Theta(\zeta)}\left[\prod_{\zeta'\in\xi}\int\left|\frac{\partial I}{\partial x}\right|_{c1,\zeta'}(y)e^{-\beta E(\zeta')}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'}\right]\right]$$
$$=\frac{1}{n!}\sum_{\theta\in\Theta(n)}\left[\sum_{\theta'\in\Theta(N_\theta)}N_{\theta'}!(-1)^{N_{\theta'}}\right]\prod_{\sigma\in\theta}\left[\sum_{\theta'\in\Theta(\sigma)}\left[\prod_{\sigma'\in\theta'}N_{\sigma'}!\right]\right.$$
$$\left.\times\sum_{\zeta\in\Theta(\theta')}\left[\prod_{\theta''\in\zeta}(-1)^{N_{\theta''}-1}(N_{\theta''}-1)!\right]\int\left|\frac{\partial I}{\partial x}\right|_{c1,\zeta}(y)e^{-\beta E(\zeta)}\prod_{\theta'\in\zeta}\mathrm{d}x_{\theta'}\right]. \tag{E4}$$

In this equality, we have changed the order of the sums. Using a relation

$$\sum_{\theta\in\Theta(n)}N_\theta!(-1)^{N_\theta}=(-1)^n \tag{E5}$$

for simplification of the first term of (E4), we obtain the right-hand side of (E1).

APPENDIX F: SYMMETRIZATION OF THE PATHS OF INTEGRALS

In this appendix, we prove a relation,

$$\int_{-\infty+\delta i}^{\infty+\delta i} dx\, f_0(x) \prod_{n=1}^{N} \left[\int_{-\infty}^{\infty} \frac{dy_n}{2\pi i} \frac{1}{y_n - x} f_n(y_n) \right]$$
$$= \sum_{\sigma \subseteq \{1,\ldots,N\}} B_{N_\sigma} \int_{\mathrm{sym}} f_0(x) \left[\prod_{n \in \sigma} f_n(x) \right] \left[\prod_{n \in \{1,\ldots,N\}-\sigma} \frac{1}{y_n - x} f_n(y_n) \frac{dy_n}{2\pi i} \right] dx. \quad \text{(F1)}$$

Here, the definitions of B_n and $\int_{\mathrm{sym}}$ are in (D6) and (D8), respectively, and we assume that $f_n(x)$ is an analytic function on the real axis.

The paths of integrations on the right-hand side of (F1) are changed into ones on the left-hand side of (F1). In other words, symmetrical paths of integrations are changed into ones which keep the relation $\Im y_n < \Im x$. Then, the right-hand side of (F1) becomes

$$\sum_{\sigma \subseteq \{1,\ldots,N\}} \left[\sum_{m=0}^{N_\sigma} (-1)^{N_\sigma - m} \frac{N_\sigma!}{(N_\sigma - m)!\, m!} \left[\sum_{l=0}^{N-N_\sigma} \frac{(l + N_\sigma - m)!}{l!} \frac{(N - N_\sigma)!}{(N - m + 1)!} \right] B_m \right]$$
$$\times \int_{-\infty+\delta i}^{\infty+\delta i} dx\, f_0(x) \left[\prod_{n \in \sigma} f_n(x) \right] \prod_{n \in \{1,\ldots,N\}-\sigma} \left[\int_{-\infty}^{\infty} \frac{dy_n}{2\pi i} \frac{1}{y_n - x} f_n(y_n) \right]. \quad \text{(F2)}$$

Using the following two relations which are easily shown,

$$\sum_{l=0}^{n} \frac{(l+m)!}{l!} = \frac{(n+m+1)!}{n!(m+1)}, \quad \text{(F3)}$$

$$\sum_{m=0}^{n} (-1)^{n-m} \frac{n!}{(n-m+1)!\, m!} B_m = \delta_{n,0} \quad \text{(F4)}$$

for (F2), we obtain the the left-hand side of (F1).

APPENDIX G: ALTERNATIVE REPRESENTATION OF THE MODIFIED JACOBIAN

In this appendix, we show that

$$(2\pi)^{N_\zeta} \left| \frac{\partial I}{\partial x} \right|_{1,\zeta} (y) = \left[\prod_{\theta \in \zeta} N_\theta \right]^{-1} \sum_{\lambda \in \Lambda_c(\zeta)} \sum_{\theta \in \zeta} \sum_{s=1,-1} \frac{s N_\theta}{s M_\theta - (x_\theta - y) i}$$
$$\times \left[\prod_{\{\theta', \theta''\} \in \lambda} \prod_{\theta', \theta'' \neq \theta} C(\theta', \theta'') \right] \left[\prod_{\{\theta, \theta'\} \in \lambda} E(\theta, \theta') \right] \quad \text{(G1)}$$

is an alternative representation of the modified Jacobian (3.4). Here, $C(\theta, \theta')$ and $E(\theta, \theta')$ are defined in (D9) and (D10), respectively.

We can rewrite (3.4) as

$$(2\pi)^{N_\xi}\left|\frac{\partial I}{\partial x}\right|_{1,\zeta}(y)=\left[\prod_{\theta\in\zeta}N_\theta\right]^{-1}\sum_{\lambda\in\Lambda_c(\zeta)}\sum_{\theta\in\zeta}\left[\prod_{\{\theta',\theta''\}\in\lambda}\prod_{\theta',\theta''\neq\theta}C(\theta',\theta'')\right]\frac{2N_\theta M_\theta}{M_\theta^2+(x_\theta-y)^2}$$
$$\times\sum_{\zeta'\subseteq\{\theta'|\{\theta,\theta'\}\in\lambda\}}\frac{1}{N_{\zeta'}+1}\left[\prod_{\theta'\in\{\theta'|\{\theta,\theta'\}\in\lambda\}-\zeta'}C(\theta,\theta')\right]$$
$$\times\left[\prod_{\theta'\in\zeta'}\frac{2N_{\theta'}M_{\theta'}}{M_{\theta'}^2+(x_{\theta'}-y)^2}\right]$$
$$=\left[\prod_{\theta\in\zeta}N_\theta\right]^{-1}\sum_{\lambda\in\Lambda_c(\zeta)}\sum_{\theta\in\zeta}\sum_{s=1,-1}\frac{sN_\theta}{sM_\theta-(x_\theta-y)i}\left[\prod_{\{\theta',\theta''\}\in\lambda}\prod_{\theta',\theta''\neq 0}C(\theta',\theta'')\right]$$
$$\times\prod_{\{\theta,\theta'\}\in\lambda}\left[C(\theta,\theta')+\frac{2N_{\theta'}M_{\theta'}}{M_{\theta'}^2+(x_{\theta'}-x_\theta-sM_\theta)^2}\right]. \tag{G2}$$

In the first equality, we have changed the order of the sums. In the second equality, we have used the relation (H1) proved in Appendix H. Applying a relation

$$K_{M_\theta,M_{\theta'}}(x_\theta-x_{\theta'})-\frac{2M_{\theta'}}{M_{\theta'}^2+(x_{\theta'}-x_\theta-sM_\theta i)^2}=K_{M_\theta-1,M_{\theta'}}(x_\theta-x_{\theta'}-si)$$
$$+\frac{2M_{\theta'}}{M_{\theta'}^2+(x_\theta-x_{\theta'}+s(M_\theta-2)i)^2} \tag{G3}$$

to (G2), we obtain the right-hand-side of (G1). In relation (G3), it is supposed that s is ±1.

APPENDIX H: A PROOF OF A FRACTIONAL RELATION

In this appendix, we prove

$$\sum_{n=1}^{N}\sum_{\sigma\subseteq\{1,\ldots,N\}-\{n\}}\frac{1}{N-N_\sigma}\left[\prod_{m\in\sigma}c_m\right]\left[\prod_{m\in\{1,\ldots,N\}-\sigma}\frac{2a_md_m}{a_m^2+(y-x_m)^2}\right]$$
$$=\sum_{s=\pm1}\sum_{n=1}^{N}\frac{sd_n}{sa_n-(x_n-y)i}\prod_{m\neq n}\left[c_m+\frac{2a_md_m}{a_m^2+(x_m-x_n-sa_ni)^2}\right], \tag{H1}$$

where a_n, c_n, d_n, x_n, and y are arbitrary numbers.

We first prove a relation

$$1=\sum_{n=1}^{N}\prod_{m\neq n}\frac{s_ma_m-(x_m-y)i}{(s_ma_m-s_na_n)-(x_m-x_n)i}. \tag{H2}$$

We regard the right-hand side as a polynomial of degree $N-1$ with respect to y. It is clear that this relation holds on the N points $y=x_n+s_na_ni$. Therefore, this equation is nothing but an identical equation. Dividing both sides of this identical equation by $\Pi_n[a_n-s_n(x_n-y)i]d_n^{-1}$, we get

$$\prod_n\frac{s_nd_n}{s_na_n-(x_n-y)i}=\sum_{n=1}^{N}\frac{s_nd_n}{s_na_n-(x_n-y)i}\prod_{m\neq n}\frac{s_md_m}{(s_ma_m-s_na_n)-(x_m-x_n)i}. \tag{H3}$$

Here, we restrict that s_n is ±1. The sum of each side of this equation with respect to $\{s_n\}$ gives

$$\prod_n \frac{2a_n d_n}{a_n^2+(y-x_n)^2} = \sum_{s=\pm 1} \sum_{n=1}^{N} \frac{2d_n}{sa_n-(x_n-y)i} \prod_{m\neq n} \frac{2a_m d_m}{a_m^2+(x_m-x_n-sa_n i)^2}. \tag{H4}$$

We are in a position to prove the main issue of this appendix. Using (H4) for the left-hand side of (H1), we get

$$\sum_{s=\pm 1} \sum_{n=1}^{N} \frac{sd_n}{sa_n-(x_n-y)i} \sum_{\sigma\subseteq\{1,\ldots,N\}-\{n\}} \left[\prod_{m\in\sigma} c_m\right] \left[\prod_{m\subseteq\{1,\ldots,N\}-\{n\}-\sigma} \frac{2a_m d_m}{a_m^2+(x_m-x_n-sa_n i)^2}\right]. \tag{H5}$$

Expanding the right-hand side of (H1), we also get (H5). This completes a proof of (H1).

Extensive form of equilibrium nonextensive statistics

Qiuping A. Wang[a] and Alain Le Méhauté
Institut Supérieur des Matériaux du Mans, 44, Avenue F.A. Bartholdi, 72000 Le Mans, France

(Received 3 April 2002; accepted for publication 8 May 2002)

It is argued that, in nonextensive statistical mechanics with Tsallis entropy, the factorization of compound probability over subsystems is a consequence of the existence of thermodynamic equilibrium in the composite system and should be respected by all exact calculations concerning equilibrium subsystems. Using nonadditive energy satisfying this factorization, we propose an additive formalism of nonextensive statistical mechanics with additive q-deformed physical quantities and exponential distributions. This formalism leads to exact quantum gas distributions different from those given by factorization approximation with additive energy. The fermion distribution of the present work shows similar characteristics to the distribution of strongly correlated electrons given by numerical analysis with the Kondo t-J model. © *2002 American Institute of Physics.*

I. INTRODUCTION

In this paper we will discuss some problems of nonextensive statistical mechanics (NSM) relevant to the factorization of compound probability into the product of single body probability

$$\rho=\prod_{n=1}^{N}\rho_n, \tag{1}$$

where N is the number of subsystems in the system of interest, ρ is the q-exponential distribution (QED): $\rho\propto[1-(1-q)\beta H]^{1/(1-q)}$ ($[.]\geqslant 0$), as given by the maximization of Tsallis entropy $S_q=-\mathrm{Tr}(\rho-\rho^q)/(1-q)$ (Boltzmann constant $k_B=1$ and $q>0$) under some constraints.[1–3] This factorization Eq. (1) has been viewed as a result of the independence of noninteracting subsystems having additive energy, just as in Boltzmann–Gibbs statistics (BGS) supposing short-range interactions, and caused confusion in some theoretical studies of NSM and its applications to many-body problems. On the basis of a new idea relating Eq. (1) to thermodynamic equilibrium, we will argue that the confusion can be avoided if we introduce suitable nonadditive thermodynamic variables satisfying Eq. (1). Some theoretical consequences for quantum distributions of this ''equilibrium version'' of NSM will be studied.

Due to the necessity of defining additive average value of some extensive q-deformed thermodynamic variables, the discussions will be made within the formalism of incomplete statistics (IS) with $\mathrm{Tr}\,\rho^q=1$ and normalized average $\overline{x}=\mathrm{Tr}\,\rho^q x$.[3] The reader will find that the quantum distributions of IS indeed show some particular properties already noticed with strongly correlated electrons.

II. ABOUT INCOMPLETE NORMALIZATION

IS as an alternative version of NSM was originally motivated by some theoretical peculiarities in the last Tsallis version of NSM based on the conventional normalization and unnormalized expectations.[3]

[a]Electronic mail: awang@ismans.univ-lemans.fr

The basic assumption of IS is that our knowledge about physical systems is in general incomplete due to unknown space–time correlations or the effects of known interactions which cannot be exactly described. In this case, probability distributions are incomplete, i.e., $\mathrm{Tr}\,\rho = Q \neq 1$[4] (or $\Sigma_{i=1}^{w} p_i = Q$ where w is only the number of accessible states in phase space). One can only write $\mathrm{Tr}\,F(\rho) = 1$ where F is a certain function of ρ. In the case of complete or approximately complete distribution (such as in BGS), F is an identity function. Recently, in order to overcome some of the theoretical difficulties of NSM in keeping the framework prescribed by Tsallis entropy, we proposed[3] $F(\rho) = \rho^q$ so that

$$\mathrm{Tr}\,\rho^q = 1, \tag{2}$$

where q is incompleteness index.[3] Since $\rho < 1$, we have to set $q \in [0,\infty]$. $q = 0$ should be avoided because it leads to $\rho = 0$ for all states. We note that Eq. (2) has been successfully employed to deduce some power laws based on Rényi's entropy.[5] This kind of *incomplete normalization* is possible whenever the phase space is partially known or accessible. With a fractal or chaotic phase space, e.g., a complete calculation of probability becomes, in general, impossible. In this sense, a plausible justification of Eq. (2) may be inspired by a work of Tsallis[6] discussing nonadditive energy and probability distributions on fractal supports, although at that stage the work was not connected to anomalous normalization like Eq. (2). In that work, considering some simple self-similar fractal structures (e.g., Cantor set), one can obtain

$$\sum_{i=1}^{W} \left[\frac{V_i(k)}{V(0)} \right]^{d_f/d} = 1, \tag{3}$$

where $V_i(k)$ may be seen as the segments of the fractal structure at a given iteration of order k, $V(0)$ a characteristic volume of the fractal structure embedded in a d-dimension Euclidean space, $d_f = \ln n / \ln m$ is the fractal dimension, n the number of segments replacing a segment of the precedent iteration, m the scale factor of the iterations, and $W = n^k$ the total number of segments at the kth iteration. If we suppose that the fractal structure with $k \to \infty$ is a phase space containing homogeneously distributed points, the *exact microcanonical probability distribution* of the kth iteration can be defined as

$$p_i = \frac{V_i(k)}{V} = \frac{V_i(k)}{\Sigma_i^W V_i(k)}$$

where V is the total volume of the phase space. This distribution obviously sums to one. The problem is that V is an indefinite volume as $k \to \infty$ and impertinent for exact probability definition. In addition, V is not differentiable and contains inaccessible points. Thus exact summation in V would be impossible. Now if we define $p_i = V_i(k)/V_0$ as a physical or effective distribution, then we have $\Sigma_{i=1}^{W} p_i^{d_f/d} [V_0/V(0)]^{d_f/d} = 1$, where V_0 is *a completely accessible and infinitely differentiable support* on which the calculation of p_i is possible. If we choose $V_0 = V(0)$, we can write Eq. (2) with $q = d_f/d$. The conventional normalization $\Sigma_{i=1}^{W} p_i = 1$ can be recovered when $d_f = d$.

The above-given example is only a case of equiprobable distribution on simple fractal structure, but it illustrates very well the possibility that, in complex cases, a physical probability may not sum to one and may sum to unity only through a kind of power normalization, which, pertinent and useful for incomplete distributions, is consistent with the discussions of Ref. 6 on the mass calculation and the information consideration in porous structures.

III. FACTORIZATION OF COMPOUND PROBABILITY AND THERMODYNAMIC EQUILIBRIUM

In NSM, there are two major problems connected tightly to the factorization of compound probability. The first concerns the application of NSM to many-body systems via one-body distribution. NSM is originally intended to describe complex systems with long-range interactions or

fractal structure of space–time showing nonextensive phenomena. So from the beginning of this theory, Eq. (1) is supposed for composite systems containing N *statistically* independent subsystems in order to elicit the nonextensive character by the following relation:

$$\ln[1+(1-q)S_q]=\sum_{n=1}^{N}\ln[1+(1-q)S_q(n)]. \tag{4}$$

For $N=2$, $S_q=S_q(1)+S_q(2)+(1-q)S_q(1)S_q(2)$ as one often finds in the literature. Due to this *independence*, it has been believed by many that exact calculations within NSM should use the additive Hamiltonian $H_0=\Sigma_{n=1}^{N}H_n$, where H_n is the Hamiltonian of nth subsystem.[2,7–11] However, this Hamiltonian is not compatible with either Eq. (1) or Eq. (4) since these equations applied to QED mean:[1,12,13]

$$H=\sum_{n=1}^{N}H_n+\sum_{k=2}^{N}[(q-1)\beta]^{k-1}\sum_{n_1<n_2<\cdots<n_k}^{N}\prod_{j=1}^{k}H_{n_j}=H_0+H_c, \tag{5}$$

where β is the inverse temperature. In order to reconcile H_0 and Eq. (1), a so-called *factorization approximation* is proposed[14] by neglecting the second term on the right-hand side of Eq. (5). This approximation has been, explicitly or not, employed in most of the applications of NSM[13–18] via one-body QED. These applications certainly show the usefulness of one-body QED, but the approximation neglecting the correlation energy by supposing sometimes weak interacting dilute particles[19] is not a reassuring basis. Indeed, some recent works show that the correlation energy (H_c) given by the second term of Eq. (5) is in general not negligible[12] and that the partition function given by using additive energy is completely different from that given by using Eq. (5) when N is large.[11] So a doubt arises about the connection between independence of subsystems and additive energy. Recently, an interesting idea is forwarded to define a ''quasi-independence'' according to nonadditive energy Eq. (5) in order to apply NSM to turbulence flow problems.[19] As a matter of fact, this proposal implies rejection of classical independence for Eq. (1).

The second problem connected with probability factorization is the establishment of zeroth law and the definition of temperature for NSM. It was believed that the zeroth law of thermodynamics was absent within NSM[20] due to the paradox between Eq. (1) and the additive energy. Recently, a series of works have been published on this issue[21] claiming the establishment of zeroth law and the definition of a generalized temperature on the basis of additive Hamiltonian H_0 and Eq. (4) by neglecting H_c. It is evident that the above-mentioned paradox persists behind this approximate zeroth law.

The central question is as follows. Equation (1) certainly implies independence of noninteracting systems for BGS, but does it mean the same thing for NSM? Very recently, Abe[22] proposed a general pseudoadditivity for entropy required by the existence of thermal equilibrium in composite nonextensive systems. For a system containing N subsystems, the pseudoadditivity is

$$\ln[1+\lambda_S f(S)]=\sum_{n=1}^{N}\ln[1+\lambda_S f(S_n)], \tag{6}$$

where f is certain differentiable function satisfying $f(0)=0$ and λ_S a constant depending on the nature of the system of interest. On the other hand, Eq. (6) applied to Tsallis entropy means $f(S)=S$ and $\lambda_S=1-q$,[22] which directly leads to $\ln \mathrm{Tr}\,\rho^q=\Sigma_{i=1}^{N}\ln \mathrm{Tr}\,\rho_i^q$ or Eq. (1) (i.e., with classical probability p_i of the state i, $(p_ip_j)^q=p_{ij}^q$ means $p_ip_j=p_{ij}$). So Eq. (1) *has nothing to do with statistical independence of subsystems. It is a consequence of the existence of thermodynamic equilibrium* and must be rigorously respected by all exact calculations. Equilibrium energy has been proved[23] to satisfy the same kind of pseudoadditivity as Eq. (6) (S is replaced by H). If we choose $f(H)=H$ and $\lambda_H=(q-1)\beta$, we get

$$\ln[1+(q-1)\beta H]=\sum_{n=1}^{N}\ln[1+(q-1)\beta H_n], \tag{7}$$

which is just Eq. (5) satisfying Eq. (1). In this way, the zeroth law becomes evident and a temperature can be straightforwardly defined at maximum entropy and minimum energy.[3,12]

IV. ADDITIVE FORMALISM OF NSM

A. Information measure

The g-logarithmic information measure

$$I_\nu=\frac{(1/\rho)^\nu-1}{\nu} \tag{8}$$

is a nonadditive generalization of Hartley formula $I=\ln(1/\rho)$ and can be employed to deduce Tsallis entropy.[1,3,24] I_g or I is the information needed to specify at which state the system is localized. ν equals $1-q$ or $q-1$, depending on the normalization procedures of ρ.[25] Using Eq. (1), we get

$$\ln(1+\nu I_\nu)=\sum_{n=1}^{N}\ln(1+\nu I_\nu^{(n)}), \tag{9}$$

where $I_\nu^{(n)}$ is the information needed to specify the nth subsystem. This pseudoadditivity is evident if we recast the generalized Hartley formula, Eq. (8), as follows

$$I_\nu=\frac{e^{-\nu\ln\rho}-1}{\nu}=\frac{e^{\nu I}-1}{\nu}, \tag{10}$$

where

$$I=\ln\frac{1}{\rho}=\frac{\ln(1+\nu I_\nu)}{\nu} \tag{11}$$

can be referred to as q-deformed information measure and is additive supposed Eq. (1). It is noteworthy that this I is not the quantity of Hartley information if ρ is a nonextensive distribution for $\nu\neq 0$.

B. Canonical ensemble

Now let us define an additive entropy S as follows:

$$S=\mathrm{Tr}\,\rho^q\ln\frac{1}{\rho} \tag{12}$$

and an additive q-deformed ''Hamiltonian''

$$h=\frac{\ln[1+(q-1)\beta H]}{(q-1)\beta}. \tag{13}$$

So Eq. (7) becomes

$$h=\sum_{n=1}^{N}h_n. \tag{14}$$

This means the following transformations:

$$H=\frac{e^{(q-1)\beta h}-1}{(q-1)\beta}, \quad H_n=\frac{e^{(q-1)\beta h_n}-1}{(q-1)\beta} \tag{15}$$

and

$$\rho=\frac{1}{Z}[1+(q-1)\beta H]^{1/(1-q)}=\frac{1}{Z}e^{-\beta h}, \tag{16}$$

where $Z^q=\mathrm{Tr}\, e^{-q\beta h}$.[3] It should be noticed that, when addressing a system of N particles, we have to write $H_n=p_n^2/2m+V_n$ for a single particle so that

$$h_n=\frac{\ln\left[1+(q-1)\beta\left(\frac{p_n^2}{2m}+V_n\right)\right]}{(q-1)\beta}$$

where $p_n^2/2m$ is the classical kinetic energy and V_n is the potential energy. It is clear that H_n, instead of h_n, is the physical energy. When $q=1$ ($H_c=0$), we recover $H_n=h_n$ and $H=h=\Sigma_{n=1}^{N} p_n^2/2m$. The q-deformed internal energy u is defined as follows:

$$u=\mathrm{Tr}\,\rho^q h. \tag{17}$$

We can easily show that the distribution Eq. (16) can be yielded by the maximum of the additive "entropy" S (which surely exists due to the monotonic relation between I and I_ν) under the constraints of Eq. (17) and incomplete normalization $\mathrm{Tr}\,\rho^q=1$. It is easy to verify that $S=\ln Z+\beta u$ and, via the zeroth law, $\partial S/\partial u=\beta=1/T$. The "first law" is given by $\mathrm{d}u=T\,dS-p\mathrm{d}V$ where p is q-deformed pressure and V the volume of the system which is chosen to be additive here. The q-deformed Helmholtz free energy f is defined as $f=u-TS=-T\ln Z$ and can be connected to the nonadditive one

$$F_q=-T\frac{Z^{1-q}-1}{1-q}$$

(Refs. 1 and 3) as follows:

$$f=\frac{\ln[1+(q-1)\beta F_q]}{(q-1)\beta}. \tag{18}$$

So $p=-(\partial f/\partial V)_T=P/Z^{1-q}$ where $P=-(\partial F_q/\partial V)_T$ is the real pressure. In this scenario, the thermodynamic equilibrium of a system C containing two equilibrium systems A and B satisfying $V(C)=V(A)+V(B)$ corresponds to $\beta(A)=\beta(B)$ and $p(A)=p(B)$. This implies that $P(A)\neq P(B)$ if $Z(A)\neq Z(B)$. This is because we have supposed nonadditive energy and additive volume. As a matter of fact, in this formalism, if we want $P(A)=P(B)$ at equilibrium, we must accept nonadditive volume and additive q-deformed volume v with which the first law becomes $\mathrm{d}u=T\,\mathrm{d}S-P\,\mathrm{d}v$. This means: $P=-(\partial F_q/\partial V)_T=-(\partial f/\partial v)_T$. This relation can help to deduce the $v-V$ relation. We also have $v=(\partial g/\partial P)_T$ where the q-deformed Gibbs energy is given by $g=f+Pv$. Since v is additive, V will be nonadditive if v is not a linear function of V. We will come back to this issue later in this paper.

C. Grand canonical ensemble

It is known that the grand canonical ensemble QED has been given by[1,9,14]

$$\rho\propto[1-(1-q)\beta(H-\mu N)]^{1/(1-q)} \tag{19}$$

for N identical particle systems, where μ is chemical potential. This distribution has been widely used for quantum particle systems.[14–16,26] But the zeroth law has never been rigorously established for this ensemble. In a previous work,[26] one of the authors of present paper (Q.A.W.) deduced exact quantum distributions on the basis of Eq. (19) and the following relation suggested by Eq. (1):

$$\rho \propto [1-(1-q)\beta(H_n-\mu)]^{N/(1-q)}. \tag{20}$$

In the framework of IS,[3,26] the exact distributions are given by

$$\overline{n_k}=\frac{1}{[1+(q-1)\beta(e_k-\mu)]^{q/(q-1)}\pm 1}, \tag{21}$$

where e_k is the energy of the one-particle state k and "+" and "−" correspond to fermions and bosons, respectively. Now we show that this distribution can be written in exponential form just as for conventional noninteracting quantum gases and that the zeroth law can be rigorously verified.

Let us suppose $\beta=\beta'/[1+(q-1)\beta'\mu]=\beta'[1-(q-1)\beta'\mu']$ (or $\beta'=\beta/[1-(q-1)\beta\mu]$) and $\mu=\mu'/[1+(1-q)\beta'\mu']$ (or $\mu'=\mu/[1+(q-1)\beta'\mu]=\mu[1-(q-1)\beta\mu]$) which imply $\beta'\mu'=\beta\mu$. Equation (20) can be recast as

$$\rho=\frac{1}{Z}[1-(1-q)\beta' H_n]^{N/(1-q)}[1+(1-q)\beta'\mu']^{N/(1-q)}=\frac{1}{Z}e^{-N\beta(h_n-\omega)}, \tag{22}$$

where

$$\omega=\frac{\ln[1+(1-q)\beta'\mu']}{(1-q)\beta'}, \quad h_n=\frac{\ln[1+(q-1)\beta' H_n]}{(q-1)\beta'}.$$

$Z^q=\mathrm{Tr}[1-(1-q)\beta(H-\mu N)]^{q/(1-q)}=\{\mathrm{Tr}[1-(1-q)\beta' H_n]^{q/(1-q)}[1+(1-q)\beta'\mu']^{q/(1-q)}\}^N$ $=(\mathrm{Tr}\, e^{-q\beta(h_n-\omega)})^N=z^N$ and where z is one-particle partition function. Just as for the canonical ensemble, this exponential distribution can be shown to be the result of the maximization of S under the constraint $\overline{N}=\mathrm{Tr}\,\rho^q N$ in addition to Eq. (17) and incomplete normalization. Now Eq. (21) can be written as

$$\overline{n_k}=\mathrm{Tr}\,\rho^q n_k=\frac{1}{e^{q\beta'(\epsilon_k-\omega)}\pm 1}=\frac{1}{[1+(q-1)\beta' e_k]^{q/(q-1)}[1-(q-1)\beta'\mu']^{q/(q-1)}\pm 1}, \tag{23}$$

where ϵ_k is the eigenvalue of h_n. From Eq. (21), we see that, for free particles (*in the sense that we do not write the energy of interaction between particles in the Hamiltonian and let it be "absorbed" in the nonextensive part of energy H_c and related to q different from unity*), we have to set $q<1$ to ensure positive $[1+(q-1)\beta(H_n-\mu)]$ for fermions when $T\to 0$. This means that, at low temperatures, there will be few fermions beyond Fermi energy. For bosons with $\mu<0$, we have to put $q>1$.

It is straightforward to write $S=\ln Z+\beta' u+\beta'\omega\overline{N}$ and, with the method employed in Refs. 3 and 12 to show that, for a system C containing two equilibrium systems A and B satisfying $\overline{N}(C)=\overline{N}(A)+\overline{N}(B)$, $\beta'(A)=\beta'(B)$, and $\omega(A)=\omega(B)$ thus $\mu'(A)=\mu'(B)$, $\mu(A)=\mu(B)$ and $\beta(A)=\beta(B)$ or $T(A)=T(B)$. The zeroth law is verified. One may ask why we identify β, instead of β', to real temperature. The possible reasons are the following: (1) β is the Lagrange multiplier of the constraint on real energy in entropy maximization; (2) if β' is inverse temperature, then μ' must be chemical potential, which makes it impossible to get distribution Eq. (22) by real entropy maximization with the constraint on $\overline{N}$; (3) e_f would be different from the chemical potential μ' and equal to $\mu'/[1+(1-q)\beta'\mu']$ which inevitably drops to zero when $T\to 0$.

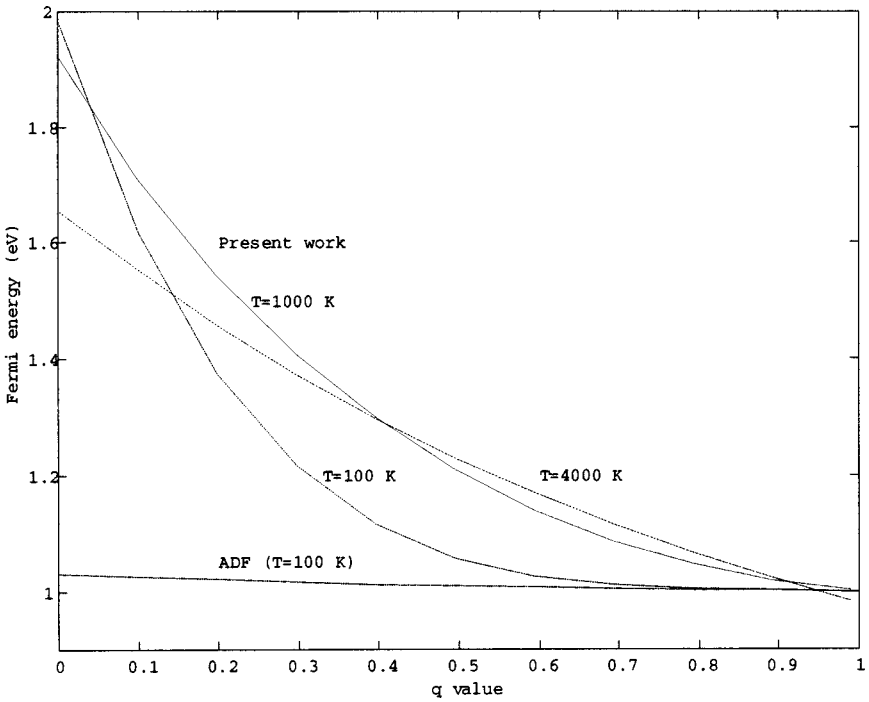

FIG. 1. q-dependence of Fermi energy e_f of IS quantum distribution in the present work and of ADF given by the factorization approximation with additive energy. The fermion density σ is chosen to give $e_f^0=1$ eV for CFD distribution at $T=0$. IS e_f shows strong increase with decreasing q up to two times e_{f_0}. But ADF e_f depends only slightly on q. We also notice that the T-dependence of IS e_f is not monotonic as shown in Fig. 2.

Now we will focus the discussion on two-dimensional fermion distribution. According to Eq. (21) the Fermi energy e_{f_0} at $T=0$ is given by $e_{f_0}=2\pi\hbar^2\sigma/m$ where σ is the particle density and $\hbar$ Planck constant.

When $T>0$, the summation $\overline{N}=\Sigma_k \overline{n_k}$ cannot be calculated for arbitrary q to give an explicit expression of e_f. So we have recourse to numerical calculation of q-dependence of e_f for given temperatures (Fig. 1) and T dependence for given q values (Fig. 2). We see that, for the approximate distributions functions (ADF) $n_k=1/\{[1+(q-1)\beta(e_k-\mu)]^{1/(q-1)}+1\}$ deduced from Eq. (19) with factorization approximation and additive energy,[14] e_f depends only slightly on q. On the other hand, the e_f of IS in the present work shows a strong increase with decreasing q up to two times e_{f_0} of conventional Fermi–Dirac distribution (CFD). This e_f increase has indeed been noticed through numerical calculations for strongly correlated heavy electrons on the basis of a tight-binding Kondo lattice model.[27,28] In Fig. 2, we show that e_f of IS does not monotonically decrease with increasing temperature, in contrast with the e_f behavior of CFD. This kind of nonmonotonic temperature evolution of e_f was also seen through numerical work for correlated electrons in the two-dimensional $t-J$ model.[29]

The IS distribution given by Eq. (21) is plotted in Fig. 3 for $T=100$ K. The particle density σ is chosen to give $e_{f_0}=1$ eV. As expected, the distribution changes drastically with q. When q decreases, we notice a flattening of the distribution always with a sharp drop of occupation number n at e_f which increases. This flattening is also noticed in numerical calculations for strong coupling electrons.[27,28]

The grand canonical partition function Z can be calculated to give the q-deformed grand potential $\overline{\omega}=-T'\ln Z=(T'/q)\Sigma_k \ln(1-\overline{n_k})$ as usual, where $T'=1/\beta'=T+(1-q)\mu$. The grand potential is given by

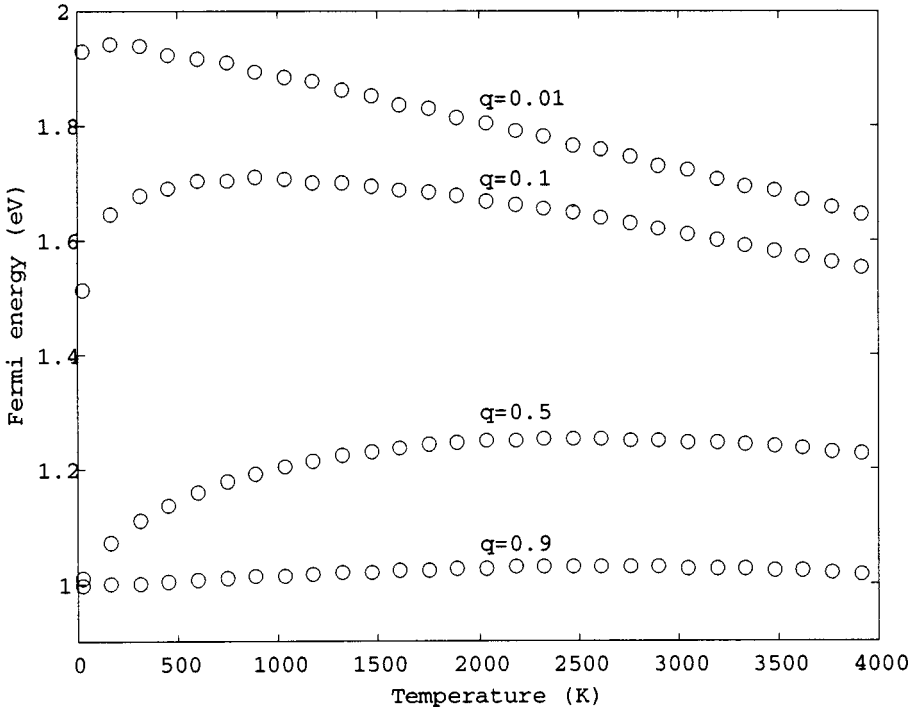

FIG. 2. T-dependence of Fermi energy e_f of IS quantum distribution in present work. The fermion density σ is chosen to give $e_f^0=1$ eV for CFD distribution at $T=0$. The T-dependence of e_f is in general not monotonic, in contrast with the classical decreasing behavior of e_f with increasing temperature. We notice that, at low temperature, e_f shows an increase with increasing T.

$$\Omega=\frac{e^{(q-1)\beta'\overline{\omega}}-1}{(q-1)\beta}=T\frac{\Pi_k(1-\overline{n_k})^{(q-1)/q}-1}{(q-1)}. \tag{24}$$

In this q-deformed extensive formalism, Euler theorem applies just as in BGS. So we have $g=\omega\overline{N}=u+pV-T'S$. Compare this with $S=\ln Z+\beta' u-\beta'\omega\overline{N}$ to obtain the following equations of state:

$$pV=T'\ln Z=\frac{T'}{q}\sum_k \ln(1-\overline{n_k}). \tag{25}$$

V. DISCUSSION AND CONCLUSION

The formalism of NSM presented here is required by the existence of thermodynamic equilibrium or by Eq. (1) for nonextensive systems described by Tsallis entropy. Theoretically the formalism is self-consistent. Experimental or numerical evidence is needed to verify the thermodynamic relations. In this framework, all the successful applications of NSM conforming with Eq. (1) are still valid. But the approximate applications carried out for many-body systems using additive energy as exact Hamiltonian (not consistent with the existence of thermodynamic equilibrium) should be carefully reviewed.

As mentioned previously, we have noticed similar properties between the IS fermion distribution and that of strongly correlated electrons.[27,28] This similarity shows the merit of NSM in describing strong interacting systems. On the other hand, we noticed that a flattening of n drop at e_f with increasing correlation, observed experimentally and numerically with weakly correlated

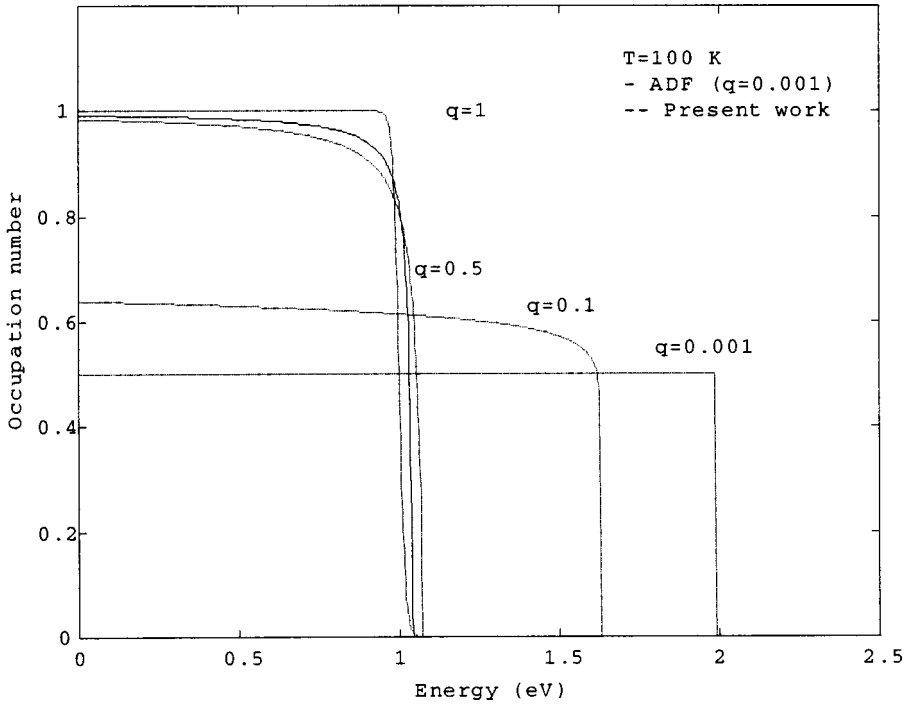

FIG. 3. Fermion distributions of ADF and of IS in the present work. ADF distribution is only slightly different from that at $q=1$ (CFD one) even with q very different from unity. The IS distribution of the present work changes drastically with decreasing q. As $q\to 0$, the occupation number tends to 1/2 for all states below e_f which increases up to 2 times e_{f_0}.

electrons,[27,28,30–32] is absent within NSM fermion distributions which always show very sharp n drop at e_f at low temperatures. A detailed study of this problem will be presented in another paper of ours.

It is worth mentioning that, in the present work, energy is nonadditive to satisfy the requirement of thermodynamic equilibrium. Nonadditive energy can happen if interaction is no longer of short-range and not localized only between the containing walls of subsystems. But in the literature, there are rarely explicit expressions of nonadditive energy. One of explicit examples is the long-range Ising model[33] where the internal energy $U(N,T)$ may be proportional to N^c (c is a constant), instead of N, the number of spins in the system. This energy can be shown to satisfy Abe's pseudoadditivity for energy[23] if we choose $f(U)$ to be proportional, e.g., to N (with $\lambda_H=0$) or to e^N-1 (with $\lambda_H=1$).

Indeed, theoretically, nonadditive physical quantities (energy, volume, ...) are not evident within the statistics with complete distributions because all possible states (all points in phase space) are counted and summed here. But from the viewpoint of incomplete statistics, nonadditivity may be interpreted as a consequence of incomplete summation of state points in phase space due to the incompleteness of our knowledge about the physical systems.[3]

Nevertheless, the fact that the correlation energy H_c of NSM depends on temperature, as shown in Eq. (5) or Eq. (7), is not an easy aspect to be understood. A possible interpretation is that these nonadditive equations are required or prescribed by thermal equilibrium with Tsallis entropy and so naturally change with temperature. This implies that the effect of correlations may depend on temperature.

Summing up, within the framework of *incomplete statistics*, it is argued that the nonextensive thermostatistics should be based on the factorization of compound probability suggested, not by ''independence'' of noninteracting systems, but by *existence of thermodynamic equilibrium in interacting systems having Tsallis entropy*. So this factorization must be viewed as a fundamental hypothesis of NSM and rigorously satisfied by all exact calculations relative to equilibrium sys-

tems. On this basis, we have elaborated an additive formalism of NSM based on the maximization of an additive deformed entropy subject to constraints on additive particle number and additive q-deformed energy. The IS quantum distributions of this formalism are compared with the distributions previously obtained by using complete probability and additive energy in factorization approximation and also with numerical results for strongly correlated electrons. It is shown that some effects of strong correlations—the flattening of the fermion distribution and the sharp cutoff of occupation number at e_f which shows strong increase with increasing interaction—can be observed in IS fermion distribution with decreasing q value.

[25] Tsallis entropy S_q can be given by averaging I_g in several ways according to the normalization of ρ: (1) Supposing complete distribution with $\mathrm{Tr}\,\rho=1$, let $g=1-q$, we have $S_q=k\,\mathrm{Tr}\,\rho I_g=k\mathrm{Tr}\rho[(1/\rho)^{1-q}-1]/(1-q)=-k\mathrm{Tr}(\rho-\rho^q)/(1-q)$—Ref. 24. k is Boltzmann constant. (2) Supposing incomplete distribution with $\mathrm{Tr}\,\rho^q=1$, let $g=q-1$, we have $S_q=k\,\mathrm{Tr}\,\rho^q[(1/\rho)^{q-1}-1]/(q-1)=-k\,\mathrm{Tr}(\rho-\rho^q)/(1-q)$—Ref. 3. This calculation also holds if we suppose complete distribution and the unnormalized average of an operator x: $\overline{x}=\mathrm{Tr}\,\rho^q x$ (Ref. 1).

d-dimensional Lévy flights: Exact and asymptotic

T. M. Garoni and N. E. Frankel[a)]
School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia

(Received 29 January 2002; accepted for publication 10 May 2002)

The analytic and asymptotic properties of the spherically symmetric d-dimensional Lévy stable probability density function, $p_\alpha^d(r)$, are discussed in detail. These isotropic stable probability density functions (pdfs) are analogous to the one-dimensional symmetric Lévy stable pdfs previously studied by the present authors [J. Math. Phys. **43**, 2670 (2002)]. We construct a hypergeometric representation of $p_\alpha^d(r)$ when α is rational, and find a number of new representations of $p_\alpha^d(r)$ in terms of special functions for various values of d and α. A recursion relation is found between $p_\alpha^d(r)$ and $p_\alpha^{d+2}(r)$, which, in particular, implies there exists a simple map between $p_\alpha^1(r)$ and $p_\alpha^3(r)$. As in our previous paper, we discuss the properties of $p_\alpha^d(r)$ for both the cases $\alpha \leqslant 2$ and $\alpha > 2$. We demonstrate the existence of intricate exponentially small series in the large r asymptotics of $p_\alpha^d(r)$ when α is an integer, which are dominant when α is even. We explicitly construct this beyond all orders expansion of $p_\alpha^d(r)$ for arbitrary integral α and d. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1500423]

I. INTRODUCTION

Applications of the Lévy stable probability density function (pdf) abound, in disciplines as diverse as physics, biology, and finance, as a mechanism for constructing stochastic models which possess no characteristic scale.[1] In d spatial dimensions, isotropic Lévy stable pdfs, denoted $p_\alpha^d(r)$, display large r asymptotic behavior of the form $p_\alpha^d(r) \to r^{-d-\alpha}$, where the parameter $0 < \alpha \leqslant 2$ is referred to as the order of the given pdf.[2] This asymptotic power law behavior leads to the divergence of all moments $\langle |\mathbf{r}|^n \rangle$ for $n > \alpha$. Random flights whose steps are chosen via an isotropic pdf displaying $r^{-d-\alpha}$ large r behavior have been used to model widely varied phenomena from the paths followed by animals searching for food,[3] to classical problems in statistical mechanics, e.g., Ref. 4. It has recently been argued[5,6] that the drip paintings of Jackson Pollock involve paint trajectories displaying $r^{-d-\alpha}$ behavior. The Lévy walk[1,7] model, which is a continuous time random walk whose step pdf is asymptotic to $r^{-d-\alpha}$, and its generalizations,[8] are popular methods for modeling systems displaying anomalous diffusion.[9–11]

A number of interesting mathematical questions concerning d-dimensional random flights whose steps are chosen via isotropic Lévy stable pdfs have been addressed recently, e.g., Refs. 12 and 13. However, the mathematical treatises on the analytic properties of the Lévy stable pdf are largely restricted to one dimension.[14,15] We recently demonstrated that the one-dimensional symmetric Lévy stable pdfs of rational order can be expressed in terms of hypergeometric functions, and listed a number of new representations for various values of α in terms of special functions.[16] We also discussed the utility of the symmetric stable densities when the order is larger than two. In such cases $p_\alpha^1(r)$ fails to satisfy the non-negativity condition required of a pdf despite being stable in every sense, but does however display remarkably intricate and interesting exponential asymptotic behavior when α is an even integer. A link between $p_4^1(r)$ and Pearcey's integral was demonstrated. In this work we investigate in detail the analytic and asymptotic properties of $p_\alpha^d(r)$. These functions are the natural generalization to higher dimensions of the symmetric one-dimensional Lévy stable pdfs studied in Ref. 16, and it is found that analogs of virtually all

a)Electronic mail: frankel@physics.unimelb.edu.au

results obtained in that work can be carried through to the d-dimensional case.

The isotropic d-dimensional Lévy stable pdf can be defined in an identical way to the one-dimensional case. Let X_1 and X_2 be independent random d vectors with the same pdf $p_\alpha^d(r)$, then $p_\alpha^d(r)$ is defined to be Lévy stable[17,18] if it is a solution to the following, for all positive c_1 and c_2:

$$c_1X_1+c_2X_2=cX, \tag{1.1}$$

where X has the same pdf as X_1 and X_2.

The isotropic solutions of this equation have characteristic functions of the form[17,18]

$$\tilde{p}_\alpha^d(q)=\exp(-|\mathbf{q}|^\alpha), \tag{1.2}$$

which is identical to the characteristic function of the one-dimensional symmetric Lévy stable pdfs (with the domain considered as $\mathbb{R}_{\geqslant 0}$ rather than $\mathbb{R}^d$). It is interesting to note that pdfs with characteristic functions of the form (1.2) are stable for all positive α, including $\alpha>2$, as stressed by Bouchaud.[1] Due to the form of (1.2), the only d dependence appears via the inverse Fourier transform that yields the pdf. The isotropy of $\tilde{p}_\alpha^d(q)$ implies that its d-dimensional Fourier transform decomposes into one integral over the radial variable,

$$p_\alpha^d(r)=\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d} d^dq e^{-i\mathbf{r}\cdot\mathbf{q}}\exp(-|\mathbf{q}|^\alpha), \tag{1.3}$$

$$p_\alpha^d(r)=\frac{r}{(2\pi r)^{d/2}}\int_0^\infty \mathrm{d}q\, J_{(d/2)-1}(qr)q^{d/2}e^{-q^\alpha}, \tag{1.4}$$

$J_{(d/2)-1}(qr)$ is a Bessel function.

An interesting property of (1.4) that we will make use of later is the following recursion relation linking $p_\alpha^d(r)$ to $p_\alpha^{d+2}(r)$:

$$\frac{-1}{2\pi r}\frac{\partial}{\partial r}p_\alpha^d(r)=p_\alpha^{d+2}(r). \tag{1.5}$$

The proof of this relation is straightforward, and relies only on the identity $(-\mathrm{d}/\mathrm{d}z)[z^{-\nu}J_\nu(z)]=z^{-\nu-1}J_{\nu+1}(z)$.[19] As such, (1.5) is just a special case of a general relation that holds between the d-dimensional and $d+2$-dimensional Fourier transforms of any isotropic function $f(\mathbf{q})=f(q)$. An important consequence of (1.5) is that it allows us to construct the three-dimensional analog of all the one-dimensional results in Ref. 16, in particular the analogs of the special function representations of $p_\alpha^1(r)$ for various α.

It is the analytic and asymptotic properties of (1.4) that we shall study in detail in this work, both when $0<\alpha\leqslant 2$ and $p_\alpha^d(r)$ defines a pdf, and also when $\alpha>2$. We begin by displaying a number of special functions representations of $p_\alpha^d(r)$ for various α in both two and three dimensions, using the dimensional recursion relation (1.5). The large and small r power series of $p_\alpha^d(r)$ are constructed using standard Mellin transform techniques, and we then utilize these representations to construct hypergeometric representations of $p_\alpha^d(r)$ when α is rational. The similarities and differences between this and the one-dimensional result[16] are discussed. We go on to demonstrate that as in the one-dimensional case $p_\alpha^d(r)$ displays intricate exponential asymptotic behavior when $\alpha\in\mathbb{Z}_{\geqslant 3}$, which deserves attention for its own intrinsic interest despite the fact that $p_\alpha^d(r)$ does not define a pdf when $\alpha>2$. We obtain the complete asymptotic expansion of $p_\alpha^d(r)$ for general d, and arbitrary $\alpha\in\mathbb{Z}_{\geqslant 3}$. This not only generalizes the asymptotic results in Ref. 16 from one dimension to d dimensions, but it also generalizes from the specific cases of α considered in Ref. 16 to arbitrary integral $\alpha\geqslant 3$. Finally, we calculate the absolute moments for $p_\alpha^d(r)$, whose convergence or divergence is intimately linked to the question of whether the dominant behavior of the large r asymptotics is exponential or algebraic.

II. ISOTROPIC STABLE PDFS vs LÉVY FLIGHTS

Before beginning our investigation of (1.4), we think it useful to clarify a distinction between $p_\alpha^d(r)$ and a related pdf which is often referred to in the literature.

Any isotropic pdf $p(\mathbf{r})$ can be written in the form[17]

$$p(\mathbf{r}) = \frac{1}{S_d|\mathbf{r}|^{d-1}} w(r), \tag{2.1}$$

where S_d is the surface area of the unit d-sphere, and we refer to $w(r)$ as the *step length* pdf. Recasting $p_\alpha^d(r)$ into this form we obtain

$$p_\alpha^d(r) = \frac{1}{S_d|\mathbf{r}|^{d-1}} w_\alpha^d(r), \tag{2.2}$$

$$w_\alpha^d(r) = \frac{2}{\Gamma\left(\frac{d}{2}\right)} \int_0^\infty dq \left(\sqrt{\frac{qr}{2}}\right)^d J_{(d/2)-1}(qr) e^{-q^\alpha}. \tag{2.3}$$

In physical applications[3,4,9,10,13,20] the pdf underlying $r^{-d-\alpha}$ asymptotic behavior appears to be generally regarded as an isotropic pdf with a stable *step length* pdf. Such a pdf, which we denote $m_\alpha^d(\mathbf{r})$, has the form

$$m_\alpha^d(\mathbf{r}) = \frac{1}{S_d|\mathbf{r}|^{d-1}} 2p_\alpha^1(|\mathbf{r}|) = \frac{1}{S_d|\mathbf{r}|^{d-1}} w_\alpha^1(r). \tag{2.4}$$

Despite being constructed from a stable pdf, $m_\alpha^d(\mathbf{r})$ itself is not stable (except trivially when $d=1$). This is easily observed by taking its Fourier transform and noting that one does not obtain (1.2). The difference between $m_\alpha^d(\mathbf{r})$ and $p_\alpha^d(r)$ is clearly that the *step length* pdf of $p_\alpha^d(r)$ is highly d dependent, which is how it manages to satisfy stability for arbitrary d, whereas the *step length* pdf for $m_\alpha^d(\mathbf{r})$ is independent of d. There appears to be no advantage in taking $m_\alpha^d(\mathbf{r})$ as the ansatz for pdfs displaying $r^{-d-\alpha}$ asymptotic behavior. As we demonstrate, $p_\alpha^d(r)$ is no more complicated to handle than $p_\alpha^1(r)$. Stability is especially useful in the simple case of an n step random flight, because by definition stability of the step pdf implies that the pdf for the position of the walker after n steps is simply the step pdf rescaled.

III. SOME SPECIAL FUNCTION REPRESENTATIONS

A number of special function representations for the case of $d=1$ are listed in Ref. 16. We find here the three-dimensional analogs of these results, by utilizing the dimensional recursion relation, (1.5), or via more direct methods where appropriate. The case of $d=2$ is more complicated since we cannot generate any of the two-dimensional results from the known one-dimensional results. We will construct however a hitherto unknown representation of $p_{1/2}^2(r)$ in terms of Bessel functions. We begin this section by listing the simple known cases of $p_2^d(r)$ and $p_1^d(r)$, which correspond to the d-dimensional Gaussian and Cauchy pdfs, respectively. These are the only known cases where (1.4) can be simplified for arbitrary d.

Starting with (1.3) it is trivial to obtain

$$p_2^d(r) = \frac{e^{-r^2/4}}{(\sqrt{4\pi})^d}. \tag{3.1}$$

The Cauchy result can be recovered from (1.4), since when $\alpha=1$ this is a known integral[21]

$$p_1^d(r)=\frac{\Gamma\left(\frac{d+1}{2}\right)}{\pi^{(d+1)/2}}\frac{1}{(1+r^2)^{(d+1)/2}}. \tag{3.2}$$

A. Three dimensions

Representations of $p_\alpha^3(r)$ in the cases of $\alpha=3$, $\frac{1}{3}$, and $\frac{2}{3}$ can all be generated in a straightforward fashion from the results in Ref. 16 via (1.5), and we find that

$$p_{2/3}^3(r)=\frac{5}{2^{4/3}3^{5/2}\pi^{3/2}}r^{-8/3}\Psi\left(\frac{5}{6},\frac{2}{3};\frac{4}{27r^2}\right)-\frac{5}{2^{1/3}3^{11/2}\pi^{3/2}}r^{-14/3}\Psi\left(\frac{11}{6},\frac{5}{3};\frac{4}{27r^2}\right), \tag{3.3}$$

$$\begin{aligned}p_{1/3}^3(r)=&\frac{5e^{-(\pi/4)i}}{18\sqrt{3}\pi^2}S_{0,1/3}\left(\frac{2e^{(\pi/4)i}}{3\sqrt{3r}}\right)+\frac{5e^{(\pi/4)i}}{18\sqrt{3}\pi^2}S_{0,1/3}\left(\frac{2e^{-(\pi/4)i}}{3\sqrt{3r}}\right)\\&-\frac{2}{81\pi^2r^4}S_{-1,4/3}\left(\frac{2e^{(\pi/4)i}}{3\sqrt{3r}}\right)-\frac{2}{81\pi^2r^4}S_{-1,4/3}\left(\frac{2e^{-(\pi/4)i}}{3\sqrt{3r}}\right),\end{aligned} \tag{3.4}$$

$$\begin{aligned}p_3^3(r)=&\frac{e^{-(3\pi/4)i}}{6\sqrt{3}\pi^2r^{3/2}}S_{0,1/3}\left[2e^{(3\pi/4)i}\left(\frac{r}{3}\right)^{3/2}\right]+\frac{e^{(3\pi/4)i}}{6\sqrt{3}\pi^2r^{3/2}}S_{0,1/3}\left[2e^{-(3\pi/4)i}\left(\frac{r}{3}\right)^{3/2}\right]\\&-\frac{2}{27\pi^2}S_{-1,4/3}\left[2e^{(3\pi/4)i}\left(\frac{r}{3}\right)^{3/2}\right]-\frac{2}{27\pi^2}S_{-1,4/3}\left[2e^{-(3\pi/4)i}\left(\frac{r}{3}\right)^{3/2}\right],\end{aligned} \tag{3.5}$$

where $\Psi(z)$ is the Tricomi confluent hypergeometric function,[22] and $S_{\mu,\nu}(z)$ is a Lommel function.[22]

Recalling that $J_{1/2}(z)=(2/\pi z)\sin(z)$, the integral representation of $p_{1/2}^3(r)$ can be found directly in Ref. 23 in terms of a sum of parabolic cylinder functions, $D_{-4}(z)$,

$$p_{1/2}^3(r)=\frac{1}{2r\pi^2}\int_0^\infty \mathrm{d}t\, e^{-\sqrt{t}}t\sin(rt) \tag{3.6}$$

$$=\frac{3}{4\pi^2r^3}\left[\exp\left(\frac{i}{2}\left[\pi+\frac{1}{4r}\right]\right)D_{-4}\left(\frac{e^{i(\pi/4)}}{\sqrt{2r}}\right)+\exp\left(-\frac{i}{2}\left[\pi+\frac{1}{4r}\right]\right)D_{-4}\left(\frac{e^{-i(\pi/4)}}{\sqrt{2r}}\right)\right]. \tag{3.7}$$

B. Two dimensions

Finding special function representations for $p_\alpha^2(r)$ is more time consuming than the three-dimensional case since we do not have a stock pile of zero-dimensional results with which to apply the dimensional recursion relation (1.5). We note however that in general $p_\alpha^0(r)$, defined via (1.4), is a simpler object than $p_\alpha^2(r)$, and in fact $p_{1/2}^0(r)$ is listed in Ref. 22 in terms of parabolic cylinder functions. Hence the dimensional recursion relation leads to

$$p_{1/2}^2(r)=-\frac{1}{2\pi r}\frac{\partial}{\partial r}\frac{1}{\sqrt{2r}}D_{-1/2}\left(\frac{e^{(\pi/4)i}}{\sqrt{2r}}\right)D_{-1/2}\left(\frac{e^{-(\pi/4)i}}{\sqrt{2r}}\right), \tag{3.8}$$

$$p_{1/2}^2(r) = -\frac{1}{2\pi r}\frac{\partial}{\partial r}\frac{\pi^3}{16r}\left[J_{1/4}^2\left(\frac{1}{8r}\right)+Y_{1/4}^2\left(\frac{1}{8r}\right)\right], \tag{3.9}$$

where $Y_{1/4}(1/8r)$ is a Neumann function. In obtaining this last step we have used the fact that $D_{-1/2}(z)=\sqrt{(\pi z/2)}K_{1/4}(z^2/4)$, where $K_{1/4}(z^2/4)$ is a modified Bessel function of the third kind.[22–24]

IV. POWER SERIES REPRESENTATIONS FOR $p_\alpha^d(r)$

We now construct the convergent series, and asymptotic power series representations of $p_\alpha^d(r)$, since we shall have need to employ these expansions in later discussions. This process is a straightforward generalization of that employed in the construction of the series representations of $p_\alpha^1(r)$.[16,17] One can easily construct the Mellin–Barnes integral representation of $p_\alpha^d(r)$ by simply calculating its Mellin transform and then using the inverse Mellin transform formula. The Mellin transform of $p_\alpha^d(r)$ is listed in Ref. 23,

$$p_\alpha^d(r) = \frac{1}{\alpha(2\sqrt{\pi})^d}\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} ds\left(\frac{r}{2}\right)^{-s}\frac{\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{d-s}{\alpha}\right)}{\Gamma\left(\frac{d-s}{2}\right)} \tag{4.1}$$

$$= \frac{1}{\alpha(2\sqrt{\pi})^d}H_{1,2}^{1,1}\left[\frac{r}{2}\middle|\begin{matrix}\left(1-\frac{d}{\alpha},\frac{1}{\alpha}\right)\\ \left(0,\frac{1}{2}\right);\left(1-\frac{d}{2},\frac{1}{2}\right)\end{matrix}\right], \tag{4.2}$$

where $0<c<\min((d+1)/2,d)$, and we have observed that (4.1) defines a Fox H function[23] for all values of d and α. We also mention here that if α is rational the ratio of gamma functions in (4.1) can be so massaged that each gamma function has the form $\Gamma(\pm s+\text{stuff})$, and we can hence identify this result with a Meijer G-function. We shall return to this point in Sec. V when we obtain the hypergeometric representation of $p_{p/q}^d(r)$ via a slightly different, yet equivalent route using the small r power series representation of $p_\alpha^d(r)$. This expansion is found from (4.1) by simply closing the contour to the left,

$$p_\alpha^d(r) = \frac{1}{2^{d-1}\alpha\pi^{d/2}}\sum_{k=0}^{\infty}\frac{(-1)^k}{k!}\frac{\Gamma\left(\frac{2k+d}{\alpha}\right)}{\Gamma\left(k+\frac{d}{2}\right)}\left(\frac{r}{2}\right)^{2k}, \quad \forall r, \quad \alpha>1,$$

$$p_\alpha^d(r) \sim \frac{1}{2^{d-1}\alpha\pi^{d/2}}\sum_{k=0}^{\infty}\frac{(-1)^k}{k!}\frac{\Gamma\left(\frac{2k+d}{\alpha}\right)}{\Gamma\left(k+\frac{d}{2}\right)}\left(\frac{r}{2}\right)^{2k}, \quad r\to 0, \quad \alpha<1. \tag{4.3}$$

Applying the ratio test it can be shown that (4.3) is absolutely convergent for all r when $\alpha>1$. The gamma function structure of (4.3) should be compared to that of the $d=1$ result discussed in Ref. 16, which we list here for ease of comparison,

$$p_\alpha^1(r)=\frac{1}{\alpha\sqrt{\pi}}\sum_{k=0}^{\infty}\frac{(-1)^k\Gamma\left[\dfrac{2k+1}{\alpha}\right]}{\sqrt{\pi}\Gamma[2k+1]}r^{2k},\quad \forall r,\quad \alpha>1. \tag{4.4}$$

Note in particular that (4.4) contains only one gamma function in the denominator, whereas (4.3) contains two. Via the duplication formula we see that (4.3) with $d=1$ is equivalent to (4.4) since $2^{2k}\Gamma(k+1)\Gamma(k+\frac{1}{2})=\sqrt{\pi}\Gamma(2k+1)$. For general d however, $k!\Gamma(k+d/2)$ cannot be reduced to a single gamma function. The essence of the difference is that the duplication formula provides us a relation of the form $\Gamma(z)\Gamma(z+\frac{1}{2})\propto\Gamma(2z)$, but the objects that we see for general d are of the form $\Gamma(z)\Gamma(z+d/2)$, for which no similar simplification is known. This observation will be important when we identify (4.3) as a sum of hypergeometric functions in Sec. V. Similar behavior is again present in the large r power series for general d, which we construct by closing the contour to the right,

$$p_\alpha^d(r)=\frac{1}{\pi(\sqrt{\pi}r)^d}\sum_{k=1}^{\infty}\frac{(-1)^{k+1}}{k!}\sin\left(\frac{k\alpha\pi}{2}\right)\Gamma\left(\frac{k\alpha}{2}+1\right)\Gamma\left(\frac{k\alpha}{2}+\frac{d}{2}\right)\left(\frac{2}{r}\right)^{\alpha k},\quad r>0,\quad \alpha<1,$$

$$p_\alpha^d(r)\sim\frac{1}{\pi(\sqrt{\pi}r)^d}\sum_{k=1}^{\infty}\frac{(-1)^{k+1}}{k!}\sin\left(\frac{k\alpha\pi}{2}\right)\Gamma\left(\frac{k\alpha}{2}+1\right)\Gamma\left(\frac{k\alpha}{2}+\frac{d}{2}\right)\left(\frac{2}{r}\right)^{\alpha k},\quad r\to\infty,\quad \alpha>1. \tag{4.5}$$

It is readily verified that (4.5) is absolutely convergent when $\alpha<1$. For $\alpha>1$ (4.5) provides the asymptotic power series for $p_\alpha^d(r)$, but as we shall show later there exist interesting cases in which this expansion is not complete, precisely as was found when $d=1$.[16] For $\alpha=3,4,5,6,7$ we found in Ref. 16 that there exist series of exponentially small terms lying beyond all orders of the large r asymptotic power series of $p_\alpha^1(r)$. We will show that this same behavior arises for general d, $\forall\,\alpha\in\mathbb{Z}_{\geqslant 3}$. It was also noted in Ref. 16 that when α is an even integer that the large r power series expansion of $p_\alpha^1(r)$ vanishes identically, and from (4.5) we see that this is true also for general d. In the case of $\alpha=2$ in which $p_\alpha^d(r)$ simplifies to the d-dimensional Gaussian, $(4\pi)^{-d/2}e^{-|\mathbf{r}|^2/4}$, this simply expresses the fact that the large r asymptotic behavior of a Gaussian is smaller than any power. When $\alpha>2$ and an even integer we see that these exponentially small series occurring in the large r expansions of $p_\alpha^d(r)$ again become dominant precisely as they did for $p_\alpha^1(r)$. The explicit construction of these exponentially small series will be studied in detail, but first we will show how to obtain hypergeometric representations for $p_{p/q}^d(r)$. These representations are interesting in their own right, and will be the starting point for our asymptotic work.

V. HYPERGEOMETRIC REPRESENTATION OF $p_\alpha^d(r)$

We demonstrated in Ref. 16 that with p,q integers, $p_{p/q}^1(r)$ can be identified with a finite sum of generalized hypergeometric functions, or Meijer G-functions. We now show that essentially the same procedure can be utilized to make a similar identification for $p_{p/q}^d(r)$. We begin with (4.3) which, as mentioned previously, is convergent for $\alpha>1$. As discussed in Refs. 16 and 25, we can still identify $p_{p/q}^d(r)$ with (4.3) for $p/q<1$, and utilize Borel summation[26] where necessary.

The series representation for the generalized hypergeometric function is

$${}_aF_b\left(\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_a\\ \beta_1,\beta_2,\ldots,\beta_b\end{matrix}\middle|z\right)=\sum_{m=0}^{\infty}\frac{z^m}{m!}\frac{\Pi_{h=1}^a(\alpha_h)_m}{\Pi_{h=1}^b(\beta_h)_m}, \tag{5.1}$$

where $(a)_m$ is Pochhammer's symbol,

$$(a)_m=\frac{\Gamma(a+m)}{\Gamma(a)}. \tag{5.2}$$

As in the $d=1$ case[16] we begin by making the change of summation index $k=mp+l$ in (4.3), with the goal of transforming the ratio of gamma functions into the form required by (5.1) and (5.2). We obtain

$$p^d_{p/q}(r)=\frac{q}{2^{d-1}\pi^{d/2}p}\sum_{l=0}^{p-1}(-1)^l\left(\frac{r}{2}\right)^{2l}\sum_{m=0}^{\infty}\left[(-1)^p\left(\frac{r}{2}\right)^{2p}\right]^m\frac{\Gamma\left[2qm+\frac{2ql}{p}+\frac{dq}{p}\right]}{\Gamma[pm+l+1]\Gamma\left[pm+l+\frac{d}{2}\right]}. \tag{5.3}$$

We now apply Gauss' multiplication formula,

$$\Gamma(mz)\propto\Pi_{h=0}^{m-1}\Gamma\left(z+\frac{h}{m}\right),$$

to the gamma functions in (5.3),

$$\begin{aligned}\frac{\Gamma\left[2mq+\frac{2ql}{p}+\frac{dq}{p}\right]}{\Gamma[pm+l+1]\Gamma\left[pm+l+\frac{d}{2}\right]}=&\left(\frac{(2\pi)^{p-q-1/2}(2q)^{qd/p-1/2}}{p^{d/2}}\right)\\&\times\left(\left[\frac{(2q)^{2q}}{p^{2p}}\right]^{l/p}\frac{\Pi_{h=1}^{2q-1}\Gamma\left[\frac{l+\frac{d}{2}}{p}+\frac{h}{2q}\right]}{\Pi_{h=1}^{p-1}\Gamma\left[\frac{l+\frac{d}{2}+h}{p}\right]\Pi_{h=1}^{p}\Gamma\left[\frac{l+h}{p}\right]}\right)\\&\times\left(\left[\frac{(2q)^{2q}}{p^{2p}}\right]^{m}\frac{\Pi_{h=1}^{2q-1}\left(\frac{l+\frac{d}{2}}{p}+\frac{h}{2q}\right)_m}{\Pi_{h=1}^{p-1}\left(\frac{l+\frac{d}{2}+h}{p}\right)_m\Pi_{h=1}^{p}\left(\frac{l+h}{p}\right)_m}\right).\end{aligned} \tag{5.4}$$

Inserting (5.4) into (5.3), and comparing with (5.1) we can immediately make the following identification:

$$p^d_{p/q}(r)=\frac{(2q)^{dq/p+1/2}}{p^{d/2+1}2^{d/2}(2\pi)^{(d+1)/2+q-p}}\sum_{l=0}^{p-1}(-1)^l\left[\frac{(2q)^{2q}r^{2p}}{(2p)^{2p}}\right]^{l/p}$$
$$\times\frac{\Pi_{h=1}^{2q-1}\Gamma\left(\dfrac{l+\dfrac{d}{2}}{p}+\dfrac{h}{2q}\right)}{\Pi_{h=1}^{p-1}\Gamma\left(\dfrac{l+\dfrac{d}{2}+h}{p}\right)\Pi_{h=1}^{p}\Gamma\left(\dfrac{l+h}{p}\right)}$$
$$\times{}_{2q}F_{2p-1}\left(\left.\begin{matrix}1,\dfrac{l+\frac{d}{2}}{p}+\dfrac{1}{2q},\dfrac{l+\frac{d}{2}}{p}+\dfrac{2}{2q},\ldots,\dfrac{l+\frac{d}{2}}{p}+\dfrac{2q-1}{2q}\\ \dfrac{l+\frac{d}{2}+1}{p},\dfrac{l+\frac{d}{2}+2}{p},\ldots,\dfrac{l+\frac{d}{2}+p-1}{p},\dfrac{l+1}{p},\dfrac{l+2}{p},\ldots,\dfrac{l+p}{p}\end{matrix}\right|(-1)^p\frac{(2q)^{2q}r^{2p}}{(2p)^{2p}}\right). \tag{5.5}$$

We can also use the relationship between the generalized hypergeometric function and the Meijer G-function[27] to exhibit (5.5) in the following form:

$$p^d_{p/q}(r)=\frac{(2q)^{dq/p+1/2}}{p^{d/2+1}2^{d/2}(2\pi)^{(d+1)/2+q-p}}\sum_{l=0}^{p-1}\left[\frac{(2q)^{2q}r^{2p}}{(2p)^{2p}}\right]^{l/p}$$
$$\times G^{1,2q}_{2q,2p}\left(\left.(-1)^{p+1}\frac{(2q)^{2q}r^{2p}}{(2p)^{2p}}\right|\begin{matrix}0,\dfrac{1}{2q}-\dfrac{l+\frac{d}{2}}{p},\dfrac{2}{2q}-\dfrac{l+\frac{d}{2}}{p},\ldots,\dfrac{2q-1}{2q}-\dfrac{l+\frac{d}{2}}{p}\\ 0,\dfrac{1-l-\frac{d}{2}}{p},\dfrac{2-l-\frac{d}{2}}{p},\ldots\dfrac{p-1-l-\frac{d}{2}}{p},-\dfrac{l}{p},\dfrac{1-l}{p},\dfrac{2-l}{p},\ldots,\dfrac{p-1-l}{p}\end{matrix}\right). \tag{5.6}$$

As discussed in Sec. IV this result could equivalently have been obtained by performing similar manipulations on the ratio of gamma functions in (4.1) and we could then have obtained the hypergeometric functions from the Meijer G-functions.

Comparing (5.5) to the $d=1$ result given in Ref. 16 we note that in the general d case we have only half as many hypergeometric functions in the sum, but that each one has twice as many parameters as in the $d=1$ case. We shall again make use of the notation used in Ref. 16, $f(\pm z)^+\equiv f(z)+f(-z)$ for some function f, and we refer to $f(\pm z)^+$ as a symmetrized pair. In the $d=1$ case it is possible to express $p^d_{p/q}(r)$ in terms of a sum of symmetrized pairs of generalized hypergeometric functions, since we can utilize the duplication formula to simplify the product of the two gamma functions in the denominator of (4.3). By making such a simplification we are able in the $d=1$ case to make a second change of summation index to (5.3), $s=2m$, before using the multiplication formula. The effect of this is to simultaneously introduce the factor

$$\left[\frac{1+(-1)^s}{2}\right],$$

which accounts for the appearance of the symmetrized pairs, and also to halve the number of both numerator and denominator parameters. Such a process is not possible for general d for all p,q. It is useful to have representations of $p^d_{p/q}(r)$ with the smallest number of parameters possible, and to this end we ask the question "when $d\neq 1$, are there any values of p/q for which we can symmetrize (5.5)?" Observing the form of (5.3) we see that when p is even we can indeed make

the change of summation index $s=2m$ before using Gauss' multiplication formula and therefore halve the number of parameters appearing in (5.5), at the cost of replacing the single hypergeometric functions in the sum by symmetrized pairs,

$$p^d_{p/q}(r)=\frac{(2\pi)^{(p-q-1-d)/2}q^{dq/p\,+\,1/2}}{p^{d/2+1}}\sum_{l=0}^{p-1}(-1)^l\left(\frac{q^q r^p}{p^p}\right)^{2l/p}$$
$$\times\frac{\Pi_{h=1}^{q-1}\Gamma\left(\dfrac{2l+d}{p}+\dfrac{h}{q}\right)}{\Pi_{h=1}^{p/2-1}\Gamma\left(\dfrac{2l+d+2h}{p}\right)\Pi_{h=0}^{p/2-1}\Gamma\left(\dfrac{2l+2+2h}{p}\right)}$$
$$\times{}_qF_{p-1}\left(\left.\begin{matrix}1,\dfrac{2l+d}{p}+\dfrac{1}{q},\dfrac{2l+d}{p}+\dfrac{2}{q},\ldots,\dfrac{2l+d}{p}+\dfrac{q-1}{q}\\ \dfrac{2l+d+2}{p},\dfrac{2l+d+4}{p},\ldots,\dfrac{2l+d+p-2}{p},\dfrac{2l+2}{p},\dfrac{2l+4}{p},\ldots,\dfrac{2l+p}{p}\end{matrix}\right|\pm\frac{q^q r^p}{p^p}\right)^{+},\quad p\in\mathbb{N}_{\text{even}}. \tag{5.7}$$

We see therefore that when p is even the structure of the hypergeometric representation for general d is much closer to the $d=1$ case,[16] with $p^d_{p/q}(r)$ a sum of symmetrized ${}_qF_{p-1}$ functions with d-dependent parameters. Compare this to the odd p case where we have a sum over single ${}_{2q}F_{2p-1}$ functions when $d\neq 1$. Thus for even p, extrapolating from Ref. 1 to $d>1$ essentially just generalizes the parameters, but when p is odd the $d>1$ generalization changes the structure of the hypergeometric representation. It is instructive to observe that the explicit structure of $p^d_{2n}(r)$ can be simplified still further by noticing some drastic cancellations which occur between the $0\leqslant l\leqslant n-1$ terms and the $n\leqslant l\leqslant 2n-1$ terms of (5.7),

$$p^d_{2n}(r)=\frac{2(2\pi)^{(p-2-d)/2}}{p^{d/2+1}}\sum_{l=0}^{n-1}(-1)^l\left(\frac{r^p}{p^p}\right)^{l/n}\frac{1}{\Pi_{h=1}^{n-1}\Gamma\left(\dfrac{\dfrac{d}{2}+l+h}{n}\right)\Pi_{h=1}^{n}\Gamma\left(\dfrac{l+h}{n}\right)}$$
$$\times{}_0F_{p-2}\left(\left\{\frac{d}{2n}+\frac{l+h}{n}\,\middle|\,h\in\{1,\ldots,n-1\}\right\}\cup\left\{\frac{l+h}{n}\,\middle|\,h\in\{1,\ldots,n\}\backslash\{n-l\}\right\}\,\middle|\,(-1)^n\left(\frac{r^p}{p^p}\right)\right). \tag{5.8}$$

From this representation of $p^d_{2n}(r)$ we gain a new perspective on why $p^d_{2n}(r)$ has no algebraic terms in its large r asymptotic expansion, since it is known[27] that generalized hypergeometric functions with no numerator parameters always display purely transcendental asymptotic behavior.

VI. ASYMPTOTICS BEYOND ALL ORDERS

We now turn our attention to the asymptotic properties of $p^d_p(r)$, where $p\geqslant 3$ is an integer. The treatment here is not only a generalization of the results in Ref. 16 to general d, but also to general p; in Ref. 16 we listed the $d=1$ complete asymptotic expansions for $p=3,4,5,6,7$, whereas we now proceed to construct the complete asymptotic expansions for arbitrary values of p and d. We demonstrated in Sec. V that the hypergeometric representation of $p^d_{2n}(r)$ can be written in a much simplified form that is of precisely the same structure as the analogous one-dimensional case. For p an odd integer such a simplification is only possible when $d=1$. As we

shall see however, the structure of the asymptotic expansion of $p_p^d(r)$ is only weakly dependent on d, and for both odd and even p the expansions for general d are surprisingly similar in appearance to the one-dimensional results discussed in Ref. 16.

Our starting point is the following hypergeometric representation for $p_p^d(r)$:

$$p_p^d(r)=\phi_p^d\sum_{l=0}^{p-1}(-)^l z^{l/p}\frac{\Gamma\left(\frac{l}{p}+\frac{d}{2p}+\frac{1}{2}\right)}{\Pi_{h=1}^{p-1}\Gamma\left(\frac{d}{2p}+\frac{l+h}{p}\right)\Pi_{h=1}^{p}\Gamma\left(\frac{l+h}{p}\right)}$$
$$\times{}_1F_{2p-2}\left(\left(\frac{l}{p}+\frac{d}{2p}+\frac{1}{2}\right);\left\{\frac{d}{2p}+\frac{l+h}{p}\,\middle|\,h\in\{1,\ldots,p-1\}\right\}\cup\left\{\frac{l+h}{p}\,\middle|\,h\in\{1,\ldots,p\}\backslash\{p-l\}\right\};(-)^p z\right) \tag{6.1}$$

with

$$z\equiv\frac{2^{2(1-p)}}{p^{2p}}r^{2p}\in\mathbb{R}_{\geqslant 0},\quad \phi_p^d\equiv\frac{2^{d/p+p-d-1}}{p^{d/2+1}\pi^{d/2+3/2-p}}.$$

The complete large r asymptotic expansions of $p_p^d(r)$ will be derived by applying the general results in Ref. 27 for the complete asymptotic expansions of the generalized hypergeometric functions to (6.1).

From Ref. 27 we have in general, when $\beta=b+1-a>3\in\mathbb{Z}_{even}$,

$$\frac{\Pi_{h=1}^{a}\Gamma(\alpha_h)}{\Pi_{h=1}^{b}\Gamma(\rho_h)}{}_aF_b\left(\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_a\\ \rho_1,\rho_2,\ldots,\rho_b\end{matrix}\,\middle|\,-z\right)\sim L_{a,b}(z)$$
$$+\sum_{k=0}^{\beta/2-1}\left[\Gamma_{b+1}^{1,a}(k)K_{a,b}(ze^{-i\pi(2k+1)})+\overline{\Gamma}_{b+1}^{1,a}(k)K_{a,b}(ze^{i\pi(2k+1)})\right], \tag{6.2}$$

$$K_{a,b}(z)=\frac{(2\pi)^{(1-\beta)/2}}{\sqrt{\beta}}e^{\beta z^{1/\beta}}z^{\gamma}\sum_{m=0}^{\infty}N_m z^{-m/\beta}, \tag{6.3}$$

$$\gamma=\frac{(\beta-1)}{2\beta}+\frac{1}{\beta}\sum_{h=1}^{a}\alpha_h-\frac{1}{\beta}\sum_{h=1}^{b}\rho_h, \tag{6.4}$$

$$\arg(z)\in[\delta-2\pi,2\pi-\delta],\quad \delta>0. \tag{6.5}$$

$L_{a,b}(z)$ is the power series contribution to the complete asymptotic expansion of ${}_aF_b$, and vanishes identically when $a=0$. This implies that the asymptotic expansions of $p_{2n}^d(r)$ will be purely transcendental. For odd p not all the $L_{a,b}(z)$ will vanish, but their sum merely produces the large r asymptotic power series derived in Sec. IV so we need not focus on them in this section. In what follows it is to be understood that the power series is to be appended to the beyond all orders asymptotic expansions here constructed, in order to yield the complete expansions.

The N_m and $\Gamma_{b+1}^{1,a}$ are found recursively, and their construction is discussed in depth in Ref. 27.

We now apply these general results to (6.1),

$$\beta=2p-2>3,\quad \gamma=-\frac{l}{p}-\frac{(p-2)}{4p(p-1)}d, \tag{6.6}$$

$$p_p^d(r)\sim\phi_p^d\sum_{l=0}^{p-1}(-)^l z^{l/p}\sum_{k=0}^{p-2}\Gamma_{2p-1}^{1,1}(k)K_{1,2p-2}[(-)^{p+1}ze^{-i\pi(2k+1)}]$$
$$+\phi_p^d\sum_{l=0}^{p-1}(-)^l z^{l/p}\sum_{k=0}^{p-2}\overline{\Gamma}_{2p-1}^{1,1}(k)K_{1,2p-2}[(-)^{p+1}ze^{i\pi(2k+1)}], \tag{6.7}$$

$$\Gamma_{2p-1}^{1,1}(2m)=\Gamma_{2p-1}^{1,1}(2m+1)=\sum_{j=0}^{m}\exp\left(-2j\frac{(2l+d)\pi i}{p}\right),\quad m\in\left\{0,1,2,\ldots,\left[\frac{p-1}{2}\right]\right\}, \tag{6.8}$$

where $[n]$ represents the integer part of n. The derivation of the $\Gamma_{2p-1}^{1,1}$ is discussed in an Appendix. To avoid notational clutter we shall drop the subscripts and superscripts on the $\Gamma_{2p-1}^{1,1}$ and $K_{1,2p-2}$ in what follows; since no gamma functions are encountered for the remainder of this section no confusion should arise.

It is straight forward to show using Ref. 27 that the N_m for all choices of l are the same; thus N_m depends only on m, and on p and d. The recursion relation is as follows:

$$N_k=\sum_{s=1}^{2(p-1)}\sum_{r=0}^{2(p-1)-s}\left(\frac{p}{2(p-1)}(r+s-k)-(p-1)+\frac{dp}{4(p-1)}\right)_{p-1}$$
$$\times\left(\frac{p}{2(p-1)}(r+s-k)-(p-1)-\frac{(p-2)d}{4(p-1)}\right)_p\times\frac{(-)^{s+r}[2(p-1)]^{2p-s-2}}{r![2(p-1)-s-r]!p^{2p-1}k}N_{k-s}, \tag{6.9}$$

$$N_s=0,\quad s<0,\quad N_0=1. \tag{6.10}$$

We list the first four values of N_k for $d=1,2,3$ and $\alpha=3,4,5,6$, in Tables I–IV

According to (6.5) we have the following restriction on $\arg[(-)^{p+1}z]$:

$$(-)^{p+1}z=\begin{cases}z & \text{if } p \text{ is odd}\\ e^{\pm i\pi}z & \text{if } p \text{ is even.}\end{cases} \tag{6.11}$$

Thus our choice of phase depends on the parity of p, but we can get around this and treat both odd and even p cases simultaneously by introducing

$$\sigma=\begin{cases}0 & \text{if } p \text{ is odd}\\ 1 & \text{if } p \text{ is even}\end{cases}\qquad (-)^{p+1}z=e^{\sigma\pi i}z. \tag{6.12}$$

Notice that we have chosen $(-)^{p+1}z=e^{i\pi}z$ for the even p case; substituting the choice $(-)^{p+1}z=e^{-i\pi}z$ into (6.7) merely results in the conjugate expression, but since our final result is real this introduces nothing new. Inserting (6.12) into (6.7), and massaging suitably results in

$$p_p^d(r)\sim\phi_p^d\sum_{l=0}^{\infty}(-)^l z^{l/p}\sum_{k=\sigma}^{p-2+\sigma}[\Gamma(k)K(ze^{-i\pi(2k+1-\sigma)})+\overline{\Gamma}(k-\sigma)K(ze^{i\pi(2k+1-\sigma)})]$$
$$+\phi_p^d\sum_{l=0}^{\infty}(-)^l z^{l/p}\delta_{\sigma,1}[K(z)-\Gamma(p-1)K(ze^{-i\pi 2(p-1)})], \tag{6.13}$$

where $\delta_{n,m}$ is the Kronecker delta.

It is convenient to simplify the two terms of (6.13) multiplied by $\delta_{\sigma,1}$ using (6.3) and (6.8) at this stage before proceeding to tackle the remaining piece. First however, we introduce the following convenient notation:

$$\tau = 2p\phi_p^d \frac{(2\pi)^{[1-2(p-1)]/2}}{\sqrt{2(p-1)}} z^{-d[(p-2)]/[4p(p-1)]} = \frac{2}{\sqrt{(p-1)}(\sqrt{2\pi(pr^{(p-2)})^{1/(p-1)}})^d}, \quad (6.14)$$

$$\bigwedge_{m=0}^{\infty} = \tau \sum_{m=0}^{\infty} N_m z^{-m/[2(p-1)]} = \frac{2}{\sqrt{(p-1)}(\sqrt{2\pi(pr^{(p-2)})^{1/(p-1)}})^d} \sum_{m=0}^{\infty} 2^m N_m \left(\frac{p}{r}\right)^{mp/(p-1)}. \quad (6.15)$$

We observe that the $\delta_{\sigma,1}K(z)$ term vanishes identically since

$$\phi_p^d \sum_{l=0}^{p-1} (-)^l z^{l/p} \delta_{\sigma,1} K(z) = \frac{e^{\beta z^{1/\beta}}}{2p} \bigwedge_{m=0}^{\infty} \delta_{\sigma,1} \sum_{l=0}^{p-1} (-)^l = 0 \quad (6.16)$$

and the sum over l vanishes when p is even ($\sigma = 1$).

The last term in (6.13) is only nonzero for certain values of p; by inserting the explicit form of $\Gamma(p-1)$ and massaging this term becomes

$$\frac{e^{-\beta z^{1/\beta}}}{2p} \bigwedge_{m=0}^{\infty} (-)^m \sum_{j=0}^{p/2-1} \exp\left[\frac{2d\pi i}{p}\left(j - \frac{(p-2)}{4}\right)\right] \delta_{\sigma,1} \sum_{l=0}^{p-1} (-)^l \exp\left(-l\frac{[4j-2(p-1)]\pi i}{p}\right). \quad (6.17)$$

For even p this l sum is only nonvanishing when $[4j-2(p-1)]/p$ is an odd integer which is only possible for $j=(p-2)/4$, which in turn is only possible when $p \equiv 2 \pmod 4$. We see then from this analysis of the last two terms in (6.13) that the l sum acts as a powerful selection rule, and that this selection rule introduces a structure into the expansion of $p_p^d(r)$ that depends on a simple arithmetic property of p, namely on the residue of p modulo 4. We now investigate the remaining terms in (6.13) and we shall see shortly that both of these phenomena arise again. In order to substitute the explicit forms of $\Gamma(k)$ and $\overline{\Gamma}(k-\sigma)$ from (6.8) into (6.13) we need to write the k sum in terms of its even and odd terms separately,

$$\begin{aligned} p_p^d(r) \sim{}& \phi_p^d \sum_{l=0}^{p-1} (-)^l z^{l/p} \sum_{k=\sigma}^{[p/2]-1} \sum_{j=0}^{k} \left[\exp\left(\pm\frac{(2l+d)\pi i}{p} 2j\right) K(ze^{\pm i\pi(4k+1-\sigma)})\right]^+ \\ &+ \phi_p^d \sum_{l=0}^{p-1} (-)^l z^{l/p} \sum_{k=0}^{[p/2]-1} \sum_{j=0}^{k} \left[\exp\left(\pm\frac{(2l+d)\pi i}{p} 2j\right) K(ze^{\pm i\pi(4k+3-\sigma)})\right]^+ \\ &- \frac{\delta_{s,2}}{2} \bigwedge_{m=0}^{\infty} (-)^m e^{-\beta z^{1/\beta}} - \delta_{\sigma,1}\phi_p^d \sum_{l=0}^{p-1} (-)^l z^{l/p} \sum_{k=\sigma}^{[p/2]-1} \exp\left(\frac{(2l+d)\pi i}{p} 2k\right) K(ze^{i\pi 4k}). \end{aligned} \quad (6.18)$$

If we insert the explicit form for $K[ze^{i\pi 4k}]$ from (6.3) into the last term of Eq. (6.18) we find that the l sum vanishes for even p and so this term is identically zero. We now need only to simplify the first two terms in (6.18). To do this it is expedient to observe the following result which is a straightforward consequence of (6.3),

$$\begin{aligned} [e^{\pm i\epsilon} K_{p,q}(ye^{\pm m\pi i})]^+ &= e^{i\epsilon} K_{p,q}(ye^{m\pi i}) + e^{-i\epsilon} K_{p,q}(ye^{-m\pi i}) \\ &= 2\frac{(2\pi)^{(1-\beta)/2}}{\sqrt{\beta}} y^{\gamma} \sum_{r=0}^{\infty} N_r y^{-r/\beta} \exp\left(\beta y^{1/\beta} \cos\left[\frac{m\pi}{\beta}\right]\right) \\ &\quad \times \cos\left(\beta y^{1/\beta} \sin\left[\frac{m\pi}{\beta}\right] + \gamma m\pi + \epsilon - \frac{r\pi m}{\beta}\right). \end{aligned} \quad (6.19)$$

We apply this to (6.18),

$$p_p^d(r)\sim \bigwedge_{m=0}^{\infty} \sum_{k=\sigma}^{[p/2]-1} \sum_{j=0}^{k} \exp(\beta\eta_{1-\sigma}z^{1/\beta})\frac{1}{p}\sum_{l=0}^{p-1}\cos\left(\theta_{1-\sigma}(j)-\frac{l\pi}{p}(4k-4j+1-\sigma)\right)$$
$$+\bigwedge_{m=0}^{\infty} \sum_{k=0}^{[p/2]-1} \sum_{j=0}^{k} \exp(\beta\eta_{3-\sigma}z^{1/\beta})\frac{1}{p}\sum_{l=0}^{p-1}\cos\left(\theta_{3-\sigma}(j)-\frac{l\pi}{p}(4k-4j+3-\sigma)\right)$$
$$-\frac{\delta_{s,2}}{2}\bigwedge_{m=0}^{\infty}(-)^m\exp(-\beta z^{1/\beta}), \tag{6.20}$$

$$\theta_t(j)=2(p-1)\sin\left[\frac{(4k+t)\pi}{2(p-1)}\right]z^{1/[2(p-1)]}-\frac{m\pi(4k+t)}{2(p-1)}+\frac{d\pi}{p}\left[2j-\frac{(p-2)}{4(p-1)}(4k+t)\right], \tag{6.21}$$

$$\eta_t=\cos\left[\frac{(4k+t)\pi}{2(p-1)}\right]. \tag{6.22}$$

We now have the first two terms of (6.20) in a form where we can easily utilize the selection rule properties of the l sum. It is a simple matter to verify the following identity:

$$\sum_{l=0}^{n-1}(-)^l\cos\left(\phi+\frac{m\pi l}{n}\right)=\begin{cases}0 & \text{if } \dfrac{m}{n}\notin\mathbb{Z}_{\text{odd}}\\ n\cos(\phi) & \text{if } \dfrac{m}{n}\in\mathbb{Z}_{\text{odd}}\end{cases} \tag{6.23}$$

with m, $n\in\mathbb{Z}$, and providing m and n have the same parity.

From this result we see that the only terms in (6.20) which can survive are those for which $(4k-4j+f-\sigma)/p$ is an odd integer, where $f=1,3$ in the first and second pieces of (6.20), respectively. By analyzing the summation limits on k and j it can be seen that $(4k-4j+f-\sigma)/p$ can only be an odd integer when $(4k-4j+f-\sigma)/p=1$. Hence it is only the $j=k-([p-(f-\sigma)]/4)$ components that result in a nonvanishing contribution. But j is an integer, so it is only those terms for which $p\equiv(f-\sigma)(\mathrm{mod}\,4)$ that can survive. So the $f=1$ term only survives for the specific p values when $p\equiv(1-\sigma)(\mathrm{mod}\,4)$, i.e., when $p\equiv s(\mathrm{mod}\,4)$ with $s=0,1$. Likewise the $f=3$ term only survives when $p\equiv s(\mathrm{mod}\,4)$ with $s=2,3$. So for any choice of p, only one of the first two pieces of (6.20) will be nonzero. Further, since $j\geqslant 0$, only the $k\geqslant[p-(f-\sigma)]/4$ components of the k sum will contribute. Utilizing all these observations we can write the beyond all orders contribution of the complete asymptotic expansion of $p_p^d(r)$ in a rather simple form, which depends in an essential way on the parameter s which is defined as the arithmetic residue of p modulo 4,

$$p_p^d(r)\sim\bigwedge_{m=0}^{\infty}\sum_{k=(p-s)/4}^{[p/2]-1}\exp\left(\beta z^{1/\beta}\eta_s\right)\cos\left[\theta_s\left(k-\frac{(p-s)}{4}\right)\right]$$
$$-\frac{\delta_{s,2}}{2}\bigwedge_{m=0}^{\infty}(-)^m\exp(-2(p-1)z^{1/2(p-1)}), \tag{6.24}$$

$$p_p^d(r)\sim \frac{2}{\sqrt{(p-1)}(\sqrt{2\pi(pr^{(p-2)})^{1/(p-1)}})^d}\sum_{m=0}^{\infty}2^m N_m\left(\frac{p}{r}\right)^{mp/(p-1)}$$
$$\times\sum_{k=(p-s)/4}^{[p/2]-1}\exp\left((p-1)\cos\left[\frac{(4k+s)\pi}{2(p-1)}\right]\left(\frac{r}{p}\right)^{p/(p-1)}\right)$$
$$\times\cos\left((p-1)\sin\left[\frac{(4k+s)\pi}{2(p-1)}\right]\left(\frac{r}{p}\right)^{p/(p-1)}-\frac{m\pi(4k+s)}{2(p-1)}+\frac{dk\pi}{(p-1)}-\frac{[2p-(s+2)]d\pi}{4(p-1)}\right)$$
$$-\frac{\delta_{s,2}}{\sqrt{(p-1)}(\sqrt{2\pi(pr^{(p-2)})^{1/(p-1)}})^d}\sum_{m=0}^{\infty}2^m N_m\left(\frac{p}{r}\right)^{mp/(p-1)}(-)^m\exp\left(-(p-1)\left(\frac{r}{p}\right)^{p/(p-1)}\right). \tag{6.25}$$

This general expression should be compared to the specific results listed in Ref. 16, in particular note the increasing number of different exponentially decaying oscillatory series as p increases, which verifies our conjecture in Ref. 16 that such behavior should be expected. It is also interesting to note that although increasing p increases the number of series in the transcendental expansion, increasing d has no such effect. We see then from this result, and from the asymptotic power series of Sec. IV, that the asymptotics of $p_p^d(r)$ is only weakly dependent on d. The number of exponentially decaying oscillatory series depends only on α, and the power series vanishes only when α is an even integer, regardless of d. The structure of the complete asymptotic expansion of $p_p^d(r)$ is affected by the introduction of general d only in so far as d appears as a factor or and index in certain places.

VII. MOMENTS

Consider any isotropic pdf of a d-dimensional random walker, call it $p(r)$, then if $p(r)$ possess finite absolute moments the characteristic function will possess a power series expansion of the form

$$\tilde{p}(q)=\sum_{k=0}^{\infty}\frac{(-)^k}{k!}\frac{\langle|\mathbf{r}|^{2k}\rangle}{2^{2k}(d/2)_k}q^{2k}, \tag{7.1}$$

where we define the absolute moments of $p(r)$ in the usual way via

$$\langle|\mathbf{r}|^n\rangle=\int_{\mathbb{R}^d}d^d r p(r)|\mathbf{r}|^n \tag{7.2}$$

$$=\frac{2\pi^{d/2}}{\Gamma(d/2)}\int_0^{\infty}d^d r p(r)r^{n+d-1}. \tag{7.3}$$

Thus the analyticity of the characteristic function and the existence of the even absolute moments of the pdf are mutually implicative. From this result we can deduce that since $\tilde{p}_\alpha^d(q)=e^{-q^\alpha}$ is only analytic when α is an even integer, that $p_\alpha^d(r)$ can possess finite absolute moments to all orders only when α is an even integer. This is completely in agreement with what we found in our asymptotic results since it is only when α is even that the algebraic terms in the asymptotic expansion of $p_\alpha^d(r)$ vanish, which implies the existence of a characteristic scale. This characteristic scale is provided by the finite moments when α is even. In this section we list the absolute moments of $p_\alpha^d(r)$ when they exist, or describe how they diverge when they do not, in order to fully elucidate the connections between moments, exponential asymptotics of $p_\alpha^d(r)$, and analyticity of $\tilde{p}_\alpha^d(q)$.

To ascertain the divergence or values of the moments for various α it is convenient to consider a slightly generalized integral, $\langle|\mathbf{r}|^n\rangle_\lambda$, in which we insert the factor $e^{-\lambda r}$ into the integrand, which tends to $\langle|\mathbf{r}|^n\rangle$ as $\lambda\to 0$. The Mellin Barnes representation of $\langle|\mathbf{r}|^n\rangle_\lambda$ is easily shown to be

$$\langle|\mathbf{r}|^n\rangle_\lambda=\frac{-1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty}ds\,\frac{2^{s+1}}{\alpha\Gamma(d/2)}\Gamma\left(\frac{-s}{\alpha}\right)\Gamma\left(\frac{d+s}{2}\right)\frac{\Gamma(n-2)}{\Gamma\left(\frac{-s}{2}\right)}\lambda^{s-n}-d<\sigma<-\frac{(d-1)}{2}. \quad (7.4)$$

By inspecting the small λ behavior of this well behaved integral we can determine whether the $2m$th moment diverges for a given α, and if this moment is finite we can calculate its numerical value by taking $\lambda\to 0$. The small λ expansion of $\langle|\mathbf{r}|^n\rangle_\lambda$ is obtained by closing the contour to the right. We find that the pole structure of (7.4) is identical to that of the analogous $d=1$ result examined in Ref. 16. Hence whether $\langle|\mathbf{r}|^n\rangle$ diverges, vanishes, or converges to a finite value depends only on α and not on d. As noted in Ref. 16, the moments may become negative when $\alpha>2$ since then $p_\alpha^d(r)$ can take on negative values. The only effect that leaving d arbitrary has on the calculation is to generalize the finite nonzero moments when α is an even integer. This is to be expected since the existence or otherwise of the asymptotic power series is determined by the form of α alone, as is the analyticity of the characteristic function $\tilde{p}_\alpha^d(q)$. Following the procedure in Ref. 16 we arrive at the following results for the $2m$th absolute moment of $p_\alpha^d(r)$ for general d:

$$\langle|\mathbf{r}|^{2m}\rangle=\begin{cases}(-1)^{m+j}2^{2m}(d/2)_m\dfrac{(m)!}{j!}, & \alpha=2\dfrac{m}{j}\in\{2,4,6,\ldots\}\\ +\infty, & 2m>\alpha\in\cup_{k=0}^{\infty}(4k,4k+2)\\ -\infty, & 2m>\alpha\in\cup_{k=0}^{\infty}(4k+2,4k+4)\\ 0, & \text{otherwise.}\end{cases} \quad (7.5)$$

VIII. DISCUSSION

As Pólya[28] generalized Rayleigh's[29] work on Pearson's original random walk problem, from specific dimensions to arbitrary, so we, humbly, have now generalized our first investigation (Ref. 16) on the properties of the symmetric Lévy stable pdfs. The analytic results for $p_\alpha^d(r)$, i.e., the dimensional recursion relation and the identification of $p_\alpha^d(r)$ with certain special functions for various α and d will no doubt be of use in the diverse applications to random phenomena that $p_\alpha^d(r)$ enjoys when $\alpha\leqslant 2$ and it defines a pdf. Equally as exciting is the intricate exponentially small asymptotic behavior of $p_\alpha^d(r)$ which occurs for integral $\alpha\geqslant 3$, and which is dominant when α is even. By constructing this asymptotic expansion for arbitrary integral α and d we have exhibited a family of functions displaying dominant asymptotics beyond all orders, which provides a detailed case study for the exciting new field of asymptotics beyond all orders. As discussed in Ref. 16 we feel for this reason that $p_\alpha^d(r)$ for $\alpha>2$ will in time find interesting physical applications. A final interesting observation involves a number theoretic series which we referred to in Ref. 16 as the generalized Euler Jacobi series.[25] As discussed therein, there is a direct link between $p_\alpha^1(r)$ and the generalized Euler Jacobi series. As a consequence of the asymptotic analysis undertaken herein the general expression for the asymptotics of this series is now known.

APPENDIX: CALCULATING $\Gamma^{1,1}_{2p-1}(k)$

Proposition 1:

$$\Gamma^{1,1}_{2p-1}(2m)=\Gamma^{1,1}_{2p-1}(2m+1)=\sum_{j=0}^{m}\exp\left(-2j\frac{(2l+d)\pi i}{p}\right),\quad m\in\left\{0,1,2,\ldots,\left[\frac{p-1}{2}\right]\right\}, \tag{A1}$$

where $[n]$ *represents the integer part of* n.

The proof of Proposition 1 begins with the following two recursion relations which we deduce from the general result 5.11.1(16) on page 197 of Ref. 27.

$$2m\Gamma^{1,1}_{2p-1}(2m)=\sum_{r=0}^{m-1}\left[1+2\exp\left(-\frac{2(r+1)(2l+d)\pi i}{p}\right)\right]\Gamma^{1,1}_{2p-1}[2(m-r-1)]$$
$$+\sum_{r=0}^{m-1}\Gamma^{1,1}_{2p-1}[2(m-r-1)+1]\qquad m\in\left\{1,2,\ldots,\left[\frac{p}{2}\right]\right\}, \tag{A2}$$

$$(2m+1)\Gamma^{1,1}_{2p-1}(2m+1)=\sum_{r=0}^{m-1}\left[1+2\exp\left(-\frac{2(r+1)(2l+d)\pi i}{p}\right)\right]\Gamma^{1,1}_{2p-1}[2(m-r-1)+1]$$
$$+\sum_{r=0}^{m}\Gamma^{1,1}_{2p-1}[2(m-r)],\quad m\in\left\{0,1,2,\ldots,\left[\frac{p-1}{2}\right]\right\}. \tag{A3}$$

Next we observe the validity of the following two lemmas, the second being a consequence of the first

Lemma 1:

$$\sum_{r=0}^{m-1}\sum_{j=0}^{m-r-1}\theta^{2j}+\sum_{r=0}^{m-1}[1+2\theta^{2(r+1)}]\sum_{j=0}^{m-r-1}\theta^{2j}=(2m)\sum_{j=0}^{m}\theta^{2j},\quad \forall m\in\mathbb{Z}_{>0}. \tag{A4}$$

Lemma 2:

$$\sum_{r=0}^{m}\sum_{j=0}^{m-r}\theta^{2j}+\sum_{r=0}^{m-1}[1+2\theta^{2(r+1)}]\sum_{j=0}^{m-r-1}\theta^{2j}=(2m+1)\sum_{j=0}^{m}\theta^{2j},\quad \forall m\in\mathbb{Z}_{\geqslant 0}, \tag{A5}$$

$\Gamma^{1,p}_{q+1}(0)=1$ always, so from (A2) and (A3) we obtain

$$\Gamma^{1,p}_{q+1}(0)=\Gamma^{1,1}_{2p-1}(1)=1,\quad \Gamma^{1,1}_{2p-1}(2)=\Gamma^{1,1}_{2p-1}(3)=1+\exp\left(-2\frac{(2l+d)\pi i}{p}\right), \tag{A6}$$

etc., which suggests the form

$$\Gamma^{1,1}_{2p-1}(2s)=\Gamma^{1,1}_{2p-1}(2s+1)=\sum_{j=0}^{s}\exp\left(-2j\frac{(2l+d)\pi i}{p}\right). \tag{A7}$$

If we assume that all the $\Gamma^{1,p}_{q+1}[2(m-r-1)]$ and $\Gamma^{1,p}_{q+1}[2(m-r-1)+1]$ in (A2) are of the form (A7) then by applying Lemma 1 we induce that

$$\Gamma^{1,1}_{2p-1}(2m)=\sum_{j=0}^{m}\exp\left(-2j\frac{(2l+d)\pi i}{p}\right),\quad m\in\left\{1,2,\ldots,\left[\frac{p}{2}\right]\right\}. \tag{A8}$$

Similarly, applying Lemma 2 to (A3) we induce

$$\Gamma^{1,1}_{2p-1}(2m+1)=\sum_{j=0}^{m}\ \exp\left(-2j\,\frac{(2l+d)\pi i}{p}\right),\quad m\in\left\{0,1,2,\ldots,\left[\frac{p-1}{2}\right]\right\},\tag{A9}$$

which proves Proposition 1.

A new parametrization and all integral realizations of the Lorentz group

James D. Louck[a)]
Los Alamos National Laboratory, Los Alamos, New Mexico 87545

(Received 18 June 2001; accepted for publication 17 June 2002)

A simple linear transformation of the biquaternionic parameters α and β of the group SL(2, **C**), which is two-to-one homomorphic to the restricted Lorentz group $\mathcal{L}$, is used to express each element of SL(2, **C**) and $\mathcal{L}$ in terms of the first column of an element of $\mathcal{L}$ and the quaternionic parameters α. This parametrization is shown to bring the determination of the integral realizations of the restricted Lorentz group under the purview of classical Diophantine analysis, involving the expression of a given pair of integers, respectively, as a sum of three squares and a sum of four squares. These solutions are further constrained by the condition that a set of four integers, which is linear in the solution of the three squares problem and in the solution of the four squares problem, have a common factor. These are all classical problems addressed and solved by Euclid, Euler, Fermat, Gauss, Jacobi, and others. The corresponding realizations of SL(2, **C**) fall into three distinct classes: those in which the elements of the matrix are Gaussian integers, Gaussian integers divided by $\sqrt{2}$, and Gaussian half-odd integers. These results apply also to the principal subgroups of SL(2, **C**). [DOI: 10.1063/1.1505124]

I. INTRODUCTION

P. A. M. Dirac[1] pointed out in 1972 the interesting structure possessed by the Gaussian integer and half-odd integer realizations of the group SL(2, **C**), which leads through the two-to-one homomorphism of this group onto the restricted Lorentz group $\mathcal{L}=\mathrm{SO}(3,1)$ to integral realizations of $\mathcal{L}$. He gave a parametrization of SL(2, **C**) in terms of biquaternionic parameters which he suggested was useful for such studies, but did not go very far in determining such integer realizations, nor was he specific about the applications he had in mind. Schild[2] earlier had studied such integer realizations of $\mathcal{L}$ with the purpose of using them to model a discrete space–time viewpoint of the physical world. Lorente[3] has used the Cayley parametrization, which is essentially the same as the biquaternionic parametrization, of the classical groups in a series of papers (see References in Ref. 3), and more recently in collaborations with Kramer,[4–7] and applied integral realizations of the Lorentz group to physical law formulated on a lattice. Balazs *et al.*[8,9] use integer representations of the Lorentz group in their construction of a relativistic lattice dynamics for modeling the dynamics of points of a relativistic fluid.

Lorente and Kramer,[6,7] using a set of generators attributed to Coxeter by Schild (Ref. 2. p. 47) and a result of Kac,[10] give a general expression for all integral representations of $\mathcal{L}$ in terms of these generators (see Remark 2 in Sec. VIII). Knowing a set of generators of a group, while eloquently specifying uniquely the group, is not always the easiest way to characterize the group elements themselves, and we shall proceed differently.

The author,[11] in a paper presenting a unified viewpoint of the role of the quantum mechanical rotation group SU(2) in its action in Euclidean three-space $\mathbf{R}^3$ and in spin space, used the methods of Cartan[12] and Wigner,[13] and the paper of Dirac,[1] to derive the following formula relating the elements $Z \in \mathrm{SL}(2,\mathbf{C})$ to the elements $L \in \mathcal{L}$:

[a)]Electronic mail: jimlouck@aol.com

$$L = A_0^{\dagger}(Z \otimes Z^*)A_0, \tag{1.1}$$

where $\otimes$ denotes the Kronecker product, and A is the numerical unitary matrix given by

$$A_0 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & -i & 0 \\ 0 & 1 & i & 0 \\ 1 & 0 & 0 & -1 \end{pmatrix}. \tag{1.2}$$

The real matrix L is defined so as to leave invariant the quadratic form $x^T G x$, $G = \mathrm{diag}(1,-1,-1,-1)$, $x = \mathrm{col}(x^0,x^1,x^2,x^3)$ (T denotes matrix transposition) under the linear transformation $x \mapsto Lx$. Thus, the matrix $L = (L)_{0 \leqslant \mu,\nu \leqslant 3}$ satisfies $L^T G L = G$, and may be shown also to satisfy $\det L = 1$, $L_{00} \geqslant 1$. Thus, L is an element of the restricted Lorentz group.

Relation (1.1) is not only quite easy to solve for Z in terms of L, but is especially useful for relating the biquaternionic parametrization of SL(2, **C**) to that of $\mathcal{L}$. This relationship can then be used in an obvious manner to parametrize all matrices in $Z \in \mathrm{SL}(2,\mathbf{C})$ and $L \in \mathcal{L}$ in terms of the first column of L and one set of the biquaternionic parameters. This parametrization, in turn, brings the problem of determining all integral realizations of $\mathcal{L}$ within the purview of classical methods in number theory, known and solved since the time of Euclid, Euler, Fermat, Gauss, Jacobi, and others. These methods are all described in the elementary and readable book by Uspensky and Heaslet.[14]

The purpose of this article is to effect the steps described above. A principal feature that emerges is the existence of a 384 element finite group, which acts in the biquaternionic parameter space to effect signed permutations of these parameters, that is, permutations as well as $\pm$ signs on the permuted quantities, and the transfer of this action to that of a second finite group with 48 elements, which acts on the elements of the Lorentz matrix to effect signed permutations of these elements. It is this structure, together with the classical number theory mentioned above, that leads to algorithms for the construction of all integral L, and to the elements of Z that are homomorphic to the integral L. A somewhat unexpected feature is that the matrices in SL(2, **C**) mapping to integral matrices in $\mathcal{L}$ fall into the two classes with elements given by Gaussian integers and Gaussian half-odd integers, as pointed out by Dirac,[1] and a third class with elements given by (Gaussian integers)/$\sqrt{2}$.

The plan of the article is as follows: In the Introduction, we continue with the review of the biquaternionic parametrization of SL(2, **C**), deriving quite easily from Eq. (1.1) a result given by MacFarlane.[15] It is quite tedious to obtain the form given by Eqs. (1.12)–(1.14) from MacFarlane's result, despite its eloquent compactness. In Sec. II, we introduce a finite group with 384 elements, denoted H_4, of signed permutations, which is a finite symmetry group of the Lorentz group, where the action of the group H_4 is defined on the biquaternionic parameters. A second finite group with 48 elements, denoted H_3, of signed permutations is also introduced, and its action defined on the elements of a given Lorentz matrix L. In Sec. III, we establish an eight-to-one homomorphism between the groups H_4 and H_3. In Sec. IV, we give the explicit parametrization of each matrix $L \in \mathcal{L}$ in terms of its first column, as well as the corresponding elements $Z \in \mathrm{SL}(2,\mathbf{C})$. In Sec. V, we apply these results to the four principal subgroups of SL(2, **C**). In Sec. VI, this general parametrization in terms of the first column leads easily to the integral realizations of the Lorentz group $\mathcal{L}$, and the corresponding elements of SL(2, **C**), falling into the three classes mentioned above. Explicit algorithms are given for constructing these three classes using classical number theory for a pair of Diophantine equations expressing a given pair of integers, respectively, as the sum of three squares and the sum four squares, and the Euclidean algorithm for determining the greatest common divisor of a related set of four integers.

We now continue in this Introduction with solving relation (1.1) for the matrix Z in terms of L. We write Eq. (1.1) in the form

$$A_0 L A_0^\dagger = Z \otimes Z^* = \text{Kronecker product of } Z \text{ and } Z^* = \begin{pmatrix} z_{11}Z^* & z_{12}Z^* \\ z_{21}Z^* & z_{22}Z^* \end{pmatrix}. \tag{1.3}$$

We work out the left-hand side of this relation and write it in the 2×2 block form

$$A_0 L A_0^\dagger = \frac{1}{2}\begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22}. \end{pmatrix}, \tag{1.4}$$

where

$$\begin{aligned}
M_{11} &= \begin{pmatrix} L_{00}+L_{33}+L_{03}+L_{30} & L_{01}+L_{31}+i(L_{02}+L_{32}) \\ L_{10}+L_{13}-i(L_{20}+L_{23}) & L_{11}+L_{22}+i(L_{12}-L_{21}) \end{pmatrix}, \\
M_{12} &= \begin{pmatrix} L_{01}+L_{31}-i(L_{02}+L_{32}) & L_{00}+L_{33}-L_{03}+L_{30} \\ L_{11}-L_{22}-i(L_{21}+L_{12}) & L_{10}-L_{13}-i(L_{20}-L_{23}) \end{pmatrix}, \\
M_{21} &= \begin{pmatrix} L_{10}+L_{13}+i(L_{20}+L_{23}) & L_{11}-L_{22}+i(L_{21}+L_{12}) \\ L_{00}-L_{33}+L_{03}-L_{30} & L_{01}-L_{31}+i(L_{02}-L_{32}) \end{pmatrix}, \\
M_{22} &= \begin{pmatrix} L_{11}+L_{22}+i(L_{21}-L_{12}) & L_{00}-L_{13}+i(L_{20}-L_{23}) \\ L_{01}-L_{31}-i(L_{02}-L_{32}) & L_{00}+L_{33}-L_{03}-L_{30} \end{pmatrix}.
\end{aligned} \tag{1.5}$$

Here we write L in the following form with elements $L_{\mu\nu}, 0\leqslant \mu,\nu\leqslant 3$:

$$L = \begin{pmatrix} L_{00} & L_{01} & L_{02} & L_{03} \\ L_{10} & L_{11} & L_{12} & L_{13} \\ L_{20} & L_{21} & L_{22} & L_{23} \\ L_{30} & L_{31} & L_{32} & L_{33} \end{pmatrix}. \tag{1.6}$$

We next solve for Z, noting the several other relations that come from the present approach. We first have from Eqs. (1.2) and (1.3) that

$$z_{ij}Z^* = \tfrac{1}{2}M_{ij}, \quad i,j=1,2. \tag{1.7}$$

Moreover, we have from Eq. (1.3) that

$$\operatorname{tr} L = \operatorname{tr} Z \operatorname{tr} Z^* = |\operatorname{tr} Z|^2, \tag{1.8}$$

while from (1.7) we have

$$z_{ij} \operatorname{tr} Z^* = \tfrac{1}{2}\operatorname{tr} M_{ij}, \quad z_{ij}^2 = \tfrac{1}{4}\det M_{ij}. \tag{1.9}$$

If $\operatorname{tr} L \neq 0$, we obtain immediately from these relations and $\det Z = 1$ that

$$Z = \frac{1}{2\operatorname{tr} Z^*}A = \frac{A}{\sqrt{\det A}}, \quad \text{for} \quad \operatorname{tr} L \neq 0, \tag{1.10}$$

where

$$A = \begin{pmatrix} \operatorname{tr} M_{11} & \operatorname{tr} M_{12} \\ \operatorname{tr} M_{21} & \operatorname{tr} M_{22} \end{pmatrix}, \tag{1.11}$$

$$\begin{aligned}
\operatorname{tr} M_{11} &= \operatorname{tr} L + (L_{03}+L_{30}) + i(L_{12}-L_{21}),\\
\operatorname{tr} M_{12} &= (L_{01}+L_{10}) - (L_{13}-L_{31}) + i(-L_{02}-L_{20}+L_{23}-L_{32}),\\
\operatorname{tr} M_{21} &= (L_{01}+L_{10}) + (L_{13}-L_{31}) - i(-L_{02}-L_{20}-L_{23}+L_{32}),\\
\operatorname{tr} M_{22} &= \operatorname{tr} L - (L_{03}+L_{30}) - i(L_{12}-L_{21}).
\end{aligned} \tag{1.12}$$

In general, $\det A$ is complex in Eq. (1.10), and this must be taken into account in extracting the square root. Moreover, if the singular case $\det L=0$ holds, then one appeals directly to the second of Eqs. (1.9) for the solution.

The result given by Eqs. (1.10)–(1.12) is the same as that obtained from MacFarlane's[15] Eq. (69) with $L_{00}=L_0^0$, $L_{0i}=-L_i^0$, $L_{i0}=-L_0^i$, $L_{ij}=L_j^i$, $i,j=1,2,3$. This is accounted for by the fact that MacFarlane's homomorphism of SL(2, **C**) onto $\mathcal{L}$ is related to the one given by relation (1.1) as follows: For $Z' \mapsto L'$ in the MacFarlane homomorphism, then $Z \mapsto L = GL'G$ in the homomorphism (1.1), where $G=\operatorname{diag}(1,-1,-1,-1)$. [See also relation (1.19)].

The parametrization of Z in terms of biquaternionic parameters (see Refs. 1 and 11) is given as follows:

$$\begin{aligned}
Z = Z(\alpha,\beta) &= \begin{pmatrix} \alpha_0 - i\alpha_3 & -i\alpha_1-\alpha_2 \\ -i\alpha_1+\alpha_2 & \alpha_0+i\alpha_3 \end{pmatrix} + i\begin{pmatrix} \beta_0 - i\beta_3 & -i\beta_1-\beta_2 \\ -i\beta_1+\beta_2 & \beta_0+i\beta_3 \end{pmatrix}\\
&= \begin{pmatrix} \alpha_0+\beta_3 - i(\alpha_3-\beta_0) & -\alpha_2+\beta_1 - i(\alpha_1+\beta_2) \\ \alpha_2+\beta_1 - i(\alpha_1-\beta_2) & \alpha_0-\beta_3+i(\alpha_3+\beta_0) \end{pmatrix},
\end{aligned} \tag{1.13}$$

where the condition that $Z \in \mathrm{SL}(2,\mathbf{C})$ is expressed by

$$\alpha^2-\beta^2=1, \quad \alpha\cdot\beta=\alpha_0\beta_0+\alpha_1\beta_1+\alpha_2\beta_2+\alpha_3\beta_3=0,$$

in which

$$\alpha=(\alpha_0,\alpha_1,\alpha_2,\alpha_3), \quad \beta=(\beta_0,\beta_1,\beta_2,\beta_3)$$

are real points. These parameters are given in terms of Z by

$$\begin{aligned}
\alpha_0+i\beta_0 &= \frac{1}{2}(z_{11}+z_{22}), \quad \alpha_1+i\beta_1=\frac{i}{2}(z_{12}+z_{21}),\\
\alpha_2+i\beta_2 &= \frac{-1}{2}(z_{12}-z_{21}), \quad \alpha_3+i\beta_3=\frac{i}{2}(z_{11}-z_{22}),
\end{aligned} \tag{1.14}$$

which show that each $Z \in \mathrm{SL}(2,\mathbf{C})$ defines a unique set of real parameters α and β. These real parameters are also given in terms of L by

$$\begin{aligned}
\alpha_0+i\beta_0 &= \frac{\operatorname{tr} L}{\sqrt{\det A}}, \quad \alpha_1+i\beta_1=\frac{L_{32}-L_{23}+i(L_{01}+L_{10})}{\sqrt{\det A}},\\
\alpha_2+i\beta_2 &= \frac{L_{13}-L_{31}+i(L_{02}+L_{20})}{\sqrt{\det A}}, \quad \alpha_3+i\beta_3=\frac{L_{21}-L_{12}+i(L_{03}+L_{30})}{\sqrt{\det A}}.
\end{aligned} \tag{1.15}$$

Recall that in general $\det A$ is complex, and this must be accounted for in solving these relations for α and β. The biquaternion parameters α and β are related to the Cayley parameters used by Lorente[3] by $\alpha=(m,-q,p,-n), \beta=(-\lambda,-r,s,-t)$.

The expression of the matrix $L \in \mathcal{L}$ in terms of the quaternionic parameters α and β is obtained directly from Eqs. (1.1) and (1.13). For a concise expression of this result, it is convenient to write $L(\alpha,\beta)$ in the form

$$L(\alpha,\beta)=\begin{pmatrix} y_0(\alpha,\beta) & x_1(\alpha,\beta) & x_2(\alpha,\beta) & x_3(\alpha,\beta) \\ y_1(\alpha,\beta) & w_1(\alpha,\beta) & u_3(\alpha,\beta) & v_2(\alpha,\beta) \\ y_2(\alpha,\beta) & v_3(\alpha,\beta) & w_2(\alpha,\beta) & u_1(\alpha,\beta) \\ y_3(\alpha,\beta) & u_2(\alpha,\beta) & v_1(\alpha,\beta) & w_3(\alpha,\beta) \end{pmatrix}, \tag{1.16}$$

where

$$\begin{aligned} y_0(\alpha,\beta)&=\alpha^2+\beta^2=2(\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2)-1, \\ y_i(\alpha,\beta)&=2(\alpha_0\beta_i-\alpha_i\beta_0+\alpha_j\beta_k-\alpha_k\beta_j), \\ x_i(\alpha,\beta)&=2(\alpha_0\beta_i-\alpha_i\beta_0-\alpha_j\beta_k+\alpha_k\beta_j), \\ u_i(\alpha,\beta)&=2(-\alpha_0\alpha_i+\alpha_j\alpha_k-\beta_0\beta_i+\beta_j\beta_k), \\ v_i(\alpha,\beta)&=2(\alpha_0\alpha_i+\alpha_j\alpha_k+\beta_0\beta_i+\beta_j\beta_k), \\ w_i(\alpha,\beta)&=2(\alpha_0^2+\beta_0^2+\alpha_i^2+\beta_i^2)-(\alpha^2+\beta^2)=2(\alpha_0^2+\alpha_i^2-\beta_j^2-\beta_k^2)-1, \\ &(i,j,k) \text{ is cyclic in } 1,2,3. \end{aligned} \tag{1.17}$$

The two-to-one homomorphism $\mathrm{SL}(2,\mathbf{C})\to\mathcal{L}$ is expressed in terms of the parameters α and β by

$$Z(\alpha,\beta)\mapsto L(\alpha,\beta), \quad Z(-\alpha,-\beta)=-Z(\alpha,\beta)\mapsto L(\alpha,\beta). \tag{1.18}$$

We also note that the MacFarlane homomorphism $\mathrm{SL}(2,\mathbf{C})\to\mathcal{L}$ is given by

$$Z'(\alpha,\beta)=Z(-\alpha_0,\alpha_1,\alpha_2,\alpha_3;-\beta_0,\beta_1,\beta_2,\beta_3). \tag{1.19}$$

Observe that Eqs. (1.17) show explicitly that $L_{00}\geqslant 1$ and also imply the following: *Every Gaussian integer element of* $\mathrm{SL}(2,\mathbf{C})$ *maps to a real integer element of* $\mathcal{L}$.

II. DISCRETE SYMMETRIES IN THE PARAMETERS α AND β

Let S_n denote the group of permutations of the integers $(1,2,...,n)$ with action on an arbitrary sequence $x=(x_1,x_2,\ldots,x_n)$ defined by

$$\pi: x\mapsto \pi(x_1,x_2,\ldots,x_4)=(x_{\pi_1},x_{\pi_2},\ldots,x_{\pi_n}), \quad \text{for } \pi=\begin{pmatrix} 1 & 2 & \ldots & n \\ \pi_1 & \pi_2 & \ldots & \pi_n \end{pmatrix}. \tag{2.1}$$

Thus, the action of the permutation π is a substitution of the subscripts $(1,2,\ldots,n)$ by $(\pi_1,\pi_2,\ldots,\pi_n)$. The parity of a permutation is even or odd if it takes an even or odd number of transpositions to restore the sequence $(\pi_1,\pi_2,\ldots,\pi_n)$ to the order $(1,2,\ldots,n)$.

Let Σ_n denote the set of sequences defined by

$$\Sigma_n=\{\sigma=(\sigma_1,\sigma_2,\ldots,\sigma_n)| \quad \text{each } \sigma_i=\pm 1\}. \tag{2.2}$$

The set Σ_n is an Abelian group under component-wise multiplication of sequences, which is a realization of the direct product group $S_2\times S_2\times\cdots\times S_2$.

The direct product group $H_n=\Sigma_n\times S_n$ is the group of order $2^n n!$ of *signed permutations* with elements given by the ordered pairs (σ,π) with multiplication rule

$$(\sigma'\times\pi')(\sigma\times\pi)=(\sigma'\sigma)\times(\pi'\pi), \tag{2.3}$$

and action on x defined by

$$x\rightarrow(\sigma,\pi)x=(\sigma_1 x_{\pi_1},\sigma_2 x_{\pi_2},\ldots,\sigma_n x_{\pi_n}). \tag{2.4}$$

We define the sequence $\sigma=(\sigma_1,\sigma_2,\ldots,\sigma_n)$ to have *even parity* if $\sigma_1\sigma_2\cdots\sigma_n=1$ and *odd parity* if $\sigma_1\sigma_2\cdots\sigma_n=-1$.

We choose S_4 to be the group of permutations on (0,1,2,3) for application to the pair of sequences $\alpha=(\alpha_0,\alpha_1,\alpha_2,\alpha_3)$ and $\beta=(\beta_0,\beta_1,\beta_2,\beta_3)$. The action of S_4 on the pair (α,β) of sequences is to effect the same permutation on each sequence:

$$\pi:(\alpha,\beta)\mapsto(\pi(\alpha),\pi(\beta)),$$

$$\pi(\alpha)=(\alpha_{\pi_0},\alpha_{\pi_1},\alpha_{\pi_2},\alpha_{\pi_3}),\quad \pi(\beta)=(\beta_{\pi_0},\beta_{\pi_1},\beta_{\pi_2},\beta_{\pi_3}), \tag{2.5}$$

$$\pi=\begin{pmatrix}0&1&2&3\\ \pi_0&\pi_1&\pi_2&\pi_3\end{pmatrix}.$$

For symmetry of notation, we also denote the elements of Σ_4 by $(\sigma_0,\sigma_1,\sigma_2,\sigma_3)$.

The significance of the group $H_4=\Sigma_4\times S_4$ of signed substitutions is that $\det Z(\alpha,\beta)=\alpha^2-\beta^2+2i\alpha\cdot\beta$ is invariant under the simultaneous transformations

$$\begin{aligned}\alpha&\mapsto h(\alpha)=(\sigma_0\alpha_{\pi_0},\sigma_1\alpha_{\pi_1},\sigma_2\alpha_{\pi_2},\sigma_3\alpha_{\pi_3}),\\ \beta&\mapsto h(\beta)=(\sigma_0\beta_{\pi_0},\sigma_1\beta_{\pi_1},\sigma_2\beta_{\pi_2},\sigma_3\beta_{\pi_3}),\end{aligned} \tag{2.6}$$

where the action of $h\in H_4$ on $Z(\alpha,\beta)$ is defined by

$$h:Z(\alpha,\beta)\mapsto Z(h(\alpha),h(\beta)). \tag{2.7}$$

For the group SL(2, **C**), where $\alpha^2-\beta^2=1$ and $\alpha\cdot\beta=0$, the group $H_4=\Sigma_4\times S_4$ can be enlarged by adjoining the two element group $\Sigma_2=\{(1,1),(1,-1)\}$ to form the direct product group

$$H_{2,4}=\Sigma_2\times H_4=\Sigma_2\times(\Sigma_4\times S_4) \tag{2.8}$$

with elements (τ,σ,π) having action on the pair (α,β) given by

$$(\tau,\sigma,\pi):(\alpha,\beta)\rightarrow(\tau,\sigma,\pi)(\alpha,\beta)=(\tau_1 h(\alpha),\tau_2 h(\beta)). \tag{2.9}$$

The group $H_{2,4}$ is a symmetry group of SL(2, **C**) of order 776, that is,

$$Z(h'(\alpha,\beta))\in \mathrm{SL}(2,\mathbf{C}),\quad \text{each}\quad h'\in H_{2,4}. \tag{2.10}$$

Since the extra symmetry

$$Z(-\alpha,\beta)=Z(\alpha,\beta)=-Z(\alpha,\beta) \tag{2.11}$$

originated from the group $H_{2,4}$ is easily taken into account, we restrict our attention to the group H_4, which is a normal subgroup of $H_{2,4}$, and Σ_2 is the factor group $H_{2,4}/H_4$.

Let us note that the mapping $h:\mathrm{SL}(2,\mathbf{C})\rightarrow\mathrm{SL}(2,\mathbf{C})$ is an inner automorphism if and only if one can write

$$Z(h(\alpha,\beta))=A_h Z(\alpha,\beta)A_h^{-1}, A_h\in \mathrm{SL}(2,\mathbf{C}); \tag{2.12}$$

otherwise the mapping is an outer automorphism. We have not determined which elements of H_4 are inner and which are outer automorphisms.

For each $h\in H_4$, we have the mapping of elements of SL(2, **C**) to elements of $\mathcal{L}$ given by

$$Z(h(\alpha,\beta))\mapsto L(h(\alpha,\beta)). \tag{2.13}$$

Thus, in the general case, 384 distinct matrices in SL(2, **C**) map to matrices in $\mathcal{L}$. But, as we shall show, at most 48 distinct matrices in $\mathcal{L}$ can arise, and these correspond to signed permutations of the elements of L. This result is an easy consequence of the explicit results we give below.

No ambiguity will arise if we write the ordered pair of elements in Eq. (2.3) in juxtaposition:

$$h(\sigma,\pi)=(\sigma_0,\sigma_1,\sigma_2,\sigma_3)\begin{pmatrix}0&1&2&3\\ \pi_0&\pi_1&\pi_2&\pi_3\end{pmatrix}. \tag{2.14}$$

Observing the permutational symmetry of the elements in column 1 of $L(\alpha,\beta)$ given by Eq. (1.17), especially the distinguished position of α_0, we are led to enumerate the set of 384 signed permutations in H_4 by the following notation:

$$\begin{aligned}
h^{(0)}_{\sigma_0}(\tau,\rho)&=(\sigma_0,\sigma_0\tau_1,\sigma_0\tau_2,\sigma_0\tau_3)\begin{pmatrix}0&1&2&3\\ 0&\rho_1&\rho_2&\rho_3\end{pmatrix},\\
h^{(1)}_{\sigma_1}(\tau,\rho)&=(-\sigma_1\tau_1,\sigma_1,\sigma_1\tau_3,-\sigma_1\tau_2)\begin{pmatrix}0&1&2&3\\ \rho_1&0&\rho_3&\rho_2\end{pmatrix},\\
h^{(2)}_{\sigma_2}(\tau,\rho)&=(-\sigma_2\tau_2,-\sigma_2\tau_3,\sigma_2,\sigma_2\tau_1)\begin{pmatrix}0&1&2&3\\ \rho_2&\rho_3&0&\rho_1\end{pmatrix},\\
h^{(3)}_{\sigma_3}(\tau,\rho)&=(-\sigma_3\tau_3,\sigma_3\tau_2,-\sigma_3\tau_1,\sigma_3)\begin{pmatrix}0&1&2&3\\ \rho_3&\rho_2&\rho_1&0\end{pmatrix},
\end{aligned} \tag{2.15}$$

where $\tau\in\Sigma_3$ and

$$\begin{pmatrix}1&2&3\\ \rho_1&\rho_2&\rho_3\end{pmatrix}\in S_3.$$

Thus, introducing the notation

$$p(\tau,\rho)=(\tau_1,\tau_2,\tau_3)\begin{pmatrix}1&2&3\\ \rho_1&\rho_2&\rho_3\end{pmatrix} \tag{2.16}$$

for an element of H_3, we have partitioned the group H_4 into 48 subsets $S(\tau,\rho)$, each containing eight elements, and defined by

$$S(\tau,\rho)=\{h^{(k)}_{\sigma_k}(\tau,\rho)\,|\,k=0,1,2,3;\ \text{each}\ \ \sigma_k=\pm 1,\ \ p(\tau,\rho)\in H_3\}. \tag{2.17}$$

The actions of the group elements $h^{(k)}_{\sigma_k}(\tau,\rho)\in H_4$ are implemented directly on the elements of the Lorentz matrix $L(\alpha,\beta)$ by applying

$$h{:}L_{\mu,\nu}(\alpha,\beta)\mapsto L_{\mu,\nu}(h(\alpha),h(\beta)),\ \ \text{each}\ \ h\in H_4. \tag{2.18}$$

The group elements $p(\tau,\rho)\in H_3$ act on the indices of an arbitrary sequence (z_1,z_2,z_3) is to effect the signed permutation $(\tau_1 z_{\rho_1},\tau_2 x_{\rho_2},\tau_3 z_{\rho_3})$. It is the case that action of each $h\in H_4$ effects a signed permutation $p(\tau,\sigma)$ of the elements in $L(\alpha,\beta)$. For a concise description of this latter action, it is notationally convenient to suppress the parameters α and β and write $L(\alpha,\beta)$ in the form

$$L(\alpha,\beta)=\begin{pmatrix} y_0 & x_1 & x_2 & x_3 \\ y_1 & w_1 & u_3 & v_2 \\ y_2 & v_3 & w_2 & u_1 \\ y_3 & u_2 & v_1 & w_3 \end{pmatrix}, \tag{2.19}$$

where $y_0=L_{0,0}$ and

$$\begin{gathered} x_i=L_{0,i}(\alpha,\beta),y_i=L_{i,0}(\alpha,\beta),w_i=L_{i,i}(\alpha,\beta), \quad \text{for } i=1,2,3 \\ u_i=L_{j,k}(\alpha,\beta),v_i=L_{k,j}(\alpha,\beta), \\ (i,j,k) \text{ an even permutation of } (1,2,3). \end{gathered} \tag{2.20}$$

The explicit calculations given in Eqs. (4.14)–(4.17) in Sec. IV show that *the action of the group H_4 is transferred to the action of the group H_3* on the elements (x_1,x_2,x_3), (y_1,y_2,y_3), (u_l,u_2,u_3), (v_1,v_2,v_3), (w_1,w_2,w_3) of $L(\alpha,\beta)$ in accordance with the rule

$$h^{(k)}_{\sigma_k}(\tau,\rho):(z_1,z_2,z_3)\mapsto p(\tau',\rho)(z_1,z_2,z_3), \quad k=0,1,2,3, \quad \sigma_k=\pm 1, \tag{2.21}$$

where the sequence τ' depends only on the index k, and the identification of (z_1,z_2,z_3) with one of (x_1,x_2,x_3), (y_1,y_2,y_3), (u_l,u_2,u_3), (v_1,v_2,v_3), (w_1,w_2,w_3).

The complete set of group actions is given in Eqs. (4.14)–(4.17) in Sec. IV, after we develop the properties of the groups H_4 and H_3.

III. RELATIONSHIP BETWEEN THE GROUPS H_4 AND H_3

We can obtain the relationship between the groups H_4 and H_3 by determining the *little group* (also called the stabilizer) that leaves the column sequence (y_1,y_2,y_3) fixed. This group is found from Eqs. (1.17) and definitions (2.15) to be the group S containing eight elements:

$$S=S((1,1,1),(123))=\{S^{(0)}_{\sigma_0},S^{(1)}_{\sigma_1},S^{(2)}_{\sigma_2},S^{(3)}_{\sigma_3}| \text{ each } \sigma_k=\pm 1\}, \tag{3.1}$$

where

$$\begin{gathered} S^{(0)}_{\sigma_0}=\sigma_0(1,1,1,1)\cdot(0)(1))(2)(3), \quad S^{(1)}_{\sigma_1}=\sigma_1(-1,1,1,-1)\cdot(01)(23), \\ S^{(2)}_{\sigma_2}=\sigma_2(-1,-1,1,1)\cdot(02)(13), \quad S^{(3)}_{\sigma_3}=\sigma_3(-1,1,-1,1)\cdot(03)(12), \end{gathered} \tag{3.2}$$

where the cycle notation for permutations is used, and a $\cdot$ is placed between elements of Σ_4 and elements of S_4 for clarity. The four even elements $\{(0)(1)(2)(3),(01)(23),(02)(13),(03)(12)\}$ constitute a normal subgroup of S_4, and S is a normal subgroup of the direct product group $H_4=\Sigma_4\times S_4$.

The above result establishes an eight-to-one homomorphism between the groups H_4 and H_3 given by

$$S(\tau,\rho)\mapsto(\tau_1,\tau_2,\tau_3)\begin{pmatrix} 1 & 2 & 3 \\ \rho_1 & \rho_2 & \rho_3 \end{pmatrix}=p(\tau,\rho). \tag{3.3}$$

Since S is a normal subgroup of H_4, left cosets and right cosets are equal. Representatives of the 48 cosets, or equivalently of the factor group H_4/S, may be chosen as follows. Define the following elements of S_4, using cycle notation:

$$\begin{aligned} &s_1=(0)(1)(2)(3), \quad s_2=(0)(123), \quad s_3=(1)(023), \quad \text{even elements,} \\ &s_4=(01)(2)(3), \quad s_5=(02)(1)(3), \quad s_6=(03)(1)(2), \quad \text{odd elements.} \end{aligned} \tag{3.4}$$

Define the following representative elements of the factor group H_4/S:

$$f_m(\sigma_1,\sigma_2,\sigma_3)=(1,\sigma_1,\sigma_2,\sigma_3)s_m, \quad m=1,2,\ldots,6; \ \text{each} \ \sigma_i=\pm 1. \tag{3.5}$$

The cosets of S in H_4 are given by

$$\{Sf_m(\sigma_1,\sigma_2,\sigma_3)|m=1,2,\ldots,6; \ \text{each} \ \sigma_i=\pm 1\}. \tag{3.6}$$

The results given in this section are important for enumerating the symmetries of the new parametrization of the restricted Lorentz group given in the next section.

IV. PARAMETRIZATION OF L IN TERMS OF ITS FIRST COLUMN AND THE QUATERNIONIC PARAMETERS α

In this section, we make a transformation of parameters α and β such that every Lorentz matrix $L(\alpha,\beta)$ as given by Eqs. (1.16) and (1.17) is expressed in terms of its first column (y_0,y_1,y_2,y_3) and the parameters α alone. The resulting new Lorentz matrix, which we denote by $(y|\alpha)$, is given explicitly in relations (4.6) and Eqs. (4.11) and (4.12).

Let us first mention some general features of this new parametrization. The elements in the first column of L satisfy

$$y_1^2+y_2^2+y_3^2=y_0^2-1, \tag{4.1}$$

and the parameters $(\alpha_0,\alpha_1,\alpha_2,\alpha_3)$ satisfy

$$\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=\frac{y_0+1}{2}. \tag{4.2}$$

We define the sphere $S_n(r)$ of radius r to be the set of real points x as follows:

$$S_n(r)=\{x=(x_1,x_2,\ldots,x_n)|x_1^2+x_2^2+\ldots+x_n^2=r^2)\}. \tag{4.3}$$

Thus, the first column of the Lorentz matrix Z is any point $(y_1,y_2,y_3)\in S_3(r_1)$, $r_1^2=y_0^2-1$, $y_0 \geqslant 1$. The quaternionic parameter sequence $(\alpha_0,\alpha_1,\alpha_2,\alpha_3)$ is any point $\alpha\in S_4(r_2)$, $r_2^2=(1+y_0)/2$. From a given pair of points solving Eqs. (4.1) and (4.2), we obtain a set of new points that are signed partitions of the old ones by applying the group elements of H_3 and H_4, respectively, namely, $p(\tau',\rho')y$ and $h^{(k)}_{\sigma_k}(\tau,\rho)\alpha$.

By adjoining the relation $\alpha\cdot\beta=0$ to the three relations for $L_{10}(\alpha,\beta)$, $L_{20}(\alpha,\beta)$, $L_{30}(\alpha,\beta)$ given by Eqs. (1.17), and writing $\beta=\text{col}(\beta_0,\beta_1,\beta_2,\beta_3)$ and $\hat{y}=\text{col}(y_1,y_2,y_3,0)$, we obtain

$$A^T(\alpha)\beta=\frac{1}{2}\hat{y}, \quad A(\alpha)=A(\alpha_0,\alpha_1,\alpha_2,\alpha_3)=\begin{pmatrix} -\alpha_1 & -\alpha_2 & -\alpha_3 & \alpha_0 \\ \alpha_0 & \alpha_3 & -\alpha_2 & \alpha_1 \\ -\alpha_3 & \alpha_0 & \alpha_1 & \alpha_2 \\ \alpha_2 & -\alpha_1 & \alpha_0 & \alpha_3 \end{pmatrix}. \tag{4.4}$$

Noting that $A(\alpha)A^T(\alpha)=(\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2)I_4=[(y_0+1)/2]I_4$, we thus obtain

$$\beta=\beta(y,\alpha)=\frac{1}{1+y_0}\gamma(y,\alpha),\quad \gamma(y,\alpha)=A(\alpha)\hat{y}. \tag{4.5}$$

The γ_μ are given by

$$\begin{aligned}&\gamma_0(y,\alpha)=-\alpha_1y_1-\alpha_2y_2-\alpha_3y_3,\quad \gamma_1(y,\alpha)=\alpha_0y_1+\alpha_3y_2-\alpha_2y_3,\\&\gamma_2(y,\alpha)=-\alpha_3y_1+\alpha_0y_2+\alpha_1y_3,\quad \gamma_3(y,\alpha)=\alpha_2y_1-\alpha_1y_2+\alpha_0y_3.\end{aligned} \tag{4.6}$$

One verifies directly that the following relations are satisfied:

$$\beta_0^2+\beta_1^2+\beta_2^2+\beta_3^2=\frac{y_0-1}{2},\quad \alpha^2-\beta^2=1,\quad \alpha\cdot\beta=0. \tag{4.7}$$

We now eliminate the parameters β from $L(\alpha,\beta)$ by using relation (4.5). We denote the corresponding Lorentz matrix by $(y|\alpha)$, suppressing L_{00}, but regaining it through $(y|\alpha)_{00}=L_{00}=y_0$. The elements of this matrix are denoted by $(y|\alpha)_{\mu\nu}$, $0\leqslant\mu,\ \nu\leqslant3$.

We summarize the results for this new parametrization of the Lorentz matrices in $\mathcal{L}$:

For each point $y\in S_3(r_1)\subset\mathbf{R}^3$ *and for each point* $\alpha\in S_4(r_2)\subset\mathbf{R}^4$, *that is,*

$$y_1^2+y_2^2+y_3^2=y_0^2-1,\quad \alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=\frac{y_0+1}{2}, \tag{4.8}$$

the set of restricted Lorentz matrices $\mathcal{L}$ *is given by*

$$(y|\alpha)=L\left(\alpha,\frac{1}{1+y_0}\gamma(y,\alpha)\right),\quad \gamma(y,\alpha)=A(\alpha)\hat{y}. \tag{4.9}$$

The homomorphism of SL(2, **C**) *onto* $\mathcal{L}$ *is given by*

$$Z(y|\alpha)=Z(\alpha,\beta(y,\alpha))\mapsto(y|\alpha), \tag{4.10}$$

where

$$(y|\alpha)=\begin{pmatrix}y_0 & x_1(y,\alpha) & x_2(y,\alpha) & x_3(y,\alpha)\\ y_1 & w_1(y,\alpha) & u_3(y,\alpha) & v_2(y,\alpha)\\ y_2 & v_3(y,\alpha) & w_2(y,\alpha) & u_1(y,\alpha)\\ y_3 & u_2(y,\alpha) & v_1(y,\alpha) & w_3(y,\alpha)\end{pmatrix}, \tag{4.11}$$

$$x_i(y,\alpha)=(y|\alpha)_{0,i}=\frac{2}{1+y_0}[\alpha_0\gamma_i(y,\alpha)-\alpha_i\gamma_0(y,\alpha)-\alpha_j\gamma_k(y,\alpha)+\alpha_k\gamma_j(y,\alpha)],$$

$$u_i(y,\alpha)=(y|\alpha)_{j,k}=2(-\alpha_0\alpha_i+\alpha_j\alpha_k)+\frac{2}{(1+y_0)^2}[-\gamma_0(y,\alpha)\gamma_i(y,\alpha)+\gamma_j(y,\alpha)\gamma_k(y,\alpha)],$$

$$v_i(y,\alpha)=(y|\alpha)_{k,j}=2(\alpha_0\alpha_i+\alpha_j\alpha_k)+\frac{2}{(1+y_0)^2}[\gamma_0(y,\alpha)\gamma_i(y,\alpha)+\gamma_j(y,\alpha)\gamma_k(y,\alpha)], \tag{4.12}$$

$$w_i(y,\alpha)=2(\alpha_0^2+\alpha_i^2)-1-\frac{2}{(1+y_0)^2}[\gamma_j^2(y,\alpha)+\gamma_k^2(y,\alpha)],$$

(i,j,k) *is a cyclic permutation of* (1,2,3).

The homomorphism of SL(2, **C**) *onto the restricted Lorentz group* $\mathcal{L}$ *is now given by*

$$Z(y|\alpha) =$$

$$\left(\begin{array}{c|c} (\alpha_0 - i\alpha_3)(1+\frac{y_3}{y_0+1}) - \frac{(\alpha_1+i\alpha_2)(iy_1+y_2)}{y_0+1} & -(\alpha_2+i\alpha_1)(1+\frac{y_3}{y_0+1}) + \frac{(\alpha_0+i\alpha_3)(y_1-iy_2)}{y_0+1} \\ \hline (\alpha_2 - i\alpha_1)(1-\frac{y_3}{y_0+1}) + \frac{(\alpha_0-i\alpha_3)(y_1+iy_2)}{y_0+1} & (\alpha_0+i\alpha_3)(1-\frac{y_3}{y_0+1}) - \frac{(i\alpha_1+\alpha_2)(y_1+iy_2)}{y_0+1} \end{array}\right)$$

$$\mapsto (y|\alpha). \tag{4.13}$$

By construction, we have that $\det Z(y|\alpha)=1$ *for all* $y \in S_3(r_1)$ *and all* $\alpha \in S_4(r_2)$. *The property* $Z(y|-\alpha) = -Z(y|\alpha) \mapsto (y|-\alpha) = (y|\alpha)$ *is exhibited directly by the mapping (4.13).*

We now give explicitly the transfer of the action of the group H_4 on the parameters α to the action of the group H_3 on the parameters y,x,u,v,w in terms of the notation in Eq. (4.11) for the Lorentz matrix $(y|\alpha)$:

$$h^{(0)}_{\sigma_0}(\tau,\rho): \quad (y_1,y_2,y_3) \mapsto p(\tau,\rho)(y_1,y_2,y_3),$$

$$(x_1,x_2,x_3) \mapsto p(\tau,\rho)(x_1,x_2,x_3),$$

$$(u_1,u_2,u_3) \mapsto p(\tau,\rho)(u_1,u_2,u_3),$$

$$(v_1,v_2,v_3) \mapsto p(\tau,\rho)(v_1,v_2,v_3),$$

for parity of (τ,ρ) (even,even) or (odd,odd);

$$(y_1,y_2,y_3) \mapsto p(\tau,\rho)(x_1,x_2,x_3), \tag{4.14}$$

$$(x_1,x_2,x_3) \mapsto p(\tau,\rho)(y_1,y_2,y_3),$$

$$(u_1,u_2,u_3) \mapsto p(-\tau,\rho)(v_1,v_2,v_3),$$

$$(v_1,v_2,v_3) \mapsto p(-\tau,\rho)(u_1,u_2,u_3),$$

for parity of (τ,ρ) (even,odd) or (odd,even);

$$(w_1,w_2,w_3) \mapsto p((1,1,1),\rho)(w_1,w_2,w_3).$$

$$h^{(1)}_{\sigma_1}(\tau,\rho): \quad (y_1,y_2,y_3) \mapsto p((\tau_1,\tau_2,\tau_3),\rho)(y_1,y_2,y_3),$$

$$(x_1,x_2,x_3) \mapsto p((\tau_1,-\tau_2,-\tau_3),\rho)(x_1,x_2,x_3),$$

$$(u_1,u_2,u_3) \mapsto p((-\tau_1,\tau_2,-\tau_3),\rho)(u_1,u_2,u_3),$$

$$(v_1,v_2,v_3) \mapsto p((-\tau_1,-\tau_2,\tau_3),\rho)(v_1,v_2,v_3),$$

for parity of (τ,ρ) (even,even) or (odd,odd);

$$(y_1,y_2,y_3)\mapsto p((\tau_1,\tau_2,\tau_3),\rho)(x_1,x_2,x_3), \tag{4.15}$$

$$(x_1,x_2,x_3)\mapsto p((\tau_1,-\tau_2,-\tau_3),\rho)(y_1,y_2,y_3),$$

$$(u_1,u_2,u_3)\mapsto p((\tau_1,-\tau_2,\tau_3),\rho)(v_1,v_2,v_3),$$

$$(v_1,v_2,v_3)\mapsto p((\tau_1,\tau_2,-\tau_3)\rho)(u_1,u_2,u_3),$$

for parity of (τ,ρ) (even,odd) or (odd,even);

$$(w_1,w_2,w_3)\mapsto p((1,-1,-1),\rho)(w_1,w_2,w_3).$$

$h^{(2)}_{\sigma_2}(\tau,\rho)$: $(y_1,y_2,y_3)\mapsto p((\tau_1,\tau_2,\tau_3),\rho)(y_1,y_2,y_3)$,

$$(x_1,x_2,x_3)\mapsto p((-\tau_1,\tau_2,-\tau_3),\rho)(x_1,x_2,x_3),$$

$$(u_1,u_2,u_3)\mapsto p((-\tau_1,-\tau_2,\tau_3),\rho)(u_1,u_2,u_3),$$

$$(v_1,v_2,v_3)\mapsto p((\tau_1,-\tau_2,-\tau_3),\rho)(v_1,v_2,v_3),$$

for parity of (τ,ρ) (even,even) or (odd,odd);

$$(y_1,y_2,y_3)\mapsto p((\tau_1,\tau_2,\tau_3),\rho)(x_1,x_2,x_3), \tag{4.16}$$

$$(x_1,x_2,x_3)\mapsto p((-\tau_1,\tau_2,-\tau_3),\rho)(y_1,y_2,y_3),$$

$$(u_1,u_2,u_3)\mapsto p((\tau_1,\tau_2,-\tau_3),\rho)(v_1,v_2,v_3),$$

$$(v_1,v_2,v_3)\mapsto p((-\tau_1,\tau_2,\tau_3)\rho)(u_1,u_2,u_3),$$

for parity of (τ,ρ) (even,odd) or (odd,even);

$$(w_1,w_2,w_3)\mapsto p(-1,1,-1),\rho)(w_1,w_2,w_3).$$

$h^{(3)}_{\sigma_3}(\tau,\rho)$: $(y_1,y_2,y_3)\mapsto p((\tau_1,\tau_2,\tau_3),\rho)(y_1,y_2,y_3)$,

$$(x_1,x_2,x_3)\mapsto p((-\tau_1,-\tau_2,\tau_3),\rho)(x_1,x_2,x_3),$$

$$(u_1,u_2,u_3)\mapsto p((\tau_1,-\tau_2,-\tau_3),\rho)(u_1,u_2,u_3),$$

$$(v_1,v_2,v_3)\mapsto p((-\tau_1,\tau_2,-\tau_3),\rho)(v_1,v_2,v_3),$$

for parity of (τ,ρ) (even,even) or (odd,odd);

$$(y_1,y_2,y_3)\mapsto p((\tau_1,\tau_2,\tau_3),\rho)(x_1,x_2,x_3), \tag{4.17}$$

$$(x_1,x_2,x_3)\mapsto p((-\tau_1,-\tau_2,\tau_3),\rho)(y_1,y_2,y_3),$$

$$(u_1,u_2,u_3)\mapsto p((-\tau_1,\tau_2,\tau_3),\rho)(v_1,v_2,v_3),$$

$$(v_1,v_2,v_3)\mapsto p((\tau_1,-\tau_2,\tau_3)\rho)(u_1,u_2,u_3),$$

for parity of (τ,ρ) (even,odd) or (odd,even);

$$(w_1,w_2,w_3)\mapsto p(-1,-1,1),\rho)(w_1,w_2,w_3).$$

For the application of the above results to integral realizations in Sec. VI, it is useful to formulate them in a coset presentation. Thus, we first write out the special case of the above transformations for the eight group elements in the normal subgroup S, and then replace α by $h(\alpha), h\in H_4$ to obtain the following relations:

$$Z(y|(S^{(0)}_{\sigma_0}h)(\alpha))\mapsto\begin{pmatrix} y_0 & x_1(y,h(\alpha)) & x_2(y,h(\alpha)) & x_3(y,h(\alpha)) \\ y_1 & w_1(y,h(\alpha)) & u_3(y,h(\alpha)) & v_2(y,h(\alpha)) \\ y_2 & v_3(y,h(\alpha)) & w_2(y,h(\alpha)) & u_1(y,h(\alpha)) \\ y_3 & u_2(y,h(\alpha)) & v_1(y,h(\alpha)) & w_3(y,h(\alpha)) \end{pmatrix},$$

$$Z(y|(S^{(1)}_{\sigma_1}h)(\alpha))\mapsto\begin{pmatrix} y_0 & x_1(y,h(\alpha)) & -x_2(y,h(\alpha)) & -x_3(y,h(\alpha)) \\ y_1 & w_1(y,h(\alpha)) & -u_3(y,h(\alpha)) & -v_2(y,h(\alpha)) \\ y_2 & v_3(y,h(\alpha)) & -w_2(y,h(\alpha)) & -u_1(y,h(\alpha)) \\ y_3 & u_2(y,h(\alpha)) & -v_1(y,h(\alpha)) & -w_3(y,h(\alpha)) \end{pmatrix},$$

$$Z(y|(S^{(2)}_{\sigma_2}h)(\alpha))\mapsto\begin{pmatrix} y_0 & -x_1(y,h(\alpha)) & x_2(y,h(\alpha)) & -x_3(y,h(\alpha)) \\ y_1 & -w_1(y,h(\alpha)) & u_3(y,h(\alpha)) & -v_2(y,h(\alpha)) \\ y_2 & -v_3(y,h(\alpha)) & w_2(y,h(\alpha)) & -u_1(y,h(\alpha)) \\ y_3 & -u_2(y,h(\alpha)) & v_1(y,h(\alpha)) & -w_3(y,h(\alpha)) \end{pmatrix}, \tag{4.18}$$

$$Z(y|(S^{(3)}_{\sigma_3}h)(\alpha))\mapsto\begin{pmatrix} y_0 & -x_1(y,h(\alpha)) & -x_2(y,h(\alpha)) & x_3(y,h(\alpha)) \\ y_1 & -w_1(y,h(\alpha)) & -u_3(y,h(\alpha)) & v_2(y,h(\alpha)) \\ y_2 & -v_3(y,h(\alpha)) & -w_2(y,h(\alpha)) & u_1(y,h(\alpha)) \\ y_3 & -u_2(y,h(\alpha)) & -v_1(y,h(\alpha)) & w_3(y,h(\alpha)) \end{pmatrix}.$$

The cosets of H_4 are enumerated by taking

$$h\in\{Sf_m(\sigma_1,\sigma_2,\sigma_3)|m=1,2,\ldots,6;\ \text{each}\ \ \sigma_i=\pm 1\},$$

where the set of factor group representatives is defined by Eq. (3.6). The elements

$$x(y,h(\alpha)),u(y,h(\alpha)),v(y,h(\alpha)),w(y,h(\alpha)) \tag{4.19}$$

of the Lorentz matrices in Eq. (4.18) are, of course, signed permutations of $x(y,\alpha)$, $u(y,\alpha)$, $v(y,\alpha)$, $w(y,\alpha)$, which may be obtained explicitly from Eqs. (4.14)–(4.17). The forms given by Eqs. (4.18) are needed in Sec. VI. The cosets of S in H_4 partition the set of signed permutations of the parameters α into *orbits* under the action of the normal subgroup S, as given by

$$[h(\alpha)]=\{(sh)(\alpha)|s\in S,h=\text{any coset representative of } H_4/S\}. \tag{4.20}$$

For general sequences α having distinct, nonzero components, the 384 signed permutations of α are partitioned into 48 distinct orbits with eight sequences in each orbit. If, however, one chooses sequences such as $(\alpha_1,\alpha_2,0,0),\alpha_1\neq\alpha_2$, there are only six distinct orbits. In the extreme case of a sequence $(\alpha_1,0,0,0)$, all orbits coincide with $[(\alpha_1,0,0,)]$. One can, of course, enumerate all such degenerate cases.

The results given in this section for the restricted Lorentz group extend to the full Lorentz group (see Ref. 13) by adjoining the operations of space inversion $\Sigma=G$, time inversion $\Theta=-G$, and their product, thus obtaining the full Lorentz group $\{\mathcal{L}I_4,\mathcal{L}\Sigma,\mathcal{L}\Theta,\mathcal{L}\Sigma\Theta\}$ of which $\mathcal{L}$ is a normal subgroup, and $\{I_4,\Sigma,\Theta,\Sigma\Theta\}$ are the elements of the factor group. Thus, writing the

matrix $L=(y|\alpha)\in\mathcal{L}$ given by Eq. (4.11) in terms of its columns, $(y|\alpha)=(L_0(y),L_1(y,\alpha),L_2(y,\alpha),L_3(y,\alpha))$, we obtain the full Lorentz group by adjoining the elements of the cosets, which are, respectively,

$$\begin{aligned} L\Sigma&=(-L_0(y),L_1(y,\alpha),L_2(y,\alpha),L_3(y,\alpha)),\\ L\Theta&=(L_0(y),-L_1(y,\alpha),-L_2(y,\alpha),-L_3(y,\alpha)),\\ L\Sigma\Theta&=(-L_0(y),-L_1(y,\alpha),-L_2(y,\alpha),-L_3(y,\alpha)). \end{aligned} \tag{4.21}$$

V. PRINCIPAL SUBGROUPS

In this section, we given the two-to-one homomorphisms between several subgroups of SL(2, **C**) to subgroups of the restricted Lorentz group in the $(y|\alpha)$ parametrization. The development of the integral realizations of $(y|\alpha)$ given in the next section then applies, as well, to the results given below. In order to give a uniform presentation of the SL(2,**R**), SU(1,1), and K subgroup cases below, it is convenient to introduce the indicated notational changes.

(1) Subgroup $\mathrm{SU}(2)\subset\mathrm{SL}(2,\mathbf{C})$. This is the case $y_0=1$, $y=(0,0,0)$, where the point α belongs to the unit sphere in $\mathbf{R}^4$: $\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=1$. The two-to-one correspondence of the group SU(2) onto the special Lorentz matrices $((0,0,0)|\alpha)$ is given by

$$Z((0,0,0)|\alpha)=\begin{pmatrix} \alpha_0-i\alpha_3 & -i\alpha_1-\alpha_2\\ -i\alpha_1+\alpha_2 & \alpha_0+i\alpha_3\end{pmatrix}\mapsto((0,0,0)|\alpha)=\begin{pmatrix} 1&0&0&0\\ 0& & & \\ 0& & R(\alpha)& \\ 0& & & \end{pmatrix}, \tag{5.1}$$

where $R(\alpha)\in\mathrm{SO}(3,\mathbf{R})$ is the proper orthogonal matrix given by

$$R=\begin{pmatrix} 2(\alpha_0^2+\alpha_1^2)-1 & 2(\alpha_1\alpha_2-\alpha_0\alpha_3) & 2(\alpha_1\alpha_3+\alpha_0\alpha_2)\\ 2(\alpha_2\alpha_1+\alpha_0\alpha_3) & 2(\alpha_0^2+\alpha_2^2)-1 & 2(\alpha_2\alpha_3-\alpha_0\alpha_1)\\ 2(\alpha_3\alpha_1-\alpha_0\alpha_2) & 2(\alpha_3\alpha_2+\alpha_0\alpha_1) & 2(\alpha_0^2+\alpha_3^2)-1\end{pmatrix}. \tag{5.2}$$

The β parameters are

$$\beta_0=0,\quad \beta_1=0,\quad \beta_2=0,\quad \beta_3=0. \tag{5.3}$$

(2) Subgroup $\mathrm{SL}(2,\mathbf{R})\subset\mathrm{SL}(2,\mathbf{C})$. Notation: $y_0=\lambda$, $(y_1,y_2,y_3)=(x,0,y)$, $\alpha=(v,0,u,0)$. These parameters then satisfy

$$x^2+y^2=\lambda^2-1,\quad u^2+v^2=\frac{1+\lambda}{2}. \tag{5.4}$$

The two-to-one correspondence of SL(2, **R**) onto the special Lorentz matrices $((x,0,y)|(v,0,u,0))$ is given by

$$\begin{pmatrix} v+\dfrac{ux+vy}{1+\lambda} & -u+\dfrac{vx-uy}{1+\lambda}\\ u+\dfrac{vx-uy}{1+\lambda} & v-\dfrac{ux+vy}{1+\lambda}\end{pmatrix}\mapsto\begin{pmatrix} \lambda & x_1 & 0 & x_3\\ x & w_1 & 0 & v_2\\ 0 & 0 & 1 & 0\\ y & u_2 & 0 & w_3\end{pmatrix}, \tag{5.5}$$

where

$$x_1=x-\frac{4u(ux+vy)}{1+\lambda},\quad x_3=y+\frac{4u(vx-uy)}{1+\lambda},$$

$$w_1=2v^2-1-2\left(\frac{ux+vy}{1+\lambda}\right)^2,\quad v_2=2uv+\frac{2(ux+vy)(vx-uy)}{(1+\lambda)^2},\tag{5.6}$$

$$u_2=-2uv+\frac{2(ux+vy)(vx-uy)}{(1+\lambda)^2},\quad w_3=2v^2-1-2\left(\frac{vx-uy}{1+\lambda}\right)^2.$$

(3) Subgroup SU(1,1)$\subset$SL(2,**C**). Notation: $y_0=\lambda$, $(y_1,y_2,y_3)=(x,y,0))$, $\alpha=(u,0,0,v)$. These parameters then satisfy

$$x^2+y^2=\lambda^2-1,\ u^2+v^2=\frac{1+\lambda}{2}.\tag{5.7}$$

The two-to-one correspondence of SU(1,1) onto the special Lorentz matrices $((x,y,0)|(u,0,0,v))$ is given by

$$\begin{pmatrix} u-iv & \dfrac{(u+iv)(x-iy)}{1+\lambda} \\ \dfrac{(u-iv)(x+iy)}{1+\lambda} & u+iv \end{pmatrix}\mapsto\begin{pmatrix} \lambda & x_1 & x_2 & 0 \\ x & w_1 & u_3 & 0 \\ y & v_3 & w_2 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},\tag{5.8}$$

where

$$x_1=-x+\frac{4u(ux+vy)}{1+\lambda},\quad x_2=-y-\frac{4u(vx-uy)}{1+\lambda},$$

$$w_1=2u^2-1-2\left(\frac{vx-uy}{1+\lambda}\right)^2,\quad u_3=-2uv-\frac{2(ux+vy)(vx-uy)}{(1+\lambda)^2},\tag{5.9}$$

$$v_3=2uv-\frac{2(ux+vy)(vx-uy)}{(1+\lambda)^2},\quad w_2=2u^2-1-2\left(\frac{ux+vy}{1+\lambda}\right)^2.$$

(4) Subgroup $K\subset$SL(2,**C**). Notation: $y_0=\lambda$, $(y_1,y_2,y_3)=(0,x,y)$, $\alpha=(u,v,0,0)$. These parameters then satisfy

$$x^2+y^2=\lambda^2-1,\ u^2+v^2=\frac{1+\lambda}{2}.\tag{5.10}$$

The two-to-one correspondence of K onto the special Lorentz matrices $((0,x,y)|(u,v,0,0))$ is given by

$$\begin{pmatrix} u-\dfrac{vx-uy}{1+\lambda} & -i\left(v+\dfrac{ux+vy}{1+\lambda}\right) \\ -i\left(v-\dfrac{ux+vy}{1+\lambda}\right) & u+\dfrac{vx-uy}{1+\lambda} \end{pmatrix}\mapsto\begin{pmatrix} \lambda & 0 & x_2 & x_3 \\ 0 & 1 & 0 & 0 \\ x & 0 & w_2 & u_1 \\ y & 0 & v_1 & w_3 \end{pmatrix},\tag{5.11}$$

where

$$x_2=-x+\frac{4u(ux+vy)}{1+\lambda},\quad x_3=-y-\frac{4u(vx-uy)}{1+\lambda},$$

$$w_2=2u^2-1-2\left(\frac{vx-uy}{1+\lambda}\right)^2, \quad u_1=-2uv-\frac{2(ux+vy)(vx-uy)}{(1+\lambda)^2}, \tag{5.12}$$

$$v_1=2uv-\frac{2(ux+vy)(vx-uy)}{(1+\lambda)^2}, \quad w_3=2u^2-1-2\left(\frac{ux+vy}{1+\lambda}\right)^2.$$

While the subgroups SL(2,**R**), SU(1,1), and K have distinct structures, they are parameterized in a uniform way in that the parameters satisfy the same relations (5.4), (5.7), and (5.10), and the elements of the matrix have the same factors $ux+vy$ and $vx-uy$. This is important in Sec. VII for integral realizations.

VI. ALGORITHMS FOR THE CONSTRUCTION OF ALL INTEGRAL LORENTZ MATRICES

We have given in Sec. IV a parametrization that is not only suitable for obtaining all the integral realizations of the Lorentz group, but which also casts the problem in a form that brings it within the purview of classical number theory, known since the time of Euclid, Fermat, and Gauss. In this section, we apply these results to the determination of all integral realizations of the restricted Lorentz group, which we denote by $I(\mathcal{L})$ with elements $I(y|\alpha)$.

Necessary and sufficient conditions that a matrix $(y|\alpha)\in I(\mathcal{L})$ are that the following set of conditions be true:

Condition I: For $y_0=m\in\{1,2,\ldots\}$, the first column solves, in integers,

$$y_1^2+y_2^2+y_3^2=m^2-1, \tag{6.1}$$

Condition II: The integer $m+1$ divides each of the quantities

$$\begin{aligned}&\gamma_0(y,\alpha)=-\alpha_1y_1-\alpha_2y_2-\alpha_3y_3, \quad \gamma_1(y,\alpha)=\alpha_0y_1+\alpha_3y_2-\alpha_2y_3,\\ &\gamma_2(y,\alpha)=-\alpha_3y_1+\alpha_0y_2+\alpha_1y_3, \quad \gamma_3(y,\alpha)=\alpha_2y_1-\alpha_1y_2+\alpha_0y_3.\end{aligned} \tag{6.2}$$

Condition III: The parameters $\alpha=(\alpha_0,\alpha_1,\alpha_2,\alpha_3)$ satisfy

$$\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=\frac{m+1}{2},$$

$$2(\alpha_0^2+\alpha_i^2)=n_i\in\{0,1,\ldots\}, \quad -2\alpha_0\alpha_i+2\alpha_j\alpha_k=\text{ integer}, \tag{6.3}$$

$$2\alpha_0\alpha_i+2\alpha_j\alpha_k=\text{ integer}, \quad (i,j,k)\text{ cyclic in }(1,2,3).$$

It follows from $2(\alpha_0^2+\alpha_i^2)=n_i=$ non-negative integer and $\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=(m+1)/2$ that $4\alpha_0^2+m+1=n_1+n_2+n_3$, hence, $4\alpha_0^2=$ non-negative integer. There are three distinct possibilities: $\alpha_0=$integer, $\alpha_0=$(integer)/$\sqrt{2}$, $\alpha_0=$(odd integer)/2. It then follows from $2\alpha_i^2=n_i-2\alpha_0^2$ that the sequence $(\alpha_0,\alpha_1,\alpha_2,\alpha_3)$ is either all integral, all (integer)/$\sqrt{2}$, or all (odd integer)/2. All cases satisfy the criteria in Condition III that the entries in $(y|\alpha)$ be integral.

The three classes of integral matrices $I(y|\alpha)\in I(\mathcal{L})$ are given explicitly as follows:

Class I. $y_0=m=2k+1$, the α_μ are all integers, and $y=(y_1,y_2,y_3)$ and $\alpha=(\alpha_0,\alpha_1,\alpha_2,\alpha_3)$ satisfy

$$\begin{aligned}&y_1^2+y_2^2+y_3^2=4k(k+1),\\ &\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=k+1.\end{aligned} \tag{6.4}$$

Class II. $y_0=m=k$, $\alpha_\mu=a_\mu/\sqrt{2}$, where the a_μ are all integers, and $y=(y_1,y_2,y_3)$ and $a=(a_0,a_1,a_2,a_3)$ satisfy

$$\begin{aligned} y_1^2+y_2^2+y_3^2&=k^2-1,\\ a_0^2+a_1^2+a_2^2+a_3^2&=k+1. \end{aligned} \tag{6.5}$$

Class III. $y_0=m=k$, $\alpha_\mu=b_\mu/2$, where the b_μ are all odd integers, and $y=(y_1,y_2,y_3)$ and $b=(b_0,b_1,b_2,b_3)$ satisfy

$$\begin{aligned} y_1^2+y_2^2+y_3^2&=k^2-1,\\ b_0^2+b_1^2+b_2^2+b_3^2&=2k+2,\ \text{each}\ \ b_\mu\ \ \text{odd}. \end{aligned} \tag{6.6}$$

The problems posed in each of these three classes are all classical number theoretic problems, and were considered by Euclid, Euler, Fermat, and Gauss, and others (see Ref. 14). Two relevant results are the following:

(1) Each positive integer, except those of the form $4^s(8N+7), s,N\in\{0,1,2,\ldots\}$, can be expressed as the sum of at most three squares.
(2) Each positive integer can be expressed as the sum of at most four squares.

Note that the condition given in (1) excludes certain k in each of the three classes. For example, there are no integer solutions y of (6.4) for $k=12$, since $(4)(12)(13)=4(156)=(4^2)(39)=4[(8)(4)+7]$, and none for $k=4$ of (6.5) and (6.6), since $4^2-1=15=8(1)+7$.

We mention that methods for solving Diophantine equations of the type occurring in the three classes above are developed in Refs. 16 and 17. Also, Uspensky and Heaslet[14] is a very readable book on number theory that introduces basic concepts and proves statements (1) and (2). The general problem of solving, in non-negative integers, the pair of relations

$$n_1+n_2+\cdots n_k=n,\quad n_1^2+n_2^2+\cdots+n_k^2=m,\quad (n,m)\ \text{positive integers} \tag{6.7}$$

is considered in Refs. 16 and 17, where these relations are treated in the context of the number theoretic degeneracy of the energy levels of an n-dimensional perturbed isotropic quantum harmonic oscillator. The main idea is to transform these relations to ''center-of-mass'' coordinates. In particular for $n=3$, this leads to barycentric or Möbius coordinates familiar from the eightfold way in particle physics. One is then able to classify the solutions in terms of finite multiplets consisting of sets of lattice points lying on cirlces in the Möbius plane. For $n>3$, one loses the elegance of the Möbius plane construction, but nonetheless still has a classification in terms of finite multiplets.[17] There are, of course, no closed forms for the set of all solutions of such Diophantine equations. We refer to these references and Ref. 14 for these procedures, and consider the Diophantine problems for Eqs. (6.4)–(6.6) as solved for the purpose of the discussion that follows.

In each of the three classes, the main problem is to determine the first column sequence $y=(y_1,y_2,y_3)$ and integral parameters $(\alpha_0,\alpha_1,\alpha_2,\alpha_3),(a_0,a_1,a_2,a_3)$, and (b_0,b_1,b_2,b_3), respectively, such that the factor $m+1$ divides the sequence

$$\begin{aligned} \gamma(y,\delta)&=(\gamma_0(y,\delta),\gamma_1(y,\delta),\gamma_2(y,\delta),\gamma_3(y,\delta)),\\ \delta&=\alpha,\quad \delta=\alpha/\sqrt{2}=a,\quad \delta=\alpha/2=b, \end{aligned} \tag{6.8}$$

defined in relation (6.2), where to unify the discussion of the three classes we let the sequence δ run over the three sequences that occur in the three classes.

The determination of a common factor in a sequence of integers is a classic number theoretical problem solved, in principle, by Euclid's algorithm. One can see how the general result goes from

a single example (see Ref. 14 for a proof of the general method): Find the greatest common divisor (gcd) of the integers 19332 and 1368: We perform the successive divisions given by

$$19332=14\cdot 1368+180,\ \ 1368=7\cdot 180+108,\ \ 180=1\cdot 72+36,\ \ 72=2\cdot 36,$$

thus arriving at 36, which is the gcd of the pair (19332, 1368). *Then, every divisor of this pair is a divisor of* 36, *namely*, 1, 2, 3, 4, 6, 9, 12, 18, 36.

The determination of the gcd D of a finite sequence of $n+2,\ n\geqslant 1$, integers $(d_1,d_2,\ldots,d_{n+2})$ is as follows. One calculates successively

$$D_1=\gcd(d_1,d_2),\quad D_2=\gcd(D_1,d_3),\quad D_3=\gcd(D_2,d_4),\quad \ldots,\quad D_{n+1}=\gcd(D_n,d_{n+2}),$$

and finds that

$$D=\gcd(d_1,d_2,\ldots,d_{n+2})=D_{n+1}.$$

Finally, each divisor of the sequence $(d_1,d_2,\ldots,d_{n+2})$ is a divisor of D.

For our problem and the three classes introduced above, we have $n=2$, and $y_0+1=m+1$ must be a factor of $D=\gcd(\gamma(y,\delta))$.

We have found no way to implement Euclid's algorithm such that for each $(y,\delta),\delta=\alpha,a,b$ solving Eqs. (6.4)–(6.6), respectively, one obtains algebraic constraints on the sequence of integers δ such that the sequence $\gamma(y,\delta)$ has divisor $m+1$. There are, however, several properties of the sequence $\gamma(y,\delta)$ that reduce the labor involved in implementing Condition II. Three obvious properties are

$$\gamma(-y,\delta)=-\gamma(y,\delta),\ \ \gamma(y,-\delta)=-\gamma(y,\delta),\gamma(-y,-\delta)=\gamma(y,\delta),\tag{6.9}$$

which are also consequences of the factor group Σ_2 introduced in Eq. (2.8). There is also a simplification originating from the transfer of the action of the group H_4 on the parameters δ [see Eq. (6.8)] to the action of the group H_3 on the parameters y. To describe this, we introduce the little group $H_3(y)\subset H_3$ that leaves y fixed:

$$H_3(y)=\{p(\tau,\rho)|p(\tau,\rho)(y)=y,p(\tau,\rho)\in H_3\}.\tag{6.10}$$

This, in turn, leads us to introduce the *set* $H_4(y)\subset H_4$ defined by

$$H_4(y)=\{h^{(k)}_{\sigma_k}(\tau,\rho)|p(\tau,\rho)\in H_3(y),k\in\{0,1,2,3\},\sigma_k\in\{1,-1\}\}.\tag{6.11}$$

We then have the identity

$$\gamma(y,h_y(\delta))=\gamma(y,\delta),\ \ \text{each}\ \ h_y\in H_4(y).\tag{6.12}$$

We conclude from relations (6.9) and (6.12) that, *if the pair of sequences* (y,δ) *satisfies Condition II given by Eq. (6.2), then so do all the pairs of sequences given by*

$$(-y,\delta),(y,-\delta),(-y,-\delta),\{(y,h_y(\delta))|\ \ each\ \ h_y\in H_4(y)\}.\tag{6.13}$$

The normal subgroup S of H_4 satisfies $S\subset H_4(y)$. It follows then that every $h_y\in H_4(y)$ belongs to a coset of S, that is, $h_y(\delta)$ is in one of the coset orbits of the normal subgroup S. It now follows from Eq. (6.12) that for sequences in the same coset orbit of S, either all or none satisfy Condition II.

We now give the details of the algorithms for constructing all integral Lorentz matrices in $\mathcal{L}$ and the corresponding matrices SL(2, **C**) in three subsections. One easily extends these results to obtain all integral realizations of the full Lorentz group by adjoining the additional signed elements originating from relations (4.21).

A. Class I: Integral Gaussian matrices in SL(2, C) mapping to $I(\mathcal{L})$

It is evident from Eq. (6.4) that we must have

$$(y_1,y_2,y_2)=2(z_1,z_2,z_3). \tag{6.14}$$

The above results for Class I may be summarized in the following algorithm for calculating all integral realizations $I(2z|\alpha)$ of the restricted Lorentz group $\mathcal{L}$ together with the Gaussian integer matrices $\pm Z(2z|\alpha)$ of SL(2, **C**) corresponding to $I(2z|\alpha)$.

Algorithm I.

(1) Fix a solution z of

$$z_1^2+z_2^2+z_3^2=k(k+1). \tag{6.15}$$

(2) Classify all solutions of

$$\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=k+1 \tag{6.16}$$

into disjoint coset orbits with respect to the normal subgroup S, defining the orbit $[\alpha]$ *by*

$$\begin{aligned}[\alpha]=S(\alpha)=\{&\pm(\alpha_0,\alpha_1,\alpha_2,\alpha_3),\pm(\alpha_1,-\alpha_0,\alpha_3,-\alpha_2),\\ &\pm(-\alpha_2,-\alpha_3,\alpha_0,\alpha_1),\pm(-\alpha_3,\alpha_2,-\alpha_1,\alpha_0)\}.\end{aligned} \tag{6.17}$$

(3) Select an α-sequence in each of the orbits obtained in (2). If the selected sequence satisfies the conditions that the integer $k+1$ *divides each of the quantities*

$$\begin{aligned}&\gamma_0(z,\alpha)=-\alpha_1z_1-\alpha_2z_2-\alpha_3z_3,\ \gamma_1(z,\alpha)=\alpha_0z_1+\alpha_3z_2-\alpha_2z_3,\\ &\gamma_2(z,\alpha)=-\alpha_3z_1+\alpha_0z_2+\alpha_1z_3,\quad \gamma_3(z,\alpha)=\alpha_2z_1-\alpha_1z_2+\alpha_0z_3,\end{aligned} \tag{6.18}$$

retain all sequences in the orbit, but otherwise reject the orbit, denoting the retained orbits by $[\alpha^{(1)}],[\alpha^{(2)}],\ldots$. *Then, the integer Lorentz matrices with fixed column sequence* $(y_1,y_2,y_3)=(2z_1,2z_2,2z_3)$ *are those in the set*

$$\{I(2z|\alpha)|\alpha\in[\alpha^{(1)}],\ \alpha\in[\alpha^{(2)}],\ldots\}. \tag{6.19}$$

The two-to-one homomorphism from Gaussian integer matrices in SL(2, **C**) *to* $I(\mathcal{L})$ *is given by*

$$\pm Z(2z|\alpha)\mapsto I(2z|\alpha),\quad \alpha\in[\alpha^{(1)}],\ \alpha\in[\alpha^{(2)}],\ldots \tag{6.20}$$

In selecting a solution of Eq. (6.15), in consequence of Eq. (6.17), it is only necessary to consider those solutions y that have parity (even,even) and (even,odd) with respect to H_3. The Lorentz matrices $I(2z|\alpha)$ given by this algorithm are obtained from relations (4.11) and (4.12) or (4.18) for $y_0=2k+1$, $y=(2z_1,2z_2,2z_3)$, where the sequences $h(\alpha)\in[\alpha^{(1)}],h(\alpha)\in[\alpha^{(2)}],\ldots$, and $Z(2z|\alpha)$ is obtained from Eq. (4.13).

An example is useful for illustrating the algorithm. Choose $k=8$, so that we must find solutions, in integers, of the two equations

$$z_1^2+z_2^2+z_3^2=72, \tag{6.21}$$

$$\alpha_0^2+\alpha_1^2+\alpha_2^2+\alpha_3^2=9, \tag{6.22}$$

subject to the condition that the integer 9 must divide each of the four quantities given by Eq. (6.18).

We also fix $|z_1|+|z_2|+|z_3|=12$, and apply the methods of Refs. 14 and 16 for solving Eqs. (6.21) and (6.22) (or by inspection). The solutions of Eq. (6.21) are (6,6,0),(8,2,2), and all signed permutations of these sequences. The solutions of Eq. (6.22) are (3,0,0,0),(2,2,1,0), and all signed permutations of these sequences.

We consider two subcases:

(1) Fix $z=(6,6,0)$. There are eight signed permutations of (3,0,0,0) They must therefore all fall in the normal subgroup orbit $[(3,0,0,0)]$, and all other coset orbits are equal to this one. Conditions (6.18) are satisfied by (3,0,0,0), giving $\gamma=(0,18,18,0)$, hence, by all sequences in the orbit $[(3,0,0,0)]$. Thus, we have the following results from Eq. (4.18):

$$\pm\begin{pmatrix} 3 & 2(1+i) \\ 2(1-i) & 3 \end{pmatrix} \to \begin{pmatrix} 17 & 12 & 12 & 0 \\ 12 & 9 & 8 & 0 \\ 12 & 8 & 9 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

$$\pm\begin{pmatrix} 2(1+i) & 3i \\ 3i & 2(-1+i) \end{pmatrix} \to \begin{pmatrix} 17 & 12 & -12 & 0 \\ 12 & 9 & -8 & 0 \\ 12 & 8 & -9 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix},$$

$$\pm\begin{pmatrix} 2(1-i) & -3 \\ 3 & -2(1+i) \end{pmatrix} \to \begin{pmatrix} 17 & -12 & 12 & 0 \\ 12 & -9 & 8 & 0 \\ 12 & -8 & 9 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix},$$

$$\pm\begin{pmatrix} -3i & 2(1+i) \\ 2(1-i) & 3i \end{pmatrix} \to \begin{pmatrix} 17 & -12 & -12 & 0 \\ 12 & -9 & -8 & 0 \\ 12 & -8 & -9 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

There are 96 signed permutations of (2,2,1,0). They must, therefore, be distributed into 12 disjoint coset orbits, which may be taken to be the orbit $[(2,2,1,0)]$ and all orbits obtained from the 12 permutations of the integers (2,2,1,0), that is, $[(2,2,0,1)]$,$[(2,1,2,0)]$, etc. From conditions (6.18), we have $\gamma_0=-6(\alpha_1+\alpha_2)$, $\gamma_1=6(\alpha_0+\alpha_3)$. Since $\alpha_0+\alpha_1+\alpha_2+\alpha_3=5$, the integers γ_0 and γ_1 are divisible by 9 if and only if both $\alpha_1+\alpha_2=3$ and $\alpha_0+\alpha_3=3$, which is impossible. We conclude there are no solutions of Eqs. (6.18), (6.21), and (6.22).

(2) Fix $z=(8,2,2)$. As in (1), all signed permutations of (3,0,0,0) fall in the normal subgroup orbit $[(3,0,0,0)]$. But now conditions (6.18) fail for (3,0,0,0), and we obtain no solutions of Eqs.

(6.18), (6.21), and (6.22). There are 96 signed permutations of (2,2,1,0). They must, therefore, be distributed into 12 disjoint coset orbits, just as in case 1. Conditions (6.18) now read:

$$\gamma_0=-8\alpha_1-2\alpha_2-2\alpha_3, \quad \gamma_1=8\alpha_0-2\alpha_2+2\alpha_3,$$

$$\gamma_2=2\alpha_0+2\alpha_1-8\alpha_3, \quad \gamma_3=2\alpha_0-2\alpha_1+8\alpha_2.$$

The form of γ_0 shows that no sequence with $\alpha_1=0$ can occur, and the form of γ_2 shows that no sequence with $\alpha_3=0$ can occur. Checking each of the remaining six candidates in which either $\alpha_0=0$ or $\alpha_2=0$, we find that only the sequence (2,2,0,1) gives a solution, hence, all eight sequences in the orbit

$$[(2,2,0,1)]=\{\pm(2,2,0,1),\pm(-2,2,1,0),\pm(0,-1,2,2),\pm(-1,0,-2,2)\}$$

give solutions of relations (6.18). We have the following results from Eq. (4.18):

$$\pm\begin{pmatrix} 2-3i & 2(1-i) \\ 2(1-i) & 2-i \end{pmatrix}\mapsto\begin{pmatrix} 17 & 16 & -4 & 4 \\ 16 & 15 & -4 & 4 \\ 4 & 4 & -1 & 0 \\ 4 & 4 & 0 & 1 \end{pmatrix},$$

$$\pm\begin{pmatrix} 2(1+i) & 3+2i \\ 1+2i & 2(1+i) \end{pmatrix}\mapsto\begin{pmatrix} 17 & 16 & 4 & -4 \\ 16 & 15 & 4 & -4 \\ 4 & 4 & 1 & 0 \\ 4 & 4 & 0 & -1 \end{pmatrix},$$

$$\pm\begin{pmatrix} 2(1-i) & -2+3i \\ 2-i & -2(1-i) \end{pmatrix}\mapsto\begin{pmatrix} 17 & -16 & -4 & -4 \\ 16 & -15 & -4 & -4 \\ 4 & -4 & -1 & 0 \\ 4 & -4 & 0 & -1 \end{pmatrix},$$

$$\pm\begin{pmatrix} -3-2i & 2(1+i) \\ -2(1+i) & 1+2i \end{pmatrix}\mapsto\begin{pmatrix} 17 & -16 & 4 & 4 \\ 16 & -15 & 4 & 4 \\ 4 & -4 & 1 & 0 \\ 4 & -4 & 0 & 1 \end{pmatrix}.$$

B. Class II: (Integral Gaussian/$\sqrt{2}$) matrices in SL(2, C) mapping to $I(\mathcal{L})$

We have the following results:

$$y_1^2+y_2^2+y_3^2=k^2-1,$$
$$a_0^2+a_1^2+a_2^2+a_3^2=k+1. \tag{6.23}$$

$$\frac{1}{\sqrt{2}}\left(\begin{array}{c|c} (a_0-ia_3)(1+\frac{y_3}{k+1})-\frac{(a_1+ia_2)(iy_1+y_2)}{k+1} & -(a_2+ia_1)(1+\frac{y_3}{k+1})+\frac{(a_0+ia_3)(y_1-iy_2)}{k+1} \\ \hline (a_2-ia_1)(1-\frac{y_3}{k+1})+\frac{(a_0-ia_3)(y_1+iy_2)}{k+1} & (a_0+ia_3)(1-\frac{y_3}{k+1})-\frac{(ia_1+a_2)(y_1+iy_2)}{k+1} \end{array}\right)$$

$$\mapsto (y|a)=\begin{pmatrix} k & x_1(y,a) & x_2(y,a) & x_3(y,a) \\ y_1 & w_1(y,a) & u_3(y,a) & v_2(y,a) \\ y_2 & v_3(y,a) & w_2(y,a) & u_1(y,a) \\ y_3 & u_2(y,a) & v_1(y,a) & w_3(y,a) \end{pmatrix}; \tag{6.24}$$

$$x_i(y,a)=(y|a)_{0,i}=\frac{1}{k+1}[a_0\gamma_i(y,a)-a_i\gamma_0(y,a)-a_j\gamma_k(y,a)+a_k\gamma_j(y,a)],$$

$$u_i(y,a)=(y|a)_{j,k}=-a_0a_i+a_ja_k+\frac{1}{(k+1)^2}[-\gamma_0(y,a)\gamma_i(y,a)+\gamma_j(y,a)\gamma_k(y,a)],$$

$$v_i(y,a)=(y|a)_{k,j}=a_0a_i+a_ja_k+\frac{1}{(k+1)^2}[\gamma_0(y,a)\gamma_i(y,a)+\gamma_j(y,a)\gamma_k(y,a)], \tag{6.25}$$

$$w_i(y,a)=(y|a)_{i,i}=a_0^2+a_i^2-1-\frac{1}{(k+1)^2}[\gamma_j^2(y,a)+\gamma_k^2(y,a)],$$

(i,j,k) is a cyclic permutation of (1,2,3);

$$\gamma_0(y,a)=-a_1y_1-a_2y_2-a_3y_3, \quad \gamma_1(y,a)=a_0y_1+a_3y_2-a_2y_3,$$
$$\gamma_2(y,a)=-a_3y_1+a_0y_2+a_1y_3, \quad \gamma_3(y,a)=a_2y_1-a_1y_2+a_0y_3. \tag{6.26}$$

It is important to note that for general Lorentz matrices, the scaling above gives no new results, since it just changes how one describes the parameter domain. However, for integral realizations, this scaling transformation introduces an entirely new class of integral Lorentz matrices, now corresponding to matrices in SL(2, **C**) that have Gaussian integers divided by $\sqrt{2}$ as elements.

The modification of Algorithm I for Class II solutions is the following.

Algorithm II. In Algorithm I, replace Eqs. (6.15) and (6.16) by Eqs. (6.23), the sequence $2z$ by the sequence y, and the sequence α by the sequence a, using now relations (6.24)–(6.26) to obtain the explicit results for the mapping of (Gaussian integers)/$\sqrt{2}$ in SL(2, **C**) to integral matrices in $I(\mathcal{L})$. [One can also use the obvious modification of Eq. (4.18).]

C. Class III: Gaussian half-odd integral matrices in SL(2, C) mapping to $I(\mathcal{L})$

We have the following results:

$$y_1^2+y_2^2+y_3^2=k^2-1,$$
$$b_0^2+b_1^2+b_2^2+b_3^2=2k+2, \text{ each } b_\mu \text{ odd.} \tag{6.27}$$

$$\frac{1}{2}\left(\begin{array}{c|c} (b_0-ib_3)(1+\frac{y_3}{k+1})-\frac{(b_1+ib_2)(iy_1+y_2)}{k+1} & -(b_2+ib_1)(1+\frac{y_3}{k+1})+\frac{(b_0+ib_3)(y_1-iy_2)}{k+1} \\ \hline (b_2-ib_1)(1-\frac{y_3}{k+1})+\frac{(b_0-ib_3)(y_1+iy_2)}{k+1} & (b_0+ib_3)(1-\frac{y_3}{k+1})-\frac{(ib_1+b_2)(y_1+iy_2)}{k+1} \end{array}\right)$$

$$\mapsto (y|b)=\left(\begin{array}{cccc} k & x_1(y,b) & x_2(y,b) & x_3(y,b) \\ y_1 & w_1(y,b) & u_3(y,b) & v_2(y,b) \\ y_2 & v_3(y,b) & w_2(y,b) & u_1(y,b) \\ y_3 & u_2(y,b) & v_1(y,b) & w_3(y,b) \end{array}\right); \tag{6.28}$$

$$x_i(y,b)=(y|b)_{0,i}=\frac{1}{2(k+1)}[b_0\gamma_i(y,b)-b_i\gamma_0(y,b)-b_j\gamma_k(y,b)+b_k\gamma_j(y,b)],$$

$$u_i(y,b)=(y|b)_{j,k}=\frac{-b_0b_i+b_jb_k}{2}+\frac{1}{2(k+1)^2}[-\gamma_0(y,b)\gamma_i(y,b)+\gamma_j(y,b)\gamma_k(y,b)],$$

$$v_i(y,b)=(y|b)_{k,j}=\frac{b_0b_i+b_jb_k}{2}+\frac{1}{2(k+1)^2}[\gamma_0(y,b)\gamma_i(y,b)+\gamma_j(y,b)\gamma_k(y,b)], \tag{6.29}$$

$$w_i(y,b)=(y|b)_{i,i}=\frac{b_0^2+b_i^2}{2}-1-\frac{1}{2(k+1)^2}[\gamma_j^2(y,b)+\gamma_k^2(y,b)],$$

$$(i,j,k) \text{ is a cyclic permutation of } (1,2,3);$$

$$\gamma_0(y,b)=-b_1y_1-b_2y_2-b_3y_3, \quad \gamma_1(y,b)=b_0y_1+b_3y_2-b_2y_3,$$
$$\gamma_2(y,b)=-b_3y_1+b_0y_2+b_1y_3, \quad \gamma_3(y,b)=b_2y_1-b_1y_2+b_0y_3. \tag{6.30}$$

The modification of Algorithm I for Class III solutions is as follows.

Algorithm III. In Algorithm I, replace Eqs. (6.15) and (6.16) by Eqs. (6.27), the sequence $2z$ by the sequence y, and the sequence α by the sequence b, using now relations (6.28)–(6.30) to obtain the explicit results for the mapping of (Gaussian integers)/2 in SL(2, **C**) to integral matrices in $I(\mathcal{L})$. [One can also use the obvious modification of Eq. (4.18).]

We note that the denominator factor $k+1$ in relations (6.29) is removed because, by construction, $k+1$ divides the factors $\gamma_\mu(y,b)$; the denominator factor 2 is removed by the property that the b_μ are odd integers, which results in only integers appearing in $(y|b)$.

VII. INTEGRAL REALIZATIONS OF THE PRINCIPAL SUBGROUPS

As a by-product of the above construction of the integral realizations of the restricted Lorentz group, we also obtain all the integral realizations of the principal subgroups given in Sec. V.

A. Integral realizations of the orthogonal group SO(3, R)

In this case, we turn the situation around and identify first the integral representations of SO(3, **R**), and then the matrices in SL(2, **C**) corresponding to them. The integral realizations of the proper orthogonal group can only be permutations of the columns of the matrix $(\pm e_1, \pm e_2, \pm e_3)$, where e_i is a unit column vector. Since we must have $\det R=1$, we can have zero or two minus signs and all even column permutations, or one or three minus signs and all odd column permutations, thus obtaining a group of 24 discrete orthogonal matrices with unit determinant. This is the group of rotations that carries the cube with vertices at $(1,1,1)$, $(-1,1,1)$, $(-1,-1,1)$, $(1,-1,1)$, $(1,1,-1)$, $(-1,1,-1)$, $(-1,-1,-1)$, $(1,-1,-1)$ into itself, or, equivalently, the octahedron with vertices at $(1,0,0)$, $(0,1,0)$, $(0,0,1)$, $(-1,0,0)$, $(0,-1,0)$, $(0,0,-1)$. The corresponding subgroup of SU(2) is the so-called double covering group with 48 elements. An interesting point is that the elements of SU(2) that are Gaussian integers divided by $\sqrt{2}$ already make their appearance. For example, we have

$$\pm\frac{1}{\sqrt{2}}\begin{pmatrix}1 & 1\\ -1 & 1\end{pmatrix}\mapsto\begin{pmatrix}0 & 0 & -1\\ 0 & 1 & 0\\ 1 & 0 & 0\end{pmatrix},\quad \pm\frac{i}{\sqrt{2}}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}\mapsto\begin{pmatrix}0 & 0 & 1\\ 0 & -1 & 0\\ 1 & 0 & 0\end{pmatrix},$$

$$\pm i\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\mapsto\begin{pmatrix}1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & -1\end{pmatrix},\quad \pm\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\mapsto\begin{pmatrix}-1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & -1\end{pmatrix},$$

$$\pm i\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\mapsto\begin{pmatrix}-1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & 1\end{pmatrix},\quad \text{etc.}$$

It is interesting to note that the half-odd integral realizations of SL(2, **C**), which are allowed in the general theory, are excluded here because there is no solution, by four odd integers, of the relation $b_0^2+b_1^2+b_2^2+b_3^2=2$.

B. Gaussian integer realizations of SL(2,R), SU(1,1), and K

We have already noted at the end of Sec. V that these subgroups can be parametrized in a uniform manner. For integral realizations this transcribes to the following special cases, respectively, of Algorithms I, II, and III:

Algorithm I′:

(1) Set $x=2s$, $y=2t$. *Select and fix a solution* (s,t) *of*

$$s^2+t^2=k(k+1). \tag{7.1}$$

(2) Select any solution (u,v) *with non-negative components of*

$$u^2+v^2=k+1. \tag{7.2}$$

(3) The mappings given by Eqs. (5.5), (5.8), and (5.11) for the integer pair (u,v), *and by each of the substitutions* $(u,v)\to(-u,-v)$, $(u,v)\to(-v,u)$, $(u,v)\to(v,-u)$, *all give mappings of Gaussian integer realizations of the respective subgroups to the corresponding integral realization of the Lorentz group if and only if* $k+1$ *is a divisor of* $\gcd(us+vt, vs-ut)$. *The mappings given by Eqs. (5.5), (5.8), and (5.11) for the integer pair* (v,u), *and by each of the substitutions*

$(v,u)\to(-v,-u),(v,u)\to(-u,v),(v,u)\to(u,-v)$, *all give mappings of Gaussian integer realizations of the respective subgroups to the corresponding integral realization of the Lorentz group if and only if* $k+1$ *is a divisor of* $\gcd(vs+ut,us-vt)$.

Algorithm II′:

(1) Select and fix a solution (x,y) *of*

$$x^2+y^2=k^2-1. \tag{7.3}$$

(2) Select a non-negative solution (u,v)

$$u^2+v^2=k+1. \tag{7.4}$$

(3) The mappings given by Eqs. (5.5), (5.8), and (5.11) for the integer pair (u,v), *and by each of the substitutions* $(u,v)\to(-u,-v),(u,v)\to(-v,u),(u,v)\to(v,-u)$, *all give mappings of* (Gaussian integer)/$\sqrt{2}$ *realizations of the respective subgroups to the corresponding integral realization of the Lorentz group if and only if* $k+1$ *is a divisor of* $\gcd(ux+vy,vx-uy)$. *The mappings given by Eqs. (5.5), (5.8), and (5.11) for the integer pair* (v,u), *and by each of the substitutions* $(v,u)\to(-v,-u),(v,u)\to(-u,v),(v,u)\to(u,-v)$, *all give mappings of* (Gaussian integer)/$\sqrt{2}$ *realizations of the respective subgroups to the corresponding integral realization of the Lorentz group if and only if* $k+1$ *is a divisor of* $\gcd(vx+uy,ux-vy)$.

Algorithm III′:

(1) Select and fix a solution (x,y) *of*

$$x^2+y^2=k^2-1. \tag{7.5}$$

(2) Select a non-negative solution $(u,v)=(odd,odd)$

$$u^2+v^2=2(k+1). \tag{7.6}$$

(3) The mappings given by Eqs. (5.5), (5.8), and (5.11) for the integer pair (u,v), *and by each of the substitutions* $(u,v)\to(-u,-v),(u,v)\to(-v,u),(u,v)\to(v,-u)$, *all give mappings of* (Gaussian integer)/$\sqrt{2}$ *realizations of the respective subgroups to the corresponding integral realization of the Lorentz group if and only if* $k+1$ *is a divisor of* $\gcd(ux+vy,vx-uy)$. *The mappings given by Eqs. (5.5), (5.8), and (5.11) for the integer pair* (v,u), *and by each of the substitutions* $(v,u)\to(-v,-u),(v,u)\to(-u,v),(v,u)\to(u,-v)$, *all give mappings of (Gaussian odd integer)/2 realizations of the respective subgroups to the corresponding integral realization of the Lorentz group if and only if* $k+1$ *is a divisor of* $\gcd(vx+uy,ux-vy)$.

A comprehensive theory, using Algorithms I′–III′, can now be used to construct all Gaussian integer, (Gaussian integer)/$\sqrt{2}$, and (Gaussian odd integer)/2 realizations of the subgroups SL(2, **R**), SU(1,1), and K from classical results of number theory (see Ref. 14). We close our discussion by noting examples showing interesting aspects of such solutions:

$$\text{Algorithm I}'\text{: Choose } (x,y)=(2au,2av), \text{ where } u^2+v^2=a^2+1.$$

$$\text{Algorithm II}'\text{: Choose } (x,y)=(bu,bv), \text{ where } u^2+v^2=b^2+2.$$

In particular, if $a^2+1=$prime number is of form $4r+1$, or if b^2+2 is of this same form, then the solution (u,v) is unique, up to signed permutations, for each such r, and the integers u and v are relatively prime. On the other hand, if $u=v$, we obtain, respectively, Pell equations, $a^2-2u^2=-1$ and $b^2-2u^2=-2$, which have infinitely many solutions given by

$$\begin{pmatrix} a \\ u \end{pmatrix} = \begin{pmatrix} 3 & 4 \\ 2 & 3 \end{pmatrix}^m \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad m = 0,1,2,\ldots,$$

$$\begin{pmatrix} b \\ u \end{pmatrix} = \begin{pmatrix} 3 & 4 \\ 2 & 3 \end{pmatrix}^m \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad m = 0,1,2,\ldots .$$

Pell's equation has fascinating applications to the determination of zeros of $3j$ and $6j$ coefficients that arise in the theory of angular momentum [the group SU(2)]. An elementary example is given in Ref. 18, and a brief summary of papers on such zeros is given in Ref. 19.

VIII. CONCLUDING REMARKS

(1) Using the biquaternionic parameters (α, β) introduced by Dirac (equivalent to the Cayley parameters) to parametrize the group SL(2, **C**), we have obtained a corresponding parametrization of the restricted Lorentz group $\mathcal{L}$ in terms of the first column of an element of $\mathcal{L}$ and the quaternionic parameters α. It is this parametrization that is used to address the problem of determining all integral realizations of the restricted Lorentz group. This leads to the problem of solving simultaneously three classical Diophantine problems, as follows: One is given a pair (n_1, n_2) of positive integers, the first expressed as a quadractic function of a positive integer k and the second linear in k. One must then express n_1 as a sum of three squares; n_2 as a sum of four squares, and then select from the set of solutions of the three-squares problem and the set of solutions of the four-squares problem those particular pairs of solutions such that four new integers, each linear in the three-squares solution and in the four-squares solution, possess a common factor. It is the interrelations between the solutions of these three classical Diophantine problems that makes the general determination of the integer representations of the restricted Lorentz group difficult. The algorithmic character of the procedure may, however, make computer calculations quite tractable. In any case, the recognition of the underlying classical Diophantine structure of the problem is intriguing and interesting. That there are three classes of SL(2, **C**) matrices, Gaussian integral, half-odd Gaussian integral, and Gaussian integral/$\sqrt{2}$, each class giving integral restricted Lorentz matrices, is a bonus of addressing the problem through the homomorphism between the groups, from which one also obtains corresponding results for the principal subgroups of $\mathcal{L}$.

(2) The method presented here, as summarized in (1), is to be contrasted with the generator method described by Lorente and Kramer,[6,7] and attributed to Coxeter and Kac,[10] which asserts the following. All integral Lorentz transformations L of the point (x_0, x_1, x_2, x_3) that leave the upper half of the light cone invariant are generated by the four transformations

$$S_1 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad S_2 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix},$$

$$S_3 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \quad S_4 = \begin{pmatrix} 2 & 1 & 1 & 1 \\ -1 & 0 & -1 & -1 \\ -1 & -1 & 0 & -1 \\ -1 & -1 & -1 & 0 \end{pmatrix}.$$

Based on this result, Lorente and Kramer[6,7] give a polynomial form in these four generators for the general integral transformation L. It is a rather unwieldy appearing expression, but the authors use it effectively to present various classes of special matrices. Moreover, in Ref. 7, they also relate their results to matrices in SL(2, **C**).

(3) In consequence of the observations made in (1) and (2), it must be the case that one can transform the results obtained in this article into generator expressions. This poses the interesting question as to how the generator method solves the three interrelated classical Diophantine problems presented here.

ACKNOWLEDGMENTS

In preliminary work to this article, Christine Kelley, a graduate of the University of Puget Sound in transition to graduate studies, for whom I was mentor at Los Alamos National Laboratory, transcribed MacFarlane's relation (69) into the form (1.10)–(1.12), and also listed a number of cases of SL(2, **C**) and $\mathcal{L}$ integral matrices. This was all very useful for arriving at the viewpoint presented in this article. The author became interested in the integral realizations of the Lorentz group through numerous conversations with Professor Nandor Balazs of the Physics Department, SUNY, Stony Brook, and thanks him for the encouragement to investigate the problem. The author is also indebted to the referee for a careful reading of the article and suggestions leading to the remarks in Sec. VIII. This work was performed under the auspices of the Department of Energy, Contract W-7405-ENG-36.

(Received 21 March 2002; accepted for publication 8 July 2002)

We present a method to calculate integrals over monomials of matrix elements with invariant measures in terms of Wick contractions. The method gives exact results for monomials of low order. For higher-order monomials, it leads to an error of order $1/N^{\alpha}$, where N is the dimension of the matrix and where α is independent of the degree of the monomial. We give a lower bound on the integer α and show how α can be increased systematically. The method is particularly suited for symbolic computer calculation. Explicit results are given for O(N), U(N), and for the circular orthogonal ensemble. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1506955]

I. INTRODUCTION

The calculation of group integrals of monomials of matrix elements for compact Lie groups has a long tradition going back to Ullah and Porter.[1] Their results were later extended[2] to the space of symmetric unitary matrices endowed with Dyson's invariant measure.[3] The problem was nearly dormant for some years but was recently solved completely for the orthogonal group by recursion.[4] Unfortunately, it seems that there is no easy generalization of this method to other groups. The method proposed in Ref. 2, on the other hand, is quite general but soon becomes rather cumbersome. Moreover, that method is not suited for computer-supported analytical work.

Aside from their immanent group-theoretical significance, group integrals over monomials of matrix elements for compact Lie groups are important in many applications. This is true not only of random-matrix theory which has seen an explosive growth over the last decade and has become an important tool in a great variety of fields in physics, chemistry, and related areas.[5] The statement applies likewise to a number of mathematical fields where integrals of the Itzykson–Zuber-type appear. Such integrals typically extend over the Haar measure of some group. As examples, we mention the Itzykson–Zuber model itself,[6] the Bessel functions associated with Jack polynomials,[7] or multivariate analysis.[8] The wide occurrence of such group integrals then lends further urgency to the evaluation of the above-mentioned group integrals.

In this paper, we present and analyze a novel approach to the problem. We encountered the problem in the study of a random-matrix model for a class of chaotic systems (the semiseparable systems).[9] We found that we could use the invariants of the orthogonal group to construct a weight function. With the help of this function, it was possible to evaluate the group integrals in question by simple Wick contractions. We implemented the scheme on the computer and found that beyond the expected exact results for low-order monomials, monomials of higher order were also calcu-

a)Electronic mail: prosen@fiz.uni-lj.si

lated correctly up to and including the subleading order in $1/N$, where N is the dimension of the matrices under consideration. We conjectured that this statement holds for monomials of any order. It is the purpose of the present paper to extend and prove the conjecture and to explore the scope of its validity beyond the orthogonal group.

The group integrals extend over a compact matrix space with a measure which is uniquely determined by the underlying symmetry group. In order to reduce the computation to Wick contractions, we consider an extended matrix space where all matrix elements are independent Gaussian variables. In this space, all integrations trivially reduce to Wick contractions and can easily be implemented in many programming languages. The constraints due to the group structure are then introduced in an approximate fashion through a weight function w appearing as factor in the integrand. This function is chosen in such a way that the integrals yield the exact values for the lowest-order invariants of the group. It turns out that w is not always positive and, thus, not a measure. This, however, is not a significant obstacle.

Candidates for our spaces are the orthogonal group $\mathrm{O}(N)$, the unitary group $\mathrm{U}(N)=\mathrm{CUE}(N)$, also known as the circular unitary ensemble, the circular orthogonal ensemble of symmetric unitary matrices $\mathrm{COE}(N)$, and the circular symplectic ensemble which is isomorphic to the unitary symplectic group $\mathrm{CSE}(N)=\mathrm{USP}(2N)$. We note that $\mathrm{COE}(N)$ is not a group—for all other cases we can use the Haar measure, while in this case we have to use Dyson's invariant measure.

We first present our arguments for the case of the orthogonal group. In Sec. II we construct the weight function w from the invariants of the orthogonal group. We show that the defining equations for w always have a unique solution. We give explicit expressions for w in the simplest cases. We show that low-order monomials are calculated exactly using Wick contraction. In Sec. III, we show that monomials of higher order are evaluated correctly by Wick contraction, up to an error of order $N^{-\alpha}$. We establish a lower bound for the exponent α. In Sec. IV we extend our arguments to other matrix spaces. We give explicit expressions for the weight functions for $\mathrm{U}(N)$ and for $\mathrm{COE}(N)$. The more involved and less important case of CSE is only touched upon.

II. THE WEIGHT FUNCTION FOR O(N)

As explained in Sec. I, we start with a space of real matrices M. The elements are taken as independent Gaussian-distributed variables with zero mean and identical variances. In other words, our measure $\mathrm{d}\mu_g$ for integration is the product of the differentials of all matrix elements times $\mathcal{N}\exp\{-N\ \mathrm{tr}(MM^T)\}$ where $\mathcal{N}$ is a normalization factor. We recall that N is the dimension of the matrices M. We are interested in values of $N\gg 1$. The measure is invariant under right or left multiplication of M with any orthogonal matrix. To restrict the integration to the orthogonal group, we could think of multiplying $\mathrm{d}\mu_g$ with a set of delta functions expressing all the constraints due to orthonormality. This is clearly impractical. Instead, we modify the measure by multiplying $\mathrm{d}\mu_g$ with a weight function w_κ. This function is chosen in such a way that all orthogonal invariants up to and including order 2κ are exactly reproduced when we use w_κ as a weight function under the integrals over M. We note in passing that our present notation differs from that of Ref. 9. Our index κ equals half of the even index k used there.

To determine w_κ, we consider all invariants $I_j(O)$ up to order 2κ in the matrix elements O of the orthogonal group. Here, j is a running index. We recall that all such invariants are even in the O's. In every invariant $I_j(O)$, we replace O by M to obtain $I_j(M)$. We write w_κ as a linear combination of all the $I_j(M)$'s up to order 2κ in M. The coefficients of the linear combination are determined by the requirement that the average of every $I_j(M)$, calculated by integration over $\mathrm{d}\mu_g$ with weight function w_κ, yields the same result as integration of $I_j(O)$ over the orthogonal group. We recall that with n a positive integer, the invariants of the orthogonal group are given by expressions of the form $\mathrm{tr}\{(OO^T)^n\}$, or by products of such expressions. We accordingly write the quantities $I_j(M)$ in the form

$$I_{\mathbf{k}}^{(k)}(M)=\prod_{k_i}\ \mathrm{tr}\{(MM^T)^{k_i}\}. \tag{1}$$

Here $2k$ denotes the degree of I in M, and $\mathbf{k}=(k_1,k_2,\ldots)$ is a partition of k into positive integers $k_i\geqslant 1$ with $k_1+k_2+\cdots=k$. Without loss of generality we require that $k_1\geqslant k_2\geqslant\cdots$. The weight function w_κ is now written as

$$w_\kappa(M)=a_0^{(\kappa)}+\sum_{k=1}^{\kappa}\ \sum_{\mathbf{k}}\ a_{\mathbf{k}}^{(\kappa)}I_{\mathbf{k}}^{(k)}(M). \tag{2}$$

The sum on the right-hand side of Eq. (2) extends over a complete set of linearly independent invariants up to order 2κ in M.

We determine the coefficients $a_{\mathbf{k}}^{(\kappa)}$ from the conditions of orthonormality. More precisely, we require that the relations

$$\int\ \mathrm{d}\mu_g w_\kappa(M)=1,$$

$$\int\ \mathrm{d}\mu_g w_\kappa(M)(MM^T)_{i_1j_1}=\delta_{i_1,j_1},$$

$$\int\ \mathrm{d}\mu_g w_\kappa(M)(MM^T)_{i_1j_1}(MM^T)_{i_2j_2}=\delta_{i_1,j_1}\delta_{i_2,j_2}, \tag{3}$$

$$\cdots$$

$$\int\ \mathrm{d}\mu_g w_\kappa(M)(MM^T)_{i_1j_1}(MM^T)_{i_2j_2}\cdots(MM^T)_{i_\kappa j_\kappa}=\delta_{i_1,j_1}\delta_{i_2,j_2}\times\cdots\times\delta_{i_\kappa,j_\kappa}$$

be fulfilled identically. Relations of the form (3) hold for any value of κ for the orthogonal group but must be imposed for the integration over the matrices M.

Equation (3) determines the coefficients $a_{\mathbf{k}}^{(\kappa)}$ uniquely. To show this, we take traces over these equations in such a way that the integrals on the left-hand sides take the form $\int \mathrm{d}\mu_g w_\kappa(M)I_{\mathbf{k}}^{(k)}(M)$. The resulting set of equations has the form

$$\int\ \mathrm{d}\mu_g w_\kappa(M)I_{\mathbf{k}}^{(k)}(M)=B_{\mathbf{k}}^{(k)}, \tag{4}$$

where the coefficients $B_{\mathbf{k}}^{(k)}$ are given by powers of N, with N the dimension of the matrices M. Recalling Eq. (2), we see that Eq. (4) constitutes a set of linear equations for the coefficients $a_{\mathbf{k}}^{(\kappa)}$. There are obviously as many equations as there are coefficients $a_{\mathbf{k}}^{(\kappa)}$. We conclude that Eq. (4) possesses a unique solution unless the determinant of the matrix C with elements $C_{\mathbf{k}_1\mathbf{k}_2}^{(k_1k_2)}=\int \mathrm{d}\mu_g I_{\mathbf{k}_1}^{(k_1)}I_{\mathbf{k}_2}^{(k_2)}$ vanishes. But if $\det(C_{\mathbf{k}_1\mathbf{k}_2}^{(k_1k_2)})=0$, there exists a nontrivial solution $b_{\mathbf{k}_2}^{(k_2)}$ of the homogeneous equation $\Sigma_{k_2\mathbf{k}_2}C_{\mathbf{k}_1\mathbf{k}_2}^{(k_1k_2)}b_{\mathbf{k}_2}^{(k_2)}=0$. The existence of this solution implies that we also have $\Sigma_{k_1k_2}\Sigma_{\mathbf{k}_1\mathbf{k}_2}b_{\mathbf{k}_1}^{(k_1)}C_{\mathbf{k}_1\mathbf{k}_2}^{(k_1k_2)}b_{\mathbf{k}_2}^{(k_2)}=0$. Recalling the definition of the matrix C, we observe that the last relation can be written as $\int \mathrm{d}\mu_g|\Sigma_{\mathbf{k}_1\mathbf{k}_1}I_{\mathbf{k}_1}^{(k_1)}b_{\mathbf{k}_1}^{(k_1)}|^2=0$. But the integrand in the last expression is positive semidefinite and does not vanish identically. Therefore, it is not possible that $\det(C_{\mathbf{k}_1\mathbf{k}_2}^{(k_1k_2)})$ vanishes, and the solution of Eq. (4) exists and is unique. This solution also solves Eq. (3). To see this, let us assume the contrary and focus attention on the second equation of (3). [The argument is easily extended to the entire set of equations (3).] Inserting the solution of (4) into the left-hand side of that equation yields on the right-hand side the terms $\delta_{i_1j_1}+A_{i_1j_1}$ where the matrix A is both

traceless and invariant under every orthogonal transformation. This implies $A=0$, in contradiction to the assumption that we did not find a solution of the second equation of (3).

Equation (3) implies that the integrals over all polynomials of degree $n\leqslant 2\kappa$ in M are equal to the corresponding expressions for O(N). To see this, it suffices to consider the integral over an arbitrary monomial of degree n. It is obvious that the integral vanishes unless n is even, $n=2k$. We write the monomial as $\mathcal{M}^{(n)}=M_{i_1j_1}M_{i_2j_2}\cdots M_{i_nj_n}$. The integral over $\mathcal{M}^{(n)}$ is obviously invariant under right or left multiplication with any orthogonal transformation. Therefore, the integral over $\mathcal{M}^{(n)}$ must be a linear combination of invariants multiplied by a suitable set of Kronecker deltas in the indices $i_1,\ldots,i_n$ and $j_1,\ldots,j_n$. By construction the invariants have the same values as in O(N).

Inspection shows that the weight function $w_0=1$ fulfills the second equation of (3) automatically. Thus, $w_1=w_0$ and, therefore, $a_0^{(1)}=1$, $a_1^{(1)}=0$. The first nontrivial condition is, therefore, the one appearing in line 3 of (3). This condition (and all that follow below it) is violated by w_0. We now give the explicit results for the first few weight functions w_κ. These were obtained with the help of the MATHEMATICA program. For $\kappa=2$, we find

$$\begin{aligned} a_0^{(2)}&=1-\frac{N^2}{4},\\ a_1^{(2)}&=\frac{N}{2},\\ a_2^{(2)}&=-\frac{N^3}{4(-1+N)(2+N)},\\ a_{11}^{(2)}&=\frac{N^2}{4(-1+N)(2+N)}. \end{aligned} \tag{5}$$

For $\kappa=3$, we have

$$\begin{aligned} a_0^{(3)}&=1-\frac{7N^2}{12},\\ a_1^{(3)}&=\frac{3N}{2},\\ a_2^{(3)}&=-\frac{5N^3}{4(-1+N)(2+N)},\\ a_{11}^{(3)}&=\frac{5N^2}{4(-1+N)(2+N)},\\ a_3^{(3)}&=\frac{N^5}{3(-2+N)(-1+N)(2+N)(4+N)},\\ a_{21}^{(3)}&=-\frac{N^4}{(-2+N)(-1+N)(2+N)(4+N)},\\ a_{111}^{(3)}&=\frac{2N^3}{3(-2+N)(-1+N)(2+N)(4+N)}. \end{aligned} \tag{6}$$

For $\kappa=4$, we have

$$a_0^{(4)}=1-\frac{23\ N^2}{24}+\frac{N^4}{32},$$

$$a_1^{(4)}=3\ N-\frac{N^3}{8},$$

$$a_2^{(4)}=\frac{-60\ N^3+N^5}{16(-1+N)(2+N)},$$

$$a_{11}^{(4)}=\frac{56\ N^2+2\ N^3+N^4}{16(-1+N)(2+N)},$$

$$a_3^{(4)}=\frac{7\ N^5}{3(-2+N)(-1+N)(2+N)(4+N)},$$

$$a_{21}^{(4)}=\frac{-48\ N^4-2\ N^5-N^6}{8(-2+N)(-1+N)(2+N)(4+N)},$$

$$a_{111}^{(4)}=\frac{88\ N^3+6\ N^4+3\ N^5}{24\ (-2+N)(-1+N)(2+N)(4+N)}, \tag{7}$$

$$a_4^{(4)}=-\frac{N^7\ (6+5\ N)}{8(-3+N)(-2+N)(-1+N)(1+N)(2+N)(4+N)(6+N)},$$

$$a_{31}^{(4)}=\frac{N^6\ (6+5\ N)}{2(-3+N)(-2+N)(-1+N)(1+N)(2+N)(4+N)(6+N)},$$

$$a_{22}^{(4)}=\frac{N^7\ (18+5\ N+N^2)}{32\ (-3+N)(-2+N)(-1+N)(1+N)(2+N)(4+N)(6+N)},$$

$$a_{211}^{(4)}=-\frac{N^5\ (72+78\ N+5\ N^2+N^3)}{16\ (-3+N)\ (-2+N)(-1+N)(1+N)(2+N)(4+N)(6+N)},$$

$$a_{1111}^{(4)}=\frac{N^4\ (72+78\ N+5\ N^2+N^3)}{32\ (-3+N)(-2+N)(-1+N)(1+N)(2+N)(4+N)(6+N).}$$

We note that with increasing κ, the expressions become rather involved. Moreover, the coefficients $a_{\mathbf{k}}^{(\kappa)}$ with the same lower indices $\mathbf{k}$ change with κ.

III. MONOMIALS OF HIGHER ORDER FOR O(N): THE 1/N EXPANSION

We have seen that integrals over all polynomials of degree $n\leqslant 2\kappa$ have the same values as for O(N). What about polynomials of higher order? Again, it suffices to consider monomials $\mathcal{M}^{(2)}$ of even degree $2k$ with $k>\kappa$. We show that the integral over $\mathcal{M}^{(2)}$ coincides with the result for O(N) up to terms of order $N^{-\alpha}$ where the integer exponent α is positive and independent of k. More precisely, we show that for $k>\kappa$, we have

$$N^k\int \mathrm{d}\mu_g w_\kappa(M)\prod_{\nu=1}^{2k} M_{i_\nu j_\nu}=N^k\int \mathrm{d}h_{\mathrm{O}(N)}\prod_{\nu=1}^{2k} O_{i_\nu j_\nu}+\mathcal{O}(1/N^\alpha)\ \text{ where }\ \alpha\geqslant[\kappa/2]+1. \tag{8}$$

Here $[\kappa/2]$ indicates the integer part of $\kappa/2$, and $\mathrm{d}h_{\mathrm{O}(N)}$ denotes the Haar measure for integration over O(N). We note that the factors N^k in front of the integrals normalize the N dependence so

that these terms are (at most) of order 1. Another equivalent form of Eq. (8) is obtained by summing over pairs of indices $j_1=j_2, j_3=j_4, \ldots$. This removes the factors N^k and yields

$$\int \mathrm{d}\mu_g w_\kappa(M) \prod_{\nu=1}^{k} (MM^T)_{i_\nu l_\nu} = \int dh_{\mathrm{O}(N)} \prod_{\nu=1}^{k} (OO^T)_{i_\nu l_\nu} + \mathcal{O}(1/N^\alpha) \quad \text{where} \quad \alpha \geqslant [\kappa/2]+1. \tag{9}$$

The equivalence of Eq. (8) and Eq. (9) follows from the fact the matrix C discussed previously, if defined with respect to properly scaled monomials, does not depend on N. The remainder of this section is devoted to proving Eq. (9).

It is useful to introduce a few auxiliary concepts. We consider Gaussian integrals over monomials of M without the weight function w_κ. We write for brevity

$$\int \mathrm{d}\mu_g \prod_{\nu=1}^{k} (MM^T)_{i_\nu l_\nu} = \langle (MM^T)^k \rangle_g, \tag{10}$$

where the index g indicates the purely Gaussian integration. To define the completely correlated part of this expression, we consider first the case $k=2$. We use Wick contraction and have

$$\langle (MM^T)^2 \rangle_g = \langle (MM^T) \rangle_g \langle (MM^T) \rangle_g + \langle (MM^T)^2 \rangle_{gc}. \tag{11}$$

The last term on the right-hand side of Eq. (11) is the completely correlated term. For the general case of arbitrary order $2k$, we define the correlated part $\langle (MM^T)^k \rangle_{gc}$ as that contribution to $\langle (MM^T)^k \rangle_g$ which cannot be written in the form of products of two or more factors, each of which is a complete Wick contraction of powers of MM^T. It is easy to see that

$$\langle (MM^T)^k \rangle_{gc} = \mathcal{O}(1/N^{k-1}). \tag{12}$$

The linear increase with k in inverse powers of N in Eq. (12) is due to the fact that every Wick contraction which connects two M's appearing in different factors MM^T suppresses one summation index. Therefore, the correlated part $\langle (MM^T)^k \rangle_{gc}$ contributes the highest-order terms in $1/N$ to $\langle (MM^T)^k \rangle_g$.

We now consider integrals involving the weight function w_κ and use the same notation,

$$\int \mathrm{d}\mu_g w_\kappa \prod_{\nu=1}^{k} (MM^T)_{i_\nu l_\nu} = \langle w_\kappa (MM^T)^k \rangle_g. \tag{13}$$

Again using Wick contraction, we define the correlated part $\langle w_\kappa (MM^T)^k \rangle_{gc}$ of this expression as that part which cannot be written as the product of two or more factors, each of which is a complete Wick contraction of powers of MM^T and/or w_κ.

We proceed to show that in the equations relating the integral $\langle w_\kappa (MM^T)^k \rangle_g$ to the integral over the Haar measure, the leading correction term (lowest order in $1/N$) which does not cancel is given by

$$\langle w_\kappa (MM^T)^k \rangle_{gc} = \mathcal{O}(1/N^{[(k+1)/2]}) \quad \text{for } 1 < k \leqslant \kappa. \tag{14}$$

This relation is based upon the assumption that there is no accidental cancellation among the terms contributing to lowest order in $1/N$. Therefore, $[(k+1)]/2$ actually constitutes a lower bound on the exponent of $1/N$.

To prove relation (14), we rewrite the defining equations for w_κ, Eq. (3), as follows. We consider the expression $\langle w_\kappa (MM^T)^k \rangle_g$ with k integer and $k \leqslant \kappa$. We decompose this expression into correlated contributions. These originate from all partitions $\mathbf{k}=(k_1,k_2,\ldots)$ of k with $k_i \geqslant k_{i+1}$ and $\Sigma_i k_i = k$. We denote by i_0 the smallest index for which all k_i with $i > i_0$ are equal to one. Then, we have

$$\langle w_\kappa (MM^T)^k\rangle_g = \sum_{\mathbf{k}} \prod_i \langle (MM^T)^{k_i}\rangle_{gc} + \sum_{\mathbf{k}\neq \mathbf{1}^k} \sum_i^{i_0} \langle w_\kappa (MM^T)^{k_i}\rangle_{gc} \prod_{j\neq i} \langle (MM^T)^{k_j}\rangle_{gc}. \quad (15)$$

In the first term on the right-hand side, we have used that $\langle w_\kappa\rangle_g = 1$. In the second term, we have used that $\langle w_\kappa (MM^T)\rangle_{gc} = 0$. Trivially, the second sum on the right-hand side of Eq. (15) does not extend over the partition $\mathbf{1}^k = (1,1,1,\ldots)$ (k terms unity). According to (3), the expression in Eq. (15) equals $(\langle (MM^T)\rangle_g)^k$. This equals the contribution from the first sum on the right-hand side for the partition $\mathbf{1}^k$. The remaining terms must vanish,

$$\sum_{\mathbf{k}\neq \mathbf{1}^k} \prod_i \langle (MM^T)^{k_i}\rangle_{gc} + \sum_{\mathbf{k}\neq \mathbf{1}^k} \sum_i^{i_0} \langle w_\kappa (MM^T)^{k_i}\rangle_{gc} \prod_{j\neq i} \langle (MM^T)^{k_j}\rangle_{gc} = 0. \quad (16)$$

Equation (16) must hold for all values of k with $k \leqslant \kappa$. To proceed, we observe that the partitions of k can be grouped into classes as follows: Partitions within the same class carry the same number p of k_i's that have value unity. The classes are labeled by p, namely $\mathcal{C}_p$. For instance, for $k=6$, class $\mathcal{C}_2$ contains the partitions (4,1,1) and (2,2,1,1). In Eq. (16), we order the sum over $\mathbf{k}$ by grouping together all partitions which belong to the same class. We show presently that each such contribution must vanish separately. Then, we have for every $p = 0,1,\ldots,k-2$ that

$$\sum_{\mathbf{k}\neq \mathbf{1}^k, \mathbf{k}\in \mathcal{C}_p} \prod \langle (MM^T)^{k_i}\rangle_{gc} + \sum_{\mathbf{k}\in \mathcal{C}_p} \sum_i^{i_0} \langle w_\kappa (MM^T)^{k_i}\rangle_{gc} \prod_{j\neq i} \langle (MM^T)^{k_j}\rangle_{gc} = 0. \quad (17)$$

Equation (17) follows directly from the facts that Eq. (16) holds for all $k \leqslant \kappa$, and that the contributions from class $\mathcal{C}_p$ to a partition of k are the same as the contributions of class $\mathcal{C}_0$ to a partition of $k-p$, except for a string of Kronecker delta's due to the factors $(\langle (MM^T)\rangle_g)^p$.

We are now in the position to prove relation (14). We observe that in (17), the term $\langle w_\kappa (MM^T)^k\rangle_{gc}$ appears only in the class $\mathcal{C}_0$. Therefore, we have

$$\langle w_\kappa (MM^T)^k\rangle_{gc} = -\sum_{\mathbf{k}\in \mathcal{C}_0} \prod_i \langle (MM^T)^{k_i}\rangle_{gc} - \sum_{\mathbf{k}\in \mathcal{C}_0, \mathbf{k}\neq (k)} \sum_i \langle w_\kappa (MM^T)^{k_i}\rangle_{gc} \prod_{j\neq i} \langle (MM^T)^{k_j}\rangle_{gc}. \quad (18)$$

Using complete induction, i.e., assuming that relation (14) holds for all values of k' with $k' < k$, and using Eq. (12), we conclude from Eq. (18) that relation (14) also holds for $k'+1 = k$. The terms of lowest order in $1/N$ originate from partitions which have either the form (2,2,2,...) (for even k) or (3,2,2,2,...) (for odd k). Again, we cannot rule out the occurrence of accidental cancellations which would increase the power $[(k+1)]/2$ in relation (14).

Having established relation (14), we turn to the center piece of this section, Eq. (9). We first consider the case $k = \kappa+1$ and decompose the integral into correlated terms with contributions from all partitions of $\kappa+1$. For these partitions, we write $\mathbf{K+1} = (k_1, k_2, \ldots)$ with $k_1 + k_2 + \cdots = \kappa+1$ and $k_1 \geqslant k_2 \geqslant \cdots$. We use the notation introduced previously. Then,

$$\langle w_\kappa (MM^T)^{\kappa+1}\rangle_g = \sum_p \sum_{(\mathbf{K+1})\in \mathcal{C}_p} \prod_i \langle (MM^T)^{k_i}\rangle_{gc} + \sum_p \sum_{(\mathbf{K+1})\in \mathcal{C}_p} \sum_i^{i_0} \langle w_\kappa (MM^T)^{k_i}\rangle_{gc} \prod_{j\neq i} \langle (MM^T)^{k_j}\rangle_{gc}. \quad (19)$$

Equation (17) implies that all terms with $p \neq 0$ and $p \neq \kappa+1$ vanish, and we are left with

$$\langle w_\kappa (MM^T)^{\kappa+1}\rangle_g = (\langle (MM^T)\rangle_g)^{\kappa+1} + \sum_{(\mathbf{K+1})\in \mathcal{C}_0} \prod_i \langle (MM^T)^{k_i}\rangle_{gc}$$

$$+ \sum_{(\mathbf{K+1})\in \mathcal{C}_0} \sum_i \langle w_\kappa (MM^T)^{k_i}\rangle_{gc} \prod_{j\neq i} \langle (MM^T)^{k_j}\rangle_{gc}. \tag{20}$$

We use the same argument as in the previous paragraph and the result (14) and Eq. (12). We conclude that the contributions of lowest order in $1/N$ result from the partitions (2,2,2,...) or (3,2,2,2,...), respectively, and arrive at Eq. (9). The exponent α has the value $\alpha \geqslant [\kappa/2]+1$. In writing the inequality sign, we again allow for the possibility that an accidental cancellation of contributions from these partitions occurs.

We finally have to consider the case where $k-\kappa=n>1$. Decomposing the expression $\langle w_\kappa (MM^T)^{\kappa+n}\rangle_g$ as in Eq. (19), we easily see that the terms of lowest nonvanishing order in $1/N$ stem from the partitions in class $\mathcal{C}_{n-1}$. But these give exactly the same contributions as those for $k=\kappa+1$ that were estimated in the last paragraph. This completes the proof of Eq. (9).

IV. THE UNITARY GROUP AND OTHER UNITARY ENSEMBLES

In this section, we primarily address integrals over momomials of unitary matrices U with respect to the Haar measure of the unitary group. We start with Gaussian integrals over complex matrices M. The real and imaginary parts of the matrix elements are independent and Gaussian-distributed. The integrals are again worked out using Wick contractions. For the weight function w_κ^u, we write in analogy to Eq. (2)

$$w_\kappa^u(M) = b_0^{(\kappa)} + \sum_{k=1}^{\kappa} \sum_{\mathbf{k}} b_{\mathbf{k}}^{(\kappa)} I_{\mathbf{k}}^{(k)}(M). \tag{21}$$

The invariants are defined as in Eq. (1) with MM^T replaced by $MM^\dagger$ where a dagger stands for Hermitean conjugation. The upper index u refers to the unitary case. The values of the coefficients $b_{\mathbf{k}}^\kappa$ are, of course, not the same as for the orthogonal case. The arguments for the existence and uniqueness of the solutions carry over without change, and again computer programs are available to perform the contractions and calculate the coefficients $b_{\mathbf{k}}^\kappa$. For w_2^u and w_4^u we find

$$\begin{aligned} b_0^2 &= 1 - \frac{N^2}{2}, \\ b_1^2 &= N, \\ b_2^2 &= -\frac{N^3}{2(N-1)(N+1)}, \\ b_{11}^2 &= \frac{N^2}{2(N-1)(N+1)}, \end{aligned} \tag{22}$$

and

$$b_0^4 = \frac{24 - 46\,N^2 + 3\,N^4}{24},$$

$$b_1^4 = \frac{-(N(-12+N^2))}{2},$$

$$b_2^4=\frac{N^3\ (-30+N^2)}{4(-1+N)(1+N)},$$

$$b_{11}^4=\frac{N^2\ (28+N^2)}{4(-1+N)(1+N)},$$

$$b_3^4=\frac{14\ N^5}{3(-2+N)(-1+N)(1+N)(2+N)},$$

$$b_{21}^4=\frac{-N^4\ (24+N^2)}{2(-2+N)(-1+N)(1+N)(2+N)},$$

$$b_{111}^4=\frac{N^3\ (44+3N^2)}{6(-2+N)(-1+N)(1+N)(2+N)},$$

$$b_4^4=\frac{-5N^7}{4(-3+N)(-2+N)(-1+N)(1+N)(2+N)(3+N)},$$

$$b_{31}^4=\frac{5\ N^6}{(-3+N)(-2+N)(-1+N)(1+N)(2+N)(3+N)},$$

$$b_{22}^4=\frac{N^6\ (6+N^2)}{8(-3+N)(-2+N)(-1+N)(1+N)(2+N)(3+N)},$$

$$b_{211}^4=\frac{-N^5\ (36+N^2)}{4(-3+N)(-2+N)(-1+N)(1+N)(2+N)(3+N)},$$

$$b_{1111}^4=\frac{N^4\ (36+N^2)}{8(-3+N)(-2+N)(-1+N)(1+N)(2+N)(3+N)}. \tag{23}$$

The arguments determining the leading contribution to the $1/N$ expansion are the same ones as for the orthogonal group. Thus, we have to increase κ by two to improve the error by one order in $1/N$ in the calculation of monomials of high order. This is the reason for our not giving w_3^u but only w_4^u which yields correct values for the integrals up to order $1/N^2$.

For COE and CSE, the situation is slightly more complicated. The constraints on the matrices are not expressible in a simple way in terms of products as done in (3). It seems, therefore, most convenient to limit the space of independent matrix elements from the outset. In the case of the COE this is fairly simple: The symmetry reduces the number of independent complex matrix elements to $N(N+1)/2$. Therefore, we consider Gaussian averages in the space of complex symmetric matrices $S=S^T$. We accordingly have a contraction rule with two terms,

$$\int \mathrm{d}\mu_g(S)S_{ij}^*S_{kl}=\frac{1}{N}(\delta_{ik}\delta_{jl}+\delta_{il}\delta_{jk}). \tag{24}$$

The invariants are now defined in terms of SS^*. Introducing the rule (24) into our program we can again calculate w_κ^c. As an example we compute the coefficients $c_{\mathbf{k}}^2$ for w_2^c,

$$c_0^2=1-\frac{N(N+1)}{4},$$

$$c_1^2=\frac{N+1}{2},$$
$$c_2^2=-\frac{(N+1)^3}{4N(N+3)}, \tag{25}$$
$$c_{11}^2=\frac{(N+1)^2}{4N(N+3)}.$$

In addition, the following subtle point must be considered. In Sec. II we have used the invariance of the Haar measure to justify that contraction with w_κ gives exact results for all polynomials up to order 2κ in the matrix elements. In the present case we have no invariance group and by consequence no Haar measure. On the other hand Dyson's measure with respect to which we integrate is also totally defined by an invariance group albeit a smaller one than that of U(N). The important point is that again the measure is uniquely defined by a linear group of transformations. The orthogonality conditions resulting from the unitarity of the matrices are the same and symmetry is taken into account explicitly in the contractions. Therefore all arguments again go through and indeed inspection of the results obtained by our code with those obtained in Ref. 2 shows agreement.

The case of CSE is simpler because it involves an invariance group, but more complicated because the matrices are symplectic. Two ways seem open to address this case. We might include the symplectic property from the outset in the contraction rules, or we might introduce this property as a constraint in the expression for the weight function. While both ways seem possible it is not clear which one is easier to follow. In view of the fact that CSE is of minor importance for practical applications, we have left this problem open. It is clear, however, that it can be tackled along the same lines.

V. CONCLUSIONS

We have presented a systematic way to calculate integrals over monomials of matrix elements for compact matrix groups and for other matrix ensembles whose measure is defined uniquely by an invariance group, such as the circular orthogonal ensemble of unitary symmetric matrices. This method gives exact results for monomials of low order. For higher-order monomials, it leads to an error of order $1/N^\alpha$ which is independent of the degree of the monomial. We have given a lower bound on the integer α, and we have shown how α can be increased systematically. The method is particularly suited for symbolic computer calculation. Codes are available for O(N), U(N) as well as for the circular orthogonal ensemble in MATHEMATICA and in C from one of the authors (T.P.).

F-Lie algebras are natural generalizations of Lie algebras ($F=1$) and Lie superalgebras ($F=2$). When $F>2$ not many finite-dimensional examples are known. In this article we construct finite-dimensional F-Lie algebras $F>2$ by an inductive process starting from Lie algebras and Lie superalgebras. Matrix realizations of F-Lie algebras constructed in this way from $\mathfrak{su}(n)$,$\mathfrak{sp}(2n)$ $\mathfrak{so}(n)$ and $\mathfrak{sl}(n|m)$, $\mathfrak{osp}(2|m)$ are given. We obtain nontrivial extensions of the Poincaré algebra by Inönü–Wigner contraction of certain F-Lie algebras with $F>2$. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1503148]

I. INTRODUCTION

The classification of algebraic objects satisfying certain axioms may be considered a fundamental objective on purely mathematical grounds. If, in addition, these objects turn out to to be relevant for the description of the possible symmetries of a physical system, such a classification takes on a whole new meaning. The main question is, of course, what are the mathematical structures which are useful in describing the laws of physics? Simple complex finite-dimensional Lie algebras were classified at the end of the 19th century by W. Killing and E. Cartan well before any physical applications were known. Since then, Lie algebras have become essential for the description of space–time symmetries and fundamental interactions. On the other hand, it was the discovery of supersymmetry in relativistic quantum field theory or as a possible extension of Poincaré invariance[1] which gave rise to the concept of Lie superalgebras and their subsequent classification.[2,3]

It is generally accepted that because of the theorems of Coleman and Mandula[4] and Haag, Lopuszanski, and Sohnius,[5] one cannot go beyond supersymmetry. However, if one weakens the hypotheses of these two theorems, one can imagine symmetries which go beyond supersymmetry,[6–28] the idea being that then the generators of the Poincaré algebra can be obtained as an appropriate product of more than two fundamental additional symmetries. These new generators are in a representation of the Lorentz algebra which is neither bosonic nor fermionic. Two kinds of representations are generally taken: parafermionic representations,[29] or infinite-dimensional representations (Verma module).[30]

Fractional supersymmetry (FSUSY)[9–28] is among the possible extensions of supersymmetry which have been studied in the literature. Basically, in such extensions, the generators of the Poincaré algebra are obtained as F-fold ($F\in\mathbb{N}^\star$) symmetric products of more fundamental generators. A natural generalization of Lie (super)algebras which is relevant for the algebraic description of FSUSY was defined in Ref. 24 and 28 and called an F-Lie algebra. An F-Lie algebra admits a $\mathbb{Z}_F$-gradation, the zero-graded part being a Lie algebra. An F-fold symmetric product (playing the role of the anticommutator in the case $F=2$) expresses the zero-graded part in terms of the non-zero-graded part.

a)Electronic mail: rausch@lpt1.u-strasbg.fr

The purpose of this article is to show how one can construct many examples of finite-dimensional F-Lie algebras by an inductive process starting from Lie algebras and Lie superalgebras. Some preliminary results is this direction were given in Ref. 28. Two types of finite-dimensional F-Lie algebras will be constructed. The first family of examples, which we call trivial, are obtained by taking the direct sum of a Lie (super)algebra with the trivial representation. The second family is more interesting: by an inductive procedure we show how one can give the underlying vector space of any Lie algebra or any classical Lie superalgebra the structure of an F-Lie algebra. This procedure involves Casimir operators in the case of Lie algebras and invariant symmetric forms on the odd part of the algebra in the case of Lie superalgebras.

The article is organized as follows. In Sec. II we recall the definition of an F-Lie algebra and show how one can construct an F-Lie algebra of order F_1+F_2 from an F-Lie algebra of order $F_1\geqslant 2$ and an invariant symmetric form of order F_2 on its non-zero-graded part (c.f. Theorem II.6). In Sec. III we introduce the notion of a graded 1-Lie algebra in order to prove a version of Theorem II.6 when $F_1=1$ (Theorem III.6), and give some explicit examples of F-Lie algebras associated to Lie algebras. In Sec. IV we give explicit examples of F-Lie algebras associated to Lie superalgebras. In Sec. V we obtain FSUSY extensions of the Poincaré algebra by Inönü–Wigner contraction of certain F-Lie algebras constructed in the two previous sections. In Sec. VI we define a notion of simplicity for F-Lie algebras and give examples of simple and non-simple F-Lie algebras. Finally, in Sec. VII we give finite-dimensional matrix realizations of the F-Lie algebras of Sec. IV induced from $\mathfrak{sl}(m|n)$ and $\mathfrak{osp}(2|2n)$ and a quadratic form. Using finite-dimensional matrices, we also show that the underlying vector spaces of the graded 1-Lie algebras $\mathfrak{su}(n)\oplus\mathfrak{su}(n),\mathfrak{so}(n)\oplus\mathfrak{so}(n)$ and $\mathfrak{sp}(2n)\oplus\mathfrak{sp}(2n)$ can be given F-Lie algebra structures which cannot be obtained by our inductive process.

II. *F*-LIE ALGEBRAS

A. Definition of *F*-Lie algebras

In this section, we recall briefly the definition of F-Lie algebras given in Refs. 24 and 28. Let F be a positive integer and let $q=e^{2\pi i/F}$. We consider S a complex vector space and ε an automorphism of S satisfying $\varepsilon^F=1$. We set $\mathcal{A}_k=S_{q^k},1\leqslant k\leqslant F-1$, and $\mathcal{B}=S_1$ (S_{q^k} is the eigenspace corresponding to the eigenvalue q^k of ε). Then we have $S=\mathcal{B}\oplus\sum_{k=1}^{F-1}\mathcal{A}_k$.

Definition II.1: $S=\mathcal{B}\oplus\sum_{k=1}^{F-1}\mathcal{A}_k$ is called a (complex) F-Lie algebra if it is endowed with the following structure:

(1) $\mathcal{B}$ is a (complex) Lie algebra and $\mathcal{A}_k,1\leqslant k\leqslant F-1$, are representations of $\mathcal{B}$. If $[,]$ denotes the bracket on $\mathcal{B}$ and the action of $\mathcal{B}$ on S, it is clear that $\forall b\in\mathcal{B},\forall s\in S,[\varepsilon(b),\varepsilon(s)]=\varepsilon([b,s])$.

(2) There exist multilinear $\mathcal{B}$-equivariant maps $\{,\ldots,\}$: $\mathcal{S}^F(\mathcal{A}_k)\to\mathcal{B}$, where $\mathcal{S}^F(D)$ denotes the F-fold symmetric product of D. It is easy to see that $\{\varepsilon(a_1),\ldots,\varepsilon(a_F)\}=\varepsilon(\{a_1,\ldots,a_F\}),\forall a_1,\ldots,a_F\in\mathcal{A}_k$.

(3) For $b_i\in\mathcal{B}$ and $a_j\in\mathcal{A}_k$ the following "Jacobi identities" hold:

$$[[b_1,b_2],b_3]+[[b_2,b_3],b_1]+[[b_3,b_1],b_2]=0,$$
$$[[b_1,b_2],a_3]+[[b_2,a_3],b_1]+[[a_3,b_1],b_2]=0,$$
$$[b,\{a_1,\ldots,a_F\}]=\{[b,a_1],\ldots,a_F\}+\cdots+\{a_1,\ldots,[b,a_F]\},$$
$$\sum_{i=1}^{F+1}[a_i,\{a_1,\ldots,a_{i-1},a_{i+1},\ldots,a_{F+1}\}]=0. \qquad (J_4)$$

Note that the three first identities are automatic, but the fourth, which we will refer to as J_4, is an extra constraint.

Remark II.2: An F-Lie algebra is more than a Lie algebra $\mathfrak{g}_0$, a representation $\mathfrak{g}_1$ of $\mathfrak{g}_0$ and a $\mathfrak{g}_0$-valued $\mathfrak{g}_0$-equivariant symmetric form on $\mathfrak{g}_1$. Indeed, although the three first Jacobi identities

are manifest in this situation, the fourth is not necessarily true. As an example, consider $\mathfrak{g}_0=\mathfrak{sl}(2,\mathbb{C})$ *and* $\mathfrak{g}_1=\mathcal{S}_{2k+1}$, $k\in\mathbb{N}$ *(the irreducible representation of dimension* $2k+2$*). From the decomposition* $\mathcal{S}^2(\mathcal{S}_{2k+1})=\mathcal{S}_{4k+2}\oplus\mathcal{S}_{4k-2}\oplus\cdots\oplus\mathcal{S}_2$ *one has an* $\mathfrak{sl}(2,\mathbb{C})$*-equivariant mapping from* $\mathcal{S}^2(\mathcal{S}_{2k+1})\to\mathcal{S}_2\to\mathfrak{sl}(2,\mathbb{C})$. *But* $\mathfrak{g}=\mathfrak{sl}(2,\mathbb{C})\oplus\mathcal{S}_{2k+1}$ *is not a Lie superalgebra (the fourth Jacobi identity is not satisfied) except when* $k=0$ *where it reduces to* $\mathfrak{osp}(1|2)$.

Remark II.3: A 1*-Lie algebra is a Lie algebra, and a* 2*-Lie algebra is a Lie superalgebra. We will also refer to these objects as* F*-Lie algebras of order* 1 *and* 2*, respectively.*

Remark II.4: Notice that $\{a_1,\ldots,a_F\}$ *is only defined if the* a_i *are in the same* $\mathcal{A}_k$ *and that* $\forall k=1,\ldots,F-1$*, the spaces* $S_k=\mathcal{B}\oplus\mathcal{A}_k$ *are* F*-Lie algebras.*

From now on, we consider only F**-Lie algebras** $S=\mathcal{B}\oplus\mathcal{A}$ **such that** $\mathcal{A}$ **is an eigenspace of** ε.

Remark II.5: If $\mathfrak{h}\subset\mathcal{B}$ *is a Cartan subalgebra and* $F_{\lambda_1},\ldots,F_{\lambda_F}\in\mathcal{F}$ *are respectively of weight* $\lambda_1,\ldots,\lambda_F$*, then* $\{F_{\lambda_1},\ldots,F_{\lambda_F}\}\in\mathcal{B}$ *is of weight* $\lambda_1+\cdots+\lambda_F$. *In particular, if* $\lambda_1+\cdots+\lambda_F\neq 0$ *is not a root of* $\mathcal{B}$*, this bracket is zero.*

This structure can be seen as a possible generalization of Lie algebras ($F=1$) or Lie superalgebras ($F=2$) and can be compared, in some sense, to the ternary algebras ($F=3$) considered in Ref. 31, and to the n-ary algebras ($F=n$) introduced in Ref. 32 but in a different context. We have shown[24,28] that all examples of FSUSY considered in the literature can be described within the framework of F-Lie algebras.

B. An inductive construction of *F*-Lie algebras

Let $\mathfrak{g}$ be a complex Lie algebra and let $\mathfrak{r},\mathfrak{r}'$ be representations of $\mathfrak{g}$ such that there is a $\mathfrak{g}$-equivariant map $\mu_F:S^F(\mathfrak{r})\to\mathfrak{r}'$. We set

$$S=\mathcal{B}\oplus\mathcal{A}_1=(\mathfrak{g}\oplus\mathfrak{r}')\oplus\mathfrak{r}.$$

Then, $\mathcal{B}=\mathfrak{g}\oplus\mathfrak{r}'$ is a Lie algebra as the semi-direct product of $\mathfrak{g}$ and $\mathfrak{r}'$ (the latter with the trivial bracket). We can extend the action of $\mathfrak{g}$ on $\mathfrak{r}$ to an action of $\mathcal{B}$ on $\mathfrak{r}$ by letting $\mathfrak{r}'$ act trivially on $\mathfrak{r}$. This defines the bracket $[,]$ on S. For the map $\{\cdots\}$ we take μ_F. The first three Jacobi identities are clearly satisfied, and the fourth is also satisfied as each term in the expression on the lhs of J_4 vanishes. Hence S is an F-Lie algebra. There are two essentially opposite ways of giving explicit examples of F-Lie algebras of this type. One can either start from $\mathfrak{g}$ and $\mathfrak{r}'$ and extract an "F-root" of $\mathfrak{r}'$, or one can decompose $\mathcal{S}^F(\mathfrak{r})$ into irreducible summands and project onto one of them.[24] The first approach is the more difficult since, in general, it involves infinite-dimensional representation theory. For example, if one starts with $\mathfrak{r}'=\mathfrak{D}_{\mu_1}$, the vector representation of $\mathfrak{so}(1,d-1)$ of highest weight μ_1, the representation $\mathfrak{r}=\mathfrak{D}_{\mu_1/F}$ of highest weight μ_1/F is not exponentializable (see, e.g., Ref. 33) and does not define a representation of the Lie group $\mathrm{SO}(1,d-1)$, except when $d=3$ where such representations describe relativistic anyons.[34] The second approach, on the other hand, will always give finite-dimensional F-Lie algebras if one starts from finite-dimensional representations.

The following theorem gives an inductive procedure for constructing finite-dimensional F-Lie algebras.

Theorem II.6: *Let* $\mathfrak{g}_0$ *be a Lie algebra and* $\mathfrak{g}_1$ *a representation of* $\mathfrak{g}_0$ *such that*

(i) $S_1=\mathfrak{g}_0\oplus\mathfrak{g}_1$ *is an* F*-Lie algebra of order* $F_1>1$;
(ii) $\mathfrak{g}_1$ *admits a* $\mathfrak{g}_0$*-equivariant symmetric form* μ_2 *of order* $F_2\geqslant 1$.

Then $S=\mathfrak{g}_0\oplus\mathfrak{g}_1$ *admits an* F*-Lie algebra structure of order* F_1+F_2*, which we call the* F*-Lie algebra induced from* S_1 *and* μ_2.

Proof: By hypothesis, there exist $\mathfrak{g}_0$-equivariant maps $\mu_1:\mathcal{S}^{F_1}(\mathfrak{g}_1)\to\mathfrak{g}_0$ and $\mu_2:\mathcal{S}^{F_2}(\mathfrak{g}_1)\to\mathbb{C}$. Now, consider $\mu:\mathcal{S}^{F_1+F_2}(\mathfrak{g}_1)\to\mathfrak{g}_0\otimes\mathbb{C}\cong\mathfrak{g}_0$ defined by

$$\mu(f_1,\ldots,f_{F_1+F_2})=\frac{1}{F_1!}\frac{1}{F_2!}\sum_{\sigma\in S_{F_1+F_2}}\mu_1(f_{\sigma(1)},\ldots,f_{\sigma(f_{F_1})})\otimes\mu_2(f_{\sigma(f_{F_1+1})},\ldots,f_{\sigma(f_{F_1+F_2})}),\tag{2.1}$$

where $f_1,\ldots,f_{F_1+F_2}\in\mathfrak{g}_1$ and $S_{F_1+F_2}$ is the group of permutations on F_1+F_2 elements. By construction, this is a $\mathfrak{g}_0$-equivariant map from $\mathcal{S}^{F_1+F_2}(\mathfrak{g}_1)\to\mathfrak{g}_0$, thus the three first Jacobi identities are satisfied. The last Jacobi identity J_4, is more difficult to check and is a consequence of J_4 for the F-Lie algebra S_1 and a factorization property. Indeed, setting $F=F_1+F_2$, the identity J_4 for the terms in

$$\sum_{i=0}^{F}[f_i,\mu(f_1,\ldots,f_{i-1},f_{i+1},\ldots,f_F)],$$

of the form $\mu_1(f_{\sigma(1)},\ldots,f_{\sigma(f_{F_1})})\otimes\mu_2(f_{\sigma(f_{F_1+1})},\ldots,f_{\sigma(f_{F_1+F_2})}$ with $\sigma\in S_{F_1+F_2+1}$, reduces to

$$\sum_{i=0}^{F_1}[f_{\sigma(i)},\mu_1(f_{\sigma(1)},\ldots,f_{\sigma(i-1)},f_{\sigma(i+1)},\ldots,f_{\sigma(f_{F_1})})]\otimes\mu_2(f_{\sigma(f_{F_1+1})},\ldots,f_{\sigma(f_{F_1+F_2})})=0,$$

using $\mu_2(f_{\sigma(f_{F_1+1})},\ldots,f_{\sigma(f_{F_1+F_2})})\in\mathbb{C}$. But the lhs vanishes by J_4 for the F-Lie algebra S_1. A similar argument works for the other terms and hence J_4 is satisfied and S is an F-Lie algebra of order F_1+F_2. Q.E.D.

Remark II.7: Theorem II.6 is equivalent to the fact that the product of two $\mathfrak{g}_0$-equivariant symmetric forms satisfying J_4 also satisfies J_4 if one of them is scalar-valued.

III. FINITE-DIMENSIONAL *F*-LIE ALGEBRAS ASSOCIATED TO LIE ALGEBRAS

In this section we first introduce the notion of a graded 1-Lie algebra in order to have a version of Theorem II.6 when $F_1=1$.

A. Graded 1-Lie algebras

Definition III.1: A graded 1*-Lie algebra is a $\mathbb{Z}_2$-graded vector space $S=\mathcal{B}\oplus\mathcal{F}$ such that*
(1) *$\mathcal{B}$ is a Lie algebra*;
(2) *$\mathcal{F}$ is a representation of $\mathcal{B}$*;
(3) *there is a $\mathcal{B}$-equivariant map $\mu:\mathcal{F}\to\mathcal{B}$; and*
(4) $[\mu(f_1),f_2]+[\mu(f_2),f_1]=0,\forall f_1,f_2\in\mathcal{F}$.

Example III.2: Let $\mathfrak{g}$ be a Lie algebra. Set $\mathcal{B}=\mathfrak{g}$, $\mathcal{F}=\mathrm{ad}\mathfrak{g}$ and $S=\mathcal{B}\oplus\mathcal{F}$. If $\mu:\mathcal{F}\to\mathcal{B}$ is the identity, then (S,μ) is a graded 1*-Lie algebra.*

Remark III.3: A graded 1*-Lie algebra is not a priori a Lie algebra but it easy to see that, in fact, it has a natural graded Lie algebra structure.*

Remark III.4: $\mathrm{Ker}\mu$ is a $\mathcal{B}$-invariant subspace of $\mathcal{F}$ and $\mathrm{Im}\mu$ is a $\mathcal{B}$-invariant subspace of $\mathcal{B}$. In particular, if $\mathcal{B}$ is simple, $\mathcal{F}$ irreducible, and μ nontrivial, then μ defines a $\mathcal{B}$-equivariant isomorphism between $\mathcal{F}$ and $\mathcal{B}$.

A graded 1-Lie algebra is a graded Lie algebra in the usual sense. In general, however, a graded Lie algebra is not a graded 1-Lie algebra since there is no preferred map from the odd to the even part.

Proposition III.5: Let $\mathfrak{g}=\mathfrak{g}_+\oplus\mathfrak{g}_-$ be a graded Lie algebra, and let $\mu:\mathfrak{g}\to\mathfrak{g}$ be an odd $\mathfrak{g}_+$-equivariant map of $\mathfrak{g}$ such that μ is injective on $[\mathfrak{g}_+,\mathfrak{g}_-]$. Then $(\mathfrak{g},\mu)$ is a graded 1*-Lie algebra.*

Proof: One only has to check Definition III.1(4). One has $\forall f_1,f_2\in\mathfrak{g}_-$, $\mu([\mu(f_1),f_2]+[\mu(f_2),f_1])=[\mu(f_1),\mu(f_2)]+[\mu(f_2),\mu(f_1)]=0$. Since μ is injective on $[\mathfrak{g}_+,\mathfrak{g}_-]$ this implies Definition III.1(4). Q.E.D.

Theorem III.6 (II.6-bis): *Let* $\mathfrak{g}_0$ *be a Lie algebra and* $\mathfrak{g}_1$ *a representation of* $\mathfrak{g}_0$ *such that*

(i) $S_1=\mathfrak{g}_0\oplus\mathfrak{g}_1$ *is a graded* 1*-Lie algebra* and
(ii) $\mathfrak{g}_1$ *admits a* $\mathfrak{g}_0$*-equivariant symmetric* μ_2 *form of order* $F_2\geqslant 1$.

Then $S=\mathfrak{g}_0\oplus\mathfrak{g}_1$ *admits an F-Lie algebra structure of order* $1+F_2$ *which we call the F-Lie algebra induced from* S_1 *and* μ_2.

Proof: Analogous to Theorem II.6. Q.E.D.

B. Trivial and induced *F*-Lie algebras

Consider the graded 1-Lie algebra $S=\mathfrak{g}_0\oplus\mathfrak{g}_1$ where $\mathfrak{g}_0$ is a Lie algebra, $\mathfrak{g}_1$ is the adjoint representation of $\mathfrak{g}_0$ and $\mu:\mathfrak{g}_1\to\mathfrak{g}_0$ is the identity. Let $J_1,\ldots,J_{\dim\mathfrak{g}_0}$ be a basis of $\mathfrak{g}_0$, and $A_1,\ldots,A_{\dim\mathfrak{g}_0}$ be the corresponding basis of $\mathfrak{g}_1$. The graded 1-Lie algebra structure on S is then

$$[J_a,J_b]=f_{ab}{}^cJ_c,\quad [J_a,A_b]=f_{ab}{}^cA_c,\quad \mu(A_a)=J_a, \tag{3.1}$$

where $f_{ab}{}^c$ are the structure constant of $\mathfrak{g}_0$, Two types of F-Lie algebras associated to S will be defined.

The first type of F-Lie algebra associated to S will be called trivial and is constructed as follows:

Theorem III.7: *Let* $\mathfrak{g}_0$ *be a Lie algebra and let* $F\geqslant 1$ *be an integer. Then* $S=\mathfrak{g}_0\oplus(\mathfrak{g}_1\oplus\mathbb{C})$ *can be given the structure of an F-Lie algebra (graded* 1*-Lie algebra if* $F=1$*) where* $\mathfrak{g}_1$ *is the adjoint representation of* $\mathfrak{g}_0$ *and* $\mathbb{C}$ *is the trivial representation.*

Proof: The map $\mu:\mathcal{S}^F(\mathfrak{g}_1\oplus\mathbb{C})\to\mathfrak{g}_0$ is given by projection on $\mathfrak{g}_1$ in the decomposition $\mathcal{S}^F(\mathfrak{g}_1\oplus\mathbb{C})=\mathcal{S}^F(\mathfrak{g}_1)\oplus\mathcal{S}^{F-1}(\mathfrak{g}_1)\oplus\cdots\oplus\mathcal{S}^2(\mathfrak{g}_1)\oplus\mathfrak{g}_1\oplus\mathbb{C}$, followed by the identification of $\mathfrak{g}_1$ with $\mathfrak{g}_0$.

With the notations of (3.1) the brackets are

$$\begin{gathered}\{\lambda,\ldots,\lambda\}=0\\ \{\lambda,\ldots,\lambda,A_a\}=J_a\\ \vdots\\ \{\lambda,\ldots,\lambda,A_{a_1},\ldots,A_{a_k}\}=0,\quad 1<k\leqslant F\\ \vdots\\ \{A_{a_1},\ldots,A_{a_F}\}=0\end{gathered} \tag{3.2}$$

with $A_a,\in\mathfrak{g}_1,\lambda\in\mathbb{C}$, and $J_a\in\mathfrak{g}_0$.

It is easy to check that the four Jacobi identities are satisfied. Q.E.D.

The second type of F-Lie algebras associated to S are those induced from S and Casimir operators of $\mathfrak{g}_0$ (see Theorem III.6). It is well known that the invariant tensors on $\mathfrak{g}_0^\star$ are generated by primitive invariant tensors which are either fully symmetric or fully antisymmetric.[35] By duality, symmetric invariant tensors are related to the Casimir operators of $\mathfrak{g}_0$, and it is well known that for a rank r Lie algebra one can find r independent primitive Casimir operators.

Theorem III.8: *Let* $\mathfrak{g}_0$ *be a simple (complex) Lie algebra and* $\mathfrak{g}_1$ *be the adjoint representation of* $\mathfrak{g}_0$. *Then a Casimir operator of* $\mathfrak{g}_0$ *of order m induces the structure of an F-Lie algebra of order* $m+1$ *on* $S_{m+1}=\mathfrak{g}_0\oplus\mathfrak{g}_1$.

Proof: By Example III.2 $\mathfrak{g}_0\oplus\mathfrak{g}_1$ is a graded 1-Lie algebra and the result follows from Theorem III.6. Q.E.D.

Remark III.9: One can give explicit formulas for the bracket of these F-Lie algebras as follows. Let $J_a,a=1,\ldots,\dim(\mathfrak{g}_0)$ *and let* $A_a,a=1,\ldots,\dim(\mathfrak{g}_0)$ *be bases as at the beginning of this*

section. Let $h_{a_1\cdots a_m}$ *be a Casimir operator of order* m *[for* $m=2$*, the Killing form* $g_{ab}=\mathrm{Tr}(A_aA_b)$ *is a primitive Casimir of order* 2*]. Then, the* F*-bracket of the* F*-Lie algebra is*

$$\{A_{a_1},A_{a_2},\ldots,A_{a_{m+1}}\}=\sum_{\ell=1}^{m+1} h_{a_1\cdots a_{\ell-1}a_{\ell+1}\cdots a_{m+1}}J_{a_\ell}. \tag{3.3}$$

For the Killing form this gives

$$\{A_a,A_b,A_c\}=g_{ab}J_c+g_{ac}J_b+g_{bc}J_a. \tag{3.4}$$

If $\mathfrak{g}_0=\mathfrak{sl}(2)$, the F-Lie algebra of order 3 induced from the Killing form is the F-Lie algebra of Ref. 36.

IV. FINITE-DIMENSIONAL *F*-LIE ALGEBRAS ASSOCIATED TO LIE SUPERALGEBRAS

In this section we will consider some F-Lie algebras which can be associated to Lie superalgebras using Theorem II.6.

A. Lie superalgebras

We first recall some basic results on simple complex Lie superalgebras (for more details, see Ref. 37 and 38). Simple Lie superalgebras can be divided into two types: classical and Cartan type. Classical Lie superalgebras can be further divided into two families: basic and strange. A basic Lie superalgebra $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ is said to be respectively of type I or type II depending on whether the $\mathfrak{g}_0$-module $\mathfrak{g}_1$ is respectively reducible or irreducible. Here is the complete list of simple classical Lie superalgebras.[2,3] In the statement of 1(i) the symbol $(\overline{\mathbf{m+1}},\mathbf{n+1})^+\oplus(\mathbf{m+1},\overline{\mathbf{n+1}})^-$ denotes $(\mathbb{C}^{m+1\star}\otimes\mathbb{C}^{n+1}\otimes\mathbb{C})\oplus(\mathbb{C}^{m+1}\otimes\mathbb{C}^{n+1\star}\otimes\mathbb{C}^\star)$, where $\mathbb{C}^{m+1}$ is the fundamental representation of $\mathfrak{sl}(m+1)$, $\mathbb{C}^{m+1\star}$ is its dual representation and $\mathbb{C}$ is the standard one-dimensional representation of $\mathfrak{gl}(1)$. In the rest of the theorem we use analogous notation.

Theorem IV.1: *Let* $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ *be a classical simple complex Lie superalgebra. Then* $\mathfrak{g}$ *is isomorphic to one of the following:*

(1) *Basic of type I:*

(i) $A(m,n):m>n\geqslant 0,\mathfrak{g}_0=\mathfrak{sl}(m+1)\oplus\mathfrak{sl}(n+1)\oplus\mathfrak{gl}(1),\mathfrak{g}_1=(\overline{\mathbf{m+1}},\mathbf{n+1})^+\oplus(\mathbf{m+1},\overline{\mathbf{n+1}})^-$.
(ii) $A(n,n):n\geqslant 1,\mathfrak{g}_0=\mathfrak{sl}(n+1)\oplus\mathfrak{sl}(n+1),\mathfrak{g}_1=(\overline{\mathbf{n+1}},\mathbf{n+1})\oplus(\mathbf{n+1},\overline{\mathbf{n+1}})$.
(iii) $C(n+1):n\geqslant 1,\mathfrak{g}_0=\mathfrak{sp}(2n)\oplus\mathfrak{gl}(1),\mathfrak{g}_1=\mathbf{2n}^+\oplus\mathbf{2n}^-$.

(2) *Basic of type II:*

(i) $B(m,n):m\geqslant 0,n\geqslant 1,\mathfrak{g}_0=\mathfrak{so}(2m+1)\oplus\mathfrak{sp}(2n),\mathfrak{g}_1=(\mathbf{2m+1},\mathbf{2n})$.
(ii) $D(m,n):m\geqslant 2,n\geqslant 1,m\neq n+1,\mathfrak{g}_0=\mathfrak{so}(2m)\oplus\mathfrak{sp}(2n),\mathfrak{g}_1=(\mathbf{2m},\mathbf{2n})$.
(iii) $D(n+1,n):\mathfrak{g}_0=\mathfrak{so}(2(n+1))\oplus\mathfrak{sp}(2n),\mathfrak{g}_1=(\mathbf{2(n+1)},\mathbf{2n})$.
(iv) $D(2,1;\alpha):\alpha\in\mathbb{C}-\{0,-1\},\mathfrak{g}_0=\mathfrak{sl}(2)\oplus\mathfrak{sl}(2)\oplus\mathfrak{sl}(2),\mathfrak{g}_1=(\mathbf{2},\mathbf{2},\mathbf{2})$.
(v) $F(4):\mathfrak{g}_0=\mathfrak{sl}(2)\oplus\mathfrak{so}(7),\mathfrak{g}_1=(\mathbf{2},\mathbf{8})$.
(vi) $G(3):\mathfrak{g}_0=\mathfrak{sl}(2)\oplus G_2,\mathfrak{g}_1=(\mathbf{2},\mathbf{7})$.

(3) *(Strange):*

(i) $Q(n):n>1\,\mathfrak{g}_0=\mathfrak{sl}(n),\mathfrak{g}_1=\mathrm{ad}(\mathfrak{sl}(n))$, *with ad the adjoint representation.*
(ii) $P(n):n>1\,\mathfrak{g}_0=\mathfrak{sl}(n),\mathfrak{g}_1=[2]\oplus[1^{n-2}]$, *where* $[2]$ *denotes* $\mathcal{S}^2(\mathbb{C}^n)$ *the twofold symmetric representation and* $[1^{n-2}]$ *denotes* $\Lambda^{n-2}(\mathbb{C}^n)$ *the* $(n-2)$*-fold antisymmetric representation.*

[The superscript in 1(i) and 1(iii) indicates the $\mathfrak{gl}(1)$ *charge.]*

B. Symmetric invariant forms

By Theorem II.6 one can construct an F-Lie algebra from a Lie superalgebra $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ and a $\mathfrak{g}_0$-invariant symmetric form on $\mathfrak{g}_1$. In general determining *all* invariant symmetric forms on a given representation of a given Lie algebra is very difficult. However, for the Lie superalgebras given in the above list we will show how one can construct many invariant symmetric forms. The key observation is that for each basic Lie superalgebra in the list, the odd part $\mathfrak{g}_1$ is either a tensor product (type II) or a sum of two dual tensor products (type I) as a representation of $\mathfrak{g}_0$. Thus, to find $\mathfrak{g}_0$-invariant symmetric forms on $\mathfrak{g}_1$, one can use the following well known isomorphisms of representations of $\mathrm{GL}(A)\times\mathrm{GL}(B)$:[39]

$$\mathcal{S}^p(A\oplus B)=\sum_{k=0}^{p}\mathcal{S}^k(A)\otimes\mathcal{S}^{p-k}(B), \tag{4.1}$$

$$\mathcal{S}^p(A\otimes B)=\sum_{\Gamma}\$^{\Gamma}(A)\otimes\$^{\Gamma}(B), \tag{4.2}$$

where the second sum is taken over all Young diagrams Γ of length p and $\$^{\Gamma}(A)$ denotes the irreducible representation of $\mathrm{GL}(A)$ corresponding to the Young symmetrizer of Γ.

1. Type I

We consider the Lie superalgebra $A(m,n)$. The case of the other basic type I Lie superalgebras is similar. Then $\mathfrak{g}_0=\mathfrak{sl}(m+1)\oplus\mathfrak{sl}(n+1)\oplus\mathfrak{gl}(1)$ and $\mathfrak{g}_1=(\mathbb{C}^{m+1\star}\otimes\mathbb{C}^{n+1}\otimes\mathbb{C})\oplus(\mathbb{C}^{m+1\star}\otimes\mathbb{C}^{n+1}\otimes\mathbb{C})^{\star}$. Using the formulas (4.1) and (4.2), one sees that $\mathcal{S}^p(\mathfrak{g}_1)$ is a direct sum of terms of the form

$$\$^{\Gamma}(\mathbb{C}^{m+1\star})\otimes\$^{\Gamma'}(\mathbb{C}^{m+1})\otimes\$^{\Gamma}(\mathbb{C}^{n+1})\otimes\$^{\Gamma'}(\mathbb{C}^{n+1\star})\otimes\mathbb{C}^{|\Gamma|-|\Gamma'|}, \tag{4.3}$$

where $|\Gamma|$ is the length of Γ and $|\Gamma|+|\Gamma'|=p$. If this term contains the trivial representation, then n must be even and $|\Gamma|=|\Gamma'|$. Furthermore, the dimension of the vector space of $\mathfrak{g}_0$ invariants is then

$$I_{\Gamma,\Gamma'}=\dim\ \mathrm{Hom}_{\mathfrak{sl}(m+1)}(\$^{\Gamma'}(\mathbb{C}^{m+1}),\$^{\Gamma}(\mathbb{C}^{m+1}))\times\dim\ \mathrm{Hom}_{\mathfrak{sl}(n+1)}(\$^{\Gamma'}(\mathbb{C}^{n+1}),\$^{\Gamma}(\mathbb{C}^{n+1})), \tag{4.4}$$

where $\mathrm{Hom}_{\mathfrak{sl}(m+1)}$ denotes homomorphisms which are $\mathfrak{sl}(n+1)$ equivariant. One can calculate the dimensions of these spaces using well known results.[39] If $\Gamma=\Gamma'$, then $I_{\Gamma,\Gamma'}\geqslant 1$; if $\Gamma=\Gamma'$ and $|\Gamma|=|\Gamma'|=1$, then $I_{\Gamma,\Gamma'}=1$ and the invariant quadratic form corresponds to the tautological metric on $\mathfrak{g}_1$. In Ref. 28 F-Lie algebras were constructed using this symmetric form.

2. Type II

All basic type II Lie superalgebras except (iv) have $\mathfrak{g}_0=\mathfrak{g}_0'\oplus\mathfrak{g}_0''$ and $\mathfrak{g}_1=\mathcal{D}'\otimes\mathcal{D}''$, where $\mathcal{D}'$ and $\mathcal{D}''$ are irreducible self-dual representations of respectively $\mathfrak{g}_0'$ and $\mathfrak{g}_0''$. Therefore, $\mathcal{S}^p(\mathfrak{g}_1)$ is the direct sum of terms of the form

$$\$^{\Gamma}(\mathcal{D}')\otimes\$^{\Gamma}(\mathcal{D}''), \tag{4.5}$$

where $|\Gamma|=p$. The dimension of the vector space of $\mathfrak{g}_0$ invariants is

$$I_{\Gamma}=\dim\$^{\Gamma}(\mathcal{D}')^{\mathfrak{g}_0'}\times\dim\$^{\Gamma}(\mathcal{D}'')^{\mathfrak{g}_0''}, \tag{4.6}$$

where $\$^{\Gamma}(\mathcal{D}')^{\mathfrak{g}_0'}$ denotes the space of $\mathfrak{g}_0'$ invariant vectors in $\$^{\Gamma}(\mathcal{D}')$. Although the respective factors in the product (4.5) are irreducible for $\mathrm{GL}(\mathcal{D}')$ and $\mathrm{GL}(\mathcal{D}'')$, they may become reducible for $\mathfrak{g}_0'$, $\mathfrak{g}_0''$. For example the representations associated to the Young diagram $\boxplus$ are reducible for both $\mathfrak{g}_0'=\mathfrak{so}(m)$ and $\mathfrak{g}_0''=\mathfrak{sp}(2n)$.

3. The strange superalgebra $Q(n)$

Up to duality $\mathcal{S}^\star(\mathfrak{g}_1)$ (the symmetric algebra on $\mathfrak{g}_1$) is generated by the Casimir operators of $\mathfrak{sl}(n)$ (see Sec. III).

4. The strange superalgebra $P(n)$

In this case $\mathcal{S}^\star(\mathfrak{g}_1)$ is a direct sum of terms of the form

$$\mathcal{S}^k(\mathcal{S}^2(\mathbb{C}^n))\otimes\mathcal{S}^{p-k}(\Lambda^{n-2}(\mathbb{C}^n)). \tag{4.7}$$

This representation is in general reducible, but we do not know of a simple general formula for the dimension of $\mathfrak{sl}(n)$ invariants.

C. Trivial and induced *F*-Lie algebras

In this section F-Lie algebras associated to Lie superalgebras will be constructed explicitly. To fix our notations, consider $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ a classical Lie superalgebra. Let $J_a, 1\leqslant a\leqslant \dim\ \mathfrak{g}_0$, be a basis of $\mathfrak{g}_0$ and $F_\alpha, 1\leqslant\alpha\leqslant\dim\ \mathfrak{g}_1$, be a basis of $\mathfrak{g}_1$. The structure constants of $\mathfrak{g}$ are given by

$$\begin{aligned}[J_a,J_b]&=f_{ab}{}^cJ_c,\\ [J_a,F_\alpha]&=(R_a)_\alpha{}^\beta F_\beta,\\ \{F_\alpha,F_\beta\}&=E_{\alpha\beta}=S^a_{\alpha\beta}J_a.\end{aligned} \tag{4.8}$$

The structure constants are given, e.g., in Ref. 38 for particular choices of bases.

The first type of F-Lie algebra associated to $\mathfrak{g}$ will be called trivial and are constructed as follows:

Theorem IV.2: *Let $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ be a Lie superalgebra and let $F\geqslant 1$ be an integer. Then $S=\mathfrak{g}_0\oplus(\mathfrak{g}_1\oplus\mathbb{C})$ (with $\mathbb{C}$ the trivial representation of $\mathfrak{g}_0$) can be given the structure of an F-Lie algebra.*

Proof: The proof is analogous to the proof of Theorem III.7. Q.E.D.

The second type of F-Lie algebra associated to $\mathfrak{g}$ are those induced from $\mathfrak{g}$ and symmetric forms on $\mathfrak{g}_1$. Let $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ be one of the classical Lie superalgebras in the statement of Theorem IV.1 and let g be a $\mathfrak{g}_0$ invariant symmetric form of order m on $\mathfrak{g}_1$. The bracket of the associated F-Lie algebra of order $m+2$ in the above basis is given by (2.1):

$$\{F_{\alpha_1},\cdots,F_{\alpha_{m+2}}\}=\frac{1}{m!}\sum_{i<j}g_{\alpha_1\cdots\alpha_{i-1}\alpha_{i+1}\cdots\alpha_{j-1}\alpha_{j+1}\cdots\alpha_{m+2}}E_{\alpha_i\alpha_j}. \tag{4.9}$$

Example IV.3: We denote by S the F-Lie algebra of order 4 induced from the Lie superalgebra

$$A(m-1,n-1)=(\mathfrak{sl}(m)\oplus\mathfrak{sl}(n)\oplus\mathfrak{gl}(1))\oplus(\mathbb{C}^m\otimes\mathbb{C}^{n\star}\otimes\mathbb{C})\oplus(\mathbb{C}^m\otimes\mathbb{C}^{n\star}\otimes\mathbb{C})^\star,$$

and the tautological quadratic form on $(\mathbb{C}^m\otimes\mathbb{C}^{n\star}\otimes\mathbb{C})\oplus(\mathbb{C}^m\otimes\mathbb{C}^{n\star}\otimes\mathbb{C})^\star$. Let $\{E_{IJ}\}_{1\leqslant J\leqslant m}^{1\leqslant I\leqslant m}$ and $\{E_{IJ}\}_{m+1\leqslant J\leqslant m+n}^{m+1\leqslant I\leqslant m+n}$ be the standard bases of $\mathfrak{gl}(m)$ and $\mathfrak{gl}(n)$, respectively. Let $\{F_{IJ}\}_{m+1\leqslant J\leqslant m+n}^{1\leqslant I\leqslant m}$ and $\{F_{IJ}\}_{1\leqslant J\leqslant m}^{m+1\leqslant I\leqslant m+n}$ be bases of $(\overline{\mathbf{m}},\mathbf{n})^+$ and $(\mathbf{m},\overline{\mathbf{n}})^-$, respectively.

Then the four brackets of S have the following simple form:

$$\begin{aligned}\{F_{I_1J_1},F_{I_2J_2},F_{I_3J_3},F_{I_4J_4}\}=&\ \delta_{I_1I_2}\delta_{J_1J_2}(\delta_{I_3J_4}E_{J_3I_4}+\delta_{J_3I_4}E_{I_3J_4})+\delta_{I_1I_3}\delta_{J_1J_3}(\delta_{I_2J_4}E_{J_2I_4}+\delta_{J_2I_4}E_{I_2J_4})\\ &+\delta_{I_1I_4}\delta_{J_1J_4}(\delta_{I_2J_3}E_{J_2I_3}+\delta_{J_2I_3}E_{I_2J_3})+\delta_{I_2I_3}\delta_{J_2J_3}(\delta_{I_1J_4}E_{J_1I_4}\\ &+\delta_{J_1I_4}E_{I_1J_4})+\delta_{I_2I_4}\delta_{J_2J_4}(\delta_{I_1J_3}E_{J_1I_3}+\delta_{J_1I_3}E_{I_1J_3})\end{aligned}$$

$$+\delta_{I_3I_4}\delta_{J_3J_4}(\delta_{I_1J_2}E_{J_1I_2}+\delta_{J_1I_2}E_{I_1J_2}). \tag{4.10}$$

The fact that the rhs is in $\mathfrak{sl}(m)\oplus\mathfrak{sl}(n)\oplus\mathfrak{gl}(1)$ *is a consequence of Theorem II.6.*

Example IV.4: We denote by S the F-Lie algebra of order 4 *induced from the Lie superalgebra*

$$\mathfrak{osp}(2|2m)=(\mathfrak{so}(2)\oplus\mathfrak{sp}(2m))\oplus\mathbb{C}^2\otimes\mathbb{C}^{2m},$$

and the quadratic form $g=\varepsilon\otimes\Omega$, *where* ε *is the invariant symplectic form on* $\mathbb{C}^2$ *and* Ω *is the invariant symplectic form on* $\mathbb{C}^{2m}$. *Let* $\{S_{\alpha\beta}=S_{\beta\alpha}\}_{\substack{1\leqslant\alpha\leqslant 2m\\1\leqslant\beta\leqslant 2m}}$ *be a basis of* $\mathfrak{sp}(2m)$ *and* $\{h\}$ *be a basis of* $\mathfrak{so}(2)$. *Let* $\{F_{q\alpha}\}_{\substack{q=\pm 1\\1\leqslant\alpha\leqslant 2m}}$ *be a basis of* $\mathbb{C}^2\otimes\mathbb{C}^{2m}$. *Then the four brackets of S take the following form:*

$$\begin{aligned}\{F_{q_1\alpha_1},F_{q_2\alpha_2},F_{q_3\alpha_3},F_{q_4\alpha_4}\}=&\varepsilon_{q_1q_2}\Omega_{\alpha_1\alpha_2}(\delta_{q_3+q_4}S_{\alpha_3\alpha_4}+\varepsilon_{q_3+q_4}\Omega_{\alpha_3\alpha_4}h)\\&+\varepsilon_{q_1q_3}\Omega_{\alpha_1\alpha_3}(\delta_{q_2+q_4}S_{\alpha_2\alpha_4}+\varepsilon_{q_2+q_4}\Omega_{\alpha_2\alpha_4}h)\\&+\varepsilon_{q_1q_4}\Omega_{\alpha_1\alpha_4}(\delta_{q_2+q_3}S_{\alpha_2\alpha_3}+\varepsilon_{q_2+q_3}\Omega_{\alpha_2\alpha_3}h)\\&+\varepsilon_{q_2q_3}\Omega_{\alpha_2\alpha_3}(\delta_{q_1+q_4}S_{\alpha_1\alpha_4}+\varepsilon_{q_1+q_4}\Omega_{\alpha_1\alpha_4}h)\\&+\varepsilon_{q_2q_4}\Omega_{\alpha_2\alpha_4}(\delta_{q_1+q_3}S_{\alpha_1\alpha_3}+\varepsilon_{q_1+q_3}\Omega_{\alpha_1\alpha_3}h)\\&+\varepsilon_{q_3q_4}\Omega_{\alpha_3\alpha_4}(\delta_{q_1+q_2}S_{\alpha_1\alpha_2}+\varepsilon_{q_1+q_2}\Omega_{\alpha_1\alpha_2}h).\end{aligned} \tag{4.11}$$

Other extensions of Lie superalgebras have been considered in the literature. For instance, extensions of the orthosymplectic superalgebra $\mathfrak{osp}(1|4)$ or the unitary $\mathfrak{sl}(4|1)$ were constructed by means of parafermions and parabosons.[40] The first example of an F-Lie algebra was considered in Refs. 20 and 21 as a possible extension of the Virasoro algebra. In Ref. 36 an example of a ''trivial'' F-Lie algebra, related to the superalgebra $\mathfrak{osp}(1|2)$, was constructed.

Remark IV.5: By repeated application of Theorem II.6 one can construct F-Lie algebras of higher and higher order.

V. FINITE-DIMENSIONAL FSUSY EXTENSIONS OF THE POINCARÉ ALGEBRA

It is well known that supersymmetric extensions of the Poincaré algebra can be obtained by Inönü–Wigner contraction of certain Lie superalgebras. In fact, one can also obtain FSUSY extensions of the Poincaré algebra by Inönü–Wigner contraction of certain F-Lie algebras as we now show with two examples.

For the first example, we let $S_3=\mathfrak{sp}(4)\oplus\mathrm{ad}\mathfrak{sp}(4)$ be the real F-Lie algebra of order 3 (see Remark III.9) induced from the real graded 1-Lie algebra $S_1=\mathfrak{sp}(4)\oplus\mathrm{ad}\mathfrak{sp}(4)$ (see Example III.2) and the Killing form on $\mathrm{ad}\mathfrak{s}p(4)$. Using vector indices of $\mathfrak{so}(1,3)$ coming from the inclusion $\mathfrak{so}(1,3)\subset\mathfrak{so}(2,3)\cong\mathfrak{sp}(4)$, the bosonic part of S_3 is generated by $M_{\mu\nu},M_{\mu 4}$, with $\mu,\nu=0,1,2,3$, and the graded part by $J_{\mu\nu},J_{4\mu}$. Letting $\lambda\to 0$ after the Inönü–Wigner contraction,

$$\begin{aligned}&M_{\mu\nu}\to L_{\mu\nu},\quad M_{\mu 4}\to\frac{1}{\lambda}P_\mu\\&J_{\mu\nu}\to\frac{1}{\sqrt[3]{\lambda}}Q_{\mu\nu},\quad J_{4\mu}\to\frac{1}{\sqrt[3]{\lambda}}Q_\mu,\end{aligned} \tag{5.1}$$

one sees that $L_{\mu\nu}$ and P_μ generate the $(1+3)D$ Poincaré algebra and that $Q_{\mu\nu},Q_\mu$ are the fractional supercharges in respectively the adjoint and vector representations of $\mathfrak{so}(1,3)$. This F-Lie algebra of order 3 is therefore a nontrivial extension of the Poincaré algebra where trans-

lations are cubes of more fundamental generators. The subspace generated by $L_{\mu\nu}, P_\mu, Q_\mu$ is also an F-Lie algebra of order 3 extending the Poincaré algebra in which the trilinear symmetric brackets have the simple form

$$\{Q_\mu, Q_\nu, Q_\rho\} = \eta_{\mu\nu} P_\rho + \eta_{\mu\rho} P_\nu + \eta_{\rho\nu} P_\mu, \tag{5.2}$$

where $\eta_{\mu\nu}$ is the Minkowski metric. This algebra should be compared to the algebra recently obtained in a different context, where a ''trilinear'' extension of the Poincaré algebra involving ''supercharges'' in the vector representation was constructed.[41]

For the second example, we let $S_4 = (\mathfrak{so}(2) \oplus \mathfrak{sp}(4)) \oplus \underline{\mathbf{2}} \otimes \underline{\mathbf{4}}$ be the real F-Lie algebra of order four induced from $\mathfrak{osp}(2|4)$ and the symmetric form $\varepsilon \otimes \Omega$, where Ω is the symplectic form on $\mathbf{4}$ and ε the antisymmetric two-form on $\underline{\mathbf{2}}$. Using spinor indices coming from $\mathfrak{sl}(2,\mathbb{C}) \cong \mathfrak{so}(1,3) \subset \mathfrak{so}(2,3)$ the bosonic part is generated by $E_{\alpha\beta}, E_{\dot\alpha\dot\beta}, E_{\dot\alpha\beta}$ and the fermionic part by $F^{\pm}_{\alpha}, \overline{F}^{\pm}_{\dot\alpha}, \alpha, \beta = 1,2$ and $\dot\alpha, \dot\beta = \dot1, \dot2$. Letting $\lambda \to 0$ after the Inönü–Wigner contraction

$$E_{\alpha\beta} \to L_{\alpha\beta}, \quad E_{\dot\alpha\dot\beta} \to L_{\dot\alpha\dot\beta}, \quad E_{\alpha\dot\alpha} \to \frac{1}{\lambda} P_{\alpha\dot\alpha}, \quad h \to \frac{1}{\lambda} Z, \quad F^{\pm}_{\alpha} \to \frac{1}{\sqrt[4]{\lambda}} Q^{\pm}_{\alpha}, \quad \overline{F}^{\pm}_{\dot\alpha} \to \frac{1}{\sqrt[4]{\lambda}} \overline{Q}^{\pm}_{\dot\alpha}, \tag{5.3}$$

one sees that $L_{\alpha\beta}, L_{\dot\alpha\dot\beta}$ and $P_{\alpha\dot\alpha}$ generate the $(1+3)D$ Poincaré algebra, that Z is central and that $Q^{\pm}_{\alpha}, \overline{Q}^{\pm}_{\dot\alpha}$ are the fractional supercharges in the spinor representations of $\mathfrak{so}(1,3)$. This F-Lie algebra of order 4 is therefore a nontrivial extension of the Poincaré algebra where translations are fourth powers of more fundamental generators. The four bracket can be expressed simply if we introduce the following notation: $\sigma^{\mu}_{\alpha\dot\alpha}, \overline{\sigma}^{\mu\dot\alpha\alpha}$ are the Dirac matrices, and $\sigma^{\mu\nu}_{\alpha\beta}$, $\overline{\sigma}^{\mu\nu}_{\dot\alpha\dot\beta}$ and P_μ are the Poincaré generators (for details, e.g., Ref. 42). One then has

$$\begin{aligned}
\{Q^{q_1}_{\alpha_1}, Q^{q_2}_{\alpha_2}, Q^{q_3}_{\alpha_3}, Q^{q_4}_{\alpha_4}\} &= 2\varepsilon^{q_1q_2}\varepsilon^{q_3q_4}\varepsilon_{\alpha_1\alpha_2}\varepsilon_{\alpha_3\alpha_4} Z + 2\varepsilon^{q_1q_4}\varepsilon^{q_2q_3}\varepsilon_{\alpha_1\alpha_4}\varepsilon_{\alpha_2\alpha_3} Z \\
&\quad + 2\varepsilon^{q_1q_3}\varepsilon^{q_2q_4}\varepsilon_{\alpha_1\alpha_3}\varepsilon_{\alpha_2\alpha_4} Z, \\
\{Q^{q_1}_{\alpha_1}, Q^{q_2}_{\alpha_2}, Q^{q_3}_{\alpha_3}, \overline{Q}^{q_4}_{\dot\alpha_4}\} &= \delta^{q_1+q_4}\varepsilon^{q_2q_3}\varepsilon_{\alpha_2\alpha_3}\sigma^{\mu}_{\alpha_1\dot\alpha_4} P_\mu + \delta^{q_2+q_4}\varepsilon^{q_1q_3}\varepsilon_{\alpha_1\alpha_3}\sigma^{\mu}_{\alpha_2\dot\alpha_4} P_\mu \\
&\quad + \delta^{q_3+q_4}\varepsilon^{q_1q_2}\varepsilon_{\alpha_1\alpha_2}\sigma^{\mu}_{\alpha_3\dot\alpha_4} P_\mu, \\
\{Q^{q_1}_{\alpha_1}, Q^{q_2}_{\alpha_2}, \overline{Q}^{q_3}_{\dot\alpha_3}, \overline{Q}^{q_4}_{\dot\alpha_4}\} &= 0,
\end{aligned} \tag{5.4}$$

together with similar relations involving $\{Q^{q_1}_{\alpha_1}, \overline{Q}^{q_2}_{\dot\alpha_2}, \overline{Q}^{q_3}_{\dot\alpha_3}, \overline{Q}^{q_4}_{\dot\alpha_4}\}$ and $\{\overline{Q}^{q_1}_{\dot\alpha_1}, \overline{Q}^{q_2}_{\dot\alpha_2}, \overline{Q}^{q_3}_{\dot\alpha_3}, \overline{Q}^{q_4}_{\dot\alpha_4}\}$.

Analogous constructions lead to FSUSY extensions of the Poincaré algebra in any space–time dimensions.

VI. SIMPLE *F*-LIE ALGEBRAS

By analogy with the case of Lie (super)algebras we define ideals and the notion of simplicity for F-Lie algebras.

Definition VI.1: Let $S = \mathcal{B} \oplus \mathcal{F}$ be an F-Lie algebra, or a graded 1-Lie algebra. Then $\mathcal{I} = \mathcal{B}' \oplus \mathcal{F}'$ is an ideal of S if and only if

(i) $\forall f'_1 \in \mathcal{F}', \forall f_2, \ldots, f_F \in \mathcal{F}: \{f'_1, f_2, \ldots, f_F\} \in \mathcal{B}'$.
(ii) $\mathcal{B}'$ *is an ideal of* $\mathcal{B}$ $(\forall b' \in \mathcal{B}', \forall b \in \mathcal{B}, [b, b'] \in \mathcal{B}')$.
(iii) $\forall b \in \mathcal{B}, \forall f' \in \mathcal{F}' [b, f'] \in \mathcal{F}'$.
(iv) $\forall b' \in \mathcal{B}', \forall f \in \mathcal{F} [b', f] \in \mathcal{F}'$.

Remark VI.2: For a graded 1*-Lie algebra* $S=\mathcal{B}\oplus\mathcal{F}$*, denoting* μ *the map from* $\mathcal{F}$ *to* $\mathcal{B}$*, the property (i) of Theorem VI.1 becomes* $\mathrm{Im}\,\mu\subset\mathcal{B}'$.

Remark VI.3: By Theorem VI.1, $\mathrm{Im}\,\mu\oplus\mathcal{F}$ *is an ideal of* S *[*μ *denotes the* $\mathcal{B}$*-equivariant map from* $\mathcal{S}^F(\mathcal{F})\to\mathcal{B}$*].*

Remark VI.4: In the case of Lie algebras and Lie superalgebras, this is the usual definition. In the case of a graded 1*-Lie algebra* $S=\mathcal{B}\oplus\mathcal{F}$*,* $S'=\mathcal{B}'\oplus\mathcal{F}'$ *is an ideal if and only if it is a* $\mathbb{Z}_2$*-graded ideal for the natural Lie bracket on* S (*cf. Remark III.3*).

Definition VI.5: An F*-Lie algebra* S *is said to be simple if and only if its only ideals are* S *and* $\{0\}$*, and* $\mu:\mathcal{S}^F(\mathcal{F})\to\mathcal{B}$ *is nonzero.*

Remark VI.6: Let $S=\mathcal{B}\oplus\mathcal{F}$ *be a graded* 1*-Lie algebra such that* $\mu:\mathcal{F}\to\mathcal{B}$ *is nonzero. Then,* S *is simple if and only if* $\mathcal{B}$ *is a simple Lie algebra and* $\mathcal{F}$ *is an irreducible representation of* $\mathcal{B}$*.*

Remark VI.7: If $\mathfrak{g}$ *is a simple Lie algebra, and* $S=\mathfrak{g}\oplus\mathrm{ad}\mathfrak{g}$ *is the graded* 1*-Lie algebra of Example III.2, then* S *is simple as a graded* 1*-Lie algebra but is not simple as a Lie algebra, with respect to the natural Lie bracket III.3.*

Proposition VI.8: Let $S=\mathcal{B}\oplus\mathcal{F}$ *be an* F*-Lie algebra such that (i)* $\mathcal{B}$ *is semi-simple, (ii) the map* $\mu:\mathcal{S}^F(\mathcal{F})\to\mathcal{B}$ *is a surjection and (iii) no nonzero ideal of* $\mathcal{B}$ *has nonzero fixed points in* $\mathcal{F}$*. Then*

(a) S *is simple and*
(b) the F*-Lie algebra of order* $(F+2)$ *induced from a* $\mathcal{B}$*-equivariant nondegenerate quadratic form on* $\mathcal{F}$ *(see II.6–III.6) also satisfies (i) and (ii).*

Proof: Let $\mathfrak{I}=\mathcal{B}'\oplus\mathcal{F}'$ be a nontrivial ideal of S. Then $\mathcal{B}'$ is an ideal of $\mathcal{B}$ and $[\mathcal{B}',\mathcal{F}]\subset\mathcal{F}'$. But if $\mathcal{F}=\mathcal{F}'\oplus\mathcal{F}''$ as $\mathcal{B}'$-modules, then $[\mathcal{B}',\mathcal{F}'']=0$, and, therefore, $\mathcal{F}''=\{0\}$ since by hypothesis $\mathcal{B}'$ does not admit nonzero fixed points. This proves (a).
To prove (b) it is enough to prove that the induced $(F+2)$-bracket is surjective. Since the F-bracket $\mu:\mathcal{S}^F(\mathcal{F})\to\mathcal{B}$ is surjective, by diagonalizing the quadratic form, it is easy to see that the $(F+2)$-bracket (2.1) is also surjective. Q.E.D.

Remark VI.9: If $\mathfrak{g}$ *is a simple Lie algebra, the graded* 1*-Lie algebras* $\mathfrak{g}\oplus\mathrm{ad}\mathfrak{g}$ *satisfies (i), (ii) and (iii) above. As one can check, the Lie superalgebras in the list IV.1 also satisfy (i), (ii) and (iii). Thus the induced* F*-Lie algebras associated to nondegenerate quadratic forms and these graded* 1*-Lie algebras or Lie superalgebras are always simple.*

The trivial F-Lie algebras associated to graded 1-Lie algebras or Lie superalgebras III.7–IV.2 are not simple since in both cases $\mathfrak{g}_0\oplus\mathfrak{g}_1$ is an ideal of S. In particular, when $F=2$, the trivial Lie superalgebras associated to graded 1-Lie algebras are not simple. The direct sum of two simple F-Lie algebras of the same order is clearly not simple. These two kinds of examples of nonsimple F-Lie algebras indicate that probably, as for Lie superalgebras, there are different inequivalent ways to define semi-simple F-Lie algebras.

VII. REPRESENTATIONS

Definition VII.1: A representation of an F*-Lie algebra* S *is a linear map* $\rho:S\to\mathrm{End}(H)$ *and an automorphism* $\hat{\varepsilon}$ *such that* $\hat{\varepsilon}^F=1$ *which satisfy*

$$\rho([x,y])=\rho(x)\rho(y)-\rho(y)\rho(x), \tag{7.1a}$$

$$\rho\{a_1,\ldots,a_F\}=\Sigma_{\sigma\in S_F}\rho(a_{\sigma(1)})\ldots\rho(a_{\sigma(F)}), \tag{7.1b}$$

$$\hat{\varepsilon}\rho(s)\hat{\varepsilon}^{-1}=\rho(\varepsilon(s)) \tag{7.1c}$$

(S_F *being the group of permutations of* F *elements).*

As a consequence of these properties, since the eigenvalues of $\hat{\varepsilon}$ are Fth roots of unity, we have the following decomposition,

$$H=\bigoplus_{k=0}^{F-1} H_k,$$

where $H_k=\{|h\rangle\in H:\hat{\varepsilon}|h\rangle=q^k|h\rangle\}$. The operator $N\in\mathrm{End}(H)$ defined by $N|h\rangle=k|h\rangle$ if $|h\rangle\in H_k$ is the "number operator" (obviously $q^N=\hat{\varepsilon}$). Since $\hat{\varepsilon}\rho(b)=\rho(b)\hat{\varepsilon},\forall b\in\mathcal{B}$ each H_k provides a representation of the Lie algebra $\mathcal{B}$. Furthermore, for $a\in\mathcal{A}_{\not}$, $\hat{\varepsilon}\rho(a)=q^{\not}\rho(a)\hat{\varepsilon}$, and so we have $\rho(a).H_k\subseteq H_{k+\not(\mathrm{mod}\ F)}$.

Example VII.2: Let X,Y,Z be $n\times n$ (resp. $2n\times 2n$) matrices in $\mathfrak{so}(n)$ [resp. $\mathfrak{sp}(2n)$]. Then, it is easy to see that $\{X,Y,Z\}$ is also in $\mathfrak{so}(n)$ [resp. $\mathfrak{sp}(2n)$]. Consequently, $S=\mathfrak{so}(n)\oplus\mathfrak{so}(n)$ [resp. $S=\mathfrak{sp}(2n)\oplus\mathfrak{sp}(2n)$] is an F-Lie algebra of order 3 [the only nontrivial point to be checked is the Jacobi identity (J4) in Definition II.1]. A similar property is true for any odd number of matrices. We will calculate the structure constants in the case of $\mathfrak{so}(n)$, the calculation for $\mathfrak{sp}(2n)$ being analogous. If X_a, $1\leqslant a\leqslant\dim\ \mathfrak{so}(n)$, is a basis of $\mathfrak{so}(n)$, then the three-bracket of S is given by

$$\{X_a,X_b,X_c\}=k_{abc}^{d}X_d. \tag{7.2}$$

Writing $\{X_a,X_b,X_c,X_d\}=(\{X_a,X_b,X_c\}X_d+\{X_a,X_b,X_d\}X_c+\{X_a,X_c,X_d\}X_b+\{X_b,X_c,X_d\}X_a)$ and taking the trace using (7.2), we get $4k_{abc}{}^{d}tr(X_dX_e)=\mathrm{Tr}(\{X_a,X_b,X_c,X_e\})$. Since the trace defines a metric on $\mathfrak{so}(n)$ this gives $k_{abc}{}^{d}=\frac{1}{4}\mathrm{Tr}\{X_a,X_b,X_c,X_d\}g^{de}$.

This F-Lie algebra of order 3 is not induced from the graded 1-Lie algebra $\mathfrak{so}(n)\oplus\mathfrak{so}(n)$ and the Killing form: if this were the case we would have $\{X_a,X_b,X_c\}=\mathrm{Tr}(X_aX_b)X_c+\mathrm{Tr}(X_aX_c)X_b+\mathrm{Tr}(X_bX_c)X_a$, which is clearly false if $a=b=c$. However, by Proposition VI.8, S is simple.

We can construct a representation of S in $\mathbb{C}^n\otimes\mathbb{C}^3$ as follows: define $\rho:S\to\mathrm{End}(\mathbb{C}^n\otimes\mathbb{C}^3)$ by

$$\rho(X)=\begin{cases}X\otimes\mathbf{Id} & \text{if } X \text{ is in the first } \mathfrak{so}(n),\\ X\otimes Q & \text{if } X \text{ is in the second } \mathfrak{so}(n),\end{cases} \tag{7.3}$$

where $Q:\mathbb{C}^3\to\mathbb{C}^3$ is any linear map whose minimal polynomial is λ^3-1 (i.e., $Q^3=\mathbf{Id}$ and Q has three distinct eigenvalues).

Related results were obtained for $\mathfrak{so}(n)$ and $\mathfrak{sp}(2n)$ in Ref. 43.

Example VII.3: Let X,Y,Z be three $n\times n$ matrices in $\mathfrak{u}(n)$. Then, it is easy to see that $\{X,Y,Z\}$ is also in $\mathfrak{u}(n)$. As in the previous example, this simple observation enables us to give $\mathfrak{u}(n)\oplus\mathfrak{u}(n)$ or $\mathfrak{u}(n)\oplus\mathfrak{su}(n)$ the structure of an F-Lie algebra of order 3.

Example VII.4: Let $A(m-1,n-1)$, $n\neq m$, be the Lie superalgebra of $(n+m)\times(n+m)$ matrices,[3,38]

$$M=\begin{pmatrix}E_{mm} & F_{mn}\\ F_{nm} & E_{nn}\end{pmatrix},$$

of supertrace zero (i.e., $\mathrm{sTr}M=\mathrm{tr}E_{mm}-\mathrm{tr}E_{nn}=0$).

If $J_{i_1},\ldots,J_{i_{2F}}$ are arbitrary matrices, then

$$\{J_{i_1},\ldots,J_{i_{2F}}\}=\sum_{\substack{a<b=1\\ a\neq b}}^{F}\{\{J_{i_a},J_{i_b}\},\{\hat{J}_{i_a},\hat{J}_{i_b},J_{i_1},\ldots,J_{i_{2F}}\}\}. \tag{7.4}$$

Applying this formula to $2F$ odd matrices in $A(m-1,n-1)$, one sees by an induction that the supertrace of the $2F$-bracket (7.4) vanishes. Using the $\mathbb{Z}_2$ graduation of $A(m-1,n-1)$ one sees that this bracket belongs to the even part of the algebra and hence defines the structure of an F-Lie algebra of order $2F$ on the underlying vector space of $A(m-1,n-1)$. For $F=4$ this is just the F-Lie algebra of order 4 induced by the tautological quadratic form of Example IV.3. Indeed, let $V=\mathbb{C}^{\star n}\otimes\mathbb{C}^m\otimes\mathbb{C}$ and let $\mathfrak{g}_0=\mathfrak{sl}(n)\oplus\mathfrak{sl}(m)\oplus\mathfrak{gl}(1)$. Then, comparing $\mathfrak{gl}(1)$ charges, we have $\mathrm{Hom}_{\mathfrak{g}_0}(\mathcal{S}^4(V\oplus V^\star),\mathfrak{g}_0)=\mathrm{Hom}_{\mathfrak{g}_0}(\mathcal{S}^2(V)\otimes\mathcal{S}^2(V^\star),\mathfrak{g}_0)$. Since

$$\mathcal{S}^2(V)\otimes\mathcal{S}^2(V^\star)\cong(\mathcal{S}^2(\mathbb{C}^{\star n})\otimes\mathcal{S}^2(\mathbb{C}^m)\oplus\Lambda^2(\mathbb{C}^{\star n})\otimes\Lambda^2(\mathbb{C}^m))\otimes(\mathcal{S}^2(\mathbb{C}^n)\otimes\mathcal{S}^2(\mathbb{C}^{\star m})\oplus\Lambda^2(\mathbb{C}^n)\otimes\Lambda^2(\mathbb{C}^{\star m}))$$

and since the representations **1** *and* $\mathfrak{sl}(n)$ *occur exactly once in* $\mathcal{S}^2(\mathbb{C}^n)\otimes\mathcal{S}^2(\mathbb{C}^{\star n})$ *and not at all in* $\Lambda^2(\mathbb{C}^n)\otimes\Lambda^2(\mathbb{C}^{\star n})$, *we deduce that* $\mathrm{Hom}_{\mathfrak{g}_0}(\mathcal{S}^4(V\oplus V^\star),\mathfrak{g}_0)$ *is of dimension one.*

By definition, the fundamental $(n+m)\times(n+m)$ *matrix representation of the Lie superalgebra* $A(m-1,n-1)$ *is also a representation of the* F*-Lie algebra of order* $2F$ *constructed above. In general, this is not true: for instance, if* $m=2,n=1$, *one can check that the six-dimensional representation of* $A(2,1)$ *is not a representation of the associated* F*-Lie algebra of order* 4.

Example VII.5: Let S *be the set of all matrices of the form*

$$M=\begin{pmatrix} q & 0 & F_+ \\ 0 & -q & F_- \\ -\Omega F_-^t & -i\Omega F_+^t & S \end{pmatrix}, \tag{7.5}$$

where q *is a complex number,* $F_\pm$ *are two* $1\times 2n$ *matrices,* Ω *is the standard* $2n\times 2n$ *symplectic form on* $\mathbb{C}^{2n}$ *and* S *is a* $2n\times 2n$ *matrix in* $\mathfrak{sp}(2n)$, *i.e.,* $S^t=\Omega S\Omega$. *Let*

$$\mathcal{B}=\left\{\begin{pmatrix} q & 0 & 0 \\ 0 & -q & 0 \\ 0 & 0 & S \end{pmatrix}, q\in\mathbb{C}, S\in\mathfrak{sp}(2n)\right\}\cong\mathfrak{so}(2)\oplus\mathfrak{sp}(2n)$$

and let

$$\mathcal{F}=\left\{\begin{pmatrix} 0 & 0 & F_+ \\ 0 & 0 & F_- \\ -\Omega F_-^t & -i\Omega F_+^t & 0 \end{pmatrix}, F_\pm\in\mathcal{M}_{1,2n}(\mathbb{C})\right\}.$$

If one now takes

$$\mathcal{F}_{a+}=\begin{pmatrix} 0 & 0 & F_{a+} \\ 0 & 0 & 0 \\ 0 & -i\Omega F_{a+}^t & 0 \end{pmatrix}, \mathcal{F}_{a-}=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & F_{a-} \\ -\Omega F_{a-}^t & 0 & 0 \end{pmatrix},$$

and $\mathcal{F}_a=\mathcal{F}_{a+}+\mathcal{F}_{a-}$, *we get*

$$\{\mathcal{F}_a,\mathcal{F}_b\}=\begin{pmatrix} \alpha_{ab} & 0 & 0 \\ 0 & -i\alpha_{ab} & 0 \\ 0 & 0 & A_{ab} \end{pmatrix},$$

where $A_{ab}=-\Omega F_{a-}^t F_{b+}-i\Omega F_{a+}^t F_{b-}-\Omega F_{b-}^t F_{a+}-i\Omega F_{b+}^t F_{a-}$ *and where* $\alpha_{ab}=-F_{a+}\Omega F_{b-}^t-F_{b+}\Omega F_{a-}^t$. *This shows that* $\mathcal{B}\oplus\mathcal{F}$ *is not closed under the superbracket. From the formula* $\{\mathcal{F}_{a_1},\mathcal{F}_{a_2},\mathcal{F}_{a_3},\mathcal{F}_{a_4}\}=\{\{\mathcal{F}_{a_1},\mathcal{F}_{a_2}\},\{\mathcal{F}_{a_3},\mathcal{F}_{a_4}\}\}+\{\{\mathcal{F}_{a_1},\mathcal{F}_{a_3}\},\{\mathcal{F}_{a_2},\mathcal{F}_{a_4}\}\}+\{\{\mathcal{F}_{a_1},\mathcal{F}_{a_4}\},\{\mathcal{F}_{a_2},\mathcal{F}_{a_3}\}\}$, *observing that* $\{\mathcal{F}_{a+},\mathcal{F}_{b+}\}=\{\mathcal{F}_{a-},\mathcal{F}_{b-}\}=0$, *the four-bracket* $\{\mathcal{F}_{a_1q_1},\mathcal{F}_{a_2q_2},\mathcal{F}_{a_3q_3},\mathcal{F}_{a_4q_4}\}=0$ *if* $q_1+q_2+q_3+q_4\neq 0$. *We then calculate four-brackets for* $q_1=q_2=-q_3=-q_4=1$ *and obtain*

$$\{\mathcal{F}_{a+},\mathcal{F}_{b+},\mathcal{F}_{c-},\mathcal{F}_{d-}\}=\begin{pmatrix} q & 0 & 0 \\ 0 & -q & 0 \\ 0 & 0 & S \end{pmatrix},$$

$$q=2(F_{a+}\Omega F_{c-}^t)(F_{b+}\Omega F_{d-}^t)+2(F_{a+}\Omega F_{d-}^t)(F_{b+}\Omega F_{c-}^t) \tag{7.6}$$

$$\begin{aligned}S=&F_{a+}\Omega F_{d-}^t(\Omega F_{c-}^t F_{b+}+\Omega F_{b+}^t F_{c-})+F_{a+}\Omega F_{c-}^t(\Omega F_{d-}^t F_{b+}+\Omega F_{b+}^t F_{d-})\\&+F_{b+}\Omega F_{d-}^t(\Omega F_{c-}^t F_{a+}+\Omega F_{a+}^t F_{c-})+F_{b+}\Omega F_{c-}^t(\Omega F_{d-}^t F_{a+}+\Omega F_{a+}^t F_{d-}).\end{aligned}$$

This shows that $\mathcal{B}\oplus\mathcal{F}$ is an F-Lie algebra of order 4 since $S^t=\Omega S\Omega$.

In fact, the matrices of $\mathcal{B}\oplus\mathcal{F}$ define a representation of the F-Lie algebra of order 4 induced from $\mathfrak{osp}(2|2m)$ and $\varepsilon\otimes\Omega$ (see Example IV.4). Indeed, setting

$$\overline{\mathcal{F}}_{a+}=\begin{pmatrix}0&0&F_{a+}\\0&0&0\\0&-\Omega F_{a+}^t&0\end{pmatrix},\overline{\mathcal{F}}_{a-}=\begin{pmatrix}0&0&0\\0&0&F_{a-}\\-\Omega F_{a-}^t&0&0\end{pmatrix},$$

we see that $\mathcal{B}\oplus\overline{\mathcal{F}}\cong\mathfrak{osp}(2|2m)$ and that $\{\mathcal{F}_{a+},\mathcal{F}_{b+},\mathcal{F}_{c-},\mathcal{F}_{d-}\}=\langle\overline{\mathcal{F}}_{a+},\overline{\mathcal{F}}_{c-}\rangle\{\overline{\mathcal{F}}_{b+},\overline{\mathcal{F}}_{d-}\}+\langle\overline{\mathcal{F}}_{b+},\overline{\mathcal{F}}_{d-}\rangle\{\overline{\mathcal{F}}_{a+},\overline{\mathcal{F}}_{c-}\}+\langle\overline{\mathcal{F}}_{a+},\overline{\mathcal{F}}_{d-}\rangle\{\overline{\mathcal{F}}_{b+},\overline{\mathcal{F}}_{c-}\}+\langle\overline{\mathcal{F}}_{b+},\overline{\mathcal{F}}_{c-}\rangle\{\overline{\mathcal{F}}_{a+},\overline{\mathcal{F}}_{d-}\}$ where $\langle\overline{\mathcal{F}}_{a+},\overline{\mathcal{F}}_{c-}\rangle$ denotes the $\varepsilon\otimes\Omega$ invariant form.

Given an F-Lie algebra $S=\mathcal{B}\oplus\mathcal{F}$ one can define the universal enveloping algebra $\mathcal{U}(S)$ by taking the quotient of the tensor algebra $\mathcal{T}(S)$ by the two-sided ideal generated by (see Definition II.1)

$$\begin{gathered}\Sigma_{\sigma\in\Sigma_F}a_{\sigma(1)}\otimes\cdots\otimes a_{\sigma(F)}-\{a_1,\ldots,a_F\},\\b_1\otimes b_2-b_2\otimes b_1-[b_1,b_2],\\b_1\otimes a_2-a_2\otimes b_1-[b_1,a_2],\end{gathered}\tag{7.7}$$

with $a_1,\ldots,a_F\in\mathcal{A}_1,b_1,b_2\in\mathcal{B}$. It is not necessary to impose the Jacobi identity (J4) since it is true in $\mathcal{T}(S)$.

The natural filtration of $\mathcal{T}(S)$ factors to a filtration of $\mathcal{U}(S)$ and, denoting the associated graded algebra by $\mathrm{gr}(\mathcal{U}(S))$, we conjecture the following:

(1) $\mathrm{gr}(\mathcal{U}(S))$ is isomorphic to $\mathcal{T}(S)/\overline{I}$, where $\overline{I}$ is the two-sided ideal generated by

$$\begin{gathered}\Sigma_{\sigma\in\Sigma_F}a_{\sigma(1)}\otimes\cdots\otimes a_{\sigma(F)},\\b_1\otimes b_2-b_2\otimes b_1,\\b_1\otimes a_2-a_2\otimes b_1.\end{gathered}$$

[This would then imply that $\mathrm{gr}(\mathcal{U}(S))\cong S(\mathcal{B})\otimes\Lambda_F(\mathcal{F})$, where $S(\mathcal{B})$ is the symmetric algebra on $\mathcal{B}$ and $\Lambda_F(\mathcal{F})$ is the F-exterior algebra on $\mathcal{F}$.[44]]

(2) The natural map $\pi:\mathcal{U}(S)\to\mathrm{gr}(\mathcal{U}(S))$ is a linear isomorphism. (This would be an analog of the Poincaré–Birkhoff–Witt theorem.)

In the usual way, the representations of S are in bijective correspondence with the representations of the associative algebra $\mathcal{U}(S)$. Consequently, if $\mathcal{I}\subset\mathcal{U}(S)$ is a two-sided ideal, then the quotient $\mathcal{U}(S)/\mathcal{I}$ gives a representation of S. It would be very convenient to have a theory of "Cartan sub-algebras," "roots" and "weights" for S. However, even for simple Lie superalgebras this kind of theory only works well for basic Lie superalgebras.[38] One might expect F-Lie algebras induced from basic Lie superalgebras to be amenable to this approach. This seems not to be the case. Indeed, recall that if S is a basic Lie superalgebra with Borel decomposition $S=\mathfrak{h}\oplus\mathfrak{n}_+\oplus\mathfrak{n}_-$ and $\lambda\in\mathfrak{h}^\star$ is a dominant weight, then $\mathcal{V}_\lambda=\mathcal{U}/\mathcal{I}_\mu$ (where $\mathcal{I}_\lambda$ is the ideal corresponding to λ) is (i) generated by the action of $\mathfrak{n}_+$ on the vacuum and (ii) has a unique quotient $\mathcal{D}_\lambda$ on which the action of $\mathfrak{n}_+$ is nilpotent and which is therefore finite-dimensional. However, if S_g is the F-Lie

algebra induced from S and a symmetric form g, the quotient $\mathcal{V}'_\lambda = \mathcal{U}(S_g)/\mathcal{I}'_\lambda$ is (i) not generated by the action of $\mathfrak{n}_+$ on the vacuum and (ii) the nilpotence of the action of $\mathfrak{n}_+$ in a quotient does not guarantee finite-dimensionality. This means that in finite-dimensional representations of S, as in the examples of Sec. VII, the elements of $\mathfrak{n}_+$ are not only nilpotent but also satisfy additional relations.

VIII. CONCLUSION

The mathematical structure underlying supersymmetry is that of a Lie superalgebra. Given the classification of Lie superalgebras, one can list the possible supersymmetric extensions of the Poincaré algebra. These extensions have had a wide range of applications in physics.

Fractional supersymmetries were first studied in the early 1990s in relation with low dimensional physics ($D \leqslant 3$) where fields which are neither bosonic nor fermionic[34] do exist. It was understood a few years later that FSUSY can be considered in arbitrary dimensions and the definition of an F-Lie algebra, the underlying mathematical structure, was given.[24] However, when $F > 2$, most of the examples of F-Lie algebras which have been found since then are of infinite dimensions. In this article, we show how one can construct many finite-dimensional F-Lie algebras starting from Lie algebras or Lie superalgebras equipped with appropriate symmetric forms. We define a notion of simplicity in this context and show that some of our examples are simple. Furthermore, we construct the first finite-dimensional FSUSY extensions of the Poincaré algebra by Inönü–Wigner contraction of certain F-Lie algebras.

These results can be seen as a first step in classifying F-Lie algebras.

(Received 4 April 2002; accepted for publication 24 April 2002)

The main aim of the present paper is using a Chernoff theorem (i.e., the Chernoff formula) to formulate and to prove some rigorous results on representations for solutions of Schrödinger equations by the Hamiltonian Feynman path integrals (=Feynman integrals over trajectories in the phase space). The corresponding theorem is related to the original (Feynman) approach to Feynman path integrals over trajectories in the phase space in much the same way as the famous theorem of Nelson is related to the Feynman approach to the Feynman path integral over trajectories in the configuration space. We also give a representation for solutions of some Schrödinger equations by a series which represents an integral with respect to the complex Poisson measure on trajectories in the phase space. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1500422]

I. INTRODUCTION

The Hamiltonian Feynman map (pseudomeasure) is a linear functional (its precise definition in our frame is given in the following) on a vector space of functionals whose common domain is a (vector) space of functions defined on a segment $[0,t]$, $t>0$ and taking values in the phase space $E=Q\times P$ of a classical Hamiltonian system. The value $\Phi(F)$ which the Feynman map Φ takes on a functional F is called the Hamiltonian Feynman path integral, or Feynman integral over trajectories in the phase space, of F; the number $\Phi(F)$ is often denoted by

$$\int F(q(\cdot),p(\cdot))\exp\left(i\int_0^t p(\tau)q'(\tau)\mathrm{d}\tau\right)\prod_0^t \mathrm{d}q(\tau)\mathrm{d}p(\tau)$$

and coincides with (can even be defined as) the limit of a suitable sequence of finite dimensional integrals of functions which are finite dimensional approximations for F. Such a definition can be traced back to Feynman himself;[1,2] there also exist some other definitions (see Refs. 3–8); in particular a definition of the Hamiltonian Feynman map by an analytical continuation of a Gaussian measure, which refutes a claim of Berezin,[9] was suggested in 1985[4,5] (see also Ref. 10).

If H is a classical Hamiltonian (i.e., a number valued function on the phase space) then one can show (under some additional assumptions) that the function

$$(t,z)\mapsto\int \exp\left(-i\int_0^t H(q(\tau)+z,p(\tau))d\tau+i\int_0^t p(\tau)q'(\tau)\mathrm{d}\tau\right)\phi_0(q(0)+z)\prod_0^t \mathrm{d}q(\tau)\mathrm{d}p(\tau)$$

gives a solution (in a proper space) to the Cauchy problem for the Schrödinger equation $i\phi'(t)$

[a]Electronic mail:a.tokarev@swansea.ac.uk

$=\hat{H}\phi(t)$, where $\hat{H}$ is a pseudodifferential operator (PDO) with the symbol (e.g., in the sense of Weyl) H. If $\hat{H}$ is a self-adjoint operator in a suitable domain then this formula gives an explicit representation of the one parameter unitary group $e^{-it\hat{H}}$, $t\in\mathbb{R}$.

The main aim of the present paper is to formulate and to prove some rigorous versions of these assertions using a Chernoff theorem[11] (i.e., the Chernoff formula). The corresponding Theorem 1 in the following is related to the original (Feynman) approach to Feynman path integrals over trajectories in the phase space in much the same way as the famous theorem from the paper (Ref. 12) of Nelson is related to the Feynman approach to the Feynman path integral over trajectories in the configuration space.

We give also a representation for solutions of some Schrödinger equations by a series which represents an integral with respect to the complex Poisson measure on trajectories in the phase space (Refs. 3–5; see also Refs. 13–16 for the case of configuration space). The corresponding result (in the proof of which we again use the Chernoff formula) is an improvement of a theorem from Ref. 3 (cf. Ref. 17).

Let E be a (real) vector space and for any $x\in E$ and any linear functional g on E let $\phi_g(x)=e^{ig(x)}$. If F_E is a locally convex space (LCS) of some complex valued functions on E, G is a vector space of some linear functionals on E distinguishing elements of E and, for any $g\in G$, $\phi_g\in F_E$ then the Fourier (G-)transform of any element $\eta\in F_E^*$ is the function on G which is denoted by $\tilde{\eta}$ or by $\mathcal{F}\eta$ and is defined by $\tilde{\eta}(g)(\equiv\mathcal{F}\eta(g))=\eta(\phi_g)$. If the set $\{\phi_g:g\in G\}$ is total in F_E (that means that the linear span of $\{\phi_g:g\in G\}$ is dense in F_E) then the element η (which can be called in this respect an F_E-distribution, or a distribution on E) is uniquely defined by its Fourier transform. In the following sometimes we do not define explicitly the space F_E and even drop the symbol F_E.

If b is a quadratic functional on E^*, $a\in E$ and $\alpha\in\mathbb{C}$ then the Feynman α-pseudomeasure on E, with the correlation functional b and mean value a, is the distribution $\Phi_{b,a,\alpha}$ on E whose Fourier transform is defined by

$$\mathcal{F}\Phi_{b,a,\alpha}(g)=\exp\left\{\frac{\alpha b(g)}{2}+ig(a)\right\}.$$

Let $E=Q\times P$, where Q and P are LCS, $Q=P^*$, $P=Q^*$ (as vector spaces); the space $G=P\times Q$ is identified with a space of linear functionals on E [for any $g=(p_g,q_g)\in G$ and $x=(q,p)\in E$ $g(x)=p_g(q)+p(q_g)$]. Then the Hamiltonian (or symplectic) Feynman pseudomeasure on E is any Feynman i-pseudomeasure on E with the correlational functional b defined by $b(p_g,q_g)=2p_g(q_g)$. The Hamiltonian Feynman pseudomeasure which we use in the following is a so-called sequential Feynman pseudomeasure.

The sequential Feynman pseudomeasure on E is defined as follows (now we only define what one can call a sequential Feynman pseudomeasure with the zero mean value but the general case is quite similar). Let $\{E_n:n\in\mathbb{N}\}$ be an increasing sequence of finite dimensional vector subspaces of $E(=Q\times P)$ such that, for any $n\in\mathbb{N}$, $E_n=Q_n\times P_n$, where Q_n and P_n are vector subspaces of Q and P, respectively. Then the value of the sequential Feynman pseudomeasure $\Phi_{\{E_n\}}$, associated with the sequence $\{E_n:n\in\mathbb{N}\}$, on a function $f:E\to\mathbb{C}$ [this value is called a sequential Feynman (path) integral of f] is defined by

$$\Phi_{\{E_n\}}(f)=\lim\left(\int_{E_n}e^{i\langle p,q\rangle}\mathrm{d}q\,\mathrm{d}p\right)^{-1}\int_{E_n}f(q,p)e^{i\langle p,q\rangle}\mathrm{d}q\,\mathrm{d}p$$

[where $\langle p,q\rangle=p(q)$] if this limit exists. So the fact that a function belongs to the domain of $\Phi_{\{E_n\}}$ depends only on its restrictions to E_n. In the preceding formula we used some regularized integrals whose definition is given in the following.

A locally integrable in the sense of Bochner function g on $\mathbb{R}^n$ taking values in a Banach space is called integrable if there exists the limit $\lim_{\epsilon\to 0}\int_{\mathbb{R}^n} g(s)e^{-\epsilon|s|^2}\mathrm{d}s$ $(\epsilon>0)$; then the integral $\int_{\mathbb{R}^n} g(s)\mathrm{d}s$ is defined by $\int_{\mathbb{R}^n} g(s)\mathrm{d}s=\lim_{\epsilon\to 0}\int_{\mathbb{R}^n} g(s)e^{-\epsilon|s|^2}\mathrm{d}s$, $\epsilon>0$.

If $f(\cdot,\cdot):\mathbb{R}^m\times\mathbb{R}^k\to\mathbb{C}$ is a measurable function then we define the integral $\int_{\mathbb{R}^k} f(q,u)\mathrm{d}u$ as follows. We assume that $\int_{\mathbb{R}^k} e^{-\epsilon|u|^2}|f(q,u)|\mathrm{d}u<\infty$ for almost all $q\in\mathbb{R}^m$ and for all $\epsilon>0$. We also assume that the function I_ϵ which is defined by $I_\epsilon(q)=\int_{\mathbb{R}^k} e^{-\epsilon|u|^2}f(q,u)\mathrm{d}u$ belongs to $L^2(\mathbb{R}^m)$ and I_ϵ converges in $L^2(\mathbb{R}^m)$ when $\epsilon\to 0$. Finally we put $\int_{\mathbb{R}^k} f(\cdot,u)\mathrm{d}u=\lim_{\epsilon\to 0} I_\epsilon(\cdot)$, where the limit is taken in $L^2(\mathbb{R}^m)$.

One could also define $\int g(s)\mathrm{d}s$ to be equal to the limit $\lim_{\epsilon\to 0}\int g(s)\phi(\epsilon s)\mathrm{d}s$ where $\phi\in\mathcal{D}(\mathbb{R}^n)$, $\phi(0)=1$ if this limit exists for any such ϕ (then it does not depend on the choice of ϕ). We have chosen the above-formulated more restricted definition for the sake of simplicity.

In what follows the spaces Q and P will be spaces of some functions defined on subsets of the real line and taking values in finite dimensional vector spaces (in applications they are configuration and momentum spaces of some Hamiltonian systems).

Namely for any Banach space T and any $a>0$ let $C_g([0,a],T)$ be the vector space of all functions on $[0,a]$ taking values in T whose distributional derivatives are measures with finite supports and let $C_g^0([0,a],T)$ (respectively, $C_g^1([0,a],T)$) denote the vector space of all right continuous (respectively, left continuous) functions from $C_g([0,a],T)$. For any $\tau\in(0,1)$ let $C_g^\tau([0,a],T)$ be the collection of functions f having the form $f=(1-\tau)g_f^0+\tau g_f^1$, where $g_f^0\in C_g^0([0,a],T)$, $g_f^1\in C_g^1([0,a],T)$ and distributional derivatives of g_f^0 and g_f^1 coincide.

Let $\mathcal{Q}$, $\mathcal{P}$ be finite dimensional Euclidean spaces and for any $t>0$, $\tau\in[0,1]$ let Q_t be the image of $C_g^0([0,t],\mathcal{Q})$ in $L_2([0,t],\mathcal{Q})$, $P_t^\tau=C_p^\tau([0,t],\mathcal{P})$, $E_t^\tau=Q_t\times P_t^\tau$. The spaces Q_t and P_t^τ are taken in duality by the form $(q(\cdot),p(\cdot))\mapsto\int_0^t p(s)q'(s)\mathrm{d}s$ where $q'(s)\mathrm{d}s$ denotes the measure which is the distributional derivative of $q(\cdot)$. We will consider elements of E_t^τ as functions taking values in $\mathcal{Q}\times\mathcal{P}$.

Now we will define a sequence $\{E_n\}$ of subspaces of E_t^τ to which we associate the sequential Feynman pseudomeasure. Let $t_0=0$ and, for any $n\in\mathbb{N}$ and any $k\in\mathbb{N}, k\leqslant 2^n$ let $t_k=k2^{-n}t$. We define E_n to be equal to the collection of functions from E_t^τ the restrictions of which to any interval $((k-1)2^{-n},k2^{-n})(k\in\mathbb{N})$ are constant functions. If f is a function on E_t^τ then the sequential Feynman integral over this space, of f, denoted by

$$\int_{E_t^\tau} f(q(\cdot),p(\cdot))\exp\left(i\int_0^t p(s)q'(s)\mathrm{d}s\right)\prod_0^t \mathrm{d}q(s)\mathrm{d}p(s),$$

is defined to be equal to $\Phi_{\{E_n\}}(f)$ (for the sake of simplicity we assume that $z=0$). One can check immediately that for any $\tau\in[0,1]$ the sequential Feynman integral defines a Hamiltonian Feynman pseudomeasure Φ^τ on E_t^τ: $\Phi^\tau(f)=\int_{E_t^\tau} f(q(\cdot),p(\cdot))\exp(i\int_0^t p(s)q'(s)\mathrm{d}s)\Pi_0^t\mathrm{d}q(s)\mathrm{d}p(s)$.

The main result of the paper, about the representation of solutions to the Schrödinger equation by the Feynman integral over trajectories in the phase space, is based on the observation that if $f(q,p)=\exp(-i\int_0^t H(q(\tau),p(\tau))\mathrm{d}\tau)\phi_0(q(0))$ then the finite dimensional integrals which were used above to define the sequential Feynman pseudomeasure coincide with $[\widehat{(e^{-i(t/n)H})^n}\phi_0](0)$; then one can use the Chernoff theorem according to which

$$e^{-it\hat{H}}\phi=\lim_{n\to\infty}\widehat{(e^{-i(t/n)H})^n}\phi,$$

where the caret means the PDO with the corresponding τ-symbol. It is worth mentioning that just the representation of the latter limit as a Feynman path integral allows are to discover its various connections with stochastic analysis.

Now we would like to mention some related results about Feynman path integrals over trajectories in the phase space. Actually there exists a surprisingly small number of mathematical papers devoted to such Feynman path integrals; even in the very recent book—Ref. 18—there is

actually no information on the subject. Nevertheless one can point out some mathematical texts on the problem. In particular in papers Refs. 19 and 20 the authors proved a convergence of some approximations to Feynman path integrals over trajectories in the phase space using the method of finite differences. A similar convergence was proved in Ref. 21 using some direct calculations. On the other hand in Refs. 4 and 5 (cf. Refs. 8, 22, and 23) an analytical continuation and Parseval equality (i.e., Fourier transform) were suggested to investigate Feynman path integrals over trajectories in the phase space; the latter approach uses a Poisson-type measure on the trajectories in the phase space and can be considered as an extension to the phase space of the approach of Albeverio–Hoegh–Krohn–Maslov–Chebotarev, which was originally applied only to Feynman integrals over trajectories either in the configuration or in the momentum space. Both these approaches—for Hamiltonian Feynman path integrals—were developed in some detail in Ref. 3; in particular using an integration over a Poisson-type measure some decompositions of solutions to Schrödinger equations were obtained (for an approach via analytical continuation to Feynman integrals for the Dirac equation see Ref. 24).

The main novelty in the approach which we use in the present paper is the direct application of the Chernoff formula (see Ref. 17) rather than the Trotter formula; besides we use the same Chernoff formula in order to improve some results from Ref. 3 (cf. Refs. 17 and 25) about representations of solutions of Schrödinger equations by Feynman integrals over Poisson-type measures. In both cases the more direct approach allows us to get representation theorems for new classes of Hamiltonians.

Notations and terminology of Refs. 26 and 27 are usually used without explanations. For any topological space X the symbol $\mathcal{B}(X)$ denotes the σ algebra of its Borel subsets; the symbol δ_x denotes the Dirac measure concentrated at the point $x \in X$; if μ is a measure on $(X,\mathcal{B}(X))$ and h is a $(\mathcal{B}(Y),\mathcal{B}(X))$ measurable mapping of X into a topological space Y then μh^{-1} is the image of μ with respect to this mapping; $v(\mu)$ is the total variation of μ. Besides $\mu \otimes \nu$ is the product of measures μ and ν, $\nu^{\otimes n}$ is the nth product power of the measure ν.

If X and Y are real Banach spaces, then $M(X)$ is the space of all complex-valued σ-additive measures on $(X,\mathcal{B}(X))$; we assume that $M(X)$ is equipped with the norm $v(\cdot)$. For $\mu,\nu \in M(X)$ let $\mu * \nu$ be the convolution of measures μ and ν; ν^{*n}—the nth convolution power of the measure ν, $\nu^{*0} = \delta_0$. For any $p \in X$ let ν_p be the shift of the measure ν with respect to the vector $p \in X$: $\nu_p(A) = \nu(A+p)$, $A \in \mathcal{B}(X)$.

Any measure $\mu \in M(X)$ is considered as an F_X-distribution for a proper F_X; if $\langle \cdot,\cdot \rangle : X \times Y \to \mathbb{R}$ is a duality between X and Y then for the Fourier Y-transform of μ the following identity holds: $\tilde{\mu}(z) (= \mathcal{F}\mu) = \int_X e^{i\langle z,x \rangle} \mu(\mathrm{d}x)$. In a similar way if $\phi \in L^2(\mathbb{R}^n)$ then $\tilde{\phi}(z) = \int_{\mathbb{R}^n} e^{i(z,x)_{\mathbb{R}^n}} \phi(x) \mathrm{d}x$ (the signs under the exponents depend on agreements).

The paper is organized as follows. In Sec. II we formulate a theorem which is an (easy) generalization of the Chernoff theorem; in Sec. III we apply this theorem to obtain some representations of solutions for Schrödinger equations. We call our main formula here a Feynman formula. What is done in Sec. IV can be described as obtaining representations of solutions for Schrödinger equations by integrals over Poisson-type complex measures on trajectories in the phase space. As was already mentioned, we again use the Chernoff theorem in the proof.

II. THE CHERNOFF THEOREM

Let X be a Banach space, $\mathcal{L}(X)$—the space of all bounded linear operators in X equipped, if otherwise not mentioned, with the topology of pointwise convergence (strong operator topology), $\|\cdot\|$—the operator norm on $\mathcal{L}(X)$, I—the identity operator in X. For any linear operator A in X let $D(A)$ be the domain of A.

The (strong) derivative at zero of a function $F:[0,\infty) \to \mathcal{L}(X)$ is a linear operator $F'(0):D(F'(0)) \to X$ defined by $F'(0)\phi = \lim_{h \to 0} h^{-1}(F(h)\phi - F(0)\phi)$, where $D(F'(0))$ is the space of all $\phi \in X$ such that the limit exists.

In this paper the following theorem is called the Chernoff theorem (this theorem is an immediate generalization of the theorem proved in Ref. 11).

Theorem 1: *Let X be a Banach space. Let $F:[0,\infty)\to\mathcal{L}(X)$ be a strongly continuous mapping such that $F(0)=I$, $\|F(t)\|\leqslant\exp(at)$ for some $a\in\mathbb{R}$, D be a linear subspace in $D(F'(0))$ and the restriction of $F'(0)$ to D be a closable operator whose closure we denote by C. If C is the generator of a strongly continuous semigroup $\exp(tC)$, then $F(t/n)^n$ converges to $\exp(tC)$ as $n\to\infty$ in the strong operator topology uniformly with respect to $t\in[0,T]$ for each $T>0$.*

III. THE FEYNMAN FORMULA VIA THE CHERNOFF THEOREM

Let the caret be a mapping from a space of functions on $\mathbb{R}^N\times\mathbb{R}^N$ into the space of linear operators in $L^2(\mathbb{R}^N)$, $\hat{}:H\to\hat{H}$ (then one can say that H is a symbol of $\hat{H}$). We say that the Feynman formula is valid for an operator $\hat{H}|_L$ which is the restriction of $\hat{H}$ to a domain $L\subset D(\hat{H})$ if $D(\widehat{e^{-i(t/n)H}})=L^2(\mathbb{R}^N)$ for any $n\in\mathbb{N}$ and $t\in[0,\infty)$, there exists the closure $\hat{H}^c$ of the operator $\hat{H}|_L$ and $-i\hat{H}^c$ is the generator of a strongly continuous semigroup $\exp(-it\hat{H}^c)$, $t\in[0,\infty)$,

$$e^{-it\hat{H}^c}\phi=\lim_{n\to\infty}\widehat{(e^{-i(t/n)H})}^n\phi, \tag{1}$$

for all $\phi\in L^2(\mathbb{R}^N)$ and $t\in[0,\infty)$. Of course, if $\hat{H}^c$ is self-adjoint, $e^{-it\hat{H}^c}$ is a unitary group.

For a function $\psi:\Omega\to\mathbb{C}$ and $a>0$ define $\overline{\psi}_a:\Omega\to\mathbb{C}$ by $\overline{\psi}_a(\omega)=\psi(\omega)$ if $|\psi(\omega)|\leqslant a$ and $\overline{\psi}_a(\omega)=0$ if $|\psi(\omega)|>a$.

Let $H:\mathbb{R}^N\times\mathbb{R}^N\to\mathbb{C}$ be a measurable function and $\tau\in[0,1]$. We define the operator $\hat{H}:D(\hat{H})\to L^2(\mathbb{R}^N)$ by

$$(\hat{H}\phi)(q)=\lim_{a\to\infty}(2\pi)^{-N}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\overline{H}_a((1-\tau)q+\tau q',p)e^{ip(q-q')}\phi(q')\,dq'\,dp, \tag{2}$$

where the limit is taken in $L^2(\mathbb{R}^N)$. We assume that $D(\hat{H})$ is the set of all $\phi\in L^2(\mathbb{R}^N)$ such that $(\hat{H}\phi)(\cdot)$ exists. We say that the function $H(\cdot,\cdot)$ is the τ-symbol of the pseudodifferential operator $\hat{H}$ and the mapping caret is the τ-quantization.

Note that the zero-quantization is the qp-quantization, the one-quantization is the pq-quantization and the one-half-quantization is the Weyl quantization.

Lemma 2: Let $\mu\in M(\mathbb{R}^N\times\mathbb{R}^N)$, $h=\tilde{\mu}$, $F:\mathbb{R}^N\to\mathbb{C}$ be a bounded measurable function, $H(q,p)=h(q,p)F(p)$ and the caret be the τ-quantization ($\tau\in[0,1]$). Then $D(\hat{H})=L^2(\mathbb{R}^N)$,

$$\hat{H}\phi=\mathcal{F}\int_{\mathbb{R}^N\times\mathbb{R}^N}F(\cdot-(1-\tau)y)e^{i(\cdot-(1-\tau)y)x}[\mathcal{F}^{-1}\phi](\cdot-y)\,\mu(dy,dx), \tag{3}$$

for all $\phi\in L^2(\mathbb{R}^N)$ and $\|\hat{H}\|\leqslant\|F\|_\infty v(\mu)$. In particular, $\hat{h}\in\mathcal{L}(L^2(\mathbb{R}^N))$ and $\|\hat{h}\|\leqslant v(\mu)$.

Proof: Let $\phi\in L^2(\mathbb{R}^N)$, $\epsilon>0$ and $(P_\epsilon(H)\phi)(q)=(2\pi)^{-N}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\exp(-\epsilon|p|^2-\epsilon|q'|^2)H((1-\tau)q+\tau q',p)e^{ip(q-q')}\phi(q')\,dq'\,dp$. Using the Fubini theorem we get

$$\begin{aligned}(P_\epsilon(H)\phi)(q)&=(2\pi)^{-N}\int_{\mathbb{R}^N\times\mathbb{R}^N}\Bigg(\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}F(p)\\&\quad\times e^{-\epsilon|p|^2-\epsilon|q'|^2}e^{i(1-\tau)qy+i\tau q'y+ipx}e^{ip(q-q')}\phi(q')\,dq'\,dp\Bigg)\mu(dy,dx)\\&=\mathcal{F}\Bigg[\int_{\mathbb{R}^N\times\mathbb{R}^N}f_\epsilon(y,x;\cdot)\,\mu(dy,dx)\Bigg](q),\end{aligned} \tag{4}$$

where $f_\epsilon(y,x;p)=F(p-(1-\tau)y)\chi_\epsilon(p-(1-\tau)y)e^{i(p-(1-\tau)y)x}[\mathcal{F}^{-1}\chi_\epsilon\phi](p-y)$ and $\chi_\epsilon(\cdot)=e^{-\epsilon|\cdot|^2}$.

The latter integral in (4) is the Bochner integral of the function $g_\epsilon:\mathbb{R}^N\times\mathbb{R}^N\to L^2(\mathbb{R}^N)$, $g_\epsilon(y,x)(\cdot)=f_\epsilon(y,x;\cdot)$ with respect to the measure μ. We observe that $\|g_\epsilon(y,x)\|\leqslant\|\mathcal{F}^{-1}\|\|\phi\|_{L^2}\|F\|_\infty$ and that $\lim_{\epsilon\to\infty}g_\epsilon(y,x)=g(y,x)$ in $L^2(\mathbb{R}^N)$, where $g(y,x)=F(\cdot-(1-\tau)y)e^{i(\cdot-(1-\tau)y)x}[\mathcal{F}^{-1}\phi](\cdot-y)$. Applying Lebesgue's dominated convergence theorem to the Bochner integral we see that $P(H)\phi=\lim_{\epsilon\to0}P_\epsilon(H)\phi=\mathcal{F}\int_{\mathbb{R}^N\times\mathbb{R}^N}g(y,x)\mu(\mathrm{d}y,\mathrm{d}x)\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$. Since H is a bounded function we see that $\overline{H_a}=H$ for sufficiently large $a>0$. From this it follows that $\hat{H}\phi$ is defined for all $\phi\in L^2(\mathbb{R}^N)$ and $\hat{H}\phi=P(H)\phi$. Thus (3) is valid. From (3) it follows that $\|\hat{H}\|\leqslant\|F\|_\infty v(\mu)$. The lemma is proved.

Corollary 3: Let $\mu\in M(\mathbb{R}^N\times\mathbb{R}^N)$, $h=\tilde{\mu}$, $b:\mathbb{R}^N\to\mathbb{C}$ be a measurable function such that $\operatorname{Im}b\leqslant C_b$ *for some $C_b\in\mathbb{R}$, $B,H:\mathbb{R}^N\times\mathbb{R}^N\to\mathbb{C}$, $B(q,p)=b(p)$, $H(q,p)=b(p)+h(q,p)$, the caret be a τ-quantization ($\tau\in[0,1]$), $f_t(q,p)=\exp(-itH(q,p))$ and $A(t)=\hat{f}_t$. Then $A(t)\in\mathcal{L}(L^2(\mathbb{R}^N))$ for $t\in[0,\infty)$, $A(0)=I$, $\|A(t)\|\leqslant e^{ta}$ for some $a\in\mathbb{R}$, the function $A:[0,\infty)\to\mathcal{L}(L^2(\mathbb{R}^N))$ is strongly continuous, $A'(0)=-i\hat{B}-i\hat{h}$ and $D(A'(0))=D(\hat{B})$.*

Proof: For $k\in\mathbb{N}$ and $t\in[0,\infty)$ define operator $A_k(t):L^2(\mathbb{R}^N)\to L^2(\mathbb{R}^N)$, $A_k(t)\phi=\mathcal{F}\int_{\mathbb{R}^N\times\mathbb{R}^N}e^{-itb(\cdot-(1-\tau)y)}e^{i(\cdot-(1-\tau)y)x}[\mathcal{F}^{-1}\phi](\cdot-y)\mu^{*k}(\mathrm{d}y,\mathrm{d}x)$. Since $\|e^{-itb}\|_\infty\leqslant e^{tC_b}$ we have $\|A_k(t)\phi\|\leqslant e^{tC_b}\|\phi\|_{L^2}v(\mu)^k$. Therefore $\|A_k(t)\|\leqslant e^{tC_b}v(\mu)^k$.

Since $\exp(-ith)=\tilde{\nu}$ for $\nu=\delta_0+\sum_{k=1}^\infty((-it)^k/k!)\mu^{*k}$ from Lemma 2 it follows that $D(A(t))=L^2(\mathbb{R}^N)$ and we have $A(t)\phi=e^{-it\hat{B}}\phi+\sum_{k=1}^\infty((-it)^k/k!)A_k(t)\phi$ for $\phi\in L^2(\mathbb{R}^N)$. Therefore $\|A(t)\|\leqslant e^{tC_b}+\sum_{k=1}^\infty e^{tC_b}v(\mu)^kt^k/k!=e^{t(C_b+v(\mu))}$. It is clear that $A(0)=I$. Since $A_k(\cdot):[0,\infty)\to\mathcal{L}(L^2(\mathbb{R}^N))$ is strongly continuous we see that $A(\cdot)$ is strongly continuous.

Note that $A_1(0)\phi=\lim_{t\to0}A_1(t)\phi=\hat{h}\phi$ for $\phi\in L^2(\mathbb{R}^N)$ (see Lemma 2). Therefore $\lim_{t\to0}\sum_{k=1}^\infty(-it)^kA_k(t)\phi/k!t=-i\hat{h}\phi+\sum_{k=2}^\infty(-i)^k\lim_{t\to0}t^{k-1}A_k(t)\phi/k!=-i\hat{h}\phi$ for all $\phi\in L^2(\mathbb{R}^N)$. Thus $A'(0)=-i\hat{B}-i\hat{h}$ and $D(A'(0))=D(\hat{B})$. The corollary is proved.

Lemma 4: Let $\mu\in M(\mathbb{R}^N\times\mathbb{R}^N)$, $h=\tilde{\mu}$, the caret be the qp- or pq-quantization, $k\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ be a real function, $H=h+k$, $g_t(q,p)=\exp(-itH(q,p))$ and $V(t)=\hat{g}_t$, $t\geqslant0$. Then

(a) $\hat{H}\in\mathcal{L}(L^2(\mathbb{R}^N))$ and $\|\hat{H}\|\leqslant v(\mu)+\varkappa\|k\|_{L^2}$ for some $\varkappa>0$,

(b) $V(t)\in\mathcal{L}(L^2(\mathbb{R}^N))$, $V(0)=I$, $\|V(t)\|\leqslant\exp(at)$ for some $a\in\mathbb{R}$, the function $V:[0,\infty)\to\mathcal{L}(L^2(\mathbb{R}^N))$ is strongly continuous and $V'(0)=-i\hat{H}$, $D(V'(0))=L^2(\mathbb{R}^N)$.

(c) Let $F_0,G_0:\mathbb{R}^N\to\mathbb{C}$ be bounded measurable functions and $F:\mathbb{R}^N\times\mathbb{R}^N\to\mathbb{C}$. Let $F(q,p)=F_0(p)$, $G(q,p)=G_0(q)$. If the caret is the qp-quantization then $\widehat{FG}_t=\hat{G}\hat{g}_t\hat{F}$. If the caret is the pq-quantization then $\widehat{FG}_t=\hat{F}\hat{g}_t\hat{G}$.

Proof: We give the proof only in the case when the caret is the qp-quantization. For the pq-quantization the proof is analogous. Let $\sigma\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$. Define operator $U(\sigma):L^2(\mathbb{R}^N)\to L^2(\mathbb{R}^N)$, $[U(\sigma)\phi](q)=\int_{\mathbb{R}^N}\sigma(q,p)e^{ipq}\phi(p)\mathrm{d}p$. Note that $|\int_{\mathbb{R}^N}\sigma(q,p)e^{ipq}\phi(p)\mathrm{d}p|\leqslant(\int_{\mathbb{R}^N}|\sigma(q,p)|^2\mathrm{d}p)^{1/2}\|\phi\|_{L^2}$ for all $\sigma\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ and $\phi\in L^2(\mathbb{R}^N)$; hence $U(\sigma)\in\mathcal{L}(L^2(\mathbb{R}^N))$ and $\|U(\sigma)\|\leqslant\|\sigma\|_{L^2}$ for all $\sigma\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$.

For $\epsilon,a>0$ let $(P_{\epsilon,a}\phi)(q)=(2\pi)^{-N}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}e^{-\epsilon|p|^2-\epsilon|q'|^2}\overline{\sigma_a}(q,p)e^{ip(q-q')}\phi(q')\mathrm{d}q'\,\mathrm{d}p$. Then $P_{\epsilon,a}\phi=U(\overline{\sigma_a})C_\epsilon\mathcal{F}^{-1}C_\epsilon\phi$, where C_ϵ is the multiplication operator by the function $e^{-\epsilon|\cdot|^2}$. Hence $P_a\phi=\lim_{\epsilon\to0}P_{\epsilon,a}\phi=U(\overline{\sigma_a})\mathcal{F}^{-1}\phi$. Since $\overline{\sigma_a}\to\sigma$ as $a\to\infty$ in $L^2(\mathbb{R}^N\times\mathbb{R}^N)$ we get $\hat{\sigma}\phi=\lim_{a\to\infty}P_a\phi=U(\sigma)\mathcal{F}^{-1}\phi$. Thus $\hat{\sigma}\in\mathcal{L}(L^2(\mathbb{R}^N))$ and $\|\hat{\sigma}\|\leqslant\|\sigma\|_{L^2}\|\mathcal{F}^{-1}\|$. Since $k\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ and $H=h+k$, in view of Lemma 2 we get $\hat{H}=\hat{h}+\hat{k}$, $\hat{H}\in\mathcal{L}(L^2(\mathbb{R}^N))$ and $\|\hat{H}\|\leqslant v(\mu)+\varkappa\|k\|_{L^2}$ for some $\varkappa>0$.

Let $f_t(q,p)=e^{-ith(q,p)}$, $A(t)=\hat{f}_t$ and

$$w_t(q,p)=(e^{-itk(q,p)}-1+itk(q,p))e^{-ith(q,p)},\quad u_t(q,p)=-itk(q,p)e^{-ith(q,p)}.$$

For $x\in\mathbb{R}$ we have $|\exp(-ix)-1+ix|=|x|\varepsilon(x)$, where the function $\varepsilon(\cdot)$ is bounded and $\varepsilon(x)\to0$ as $|x|\to0$. Therefore $w_t\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$. Hence $\hat{w}_t\in\mathcal{L}(L^2(\mathbb{R}^N))$ and $\|\hat{w}_t\|\leqslant\varkappa\|w_t\|_{L^2}$

$\leqslant t\varkappa \exp(tM)\|k\varepsilon(tk)\|_{L^2}=t\varepsilon_1(t)$ and $\varepsilon_1(t)\to 0$ as $t\to 0$, where $M=\sup_{q,p}|h(q,p)|$. This implies that if $B(t)=\hat{w}_t$ then $B'(0)=0$. Since $u_t\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ we have $\hat{u}_t\in\mathcal{L}(L^2(\mathbb{R}^N))$. From Corollary 3 it follows that $\hat{f}_t\in\mathcal{L}(L^2(\mathbb{R}^N))$ and we see that $V(t)=A(t)+\hat{u}_t+\hat{w}_t$. Hence $V(t)\in\mathcal{L}(L^2(\mathbb{R}^N))$. By Corollary 3 we get $A'(0)=-i\hat{h}$ and $D(A'(0))=L^2(\mathbb{R}^N)$. Direct calculations show that if $E(t)=\hat{u}_t$ then $E'(0)=-i\hat{k}$ and $D(E'(0))=L^2(\mathbb{R}^N)$. Thus $V'(0)=-i\hat{h}-i\hat{k}=-i\hat{H}$ and $D(V'(0))=L^2(\mathbb{R}^N)$. Since $\|\hat{u}_t\|\leqslant bt\exp(tM)$ and $\|\hat{w}_t\|\leqslant ct\exp(tM)$ for some $b,c>0$ we obtain $\|V(t)\|\leqslant\exp(t(v(\mu)+b+c+M))$. From the fact that for all $t_0\in[0,\infty)$ $\|u_t-u_{t_0}\|_{L^2}\to 0$ and $\|w_t-w_{t_0}\|_{L^2}\to 0$ as $t\to t_0$ it follows that $\|\hat{u}_t-\hat{u}_{t_0}\|\to 0$ and $\|\hat{w}_t-\hat{w}_{t_0}\|\to 0$ as $t\to t_0$. By virtue of Corollary 3 the mapping $A:[0,\infty)\to\mathcal{L}(L^2(\mathbb{R}^N))$ is strongly continuous. Hence the mapping $V(\cdot)$ is strongly continuous. It is clear that $V(0)=I$.

To prove (c) we note that for all $\sigma\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ we have $FG\sigma\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ and $\widehat{FG\sigma}=U(FG\sigma)\mathcal{F}^{-1}=\hat{G}U(\sigma)\mathcal{F}^{-1}\hat{F}=\hat{G}\hat{\sigma}\hat{F}$. If $\sigma=\tilde{\nu}$ for some $\nu\in M(\mathbb{R}^N\times\mathbb{R}^N)$ then it follows from (3) that $\widehat{F\sigma}=\hat{\sigma}\hat{F}$. Since F,G,σ are bounded functions, from (2) it follows that $\widehat{FG\sigma}=\hat{G}\widehat{F\sigma}$. Hence $\widehat{FG\sigma}=\hat{G}\hat{\sigma}\hat{F}$. Thus $\widehat{FGf_t}=\hat{G}\hat{f}_t\hat{F}$. Therefore since $w_t,u_t\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ and $g_t=f_t+w_t+u_t$ we get $\widehat{FGg_t}=\hat{G}\hat{g}_t\hat{F}$. The lemma is proved.

In the next theorem we assume that measurable functions $f_0,g_0:\mathbb{R}^N\to\mathbb{C}$ satisfy the following conditions. We assume that $\operatorname{Im} f_0\leqslant\tilde{c}$ and $\operatorname{Im} g_0\leqslant\tilde{c}$ for some $\tilde{c}\in\mathbb{R}$. Let $f,g:\mathbb{R}^N\times\mathbb{R}^N\to\mathbb{C}$, $f(q,p)=f_0(p)$, $g(q,p)=g_0(q)$. Suppose that there exists the closure A of the operator $\hat{f}+\hat{g}|_L$ defined on a subspace $L\subset D(\hat{f})\cap D(\hat{g})$. We assume that $-iA$ is the generator of a strongly continuous semigroup. For example in the case of $\mathbb{R}^3$ real functions $f_0(p)=p^2$, $p\in\mathbb{R}^3$ and $g_0\in L^2(\mathbb{R}^3)+L^\infty(\mathbb{R}^3)$ satisfy the introduced condition (see Ref. 28 Chap. X,2, Theorem X.15).

Theorem 5: *Let the caret be the qp- or pq-quantization, $\mu\in M(\mathbb{R}^N\times\mathbb{R}^N)$, $h=\tilde{\mu}$, $k\in L^2(\mathbb{R}^N\times\mathbb{R}^N)$ be a real function, $H(q,p)=f_0(p)+g_0(q)+h(q,p)+k(q,p)$. Then the Feynman formula is valid for the operator $\hat{H}|_L$.*

Proof: We give a proof only when the caret is the qp-quantization. For the case of pq-quantization the proof is analogous. It is sufficient to apply the Chernoff theorem to the function $F(t)=e^{\widehat{-itH}}$ choosing $D=L(\subset D(\hat{f})\cap D(\hat{g}))$. According to Lemma 4(c) we get $F(t)=e^{\widehat{-itg}}e^{\widehat{-it(h+k)}}e^{\widehat{-itf}}=e^{-it\hat{g}}e^{\widehat{-it(h+k)}}e^{-it\hat{f}}$. In view of Lemma 4(b) the restriction $F'(0)|_D$ of the strong derivative $F'(0)$ to $D(=L)$ coincides with $-i(\hat{f}+\hat{g}+\hat{h}+\hat{k})$ on D. Hence $F'(0)|_D=\hat{H}|_L$. By Lemma 4(a) we have $\hat{h}+\hat{k}\in\mathcal{L}(L^2(\mathbb{R}^N))$. Therefore the closure $\hat{H}^c$ of $\hat{H}|_L$ exists and is equal to $-i(A+\hat{h}+\hat{k})$ with $D(\hat{H}^c)=D(A)$. From the theorem on perturbations of generators of semigroups (Ref. 26, Chap. VIII,1, Theorem 19) it follows that $-i\hat{H}^c$ is the generator of a strongly continuous semigroup $\exp(-it\hat{H}^c)$. Using Lemma 4 one can verify the other conditions of Theorem 1. The theorem is proved.

Direct application of Theorem 1 and Corollary 3 gives a proof of Theorem 6.

Theorem 6: *Let the caret be a τ-quantization ($\tau\in[0,1]$), $f:\mathbb{R}^N\to\mathbb{C}$ be a measurable function such that $\operatorname{Im} f\leqslant C_f$ for some $C_f\in\mathbb{R}$, $h=\tilde{\mu}$, where $\mu\in M(\mathbb{R}^N\times\mathbb{R}^N)$, and $H(q,p)=f(p)+h(q,p)$. Then the Feynman formula is valid for $\hat{H}$ defined on $D(\hat{H})$.*

We expect that a similar approach can be used to extend Theorems 5 and 6 to a more general situation. In order to do that it is of course necessary to generalize properly the Chernoff theorem.

The Feynman formula (1) gives a representation of solutions of the Schrödinger equation $i\,\mathrm{d}\phi/\mathrm{d}t=\hat{H}\phi$. One can prove statements similar to Theorems 5 and 6 for the "heat equation" $\mathrm{d}\phi/\mathrm{d}t=\hat{H}\phi$ if one substitutes hypotheses of Theorem 5 by some additional proper conditions. In particular: the operators $\hat{f}$, $\hat{g}$ and the closure C of the operator $(\hat{f}+\hat{g})|_L$ defined on a subspace $L\subset D(\hat{f})\cap D(\hat{g})$ are the generators of strongly continuous semigroups.

IV. THE SERIES REPRESENTATIONS OF SOLUTIONS

Let $D_m(t)=\{(t_1,\ldots,t_m)|0\leqslant t_m\leqslant\cdots\leqslant t_1\leqslant t\}$ for $t\geqslant 0$ and $D_m^0(t)=\{(t_1,\ldots,t_m)|0<t_m<\ldots<t_1<t\}$. Let λ_m be the Lebesgue measure on $\mathbb{R}^m$, $\lambda_{m,n}^t$ be the measure on $D_m(t)$ concentrated on

the set of elements $y \in D_m(t)$ such that $y_j \in T_n$, $T_n = \{(lt/n) \mid l = 1,\ldots,n\}$ and $\lambda^t_{m,n}(\{y\}) = (t/n)^m/k_1!\cdots k_n!$, where $0! = 1$ and k_l is the number of components of y equal to $lt/n, 1 \leqslant l \leqslant n$.

Lemma 7: $\lambda_m(D_m(t)) = v(\lambda^t_{m,n}) = t^m/m!$. *If* $f: D_m(t) \to \mathbb{R}$ *is a bounded function such that the restriction of* f *to* $D^0_m(t)$ *is continuous then* $\int_{D_m(t)} f \, d\lambda^t_{m,n} \to \int_{D_m(t)} f \, d\lambda_m$ *as* $n \to \infty$.

Proof: Fix $t > 0$, $m \in \mathbb{N}$ and for $y = (y_1, \ldots, y_m) \in (T_n)^m \cap D_m(t)$, $n \in \mathbb{N}$ we define the set $C_{n,y} = \{x \in \mathbb{R}^m \mid y_j - 1/n \leqslant x_j \leqslant y_j, j = 1, \ldots, m\} \cap D_m(t)$. The direct calculation shows that $\lambda_m(C_{n,y}) = \lambda^t_{m,n}(\{y\})$, $y \in (T_n)^m \cap D_m(t)$. Thus we get $v(\lambda^t_{m,n}) = \lambda_m(D_m(t))$. Direct calculations show that $\lambda_m(D_m(t)) = t^m/m!$.

Let $R_n(f) = \Sigma f(y) \lambda_m(C_{n,y})$, where the sum is taken over all $y \in (T_n)^m \cap D_m(t)$. Then $R_n(f)$ is a Riemannian sum for the integral $\int_{\mathbb{R}^m} F \, d\lambda_m$, where $F(x) = f(x)$ for $x \in D_m(t)$ and $F(x) = 0$ for $x \notin D_m(t)$. Since the set of points where the function F is discontinuous belongs to the boundary $\partial D_m(t)$ of $D_m(t)$ and $\lambda_m(\partial D_m(t)) = 0$ we get $\lim_{n \to \infty} R_n(f) = \int_{\mathbb{R}^m} F \, d\lambda_m = \int_{D_m(t)} f \, d\lambda_m$. The lemma is proved.

Actually the following theorem is an improvement of the Smolyanov–Shavgulidze formula.[17,25]

Theorem 8: *Let the caret denote the qp-quantization,* $P = Q = \mathbb{R}^N$, $a: P \to \mathbb{C}$ *be a measurable function such that* $\operatorname{Im} a \leqslant C_a$ *for some* $C_a \in \mathbb{R}$, $h: Q \times P \to \mathbb{C}$ *be the Fourier transform of a measure* $\nu \in M(P \times Q)$. *For* $t \in [0, \infty)$, $m = 0,1,\ldots$ *define functions* $U^m_t: \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{C}$, $U^0_t(q,p) = e^{-ita(p)}$ *and*

$$
\begin{aligned}
U^m_t(q,p) = (-i)^m \int_0^t dt_1 \int_0^{t_1} dt_2 \ldots \int_0^{t_{m-1}} dt_m \\
\times \int_{(P \times Q)^m} \exp\left(i \left\langle q, \sum_{l=1}^m p_l \right\rangle - ia\left(p + \sum_{l=1}^m p_l \right)(t - t_1) \right. \\
\left. - i \sum_{k=2}^m a\left(p + \sum_{l=k}^m p_l \right)(t_{k-1} - t_k) - ia(p) t_m \right) \\
\times \exp\left(i \sum_{k=1}^{m-1} \left\langle q_k, p + \sum_{l=k+1}^m p_l \right\rangle + i \langle q_m, p \rangle \right) \nu(dp_1, dq_1) \ldots \nu(dp_m, dq_m). \qquad (5)
\end{aligned}
$$

Then $\Sigma^\infty_{m=0} |U^m_t(q,p)| < \infty$ *and if* $U_t(q,p) = \Sigma^\infty_{m=0} U^m_t(q,p)$ *then* $\hat{U}_t \in \mathcal{L}(L^2(Q))$ *and* $t \mapsto \hat{U}_t$ *is a strongly continuous semigroup in* $L^2(Q)$ *with the generator* $-i\hat{H}$, *where* $H(q,p) = a(p) + h(q,p)$. *Moreover* $\hat{U}^m_t \in \mathcal{L}(L^2(Q))$ *and* $\hat{U}_t = \Sigma^\infty_{m=0} \hat{U}^m_t$, *where the sum converges in the uniform operator topology in* $\mathcal{L}(L^2(Q))$.

Proof: Let $A(q,p) = a(p)$. Note that $\hat{A}$ is the generator of the strongly continuous semigroup $B(t) = \hat{f}_t$, $f_t = \exp(-itA)$. Since $g_t = \exp(-ith) = \widetilde{\varkappa_t}$ for $\varkappa_t = \delta_0 + \Sigma^\infty_{k=1} ((-it)^k/k!) \nu^{*k}$, by Lemma 2 we get $\hat{g}_t = \Sigma^\infty_{k=0} ((-it)^k/k!) \widehat{h^k}$. From this it follows that the function $F(t) = \hat{g}_t \exp(-it\hat{A})$ satisfies the conditions of Theorem 1. In particular $F'(0) = -i(\hat{A} + \hat{h}) = -i\hat{H}$ and $D = D(\hat{A})$. Since by Lemma 2 $\hat{h} \in \mathcal{L}(L^2(\mathbb{R}^N))$, from the theorem on perturbation of generators of strongly continuous semigroups (see Ref. 26, Chap. VIII, 1, Theorem 19), it follows that $-i\hat{H} = -i(\hat{A} + \hat{h})$ is the generator of a semigroup $V_t = \exp(-it\hat{H})$. Thus by Theorem 1 we get

$$
e^{-it\hat{H}}\phi = \lim_{n \to \infty} (\widehat{e^{-i(t/n)h}} \widehat{e^{-i(t/n)A}})^n \phi
$$

for all $\phi \in L^2(Q)$.

Define the measures $\nu_n \in M(P\times Q)$, $\nu_n = \delta_0 + \Sigma_{k=1}^{\infty}((-it)^k/k!n^k)\nu^{*k}$, $n\in\mathbb{N}$. Then $\exp(-ith/n)=\widetilde{\nu}_n$. Denote $V_{n,t}=(\widehat{e^{-i(t/n)h}e^{-i(t/n)A}})^n$. Using Lemma 2 (with $\tau=0$ and $F\equiv 1$) and direct calculations we get

$$V_{n,t}\phi = \mathcal{F}\int_{(P\times Q)^n} \exp(i\Sigma_{k=1}^{n}\langle q_k, \cdot - \Sigma_{m=1}^{k} p_m\rangle)\exp\left(-i\frac{t}{n}\sum_{k=1}^{n} a(\cdot - \Sigma_{m=1}^{k} p_m)\right)$$
$$\times[\mathcal{F}^{-1}\phi](\cdot - p_1 - \cdots - p_n)\,\nu_n(dp_1,dq_1)\cdots\nu_n(dp_n,dq_n).$$

Let $(t_1,\ldots,t_r,(p_1,q_1),\ldots,(p_r,q_r))\in D_r(t)\times(P\times Q)^r$. Let $\overline{r}$ be the number of different elements in the set $\{t_1,\ldots,t_r\}$ and $j_0=0$, $1\leq j_1<\cdots<j_{\overline{r}}=r$ be such that $t_m=t_{j_k}$ for $j_{k-1}<m\leq j_k$ $(m=1,\ldots,r)$ and $t_{j_k}\neq t_{j_l}$ for $k\neq l$. For $1\leq k\leq\overline{r}$ we put $\overline{q_k}=\Sigma_{j_{k-1}<m\leq j_k} q_m$ and $\overline{p_k}=\Sigma_{j_{k-1}<m\leq j_k} p_m$.

Let $A_0=\mathcal{F}[e^{-ita(\cdot)}\mathcal{F}^{-1}\phi]$. Direct calculations show that

$$V_{n,t}\phi = A_0 + \sum_{r=1}^{\infty}(-i)^r\mathcal{F}\int_{D_r(t)}\int_{(P\times Q)^r}\exp(i\Sigma_{k=1}^{\overline{r}}\langle\overline{q_k},\cdot-\Sigma_{m=1}^{k}\overline{p_m}\rangle)\times\exp(-ia(\cdot)(t-t_1)$$
$$-i\Sigma_{k=2}^{r}a(\cdot-\Sigma_{m=1}^{k-1}p_m)(t_{k-1}-t_k)-ia(\cdot-\Sigma_{m=1}^{r}p_m)t_r)[\mathcal{F}^{-1}\phi](\cdot-p_1-\ldots-p_r)d\lambda_{r,n}^{t}$$
$$\otimes\nu^{\otimes r} = A_0 + \sum_{r=1}^{\infty}(-i)^r\mathcal{F}\int_{D_r(t)}\int_{(P\times Q)^r}\zeta_{r,\phi}\,d\lambda_{r,n}^{t}\otimes\nu^{\otimes r}, \tag{6}$$

where $\zeta_{r,\phi}: D_r(t)\times(P\times Q)^r\to L^2(\mathbb{R}^N)$, $\zeta_{r,\phi}(t_1,\ldots,t_r,(p_1,q_1),\ldots,(p_r,q_r))=\exp(i\Sigma_{k=1}^{\overline{r}}\langle\overline{q_k},\cdot-\Sigma_{m=1}^{k}\overline{p_m}\rangle - ia(\cdot)(t-t_1) - i\Sigma_{k=2}^{r}a(\cdot-\Sigma_{m=1}^{k-1}p_m)(t_{k-1}-t_k) - ia(\cdot-\Sigma_{m=1}^{r}p_m)t_r)[\mathcal{F}^{-1}\phi](\cdot-p_1-\ldots-p_r)$. Note that $\|\zeta_{r,\phi}\|_{\infty}\leq e^{tC_a}\|\phi\|_{L^2}\|\mathcal{F}^{-1}\|$.

For $\phi\in L^2(Q)$ let $A_{r,n}\phi=(-i)^r\mathcal{F}\int_{D_r(t)}\int_{(P\times Q)^r}\zeta_{r,\phi}\,d\lambda_{r,n}^{t}\otimes\nu^{\otimes r}$ and $A_r\phi=(-i)^r\mathcal{F}\int_{D_r(t)}\int_{(P\times Q)^r}\zeta_{r,\phi}\,d\lambda_{r,n}^{t}\otimes\nu^{\otimes r}$, $r\in\mathbb{N}$. Let $\eta_{r,n}((p_1,q_1),\ldots,(p_r,q_r))=\int_{D_r(t)}\zeta_{r,\phi}(t_1,\ldots,t_r,(p_1,q_1),\ldots,(p_r,q_r))d\lambda_{r,n}^{t}$ and $\eta_r((p_1,q_1),\ldots,(p_r,q_r))=\int_{D_r(t)}\zeta_{r,\phi}(t_1,\ldots,t_r,(p_1,q_1),\ldots,(p_r,q_r))d\lambda_r$.

Since for all fixed $q_1,\ldots,q_r,p_1,\ldots,p_r$ the function $\zeta_{r,\phi}$ is bounded on the set $D_r(t)$ and continuous on the set $D_r^0(t)$ from Lemma 7 it follows that $\lim_{n\to\infty}\eta_{r,n}((p_1,q_1),\ldots,(p_r,q_r))=\lim_{n\to\infty}\int_{D_r(t)}\zeta_{r,\phi}(t_1,\ldots,t_r,(p_1,q_1),\ldots,(p_r,q_r))d\lambda_{r,n}^{t}=\int_{D_r(t)}\zeta_{r,\phi}(t_1,\ldots,t_r,(p_1,q_1),\ldots,(p_r,q_r))d\lambda_r=\eta_r((p_1,q_1),\ldots,(p_r,q_r))$.

Using Lemma 7 we get $\|\eta_{r,n}\|_{\infty}\leq\|\zeta_{r,\phi}\|_{\infty}v(\lambda_{r,n}^{t})\leq e^{tC_a}t^r\|\phi\|_{L^2}\|\mathcal{F}^{-1}\|/r!$ and $\|\eta_r\|_{\infty}\leq\|\zeta_{r,\phi}\|_{\infty}\lambda_r(D_r(t))=e^{tC_a}t^r\|\phi\|_{L^2}\|\mathcal{F}^{-1}\|/r!$. Thus by the Lebesgue theorem on the dominated convergence we get $\lim_{n\to\infty}A_{r,n}\phi=\lim_{n\to\infty}(-i)^r\mathcal{F}\int_{(P\times Q)^r}\eta_{r,n}((p_1,q_1),\ldots,(p_r,q_r))d\nu^{\otimes r}=(-i)^r\mathcal{F}\int_{(P\times Q)^r}\eta_r((p_1,q_1),\ldots,(p_r,q_r))d\nu^{\otimes r}=A_r\phi$.

Note that $\|A_{r,n}\phi\|_{L^2}\leq\|\eta_{r,n}\|_{\infty}|\nu|^r\|\mathcal{F}\|\leq e^{tC_a}\|\phi\|_{L^2}|\nu|^r t^r/r!$ and $\|A_r\phi\|_{L^2}\leq\|\eta_{r,n}\|_{\infty}|\nu|^r\|\mathcal{F}\|\leq e^{tC_a}|\nu|^r\|\phi\|_{L^2}t^r/r!$. From this it follows that $A_{r,n}$, $A_r\in\mathcal{L}(L^2(Q))$ and that $V_t\phi=\lim_{n\to\infty}V_{n,t}\phi=\lim_{n\to\infty}(A_0\phi+\Sigma_{r=1}^{\infty}A_{r,n}\phi)=A_0\phi+\Sigma_{r=1}^{\infty}\lim_{n\to\infty}A_{r,n}\phi=\Sigma_{r=0}^{\infty}A_r\phi$.

Let $\phi\in L^2(Q)$, $\epsilon>0$ and $\overline{\phi_\epsilon}=\chi_\epsilon\mathcal{F}^{-1}\chi_\epsilon\phi$, where χ_ϵ is the multiplication operator by the function $e^{-\epsilon|\cdot|^2}$. For $r\in\mathbb{N}$ let $(\hat{U}_{t,\epsilon}^{r}\phi)(q)=(2\pi)^{-N}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}U_t^r(q,p)e^{ip(q-q')}e^{-\epsilon|p|^2-\epsilon|q'|^2}\times\phi(q')dq'dp$. Then $(\hat{U}_{t,\epsilon}^{r}\phi)(q)=\int_{\mathbb{R}^N}U_t^r(q,p)e^{i\langle p,q\rangle}\overline{\phi_\epsilon}(p)dp$ and by Fubini's theorem we get

$$(\hat{U}_{t,\epsilon}^{r}\phi)(q)=(-i)^r\int_{\mathbb{R}^N}dp\int_0^t dt_1\int_0^{t_1}dt_2\cdots\int_0^{t_{r-1}}dt_r\int_{(P\times Q)^r}\exp(i\langle q,\Sigma_{l=1}^{r}p_l\rangle$$
$$-ia(p+\Sigma_{l=1}^{r}p_l)(t-t_1)-i\Sigma_{k=2}^{r}a(p+\Sigma_{l=k}^{r}p_l)(t_{k-1}-t_k)-ia(p)t_r)$$
$$\times\exp(i\Sigma_{k=1}^{r-1}\langle q_k,p+\Sigma_{l=k+1}^{r}p_l\rangle+i\langle q_r,p\rangle)e^{i\langle p,q\rangle}\overline{\phi_\epsilon}(p)\,\nu(dp_1,dq_1)\cdots\nu(dp_r,dq_r).$$

Changing the variable $p \to p - p_1 - \cdots - p_r$ we get

$$(\hat{U}^r_{t,\epsilon}\phi)(q) = (-i)^r \int_{\mathbb{R}^N} dp \int_0^t dt_1 \int_0^{t_1} dt_2 \cdots \int_0^{t_{r-1}} dt_r \int_{(P\times Q)^r} \exp(i\Sigma_{k=1}^r \langle q_k, p - \Sigma_{m=1}^k p_m\rangle)$$
$$\times \exp(-ia(p)(t-t_1) - i\Sigma_{k=2}^r a(p - \Sigma_{m=1}^{k-1} p_m)(t_{k-1} - t_k)$$
$$- ia(p - \Sigma_{m=1}^r p_m)t_r) e^{i\langle p,q\rangle} \times \overline{\phi}_\epsilon(p - p_1 - \ldots - p_r)\, \nu(dp_1, dq_1) \cdots \nu(dp_r, dq_r)$$
$$= A_r \mathcal{F}\overline{\phi}_\epsilon(q).$$

Therefore we get the Bochner integral

$$\hat{U}^r_{t,\epsilon}\phi = (-i)^r \mathcal{F} \int_0^t dt_1 \int_0^{t_1} dt_2 \cdots \int_0^{t_{r-1}} dt_r \int_{(P\times Q)^r} \exp(i\Sigma_{k=1}^r \langle q_k, \cdot - \Sigma_{m=1}^k p_m\rangle)$$
$$\times \exp(-ia(\cdot)(t-t_1) - i\Sigma_{k=2}^r a(\cdot - \Sigma_{m=1}^{k-1} p_m)(t_{k-1} - t_k) - ia(\cdot - \Sigma_{m=1}^r p_m)t_r)$$
$$\times \overline{\phi}_\epsilon(\cdot - p_1 - \cdots - p_r)\, \nu(dp_1, dq_1) \cdots \nu(dp_r, dq_r)$$
$$= A_r \mathcal{F}\overline{\phi}_\epsilon.$$

Since $\lim_{\epsilon\to 0} \overline{\phi}_\epsilon = \mathcal{F}^{-1}\phi$ by the Lebesgue theorem on dominated convergence we obtain that $\lim_{\epsilon\to 0} \hat{U}^r_{t,\epsilon}\phi = A_r\phi$. Therefore from the fact that $U^r_t(\cdot,\cdot)$ is a bounded function we get $\hat{U}^r_t\phi = A_r\phi$. From this it follows that $\hat{U}^r_t \in \mathcal{L}(L^2(\mathbb{R}^N))$, $\|\hat{U}^r_t\| = \|A_r\| \le e^{tC_a}|\nu|^r t^r/r!$ and the series $\Sigma_{r=0}^\infty \hat{U}^r_t$ converges in the uniform operator topology. Since $\hat{U}^0_t = A_0$ we see that $V_t = \Sigma_{r=0}^\infty \hat{U}^r_t$.

Note that $|U^r_t(q,p)| \le e^{tC_a}|\nu|^r \lambda_r(D_r(t)) = e^{tC_a}|\nu|^r t^r/r!$. From this it follows that $\Sigma_{m=0}^\infty |U^m_t(q,p)| < \infty$ and $|U_t(q,p)| \le e^{tC_a + |\nu|t}$. For $\epsilon > 0$ let $(\hat{U}_{t,\epsilon}\phi)(q) = (2\pi)^{-N} \int_{\mathbb{R}^N} U_t(q,p) \exp(-\epsilon|p|^2 - \epsilon|q'|^2) e^{ip(q-q')}\phi(q')\, dq'\, dp$. Then $(\hat{U}_{t,\epsilon}\phi)(\cdot) = \mathcal{F}[e^{-ita(\cdot)}\overline{\phi}_\epsilon(\cdot)] + \Sigma_{r=1}^\infty (\hat{U}^r_{t,\epsilon}\phi)(\cdot)$. Since $\hat{U}^r_{t,\epsilon}\phi = A_r\mathcal{F}\overline{\phi}_\epsilon$ we get $\|\hat{U}^r_{t,\epsilon}\phi\|_{L^2} \le \|\phi\|_{L^2}|\nu|^r e^{tC_a} t^r/r!$. Therefore $\lim_{\epsilon\to 0} \hat{U}_{t,\epsilon}\phi = \lim_{\epsilon\to 0}(\mathcal{F}[e^{-ita(\cdot)}\overline{\phi}_\epsilon(\cdot)] + \Sigma_{r=1}^\infty \hat{U}^r_{t,\epsilon}\phi) = \hat{U}^0_t\phi + \Sigma_{r=1}^\infty \lim_{\epsilon\to 0} \hat{U}^r_{t,\epsilon}\phi = \hat{U}^0_t\phi + \Sigma_{r=1}^\infty \hat{U}^r_t\phi$ in $L^2(Q)$. Since $U_t(\cdot,\cdot)$ is bounded we obtain $\hat{U}_t\phi = \hat{U}^0_t\phi + \Sigma_{r=1}^\infty \hat{U}^r_t\phi$. From this it follows that $\hat{U}_t \in \mathcal{L}(L^2(Q))$ and $\hat{U}_t = V_t$.

The theorem is proved.

Let us notice that if the conditions of Theorem 8 are valid then from the representation of the symbol $U_t(q,p)$ of the propagator for the Schrödinger equation $i\,du/dt = \hat{H}u$, where $H(q,p) = a(p) + h(q,p)$, one can get the following identity for representation of a solution for this equation:

$$u(t,z) = \int u_0(q(0)+z) \exp\left(-i\int_0^t a(p(\tau))\,d\tau - i\int_0^t h(q(\tau)+z, p(\tau))\,d\tau\right) \Phi_{a^-}(dq, dp),$$

where the symbol on the right-hand side denotes the functional integral (corresponding to the quadratic form a^-) defined with the help of the Parseval equality (see Ref. 3, Chap. 3, Sec. 2). Therefore as a corollary of Theorem 8 we again get a theorem on the representation of solutions for the Schrödinger equation by the Feynman path integral over trajectories in the phase space.

It is also worth noticing that similar considerations can be also applied to pq, Weyl and other types of symbols. We plan to do this in the next paper.

The spherical components of the multipole expansion of a plane wave with arbitrary spin are obtained in terms of spin-weighted spherical harmonics. It is shown that the expansion coefficients are essentially spin-weighted spherical harmonics evaluated at the direction of propagation of the wave. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1500425]

I. INTRODUCTION

In the standard treatment of the multipole expansion of nonscalar fields a huge variety of vector, tensor, or spinor fields is employed (see, e.g., Refs. 1–3) with widely variable notations and conventions. A uniform formalism applicable to fields of any spin is based on the use of two-component spinors and spin-weighted spherical harmonics.[4–7] The fact that, in a three-dimensional space, the spinor indices take two values only (as in the case of the two-component spinors employed in general relativity) leads to many simplifications in the algebraic manipulations.

The spin-weighted spherical harmonics appear in the solution by separation of variables in spherical coordinates of linear partial differential equations for nonscalar fields, when the equations are written in terms of quantities with a well-defined spin weight (see, e.g., Refs. 5 and 7). Each spin-weighted spherical harmonic, ${}_sY_{jm}$, is an eigenfunction of the square of the total angular momentum, J^2, and of the z component of the total angular momentum, J_z. As shown in the following, the expansion of a plane wave of any spin in terms of spin-weighted spherical harmonics can be easily obtained and the coefficients of the expansion are essentially spin-weighted spherical harmonics evaluated in the direction of propagation of the wave.

In Sec. II some basic notions about the two-component spinor formalism are summarized and some useful expressions for the spin-weighted spherical harmonics are given which are employed in Sec. III to find the expression of a plane wave in terms of spin-weighted spherical harmonics.

II. SPINORS AND SPIN-WEIGHTED SPHERICAL HARMONICS

The components of a field with arbitrary spin in Euclidean three-dimensional space can be expressed in a unified way using two-component spinors, which are well known from the treatment of electron's spin in nonrelativistic quantum mechanics. The two-component spinor formalism in three-dimensional space is relatively simple because, among other things, a single nonzero one-index spinor gives rise to bases for tensors or spinors of any rank. If ψ^A $(A,B,\ldots=1,2)$ are the components of a spinor field and the mate of ψ^A, denoted by $\hat{\psi}^A$, is defined by

$$\hat{\psi}_A=\overline{\psi^A}$$

or

a)Electronic mail: gtorres@fismat1.fcfm.buap.mx

$$\hat{\psi}^A = -\overline{\psi_A}, \tag{1}$$

where the bar denotes complex conjugation, then at each point where ψ^A does not vanish, $\{\psi^A, \hat{\psi}^A\}$ is linearly independent and, hence, a basis for the one-index spinors. The spinor indices are raised or lowered following the rules

$$\psi_A = \varepsilon_{AB}\psi^B, \quad \psi^A = -\varepsilon^{AB}\psi_B, \tag{2}$$

where

$$(\varepsilon_{AB}) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = (\varepsilon^{AB}). \tag{3}$$

Therefore, $\psi_A\phi^A = -\psi^A\phi_A$ and $\psi_A\psi^A = 0$.

A symmetric two-index spinor, $v_{AB} = v_{BA}$, corresponds to a (possibly complex) vector v_i $(i,j,\ldots = 1,2,3)$ with Cartesian components

$$v_i = -\frac{1}{\sqrt{2}}\sigma_i{}^{AB}v_{AB}, \tag{4}$$

where the connection symbols σ_{iAB} satisfy

$$\sigma_{iAB} = \sigma_{iBA} \tag{5}$$

and

$$\sigma_{iAB}\sigma_j{}^{AB} = -2\,\delta_{ij}. \tag{6}$$

The connection symbols can be chosen as

$$(\sigma_{1AB}) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad (\sigma_{2AB}) = \begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix}, \quad (\sigma_{3AB}) = \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix}, \tag{7}$$

which satisfy the condition

$$\overline{\sigma_{iAB}} = -\sigma_i{}^{AB}. \tag{8}$$

Thus, a symmetric two-index spinor v_{AB} corresponds to a real vector if and only if $\overline{v_{AB}} = -v^{AB}$. [The matrices (7) are the products of (ε_{AB}) by the usual Pauli matrices.]

Making use of the relation

$$\sigma^i{}_{AB}\sigma_{iCD} = -(\varepsilon_{AC}\varepsilon_{BD} + \varepsilon_{AD}\varepsilon_{BC}), \tag{9}$$

which follows from Eq. (6), one finds that Eq. (4) is equivalent to

$$v_{AB} = \frac{1}{\sqrt{2}}\sigma^i{}_{AB}v_i. \tag{10}$$

(The tensor indices are raised or lowered by means of δ^{ij} and δ_{ij}.) More generally, the spinor equivalent of a tensor $t_{ij\cdots k}$ is defined by

$$t_{ABCD\cdots EF} = \frac{1}{\sqrt{2}}\sigma^i{}_{AB}\frac{1}{\sqrt{2}}\sigma^j{}_{CD}\cdots\frac{1}{\sqrt{2}}\sigma^k{}_{EF}t_{ij\cdots k}. \tag{11}$$

Then $t_{ABCD\cdots EF}$ is totally symmetric if and only if $t_{ij\cdots k}$ is symmetric and trace free. A spin-S field ($S=1/2,1,3/2,\ldots$) corresponds to a $2S$-index totally symmetric spinor field (or, as in the case of the Dirac equation, to several $2S$-index totally symmetric spinor fields).

Starting from a one-index spinor field ψ^A one can construct the real vector field

$$R_i=-\sigma_{iAB}\psi^A\hat{\psi}^B \tag{12}$$

and the complex vector field

$$M_i=\sigma_{iAB}\psi^A\psi^B, \tag{13}$$

which, according to Eq. (9), satisfy

$$R_iR^i=-(\varepsilon_{AC}\varepsilon_{BD}+\varepsilon_{AD}\varepsilon_{BC})\psi^A\hat{\psi}^B\psi^C\hat{\psi}^D=(\psi^A\hat{\psi}_A)^2,$$

$$\overline{M_i}M^i=(\varepsilon_{AC}\varepsilon_{BD}+\varepsilon_{AD}\varepsilon_{BC})\hat{\psi}^A\hat{\psi}^B\psi^C\psi^D=2(\psi^A\hat{\psi}_A)^2,$$

and, similarly, $R_iM^i=0$, $M_iM^i=0$; hence, R_i, $\mathrm{Re}\,M_i$, $\mathrm{Im}\,M_i$ are orthogonal to each other and have the magnitude $\psi^A\hat{\psi}_A$. (Note that for any one-index spinor ϕ^A, $\phi^A\hat{\phi}_A=|\phi^1|^2+|\phi^2|^2$, which is always real and non-negative.)

In what follows we will make use of the spinor field o^A, with components

$$\begin{pmatrix} o^1 \\ o^2 \end{pmatrix}=\begin{pmatrix} e^{-i\varphi/2}\cos(\theta/2) \\ e^{i\varphi/2}\sin(\theta/2) \end{pmatrix}, \tag{14}$$

where θ and φ are the usual polar and azimuth angles associated with the spherical coordinates. The spinor field o^A satisfies $o^A\hat{o}_A=1$ and the three mutually orthogonal vectors defined by o^A form the orthonormal basis, $\{\mathbf{e}_r,\mathbf{e}_\theta,\mathbf{e}_\varphi\}$, induced by the spherical coordinates r,θ,φ, i.e.,

$$(\mathbf{e}_r)_j=-\sigma_{jAB}o^A\hat{o}^B, \quad (\mathbf{e}_\theta+i\mathbf{e}_\varphi)_j=\sigma_{jAB}o^Ao^B. \tag{15}$$

In terms of o^A and $\hat{o}^A$ the spherical harmonics are given by

$$Y_{lm}=(-1)^m\frac{(2l)!}{l!}\left[\frac{2l+1}{4\pi}\,\frac{1}{(l+m)!(l-m)!}\right]^{1/2}\overbrace{\underbrace{o^{(1}o^1\cdots o^1}_{l}\underbrace{\hat{o}^1\hat{o}^2\cdots\hat{o}^{2)}}_{l}}^{(l-m)1\text{'s},\,(l+m)2\text{'s}}, \tag{16}$$

where the parentheses denote symmetrization on the indices enclosed. Since the number of o^A's and of $\hat{o}^A$'s appearing in (16) coincide, the spherical harmonics (16) are invariant under the transformation

$$o^A\mapsto e^{i\alpha/2}o^A \tag{17}$$

(which implies that $\hat{o}^A\mapsto e^{-i\alpha/2}\hat{o}^A$). A quantity η has spin weight s if under the transformation (17) transforms according to $\eta\mapsto e^{is\alpha}\eta$.[4] Thus, the ordinary spherical harmonics have spin weight 0.

The spherical components of a totally symmetric $2S$-index spinor field, $\phi_{AB\cdots D}$, are obtained by contracting all its indices with o^A's and $\hat{o}^A$'s. For $s=-S,-S+1,\ldots,S$, the spherical component of $\phi_{AB\cdots D}$,

$${}_s\phi\equiv\phi_{AB\cdots D}\underbrace{o^Ao^B\cdots\hat{o}^D}_{(S+s)o\text{'s},(S-s)\hat{o}\text{'s}} \tag{18}$$

has spin weight s. For instance, the three spherical components of a spin-1 field (which is just a possibly complex vector field) are [see Eqs. (10) and (15)]

$$
{}_1\phi = \phi_{AB} o^A o^B = \frac{1}{\sqrt{2}}\,\boldsymbol{\phi}\cdot(\mathbf{e}_\theta + i\mathbf{e}_\varphi),
$$

$$
{}_0\phi = \phi_{AB} o^A \hat{o}^B = -\frac{1}{\sqrt{2}}\,\boldsymbol{\phi}\cdot\mathbf{e}_r\,, \tag{19}
$$

$$
{}_{-1}\phi = \phi_{AB} \hat{o}^A \hat{o}^B = -\frac{1}{\sqrt{2}}\,\boldsymbol{\phi}\cdot(\mathbf{e}_\theta - i\mathbf{e}_\varphi),
$$

where $\boldsymbol{\phi}$ is the vector field with Cartesian components $\phi_i = -(1/\sqrt{2})\sigma_{iAB}\phi^{AB}$ [see Eq. (4)]. Hence, $\boldsymbol{\phi} = -{}_{-1}\phi\,(1/\sqrt{2})(\mathbf{e}_\theta + i\mathbf{e}_\varphi) + {}_1\phi\,(1/\sqrt{2})(\mathbf{e}_\theta - i\mathbf{e}_\varphi) - {}_0\phi\,\sqrt{2}\mathbf{e}_r$. Similarly, any one-index spinor field, ϕ^A, can be expressed as $\phi^A = (\phi_B o^B)\hat{o}^A - (\phi_B \hat{o}^B) o^A = {}_{1/2}\phi\,\hat{o}^A - {}_{-1/2}\phi\, o^A$.

The spin-weighted spherical harmonics,[4–6] ${}_sY_{jm}$, can also be expressed in terms of o and $\hat{o}$ as[7]

$$
{}_sY_{jm} = (-1)^m \left[\frac{2j+1}{4\pi}\,\frac{(2j)!}{(j+m)!(j-m)!}\,\frac{(2j)!}{(j+s)!(j-s)!}\right]^{1/2} \underbrace{\overbrace{o^{(1} o^1 \cdots o^1}^{j+s}\,\overbrace{\hat{o}^1 \hat{o}^2 \cdots \hat{o}^{2)}}^{j-s}}^{(j-m)1\text{'s},\,(j+m)2\text{'s}}, \tag{20}
$$

with $j = 0, 1/2, 1, \ldots$, $m = -j, -j+1, \ldots, j$, $s = -j, -j+1, \ldots, j$. Thus, $Y_{jm} = {}_0Y_{jm}$ and ${}_sY_{jm}$ has spin weight s. The spin-weighted spherical harmonics are related to the Wigner D functions by[5,7]

$$
\overline{D^l_{m'm}(\varphi,\theta,\chi)} = (-1)^{-m}\sqrt{\frac{4\pi}{2l+1}}\,{}_{-m}Y_{lm'}(\theta,\varphi)e^{im\chi}, \tag{21}
$$

where φ, θ, χ are Euler angles; therefore, from[8,9]

$$
D^j_{ms}(\varphi,\theta,\chi) D^{j'}_{m's'}(\varphi,\theta,\chi) = \sum_{J,M,S} \langle jj';mm'|jj';JM\rangle\ \langle jj';ss'|jj';JS\rangle\ D^J_{MS}(\varphi,\theta,\chi),
$$

where the $\langle jj';mm'|jj';JM\rangle$ denote the Clebsch–Gordan coefficients, it follows that

$$
\begin{aligned}
{}_sY_{jm}(\theta,\varphi)\ {}_{s'}Y_{j'm'}(\theta,\varphi) = \sum_{J,M,S} (-1)^{j+j'-J}\sqrt{\frac{(2j+1)(2j'+1)}{4\pi(2J+1)}}\ \langle jj';mm'|jj';JM\rangle \\
\times \langle jj';ss'|jj';JS\rangle\ {}_SY_{JM}(\theta,\varphi).
\end{aligned} \tag{22}
$$

III. PLANE WAVES

The totally symmetric $2S$-index spinor field

$$
\phi_{AB\cdots D} = \chi_{AB\cdots D} e^{i(\mathbf{k}\cdot\mathbf{r} - \omega t)}, \tag{23}
$$

where $\chi_{AB\cdots D}$ is a *constant* totally symmetric spinor, corresponds to a spin-S plane wave propagating in the direction of the wave vector $\mathbf{k}$. The Cartesian components of $\mathbf{k}$ can be written in terms of the constant one-index spinor

$$
\begin{pmatrix} \kappa^1 \\ \kappa^2 \end{pmatrix} = \begin{pmatrix} e^{-i\varphi'/2}\cos(\theta'/2) \\ e^{i\varphi'/2}\sin(\theta'/2) \end{pmatrix}, \tag{24}
$$

where θ' and φ' are the polar and azimuth angles of the wave vector $\mathbf{k}$ [cf. Eq. (14)], which satisfies $\kappa^A \hat{\kappa}_A = 1$, according to

$$k_i = -|\mathbf{k}|\,\sigma_{iAB}\kappa^A\hat{\kappa}^B \tag{25}$$

[cf. Eq. (12)]. Then the spinor $\chi_{AB\cdots D}$ can be expressed as a linear combination (with constant coefficients) of the $2S+1$ symmetrized products $\kappa_A\kappa_B\cdots\kappa_D$, $\hat{\kappa}_{(A}\kappa_B\cdots\kappa_{D)}$, $\hat{\kappa}_{(A}\hat{\kappa}_B\cdots\kappa_{D)},\ldots,$ $\hat{\kappa}_A\hat{\kappa}_B\cdots\hat{\kappa}_D$; therefore, it suffices to consider plane waves of the form

$$\underbrace{\kappa_{(A}\kappa_B\cdots\hat{\kappa}_{D)}}_{(S+s')\kappa\text{'s},(S-s')\hat{\kappa}\text{'s}}\ \mathrm{e}^{i(\mathbf{k}\cdot\mathbf{r}-\omega t)},\quad s'=-S,-S+1,\ldots,S. \tag{26}$$

The parameter s' corresponds to the helicity[3] of the wave.

The allowed values of s' depend on the equations satisfied by the field under consideration. For instance, the equations for a massless free field are

$$\sqrt{2}\,\partial^R{}_{(A}\phi_{B\cdots D)R} = \pm\frac{1}{c}\frac{\partial}{\partial t}\phi_{AB\cdots D}, \tag{27}$$

and

$$\partial^{AB}\phi_{AB\cdots D} = 0, \tag{28}$$

where $\partial_{AB} = (1/\sqrt{2})\sigma^i{}_{AB}(\partial/\partial x^i)$, $\phi_{AB\cdots D}$ is a $2S$-index totally symmetric spinor and the sign on the right-hand side of Eq. (27) depends on the helicity of the field. Substituting Eq. (23) into Eqs. (27) and (28), assuming $\omega>0$, one finds that $\chi_{AB\cdots D}$ must be equal to $\kappa_A\kappa_B\cdots\kappa_D$ or to $\hat{\kappa}_A\hat{\kappa}_B\cdots\hat{\kappa}_D$, according to whether the sign on the right-hand side of Eq. (27) is plus or minus, respectively. Thus, s' only takes the values S and $-S$. In the case of the Weyl equation for the (massless) neutrino the only possible value of s' is $-1/2$.

According to Eq. (18), the spherical (or spin-weighted) components of the plane wave (26) are

$${}_s\phi = \underbrace{o^A o^B\cdots\hat{o}^D}_{(S+s)o\text{'s},(S-s)\hat{o}\text{'s}}\ \underbrace{\kappa_{(A}\kappa_B\cdots\hat{\kappa}_{D)}}_{(S+s')\kappa\text{'s},(S-s')\hat{\kappa}\text{'s}}\ \mathrm{e}^{i(\mathbf{k}\cdot\mathbf{r}-\omega t)}. \tag{29}$$

Making use of Eq. (20) one finds that

$$\underbrace{o^A o^B\cdots\hat{o}^D}_{(S+s)o\text{'s},(S-s)\hat{o}\text{'s}}\ \underbrace{\kappa_{(A}\kappa_B\cdots\hat{\kappa}_{D)}}_{(S+s')\kappa\text{'s},(S-s')\hat{\kappa}\text{'s}} = (-1)^{S+s'}\frac{4\pi}{2S+1}\left[\frac{(S+s)!(S-s)!}{(2S)!}\,\frac{(S+s')!(S-s')!}{(2S)!}\right]^{1/2}$$
$$\times\sum_{m=-S}^{S}{}_sY_{Sm}(\theta,\varphi)\ \overline{{}_{-s'}Y_{Sm}(\theta',\varphi')}. \tag{30}$$

From this last relation, taking $\kappa^A = o^A$, one obtains the formula

$$\sum_{m=-S}^{S}{}_sY_{Sm}(\theta,\varphi)\ \overline{{}_{s'}Y_{Sm}(\theta,\varphi)} = \frac{2S+1}{4\pi}\,\delta_{ss'},$$

which also follows from Eq. (21) using the fact that the Wigner functions are the matrix elements of a representation of the rotation group.[7]

Using now Eqs. (22) and (30), the expansion

$$e^{i\mathbf{k}\cdot\mathbf{r}} = 4\pi\sum_{l=0}^{\infty}\sum_{m=-l}^{l} i^l j_l(kr)Y_{lm}(\theta,\varphi)\ \overline{Y_{lm}(\theta',\varphi')}, \tag{31}$$

and the properties of the Clebsch–Gordan coefficients we find that the component ${}_s\phi$, defined by Eq. (29), has the expansion

$$
{}_s\phi=(-1)^{S+s'}4\pi\left[\frac{(S+s)!(S-s)!}{(2S)!}\,\frac{(S+s')!(S-s')!}{(2S)!}\right]^{1/2}\sum_{J,M}\overline{{}_{-s'}Y_{JM}(\theta',\varphi')}
$$

$$
\times\left[\sum_{l=|J-S|}^{J+S}\frac{2l+1}{2J+1}\langle lS;Js|lS;0s\rangle\ \langle lS;0,-s'|lS;J,-s'\rangle i^l j_l(kr)\right]{}_sY_{JM}(\theta,\varphi)e^{-i\omega t},
\tag{32}
$$

which expresses each spherical component of the helicity-s' plane wave (26) as a superposition of eigenfunctions of the square of the total angular momentum and of the z component of the total angular momentum.

For example, according to Eq. (32), the multipole expansion of the Weyl neutrino field $\phi_A=\hat{\kappa}_A e^{i(\mathbf{k}\cdot\mathbf{r}-\omega t)}$, is given by

$$
\begin{pmatrix}{}_{1/2}\phi\\ {}_{-1/2}\phi\end{pmatrix}=2\pi\sum_{J,M}\overline{{}_{1/2}Y_{JM}(\theta',\varphi')}i^{J-1/2}\begin{pmatrix}(j_{J-1/2}(kr)+ij_{J+1/2}(kr)){}_{1/2}Y_{JM}(\theta,\varphi)\\ (j_{J-1/2}(kr)-ij_{J+1/2}(kr)){}_{-1/2}Y_{JM}(\theta,\varphi)\end{pmatrix}e^{-i\omega t}.
\tag{33}
$$

Similarly, for the spin-3/2 field $\phi_{ABC}=\hat{\kappa}_A\hat{\kappa}_B\hat{\kappa}_C e^{i(\mathbf{k}\cdot\mathbf{r}-\omega t)}$ one readily obtains

$$
\begin{pmatrix}{}_{3/2}\phi\\ {}_{1/2}\phi\\ {}_{-1/2}\phi\\ {}_{-3/2}\phi\end{pmatrix}=\frac{\pi}{2}\sum_{J,M}\overline{{}_{3/2}Y_{JM}(\theta',\varphi')}i^{J-3/2}\begin{pmatrix}f_J^+(kr){}_{3/2}Y_{JM}(\theta,\varphi)\\ g_J^+(kr){}_{1/2}Y_{JM}(\theta,\varphi)\\ g_J^-(kr){}_{-1/2}Y_{JM}(\theta,\varphi)\\ f_J^-(kr){}_{-3/2}Y_{JM}(\theta,\varphi)\end{pmatrix}e^{-i\omega t},
\tag{34}
$$

where

$$
f_J^{\pm}(x)\equiv\frac{1}{J(J+1)}\left[(J+1)\left(J+\frac{3}{2}\right)j_{J-3/2}(x)\pm 3iJ\left(J+\frac{3}{2}\right)j_{J-1/2}(x)-3\left(J-\frac{1}{2}\right)(J+1)j_{J+1/2}(x)\right.
$$

$$
\left.\mp iJ\left(J-\frac{1}{2}\right)j_{J+3/2}(x)\right],
$$

$$
g_J^{\pm}(x)\equiv\frac{\sqrt{(J-\frac{1}{2})(J+\frac{3}{2})}}{J(J+1)}[(J+1)j_{J-3/2}(x)\pm iJj_{J-1/2}(x)+(J+1)j_{J+1/2}(x)\mp iJj_{J+3/2}(x)].
$$

It may be remarked that the fields

$$
\begin{pmatrix}{}_{3/2}\phi\\ {}_{1/2}\phi\\ {}_{-1/2}\phi\\ {}_{-3/2}\phi\end{pmatrix}=\begin{pmatrix}f_J^+(kr){}_{3/2}Y_{JM}(\theta,\varphi)\\ g_J^+(kr){}_{1/2}Y_{JM}(\theta,\varphi)\\ g_J^-(kr){}_{-1/2}Y_{JM}(\theta,\varphi)\\ f_J^-(kr){}_{-3/2}Y_{JM}(\theta,\varphi)\end{pmatrix}e^{-i\omega t},
$$

appearing in Eq. (34), are separable solutions in spherical coordinates of Eqs. (27) and (28) with $S=3/2$, $s'=-3/2$, and Eq. (34) is the relation between two different bases of the solutions of these equations, with $\overline{{}_{3/2}Y_{JM}(\theta',\varphi')}$ being essentially the matrix elements of this relation. Similarly, Eqs. (31)–(33) correspond to changes of bases and, in all cases, the matrix elements of these (unitary) transformations are proportional to $\overline{{}_{-s'}Y_{JM}(\theta',\varphi')}$.

Remarks on the connection between the additive separation of the Hamilton–Jacobi equation and the multiplicative separation of the Schrödinger equation. I. The completeness and Robertson conditions

S. Benenti,[a] C. Chanu, and G. Rastelli
Department of Mathematics, University of Turin, 10123 Torino, Italy

(Received 1 March 2002; accepted 27 June 2002)

The fundamental elements of the variable separation theory are revisited, including the Eisenhart and Robertson theorems, Kalnins–Miller theory, and the intrinsic characterization of the separation of the Hamilton–Jacobi equation, in a unitary and geometrical perspective. The general notion of complete integrability of first-order normal systems of PDEs leads in a natural way to completeness conditions for separated solutions of the Schrödinger equation and to the Robertson condition. Two general types of multiplicative separation for the Schrödinger equation are defined and analyzed: they are called ''free'' and ''reduced'' separation, respectively. In the free separation the coordinates are necessarily orthogonal, while the reduced separation may occur in nonorthogonal coordinates, but only in the presence of symmetries (Killing vectors). © *2002 American Institute of Physics.*

I. INTRODUCTION

With a smooth real function V (potential energy) on a Riemannian manifold $(Q_n, \mathbf{g})$ (configuration manifold) we associate two differential equations, the time-independent Hamilton–Jacobi equation

$$\tfrac{1}{2}\nabla W \cdot \nabla W + V = E, \tag{1.1}$$

and the corresponding steady-state Schrödinger equation

$$-\frac{\hbar^2}{2}\Delta\psi + (V-E)\psi = 0. \tag{1.2}$$

In these equations, E is a constant parameter (the energy constant), ∇ is the gradient operator

$$(\nabla W)^i = g^{ij}\partial_j W,$$

and Δ is the Laplace–Beltrami operator

$$\Delta\psi = g^{ij}\nabla_i\nabla_j\psi,$$

where ∇_i is the covariant derivative with respect to the Levi-Civita connection. Besides the well-known physical connection between these two equations (we consider here the time-independent case only), there is an interesting mathematical connection due to the phenomenon of the *separation of variables*.

It is well known that, in many interesting cases, these equations admit *local separated solutions* of the form

[a]Electronic mail: benenti@dm.unito.it

$$W(\underline{q},\underline{c})=\sum_{i=1}^{n} W_i(q^i,\underline{c}) \tag{1.3}$$

for the Hamilton–Jacobi equation, and of the form

$$\psi(\underline{q},\underline{c})=\prod_{i=1}^{n} \psi_i(q^i,\underline{c}), \tag{1.4}$$

or

$$\psi(\underline{q},\underline{c})=e^{R(\underline{q})}\prod_{i=1}^{n} \psi_i(q^i,\underline{c}), \tag{1.5}$$

for the Schrödinger equation, where $\underline{q}=(q^i)$ is a suitable coordinate system on Q, and $\underline{c}$ denotes a set of constant parameters, whose number depends on an appropriate definition of *separation*. Note that in (1.5) the function $R(\underline{q})$ does not depend on the constant parameters: this kind of separation is called *R-separation*.

It happens that for solutions of this kind, Eqs. (1.1) and (1.2) become equivalent to a system of ordinary differential *separated equations*, each one involving a single coordinate. The interesting fact is that, in most cases, the separation of variables occurs simultaneously for both equations and in the same coordinate system. Although this fact is easy to illustrate for basic important examples, its general description and motivation is rather difficult and subtle to understand. Let us consider, for instance, the particular case of the orthogonal separation, where $g^{ij}=0$ for $i\neq j$. For this kind of separation we usually refer to three classical theorems of Stäckel, Robertson, and Eisenhart.[1–3]

Theorem 1.1: (Stäckel, 1893) *The Hamilton–Jacobi equation is separable in orthogonal coordinates $\underline{q}$ if and only if the diagonal components g^{ii} of the metric tensor and the potential V have the form*

$$g^{ii}=\varphi^i_{(n)}, \quad V=\phi_i g^{ii}=\phi_i\varphi^i_{(n)}, \tag{1.6}$$

where $\varphi^i_{(n)}$ is the last row of the inverse $[\varphi^i_{(j)}]$ of an $n\times n$ Stäckel matrix $[\varphi^{(j)}_i]$ and ϕ_i are functions of the coordinate corresponding to the index only.

A *Stäckel matrix* is a regular $n\times n$ matrix whose components $\varphi^{(j)}_i(q^i)$ are functions depending on the coordinate corresponding to the lower index only. A function V of the kind (1.6) is then called a *Stäckel multiplier*.

Theorem 1.2: (Robertson, 1927) *The Schrödinger equation is separable in orthogonal coordinates $\underline{q}$ if and only if in these coordinates the Hamilton–Jacobi equation is separable (i.e., the Stäckel requirements are satisfied) and moreover, the following condition is satisfied*

$$\sqrt{\Pi^n_{i=1}g^{ii}}\det(\varphi^{(j)}_i)=\Pi^n_{i=1}f_i(q^i), \tag{1.7}$$

where $f_i(q^i)$ are functions of the corresponding coordinate only.

This additional requirement is called the *Robertson condition*. It has a meaningful geometrical interpretation:

Theorem 1.3: (Eisenhart, 1934) *The Robertson condition is satisfied if and only if the Ricci tensor is diagonal:*

$$R_{ij}=0, \quad i\neq j.$$

However, while it can be easily seen that requirements (1.6) and (1.7) are sufficient for reducing the Schrödinger equation to separated equations, the proof given by Robertson (and

accepted by Eisenhart) that they are also necessary for the separation is not satisfactory. This is due to the fact that for the separability of the Schrödinger equation these authors assumed (apparently) the existence of a single solution of the kind

$$\psi(\underline{q}) = \Pi_{i=1}^{n} \psi_i(q^i),$$

without any reference to the presence and to the role of constant (real or complex) parameters [as is done in analytical mechanics for a complete solution of the Hamilton–Jacobi (HJ) equation]. Indeed, as we shall see in the following, the existence of a single separated solution of the Schrödinger equation does not imply the separation of the HJ equation for the same reason that the existence of a single solution of a first-order differential system does not imply, in general, its complete integrability. In other words, while for the HJ equation one looks for a separated solution (1.3) containing n constant parameters $\underline{c} = (c_i)$ satisfying the *completeness condition*

$$\det\left[\frac{\partial^2 W}{\partial q^i \partial c_j}\right] = \det\left[\frac{\partial p_i}{\partial c_j}\right] \neq 0, \quad p_i = W_i', \tag{1.8}$$

a similar requirement for a separated solution (1.4) of the Schrödinger equation does not appear explicitly either in the celebrated works cited previously or in many other standard reference books.[4,5] In fact, also for the Schrödinger equation we are not interested in a single separated solution, but in a parametrized family of local solutions, in order to build up a global one satisfying suitable boundary or normalization conditions. In conclusion: the statements of Robertson and Eisenhart (Theorems 1.2 and 1.3) are meaningless without a proper definition of *separation* of the Schrödinger equation.

A first ''precise'' definition of separation has been proposed by Koornwinder[6] within a rather general context, and strongly related to the basic properties of the Stäckel matrices. However, the systematic use of these matrices hides many interesting intrinsic features of the separation connected, for instance, with the existence of Killing tensors and of second-order symmetries of the Schrödinger equation. Other definitions of separation have been introduced by Olevsky[7] and more recently by Zhdanov and Zhalij[8] (both for the case $n=3$).

A crucial contribution to this matter is due to Kalnins and Miller.[9,10] Their approach is based on a definition of *regular* additive separation of a generalized Hamilton–Jacobi equation of any order, which is equivalent to the complete integrability of a suitable first-order differential system. In such a way they give an extension of the classical Levi-Civita separability conditions.[11] As a second step, they relate the definition of multiplicative separation of the Schrödinger equation to the additive separation of a suitable second-order Hamilton–Jacobi equation. A similar approach has been followed earlier by Agostinelli.[12] Kalnins and Miller begin their analysis of the separation of the Schrödinger equation by assuming that the coordinates are orthogonal, while in Agostinelli's paper (as well as in that of Koornwinder) it is shown that for the regular separation of the Schrödinger equation (in the sense of Kalnins and Miller) the coordinates are in fact necessarily orthogonal. Furthermore, Agostinelli shows that the nonorthogonal separation occurs when some of the separated factors ψ_i in (1.4) are of a special kind and the corresponding coordinates are ignorable. However, Agostinelli's approach is heavily coordinate dependent and somehow unsatisfactory, since at that time the geometrical theory of the variable separation of the Hamilton–Jacobi equation was not yet developed.

These remarks show that a revisitation and a resetting of all this matter is needed, from the very beginning, in light of the recent developments of the separability theory. The crucial question for a correct definition of separation for the Schrödinger equation is, as we said previously, how many constant parameters should enter a multiplicative separated solution and which conditions should they satisfy; in other words, as well as for the Hamilton–Jacobi equation, we need a *completeness condition* for a solution of the Schrödinger equation.

In the present paper it is shown that a completeness condition follows necessarily and in a ''natural'' way (i.e., without any consideration concerning the particular kind of equation we are

dealing with) from the general theory of the first-order normal differential systems (recalled in Sec. II, from a geometrical view point) applied to the general theory of the additive separation of Kalnins and Miller. The resulting definition of separation is quite different from those previously proposed in Refs. 6–8. First of all because it is not unique. Indeed, following our general approach we are led, again in a ''natural'' way, to consider at least two types of separation for the Schrödinger equation, which we have called *free* and *constrained*, respectively. These terms are motivated by the fact that one can impose ''constraints'' on some of the factors $\psi_i(q^i)$ of a separated solution; in other words, one can assume that some of these factors have a special form or satisfy a special kind of equations. One can, for instance, impose that $n-m$ factors have the form $\psi_\alpha = \exp(c_\alpha q^\alpha)$, for $\alpha = m+1,...,n$, where c_α are arbitrary constants (see Refs. 12 and 13). We call *reduced separation* a constrained separation of this type. The remarkable fact is that, as a consequence of these assumptions, in the free separation the coordinates are necessarily orthogonal and the number of essential parameters entering the completeness condition is $2n$, while the reduced separation may occur in nonorthogonal coordinates and the number of the essential parameters reduces to $m+n<2n$, including (c_α). This is apparently in contrast to a common ''ansatz'' which considers only n parameters in a separated solution.[6,13,14] In fact, as we shall see, up to a transformation of the $2n$ parameters entering the completeness condition for the free separation, half of them are true ''separation constants'' corresponding to constants of motion (first integrals), while the remaining n are integration constants. This is quite reasonable since we are dealing with second-order equations. For a correct definition of ''completeness'' both groups of constant parameters are jointly involved, but in the process of integration by separation of variables all these essential constants automatically find their own place. This explains the curious fact that, in spite of the absence of the notion of ''complete separable solution,'' the method of separation of variables in the Schrödinger equation has been applied with success, at least in the elementary cases. Thus, the content of the present paper is essentially theoretical and propedeutical to a further analysis of remaining topics on the separation: the relationship between first integrals and symmetry operators, the *R*-separation, the extensions to the case in which a vector potential is present, and to the case of a Lorentzian metric. As we shall see, a conspicuous and rich matter is hidden behind the usual approach to the separation of the Schrödinger equation.

II. FIRST-ORDER DIFFERENTIAL SYSTEMS AND THE GENERAL DEFINITION OF SEPARATION

Let us recall some classical basic facts concerning normal systems of first-order partial differential equations, from a geometrical viewpoint and in a way suitable for our purposes.

Let us consider a trivial fibration $\pi: M = Q \times Z \to Q$, where Z is an N-dimensional linear space (over $\mathbb{C}$ or $\mathbb{R}$) with coordinates $\underline{z} = (z_A)$ (capital indices $A,B,...$ will run from 1 to N) and Q is an n-dimensional real differentiable manifold, with local coordinates $\underline{q} = (q^i)$ (latin indices $h,i,j,...$ will run from 1 to n). A *connection* over this fibration is a regular distribution C over the tangent bundle TZ transversal and complementary to the fibers of π. This means that C is a subbundle of TM such that at each point $x \in M$ the set $C_x = C \cap T_x M$ is an n-dimensional subspace transversal to the fiber at the point z. A vector field D over M is *horizontal* if $D(M) \subset C$ i.e., if $D(x) \in C_x$ for each $x \in M$. A vector field V over M is *vertical* if it is tangent to the fibers. The only field which is simultaneously vertical and horizontal is the zero-vector field. If we consider local coordinates $(\underline{q},\underline{z}) = (q^i, z_A)$ of M, then the distribution C is locally spanned by the following n horizontal vector fields (interpreted as derivations):

$$D_i = \frac{\partial}{\partial q^i} + C_{iA}\frac{\partial}{\partial z_A}, \tag{2.1}$$

called *generators* of C. The functions C_{iA} are the *coefficients* of the connection in these coordinates. It can be seen that the Lie brackets of two generators (as well as of any two horizontal vector fields) are vertical. Hence, by the Frobenius theorem, the distribution C is completely integrable (i.e., the connection C is *flat*) if and only if the generators commute,

$$[D_i, D_j] = 0. \tag{2.2}$$

The complete integrability of C means that there exists a foliation of integral manifolds transversal to the fibers and locally represented by equations of the kind

$$z_A = f_A(\underline{q}, \underline{c}), \tag{2.3}$$

where the N functions f_A depend on N constant parameters $\underline{c} = (c_A)$ which must be uniquely determined by assigning at any fixed point $q_0 \in Q$ (belonging to the domain of the coordinates) any arbitrary set of values of $\underline{z}$. This means that the functions (2.3) satisfy the *completeness condition*

$$\det\left[\frac{\partial \underline{z}}{\partial \underline{c}}\right] \neq 0. \tag{2.4}$$

Moreover, since the integral manifolds are tangent to the generators, equations

$$D_i(z_A - f_A(\underline{q}, \underline{c})) = 0$$

must be identically satisfied. Due to (2.1), these equations are equivalent to

$$\partial_i z_A = C_{iA}(\underline{q}, \underline{z}). \tag{2.5}$$

This proves that

Theorem 2.1: *A first-order differential system in the* normal form (2.5) *is* completely integrable, *i.e., it admits a local* complete solution (2.3) *satisfying the completeness condition* (2.4) *if and only if the generators* D_i *commute,* $[D_i, D_j] = 0$.

On the basis of these general considerations, we can reformulate the definition of separation of Kalnins and Miller[9,10] as follows. Let us consider a partial differential equation

$$\mathcal{H}(\underline{q}, u, u_i, u_{ij}, \ldots, u_{ij\cdots h}) = E, \tag{2.6}$$

in the independent variables $\underline{q} = (q^i)$ and in the unknown function $u(\underline{q})$. Here $u_{ij\cdots h}$ denote the partial derivatives of u with respect to these variables, E is a constant parameter, and $\mathcal{H}$ is a smooth real function of the variables $\underline{q}$, u and its partial derivatives up to a degree l. A *separable solution* of this equation is a solution of the form

$$u = \sum_{i=1}^{n} S_i(q^i, E), \tag{2.7}$$

i.e., a sum of functions depending on a single variable. For separable solutions all the mixed partial derivatives (corresponding to distinct indices) vanish identically, so that Eq. (2.6) gets the simpler form

$$\mathcal{H}_s(\underline{q}, u, \underline{u}^{(1)}, \underline{u}^{(2)}, \ldots, \underline{u}^{(l)}) = E, \tag{2.8}$$

where $\underline{u}^{(1)} = (u_i^{(1)}) = (u_i)$, $\underline{u}^{(2)} = (u_i^{(2)}) = (u_{ii})$, etc., and $\mathcal{H}_s$ is the function we get by replacing $u_{i\cdots j} = 0$ in $\mathcal{H}$, for at least two distinct indices. Note that $\mathcal{H}_s$ in (2.8) is in general a function different from $\mathcal{H}$ in (2.6). However, for the sake of simplicity, in the following discussion we shall use the same symbol $\mathcal{H}$. Since for any solution of this equation the left-hand side of (2.8) reduces to a constant, the total derivatives of $\mathcal{H}$ with respect to the coordinates must vanish identically,

$$\frac{\partial \mathcal{H}}{\partial q^i} + \frac{\partial \mathcal{H}}{\partial u} u_i + \frac{\partial \mathcal{H}}{\partial u_i} u_i^{(2)} + \frac{\partial \mathcal{H}}{\partial u_i^{(2)}} u_i^{(3)} + \cdots + \frac{\partial \mathcal{H}}{\partial u_i^{(l)}} u_i^{(l+1)} = 0. \tag{2.9}$$

Hence, for

$$\frac{\partial \mathcal{H}}{\partial u_i^{(l)}} \neq 0$$

we can define the function

$$R_i(\underline{q},u,\underline{u}^{(1)},\underline{u}^{(2)},\ldots,\underline{u}^{(l)}) = -\left(\frac{\partial \mathcal{H}}{\partial u_i^{(l)}}\right)^{-1} \times\left(\frac{\partial \mathcal{H}}{\partial q^i}+\frac{\partial \mathcal{H}}{\partial u}u_i^{(1)}+\frac{\partial \mathcal{H}}{\partial u_i}u_i^{(2)}+\frac{\partial \mathcal{H}}{\partial u_i^{(2)}}u_i^{(3)}+\cdots+\frac{\partial \mathcal{H}}{\partial u_i^{(l-1)}}u_i^{(l)}\right), \tag{2.10}$$

so that Eq. (2.9) becomes

$$u_i^{(l+1)} = R_i(\underline{q},u,\underline{u}^{(1)},\underline{u}^{(2)},\ldots,\underline{u}^{(l)}).$$

Now, let us consider the following first-order differential system where $j \neq i$ and $\partial_i = \frac{\partial}{\partial q i}$:

$$\begin{aligned} &\partial_i u = u_i^{(1)}, \\ &\partial_i u_i^{(1)} = u_i^{(2)}, \quad \partial_i u_j^{(1)} = 0, \\ &\partial_i u_i^{(2)} = u_i^{(3)}, \quad \partial_i u_j^{(2)} = 0, \\ &\cdots \quad \cdots \\ &\partial_i u_i^{(l)} = R_i, \quad \partial_i u_j^{(l)} = 0. \end{aligned} \tag{2.11}$$

This is a normal system of the kind (2.5) in the unknown $N = n \cdot l + 1$ functions

$$\underline{z} = (z_A) = (u,\underline{u}^{(1)},\underline{u}^{(2)},\ldots,\underline{u}^{(l)}).$$

The comparison with (2.1) and (2.5) shows that the corresponding generators are

$$D_i = \partial_i + u_i^{(1)}\frac{\partial}{\partial u} + u_i^{(2)}\frac{\partial}{\partial u_i^{(1)}} + u_i^{(3)}\frac{\partial}{\partial u_i^{(2)}} + \cdots + R_i\frac{\partial}{\partial u_i^{(l)}}. \tag{2.12}$$

We remark that a separable solution (2.7) corresponds to a solution of this system. Due to Theorem 2.1 we can introduce the following

Definition 2.2: We say that Eq. (2.6) is *separable* in the coordinates $\underline{q}$ if it admits a *complete separable* solution, i.e., a solution of the form

$$u = \sum_{i=1}^{n} S_i(q^i,\underline{c}) \tag{2.13}$$

depending on $N = nl + 1$ constant parameters $\underline{c} = (c_A)$ and satisfying the *completeness condition*

$$\det\left[\frac{\partial \underline{z}}{\partial \underline{c}}\right] = \det\left[\frac{\partial u}{\partial c_A}\middle|\frac{\partial u_i}{\partial c_A}\middle|\frac{\partial u_i^{(2)}}{\partial c_A}\middle|\cdots\middle|\frac{\partial u_i^{(l)}}{\partial c_A}\right] \neq 0. \tag{2.14}$$

It follows that

Theorem 2.3: *Equation (2.6) is separable (i.e., it admits a complete separable solution) in the coordinates $\underline{q}$ if and only if the first-order system (2.11) is completely integrable, i.e., if and only if the separability conditions*

$$[D_i, D_j] = 0 \tag{2.15}$$

are identically satisfied for D_i defined by (2.12) and R_i defined by (2.10).

Remark 2.4: In the following applications we shall deal with equations of the kind (2.6) or (2.8) where $\mathcal{H}$ does not depend on u. In this case the dependent variables are

$$\underline{z} = (z_A) = (\underline{u}^{(1)}, \underline{u}^{(2)}, \ldots, \underline{u}^{(l)}),$$

and the first line of system (2.11) disappears, as well as the term $\partial/\partial u$ in the generators (2.12). Moreover, the number of the constants $\underline{c} = (c_A)$ entering a complete solution (2.13) is $n \cdot l$, and the completeness condition (2.14) reduces to

$$\det\left[\frac{\partial \underline{z}}{\partial \underline{c}}\right] = \det\left[\frac{\partial u_i}{\partial c_A} \middle| \frac{\partial u_i^{(2)}}{\partial c_A} \middle| \cdots \middle| \frac{\partial u_i^{(l)}}{\partial c_A}\right] \neq 0. \tag{2.16}$$

Remark 2.5: The case in which the complete integrability conditions (2.15) are identically satisfied corresponds to the case of *regular separation* of Kalnins and Miller.[9] They call *non-regular* a type of separation in which these conditions are nonidentically satisfied and, consequently, separable solutions may exist, but depending on a reduced number of constants. However, the meaning of this non-regular separation is rather obscure. As we shall see (Sec. V), in dealing with the Schrödinger equation we are led to introduce, in natural way, an alternative definition of the regular separation: the reduced separation.

Remark 2.6: Definition 2.2 and Theorem 2.3 are the basic statements for the theory of variable separation (additive, multiplicative, or any other kind) provided the kind of separation we are dealing with can be transformed, by a suitable transformation, into an additive separation. This is in fact the case of the multiplicative separation: the transformation is $u = \ln \psi$.

III. THE LEVI-CIVITA SEPARABILITY CONDITIONS AND THEIR CONSEQUENCES

Let us apply the general theory illustrated in Sec. II to the case of the Hamilton–Jacobi equation corresponding to a Hamiltonian $H: T^*Q \to \mathbb{R}$ over a cotangent bundle T^*Q. In this case we deal with the cotangent fibration $\pi: M = T^*Q \to Q$ of a configuration manifold Q. This is (in general) a nontrivial fibration, but our previous considerations can be applied, since they have a local character.

The differential equation (2.6) is now

$$H(\underline{q}, \underline{u}^{(1)}) = E, \tag{3.1}$$

with $\mathcal{H} = H$ and, according to the standard notation,

$$u = W, \quad \underline{u}^{(1)} = (u_i) = (p_i) = (\partial_i W).$$

Now $l = 1$ and $\underline{z} = (\underline{u}^{(1)}) = (p_i)$. In a complete solution we have exactly n constants $\underline{c} = (c_i)$ and the completeness condition (2.16) takes the form (1.8),

$$\det\left[\frac{\partial p_i}{\partial c_j}\right] \neq 0. \tag{3.2}$$

The differential system (2.11) reads

$$\partial_i p_i = R_i, \quad \partial_i p_j = 0 \quad (j \neq i), \tag{3.3}$$

where the functions R_i (2.10) are

$$R_i = -\frac{\partial_i H}{\partial^i H} \quad \left(\partial_i = \frac{\partial}{\partial q^i}, \partial^i = \frac{\partial}{\partial p_i}\right).$$

Since the generators D_i (2.14) are

$$D_i = \partial_i + R_i \partial^i,$$

the separability conditions $[D_i, D_j] = 0$ (2.15) are equivalent to the well-known *Levi-Civita separability conditions*

$$\partial^i \partial^j H \partial_i H \partial_j H + \partial_i \partial_j H \partial^i H \partial^j H - \partial^i \partial_j H \partial_i H \partial^j H - \partial_i \partial^j H \partial^i H \partial_j H = 0, \quad i \neq j, \ \text{n.s.}, \tag{3.4}$$

where "n.s." means that there is no summation over the repeated indices. As a consequence, Theorem 2.3 reduces to the celebrated *Levi-Civita theorem*,

Theorem 3.1: *The Hamilton–Jacobi equation (3.1) is separable in the coordinates* $\underline{q} = (q^i)$ *i.e., it admits a solution of the kind (2.3) satisfying the completeness condition (3.2), if and only if (3.4) are identically satisfied.*

This theorem holds for any kind of Hamiltonian. We can apply it to a *natural Hamiltonian*

$$H = G + V = \tfrac{1}{2} g^{ij}(\underline{q}) p_i p_j + V(\underline{q}),$$

where G is the geodesic Hamiltonian, $V: Q \to \mathbb{R}$ a potential energy. The corresponding Hamilton–Jacobi equation is now Eq. (1.1), which in any local canonical coordinate system becomes

$$\tfrac{1}{2} g^{ij} \partial_i W \partial_j W + V = E.$$

Moreover, we can consider two special types of coordinates: *orthogonal* and *standard* coordinates (Definition 3.3). It is straightforward to prove that

Proposition 3.2: If the coordinates are orthogonal ($g^{ij} = 0$ *for* $i \neq j$)*, then the Levi-Civita separability conditions are equivalent to*

$$\begin{array}{c} g^{ii} g^{jj} \partial_i \partial_j g^{hh} - g^{ii} \partial_i g^{jj} \partial_j g^{hh} - g^{jj} \partial_j g^{ii} \partial_i g^{hh} = 0, \\ g^{ii} g^{jj} \partial_i \partial_j V - g^{ii} \partial_i g^{jj} \partial_j V - g^{jj} \partial_j g^{ii} \partial_i V = 0, \end{array} \quad i \neq j, \ \text{n.s.} \tag{3.5}$$

These equations do not involve the momenta $\underline{p}$. An equivalent form of these equations were first established by Eisenhart.[3] It can be shown that their general solutions have the Stäckel form (1.6).[15] It follows that the Hamilton–Jacobi equations split into separated equations of the form

$$\tfrac{1}{2} p_i^2 = \varphi_i^{(j)} c_j - \phi_i,$$

where $\underline{c} = (c_j)$ are arbitrary constants satisfying the completeness condition. Equation (3.5) can also be written in the form

$$\begin{array}{c} \partial_i \partial_j g^{hh} - \partial_i \ln g^{jj} \partial_j g^{hh} - \partial_j \ln g^{ii} \partial_i g^{hh} = 0, \\ \partial_i \partial_j V - \partial_i \ln g^{jj} \partial_j V - \partial_j \ln g^{ii} \partial_i V = 0, \end{array} \quad i \neq j, \ \text{n.s.} \tag{3.5$'$}$$

Note that the first equations (3.5′) characterize the orthogonal separation of the pure geodesic Hamiltonian.

Definition 3.3: A *standard coordinate system* is a coordinate system $(q^i) = (q^a, q^\alpha)$ with $a = 1,...,m$ and $\alpha = m+1,...,n$, such that (i) the metric tensor assumes the semidiagonal *standard form*

$$\mathbf{G} = g^{aa} \partial_a \otimes \partial_a + g^{\alpha\beta} \partial_\alpha \otimes \partial_\beta, \tag{3.6}$$

and (ii) the coordinates (q^{α}) are *ignorable*,

$$\partial_{\alpha} g^{ij} = 0, \quad \partial_{\alpha} V = 0. \tag{3.7}$$

We call *essential* the coordinates (q^{a}).
It is straightforward to prove that

Proposition 3.4: In standard coordinates the Levi-Civita separability conditions are equivalent to the following:

$$\begin{gathered} g^{aa} g^{bb} \partial_a \partial_b g^{cc} - g^{aa} \partial_a g^{bb} \partial_b g^{cc} - g^{bb} \partial_b g^{aa} \partial_a g^{cc} = 0, \\ g^{aa} g^{bb} \partial_a \partial_b g^{\alpha\beta} - g^{aa} \partial_a g^{bb} \partial_b g^{\alpha\beta} - g^{bb} \partial_b g^{aa} \partial_a g^{\alpha\beta} = 0, \\ g^{aa} g^{bb} \partial_a \partial_b V - g^{aa} \partial_a g^{bb} \partial_b V - g^{bb} \partial_b g^{aa} \partial_a V = 0, \end{gathered} \tag{3.8}$$

with $a \neq b$ not summed.

These equations can be written in the equivalent form

$$\begin{gathered} \partial_a \partial_b g^{cc} - \partial_a \ln g^{bb} \partial_b g^{cc} - \partial_b \ln g^{aa} \partial_a g^{cc} = 0, \\ \partial_a \partial_b g^{\alpha\beta} - \partial_a \ln g^{bb} \partial_b g^{\alpha\beta} - \partial_b \ln g^{aa} \partial_a g^{\alpha\beta} = 0, \\ \partial_a \partial_b V - \partial_a \ln g^{bb} \partial_b V - \partial_b \ln g^{aa} \partial_a V = 0. \end{gathered} \tag{3.8$'$}$$

Their general solutions are still of Stäckel type, but involving an $m \times m$ Stäckel matrix $[\varphi_a^{(b)}]$ of functions depending on the essential coordinates only,

$$g^{aa} = \varphi^{a}_{(m)}, \quad g^{\alpha\beta} = \phi_a^{\alpha\beta} g^{aa}, \quad V = \phi_a g^{aa}, \tag{3.9}$$

with functions $(\phi_a^{\alpha\beta}, \phi_a)$ depending on the essential coordinate corresponding to the lower index only. Then the Hamilton–Jacobi equation splits into separated equations of the kind

$$p_{\alpha} = c_{\alpha}, \quad \tfrac{1}{2} p_{\alpha}^2 = \varphi_a^{(b)} c_b - \phi_a^{\alpha\beta} c_{\alpha} c_{\beta} - \phi_a,$$

where $c = (c_i) = (c_a, c_{\alpha})$ are n arbitrary constants.

Remark 3.5: The above-given definition of standard coordinates needs some comments. (i) In a given standard coordinate system (q^{i}) the distinction between ''ignorable'' and ''essential'' coordinates is in general not univocal. Indeed, an ignorable coordinate may be orthogonal to the other ones and considered as essential; conversely, an essential coordinate may be ignorable, i.e., it may satisfy (3.7). However, in the process of integration by separation of variables of the Hamilton–Jacobi equation it is useless to consider an ignorable coordinate as ''essential,'' since it corresponds to a linear homogeneous first integral and thus to a trivial separated equation. (ii) The distinction between ignorable and essential coordinates becomes univocal and assumes a full meaning when related to a given separable Killing web,[16,17] that is when related to the geometrical characterization of the separation (see Sec. VII).

Remark 3.6: It is known that there is no loss of generality in considering separable standard coordinates. Indeed, the analysis of the Levi-Civita separability conditions shows that any separable coordinate system admits an equivalent standard system (q^{a}, q^{α}) where the number of essential coordinates is minimalized, i.e., it coincides with the number of second-class coordinates, according to the classification of Levi-Civita. This number is invariant within an equivalence class of separable coordinates. A standard coordinate system in which the essential coordinates (q^{a}) are exactly those of second class has been called *normal*.[17] For our present purposes we do not need to take into account the classification of Levi-Civita and the subtle distinction between ''normal'' and ''standard'' coordinates. We need only to refer to the above-given definition of standard coordinates and to the corresponding separability conditions (3.8) or (3.8$'$).

Definition 3.7: We say that a symmetric two-tensor $\mathbf{K}=(K^{ij})$ has a *standard form* or that it is a *standard tensor* with respect to a standard coordinate system if it assumes the form

$$\mathbf{K}=K^{aa}\partial_a\otimes\partial_a+K^{\alpha\beta}\partial_\alpha\otimes\partial_\beta=\lambda^a g^{aa}\partial_a\otimes\partial_a+K^{\alpha\beta}\partial_\alpha\otimes\partial_\beta, \tag{3.10}$$

where (λ^a) and $K^{\alpha\beta}$ do not depend on the ignorable coordinates (q^α). Then the matrix $[K^{ij}]$ has a form similar to (3.6).

Note that a tensor may be simultaneously in standard form with respect to nonequivalent separable standard coordinate systems.

IV. THE FREE SEPARATION OF THE SCHRÖDINGER EQUATION

In this section we shall show that a convenient and precise ''ansatz'' for the multiplicative separation of the Schrödinger equation (1.2) is given by the following

Definition 4.1: A *complete separated solution* of the Schrödinger equation is a solution of the form $\psi(\underline{q},\underline{c})=\Pi_i^n\ \psi_i(q^i,\underline{c})$, depending on $2n$ parameters $\underline{c}=(c_I)$ satisfying the *completeness condition*

$$\det\left[\begin{array}{c}\dfrac{\partial u_i}{\partial c_I}\\[2ex]\dfrac{\partial v_i}{\partial c_I}\end{array}\right]\neq 0,\quad u_i=\frac{\psi_i'}{\psi_i},\quad v_i=\frac{\psi_i''}{\psi_i}. \tag{4.1}$$

When such a solution exists we say that the Schrödinger equation is *separable* (or *freely separable*) in the coordinates $\underline{q}=(q^i)$.

The completeness condition (4.1) means that the $2n$ constants (c_I) can be uniquely determined by assigning arbitrary values to the $2n$ ratios $(\underline{u},\underline{v})$, at any fixed point. Hence, no restriction is imposed on the values that the functions $(\psi_i,\psi_i',\psi_i'')$ can assume at any given point of the domain of the coordinates, for $\psi\neq 0$. For this reason we call this kind of separation *free*. As we shall see in Sec. V, we can in fact consider another kind of separation in which such a ''freedom'' is lost. As we shall see in the following (Remark 4.8), the $2n$ parameters appearing in a free separated solution have a different role: in the process of integration n of them are related to constants of motion in involution or, equivalently, to second-order commuting symmetries of the Schrödinger operator, so that they can be interpreted as ''separation constants,'' while the remaining n parameters arise as ''integration constants.''

By assuming Definition 4.1 we shall prove

Theorem 4.2: *The Schrödinger equation is freely separable in a coordinate system $\underline{q}$ if and only if: (i) these coordinates are orthogonal, (ii) the corresponding Hamilton–Jacobi equation is separable, (iii) the following conditions are satisfied:*

$$\partial_i\Gamma_j=0\quad (i\neq j), \tag{4.2}$$

where

$$\Gamma_i=g^{hj}\Gamma_{hj,i},\quad \Gamma_{hj,i}=\tfrac{1}{2}(\partial_h g_{ji}+\partial_j g_{ih}-\partial_i g_{hj}). \tag{4.3}$$

Since $\Gamma_{hj,i}$ are the Christoffel symbols of the Levi-Civita connection, we call the functions Γ_i the *contracted Christoffel symbols*, associated with the coordinates $\underline{q}$. From their definition (4.3) it follows that

$$\Gamma_i=\tfrac{1}{2}\partial_i\ln\det[g^{hj}]-g_{ik}\partial_h g^{hk}. \tag{4.4}$$

We call the whole set of equations (4.2) the *Robertson condition for the free separation* of the Schrödinger equation. In this form the Robertson condition means that each contracted Christoffel

symbol Γ_i is a function of the corresponding coordinate q^i only (see Remark 4.7). As we know, an equivalent form of the Robertson condition is the diagonalization of the Ricci tensor. We shall discuss this equivalence in Sec. VI.

In order to justify all the above-given statements, let us start from the local coordinate expression of the Schrödinger equation (1.2),

$$g^{ij}\partial_i\partial_j\psi-\Gamma^k\partial_k\psi+\frac{2}{\hbar^2}(E-V)\psi=0, \quad \Gamma^k=g^{ki}\Gamma_i. \tag{4.5}$$

Since the constant factor $2/\hbar^2$ is inessential for our consideration, from now on we shall replace $(2/\hbar^2)V$ with V and $(2/\hbar^2)E$ by E.

For a separated solution of the kind (1.4) we have

$$\partial_i\psi=\frac{\psi_i'}{\psi_i}\psi, \quad \partial_i\partial_j\psi=\frac{\psi_i'\psi_j'}{\psi_i\psi_j}\psi \quad (i\neq j), \quad \partial_i\partial_i\psi=\frac{\psi_i''}{\psi_i}\psi. \tag{4.6}$$

Here the prime denotes the derivative operator on a function of a single variable. We remark that in these formulas the fraction ψ/ψ_i is the product $\psi_1\cdots\hat{\psi}_i\cdots\psi_n$, without the factor ψ_i. Thus, expressions (4.6) also hold at the points where $\psi_i=0$. If we set $u=\ln\psi$, then

$$u_i=\partial_i u=\frac{\partial_i\psi}{\psi}=\frac{\psi_i'}{\psi_i} \tag{4.7}$$

are functions of the corresponding variable q^i and moreover,

$$\partial_i\psi=\psi u_i,$$

$$\partial_i\partial_j\psi=\psi u_i u_j \quad (i\neq j),$$

$$\partial_i\partial_i\psi=\psi(u_i^2+u_i^{(2)}), \quad u_i^{(2)}=u_{ii}=\partial_i\partial_i u.$$

It follows that for a separated solution Eq. (4.5) assumes the form

$$(g^{ij}u_iu_j+g^{ii}u_i^{(2)}-\Gamma^i u_i+E-V)\psi=0, \tag{4.8}$$

where the sum over the repeated indices is understood. Thus, for $\psi\neq 0$ we get a partial differential equation of the kind (2.8) with $l=2$,

$$\mathcal{S}(\underline{q},\underline{u}^{(1)},\underline{u}^{(2)})=-E,$$

by setting (see Ref. 12)

$$\begin{gathered}\mathcal{S}(\underline{q},\underline{u}^{(1)},\underline{u}^{(2)})=g^{ij}u_iu_j+g^{ii}u_i^{(2)}-\Gamma^i u_i-V,\\ \underline{u}^{(1)}=(u_i), \quad \underline{u}^{(2)}=(u_{ii}).\end{gathered} \tag{4.9}$$

As a consequence, by applying Definition 2.2 to the present case and Theorem 2.3 related to the general equation (2.8), taking into account Remark 2.4, the completeness condition (2.16), and expression (4.7), we are led to the following definition and theorem.

Definition 4.3: A complete separated solution of the Schrödinger equation (4.5) is a solution of the form (1.4) depending on $2n$ constant parameters $\underline{c}=(c_I)$ satisfying the completeness condition

$$\det\begin{bmatrix} \dfrac{\partial u_i}{\partial c_I} \\ \dfrac{\partial u_i^{(2)}}{\partial c_I} \end{bmatrix} \neq 0, \quad u_i = \frac{\psi_i'}{\psi_i}, \quad u_i^{(2)} = u_{ii} = \left(\frac{\psi_i'}{\psi_i}\right)'. \tag{4.10}$$

Theorem 4.4: *The Schrödinger equation (4.5) is separable in the coordinates $\underline{q}$ if and only if the following first-order differential system is completely integrable*

$$\begin{aligned} \partial_i u_i^{(1)} &= u_i^{(2)}, \quad & \partial_i u_j^{(1)} &= 0, \\ \partial_i u_i^{(2)} &= R_i, \quad & \partial_i u_j^{(2)} &= 0, \end{aligned} \quad (i \neq j), \tag{4.11}$$

where

$$R_i(\underline{q}, \underline{u}^{(1)}, \underline{u}^{(2)}) = -\left(\frac{\partial \mathcal{S}}{\partial u_i^{(2)}}\right)^{-1}\left(\frac{\partial \mathcal{S}}{\partial q^i} + \frac{\partial \mathcal{S}}{\partial u_i} u_i^{(2)}\right), \tag{4.12}$$

$\mathcal{S}$ being defined as in (4.9) i.e., if and only if the commutation relations

$$[D_i, D_j] = 0, \tag{4.13}$$

are identically satisfied for

$$D_i = \partial_i + u_i^{(2)} \frac{\partial}{\partial u_i} + R_i \frac{\partial}{\partial u_i^{(2)}}.$$

Remark 4.5: If we replace the $2n$ variables $(\underline{u}^{(1)}, \underline{u}^{(2)})$ with the variables

$$(\underline{u}, \underline{v}) = (u_i, v_i)$$

where

$$v_i = u_i^{(2)} + u_i^2 = \frac{\psi_i''}{\psi_i}, \tag{4.14}$$

then the completeness condition (4.10) becomes equivalent to (4.1), so that Definition 4.3 is equivalent to Definition 4.1.

This transformation of dependent variables turns out to be convenient for the analysis of the integrability (or separability) conditions (4.13). We note first of all that

$$\frac{\partial \mathcal{S}}{\partial u_i^{(2)}} = g^{ii},$$

so that the definition (4.12) becomes

$$R_i(\underline{q}, \underline{u}^{(1)}, \underline{u}^{(2)}) = -(g^{ii})^{-1}\left(\frac{\partial \mathcal{S}}{\partial q^i} + \frac{\partial \mathcal{S}}{\partial u_i} u_i^{(2)}\right).$$

In the new variables we have

$$\mathcal{S}(\underline{q}, \underline{u}, \underline{v}) = g^{ij} u_i u_j + g^{ii}(v_i - u_i^2) - \Gamma^i u_i - V,$$

$$R_i(\underline{q}, \underline{u}, \underline{v}) = -\frac{1}{g^{ii}}\left(\frac{\partial \mathcal{S}}{\partial q^i} + (v_i - u_i^2)\frac{\partial \mathcal{S}}{\partial u_i}\right), \tag{4.15}$$

$$D_i=\partial_i+(v_i-u_i^2)\frac{\partial}{\partial u_i}+R_i\frac{\partial}{\partial v_i},$$

and system (4.11) becomes equivalent to

$$\begin{array}{ll}\partial_i u_i=v_i-u_i^2, & \partial_i u_j=0,\\ \partial_i v_i=R_i, & \partial_i v_j=0,\end{array}\quad (i\neq j). \tag{4.16}$$

Using (4.15), a straightforward calculation shows that

$$[D_i,D_j]=\left((v_i-u_i^2)\frac{\partial R_j}{\partial u_i}+R_i\frac{\partial R_j}{\partial v_i}+\frac{\partial R_j}{\partial q^i}\right)\frac{\partial}{\partial v_j}-\left((v_j-u_j^2)\frac{\partial R_i}{\partial u_j}+R_j\frac{\partial R_i}{\partial v_j}+\frac{\partial R_i}{\partial q^j}\right)\frac{\partial}{\partial v_i}.$$

Hence, the integrability conditions (4.13) become equivalent to

$$(v_i-u_i^2)\frac{\partial R_j}{\partial u_i}+R_i\frac{\partial R_j}{\partial v_i}+\frac{\partial R_j}{\partial q^i}=0\quad (i\neq j). \tag{4.17}$$

Because of (4.15),

$$\frac{\partial R_i}{\partial q^i}=-\frac{1}{g^{jj}}\partial_i g^{jj}R_j-\frac{1}{g^{jj}}\left[\partial_i\partial_j\mathcal{S}+\frac{\partial^2\mathcal{S}}{\partial q^i\partial u_j}(v_j-u_j^2)\right]$$

and, for $i\neq j$,

$$\frac{\partial R_j}{\partial v_i}=-\frac{1}{g^{jj}}\left[\frac{\partial^2\mathcal{S}}{\partial q^j\partial v_i}+\frac{\partial^2\mathcal{S}}{\partial v_i\partial u_j}(v_j-u_j^2)\right]=-\frac{1}{g^{jj}}\partial_j g^{ii}\quad (i\neq j).$$

Moreover,

$$\frac{\partial\mathcal{S}}{\partial u_i}=2g^{ik}u_k-2g^{ii}u_i-\Gamma^i.$$

Thus,

$$\frac{\partial^2\mathcal{S}}{\partial u_i\partial u_j}=2g^{ij}\quad (i\neq j).$$

It follows that

$$\frac{\partial R_j}{\partial u_i}=-\frac{1}{g^{jj}}\left[\frac{\partial^2\mathcal{S}}{\partial u_i\partial q^j}+2g^{ij}(v_j-u_j^2)\right]\quad (i\neq j).$$

Due to these last equations, the integrability conditions (4.17) become equivalent to

$$2g^{ij}(v_i-u_i^2)(v_j-u_j^2)+\frac{\partial^2\mathcal{S}}{\partial q^i\partial u_j}(v_j-u_j^2)+\frac{\partial^2\mathcal{S}}{\partial q^j\partial u_i}(v_i-u_i^2)+\partial_i\partial_j\mathcal{S}+R_i\partial_j g^{ii}+R_j\partial_i g^{jj}=0$$

$$(i\neq j). \tag{4.18}$$

Note that in this form they are symmetric in the distinct indices (i,j). We remark that these are algebraic equations in the variables $(\underline{u},\underline{v})$ and that they must be identically satisfied for all values of these variables, due to the completeness condition. A closer analysis of expressions (4.15) shows that (4.18) are of second degree in $\underline{v}$, and that the corresponding second-degree homogeneous polynomial is given by the first term $g^{ij}v_iv_j$, with $i\neq j$ not summed. This implies

$$g^{ij}=0 \quad (i\neq j) \tag{4.19}$$

and shows that

Proposition 4.6: In the free separation of the Schrödinger equation the coordinates are necessarily orthogonal.

In orthogonal coordinates, Eqs. (4.18) and (4.15) assume the simpler form

$$\frac{\partial^2\mathcal{S}}{\partial q^i\partial u_j}(v_j-u_j^2)+\frac{\partial^2\mathcal{S}}{\partial q^j\partial u_i}(v_i-u_i^2)+\partial_i\partial_j\mathcal{S}+R_i\partial_j g^{ii}+R_j\partial_i g^{jj}=0 \quad (i\neq j) \tag{4.20}$$

and

$$\mathcal{S}=g^{ii}v_i-\Gamma^i u_i-V, \quad R_i=\frac{1}{g^{ii}}[\Gamma^i(v_i-u_i^2)-\partial_i\mathcal{S}]. \tag{4.21}$$

It follows that

$$R_i=\frac{1}{2g^{ii}}[2\Gamma^i(v_i-u_i^2)-\partial_i g^{kk}v_k+\partial_i\Gamma^k u_k+\partial_i V].$$

By inserting this last expression of R_i into (4.20) we conclude that the integrability conditions of system (4.16) are equivalent to the orthogonality conditions (4.19) and to the following:

$$\begin{aligned}&2(u_j^2-v_j)(\partial_i\Gamma^j-\Gamma^j\partial_i\ln g^{jj})+2(u_i^2-v_i)(\partial_j\Gamma^i-\Gamma^i\partial_j\ln g^{ii})\\&\quad+v_k(\partial_i\partial_j g^{kk}-\partial_i\ln g^{jj}\partial_j g^{kk}-\partial_j\ln g^{ii}\partial_i g^{kk})-u_k(\partial_i\partial_j\Gamma^k-\partial_i\ln g^{jj}\partial_j\Gamma^k-\partial_j\ln g^{ii}\partial_i\Gamma^k)\\&\quad-(\partial_i\partial_j V-\partial_i\ln g^{jj}\partial_j V-\partial_j\ln g^{ii}\partial_i V)=0 \quad (i\neq j).\end{aligned} \tag{4.22}$$

Since these last equations are polynomial in the variables $(\underline{u},\underline{v})$, they are identically satisfied if and only if all the coefficients vanish, namely:

$$\begin{gathered}\partial_i\partial_j g^{kk}-\partial_i\ln g^{jj}\partial_j g^{kk}-\partial_j\ln g^{ii}\partial_i g^{kk}=0,\\ \partial_i\partial_j V-\partial_i\ln g^{jj}\partial_j V-\partial_j\ln g^{ii}\partial_i V=0,\\ \partial_j\Gamma^i-\Gamma^i\partial_j\ln g^{ii}=0,\\ \partial_i\partial_j\Gamma^k-\partial_i\ln g^{jj}\partial_j\Gamma^k-\partial_j\ln g^{ii}\partial_i\Gamma^k=0.\end{gathered} \quad (i\neq j) \tag{4.23}$$

These equations are in fact redundant. Indeed, it can be seen that due to the first and third equations, the last equation is identically satisfied. Moreover, the third equation is equivalent to

$$\partial_j\Gamma_i=0 \quad (i\neq j),$$

where, in orthogonal coordinates,

$$\Gamma_i=g_{ii}\Gamma^i=\tfrac{1}{2}\Sigma_{k\neq i}\partial_i\ln g^{kk}-\tfrac{1}{2}\partial_i\ln g^{ii}=\partial_i\ln(g_{ii}\sqrt{\Pi_k g^{kk}}). \tag{4.24}$$

Finally, we recognize in the first two equations of (4.23) the necessary and sufficient conditions (3.5') for the orthogonal separation of the Hamilton–Jacobi equation. Thus, due to Theorem 4.4, Theorem 4.2 is proved.

Remark 4.7: After Theorem 4.2, the integration of the Schrödinger equation by separation of variables is accomplished as follows. Due to the Stäckel form (1.6) of the metric tensor components and of the potential, the Schrödinger equation (4.8) takes the form

$$\varphi^i_{(n)}(u_i'+u_i^2-\Gamma_i u_i-\phi_i)=-E, \quad u_i=\frac{\psi_i'}{\psi_i}.$$

This equation is interpreted as the last one of a system of n equations involving all the remaining rows of the matrix $[\varphi^i_{(j)}]$ and n constants $\underline{a}=(a_i)$,

$$\varphi^i_{(j)}(u_i'+u_i^2-\Gamma_i u_i-\phi_i)=-a_j, \quad a_n=E, \tag{4.25}$$

which is equivalent to the following system of separated equations:

$$u_i'+u_i^2-\Gamma_i u_i-\phi_i+\varphi_i^{(j)}a_j=0. \tag{4.26}$$

These are first-order Riccati equations in the unknown functions $u_i(q^i)$, depending on the n constant parameters $\underline{a}=(a_j)$. Their integration yields functions

$$u_i=u_i(q^i,\underline{a},b_i), \tag{4.27}$$

each one depending on a further constant b_i. The complete separated solution is then given, up to an inessential constant factor, by

$$\psi=\exp\int u_i\,\mathrm{d}q^i. \tag{4.28}$$

We note that (as happens for any Riccati equation) (4.26) are equivalent to the linear second-order equations

$$\psi_i''-\Gamma_i\psi_i'-(\phi_i-\varphi_i^{(j)}a_j)\psi_i=0 \tag{4.29}$$

in the original unknown functions ψ_i.

Remark 4.8: The $2n$ constants $\underline{c}=(c_I)=(\underline{a},\underline{b})=(a_i,b_i)$, appearing in a separated solution (4.28) as a result of the process of integration by separation of variables illustrated previously, play a different role. While $\underline{b}$ arise as integration constants from the integration of the first-order Riccati equations (4.26), or of the second-order linear equations (4.29), the constants $\underline{a}$ have two interpretations. (i) They are the constant values taken by the quadratic first integrals in involution related to the separation of the Hamilton–Jacobi equation (see Theorem 7.14), whose expressions in orthogonal separable coordinates are

$$H_j=\tfrac{1}{2}\varphi^i_{(j)}(p_i^2+2\phi_i). \tag{4.30}$$

(ii) They are the eigenvalues of the second-order symmetry operators of the Schrödinger equation corresponding to H_j,

$$\hat{H}_j\psi=\psi^i_{(j)}(-\partial_i^2\psi+\Gamma_i\partial_i\psi+\phi_i\psi). \tag{4.31}$$

The link between H_j and $\hat{H}_j$ will be discussed in a following paper.[18] If we apply these operators to a separated solution (1.4) then, due to (4.6), (4.7) and (4.14), we get

$$\hat{H}_j\psi=\varphi^i_{(j)}(\Gamma_i u_i-v_i+\phi_i)\psi, \tag{4.32}$$

which shows that the eigenvalues are

$$a_j=\varphi^i_{(j)}(\Gamma_i u_i-v_i+\phi_i). \tag{4.33}$$

Remark 4.9: The values of the constants $\underline{a}$ are determined through (4.25), which are equivalent to (4.33), by the initial values at a point q_0 of (u_i,u_i') i.e., by the initial values of $(\psi_i,\psi_i',\psi_i'')$, for $\psi_i(q_0)\neq 0$. The values of $\underline{b}$ are then determined by reversing (4.27) at the initial point q_0: $u_i(q_0)=u_i(q_0^i,\underline{a},b_i)$. If instead of the first-order equations (4.26) we consider the equivalent second-order equations (4.29), the resulting integration constants are $2n$, but only half

of them are essential, since the functions ψ_i are determined up to a constant factor. Thus, also in this case we reduce to n essential constants (b_i). See Sec. IX for an example.

V. THE REDUCED SEPARATION OF THE SCHRÖDINGER EQUATION

In Sec. IV we have considered a kind of multiplicative separation of the Schrödinger equation involving $2n$ constant parameters $\underline{c}$ which can be uniquely determined by assigning the values, at any chosen point, of the functions $u_i=\psi_i'/\psi_i$ and $v_i=\psi_i''/\psi_i$. This means that we have no restriction on the values that the functions $(\psi_i,\psi_i',\psi_i'')$ can assume at any given point of the domain of the coordinates, for $\psi\neq 0$. As we have seen, this freedom implies the orthogonality of the separable coordinates.

However, we can think of a kind of separation in which *constraints* are "*a priori*" imposed on some of the factors ψ_i.

Although it is not interpreted in this sense, a usual constraint appearing in the literature is represented by the following supplementary conditions (see for instance Refs. 9, 10, and 12):

$$\psi_\alpha'=\kappa_\alpha\psi_\alpha, \quad \alpha=m+1,...,n, \tag{5.1}$$

where (κ_α) are arbitrary (real or complex) constants. This means that, up to an inessential multiplicative constant,

$$\psi_\alpha(q^\alpha)=\exp(\kappa_\alpha q^\alpha). \tag{5.2}$$

In this way we define a kind of *constrained separation*, which we call *reduced separation*. As we shall see, for this separation the coordinates are not necessarily orthogonal and the number of essential constants appearing in a separated solution is $n+m<2n$ (the case $m=n$ corresponds to the free separation). We base our approach on a definition similar to Definition 4.1.

Definition 5.1: A *reduced separated solution* of the Schrödinger equation is a solution (1.4) where the factors ψ_α are of the type (5.2) for $\alpha=m+1,...,n$ and where all factors ψ_α depend on further $2m$ parameters $\underline{c}=(c_A)$ $(A=1,...,2m)$ satisfying the *completeness condition*

$$\det\begin{bmatrix}\dfrac{\partial u_a}{\partial c_A}\\[2ex] \dfrac{\partial v_a}{\partial c_A}\end{bmatrix}\neq 0, \quad u_a=\frac{\psi_a'}{\psi_a}, \quad v_a=\frac{\psi_a''}{\psi_a} \quad (a=1,...,m). \tag{5.3}$$

When such a solution exists we say that the Schrödinger equation is *reductively separable* in the coordinates (q^a,q^α). The coordinates (q^α) and (q^a) are called *constrained* and *free* coordinates, respectively.

The completeness condition (5.3) means that the $2m$ constant parameters (c_A) can be uniquely determined by assigning arbitrary values of the $2m$ ratios (u_a,v_a) at any given point. Hence, we have no restriction on the values that the functions $(\psi_a,\psi_a',\psi_a'')$ can assume at any given point of the domain of the coordinates, for $\psi\neq 0$. Moreover, we remark that the total number of constant parameters in a reduced separated solution is $m+n$. Indeed, besides the $2m$ constants (c_A), also the $n-m$ constants (κ_α) are present, although they are not involved in the completeness condition.

In this section we shall prove the following theorem (analogous to Theorem 4.2).

Theorem 5.2: *The Schrödinger equation is reductively separable in a coordinate system* $\underline{q}=(q^a,q^\alpha)$ *if and only if: (i) the constrained coordinates* (q^α) *are ignorable,*

$$\partial_\alpha g^{ij}=0, \quad \partial_\alpha V=0,$$

(ii) the free coordinates (q^a) *are orthogonal,*

$$g^{ab}=0, \quad a\neq b,$$

(iii) there exists a coordinate transformation leaving the coordinates (q^a) *invariant, preserving the constraints and the separation, in which the metric tensor assumes the standard form (3.6) and such that (iv) the Hamilton–Jacobi equation is separable and (v) the following conditions are satisfied:*

$$\partial_a\Gamma_b=0 \quad (a\neq b), \quad \Gamma_a=g^{ij}\Gamma_{ij,a}. \tag{5.4}$$

We call Eq. (5.4) the *Robertson condition for the reduced separation* of the Schrödinger equation. As will be discussed in Sec. VI, this is in fact equivalent to $R_{ab}=0$ for $a\neq b$.

In order to justify Definition 5.1 and prove Theorem 5.2 we begin by observing that the constraints (5.1) imply that the functions u_i, defined as in (4.7) and labeled with Greek indices (running from $m+1$ to n) are constant

$$u_\alpha=\frac{\psi'_\alpha}{\psi_\alpha}=\kappa_\alpha, \quad u^{(2)}_\alpha=0,$$

so that, for such a separated solution, Eq. (4.8) becomes equivalent (for $\psi\neq 0$) to

$$g^{ab}u_au_b+g^{aa}u^{(2)}_a+2g^{a\alpha}u_a\kappa_\alpha+g^{\alpha\beta}\kappa_\alpha\kappa_\beta-\Gamma^au_a-\Gamma^\alpha\kappa_\alpha-V+E=0,$$

with summation over the repeated indices a, $b=1,\ldots,m$ and α, $\beta=m+1,...,n$. This equation can be written in the form

$$\mathcal{S}(\underline{q},\underline{u}^{(1)},\underline{u}^{(2)},\kappa_\alpha)=-E, \tag{5.5}$$

by setting

$$\begin{gathered}\mathcal{S}(\underline{q},\underline{u}^{(1)},\underline{u}^{(2)},\kappa_\alpha)=g^{ab}u_au_b+g^{aa}u^{(2)}_a+2g^{a\alpha}u_a\kappa_\alpha+g^{\alpha\beta}\kappa_\alpha\kappa_\beta-\Gamma^au_a-\Gamma^\alpha\kappa_\alpha-V,\\ \underline{u}^{(1)}=(u_a), \quad \underline{u}^{(2)}=(u_{aa}).\end{gathered} \tag{5.6}$$

Equation (5.5) is of the type (2.8). The constants (κ_α) play the role of independent constant parameters and the relevant dependent variables are $\underline{z}=(\underline{u}^{(1)},\underline{u}^{(2)})=(u_a,u_{aa})$. Their number is $2m$. By applying the method of Sec. II, we have for a solution of this equation

$$\sum_{a=1}^{m}\left(\frac{\partial\mathcal{S}}{\partial q^i}+\frac{\partial\mathcal{S}}{\partial u^{(1)}_a}\frac{\partial u^{(1)}_a}{\partial q^i}+\frac{\partial\mathcal{S}}{\partial u^{(2)}_a}\frac{\partial u^{(2)}_a}{\partial q^i}\right)=0,$$

thus (no sum over the index a)

$$\frac{\partial\mathcal{S}}{\partial q^a}+\frac{\partial\mathcal{S}}{\partial u^{(1)}_a}\frac{\partial u^{(2)}_a}{\partial q^a}+\frac{\partial\mathcal{S}}{\partial u^{(2)}_a}\frac{\partial u^{(2)}_a}{\partial q^a}=0, \quad \frac{\partial\mathcal{S}}{\partial q^\alpha}=0.$$

As a consequence, by adapting Definition 2.2 to the present case, we are led to the following

Definition 5.3: A *reduced separable solution* of the Schrödinger equation is a solution of the form (1.4)–(5.2), depending on $2m$ parameters $\underline{c}=(c_A)$ $(A=1,...,2m)$ satisfying the completeness condition

$$\det\begin{bmatrix} \dfrac{\partial u_a}{\partial c_A} \\ \dfrac{\partial u_a^{(2)}}{\partial c_A} \end{bmatrix} \neq 0, \quad u_a = \frac{\psi_a'}{\psi_a}, \quad u_a^{(2)} = u_{aa} = \left(\frac{\psi_a'}{\psi_a}\right)'. \tag{5.7}$$

Hence, by applying Theorem 2.3 and recalling (2.5) and (2.2), we get

Proposition 5.4: The Schrödinger equation is reductively separable in the coordinates $\underline{q} = (q^a, q^\alpha)$ *if and only if*

$$\partial_\alpha \mathcal{S} = 0, \tag{5.8}$$

$\mathcal{S}$ *being defined as in (5.6), and the first-order differential system*

$$\begin{aligned} &\partial_a u_a^{(i)} = u_a^{(2)}, \quad \partial_i u_a^{(1)} = 0, \\ &\partial_a u_a^{(2)} = R_a, \quad \partial_i u_a^{(2)} = 0, \end{aligned} \quad (i \neq a) \tag{5.9}$$

is completely integrable for

$$R_a(\underline{q}, \underline{u}^{(1)}, \underline{u}^{(2)}) = -\left(\frac{\partial \mathcal{S}}{\partial u_a^{(2)}}\right)^{-1}\left(\frac{\partial \mathcal{S}}{\partial q^a} + \frac{\partial \mathcal{S}}{\partial u_a} u_a^{(2)}\right).$$

The complete integrability conditions for this system are

$$[D_i, D_j] = 0, \quad \begin{cases} D_a = \partial_a + u_a^{(2)} \dfrac{\partial}{\partial u_a} + R_a \dfrac{\partial}{\partial u_a^{(2)}}, \\ D_\alpha = \partial_\alpha. \end{cases} \tag{5.10}$$

From (5.8) and (5.6) it follows that

$$\partial_\alpha g^{ij} = 0, \quad \partial_\alpha \Gamma^i = 0, \quad \partial_\alpha V = 0,$$

since $\mathcal{S}$ is a polynomial function in the variables $(\underline{u}, \underline{u}^{(2)}, \kappa_\alpha)$ assuming arbitrary values. This proves that

Proposition 5.5: In the reduced separation of the Schrödinger equation the constrained coordinates (q^α) *are ignorable.*

It follows that the significant part of the integrability conditions (5.10) is that related to the free (and nonignorable) coordinates, $[D_a, D_b] = 0$ (for $a \neq b$). For examining these conditions, as in the case of the free separation, it is convenient to deal with the new $2m$ variables

$$(\underline{u}, \underline{v}) = (u_a, v_a), \quad v_a = u_{aa} + u_a^2 = \frac{\psi_\alpha''}{\psi_\alpha}.$$

Remark 5.6: Under such a transformation the completeness condition (5.7) is equivalent to (5.3), so that Definition 5.3 is equivalent to Definition 5.1.

Furthermore, the differential system (5.9) becomes equivalent to

$$\begin{aligned} &\partial_i u_a = 0, \\ &\partial_i v_a = 0, \\ &\partial_a u_a = v_a - u_a^2, \\ &\partial_a v_a = R_a, \end{aligned} \quad (i \neq a = 1, \ldots, m), \tag{5.11}$$

where

$$R_a = -\frac{1}{g^{aa}}\left(\frac{\partial \mathcal{S}}{\partial q^a} + \frac{\partial \mathcal{S}}{\partial u_a}(v_a - u_a^2)\right),$$

$$\mathcal{S}(\underline{q},\underline{u},\underline{v}) = g^{aa}(v_a - u_a^2) + g^{ab}u_a u_b + 2g^{a\alpha}u_a\kappa_\alpha + g^{\alpha\beta}\kappa_\alpha\kappa_\beta - \Gamma^a u_a - \Gamma^\alpha\kappa_\alpha - V,$$

$$D_a = \partial_a + (v_a - u_a^2)\frac{\partial}{\partial u_a} + R_a\frac{\partial}{\partial v_a},$$

$$D_\alpha = \partial_\alpha .$$

The complete integrability conditions $[D_a, D_b] = 0$ of system (5.11) are then equivalent to equations similar to (4.17),

$$(v_a - u_a^2)\frac{\partial R_b}{\partial u_a} + R_a\frac{\partial R_b}{\partial v_a} + \frac{\partial R_b}{\partial q^a} = 0 \quad (a \neq b).$$

A calculation similar to that of Sec. IV shows that

Proposition 5.7: In a reduced separation the free coordinates are orthogonal,

$$g^{ab} = 0, \quad a \neq b,$$

and the integrability conditions of system (5.11) are equivalent to

$$\frac{\partial^2 \mathcal{S}}{\partial q^a \partial u_b}(v_b - u_b^2) + \frac{\partial^2 \mathcal{S}}{\partial q^b \partial u_a}(v_a - u_a^2) + \partial_a\partial_b\mathcal{S} + R_a\partial_b g^{aa} + R_b\partial_a g^{bb} = 0 \quad (a \neq b), \tag{5.12}$$

where

$$\begin{aligned} \mathcal{S} &= g^{aa}v_a + 2g^{a\alpha}u_a\kappa_\alpha + g^{\alpha\beta}\kappa_\alpha\kappa_\beta - \Gamma^a u_a - \Gamma^\alpha\kappa_\alpha - V, \\ R_a &= \frac{1}{g^{aa}}((\Gamma^a - 2g^{a\alpha}\kappa_\alpha)(v_a - u_a^2) - \partial_a S). \end{aligned} \tag{5.13}$$

From these last equations we can derive the following

Proposition 5.8: The reduced separation of the Schrödinger equation always occurs in a standard coordinate system $(q^i) = (q^a, q^\alpha)$*, for which (3.6) and (3.7) hold, and such that the following equations are satisfied for* $a \neq b$:

$$\begin{aligned} &\partial_a\partial_b g^{cc} - \partial_b \ln g^{aa}\partial_a g^{cc} - \partial_a \ln g^{bb}\partial_b g^{cc} = 0, \\ &\partial_a\partial_b g^{\alpha\beta} - \partial_b \ln g^{aa}\partial_a g^{\alpha\beta} - \partial_a \ln g^{bb}\partial_b g^{\alpha\beta} = 0, \\ &\partial_a\partial_b V - \partial_b \ln g^{aa}\partial_a V - \partial_a \ln g^{bb}\partial_b V = 0, \\ &\partial_b\Gamma_a = 0, \end{aligned} \tag{5.14}$$

where

$$\Gamma_a = g_{aa}\Gamma^a = \frac{1}{2}\sum_{c \neq a}\partial_c \ln g^{cc} - \frac{1}{2}\partial_a \ln g^{aa} + \frac{1}{2}\partial_a \ln \det[g^{\alpha\beta}]. \tag{5.15}$$

Proof: By setting

$$\hat{\Gamma}^a = \Gamma^a - 2g^{a\alpha}\kappa_\alpha, \quad \hat{V} = V + \Gamma^\alpha\kappa_\alpha - g^{\alpha\beta}\kappa_\alpha\kappa_\beta,$$

(5.13) assume the form

$$\mathcal{S}=g^{aa}v_a-\hat{\Gamma}^a u_a-\hat{V},\quad R_a=\frac{1}{g^{aa}}((\hat{\Gamma}^a(v_a-u_a^2)-\partial_a\mathcal{S}),\tag{5.16}$$

so that the integrability conditions (5.12) become

$$\begin{aligned}&2(u_b^2-v_b)(\partial_a\hat{\Gamma}^b-\hat{\Gamma}^b\partial_a\ln g^{bb})+2(u_a^2-v_a)(\partial_b\hat{\Gamma}^a-\hat{\Gamma}^a\partial_b\ln g^{aa})+v_c(\partial_a\partial_b g^{cc}-\partial_a\ln g^{bb}\partial_b g^{cc}\\&\quad-\partial_b\ln g^{aa}\partial_a g^{cc})-u_c(\partial_a\partial_b\hat{\Gamma}^c-\partial_a\ln g^{bb}\partial_b\hat{\Gamma}^c-\partial_b\ln g^{aa}\partial_a\hat{\Gamma}^c)\\&\quad-(\partial_a\partial_b\hat{V}-\partial_a\ln g^{bb}\partial_b\hat{V}-\partial_b\ln g^{aa}\partial_a\hat{V})=0.\end{aligned}\tag{5.17}$$

We remark that (5.12) and (5.16) are similar to (4.20) and (4.21), so that (5.17) are similar to (4.22) and, since (u_a,v_a) can assume arbitrary values, we get equations similar to (4.23),

$$\begin{gathered}\partial_a\partial_b g^{cc}-\partial_a\ln g^{bb}\partial_b g^{cc}-\partial_b\ln g^{aa}\partial_a g^{cc}=0,\\\partial_a\partial_b\hat{V}-\partial_a\ln g^{bb}\partial_b\hat{V}-\partial_b\ln g^{aa}\partial_a\hat{V}=0,\\\partial_a\hat{\Gamma}^b-\hat{\Gamma}^b\partial_a\ln g^{bb}=0,\\\partial_a\partial_b\hat{\Gamma}^c-\partial_a\ln g^{bb}\partial_b\hat{\Gamma}^c-\partial_b\ln g^{aa}\partial_a\hat{\Gamma}^c=0.\end{gathered}\tag{5.18}$$

The first equations are just the first equations in (5.14). Since also the constant parameters (κ_α) assume arbitrary values, the fourth equations (5.18) are equivalent to

$$\begin{gathered}\partial_a\partial_b\Gamma^c-\partial_a\ln g^{bb}\partial_b\Gamma^c-\partial_b\ln g^{aa}\partial_a\Gamma^c=0,\\\partial_a\partial_b g^{c\alpha}-\partial_a\ln g^{bb}\partial_b g^{c\alpha}-\partial_b\ln g^{aa}\partial_a g^{c\alpha}=0,\end{gathered}\tag{5.19}$$

while the second equations (5.18) are equivalent to the second and third equations of (5.14) and

$$\partial_a\partial_b\Gamma^\alpha-\partial_a\ln g^{bb}\partial_b\Gamma^\alpha-\partial_b\ln g^{aa}\partial_a\Gamma^\alpha=0.\tag{5.20}$$

Finally, the third equations (5.18) are equivalent to

$$\partial_a\Gamma^b-\Gamma^b\partial_a\ln g^{bb}=0,\quad \partial_a g^{b\alpha}-g^{b\alpha}\partial_a\ln g^{bb}=0,$$

which can be written in the form

$$\partial_a\left(\frac{\Gamma^b}{g^{bb}}\right)=0,\quad \partial_a\left(\frac{g^{b\alpha}}{g^{bb}}\right)=0,\quad a\neq b.\tag{5.21}$$

These last equations show that

$$\Gamma^a=g^{aa}f_a,\quad g^{a\alpha}=g^{aa}f_a^\alpha,\tag{5.22}$$

where (f_a,f_a^α) are functions of the coordinate corresponding to the lower index only. As a consequence, due to the first equations (5.18), (5.19) are identically satisfied and do not add further information. But (5.22) have another important consequence which allows a remarkable simplification of our analysis (a similar argument has been used in Refs. 15, 17 in the discussion of the separation of the HJ equations). Indeed, let us consider a coordinate transformation of the kind

$$\mathrm{d}x^a=\mathrm{d}q^a,\quad \mathrm{d}x^a=\mathrm{d}q^\alpha-f_a^\alpha\,\mathrm{d}q^a.\tag{5.23}$$

For the components $g_x^{ij}=\mathrm{d}x^i\cdot\mathrm{d}x^j$ of the metric tensor in the new coordinates $(x^i)=(x^a,x^\alpha)$ we have $g_x^{ab}=g^{ab}$ and

$$g_x^{a\alpha}=\mathrm{d}x^a\cdot\mathrm{d}x^\alpha=\mathrm{d}q^a\cdot(\mathrm{d}q^\alpha-f_b^\alpha\mathrm{d}q^b)=g^{a\alpha}-f_b^\alpha g^{ab}=g^{a\alpha}-f_a^\alpha g^{aa}=0.$$

This coordinate transformation is compatible with the separation, in the sense that in the new coordinates the solution of the Schrödinger equation is still separable and the constraint equations (5.1) hold (with the same constants κ_α). Indeed, the essential coordinates remain unchanged ($x^a=q^a$ up to inessential additive constants) and moreover,

$$\frac{\mathrm{d}\psi_\alpha}{\mathrm{d}x^\alpha}=\frac{\partial\psi_\alpha\partial q^\beta}{\partial q^\beta\partial x^\alpha}=\frac{\mathrm{d}\psi_\alpha\mathrm{d}q^\alpha}{\mathrm{d}q^\alpha\mathrm{d}x^\alpha}=\frac{\mathrm{d}\psi_\alpha}{\mathrm{d}q^\alpha}.$$

Hence, *without loss of generality* we can assume

$$g^{a\alpha}=0, \tag{5.24}$$

so that the metric tensor takes the standard form (3.6), with ignorable coordinates (q^α). For a metric of this kind,

$$\Gamma_a=g_{ai}\Gamma^i=g_{aa}\Gamma^a=(g^{aa})^{-1}\Gamma^a.$$

Thus, the first equations (5.21) are equivalent to the fourth equations (5.14). Moreover, $\Gamma^\alpha=0$ (see Sec. VI) so that (5.20) are identically satisfied. We conclude that the integrability conditions (5.12) of system (5.11), up to a coordinate transformation preserving the separation and reducing the metric tensor in the standard form, are equivalent to (5.14). ■

We recognize in the first three lines of system (5.14) the necessary and sufficient conditions (3.8′) for the separation of the Hamilton–Jacobi equation in standard coordinates. Hence, we have proved the following

Proposition 5.9: Up to a coordinate transformation of the kind (5.23), the reduced separation of the Schrödinger equation always occurs in standard separable coordinates $\underline{q}=(q^a,q^\alpha)$ $(a=1,...,m,\alpha=m+1,...,n)$ *for which* $\partial_b\Gamma_a=0$ *for* $a\neq b$.

As a conclusion, from Propositions 5.5, 5.7, 5.8, and 5.9, we derive Theorem 5.2.

Remark 5.10: Let us see how the integration by separation of variables is performed when the items in Theorem 5.2 are satisfied (this will give a further proof of the sufficiency of these items for the separation) and how the $m+n$ constants arise in a reduced separated solution. Due to the factorization

$$\psi=\Pi_{a=1}^m\psi_a\cdot\Pi_{\alpha=m+1}^n\psi_\alpha,$$

and to the constraints (5.1), since $\Gamma^\alpha=0$, the Schrödinger equation (4.5) becomes equivalent to the following *reduced Schrödinger equation:*

$$g^{aa}\partial_a^2\tilde{\psi}+\Gamma^a\partial_a\tilde{\psi}+(E-V+g^{\alpha\beta}\kappa_a\kappa_\beta)\tilde{\psi}=0,\quad \tilde{\psi}=\Pi_{a=1}^m\psi_a. \tag{5.25}$$

The additional condition $\partial_b\Gamma_a=0$ for $a\neq b$ means that the contracted Christoffel symbols Γ_a (with indices $a=1,...,m$) are functions of the corresponding coordinate q^a only. By a method similar to that illustrated in Remark 4.7, due to expressions (3.9), the integration of the Schrödinger equation is reduced to the integration of m separated Riccati equations,

$$u_a'+u_a^2-\Gamma_a u_a-\phi_a+\phi_a^{\alpha\beta}\kappa_\alpha\kappa_\beta+\varphi_a^{(b)}\tilde{a}_b=0 \tag{5.26}$$

parametrized by n constants $(\tilde{a}_b,\kappa_\alpha)$, with $\tilde{a}_m=E$. Its solutions $u_a=u_a(q^a;\tilde{a}_b,\kappa_\alpha,\tilde{b}_a)$ give rise, separately, to other m constants $(\tilde{b}_a)$ and generate, by a further integration, the reduced separated solution (summation over the indices)

$$\psi=\exp\left(\kappa_\alpha q^\alpha+\int u_a\,\mathrm{d}q^a\right)=\Pi_{a=1}^m\psi_a\cdot\Pi_{\alpha=m+1}^n\psi_\alpha.$$

Equations (5.26) are equivalent to the m linear second-order equations

$$\psi_a''-\Gamma_a\psi_a'+(\phi_a^{\alpha\beta}\kappa_\alpha\kappa_\beta+\varphi_a^{(b)}\tilde{a}_b-\phi_a)\psi_a=0 \tag{5.27}$$

in the functions ψ_a. In the reduced separation the number of the constants appearing in a complete solution (1.4), as a result of this process of integration, is $m+n<2n$, but only the $2m$ constants $(\tilde{a}_a,\tilde{b}_a)$ are involved in the completeness condition.

Remark 5.11: A coordinate transformation of the kind

$$q^a=\overline{q}^a,\quad q^\alpha=\sum_i F_i^\alpha(\overline{q}^I)=\sum_a F_a^\alpha(q^a)+\sum_\beta F_\beta^\alpha(\overline{q}^\beta),$$

with

$$\det[f_\beta^\alpha]\neq 0,\quad f_\beta^\alpha=(F_\beta^\alpha)',$$

composed by any transformation over single coordinates, is the most general transformation leading to nonstandard separable coordinates $(\overline{q}^a,\overline{q}^\alpha)$ for the Hamilton–Jacobi equation.[15,17] The same transformation applied to standard separable coordinates, in general, does not preserve (5.24), $g^{a\alpha}\neq 0$, and the coordinates $(\overline{q}^\alpha)$ are no longer ignorable. However, this transformation preserves the multiplicative separation of the Schrödinger equation. Indeed, the factors $\psi_a(q^a)$ remain unchanged, while the factors $\psi_\alpha(q^\alpha)$ are transformed as follows:

$$\psi_\alpha(q^\alpha)=\exp(\kappa_\alpha q^\alpha)=\exp(\kappa_\alpha F_\beta^\alpha(\overline{q}^\beta))\cdot\exp(\kappa_\alpha F_a^\alpha(q^a))=\prod_\beta\tilde{\psi}_\beta(\overline{q}^\beta)\cdot\prod_a\tilde{\psi}_a(q^a),$$

where

$$\tilde{\psi}_\beta(\overline{q}^\beta)=\exp(\kappa_\alpha F_\beta^\alpha(\overline{q}^\beta)),\quad \tilde{\psi}_a(q^a)=\exp(\kappa_\alpha F_a^\alpha(q^a)),$$

and we finally get a solution of the kind

$$\psi=\prod_\beta\tilde{\psi}_\beta(\overline{q}^\beta)\prod_a\psi_a(q^a)\tilde{\psi}_a(q^a).$$

We observe that

$$\tilde{\psi}_\beta'=\kappa_\alpha f_\beta^\alpha(\overline{q}^\beta)\tilde{\psi}_\beta,$$

where $f=F'$. This shows that a constraint of the kind (5.1) is still satisfied if and only if $f_\beta^\alpha=\delta_\beta^\alpha c'_\beta$ with arbitrary constants (c'_β). It shows also that a constraint of the kind

$$\psi'_\beta=\kappa_\alpha f_\beta^\alpha(q^\beta)\psi_\beta,\quad \det[f_\beta^\alpha]\neq 0$$

could be considered, but that it is equivalent to (5.1).

Remark 5.12: A remark analogous to Remark 4.8 is in order. The constants $\tilde{a}_b$ have two interpretations: (i) They are the constant values taken by the quadratic first integrals in involution related to the nonorthogonal separation of the Hamilton–Jacobi equation in standard coordinates (cf. Theorem 7.25) whose expressions are

$$H_a=\tfrac{1}{2}\varphi_{(a)}^b(p_b^2+\phi_a^{\alpha\beta}p_\alpha p_\beta+\phi_a). \tag{5.28}$$

(ii) They are the eigenvalues of the second-order symmetry operators corresponding to H_a of the reduced Schrödinger equation (5.25):

$$\hat{H}_b\tilde{\psi}=\varphi^a_{(b)}(-\partial_a^2\tilde{\psi}+\Gamma_a\partial_a\tilde{\psi}+(\phi_a-\phi_a^{\alpha\beta}\kappa_\alpha\kappa_\beta)\psi). \tag{5.29}$$

About the constants κ_α introduced in the constraint equations (5.1), we observe that they correspond to the eigenvalues of the first-order symmetry operators of the Schrödinger equation

$$\hat{H}_\alpha\psi=-i\hbar\partial_\alpha\psi. \tag{5.30}$$

Indeed, from (5.1) it follows that

$$\partial_\alpha\psi=\kappa_\alpha\psi.$$

Thus,

$$\hat{H}_\alpha\psi=-i\hbar\kappa_\alpha\psi. \tag{5.31}$$

As will be shown in Ref. 18, these operators are related to the linear first integrals

$$H_\alpha=p_\alpha \tag{5.32}$$

corresponding to the ignorable coordinates and thus to the Killing vectors characterizing the separation in standard coordinates (see Sec. VII). From (5.31) we observe that κ_α must be pure imaginary, since the operators $\hat{H}_\alpha$ are self-adjoint. This is in agreement with the fact that the choice of the constraint equations (5.2) does not change the state represented by ψ.

VI. THE ROBERTSON CONDITION

In this section we analyze the Robertson condition in a standard separable coordinate system. We shall extend to the reduced separation the analysis on the Robertson condition done by Eisenhart[3] in the case of the orthogonal separation. This extension has already been discussed in Ref. 19; here we give an improved and simplified version.

For a metric tensor in the standard form (3.6), where (q^α) are ignorable, the nonvanishing Christoffel symbols are

$$\begin{gathered}\Gamma_{\alpha\beta a}=-\tfrac{1}{2}\partial_a g_{\alpha\beta},\quad \Gamma^a_{\alpha\beta}=-\tfrac{1}{2}g^{aa}\partial_a\partial_{\alpha\beta},\\ \Gamma_{\alpha a\beta}=\tfrac{1}{2}\partial_a g_{\alpha\beta},\quad \Gamma^\beta_{\alpha a}=\tfrac{1}{2}\sum_\gamma g^{\beta\gamma}\partial_a g_{\alpha\gamma},\\ \Gamma_{aba}=\tfrac{1}{2}\partial_b g_{aa},\quad \Gamma^a_{ac}=\tfrac{1}{2}g^{aa}\partial_c g_{aa},\\ \Gamma_{aab}=-\tfrac{1}{2}\partial_b g_{aa}\quad (a\neq b),\quad \Gamma^b_{aa}=-\tfrac{1}{2}g^{bb}\partial_b g_{aa}\quad (a\neq b).\end{gathered} \tag{6.1}$$

It follows that

$$\Gamma^\alpha=g^{ij}\Gamma^\alpha_{ij}=0,\quad \Gamma^i_{i\alpha}=0, \tag{6.2}$$

and from (4.3),

$$\Gamma_a=g_{aa}\Gamma^a=-\partial_a\ln g^{aa}+\tfrac{1}{2}\partial_a\ln\det[g^{ij}]=-\partial_a\ln g^{aa}+\tfrac{1}{2}\partial_a\ln\det[g^{\alpha\beta}]+\tfrac{1}{2}\sum_{c=1}^{m}\partial_a\ln g^{cc}. \tag{6.3}$$

Moreover,

$$\Gamma^i_{ia}=\Gamma^b_{ba}+\Gamma^\alpha_{a\alpha}=\tfrac{1}{2}g^{bb}\partial_a g_{bb}+\tfrac{1}{2}g^{\alpha\beta}\partial_a g_{\alpha\beta},$$

so that

$$\Gamma^i_{ia}=-\tfrac{1}{2}\partial_a \ln\det[g^{ij}]=-\Gamma_a-\partial_a \ln g^{aa}. \tag{6.4}$$

Let us consider the Riemann tensor and the Ricci tensor defined as follows:

$$R^l_{ijk}=\partial_i\Gamma^l_{jk}-\partial_j\Gamma^l_{ik}+\Gamma^r_{jk}\Gamma^l_{ir}-\Gamma^r_{ik}\Gamma^l_{jr},\quad R_{jk}=R^l_{ljk}.$$

By a straightforward calculation it can be seen that the Riemann tensor components which are needed for the computation of the nondiagonal Ricci tensor components, R_{ab}, $a\neq b$, have the following expressions:

$$R^c_{cab}=\tfrac{3}{4}\partial_a\partial_b \ln g^{cc}-\tfrac{1}{4}g_{cc}(\partial_a\partial_b g^{cc}-\partial_b \ln g^{aa}\partial_a g^{cc}-\partial_a \ln g^{bb}\partial_b g^{cc})\quad (c\neq a,b;c \text{ n.s.}),$$

$$R^a_{aab}=0, \tag{6.5}$$

$$R^\alpha_{\alpha ab}=\tfrac{3}{4}\partial_a(g_{\alpha\beta}\partial_b g^{\alpha\beta})-\tfrac{1}{4}g_{\alpha\beta}(\partial_a\partial_b g^{\alpha\beta}-\partial_b \ln g^{aa}\partial_a g^{\alpha\beta}-\partial_a \ln g^{bb}\partial_b g^{\alpha\beta})\quad (\alpha \text{ n.s.})$$

and that

$$R_{a\alpha}=0. \tag{6.6}$$

A remarkable fact is that, due to the separability conditions (3.8′), expressions (6.5) reduce to

$$R^c_{cab}=\tfrac{3}{4}\partial_a\partial_b \ln g^{cc},\quad R^\alpha_{\alpha ab}=\tfrac{3}{4}\partial_a(g_{\alpha\beta}\partial_b g^{\alpha\beta}),$$

so that

$$R_{ab}=\frac{3}{4}\partial_a\partial_b\left(\sum_{c\neq a,b}\ln g^{cc}+\ln\det[g^{\alpha\beta}]\right)\quad (a\neq b). \tag{6.7}$$

For the case $m=n$ the second term on the right-hand side of (6.7) disappears and we find a formula first stated by Eisenhart[20] and related to the orthogonal separation.

Another remarkable fact is that for $c=a$ the first equation (3.8′) is equivalent to

$$\partial_a\partial_b \ln g^{aa}=\partial_a \ln g^{bb}\partial_b \ln g^{aa}\quad (a\neq b),$$

so that, due to the symmetry in the indices of the right-hand side of this equation, we can write

$$\partial_a\partial_b \ln g^{aa}=\tfrac{1}{2}(\partial_a\partial_b \ln g^{aa}+\partial_a\partial_b \ln g^{bb}),$$

and from (6.3) we get

$$\partial_b\Gamma_a=\frac{1}{2}\partial_a\partial_b\left(\sum_{c\neq a,b}\ln g^{cc}+\ln\det[g^{\alpha\beta}]\right). \tag{6.8}$$

Formula (6.6) and the comparison between (6.8) and (6.7) show that

Theorem 6.1: *(i) In standard separable coordinates* (q^a,q^α),

$$R_{ab}=\tfrac{3}{2}\partial_b\Gamma_a\quad (a\neq b),\quad R_{a\alpha}=0. \tag{6.9}$$

(ii) In orthogonal separable coordinates,

$$R_{ij}=\tfrac{3}{2}\partial_j\Gamma_i, \quad i\neq j. \tag{6.10}$$

This last equation is simply the reduction of (6.9) to the case $m=n$ (no greek indices). Thus,

Theorem 6.2: *The Robertson condition in orthogonal separable coordinates* $\partial_i\Gamma_j=0$ $(i\neq j)$ *is equivalent to*

$$R_{ij}=0 \quad (i\neq j).$$

The Robertson condition in standard separable coordinates $\partial_a\Gamma_b=0$ $(a\neq b)$ *is equivalent to*

$$R_{ab}=0 \quad (a\neq b).$$

Remark 6.3: Theorem 6.2 gives a geometrical meaning of the Robertson condition for the free and the reduced separation. For the reduced separation we take the standard coordinates as required by Proposition 5.8.

Since $R_{a\alpha}=0$, it is proved that

Theorem 6.4: *The Robertson condition in standard coordinates is fulfilled if and only if the Ricci tensor assumes the standard form*.

Remark 6.5: The Robertson condition is identically satisfied, so that there is a simultaneous separation of the Schrödinger and Hamilton–Jacobi equations, for Einstein manifolds, where the Ricci tensor is proportional to the metric tensor, $\mathbf{R}=a\mathbf{G}$ (thus, in particular, for constant curvature manifolds and Ricci-flat manifolds).

VII. THE EISENHART–KILLING EQUATIONS AND THE INTRINSIC CHARACTERIZATION OF THE SEPARATION

As has been illustrated in the preceding sections, the separation of variables is apparently a strictly ''coordinate dependent'' matter. This is perhaps the reason why for long it has not been recognized as a ''modern'' theory. However, as we know today, the existence of separable coordinates for the Hamilton–Jacobi and Schrödinger equations requires the presence on the underlying Riemannian manifold of a rich intrinsic (coordinate independent) structure, described by algebraic or geometrical objects: Killing vectors, Killing tensors, and webs (sets of foliations).

The first fundamental contibution to the intrinsic theory of the variable separation dates back to Levi-Civita.[11] He pointed out first, that the separation of the geodesic Hamiltonian is a necessary condition for the separation of all the associated natural Hamiltonians with scalar and vector potentials.[21] This gives a prominent role to the separation of the geodesic Hamilton–Jacobi equation. Second, he proposed a classification of the separable coordinates into two classes and, by using his methods of ''calcolo differenziale assoluto,'' developed together with Ricci[22] a few years earlier, he proved that when all the coordinates are of first class then the manifold is necessarily locally flat. This result was later extended to the general case by Agostinelli,[23] who proved that the separation associated with r first-class coordinates corresponds to the existence of a foliation of r-dimensional locally flat submanifolds. These pioneering results have recently been incorporated within a general geometrical framework of the geodesic separation, based on the notion of *separable Killing web*.[16] However, a milestone in this way is represented by the contribution of Eisenhart,[3] which we shall revisit in the present section, with suitable modifications and extensions.

We recall that a contravariant symmetric tensor $\mathbf{K}=(K^{i\cdots j})$ is said to be a *Killing tensor* if its components satisfy the *Killing equation*

$$\nabla^{(h}K^{i\cdots j)}=0,$$

where ∇ denotes the covariant derivative with respect to the Levi-Civita connection and the parentheses (...) denote the symmetrization of the indices. There is however an alternative equivalent definition of Killing tensor, which is not related to the covariant derivative but to the canonical

symplectic structure of a cotangent bundle. This definition is based on the one-to-one correspondence between the contravariant symmetric tensors and the homogeneous polynomial functions on T^*Q,

$$P(\mathbf{K}) = P_{\mathbf{K}} = K^{i\cdots j} p_i \cdots p_j .$$

We say that two tensors $\mathbf{K}$ and $\mathbf{K}'$ are *in involution* if the corresponding polynomial functions are in involution, i.e., if their Poisson bracket vanishes identically:

$$\{P(\mathbf{K}), P(\mathbf{K}')\} = 0.$$

Then a tensor $\mathbf{K}$ is a Killing tensor if and only if $P(\mathbf{K})$ is a first integral of the geodesic flow, i.e., it is in involution with the geodesic Hamiltonian $G = \frac{1}{2} P_{\mathbf{G}}$:

$$\{P_{\mathbf{K}}, G\} = 0. \tag{7.1}$$

Also this definition does not depend on the choice of the coordinates. Let us call (7.1) the *Poisson–Killing equation*.

In the theory of the separation of variables a fundamental role is played by Killing vectors, corresponding to linear first integrals and to one-parameter groups of isometries, and by Killing two-tensors, interpreted as symmetric linear operators on one-forms or vector fields. Thus, in the following discussion by ''Killing tensor'' we mean ''Killing two-tensor.''

Remark 7.1: We shall use the following notation. If $\mathbf{K} = (K^{ij})$ is a contravariant two-tensor and $\mathbf{X} = (X^i)$ a vector field, then by $\mathbf{KX}$ we denote the vector field image of $\mathbf{X}$ by $\mathbf{K}$ (as linear operator) whose components are

$$(\mathbf{KX})^i = K^{ij} g_{jh} X^h = K^i_{\cdot j} X^j,$$

and by $\mathbf{K}\varphi$ the one-form image by $\mathbf{K}$ of the one-form $\varphi = \varphi_i \mathrm{d}q^i$ whose components are

$$(\mathbf{K}\varphi)_i = g_{ih} K^{hj} \varphi_j = K_i^{\cdot j} \varphi_j .$$

If $\mathbf{K}$ and $\mathbf{L}$ are two such tensors then by $\mathbf{LK}$ we mean their composition as linear operators. It is a contravariant two-tensor whose components are

$$(\mathbf{LK})^{ij} = L^{ih} g_{hk} K^{kj} = L^{i\cdot}_{\cdot k} K^{kj} = L^{ih} K_h^{\cdot j} .$$

We begin by considering the orthogonal separation. The link between the orthogonal separation and the existence of Killing tensors is based on the following statement due to Eisenhart:[20]

Proposition 7.2: Let $\mathbf{K}$ *be a symmetric tensor on a Riemannian manifold* $(Q, \mathbf{g})$ *which is diagonalized in an orthogonal coordinate system* $\underline{q} = (q^i)$. *Then* $\mathbf{K}$ *is a Killing tensor if and only if its eigenvalues* (λ^i) *satisfy*

$$\partial_i \lambda^j = (\lambda^i - \lambda^j) \partial_i \ln g^{jj}. \tag{7.2}$$

Proof: In the coordinates $\underline{q}$ the components of $\mathbf{K}$ are

$$K^{ii} = \lambda^i g^{ii}, \quad K^{ij} = 0 \quad (i \neq j),$$

so that $P(\mathbf{K}) = \lambda^i g^{ii} p_i^2$. A straightforward calculation shows that (7.1) are equivalent to (7.2). ■

We call (7.2) the *Eisenhart–Killing equations*. These equations can be interpreted as a linear normal first-order differential system in the unknown functions (λ^i), of the kind considered in Sec. II. It is a crucial fact that its complete integrability conditions (as shown by a straightforward calculation) are

$$(\lambda^i - \lambda^j) S^k_{ij} = 0 \quad (i \neq j, \ \text{n.s.}), \tag{7.3}$$

where

$$S_{ij}^{k}=\partial_i\partial_j g^{kk}-\partial_i \ln g^{jj}\partial_j g^{kk}-\partial_j \ln g^{ii}\partial_i g^{kk}$$

are just the left-hand sides of the first separability conditions (3.5).

Remark 7.3: The orthogonal separability theory lies in the following rather surprising circumstance: there are three ''different'' first-order differential systems with the ''same'' complete integrability conditions, $S_{ij}^{k}=0$ $(i\neq j)$. They are: (i) system (3.3), with

$$R_i(\underline{q},\underline{p})=-\frac{\partial_i G}{\partial^i G},\quad G=\frac{1}{2}g^{ii}p_i^2,$$

related to the orthogonal separation of the geodesic Hamilton–Jacobi equation; (ii) system (4.11) with

$$R_i(\underline{q},\underline{u}^{(1)},\underline{u}^{(2)})=-\left(\frac{\partial \mathcal{S}}{\partial u_i^{(2)}}\right)^{-1}\left(\frac{\partial \mathcal{S}}{\partial q^i}+\frac{\partial \mathcal{S}}{\partial u_i}u_i^{(2)}\right),\quad \mathcal{S}(\underline{q},\underline{u}^{(1)},\underline{u}^{(2)})=g^{ij}u_iu_j+g^{ii}u_i^{(2)}-\Gamma^i u_i,$$

related to the free (thus, orthogonal) separation of the geodesic Schrödinger equation $(V=0)$; (iii) system (7.2) related to the existence of Killing tensors diagonalized in orthogonal coordinates. Actually, as we have seen, the complete integrability of the second system requires an additional condition: the Robertson condition $R_{ij}=0$ for $i\neq j$. The same remarkable property holds for a nonconstant potential V.

According to this remark, it is convenient to introduce the following

Definition 7.4: We call *Killing–Stäckel algebra* an n-dimensional linear space $\mathcal{K}$ of Killing tensors which are (i) simultaneously diagonalized in orthogonal coordinates, or equivalently, (ii) with n common normal (i.e., orthogonally integrable or surface forming) eigenvectors.

Item (ii) in this definition is a coordinate-free translation of item (i). Thus, we can affirm that

Theorem 7.5: *The orthogonal separation of the geodesic Hamilton–Jacobi equation is equivalent to the complete integrability of the Eisenhart–Killing equations i.e., to the existence of a Killing–Stäckel algebra.*

This is a synthetic and simplified version of the classical theorem of Eisenhart on ''separable systems of Stäckel.''[3]

Remark 7.6: The submanifolds of codimension 1 orthogonal to the normal eigenvectors of a Killing–Stäckel algebra form an *orthogonal separable web*. A coordinate system $\underline{q}$ is called *adapted* to this web if the corresponding coordinate hypersurfaces belong to the web. Any coordinate system adapted to a separable web is orthogonal and separable. It follows that: *an orthogonal web is separable if and only if its leaves are orthogonal to the eigenvectors of a Killing–Stäckel algebra.*

Remark 7.7: A Killing–Stäckel algebra, as well as a separable orthogonal web, may not be defined on the whole configuration manifold Q. The points of Q where the requirements of Definition 7.4 are not fulfilled (or where the manifolds orthogonal to the normal eigenvectors are not defined) form the *singular set* of the algebra (or of the web).

Due to Theorem 7.5, the analysis of the orthogonal separation is now related to the analysis of the Killing–Stäckel algebras. Going back to Definition 7.4, we observe that: (i) when the Eisenhart–Killing equations are completely integrable, we can always find, locally, a solution such that $\lambda^i\neq\lambda^j$ for $i\neq j$; (ii) as shown by a straightforward calculation, two functions $P(\mathbf{K})$ and $P(\mathbf{K}')$ corresponding to two solutions of system (7.2) are in involution; (iii) $\lambda^i=1$ is a trivial solution. Thus,

Theorem 7.8: *(i) A Killing–Stäckel algebra admits locally a Killing tensor with pointwise distinct eigenvalues. (ii) All Killing tensors in a Killing–Stäckel algebra are in involution. (iii) The metric tensor* $\mathbf{G}$ *belongs to any Killing–Stäckel algebra.*

Furthermore, the presence of the term $\lambda^i-\lambda^j$ in (7.3) implies that if there exists a Killing tensor which is diagonalized in orthogonal coordinates and with pointwise simple eigenvalues,

$\lambda^i \neq \lambda^j$, then all S^k_{ij} $(i \neq j)$ vanish identically (these are functions of the coordinates only), so that the Eisenhart–Killing equations are completely integrable.[24] This proves that

Theorem 7.9: *A Killing–Stäckel algebra is uniquely determined by a Killing tensor with normal eigenvectors and pointwise simple eigenvalues.*

Remark 7.10: The "uniqueness" in this last statement has a local meaning. It means that if $\mathcal{K}$ and $\mathcal{K}'$ are two Killing–Stäckel algebras both containing a Killing tensor **K** with simple eigenvalues, then $\mathcal{K}=\mathcal{K}'$ at least in the domain of definition of **K**. Then we say that **K** is a *characteristic tensor* of the Killing–Stäckel algebra $\mathcal{K}$. Note that it is not uniquely determined in $\mathcal{K}$. We also remark that there are cases in which a Killing–Stäckel algebra does not admit a "global" characteristic Killing tensor. An example is the parabolic translational web in the Euclidean three-space (see Ref. 25 for a description of this web).

Remark 7.11: As a consequence of the preceding remarks and statements, we have at least two ways for characterizing intrinsically the orthogonal separation of a geodesic Hamilton–Jacobi equation: (A) by means of a Killing–Stäckel algebra $\mathcal{K}$, or (B) by means of a characteristic Killing tensor **K**, i.e., a Killing tensor with simple eigenvalues and normal eigenvectors. This second characterization seems to be more effective that the first one, since it involves only one Killing tensor **K**.[24] But difficulties could arise in checking if first, this tensor has simple eigenvalues (via the analysis of the discriminant of the corresponding characteristic equation) and second, if its eigenvectors are normal. Of course, analogous problems arise in dealing with a whole Killing–Stäckel algebra (i.e., with n independent Killing tensors) at least as it is defined in Definition 7.4, item (ii): we still have the algebraic problem of checking if n independent tensors have common eigenvectors, and the differential problem of checking if these eigenvectors are normal. However, these problems can be simultaneously solved by using the following characterization of a Killing–Stäckel algebra:

Theorem 7.12: *An n-dimensional space $\mathcal{K}$ of Killing tensors is a Killing–Stäckel algebra if and only if its elements (i) commute as linear operators,*

$$\mathbf{K}_1\mathbf{K}_2-\mathbf{K}_2\mathbf{K}_1=0, \quad \forall \mathbf{K}_1,\mathbf{K}_2 \in \mathcal{K}, \tag{7.4}$$

and (ii) are in involution,

$$\{P(\mathbf{K}_1),P(\mathbf{K}_2)\}=0, \quad \forall \mathbf{K}_1,\mathbf{K}_2 \in \mathcal{K}. \tag{7.5}$$

We postpone the proof of this theorem to Sec. VIII. What is important in this characterization is that, (i) as first pointed out by Kalnins and Miller,[26] if n independent Killing tensors have n common eigenvectors and are in involution, then the eigenvectors are necessarily normal; (ii) if they commute as linear operators, then they have necessarily the same eigenvectors (this holds, however, only in a positive-definite metric); (iii) both conditions (7.4) and (7.5) require simple calculations, of algebraic and differential character, respectively.

Going back to Remark 7.11, we emphasize the advantage of dealing with a single characteristic tensor in the nongeodesic case, i.e., when a potential V is present. Indeed, it can be proved[24] that

Theorem 7.13: *The Hamilton–Jacobi equation associated with a natural Hamiltonian $H=G+V$ is orthogonally separable if and only if (i) there exists a first integral*

$$H_{\mathbf{K}}=\tfrac{1}{2}P_{\mathbf{K}}+U=\tfrac{1}{2}K^{ij}p_ip_j+U,$$

where **K** *is a tensor with pointwise simple eigenvalues and normal eigenvectors, or equivalently, (ii) if and only if there exists a Killing tensor* **K** *with pointwise simple eigenvalues and normal eigenvectors such that the one-form image of* $\mathrm{d}V$ *by* **K** *is closed:*

$$\mathrm{d}(\mathbf{K}\mathrm{d}V)=0. \tag{7.6}$$

In fact, the equivalence of items (i) and (ii) is only "local." Indeed, a function $H_{\mathbf{K}}$ is in involution with $H=G+V$ if and only if

$$\{G, P_{\mathbf{K}}\} = 0, \quad \mathrm{d}U = \mathbf{K}\,\mathrm{d}V.$$

The first equation is the Poisson–Killing equation, while the second one implies (7.6) and is implied by (7.6) only locally. However, in most of the applications this equivalence turns out to be global (that is, the closed one-form $\mathbf{K}\,\mathrm{d}V$ is exact) at least on the manifold Q deprived of the singular set of the Killing tensor $\mathbf{K}$ (where the eigenvalues are not simple).

Equation (7.6) has been called the *characteristic equation of a separable potential*. Indeed, for checking if a potential V is separable in an orthogonal separable web (thus, in any orthogonal coordinate system adapted to this web) it is sufficient to apply this equation to a single characteristic Killing tensor, and not to all elements of a basis of the corresponding Killing–Stäckel algebra. In fact, it can be proved that[24]

Theorem 7.14: *If the characteristic equation is satisfied by a characteristic Killing tensor* $\mathbf{K}$*, then it is satisfied by all elements of the Killing–Stäckel algebra* $\mathcal{K}$ *generated by* $\mathbf{K}$*, and the functions on* T^*Q*,*

$$H_{\mathbf{K}} = \tfrac{1}{2}P_{\mathbf{K}} + V_{\mathbf{K}}, \quad \mathrm{d}V_{\mathbf{K}} = \mathbf{K}\,\mathrm{d}V, \quad \forall \mathbf{K} \in \mathcal{K}, \tag{7.7}$$

form an n-dimensional space of quadratic first integrals in involution. A basis (H_j) *of this space is expressed in terms of Stäckel matrices by formula (4.30).*

By combining Theorem 7.12 and Theorems 7.13, 7.14, we get a further characterization of the separation, which uses n Killing tensors (the metric tensor $\mathbf{G}$ may be included) but which avoids the use of eigenvectors and their normality conditions:

Theorem 7.15: *The Hamilton–Jacobi equation associated with a natural Hamiltonian* $H = G + V$ *is orthogonally separable if and only if there exist n pointwise independent Killing tensors* $(\mathbf{K}_j)$ *one other (i) commuting as linear operators, (ii) in involution and such that (iii)*

$$\mathrm{d}(\mathbf{K}_j \mathrm{d}V) = 0$$

or equivalently, such that (iii′)

$$\mathrm{d}(\mathbf{K}\mathrm{d}V) = 0$$

for a suitable linear combination $\mathbf{K} = c^j\mathbf{K}_j$, $c^j \in \mathbb{R}$*, with simple eigenvalues.*

After Theorem 7.13, we can give an intrinsic translation of Theorem 4.2 by applying Theorem 6.2:

Theorem 7.16: *The Schrödinger equation is freely separable if and only if there exists a Killing tensor* $\mathbf{K}$ *with simple eigenvalues and normal eigenvectors, satisfying the characteristic equation (7.6) and commuting with the Ricci tensor*

$$\mathbf{KR} - \mathbf{RK} = 0. \tag{7.8}$$

Indeed, since $\mathbf{K}$ has simple eigenvalues, the commutation relation (7.8) means that $\mathbf{R}$ has the same eigenvectors of $\mathbf{K}$.

For a general treatment of the separation (orthogonal or nonorthogonal) we follow a similar way, starting from a suitable extension of the Eisenhart equations, that is from the following extension of Proposition 7.1, which can be easily proved by using the Poisson–Killing equations (7.1):

Theorem 7.17: *Let* $\mathbf{K}$ *be a symmetric tensor on a Riemannian manifold. Assume that in a coordinate system* (q^a, q^α) *both the contravariant metric tensor* $\mathbf{G}$ *and* $\mathbf{K}$ *assume the standard form (3.6) and (3.10), with* (q^α) *ignorable for both tensors, so that*

$$\mathbf{G} = g^{aa}\partial_a \otimes \partial_a + g^{\alpha\beta}\partial_\alpha \otimes \partial_\beta, \quad \mathbf{K} = \lambda^a g^{aa}\partial_a \otimes \partial_a + K^{\alpha\beta}\partial_\alpha \otimes \partial_\beta,$$

where (λ^a) *are the eigenvalues of* $\mathbf{K}$ *corresponding to the eigenforms* $(\mathrm{d}q^a)$*. Then* $\mathbf{K}$ *is a Killing tensor if and only if*

$$\partial_a \lambda^b = (\lambda^a - \lambda^b)\partial_a \ln g^{bb}, \quad \partial_a K^{\alpha\beta} = \lambda^a \partial_a g^{\alpha\beta}. \tag{7.9}$$

These equations can be interpreted as a linear normal first-order differential system in the unknown functions $(\lambda^a, K^{\alpha\beta})$. The complete integrability conditions assume the form

$$(\lambda^a - \lambda^b) S^{cc}_{ab} = 0, \quad (\lambda^a - \lambda^b) S^{\alpha\beta}_{ab} = 0 \quad (a \neq b, \text{ n.s}),$$

where

$$S^{hk}_{ab} = \partial_a \partial_b g^{hk} - \partial_a \ln g^{bb} \partial_b g^{hk} - \partial_b \ln g^{aa} \partial_a g^{hk} \quad (a \neq b, \text{ n.s.})$$

are just the left-hand sides of the first two separability conditions (3.8′).

Thus, remarks and theorems similar to those illustrated for the orthogonal separation are in order. The only difference is that now Eqs. (7.9), when completely integrable, generates a space $\mathcal{K}$ of Killing tensors of dimension $m < n$. The lost dimensions are replaced by a linear space D of Killing vectors. The resulting structure is a pair $(D, \mathcal{K})$ having the properties listed in the following

Definition 7.18: We call *separable Killing algebra* a pair $(D, \mathcal{K})$ where (I) D is an r-dimensional linear space of commuting Killing vectors, (II) $\mathcal{K}$ is a D-invariant $n-r$-dimensional linear space of Killing two-tensors with $m = n - r$ normal eigenvectors in common and orthogonal to D. We call these eigenvectors *essential*.

As has been proved in Ref. 16,

Theorem 7.19: *The separation of the geodesic Hamilton–Jacobi equation is equivalent to the existence of a separable Killing algebra.*

Remark 7.20: The m orthogonal foliations $\mathcal{S}^a$ of the one-codimensional submanifolds orthogonal to the essential eigenvectors of $\mathcal{K}$ (thus tangent to D and containing the orbits of D) form a geometrical structure called *separable Killing web*. A standard coordinate system (q^a, q^α) is related to such a structure in the following way: (i) $(\mathrm{d}q^a)$ are common (local) eigenforms of all elements of $\mathcal{K}$ corresponding to the common essential eigenvectors, or equivalently, their coordinate hypersurfaces belong to the web $\mathcal{S}^a$, (ii) the partial derivatives (∂_α), interpreted as vector fields, are commuting Killing vectors and form a local basis of D.

Furthermore, by a straightforward analysis of system (7.9) we can prove the following two statements:[16]

Theorem 7.21: *In a separable Killing algebra: (i) there are Killing tensors with distinct eigenvalues corresponding to the essential eigenvectors, (ii) all Killing tensors are in involution, (iii) the metric tensor is included, (iv) D is normal (i.e., orthogonally integrable).*

Theorem 7.22: *A separable Killing algebra is uniquely determined by a characteristic Killing pair* $(D, \mathbf{K})$ *where D is an r-dimensional space of Killing vectors in involution and* $\mathbf{K}$ *is a D-invariant Killing tensor with* $m = n - r$ *normal eigenvectors orthogonal to D and corresponding to pointwise distinct eigenvalues.*

Remark 7.23: Also for the general separation we have two equivalent intrinsic characterizations: (A) by means of a separable Killing algebra $(D, \mathcal{K})$ or, (B) by a characteristic Killing pair $(D, \mathbf{K})$, and what has been said in Remark 7.11 can be adapted to this case.

The use of a separable Killing algebra is made more effective by the following theorem analogous to Theorem 7.12 (see Sec. VIII for the proof).

Theorem 7.24: *A pair* $(D, \mathcal{K})$, *where D is an r-dimensional space of Killing vectors in involution and* $\mathcal{K}$ *is an m-dimensional space of D-invariant Killing tensors, is a separable Killing algebra if and only if: (i) the distribution* $\Delta^\perp$ *orthogonal to D is invariant under the elements of* $\mathcal{K}$ *interpreted as linear operators, (ii) the restrictions to* $\Delta^\perp$ *of the elements of* $\mathcal{K}$ *form at each point an m-dimensional space and commute; (iii) the elements of* $\mathcal{K}$ *are in involution.*

Finally, it can be proved[16] that

Theorem 7.25: *The Hamilton–Jacobi equation associated with a natural Hamiltonian* $H = G + V$ *is separable if and only if there exists a characteristic Killing pair* $(D, \mathbf{K})$ *such that V is D-invariant and the characteristic equation (7.6) is satisfied. In this case the functions*

$$H_{\mathbf{K}}=\tfrac{1}{2}P_{\mathbf{K}}+V_{\mathbf{K}}, \quad \mathrm{d}V_{\mathbf{K}}=\mathbf{K}\,\mathrm{d}V, \quad \mathbf{K}\in\mathcal{K},$$

$$\mathcal{H}_{\mathbf{X}}=P_{\mathbf{X}}, \quad \mathbf{X}\in D,$$

form an n-dimensional space of first integrals in involution. A basis (H_a,H_α) *of this space is expressed in terms of Stäckel matrices by formulas (5.28) and (5.32).*

Hence, the corresponding Hamiltonian system is integrable in the Arnold–Liouville sense. This theorem shows that the existence of m quadratic and $n-m$ linear first integrals in involution is a necessary condition for the separation.

Remark 7.26: It is important to remark that the use of a characteristic Killing pair $(D,\mathbf{K})$ provides a finer classification of the orthogonal separation. Indeed, an orthogonal web could admit two (or more) different characteristic Killing pairs, thus two (or more) different classes of separable potentials. This is the case, for instance, of the translational or rotational webs in the Euclidean three-space, as described in Ref. 25, where an orthogonal coordinate system may be interpreted in more than one way as a standard separable coordinate system (see the examples in Ref. 21).

As a consequence of Theorem 7.25, we get the following intrinsic translation of Theorems 5.2 and 6.4 related to the reduced separation of the Schrödinger equation. We observe that, $\mathbf{K}$ and $\mathbf{R}$ being in standard form, the tangent subspaces orthogonal to D are invariant subspaces for both.

Theorem 7.27: *The Schrödinger equation is reductively separable if and only if there exists a characteristic Killing pair* $(D,\mathbf{K})$ *such that: (i) the potential V is D-invariant; (ii) the characteristic equation (7.6) is satisfied; (iii) the spaces orthogonal to D are invariant under the Ricci tensor* $\mathbf{R}$*, interpreted as a linear operator, and the restrictions to these spaces of* $\mathbf{R}$ *and* $\mathbf{K}$ *commute or equivalently, (iii′) the essential eigenvectors are eigenvectors of the Ricci tensor* $\mathbf{R}$ *(i.e., "Ricci principal directions").*

Remark 7.28: Let $\widetilde{Q}$ be the quotient of the manifold Q by the orbits of D (that is the set of the orbits of D). At least locally, it is an m-dimensional *reduced Riemannian manifold*, whose *reduced metric tensor* $\widetilde{\mathbf{G}}=(g^{ab})$ is the result of the projection of $\mathbf{G}$ by the $(n-m)$-dimensional group of isometries associated with D. Due to the D-invariance, the separable Killing algebra $(D,\mathcal{K})$ is projectable onto an m-dimensional *reduced Killing–Stäckel algebra* $\widetilde{\mathcal{K}}$, and a characteristic Killing tensor $\mathbf{K}=(K^{ij})$ onto a *reduced characteristic Killing tensor* $\widetilde{\mathbf{K}}=(K^{ab})$. Then, the *reduced Schrödinger equation* (5.25) is just the Schrödinger equation written on the reduced manifold, but with respect to the *reduced potential*

$$\widetilde{V}=V-g^{\alpha\beta}\kappa_\alpha\kappa_\beta.$$

For this reduced equation we have a free separation.

Remark 7.29: All the preceding discussion and statements hold for pseudo-Riemannian manifolds, by excluding the case of null (or isotropic) coordinates, i.e., under the assumption $g^{ii}\neq 0$ for the free separation and $g^{aa}\neq 0$ for the reduced separation.

VIII. INTEGRABILITY OF FRAMES

As mentioned in Sec. VII, n independent Killing tensors in involution and commuting as linear operators have common and normal eigenvectors. This remarkable fact, discovered by Kalnins and Miller,[27] reduces the number of sufficient conditions for the geodesic separation listed in the original version of the Eisenhart theorem,[3] as well as in the version given by Woodhouse.[28] We illustrate in this section a detailed proof of this property, showing that in fact it lies in basic properties of frames in pure differential manifolds, apart from any Riemannian structure, which plays a role only at the very end.

A *frame* (a "moving frame" in the classical literature) on a differentiable manifold Q_n is a set of n pointwise independent vector fields $(\mathbf{X}_i)$. In general, frames exist only locally. A manifold Q

admits global frames if and only if it is parallelizable, that is $TQ=Q\times\mathbb{R}^n$. Two frames $(\mathbf{X}_i)$ and $(\mathbf{X}'_i)$ are said to be *equivalent* if there are (nowhere vanishing) functions (f_i) such that $\mathbf{X}'_i = f_i\mathbf{X}_i$.

Definition 8.1: A frame is *integrable* if for each index $i=1,...,n$ the distribution $\Delta_{\hat{i}}$ of rank $n-1$ spanned by all vectors of the frame with the exception of $\mathbf{X}_i$ is completely integrable.

Remark 8.2: The integrability is an invariant property within a class of equivalent frames.

We have two equivalent definitions of integrability, illustrated in the two following propositions.

Proposition 8.3: A frame is integrable if and only if there exist local coordinate systems (q^i) *such that the frame is equivalent to* (∂_i),

$$\partial_i = f_i\mathbf{X}_i .$$

Proof: (i) Assume that the frame is integrable. Let us consider the distribution $\Delta_{\hat{1}}$ spanned by $(\mathbf{X}_2,\ldots,\mathbf{X}_n)$. The corresponding foliation can be locally parametrized by a regular function q^1; $\mathrm{d}q^1\neq 0$ is a characteristic one-form, so that $\langle \mathbf{X}_i,\mathrm{d}q^1\rangle = 0$ for $i\neq 1$. Moreover, $\langle \mathbf{X}_1,\mathrm{d}q^1\rangle = g_1\neq 0$, otherwise $\mathrm{d}q^1=0$. Thus, $\langle f_1\mathbf{X}_1,\mathrm{d}q^1\rangle = 1$, with $f_1 = 1/g_1$. By the same procedure applied to all distributions $\Delta_{\hat{i}}$ we get a system of functions (q^i) such that $\langle f_i\mathbf{X}_i,\mathrm{d}q^j\rangle = \delta^j_i$. Hence, (q^i) are independent functions forming a coordinate system such that $\partial_i = f_i\mathbf{X}_i$. (ii). The natural frame (∂_i) associated with coordinates is obviously integrable; hence the equivalent frame $(\mathbf{X}_i)$ is integrable (Remark 8.2). ■

Proposition 8.4: A frame is integrable if and only if for each pair of indices $i\neq j$ *the distribution* Δ_{ij} *spanned by the two vectors* $(\mathbf{X}_i,\mathbf{X}_j)$ *is completely integrable*.

Proof: With each frame $(\mathbf{X}_i)$ we can always associate a *co-frame* (ξ^i) made of independent one-forms such that $\langle \mathbf{X}_i,\xi^j\rangle = \delta^j_i$. Then ξ^i is a characteristic form of the distribution $\Delta_{\hat{i}}$, that is $\langle \Delta_{\hat{i}},\xi^i\rangle = 0$. As we know, this distribution is completely integrable if and only if $\mathrm{d}\xi^i\wedge\xi^i = 0$. Moreover, each distribution Δ_{ij} is characterized by the $n-2$ forms (ξ^a), $a\neq i,j$, and for instance, Δ_{12} is completely integrable if and only if $(\dagger)\,\mathrm{d}\xi^a\wedge\xi^3\wedge\cdots\wedge\xi^n = 0$ for $a=3,...,n$. (i) Assume that the frame $(\mathbf{X}_i)$ is integrable: all $\Delta_{\hat{i}}$ are completely integrable, thus $\mathrm{d}\xi^i\wedge\xi^i = 0$ for all i. Then $(\dagger)$ is satisfied, as well as the similar equations associated with all pairs of distinct indices. (ii) Assume that all Δ_{ij} are completely integrable. Then, by the Frobenius theorem each Lie bracket $[\mathbf{X}_i,\mathbf{X}_j]$ is a linear combination of the same vectors $(\mathbf{X}_i,\mathbf{X}_j)$. This is enough for the complete integrability of any distribution (of any rank) spanned by any choice of the vectors of the frame. ■

Remark 8.5: There is a geometrical (and intuitive) proof of this proposition. (i) If the frame is integrable, let us consider the integral foliations $\mathcal{S}_{\hat{i}}$ of $\Delta_{\hat{i}}$. They are made of submanifolds of codimension 1. Submanifolds belonging to different foliations are transversal. For any choice of $i\neq j$ the foliation given by the intersection of all $\mathcal{S}_{\hat{k}}$ with $k\neq i,j$ is made of submanifolds of dimension 2 which are tangent to $(\mathbf{X}_i,\mathbf{X}_j)$. Hence, Δ_{ij} is integrable. (ii) Conversely, assume that all Δ_{ij} are integrable and let us consider the corresponding foliations $\mathcal{S}_{ij}$ made of submanifolds of dimension 2. For any fixed i, let us consider the foliation $\mathcal{S}_{\hat{i}}$ given by the union of the foliations $\mathcal{S}_{jk}$ with $j,k\neq i$. This is a foliation of submanifolds of codimension 1 tangent to $\Delta_{\hat{i}}$; then this distribution is integrable.

We base our discussion on the following general considerations. As we have seen in Sec. VII, we have a one-to-one correspondence between contravariant symmetric tensors of any order $\mathbf{K}=(K^{i\cdots j})$ on Q and homogeneous polynomial functions $P(\mathbf{K})=K^{i\cdots j}p_i\cdots p_j$ on T^*Q. For a function f (zero-order tensor) on Q, $P(f)$ is by definition the canonical lift to T^*Q (constant along the fibers), which we denote by the same symbol f, so that

$$P(f)=f.$$

By this correspondence we define two operations over symmetric tensors. (i) The symmetric tensor product $\odot$,

$$P(\mathbf{K}\odot\mathbf{L}) = P(\mathbf{K})P(\mathbf{L}).$$

This product is comutative and associative. In particular, for vector fields $\mathbf{X}$ and $\mathbf{Y}$,

$$\mathbf{X}\odot\mathbf{Y}=\tfrac{1}{2}(\mathbf{X}\otimes\mathbf{Y}+\mathbf{Y}\otimes\mathbf{X}).$$

(ii) The Lie–Nijenhuis bracket $[\cdot,\cdot]$,

$$P([\mathbf{K},\mathbf{L}])=\{P(\mathbf{K}),P(\mathbf{L})\},$$

where $\{,\}$ is the canonical Poisson–Lie bracket of functions on T^*Q, defined in local canonical coordinates (q^i,p_i) by

$$\{E,F\}=\partial^i E\,\partial_i F-\partial^i F\,\partial_i E,\quad \partial_i=\frac{\partial}{\partial q^i},\quad \partial^i=\frac{\partial}{\partial p_i}.$$

In particular, for vector fields $\mathbf{X}$ and $\mathbf{Y}$,

$$\{P(\mathbf{X}),P(\mathbf{Y})\}=P([\mathbf{X},\mathbf{Y}]),$$

where $[,]$ is the ordinary Lie bracket, and

$$\{P(\mathbf{X}),P(f)\}=[\mathbf{X},f]=\langle\mathbf{X},\mathrm{d}f\rangle.$$

This bracket is anticommutative, bilinear, and obeys the Jacobi rule. Since the Poisson bracket is a bi-derivation, the Leibnitz rule holds,

$$[\mathbf{K},\mathbf{L}\odot\mathbf{M}]=[\mathbf{K},\mathbf{L}]\odot\mathbf{M}+[\mathbf{K},\mathbf{M}]\odot\mathbf{L}.$$

Moreover, two tensors are said to be in involution if $[\mathbf{K},\mathbf{L}]=0$, i.e., $\{P(\mathbf{K}),P(\mathbf{L})\}=0$.

Let $(\mathbf{X}_i)$ be a frame on Q. Let us set

$$[\mathbf{X}_i,\mathbf{X}_j]=\Omega_{ij}{}^h\mathbf{X}_h,\quad \Omega_{ij}{}^h=-\Omega_{ji}{}^h,$$

and use the notation

$$P(\mathbf{X}_i)=x_i, \tag{8.1}$$

so that

$$\{x_i,f\}=\langle\mathbf{X}_i,\mathrm{d}f\rangle,\quad \{x_i,x_j\}=P([\mathbf{X}_i,\mathbf{X}_j])=\Omega_{ij}{}^h x_h.$$

Let us consider two contravariant symmetric two-tensors $\mathbf{K}$ and $\mathbf{L}$. Suppose that they are diagonalized in the frame, i.e.,

$$\mathbf{K}=K^i\mathbf{X}_i\odot\mathbf{X}_i,\quad \mathbf{L}=L^i\mathbf{X}_i\odot\mathbf{X}_i.$$

By using the previous formulas, it is straightforward to compute the Poisson bracket of the corresponding quadratic functions:

$$\begin{aligned}\{P(\mathbf{K}),P(\mathbf{L})\}&=\{P(K^i\mathbf{X}_i\odot\mathbf{X}_i),P(L^h\mathbf{X}_h\odot\mathbf{X}_h)\}\\&=\{K^i x_i^2,L^h x_h^2\}\\&=K^iL^h\{x_i^2,x_h^2\}+K^i\{x_i^2,L^h\}x_h^2+L^h\{K^i,x_h^2\}x_i^2\\&=4K^iL^h\Omega_{ih}{}^j x_i x_h x_j+2(K^i\langle\mathbf{X}_i,\mathrm{d}L^h\rangle-L^i\langle\mathbf{X}_i,\mathrm{d}K^h\rangle)x_i x_h^2\\&=2(2K^iL^h\Omega_{ih}{}^j+(K^i\langle\mathbf{X}_i,\mathrm{d}L^k\rangle-L^i\langle\mathbf{X}_i,\mathrm{d}K^k\rangle)\,\delta_k^h\delta_k^j)x_i x_h x_j.\end{aligned} \tag{8.2}$$

By using this formula we can prove

Theorem 8.6: *Suppose that n contravariant two-tensors* $(\mathbf{K}_a)$ *are (i) pointwise independent, (ii) in involution, and (iii) simultaneously diagonalized in a frame* $(\mathbf{X}_i)$. *Then the distributions* Δ_{ij} *spanned by pairs of vectors* $(\mathbf{X}_i,\mathbf{X}_j)$ *are completely integrable*.

Proof: By assumption (iii), $\mathbf{K}_a=K_a^i\mathbf{X}_i\odot\mathbf{X}_i$, and the independence of the tensors is equivalent to

$$\det[K_a^i]\neq 0.$$

Due to (8.2), equation $\{P(\mathbf{K}_a),P(\mathbf{K}_b)\}=0$ is equivalent to

$$(2K_a^iK_b^h\Omega_{ih}{}^j+(K_a^i\langle\mathbf{X}_i,\mathrm{d}K_b^k\rangle-K_b^i\langle\mathbf{X}_i,\mathrm{d}K_a^k\rangle)\,\delta_k^h\delta_k^j)x_ix_hx_j=0.$$

This is a homogeneous polynomial equation which must be identically satisfied for all values of the variables (p_k), thus for all values of the variables (x_i), since $x_i=P(\mathbf{X}_i)=X_i^kp_k$, and $\det[X_i^k]\neq 0$. Thus, all coefficients vanish. In particular, the coefficient of $x_1x_2x_3$ (as well as for all possible choice of three distinct indices) gives rise to

$$K_a^1K_b^2\Omega_{12}{}^3+K_a^1K_b^3\Omega_{13}{}^2+K_a^2K_b^3\Omega_{23}{}^1+K_a^2K_b^1\Omega_{21}{}^3+K_a^3K_b^1\Omega_{31}{}^2+K_a^3K_b^2\Omega_{32}{}^1=0,$$

i.e., due to the skew-symmetry of Ω,

$$\Omega_{12}{}^3(K_a^1K_b^2-K_a^2K_b^1)+\Omega_{23}{}^1(K_a^2K_b^3-K_a^3K_b^2)+\Omega_{31}{}^2(K_a^3K_b^1-K_a^1K_b^3)=0.$$

This equation can be represented in the form

$$\det\begin{bmatrix}\Omega_{23}{}^1 & \Omega_{31}{}^2 & \Omega_{12}{}^3\\ K_a^1 & K_a^2 & K_a^3\\ K_b^1 & K_b^2 & K_b^3\end{bmatrix}=0.$$

This means that the three vectors of $\mathbb{R}^3$,

$$\boldsymbol{\omega}=(\Omega_{23}{}^1,\Omega_{31}{}^2,\Omega_{12}{}^3),\quad \boldsymbol{\kappa}_a=(K_a^1,K_a^2,K_a^3),\quad \boldsymbol{\kappa}_b=(K_b^1,K_b^2,K_b^3)$$

are linearly dependent (i.e., coplanar). Assume that $\boldsymbol{\omega}\neq 0$. It follows that all vectors $(\boldsymbol{\kappa}_1,\ldots,\boldsymbol{\kappa}_n)$ belong to a same three-plane (containing $\boldsymbol{\omega}$). This means that, for any choice of three distinct indices (a,b,c), we have

$$\det\begin{bmatrix}K_a^1 & K_a^2 & K_a^3\\ K_b^1 & K_b^2 & K_b^3\\ K_c^1 & K_c^2 & K_c^3\end{bmatrix}=0.$$

As a consequence, by applying the Laplace rule to the lines (1,2,3) of the matrix $[K_a^i]$ for the calculus of its determinant, we get $\det[K_a^i]=0$: absurd. Thus $\boldsymbol{\omega}=0$. This means that $\Omega_{23}{}^1=\Omega_{31}{}^2=\Omega_{12}{}^3=0$. So, we have proved that $\Omega_{ij}{}^h=0$ for any choice of distinct indices. This means that $[\mathbf{X}_i,\mathbf{X}_j]$ is a linear combination of $\mathbf{X}_i$ and $\mathbf{X}_j$ only. Due to Frobenius' theorem, the statement is proved. ■

Due to Propositions 8.3 and 8.4 it follows that

Theorem 8.7: *Under the same assumptions of Theorem 8.6, the frame* $(\mathbf{X}_i)$ *is integrable and there are coordinates* (q^i) *in which all tensors are simultaneously diagonalized:* $K_a^{ij}=0$ *for* $i\neq j$.

We remark that the preceding statements hold in a pure differential framework; they do not involve a metric at all. When a metric tensor **G** is present, we can consider the case in which the frame is orthogonal and made of common eigenvectors of *n* independent symmetric two-tensors (not necessarily Killing tensors) $(\mathbf{K}_a)$. Then we can write

$$\mathbf{K}_a=\lambda_a^i\varepsilon^i\mathbf{X}_i\odot\mathbf{X}_i,\quad \mathbf{X}_i\cdot\mathbf{X}_j=0,\quad i\neq j,$$

where λ_a^i is the eigenvalue of $\mathbf{K}_a$ corresponding to the eigenvector $\mathbf{X}_i$,

$$\mathbf{K}_a\mathbf{X}_i=\lambda_a^i\mathbf{X}_i,$$

and

$$\varepsilon^i=\varepsilon_i^{-1},\quad \varepsilon_i=\mathbf{X}_i\cdot\mathbf{X}_i.$$

Thus, we can assert that

Theorem 8.8: *An orthogonal frame made of common eigenvectors of n independent symmetric two-tensors in involution is integrable and the tensors are simultaneously diagonalzed in an orthogonal coordinate system.*

Note that the metric tensor **G** may be one of the tensors considered in this statement (as it happens in a Killing–Stäckel algebra). Then all the two-tensors are Killing tensors. This proves Theorem 7.12, by remarking that item (i) is equivalent to the existence of common eigenvectors, according to the following

Proposition 8.9: Let $(\mathbf{K}_a)$ *be a set of n pointwise independent symmetric two-tensors on a Riemannian manifold. If they commute as linear operators then they generate locally a unique orthogonal frame (up to an equivalence) made of common eigenvectors.*

This is a pure algebraic property, which follows from the spectral theorem of self-adjoint linear operators (see for instance Ref. 29, Secs. 79, 84). However, for the sake of completeness, here we give direct proof based on the following

Proposition 8.10: Let **K** *and* **L** *be two symmetric linear operators over an n-dimensional real Euclidean vector space* $\mathbb{E}_n$. *If they commute, then they have n common eigenvectors.*

Proof: Let us denote by $\mathbf{u}\cdot\mathbf{v}=\mathbf{g}(\mathbf{u},\mathbf{v})$ the scalar product of vectors of $\mathbb{E}_n$, defined by a positive-definite metric tensor **g**. A linear operator $\mathbf{K}:\mathbb{E}_n\to\mathbb{E}_n$ is, by definition, symmetric if $\mathbf{v}\cdot\mathbf{K}\mathbf{u}=\mathbf{u}\cdot\mathbf{K}\mathbf{v}$ for each pair of vectors. It is well known that, for a metric tensor of any signature, (i) eigenvectors corresponding to distinct eigenvalues are orthogonal:

$$\mathbf{K}\mathbf{u}=\lambda\mathbf{u},\quad \mathbf{K}\mathbf{u}'=\lambda'\mathbf{u}',\quad \lambda\neq\lambda'\Leftrightarrow\mathbf{u}\cdot\mathbf{u}'=0.$$

(ii) An eigenvalue λ determines a maximal invariant linear subspace $S(\lambda)\subseteq\mathbb{E}_n$ of eigenvectors; if λ is complex, then also the conjugate λ^* is an eigenvalue (with the same multiplicity) and the dimension of $S(\lambda)$ is even. (iii) $\mathrm{am}(\lambda)\geqslant\mathrm{gm}(\lambda)$, where $\mathrm{am}(\lambda)$ is the *algebraic multiplicity* of λ as root of the characteristic equation, and $\mathrm{gm}(\lambda)$ is its *geometric multiplicity*, which is the dimension of $S(\lambda)$, if λ is real, or half of this dimension if complex. However, in a positive definite metric the eigenvalues are real and $\mathrm{am}(\lambda)=\mathrm{gm}(\lambda)=\dim S(\lambda)$. It follows that if all the eigenvalues are simple, $\dim S(\lambda)=1$ and the eigenvectors form (up to factors) a canonical basis. Let **L** be a linear operator commuting with **K**. Then

$$\mathbf{v}\in S(\lambda)\Leftrightarrow\mathbf{K}\mathbf{v}=\lambda\mathbf{v}\Rightarrow\mathbf{L}\mathbf{K}\mathbf{v}=\lambda\mathbf{L}\mathbf{v}\Rightarrow\mathbf{K}\mathbf{L}\mathbf{v}=\lambda\mathbf{L}\mathbf{v}\Rightarrow\mathbf{L}\mathbf{v}\in S(\lambda).$$

This means that $S(\lambda)$ is an invariant space of **L**. If λ is a simple root of **K**, then **v** is also an eigenvector of **L**. It follows that the space $\mathbb{E}_n$ is decomposed into a direct sum

$$\mathbb{E}_n=V_1\oplus\cdots\oplus V_k\oplus W_1\oplus\cdots\oplus W_l,$$

of mutually orthogonal subspaces, where $(V_1,\ldots,V_k)$ are one-dimensional subspaces of common eigenvectors generated by simple eigenvalues of **K** and **L**, and $(W_1,\ldots,W_k)$ are subspaces of dimension $\geqslant 2$ made of simultaneous eigevectors of **K** and **L**. By choosing an orthogonal basis on each of these subspaces we find a basis made of orthogonal common eigenvectors. ■

If, instead of two operators, we consider a set of *n* commuting symmetric operators $(\mathbf{K}_a)$ we find again a direct-sum decomposition as previously and an orthogonal basis made of common

eigenvectors. But if these operators are independent, the spaces W are not present and the basis is uniquely determined up to constant factors. Indeed, if $(\mathbf{X}_i)$ is a basis of common eigenvectors, then $\mathbf{K}_a\mathbf{X}_i=\lambda_a^i\mathbf{X}_i$ and the independence of $(\mathbf{K}_a)$ is equivalent to $\det[\lambda_a^i]\neq 0$. It follows that we can always find a linear combination of $(\mathbf{K}_a)$ which has all distinct eigenvalues. This proves Proposition 8.9.

Finally, we prove Theorem 7.24.

Proof: Conditions (i)–(ii)–(iii) are obviously necessary. To prove that they are also sufficient, let us apply Proposition 8.9 to the restrictions $\mathcal{K}^\perp$ of $\mathcal{K}$ to the orthogonal distribution $\Delta^\perp$; it follows that they define, in a unique way up to an equivalence, a *subframe* $(\mathbf{X}_a)$ $(a=1,...,m)$ of eigenvectors of $\mathcal{K}$. Since $\mathcal{K}$ is D-invariant, this subframe can be chosen to be D-invariant. If $(\mathbf{X}_\alpha)$ $(\alpha=m+1,...,n)$ is a (local) basis of D, then $(\mathbf{X}_a,\mathbf{X}_\alpha)$ form a frame such that $[\mathbf{X}_a,\mathbf{X}_\alpha]=0$, and two elements of $\mathcal{K}$ can be written in the form

$$\mathbf{K}=K^a\mathbf{X}_a\odot\mathbf{X}_a+K^{\alpha\beta}\mathbf{X}_\alpha\odot\mathbf{X}_\beta,\quad \mathbf{L}=L^a\mathbf{X}_a\odot\mathbf{X}_a+L^{\alpha\beta}\mathbf{X}_\alpha\odot\mathbf{X}_\beta,$$

where all the components are D-invariant. Recalling notation (8.1) we have

$$\{x_a,x_\alpha\}=0,\quad \{x_\alpha,x_\beta\}=0,\quad \{x_a,x_b\}=\Omega_{ab}^c x_c+\Omega_{ab}^\alpha,x_\alpha,$$

where Ω's are D-invariant. A calculation similar to that in the proof of Theorem 8.6, shows that the involutivity of a basis $(\mathbf{K}_a)$ of $\mathcal{K}$ implies that all Ω's with distinct indices vanish. Then we apply Proposition 8.4. ■

The second part of this proof can be replaced by the following geometrical (and intuitive) reasoning. We can consider (at least locally) the reduced manifold $\tilde{Q}$ (see Remark 7.28). Due to the D-invariance of $\mathcal{K}$, the vector fields $\mathbf{X}_a$ can be chosen (up to factors) to be projectable onto an orthogonal frame $\tilde{\mathbf{X}}_a$ of $\tilde{Q}$ and the orthogonal components of the elements of $\mathcal{K}$ onto the m-dimensional reduced Killing–Stäckel algebra $\tilde{\mathcal{K}}$. Then we can apply to this algebra the above-given results related to Killing–Stäckel algebras, remarking that the involutivity of $\mathcal{K}$ implies the involutivity of $\tilde{\mathcal{K}}$. It follows that the frame $(\tilde{\mathbf{X}}_a)$ is integrable. Pulling back the integral orthogonal manifolds, we get submanifolds of dimension $m-1$ whose unions with the orbits of D are manifolds of dimension $n-1$ orthogonal to the $(\mathbf{X}_a)$. Thus, these vectors are normal.

IX. AN ILLUSTRATIVE EXAMPLE: THE COMPARISON BETWEEN THE FREE AND THE REDUCED SEPARATION

Let us consider in the Euclidean three-space $Q=\mathbb{E}_3$ the Hamilton–Jacobi equation of the Kepler problem, $V=-k/r$,

$$\frac{1}{2}|\mathbf{p}|^2-\frac{k}{r}-E=0,$$

where r is the distance from the origin, and the corresponding Schrödinger equation of the ''hydrogen atom'' (as usual, see Sec. IV, we replace $(2/\hbar^2)V$ and $(2/\hbar^2)E$ with V and E)

$$\Delta\psi+\left(E+\frac{k}{r}\right)\psi=0.$$

It is known that the Kepler problem is separable with respect to four separable webs: spherical, spherical conical, parabolic, all centered at the origin, and prolate spheroidal centered at any point with focus at the origin (see Ref. 30 for a group-theoretical approach and Ref. 31 for a geometrical and tensorial approach). Since $\mathbf{R}=0$, the Schrödinger equation is separable in all possible coordinate systems associated with these webs. In order to analyze the different features between the free and the reduced separation, let us consider the spherical web, which is orthogonal (thus

allowing the free separation) and rotational (thus allowing the reduced separation). This web can be parametrized by the usual spherical coordinates $(q^1,q^2,q^3)=(r,\theta,\varphi)$.

Free separation. The Killing–Stäckel algebra $\mathcal{K}_3$ associated with the spherical web has the following basis:

$$\mathbf{K}_1=\partial_\theta\otimes\partial_\theta+\frac{1}{\sin^2\theta}\partial_\varphi\otimes\partial_\varphi,$$

$$\mathbf{K}_2=\partial_\varphi\otimes\partial_\varphi, \tag{9.1}$$

$$\mathbf{G}=\partial_r\otimes\partial_r+\frac{1}{r^2}\partial_\theta\otimes\partial_\theta+\frac{1}{r^2\sin^2\theta}\partial_\varphi\otimes\partial_\varphi.$$

The (diagonal) components of these tensors form the inverse matrix

$$[\varphi^i_{(j)}]=\begin{bmatrix}0 & 1 & \frac{1}{\sin^2\theta}\\ 0 & 0 & 1\\ 1 & \frac{1}{r^2} & \frac{1}{r^2\sin^2\theta}\end{bmatrix} \tag{9.2}$$

of the Stäckel matrix

$$[\varphi^{(j)}_i]=\begin{bmatrix}-\frac{1}{r^2} & 1 & 0\\ 0 & -\frac{1}{\sin^2\theta} & 1\\ 1 & 0 & 0\end{bmatrix}.$$

The last line of matrix (9.2) represents the diagonal components g^{ii} of the metric tensor. The contracted Christoffel symbols (4.3) are

$$\Gamma_1=-\frac{2}{r},\quad \Gamma_2=-\frac{1}{\tan\theta},\quad \Gamma_3=0. \tag{9.3}$$

Looking at the expression of the Newtonian potential energy, written as a Stäckel multiplier (1.6),

$$V=-\frac{k}{r}=\phi_i g^{ii}=\phi_i\varphi^i_{(3)}=\phi_1(r)+\phi_2(\theta)\frac{1}{r^2}+\phi_3(\varphi)\frac{1}{r^2\sin^2\theta},$$

we get (at least) two solutions,

$$\phi_1=-\frac{k}{r}-\frac{c}{r^2},\quad \phi_2=c\in\mathbb{R},\quad \phi_3=0,$$

or

$$\phi_1=-\frac{k}{r},\quad \phi_2=-\frac{c}{\sin^2\theta},\quad \phi_3=c\in\mathbb{R}.$$

However, for our purposes, there is no loss of generality in choosing $c=0$, so that they coincide:

$$\phi_1 = -\frac{k}{r}, \quad \phi_2 = 0, \quad \phi_3 = 0. \tag{9.4}$$

In the free separation the Killing tensors of the spherical Killing–Stäckel algebra correspond to the constants of motion $a=(a_j)$ entering Eqs. (4.32),

$$\varphi^i_{(j)}\left(\frac{\psi_i''}{\psi_i} - \Gamma_i \frac{\psi_i'}{\psi_i} - \phi_i\right) + a_j = 0.$$

Due to (9.3) and (9.4), these equations are equivalent to the well-known separated ordinary differential equations of the kind (4.29),

$$\psi_1'' + \frac{2}{r}\psi_1' + \left(a_3 - \frac{1}{r^2}a_1 + \frac{k}{r}\right)\psi_1 = 0 \quad (a_3 = E),$$

$$\psi_2'' + \cot\theta\,\psi_2' + \left(a_1 - \frac{1}{\sin^2\theta}a_2\right)\psi_2 = 0, \tag{9.5}$$

$$\psi_3'' + a_2\psi_3 = 0,$$

in the unknown functions $\psi_1(r)$, $\psi_2(\theta)$, $\psi_3(\varphi)$. The general solution of the first equation (9.5) can be written

$$\psi_1 = c_1 F_1 + c_2 F_2$$

where $F_1(a_1,a_3;r)$ and $F_2(a_1,a_3;r)$ are two independent confluent hypergeometric functions[32] and (c_1,c_2) arbitrary constants. Since any ψ_i can be determined up to an inessential multiplicative constant, we can choose the solution

$$\psi_1 = F_1 + b_1 F_2, \quad b_1 \in \mathbb{R}.$$

In a similar way, for the second equation (9.5) we consider the solution

$$\psi_2 = S_1(a_1,a_2;\theta) + b_2 S_2(a_1,a_2;\theta),$$

where S_1 and S_2 are independent spherical harmonics.[32] For the last equation (9.5) we can consider the solution

$$\psi_3 = e^{-\sqrt{-a_2}\varphi} + b_3 e^{\sqrt{-a_2}\varphi}.$$

Thus, the resulting separated solution $\psi = \psi_1\psi_2\psi_3$ depends on $2n=6$ constants (a_i,b_i). However, in order to get solutions $\psi = \psi_1\psi_2\psi_3$ with a physical meaning, the constant parameters (a_1,a_2,a_3), corresponding to the constants of motion, must verify further well known (quantization) conditions, assuring for instance, the summability of ψ_1 and ψ_2, and the periodicity of ψ_3. These are the results of the free separation, as explained in Remarks 4.7, 4.8, and 4.9.

Reduced separation. Since the spherical web is rotational, so that φ is ignorable, we can consider the reduced separation according to Definition 5.1 and Theorem 5.2, by setting (being $\alpha=3$)

$$\psi_3 = e^{\kappa_3\varphi}. \tag{9.6}$$

Now the Stäckel matrix and its inverse are the 2×2 matrices

$$[\varphi_b^{(a)}]=\begin{bmatrix} -\frac{1}{r^2} & 1 \\ 1 & 0 \end{bmatrix}, \quad [\varphi_{(a)}^b]=\begin{bmatrix} 0 & 1 \\ 1 & \frac{1}{r^2} \end{bmatrix},$$

respectively. The other two functions $\psi_1(r)$ and $\psi_2(\theta)$ must satisfy the separated equations (5.27). In the present case, from the general expressions (3.9), where $\alpha=\beta=3$, we derive

$$g^{33}=\frac{1}{r^2\sin^2\theta}=\phi_1^{33}+\phi_2^{33}\frac{1}{r^2},$$

thus,

$$\phi_1^{33}=\frac{c}{r^2}, \quad \phi_2^{33}=\frac{1}{\sin^2\theta}-c, \quad c\in\mathbb{R},$$

and ϕ_1, ϕ_2, Γ_1, and Γ_2 are as above. For $c=0$ (5.27) become

$$\psi_1''+\frac{2}{r}\psi_1'+\left(\tilde{a}_2-\frac{1}{r^2}\tilde{a}_1+\frac{k}{r}\right)\psi_1=0 \quad (\tilde{a}_2=E),$$

$$\psi_2''+\cot\theta\psi_2'+\left(\tilde{a}_1+\frac{1}{\sin^2\theta}\kappa_3^2\right)\psi_2=0.$$

Up to the transformation of the constant parameters,

$$\tilde{a}_1=a_1, \quad \tilde{a}_2=a_3, \quad \kappa_3^2=-a_2,$$

these equations coincide with the first two equations (9.5), and ψ_3 given by the constraint (9.1) is a solution of the third equation (9.5). Finally, we observe that the Killing–Stäckel algebra $\mathcal{K}_3$ associated with the free separation in the spherical web is determined by the Killing tensors $(\mathbf{G},\mathbf{K}_1,\mathbf{K}_2)$ given in (9.1). With the same web we associate the separable Killing algebra $(D_1,\mathcal{K}_2)$, with $\mathcal{K}_2=\text{span}(\mathbf{G},\mathbf{K}_1)$ and $D=\text{span}(\partial_\varphi)$. This geometrical structure can be interpreted in two different ways. (i) We can use ∂_φ for constructing $\mathbf{K}_2=\partial_\varphi\otimes\partial_\varphi$, by interpreting φ as an essential coordinate (this is possible since the web is orthogonal). In this way we reconstruct the Killing–Stäckel algebra $\mathcal{K}_3$, associated with the free separation. (ii) We can associate with D the solution (9.6), by interpreting φ as an ignorable coordinate, and we reduce the problem of the separation to the remaining two essential coordinates: this is the reduced separation.

Department of Mathematics, University of Turin, 10123 Torino, Italy

(Received 1 March 2002; accepted 27 June 2002)

The commutation relations of the first-order and second-order operators associated with the first integrals in involution of a Hamiltonian separable system are examined. It is shown that these operators commute if and only if a ''pre-Robertson condition'' is satisfied. This condition involves the Ricci tensor of the configuration manifold and it is implied by the Robertson condition, which is necessary and sufficient for the separability of the Schrödinger equation. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1506181]

I. INTRODUCTION

The connection between the additive separation of the Hamilton–Jacobi equation and the multiplicative separation of the corresponding Schrödinger equation has been examined in paper 1.[1] Two different kinds of separation have been introduced for the Schrödinger equation, called ''free'' and ''reduced separation,'' respectively, related to two suitable completeness conditions for a separated solution and geometrically characterized in terms of ''Killing–Stäckel algebras'' and of ''separable Killing algebras.'' These are linear spaces of Killing tensors and Killing vectors which generate complete systems of first integrals in involution, and which characterize the separation of the Hamilton–Jacobi equation in orthogonal and in standard coordinates, respectively. The corresponding Schrödinger equation is then separable in the same coordinate system if and only if a ''Robertson condition'' is satisfied. This condition involves the Ricci tensor of the configuration manifold and it is fulfilled in the most common applications of the theory (for instance, on Einstein manifolds).

In the present paper we revisit the matter relating the separation of the Schrödinger equation to the existence of ''symmetry operators,'' [2] i.e., to the existence of linear second-order operators on wave functions which commute with the Schrödinger operator. These operators are in one-to-one correspondence with the quadratic first integrals associated with the separation. We shall show that the ''quantization problem,'' i.e., the problem of defining a correspondence between classical observables and linear operators preserving the commutation relations,[3] is solvable for the involutive algebra of first integrals associated with the separation of the Hamilton–Jacobi equation provided a ''pre-Robertson'' condition is satisfied. This condition is implied by the Robertson condition, so that the quantization problem for a classical natural Hamiltonian system is solvable if the corresponding Schrödinger equation is separable. The main theorems and remarks are stated in Secs. III and VI in the case of the orthogonal and general separation, respectively. The proofs are given in Secs. V and VIII, after general considerations about Killing tensors in orthogonal and standard form illustrated in Secs. IV and VII.

II. GENERAL COMMUTATION RELATIONS FOR SECOND-ORDER DIFFERENTIAL LINEAR OPERATORS

By the "quantization problem" [3] we mean the problem of defining a correspondence $F \mapsto \hat{F}$ between classical and quantum observables, i.e., between smooth real functions on the cotangent bundle T^*Q (the "phase space") of the configuration manifold of a mechanical system and self-adjoint linear operators on a suitable "state-space" of complex-valued functions (or distributions) on Q. This correspondence is required to be $\mathbb{R}$-linear and preserving the Lie-algebra structure of classical and quantum observables:

$$(F+G)\hat{} = \hat{F}+\hat{G}, \quad (cF)\hat{} = c\hat{F} \quad (c \in \mathbb{R}), \quad \{F,G\}\hat{} = \gamma[\hat{F},\hat{G}].$$

Here, $\{F,G\}$ denotes the canonical Poisson bracket of functions, γ is a universal constant, and

$$[\hat{F},\hat{G}] = \hat{F}\hat{G} - \hat{G}\hat{F}$$

is the commutator of linear operators.

The quantization problem is not solvable on the whole set of observables of a phase space.[4–6] (see Ref. 3 for details, comments, and references). In accordance with Schwinger (Ref. 7, Sec. 2.4) we can say not only that "it is a convenient fiction to assert that every Hermitian operator symbolizes a physical quantity [...]" but also that it is a "convenient fiction" to assert that with every classical observable we can associate an Hermitian operator (i.e., a quantum observable). However, as we shall see, the quantization problem is solvable for the classical observables involved in the separation of variables of a natural Hamiltonian system, which are polynomials of second degree in the momenta (p_i).

We consider as a starting point the following assumptions: (i) The universal constant γ is a positive-imaginary number: $\gamma = i/h$, $\hbar \in \mathbb{R}_+$. (ii) The operator $\hat{f}$ corresponding to a function f on Q, interpreted as a function on T^*Q constant on the fibers, is defined by

$$\hat{f}\psi = f \cdot \psi.$$

As usual, the operator $\hat{f}$ will be simply denoted by f. (iii) The operator $\hat{P}_{\mathbf{X}}$ corresponding to a first-degree homogeneous polynomial

$$P_{\mathbf{X}} = X^i p_i$$

associated with a vector field $\mathbf{X}$ on Q, is defined by

$$\hat{P}_{\mathbf{X}}\psi = \frac{1}{\gamma}\langle \mathbf{X}, \mathrm{d}\psi \rangle = -i\hbar \langle \mathbf{X}, \mathrm{d}\psi \rangle.$$

(iv) The operator $\hat{P}_{\mathbf{K}}$ corresponding to a second-degree homogeneous polynomial

$$P_{\mathbf{K}} = K^{ij} p_i p_j$$

associated with a symmetric contravariant two-tensor $\mathbf{K}$ on Q, is defined by

$$\hat{P}_{\mathbf{K}}\psi = -\hbar^2 \Delta_{\mathbf{K}}\psi = -\hbar^2 \nabla_i (K^{ij} \nabla_j \psi),$$

where $\Delta_{\mathbf{K}}$ is the *pseudo-Laplacian* operator defined by

$$\Delta_{\mathbf{K}}\psi = \nabla_i (K^{ij} \nabla_j \psi) \tag{2.1}$$

(by ∇_i we denote the covariant derivative with respect to the Levi-Civita connection). For $\mathbf{K} = \mathbf{G}$ (the contravariant metric tensor) we find the Laplace–Beltrami operator $\Delta_{\mathbf{G}} = \Delta$,

$$\Delta\psi = g^{ij}\nabla_i\nabla_j\psi.$$

We shall use the *co-differential or divergence operator* δ on contravariant skew-symmetric tensors **A**, defined by

$$(\delta\mathbf{A})^{j\cdots k} = \nabla_i A^{ij\cdots k}.$$

For a function (zero-tensor), $\delta f = 0$. It follows that $\delta^2 = 0$.

According to the notation used in Ref. 1, Remark 7.1, we shall identify a (contravariant) two-tensor $\mathbf{K} = (K^{ij})$ with the corresponding linear endomorphisms on vectors and one-forms, so that we shall denote by $\mathbf{K}\nabla\psi$ the vector field image of the gradient $\nabla\psi$ (whose components are $K^{ij}\partial_j\psi$) and by $\mathbf{K}\,\mathrm{d}\psi$ the one-form image of the differential $\mathrm{d}\psi$ (whose components are $g_{ih}K^{hj}\partial_j\psi$). With this notation, the coordinate independent definition of the pseudo-Laplacian (2.1) is

$$\Delta_{\mathbf{K}}\psi = \delta(\mathbf{K}\nabla\psi).$$

We shall deal with quadratic classical observables of the kind

$$H_{\mathbf{K}} = \tfrac{1}{2}P_{\mathbf{K}} + V_{\mathbf{K}}, \quad V_{\mathbf{K}}: Q \to \mathbb{R},$$

and with the corresponding second-order operators

$$\hat{H}_{\mathbf{K}} = \frac{1}{2}\hat{P}_{\mathbf{K}} + V_{\mathbf{K}} = -\frac{\hbar^2}{2}\Delta_{\mathbf{K}} + V_{\mathbf{K}}. \tag{2.2}$$

For $\mathbf{K} = \mathbf{G}$ we find the *Hamiltonian* and the *Schrödinger operator*,

$$H = H_G = \frac{1}{2}P_{\mathbf{G}} + V, \quad \hat{H} = \frac{1}{2}\hat{P}_{\mathbf{G}} + V = -\frac{\hbar^2}{2}\Delta + V.$$

A classical observable F in involution with H, $\{F,H\} = 0$, is a *first integral* (or *constant of motion*) of the Hamiltonian system generated by H. A linear operator $\hat{F}$ commuting with $\hat{H}$,

$$[\hat{F},\hat{H}] = 0,$$

is called a *symmetry operator* of the Schrödinger equation. The following commutation rules hold for these classical observables,

$$\begin{aligned} \{H_{\mathbf{K}_1}, H_{\mathbf{K}_2}\} &= \{P_{\mathbf{K}_1}, P_{\mathbf{K}_2}\} + P_{\mathbf{K}_1\nabla V_{\mathbf{K}_2}} - P_{\mathbf{K}_2\nabla V_{\mathbf{K}_1}}, \\ \{H_{\mathbf{K}}, H\} &= \{P_{\mathbf{K}}, P_{\mathbf{G}}\} + P_{\mathbf{K}\nabla V} - P_{\nabla V_{\mathbf{K}}}. \end{aligned} \tag{2.3}$$

We recall that a *Killing tensor* is a symmetric tensor (of any order) satisfying one of the following two equivalent conditions:

$$\{P_{\mathbf{K}}, P_G\} = 0 \;\Leftrightarrow\; \nabla^{(i}K^{j\cdots k)} = 0, \tag{2.4}$$

where $P_{\mathbf{K}} = K^{ij\cdots k}p_i p_j \ldots p_k$ and the brackets $(\cdots)$ denote the symmetrization of the indices. The first equation (2.4) means that $P_{\mathbf{K}}$ is a first integral of the godesic flow.

In the second equation (2.3) the term $\{P_{\mathbf{K}}, P_{\mathbf{G}}\}$ is a third-degree homogeneous polynomial in the momenta (p_i), while the remaining term is of first degree. This shows that

Theorem 2.1: *The quadratic function $H_{\mathbf{K}}$ is a first integral of the Hamiltonian flow generated by H if and only if $\mathbf{K}$ is a Killing tensor and $\mathbf{K}\,\mathrm{d}V = \mathrm{d}V_{\mathbf{K}}$ i.e., the following conditions are equivalent*

$$\{H_{\mathbf{K}},H\}=0 \Leftrightarrow \begin{array}{c}\{P_{\mathbf{K}},P_{\mathbf{G}}\}=0 \quad (\mathbf{K} \text{ Killing tensor}),\\ \nabla V_{\mathbf{K}}=\mathbf{K}\nabla V.\end{array} \tag{2.5}$$

For the related operators we have

Theorem 2.2: *The following conditions are equivalent*

$$[\hat{H}_{\mathbf{K}},\hat{H}]=0 \Leftrightarrow \begin{array}{c}\{P_{\mathbf{K}},G_{\mathbf{G}}\}=0 \quad (\mathbf{K} \text{ Killing tensor}),\\ \mathbf{K}\nabla V-\nabla V_{\mathbf{K}}+\dfrac{\hbar^2}{6}\delta\mathbf{C}=0,\end{array} \Leftrightarrow \{H_{\mathbf{K}},H\}=-\frac{\hbar^2}{6}P_{\delta\mathbf{C}}, \tag{2.6}$$

where

$$\mathbf{C}=\mathbf{KR}-\mathbf{RK}, \quad C^{ij}=K^{ih}R^j_h-R^{ih}K^j_h=K^{ih}g_{hk}R^{kj}-R^{ih}g_{hk}K^{kj}, \quad C^{ij}=-C^{ji},$$

and $\mathbf{R}$ *is the Ricci tensor:*

Proof: In accordance with the above-given definitions we have

$$\hat{H}\hat{H}_{\mathbf{K}}\psi=-\frac{\hbar^2}{2}\Delta\left(-\frac{\hbar^2}{2}\Delta_{\mathbf{K}}\psi+V_{\mathbf{K}}\psi\right)+V\left(-\frac{\hbar^2}{2}\Delta_{\mathbf{K}}\psi+V_{\mathbf{K}}\psi\right)$$

$$=\frac{\hbar^4}{4}\Delta\Delta_{\mathbf{K}}\psi-\frac{\hbar^2}{2}(\Delta(V_{\mathbf{K}}\psi)+V\Delta_{\mathbf{K}}\psi)+VV_{\mathbf{K}}\psi,$$

$$\hat{H}_{\mathbf{K}}\hat{H}\psi=\frac{\hbar^4}{4}\Delta_{\mathbf{K}}\Delta\psi-\frac{\hbar^2}{2}(\Delta_{\mathbf{K}}(V\psi)+V_{\mathbf{K}}\Delta\psi)+V_{\mathbf{K}}V\psi,$$

$$\Delta_{\mathbf{K}}(V\psi)=\psi\Delta_{\mathbf{K}}V+2\mathbf{K}(\mathrm{d}V,\mathrm{d}\psi)+V\Delta_{\mathbf{K}}\psi,$$

$$\Delta(V_{\mathbf{K}}\psi)=\psi\Delta V_{\mathbf{K}}+2\mathbf{G}(\mathrm{d}V_{\mathbf{K}},\mathrm{d}\psi)+V_{\mathbf{K}}\Delta\psi.$$

Hence,

$$[\hat{H},\hat{H}_{\mathbf{K}}]\psi=\frac{\hbar^4}{4}[\Delta,\Delta_{\mathbf{K}}]\psi+\frac{\hbar^2}{2}(\psi\Delta_{\mathbf{K}}V+2\mathbf{K}(\mathrm{d}V,\mathrm{d}\psi)-\psi\Delta V_{\mathbf{K}}-2\mathbf{G}(\mathrm{d}V_{\mathbf{K}},\mathrm{d}\psi))$$

$$=\frac{\hbar^4}{4}[\Delta,\Delta_{\mathbf{K}}]\psi+\hbar^2(\mathbf{K}\nabla V-\nabla V_{\mathbf{K}})\cdot\nabla\psi+\frac{\hbar^2}{2}(\Delta_{\mathbf{K}}V-\Delta V_{\mathbf{K}})\psi. \tag{2.7}$$

Now we use a formula due to Carter[8] which gives an explicit expression of the commutator of a pseudo-Laplacian with the ordinary Laplacian,

$$[\Delta,\Delta_{\mathbf{K}}]\psi=2\nabla^hK^{ij}\nabla_{(i}\nabla_j\nabla_{h)}\psi+3\nabla_h\nabla^{(h}K^{ij)}\nabla_{(i}\nabla_{j)}\psi$$
$$+\nabla_j(\tfrac{1}{2}g_{hk}(\nabla^j\nabla^{(i}K^{hk)}-\nabla^i\nabla^{(j}K^{hk)})+\tfrac{4}{3}K^{[j}_hR^{i]h})\nabla_i\psi, \tag{2.8}$$

where the brackets $[\cdots]$ denote the skew-symmetrization of the indices. Gathering together and equating to zero the terms of third, first-, and zero-order derivatives of ψ on the right-hand side of (2.7) we get the following equations, respectively,

$$\nabla^{(h}K^{ij)}=0 \quad (\mathbf{K} \text{ is a Killing tensor}),$$

$$\mathbf{K}\nabla V-\nabla V_{\mathbf{K}}+\frac{\hbar^2}{6}\delta(\mathbf{KR}-\mathbf{RK})=0, \tag{2.9}$$

$$\Delta_{\mathbf{K}}V-\Delta V_{\mathbf{K}}=0.$$

The second-order terms in (2.7) disappear because of the first equation (2.9). The last equation (2.9) can be written $\delta(\mathbf{K}\nabla V-\nabla V_{\mathbf{K}})=0$, so that it becomes a consequence of the second equation, since $\mathbf{C}=\mathbf{KR}-\mathbf{RK}$ is skew-symmetric and $\delta^2=0$. This proves the first equivalence (2.6). The second equivalence follows from the last equation (2.3), since $\{P_{\mathbf{K}},P_{\mathbf{G}}\}$ is a homogeneous polynomial of third degree in (p_i), while $P_{\mathbf{K}\nabla V}-P_{\nabla V_{\mathbf{K}}}$ and $P_{\delta\mathbf{C}}$ are of first degree. ■

The following three propositions are a consequence of Theorem 2.2 and of the *Carter formula* (2.8).

Proposition 2.3: If $\mathbf{K}=(K^{ij})$ *is a symmetric tensor, then* $[\hat{P}_{\mathbf{K}},\hat{P}_{\mathbf{G}}]=0$ *if and only if* $\mathbf{K}$ *is a Killing tensor and*

$$\delta\mathbf{C}=\delta(\mathbf{KR}-\mathbf{RK})=0. \tag{2.10}$$

Proof: This is a special case of the first equivalence (2.6), for $V=0$ and $V_{\mathbf{K}}=0$. ■

We call (2.10) the *Carter condition*. Note that $[\hat{P}_{\mathbf{K}},\hat{P}_{\mathbf{G}}]=0$ is equivalent to $[\Delta_{\mathbf{K}},\Delta]=0$.

Proposition 2.4: If $\mathbf{K}$ *is a Killing tensor, then*

$$\{H,H_{\mathbf{K}}\}=0 \Rightarrow [\hat{H},\hat{H}_{\mathbf{K}}]\psi=\frac{\hbar^4}{6}\,\delta\mathbf{C}\cdot\nabla\psi. \tag{2.11}$$

Proof: For a Killing tensor the Carter formula (2.8) reduces to

$$[\Delta,\Delta_{\mathbf{K}}]\psi=\tfrac{2}{3}\delta\mathbf{C}\cdot\nabla\psi$$

so that (2.7) becomes

$$[\hat{H},\hat{H}_{\mathbf{K}}]\psi=\frac{\hbar^4}{6}\,\delta C\cdot\nabla\psi+\hbar^2(\mathbf{K}\nabla V-\nabla V_{\mathbf{K}})+\frac{\hbar^2}{2}\,\delta(\mathbf{K}\nabla V-\nabla V_{\mathbf{K}}).$$

Because of the equivalence (2.5), we get the second equation (2.11). ■

Proposition 2.5: Let $H_{\mathbf{K}}=\frac{1}{2}P_{\mathbf{K}}+V_{\mathbf{K}}$ *be a quadratic first integral i.e.,* $\{H_{\mathbf{K}},H\}=0$. *Then,* $[\hat{H}_{\mathbf{K}},\hat{H}]=0$ *if and only if the Carter condition (2.10) is satisfied.*

Proof: If (2.10) holds, then $[\hat{H}_{\mathbf{K}},\hat{H}]=0$ because of the implication (2.11). Conversely, the simultaneous conditions $[\hat{H}_{\mathbf{K}},\hat{H}]=0$ and $\{H_{\mathbf{K}},H\}=0$ imply $\delta\mathbf{C}=0$ because of the equivalence (2.6) ■

As a corollary of Theorem 2.2 we have

Theorem 2.6: *If* $\mathbf{R}=\kappa\mathbf{G}$, *then*

$$\{H_{\mathbf{K}},H\}=0 \Leftrightarrow [\hat{H}_{\mathbf{K}},\hat{H}]=0.$$

This shows that on Einstein manifolds (in particular, on manifolds with constant curvature, on flat manifolds, on Ricci-flat manifolds, etc.) a quadratic function $H_{\mathbf{K}}=\frac{1}{2}P_{\mathbf{K}}+V_{\mathbf{K}}$ is a first integral if and only if the corresponding operator $\hat{H}_{\mathbf{K}}$, defined according to (2.1) and (2.2), is a symmetry of the Schrödinger equation.

For a first-order operator $\hat{P}_{\mathbf{X}}$ we have a similar equivalence, but without any condition (like the Carter condition) involving the Ricci tensor:

Theorem 2.7: *The operator* $\hat{P}_{\mathbf{X}}$ *commutes with the Laplacian if and only if* $\mathbf{X}$ *is a Killing vector,*

$$[\hat{P}_{\mathbf{X}},\Delta]=0 \Leftrightarrow \{P_{\mathbf{X}},P_{\mathbf{G}}\}=0.$$

Proof: This follows from three basic facts. (i) A vector field is a Killing vector if and only if its covariant components satisfy equation

$$\nabla_i X_j + \nabla_j X_i = 0. \tag{2.12}$$

This is in accordance with (2.4). (ii) If $\mathbf{X}=(X^i)$ is a Killing vector, then[9]

$$\Delta X^i + R^i_j X^j = 0, \tag{2.13}$$

where R_{ij} is the Ricci tensor. This follows from the general commutation rule

$$\nabla_l \nabla_k X_i - \nabla_k \nabla_l X_i = X_m R^m_{\cdot ikl}, \tag{2.14}$$

where $R^m_{\cdot ikl}$ are the components of the Riemann tensor. Indeed, by setting $g^{il}R^m_{\cdot ikl}=R^m_k$, we get

$$g^{il}(\nabla_l \nabla_k X_i - \nabla_k \nabla_l X_i) = R^m_k X_m .$$

For a Killing vector, $\nabla_k X_i$ is skew-symmetric due to (2.12) thus,

$$-g^{il}\nabla_l \nabla_i X_k = R^m_k X_m ,$$

and this equation is equivalent to (2.13). (iii) For any vector field $\mathbf{X}$, the general commutation relation

$$[\mathbf{X},\Delta]\psi = -(\Delta X^l + X^i R^l_i)\nabla_l \psi - 2\nabla^h X^i \nabla_h \nabla_i \psi, \tag{2.15}$$

holds, where $\mathbf{X}(\psi)=X^i\nabla_i\psi$. Indeed,

$$\begin{aligned}[\mathbf{X},\Delta]\psi &= [X^i\nabla_i, g^{hk}\nabla_h\nabla_k]\psi \\ &= X^i g^{hk}\nabla_i\nabla_h\nabla_k\psi - g^{hk}\nabla_h\nabla_k(X^i\nabla_i\psi) \\ &= g^{hk}(X^i\nabla_i\nabla_h\nabla_k\psi - X^i\nabla_h\nabla_k\nabla_i\psi - \nabla_h\nabla_k X^i\nabla_i\psi - \nabla_k X^i\nabla_h\nabla_i\psi - \nabla_h X^i\nabla_k\nabla_i\psi)\end{aligned} \tag{2.16}$$

However, because of (2.14),

$$\nabla_i\nabla_h\nabla_k\psi = \nabla_h\nabla_i\nabla_k\psi = \nabla_j\psi R^j_{\cdot khi} = \nabla_h\nabla_k\nabla_i\psi + \nabla_j\psi R^j_{\cdot khi},$$

since $\nabla_i\nabla_k\psi$ is symmetric. Thus, the last expression (2.16) becomes

$$[\mathbf{X},\Delta]\psi = g^{hk}X^i R^j_{\cdot khi}\nabla_j\psi - \Delta X^i\nabla_i\psi - 2\nabla^h X^i\nabla_h\nabla_i\psi$$

and (2.15) is proved. Assume that $\mathbf{X}$ is a Killing vector. Then the first term on the right-hand side of (2.15) vanishes because of (2.13), as well as the second term, since $\nabla^h X^i$ is skew-symmetric because of (2.12). Conversely, assume that (2.15) is satisfied for all functions ψ. Then the coefficients of the first and second derivatives of ψ must vanish separately. The coefficients of the second derivatives yield equation $\nabla^h X^i \partial_h \partial_i \psi = 0$, which shows that $\nabla^h X^i$ is skew-symmetric. Thus, $\mathbf{X}$ is a Killing vector according to (2.12), and the first-order terms vanish due to (2.13). ■

From Theorem 2.7 it follows that

Theorem 2.8: *The operator $\hat{P}_{\mathbf{X}}$ commutes with the Schrödinger operator $\hat{H}$ if and only if $\mathbf{X}$ is a Killing vector and $\langle \mathbf{X}, \mathrm{d}V\rangle = 0$ i.e.,*

$$[\hat{P}_{\mathbf{X}}, \hat{H}] = 0 \Leftrightarrow \{P_{\mathbf{X}}, H\} = 0. \tag{2.17}$$

Proof: Since

$$[\hat{P}_{\mathbf{X}}, \tfrac{1}{2}\hat{P}_{\mathbf{G}} + V]\psi = \tfrac{1}{2}[\hat{P}_{\mathbf{X}}, \hat{P}_{\mathbf{G}}]\psi + \hat{P}_{\mathbf{X}}(V\psi) - V\hat{P}_{\mathbf{X}}\psi = \tfrac{1}{2}[\hat{P}_{\mathbf{X}}, \hat{P}_{\mathbf{G}}]\psi + \hat{P}_{\mathbf{X}}(V)\psi,$$

the first commutation relation (2.17) is equivalent to

$$[\hat{P}_{\mathbf{X}},\Delta]=0, \quad \hat{P}_{\mathbf{X}}(V)=0.$$

Moreover,

$$\{P_{\mathbf{X}},\tfrac{1}{2}P_{\mathbf{G}}+V\}=\tfrac{1}{2}\{P_{\mathbf{X}},P_{\mathbf{G}}\}+\{P_{\mathbf{X}},V\}=\tfrac{1}{2}\{P_{\mathbf{X}},P_{\mathbf{G}}\}+\langle\mathbf{X},\mathrm{d}V\rangle,$$

and the second commutation relation (2.17) is equivalent to

$$\{P_{\mathbf{X}},P_{\mathbf{G}}\}=0, \quad \langle\mathbf{X},\mathrm{d}V\rangle=0.$$

Thus, the two commutation relations are equivalent due to Theorem 2.7. ■

III. SYMMETRY OPERATORS ASSOCIATED WITH THE ORTHOGONAL SEPARATION OF THE HAMILTON–JACOBI EQUATION

A *Killing–Stäckel algebra* is an n-dimensional linear space $\mathcal{K}$ of Killing two-tensors with common normal eigenvectors.[1] It can be proved that $\mathbf{G}\in\mathcal{K}$ and that all functions $P_{\mathbf{K}}$, $\mathbf{K}\in\mathcal{K}$, are in involution. The Hamilton–Jacobi equation associated with a natural Hamiltonian

$$H=\tfrac{1}{2}P_{\mathbf{G}}+V=\tfrac{1}{2}g^{ij}(\underline{q})p_ip_j+V(\underline{q})$$

is separable (i.e., integrable by separation of variables) in orthogonal coordinates if and only if there exists a Killing–Stäckel algebra such that equation $\mathrm{d}(\mathbf{K}\,\mathrm{d}V)=0$ is satisfied for all $\mathbf{K}\in\mathcal{K}$, or for a single Killing tensor $\mathbf{K}$ with simple eigenvalues (such a tensor is called a *characteristic tensor* of $\mathcal{K}$). Then: (i) The separation occurs in any coordinate system (q^i) such that $\mathrm{d}q^i$ are (common) eigenforms of the elements of $\mathcal{K}$. In these coordinates all elements of $\mathcal{K}$ are diagonalized,

$$\mathbf{K}=K^{ii}\partial_i\otimes\partial_i=\lambda^i g^{ii}\partial_i\otimes\partial_i, \tag{3.1}$$

λ^i being the eigenvalues of $\mathbf{K}$ (for $\mathbf{K}=\mathbf{G}$ we have $\lambda^i=1$). (ii) There are local functions $V_{\mathbf{K}}$ on Q such that $\mathrm{d}V_{\mathbf{K}}=\mathbf{K}\,\mathrm{d}V$ or

$$\nabla V_{\mathbf{K}}=\mathbf{K}\nabla V \tag{3.2}$$

for all $\mathbf{K}\in\mathcal{K}$. It follows that the functions

$$H_{\mathbf{K}}=\tfrac{1}{2}P_{\mathbf{K}}+V_{\mathbf{K}}, \quad \mathbf{K}\in\mathcal{K},$$

are first integrals in involution,

$$\{H_{\mathbf{K}_1},H_{\mathbf{K}_2}\}=0, \quad \forall\mathbf{K}_1,\mathbf{K}_2\in\mathcal{K}.$$

We denote by

$$\mathcal{H}=(\mathcal{K},V)$$

the n-dimensional space of these first integrals determined by a Killing-Stäckel algebra $\mathcal{K}$ and by a potential V satisfying (3.2).

In general, the linear operators $\hat{H}_{\mathbf{K}}$ (2.2) corresponding to these quadratic first integrals do not commute, as shown by the following

Theorem 3.1: *Let $\mathcal{H}=(\mathcal{K},V)$ be the space of first integrals in involution associated with the orthogonal separation of the Hamilton–Jacobi equation. Then the following conditions are equivalent*

$$\begin{aligned}
&\text{(a)}\quad [\hat{H}_{\mathbf{K}},\hat{H}]=0, \quad \forall \mathbf{K}\in\mathcal{K},\\
&\text{(b)}\quad \delta(\mathbf{KR}-\mathbf{RK})=0, \quad \forall \mathbf{K}\in\mathcal{K},\\
&\text{(c)}\quad \partial_i R_{ij}-\Gamma_i R_{ij}=0, \quad i\neq j,\ \ i \ \text{ n.s.},\\
&\text{(d)}\quad [\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0, \quad \forall \mathbf{K}_1,\mathbf{K}_2,\in\mathcal{K},\\
&\text{(e)}\quad \delta(\mathbf{K}_1\mathbf{R}\mathbf{K}_2-\mathbf{K}_2\mathbf{R}\mathbf{K}_1)=0, \quad \forall \mathbf{K}_1,\mathbf{K}_2,\in\mathcal{K},
\end{aligned} \tag{3.3}$$

where $\mathbf{R}$ *is the Ricci tensor,* R_{ij} *are its components in any orthogonal separable coordinate system and* Γ_i *are the contracted Christoffel symbols,* $\Gamma_i=g^{hj}\Gamma_{hj,i}$.

The proof will be given in Sec. V. In Sec. VI, a theorem analogous to Theorem 3.1 will be stated for the general nonorthogonal separation of the Hamilton–Jacobi equation, where the Killing tensors involved are in ''standard form.'' For the proofs of these theorems we need preliminary general results about Killing tensors and second-order operators. Indeed, since we do not know how to extend the Carter formula to two arbitrary symmetric tensors, we are able to study the commutator $[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]$ only for Killing tensors in orthogonal form (Secs. IV and V) or in standard form (Secs. VII and VIII).

Remark 3.2: Note that conditions (b), (c), and (e) in (3.3) do not involve the potentials $V_{\mathbf{K}}$.

Remark 3.3: Since $\mathbf{G}\in\mathcal{K}$, equation (3.3a) is an obvious consequence of (3.3d), while (3.3b) is a consequence of (3.3e). Moreover, the equivalence of (3.3a) and (3.3b) follows from Theorems 2.1 and 2.2. We call condition (3.3b),

$$\delta(\mathbf{KR}-\mathbf{RK})=0, \quad \forall \mathbf{K}\in\mathcal{K}$$

the *pre-Robertson condition*. It means that the Carter condition (2.10) is satisfied by all elements of the Killing–Stäckel algebra. Theorem 3.1 shows that Eq. (3.3c),

$$\partial_i R_{ij}-\Gamma_i R_{ij}=0 \quad (i\neq j,\ \ i \ \text{ n.s.})$$

is the coordinate expression of the pre-Robertson condition. The pre-Robertson condition (3.3b) is an obvious consequence of the *Robertson condition*[1]

$$\mathbf{KR}-\mathbf{RK}=0, \quad \forall \mathbf{K}\in\mathcal{K},$$

whose coordinate expression is

$$R_{ij}=0, \quad i\neq j. \tag{3.4}$$

Note that both conditions are fulfilled when $\mathbf{R}=\kappa\mathbf{G}$. We know[1] that in separable orthogonal coordinates

$$\partial_i\Gamma_j=\tfrac{2}{3}R_{ij}, \quad i\neq j, \tag{3.5}$$

and that the Schrödinger equation is freely separable if and only if the Hamilton–Jacobi equation is orthogonally separable and the Robertson condition holds. Hence,

Theorem 3.4: *If the Schrödinger equation associated with an orthogonal separable Hamiltonian system is freely separable, then all the operators* $\hat{H}_{\mathbf{K}}$ *corresponding to the quadratic first integrals in involution* $H_{\mathbf{K}}\in\mathcal{H}$ *commute.*

In particular, they commute with the Schrödinger operator $\hat{H}=\hat{H}_{\mathbf{G}}$. From Theorem 3.1 we derive an extension of Theorem 2.6,

Theorem 3.5: *On Einstein manifolds all operators* $\hat{H}_{\mathbf{K}}$, $\mathbf{K}\in\mathcal{K}$, *associated with the quadratic first integrals of an orthogonal separable system commute.*

Remark 3.6: In orthogonal separable coordinates the components of the Killing tensors and the potential functions assume the *Stäckel form*

$$g^{ii}=\varphi^i_{(n)}, \quad V=\phi_i(q^i)\varphi^i_{(n)}, \quad K^{ii}_j=\varphi^i_{(j)}, \quad V_{\mathbf{K}_j}=\phi_i(q^i)\varphi^i_{(j)},$$

where $(\mathbf{K}_j)$ is a local basis of $\mathcal{K}$, with $\mathbf{K}_n=\mathbf{G}$. Thus, in terms of Stäckel matrices, a local basis of $\mathcal{H}$ is given by

$$H_j=\tfrac{1}{2}\varphi^i_{(j)}(p_i^2+2\phi_i).$$

As it will be shown (Remark 5.2), the corresponding operators assume the form

$$\hat{H}_j\psi=-\frac{\hbar^2}{2}\varphi^i_{(j)}\left(\partial_i^2\psi-\Gamma_i\partial_i\psi-\frac{2}{\hbar^2}\phi_i\psi\right). \tag{3.6}$$

The Robertson condition is equivalent to $\partial_j\Gamma_i=0$ for $i\neq j$. This means that the contracted Christoffel symbols Γ_i are functions of the corresponding coordinate q^i only.

IV. KILLING TENSORS DIAGONALIZED IN ORTHOGONAL COORDINATES

In the next section we shall analyze the commutation relations of the second-order operators assuming that all the tensors **K** involved, including the metric tensor **G**, are simultaneously diagonalized in orthogonal coordinates (q^i), so that they assume the *orthogonal form* (3.1). This is equivalent to assume that all these tensors have common normal eigenvectors (or closed eigenforms). For this purpose we need some preliminary theorems about Killing tensors diagonalized in orthogonal coordinates. For such a Killing tensor the following equations hold:

$$\begin{gathered}\partial_i\lambda^j=(\lambda^i-\lambda^j)\partial_i\ln g^{jj}\\ \partial_i\lambda^i=0\\ \partial_i(\lambda^j g^{jj})=\lambda^i\partial_i g^{jj}\qquad (i,j \text{ n.s.})\\ \partial_i^2(\lambda^j g^{jj})=\lambda^i\partial_i^2 g^{jj}.\end{gathered} \tag{4.1}$$

We call *Eisenhart–Killing equations* the first equations (4.1).[10] They characterize a Killing tensor and imply the remaining equations.

In orthogonal coordinates, the nonvanishing Christoffel symbols are

$$\begin{gathered}\Gamma^j_{ij}=\Gamma^j_{ji}=-\tfrac{1}{2}\partial_i\ln g^{jj}, \quad i \text{ n.s.},\\ \Gamma^i_{jj}=-\tfrac{1}{2}g^{ii}\partial_i g_{jj}, \quad i\neq j.\end{gathered} \tag{4.2}$$

It follows that

$$\Gamma_i=\frac{1}{2}\partial_i\sum_k \ln g^{kk}-\partial_i\ln g^{ii}, \tag{4.3}$$

and

$$\sum_i \Gamma^i_{ih}=-\Gamma_h-\partial_h\ln g^{hh}. \tag{4.4}$$

Proposition 4.1: If (q^i) *are orthogonal coordinates in which a Killing tensor* **K** *is diagonalized, then*

$$(\lambda^i-\lambda^j)(\partial_i\Gamma_j-\partial_j\Gamma_i)=0 \quad (i,j \text{ n.s.}). \tag{4.5}$$

Proof: For $\lambda^i=\lambda^j$ Eq. (4.5) is obviously satisfied. Assume $\lambda^i\neq\lambda^j$. Because of (4.3) and (4.1),

$$\begin{aligned}\partial_i\Gamma_j-\partial_j\Gamma_i&=-\partial_i\partial_j\ln g^{jj}+\partial_j\partial_i\ln g^{ii}\\&=\partial_i\partial_j\ln g^{ii}-\partial_j\partial_i\ln g^{jj}=\partial_i\frac{\partial_j\lambda^i}{\lambda^j-\lambda^i}-\partial_j\frac{\partial_i\lambda^j}{\lambda^i-\lambda^j}\\&=\frac{1}{(\lambda^i-\lambda^j)^2}[\partial_i\partial_j\lambda^i(\lambda^j-\lambda^i)-\partial_j\lambda^i\partial_i(\lambda^j-\lambda^i)-\partial_j\partial_i\lambda^j(\lambda^i-\lambda^j)+\partial_i\lambda^j\partial_j(\lambda^i-\lambda^j)]=0,\end{aligned}$$

since $\partial_i\lambda^i=0$. ■

Proposition 4.2: Let $\mathbf{K}_I$, $I=1, 2$, *be two Killing tensors simultaneously diagonalized in orthogonal coordinates. Then,*

$$(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)(\partial_i\Gamma_j-\partial_j\Gamma_i)=0\quad(i\neq j\ \text{ n.s.}).\tag{4.6}$$

Proof: Because of (4.5),

$$(\lambda_1^i-\lambda_1^j)(\partial_i\Gamma_j-\partial_j\Gamma_i)=0,\quad(\lambda_2^i-\lambda_2^j)(\partial_i\Gamma_j-\partial_j\Gamma_i)=0.\tag{4.7}$$

Assume $\lambda_I^j\neq0$. If we multiply the first equation (4.7) by λ_2^j, the second one by λ_1^j and subtract the two resulting equations, then we get (4.6). If $\lambda_2^j=0$, then the second equation (4.7) becomes $\lambda_2^i(\partial_i\Gamma_j-\partial_j\Gamma_i)=0$ and (4.6) is satisfied. Similarly for $\lambda_1^j=0$. ■

Proposition 4.3: Let $\mathbf{K}_I=(K_I^{ij})$, $I=1, 2$, *be two Killing tensors simultaneously diagonalized in orthogonal coordinates. Let us define*

$$\mathbf{C}=\mathbf{K}_1\mathbf{D}\mathbf{K}_2-\mathbf{K}_2\mathbf{D}\mathbf{K}_1,\quad C^{ij}=K_1^{ih}D_{hk}K_2^{kj}-K_2^{ih}D_{hk}K_1^{kj},\tag{4.8}$$

where $\mathbf{D}=(D_{ij})$ *is a geometrical object. Then,*

$$C^{ij}=g^{ii}g^{jj}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)D_{ij},\quad C_j^i=C^i_{\cdot j}=g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)D_{ij}\tag{4.9}$$

and

$$\nabla_iC_j^i=\sum_i\ g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)\left(\partial_iD_{ij}-\Gamma_iD_{ij}+\frac{1}{2}\partial_i\ln g^{jj}(D_{ji}-D_{ij})\right).\tag{4.10}$$

Proof: In orthogonal coordinates

$$C^{ij}=K_1^{ii}D_{ij}K_2^{jj}-K_2^{ii}D_{ij}K_1^{jj}$$

and (4.9) follow from $K_I^{ii}=\lambda_I^ig^{ii}$. Moreover, by definition of covariant derivative,

$$\nabla_iC_j^i=\partial_iC_j^i+\Gamma^i_{ih}C_j^h-\Gamma^h_{ij}C_h^i.\tag{4.11}$$

We compute these three terms separately by using Eqs. (4.1). For the first term,

$$\begin{aligned}\partial_iC_j^i&=\partial_ig^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)D_{ij}+g^{ii}D_{ij}(\lambda_1^i\partial_i\lambda_2^j-\lambda_2^i\partial_i\lambda_1^j)+g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)\partial_iD_{ij}\\&=g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)(D_{ij}\partial_i\ln g^{ii}+\partial_iD_{ij})+g^{ii}D_{ij}(\lambda_1^i(\lambda_2^i-\lambda_2^j)-\lambda_2^i(\lambda_1^i-\lambda_1^j))\partial_i\ln g^{jj}\\&=g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)[(\partial_i\ln g^{ii}-\partial_i\ln g^{jj})D_{ij}+\partial_iD_{ij}].\end{aligned}\tag{4.12}$$

To compute the second term we use formula (4.4),

$$\Gamma^i_{ih}C_j^h=-g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)(\Gamma_i+\partial_i\ln g^{ii})D_{ij}.\tag{4.13}$$

To compute the third term we use formulas (4.2),

$$\sum_{i,h}\Gamma^h_{ij}C^i_h=\sum_{h\neq j}\Gamma^h_{jj}C^j_h+\sum_{i\neq j}\sum_h\Gamma^h_{ij}C^i_h=\cdots.$$

Since $C^i_i=0$ (i n.s.),

$$\begin{aligned}\cdots&=\sum_h\Gamma^h_{jj}C^j_h+\sum_{i\neq j}\Gamma^i_{ij}C^i_i+\sum_{i\neq j}\sum_{h\neq i}\Gamma^h_{ij}C^i_h\\&=\sum_i\Gamma^i_{jj}C^j_i+\sum_{i\neq j}\Gamma^j_{ij}C^i_j\\&=-\frac{1}{2}\sum_i g^{ii}(\lambda^i_1\lambda^j_2-\lambda^i_2\lambda^j_1)[-\partial_i g_{jj}g^{jj}D_{ji}+\partial_i\ln g^{jj}D_{ij}]\\&=-\frac{1}{2}\sum_i g^{ii}(\lambda^i_1\lambda^j_2-\lambda^i_2\lambda^j_1)\partial_i\ln g^{jj}(D_{ij}+D_{ji}).\end{aligned}\tag{4.14}$$

Thus, (4.10) follows from (4.12)+(4.13)−(4.14). ■

Remark 4.4: From the first equations (4.9), it follows that: (i) $C^{ii}=0$, (ii) the diagonal components D_{ii} are not involved in the definition (4.8) of **C**, (iii) if **D** is symmetric, $D_{ij}=D_{ji}$, then $C^{ij}+C^{ji}=0$ and **C** is skew-symmetric.

Remark 4.5: For $D_{ij}=\partial_i\Gamma_j$, due to (4.6), Eq. (4.10) becomes

$$\nabla_i C^i_j=\sum_i g^{ii}(\lambda^i_1\lambda^j_2-\lambda^i_2\lambda^j_1)(\partial^2_i\Gamma_j-\Gamma_i\partial_i\Gamma_j),\tag{4.15}$$

and, due to the first equations (4.9), $C^{ij}+C^{ji}=0$. Hence, **C** is skew-symmetric and (4.15) gives the components of $\delta\mathbf{C}$. It follows that

$$\delta\mathbf{C}=0\Leftrightarrow\sum_i g^{ii}(\lambda^i_1\lambda^j_2-\lambda^i_2\lambda^j_1)(\partial^2_i\Gamma_j-\Gamma_i\partial_i\Gamma_j)=0.\tag{4.16}$$

Remark 4.6: For $\mathbf{K}_1=\mathbf{K}$ and $\mathbf{K}_2=\mathbf{G}$, the definition (4.8) and equations (4.9) become

$$\mathbf{C}=\mathbf{KD}-\mathbf{DK},\quad C^{ij}=g^{ii}g^{jj}(\lambda_i-\lambda_j)D_{ij},\quad C^i_j=g^{ii}(\lambda^i-\lambda^j)D_{ij},$$

and (4.10) reduces to

$$\nabla_i C^i_j=\sum_i g^{ii}(\lambda^i-\lambda^j)(\partial_i D_{ij}-\Gamma_i D_{ij}+\tfrac{1}{2}\partial_i\ln g^{jj}(D_{ji}-D_{ij})).$$

For $D_{ij}=\partial_i\Gamma_j$, because of (4.5), we have

$$\nabla_i C^i_j=\sum_i g^{ii}(\lambda^i-\lambda^j)(\partial^2_i\Gamma_j-\Gamma_i\partial_i\Gamma_j).\tag{4.17}$$

C is skew-symmetric and (4.17) gives the components of $\delta\mathbf{C}$. Thus,

$$\delta\mathbf{C}=0\Leftrightarrow\sum_i g^{ii}(\lambda^i-\lambda^j)(\partial^2_i\Gamma_j-\Gamma_i\partial_i\Gamma_j)=0.\tag{4.18}$$

Remark 4.7: If the Killing tensor **K** in Proposition 4.1 has simple eigenvalues, $\lambda^i \neq \lambda^j$ for $i \neq j$, then (4.5) implies

$$\partial_i \Gamma_j = \partial_j \Gamma_i . \tag{4.19}$$

This is the case of a characteristic Killing tensor associated with the orthogonal separation. This proves

Proposition 4.8: Equation (4.19) holds for any separable orthogonal coordinate system.

This property has some interesting consequences. First, from (4.19) and (4.3) it follows that

Proposition 4.9: In any orthogonal separable coordinate system

$$\partial_i \partial_j \ln g^{ii} = \partial_i \partial_j \ln g^{jj}, \quad i \neq j.$$

A second consequence is concerned with the eigenvalues of a characteristic Killing tensor.

Proposition 4.10: For the eigenvalues (λ^i) *of a characteristic Killing tensor of a Killing–Stäckel algebra the following equations hold:*

$$\partial_i \partial_j \ln g^{ii} = -\frac{\partial_j \lambda^i \partial_i \lambda^j}{(\lambda^i - \lambda^j)^2}, \quad i \neq j, \tag{4.20}$$

Proof: For $\lambda^i \neq \lambda^j$, the first equations (4.1) can be written

$$\partial_j \ln g^{ii} = \frac{\partial_j \lambda^i}{\lambda^j - \lambda^i}.$$

If we apply the partial derivative ∂_i to this formula, and use again (4.1), then we get Eq. (4.20).■

A third consequence is concerned with the Robertson and the pre-Roberston conditions.

Proposition 4.11: For any orthogonal separable coordinate system $\underline{q} = (q^i)$ *there are local functions* $F(\underline{q})$ *such that*

$$\Gamma_i = \partial_i F.$$

The Robertson condition (3.3c) is equivalent to

$$\partial_i \partial_j F = 0, \quad i \neq j, \tag{4.21}$$

and the pre-Robertson condition (3.4) is equivalent to

$$\partial_j [\, \partial_i^2 F - \tfrac{1}{2} (\partial_i F)^2] = 0, \quad i \neq j. \tag{4.22}$$

Equation (4.21) means that the function F is a sum of functions depending on a single coordinate i.e., of functions constant on the leaves of the web: $F = \Sigma_i F_i(q^i)$. Equation (4.22) means that each function $\partial_i^2 F - 1/2(\partial_i F)^2$ is a function of the coordinate corresponding to the index only. A further interpretation of the pre-Robertson condition is expressed by the following

Proposition 4.12: The pre-Robertson condition is equivalent to

$$\partial_i Q_{ij} = 0, \quad i \neq j \quad \text{n.s.},$$

where

$$Q_{ij} = e^{-F} R_{ij}. \tag{4.23}$$

Proof: $\partial_i Q_{ij} = e^{-F}(\partial_i R_{ij} - \partial_i F R_{ij})$. ■

Remark 4.13: Let $\underline{q} = (q^i)$ and $\underline{q}' = (q^{i'})$ be two equivalent and equioriented orthogonal separable coordinate systems. Let us set

$$A_i^{i'}=\frac{\partial q^{i'}}{\partial q^i},\quad A_{i'}^{i}=\frac{\partial q^{i}}{\partial q^{i'}},\quad A=\det[A_i^{i'}]=\prod_i A_i^{i'},$$
$$G=\det[g^{ij}]=\prod_i g^{ii},\quad G'=\det[g^{i'j'}]=\prod_{i'} g^{i'i'}. \tag{4.24}$$

Note that $A_i^{j'}=0$ for $i\neq j$ and that $A>0$. The link between functions F and F' corresponding to these coordinates is

$$F'=F-\ln A+\text{const.}$$

i.e.,

$$e^{-F'}=cAe^{-F}. \tag{4.25}$$

Indeed, the relationship between the contracted Christoffel symbols is

$$\Gamma_{i'}=A_{i'}^{i}(\Gamma_i-\partial_i\ln A_i^{i'})=A_{i'}^{i}(\Gamma_i-\partial_i\ln A). \tag{4.26}$$

To prove (4.26) we observe that, since $A_i^{i'}$ is a function of q^i only,

$$\partial_i\ln A=\partial_i\ln\prod_j A_j^{j'}=\partial_i\ln A_i^{i'}.$$

Moreover, since $A>0$, from (4.24) it follows that

$$\sqrt{G'}=A\sqrt{G},$$
$$\partial_{i'}\ln\sqrt{G'}=A_{i'}^{i}(\partial_i\ln A+\partial_i\ln\sqrt{G}), \tag{4.27}$$
$$\partial_{i'}\ln g^{i'i'}=A_{i'}^{i}(2\partial_i\ln A_i^{i'}+\partial_i\ln g^{ii}).$$

By (4.3) and (4.27) we get

$$\begin{aligned}\Gamma_{i'}&=\partial_{i'}\ln\sqrt{G'}-\partial_{i'}\ln g^{i'i'}\\&=A_{i'}^{i}(\partial_i\ln A+\partial_i\ln\sqrt{G}-2\partial_i\ln A_i^{i'}-\partial_i\ln g^{ii})\\&=A_{i'}^{i}(\Gamma_i+\partial_i\ln A-2\partial_i\ln A_i^{i'}),\end{aligned}$$

which implies both equations (4.26). Finally, we observe that the object Q_{ij} is defined by (4.23) up to a multiplicative constant, since F is defined up to an additive constant. From (4.23), (4.25) and the first equation (4.27) it follows that

$$Q_{i'j'}=e^{-F'}R_{i'j'}=cAe^{-F}A_{i'}^{i}A_{j'}^{j}R_{ij}=cAA_{i'}^{i}A_{j'}^{j}Q_{ij}.$$

Thus,

$$\frac{1}{\sqrt{G'}}Q_{i'j'}=\frac{c}{\sqrt{G}}A_{i'}^{i}A_{j'}^{j}Q_{ij}.$$

V. COMMUTATION RELATIONS IN ORTHOGONAL COORDINATES

Proposition 5.1: If a symmetric tensor $\mathbf{K}=(K^{ij})$ *is diagonalized in orthogonal coordinates, then the corresponding pseudo-Laplacian assumes the form*

$$\Delta_{\mathbf{K}}\psi=A^i\partial_i^2\psi+B^i\partial_i\psi, \quad A^i=K^{ii}=\lambda^i g^{ii}, \quad B^i=g^{ii}(\partial_i\lambda^i-\lambda^i\Gamma_i). \tag{5.1}$$

Proof: By definition (2.1) and formula (4.4),

$$\begin{aligned}\Delta_{\mathbf{K}}\psi&=\nabla_i(K^{ij}\partial_j\psi)\\&=\partial_i(K^{ij}\partial_j\psi)+\Gamma^i_{ih}K^{hj}\partial_j\psi\\&=\partial_i(K^{ii}\partial_i\psi)+\Gamma^i_{ih}K^{hh}\partial_h\psi\\&=K^{ii}\partial_i^2\psi+(\partial_hK^{hh}+\Gamma^i_{ih}K^{hh})\partial_h\psi\\&=\lambda^i g^{ii}\partial_i^2\psi+(\partial_h(\lambda^h g^{hh})-\lambda^h g^{hh}(\Gamma_h+\partial_h\ln g^{hh}))\partial_h\psi\\&=\lambda^i g^{ii}\partial_i^2\psi+g^{hh}(\partial_h\lambda^h-\lambda^h\Gamma_h)\partial_h\psi.\end{aligned}$$

■

Remark 5.2: For the ordinary Laplacian, $K^{ii}=g^{ii}$, $\lambda^i=1$, and $B^i=-g^{ii}\Gamma_i$, so that

$$\Delta\psi=g^{ii}[\partial_i^2\psi-\Gamma_i\partial_i\psi].$$

A second-order operator (2.12) assumes the form

$$\hat{H}_{\mathbf{K}}\psi=\frac{\hbar^2}{2}(A^i\partial_i^2\psi+B^i\partial_i\psi)+V_{\mathbf{K}}\psi=\frac{\hbar^2}{2}g^{ii}(\lambda^i\partial_i^2\psi+(\partial_i\lambda^i-\lambda^i\Gamma_i)\partial_i\psi)+V_{\mathbf{K}}\psi. \tag{5.2}$$

For a Killing tensor **K** Eqs. (4.1) hold, so that

$$\Delta_{\mathbf{K}}\psi=g^{ii}\lambda^i[\partial_i^2\psi-\Gamma_i\partial_i\psi].$$

For a basis $(\mathbf{K}_j)$ of a Killing–Stäckel algebra we have $\varphi^i_{(j)}=\lambda^i_j g^{ii}$ (Remark 3.6) and we find expressions (3.6) of the corresponding operators $\hat{H}_j$.

Proposition 5.3: The commutator of two second-order operators of the kind (5.2) has the following expression:

$$\begin{aligned}[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]\psi=&\frac{\hbar^4}{2}(A^i_1\partial_iA^j_2-A^i_2\partial_iA^j_1)\partial_i\partial_j^2\psi+\frac{\hbar^4}{4}(A^i_1\partial_i^2A^j_2-A^i_2\partial_i^2A^j_1+B^i_1\partial_iA^j_2-B^i_2\partial_iA^j_1)\partial_j^2\psi\\&+\frac{\hbar^4}{2}(A^i_1\partial_iB^j_2-A^i_2\partial_iB^j_1)\partial_i\partial_j\psi+\Bigg(\frac{\hbar^4}{4}(A^i_1\partial_i^2B^j_2+B^i_1\partial_iB^j_2-A^i_2\partial_i^2B^j_1-B^i_2\partial_iB^j_1)\\&-\hbar^2(A^j_1\partial_jV_{\mathbf{K}_2}-A^j_2\partial_jV_{\mathbf{K}_1})\Bigg)\partial_j\psi-\frac{\hbar^2}{2}(\Delta_{\mathbf{K}_1}V_{\mathbf{K}_2}-\Delta_{\mathbf{K}_2}V_{\mathbf{K}_1})\psi.\end{aligned} \tag{5.3}$$

Proof: For two second-order operators (2.2),

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=\left[\frac{1}{2}\hat{P}_{\mathbf{K}_1}+V_{\mathbf{K}_1},\frac{1}{2}\hat{P}_{\mathbf{K}_2}+V_{\mathbf{K}_2}\right]$$
$$=\frac{1}{4}[\hat{P}_{\mathbf{K}_1},\hat{P}_{\mathbf{K}_2}]+\frac{1}{2}[\hat{P}_{\mathbf{K}_1},V_{\mathbf{K}_2}]-\frac{1}{2}[\hat{P}_{\mathbf{K}_2},V_{\mathbf{K}_1}]$$
$$=\frac{\hbar^4}{4}[\Delta_{\mathbf{K}_1},\Delta_{\mathbf{K}_2}]-\frac{\hbar^2}{2}[\Delta_{\mathbf{K}_1},V_{\mathbf{K}_2}]+\frac{\hbar^2}{2}[\Delta_{\mathbf{K}_2},V_{\mathbf{K}_1}].$$

Since

$$\delta(f\mathbf{X})=\mathbf{X}\cdot\nabla f+f\delta\mathbf{X},$$

we have

$$[\Delta_{\mathbf{K}},V]\psi=\Delta_{\mathbf{K}}(V\psi)-V\Delta_{\mathbf{K}}\psi$$
$$=\delta(\mathbf{K}\nabla(V\psi))-V\Delta_{\mathbf{K}}\psi$$
$$=\delta((\mathbf{K}\nabla V)\psi+(\mathbf{K}\nabla\psi)V)-V\Delta_{\mathbf{K}}\psi$$
$$=\psi\Delta_{\mathbf{K}}V+2\mathbf{K}(\nabla\psi,\nabla V)$$
$$=\Delta_{\mathbf{K}}V\psi+2A^i\partial_iV\partial_i\psi.$$

Hence,

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]\psi=\frac{\hbar^4}{4}[\Delta_{\mathbf{K}_1},\Delta_{\mathbf{K}_2}]\psi+\frac{\hbar^2}{2}(\Delta_{\mathbf{K}_2}V_{\mathbf{K}_1}-\Delta_{\mathbf{K}_1}V_{\mathbf{K}_2})\psi+\hbar^2(\mathbf{K}_2\nabla V_{\mathbf{K}_1}-\mathbf{K}_1\nabla V_{\mathbf{K}_2})\cdot\nabla\psi, \tag{5.4}$$

Because of (5.1),

$$\Delta_{\mathbf{K}_1}\Delta_{\mathbf{K}_2}\psi=A_1^i\partial_i^2(A_2^j\partial_j^2\psi+B_2^j\partial_j\psi)+B_1^i\partial_i(A_2^j\partial_j^2\psi+B_2^j\partial_j\psi)$$
$$=A_1^i(\partial_i^2A_2^j\partial_j^2\psi+2\partial_iA_2^j\partial_i\partial_j^2\psi+A_2^j\partial_i^2\partial_j^2\psi+\partial_i^2B_2^j\partial_j\psi+2\partial_iB_2^j\partial_i\partial_j\psi+B_2^j\partial_i^2\partial_j\psi)$$
$$+B_1^i(\partial_iA_2^j\partial_j^2\psi+A_2^j\partial_i\partial_j^2\psi+\partial_iB_2^j\partial_j\psi+B_2^j\partial_i\partial_j\psi)$$
$$=A_1^iA_2^j\partial_i^2\partial_j^2\psi+(2A_1^i\partial_iA_2^j+B_1^iA_2^j+A_1^jB_2^i)\partial_i\partial_j^2\psi+(A_1^i\partial_i^2A_2^j+B_1^i\partial_iA_2^j)\partial_j^2\psi$$
$$+(2A_1^i\partial_iB_2^j+B_1^iB_2^j)\partial_i\partial_j\psi+(A_1^i\partial_i^2B_2^j+B_1^i\partial_iB_2^j)\partial_j\psi,$$

so that,

$$[\Delta_{\mathbf{K}_1},\Delta_{\mathbf{K}_2}]\psi=\Delta_{\mathbf{K}_1}\Delta_{\mathbf{K}_2}\psi-\Delta_{\mathbf{K}_2}\Delta_{\mathbf{K}_1}\psi$$
$$=2(A_1^i\partial_iA_2^j-A_2^i\partial_iA_1^j)\partial_i\partial_j^2\psi+(A_1^i\partial_i^2A_2^j-A_2^i\partial_i^2A_1^j+B_1^i\partial_iA_2^j-B_2^i\partial_iA_1^j)\partial_j^2\psi$$
$$+2(A_1^i\partial_iB_2^j-A_2^i\partial_iB_1^j)\partial_i\partial_j\psi+(A_1^i\partial_i^2B_2^j+B_1^i\partial_iB_2^j-A_2^i\partial_i^2B_1^j-B_2^i\partial_iB_1^j)\partial_j\psi.$$

Thus, from (5.4) we derive (5.3). ■

Proposition 5.4: Let $\mathbf{K}_1$ *and* $\mathbf{K}_2$ *be symmetric tensors simultaneously diagonalized in orthogonal coordinates. Then,* $[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0$ *if and only if*

$$A_1^i\partial_iA_2^j-A_2^i\partial_iA_1^j=0 \quad (i \text{ n.s.}), \tag{5.5a}$$

$$\sum_i \left(A_1^i\partial_i^2 A_2^j - A_2^i\partial_i^2 A_1^j + B_1^i\partial_i A_2^j - B_2^i\partial_i A_1^j\right) + 2\left(A_1^j\partial_j B_2^j - A_2^j\partial_j B_1^j\right) = 0, \tag{5.5b}$$

$$A_1^i\partial_i B_2^j - A_2^i\partial_i B_1^j + A_1^j\partial_j B_2^i - A_2^j\partial_j B_1^j = 0 \quad (i \neq j \text{ n.s.}), \tag{5.5c}$$

$$\frac{\hbar^2}{4}\sum_i \left(A_1^i\partial_i^2 B_2^j + B_1^i\partial_i B_2^j - A_2^i\partial_i^2 B_1^j - B_2^i\partial_i B_1^j\right) - A_1^j\partial_j V_{\mathbf{K}_2} + A_2^j\partial_j V_{\mathbf{K}_1} = 0 \quad (j \text{ n.s.}), \tag{5.5d}$$

$$\Delta_{\mathbf{K}_1} V_{\mathbf{K}_2} - \Delta_{\mathbf{K}_2} V_{\mathbf{K}_1} = 0. \tag{5.5e}$$

Proof: (i) Assume that (5.3) vanishes identically for all functions ψ. For $\psi = 1$ we get (5.5e) and the last term in (5.3) disappears. For $\psi = q^j$ we get (5.5d), so that also the fourth term in (5.3) disappears. As a consequence, for $\psi = (q^j)^2$ we get (5.5b) and we reduce the vanishing of (5.3) to

$$\sum_{i,j} \left(A_1^i\partial_i A_2^j - A_2^i\partial_i A_1^j\right)\partial_i\partial_j^2\psi + \sum_{i,j\neq} \left(A_1^i\partial_i B_2^j - A_2^i\partial_i B_1^j\right)\partial_i\partial_j\psi = 0. \tag{5.6}$$

For $\psi = q^1 q^2$, we have $\partial_i\partial_j\psi = \delta_j^1\delta_i^2 + \delta_i^1\delta_j^2$, thus we get (5.5c) for distinct indices and moreover, (5.6) reduces to

$$\sum_{i,j} \left(A_1^i\partial_i A_2^j - A_2^i\partial_i A_1^j\right)\partial_i\partial_j^2\psi = 0. \tag{5.7}$$

Finally, for $\psi = q^1(q^2)^2$ we have $\partial_j^2\partial_i\psi = \partial_j^2(\delta_i^1(q^2)^2 + 2q^1q^2\delta_i^2) = 2\delta_i^1\delta_j^2 + 4\delta_j^1\delta_j^2\delta_i^2 = 2\delta_i^1\delta_j^2$. Thus, we get (5.5a) for distinct indices (and no summation), so that (5.7) reduces to

$$\sum_j \left(A_1^j\partial_j A_2^j - A_2^j\partial_j A_1^j\right)\partial_j^3\psi = 0.$$

This shows that (5.5a) also holds for $i = j$. (ii) Conversely, assume that (5.5) hold. Then, due to (5.5a,d,e), Eq. (5.3) reduces to

$$[\hat{H}_{\mathbf{K}_1}, \hat{H}_{\mathbf{K}_2}]\psi = \frac{\hbar^4}{4}\left(A_1^i\partial_i^2 A_2^j - A_2^i\partial_i^2 A_1^j + B_1^i\partial_i A_2^j - B_2^i\partial_i A_1^j\right)\partial_j^2\psi + \frac{\hbar^4}{2}\left(A_1^i\partial_i B_2^j - A_2^i\partial_i B_1^j\right)\partial_i\partial_j\psi$$

and, because of (5.5b), we obtain

$$[\hat{H}_{\mathbf{K}_1}, \hat{H}_{\mathbf{K}_2}]\psi = \frac{\hbar^4}{2}\sum_{i,j\neq} \left(A_1^i\partial_i B_2^j - A_2^i\partial_i B_1^j\right)\partial_i\partial_j\psi.$$

But this last expression vanishes identically because of the skew-symmetry of Eq. (5.5c). ■

Remark 5.5: Since

$$\{P_{\mathbf{K}_1}, P_{\mathbf{K}_2}\} = \{A_1^i p_i^2, A_2^j p_j^2\} = 2p_i p_j^2\left(A_1^i\partial_i A_2^j - A_2^i\partial_i A_1^j\right), \tag{5.8}$$

Eq. (5.5a) is equivalent to $\{P_{\mathbf{K}_1}, P_{\mathbf{K}_2}\} = 0$. Thus,

$$[\hat{H}_{\mathbf{K}_1}, \hat{H}_{\mathbf{K}_2}] = 0 \Rightarrow \{P_{\mathbf{K}_1}, P_{\mathbf{K}_2}\} = 0. \tag{5.9}$$

Theorem 5.6: *Let* **K** *be a symmetric tensor diagonalized in orthogonal coordinates. Then the following conditions are equivalent:*

$$[\hat{H}_{\mathbf{K}},\hat{H}]=0 \Leftrightarrow \begin{matrix}\{P_{\mathbf{K}},P_{\mathbf{G}}\}=0 \quad (\mathbf{K}\ \text{Killing tensor})\\ \dfrac{\hbar^2}{4}\delta\mathbf{C}+\mathbf{K}\nabla V-\nabla V_{\mathbf{K}}=0\end{matrix} \Leftrightarrow \{H_{\mathbf{K}},H\}=-\frac{\hbar^2}{4}P_{\delta C}, \tag{5.10}$$

where

$$C=\mathbf{KD}-\mathbf{DK}, \quad \mathbf{D}=(D_{ij})=(\partial_i\Gamma_j).$$

Proof: We use (5.5) of Proposition 5.4 for the case

$$\begin{matrix}\mathbf{K}_1=\mathbf{K}\\ \mathbf{K}_2=\mathbf{G}\end{matrix}\overset{\Leftrightarrow}{}\begin{matrix}\lambda_1^i=\lambda^i\\ \lambda_2^i=1\end{matrix}\overset{\Leftrightarrow}{}\begin{matrix}A_1^i=\lambda^i g^{ii}, & B_1^i=g^{ii}(\partial_i\lambda^i-\lambda^i\Gamma_i)\\ A_2^i=g^{ii}, & B_2^i=-g^{ii}\Gamma_i\end{matrix}.$$

Assume $[\hat{H}_{\mathbf{K}},\hat{H}_{\mathbf{G}}]=0$. From (5.9) it follows that $\mathbf{K}$ is a Killing tensor. Then we use (4.1) and in (5.5) we consider

$$B_1^i=-g^{ii}\lambda^i\Gamma_i, \quad B_2^i=-g^{ii}\Gamma_i, \tag{5.11}$$

and

$$\begin{aligned}&\partial_i A_1^j=\lambda^i\partial_i g^{jj}, \quad \partial_i B_1^j=-\partial_i(g^{jj}\lambda^j\Gamma_j)=-\lambda^i\partial_i g^{jj}\Gamma_j-g^{jj}\lambda^j\partial_i\Gamma_j,\\ &\partial_i A_2^j=\partial_i g^{jj}, \quad \partial_i B_2^j=-\partial_i(g^{jj}\Gamma_j)=-\partial_i g^{jj}\Gamma_j-g^{jj}\partial_i\Gamma_j,\\ &\partial_i^2 A_1^j=\lambda^i\partial_i^2 g^{jj}, \quad \partial_i^2 B_1^j=-\lambda^i\partial_i^2 g^{jj}\Gamma_j-2\lambda^i\partial_i g^{jj}\partial_i\Gamma_j-g^{jj}\lambda^j\partial_i^2\Gamma_j,\\ &\partial_i^2 A_2^j=\partial_i^2 g^{jj}, \quad \partial_i^2 B_2^j=-\partial_i^2 g^{jj}\Gamma_j-2\partial_i g^{jj}\partial_i\Gamma_j-g^{jj}\partial_i^2\Gamma_j,\end{aligned} \tag{5.12}$$

Equations (5.5a) and (5.5b) are then identically satisfied, while the remaining three equations become

$$\begin{aligned}&(\lambda^i-\lambda^j)(\partial_i\Gamma_j-\partial_j\Gamma_i)=0 \quad (i\neq j \ \text{ n.s.}),\\ &\frac{\hbar^2}{4}\sum_i g^{ii}(\lambda^i-\lambda^j)(\partial_i^2\Gamma_j-\Gamma_i\partial_i\Gamma_j)+\lambda^j\partial_j V-\partial_j V_{\mathbf{K}}=0 \quad (j \ \text{ n.s.}),\\ &\delta(\mathbf{K}\nabla V-\nabla V_{\mathbf{K}})=0.\end{aligned} \tag{5.13}$$

Due to (4.5), the first equation is identically satisfied. According to Remark 4.6 and Eq. (4.17), the second equation (5.13) is equivalent to

$$\frac{\hbar^2}{4}\delta\mathbf{C}+\mathbf{K}\nabla V-\nabla V_{\mathbf{K}}=0,$$

where $\mathbf{C}$ is skew-symmetric. Since $\delta^2\mathbf{C}=0$, the last equation (5.13) is a consequence of the second equation (5.13). The above-given reasoning is reversible, and the first equivalence (5.10) is proved. The second equivalence follows from last equation (2.3). ■

Remark 5.7: The comparison between Theorem 2.2, proved by using the Carter formula (2.8) without any special assumption on $\mathbf{K}$, and Theorem 5.6, proved under the assumption that $\mathbf{K}$ is diagonalized in orthogonal coordinates, shows that for such a Killing tensor the following equation holds:

$$\delta(\mathbf{KD}-\mathbf{DK})=\tfrac{2}{3}\delta(\mathbf{KR}-\mathbf{RK}), \tag{5.14}$$

where $\mathbf{D}=(\partial_i\Gamma_j)$. Note that the components D_{ii} are not involved in the definition of $\mathbf{C}=\mathbf{KD}-\mathbf{DK}$ (Remark 4.4). This is in accordance with formula (3.5), which holds in separable orthogonal coordinates.

Now we apply Proposition 5.4 to the case of two Killing tensors.

Theorem 5.8: *Let* $\mathbf{K}_1$ *and* $\mathbf{K}_2$ *be Killing tensors simultaneously diagonalized in orthogonal coordinates. Then* $\{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=0$ *and the following conditions are equivalent:*

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0 \Leftrightarrow \frac{\hbar^2}{4}\delta\mathbf{C}+\mathbf{K}_1\nabla V_{\mathbf{K}_2}-\mathbf{K}_2\nabla V_{\mathbf{K}_1}=0 \Leftrightarrow \{H_{\mathbf{K}_1},H_{\mathbf{K}_2}\}=-\frac{\hbar^2}{4}P_{\delta\mathbf{C}}, \tag{5.15}$$

where

$$\mathbf{C}=\mathbf{K}_1\mathbf{D}\mathbf{K}_2-\mathbf{K}_2\mathbf{D}\mathbf{K}_1, \quad \mathbf{D}=(\partial_i\Gamma_j). \tag{5.16}$$

Proof: The components of $\mathbf{C}$ defined in (5.16) are [recall (4.8) and (4.9)]

$$C^{ij}=g^{ii}g^{jj}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)\partial_i\Gamma_j, \quad C^i_j=C^{i\cdot}_{\cdot j}=g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)\partial_i\Gamma_j.$$

The involutivity condition $\{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=0$ follows from (5.8), (5.1), and (4.1). We use (5.5). According to (5.1), (5.11), and (5.12), for a Killing tensor $\mathbf{K}_I$ $(I=1,2)$ we have

$$\begin{aligned}
&A_I^i=\lambda_I^i g^{ii}, \quad B_I^i=-A_I^i\Gamma_i,\\
&\partial_i A_I^j=A_I^i\partial_i g^{jj}=\lambda_I^i\partial_i g^{jj},\\
&\partial_i^2 A_I^j=A_I^i\partial_i^2 g^{jj}=\lambda_I^i\partial_i^2 g^{jj}\\
&\partial_i B_I^j=-\partial_i(A_I^j\Gamma_j)=-\partial_i A_I^j\Gamma_j-A_I^j\partial_i\Gamma_j,\\
&\partial_i^2 B_I^j=-\partial_i^2 A_I^j\Gamma_j-2\partial_i A_I^j\partial_i\Gamma_j-A_I^j\partial_i^2\Gamma_j.
\end{aligned} \tag{5.17}$$

Because of the first two equations (5.17), Eq. (5.5a) is identically satisfied and the sum of the first two terms in Eq. (5.5b) vanishes, so that this equation reduces to

$$\sum_i \Gamma_i[A_1^i\partial_i A_2^j-A_2^i\partial_i A_1^j]+2[A_1^j\partial_j(A_2^j\Gamma_j)-A_2^j\partial_j(A_1^j\Gamma_j)]=0.$$

But all the terms in this sum vanish because of (5.5a). Thus, also (5.5b) is identically satisfied. Equation (5.5c) becomes

$$A_1^i\partial_i(A_2^j\Gamma_j)-A_2^i\partial_i(A_1^j\Gamma_j)+A_1^j\partial_j(A_2^i\Gamma_i)-A_2^j\partial_j(A_1^i\Gamma_i)=0.$$

Because of (5.5a) it reduces to

$$(A_1^iA_2^j-A_2^iA_1^j)(\partial_i\Gamma_j-\partial_j\Gamma_i)=0 \quad (i\neq j, \text{ n.s.}),$$

that is (up to a factor $g^{ii}g^{jj}$) to (4.6), which is identically satisfied. Due to the last two equations (5.17), Eq. (5.5d) becomes

$$\frac{\hbar^2}{4}\sum_i [A_1^i\partial_i^2(A_2^j\Gamma_j)-A_1^i\Gamma_i\partial_i(A_2^j\Gamma_j)-A_2^i\partial_i^2(A_1^j\Gamma_j)+A_2^i\Gamma_i\partial_i(A_1^j\Gamma_j)]+A_1^j\partial_j V_{\mathbf{K}_2}-A_2^j\partial_j V_{\mathbf{K}_1}=0,$$

thus,

$$\frac{\hbar^2}{4}\sum_i\,[(A_1^iA_2^j-A_2^iA_1^j)\partial_i^2\Gamma_j]+\frac{\hbar^2}{4}\sum_i\,[A_1^i\Gamma_j\partial_i^2A_2^j-A_2^i\Gamma_j\partial_i^2A_1^j+2A_1^i\partial_iA_2^j\partial_i\Gamma_j-2A_2^i\partial_iA_1^j\partial_i\Gamma_j]$$

$$-\frac{\hbar^2}{4}\sum_i\,\Gamma_i[A_1^i\partial_i(A_2^i\Gamma_j)-A_2^i\partial_i(A_1^j\Gamma_j)]+A_1^j\partial_jV_{\mathbf{K}_2}-A_2^j\partial_jV_{\mathbf{K}_1}=0.$$

Because of the second equation (5.17) and (5.5a), the second sum vanishes identically and this equation reduces to

$$\frac{\hbar^2}{4}\sum_i\,[(A_1^iA_2^j-A_2^iA_1^j)\partial_i^2\Gamma_j]-\frac{\hbar^2}{4}\sum_i\,[\Gamma_i(A_1^iA_2^j-A_2^iA_1^j)\partial_i\Gamma_j]+A_1^j\partial_jV_{\mathbf{K}_2}-A_2^j\partial_jV_{\mathbf{K}_1}=0,$$

which is equivalent to

$$\frac{\hbar^2}{4}\sum_i\,[g^{ii}(\lambda_1^i\lambda_2^j-\lambda_2^i\lambda_1^j)(\partial_i^2\Gamma_j-\Gamma_i\partial_i\Gamma_j)]+\lambda_1^j\partial_jV_{\mathbf{K}_2}-\lambda_2^j\partial_jV_{\mathbf{K}_1}=0. \tag{5.18}$$

Due to (4.15) this equation is equivalent to the second equation in (5.15). So, the first commutation relation (5.15) is equivalent to the second equation (5.15) plus the last equation (5.5). However, **C** is skew-symmetric (Remark 4.5), so that the second equation (5.15) implies equation $\delta(\mathbf{K}_1\nabla V_{\mathbf{K}_2}-\mathbf{K}_2\nabla V_{\mathbf{K}_1})=0$, that is (5.5e). This proves the first equivalence (5.15). The second equivalence follows from the first equation (2.3), which now reads $\{H_{\mathbf{K}_1},H_{\mathbf{K}_2}\}=P(\mathbf{K}_1\nabla V_{\mathbf{K}_2}-\mathbf{K}_2\nabla V_{\mathbf{K}_1})$.

Proposition 5.9: Let $\mathbf{K}_1$ *and* $\mathbf{K}_2$ *be Killing tensors simultaneously diagonalized in orthogonal coordinates. Then*

$$[\hat{H}_{\mathbf{K}_1},\hat{H}]=0,\quad [\hat{H}_{\mathbf{K}_2},\hat{H}]=0\Rightarrow[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0. \tag{5.19}$$

Proof: Since $\{P_{\mathbf{K}_1},P_{\mathbf{G}}\}=0$, due to Theorem 5.6 the first two conditions (5.19) are equivalent to

$$\frac{\hbar^2}{4}\delta\mathbf{C}+\mathbf{K}_I\nabla V-\nabla V_{\mathbf{K}_I}=0,\quad I=1,2.$$

Because of (4.17), Remark 4.6, these equations are equivalent to

$$\begin{aligned}&\frac{\hbar^2}{4}\sum_i\,g^{ii}(\lambda_1^i-\lambda_1^j)(\partial_i^2\Gamma_j-\Gamma_i\partial_i\Gamma_j)+\lambda_1^j\partial_jV-\partial_jV_{\mathbf{K}_1}=0,\\&\frac{\hbar^2}{4}\sum_i\,g^{ii}(\lambda_2^i-\lambda_2^j)(\partial_i^2\Gamma_j-\Gamma_i\partial_i\Gamma_j)+\lambda_2^j\partial_jV-\partial_jV_{\mathbf{K}_2}=0.\end{aligned} \tag{5.20}$$

As we have done above, if we multiply the first equation by $\lambda_2^j\neq0$, the second one by $\lambda_1^j\neq0$ and subtract the two resulting equations, then we get (5.18), which is equivalent to the first equation (5.15). For $\lambda_2^j=0$, Eq. (5.18) follows from the first equation (5.20) multiplied by $\lambda_1^j\neq0$. For $\lambda_1^j=\lambda_2^j=0$, (5.18) is obviously satisfied. ■

Now we are able to prove Theorem 3.1 by applying the preceding results to the space $\mathcal{H}=(\mathcal{K},V)$ of the first integrals in involution associated with the orthogonal separation of the Hamilton–Jacobi equation (Sec. III). First, we prove the equivalence of the first three conditions (3.3).

Proposition 5.10: Let $\mathcal{H}=(\mathcal{K},V)$ be the space of quadratic first integrals in involution associated with the orthogonal separation of the Hamilton–Jacobi equation. Then the following conditions are equivalent:

$$[\hat{H}_{\mathbf{K}},\hat{H}]=0, \quad \forall \mathbf{K}\in\mathcal{K},$$

$$\delta(\mathbf{KR}-\mathbf{RK})=0, \quad \forall \mathbf{K}\in\mathcal{K}, \tag{5.21}$$

$$\partial_i R_{ij}-\Gamma_i R_{ij}=0, \quad (i\neq j \ \text{ n.s.}).$$

Proof: Let us use Theorem 5.6. Since $\{H_{\mathbf{K}},H\}=0$, the first equation (5.21), coinciding with the first equation (5.10), is equivalent to $\delta\mathbf{C}=0$ for $\mathbf{C}=\mathbf{KD}-\mathbf{DK}$ and $D_{ij}=\partial_i\Gamma_j$. However, since the components D_{ii} are not involved in this definition of $\mathbf{C}$ (Remark 4.4), we can replace $\mathbf{D}$ with $\frac{2}{3}\mathbf{R}$, in agreement with (5.14). This proves the equivalence of the first two conditions (5.21). From the equivalence (4.18) it follows that the coordinate expression of the second equation (5.21) is

$$\sum_i g^{ii}(\lambda^i-\lambda^j)(\partial_i R_{ij}-\Gamma_i R_{ij})=0, \tag{5.22}$$

where only the nondiagonal covariant components of $\mathbf{R}$ are involved. If we introduce the vectors

$$\mathbf{X}_j=(X_j^i)=(g^{ii}(\partial_i R_{ij}-\Gamma_i R_{ij})), \quad \mathbf{Y}_j=(Y_j^i)=(\lambda^i-\lambda^j),$$

then equation (5.22) can be written

$$\mathbf{X}_j\cdot\mathbf{Y}_j=0. \tag{5.23}$$

Let us consider a basis $(\mathbf{K}_a)=(K_a^{ii})=(\lambda_a^i g^{ii})$ of $\mathcal{K}$, $a=1,...,n$, with $\mathbf{K}_n=\mathbf{G}$. We have $\det[\lambda_a^i]\neq 0$ and $\lambda_n^i=1$. Let us chose a value of the index j, say $j=1$. Then the $n-1$ vectors $\mathbf{Y}_{1a}=(\lambda_a^i-\lambda_a^1)$, $a=1,2,...,n-1$, are independent vectors in the $(n-1)$-space Π_1 orthogonal to the vector (1, 0,..., 0). Indeed, the rank of the $n\times(n-1)$ matrix $[\lambda_a^i-\lambda_a^1]$ is maximal. According to the second equation (5.21), Eq. (5.23) must be satisfied by all these vectors:

$$\mathbf{X}_1\cdot\mathbf{Y}_{1a}=0.$$

This means that $\mathbf{X}_1$ is orthogonal to Π_1, i.e., that $X_1^i=0$ for $i\neq 1$. In a similar way we prove that $X_j^i=0$ for $j\neq i$. Thus, the second equation (5.21) implies the third one. The converse is obvious.■

Proposition 5.11: Let $\mathcal{H}=(\mathcal{K},V)$ be the space of quadratic first integrals in involution associated with the orthogonal separation of the Hamilton–Jacobi equation. Then the following conditions are equivalent,

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0, \quad \forall \mathbf{K}_1,\mathbf{K}_2,\in\mathcal{K},$$

$$\delta(\mathbf{K}_1\mathbf{R}\mathbf{K}_2-\mathbf{K}_2\mathbf{R}\mathbf{K}_1)=0, \quad \forall \mathbf{K}_1,\mathbf{K}_2,\in\mathcal{K}, \tag{5.24}$$

$$\partial_i R_{ij}-\Gamma_i R_{ij}=0, \quad i\neq j.$$

Proof: The first condition is equivalent to $\delta\mathbf{C}=0$, because of the second equivalence (5.15) (Theorem 5.8), with $\mathbf{C}$ defined in (5.16). However, in definition (5.16) $\mathbf{D}$ can be replaced by $\mathbf{R}$, due to (5.14) and Remark 4.4(ii). Thus, the first two conditions (5.24) are equivalent. The second equation (5.24) implies the second equation (5.21), since $\mathbf{G}\in\mathcal{K}$, and the last equation (5.24) because of Proposition 5.10. The last condition (5.24) implies the second condition (5.24) because of (4.16). ■

The last condition (5.24) appears also in (5.21). Thus, all the conditions (5.24) and (5.21) are equivalent. This proves Theorem 3.1.

VI. SYMMETRY OPERATORS ASSOCIATED WITH THE GENERAL SEPARATION OF THE HAMILTON–JACOBI EQUATION

A *separable Killing algebra*[1] is a pair $(D,\mathcal{K})$ where D is an r-dimensional linear space of commuting Killing vectors and $\mathcal{K}$ is a D-invariant $(n-r)$-dimensional linear space of Killing two-tensors with $m=n-r$ normal eigenvectors orthogonal to D. These eigenvectors are called *essential eigenvectors*. The eigenvalues of a $\mathbf{K}\in\mathcal{K}$ corresponding to essential eigenvectors are called *essential eigenvalues*. It can be proved that: (i) D is normal, i.e., the distribution $\Delta^{\perp}$ orthogonal to the vectors of D is completely integrable, (ii) $\mathcal{K}$ contains the metric tensor $\mathbf{G}$ and Killing tensors with distinct essential eigenvalues (called *characteristic Killing tensors*); (iii) all functions $P_{\mathbf{X}}$ and $P_{\mathbf{K}}$, with $\mathbf{X}\in D$ and $\mathbf{K}\in\mathcal{K}$ are in involution; (iv) there exist *standard coordinates* (q^a,q^α) such that $\mathrm{d}q^a$ are eigenforms of $\mathcal{K}$ corresponding to the essential eigenvectors and ∂_α form a local basis of D, so that (q^α) are ignorable; (v) these coordinates are separable for the geodesic flow; (vi) in these coordinates all elements of $\mathcal{K}$ assume the *standard form*

$$\mathbf{K}=K^{aa}\partial_a\otimes\partial_a+K^{\alpha\beta}\partial_\alpha\otimes\partial_\beta=\lambda^a g^{aa}\partial_a\otimes\partial_a+K^{\alpha\beta}\partial_\alpha\otimes\partial_\beta, \tag{6.1}$$

where λ^a are the essential eigenvalues of $\mathbf{K}$ and the coordinates (q^α) are ignorable; (vii) the natural Hamiltonian $H=\frac{1}{2}P_{\mathbf{G}}+V$ is separable if and only if there exists a separable Killing algebra such that $DV=0$ and the *characteristic equation* $\mathrm{d}(\mathbf{K}\mathrm{d}V)=0$ is satisfied for a single characteristic Killing tensor of $\mathcal{K}$. It follows that (viii) the characteristic equation is satisfied for all $\mathbf{K}\in\mathcal{K}$ and that there are local D-invariant functions $V_{\mathbf{K}}$ such that $\mathrm{d}V_{\mathbf{K}}=\mathbf{K}\mathrm{d}V$, i.e.,

$$\nabla V_{\mathbf{K}}=\mathbf{K}\nabla V,\quad DV_{\mathbf{K}}=0;$$

(ix) the functions

$$P_{\mathbf{X}},\quad \mathbf{X}\in D,$$

$$H_{\mathbf{K}}=\tfrac{1}{2}P_{\mathbf{K}}+V_{\mathbf{K}},\quad \mathbf{K}\in\mathcal{K}$$

are first integrals in involution. We denote by

$$\mathcal{H}=(\mathcal{K},V)$$

the m-dimensional linear space of the quadratic first integrals $H_{\mathbf{K}}$.

For the first- and second-order operators corresponding to these first integrals in involution the commutation relations

$$[\hat{P}_{\mathbf{X}_1},\hat{P}_{\mathbf{X}_2}]=0,\quad [\hat{P}_{\mathbf{X}},\hat{H}_{\mathbf{K}}]=0,\quad \forall\mathbf{X}_1,\mathbf{X}_2,\mathbf{X}\in D,\quad \forall\mathbf{K}\in\mathcal{K},$$

hold. This follows from the fact that $\mathbf{X}\in D$ are commuting Killing vectors and the elements of $\mathcal{H}$ are D-invariant. However, in general the operators $\hat{H}_{\mathbf{K}}$ do not commute one other. Indeed, we have a theorem similar to Theorem 3.1,

Theorem 6.1: *Let $\mathcal{H}=(\mathcal{K},V)$ be the space of quadratic first integrals in involution associated with the separation of the Hamilton–Jacobi equation. Then the following conditions are equivalent:*

$$[\hat{H}_{\mathbf{K}},\hat{H}]=0,\quad \forall\mathbf{K}\in\mathcal{K}, \tag{6.2a}$$

$$\delta(\mathbf{KR}-\mathbf{RK})=0,\quad \forall\mathbf{K}\in\mathcal{K}, \tag{6.2b}$$

$$\partial_a R_{ab}-\Gamma_a R_{ab}=0,\quad a\neq b \ \text{ n.s.}, \tag{6.2c}$$

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0,\quad \forall\mathbf{K}_1,\mathbf{K}_2,\in\mathcal{K}, \tag{6.2d}$$

$$\delta(\mathbf{K}_1\mathbf{R}\mathbf{K}_2-\mathbf{K}_2\mathbf{R}\mathbf{K}_1)=0, \quad \forall \mathbf{K}_1,\mathbf{K}_2, \in \mathcal{K}, \tag{6.2e}$$

where $R_{ab}=\mathbf{R}(\partial_a,\partial_b)$ *are the essential covariant components of the Ricci tensor* $\mathbf{R}$ (*corresponding to essential separable coordinates* (q^a)) *and* $\Gamma_a=g^{ij}\Gamma_{ij,a}$ *are the essential contracted Christoffel symbols*.

The proof of this theorem will be given in Sec. VIII.

Remark 6.2: Formulas (6.2) are formally identical to formulas (3.3) concerning the orthogonal separation, and a remark similar to Remark 3.2 also holds in the present case. The only difference is that now the coordinate expression of the pre-Robertson condition (6.2c) involves only the essential components R_{ab} of the Ricci tensor. In standard separable coordinates the Ricci tensor $\mathbf{R}$ assume the form (cf. Ref. 1, Sec. VI)

$$\mathbf{R}=R^{ab}\partial_a\otimes\partial_b+R^{\alpha\beta}\partial_\alpha\otimes\partial_\beta, \tag{6.3}$$

and moreover,

$$\partial_a\Gamma_b=\tfrac{2}{3}R_{ab}, \quad a\neq b. \tag{6.4}$$

It assumes the standard form, i.e.,

$$R_{ab}=0, \quad a\neq b, \tag{6.5}$$

if and only if the Schrödinger equation is separable in the reduced sense (Robertson condition). The Robertson condition (6.5) obviously implies the pre-Robertson condition (6.3). Hence,

Theorem 6.3: *If the Schrödinger equation associated with a separable Hamiltonian is reductively separable, then all operators* $\hat{P}_{\mathbf{X}}$ *and* $\hat{H}_{\mathbf{K}}$ *corresponding to the linear and quadratic first integrals in involution commute*.

In particular they commute with the Schrödinger operator $\hat{H}=\hat{H}_{\mathbf{G}}$. The Robertson and pre-Robertson conditions are obviously satisfied for $\mathbf{R}=\kappa\mathbf{G}$. Hence,

Theorem 6.4: *On Einstein manifolds all operators* $\hat{P}_{\mathbf{X}}$ *and* $\hat{H}_{\mathbf{K}}$ *corresponding to the first integrals in involution of a separable Hamiltonian system commute*.

Remark 6.5: An algebraic form of the Robertson condition is expressed by the commutability of the Ricci tensor $\mathbf{R}$ with a characteristic tensor (thus, with all the Killing tensors) $\mathbf{K}\in\mathcal{K}$, interpreted as linear operators, when restricted to the distribution $\Delta^\perp$ orthogonal to D,

$$(\mathbf{K}\mathbf{R}-\mathbf{R}\mathbf{K})\big|\Delta^\perp=0, \quad \forall \mathbf{K}\in\mathcal{K}. \tag{6.6}$$

Indeed, this distribution is invariant with respect to these linear operators. If we denote by $\mathbf{R}'$ and $\mathbf{K}'$ the restrictions to $\Delta^\perp$, cf. (7.1), then (6.6) is equivalent to

$$\mathbf{K}'\mathbf{R}-\mathbf{R}\mathbf{K}'=0, \tag{6.7}$$

or to $\mathbf{K}\mathbf{R}'-\mathbf{R}'\mathbf{K}=\mathbf{K}'\mathbf{R}'-\mathbf{R}'\mathbf{K}'=0$. Condition (6.7) obviously implies

$$\delta(\mathbf{K}'\mathbf{R}-\mathbf{R}\mathbf{K}')=0. \tag{6.8}$$

As we shall see in Sec. VIII, the fact that (6.8) is equivalent to (6.2b) is remarkable.

Remark 6.6: In standard separable coordinates the components of the elements of $\mathcal{K}$ and the potential functions assume the form

$$g^{aa}=\varphi^a_{(m)}, \quad g^{\alpha\beta}=\phi_a^{\alpha\beta}(q^a)\varphi^a_{(m)}, \quad V=\phi_a(q^a)\varphi^a_{(m)},$$

$$K_b^{aa}=\varphi^a_{(b)}, \quad K_b^{\alpha\beta}=\phi_a^{\alpha\beta}(q^a)\varphi^a_{(b)}, \quad V_{K_b}=\phi_a(q^a)\varphi^a_{(b)},$$

where $(\mathbf{K}_b)$ is a local basis of $\mathcal{K}$, with $\mathbf{K}_m=\mathbf{G}$. Then, a local basis of $\mathcal{H}$ is

$$H_b = \tfrac{1}{2}\varphi^a_{(b)}(p_a^2 + \phi_a^{\alpha\beta} p_\alpha p_\beta + 2\phi_a).$$

The corresponding operators assume the form (see Remark 8.2 and Ref. 1, Sec. V).

$$\hat{H}_b\tilde{\psi} = -\frac{\hbar^2}{2}\varphi^a_{(b)}\left(\partial_a^2\tilde{\psi} - \Gamma_a\partial_a\tilde{\psi} + \left(\phi_a^{\alpha\beta}\kappa_\alpha\kappa_\beta - \frac{2}{\hbar^2}\phi_a\right)\tilde{\psi}\right),$$

where $\psi = \tilde{\psi}\cdot\Pi_\alpha e^{\kappa_\alpha q^\alpha}$, $\tilde{\psi} = \Pi_a\psi_a(q^a)$. The Robertson condition in standard separable coordinates is equivalent to $\partial_b\Gamma_a = 0$ for $a \neq b$. This means that $\Gamma_a = \Gamma_a(q^a)$.

VII. KILLING TENSORS IN STANDARD FORM

In the next section we shall analyze the commutation relations of the second-order operators assuming that all the tensors **K** involved, including the metric tensor **G**, are simultaneously in standard form (6.1) with respect to a given standard coordinate system $(q^i) = (q^a, q^\alpha)$. We shall use the decomposition

$$\mathbf{K} = \mathbf{K}' + \mathbf{K}'',$$

$$\mathbf{K}' = K^{aa}\partial_a\otimes\partial_a = \lambda^a g^{aa}\partial_a\otimes\partial_a, \tag{7.1}$$

$$\mathbf{K}'' = K^{\alpha\beta}\partial_\alpha\otimes\partial_\beta.$$

In analogy with Sec. IV, in this section we state some general properties concerning Killing tensors. For a Killing tensor in standard form the following equations hold:

$$\begin{aligned}
&\partial_a\lambda^b = (\lambda^a - \lambda^b)\partial_a \ln g^{bb}\\
&\partial_a K^{\alpha\beta} = \lambda^a\partial_a g^{\alpha\beta}\\
&\partial_a\lambda^a = 0\\
&\partial_a(\lambda^b g^{bb}) = \lambda^a\partial_a g^{bb} \qquad (a,b \text{ n.s.}).\\
&\partial_a^2(\lambda^b g^{bb}) = \lambda^a\partial_a^2 g^{bb}\\
&\partial_a^2 K^{\alpha\beta} = \lambda^a\partial_a^2 g^{\alpha\beta}
\end{aligned} \tag{7.2}$$

We call the two first equations (7.2) the *extended Eisenhart–Killing equations*. They characterize the Killing tensors in standard form and imply the remaining equations.

Proposition 7.1: If (q^a, q^α) *are standard coordinates in which a Killing tensor* **K** *assumes the standard form (6.1), then*

$$(\lambda^a - \lambda^b)(\partial_a\Gamma_b - \partial_b\Gamma_a) = 0 \quad (a,b \text{ n.s.}). \tag{7.3}$$

Proof: The proof follows the same pattern of the proof of Proposition 4.1. The only difference is that (4.3) is replaced by (cf. Ref. 1, Sec. VI)

$$\Gamma_a = \tfrac{1}{2}\partial_a\sum_c \ln g^{cc} - \partial_a \ln g^{aa} + \tfrac{1}{2}\partial_a \ln\det[g^{\alpha\beta}],$$

but the last term does not give any contribution to the difference $\partial_a\Gamma_b - \partial_b\Gamma_a$. ■

In a similar way we can prove

Proposition 7.2: Let $\mathbf{K}_I$, $I = 1,2$, *be two Killing tensors in standard form (6.1). Then*

$$(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)(\partial_a\Gamma_b-\partial_b\Gamma_a)=0 \quad (a\neq b \ \text{ n.s.}). \tag{7.4}$$

Proposition 7.3: Let $\mathbf{K}_I$, $I=1,2$, *be two Killing tensors in standard form (6.1). If*

$$\mathbf{C}=\mathbf{K}_1'\mathbf{D}\mathbf{K}_2'-\mathbf{K}_2'\mathbf{D}\mathbf{K}_1', \quad C^{ij}=(K_1')^{ih}D_{hk}(K_2')^{kj}-(K_2')^{ih}D_{hk}(K_1')^{kj}, \tag{7.5}$$

where $\mathbf{D}=(D_{ij})$ *is a geometrical object, then*

$$\begin{aligned} &C^{ab}=g^{aa}g^{bb}(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)D_{ab}, \quad C^{a\alpha}=C^{\alpha a}=C^{\alpha\beta}=0,\\ &C_b^a=C^a_{\cdot b}=g^{aa}(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)D_{ab}, \quad C_\alpha^a=C_a^\alpha=C_\alpha^\beta=0, \end{aligned} \tag{7.6}$$

and

$$\nabla_iC^i_\alpha=0, \quad \nabla_iC^i_b=\sum_a g^{aa}(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)(\partial_aD_{ab}-\Gamma_aD_{ab}+\tfrac{1}{2}\partial_a\ln g^{bb}(D_{ba}-D_{ab})). \tag{7.7}$$

Proof: Equations (7.6) are a direct consequence of definitions (7.5) and (7.1). In standard coordinates (cf. Ref. 1, Sec. VI)

$$\Gamma^i_{i\alpha}=0, \quad \Gamma^i_{ia}=-\tfrac{1}{2}\partial_a(\ln\det[g^{ij}])=-\partial_a\ln g^{aa}-\Gamma_a, \tag{7.8}$$

and formula (4.11) reduces to

$$\nabla_iC^i_j=\partial_aC^a_j+\Gamma^i_{ia}C^a_j-\Gamma^h_{ij}C^i_h.$$

It follows that $\nabla_iC^i_\alpha=0$ and

$$\nabla_iC^i_b=\partial_aC^a_b-(\Gamma_a+\partial_a\ln g^{aa})C^a_b-\Gamma^c_{ab}C^a_c.$$

The development of this last expression follows the same pattern of the proof of Proposition 4.3.■

Remark 7.4: From (7.6) it follows that: (i) $C^{ii}=0$, (ii) only the nondiagonal components D_{ab}, $a\neq b$, are involved in the definition (7.5) of $\mathbf{C}$, (iii) if the essential components of D are symmetric, $D_{ab}=D_{ba}$, then $\mathbf{C}$ is skew-symmetric.

Remark 7.5: Let us apply Proposition 7.3 to the cases $D_{ij}=\partial_i\Gamma_j$. In standard coordinates $\Gamma_\alpha=0$ and $\partial_\alpha\Gamma_a=0$. Thus, $D_{\alpha\beta}=D_{a\alpha}=D_{\alpha a}=0$ and $\mathbf{C}$ defined in (7.5) is equal to

$$\mathbf{C}=\mathbf{K}_1\mathbf{D}\mathbf{K}_2-\mathbf{K}_2\mathbf{D}\mathbf{K}_1, \quad \mathbf{D}=(\partial_i\Gamma_j).$$

Equations (7.6) hold with D_{ab} replaced by $\partial_a\Gamma_b$,

$$C^{ab}=g^{aa}g^{bb}(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)\partial_a\Gamma_b, \quad C^a_b=g^{aa}(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)\partial_a\Gamma_b, \tag{7.9}$$

and, due to (7.4), equations (7.7) become

$$\nabla_iC^i_\alpha=0, \quad \nabla_iC^i_b=\sum_a g^{aa}(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)(\partial_a^2\Gamma_b-\Gamma_a\partial_a\Gamma_b). \tag{7.10}$$

From (7.4) and (7.9) it follows that $C^{ij}+C^{ji}=0$. Hence, $\mathbf{C}$ is skew-symmetric and (7.10) give the components of $\delta\mathbf{C}$. Thus,

$$\delta\mathbf{C}=0\Leftrightarrow\sum_a g^{aa}(\lambda_1^a\lambda_2^b-\lambda_2^a\lambda_1^b)(\partial_a^2\Gamma_b-\Gamma_a\partial_a\Gamma_b)=0.$$

Remark 7.6: For $\mathbf{K}_2=\mathbf{G}$ and $\mathbf{K}_1=\mathbf{K}$, definition (7.5) and equations (7.6) become

$$\mathbf{C}=\mathbf{K}'\mathbf{D}-\mathbf{D}\mathbf{K}', \quad C^{ab}=g^{aa}g^{bb}(\lambda^a-\lambda^b)D_{ab}, \quad C^a_b=g^{aa}(\lambda^a-\lambda^b)D_{ab}, \tag{7.11}$$

the remaining components being identically zero. Equations (7.7) become

$$\nabla_i C^i_\alpha=0, \quad \nabla_i C^i_b=\sum_a g^{aa}(\lambda^a-\lambda^b)(\partial_a D_{ab}-\Gamma_a D_{ab}+\tfrac{1}{2}\partial_a \ln g^{bb}(D_{ba}-D_{ab})).$$

For $D_{ij}=\partial_i\Gamma_j$ the definition (7.11) is equivalent to

$$\mathbf{C}=\mathbf{K}\mathbf{D}-\mathbf{D}\mathbf{K}$$

and

$$\nabla_i C^i_\alpha=0, \quad \nabla_i C^i_b=\sum_a g^{aa}(\lambda^a-\lambda^b)(\partial_a^2\Gamma_b-\Gamma_a\partial_a\Gamma_b). \tag{7.12}$$

$\mathbf{C}$ is skew-symmetric and (7.12) give the components of $\delta\mathbf{C}$. Thus,

$$\delta\mathbf{C}=0 \Leftrightarrow \sum_a g^{aa}(\lambda^a-\lambda^b)(\partial_a^2\Gamma_b-\Gamma_a\partial_a\Gamma_b)=0. \tag{7.13}$$

Remarks and propositions similar to Remarks 4.6, 4.7, 4.13, 4.14 and Propositions 4.8–12 hold in the present case, with obvious modifications.

VIII. COMMUTATION RELATIONS IN STANDARD COORDINATES

Proposition 8.1: If $\mathbf{K}$ *is a symmetric tensor in standard form (6.1), then the corresponding pseudo-Laplacian assumes the form*

$$\Delta_{\mathbf{K}}\psi=A^a\partial_a^2\psi+B^a\partial_a\psi+K^{\alpha\beta}\partial_\alpha\partial_\beta\psi,$$

$$A^a=K^{aa}=\lambda^a g^{aa}, \tag{8.1}$$

$$B^a=g^{aa}(\partial_a\lambda^a-\lambda^a\Gamma_a).$$

Proof:

$$\Delta_{\mathbf{K}}\psi=\partial_i(K^{ij}\partial_j\psi)+\Gamma^i_{ih}K^{hj}\partial_j\psi=\partial_iK^{ij}\partial_j\psi+K^{ij}\partial_i\partial_j\psi+\Gamma^i_{ia}K^{aj}\partial_j\psi$$
$$=\partial_aK^{aa}\partial_a\psi+K^{aa}\partial_a^2\psi+K^{\alpha\beta}\partial_\alpha\partial_\beta\psi+\Gamma^i_{ia}K^{aa}\partial_a\psi.$$

Then (8.1) follow from (7.8) and $K^{aa}=\lambda^a g^{aa}$. ■

Remark 8.2: For a pseudo-Laplacian we use the decomposition

$$\Delta_{\mathbf{K}}=\Delta'_{\mathbf{K}}+\Delta''_{\mathbf{K}},$$

$$\Delta'_{\mathbf{K}}\psi=A^a\partial_a^2\psi+B^a\partial_a\psi=g^{aa}(\lambda^a\partial_a^2\psi+(\partial_a\lambda^a-\lambda^a\Gamma_a)\partial_a\psi),$$

$$\Delta''_{\mathbf{K}}\psi=K^{\alpha\beta}\partial_\alpha\partial_\beta\psi.$$

Note that, in accordance with the decomposition (7.1), we have

$$\Delta'_{\mathbf{K}}=\Delta_{\mathbf{K}'}.$$

For a Killing tensor,

$$\Delta'_{\mathbf{K}}=\lambda^a g^{aa}(\partial_a^2\psi-\Gamma_a\partial_a\psi).$$

For a second-order operator (2.12) we use the decomposition

$$\hat{H}_{\mathbf{K}}=\hat{H}'_{\mathbf{K}}+\hat{H}''_{\mathbf{K}},\quad \hat{H}'_{\mathbf{K}}=-\frac{\hbar^2}{2}\Delta'_{\mathbf{K}}+V_{\mathbf{K}},\quad \hat{H}''_{\mathbf{K}}=-\frac{\hbar^2}{2}\Delta''_{\mathbf{K}},$$

so that

$$\begin{aligned}\hat{H}_{\mathbf{K}}\psi&=-\frac{\hbar^2}{2}(\Delta'_{\mathbf{K}}+\Delta''_{\mathbf{K}})\psi+V_{\mathbf{K}}\psi\\&=-\frac{\hbar^2}{2}(A^a\partial_a^2\psi+B^a\partial_a\psi+K^{\alpha\beta}\partial_\alpha\partial_\beta\psi)+V_{\mathbf{K}}\psi\\&=-\frac{\hbar^2}{2}[g^{aa}(\lambda^a\partial_a^2\psi+(\partial_a\lambda^a-\lambda^a\Gamma_a)\partial_a\psi)+K^{\alpha\beta}\partial_\alpha\partial_\beta\psi]+V_{\mathbf{K}}\psi.\end{aligned}\tag{8.2}$$

For a Killing tensor,

$$\hat{H}_{\mathbf{K}}\psi=-\frac{\hbar^2}{2}[\lambda^a g^{aa}(\partial_a^2\psi-\Gamma_a\partial_a\psi)+K^{\alpha\beta}\partial_\alpha\partial_\beta\psi]+V_{\mathbf{K}}\psi.$$

In all the above-given expressions the coordinates (q^α) are ignorable.

Proposition 8.3: The commutator of two second-order operators of the kind (8.2) has the following expression:

$$\begin{aligned}[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]\psi&=[\hat{H}'_{\mathbf{K}_1},\hat{H}'_{\mathbf{K}_2}]\psi+\frac{\hbar^4}{2}(A_1^a\partial_a^2K_2^{\alpha\beta}-A_2^a\partial_a^2K_1^{\alpha\beta}+B_1^a\partial_aK_2^{\alpha\beta}-B_2^a\partial_aK_1^{\alpha\beta})\partial_{\alpha\beta}\psi\\&\quad+\hbar^4(A_1^a\partial_aK_2^{\alpha\beta}-A_2^a\partial_aK_1^{\alpha\beta})\partial_a\partial_\alpha\partial_\beta\psi,\end{aligned}\tag{8.3}$$

where

$$[\hat{H}'_{\mathbf{K}_1},\hat{H}'_{\mathbf{K}_2}]\psi=\frac{\hbar^4}{4}[\Delta'_{\mathbf{K}_1},\Delta'_{\mathbf{K}_2}]\psi-\hbar^2(A_1^a\partial_aV_{\mathbf{K}_2}-A_2^a\partial_aV_{\mathbf{K}_1})\partial_a\psi-\frac{\hbar^2}{2}(\Delta'_{\mathbf{K}_1}V_{\mathbf{K}_2}-\Delta'_{\mathbf{K}_2}V_{\mathbf{K}_1})\psi.\tag{8.4}$$

Proof: Since

$$\begin{aligned}\Delta'_{\mathbf{K}_1}\Delta'_{\mathbf{K}_2}\psi&=A_1^b\partial_b^2(A_2^a\partial_a^2\psi+B_2^a\partial_a\psi)+B_1^b\partial_b(A_2^a\partial_a^2\psi+B_2^a\partial_a\psi)\\&=A_1^bA_2^a\partial_b^2\partial_a^2\psi+A_1^b\partial_b^2A_2^a\partial_a^2\psi+2A_1^b\partial_bA_2^a\partial_b\partial_a^2\psi+A_1^b\partial_b^2B_2^a\partial_a\psi+A_1^bB_2^a\partial_b^2\partial_a\psi\\&\quad+2A_1^b\partial_bB_2^a\partial_a\partial_b\psi+B_1^bA_2^a\partial_b\partial_a^2\psi+B_1^b\partial_bA_2^a\partial_a^2\psi+B_1^bB_2^a\partial_b\partial_a\psi+B_1^b\partial_bB_2^a\partial_a\psi,\end{aligned}$$

we have

$$\begin{aligned}[\Delta'_{\mathbf{K}_1},\Delta'_{\mathbf{K}_2}]&=2(A_1^a\partial_aA_2^b-A_2^a\partial_aA_1^b)\partial_a\partial_b^2\psi+(A_1^a\partial_a^2A_2^b-A_2^a\partial_a^2A_1^b+B_1^a\partial_aA_2^b-B_2^a\partial_aA_1^b)\partial_b^2\psi\\&\quad+2(A_1^a\partial_aB_2^b-A_2^a\partial_aB_1^b)\partial_a\partial_b\psi+(A_1^a\partial_a^2B_2^b+B_1^a\partial_aB_2^b-A_2^a\partial_a^2B_1^b-B_2^a\partial_aB_1^b)\partial_b\psi.\end{aligned}$$

Since

$$\Delta''_{\mathbf{K}_1},\Delta''_{\mathbf{K}_2}\psi=K_1^{\alpha\beta}K_2^{\mu\nu}\partial_{\alpha\beta\mu\nu}\psi,$$

we have

$$[\Delta''_{\mathbf{K}_1},\Delta''_{\mathbf{K}_2}]=0, \quad [\hat{H}''_{\mathbf{K}_1},\hat{H}''_{\mathbf{K}_2}]=0.$$

Thus,

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=[\hat{H}'_{\mathbf{K}_1},\hat{H}'_{\mathbf{K}_2}]+[\hat{H}'_{\mathbf{K}_1},\hat{H}''_{\mathbf{K}_2}]+[\hat{H}''_{\mathbf{K}_1},\hat{H}'_{\mathbf{K}_2}].$$

A straightforward calculation shows that

$$[\hat{H}'_{\mathbf{K}_1},\hat{H}'_{\mathbf{K}_2}]\psi=\frac{\hbar^4}{2}(A_1^a\partial_a^2K_2^{\alpha\beta}+B_1^a\partial_aK_2^{\alpha\beta})\partial_\alpha\partial_\beta\psi+\hbar^4A_1^a\partial_aK_2^{\alpha\beta}\partial_a\partial_\alpha\partial_\beta\psi.$$

These two last equations prove (8.3) and (8.4). ■

Proposition 8.4: Let $\mathbf{K}_1$ *and* $\mathbf{K}_2$ *be symmetric tensors in standard form. Then* $[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0$ *if and only if*

$$A_1^a\partial_aA_2^b-A_2^a\partial_aA_1^b=0 \quad (a, \text{ n.s.}), \tag{8.5a}$$

$$\sum_a (A_1^a\partial_a^2A_2^b-A_2^a\partial_a^2A_1^b+B_1^a\partial_aA_2^b-B_2^a\partial_aA_1^b)+2(A_1^b\partial_bB_2^b-A_2^b\partial_bB_1^b)=0, \tag{8.5b}$$

$$A_1^a\partial_aB_2^b-A_2^a\partial_aB_1^b+A_1^b\partial_bB_2^a-A_2^b\partial_bB_1^a=0 \quad (a\neq b \text{ n.s.}), \tag{8.5c}$$

$$\frac{\hbar^2}{4}\sum_a (A_1^a\partial_a^2B_2^b+B_1^a\partial_aB_2^b-A_2^a\partial_a^2B_1^b-B_2^a\partial_aB_1^b)-A_1^b\partial_bV_{\mathbf{K}_2}+A_2^b\partial_bV_{\mathbf{K}_1}=0 \quad (b \text{ n.s.}), \tag{8.5d}$$

$$\Delta'_{\mathbf{K}_1}V_{\mathbf{K}_2}-\Delta'_{\mathbf{K}_2}V_{\mathbf{K}_1}=0, \tag{8.5e}$$

and

$$A_1^a\partial_a^2K_2^{\alpha\beta}-A_2^a\partial_a^2K_1^{\alpha\beta}+B_1^a\partial_aK_2^{\alpha\beta}-B_2^a\partial_aK_1^{\alpha\beta}=0, \tag{8.6a}$$

$$A_1^a\partial_aK_2^{\alpha\beta}-A_2^a\partial_aK_1^{\alpha\beta}=0. \tag{8.6b}$$

Proof: Equations (8.6) follow from the second and third term in (8.3) i.e., from the vanishing of the coefficients of $\partial_\alpha\partial_\beta\psi$ and of $\partial_a\partial_\alpha\partial_\beta\psi$. The first term (8.3) involves only the partial derivatives ∂_a and a factor of ψ, and it is similar (with an obvious change of indices) to (5.3). Thus, (8.5) are similar to (5.5).

Remark 8.5: Since,

$$\{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=2(A_1^a\partial_1^aA_2^b-A_2^a\partial_aA_1^b)p_ap_b^2+2(A_1^a\partial_aK_2^{\alpha\beta}-A_2^a\partial_aK_1^{\alpha\beta})p_ap_\alpha p_\beta, \tag{8.7}$$

Eqs. (8.5a) and (8.6a) are equivalent to $\{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=0$. Thus,

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0 \Rightarrow \{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=0. \tag{8.8}$$

Theorem 8.6: *Let* $\mathbf{K}$ *be a symmetric tensor in standard form. Then the following conditions are equivalent:*

$$\{P_{\mathbf{K}},P_{\mathbf{G}}\}=0 \quad (\mathbf{K} \text{ Killing tensor}),$$
$$[\hat{H}_{\mathbf{K}},\hat{H}]=0 \Leftrightarrow \frac{\hbar^2}{4}\delta\mathbf{C}+\mathbf{K}\nabla V-\nabla V_{\mathbf{K}}=0 \Leftrightarrow \{H_{\mathbf{K}},H\}=-\frac{\hbar^2}{4}P_{\delta\mathbf{C}}, \tag{8.9}$$

where

$$\mathbf{C}=\mathbf{K}\mathbf{D}-\mathbf{D}\mathbf{K}=\mathbf{K}'\mathbf{D}-\mathbf{D}\mathbf{K}', \quad \mathbf{D}=(\partial_i\Gamma_j). \tag{8.10}$$

Proof: The equivalence of the two definitions (8.10) of **C** follows from Remarks 7.5 and 7.6. We use (8.5), Proposition 8.4, for $\mathbf{K}_1=\mathbf{K}$ and $\mathbf{K}_2=\mathbf{G}$. Assume $[\hat{H}_{\mathbf{K}},\hat{H}]=0$. From (8.8) it follows that **K** is a Killing tensor. For a Killing tensor in standard form we have formulas similar to (5.11) and (5.12), with indices (a,b). Equations (8.5a, b) and (8.6b) are then identically satisfied. The remaining equations are similar to (5.13),

$$(\lambda^a-\lambda^b)(\partial_a\Gamma_b-\partial_b\Gamma_a)=0,$$

$$\frac{\hbar^2}{4}\sum_a g^{aa}(\lambda^a-\lambda^b)(\partial_a^2\Gamma_b-\Gamma_a\partial_a\Gamma_b)+\lambda^b\partial_b V-\partial_b V_{\mathbf{K}}=0 \quad (b \text{ n.s.}), \tag{8.11}$$

$$\delta(\mathbf{K}\nabla V-\nabla V_{\mathbf{K}})=0.$$

Due to (7.3), the first equation is identically satisfied. According to Remark 7.6 and Eq. (7.12), the second equation (8.11) is equivalent to

$$\frac{\hbar^2}{4}\delta\mathbf{C}+\mathbf{K}\nabla V-\nabla V_{\mathbf{K}}=0,$$

where **C** is skew-symmetric. Since $\delta^2\mathbf{C}=0$, the last equation (8.11) is a consequence of the second equation (8.11). The above-noted reasoning is reversible, and the first equivalence (8.9) is proved. The second equivalence follows from the last equation (2.3). ■

Theorem 8.7: *Let* $\mathbf{K}_1$ *and* $\mathbf{K}_2$ *be Killing tensors in standard form. Then* $\{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=0$, *and the following conditions are equivalent:*

$$[\hat{H}_{\mathbf{K}_1},\hat{H}_{\mathbf{K}_2}]=0 \Leftrightarrow \frac{\hbar^2}{4}\delta\mathbf{C}+\mathbf{K}_1\nabla V_{\mathbf{K}_2}-\mathbf{K}_2\nabla V_{\mathbf{K}_1}=0 \Leftrightarrow \{H_{\mathbf{K}_1},H_{\mathbf{K}_2}\}=-\frac{\hbar^2}{4}P_{\delta\mathbf{C}}, \tag{8.12}$$

where

$$\mathbf{C}=\mathbf{K}_1\mathbf{D}\mathbf{K}_2-\mathbf{K}_2\mathbf{D}\mathbf{K}_1=\mathbf{K}_1'\mathbf{D}\mathbf{K}_2'-\mathbf{K}_2'\mathbf{D}\mathbf{K}_1', \quad \mathbf{D}=(\partial_i\Gamma_j). \tag{8.13}$$

Proof: The equivalence of the two definitions of **C** in (8.13) follows from Remark 7.5. The components of **C** are given in (7.9). The involutivity condition $\{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=0$ follow from (8.7), (8.5a), (8.6b), and (7.2). We use Eqs. (8.5) and (8.6). For Killing tensors $\mathbf{K}_I$ $(I=1,2)$ in standard form we have, cf. (8.1) and (7.2),

$$A_1^a=\lambda_I^a g^{aa}, \quad B_I^a=-g^{aa}\lambda_I^a\Gamma_a,$$

$$\partial_a K_I^{\alpha\beta}=\lambda_I^a\partial_a g^{\alpha\beta}, \quad \partial_a^2 K^{\alpha\beta}=\lambda_I^a\partial_a^2 g^{\alpha\beta}.$$

Thus, (8.6) are identically satisfied. Moreover, formulas similar to (5.17) hold with indices (a,b),

$$A_I^a=\lambda_I^a g^{aa},\quad B_I^a=-A_I^a\Gamma_a,$$

$$\partial_a A_I^b=A_I^a\partial_a g^{bb}=\lambda_I^a\partial_a g^{bb},$$

$$\partial_a^2 A_I^b=A_I^a\partial_a^2 g^{bb}=\lambda_I^a\partial_a^2 g^{bb},$$

$$\partial_a B_I^b=-\partial_a(A_I^b\Gamma_b)=-\partial_a A_I^b\Gamma_b-A_I^b\partial_a\Gamma_b,$$

$$\partial_a^2 B_I^b=-\partial_a^2 A_I^b\Gamma_b-2\partial_a A_I^b\partial_a\Gamma_b-A_I^b\partial_a^2\Gamma_b.$$

Since the coordinates q^α are ignorable and no greek index is involved in (8.5) the proof of the first equivalence (8.12) is similar to that of the first equivalence (5.15) in Theorem 5.8. The second equivalence (8.12) follows from the first equation (2.3) (cf. the end of the proof of Theorem 5.8). ■

Proposition 8.8: Let $\mathbf{K}_1$ *and* $\mathbf{K}_2$ *be Killing tensors in standard form. Then*

$$[\hat H_{\mathbf{K}_1},\hat H]=0,\quad [\hat H_{\mathbf{K}_2},\hat H]=0\Rightarrow[\hat H_{\mathbf{K}_1},\hat H_{\mathbf{K}_2}]=0.$$

Proof: This implication is similar to (5.19) of Proposition 5.9. The proof follows the same pattern. ■

Propositions similar to Propositions 5.10 and 5.11 hold.

Proposition 8.9: Let $\mathcal{H}=(\mathcal{K},V)$ *be the space of quadratic first integrals in involution associated with the separation of the Hamilton–Jacobi equation. Then the following conditions are equivalent:*

$$[\hat H_{\mathbf{K}},\hat H]=0,\quad \forall\mathbf{K}\in\mathcal{K},$$

$$\delta(\mathbf{K}'\mathbf{R}-\mathbf{R}\mathbf{K}')=0,\quad \forall\mathbf{K}\in\mathcal{K},\tag{8.14}$$

$$\partial_a R_{ab}-\Gamma_a R_{ab}=0,\quad (a\neq b\ \text{ n.s.}).$$

Proof: We apply the equivalence of the first and last conditions (8.9) in Theorem 8.6. Since $H_{\mathbf{K}}$ are first integrals, the commutation relation $[\hat H_{\mathbf{K}},\hat H]=0$ is equivalent to $\delta\mathbf{C}=0$ with $\mathbf{C}=\mathbf{K}\mathbf{D}-\mathbf{D}\mathbf{K}=\mathbf{K}'\mathbf{D}-\mathbf{D}\mathbf{K}'$ and $\mathbf{D}=(\partial_i\Gamma_j)$. If we consider $\mathbf{C}=\mathbf{K}'\mathbf{D}-\mathbf{D}\mathbf{K}'$ then only the components $D_{ab}=\partial_a\Gamma_b$ with $a\neq b$ are involved and, since the coordinates are separable, we can replace $\mathbf{D}$ by $\frac{2}{3}\mathbf{R}$, because of (8.13) and (6.4). This proves the equivalence of the first two conditions (8.14). On the other hand, due to Remark 7.5 and (6.4), in the equivalence (7.13) we can replace $\partial_a\Gamma_b$ by R_{ab}, since only the indices $a\neq b$ are involved. This proves the equivalence between $\delta\mathbf{C}=0$ and the last condition (8.14). ■

Proposition 8.10: Let $\mathcal{H}=(\mathcal{K},V)$ *be the space of quadratic first integrals in involution associated with the separation of the Hamilton–Jacobi equation. Then the following conditions are equivalent:*

$$[\hat H_{\mathbf{K}_1},\hat H_{\mathbf{K}_2}]=0,\quad \forall\mathbf{K}_1,\mathbf{K}_2,\in\mathcal{K},$$

$$\delta(\mathbf{K}_1'\mathbf{R}\mathbf{K}_2'-\mathbf{K}_2'\mathbf{R}\mathbf{K}_1')=0,\quad \forall\mathbf{K}_1,\mathbf{K}_2,\in\mathcal{K},\tag{8.15}$$

$$\partial_a R_{ab}-\Gamma_a R_{ab}=0,\quad a\neq b.$$

The proof is similar to that of Proposition 5.11. The last condition (8.15) also appears in (8.14). Thus all these conditions are equivalent. For proving Theorem 6.1 it remains to prove that

$$\delta(\mathbf{K}'\mathbf{R}-\mathbf{R}\mathbf{K}')=\delta(\mathbf{K}\mathbf{R}-\mathbf{R}\mathbf{K})\tag{8.16}$$

and

$$\delta(\mathbf{K}_1'\mathbf{R}\mathbf{K}_2'-\mathbf{K}_2'\mathbf{R}\mathbf{K}_1')=\delta(\mathbf{K}_1\mathbf{R}\mathbf{K}_2-\mathbf{K}_2\mathbf{R}\mathbf{K}_1). \tag{8.17}$$

These equalities can be proved by the following general considerations on the tensors in *prestandard form*. We say that a contravariant two-tensor $\mathbf{T}=(T^{ij})$ has a prestandard form with respect to a standard coordinate system $(q^i)=(q^a,q^\alpha)$ if $T^{a\alpha}=T^{\alpha a}=0$ and all the remaining components do not depend on the ignorable coordinates (q^α).

Proposition 8.11: For a tensor in prestandard form $\nabla_i T^{i\alpha}=0$.

Proof: Since (q^α) are ignorable, $\partial_i T^{i\alpha}=\partial_a T^{a\alpha}=0$ and we have

$$\nabla_i T^{i\alpha}=\partial_i T^{i\alpha}+\Gamma^i_{il}T^{l\alpha}+\Gamma^\alpha_{il}T^{il}=\Gamma^i_{i\beta}T^{\beta\alpha}+\Gamma^\alpha_{il}T^{il}.$$

However, in standard coordinates $\Gamma^i_{i\beta}=0$ and Γ^α_{il} are all vanishing except for $(i,l)=(a,\beta)$ or (β,a). ■

Proposition 8.12: If $\mathbf{T}_1$ *and* $\mathbf{T}_2$ *are in prestandard form, then also the commutator* $\mathbf{C}=\mathbf{T}_1\mathbf{T}_2-\mathbf{T}_2\mathbf{T}_1$ *is in prestandard form.*

Proof: By definition of commutator,

$$C^{ij}=T_1^{il}g_{lm}T_2^{mj}-T_2^{il}g_{lm}T_1^{mj}=T_1^{ic}g_{cd}T_2^{dj}+T_1^{i\mu}g_{\mu\nu}T_2^{\nu j}-T_2^{ic}g_{cd}T_1^{dj}-T_2^{i\mu}g_{\mu\nu}T_1^{\nu j},$$

so that

$$C^{ab}=T_1^{ac}g_{cd}T_2^{db}-T_2^{ac}g_{cd}T_1^{db}=T_1^{ac}g_{cc}T_2^{cb}-T_2^{ac}g_{cc}T_1^{cb},$$

$$C^{a\alpha}=C^{\alpha a}=0, \tag{8.18}$$

$$C^{\alpha\beta}=T_1^{\alpha\mu}g_{\mu\nu}T_2^{\nu\beta}-T_2^{\alpha\mu}g_{\mu\nu}T_1^{\nu\beta}.$$

■

For a tensor in a prestandard form let us use the decomposition

$$\mathbf{T}=\mathbf{T}'+\mathbf{T}''=T^{ab}\partial_a\otimes\partial_b+T^{\alpha\beta}\partial_\alpha\otimes\partial_\beta.$$

By setting $T_1^{\alpha\beta}=0$ or $T_2^{\alpha\beta}=0$ in (8.18) we get

$$\mathbf{T}_1'\mathbf{T}_2-\mathbf{T}_2\mathbf{T}_1'=\mathbf{T}_1\mathbf{T}_2'-\mathbf{T}_2'\mathbf{T}_1=\mathbf{T}_1'\mathbf{T}_2'-\mathbf{T}_2'\mathbf{T}_1'=\mathbf{C}'.$$

Proposition 8.13: If $\mathbf{C}$ *is a skew-symmetric tensor in prestandard form then* $\delta\mathbf{C}=\delta\mathbf{C}'$.

Proof: Since also $\mathbf{C}'$ is in prestandard form, due to Proposition 8.11 we have $\nabla_i C^{i\alpha}=\nabla_i C'^{i\alpha}=0$. Moreover, $\nabla_i C^{ia}=\partial_i C^{ia}+\Gamma^i_{il}C^{la}+\Gamma^a_{il}C^{il}=\partial_b C^{ba}+\Gamma^i_{ib}C^{ba}$, since $\Gamma^i_{i\alpha}=0$, $\Gamma^a_{il}=\Gamma^a_{li}$ and $C^{il}=-C^{li}$. In this last expression the components $C^{\alpha\beta}$ are not involved. Thus, $\nabla_i C^{ia}=\nabla_i C'^{ia}$. ■

Proposition 8.14: If $\mathbf{T}_1$ *and* $\mathbf{T}_2$ *are symmetric tensors in prestandard form, then*

$$\delta(\mathbf{T}_1'\mathbf{T}_2-\mathbf{T}_2\mathbf{T}_1')=\delta(\mathbf{T}_1\mathbf{T}_2-\mathbf{T}_2\mathbf{T}_1).$$

Proof: The commutator $\mathbf{C}=\mathbf{T}_1\mathbf{T}_2-\mathbf{T}_2\mathbf{T}_1$ is skew-symmetric and in prestandard form (Proposition 8.12). The same for $\mathbf{T}_1'\mathbf{T}_2-\mathbf{T}_2\mathbf{T}_1'=\mathbf{C}'$. Then we apply Proposition 8.13. ■

For $\mathbf{T}_1=\mathbf{K}$ (which is in standard form) and $\mathbf{T}_2=\mathbf{R}$ (which is in prestandard form) we get (8.16).

Proposition 8.15: If $\mathbf{T}$, $\mathbf{T}_1$, *and* $\mathbf{T}_2$ *are symmetric tensors in prestandard form, then*

$$\delta(\mathbf{T}_1'\mathbf{T}\mathbf{T}_2'-\mathbf{T}_2'\mathbf{T}\mathbf{T}_1')=\delta(\mathbf{T}_1\mathbf{T}\mathbf{T}_2-\mathbf{T}_2\mathbf{T}\mathbf{T}_1).$$

Proof: The components of $\mathbf{C}=\mathbf{T}_1\mathbf{T}\mathbf{T}_2-\mathbf{T}_2\mathbf{T}\mathbf{T}_1$ are

$$C^{ij}=T_1^{il}T_{lm}T_2^{mj}-T_2^{il}T_{lm}T_1^{mj}=T_1^{ic}T_{cd}T_2^{dj}+T_1^{i\mu}T_{\mu\nu}T_2^{\nu j}-T_2^{ic}T_{cd}T_1^{dj}-T_2^{i\mu}T_{\mu\nu}T_1^{\nu j},$$

so that

$$C^{ab}=T_1^{ac}T_{cd}T_2^{db}-T_2^{ac}T_{cd}T_1^{db},$$

$$C^{a\alpha}=C^{\alpha a}=0,$$

$$C^{\alpha\beta}=T_1^{\alpha\mu}T_{\mu\nu}T_2^{\nu\beta}-T_2^{\alpha\mu}T_{\mu\nu}T_1^{\nu\beta}.$$

This shows that $\mathbf{C}$ is skew-symmetric and in prestandard form. By setting $T_1^{\alpha\beta}=T_2^{\alpha\beta}=0$ we get $C^{\alpha\beta}=0$. This shows that $\mathbf{T}_1'\mathbf{T}\mathbf{T}_2'-\mathbf{T}_2'\mathbf{T}\mathbf{T}_1'=\mathbf{C}'$. Then we apply Proposition 8.13. ■

For $\mathbf{T}_1=\mathbf{K}_1$, $\mathbf{T}_2=\mathbf{K}_2$, and $\mathbf{T}=\mathbf{R}$ we get (8.17). This completes the proof of Theorem 6.1.

IX. FINAL REMARKS

In this paper we have considered the symmetry operators corresponding to the separation of the Schrödinger equation, but deeper and wider research on this topic still has to be done. Indeed, we have not included here a revisitation of the *R*-separation, leading to a different development of the separation of variables for both Schrödinger and Hamilton–Jacobi equations. This will be the subject of a future paper. A further topic to be investigated is the link between the commutation relations of second-order polynomial observables $H_{\mathbf{K}}$ and the associated second-order operators $\hat{H}_{\mathbf{K}}$, for generic two-tensors $\mathbf{K}$ on Riemannian manifolds. This matter is concerned mainly with integrability of systems with quadratic first integrals, and the separability appears only as a special case.

(Received 12 July 2002; accepted 17 July 2002)

The energy-based stochastic extension of the Schrödinger equation is a rather special nonlinear stochastic differential equation on Hilbert space, involving a single free parameter, that has been shown to be very useful for modeling the phenomenon of quantum state reduction. Here we construct a general closed form solution to this equation, for any given initial condition, in terms of a random variable representing the terminal value of the energy and an independent Brownian motion. The solution is essentially algebraic in character, involving no integration, and is thus suitable as a basis for efficient simulation studies of state reduction in complex systems. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1512975]

The standard energy-based stochastic extension of the Schrödinger equation is given by the following stochastic differential equation:

$$\mathrm{d}|\psi_t\rangle = -\mathrm{i}\hat{H}|\psi_t\rangle \mathrm{d}t - \tfrac{1}{8}\sigma^2(\hat{H}-H_t)^2|\psi_t\rangle \mathrm{d}t + \tfrac{1}{2}\sigma(\hat{H}-H_t)|\psi_t\rangle \mathrm{d}W_t, \tag{1}$$

with initial condition $|\psi_0\rangle$. Here $|\psi_t\rangle$ is the state vector at time t, $\hat{H}$ is the Hamiltonian operator, W_t denotes a one-dimensional Brownian motion, and

$$H_t = \frac{\langle\psi_t|\hat{H}|\psi_t\rangle}{\langle\psi_t|\psi_t\rangle} \tag{2}$$

is the expectation of $\hat{H}$ in the state $|\psi_t\rangle$. The parameter σ, which has the units $\sigma \sim [\text{energy}]^{-1}[\text{time}]^{-1/2}$, governs the characteristic timescale τ_R associated with the collapse of the wave function induced by (1). This is given by $\tau_R = 1/\sigma^2 V_0$, where V_0 is the initial value of the squared energy uncertainty, which at time t is

$$V_t = \frac{\langle\psi_t|(\hat{H}-H_t)^2|\psi_t\rangle}{\langle\psi_t|\psi_t\rangle}. \tag{3}$$

The stochastic equation (1) is perhaps the simplest known dynamic model for state reduction in quantum mechanics consistent with both the Born probability rules and the principle of energy conservation. Although the mathematical and phenomenological properties of (1) have been studied extensively,[1–4] it has hitherto been necessary to resort to numerical methods to solve dynamical equations of this type,[5] and exact solutions have been unavailable except in very simple cases. The purpose of this article is to present a general analytic solution for the dynamics of $|\psi_t\rangle$.

We begin with a brief overview of the stochastic framework implicit in the extended Schrödinger dynamics given by Eq. (1), following a line of argument developed in Ref. 4. Specifically,

a)Electronic mail: dorje@ic.ac.uk
b)Electronic mail: lane.hughston@kcl.ac.uk

we introduce the key notions of filtration, conditional expectation, martingale, and supermartingale, and show how these concepts can be used effectively to characterize the reductive properties of (1). We then proceed to establish, by novel use of a *nonlinear filtering* technique, that the energy expectation process (2) can be expressed as the conditional expectation of a random variable representing the terminal value of the energy. As a consequence, we are led to simple analytic expressions for the energy (20) and the state vector (33) in terms of a pair of independent state variables. These results open up the possibility of efficiently simulating the reduction process for a variety of models. Finally, we illustrate the practical advantages of our method by analyzing the timescale associated with the reduction process in the case of a two-state system.

The dynamics of $|\psi_t\rangle$ are defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with filtration $\{\mathcal{F}_t\}$ $(0 \leqslant t < \infty)$. Here Ω is the sample space over which $\mathcal{F}$ is a σ-field of open sets upon which the probability measure $\mathbb{P}$ is defined.

The filtration determines for each $t \geqslant 0$ the information available at that time. More specifically, the filtration consists of a family $\{\mathcal{F}_t\}$ of σ-subfields of $\mathcal{F}$ such that $s \leqslant t$ implies $\mathcal{F}_s \subset \mathcal{F}_t$. Given a random variable X on $(\Omega, \mathcal{F}, \mathbb{P})$, we write $\mathbb{E}[X|\mathcal{F}_t]$ for the *conditional expectation* of X with respect to the σ-subfield $\mathcal{F}_t \subset \mathcal{F}$. Intuitively, conditioning with respect to $\mathcal{F}_t$ means giving all the information available up to time t. The nesting $\mathcal{F}_s \subset \mathcal{F}_t$ for $s \leqslant t$ thus embodies a notion of causality. For convenience, we use the abbreviation $\mathbb{E}_t[X] = \mathbb{E}[X|\mathcal{F}_t]$, and we note that the conditional expectation satisfies the tower property $\mathbb{E}_s[\mathbb{E}_t[X]] = \mathbb{E}_s[X]$ for $s \leqslant t$. If $\mathbb{E}_t[X] = X$, we say that X is $\mathcal{F}_t$*-measurable*.

The conditional expectation operation allows us to introduce the concept of a martingale, the stochastic analog of a conserved quantity. A process X_t is said to be an $\{\mathcal{F}_t\}$*-martingale* if $\mathbb{E}[|X_t|] < \infty$ and $\mathbb{E}_s[X_t] = X_s$ for all $0 \leqslant s \leqslant t < \infty$. In other words, X_t is an $\{\mathcal{F}_t\}$-martingale if it is integrable and if its conditional expectation, given information up to time s, is the value X_s of the process at that time.

For a concise mathematical representation of the state reduction process, we also require the concept of a supermartingale. A process X_t is an $\{\mathcal{F}_t\}$*-supermartingale* if $\mathbb{E}[|X_t|] < \infty$ and $\mathbb{E}_s[X_t] \leqslant X_s$ for all $0 \leqslant s \leqslant t < \infty$. Intuitively, a supermartingale is on average a nonincreasing process.

The filtration $\{\mathcal{F}_t\}$ with respect to which the state vector $|\psi_t\rangle$ evolves is generated in a standard way by the Wiener process W_t. We signify this by writing $\{\mathcal{F}_t\} = \{\mathcal{F}_t^W\}$. It is straightforward to verify that the energy process H_t is an $\{\mathcal{F}_t^W\}$-martingale, and that the variance process V_t is an $\{\mathcal{F}_t^W\}$-supermartingale. That is to say,

$$\mathbb{E}_s[H_t] = H_s, \tag{4}$$

and

$$\mathbb{E}_s[V_t] \leqslant V_s. \tag{5}$$

These relations can be deduced by applying Ito's lemma to (2) and (3), from which we infer that

$$\mathrm{d}H_t = \sigma V_t \mathrm{d}W_t, \tag{6}$$

and that

$$\mathrm{d}V_t = -\sigma^2 V_t^2 \mathrm{d}t + \sigma \beta_t \mathrm{d}W_t, \tag{7}$$

where

$$\beta_t = \frac{\langle \psi_t | (\hat{H} - H_t)^3 | \psi_t \rangle}{\langle \psi_t | \psi_t \rangle} \tag{8}$$

is the *skewness* of the energy distribution at time t. The fact that (6) has no drift shows that H_t is a martingale, and the fact that the drift in (7) is negative shows that V_t is a supermartingale.

In the case of the ordinary Schrödinger equation with a time-independent Hamiltonian, the energy process (2) is constant. This is usually interpreted as the quantum mechanical expression of an energy conservation law. However, if a system is in an indefinite state of energy, then it is not immediately evident what is meant by energy conservation. The martingale condition $\mathbb{E}_s[H_t] = H_s$ can be interpreted as a *generalized energy conservation law* applicable if a system is in an indefinite state of energy. In particular, it implies that once state reduction has occurred, the probabilistic average of the outcome for the energy must equal the initial expectation.

The supermartingale property satisfied by V_t is the essence of what is meant by a *reduction process*. In fact, it follows from Eq. (7) that the asymptotic behavior of V_t is given by

$$\lim_{t\to\infty} \mathbb{E}[V_t] = 0, \tag{9}$$

which signifies the collapse of the wave function. A positive supermartingale with the property that its expectation vanishes in the limit as t goes to infinity is called a *potential* process. Writing H_∞ for the random terminal value of the energy, one can then prove as a consequence of (6) and (7) that

$$H_t = \mathbb{E}_t[H_\infty] \tag{10}$$

and that

$$V_t = \mathbb{E}_t[(H_\infty - H_t)^2]. \tag{11}$$

That is to say, the processes H_t and V_t are respectively the $\mathcal{F}_t^W$-conditional mean and variance of H_∞.

With these facts in hand, we now present a method for solving the stochastic equation (1). Our approach is based on the theory of nonlinear filtering.[6] Filtering techniques have been shown to be useful in quantum optics in connection with the theory of continuous observations, and in some situations phenomenological equations similar to (1) for the *a posteriori* dynamics of a continuously observed system can be derived.[7] We shall, however, regard the dynamics of $|\psi_t\rangle$ as being given, and use the filtering methodology with a different end in view: namely, to construct the *solution* of (1).

The setup is as follows. We denote by E_i $(i=1,2,...)$ the eigenvalues of the Hamiltonian of a given quantum system, and write

$$\pi_i = \frac{|\langle \psi_0|\psi_i\rangle|^2}{\langle \psi_0|\psi_0\rangle\langle \psi_i|\psi_i\rangle} \tag{12}$$

for the transition probability from the given initial state $|\psi_0\rangle$ to the eigenstate $|\psi_i\rangle$ with energy E_i. If the spectrum of $\hat{H}$ is degenerate, then $|\psi_i\rangle$ denotes the Lüders state, i.e., the projection of $|\psi_0\rangle$ onto the linear subspace of states corresponding to the eigenvalue E_i.

Now let the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ be given, and on it specify a random variable H that takes the values E_i with probabilities π_i. We assume that $(\Omega, \mathcal{F}, \mathbb{P})$ comes equipped with a filtration $\{\mathcal{G}_t\}$ with respect to which a standard Brownian motion B_t is specified, and that H and B_t are *independent*. We assign no *a priori* physical significance to H and B_t, which are introduced here simply as an ansatz for obtaining a solution for (1). Next we define the process

$$\xi_t = \sigma H t + B_t. \tag{13}$$

Intuitively, we can think of ξ_t as giving us a ''noisy'' representation of the information encoded in the random variable H.

We let $\{\mathcal{F}_t^\xi\}$ denote the filtration generated by the process ξ_t, i.e., the information generated by ξ_t as time progresses, and consider the conditional expectation

$$H_t = \mathbb{E}[H|\mathcal{F}_t^{\xi}]. \tag{14}$$

Clearly, $\mathcal{F}_t^{\xi} \subset \mathcal{G}_t$ since knowledge of H together with the path $\{B_s\}_{0\leqslant s\leqslant t}$ implies knowledge of the path $\{\xi_s\}_{0\leqslant s\leqslant t}$, although the converse is not the case.

It follows from the tower property that H_t is an $\{\mathcal{F}_t^{\xi}\}$-martingale. One can think of H_t as representing an estimate for the value of H given the history of the process ξ_s from time 0 up to time t. More precisely, an $\{\mathcal{F}_t^{\xi}\}$-measurable random variable H_t minimizes the expectation of the squared deviation of H from H_t, given the history of ξ_s from time 0 to time t, if and only if (14) holds. This can be seen by varying the expression $\mathbb{E}[(H-H_t)^2|\mathcal{F}_t^{\xi}]$ with respect to H_t.

We shall now establish the remarkable fact that the *process H_t defined by (14) is statistically indistinguishable from the energy process (2) associated with the stochastic extension of the Schrödinger equation (1).*

The argument goes as follows. First, because ξ_t is a Markov process satisfying

$$\lim_{t\to\infty} t^{-1}\xi_t = \sigma H, \tag{15}$$

we can replace (14) with the simpler relation $H_t = \mathbb{E}[H|\xi_t]$. In other words, to determine the conditional expectation of H given the path $\{\xi_s\}_{0\leqslant s\leqslant t}$, it suffices to condition on the value ξ_t of the process at the end of the path.

To calculate $\mathbb{E}[H|\xi_t]$, we require a version of the Bayes formula applicable when we consider the probability of a discrete random variable conditioned on the value of a continuous random variable. This is given by

$$\mathbb{P}(H=E_i|\xi_t) = \frac{\pi_i \rho(\xi_t|H=E_i)}{\Sigma_i \pi_i \rho(\xi_t|H=E_i)}, \tag{16}$$

where

$$\pi_i = \mathbb{P}(H=E_i). \tag{17}$$

Here $\rho(\xi_t|H=E_i)$ denotes the conditional probability density for the continuous random variable ξ_t given that $H=E_i$. Since B_t is a standard Brownian motion, the conditional density for ξ_t is

$$\rho(\xi_t|H=E_i) = \frac{1}{\sqrt{2\pi t}} \exp\left(-\frac{1}{2t}(\xi_t - \sigma E_i t)^2\right). \tag{18}$$

It follows from the Bayes law (16) that the conditional probability for the random variable H is

$$\mathbb{P}(H=E_i|\xi_t) = \frac{\pi_i \exp(\sigma E_i \xi_t - \frac{1}{2}\sigma^2 E_i^2 t)}{\Sigma_i \pi_i \exp(\sigma E_i \xi_t - \frac{1}{2}\sigma^2 E_i^2 t)}. \tag{19}$$

Therefore, multiplying each side of (19) by E_i and summing over i, we deduce that the conditional expectation of the random variable H given ξ_t is

$$H_t = \frac{\Sigma_i \pi_i E_i \exp(\sigma E_i \xi_t - \frac{1}{2}\sigma^2 E_i^2 t)}{\Sigma_i \pi_i \exp(\sigma E_i \xi_t - \frac{1}{2}\sigma^2 E_i^2 t)}. \tag{20}$$

In order to show that H_t is the energy process associated with (1), one further key result is required: namely, that *the process W_t defined by*

$$W_t = \xi_t - \sigma \int_0^t H_s \, \mathrm{d}s \tag{21}$$

is an $\{\mathcal{F}_t^\xi\}$*-Brownian motion*. To verify this, it suffices, by virtue of Lévy's characterization of Brownian motion,[6] to demonstrate (a) that $(\mathrm{d}W_t)^2=\mathrm{d}t$ and (b) that W_t is an $\{\mathcal{F}_t^\xi\}$-martingale. To verify (a) we note that (13) implies

$$\mathrm{d}\xi_t=\sigma H\mathrm{d}t+\mathrm{d}B_t, \tag{22}$$

and thus $(\mathrm{d}\xi_t)^2=\mathrm{d}t$. On the other hand, (21) implies that $\mathrm{d}W_t=\mathrm{d}\xi_t-\sigma H_t\mathrm{d}t$, and hence $(\mathrm{d}W_t)^2=(\mathrm{d}\xi_t)^2$. To establish (b), let (20) define a function $H(\xi,t)$ of two variables such that $H_t=H(\xi_t,t)$:

$$H(\xi,t)=\frac{\Sigma_i\pi_iE_i\exp(\sigma E_i\xi-\frac{1}{2}\sigma^2E_i^2t)}{\Sigma_i\pi_i\exp(\sigma E_i\xi-\frac{1}{2}\sigma^2E_i^2t)}. \tag{23}$$

Then applying Ito's lemma and using the relation $(\mathrm{d}\xi_t)^2=\mathrm{d}t$, we obtain

$$\mathrm{d}H_t=(\partial_tH(\xi_t,t)+\tfrac{1}{2}\partial_\xi^2H(\xi_t,t))\mathrm{d}t+\partial_\xi H(\xi_t,t)\mathrm{d}\xi_t, \tag{24}$$

where $\partial_tH(\xi_t,t)$ denotes $\partial H(\xi,t)/\partial t$ valued at $\xi=\xi_t$, and so on. A calculation making use of (21), (23), and (24) then shows that

$$\mathrm{d}H_t=\sigma V(\xi_t,t)\mathrm{d}W_t, \tag{25}$$

where the function $V(\xi,t)$ is

$$V(\xi,t)=\frac{\Sigma_i\pi_i(E_i-H(\xi,t))^2\exp(\sigma E_i\xi-\frac{1}{2}\sigma^2E_i^2t)}{\Sigma_i\pi_i\exp(\sigma E_i\xi-\frac{1}{2}\sigma^2E_i^2t)}. \tag{26}$$

Because H_t is an $\{\mathcal{F}_t^\xi\}$-martingale, we conclude that W_t is also an $\{\mathcal{F}_t^\xi\}$-martingale, and that establishes (b). We thus deduce that W_t is an $\{\mathcal{F}_t^\xi\}$-Brownian motion, with respect to which ξ_t is a diffusion process satisfying

$$\mathrm{d}\xi_t=\sigma H(\xi_t,t)\mathrm{d}t+\mathrm{d}W_t. \tag{27}$$

Now let $|\psi_0\rangle$ be the initial normalized state vector of the quantum system, and let $\hat{P}_i$ denote for each value of i the projection operator onto the Hilbert subspace corresponding to the energy eigenvalue E_i. We let

$$|\psi_i\rangle=\pi_i^{-1/2}\hat{P}_i|\psi_0\rangle \tag{28}$$

denote the Lüders state corresponding to E_i, and write

$$\Pi_{it}=\mathbb{P}(H=E_i|\xi_t) \tag{29}$$

for the process defined by (19). Then we can establish our main result, that

$$|\psi_t\rangle=\sum_i e^{-\mathrm{i}E_it}\Pi_{it}^{1/2}|\psi_i\rangle \tag{30}$$

satisfies the stochastic extension of the Schrödinger equation (1) with the given initial condition. In particular, by applying Ito's lemma to (19) and using (27) we obtain

$$\mathrm{d}\Pi_{it}=\sigma(E_i-H_t)\Pi_{it}\mathrm{d}W_t. \tag{31}$$

With another application of Ito's lemma we deduce that

$$d\Pi_{it}^{1/2} = -\tfrac{1}{8}\sigma^2(E_i - H_t)^2\Pi_{it}^{1/2}dt + \tfrac{1}{2}\sigma(E_i - H_t)\Pi_{it}^{1/2}dW_t. \tag{32}$$

A short calculation then shows that (30) satisfies the stochastic equation (1), and that the expectation of the operator $\hat{H}$ in the state $|\psi_t\rangle$ is the process (20).

In summary, the stochastic equation (1) can be solved as follows. We let H be a random variable taking the values E_i with the probabilities π_i defined by (12). Letting B_t denote an independent Brownian motion, we define ξ_t as in (13). The solution of (1) is then given by

$$|\psi_t\rangle = \frac{\Sigma_i \sqrt{\pi_i}\exp(-iE_it + \frac{1}{2}\sigma E_i\xi_t - \frac{1}{4}\sigma^2E_i^2t)|\psi_i\rangle}{(\Sigma_i \pi_i \exp(\sigma E_i\xi_t - \frac{1}{2}\sigma^2E_i^2t))^{1/2}}, \tag{33}$$

where the $\{\mathcal{F}_t^\xi\}$-Brownian motion W_t driving $|\psi_t\rangle$ in (1) is given by (21). Expression (20) for H_t follows at once from (33) since $\langle\psi_i|\hat{H}|\psi_j\rangle = E_i\delta_{ij}$, and for the variance of the energy we deduce that $V_t = V(\xi_t, t)$. To obtain a realization of the process $|\psi_t\rangle$, i.e., to carry out a simulation, we simply choose a value for H in accordance with the given probability law, and then let B_t run its course.

The fact that (20) is indeed a reduction process can be verified directly as follows. Suppose, in a particular realization of the process H_t, the random variable H takes the value E_j for some choice of the index j. Writing $\omega_{ij} = E_i - E_j$ and seting $\xi_t = \sigma E_j t + B_t$, we obtain

$$H_t = \frac{\pi_jE_j + \Sigma_{i(\neq j)}\pi_iE_i\exp(\sigma\omega_{ij}B_t - \frac{1}{2}\sigma^2\omega_{ij}^2t)}{\pi_j + \Sigma_{i(\neq j)}\pi_i\exp(\sigma\omega_{ij}B_t - \frac{1}{2}\sigma^2\omega_{ij}^2t)}, \tag{34}$$

for the corresponding realization of H_t. However, the exponential martingale M_{ijt} defined for $i \neq j$ by

$$M_{ijt} = \exp(\sigma\omega_{ij}B_t - \tfrac{1}{2}\sigma^2\omega_{ij}^2t) \tag{35}$$

that appears in expression (34) has the property

$$\lim_{t\to\infty} \mathbb{P}(M_{ijt} > 0) = 0. \tag{36}$$

Given that

$$H_t = \frac{\pi_jE_j + \Sigma_{i(\neq j)}\pi_iE_iM_{ijt}}{\pi_j + \Sigma_{i(\neq j)}\pi_iM_{ijt}}, \tag{37}$$

we see that H_t converges to the value E_j with probability one. A similar argument shows that if $H = E_j$, then for each value of i we have $\lim_{t\to\infty}\Pi_{it} = 0$ unless $i = j$, which allows us to verify that $|\psi_t\rangle$ converges to the Lüders state corresponding to the energy eigenvalue E_j with probability one.[4]

Therefore, we see that the random variable H can be identified with the terminal value H_∞ of the energy process. The fact that H is not $\mathcal{F}_t^W$-measurable for $t < \infty$ indicates that the "true value" of H is "hidden" until the reduction process is complete. On a related point we note that in stochastic models for state reduction it is sometimes assumed that the driving process W_t is in some way "external" to the quantum system. This assumption, however, is unnecessary: the filtrations associated with W_t, ξ_t, H_t, and $|\psi_t\rangle$ all coincide, and it is thus consistent to regard the innovation process W_t as being endogenous.

The advantage of expressions (20) and (33) from a computational point of view is that H_t and $|\psi_t\rangle$ are expressed *algebraically* in terms of the underlying random variable H and the Brownian motion B_t. These quantities can be thought of as representing independent *state variables* for the

reduction dynamics. As a consequence, we are able to investigate properties of the process (1) directly without having to resort to numerical integration. In particular, by use of (33), a numerical simulation of the state reduction of complex systems is feasible, including cases for which the Hamiltonian has a nondiscrete spectrum. It should be emphasized that in our simulation methodology there is no need at any stage for the introduction of a change of probability measure.

In conclusion we present a probabilistic analysis of the timescale associated with the reduction process, in the case of a two-state system with energies E_1 and E_2. The initial state is given by $|\psi_0\rangle$, and the transition probabilities to the energy eigenstates $|E_1\rangle$ and $|E_2\rangle$ are given by π_1 and π_2.

Suppose a measurement of the energy is made, and we condition on the outcome of the measurement being E_1. In that case, according to (37), we have

$$H_t=\frac{\pi_1 E_1+\pi_2 E_2 M_{21t}}{\pi_1+\pi_2 M_{21t}}, \tag{38}$$

where

$$M_{21t}=\exp\left(\sigma\omega_{21}B_t-\tfrac{1}{2}\sigma^2\omega_{21}^2 t\right). \tag{39}$$

Writing $\beta=\frac{1}{4}\sigma^2\omega_{21}^2$ for the parameter that determines the characteristic rate of reduction, we can work out the probability that $M_{21t}<e^{-n}$ for some value of n. Since B_t is normally distributed with zero mean and variance t, we find

$$\mathbb{P}(M_{21t}<e^{-n})=N((\beta t)^{1/2}-\tfrac{1}{2}n(\beta t)^{-1/2}), \tag{40}$$

where $N(x)$ is the standard normal distribution function. Therefore, for example, we see that provided $t>5\tau_R$, we have

$$\mathbb{P}(M_{21t}<e^{-10})>\tfrac{1}{2}, \tag{41}$$

where $\tau_R=1/\beta$. In particular, as H_t draws near E_1 we have the relation

$$H_t-E_1\sim\frac{\pi_2}{\pi_1}(E_2-E_1)M_{21t}. \tag{42}$$

Thus, after only a relatively few multiples of the characteristic reduction timescale, the amount by which H_t differs from E_1 will with high probability be reduced to a tiny fraction of the energy difference E_2-E_1.

The Schwinger oscillator operator representation of SU(3) is analyzed with particular reference to the problem of multiplicity of irreducible representations. It is shown that with the use of an $\mathrm{Sp}(2,R)$ unitary representation commuting with the SU(3) representation, the infinity of occurrences of each SU(3) irreducible representation can be handled in complete detail. A natural ''generating representation'' for SU(3), containing each irreducible representation exactly once, is identified within a subspace of the Schwinger construction, and this is shown to be equivalent to an induced representation of SU(3). © *2002 American Institute of Physics.* [DOI: 10.1063/1.1508810]

I. INTRODUCTION

The well known Schwinger representation of the Lie algebra of SU(2),[1] constructed using the annihilation and creation operators of two independent quantum mechanical harmonic oscillators, has played an important role in many widely differing contexts. Within the quantum theory of angular momentum it has made the calculation of various quantities somewhat easier than by other methods. Beyond this, it has been very effectively exploited in the physics of strongly correlated systems,[2] in quantum optics of two mode radiation fields,[3] and in the study of certain classes of partially coherent optical beams,[4] namely to obtain the coherent mode decomposition of anisotropic Gaussian Schell model beams. It arises quite naturally in the context of a classical description of particles with non-Abelian charges[5] and has also been used in a recent investigation of the Pauli spin-statistics theorem.[6]

Bargmann has presented an entire function Hilbert space analog of the Schwinger construction, which is extremely elegant and possesses special merits of its own.[7] This may be viewed as a counterpart to the Fock space description of quantum mechanical oscillator systems.

Certain specially attractive features of the Schwinger SU(2) construction should be mentioned. It leads upon exponentiation to a unitary representation (UR) of SU(2) in which each unitary irreducible representation (UIR), labeled as usual by the spin quantum number j with possible values $0,\frac{1}{2},1,\ldots$, appears exactly once. In other words, it is complete in the sense that no UIR of SU(2) is missed, and also economical in the sense of being multiplicity free. Thus, reflecting these two features, it may be regarded as a ''generating representation'' for SU(2), a concept that has been effectively used in understanding the structures of various kinds of Clebsch–Gordan series for UIRs of the noncompact group SU(1,1).[8] In addition, of course, the use of boson operator methods makes many operator and state vector calculations relatively easy to carry out.

It is of considerable interest to extend the Schwinger construction to other compact Lie groups, the next natural case after SU(2) being SU(3). The aims behind any such attempt would be

[a)]Electronic mail: scsp@uohyd.ernet.in

to preserve the simplicity of the boson calculus, to cover all UIRs of the concerned group, and to do it in a multiplicity free manner.

The case of SU(3) has been studied by several authors since the work of Moshinsky.[9] The aim of the present article is somewhat different from previous studies, being motivated by the particular points of view mentioned above. In particular our aim is to see to what extent the attractive features of the SU(2) construction survive when we consider SU(3), and which ones have to be given up.

A brief overview of this article is as follows. In Sec. II we collect together some relevant facts regarding unitary representations of compact Lie groups with special attention to SU(3). In particular, we highlight the fact that the theory of induced representations leads to a unitary representation of SU(3) which has all the properties becoming of a ''generating representation'' of SU(3) in that it contains all the UIRs of SU(3) exactly once each. The Hilbert space carrying this unitary representation turns out to be the Hilbert space of functions on unit sphere in C^3. In Sec. III, we turn to the Schwinger oscillator construction for SU(3) and show that a naive extension of the Schwinger SU(2)-construction making use of six oscillators leads to a very ''fat'' UR of SU(3) containing each UIR of SU(3) infinitely many times. We then show how the group $\mathrm{Sp}(2,R)$ enables us to completely handle this multiplicity and also neatly isolate from this rather large space a subspace carrying a UR of SU(3) of a ''generating representation'' type. At this stage, we have two ''generating representations'' of SU(3), one based on the Hilbert space of functions on a unit sphere in C^3 and the other based on the Fock space of six oscillators, and a natural question to ask is how the two are related. To this end, in Sec. IV, we make use of the Bargmann representation, to transcribe the Fock space description into a description based on a Hilbert space of square integrable functions in six complex variables satisfying certain conditions. This transcription enables us to establish an equivalence map between the Hilbert spaces supporting the two incarnations of the ''generating representation'' for SU(3), details of which are given in Secs. V and VI. Section VII contains concluding remarks and further outlook, and an appendix gives the details of the construction of $\mathrm{SU}(3)\times\mathrm{Sp}(2,R)$ basis states.

II. UNITARY REPRESENTATIONS OF COMPACT LIE GROUPS, THE SU(3) CASE

It is useful to first recall some basic facts concerning the representation theory of any compact simple Lie group G. The basic building blocks are the UIRs of G. Each UIR carries certain identifying labels (eigenvalues of Casimir operators), such as j for SU(2). It is of a characteristic dimension, such as $2j+1$ for SU(2). In addition, we may set up some convenient orthonormal basis in the space of the UIR, as simultaneous eigenvectors of some complete commuting set of Hermitian operators. The eigenvalue sets labeling the basis vectors are generalizations of the single magnetic quantum number m for SU(2).

A general UR of G is reducible into UIRs, each occurring with some multiplicity. Thus the UR as a whole is in principle completely determined upto equivalence by these multiplicities. However, certain URs have special significance, reflecting the way they are constructed, and so deserve special attention. We consider two cases—the regular representation, and representations induced from various Lie subgroups of G.

The Hilbert space carrying the regular representation of G is the space $L^2(G)$ of all complex square integrable functions on G, the integration being with respect to the (left and right) translation invariant volume element on G. On this space there are in fact two (mutually commuting) regular representations of G, the left and the right regular representations. Upon reduction into UIRs each of these contains every UIR of G without exception, the multiplicity of occurrence of a particular UIR is just its dimension. Thus the regular representations possess the completeness property of the Schwinger SU(2) construction, but not its economy.

Next we look at the family of induced URs of G.[10] Let H be some Lie subgroup of G, and let $D(h)$, $h\in H$, be the operators of a UIR of H on some Hilbert space $\mathcal{V}$. Then a certain unique UR of G, with operators $\mathcal{D}_H^{(\mathrm{ind},D)}(g)$ for $g\in G$, can be constructed. As the labels indicate, this UR is induced from the UIR $D(\cdot)$ of H. The Hilbert space $\mathcal{H}_H^{(\mathrm{ind},D)}$ of this UR consists of functions on

G with values in $\mathcal{V}$ obeying a covariance condition and having finite norm:

$$\psi \in \mathcal{H}_H^{(\mathrm{ind},D)}: \quad \psi(g) \in \mathcal{V}, g \in G,$$
$$\psi(gh) = D(h^{-1})\psi(g), h \in H, \tag{2.1}$$
$$\|\psi\|^2 = \int_G dg\,(\psi(g), \psi(g))_{\mathcal{V}} < \infty.$$

Here dg is the (suitably normalized) invariant volume element on G, and the integrand is the squared norm of $\psi(g) \in \mathcal{V}$. The covariance condition means that $\psi(g)$ is essentially a function on the coset space G/H, in the sense that the ''values'' of $\psi(g)$ all over a coset are determined by its ''value'' at any one representative point. Correspondingly, due to unitarity of $D(h)$, $(\psi(g), \psi(g))_{\mathcal{V}}$ is constant over each coset; so, the expression for $\|\psi\|^2$ can be simplified and expressed in terms of a G-invariant volume element on G/H. The action of $\mathcal{D}_H^{(\mathrm{ind},D)}(g)$ on ψ is then given by

$$g \in G: \mathcal{D}_H^{(\mathrm{ind},D)}(g)\psi = \psi',$$
$$\psi'(g') = \psi(g^{-1}g'). \tag{2.2}$$

It is clear that G action preserves the covariance condition, and we have a UR of G on $\mathcal{H}_H^{(\mathrm{ind},D)}$.

Whereas $D(\cdot)$ was assumed to be a UIR of H, $\mathcal{D}_H^{(\mathrm{ind},D)}(\cdot)$ is in general reducible; so it is a direct sum of the various UIRs of G, each occurring with some multiplicity. These multiplicities are determined by the reciprocity theorem:[10] Each UIR $\mathcal{D}(\cdot)$ of G appears in $\mathcal{D}_H^{(\mathrm{ind},D)}(\cdot)$ as often as $\mathcal{D}(\cdot)$ contains $D(\cdot)$ upon restriction from G to H.

With this general background we now take up the specific case of SU(3). The defining representation of this group is

$$\mathrm{SU}(3) = \{A = 3\times 3 \ \text{ complex matrix} | A^\dagger A = I_{3\times 3}, \det A = 1\}, \tag{2.3}$$

with the group operation given by matrix multiplication. In this representation the eight Hermitian generators are $\frac{1}{2}\lambda_\alpha$, $\alpha = 1,2,\ldots,8$, where the matrices λ_α and the structure constants $f_{\alpha\beta\gamma}$ occurring in the commutation relations

$$[\lambda_\alpha, \lambda_\beta] = 2if_{\alpha\beta\gamma}\lambda_\gamma, \quad \alpha,\beta,\gamma = 1,2,\ldots,8, \tag{2.4}$$

are all very well known.[11]

A general UIR of SU(3) is determined by two independent nonnegative integers p and q, so it may be denoted as (p,q). It is of dimension $d(p,q) = \frac{1}{2}(p+1)(q+1)(p+q+2)$. The defining three-dimensional UIR in (2.3) is (1,0), while the inequivalent complex conjugate UIR is (0,1). In general the complex conjugate of (p,q) is (q,p), and the adjoint UIR is (1,1) of dimension eight. Various choices of ''magnetic quantum numbers'' within a UIR may be made. The one corresponding to the canonical subgroup $\mathrm{SU}(2)\times\mathrm{U}(1)/Z_2 = \mathrm{U}(2) \subset \mathrm{SU}(3)$ leads to the three quantum numbers I, M, Y in standard notation. Here I and M are the isospin and magnetic quantum number labels for a general UIR of SU(2), while Y is the eigenvalue of the (suitably normalized) U(1) or hypercharge generator. The subgroups SU(2) and U(1) commute, and for definiteness we take SU(2) to be the one acting on the first two dimensions of the three dimensions in the UIR (1,0). The spectrum of ''$I-Y$'' multiplets present in the UIR (p,q) can be described thus:

$$I = \tfrac{1}{2}(r+s), \quad Y = r - s + \tfrac{2}{3}(q-p), \quad 0 \leqslant r \leqslant p, \quad 0 \leqslant s \leqslant q. \tag{2.5}$$

Thus for each pair of integers (r,s) in the above ranges, we have one $I-Y$ multiplet, with M going over the usual $2I+1$ values $I, I-1, \ldots, -I+1, -I$. Then the orthonormal basis vectors for the UIR (p,q) of SU(3) may be written as $|p,q;IMY\rangle$. This UIR can be realized via suitably

constructed irreducible tensors. A tensor T with p indices belonging to the UIR (1,0) and q indices to the UIR (0,1) is a collection of complex components $T^{j_1\cdots j_p}_{k_1\cdots k_q}$, j and $k=1,2,3$, transforming under $A\in \mathrm{SU}(3)$ by the rule

$$T'^{j_1\cdots j_p}_{k_1\cdots k_q}=A^{j_1}_{l_1}\cdots A^{j_p}_{l_p}A^{k_1*}_{m_1}\cdots A^{k_q*}_{m_q}T^{l_1\cdots l_p}_{m_1\cdots m_q}. \tag{2.6}$$

If in addition T is completely symmetric separately in the superscripts and in the subscripts, and is traceless, i.e., contraction of any upper index with any lower index leads to zero, then all these properties are maintained under SU(3) action and T is an irreducible tensor. It then has precisely $d(p,q)$ independent components (in the complex sense), and the space of all such tensors carries the UIR (p,q). The explicit transition from the tensor components $T^{j_1\cdots j_p}_{k_1\cdots k_q}$ to the canonical components $T^{(p,q)}_{IMY}$ may be found in Ref. 12

The regular representations of SU(3) act on the space $L^2(\mathrm{SU}(3))$, and in each of them the UIR (p,q) appears $d(p,q)$ times. We shall not be concerned with this UR of SU(3) in our work. Instead we give now the UIR contents of some selected induced URs of SU(3). For illustrative purposes we consider the following four subgroups:

$$\mathrm{U}(1)\times\mathrm{U}(1)=\{A=\mathrm{diag}(e^{i(\theta_1+\theta_2)},e^{i(\theta_1-\theta_2)},e^{-2i\theta_1})\,|\,0\leqslant\theta_1,\theta_2\leqslant 2\pi\}; \tag{2.7a}$$

$$\mathrm{SU}(2)=\left\{A=\begin{pmatrix} a & \mathbf{0}\\ \mathbf{0} & 1\end{pmatrix}\,\middle|\, a\in\mathrm{SU}(2)\right\}; \tag{2.7b}$$

$$\mathrm{U}(2)=\left\{A=\begin{pmatrix} u & \mathbf{0}\\ \mathbf{0} & (\det u)^{-1}\end{pmatrix}\,\middle|\, u\in\mathrm{U}(2)\right\}; \tag{2.7c}$$

$$\mathrm{SO}(3)=\{A\in\mathrm{SU}(3)\,|\,A^*=A\}. \tag{2.7d}$$

In each case, we look at the induced UR of SU(3) arising from the trivial one-dimensional UIR of the subgroup. In the first two cases, in order to apply the reciprocity theorem, we can use the information in (2.5) giving the $\mathrm{SU}(2)\times\mathrm{U}(1)/Z_2$ content of the UIR (p,q) of SU(3). Defining by a zero in the superscript the trivial UIR of the relevant subgroup, we have the results:

$$\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{U}(1)\times\mathrm{U}(1)}=\sum_{\substack{p,q=0,1,\cdots\\ p=q\,\mathrm{mod}3}}^{\infty}\oplus n_{p,q}(p,q),\quad n_{p,q}=\min(p+1,q+1); \tag{2.8a}$$

$$\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}=\sum_{p,q=0,1,\cdots}^{\infty}\oplus(p,q); \tag{2.8b}$$

$$\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{U}(2)}=\sum_{p=0,1,\cdots}^{\infty}\oplus(p,p). \tag{2.8c}$$

The real dimensions of the corresponding coset spaces $\mathrm{SU}(3)/\mathrm{U}(1)\times\mathrm{U}(1)$, $\mathrm{SU}(3)/\mathrm{SU}(2)$ and $\mathrm{SU}(3)/\mathrm{U}(2)$ are 6, 5 and 4, respectively. In the case of induction from the trivial UIR of SO(3), we need to use the fact that the UIR (p,q) of SU(3) does not contain an SO(3) invariant state if either p or q or both are odd, while it contains one such state if both p and q are even. Then we arrive at the reduction

$$\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SO}(3)}=\sum_{r,s=0,1,\cdots}^{\infty}\oplus(2r,2s), \tag{2.9}$$

with $\mathrm{SU}(3)/\mathrm{SO}(3)$ being of real dimension 5.

From the above discussion we see that the induced UR $\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$ of SU(3) is particularly interesting in that it captures both the completeness and the economy properties of the Schwinger SU(2) construction: each UIR of SU(3) is present, exactly once. Thus we may call this a generating representation of SU(3); it is much leaner than the regular representations.

III. THE MINIMAL SU(3) SCHWINGER OSCILLATOR CONSTRUCTION

An elementary oscillator operator construction of the SU(3) generators is based on three independent pairs of annihilation and creation operators $\hat{a}_j$, $\hat{a}_j^\dagger$ obeying

$$[\hat{a}_j,\hat{a}_k^\dagger]=\delta_{jk}, \quad [\hat{a}_j,\hat{a}_k]=[\hat{a}_j^\dagger,\hat{a}_k^\dagger]=0, \quad j,k=1,2,3. \tag{3.1}$$

We write $\mathcal{H}^{(a)}$ for the Hilbert space on which these operators act irreducibly. The individual and total number operators are

$$\hat{N}_1^{(a)}=\hat{a}_1^\dagger\hat{a}_1, \quad \hat{N}_2^{(a)}=\hat{a}_2^\dagger\hat{a}_2, \quad \hat{N}_3^{(a)}=\hat{a}_3^\dagger\hat{a}_3, \quad \hat{N}^{(a)}=\hat{a}_j^\dagger\hat{a}_j. \tag{3.2}$$

If we now define the bilinear operators

$$Q_\alpha^{(a)}=\tfrac{1}{2}\hat{a}^\dagger\lambda_\alpha\hat{a}, \quad \alpha=1,2,\ldots,8, \tag{3.3}$$

each $Q_\alpha^{(a)}$ is Hermitian, and they obey the SU(3) Lie algebra commutation relations

$$[Q_\alpha^{(a)},Q_\beta^{(a)}]=if_{\alpha\beta\gamma}Q_\gamma^{(a)}. \tag{3.4}$$

In addition they conserve the total number operator:

$$[Q_\alpha^{(a)},\hat{N}^{(a)}]=0. \tag{3.5}$$

Upon exponentiation of these generators we obtain a particular UR, $\mathcal{U}^{(a)}(A)$ say, of SU(3) acting on $\mathcal{H}^{(a)}$, under which the creation (annihilation) operators $\hat{a}_j^\dagger$ ($\hat{a}_j$) transform via the UIR (1,0) ((0,1)):

$$\begin{aligned}\mathcal{U}^{(a)}(A)\hat{a}_j^\dagger\mathcal{U}^{(a)}(A)^{-1}&=A_j^k\hat{a}_k^\dagger,\\ \mathcal{U}^{(a)}(A)\hat{a}_j\mathcal{U}^{(a)}(A)^{-1}&=A_j^{k*}\hat{a}_k.\end{aligned} \tag{3.6}$$

However, upon reduction, $\mathcal{U}^{(a)}(A)$ contains only the "triangular" UIRs $(p,0)$ of SU(3), once each. In that sense this UR may be regarded as the "generating representation" for this subset of UIRs. For any given $p\geqslant 0$, the UIR $(p,0)$ is realized on that subspace $\mathcal{H}^{(p,0)}$ of $\mathcal{H}^{(a)}$ over which the total number operator $\hat{N}^{(a)}$ takes the eigenvalue p; and the connection between the tensor and the Fock space descriptions is given in this manner:

$$\begin{gathered}\{T^{j_1\cdots j_p}\}\rightarrow|T\rangle=T^{j_1\cdots j_p}\hat{a}_{j_1}^\dagger\cdots\hat{a}_{j_p}^\dagger|\underline{0}\rangle\in\mathcal{H}^{(p,0)}\subset\mathcal{H}^{(a)},\\ \hat{a}_j|\underline{0}\rangle=0;\\ \mathcal{U}^{(a)}(A)|T\rangle=|T'\rangle,\\ T'^{j_1\cdots j_p}=A_{l_1}^{j_1}\cdots A_{l_p}^{j_p}T^{l_1\cdots l_p}.\end{gathered} \tag{3.7}$$

Therefore we have the (orthogonal) direct sum decompositions

$$\mathcal{H}^{(a)}=\sum_{p=0,1,\cdots}^{\infty}\oplus\mathcal{H}^{(p,0)},$$

$$\mathcal{H}^{(p,0)}=\mathrm{Sp}\{\hat{a}_{j_1}^{\dagger}\cdots\hat{a}_{j_p}^{\dagger}|\underline{0}\rangle\}, \tag{3.8}$$

$$\mathcal{U}^{(a)}=\sum_{p=0,1,\cdots}^{\infty}\oplus(p,0).$$

To be able to obtain the other UIRs as well, we bring in another independent triplet of oscillator operators $\hat{b}_j$ and $\hat{b}_j^{\dagger}$ obeying the same commutation relations (3.1) and commuting with $\hat{a}$'s and $\hat{a}^{\dagger}$'s:

$$\begin{gathered}[\hat{b}_j,\hat{b}_k^{\dagger}]=\delta_{jk},\quad [\hat{b}_j,\hat{b}_k]=[\hat{b}_j^{\dagger},\hat{b}_k^{\dagger}]=0,\quad j,k=1,2,3,\\ [\hat{a}_j\ \text{or}\ \hat{a}_j^{\dagger},\ \hat{b}_k\ \text{or}\ \hat{b}_k^{\dagger}]=0.\end{gathered} \tag{3.9}$$

The corresponding Hilbert space is $\mathcal{H}^{(b)}$, and the b-type number operators are

$$\hat{N}_1^{(b)}=\hat{b}_1^{\dagger}\hat{b}_1,\quad \hat{N}_2^{(b)}=\hat{b}_2^{\dagger}\hat{b}_2,\quad \hat{N}_3^{(b)}=\hat{b}_3^{\dagger}\hat{b}_3,\quad \hat{N}^{(b)}=\hat{b}_j^{\dagger}\hat{b}_j. \tag{3.10}$$

We define the b-type SU(3) generators as

$$Q_{\alpha}^{(b)}=-\tfrac{1}{2}\hat{b}^{\dagger}\lambda_{\alpha}^{*}\hat{b},\quad \alpha=1,2,\ldots,8, \tag{3.11}$$

and they obey

$$\begin{gathered}[Q_{\alpha}^{(b)},Q_{\beta}^{(b)}]=if_{\alpha\beta\gamma}Q_{\gamma}^{(b)},\\ [Q_{\alpha}^{(b)},\hat{N}^{(b)}]=0.\end{gathered} \tag{3.12}$$

Exponentiation of these generators leads to a UR $\mathcal{U}^{(b)}(A)$ acting on $\mathcal{H}^{(b)}$, under which the creation (annihilation) operators $\hat{b}_j^{\dagger}$ ($\hat{b}_j$) transform via the UIR (0,1) ((1,0)):

$$\begin{gathered}\mathcal{U}^{(b)}(A)\hat{b}_j^{\dagger}\mathcal{U}^{(b)}(A)^{-1}=A_j^{k*}\hat{b}_k^{\dagger},\\ \mathcal{U}^{(b)}(A)\hat{b}_j\mathcal{U}^{(b)}(A)^{-1}=A_j^{k}\hat{b}_k.\end{gathered} \tag{3.13}$$

Now this UR of SU(3) contains each of the triangular UIRs $(0,q)$ for $q\geqslant 0$ once each, so it is a generating representation for this family of UIRs. For each $q\geqslant 0$, the UIR $(0,q)$ is realized on that subspace $\mathcal{H}^{(0,q)}$ of $\mathcal{H}^{(b)}$ over which the total number operator $\hat{N}^{(b)}$ takes the eigenvalue q. Analogous to (3.7), the tensor-Fock space connection is now

$$\begin{gathered}\{T_{k_1\cdots k_q}\}\rightarrow|T\rangle=T_{k_1\cdots k_q}\hat{b}_{k_1}^{\dagger}\cdots\hat{b}_{k_q}^{\dagger}|\underline{0}\rangle\in\mathcal{H}^{(0,q)}\subset\mathcal{H}^{(b)},\\ \hat{b}_k|\underline{0}\rangle=0;\\ \mathcal{U}^{(b)}(A)|T\rangle=|T'\rangle,\\ T'_{k_1\cdots k_q}=A_{m_1}^{k_1*}\cdots A_{m_q}^{k_q*}T_{m_1\cdots m_q}.\end{gathered} \tag{3.14}$$

[The use of a common symbol $|\underline{0}\rangle$ for the Fock ground states in $\mathcal{H}^{(a)}$ and $\mathcal{H}^{(b)}$, and $|T\rangle$ in (3.7) and (3.14), should cause no confusion as the meanings are always clear from the context.] In place of (3.8) we now have

$$\mathcal{H}^{(b)}=\sum_{q=0,1,\cdots}^{\infty}\oplus\mathcal{H}^{(0,q)},$$

$$\mathcal{H}^{(0,q)}=\mathrm{Sp}\{\hat{b}_{k_1}^{\dagger}\cdots\hat{b}_{k_q}^{\dagger}|\underline{0}\rangle\}, \tag{3.15}$$

$$\mathcal{U}^{(b)}=\sum_{q=0,1,\cdots}^{\infty}\oplus(0,q).$$

From these considerations it is clear that if we want to obtain all the UIRs (p,q) of SU(3), missing none, the minimal scheme is to use all six independent oscillators $\hat{a}_j$, $\hat{a}_j^{\dagger}$, $\hat{b}_j$, $\hat{b}_j^{\dagger}$ and define the SU(3) generators[13]

$$Q_\alpha=Q_\alpha^{(a)}+Q_\alpha^{(b)}. \tag{3.16}$$

They act on the product Hilbert space $\mathcal{H}=\mathcal{H}^{(a)}\times\mathcal{H}^{(b)}$, of course obey the SU(3) commutation relations, and upon exponentiation lead to the UR $\mathcal{U}(A)=\mathcal{U}^{(a)}(A)\times\mathcal{U}^{(b)}(A)$. However, as we see in a moment, while each UIR (p,q) is certainly present in $\mathcal{U}(A)$, it occurs infinitely many times. A systematic group theoretic procedure to handle this multiplicity, based on the noncompact group $\mathrm{Sp}(2,R)$, will be set up below. The tensor-Fock space connection is now given as follows. To an irreducible tensor $T_{k_1\cdots k_q}^{j_1\cdots j_p}$ which is symmetric and traceless and so "belongs" to the UIR (p,q) we associate the vector $|T\rangle\in\mathcal{H}$ by

$$|T\rangle=T_{k_1\cdots k_q}^{j_1\cdots j_p}\hat{a}_{j_1}^{\dagger}\cdots\hat{a}_{j_p}^{\dagger}\hat{b}_{k_1}^{\dagger}\cdots\hat{b}_{k_q}^{\dagger}|\underline{0},\underline{0}\rangle\in\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}\subset\mathcal{H},$$

$$\hat{a}_j|\underline{0},\underline{0}\rangle=\hat{b}_j|\underline{0},\underline{0}\rangle=0, \tag{3.17}$$

$$\mathcal{U}(A)|T\rangle=|T'\rangle,$$

the components of T' being given by (2.6). While this vector $|T\rangle$ is certainly a simultaneous eigenvector of the two number operators $\hat{N}^{(a)}$, $\hat{N}^{(b)}$ with eigenvalues p, q, respectively, the tracelessness of the tensor $T_{k_1\cdots k_q}^{j_1\cdots j_p}$ implies that (unless at least one of p and q vanishes) we do not get all such independent vectors in $\mathcal{H}$. This aspect is further clarified below. On the other hand, if we drop the tracelessness condition and retain only symmetry, we do span all of $\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$ via (3.17).

The decomposition of $\mathcal{U}(A)$ into UIRs, and the counting of multiplicities, is accomplished by appealing to the Clebsch–Gordan series for the product of two triangular UIRs $(p,0)$ and $(0,q)$:[14]

$$(p,0)\times(0,q)=(p,q)\oplus(p-1,q-1)\oplus(p-2,q-2)\oplus\ldots\oplus(p-r,q-r),\quad r=\min(p,q). \tag{3.18}$$

Therefore, at the Hilbert space level one has the orthogonal subspace decomposition

$$\mathcal{H}=\mathcal{H}^{(a)}\times\mathcal{H}^{(b)}=\left(\sum_{p=0,1,\cdots}^{\infty}\oplus\mathcal{H}^{(p,0)}\right)\times\left(\sum_{q=0,1,\cdots}^{\infty}\oplus\mathcal{H}^{(0,q)}\right)=\sum_{p,q=0,1,\cdots}^{\infty}\oplus\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}, \tag{3.19}$$

$$\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}=\sum_{\rho=0,1,\cdots}^{r}\oplus\mathcal{H}^{(p-\rho,q-\rho;\rho)},\quad r=\min(p,q).$$

Here $\mathcal{H}^{(p-\rho,q-\rho;\rho)}$ is that unique subspace of $\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$ carrying the UIR $(p-\rho,q-\rho)$ present on the right hand side of (3.18). All vectors in $\mathcal{H}^{(p-\rho,q-\rho;\rho)}$ are eigenvectors of $\hat{N}^{(a)}$ and $\hat{N}^{(b)}$ with eigenvalues p and q, respectively; and if the tensor T in (3.17) is assumed traceless, only vectors in $\mathcal{H}^{(p,q;0)}\subset\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$ are obtained on the right in that equation.

Focusing on a given UIR (p,q), we see that it appears once each in $\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)},\mathcal{H}^{(p+1,0)}\times\mathcal{H}^{(0,q+1)},\ldots$, in the respective irreducible subspaces $\mathcal{H}^{(p,q;0)},\mathcal{H}^{(p,q;1)},\ldots$. Thus it is the leading piece in $\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$, the next to the leading piece in $\mathcal{H}^{(p+1,0)}\times\mathcal{H}^{(0,q+1)}$, and so on. Therefore, the decomposition (3.19) of $\mathcal{H}$ can be presented in the alternative manner

$$\mathcal{H}=\sum_{p,q=0,1.\cdots}^{\infty}\ \oplus\ \sum_{\rho=0,1.\cdots}^{\infty}\oplus\mathcal{H}^{(p,q;\rho)},\mathcal{H}^{(p,q;\rho)}\subset\mathcal{H}^{(p+\rho,0)}\times\mathcal{H}^{(0,q+\rho)}, \tag{3.20}$$

each $\mathcal{H}^{(p,q;\rho)}$ carrying the same UIR (p,q). Thus the index ρ is an (orthogonal) multiplicity label with an infinite number of values. For $\rho\neq\rho'$, $\mathcal{H}^{(p,q;\rho')}$ and $\mathcal{H}^{(p,q;\rho)}$ are mutually orthogonal. This is also evident as $\hat{N}^{(a)}=p+\rho'$, $\hat{N}^{(b)}=q+\rho'$ in the former and $\hat{N}^{(a)}=p+\rho$, $\hat{N}^{(b)}=q+\rho$ in the latter.

We now introduce the group Sp(2,R) to handle in a systematic way the multiplicity index ρ. The Hermitian generators of Sp(2,R) and their commutation relations are[15]

$$\begin{gathered}J_0=\tfrac{1}{2}(\hat{N}^{(a)}+\hat{N}^{(b)}+3),\\ K_1=\tfrac{1}{2}(\hat{a}_j^\dagger\hat{b}_j^\dagger+\hat{a}_j\hat{b}_j),\\ K_2=-\frac{i}{2}(\hat{a}_j^\dagger\hat{b}_j^\dagger-\hat{a}_j\hat{b}_j);\end{gathered}\tag{3.21}$$

$$[J_0,K_1]=iK_2,\quad [J_0,K_2]=-iK_1,\quad [K_1,K_2]=-iJ_0.$$

Using the raising and lowering combinations $K_\pm=K_1\pm iK_2$ we have

$$\begin{gathered}K_+=\hat{a}_j^\dagger\hat{b}_j^\dagger,\quad K_-=K_+^\dagger=\hat{a}_j\hat{b}_j;\\ [J_0,K_\pm]=\pm K_\pm,\quad [K_+,K_-]=-2J_0.\end{gathered}\tag{3.22}$$

The significance of this construction is that the two groups SU(3) and Sp(2,R), both acting unitarily on $\mathcal{H}$, commute with one another:

$$[J_0\ \text{ or }\ K_1\ \text{ or }\ K_2,Q_\alpha]=0. \tag{3.23}$$

It is this that helps us handle the multiplicity of occurrences of each SU(3) UIR (p,q) in $\mathcal{H}$:ρ becoming a ''magnetic quantum number'' within a suitable UIR of Sp(2,R).

The family of (infinite dimensional) UIRs of Sp(2,R) relevant here is the positive discrete family $D_k^{(+)}$, labeled by $k=\frac{1}{2},1,\frac{3}{2},2,2\ldots$. (Actually we encounter only $k\geqslant\frac{3}{2}$.) Within the UIR $D_k^{(+)}$ we have an orthonormal basis $|k,m\rangle$ on which the generators act as follows:[16]

$$\begin{gathered}J_0|k,m\rangle=m|k,m\rangle,\quad m=k,k+1,k+2,\ldots,\\ K_\pm|k,m\rangle=\sqrt{(m\pm k)(m\mp k\pm 1)}\,|k,m\pm 1\rangle.\end{gathered}\tag{3.24}$$

From these follow the useful results

$$K_1^2+K_2^2-J_0^2=k(1-k), \tag{3.25a}$$

$$|k,m\rangle = \sqrt{\frac{(2k-1)!}{(m-k)!(m+k-1)!}} K_+^{m-k}|k,k\rangle, \tag{3.25b}$$

$$K_+^{m-k}K_-^{m-k}|k,m\rangle = \frac{(m-k)!(m+k-1)!}{(2k-1)!}|k,m\rangle. \tag{3.25c}$$

Going back to the generators (3.21) it is clear that on all of $\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$, and so on each $\mathcal{H}^{(p-\rho,q-\rho;\rho)}$, J_0 has the eigenvalue $\frac{1}{2}(p+q+3)$; therefore on $\mathcal{H}^{(p,q;\rho)}$ it has the eigenvalue $\frac{1}{2}(p+q+3)+\rho$. It is also clear that action by $K_\pm$ on $\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$ leads to a subspace of $\mathcal{H}^{(p\pm1,0)}\times\mathcal{H}^{(0,q\pm1)}$. Therefore, because of (3.23), we see that $K_\pm$ acting on $\mathcal{H}^{(p,q;\rho)}$ yield $\mathcal{H}^{(p,q;\rho\pm1)}$. Of course $\mathcal{H}^{(p,q;0)}$ is annihilated by K_-.

Reflecting all this we see that an orthonormal basis for $\mathcal{H}$ can be set up labeled as follows:

$$\begin{gathered}|p,q;IMY;m\rangle : p,q=0,1,2,\ldots;\\ m=k,k+1,k+2,\ldots,\\ k=\tfrac{1}{2}(p+q+3);\\ N^{(a)}=p+m-k,\quad N^{(b)}=q+m-k.\end{gathered} \tag{3.26}$$

Since k is determined in terms of p and q, we do not include it as an additional label in the basis kets above. [The ranges for I, M, Y within the SU(3) UIR (p,q) are given in (2.5).] The SU(3) UIR labels p, q determine k and so the associated UIR $D_k^{(+)}$ of Sp(2,R). For fixed p, q as I, M, Y, m vary we get a set of states carrying the UIR $(p,q)\times D_k^{(+)}$ of SU(3)$\times$Sp(2,R). We can now appreciate the following relationships:

$$\mathcal{H}^{(p,q;\rho)} = \mathrm{Sp}\{|p,q;IMY;k+\rho\rangle | IMY \ \text{ varying}\},$$

$$\rho = 0,1,2,\ldots; \tag{3.27a}$$

$$\mathcal{H}^{(p,q;\rho)} = K_+^\rho \mathcal{H}^{(p,q;0)}; \tag{3.27b}$$

$$K_-\mathcal{H}^{(p,q;0)} = 0. \tag{3.27c}$$

Therefore, the null space of K_- within $\mathcal{H}$ is the subspace

$$\mathcal{H}_0 = \sum_{p,q=0,1,\ldots}^{\infty} \oplus \mathcal{H}^{(p,q;0)} = \mathrm{Sp}\{|p,q;IMY;k\rangle | p,q,IMY \ \text{ varying}\}, \tag{3.28}$$

and we see that the UR $\mathcal{U}(A)$ of SU(3) on $\mathcal{H}$ when restricted to $\mathcal{H}_0$ gives a UR $\mathcal{D}_0$ which is multiplicity free and includes every UIR of SU(3). It is thus identical in structure to the induced representation $\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$ in (2.8b). We see how the use of Sp(2,R) helps us isolate $\mathcal{H}_0$ in a neat manner.

In addition to the subspaces $\mathcal{H}^{(p,q;\rho)}$, $\mathcal{H}_0$ of $\mathcal{H}$ defined above, it is also useful to define the series of mutually orthogonal infinite dimensional subspaces

$$\mathcal{H}^{(p,q)} = \sum_{\rho=0}^{\infty} \oplus \mathcal{H}^{(p,q;\rho)} = \mathrm{Sp}\{|p,q;IMY;m\rangle | IMYm \ \text{ varying}\},$$

$$p,q = 0,1,2,\ldots. \tag{3.29}$$

Thus the infinity of occurrences of the SU(3) UIR (p,q) are collected together in $\mathcal{H}^{(p,q)}$.

In the Appendix we give explicit formulas for the state vectors $|p,q;IMY;m\rangle$ as functions of the operators $\hat{a}_j^\dagger$, $\hat{b}_j^\dagger$ acting on the Fock vacuum $|\underline{0},\underline{0}\rangle$.

IV. THE BARGMANN REPRESENTATION

For some purposes the use of the Bargmann representation of the canonical commutation relations is more convenient than the Fock space description.[17] We outline the definitions of $\mathcal{H}$ and the SU(3) UR $\mathcal{U}(A)=\mathcal{U}^{(a)}(A)\times\mathcal{U}^{(b)}(A)$ in this language, and then turn to the problem of isolating the subspace $\mathcal{H}_0$ in $\mathcal{H}$.

Vectors in $\mathcal{H}$ correspond to entire functions $f(\underline{z},\underline{w})$ in six independent complex variables $\underline{z}=(z_j)$, $\underline{w}=(w_j)$, $j=1,2,3$, with the squared norm defined as

$$\|f\|^2=\int\prod_{j=1}^{3}\left(\frac{d^2z_j}{\pi}\right)\left(\frac{d^2w_j}{\pi}\right)e^{-z^\dagger z-w^\dagger w}|f(\underline{z},\underline{w})|^2. \tag{4.1}$$

Any such $f(\underline{z},\underline{w})$ has a unique Taylor series expansion

$$f(\underline{z},\underline{w})=\sum_{p,q=0,1,\cdots}^{\infty}f^{j_1\cdots j_p}_{k_1\cdots k_q}z_{j_1}\cdots z_{j_p}w_{k_1}\cdots w_{k_q}, \tag{4.2}$$

involving the tensor components $f^{j_1\cdots j_p}_{k_1\cdots k_q}$ separately symmetric in the superscripts and the subscripts. In terms of these the squared norm is

$$\|f\|^2=\sum_{p,q=0,1,\cdots}^{\infty}p!q!f^{j_1\cdots j_p\,*}_{k_1\cdots k_q}f^{j_1\cdots j_p}_{k_1\cdots k_q}. \tag{4.3}$$

The operators $\hat{a}_j$, $\hat{a}_j^\dagger$, $\hat{b}_j$, $\hat{b}_j^\dagger$ act on $f(\underline{z},\underline{w})$ as follows:

$$\hat{a}_j\to\frac{\partial}{\partial z_j},\quad \hat{a}_j^\dagger\to z_j,\quad \hat{b}_j\to\frac{\partial}{\partial w_j},\quad \hat{b}_j^\dagger\to w_j. \tag{4.4}$$

The UR $\mathcal{U}(A)$ of SU(3) acts very simply via point transformations:

$$(\mathcal{U}(A)f)(\underline{z},\underline{w})=f(A^{-1}\underline{z},A^{-1*}\underline{w}). \tag{4.5}$$

The Sp(2,R) generators are particularly simple:

$$\begin{aligned}J_0&=\frac{1}{2}\left(z_j\frac{\partial}{\partial z_j}+w_j\frac{\partial}{\partial w_j}+3\right),\\ K_+&=z_jw_j\equiv\underline{z}\cdot\underline{w},\\ K_-&=\frac{\partial^2}{\partial z_j\partial w_j}\equiv\frac{\partial}{\partial\underline{z}}\cdot\frac{\partial}{\partial\underline{w}}.\end{aligned} \tag{4.6}$$

We will use these below.

It is clear that the terms in (4.2) and (4.3) for fixed p and q are contributions from $\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$. The action by K_+ obeys

$$f(\underline{z},\underline{w})\in\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}\to K_+f(\underline{z},\underline{w})=\underline{z}\cdot\underline{w}f(\underline{z},\underline{w})\in\mathcal{H}^{(p+1,0)}\times\mathcal{H}^{(0,q+1)}. \tag{4.7}$$

On the other hand, action by K_- is the analytic equivalent of taking the trace: starting with (4.2) we get

$$K_-f(\underline{z},\underline{w})=\sum_{p,q=0,1,\cdots}^{\infty} pq f^{jj_1\cdots j_{p-1}}_{jk_1\cdots k_{q-1}} z_{j_1}\cdots z_{j_{p-1}} w_{k_1}\cdots w_{k_{q-1}}. \tag{4.8}$$

From these and earlier remarks we can see that the correspondences between (symmetric, traceless) tensors, entire functions, and subspaces of $\mathcal{H}$ are

$$\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}\leftrightarrow\{f^{j_1\cdots j_p}_{k_1\cdots k_q}\}\leftrightarrow f(\underline{z},\underline{w}):$$
$$f(\lambda\underline{z},\mu\underline{w})=\lambda^p\mu^q f(\underline{z},\underline{w}); \tag{4.9a}$$

$$f(\underline{z},\underline{w})\in\mathcal{H}^{(p,q;\rho)}\Leftrightarrow f(\underline{z},\underline{w})=(\underline{z}\cdot\underline{w})^\rho f_0(\underline{z},\underline{w}), f_0(\underline{z},\underline{w})\in\mathcal{H}^{(p,q;0)}\subset\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)},$$
$$\frac{\partial}{\partial\underline{z}}\cdot\frac{\partial}{\partial\underline{w}}f_0(\underline{z},\underline{w})=0. \tag{4.9b}$$

Thus traceless symmetric tensors of type (p,q) are in correspondence with entire functions $f_0(\underline{z},\underline{w})$ of degrees of homogeneity p and q, respectively, obeying the partial differential equation (4.9b). Alternatively, given any $f(\underline{z},\underline{w})\in\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$, there is a unique "traceless" part $f_0(\underline{z},\underline{w})$ belonging to the leading subspace $\mathcal{H}^{(p,q;0)}$ and annihilated by K_-. Thus "trace removal" can be accomplished by analytical means. We now give the procedure to pass from $f(\underline{z},\underline{w})$ to $f_0(\underline{z},\underline{w})$.

For any $f(\underline{z},\underline{w})\in\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$ we can easily establish the general formula

$$K_-\{(\underline{z}\cdot\underline{w})^nK_-^nf(\underline{z},\underline{w})\}=n(p+q+2-n)(\underline{z}\cdot\underline{w})^{n-1}K_-^nf(\underline{z},\underline{w})+(\underline{z}\cdot\underline{w})^nK_-^{n+1}f(\underline{z},\underline{w}). \tag{4.10}$$

We try for $f_0(\underline{z},\underline{w})$ the expression

$$f_0(\underline{z},\underline{w})=f(\underline{z},\underline{w})-\sum_{n=1,2,\cdots}\alpha_n(\underline{z}\cdot\underline{w})^nK_-^nf(\underline{z},\underline{w}), \tag{4.11}$$

and get, using (4.10) (and omitting the arguments $\underline{z},\underline{w}$),

$$K_-f_0=K_-f-(p+q+1)\alpha_1K_-f-\sum_{n=1,2,\cdots}\{\alpha_n+(n+1)(p+q+1-n)\alpha_{n+1}\}(\underline{z}\cdot\underline{w})^nK_-^{n+1}f. \tag{4.12}$$

We can therefore attain $K_-f_0=0$ by choosing

$$\alpha_n=(-1)^{n-1}\frac{(p+q+1-n)!}{n!(p+q+1)!},\quad n=1,2,\ldots. \tag{4.13}$$

Therefore, for any (bihomogeneous) polynomial $f(\underline{z},\underline{w})\in\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$ the leading traceless part annihilated by K_- is an element $f_0(\underline{z},\underline{w})$ in $\mathcal{H}^{(p,q;0)}$:

$$f_0(\underline{z},\underline{w})=f(\underline{z},\underline{w})-\sum_{n=1,2,\cdots}(-1)^{n-1}\frac{(p+q+1-n)!}{n!(p+q+1)!}(\underline{z}\cdot\underline{w})^nK_-^nf(\underline{z},\underline{w}). \tag{4.14}$$

This result can be extended and expressed in the Fock space language. Any $|\psi\rangle\in\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}$ has a unique orthogonal decomposition into various parts belonging to various UIRs of SU(3); using (3.25c) this reads

$$|\psi\rangle\in\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}=\mathcal{H}^{(p,q;0)}\bigoplus\mathcal{H}^{(p-1,q-1;1)}\bigoplus\mathcal{H}^{(p-2,q-2;2)}\bigoplus\cdots:$$

$$
\begin{aligned}
&|\psi\rangle = |\psi_0\rangle + |\psi_1\rangle + |\psi_2\rangle + \cdots,\\
&|\psi_0\rangle \in \mathcal{H}^{(p,q;0)},\ \ K_-|\psi_0\rangle = 0;\\
&|\psi_1\rangle = K_+|\phi_1\rangle \in \mathcal{H}^{(p-1,q-1;1)},\\
&|\phi_1\rangle = \frac{(p+q)!}{1!(p+q+1)!} K_-|\psi_1\rangle \in \mathcal{H}^{(p-1,q-1;0)},\\
&K_-^2|\psi_1\rangle = 0;\\
&|\psi_2\rangle = K_+^2|\phi_2\rangle \in \mathcal{H}^{(p-2,q-2;2)},\\
&|\phi_2\rangle = \frac{(p+q-2)!}{2!(p+q)!} K_-^2|\psi_2\rangle \in \mathcal{H}^{(p-2,q-2;0)},\\
&K_-^3|\psi_2\rangle = 0;\cdots.
\end{aligned}
\tag{4.15}
$$

The "leading" piece in $|\psi\rangle$ is thus

$$
\begin{aligned}
&|\psi_0\rangle = |\psi\rangle - |\psi_1\rangle - |\psi_2\rangle - \cdots = |\psi\rangle - \hat{\underline{a}}^\dagger \cdot \hat{\underline{b}}^\dagger |\phi\rangle,\\
&|\phi\rangle = |\phi_1\rangle + \hat{\underline{a}}^\dagger \cdot \hat{\underline{b}}^\dagger |\phi_2\rangle + \cdots \in \mathcal{H}^{(p-1,0)} \times \mathcal{H}^{(0,q-1)}.
\end{aligned}
\tag{4.16}
$$

We can now infer that if to begin with we had $|\psi\rangle = \hat{\underline{a}}^\dagger \cdot \hat{\underline{b}}^\dagger |\phi\rangle$ for some $\phi \in \mathcal{H}^{(p-1,0)} \times \mathcal{H}^{(0,q-1)}$, then $|\psi_0\rangle$ necessarily vanishes:

$$
|\psi\rangle = \hat{\underline{a}}^\dagger \cdot \hat{\underline{b}}^\dagger |\phi\rangle \Leftrightarrow |\psi_0\rangle = 0. \tag{4.17}
$$

In the Bargmann description this means in terms of (4.14)

$$
f(\underline{z},\underline{w}) = \underline{z} \cdot \underline{w} g(\underline{z},\underline{w}) \Leftrightarrow f_0(\underline{z},\underline{w}) = 0, \tag{4.18}
$$

a result which can be directly verified with some effort.

The subspace $\mathcal{H}_0 \subset \mathcal{H}$ identified in (3.28) is describable in the Bargmann language as follows:

$$
\mathcal{H}_0 = \left\{ f(\underline{z},\underline{w}) \in \mathcal{H} \left| \frac{\partial}{\partial \underline{z}} \cdot \frac{\partial}{\partial \underline{w}} f(\underline{z},\underline{w}) = 0 \right. \right\}. \tag{4.19}
$$

In the Taylor series expansion (4.2) for such $f(\underline{z},\underline{w})$, the tensors $f^{j_1 \cdots j_p}_{k_1 \cdots k_q}$ are traceless and vice versa. The squared norm and SU(3) action are given for $\mathcal{H}_0$ by (4.3) and (4.5), respectively.

V. THE UR $\mathcal{D}^{(\mathrm{IND},0)}_{\mathrm{SU}(2)}$ OF SU(3)

The Hilbert space $\mathcal{H}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$ carrying the UR $\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$ of SU(3) consists of single component (scalar) complex functions on the coset space SU(3)/SU(2). This coset space is the unit sphere in three-dimensional complex space C^3, with the natural norm and SU(3) action. Temporarily omitting the superscript zero and subscript SU(2) for simplicity, we have

$$
\begin{aligned}
&\mathcal{H}^{(\mathrm{ind})} = \left\{ \psi(\underline{\xi}) \in C, \underline{\xi} \in C^3 \left| \|\psi\|^2 = \int \prod_{j=1}^{3} \left(\frac{d^2\xi_j}{\pi} \right) \delta(\underline{\xi}^\dagger \underline{\xi} - 1) |\psi(\underline{\xi})|^2 \right. \right\},\\
&(\mathcal{D}^{(\mathrm{ind})}(A)\psi)(\underline{\xi}) = \psi(A^{-1}\underline{\xi}).
\end{aligned}
\tag{5.1}
$$

Clearly only the values of $\psi(\underline{\xi})$ for $\xi^\dagger\xi=1$ are relevant. For a general $\psi(\underline{\xi})$ with a Taylor series expansion we write

$$\psi(\underline{\xi})=\sum_{p,q=0,1,\cdots}^{\infty}\psi^{j_1\cdots j_p}_{k_1\cdots k_q}\xi_{j_1}\cdots\xi_{j_p}\xi^*_{k_1}\cdots\xi^*_{k_q}. \tag{5.2}$$

[Strictly speaking, such an expansion holds only for $\psi(\underline{\xi})$ in some dense subset of $\mathcal{H}^{(\mathrm{ind})}$.] We note that here $\psi(\underline{\xi})$ is not an entire function of ξ_j, and since $\xi^\dagger\xi=1$, the tensor components $\psi^{j_1\cdots j_p}_{k_1\cdots k_q}$ may be assumed to be traceless apart from being symmetric. Then they determine $\psi(\underline{\xi})$ uniquely and vice versa.

To express the inner product (ϕ,ψ) for general $\phi,\psi\in\mathcal{H}^{(\mathrm{ind})}$ in terms of their tensor components, we need to evaluate

$$I^{k\cdots l\cdots}_{j\cdots m\cdots}=\int\prod_{j=1}^{3}\left(\frac{d^2\xi_j}{\pi}\right)\delta(\xi^\dagger\xi-1)\xi_{j_1}\cdots\xi_{j_p}(\xi_{k_1}\cdots\xi_{k_q})^*(\xi_{l_1}\cdots\xi_{l_{p'}})^*(\xi_{m_1}\cdots\xi_{m_{q'}}), \tag{5.3}$$

for general p, q, p', q' and indices j, k, l, m. Using SU(3) invariance and symmetry, we see that the result must be expressible in terms of products of Kronecker deltas. Combining this with the tracelessness of the tensor components of ϕ and ψ, we can check first that we need only consider the case $p=p'$, $q=q'$, and next that

$$I^{k\cdots l\cdots}_{j\cdots m\cdots}=\mathcal{N}\sum_{P\in S_p}\sum_{Q\in S_q}\delta^{l_{P(1)}}_{j_1}\cdots\delta^{l_{P(p)}}_{j_p}\delta^{k_1}_{m_{Q(1)}}\cdots\delta^{k_q}_{m_{Q(q)}}+\cdots. \tag{5.4}$$

Here $\mathcal{N}$ is a normalizing factor, and the dots denote terms with factors δ^k_j or δ^m_l or both. Again the latter can be ignored. The factor $\mathcal{N}$ can be computed say by setting all $j=l=1$ and all $k=m=2$:

$$\mathcal{N}=\frac{1}{(p+q+2)!}. \tag{5.5}$$

We then get the result for any $\phi,\psi\in\mathcal{H}^{(\mathrm{ind})}$:

$$(\phi,\psi)=\sum_{p,q=0,1,\cdots}\frac{p!q!}{(p+q+2)!}\phi^{j_1\cdots j_p}{}^*_{k_1\cdots k_q}\psi^{j_1\cdots j_p}_{k_1\cdots k_q}. \tag{5.6}$$

With these results, all details of the induced UR $\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$ of SU(3) are in hand: the Hilbert space $\mathcal{H}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$ in (5.1), the expression (5.6) for inner products, and the SU(3) action as in (5.1).

VI. EQUIVALENCE MAP

The full equivalence of the two UR's of SU(3), one on the subspace $\mathcal{H}_0\subset\mathcal{H}$ based on the six oscillator Schwinger construction of Sec. III, and the other the induced representation $\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$, can now be set up. The tensor component expressions (4.2) and (5.2) for vectors, and (4.3) and (5.6) for inner products, determine the one-to-one map to achieve this in full detail:

$$f(\underline{z},\underline{w})=\{f^{j_1\cdots j_p}_{k_1\cdots k_q}\}\in\mathcal{H}_0\leftrightarrow\psi(\underline{\xi})=\{\psi^{j_1\cdots j_p}_{k_1\cdots k_q}\}\in\mathcal{H}^{(\mathrm{ind})}:$$

$$\psi^{j_1\cdots j_p}_{k_1\cdots k_q}=\sqrt{(p+q+2)!}\,f^{j_1\cdots j_p}_{k_1\cdots k_q},p,q=0,1,\ldots. \tag{6.1}$$

The two inner products then match, and the SU(3) actions given in (4.5) and (5.1) on $f(\underline{z},\underline{w})$ and $\psi(\underline{\xi})$ also match.

It is worth emphasizing here the two different arguments leading to the tracelessness of the symmetric tensors on the two sides of (6.1). In the case of the left hand side, the reason is that the argument of $\psi(\underline{\xi})$ obeys the constraint $\underline{\xi}^\dagger\underline{\xi}=1$. As for the right hand side, it happens because entire functions $f(\underline{z},\underline{w})\in\mathcal{H}_0$ obey the partial differential equation in (4.19). In both cases tracelessness leads to the UR being multiplicity free, apart from being complete in the sense that all SU(3) UIR's do appear.

VII. CONCLUDING REMARKS

To conclude, we have brought out the difficulties one encounters in naively extending the Schwinger SU(2) construction to SU(3) particularly if one wishes to retain the simplicity and economy intrinsic to the SU(2) case. We have shown how these difficulties can be overcome by exploiting the group Sp(2,R) to obtain a ''generating representation'' of SU(3) based on six bosonic oscillators. This UR of SU(3) contains all the representations of SU(3) exactly once. (It has been drawn to our attention by the referee that this result of ours is a special case of more general results available in mathematics literature.[18,19]) Further, we have shown how this ''generating representation'' for SU(3) can also be constructed using the theory of induced representations and have constructively established the equivalence between the two by making use of the Bargmann representation. It is hoped that the construction presented here will have useful applications in various branches of physics much the same way as the SU(2) construction has. Indeed, the work presented here has direct relevance to SU(3) coherent states as will be shown in a succeeding publication.

ACKNOWLEDGMENTS

This work was begun while N.M. was a Jawaharlal Nehru Chair Professor of the University of Hyderabad during September 1999. N.M. gratefully acknowledges the hospitality extended to him during his stay by the School of Physics, University of Hyderabad. We are also grateful to the referee for bringing Refs. 18 and 19 to our attention.

APPENDIX: BOSON OPERATOR CONSTRUCTION OF $SU(3)\times$Sp(2,R) BASIS STATES

We give here the explicit construction of the orthonormal basis states $|p,q;IMY;m\rangle$ for $\mathcal{H}$ introduced in Eq. (3.26). We deal first with the states $|p,q;IIY;k\rangle\in\mathcal{H}^{(p,q;0)}\subset\mathcal{H}^{(p,q)}\cap\mathcal{H}_0$ having highest SU(2) weight; then by repeated use of the Sp(2,R) raising operator $K_+=\hat{\underline{a}}^\dagger\cdot\hat{\underline{b}}^\dagger$ with $|p,q;IIY;m\rangle\in\mathcal{H}^{(p,q;m-k)}\subset\mathcal{H}^{(p,q)}$; and finally with the general state $|p,q;IMY;m\rangle$ using the SU(2) lowering operator. At each stage the normalization will be ensured.

As is well known, the boson operators $\hat{a}_j^\dagger$, $\hat{b}_j^\dagger$ carry the following U(2) quantum numbers:[11]

$$\begin{array}{cccc} & I & M & Y \\ \hat{a}_1^\dagger,\hat{a}_2^\dagger & \frac{1}{2} & \pm\frac{1}{2} & \frac{1}{3} \\ \hat{a}_3^\dagger & 0 & 0 & -\frac{2}{3} \\ \hat{b}_2^\dagger,-\hat{b}_1^\dagger & \frac{1}{2} & \pm\frac{1}{2} & -\frac{1}{3} \\ \hat{b}_3^\dagger & 0 & 0 & \frac{2}{3} \end{array}. \tag{A1}$$

Therefore, $\hat{a}_\alpha^\dagger\hat{b}_\alpha^\dagger\equiv\hat{a}_1^\dagger\hat{b}_1^\dagger+\hat{a}_2^\dagger\hat{b}_2^\dagger$, $\hat{a}_3^\dagger$ and $\hat{b}_3^\dagger$ are SU(2) scalars. The I-Y multiplets present in the SU(3) UIR (p,q) are listed in Eq. (2.5), and are parametrized by two integers r, s. The state $|p,q;IIY;k\rangle\in\mathcal{H}_0$ involves p factors $\hat{a}^\dagger$ and q factors $\hat{b}^\dagger$ acting on the Fock vacuum $|\underline{0},\underline{0}\rangle$, and in addition it is annihilated by $K_-=\hat{\underline{a}}\cdot\hat{\underline{b}}$. We therefore start with the expression [guided by (A1)]:

$$|p,q;IIY;k\rangle=(\hat{a}_1^\dagger)^r(\hat{b}_2^\dagger)^s\sum_{n=0,1,\ldots}^{(p-r,q-s)_<}C_n(\hat{a}_\alpha^\dagger\hat{b}_\alpha^\dagger)^n(\hat{a}_3^\dagger)^{p-r-n}(\hat{b}_3^\dagger)^{q-s-n}|\underline{0},\underline{0}\rangle,$$
$$r=I+\frac{Y}{2}+\frac{1}{3}(p-q),\quad s=I-\frac{Y}{2}+\frac{1}{3}(q-p). \tag{A2}$$

The condition

$$K_-|p,q;IIY;k\rangle=0 \tag{A3}$$

gives the recursion relation

$$n(r+s+n+1)C_n=-(p-r-n+1)(q-s-n+1)C_{n-1},\quad n=1,2,\ldots, \tag{A4}$$

with the solution

$$C_n=\frac{(-1)^n}{n!}\frac{(p-r)!(q-s)!(r+s+1)!}{(p-r-n)!(q-s-n)!(r+s+n+1)!}C_0,\quad n=1,2,\ldots. \tag{A5}$$

Using this in Eq. (A2), and after some algebra, the normalized state is found to be

$$|p,q;IIY;k\rangle=\mathcal{N}_{pqIY}\frac{(\hat{a}_1^\dagger)^r}{r!}\frac{(\hat{b}_2^\dagger)^s}{s!}\times\sum_{n=0,1,\ldots}^{(p-r,q-s)_<}\frac{(-1)^n}{(r+s+n+1)!}\frac{(\hat{a}_\alpha^\dagger\hat{b}_\alpha^\dagger)^n}{n!}\frac{(\hat{a}_3^\dagger)^{p-r-n}}{(p-r-n)!}\frac{(\hat{b}_3^\dagger)^{q-s-n}}{(q-s-n)!}|\underline{0},\underline{0}\rangle\in\mathcal{H}^{(p,q;0)},$$
$$\mathcal{N}_{pqIY}=\{r!s!(r+s+1)!(p-r)!(q-s)!(p+s+1)!(q+r+1)!/(p+q+1)!\}^{1/2}. \tag{A6}$$

From Eq. (3.27a) we know that vectors in $\mathcal{H}^{(p,q;m-k)}$ for $m>k$ are obtained from vectors in $\mathcal{H}^{(p,q;0)}$ by applying K_+^{m-k}. Further, the normalization is controlled by Eq. (3.25b). We thus obtain

$$|p,q;IIY;m\rangle=\{(2k-1)!/(m-k)!(m+k-1)!\}^{1/2}(\underline{\hat{a}}^\dagger\cdot\underline{\hat{b}}^\dagger)^{m-k}|p,q;IIY;k\rangle\in\mathcal{H}^{(p,q;m-k)}. \tag{A7}$$

The last step is to reach a general value $M\leqslant I$ for the SU(2) magnetic quantum number. For this we apply the SU(2) lowering operator $J_-=\hat{a}_2^\dagger\hat{a}_1-\hat{b}_1^\dagger\hat{b}_2(I-M)$ times to the state (A7), keeping track of normalization. This leads to the result

$$|p,q;IMY;m\rangle=\{(I+M)!/2I!(I-M)!\}^{1/2}(\hat{a}_2^\dagger\hat{a}_1-\hat{b}_1^\dagger\hat{b}_2)^{I-M}|p,q;IIY;m\rangle. \tag{A8}$$

If we combine Eqs. (A6) to (A8) we get the complete expression

$$|p,q;IMY;m\rangle=\mathcal{N}_{pqIY}\{(2k-1)!(I+M)!(I-M)!/(m-k)!(m+k-1)!2I!\}^{1/2}\times(\underline{\hat{a}}^\dagger\cdot\underline{\hat{b}}^\dagger)^{m-k}\sum_{L=0}^{I-M}\sum_{n=0}^{(p-r,q-s)_<}\frac{(-1)^{n+I-M-L}}{(r+s+n+1)!}\cdot\frac{(\hat{a}_\alpha^\dagger\hat{b}_\alpha^\dagger)^n}{n!}\times\frac{(\hat{a}_3^\dagger)^{p-r-n}}{(p-r-n)!}\frac{(\hat{b}_3^\dagger)^{q-s-n}}{(q-s-n)!}\frac{(\hat{a}_1^\dagger)^{r-L}}{(r-L)!}\frac{(\hat{a}_2^\dagger)^L}{L!}\frac{(\hat{b}_2^\dagger)^{s-I+M+L}}{(s-I+M+L)!}\frac{(\hat{b}_1^\dagger)^{I-M-L}}{(I-M-L)!}|\underline{0},\underline{0}\rangle. \tag{A9}$$

We thus have explicit expressions for all the normalized basis states $|p,q;IMY;m\rangle$ of $\mathcal{H}$.

(Received 20 April 2002; accepted 16 May 2002)

The Schwinger oscillator operator representation of SU(3), studied in a previous paper from the representation theory point of view, is analyzed to discuss the intimate relationships between standard oscillator coherent state systems and systems of SU(3) coherent states. Both SU(3) standard coherent states, based on choice of highest weight vector as fiducial vector, and certain other specific systems of generalized coherent states, are found to be relevant. A complete analysis is presented, covering all the oscillator coherent states without exception, and amounting to SU(3) harmonic analysis of these states. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1508811]

I. INTRODUCTION

In a previous paper[1] we have presented an analysis of the reducible unitary representation(UR) of SU(3) that is obtained by a generalization of the well-known Schwinger oscillator operator construction in the case of SU(2).[2] This construction, based on six independent pairs of oscillator operators, is a minimal one in the sense that all unitary irreducible representations (UIRs) of SU(3) are obtained without exception. However, in contrast to the SU(2) case, there is an unavoidable multiplicity in that each UIR occurs a denumerably infinite number of times. A systematic way to handle this multiplicity, based on the use of the noncompact group $\mathrm{Sp}(2,R)$, has been developed; its salient features are recapitulated in the next section.

The aim of the present article is to extend this study and discuss various properties of coherent states in this framework. The use of oscillator operators automatically brings in the Heisenberg–Weyl (H-W) group with a dimension appropriate to the number of independent oscillators or degrees of freedom. And it is indeed in the context of this group that the standard coherent states in quantum mechanics were originally defined and applied to a very large number of problems.[3] On the other hand, the basic kinematic relations for any system of independent oscillator operators have a well-defined covariance group associated with them—a group of linear inhomogeneous transformations on the oscillator operators which leave their commutation relations invariant. The homogeneous part of this covariance group is the metaplectic group of appropriate dimension, containing a unitary group as its maximal compact subgroup. Thus for n oscillators or n canonical pairs of degrees of freedom, we encounter the groups $\mathrm{Mp}(2n)$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$, and certain of their URs, in a natural way.[4]

Now the original concept of coherent states has been generalized from the H-W case to a general Lie group, and it consists of the orbit of a chosen fiducial vector under group action in any UIR of the group.[5] The usual coherent states arise by the action of the elements of the H-W group on the Fock vacuum. Given all this, it is natural and to be expected that via the Schwinger type construction we have an intricate interplay between the familiar H-W coherent states, and certain

systems of coherent states associated with the groups $\mathrm{Mp}(2n)$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$.

In passing we may also mention that with this generalization, even for the H-W group we have not only the originally defined coherent states, which may be called standard coherent states (SCSs), but other systems of generalized coherent states (GCSs).[6] These are based on choices of states other than the Fock vacuum as the fiducial state. Similarly, for the unitary group $\mathrm{SU}(n)$, within any given UIR the SCSs are obtained when the highest weight state is used as the fiducial state, while for other choices we have systems of GCSs.[7] It is therefore of interest to see how these various systems of coherent states for different groups get interconnected via the Schwinger construction. This is the main aim of the present work, in the particular case of the H-W group for six oscillators, and SU(3).

A brief outline of this work is as follows. Our earlier work[1] has shown how in a natural manner we can identify and isolate a subspace $\mathcal{H}_0$ carrying a complete and multiplicity-free UR of SU(3) [a ''generating representation'' for SU(3)], within the full Schwinger representation characterized by infinite multiplicity. As this decomposition, in which the compact generator J_0 of $\mathrm{Sp}(2,R)$ plays a crucial role, provides the starting point of the present work, to set the notation and to make the article reasonably self-contained, we briefly recapitulate the relevant details of Ref. 1 in Sec. II. In Sec. III, we recall the largely familiar interconnections between H-W and U(1) and SU(2) coherent states, to highlight some special features of the Klauder resolution of the identity and its modifications. This helps set the stage for a unified analysis of the relations between the appropriate H-W SCS and SU(3) SCSs and GCSs carried out in detail in Secs. IV–VI. Section IV contains a detailed classification of the orbits of H-W SCSs, under SU(3) action; we identify both generic orbits of maximal dimension, and nongeneric lower order ones. The rest of Sec. IV carries out the SU(3) harmonic analysis of generic orbits lying in the subspace $\mathcal{H}_0$. In Sec. V we examine the remaining generic orbits, lying in subspaces $\mathcal{H}_\kappa$ which are generalizations of $\mathcal{H}_0$ and are labeled by a complex parameter κ. Some calculational details pertaining to this section are put together in an appendix. Section VI contains an analysis of the SU(3) content of a family of H-W SCSs belonging to a nongeneric orbit under SU(3) action. Some concluding remarks are presented in Sec. VII.

II. REVIEW OF SCHWINGER CONSTRUCTION FOR SU(3)

This construction uses six independent sets of oscillator creation and annihilation operators $\hat{a}_j^\dagger, \hat{b}_j^\dagger, \hat{a}_j, \hat{b}_j, j=1,2,3$, among which the only nonvanishing commutators are

$$[\hat{a}_j, \hat{a}_k^\dagger] = [\hat{b}_j, \hat{b}_k^\dagger] = \delta_{jk}, \quad j,k=1,2,3. \tag{2.1}$$

The Hilbert space $\mathcal{H}$ carrying an irreducible representation of these operators is the tensor product $\mathcal{H}=\mathcal{H}^{(a)}\times\mathcal{H}^{(b)}$, where $\mathcal{H}^{(a)}$ and $\mathcal{H}^{(b)}$ are the individual Hilbert spaces carrying irreducible representations of the independent sets $\hat{a}_j, \hat{a}_j^\dagger$ and $\hat{b}_j, \hat{b}_j^\dagger$, respectively. The Schwinger UR of SU(3) acts on $\mathcal{H}$, and its Hermitian generators are[1]

$$\begin{gathered} Q_\alpha = Q_\alpha^{(a)} + Q_\alpha^{(b)}, \\ Q_\alpha^{(a)} = \tfrac{1}{2}\hat{a}^\dagger \lambda_\alpha \hat{a}, \quad Q_\alpha^{(b)} = -\tfrac{1}{2}\hat{b}^\dagger \lambda_\alpha^* \hat{b}, \quad \alpha = 1,2,\ldots,8. \end{gathered} \tag{2.2}$$

Here $\frac{1}{2}\lambda_\alpha$ are the eight Hermitian traceless 3×3 matrices generating the defining UIR (1,0) of SU(3).[8] [For ease in writing, the UIRs of SU(3) will be denoted by (p,q) where $p,q=0,1,2,\ldots$, independently, instead of the more elaborate notation $D^{(p,q)}$.]

The independent mutually commuting generators $Q_\alpha^{(a)}, Q_\alpha^{(b)}$ lead to specific multiplicity-free URs $\mathcal{U}^{(a)}(A), \mathcal{U}^{(b)}(A)$ of SU(3) on $\mathcal{H}^{(a)}, \mathcal{H}^{(b)}$, respectively. Here A is a general matrix in the UIR (1,0). The UR $\mathcal{U}^{(a)}(A)$ is a direct sum of the ''triangular'' UIRs $(p,0)$ of SU(3), for $p=0,1,2,\ldots$, and similarly $\mathcal{U}^{(b)}(A)$ is a direct sum of the conjugate ''triangular'' UIRs $(0,q)$. We indicate this by

$$\mathcal{U}^{(a)}=\sum_{p=0,1,\ldots}^{\infty}\oplus(p,0),$$

$$\mathcal{U}^{(b)}=\sum_{q=0,1,\ldots}^{\infty}\oplus(0,q). \tag{2.3}$$

The total generators Q_α defined in Eq. (2.2) then generate the product UR $\mathcal{U}(A)=\mathcal{U}^{(a)}(A)\times\mathcal{U}^{(b)}(A)$ on $\mathcal{H}$, and this is the Schwinger UR of SU(3). It does contain every UIR (p,q) of SU(3), but each one occurs an infinite number of times. This can be seen from the Clebsch–Gordan decomposition of the direct product $(p,0)\times(0,q)$ of two triangular UIRs:[9]

$$(p,0)\times(0,q)=\sum_{\rho=0,1,\ldots}^{r}\oplus(p-\rho,q-\rho),\quad r=\min(p,q), \tag{2.4}$$

which is multiplicity-free. Applying this to each pair in the product $\mathcal{U}^{(a)}\times\mathcal{U}^{(b)}$ we easily reach the stated conclusion.

An efficient way to handle this infinite multiplicity is based on the use of the semi-simple noncompact Lie group Sp(2,R), more specifically some of its UIRs belonging to the positive discrete class.[10] In the present context the Hermitian Sp(2,R) generators and their commutation relations are

$$J_0=\tfrac{1}{2}(\hat{a}_j^\dagger\hat{a}_j+\hat{b}_j^\dagger\hat{b}_j+3),$$

$$K_1=\tfrac{1}{2}(\hat{a}_j^\dagger\hat{b}_j^\dagger+\hat{a}_j\hat{b}_j), \tag{2.5a}$$

$$K_2=\frac{-i}{2}(\hat{a}_j^\dagger\hat{b}_j^\dagger-\hat{a}_j\hat{b}_j);$$

$$[J_0,K_1]=i\ K_2,\quad [J_0,K_2]=-i\ K_1,\quad [K_1,K_2]=-i\ J_0. \tag{2.5b}$$

The crucial property is that the SU(3) and the Sp(2,R) generators mutually commute:

$$[J_0\ \text{or}\ K_1\ \text{or}\ K_2,\quad Q_\alpha]=0. \tag{2.6}$$

Thus the two URs commute as well, and Sp(2,R) is just large enough to be able to completely lift the degeneracy or multiplicity of SU(3) UIRs. In other words, the UIRs of the product group SU(3)$\times$Sp(2,R) that occur in $\mathcal{H}$ do so in a multiplicity-free manner. This is reflected at the Hilbert space level in the following manner. We first decompose the individual Hilbert spaces $\mathcal{H}^{(a)},\mathcal{H}^{(b)}$ into mutually orthogonal subspaces reflecting the decompositions (2.3):

$$\mathcal{H}^{(a)}=\sum_{p=0,1,\ldots}^{\infty}\oplus\mathcal{H}^{(p,0)},$$

$$\mathcal{H}^{(b)}=\sum_{q=0,1,\ldots}^{\infty}\oplus\mathcal{H}^{(0,q)}. \tag{2.7}$$

The subspace $\mathcal{H}^{(p,0)}\subset\mathcal{H}^{(a)}$ is of dimension $d(p,0)=\frac{1}{2}(p+1)(p+2)$, consists of all eigenvectors in $\mathcal{H}^{(a)}$ of the total a-type number operator $\hat{a}_j^\dagger\hat{a}_j$ with eigenvalue p, and carries the UIR $(p,0)$ of SU(3). Similarly the subspace $\mathcal{H}^{(0,q)}\subset\mathcal{H}^{(b)}$ is of dimension $d(0,q)=\frac{1}{2}(q+1)(q+2)$, consists of all eigenvectors in $\mathcal{H}^{(b)}$ of the total b-type number operator $\hat{b}_j^\dagger\hat{b}_j$ with eigenvalue q, and carries

the UIR $(0,q)$ of SU(3). After forming the direct product $\mathcal{H}^{(a)}\times\mathcal{H}^{(b)}$, using Eq. (2.7) and the Clebsch–Gordan decomposition (2.4), we arrive at an orthogonal subspace decomposition for $\mathcal{H}=\mathcal{H}^{(a)}\times\mathcal{H}^{(b)}$:

$$\mathcal{H}=\sum_{p,q=0,1,\ldots}^{\infty}\oplus\mathcal{H}^{(p,0)}\times\mathcal{H}^{(0,q)}=\sum_{p,q=0,1,\ldots}^{\infty}\sum_{\rho=0,1,\ldots}^{\infty}\oplus\mathcal{H}^{(p,q;\rho)},$$
$$\mathcal{H}^{(p,q;\rho)}\subset\mathcal{H}^{(p+\rho,0)}\times\mathcal{H}^{(0,q+\rho)}. \tag{2.8}$$

For each $\rho,\mathcal{H}^{(p,q;\rho)}$ is of dimension $d(p,q)=\frac{1}{2}(p+1)(q+1)(p+q+2)$ and carries the ρth occurrence of the UIR (p,q) of SU(3). For $\rho'\neq\rho,\mathcal{H}^{(p,q;\rho')}$ and $\mathcal{H}^{(p,q;\rho)}$ are mutually orthogonal subspaces; and if $p'\neq p$ and/or $q'\neq q$, again $\mathcal{H}^{(p',q';\rho)}$ and $\mathcal{H}^{(p,q;\rho)}$ are mutually orthogonal. An orthonormal basis for $\mathcal{H}$ consists of vectors labeled as follows:

$$|p,q;\ I,M,Y;m\rangle:$$
$$p,q=0,1,2,\ldots,$$
$$m=k,k+1,k+2,\ldots,$$
$$k=\tfrac{1}{2}(p+q+3)=\tfrac{3}{2},2,\tfrac{5}{2},\ldots. \tag{2.9}$$

Here I,M,Y are "magnetic quantum numbers" within the UIR (p,q) of SU(3), with well-known ranges,[11] and m is the eigenvalue of the Sp(2,R) generator J_0. The total numbers of a-type quanta and of b-type quanta in the state displayed in Eq. (2.9) are

$$N_a=\text{eigenvalue of } \hat{a}_j^{\dagger}\hat{a}_j=p+m-k,$$
$$N_b=\text{eigenvalue of } \hat{b}_j^{\dagger}\hat{b}_j=q+m-k. \tag{2.10}$$

For fixed p,q and m, as I,M,Y vary within the UIR (p,q) of SU(3), we obtain an orthonormal basis for $\mathcal{H}^{(p,q;m-k)}$. Switching to $\rho=m-k$ we can say

$$\mathcal{H}^{(p,q;\rho)}=\mathrm{Sp}\{|p,q;I,M,Y;k+\rho\rangle|p,q,\rho \text{ fixed},I,M,Y \text{ varying}\}, \tag{2.11}$$

where Sp$\{\cdot\}$ stands for the linear span of the set of vectors $\{\cdot\}$. On the other hand, if we keep p,q,I,M,Y fixed and let m vary, we get an orthonormal basis for a subspace of $\mathcal{H}$ carrying the infinite dimensional positive discrete class UIR $D_k^{(+)}$ of Sp(2,R).[10] In other words, each of these UIRs $D_k^{(+)}$ of Sp(2,R) occurs $d(2k-3,0)+d(2k-4,1)+\cdots+d(1,2k-4)+d(2k-3)$ times, being the sum of the dimensions of the SU(3) UIRs $(2k-3,0),(2k-4,1),\ldots,(1,2k-4),(0,2k-3)$. (The range of $2k$ is 3,4,5,....) Since our main interest is in URs and UIRs of SU(3), and we wish to use UIRs of Sp(2,R) mainly to keep track of the multiplicities of the former, we do not introduce special notations for the subspaces of $\mathcal{H}$ carrying the various Sp(2,R) UIRs. However, we do note that, as stated earlier, each of the UIRs $(p,q)\times D^{(+)}_{(1/2)(p+q+3)}$ of SU(3)$\times$Sp(2,R) appears just once in $\mathcal{H}$, for $p,q=0,1,2,\ldots$.

At the generator level we can say that when the SU(3) generators Q_α act on $|p,q;I,M,Y;m\rangle$, they alter only the quantum numbers I,M,Y in a manner known from the representation theory of SU(3),[12] while the actions by the Sp(2,R) generators J_0,K_1,K_2 lead only to changes in the quantum number m according to the UIR $D_k^{(+)}$.[10]

It is in this manner that the Sp(2,R) structure helps us handle the multiplicity problem of UIRs of SU(3) which is an unavoidable feature of the Schwinger construction. One can now look for a natural subspace of $\mathcal{H},\mathcal{H}_0$ say, such that it carries every UIR (p,q) of SU(3) exactly once. This can be done if we restrict ourselves to the "ground state" within each Sp(2,R) UIR $D_k^{(+)}$, namely

if we set $m=k$. This amounts to picking up the "first" occurrence of each UIR (p,q) of SU(3) corresponding to $\rho=0$, or to the "leading piece" in the reduction of each tensor product $\mathcal{H}^{(p,0)} \times \mathcal{H}^{(0,q)}$:

$$\mathcal{H}_0 = \sum_{p,q=0,1,\ldots}^{\infty} \oplus \mathcal{H}^{(p,q;0)} = \mathrm{Sp}\{|p,q;I,M,Y;k\rangle | p,q,I,M,Y \ \text{ varying}\}$$

$$= \{|\psi\rangle \in \mathcal{H} | (K_1 - iK_2)|\psi\rangle = 0\}. \tag{2.12}$$

The UR of SU(3) carried by $\mathcal{H}_0$, $\mathcal{D}_0$ say, may be called a generating representation for this group, in the sense that each UIR is present, and exactly once:

$$\mathcal{D}_0 = \sum_{p,q=0,1,\ldots}^{\infty} \oplus (p,q). \tag{2.13}$$

It now turns out that just this property is also present in the UR $\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$ of SU(3) induced from the trivial one-dimensional UIR of the canonical SU(2) subgroup.[13] The corresponding Hilbert space is denoted by $\mathcal{H}^{(\mathrm{ind},0)}_{\mathrm{SU}(2)}$. [Hereafter, for simplicity, the superscript zero and the subscript SU(2) will be omitted.] We can set up a one-to-one mapping between $\mathcal{H}_0$ and $\mathcal{H}^{(\mathrm{ind})}$ preserving scalar products and SU(3) actions, thus realizing the equivalence of $\mathcal{D}_0$ and $\mathcal{D}^{(\mathrm{ind})}$. First we describe $\mathcal{H}_0$ and $\mathcal{D}_0$ more explicitly. Denote by $|\underline{0},\underline{0}\rangle$ the Fock vacuum in $\mathcal{H}$ annihilated by $\hat{a}_j$ and $\hat{b}_j$, $j=1,2,3$. Then a general vector in $\mathcal{H}_0$ is a collection of symmetric traceless tensors with respect to SU(3), one for each UIR (p,q):

$$|\psi\rangle \in \mathcal{H}_0 :$$

$$|\psi\rangle = \sum_{p,q=0,1,\ldots}^{\infty} \psi^{j_1 \ldots j_p}_{k_1 \ldots k_q} \hat{a}^{\dagger}_{j_1} \ldots \hat{a}^{\dagger}_{j_p} \hat{b}^{\dagger}_{k_1} \ldots \hat{b}^{\dagger}_{k_q} |\underline{0},\underline{0}\rangle; \tag{2.14a}$$

$$\psi^{j_{P(1)} \ldots j_{P(p)}}_{k_{Q(1)} \ldots k_{Q(q)}} = \psi^{j_1 \ldots j_p}_{k_1 \ldots k_q}, \quad P \in S_p, \quad Q \in S_q; \tag{2.14b}$$

$$\psi^{j \ j_2 \ldots j_p}_{j \ k_2 \ldots k_q} = 0, \tag{2.14c}$$

$$\langle \psi | \psi \rangle = \|\psi\|^2 = \sum_{p,q=0,1,\ldots}^{\infty} p!\,q!\, \psi^{j_1 \ldots j_p}_{k_1 \ldots k_q} * \psi^{j_1 \ldots j_p}_{k_1 \ldots k_q}; \tag{2.14d}$$

$$\mathcal{D}_0(A)|\psi\rangle = |\psi'\rangle,$$

$$\psi'^{j_1 \ldots j_p}_{k_1 \ldots k_q} = A^{j_1}{}_{\ell_1} \ldots A^{j_p}{}_{\ell_p} A^{k_1}{}_{m_1} * \ldots A^{k_q}{}_{m_q} * \ldots \psi^{\ell_1 \ldots \ell_p}_{m_1 \ldots m_q}. \tag{2.14e}$$

Here S_p and S_q are the permutation groups on p and on q objects, respectively. Turning to $\mathcal{H}^{(\mathrm{ind})}$ and $\mathcal{D}^{(\mathrm{ind})}$, the former consists of complex square integrable functions on the coset space SU(3)/SU(2), namely the unit sphere in $\mathcal{C}^3$:[14]

$$\mathcal{H}^{(\mathrm{ind})} = \left\{ \psi(\underline{\xi}) \in \mathcal{C}, \underline{\xi} \in \mathcal{C}^3 \,|\, \|\psi\|^2 = \int \prod_{j=1}^{3} \left(\frac{d^2 \xi_j}{\pi} \right) \delta(\underline{\xi}^{\dagger} \underline{\xi} - 1) |\psi(\underline{\xi})|^2 \right\}. \tag{2.15}$$

The group action is by change of argument:

$$\mathcal{D}^{(\mathrm{ind})}(A)\psi = \psi',$$

$$\psi'(\underline{\xi}) = \psi(A^{-1}\underline{\xi}). \tag{2.16}$$

Then the one-to-one mapping between $\mathcal{H}_0$ and $\mathcal{H}^{(\mathrm{ind})}$ consistent with the two norm definitions (2.14d) and (2.15) and the two group actions (2.14e) and (2.16) is

$$|\psi\rangle = \{\psi^{j_1\ldots j_p}_{k_1\ldots k_q}\} \in \mathcal{H}_0 \leftrightarrow$$

$$\psi(\underline{\xi}) = \sum_{p,q=0,1,\ldots}^{\infty} \sqrt{(p+q+2)!}\,\psi^{j_1\ldots j_p}_{k_1\ldots k_q}\xi_{j_1}\ldots\xi_{j_p}\xi^*_{k_1}\ldots\xi^*_{k_q} \in \mathcal{H}^{(\mathrm{ind})}. \tag{2.17}$$

The fact that $\psi(\underline{\xi}) \in \mathcal{H}^{(\mathrm{ind})}$ is expressible in this way in terms of traceless symmetric tensors is a consequence of the constraint $\underline{\xi}^\dagger\underline{\xi} = 1$.

In this way we see how the Schwinger UR $\mathcal{U}(A)$ of SU(3) contains within it a multiplicity-free UR $\mathcal{D}_0$ including every UIR of SU(3), which is also accessible by the method of induced representations. We will see later that in fact there is a continuously infinite family of subspaces $\mathcal{H}_\kappa \subset \mathcal{H}$, labeled by a complex number κ, such that each $\mathcal{H}_\kappa$ is SU(3) invariant and carries a UR $\mathcal{D}_\kappa$ of SU(3) which, like $\mathcal{D}_0$, is multiplicity-free and contains each UIR (p,q) without exception.

III. INTERPLAY BETWEEN HEISENBERG–WEYL AND UNITARY GROUP COHERENT STATES—ONE AND TWO DEGREES OF FREEDOM

We now turn to an examination of the interconnections between H-W coherent states and unitary group coherent states. In each case there are both standard and generalized coherent state systems. In this section we look at the cases of $n=1$ and $n=2$ degrees of freedom, the relevant unitary groups being U(1) and SU(2) and there being no multiplicity problems. We review briefly some known material, but highlight some special aspects. This material is then used as guidance when we take up in the next section the case $n=6$ and the Schwinger SU(3) construction.

A. One degree of freedom

It is convenient to be able to switch between the use of non-Hermitian creation and annihilation operators $\hat{a}^\dagger$, $\hat{a}$ and their Hermitian position and momentum components $\hat{q}$, $\hat{p}$:

$$\hat{a} = \frac{1}{\sqrt{2}}(\hat{q} + i\hat{p}), \quad \hat{a}^\dagger = \frac{1}{\sqrt{2}}(\hat{q} - i\hat{p}). \tag{3.1}$$

For one degree of freedom, the canonical commutation relation,

$$\begin{aligned} [\hat{a},\hat{a}^\dagger] &= 1, \\ [\hat{q},\hat{p}] &= i, \end{aligned} \tag{3.2}$$

is preserved under the linear inhomogeneous transformation

$$\begin{aligned} \begin{pmatrix} \hat{q} \\ \hat{p} \end{pmatrix} \to \begin{pmatrix} \hat{q}' \\ \hat{p}' \end{pmatrix} &= S\begin{pmatrix} \hat{q} \\ \hat{p} \end{pmatrix} + \begin{pmatrix} q_0 \\ p_0 \end{pmatrix}; \\ S = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad ad - bc &= 1; \quad q_0, p_0 \in \mathcal{R}. \end{aligned} \tag{3.3}$$

Here S is an element of $\mathrm{Sp}(2,R) = \mathrm{SL}(2,R)$, and these transformations constitute the semi-direct product of $\mathrm{Sp}(2,R)$ with the two-dimensional Abelian group of phase-space translations. However, as is well known, these transformations are realized on the Hilbert space $\mathcal{H}$, on which $\hat{a}^\dagger$, $\hat{a}$ or $\hat{q}$, $\hat{p}$ act irreducibly, by unitary transformations forming a faithful UIR of a group $G^{(1)}$ which is the semi-direct product of the metaplectic group Mp(2) with the H-W group:[15]

$$G^{(1)} = \mathrm{Mp}(2) \times \{\text{H-W group}\}. \tag{3.4}$$

Each factor here is a three parameter Lie group, so $G^{(1)}$ is a six-parameter Lie group. The H-W group is the invariant subgroup; it is non-Abelian because of the nonzero right hand sides in the commutators (3.2). Its generators are $\hat{q}$, $\hat{p}$ and the unit operator on $\mathcal{H}$. The homogeneous part Mp(2) is a double cover of Sp(2,R); its generators are Hermitian quadratic expressions in $\hat{a}^\dagger$ and $\hat{a}$, or in $\hat{q}$ and $\hat{p}$.[16] In particular, the U(1) generator is $\frac{1}{2}(\hat{a}^\dagger\hat{a}+\frac{1}{2})$, and this is the analog of J_0 in the Sp(2,R) Lie algebra (2.5).

As stated above, $\mathcal{H}$ carries a particular UIR of $G^{(1)}$. Upon restriction to the H-W subgroup, this representation remains irreducible; it is the result of exponentiating the well-known unique Stone–von Neumann representation of the commutation relations (3.2).[17] On the other hand, upon restriction to the Mp(2) subgroup, we get a direct sum of two UIRs of the positive discrete class, namely $D^{(+)}_{1/4}$ and $D^{(+)}_{3/4}$.[18] These act on the subspaces $\mathcal{H}^{(\pm)}$ of $\mathcal{H}$ consisting of even/odd parity states or Schrodinger wave functions. The nontrivial H-W generators $\hat{q}$ and $\hat{p}$ intertwine these two UIRs of Mp(2).

With this background, we collect some remarks regarding various systems of coherent states. As both $G^{(1)}$ and the H-W group are represented irreducibly on $\mathcal{H}$, for any choice of a (normalized) fiducial vector $\psi_0 \in \mathcal{H}$ we can build up a family of $G^{(1)}$—GCSs or a family of H-W GCSs.[5] These are the orbits of ψ_0 under $G^{(1)}$ action and under H-W action, respectively, and the latter orbit is a subset of the former. In the case of Mp(2), we can construct systems of GCS separately in $\mathcal{H}^{(+)}$ and in $\mathcal{H}^{(-)}$, associated with any choices of fiducial vectors in these subspaces. Examples are the single mode squeezed coherent states and their variations.[18]

Now let us limit ourselves to H-W coherent states, and to their behaviors under the maximal compact U(1) subgroup of Mp(2). As mentioned earlier, the generator of this U(1) is $\frac{1}{2}(\hat{a}^\dagger\hat{a}+\frac{1}{2})$. However, for simplicity we shall work with

$$\overline{U}(\alpha)=e^{-i\alpha\hat{a}^\dagger\hat{a}}, \quad 0\leqslant\alpha<2\pi. \tag{3.5}$$

Conjugation by $\overline{U}(\alpha)$ has these effects on $\hat{a}$, $\hat{a}^\dagger$, and the unitary phase space displacement operators $D(z)$ which represent elements of the H-W group:

$$\begin{gathered}\overline{U}(\alpha)\hat{a}\overline{U}(\alpha)^{-1}=e^{i\alpha}\hat{a},\\ \overline{U}(\alpha)\hat{a}^\dagger\overline{U}(\alpha)^{-1}=e^{-i\alpha}\hat{a}^\dagger;\\ D(z)=\exp(z\hat{a}^\dagger-z^*\hat{a}),\\ \overline{U}(\alpha)D(z)\overline{U}(\alpha)^{-1}=D(e^{-i\alpha}z).\end{gathered} \tag{3.6}$$

The H-W SCSs correspond to the choice of the Fock vacuum $|0\rangle$ as the fiducial vector:[3]

$$|z\rangle=D(z)|0\rangle, \quad z\in\mathcal{C}. \tag{3.7}$$

Invariance of $|0\rangle$ under $\overline{U}(\alpha)$ action then leads to the behavior

$$\overline{U}(\alpha)|z\rangle=|e^{-i\alpha}z\rangle. \tag{3.8}$$

These states enjoy the well-known Klauder formula for resolution of the identity operator:

$$\int_{\mathcal{C}}\frac{d^2z}{\pi}|z\rangle\langle z|=1 \text{ on } \mathcal{H}. \tag{3.9}$$

This can be viewed as a consequence of the Schur lemma and the square integrability of the Stone–von Neumann UIR of the H-W group,[19] since the uniform integration measure on the complex plane in (3.9) is essentially the invariant measure on the H-W group.

We now examine two variations of these familiar results. By Eq. (3.8), the left hand side of Eq. (3.9) is explicitly U(1)-invariant. We can consider including some nontrivial function $f(z^*z)$ inside the integral, which would maintain U(1) invariance, and define the operator

$$A(f)=\int_{\mathcal{C}}\frac{d^2z}{\pi}f(z^*z)\ \ |z\rangle\langle z|. \tag{3.10}$$

As long as $f(z^*z)$ is not a constant, the integration measure here is no longer the invariant measure on the H-W group, so the Schur lemma is not available. Formally,

$$f(z^*z)\neq \text{const}\Leftrightarrow D(z)A(f)\neq A(f)D(z), \tag{3.11}$$

so there is no reason to expect $A(f)$ to be a multiple of the identity. However, U(1) invariance,

$$\overline{U}(\alpha)A(f)=A(f)\overline{U}(\alpha), \tag{3.12}$$

implies that $A(f)$ is a linear combination of projections on to the various Fock states, and indeed we find

$$A(f)=\sum_{n=0}^{\infty}\int_0^{\infty}dx f(x)x^n e^{-x}\cdot\frac{|n\rangle\langle n|}{n!}. \tag{3.13}$$

Clearly the only choice of f leading to the Klauder formula (3.9) is $f=1$. On the other hand, if we choose $f(z^*z)=\delta(z^*z-r_0^2)$ for some real positive r_0, we are limiting ourselves to a subset of H-W SCSs lying on a circle in the complex plane. This is essentially the U(1) group manifold; and, if $r_0=1$, we have exactly the manifold S^1, that is, we have a U(1)-worth of H-W SCSs. In this case, we find

$$f(x)=\delta(x-r_0^2):$$

$$\begin{aligned}A(f)&=\int\frac{d^2z}{\pi}\delta(z^*z-r_0^2)|z\rangle\langle z|\\&=\int_0^{2\pi}\frac{d\theta}{2\pi}|r_0e^{i\theta}\rangle\langle r_0e^{i\theta}|\\&=\sum_{n=0}^{\infty}e^{-r_0^2}\frac{r_0^{2n}}{n!}|n\rangle\langle n|\\&=e^{-r_0^2}\cdot r_0^{2\hat{N}}/\hat{N}!,\end{aligned} \tag{3.14}$$

$$\hat{N}=\hat{a}^{\dagger}\hat{a}.$$

This means that even though the subset of H-W SCSs $\{|r_0e^{i\theta}\rangle,0\leqslant\theta<2\pi\}$ lying on a circle in the complex plane is "total," [20] and each Fock state $|n\rangle$ can be projected out of this subset as

$$|n\rangle=e^{r_0^2/2}\cdot\sqrt{n!}r_0^{-n}\cdot\int_0^{2\pi}\frac{d\theta}{2\pi}\cdot e^{-in\theta}\cdot|r_0e^{i\theta}\rangle, \tag{3.15}$$

we cannot obtain a Klauder-type resolution of the identity using them. Thus this U(1)-worth of SCSs does not form a system of GCSs in the Klauder sense.

The next variation we consider is replacing the Fock vacuum $|0\rangle$ by a generic unit vector $|\psi_0\rangle\in\mathcal{H}$ as fiducial vector. We then get a family of H-W GCSs:[21]

$$|z;\psi_0\rangle = D(z)|\psi_0\rangle, \quad z \in \mathcal{C}. \tag{3.16}$$

Once again, the Schur lemma leads to the Klauder resolution of the identity,

$$\int \frac{d^2z}{\pi} |z;\psi_0\rangle\langle z;\psi_0| = c.1, \tag{3.17}$$

for some constant c, and square integrability ensures that c is finite. If in the manner of Eq. (3.10) we next define

$$A(f;\psi_0) = \int \frac{d^2z}{\pi} f(z^*z)|z;\psi_0\rangle\langle z;\psi_0|, \tag{3.18}$$

then, on the one hand, we do not expect $A(f;\psi_0)$ to be a multiple of the unit operator since we lose Schur lemma; and, on the other hand, we do not even expect $A(f;\psi_0)$ to commute with $\overline{U}(\alpha)$. That is, in general $A(f;\psi_0)$ is not a linear combination of the projections $|n\rangle\langle n|$ on to the Fock states. The exceptions are when $|\psi_0\rangle$ is an eigenstate of $\hat{a}^\dagger\hat{a}$, i.e., a Fock state $|n_0\rangle$ for some integer n_0. This possibility arises because U(1) is Abelian, and its UIRs are all one-dimensional. In that case we find[22]

$$\begin{gathered}
|\psi_0\rangle = |n_0\rangle: \\
\overline{U}(\alpha)|z;n_0\rangle = e^{-i\alpha n_0}|e^{-i\alpha}z;n_0\rangle, \\
\overline{U}(\alpha)A(f;n_0) = A(f;n_0)\overline{U}(\alpha); \\
A(f;n_0) = \sum_{n=0}^{\infty} C_{n,n_0}(f)|n\rangle\langle n|,
\end{gathered} \tag{3.19}$$

$$C_{n,n_0}(f) = \frac{n_<!}{n_>!}\int_0^\infty dx f(x) x^{|n-n_0|} e^{-x} (L_{n_<}^{|n-n_0|}(x))^2,$$

$$n_> = \max(n,n_0), n_< = \min(n,n_0).$$

When $n_0 = 0$ we recover Eq. (3.13). If we next choose $f(z^*z) = \delta(z^*z - r_0^2)$, thus limiting ourselves to a U(1)-worth of H-W GCSs, we find, in place of Eq. (3.14),

$$\begin{gathered}
f(x) = \delta(x - r_0^2): \\
A(f;n_0) = \int \frac{d^2z}{\pi} \delta(z^*z - r_0^2)|z;n_0\rangle\langle z;n_0| \\
= \int_0^{2\pi} \frac{d\theta}{2\pi} |r_0 e^{i\theta};n_0\rangle\langle r_0 e^{i\theta};n_0| \\
= \sum_{n=0}^{\infty} e^{-r_0^2} r_0^{2n} (L_{n_<}^{|n-n_0|}(r_0^2))^2 \frac{n_<!}{n_>!} |n\rangle\langle n|.
\end{gathered} \tag{3.20}$$

The main result of these considerations is that with SCSs or GCSs for the H-W group for one degree of freedom, we can get a Klauder-type resolution of the identity only if we use the invariant measure on the group, but understandably not if we limit ourselves to a subset amounting to a U(1)-worth of these states.

B. Two degrees of freedom

Here we are interested in the interplay between coherent state systems for the relevant five-parameter H-W group, and the unitary groups U(2) and SU(2) which were the subject of the original Schwinger construction.

The nonvanishing commutators in non-Hermitian and Hermitian forms are

$$[\hat{a}_r,\hat{a}_s^\dagger]=\delta_{rs},$$
$$[\hat{q}_r,\hat{p}_s]=i\delta_{rs},\quad r,s=1,2. \tag{3.21}$$

There is no cause for confusion if again we write $\mathcal{H}$ for the Hilbert space carrying the irreducible Stone–von Neumann representation of these relations. The largest natural invariance group now acts on the four $\hat{q}$'s and $\hat{p}$'s as follows:

$$\begin{pmatrix}\hat{q}_r\\ \hat{p}_r\end{pmatrix}\to\begin{pmatrix}\hat{q}_r'\\ \hat{p}_r'\end{pmatrix}=S\begin{pmatrix}\hat{q}_r\\ \hat{p}_r\end{pmatrix}+\begin{pmatrix}q_{r,0}\\ p_{r,0}\end{pmatrix}. \tag{3.22}$$

Here $S\in \mathrm{Sp}(4,R)$ is a four-dimensional real symplectic matrix, and $q_{r,0},p_{r,0}$ denote an Abelian phase space translation.[23] These 14 parameter transformations preserve (3.21). They make up the semi-direct product of $\mathrm{Sp}(4,R)$, which is ten-dimensional, with the four-dimensional Abelian translations. On the space $\mathcal{H}$, however, these transformations are realized as a faithful UIR of the fifteen-parameter semi-direct product

$$G^{(2)}=\mathrm{Mp}(4)\times\{\text{H-W group}\}. \tag{3.23}$$

Here the invariant subgroup is the five-parameter non-Abelian H-W group appropriate for two degrees of freedom, while the homogeneous part is the metaplectic group Mp(4), a double cover of $\mathrm{Sp}(4,R)$. The generators of the former are $\hat{q}_r,\hat{p}_r$ and the unit operator, while those of the latter are Hermitian symmetrized quadratics in $\hat{q}_r,\hat{p}_r$.

The Hilbert space $\mathcal{H}$ carries a UIR of $G^{(2)}$, which remains irreducible when restricted to the H-W group. On the other hand, Mp(4) is represented by the direct sum of two UIRs, one each on the subspaces of even and odd parity states in $\mathcal{H}$. The general statements that can be made about GCS with respect to $G^{(2)}$, Mp(4) and the H-W group are similar to those in the one degree of freedom case. Once again, our main interest is in the connections between H-W and SU(2) coherent state systems.

The maximal compact subgroup of Mp(4) is U(2). The SU(2) part of U(2) has the generators and commutation relations (Schwinger construction)

$$J_j=\tfrac{1}{2}\hat{a}^\dagger\sigma_j\hat{a},$$
$$[J_j,J_k]=i\ \epsilon_{jk\not j}J_{\not j},\quad j,k=1,2,3. \tag{3.24}$$

The U(1) part of U(2) has as generator the total number operator

$$\hat{N}=\hat{N}_1+\hat{N}_2,$$
$$\hat{N}_r=\hat{a}_r^\dagger\hat{a}_r, \tag{3.25}$$
$$[J_j,\hat{N}]=0.$$

For general $u\in \mathrm{U}(2)$, we write $\overline{\mathrm{U}}(u)$ for the corresponding unitary operator on $\mathcal{H}$, generated by $J_j,\hat{N}$. Then, in place of Eq. (3.6), we now have

$$\begin{aligned}
&\overline{\mathrm{U}}(u)\hat{a}\overline{\mathrm{U}}(u)^{-1}=u^{-1}\hat{a},\\
&\overline{\mathrm{U}}(u)\hat{a}^{\dagger}\overline{\mathrm{U}}(u)^{-1}=\hat{a}^{\dagger}u;\\
&D(\underline{z})=\exp(\hat{a}^{\dagger}\underline{z}-\underline{z}^{\dagger}\hat{a}),\\
&\overline{\mathrm{U}}(u)D(\underline{z})\overline{\mathrm{U}}(u)^{-1}=D(u\underline{z}).
\end{aligned} \tag{3.26}$$

Here $\underline{z}=(z_1,z_2)^T$ is a complex two-component column vector, while $\hat{a}$ and $\hat{a}^{\dagger}$ are written as column and row vectors, respectively.

The reduction of $\overline{\mathrm{U}}(u)$ into UIRs is accomplished by the break-up of $\mathcal{H}$ into the mutually orthogonal eigenspaces $\mathcal{H}^{(j)}$ of $\hat{N}$ with eigenvalues $2j$, where $j=0,\frac{1}{2},1,\ldots$. The orthonormal Fock basis for $\mathcal{H}$ is made up of the simultaneous eigenvectors of $\hat{N}_1$ and $\hat{N}_2$:

$$\begin{aligned}
&|n_1,n_2\rangle=\frac{(\hat{a}_1^{\dagger})^{n_1}(\hat{a}_2^{\dagger})^{n_2}}{\sqrt{n_1!n_2!}}|0,0\rangle,\\
&\hat{N}_r|n_1,n_2\rangle=n_r|n_1,n_2\rangle,\quad r=1,2.
\end{aligned} \tag{3.27}$$

For the purposes of reduction of $\overline{\mathrm{U}}$, with no danger of confusion we use vectors labeled $|j,m\rangle$ and defined in terms of these Fock states by

$$\begin{aligned}
&|j,m\rangle=|n_1,n_2\rangle,\\
&n_1=\tfrac{1}{2}(j+m),\quad n_2=\tfrac{1}{2}(j-m),\\
&j=0,\tfrac{1}{2},1,\ldots,\quad m=j,j-1,\ldots,-j.
\end{aligned} \tag{3.28}$$

Then the subspaces $\mathcal{H}^{(j)}$ are given by

$$\begin{aligned}
&\mathcal{H}^{(j)}=\mathrm{Sp}\{|j,m\rangle|j\ \text{ fixed},\quad m=j,j-1,\ldots,-j\},\\
&j=0,\tfrac{1}{2},1,\ldots.
\end{aligned} \tag{3.29}$$

The operators $\overline{\mathrm{U}}(u)$ leave each $\mathcal{H}^{(j)}$, of dimension $(2j+1)$, invariant, and reduce thereon to the spin j UIR of SU(2), along with the value $2j$ for the U(1) generator $\hat{N}$. This is the known multiplicity-free reduction of the SU(2) Schwinger construction.[2] The projection operator P_j onto the subspace $\mathcal{H}^{(j)}$, which will be needed later, is

$$P_j=\sum_{m=-j}^{+j}|j,m\rangle\langle j,m|=\delta_{\hat{N},2j}\,. \tag{3.30}$$

The H-W SCSs use the Fock vacuum $|0,0\rangle$ as the fiducial vector:

$$|\underline{z}\rangle=D(\underline{z})|0,0\rangle, \tag{3.31}$$

and, on account of Eq. (3.26), they have the U(2) behavior

$$\overline{\mathrm{U}}(u)|\underline{z}\rangle=|u\underline{z}\rangle. \tag{3.32}$$

This is because $|0,0\rangle$ is invariant under U(2) action; in fact, it is the only such vector in $\mathcal{H}$. Therefore, the general H-W SCS $|\underline{z}\rangle$ is obtainable by suitable U(2) action from a SCS for the first degree of freedom alone:

$$|\underline{z}\rangle = \overline{\mathrm{U}}(u)|\underline{z}^{(0)}\rangle, \quad \text{suitable } u \in \mathrm{U}(2),$$

$$\underline{z}^{(0)} = r\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \tag{3.33}$$

$$r^2 = \underline{z}^\dagger \underline{z}, \quad 0 \leqslant r < \infty.$$

To bring out the connection between these H-W SCSs and SU(2) SCSs (identified below) in the clearest possible manner, we parametrize $\underline{z}$ and define elements $A(\theta,\phi) \in \mathrm{SU}(2)$ in a coordinated manner:

$$\underline{z} = e^{i\alpha} A(\theta,\phi)\underline{z}^{(0)},$$

$$A(\theta,\phi) = e^{(-i/2)\,\phi\sigma_3} e^{(-i/2)\,\theta\sigma_2} \in \mathrm{SU}(2),$$

$$0 \leqslant \theta \leqslant \pi, \quad 0 \leqslant \alpha, \quad \phi \leqslant 2\pi; \tag{3.34}$$

$$z_1 = r\ \ e^{i\alpha} e^{-i\phi/2} \cos\theta/2, \quad z_2 = r\ \ e^{i\alpha} e^{i\phi/2} \sin\theta/2.$$

We view θ, ϕ as spherical polar angles on S^2. Then Eq. (3.33) assumes the more detailed form

$$|\underline{z}\rangle = e^{i\alpha\hat{N}} \overline{\mathrm{U}}(A(\theta,\phi))|\underline{z}^{(0)}\rangle,$$

$$|\underline{z}^{(0)}\rangle = e^{r(\hat{a}_1^\dagger - \hat{a}_1)}|0,0\rangle = e^{-(1/2)r^2} \sum_{j=0,1/2,1,\ldots}^{\infty} \frac{r^{2j}}{\sqrt{2j!}}|j,j\rangle. \tag{3.35}$$

The component of $|\underline{z}^{(0)}\rangle$ within $\mathcal{H}^{(j)}$ is a multiple of $|j,j\rangle$, the highest weight vector in the spin j UIR of SU(2). By definition, the SU(2) SCSs in any UIR are based on the choice of highest weight vector [or any SU(2) transform of it] as fiducial vector.[24] This vector is the eigenvector of J_3 with maximum eigenvalue j, so any SU(2) transform of it is an eigenvector of a suitable combination of J_k with the same (maximum) eigenvalue. These remarks lead to the following notations for SU(2) SCS:

$$\overline{\mathrm{U}}(A(\theta,\phi))|j,j\rangle \equiv |j,\hat{n}(\theta,\phi)\rangle = \sum_{m=-j}^{j} \sqrt{\frac{2j!}{(j+m)!(j-m)!}}\, e^{-im\phi} (\cos\theta/2)^{j+m} (\sin\theta/2)^{j-m} |j,m\rangle,$$

$$\hat{n}(\theta,\phi)\cdot\vec{J}|j,\hat{n}(\theta,\phi)\rangle = j|j,\hat{n}(\theta,\phi)\rangle, \tag{3.36}$$

$$\hat{n}(\theta,\phi) = (\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta) = \frac{1}{r^2}\underline{z}^\dagger \underline{\sigma}\underline{z} \in S^2.$$

Thus the family of SU(2) SCSs in the spin j UIR is $\{|j,\hat{n}(\theta,\phi)\rangle\}$, one for each point on S^2 which is the coset space SU(2)/U(1). For these states we have the well-known properties

$$\langle j,\hat{n}(\theta',\phi')|j,\hat{n}(\theta,\phi)\rangle = (\cos\theta'/2\cos\theta/2 e^{i(\phi'-\phi)/2} + \sin\theta'/2\sin\theta/2 e^{i(\phi-\phi')/2})^{2j}, \tag{3.37a}$$

$$A \in \mathrm{SU}(2): \overline{\mathrm{U}}(A)|j,\hat{n}\rangle = e^{i\omega(A;\hat{n})}|j, \quad R(A)\hat{n}\rangle, \tag{3.37b}$$

where $R(A) \in \mathrm{SO}(3)$ is the image of $A \in \mathrm{SU}(2)$ under the $\mathrm{SU}(2) \to \mathrm{SO}(3)$ homomorphism, and $\omega(A;\hat{n})$ is a (Wigner) phase angle.[25] Combining Eqs. (3.35) and (3.36) we get the connection between H-W and SU(2) SCSs:

$$|\underline{z}\rangle = e^{-(1/2)r^2} \sum_{j=0,1/2,1,\ldots}^{\infty} \frac{(r\ e^{i\alpha})^{2j}}{\sqrt{2j!}} |j,\hat{n}(\theta,\phi)\rangle. \tag{3.38}$$

We trace this direct connection to the simple U(2) action (3.32), and the expansion (3.35) of $|\underline{z}^{(0)}\rangle$ in terms of SU(2) highest weight states.

We now look at the Klauder resolution of unity for the H-W SCS, highlighting the SU(2) SCS structure. Using the parametrization (3.34) for $\underline{z}$ we find

$$\begin{aligned}\int \frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}|\underline{z}\rangle\langle\underline{z}| &= \frac{1}{4\pi^2}\int_0^\infty r^3dr\int_0^{2\pi}d\alpha\int_{S^2}d\Omega(\theta,\phi)|\underline{z}\rangle\langle\underline{z}| \\ &= \frac{1}{4\pi^2}\int r^3drd\alpha d\Omega(\theta,\phi)\sum_{j,j'=0,1/2,1,\ldots}^{\infty} e^{-r^2}r^{2(j+j')}e^{2i\alpha(j-j')} \\ &\quad\times|j,\hat{n}(\theta,\phi)\rangle\langle j',\hat{n}(\theta,\phi)|/\sqrt{2j!2j'!} \\ &= \frac{1}{2\pi}\sum_{j=0,1/2,1,\ldots}^{\infty}\frac{1}{2j!}\int_0^\infty r^3dre^{-r^2}r^{4j}\int_{S^2}d\Omega(\theta,\phi)|j,\hat{n}(\theta,\phi)\rangle\langle j,\hat{n}(\theta,\phi)|.\end{aligned} \tag{3.39}$$

Here $d\Omega(\theta,\phi)$ is the element of solid angle on S^2. Using Eq. (3.37b) we see that the integral over S^2 results in an operator invariant under the spin j UIR of SU(2) appearing on $\mathcal{H}^{(j)}$, therefore by Schur lemma for this UIR we have

$$\int_{S^2}d\Omega(\theta,\phi)|j,\hat{n}(\theta,\phi)\rangle\langle j,\hat{n}(\theta,\phi)| = \frac{4\pi}{2j+1}P_j. \tag{3.40}$$

Substituting this in Eq. (3.39) we get

$$\int \frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}|\underline{z}\rangle\langle\underline{z}| = 2\sum_{j=0,1/2,1,\ldots}^{\infty}\frac{1}{(2j+1)!}\int_0^\infty r^3dre^{-r^2}\cdot r^{4j}\cdot P_j = \sum_{j=0,1/2,1,\ldots}^{\infty}P_j = 1 \ \text{ on } \ \mathcal{H}. \tag{3.41}$$

This is known and expected on account of the Schur lemma for the H-W UIR, since the integration measure is the invariant one on the H-W group. At the same time we can immediately trace the consequences of modifying the measure in a U(2)-invariant way, when we lose the possibility of using the lemma for the H-W UIR:

$$A(f) = \int \frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}f(\underline{z}^\dagger\underline{z})|\underline{z}\rangle\langle\underline{z}| = \sum_{j=0,1/2,1,\ldots}^{\infty}\int_0^\infty dxf(x)x^{2j+1}e^{-x}\frac{P_j}{(2j+1)!}, \tag{3.42}$$

$$f \neq \text{const} \Leftrightarrow D(\underline{z})A(f) \neq A(f)D(\underline{z}).$$

With the particular choice $f(x) = \delta(x - r_0^2)$ for real positive r_0, we limit ourselves to an ''SU(2)-worth'' of H-W SCS, and in that case we have

$$f(x)=\delta(x-r_0^2):$$

$$A(f)=\int \frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}\,\delta(\underline{z}^\dagger\underline{z}-r_0^2)|\underline{z}\rangle\langle\underline{z}|$$

$$=r_0^2\int_0^{2\pi}\frac{d\alpha}{2\pi}\cdot\int_{S^2}\frac{d\Omega(\theta,\phi)}{4\pi}\cdot\left|e^{i\alpha}A(\theta,\phi)\begin{pmatrix}r_0\\0\end{pmatrix}\right\rangle\left\langle e^{i\alpha}A(\theta,\phi)\begin{pmatrix}r_0\\0\end{pmatrix}\right|$$

$$=\sum_{j=0,1/2,1,\ldots}^{\infty}e^{-r_0^2}\cdot\frac{(r_0^2)^{2j+1}}{(2j+1)!}P_j\,. \tag{3.43}$$

The structure of these results (3.42) and (3.43) is as expected since $A(f)$ does commute with $\overline{\mathrm{U}}(u)$.

Lastly we consider briefly some aspects of H-W GCS in the case of two degrees of freedom. These arise by replacing the Fock vacuum $|0,0\rangle$ by some other (normalized) vector $|\psi_0\rangle\in\mathcal{H}$ as fiducial vector:

$$|\underline{z};\psi_0\rangle=D(\underline{z})|\psi_0\rangle. \tag{3.44}$$

The Schur lemma and square integrability of the H-W UIR ensure the Klauder formula

$$\int\frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}|\underline{z};\psi_0\rangle\langle\underline{z};\psi_0|=c.1, \tag{3.45}$$

for some finite constant c. However, if $|\psi_0\rangle\neq|0,0\rangle$, we never have any simple behavior for these GCSs under U(2) action. This is in contrast to Eq. (3.19) in the case of one degree of freedom. The reason is that the only one-dimensional UIR of SU(2) is the trivial UIR, all others are of dimension two or greater. This can be traced to the non-Abelian nature of SU(2), in contrast to U(1). For this reason we are unable to obtain $|\underline{z};\psi_0\rangle$ for general $\underline{z}$ from some specially chosen and simpler state $|\underline{z}^{(0)};\psi_0\rangle$ via U(2) action; so, the possibility of relating H-W GCS to some sequence of SU(2) GCSs within each subspace $\mathcal{H}^{(j)}$ is also lost. Going one step further, if we consider a modified U(2)-invariant measure in place of the translation invariant one in Eq. (3.45), but for a GCS system, and if we define

$$A(f;\psi_0)=\int\frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}f(\underline{z}^\dagger\underline{z})|\underline{z};\psi_0\rangle\langle\underline{z};\psi_0|, \tag{3.46}$$

for $|\psi_0\rangle\neq|0,0\rangle$, this will not commute with $\overline{\mathrm{U}}(u)$ and will not reduce to a linear combination of the projections P_j.

IV. RELATION BETWEEN H-W AND SU(3) SCS, RESTRICTION TO $\mathcal{H}_0$

Now that we have explored the relationships between H-W SCS and unitary group SCS for one and two degrees of freedom, we proceed to the SU(3) Schwinger construction recalled in Sec. II, and the corresponding H-W SCS for six oscillators. Here we invert the order of development as compared to the previous section. We recall first the definition of SU(3) SCS within each UIR, then proceed to the H-W system. The specific new feature is the multiplicity problem, to be handled using $\mathrm{Sp}(2,R)$.

A. SU(3) standard coherent states

The familiar orthonormal basis states within the UIR (p,q) of SU(3), corresponding to the canonical subgroup chain $\mathrm{U}(1)\subset\mathrm{U}(2)\subset\mathrm{SU}(3)$, consist of a set of isospin-hypercharge multiplets [cf. Eqs. (2.9) and (2.11)]:[26]

$$
\begin{gathered}
|p,q;IMY\rangle, \\
I=\tfrac{1}{2}(r+s), \quad Y=\tfrac{2}{3}(q-p)+r-s, \\
M=I,I-1,\ldots, \quad -I+1,-I, \\
0\leqslant r\leqslant p, \quad 0\leqslant s\leqslant q.
\end{gathered}
\tag{4.1}
$$

The highest weight state is the one with maximum possible value of M:

$$
|p,q;\tfrac{1}{2}(p+q),\ \tfrac{1}{2}(p+q),\ \tfrac{1}{3}(p-q)\rangle. \tag{4.2}
$$

In terms of the realization of the UIR (p,q) via irreducible tensors $T=\{T^{j_1\cdots j_p}_{k_1\cdots k_q}\}$, this state corresponds to the component

$$
T^{11\ldots1}_{22\ldots2}. \tag{4.3}
$$

From this one can see that the stability group (upto phase factors) of the state (4.2) is a subgroup $H\subset \mathrm{SU}(3)$ dependent on p and q. Disregarding the trivial UIR (0,0), we have

$$
p\geqslant 1, q=0: H=\mathrm{U}(2) \ \text{ on dimensions } \ 2,3; \tag{4.4a}
$$

$$
p=0, q\geqslant 1: H=\mathrm{U}(2) \ \text{ on dimensions } \ 1,3; \tag{4.4b}
$$

$$
p,q\geqslant 1: H=\text{diagonal subgroup of } \mathrm{SU}(3)\,. \tag{4.4c}
$$

[Here the dimensions 1,2,3 refer to the space of the defining UIR (1,0).] In Eq. (4.4a) [Eq. (4.4b)], a U(2) transformation on dimensions 2 and 3 (1 and 3) is to be accompanied by a phase change in dimension 1(2) to preserve unimodularity of the SU(3) transformation. The dimensionalities of these three stability groups are four, four and two, respectively.

The SU(3) SCSs within the UIR (p,q) are the states obtained by acting with all SU(3) elements on the highest weight state (4.2). They may be written as $|p,q;A\rangle$, $A\in \mathrm{SU}(3)$:

$$
|p,q;A\rangle=\overline{\mathrm{U}}(A)|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q),\tfrac{1}{3}(p-q)\rangle. \tag{4.5}
$$

Therefore in the UIRs $(p,0)$ and $(0,q)$, they form four-parameter continuous families of normalized states, while in (p,q) with $p,q\geqslant 1$ we have six-parameter continuous families. Referring to Eq. (4.4) we have

$$
h\in \ H: |p,q;Ah\rangle=e^{i\varphi(h)}|p,q;A\rangle, \tag{4.6}
$$

for some phase $\varphi(h)$.

These SU(3) SCSs have been studied in detail in Ref. 27, individually within each UIR. As we see below, the Schwinger construction helps us generate them collectively and explore some of their properties in an efficient manner, just as in Eq. (3.38) we have a construction of the SU(2) SCS in all its UIRs at one stroke.

If within the UIR (p,q) we choose as fiducial vector some vector other than the highest weight vector (4.2) or any SU(3) transform of it, then we obtain a family of SU(3) GCSs. For the present we consider only SCSs, turning to particular GCSs in subsequent sections.

In the Hilbert space $\mathcal{H}$ of the SU(3) Schwinger construction the ''first'' occurrence of the UIR (p,q) is in the subspace $\mathcal{H}^{(p,q;0)}\subset\mathcal{H}_0$ which is annihilated by K_-. The corresponding highest weight state (4.2), using the complete notation of Eq. (2.9) and recalling Eq. (4.3), is

$$|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q),\tfrac{1}{3}(p-q);\tfrac{1}{2}(p+q+3)\rangle=\frac{(\hat{a}_1^\dagger)^p(\hat{b}_2^\dagger)^q}{\sqrt{p!q!}}|\underline{0},\underline{0}\rangle\in\mathcal{H}^{(p,q;0)}\subset\mathcal{H}_0. \quad (4.7)$$

It follows that all these highest weight states, one for each UIR (p,q), are generated by the special H-W SCS

$$|z_1,0,0;0,w_2,0\rangle=D(z_1,0,0,0,w_2,0)|\underline{0},\underline{0}\rangle\in\mathcal{H}_0,$$

$$D(\underline{z},\underline{w})=\exp(\underline{z}\cdot\hat{\underline{a}}^\dagger-\underline{z}^*\cdot\hat{\underline{a}}+\underline{w}\cdot\hat{\underline{b}}^\dagger-\underline{w}^*\cdot\hat{\underline{b}})=\exp(-\tfrac{1}{2}\underline{z}^\dagger\underline{z}-\tfrac{1}{2}\underline{w}^\dagger\underline{w}+\underline{z}\cdot\hat{\underline{a}}^\dagger+\underline{w}\cdot\hat{\underline{b}}^\dagger). \quad (4.8)$$

Here $\underline{z}$ and $\underline{w}$ are independent complex three-vectors, and $D(\underline{z},\underline{w})$ are the displacement operators for the six-oscillator system of the Schwinger construction. Indeed we have:

$$|z_1,0,0;0,w_2,0\rangle=e^{-(1/2)|z_1|^2-(1/2)|w_2|^2}\sum_{p,q=0}^{\infty}\frac{z_1^p w_2^q}{\sqrt{p!q!}}$$
$$\times|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q),\tfrac{1}{3}(p-q);\tfrac{1}{2}(p+q+3)\rangle, \quad (4.9)$$

which is analogous to the second of Eqs. (3.35). We will use this below.

B. SU(3) analysis of the H-W SCS

For the six-oscillator system used in the Schwinger SU(3) construction the H-W SCSs are labeled by two complex three-dimensional vectors $\underline{z}$ and $\underline{w}$, thus the pair $(\underline{z},\underline{w})$ is a point in $\mathcal{C}^6$. They are obtained by applying the displacement operators $D(\underline{z},\underline{w})$ to the Fock vacuum $|\underline{0},\underline{0}\rangle$ as fiducial vector:

$$|\underline{z},\underline{w}\rangle=D(\underline{z},\underline{w})|\underline{0},\underline{0}\rangle. \quad (4.10)$$

We see from Eq. (2.5) that they are eigenstates of the Sp(2,R) lowering operator $K_-=K_1-iK_2$:

$$\hat{a}_j|\underline{z},\underline{w}\rangle=z_j|\underline{z},\underline{w}\rangle,$$
$$\hat{b}_j|\underline{z},\underline{w}\rangle=w_j|\underline{z},\underline{w}\rangle, \quad (4.11)$$
$$K_-|\underline{z},\underline{w}\rangle=\underline{z}^T\underline{w}|\underline{z},\underline{w}\rangle.$$

Therefore only those SCSs $|\underline{z},\underline{w}\rangle$ for which $\underline{z}^T\underline{w}=0$ belong to $\mathcal{H}_0$. The complete set of SCSs obeys the Klauder resolution of the identity,

$$\int_{\mathcal{C}^6}\prod_{j=1}^{3}\left(\frac{d^2z_j}{\pi}\frac{d^2w_j}{\pi}\right)|\underline{z},\underline{w}\rangle\langle\underline{z},\underline{w}|=1 \ \text{ on } \ \mathcal{H}, \quad (4.12)$$

the integration measure being the invariant one on the H-W group.

We now explore the behavior of these SCSs under SU(3) action. From the manner in which the generators Q_α are constructed in Eq. (2.2) we have

$$A\in\mathrm{SU}(3):\mathcal{U}(A)D(\underline{z},\underline{w})\mathcal{U}(A)^{-1}=D(A\underline{z},A^*\underline{w}), \quad (4.13)$$

from which it follows that

$$\mathcal{U}(A)|\underline{z},\underline{w}\rangle=|A\underline{z},A^*\underline{w}\rangle. \quad (4.14)$$

The independent invariants under this action are $\underline{z}^\dagger\underline{z}$, $\underline{w}^\dagger\underline{w}$ and $\underline{z}^T\underline{w}$, the last being the eigenvalue of K_-. We describe them using four real independent parameters u, v, x, y as

$$\underline{z}^\dagger\underline{z}=u^2,\quad \underline{w}^\dagger\underline{w}=v^2,\quad \underline{z}^T\underline{w}=uv(x+iy),$$
$$u,v\geqslant 0,\quad 0\leqslant x^2+y^2\leqslant 1. \tag{4.15}$$

The upper bound on x^2+y^2 is an expression of the Cauchy–Schwarz inequality. For each set of values of (u,v,x,y), the SCS $|\underline{z},\underline{w}\rangle$ form an orbit under SU(3) action. On each orbit we can choose a convenient representative point $(\underline{z}^{(0)},\underline{w}^{(0)})$, with any other point $(\underline{z},\underline{w})$ on the orbit arising from $(\underline{z}^{(0)},\underline{w}^{(0)})$ via suitable SU(3) action as $(A\underline{z}^{(0)},A^*\underline{w}^{(0)})$. The complete list of orbits, representative points, stability subgroups $H(\underline{z}^{(0)},\underline{w}^{(0)})\subset$SU(3) and orbit dimensions are as follows (with x, y omitted when irrelevant):

$$(a)\quad \vartheta_1=\{u,v|u=v=0\},(\underline{z}^{(0)},\underline{w}^{(0)})=(\underline{0},\underline{0}),H=\mathrm{SU}(3),\text{dimension }0;$$

$$(b)\quad \vartheta_2=\{u,v|u\rangle 0,v=0\},\underline{z}^{(0)}=u(1,0,0)^T,\underline{w}^{(0)}=\underline{0},H=\mathrm{SU}(2),\text{ dimension }5;$$

$$(c)\quad \vartheta_3=\{u,v|u=0,v\rangle 0\},\underline{z}^{(0)}=\underline{0},\underline{w}^{(0)}=v(0,1,0)^T,H=\mathrm{SU}(2),\text{ dimension }5;$$

$$(d)\quad \vartheta_4=\{u,v,x,y|u,v\rangle 0,0\leqslant x^2+y^2<1\}, \tag{4.16}$$

$$\underline{z}^{(0)}=u(1,0,0)^T,\underline{w}^{(0)}=v(x+iy,\sqrt{1-x^2-y^2},0)^T,H=\{e\},\text{ dimension }8;$$

$$(e)\quad \vartheta_5=\{u,v,x,y|u,v\rangle 0,x^2+y^2=1\},$$

$$\underline{z}^{(0)}=u(0,0,1)^T,\underline{w}^{(0)}=v(x+iy)(0,0,1)^T,H=\mathrm{SU}(2),\text{ dimension }5.$$

We add some comments: Class (a) comprises just the Fock vacuum $|\underline{0},\underline{0}\rangle$, invariant under SU(3) and forming a trivial orbit by itself. Classes (b) and (c) form collections of orbits with one of $\underline{z}$ and $\underline{w}$ vanishing identically, so these are simply SCSs for systems of three oscillators. Class (d) is a four-parameter family consisting of generic orbits. Each orbit in this class is eight-dimensional and is essentially the SU(3) group manifold. Class (e) is a limiting form, as $x^2+y^2\to 1$, of class (d); in these orbits, $\underline{w}$ is a complex multiple of $\underline{z}^*$. However, the limit is a singular one, as is evident from the rise in the dimension of H from zero to three, and the drop in orbit dimension from eight to five. This is why we have listed class (e) separately. Moreover, the representative point $(z^{(0)},w^{(0)})$ in this class has been chosen so that the stability group SU(2) acts on dimensions 1 and 2, thus coinciding with the subgroup relevant for the canonical basis (4.21). Disregarding class (a), and recalling that $\mathcal{C}^6$ is of real dimension 12, we see that classes (b), (c), (d), and (e) are nonoverlapping regions in $\mathcal{C}^6$ of real dimensions 6, 6, 12, and 8, respectively. Thus almost all of $\mathcal{C}^6$ is covered by orbits of class (d).

Based on this orbit structure, we now express the Klauder resolution of the identity, Eq. (4.12), in a manner similar to Eq. (3.39), namely as an integration over the SU(3) manifold followed by an integration over the invariants (4.15). [The difference compared to the case of two degrees of freedom is that here we integrate over the whole of SU(3), not just over a coset space such as $\mathrm{SU}(2)/\mathrm{U}(1)=S^2$ in Eq. (3.39).] In this process we can limit ourselves to class (d) orbits which are generic, as long as we do not at any later stage alter the integrand of Eq. (4.12) by inserting a Dirac delta function with support in one of the exceptional orbits in Eq. (4.16). To obtain a general pair $(\underline{z},\underline{w})$ from $(\underline{z}^{(0)},\underline{w}^{(0)})$ in Eq. (4.16) class (d), we need to parametrize (almost all) elements of SU(3) in a convenient manner. Here we use the fact that, except on a set of vanishing measure, each $A\in\mathrm{SU}(3)$ is uniquely determined by a pair $(\hat{\underline{\eta}},\hat{\underline{\xi}})$, where $\hat{\underline{\eta}}$ is a complex three-component unit vector and $\hat{\underline{\xi}}$ is a complex two-component unit vector:[28]

$$\underline{\hat{\eta}}=(\hat{\eta}_1,\hat{\eta}_2,\hat{\eta}_3)^T,\quad \underline{\hat{\xi}}=(\hat{\xi}_2,\hat{\xi}_3)^T,$$
$$\underline{\hat{\eta}}^\dagger\underline{\hat{\eta}}=\underline{\hat{\xi}}^\dagger\underline{\hat{\xi}}=1. \tag{4.17}$$

Then we have

$$A\in \mathrm{SU}(3)\Leftrightarrow A=A(\underline{\hat{\eta}},\underline{\hat{\xi}}=A_3(\underline{\hat{\eta}})A_2(\underline{\hat{\xi}}),$$
$$A_3(\underline{\hat{\eta}})=\begin{pmatrix}\hat{\eta}_1 & \rho_1 & 0\\ \hat{\eta}_2 & -\hat{\eta}_2\hat{\eta}_1^*/\rho_1 & \hat{\eta}_3^*/\rho_1\\ \hat{\eta}_3 & -\hat{\eta}_3\hat{\eta}_1^*/\rho_1 & -\hat{\eta}_2^*/\rho_1\end{pmatrix}\in \mathrm{SU}(3),$$
$$\rho_1=(1-|\hat{\eta}_1|^2)^{1/2}; \tag{4.18}$$
$$A_2(\underline{\hat{\xi}})=\begin{pmatrix}1 & 0 & 0\\ 0 & \hat{\xi}_2 & -\hat{\xi}_3^*\\ 0 & \hat{\xi}_3 & \hat{\xi}_2^*\end{pmatrix}\in \mathrm{SU}(2)\subset \mathrm{SU}(3).$$

For each $\underline{\hat{\eta}}$ (provided $|\hat{\eta}_1|<1$), $A_3(\underline{\hat{\eta}})$ is a particular SU(3) element completely determined by its first column which is $\underline{\hat{\eta}}$; and for each $\underline{\hat{\xi}}$, $A_2(\underline{\hat{\xi}})$ is an element in the SU(2) subgroup leaving $\underline{z}^{(0)}$ invariant. We can picture $\underline{\hat{\eta}}$ and $\underline{\hat{\xi}}$ as representing points on $S^5\subset\mathcal{R}^6$ and $S^3\subset\mathcal{R}^4$, respectively. Then the normalized invariant volume element on SU(3) is a numerical factor times the product of the solid angle elements on S^5 and S^3:

$$dA(\underline{\hat{\eta}},\underline{\hat{\xi}})=(2\pi^5)^{-1}d\Omega_5(\underline{\hat{\eta}})d\Omega_3(\underline{\hat{\xi}}),$$
$$\int_{\mathrm{SU}(3)}dA=1. \tag{4.19}$$

The expressions for $(\underline{z},\underline{w})$ in terms of $A(\underline{\hat{\eta}},\underline{\hat{\xi}})$ and $(\underline{z}^{(0)},\underline{w}^{(0)})$ are

$$\underline{z}=A(\underline{\hat{\eta}},\underline{\hat{\xi}})\underline{z}^{(0)}(u)=u\,\underline{\hat{\eta}},$$
$$\underline{w}=A(\underline{\hat{\eta}},\underline{\hat{\xi}})^*\underline{w}^{(0)}(v,x,y)=vA_3(\underline{\hat{\eta}})^*\begin{pmatrix}x+iy & \\ \sqrt{1-x^2-y^2} & \hat{\xi}_2^*\\ \sqrt{1-x^2-y^2} & \hat{\xi}_3^*\end{pmatrix}. \tag{4.20}$$

These are the generalizations of Eq. (3.34). Straightforward computations of the Jacobians yield

$$\prod_{j=1}^{3}(d^2z_j\ d^2w_j)=u^5v^5(1-x^2-y^2)du\ \ dv\ \ dx\ \ dy\ \ d\Omega_5(\underline{\hat{\eta}})\ \ d\Omega_3(\underline{\hat{\xi}}). \tag{4.21}$$

We can now rewrite the Klauder result (4.12) as

$$\frac{2}{\pi}\int_0^\infty u^5du\int_0^\infty v^5dv\int_{x^2+y^2\leqslant 1}(1-x^2-y^2)dx\ \ dy\int_{\mathrm{SU}(3)}dA\mathcal{U}(A)|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle$$
$$\times\langle\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)|\mathcal{U}(A)^{-1}=1\ \text{ on }\ \mathcal{H}. \tag{4.22}$$

This is the analog of (the initial form of) Eq. (3.39).

In the spirit of Eqs. (3.10) and (3.42) we can now consider modifications of Eq. (4.22) by including in the integrand a function of the SU(3) invariants. Thus we define

$$A(f)=\int\prod_{j=1}^{3}\left(\frac{d^2z_j}{\pi}\frac{d^2w_j}{\pi}\right)f(u,v,x,y)|\underline{z},\underline{w}\rangle\langle\underline{z},\underline{w}|$$

$$=\frac{2}{\pi}\int_0^\infty u^5du\int_0^\infty v^5dv\int_{x^2+y^2\leq 1}(1-x^2-y^2)dx\ \ dy\ \ f(u,v,x,y)$$

$$\times\int_{\mathrm{SU}(3)}dA\mathcal{U}(A)|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle\langle\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)|\mathcal{U}(A)^{-1}. \tag{4.23}$$

Such an operator definitely obeys

$$\mathcal{U}(A)A(f)=A(f)\mathcal{U}(A),\ \ \text{all}\ \ A\in\mathrm{SU}(3). \tag{4.24}$$

However, as long as $f(u,v,x,y)$ is nontrivial, the measure in Eq. (4.23) is not the invariant one on the H-W group, we do not have recourse to the Schur lemma for the UIR of this group, and $A(f)$ is not proportional to the identity operator on $\mathcal{H}$. The presence of (infinite!) multiplicity in the reduction of $\mathcal{U}(A)$ on $\mathcal{H}$ into UIRs of SU(3) means, furthermore, that we do not immediately get for $A(f)$ a simple combination of SU(3)-invariant projections as we did in Eqs. (3.42) and (3.43) with SU(2).

C. The restriction to $\mathcal{H}_0$

Now we limit ourselves to the SCS $|\underline{z},\underline{w}\rangle$ belonging to $\mathcal{H}_0\subset\mathcal{H}$, as in this subspace the multiplicity problem is avoided. As noted following Eq. (4.11), the condition $\underline{z}^T\underline{w}=0$ ensures $|\underline{z},\underline{w}\rangle\in\mathcal{H}_0$. This happens in classes (a)–(c) of Eq. (4.16) in a trivial manner, and in class (d) when $x=y=0$. The former can be disregarded as being sets of vanishing measure.

We deal first with vector level relations in $\mathcal{H}_0$, then look at modifications of $A(f)$ in Eq. (4.23). We begin with Eq. (4.9). For the highest weight states of SU(3) UIRs occurring there, we introduce a simpler notation:

$$|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q);\tfrac{1}{3}(p-q);\tfrac{1}{2}(p+q+3)\rangle$$

$$\equiv|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q);\tfrac{1}{3}(p-q)\rangle_0\in\mathcal{H}^{(p,q;0)}\subset\mathcal{H}_0. \tag{4.25}$$

We have omitted the Sp(2,R) quantum number m as it is superfluous within $\mathcal{H}_0$. Then Eq. (4.9) takes the form

$$\underline{z}^{(0)}(u)=u(1,0,0)^T,\underline{w}^{(0)}(v,0,0)=v(0,1,0)^T:$$

$$|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,0,0)\rangle=e^{-(1/2)(u^2+v^2)}\sum_{p,q=0}^{\infty}\frac{u^pv^q}{\sqrt{p!q!}} \tag{4.26}$$

$$|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q),\tfrac{1}{3}(p-q)\rangle_0\in\mathcal{H}_0.$$

In place of Eq. (4.5), the SU(3) SCS within each UIR (p,q) contained in $\mathcal{H}_0$ can be written as

$$A\in\mathrm{SU}(3):|p,q;A\rangle_0=\mathcal{U}(A)|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q),\tfrac{1}{3}(p-q)\rangle_0\in\mathcal{H}^{(p,q;0)}. \tag{4.27}$$

Applying $\mathcal{U}(A)$ for general $A\in\mathrm{SU}(3)$ to both sides of Eq. (4.26) we get a result linking those H-W SCSs that lie in $\mathcal{H}_0$, and the SU(3) SCS (4.27) within each UIR (p,q) in $\mathcal{H}_0$:

$$A \in \mathrm{SU}(3), \quad \underline{z} = A\underline{z}^{(0)}(u), \quad \underline{w} = A^* \underline{w}^{(0)}(v,0,0):$$

$$|\underline{z},\underline{w}\rangle = e^{-(1/2)(u^2+v^2)} \sum_{p,q=0}^{\infty} \frac{u^p v^q}{\sqrt{p!q!}} |p,q;A\rangle_0 \in \mathcal{H}_0 . \tag{4.28}$$

This is the SU(3) analog to the SU(2) relation (3.38).

Now we turn to the operator $A(f)$ in Eq. (4.23) and make the choice

$$f(u,v,x,y) = f_0(u,v)\,\delta(x)\,\delta(y). \tag{4.29}$$

This leads to

$$A(f_0) = \frac{2}{\pi} \int_0^{\infty} u^5 du \int_0^{\infty} v^5 dv\, f_0(u,v) \int_{\mathrm{SU}(3)} dA \mathcal{U}(A)$$

$$|\underline{z}^{(0)}(u), \underline{w}^{(0)}(v,0,0)\rangle\langle \underline{z}^{(0)}(u), \underline{w}^{(0)}(v,0,0)| \mathcal{U}(A)^{-1}. \tag{4.30}$$

Such an operator obeys the following:

$$\psi \in \mathcal{H}_0^{\perp} : A(f_0)\psi = 0;$$

$$\psi \in \mathcal{H}_0 : A(f_0)\psi \in \mathcal{H}_0; \tag{4.31}$$

$$A \in \mathrm{SU}(3) : \mathcal{U}(A) A(f_0) = A(f_0) \mathcal{U}(A).$$

Therefore $A(f_0)$ must be a linear combination of the projection operators $P^{(p,q;0)}$ onto the subspaces $\mathcal{H}^{(p,q;0)} \subset \mathcal{H}_0$; it is here that we exploit the multiplicity-free reduction of the SU(3) UR $\mathcal{D}_0$ on $\mathcal{H}_0$. To get $A(f_0)$ explicitly, we use the following immediate consequences of the Schur lemma applied to SU(3), the multiplicity-free nature of $\mathcal{D}_0$, and the orthogonality of inequivalent UIRs:

$$\int_{\mathrm{SU}(3)} dA |p,q;A\rangle_{0\,0}\langle p',q';A| = \delta_{p'p}\delta_{q'q} P^{(p,q;0)}/d(p,q). \tag{4.32}$$

Then a combination of Eqs. (4.30), (4.26), (4.27), and (4.32) immediately gives

$$A(f_0) = \sum_{p,q=0}^{\infty} C(f_0;p,q) P^{(p,q;0)},$$

$$C(f_0;p,q) = \{p!q!d(p,q)\}^{-1} \cdot \frac{2}{\pi} \cdot \int_0^{\infty} u^5 du \int_0^{\infty} v^5 dv\, f_0(u,v) u^{2p} v^{2q} e^{-(u^2+v^2)}. \tag{4.33}$$

This is an SU(3) analog of the SU(2) result (3.42), but it is valid only after the restriction to $\mathcal{H}_0$. On account of the freedom still remaining in Eqs. (4.30) and (4.33) in the choice of the function $f_0(u,v)$, we see that the H-W SCSs occurring there are overcomplete in $\mathcal{H}_0$. If we wish to limit ourselves to an exact "SU(3)-worth" of H-W SCSs within $\mathcal{H}_0$, then we have the analogue to Eq. (3.43):

$$f_0(u,v)=\delta(u-u_0)\,\delta(v-v_0):$$
$$A(f_0)=\int\prod_{j=1}^{3}\left(\frac{d^2z_j}{\pi}\,\frac{d^2w_j}{\pi}\right)\delta(u-u_0)\,\delta(v-v_0)\,\delta(x)\,\delta(y)|\underline{z},\underline{w}\rangle\langle\underline{z},\underline{w}| \tag{4.34}$$
$$=e^{-(u_0^2+v_0^2)}.\,\frac{2}{\pi}\sum_{p,q=0}^{\infty}u_0^{2p+5}v_0^{2q+5}P^{(p,q;0)}/p!q!d(p,q).$$

The point to be emphasized is how far this result departs from being the identity operator in $\mathcal{H}_0$, leave alone in $\mathcal{H}$, but understandably so.

D. Description in $\mathcal{H}^{(\mathrm{ind})}$

As recalled in Sec. II, and established in detail in Sec. I, the multiplicity-free UR $\mathcal{D}_0$ of SU(3) on $\mathcal{H}_0$ is equivalent to an induced UR $\mathcal{D}^{(\mathrm{ind})}$ of SU(3), namely the one arising from the trivial representation of an SU(2) subgroup of SU(3). The isomorphism between $\mathcal{H}_0$ and $\mathcal{H}^{(\mathrm{ind})}$ carrying $\mathcal{D}^{(\mathrm{ind})}$, consistent with the two group actions, is given in Eq. (2.17). It is of interest to see what wave functions $\psi(\underline{\xi})\in\mathcal{H}^{(\mathrm{ind})}$ one obtains for the various vectors in $\mathcal{H}_0$ that have played a role earlier in this section. We now give these wave functions and comment briefly on them.

For the highest weight state in the SU(3) UIR (p,q) on $\mathcal{H}^{(p,q;0)}$, and the associated SU(3) SCS, we find the following wavefunctions in $\mathcal{H}^{(\mathrm{ind})}$:

$$|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q),\tfrac{1}{3}(p-q)\rangle_0\rightarrow\sqrt{\frac{(p+q+2)!}{p!q!}}(\xi_1)^p(\xi_2^*)^q;$$
$$|p,q;A\rangle_0=\mathcal{U}(A)|p,q;\tfrac{1}{2}(p+q),\tfrac{1}{2}(p+q),\tfrac{1}{3}(p-q)\rangle_0\rightarrow\sqrt{\frac{(p+q+2)!}{p!q!}}(A_{j1}^*\xi_j)^p(A_{k2}\xi_k^*)^q. \tag{4.35}$$

For the H-W SCS in $\mathcal{H}_0$ generating these states within each UIR we have

$$|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,0,0)\rangle\rightarrow e^{-(1/2)(u^2+v^2)}\sum_{p,q=0}^{\infty}\sqrt{(p+q+2)!}\frac{(u\xi_1)^p}{p!}\,\frac{(v\xi_2^*)^q}{q!};$$
$$|\underline{z},\underline{w}\rangle=\mathcal{U}(A)|\underline{z}^{(0}(u),\underline{w}^{(0)}(v,0,0)\rangle\rightarrow e^{-(1/2)(u^2+v^2)}\sum_{p,q=0}^{\infty}\sqrt{(p+q+2)!}\frac{(uA_{j1}^*\xi_j)^p}{p!}\,\frac{(vA_{k2}\xi_k^*)^q}{q!}. \tag{4.36}$$

The principal comment we may make is that these particular H-W SCS do not have wave functions in $\mathcal{H}^{(\mathrm{ind})}$ in the form of any simple expressions involving exponential functions. The reason for this can be traced to the factorial in Eq. (2.17) as compared to Eq. (2.14a). Another way of understanding this situation is to realize that $\mathcal{H}_0$ (and so $\mathcal{H}^{(\mathrm{ind})}$ as well) is too small to carry a representation of the H-W system used in the Schwinger SU(3) construction; in addition the argument $\underline{\xi}$ in $\psi(\underline{\xi})$ is a complex unit vector in three dimensions rather than a variable in all of $\mathcal{C}^3$.

V. GENERAL EIGENSPACES $\mathcal{H}_\kappa$ OF K_-

The subspace $\mathcal{H}_0\subset\mathcal{H}$ carrying the multiplicity-free UR $\mathcal{D}_0$ of SU(3), the focus of analysis in the preceding section, is spanned by those H-W SCSs $|\underline{z},\underline{w}\rangle$ for which $\underline{z}^T\underline{w}=0$, and belonging to a particular collection of orbits under class (d) of Eq. (4.16):

$$\mathcal{H}_0=\mathrm{Sp}\{|\underline{z},\underline{w}\rangle|\underline{z},\underline{w}\in\mathcal{C}^3,\underline{z}^T\underline{w}=0\}. \tag{5.1}$$

As noted earlier, these SCS are actually overcomplete within $\mathcal{H}_0$. Since, by Eq. (4.11), $\underline{z}^T\underline{w}$ is the eigenvalue of the SU(3) invariant Sp(2,R) lowering operator K_-, this means that $\mathcal{H}_0$ is spanned

by those H-W SCSs that are eigenvectors of K_- with eigenvalue zero. Moreover, Eqs. (4.26) and (4.28) show that these H-W SCSs are directly connected to the SU(3) SCSs within each SU(3) UIR (p,q), carried by $\mathcal{H}^{(p,q;0)}\subset\mathcal{H}_0$.

It now turns out that a somewhat similar situation exists involving eigenvectors of K_- corresponding to nonzero eigenvalues as well, but with one major difference: we encounter certain specific SU(3) GCS systems. This also connects up with a certain class of coherent states within the UIRs $D_k^{(+)}$ of Sp(2,R). We analyze these matters in this section. It turns out that H-W SCSs of both classes (d) and (e) are involved.

We begin by generalizing Eq. (5.1) and defining a subspace $\mathcal{H}_\kappa\subset\mathcal{H}$, for any complex number κ, as consisting of eigenvectors of K_- with eigenvalue κ; equally well it is the span of all those H-W SCSs which obey this condition:

$$\mathcal{H}_\kappa=\{|\psi\rangle\in\mathcal{H}|K_-|\psi\rangle=\kappa|\psi\rangle\}=\mathrm{Sp}\{|\underline{z},\underline{w}\rangle|\underline{z},\underline{w}\in\mathcal{C}^3,\underline{z}^T\underline{w}=\kappa\}\subset\mathcal{H}. \tag{5.2}$$

These H-W SCSs comprise a particular subset of class (d) orbits in Eq. (4.16); for $\kappa=0$ we get back $\mathcal{H}_0$. It is important to remark that even though κ varies over a continuum, each $\mathcal{H}_\kappa$ consists of bona fide (i.e., normalizable) vectors in $\mathcal{H}$; and for $\kappa'\neq\kappa$, $\mathcal{H}_{\kappa'}$ and $\mathcal{H}_\kappa$ are not mutually orthogonal. As in the case of the oscillator annihilation operator, these are consequences of K_- being non-Hermitian. Since K_- is SU(3) invariant, each $\mathcal{H}_\kappa$ is SU(3) invariant as well:

$$A\in\mathrm{SU}(3),|\psi\rangle\in\mathcal{H}_\kappa\Rightarrow\mathcal{U}(A)|\psi\rangle\in\mathcal{H}_\kappa. \tag{5.3}$$

Therefore the UR $\mathcal{U}(A)$ of SU(3) on $\mathcal{H}$, when restricted to $\mathcal{H}_\kappa$, leads to a UR $\mathcal{D}_\kappa$ acting on $\mathcal{H}_\kappa$. We will see that this UR contains each UIR (p,q) exactly once, just like $\mathcal{D}_0$ on $\mathcal{H}_0$. Thus it is also multiplicity-free and complete.

To exhibit these properties, we first recall the construction of eigenvectors of K_- in any discrete class UIR $D_k^{(+)}$ of Sp(2,R).[29] (Though the following results are valid for all real $k>0$, we require only the cases $k=\frac{3}{2},2,\frac{5}{2}\ldots$.) As in Eqs. (I.3.24) and (I.3.25), denote the eigenvectors of J_0 in $D_k^{(+)}$ by $|k,m\rangle$. Then we have the well-known results

$$|k,\kappa\rangle=({}_0F_1(2k;|\kappa|^2))^{-1/2}\sum_{m=k}^{\infty}(\Gamma(2k)/(m-k)!\Gamma(m+k))^{1/2}\kappa^{m-k}|k,m\rangle,$$
$$K_-|k,\kappa\rangle=\kappa|k,\kappa\rangle,\kappa\in\mathcal{C}; \tag{5.4a}$$

$$\langle k,\kappa'|k,\kappa\rangle={}_0F_1(2k;\kappa'^*\kappa)/\{{}_0F_1(2k;|\kappa'|^2)\,{}_0F_1(2k;|\kappa|^2)\}^{1/2}; \tag{5.4b}$$

$$\int_{\mathcal{C}}\frac{d^2\kappa}{\pi}\sigma(|\kappa|^2)|k,\kappa\rangle\langle k,\kappa|=1,$$
$$\sigma(|\kappa|^2)=\frac{2}{\Gamma(2k)}\,{}_0F_1(2k;|\kappa|^2)|\kappa|^{2k-1}K_{1/2-k}(2|\kappa|), \tag{5.4c}$$

where $K_\nu(z)$ denotes modified Bessel function of the third kind. (For simplicity the k-dependence of the weight function σ is omitted.) We note that even though these states $|k,\kappa\rangle$ within $D_k^{(+)}$ do not form an Sp(2,R) orbit, they do furnish a Klauder-type resolution of the identity.

We now exploit this construction in the present context. We begin with two facts: (a) the vectors $|p,q;IMY;m\rangle$, as all labels vary, form an orthonormal basis for the total Hilbert space $\mathcal{H}$; and (b) if we keep p,q,IMY fixed and allow only m to vary, we get an orthonormal basis for a subspace carrying just the UIR $D_k^{(+)}$ of Sp(2,R). Therefore, in view of the construction (5.4), within each such subspace we can define and have

$$|p,q;IMY\rangle_\kappa=\{{}_0F_1(2k;|\kappa|^2)\}^{-1/2}\sum_{m=k}^{\infty}((2k-1)!/(m-k)!(m+k-1)!)^{1/2}\kappa^{m-k}|p,q;IMY;m\rangle,$$

$$K_-|p,q;IMY\rangle_\kappa=\kappa|p,q;IMY\rangle_\kappa; \tag{5.5}$$

$${}_{\kappa'}\langle p',q';I'M'Y'|p,q;IMY\rangle_\kappa=\delta_{p'p}\delta_{q'q}\delta_{I'I}\delta_{M'M}\delta_{Y'Y}\times{}_0F_1(2k;\kappa'^*\kappa)/\{{}_0F_1(2k;|\kappa'|^2){}_0F_1(2k;|\kappa|^2)\}^{1/2}.$$

[For fixed p,q,IMY we also have a resolution of the appropriate identity in the form of Eq. (5.4c), but we omit it.] For $\kappa=0$ we recover the orthonormal basis for $\mathcal{H}_0$. However, for $\kappa\neq0$, these vectors are not eigenvectors of the total a- and b-type number operators $\hat{N}^{(a)},\hat{N}^{(b)}$. It is now evident that if we keep κ fixed, allow $pqIMY$ to vary, and recall that the range $\mathcal{C}$ of κ is k-independent, we get an orthonormal basis for $\mathcal{H}_\kappa$:

$$\mathcal{H}_\kappa=\mathrm{Sp}\{|p,q;IMY\rangle_\kappa|\kappa\ \text{fixed},pqIMY\ \text{varying}\},$$
$${}_\kappa\langle p',q';I'M'Y'|p,q;IMY\rangle_\kappa=\delta_{p'p}\delta_{q'q}\delta_{I'I}\delta_{M'M}\delta_{Y'Y}. \tag{5.6}$$

It is also clear that each UIR (p,q) of SU(3), carried by the $d(p,q)$ vectors $|p,q;IMY\rangle_\kappa\in\mathcal{H}_\kappa$ as IMY alone vary, appears exactly once in $\mathcal{H}_\kappa$. In other words, $\mathcal{D}_\kappa$ is multiplicity-free. In Eqs. (5.2) and (5.6) we have three equally good ways of identifying the subspace $\mathcal{H}_\kappa\subset\mathcal{H}$.

We next relate the orthonormal basis vectors (5.6) for $\mathcal{H}_\kappa$ to the corresponding ones for $\mathcal{H}_0$ in Eq. (2.12), in a compact manner. For this we use Eq. (I.3.25b) valid within each UIR $D_k^{(+)}$ of Sp(2,R), along with $K_+=\hat{\underline{a}}^\dagger\cdot\hat{\underline{b}}^\dagger$:

$$|p,q;IMY;m\rangle=((2k-1)!/(m-k)!(m+k-1)!)^{1/2}(\hat{\underline{a}}^\dagger\cdot\hat{\underline{b}}^\dagger)^{m-k}|p,q;IMY;k\rangle;$$

$$|p,q;IMY\rangle_\kappa=\{{}_0F_1(2k;|\kappa|^2)\}^{-1/2}\sum_{m=k}^{\infty}\frac{(2k-1)!}{(m-k)!(m+k-1)!}(\kappa\hat{\underline{a}}^\dagger\cdot\hat{\underline{b}}^\dagger)^{m-k}|p,q;IMY;k\rangle$$
$$=A^\dagger_{k,\kappa}|p,q;IMY\rangle_0, \tag{5.7}$$

$$A^\dagger_{k,\kappa}=\{{}_0F_1(2k;|\kappa|^2)\}^{-1/2}\sum_{m=k}^{\infty}\frac{(2k-1)!}{(m-k)!(m+k-1)!}(\kappa\hat{\underline{a}}^\dagger\cdot\hat{\underline{b}}^\dagger)^{m-k}$$
$$={}_0F_1(2k;\kappa\hat{\underline{a}}^\dagger\cdot\hat{\underline{b}}^\dagger)/\{{}_0F_1(2k;|\kappa|^2)\}^{1/2}.$$

It is important to notice that there is a dependence on $k=\frac{1}{2}(p+q+3)$ in the operator $A^\dagger_{k,\kappa}$; so the basis vectors $|p,q;IMY\rangle_\kappa$ for $\mathcal{H}_\kappa$ do not arise from the basis vectors $|p,q;IMY\rangle_0$ for $\mathcal{H}_0$ by application of a single operator dependent on κ alone. In spite of this, we will see below the usefulness of the connection (5.7).

We now obtain an expansion of the H-W SCS $|\underline{z},\underline{w}\rangle$ with $\underline{z}^T\underline{w}=\kappa$, in the orthonormal basis (5.6) for $\mathcal{H}_\kappa$. Thus we seek analog to Eqs. (4.26) and (4.28), as well as to Eqs. (4.27) and (4.32), in the case of $\mathcal{H}_0$. Given $|\underline{z},\underline{w}\rangle\in\mathcal{H}_\kappa$, by a suitable SU(3) transformation we can relate it to a standard state $|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle$ on its orbit. We parametrize the latter as in Eq. (4.16) class (d) (assume here for definiteness that $x^2+y^2<1$, the possibility $x^2+y^2=1$ which is of vanishing measure being handled in the next section):

$$\underline{z}^{(0)}(u)=u(1,0,0)^T,$$
$$\underline{w}^{(0)}(v,x,y)=v(x+iy,\sqrt{1-x^2-y^2},0)^T, \tag{5.8}$$
$$uv(x+iy)=\kappa.$$

We develop first the replacement for Eq. (4.26). The point of interest is to see which vector within each UIR (p,q) in $\mathcal{D}_\kappa$ appears, in place of the higher weight vector present in Eq. (4.26). Thanks to Eq. (5.7), the relevant overlap simplifies to a calculation in $\mathcal{H}_0$:

$$\begin{aligned}{}_\kappa\langle p,q;IMY|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle &= {}_0\langle p,q;IMY|A_{k,\kappa}|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle \\ &= \{{}_0F_1(2k;|\kappa|^2)\}^{1/2}\langle p,q;IMY;k|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle.\end{aligned} \tag{5.9}$$

Here the bra vector, in $\mathcal{H}_0$, is an eigenvector of $\hat{N}^{(a)},\hat{N}^{(b)}$ with eigenvalues p,q, respectively. This leads to further simplification:

$$\begin{aligned}\langle p,q;IMY;k|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle = e^{-(1/2)(u^2+v^2)}\frac{u^p}{p!}\frac{v^q}{q!}\langle p,q;IMY;k|(\hat{a}_1^\dagger)^p((x+iy)\hat{b}_1^\dagger \\ +\sqrt{1-x^2-y^2}\hat{b}_2^\dagger)^q|\underline{0},\underline{0}\rangle.\end{aligned} \tag{5.10}$$

The ket vector here has hypercharge $\frac{1}{3}(p-q)$, as does the highest weight state in (p,q), so this overlap is nonzero only if $Y=\frac{1}{3}(p-q)$. This then determines the possible values of I:

$$\begin{aligned}I &= I_0, I_0-1,\ldots,\tfrac{1}{2}|p-q|, \\ I_0 &= \tfrac{1}{2}(p+q).\end{aligned} \tag{5.11}$$

Notice that I_0 is the highest possible value of I in the UIR (p,q). For the bra vector in Eq. (5.10) we have the explicit expression [Eq. (I.A9)]:

$$\begin{aligned}\langle p,q;IMY;k| = \mathcal{N}_{pqIY}((I+M)!(I-M)!/2I!)^{1/2}\sum_{n=0}^{(p-r,q-s)_<}\sum_{L=0}^{I-M}\frac{(-1)^{n+I-M-L}}{(r+s+n+1)!} \\ \times\langle\underline{0},\underline{0}|\frac{(\hat{a}_\alpha\hat{b}_\alpha)^n}{n!}\frac{\hat{a}_1^{r-L}}{(r-L)!}\frac{\hat{a}_2^L}{L!} \\ \times\frac{\hat{b}_1^{I-M-L}}{(I-M-L)!}\frac{\hat{b}_2^{s-I+M+L}}{(s-I+M+L)!}\frac{\hat{a}_3^{p-r-n}}{(p-r-n)!}\frac{\hat{b}_3^{q-s-n}}{(q-s-n)!},\end{aligned}$$

$$\hat{a}_\alpha\hat{b}_\alpha = \hat{a}_1\hat{b}_1+\hat{a}_2\hat{b}_2,$$

$$\mathcal{N}_{pqIY} = \{r!s!(r+s+1)!(p-r)!(q-s)!(p+s+1)!(q+r+1)!/(p+q+1)!\}^{1/2},$$

$$r = I+\frac{Y}{2}+\frac{1}{3}(p-q), S = I-\frac{Y}{2}+\frac{1}{3}(q-p). \tag{5.12}$$

Here, as before, $(p,q)_<$ stands for smaller of the two integers p,q.

Use of this in Eq. (5.10) leads to further simplifications. The condition $Y=\frac{1}{3}(p-q)$ gives

$$\begin{aligned}r &= I+M_0, \quad s = I-M_0, \\ p-r &= q-s = I_0-I, \\ M_0 &= \tfrac{1}{2}(p-q).\end{aligned} \tag{5.13}$$

Then, in the sums over n and L in Eq. (5.12), only the terms $n=p-r=q-s$ and $L=0$ survive. Using all this, the scalar product in Eq. (5.9) can be explicitly computed:

$$
\begin{aligned}
{}_\kappa\langle p,q;IMY|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle &= \{{}_0F_1(2k;|\kappa|^2)\}^{1/2}\cdot e^{-(1/2)(u^2+v^2)}\cdot u^p v^q \\
&\quad\times\delta_{Y,(1/3)(p-q)}\frac{(-1)^{I_0-M}}{(M-M_0)!}\{(2I+1)(I+M)!(I-M_0)!/ \\
&\quad(2I_0+1)!(I-M)!(I+M_0)!\}^{1/2} \\
&\quad\times(x+iy)^{I_0-M}(1-x^2-y^2)^{(1/2)(M-M_0)}, \\
&\quad uv(x+iy)=\kappa.
\end{aligned}
\tag{5.14}
$$

We see that, provided $Y=\frac{1}{3}(p-q)$ and $M\geqslant M_0$, this overlap is nonzero for all values of I in the range (5.11). This shows how far the projection of $|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle$ onto the subspace of $\mathcal{H}_\kappa$ carrying the UIR (p,q) differs from the highest weight state.

We can now obtain the replacement for the previous Eq. (4.26). It is unavoidably somewhat more complicated. Using Eq. (5.14) and with $\kappa=uv(x+iy)$, we have

$$
\begin{aligned}
|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle &= e^{-(1/2)(u^2+v^2)}\sum_{p,q=0}^{\infty}u^p v^q\{{}_0F_1(2k;|\kappa|^2)/(p+q+1)!\}^{1/2} \\
&\quad\times\mathcal{N}'(p,q;|\kappa|/uv)|p,q;\kappa/uv\rangle_\kappa, \\
\mathcal{N}'(p,q;|\kappa|/uv)|p,q;\kappa/uv\rangle_\kappa &= \sum_{I=|M_0|}^{I_0}\sum_{M=M_0}^{I}\frac{(-1)^{I_0-M}}{(M-M_0)!}(\kappa/uv)^{I_0-M} \\
&\quad\times\left(1-\frac{|\kappa|^2}{u^2v^2}\right)^{(1/2)(M-M_0)}\{(2I+1)(I-M_0)!(I+M)!/ \\
&\quad(I+M_0)!(I-M)!\}^{1/2}|p,q;I,M,\tfrac{1}{3}(p-q)\rangle_\kappa, \\
\mathcal{N}'(p,q;|\kappa|/uv) &= \left\{\sum_{I=|M_0|}^{I_0}\sum_{M=M_0}^{I}\frac{(2I+1)(I-M_0)!(I+M)!}{(I+M_0)!(I-M)!(M-M_0)!^2}(|\kappa|/uv)^{2(I_0-M)}\right. \\
&\quad\left.\times\left(1-\frac{|\kappa|^2}{u^2v^2}\right)^{M-M_0}\right\}^{1/2},
\end{aligned}
\tag{5.15}
$$

which, as shown in the Appendix, can be compactly written as

$$
\begin{aligned}
\mathcal{N}'(p,q;|\kappa|/uv) &= \{(I_0-|M_0|+1)(I_0+|M_0|+1)_2F_1(-(I_0-|M_0|),-(I_0+|M_0|),2,1 \\
&\quad-|\kappa|^2/(u^2v^2))\}^{1/2}.
\end{aligned}
\tag{5.16}
$$

The normalization factor $\mathcal{N}'(p,q;|\kappa|/uv)$ has been defined so as to make the vector $|p,q;\kappa/uv\rangle_\kappa$ have unit norm; this vector lies in the subspace of $\mathcal{H}_\kappa$ carrying the (single occurrence of the) UIR (p,q) in $\mathcal{D}_\kappa$. Now we apply $\mathcal{U}(A)$ to both sides of Eq. (5.15) and get the replacements for Eqs. (4.27) and (4.28):

$$
\begin{aligned}
&A\in\mathrm{SU}(3),\underline{z}=A\underline{z}^{(0)}(u),\underline{w}=A^*\underline{w}^{(0)}(v,x,y),\underline{z}^T\underline{w}=\kappa: \\
|\underline{z},\underline{w}\rangle &= e^{-(1/2)(u^2+v^2)}\sum_{p,q=0}^{\infty}u^p v^q\{{}_0F_1(2k;|\kappa|^2)/(p+q+1)!\}^{1/2}\mathcal{N}'(p,q;|\kappa|/uv) \\
&\quad\times|p,q;\kappa/uv;A\rangle_\kappa, \\
&|p,q;\kappa/uv;A\rangle_\kappa=\mathcal{U}(A)|p,q;\kappa/uv\rangle_\kappa.
\end{aligned}
\tag{5.17}
$$

We see that for $(\underline{z},\underline{w})\in\mathcal{C}^6$ with given u,v,κ, corresponding to class (d) in Eq. (4.16), the H-W SCS $|\underline{z},\underline{w}\rangle$ is expressible in terms of a sequence of SU(3) GCS, all contained in $\mathcal{H}_\kappa$. The SU(3) GCSs within the UIR (p,q) use $|p,q;\kappa/uv\rangle_\kappa$ as the fiducial vector, and this is very different from the highest weight vector. For this family of SU(3) GCSs we have in place of Eq. (4.32)

$$\int_{\mathrm{SU(3)}} dA|p,q;\kappa/uv;A\rangle_{\kappa\kappa}\langle p',q';\kappa/uv;A|=\delta_{p'p}\delta_{q'q}\frac{P^{(p,q;\kappa)}}{d(p,q)}, \tag{5.18}$$

where $P^{(p,q;\kappa)}$ is the projection operator onto the subspace of $\mathcal{H}_\kappa$ carrying the UIR (p,q). This follows from the Schur lemma for SU(3) UIRs, and the fact that $\mathcal{D}_\kappa$ is multiplicity-free.

With these replacements for Eqs. (4.26)–(4.28) and (4.32) in hand, we can study the analog of the operator $A(f_0)$ in Eq. (4.30). We begin with the general definition (4.23) of $A(f)$ and choose

$$f(u,v,x,y)=f_0(u,v)\,\delta^{(2)}(x+iy-\kappa/uv)=f_0(u,v)\,\delta(x-\mathrm{Re}\,\kappa/uv)\,\delta/y-\mathrm{Im}\,\kappa/uv). \tag{5.19}$$

This achieves the restriction to $\mathcal{H}_\kappa$. We then define

$$\begin{aligned}A(f_0)&=\int\prod_{j=1}^{3}\left(\frac{d^2z_j}{\pi}\frac{d^2w_j}{\pi}\right)f_0(u,v)\,\delta^{(2)}(x+iy-\kappa/uv)|\underline{z},\underline{w}\rangle\langle\underline{z},\underline{w}|\\&=\frac{2}{\pi}\int_0^\infty u^5du\int_0^\infty v^5dv\,f_0(u,v)\,\theta(uv-|\kappa|)\left(1-\frac{|\kappa|^2}{u^2v^2}\right)\\&\quad\times\int_{\mathrm{SU(3)}}dA\mathcal{U}(A)|\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)\rangle\langle\underline{z}^{(0)}(u),\underline{w}^{(0)}(v,x,y)|\mathcal{U}(A)^{-1},\end{aligned} \tag{5.20}$$

it being understood in the last expression that $x+iy=\kappa/uv$. We can now use Eqs. (5.17) and (5.18) here and get the final result replacing Eq. (4.33):

$$A(f_0)=\sum_{p,q=0}^{\infty}C(f_0;p,q;\kappa)P^{(p,q;\kappa)},$$

$$\begin{aligned}C(f_0;p,q;\kappa)&=\frac{2}{\pi}\{{}_0F_1(2k;|\kappa|^2)/(p+q+1)!\,d(p,q)\}\int_0^\infty u^5du\int_0^\infty v^5dv\,f_0(u,v)\\&\quad\times\theta(uv-|\kappa|)\left(\left|-\frac{|\kappa|^2}{u^2v^2}\right)e^{-(u^2+v^2)}u^{2p}v^{2q}\{\mathcal{N}'(p,q;|\kappa|/uv)\}^2.\end{aligned} \tag{5.21}$$

The freedom remaining in the choice of $f_0(u,v)$ displays the overcompleteness, within $\mathcal{H}_\kappa$, of the H-W SCS belonging to $\mathcal{H}_\kappa$. To limit ourselves to an exact "SU(3)-worth" of these states, we choose $f_0(u,v)$ to be the product of two delta functions. Then we get a generalization of Eq. (4.34):

$$\begin{aligned}&f_0(u,v)=\delta(u-u_0)\,\delta(v-v_0),\quad u_0v_0>|\kappa|:\\&A(f_0)=\int\prod_{j=1}^{3}\left(\frac{d^2z_j}{\pi}\frac{d^2w_j}{\pi}\right)\delta(u-u_0)\,\delta(v-v_0)\,\delta^{(2)}\left(x+iy-\frac{\kappa}{uv}\right)|\underline{z},\underline{w}\rangle\langle\underline{z},\underline{w}|\\&=\frac{2}{\pi}\cdot e^{-(u_0^2+v_0^2)}\sum_{p,q=0}^{\infty}\{{}_0F_1(2k;|\kappa|^2)/(p+q+1)!\,d(p,q)\}\\&\quad\times u_0^{2p+5}v_0^{2q+5}\left(1-\frac{|\kappa|^2}{u_0^2v_0^2}\right)\{\mathcal{N}'(p,q;|\kappa|/u_0v_0)\}^2P^{(p,q;\kappa)}.\end{aligned} \tag{5.22}$$

In this manner all the results found in the preceeding section for the subspace $\mathcal{H}_0 \subset \mathcal{H}$, the null space of K_-, generalize to a general eigenspace $\mathcal{H}_\kappa \subset \mathcal{H}$ of K_-. Here again, limiting oneself to an exact "SU(3)-worth" of H-W SCSs does give us a total set of vectors, but they do not obey the Klauder resolution of the identity within $\mathcal{H}_\kappa$

VI. H-W SCSs OF CLASS (e) AND THEIR SU(3) CONTENT

In the listing of SU(3) orbits of H-W SCSs given in Eq. (4.16), it was pointed out that only classes (d) and (e) involve all six oscillators of the Schwinger SU(3) construction in a nontrivial manner. Furthermore, of these, only the former are generic. As we have seen, class (d) orbits form a four-parameter continuous family, each orbit being of dimension eight. In contrast, class (e) orbits are a three-parameter family, with each orbit of dimension five. Another characteristic is that each H-W SCS $|\underline{z},\underline{w}\rangle$ in class (d) is such that the complex three-vectors $\underline{z}^*$ and $\underline{w}$ are linearly independent; on the other hand, if $|\underline{z},\underline{w}\rangle$ is in class (e), then $\underline{w}$ is a (complex) multiple of $\underline{z}^*$.

In Secs. IV and V we have analyzed in detail the SU(3) structure and representation content of H-W SCSs on all class (d) orbits, for $\underline{z}^T\underline{w}=0$ and $\underline{z}^T\underline{w}=\kappa\neq 0$, respectively. Now we turn to a similar analysis of the class (e) orbits.[30] There is, however, a difficulty in handling this case by starting with the Klauder resolution of the identity, Eq. (4.12), and then modifying the integrand by inserting some function of the SU(3) invariants with the aim of restricting the integration to a chosen subset of orbits. We are unable to use the methods of Secs. IV and V here. The reason is that in terms of the SU(3) invariant parameters u,v,x,y in Eq. (4.15), class (e) corresponds to $x^2+y^2=1$, while in the volume element (4.21) on the H-W group there is an explicit factor $(1-x^2-y^2)$. For this reason, we handle class (e) orbits more directly, guided, however, by the results in class (d).

A convenient representative point on a general class (e) orbit is given by the pair of complex three-vectors

$$\begin{gathered}\underline{z}^{(0)}(u)=u(0,0,1)^T, \quad u>0,\\ \underline{w}^{(0)}(ve^{i\alpha})=ve^{i\alpha}(0,0,1)^T, \quad v>0,\ 0\leqslant\alpha<2\pi,\\ \underline{z}^{(0)}(u)^T\underline{w}^{(0)}(ve^{i\alpha})=uve^{i\alpha}.\end{gathered} \tag{6.1}$$

[As mentioned earlier in Sec. IV, the reason for choosing this configuration is that the corresponding stability group is the SU(2) subgroup acting on dimensions 1 and 2 in the defining representation (1,0), and it is just this subgroup that is involved in the canonical basis vectors $|p,q;IMY\rangle$ in a general SU(3) UIR (p,q).] Acting with a general $A\in \mathrm{SU}(3)$, we reach a general point $(\underline{z},\underline{w})$ on the orbit given by

$$\begin{gathered}\underline{z}=A\underline{z}^{(0)}(u),\\ \underline{w}=A^*\underline{w}^{(0)}(ve^{i\alpha})=\left(\frac{ve^{i\alpha}}{u}\right)\underline{z}^*,\\ \underline{z}^T\underline{w}=uve^{i\alpha}=e^{i\alpha}(\underline{z}^\dagger\underline{z}\underline{w}^\dagger\underline{w})^{1/2}.\end{gathered} \tag{6.2}$$

The H-W SCS $|\underline{z}^{(0)}(u),\underline{w}^{(0)}(ve^{i\alpha})\rangle$ is of course given by

$$|\underline{z}^{(0)}(u),\underline{w}^{(0)}(ve^{i\alpha})\rangle=e^{-(1/2)(u^2+v^2)+u\hat{a}_3^\dagger+ve^{i\alpha}\hat{b}_3^\dagger}|\underline{0},\underline{0}\rangle. \tag{6.3}$$

We can expand this in the orthonormal basis $|p,q;IMY;m\rangle$ for $\mathcal{H}$, recognizing that the only states that appear have $I=M=0, Y=\frac{2}{3}(q-p)$ for various (p,q). We need the results (I.A6) and (I.A7):

$$|p,q;0,0,\tfrac{2}{3}(q-p);k\rangle = p!q!\{(p+1)(q+1)/(p+q+1)!\}^{1/2} \times \sum_{n=0}^{(p,q)_<} \frac{(-1)^n}{(n+1)!}\frac{(\hat{a}_\alpha^\dagger \hat{b}_\alpha^\dagger)^n}{n!}\frac{(\hat{a}_3^\dagger)^{p-n}}{(p-n)!}\frac{(\hat{b}_3^\dagger)^{q-n}}{(q-n)!}|\underline{0},\underline{0}\rangle, \qquad \hat{a}_\alpha^\dagger \hat{b}_\alpha^\dagger = \hat{a}_1^\dagger \hat{b}_1^\dagger + \hat{a}_2^\dagger \hat{b}_2^\dagger; \tag{6.4a}$$

$$|p,q;0,0,\tfrac{2}{3}(q-p);m\rangle = \{(2k-1)!/(m-k)!(m+k-1)!\}^{1/2}\cdot(\hat{\underline{a}}^\dagger\cdot\hat{\underline{b}}^\dagger)^{m-k}|p,q;0,0,\tfrac{2}{3}(q-p);k\rangle. \tag{6.4b}$$

We can now easily compute the desired overlap:

$$\begin{aligned}
&\langle p,q;0,0,\tfrac{2}{3}(q-p);m|\underline{z}^{(0)}(u),\underline{w}^{(0)}(ve^{i\alpha})\rangle \\
&\quad = \{(2k-1)!/(m-k)!(m+k-1)!\}^{1/2}\times(uve^{i\alpha})^{m-k}\langle p,q;0,0,\tfrac{2}{3}(q-p);k|\underline{z}^{(0)}(u),\underline{w}^{(0)}(ve^{i\alpha})\rangle \\
&\quad = \{(2k-1)!/(m-k)!(m+k-1)!\}^{1/2}(uve^{i\alpha})^{m-k}\cdot p!q!\{(p+1)(q+1)/ \\
&\qquad (p+q+1)!\}^{1/2}\langle\underline{0},\underline{0}|\frac{\hat{a}_3^p}{p!}\frac{\hat{b}_3^q}{q!}|\underline{z}^{(0)}(u),\underline{w}^{(0)}(ve^{i\alpha})\rangle \\
&\quad = \{(p+1)(q+1)(2k-1)!/(p+q+1)!(m-k)!(m+k-1)!\}^{1/2}(uve^{i\alpha})^{m-k} \\
&\quad \times e^{-(1/2)(u^2+v^2)}u^p(ve^{i\alpha})^q.
\end{aligned} \tag{6.5}$$

In the second step here, when using the expansion (6.4a), only the term $n=0$ contributes. We therefore have the expansion of the representative class (e) H-W SCS in the SU(3)×Sp(2,*R*) basis:

$$\begin{aligned}
|\underline{z}^{(0)}(u),\underline{w}^{(0)}(ve^{i\alpha})\rangle &= e^{-(1/2)(u^2+v^2)}\sum_{p,q=0}^{\infty}\{(p+1)(q+1)/(p+q+1)!\}^{1/2}u^p(ve^{i\alpha})^q \\
&\quad\times\sum_{m=k}^{\infty}\{(2k-1)!/(m-k)!(m+k-1)!\}^{1/2}(uve^{i\alpha})^{m-k}|p,q;0,0,\tfrac{2}{3}(q-p);m\rangle \\
&= e^{-(1/2)(u^2+v^2)}\sum_{p,q=0}^{\infty}\{(p+1)(q+1/(p+q+1)!\}^{1/2}u^p(ve^{i\alpha})^q \\
&\quad\times\{{}_0F_1(2k;u^2v^2)\}^{1/2}|p,q;0,0,\tfrac{2}{3}(q-p))_{uve^{i\alpha}}.
\end{aligned} \tag{6.6}$$

As we would expect, this expansion involves just the K_- eigenstate defined in Eq. (5.5), namely the $I=M=0$, $Y=2/3(q-p)$ member of the orthonormal basis $\{|p,q;IMY\rangle_{uve^{i\alpha}}\}$ for $\mathcal{H}_{uve^{i\alpha}}$. As in the case of the SU(3) SCS, where the fiducial vector within the UIR (p,q) is the single highest weight vector $|p,q;1/2(p+q),1/2(p+q),1/3(p-q)\rangle$, here too a single vector of the canonical basis appears as fiducial vector, but it is of course not the highest weight state.

Now within each UIR (p,q) contained in the UR $\mathcal{D}_{uve^{i\alpha}}$ on $\mathcal{H}_{uve^{i\alpha}}$, we define the family of SU(3) GCSs:

$$A\in\mathrm{SU}(3):|p,q;0,0,\tfrac{2}{3}(q-p);A\rangle_{uve^{i\alpha}} = \mathcal{U}(A)|p,q;0,0,\tfrac{2}{3}(q-p)\rangle_{uve^{i\alpha}}. \tag{6.7}$$

Then, applying $\mathcal{U}(A)$ to both sides of Eq. (6.6), we have the general connection between class (e) H-W SCS and the SU(3) GCS (6.7):

$$|A\underline{z}^{(0)}(u),\ A^*\underline{w}^{(0)}(ve^{i\alpha})\rangle = e^{-(1/2)(u^2+v^2)} \sum_{p,q=0}^{\infty} \{(p+1)(q+1)/(p+q+1)!\}^{1/2} \times u^p (ve^{i\alpha})^q \{{}_0F_1(2k;u^2v^2)\}^{1/2} |p,q;0,0,\tfrac{2}{3}(q-p);A\rangle_{uve^{i\alpha}}. \tag{6.8}$$

We recognize that Eqs. (6.6)–(6.8) are replacements for Eqs. (4.26)–(4.28) and Eqs. (5.15) and (5.17) of class (d).

Keeping $uve^{i\alpha}$ fixed, the SU(3) GCSs (6.7) all belong to $\mathcal{H}_{uve^{i\alpha}}$, and from the Schur lemma they obey the analogs to Eqs. (4.32) and (5.18):

$$\int_{\mathrm{SU}(3)} dA |p,q;0,0,\tfrac{2}{3}(q-p);A\rangle_{uve^{i\alpha}uve^{i\alpha}} \langle p',q';0,0,\tfrac{2}{3}(q'-p');A| = \delta_{p'p}\delta_{q'q} \frac{P^{(p,q;uve^{i\alpha})}}{d(p,q)}. \tag{6.9}$$

Here, of course, we exploit the multiplicity-free reduction of $\mathcal{D}_{uve^{i\alpha}}$. It follows that for the H-W SCS (6.8) we have

$$\int_{\mathrm{SU}(3)} dA |A\underline{z}^{(0)}(u), A^*\underline{w}^{(0)}(ve^{i\alpha})\rangle\langle A\underline{z}^{(0)}(u), A^*\underline{w}^{(0)}(ve^{i\alpha})| = 2e^{-(u^2+v^2)} \sum_{p,q=0}^{\infty} u^{2p}v^{2q}\, {}_0F_1(2k;u^2v^2) P^{(p,q;uve^{i\alpha})}/(p+q+2)! \tag{6.10}$$

The integration over SU(3) here is in effect only over the five-dimensional coset space SU(3)/SU(2), in contrast to Eqs. (4.32) and (5.18) in class (d).

If we write $\kappa = uve^{i\alpha}$ and allow u and v to vary reciprocally, and also keep α fixed so that κ stays fixed, we never leave the subspace $\mathcal{H}_{uve^{i\alpha}}$ and the projection operators $P^{(p,q;uve^{i\alpha})}$. Therefore we can multiply both sides of Eq. (6.10) by any function

$$f(u,v) = f_0(u)\,\delta(uv - |\kappa|), \tag{6.11}$$

and integrate over both u and v to get results similar to Eqs. (4.33) and (5.21). Here $f_0(u)$ is free. This then shows that for each fixed κ, the class (e) H-W SCSs $|\underline{z},\underline{w}\rangle$ with $\underline{z}^T\underline{w} = \kappa$ are overcomplete in $\mathcal{H}_\kappa$.

VII. CONCLUDING REMARKS

To conclude, we have given a unified analysis of the interconnections between the Heisenberg–Weyl standard coherent states and the standard coherent states as well as certain generalized coherent states of SU(3). The specific family of SU(3) coherent states to be used is dependent on the type of orbit of the H-W SCSs belong to. This situation is describable in detail as follows. In terms of the SU(3) invariant parameters x and y, at $x=y=0$ we have those generic class (d) orbits which lie entirely within the subspace $\mathcal{H}_0$. For these H-W SCSs, the SU(3) harmonic analysis involves precisely the SU(3) SCS within each UIR. For $0<x^2+y^2<1$ we deal with the subspaces $\mathcal{H}_\kappa \subset \mathcal{H}$ which generalize $\mathcal{H}_0$; the corresponding orbits consist of H-W SCS whose SU(3) content brings in the SU(3) GCS studied in Sec. V. The fiducial vectors here are rather complicated, at any rate in the canonical basis for SU(3) UIRs. In the limit $x^2+y^2=1$, we have the class (e) orbits. These H-W SCS involve yet another family of SU(3) GCSs, though now the fiducial vectors are the unique SU(2) scalar states within each SU(3) UIR, and their properties are studied in Sec. VI. In this entire development the group $\mathrm{Sp}(2,R)$ plays a particularly helpful role and so does the Schur lemma wherever it is available. Indeed we have used this lemma for UIRs of the H-W group wherever possible, and, after modifications of the completeness identity,

used it for UIRs of SU(3). This systematic use of the Schur lemma makes several computations much easier than they would otherwise be. It must be emphasized that all the Heisenberg standard coherent states have been included in our study in the spirit of SU(3) harmonic analysis, so that there is a satisfactory completeness in our analysis. The significant property of the discrete series UIRs of Sp(2,R), which we have exploited, is worth mention. It is that while the spectrum of the compact generator J_0 depends on k, hence on the UIR, the "spectrum" of the non-Hermitian lowering operator K_- is the entire complex plane, thus being UIR independent. The calculations in Sec. V clearly show the importance of these facts.

APPENDIX

We outline here the steps involved in going from (5.15) to (5.16). Equation (5.15),

$$\mathcal{N}'(p,q;|\kappa|/uv)=\left\{\sum_{I=|M_0|}^{I_0}\sum_{M=M_0}^{I}\frac{(2I+1)(I-M_0)!(I+M)!}{(I+M_0)!(I-M)!(M-M_0)!^2}\right.$$
$$\left.\times(|\kappa|/uv)^{2(I_0-M)}\left(1-\frac{|\kappa|^2}{u^2v^2}\right)^{M-M_0}\right\}^{1/2}, \tag{A1}$$

can be written in terms of the Jacobi polynomials

$$P_n^{(\alpha,\beta)}(x)\equiv\frac{\Gamma(\alpha+n+1)}{n!\Gamma(\alpha+\beta+n+1)}\sum_{m=0}^{n}\binom{n}{m}\frac{\Gamma(\alpha+\beta+n+m+1)}{2^m\Gamma(\alpha+m+1)}(x-1)^m, \tag{A2}$$

as

$$\mathcal{N}'(p,q;|\kappa|/uv)=\left\{\sum_{I=|M_0|}^{I_0}(2I+1)\left(\frac{|\kappa|}{uv}\right)^{2(I_0-M_0)}P_{I-M_0}^{(0,2M_0)}\left(\frac{2u^2v^2}{|\kappa|^2}-1\right)\right\}^{1/2} \tag{A3}$$

Using the fact that $P_n^{(\alpha,\beta)}$ can also be written as

$$P_n^{(\alpha,\beta)}(x)=\frac{1}{2^n}\sum_{m=0}^{n}\binom{n+\alpha}{m}\binom{n+\beta}{n-m}(x-1)^{n-m}(x+1)^m, \tag{A4}$$

one can show that

$$x^{M_0}P_{I-M_0}^{(0,2M_0)}(2x-1)=x^{-M_0}P_{I+M_0}^{(0,-2M_0)}(2x-1), \tag{A5}$$

which implies that $\mathcal{N}'$ depends on M_0 only through its magnitude $|M_0|$. Replacing M_0 on the rhs of (A1) by $|M_0|$ and rewriting it as a polynomial in $(1-|\kappa|^2/u^2v^2)$, we obtain

$$\mathcal{N}'(p,q;|\kappa|/uv)=\left\{\sum_{k=0}^{I_0-|M_0|}a_k\left(1-\frac{|\kappa|^2}{u^2v^2}\right)^k\right\}^{1/2}, \tag{A6}$$

where

$$a_k=\sum_{M=0}^{k}\sum_{I=M}^{I_0-|M_0|}(2I+2|M_0|+1)\binom{I+2|M_0|+M}{M}\binom{I}{M}\binom{I-|M_0|-M}{k-M}(-1)^{k-M}, \tag{A7}$$

which, after some rearrangement, can be written as

$$a_k=\sum_{M=0}^{k}(-1)^M\binom{I_0-|M_0|+M-k}{M}\cdot\sum_{I=0}^{I_0-|M_0|-k+M}(2I+2k+2|M_0|-2M+1)\binom{I+k-M}{I}\times\binom{I+2k+2|M_0|-2M}{k-M}. \tag{A8}$$

Using the identities

$$\sum_{I=0}^{I_0-|M_0|-k+M}(2I+2k+2|M_0|-2M+1)\binom{I+k-M}{I}\binom{I+2k+2|M_0|-2M}{k-M}=(I_0-|M_0|+1)\binom{I_0+|M_0|+k-M+1}{I_0+|M_0|}\binom{I_0-|M_0|}{k-M} \tag{A9}$$

and

$$\sum_{M=0}^{k}(-1)^M\binom{I_0-|M_0|+M-k}{M}\binom{I_0+|M_0|+k-M+1}{I_0+|M_0|}\binom{I_0-|M_0|}{k-M}=\binom{I_0+|M_0|+1}{k+1}\binom{I_0-|M_0|}{k}, \tag{A10}$$

we obtain

$$a_k=(k+1)\binom{I_0+|M_0|+1}{k+1}\binom{I_0-|M_0|+1}{k+1}. \tag{A11}$$

Substituting this in (A6) we finally obtain the result (5.16).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 11 NOVEMBER 2002

New classes of quasi-solvable potentials, their exactly solvable limit, and related orthogonal polynomials

Asish Ganguly[a)]
Department of Applied Mathematics, University of Calcutta, 92 Acharya Prafulla Chandra Road, Kolkata-700009, India

(Received 12 June 2002; accepted 20 July 2002)

We have generated, using an sl(2,R) Lie-algebraic formalism, several new classes of quasi-solvable elliptic potentials, which in the appropriate limit go over to the exactly solvable forms. We have obtained exact solutions of the corresponding spectral problem for some real values of the potential parameters. We have also given explicit expressions of the families of associated orthogonal polynomials in the energy variable. © *2002 American Institute of Physics.*

I. INTRODUCTION

In recent times elliptic potentials have proved to be an important addition[1–3] to the class of solvable[4,5] and quasi-solvable[6–8] potentials in quantum mechanics. In particular, within the sl(2,R) algebra, exact solutions of Lamé and associated Lamé equation have been obtained[9–12] for various ranges of the potential parameters. Indeed a handful of theorems relating to the properties of elliptic potentials are known for a long time[13–16] including the study of the properties of the corresponding wavefunctions.[14] The solutions of associated Lamé equation have also been obtained[17] by using these theorems which, however, do not use the sl(2,R) technique. Note that some new elliptic models based on Weierstrass $\wp$ function have recently been proposed[18] wherein it is shown that the corresponding Hamiltonians possess the so-called energy-reflection symmetry.[19]

By the term quasi-exactly solvable (QES) periodic potentials we mean potentials consisting of finite number of allowed bands and expressible as doubly periodic elliptic functions which are either Jacobian elliptic functions $snx \equiv sn(x,k)$, $cnx \equiv cn(x,k)$, $dnx \equiv dn(x,k)$ of real elliptic modulus parameter $k(0<k^2<1)$ or Weierstrass $\wp$ function. This is in sharp contrast with the ordinary ES periodic potentials with a single period.

There is an intriguing relation between ES and QES class. In fact, an sl(2) based construction with an n-dimensional finite space representation gives $(n+1)$ levels for a Hamiltonian designated as a QES model. It was pointed out in Ref. 8 that if one can construct a Hamiltonian having no explicit dependence on n, then in the limit $n \to \infty$ the ES models are recovered. This provides a sufficient reason to believe that corresponding to every ES model there ought to exist a QES model which in the proper limit goes over to the former.

In this article we show that the elliptic parameter k can be used for passage from QES to ES in the periodic models. We derive three new QES periodic potentials involving Jacobian elliptic functions. The elliptic functions having real and imaginary period reduce to ordinary periodic functions, namely hyperbolic (imaginary period) and trigonometric (real period) functions as the modulus parameter k goes to 1 and 0. We exploit this interesting property of elliptic functions to show that our QES models are connected with some well known ES periodic class. Note that we do not intend to take the limit $n \to \infty$ and as such we cannot expect to recover the whole spectrum for ES models. Rather we show that the limit $k \to 1$ and 0 correctly map the few lower states of the QES and ES periodic potentials.

a)Electronic mail: asish@cucc.ernet.in

The plan of this article is as follows. In Sec. II we briefly review the basics of the sl(2,R) Lie-algebraic formalism and generate type I, II and III models within this framework. The method of construction of the related orthogonal polynomials is also sketched here. Specific examples are constructed in Sec. III for each of them based on some real values of the potential parameters. In Sec. IV we systematically analyze the ES limit of our results to show how this limit can reproduce the ES results. Finally we present our conclusions in Sec. V.

II. NEW QES POTENTIALS FROM sl(2,R) AND RELATED ORTHOGONAL POLYNOMIALS

To start with, let us adopt the following differential realization of the sl(2,R) generators

$$T^+=\xi^2\partial_\xi-n\xi,\quad T^0=\xi\partial_\xi-\tfrac{1}{2}n,\quad T^-=\partial_\xi, \tag{2.1}$$

obeying commutation relations

$$[T^+,T^-]=-2T^0,\quad [T^0,T^\pm]=\pm T^\pm, \tag{2.2}$$

where n is a non-negative integer. The gauged Hamiltonian is taken as the standard homogeneous quadratic combination of sl(2,R) generators along with linear terms:

$$H_G=-C_{++}T^{+^2}-C_{00}T^{0^2}-C_{--}T^{-^2}-C_+T^+-C_0T^0-C_-T^--d, \tag{2.3}$$

where C_{ii}, $C_j(i,j=0,\pm)$ are numerical parameters and d is a suitably chosen constant taken as function of C_j. Note that d plays the role of an overall shift in the energy scale. This pseudo degree of freedom allows us to obtain QES models in the desired form.

Substitution of (2.1) into (2.3) yields

$$\begin{aligned}H_G(\xi)=&-(C_{++}\xi^4+C_{00}\xi^2+C_{--})\partial_\xi^2\\&-[2(1-n)C_{++}\xi^3+C_+\xi^2+\{(1-n)C_{00}+C_0\}\xi+C_-]\partial_\xi\\&-\left[n(n-1)C_{++}\xi^2-nC_+\xi+\frac{n^2}{4}C_{00}-\frac{n}{2}C_0+d\right],\end{aligned} \tag{2.4}$$

which after a coordinate transformation

$$x(\xi)=\int^\xi d\tau/\sqrt{C_{++}\tau^4+C_{00}\tau^2+C_{--}}, \tag{2.5}$$

converts H_G into the form

$$\begin{aligned}H_G(x)=&-\partial_x^2+\frac{2nC_{++}\xi^3(x)-C_+\xi^2(x)+(nC_{00}-C_0)\xi(x)-C_-}{\sqrt{C_{++}\xi^4(x)+C_{00}\xi^2(x)+C_{--}}}\partial_x\\&-\left[n(n-1)C_{++}\xi^2(x)-nC_+\xi(x)+\frac{n^2}{4}C_{00}-\frac{n}{2}C_0+d\right],\end{aligned} \tag{2.6}$$

where $\xi=\xi(x)$ is determined by (2.5).

Let us now consider the Schrödinger equation with the potential $V(x)$

$$H(x)\psi(x)\equiv[-\partial_x^2+V(x)]\psi(x)=E\psi(x). \tag{2.7}$$

Writing $\psi(x)$ in the form

$$\psi(x)=\mu(x)\chi(x), \tag{2.8}$$

we obtain

$$H_G(x)\chi(x)\equiv\left[-\partial_x^2-2\left(\frac{\mu'}{\mu}\right)\partial_x-\left(\frac{\mu'}{\mu}\right)^2-\left(\frac{\mu'}{\mu}\right)'+V\right]\chi(x)=E\chi(x). \tag{2.9}$$

Comparing (2.6) and (2.9) we find for the potential $V(x)$ and the gauge factor $\mu(x)$ the following relationships

$$V(x)=\left(\frac{\mu'}{\mu}\right)^2+\left(\frac{\mu'}{\mu}\right)'-\left[n(n-1)C_{++}\xi^2-nC_+\xi+\frac{n^2}{4}C_{00}-\frac{n}{2}C_0+d\right], \tag{2.10}$$

$$\mu(x)=[C_{++}\xi^4+C_{00}\xi^2+C_{--}]^{-n/4}\exp\left[\int^{\xi}\frac{C_+\tau^2+C_0\tau+C_-}{2(C_{++}\tau^4+C_{00}\tau^2+C_{--})}d\tau\right]. \tag{2.11}$$

Note that the choice of numerical parameters C_{ii} must be such that Eq. (2.5) may be invertible in terms of $\xi=\xi(x)$. For our purpose $\xi(x)$ needs to be expressed in terms of Jacobian elliptic functions. In Ref. 12 we gave an almost exhaustive list of the choice of C_{ii} leading to various new classes of elliptic potentials. Here we consider the following three types of combinations of parameters, namely,

$$\text{type I:}\quad C_{++}=-k^2,\quad C_{00}=2k^2-1,\quad C_{--}=k'^2, \tag{2.12}$$

$$\text{type II:}\quad C_{++}=k^2,\quad C_{00}=-(1+k^2),\quad C_{--}=1, \tag{2.13}$$

$$\text{type III:}\quad C_{++}=k'^2,\quad C_{00}=1+k'^2,\quad C_{--}=1, \tag{2.14}$$

where $k^2\in(0,1)$ and $k'^2=1-k^2$. Each of the above types defines different coordinate transformations through (2.5). These give respectively $\xi=-cnx$, $-cnx/dnx$ and snx/cnx for the three types mentioned above.

In this way we are then led to the following new classes of elliptic potentials:

$$\text{type I:}\quad V(x)=[B^2+A(A+1)]\frac{dn^2x}{sn^2x}-2B\left(A+\frac{1}{2}\right)\frac{cnx}{sn^2x},\quad x\in(0,2K), \tag{2.15}$$

$$\text{type II:}\quad V(x)=B(B+1)\frac{dn^2x}{sn^2x}-A(A+1)dn^2x,\quad x\in(0,2K), \tag{2.16}$$

$$\text{type III:}\quad V(x)=[B^2-A(A+1)]k^2cn^2x+2Bk^2(A+\tfrac{1}{2})snxcnx,\quad x\in(-\infty,\infty), \tag{2.17}$$

where $K=\int_0^{\pi/2}d\alpha/\sqrt{1-k^2\sin^2\alpha}$ is the complete elliptic integral of the first kind. Note that in (2.15)–(2.17) the potential parameters $A,B\in R$ and the choices of C_j and the spin parameter n in (2.10) in terms of A,B are given in Table I. The constant d is chosen as

$$\text{type I:}\quad d=\frac{C_0}{4}\{C_0-4k'^2(n+1)\}+\frac{C_+}{2k^2}(k^2C_--k'^2C_+)+\frac{n(n+2)}{2}k'^2, \tag{2.18}$$

$$\text{type II:}\quad d=\left(\frac{C_+}{2k}\right)^2-\frac{C_0}{2}(n+1)+\frac{n(n+2)}{4}(1+k^2), \tag{2.19}$$

$$\text{type III:}\quad d=\frac{1}{4}\left[\left(\frac{C_+}{k'}\right)^2-n(n+2)(2-k^2)-2C_0(n+1)\right]. \tag{2.20}$$

TABLE I. Different algebraizations for type I–III potentials are given. Last column gives restrictions on potential parameters to keep n to a non-negative integer.

Classification	Solution no.	n	C_+	C_-	C_0	Restrictions on A, B
	1.1	A	$2k^2B$	$2k'^2B$	A	$A\in\mathrm{N}-1$, $B\in\mathrm{R}$
	1.2	$A-1$	$2k^2B$	$2k'^2B$	$A+1$	$A\in\mathrm{N}$, $B\in\mathrm{R}$
Type I	1.3	$B-1$	$2k^2(A+\frac{1}{2})-ikk'$	$2k'^2(A+\frac{1}{2})+ikk'$	B	$A\in\mathrm{R}$, $B\in\mathrm{N}$
	1.4	$A-\frac{1}{2}$	$2k^2B-ikk'$	$2k'^2B+ikk'$	$A+\frac{1}{2}$	$A\in\mathrm{N}-\frac{1}{2}$, $B\in\mathrm{R}$
	1.5	$B-\frac{1}{2}$	$2k^2(A+\frac{1}{2})$	$2k'^2(A+\frac{1}{2})$	$B-\frac{1}{2}$	$A\in\mathrm{R}$, $B\in\mathrm{N}-\frac{1}{2}$
	1.6	$B-\frac{3}{2}$	$2k^2(A+\frac{1}{2})$	$2k'^2(A+\frac{1}{2})$	$B+\frac{1}{2}$	$A\in\mathrm{R}$, $B\in\mathrm{N}+\frac{1}{2}$
Type II	2.1	$A-\frac{1}{2}$	$-2k^2(B+\frac{1}{2})$	$2(B+\frac{1}{2})$	$-k'^2(A+\frac{1}{2})$	$A\in\mathrm{N}-\frac{1}{2}$, $B\in\mathrm{R}$
	2.2	$A-\frac{1}{2}$	$2k^2(B+\frac{1}{2})$	$-2(B+\frac{1}{2})$	$-k'^2(A+\frac{1}{2})$	$A\in\mathrm{N}-\frac{1}{2}$, $B\in\mathrm{R}$
	3.1	A	$-2k'^2B$	$-2B$	$-Ak^2$	$A\in\mathrm{N}-1$,$B\in\mathrm{R}$
Type III	3.2	$A-1$	$-2k'^2B$	$-2B$	$-(A+1)k^2$	$A\in\mathrm{N}$, $B\in\mathrm{R}$
	3.3	$A-\frac{1}{2}$	$-2k'^2B+ik'$	$-2B+ik'$	$-(A+\frac{1}{2})k^2$	$A\in\mathrm{N}-\frac{1}{2}$, $B\in\mathrm{R}$

Note that while the type III potential is defined over the entire x-axis, type I and II potentials are singular at $x=0,2K$ and so defined over an open domain $(0,2K)$. It follows from the oscillation theorem that we need to find the periodic solutions [of period 4K(or 8K)] for 4K-periodic potential of type I and periodic solutions [of period 2K(or 4K)] for 2K-periodic potentials of types II and III at $E=E_j$. The monotonic increasing sequence $\{E_j\}$, where $E_0<E_1\leqslant E_2<E_3\leqslant E_4\ldots$, gives the characteristic values of the energy parameter.

Following the analysis made in Ref. 12 we can find the effective combinations of the potential parameters A,B. We see that the type I and III potentials are invariant under the translation $A,B\to A'$, B' where $A'=-A-1$, $B'=-B$ and type II potential is invariant under $A,B\to A'$, B' where $A'=-A-1$, $B'=-B-1$. Further, due to the periodic relations $sn(x+2K)=-snx$, $cn(x+2K)=-cnx$, $dn(x+2K)=dnx$, it results that the effective regions in the $A-B$ plane for type I-III models are bounded by the constraints $A\geqslant-\frac{1}{2}$, $B\geqslant0$; A, $B\geqslant-\frac{1}{2}$ and $A\geqslant-\frac{1}{2}$,$B\in R$, respectively. It may be pointed out that the eigenstates and spectra of type I potential for $B<0$ can be obtained from those for $B>0$ under the coordinate translation $x\to x+2K$.

Before concluding this section let us briefly describe the method of construction of families of orthogonal polynomials[12,20,21] generated by the eigenstates of a QES Hamiltonian. Let us consider a gauged eigenvalue equation

$$H_G(\xi)\chi(\xi)=E\chi(\xi), \tag{2.21}$$

where we identify $\chi(\xi(x))\equiv\chi(x)$ as given in (2.8). We now expand the gauged eigenfunction $\chi(\xi)$ in the form

$$\chi(\xi)=\left(\frac{\xi_2-\xi}{\xi_1-\xi_2}\right)^n\sum_{j=0}^{\infty}\frac{P_j(E)}{j!}\left(\frac{\xi_1-\xi}{\xi_2-\xi}\right)^j, \tag{2.22}$$

where ξ_1, ξ_2 are two distinct roots of the coeffecient of ∂_ξ^2 in (2.4). Now a suitable choice of ξ_1, ξ_2 (note that ξ_1, ξ_2 can be chosen in six ways) gives us a three-term recursion relation satisfied by $\{P_j(E)\}$,

$$
\begin{aligned}
&-[(2j-n+1)\hat{C}_{0-}+\hat{C}_{-}]P_{j+1}\\
&\quad=\left[E+d_1+\hat{C}_0\left(j-\frac{n}{2}\right)+\hat{C}_{00}\left(j-\frac{n}{2}\right)^2\right]P_j\\
&\qquad+j(j-1-n)[(2j-n-1)\hat{C}_{+0}+\hat{C}_{+}]P_{j-1}, \quad (j\geqslant 0),
\end{aligned}
\tag{2.23}
$$

where $\hat{C}_{ij}$ are determined from the relations

$$
\begin{aligned}
\hat{C}_{+0}&=-\frac{1}{(\xi_1-\xi_2)^2}[2\xi_1\xi_2^3C_{++}+\xi_2(\xi_1+\xi_2)C_{00}+2C_{--}],\\
\hat{C}_{00}&=\frac{1}{(\xi_1-\xi_2)^2}[6\xi_1^2\xi_2^2C_{++}+(\xi_1^2+\xi_2^2+4\xi_1\xi_2)C_{00}+6C_{--}],\\
\hat{C}_{0-}&=-\frac{1}{(\xi_1-\xi_2)^2}[2\xi_1^3\xi_2C_{++}+\xi_1(\xi_1+\xi_2)C_{00}+2C_{--}],
\end{aligned}
\tag{2.24}
$$

and $\hat{C}_j$, d_1 are given by

$$
\begin{aligned}
\hat{C}_{+}&=\frac{1}{\xi_1-\xi_2}[\xi_2^2C_{+}+\xi_2C_0+C_{-}],\\
\hat{C}_0&=-\frac{1}{\xi_1-\xi_2}[2\xi_1\xi_2C_{+}+(\xi_1+\xi_2)C_0+2C_{-}],\\
\hat{C}_{-}&=\frac{1}{\xi_1-\xi_2}[\xi_1^2C_{+}+\xi_1C_0+C_{-}],\\
d_1&=d+\frac{n(n+2)}{12}(C_{00}-\hat{C}_{00}).
\end{aligned}
\tag{2.25}
$$

From Eq. (2.23)–(2.25) it transpires that the eigenstates of type I–III Hamiltonians generate, in general, different orthogonal family of polynomials in the energy variable corresponding to each algebraization of Table I provided

$$
(2j-n+1)\hat{C}_{0-}+\hat{C}_{-}\neq 0, \quad \forall j\geqslant 0. \tag{2.26}
$$

The family $\{P_j(E)\}$ can be expressed in terms of monic polynomials $\{\tilde{P}_j(E)\}$ satisfying the recurrence relation

$$
\tilde{P}_{j+1}=(E-\lambda_j)\tilde{P}_j-\rho_j\tilde{P}_{j-1}, \tag{2.27}
$$

$$
\tilde{P}_j=\omega_jP_j, \quad j\geqslant 0, \tag{2.28}
$$

where $\tilde{P}_{-1}=P_1\equiv 0$ and $\tilde{P}_0=P_0\equiv 1$. It is now straightforward to write down the expression of eigenfunctions from (2.8) and (2.22). It follows from Eq. (2.23) that $\rho_0=0$ and $\rho_{n+1}=0$; so the infinite power series expansion in (2.22) truncates after the $(n+1)$-th term since the coeffecients $P_j(E_i)$ vanishes for $j>n$, where $E_i(i=0,1,...,n)$ are the zeros of the critical polynomial $\tilde{P}_{n+1}(E)$. This points to the fact that type I–III potentials belong to QES class having $(n+1)$ levels for each algebraization. The final expression of the band-edge eigenfunctions may be written in the form

TABLE II. The coeffecients ρ_j, λ_j, ω_j of the recurrence relation (2.26) and (2.27) are given for type I model. The choice of roots ξ_1, ξ_2 and the overall restrictions on potential parameters are also provided for each algebraization.

Solution no.	n	ρ_j	λ_j	ω_j	(ξ_1, ξ_2)	Overall restrictions on A, B
1.1	A	$(\frac{1}{2})^2 j(j-1-A)(2j+2B-1)(2B-2A+2j-1)$	$\frac{1-2k^2}{2}[A(A+1)+(A-2j)(2B-A+2j)]$	$(\frac{1}{2})^j \frac{\Pi_{r=0}^{[B]-A+j}(2B-2A+2j-1-2r)}{\Pi_{r=0}^{[B]-A}(2B-2A-1-2r)}$	$(-1,1)$	$A \in N-1,\ B \in R,$ $B-A \geqslant 0.$
1.2	$A-1$	$(\frac{1}{2})^2 j(j-A)(2j+2B+1)(2B-2A+2j-1)$	$\frac{1-2k^2}{2}[A(A+1)+(A-1-2j)(2B+2j-A+1)]$	,,	,,	$A \in N,\ B \in R,$ $B-A \geqslant 0.$
1.3	$B-1$	$(\frac{1}{2})^2 j(j-B)(2j+1)(2j-2B+1)$	$\frac{1-2k^2}{4}[2B^2-1+2(B-1-2j)(2j-B+2)]$ $+\frac{1}{2}ikk'(2A+1)(2B-2A-4j-3)$	$(\frac{-1}{2})^j \Pi_{r=0}^{j}(2j+1-2r)$	$\left(\frac{ik'}{k}, \frac{-ik'}{k}\right)$	$A \in R,\ B \in N,$ $A-B+1 \geqslant 0.$
1.4	$A-\frac{1}{2}$	$(\frac{1}{2})^2 j(2j-2A-1)(j-A)(2j+1)$	$\frac{1-2k^2}{8}[4A(A+1)-1+(2A-4j-1)(4j-2A+3)]$ $+2Bikk'(A-2j-1)$	,,	,,	$A \in N-\frac{1}{2},\ B \in R,$ $B-A \geqslant 0.$
1.5	$B-\frac{1}{2}$	$(\frac{1}{2})^2 j(j+A)(2j-2B-1)(2A-2B+2j+1)$	$\frac{1-2k^2}{8}[4B^2-1+(2B-4j-1)(4j+4A-2B+3)]$	$(\frac{1}{2})^j \frac{\Pi_{r=0}^{[A-B]+j}(2A-2B+2j-2r+1)}{\Pi_{r=0}^{[A-B]}(2A-2B-2r+1)}$	$(-1,1)$	$A \in R,\ B \in N-\frac{1}{2},$ $A-B+1 \geqslant 0.$
1.6	$B-\frac{3}{2}$	$(\frac{1}{2})^2 j(2j-2B+1)(j+A+1)(2A-2B+2j+1)$	$\frac{1-2k^2}{8}[4B^2-1+(2B-4j-3)(4j+4A-2B+5)]$	,,	,,	$A \in R,\ B \in N+\frac{1}{2},$ $A-B+1 \geqslant 0$

$$\psi_{E_i}(x)=\mu(x)(\xi(x)-\xi_2)^n\sum_{j=0}^{n}\frac{P_j(E_i)}{j!}\left(\frac{\xi(x)-\xi_1}{\xi(x)-\xi_2}\right)^j,\quad (i=0,1,,\ldots,n),\tag{2.29}$$

where $\mu(x)$ is determined from (2.11) for each of the three types given by (2.12)–(2.14) and the band-edge eigenvalues are E_0, $E_1,\ldots,E_n$. Note that n is to be computed for each of the algebraization in Table I.

III. EIGENSTATES AND SPECTRA OF TYPE I–III MODELS FOR SOME REAL VALUES OF THE POTENTIAL PARAMETERS

In this section we construct some examples based upon the general results obtained in the previous section. It may be useful to collect the following identities and differential relations among the Jacobian elliptic functions which will be frequently used:

$$sn^2x+cn^2x=1,\ \ dn^2x+k^2sn^2x=1,$$

$$sn'x=cnxdnx,\quad cn'x=-snxdnx,\quad dn'x=-k^2snxcnx.$$

In the following examples we denote the eigenstates[spectra] by $\phi_r(x)[e_r]$ whenever ordering is possible. Otherwise we denote them by $\psi_{E_i}[E_i]$, and $\psi_{E_i'}[E_i']$, indicating different algebraizations.

A. Type I model [defined on the domain (0,2K)]

We have got six algebraizations (see the solution 1.1–1.6 of Table I) for type I Hamiltonian (2.15). For each of them the corresponding eigenstates generate an orthogonal family of polynomials satisfying the recurrence relation (2.26). The explicit expressions of $\rho_j,\lambda_j,\omega_j$ together with the choice of ξ_1,ξ_2 and the overall restrictions on potential parameters are given in Table II.

It is clear that the algebraic solutions are obtained for the following two cases:

Case 1: $A\in(N-1)\cup(N-\frac{1}{2}),B\in R$

Here B is any real parameter and for each real values of B, A is allowed to take $0,\frac{1}{2},1,\frac{3}{2},\ldots,\Lambda\leqslant B$ (Λ is an integer or half-integer). For integer values of A, from the algebraizations 1.1–1.2 we get $(2A+1)$ band edge eigenstates and eigenvalues. Also for half-integer values of A the algebraization 1.4 gives $(A+\frac{1}{2})$ solutions of the Schrödinger equation.

Case 2: $B\in N\cup N-\frac{1}{2},A\in R$

Here A is any real number and B is allowed to take values $\frac{1}{2},1,\frac{3}{2},\ldots,\Lambda\leqslant A+1$ (Λ is integer or half-integer). It is to be noted that algebraization 1.3 is considered for integer values of B and 1.5–1.6 for half-integer B.

We now consider some specific examples when both of A and B are integer or half-integer.

1. $A=0$, $B=\frac{1}{2}$

$$V(x)=\frac{1}{4}\frac{dn^2x}{sn^2x}-\frac{1}{2}\frac{cnx}{sn^2x},$$
$$\phi_0(x)=\sqrt{\frac{snx}{1+cnx}},\quad e_0=0.\tag{3.1}$$

2. $A=0$, $B=\frac{3}{2}$

$$V(x)=\frac{9}{4}\frac{dn^2x}{sn^2x}-\frac{3}{2}\frac{cnx}{sn^2x},\tag{3.2}$$

$$\phi_0(x)=\left(\frac{snx}{1+cnx}\right)^{3/2}, \quad e_0=0.$$

3. A=½, B=1

$$V(x)=\frac{7}{4}\frac{dn^2x}{sn^2x}-2\frac{cnx}{sn^2x},$$
$$\phi_0(x)=\frac{\sqrt{snxdnx}}{1+cnx}exp\left(-\frac{i}{2}tan^{-1}\frac{kcnx}{k'}\right), \quad e_0=\frac{1-2k^2}{4}-ikk'. \tag{3.3}$$

4. A=½, B=2

$$V(x)=\frac{19}{4}\frac{dn^2x}{sn^2x}-4\frac{cnx}{sn^2x},$$
$$\phi_0(x)=\frac{\sqrt{dnx}sn^{3/2}x}{(1+cnx)^2}\exp\left(-\frac{i}{2}\tan^{-1}\frac{kcnx}{k'}\right), \quad e_0=\frac{1-2k^2}{4}-2ikk'. \tag{3.4}$$

5. A=1, B=3/2

$$V(x)=\frac{17}{4}\frac{dn^2x}{sn^2x}-\frac{9}{2}\frac{cnx}{sn^2x}.$$

For $0<k^2<\frac{1}{2}$,

$$\phi_{0,1}(x)=\frac{\sqrt{snx}}{(1+cnx)^{5/2}}[g_{\mp}(k)cn^2x+4cnx+4-g_{\mp}(k)], \quad e_{0,1}=1-4k^2+\frac{1}{2}g_{\mp}(k), \tag{3.5}$$

$$\phi_2(x)=\frac{dnx\sqrt{snx}}{(1+cnx)^{3/2}}, \quad e_2=1-2k^2, \tag{3.6}$$

where $g_{\pm}(k)=6k^2-1\pm\sqrt{1-36k^2k'^2}$.

For $\frac{1}{2}<k^2<1$, the suffixes 0,1,2 have to be replaced by 1,2,0, respectively.

Proceeding in the same fashion, we can find the eigenstates and spectra for higher values of A and B.

B. Type II model [defined on the domain (0,2K)]

Here two algebraizations are obtained (see the solution 2.1–2.2 of Table I). The related orthogonal polynomials are determined by the entries 2.1–2.2 of Table III. Note that both algebraizations are valid provided A is restricted to positive half-integer values only while the other parameter B is arbitrary.

Some examples are furnished below.

1. A=½

$$V(x)=B(B+1)\frac{dn^2x}{sn^2x}-\frac{3}{4}dn^2x,$$
$$\phi_0(x)=\frac{sn^{B+1}x}{(cnx+dnx)^{B+1/2}}, \quad e_0=-\frac{k'^2}{2}-\frac{k^2}{4}(2B+1)^2. \tag{3.7}$$

For $B\leqslant 0$, the following degenerated state is found:

TABLE III. The coeffecients ρ_j, λ_j, ω_j of the recurrence relation (2.26) and (2.27) together with the choice of ξ_1, ξ_2 and the overall restrictions on potential parameters are provided for type II (first two rows) and type III models.

Solution no.	n	ρ_j	λ_j	ω_j	(ξ_1, ξ_2)	Overall restrictions on A, B
2.1	$A-\frac{1}{2}$	$\left(\frac{k'^2}{2}\right)^2 j(2j-2A-1)(j-A+B)(2j+2B+1)$	$-\frac{k^2}{4}(2B+1)^2-\frac{k'^2}{8}(2A+1)^2+\frac{1+k^2}{8}$ $\times(2A-4j-1)(4B-2A+4j+3)$	$\left(\frac{k'^2}{2}\right)^j \frac{\Pi_{r=0}^{j+[B]}(2j+2B-2r+1)}{\Pi_{r=0}^{[B]}(2B-2r+1)}$	$(-1,1)$	$A \in N-\frac{1}{2},\ B \in R.$
2.2	$A-\frac{1}{2}$	$\left(\frac{k'^2}{2}\right)^2 j(2j-2A-1)(j-A-B-1)(2j-2B-1)$	$-\frac{k^2}{4}(2B+1)^2-\frac{k'^2}{8}(2A+1)^2+\frac{1+k^2}{8}$ $\times(2A-4j-1)(4j-2A-4B-1)$	$\left(\frac{k'^2}{2}\right)^j \frac{\Pi_{r=0}^{j}(2j-2B-2r-1)}{-2B-1}$	$(-1,1)$	$A \in N-\frac{1}{2},\ B \in R,$ $B \leqslant 0.$
3.1	A	$\left(\frac{k^2}{2}\right)^2 j(j-A-1)(2j-1)(2j-2A-1)$	$\frac{2j-A}{2}[(2j-A)(2-k^2)+4Bik']$ $-B^2k'^2-A(A+1)k^2/2$	$\left(\frac{k^2}{2}\right)^j \frac{\Pi_{r=0}^{j}(2j-1-2r)}{(-1)}$	$\left(\frac{i}{k'}, \frac{-i}{k'}\right)$	$A \in N-1,\ B \in R.$
3.2	$A-1$	$\left(\frac{k^2}{2}\right)^2 j(j-A)(2j-2A-1)(2j+1)$	$\frac{2j-A+1}{2}[(2j-A+1)(2-k^2)+4Bik']$ $-B^2k'^2-A(A+1)k^2/2$	$\left(\frac{k^2}{2}\right)^j \Pi_{r=0}^{j}(2j+1-2r)$	,,	$A \in N,\ B \in R.$
3.3	$A-\frac{1}{2}$	,,	$\left(\frac{1+2Bik'}{2}\right)^2-\frac{k^2}{8}(2A+1)^2+\frac{1}{8}(2A-4j-1)$ $\times[(k^2-2)(4j-2A+3)-8Bik']$	,,	,,	$A \in N-\frac{1}{2},\ B \in R.$

$$\psi_0(x)=(cnx+dnx)^{B+1/2}/sn^B x.$$

2. $A=\frac{3}{2}$

$$V(x)=B(B+1)\frac{dn^2x}{sn^2x}-\frac{15}{4}dn^2x,$$

$$\phi_{0,1}(x)=\frac{sn^{B+1}x}{(cnx+dnx)^{B+3/2}}\left[\left\{(1+k^2)\left(B+\frac{3}{2}\right)+\eta_{\mp}(k)\right\}cn^2x\right.$$
$$\left.+2\left(B+\frac{3}{2}\right)cnxdnx+k'^2\left(B+\frac{3}{2}\right)-\eta_{\mp}(k)\right], \tag{3.8}$$

$$e_{0,1}=\frac{6k^2-10-k^2(2B+1)^2}{4}\mp\sqrt{2(1+k^4)\left(B+\frac{1}{2}\right)^2-k'^4},$$

where

$$\eta_{\pm}(k)=-(1+k^2)\left(B+\frac{1}{2}\right)\pm\sqrt{2(1+k^4)\left(B+\frac{1}{2}\right)^2-k'^4}.$$

For $B\leqslant 0$, two other degenerated states are obtained:

$$\psi_{0,1}(x)=\frac{(cnx+dnx)^{B-1/2}}{sn^B x}\left[\left\{(1+k^2)\left(B+\frac{3}{2}\right)+\eta_{\mp}(k)\right\}cn^2x\right.$$
$$\left.+(1-2B)cnxdnx-k'^2\left(B-\frac{1}{2}\right)-(1+k^2)(2B+1)-\eta_{\mp}(k)\right].$$

C. Type III model [defined on the entire real line]

This corresponds to three algebraizations (see the solution 3.1–3.3 of Table I), the first two of which are for an integer A while the third one is for a half-integer A. As before, the eigenstates generate an orthogonal family of polynomials in the energy variable for each algebraization. The recurrence relation (2.26) is determined by the entries 3.1–3.3 of Table III. The other parameter B takes arbitrary values.

We now consider some examples.

1. $A=0$

$$V(x)=B^2k^2cn^2x+Bk^2snxcnx,$$
$$\phi_0(x)=\exp\left(-B\tan^{-1}\frac{snx}{cnx}\right),\quad e_0=-B^2k'^2. \tag{3.9}$$

2. $A=\frac{1}{2}$

$$V(x)=(B^2-\tfrac{3}{4})k^2cn^2x+2Bk^2snxcnx,$$

$$\phi_0(x)=\sqrt{dnx}\exp\left[-B\tan^{-1}\left(\frac{snx}{cnx}\right)+\frac{i}{2}\tan^{-1}\left(\frac{k'snx}{cnx}\right)\right], \tag{3.10}$$

$$e_0=-\frac{k^2}{2}+\left(\frac{1+2Bik'}{2}\right)^2.$$

3. $A=1$

$$V(x)=(B^2-2)k^2cn^2x+3Bk^2snxcnx,$$

$$\phi_0(x)=dnx\exp\left(-B\tan^{-1}\frac{snx}{cnx}\right),\quad e_0=-B^2k'^2-k^2, \tag{3.11}$$

$$\phi_{1,2}^{(i)}(x)=[(k^2\mp\sqrt{k^4-16k'^2B^2})snx+4Bcnx]\exp\left(-B\tan^{-1}\frac{snx}{cnx}\right),$$

$$\phi_{1,2}^{(ii)}(x)=[4Bk'^2snx+(k^2\pm\sqrt{k^4-16k'^2B^2})cnx]\exp\left(-B\tan^{-1}\frac{snx}{cnx}\right),$$

$$e_{1,2}=1-\tfrac{3}{2}k^2-B^2k'^2\mp\tfrac{1}{2}\sqrt{k^4-16k'^2B^2},$$

where the superscripts in the eigenstates indicate their double-degeneracy.

IV. ES LIMIT OF QES MODELS

We have so far constructed three new classes of QES potentials and explicitly obtained their eigenstates and spectra. Our purpose in this section is to show that corresponding to each type there is associated an ES class potential. It is useful to write down the following results of the ES limit:

$$sn(x,k)\underset{k\to0}{\overset{k\to1}{\to}}\begin{cases}\tanh x\\ \sin x\end{cases},\quad cn(x,k)\underset{k\to0}{\overset{k\to1}{\to}}\begin{cases}\operatorname{sech}x\\ \cos x\end{cases},\quad dn(x,k)\underset{k\to0}{\overset{k\to1}{\to}}\begin{cases}\operatorname{sech}x\\ 1\end{cases}. \tag{4.1}$$

Each of the three types of potentials are doubly periodic, one is real and the other imaginary. As $k\to1$ (or 0) we get an ES potential having an imaginary (or real) period.

A. ES classes associated to type I model

We have already shown that the type I model [cf. Eq. (2.15)] belongs to the QES periodic class. The potential has a real period $4K$ and imaginary period $4K'$, where $K'\equiv K(k')$. Using the relation (4.1) and the relation

$$K[K']\underset{k\to0}{\overset{k\to1}{\to}}\begin{cases}\infty & [\pi/2]\\ \pi/2 & [\infty]\end{cases}, \tag{4.2}$$

we see that the QES model is also exactly solvable when the modulus parameter $k\to1$ and 0. The associated ES classes are given by

$$k\to1:V_1(x)=[B^2+A(A+1)]\operatorname{cosech}^2x-2B(A+\tfrac{1}{2})\operatorname{cosech}x\coth x,\quad x\in(0,\infty), \tag{4.3}$$

$$k\to0:V_2(x)=[B^2+A(A+1)]\operatorname{cosec}^2x-2B(A+\tfrac{1}{2})\operatorname{cosec}x\cot x,\quad x\in(0,\pi), \tag{4.4}$$

whose eigenstates and spectra are[4]

$$\begin{aligned}\psi_r^{(1)}(x)&=(\cosh x-1)^{(B-A)/2}(\cosh x+1)^{-(B+A)/2}P_r^{(B-A-1/2,-B-A-1/2)}(\cosh x),\\ \psi_r^{(2)}(x)&=(1-\cos x)^{(B-A)/2}(1+\cos x)^{-(B+A)/2}P_r^{(B-A-1/2,-B-A-1/2)}(\cos x),\end{aligned} \tag{4.5}$$

$$E_r^{(1)}=-(A-r)^2,\quad E_r^{(2)}=(A-r)^2,\quad (r=0,1,2,\ldots), \tag{4.6}$$

where $P_r^{(\alpha,\beta)}(x)$ is the Jacobi polynomial and the superscripts 1 and 2 indicate the potentials $V_1(x)$ and $V_2(x)$, respectively. Note that we have solved the type I spectral problem (see Sec. III A) when at least one of the parameters A,B is an integer or a half-integer. Thus the ES results (4.5) and (4.6) can be reproduced from the associated QES results for this restricted domain of potential parameters only.

We now consider the ES limits of the examples given in Sec. III A [see Eqs. (3.1)–(3.5)]. In the following the superscripts in the eigenstates indicate whether they correspond to the potentials $V_1(x)$ and $V_2(x)$.

1. $A=0$, $B=\frac{1}{2}$

$$V_1(x)=\tfrac{1}{4}\operatorname{cosech}^2 x-\tfrac{1}{2}\operatorname{cosech} x\coth x, \tag{4.7}$$

$$V_2(x)=\tfrac{1}{4}\operatorname{cosec}^2 x-\tfrac{1}{2}\operatorname{cosec} x\cot x, \tag{4.8}$$

$$\phi_0^{(1)}(x)=\sqrt{\tanh\frac{x}{2}},\quad \phi_0^{(2)}(x)=\sqrt{\tan\frac{x}{2}},\quad e_0^{(1)}=e_0^{(2)}=0.$$

From (4.5) and (4.6) it follows that we can reproduce the ground states for the two ES classes.

2. $A=0$, $B=\frac{3}{2}$

$$V_1(x)=\tfrac{9}{4}\operatorname{cosech}^2 x-\tfrac{3}{2}\operatorname{cosech} x\coth x, \tag{4.9}$$

$$V_2(x)=\tfrac{9}{4}\operatorname{cosec}^2 x-\tfrac{3}{2}\operatorname{cosec} x\cot x, \tag{4.10}$$

$$\phi_0^{(1)}(x)=\tanh^{3/2}\frac{x}{2},\quad \phi_0^{(2)}(x)=\tan^{3/2}\frac{x}{2},\quad e_0^{(1)}=e_0^{(2)}=0.$$

Again ground levels for two ES potentials (4.9) and (4.10) are reproduced.

3. $A=\frac{1}{2}$, $B=1$

$$V_1(x)=\tfrac{7}{4}\operatorname{cosech}^2 x-2\operatorname{cosech} x\coth x, \tag{4.11}$$

$$V_2(x)=\tfrac{7}{4}\operatorname{cosec}^2 x-2\operatorname{cosec} x\cot x, \tag{4.12}$$

$$\phi_0^{(1)}(x)=\frac{\sqrt{\operatorname{sech} x\tanh x}}{1+\operatorname{sech} x},\quad \phi_0^{(2)}(x)=\frac{\sqrt{\sin x}}{1+\cos x},\quad e_0^{(1)}=-\frac{1}{4}=-e_0^{(2)}.$$

These are the ground states for the ES classes.

4. $A=\frac{1}{2}$, $B=2$

$$V_1(x)=\tfrac{19}{4}\operatorname{cosech}^2 x-4\operatorname{cosech} x\coth x, \tag{4.13}$$

$$V_2(x)=\tfrac{19}{4}\operatorname{cosec}^2 x-4\operatorname{cosec} x\cot x, \tag{4.14}$$

$$\phi_0^{(1)}(x)=\frac{\sinh^{3/2} x}{(1+\cosh x)^2},\quad \phi_0^{(2)}(x)=\frac{\sin^{3/2} x}{(1+\cos x)^2},\quad e_0^{(1)}=-\frac{1}{4}=-e_0^{(2)}.$$

These are the ground levels for ES potentials.

5. $A=1$, $B=\frac{3}{2}$

$$V_1(x)=\tfrac{17}{4}\operatorname{cosech}^2 x-\tfrac{9}{2}\operatorname{cosech} x\coth x, \tag{4.15}$$

$$V_2(x)=\tfrac{17}{4}\operatorname{cosec}^2 x-\tfrac{9}{2}\operatorname{cosec} x\cot x, \tag{4.16}$$

$$\phi_0^{(1)}(x)=\frac{\sqrt{\sinh x}}{(1+\cosh x)^{3/2}},\quad \phi_1^{(2)}(x)=\frac{\sqrt{\sin x}}{(1+\cos x)^{3/2}},\quad e_0^{(1)}=-1=-e_1^{(2)},$$

$$\phi_1^{(1)}(x)=\frac{\sqrt{\sinh x}(\cosh x-3)}{(1+\cosh x)^{3/2}},\quad \phi_0^{(2)}(x)=\frac{\sqrt{\sin x}(\cos x-3)}{(1+\cos x)^{3/2}},\quad e_1^{(1)}=0=e_0^{(2)}.$$

Here two ES levels are reproduced.

B. ES class associated to type II model

Using as before the relations (4.1) and (4.2), we see that in the limit $k\to 1$ type II potential (2.16) goes over to the following ES class known as the generalized Pöschl–Teller potential:

$$V_3(x)=B(B+1)\operatorname{cosech}^2 x-A(A+1)\operatorname{sech}^2 x, \tag{4.17}$$

its eigenstates and spectra being given by

$$\begin{gathered}\psi_r^{(3)}(x)=(\cosh 2x-1)^{-B/2}(\cosh 2x+1)^{-A/2}P_r^{(-B-1/2,-A-1/2)}(\cosh 2x),\\ E_r^{(3)}=-(A+B-2r)^2\quad (r=0,1,2,\ldots),\end{gathered} \tag{4.18}$$

where the superscripts indicate correspondance with $V_3(x)$.

We recall that the QES levels for the type II model are obtained for half-integer values of A. Let us now take the ES limit of the examples given in Sec III B [see Eqs. (3.6) and (3.7)]. The other parameter B is taken as negative real number.

1. $A=\frac{1}{2}$

$$\begin{gathered}V_3(x)=B(B+1)\operatorname{cosech}^2 x-\tfrac{3}{4}\operatorname{sech}^2 x,\\ \psi_0^{(3)}(x)=\operatorname{cosech}^B x\sqrt{\operatorname{sech} x},\quad e_0^{(3)}=-\frac{(2B+1)^2}{4}.\end{gathered} \tag{4.19}$$

Here $\psi_0^{(3)}$, $e_0^{(3)}$ are ground level for the ES potential $V_3(x)$.

2. $A=\frac{3}{2}$

$$\begin{gathered}V_3(x)=B(B+1)\operatorname{cosech}^2 x-\tfrac{15}{4}\operatorname{sech}^2 x,\\ \psi_0^{(3)}(x)=\sinh^{-B} x\cosh^{-3/2} x,\quad e_0^{(3)}=-(B+\tfrac{3}{2})^2,\\ \psi_1^{(3)}(x)=\frac{\sinh^{-B} x}{\cosh^{3/2} x}[(2B+1)\cosh^2 x-2],\quad e_1^{(3)}=-(B-\tfrac{1}{2})^2.\end{gathered} \tag{4.20}$$

Here $\psi_{0,1}^{(3)}$, $e_{0,1}^{(3)}$ are two levels for the ES potential (4.20).

C. ES class associated to type III model

The type III potential (2.17) is defined on the entire real line. This is a QES periodic potential having a real period $2K$ and an imaginary period $4K'$. The algebraic sector is determined for an integer or a half-integer A, while B is arbitrary real parameter. In the limit $k\to 1$, this potential coincides to the following ES class:

$$V_4(x)=[B^2-A(A+1)]\operatorname{sech}^2 x+2B(A+\tfrac{1}{2})\operatorname{sech} x\tanh x. \tag{4.21}$$

The eigenstates and spectra of the potential (4.21) are

$$\psi_r^{(4)}(x)=\operatorname{sech}^A x\exp[-B\tan^{-1}(\sinh x)]P_r^{(-iB-A-1/2,iB-A-1/2)}(i\sinh x),$$

$$E_r^{(4)}=-(A-r)^2 \quad (r=0,1,2,\ldots). \tag{4.22}$$

We now take the ES limit (here $k\to 1$ only) of the examples given in Sec III C. Note that the limit $k\to 0$ gives a free particle motion.

1. $A=0$

$$\begin{aligned} V_4(x)&=B^2\operatorname{sech}^2 x+B\operatorname{sech} x\tanh x,\\ \phi_0^{(4)}(x)&=\exp(-B\tan^{-1}\sinh x),\quad e_0^{(4)}=0. \end{aligned} \tag{4.23}$$

Clearly, the ground state for (4.23) agrees with the general results (4.22) for $A=0$.

2. $A=\frac{1}{2}$

$$\begin{aligned} V_4(x)&=(B^2-\tfrac{3}{4})\operatorname{sech}^2 x+2B\operatorname{sech} x\tanh x,\\ \phi_0^{(4)}(x)&=\sqrt{\operatorname{sech} x}\exp[-B\tan^{-1}(\sinh x)],\quad e_0^{(4)}=-\tfrac{1}{4}. \end{aligned} \tag{4.24}$$

This is also in agreement with (4.22) for $A=\frac{1}{2}$.

3. $A=1$

$$\begin{aligned} V_4(x)&=(B^2-2)\operatorname{sech}^2 x+3B\operatorname{sech} x\tanh x,\\ \phi_0^{(4)}(x)&=\operatorname{sech} x\exp(-B\tan^{-1}\sinh x)=\phi_1^{(4)}(x),\quad e_0^{(4)}=-1=e_1^{(4)},\\ \phi_2^{(4)}(x)&=\operatorname{sech} x(\sinh x+2B)\exp(-B\tan^{-1}\sinh x),\quad e_2^{(4)}=0. \end{aligned} \tag{4.25}$$

Thus two ES levels are reproduced from the corresponding QES levels.

Hence we have shown that corresponding to three QES models types I, II and III, there is associated some definite ES classes namely V_1, V_2 (for type I),V_3 (for type II) and V_4 (for type III), respectively. In the ES limit we can reproduce some ES levels from the corresponding QES levels as well.

V. CONCLUSION

To conclude, we have constructed three new QES elliptic potentials types I–III using an sl(2,R) Lie-algebraic scheme and obtained their algebraic levels analytically. Further, we have shown that the eigenstates of QES Hamiltonians generate an orthogonal family of polynomials in the energy variable. The interesting point is that the elliptic parameter $k(0<k^2<1)$ in the models

turns out to be responsible for QES class and, when it touches the end-points 0 and 1 of its domain, the ES classes are revealed. We have explicitly shown that some ES levels can be reproduced on a restricted domain of potential parameters.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 11 NOVEMBER 2002

Density and current of a dissipative Schrödinger operator

Hans-Christoph Kaiser,[a] Hagen Neidhardt,[b] and Joachim Rehberg[c]
Weierstrass Institute for Applied Analysis and Stochastics,
Mohrenstrasse 39, D-10117 Berlin, Germany

(Received 29 May 2002; accepted 10 July 2002)

We regard a current flow through an open one-dimensional quantum system which is determined by a dissipative Schrödinger operator. The imaginary part of the corresponding form originates from Robin boundary conditions with certain complex valued coefficients imposed on Schrödinger's equation. This dissipative Schrödinger operator can be regarded as a pseudo-Hamiltonian of the corresponding open quantum system. The dilation of the dissipative operator provides a (self-adjoint) quasi-Hamiltonian of the system, more precisely, the Hamiltonian of the minimal closed system which contains the open one is used to define physical quantities such as density and current for the open quantum system. The carrier density turns out to be an expression in the generalized eigenstates of the dilation while the current density is related to the characteristic function of the dissipative operator. Finally a rigorous setup of a dissipative Schrödinger–Poisson system is outlined. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1507825]
