I. INTRODUCTION

Quantum wells are an important feature of many optoelectronic devices, e.g., semiconductor quantum well lasers. While the drift-diffusion and energy models in general provide an adequate description, see, e.g., Refs. 1 and 2, the optical active zones and their environment require a more refined modeling because genuine quantum effects come to bear.[3]

A comprehensive model reflecting both the necessity of quantum mechanical simulations and their restriction for technical and economic reasons will combine some quantum mechanical model for the optical active zone and a drift-diffusion or energy model elsewhere. The main conceptual problem in matching macroscopic and quantum mechanical quantities, see, e.g., Refs. 4 and 5, is to obtain some form of current continuity all over the device. The main idea is to postulate the continuity of the the normal components of the currents at the model interface. This poses a variety of problems on both sides—the macroscopic model and the quantum mechanical one. In particular many quantum mechanical models for the active zone such as the stationary Kohn–Sham system, see, e.g., Refs. 6 and 7, are closed systems and thus, the flow vanishes identically all over the system. This assumption is not justified in the intended combined model in view of the electric flow through the interface. Hence, one has to pass to open quantum systems; and here the first difficulty consists in defining particle densities and currents at all. The aim of this paper is a rigorous definition of these physical quantities with respect to the dissipative Schrödinger operator related to an open quantum system which might serve as a quantum mechanical model for one-dimensional semiconductor nanostructures, as quantum wells or multi-quantum wells.

Let us first have a look at the case of a closed quantum system situated in a bounded one-dimensional spatial domain $\Omega=[a,b]$. We regard Schrödinger's equation

[a]Electronic mail: kaiser@wias-berlin.de
[b]Electronic mail: neidhard@wias-berlin.de
[c]Electronic mail: rehberg@wias-berlin.de

$$-\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{1}{m(x)}\frac{\mathrm{d}\psi(x)}{\mathrm{d}x}\right)+V(x)\psi(x)=\lambda\psi(x),\quad x\in[a,b] \tag{1.1}$$

with a real valued potential V and a positive function m, which represents the position-dependent effective mass multiplied by $1/\hbar^2$. If we impose homogeneous Neumann or Dirichlet boundary conditions at a and b, then the corresponding operator H on the Hilbert space $L^2([a,b])$ of complex valued, square integrable functions on $[a,b]$ becomes a self-adjoint one. For that case the formalism of quantum mechanics is well developed and one obtains the carrier density in the following way: H is an operator with compact resolvent. Let us denote by $\{\mathcal{E}_l\}_{l=1}^{\infty}$ and $\{\psi_l\}_{l=1}^{\infty}$ the sequence of eigenvalues and eigenfunctions counting multiplicities and let $\hat{\varrho}:=\{\varrho_l\}_{l=1}^{\infty}$ be a sequence of occupation numbers which add up to the total number N of carriers in the system

$$N:=\sum_{l=1}^{\infty}\varrho_l. \tag{1.2}$$

The carrier density is given by

$$u_{\hat{\varrho}}(x)=\sum_{l=1}^{\infty}\varrho_l|\psi_l(x)|^2,\qquad x\in[a,b]. \tag{1.3}$$

Usually, the sequence $\hat{\varrho}$ is expressed in terms of an equilibrium distribution function f which is non-negative and decreasing:

$$\varrho_l:=f(\mathcal{E}_l),\quad l=1,2,\ldots. \tag{1.4}$$

Thus, the operator

$$\varrho:=f(H) \tag{1.5}$$

is self-adjoint and non-negative. If the equilibrium distribution function $f(\lambda)$ tends to zero sufficiently fast as $\lambda\to+\infty$, then ϱ is nuclear. Moreover, there is $N=\mathrm{tr}(\varrho)=\mathrm{tr}(f(H))$. Non-negative, self-adjoint, nuclear operators are density matrices. Since ϱ commutes with H the density matrix ϱ remains unchanged in time, i.e., ϱ is a steady state. If the density matrix is given, then the number of carriers $N_\varrho(\omega)$ in the set $\omega\subseteq[a,b]$ can be expressed by

$$N_\varrho(\omega)=\mathrm{tr}(\varrho\chi_\omega), \tag{1.6}$$

where $\chi_\omega(\cdot)$ is the indicator function of the subset ω. It turns out that (1.6) defines an absolutely continuous measure (with respect to the Lebesgue measure). One verifies that its Radon–Nikodym derivative u_ϱ coincides with the carrier density defined by (1.3), i.e., $u_{\hat{\varrho}}=u_\varrho$.

The system described by H is closed. Hence, there is no interaction with the environment, in particular, no carrier exchange. Consequently, the current density $j_{\hat{\varrho}}(x)$ defined by

$$j_{\hat{\varrho}}(x):=\sum_{l=1}^{\infty}\varrho_l j_l(x),\quad x\in[a,b], \tag{1.7}$$

is identical zero, where in accordance with Ref. 8 the current density $j_l(x)$ of the eigenstate ψ_l is given by

$$j_l(x):=\mathrm{Im}\left(\frac{1}{m(x)}\psi_l'(x)\overline{\psi_l(x)}\right),\quad x\in[a,b],\quad l=1,2,\ldots. \tag{1.8}$$

This consequence is unacceptable, if we want to model a net current flow through the boundary of the system. To that end we devised non-self-adjoint boundary conditions for Schrödinger's equation, see Refs. 6, 7, and 5, i.e., we regard the Schrödinger operator H with the domain

$$\mathrm{dom}(H)=\left\{ g\in W^{1,2}([a,b]):\ \begin{array}{l} \dfrac{1}{m(x)}g'(x)\in W^{1,2}([a,b]),\\ \dfrac{1}{2m(a)}g'(a)=-\kappa_a g(a),\\ \dfrac{1}{2m(b)}g'(b)=\kappa_b g(b) \end{array} \right\}, \tag{1.9}$$

where $\kappa_a,\kappa_b\in\mathbb{C}$. If at least one of the imaginary parts is different from zero, then the operator H is non-self-adjoint. However, this non-self-adjointness implies several complications. In particular, the notion of carrier density becomes unclear.

This situation can be handled if we restrict ourselves to dissipative operators. Let us recall that an operator is called dissipative if the imaginary part of its associated quadratic form is nonpositive. In the present case the operator H is dissipative if $\kappa_a,\kappa_b\in\mathbb{C}_+:=\{z\in\mathbb{C}:\mathrm{Im}(z)>0\}$. Moreover, under this assumption the operator H becomes maximal dissipative, i.e., it admits no proper dissipative extension, see Ref. 5. The main technical tool to overcome the difficulties is the dilation theory for maximal dissipative operators. In Ref. 9 the minimal self-adjoint dilation K of H was explicitly constructed and analyzed in detail. From the physical point of view the minimal self-adjoint dilation plays the role of the Hamiltonian of a larger closed system which contains the original system described by the pseudo-Hamiltonian H, i.e., it acts as a quasi-Hamiltonian of the open system, cf. Ref. 5. Using this fact one defines steady states, carrier densities and current densities of the dissipative quantum system by means of the corresponding quantities derived from the quasi-Hamiltonian K. In this paper we aim at expressing these quantities in terms of the pseudo-Hamiltonian H itself. Indeed, the carrier and current densities are expectation values of the corresponding observables which are composites of H. In particular, the current density observable is related to the characteristic function of the operator H. It turns out that the current density is independent of $x\in[a,b]$ and, in general, different from zero. So we have a constant current through $[a,b]$.

This formal approach to the net current flow problem fits into scattering models, see, e.g., Refs. 10–12 and in particular the concept of transparent boundary conditions, (see e.g., Refs. 13 and 14), which has been extended to the multi dimensional case in Refs. 15 and 16. In these models one replaces the maximal dissipative operator H by a family of maximal dissipative operators $\{H(z)\}_{z\in\overline{\mathbb{C}_+}}$ defined on $L^2([a,b])$. If $a=0$, $b=1$, and $m(x)\equiv 1/2$, then $H(z)$ is given by

$$\begin{aligned} \mathrm{dom}(H(z))&:=\left\{ g\in W^{2,2}([0,1]):\ \begin{array}{l} g'(1)=\kappa_1(z)g(1)\\ g'(0)=-\kappa_0(z)g(0), \end{array} \right\},\\ (H(z)g)(x)&:=-\frac{\mathrm{d}^2}{\mathrm{d}x^2}g(x)+V(x)g(x),\quad g\in\mathrm{dom}(H(z)), \end{aligned} \tag{1.10}$$

with

$$\kappa_1(z):=i\sqrt{z}\quad\text{and}\quad\kappa_0(z):=i\sqrt{z-V_-},\quad z\in\overline{\mathbb{C}_+}, \tag{1.11}$$

see Ref. 10, where the cut of the square root is along $[0,\infty)$ and $\mathrm{Im}(\sqrt{z})\geqslant 0$ for $z\in\mathbb{C}_+$. Let us consider the self-adjoint Schrödinger operator K,

$$\begin{aligned} \mathrm{dom}(K) &:= W^{2,2}(\mathbb{R}), \\ (Kf)(x) &:= -\frac{\mathrm{d}^2}{\mathrm{d}x^2} f(x) + V_{KL}(x) f(x), \quad f \in \mathrm{dom}(K), \end{aligned} \tag{1.12}$$

on the Hilbert space $L^2(\mathbb{R})$ whose potential $V_{KL} \in C(\mathbb{R})$ looks like

$$V_{KL} = \begin{cases} V_- & : \ x \in \mathbb{R}_- \\ V & : \ x \in [0,1] \\ 0 & : \ x \in (1,+\infty) \end{cases}, \tag{1.13}$$

where $V_- > 0$,

$$V(0) = V_- \quad \text{and} \quad V(1) = 0. \tag{1.14}$$

Operators of this type have been investigated in Ref. 17. It turns out that

$$P(K-z)^{-1}\big|_{L^2([0,1])} = (H(z)-z)^{-1}, \quad z \in \mathbb{C}_+, \tag{1.15}$$

where P is the orthogonal projector from $L^2(\mathbb{R})$ onto $L^2([0,1])$. This means that the operator K can be regarded as a self-adjoint dilation of the family $\{H(z)\}_{z \in \overline{\mathbb{C}_+}}$. Moreover,

$$\bigvee_{z \in \mathbb{C} \setminus \mathbb{R}} (K-z)^{-1} L^2([0,1]) = L^2(\mathbb{R}), \tag{1.16}$$

i.e., K is a minimal self-adjoint dilation, hence, uniquely determined up to an isomorphism. Thus, if we want to compute quantities which are related to the subspace $L^2([0,1])$, for instance, carrier densities on the interval $[0,1]$, we can do this using either the self-adjoint operator K or the family $\{H(\lambda)\}_{\lambda \in \mathbb{R}}$ of maximal dissipative operators. Moreover, if we are only interested in quantities with respect to a small energy interval around the energy $\lambda_0 \in \mathbb{R}$ (in the limit only quantities for the energy λ_0), then it suffices to consider the maximal dissipative operator $H(\lambda_0)$ which leads to a model described at the beginning.

The paper is organized as follows. In Sec. II we rigorously define Schrödinger-type operators and briefly recall their properties, see Ref. 5. Moreover, we introduce the important notion of the characteristic function $\Theta_H(z)$ and briefly describe the minimal self-adjoint dilation K of H. Further we state its generalized eigenfunction expansion following Ref. 9. In Sec. III we introduce generalized steady states and define carrier densities. In Sec. IV we define the current density and express it in terms of the characteristic function. In particular, it turns out that if the steady state is given by $\varrho = f(K)$, then the current density is zero. In Sec. V we comment on the results, in particular, we clarify the relation to the Lax–Phillips scattering theory and verify the continuity equation. Finally, we give a rigorous setting of dissipative Schrödinger–Poisson systems which have the advantage that their current densities are different from zero for suitably chosen steady states.

II. SCHRÖDINGER-TYPE OPERATORS

Following the proposal of Ref. 6 we consider the non-self-adjoint Schrödinger-type operator H on the Hilbert space $\mathfrak{h} = L^2([a,b])$ given by the domain (1.9) and

$$(Hg)(x) = (l(g))(x), \quad g \in \mathrm{dom}(H), \tag{2.1}$$

where

$$(l(g))(x) := -\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}x}\frac{1}{m(x)}\frac{\mathrm{d}}{\mathrm{d}x} g(x) + V(x) g(x), \tag{2.2}$$

and $V\in L^2([a,b])$ is a real potential, the effective mass $m(x)>0$ obeys $m(x)+1/m(x)\in L^\infty([a,b])$ and κ_a, $\kappa_b\in\mathbb{C}_+$. The operator H is maximal dissipative and completely non-self-adjoint, see Ref. 5. The spectrum of H consists of isolated eigenvalues in the lower half-plane with the only accumulation point at infinity. Since the operator H is completely non-self-adjoint there do not exist real eigenvalues. To analyze the operator H it is useful to introduce the elementary solutions $v_a(x,z)$ and $v_b(x,z)$,

$$l(v_a(x,z))-zv_a(x,z)=0,\quad v_a(a,z)=1,\quad \frac{1}{2m(a)}v_a'(a,z)=-\kappa_a, \tag{2.3}$$

$$l(v_b(x,z))-zv_b(x,z)=0,\quad v_b(b,z)=1,\quad \frac{1}{2m(b)}v_b'(b,z)=\kappa_b, \tag{2.4}$$

$x\in[a,b]$, $z\in\mathbb{C}$, which always exist. The Wronskian $W(z)$ of $v_a(x,z)$ and $v_b(x,z)$ is defined by

$$W(z)=v_a(x,z)\frac{1}{2m(x)}v_b'(x,z)-v_b(x,z)\frac{1}{2m(x)}v_a'(x,z). \tag{2.5}$$

We note that the Wronskian does not depend on x. Similarly, the functions $v_{*a}(x,z)$ and $v_{*b}(x,z)$,

$$v_{*a}(x,z):=\overline{v_a(x,\overline{z})}\qquad\text{and}\qquad v_{*b}(x,z):=\overline{v_b(x,\overline{z})},\quad z\in\mathbb{C}, \tag{2.6}$$

$x\in[a,b]$, $z\in\mathbb{C}$, are elementary solutions of

$$l(v_{*a}(x,z))-zv_{*a}(x,z)=0,\quad v_{*a}(a,z)=1,\quad \frac{1}{2m(a)}v_{*a}'(a,z)=-\overline{\kappa_a}, \tag{2.7}$$

$$l(v_{*b}(x,z))-zv_{*b}(x,z)=0,\quad v_{*b}(b,z)=1,\quad \frac{1}{2m(b)}v_{*b}'(b,z)=\overline{\kappa_b}, \tag{2.8}$$

$x\in[a,b]$. The Wronskian of $v_{*a}(x,z)$ and $v_{*b}(x,z)$ is denoted by $W_*(z)$ and is also independent of x. By these elementary solutions one gets for the resolvents the representations

$$((H-z)^{-1}f)(x)=-\frac{v_b(x,z)}{W(z)}\int_a^x dy\, v_a(y,z)f(y)-\frac{v_a(x,z)}{W(z)}\int_x^b dy\, v_b(y,z)f(y), \tag{2.9}$$

for $z\in\varrho(H)$, $f\in L^2([a,b])$ and

$$((H^*-z)^{-1}f)(x)=-\frac{v_{*b}(x,z)}{W_*(z)}\int_a^x dy\, v_{*a}(y,z)f(y)-\frac{v_{*a}(x,z)}{W_*(z)}\int_x^b dy\, v_{*b}(y,z)f(y), \tag{2.10}$$

for $z\in\varrho(H^*)$ and $f\in L^2([a,b])$, see Ref. 9.

Since H is completely non-self-adjoint the maximal dissipative operator H can be completely characterized by its characteristic function $\Theta_H(z)$, $z\in\varrho(H)\cap\varrho(H^*)$, cf. Ref. 18. The definition of the characteristic function relies on the so-called boundary operators $T(z):\mathfrak{h}\to\mathbb{C}^2$, $z\in\varrho(H)$ and $T_*(z):\mathfrak{h}\to\mathbb{C}^2$, $z\in\varrho(H^*)$, which are defined in Ref. 9. Writing

$$\kappa_a=q_a+\frac{i}{2}\alpha_a^2\quad\text{and}\quad\kappa_b=q_b+\frac{i}{2}\alpha_b^2,\quad \alpha_a,\alpha_b>0, \tag{2.11}$$

the boundary operators are defined by

$$T(z)f := \begin{pmatrix} \alpha_b((H-z)^{-1}f)(b) \\ -\alpha_a((H-z)^{-1}f)(a) \end{pmatrix} \tag{2.12}$$

and

$$T_*(z)f := \begin{pmatrix} \alpha_b((H^*-z)^{-1}f)(b) \\ -\alpha_a((H^*-z)^{-1}f)(a) \end{pmatrix}, \tag{2.13}$$

$f \in L^2([a,b])$. Using the resolvent representations (2.9) and (2.10) we obtain

$$T(z)f = \frac{1}{W(z)} \begin{pmatrix} -\alpha_b \int_a^b dy\, v_a(y,z)f(y) \\ \alpha_a \int_a^b dy\, v_b(y,z)f(y) \end{pmatrix} \tag{2.14}$$

and

$$T_*(z)f = \frac{1}{W_*(z)} \begin{pmatrix} -\alpha_b \int_a^b dy\, v_{*a}(y,z)f(y) \\ \alpha_b \int_a^b dy\, v_{*b}(y,z)f(y) \end{pmatrix}, \tag{2.15}$$

$f \in L^2([a,b])$. The adjoint operators are given by

$$(T(z)^*\xi)(x) = \frac{1}{\overline{W(z)}}(-\alpha_b \overline{v_a(x,z)}, \alpha_a \overline{v_b(x,z)})\xi = \frac{1}{W_*(\overline{z})}(-\alpha_b v_{*a}(x,\overline{z}), \alpha_a v_{*b}(x,\overline{z}))\xi, \tag{2.16}$$

and

$$(T_*(z)^*\xi)(x) = \frac{1}{\overline{W_*(z)}}(-\alpha_b \overline{v_{*a}(x,z)}, \alpha_a \overline{v_{*b}(x,z)})\xi = \frac{1}{W(\overline{z})}(-\alpha_b v_a(x,\overline{z}), \alpha_a v_b(x,\overline{z}))\xi, \tag{2.17}$$

where

$$\xi = \begin{pmatrix} \xi^b \\ \xi^a \end{pmatrix} \in \mathbb{C}^2. \tag{2.18}$$

The characteristic function Θ_H of the maximal dissipative operator H is a two-by-two matrix-valued function which satisfies

$$\Theta_H(z)T(z)f = T_*(z)f, \quad z \in \varrho(H) \cap \varrho(H^*), \tag{2.19}$$

$f \in L^2([a,b])$. It depends meromorphically on $z \in \varrho(H) \cap \varrho(H^*)$ and is contractive in $\mathbb{C}_-$, i.e.,

$$\|\Theta_H(z)\| \leqslant 1 \quad \text{for} \quad z \in \mathbb{C}_-. \tag{2.20}$$

Using the elementary solutions the characteristic function Θ_H takes the form

$$\Theta_H(z) = I_{\mathbb{C}^2} + i\frac{1}{W_*(z)} \begin{pmatrix} \alpha_b^2 v_{*a}(b,z) & -\alpha_b\alpha_a \\ -\alpha_b\alpha_a & \alpha_a^2 v_{*b}(a,z) \end{pmatrix}. \tag{2.21}$$

for $z \in \varrho(H) \cap \varrho(H^*)$, cf. Ref. 9.

Since H is a maximal dissipative operator there is a larger Hilbert space $\mathfrak{k} \supseteq \mathfrak{h}$ and a self-adjoint operator K on $\mathfrak{k}$ such that

$$P_{\mathfrak{h}}^{\mathfrak{k}}(K-z)^{-1}|\mathfrak{h} = (H-z)^{-1}, \quad \mathrm{Im}(z) > 0, \tag{2.22}$$

see Ref. 18. The operator K is called a self-adjoint dilation of the maximal dissipative operator H. Obviously, from the condition (2.22) one gets

$$P_{\mathfrak{h}}^{\mathfrak{k}}(K-z)^{-1}|\mathfrak{h} = (H^*-z)^{-1}, \quad \mathrm{Im}(z) < 0. \tag{2.23}$$

K is called a minimal self-adjoint dilation of H if the condition

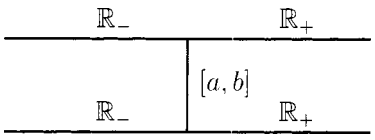
$$\bigvee_{z \in \mathbb{C} \setminus \mathbb{R}} (K-z)^{-1}\mathfrak{h} = \mathfrak{k} \tag{2.24}$$

is satisfied. Minimal self-adjoint dilations of maximal dissipative operators are determined up to a certain isomorphism, in particular, all minimal self-adjoint dilations are unitarily equivalent.

In the present case the minimal self-adjoint dilation of the maximal dissipative operator H can be constructed in an explicit manner. Following Ref. 9 we introduce the larger Hilbert space

$$\mathfrak{k} = \mathcal{D}_- \oplus \mathfrak{h} \oplus \mathcal{D}_+, \tag{2.25}$$

where $\mathcal{D}_\pm := L^2(\mathbb{R}_\pm, \mathbb{C}^2)$. Introducing the graph $\hat{\Omega}$,



one can write the Hilbert space $\mathfrak{k}$ as $L^2(\hat{\Omega})$. Furthermore, we define

$$\vec{g} := g_- \oplus g \oplus g_+, \tag{2.26}$$

where

$$g_-(x) := \begin{pmatrix} g_-^b(x) \\ g_-^a(x) \end{pmatrix} \quad \text{and} \quad g_+(x) := \begin{pmatrix} g_+^b(x) \\ g_+^a(x) \end{pmatrix}, \tag{2.27}$$

for $x \in \mathbb{R}_-$ and $x \in \mathbb{R}_+$, respectively. Let the matrices $K_\pm^a$ and $K_\pm^b$ given by

$$K_-^a := \frac{1}{\alpha_a}\begin{pmatrix} 0 & 0 \\ 1 & \kappa_a \end{pmatrix} \quad \text{and} \quad K_+^a := \frac{1}{\alpha_a}\begin{pmatrix} 0 & 0 \\ 1 & \overline{\kappa_a} \end{pmatrix} \tag{2.28}$$

as well as

$$K_-^b := \frac{1}{\alpha_b}\begin{pmatrix} 1 & -\kappa_b \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad K_+^b := \frac{1}{\alpha_b}\begin{pmatrix} 1 & -\overline{\kappa_b} \\ 0 & 0 \end{pmatrix}. \tag{2.29}$$

Using these notations the self-adjoint dilation K is defined by

$$\mathrm{dom}(K) := \left\{ \vec{g} \in \mathfrak{k}: \begin{array}{l} g_\pm \in W^{1,2}(\mathbb{R}_\pm, \mathbb{C}^2) \\ g, \dfrac{1}{m} g' \in W^{1,2}([a,b]) \\ K_-^a g_a + K_-^b g_b = g_-(0) \\ K_+^a g_a + K_+^b g_b = g_+(0) \end{array} \right\} \tag{2.30}$$

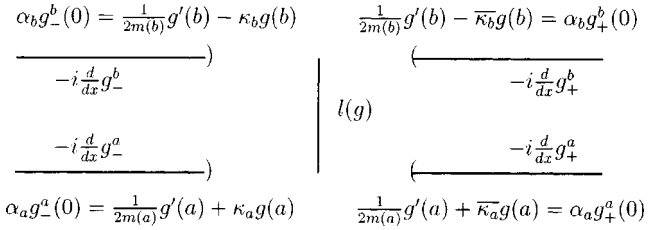
and

$$K\vec{g} := -i\frac{\mathrm{d}}{\mathrm{d}x} g_- \oplus l(g) \oplus -i\frac{\mathrm{d}}{\mathrm{d}x} g_+, \quad \vec{g} \in \mathrm{dom}(K), \tag{2.31}$$

where

$$g_a = \begin{pmatrix} \dfrac{1}{2m(a)} g'(a) \\ g(a) \end{pmatrix} \quad \text{and} \quad g_b = \begin{pmatrix} \dfrac{1}{2m(b)} g'(b) \\ g(b) \end{pmatrix}. \tag{2.32}$$

With respect to a graph picture the operator K looks like



The self-adjoint operator K is absolutely continuous and its spectrum coincides with the real axis, i.e., $\sigma(K) = \mathbb{R}$. The multiplicity of its spectrum is two. The resolvent of K admits the representation

$$\begin{aligned} (K-z)^{-1}(f_- \oplus f \oplus f_+) = {} & i\int_{-\infty}^{x} \mathrm{d}y\, e^{i(x-y)z} f_-(y) \oplus (H-z)^{-1} f + iT_*(\overline{z})^* \int_{-\infty}^{0} \mathrm{d}y\, e^{-iyz} f_-(y) \\ & \oplus i\int_{0}^{x} \mathrm{d}y\, e^{i(x-y)z} f_+(y) + ie^{izx} T(z) f + i\Theta_H(\overline{z})^* \int_{-\infty}^{0} \mathrm{d}y\, e^{i(x-y)z} f_-(y) \end{aligned} \tag{2.33}$$

for $\mathrm{Im}(z) > 0$ and

$$\begin{aligned} (K-z)^{-1}(f_- \oplus f \oplus f_+) = {} & -i\int_{x}^{0} \mathrm{d}y\, e^{i(x-y)z} f_-(y) - ie^{izx} T_*(z) f - i\Theta_H(z) \int_{0}^{\infty} \mathrm{d}y\, e^{i(x-y)z} f_+(y) \\ & \oplus (H^*-z)^{-1} f - iT(\overline{z})^* \int_{0}^{\infty} \mathrm{d}y\, e^{-iyz} f_+(y) \oplus -i\int_{x}^{\infty} \mathrm{d}y\, e^{i(x-y)z} f_+(y) \end{aligned} \tag{2.34}$$

for $\mathrm{Im}(z) < 0$. The generalized eigenfunctions $\vec{\psi}^-(\cdot, \lambda, \tau)$, $\lambda \in \mathbb{R}$, $\tau = a, b$, of K are given by

$$\vec{\psi}^-(x,\lambda,\tau) := \psi_-^-(x,\lambda,\tau) \oplus \psi^-(x,\lambda,\tau) \oplus \psi_+^-(x,\lambda,\tau)$$
$$= \frac{1}{\sqrt{2\pi}} e^{ix\lambda} e_\tau \oplus \frac{1}{\sqrt{2\pi}} (T_*(\lambda) * e_\tau)(x) \oplus \frac{1}{\sqrt{2\pi}} e^{ix\lambda} \Theta_H(\lambda) * e_\tau, \tag{2.35}$$

where

$$e_b := \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \text{and} \quad e_a := \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{2.36}$$

The functions are mutually orthogonal, i.e., one has

$$(\vec{\psi}^-(\cdot,\lambda,\tau), \vec{\psi}^-(\cdot,\lambda',\tau'))_{L^2(\hat{\Omega})} = \delta(\lambda-\lambda')\,\delta_{\tau\tau'}, \tag{2.37}$$

in the sense of distribution for $\lambda,\lambda' \in \mathbb{R}$, $\tau,\tau' = a,b$. Moreover, elements of the form

$$\int_{\mathbb{R}} d\lambda \sum_{\tau=a,b} \vec{\psi}^-(\cdot,\lambda,\tau)\hat{g}^\tau(\lambda) \tag{2.38}$$

where $\hat{g}^\tau(\cdot)$, $\tau = a,b$, are smooth functions with compact support, are dense in $\mathfrak{k}$. We note that the generalized eigenfunctions $\vec{\psi}^-(\cdot,\lambda,\tau)$ are usually called the incoming eigenfunctions. Using the incoming eigenfunctions one defines a transformation $\Phi_- : \mathfrak{k} \to \hat{\mathfrak{k}} = L^2(\mathbb{R},\mathbb{C}^2)$,

$$(\Phi_- \vec{g})(\lambda) =: \hat{g}(\lambda) = \begin{pmatrix} \hat{g}^b(\lambda) \\ \hat{g}^a(\lambda) \end{pmatrix}, \tag{2.39}$$

where

$$\hat{g}^\tau(\lambda) := \int_{\hat{\Omega}} dx\ (\vec{g}(x), \vec{\psi}^-(x,\lambda,\tau)), \quad \tau = a,b. \tag{2.40}$$

Φ_- is unitary and called the incoming Fourier transformation. The inverse incoming Fourier transformation Φ_-^{-1} is given by

$$(\Phi_-^{-1}\hat{g})(x) = \int_{\mathbb{R}} d\lambda \sum_{\tau=a,b} \vec{\psi}^-(x,\lambda,\tau)\hat{g}^\tau(\lambda), \quad \hat{g} \in L^2(\mathbb{R},\mathbb{C}^2). \tag{2.41}$$

We note that

$$\Phi_- K \Phi_-^{-1} = M, \tag{2.42}$$

where M is the multiplication operator by the independent variable λ on $\hat{\mathfrak{k}}$, i.e.,

$$\mathrm{dom}(M) := \{\hat{g} \in L^2(\mathbb{R},\mathbb{C}^2) : \lambda\hat{g}(\lambda) \in L^2(\mathbb{R},\mathbb{C}^2)\},$$
$$(M\hat{g})(\lambda) := \lambda\hat{g}(\lambda), \quad \hat{g} \in \mathrm{dom}(M). \tag{2.43}$$

The representation (2.43) induced by Φ_- is called the incoming spectral representation of K.

Finally, we note that each bounded self-adjoint operator G on $\mathfrak{k}$, which commutes with K, corresponds to a measurable family $\{G(\lambda)\}_{\lambda\in\mathbb{R}}$ of two-by-two matrices, which are uniformly bounded, i.e., $G(\cdot) \in L^\infty(\mathbb{R},\mathcal{B}(\mathbb{C}^2))$, such that the multiplication operator $\hat{G}$ on $L^2(\mathbb{R},\mathbb{C}^2)$ defined by

$$\begin{aligned} \mathrm{dom}(\hat{G}) &:= \{\hat{g} \in L^2(\mathbb{R}, \mathbb{C}^2) : G(\lambda)\hat{g}(\lambda) \in L^2(\mathbb{R}, \mathbb{C}^2)\}, \\ (\hat{G}\hat{g})(\lambda) &:= G(\lambda)\hat{g}(\lambda), \quad \hat{g} \in \mathrm{dom}(\hat{G}(\cdot)) \end{aligned} \tag{2.44}$$

is unitarily equivalent to G, i.e.,

$$\Phi_- G \Phi_-^{-1} = \hat{G}. \tag{2.45}$$

Indeed, if G commutes with K, then $\hat{G}$ commutes with M. Applying Theorem VII.2.3 of Ref. 19 one immediately gets that $\hat{G}$ is a multiplication operator of type (2.44). The representation (2.44) is called the incoming spectral representation of G.

III. CARRIER DENSITY

In the following we call an operator $\varrho : \mathfrak{k} \to \mathfrak{k}$ a density matrix if ϱ is a bounded, non-negative operator. The operator ϱ is called a steady state if ϱ commutes with K. Obviously, a steady state does not change in time. If ϱ is a steady state, then there is a measurable matrix-valued function $\varrho(\cdot) \in L^\infty(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$ such that the multiplication operator $\hat{\varrho}$ on $L^2(\mathbb{R}, \mathbb{C}^2)$ generated by $\varrho(\cdot)$ is unitarily equivalent to ϱ, i.e.,

$$\varrho = \Phi_-^{-1} \hat{\varrho} \Phi_-, \tag{3.1}$$

see above. Obviously, the measurable function $\varrho(\cdot)$ takes the form

$$\varrho(\lambda) = \begin{pmatrix} \varrho^{bb}(\lambda) & \varrho^{ba}(\lambda) \\ \varrho^{ab}(\lambda) & \varrho^{aa}(\lambda) \end{pmatrix}, \tag{3.2}$$

where $\varrho^{\tau\nu}(\cdot) \in L^\infty(\mathbb{R})$, $\tau, \nu = a, b$. Since $\varrho \geqslant 0$ one gets that $\varrho(\lambda) \geqslant 0$ a.e. (with respect to the Lebesgue measure).

Definition 3.1: A bounded self-adjoint operator A on $\mathfrak{k}$ is called an observable. We say the observable A

(i) is admissible with respect to ϱ if ϱA is a nuclear operator on $\mathfrak{k}$, i.e., $\varrho A \in \mathcal{L}_1(\mathfrak{k})$,
(ii) is admissible with respect to K if $E_K(\Delta)A \in \mathcal{L}_1(\mathfrak{k})$ for each bounded interval $\Delta \subseteq \mathbb{R}$ where $E_K(\cdot)$ denotes the spectral measure of K.

If the observable A is admissible with respect to ϱ, then its expectation value $\mathbb{E}_\varrho(A)$ with respect to the density matrix ϱ is defined by

$$\mathbb{E}_\varrho(A) := \mathrm{tr}(\varrho A). \tag{3.3}$$

In the following we show that the admissibility of A with respect to K leads to a certain localization in the incoming spectral representation:

Proposition 3.2: Assume $m + 1/m \in L^\infty([a,b])$, $V \in L^2([a,b])$ *and* $\kappa_a, \kappa_b \in \mathbb{C}_+$. *If the observable A is admissible with respect to K, then there exists a measurable matrix-valued function* $A(\cdot) \in L^1_{loc}(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$, *such that* $A(\lambda) = A(\lambda)^*$ *for a.e.* $\lambda \in \mathbb{R}$ *and*

$$\mathrm{tr}(\varrho A E_K(\Delta)) = \int_\Delta d\lambda \, \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)A(\lambda)) \tag{3.4}$$

for any bounded Borel set $\Delta \subseteq \mathbb{R}$ *and any steady state* ϱ *of K. The measurable function* $A(\cdot)$ *is uniquely defined up to a Borel set of Lebesgue measure zero.*

If the observable A is in addition admissible with respect to the steady state ϱ, *then* $\mathrm{tr}_{\mathbb{C}^2}(\varrho(\cdot)A(\cdot)) \in L^1(\mathbb{R})$ *and the representation*

$$\mathrm{tr}(\varrho A)=\int_{\mathbb{R}} d\lambda\ \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)A(\lambda)) \tag{3.5}$$

holds.

Proof: Notice that the spectral measure $E_K(\cdot)$ of K is absolutely continuous with respect to the Lebesgue measure. Hence, the set function

$$\mu_{\varrho,A}(\Delta):=\mathrm{tr}(\varrho A E_K(\Delta)), \tag{3.6}$$

where Δ is bounded Borel set of $\mathbb{R}$, is in fact a Lebesgue absolutely continuous measure. Let $d\mu_{\rho,A}/d\lambda$ denote its Radon–Nikodym derivative and define

$$T_A(\hat{\varrho}):=\frac{d\mu_{\varrho,A}}{d\lambda}. \tag{3.7}$$

Then $T_A(\cdot)$ maps $L^\infty(\mathbb{R},\mathcal{B}(\mathbb{C}^2))$ continuously into $L^1_{\mathrm{loc}}(\mathbb{R})$ (the latter in its canonic Fréchet topology) and, additionally, one has

$$\mathrm{tr}(\varrho A E_K(\Delta))=\int_\Delta d\lambda\ \frac{d\mu_{\varrho,A}}{d\lambda}(\lambda)=\int_\Delta d\lambda\ T_A(\hat{\varrho})(\lambda) \tag{3.8}$$

for any bounded Borel set $\Delta\subset\mathbb{R}$. It is not hard to see that (3.8) implies the equality

$$T_A(\chi_\Delta\hat{\varrho})=\chi_\Delta T_A(\hat{\varrho}) \tag{3.9}$$

for any bounded Borel set $\Delta\subseteq\mathbb{R}$ where χ_Δ denotes its indicator function. We put

$$e_{bb}:=\begin{pmatrix}1&0\\0&0\end{pmatrix},\quad e_{ba}:=\begin{pmatrix}0&1\\0&0\end{pmatrix},\quad e_{ab}:=\begin{pmatrix}0&0\\1&0\end{pmatrix},\quad e_{aa}:=\begin{pmatrix}0&0\\0&1\end{pmatrix} \tag{3.10}$$

and define for any $h\in L^\infty(\mathbb{R})$,

$$A_{ij}(h):=T_A(h\cdot e_{ji}),\quad i,j=a,b. \tag{3.11}$$

Clearly, each of the mappings $A_{ij}(\cdot)$ then maps $L^\infty(\mathbb{R})$ continuously into $L^1_{\mathrm{loc}}(\mathbb{R})$ and (3.11) implies

$$A_{ij}(\chi_\Delta h)=\chi_\Delta A_{ij}(h) \tag{3.12}$$

for any $h\in L^\infty(\mathbb{R})$ and any Borel set Δ. Taking in particular $h\equiv 1$, this yields

$$A_{ij}(\chi_\Delta)=\chi_\Delta A_{ij}(1). \tag{3.13}$$

Obviously, by the linearity of the mappings $A_{ij}(\cdot)$, this last equation remains true if χ_Δ is there replaced by any (finite) linear combination of indicator functions. Because the set of finite linear combinations of indicator functions is dense in $L^\infty(\mathbb{R})$, one gets for all $h\in L^\infty(\mathbb{R})$

$$A_{ij}(h)=h\cdot A_{ij}(1). \tag{3.14}$$

Since

$$\varrho(\cdot)=\varrho^{bb}(\cdot)e_{bb}+\varrho^{ba}(\cdot)e_{ba}+\varrho^{ab}(\cdot)e_{ab}+\varrho^{aa}(\cdot)e_{aa} \tag{3.15}$$

one gets

$$\mathrm{tr}(\varrho A E_K(\Delta)) = \int_\Delta \mathrm{d}\lambda\, T_A(\hat{\varrho})(\lambda) = \sum_{i,j=a,b} \int_\Delta \mathrm{d}\lambda\, A_{ij}(\varrho^{ij})(\lambda)$$

$$= \sum_{i,j=a,b} \int_\Delta \mathrm{d}\lambda\, \varrho^{ij}(\lambda) A_{ji}(1)(\lambda). \tag{3.16}$$

Setting

$$A(\cdot) := \begin{pmatrix} A_{bb}(1)(\cdot) & A_{ba}(1)(\cdot) \\ A_{ab}(1)(\cdot) & A_{aa}(1)(\cdot) \end{pmatrix} \tag{3.17}$$

we finally obtain (3.4) for any bounded Borel set $\Delta \subset \mathbb{R}$ and any steady state ϱ of K.

Assume that $\tilde{A}(\cdot)$ obeys also the conditions of the proposition. Setting $G(\lambda) := A(\lambda) - \tilde{A}(\lambda)$, $\lambda \in \mathbb{R}$, one gets that

$$\int_\Delta \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda) G(\lambda)) = 0 \tag{3.18}$$

for any bounded Borel set Δ and any steady state ϱ. Hence $\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)G(\lambda)) = 0$ for a.e. λ and any steady state ϱ which immediately yields $G(\lambda) = 0$ or $A(\lambda) = \tilde{A}(\lambda)$ for a.e. $\lambda \in \mathbb{R}$.

If ϱ is admissible with respect to A, then $|\mathrm{tr}(\varrho A E_K(\Delta)| < \|\varrho A\|_{\mathcal{L}_1}$ for any Borel set $\Delta \subseteq \mathbb{R}$. By (3.4) this implies that $\mathrm{tr}(\varrho(\cdot)A(\cdot)) \in L^1(\mathbb{R})$. Since one has $\lim_{\Delta \uparrow \mathbb{R}} \mathrm{tr}(\varrho A E_K(\Delta)) = \mathrm{tr}(\varrho A)$ we obtain from (3.4) the equality (3.5). □

Proposition 3.2 says that the averaging procedure localizes with respect to the incoming spectral representation. Indeed, the quantity $\mathrm{tr}(\varrho(\lambda)A(\lambda))$ can be regarded as the local average of the observable $A(\lambda)$ with respect to the density matrix $\varrho(\lambda)$ at energy $\lambda \in \mathbb{R}$, i.e.,

$$\mathbb{E}_{\varrho(\lambda)}(A(\lambda)) := \mathrm{tr}(\varrho(\lambda)A(\lambda)). \tag{3.19}$$

Formula (3.5) has the meaning that the total average $\mathbb{E}_\varrho(A)$ is the sum of the local averages $\mathbb{E}_{\varrho(\lambda)}(A(\lambda))$, i.e.,

$$\mathbb{E}_\varrho(A) = \int_{\mathbb{R}} \mathrm{d}\lambda\, \mathbb{E}_{\varrho(\lambda)}(A(\lambda)). \tag{3.20}$$

Proposition 3.2 gives rise to the following

Definition 3.3: Let A be an observable which is admissible with respect to K. An element $A(\cdot) \in L^1_{\mathrm{loc}}(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$ is called a localizer of A with respect to K if $A(\lambda)^* = A(\lambda)$ for a.e. $\lambda \in \mathbb{R}$ and

$$\mathrm{tr}(\varrho A E_K(\Delta)) = \int_\Delta \mathrm{d}\lambda\, \mathrm{tr}(\varrho(\lambda)A(\lambda)) \tag{3.21}$$

holds for any bounded Borel subset $\Delta \subseteq \mathbb{R}$ and any steady state ϱ.

Proposition 3.2 says that an observable which is admissible with respect to K has always a unique localizer.

To calculate the carrier density we consider the observable $U(\omega)$, $\omega \subseteq \Omega$, given by

$$(U(\omega)\vec{f})(x) = 0 \oplus \chi_\omega(x) f(x) \oplus 0, \quad \vec{f} \in L^2(\hat{\Omega}), \tag{3.22}$$

for any Borel subset $\omega \subseteq \Omega$. We note that the observable $U(\omega)$ is a projection on $\mathfrak{k}$ with $\mathrm{ran}(U(\omega)) \subseteq \mathfrak{h}$. Loosely speaking, the projection acts in fact only on the subspace $\mathfrak{h} \subseteq \mathfrak{k}$.

Lemma 3.4: Assume $m+1/m \in L^{\infty}([a,b])$, $V \in L^2([a,b])$ *and* $\kappa_a, \kappa_b \in \mathbb{C}_+$. *Then for any Borel set* $\omega \subseteq \Omega$ *the observable* $U(\omega)$ *is admissible with respect to the minimal self-adjoint dilation* K *of the maximal dissipative operator* H. *If the steady state* ϱ *satisfies the condition*

$$C_{\hat{\varrho}} := \sup_{\lambda \in \mathbb{R}} \sqrt{\lambda^2+1}\,\|\varrho(\lambda)\|_{\mathcal{B}(\mathbb{C}^2)} < \infty, \tag{3.23}$$

then for any Borel set $\omega \subseteq \Omega$ *the observable* $U(\omega)$ *is admissible with respect to* ϱ.

Proof: Relation (2.33) implies

$$U(\omega)(K-z)^{-1}\vec{f} = 0 \oplus \chi_\omega (H-z)^{-1} f + i\chi_\omega T_*(\overline{z})^* \int_{-\infty}^{0} dy\, e^{-iyz} f_-(y) \oplus 0 \tag{3.24}$$

for $\vec{f} \in \mathfrak{k}$ and $z \in \mathbb{C}_+$. By Theorem 3.1 of Ref. 5 one gets that $(H-z)^{-1}$ is a trace class operator for each $z \in \mathbb{C}_+$. Hence $U(\omega)(H-z)^{-1}$ is a trace class operator for each $\omega \subseteq \Omega$. Since the operator $T_*(\overline{z})^*$ acts from the two-dimensional Hilbert space $\mathbb{C}^2$ into $\mathfrak{h}$ one easily gets that the second addend of (3.24) is a trace class operator, too. Hence $U(\omega)(K-z)^{-1} \in \mathcal{L}_1(\mathfrak{k})$ for each Borel set $\omega \subseteq \Omega$ and $z \in \mathbb{C}_+$. Using the representation

$$U(\omega)E_K(\Delta) = U(\omega)(K-z)^{-1}(K-z)E_K(\Delta), \quad z \in \mathbb{C}_+, \tag{3.25}$$

we find that $U(\omega)E_K(\Delta)$ is a trace class operator for each Borel sets $\omega \subseteq \Omega$ and each bounded interval $\Delta \subseteq \mathbb{R}$. Hence, the observable $U(\omega)$ is admissible with respect to K for each Borel set $\omega \subseteq \Omega$.

Moreover, taking into account (3.23) and the representation

$$U(\omega)\varrho = U(\omega)(K-i)^{-1}(K-i)\varrho \tag{3.26}$$

one immediately gets that $U(\omega)\,\varrho$ is a trace class operator for each $\omega \subseteq \Omega$, because $(K-i)\varrho$ is bounded. Hence, $\varrho\, U(\omega)$ is a trace class operator for each Borel set $\omega \subseteq \Omega$ which yields that $U(\omega)\,\varrho$ is admissible with respect to ϱ. □

Since $U(\omega)$ is admissible with respect to K for any Borel set $\omega \subseteq \Omega$ by Proposition 3.2 there is a unique localizer $U(\omega)(\cdot): \mathbb{R} \to \mathcal{B}(\mathbb{C}^2)$. We are going to calculate this localizer.

Proposition 3.5: Assume $m+1/m \in L^{\infty}([a,b])$, $V \in L^2([a,b])$ *and* $\kappa_a, \kappa_b \in \mathbb{C}_+$. *Then for any Borel set* $\omega \subseteq \Omega$ *the localizer of* $U(\omega)(\cdot)$ *of the observable* $U(\omega)$ *is given by*

$$U(\omega)(\lambda) = \int_\omega dx\, D(x,\lambda), \tag{3.27}$$

where

$$D(x,\lambda) := \begin{pmatrix} |\psi^-(x,\lambda,b)|^2 & \psi^-(x,\lambda,a)\overline{\psi^-(x,\lambda,b)} \\ \psi^-(x,\lambda,b)\overline{\psi^-(x,\lambda,a)} & |\psi^-(x,\lambda,a)|^2 \end{pmatrix} \tag{3.28}$$

$x \in \Omega,\ \lambda \in \mathbb{R}$.

If the steady state ϱ *satisfies the condition (3.23), then*

$$\mathbb{E}_\varrho(U(\omega)) = \int_{\mathbb{R}} d\lambda\, \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)U(\omega)(\lambda)) \tag{3.29}$$

for any Borel subset $\omega \subseteq \Omega$.

Proof: By Lemma 3.4 the observable $U(\omega)$ is admissible for any Borel set $\omega\subseteq\Omega$. By Proposition 3.2 there is a unique localizer $U(\omega)(\cdot)\in L^1_{\mathrm{loc}}(\mathbb{R},\mathcal{B}(\mathbb{C}^2))$ such that (3.21) is satisfied for any bounded Borel set $\Delta\subseteq\mathbb{R}$ and any steady state ϱ. Following the proof of Proposition 3.2 we consider the measure

$$\mu_{\varrho,U(\omega)}(\Delta)=\mathrm{tr}(\varrho U(\omega)E_K(\Delta)) \tag{3.30}$$

for any bounded Borel set $\Delta\subseteq\mathbb{R}$. We set

$$\hat{U}(\omega):=\Phi_- U(\omega)\Phi_-^{-1},\quad \hat{U}_\Delta(\omega):=E_M(\Delta)\hat{U}E_M(\Delta),$$

where $M=\Phi_- K\Phi_-^{-1}$, see (2.42). By Lemma 3.4 the operator $\hat{U}_\Delta(\omega)$ is nuclear. Hence, we find

$$\mu_{\varrho,U(\omega)}(\Delta)=\mathrm{tr}(\hat{\varrho}\hat{U}_\Delta(\omega)). \tag{3.31}$$

Let us calculate the kernel of $\hat{U}_\Delta(\omega)$. To this end we consider the scalar product $(\hat{U}_\Delta(\omega)\hat{g},\hat{f})$, $\hat{g},\hat{f}\in L^2(\Delta,\mathbb{C}^2)$. Using (2.41) one has

$$(\hat{U}_\Delta(\omega)\hat{g},\hat{f})=\int_\omega \mathrm{d}x\int_\Delta \mathrm{d}\lambda\sum_{\tau=a,b}\psi^-(x,\lambda,\tau)\hat{g}^\tau(\lambda)\overline{\int_\Delta \mathrm{d}\mu\sum_{\xi=a,b}\psi^-(x,\mu,\xi)\hat{f}^\xi(\mu)}. \tag{3.32}$$

Setting

$$U_\Delta^{\tau\xi}(\omega)(\mu,\lambda):=\int_\omega \mathrm{d}x\,\psi^-(x,\lambda,\xi)\overline{\psi^-(x,\mu,\tau)},\quad \tau,\xi=a,b, \tag{3.33}$$

we get

$$(\hat{U}_\Delta(\omega)\hat{g},\hat{f})=\int_\Delta \mathrm{d}\mu\left(\int_\Delta \mathrm{d}\lambda\begin{pmatrix}U_\Delta^{bb}(\omega)(\mu,\lambda) & U_\Delta^{ba}(\omega)(\mu,\lambda)\\ U_\Delta^{ab}(\omega)(\mu,\lambda) & U_\Delta^{aa}(\omega)(\mu,\lambda)\end{pmatrix}\begin{pmatrix}\hat{g}^b(\lambda)\\ \hat{g}^a(\lambda)\end{pmatrix},\begin{pmatrix}\hat{f}^b(\mu)\\ \hat{f}^a(\mu)\end{pmatrix}\right), \tag{3.34}$$

which shows that

$$U_\Delta(\omega)(\mu,\lambda):=\begin{pmatrix}U_\Delta^{bb}(\omega)(\mu,\lambda) & U_\Delta^{ba}(\omega)(\mu,\lambda)\\ U_\Delta^{ab}(\omega)(\mu,\lambda) & U_\Delta^{aa}(\omega)(\mu,\lambda)\end{pmatrix} \tag{3.35}$$

is the kernel of the integral operator $\hat{U}_\Delta(\omega)$. Setting

$$D(x,\mu,\lambda):=\begin{pmatrix}\psi^-(x,\lambda,b)\overline{\psi^-(x,\mu,b)} & \psi^-(x,\lambda,a)\overline{\psi^-(x,\mu,b)}\\ \psi^-(x,\lambda,b)\overline{\psi^-(x,\mu,a)} & \psi^-(x,\lambda,a)\overline{\psi^-(x,\mu,a)}\end{pmatrix} \tag{3.36}$$

we obtain the representation

$$U_\Delta(\omega)(\mu,\lambda)=\int_\omega \mathrm{d}x\,D(x,\mu,\lambda),\quad \mu,\lambda\in\Delta. \tag{3.37}$$

Since $U_\Delta(\omega)(\mu,\lambda)=U_{\Delta'}(\omega)(\mu,\lambda)$ for $\mu,\lambda\in\Delta\subseteq\Delta'$ it makes sense to define $U(\omega)(\mu,\lambda):=\lim_{\Delta\uparrow\mathbb{R}}U_\Delta(\omega)(\mu,\lambda)$, $\mu,\lambda\in\mathbb{R}$. Hence $U_\Delta(\omega)(\mu,\lambda)=U(\omega)(\mu,\lambda)$ for $\mu,\lambda\in\Delta$ and

$$U(\omega)(\mu,\lambda)=\int_\omega \mathrm{d}x\,D(x,\mu,\lambda),\quad \mu,\lambda\in\Delta. \tag{3.38}$$

Since the kernel depends continuously on μ and λ one gets that

$$\mathrm{tr}(\hat{\varrho}\hat{U}_\Delta(\omega))=\int_\Delta \mathrm{d}\lambda\ \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)U(\omega)(\lambda,\lambda)) \tag{3.39}$$

for any bounded Borel set $\Delta\subseteq\mathbb{R}$ and any steady state ϱ. From (3.38) we find that $U(\omega)(\lambda,\lambda)^* = U(\omega)(\lambda,\lambda)$ for $\lambda\in\mathbb{R}$. Since the eigenfunctions $\psi^-(x,\lambda,b)$ and $\psi^-(x,\lambda,a)$ are bounded on compact sets of x and λ we obtain that $U(\omega)(\lambda,\lambda)\in L^1_{loc}(\mathbb{R},\mathcal{B}(\mathbb{C}^2))$. By (3.39) the matrix-valued function $U(\omega)(\lambda):=U(\omega)(\lambda,\lambda)$, $\lambda\in\mathbb{R}$, is the unique localizer of the observable $U(\omega)$. By condition (3.23) the observable $U(\omega)$ is admissible with respect to ϱ. Applying Proposition 3.2 we verify (3.29).

It remains to verify (3.27) and (3.28). From (3.38) and (3.39) we obtain the representation

$$\mathrm{tr}(\hat{\varrho}\ \ \hat{U}_\Delta(\omega))=\int_\Delta \mathrm{d}\lambda\ \ \int_\omega \mathrm{d}x\ \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)D(x,\lambda,\lambda)). \tag{3.40}$$

Setting $D(x,\lambda):=D(x,\lambda,\lambda)$, $x\in\Omega$, $\lambda\in\mathbb{R}$, we immediately obtain (3.27) and (3.28). □

We set

$$u_{\hat{\varrho}}(x,\lambda):=\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)D(x,\lambda)) \tag{3.41}$$

for $x\in\Omega$ and $\lambda\in\mathbb{R}$. A simple computation shows that the eigenvalues of $D(x,\lambda)$ are equal to $|\psi^-(x,\lambda,b)|^2$ and $|\psi^-(x,\lambda,a)|^2$, which shows that the matrix $D(x,\lambda)$ is non-negative for each $x\in\Omega$ and $\lambda\in\mathbb{R}$. Since for a.e. $\lambda\in\mathbb{R}$ the matrix $\varrho(\lambda)$ is non-negative, too, one gets that $u_{\hat{\varrho}}(x,\lambda)\geqslant 0$ for $x\in\Omega$ and a.e. $\lambda\in\mathbb{R}$. This fact can also be verified taking into account the representation

$$u_{\hat{\varrho}}(x,\lambda)=\left\langle \varrho^t(\lambda)\begin{pmatrix}\psi^-(x,\lambda,b)\\ \psi^-(x,\lambda,a)\end{pmatrix},\begin{pmatrix}\psi^-(x,\lambda,b)\\ \psi^-(x,\lambda,a)\end{pmatrix}\right\rangle, \tag{3.42}$$

where $\varrho^t(\lambda)$ is the transposed matrix to (3.2). Moreover, if condition (3.23) is satisfied, then from Proposition (3.5) we obtain the representation

$$\mathbb{E}_\varrho(U(\omega))=\int_{\mathbb{R}} \mathrm{d}\lambda\ \ \int_\omega \mathrm{d}x\ u_{\hat{\varrho}}(x,\lambda) \tag{3.43}$$

for Borel sets $\omega\subseteq\Omega$. Taking into account Fubini's theorem we find that

$$\mathbb{E}_\varrho(U(\omega))=\int_\omega \mathrm{d}x\ u_{\hat{\varrho}}(x), \tag{3.44}$$

where

$$u_{\hat{\varrho}}(x):=\int_{\mathbb{R}} \mathrm{d}\lambda\ u_{\hat{\varrho}}(x,\lambda)\geqslant 0,\quad x\in\Omega, \tag{3.45}$$

and $u_{\hat{\varrho}}\in L^1(\Omega)$. The representation (3.44) shows that $\mathbb{E}_\varrho(U(\cdot))$ defines a measure on Ω which is absolutely continuous with respect to the Lebesgue measure. Since the expectation value $\mathbb{E}_\varrho(U(\omega))$ has the meaning of the number of carriers in $\omega\subseteq\Omega$ its Radon–Nikodym derivative can be interpreted as the carrier density of the system described by K and mutatis mutandis by H.

Definition 3.6: Assume $m+1/m\in L^\infty([a,b])$, $V\in L^2([a,b])$ and $\kappa_a,\kappa_b\in\mathbb{C}_+$. Then the matrix $D(x,\lambda)$, $x\in\Omega$, and the value $u_{\hat{\varrho}}(x,\lambda)$ are called carrier density observable and carrier density at $x\in\Omega$ and at energy $\lambda\in\mathbb{R}$ of the system described by H, respectively.

This definition is justified by the fact that by (3.41) the carrier density $u_{\hat{\varrho}}(x,\lambda)$ is the expectation value of the carrier density observable $D(x,\lambda)$, i.e., $u_{\hat{\varrho}}(x,\lambda)=\mathbb{E}_{\varrho(\lambda)}(D(x,\lambda))$ at $x\in\Omega$ and at $\lambda\in\mathbb{R}$. Moreover, we note that (3.45) can be written as

$$u_{\hat{\varrho}}(x)=\int_{\mathbb{R}} d\lambda\ \mathbb{E}_{\varrho(\lambda)}(D(x,\lambda)),\quad x\in\Omega, \tag{3.46}$$

i.e, the carrier density at $x\in\Omega$ is the sum of expectation values of the carrier density observable at $x\in\Omega$ over all energies.

On the Hilbert space $\mathfrak{k}=L^2(\hat{\Omega})$ we consider the multiplication operator $M(h)$,

$$(M(h)\vec{f})(x)=0\oplus h(x)f(x)\oplus 0,\quad x\in\Omega, \tag{3.47}$$

for real functions $h\in L^\infty(\Omega)$. We note that $M(\chi_\omega)=U(\omega)$ for any Borel set $\omega\subseteq\Omega$. In particular, one has $M(\chi_\Omega)=U(\Omega)=P^{\mathfrak{k}}_{\mathfrak{h}}$. Obviously, the representation

$$\varrho M(h)=\varrho U(\Omega)M(h),\quad h\in L^\infty(\Omega) \tag{3.48}$$

is valid. Since the observable $U(\Omega)$ is admissible with respect to ϱ the product $\varrho U(\Omega)$ is a nuclear operator on $\mathfrak{k}$ which yields that $\varrho M(h)$ is a nuclear operator on $\mathfrak{k}$, i.e., the observable $M(h)$ is admissible with respect to ϱ.

Proposition 3.7: Assume $m+1/m\in L^\infty([a,b])$, $V\in L^2([a,b])$ and $\kappa_a,\kappa_b\in\mathbb{C}_+$. If the steady state ϱ satisfies the condition (3.23), then the carrier density $u_{\hat{\varrho}}$ defined by (3.45) is a nonnegative L^1-function such that

$$\mathrm{tr}(\varrho M(h))=\int_\Omega dx\, u_{\hat{\varrho}}(x)h(x) \tag{3.49}$$

for real functions $h\in L^\infty(\Omega)$. In particular, one has

$$\|u_{\hat{\varrho}}\|_{L^1(\omega)}=\mathrm{tr}(\varrho\ U(\omega))\leqslant C_{\hat{\varrho}}\|(K-i)^{-1}P^{\mathfrak{k}}_{\mathfrak{h}}\|_{\mathcal{L}_1(\mathfrak{k})} \tag{3.50}$$

for each Borel set $\omega\subseteq\Omega$.

Proof: Setting $\omega=\Omega$ we obtain from (3.44) that $u_{\hat{\varrho}}\in L^1(\Omega)$. We choose $h=\chi_\omega$, $\omega\subseteq\Omega$. By (3.44) we get

$$\mathrm{tr}(\varrho M(\chi_\omega))=\int_\Omega dx\, u_{\hat{\varrho}}(x)\chi_\omega(x). \tag{3.51}$$

By linearity this equation extends to

$$\mathrm{tr}(\varrho M(h))=\int_\Omega dx\, u_{\hat{\varrho}}(x)h(x), \tag{3.52}$$

where h is an arbitrary step function on Ω. Since $u_{\hat{\varrho}}$ is from $L^1(\Omega)$ and $\varrho U(\Omega)$ is a nuclear operator both sides of (3.52) admit a continuation to L^∞-functions which verifies (3.49).

It remains to show the estimate (3.50). From (3.44) we immediately get

$$\int_\Omega dx\, u_g(x)=\mathrm{tr}(\varrho U(\Omega))=\mathrm{tr}(\varrho(K-i)(K-i)^{-1}U(\Omega)). \tag{3.53}$$

Since $U(\Omega)(K-i)^{-1}\in\mathcal{L}_1(\mathfrak{k})$ and $\varrho(K-i)$ is a bounded operator which norm can be estimated by $C_{\hat{\varrho}}$ we obtain

$$\mathrm{tr}(\varrho(K-i)(K-i)^{-1}U(\omega)) \leqslant C_{\hat{\varrho}} \|(K-i)^{-1}P_{\mathfrak{h}}^{\mathfrak{k}}\|_{\mathcal{L}_1(\mathfrak{k})}, \tag{3.54}$$

which verifies (3.50). □

Obviously, the relation (3.49) takes the form

$$\mathrm{tr}(\varrho M(h)) = \langle u_{\hat{\varrho}}, h\rangle_{L^1} \tag{3.55}$$

where by $\langle \cdot, h\rangle_{L^1}$, $h \in L^\infty(\Omega)$, we denote the linear functionals on $L^1(\Omega)$.

We conclude this section with some considerations which we need in the following section. Since $\{\varrho(\lambda)\}_{\lambda\in\mathbb{R}}$ is a measurable family of non-negative self-adjoint operators there is a measurable family $\{V(\lambda)\}_{\lambda\in\mathbb{R}}$ of unitary operators on $\mathbb{C}^2$ such that

$$\varrho(\lambda) = V(\lambda)\begin{pmatrix} \mu_b(\lambda) & 0 \\ 0 & \mu_a(\lambda)\end{pmatrix} V(\lambda)^* \tag{3.56}$$

for a.e. $\lambda \in \mathbb{R}$ where $\mu_b(\lambda)$ and $\mu_a(\lambda)$ are the non-negative eigenvalues of $\varrho(\lambda)$. From (3.56) we get that

$$\varrho^t(\lambda) = V^t(\lambda)^*\begin{pmatrix} \mu_b(\lambda) & 0 \\ 0 & \mu_a(\lambda)\end{pmatrix} V^t(\lambda) \tag{3.57}$$

for a.e. $\lambda \in \mathbb{R}$ where $V^t(\lambda)$ is the transposed matrix to $V(\lambda)$. Inserting (3.57) into (3.42) we obtain

$$u_{\hat{\varrho}}(x,\lambda) = \left\langle \begin{pmatrix} \mu_b(\lambda) & 0 \\ 0 & \mu_a(\lambda)\end{pmatrix} V^t(\lambda)\begin{pmatrix} \psi^-(x,\lambda,b) \\ \psi^-(x,\lambda,a)\end{pmatrix}, V^t(\lambda)\begin{pmatrix} \psi^-(x,\lambda,b) \\ \psi^-(x,\lambda,a)\end{pmatrix}\right\rangle. \tag{3.58}$$

Let us introduce the unit vectors $e_\tau(\lambda)$,

$$e_\tau(\lambda) = V(\lambda)e_\tau, \quad \tau = b,a \tag{3.59}$$

which perform an orthonormal basis in $\mathbb{C}^2$. We set

$$\begin{aligned}\vec{\psi}(x,\lambda,e_\tau(\lambda)) &:= \psi_-(x,\lambda,e_\tau(\lambda)) \oplus \psi(x,\lambda,e_\tau(\lambda)) \oplus \psi_+(x,\lambda,e_\tau(\lambda)) \\ &= \frac{1}{\sqrt{2\pi}} e^{ix\lambda} e_\tau(\lambda) \oplus \frac{1}{\sqrt{2\pi}} (T_*(\lambda)^* e_\tau(\lambda))(x) \oplus \frac{1}{\sqrt{2\pi}} e^{ix\lambda}\Theta_H(\lambda)^* e_\tau(\lambda).\end{aligned} \tag{3.60}$$

Obviously, the system $\{\vec{\psi}(x,\lambda,e_\tau(\lambda))\}_{\tau=b,a}$ performs an orthonormal basis of generalized eigenfunctions. Moreover, a straightforward computation shows that

$$V^t(\lambda)\begin{pmatrix} \psi^-(x,\lambda,b) \\ \psi^-(x,\lambda,a)\end{pmatrix} = \begin{pmatrix} \psi(x,\lambda,e_b(\lambda)) \\ \psi(x,\lambda,e_a(\lambda))\end{pmatrix}, \tag{3.61}$$

which leads to

$$u_{\hat{\varrho}}(x,\lambda) = \mu_b(\lambda)|\psi(x,\lambda,e_b(\lambda))|^2 + \mu_a(\lambda)|\psi(x,\lambda,e_a(\lambda))|^2 \tag{3.62}$$

for $x \in \Omega$ and $\lambda \in \mathbb{R}$.

IV. CURRENT DENSITY

In accordance with (1.8) the current density $j_{\hat{\varrho}}(x,\lambda)$ for the energy $\lambda \in \mathbb{R}$ is defined by

$$j_{\hat{\varrho}}(x,\lambda) := \mu_b(\lambda)\mathrm{Im}\left(\frac{1}{m(x)}\psi(x,\lambda,e_b(\lambda))'\overline{\psi(x,\lambda,e_b(\lambda))}\right) + \mu_a(\lambda)\mathrm{Im}\left(\frac{1}{m(x)}\psi(x,\lambda,e_a(\lambda))'\overline{\psi(x,\lambda,e_a(\lambda))}\right), \tag{4.1}$$

$x \in \Omega$, where the eigenfunctions $\psi(x,\lambda,e_\tau(\lambda))$, $\tau = a,b$, are defined by (3.61). We are going to relate the current density to the characteristic function of the maximal dissipative operator H.

Proposition 4.1: Assume $m + 1/m \in L^\infty([a,b])$, $V \in L^2([a,b])$ *and* $\kappa_a, \kappa_b \in \mathbb{C}_+$. *Further, let* ϱ *be a steady state. Then the current density* $j_{\hat{\varrho}}(x,\lambda)$, $x \in \Omega$, $\lambda \in \mathbb{R}$, *is independent of* x *and admits the representation*

$$j_{\hat{\varrho}}(\lambda) = \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)C(\lambda)) \tag{4.2}$$

where

$$C(\lambda) := -\frac{1}{2\pi i}\frac{\alpha_a\alpha_b}{\overline{W(\lambda)}}E\Theta_H(\lambda)^* = \frac{1}{2\pi i}\frac{\alpha_b\alpha_a}{W(\lambda)}\Theta_H(\lambda)E, \tag{4.3}$$

$\lambda \in \mathbb{R}$. *Moreover, if* $\mathrm{tr}_{\mathbb{C}^2}(\varrho(\cdot)) \in L^1(\mathbb{R})$, *then the total current* $j_{\hat{\varrho}}$,

$$j_{\hat{\varrho}} := \int_{\mathbb{R}} d\lambda\, j_{\hat{\varrho}}(\lambda), \tag{4.4}$$

is finite and satisfies the estimate

$$|j_{\hat{\varrho}}| \leqslant \frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)). \tag{4.5}$$

Proof: From the definition (4.2) one gets that

$$j_{\hat{\varrho}}(x,\lambda) = \mathrm{Im}\left(\left\langle \begin{pmatrix} \mu_b(\lambda) & 0 \\ 0 & \mu_a(\lambda) \end{pmatrix} \begin{pmatrix} \frac{1}{m(x)}\psi(x,\lambda,e_b(\lambda))' \\ \frac{1}{m(x)}\psi(x,\lambda,e_a(\lambda))' \end{pmatrix}, \begin{pmatrix} \psi(x,\lambda,e_b(\lambda)) \\ \psi(x,\lambda,e_a(\lambda)) \end{pmatrix} \right\rangle\right). \tag{4.6}$$

Taking into account (3.57) and (3.61) we get

$$j_{\hat{\varrho}}(x,\lambda) = \mathrm{Im}\left(\left\langle \varrho^t(\lambda) \begin{pmatrix} \frac{1}{m(x)}\psi^-(x,\lambda,b)' \\ \frac{1}{m(x)}\psi^-(x,\lambda,a)' \end{pmatrix}, \begin{pmatrix} \psi^-(x,\lambda,b) \\ \psi^-(x,\lambda,a) \end{pmatrix} \right\rangle\right) \tag{4.7}$$

which can be expressed by

$$j_{\hat{\varrho}}(x,\lambda) = \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)C(x,\lambda)), \tag{4.8}$$

where

$$C(x,\lambda):=\mathrm{Im}\left(\begin{pmatrix} \frac{1}{m(x)}\psi^-(x,\lambda,b)'\overline{\psi^-(x,\lambda,b)} & \frac{1}{m(x)}\psi^-(x,\lambda,a)'\overline{\psi^-(x,\lambda,b)} \\ \frac{1}{m(x)}\psi^-(x,\lambda,b)'\overline{\psi^-(x,\lambda,a)} & \frac{1}{m(x)}\psi^-(x,\lambda,a)'\overline{\psi^-(x,\lambda,a)} \end{pmatrix}\right). \tag{4.9}$$

We note that

$$C(x,\lambda)=\frac{1}{i}\begin{pmatrix} W(\overline{\psi^-(x,\lambda,b)},\psi^-(x,\lambda,b)) & W(\overline{\psi^-(x,\lambda,b)},\psi^-(x,\lambda,a)) \\ W(\overline{\psi^-(x,\lambda,a)},\psi^-(x,\lambda,b)) & W(\overline{\psi^-(x,\lambda,a)},\psi^-(x,\lambda,a)) \end{pmatrix} \tag{4.10}$$

where $W(\cdot,\cdot)$ is the Wronskian defined by (2.5). Since

$$W(\overline{\psi^-(x,\lambda,b)},\psi^-(x,\lambda,b))=-\frac{i}{2\pi}\frac{\alpha_b^2\alpha_a^2}{|W(\lambda)|^2}, \tag{4.11}$$

$$W(\overline{\psi^-(x,\lambda,a)},\psi^-(x,\lambda,b))=\frac{1}{2\pi}\frac{\alpha_b\alpha_a}{|W(\lambda)|^2}\{W(\lambda)-i\alpha_b^2 v_a(b,\lambda)\}, \tag{4.12}$$

$$W(\overline{\psi^-(x,\lambda,b)},\psi^-(x,\lambda,a))=-\frac{1}{2\pi}\frac{\alpha_b\alpha_a}{|W(\lambda)|^2}\{W(\lambda)-i\alpha_a^2 v_b(a,\lambda)\}, \tag{4.13}$$

$$W(\overline{\psi^-(x,\lambda,a)},\psi^-(x,\lambda,a))=\frac{i}{2\pi}\frac{\alpha_a^2\alpha_b^2}{|W(\lambda)|^2}, \tag{4.14}$$

we find

$$C(x,\lambda)=\frac{1}{2\pi i}\frac{\alpha_b\alpha_a}{|W(\lambda)|^2}\begin{pmatrix} -i\alpha_b\alpha_a & -(W(\lambda)-i\alpha_a^2 v_b(a,\lambda)) \\ W(\lambda)-i\alpha_b^2 v_a(b,\lambda) & i\alpha_a\alpha_b \end{pmatrix}. \tag{4.15}$$

This yields

$$C(x,\lambda)=-\frac{1}{2\pi i}\frac{\alpha_b\alpha_a}{|W(\lambda)|^2}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} W(\lambda)-i\alpha_b^2 v_a(b,\lambda) & i\alpha_b\alpha_a \\ i\alpha_b\alpha_a & W(\lambda)-i\alpha_a^2 v_b(a,\lambda) \end{pmatrix}. \tag{4.16}$$

From (2.21) we obtain

$$\Theta_H(\lambda)^*=\frac{1}{W(\lambda)}\begin{pmatrix} W(\lambda)-i\alpha_b^2 v_a(b,\lambda) & i\alpha_b\alpha_a \\ i\alpha_b\alpha_a & W(\lambda)-i\alpha_a^2 v_b(a,\lambda) \end{pmatrix}. \tag{4.17}$$

Hence, one has

$$C(x,\lambda)=-\frac{1}{2\pi i}\frac{\alpha_b\alpha_a}{\overline{W(\lambda)}}E\Theta_H(\lambda)^*, \tag{4.18}$$

where

$$E:=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{4.19}$$

This shows that $C(x,\lambda)$ is actually independent of $x\in\Omega$. By (4.8) this leads to the representation

$$j_{\hat{\varrho}}(x,\lambda) = -\frac{1}{2\pi i}\frac{\alpha_b\alpha_a}{\overline{\overline{W(\lambda)}}}\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)E\Theta_H(\lambda)^*), \tag{4.20}$$

which shows that the current density is also independent of $x\in\Omega$. Thus it makes sense to denote $C(x,\lambda)$ and $j_{\hat{\varrho}}(x,\lambda)$ by $C(\lambda)$ and $j_{\hat{\varrho}}(\lambda)$, respectively. Hence, we have proved one part of the assertion (4.2) and (4.3). Taking into account the identity

$$\frac{1}{\overline{\overline{W(\lambda)}}}E\Theta_H(\lambda)^* = -\frac{1}{W(\lambda)}\Theta_H(\lambda)E \tag{4.21}$$

we verify the other part.

It remains to show (4.4) and (4.5). To this end we note that from (4.17) one gets

$$J\Theta_H(\lambda)^* = J + \frac{i}{W(\lambda)}\begin{pmatrix} \alpha_b\alpha_a & -\alpha_a^2 v_b(a,\lambda) \\ -\alpha_b^2 v_a(b,\lambda) & \alpha_b\alpha_a \end{pmatrix}, \tag{4.22}$$

where

$$J := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{4.23}$$

Hence we find

$$\mathrm{tr}_{\mathbb{C}^2}(J\Theta_H(\lambda)^*) = 2i\frac{\alpha_b\alpha_a}{W(\lambda)}, \tag{4.24}$$

which yields

$$\frac{1}{2\pi i}\frac{\alpha_b\alpha_a}{W(\lambda)} = -\frac{1}{4\pi}\mathrm{tr}_{\mathbb{C}^2}(J\Theta_H(\lambda)^*). \tag{4.25}$$

Using the definition (4.3) we finally obtain

$$j_{\hat{\varrho}}(\lambda) = -\frac{1}{4\pi}\mathrm{tr}_{\mathbb{C}^2}(J\Theta_H(\lambda)^*)\ \ \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)\Theta_H(\lambda)E). \tag{4.26}$$

This leads to the estimate

$$|j_{\hat{\varrho}}(\lambda)| \leqslant \frac{1}{4\pi}\|\Theta_H(\lambda)^*\|_{\mathcal{L}_1(\mathbb{C}^2)}\|\varrho(\lambda)\|_{\mathcal{L}_1(\mathbb{C}^2)}. \tag{4.27}$$

Since $\|\Theta_H(\lambda)^*\|_{\mathcal{L}_1(\mathbb{C}^2)} \leqslant 2$ and $\|\varrho(\lambda)\|_{\mathcal{L}_1(\mathbb{C}^2)} = \mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda))$ we find

$$|j_{\hat{\varrho}}(\lambda)| \leqslant \frac{1}{2\pi}\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)), \tag{4.28}$$

which immediately proves (4.5). □

In correspondence to the carrier density it seems to be useful to introduce the following definition.

Definition 4.2: Assume $m+1/m\in L^\infty([a,b])$, $V\in L^2([a,b])$ and $\kappa_a,\kappa_b\in\mathbb{C}_+$. Then the matrix $C(\lambda)$ and the value $j_\varrho(\lambda)$ are called the current density observable and the current density at energy $\lambda\in\mathbb{R}$ of the system described by H, respectively.

The definition is again justified by the fact that the current density at energy $\lambda \in \mathbb{R}$ is the expectation value of the current density observable at energy $\lambda \in \mathbb{R}$, i.e., $j_{\hat{\varrho}}(\lambda) = \mathbb{E}_{\varrho(\lambda)}(C(\lambda))$ for $\lambda \in \mathbb{R}$. Using this notation formula (4.4) takes the form

$$j_{\hat{\varrho}} = \int_{\mathbb{R}} d\lambda \, \mathbb{E}_{\varrho(\lambda)}(C(\lambda)). \tag{4.29}$$

In the following corollary we consider the case that the steady state ϱ is a function of K, i.e.,

$$\varrho = f(K), \tag{4.30}$$

where, of course, $f(\cdot) \in L^{\infty}(\mathbb{R})$ and $f(\lambda) \geqslant 0$ for a.e. $\lambda \in \mathbb{R}$ and. In this case the density matrix ϱ belongs to the bicommutant of K.

Corollary 4.3: Assume $m + 1/m \in L^{\infty}([a,b])$, $V \in L^2([a,b])$ *and* $\kappa_a, \kappa_b \in \mathbb{C}_+$. *If the steady state* ϱ *is given by (4.30) with a non-negative function* $f(\cdot) \in L^{\infty}(\mathbb{R})$, *then* $j_{\hat{\varrho}}(\lambda) = 0$ *for a.e.* $\lambda \in \mathbb{R}$.

Proof: In this case one has

$$\varrho(\lambda) = f(\lambda) I_{\mathbb{C}^2}, \quad \lambda \in \mathbb{R}. \tag{4.31}$$

which gives

$$j_{\hat{\varrho}}(\lambda) = f(\lambda)\mathrm{tr}(C(\lambda)) = -\frac{1}{2\pi i} f(\lambda) \frac{\alpha_b \alpha_a}{\overline{W(\lambda)}} \mathrm{tr}_{\mathbb{C}^2}(E\Theta_H(\lambda)^*). \tag{4.32}$$

By (4.17) we immediately get that $\mathrm{tr}_{\mathbb{C}^2}(E\Theta_H(\lambda)^*) = 0$ for $\lambda \in \mathbb{R}$. □

If the steady state ϱ has the form

$$\varrho(\lambda) = \begin{pmatrix} \varrho^{bb}(\lambda) & 0 \\ 0 & \varrho^{aa}(\lambda) \end{pmatrix}, \tag{4.33}$$

then the current density is given by

$$j_{\hat{\varrho}}(\lambda) = -\frac{1}{2\pi} \frac{\alpha_a^2 \alpha_b^2}{|W(\lambda)|^2} (\varrho^{bb}(\lambda) - \varrho^{aa}(\lambda)). \tag{4.34}$$

This current density is different from zero if $\varrho^{bb}(\lambda) \neq \varrho^{aa}(\lambda)$ at least for a set of positive Lebesgue measure. So a current density different from zero arises only if we have an occupation disparity between the two eigenstates $\psi^-(x,\lambda,b)$ and $\psi^-(x,\lambda,a)$. This is the case if the steady state ϱ belongs to the commutant of K but not to the bicommutant. In other words, the density matrix (1.5) used for self-adjoint boundary conditions and generalized by (4.30) to the dissipative case leads to a zero current density.

V. CONCLUDING REMARKS

A. Density and current

The carrier density $u_{\hat{\varrho}}(\cdot)$ defined by (3.41) and (3.44) is a straightforward generalization of the corresponding definition (1.3) of the carrier density in the self-adjoint case. Indeed, this correspondence relies on the replacements

$$
\begin{gathered}
l \leftrightarrow \{a,b,\lambda\}, \\
\{\psi_l\}_{l=1}^{\infty} \leftrightarrow \{\vec{\psi}(\cdot,\lambda,\tau)\}_{\lambda\in\mathbb{R},\tau=a,b}, \\
\sum_{l=1}^{\infty} \leftrightarrow \int_{\lambda\in\mathbb{R}} d\lambda \sum_{\tau=a,b} \\
\varrho_l \leftrightarrow \varrho(\lambda).
\end{gathered}
\tag{5.1}
$$

The same holds true for the current density defined by (4.1) which is a straightforward generalization of (1.8). However, in contrast to the self-adjoint case the current density now is not necessarily zero.

B. Lax–Phillips scattering theory

There is consensus in the conviction that scattering states are responsible for the current. This usually leads to a a relation between current density and scattering matrix. Actually, the same takes place here. Formulas (4.2) and (4.3) relate the current density $j_{\hat{\varrho}}(\lambda)$ with the characteristic function $\Theta_{H*}(\lambda)$ of H^*. It turns out that the characteristic function $\Theta_{H*}(\lambda)$ of H^* can be regarded as the scattering matrix of an associated scattering system. Indeed, with the self-adjoint dilation K one can associate a Lax–Phillips scattering theory.[20,21] To this end one introduces the Hilbert space $\mathfrak{k}_0$,

$$
\mathfrak{k}_0 := L^2(\mathbb{R},\mathbb{C}^2) = \mathcal{D}_- \oplus \mathcal{D}_+ \subseteq \mathfrak{k}. \tag{5.2}
$$

and the identification operators $J_\pm : \mathfrak{k}_0 \to \mathfrak{k}$,

$$
\begin{aligned}
\vec{f} = J_- f &:= P_{\mathcal{D}_-}^{\mathfrak{k}_0} f \oplus 0 \oplus 0, \quad f \in \mathfrak{k}_0, \\
\vec{f} = J_+ f &:= 0 \oplus 0 \oplus P_{\mathcal{D}_+}^{\mathfrak{k}_0} f, \quad f \in \mathfrak{k}_0.
\end{aligned}
\tag{5.3}
$$

The subspaces $\mathcal{D}_-$ and $\mathcal{D}_+$ are called incoming and outgoing subspaces, respectively. On the Hilbert space $\mathfrak{k}_0$ one defines the self-adjoint operator K_0,

$$
(K_0 f)(x) = -i \frac{d}{dx} f(x) \tag{5.4}
$$

with the domain $\mathrm{dom}(K_0) := W^{1,2}(\mathbb{R},\mathbb{C}^2)$. The Lax–Phillips wave operators

$$
W_\pm = s - \lim_{t\to\pm\infty} e^{itK} J_\pm e^{-itK_0} \tag{5.5}
$$

exist and are complete, i.e., $\mathrm{ran}(W_\pm) = \mathfrak{k}$. The corresponding Lax–Phillips scattering operator $S = W_+^* W_- : \mathfrak{k}_0 \to \hat{\mathfrak{k}}$, is unitary and commutes with the self-adjoint operator K_0. By $\mathcal{F}: \mathfrak{k}_0 \to \hat{\mathfrak{k}}$ we denote the Fourier transform

$$
(\mathcal{F} f)(\lambda) = \hat{f}(\lambda) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} dx\, e^{-i\lambda x} f(x), \quad f \in \mathfrak{k}_0, \quad \lambda \in \mathbb{R}. \tag{5.6}
$$

We note that $\mathcal{F} K_0 \mathcal{F}^{-1} = M$ where M is defined by (2.43). Since S commutes with K_0 the operator $\hat{S} = \mathcal{F} S \mathcal{F}^{-1} : \hat{\mathfrak{k}} \to \hat{\mathfrak{k}}$ commutes with M. Hence $\hat{S}$ is a multiplication operator given by

$$
(\hat{S}\hat{f})(\lambda) = S(\lambda)\hat{f}(\lambda), \quad \hat{f} \in \hat{\mathfrak{k}}, \quad \lambda \in \mathbb{R}, \tag{5.7}
$$

where $\{S(\lambda)\}_{\lambda\in\mathbb{R}}$ is a measurable family of unitary operators which is called the Lax–Phillips scattering matrix. A rather involved computation shows that

$$S(\lambda)=\Theta_{H^*}(\lambda) \tag{5.8}$$

for a.e. $\lambda\in\mathbb{R}$, see, e.g., Ref. 22. By the way one has

$$\Phi_-=\mathcal{F}W_+^*, \quad \Phi_+=\mathcal{F}W_-^*, \tag{5.9}$$

where is Φ_- is the incoming Fourier transformation, cf. (2.41) and (2.42), and Φ_+ is the so-called outgoing Fourier transform which was introduced in Ref. 9.

C. Continuity equation

As mentioned above the quantity $N_\varrho(\omega)$,

$$N_\varrho(\omega):=\|u_{\hat{\varrho}}\|_{L^1(\omega)}=\int_\omega \mathrm{d}x\, u_{\hat{\varrho}}(x), \tag{5.10}$$

has the meaning of the number of carriers on the Borel set subset $\omega\subseteq\Omega=[a,b]$. By (3.44) one has the representation

$$N_\varrho(\omega)=\mathrm{tr}(\varrho U(\omega)). \tag{5.11}$$

Obviously $N:=N_\varrho(\Omega)$ is the total number of carriers on the interval $[a,b]$. We note that under condition (3.23) by Proposition 3.7 the total number of carriers in Ω is always finite.

In accordance with Ref. 8 the time evolution of the density matrix ϱ is given by

$$\varrho(t)=e^{-itK}\varrho e^{itK}, \quad t\in\mathbb{R}. \tag{5.12}$$

Hence, the number of particles at time $t\in\mathbb{R}$ on ω is given by

$$N_{\varrho(t)}(\omega):=\mathrm{tr}(\varrho(t)U(\omega)), \quad t\in\mathbb{R}. \tag{5.13}$$

Since ϱ commutes with K one has $\varrho(t)=\varrho$ and $N_{\varrho(t)}(\omega)=N_\varrho(\omega)$ or

$$\frac{\mathrm{d}}{\mathrm{d}t}N_{\varrho(t)}(\omega)=0, \quad \omega\subseteq\Omega, \quad t\in\mathbb{R}. \tag{5.14}$$

If the condition

$$C_{\hat{\varrho}}:=\sup_{\lambda\in\mathbb{R}}(1+\lambda^2)\|\varrho(\lambda)\|_{\mathcal{B}(\mathbb{C}^2)}<\infty \tag{5.15}$$

is satisfied, then

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}N_{\varrho(t)}(\omega)&=-i\,\mathrm{tr}(K\varrho(t)U(\omega))+i\,\mathrm{tr}(\varrho(t)KU(\omega))\\&=-i\,\mathrm{tr}(K\varrho U(\omega))+i\,\mathrm{tr}(\varrho KU(\omega))\\&=-i\int_{\mathbb{R}}\mathrm{d}\lambda\int_\omega \mathrm{d}x\,\lambda\,\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)D(x,\lambda))+i\int_{\mathbb{R}}\mathrm{d}\lambda\int_\omega \mathrm{d}x\,\lambda\,\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)D(x,\lambda)).\end{aligned} \tag{5.16}$$

By formula (3.42) we find

$$\int_\omega dx\,\lambda\left(\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)D(x,\lambda)\right)=\int_\omega dx\,\lambda\left\langle \varrho^t(\lambda)\begin{pmatrix}\psi^-(x,\lambda,b)\\ \psi^-(x,\lambda,a)\end{pmatrix},\begin{pmatrix}\psi^-(x,\lambda,b)\\ \psi^-(x,\lambda,a)\end{pmatrix}\right\rangle. \tag{5.17}$$

Since $l(\psi^-(x,\lambda,\tau))=\lambda\psi^-(x,\lambda,\tau)$ one gets

$$\int_\omega dx\,\lambda\left(\mathrm{tr}_{\mathbb{C}^2}(\varrho(\lambda)D(x,\lambda)\right)=\int_\omega dx\left\langle \varrho^t(\lambda)\begin{pmatrix}l(\psi^-(x,\lambda,b))\\ l(\psi^-(x,\lambda,a))\end{pmatrix},\begin{pmatrix}\psi^-(x,\lambda,b)\\ \psi^-(x,\lambda,a)\end{pmatrix}\right\rangle. \tag{5.18}$$

Hence

$$\begin{aligned}\frac{d}{dt}N_{\varrho(t)}(\omega)=&-i\int_{\mathbb{R}}d\lambda\int_\omega dx\left\langle \varrho^t(\lambda)\begin{pmatrix}l(\psi^-(x,\lambda,b))\\ l(\psi^-(x,\lambda,a))\end{pmatrix},\begin{pmatrix}\psi^-(x,\lambda,b)\\ \psi^-(x,\lambda,a)\end{pmatrix}\right\rangle\\ &+i\int_{\mathbb{R}}d\lambda\int_\omega dx\left\langle \varrho^t(\lambda)\begin{pmatrix}\psi^-(x,\lambda,b)\\ \psi^-(x,\lambda,a)\end{pmatrix},\begin{pmatrix}l(\psi^-(x,\lambda,b))\\ l(\psi^-(x,\lambda,a))\end{pmatrix}\right\rangle.\end{aligned} \tag{5.19}$$

Let $\omega=[c,d]\subseteq[a,b]$. Integrating by parts and taking into account formula (4.7) we get

$$\frac{d}{dt}N_{\varrho(t)}(\omega)=\int_{\mathbb{R}}d\lambda\{j_{\hat\varrho}(c,\lambda)-j_{\hat\varrho}(d,\lambda)\}. \tag{5.20}$$

The total current $j_{\hat\varrho}(x)$ at the point $x\in[a,b]$ is defined by

$$j_{\hat\varrho}(x):=\int_{\mathbb{R}}d\lambda\,j_{\hat\varrho}(x,\lambda). \tag{5.21}$$

This yields

$$\frac{d}{dt}N_{\varrho(t)}(\omega)=j_{\hat\varrho}(c)-j_{\hat\varrho}(d) \tag{5.22}$$

which shows that the change of the number of carriers in the set $[c,d]$ is equal to the difference between the incoming current $j_{\hat\varrho}(c)$ at point c and the outgoing current $j_{\hat\varrho}(d)$ at point d which very well corresponds to the physical intuition. Since by Proposition 4.1 the current density $j_{\hat\varrho}(x,\lambda)$ does not depend on $x\in[a,b]$ one gets $j_{\hat\varrho}(d)=j_{\hat\varrho}(c)$ which again verifies (5.14). Relation (5.22) is the integral form of the continuity equation which has the differential form

$$\frac{\partial}{\partial t}u_{\hat\varrho(t)}(x)+\frac{\partial}{\partial x}j_{\hat\varrho(t)}(x)=0,\quad t\in\mathbb{R},\quad x\in\Omega, \tag{5.23}$$

where $u_{\hat\varrho(t)}(x)$ is the carrier density at time $t\in\mathbb{R}$ and $j_{\hat\varrho(t)}(x)$ is the current density at time t given by (5.21). Since $u_{\hat\varrho(t)}(x)=u_{\hat\varrho}(x)$ is independent of t and $j_{\hat\varrho(t)}(x)$ is independent of x the continuity equation (5.23) obviously holds in the present situation.

D. Schrödinger–Poisson systems

Schrödinger–Poisson systems are of great interest in semiconductor physics, see, e.g., Ref. 1. In the following we are interested in a Schrödinger–Poisson system on the interval $\Omega=[a,b]$ of the real axis $\mathbb{R}$. Systems of this type were considered in Ref. 6. By φ we denote the electrostatic potential on Ω which is determined by Poisson's equation

$$-\frac{d}{dx}\epsilon(x)\frac{d}{dx}\varphi=q(C(x)+u^+-u^-),\quad x\in\Omega, \tag{5.24}$$

where u^+ and u^- are the densities of holes and electrons, respectively, q is the magnitude of the elementary charge, $C(\cdot)$ is a given concentration of ionized dopants, and $\epsilon=\epsilon(x)>0$ denotes the dielectric permittivity which satisfies the condition

$$\epsilon(\cdot)+\frac{1}{\epsilon(\cdot)}\in L^\infty([a,b]). \tag{5.25}$$

The Poisson equation (5.24) is completed by the boundary conditions

$$\varphi(a)=\varphi_a, \quad \text{and} \quad \varphi(b)=\varphi_b. \tag{5.26}$$

Next we have to specify Schrödinger-operators of the type (2.1) for different species of particles—holes and electrons indexed by $\pm$, respectively. We assume that for these species the effective masses $m_\pm$, external potentials $V_0^\pm$, and coefficients $\kappa_a^\pm, \kappa_b^\pm \in \mathbb{C}_+$ are given. For each species this leads to different dissipative Schrödinger operators $H^\pm(V_\pm)$ defined in accordance with (1.9), (2.1), and (2.2). The potential V entering into the definition of the Schrödinger operators has the form

$$V_\pm := V_0^\pm \pm \varphi(u), \tag{5.27}$$

where the electrostatic potential φ is a solution of the Poisson equation (5.24) with boundary condition (5.26). The carrier densities $u^\pm$ entering into Poisson's equation are obtained from the dissipative Schrödinger operators $H^\pm(V_\pm)$ in accordance with Sec. III. To this end we assume that the families of matrices $\{\varrho_\pm(\lambda)\}_{\lambda\in\mathbb{R}}$, which obey

$$C_{\hat{\varrho}_\pm} := \sup_{\lambda\in\mathbb{R}} \sqrt{\lambda^2+1}\,\|\varrho_\pm(\lambda)\|_{\mathcal{B}(\mathbb{C}^2)} < \infty, \tag{5.28}$$

are given. If $D^\pm(V_\pm)(x)$ are the carrier density observables at $x\in\Omega$ and at energy $\lambda\in\mathbb{R}$, then the carrier densities are computed by

$$u^\pm_{\hat{\varrho}_\pm}(V_\pm)(x)=\int_{\mathbb{R}} d\lambda\, u^\pm_{\hat{\varrho}_\pm}(V_\pm)(x,\lambda), \quad x\in\Omega, \tag{5.29}$$

where

$$u^\pm_{\hat{\varrho}_\pm}(V_\pm)(x,\lambda)=\mathrm{tr}_{\mathbb{C}^2}(\varrho_\pm(\lambda)D^\pm(V_\pm)(x,\lambda)), \quad x\in\Omega, \quad \lambda\in\mathbb{R}. \tag{5.30}$$

Moreover, if $\mathrm{tr}_{\mathbb{C}^2}(\varrho_\pm(\cdot))\in L^1(\mathbb{R})$ is valid, then the current densities $j^\pm_{\hat{\varrho}_\pm}$,

$$j^\pm_{\hat{\varrho}_\pm}=\int_{\mathbb{R}} d\lambda\, j^\pm_{\hat{\varrho}_\pm}(V_\pm)(\lambda) \tag{5.31}$$

are also well-defined and finite, cf. Sec. IV. The so described system is called a dissipative Schrödinger–Poisson system. We note that the total number of carriers $N^\pm(V_\pm)$ is given by

$$N^\pm(V_\pm)=\int_\Omega dx\, u^\pm_{\hat{\varrho}_\pm}(V_\pm)(x) \tag{5.32}$$

and is not fixed.

In a forthcoming paper[23] we show that under suitable conditions on $\epsilon(\cdot)$, $C(\cdot)$, $m_\pm(\cdot)$, $V_0^\pm(\cdot)$, $\kappa_b^\pm$, $\kappa_a^\pm$ and $\varrho_\pm$ this dissipative Schrödinger–Poisson system always admits a self-consistent solution.

(Received 5 June 2002; accepted 4 August 2002)

We generalize Schwinger boson representation of SU(2) algebra to SU(N) and define coherent states of SU(N) using $2(2^{N-1}-1)$ bosonic harmonic oscillator creation and annihilation operators. We give an explicit construction of all (N-1) Casimirs of SU(N) in terms of these creation and annihilation operators. The SU(N) coherent states belonging to any irreducible representations of SU(N) are labeled by the eigenvalues of the Casimir operators and are characterized by (N-1) complex orthonormal vectors describing the SU(N) manifold. The coherent states provide a resolution of identity, satisfy the continuity property, and possess a variety of group theoretic properties. © *2002 American Institute of Physics.*

I. INTRODUCTION

The idea of a coherent state for a quantum system was realized by Schrödinger[1] way back in 1926 in the context of quantum state of classical motion for a harmonic oscillators. This simplest coherent state construction is associated with the Heisenberg–Weyl group whose Lie algebra is given in terms of a harmonic oscillator creation and annihilation operators. These states have been widely used in physics.[2–4] Later, coherent states associated with an arbitrary Lie group in a given representation were constructed[5] by applying group operators to a weight vector in that particular representation. In the special case of the SU(2) group, another equivalent way of constructing the coherent states was by exploiting the Schwinger representation of the SU(2) algebra.[6] This representation involves a doublet of harmonic oscillator creation annihilation operators in terms of which one generalizes the simplest Heisenberg–Weyl coherent state construction to the SU(2) group. In Ref. 7, using the Schwinger representation of SU(3) algebra, we had constructed coherent states belonging to an arbitrary representation of SU(3). The motivation of the present work is: (a) to further generalize this Schwinger representation of SU(3) to SU(N) Lie algebra for arbitrary N, (b) exploit it to construct coherent states belonging to arbitrary irreducible representations of SU(N). We also give an explicit characterization of the SU(N) coherent states in terms of (N-1) complex N-plets describing the SU(N) manifold. In Ref. 8, SU(N) coherent states were constructed by applying the standard procedure of applying SU(N) group operator on the highest weight state of a SU(N) representation.

The organization of the paper is as follows. In Sec. II we will briefly describe the Heisenberg–Weyl and SU(2) coherent states in terms of harmonic oscillators. Sec. II is not only for the sake of completeness but also for setting up notation and language in a simpler setting before dealing with the larger SU(N) groups. This section also emphasizes the common spirit between them and our SU(N) coherent state formalism. However, with these groups being too simple, many features of larger SU(N) groups become redundant and hence this section fails to bring out a technique which can be generalized to SU(N). Therefore, in Sec. III, we briefly mention the SU(3) coherent state construction in a framework which is equivalent to the one in Ref. 7 but can be easily generalized to SU(N). In Sec. IV, we generalize this SU(3) procedure and explicitly construct SU(N) coherent states for arbitrary N.

II. HEISENBERG–WEYL AND SU(2) COHERENT STATES

Given a group G and its manifold $\mathcal{M}$, the coherent states in a given representation R are functions of q parameters denoted by $\{z^1,z^2,\ldots,z^q\}$ describing $\mathcal{M}$, and are defined as

$$|\vec{z}\rangle_R \equiv T_R(g(\vec{z}))\ \ |0\rangle_R . \tag{1}$$

Here $T_R(g(\vec{z}))$ is a group element in the representation R, and $|0\rangle_R$ is a fixed vector belonging to R. In the simplest example of the Heisenberg–Weyl group, the Lie algebra contains three generators. It is defined in terms of creation–annihilation operators $(a,a^\dagger)$ satisfying

$$[a,a^\dagger]=\mathcal{I},\quad [a,\mathcal{I}]=0,\quad [a^\dagger,\mathcal{I}]=0. \tag{2}$$

This algebra has only one infinite dimensional irreducible representation which can be characterized by occupation number states

$$|n\rangle \equiv \frac{(a^\dagger)^n}{\sqrt{n!}}|0\rangle$$

with $n=0,1,2,\ldots$. A generic group element in Eq. (1) can be characterized by $T(g)=\exp(i\alpha\mathcal{I}+za^\dagger-\overline{z}a)$ with an angle α and a complex parameter z. Therefore,

$$\begin{aligned} |\alpha,z\rangle_\infty &= \exp(i\alpha)\ \ |z\rangle_\infty , \\ |z\rangle_\infty &= \exp(za^\dagger-\overline{z}a)\ \ |0\rangle = \sum_{n=0}^{\infty} F_n(z)\ \ |n\rangle, \end{aligned} \tag{3}$$

where the sum runs over all the basis vectors of the infinite dimensional representation, and

$$F_n(z)=\frac{z^n}{\sqrt{n!}} \tag{4}$$

are the coherent state expansion coefficients. This feature, i.e., an expansion of the coherent states in terms of basis vectors of a given representation with analytic functions of complex variables $(F_n(z))$ as coefficients, will also be present in the case of SU(N) groups. It is easy to see that Eq. (3) provides a resolution of identity with the measure $d\mu(z)=dz\,d\overline{z}\exp(-|z|^2/2)$.

We now briefly review the next simplest example, i.e., the Schwinger representation of SU(2) Lie algebra and the associated coherent states. The Lie algebra is

$$[J^a,J^b]=i\epsilon^{abc}J^c. \tag{5}$$

The algebra (5) can be realized in terms of a doublet of harmonic oscillator creation and annihilation operators $a\equiv(a^1,a^2)$ and $\vec{a}^\dagger\equiv(a_1^\dagger,a_2^\dagger)$, respectively.[6] They satisfy the simpler bosonic commutation relation $[a^i,a_j^\dagger]=\delta^i_j$ with $i,j=1,2$. The vacuum state is $|0,0\rangle$. In terms of these operators,

$$Q^a \equiv \tfrac{1}{2}a_i^\dagger(\sigma^a)^i_j a^j, \tag{6}$$

where σ^a denote the Pauli matrices. (We will generally use the convention that repeated indices are summed over.) It is easy to check that the operators in (6) satisfy the SU(2) Lie algebra

$$[Q^a,Q^b]=i\epsilon^{abc}Q^c. \tag{7}$$

We also note that

$$[Q^a, a_i^\dagger] = a_j^\dagger \tfrac{1}{2}(\sigma^a)_i^j. \tag{8}$$

Equation (8) implies that $(a_1^\dagger, a_2^\dagger)$ transform like a SU(2) doublet. This fundamental representation of SU(2) will be denoted by the Young diagram $\Sigma_{[1]}$, which is a single box. Therefore, we can realize all SU(2) irreducible representations on the Hilbert space of harmonic oscillators created by creation operators acting on the vacuum which is a direct product of the vacuum states for a_1 and a_2. The SU(2) Casimir operator is given by

$$\mathcal{C} = \sum_{i=1}^{2} a_i^\dagger \cdot a^i \equiv a^\dagger \cdot a. \tag{9}$$

The eigenvalues of the Casimir $\mathcal{C}$ will be denoted by C. The various irreducible representations of SU(2) are characterized by the eigenvalues of the Casimir (or occupation number operator) in (9). We also know that any irreducible representation of SU(2) can also be defined by its Young diagram, which is obtained by arranging a certain number of boxes in a row. It is easy to see that $\mathcal{C}$ just counts this number. The basis vectors of the SU(2) irreducible representation with $\mathcal{C} = C$ are given by

$$\|i_1 i_2 \cdots i_C\rangle \equiv a_{i_1}^\dagger a_{i_2}^\dagger \cdots a_{i_C}^\dagger |0\rangle. \tag{10}$$

The dimension of the above-given irreducible representation is $(C+1)$. With the harmonic oscillator creation and annihilation operators, SU(2) coherent states can be obtained by directly generalizing (3). We define a doublet of complex numbers (z^1, z^2) with the constraint:

$$|z|^2 \equiv |z^1|^2 + |z^2|^2 = 1. \tag{11}$$

The above-given constraint gives three independent real compact parameters which define the sphere $\mathcal{M} = S^3$. The SU(2) coherent state in the representation C is now defined as

$$|z\rangle_C \equiv |z^1, z^2\rangle_C = \exp(\vec{z}\cdot\vec{a}^\dagger)|0,0\rangle|_{\vec{a}^\dagger\cdot\vec{a}=C} \cdot = F^{i_1 i_2 \cdots i_C} a_{i_1}^\dagger a_{i_2}^\dagger \cdots a_{i_C}^\dagger |0\rangle = F^{i_1 i_2 \cdots i_C} \|i_1 i_2 \cdots i_C\rangle, \tag{12}$$

where

$$F^{i_1 i_2 \cdots i_C} = \frac{1}{C!} z^{i_1} z^{i_2} \cdots z^{i_C}. \tag{13}$$

Note that F in (13) are analytic functions of z^1 and z^2. Under SU(2) transformations:

$$z^i \to z'^i = \exp i\left(\theta^a \frac{\sigma^a}{2}\right)_j^i z^j. \tag{14}$$

Thus the constraint (11) remains invariant under the SU(2) transformations (14). Therefore, the coherent states $|z\rangle \equiv |z_1, z_2\rangle$ transform amongst themselves on S^3. It is easy to check the resolution of identity:

$$\int d^2 z^1 d^2 z^2 \delta(|z^1|^2 + |z^2|^2 - 1)|z\rangle_{CC}\langle z| = \frac{1}{1+C} \sum_{i_1,\ldots,i_C=1}^{2} \|i_1 i_2 \ldots i_C\rangle\langle i_1 i_2 \cdots i_C\|. \tag{15}$$

III. THE SCHWINGER SU(3) REPRESENTATION

The basic technique behind the construction of SU(N) coherent states is to generalize the Schwinger representation of SU(3) Lie algebra[7] to SU(N) Lie algebra. We will, therefore, briefly

describe the construction of SU(3) Lie algebra in terms of harmonic oscillators here in a new framework which is equivalent to that in Ref. 7 but is directly generalizable to SU(N).

The rank of the SU(3) group is 2 and therefore it has two fundamental representations: Any SU(3) irreducible representation can be built up from the two fundamental representations, a triplet 3 and an anti-triplet $\bar{3}$. The latter is an antisymmetric combination of the two triplets. The two fundamental representations will be associated with the two (fundamental) Young diagrams $\Sigma_{[1,0]}$, for the triplet representation and $\Sigma_{[0,1]}$, for its conjugate (anti-triplet) representation. The Young diagram $\Sigma_{[1,0]}$ is one box and $\Sigma_{[0,1]}$ is two boxes arranged vertically. We will also label the fundamental representations by the Greek indices $[\alpha]$,$[\beta]$ taking values 1 and 2. The components of any irreducible tensor T transforming according to $\Sigma_{[1,0]}(\Sigma_{[0,1]})$ will be denoted by $T[\alpha=1]_{i_1}(T[\alpha=2]_{i_1 i_2} \equiv -T_{i_1 i_2}, (i_1, i_2 = 1,2,3))$. (The components of the complex conjugate of these tensors will be denoted by $T^*[1]^{j_1} T^*[2]^{j_1 j_2}$.) Further, the eight representation matrices corresponding to these two fundamental representations will be denoted by $\lambda^a[\alpha]$. (Note that $\lambda^a[2]^{i_1 i_2}_{j_1 j_2} \equiv \frac{1}{2}\epsilon^{i_1 i_2 k}\epsilon_{j_1 j_2 l}(-\lambda^{*a}[1])^l_k$.) If Q^a are the generators of SU(3) then under the SU(3) they transform as

$$
\begin{aligned}
[Q^a, T[1]_{i_1}] &= T[1]_{j_1}\lambda^a[1]^{j_1}_{i_1}, \\
[Q^a, T[2]_{i_1 i_2}] &= T[2]_{j_1 j_2}\lambda^a[2]^{j_1 j_2}_{i_1 i_2}.
\end{aligned}
\tag{16}
$$

The matrices on the right-hand side of (16) are the matrices belonging to the fundamental representations of SU(3) and satisfy the SU(3) Lie algebra:

$$
\begin{aligned}
[\lambda^a[1], \lambda^b[1]] &= i f^{abc}\lambda^c[1], \\
[\lambda^a[2], \lambda^b[2]] &= i f^{abc}\lambda^c[2].
\end{aligned}
\tag{17}
$$

The direct product of these two tensors (representations) span the whole SU(3) representation space. In fact, any irreducible tensor can be obtained by taking direct products of C_1 of T[1] and C_2 of T[2] tensors. The corresponding Young diagram is represented by arranging C_2 of $\Sigma[2]$ Young diagrams and C_1 of $\Sigma[1]$ diagrams from left to right side by side. Following Schwinger's representation of SU(2) Lie algebra, we introduce two sets of creation–annihilation operators $a[\alpha], a^\dagger[\alpha], \alpha = 1,2$. The set $a[\alpha=1]$ represents three annihilation operators denoted by $a^{i_1}[1] \equiv (a[1]^1, a[1]^2, a[1]^3)$ and $a[\alpha=2]$ represents another set of three annihilation operators, $a[2]^{i_1 i_2} = -a[2]^{i_2 i_1}$ having three independent components $(a[2]^{12}, a[2]^{23}, a[2]^{31})$. (In Ref. 7, we had chosen $b_1 = a[2]^{23}, b_2 = a[2]^{31}, b_3 = a[2]^{12}$.) We impose the following commutation relations on them:

$$
\begin{aligned}
&[a[1]^{i_1}, a^\dagger[1]_{j_1}] = \delta^{i_1}_{j_1}, \quad [a^{i_1}[1], a^{i_2}[1]] = 0, \\
&[a[2]^{i_1 i_2}, a^\dagger[2]_{j_1 j_2}] = \delta^{i_1}_{j_1}\delta^{i_2}_{j_2} - \delta^{i_1}_{j_2}\delta^{i_2}_{j_1}, \quad [a[2]^{i_1 i_2}, a[2]^{j_1 j_2}] = 0, \\
&[a[1]^{i_1}, a[2]^{i_2 i_3}] = 0, \quad [a^\dagger[1]_{i_1}, a[2]^{i_2 i_3}] = 0.
\end{aligned}
\tag{18}
$$

We now define the SU(3) generators in the Hilbert space of Harmonic oscillators as:

$$
Q^a = a^\dagger[1]_{i_1}\lambda^a[1]^{i_1}_{i_2}a[1]^{i_2} + \frac{1}{2!}a^\dagger[2]_{i_1 i_2}\lambda^a[2]^{i_1 i_2}_{j_1 j_2}a[2]^{j_1 j_2}. \tag{19}
$$

Using (18), it is easy to check that

$$
[Q^a, Q^b] = i f^{abc} Q^c. \tag{20}
$$

Further,

$$[Q^a,a^\dagger[1]_{i_1}]=a^\dagger[1]_{j_1}\lambda^a[1]^{j_1}_{i_1},$$
$$[Q^a,a^\dagger[2]_{i_1i_2}]=a^\dagger[2]_{j_1j_2}\lambda^a[2]^{j_1j_2}_{i_1i_2}. \tag{21}$$

Equation (21) implies that $a^\dagger[1]$ and $a^\dagger[2]$ transform like $\Sigma_{[1,0]}$ and $\Sigma_{[0,1]}$ fundamental representations, respectively. Therefore, all the irreducible representations of (20) can be realized on the Hilbert space created by creation operators $a^\dagger[1]_{i_1}$ and $a^\dagger[2]^{i_1i_2}$ acting on the vacuum state $|0\rangle$, which is direct product of vacuum states associated with each of the six harmonic oscillators. Further, the two Casimir operators of SU(3) in this generalization of Schwinger representation are given by

$$\mathcal{C}[1]=\sum_{i_1=1}^{3} a^\dagger_{i_1}[1]a^{i_1}[1],$$
$$\mathcal{C}[2]=\sum_{i_1,i_2=1}^{3} a^\dagger_{i_1i_2}[2]a^{i_1i_2}[2]. \tag{22}$$

The eigenvalues of the two Casimirs in (22) will be denoted by C_1 and C_2, respectively.

A. Irreducible representations of SU(3)

The eigenvalues of Casimirs (C_1,C_2) characterize all the irreducible representations of SU(3). On the other hand, we can also define irreducible representations by its Young diagram, which is built up by arranging certain numbers of $\Sigma_{[1,0]}$ followed by $\Sigma_{[0,1]}$ horizonally from right to left. It is easy to see that $\mathcal{C}_1$ and $\mathcal{C}_2$ just count these numbers. Therefore, we will denote a general SU(3) Young diagram by $\Sigma_{[C_1,C_2]}$ which contains C_1 of $\Sigma_{[1,0]}$ and C_2 of $\Sigma_{[2]}$ put together from from right to left. Therefore, a general basis vector in $\Sigma_{[C_1,C_2]}$ can be written as

$$\|i^1_1i^2_1\cdots i^{C_2+C_1}_1;i^1_2i^2_2\cdots i^{C_2}_2\rangle_{\Sigma_{[C_1,C_2]}}$$
$$\equiv(e_{\Sigma_{[C_1,C_2]}})a^\dagger[2]_{i^1_1i^1_2}a^\dagger[2]_{i^2_1i^2_2}\cdots a^\dagger[2]_{i^{C_2}_1i^{C_2}_2}[2]a^\dagger[1]_{i^{C_2+1}_1}a[1]^\dagger_{i^{C_2+2}_1}\cdots a^\dagger[1]_{i^{C_2+C_1}_1}|0\rangle. \tag{23}$$

In (23), we have characterized the basis vectors of $\Sigma_{[C_1,C_2]}$ representation by the various box indices appearing in the Young Tableau $\Sigma_{[C_1,C_2]}$. More explicitly, the index i^c_r represents the index corresponding to the box appearing in the rth row and cth column. $e_{\Sigma_{[C_1,C_2]}}$ is the idempotent associated with the Young tableau $\Sigma_{[C_1,C_2]}$. In general, it is an element of group algebra corresponding to the permutation group $S(C_1+2C_2)$. It is defined as the product of the two symmetrizers $\mathcal{S}_1$ (symmetrizing the indices in the first row $(i^1_1,i^2_1,\ldots,i^{C_1+C_2}_1)$, $\mathcal{S}_2$ (symmetrizing the indices in the second row $(i^1_2,i^2_2,\ldots,i^{C_1+C_2}_2)$, and C_2 antisymmetrizers (acting on the C_2 columns indices $((i^1_1,i^1_2),(i^2_1,i^2_2),\ldots,(i^{C_2}_1,i^{C_2}_2))$. In fact, the idempotent for a particular Young tableau can be constructed in two different ways, first symmetrizing the indices in each row and then antisymmetrizing the indices in each column or first antisymmetrizing the indices in each column followed by symmetrizing the indices of each row. Both procedures lead to equivalent results. Here, since the column indices are already antisymmetric, we choose the latter alternative and need to consider only the two symmetry operations along the two rows of $\Sigma_{[C_1,C_2]}$

respectively:

$$\mathcal{S}[1]=\sum_{p\in S_{C_2+C_1}} p, \tag{24}$$

$$\mathcal{S}[2]=\sum_{p\in S_{C_2}} p. \tag{25}$$

(In (24) and (25), $p\in S_n$ is an element of the permutation group S_n and it denotes the permutation $\binom{1\ 2\ \ldots N}{p_1\ p_2\ \ldots p_N}$ element of the permutation group S_N. Henceforth, we follow this notation throughout the paper.) The idempotent is just the product of (24) and (25) and is given by

$$e_{\Sigma_{[C_1,C_2]}}=\mathcal{S}[1]_{[i]}\mathcal{S}[2]_{[j]}. \tag{26}$$

One can easily see that:

$$\begin{aligned}\mathcal{C}[1]|i_1^1 i_1^2\cdots i_1^{C_2+C_1};i_2^1 i_2^2\ldots i_2^{C_2}\rangle&=C_1|i_1^1 i_1^2\cdots i_1^{C_2+C_1};i_2^1 i_2^2\cdots i_2^{C_2}\rangle,\\ \mathcal{C}[2]|i_1^1 i_1^2\cdots i_1^{C_2+C_1};i_2^1 i_2^2\cdots i_2^{C_2}\rangle&=C_2|i_1^1 i_1^2\cdots i_1^{C_2+C_1};i_2^1 i_2^2\cdots i_2^{C_2}\rangle.\end{aligned} \tag{27}$$

Thus all the irreducible representations are eigenvectors of the two casimirs $\mathcal{C}[1]$ and $\mathcal{C}[2]$. As an example we consider $C_1=C_2=1$ corresponding to the octet representation of SU(3). For this representation, $\mathcal{S}[1]=(e+(i_1^1,i_1^2))$ and $\mathcal{S}[2]=e$. Therefore, (1,1) representation is given by: $\|i_1^1,i_1^2;i_2^1\rangle_{\Sigma_{[1,1]}}=[a^\dagger[2]_{i_1^1 i_2^1}a^\dagger[1]_{i_1^2}+a^\dagger[2]_{i_1^2 i_2^1}a^\dagger[1]_{i_1^1}]|0\rangle$.

In Ref. 9 similar results as in this section have been obtained by using Bargmann's techniques for SU(3). More recently, SU(3) multiplicity problem has been analyzed by exploiting the above-given Schwinger construction and a mutually commuting Sp(2,R) group.[10]

B. The SU(3) coherent states

We consider two triplets of complex numbers $z[\alpha](=z^1[\alpha],z^2[\alpha],z^3[\alpha]),\alpha=1,2$ describing the Euclidean manifold $R^6\otimes R^6$. We impose the orthonormality conditions:

$$\overline{z}[\alpha]\cdot z[\beta]\equiv\sum_{i=1}^{3} z_i^*[\alpha]z^i[\beta]=\delta_{\alpha,\beta}. \tag{28}$$

We now define another vector $z[1,2]$ transforming as $\Sigma_{[0,1]}$ with components:

$$z^{i_1 i_2}[12]\equiv\sqrt{\frac{1}{2}}(z[1]^{i_1}z[2]^{i_2}-z[2]^{i_1}z[1]^{i_1})=\sqrt{\frac{1}{2}}\,\epsilon^{\alpha_1\alpha_2}z[\alpha_1]^{i_1}z[\alpha_2]^{i_2}. \tag{29}$$

Using (28), we find:

$$\begin{aligned}z[1,2]\cdot z[1,2]^*&\equiv z^{i_1 i_2}[[12]z^*_{i_1 i_2}[12]=1,\\ \tilde{z}[12]\cdot z[1]\equiv\epsilon_{i_1 i_2 i_3}z^{i_1 i_2}[12]z^{i_3}[1]=0,&\quad \tilde{z}[12]\cdot z[2]\equiv\epsilon_{i_1 i_2 i_3}z^{i_1 i_2}[12]z^{i_3}[2]=0.\end{aligned} \tag{30}$$

We can now construct any 3×3 SU(3) matrix $\mathcal{U}_3$ in terms of $z[1]$ and $z[2]$:

$$\mathcal{U}_3=\begin{pmatrix} z[1]_1 & z[1]_2 & z[1]_3\\ z[2]_1 & z[2]_2 & z[2]_3\\ \tilde{z}[12]_1 & \tilde{z}[12]_2 & \tilde{z}[12]_3\end{pmatrix}. \tag{31}$$

Thus we immediately see that $z[1]$ and $z[2]$ with (28) and (30) completely describe the SU(3) manifold. At this stage we define the SU(3) coherent states generating function as

$$|z[1],z[2]\rangle_{C_1,C_2}\equiv\exp(z[1]^{i_1}a^\dagger[1]_{i_1}+z[1,2]^{i_1i_2}a^\dagger[2]_{i_1i_2})|0\rangle|^{a^\dagger[1]\cdot a[1]=C_1}_{a^\dagger[2]\cdot a[2]=C_2}. \tag{32}$$

One can see that in the expansion of (32), due to the constraints (28) and (30), each irreducible representation occurs *once and only once*. We will now show that (32) indeed generates all the coherent states of SU(3). The constraints on the right-hand side of (32), ($a^\dagger[1]\cdot a[1]=C_1$ and $a^\dagger[2]\cdot a[2]=C_2$), select different possible irreducible representations of SU(3). Note that the states in (32) are characterized by the continuous parameters ($z[1],z[2]$) on the SU(3) manifold. It is easy to check the SU(3) transformation properties of $z[1]$ and $z[1,2]$,

$$\begin{aligned} z[1]^{i_1}&\to z'[1]^{i_1}=(\exp i\theta^a\lambda^a[1])^{i_1}_{i_2}z[1]^{i_2},\\ z[1,2]^{i_1i_2}&\to z'[12]^{i_1i_2}=(\exp i\theta^a\lambda^a[12])^{i_1i_2}_{j_1j_2}z[1,2]^{j_1j_2}. \end{aligned} \tag{33}$$

In (33) θ^a are the eight transformations associated with the SU(3) group transformation. Therefore, under SU(3) transformations both $z[1]$ and $z[2]$ transform like a triplet and the orthonormality conditions (28) and (30) remain invariant under the SU(3) transformations and the state in (32) defined at a point ($z[1],z[2]$) transforms to the coherent state at ($z'[1],z'[2]$) on the SU(3) manifold.

From the generating function (32) we find:

$$|z[1],z[2]\rangle_{C_1,C_2}=F^{i_1^1\cdots i_1^{C_1+C_2};i_2^1\cdots i_2^{C_2}}a[2]^\dagger_{i_1^1i_2^1}\cdots a^\dagger[2]_{i_1^{C_2}i_2^{C_2}}a^\dagger[1]_{i_1^{C_2+1}}\cdots a^\dagger[1]_{i_1^{C_2+C_1}}|0\rangle, \tag{34}$$

where

$$\begin{aligned} &C_1!C_2!F(z[1],z[2])^{i_1^1\cdots i_1^{C_1+C_2};i_2^1\cdots i_2^{C_2}}\\ &\quad=z[1,2]^{i_1^1i_1^1}z[1,2]^{i_1^2i_2^2}\cdots z[1,2]^{i_1^{C_2}i_2^{C_2}}z[1]^{i_1^{C_2+1}}z[1]^{i_1^{C_2+2}}\cdots z[1]^{i_1^{C_2+C_1}}\\ &\quad=P_2z[1]^{i_1^1i_2^1}z[1]^{i_1^2}\cdots z[1]^{i_1^{C_2}}z[1]^{i_1^{C_2+1}}\cdots z[1]^{i_1^{C_2+C_1}}z[2]^{i_2^1i_2^2}z[2]^{i_2^2}\cdots z[2]^{i_2^{C_2}}. \end{aligned} \tag{35}$$

In the second step in (35), we have used the antisymmetry properties of $a^\dagger[2]'s$ under the interchange of its two indices leading to $P_2=(2!)^{C_2/2}$. Equation (35) clearly illustrates the following two important properties of the tensor $F(z[1],z[2])$.

(1) It is an analytic function of ($z[1]$, $z[2]$) which describes the SU(3) manifold.

(2) It has exactly the same symmetry as that of $e_{\Sigma_{[C_1,C_2]}}$, i.e.,

$$F(z[1],z[2])^{i_1^1\cdots i_1^{C_1+C_2};i_2^1\cdots i_2^{C_2}}=F(z[1],z[2])^{i_1^1\cdots i_1^{C_1+C_2};i_2^1\cdots i_2^{C_2}}e_{\Sigma_{[C_1,C_2]}}. \tag{36}$$

Therefore, we can write (34) as

$$\begin{aligned} |z[1],z[2]\rangle_{C_1,C_2}&=F^{i_1\cdots i_{C_1+C_2}j_1\cdots j_{C_2}}e_{\Sigma_{[C_1,C_2]}}a[2]^\dagger_{i_1j_1}\cdots a^\dagger[2]_{i_{C_2}j_{C_2}}a[1]^\dagger_{i_{C_2+1}}\cdots a[1]^\dagger_{i_{C_2+C_1}}|0\rangle\\ &=F^{i_1\cdots i_{C_1+C_2}j_1\cdots j_{C_2}}\|i_1j_1,i_2j_2\cdots i_{C_2}j_{C_2}i_{C_2+1},i_{C_2+2}\cdots i_{C_2+C_1}\rangle_{[C_1,C_2]}. \end{aligned} \tag{37}$$

All these features are similar to Heisenberg–Weyl and SU(2) Schwinger coherent states of the previous section and are discussed in detail in Ref. 7.

We now check the resolution of identity. The Haar measure on SU(3) manifold is given by

$$\int \mathrm{d}\mu(z) \equiv \left(\int \prod_{\alpha=1}^{2} \mathrm{d}z[\alpha] \right) \left(\prod_{\alpha,\beta} \delta(z[\alpha]\cdot z^*[\beta] - \delta_{\alpha,\beta}) \right). \tag{38}$$

We construct an operator $\mathcal{O}_{[3]}$:

$$\mathcal{O}_3 \equiv \int \mathrm{d}\mu(z) |z[1],z[2]\rangle_{C_1,C_2\ C_1,C_2} \langle z[1],z[2]| \,. \tag{39}$$

Under SU(3) transformations (33), $\mathcal{O}_{[3]}$ remains invariant. Therefore,

$$[Q^a, \mathcal{O}_{[3]}] = 0, \quad \forall a = 1,2,\ldots,8. \tag{40}$$

Schur's Lemma implies:

$$\mathcal{O}_{[3]} = K I_{[C_1,C_2]} \,. \tag{41}$$

In (41), K is a constant and $I_{[C_1,C_2]}$ is the identity operator in the $\Sigma_{[C_1,C_2]}$ irreducible representation subspace. Thus we finally get:

$$\begin{aligned}
&\int \mathrm{d}\mu(z[1],z[2]) |z[1],z[2]\rangle_{C_1,C_2 C_1,C_2} \langle z[1],z[2]| \\
&= \int \mathrm{d}^6 z[1] \mathrm{d}^6 z[2] \prod_{\alpha,\beta=1}^{2} \delta(z^*[\alpha]\cdot z[\beta] \\
&\quad - \delta_{\alpha,\beta}) F^{i_1\cdots i_{C_1+C_2} j_1\cdots j_{C_2}} F^*{}_{k_1\cdots k_{C_1+C_2} l_1\cdots l_{C_2}} \big|_{i_1 j_1\cdots i_{C_2} j_{C_2}; i_{C_2+1}\cdots i_{C_2+C_1}} \big\rangle_{[C_1,C_2]\ [C_1,C_2]} \\
&\quad \times \big\langle {}^{k_1 l_1\cdots k_{C_2} l_{C_2}; k_{C_2+1}\cdots k_{C_2+C_1}} \big| \\
&= K \big|_{i_1 j_1, i_2 j_2\cdots i_{C_2} j_{C_2}; i_{C_2+1}\cdots i_{C_2+C_1}} \big\rangle_{[C_1,C_2]\ [C_1,C_2]} \big\langle {}^{i_1 j_1, i_2 j_2\cdots i_{C_2} j_{C_2}; i_{C_2+1}\cdots i_{C_2+C_1}} \big| \equiv K I_{[C_1,C_2]} \,.
\end{aligned} \tag{42}$$

IV. THE SCHWINGER SU(N) REPRESENTATION

We now generalize the ideas developed in Sec. III in the case of SU(3) to the group SU(N) for arbitrary N. The rank of the SU(N) group is (N-1). Therefore, there are (N-1) fundamental representations denoted by the Young diagrams with 1,2,…., (N-1) vertical boxes, respectively. Any irreducible representation of SU(N) can be built by taking direct products of the above-mentioned (N-1) fundamental representations. Following SU(2) and SU(3), we introduce (N-1) sets of creation–annihilations operators $(a[1]^{i_1}, a^\dagger[1]_{i_1}); (a[2]^{i_1 i_2}, a^\dagger[2]_{i_1 i_2}); \ldots; (a[N-1]^{i_1 i_2\cdots i_{N-1}}, a^\dagger[N-1]_{i_1 i_2\cdots i_{N-1}})$, which can be written in a compact form as $(a[\alpha]^{i_1 i_2\cdots i_\alpha}, a^\dagger[\alpha]_{i_1 i_2\cdots i_\alpha}), \alpha = 1,2\cdots(N-1)$. The commutation relations are straightforward generalizations of (18) and are given by

$$\begin{aligned}
[a[\alpha]^{i_1 i_2\cdots i_\alpha}, a^\dagger[\beta]_{j_1 j_2\cdots j_\beta}] &= \delta_{\alpha,\beta} \sum_{p\in S_\alpha} (-)^{|p|} \delta^{i_1}_{j_{p_1}} \delta^{i_2}_{j_{p_2}} \cdots \delta^{i_\alpha}_{j_{p_\alpha}} \,, \\
[a[\alpha]^{i_1 i_2\cdots i_\alpha}, a[\beta]^{j_1 j_2\cdots j_\beta}] &= 0, \quad [a^\dagger[\alpha]_{i_1 i_2\cdots i_\alpha}, a^\dagger[\beta]_{j_1 j_2\cdots j_\beta}] = 0.
\end{aligned} \tag{43}$$

In (43), $|p| = 0$ if p is an even permutation and $|p| = 1$ if it is an odd permutation. We denote the (N-1) generators belonging to (N-1) fundamental representation of SU(N) by $\lambda^a[\alpha]$, $a = 1,2,\ldots,(N^2-1)$. They satisfy the SU(N) algebra:

$$[\lambda^a[\alpha], \lambda^b[\alpha]] = i f^{abc} \lambda^c[\alpha], \quad \alpha = 1,2,\ldots,(N-1). \tag{44}$$

In (44) f^{abc} are the SU(N) structure constants. The SU(3) generators in terms of harmonic oscillators are given by

$$\begin{aligned} Q^a &= a^\dagger[1]_{i_1}[1]\lambda^a[1]^{i_1}_{i_2}a[1]^{i_2} + \frac{1}{2!}a^\dagger[2]_{i_1 i_2}\lambda^a[2]^{i_1 i_2}_{j_1 j_2}a[2]^{j_1 j_2} + \cdots \\ &\quad + \frac{1}{(N-1)!}a^\dagger[N-1]_{i_1 i_2 \cdots i_{N-1}}\lambda^a[N-1]^{i_1 \cdots i_{N-1}}_{j_1 \cdots j_{N-1}}a[N-1]^{j_1 j_2 \cdots j_{N-1}} \\ &= \sum_{\alpha=1}^{N-1}\frac{1}{\alpha!}a^\dagger[\alpha]_{i_1, i_2 \cdots i_\alpha}\lambda^a[\alpha]^{i_1 i_2 \cdots i_\alpha}_{j_1 j_2 \cdots j_\alpha}a[\alpha]^{j_1 j_2 \cdots j_\alpha}. \end{aligned} \tag{45}$$

The commutation relations (43) imply

$$[Q^a, Q^b] = i f^{abc} Q^c. \tag{46}$$

It is easy to verify that under SU(3) transformations the various creation operators belonging to the αth representation transform amongst themselves as

$$[Q^a, a^\dagger_{i_1 i_2 \cdots i_\alpha}[\alpha]] = a^\dagger_{j_1 j_2 \cdots j_\alpha}[\alpha](\lambda^a)^{j_1 j_2 \cdots j_\alpha}_{i_1 i_2 \cdots i_\alpha}[\alpha]. \tag{47}$$

This implies that all the irreducible representations of SU(N) can be realized on the Hilbert space created by the above-given creation operators acting on the vacuum. Further, the (N-1) Casimir operators are just the (N-1) number operators corresponding to (N-1) types of creation–annihilation operators and are given by

$$\begin{aligned} \mathcal{C}[1] &= \sum_{i_1=1}^{N} a^\dagger[1]_{i_1}a[1]^{i_1}, \\ \mathcal{C}[2] &= \frac{1}{2!}\sum_{i_1, i_2=1}^{N} a^\dagger[2]_{i_1 i_2}a[2]^{i_1 i_2}, \\ &\cdots \\ \mathcal{C}[N-1] &= \frac{1}{(N-1)!}\sum_{i_1, i_2, \ldots, i_{N-1}=1}^{N} a^\dagger[N-1]_{i_1 i_2 \cdots i_{N-1}}a[N-1]^{i_1 i_2 \cdots i_{N-1}}. \end{aligned} \tag{48}$$

It is easy to check that the (N-1) Casimir operators in (48) commute with all the (N^2-1) SU(N) generators in (45).

A. The irreducible representations of SU(N)

All irreducible representations of SU(N) can be constructed by taking direct products of the (N-1) fundamental representations and then applying appropriate projection operators. Like the SU(3) case in the previous section, we now consider the most general SU(N) irreducible representation $\Sigma_{[C_1, C_2 \cdots C_{N-1}]}$ containing C_α copies of the αth fundamental representations. We formally write:

$$|C_1, C_2, \ldots, C_{N-1}\rangle \equiv e_{\Sigma_{[C_1 \cdots C_{N-1}]}}(a^\dagger[1])^{C_1}(a^\dagger[2])^{C_2}(a^\dagger[3])^{C_3}\cdots(a^\dagger[N-1])^{C_{N-1}}|0\rangle. \tag{49}$$

(The explicit form of these basis vectors are given at the end of Sec. IV B—(64) and (65).) Just as in the case of SU(3) in the previous sections, all the creation operators being completely antisymmetric in their indices, the idempotent $e_{\Sigma_{[C_1\cdots C_{N-1}]}}$ in (49) is constructed by multiplying all (N-1) symmetrizers:

$$e_{\Sigma_{[C_1\cdots C_{N-1}]}}=\mathcal{S}_1\mathcal{S}_2\cdots\mathcal{S}_{N-1}, \tag{50}$$

where $\mathcal{S}_1,\mathcal{S}_2\cdots\mathcal{S}_{N-1}$ are the elements of permutation group algebras associated with the permutation groups $S_{C_1+\cdots+C_{N-1}},S_{C_2+\cdots+C_{N-1}},\ldots,S_{C_{N-1}}$, respectively,

$$\begin{aligned}
\mathcal{S}_1&\equiv\frac{1}{(C_1+\cdots+C_{N-1})!}\sum_{p\in S_{C_1+\cdots+C_{N-1}}}p,\\
\mathcal{S}_2&\equiv\frac{1}{(C_2+\cdots+C_{N-1})!}\sum_{p\in S_{C_2+\cdots+C_{N-1}}}p,\\
&\cdots\\
\mathcal{S}_{N-1}&\equiv\frac{1}{(C_{N-1})!}\sum_{p\in S_{C_{N-1}}}p.
\end{aligned} \tag{51}$$

Again, as in the case of SU(3), it is easy to verify:

$$\mathcal{C}_\alpha|C_1,C_2,..,C_{N-1}\rangle=C_\alpha|C_1,C_2,..,C_{N-1}\rangle. \tag{52}$$

Therefore, the Casimir operator $\mathcal{C}_\alpha$ acting on an irreducible representation generated by the basis vectors $\mathcal{C}_\alpha|C_1,C_2,\ldots,C_{N-1}\rangle$ just counts the number of times the αth fundamental representation appears in it. This is again similar to the SU(3) case in the previous section. We now exploit this feature to construct the SU(N) coherent states.

B. The SU(N) coherent states

We consider (N-1) N-plets of complex numbers $z[\alpha](=z^1[\alpha],z^2[\alpha],\ldots,z^N[\alpha]),\alpha=1,2,...,N-1$ describing the Eucledian manifold which is a direct product of (N-1) R^{2N}. We impose the orthonormality conditions:

$$z^*[\alpha]\cdot z[\beta]=\delta_{\alpha,\beta}. \tag{53}$$

We now define another vector $z[1,N-1]$ with components:

$$\begin{aligned}
z^{i_1i_2\cdots i_{N-1}}[1,N-1]&\equiv\sqrt{\frac{1}{(N-1)!}}\sum_{p\in S_{N-1}}(-)^{|p|}(z[1]^{i_{p_1}}z[2]^{i_{p_2}}\cdots z[N-1]^{i_{p_{N-1}}})\\
&=\sqrt{\frac{1}{(N-1)!}}\,\epsilon^{\alpha_1\alpha_2\cdots\alpha_{N-1}}z[\alpha_1]^{i_1}z[\alpha_2]^{i_2}\cdots z[\alpha_{N-1}].
\end{aligned} \tag{54}$$

Using (53), we find:

$$\begin{aligned}
z[1,N-1]\cdot z[1,N-1]^*&\equiv z^{i_1i_2\cdots i_{N-1}}[1,N-1]z^*{}_{i_1i_2\cdots i_{N-1}}[1,N-1]=1,\\
\tilde{z}[1,N-1]\cdot z[\alpha]&\equiv\epsilon_{i_1i_2\cdots i_N}z^{i_1i_2\cdots i_{N-1}}[1,N-1]z^{i_N}[\alpha]=0.
\end{aligned} \tag{55}$$

We can now construct any $N\times N$ SU(N) matrix $\mathcal{U}_N$ in terms of $z[1]$, $z[2],\ldots,z[N-1]$:

$$\mathcal{U}_N=\begin{pmatrix} z[1]^1 & z[1]^2 & \dots\ z[1]^N \\ z[2]^1 & z[2]^2 & \dots\ z[2]^N \\ \vdots & & \\ \vdots & & \\ z[N-1]^1 & z[N-1]^2 & \dots z[N-1]^N \\ \bar{z}[1\cdots N-1]^1 & \bar{z}[1\cdots N-1]^2 & \bar{z}[1\cdots N-1]^N \end{pmatrix}. \tag{56}$$

Thus we immediately see that $z[1]$, $z[2],\dots,z[N-1]$ with (55) describe SU(N) manifold. We will now exploit this simple characterization of SU(N) manifold to construct coherent states belonging to all the irreducible representations of SU(N) group. For this purpose, we construct a new set of (N-1) parameters:

$$z[1,1]^{i_1}\equiv z[1]^{i_1},$$

$$z[1,2]^{i_1 i_2}\equiv \sqrt{\frac{1}{2!}}\sum_{p\in S_2}(-)^{|p|}z[1]^{i_{p_1}}z[2]^{i_{p_2}},$$

$$z[1,3]^{i_1 i_2 i_3}\equiv \sqrt{\frac{1}{3!}}\sum_{p\in S_3}(-)^{|p|}z[1]^{i_{p_1}}z[2]^{i_{p_2}}z[3]^{i_{p_3}}, \tag{57}$$

$$\dots$$

$$z[1,N-1]^{i_1 i_2\cdots i_{N-1}}\equiv \sqrt{\frac{1}{(N-1)!}}\sum_{p\in S_{N-1}}(-)^{|p|}z[1]^{i_{p_1}}z[2]^{i_{p_2}}\cdots z[N-1]^{i_{p_{N-1}}}.$$

We now define the SU(N) coherent states generating function as:

$$\begin{aligned} &|z[1],z[2],\dots,z[N-1]\rangle_{C_1,C_2\cdots C_{N-1}} \\ &\quad\equiv\exp\left(\sum_{\beta=1}^{N-1} z[1,\beta]\cdot a^\dagger[\beta]\right)|0\rangle|_{a^\dagger[\alpha]\cdot a[\alpha]=C_\alpha} \\ &\quad\equiv\exp(z[1]^{i_1^1}a^\dagger[1]_{i_1^1}+z[1,2]^{i_1^2 i_2^2}a^\dagger[2]_{i_1^2 i_2^2} \\ &\qquad+\cdots+z[1,N-1]^{i_1^{N-1}i_2^{N-1}\cdots i_{N-1}^{N-1}}a^\dagger[N-1]_{i_1^{N-1}i_2^{N-1}\cdots i_{N-1}^{N-1}})|0\rangle|_{a^\dagger[\alpha]\cdot a[\alpha]=C_\alpha}. \end{aligned} \tag{58}$$

The constraints on the right-hand side of the generating function (58) ensure that we only generate the states which are eigenstates of all the (N-1) Casimir operators and thus selecting all possible irreducible representations of SU(N), i.e.,

$$\mathcal{C}[\alpha]|z[1],z[2],\dots,z[N-1]\rangle_{C_1,C_2\cdots C_{N-1}}=C[\alpha]|z[1],z[2],\dots,z[N-1]\rangle_{C_1,C_2\cdots C_{N-1}} \tag{59}$$

for $\alpha=1,2,\dots,(N-1)$. We will now show that the states thus obtained are the coherent states. All states in (58) are defined continuously over the SU(N) manifold parametrized by $(z[1],z[2],\dots,z[N-1])$. It is easy to check the SU(N) transformation properties of $z[1,\alpha],\alpha=1,2,...(N-1)$,

$$z[1,\alpha]^{i_1\cdots i_\alpha}\to z'[1,\alpha]^{i_1\cdots i_\alpha}=\left(\exp i\sum_{a=1}^{N^2-1}\theta^a\lambda^a[\alpha]\right)^{j_{1_1\cdots i_\alpha}}_{i_1\cdots j_\alpha} z[1,\alpha]^{j_1\cdots j_\alpha}. \tag{60}$$

In (60) θ^a are (N^2-1) parameters describing a point on the SU(N) manifold. Equation (60) implies that all $z[\alpha]$ ($\alpha=1,2,...,N-1$) transform as N-plets of SU(N), i.e.,

$$z[\alpha]\to z'[\alpha]=\left(\exp i\sum_{a=1}^{N^2-1}\theta^a\lambda^a[1]\right)^{i_1}_{j_1}z[\alpha]^{j_1}. \tag{61}$$

We see that the orthonormality conditions (53) remain invariant under the SU(N) transformations. The coherent states defined at a point $(z[1],z[2],\ldots,z[1,N-1])$ transform to the coherent states at $(z'[1],z'[2],\cdot z'[1,N-1])$ of the SU(N) manifold.

Expanding the exponential we find:

$$\begin{aligned}&|z[1],\ldots,z[N-1]\rangle_{C_1,\ldots,C_{N-1}}\\&\quad=P\left[\prod_{h=1}^{h_{\max}}\prod_{v=1}^{(C_h+C_{h+1}\cdots+C_{N-1})}z^{i^v_h}[h]\right]\left[\prod_{v(1)=1}^{C_{N-1}}a^\dagger[N-1]_{i_1^{v(1)}i_2^{v(1)}\ldots i_{N-1}^{v(1)}}\right]\\&\qquad\times\left[\prod_{v(2)=C_{N-1}+1}^{C_{N-1}+C_{N-2}}a^\dagger[N-2]_{i_1^{v(2)}i_2^{v(2)}\ldots i_{N-2}^{v(2)}}\right]\cdots\left[\prod_{v(N-1)=C_{N-1}+\cdots+C_2+1}^{C_{N-1}+\cdots+C_1}a^\dagger[1]_{i_1^{v(N-1)}}\right]|0\rangle.\end{aligned} \tag{62}$$

In (62), we have chosen those terms in the expansion which are eigenvectors of the Casimir operators $\mathcal{C}_\beta$ with eigenvalues C_β and $h_{\max}$ is the maximum value of β such that $C_\beta\neq 0$. $P=[\Pi_{\alpha=1}^{N-1}P_\alpha]$ with $P_\alpha=(\alpha!)^{C_\alpha/2}$. (In (62) $h=1,2\cdots h_{\max}$ counts the horizontal rows and v is used to count the vertical columns of $\Sigma_{[C_1,\ldots,C_{N-1}]}$. Note that it is the maximum number of horizontal rows in the Young diagram.) We note the following important symmetry and anti-symmetry properties of (62):

(1) The $(z[1],z[2],\ldots,z[N-1])$ dependent part of (62) has inbuilt invariance under interchange of any two indices along a row of the Young tableau $\Sigma_{[C_1,C_2,\ldots,C_{N-1}]}$, i.e., it is invariant under all the symmetry operations given in (51),

$$\left(\prod_{h=1}^{h_{\max}}\prod_{v=1}^{(C_h+C_{h+1}\cdots+C_{N-1})}z^{i^v_h}[h]\right)\mathcal{S}_\alpha=\left(\prod_{h=1}^{h_{\max}}\prod_{v=1}^{(C_h+C_{h+1}\cdots+C_{N-1})}z^{i^v_h}[h]\right). \tag{63}$$

(2) The harmonic oscillator dependent part of (62) has inbuilt antisymmetric properties along any column indices of the Young tableau $\Sigma_{[C_1,C_2,\ldots,C_{N-1}]}$.

Therefore, we can write (62) as:

$$\begin{aligned}|z[1],\ldots,z[N-1]\rangle_{C_1,\ldots,C_{N-1}}=&\prod_{h=1}^{h_{\max}}\prod_{v=1}^{(C_h+C_{h+1}\cdots+C_{N-1})}z^{i^v_h}[h]\quad e_{\Sigma_{[C_1,C_2,\ \ldots\ ,C_{N-1}]}}\\&\times\prod_{v(1)=1}^{C_{N-1}}a^\dagger[N-1]_{i_1^{v(1)}i_2^{v(1)}\ldots i_{N-1}^{v(1)}}\prod_{v(2)=C_{N-1}+1}^{C_{N-1}+C_{N-2}}a^\dagger[N\\&-2]_{i_1^{v(2)}i_2^{v(2)}\ldots i_{N-2}^{v(2)}}\cdots\prod_{v(N-1)=C_{N-1}+\cdots C_2+1}^{C_{N-1}+\cdots+C_1}a^\dagger[1]_{i_1^{v(N-1)}}|0\rangle.\end{aligned} \tag{64}$$

In (64), $e_{\Sigma_{[C_1,C_2,\ldots,C_{N-1}]}}$ is defined by Eq. (50). In fact, these are exactly basis vectors of the irreducible representation $\Sigma_{[C_1,C_2,\ldots,C_{N-1}]}$. We denote them by

$$\|(i_1^1 i_1^2 \cdots i_1^{C_1+\cdots+C_{N-1}});(i_2^1 i_2^2 \cdots i_2^{C_2+\cdots+C_{N-1}});\ldots;(i_{N-1}^1 i_{N-1}^2 \cdots i_{N-1}^{C_2+\cdots+C_{N-1}})\rangle_{\Sigma_{[C_1,C_2,\ \ldots\ ,C_{N-1}]}}$$

$$\equiv e_{\Sigma_{[C_1,C_2,\ldots,C_{N-1}]}} \prod_{v(1)=1}^{C_{N-1}} a^\dagger[N-1]_{i_1^{v(1)} i_2^{v(1)} \ldots i_{N-1}^{v(1)}} \prod_{v(2)=C_{N-1}+1}^{C_{N-1}+C_{N-2}} a^\dagger[N-2]_{i_1^{v(2)} i_2^{v(2)} \ldots i_{N-2}^{v(2)}}$$

$$\cdots \prod_{v(N-1)=C_{N-1}+\cdots C_2+1}^{C_{N-1}+\cdots+C_1} a^\dagger[1]_{i_1^{v(N-1)}}|0\rangle. \tag{65}$$

Thus the states belonging to $\Sigma_{[C_1,\ldots,C_{N-1}]}$ in (58) irreducible representations are given by

$$|z[1],z[2],\ldots,z[N-1]\rangle_{C_1,C_2\cdot C_{N-1}}$$

$$= \left(\prod_{h=1}^{h_{\max}} \prod_{v=1}^{(C_h+C_{h+1}\cdots+C_{N-1})} z_h^{i^v}[h] \right) \|(i_1^1 i_1^2 \cdots i_1^{C_1+\cdots+C_{N-1}});(i_2^1 i_2^2 \cdots i_2^{C_2+\cdots+C_{N-1}});\ldots;$$

$$\times (i_{N-1}^1 i_{N-1}^2 \cdots i_{N-1}^{C_2+\cdots+C_{N-1}})\rangle_{\Sigma_{[C_1,C_2,\ \ldots\ ,C_{N-1}]}}. \tag{66}$$

We now check the resolution of identity. This is similar to the SU(3) case in the previous sections. The SU(N) Haar measure is

$$\int \mathrm{d}\mu(z) \equiv \left(\int \prod_{\alpha=1}^{N-1} \mathrm{d}z[\alpha] \right) \left(\prod_{\alpha,\beta} \delta(z[\alpha]\cdot z^*[\beta] - \delta_{\alpha,\beta}) \right). \tag{67}$$

We construct an operator $\mathcal{O}_{[N]}$:

$$\mathcal{O}_N \equiv \left(\int \mathrm{d}\mu(z) \left| z[1],z[2],\ldots,z[N-1] \right\rangle \right)_{C_1,C_2\cdots C_{N-1}} \quad {}_{C_1,C_2\cdots C_{N-1}} \langle z[1],z[2],\ldots,z[N-1]|. \tag{68}$$

Under SU(N) transformations (60), $\mathcal{O}_{[3]}$ remains invariant. Therefore,

$$[Q^a,\mathcal{O}_{[N]}]=0, \quad \forall a=1,2,\ldots,N^2-1 \tag{69}$$

The Schur's Lemma implies

$$\mathcal{O}_{[N]} = K I_{[C_1,C_2,\ldots,C_{N-1}]}. \tag{70}$$

In (70), K is a constant and $I_{[C_1,\ldots,C_{N-1}]}$ is the identity operator in the $\Sigma_{[C_1,\ldots,C_{N-1}]}$ irreducible representation subspace. Therefore, the states in (66) are indeed the coherent states. We have thus constructed all the SU(N) coherent states belonging to different irreducible representations of SU(N).

V. SUMMARY AND DISCUSSION

We have generalized Schwinger representation of SU(2) algebra in terms of harmonic oscillators to the group SU(N). We have exploited this construction to construct SU(N) coherent states and characterized SU(N) manifold in terms of complex vectors. In this sense our SU(N) coherent states definition is analogous to that of Heisenberg–Weyl coherent states. This method is quite general and can be generalized to other Lie groups and their manifolds. We feel our approach is more useful for practical calculations compared to the standard group theoretical approach and can be applied to various problems. In condensed matter physics, coherent states for the Lie group SU(2) have been very useful for studying Heisenberg spin systems using the path integral formalism.[11–15] These studies have been generalized to systems with SU(N) symmetry, although

such studies have usually been restricted to the completely symmetric representations.[12,16] Therefore, our formulation can be used to write down the field theory for the SU(N) Heisenberg model and study its spectrum and topological aspects as in the SU(2) case.[17] Using the techniques discussed in the paper, one can also construct SU(N) coherent states with fixed values of Cartan diagonal generators. The special cases of SU(2) coherent states with fixed charge and SU(3) nonlinear coherent states with fixed charge and hypercharge were constructed in Refs. 18 and 19, respectively.

ACKNOWLEDGMENTS

We would like to thank Professor Binayak Dutta Roy for useful discussions. M.M. would also like to thank Professor Diptiman Sen for his involvement and discussions at the initial stages of this work.

On bound states for systems of weakly coupled Schrödinger equations in one space dimension

Michael Melgaard[a)]
Department of Mathematics, Chalmers University of Technology, and Göteborg University, Eklandagatan 86, S-412 96 Göteborg, Sweden

(Received 4 April 2002; accepted 18 July 2002)

We establish the Birman–Schwinger relation for a class of Schrödinger operators $-d^2/dx^2\otimes 1_{\mathcal{H}}+V$ on $L^2(\mathbb{R},\mathcal{H})$, where $\mathcal{H}$ is an auxiliary Hilbert space and V is an operator-valued potential. As an application we give an asymptotic formula for the bound states which may arise for a weakly coupled Schrödinger operator with a matrix potential (having one or more thresholds). In addition, for a two-channel system with eigenvalues embedded in the continuous spectrum we show that, under a small perturbation, such eigenvalues turn into resonances. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1510175]

I. INTRODUCTION

In a recent paper[22] (see also Ref. 21) we studied spectral and scattering theory for the two-channel Schrödinger operator

$$\mathbf{H}=\tilde{\mathbf{H}}_0+\mathbf{V}=\begin{pmatrix} -\dfrac{d^2}{dx^2} & 0 \\ 0 & -\dfrac{d^2}{dx^2}+1 \end{pmatrix}+\begin{pmatrix} V_{11} & V_{12} \\ V_{21} & V_{22} \end{pmatrix} \tag{1.1}$$

on the Hilbert space $L^2(\mathbb{R})\oplus L^2(\mathbb{R})$. In the low-energy limit, where the spectral parameter tends to the boundary point of the continuous spectrum of $\mathbf{H}$, viz. the point zero, we deduced asymptotic expansions for the resolvent of $\mathbf{H}$ and, as an application, we obtained asymptotic expansions for the scattering matrix associated with the pair $(\mathbf{H},\tilde{\mathbf{H}}_0)$ as the energy parameter tends to zero. Besides being interesting from the mathematical point of view, the study of spectral and scattering theory for $\mathbf{H}$, having thresholds at 0 and 1, also works as a useful exercise towards analogous investigations for various multichannel quantum system with more than one threshold (see, e.g., Ref. 23) because it describes many actual physical phenomena to a good approximation.

If we replace $\tilde{\mathbf{H}}_0$ in (1.1) by $\mathbf{H}_0=-d^2/dx^2\otimes 1_{\mathbb{C}^N}$ and $\mathbf{V}$ by an $N\times N$ matrix potential, we obtain the (usual) matrix Schrödinger operator on $L^2(\mathbb{R},\mathbb{C}^N)$ having a single threshold at 0. The latter, of course, has attracted a lot of attention during the years. Among recent results we mention low-energy asymptotics for the corresponding scattering matrix,[2,3] Levinson's theorem,[14] Lieb–Thirring inequalities[4,20] and quantum design.[7]

A natural question, which seems not to have been addressed in the literature, concerns how negative energy levels may arise in a system of weakly coupled Schrödinger equations. In the scalar-valued setting, weakly coupled bound states for Schrödinger operators have been investigated in various dimensions (see Ref. 19, Chapter VI, and Refs. 31, 15, and 16).

In this work we generalize the scalar-valued result obtained by Simon in dimension one[31] to the analogous matrix-valued setting.

We begin in the more abstract framework of Schrödinger operators with operator-valued potentials given formally by $H=-d^2/dx^2\otimes 1_{\mathcal{H}}+V$ on $L^2(\mathbb{R},\mathcal{H})$, where $\mathcal{H}$ is an auxiliary Hilbert

a)Electronic mail: melgaard@math.chalmers.se

space and the potential V is a $\mathcal{B}(\mathcal{H})$-valued, measurable function on $\mathbb{R}$ such that $V(x)$ is symmetric for almost all x. In Sec. III we define the Hamiltonian H by means of quadratic forms (Proposition 3.1) and in Sec. IV we establish the celebrated Birman–Schwinger relation (Proposition 4.2), which transforms the eigenvalue problem for H into an eigenvalue problem for a compact operator; the so-called Birman–Schwinger operator.

Equipped with the Birman–Schwinger relation we study weakly coupled bound states in Sec. V. We restrict our attention to Schrödinger operators with matrix-valued potentials. In Sec. V A we consider two-channel Hamiltonians with one and two thresholds, respectively. First we consider $\mathbf{H}(g)=-d^2/dx^2\otimes 1_{\mathbb{C}^2}+g\mathbf{V}(x)$, where $\mathbf{V}$ is a 2×2 matrix potential. Theorem 5.2 reveals how nonpositive eigenvalues of an auxiliary matrix $\mathbf{S}$, defined in (5.2), give rise to negative eigenvalues E_{ij} of $\mathbf{H}(g)$ provided g is small enough. The eigenvalues E_{ij} satisfy an asymptotic perturbation formula in which we derive the first few coefficients explicitly [see (5.3)]. Second, we consider the above-mentioned Hamiltonian (1.1), henceforth denoted $\tilde{\mathbf{H}}(g)$, having thresholds at 0 and 1. In Theorem 5.6 we show how a negative eigenvalue of an auxiliary matrix $\tilde{\mathbf{S}}$, defined in (5.9), generates a negative eigenvalue of $\tilde{\mathbf{H}}(g)$. However, if one compares the proofs of Theorems 5.2 and 5.6 (in particular, the expressions for the matrices $\mathbf{T}_0$ and $\tilde{\mathbf{T}}_0$), it seems that the argument used in the proof of Theorem 5.2 (ii) cannot be modified in order to treat the situation where zero is an eigenvalue of $\tilde{\mathbf{S}}$. Thus, it remains an attractive open problem to show that the zero eigenvalue of $\tilde{\mathbf{S}}$ (may) gives rise to a negative eigenvalue of $\tilde{\mathbf{H}}(g)$. In Sec. V B we state the generalization of Theorem 5.2 to the N-channel Hamiltonian $-d^2/dx^2\otimes 1_{\mathbb{C}^N}+\mathbf{V}(x)$, where $\mathbf{V}$ is an $N\times N$ matrix potential.

Having studied how negative eigenvalues arise for multichannel Hamiltonians under weak coupling, it is natural to address the problem of perturbation of embedded eigenvalues for a multichannel Schrödinger operator with a matrix-valued potential. In Sec. VI we consider a two-channel Hamiltonian having eigenvalues embedded in its continuous spectrum. When perturbed by a ''short range'' potential, we show that such eigenvalues move into the complex plane and become resonances. In particular, we verify Fermi's golden rule (see, e.g., Refs. 27 and 32).

There is a vast literature on 2×2 operator-valued matrices, e.g., in system theory (see, e.g., Ref. 8) and in semigroup theory (see, e.g., Ref. 11). Most notably in this context is the substantial number of questions of a general nature which have been answered on spectral theory recently, see, e.g., the survey in Ref. 33. However, the methods therein are not related to ours although some of the questions addressed clearly are, e.g., the appearance of resonances discussed by Mennicken and Motovilov.[24]

II. PRELIMINARIES

A. Vector-valued functions

Let $\mathcal{H}$ be a separable Hilbert space with scalar product and norm denoted by $\langle\cdot,\cdot\rangle_{\mathcal{H}}$ and $\|\cdot\|_{\mathcal{H}}$. Then a function $\psi(x)$ from $\mathbb{R}$ to $\mathcal{H}$ is measurable if the scalar-valued functions $\langle\psi(x),\phi\rangle_{\mathcal{H}}$ are measurable, where ϕ denotes an arbitrary vector of $\mathcal{H}$. If $\psi(x)$ is such a measurable function, then $\|\psi(x)\|_{\mathcal{H}}$ is also measurable (as a function with non-negative values). Thus $L^p(\mathbb{R},\mathcal{H})$ is defined as the set of equivalence classes of measurable functions $\psi(x)$ from $\mathbb{R}$ to $\mathcal{H}$, which satisfy that $\int_{\mathbb{R}}\|\psi(x)\|_{\mathcal{H}}^p dx$ is finite if $p<\infty$ and $\|\psi\|_\infty=\operatorname{ess\,sup}\|\psi(x)\|_{\mathcal{H}}<\infty$ if $p=\infty$. The measure dx is the Lebesgue measure. For any p the $L^p(\mathbb{R},\mathcal{H})$ space is a Banach space with norm $\|\cdot\|_p=(\int_{\mathbb{R}}\|\cdot\|_{\mathcal{H}}^p dx)^{1/p}$. In the case $p=2$, $L^2(\mathbb{R},\mathcal{H})$ is a complex and separable Hilbert space with scalar product $\langle\phi,\psi\rangle_2=\int_{\mathbb{R}}\langle\phi,\psi\rangle_{\mathcal{H}}dx$ and corresponding norm $\|\psi\|_2=\langle\psi,\psi\rangle_2^{1/2}$. For $n\in\mathbb{N}$, $1\leqslant p<\infty$, the Sobolev space $W^{n,p}(\mathbb{R},\mathcal{H})$ is defined as the space of those $\psi\in L^p(\mathbb{R},\mathcal{H})$, for which all derivatives (weak sense) up to order n are in $L^p(\mathbb{R},\mathcal{H})$. If $p=2$, $W^{n,2}(\mathbb{R},\mathcal{H})$ is a separable Hilbert space denoted by $H^n(\mathbb{R},\mathcal{H})$ with scalar product $\langle\phi,\psi\rangle_{H^n(\mathbb{R},\mathcal{H})}=\int_{\mathbb{R}}\Sigma_{\alpha=0}^n\langle(d/dx)^\alpha\phi,(d/dx)^\alpha\psi\rangle_{\mathcal{H}}$ and norm denoted by $\|\psi\|_{H^n(\mathbb{R},\mathcal{H})}$.

B. Operators

Below $\mathcal{H}$, $\mathcal{H}_1$, $\mathcal{H}_2$ are separable Hilbert spaces. For a linear operator T, the notations $\mathcal{D}(T)$, $\mathrm{Ran}(T)$, $\mathrm{Ker}(T)$, T^*, $\overline{T}$, $\sigma(T)$, $\rho(T)$ are standard (see, for example, Ref. 25). By I we denote the identity operator. The resolvent of a self-adjoint operator T is denoted by $R(T,z)=(T-zI)^{-1}$. By $\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)$ and $\mathbf{S}_\infty(\mathcal{H}_1,\mathcal{H}_2)$ we denote respectively the sets of bounded and compact operators acting from $\mathcal{H}_1$ into $\mathcal{H}_2$. With the usual operator norm $\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)$ is a Banach space. We set $\mathcal{B}(\mathcal{H}):=\mathcal{B}(\mathcal{H},\mathcal{H})$ and $\mathbf{S}_\infty(\mathcal{H}):=\mathbf{S}_\infty(\mathcal{H},\mathcal{H})$.

C. Trace classes of compact operators

If $T\in\mathbf{S}_\infty(\mathcal{H})$, then the nonzero eigenvalues of $|T|=\sqrt{T^*T}$ are called the singular numbers or s-numbers of T. Let $\{s_j(T)\}$ denote the (possibly finite) nonincreasing sequence of the singular numbers of T; every number counted according to its multiplicity as an eigenvalue of $|T|$. For $0<p<\infty$ the von Neumann–Schatten class $\mathbf{S}_p(\mathcal{H}_1,\mathcal{H}_2)$ is the set of $T\in\mathbf{S}_\infty(\mathcal{H}_1,\mathcal{H}_2)$ for which the functional

$$\|T\|^p_{\mathbf{S}_p(\mathcal{H}_1,\mathcal{H}_2)}:=\sum_j\,[s_j(T)]^p$$

is finite. The functional $\|\cdot\|_{\mathbf{S}_p(\mathcal{H}_1,\mathcal{H}_2)}$ is a norm for $p\geqslant 1$ and the normed space $\mathbf{S}_p(\mathcal{H}_1,\mathcal{H}_2)$ is a Banach space. For $p<1$ the functional is a quasinorm. For additional properties of the spaces $\mathbf{S}_p$ of compact operators we refer to Ref. 5, Chap. 11. The sets $\mathbf{S}_1(\mathcal{H}_1,\mathcal{H}_2)$ and $\mathbf{S}_2(\mathcal{H}_1,\mathcal{H}_2)$ are called the trace class and Hilbert–Schmidt class, respectively.

D. Operator-valued functions

Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be two separable Hilbert spaces. From above, a function $\mathbb{R}\ni x\to\psi(x)\in\mathcal{H}$ is measurable if and only if all the functions $\mathbb{R}\ni x\to\langle\psi(x),\phi\rangle_{\mathcal{H}}\in\mathbb{C}$ are measurable. As a result of the Pettis measurability theorem (see, e.g., Ref. 10 Theorem II.1.2) the following properties are equivalent for a $\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)$-valued function $\mathbb{R}\ni x\mapsto T(x)$:

(i) $\forall\,\phi\in\mathcal{H}_2$, $\forall\,\psi\in\mathcal{H}_1$, $\mathbb{R}\ni x\to\langle\phi,T(x)\psi\rangle_{\mathcal{H}_2}\in\mathbb{C}$ is measurable, and
(ii) $\forall\,\psi\in\mathcal{H}_1$, $\mathbb{R}\ni x\to T(x)\psi\in\mathcal{H}_2$ is measurable.

We say that a function $\mathbb{R}\ni x\mapsto T(x)\in\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)$ is measurable if it satisfies any one of the above properties (i)–(ii). In the affirmative case, $\|T(x)\|_{\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)}$ is also measurable because

$$\|T(x)\|_{\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)}=\sup_{\psi\in\mathcal{D}_1}(\|T(x)\psi\|_{\mathcal{H}_2}/\|\psi\|_{\mathcal{H}_1}),$$

where $\mathcal{D}_1$ is a countable dense subset of $\mathcal{H}_1$. Moreover, we can define $L^p(\mathbb{R},\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2))$ as the linear space of (equivalence classes of) measurable functions $T:\mathbb{R}\to\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)$ such that $\|T(\cdot)\|_{\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)}\in L^p(\mathbb{R})$.

For the functional calculus for self-adjoint operators we recall the following result which can be found in, e.g., Ref. 6, Proposition V.1.2.

Proposition 2.1: If for each $x\in\mathbb{R}$, $T(x)$ is a self-adjoint operator on $\mathcal{H}$ and $\{E_{T(x)}(A);A\,\text{Borel set of}\,\mathbb{R}\}$ denotes its resolution of the identity, the following three properties are equivalent:

(i) $\mathbb{R}\ni x\to E_{T(x)}(A)\in\mathcal{B}(\mathcal{H})$ *is measurable for all Borel sets A,*
(ii) $\mathbb{R}\ni x\to e^{-itT(x)}\in\mathcal{B}(\mathcal{H})$ *is measurable for all $t\in\mathbb{R}$, and*
(iii) $\mathbb{R}\ni x\to(T(x)-\zeta)^{-1}\in\mathcal{B}(\mathcal{H})$ *is measurable for all $\zeta\in\mathbb{C}\setminus\mathbb{R}$.*

E. Fourier transform

Suppose $\psi \in L^1(\mathbb{R}^d,\mathcal{H})$. Then we define its Fourier transform $(\mathcal{F}\psi)(\xi)=\hat{\psi}(\xi) := (2\pi)^{-1/2}\int_{\mathbb{R}} e^{ix\xi}\psi(x)\,dx$ which is an element of $L^\infty(\mathbb{R},\mathcal{H})$. If $\psi \in L^1(\mathbb{R},\mathcal{H})\cap L^2(\mathbb{R},\mathcal{H})$, then $\hat{\psi} \in L^2(\mathbb{R},\mathcal{H})$ with $\|\hat{\psi}\|_{L^2}=\|\psi\|_{L^2}$. The Fourier transform can then be extended by continuity to a unitary mapping of the Hilbert space $L^2(\mathbb{R},\mathcal{H})$ into itself.

We have the following criterion.

Lemma 2.2: Let T be an operator on $L^2(\mathbb{R},\mathcal{H})$ defined by

$$(T\phi)(x)=\int_{\mathbb{R}} t(x,\xi)\phi(\xi)\,d\xi, \tag{2.1}$$

where $t(x,\xi)\in\mathcal{B}(\mathcal{H})$ for each (x,ξ). Then T is a Hilbert–Schmidt operator on $L^2(\mathbb{R},\mathcal{H})$ if and only if

$$\int_{\mathbb{R}_x}\int_{\mathbb{R}_\xi} \mathrm{tr}_{\mathcal{H}}[t(x,\xi)^* t(x,\xi)]\,d\xi dx<\infty.$$

In this case,

$$\|T\|^2_{\mathbf{S}_2(L^2(\mathbb{R},\mathcal{H}))}=\int_{\mathbb{R}_x}\int_{\mathbb{R}_\xi} \mathrm{tr}_{\mathcal{H}}[t(x,\xi)^* t(x,\xi)]\,d\xi dx.$$

Proof: The Hilbert space $\mathcal{H}$ is isomorphic to some $L^2(Y)$ space and therefore it suffices to establish the statement for an operator T on $L^2(\mathbb{R},L^2(Y))$ defined by (2.1) for some $t(x,\xi)\in\mathcal{B}(L^2(Y))$. Since $L^2(\mathbb{R},L^2(Y))$ is isomorphic to $L^2(\mathbb{R}\times Y)$, the rephrased assertion follows immediately from Ref. 25, Theorem VI.23. □

III. THE HAMILTONIAN $H=H_0+V$

As in the scalar-valued case the quadratic form

$$h_0[\psi,\psi] := \int_{\mathbb{R}} \|(d/dx)\psi(x)\|^2_{\mathcal{H}}\,dx \tag{3.1}$$

is closed in $L^2(\mathbb{R},\mathcal{H})$ on the domain $H^1(\mathbb{R},\mathcal{H})$. Thus, this form generates a self-adjoint operator H_0 on $L^2(\mathbb{R},\mathcal{H})$. The free Hamiltonian H_0 corresponds to the "Laplacian" $-d^2/dx^2\otimes 1_{\mathcal{H}}$ on $L^2(\mathbb{R},\mathcal{H})$.

A potential V is a $\mathcal{B}(\mathcal{H})$-valued, measurable function on $\mathbb{R}$. Assume that $V(x)$ is symmetric for almost all x, i.e., $V(x)^*=V(x)$ for almost all x. The operator $V(x)\in\mathcal{B}(\mathcal{H})$ has a unique representation in the form $V(x)=U(x)|V(x)|$, where $|V(x)|$ is the modulus of $V(x)$ defined by $|V(x)|=(V(x)^*V(x))^{1/2}=(V(x)V(x))^{1/2}$. (The representation is not unique if the potential vanishes on a set of positive measure.) We have that $|V(x)|$ is a non-negative, self-adjoint operator belonging to $\mathcal{B}(\mathcal{H})$ and, moreover, $\||V(x)|\|_{\mathcal{B}(\mathcal{H})}=\|V(x)\|_{\mathcal{B}(\mathcal{H})}$. The operator $U(x)$ is a partial isometry with initial domain $\overline{\mathrm{Ran}|V(x)|}$, final domain $\overline{\mathrm{Ran}V(x)}$ and $\mathrm{Ker}\,U(x)=\mathrm{Ker}\,V(x)$. Observe that $U(x)^*U(x)=P_{\overline{\mathrm{Ran}\,|V(x)|}}$ and $U(x)U(x)^*=P_{\overline{\mathrm{Ran}\,V(x)}}$, where P_M denotes the orthogonal projection onto a closed subspace M. The modulus $|V(x)|$ possesses exactly one non-negative, self-adjoint square-root $|V(x)|^{1/2}\in\mathcal{B}(\mathcal{H})$. The square-root $|V(x)|^{1/2}$ commutes with every bounded operator which commutes with $|V(x)|$. We may define $V(x)^{1/2}=U(x)|V(x)|^{1/2}$ such that $V(x)=V(x)^{1/2}|V(x)|^{1/2}$. Moreover, $V(x)^{1/2}\in\mathcal{B}(\mathcal{H})$ with $\|V(x)^{1/2}\|_{\mathcal{B}(\mathcal{H})}=[\|V(x)\|_{\mathcal{B}(\mathcal{H})}]^{1/2}$ and adjoint $(V(x)^{1/2})^*=|V(x)|^{1/2}U(x)^*$. From Proposition 2.1 it follows that $|V|$, $|V|^{1/2}$ and $V^{1/2}$ are $\mathcal{B}(\mathcal{H})$-valued measurable functions on $\mathbb{R}$.

We want to establish the following result.

Proposition 3.1:

(i) If $V\in L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))$, then the real-valued quadratic form

$$v[\psi,\psi]:=\int_{\mathbb{R}}\langle V(x)^{1/2}\psi(x),|V(x)|^{1/2}\psi(x)\rangle_{\mathcal{H}}\,dx$$

is H_0 form-bounded with relative bound zero.

(ii) If $V\in L^1(\mathbb{R},\mathbf{S}_2(\mathcal{H}))$, then v is H_0 form-compact.

It follows from Proposition 3.1 (i) and the KLMN theorem (Ref. 26, Theorem X.17) that the form sum

$$h[\psi,\psi]:=h_0[\psi,\psi]+v[\psi,\psi]$$

is closed and semi-bounded from below on $H^1(\mathbb{R}^d,\mathcal{H})$ and thus generates a self-adjoint operator $H=H_0+V$ on $L^2(\mathbb{R},\mathcal{H})$. From Proposition 3.1 (ii) and Weyl's essential spectrum theorem it follows that $\sigma_{\mathrm{ess}}(H)=\sigma_{\mathrm{ess}}(H_0)=[0,\infty)$.

Proof of Proposition 3.1: The "kernel" of the resolvent of H_0 is given by (see, e.g., Ref. 28, Theorem 9.5.2)

$$Q(x-y;\ \sqrt{|E|})=\frac{e^{-\sqrt{|E|}|x-y|}}{2\sqrt{|E|}},\quad E<0. \tag{3.2}$$

(i) To show that the form v is infinitesimally H_0 form-bounded, it suffices to show that the form

$$w[\phi]=\langle|V|^{1/2}(H_0-E)^{-1/2}\phi,V^{1/2}(H_0-E)^{-1/2}\phi\rangle_{L^2(\mathbb{R},\mathcal{H})}$$

is bounded on $L^2(\mathbb{R},\mathcal{H})$ and that its norm

$$\|w\|:=\inf_{\phi\in L^2(\mathbb{R},\mathcal{H})}\frac{|\langle|V|^{1/2}(H_0-E)^{-1/2}\phi,V^{1/2}(H_0-E)^{-1/2}\phi\rangle|}{\|\phi\|^2}$$

tends to zero as $E\to-\infty$. By the definition of $\|w\|$, and since U in $V^{1/2}=U|V|^{1/2}$ is a partial isometry, we have that

$$\|w\|\leqslant\||V|^{1/2}(H_0-E)^{-1/2}\|^2_{\mathcal{B}(L^2(\mathbb{R},\mathcal{H}))}. \tag{3.3}$$

Therefore, it is enough to show that the right-hand side of the latter tends to zero as $E\to-\infty$.

We consider first $V\in L^\infty(\mathbb{R},\mathcal{B}(\mathcal{H}))$. For such V we have that

$$\||V|^{1/2}(H_0-E)^{-1/2}\|^2_{\mathcal{B}(L^2)}=\||V|^{1/2}(H_0-E)^{-1}|V|^{1/2}\|_{\mathcal{B}(L^2)}. \tag{3.4}$$

Let $\alpha=\sqrt{|E|}$ and $\phi\in L^2(\mathbb{R},\mathcal{H})$. Then Hölder's inequality yields that

$$\|[|V|^{1/2}(H_0+\alpha^2)^{-1}|V|^{1/2}\phi](x)\|_{\mathcal{H}}\leqslant\frac{1}{2\alpha}\|V(x)\|^{1/2}_{\mathcal{B}(\mathcal{H})}\|V\|_{L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))}\|\phi\|_{L^2(\mathbb{R},\mathcal{H})}.$$

The latter implies that

$$\begin{aligned}\||V|^{1/2}(H_0+\alpha^2)^{-1}|V|^{1/2}\phi\|^2_{L^2(\mathbb{R},\mathcal{H})}&\leqslant\int_{\mathbb{R}}\frac{1}{4\alpha^2}\|V(x)\|_{\mathcal{B}(\mathcal{H})}\|V\|^2_{L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))}\|\phi\|^2_{L^2(\mathbb{R},\mathcal{H})}\,dx\\&\leqslant\frac{1}{4\alpha^2}\|V\|^3_{L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))}\|\phi\|^2_{L^2(\mathbb{R},\mathcal{H})}.\end{aligned}$$

In conjunction with (3.4), the latter shows that the right-hand side of (3.3) tends to zero as $E \to -\infty$, which establishes assertion (i) for $V \in L^{\infty}(\mathbb{R},\mathcal{H})$. A standard approximation argument yields the assertion for general V.
(ii) It suffices to show that the form

$$w[\phi]=\langle |V|^{1/2}(H_0-E)^{-1/2}\phi, V^{1/2}(H_0-E)^{-1/2}\phi\rangle$$

defines a compact operator in $L^2(\mathbb{R},\mathcal{H})$. Under the assumption in (i) we already know that w generates a bounded, self-adjoint operator W in $L^2(\mathbb{R},\mathcal{H})$. Let us show that W is a Hilbert–Schmidt operator. From

$$\mathrm{tr}_{L^2}(W^*W)=\mathrm{tr}(V^{1/2}(H_0-E)^{-1}(V^{1/2})^*|V|^{1/2}(H_0-E)^{-1}(|V|^{1/2})^*),$$

we see that it is enough to show that $W_1=|V|^{1/2}(H_0-E)^{-1}(|V|^{1/2})^*$ and $W_2=V^{1/2}(H_0-E)^{-1}(V^{1/2})^*$ are Hilbert-–Schmidt operators on $L^2(\mathbb{R},\mathcal{H})$. It is enough to show it for W_2; the proof for W_1 is similar. The operator W_2 has integral "kernel"

$$K_{W_2}(x-y;\alpha)=V(x)^{1/2}(2\alpha)^{-1}e^{-\alpha|x-y|}(V(y)^{1/2})^*, \quad \alpha=\sqrt{-E}>0.$$

Using the criterion in Lemma 2.2 and the assumption in (ii), we estimate as follows:

$$\begin{aligned}
&\int_{\mathbb{R}}\int_{\mathbb{R}} \mathrm{tr}_{\mathcal{H}}[K_{W_2}(x-y;\alpha)^*K_{W_2}(x-y;\alpha)]\,dxdy\\
&\quad=\int_{\mathbb{R}}\int_{\mathbb{R}}\left(\frac{e^{-\alpha|x-y|}}{2\alpha}\right)^2 \mathrm{tr}_{\mathcal{H}}[(V(y)^{1/2})^{**}(V(x)^{1/2})^*V(x)^{1/2}(V(y)^{1/2})^*]\,dxdy\\
&\quad=\int_{\mathbb{R}}\int_{\mathbb{R}}\left(\frac{e^{-\alpha|x-y|}}{2\alpha}\right)^2 \mathrm{tr}_{\mathcal{H}}[V(y)^{1/2}|V(x)|^{1/2}U(x)^*U(x)|V(x)|^{1/2}(V(y)^{1/2})^*]\,dxdy\\
&\quad=\int_{\mathbb{R}}\int_{\mathbb{R}}\left(\frac{e^{-\alpha|x-y|}}{2\alpha}\right)^2 \mathrm{tr}_{\mathcal{H}}[|V(x)||V(y)|]\,dxdy\\
&\quad\leqslant\frac{1}{4\alpha^2}\int_{\mathbb{R}}\|V(x)\|_{\mathbf{s}_2(\mathcal{H})}\,dx\int_{\mathbb{R}}\|V(y)\|_{\mathbf{s}_2(\mathcal{H})}\,dy.
\end{aligned}$$

This shows that W_2 is a Hilbert–Schmidt operator in $L^2(\mathbb{R},\mathcal{H})$. □

We note that $V \in L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))$ implies that $|V| \in L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))$ and, in view of Proposition 3.1 (i), $|V|$ is infinitesimally H_0 form-bounded. Consequently, the following mappings are bounded:

$$V,|V|: \quad H^1(\mathbb{R},\mathcal{H})\to H^{-1}(\mathbb{R},\mathcal{H}), \tag{3.5}$$

$$|V|^{1/2},V^{1/2}: \quad H^1(\mathbb{R},\mathcal{H})\to L^2(\mathbb{R},\mathcal{H}), \tag{3.6}$$

$$|V|^{1/2},V^{1/2}: \quad L^2(\mathbb{R},\mathcal{H})\to H^{-1}(\mathbb{R},\mathcal{H}). \tag{3.7}$$

The qualitative behavior of any possible negative eigenvalues of H_0+gV as $g\to 0$ is described by the following simple result.

Proposition 3.2: If $V \in L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))$, then any negative eigenvalues of H_0+gV approach zero as g tends to zero.

Proof: Following Ref. 31 it suffices to show that there are positive constants g_0 and C such that $H_0+gV \geqslant -Cg$ for all $g_0>g>0$.

Let $\mathcal{F}$ denote the Fourier transform of vector-valued functions in $L^2(\mathbb{R},\mathcal{H})$ (see Sec. II E). We observe that, as for scalar-valued functions, a function ϕ whose Fourier transform is integrable is bounded and continuous with the usual estimate

$$\|\phi(x)\|_{\mathcal{H}} \leqslant \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} \|\mathcal{F}\phi(\xi)\|_{\mathcal{H}}\, d\xi. \tag{3.8}$$

For an arbitrary $\gamma>0$, Hölder's inequality yields that

$$\begin{aligned}\left(\int_{\mathbb{R}} \|\mathcal{F}\phi(\xi)\|_{\mathcal{H}}\, d\xi \right)^2 &\leqslant \left(\int_{\mathbb{R}} (\xi^2+\gamma^2)^{-1}\, d\xi \right) \left(\int_{\mathbb{R}} (\xi^2+\gamma^2) \|\mathcal{F}\phi(\xi)\|_{\mathcal{H}}^2\, d\xi \right) \\ &= \frac{\pi}{\gamma} \|(-i\xi+\gamma)\mathcal{F}\phi\|_{L^2(\mathbb{R},\mathcal{H})}^2 \\ &= \frac{\pi}{\gamma} \|(H_0^{1/2}+\gamma)\phi\|_{L^2(\mathbb{R},\mathcal{H})}^2 \\ &\leqslant \frac{2\pi}{\gamma} \{\|H_0^{1/2}\phi\|_{L^2(\mathbb{R},\mathcal{H})}^2 + \|\gamma\phi\|_{L^2(\mathbb{R},\mathcal{H})}^2\}. \end{aligned} \tag{3.9}$$

Let $d=\max\{1/\gamma,1\}$. Then (3.8) and (3.9) imply that

$$\|\phi(x)\|_{\mathcal{H}} \leqslant d\{\|H_0^{1/2}\phi\|_{L^2(\mathbb{R},\mathcal{H})}^2 + \|\phi\|_{L^2(\mathbb{R},\mathcal{H})}^2\} \tag{3.10}$$

for any $\phi \in \mathcal{D}(H_0^{1/2}) = H^1(\mathbb{R},\mathcal{H})$. The Sobolev type inequality (3.10) implies that

$$h_g[\phi] \geqslant \|H_0^{1/2}\|_{L^2(\mathbb{R},\mathcal{H})}^2 - g\int_{\mathbb{R}} \|V(x)\|_{\mathcal{B}(\mathcal{H})} \|\phi(x)\|_{\mathcal{H}}^2\, dx \geqslant (1-gd_1)\|H_0^{1/2}\|_{L^2(\mathbb{R},\mathcal{H})}^2 - gd_1\|\phi\|_{L^2(\mathbb{R},\mathcal{H})}^2,$$

where $d_1 = d\|V\|_{L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))}^2$. When we take $C=d_1$, $g_0=d_1^{-1}$ and $0<g<g_0$, we arrive at $h_g[\phi] \geqslant -Cg$ as desired. □

IV. THE BIRMAN–SCHWINGER RELATION

The Birman–Schwinger relation has been established rigorously for various classes of operators in the scalar-valued setting (see, e.g., Ref. 30, 31, and 17). It asserts that E is a negative eigenvalue of $H=-d^2/dx^2+V$ if and only if -1 is an eigenvalue of the operator $V^{1/2}(-d^2/dx^2-E)^{-1}|V|^{1/2}$. Formally this is obvious since $\phi=V^{1/2}\psi$ is a solution to $V^{1/2}(-d^2/dx^2-E)^{-1}|V|^{1/2}\phi=-\phi$.

Here we provide a simple proof of the Birman–Schwinger relation in our concrete operator-valued setting. For this purpose we introduce the Birman–Schwinger operator $K_E(V)=V^{1/2}(H_0-E)^{-1}|V|^{1/2}$, $E<0$, where H_0 is the non-negative, self-adjoint operator associated with the quadratic form h_0 in (3.1). Setting $\alpha^2=-E$, its integral "kernel" is given by

$$K_\alpha(x,y) = V(x)^{1/2}(2\alpha)^{-1}e^{-\alpha|x-y|}|V(y)|^{1/2}, \quad \alpha>0.$$

We have the following result.

Lemma 4.1: If $V\in L^1(\mathbb{R},\mathbf{S}_2(\mathcal{H}))$, then the Birman–Schwinger operator $K_E(V)$, $E<0$, is a Hilbert–Schmidt operator on $L^2(\mathbb{R},\mathcal{H})$; in particular $K_E(V)$ is a compact operator. Moreover, $\|K_E(V)\|_{\mathcal{B}(L^2(\mathbb{R},\mathcal{H}))}\to 0$ as $E\to-\infty$.

Proof: We argue as for the operator W_2 in the proof of Proposition 3.1 (ii). We omit the details. □

Having introduced the compact Birman–Schwinger operator we may formulate the Birman–Schwinger relation.

Proposition 4.2: Let $V\in L^1(\mathbb{R},\mathbf{S}_2(\mathcal{H}))$. *Then $E<0$ is an eigenvalue of $H=H_0+V$ (defined by a quadratic form) having multiplicity $\varkappa$ if and only if -1 is an eigenvalue of $K_E(V)$ having geometric multiplicity $\varkappa$.*

To establish Proposition 4.2 we need the following two results.

Lemma 4.3: If $V\in L^1(\mathbb{R},\mathcal{B}(\mathcal{H}))$, *then for* $E<0$ *the operators* $|V|^{1/2}\times(H_0-E)^{-1/2}$ *and* $V^{1/2}(H_0-E)^{-1/2}$ *are bounded on* $L^2(\mathbb{R},\mathcal{H})$.

Proof: Since V is H_0 form-bounded, it follows immediately from (3.6) and (3.7) in conjunction with the fact that the operator $(H_0-E)^{-1/2}$ is a bounded map from the domain $L^2(\mathbb{R},\mathcal{H})$ to the range $H^1(\mathbb{R},\mathcal{H})$. □

Lemma 4.4: Let S *and* T *be bounded operators on the Hilbert space* $\mathcal{K}$. *Then* $\sigma(ST)\setminus\{0\}=\sigma(TS)\setminus\{0\}$. *Moreover,* $\lambda\neq 0$ *is an eigenvalue of* ST *having geometric multiplicity* m *if and only if* λ *is an eigenvalue of* TS *having geometric multiplicity* m.

Proof: This is a simplified version of Theorem 2 (i) in Ref. 9. □

Proof Proposition 4.2: Let h_0 be the form of H_0, let v be the form of V and let $h=h_0+v$ be their form sum. According to Lemma 4.3 the operators $|V|^{1/2}(H_0-E)^{-1/2}$ and $V^{1/2}(H_0-E)^{-1/2}$ are bounded on $L^2(\mathbb{R},\mathcal{H})$ and, consequently, the operator $I+[|V|^{1/2}(H_0-E)^{-1/2}]^*V^{1/2}$ $(H_0-E)^{-1/2}$ is bounded on $L^2(\mathbb{R},\mathcal{H})$. Moreover, the operator $A^{-1}=(H_0-E)^{1/2}$ has domain $H^1(\mathbb{R},\mathcal{H})$ and range $L^2(\mathbb{R},\mathcal{H})$. Thus, we may introduce an auxiliary sesquilinear form a defined on the form domain $H^1(\mathbb{R},\mathcal{H})\times H^1(\mathbb{R},\mathcal{H})$ by

$$a[\phi,\psi]=\langle[I+(|V|^{1/2}A)^*V^{1/2}A]A^{-1}\phi,A^{-1}\psi\rangle. \tag{4.1}$$

We rewrite a and find that

$$a[\phi,\psi]=\underbrace{\langle A^{-1}\phi,A^{-1}\psi\rangle}_{a_1[\phi,\psi]}+\underbrace{\langle(|V|^{1/2}A)^*V^{1/2}AA^{-1}\phi,A^{-1}\psi\rangle}_{a_2[\phi,\psi]}.$$

Clearly,

$$a_1[\phi,\psi]=h_0[\phi,\psi]-E\langle\phi,\psi\rangle \tag{4.3}$$

and, since $|V|^{1/2}A$ is bounded on $L^2(\mathbb{R},\mathcal{H})$,

$$a_2[\phi,\psi]=\langle V^{1/2}AA^{-1}\phi,[|V|^{1/2}A]^{**}A^{-1}\psi\rangle=\langle V^{1/2}\phi,|V|^{1/2}AA^{-1}\psi\rangle=v[\phi,\psi]. \tag{4.4}$$

Hence, (4.2)–(4.4) shows that the forms a and $h-E$ are identical.

Suppose that $E<0$ is an eigenvalue of $H=H_0+V$, i.e., there exists an eigenfunction $\psi\in\mathcal{D}(H)$, $\psi\neq 0$, such that $(H-E)\psi=0$. This is equivalent to $(h-E)[\psi,\phi]=0$ for all $\phi\in H^1(\mathbb{R},\mathcal{H})$. Since the forms h and a are identical, we may introduce $u=A^{-1}\phi$ and deduce that

$$\begin{aligned}0=a[\psi,\phi]&=\langle[I+(|V|^{1/2}A)^*V^{1/2}A]A^{-1}\psi,A^{-1}\phi\rangle,\quad \forall\,\phi\in H^1(\mathbb{R},\mathcal{H}),\\&=\langle[I+(|V|^{1/2}A)^*V^{1/2}A]A^{-1}\psi,u\rangle,\ \ \forall\,\phi\in L^2(\mathbb{R},\mathcal{H}),\end{aligned}$$

because u runs through $L^2(\mathbb{R},\mathcal{H})$ as ϕ runs through $H^1(\mathbb{R},\mathcal{H})$. Consequently, $(I+[|V|^{1/2}A]^*V^{1/2}A)v=0$, where $v=A^{-1}\psi=(H_0-E)^{1/2}\psi$, so $-1\in\sigma_p([|V|^{1/2}A]^*V^{1/2}A)$. By reversing the arguments leading to the latter conclusion, we infer that

$$E\in\sigma_p(H_0+V)\ \text{ if and only if }\ -1\in\sigma_p([|V|^{1/2}A]^*V^{1/2}A). \tag{4.5}$$

Since $(H_0-E)^{1/2}$ is injective from the domain $L^2(\mathbb{R},\mathcal{H})$ to the range $H^1(\mathbb{R},\mathcal{H})$, the arguments above also show that the multiplicities of the eigenvalues E and -1 must be equal. In view of Lemma 4.4 and the definition of A, (4.5) implies that

$$E\in\sigma_p(H_0+V)\ \text{ if and only if }\ -1\in\sigma_p(V^{1/2}(H_0-E)^{-1/2}[|V|^{1/2}(H_0-E)^{-1/2}]^*) \tag{4.6}$$

and the multiplicities of E and -1 are equal. But $[|V|^{1/2}(H_0-E)^{-1/2}]^*=(H_0-E)^{-1/2}|V|^{1/2}$ and, therefore, in view of the definition of $K_E(V)$, (4.6) yields that $E\in\sigma_p(H_0+V)$ if and only if $-1\in\sigma_p(K_E(V))$. □

If g is fixed and $\lambda(\alpha)$ is an eigenvalue of $K_\alpha(V)$, then the Birman–Schwinger relation asserts that any solution $\alpha_g>0$ of

$$g\lambda(\alpha_g)=-1 \tag{4.7}$$

is associated to the eigenvalue $E(g)=-\alpha_g^2$ of $H(g)$. The latter equation plays a crucial role in Sec. V.

Define the operators L_α and M_α by their ''kernels:''

$$L_\alpha(x,y)=\frac{1}{2\alpha}V(x)^{1/2}|V(y)|^{1/2}, \tag{4.8}$$

$$M_\alpha(x,y)=\frac{1}{2\alpha}V(x)^{1/2}[[e^{-\alpha|x-y|}-1]|V(y)|^{1/2}. \tag{4.9}$$

Moreover, we introduce the operator M_0 with ''kernel''

$$M_0(x,y)=-\tfrac{1}{2}V(x)^{1/2}|x-y||V(y)|^{1/2}. \tag{4.10}$$

Imitating Ref. 31 we obtain the following result.

Lemma 4.5: If $\int_{\mathbb{R}}(1+|x|^2)\|V(x)\|_{\mathbf{s}_2(\mathcal{H})}\,dx<\infty$, *then the following assertions are valid:*

(i) The operator M_0 *is Hilbert–Schmidt on* $L^2(\mathbb{R},\mathcal{H})$.
(ii) As $\alpha\downarrow 0$, *the operator* M_α *converges to* M_0 *in the Hilbert–Schmidt norm on* $L^2(\mathbb{R},\mathcal{H})$.
(iii) The Birman–Schwinger operator $gK_\alpha(V)$ *has eigenvalue* -1 *if and only if the same is true for* $g(1+gM_\alpha)^{-1}L_\alpha$.

Proof:

(i) It follows from the estimate

$$\int_{\mathbb{R}}\int_{\mathbb{R}}\mathrm{tr}_{\mathcal{H}}[M_0(x,y)^*M_0(x,y)]\,dxdy\leqslant\frac{1}{2}\int\int(|x|^2+|y|^2)\|\,|V(x)|\,\|_{\mathbf{s}_2(\mathcal{H})}\|\,|V(y)|\,\|_{\mathbf{s}_2(\mathcal{H})}\,dxdy<\infty.$$

(ii) We want to show that

$$\int\int\mathrm{tr}_{\mathcal{H}}[(M_\alpha-M_0)(x,y)^*(M_\alpha-M_0)(x,y)]\,dxdy\to 0 \tag{4.11}$$

as $\alpha\downarrow 0$. Now,

$$\mathrm{tr}_{\mathcal{H}}[(M_\alpha-M_0)(x,y)^*(M_\alpha-M_0)(x,y)]=\left|\frac{1}{2\alpha}(e^{-\alpha|x-y|}-1)+\frac{1}{2}|x-y|\right|^2\mathrm{tr}_{\mathcal{H}}[|V(x)||V(y)|],$$

and since $|(1/2\alpha)(e^{-\alpha|x-y|}-1)+(1/2)|x-y||\to 0$ as $\alpha\downarrow 0$, we have the pointwise convergence

$$\mathrm{tr}_{\mathcal{H}}[(M_\alpha-M_0)(x,y)^*(M_\alpha-M_0)(x,y)]\to 0\ \text{ as }\ \alpha\downarrow 0. \tag{4.12}$$

Moreover,

$$\begin{aligned}\mathrm{tr}_{\mathcal{H}}[M_\alpha(x,y)^* M_\alpha(x,y)] &= \left|\frac{1}{2\alpha}(e^{-\alpha|x-y|}-1)\right|^2 \mathrm{tr}_{\mathcal{H}}[|V(x)||V(y)|] \\ &\leqslant |\tfrac{1}{2}|x-y||^2 \mathrm{tr}_{\mathcal{H}}[|V(x)||V(y)|] \\ &= \mathrm{tr}_{\mathcal{H}}[M_0(x,y)^* M_0(x,y)]. \end{aligned} \tag{4.13}$$

It follows from (i) and (4.12) and (4.13) in conjunction with Lebesgue's dominated convergence theorem that (4.11) holds.

(iii) It follows from (4.13) that $\|M_\alpha\|_{\mathcal{B}(L^2(\mathbb{R},\mathcal{H}))} \leqslant \|M_\alpha\|_{HS} \leqslant \|M_0\|_{HS}$. Hence, $\|M_\alpha\|_{\mathcal{B}(L^2(\mathbb{R},\mathcal{H}))}$ is bounded *independently* of $\alpha \in (0,\alpha_0]$ for some $\alpha_0 > 0$. Therefore, for g small enough, $\|gM_\alpha\|_{\mathcal{B}(L^2(\mathbb{R},\mathcal{H}))} < 1$ and, consequently, $(1+gM_\alpha)^{-1}$ exists and is bounded for these g and α. In particular, we may write $1+gK_\alpha(V) = (1+gM_\alpha)[1+g(1+gM_\alpha)^{-1}L_\alpha]$ from which the assertion follows. □

V. WEAKLY COUPLED BOUND STATES

Throughout this section operators (resp. vectors) are denoted by boldface capital (resp. small) letters to emphasize their matrix (resp. vector) structure.

A. Two-channel Hamiltonians with matrix-valued potentials

We consider the case where the potential is a 2×2 matrix-valued potential $\mathbf{V}(x)$ with measurable functions V_{ij} on $\mathbb{R}$ as entries. The Euclidean inner product and norm in $\mathbb{C}^2$ are denoted by $\langle \cdot,\cdot \rangle_{\mathbb{C}^2}$ and $\|\cdot\|_{\mathbb{C}^2}$, respectively.

Assumption 5.1:

(a) $\mathbf{V}(x)$ is symmetric, i.e., $\overline{V_{ji}} = V_{ij}$.

(b) $\int_{\mathbb{R}} (1+|x|^2)\|\mathbf{V}(x)\|_{\mathcal{B}(\mathbb{C}^2)}\, dx < \infty$.

(c) The functions V_{ij} are real-valued.

1. Two-channel Hamiltonian with a single threshold

First we consider the Hamiltonian $\mathbf{H}(g) = \mathbf{H}_0 + g\mathbf{V}(x)$ in $L^2(\mathbb{R},\mathbb{C}^2)$, defined in Proposition 3.1 by means of forms. Formally, we may write the Hamiltonian as

$$\mathbf{H}(g) = \mathbf{H}_0 + g\mathbf{V} = \begin{pmatrix} -\dfrac{d^2}{dx^2} & 0 \\ 0 & -\dfrac{d^2}{dx^2} \end{pmatrix} + g\begin{pmatrix} V_{11} & V_{12} \\ V_{21} & V_{22} \end{pmatrix} \tag{5.1}$$

in $L^2(\mathbb{R},\mathbb{C}^2) = L^2(\mathbb{R}) \oplus L^2(\mathbb{R})$. Under Assumption 5.1 we know that its essential spectrum equals the half-axis starting at the (threshold) point zero.

Define the matrices $\mathbf{S}$ and $\mathbf{T}$ by

$$\mathbf{S} = \int_{\mathbb{R}} \mathbf{V}(x)\, dx, \quad \mathbf{T}_0 = -\frac{1}{2}\int_{\mathbb{R}}\int_{\mathbb{R}} \mathbf{V}(x)|x-y|\mathbf{V}(y)\, dy dx. \tag{5.2}$$

We establish the following result.

Theorem 5.2: *Let* $\mathbf{V}$ *obey Assumption 5.1 (a) and (b) and let* $\mathbf{H}(g) = \mathbf{H}_0 + g\mathbf{V}(x)$ *be the self-adjoint Hamiltonian on* $L^2(\mathbb{R},\mathbb{C}^2)$ *defined in Proposition 3.1 by means of forms.*

(i) Assume that the matrix $\mathbf{S}$*, defined in (5.2), has* $n(\leqslant 2)$ *negative eigenvalues, denoted by* s_i*, with multiplicities* $\varkappa_i$*. Then, for a small enough* g*, the two-channel Hamiltonian* $\mathbf{H}(g)$ *has precisely* $\Sigma_{i=1}^n \varkappa_i$ *negative eigenvalues (taking into account multiplicity)* E_{ij} *satisfying the formulas*

$$(-E_{ij}(g))^{1/2}=-\frac{g}{2}s_i+\frac{g^2}{2}\langle \mathbf{v}_{ij},\mathbf{T}_0\mathbf{v}_{ij}\rangle_{\mathbb{C}^2}+O(g^3),$$
$$i=1,\ldots,n,\quad j=1,\ldots,\varkappa_i, \tag{5.3}$$

where $\mathbf{T}_0$ *is defined in (5.2) and* $\mathbf{v}_{ij}$ *are the eigenvectors corresponding to the eigenvalue* s_i *of* $\mathbf{S}$.

(ii) Suppose that $\mathbf{V}$ *obey Assumption 5.1(c) and that the matrix* $\mathbf{S}$ *has n nonpositive eigenvalues, denoted by* s_i, *with multiplicities* $\varkappa_i$. *If the eigenvectors* $\mathbf{v}_{0j}$, $j=1,\ldots,\varkappa_i$, *associated with the eigenvalue zero of* $\mathbf{S}$ *satisfy* $\langle \mathbf{v}_{0j},\mathbf{T}_0\mathbf{v}_{0j}\rangle_{\mathbb{C}^2}\neq 0$, *then the conclusion of part (i) remains valid.*

Proof: According to the Birman–Schwinger relation formulated in Proposition 4.2, $E(g)<0$ is an eigenvalue of $\mathbf{H}(g)$ if and only if -1 is an eigenvalue of $g\mathbf{K}_\alpha(\mathbf{V})$ with $\alpha^2=-E(g)$. Furthermore, in view of Lemma 4.5(iii), the operator $g\mathbf{K}_\alpha(\mathbf{V})$ has eigenvalue -1 if and only if the same is true for $g(1+g\mathbf{M}_\alpha)^{-1}\mathbf{L}_\alpha$. Now let us denote the (unknown) eigenvalues and eigenfunctions of $(1+g\mathbf{M}_\alpha)^{-1}\mathbf{L}_\alpha$ by $\mu_k(g,\alpha)$ and $\mathbf{\Psi}_k(x;g,\alpha)$, respectively, viz.

$$(1+g\mathbf{M}_\alpha)^{-1}\mathbf{L}_\alpha\mathbf{\Psi}_k(x;g,\alpha)=\mu_k(g,\alpha)\mathbf{\Psi}_k(x;g,\alpha). \tag{5.4}$$

Let $\mathbf{u}_k\in\mathbb{C}^2$ be a constant vector. We insert

$$\mathbf{\Psi}_k(x;g,\alpha)=\frac{1}{2\alpha}(1+g\mathbf{M}_\alpha)^{-1}|\mathbf{V}(x)|^{1/2}\mathbf{u}_k$$

into (5.4) and obtain

$$\mathbf{R}_g\mathbf{u}_k=\mu_k(g,\alpha)\mathbf{u}_k, \tag{5.5}$$

where $\mathbf{R}_g$ is the matrix

$$\mathbf{R}_g=\frac{1}{2\alpha}\int_{\mathbb{R}}\mathbf{V}^{1/2}(x)[(1+g\mathbf{M}_\alpha)^{-1}|\mathbf{V}|^{1/2}](x)\,dx.$$

Define $\mathbf{S}$ as in (5.2) and, moreover, define

$$\mathbf{T}(\alpha)=\int_{\mathbb{R}}\mathbf{V}^{1/2}(x)[\mathbf{M}_\alpha|\mathbf{V}|^{1/2}](x)\,dx.$$

Then we have that

$$\mathbf{R}_g=\frac{1}{2\alpha}\mathbf{S}-\frac{g}{2\alpha}\mathbf{T}(\alpha)+\mathrm{O}(g^2)$$

for small g.

(i) By assumption the matrix $\mathbf{S}$ has n negative eigenvalues, denoted by s_k. For simplicity we assume that the eigenvalues s_k are simple. The corresponding eigenvectors are denoted by $\mathbf{v}_k$. We apply the regular perturbation theory to the eigenvalue problem (5.5) and we find that

$$\mu_k(g,\alpha)=\frac{1}{2\alpha}s_k-\frac{g}{2\alpha}\langle \mathbf{v}_k,\mathbf{T}(\alpha)\mathbf{v}_k\rangle_{\mathbb{C}^2}+\mathrm{O}(g^2).$$

Define the matrix $\mathbf{T}_0$ as in (5.2) and

$$\mathbf{T}_1=\frac{1}{4}\int_{\mathbb{R}}\int_{\mathbb{R}}\mathbf{V}(x)|x-y|^2\mathbf{V}(y)\,dxdy.$$

Then we have that $\mathbf{T}(\alpha)=\mathbf{T}_0+\alpha\mathbf{T}_1+\mathrm{O}(\alpha^2)$. In this way we find that the eigenvalues associated with the eigenvalue problem (5.5) are

$$\mu_k(g,\alpha)=\frac{1}{2\alpha}s_k-\frac{g}{2\alpha}\langle\mathbf{v}_k,\mathbf{T}_0\mathbf{v}_k\rangle_{\mathbb{C}^2}+\mathrm{O}(g^2).$$

Together with the comments following the proof of Proposition 4.2, the latter implies that the solution to (4.7) is

$$\alpha_g=-\frac{g}{2}s_k+\frac{g^2}{2}\langle\mathbf{v}_k,\mathbf{T}_0\mathbf{v}_k\rangle_{\mathbb{C}^2}+\mathrm{O}(g^2). \tag{5.6}$$

Clearly, (5.6) implies that each negative eigenvalue s_k of $\mathbf{S}$ gives rise to precisely one negative eigenvalue $E_k(g)$ of $\mathbf{H}(g)$ obeying the asymptotic formula

$$(-E_k(g))^{1/2}=-\frac{g}{2}s_k+\frac{g^2}{2}\langle\mathbf{v}_k,\mathbf{T}_0\mathbf{v}_k\rangle_{\mathbb{C}^2}+\mathrm{O}(g^3).$$

(ii) We investigate the situation where zero is an eigenvalue of $\mathbf{S}$ (as above we restrict ourselves to the case where zero is simple). Let $\mathbf{S}\mathbf{v}_0=0$ for some $\mathbf{v}_0\neq 0$. Taylor's formula yields

$$\begin{aligned}\left\langle \mathbf{v}_0,\int_{\mathbb{R}}\int_{\mathbb{R}}\mathbf{V}(x)\frac{e^{-\alpha|x-y|}}{2\alpha}\mathbf{V}(y)\,dx\,dy\mathbf{v}_0\right\rangle_{\mathbb{C}^2}&\\ =\frac{1}{2\alpha}\langle\mathbf{v}_0,\mathbf{S}^2\mathbf{v}_0\rangle_{\mathbb{C}^2}-\frac{1}{2}\left\langle \mathbf{v}_0,\int_{\mathbb{R}}\int_{\mathbb{R}}\mathbf{V}(x)|x-y|\mathbf{V}(y)\,dx\,dy\mathbf{v}_0\right\rangle_{\mathbb{C}^2}&\\ +\alpha\left\langle \mathbf{v}_0,\int_{\mathbb{R}}\int_{\mathbb{R}}\mathbf{V}(x)O(|x-y|^2)\mathbf{V}(y)\,dx\,dy\mathbf{v}_0\right\rangle_{\mathbb{C}^2}.&\end{aligned}$$

Since $\mathbf{S}\mathbf{v}_0=0$ by assumption, the first term equals zero. As $\alpha\downarrow 0$, we obtain that

$$\begin{aligned}\langle\mathbf{v}_0,\mathbf{T}_0\mathbf{v}_0\rangle_{\mathbb{C}^2}&=\lim_{\alpha\downarrow 0}\left\langle \mathbf{v}_0,\int\int\mathbf{V}(x)\frac{e^{-\alpha|x-y|}}{2\alpha}\mathbf{V}(y)\,dxdy\,\mathbf{v}_0\right\rangle_{\mathbb{C}^2}\\ &=\lim_{\alpha\downarrow 0}\sum_{i,j,k}\int\int\frac{e^{-\alpha|x-y|}}{2\alpha}V_{ik}(x)V_{kj}(y)(\mathbf{v}_0)_i\overline{(\mathbf{v}_0)_j}\,dxdy.\end{aligned} \tag{5.7}$$

Let $\mathcal{F}$ denote the one-dimensional Fourier transform and let $(\mathcal{F}\mathbf{V})(\xi)$ denote the matrix with elements $(\mathcal{F}\mathbf{V})_{ij}(\xi)=(\mathcal{F}V_{ij})(\xi)$ satisfying $\mathcal{F}V_{ij}=\mathcal{F}V_{ji}$ because V is symmetric and V_{ij} are real-valued. Using the latter in conjunction with the Fourier transform of $(1/2\alpha)e^{-\alpha|x|}$, which equals $1/(\xi^2+\alpha^2)$, we find that

$$\begin{aligned}\text{rhs of (5.7)}&=\lim_{\alpha\downarrow 0}\sum_{i,j,k}\int\frac{1}{\xi^2+\alpha^2}(\mathcal{F}V_{ik})(\xi)\overline{(\mathcal{F}V_{kj})(\xi)}(\mathbf{v}_0)_i\overline{(\mathbf{v}_0)_j}\,d\xi\\ &=\int\frac{1}{\xi^2}\langle\mathbf{v}_0,(\mathcal{F}\mathbf{V})^*(\xi)(\mathcal{F}\mathbf{V})(\xi)\mathbf{v}_0\rangle_{\mathbb{C}^2}\,d\xi\\ &=\int\frac{1}{\xi^2}\|(\mathcal{F}\mathbf{V})(\xi)\mathbf{v}_0\|_{\mathbb{C}^2}^2\,d\xi\geqslant 0,\end{aligned} \tag{5.8}$$

By assumption, $\langle \mathbf{v}_0, \mathbf{T}_0 \mathbf{v}_0 \rangle_{\mathbb{C}^2} \neq 0$ and therefore (5.8) implies that there is also a negative eigenvalue of $\mathbf{H}(g)$ associated with the eigenvalue zero of $\mathbf{S}$. □

Remark 5.3: The reasoning in the proof of Theorem 5.2(ii) requires that the entries V_{ij} in the potential $\mathbf{V}$ are real-valued. A substantial improvement would be to establish the result for complex-valued entries.

Example 5.4 (Square-well potentials): Let $\chi_{[0,1]}$ denote the characteristic function associated with the interval $[0,1]$. Choose the following entries of **V:**

$$V_{11}(x) = -5\chi_{[0,1]}(x), \quad V_{22}(x) = -3\chi_{[0,1]}(x),$$

$$V_{12}(x) = V_{21}(x) = -3a\chi_{[0,1]}(x), \quad a > 0.$$

Then the matrix $\mathbf{S}$ equals

$$\mathbf{S} = \begin{pmatrix} -5 & -3a \\ -3a & -3 \end{pmatrix}$$

and it has two real eigenvalues given by $-4 \pm \sqrt{1+9a^2}$. Thus the following cases are possible: (1) If $a > \sqrt{\frac{5}{3}}$, there is exactly one negative eigenvalue of $\mathbf{S}$, namely $-4-\sqrt{1+9a^2}$. (2) If $a < \sqrt{\frac{5}{3}}$ there are two negative eigenvalues of $\mathbf{S}$, namely $-4 \pm \sqrt{1+9a^2}$. (3) If $a = \sqrt{\frac{5}{3}}$, there are two nonpositive eigenvalues of $\mathbf{S}$, namely $-4-\sqrt{1+9a^2}$ and 0.

2. Two-channel Hamiltonian with two thresholds

As an example of a Hamiltonian with more than one threshold, we consider the one in (1.1), having thresholds at 0 and 1. Henceforth, its free Hamiltonian is denoted by $\tilde{\mathbf{H}}_0$. The essential spectrum of $\tilde{\mathbf{H}}_0$ is the union of the half-axes starting at the thresholds, i.e., $\sigma_{\mathrm{ess}}(\tilde{\mathbf{H}}_0) = [0,\infty)$. The resolvent of $\tilde{\mathbf{H}}_0$ is given by

$$(\tilde{\mathbf{H}}_0 + \alpha^2)^{-1} = \begin{pmatrix} (-d^2/dx^2 + \alpha^2)^{-1} & 0 \\ 0 & (-d^2/dx^2 + \alpha^2 + 1)^{-1} \end{pmatrix}, \quad \alpha > 0,$$

where the entries have the integral kernels

$$\frac{1}{2\alpha} e^{-\alpha|x-y|} \quad \text{and} \quad \frac{1}{2\sqrt{\alpha^2+1}} e^{-\sqrt{\alpha^2+1}|x-y|}.$$

It is easy to show that the assertions of Proposition 3.1 are valid if one replaces $\mathbf{H}_0$ by $\tilde{\mathbf{H}}_0$. In this way we obtain a self-adjoint realization of the formal Hamiltonian $\tilde{\mathbf{H}}_0 + g\mathbf{V}$ in $L^2(\mathbb{R}, \mathbb{C}^2)$. Moreover, the Birman–Schwinger relation in Proposition 4.2 holds for $\tilde{\mathbf{H}}(g) = \tilde{\mathbf{H}}_0 + g\mathbf{V}$.

Define the operators $\tilde{\mathbf{L}}_\alpha$ and $\tilde{\mathbf{M}}_\alpha$ by their "kernels"

$$\tilde{\mathbf{L}}_\alpha(x,y) = \frac{1}{2\alpha} \mathbf{V}(x)^{1/2} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} |\mathbf{V}(y)|^{1/2},$$

$$\tilde{\mathbf{M}}_\alpha(x,y) = \mathbf{V}(x)^{1/2} \begin{pmatrix} \frac{1}{2\alpha}[e^{-\alpha|x-y|} - 1] & 0 \\ 0 & \frac{e^{-\sqrt{\alpha^2+1}|x-y|}}{2\sqrt{\alpha^2+1}} \end{pmatrix} |\mathbf{V}(y)|^{1/2}.$$

Moreover, we introduce the operator $\tilde{\mathbf{M}}_0$ by its kernel

$$\tilde{\mathbf{M}}_0(x,y)=\mathbf{V}(x)^{1/2}\begin{pmatrix} -\frac{1}{2}|x-y| & 0 \\ 0 & \frac{1}{2}e^{-|x-y|} \end{pmatrix}|\mathbf{V}(y)|^{1/2}.$$

By making a few obvious changes to the proof of Lemma 4.5 we obtain the following result.

Lemma 5.5: Assume that $\int_{\mathbb{R}}(1+|x|^2)\|\mathbf{V}(x)\|_{\mathcal{B}(\mathbb{C}^2)}\,dx<\infty$. *If* K_α, L_α, M_α *and* M_0 *in Lemma 4.5 are replaced by* $\tilde{\mathbf{K}}_\alpha$, $\tilde{\mathbf{L}}_\alpha$, $\tilde{\mathbf{M}}_\alpha$ *and* $\tilde{\mathbf{M}}_0$, *then the assertions (i)–(iii) of Lemma 4.5 are still valid.*

Define the matrices

$$\tilde{\mathbf{S}}=\begin{pmatrix} \int_{\mathbb{R}}V_{11}(x)\,dx & \int_{\mathbb{R}}V_{12}(x)\,dx \\ 0 & 0 \end{pmatrix}, \tag{5.9}$$

$$\tilde{\mathbf{T}}_0=\int_{\mathbb{R}}\int_{\mathbb{R}}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\mathbf{V}(x)\begin{pmatrix} -\frac{1}{2}|x-y| & 0 \\ 0 & \dfrac{e^{-|x-y|}}{2} \end{pmatrix}\mathbf{V}(y)\,dxdy. \tag{5.10}$$

For the Hamiltonian $\tilde{\mathbf{H}}(g)$ we are able to derive an analog of part (i) in Theorem 5.2.

Theorem 5.6: *Let* $\mathbf{V}$ *obey Assumption 5.1(a)–(c) and let* $\tilde{\mathbf{H}}(g)=\tilde{\mathbf{H}}_0+g\mathbf{V}(x)$ *be the self-adjoint Hamiltonian on* $L^2(\mathbb{R},\mathbb{C}^2)$ *defined in Proposition 3.1 by means of forms.*

Assume that the matrix $\tilde{\mathbf{S}}$, *defined in (5.9), has a negative eigenvalue* $\tilde{s}$ *(such an eigenvalue is simple if it exists). Then, for a small enough coupling constant* g, *the eigenvalue* $\tilde{s}$ *of* $\tilde{\mathbf{S}}$ *gives rise to exactly one negative eigenvalue* $\tilde{E}$ *of the two-channel Hamiltonian* $\tilde{\mathbf{H}}(g)$. *The negative eigenvalue* $\tilde{E}$ *satisfies the formula*

$$(-\tilde{E}(g))^{1/2}=-\frac{g}{2}\tilde{s}+\frac{g^2}{2}\langle\tilde{\mathbf{v}},\tilde{\mathbf{T}}_0\tilde{\mathbf{v}}\rangle_{\mathbb{C}^2}+O(g^3), \tag{5.11}$$

where $\tilde{\mathbf{T}}_0$ *is defined in (5.10) and* $\tilde{\mathbf{v}}$ *is the eigenvector corresponding to the eigenvalue* $\tilde{s}$ *of* $\tilde{\mathbf{S}}$.

Proof: Imitating the proof of Theorem 5.2 we arrive at the eigenvalue problem

$$\tilde{\mathbf{R}}_g\mathbf{u}_k=\mu_k(g,\alpha)\mathbf{u}_k, \tag{5.12}$$

where $\tilde{\mathbf{R}}_g$ is the matrix

$$\tilde{\mathbf{R}}_g=\frac{1}{2\alpha}\int_{\mathbb{R}}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\mathbf{V}^{1/2}(x)[(1+g\tilde{\mathbf{M}}_\alpha)^{-1}|\mathbf{V}|^{1/2}](x)\,dx.$$

Define the matrix $\tilde{\mathbf{S}}$ as in (5.9) and, moreover, define

$$\tilde{\mathbf{T}}(\alpha)=\int_{\mathbb{R}}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\mathbf{V}^{1/2}(x)[\tilde{\mathbf{M}}_\alpha|\mathbf{V}|^{1/2}](x)\,dx.$$

Then we may write

$$\tilde{\mathbf{R}}_g=\frac{1}{2\alpha}\tilde{\mathbf{S}}-\frac{g}{2\alpha}\tilde{\mathbf{T}}(\alpha)+\mathrm{O}(g^2)$$

for small g. From here on everything depends on the possible eigenvalues of $\tilde{\mathbf{S}}$. Let

$$a=\int_{\mathbb{R}} V_{11}(x)\,dx.$$

The following cases may occur: (I) If $a\neq 0$, then there are two subcases. (I.1) If $a>0$, then $\tilde{\mathbf{S}}$ has the eigenvalue zero and the positive eigenvalue a, each of multiplicity one. (I.2) If $a<0$, then $\tilde{\mathbf{S}}$ has the eigenvalue zero and the negative eigenvalue a, each having multiplicity one. (II) If $a=0$, then $\tilde{\mathbf{S}}$ has the eigenvalue zero with multiplicity one.

Repeating the reasoning in the first part of the proof of Theorem 5.2 we show that a negative eigenvalue of $\tilde{\mathbf{S}}$ [from (I.2) it has multiplicity one] generates exactly one negative eigenvalue of $\tilde{\mathbf{H}}(g)$ provided g is small enough. □

Remark 5.7: The matrix $\tilde{\mathbf{S}}$ always has the eigenvalue zero. It remains an open problem to settle whether or not the latter gives rise to a negative eigenvalue of $\tilde{\mathbf{H}}(g)$ for a sufficiently small g.

B. *N*-channel Hamiltonian with matrix-valued potentials

In this section we consider the case where the potential is a $N\times N$ matrix-valued potential $\mathbf{V}(x)$ with measurable functions V_{ij} on $\mathbb{R}$ as entries.

Assumption 5.8:

(a) $\mathbf{V}(x)$ is symmetric, i.e., $\overline{V_{ji}}=V_{ij}$.

(b)

$$\int_{\mathbb{R}}(1+|x|^2)\|V(x)\|_{\mathcal{B}(\mathbb{C}^N)}\;dx<\infty.$$

(c) The functions V_{ij} are real-valued.

Define the matrices $\mathbf{S}$ and $\mathbf{T}_0$ by

$$\mathbf{S}=\int_{\mathbb{R}}\mathbf{V}(x)\,dx,\quad \mathbf{T}_0=-\frac{1}{2}\int_{\mathbb{R}}\int_{\mathbb{R}}\mathbf{V}(x)|x-y|\mathbf{V}(y)\,dydx. \tag{5.13}$$

We have the following result.

Theorem 5.9: *Let* $\mathbf{V}$ *obey Assumption 5.8 (a) and (b) and let* $\mathbf{H}(g)=\mathbf{H}_0+g\mathbf{V}(x)$ *be the self-adjoint Hamiltonian on* $L^2(\mathbb{R},\mathbb{C}^2)$ *defined in Proposition 3.1 by means of forms.*

(i) Assume that the matrix $\mathbf{S}$*, defined in (5.13), has n negative eigenvalues, denoted by* s_i*, with multiplicities* $\varkappa_i$*. Then, for a small enough* g*, the N-channel Hamiltonian* $\mathbf{H}(g)$ *has precisely* $\Sigma_{i=1}^{n}\varkappa_i$ *negative eigenvalues (taking into account multiplicity)* E_{ij} *satisfying the formulas*

$$(-E_{ij}(g))^{1/2}=-\frac{g}{2}s_i+\frac{g^2}{2}\langle\mathbf{v}_{ij},\mathbf{T}_0\mathbf{v}_{ij}\rangle_{\mathbb{C}^N}+O(g^3), \tag{5.14}$$

$$i=1,\ldots,n,\quad j=1,\ldots,\varkappa_i,$$

where $\mathbf{T}_0$ *is defined in (5.13) and* $\mathbf{v}_{ij}$ *are the eigenvectors corresponding to the eigenvalue* s_i *of* $\mathbf{S}$.

(ii) Suppose that $\mathbf{V}$ *obey Assumption 5.8(c) and that the matrix* $\mathbf{S}$ *has n nonpositive eigenvalues, denoted by* s_i*, with multiplicities* $\varkappa_i$*. If the eigenvectors* $\mathbf{v}_{0j}$*,* $j=1,\ldots,\varkappa_i$*, associated with the eigenvalue zero of* $\mathbf{S}$ *satisfy* $\langle\mathbf{v}_{0j},\mathbf{T}_0\mathbf{v}_{0j}\rangle_{\mathbb{C}^N}\neq 0$*, then the conclusion of part (i) remains valid.*

Proof: The proof is a straightforward generalization of the proof of Theorem 5.2. □

Remark 5.10: One of the referees pointed out that Theorem 5.9 was proven in Šeba.[29] Therein, however, Theorem 3 is incorrect because the quantity $\int_{\mathbb{R}}(1/p^2)(\mathbf{a}_0,\mathcal{F}(V)^2(p)\mathbf{a}_0)_n\,dp$ (in Šeba's notation) is not necessarily different from zero. Moreover, the Birman–Schwinger relation (in the matrix-valued setting) is stated without proof.

VI. PERTURBATION OF EMBEDDED EIGENVALUES

For the sake of completeness we consider perturbation of two-channel diagonal Hamiltonians with one-dimensional Schrödinger operators as component Hamiltonians, having eigenvalues embedded in its continuous spectrum.

A. Two-channel Hamiltonians

Consider the formal expression

$$\mathbf{H}(g)=\mathbf{H}(0)+g\mathbf{V}=\begin{pmatrix} H_{11} & 0 \\ 0 & H_{22} \end{pmatrix}+g\begin{pmatrix} V_{11}(x) & V_{12}(x) \\ V_{21}(x) & V_{22}(x) \end{pmatrix} \tag{6.1}$$

in $\mathcal{H}=L^2(\mathbb{R})\oplus L^2(\mathbb{R})$, where

$$H_{11}=-\frac{d^2}{dx^2}+W_{11}(x) \quad \text{and} \quad H_{22}=-\frac{d^2}{dx^2}+1+W_{22}(x). \tag{6.2}$$

We impose the following assumptions on the potentials W_{jj}, $j=1,2$.

Assumption 6.1: Suppose that the real-valued, measurable functions W_{jj}, $j=1,2$, satisfy the following.

(a) $W_{jj}\neq 0$.

(b) The bound

$$|W_{jj}(x)|\leqslant C\,(1+|x|^2)^{-1-\delta} \tag{6.3}$$

holds for some $C,\delta>0$ and all x.

(c) $\int_{\mathbb{R}} W_{jj}(x)\,dx\leqslant 0$.

(d) W_{jj} extends to a function analytic in the sector

$$\mathcal{A}_{\alpha_0}=\{\,z\in\mathbb{C}:|\arg z|\leqslant\alpha_0\,\}$$

for some $\alpha_0>0$. Moreover, the bound (6.3) holds in this sector.

Under Assumption 6.1(a)–(c) the operator $H_{11}=-d^2/dx^2+W_{11}(x)$ is self-adjoint in $L^2(\mathbb{R})$ and $\sigma(H_{11})=\sigma_d(H_{11})\cup\sigma_{\text{ess}}(H_{11})=\sigma_d(H_{11})\cup[0,\infty)$ with a nonempty discrete spectrum $\mu_1<\mu_2<\cdots<\mu_N<0$, which is simple and finite.[31] The corresponding normalized eigenfunctions ϕ_n, $n=1,2,\ldots,N$, are exponentially decaying. The analyticity requirement in Assumption 6.1(d) is convenient to adopt for analyzing the resonance behavior. Similarly, the operator $H_{22}=-d^2/dx^2+1+W_{22}(x)$ is self-adjoint in $L^2(\mathbb{R})$ and $\sigma(H_{22})=\sigma_d(H_{22})\cup\sigma_{\text{ess}}(H_{22})=\sigma_d(H_{22})\cup[1,\infty)$ with a nonempty discrete spectrum $\nu_1<\nu_2<\cdots<\nu_M<1$ which is simple and finite. The corresponding normalized eigenfunctions χ_m, $m=1,2,\ldots,M$, are exponentially decaying.

Consider the unperturbed Hamiltonian $\mathbf{H}(0)=\text{diag}\,(H_{11},H_{22})$. Assumption 6.1 ensures that

$$\sigma_c(\mathbf{H}(0))=\sigma_{\text{ess}}(\mathbf{H}(0))=\sigma_{\text{ess}}(H_{11})\cup\sigma_{\text{ess}}(H_{22})=[0,\infty)\cup[1,\infty)=[0,\infty).$$

Thus, the continuous spectrum of $\mathbf{H}(0)$ is the union of the two halflines starting at 0 and 1. This motivates the definition of the threshold set $\mathsf{T}=\{0,1\}$. Furthermore, $\sigma_p(\mathbf{H}(0))=\sigma_p(H_{11})\cup\sigma_p(H_{22})$. Among this (finite) set of eigenvalues, a (finite) subset is isolated or situated at the threshold 0, while the rest satisfying the condition $0<\nu_m<1$ is embedded in the continuous spectrum of $\mathbf{H}(0)$. For the sake of simplicity we make the following assumption.

Assumption 6.2: Suppose that none of the embedded eigenvalues ν_m of $\mathbf{H}(0)$ coincide with the threshold 0.

We impose the following conditions on the components of the perturbation $\mathbf{V}$.

Assumption 6.3: Suppose that the real-valued, measurable functions V_{ij}, $i,j=1,2$, satisfy the following.

(a) The bound

$$|V_{ij}(x)| \leqslant C\,(1+|x|^2)^{-1-\delta} \tag{6.4}$$

holds for some $C,\delta>0$ and all x.

(b) V_{ij} extends to a function analytic in the sector $\mathcal{A}_{\alpha_0}$ [see Assumption 6.1(d)] for some $\alpha_0>0$. Moreover, the bound (6.4) holds in this sector.

B. Complex dilation

We use a complex deformation. For θ real define S_θ on $L^2(\mathbb{R})$ by the unitary operator

$$(S_\theta\psi)=e^{\theta/2}\psi(e^\theta x),\quad \psi\in L^2(\mathbb{R}). \tag{6.5}$$

S_θ is a one-parameter unitary group on $L^2(\mathbb{R})$. It is easy to see that S_θ leave $\mathcal{D}(-d^2/dx^2)=H^2(\mathbb{R})$ invariant and that

$$H_{11,\theta}:=S_\theta H_{11}S_\theta^{-1}=-e^{-2\theta}\frac{d^2}{dx^2}+W_{11,\theta}(x)=-e^{-2\theta}\frac{d^2}{dx^2}+W_{11}(e^\theta x).$$

Let $\mathcal{A}_0=\{\theta:|\mathrm{Im}\,\theta|\leqslant\min\{\alpha_0,\pi/4\}$ [cf. Assumption 6.1(d)]. Under Assumption 6.1, $H_{11,\theta}$ obviously has a continuation to a type (A) family of m-sectorial operators analytic in the sense of Kato[13] for $\theta\in\mathcal{A}_0$. Likewise,

$$H_{22,\theta}:=S_\theta H_{22}S_\theta^{-1}=-e^{-2\theta}\frac{d^2}{dx^2}+1+W_{22,\theta}(x)=-e^{-2\theta}\frac{d^2}{dx^2}+1+W_{22}(e^\theta x)$$

has a continuation to a type (A) analytic family of operators on $\mathcal{A}_0$. From standard Aguilar–Combes theory[1] we determine the spectra of $H_{11,\theta}$ and $H_{22,\theta}$:

$$\sigma(H_{11,\theta})=\{\mu_1,\mu_2,\ldots,\mu_N\}\cup\{e^{-2\theta}\lambda:\lambda\in[0,\infty)\},$$

$$\sigma(H_{22,\theta})=\{\nu_1,\nu_2,\ldots,\nu_M\}\cup\{e^{-2\theta}\lambda+1:\lambda\in[0,\infty)\}.$$

Having extended S_θ in (6.5) analytically to $\mathcal{A}_0$ we may define

$$\mathbf{S}_\theta\Psi=\begin{pmatrix}S_\theta & 0\\ 0 & S_\theta\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix},\quad \Psi\in\mathcal{H}.$$

Due to its diagonal structure, the Hamiltonian

$$\mathbf{H}_\theta(0):=\mathbf{S}_\theta\mathbf{H}(0)\mathbf{S}_\theta^{-1}=\begin{pmatrix}H_{11,\theta} & 0\\ 0 & H_{22,\theta}\end{pmatrix}$$

has a continuation to a type (A) analytic family of operators in the sector $\mathcal{A}_0$. Furthermore,

$$\sigma(\mathbf{H}_\theta(0))=\sigma(H_{11,\theta})\cup\sigma(H_{22,\theta})=\{\mu_1,\mu_2,\ldots,\mu_N\}\cup\{\nu_1,\nu_2,\ldots,\nu_M\}\cup\{e^{-2\theta}\lambda:\lambda\in[0,\infty)\}\cup\{e^{-2\theta}\lambda+1:\lambda\in[0,\infty)\}.$$

In particular, the eigenvalues embedded in $\sigma(\mathbf{H}(0))$ are discrete eigenvalues of $\mathbf{H}_\theta(0)$ for θ nonreal.

Henceforth E_0 denotes any of the embedded eigenvalues ν_m of $\mathbf{H}(0)$. Let $\mathbf{R}_0(\theta;\zeta)$ denote the resolvent of $\mathbf{H}_\theta(0)$. Since E_0 is an isolated eigenvalue of $\mathbf{H}_\theta(0)$, we may choose a contour Γ

around E_0 such that Γ belongs to the resolvent set of $\mathbf{H}_\theta(0)$ and E_0 is the only eigenvalue of $\mathbf{H}_\theta(0)$ contained inside of Γ. Moreover, let $\mathbf{P}_\theta$ denote the eigenprojection associated with the eigenvalue E_0 and put

$$\mathbf{S}_\theta^{(p)} := \frac{1}{2\pi i}\int_\Gamma \frac{\mathbf{R}_0(\theta;\zeta)}{(E_0-\zeta)^p}\,d\zeta, \quad p \geqslant 1. \tag{6.6}$$

Then $\mathbf{P}_\theta = -\mathbf{S}_\theta^{(0)}$ and $\hat{\mathbf{R}}_0(\theta;\zeta) := \mathbf{S}_\theta^{(1)}$ is the reduced resolvent of $\mathbf{H}_\theta(0)$ at the point ζ. Define

$$\mathbf{V}_\theta = \mathbf{S}_\theta \mathbf{V} \mathbf{S}_\theta^{-1} = \begin{pmatrix} V_{11,\theta} & V_{12,\theta} \\ V_{21,\theta} & V_{22,\theta} \end{pmatrix} \quad \text{with} \quad V_{ij,\theta}(x) = V_{ij}(e^\theta x).$$

Then we have the following result.

Lemma 6.4: Let Assumptions 6.1 and 6.3 hold. Let Γ *be the contour described above and let* $\mathbf{S}_\theta^{(p)}$ *be defined in (6.6).*

(i) If $\operatorname{Im}\theta \in (0,\alpha_0)$ *then there exists a constant* $C_\theta > 0$ *such that*

$$\max_{\zeta\in\Gamma} \|g\mathbf{V}_\theta \mathbf{R}(\theta;\zeta)\| \leqslant C_\theta |g|. \tag{6.7}$$

If ζ *is replaced by* $\zeta_0 = \min\{\mu_1,\nu_1\} - 1$, *then the constant in (6.7) is independent of* θ *and the estimate holds for all* $|\operatorname{Im}\theta| < \alpha_0$.

(ii) For $p \geqslant 0$ *there exists a constant* $C_\theta > 0$ *such that*

$$\|g\mathbf{V}_\theta \mathbf{S}_\theta^{(p)}\| \leqslant C_\theta \frac{|\Gamma|}{2\pi} \frac{|g|}{[\operatorname{dist}(E_0,\Gamma)]^p}.$$

Proof: The contour Γ is by assumption contained in the resolvent of $\mathbf{H}_\theta(0)$. Since $\mathbf{R}_0(\theta;\cdot)$ is bounded and continuous and Γ is compact, there exists a constant $\tilde{C}_\theta$ such that $\max_{\zeta\in\Gamma}\|\mathbf{R}_0(\theta;\zeta)\| \leqslant \tilde{C}_\theta$.

Thus, $\max_{\zeta\in\Gamma}\|\mathbf{V}_\theta \mathbf{R}_0(\theta;\zeta)\| \leqslant \tilde{C}_\theta C_{\mathbf{V}}$, where $C_{\mathbf{V}}$ denotes a bound on the norm of $\mathbf{V}_\theta$, which is independent of θ by Assumption 6.3(b). This shows the first claim. Moreover, ζ_0 is to the left of the numerical range $\Theta(\mathbf{H}_\theta(0))$ of $\mathbf{H}_\theta(0)$ at the unit distance. Hence $\|\mathbf{R}_0(\theta;\zeta_0)\| = 1/[\operatorname{dist}(\zeta_0,\Theta(\mathbf{H}_\theta(0)))] = 1$. Therefore the constant $\tilde{C}_\theta$ in the above estimate may be replaced by 1. This verifies (i). The assertion (ii) follows immediately. □

Hence, provided g is small enough, it follows from Lemma 6.4(i) that $g\mathbf{V}_\theta$ is $\mathbf{H}_\theta(0)$-compact. The latter, in conjunction with Ref. 27, Lemma 1, p. 16, implies that the perturbed operators $\mathbf{H}_\theta(g) = \mathbf{H}_\theta(0) + g\mathbf{V}_\theta$ are a type (A) analytic family of operators for $\theta \in \mathcal{A}_0$ and suitable small g. Since E_0 is an isolated, simple eigenvalue of $\mathbf{H}_\theta(0)$, the analyticity of $\mathbf{H}_\theta(g)$ allows us to apply regular perturbation theory. The next section is devoted to this task.

C. Perturbation series and Fermi's golden rule

Following Kato (Ref. 13, Secs. II.2 and VII.1) and using Lemma 6.4 we infer that $\mathbf{H}_\theta(g)$ has an eigenvalue near E_0 given by a convergent power series in g. The convergent series is given by

$$E(g) = E_0 + \sum_{j=1}^{\infty} E_j(g), \tag{6.8}$$

where

$$E_j(g) = \sum_{p_1+\cdots+p_j=j-1} \frac{(-1)^j}{j} \operatorname{tr} \prod_{i=1}^{j} g\mathbf{V}_\theta \mathbf{S}_\theta^{(p_i)}. \tag{6.9}$$

In view of Lemma 6.4(ii), we see that $E_j(g)=O(g^j)$.

Let us compute the lowest-order terms of the series (6.8). Since Rank $\mathbf{P}_\theta=1$, $\mathbf{P}_\theta$ can be represented as

$$\mathbf{P}_\theta=\left\langle \cdot,\begin{pmatrix}0\\ \chi_m^\theta\end{pmatrix}\right\rangle\begin{pmatrix}0\\ \chi_m^\theta\end{pmatrix}$$

with $\chi_m^\theta:=S_\theta\chi_m$, where χ_m is the eigenfunction associated with the eigenvalue E_0 of H_{22}. Indeed, $H_{22,\theta}=\chi_m^\theta=S_\theta H_{22}S_\theta^{-1}S_\theta\chi_m=E_0S_\theta\chi_m=E_0\chi_m^\theta$ and, consequently,

$$\mathbf{H}_\theta(0)\begin{pmatrix}0\\ \chi_m^\theta\end{pmatrix}=\begin{pmatrix}H_{11,\theta}&0\\ 0&H_{22,\theta}\end{pmatrix}\begin{pmatrix}0\\ \chi_m^\theta\end{pmatrix}=E_0\begin{pmatrix}0\\ \chi_m^\theta\end{pmatrix}.$$

We compute $E_1(g)$:

$$E_1(g)=\mathrm{tr}(g\mathbf{V}_\theta\mathbf{P}_\theta)=g\left\langle\begin{pmatrix}0\\ \chi_m^\theta\end{pmatrix},\ \mathbf{V}_\theta\begin{pmatrix}0\\ \chi_m^\theta\end{pmatrix}\right\rangle_{\mathcal{H}}=g\left\langle\begin{pmatrix}0\\ \chi_m\end{pmatrix},\mathbf{V}\begin{pmatrix}0\\ \chi_m\end{pmatrix}\right\rangle_{\mathcal{H}}=g\langle\chi_m,V_{22}\chi_m\rangle_{L^2(\mathbb{R})}. \tag{6.10}$$

We see that the first-order term is real and does not contribute to the resonance width. Next, we consider $E_2(g)$. According to (6.9),

$$E_2(g)=-g^2\mathrm{tr}\,(\mathbf{P}_0\mathbf{V}_\theta\hat{\mathbf{R}}_0(\theta;E_0-i0)\mathbf{V}_\theta\mathbf{P}_0).$$

Due to the standard constancy-in-θ argument (see, e.g., Ref. 27, pp. 55–56), we may take the limit $\mathrm{Im}\,\theta\to0$ and in this way we arrive at

$$\begin{aligned}E_2(g)&=-g^2\mathrm{tr}\,(\mathbf{P}_0\mathbf{V}\hat{\mathbf{R}}_0(0;E_0-i0)\mathbf{V}\mathbf{P}_0)\\&=-g^2\left\langle\begin{pmatrix}0\\ \chi_m\end{pmatrix},\ \mathbf{V}\hat{\mathbf{R}}_0(0;E_0-i0)\mathbf{V}\begin{pmatrix}0\\ \chi_m\end{pmatrix}\right\rangle_{\mathcal{H}}\\&=-g^2\langle\chi_m,V_{21}[(H_{11}-E_0+i0)^{-1}]\hat{}\,V_{12}\chi_m\rangle_{L^2}-g^2\langle\chi_m,V_{22}[(H_{22}-E_0+i0)^{-1}]\hat{}\,V_{22}\chi_m\rangle_{L^2}\\&=-g^2\langle V_{12}\chi_m,[(H_{11}-E_0+i0)^{-1}]\hat{}\,V_{12}\chi_m\rangle_{L^2}-g^2\langle V_{22}\chi_m,[(H_{22}-E_0+i0)^{-1}]\hat{}\,V_{22}\chi_m\rangle_{L^2},\end{aligned} \tag{6.11}$$

where the notation $[(H_{jj}-E_0+i0)^{-1}]\hat{}$ refers to the reduced resolvent of H_{jj}, $j=1,2$.

We restrict our focus to the imaginary part of $E_2(g)$, which determines the resonance width to leading order. For this purpose we introduce

$$R_k=((-d^2/dx^2+W_{kk}(x)-E_0+\mathfrak{t}_k-i0)^{-1})\hat{}\,,\quad k=1,2,$$

where $\mathfrak{t}_1=0$ and $\mathfrak{t}_2=1$ are the thresholds. Clearly,

$$\mathrm{Im}\,E_2(g)=-g^2\sum_{k=1}^{2}\langle V_{k2}\chi_m(\mathrm{Im}\,R_k)V_{k2}\chi_m\rangle_{L^2(\mathbb{R})}. \tag{6.12}$$

Now, for $E>0$, the resolvent equation yields that

$$\mathrm{Im}\,(-d^2/dx^2+W_{kk}(x)-E-i0)^{-1}=t_k(E+i0)^*\mathrm{Im}\,(-d^2/dx^2-E-i0)^{-1}t_k(E+i0), \tag{6.13}$$

where

$$t_k(\zeta)=[I+|W_{kk}|^{1/2}(-\partial_x^2-\zeta)^{-1}|W_{kk}|^{1/2}\mathrm{Sgn}\,(W_{kk})]^{-1}.$$

The quantities $t_k(E+i0)$ are well-defined in view of Assumption 6.1. Furthermore, again for $E>0$,

$$\mathrm{Im}\,(-d^2/dx^2-E-i0)^{-1}=\frac{\pi}{2\sqrt{E}}\sum_{\sigma=\pm}(\gamma_E^\sigma)^*\gamma_E^\sigma, \tag{6.14}$$

where $\gamma_E^\sigma: H^1\to\mathbb{C}$ is the trace operator which acts on the first Sobolev space $H^1(\mathbb{R})$ as follows (see, e.g., Ref. 18, Sec. IV.1),

$$\gamma_E^\sigma\phi:=\hat{\phi}(\sigma\sqrt{E}),\quad \sigma=\pm,\quad E>0.$$

Here, as usual, $\hat{\phi}$ denotes the Fourier transform of ϕ. Using (6.13) and (6.14) we can rewrite the expression (6.12) in the following way:

$$\begin{aligned}
\mathrm{Im}\,E_2(g)&=-g^2\sum_{k=1}^{2}\langle V_{k2}\chi_m,(\mathrm{Im}\,R_k)V_{k2}\chi_m\rangle_{L^2}\\
&=-g^2\sum_{k=1}^{2}\langle V_{k2}\chi_m,t_k(E_0-\mathfrak{t}_k+i0)^*\\
&\quad\times\mathrm{Im}\,(-d^2/dx^2-E_0+\mathfrak{t}_k-i0)^{-1}t_k(E_0-\mathfrak{t}_k+i0)V_{k2}\chi_m\rangle_{L^2}\\
&=-g^2\sum_{k=1}^{2}\langle t_k(E_0-\mathfrak{t}_k+i0)V_{k2}\chi_m,\mathrm{Im}\,(-d^2/dx^2-E_0+\mathfrak{t}_k-i0)^{-1}\\
&\quad\times t_k(E_0-\mathfrak{t}_k+i0)V_{k2}\chi_m\rangle_{L^2}\\
&=-g^2\sum_{k=1}^{2}\sum_{\sigma=\pm}\frac{\pi}{2\sqrt{E_0-\mathfrak{t}_k}}\langle\gamma^\sigma_{E_0-\mathfrak{t}_k}t_k(E_0-\mathfrak{t}_k+i0)V_{k2}\chi_m,\gamma^\sigma_{E_0-\mathfrak{t}_k}\\
&\quad\times t_k(E_0-\mathfrak{t}_k+i0)V_{k2}\chi_m\rangle_{\mathbb{C}}\\
&=-g^2\sum_{k=1}^{2}\sum_{\sigma=\pm}\frac{\pi}{2\sqrt{E_0-\mathfrak{t}_k}}|\gamma^\sigma_{E_0-\mathfrak{t}_k}t_k(E_0-\mathfrak{t}_k+i0)V_{k2}\chi_m|^2.
\end{aligned}\tag{6.15}$$

In this way we have established the following result.

Theorem 6.5: *Let Assumptions 6.1 and 6.3 hold. Let ν_m be a simple eigenvalue of the operator H_{22} defined in (6.2) giving rise to the eigenvalue $E_0=\nu_m$ embedded in the continuous spectrum of $\mathbf{H}(0)$. Let E_0 satisfy Assumption 6.2. For a small enough coupling constant g, the eigenvalue E_0 of $\mathbf{H}(0)$ turns into a resonance, i.e., $E_0\notin\sigma(\mathbf{H}(g))$. The coordinates of its corresponding pole is given by (6.9)–(6.11). In particular, Fermi's golden rule takes the explicit form (6.15).*

Remark 6.6: If Assumption 6.2 is not fulfilled, i.e., we have an eigenvalue of H_{22} at the threshold point 0 of the continuous spectrum of $\mathbf{H}(0)$, complex dilation breaks down. An insight into this problem was established in Ref. 12. For abstract Hamiltonians $\mathbf{H}(g)$ having the structure found in (6.1), it was shown that under small off-diagonal perturbations this eigenvalue never moves into the continuous spectrum.

(Received 13 August 2001; accepted 2 June 2002)

We show how the scattering-into-cones and flux-across-surfaces theorems in quantum mechanics have very intuitive pathwise probabilistic versions based on some results by Carlen about large time behavior of paths of Nelson's diffusions. The quantum mechanical results can then be recovered by taking expectations in our pathwise statements. © *2002 American Institute of Physics.*

I. INTRODUCTION

The problem of finding the basic mathematical relationships between theoretical previsions and experimental observable quantities has been, for a long time, an open problem in quantum theory of scattering.

In this direction there exists two relevant theorems. The first one is due to Dollard (1969) and states that the probability of asympotically observing the particle in some cone $C\subset\mathbb{R}^3$ with vertex in the scattering center is equal to the probability of finding its asymptotic momentum exactly in the same cone, i.e.,

$$\lim_{t\uparrow\infty}\int_C \mathrm{d}x|\psi_t(x)|^2=\lim_{t\uparrow\infty}\int_{C\cap B_R^c}\mathrm{d}x|\psi_t(x)|^2=\int_C \mathrm{d}k\,|\hat{\psi}_{\mathrm{out}}(k)|^2, \tag{1.1}$$

where B_R^c is the complement of B_R, the ball of radius R, $\hat{\psi}_{\mathrm{out}}$ denotes the Fourier transform of the outgoing state $\psi_{\mathrm{out}}:=\Omega_+^*\psi_0$, Ω_+ being the wave operator. It is well known that the differential cross section for the time-independent scattering theory can be derived from the right-hand side of (1.1). Nevertheless the importance of (1.1) is primarily conceptual since the probability of observation which it refers to is a time-asymptotic one.

Instead, in the usual experimental situation, the detector being sufficiently far away from the scattering center, one actually measures the probability that the particle crosses the active surface of the detector $C\cap S_R$ (S_R denoting the sphere of radius R) at some random time. The theorem which takes care of this experimental setting is the so-called flux-across-surfaces theorem. It was conjectured in 1975 by Combes, Newton, and Shtokhamer under the form of the following relation:

$$\lim_{R\uparrow\infty}\int_{t_0}^{+\infty}\mathrm{d}t\int_{C\cap S_R} d\sigma(x)\,J^{\psi_t}(x)\cdot n(x)=\int_C \mathrm{d}k|\hat{\psi}_{\mathrm{out}}(k)|^2, \tag{1.2}$$

where $J^{\psi_t}:=\mathrm{Im}\,\psi_t^*\nabla\psi_t$ is the quantum probability current density, n denotes the outward unit normal vector along $C\cap S_R$, and σ is the surface measure.

a)Electronic mail: andreap@uninsubria.it
b)Electronic mail: ugolini@mat.unimi.it

No rigorous proof of this conjecture was known until 1996 when Daumer, Dürr, Goldstein, and Zanghì proved the flux-across-surfaces theorem in the free case. Successively the result has been extended to the interacting case by Amrein and Zuleta (1997) and by Teufel, Dürr, and Münch-Berndl (1999) for short-range potentials, and by Amrein and Pearson (1997) for long-range potentials. The case with zero-energy resonances or eigenvalues has been treated by Dell'Antonio and Panati (2001) in and the case with a delta interaction by Panati and Teta (2000).

In view of our approach, the most interesting proof is the one given in Amrein and Pearson (1997). From such a paper one can extract the following clarifying scheme:

Integrating with respect to time the equation of continuity for quantum probability density

$$\frac{\partial}{\partial t}|\psi_t|^2+\nabla J^{\psi_t}=0 \tag{1.3}$$

and inserting the result into relation (1.1) given by Dollard's theorem one obtains

$$\int_C \mathrm{d}k|\hat{\psi}_{\mathrm{out}}(k)|^2=\int_{C\cap B_R^c}\mathrm{d}x|\psi_{t_0}(x)|^2-\lim_{t\uparrow\infty}\int_{t_0}^t \mathrm{d}s\int_{C\cap B_R^c}\mathrm{d}x\,\nabla J^{\psi_s}(x).$$

Then by taking the limit $R\uparrow\infty$ and by Gauss–Green divergence theorem one has

$$\int_C \mathrm{d}k|\hat{\psi}_{\mathrm{out}}(k)|^2=\lim_{R\uparrow\infty}\lim_{t\uparrow\infty}\int_{t_0}^t \mathrm{d}s\int_{(C\cap S_R)\cup(\partial C\cap B_R^c)}\mathrm{d}\sigma(x)\,n(x)\cdot J^{\psi_s}(x),$$

and so the flux-across-surfaces theorem is a consequence of the scattering-into-cones theorem plus the condition

$$\lim_{R\uparrow\infty}\lim_{t\uparrow\infty}\int_{t_0}^t \mathrm{d}s\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)\,n(x)\cdot J^{\psi_s}(x)=0, \tag{1.4}$$

i.e., the flux across the lateral boundary of the cone asymptotically vanishes.

In this paper we give a pathwise formulation of scattering-into-cones and flux-across-surfaces theorems following in some way the pathwise analog of the above-given analytic argument. This has the advantage of giving a pictorial view of the scattering behavior. In doing that we exploit the relevant results, obtained by Carlen (1985), about potential scattering in stochastic mechanics.

It is known that stochastic mechanics, introduced by Nelson in 1966 [see also Nelson (1967) and (1985)], allows a pathwise approach to quantum mechanics by providing a suitable class of diffusion processes. Indeed to a solution ψ_t of the Schrödinger equation there is associated a well-defined (see Theorem 1) diffusion process X_t solution of the stochastic differential equation

$$\mathrm{d}X_t=b(t,X_t)\mathrm{d}t+dB_t,$$

where B_t is a Brownian motion and the drift vector field $b_t(x)\equiv b(t,x)$ is given by

$$b_t=|\psi_t|^{-2}(\nabla|\psi_t|^2+J^{\psi_t}).$$

Moreover the probability density of the process X_t is given by $|\psi_t|^2$ and it satisfies the continuity (or Fokker–Planck) equation (1.3). In connection with the problem of potential scattering, Carlen studied the time evolution of the process $(1/t)\,X_t$ proving the following (see Theorem 3).

(1) The scattering diffusions (i.e., the ones associated with the scattering states of the corresponding Schrödinger equation) are such that the limit

$$\lim_{t\uparrow\infty}\frac{1}{t}X_t=p_+$$

exists almost surely.

(2) The random variable p_+ is square integrable and has the same distribution as does the quantum mechanical final momentum.

These facts imply that almost surely the diffusion paths are definitively inside or outside the cone C, a pathwise analog of (1.4). Then the following pathwise version of Dollard's theorem immediately follows:

$$\lim_{t\uparrow\infty}\chi_C(X_t)=\lim_{t\uparrow\infty}\chi_{C\cap B_R^c}(X_t)=\chi_C(p_+),$$

χ_D denoting the characteristic function of the set D; the usual quantum mechanical version is then obtained by taking expectations (see Theorems 4 and 5).

As regards the flux-across-surfaces theorem the situation is almost equally simple. If $N_{C\cap S_R}$ were finite, where

$$N_{C\cap S_R}:=N^+_{C\cap S_R}-N^-_{C\cap S_R},$$

$N^+_{C\cap S_R}(\gamma)$ [respectively, $N^-_{C\cap S_R}(\gamma)$] denoting the number of outward (respectively, inward) crossing by the path $t\mapsto\gamma(t)$ of $C\cap S_R$, then, again by (1) and (2) noted previously, one would obtain the following pathwise version of the flux-across-surfaces theorem:

$$\lim_{R\uparrow\infty}N_{C\cap S_R}=\chi_C(p_+). \tag{1.5}$$

Let us remark here that the relevance of $N_{C\cap S_R}$ for the flux-across-surfaces theorem was already pointed out (in the framework of Bohmian mechanics) in Daumer *et al.* (1997). The problem here is that almost surely the diffusion X_t intersects $C\cap S_R$ on a set of times that has no isolated point and is uncountable. Therefore the above-given definition of $N_{C\cap S_R}$ makes no sense in general. However, by a suitable redefinition of $N_{C\cap S_R}$ as the total mass of an almost surely compactly supported random distribution (see Sec. III for details), (1.5) can be made rigorous (see Theorem 6). After showing (see Theorem 7) how to explicitly compute, by using the continuity equation (1.3), the expectation of $N_{C\cap S_R}$ in terms of the quantum probability current density J^{ψ_t}, the flux-across-surfaces theorem then follows by taking expectation in (1.5) (see Theorem 9).

In our opinion these results show how the probabilistic approach we use is very fruitful and extremely intuitive from the physical point of view.

As regards the analytical hypotheses we impose, our proofs of the pathwise results need, beside the existence of the asymptotic velocity (see Hypotheses 3 and 4 in definition 2), the following condition on the quantum evolution:

$$\int_{t_0}^{+\infty}\frac{\mathrm{d}t}{t}\left\|\left(P-\frac{Q}{t}\right)\psi_t\right\|_{L^2}<+\infty,\quad t_0>0, \tag{1.6}$$

where $P\psi(x):=-i\nabla\psi(x)$ and $Q\psi(x)=x\phi(x)$ denote the usual momentum and position operators of quantum mechanics in Schrödinger representation. Let us remark that the original results by Carlen were obtained by requiring the existence and completeness of wave operators, which is a hypothesis stronger than our Hypotheses 3 and 4. It is not clear to us if our weaker hypotheses together with (1.6) in any case imply the existence and completeness of wave operators. Therefore it could be interesting to find examples (if any) of cases in which the pathwise scattering-into-cones and flux-across-surfaces theorems hold true notwithstanding there are no wave operators.

In order to obtain then the quantum mechanical results by taking expectations, (1.6) is still sufficient to get Dollard's theorem, whereas the flux-across-surfaces theorem requires that the property of paths being definitively always inside or outside cone C holds not only pathwise but in the mean, i.e, as we already know, (1.4) must be true. This condition is a consequence of

$$\int_{t_0}^{+\infty} \mathrm{d}t \, \| \theta(Q) \psi_t \|_{H^1} \left\| \left(P - \frac{Q}{t} \right) \psi_t \right\|_{H^1} < +\infty, \tag{1.7}$$

where $\theta \in C_b^2(\mathbb{R}^3;\mathbb{C})$, $\theta = 1$ on a neighborhood of $\partial C \cap B_R^c$ for some $R>0$, and $H^s(\mathbb{R}^3)$ denotes the Sobolev space of tempered distributions with a Fourier transform which is integrable with respect to the measure with density $(1+|x|^2)^s$.

Conditions (1.6) and (1.7) both follow from propagation estimates on ψ_t. This is a well-known topic in mathematical physics and much literature exists on them. Thus by using known results on time-decay of the solutions of the Schrödinger equation it is possible to deduce (1.6) and (1.7) from explicit conditions imposed on the initial state ψ_0 and on the potential V, which are the natural prescriptions for a physicist. In particular, beside some technical condition on the initial state ψ_0, (1.6) holds true with potential functions decaying at infinity like $\|x\|^{-\epsilon}$, $\epsilon>0$, whereas (1.7) requires potentials decaying faster that $\|x\|^{-2/3}$ (see Sec. V for more details). These conditions on ψ_0 and V also lead to the existence and completeness of (modified) wave operators.

Our probabilistic proof remains unchanged in the case of the presence either of a time-dependent potential or of a magnetic field, the only difference being, if A denotes the magnetic potential, the replacement of P by $P-A$ and of J^{ψ_t} by $J^{\psi_t} - |\psi_t|^2 A$. We plan to work out the details in a future work.

Finally let us remark that all our results hold true every time we can find a stochastic process X_t having $|\psi_t|^2$ as its density and for which Theorem 3 can be proven. By Theorem 1 we realized such a process as a Nelson diffusion, but this is not the only possible choice. Another one is given by Bohmian mechanics (see Durr, Goldstein, and Zanghì (1992) for a thorough introduction to the subject], where one considers the stochastic process $\tilde{X}_t$, solution of the ordinary differential equation $(\mathrm{d}/\mathrm{d}t)\, \tilde{X}_t = |\psi_t(\tilde{X}_t)|^{-2} J^{\psi_t}(\tilde{X}_t)$ with a random initial condition with density $|\psi_0|^2$. Also in this case, under the same hypotheses plus the technical condition $\psi_{t_0} \in C^\infty(\mathbb{R}^3)$ [the Bohmian analog of Theorem 1, see Berndl *et al.* (1995), needs more regularity], Theorem 3 holds true, the proof being essentially the same, and so all our results can be stated in a Bohmian context. We decided to work with Nelson's stochastic mechanics since it does not necessarily need the Schrödinger equation in its formulation. Indeed it can be derived either from a stochastic analog of Newton's law [see Nelson (1966, 1967)] or from a stochastic variational principle [see Guerra and Morato (1983); Nelson (1985)].

II. POTENTIAL SCATTERING IN STOCHASTIC MECHANICS

At first let us recall that, by Nelson's stochastic mechanics [see Nelson (1966, 1967, 1985)], it is possible to associate to a solution ψ_t of the Schrödinger equation a diffusion process which has $|\psi_t|^2$ as its density. More precisely one has the following [in Carlen (1984) V is a Rellich-class potential but the results obtained there can be extended to the more general potentials used here by proceeding as in Dell'Antonio and Posilicano (1991), Theorem 2.1]:

Theorem 1: *Let $V = V_1 + V_2$, with V_1 bounded from below and V_2 $(-\Delta)$-form-bounded with relative bound smaller than one. Let $H = -\frac{1}{2}\Delta + V$ be defined as a sum of quadratic forms, and let ψ_0 be a normalized state in its form domain $\mathcal{Q}(H) = H^1(\mathbb{R}^3) \cap \mathcal{Q}(V_1)$. If $\psi_t := e^{-itH}\psi_0$, then define*

$$b(t,x) := b_t(x), \quad b_t := |\psi_t|^{-2}(\nabla |\psi_t|^2 + J^{\psi_t}).$$

Consider the measurable space $(\Omega,\mathcal{F})$, with $\Omega = C([t_0,+\infty);\mathbb{R}^d)$, $t_0 \geqslant 0$, $\mathcal{F}$ the Borel σ-algebra, and let $(\Omega,\mathcal{F},\mathcal{F}_t,X_t)$ be the evaluation stochastic process $X_t(\gamma) := \gamma(t)$, with $\mathcal{F}_t = \sigma(X_s, t_0 \leqslant s \leqslant t)$ the natural filtration. Then there exists a unique Borel probability measure $\mathbb{P}$ on $(\Omega,\mathcal{F})$ such that:

(a) $(\Omega,\mathcal{F},\mathcal{F}_t,X_t,\mathbb{P})$ is a Markov process;
(b) the image of $\mathbb{P}$ under X_t has density $|\psi_t|^2$;

(c) $B_t := X_t - X_{t_0} - \int_{t_0}^t \mathrm{d}s\, b(s,X_s)$ *is a* $(\mathbb{P},\mathcal{F}_t)$*-Brownian motion, i.e.,* $\mathbb{P}$ *is a weak solution of the stochastic differential equation* $\mathrm{d}X_t = b(t,X_t)\,\mathrm{d}t + \mathrm{d}B_t$ with initial density $|\psi_{t_0}|^2$.

From now on we will assume $t_0 > 0$ and $d = 3$.

Definition 2: With the same notation and hypotheses as in Theorem 1, let us call the couple (ψ_0, V) *weakly admissible* if

Hypothesis 1: ψ_0 is in $\mathcal{H}_c$, the spectral subspace corresponding to the continuous spectrum of H.

Hypothesis 2:

$$\int_{t_0}^{+\infty} \frac{\mathrm{d}t}{t} \left\| \left(P - \frac{Q}{t} \right) \psi_t \right\|_{L^2} < +\infty.$$

Hypothesis 3: The asymptotic velocity exists in the following sense:

$$\forall\, g \in C_c^\infty(\mathbb{R}^3), \quad \text{w-}\lim_{t\uparrow\infty} \Pi_c\, e^{itH}\, g\left(\frac{Q}{t}\right) e^{-itH} \Pi_c = \Pi_c\, g(P_+)\, \Pi_c,$$

where w-lim means the limit in the weak operator norm topology, Π_c denotes the projection onto $\mathcal{H}_c$, and P_+ is a vector of commuting self-adjoint operators;

A weakly admissible couple (ψ_0, V) is then called *admissible* if:

Hypothesis 4: ψ_0 is in the spectral subspace corresponding to the absolutely continuous spectrum of P_+.

Remark: If the (modified) wave operators $\Omega_\pm$ exist and are complete then

$$P_+ \Pi_c = \Omega_+ P \Omega_+^* \Pi_c$$

and, given $\psi_0 \in \mathcal{H}_c$,

$$\langle \psi_0, \chi_A(P_+)\psi_0 \rangle = \langle \psi_0, \Omega_+ \chi_A(P) \Omega_+^* \psi_0 \rangle = \int_A |\hat{\psi}_{\text{out}}(k)|^2\, \mathrm{d}k.$$

Thus in this case Hypothesis 4 holds true for all $\psi_0 \in \mathcal{H}_c$. Therefore Hypothesis 3 and 4 can be interpreted as a weaker substitute for existence and completeness of wave operators.

For explicit conditions on ψ_0 and V ensuring admissibility the reader is referred to Sec. V.

The above-given definitions permit us to extend (with the same proof) Carlen's results [see Carlen (1985), the free case $V = 0$ was already studied in Shucker (1980)] to the case where the hypothesis of existence of the wave operators is replaced by the weaker Hypothesis 3.

Theorem 3: *Let* (ψ_0, V) *be weakly admissible and let* $(\Omega, \mathcal{F}, \mathcal{F}_t, X_t, \mathbb{P})$ *be as in Theorem 1. Then*

$$\lim_{t\uparrow\infty} \frac{1}{t} X_t = p_+, \quad \mathbb{P}\text{-a.s.}, \tag{2.1}$$

for some random variable p_+. *Moreover* p_+ *is* $\mathbb{P}$*-square integrable and it has, under* $\mathbb{P}$*, the same distribution as does the quantum mechanical final momentum* P_+*, i.e., for every Borel set A one has*

$$\mathbb{E}(\chi_A(p_+)) = \langle \psi_0, \chi_A(P_+)\psi_0 \rangle,$$

where $\mathbb{E}$ *denotes expectation with respect to* $\mathbb{P}$.

Proof: The existence of the limit $\lim_{t\uparrow\infty}(1/t)\, X_t$ is proven in Carlen (1985), lemma 1. For the convenience of the reader we reproduce here the main steps of such a proof. Defining the stochastic process $\pi_t := (1/t)\, X_t$, one has the following stochastic differential equation:

$$\mathrm{d}\pi_t=\frac{1}{t}(b(t,X_t)-\pi_t)\,\mathrm{d}t+\frac{1}{t}\mathrm{d}B_t\,.$$

This implies

$$\mathbb{P}\left(\sup_{t>T}\|\pi_t-\pi_T\|>\epsilon\right)\leqslant\mathbb{P}\left(\int_T^{+\infty}\frac{\mathrm{d}t}{t}\|(b(t,X_t)-\pi_t)\|>\epsilon\right)+\mathbb{P}\left(\sup_{t>T}\left\|\int_T^t\frac{1}{t}\mathrm{d}B_t\right\|>\epsilon\right).$$

By Doob's martingale maximal inequality and the Chebychev inequality the second term on the right-hand side can be estimated by $2\epsilon^{-2}T^{-1}$. As regards the first term, by the definition of b one has

$$\begin{aligned}\mathbb{P}\left(\int_T^{+\infty}\frac{1}{t}\|(b(t,X_t)-\pi_t)\|\mathrm{d}t>\epsilon\right)&\leqslant\frac{1}{\epsilon}\int_T^{+\infty}\frac{1}{t}\mathbb{E}(\|(b(t,X_t)-\pi_t)\|)\,\mathrm{d}t\\&\leqslant\frac{1}{\epsilon}\int_T^{+\infty}\frac{1}{t}\mathbb{E}(\|(b(t,X_t)-\pi_t)\|^2)^{1/2}\,\mathrm{d}t\\&\leqslant\frac{\sqrt{2}}{\epsilon}\int_T^{+\infty}\left\|\left(-P-\frac{Q}{t}\right)\psi_t\right\|_{L^2}\frac{\mathrm{d}t}{t}.\end{aligned}$$

The above-given estimates and Hypothesis 2 say that we can find a T_n large enough that

$$\mathbb{P}\left(\bigcup_{s,t>T_n}\left\{\left\|\pi_t-\pi_s\right\|>\frac{1}{n}\right\}\right)<\frac{1}{2^n}.$$

Then, by the Borel–Cantelli lemma, one has

$$\mathbb{P}\left(\bigcap_{m=1}^{\infty}\bigcap_{n>m}\bigcup_{s,t>T_n}\left\{\left\|\pi_t-\pi_s\right\|>\frac{1}{n}\right\}\right)=0,$$

which exactly means that $\lim_{t\uparrow\infty}\pi_t$ exists $\mathbb{P}$-a.s.

By a density argument p_+ has the same distribution as does the quantum mechanical final momentum P_+ if $\mathbb{E}(g(p_+))=\langle\psi_0,g(P_+)\psi_0\rangle$ for all $g\in C_c^\infty(\mathbb{R}^3)$. By Hypothesis 3 there follows

$$\mathbb{E}(g(p_+))=\lim_{t\uparrow\infty}\mathbb{E}(g(\pi_t))=\lim_{t\uparrow\infty}\langle\psi_t,g(Q/t)\psi_t\rangle=\langle\psi_0,g(P_+)\psi_0\rangle,$$

and the proof is done. □

Remark: The proof of the above-given theorem shows that

$$\text{Hypothesis } 2\Rightarrow\frac{1}{t}X_t\to p_+ \quad \text{almost surely,}$$

$$\text{Hypothesis } 3\Leftrightarrow\frac{1}{t}X_t\to p_+ \quad \text{in distribution.}$$

Remark: Under the stronger Hypothesis 2.1

$$\int_{t_0}^{+\infty}\left\|\left(P-\frac{Q}{t}\right)\psi_t\right\|_{L^2}^2\mathrm{d}t<+\infty$$

it is possible to prove [see Carlen (1986)] that the random variable p_+ generates the tail σ-algebra

$$\mathcal{T}:=\bigcap_{t>t_0}\sigma(X_s,\ s\geqslant t).$$

This is the probabilistic analog of the fact that in quantum mechanics the only scattering observables are functions of the final momentum P_+. However we will not need such a nice result here.

Under Hypothesis 2.1, according to Carlen (1986), the proof of Theorem 3 becomes simpler:

Let $\widetilde{\mathbb{P}}$ be the weak solution of the simple stochastic differential equation

$$\mathrm{d}X_t=\frac{1}{t}X_t\,\mathrm{d}t+\mathrm{d}\widetilde{B}_t.$$

Therefore

$$\mathrm{d}\left(\frac{1}{t}X_t\right)=-\frac{1}{t^2}X_t\,\mathrm{d}t+\frac{1}{t}\mathrm{d}X_t=\frac{1}{t}\widetilde{B}_t$$

and so

$$\frac{1}{t}X_t=\frac{1}{t_0}X_{t_0}+\int_{t_0}^{t}\frac{1}{s}\mathrm{d}\widetilde{B}_s.$$

Since

$$\widetilde{\mathbb{E}}\left(\int_{t_0}^{+\infty}\frac{1}{s}\mathrm{d}\widetilde{B}_s\right)^2=\int_{t_0}^{+\infty}\frac{\mathrm{d}s}{s^2}<+\infty,$$

by Doob's martingale convergence theorem one gets $\widetilde{\mathbb{P}}$-a.s. convergence of $(1/t)\ X_t$. Thus the proof of Theorem 3 is then concluded by observing that Hypothesis 2.1 implies

$$\mathbb{E}\left(\int_{t_0}^{+\infty}\mathrm{d}t\|b(t,X_t)-X_t/t\|^2\right)<+\infty$$

and so, by Ershov (1972)—Proposition 2.11, $\mathbb{P}$ is absolutely continuous with respect to $\widetilde{\mathbb{P}}$.

III. THE PATHWISE SCATTERING-INTO-CONES AND FLUX-ACROSS-SURFACES THEOREMS

From now on by an open cone C we will mean a set of the kind

$$\{\lambda x\in\mathbb{R}^3\ :\ x\in\Sigma,\ \lambda>0\},$$

where Σ is an open subset of the unit sphere with $\partial\Sigma$ a finite union of C^1 manifolds.

In the framework of stochastic mechanics, thanks to Theorem 3, the pathwise version of Dollard's scattering-into-cones theorem [see Dollard (1969)] is obvious:

Theorem 4: *Let (ψ_0,V) be admissible and let $(\Omega,\mathcal{F},\mathcal{F}_t,X_t,\mathbb{P})$ be as in Theorem 1. Then for every open cone C and for every ball B_R of radius R one has*

$$\lim_{t\uparrow\infty}\chi_{C\cap B_R^c}(X_t)=\lim_{t\uparrow\infty}\chi_C(X_t)=\chi_C(p_+),\quad \mathbb{P}\text{-a.s.}$$

Proof: By Theorem 3 and Hypothesis 4 $p_+\notin\partial C$, $\mathbb{P}$-a.s.. Thus by (2.1) X_t is $\mathbb{P}$-a.s. definitively either in C or in $\overline{C}^c$ for every open cone C. Moreover, by (2.1) again, being $p_+\neq 0$ $\mathbb{P}$-a.s. by Hypothesis 4, we have

$$\lim_{t\uparrow\infty}\|X_t\|=+\infty,\quad \mathbb{P}\text{-a.s.} \tag{3.1}$$

Therefore

$$\lim_{t\uparrow\infty}\chi_{C\cap B_R^c}(X_t)=\lim_{t\uparrow\infty}\chi_C(X_t)=\lim_{t\uparrow\infty}\chi_C\left(\frac{1}{t}X_t\right)=\chi_C(p_+),\quad \mathbb{P}\text{-a.s.}$$

□

Let us now come to the flux-across-surfaces theorem.
We would like to define the function

$$N_{C\cap S_R}(\gamma):=N^+_{C\cap S_R}(\gamma)-N^-_{C\cap S_R}(\gamma),$$

where $N^+_{C\cap S_R}(\gamma)$ [respectively, $N^-_{C\cap S_R}(\gamma)$] denotes the number of outward (respectively, inward) crossing by $[t_0,+\infty)\ni t\mapsto\gamma(t)$ of $C\cap S_R$, the intersection of the cone C with S_R, the sphere of radius R. The problem is that the above-given definition makes no sense since $\mathbb{P}$-a.s. the set $\{t:X_t\in C\cap S_R\}$ has no isolated point and is uncountable. Therefore we are forced to proceed in an alternative way:

Let us observe that if $\#\{t:\gamma(t)\in C\cap S_R\}<+\infty$ then $N_{C\cap S_R}(\gamma)$ is the total mass of the random distribution

$$\sum_{t\in\{s:\gamma(s)\in C\cap S_R\}}c(t)\,\delta_t,$$

where $c(t)=+1$ if t corresponds to an outward crossing and $c(t)=-1$ if t corresponds to an inward crossing. Since $t\mapsto\gamma(t)$ is definitively either in C or in $\overline{C^c}$ by Hypothesis 4 and (2.1), if R is sufficiently large (then we will consider the limit $R\uparrow\infty$) one has

$$\sum_{t\in\{s:\gamma(s)\in C\cap S_R\}}c(t)\,\delta_t=\sum_{t\in\{s:\gamma(s)\in(C\cap S_R)\cup(\partial C\cap B_R^c)\}}c(t)\,\delta_t=\frac{\mathrm{d}}{\mathrm{d}t}\chi_{C\cap\overline{B_R^c}}(\gamma(t)),$$

where the derivative has to be intended in distributional sense. The advantage of this rewriting is that for every path γ the distribution $(\mathrm{d}/\mathrm{d}t)\chi_{C\cap\overline{B_R^c}}(\gamma(t))$ is well defined.

Definition: Given an open domain D, we define the random distribution

$$\mu_D:\Omega\to\mathcal{D}'(\mathbb{R})$$

by

$$\mu_D(\gamma):=\frac{\mathrm{d}}{\mathrm{d}t}\chi_D(\tilde\gamma(t)),\quad \tilde\gamma(t):=\begin{cases}\gamma(t) & \text{for } t\geqslant t_0\\ \gamma(t_0) & \text{for } t<t_0,\end{cases}$$

i.e., for every test function $\phi\in\mathcal{D}(\mathbb{R})\equiv C_c^\infty(\mathbb{R})$,

$$\langle\mu_D(\gamma),\phi\rangle:=-\chi_D(\gamma(t_0))\,\phi(t_0)-\int_{t_0}^{+\infty}\mathrm{d}t\,\chi_D(\gamma(t))\,\dot\phi(t).$$

Note that $\mathrm{supp}[\mu_D(\gamma)]=\gamma^{-1}(\partial D)$. In the case $\mu_D(\gamma)\in\mathcal{E}'(\mathbb{R})$, i.e., it has compact support, we define as usual its mass by

$$M_D(\gamma):=\langle\mu_D(\gamma),\phi_\gamma\rangle,$$

where ϕ_γ is a test function such that $\phi_\gamma=1$ on a neighborhood of $\mathrm{supp}[\mu_D(\gamma)]$.

By the previous definition and by Theorem 3 we then have the following pathwise version of the flux-across-surfaces theorem:

Theorem 5: *Let* (ψ_0,V) *be admissible and let* $(\Omega,\mathcal{F},\mathcal{F}_t,X_t,\mathbb{P})$ *be as in Theorem 1. Then*

$$\mu_{C\cap\overline{B_R^c}}\in\mathcal{E}'(\mathbb{R}),\quad \mathbb{P}\text{-}a.s.$$

and, defining $N_{C\cap S_R}:=M_{C\cap\overline{B_R^c}}$, *one has*

$$\lim_{R\uparrow\infty} N_{C\cap S_R}=\chi_C(p_+),\quad \mathbb{P}\text{-}a.s.$$

Proof: Let

$$\tau_R(\gamma):=\sup\{t\in\mathbb{R}:X_t(\gamma)\in\partial(C\cap\overline{B_R^c})\}.$$

By (3.1) and since X_t is $\mathbb{P}$-a.s. definitively either in C or in $\overline{C^c}$ by Hypothesis 4 and Theorem 3, one has $\tau_R<+\infty$, $\mathbb{P}$-a.s. Thus $\mu_{C\cap\overline{B_R^c}}\in\mathcal{E}'(\mathbb{R})$, $\mathbb{P}$-$a.s.$, being $\mathrm{supp}[\mu_{C\cap\overline{B_R^c}}]\subseteq[t_0,\tau_R(\gamma)]$.

Let $\phi_\gamma\in\mathcal{D}(\mathbb{R})$ such that $\phi_\gamma=1$ on a neighborhood of $[t_0,\tau_R(\gamma)]$. By the definition of $\mu_{C\cap\overline{B_R^c}}$ one has

$$\begin{aligned}\langle\mu_{C\cap\overline{B_R^c}}(\gamma),\phi_\gamma\rangle&=-\chi_{C\cap\overline{B_R^c}}(\gamma(t_0))-\chi_C(p_+(\gamma))\int_{\tau_R(\gamma)}^{+\infty}\mathrm{d}t\,\dot\phi_\gamma(t)\\&=-\chi_{C\cap\overline{B_R^c}}(\gamma(t_0))+\chi_C(p_+(\gamma)),\end{aligned}$$

and the thesis then immediately follows by taking the limit $R\uparrow\infty$. □

IV. THE SCATTERING-INTO-CONES AND FLUX-ACROSS-SURFACES THEOREMS IN QUANTUM MECHANICS

By taking expectations in Theorem 4 and by dominated convergence theorem one immediately obtains Dollard's theorem:

Theorem 6: *For every open cone* C, *every ball* B_R *of radius* R, *and for every admissible couple* (ψ_0,V), *one has*

$$\lim_{t\uparrow\infty}\int_{C\cap B_R^c}\mathrm{d}x|\psi_t(x)|^2=\lim_{t\uparrow\infty}\int_C\mathrm{d}x|\psi_t(x)|^2=\langle\psi_0,\chi_C(P_+)\psi_0\rangle.$$

In order to prove the flux-across-surfaces theorem we need now to compute the expectation of $\mu_{C\cap\overline{B_R^c}}$. To this end we state the following:

Theorem 7: *Let* ψ_t *and* $\mathbb{P}$ *be as in Theorem 1, with* $\psi_0\in H^2(\mathbb{R}^3)$ *and* V *a* $(-\Delta)$*-operator-bounded potential, with relative bound smaller than one. For every open domain* D, *with* ∂D *a finite union of* C^1 *manifolds, and for every test function* ϕ *one has*

$$\mathbb{E}(\langle\mu_D,\phi\rangle)=-\int_{t_0}^{+\infty}\mathrm{d}t\,\phi(t)\int_{\partial D}\mathrm{d}\sigma(x)\,J^{\psi_t}(x)\cdot n(x),$$

where n *denotes the outward unit normal vector along* ∂D *and* σ *is the surface measure.*

Proof: Since $|\psi_t|^2$ is the density of X_t under $\mathbb{P}$,

$$\mathbb{E}\langle\mu_D,\phi\rangle=-\phi(t_0)\int_D\mathrm{d}x|\psi_{t_0}(x)|^2-\int_{t_0}^{+\infty}\mathrm{d}t\,\dot\phi(t)\int_D\mathrm{d}x|\psi(t,x)|^2.$$

Since ψ_t solves the Schrödinger equation, one has [see, e.g., Carlen (1984)] for all $f \in C_b^1(\mathbb{R}^3)$ and for a.e. t, the continuity equation

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbb{R}^3} \mathrm{d}x\, |\psi_t(x)|^2 f(x) = \int_{\mathbb{R}^3} \mathrm{d}x\, J^{\psi_t}(x)\cdot \nabla f(x).$$

Since $\psi_t \in H^2(\mathbb{R}^3)$ by our hypotheses on ψ_0 and V, ∇J^{ψ_t} is an integrable function. Therefore one has, integrating by parts, for all $f \in C_b^1(\mathbb{R}^3)$,

$$\int_{t_0}^{+\infty} \mathrm{d}t\, \dot{\phi}(t) \int_{\mathbb{R}^3} \mathrm{d}x\, |\psi_t(x)|^2 f(x) = -\phi(t_0)\int_{\mathbb{R}^3} \mathrm{d}x\, |\psi_{t_0}(x)|^2 f(x) + \int_{t_0}^{+\infty} \mathrm{d}t\, \phi(t) \int_{\mathbb{R}^3} \mathrm{d}x\, \nabla J^{\psi_t}(x) f(x).$$

Taking now a uniformly bounded sequence $\{f_n\}_1^\infty \subset C_b^1(\mathbb{R}^3)$, pointwise converging to χ_D, by the dominated convergence theorem one obtains

$$\int_{t_0}^{+\infty} \mathrm{d}t\, \dot{\phi}(t) \int_{D} \mathrm{d}x\, |\psi_t(x)|^2 = -\phi(t_0)\int_{D} \mathrm{d}x\, |\psi_{t_0}(x)|^2 + \int_{t_0}^{+\infty} \mathrm{d}t\, \phi(t) \int_{D} \mathrm{d}x\, \nabla J^{\psi_t}(x).$$

Since $\psi_t \in H^2(\mathbb{R}^3)$, one has $\nabla \psi_t \in H^1(\mathbb{R}^3)$, so that both ψ_t and $\nabla \psi_t$ have traces in $L^2(\partial D)$ [see, e.g., Burenkov (1998)]. Thus J^{ψ_t} has a trace in $L^1(\partial D)$ by

$$\|J^{\psi_t}\|_{L^1(\partial D)} \leqslant \|\psi_t\|_{L^2(\partial D)} \|\nabla \psi_t\|_{L^2(\partial D)} \leqslant c\, \|\psi_t\|_{H^1(D)} \|\nabla \psi_t\|_{H^1(D)},$$

and the proof is then concluded by the Gauss–Green theorem. □

Definition 8: The admissible couple (ψ_0, V) is said to be *strongly admissible* if

Hypothesis 5: $\psi_0 \in H^2(\mathbb{R}^3)$, V is a $(-\Delta)$-operator-bounded potential and

$$\int_{t_0}^{\infty} \mathrm{d}t \| \theta(Q)\psi_t\|_{H^1} \left\| \left(P - \frac{Q}{t} \right) \psi_t \right\|_{H^1} < +\infty$$

where $\theta \in C_b^2(\mathbb{R}^3;\mathbb{C})$ such that $\theta = 1$ on a neighborhood of $\partial C \cap B_R^c$ for some $R > 0$.

In the next section we will give explicit conditions on ψ_0 and V ensuring strong admissibility.

By combining Theorems 5 and 7 the flux-across-surfaces theorem now follows:

Theorem 9: *For every open cone C and for every strongly admissible couple (ψ_0, V) one has*

$$\lim_{R\uparrow\infty} \lim_{T\uparrow\infty} \int_{t_0}^{T} \mathrm{d}t \int_{C\cap S_R} \mathrm{d}\sigma(x)\, J^{\psi_t}(x)\cdot n(x) = \langle \psi_0, \chi_C(P_+)\psi_0 \rangle.$$

Proof: By pointwise approximating, on the compact interval $[t_0, \tau_R(\gamma)]$, $t \mapsto \gamma(t)$ with a sequence of polynomials paths, the wildly oscillating function $t \mapsto \chi_{C\cap \overline{B}_R^c}(\gamma(t))$ can be pointwise approximated with a sequence $\{\chi_n\}_1^\infty$ of characteristic functions of finite unions $\cup_{k=0}^{m(n)} [s_k^{(n)}, t_k^{(n)}]$ of disjoint intervals. Therefore one obtains

$$\begin{aligned} |\langle \mu_{C\cap \overline{B}_R^c}(\gamma), \phi \rangle| &\leqslant \chi_{C\cap \overline{B}_R^c}(\gamma(t_0))\, |\phi(t_0)| + \lim_{n\uparrow\infty} \sum_{k=0}^{m(n)} \left| \int_{s_k^{(n)}}^{t_k^{(n)}} \mathrm{d}t\, \dot{\phi}(t) \right| \\ &= \chi_{C\cap \overline{B}_R^c}(\gamma(t_0))\, |\phi(t_0)| + \lim_{n\uparrow\infty} \sum_{k=0}^{m(n)} |\phi(t_k^{(n)}) - \phi(s_k^{(n)})| \\ &\leqslant \chi_{C\cap \overline{B}_R^c}(\gamma(t_0))\, |\phi(t_0)| + \mathrm{var}(\phi). \end{aligned}$$

Now let us note that in Theorem 5 we can alternatively define $N_{C\cap S_R}$ by

$$N_{C\cap S_R}(\gamma) := \lim_{n\uparrow\infty}\lim_{m\uparrow\infty}\langle \mu_{C\cap B_R^c}(\gamma), \phi_{n,m}\rangle,$$

where $\{\phi_{n,m}\}_{n,m\geqslant 1}$ is a double sequence of test functions such that $\phi_{n,m}=1$ on $[t_0,n]$, $\phi_{n,m}\to\chi_{[t_0,n]}$ pointwise. Then if we choose such test functions $\phi_{n,m}$ in such a way that their variation is bounded uniformly in n and m, by the dominated convergence theorem and by Theorem 5 one has

$$\begin{aligned}\langle \psi_0, \chi_C(P_+)\psi_0\rangle &= \mathbb{E}(\chi_C(p_+))\\ &= \lim_{R\uparrow\infty}\lim_{n\uparrow\infty}\lim_{m\uparrow\infty}\mathbb{E}(\langle \mu_{C\cap B_R^c}, \phi_{n,m}\rangle)\\ &= \lim_{R\uparrow\infty}\lim_{n\uparrow\infty}\int_{t_0}^{n}\mathrm{d}t\int_{(C\cap S_R)\cup(\partial C\cap B_R^c)}\mathrm{d}\sigma(x)\, J^{\psi_t}(x)\cdot n(x).\end{aligned}$$

The proof is then conlcuded by proving that

$$\lim_{R\uparrow\infty}\lim_{n\uparrow\infty}\int_{t_0}^{n}\mathrm{d}t\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)\, J^{\psi_t}(x)\cdot n(x)=0. \tag{4.1}$$

Since $n\cdot x=0$ on ∂C and $\|J^{\psi_t}\|\leqslant\|\psi_t^*\nabla\psi_t\|=\|\psi_t P\psi_t\|$, one has

$$\begin{aligned}\left|\int_{t_1}^{n}\mathrm{d}t\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x) J^{\psi_t}(x)\cdot n(x)\right| &\leqslant \int_{t_1}^{n}\mathrm{d}t\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)\,\|\psi_t(x)P\psi_t(x)\|\\ &= \int_{t_1}^{n}\mathrm{d}t\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)\left\|\psi_t(x)\left(P-\frac{Q}{t}\right)\psi_t(x)\right\|.\end{aligned}$$

Thus, since $\psi_t P\psi_t\in L^1(\partial C)$, by the monotone convergence theorem, (4.1) follows from

$$\int_{t_0}^{\infty}\mathrm{d}t\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)\left\|\psi_t(x)\left(P-\frac{Q}{t}\right)\psi_t(x)\right\|<+\infty \tag{4.2}$$

for some $R>0$. By trace estimates on functions in $H^1(\mathbb{R}^3)$ of the kind

$$\|\cdot\|_{L^2(\partial C)}\leqslant c\|\cdot\|_{H^1(\mathbb{R}^3)},$$

(see, e.g., Burenkov 1998, Chap. 5) one has

$$\begin{aligned}&\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)\left\|\psi_t(x)\left(P-\frac{Q}{t}\right)\psi_t(x)\right\|\left(\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)|\,\theta(x)\psi_t(x)|^2\right)^{1/2}\\ &\quad\times\left(\int_{\partial C\cap B_R^c}\mathrm{d}\sigma(x)\left\|\left(P-\frac{Q}{t}\right)\psi_t(x)\right\|^2\right)^{1/2}\leqslant c\|\,\theta(Q)\psi_t\|_{H^1}\left\|\left(P-\frac{Q}{t}\right)\psi_t\right\|_{H^1},\end{aligned}$$

so that (4.2) is a consequence of Hypothesis 5. □

V. ON THE ADMISSIBILITY CONDITIONS

When $V=0$, $\psi_0\in H^2(\mathbb{R}^3)$, and $|Q|\psi_0\in L^2(\mathbb{R}^3)$, by the explicit espression for $e^{it\Delta}\psi_0$ one has

$$\left\|\left(P-\frac{1}{t}Q\right)\psi_t\right\|_{L^2}=\frac{1}{t}\|Q\psi_0\|_{L^2},$$

and therefore the free case satisfies the admissibility Hypotheses 2–4 (with $P_+ = P$).

Now we come to the interacting case. Hypothesis 3 gives no trouble: it follows from fairly general hypotheses on the potential function V. Indeed by Derezinski [(1997)—Theorem 4.1]

$$V(-\Delta+1)^{-1} \text{ is compact} \tag{5.1}$$

and

$$\int_1^{+\infty} \mathrm{d}R \left\| (-\Delta+1)^{-1} \nabla V \chi_{[1,+\infty)} \left(\frac{\|Q\|}{R} \right) (-\Delta+1)^{-1} \right\|_{L^2,L^2} < +\infty, \tag{5.2}$$

imply (a stronger version of) Hypothesis 3. By Hilsop and Sigal [(1996), Theorem 14.9], if for all $\epsilon > 0$ we can decompose $V = V_1 + V_2$ with $V_1 \in L^2(\mathbb{R}^3)$ and $V_2 \in L^\infty(\mathbb{R}^3)$, with $\|V_2\|_\infty < \epsilon$, then (5.1) holds true. If, outside some ball, V is differentiable with its first derivatives decaying at infinity faster than $\|x\|^{-1}$ then condition (5.2) follows.

As regards Hypothesis 2, by the proof of Carlen [(1985), lemma 4] one has

$$\left\| \left(P - \frac{Q}{t} \right) \psi_t \right\|_{L^2} \leqslant \frac{1}{t} \|(P-Q)\psi_1\|_{L^2} + \frac{1}{t} \int_1^t \mathrm{d}s \, s \|\psi_s \nabla V\|_{L^2}.$$

By (5.1) V is infinitesimally $(-\Delta)$-operator-bounded [see, e.g., Hilsop and Sigal (1996), Theorem 14.2] and so [see Carlen (1984), Theorem 2.1(iv)] $\|(-P-Q)\psi_t\|_{L^2} < +\infty$ for all t if

$$\psi_0 \in H^2(\mathbb{R}^3), \quad |Q|\psi_0 \in L^2(\mathbb{R}^3).$$

Therefore Hypothesis 2 follows from

$$\|\psi_t \nabla V\|_{L^2} \leqslant c(1+|t|)^{-\sigma}, \quad \sigma > 1. \tag{5.3}$$

We introduce the notations $\langle x \rangle$ for the function $(1+\|x\|^2)^{1/2}$ and $\langle Q \rangle$ for the corresponding multiplication operator.

In the case $\langle Q \rangle^s \nabla V \in L^\infty(\mathbb{R}^3)$ and $\langle Q \rangle^s \psi_0 \in L^2(\mathbb{R}^3)$ for some s, (5.3) then follows from

$$\|\langle Q \rangle^{-s} e^{-itH} \langle Q \rangle^{-s}\|_{L^2,L^2} \leqslant c(1+|t|)^{-\sigma}. \tag{5.4}$$

Such a kind of estimates were obtained in many papers about propagation estimates for solution of Schrödinger equations [see e.g., Amrein *et al.* (1987); Cycon and Perry (1984); Jensen and Kato (1979); Jensen, Mourre, and Perry (1984); and Journé, Soffer, and Sogge (1991)]. For example, by Cycon and Perry [(1984), Theorem 1], one obtains that Hypothesis 2 holds true under the following hypotheses:

$$\psi_0 \in H^2(\mathbb{R}^3), \quad \langle Q \rangle^s \psi_0 \in L^2(\mathbb{R}^3), \quad \phi(H)\psi_0 = \psi_0, \tag{5.5}$$

$$V = V_S + V_L, \quad V_S \in C^1(\mathbb{R}^3), \quad V_L \in C^{k+3}(\mathbb{R}^3), \tag{5.6}$$

$$\|D^\alpha V_S(x)\| \leqslant c\langle x \rangle^{-2k-|\alpha|-\epsilon}, \quad |\alpha| \leqslant 1, \tag{5.7}$$

$$\|D^\alpha V_L(x)\| \leqslant c\langle x \rangle^{-|\alpha|-\epsilon}, \quad |\alpha| \leqslant k+1, \tag{5.8}$$

where $\phi \in C^\infty(0,+\infty)$ is equal to zero on a (arbitrarily small) neighborhood of zero and

$$\epsilon > 0, \quad k \geqslant 3, \quad 1 < s \leqslant k, \quad s\left(1 - \frac{1}{k}\right) > 1 \tag{5.9}$$

[$s(1-1/k) > 3/2$ gives Hypothesis 2.1].

Note that under these conditions (5.1) and (5.2) hold true. Moreover, by Hilsop and Sigal [(1996), Theorem 1] there are no strictly positive eigenvalues and, by Dereziński and Gerard [(1997), Theorem 4.7.1], one also has the existence and completeness of the (modified) wave operators, so that, for every Borel set A,

$$\langle \psi_0, \chi_A(P_+)\psi_0\rangle = \int_A \mathrm{d}k\, |\hat{\psi}_{\mathrm{out}}(k)|^2.$$

Thus Hypothesis 4 holds true and in conclusion

$$(5.5)-(5.9) \Rightarrow \text{admissibility}.$$

Remark: By Jensen and Kato [(1979), Theorem 10.3] the low energy cutoff hypothesis can be removed when 0 is neither an eigenvalue nor a resonance, $\epsilon>3$ and $s>5/2$. If 0 is not an eigenvalue but is a resonance then ψ_0 has to be orthogonal to the function corresponding to the resonance, otherwise in (5.4) one has $\sigma=1/2$, see Jensen and Kato [(1979), Theorem 10.5].

As regards strong admissibility, i.e., Hypothesis 5, the main point in the paper by Amrein and Pearson (1997) was just to find the conditions on ψ_0 and V leading to such an hypothesis. By using again (5.4) and commutator estimates, by Amrein and Pearson [(1997), Lemmas 5–8] one obtains

$$(5.5)-(5.9) \text{ with } s>5/3 \text{ and } \epsilon>2/3 \Rightarrow \text{strong admissibility}.$$

In Amrein and Pearson [(1997), Sec. 6] it is then shown how to avoid regularity hypotheses on the short-range component of V. However in this situation the hypotheses on the initial state ψ_0 become less transparent. Indeed there one requires $W_+^*\psi_0=\varphi(H_1)W_+^*\psi_0$, $\langle Q\rangle^s W_+^*\psi_0\in L^2(\mathbb{R}^3)$, $s>2$, $\varphi\in C_c(0,+\infty)$, $H_1:=-\Delta+V_1$, V_1 the smooth part of V, W_+ the relative wave operator $W_+:=\lim_{t\uparrow\infty}e^{-itH}e^{itH_1}$.

We conclude the section by listing the conditions on the couple (ψ_0,V) used in other papers (beside those of Amrein and Pearson) already quoted in order to obtain the flux-across-surfaces theorem [$\mathcal{S}(\mathbb{R}^3)$ denoting the space of functions of rapid decrease]:

(1) In Daumer *et al.* (1996) is it assumed that $V=0$ and $\psi_0\in\mathcal{S}(\mathbb{R}^3)$.

(2) In Amrein and Zuleta (1997) it is assumed that $\langle Q\rangle^s\psi_{\mathrm{out}}\in L^2(\mathbb{R}^3)$, $s>5/2$, $\psi_{\mathrm{out}}=\varphi(-\Delta)\psi_{\mathrm{out}}$, $\varphi\in C_c^\infty(0,+\infty)$, V either has local singularities and decays faster than $\|x\|^{-2}$ at infinity or is in $C^4(\mathbb{R}^3)$ and decays faster than $\|x\|^{-1}$ (in this case $\hat{\psi}_{\mathrm{out}}$ has to be in $C_c^4(\mathbb{R}^3\backslash\{0\})$). By Jensen and Nakamura (1992), when V is smooth, the condition on the outgoing state ψ_{out} is implied by a similar one (with $s>7/2$) on ψ_0.

(3) In Teufel, Dürr, and Münch-Berndl (1999) it is assumed that $\psi_{\mathrm{out}}\in\mathcal{S}(\mathbb{R}^3)$, that $V\in L^2(\mathbb{R}^3)$ is locally Hölder continuous except at a finite number of points and is decaying faster than $\|x\|^{-4}$, and that 0 is neither an eigenvalue nor a resonance. No energy cutoff condition on ψ_0 is required.

(4) In Dell'Antonio and Panati (2001) and the results in Teufel, Dürr, and Münch-Berndl (1999) are extended to the case in which 0 is either a zero-energy eigenvalue or resonance. There it is assumed that $\psi_0\in\mathcal{S}(\mathbb{R}^3)$, $V\in L^2(\mathbb{R}^3)$ is locally Hölder continuous except at a finite number of points and is decaying faster than $\|x\|^{-n}$ for all $n\in\mathbb{N}$, $\hat{\psi}_{\mathrm{out}}\in C^5(\mathbb{R}^3\backslash\{0\})$ and $\|D^\alpha\hat{\psi}_{\mathrm{out}}(k)\|\leqslant c\langle k\rangle^{-3-|\alpha|-\epsilon}$, $|\alpha|\leqslant 5$, $\epsilon>0$, $\|k\|\geqslant K_\alpha>0$.

(5) In Panati and Teta (2000) and Dell'Antonio and Panati (2001) the flux-across-surfaces theorem is proven in the case in which $\psi_0\in\mathcal{S}(\mathbb{R}^3)$ and H is the self-adjoint operator describing the Laplacean with a delta point interaction.

It is shown that if $\mathbb{H}$ is a Hilbert space for a representation of a group G, then there are triplets of spaces $(\mathcal{F}_{\mathbb{H}},\mathbb{H},\mathcal{F}^{\mathbb{H}})$, in which $\mathcal{F}^{\mathbb{H}}$ is a space of coherent state or vector coherent state wave functions and $\mathcal{F}_{\mathbb{H}}$ is its dual relative to a conveniently defined measure. It is shown also that there is a sequence of maps $\mathcal{F}_{\mathbb{H}}\to\mathbb{H}\to\mathcal{F}^{\mathbb{H}}$ which facilitates the construction of the corresponding inner products. After completion if necessary, the spaces $(\mathcal{F}_{\mathbb{H}},\mathbb{H},\mathcal{F}^{\mathbb{H}})$ become isomorphic Hilbert spaces. It is shown that the inner product for $\mathbb{H}$ is often easier to evaluate in $\mathcal{F}_{\mathbb{H}}$ than in $\mathcal{F}^{\mathbb{H}}$. Thus, we obtain integral expressions for the inner products of coherent state and vector coherent state representations. These expressions are equivalent to the algebraic expressions of K-matrix theory, but they are frequently more efficient to apply. The construction is illustrated by many examples. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1509851]

I. INTRODUCTION

Coherent state representations provide a unification of the various constructions for inducing representations of groups and Lie algebras. The method of induced representations, known originally as the ''Frobenius method,'' was introduced into physics by Wigner in two classic papers: in the first[1] he considered the vibrational spectra of molecules and, in the second,[2] he constructed all the irreducible unitary representations of the Poincaré group for positive mass particles. The theory of induced representations became an important tool in mathematics and physics following the developments of Mackey.[3] Other inducing constructions[4] are given by the Borel–Weil theorem and Harish-Chandra's constructions[5] of holomorphic discrete series representations.

Coherent states were first defined by Schrödinger[6] in 1926 as minimal uncertainty wave packets and used to exhibit the classical behavior of harmonic oscillators within the framework of quantum mechanics. Such applications has been particularly effective in quantum optics.[7] They were given general group-theoretic definitions by Klauder,[8] Perelomov,[9] and Gilmore.[10] Coherent state representations were introduced by Bargmann[11] and Segal[12] and defined more generally by Perelomov[13] and Onofri.[14] They were subsequently extended to vector-valued representations.[15,16]

It is now known that the inducing constructions are expressed naturally as coherent state, and vector coherent state, representations.[17] Moreover, the coherent state perspective adds new insights and has the advantage of being physically intuitive and easy to apply. In particular, it reveals the correspondence between the unitary representations of quantum mechanics and the nonunitary representations of classical mechanics and is closely related to the methods of geometric quantization.[18] Thus, coherent state representation theory is of considerable practical and pedagogic value.

A scalar coherent state representation is a representation of a group (or Lie algebra) on a space of complex-valued functions on a coset space. It is a representation induced from a one-dimensional representation of a subgroup. The prototype is the well-known Bargmann–Segal representation[11,12] of the Heisenberg–Weyl group on a Hilbert space of entire analytic functions. A

[a)]Electronic mail: rowe@physics.utoronto.ca

vector coherent state (VCS) representation is a representation of a group (or Lie algebra) on a space of vector-valued functions. It is a representation induced from a multi-dimensional representation of a subgroup. Such representations have been used widely in the construction of explicit representations of Lie algebras and Lie groups,[19–22] in the construction of shift tensors,[23] and for the computation of Clebsch–Gordan coefficients for reducing tensor product representations.[24,25]

In constructing a coherent state representation, one needs to identify the space of wave functions and an appropriate inner product. When the group is compact or when it is noncompact but the representation belongs to the discrete series, there are standard methods for determining a suitable volume element relative to which the coherent state wave functions are square integrable and the coherent state representation unitary. The methods are summarized for the holomorphic representations in the book of Perelomov[13] and generalized to VCS representations, by the methods of Rowe, Rosensteel and Gilmore.[16]

Central to the standard construction is the so-called "resolution of the identity." If T denotes a UIR (unitary irreducible representation) on a Hilbert space $\mathbb{H}$ of a Lie group G with invariant measure $\mathrm{d}\mu$, then, if $|0\rangle$ is any state in $\mathbb{H}$, it follows by Schur's lemma that the operator

$$\hat{I}=\int T^{\dagger}(g)|0\rangle\langle 0|T(g)\mathrm{d}\mu(g), \tag{1}$$

when defined, is a multiple of the identity. Thus, with a suitable normalization of the invariant measure, the inner product of two states of $\mathbb{H}$ is expressed

$$\langle\psi|\varphi\rangle=\int_G \Psi^*(g)\Phi(g)\mathrm{d}\mu(g), \tag{2}$$

where Φ, defined by

$$\Phi(g)=\langle 0|T(g)|\varphi\rangle, \tag{3}$$

is a coherent state wave function for the state $|\varphi\rangle$. In particular situations, these expressions simplify. For example, if H is the isotropy subgroup

$$H=\{h\in G|T(h)|0\rangle=|0\rangle\chi(h)\}, \tag{4}$$

where $\chi(h)$ is a phase factor, and if K is a set of coset representives for $H\backslash G$ so that any element $g\in G$ can be factored $h=hk$, with $h\in H$ and $k\in K$, then the coherent state wave functions can be restricted to K and their inner products defined by

$$\langle\psi|\varphi\rangle=\int_K \Psi^*(k)\Phi(k)\mathrm{d}\mu(k), \tag{5}$$

where $\mathrm{d}\mu(k)$ is the measure on K inherited from the invariant measure on G.

A problem encountered in the practical application of such methods is that the integrals are difficult to evaluate and in some cases may not converge. For this reason, an alternative K-matrix theory has been developed[15,20,17] which provides numerically tractable recursive algorithms for constructing orthonormal bases for coherent state and VCS representations. Such bases, which are needed for the explicit construction of the matrices of Lie algebra representations, have been determined by K- matrix methods (reviewed in Ref. 26) for representatives of all the classical series of Lie algebras.[15,19,20] This approach works well for the matrices of Lie algebra representations. However, for other purposes, particularly when working at the group level, it is important to have explicit integral expressions for inner products. Thus, we consider here integral expressions for the results of K-matrix theory and show that they are generally easier to derive and use than the standard methods. In this article, we consider coherent state triplets for scalar coherent state representations. VCS triplets will be considered in a following paper.

The new method makes use of overlap kernels such as

$$\mathcal{S}(g_1,g_2)=\langle 0|T(g_1)T^\dagger(g_2)|0\rangle. \tag{6}$$

Thus, if a state $|\varphi\rangle\in\mathbb{H}$ is represented by a wave function φ defined over G such that

$$|\varphi\rangle=\int T^\dagger(g)|0\rangle\varphi(g)\mathrm{d}v(g), \tag{7}$$

where $\mathrm{d}v$ is any convenient measure on the group, then the inner product of states is given by

$$\langle\psi|\varphi\rangle=\int\int \psi^*(g_1)\mathcal{S}(g_1,g_2)\varphi(g_2)\mathrm{d}v(g_1)\mathrm{d}v(g_2). \tag{8}$$

Likewise, matrix elements of the representation are given by

$$\langle\psi|T(g)|\varphi\rangle=\int\int \psi^*(g_1)\mathcal{S}(g_1g,g_2)\varphi(g_2)\mathrm{d}v(g_1)\mathrm{d}v(g_2). \tag{9}$$

The new and old methods are related as follows. From Eqs. (3) and (7), it is seen that the coherent state wave function Φ for the state $|\varphi\rangle$ is related to φ by

$$\Phi(g)=\int \mathcal{S}(g,g_2)\varphi(g_2)\mathrm{d}v(g_2). \tag{10}$$

Moreover, the inner product of two states $|\psi\rangle$ and $|\varphi\rangle$ is given by

$$\langle\psi|\varphi\rangle=\int \psi^*(g)\Phi(g)\mathrm{d}v(g). \tag{11}$$

Thus, the wave functions φ and Φ are dual to one another relative to the volume $\mathrm{d}v$. The advantage of using the space of functions dual to the coherent state wave functions with inner product given by Eq. (8) is the freedom to choose the volume $\mathrm{d}v$ such that the integrals are easy to define and evaluate. It will be shown in the following, in a number of representative examples, that there are natural choices in given situations.

The new techniques greatly facilitate the use of algebraic and group structures in the solution of physical problems. Indeed, they were developed following the discovery, while computing SU(3) Clebsch–Gordan coefficients,[25] that it is generally very much easier to compute inner products by means of Eq. (8) than by using the coherent state inner product (5) directly.

II. SCALAR COHERENT STATE TRIPLETS

A. Finite-dimensional representations

Let T be a unitary irrep (irreducible represesentation) of a real algebraic Lie group G on a finite dimensional Hilbert space $\mathbb{H}$ with inner product of two vectors $|\psi\rangle$ and $|\varphi\rangle$ denoted by $\langle\psi|\varphi\rangle$. Assume there is an extension to a representation of G^c, the complex extension of G, which is compatible with the natural complex extension of its Lie algebra. Let $|0\rangle$ be a fixed vector in $\mathbb{H}$ and let N be a subset of G^c, such that the states

$$\{T^\dagger(z)|0\rangle; z\in N\} \tag{12}$$

span $\mathbb{H}$. Then, any state $|\psi\rangle\in\mathbb{H}$ is uniquely defined by the overlaps

$$\Psi(z)=\langle 0|T(z)|\psi\rangle, \quad z\in N. \tag{13}$$

The complex function Ψ on N is a coherent-state wave function for the state $|\psi\rangle$ and the space $\mathcal{F}^{\mathbb{H}}$ of such coherent-state wave functions carries a representation Γ of G isomorphic to T and defined by

$$[\Gamma(g)\Psi](z)=\langle 0|T(z)T(g)|\psi\rangle, \quad g\in G. \tag{14}$$

For example, if $P\subset G^c$ is the isotropy subgroup

$$P=\{p\in G^c|\langle 0|T(p)|\psi\rangle=\chi(p)\langle 0|\psi\rangle, \quad \forall|\psi\rangle\in\mathbb{H}\}, \tag{15}$$

where χ is a character of a one-dimensional irrep of P, then N is often chosen to be a set of $P\backslash G^c$ coset representatives or some subgroup of G^c complementary to P such that any element $g\in G$ can be factored as $g=pz$ for some $z\in N$ and some $p\in P$.

To identify the space $\mathcal{F}^{\mathbb{H}}$ of coherent state wave functions, consider first a space $\mathcal{F}=\mathcal{L}^2(N,\mathrm{d}v)$, defined by a convenient volume element $\mathrm{d}v$ such that the map

$$\mathcal{F}\to\mathbb{H}:\varphi\to|\varphi\rangle=\int \mathrm{d}v(z)T^\dagger(z)|0\rangle\varphi(z) \tag{16}$$

is well-defined and surjective onto $\mathbb{H}$. There is then a sequence of maps $\mathcal{F}\to\mathbb{H}\to\mathcal{F}^{\mathbb{H}}$ defined by

$$\psi\to|\psi\rangle\to\Psi=\hat{\mathcal{S}}\psi, \tag{17}$$

with

$$|\psi\rangle=\int T^\dagger(x)|0\rangle\psi(x)\mathrm{d}v(x) \tag{18}$$

and

$$\Psi(z)=\langle 0|T(z)|\psi\rangle=\int \mathcal{S}(z,x)\psi(x)\mathrm{d}v(x)=[\hat{\mathcal{S}}\psi](z), \tag{19}$$

where

$$\mathcal{S}(z,x)=\langle 0|T(z)T^\dagger(x)|0\rangle. \tag{20}$$

Thus, if

$$\mathcal{F}_0=\{\varphi\in\mathcal{F}|\langle\varphi|\varphi\rangle=0\} \tag{21}$$

denotes the kernel of the map $\mathcal{F}\to\mathbb{H}$ and $\mathcal{F}_{\mathbb{H}}$ is the quotient space $\mathcal{F}/\mathcal{F}_0$, it follows that the spaces $\mathcal{F}_{\mathbb{H}}$ and $\mathcal{F}^{\mathbb{H}}$ are dual to one another relative to the volume element $\mathrm{d}v$, i.e.,

$$\langle\varphi|\psi\rangle=\int \varphi^*(z)(\hat{\mathcal{S}}\psi)(z)\mathrm{d}v(z)=\int \varphi^*(z)\Psi(z)\mathrm{d}v(z). \tag{22}$$

It also follows that matrix elements of the representation T are given by

$$\langle\varphi|T(g)|\psi\rangle=\int \varphi^*(z)[\Gamma(g)\hat{\mathcal{S}}\psi](z)\mathrm{d}v(z)]=\int \varphi^*(z)[\Gamma(g)\Psi](z)\mathrm{d}v(z). \tag{23}$$

We refer to the triple of spaces $(\mathcal{F}_{\mathbb{H}},\mathbb{H},\mathcal{F}^{\mathbb{H}})$ as a *coherent state triplet*.

The space $\mathcal{F}^{\mathbb{H}}$ of coherent state wave functions is clearly a Hilbert space with respect to an inner product inherited from $\mathbb{H}$. Thus, if the space $\mathcal{F}_{\mathbb{H}}$ is equipped with the inner product

$$(\varphi,\psi)=\langle\varphi|\psi\rangle=\int\int \mathrm{d}v(z)\varphi^*(z)\mathcal{S}(z,x)\psi(x)\mathrm{d}v(x), \tag{24}$$

the three spaces $(\mathcal{F}_{\mathbb{H}},\mathbb{H},\mathcal{F}^{\mathbb{H}})$ become isomorphic to one another. One can then use whichever gives the simplest expression in any situation. Examples will be given in the following in which it is easiest to evaluate inner products in $\mathcal{F}_{\mathbb{H}}$. One can then construct an orthonormal basis for $\mathcal{F}_{\mathbb{H}}$ and corresponding orthornormal bases for $\mathbb{H}$ and $\mathcal{F}^{\mathbb{H}}$, e.g., if $\{\psi_\nu\}$ is an orthonormal basis for $\mathcal{F}_{\mathbb{H}}$, then $\{\Phi_\nu=\hat{\mathcal{S}}\psi_\nu\}$ is an orthonormal basis for $\mathcal{F}^{\mathbb{H}}$.

The relationship of the above to K-matrix theory[26] is obtained by noting that, since $\hat{\mathcal{S}}$ is a positive definite operator on $\mathcal{F}_{\mathbb{H}}$, it can be factored

$$\hat{\mathcal{S}}=\hat{K}\hat{K}^\dagger, \tag{25}$$

and the inner product for $\mathcal{F}_{\mathbb{H}}$ expressed

$$\langle\varphi|\psi\rangle=\int(\hat{K}^\dagger\varphi)^*(z)(\hat{K}^\dagger\psi)(z)\mathrm{d}v(z). \tag{26}$$

Thus, if $\{\psi_\nu\}$ is an orthonormal basis for $\mathcal{F}_{\mathbb{H}}$, the functions $\{\varphi_\nu=\hat{K}^\dagger\psi_\nu\}$ satisfy the equation

$$\int \varphi_\mu^*(z)\varphi_\nu(z)\mathrm{d}v(z)=\delta_{\mu\nu}, \tag{27}$$

and the corresponding orthonormal coherent state basis is given by $\{\Psi_\nu=\hat{K}\hat{K}^\dagger\psi_\nu=\hat{K}\varphi_\nu\}$. Hence, if $\{\varphi_\nu\}$ is an orthonormal basis for $\mathcal{F}$, the operator $\hat{K}$ maps this basis to an orthonormal basis $\{\Psi_\nu=\hat{K}\varphi_\nu\}$ for $\mathcal{F}^{\mathbb{H}}$ by annihilating the unwanted states of $\mathcal{F}$.

The above construction of coherent state wave functions and their inner products has a powerful and, for practical applications, very significant attribute of facilitating the construction of representations in bases which reduce some desired subgroup $H\subset G$. Basically what has to be done is to choose a measure $\mathrm{d}v$ for $\mathcal{F}$ such that the restriction of the action of Γ to the subgroup $H\subset G$ is unitary on $\mathcal{F}$. Then, $\mathcal{S}$ becomes H-invariant, in the sense that

$$\mathcal{S}(zh,xh)=\langle 0|T(z)T(h)T^\dagger(h)T^\dagger(x)|0\rangle=\mathcal{S}(z,x), \tag{28}$$

and $\hat{\mathcal{S}}$ block diagonal in a basis for $\mathcal{F}$ that reduces the unitary representation of H. Specifically, if $\mathcal{F}=\Sigma_{\alpha\kappa}\mathcal{F}^{\alpha\kappa}$ is a decomposition of $\mathcal{F}$ as a direct sum of irreducible H-invariant subspaces, where κ labels an irrep of H and α distinguishes equivalent irreps, and if $\{\varphi_{\alpha\kappa\nu}\}$ is an orthonormal basis for $\mathcal{F}^{\alpha\kappa}$, then

$$\langle\varphi_{\alpha\kappa\mu}|\varphi_{\beta\kappa'\nu}\rangle=\int\int\varphi_{\alpha\kappa\mu}^*(z)\mathcal{S}(z,x)\varphi_{\beta\kappa'\nu}(x)\mathrm{d}v(z)\mathrm{d}v(x)=\delta_{\kappa\kappa'}\delta_{\mu\nu}\mathcal{S}_{\alpha\kappa\beta}. \tag{29}$$

It then follows that an orthonormal basis $\{\varphi_{\alpha\kappa\nu}\}$ for $\mathcal{F}$ which diagonalizes the matrix $\mathcal{S}_\kappa$, i.e., for which $\mathcal{S}_{\alpha\kappa\beta}=\delta_{\alpha\beta}K_{\alpha\kappa}^2$, defines a corresponding orthonormal basis $\{\Psi_{\alpha\kappa\nu}=K_{\alpha\kappa}\varphi_{\alpha\kappa\nu}\}$ of coherent state wave functions. It is shown explicitly how this is done in the following examples.

The above definitions can be generalized in several ways. For example, the condition that $\mathbb{H}$ should be irreducible can be relaxed. The representation Γ is then isomorphic to a subrepresentation of T. Moreover, if $|0\rangle$ belongs to an irreducible subspace of $\mathbb{H}$, then the space spanned by $\{T^\dagger(z)|0\rangle;z\in N\}$, as well as the corresponding coherent state representation, is irreducible.

B. Infinite-dimensional representations

The above construction extends easily to infinite-dimensional representations. However, although the extension is natural in most situations, there are technical constraints that must be

respected in the choice of state $|0\rangle$ and subset $N\subset G^c$ to ensure that the operators $\{\langle 0|T(z),z \in N\}$ are well defined and have the properties required to define a coherent state representation. For simplicity, it will be assumed here that the representation T is irreducible and unitary. One concern is that an infinite-dimensional irrep T of a real group G on a Hilbert space $\mathbb{H}$ does not automatically extend to a representation of the complex group G^c. For, whereas a real Lie algebra $\mathfrak{g}$ has a natural extension to $\mathfrak{g}^c$ by linearity,

$$T(z\otimes X)=zT(X), \quad \text{for} \quad X\in\mathfrak{g},z\in\mathbb{C}, \tag{30}$$

it can happen, for example, that if $\hat{X}=T(X)$ is the operator representing an element $X\in\mathfrak{g}^c$, then the action of the associated group element $e^{\hat{X}}=T(e^X)$ on a state $|\psi\rangle\in\mathbb{H}$ may not converge to a normalizable state $e^{\hat{X}}|\psi\rangle\in\mathbb{H}$. Nevertheless, as we show by examples in the following, it is frequently possible to choose a functional $\langle 0|$ and a subset $N\subset G^c$ so that the techniques described above can be generalized. In doing this, it is not possible to expect that the representation T can be extended so that N acts on all of $\mathbb{H}$, or that the functional $\langle 0|$ will be normalizable. Both these difficulties can be handled by working with a dense subspace of $\mathbb{H}$. A good example to keep in mind is the delta function, which is not defined on all of $\mathcal{L}^2(\mathbb{R})$, but does make sense on the dense subspace of continuous functions in $\mathcal{L}^2(\mathbb{R})$.

Specifically, what is required is a dense subspace $\mathbb{H}_D\subset\mathbb{H}$ of the Hilbert space; a subset $N\subset G^c$; an extension of the representation T from G to operators $T(z)$, $z\in N$, which are defined on $\mathbb{H}_D$; and a linear functional $\langle 0|$ on the space spanned by $\{T(z)|\psi\rangle:|\psi\rangle\in\mathbb{H}_D,z\in N\}$. The extension of T to N must be compatible at the level of the Lie algebra with Eq. (30) and have the property that

$$\{\langle 0|T(z);z\in N\} \tag{31}$$

are well-defined functionals on $\mathbb{H}_D$ and are a *sufficient set*, in the sense that any $|\psi\rangle\in\mathbb{H}_D$ is uniquely defined by the overlaps

$$\Psi(z)=\langle 0|T(z)|\psi\rangle, \quad z\in N. \tag{32}$$

The complex function Ψ on N is then a coherent-state wave function for the state $|\psi\rangle$. When the subspace $\mathbb{H}_D$ is invariant under the (real) group action, then the space $\mathcal{F}^{\mathbb{H}_D}$ of all such coherent-state wave functions carries a representation Γ of G, isomorphic to T, defined by

$$[\Gamma(g)\Psi](z)=\langle 0|T(z)T(g)|\psi\rangle, \quad g\in G. \tag{33}$$

However, sometimes it will be convenient to choose a dense subspace that is not G-invariant. The group action, defined by Eq. (33), is then extended to the G-invariant completion of the space of coherent state wave functions relative to the inner product inherited from $\mathbb{H}$.

The final step is to generalize the map (16). Since $\langle 0|$ is in general not an element of $\mathbb{H}$ (i.e., not normalizable), it is necessary to choose the measure and the space of functions carefully. Specifically, what is required is a space $\mathcal{F}$ of functions on N and a measure $\mathrm{d}\nu$ on N such that, for every $\varphi\in\mathcal{F}$, the integral

$$\int \mathrm{d}\nu(z)\varphi(z)^*\langle 0|T(z) \tag{34}$$

converges to an element of $\mathbb{H}_D^*$, the dual of the dense subspace $\mathbb{H}_D$ of $\mathbb{H}$ for which coherent state wave functions are defined. This integral then gives a map

$$\mathcal{F}\to\mathbb{H}_D^*:\varphi\to\langle\varphi|=\int \mathrm{d}\nu(z)\varphi(z)^*\langle 0|T(z) \tag{35}$$

which is well-defined for all elements of $\mathcal{F}$. We also require that the image of this map contains $\mathbb{H}_D$ and write $\mathcal{F}_D$ for the space of all elements of $\mathcal{F}$ which the map takes to elements of $\mathbb{H}_D$.

There is now a sequence of maps $\mathcal{F}_D \to \mathbb{H}_D \to \mathcal{F}^{\mathbb{H}_D}$ for which

$$\psi \to |\psi\rangle \to \Psi = \hat{\mathcal{S}}\psi, \tag{36}$$

with

$$|\psi\rangle = \int T^\dagger(x)|0\rangle \psi(x) \mathrm{d}v(x) \tag{37}$$

and

$$\Psi(z) = [\hat{\mathcal{S}}\psi](z) = \int \mathcal{S}(z,x)\psi(x)\mathrm{d}v(x), \tag{38}$$

where

$$\mathcal{S}(z,x)\psi(x) = \langle 0|T(z)T^\dagger(x)|0\rangle. \tag{39}$$

Let

$$\mathcal{F}_0 = \{\varphi \in \mathcal{F} | \langle \varphi|\varphi\rangle = 0\} \tag{40}$$

denote the kernel of the map $\mathcal{F} \to \mathbb{H}_D^*$ given in (35), i.e., $\mathcal{F}_0$ is the set of all functions in $\mathcal{F}$ that map to functionals that are zero on all of $\mathbb{H}_D$, and define $\mathcal{F}_\mathbb{H}$ to be the completion of the space $\mathcal{F}_D/\mathcal{F}_0$, relative to the inner product

$$(\varphi,\psi) = \langle \varphi|\psi\rangle = \int\int \mathrm{d}v(z)\varphi^*(z)\mathcal{S}(z,x)\psi(x)\mathrm{d}v(x), \tag{41}$$

where

$$\mathcal{S}(z,x) = \langle 0|T(z)T^\dagger(x)|0\rangle. \tag{42}$$

Then $\mathcal{F}_\mathbb{H}$ is a Hilbert space isomorphic to $\mathbb{H}$ and, if $\mathcal{F}^\mathbb{H}$ is the completion of the space of coherent state wave functions relative to the inner product inherited from $\mathbb{H}$, it too is isomorphic to $\mathbb{H}$.

Finally observe that, if the map $\mathcal{F} \to \mathbb{H}_D^*$ takes $\varphi \to \langle\varphi|$ and if a state $|\psi\rangle \in \mathbb{H}_D$ has coherent state wave function $\Psi \in \mathcal{F}^{\mathbb{H}_D}$, then

$$\langle \varphi|\psi\rangle = \int \varphi^*(z)(\hat{\mathcal{S}}\psi)(z)\mathrm{d}v(z) = \int \varphi(z)^*\Psi(z)\mathrm{d}v(z). \tag{43}$$

It follows that $\mathcal{F}_\mathbb{H}$ and $\mathcal{F}^\mathbb{H}$ are in duality relative to the volume element $\mathrm{d}v$. It also follows that matrix elements of the representation T are given by

$$\langle \varphi|T(g)|\psi\rangle = \int \varphi^*(z)[\Gamma(g)\hat{\mathcal{S}}\psi](z)\mathrm{d}v(z)] = \int \varphi^*(z)[\Gamma(g)\Psi](z)\mathrm{d}v(z). \tag{44}$$

We again refer to the triple of spaces $(\mathcal{F}_\mathbb{H}, \mathbb{H}, \mathcal{F}^\mathbb{H})$ as a *coherent state triplet*.

III. SIMPLE EXAMPLES

The following well-known examples are developed in some detail as prototypes of four classes of application of the triplets method: holomorphic representations of compact and non-

compact semisimple Lie groups; nonholomorphic representations induced from a noncanonical subgroup; and Mackey type representations[3] of a semidirect product group induced from an Abelian normal subgroup.

A. SU(2)

Let $\{J_0, J_+, J_-\}$ with commutation relations

$$[J_+, J_-] = 2J_0, \quad [J_0, J_\pm] = \pm J_\pm, \tag{45}$$

be a standard basis for the Lie algebra $\mathfrak{su}(2)^c$. Let $T^j: J_k \to \hat{J}_k$ be a UIR (unitary irreducible representation) of SU(2) of angular momentum j on a (finite-dimensional) Hilbert space $\mathbb{H}^j$ with (normalized) highest weight state $|jj\rangle$ satisfying

$$\hat{J}_+|jj\rangle = 0, \quad \hat{J}_0|jj\rangle = j|jj\rangle. \tag{46}$$

With fixed state $|0\rangle$ set equal to the highest weight state $|jj\rangle$, a natural choice of $N \subset \mathrm{SU}(2)^c$ is the nilpotent subgroup

$$N = \{e^{zJ_+}; z \in \mathbb{C}\}, \tag{47}$$

and a convenient measure $\mathrm{d}v$ on N is the Bargmann measure, relative to which the polynomial functions $\{\varphi_\nu\}$, with $\varphi_\nu(z) = z^\nu/\sqrt{\nu!}$, satisfy the orthogonality relationship

$$\int \varphi_\mu^*(z)\varphi_\nu(z)\mathrm{d}v(z) = \delta_{\mu\nu}. \tag{48}$$

The space $\mathcal{F} = \mathcal{L}^2(N, \mathrm{d}v)$ is then the Bargmann space[11] of entire analytic functions of z that are square integrable relative to $\mathrm{d}v$.

The overlap kernel, $\mathcal{S}(z,x) = \langle 0|e^{z\hat{J}_+}e^{x^*\hat{J}_-}|0\rangle$, is evaluated by noting that almost any $\mathrm{SL}(2,\mathbb{C})$ matrix has Gauss factorization

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ x & 1 \end{pmatrix}\begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix}\begin{pmatrix} 1 & z \\ 0 & 1 \end{pmatrix} = e^{xJ_-}a^{2J_0}e^{zJ_+} \tag{49}$$

with $z = b/a$ and $x = c/a$. It follows that, as elements of $\mathrm{SL}(2,\mathbb{C})$,

$$e^{zJ_+}e^{x^*J_-} = \begin{pmatrix} 1+zx^* & z \\ x^* & 1 \end{pmatrix} = e^{\alpha x^* J_-}(1+zx^*)^{2J_0}e^{\alpha z J_+}, \tag{50}$$

with $\alpha = (1+zx^*)^{-1}$. Thus, the overlap kernel is given by

$$\mathcal{S}(z,x) = \langle 0|(1+zx^*)^{2\hat{J}_0}|0\rangle = (1+zx^*)^{2j} \tag{51}$$

and has expansion

$$\mathcal{S}(z,x) = \sum_{\nu=0}^{2j} \frac{(2j)!}{(2j-\nu)!\,\nu!}(zx^*)^\nu = \sum_{\nu=0}^{2j} K_\nu^2 \varphi_\nu(z)\varphi_\nu^*(x), \tag{52}$$

with

$$K_\nu^2 = \frac{(2j)!}{(2j-\nu)!}. \tag{53}$$

The space $\mathcal{F}_j$ is now defined as the Hilbert space of holomorphic functions of a complex variable z with inner product

$$\langle\varphi|\psi\rangle=\int\int \psi^*(z)\mathcal{S}(z,x)\varphi(x)\mathrm{d}v(z)\mathrm{d}v(x). \tag{54}$$

With respect to this $\mathcal{F}_j$ inner product, the overlaps of the functions $\{\varphi_\nu\}$ are given by

$$\langle\varphi_\mu|\varphi_\nu\rangle=\delta_{\mu\nu}\times\begin{cases}K_\nu^2 & \text{for } \nu\leqslant 2j,\\ 0 & \text{for } \nu>2j.\end{cases} \tag{55}$$

Thus, with the substitution $\nu=j-m$ (to conform to convention), and choosing the positive square root of K_ν^2, an orthonormal basis for $\mathcal{F}_j$ is given by the set of holomorphic functions

$$\left\{\psi_{jm}(z)=\frac{1}{K_{j-m}}\varphi_{j-m}(z)=\sqrt{\frac{(j+m)!}{(2j)!(j-m)!}}z^{j-m};m=-j,\ldots,j\right\}. \tag{56}$$

The map $\mathcal{F}_j\to\mathbb{H}^j$, in which

$$\psi_{jm}\to|jm\rangle=\int e^{z^*\hat{J}_-}|0\rangle\psi_{jm}(z)\mathrm{d}v(z), \tag{57}$$

and the coherent-state map $\mathbb{H}^j\to\mathcal{F}^j$, given by

$$|jm\rangle\to\Psi_{jm}(z)=\langle 0|e^{z\hat{J}_+}|jm\rangle=\int\langle 0|e^{z\hat{J}_+}e^{x^*\hat{J}_-}|0\rangle\psi_{jm}(x)\mathrm{d}v(x), \tag{58}$$

are isomorphisms. Thus, orthonormal bases for $\mathbb{H}^j$ and $\mathcal{F}^j$, corresponding to the basis (56) for $\mathcal{F}_j$, are given by

$$\left\{|jm\rangle=\frac{1}{K_{j-m}}|\varphi_{j-m}\rangle=\sqrt{\frac{(j+m)!}{(2j)!(j-m)!}}(\hat{J}_-)^{j-m}|0\rangle;\quad m=-j,\ldots,j\right\}, \tag{59}$$

$$\left\{\Psi_{jm}(z)=K_{j-m}\varphi_{j-m}(z)=\sqrt{\frac{(2j)!}{(j+m)!(j-m)!}}z^{j-m};\quad m=-j,\ldots,j\right\}, \tag{60}$$

respectively.

The coherent state representation Γ^j of SU(2) on $\mathcal{F}^j$ is defined by

$$[\Gamma^j(g)\Psi](z)=\langle 0|e^{z\hat{J}_+}T^j(g)|\psi\rangle \tag{61}$$

[cf. Eq. (14)]. From the identity

$$e^{zJ_+}\begin{pmatrix}a & b\\ -b^* & a^*\end{pmatrix}=\begin{pmatrix}a-zb^* & b+za^*\\ -b^* & a^*\end{pmatrix}=e^{-\alpha b^*J_-}(a-b^*z)^{2J_0}e^{\alpha(b+a^*z)J_+} \tag{62}$$

with $\alpha=(a-b^*z)^{-1}$, the action of $\Gamma^j(g)$ is determined to be

$$[\Gamma^j(g)\Psi](z)=(a-b^*z)^{2j}\Psi(z\cdot g), \tag{63}$$

with

$$g=\begin{pmatrix}a & b\\ -b^* & a^*\end{pmatrix},\quad z\cdot g=\frac{b+a^*z}{a-b^*z}. \tag{64}$$

Finally, since the inner product can be written in the form $\langle\psi|\varphi\rangle=\int\psi^*(z)\Phi(z)\mathrm{d}\upsilon(z)$, matrix elements of the representation T are given by

$$\langle\psi|T^j(g)|\varphi\rangle=\int\psi^*(z)[\Gamma^j(g)\Phi](z)\mathrm{d}\upsilon(z), \tag{65}$$

where φ, $|\varphi\rangle$, and Φ are related by the $\mathcal{F}_j\to\mathbb{H}^j\to\mathcal{F}^j$ maps given by Eqs. (57) and (58). For example, setting $c=\cos\beta/2$ and $s=\sin\beta/2$ and

$$g=\begin{pmatrix} c & -s \\ s & c \end{pmatrix}, \tag{66}$$

one obtains, from Eq. (65), an expression for the Wigner function

$$\begin{aligned} d^j_{mn}(\beta)=\langle jm|T^j(g)|jn\rangle&=\int\psi^*_{j-m}(z)[\Gamma^j(g)\Psi_{j-n}](z)\mathrm{d}\upsilon(z)\\ &=\frac{K_{j-n}}{K_{j-m}}\int\varphi^*_{j-m}(z)[\Gamma^j(g)\varphi_{j-n}](z)\mathrm{d}\upsilon(z)\\ &=\frac{K_{j-n}}{K_{j-m}}\int\varphi^*_{j-m}(z)(c+sz)^{j+n}\varphi_{j-n}(-s+cz)\mathrm{d}\upsilon(z), \end{aligned} \tag{67}$$

which integrates to the standard result.

The coherent state representation of the $\mathfrak{su}(2)$ Lie algebra, defined by

$$[\Gamma^j(J_k)\Psi](z)=\langle jj|e^{z\hat{J}_+}\hat{J}_k|\psi\rangle, \tag{68}$$

yields the known expressions

$$\Gamma^j(J_+)=\frac{d}{dz},\quad \Gamma^j(J_0)=j-z\frac{d}{dz},\quad \Gamma^j(J_-)=2jz-z^2\frac{d}{dz}. \tag{69}$$

Acting on the orthonormal coherent state basis wave functions of Eq. (60), they give the expected results

$$\begin{aligned} \Gamma^j(J_0)\Psi_{jm}&=m\Psi_{jm},\\ \Gamma^j(J_\pm)\Psi_{jm}&=\sqrt{(j\mp m)(j\pm m+1)}\Psi_{j,m\pm1}. \end{aligned} \tag{70}$$

The above expressions may be compared to those of the standard holomorphic representations of SU(2). The latter are identical to the coherent state representations but specify the inner product for the Hilbert space $\mathcal{F}^j$ by

$$\langle\psi|\varphi\rangle=\frac{2j+1}{\pi}\int\frac{\Psi^*(z)\Phi(z)}{(1+|z|^2)^{2j+2}}\mathrm{d}^2z, \tag{71}$$

where the integral is over the complex plane with $\mathrm{d}^2z=\mathrm{d}x\mathrm{d}y$ and $z=x+iy$; cf. Ref. 13 and the Appendix. Thus, whereas $\mathcal{F}^j$ is a space of holomorphic functions with norm defined by this inner product, the space $\mathcal{F}_j$, isomorphic to $\mathcal{F}^j$, is the space of holomorphic functions with inner product

$$\langle\psi|\varphi\rangle=\int\int\psi^*(z)(1+zx^*)^{2j}\varphi(x)\mathrm{d}\upsilon(z)\mathrm{d}\upsilon(x). \tag{72}$$

The latter integrals are easier to evaluate and by regarding $\mathcal{F}_j$ and $\mathcal{F}^j$ as mutual duals, we have the still simpler hybrid expression

$$\langle \psi | \varphi \rangle = \int \psi^*(z)\Phi(z)\mathrm{d}v(z). \tag{73}$$

B. SU(1,1)

Let $\{J_0, J_+, J_-\}$ with commutation relations

$$[J_-, J_+] = 2J_0, \quad [J_0, J_\pm] = \pm J_\pm, \tag{74}$$

be a standard basis for the Lie algebra $\mathfrak{su}(1,1)^c$. Let T^λ be a UIR (unitary irreducible representation) of SU(1,1) of lowest weight λ on an infinite-dimensional Hilbert space $\mathbb{H}^\lambda$, where λ is a positive integer, defined such that, if $|0\rangle$ is the lowest weight state, then

$$\hat{J}_-|0\rangle = 0, \quad 2\hat{J}_0|0\rangle = \lambda|0\rangle, \tag{75}$$

where $\hat{J}_k = T^\lambda(J_k)$.

Gauss factorization of almost any $\mathrm{SL}(2,\mathbb{C})$ matrix gives

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \begin{pmatrix} d^{-1} & 0 \\ 0 & d \end{pmatrix} \begin{pmatrix} 1 & 0 \\ z & 1 \end{pmatrix} = e^{-xJ_+}(d)^{-2J_0}e^{zJ_-}, \tag{76}$$

with $x = b/d$ and $z = c/d$. This implies that, if g is the SU(1,1) matrix

$$g = \begin{pmatrix} a & b \\ b^* & a^* \end{pmatrix} \quad \text{with} \quad aa^* - bb^* = 1, \tag{77}$$

then $T^\lambda(g)$ can be expanded

$$T^\lambda(g) = e^{-x\hat{J}_+}(a^*)^{-2\hat{J}_0}e^{z\hat{J}_-} \tag{78}$$

and

$$\langle 0|T^\lambda(g)|\psi\rangle = (a^*)^{-\lambda}\langle 0|e^{z\hat{J}_-}|\psi\rangle, \tag{79}$$

with $x = b/a^*$ and $z = b^*/a^*$. Thus, a natural choice of $N \subset \mathrm{SU}(1,1)^c \cong \mathrm{SL}(2,\mathbb{R})^c$ is the Borel subgroup

$$N = \{e^{zJ_-}; z \in \mathbb{C}\}. \tag{80}$$

With this choice of N, the functionals

$$\{\langle 0|e^{z\hat{J}_-}; z \in \mathbb{C}\} \tag{81}$$

are well-defined on the dense subspace $\mathbb{H}_D$ of finite linear combinations of the weight vectors (the so-called K-finite vectors). Thus, a coherent state wave function for a state $|\psi\rangle \in \mathbb{H}_D$ is defined by

$$\Psi(z) = \langle 0|e^{z\hat{J}_-}|\psi\rangle. \tag{82}$$

These coherent state wave functions are polynomials in z.

Let $\mathcal{F}$ denote the Bargmann Hilbert space of holomorphic functions over $\mathbb{C}$ with orthonormal (polynomial) basis $\{\varphi_\nu; \nu = 0,1,2,\ldots\}$, where $\varphi_\nu(z) = z^\nu/\sqrt{\nu!}$. Now observe that the map

$$\varphi \to \langle \varphi | = \int \mathrm{d}v(z)\, \varphi(z)^* \langle 0 | e^{z\hat{J}_-} \tag{83}$$

takes any function $\varphi \in \mathcal{F}$ to a well-defined functional on $\mathbb{H}_D$. The image of this $\mathcal{F} \to \mathbb{H}_D^*$ map contains $\mathbb{H}_D$. Moreover, $\mathcal{F}_D \subset \mathcal{F}$ is identified as the dense subspace of finite polynomials. Thus, if $\mathcal{F}^\lambda = \mathcal{F}^{\mathbb{H}_D}$ is the space of coherent state wave functions for states in $\mathbb{H}_D$, then composition of the maps $\mathcal{F}_D \to \mathbb{H}_D$ and $\mathbb{H}_D \to \mathcal{F}^{\mathbb{H}_D}$ gives the map

$$\hat{\mathcal{S}}: \mathcal{F}_D \to \mathcal{F}^{\mathbb{H}_D}; \psi \mapsto \Psi = \hat{\mathcal{S}}\psi, \tag{84}$$

with

$$\Psi(z) = \int \mathcal{S}(z,x)\, \psi(x)\, \mathrm{d}v(x), \tag{85}$$

and

$$\mathcal{S}(z,x) = \langle 0 | e^{z\hat{J}_-} e^{x^*\hat{J}_+} | 0 \rangle. \tag{86}$$

Claim: The overlap integral $\mathcal{S}(z,x)$ is the distribution on $\mathcal{F}_D$,

$$\mathcal{S}(z,x) = \sum_\nu^\infty K_\nu^2 \varphi_\nu(z)\, \varphi_\nu^*(x), \tag{87}$$

with

$$K_\nu^2 = \frac{(\lambda+\nu-1)!}{(\lambda-1)!}. \tag{88}$$

Proof: First observe that, from its definition (86), $\mathcal{S}(z,x)$ is holomorphic in z and x^*. Thus, it is sufficient to prove the claim for z and x^* lying in some open domain of $\mathbb{C}$. In fact, the $\mathrm{SU}(1,1)^c = \mathrm{SL}(2,\mathbb{C})$ expansion

$$e^{zJ_-} e^{x^*J_+} = \begin{pmatrix} 1 & 0 \\ z & 1 \end{pmatrix} \begin{pmatrix} 1 & -x^* \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & -x^* \\ z & 1-zx^* \end{pmatrix} \tag{89}$$

$$= e^{\alpha x^* J_+} (\alpha)^{2J_0} e^{\alpha z J_-}, \tag{90}$$

with $\alpha = (1-zx^*)^{-1}$, together with the assumption that

$$T^\lambda (e^{\alpha x^* J_+} (1-zx^*)^{-2J_0} e^{\alpha z J_-}) = e^{\alpha x^* \hat{J}_+} (1-zx^*)^{-2\hat{J}_0} e^{\alpha z \hat{J}_-}, \tag{91}$$

gives the correct result for $|zx^*| < 1$:

$$\mathcal{S}(z,x) = \langle 0 | (1-zx^*)^{-2\hat{J}_0} | 0 \rangle = (1-zx^*)^{-\lambda} = \sum_\nu^\infty K_\nu^2 \varphi_\nu(z)\, \varphi_\nu^*(x), \quad \text{for} \quad |zx^*| < 1. \tag{92}$$

However, this result could be questioned because the representation T^λ of $\mathrm{SU}(1,1)$ does not in general extend to all of $\mathrm{SL}(2,\mathbb{C})$, so applying it to elements of the complex group is not, in general, justified; an infinite-dimensional irrep of $\mathrm{SL}(2,\mathbb{C})$ does not remain irreducible on restriction to $\mathrm{SU}(1,1)$. Nevertheless, Eq. (92) is valid for $|z|^2 < 1$ and $|x|^2 < 1$, because there exist matrices

$$Z_+(z^*)=\begin{pmatrix} a^{-1} & az^* \\ 0 & a \end{pmatrix}, \quad Z_-(x)=\begin{pmatrix} b^{-1} & 0 \\ -b^*x & b \end{pmatrix}, \tag{93}$$

with $|a|^2=(1-|z|^2)^{-1}$ and $|b|^2=(1-|x|^2)^{-1}$, such that

$$Z_+(z^*)e^{zJ_-}=\begin{pmatrix} a^{-1} & a^*z^* \\ 0 & a \end{pmatrix}\begin{pmatrix} 1 & 0 \\ z & 1 \end{pmatrix}=\begin{pmatrix} a^* & a^*z^* \\ az & a \end{pmatrix}, \tag{94}$$

$$e^{x^*J_+}Z_-(x)=\begin{pmatrix} 1 & -x^* \\ 0 & 1 \end{pmatrix}\begin{pmatrix} b^{-1} & 0 \\ -b^*x & b \end{pmatrix}=\begin{pmatrix} b^* & -bx^* \\ -b^*x & b \end{pmatrix} \tag{95}$$

are elements of the real Lie group SU(1,1). Factorization of the product of real SU(1,1) group elements

$$Z_+(z^*)e^{zJ_-}e^{x^*J_+}Z_-(x)=Z_+(z^*)e^{\alpha x^*J_+}(\alpha)^{2J_0}e^{\alpha zJ_-}Z_-(x), \tag{96}$$

with $\alpha=(1-zx^*)^{-1}$, then gives the result (92) and confirms the validity of the claim. Q.E.D.

For polynomial functions ψ, φ, the inner product

$$\langle\psi|\varphi\rangle=\int\int \psi^*(z)\mathcal{S}(z,x)\varphi(x)\mathrm{d}\nu(z)\mathrm{d}\nu(x)=\sum_\nu K_\nu^2\int \psi^*(z)\varphi_\nu(z)\mathrm{d}\nu(z)\int \varphi_\nu^*(x)\varphi(x)\mathrm{d}\nu(x) \tag{97}$$

is now well-defined. In particular, the wave functions $\{\varphi_\nu\}$ have inner products $\langle\varphi_\mu|\varphi_\nu\rangle=\delta_{\mu\nu}K_\nu^2$ and norms that are nonvanishing for all integers $\nu\geqslant 0$. Thus, the Hilbert space $\mathcal{F}_\lambda$, isomorphic to $\mathbb{H}^\lambda$, is the completion of the space of holomorphic polynomials with respect to the inner product (97). Relative to this inner product, the normalized functions

$$\left\{\psi_{\lambda\nu}(z)=\frac{1}{K_\nu}\varphi_\nu(z)=\sqrt{\frac{(\lambda-1)!}{(\lambda+\nu-1)!\,\nu!}}z^\nu;\quad \nu=0,1,2,\ldots\right\} \tag{98}$$

form an orthonormal basis for $\mathcal{F}_\lambda$.

The (densely defined) map $\mathcal{F}_\lambda\to\mathbb{H}^\lambda$, with

$$\psi_{\lambda\nu}\to|\lambda\,\nu\rangle=\int e^{z^*\hat{J}_+}|0\rangle\psi_{\lambda\nu}(z)\mathrm{d}\nu(z), \tag{99}$$

and the coherent state map $\mathbb{H}^\lambda\to\mathcal{F}^\lambda;|\lambda\,\nu\rangle\to\Psi_{\lambda\nu}$, with

$$\Psi_{\lambda\nu}(z)=\langle 0|e^{z\hat{J}_-}|\lambda\,\nu\rangle=\int\langle 0|e^{z\hat{J}_-}e^{x^*\hat{J}_+}|0\rangle\psi_{\lambda\nu}(x)\mathrm{d}\nu(x)=\int\mathcal{S}(z,x)\psi_{\lambda\nu}(x)\mathrm{d}\nu(x), \tag{100}$$

define corresponding orthonormal bases

$$\left\{|\lambda\,\nu\rangle=\frac{1}{K_\nu}|\varphi_\nu\rangle=\sqrt{\frac{(\lambda-1)!}{(\lambda+\nu-1)!\,\nu!}}(\hat{J}_+)^\nu|0\rangle;\quad \nu=0,1,2,\ldots\right\}, \tag{101}$$

$$\left\{\Psi_{\lambda\nu}(z)=K_\nu\varphi_\nu(z)=\sqrt{\frac{(\lambda+\nu-1)!}{(\lambda-1)!\,\nu!}}z^\nu;\quad \nu=0,1,2,\ldots\right\}, \tag{102}$$

for $\mathbb{H}^\lambda$ and $\mathcal{F}^\lambda$, respectively.

Proceeding as for SU(2), we find that the coherent state representation Γ^λ of SU(1,1) acts on $\Psi(z)\in\mathcal{F}^\lambda$ by

$$[\Gamma^{\lambda}(g)\Psi](z)=(a^*+bz)^{-\lambda}\Psi(z\cdot g), \tag{103}$$

with

$$g=\begin{pmatrix} a & b \\ b^* & a^* \end{pmatrix}, \quad z\cdot g=\frac{b^*+az}{a^*+bz}. \tag{104}$$

Matrices of the representation Γ^{λ} are easily evaluated in the basis (101). For example, for

$$g=\begin{pmatrix} c & s \\ s & c \end{pmatrix}, \quad c=\cosh\beta/2, \quad s=\sinh\beta/2, \tag{105}$$

an SU(1,1) Wigner function is given by

$$\begin{aligned}\langle\lambda\mu|T^{\lambda}(g)|\lambda\nu\rangle&=\int \psi^*_{\lambda\mu}(z)[\Gamma^{\lambda}(g)\Psi_{\lambda\nu}](z)\mathrm{d}v(z)\\ &=\frac{K_{\nu}}{K_{\mu}}\int \varphi^*_{\mu}(z)[\Gamma^{\lambda}(g)\varphi_{\nu}](z)\mathrm{d}v(z)\\ &=\sqrt{\frac{(\lambda+\nu-1)!}{(\lambda+\mu-1)!\mu!\nu!}}\int (z^*)^{\mu}(s+cz)^{\nu}(c+sz)^{-(\lambda+\nu)}\mathrm{d}v(z)\\ &=\sqrt{\frac{\mu!\nu!}{(\lambda+\mu-1)!(\lambda+\nu-1)!}}\sum_{n=0}^{\mu}(-1)^n\frac{(\lambda+\nu+n-1)!}{(\nu-\mu+n)!(\mu-n)!n!}\\ &\quad\times(\cosh\beta/2)^{\mu-\nu-\lambda-2n}(\sinh\beta/2)^{\nu-\mu+2n},\end{aligned} \tag{106}$$

cf. expressions obtained by Dunne[27] and Ui.[28]

Coherent state representations of the $\mathfrak{su}(1,1)$ Lie algebra have the known expressions

$$\Gamma^{\lambda}(J_+)=\lambda z+z^2\frac{d}{dz}, \quad \Gamma^{\lambda}(J_0)=\frac{1}{2}\lambda+z\frac{d}{dz}, \quad \Gamma^{\lambda}(J_-)=\frac{d}{dz}. \tag{107}$$

Acting on the orthonormal basis wave functions of Eq. (102), they give

$$\begin{aligned}\Gamma^{\lambda}(J_0)\Psi_{\lambda\nu}&=\tfrac{1}{2}(\lambda+2\nu)\Psi_{\lambda\nu},\\ \Gamma^{\lambda}(J_+)\Psi_{\lambda\nu}&=\sqrt{(\lambda+\nu)(\nu+1)}\,\Psi_{\lambda,\nu+1},\\ \Gamma^{\lambda}(J_-)\Psi_{\lambda,\nu}&=\sqrt{(\lambda+\nu-1)\nu}\,\Psi_{\lambda,\nu-1}.\end{aligned} \tag{108}$$

The inner product for $\mathcal{F}^{\lambda}$ is known to be given, for a holomorphic discrete series representation (for which λ is an integer greater than 1), by

$$\langle\psi|\varphi\rangle=\frac{\lambda-1}{\pi}\int_{|z|<1}\Psi^*(z)\Phi(z)(1-|z|^2)^{\lambda-2}\mathrm{d}^2z, \tag{109}$$

where $\Psi=\hat{\mathcal{S}}\psi$, $\Phi=\hat{\mathcal{S}}\varphi$ and the integral is over the interior of the unit disk.[27] When $\lambda>1$, this inner product is identical to that given for $\mathcal{F}_{\lambda}$ by Eq. (97). However, the latter is easier to evaluate. Moreover, unlike the integral of Eq. (109), it is defined for all non-negative values of λ and gives results, not only for SU(1,1), but also for its universal covering group.

C. The semidirect product group $[\mathbb{R}^6]$SO(3)

Let G be the semidirect product $[\mathbb{R}^6]\mathrm{SO}(3)$ of an Abelian normal subgroup $\mathbb{R}^6$, isomorphic to the additive group of real symmetric 3×3 matrices, and the rotation group SO(3). Elements of $[\mathbb{R}^6]\mathrm{SO}(3)$ are pairs of group elements, $\{(Q,\Omega);Q\in\mathbb{R}^6,\Omega\in\mathrm{SO}(3)\}$ with product

$$(Q,\Omega)\circ(Q',\Omega')=(Q+\Omega Q'\tilde{\Omega},\Omega\Omega'), \tag{110}$$

where $\tilde{\Omega}=\Omega^{-1}$ is the transpose of Ω. With Q expressed as a sum $Q=\Sigma_{ij}Q_{ij}\mathfrak{I}_{ij}$, where $\{\mathfrak{I}_{ij}\}$ is a basis of real symmetric matrices, this group is interpreted as the dynamical group of a rotor for which the corresponding Lie algebra is spanned by moments $\{\mathfrak{I}_{ij}\}$ of an inertia tensor $\mathfrak{I}$ and components $\{L_k\}$ of angular momentum [infinitesimal generators of SO(3)].

Let T be a UIR of G on a Hilbert space $\mathbb{H}$. The coherent-state construction of such an irrep mimics Mackey's induction.[3] The construction starts with a one-dimensional unitary irrep of the $\mathbb{R}^6$ subalgebra defined by a so-called *intrinsic inertia tensor* $\bar{\mathfrak{I}}$ which assigns numerical values $\bar{\mathfrak{I}}_{ij}$ to the moments of inertia $\mathfrak{I}_{ij}$; i.e.,

$$\bar{\mathfrak{I}}:\mathfrak{I}_{ij}\to\bar{\mathfrak{I}}_{ij}=\delta_{ij}\bar{\mathfrak{I}}_i. \tag{111}$$

A corresponding one-dimensional unitary irrep of the $\mathbb{R}^6$ group is then defined by

$$Q\to\chi^{-}_{\bar{\mathfrak{I}}}(Q)=e^{i\mathrm{Tr}(Q\bar{\mathfrak{I}})}. \tag{112}$$

Now let

$$D=\{\omega\in\mathrm{SO}(3)\,|\,\omega\bar{\mathfrak{I}}\tilde{\omega}=\bar{\mathfrak{I}}\}, \tag{113}$$

with $(\omega\bar{\mathfrak{I}}\tilde{\omega})_{ij}=\Sigma_{kl}\omega_{ik}\bar{\mathfrak{I}}_{kl}\omega_{jl}$, denote the isotropy subgroup of rotations that leave the intrinsic moments of inertia invariant. To be specific, we take the intrinsic moments of inertia $(\bar{\mathfrak{I}}_1,\bar{\mathfrak{I}}_2,\bar{\mathfrak{I}}_3)$ to be positive and distinct. Then D is the discrete group D_2 comprising the four rotations (parametrized in terms of Euler angles):

$$\omega_1\sim(0,0,0),\quad \omega_2\sim(0,\pi,0),\quad \omega_3\sim(\pi,0,0),\quad \omega_4=\omega_3\omega_2\sim(\pi,\pi,0). \tag{114}$$

This group has four irreps, all of which are one-dimensional. Thus, an irrep $\rho^{-}_{\bar{\mathfrak{I}},\varepsilon}$ of $[\mathbb{R}^6]D_2$ is defined by

$$(Q,\omega_i)\to\rho^{-}_{\bar{\mathfrak{I}},\varepsilon}(Q,\omega_i)=\chi^{-}_{\bar{\mathfrak{I}}}(Q)\varepsilon(\omega_i),\quad i=1,\ldots,4, \tag{115}$$

with $\varepsilon(\omega_1)=1$, $\varepsilon(\omega_2)=\pm 1$, $\varepsilon(\omega_3)=\pm 1$ and $\varepsilon(\omega_4)=\varepsilon(\omega_2)\varepsilon(\omega_3)$.

Let $\langle\bar{\mathfrak{I}},\varepsilon|$ be a functional on a suitably defined dense subspace $\mathbb{H}_D$ of $\mathbb{H}$ which *picks out* a particular irrep of the subgroup $[\mathbb{R}^6]D_2\subset[\mathbb{R}^6]\mathrm{SO}(3)$ in the sense that

$$\langle\bar{\mathfrak{I}},\varepsilon|T(Q,\omega)|\psi\rangle=\chi^{-}_{\bar{\mathfrak{I}}}(Q)\varepsilon(\omega)\langle\bar{\mathfrak{I}},\varepsilon|\psi\rangle,\quad \forall|\psi\rangle\in\mathbb{H}_D,\quad \forall\,\omega\in D_2. \tag{116}$$

A suitable dense subspace $\mathbb{H}_D$ is the SO(3)-invariant space of K-finite vectors in $\mathbb{H}$ comprising all states that are finite linear combinations of vectors from a multiplicity of SO(3) irreps. A coherent state wave function Ψ for a vector $|\psi\rangle\in\mathbb{H}_D$ is then defined by

$$\Psi(\Omega)=\langle\bar{\mathfrak{I}},\varepsilon|\hat{R}(\Omega)|\psi\rangle. \tag{117}$$

The space of such wave functions, $\mathcal{F}^{\mathbb{H}_D}$, carries a representation of $[\mathbb{R}^6]\mathrm{SO}(3)$ defined by

$$[\Gamma(Q,\Omega)\Psi](\Omega')=\langle\bar{\mathfrak{I}},\varepsilon|T(\Omega' Q\tilde{\Omega}',\Omega'\Omega)|\psi\rangle=\chi^{-}_{\bar{\mathfrak{I}}}(\Omega' Q\tilde{\Omega}')\Psi(\Omega'\Omega). \tag{118}$$

The action of Γ defined by Eq. (118) is unitary on $\mathcal{L}^2(\mathrm{SO}(3))$. Thus, we infer from Eq. (116) that the coherent state representation is realized on an irreducible subspace of $\mathcal{L}^2(\mathrm{SO}(3))$ that satisfies the constraint

$$\Psi(\omega\Omega)=\varepsilon(\omega)\Psi(\Omega), \quad \forall\,\omega\in D_2. \tag{119}$$

To construct the triplet, we start with an orthonormal basis for the space $\mathcal{F}=\mathcal{L}^2(\mathrm{SO}(3))$ given by functions

$$\varphi_{KLM}=\sqrt{\frac{2L+1}{8\pi^2}}\mathcal{D}^L_{KM}, \tag{120}$$

where $\mathcal{D}^L_{KM}$ is an SO(3) Wigner function. Consider the map $\mathcal{F}^*\to\mathbb{H}_D^*$ which sends

$$\varphi^*_{KLM}\mapsto\langle KLM|=\sqrt{\frac{2L+1}{8\pi^2}}\int \mathrm{d}\Omega\mathcal{D}^L_{KM}(\Omega)^*\langle\bar{\mathfrak{I}},\varepsilon|R(\Omega). \tag{121}$$

As a functional on $\mathbb{H}_D$, $\langle KLM|$ is nonzero on the finite-dimensional subspace consisting of copies of the SO(3) irrep with angular momentum L, but it is zero on the orthogonal complement of this space. In particular, it can be regarded as a linear functional on a finite-dimensional space, so it must actually be given by a vector in that space. The inner products of such vectors in $\mathbb{H}$ are then expressed

$$\begin{aligned}\langle K'L'M'|KLM\rangle&=\delta_{L'L}\delta_{M'M}\frac{2L+1}{8\pi^2}\int\int \mathcal{D}^L_{K'M}(\Omega')^*\langle\bar{\mathfrak{I}},\varepsilon|\hat{R}(\Omega'\Omega^{-1})|\bar{\mathfrak{I}},\varepsilon\rangle\mathcal{D}^L_{KM}(\Omega)\mathrm{d}\Omega\,\mathrm{d}\Omega'\\&=\delta_{L'L}\delta_{M'M}\int \mathcal{D}^L_{K'K}(\Omega)^*\langle\bar{\mathfrak{I}},\varepsilon|\hat{R}(\Omega)|\bar{\mathfrak{I}},\varepsilon\rangle\mathrm{d}\Omega.\end{aligned} \tag{122}$$

Thus, we obtain a densely defined sequence of maps $\mathcal{F}_D\to\mathbb{H}_D\to\mathcal{F}^{\mathbb{H}_D}$ in which $\varphi_{KLM}\mapsto|KLM\rangle\mapsto\Phi_{KLM}$, where the coherent state wave function Φ_{KLM} for the state $|KLM\rangle$ is given by

$$\Phi_{KLM}(\Omega)=\langle\bar{\mathfrak{I}},\varepsilon|\hat{R}(\Omega)|KLM\rangle=\int \mathcal{S}(\Omega\tilde{\Omega}')\varphi_{KLM}(\Omega')\mathrm{d}\Omega' \tag{123}$$

and $\mathcal{S}$ is the functional on $\mathcal{F}$ given by

$$\mathcal{S}(\Omega)=\langle\bar{\mathfrak{I}},\varepsilon|\hat{R}(\Omega)|\bar{\mathfrak{I}},\varepsilon\rangle. \tag{124}$$

Thus, the inner product for $\mathbb{H}$ is expressed in terms of the $\{|KLM\rangle\}$ basis,

$$\langle K'L'M'|KLM\rangle=\int \varphi^*_{K'L'M'}(\Omega)\Phi_{KLM}(\Omega)\mathrm{d}\Omega. \tag{125}$$

Clearly the functions φ_{KLM} and Φ_{KLM} are dual representations of the state vector $|KLM\rangle$ relative to the measure $\mathrm{d}\Omega$.

The norm of the functional $\langle\bar{\mathfrak{I}},\varepsilon|$, and hence of $\mathcal{S}$, is arbitrary. The essential requirement is that the coherent state functions $\{\Phi_{KLM}\}$ obtained from all basis functions $\{\varphi_{KLM}\}$ of $\mathcal{F}$ should satisfy the constraint condition of Eq. (119). Thus, $\mathcal{S}$ must satisfy the equation

$$\mathcal{S}(\omega\Omega)=\varepsilon(\omega)\mathcal{S}(\Omega), \quad \forall\,\omega\in \mathrm{D}_2. \tag{126}$$

From its definition, Eq. (124), $\mathcal{S}$ also satisfies the equation

$$(\Omega\bar{\mathcal{I}}\tilde{\Omega})\mathcal{S}(\Omega)=\bar{\mathcal{I}}\mathcal{S}(\Omega),\quad \forall\Omega\in \mathrm{SO}(3). \tag{127}$$

Thus, to within an arbitrary norm factor, it has the unique solution

$$\mathcal{S}(\Omega)=\frac{1}{4}\sum_{\omega\in \mathrm{D}_2}\varepsilon(\omega)\delta(\Omega,\omega). \tag{128}$$

With this normalization,

$$\begin{aligned}\Phi_{KLM}(\Omega)&=\sqrt{\frac{2L+1}{8\pi^2}}\int \mathrm{d}\Omega'\mathcal{S}(\Omega\tilde{\Omega}')\mathcal{D}^L_{KM}(\Omega')\\ &=\sqrt{\frac{2L+1}{8\pi^2}}\frac{(1+(-1)^K\varepsilon_3)}{4}(\mathcal{D}^L_{KM}(\Omega)+(-1)^{L+K}\varepsilon_2\mathcal{D}^L_{-K,M}(\Omega)),\end{aligned} \tag{129}$$

where $\varepsilon_2=\varepsilon(\omega_2)$ and $\varepsilon_3=\varepsilon(\omega_3)$.

It is seen that the states $\{|KLM\rangle\}$ are not all linearly independent. In particular, the wave functions Φ_{KLM} with $(-1)^K\varepsilon(\omega_3)=-1$ vanish as do those with $K=0$ and $(-1)^L\varepsilon_2=-1$. Moreover, the wave functions $\Phi_{\pm KLM}$ differ by only a phase factor. Thus, it is appropriate to restrict to labels KLM with $K\geqslant 0$ and nonvanishing wave functions Φ_{KLM}. The subspace of $\mathcal{F}$ spanned by the corresponding restricted basis functions $\{\varphi_{KLM}\}$ is then isomorphic, as a vector space, to the space obtained by factoring out the kernel of the map $\mathcal{F}\to\mathbb{H}$.

With $|KLM\rangle$ restricted in this way, the overlaps are given by

$$\langle K'L'M'|KLM\rangle=\int \varphi^*_{K'L'M'}(\Omega)\Phi_{KLM}(\Omega)d\Omega=\frac{1}{2}(1+\delta_{K,0})\,\delta_{L'L}\delta_{M'M}\delta_{K'K}. \tag{130}$$

The triplet of Hilbert spaces $\mathcal{F}_{\mathrm{H}}\sim\mathbb{H}\sim\mathcal{F}^{\mathrm{H}}$ is then defined with orthornormal bases given, respectively, by

$$\begin{gathered}\left\{\psi_{KLM}=\sqrt{\frac{2L+1}{4\pi^2(1+\delta_{K,0})}}\mathcal{D}^L_{KM};\quad K\geqslant 0\right\},\\ \left\{\sqrt{\frac{2}{(1+\delta_{K,0})}}|KLM\rangle;\quad K\geqslant 0\right\},\\ \left\{\Psi_{KLM}=\sqrt{\frac{2L+1}{16\pi^2(1+\delta_{K,0})}}[\mathcal{D}^L_{KM}+\varepsilon_2(-1)^{L+K}\mathcal{D}^L_{-K,M}];\quad K\geqslant 0\right\},\end{gathered} \tag{131}$$

with K restricted to even or odd integer values according as $\varepsilon_3=\pm 1$ and with L restricted to even or odd integer values when $K=0$ according as $\varepsilon_2=\pm 1$.

These wave functions satisfy the orthogonality relations

$$\int \psi^*_{KLM}(\Omega)\psi_{K'L'M'}\mathrm{d}\Omega=\delta_{LL'}\delta_{KK'}\delta_{MM'}. \tag{132}$$

In addition, with the chosen norm for $\mathcal{S}(\Omega)$, the coherent state wave functions on their own also satisfy

$$\int \Psi^*_{KLM}(\Omega)\psi_{K'L'M'}\mathrm{d}\Omega=\delta_{LL'}\delta_{KK'}\delta_{MM'}. \tag{133}$$

This is a special case that arises because the appropriate volume element for the Hilbert space of coherent-state wave functions for the rotor group happens to be the SO(3)-invariant volume. A

similar result occurs for the Heisenberg–Weyl group with the Bargmann measure. It is nevertheless useful to see this special case in the context of the general construction which can be applied when the end results are less easily anticipated. The following derivation of SU(3) irreps in an SO(3) basis is an example for which the construction is used with considerable advantage.

D. SU(3)⊃SO(3)

Let $|\lambda\mu\rangle$ denote a highest weight state for an SU(3) irrep $T^{(\lambda\mu)}$ of highest weight (λ,μ) with respect to the diagonal Cartan subgroup. It is known that the Hilbert space $\mathbb{H}^{(\lambda\mu)}$ for such an irrep is spanned by the set of states generated by rotating the state $|\lambda\mu\rangle$ with the elements of the subgroup $\mathrm{SO}(3)\subset\mathrm{SU}(3)$.[29] Thus, we may take N to be SO(3) and consider the coherent state representation in which a vector $|\psi\rangle\in\mathbb{H}^{(\lambda\mu)}$ is represented by a wave function over SO(3) with values

$$\Psi(\Omega)=\langle\lambda\mu|\hat{R}(\Omega)|\psi\rangle,\quad \Omega\in\mathrm{SO}(3), \tag{134}$$

where $\hat{R}$ is the restriction of $T^{(\lambda\mu)}$ to the $\mathrm{SO}(3)\subset\mathrm{SU}(3)$ subgroup.

Let $\mathcal{F}=\mathcal{L}^2(\mathrm{SO}(3))$ be the square integrable functions on SO(3) relative to its invariant measure $\mathrm{d}\Omega$. The map $\mathcal{F}\to\mathbb{H}^{(\lambda\mu)}$ is then

$$\varphi\to|\varphi\rangle=\int \hat{R}(\Omega^{-1})|\lambda\mu\rangle\varphi(\Omega)\mathrm{d}\Omega \tag{135}$$

and the space $\mathcal{F}_{(\lambda\mu)}$ isomorphic to $\mathbb{H}^{(\lambda\mu)}$ is defined by the inner product

$$(\psi,\varphi)=\langle\psi|\varphi\rangle=\int\int \psi^*(\Omega')\mathcal{S}(\Omega'\tilde{\Omega})\varphi(\Omega)\mathrm{d}\Omega'\mathrm{d}\Omega, \tag{136}$$

where

$$\mathcal{S}(\Omega)=\langle\lambda\mu|\hat{R}(\Omega)|\lambda\mu\rangle. \tag{137}$$

The overlap kernel $\mathcal{S}$ is easily evaluated by considering a realization of the SU(3) irrep in a Bargmann space[11] in which the highest weight state $|\lambda\mu\rangle$ is represented by the wave function $\phi_{\lambda\mu}$ with values

$$\phi_{\lambda\mu}(\mathbf{r},\mathbf{r}')\propto z^\lambda Y^\mu, \tag{138}$$

where z is a component of a complex vector $\mathbf{r}\equiv(x,y,z)$ and Y is a component of $\mathbf{r}\times\mathbf{r}'\equiv(X,Y,Z)$. Thus, with

$$[\hat{R}(\Omega)\phi_{\lambda\mu}](\mathbf{r},\mathbf{r}')=\phi_{\lambda\mu}(\mathbf{r}\Omega,\mathbf{r}'\Omega), \tag{139}$$

and $\Omega\equiv(\alpha,\beta,\gamma)$ parametrized by Euler angles, $\mathcal{S}$ is given by[30]

$$\mathcal{S}(\Omega)=\langle\lambda\mu|\hat{R}(\Omega)|\lambda\mu\rangle=(\cos\beta)^\lambda(\cos\alpha\cos\gamma-\sin\alpha\cos\beta\sin\gamma)^\mu. \tag{140}$$

From the Bargmann representation, it is also apparent that the state $|\lambda\mu\rangle$ spans a one-dimensional representation of the D_2 subgroup of SO(3) in which, in the notations of Eq. (114),

$$\hat{R}(\omega)|\lambda\mu\rangle=\varepsilon(\omega)|\lambda\mu\rangle,\quad \omega\in D_2, \tag{141}$$

with

$$\varepsilon(\omega_2)=(-1)^\lambda,\quad \varepsilon(\omega_3)=(-1)^\mu. \tag{142}$$

Thus, the SU(3) coherent state wave functions satisfy the symmetry property

$$\Psi(\omega\Omega)=\varepsilon(\omega)\Psi(\Omega), \quad \omega\in D_2. \tag{143}$$

According to the Peter–Weyl theorem,[31] a basis for $\mathcal{F}=\mathcal{L}^2(\mathrm{SO}(3))$ is given by the functions

$$\varphi_{KLM}=\sqrt{\frac{2L+1}{8\pi^2}}\mathcal{D}^L_{KM}, \tag{144}$$

where $\mathcal{D}^L_{KM}$ is an SO(3) Wigner (matrix coefficient) function. These functions satisfy

$$\int \varphi^*_{KLM}(\Omega)\varphi_{K'L'M'}(\Omega)\mathrm{d}\Omega=\delta_{LL'}\delta_{KK'}\delta_{MM'}. \tag{145}$$

The map $\mathcal{F}\to\mathbb{H}^{(\lambda\mu)}$ then gives

$$\varphi_{KLM}\to|KLM\rangle=\sqrt{\frac{2L+1}{8\pi^2}}\int \hat{R}(\Omega^{-1})|\lambda\mu\rangle\mathcal{D}^L_{KM}(\Omega)\mathrm{d}\Omega. \tag{146}$$

A maximal linearly independent subset of the states $\{|KLM\rangle\}$ comprises a so-called *Elliott basis* for $\mathbb{H}^{(\lambda\mu)}$. From Eq. (136), the overlaps of Elliott states are given by

$$\begin{aligned}\langle K'L'M'|KLM\rangle&=\delta_{L'L}\delta_{M'M}\frac{2L+1}{8\pi^2}\int\int \mathcal{D}^L_{K'M}(\Omega')^*\mathcal{S}(\Omega'\tilde{\Omega})\mathcal{D}^L_{KM}(\Omega)\mathrm{d}\Omega'\mathrm{d}\Omega\\&=\delta_{L'L}\delta_{M'M}\int \mathcal{D}^L_{K'K}(\Omega)^*\mathcal{S}(\Omega)\mathrm{d}\Omega.\end{aligned} \tag{147}$$

Let $\mathcal{S}^L$ be the SO(3)-invariant matrix of overlaps with elements

$$\mathcal{S}^L_{K'K}=\langle K'LM|KLM\rangle=\int \mathcal{D}^L_{K'K}(\Omega)^*\mathcal{S}(\Omega)\mathrm{d}\Omega. \tag{148}$$

From the symmetry property (143), it follows that

$$\mathcal{S}^L_{K'K}=(-1)^{\mu+K'}\mathcal{S}^L_{K'K}=(-1)^{\mu+K}\mathcal{S}^L_{K'K}=(-1)^{\lambda+L+K'}\mathcal{S}^L_{-K',K}=(-1)^{\lambda+L+K}\mathcal{S}^L_{K',-K}. \tag{149}$$

Thus, $\mathcal{S}^L_{K'K}$ is zero unless $(-1)^{K'}=(-1)^K=(-1)^\mu$ and, for K or $K'=0$, unless $(-1)^{\lambda+L}=1$. Then, with $\{|KLM\rangle\}$ restricted to a maximal linearly independent set of states with nonzero norms, the matrix $\mathcal{S}^L$ is Hermitian positive definite and can be expressed as a product $\mathcal{S}^L=\mathcal{K}(L)\mathcal{K}^\dagger(L)$; i.e.,

$$\mathcal{S}^L_{K'K}=\sum_\gamma \mathcal{K}_{K'\gamma}(L)\mathcal{K}^*_{K\gamma}(L). \tag{150}$$

Now, if we define $\overline{\mathcal{K}}(L)$ to be the inverse of the matrix $\mathcal{K}^\dagger(L)$, so that

$$\sum_{K\geqslant 0}\mathcal{K}^*_{K\beta}(L)\overline{\mathcal{K}}_{K\alpha}(L)=\delta_{\alpha\beta}, \tag{151}$$

then the transformed basis states,

$$|\alpha LM\rangle=\sum_K |KLM\rangle\overline{\mathcal{K}}_{K\alpha}(L), \tag{152}$$

satisfy

$$\langle \beta L' M' | \alpha L M \rangle = \delta_{LL'} \delta_{MM'} \sum_{K' K \gamma} \overline{\mathcal{K}}^*_{K' \beta}(L) \mathcal{K}_{K' \gamma}(L) \mathcal{K}^*_{K \gamma}(L) \overline{\mathcal{K}}_{K \alpha}(L) = \delta_{LL'} \delta_{MM'} \delta_{\beta \alpha} \quad (153)$$

and form an orthonormal basis.

Coherent state wave functions corresponding to the nonorthonormal $\{|KLM\rangle\}$ states are given by

$$\Phi_{KLM}(\Omega') = [\hat{\mathcal{S}} \varphi_{KLM}](\Omega') = \int \mathcal{S}(\Omega' \tilde{\Omega}) \varphi_{KLM}(\Omega) \mathrm{d}\Omega. \quad (154)$$

Therefore, the coefficients in the expansion

$$\Phi_{KLM}(\Omega) = \sum_{K'} a_{K'}(KL) \mathcal{D}^L_{K' M}(\Omega) \quad (155)$$

are given by

$$a_{K'}(KL) = \frac{2L+1}{8\pi^2} \int \mathcal{D}^L_{K' M}(\Omega)^* \Phi_{KLM}(\Omega) \mathrm{d}\Omega = \sqrt{\frac{2L+1}{8\pi^2}} \int \mathcal{D}^L_{K' K}(\Omega)^* \mathcal{S}(\Omega) \mathrm{d}\Omega. \quad (156)$$

It follows that

$$\begin{aligned} a_{K'}(KL) &= \sqrt{\frac{2L+1}{8\pi^2}} \mathcal{S}^L_{K' K}, \\ a_{-K'}(KL) &= (-1)^{\lambda + L + K'} a_{K'}(KL), \end{aligned} \quad (157)$$

and

$$\Phi_{KLM}(\Omega) = \sum_{K' \geqslant 0} \sqrt{\frac{2L+1}{8\pi^2}} [\mathcal{D}^L_{K' M}(\Omega) + (-1)^{\lambda + L + K'} \mathcal{D}^L_{-K' M}(\Omega)] \frac{1}{1+\delta_{K'0}} \mathcal{S}^L_{K' K}. \quad (158)$$

Because of the symmetries of the $\mathcal{S}$ matrix, given by Eq. (149), these wave functions vanish unless $(-1)^{\mu+K} = 1$ and, for $K = 0$, unless $(-1)^{\lambda+L} = 1$. Furthermore, the wave functions $\Phi_{\pm KLM}$ differ by only a phase factor. Thus, with L and K restricted to a subset of values such that the matrices $\mathcal{S}^L$ are positive definite (so that no linear combinations of the wave functions Φ_{KLM} vanish), an orthornormal basis for $\mathcal{F}_{\lambda \mu}$ is given by wave functions

$$\psi_{KLM}(\Omega) = \sum_{K \geqslant 0} \overline{\mathcal{K}}_{K \alpha}(L) \varphi_{KLM}(\Omega) = \sqrt{\frac{2L+1}{8\pi^2}} \sum_{K \geqslant 0} \overline{\mathcal{K}}_{K \alpha}(L) \mathcal{D}^L_{KM}(\Omega) \quad (159)$$

and a corresponding orthonormal basis of coherent state wave functions is given by

$$\begin{aligned} \Psi_{\alpha LM}(\Omega) &= \sum_{K \geqslant 0} \overline{\mathcal{K}}_{K \alpha}(L) \Phi_{KLM}(\Omega) \\ &= \sum_{K \geqslant 0} \sqrt{\frac{2L+1}{8\pi^2}} \frac{\mathcal{K}_{K \alpha}(L)}{1+\delta_{K0}} [\mathcal{D}^L_{KM}(\Omega) + (-1)^{\lambda+L+K} \mathcal{D}^L_{-KM}(\Omega)]. \end{aligned} \quad (160)$$

These expressions are in agreement with known results.[32,25] An explicit expression for the overlap kernel $\mathcal{S}^L_{K' K}$ is given in Ref. 25.

For a multiplicity-free representation, the $\mathcal{K}$ matrices reduce to simple numbers. For example, for an irrep of highest weight $(\lambda,\mu=0)$,

$$|\mathcal{K}(L)|^2=\langle LM|LM\rangle=4\pi^2\int_0^\pi d^L_{00}(\beta)(\cos\beta)^\lambda\sin\beta\mathrm{d}\beta. \tag{161}$$

The identity

$$\int_0^\pi d^L_{00}(\beta)(\cos\beta)^\lambda\sin\beta\mathrm{d}\beta=\int_0^1 P_L(x)x^\lambda\mathrm{d}x=\frac{\lambda!}{(\lambda-L)!!(\lambda+L+1)!!}, \tag{162}$$

inferrred from Eq. 8.14.15 of Abramowitz and Stegun,[33] then gives

$$|\mathcal{K}(L)|^2=4\pi^2\frac{\lambda!}{(\lambda-L)!!(\lambda+L+1)!!}[1+(-1)^{\lambda+L}]. \tag{163}$$

The corresponding ratios

$$\left|\frac{\mathcal{K}(L)}{\mathcal{K}(L-2)}\right|^2=\frac{\lambda-L+2}{\lambda+L+1} \tag{164}$$

agree with those derived previously[32] by requiring the representation to be unitary.

The coherent state representation of the su(3) Lie algbra is relatively simple and given explicitly in Ref. 32. The action of a group element $g\in\mathrm{SU}(3)$ on a coherent state wave function Ψ, defined by

$$[\Gamma(g)\Psi](\Omega)=\langle\lambda\mu|T^{\lambda\mu}(\Omega g)|\psi\rangle,\quad \Omega\in\mathrm{SO}(3)\subset\mathrm{SU}(3), \tag{165}$$

is more complicated. It can be obtained from the generalized Iwasawa factorization for which

$$g=Z(g)\omega(g), \tag{166}$$

where $Z(g)$ is a lower triangular matrix of the form

$$Z(g)=\begin{pmatrix} z_{11}(g) & 0 & 0\\ z_{21}(g) & z_{22}(g) & 0\\ z_{31}(g) & z_{32}(g) & z_{33}(g)\end{pmatrix} \tag{167}$$

and $\omega(g)\in\mathrm{SO}(3,\mathbb{C})$ is a complex orthogonal matrix. It follows that

$$[\Gamma(g)\Psi](\Omega)=(z_{11}(\Omega g))^{\lambda+\mu}(z_{22}(\Omega g))^{\mu}\Psi(\omega(\Omega g)), \tag{168}$$

where

$$\begin{aligned} z^2_{11}(g)&=\sum_i g^2_{1i},\\ z^2_{11}(g)z^2_{22}(g)&=\sum_i g^2_{1i}\sum_j g^2_{2j}-\sum_i (g_{1i}g_{2i})^2. \end{aligned} \tag{169}$$

The above techniques for constructing orthornormal bases were used effectively in Ref. 25 for computing SU(3) Clebsch-Gordan in an SO(3)-coupled basis.

IV. SCALAR COHERENT-STATE REPRESENTATIONS OF SEMISIMPLE LIE GROUPS

There are four classes of scalar holomorphic discrete series representations of semisimple Lie groups all of which are expressible as coherent state representations over classical domains. They are constructed when a coherent-state representation of a semisimple Lie group G is induced from a one-dimensional irrep ρ of a subgroup $K\subset G$ for which G/K is a Hermitian symmetric space. These spaces have been studied in depth by Helgason.[34] The classical domains which we discuss here were identified by Cartan.[35] The associated coherent state representations have been summarized by Hua[36] and Perelomov.[13]

Hermitian symmetric spaces[34] are easily identified at the Lie algebra level. If G is semisimple and H is a reductive subgroup of G, then G/H is a Hermitian symmetric space if the complex extension $\mathfrak{g}^c$ of the Lie algebra of G has decomposition

$$\mathfrak{g}^c=\mathfrak{h}^c+\mathfrak{n}_+ +\mathfrak{n}_- , \tag{170}$$

such that $\mathfrak{g}^c$ and $\mathfrak{h}^c$ have a Cartan subalgebra in common, $\mathfrak{n}_\pm$ are Abelian, and

$$[C,A]\in\mathfrak{n}_+ , \quad [C,B]\in\mathfrak{n}_- , \quad [A,B]\in\mathfrak{h}^c, \tag{171}$$

for all $A\in\mathfrak{n}_+$, $B\in\mathfrak{n}_-$, and $C\in\mathfrak{h}^c$. There are then holomorphic representations of G with highest weight states which carry one-dimensional irreps of H. These representations have simple expressions as scalar coherent state representations.

A. SU($p+q$) and SU(p,q)

The Lie algebras of SU$(p+q)$ and SU(p,q) have a common complex extension $\mathfrak{su}(n)^c \sim A_{n-1}=\mathfrak{sl}(n,\mathbb{C})$ with $n=p+q$. The latter is spanned by traceless linear combinations of the matrices $\{C_{\alpha\beta}\}$, where $C_{\alpha\beta}$ is an $n\times n$ matrix with entries $(C_{\alpha\beta})_{ij}=\delta_{\alpha i}\delta_{\beta j}$.

Let T^σ denote an irrep of A_{n-1}, with $T^\sigma(C_{\alpha\beta})=\hat{C}_{\alpha\beta}$, on a Hilbert space $\mathbb{H}^\sigma$ having highest weight state $|0\rangle$ and highest weight $(\sigma\ldots\sigma;0\ldots0)$ defined by

$$\begin{aligned}&\hat{C}_{i\nu}|0\rangle=\hat{C}_{ij}|0\rangle=\hat{C}_{\mu\nu}|0\rangle=0,\\ &\hat{C}_{ii}|0\rangle=\sigma|0\rangle, \quad \hat{C}_{\nu\nu}|0\rangle=0, \quad i<j<\mu<\nu,\end{aligned} \tag{172}$$

where i and j run over the range $1,\ldots,p$ and μ and ν run over the range $p+1,\ldots,n=p+q$. If λ is a positive integer, then, when $\sigma=+\lambda$, this irrep integrates to a unitary irrep of SU$(p+q)$; it integrates to a unitary irrep of SU(p,q) when $\sigma=-\lambda$. In both cases, the subgroup of elements that leave the highest weight state $|0\rangle$ invariant (to within a phase factor) is the subgroup of U$(p)\times$U(q) matrices

$$\mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)]=\left\{\begin{pmatrix}a&0\\0&b\end{pmatrix}\middle| a\in\mathrm{U}(p),b\in\mathrm{U}(q),\det b=[\det a]^{-1}\right\}. \tag{173}$$

It follows that the highest weight state $|0\rangle$ is a single basis vector for the one-dimensional irrep ρ_σ of S$[\mathrm{U}(p)\times\mathrm{U}(q)]$ for which

$$\rho_\sigma\begin{pmatrix}a&0\\0&b\end{pmatrix}=[\det a]^\sigma. \tag{174}$$

Let $\mathbb{H}_D\subseteq\mathbb{H}^\sigma$ be the space of "K-finite vectors," that is, the vectors obtained by applying polynomials in the lowering operators to the state $|0\rangle$. For $G=\mathrm{SU}(p+q)$, where $\mathbb{H}^\sigma$ is finite-dimensional, this will be all of $\mathbb{H}^\sigma$, but for $G=\mathrm{SU}(p,q)$, it is a dense subspace.

Gauss factorization of almost any SL$(p+q,\mathbb{C})$ matrix gives

$$g=\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} I_p & 0 \\ x & I_q \end{pmatrix}\begin{pmatrix} a & 0 \\ 0 & d-cz \end{pmatrix}\begin{pmatrix} I_p & z \\ 0 & I_q \end{pmatrix} \tag{175}$$

with $z=a^{-1}b$, $x=ca^{-1}$, and with I_p the $p\times p$ identity matrix. It follows that, for an irrep T^σ of $G=\mathrm{SU}(p+q)$ or $G=\mathrm{SU}(p,q)$ with highest weight state $|0\rangle$ and highest weight $(\sigma\ldots\sigma;0\ldots0)$, the coherent state wave functions satisfy

$$\langle 0|T^\sigma(g)|\psi\rangle=[\det a]^\sigma\langle 0|e^{\hat{z}}|\psi\rangle, \quad g=\begin{pmatrix} a & b \\ c & d \end{pmatrix}\in G, \tag{176}$$

where $\hat{z}=\Sigma_{i\nu}z_{i\nu}\hat{C}_{i\nu}$, for any $|\psi\rangle\in\mathbb{H}_D$. Accordingly, a suitable choice of $N\subset\mathrm{SU}(p+q)^c$ is the subgroup of upper triangular matrices

$$N=\left\{\begin{pmatrix} I_p & z \\ 0 & I_q \end{pmatrix};z\in\mathbb{C}^{p\times q}\right\}. \tag{177}$$

A coherent state wave function Ψ for a state $|\psi\rangle\in\mathbb{H}_D$ is then defined by

$$\Psi(z)=\langle 0|e^{\hat{z}}|\psi\rangle \tag{178}$$

and is seen to be a polynomial in the matrix coefficients of z.

The coherent state action $\Gamma(g)$ of a matrix

$$g=\begin{pmatrix} a & b \\ c & d \end{pmatrix}\in G, \tag{179}$$

defined for $\psi\in\mathbb{H}_D$ by

$$[\Gamma(g)\Psi](z)=\langle 0|e^{\hat{z}}T^\sigma(g)|\psi\rangle, \tag{180}$$

is determined by the generalized Gauss factorization of the product

$$\begin{pmatrix} I_p & z \\ 0 & I_q \end{pmatrix}\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} I_p & 0 \\ x & I_q \end{pmatrix}\begin{pmatrix} \alpha & 0 \\ 0 & \beta \end{pmatrix}\begin{pmatrix} I_p & y \\ 0 & I_q \end{pmatrix}, \tag{181}$$

with

$$\alpha=a+zc, \quad y=(a+zc)^{-1}(b+zd). \tag{182}$$

This gives

$$\langle 0|e^{\hat{z}}T(g)|\psi\rangle=[\det\alpha]^\sigma\langle 0|e^{\hat{y}}|\psi\rangle \tag{183}$$

and

$$[\Gamma(g)\Psi](z)=[\det(a+zc)]^\sigma\Psi((a+zc)^{-1}(b+zd)). \tag{184}$$

The space $\mathcal{F}^{\mathbb{H}}$ of coherent state wave functions is identified in the standard way. Let $\mathcal{F}$ be the Bargmann space of entire analytic functions in the z variables, i.e., $\mathcal{F}$ is the space $\mathcal{L}^2(\mathbb{C}^{p\times q},\mathrm{d}v)$, where $\mathrm{d}v$ is the Bargmann measure on $\mathbb{C}^{p\times q}$. The map of Eq. (35)

$$\mathcal{F}^*\to\mathbb{H}_D^*;\varphi^*\mapsto\langle\varphi|=\int \mathrm{d}v(z)\varphi^*(z)\langle 0|T^\sigma(z) \tag{185}$$

then takes a polynomial $\varphi^* \in \mathcal{F}^*$ to a vector $\langle 0|\varphi(\hat{C})^\dagger$ in $\mathbb{H}^* \cong \mathbb{H}$, where $\varphi(\hat{C})$ is the operator obtained by replacing every $z_{i\nu}$ in $\varphi(z)$ by the corresponding operator $\hat{C}_{i\nu}$. It follows that the dense subspace $\mathcal{F}_D$ of polynomials in $\mathcal{F}$ maps onto the dense subspace $\mathbb{H}_D \subset \mathbb{H}$ as required. Thus, the Hilbert space $\mathcal{F}_{\mathbb{H}}$ is a space of holomorphic functions with inner product

$$\langle \varphi|\psi\rangle = \int \varphi^*(z)\mathcal{S}^\sigma(z,x)\psi(x)\mathrm{d}v(z)\mathrm{d}v(x), \tag{186}$$

where $\mathcal{S}^\sigma(z,x)$ is the overlap kernel

$$\mathcal{S}^\sigma(z,x) = \langle 0|e^{\hat{z}}e^{\hat{x}^\dagger}|0\rangle. \tag{187}$$

Let $\{\psi_n\}$ denote an orthonormal polynomial basis for $\mathcal{F}_{\mathbb{H}}$. An orthonormal basis$\{|n\rangle\}$ for $\mathbb{H}$ is then defined by the map

$$\mathcal{F}_D \to \mathbb{H}_D ; \psi_n \mapsto |n\rangle \tag{188}$$

and a corresponding orthonormal basis $\{\Psi_n\}$ of coherent state wave functions for $\mathcal{F}^{\mathbb{H}}$ is defined by

$$\Psi_n(z) = \int \mathcal{S}^\sigma(z,x)\psi_n(x)\mathrm{d}v(x). \tag{189}$$

These bases for $\mathcal{F}_{\mathbb{H}}$ and $\mathcal{F}^{\mathbb{H}}$ are in duality relative to the inner product defined by $\mathrm{d}v$, i.e.,

$$\langle m|n\rangle = \int \psi_m^*(z)\Psi_n(z)\mathrm{d}v(z), \tag{190}$$

and matrix elements of the representation are given by

$$\langle m|T(g)|n\rangle = \int \psi_m^*(z)[\Gamma(g)\Psi_n](z)\mathrm{d}v(z). \tag{191}$$

For a finite-dimensional irrep, the raising and lowering operators satisfy the Hermitian adjoint relationship

$$\hat{C}_{i\nu}^\dagger = \hat{C}_{\nu i}. \tag{192}$$

Therefore, the overlap kernel for a unitary irrep of SU$(p+q)$, derived as for SU(2), is given by

$$\mathcal{S}^{\sigma=\lambda}(z,x) = \langle 0|e^{\hat{z}}e^{\hat{x}^\dagger}|0\rangle = [\det(I_p + zx^\dagger)]^\lambda. \tag{193}$$

For an infinite-dimensional unitary representation of SU(p,q), for which $\hat{C}_{i\nu}^\dagger = -\hat{C}_{\nu i}$, the overlap kernel is calculated in a manner analogous to that used to find Eq. (92) for SU(1,1); the result is given formally by

$$\mathcal{S}^{\sigma=-\lambda}(z,x) = \langle 0|e^{\hat{z}}e^{\hat{x}^\dagger}|0\rangle = [\det(I_p - zx^\dagger)]^{-\lambda}. \tag{194}$$

This expression does not converge for $|zx^\dagger| \geqslant 1$. However, it is well-defined as a distribution over the polynomial functions of $\mathcal{F}_D$ with the understanding that $\hat{\mathcal{S}}^{-\lambda}\psi$ is defined by the integral

$$[\hat{\mathcal{S}}^{-\lambda}\psi](z) = \int \mathrm{Taylor}(\mathcal{S}^{-\lambda}(z,x))\psi(x)\mathrm{d}v(x), \tag{195}$$

where Taylor $(\mathcal{S}^{-\lambda}(z,x))$ is an expansion of $\mathcal{S}^{-\lambda}(z,x)$ as a Taylor series in $zx^\dagger$ and the integration is performed term by term.

It is useful to note that, for both $G=\mathrm{SU}(p+q)$ and $G=\mathrm{SU}(p,q)$, the above construction leads naturally to irreps in bases that reduce the subgroup $\mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)]\subset G$. First observe that the action on $\mathcal{F}$ of an element

$$h=\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix} \in \mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)], \tag{196}$$

given by Eq. (184), i.e.,

$$[\Gamma(h)\varphi](x)=[\det a]^{\sigma}\varphi(a^{\dagger}xd), \tag{197}$$

is unitary. This follows from the observation that the inner product for $\mathcal{F}$, which is expressible in the form

$$\int \psi^*(x)\varphi(x)\mathrm{d}v(x)=[\psi(\partial/\partial x)\varphi(x)]_{x=0}, \tag{198}$$

satisfies the identity

$$\int \psi^*(a^{\dagger}xd)\varphi(a^{\dagger}xd)\mathrm{d}v(x)=\int \psi^*(x)\varphi(x)\mathrm{d}v(x), \tag{199}$$

and is manifestly $\mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)]$ invariant. Thus, if $\{\varphi_{\kappa\nu}\}$ is an orthonormal $\mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)]$-coupled basis for $\mathcal{F}$, then $\hat{\mathcal{S}}^{\sigma}$ is diagonal and $\mathcal{S}^{\sigma}(z,x)$ is expressible

$$\mathcal{S}^{\sigma}(z,x)=\sum_{\kappa\nu} K_{\kappa}^2\varphi_{\kappa\nu}(z)\varphi_{\kappa\nu}^*(x), \tag{200}$$

where

$$K_{\kappa}^2=\int\int \varphi_{\kappa\nu}^*(z)\mathcal{S}^{\sigma}(z,x)\varphi_{\kappa\nu}(x)\mathrm{d}v(z)\mathrm{d}v(x), \tag{201}$$

is independent of ν.

It is now relatively straightforward to construct an orthonormal $\mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)]$ basis for the Bargmann space $\mathcal{F}$ and to map it to orthonormal bases for $\mathcal{F}_{\mathrm{H}}$ and $\mathcal{F}^{\mathrm{H}}$. First observe that, in the coherent state representation, the $\mathrm{U}(p)$ and $\mathrm{U}(q)$ operators are given, respectively, by

$$\Gamma(C_{ij})=\sigma\delta_{ij}-\sum_{\nu} z_{j\nu}\partial_{i\nu}, \tag{202}$$

$$\Gamma(C_{\mu\nu})=\sum_{i} z_{i\mu}\partial_{i\nu}, \tag{203}$$

where

$$\partial_{i\nu}=\frac{\partial}{\partial z_{i\nu}}. \tag{204}$$

To simplify the notation, relabel the z indices such that $z_{p+1-i,p+\nu}$ becomes $z_{i\nu}$. The variables $\{z_{i\nu}\}$ are then ordered by their weights with $z_{i\mu}$ being of higher weight than $z_{j\nu}$ if $i<j$ or if $i=j$ and $\mu<\nu$. The space $\mathcal{F}$ is now seen to be a direct sum of irreducible $\mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)]$ subspaces spanned by homogeneous polynomials in the $\{z_{i\nu}\}$ variables. Consider the polynomial

$$\varphi_{\kappa\kappa}(z)=N_{\kappa}Z_1^{\kappa_1-\kappa_2}(z)Z_2^{\kappa_2-\kappa_3}(z)\cdots Z_m^{\kappa_m}(z), \tag{205}$$

indexed by a sequence $\kappa=(\kappa_1,\kappa_2,\ldots,\kappa_m)$ of m positive integers, satisfying the inequalities

$$\kappa_1\geqslant\kappa_2\geqslant\cdots\kappa_m\geqslant 0, \quad m\leqslant\min(p,q), \tag{206}$$

with $(Z_1(z),Z_3(z),Z_3(z),\ldots)$ the sequence of determinants

$$Z_1(z)=z_{11}, \quad Z_2(z)=\begin{vmatrix} z_{11} & z_{12} \\ z_{21} & z_{22} \end{vmatrix}, \quad Z_3(z)=\begin{vmatrix} z_{11} & z_{12} & z_{13} \\ z_{21} & z_{22} & z_{23} \\ z_{31} & z_{32} & z_{33} \end{vmatrix}, \quad \ldots; \tag{207}$$

N_{κ} is a normalization factor. The polynomial $\varphi_{\kappa\kappa}(z)$ is seen from Eqs. (202) and (203) to be of $\mathrm{U}(p)\otimes\mathrm{U}(q)$ weight

$$(\sigma,\ldots,\sigma-\kappa_m,\ldots\sigma-\kappa_1)\otimes(\kappa_1,\ldots,\kappa_m,\ldots,0). \tag{208}$$

Thus, it is the highest weight polynomial of an irreducible $\mathrm{S}[\mathrm{U}(p)\times\mathrm{U}(q)]$ invariant subspace $\mathcal{F}^{\kappa}$ of $\mathcal{F}$. Let $\{\varphi_{\kappa\tau}\}$ denote an orthonormal basis for $\mathcal{F}^{\kappa}$.

The norm factor N_{κ} is determined by the requirement that

$$\int \varphi^*_{\kappa\kappa}(z)\varphi_{\kappa\kappa}(z)\mathrm{d}v(z)=[\varphi^*_{\kappa\kappa}(\nabla)\varphi_{\kappa\kappa}(z)]_{z=0}=1, \tag{209}$$

where

$$\varphi^*_{\kappa\kappa}(\nabla)=N^*_{\kappa}\nabla_1^{\kappa_1-\kappa_2}\nabla_2^{\kappa_2-\kappa_3}\cdots\nabla_m^{\kappa_m} \tag{210}$$

with

$$\nabla_1=\partial_{11}, \quad \nabla_2=\begin{vmatrix} \partial_{11} & \partial_{12} \\ \partial_{21} & \partial_{22} \end{vmatrix}, \quad \nabla_3=\begin{vmatrix} \partial_{11} & \partial_{12} & \partial_{13} \\ \partial_{21} & \partial_{22} & \partial_{23} \\ \partial_{31} & \partial_{32} & \partial_{33} \end{vmatrix}, \ldots. \tag{211}$$

The overlap integral (209) is evaluated by use of the Capelli identity[37]

$$\nabla_n Z_n(z)=\begin{vmatrix} n+z_1\cdot\partial_1 & z_1\cdot\partial_2 & z_1\cdot\partial_3 & \cdots & \cdots & z_1\cdot\partial_n \\ z_2\cdot\partial_1 & n-1+z_2\cdot\partial_2 & z_2\cdot\partial_3 & \cdots & \cdots & z_2\cdot\partial_n \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ z_n\cdot\partial_1 & +z_n\cdot\partial_2 & z_n\cdot\partial_3 & \cdots & \cdots & 1+z_n\cdot\partial_n \end{vmatrix}, \tag{212}$$

where

$$z_i\cdot\partial_j=\sum_{\nu} z_{i\nu}\partial_{j\nu} \tag{213}$$

and it is understood that a determinant of noncommuting operators is ordered by columns, e.g.,

$$\begin{vmatrix} A & B \\ C & D \end{vmatrix}=AD-CB. \tag{214}$$

Thus, when acting on a highest weight polynomial $\varphi_{\kappa\kappa}$ for which $\kappa_n\neq 0$ but $\kappa_{n+1}=0$,

$$\nabla_n Z_n(z)\varphi_{\kappa\kappa}=(n+\kappa_1)(n-1+\kappa_2)\cdots(1+\kappa_n)\varphi_{\kappa\kappa}. \tag{215}$$

By repeated use of this identity we obtain the expression for the norm factors

$$N_\kappa^2=\frac{\Pi_{i<j}(\kappa_i-\kappa_j+j-i)}{\Pi_{i=1}^m(\kappa_i+m-i)!}. \tag{216}$$

It is interesting to note that this norm factor is related to the dimensionality of an irrep of S_N labeled by a partition κ of $N=\Sigma_i\kappa_i$ as follows:

$$\dim\ \kappa=N!N_\kappa^2. \tag{217}$$

The overlap kernel for SU$(p+q)$, given by Eq. (193), is

$$\mathcal{S}^\lambda(z,x)=\begin{vmatrix} 1+z_1\cdot x_1^* & z_1\cdot x_2^* & z_1\cdot x_3^* & \cdots & \cdots & z_1\cdot x_p^* \\ z_2\cdot x_1^* & 1+z_2\cdot x_2^* & z_2\cdot x_3^* & \cdots & \cdots & z_2\cdot x_p^* \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ z_p\cdot x_1^* & z_p\cdot x_2^* & z_p\cdot x_3^* & \cdots & \cdots & 1+z_p\cdot x_p^* \end{vmatrix}^\lambda, \tag{218}$$

where

$$z_i\cdot x_j^*=\sum_\nu z_{i\nu}x_{j\nu}^*. \tag{219}$$

Thus, $\mathcal{S}^\lambda$ is the λ power of a sum of diagonal minors of a determinant, i.e., determinants of submatrices obtained by deleting some number of rows and corresponding columns. Moreover, since $\varphi_{\kappa\kappa}$ is a highest weight polynomial, it follows that

$$\int \mathcal{S}^\lambda(z,x)\varphi_{\kappa\kappa}\mathrm{d}v(x)=\int\left(1+\sum_{n=1}^{\min(p,q)}\Lambda_n(z,x)\right)^\lambda\varphi_{\kappa\kappa}(x)\mathrm{d}v(x), \tag{220}$$

where

$$\Lambda_n(z,x)=\begin{vmatrix} z_1\cdot x_1^* & z_1\cdot x_2^* & \cdots & z_1\cdot x_n^* \\ \cdots & \cdots & \cdots & \cdots \\ z_n\cdot x_1^* & z_n\cdot x_2^* & \cdots & z_n\cdot x_n^* \end{vmatrix}=Z_n(z)Z_n^*(x). \tag{221}$$

We conclude that

$$\int \mathcal{S}^\lambda(z,x)\varphi_{\kappa\kappa}\mathrm{d}v(x)=\binom{\lambda}{(\kappa_1-\kappa_2)(\kappa_2-\kappa_3)\ldots\kappa_p}N_\kappa^{-2}\,\varphi_{\kappa\kappa}(z), \tag{222}$$

where ( ) is a multinomial coefficient, and that

$$\mathcal{S}^\lambda(z,x)=\sum_{\kappa\nu}K_\kappa^2\,\varphi_{\kappa\nu}(z)\varphi_{\kappa\nu}^*(x), \tag{223}$$

with

$$K_\kappa^2=\frac{\lambda!}{(\lambda-\kappa_1)!(\kappa_1-\kappa_2)!(\kappa_2-\kappa_3)!\ldots\kappa_p!}N_\kappa^{-2}. \tag{224}$$

For SU(p,q), instead of Eq. (220), we have

$$\int \mathcal{S}^{-\lambda}(z,x)\varphi_{\kappa\kappa}(x)\mathrm{d}v(x)=\left(1-\sum_{n=1}^{p}\Lambda_n(z,x)\right)^{-\lambda}\varphi_{\kappa\kappa}(z). \tag{225}$$

Thus, for SU(p,q), $\mathcal{S}^{-\lambda}(z,x)$ is again of the form

$$\mathcal{S}^{-\lambda}(z,x)=\sum_{\kappa\nu}K_\kappa^2\,\varphi_{\kappa\nu}(z)\varphi^*_{\kappa\nu}(x), \tag{226}$$

but now with

$$K_\kappa^2=\frac{(\lambda+\kappa_1-1)!}{(\lambda-\kappa_1)!(\kappa_1-\kappa_2)!(\kappa_2-\kappa_3)!\ldots\kappa_p!}N_\kappa^{-2}. \tag{227}$$

B. Sp$(n,\mathbb{R})$ and Sp(n)

The compact symplectic group Sp(n) is isomorphic to the subgroup of unitary matrices in Sp$(n,\mathbb{C})$; it is isomorphic to

$$\mathrm{Sp}(n)\cong\mathrm{Sp}(n,\mathbb{C})\cap\mathrm{U}(2n), \tag{228}$$

which means that an element of Sp(n) is a $2n\times 2n$ matrix of the form

$$g=\begin{pmatrix}\alpha & -\beta\\ \beta^* & \alpha^*\end{pmatrix} \tag{229}$$

with

$$\alpha\alpha^\dagger+\beta\beta^\dagger=I_n,\quad \alpha\tilde{\beta}=\beta\tilde{\alpha}, \tag{230}$$

where I_n is the $n\times n$ identity matrix and $\tilde{\beta}$ is the transpose of β. Similarly Sp$(n,\mathbb{R})$ is given by the isomorphism

$$\mathrm{Sp}(n,\mathbb{R})\cong\mathrm{Sp}(n,\mathbb{C})\cap\mathrm{U}(n,n) \tag{231}$$

and an element of Sp$(n,\mathbb{R})$ is a $2n\times 2n$ matrix of the form

$$g=\begin{pmatrix}\alpha & \beta\\ \beta^* & \alpha^*\end{pmatrix} \tag{232}$$

with

$$\alpha\alpha^\dagger-\beta\beta^\dagger=I_n,\quad \alpha\tilde{\beta}=\beta\tilde{\alpha}. \tag{233}$$

The Lie algebras of the groups Sp$(n,\mathbb{R})$ and Sp(n) have a common complex extension C_n. Let E_{ij} denote the matrix with entries $(E_{ij})_{kl}=\delta_{ik}\delta_{jl}$. Then the complex Lie algebra C_n is spanned by the matrices

$$C_{ij}=\begin{pmatrix}E_{ij} & 0\\ 0 & -E_{ji}\end{pmatrix},\quad i,j=1,\ldots,n, \tag{234}$$

$$A_{ij}=A_{ji}=\begin{pmatrix}0 & -E_{ij}-E_{ji}\\ 0 & 0\end{pmatrix},\quad i,j=1,\ldots,n, \tag{235}$$

$$B_{ij}=B_{ji}=\begin{pmatrix} 0 & 0 \\ E_{ij}+E_{ji} & 0 \end{pmatrix}, \quad i,j=1,\ldots,n, \tag{236}$$

which generate the group elements

$$g(x,y)=\exp\sum_{ij}\,[x_{ij}C_{ij}+y_{ij}A_{ij}+y_{ij}^{*}B_{ij}] \quad \in \mathrm{Sp}(n), \tag{237}$$

$$g(x,y)=\exp\sum_{ij}\,[x_{ij}C_{ij}+y_{ij}A_{ij}-y_{ij}^{*}B_{ij}] \quad \in \mathrm{Sp}(n,\mathbb{R}), \tag{238}$$

with x skew Hermitian (i.e., $x_{ij}=-x_{ji}^{*}$).

Let T denote an irrep of C_n with lowest weight in which the matrices A_{ij}, B_{ij}, and C_{ij} are mapped to linear operators $\hat{A}_{ij}$, $\hat{B}_{ij}$, and $\hat{C}_{ij}$ on a Hilbert space $\mathbb{H}$. We consider an irrep T defined by an integer σ for which the lowest weight state satisfies

$$\hat{B}_{ij}|0\rangle=0, \quad \hat{C}_{ij}|0\rangle=\delta_{ij}\sigma|0\rangle. \tag{239}$$

When $\sigma<0$, T integrates to a unitary irrep of $\mathrm{Sp}(n)$ for which

$$\hat{A}_{ij}^{\dagger}=-\hat{B}_{ij}, \quad \hat{C}_{ij}^{\dagger}=\hat{C}_{ji}. \tag{240}$$

And when $\sigma>0$, it integrates to a unitary irrep of $\mathrm{Sp}(n,\mathbb{R})$ for which

$$\hat{A}_{ij}^{\dagger}=\hat{B}_{ij}, \quad \hat{C}_{ij}^{\dagger}=\hat{C}_{ji}. \tag{241}$$

The special case $\sigma=0$ is the trivial identity representation. Note that one also obtains irreps of C_n when σ is a positive half-odd integer. These restrict to irreps of $\mathrm{sp}(n,\mathbb{R})$ that integrate to unitary irreps of the metaplectic double cover of the group $\mathrm{Sp}(n,\mathbb{R})$. In all nontrivial cases, the subgroup of elements that leave the lowest-weight state invariant is $\mathrm{U}(n)$.

As in the previous example, let $\mathbb{H}_D$ be the space of K-finite vectors. Let D denote the vector space of complex symmetric $n\times n$ matrices and let N be the group

$$N=\left\{\begin{pmatrix} I_n & 0 \\ z & I_n \end{pmatrix}; z\in D\right\}. \tag{242}$$

An element of N is then represented by the operator $\hat{z}=\exp[1/2\ \Sigma_{ij}z_{ij}\hat{B}_{ij}]$ on $\mathbb{H}_D$ and a coherent state wave function Ψ for a state $|\psi\rangle\in\mathbb{H}_D$ is defined by

$$\Psi(z)=\langle 0|e^{\hat{z}}|\psi\rangle. \tag{243}$$

Again, these coherent state wave functions are polynomials in the matrix coefficients of z.

The coherent state action $\Gamma(g)$ of an $\mathrm{Sp}(n,\mathbb{R})$ or $\mathrm{Sp}(n)$ matrix

$$g=\begin{pmatrix} \alpha & b \\ \beta^{*} & \alpha^{*} \end{pmatrix}, \quad b=\pm\beta, \tag{244}$$

defined by

$$[\Gamma(g)\Psi](z)=\langle 0|e^{\hat{z}}T(g)|\psi\rangle, \tag{245}$$

is determined by the generalized Gauss (Harish-Chandra) factorization of the product

$$\begin{pmatrix} I & 0 \\ z & I \end{pmatrix}\begin{pmatrix} \alpha & b \\ \beta^* & \alpha^* \end{pmatrix}=\begin{pmatrix} I & x \\ 0 & I \end{pmatrix}\begin{pmatrix} a & 0 \\ 0 & \tilde{a}^{-1} \end{pmatrix}\begin{pmatrix} I & 0 \\ y & I \end{pmatrix}, \quad z\in D, \tag{246}$$

with

$$a=(\alpha^\dagger+\tilde{b}z)^{-1}, \quad x=b(\alpha^*+zb)^{-1}, \quad y=(\alpha^*+zb)^{-1}(\beta^*+z\alpha). \tag{247}$$

This gives

$$\langle 0|e^{\hat{z}}T(g)|\psi\rangle=[\det a]^\sigma\langle 0|e^{\hat{y}}|\psi\rangle \tag{248}$$

and

$$[\Gamma(g)\Psi](z)=[\det(\alpha^\dagger+\tilde{b}z)]^{-\sigma}\Psi((\alpha^*+zb)^{-1}(\beta^*+z\alpha)). \tag{249}$$

For a unitary irrep of Sp(n), for which $\hat{B}_{ij}^\dagger=-\hat{A}_{ij}$, we derive the overlap kernel

$$\mathcal{S}^{\sigma=-\lambda}(z,x^\dagger)=\langle 0|e^{\hat{z}}e^{\hat{x}^\dagger}|0\rangle=[\det(I_n+zx^\dagger)]^\lambda, \tag{250}$$

where $\hat{x}^\dagger=-1/2\,\Sigma_{ij}x_{ij}^*\hat{A}_{ij}$. The Hilbert space $\mathcal{F}_{\mathbb{H}}$ is then the space of holomorphic functions in the matrix coefficients of z with inner product

$$\langle\varphi|\psi\rangle=\int\int\varphi^*(z)[\det(I_n+zx^\dagger)]^\lambda\psi(x)\mathrm{d}v(z)\mathrm{d}v(x), \tag{251}$$

where the integral is over D, which can be identified with the $n(n+1)/2$-dimensional complex plane and the measure $\mathrm{d}v$ is the corresponding Bargmann measure.

For a unitary representation of Sp($n,\mathbb{R}$), for which $\hat{B}_{ij}^\dagger=\hat{A}_{ij}$,

$$\mathcal{S}^{\sigma=\lambda}(z,x^\dagger)=\langle 0|e^{\hat{z}}e^{\hat{x}^\dagger}|0\rangle=[\det(I_n-zx^\dagger)]^{-\lambda}, \tag{252}$$

when $\det(I_n-zx^\dagger)>0$, and $\mathcal{F}_{\mathbb{H}}$ is the Hilbert space of holomorphic functions obtained by completing the space of polynomials with the inner product

$$\langle\varphi|\psi\rangle=\int\int\varphi^*(z)\psi(x)\ \mathrm{Taylor}\,([\det(I_n-zx^\dagger)]^{-\lambda})\mathrm{d}v(z)\mathrm{d}v(x), \tag{253}$$

where the integral is again over the whole $n(n+1)/2$-dimensional complex plane with the understanding that Taylor $([\det(I_n-zx^\dagger)]^{-\lambda})$ is an expansion of $[\det(I_n-zx^\dagger)]^{-\lambda}$ as a Taylor series in $zx^\dagger$ and the integration is performed term by term.

In both cases, if the map $\mathcal{F}_{\mathbb{H}}\to\mathbb{H}$ sends $\varphi\to|\varphi\rangle$ and the map $\mathbb{H}\to\mathcal{F}^{\mathbb{H}}$ sends $|\psi\rangle\to\Psi$, then the inner product of the two states is the overlap

$$\langle\varphi|\psi\rangle=\int\varphi^*(z)\Psi(z)\mathrm{d}v(z). \tag{254}$$

Thus, as usual, the spaces $\mathcal{F}_{\mathbb{H}}$ and $\mathcal{F}^{\mathbb{H}}$ are in duality with respect to the measure $\mathrm{d}v$ and matrix elements of the representation are given by

$$\langle\varphi|T(g)|\psi\rangle=\int\varphi^*(z)[\Gamma(g)\Psi](z)\mathrm{d}v(z). \tag{255}$$

An orthonormal U(n) basis $\{\varphi_{\kappa\nu}\}$ for the Bargmann space $\mathcal{F}$ can be constructed following the techniques given in Sec. IV A albeit using a generalization of the Capelli identity.[38] Similarly, by

an expansion of the overlap kernels as in Eq. (200), one can determine the renormalization factors $\{K_\kappa\}$ which map this basis for $\mathcal{F}$ to orthonormal bases $\{\psi_{\kappa\nu}=K_\kappa^{-1}\varphi_{\kappa\nu}\}$ and $\{\Psi_{\kappa\nu}=K_\kappa\varphi_{\kappa\nu}\}$ for $\mathcal{F}_{\mathbb{H}}$ and $\mathcal{F}^{\mathbb{H}}$, respectively.

C. SO(2n) and SO*(2n)

The real orthogonal group $\mathrm{SO}(2n)$ is isomorphic to the subgroup of unitary matrices in the complex orthogonal group $\mathrm{SO}(2n,\mathbb{C})$;

$$\mathrm{SO}(2n)\cong\mathrm{SO}(2n,\mathbb{C})\cap\mathrm{U}(2n). \tag{256}$$

Thus, if $\mathrm{SO}(2n,\mathbb{C})$ is realized as the group of matrices

$$\mathrm{SO}(2n,\mathbb{C})=\{M\in\mathrm{SL}(2n,\mathbb{C})\,|\,M\tilde{J}\tilde{M}=J\}, \tag{257}$$

where

$$J=\begin{pmatrix}0 & I_n\\ I_n & 0\end{pmatrix}, \tag{258}$$

then an element $g\in\mathrm{SO}(2n)$ is a $2n\times 2n$ matrix of the form

$$g=\begin{pmatrix}\alpha & \beta\\ \beta^* & \alpha^*\end{pmatrix} \tag{259}$$

with

$$\alpha\alpha^\dagger+\beta\beta^\dagger=I_n,\quad \alpha\tilde{\beta}+\beta\tilde{\alpha}=0. \tag{260}$$

Similarly, $\mathrm{SO}^*(2n)$ is given by the isomorphism

$$\mathrm{SO}^*(2n)\cong\mathrm{SO}(2n,\mathbb{C})\cap\mathrm{U}(n,n) \tag{261}$$

and an element of $\mathrm{SO}^*(2n)$ is a $2n\times 2n$ matrix of the form

$$g=\begin{pmatrix}\alpha & \beta\\ -\beta^* & \alpha^*\end{pmatrix} \tag{262}$$

with

$$\alpha\alpha^\dagger-\beta\beta^\dagger=I_n,\quad \alpha\tilde{\beta}+\beta\tilde{\alpha}=0. \tag{263}$$

The Lie algebras of the groups $\mathrm{SO}(2n)$ and $\mathrm{SO}^*(2n)$ have common complex extension D_n. Let E_{ij} denote the matrix with entries $(E_{ij})_{kl}=\delta_{ik}\delta_{jl}$. Then the complex Lie algebra D_n is spanned by the matrices

$$C_{ij}=\begin{pmatrix}E_{ij} & 0\\ 0 & -E_{ji}\end{pmatrix},\quad i,j=1,\ldots,n, \tag{264}$$

$$A_{ij}=\begin{pmatrix}0 & E_{ij}-E_{ji}\\ 0 & 0\end{pmatrix}=-A_{ji},\quad i,j=1,\ldots,n, \tag{265}$$

$$B_{ij}=\begin{pmatrix}0 & 0\\ E_{ij}-E_{ji} & 0\end{pmatrix}=-B_{ji},\quad i,j=1,\ldots,n, \tag{266}$$

which generate the group elements

$$g(x,y)=\exp\sum_{ij}\,[x_{ij}C_{ij}+y_{ij}A_{ij}+y_{ij}^{*}B_{ij}]\quad\in \mathrm{SO}(2n), \tag{267}$$

$$g(x,y)=\exp\sum_{ij}\,[x_{ij}C_{ij}+y_{ij}A_{ij}-y_{ij}^{*}B_{ij}]\quad\in \mathrm{SO}^{*}(2n), \tag{268}$$

with x skew Hermitian (i.e., $x_{ij}=-x_{ji}^{*}$).

Let T denote an irrep of D_n with lowest weight in which the matrices A_{ij}, B_{ij}, and C_{ij} are mapped to linear operators $\hat{A}_{ij}$, $\hat{B}_{ij}$, and $\hat{C}_{ij}$ on a Hilbert space $\mathbb{H}$. We consider an irrep T defined by an integer σ for which the lowest weight state satisfies

$$\hat{B}_{ij}|0\rangle=0,$$

$$\hat{C}_{ij}|0\rangle=\delta_{ij}\sigma|0\rangle. \tag{269}$$

For $\sigma\leqslant 0$ this D_n irrep integrates to a unitary irrep of $\mathrm{SO}(2n)$ for which

$$\hat{A}_{ij}^{\dagger}=-\hat{B}_{ij},\quad \hat{C}_{ij}^{\dagger}=\hat{C}_{ji}. \tag{270}$$

For $\sigma>0$ it integrates to a unitary irrep of $\mathrm{SO}^{*}(2n)$ and

$$\hat{A}_{ij}^{\dagger}=\hat{B}_{ij},\quad \hat{C}_{ij}^{\dagger}=\hat{C}_{ji}. \tag{271}$$

The special case $\sigma=0$ is the trivial identity representation. One also obtains spinor irreps when σ is a half-odd integer. In all nontrivial cases, the subgroup of elements that leave the lowest-weight state invariant is $\mathrm{U}(n)$.

Let $\mathbb{H}_D$ be the subspace of K-finite vectors in $\mathbb{H}$. Let D denote the vector space of complex symmetric $n\times n$ matrices and let N be the group of lower triangular matrices

$$N=\left\{\begin{pmatrix} I_n & 0\\ z & I_n\end{pmatrix};z\in D\right\}. \tag{272}$$

An element of N is then represented by the operator $e^{\hat{z}}$ with $\hat{z}=1/2\,\Sigma_{ij}z_{ij}\hat{B}_{ij}$ on $\mathbb{H}_D$ and a coherent state wave function Ψ for a state $|\psi\rangle\in\mathbb{H}_D$ is defined by

$$\Psi(z)=\langle 0|e^{\hat{z}}|\psi\rangle. \tag{273}$$

Again, these coherent state wave functions are polynomials in the matrix coefficients of z.

The coherent state action $\Gamma(g)$ of an $\mathrm{SO}(2n)$ or $\mathrm{SO}^{*}(2n)$ matrix

$$g=\begin{pmatrix}\alpha & \beta\\ b^{*} & \alpha^{*}\end{pmatrix},\quad b=\pm\beta, \tag{274}$$

defined by

$$[\Gamma(g)\Psi](z)=\langle 0|e^{\hat{z}}T(g)|\psi\rangle, \tag{275}$$

is determined by the generalized Gauss (Harish-Chandra) factorization of the product

$$\begin{pmatrix} I & 0\\ z & I\end{pmatrix}\begin{pmatrix}\alpha & \beta\\ b^{*} & \alpha^{*}\end{pmatrix}=\begin{pmatrix} I & x\\ 0 & I\end{pmatrix}\begin{pmatrix} a & 0\\ 0 & \tilde{a}^{-1}\end{pmatrix}\begin{pmatrix} I & 0\\ y & I\end{pmatrix},\quad z\in D, \tag{276}$$

with

$$x=\beta(\alpha^*+z\beta)^{-1},\quad a=(\alpha^\dagger-\tilde{\beta}z)^{-1},\quad y=(\alpha^*+z\beta)^{-1}(b^*+z\alpha). \tag{277}$$

This gives

$$\langle 0|e^{\hat{z}}T(g)|\psi\rangle=[\det a]^\sigma\langle 0|e^{\hat{y}}|\psi\rangle \tag{278}$$

and

$$[\Gamma(g)\Psi](z)=[\det(\alpha^\dagger-\tilde{\beta}z)]^{-\sigma}\Psi((\alpha^*+z\beta)^{-1}(b^*+z\alpha)). \tag{279}$$

For a unitary irrep of SO$(2n)$, the overlap kernel is

$$\mathcal{S}^{\sigma=-\lambda}(z,x^\dagger)=\langle 0|e^{(1/2)\,\Sigma z_{ij}\hat{B}_{ij}}e^{-(1/2)\,\Sigma x^*_{ij}\hat{A}_{ij}}|0\rangle=[\det(I+zx^\dagger)]^\lambda \tag{280}$$

and the inner product is defined by

$$\langle\psi|\varphi\rangle=\int\int\psi^*(z)[\det(I+x^\dagger z)]^\lambda\varphi(x)\mathrm{d}v(z)\mathrm{d}v(x), \tag{281}$$

where the integral is over D, which can be identified with the $n(n-1)/2$-dimensional complex plane, and the measure $\mathrm{d}v$ is the corresponding Bargmann measure. For a unitary representation of SO$^*(2n)$,

$$\mathcal{S}^{\sigma=\lambda}(z,x^\dagger)=\langle 0|e^{(1/2)\,\Sigma z_{ij}\hat{B}_{ij}}e^{(1/2)\,\Sigma x^*_{ij}\hat{A}_{ij}}|0\rangle=[\det(I-zx^\dagger)]^{-\lambda}, \tag{282}$$

when $\det(I-zx^\dagger)>0$, and the inner product is

$$\langle\psi|\varphi\rangle=\int\int\psi^*(z)\ \mathrm{Taylor}\,([\det(I-x^\dagger z)]^{-\lambda})\varphi(x)\mathrm{d}v(z)\mathrm{d}v(x), \tag{283}$$

where the integral is again over the $n(n-1)/2$-dimensional complex plane with the understanding that Taylor $([\det(I_n-zx^\dagger)]^{-\lambda})$ is an expansion of $[\det(I_n-zx^\dagger)]^{-\lambda}$ as a Taylor series in $zx^\dagger$ and the integration is performed term by term.

D. SO($p+2$) and SO(p,2)

The groups SO$(p+2)$ and SO$(p,2)$ are defined by

$$\mathrm{SO}(p+2)=\{M\in\mathrm{SL}(p+2,\mathbb{R})\,|\,MJ^+_{p+2}\tilde{M}=J^+_{p+2}\}, \tag{284}$$

$$\mathrm{SO}(p,2)=\{M\in\mathrm{SL}(p+2,\mathbb{R})\,|\,MJ^-_{p+2}\tilde{M}=J^-_{p+2}\}, \tag{285}$$

where

$$J^\pm_{p+2}=\begin{pmatrix}\pm I_2 & 0\\ 0 & I_p\end{pmatrix}; \tag{286}$$

I_p and I_2 are, respectively, the $p\times p$ and 2×2 identity matrices.

Let

$$L_{\alpha\beta}=-i(E_{\alpha\beta}-E_{\beta\alpha}),\quad \alpha,\beta=1,\ldots,p+2, \tag{287}$$

denote the infinitesimal generators (angular momenta) of SO$(p+2)$; they satisfy the commutation relations

$$[L_{\alpha\beta},L_{\gamma\delta}]=-i(\delta_{\beta\gamma}L_{\alpha\delta}-\delta_{\beta\delta}L_{\alpha\gamma}+\delta_{\alpha\delta}L_{\beta\gamma}-\delta_{\alpha\gamma}L_{\beta\delta}). \tag{288}$$

The common complex extension of the Lie algebras SO($p+2$) and SO(p,2) is then spanned by the matrices

$$\begin{gathered} L_{12} \quad \text{infinitesimal generator of SO(2)}, \\ L_{\alpha\beta} \quad \alpha,\beta=3,\ldots,p+2, \\ A_\alpha=L_{1\alpha}+iL_{2\alpha} \quad \alpha=3,\ldots,p+2, \\ B_\alpha=L_{1\alpha}-iL_{2\alpha} \quad \alpha=3,\ldots,p+2. \end{gathered} \tag{289}$$

For example, L_{12} is the matrix of block form

$$L_{12}=\begin{pmatrix} l_{12} & 0 \\ 0 & 0 \end{pmatrix}, \quad l_{12}=\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}. \tag{290}$$

Group elements are then expressed in terms of this basis by

$$g(\varphi,\theta,x)=\exp i\left[\varphi L_{12}+\sum_{\alpha\beta}\ \theta_{\alpha\beta}L_{\alpha\beta}+\sum_{\alpha}\ (x_\alpha A_\alpha+x_\alpha^* B_\alpha)\right] \quad \in \mathrm{SO}(p+2), \tag{291}$$

$$g(\varphi,\theta,x)=\exp i\left[\varphi L_{12}+\sum_{\alpha\beta}\ \theta_{\alpha\beta}L_{\alpha\beta}+\sum_{\alpha}\ (x_\alpha A_\alpha-x_\alpha^* B_\alpha)\right] \quad \in \mathrm{SO}(p,2), \tag{292}$$

where φ is real, $\theta_{\alpha\beta}$ is real and antisymmetric, and x_α is complex.

By Gauss factorization, an SO($p+2$) or SO(p,2) matrix g is expressed as a product

$$g=e^{z\cdot A}\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}e^{x^*\cdot B}, \tag{293}$$

with $a\in \mathrm{SO}(2,\mathbb{C})$ and $d\in \mathrm{SO}(p,\mathbb{C})$, where $z=(z_3,\ldots,z_{p+2})$ and $x^*=(x_3^*,\ldots,x_{p+2}^*)$ are p-component complex vectors, and

$$z\cdot A=\sum_\alpha\ z_\alpha A_\alpha, \quad x^*\cdot B=\sum_\alpha\ x_\alpha^* B_\alpha. \tag{294}$$

Therefore, as matrices,

$$z\cdot A=\begin{pmatrix} 0 & ez \\ -\tilde{z}\tilde{e} & 0 \end{pmatrix}, \quad e^{z\cdot A}=\begin{pmatrix} I_2-\dfrac{1}{2}(z\cdot z)e\tilde{e} & ez \\ -\tilde{z}\tilde{e} & I_p \end{pmatrix}, \tag{295}$$

$$x^*\cdot B=\begin{pmatrix} 0 & -e^*x^* \\ x^\dagger e^\dagger & 0 \end{pmatrix}, \quad e^{x^*\cdot B}=\begin{pmatrix} I_2-\dfrac{1}{2}(x^*\cdot x^*)e^*e^\dagger & -e^*x^* \\ x^\dagger e^\dagger & I_p \end{pmatrix}, \tag{296}$$

where $\tilde{z}$ denotes the transpose (column vector) of z, and e, e^*, $\tilde{e}$, and $e^\dagger$ are the vectors

$$e=\begin{pmatrix} -i \\ 1 \end{pmatrix}, \quad e^*=\begin{pmatrix} i \\ 1 \end{pmatrix}, \quad \tilde{e}=(-i,1), \quad e^\dagger=(i,1). \tag{297}$$

The matrix a is expressible as a function of a complex parameter ϕ in the form

$$a(\phi)=e^{\phi L_{12}}=\begin{pmatrix}\cosh\phi & -i\sinh\phi\\ i\sinh\phi & \cosh\phi\end{pmatrix}. \tag{298}$$

It has the useful property that

$$e^{\dagger}a(\phi)=e^{\phi}e^{\dagger},\quad a(\phi)e=e^{\phi}e. \tag{299}$$

We now consider a representation T with highest weight state $|0\rangle$, which maps $L_{\alpha\beta}\rightarrow\hat{L}_{\alpha\beta}$, etc., and which, for integer values of σ, satisfies the equations

$$\hat{A}_{\alpha}|0\rangle=0,\quad \hat{L}_{12}|0\rangle=\sigma|0\rangle,\quad \hat{L}_{\alpha\beta}|0\rangle=0. \tag{300}$$

For $\sigma\geqslant 0$, this irrep is finite dimensional and integrates to a unitary irrep of $\mathrm{SO}(p+2)$ for which

$$\hat{A}_{\alpha}^{\dagger}=\hat{B}_{\alpha}. \tag{301}$$

For $\sigma<0$, it is infinite dimensional and integrates to a unitary irrep of $\mathrm{SO}(p,2)$ with

$$\hat{A}_{\alpha}^{\dagger}=-\hat{B}_{\alpha}. \tag{302}$$

The special case $\sigma=0$ is the trivial identity representation. The highest weight state $|0\rangle$ is seen to span a one-dimensional irrep of the subgroup $\mathrm{SO}(2,\mathbb{C})\times\mathrm{SO}(p,\mathbb{C})$ with

$$T\begin{pmatrix}a(\phi) & 0\\ 0 & d\end{pmatrix}|0\rangle=e^{\phi\hat{L}_{12}}|0\rangle=e^{\sigma\phi}|0\rangle. \tag{303}$$

A vector $|\psi\rangle$ in the space of K-finite vectors has holomorphic coherent state wave function

$$\Psi(z)=\langle 0|e^{z\cdot\hat{A}}|\psi\rangle. \tag{304}$$

The action of a group element on coherent state wave functions is obtained by considering the actions of each of the factors in the Gauss factorization. One obtains immediately

$$[\Gamma(e^{z\cdot A})\Psi](z')=\langle 0|e^{z'\cdot\hat{A}}e^{z\cdot\hat{A}}|\psi\rangle=\Psi(z'+z). \tag{305}$$

And, from the identity

$$e^{z\cdot\hat{A}}\begin{pmatrix}a(\phi) & 0\\ 0 & d\end{pmatrix}=\begin{pmatrix}a(\phi) & 0\\ 0 & d\end{pmatrix}e^{(e^{-\phi}zd)\cdot\hat{A}}, \tag{306}$$

it follows that

$$\left[\left[\Gamma\begin{pmatrix}a(\phi) & 0\\ 0 & d\end{pmatrix}\Psi\right](z)=e^{\sigma\phi}\Psi(e^{-\phi}zd).\right. \tag{307}$$

The action

$$[\Gamma(e^{x^{*}\cdot B})\Psi](z)=\langle 0|e^{z\cdot\hat{A}}e^{x^{*}\cdot B}|\psi\rangle \tag{308}$$

is determined by Gauss factorization of the product

$$e^{z\cdot A}e^{x^{*}\cdot B}=e^{X^{*}\cdot B}\begin{pmatrix}a(\phi) & 0\\ 0 & d\end{pmatrix}e^{Z\cdot A}. \tag{309}$$

This $(p+2)\times(p+2)$ matrix identity is equivalent to the four matrix equations

$$[I_2-\tfrac{1}{2}(X^*\cdot X^*)e^*e^\dagger]a[I_2-\tfrac{1}{2}(Z\cdot Z)e\tilde{e}]+(X^*d\tilde{Z})e^*\tilde{e}$$
$$=[I_2-\tfrac{1}{2}(z\cdot z)e\tilde{e}][I_2-(x^*\cdot x^*)e^*e^\dagger]+(z\cdot x^*)ee^\dagger, \tag{310}$$

$$e^\phi eZ-e^\phi(X^*\cdot X^*)e^*Z-e^*X^*d=ez-e^*x^*+(z\cdot z)ex^*, \tag{311}$$

$$e^\phi X^\dagger e^\dagger-e^\phi(Z\cdot Z)X^\dagger\tilde{e}-d\tilde{Z}\tilde{e}=x^\dagger e^\dagger-\tilde{z}\tilde{e}+(x^*\cdot x^*)\tilde{z}e^\dagger, \tag{312}$$

$$2e^\phi X^\dagger Z+d=I_p+2\tilde{z}x^\dagger, \tag{313}$$

where we have used Eq. (299). The 2×2 matrix Eq. (310) is equivalent to the four equations

$$e^\phi=1+(x^*\cdot x^*)(z\cdot z)+2(x^*\cdot z), \tag{314}$$

$$e^\phi(Z\cdot Z)=z\cdot z, \tag{315}$$

$$e^\phi(X^*\cdot X^*)=x^*\cdot x^*, \tag{316}$$

$$e^\phi X^*dZ=x^*\cdot z, \tag{317}$$

and the $2\times p$ matrix Eq. (311) is equivalent to the two equations

$$e^\phi Z+e^\phi(X^*\cdot X^*)Z+X^*d=z+x^*+(z\cdot z)x^*, \tag{318}$$

$$e^\phi Z-e^\phi(X^*\cdot X^*)Z-X^*d=z-x^*+(z\cdot z)x^*. \tag{319}$$

Thus, we obtain

$$Z=e^{-\phi}[z+(z\cdot z)x^*]. \tag{320}$$

These results imply that

$$[\Gamma(e^{x^*\cdot B)}\Psi](z)=e^{\sigma\phi}\Psi(e^{-\phi}[z+(z\cdot z)x^*]) \tag{321}$$

with e^ϕ given by Eq. (314).

Equations (305), (308), and (321) are all special cases of the general expression

$$[\Gamma(g)\Psi](z)=e^{\sigma\phi(g)}\Psi(zg), \tag{322}$$

where, for

$$g=\begin{pmatrix} A & B \\ C & D \end{pmatrix}, \tag{323}$$

$$e^\phi(g)=\tfrac{1}{2}(e^\dagger-z\cdot z\tilde{e})Ae+zCe, \tag{324}$$

$$zg=e^{-\phi}\{\tfrac{1}{2}(e^\dagger-z\cdot z\tilde{e})B+zD\}. \tag{325}$$

For $\sigma=\lambda>0$ [unitary irrep of $O(p+2)$], the overlap integral

$$\mathcal{S}^\lambda(z,x)=\langle 0|e^{z\cdot A}e^{x^*\cdot B}|0\rangle \tag{326}$$

is determined, from Eqs. (308) and (321), to be given by

$$\mathcal{S}^{\lambda}(z,x)=[1+(z\cdot z)(x^*\cdot x^*)+2z\cdot x^*]^{\lambda}. \tag{327}$$

This expression is well-defined for all z and x^* in the p-dimensional complex plane. For $\sigma=-\lambda<0$ [unitary irrep of O(p,2)],

$$\mathcal{S}^{-\lambda}(z,x)=\langle 0|e^{z\cdot A}e^{-x^*\cdot B}|0\rangle=[1+(z\cdot z)(x^*\cdot x^*)-2z\cdot x^*]^{-\lambda} \tag{328}$$

for all z and x^* in the domain

$$D=\{z\in\mathbb{C}^p|1+|z\cdot z|^2-2z^*\cdot z>0\}. \tag{329}$$

Because $\mathcal{S}^{-\lambda}(z,x)$ is holomorphic in the components of z and $x^\dagger$, it is now defined by Eq. (328) for all z and x by the Taylor series expansion

$$\mathcal{S}^{-\lambda}(z,x)=\text{Taylor}[1+(z\cdot z)(x^*\cdot x^*)-2z\cdot x^*]^{-\lambda}, \tag{330}$$

as in (87) for SU(1,1). The integral expression given below for the inner product then makes sense for all polynomials; for any polynomials ψ, φ, only finitely many terms in the series make nonzero contributions.

In both cases, the inner products are given by

$$\langle\psi|\varphi\rangle=\int\int \psi^*(z)\mathcal{S}^{\sigma}(z,x)\varphi(x)\mathrm{d}v(z)\mathrm{d}v(x), \tag{331}$$

where the integrals are with respect to the Bargmann measure over the whole p-dimensional complex plane.

V. CONCLUDING REMARKS

The above examples show that the coherent state method is very versatile and gives all the standard irreps induced from one-dimensional subgroups. Moreover, it does so in a way that considerably simplifies the evaluation of inner products. Such simplification is invaluable in practical applications of the inducing construction, e.g., to problems in physics. For example, the analysis of Sec. IV C has recently been used effectively for the calculation of SU(3) Clebsch–Gordan coefficients in an SO(3) basis,[25] coefficients that are used widely, for example, in nuclear physics.

The above techniques become even more powerful and much more general in their extension to the vector coherent state induction of irreps from multi-dimensional irreps of a subgroup. Applications of the triplets method to VCS representations will be given in a sequel to the present article.

APPENDIX: INNER PRODUCTS FOR STANDARD HOLOMORPHIC REPRESENTATIONS

Let T be an irrep of SU(2) on a Hilbert space $\mathbb{H}$ with highest weight state $|0\rangle$. The standard method of finding the inner product of coherent state wave functions for this representation[13] makes use of the resolution of the identity

$$\hat{I}=\int_{G_0} T^{\dagger}(g)|0\rangle\langle 0|T(g)\mathrm{d}\mu(g), \tag{A1}$$

where $\mathrm{d}\mu$ is a right-invariant measure for the group G. Substituting the Gauss factorization for an SU(2) matrix

$$\begin{pmatrix} a & -b^* \\ b & a^* \end{pmatrix}=\begin{pmatrix} 1 & 0 \\ b/a & 1 \end{pmatrix}\begin{pmatrix} a & 0 \\ 0 & 1/a \end{pmatrix}\begin{pmatrix} 1 & -b^*/a \\ 0 & 1 \end{pmatrix}=e^{b/a\,J_-}a^{2J_0}e^{(-b^*/a)\,J_+}, \tag{A2}$$

and setting $z=-b^*/a$ with the constraint $|a|^2=(1+|z|^2)^{-1}$, we then have

$$\hat{I}=\int T^\dagger(z)|0\rangle\langle 0|T(z)(1+|z|^2)^{-2j}\,\mathrm{d}\sigma(z), \tag{A3}$$

where $\mathrm{d}\sigma(z)$ is the (suitably normalized) right G-invariant measure for $N=\{e^{zJ_+};z\in\mathbb{C}\}$. Taking matrix elements between states of $\mathbb{H}$ gives the inner product

$$\langle\psi|\varphi\rangle=\int \Psi^*(z)\Phi(z)(1+|z|^2)^{-2j}\mathrm{d}\sigma(z), \tag{A4}$$

in terms of coherent state wave functions. The SU(2)-invariant measure $\mathrm{d}\sigma$ for N is determined by considering the right translations of N by SU(2). The appropriate SU(2): $N\to N;z\mapsto z\cdot g$ action is obtained by observing that

$$\begin{pmatrix}1 & z\\ 0 & 1\end{pmatrix}\begin{pmatrix}a & -b^*\\ b & a^*\end{pmatrix}=\begin{pmatrix}1 & 0\\ \dfrac{b}{bz+a} & 1\end{pmatrix}\begin{pmatrix}bz+a & 0\\ 0 & \dfrac{1}{bz+a}\end{pmatrix}\begin{pmatrix}1 & \dfrac{a^*z-b^*}{bz+a}\\ 0 & 1\end{pmatrix}, \tag{A5}$$

which implies that

$$z\cdot g=\frac{a^*z-b^*}{bz+a}. \tag{A6}$$

By computing the Jacobian of the $z\to z\cdot g$ transformation, one determines the invariant volume element

$$\mathrm{d}\sigma(z)\propto(1+|z|^2)^{-2}\mathrm{d}x\mathrm{d}y \tag{A7}$$

with $z=x+iy$; the factor $(1+|z|^2)^{-2}$ which gives an SU(2)-invariant volume in terms of the corresponding Euclidean volume is known as a Bergman kernel.[36] Finally, the normalization constant is fixed by requiring the coherent-state wave function for the highest weight state to be normalized to unity. Thus, one obtains the inner product

$$\langle\psi|\varphi\rangle=\frac{2j+1}{\pi}\int\int\frac{\Psi^*(z)\Phi(z)}{(1+|z|^2)^{2j+2}}\mathrm{d}x\mathrm{d}y. \tag{A8}$$

Weak pseudo-Hermiticity and antilinear commutant

L. Solombrino[a)]

(Received 22 March 2002; accepted 15 April 2002)

We inquire into some properties of diagonalizable pseudo-Hermitian operators, showing that their definition can be relaxed and that the pseudo-Hermiticity property is strictly connected with the existence of an antilinear symmetry. This result is then illustrated by considering the particular case of the complex Morse potential. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1504485]

I. INTRODUCTION

In the last several years the study of some non-Hermitian Hamiltonians with a real spectrum, and the conjecture on the connection between the reality of the spectrum and the PT-invariance of these Hamiltonians due to Bender and Boettcher,[1] have given rise to a growing interest in the literature.[2] Indeed, the above-mentioned Hamiltonians form a subclass of the class of ''pseudo-Hermitian'' operators, i.e., those operators which satisfy

$$A^\dagger = \eta A \eta^{-1} \tag{1}$$

with

$$\eta = \eta^\dagger. \tag{2}$$

Pseudo-Hermitian operators were introduced in the early 1940s by Dirac[3] and Pauli[4] in order to overcome some divergence difficulties in physics by using an indefinite metric associated with η, and were later resumed by Lee and Wick[5] (who first, to the best of our knowledge, used the term ''pseudo-Hermiticity''). More recently, many interesting properties of such operators have been examined and their spectrum has been suitably characterized.[6,7]

In the present paper we aim to point out further properties of pseudo-Hermitian operators that are relevant from a physical viewpoint. To this end, we introduce in Sec. II the possibly broader class of *weakly* pseudo-Hermitian operators, i.e., those operators which satisfy Eq. (1) without any constraint on the (linear, invertible) operator η, and show that, whenever one considers only diagonalizable operators, this class actually coincides with the class of all pseudo-Hermitian operators. Hence the condition in Eq. (2) can be dropped when defining (diagonalizable) pseudo-Hermitian operators, which is useful from several viewpoints [in particular, it simplifies checking Eq. (1)]. Moreover, we show in Sec. III that a diagonalizable operator H is (weakly) pseudo-Hermitian if and only if an antilinear involutory operator exists which commutes with it. This result has a number of relevant consequences; in particular, in every theory which admits a time-reversal invariance, or a CPT-invariance, the Hamiltonian must necessarily be a (weakly) pseudo-Hermitian operator. Furthermore, the above-mentioned result is strictly intertwined with an old theorem[8] of group representation theory, according to which a set of operators admits an involutory antilinear mapping that commutes with it if and only if all the operators in the set can assume conjointly a real form in a suitable basis. Indeed, by using this theorem together with the above-given results, we conclude in Sec. IV that for any diagonalizable (weakly) pseudo-

a)Electronic mail: luigi.solombrino@le.infn.it

Hermitian operator H a basis exists in which H has a real form. If this basis coincides with the eigenbasis of H, then H also has a real spectrum. Finally, we illustrate our results by means of an example, considering the special case of the complex Morse potential[9] in Sec. V.

II. THE SPECTRA OF WEAKLY PSEUDO-HERMITIAN OPERATORS

As we wrote in Sec. I, here we introduce a new class of operators, whose properties will be studied in the following.

Definition 1: A linear operator A is said to be weakly pseudo-Hermitian *if a linear, invertible operator* η *exists such that*

$$\eta A \eta^{-1} = A^{\dagger}. \tag{3}$$

The above-given definition generalizes the definition of pseudo-Hermitian operators since we do not assume $\eta = \eta^{\dagger}$ as is required in the standard definition of pseudo-Hermitian operators.[5,6]

As in Refs. 6 and 7, here we consider only diagonalizable operators; moreover, for the sake of simplicity, we consider only discrete spectra (see, however, Sec. V, where a potential with a continuous spectrum is explicitly studied). Whenever H is a diagonalizable operator with a discrete spectrum, a complete biorthonormal eigenbasis $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ exists,[10] i.e., a basis such that

$$H|\psi_n,a\rangle = E_n|\psi_n,a\rangle, \quad H^{\dagger}|\phi_n,a\rangle = E_n^*|\phi_n,a\rangle, \tag{4}$$

$$\langle \phi_m,b|\psi_n,a\rangle = \delta_{mn}\delta_{ab}, \tag{5}$$

$$\sum_n \sum_{a=1}^{d_n} |\phi_n,a\rangle\langle\psi_n,a| = \sum_n \sum_{a=1}^{d_n} |\psi_n,a\rangle\langle\phi_n,a| = 1, \tag{6}$$

where d_n denotes the degeneracy of E_n, and a and b are degeneracy labels.

The operator H can then be written in the form

$$H = \sum_n \sum_{a=1}^{d_n} |\psi_n,a\rangle E_n \langle\phi_n,a|.$$

For the sake of brevity we also write the above-given basis $\{|\psi_m\rangle,|\phi_m\rangle\}$ in the following, with an obvious meaning of symbols. Then H can also be written in the form

$$H = \sum_m |\psi_m\rangle E_m \langle\phi_m|$$

(where it may occur that $E_m = E_{m'}$ even if $m \neq m'$). Furthermore, if $\{u_m\}$ is any complete, orthonormal basis in our space, we put in the following:

$$O = \sum_m |\psi_m\rangle\langle u_m|. \tag{7}$$

By using Eq. (6), we get

$$O^{-1} = \sum_m |u_m\rangle\langle\phi_m|$$

and

$$O^{-1}HO = \sum_m |u_m\rangle\langle\phi_m| \sum_{m'} |\psi_{m'}\rangle E_{m'} \langle\phi_{m'}| \sum_{m''} |\psi_{m''}\rangle\langle u_{m''}| = \sum_m |u_m\rangle E_m \langle u_m|.$$

Moreover,

$$(OO^\dagger)H^\dagger(OO^\dagger)^{-1}=\sum_m |\psi_m\rangle E_m^*\langle\phi_m|. \tag{8}$$

We can now state the following proposition, which embodies some results in Ref. 6 on pseudo-Hermitian operators.

Proposition 1: Let H be a diagonalizable operator with a discrete spectrum. Then, the following conditions are equivalent:

(i) H is weakly pseudo-Hermitian;
(ii) the eigenvalues of H occur in complex conjugate pairs, and for each pair the multiplicities of both the eigenvalues are the same;
(iii) H is pseudo-Hermitian.

Proof: The implication *(iii)⇒(ii)* is proven in Proposition 7 of Ref. 6. By observing that only the invertibility of η is used in this proof, in order to show that η^{-1} maps the eigensubspace of $H^\dagger$ associated with E_n to that of H associated with E_n^*, and both the subspaces have the same dimension, one immediately transforms this proof into a proof of the implication *(i)⇒(ii)*.

The implication *(ii)⇒(iii)* is also proven in Ref. 6. We provide here, however, a somewhat different proof of it, which produces a useful decomposition of η [see Eq. (12)].

Let us therefore assume that condition (ii) holds, and use (whenever it is necessary) the subscript "$_0$" to denote real eigenvalues and the corresponding eigenvectors, and the subscript "$_\pm$" to denote the complex eigenvalues with positive or negative imaginary part, respectively, and the corresponding eigenvectors.

Then, let us consider the involutory operator T, defined as follows:

$$T|\psi_{n_\pm},a\rangle=|\psi_{n_\mp},a\rangle, \quad \text{hence,} \quad T|\psi_{n_0},a\rangle=|\psi_{n_0},a\rangle. \tag{9}$$

The explicit form of T is

$$T=T\left(\sum_{n_0}\sum_{a=1}^{d_{n_0}}|\psi_{n_0},a\rangle\langle\phi_{n_0},a|+\sum_{n_+}\sum_{a=1}^{d_{n_+}}|\psi_{n_+},a\rangle\langle\phi_{n_+},a|+\sum_{n_-}\sum_{a=1}^{d_{n_-}}|\psi_{n_-},a\rangle\langle\phi_{n_-},a|\right)$$

$$=\sum_{n_0,a}|\psi_{n_0},a\rangle\langle\phi_{n_0},a|+\sum_{n_+,n_-,a}(|\psi_{n_-},a\rangle\langle\phi_{n_+},a|+|\psi_{n_+},a\rangle\langle\phi_{n_-},a|).$$

The action of T on the bras $\langle\phi_{n_\pm},a|$ easily follows from the above-given expression:

$$\langle\phi_{n_\pm},a|T=\langle\phi_{n_\mp},a|, \quad \text{hence,} \quad \langle\phi_{n_0},a|T=\langle\phi_{n_0},a|. \tag{10}$$

Then, by simple calculations, one has

$$THT=\sum_m |\psi_m\rangle E_m^*\langle\phi_m|, \tag{11}$$

and finally, comparing Eqs. (8) and (11), it follows

$$THT=(OO^\dagger)H^\dagger(OO^\dagger)^{-1},$$

hence condition *(iii)* follows at once, with

$$\eta=(OO^{\dagger})^{-1}T=\sum_{n_0,a}|\phi_{n_0},a\rangle\langle\phi_{n_0},a|+\sum_{n_+,n_-,a}(|\phi_{n_+},a\rangle\langle\phi_{n_-},a|+|\phi_{n_-},a\rangle\langle\phi_{n_+},a|)=\eta^{\dagger}. \tag{12}$$

Finally, the proof of the Proposition can be completed by observing that the implication $(iii)\Rightarrow(i)$ is obvious. ■

The introduction of the operator T on the above-given proof and the decomposition $\eta=(OO^{\dagger})^{-1}T$ in Eq. (12) allows one to obtain immediately the characterization of the case of real spectrum. Indeed, noting that $T=\mathsf{1}$ if and only if the spectrum of H is real, the following statement holds (see also the Theorem in Ref. 7).

Proposition 2: The spectrum of a diagonalizable weakly pseudo-Hermitian (hence, of a diagonalizable pseudo-Hermitian) operator H is real if and only if an operator η exists such that $\eta=(OO^{\dagger})^{-1}$.

Furthermore, the existence of an Hermitian operator η whenever H is weakly pseudo-Hermitian implies that also in this case one can introduce an Hermitian, indefinite inner product[4–6,11] which is invariant under the time translation generated by H.

III. WEAKLY PSEUDO-HERMITIAN OPERATORS AND ANTILINEAR SYMMETRIES

In order to properly discuss the next argument, we state the following definition.

Definition 2 (Ref. 8): Given the biorthonormal basis $\mathsf{E}=\{|\psi_m\rangle,|\phi_m\rangle\}$ in a Hilbert space, we call conjugation *associated with it the involutory antilinear operator*

$$\Theta_{\mathsf{E}}=\sum_m|\psi_m\rangle K\langle\phi_m|, \tag{13}$$

where the operator K acts transforming each complex number on the right into its complex conjugate.

Let us discuss now the connection between the (weak) pseudo-Hermiticity condition and the *antilinear commutant*[8] of H (i.e., the set of the antilinear, invertible operators which commute with it). This connection was already acknowledged in Ref. 7, where the author shows that, if H commutes with an antilinear operator A, then condition (ii) of Proposition 1 holds, and that a Hamiltonian with an antilinear symmetry A has a real spectrum if and only if the symmetry is *exact*[7] (i.e., its eigenvectors are invariant under the action of A). The latter statement can be rephrased, using Definition 2, by saying that *the spectrum of H is real if and only if* $[H,\Theta_{\mathsf{E}}]=0$.

However, the above-given results enlighten only partially the key role of the antilinear commutant of H. Indeed, the following, more complete proposition holds.

Proposition 3: Let H be a diagonalizable operator with a discrete spectrum. Then, the following conditions are equivalent:

(i) an antilinear, invertible operator Ω exists such that $[H,\Omega]=0$;

(ii) H is (weakly) pseudo-Hermitian;

(iii) an antilinear, involutory operator $\hat{\Omega}$ exists such that $[H,\hat{\Omega}]=0$.

Proof: $(i)\Rightarrow(ii)$. Let Ω exist. Then, the linear operator

$$\eta=(OO^{\dagger})^{-1}\Theta_{\mathsf{E}}\Omega$$

[where E is the biorthonormal basis associated with H, and O and Θ_{E} are defined as in Eqs. (7) and (13), respectively] fulfils the condition stated by Eq. (3), hence H is (weakly) pseudo-Hermitian. Indeed,

$$\Theta_{\mathsf{E}} H \Theta_{\mathsf{E}}^{-1} = \Theta_{\mathsf{E}} H \Theta_{\mathsf{E}} = \sum_m |\psi_m\rangle E_m^* \langle \phi_m|, \tag{14}$$

so that, recalling Eq. (8),

$$\eta H \eta^{-1} = (OO^\dagger)^{-1} \Theta_{\mathsf{E}} \Omega H \Omega^{-1} \Theta_{\mathsf{E}} (OO^\dagger) = (OO^\dagger)^{-1} \Theta_{\mathsf{E}} H \Theta_{\mathsf{E}} (OO^\dagger) = H^\dagger.$$

$(ii) \Rightarrow (iii)$. If H is (weakly) pseudo-Hermitian, the eigenvalues of H occur in complex conjugate pairs, and for each pair the multiplicities of both the eigenvalues are the same (Proposition 1). Then, one easily sees, recalling the definition of the operator T provided in the proof of Proposition 1 and Eq. (11), that

$$\Theta_{\mathsf{E}} H \Theta_{\mathsf{E}} = THT.$$

Hence the antilinear operator

$$\hat{\Omega} = \Theta_{\mathsf{E}} T = \sum_{n_0, a} |\psi_{n_0}, a\rangle K \langle \phi_{n_0}, a| + \sum_{n_+, n_-, a} (|\psi_{n_+}, a\rangle K \langle \phi_{n_-}, a| + |\psi_{n_-}, a\rangle K \langle \phi_{n_+}, a|) \tag{15}$$

commutes with H. Finally, $\hat{\Omega}$ is involutory, (i.e., $\hat{\Omega}^2 = \mathbb{1}$) as one can immediately verify by using the explicit expression of $\hat{\Omega}$ in Eq. (15).

$(iii) \Rightarrow (i)$. Obvious. ■

Proposition 3 has an interesting physical interpretation, as we have emphasized in Sec. I. Indeed, whenever H is the Hamiltonian of some physical system, it establishes a link between the properties of H (and of its spectrum) and the symmetries of the physical system described by it. For, the time-reversal symmetry is associated, in complex quantum mechanics, with an antilinear operator. Hence, whenever a physical system admits such a symmetry (or else, more generally, it is invariant under the combined action of the time-reversal operator times a linear one) the antilinear commutant of its Hamiltonian must be nonvoid, hence H is a (weakly) pseudo-Hermitian operator. Conversely, any (weakly) pseudo-Hermitian Hamiltonian admits an antilinear (involutory) symmetry.

Finally, since in the case of real spectrum the operator T defined in the proof of Proposition 1 is such that $T = \mathbb{1}$, hence $\hat{\Omega} = \Theta_{\mathsf{E}}$, one obtains the following proposition.

Proposition 4: A diagonalizable, weakly pseudo-Hermitian operator H has a real spectrum if and only if it commutes with the conjugation associated with its eigenbasis.

Remark: While we were writing the final version of this paper, some similar results have been obtained by other authors[12] [in particular, having in mind the equivalence *(i)⇔(iii)* in our Proposition 1, Theorem 2 of Ref. 12 essentially states the equivalence *(i)⇔(ii)* of our Proposition 3]. Nevertheless, our presentation is rather different and embodies the new condition *(iii)* in Proposition 3, which has a number of interesting consequences, which we are going to explore in Sec. IV.

IV. REAL FORM OF THE (WEAKLY) PSEUDO-HERMITIAN OPERATORS

According to Proposition 3, for any (weakly) pseudo-Hermitian operator H, at least one involutory antilinear operator exists which commutes with it. Then, it has been proven elsewhere[8] that any involutory antilinear operator $\hat{\Omega}$ is a conjugation in some suitable basis; moreover, in the basis associated with $\hat{\Omega}$, any operator commuting with $\hat{\Omega}$ has a real form.

The proof of the latter statement can be sketched as follows. If we denote by S the linear part of $\hat{\Omega}$, i.e., $\hat{\Omega} = SK$ (where K is the complex conjugation operator, see Sec. III), then $\hat{\Omega}^2 = \mathbb{1}$ implies $SS^* = \mathbb{1}$ and this is possible if and only if an U exists such that $S = UU^{*-1}$. Then $[H, \hat{\Omega}] = 0$ implies $HUU^{*-1} = UU^{*-1}H^*$, hence

$$U^{-1}HU=(U^{*-1}H^{*}U^{*})=(U^{-1}HU)^{*}.$$

Referring to the notation introduced in the present paper, let $\mathsf{F}=\{|v_m\rangle,|w_m\rangle\}$ be the biorthonormal basis associated, in the above-given sense, to the conjugation $\hat{\Omega}$ which commutes with H (of course, F may be an orthonormal basis, which occurs if and only if, for all m, $|v_m\rangle=|w_m\rangle$), and let us consider the matrix elements of H in such basis. It is easy to verify that they are real; indeed, on one hand,

$$\langle w_i|H|v_k\rangle=\langle w_i|\sum_n |\psi_n\rangle E_n\langle \phi_n|v_k\rangle$$

and, on the other hand

$$\begin{aligned}\langle w_i|\hat{\Omega}H\hat{\Omega}|v_k\rangle&=\langle w_i|\sum_m |v_m\rangle K\langle w_m|\sum_n |\psi_n\rangle E_n\langle \phi_n|\sum_{m'} |v_{m'}\rangle K\langle w_{m'}|v_k\rangle\\&=\sum_{m,m',n}\delta_{im}K\langle w_m|\psi_n\rangle E_n\langle \phi_n|v_{m'}\rangle K\delta_{m',k}\\&=\langle v_k|\sum_n |\phi_n\rangle E_n^{*}\langle \psi_n|w_i\rangle\\&=\left(\langle w_i|\sum_n |\psi_n\rangle E_n\langle \phi_n|v_k\rangle\right)^{*}.\end{aligned}$$

Since, trivially, every operator which assumes a real form in some basis B commutes with the conjugation associated with B, we have thus proven the following proposition.

Proposition 5: An operator H is (weakly) pseudo-Hermitian if and only if a basis exists in which it assumes a real form.

The results in Propositions 1, 3, and 5 can be collected together, obtaining a set of six equivalent conditions which can be useful in order to characterize the Hamiltonians that we are considering. In particular, the statement in Proposition 5 can be used to write a (weakly) pseudo-Hermitian operator in a more manageable form (an example of basis transformation which puts a particular Hamiltonian in real form is given in Sec. V).

V. AN EXAMPLE: THE COMPLEX MORSE POTENTIAL

Let us verify the results obtained in the previous sections in the special case of the complex Morse potential.[9] This was extensively studied, for instance, in Ref. 9, and its spectrum was predicted to be real by means of group theoretic techniques.[13]

The Morse potential is given by

$$V(x)=(A+iB)^2e^{-2x}-(A+iB)(2C+1)e^{-x}\quad (A,B,C\in\mathsf{R}). \tag{16}$$

Putting $\rho=\sqrt{A^2+B^2}$, $\theta=\arctan(2B/A)$, $k=2C+1$, we get

$$V(x)=\rho^2e^{-2x+i\theta}-k\rho e^{-x+i\theta/2}. \tag{17}$$

Following Ref. 9, let us introduce the (Hermitian) operator $e^{-\theta p}(\theta\in\mathsf{R}, p=-i(d/dx))$. Hence, we obtain[9]

$$e^{-\theta p}V(x)e^{\theta p}=V(x+i\theta)=V^{*}(x). \tag{18}$$

Equation (18) shows that V is a pseudo-Hermitian (but non-PT-symmetric) operator. Let us put now $\hat{\Omega}=SK=e^{\theta p}K$. By using Eq. (18) one gets

$$\hat{\Omega} V = V \hat{\Omega},$$

which agrees with Proposition 3. Then, a straightforward calculation shows that $S^* = e^{-\theta p} = S^{-1}$, hence $\hat{\Omega}$ is involutory, which also agrees with Proposition 3. Moreover, one gets by inspection that

$$S = e^{\theta p/2}(e^{\theta p/2})^{*-1} = UU^{*-1}.$$

Thus, finally,

$$U^{-1}VU = e^{-\theta p/2} V e^{\theta p/2} = V(x + i\theta/2) = \rho^2 e^{-2x} - k\rho e^{-x} = (U^{-1}VU)^*$$

which agrees with Proposition 5.

(Received 15 April 2002; accepted 11 June 2002)

Structures of quantum Fokker–Planck equations are characterized with respect to the properties of complete positivity, covariance under symmetry transformations and satisfaction of equipartition, referring to recent mathematical work on structures of unbounded generators of covariant quantum dynamical semigroups. In particular the quantum optical master equation and the quantum Brownian motion master equation are shown to be associated to U(1) and R symmetry, respectively. Considering the motion of a Brownian particle, where the expression of the quantum Fokker–Planck equation is not completely fixed by the aforementioned requirements, a recently introduced microphysical kinetic model is briefly recalled, where a quantum generalization of the linear Boltzmann equation in the small energy and momentum transfer limit straightforwardly leads to quantum Brownian motion. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1505126]

I. INTRODUCTION

A theory of quantum dissipation, even restricted to the Markovian case, is a subject of major interest for many different scientific communities, ranging from mathematicians to physicists and chemists, according to various perspectives. Among these in first line experimental applications in phenomena where spontaneous emission, decoherence and dissipation play an important role, but also theoretical studies regarding the connection between quantum and classical description of dynamics, since, thanks to the lack of simple quantization recipes, such as the correspondence principle, dissipative systems become a fruitful working area where typical quantum structures may emerge. This interest has led to a huge number of proposals of Markovian master equations for the description of such dissipative phenomena, based on microphysical, phenomenological or purely mathematical approaches (see references in Refs. 1–3), not always accompanied by clear statements with regard to obeyed physical and mathematical properties, thus often leading to amendments of these models in view of some missing desired feature. This is in particular true with respect to the property of positivity or complete positivity,[4] proper distinction between Hamiltonian and dissipative part,[5] translational invariance,[6,7] and decoherence effects.[8]

As a result some efforts have been made to compare and characterize the different proposals in view of relevant mathematical and physical properties: preservation of the positivity of the statistical operator, existence of a suitable canonical stationary state, and translational invariance.[9–11,2,12] The main starting point for this research work was the result of Lindblad for the most general structure of bounded generator of a completely positive quantum dynamical semigroup,[13] together with his paper on quantum Brownian motion,[14] in which some of these issues were already considered. Complete positivity, actually equivalent to positivity for the considered Markovian quasi-free systems,[15] ensures that the statistical operator preserves positivity during the time evolution, and has emerged as a typical quantum feature, corresponding to the requirement that positivity of the time evolution is preserved under entanglement. It is in fact by

[a)]Electronic mail: bassano.vacchini@mi.infn.it

now an essential property in the realm of quantum communication,[16] even though its origins lie in the theory of quantum measurement.[17] The result of Lindblad rigorously holds for bounded operators, though it is usually exploited as a starting point also for unbounded operators, leaving in this case the task open, to show that the considered structure is a proper generator of a completely positive quantum dynamical semigroup.

In this article we will try to further clarify the situation, showing that if besides complete positivity and equipartition, i.e., existence of a suitable canonical stationary solution, proper covariance properties of the generator of the dynamics, reflecting the relevant symmetries of the reservoir (and therefore not necessarily only translational invariance), are taken into account, a suitable characterization of two different classes of master equations can be given in a very neat way. In particular, with the two one-dimensional Lie groups U(1) and R two distinct type of master equations are associated, describing respectively the damped harmonic oscillator (the so-called quantum optical master equation) and the motion of a Brownian particle (the so-called quantum Brownian motion master equation), which, despite the fact that their physical realm of validity is essentially well-understood,[18] are sometimes mixed up,[7] their characterization in connection to underlying symmetry of the reservoir being usually neglected.[18] Recent work on completely positive quantum dynamical semigroups has shown that, asking for suitable covariance properties, a characterization of generators of such semigroups can be given also in the case of unbounded operators, where very few results are available,[19] so that one can check whether a proposed formal Lindblad structure is indeed a proper generator of a quantum dynamical semigroup. The room left by these mathematical and physical requirements should be covered by microphysical approaches, determining their relevance and predictive power. It turns out that the quantum optical master equation is in essence fixed by these requirements, while in the quantum Brownian motion case there is a nontrivial freedom left, thus explaining the huge, sometimes contradictory, literature devoted to the quantum Brownian motion master equation. In this connection a recently obtained[20–22] microphysical model for the quantum description of the motion of a Brownian particle is presented, derived from a quantum version of the linear Boltzmann equation,[23,24] extending previous phenomenological models[25] where dissipation effects leading to the correct stationary solution could not be accounted for. For further work relying on symmetry properties in the case of a fermionic oscillator, see Ref. 26.

The article is organized as follows: in Sec. II we recall the most general Lindblad structure corresponding to a quantum Fokker–Planck equation, further showing the expressions that come out asking for shift-covariance or translation-covariance; in Sec. III we outline the results of a microphysical model for the description of quantum Brownian motion, obtained from a quantum linear Boltzmann equation expressed in terms of the operator-valued dynamic structure factor of the reservoir; in Sec. IV we briefly comment on our results, indicating possible future extensions.

II. GENERAL EXPRESSION OF THE QUANTUM FOKKER–PLANCK EQUATION WITH A LINDBLAD STRUCTURE

In order to give a quantum description of dissipative phenomena which at the classical level are described by second-order Fokker–Planck equations, we first concentrate on generalizations of the quantum Liouville equation which preserve trace and positivity of the statistical operator, also possibly accounting for friction effects. This can be done considering the most general expression of generator of a completely positive quantum dynamical semigroup (complete positivity being for these Markovian quasi-free systems necessary in order to preserve positivity[15]), given by a Lindblad structure in which position and momentum operator for the microsystem (respectively $\hat{x}$ and $\hat{p}$) appear restricted to bilinear expressions, according to the classical approximations leading to a friction term proportional to velocity. The general expression of a Markovian quantum Fokker–Planck equation preserving the positivity of the statistical operator is thus given, in the one-dimensional case to which we will restrict for simplicity, by[14,27,10]

$$\mathcal{M}_{\hat{x}\hat{p}}[\hat{\rho}]=-\frac{i}{\hbar}\left[H_0(\hat{x},\hat{p})+\frac{\mu}{2}\{\hat{x},\hat{p}\},\hat{\rho}\right]+\sum_{i=1}^{2}\left[\hat{V}_i\hat{\rho}\hat{V}_i^{\dagger}-\frac{1}{2}\{\hat{V}_i^{\dagger}\hat{V}_i,\hat{\rho}\}\right],$$
$$\hat{V}_i=\alpha_i\hat{p}+\beta_i\hat{x},\quad \alpha_i,\beta_i\in\mathrm{C},\quad \mu\in\mathrm{R}, \tag{1}$$

where H_0 is a self-adjoint operator given by a quadratic expression in $\hat{x}$ and $\hat{p}$ describing the free system, and the added Hamiltonian term proportional to μ has been introduced for later convenience. For the sake of comparison with classical Fokker–Planck equations, in order to make the intuitive physical meaning of the different contributions clear, (1) is usually conveniently written in the following form using nested commutators and anticommutators:[10]

$$\mathcal{L}_{\hat{x}\hat{p}}[\hat{\rho}]=-\frac{i}{\hbar}[H_0(\hat{x},\hat{p}),\hat{\rho}]-\frac{i(\mu-\gamma)}{\hbar\quad 2}[\{\hat{x},\hat{p}\},\hat{\rho}]-\frac{i}{\hbar}\gamma[\hat{x},\{\hat{p},\hat{\rho}\}]-\frac{D_{pp}}{\hbar^2}[\hat{x},[\hat{x},\hat{\rho}]]$$
$$-\frac{D_{xx}}{\hbar^2}[\hat{p},[\hat{p},\hat{\rho}]]+\frac{D_{px}}{\hbar^2}[\hat{x},[\hat{p},\hat{\rho}]]+\frac{D_{xp}}{\hbar^2}[\hat{p},[\hat{x},\hat{\rho}]], \tag{2}$$

where due to $[\hat{p},[\hat{x},\cdot]]=[\hat{x},[\hat{p},\cdot]]$ actually $D_{xp}=D_{px}$ and the new coefficients are related to α_i and β_i through the equations

$$D_{xx}=\frac{\hbar}{2}\sum_{i=1}^{2}|\alpha_i|^2,\quad D_{pp}=\frac{\hbar}{2}\sum_{i=1}^{2}|\beta_i|^2,\quad D_{px}=-\frac{\hbar}{2}\Re\sum_{i=1}^{2}\alpha_i^*\beta_i,\quad \gamma=\frac{\hbar}{2}\Im\sum_{i=1}^{2}\alpha_i^*\beta_i,$$

so that the following inequalities hold,

$$D_{xx}\geqslant 0,\quad D_{pp}\geqslant 0,\quad D_{xx}D_{pp}-D_{px}^2\geqslant\frac{\gamma^2\hbar^2}{4}, \tag{3}$$

which are necessary and sufficient conditions for an expression of the form (2) to be cast in Lindblad form, corresponding to the requirement that the matrix of coefficients[27]

$$\mathbf{D}=\begin{pmatrix} D_{xx} & D_{px}+i\frac{\hbar}{2}\gamma \\ D_{px}-i\frac{\hbar}{2}\gamma & D_{pp}\end{pmatrix} \tag{4}$$

has a non-negative determinant.

An alternative but equivalent expression for (2) can be given introducing, with the aid of a length l, whose physical meaning and expression will depend on the system to be described, creation and annihilation operators $\hat{a}$ and $\hat{a}^{\dagger}$:

$$\hat{a}=\frac{1}{l\sqrt{2}}\left(\hat{x}+\frac{i}{\hbar}l^2\hat{p}\right)\quad \hat{a}^{\dagger}=\frac{1}{l\sqrt{2}}\left(\hat{x}-\frac{i}{\hbar}l^2\hat{p}\right), \tag{5}$$

satisfying the commutation relation $[\hat{a},\hat{a}^{\dagger}]=1$. One thus obtains the expression

$$\mathcal{L}_{\hat{a}\hat{a}^{\dagger}}[\hat{\rho}]=-\frac{i}{\hbar}[H_0(\hat{a},\hat{a}^{\dagger}),\hat{\rho}]-\frac{(\mu-\gamma)}{2}[\hat{a}^2-\hat{a}^{\dagger 2},\hat{\rho}]$$
$$-\frac{\gamma}{2}[[\hat{a},\{\hat{a},\hat{\rho}\}]-[\hat{a},\{\hat{a}^{\dagger},\hat{\rho}\}]]+\mathrm{h.c.}$$
$$-\frac{1}{2}\left(\frac{D_{xx}}{l^2}+\frac{D_{pp}l^2}{\hbar^2}\right)[\hat{a}^{\dagger},[\hat{a},\hat{\rho}]]+\frac{1}{2}\left(\frac{D_{xx}}{l^2}-\frac{D_{pp}l^2}{\hbar^2}-2i\frac{D_{px}}{\hbar}\right)[\hat{a},[\hat{a},\hat{\rho}]]+\mathrm{h.c.},$$

or, equivalently, collecting terms as in (1),

$$\mathcal{M}_{\hat{a}\hat{a}^\dagger}[\hat{\rho}] = -\frac{i}{\hbar}[H_0(\hat{a},\hat{a}^\dagger),\hat{\rho}] - \frac{\mu}{2}[\hat{a}^2 - \hat{a}^{\dagger 2},\hat{\rho}]$$
$$+\left(\frac{D_{xx}}{l^2} + \frac{D_{pp}l^2}{\hbar^2} + \gamma\right)\left[\hat{a}\hat{\rho}\hat{a}^\dagger - \frac{1}{2}\{\hat{\rho},\hat{a}^\dagger\hat{a}\}\right]$$
$$+\left(\frac{D_{xx}}{l^2} + \frac{D_{pp}l^2}{\hbar^2} - \gamma\right)\left[\hat{a}^\dagger\hat{\rho}\hat{a} - \frac{1}{2}\{\hat{\rho},\hat{a}\hat{a}^\dagger\}\right]$$
$$-\left(\frac{D_{xx}}{l^2} - \frac{D_{pp}l^2}{\hbar^2} - 2i\frac{D_{px}}{\hbar}\right)\left[\hat{a}\hat{\rho}\hat{a} - \frac{1}{2}\{\hat{\rho},\hat{a}^2\}\right] + \text{h.c.} \tag{6}$$

The recalled expressions essentially give the possible Lindblad structures at most bilinear in the operators $\hat{x}$ and $\hat{p}$ or $\hat{a}$ and $\hat{a}^\dagger$.

A. Shift-covariance

We now analyze the behavior of the considered expressions with respect to suitable symmetry transformations. Consider a locally compact group G and a unitary representation $\hat{U}(g)$, with $g \in G$, on the Hilbert space of the system: following Ref. 28 we say that a mapping $\mathcal{F}$ in the Schrödinger picture is G-covariant if it commutes with the mapping $\mathcal{U}_g[\,\cdot\,] = \hat{U}(g)\cdot\hat{U}^\dagger(g)$ for all $g \in G$:

$$\mathcal{F}[\mathcal{U}_g[\,\cdot\,]] = \mathcal{U}_g[\mathcal{F}[\,\cdot\,]]. \tag{7}$$

Let us now consider the following unitary representation of the group U(1),

$$\hat{U}_\phi = e^{i\phi\hat{N}},$$

where $\hat{N} = \hat{a}^\dagger\hat{a}$ is the number operator and $\phi \in [0,2\pi]$. If we now ask for the general expression (6) invariance under the action of the group U(1), i.e., shift-covariance according to[29]

$$\mathcal{M}_{\hat{a}\hat{a}^\dagger}[e^{i\phi\hat{N}}\cdot e^{-i\phi\hat{N}}] = e^{i\phi\hat{N}}\mathcal{M}_{\hat{a}\hat{a}^\dagger}[\,\cdot\,]e^{-i\phi\hat{N}}, \tag{8}$$

then the Hamiltonian has to be a function of the generator of the transformation $\hat{N}$, and the following stringent requirements appear:

$$D_{xx} = D_{pp}\frac{l^4}{\hbar^2}, \quad D_{px} = 0, \quad \mu = 0.$$

Note that the condition $\mu = 0$ appears here as a necessary condition for shift-covariance or invariance under the relevant symmetry group and not as a natural or most simple choice as sometimes advocated.[2] From a physical point of view the master equation is expected to reflect the relevant symmetry of the reservoir the microscopic system is interacting with. Considering, for example, a single mode (harmonic oscillator) interacting with the electro-magnetic field, one has a U(1) symmetry and condition (8) is actually equivalent to the rotating wave approximation, essentially saying that the master equation is invariant under the transformation

$$\hat{a} \to \hat{a}e^{-i\theta}, \quad \hat{a}^\dagger \to \hat{a}^\dagger e^{+i\theta},$$

or, equivalently, in terms of $\hat{x}$ and $\hat{p}$,

$$\hat{x} \to \hat{x}\cos\theta + \hat{p}\sin\theta, \quad \hat{p} \to -\hat{x}\sin\theta + \hat{p}\cos\theta. \tag{9}$$

The rotating wave approximation is therefore strictly linked to a U(1) symmetry and one cannot expect or try to obtain translational invariance in this case.[7]

If now one further makes the choice $H_0(\hat{\mathsf{N}})=\hbar\omega(\hat{\mathsf{N}}+\frac{1}{2})$ corresponding to a single mode (harmonic oscillator) and asks that an operator with the canonical structure $\hat{\rho}_0=e^{-\beta H_0(\hat{\mathsf{N}})}$ be a stationary solution, i.e., $\mathcal{M}_{\hat{\mathsf{a}}\hat{\mathsf{a}}^\dagger}[\hat{\rho}_0]=0$, a further connection between the coefficients of the master equation appears,[10]

$$2\frac{D_{pp}l^2}{\hbar^2}=\gamma\coth\left(\frac{1}{2}\beta\hbar\omega\right),$$

where β is the inverse temperature characterizing the thermal electromagnetic field the mode is interacting with. The requirements of complete positivity, shift-covariance and existence of the expected canonical stationary solution then fix the quantum Fokker–Planck equation to be of the form

$$\begin{aligned}\mathcal{M}^{\mathrm{QO}}_{\hat{\mathsf{a}}\hat{\mathsf{a}}^\dagger}[\hat{\rho}]=&-\frac{i}{\hbar}[H_0(\hat{\mathsf{N}}),\hat{\rho}]\\&+\gamma\left[\coth\left(\frac{1}{2}\beta\hbar\omega\right)+1\right]\left[\hat{\mathsf{a}}\hat{\rho}\hat{\mathsf{a}}^\dagger-\frac{1}{2}\{\hat{\rho},\hat{\mathsf{a}}^\dagger\hat{\mathsf{a}}\}\right]\\&+\gamma\left[\coth\left(\frac{1}{2}\beta\hbar\omega\right)-1\right]\left[\hat{\mathsf{a}}^\dagger\hat{\rho}\hat{\mathsf{a}}-\frac{1}{2}\{\hat{\rho},\hat{\mathsf{a}}\hat{\mathsf{a}}^\dagger\}\right],\end{aligned}\tag{10}$$

or in terms of the average of the number operator over a thermal distribution,

$$N_\beta(\omega)=\frac{1}{e^{\beta\hbar\omega}-1}=\frac{1}{2}\left[\coth\left(\frac{1}{2}\beta\hbar\omega\right)-1\right],$$

setting $\eta=2\gamma$,

$$\mathcal{M}^{\mathrm{QO}}_{\hat{\mathsf{a}}\hat{\mathsf{a}}^\dagger}[\hat{\rho}]=-\frac{i}{\hbar}[H_0(\hat{\mathsf{N}}),\hat{\rho}]+\eta(N_\beta(\omega)+1)\left[\hat{\mathsf{a}}\hat{\rho}\hat{\mathsf{a}}^\dagger-\frac{1}{2}\{\hat{\rho},\hat{\mathsf{a}}^\dagger\hat{\mathsf{a}}\}\right]+\eta N_\beta(\omega)\left[\hat{\mathsf{a}}^\dagger\hat{\rho}\hat{\mathsf{a}}-\frac{1}{2}\{\hat{\rho},\hat{\mathsf{a}}\hat{\mathsf{a}}^\dagger\}\right],$$

i.e., the well-known quantum optical master equation for the description of a damped harmonic oscillator (for a recent review, see Ref. 30), where the only free parameter is the decay rate η and a further freedom appears in the commutator term, where a function of $\hat{\mathsf{N}}$ corresponding to a frequency shift may be considered. The quantum optical master equation is therefore essentially fixed by formal requirements, well in accordance with its stability with respect to microphysical derivations, which are in fact predictive in so far as they give explicit expressions for η and the energy shift. As a last step, using as natural length of the problem $l=\sqrt{\hbar/M\omega}$, (10) may be written in terms of $\hat{\mathsf{x}}$ and $\hat{\mathsf{p}}$ as

$$\begin{aligned}\mathcal{M}^{\mathrm{QO}}_{\hat{\mathsf{x}}\hat{\mathsf{p}}}[\hat{\rho}]=&-\frac{i}{\hbar}\left[\frac{\hat{\mathsf{p}}^2}{2M}+\frac{1}{2}M\omega^2\hat{\mathsf{x}}^2,\hat{\rho}\right]-\frac{i\gamma}{\hbar 2}([\hat{\mathsf{x}},\{\hat{\mathsf{p}},\hat{\rho}\}]-[\hat{\mathsf{p}},\{\hat{\mathsf{x}},\hat{\rho}\}])\\&-\frac{1\gamma}{\hbar 2}\coth\left(\frac{1}{2}\beta\hbar\omega\right)\left(M\omega[\hat{\mathsf{x}},[\hat{\mathsf{x}},\hat{\rho}]]+\frac{1}{M\omega}[\hat{\mathsf{p}},[\hat{\mathsf{p}},\hat{\rho}]]\right),\end{aligned}$$

where invariance under (9) can be easily checked.

That U(1) symmetry or shift-covariance may lead, under suitable restrictions, to the quantum optical master equation can also be seen considering the recently obtained most general structure of a proper generator of a shift-covariant completely positive quantum dynamical semigroup given in Ref. 29, where also the unboundedness of the operators appearing in the formal Lindblad structure has been taken in due account, using the notion of form-generator. The formal operator expression associated to the form-generator is

$$\mathcal{L}[\hat{\rho}]=-\frac{i}{\hbar}[H(\hat{\mathrm{N}}),\hat{\rho}]+\left[A_0(\hat{\mathrm{N}})\hat{\rho}A_0^{\dagger}(\hat{\mathrm{N}})-\frac{1}{2}\{\hat{\rho},A_0^{\dagger}(\hat{\mathrm{N}})A_0(\hat{\mathrm{N}})\}\right]$$
$$+\sum_{m=1}^{\infty}\left[\hat{\mathrm{W}}^{\dagger m}A_{-m}(\hat{\mathrm{N}})\hat{\rho}A_{-m}^{\dagger}(\hat{\mathrm{N}})\hat{\mathrm{W}}^{m}-\frac{1}{2}\{\hat{\rho},A_{-m}^{\dagger}(\hat{\mathrm{N}})\hat{\mathrm{W}}^{m}\hat{\mathrm{W}}^{\dagger m}A_{-m}(\hat{\mathrm{N}})\}\right]$$
$$+\sum_{m=1}^{\infty}\left[\hat{\mathrm{W}}^{m}A_{m}(\hat{\mathrm{N}})\hat{\rho}A_{m}^{\dagger}(\hat{\mathrm{N}})\hat{\mathrm{W}}^{\dagger m}-\frac{1}{2}\{\hat{\rho},A_{m}^{\dagger}(\hat{\mathrm{N}})A_{m}(\hat{\mathrm{N}})\}\right], \tag{11}$$

where $H(\cdot)=H^{*}(\cdot)$, $A_i(\cdot)$ are functions of the number operator, and $\hat{\mathrm{W}}=\Sigma_{n=0}^{\infty}|n+1\rangle\langle n|$ it the so-called shift-operator.[31] Recalling the polar decompositions $\hat{\mathrm{a}}^{\dagger}=\hat{\mathrm{W}}\sqrt{\hat{\mathrm{N}}+1}$ and $\hat{\mathrm{a}}=\hat{\mathrm{W}}^{\dagger}\sqrt{\hat{\mathrm{N}}}$, for the following simple choice of functions,

$$H(n)=H_0(n)=\hbar\omega\left(n+\frac{1}{2}\right),$$
$$A_m(n)=0,\quad m=0,\quad |m|>1,$$
$$A_1(n)=\sqrt{\gamma(\beta)}\sqrt{n+1},$$
$$A_{-1}(n)=e^{\beta/2}\sqrt{\gamma(\beta)}\sqrt{n},$$

where

$$\gamma(\beta)=\gamma\left[\coth\left(\frac{1}{2}\beta\hbar\omega\right)-1\right],$$

one recovers from (11) the quantum optical master equation.

It is interesting to observe that complete positivity, shift-covariance and the requirement of a canonical stationary solution also allow as a proper generator of a quantum dynamical semigroup the following expression:

$$\mathcal{L}[\hat{\rho}]=-\frac{i}{\hbar}[H_0(\hat{\mathrm{N}}),\hat{\rho}]-\gamma_0[\hat{\mathrm{N}},[\hat{\mathrm{N}},\hat{\rho}]]$$
$$+\sum_{m=1}^{\infty}\gamma_m\left\{\left[\coth\left(\frac{1}{2}\beta\hbar\omega\right)+1\right]^{m}\left[\hat{\mathrm{a}}^{m}\hat{\rho}\hat{\mathrm{a}}^{\dagger m}-\frac{1}{2}\{\hat{\rho},\hat{\mathrm{a}}^{\dagger m}\hat{\mathrm{a}}^{m}\}\right]\right.$$
$$\left.+\left[\coth\left(\frac{1}{2}\beta\hbar\omega\right)-1\right]^{m}\left[\hat{\mathrm{a}}^{\dagger m}\hat{\rho}\hat{\mathrm{a}}^{m}-\frac{1}{2}\{\hat{\rho},\hat{\mathrm{a}}^{m}\hat{\mathrm{a}}^{\dagger m}\}\right]\right\}, \tag{12}$$

corresponding to the functions

$$A_0(n)=\sqrt{\gamma_0}n,$$
$$A_m(n)=\sqrt{\gamma_m(\beta)}\sqrt{\frac{(n+m)!}{n!}},$$
$$A_{-m}(n)=e^{m\beta/2}\sqrt{\gamma_m(\beta)}\sqrt{\frac{n!}{(n-m)!}},$$

where

$$\gamma_m(\beta)=\gamma_m\left[\coth\left(\frac{1}{2}\beta\hbar\omega\right)-1\right]^{m}.$$

Equation (12) provides a generalization of the quantum optical master equation in which both phase-diffusion, related to the coefficient γ_0, and m-photon processes with decay rates $\eta_m = 2^m \gamma_m$, which should quickly approach zero in order to allow for nonexplosion of the associated Markov process, can be considered. Thus far we have dealt with the case of shift-covariance, corresponding to U(1) symmetry of the system with many degrees of freedom acting as reservoir and determining the non-Hamiltonian dynamics of the microsystem.

B. Translation-covariance

We now consider the case in which the relevant symmetry is invariance under translations, corresponding to a homogeneous reservoir. Given the unitary representation of the translation group

$$\hat{U}(b) = e^{-(i/\hbar)\, b\hat{\mathrm{p}}},$$

where $\hat{\mathrm{p}}$ is the momentum operator of the microsystem and $b \in \mathrm{R}$, translation-covariance according to Ref. 32 amounts to the requirement

$$\mathcal{L}_{\hat{\mathrm{x}}\hat{\mathrm{p}}}[e^{-(i/\hbar)\, b\hat{\mathrm{p}}} \cdot e^{+(i/\hbar)\, b\hat{\mathrm{p}}}] = e^{-(i/\hbar)\, b\hat{\mathrm{p}}} \mathcal{L}_{\hat{\mathrm{x}}\hat{\mathrm{p}}}[\,\cdot\,] e^{+(i/\hbar)\, b\hat{\mathrm{p}}}. \tag{13}$$

Invariance under the group R of translations thus implies for the structure of the quantum Fokker–Planck equation that the Hamiltonian has to be a function of the generator of the transformation $\hat{\mathrm{p}}$ and the following simple requirement in the coefficients appearing in (2):

$$\mu = \gamma.$$

Considering, for example, a free particle interacting with a homogeneous reservoir, one has R symmetry corresponding to invariance under translations, which is reflected by the fact that according to (13) the master equation is invariant under the transformation

$$\hat{\mathrm{x}} \to \hat{\mathrm{x}} + b, \quad \hat{\mathrm{p}} \to \hat{\mathrm{p}},$$

or, equivalently, in terms of $\hat{\mathrm{a}}$ and $\hat{\mathrm{a}}^\dagger$,

$$\hat{\mathrm{a}} \to \hat{\mathrm{a}} + \frac{1}{\sqrt{2}} \frac{b}{l}, \quad \hat{\mathrm{a}}^\dagger \to \hat{\mathrm{a}}^\dagger + \frac{1}{\sqrt{2}} \frac{b}{l}.$$

Further, making the obvious choice $H_0(\hat{\mathrm{p}}) = \hat{\mathrm{p}}^2/2M$, corresponding to a free particle of mass M and asking that an operator with the canonical structure $\hat{\rho}_0 = e^{-\beta H_0(\hat{\mathrm{p}})}$ be a stationary solution, i.e., $\mathcal{L}_{\hat{\mathrm{x}}\hat{\mathrm{p}}}[\hat{\rho}_0] = 0$, one has the condition

$$D_{pp} = \gamma \frac{2M}{\beta},$$

with β the inverse temperature of the homogeneous reservoir. The requirement, of complete positivity, translation-covariance and existence of the expected stationary solution thus constrain the quantum Fokker–Planck equation to be of the form

$$\mathcal{L}^{\mathrm{QBM}}_{\hat{\mathrm{x}}\hat{\mathrm{p}}}[\hat{\rho}] = -\frac{i}{\hbar}[H_0(\hat{\mathrm{p}}), \hat{\rho}] - \frac{i}{\hbar}\gamma[\hat{\mathrm{x}}, \{\hat{\mathrm{p}}, \hat{\rho}\}] - \gamma \frac{2M}{\beta\hbar^2}[\hat{\mathrm{x}}, [\hat{\mathrm{x}}, \hat{\rho}]] - \frac{D_{xx}}{\hbar^2}[\hat{\mathrm{p}}, [\hat{\mathrm{p}}, \hat{\rho}]] + 2\frac{D_{px}}{\hbar^2}[\hat{\mathrm{x}}, [\hat{\mathrm{p}}, \hat{\rho}]], \tag{14}$$

i.e., the typical structure one finds in the extensive physical literature aiming at the description of quantum Brownian motion (see Refs. 1 and 3 for a review). With respect to the case of the

quantum optical master equation (10), the remaining freedom in the structure is much bigger: apart from the friction coefficient γ and a real function of $\hat{\mathrm{p}}$ correcting the Hamiltonian, the coefficients D_{xx} and D_{px} are undetermined except for the relation

$$\gamma\frac{2M}{\beta}D_{xx}-D_{px}^2\geqslant\frac{\gamma^2\hbar^2}{4}$$

stemming from (3). This is reflected by the fact that a much wider literature has been devoted to the subject, looking for microphysical derivations of the quantum Brownian motion master equation, in order to obtain expressions for the undetermined parameters.

We now compare the result (14) with the general structure of a proper generator of a translation-covariant quantum dynamical semigroup, given in Ref. 32, where also the case of an unbounded generator has been considered, introducing the notion of form-generator and specifying a suitable domain for the mapping. Restricting to the continuous component of the generator, corresponding to a quantum Fokker–Planck equation describing friction and diffusion, one has for the formal operator expression associated to the form-generator the following result:

$$\begin{gathered}\mathcal{L}[\hat{\rho}]=-\frac{i}{\hbar}[\beta\hat{\mathrm{x}}+H(\hat{\mathrm{p}}),\hat{\rho}]+\alpha\hat{\mathrm{V}}\hat{\rho}\hat{\mathrm{V}}^{\dagger}-\hat{\mathrm{K}}\hat{\rho}-\hat{\rho}\hat{\mathrm{K}}^{\dagger},\quad \beta\in\mathrm{R},\quad \alpha\geqslant 0,\\ \hat{\mathrm{V}}=\hat{\mathrm{x}}+L(\hat{\mathrm{p}}),\quad \hat{\mathrm{K}}=\frac{\alpha}{2}[\hat{\mathrm{x}}^2+2\hat{\mathrm{x}}L(\hat{\mathrm{p}})+L^{\dagger}(\hat{\mathrm{p}})L(\hat{\mathrm{p}})],\end{gathered}\tag{15}$$

$H(\cdot)=H^*(\cdot)$, $L(\cdot)$ being functions of the momentum operator $\hat{\mathrm{p}}$, and $\beta\neq 0$ implying, e.g., a constant gravitational or electric field. According to (15) one has a single operator of the form $\hat{\mathrm{V}}=\hat{\mathrm{x}}+L(\hat{\mathrm{p}})$ (or one for each Cartesian coordinate considering higher dimensions) instead of two as considered in (1). Expressing (15) in terms of nested commutators and anticommutators as in (2), restricting to the case in which $L(\cdot)$ is a linear function, according to the fact that we are considering friction effects at most linear in the velocity, the inequalities in (3), corresponding to the fact that the determinant of the matrix given in (4) be zero or positive, now become more restrictive:

$$D_{xx}\geqslant 0,\quad D_{pp}\geqslant 0,\quad D_{xx}D_{pp}-D_{px}^2=\frac{\gamma^2\hbar^2}{4},$$

corresponding to $\det\mathbf{D}=0$. Coming back to (14), this implies the further restriction

$$D_{xx}=\gamma\frac{\beta\hbar^2}{8M}+\frac{\beta}{2\gamma M}D_{px}^2,$$

so that apart from the overall multiplying coefficient γ only another coefficient D_{px} is left free, and one has

$$\begin{aligned}\mathcal{L}_{\hat{\mathrm{x}}\hat{\mathrm{p}}}^{\mathrm{QBM}}[\hat{\rho}]=&-\frac{i}{\hbar}[H_0(\hat{\mathrm{p}}),\hat{\rho}]-\frac{i}{\hbar}\gamma[\hat{\mathrm{x}},\{\hat{\mathrm{p}},\hat{\rho}\}]-\gamma\frac{2M}{\beta\hbar^2}[\hat{\mathrm{x}},[\hat{\mathrm{x}},\hat{\rho}]]-\gamma\frac{\beta}{8M}[\hat{\mathrm{p}},[\hat{\mathrm{p}},\hat{\rho}]]\\ &-\frac{\beta}{2\gamma M}\frac{D_{px}^2}{\hbar^2}[\hat{\mathrm{p}},[\hat{\mathrm{p}},\hat{\rho}]]+2\frac{D_{px}}{\hbar^2}[\hat{\mathrm{p}},[\hat{\mathrm{x}},\hat{\rho}]].\end{aligned}\tag{16}$$

Therefore, a predictive microphysical model of quantum Brownian motion essentially has to indicate an explicit expression for the coefficients γ and D_{px}.

It is interesting to express (16) in terms of the creation and annihilation operators given in (5). Setting $\beta\hbar^2/4M=\lambda_{\mathrm{th}}^2$, the square of the thermal wavelength of the microsystem undergoing Brownian motion, one has

$$\mathcal{L}^{\mathrm{QBM}}_{\hat{a}\hat{a}^\dagger}[\hat{\rho}] = -\frac{i}{\hbar}[H_0(\hat{a},\hat{a}^\dagger),\hat{\rho}] - \frac{\gamma}{2}[\hat{a}^2-\hat{a}^{\dagger 2},\hat{\rho}]$$
$$+\left[\frac{\gamma}{2}\left(\frac{\lambda_{\mathrm{th}}^2}{l^2}+\frac{l^2}{\lambda_{\mathrm{th}}^2}+2\right)+\frac{1}{\gamma\hbar^2}\frac{2\,\lambda_{\mathrm{th}}^2}{l^2}D_{px}^2\right]\left[\hat{a}\hat{\rho}\hat{a}^\dagger-\frac{1}{2}\{\hat{\rho},\hat{a}^\dagger\hat{a}\}\right]$$
$$+\left[\frac{\gamma}{2}\left(\frac{\lambda_{\mathrm{th}}^2}{l^2}+\frac{l^2}{\lambda_{\mathrm{th}}^2}-2\right)+\frac{1}{\gamma\hbar^2}\frac{2\,\lambda_{\mathrm{th}}^2}{l^2}D_{px}^2\right]\left[\hat{a}^\dagger\hat{\rho}\hat{a}-\frac{1}{2}\{\hat{\rho},\hat{a}\hat{a}^\dagger\}\right]$$
$$-\left[\frac{\gamma}{2}\left(\frac{\lambda_{\mathrm{th}}^2}{l^2}-\frac{l^2}{\lambda_{\mathrm{th}}^2}\right)+2\frac{D_{px}}{\hbar}\left(\frac{1}{\gamma}\frac{\lambda_{\mathrm{th}}^2}{l^2}\frac{D_{px}}{\hbar}-i\right)\right]\left[\hat{a}\hat{\rho}\hat{a}-\frac{1}{2}\{\hat{\rho},\hat{a}^2\}\right]+\mathrm{h.c.} \tag{17}$$

Equation (17) strongly simplifies if one takes for the length l, used in order to introduce the operators $\hat{a}$ and $\hat{a}^\dagger$ in terms of the operator position and momentum of the particle, the value $l=\lambda_{\mathrm{th}}=\sqrt{\beta\hbar^2/4M}$, naturally suggested by the underlying physics. With l the thermal de Broglie wavelength (17) reduces to

$$\mathcal{L}^{\mathrm{QBM}}_{\hat{a}\hat{a}^\dagger}[\hat{\rho}] = -\frac{i}{\hbar}[H_0(\hat{a},\hat{a}^\dagger),\hat{\rho}] - \frac{\gamma}{2}[\hat{a}^2-\hat{a}^{\dagger 2},\hat{\rho}] + 2\gamma\left[\hat{a}\hat{\rho}\hat{a}^\dagger-\frac{1}{2}\{\hat{\rho},\hat{a}^\dagger\hat{a}\}\right]$$
$$+\frac{2D_{px}^2}{\gamma\hbar^2}\left[\hat{a}\hat{\rho}\hat{a}^\dagger-\frac{1}{2}\{\hat{\rho},\hat{a}^\dagger\hat{a}\}+\hat{a}^\dagger\hat{\rho}\hat{a}-\frac{1}{2}\{\hat{\rho},\hat{a}\hat{a}^\dagger\}\right]$$
$$-2\frac{D_{px}}{\hbar}\left(\frac{1}{\gamma}\frac{D_{px}}{\hbar}-i\right)\left[\hat{a}\hat{\rho}\hat{a}-\frac{1}{2}\{\hat{\rho},\hat{a}^2\}\right]+\mathrm{h.c.}, \tag{18}$$

where the last three contributions can only vanish if the real coefficient D_{px} is equal to zero, corresponding to $L(\cdot)=-L^*(\cdot)$ in (15). Equation (16) or equivalently (18) expresses the general structure of a quantum Fokker–Planck equation which is invariant under translation, warrants the existence of the expected canonical expression as a stationary solution, thus recovering equipartition, and is furthermore a proper generator of a completely positive quantum dynamical semigroup.

C. Covariance and uniqueness of the stationary solution

In recent work[2,12] aiming at comparing and clarifying different approaches to quantum dissipation, which relies on[14] but neglects the more recent and thorough results of Refs. 32 and 29, the statement can be found that *no Markovian theory can satisfy all three criteria of positivity, translational invariance, and asymptotic approach to the canonical equilibrium state* $e^{-\beta H_0}$, *except in special cases*. This statement is always correct in view of the last observation, and these simple exceptional cases, which are usually not spelled out, can be read in (11): the microsystem has to be a free particle apart from an effective correction to the Hamiltonian, given by a real function of $\hat{p}$ describing, for example, an effective mass, and a potential term depending linearly on position (such as, e.g., a constant gravitational or electric field). These cases are often neglected, having in mind that translational invariance, mainly seen as an abstract property rather than the expression of homogeneity of the reservoir, should be always asked for. In this spirit translational invariance, i.e., R symmetry, is asked for also for the damped harmonic oscillator.

The three physical requirements one can reasonably ask together for Markovian systems in the weak-coupling limit are complete positivity, existence of the stationary solution predicted by equipartition, and invariance under the relevant symmetry, not necessarily translational invariance. Having translational invariance apart from the potential term is not physically significant since the potential term actually breaks this invariance, and would furthermore lead to high nonuniqueness of the stationary state, as argued below. The dynamics of the microsystem is driven by both the potential term (which could also arise as a mean field effect) and the contributions describing

decoherence and dissipation, so that a physically relevant symmetry should pertain to the system as a whole. Let us in fact consider a mapping $\mathcal{F}$ covariant with respect to a given symmetry group G according to (7), which admits a stationary solution $\hat{\rho}_0$, i.e., $\mathcal{F}[\hat{\rho}_0]=0$. If the operator $\hat{\rho}_0$ is not invariant under the unitary representation $\mathcal{U}_g$ of G, so that

$$\hat{\rho}_g=\mathcal{U}_g[\hat{\rho}_0]$$

is linearly independent from $\hat{\rho}_0$ at least for some g in G, due to the G-covariance of $\mathcal{F}$, $\hat{\rho}_g$ still is a stationary solution

$$\mathcal{F}[\hat{\rho}_g]=\mathcal{F}[\mathcal{U}_g[\hat{\rho}_0]]=\mathcal{U}_g[\mathcal{F}[\hat{\rho}_0]]=0,$$

so that one cannot have the expected uniqueness of the solution. In the case of the one-dimensional Lie groups considered in Sec. II, for example, a stationary solution can be unique only if it commutes with the generator of the group. Note that this simple argument is independent on whether the mapping $\mathcal{F}$ ensures complete positivity of the time evolution or not, so that the clash between the requirement of translation invariance and the existence of the correct stationary state corresponding to equipartition is not due to the requirement of complete positivity of the time evolution mapping.

III. QUANTUM FOKKER–PLANCK EQUATION FOR THE MOTION OF A BROWNIAN PARTICLE

As we have shown in Sec. II A, in the case of an underlying U(1) symmetry formal requirements are enough to essentially fix structure and coefficients of the quantum Fokker–Planck equation, apart from an energy shift and an overall coefficient. The same is not true in the case of R symmetry describing translational invariance. In this paragraph we therefore quickly recall a recently proposed quantum Fokker–Planck equation for the description of the motion of a heavy Brownian particle interacting through collisions with a homogeneous fluid made up of much lighter particles (see Refs. 20, 21, and 23 for details). This result has been obtained within a kinetic approach, where the dynamics is driven by single events described as collisions in which one generally has momentum and energy transfer, alternative to the Zwanzig Caldeira Leggett approach,[33] recently criticized in Ref. 34, where one describes the reservoir as a collection of harmonic oscillators coupled to the microsystem through its position, usually performing calculations in terms of path-integral techniques.

In the aforementioned approach one obtains in the first instance a kinetic equation for the statistical operator analogous to the classical linear Boltzmann equation given by the simple expression

$$\mathcal{L}[\hat{\rho}]=-\frac{i}{\hbar}[H_0(\hat{\mathrm{p}}),\hat{\rho}]+\frac{2\pi}{\hbar}(2\pi\hbar)^3 n\int_{\mathbf{R}^3}d^3\mathbf{q}\,|\tilde{t}(q)|^2\Big[e^{(i/\hbar)\,\mathbf{q}\cdot\hat{\mathrm{x}}}\sqrt{S(\mathbf{q},\hat{\mathrm{p}})}\hat{\rho}\sqrt{S(\mathbf{q},\hat{\mathrm{p}})}e^{-(i/\hbar)\,\mathbf{q}\cdot\hat{\mathrm{x}}}$$
$$-\frac{1}{2}\{S(\mathbf{q},\hat{\mathrm{p}}),\hat{\rho}\}\Big], \tag{19}$$

where $\tilde{t}(q)$ is the Fourier transform of the T-matrix describing the microphysical collisions and the function $S(\mathbf{q},\mathbf{p})$ appearing operator-valued in (19) is a positive two-point correlation function known in the physical community as dynamic structure factor,[35] usually expressed as a function of momentum and energy transfer, $\mathbf{q}$ and E, according to

$$S(\mathbf{q},\mathbf{p})\equiv S(\mathbf{q},E),\quad E(\mathbf{q},\mathbf{p})=\frac{(\mathbf{p}+\mathbf{q})^2}{2M}-\frac{\mathbf{p}^2}{2M},$$

with M the mass of the Brownian particle. The dynamic structure factor $S(\mathbf{q},E)$ is the Fourier transform of the two-point time dependent density autocorrelation function of the fluid

$$S(\mathbf{q},E)=\frac{1}{2\pi\hbar}\int_{\mathbf{R}}dt\int_{\mathbf{R}^3}d^3\mathbf{x}\,e^{(i/\hbar)[E(\mathbf{q},\mathbf{p})t-\mathbf{q}\cdot\mathbf{x}]}\frac{1}{N}\int_{\mathbf{R}^3}d^3\mathbf{y}\,\langle N(\mathbf{y})N(\mathbf{y}+\mathbf{x},t)\rangle, \tag{20}$$

and is always positive since it is proportional to the energy dependent scattering cross-section of a microscopic probe off a macroscopic sample,[36] giving the spectrum of its spontaneous fluctuations. Equation (19) also has the three properties of complete positivity, translational invariance and canonical stationary solution, and it actually gives a physical example of the general structure of generator of a translation-covariant quantum dynamical semigroup,[32] going beyond the diffusive case considered in (11). In order to recover from the general integral kinetic Eq. (19) a quantum Fokker–Planck equation for the description of the Brownian motion of a heavy particle, one has to consider the limit of small momentum transfer and small energy transfer (corresponding to the Brownian limit in which the mass of the test particle is much heavier than the particles of the fluid). Considering a gas of free particles obeying Maxwell–Boltzmann statistics, due to

$$S_{\mathrm{MB}}(\mathbf{q},\mathbf{p})=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}z\exp\left[-\frac{\beta}{8m}\frac{(2mE(\mathbf{q},\mathbf{p})+q^2)^2}{q^2}\right] \tag{21}$$

one has[23]

$$\mathcal{L}[\hat{\rho}]=-\frac{i}{\hbar}[H_0(\hat{\mathrm{p}}),\hat{\rho}]-\frac{i}{\hbar}\gamma\sum_{i=1}^{3}[\hat{\mathrm{x}}_i,\{\hat{\mathrm{p}}_i,\hat{\rho}\}]-\frac{D_{pp}}{\hbar^2}\sum_{i=1}^{3}[\hat{\mathrm{x}}_i,[\hat{\mathrm{x}}_i,\hat{\rho}]]-\frac{D_{xx}}{\hbar^2}\sum_{i=1}^{3}[\hat{\mathrm{p}}_i,[\hat{\mathrm{p}}_i,\hat{\rho}]]. \tag{22}$$

In this kinetic case the free parameters in (16) are now determined as

$$D_{px}=0,\quad \gamma=\frac{1}{3}z\frac{\pi^2m^2}{\beta\hbar}\int_{\mathbf{R}^3}d^3\mathbf{q}\,|\tilde{t}(q)|^2qe^{-(\beta/8m)\,q^2}$$

with $z=e^{\beta\mu}$ the fugacity of the gas,[37] while D_{xx} and D_{pp} are expressed in terms of γ as can be read in (16):

$$D_{xx}=\frac{\beta\hbar^2}{8M}\gamma,\quad D_{pp}=\frac{2M}{\beta}\gamma.$$

Also the expression of (22) in terms of the operators $\hat{\mathrm{a}}_i$ and $\hat{\mathrm{a}}_i^\dagger$ according to (18) takes in this case a particularly simple form

$$\mathcal{L}[\hat{\rho}]=-\frac{i}{\hbar}[H_0(\hat{\mathrm{a}}_i,\hat{\mathrm{a}}_i^\dagger),\hat{\rho}]-\frac{\gamma}{2}\sum_{i=1}^{3}[\hat{\mathrm{a}}_i^2-\hat{\mathrm{a}}_i^{\dagger 2},\hat{\rho}]+2\gamma\sum_{i=1}^{3}\left[\hat{\mathrm{a}}_i\hat{\rho}\hat{\mathrm{a}}_i^\dagger-\frac{1}{2}\{\hat{\rho},\hat{\mathrm{a}}_i^\dagger\hat{\mathrm{a}}_i\}\right], \tag{23}$$

so that one has a single $\hat{\mathrm{a}}_i=\sqrt{2M/\beta\hbar^2}(\hat{\mathrm{x}}_i+i\,(\beta\hbar^2/4M)\hat{\mathrm{p}}_i)$ operator for each Cartesian coordinate.

IV. CONCLUSIONS AND OUTLOOK

The main scope of this article was to show how relevant symmetries can be in the determination of structures of quantum Fokker–Planck equation. While in the literature only translational invariance is considered and asked for also in the case of the damped harmonic oscillator, leading to no go statements regarding the possibility of having quantum Fokker–Planck equations with all the physically relevant features (complete positivity, covariance and equipartition), we here considered both one-dimensional Lie groups U(1) and R, showing that they are connected to two distinct classes of quantum Fokker–Planck equations: the quantum optical master equation associated to shift-covariance and the quantum Brownian motion master equation associated to translation-covariance. That these two classes of models actually correspond to different physics can also be seen in connection with recent studies on their properties with respect to decoherence.[8]

In particular, independently of complete positivity of the time evolution, it has been shown that covariance properties put severe restrictions on the structure of the stationary solution, provided uniqueness is asked for.

In the case of shift-covariance a generalization of the quantum optical master equation has been proposed, in which also m-photon processes can be considered. Moreover, recent mathematical results by Holevo have been considered, concerning the structure of generators of completely positive quantum dynamical semigroups and leading to further restrictions in the quantum Brownian motion case. For the Brownian motion of a test particle in a fluid, where formal requirements are not enough to essentially fix the structure of the quantum Fokker–Planck equation describing the phenomenon, a recent microphysical approach has been briefly recalled, based on scattering theory, where the quantum Fokker–Planck equation is obtained as the small momentum and energy transfer limit of a quantum generalization of the classical linear Boltzmann equation. Covariance properties with respect to some physically relevant group, typically reflecting a symmetry under certain transformations of the given reservoir, can therefore be a most useful requirement in the determination of structures of quantum Fokker–Planck equations or more generally of linear kinetic equations.

An interesting extension of this work would entail the study of generators of the dynamics of systems in which one has an important correlation between internal and translational degrees of freedom, both coupled through different interactions to some reservoir, a problem recently considered in Ref. 38, where the translational degrees of freedom are treated in a classical way, assuming decoherence is strong enough. Such models could be of interest for the implementation of quantum computing, where indeed some experimental scheme actually relies on a coupling between internal and center of mass degrees of freedom.[39]

Quantum group covariance and the braided structure of deformed oscillators

A. Yildiz[a)]
Feza Gürsey Institute, P.O. Box 6, 81220, Çengelköy, Istanbul, Turkey

(Received 25 January 2002; accepted 12 July 2002)

The connection between braided Hopf algebra structure and quantum group covariance of the deformed oscillators is constructed explicitly. In this context we provide deformations of the Hopf algebra of functions on SU(1,1). Quantum subgroups and their representations are also discussed. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1509088]

I. INTRODUCTION

The covariance of the oscillator algebras attracted a lot of attention and is discussed in different contexts.[1] The covariance of an algebra under the action of a noncommutative algebra deforms the notion of defining identical copies in the transformed algebra and this leads to the deformation of the usual tensor product namely braided tensor product. The Hopf algebra axioms are replaced by the braided Hopf algebra axioms.[2] Hence braided group theory (self-contained reviews can be found in Ref. 3) unifies the notions of symmetry and statistics. Recently, we found the general braided Hopf algebra solutions of the generalized oscillators.[4] In this work we show that some of these solutions are connected with the quantum group covariance and we find the **R** matrices controlling the braiding structure and the quantum group. We also discuss the representations of quantum subgroups.

II. THE GENERALIZED OSCILLATOR, ITS COVARIANCE AND BRAIDED HOPF STRUCTURE

Suppose that the generalized oscillator algebra

$$\begin{aligned} aa^* - Q_1 a^* a &= q^{2N}, \\ a q^N &= q q^N a, \\ q^N a^* &= q a^* q^N \end{aligned} \tag{1}$$

is covariant under the transformation

$$\begin{aligned} (a)' &= aK_1 + q^N K_2 + a^* K_3, \\ (a^*)' &= a^* K_1^* + q^N K_2^* + a K_3^*, \\ (q^N)' &= a L_1 + q^N L_2 + a^* L_1^*, \end{aligned} \tag{2}$$

where the deformation parameters Q_1 and q are positive and with the $*$-structure $(a^*)^* = a$ and $(q^N)^* = q^N$. The elements K_1, K_1^*, K_2, K_2^*, K_3, K_3^*, L_1, L_1^*, and L_2 ($L_2^* = L_2$) generate some algebra. Our aim is to find that algebra if the transformation is a quantum group transformation. We write the above transformation as a co-vector transformation

a)Electronic mail: yildiz@gursey.gov.tr

$$\mathbf{x}' = \mathbf{x}\mathbf{t}, \tag{3}$$

where

$$\mathbf{x} = (a \;\; a^* \;\; q^N) \quad \text{and} \quad \mathbf{t} = \begin{pmatrix} K_1 & K_3^* & L_1 \\ K_3 & K_1^* & L_1^* \\ K_2 & K_2^* & L_2 \end{pmatrix}. \tag{4}$$

The matrix $\mathbf{t}$ is a quantum matrix satisfying

$$\mathbf{R}\mathbf{t}_1\mathbf{t}_2 = \mathbf{t}_2\mathbf{t}_1\mathbf{R} \tag{5}$$

and $\mathbf{R}$ satisfies QYBE

$$\mathbf{R}_{12}\mathbf{R}_{13}\mathbf{R}_{23} = \mathbf{R}_{23}\mathbf{R}_{13}\mathbf{R}_{12}. \tag{6}$$

To find the $\mathbf{R}$ matrix and hence the quantum group, we write the oscillator algebra as a co-vector algebra

$$\mathbf{x}_1\mathbf{x}_2 = \mathbf{x}_2\mathbf{x}_1\mathbf{R}, \tag{7}$$

where

$$\mathbf{x}_1\mathbf{x}_2 = (a^2 \;\; aa^* \;\; aq^N \;\; a^*a \;\; (a^*)^2 \;\; a^*q^N \;\; q^Na \;\; q^Na^* \;\; q^{2N}), \tag{8}$$

$$\mathbf{x}_2\mathbf{x}_1 = (a^2 \;\; a^*a \;\; q^Na \;\; aa^* \;\; (a^*)^2 \;\; q^Na^* \;\; aq^N \;\; a^*q^N \;\; q^{2N}), \tag{9}$$

and the general form of the $\mathbf{R}$ matrix

$$\mathbf{R} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & A_1 & 0 & A_6 & 0 & 0 & 0 & 0 & A_{15} \\ 0 & 0 & A_4 & 0 & 0 & 0 & A_{11} & 0 & 0 \\ 0 & A_2 & 0 & A_7 & 0 & 0 & 0 & 0 & A_{16} \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & A_9 & 0 & A_{13} & 0 \\ 0 & 0 & A_5 & 0 & 0 & 0 & A_{12} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & A_{10} & 0 & A_{14} & 0 \\ 0 & A_3 & 0 & A_8 & 0 & 0 & 0 & 0 & A_{17} \end{pmatrix}. \tag{10}$$

The constants (A_i) appearing in the $\mathbf{R}$ matrix is to be determined from the consistency of (7) with the oscillator relations (1) and from (6). The covariance of a co-vector algebra under the action of a quantum group induces a braided Hopf algebra structure whose axioms are collectively given by

$$m\circ(id\otimes m) = m\circ(m\otimes id),$$

$$m\circ(id\otimes \eta) = m\circ(\eta\otimes id) = id,$$

$$(id\otimes\Delta)\circ\Delta = (\Delta\otimes id)\circ\Delta,$$

$$(\epsilon\otimes id)\circ\Delta = (id\otimes\epsilon)\circ\Delta = id,$$

$$m\circ(id\otimes S)\circ\Delta = m\circ(S\otimes id)\circ\Delta = \eta\circ\epsilon,$$

$$\begin{gathered}
\psi\circ(m\otimes id)=(id\otimes m)\circ(\psi\otimes id)\circ(id\otimes\psi),\\
\psi\circ(id\otimes m)=(m\otimes id)\circ(id\otimes\psi)\circ(\psi\otimes id),\\
(id\otimes\Delta)\circ\psi=(\psi\otimes id)\circ(id\otimes\psi)\circ(\Delta\otimes id),\\
(\Delta\otimes id)\circ\psi=(id\otimes\psi)(\psi\otimes id)\circ(id\otimes\Delta),\\
\Delta\circ m=(m\otimes m)(id\otimes\psi\otimes id)\circ(\Delta\otimes\Delta),\\
S\circ m=m\circ\psi\circ(S\otimes S),\\
\Delta\circ S=(S\otimes S)\circ\psi\circ\Delta,\\
\epsilon\circ m=\epsilon\otimes\epsilon,\\
(\psi\otimes id)\circ(id\otimes\psi)\circ(\psi\otimes id)=(id\otimes\psi)\circ(\psi\otimes id)\circ(id\otimes\psi).
\end{gathered}\tag{11}$$

The $*$-structure for a braided algebra B is different from the nonbraided one such that

$$\begin{gathered}
\Delta\circ *=\pi\circ(*\otimes *)\circ\Delta,\\
S\circ *=*\circ S,\\
(a\otimes b)^*=b^*\otimes a^*,\quad \forall a,b\in B.
\end{gathered}\tag{12}$$

The braided co-vector algebra has a braided Hopf algebra structure

$$\Delta(\mathbf{x})=\mathbf{x}\otimes 1+1\otimes\mathbf{x},\quad \epsilon(\mathbf{x})=0,\quad S(\mathbf{x})=-\mathbf{x}\tag{13}$$

with the braiding relations

$$\psi(\mathbf{x}_1\otimes\mathbf{x}_2)=\mathbf{x}_2\otimes\mathbf{x}_1\mathbf{R}',\quad \text{i.e.,}\quad \psi(x_i\otimes x_j)=x_b\otimes x_a R'^{ab}_{ij}.\tag{14}$$

The matrix $\mathbf{R}'$ which controls the braiding relations should satisfy the following conditions:

$$\begin{gathered}
\mathbf{R}'_{12}\mathbf{R}'_{13}\mathbf{R}'_{23}=\mathbf{R}'_{23}\mathbf{R}'_{13}\mathbf{R}'_{12},\\
\mathbf{R}'_{12}\mathbf{R}'_{13}\mathbf{R}_{23}=\mathbf{R}_{23}\mathbf{R}'_{13}\mathbf{R}'_{12},\\
\mathbf{R}_{12}\mathbf{R}'_{13}\mathbf{R}'_{23}=\mathbf{R}'_{23}\mathbf{R}'_{13}\mathbf{R}_{12},\\
(\mathbf{P}\mathbf{R}'+1)(\mathbf{P}\mathbf{R}-1)=0,\\
\mathbf{R}'_{21}\mathbf{R}=\mathbf{R}_{21}\mathbf{R},
\end{gathered}\tag{15}$$

where **P** is the permutation matrix. Hence the problem of finding the quantum group leaving the generalized oscillator algebra covariant and the braidings induced by the quantum group is reduced to finding the matrices **R** and **R′**.

The general form of the matrix **R′** can be written as

$$\mathbf{R}'=\begin{pmatrix} C_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & C_2 & 0 & C_7 & 0 & 0 & 0 & 0 & C_{12} \\ 0 & 0 & C_5 & 0 & 0 & 0 & C_{11} & 0 & 0 \\ 0 & C_3 & 0 & C_8 & 0 & 0 & 0 & 0 & C_{13} \\ 0 & 0 & 0 & 0 & C_1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & C_{10} & 0 & C_6 & 0 \\ 0 & 0 & C_6 & 0 & 0 & 0 & C_{10} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & C_{11} & 0 & C_5 & 0 \\ 0 & C_4 & 0 & C_9 & 0 & 0 & 0 & 0 & C_{14} \end{pmatrix} \tag{16}$$

which gives the general form of the braiding relations.

For the three deformation parameters Q_1 and q free, it turns out that there is a unique solution for the matrices **R** and **R′**, namely,

$$R=\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{Q_1^2}{q^2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{Q_1}{q} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{(q^2-Q_1)}{q^2} & 0 & \frac{1}{Q_1} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{q} & 0 & \frac{(q^2-Q_1)}{q^2} & 0 \\ 0 & 0 & \frac{(q^2-Q_1)}{q^2} & 0 & 0 & 0 & \frac{1}{q} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{Q_1}{q} & 0 \\ 0 & \frac{Q_1}{q^2} & 0 & -\frac{1}{Q_1} & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \tag{17}$$

and

$$\mathbf{R}'=\begin{pmatrix}
\frac{q^2}{Q_1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & Q_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & q & 0 & 0 & 0 & 0 & 0 & 0\\
0 & \frac{q^2-Q_1}{Q_1} & 0 & \frac{q^2}{Q_1^2} & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & \frac{q^2}{Q_1} & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & \frac{q}{Q_1} & 0 & \frac{q^2-Q_1}{Q_1} & 0\\
0 & 0 & \frac{q^2-Q_1}{Q_1} & 0 & 0 & 0 & \frac{q}{Q_1} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & q & 0\\
0 & 1 & 0 & -\frac{q^2}{Q_1^2} & 0 & 0 & 0 & 0 & \frac{q^2}{Q_1}
\end{pmatrix}. \tag{18}$$

Similar to the R matrix of $\mathrm{SU}_q(2)$ the matrix R' is proportional to R ($R'=q^2Q_1^{-1}R$). The entries of the quantum matrix (4) generate the algebra

$$\begin{gathered}
K_1K_1^*=K_1^*K_1+q^2Q_1^{-2}L_1^*L_1+q^{-2}Q_1(q^2-Q_1)K_3^*K_3,\\
K_1K_2=qQ_1^{-1}K_2K_1,\\
K_1K_2^*=q^{-1}Q_1K_2^*K_1+qQ_1^{-1}L_2L_1+q^{-2}Q_1(q^2-Q_1)K_3^*K_2,\\
K_1K_3=q^2Q_1^{-2}K_3K_1,\\
K_1K_3^*=Q_1K_3^*K_1+L_1^2,\\
K_1L_1=qL_1K_1,\\
K_1L_1^*=qQ_1^{-1}L_1^*K_1+q^{-1}(q^2-Q_1)L_1K_3,\\
K_1L_2=L_2K_1+q^{-1}(q^2-Q_1)L_1K_2,\\
K_2K_2^*=Q_1K_2^*K_2+q^{-2}Q_1^2K_3^*K_3-K_1^*K_1+L_2^2,\\
K_2K_3=qQ_1^{-1}K_3K_2,\\
K_2K_3^*=q^{-1}Q_1^2K_3^*K_2+L_2L_1,\\
K_2L_1=Q_1L_1K_2,\\
K_2L_1^*=L_1^*K_2+q^{-1}(q^2-Q_1)L_2K_3,\\
K_2L_2=qL_2K_2-qQ_1^{-1}L_1^*K_1+q^{-1}Q_1L_1K_3),\\
K_3K_3^*=q^{-2}Q_1^3K_3^*K_3+L_1^*L_1,
\end{gathered} \tag{19}$$

$$K_3L_1=q^{-1}Q_1^2L_1K_3,$$

$$K_3L_1^*=qL_1^*K_3,$$

$$K_3L_2=Q_1L_2K_3,$$

$$L_1L_1^*=q^2Q_1^{-2}L_1^*L_1,$$

$$L_1L_2=qQ_1^{-1}L_2L_1.$$

The Hopf algebra structure is given by the group Hopf algebra

$$\Delta(\mathbf{t})=\mathbf{t}\otimes\mathbf{t},\quad \epsilon(\mathbf{t})=1,\quad S(\mathbf{t})=\mathbf{t}^{-1}, \tag{20}$$

where the inverse matrix is given by

$$\mathbf{t}^{-1}=\begin{pmatrix} L_2K_1^*-qQ_1^{-1}L_1^*K_2^* & -Q_1^{-2}L_2K_3^*+q^{-1}Q_1^{-1}L_1K_2^* & qQ_1^{-2}L_1^*K_3^*-q^{-1}L_1K_1^* \\ -Q_1^2L_2K_3+qQ_1L_1^*K_2 & L_2K_1-q^{-1}Q_1L_1K_2 & q^{-1}Q_1^2L_1K_3-qL_1^*K_1 \\ q^2Q_1^{-1}K_3K_2^*-qK_2K_1^* & q^{-2}Q_1K_3^*K_2-q^{-1}K_2^*K_1 & K_1^*K_1-q^{-2}Q_1^2K_3^*K_3 \end{pmatrix}\delta^{-1}. \tag{21}$$

The element δ which is defined to be

$$\delta\equiv L_2K_1^*K_1-q^{-2}Q_1^2L_2K_3^*K_3+L_1K_3K_2^*+L_1^*K_3^*K_2-qQ_1^{-1}L_1^*K_2^*K_1-q^{-1}Q_1L_1K_2K_1^* \tag{22}$$

has grouplike Hopf algebra structure

$$\Delta(\delta)=\delta\otimes\delta,\quad \epsilon(\delta)=1,\quad S(\delta)=\delta^{-1} \tag{23}$$

and satisfies

$$K_1\delta=\delta K_1,\ K_2\delta=q^{-1}Q_1^2\delta K_2,\ K_3\delta=q^{-2}Q_1^4\delta K_3,\ L_1\delta=qQ_1^{-2}\delta L_1,\ L_2\delta=\delta L_2 \tag{24}$$

and their *-conjugates with $\delta^*=\delta$.

The braided Hopf algebra structure of the generalized oscillator (1) implied by the quantum group covariance is given by the co-products

$$\Delta(q^N)=q^N\otimes 1+1\otimes q^N,\ \Delta(a)=a\otimes 1+1\otimes a,\ \Delta(a^*)=a^*\otimes 1+1\otimes a^*, \tag{25}$$

the co-units

$$\epsilon(q^N)=\epsilon(a)=\epsilon(a^*)=0, \tag{26}$$

the antipodes

$$S(q^N)=-q^N,\ S(a)=-a,\ S(a^*)=-a^* \tag{27}$$

and the braidings implied by (18),

$$\psi(q^N\otimes q^N)=q^2Q_1^{-1}q^N\otimes q^N,$$

$$\psi(q^N\otimes a)=qQ_1^{-1}a\otimes q^N,$$

$$\psi(a^*\otimes q^N)=qQ_1^{-1}q^N\otimes a^*,$$

$$\psi(q^N\otimes a^*)=qa^*\otimes q^N+Q_1^{-1}(q^2-Q_1)q^N\otimes a^*,$$
$$\psi(a\otimes q^N)=qq^N\otimes a+Q_1^{-1}(q^2-Q_1)a\otimes q^N,$$
$$\psi(a\otimes a)=q^2Q_1^{-1}a\otimes a,$$
$$\psi(a^*\otimes a^*)=q^2Q_1^{-1}a^*\otimes a^*,$$
$$\psi(a\otimes a^*)=Q_1^{-1}(q^2-Q_1)a\otimes a^*+Q_1a^*\otimes a+q^N\otimes q^N,$$
$$\psi(a^*\otimes a)=-q^2Q_1^{-2}q^N\otimes q^N+q^2Q_1^{-2}a\otimes a^*. \tag{28}$$

In contrast to the three parameter deformed case where there is a unique solution for the braidings, the two parameter deformed case $Q_1=q^2$ has three more solutions apart from the solution obtained by substituting $Q_1=q^2$ into (28). These solutions are as follows:

sol1,

$$C_1=1,\ C_2=q^2,\ C_3=0,\ C_4=0,\ C_5=q,\ C_6=0,\ C_7=0,$$
$$C_8=q^{-2},\ C_9=0,\ C_{10}=q^{-1},\ C_{11}=0,\ C_{12}=0,\ C_{13}=0,\quad C_{14}=-1; \tag{29}$$

sol2,

$$C_1=1,\ C_2=q^2,\ C_3=0,\ C_4=2,\ C_5=q,\ C_6=0,\ C_7=0,$$
$$C_8=q^{-2},\ C_9=0,\ C_{10}=q^{-1},\ C_{11}=0,\ C_{12}=0,\ C_{13}=0,\quad C_{14}=1; \tag{30}$$

sol3

$$C_1=1,\ C_2=q^2,\ C_3=0,\ C_4=0,\ C_5=q,\ C_6=0,\ C_7=0,$$
$$C_8=q^{-2},\ C_9=-2q^{-2},\ C_{10}=q^{-1},\ C_{11}=0,\ C_{12}=0,\quad C_{13}=0,\ C_{14}=1. \tag{31}$$

The $Q_1=q^2$ case is special not only because there are three more solutions for the braidings, but also the $\mathbf{R}$ matrix is triangular ($\mathbf{R}_{12}^{-1}=\mathbf{R}_{21}$) and $S^2=id$ is satisfied for the quantum group. We also note that in the general braided Hopf algebra solutions given in Ref. 4, only the solutions we give in this section are related with the quantum group covariance.

We should also note that when $L_1=L_1^*=K_2=K_2^*=0$ and $L_2=1$ the transformation matrix is an element of SU(1,1) in the $q=Q_1=1$ limit. Hence the group we define can be interpreted as deformations of SU(1,1).

III. SUBGROUPS AND REPRESENTATIONS

In the general form of the transformation of the generalized oscillator, the invariance quantum group is a nine-parameter quantum group with three deformation parameters. This quantum group has seven and five parameter subgroups which we discuss.

(A) The seven parameter subgroup can be obtained by setting $L_1=L_1^*=0$ in (19). Then the consistency of the relations requires $Q_1=q^2$, i.e., for the oscillator

$$aa^*-q^2a^*a=q^{2N},$$
$$aq^N=qq^Na, \tag{32}$$
$$q^Na^*=qa^*q^N$$

the transformation

$$(a \;\; a^* \;\; q^N)' = (a \;\; a^* \;\; q^N)\begin{pmatrix} K_1 & K_3^* & 0 \\ K_3 & K_1^* & 0 \\ K_2 & K_2^* & L_2 \end{pmatrix} \tag{33}$$

leaves the algebra covariant where the entries of the quantum matrix satisfy

$$\begin{gathered} K_1K_1^* = K_1^*K_1, \\ K_1K_2 = q^{-1}K_2K_1, \\ K_1K_2^* = qK_2^*K_1, \\ K_1K_3 = q^{-2}K_3K_1, \\ K_1K_3^* = q^2K_3^*K_1, \\ K_1L_2 = L_2K_1, \\ K_2K_2^* = q^2K_2^*K_2 + q^2K_3^*K_3 - K_1^*K_1 + L_2^2, \\ K_2K_3 = q^{-1}K_3K_2, \\ K_2K_3^* = q^3K_3^*K_2, \\ K_2L_2 = qL_2K_2, \\ K_3K_3^* = q^4K_3^*K_3, \\ K_3L_2 = q^2L_2K_3. \end{gathered} \tag{34}$$

The Hopf algebra structure is given by the group Hopf algebra, i.e.,

$$\Delta(\mathbf{t}) = \mathbf{t}\otimes\mathbf{t}, \quad \boldsymbol{\epsilon}(\mathbf{t}) = 1, \quad \mathbf{S}(\mathbf{t}) = \mathbf{t}^{-1} \tag{35}$$

and the matrix inverse is

$$\mathbf{t}^{-1} = \begin{pmatrix} L_2K_1^* & -q^{-4}L_2K_3^* & 0 \\ -q^4L_2K_3 & L_2K_1 & 0 \\ K_3K_2^* - qK_2K_1^* & K_3^*K_2 - q^{-1}K_2^*K_1 & K_1^*K_1 - q^2K_3^*K_3 \end{pmatrix}\delta^{-1}, \tag{36}$$

where the element

$$\delta \equiv L_2(K_1^*K_1 - q^2K_3^*K_3) \tag{37}$$

is grouplike

$$\Delta(\delta) = \delta\otimes\delta, \quad \epsilon(\delta) = 1, \quad S(\delta) = \delta^{-1} \tag{38}$$

and satisfies

$$K_1\delta = \delta K_1, \quad K_2\delta = q^3\delta K_2, \quad K_3\delta = q^6\delta K_3, \quad L_2\delta = \delta L_2, \quad \delta^* = \delta. \tag{39}$$

To construct the representation, we take the generators of this algebra as operators acting on some space. We first find the simultaneously diagonalizible operators: the operators L_2, K_1, and

K_1^* commute among themselves and taking into account that $L_2^*=L_2$ we can take these operators as diagonal operators. We take the eigenvalue of the Hermitian operator as

$$L_2|n\rangle=Aq^n|n\rangle, \tag{40}$$

where A is a real constant. The relations of the algebra suggest that

$$K_2|n\rangle\sim|n-1\rangle, \quad K_3|n\rangle\sim|n-2\rangle \tag{41}$$

and hence we take the actions of the generators as

$$\begin{gathered} K_1|n\rangle=k_{1,n}|n\rangle, \quad K_2|n\rangle=k_{2,n}|n-1\rangle, \quad K_3|n\rangle=k_{3,n}|n-2\rangle, \\ K_1^*|n\rangle=k_{1,n}^*|n\rangle, \quad K_2^*|n\rangle=k_{2,n+1}^*|n+1\rangle, \quad K_3^*|n\rangle=k_{3,n+2}^*|n+2\rangle. \end{gathered} \tag{42}$$

Substituting these into (34) we obtain

$$k_{1,n}=Bq^n, \quad k_{2,n}=Cq^n, \quad k_{3,n}=Dq^n, \tag{43}$$

where B, C, and D are complex constants satisfying

$$|B|^2=A^2+q^2|D|^2. \tag{44}$$

We note that the representation is infinite dimensional.

(B) The five parameter subgroup can be obtained by setting $L_1=L_1^*=K_3=K_3^*=0$ in the transformation (2), i.e., for the algebra

$$\begin{gathered} aa^*-Q_1a^*a=q^{2N}, \\ aq^N=qq^Na, \\ q^Na^*=qa^*q^N, \end{gathered} \tag{45}$$

the transformation

$$(a \;\; a^* \;\; q^N)'=(a \;\; a^* \;\; q^N)\begin{pmatrix} K_1 & 0 & 0 \\ 0 & K_1^* & 0 \\ K_2 & K_2^* & L_2 \end{pmatrix} \tag{46}$$

leaves the algebra covariant where the entries of the quantum matrix satisfy

$$\begin{gathered} K_1K_1^*=K_1^*K_1, \\ K_1K_2=qQ_1^{-1}K_2K_1, \\ K_1K_2^*=q^{-1}Q_1K_2^*K_1, \\ K_1L_2=L_2K_1, \\ K_2K_2^*=Q_1K_2^*K_2-K_1^*K_1+L_2^2, \\ K_2L_2=qL_2K_2. \end{gathered} \tag{47}$$

The Hopf algebra structure is given by the group Hopf algebra

$$\Delta(\mathbf{t})=\mathbf{t}\otimes\mathbf{t}, \quad \boldsymbol{\epsilon}(\mathbf{t})=\mathbf{1}, \quad \mathbf{S}(\mathbf{t})=\mathbf{t}^{-1}. \tag{48}$$

The inverse matrix is

$$\mathbf{t}^{-1}=\begin{pmatrix} L_2K_1^* & 0 & 0 \\ 0 & L_2K_1 & 0 \\ -qK_2K_1^* & -q^{-1}K_2^*K_1 & K_1^*K_1 \end{pmatrix}\delta^{-1}, \tag{49}$$

where

$$\delta\equiv L_2K_1^*K_1 \tag{50}$$

is grouplike,

$$\Delta(\delta)=\delta\otimes\delta, \quad \epsilon(\delta)=1, \quad S(\delta)=\delta^{-1}, \tag{51}$$

and satisfies

$$K_1\delta=\delta K_1, \quad K_2\delta=q^{-1}Q_1^2\delta K_2, \quad L_2\delta=\delta L_2. \tag{52}$$

Similar to the construction of the representation of the seven parameter subgroup, the elements L_2 and K_1 can be taken as diagonal operators and K_2 and K_2^* can be taken as lowering and raising operators, respectively. We take the eigenvalue of the Hermitian operator as

$$L_2|n\rangle=Aq^n|n\rangle \tag{53}$$

and for the other operators we take

$$\begin{aligned} &K_1|n\rangle=k_{1,n}|n\rangle, \quad K_2|n\rangle=k_{2,n}|n-1\rangle, \\ &K_1^*|n\rangle=k_{1,n}^*|n\rangle, \quad K_2^*|n\rangle=k_{2,n+1}^*|n+1\rangle. \end{aligned} \tag{54}$$

Substituting these into (47) we obtain

$$k_{1,n}=B\left(\frac{Q_1}{q}\right)^n, \quad |k_{2,n}|^2=A^2\frac{Q_1^n-q^{2n}}{Q_1-q^2}-|B|^2\frac{Q_1^n-\left(\frac{Q_1}{q}\right)^{2n}}{Q_1-\left(\frac{Q_1}{q}\right)^2}, \tag{55}$$

where A is real and B is complex. The quadratic Casimir of the algebra which is found to be

$$C=K_1^*K_1+(q^{-2}-1)K_2^*K_2+q^{-2}L_2^2 \tag{56}$$

has the eigenvalue

$$C|n\rangle=(A^2+q^{-2}|B|^2)|n\rangle. \tag{57}$$

In the algebra (47), when we identify

$$L_2\equiv q^H, \quad K_1=K_1^*\equiv q^{-H}, \quad K_2\equiv(q-q^{-1})^{1/2}X_-, \quad K_2^*\equiv(q-q^{-1})^{1/2}X_+, \quad Q_1=1, \tag{58}$$

the algebra turns out to be

$$q^HX_\pm=q^{\pm1}X_\pm q^H, \quad X_+X_--X_-X_+=\frac{q^{2H}-q^{-2H}}{q-q^{-1}}, \tag{59}$$

which generates $U_q(\mathrm{su}(2))$ with the *-structure

$$(q^H)^* = q^H, \quad (X_\pm)^* = X_\mp . \tag{60}$$

The transformation

$$(a \;\; a^* \;\; q^N)' = (a \;\; a^* \;\; q^N)\begin{pmatrix} q^{-H} & 0 & 0 \\ 0 & q^{-H} & 0 \\ X_- & X_+ & q^H \end{pmatrix} \tag{61}$$

leaves the commutation relations between a, a^*, and q^N invariant. The matrix multiplication gives the co-multiplication of the generators of the algebra

$$\Delta(q^H) = q^H \otimes q^H, \quad \Delta(q^{-H}) = q^{-H} \otimes q^{-H}, \quad \Delta(X_\pm) = X_\pm \otimes q^{-H} + q^H \otimes X_\pm \tag{62}$$

and the co-unit map

$$\epsilon(q^{\pm H}) = 1, \quad \epsilon(X_\pm) = 0 \tag{63}$$

is a map to the identity of the quantum group. The antipodes

$$S(q^{\pm H}) = q^{\mp H}, \quad S(X_\pm) = -q^{\mp 1} X_\pm \tag{64}$$

give the inverse of the transformation matrix.

IV. CONCLUSION

At the level of a single oscillator, the deformation of the oscillator results in a noncommutativity in the algebra whose co-action leaves the oscillator algebra covariant. At the level of two (or more) oscillators, this induces a noncommutativity (called outer noncommutativity) between independent copies. This noncommutativity is described by the braiding relations. The discussion of the n-fold braided tensor product for q-Heisenberg algebra is done in Ref. 5. Hence we give not only a generalization of the oscillator algebra but also the interaction pattern of these oscillators among themselves via the quantum group covariance. This may contribute to understand the possible connections between quantum groups and nonextensive statistical mechanics.[6] In this work we use real deformation parameters, however, the fractional supersymmetric structures require at least one of the deformation parameters to be a root of unity[7] as the generalization of the (-1) factor in the fermionic case. One more thing which deserves a separate study is the decoupling of the oscillators or the unbraiding transformations.[8]

The braided co-vector algebras covariant under quantum groups are also covariant under the braided groups obtained from quantum groups by a transmutation process.[3] The main ingredient of this construction is the **R** matrix. Hence the **R** matrix we found defines a new braided group which we do not consider here.

In this article we prove the global existence of solution of the classical Maxwell–Chern–Simons–Higgs equations in $(2+1)$-dimensional Minkowski space–time in the Lorentz gauge. We also prove that the topological solution of the Maxwell–Chern–Simons–Higgs system converges to that of Maxwell–Higgs system as the Chern–Simons constant κ goes to zero, reproducing the classical result by Moncrief [J. Math. Phys. **21**, 2291 (1980)] on the global existence of the Maxwell–Klein–Gordon system in $(2+1)$-dimension. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1507609]

I. INTRODUCTION

The Maxwell–Chern–Simons–Higgs model in $(2+1)$-space–time was proposed to construct a self-dual system having both the Maxwell and the Chern–Simons terms.[1] The Lagrangian is

$$\mathcal{L}=-\frac{1}{4}F^{\mu\nu}F_{\mu\nu}+\frac{\kappa}{4}\epsilon^{\mu\nu\rho}F_{\mu\nu}A_\rho+D_\mu\phi\overline{D^\mu\phi}+\frac{1}{2}\partial_\mu N\partial^\mu N-\frac{1}{2}(e|\phi|^2+\kappa N-ev^2)^2-e^2N^2|\phi|^2, \tag{1}$$

where $g_{\mu\nu}=\mathrm{diag}(1,-1,-1)$ is the $(2+1)$-dimensional Minkowskian metric in $\mathbf{R}^3$, ϕ is a complex scalar field, N is a real scalar field, $A=(A_0,A_1,A_2)$ is a gauge field, $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$, $D_\mu=\partial_\mu-ieA_\mu$, e is the charge of the electron, and $\kappa>0$ is the Chern–Simons constant. We are using the summation convention for Greek indices ranging 0,1,2 and for Latin indices ranging 1,2. We raise and lower the tensor indices by $g^{\mu\nu}=(g_{\mu\nu})^{-1}=\mathrm{diag}(1,-1,-1)$ and $g_{\mu\nu}$, respectively. The corresponding Euler–Lagrange equations via variation of the action taken with respect to (A,ϕ,N) are

$$\begin{aligned}&\partial_\lambda F^{\lambda\rho}+\frac{\kappa}{2}\epsilon^{\mu\nu\rho}F_{\mu\nu}+2eIm(\phi\overline{D^\rho\phi})=0,\\ &D_\mu D^\mu\phi+U_{\bar\phi}(|\phi|^2,N)=0,\\ &\partial_\mu\partial^\mu N+U_N=0,\end{aligned} \tag{2}$$

where

$$U(|\phi|^2,N)=\tfrac{1}{2}(e|\phi|^2+\kappa N-ev^2)^2+e^2N^2|\phi|^2,$$

and $U_{\bar\phi}$, U_N are formal derivations of $U(|\phi|^2,N)$ with respect to $\bar\phi$, N:

$$U_{\bar\phi}(|\phi|^2,N)=(e|\phi|^2+\kappa N-ev^2)\phi+e^2N^2|\phi|^2,$$

[a]Electronic mail: dhchae@math.snu.ac.kr
[b]Electronic mail: mjchae@math.snu.ac.kr

$$U_N(|\phi|^2,N)=\kappa(e|\phi|^2+\kappa N-ev^2)+2e^2N|\phi|^2.$$

Setting $\rho=0$ in the first equation of (2), we obtain the Gauss–Law constraint

$$\partial_j F_{j0}-\kappa F_{12}-2e\ \mathrm{Im}(\phi\overline{D_0\phi})=0. \tag{3}$$

The energy functional for the system is

$$E=\int_{\mathbf{R}^2}\left[\frac{1}{2}F_{0i}^2+\frac{1}{2}F_{12}^2+|D_\mu\phi|^2+|\partial_\mu N|^2+U(|\phi|^2,N)\right]dx. \tag{4}$$

We note that, if (A,ϕ,N) is a solution that makes E finite, then either

$$\phi\to 0 \quad \text{and} \quad N\to\frac{ev^2}{\kappa}, \tag{5}$$

or

$$|\phi|^2\to v^2 \quad \text{and} \quad N\to 0 \tag{6}$$

as $|x|\to\infty$. The former is called nontopological boundary condition, and the latter is called topological boundary condition. In the static case, integrating by parts and using (3), we can rewrite the energy functional (4) as

$$E=\int |(D_1\pm iD_2)\phi|^2+|D_0\phi\mp ie\phi N|^2+\frac{1}{2}|F_{12}\pm(e|\phi|^2+\kappa N-e)|^2dx\pm e\int F_{12}dx.$$

This implies the following lower bound for the energy:

$$E\geqslant e\left|\int F_{12}dx\right|. \tag{7}$$

The lower bound is achieved if

$$\begin{aligned}(D_1\pm iD_2)\phi&=0,\\ D_0\mp ie\phi N&=0,\\ F_{12}\pm(e|\phi|^2+\kappa N-e)&=0.\end{aligned} \tag{8}$$

The above system (8) together with (3) is called the self-dual Maxwell–Chern–Simons–Higgs system. The self-dual system was studied extensively under each of the two conditions (5) and (6) by D. Chae *et al.*,[2,3] and on a periodic boundary condition, by Tarantello.[4] They also verified the unifying feature of Maxwell–Chern–Simons–Higgs which was heuristically described in Ref. 1.

On the Cauchy problem to the Maxwell–Chern–Simons–Higgs, to the authors' knowledge there is no previous result in the literature. As a related one, Moncrief has shown the global existence of solutions for the Maxwell–Klein–Gordon equations using the Lorentz gauge in $(2+1)$-space–time.[5] The Lagrangian of the Maxwell–Klein–Gordon system is

$$\mathcal{L}=-\tfrac{1}{4}F^{\mu\nu}F_{\mu\nu}+D_\mu\phi\overline{D^\mu\phi}-m^2|\phi|^2.$$

He proved the global existence of solutions by showing that a suitably defined higher order energy, though not strictly conserved, does not blow up in a finite time. In this article, we prove the global existence of Maxwell–Chern–Simons–Higgs in both nontopological and topological cases in the

Lorentz gauge, and prove that our topological solution converges to that of the Maxwell–Higgs system in the limit, $\kappa \to 0$. We remark that a similar convergence problem was considered for the static cases in Refs. 2 and 4.

In Sec. II we drive sets of equations for Maxwell–Chern–Simons–Higgs from (2) in the Lorentz gauge, and obtain the local existence result by the standard contraction mapping argument. In Sec. III we define the higher order energy and prove that it does not blow up in a finite time. From this result, we show that the $H^2 \times H^1$ norm of a solution can not blow up in any bounded interval of time, which completes the global existence proof. We remark that we could obtain the global boundedness of $H^2 \times H^1$ norm for a solution without introducing the Coulomb transform used in Ref. 5, instead we use the covariant Sobolev inequality which was already used in Ref. 6. Finally, in Sec. IV we verify that the topological solution of Maxwell–Chern–Simons–Higgs converges to that of Maxwell–Higgs which is identified with the Maxwell–Klein–Gordon system by setting $v=0$.

II. THE LOCAL EXISTENCE

The unknowns for the Maxwell–Chern–Simons–Higgs system consist of a vector potential A, a complex scalar field ϕ and a neutral scalar field N. The Lagrangian (1) is invariant through the gauge transformation,

$$A_i' = A_i + \partial_i \lambda,$$

$$\phi' = \exp(i\lambda)\phi.$$

In this article, we fix the gauge by giving the Lorentz gauge condition $\partial^\mu A_\mu = 0$ to the system (2). Using the relation $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$, the Euler–Lagrange equations (2) are rewritten in terms of (A, ϕ, N) in the Lorentz gauge by

$$\begin{aligned} \Box A_0 &= -\kappa F_{12} - 2e\ \mathrm{Im}(\phi \overline{D_0 \phi}), \\ \Box A_i &= -\kappa \epsilon^{ij} F_{0j} - 2e\ \mathrm{Im}(\phi \overline{D_i \phi}), \\ \Box \phi &= 2ieA_0 \partial_0 \phi - 2ieA_j \partial_j \phi - e^2 A_j^2 \phi + e^2 A_0^2 \phi - U_{\bar{\phi}}, \\ \Box N &= -U_N, \end{aligned} \tag{9}$$

with given initial data $A_\mu(0,x)$, $\phi(0,x)$, $N(0,x)$, $\partial_0 A_\mu(0,x)$, $\partial_0 \phi(0,x)$, $\partial_0 N(0,x)$ satisfying

$$\begin{aligned} &\partial_\mu A^\mu = 0, \\ &\Delta A_0 - \partial_j \partial_0 A_j - \kappa F_{12} - 2e\ \mathrm{Im}(\phi \overline{D_0 \phi}) = 0. \end{aligned} \tag{10}$$

We write the Maxwell–Chern–Simons–Higgs equations in first order form as follows. Let us introduce the new unknowns $(P_\mu, \psi_\mu, \Omega_\mu)$ defined by

$$P_\mu = \partial_t A_\mu, \quad \psi_\mu = D_\mu \phi, \quad \Omega_\mu = \partial_\mu N.$$

In terms of those unknowns, the Maxwell–Chern–Simons–Higgs system in the Lorentz gauge is written as follows:

$$\partial_0 A_0 = P_0,$$

$$\partial_0 P_0 = \Delta A_0 - \kappa F_{12} - 2e\ \mathrm{Im}(\phi \overline{\psi_0}),$$

$$\partial_0 A_j = P_j,$$

$$\begin{gathered}\partial_0 P_j=\Delta A_j-\kappa\epsilon^{ji}F_{0i}-2e\ \mathrm{Im}(\phi\overline{\psi_j}),\\ \partial_0\phi=\psi_0+ieA_0\phi,\\ \partial_0\psi_0=D_j\psi_j+ieA_0\psi_0-U_{\bar{\psi}},\\ \partial_0\psi_j=D_j\psi_0-ieA_0\psi_j-ieF_{0j}\phi,\\ \partial_0 N=\Omega_0,\\ \partial_0\Omega_0=\partial_j\Omega_j-U_N,\\ \partial_0\Omega_j=\partial_j\Omega_0,\end{gathered}\tag{11}$$

supplemented by constraints (10).

Introduce $\tilde{N}$ satisfying $\tilde{N}+ev^2/\kappa=N$ for the nontopological boundary condition. Then we have

$$(A,\phi,\tilde{N})\to 0 \quad \text{as} \quad |x|\to\infty.$$

In this case the system (11) changes harmlessly (i.e., $U_N\to U_{\tilde{N}}$). For the topological case we may assume $\lim_{|x|\to\infty}\phi=\lambda$ for a complex scalar λ with $|\lambda|=v$. Introducing φ satisfying $\varphi+\lambda=\phi$, we also have

$$(A,\varphi,N)\to 0 \quad \text{as} \quad |x|\to\infty.$$

Let us remark on notations. If no confusion arises, we denote $u=(A,\phi,\tilde{N})$ or (A,φ,N), where $A=(A_0,A_1,A_2)$. Then we denote

$$\|u(t)\|_{H^s}=\|A(t)\|_{H^s}+\|\phi(t)\|_{H^s}+\|\tilde{N}(t)\|_{H^s},$$

in the nontopological case, while

$$\|u(t)\|_{H^s}=\|A(t)\|_{H^s}+\|\varphi(t)\|_{H^s}+\|N(t)\|_{H^s}$$

in the topological case. We also denote

$$\|u(t)\|_{H^s\times H^{s-1}}=\|u(t)\|_{H^s}+\|\partial_0 u(t)\|_{H^{s-1}}.$$

Let $u_0=u(0,\cdot)$. Then $\|u_0\|_{H^2\times H^1}=\|u(0)\|_{H^2}+\|\partial_0 u(0)\|_{H^1}$.

The following is our local existence result for the Maxwell–Chern–Simons–Higgs systems.

Theorem 2.1: *Consider the Maxwell–Chern–Simons–Higgs system (9) with Lorentz gauge constraints (10). Given a data set* $u_0\in H^2\times H^1$ *satisfying* (10) *and either nontopological or topological boundary conditions, there exists a unique local solution u of the Maxwell–Chern–Simons–Higgs system (9) and (10) such that*

$$u\in C([0,T];H^2(\mathbf{R}^2))\cap C^1([0,T];H^1(\mathbf{R}^2)).$$

The existence time interval $[0,T]$ *depends only on* $\|u_0\|_{H^2\times H^1}$.

Proof: We present the local existence proof for the nontopological case only. The topological case is completely similar. We set

$$X_T=C([0,T);H^2(\mathbf{R}^2))\cap C^1([0,T);H^1(\mathbf{R}^2)).$$

Given $T>0$, we introduce the norm $\|\cdot\|_{X_T}$ by $\|f\|_{X_T}=\sup_{0\leqslant t\leqslant T}\|f(t)\|_{H^2\times H^1}$. We seek constants T and Δ_0 so that the equation (9) induces a contraction mapping $\mathcal{F}$ on the closed ball

$$\mathcal{B}=\{(u,\partial_0 u)\in C([0,T];H^2\times H^1):\|u\|_{X_T}\leqslant\Delta_0\},$$

subject to the given initial data $(u_o,\partial_0 u_0)\in H^2\times H^1$. We define the mapping $\mathcal{F}:X_T\to X_T$ as follows: $(A,\phi,\tilde{N})=\mathcal{F}(A',\phi',\tilde{N}')$ solves the following linear wave equations:

$$\begin{aligned}
\Box A_0&=-\kappa(\partial_1 A_2'-\partial_2 A_1')-2e\,\mathrm{Im}(\phi'\overline{D_0'\phi'}),\\
\Box A_i&=-\kappa\epsilon^{ij}(\partial_0 A_j'-\partial_j A_0')-2e\,\mathrm{Im}(\phi'\overline{D_i'\phi'}),\\
\Box\phi&=2ieA_0'\partial_0\phi'-2ieA_j'\partial_j\phi'-e^2A_j'^2\phi'+e^2A_0'^2\phi'-U'_{\overline{\phi'}},\\
\Box\tilde{N}&=-U_{\tilde{N}'}.
\end{aligned}\tag{12}$$

Let $\|u_0\|_{H^2\times H^1}=d$. Applying the standard energy estimates to (12), we have

$$\|A(t)\|_{H^2\times H^1}\leqslant d+C\int_0^t\|\partial A'(s)\|_{H^1}+\|(\mathrm{Im}\,\phi'\overline{D'\phi'})\|_{H^1}ds,$$

$$\|\phi(t)\|_{H^2\times H^1}\leqslant d+C\int_0^t\|(A'\partial\phi')(s)\|_{H^1}+\|(A'^2\phi')(s)\|_{H^1}+\|U'_{\overline{\phi'}}(s)\|_{H^1}ds,$$

$$\|N(t)\|_{H^2\times H^1}\leqslant d+C\int_0^t\|U'_{\tilde{N}'}(s)\|_{H^1},$$

where the symbol ∂ represents a space–time derivative, ∂_0 or ∂_j, and D represents D_0 or D_j, and C depends on κ, e. We use the Nirenberg–Gagliardo inequality, $\|u\|_{L^4}\leqslant\|u\|_{L^2}^{1/2}\Sigma_{j=1}^2\|\partial_j u\|_{L^2}^{1/2}$, and the Sobolev embedding, $\|u\|_{L^\infty}\leqslant C\|u\|_{H^2}$, to estimate the terms in the time integral. The highest order terms are estimated by

$$\begin{aligned}
\|A'\partial\phi'\|_{H^1}&\leqslant\|A'\partial\phi'\|_{L^2}+\sum_{j=1}^2(\|\partial_j A'\partial\phi'\|_{L^2}+\|A'\partial_j\partial\phi'\|_{L^2})\\
&\leqslant C\|A'\|_{H^2}\|\partial\phi'\|_{L^2}+\sum_{i,j,k=1}^2\|\partial_j A'\|_{L^2}^{1/2}\|\partial\phi'\|_{L^2}^{1/2}\|\partial_i\partial_j A'\|_{L^2}^{1/2}\|\partial_k\partial\phi'\|_{L^2}^{1/2}\\
&\quad+C\|A'\|_{H^2}\|\phi'\|_{H^2\times H^1}\leqslant C\|u'\|_{H^2\times H^1},
\end{aligned}$$

and, similarly,

$$\|\phi'\overline{D'\phi'}\|_{H^1}\leqslant C\|u'\|_{H^2\times H^1}.$$

Then we find easily

$$\|u(t)\|_{H^2\times H^1}\leqslant d+C\int_0^t(1+\|u'(s)\|_{H^2\times H^1}^2)\;ds.$$

Using $\|u'\|_{X_T}\leqslant\Delta_0$, we have

$$\|u(t)\|_{H^2\times H^1}\leqslant d+C(1+\Delta_0^2)t$$

for $0\leqslant t\leqslant T$. Therefore, taking $\Delta_0=d+1$ and $T<1/C(1+(d+1)^2)$, we obtain $\|u\|_{X_T}\leqslant\Delta_0$, i.e., we find $\mathcal{F}:\mathcal{B}\to\mathcal{B}$. Using this, we compute easily that

$$\|(\mathcal{F}(u')-\mathcal{F}(v'))(t)\|_{H^2\times H^1}\leqslant C\int_0^t(1+\Delta_0^2)\|(u'-v')(s)\|_{H^2\times H^1}ds$$

for $0\leqslant t\leqslant T$. Choosing T small so that

$$C(1+\Delta_0^2)T\leqslant\tfrac{1}{2}, \tag{13}$$

we deduce that the mapping $\mathcal{F}:\mathcal{B}\to\mathcal{B}$ is a contraction mapping. We can apply the fixed point argument to obtain the unique solution of (9) with $u\in C([0,T];H^2(R^2))\cap C^1([0,T];H^1(R^2))$. To show continuous dependence on the initial data of the solution, we let u,v be each solution to the initial data u_0,v_0. If $\|u_0\|_{H^2},\|v_0\|_{H^2}\leqslant d$, we find that

$$\|u-v\|_{X_T}\leqslant\|u_0-v_0\|_{H^2}+C(1+d^2)T\|u-v\|_{X_T}$$

similarly. Choosing T so small as to T satisfying (13), we obtain

$$\|u-v\|_{X_T}\leqslant 2\|u_0-v_0\|_{X_T}.$$

Next, we show that the constraint equations (10) are propagated by the evolution equations following the argument in Ref. 5. We write

$$\begin{aligned} U&\equiv P_0-\partial_iA_i,\\ V&\equiv\partial_i(\partial_iA_0-\partial_0A_i)-\kappa F_{12}-2e\ \mathrm{Im}\ \phi\overline{D_0\phi}, \end{aligned} \tag{14}$$

and compute, using (11),

$$\frac{d}{dt}\begin{pmatrix}U\\V\end{pmatrix}=\begin{pmatrix}0&I\\\Delta&0\end{pmatrix}\begin{pmatrix}U\\V\end{pmatrix}.$$

We note from the expression (14) that $U\in H^2$ and $V\in H^1$ whenever $u(t)\in H^3\times H^2$. Since the linear wave equation has a unique global solution on $H^2\times H^1$, it follows $U(t)$, $V(t)$ vanish throughout the interval of existence of u. For initial data $u_0\in H^2\times H^1$, we obtain the desired result by the standard density argument. □

III. THE GLOBAL EXISTENCE

In this section we estimate various gauge invariant quantities constructed from $(F_{\mu\nu},\phi,\psi)$. The conserved, gauge invariant energy $E_0(t)$ for Maxwell–Chern–Simons–Higgs is

$$E_0(t)=\int_{\mathbf{R}^2}\left[\frac{1}{2}F_{0i}^2+\frac{1}{2}F_{12}^2+|D_\mu\phi|^2+|\partial_\mu N|^2+U(|\phi|^2,N)\right]dx. \tag{15}$$

Following Ref. 5 we introduce the pseudo-energy $E_1(t)$ defined by

$$E_1(t)=\int_{\mathbf{R}^2}\left[\frac{1}{2}(\partial_lF_{0i})^2+\frac{1}{2}(\partial_lF_{12})^2+|D_l\psi_\mu|^2+(\partial_l\Omega_\mu)^2\right]dx$$

where $\psi_\mu=D_\mu\phi$, $\Omega_\mu=\partial_\mu N$.

The global existence result will be established after several lemmas.

Lemma 3.1: Let $u \in C([0,T];H^2(\mathbf{R}^2)) \cap C^1([0,T];H^1(\mathbf{R}^2))$ *be the solution of systems (9) and (10) with initial data given either nontopological or topological boundary conditions. Then* $\|u(t)\|_{L^2}$ *is estimated in terms of the initial data for all* $t \in [0,T]$.

Proof: We first need to bound $\|A(t)\|_{L^2}$ by the initial data. To derive this, consider the integral

$$\|A(t)\|_{L^2}^2 = \int_{\mathbf{R}^2} A_0^2 + A_i^2 dx.$$

Taking the time derivative of this integral and using the Lorentz gauge condition, we obtain

$$\frac{d}{dt}\|A(t)\|_{L^2}^2 = -\int_{\mathbf{R}^2} 2A_i F_{0i}\ dx \leqslant 2E_0^{1/2}\|A(t)\|_{L^2},$$

where E_0 is the conserved energy of the solution considered. It follows that, for $t \geqslant 0$,

$$\|A(t)\|_{L^2} \leqslant \|A(0)\|_{L^2} + 2E_0^{1/2} t. \tag{16}$$

In a similar way, we obtain the bounds for $(\phi, \tilde{N})$ and (φ, N):

$$\frac{d}{dt}\|\phi(t)\|_{L^2}^2 = 2\ \mathrm{Re}\int_{\mathbf{R}^2} \overline{\phi}\partial_0\phi = 2\ \mathrm{Re}\int_{\mathbf{R}^2} \overline{\phi} D_0\phi dx \leqslant 2E_0^{1/2}\|\phi(t)\|_{L^2},$$

$$\frac{d}{dt}\|\tilde{N}(t)\|_{L^2}^2 = 2\int_{\mathbf{R}^2} \tilde{N}\partial_0 N\ dx \leqslant 2E_0^{1/2}\|\tilde{N}(t)\|_{L^2},$$

$$\frac{d}{dt}\|N(t)\|_{L^2}^2 = 2\int_{\mathbf{R}^2} N\partial_0 N\ dx \leqslant 2E_0^{1/2}\|N(t)\|_{L^2}.$$

To obtain the bound for $\|\varphi(t)\|_{L^2}$, recall $\varphi = \phi - \lambda$. Then we have

$$\|D_0\varphi(t)\|_{L^2} \leqslant \|D_0\phi(t)\|_{L^2} + ev^2\|A(t)\|_{L^2} \leqslant E_0^{1/2} + ev(\|A(0)\|_{L^2} + 2E_0^{1/2} t) \ \text{ by (16)},$$

from which we obtain

$$\frac{d}{dt}\|\varphi(t)\|_{L^2}^2 \leqslant 2\ \mathrm{Re}\int_{\mathbf{R}^2} \overline{\varphi} D_0\varphi dx \leqslant 2\|\varphi(t)\|_{L^2}(E_0^{1/2} + ev(\|A(0)\|_{L^2} + 2E_0^{1/2} t)).$$

The above inequalities imply that

$$\|u(t)\|_{L^2} \leqslant C\|u_0\|_{L^2} + (1+2t)E_0^{1/2} \tag{17}$$

for both $u = (A, \phi, \tilde{N})$ and (A, φ, N). □

Now consider the gauge invariant pseudo-energy $E_1(t)$. We shall show that $E_1(t)$ does not blow up in a finite time.

Lemma 3.2: Let $u \in C([0,T];H^2(\mathbf{R}^2)) \cap C^1([0,T];H^1(\mathbf{R}^2))$ *be the solution of the systems (9) and (10) with an initial data given either nontopological or topological boundary conditions. Then*

(*i*) $E_1(t)$ *is differentiable in time and*

$$\frac{d}{dt}E_1(t) = \int_{\mathbf{R}^2} -2e\partial_j F_{0i}\,\mathrm{Im}(\psi_i\overline{\psi_j}) - 2e\partial_j U_N\partial_j\Omega_0\ dx + 2\ \mathrm{Re}\int_{\mathbf{R}^2} \overline{D_j\psi_0}\cdot(ieF_{ij}\psi_i + ieF_{j0}\psi_0$$

$$-D_j U_{\overline{\phi}})\ dx + 2\ \mathrm{Re}\int_{\mathbf{R}^2} \overline{D_j\psi_i}\cdot(ieF_{ij}\psi_0 - F_{0i}\psi_j + ieF_{j0}\psi_i)\ dx. \tag{18}$$

(*ii*) $E_1(t)$ *is estimated in terms of the initial data for all* $t \in [0,T]$.

We will use the following covariant Sobolev inequality.

Lemma 3.3:[6] *Let* $1\leqslant q,r\leqslant\infty$ *and let* σ *and* p *satisfy* $0\leqslant\sigma\leqslant 1$, $1\leqslant p\leqslant\infty$, *and*

$$\frac{1}{p}=\frac{(1-\sigma)}{r}+\sigma\left(\frac{1}{q}-\frac{1}{n}\right).$$

If $p=\infty$, *then* $r<\infty$ *and* $\sigma<1$. *Let* $D_j=\partial_j-ieA_j$. *Then there exists a constant* C, *depending only on* n, p, q, r, *such that, for any* $u\in L^r$ *for which* $\partial_j u\in L^q$ *and* $A_j u\in L^q$, $j=1,\ldots,n$, *the following inequality holds:*

$$\|u\|_p\leqslant C\|u\|_r^{1-\sigma}\left(\sum_{j=1,2}\|D_j u\|_q\right)^{\sigma}.$$

Proof: See Proposition A.1 in Ref. 6. □

In case $n=2$, $r=2$, we have in particular

$$\|u\|_{L^p}\leqslant C\|u\|_{L^2}^{2/p}\left(\sum_{j=1,2}\|D_j u\|_{L^2}\right)^{1-2/p},\quad 2<p<\infty. \tag{19}$$

Proof of Lemma 3.2: (i) Let us assume an initial data u_0 in $H^3\times H^2$. By the local existence result, we obtain u, the solution of systems (9) and (10) in $C([0,T];H^3(\mathbf{R}^2))\cap C^1([0,T];H^2(\mathbf{R}^2))$. We freely differentiate $E_1(t)$, the pseudo-energy of u, and compute (18) using the equations of motion (11). For an initial data u_0 in $H^2\times H^1$, choose u_0^n in $H^3\times H^2$ so $u_0^n\to u_0$ in the $H^2\times H^1$ sense. Let u^n be the local solution evolving from u_0^n and $E_1^n(t)$ be the corresponding pseudo-energy. Noting that continuous dependence on initial data of the solution assures the uniform existence time interval $[0,T]$ of $\{u_n\}$, we obtain $E_1^n(t)\to E_1(t)$ since $u^n\to u$ in $C([0,T];H^2\times H^1(\mathbf{R}^2))$ by passing to $n\to\infty$. Therefore we obtain the desired result.

(ii) We may express the right hand side of (18), ignoring subscripts, as

$$\int_{\mathbf{R}^2}\partial F\cdot\psi^2+\partial U_N\cdot\partial\Omega+D\psi\cdot\psi\cdot F+D\psi\cdot DU_{\bar{\phi}}dx. \tag{20}$$

We will show that each term of (20) is estimated to be at most linear with respect to $E_1(t)$.

Let us begin with the nontopological case. From (19) we have

$$\|\phi\|_{L^p}\leqslant C\|\phi\|_{L^2}^{2/p}\|\psi\|_{L^2}^{1-2/p}\leqslant C(\|u_0\|_{L^2}+tE_0^{1/2})^{2/p}E_0^{(1/2)}(1-2/p),\quad 2<p<\infty,$$

$$\|\psi\|_{L^4}\leqslant C\|\psi\|_{L^2}^{1/2}\|D\psi\|_{L^2}^{1/2}\leqslant CE_0^{1/4}E_1^{1/4}(t).$$

Note that any power of $\|\phi\|_{L^p}$ $(2<p<\infty)$ is estimated by the initial data since E_0 is conserved. We get

$$\int_{\mathbf{R}^2}\partial F\cdot\psi^2 dx\leqslant\|\partial F\|_{L^2}\|\psi\|_{L^4}^2\leqslant CE_1^{1/2}(t)\|\psi(t)\|_{L^2}\|D\psi(t)\|_{L^2}\leqslant CE_0^{1/2}E_1(t),$$

and

$$\begin{aligned}\int_{\mathbf{R}^2}DF\cdot\psi\cdot F dx&\leqslant\|\psi(t)F(t))\|_{L^2}\|D\psi\|_{L^2}\\&\leqslant C\|F(t)\|_{L^4}\|\psi(t)\|_{L^4}E_1^{1/2}(t)\\&\leqslant C\|\psi(t)\|_{L^2}^{1/2}\|D\psi(t)\|_{L^2}^{1/2}\|F(t)\|_{L^2}^{1/2}\|\partial F(t)\|_{L^2}^{1/2}E_1^{1/2}(t)\leqslant CE_0^{1/2}E_1(t).\end{aligned}$$

Next, we estimate $\partial U_N \cdot \partial\Omega$, $D\psi \cdot DU_{\bar{\phi}}$. Note that ∂U_N, $DU_{\bar{\phi}}$ are expressed by gauge invariant terms using $\partial_l |\phi|^2 = 2\,\mathrm{Re}(\bar{\phi} D_l \phi)$:

$$\partial U_N = 2\kappa(2e\,\mathrm{Re}\,\psi\bar{\phi} + \kappa\Omega) + 2e\kappa^2\left(\Omega|\phi|^2 + 2\left(\tilde{N} + \frac{ev^2}{\kappa}\right)\mathrm{Re}\,\psi\bar{\phi}\right), \tag{21}$$

$$DU_{\bar{\phi}} = \psi|\phi|^2 + 2\phi\,\mathrm{Re}\,\psi\bar{\phi} + \kappa(\phi\Omega + \tilde{N}\psi) + e\kappa^2\left(\tilde{N} + \frac{ev^2}{\kappa}\right)\left(2\Omega\phi + \left(\tilde{N} + \frac{ev^2}{\kappa}\right)\psi\right). \tag{22}$$

Let us pick up $\psi\phi\tilde{N}$ in (21). We may consider $\partial\Omega \cdot \psi\phi\tilde{N}$ term only since other terms of $\partial U_N \cdot \partial\Omega$, $D\psi \cdot DU_{\bar{\phi}}$ are to be estimated in a completely analogous way. First we get

$$\begin{aligned}\int_{\mathbf{R}^2} \psi\phi\tilde{N}\partial\Omega\ dx &\leqslant \|(\psi\tilde{N}\phi)(t)\|_{L^2}\|\partial\Omega\|_{L^2} \\ &\leqslant \|\tilde{N}(t)\|_{L^\infty}\|\psi(t)\|_{L^4}\|\phi(t)\|_{L^4}E_1^{1/2}(t) \\ &\leqslant \|\tilde{N}\|_{L^{2(1-a)/a}}^{1-a}\|\partial^2\tilde{N}\|_{L^2}^{a}\|\psi\|_{L^2}^{1/2}\|D\psi\|_{L^2}^{1/2}\|\phi\|_{L^2}^{1/2}\|\psi\|_{L^2}^{1/2}E_1^{1/2}(t), \quad 0<a<1,\end{aligned}$$

where we use the usual Nirenberg–Gagliardo inequality to $\|\tilde{N}\|_{L^\infty}$ and the covariant Sobolev inequality to $\|\psi\|_{L^4}$, $\|\phi\|_{L^4}$. Applying the Nirenberg–Gagliardo inequality again to $\|\tilde{N}\|_{L^{2(1-a)/a}}$, we get

$$\begin{aligned}\int_{\mathbf{R}^2} \psi\phi\tilde{N}\partial\Omega\,dx &\leqslant \|\tilde{N}(t)\|_{L^2}^{a}\|\partial\tilde{N}(t)\|_{L^2}^{1-2a}\|\partial^2\tilde{N}(t)\|_{L^2}^{a}\|\phi(t)\|_{L^2}^{1/2}E_0^{1/2}E_1^{3/4}(t) \\ &\leqslant C\|u(t)\|_{L^2}^{a+1/2}E_0^{1-a}E_1^{3/4+a/2}(t), \quad 0<a<\tfrac{1}{2}.\end{aligned}$$

Now, choosing $a = 1/4$, we obtain the estimate we want.

Summing up all the estimations of the above, we arrive at

$$\frac{d}{dt}E_1(t) \leqslant C(\|u_0\|_{L^2} + (1+2t^2)E_0^{1/2})E_0^{3/4}(1+E_1(t)) \tag{23}$$

with C depending on κ, e, v and the conserved energy E_0 of the solution considered. Finally, from Gronwall's inequality, it follows that

$$E_1(t) \leqslant C_1(t)E_1(0) + C_2(t),$$

where $C_1(t)$, $C_2(t)$ are smooth functions depending on κ, e, v, E_0 and $\|u(0)\|_{L^2}$. We also prove that for the topological solution $(d/dt)E_1(t)$ is bounded as (23), by applying the covariant Sobolev inequality to φ instead of ϕ in this case. Let $\tilde{\psi}_j = D_j\varphi$. Then

$$\tilde{\psi}_j = \psi_j - ie\lambda A_j.$$

Applying (19) with respect to φ, we find

$$\|\varphi\|_{L^p} \leqslant \|\varphi\|_{L^2}^{2/p}\|\tilde{\psi}\|_{L^2}^{1-2/p} \leqslant C\|\varphi\|_{L^2}^{2/p}(\|\psi\|_{L^2}^{1-2/p} + e\lambda\|A\|_{L^2}^{1-2/p}) \leqslant C(E_0, \|u_0\|_{L^2})(\|\psi\|_{L^2}^{1-2/p} + 1).$$

The last inequality follows from Lemma 3.1. The remaining estimates can be done similarly to the nontopological case. Observe that the Chern–Simons coupling parameter κ appears only on estimating $\partial U_N \cdot \partial\Omega$, $D\psi \cdot DU_{\bar{\phi}}$ with them depending on κ by polynomial order. Thus $E_1(t)$ is continuously increasing with respect to κ. We also see that E_0 for the topological case behaves in the same way. This fact will be used in Sec. IV. □

The following is our main theorem of this section.

Theorem 3.4. (Global existence of smooth solutions): *Consider the Maxwell–Chern–Simons–Higgs system. Then any given initial data* $(u_0,\partial_0 u_0)\in H^2\times H^1$ *satisfying (10) admits a unique, global solution in the Lorentz gauge such that*

$$(A,\phi,\tilde{N})\in C([0,\infty);H^2(\mathbf{R}^2))\cap C^1([0,\infty);H^1(\mathbf{R}^2))$$

in the nontopological case, and

$$(A,\varphi,N)\in C([0,\infty);H^s(\mathbf{R}^2))\cap C^1([0,\infty);H^1(\mathbf{R}^2))$$

in the topological case.

Proof: In order to extend our local solution globally, we show that $\|u(t)\|_{H^2\times H^1}$ is uniformly bounded on any finite interval $[0,T]$. It is sufficient to verify the nontopological case. Consider the Maxwell equations in (9),

$$\begin{aligned}\Box A_0&=-\kappa F_{12}-2e\ \mathrm{Im}(\phi\overline{D_0\phi})\equiv\mathcal{J}_0,\\ \Box A_i&=-\kappa\epsilon^{ij}F_{0j}-2e\ \mathrm{Im}(\phi\overline{D_i\phi})\equiv\mathcal{J}_i.\end{aligned}\tag{24}$$

We compute the spatial derivatives of $\mathcal{J}_0$, $\mathcal{J}_i$ as

$$\partial_j\mathcal{J}_0=-\kappa\partial_jF_{12}-2e\ \mathrm{Im}(\psi_j\overline{\psi_0}+\phi\overline{D_j\psi_0}),$$

$$\partial_j\mathcal{J}_i=-\kappa\epsilon^{ik}\partial_jF_{0k}-2e\ \mathrm{Im}(\psi_j\overline{\psi_i}+\phi\overline{D_j\psi_i}).$$

Then applying energy estimates to (24) with subscripts ignored, we have

$$\begin{aligned}\|A(t)\|_{H^2\times H^1}&\leq\|u_0\|_{H^2\times H^1}+\int_0^t\|\mathcal{J}_\mu\|_{L^2}+\|\partial_j\mathcal{J}_\mu(s)\|_{L^2}ds\\ &\leq\|u_0\|_{H^2\times H^1}+C(\kappa,e)\int_0^t\|F\|_{L^2}+\|\phi\psi\|_{L^2}+\|\partial F\|_{L^2}+\|\psi^2\|_{L^2}+\|\phi D\psi F\|_{L^2}ds\\ &\leq\|u_0\|_{H^2\times H^1}+C(\kappa,e)\int_0^t E_0^{1/2}+\|\phi\|_{L^4}\|\psi\|_{L^4}^2+E_1^{1/2}(s)+\|\psi\|_{L^4}+\|\phi\|_{L^\infty}E_1^{1/2}(s)ds.\end{aligned}$$

Applying the covariant Sobolev inequality (19) repeatedly, we get

$$\|\phi\|_{L^\infty}\leq C\|\phi\|_{L^2}^{\epsilon}\|\psi\|_{L^2}^{1-2\epsilon}\|D\psi\|_{L^2}^{\epsilon},\quad 0<\epsilon<\tfrac{1}{2}.$$

Thus, if $\epsilon=1/4$,

$$\begin{aligned}\|A(t)\|_{H^2\times H^1}&\leq\|u_0\|_{H^2\times H^1}+C(\kappa,e)\int_0^t E_0^{1/2}+\|\phi\|_{L^2}^{1/2}E_0^{1/2}E_a^{1/4}(s)+E_1^{1/2}+E_0^{1/2}E_1^{1/2}(s)\\ &\quad+\|\phi\|_{L^2}^{\epsilon}E_0^{(1-2\epsilon)/2}E_1^{(1+\epsilon)/2}(s)ds\\ &\leq\|u_0\|_{H^2\times H^1}+C(\kappa,e)\int_0^t(1+\|u\|_{L^2})(1+E_0^{1/2})(1+E_1^{1/2}(s))ds.\end{aligned}$$

From Lemmas 3.1 and 3.3, we find that $\|A(t)\|_{H^2\times H^1}$ does not blow up in any finite time. Next we consider $\|\phi\|_{H^2\times H^1}$. We begin by rewriting

$$|\partial_\mu\phi|^2=|D_\mu\phi|^2+ieA_\mu\overline{D_\mu\phi}-ieA_\mu\overline{\phi_\mu D_\mu}\phi+e^2A_\mu^2|\phi|^2\tag{25}$$

$$= |\psi|^2 + ieA_\mu \overline{\psi_\mu} - ieA_\mu \overline{\phi_\mu \psi_\mu} + e^2 A_\mu^2 |\phi|^2, \tag{26}$$

and

$$|\partial_j \partial_\mu \phi|^2 = |D_j \psi_\mu + ieA_j \psi_\mu + ie\partial_j A_\mu \cdot \phi + ieA_\mu \phi_j - e^2 A_\mu A_j \phi|^2. \tag{27}$$

Each term in (26), (27) are shown to be $L^2(R^2)$ and estimated by $\|A(t)\|_{H^2\times H^1}$ and E_0, $E_1(t)$. We present here one of those estimations

$$\begin{aligned}\int_{\mathbf{R}^2} A\psi \cdot \partial A \cdot \phi &\leqslant \|A\|_{L^\infty} \|\partial A\|_{L^2} \|\phi\psi\|_{L^2} \\ &\leqslant C\|A\|^2_{H^2\times H^1} \|\phi\|_{L^4} \|\psi\|_{L^4} \\ &\leqslant \|A\|^2_{H^2\times H^1} \|\phi\|^{1/2}_{L^2} \|\psi\|_{L^2} \|D\psi\|^{1/2}_{L^2} \leqslant C\|A\|^2_{H^2\times H^1} \|\phi\|^{1/2}_{L^2} E_0^{1/2} E_1^{1/4}(t).\end{aligned}$$

Then from the previous result on $\|A(t)\|_{H^2\times H^1}$ and Lemmas 3.1, and 3.3, we find that $\|\phi\|_{H^2\times H^1}$ is uniformly bounded in any finite time. Note that we estimate $\|\tilde{N}(t)\|_{H^2\times H^1}$ by tE_0 and $E_1(0)$ directly from Lemmas 3.1 and 3.3. We are done. □

IV. THE MAXWELL–HIGGS LIMIT

We recall the Lagrangian of Maxwell–Chern–Simons–Higgs system is

$$\mathcal{L} = -\frac{1}{4} F^{\mu\nu} F_{\mu\nu} + \frac{\kappa}{4} \epsilon^{\mu\nu\rho} F_{\mu\nu} A_\rho + D_\mu \phi \overline{D^\mu \phi} + \frac{1}{2} \partial_\mu N \partial^\mu N - \frac{1}{2}(e|\phi|^2 + \kappa N - ev^2)^2 - e^2 N^2 |\phi|^2, \tag{28}$$

and observe that setting $N=0$, $\kappa=0$ into the above formally, (28) becomes the Lagrangian of the well-known Maxwell–Higgs model,

$$\mathcal{L} = -\tfrac{1}{4} F^{\mu\nu} F_{\mu\nu} + D_\mu \phi \overline{D^\mu \phi} - \tfrac{1}{2} e^2 (|\phi|^2 - v^2)^2,$$

as was mentioned in Sec. I. We rigorously verify this connection between the two models by proving the convergence result as follows. In the case $\kappa=0$, the Euler–Lagrange equations of (28) are written by

$$\begin{aligned} \Box A_0 &= -2e \,\mathrm{Im}(\phi \overline{D_0 \phi}), \\ \Box A_i &= -2e \,\mathrm{Im}(\phi \overline{D_i \phi}), \\ \Box \phi &= 2ieA_0 \partial_0 \phi - 2ieA_j \partial_j \phi - e^2 A_j^2 \phi + e^2 A_0^2 \phi - (e|\phi|^2 - ev^2)\phi - eN^2 \phi, \\ \Box N &= -2e^2 N |\phi|^2, \end{aligned} \tag{29}$$

with given initial data $A_\mu(0,x)$, $\phi(0,x)$, $N(0,x)$, $\partial_0 A_\mu(0,x)$, $\partial_0 \phi(0,x)$, $\partial_0 N(0,x)$ satisfying

$$\begin{aligned} \partial_\mu A^\mu &= 0, \\ \Delta A_0 - \partial_j \partial_0 A_j - 2e \,\mathrm{Im}(\phi \overline{D_0 \phi}) &= 0. \end{aligned} \tag{30}$$

In particular, if we set $N(0,x) = \partial_0 N(0,x) = 0$, we have

$$\|N(t)\|_{H^2\times H^1} \leqslant \int_0^t C(s) \|N(s)\|_{H^1} ds,$$

applying the energy estimate to the equation for N of (29), where we use $\|u(t)\|_{H^2\times H^1}\leqslant C(t)$. Then, by Gronwall's inequality we obtain $N(t)=0$ in any finite time.

Theorem 4.1 (Maxwell–Higgs limit): *Consider the topological case of Maxwell–Chern–Simons–Higgs systems. Let u^κ be the global solution of (9) with coupling constant κ of $H^2\times H^1$ initial data u_0^κ and let u be the global solution of (29) of $H^2\times H^1$ initial data u_0. Let us suppose that $u_0^\kappa\to u_0$ in $H^2\times H^1$. Then, $\|u^\kappa(t)-u(t)\|_{H^2\times H^1}\to 0$ as $\kappa\to 0$ uniformly on any finite time interval.*

Proof: From (9) and (29) we write the equations satisfied by $u^\kappa-u$ in the form

$$\begin{aligned}
&\Box(A_0^\kappa-A_0)=-\kappa F_{12}^\kappa-2e\ \mathrm{Im}(\phi^\kappa\overline{D_0\phi^\kappa}-\phi\overline{D_0\phi}),\\
&\Box(A_i^\kappa-A_i)=\kappa\epsilon^{ij}F_{0j}^\kappa-2e\ \mathrm{Im}(\phi^\kappa\overline{D_i\phi^\kappa}-\phi\overline{D_i\phi}),\\
&\Box(\varphi^\kappa-\varphi)=2ie(A_0^\kappa\partial_0\phi^\kappa-A_0\partial_0\phi)-2ie(A_j^\kappa\partial_j\phi^\kappa-A_j\partial_j\phi)-e^2((A_j^\kappa)^2\phi^\kappa-A_j^2\phi)-(U_{\overline{\phi_\kappa}}+U_{\overline{\phi}}),\\
&\Box(N^\kappa-N)=-U_{N^\kappa}+U_N.
\end{aligned}\tag{31}$$

Let $\Delta^\kappa u$ denote $u^\kappa-u$. Then, ignoring subscripts, we get from first two equations of (31),

$$\|\Delta^\kappa A(t)\|_{H^2\times H^1}\leqslant\|\Delta^\kappa u_0\|_{H^2\times H^1}+C\int_0^t\kappa\|F^\kappa\|_{H^1}+\|\phi^\kappa\Delta^\kappa\psi\|_{L^2}+\|\psi\Delta^\kappa\phi\|_{H^1}ds.$$

Noting

$$\begin{aligned}
&\Delta^\kappa\phi=\Delta^\kappa\varphi,\\
&\Delta^\kappa\psi=D\Delta^\kappa\varphi=\partial\Delta^\kappa\varphi+A\Delta^\kappa\varphi,\\
&\partial\Delta^\kappa\psi=\partial^2\Delta^\kappa\varphi+\partial A\cdot\Delta^\kappa\varphi+A\partial\Delta^\kappa\varphi,
\end{aligned}$$

we obtain

$$\begin{aligned}
&\|\Delta^\kappa\phi\|_{L^4}\leqslant\|\Delta^\kappa u\|_{H^1},\\
&\|\Delta^\kappa\psi\|_{L^4}\leqslant\|\Delta^\kappa u\|_{L^4}+\|A\|_{L^\infty}\|u\|_{L^4}\leqslant\|u\|_{H^2}+\|u\|_{H^2}\|\Delta^\kappa u\|_{H^1}.
\end{aligned}\tag{32}$$

We already know that $\sup_{0\leqslant\kappa\leqslant 1}\|u^\kappa(t)\|_{H^2\times H^1}$ is bounded by a smooth function of t in the proof of Theorem 3.4. Replacing all $\|u^\kappa(t)\|_{H^2}$ terms with $C(t)$ and using (32), we get

$$\|\Delta^\kappa A\|_{H^2\times H^1}\leqslant\|\Delta^\kappa u_0\|_{H^2\times H^1}+C(t)\left(\kappa+\int_0^t\|\Delta^\kappa u(s)\|_{H^2}ds\right).$$

Similarly, we estimate $\|\Delta^\kappa\varphi\|_{H^2\times H^1}$, $\|\Delta^\kappa N\|_{H^2\times H^1}$. Thus we have

$$\|\Delta^\kappa u(t)\|_{H^2\times H^1}\leqslant\|\Delta^\kappa u_0\|_{H^2\times H^1}+C(t)\left(\kappa+\int_0^t\|\Delta^\kappa u(s)\|_{H^2}ds\right).\tag{33}$$

Applying Gronwall's inequality to the above, we obtain

$$\|(u^\kappa-u)(t)\|_{H^2\times H^1}\leqslant\kappa C(t)+\|u_0^\kappa-u_0\|_{H^2\times H^1},\tag{34}$$

thus

$$\|(u^\kappa-u)(t)\|_{H^2\times H^1}\to 0\ \text{ uniformly with respect to }\ t\tag{35}$$

as $\kappa \to 0$. If we set $u_0=(A,\varphi,0), \partial_0 u_0=(\partial_0 A, \partial_0 \varphi, 0)$, we deduce from (35) that $(A^\kappa, \varphi^\kappa, N^\kappa)$ converges to $(A,\varphi,0)$ such that $(A,\varphi+\lambda)$ is the finite energy solution of the Maxwell–Higgs system with

$$(A,\varphi) \in C([0,\infty);H^s(\mathbf{R}^2)) \cap C^1([0,\infty);H^1(\mathbf{R}^2)).$$

We complete the proof of Theorem 4.1. □

Scale invariant Euclidean field theory in any dimension

Z. Haba[a)]

(Received 4 June 2002; accepted 17 July 2002)

We discuss a D-dimensional scalar field interacting with a metric field. The metric depends on d-dimensional coordinates (where $d<D$). We choose formal Gaussian scale invariant correlation functions for the metric field. By a projection to a lower dimensional subspace we obtain a scale invariant non-Gaussian model of Euclidean quantum field theory in $D-d$ or d dimensions. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1510971]

I. INTRODUCTION

We consider a new method of a construction of Euclidean fields. A scalar field in D dimensions is interacting with a metric depending on d-dimensional coordinates. An averaging over the metric and a projection of the scalar field to an s-dimensional subspace leads to a scalar field which is Euclidean invariant in R^s (we consider $s=D-d$ and $s=d$). If the metric field is scale invariant with a scaling dimension 2γ, then the scalar field is also scale invariant with a scaling dimension depending on γ. We discuss two models for the random metric. In the first model we consider a square of a Gaussian random field. We are unable to derive an upper bound for correlation functions in this model. Then, we consider formal scale invariant Gaussian correlation functions for the metric field. Such correlation functions do not arise from any rigorous functional integral. We treat the Gaussian averaging as a tool for constructing models. We obtain scale invariant correlation functions of a scalar field with explicit upper and lower bounds. Our primary interest in this class of models[1,2] comes from quantum gravity. However, the method may be useful for a construction of relativistic quantum fields (although at the moment we are unable to prove the crucial Osterwalder–Schrader positivity[3]). The model can be interesting for statistical physics as a continuum version of spin glass models.[4]

II. *D*-DIMENSIONAL SCALAR FIELDS

We consider a complex scalar matter field Φ in D dimensions interacting with a metric varying only on a d-dimensional submanifold. We split the coordinates as $x=(X,\mathbf{x})$ with $\mathbf{x}\in R^d$. Without a self-interaction the $\Phi\Phi^*$ correlation function averaged over the metric is denoted by

$$\langle \mathcal{A}^{-1}(x,y)\rangle, \tag{1}$$

where

$$-\mathcal{A}=\frac{1}{2}\sum_{\mu=0,\nu=0}^{D-d-1} g^{\mu\nu}(\mathbf{x})\partial_\mu\partial_\nu+\frac{1}{2}\sum_{k=D-d}^{D-1}\partial_k^2. \tag{2}$$

In Eq. (2) $-2\mathcal{A}$ is the Laplace–Beltrami operator on a D-dimensional manifold with a trivial unit metric on the d-dimensional submanifold. In order to calculate the average (1) we repeat some steps of Refs. 1 and 2. We represent the Green's function by means of the proper time method

a)Electronic mail: zhab@ift.uni.wroc.pl

$$\mathcal{A}^{-1}(x,y)=\int_0^\infty d\tau(\exp(-\tau\mathcal{A}))(x,y). \tag{3}$$

For a calculation of $(\exp(\tau\mathcal{A}))(x,y)$ we apply the functional integral

$$K_\tau(x,y)=(\exp(-\tau\mathcal{A}))(x,y)$$
$$=\int \mathcal{D}x\exp\left(-\frac{1}{2}\int\frac{d\mathbf{x}}{dt}\frac{d\mathbf{x}}{dt}-\frac{1}{2}\int g^{\mu\nu}(\mathbf{x})\frac{dX_\mu}{dt}\frac{dX_\nu}{dt}\right)\delta(x(0)-x)\,\delta(x(\tau)-y). \tag{4}$$

In the functional integral (4) we make a change of variables $(x\to b)$ determined by Stratonovitch stochastic differential equations[5]

$$dx^\Omega(s)=e_A^\Omega(x(s))db^A(s), \tag{5}$$

where for $\Omega=0,1,\ldots,D-d-1$,

$$e_a^\mu e_a^\nu=g^{\mu\nu}$$

and $e_A^\Omega=\delta_A^\Omega$ if $\Omega>D-d-1$.

After such a change of variables the functional integral in Eq. (4) becomes Gaussian. In fact, this is the standard Wiener integral and $b_A(t)$ for each A are independent Brownian motions

$$E[b_A(t)b_C(s)]=\delta_{AC}\min(s,t).$$

The solution q_τ of Eq. (5) consists of two vectors $(\mathbf{Q},\mathbf{q})$ where

$$\mathbf{q}(\tau,\mathbf{x})=\mathbf{x}+\mathbf{b}(\tau) \tag{6}$$

and $\mathbf{Q}$ has the components (for $\mu=0,\ldots,D-d-1$)

$$Q^\mu(\tau,\mathbf{X})=X^\mu+\int_0^\tau e_a^\mu(\mathbf{q}(s,\mathbf{x}))dB^a(s). \tag{7}$$

The kernel is

$$K_\tau(x,y)=E[\delta(y-q_\tau(x))]=E\left[\delta(\mathbf{y}-\mathbf{x}-\mathbf{b}(\tau))\prod_\mu\delta(Y_\mu-Q_\mu(\tau,X))\right].$$

Using Eq. (7) and the Fourier representation of the δ-function we write the kernel K_τ in the form

$$K_\tau(x,y)=(2\pi)^{-D+d}\int d\mathbf{P}\exp(i\mathbf{P}(\mathbf{Y}-\mathbf{X}))$$
$$\times E\left[\delta(\mathbf{y}-\mathbf{x}-\mathbf{b}(\tau))\exp\left(-i\int P_\mu e_a^\mu(\mathbf{q}(s,\mathbf{x}))dB^a(s)\right)\right]. \tag{8}$$

We may choose a Gaussian field as a model for the tetrad in order to perform the averaging in Eq. (1) (as we did in Ref. 1):

$$\langle e_a^\mu(\mathbf{x})e_b^\nu(\mathbf{y})\rangle=\Gamma_{ab}^{\mu\nu}(\mathbf{x}-\mathbf{y})=\alpha_{ab}^{\mu\nu}|\mathbf{x}-\mathbf{y}|^{-2\gamma}, \tag{9}$$

where α is a scale invariant tensor. Then

$$\langle K_\tau(x,y)\rangle=(2\pi)^{-D+d}\int d\mathbf{P}\exp(i\mathbf{P}(\mathbf{Y}-\mathbf{X}))$$
$$\times E\left[\delta(\mathbf{y}-\mathbf{x}-\sqrt{\tau}\mathbf{b}(1))\exp\left(-\tau^{1-\gamma}P_\mu P_\nu\int_0^1 dB^a(s)\int_0^s dB^c(s')\Gamma^{\mu\nu}_{ac}(\mathbf{b}(s)-\mathbf{b}(s'))\right)\right], \tag{10}$$

where we have changed the time $s\to\tau s$, and used the equivalence $b(\tau s)=\sqrt{\tau}b(s)$ and the scale invariant form of the two-point function (9). Moreover, we renormalized the kernel K_τ removing from it the term (see Refs. 1 and 6)

$$\exp(-\tfrac{1}{2}\tau\Gamma^{\mu\nu}_{aa}(0)P_\mu P_\nu).$$

It can be seen that this procedure is equivalent to the normal ordering of the metric as a square of the tetrad

$$g^{\mu\nu}(x)=e^\mu_a(x)e^\nu_a(x)\to:e^\mu_a(x)e^\nu_a(x):=e^\mu_a(x)e^\nu_a(x)-\langle e^\mu_a(x)e^\nu_a(x)\rangle. \tag{11}$$

We can prove that the double stochastic integral in Eq. (10) is a finite square integrable random variable if $2\gamma<1$. However, it remains unclear whether the momentum integral in Eq. (10) is finite.

We can work without the stochastic integrals (8) if we explicitly integrate over B. The random variables $\mathbf{b}$ and B^a are independent. Hence, using the formula[5]

$$E\left[\exp i\int f_a(\mathbf{q})dB^a\right]=E\left[\exp\left(-\frac{1}{2}\int f_a f_a ds\right)\right],$$

we can rewrite Eq. (8) solely in terms of the metric tensor

$$K_\tau(x,y)=(2\pi)^{-D+d}\int d\mathbf{P}\exp(i\mathbf{P}(\mathbf{Y}-\mathbf{X}))$$
$$\times E\left[\delta(\mathbf{y}-\mathbf{x}-\mathbf{b}(\tau))\exp\left(-\frac{1}{2}\int_0^\tau P_\mu g^{\mu\nu}(\mathbf{q}(s,\mathbf{x}))P_\nu ds\right)\right]. \tag{12}$$

Let $\mathcal{J}$ be the characteristic function of $g^{\mu\nu}$

$$\mathcal{J}(h)=\langle\exp(-\tfrac{1}{2}g(h))\rangle \tag{13}$$

Then, the mean value of the kernel (12) can be expressed in the form

$$\langle K_\tau(x,y)\rangle=(2\pi)^{-D+d}\int d\mathbf{P}\exp(i\mathbf{P}(\mathbf{Y}-\mathbf{X}))$$
$$\times E[\delta(\mathbf{y}-\mathbf{x}-\mathbf{b}(\tau))\mathcal{J}(h)] \tag{14}$$

where $g(h)=\int d\mathbf{z}g^{\mu\nu}(\mathbf{z})h_{\mu\nu}(\mathbf{z})$ and

$$h_{\mu\nu}(\mathbf{z})=P_\mu P_\nu\int_0^\tau\delta(\mathbf{z}-\mathbf{x}-\mathbf{b}(s))ds.$$

If e^μ_a is Gaussian, then $\mathcal{J}$ can be calculated explicitly

$$\langle\exp(-\tfrac{1}{2}g(h))\rangle=\det(1+h\Gamma)^{-1/2}, \tag{15}$$

where on the rhs the renormalization of the determinant [through a multiplication by $\exp(\frac{1}{2}Tr(\Gamma h))$ defining $\det_2$, see Ref. 7 is equivalent to the normal ordering (11) [and subsequently to the renormalization of the kernel (10)].

We consider next another model where the averaging is performed under the assumption that the metric is described by a formal Gaussian field with the two-point correlation function

$$\langle g^{\mu\nu}(\mathbf{x})g^{\sigma\rho}(\mathbf{y})\rangle = -2D^{\mu\nu;\sigma\rho}(\mathbf{x}-\mathbf{y}) = -C^{\mu\nu;\sigma\rho}|\mathbf{y}-\mathbf{x}|^{-4\gamma}, \tag{16}$$

where C (a scale invariant operator) must be positive definite if the momentum integrals in the final formula are to exist. This requirement is not satisfied in a linearized Einstein gravity[8] [e.g., in the transverse-traceless gauge $p_\Omega p_\Gamma g^{\Omega\Gamma}(x)$ would be zero in a covariant D-dimensional gravity; however our gravity is d-dimensional]. Moreover, the averaging cannot be considered as a well-defined functional integral. Concerning the choice of the tensor $C^{\mu\nu;\sigma\rho}$, let us mention that the conformally flat metric $C^{\mu\nu;\sigma\rho}=\delta^{\mu\nu}\delta^{\sigma\rho}$ would be a satisfactory model for our purposes.

The average over g in Eq. (12) can be calculated

$$\langle K_\tau(x,y)\rangle = (2\pi)^{-D+d}\int d\mathbf{P}\exp(i\mathbf{P}(\mathbf{Y}-\mathbf{X})) \times E\left[\delta(\mathbf{y}-\mathbf{x}-\sqrt{\tau}\mathbf{b}(1))\exp\left(-\frac{1}{4}\tau^{2-2\gamma}\int_0^1 P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}(s)-\mathbf{b}(s'))dsds'\right)\right] \tag{17}$$

[as in Eq. (10) we have changed the time $s\to\tau s$]. By a scaling of momenta we can bring the propagator of Eq. (3) to the form

$$\langle \mathcal{A}^{-1}(x,y)\rangle = \int_0^\infty d\tau\tau^{-d/2-(D-d)(1-\gamma)/2}F_2(\tau^{-1/2}(\mathbf{y}-\mathbf{x}),\tau^{-1/2+\gamma/2}(\mathbf{Y}-\mathbf{X})). \tag{18}$$

III. A PROJECTION TO $D-d$ DIMENSIONS

The two-point function (18) has a different scaling behavior in $\mathbf{x}$ and $\mathbf{X}$ directions. We obtain a fixed scaling behavior setting $\mathbf{x}=\mathbf{y}=0$. Then, we have

$$\langle \mathcal{A}^{-1}(x,y)\rangle = R|\mathbf{X}-\mathbf{Y}|^{-D+2-[\gamma/(1-\gamma)](d-2)}, \tag{19}$$

where R is a positive constant. Hence, if all the correlation functions are scale invariant, then

$$\Phi(0,\mathbf{X}) \simeq \lambda^{(D-2)/2+[\gamma/(1-\gamma)](d-2)/2}\Phi(0,\lambda\mathbf{X}), \tag{20}$$

where the equivalence means that both sides have the same correlation functions.

In order to prove that R is finite and not zero we need upper and lower bounds for the Gaussian model (17). We show first that the bilinear form $(f_j,\langle\mathcal{A}^{-1}\rangle f_l)$ is finite and nonzero on a dense set of functions f. For this purpose we choose

$$f_{\mathbf{k}}(\mathbf{X}) = (2\pi a)^{-d/2}\exp\left(-\frac{a}{2}\mathbf{X}^2+i\mathbf{k}\mathbf{X}\right),$$

Then (we keep $\mathbf{x}\neq\mathbf{y}$ in order to show that the model of Sec. 2 is nontrivial; for a scale invariant model of this section $\mathbf{x}=\mathbf{y}=\mathbf{0}$),

$$(f_{\mathbf{k}},\langle\mathcal{A}^{-1}\rangle f_{\mathbf{k}'}) = (2\pi)^{-D+d}\int_0^\infty d\tau\tau^{-d/2}\int d\mathbf{P} \times E\left[\delta\left(\tau^{-1/2}(\mathbf{y}-\mathbf{x})-\mathbf{b}(1)\right) \times\exp\left(-\frac{1}{2a}(\mathbf{P}-\mathbf{k})^2-\frac{1}{2a}(\mathbf{P}-\mathbf{k}')^2 -\frac{1}{4}\tau^{2-2\gamma}\int_0^1 P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}(s)-\mathbf{b}(s'))dsds'\right)\right]. \tag{21}$$

In our estimates we apply Jensen inequalities in the form (for real functions A and f)

$$E[\exp A] \geqslant \exp E[A] \tag{22}$$

and

$$E\left[\exp\left(-\int_0^1 ds ds' f(s,s')\right)\right] \leqslant \int_0^1 ds ds' E[\exp(-f(s,s'))]. \tag{23}$$

An upper bound can be obtained by means of the Jensen inequality (23) expressed in the form

$$\begin{aligned}(f_{\mathbf{k}},\langle \mathcal{A}^{-1}\rangle f_{\mathbf{k}'}) \leqslant 2\int_0^\infty d\tau \int_0^1 ds \int_0^s ds' \int d\mathbf{u}_1 d\mathbf{u}_2 d\mathbf{P} \tau^{-d/2} \\ \times \exp\left(-\frac{1}{2a}(\mathbf{P}-\mathbf{k})^2 - \frac{1}{2a}(\mathbf{P}-\mathbf{k}')^2\right) p(s',\mathbf{u}_1) p(s-s',\mathbf{u}_2-\mathbf{u}_1) \\ \times p(1-s,\tau^{-1/2}(\mathbf{y}-\mathbf{x})-\mathbf{u}_2) \exp\left(-\frac{\tau^{2-2\gamma}}{4} P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{u}_1-\mathbf{u}_2)\right),\end{aligned} \tag{24}$$

where $p(s,\mathbf{u}) = (2\pi s)^{-d/2} \exp(-\mathbf{u}^2/2s)$. We can convince ourselves by means of explicit calculations (using a proper change of variables) that the integral on the rhs of Eq. (24) is finite. For the lower bound it will be useful to introduce the Brownian bridge[9] starting from **0** and ending in **u** defined on the time interval [0,1]

$$\mathbf{a}(\mathbf{u},s) = \mathbf{u}s + \mathbf{c}(s),$$

where **c** is the Gaussian process starting from **0** and ending in **0** with mean equal zero and the covariance

$$E[c_j(s')c_k(s)] = \delta_{jk} s'(1-s)$$

for $s' \leqslant s$. Then, the δ function in Eq. (21) determines the Brownian bridge and the Jensen inequality (22) takes the form

$$\begin{aligned}(f_{\mathbf{k}},\langle \mathcal{A}^{-1}\rangle f_{\mathbf{k}'}) \geqslant (2\pi)^{-D+d} \int_0^\infty d\tau \tau^{-d/2} \int d\mathbf{P} \\ \times \exp\left(-\frac{1}{2a}(\mathbf{P}-\mathbf{k})^2 - \frac{1}{2a}(\mathbf{P}-\mathbf{k}')^2 \right. \\ - \frac{1}{4}\tau^{2-2\gamma} \int_0^1 P_\mu P_\sigma P_\nu P_\rho E[D^{\mu\nu;\sigma\rho}(\mathbf{a}(\tau^{-1/2}\mathbf{y} - \tau^{-1/2}\mathbf{x}, s) - \mathbf{a}(\tau^{-1/2}\mathbf{y} \\ \left. - \tau^{-1/2}\mathbf{x}, s'))ds ds']\right),\end{aligned} \tag{25}$$

where the expectation value in the exponential on the rhs of Eq. (25) is equal to

$$\begin{aligned}\int d\mathbf{u} \int ds \int_0^s ds' (2\pi\omega(s,s'))^{-d/2} \exp\left(-\frac{1}{2\omega(s,s')}\mathbf{u}^2\right) \\ \times |\mathbf{u} - \tau^{-1/2} s(\mathbf{y}-\mathbf{x}) + \tau^{-1/2} s'(\mathbf{y}-\mathbf{x})|^{-4\gamma},\end{aligned} \tag{26}$$

where $\omega(s,s')=(s-s')(1-s+s')$. It is finite if $\gamma<\frac{1}{2}$ [the form (16) of the graviton two-point function is assumed].

We compute now higher order correlation functions in the Gaussian model,

$$\begin{aligned}
&\langle\Phi(x)\Phi(x')\Phi^*(y)\Phi^*(y')\rangle\\
&\quad=\langle\mathcal{A}^{-1}(x,y)\mathcal{A}^{-1}(x',y')\rangle+(x\to x')\\
&\quad=(2\pi)^{-2D+2d}\int d\tau_1 d\tau_2\int d\mathbf{P}d\mathbf{P}'\exp(i\mathbf{P}(\mathbf{Y}-\mathbf{X})+i\mathbf{P}'(\mathbf{Y}'-\mathbf{X}'))\\
&\qquad\times E\Big[\delta(\mathbf{y}-\mathbf{x}-\mathbf{b}(\tau_1))\,\delta(\mathbf{y}'-\mathbf{x}'-\mathbf{b}'(\tau_2))\\
&\qquad\times\exp\Big(-\frac{1}{4}\int_0^{\tau_1}\int_0^{\tau_1}P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}(s)-\mathbf{b}(s'))dsds'\\
&\qquad-\frac{1}{4}\int_0^{\tau_2}\int_0^{\tau_2}P'_\mu P'_\sigma P'_\nu P'_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}'(s)-\mathbf{b}'(s'))dsds'\\
&\qquad-\frac{1}{2}\int_0^{\tau_1}\int_0^{\tau_2}P_\mu P_\nu P'_\rho P'_\sigma D^{\mu\nu;\sigma\rho}(\mathbf{x}-\mathbf{x}'+\mathbf{b}(s)-\mathbf{b}'(s'))dsds'\Big)\Big]+(x\to x'),
\end{aligned}\tag{27}$$

where $(x\to x')$ means the same expression in which x is exchanged with x'. The fourlinear form (27) calculated on the basis f reads

$$\begin{aligned}
&\langle\Phi(f_{\mathbf{k}_1})\Phi(f_{\mathbf{k}_3})\Phi^*(f_{\mathbf{k}_2})\Phi^*(f_{\mathbf{k}_4})\rangle\\
&\quad=(2\pi)^{-2D+2d}\int d\tau_1 d\tau_2\int d\mathbf{P}d\mathbf{P}'E\Big[\delta(\mathbf{y}-\mathbf{x}-\mathbf{b}(\tau_1))\,\delta(\mathbf{y}'-\mathbf{x}'-\mathbf{b}'(\tau_2))\\
&\qquad\times\exp\Big(-\frac{1}{2a}(\mathbf{P}-\mathbf{k}_1)^2-\frac{1}{2a}(\mathbf{P}-\mathbf{k}_2)^2-\frac{1}{2a}(\mathbf{P}'-\mathbf{k}_3)^2-\frac{1}{2a}(\mathbf{P}'-\mathbf{k}_4)^2\Big)\\
&\qquad\times\exp\Big(-\frac{1}{4}\int_0^{\tau_1}\int_0^{\tau_1}P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}(s)-\mathbf{b}(s'))dsds'\\
&\qquad-\frac{1}{4}\int_0^{\tau_2}\int_0^{\tau_2}P'_\mu P'_\sigma P'_\nu P'_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}'(s)-\mathbf{b}'(s'))dsds'\\
&\qquad-\frac{1}{2}\int_0^{\tau_1}\int_0^{\tau_2}P_\mu P_\nu P'_\rho P'_\sigma D^{\mu\nu;\sigma\rho}(\mathbf{x}-\mathbf{x}'+\mathbf{b}(s)-\mathbf{b}'(s'))dsds'\Big)\Big]\\
&\qquad+(1,2\to 3,4),
\end{aligned}\tag{28}$$

where the last term means the same expression with exchanged wave numbers. We introduce the spherical coordinates on the (τ_1,τ_2)-plane $\tau_1=r\cos\theta$ and $\tau_2=r\sin\theta$. Let us rescale the momenta $\mathbf{k}=\mathbf{p}\sqrt{r}$, $\mathbf{k}'=\mathbf{p}'\sqrt{r}$, $\mathbf{K}=\mathbf{P}r^{1/2-\gamma/2}$ and $\mathbf{K}'=\mathbf{P}'r^{1/2-\gamma/2}$. Then, we can see that the four-point function (27) takes the form

$$\langle \Phi(x)\Phi(x')\Phi^*(y)\Phi^*(y')\rangle = \int d\theta dr r r^{-d-(1-\gamma)(D-d)} F_4(\theta, r^{-1/2}(\mathbf{x}-\mathbf{y}), r^{-1/2}(\mathbf{x}'-\mathbf{y}'), r^{-1/2}(\mathbf{x}'-\mathbf{x}), r^{-1/2}(\mathbf{x}'-\mathbf{y}), r^{-1/2}(\mathbf{y}'-\mathbf{x}), r^{-1/2+\gamma/2}(\mathbf{X}-\mathbf{Y}), r^{-1/2+\gamma/2}(\mathbf{X}'-\mathbf{Y}'), r^{-1/2+\gamma/2}(\mathbf{X}'-\mathbf{Y}), r^{-1/2+\gamma/2}(\mathbf{X}-\mathbf{Y}')). \tag{29}$$

It follows just by scaling of coordinates [the r-integral scales as twice the τ-integral in Eq. (18)] that at $\mathbf{x}=\mathbf{x}'=\mathbf{y}=\mathbf{y}'=0$ the correlations are scale invariant with the same scaling dimension as in Eq. (20).

It is clear from Eq. (28) that in the same way as we did it in Eqs. (24) and (25) we can obtain finite upper and lower bounds on the correlation functions (28) by means of the Jensen inequalities.

We could continue with higher order correlation functions. Again through an introduction of spherical coordinates in the $(\tau_1,\ldots,\tau_3)$ space we can show that

$$\langle \Phi(x_1)\ldots\Phi(x_3)\Phi^*(y_1)\ldots\Phi^*(y_3)\rangle \tag{30}$$

scales with the same dimension as in Eq. (20). The scaling of higher order correlation functions is now evident. We introduce the spherical coordinates for the τ-integrals. The resulting scaling is a consequence of the fact that the τ-volume and $\mathbf{P}$ integrals have the scaling dimensions proportional to the order of the correlation function.

IV. A PROJECTION TO *d* DIMENSIONS

There is still another option that we let all $X=Y=0$. In such a case

$$\langle K_\tau(\mathbf{x},\mathbf{y})\rangle = (2\pi)^{-D+d}\int d\mathbf{P} E\left[\delta(\mathbf{y}-\mathbf{x}-\sqrt{\tau}\mathbf{b}(1)) \times \exp\left(-\frac{1}{4}\tau^{2-2\gamma}\int_0^1 P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}(s)-\mathbf{b}(s'))dsds'\right)\right]. \tag{31}$$

By a scaling of momenta we can bring the propagator of Eq. (3) to the form

$$\langle \mathcal{A}^{-1}(x,y)\rangle = \int_0^\infty d\tau \tau^{-d/2-(D-d)(1-\gamma)/2} F_2(\tau^{-1/2}(\mathbf{y}-\mathbf{x})). \tag{32}$$

Hence

$$\langle \mathcal{A}^{-1}(\mathbf{x},\mathbf{y})\rangle = R|\mathbf{x}-\mathbf{y}|^{-d+2-(D-d)(1-\gamma)}, \tag{33}$$

where R is a positive constant. Hence, if all the correlation functions are scale invariant, then

$$\Phi(\mathbf{x},0) \simeq \lambda^{(d-2)/2+(D-d)(1-\gamma)/2}\Phi(\lambda\mathbf{x},0). \tag{34}$$

We can prove all the inequalities of Sec. III in this model. So, the upper bound for the two-point function reads

$$|\langle \mathcal{A}^{-1}(\mathbf{x},\mathbf{y})\rangle| \leqslant 2\int_0^\infty d\tau \int_0^1 ds \int_0^s ds' \int d\mathbf{u}_1 d\mathbf{u}_2 d\mathbf{P} \tau^{-d/2} p(s',\mathbf{u}_1) p(s-s',\mathbf{u}_2-\mathbf{u}_1)$$
$$\times p(1-s,\tau^{-1/2}(\mathbf{y}-\mathbf{x})-\mathbf{u}_2)\exp\left(-\frac{\tau^{2-2\gamma}}{4} P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{u}_1-\mathbf{u}_2)\right). \tag{35}$$

The lower bound takes the form

$$|\langle \mathcal{A}^{-1}(\mathbf{x},\mathbf{y})\rangle| \geqslant (2\pi)^{-D+d}\int_0^\infty d\tau \tau^{-d/2}\int d\mathbf{P}$$
$$\times \exp\left(-\frac{1}{4}\tau^{2-2\gamma}\int_0^1 P_\mu P_\sigma P_\nu P_\rho E[D^{\mu\nu;\sigma\rho}(\mathbf{a}(\tau^{-1/2}\mathbf{y}-\tau^{-1/2}\mathbf{x},s)\right.$$
$$\left.-\mathbf{a}(\tau^{-1/2}\mathbf{y}-\tau^{-1/2}\mathbf{x},s'))dsds']\right), \tag{36}$$

where the expectation value in the exponential on the rhs of Eq. (36) is equal to

$$\int d\mathbf{u}\int ds\int_0^s ds'(2\pi\omega(s,s'))^{-d/2}\exp\left(-\frac{1}{2\omega(s,s')}\mathbf{u}^2\right)$$
$$\times|\mathbf{u}-\tau^{-1/2}s(\mathbf{y}-\mathbf{x})+\tau^{-1/2}s'(\mathbf{y}-\mathbf{x})|^{-4\gamma}, \tag{37}$$

where $\omega(s,s')=(s-s')(1-s+s')$. It is finite if $\gamma<\frac{1}{2}$. The bounds (35) and (36) in fact have the form

$$R_1 \leqslant |\mathbf{x}-\mathbf{y}|^{d-2+(D-d)(1-\gamma)}\langle \mathcal{A}^{-1}(\mathbf{x},\mathbf{y})\rangle \leqslant R_2 \tag{38}$$

with certain positive R_1 and R_2.

The inequalities (38) can be proved from the inequlities (35) and (36) just by rescaling of variables. It is more tedious to show that the constants R_1 and R_2 are finite and not zero (but the estimates reduce to finite dimensional integrals and are straightforward).

We can project now to R^d higher order correlation functions:

$$\langle \Phi(\mathbf{x})\Phi(\mathbf{x}')\Phi^*(\mathbf{y})\Phi^*(\mathbf{y}')\rangle = \langle \mathcal{A}^{-1}(\mathbf{x},\mathbf{y})\mathcal{A}^{-1}(\mathbf{x}',\mathbf{y}')\rangle + (\mathbf{x}\to\mathbf{x}')$$
$$= (2\pi)^{-2D+2d}\int d\tau_1 d\tau_2 \int d\mathbf{P}d\mathbf{P}' E\left[\delta(\mathbf{y}-\mathbf{x}-\mathbf{b}(\tau_1))\,\delta(\mathbf{y}'-\mathbf{x}'\right.$$
$$-\mathbf{b}'(\tau_2))\exp\left(-\frac{1}{4}\int_0^{\tau_1}\int_0^{\tau_1} P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}(s)\right.$$
$$-\mathbf{b}(s'))dsds' - \frac{1}{4}\int_0^{\tau_2}\int_0^{\tau_2} P'_\mu P'_\sigma P'_\nu P'_\rho D^{\mu\nu;\sigma\rho}(\mathbf{b}'(s)$$
$$-\mathbf{b}'(s'))dsds' - \frac{1}{2}\int_0^{\tau_1}\int_0^{\tau_2} P_\mu P_\nu P'_\rho P'_\sigma D^{\mu\nu;\sigma\rho}(\mathbf{x}-\mathbf{x}'+\mathbf{b}(s)$$
$$\left.\left.-\mathbf{b}'(s'))dsds'\right)\right] + (x\to x'), \tag{39}$$

where $(x\to x')$ means the same expression in which x is exchanged with x'. We introduce the spherical coordinates on the (τ_1,τ_2)-plane $\tau_1=r\cos\theta$, $\tau_2=r\sin\theta$ and we rescale the momenta $\mathbf{k}=\mathbf{p}\sqrt{r}$, $\mathbf{k}'=\mathbf{p}'\sqrt{r}$, $\mathbf{K}=\mathbf{P}r^{1/2-\gamma/2}$. Then, we can see that the four-point function (39) takes the form

$$\langle\Phi(\mathbf{x})\Phi(\mathbf{x}')\Phi^*(\mathbf{y})\Phi^*(\mathbf{y}')\rangle = \int d\theta dr r r^{-d-(1-\gamma)(D-d)} F_4(\theta, r^{-1/2}(\mathbf{x}-\mathbf{y}), r^{-\frac{1}{2}}(\mathbf{x}'-\mathbf{y}'), r^{-1/2}(\mathbf{x}'-\mathbf{x}), r^{-1/2}(\mathbf{x}'-\mathbf{y}), r^{-1/2}(\mathbf{y}'-\mathbf{x})). \tag{40}$$

The upper bound now reads

$$\begin{aligned}
&|\langle\Phi(\mathbf{x})\Phi(\mathbf{x}')\Phi^*(\mathbf{y})\Phi^*(\mathbf{y}')\rangle| \\
&\leqslant 2(2\pi)^{-2D+2d}\int d\tau_1 d\tau_2 \int_0^1 ds \int_0^s ds' \int d\mathbf{P} d\mathbf{P}' E\Big[\delta(\mathbf{y}-\mathbf{x}-\sqrt{\tau_1}\mathbf{b}(1)) \\
&\quad\times\delta(\mathbf{y}'-\mathbf{x}'-\sqrt{\tau_2}\mathbf{b}'(1)) \\
&\quad\times\exp\Big(-\frac{\tau_1^2}{4}P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\sqrt{\tau_1}\mathbf{b}(s)-\sqrt{\tau_1}\mathbf{b}(s')) \\
&\quad-\frac{\tau_2^2}{4}P'_\mu P'_\sigma P'_\nu P'_\rho D^{\mu\nu;\sigma\rho}(\sqrt{\tau_2}\mathbf{b}'(s)-\sqrt{\tau_2}\mathbf{b}'(s')) \\
&\quad-\frac{\tau_1\tau_2}{2}P_\mu P_\nu P'_\rho P'_\sigma D^{\mu\nu;\sigma\rho}(\mathbf{x}-\mathbf{x}'+\sqrt{\tau_1}\mathbf{b}(s)-\sqrt{\tau_2}\mathbf{b}'(s'))\Big)\Big] \\
&\quad+(\mathbf{x}\to\mathbf{x}').
\end{aligned} \tag{41}$$

The expectation value (41) can be expressed by the transition functions (as usual for the Wiener process). The bound is scale invariant and the scale invariant function on the rhs could be calculated explicitly. The lower bound takes the form

$$\begin{aligned}
&\langle\Phi(\mathbf{x})\Phi(\mathbf{x}')\Phi^*(\mathbf{y})\Phi^*(\mathbf{y}')\rangle \\
&\geqslant(2\pi)^{-2D+2d}\int d\tau_1 d\tau_2 \int d\mathbf{P} d\mathbf{P}' \\
&\quad\times\exp\Big(-E\Big[\frac{1}{4}\int_0^{\tau_1}\int_0^{\tau_1} P_\mu P_\sigma P_\nu P_\rho D^{\mu\nu;\sigma\rho}(\mathbf{a}(s)-\mathbf{a}(s'))dsds' \\
&\quad+\frac{1}{4}\int_0^{\tau_2}\int_0^{\tau_2} P'_\mu P'_\sigma P'_\nu P'_\rho D^{\mu\nu;\sigma\rho}(\mathbf{a}'(s)-\mathbf{a}'(s'))dsds' \\
&\quad+\frac{1}{2}\int_0^{\tau_1}\int_0^{\tau_2} P_\mu P_\nu P'_\rho P'_\sigma D^{\mu\nu;\sigma\rho}(\mathbf{a}(s)-\mathbf{a}'(s'))dsds'\Big]\Big)+(\mathbf{x}\to\mathbf{x}').
\end{aligned} \tag{42}$$

Here

$$\mathbf{a}(s)=\mathbf{x}+(\mathbf{y}-\mathbf{x})\frac{s}{\tau_1}+\sqrt{\tau_1}\mathbf{c}\Big(\frac{s}{\tau_1}\Big)$$

and

$$\mathbf{a}'(s)=\mathbf{x}'+(\mathbf{y}'-\mathbf{x}')\frac{s}{\tau_2}+\sqrt{\tau_2}\mathbf{c}'\Big(\frac{s}{\tau_2}\Big).$$

In the exponential of the formula (42) we have the expectation over three Gaussian processes. The first is with the mean $(\mathbf{y}-\mathbf{x})(s-s')/\tau_1$ and the covariance $(s-s')(\tau_1-s+s')/\tau_1$, the second has the mean $(\mathbf{y}'-\mathbf{x}')(s-s')/\tau_2$ and the covariance $(s-s')(\tau_2-s+s')/\tau_2$, and the third has the

mean $\mathbf{x}-\mathbf{x}'+(\mathbf{y}-\mathbf{x})s/\tau_1-(\mathbf{y}'-\mathbf{x}')s'/\tau_2$ and the covariance $s(\tau_1-s)/\tau_1+s'(\tau_2-s')/\tau_2$. The lower bound can be explicitly calculated and is given by a scale invariant function. It is clear how to calculate the higher order scale invariant functions and their scale invariant lower and upper bounds.

V. DISCUSSION

The model discussed in Sec. III is invariant under Euclidean rotations in $D-d$ dimensions. Euclidean fields with the Osterwalder–Schrader positivity cannot be more regular than the free field (this follows from the Källen–Lehman representation). In D dimensions the short distance behavior of the correlation functions (18) is more regular than the one of the free fields. However, after setting all $\mathbf{x}=0$, the behavior is more singular than the canonical one in $D-d$ dimensions. For the model (11) where the metric is a square of a Gaussian field we can suggest a lattice model whose formal continuum limit coincides with the scale invariant Euclidean field theory. The simplest possibility is to take the conformally flat metric placed on a sublattice just between the lattice sites of the scalar field (as the gauge fields in Ref. 10). The model (11) could be reflection positive (reflection positivity of lattice spin models is discussed in Ref. 11, reflection positivity of lattice versions of generalized free fields is shown in Ref. 12). However, models of the type (11) require the Wick normal ordering. After this renormalization the finiteness of the τ-integral (3) and the **P** integral (10) is doubtful. However, (if finite) the continuum limit and the subsequent analytic continuation to Minkowski space would give a model of relativistic quantum field theory satisfying all Wightman axioms. The Wick square of a Gaussian field is an example of an infinitely divisible field.[13] An infinitely divisible field can take non-negative values. Its characteristic function has an explicit integral representation. Such a field can be a good candidate for a random metric.

The models of Sec. IV are more promising. The lattice version of the Lagrangian

$$L=g^{\mu\nu}(\mathbf{x})\frac{\partial}{\partial X^{\mu}}\Phi\frac{\partial}{\partial X^{\nu}}\Phi^*+\nabla_{\mathbf{x}}\Phi\nabla_{\mathbf{x}}\Phi^*$$

will have the form $-L=F+\theta F+M\theta M$ where θ is the reflection in the plane perpendicular to one of the coordinates $\mathbf{x}$ (which will be chosen as time). This representation holds true because the random metric does not mix the temporal coordinates in $\nabla_{\mathbf{x}}\Phi\nabla_{\mathbf{x}}\Phi^*$. Then, the reflection positivity results (see Ref. 11). In the lattice approximation we have to replace the (formal) Gaussian measure with a negative definite covariance (16) by a non-Gaussian measure on the metrics which has a formal Gaussian limit (e.g., replacing $\frac{1}{2}x^2$ by $1-\cos x$). There remains to be proven that such a lattice approximation is convergent to the continuum. Without such a proof the Gaussian averaging discussed in this article must be considered solely as a formal tool for a construction of scale invariant Euclidean field theories whose relevance for a quantum field theory in the Minkowski space remains obscure.

(Received 26 February 2002; accepted 2 July 2002)

As a preliminary to discussing the quantization of the foliation in a history form of general relativity, we show how the discussion in an earlier work [J. Math. Phys. **43**, 3053 (2002)] of a history version of free, scalar quantum field theory can be augmented in such a way as to include the quantization of the unit-length, timelike vector that determines a Lorentzian foliation of Minkowski space–time. We employ a Hilbert bundle construction that is motivated by (*i*) discussing the role of the external Lorentz group in the existing history quantum field theory [J. Math. Phys. **43**, 3053 (2002)] and (*ii*) considering a specific representation of the extended history algebra obtained from the multi-symplectic representation of scalar field theory. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1507605]

I. INTRODUCTION

The goal of the present article is to extend the discussion in Ref. 1 of the construction of a history version of quantum scalar field theory in Minkowski space–time. In particular, we shall show how the formalism can be developed to include the quantization of the four-vector n that determines the space–time foliation that plays a central role in the theory. The motivation for such a step, and the relevant background information, is as follows.

The ''consistent-histories'' approach to quantum theory was originally introduced to provide a novel way of reinterpreting standard quantum theory, particularly in regard to the role played by measurement. However, because of the novel way in which time is handled, consistent-history theory also has the potential for providing new and powerful ways of studying quantum theories of gravity. Most recently, in Ref. 2 the formalism was applied to construct a history version of the canonical form of classical general relativity. The possibility also arises to use this formalism in the context of generalized ideas of time and space: for example, in models where space–time is not represented by a differentiable manifold.

A first step in developing the framework with this goal in mind was taken in Ref. 3 where a new mathematical formalism—the ''History Projection Operator'' (HPO) method—was introduced. This places emphasis on the idea of ''quantum temporal logic,'' and potentially allows substantial generalizations of the notion of time. The heart of this formalism is the idea that propositions about the *temporal history* of a system should be represented by projection operators on a ''history'' Hilbert space. (This is to be contrasted with the situation in standard quantum theory in which projection operators represent propositions about the system at a *single* time.) In the case of simple, Newtonian time, and histories labeled by a finite set of discrete time points, the history Hilbert space is a tensor product of a copy of the standard canonical Hilbert space for each such time point.

The idea of representing history propositions by projection operators lead in turn to the notion of a ''*history group*.'' This is the history analog of the Weyl group and its associated canonical commutation relations; in particular, the spectral projectors of the history operators in the Lie algebra of the history group represent propositions about the associated history quantities.

The introduction of a history group is particularly useful in the context of histories with a

[a]Electronic mail: c.isham@ic.ac.uk
[b]Electronic mail: k.savvidou@ic.ac.uk

continuous time label, since it is by no means a trivial matter to define the continuous analog of a tensor product. Instead, one finds the history Hilbert space by looking for representations of the appropriate history algebra.

For example, for the case of a point particle moving in one dimension, the history algebra for histories labeled with a continuous time parameter t is[4,5]

$$[\hat{x}_t,\hat{x}_{t'}]=0 \tag{1.1}$$

$$[\hat{p}_t,\hat{p}_{t'}]=0, \tag{1.2}$$

$$[\hat{x}_t,\hat{p}_{t'}]=i\hbar\tau\delta(t-t'), \tag{1.3}$$

and the basic history propositions in the theory refer to the value of time-averaged quantities such as $(1/\tau)\int dtx_t f(t)$ and $(1/\tau)\int dtp_t h(t)$ where f and h are smearing functions. Note that, in Eq. (1.3), τ is a new constant in the theory with the dimension of time. The role of this constant is discussed in more detail (following a private communication from Tulsi Dass) in Ref. 6; from now on we shall choose units so that $\tau=1$.

In Eqs. (1.1)–(1.3), the label t on the operators $\hat{x}_t$ and $\hat{p}_t$ refers to the time at which propositions about the system are asserted—the time of ''temporal logic.'' It was to include in an explicit way such a time of temporal logic that the HPO formalism was originally developed. However, a clear notion of dynamics was not implemented for the naturally time-averaged physical quantities of the theory.

A major advance in the HPO formalism took place when time was introduced in a completely new way.[6,7] It was realized that it is natural to consider time in a twofold manner: the ''time of being''—the time at which events ''happen'' [and from this perspective, the time label t in Eqs. (1.1)–(1.3) and in Eq. (1.4) can be regarded as such], and the ''time of becoming''—the time of dynamical change, represented by a time label s. This *second* time appears in the history analog $\hat{x}_t(s)$ of the Heisenberg picture, which is defined as

$$\hat{x}_t(s):=e^{is\hat{H}/\hbar}\hat{x}_t e^{-is\hat{H}/\hbar} \tag{1.4}$$

where $\hat{H}:=\int dt\hat{H}_t$ is the history quantity that represents the time average of the energy of the system. The notion of time evolution is now recovered for the time-averaged physical quantities, for example,

$$\hat{x}_f(s):=e^{is\hat{H}/\hbar}\hat{x}_f e^{-is\hat{H}/\hbar}, \tag{1.5}$$

where $f(t)$ is a smearing function.

Associated with these two manifestations of the concept of time are two types of time transformation: the ''external'' translation

$$\hat{x}_t(s)\mapsto\hat{x}_{t+t'}(s), \tag{1.6}$$

and the ''internal'' translation

$$\hat{x}_t(s)\mapsto\hat{x}_t(s+s'). \tag{1.7}$$

The external time translation is generated by the ''Liouville'' operator[7]

$$\hat{V}:=\int dt\hat{p}_t\frac{d\hat{x}_t}{dt}, \tag{1.8}$$

whereas the internal time translation is generated by the time-averaged energy operator $\hat{H}$.

More importantly, it was shown in Ref. 7 that the generator of time translation in the HPO theory is the "action" operator $\hat{S}$ defined as

$$\hat{S} := \int dt \hat{p}_t \frac{d\hat{x}_t}{dt} - \hat{H} = \hat{V} - \hat{H}. \tag{1.9}$$

Hence the action operator is the generator of *both* types of time translation

$$\hat{x}_t(s) \mapsto \hat{x}_{t+t'}(s+s'). \tag{1.10}$$

It is a very striking result that in the HPO theory the quantum analog of the classical action functional is an actual operator in the formalism, and is the generator of time translations.[7]

The idea of "two times"—and the associated two types of time translation—has recently been generalized to relativistic field theory[1] where, in particular, it is shown that the analog of the two types of time translation is the existence of two *Poincaré* groups. The goal of the present article is to develop the ideas in Ref. 1 in one particular respect: namely, the way in which space–time foliations enter the theory.

That the idea of a Lorentzian space–time foliation should play an important role in a history quantum field theory is understandable. (By "Lorentzian" we mean that each leaf of the foliation is a hyperplane in the Minkowski space–time.) Indeed, the obvious analog of the history algebra Eqs. (1.1)–(1.3) for a quantum scalar field theory is (choosing units from now on such that $\tau = 1$)

$$[{}^n\hat{\phi}(t,\underline{x}), {}^n\hat{\phi}(t',\underline{x}')] = 0, \tag{1.11}$$

$$[{}^n\hat{\pi}(t,\underline{x}), {}^n\hat{\pi}(t',\underline{x}')]) = 0, \tag{1.12}$$

$$[{}^n\hat{\phi}(t,\underline{x}), {}^n\hat{\pi}(t',\underline{x}')] = i\hbar\,\delta(t-t')\,\delta^3(\underline{x}-\underline{x}'), \tag{1.13}$$

where, for each $t \in \mathbb{R}$, the fields ${}^n\hat{\phi}(t,\underline{x})$ and ${}^n\hat{\pi}(t,\underline{x})$ are defined on the spacelike hypersurface characterized by the unit length timelike vector n, and by the foliation parameter t. In particular, the three-vector $\underline{x}$ in ${}^n\hat{\phi}(t,\underline{x})$ or in ${}^n\hat{\pi}(t,\underline{x})$ denotes a vector in this spacelike hypersurface. Note that the pair $(t,\underline{x})$ can be used to identify a unique point X in space–time, and hence to write ${}^n\hat{\phi}(t,\underline{x})$ as ${}^n\hat{\phi}(X)$. The history algebra Eqs. (1.11)–(1.13) can then be written in the more covariant looking form

$$[\hat{\phi}(X), \hat{\phi}(X')] = 0, \tag{1.14}$$

$$[\hat{\pi}(X), \hat{\pi}(X)] = 0, \tag{1.15}$$

$$[\hat{\phi}(X), \hat{\pi}(X')] = i\hbar\,\delta^4(X-X'), \tag{1.16}$$

where we have dropped the n superscript on the fields since the algebra itself is n-independent. Of course, this does not stop individual *representations* from depending on the foliation vector n; indeed, as we shall see below, this is precisely what happens.

In what follows we shall denote by $H_+ := \{n \in M \,|\, n \cdot n = 1, n^0 > 0\}$ the set of all unit length, forward pointing timelike vectors on Minkowski space–time M. We are using a metric $\eta_{\mu\nu}$ on M with the signature $(+,-,-,-)$; also we use the notation $a \cdot b := a^\mu b^\nu \eta_{\mu\nu}$ for any four-vectors a and b in M.

It was shown in Ref. 1 that for each fixed n in H_+ it is possible to find a representation of the history algebra Eqs. (1.11)–(1.13) on a Hilbert space $\mathcal{H}_n$ with the property that the time-averaged energy exists as a well-defined self-adjoint operator ${}^n\hat{H}$ (this is the history analog of an old theorem of Araki in the context of canonical quantum field theory[8]). This operator generates

translations along the timelike direction n and, as such, is one of the generators of the *internal* Poincaré group that exists for each n: full expressions for all these generators are given in Ref. 1.

One of the key questions for our present purposes is how the external Poincaré group acts for each fixed choice of the foliation vector n. The translation part should obviously act in analog to Eq. (1.6) by taking ${}^n\hat{\phi}(X)$ to ${}^n\hat{\phi}(X+a)$ for any four-vector n. Thus there should be an operator $\hat{U}(a)$ such that

$$\hat{U}(a)\,{}^n\hat{\phi}(X)\hat{U}(a)^{-1} = {}^n\hat{\phi}(X+a), \tag{1.17}$$

with a similar action on ${}^n\hat{\pi}(X)$.

The Lorentz subgroup of the Poincaré group is more interesting since as well as acting on the space–time points, it might also be expected to act on the foliation vector n, and hence to take us out of the Hilbert space $\mathcal{H}_n$. In Ref. 1 this problem is solved by showing that even though the representations of the field algebra (1.11)–(1.13) are unitarily inequivalent for different choices of n, it is nevertheless possible to construct the fields for all n on a *common* Fock space $\mathcal{F}$ (see Sec. II of the present article for details). Hence it is meaningful to look for a unitary operator $\hat{U}(\Lambda)$ such that, for all Lorentz transformations Λ,

$$\hat{U}(\Lambda)\,{}^n\hat{\phi}(X)\hat{U}(\Lambda)^{-1} = {}^{\Lambda n}\hat{\phi}(\Lambda X), \tag{1.18}$$

and similarly for ${}^n\hat{\pi}(X)$, where the operators are all defined on $\mathcal{F}$. Of course, the operators $\hat{U}(\Lambda)$ are expected to form a unitary representation of the Lorentz group in the sense that

$$\hat{U}(\Lambda')\hat{U}(\Lambda) = \hat{U}(\Lambda'\Lambda). \tag{1.19}$$

In the present article we shall extend this formalism by quantizing the foliation vector n itself. The main motivation for this step is our belief—following the conjecture by one of us[2]—that, when constructing the quantum history theory of general relativity,[2] it will be necessary to include the space–time foliation as a genuine ''history variable,'' and which must therefore be represented by operators in the corresponding quantum theory. (In Ref. 9 also, the analog of the foliation is a part of the postulated history group, this time in the context of the Bosonic string.) In the context of our present discussion, the vector n is the Minkowskian analog of a foliation of a general space–time: hence an investigation into what is meant by quantizing n is a valuable precursor to the study of the quantization of foliations of a general space–time.

As an introduction to the quantization of n, it is useful to return to the idea that, for each n, the theory is defined on a Hilbert space $\mathcal{H}_n$, and to ask again how the external Lorentz group might act. In these circumstances, Eq. (1.18) is not meaningful since the operators ${}^n\hat{\phi}(X)$ and ${}^{\Lambda n}\hat{\phi}(\Lambda X)$ are defined on different Hilbert spaces ($\mathcal{H}_n$ and $\mathcal{H}_{\Lambda n}$, respectively). The natural thing instead is to seek a family of unitary intertwining operators $\hat{U}(n;\Lambda):\mathcal{H}_n \to \mathcal{H}_{\Lambda n}$ with the property that

$$\hat{U}(n;\Lambda)\,{}^n\hat{\phi}(X) = {}^{\Lambda n}\hat{\phi}(\Lambda X)\hat{U}(n;\Lambda), \tag{1.20}$$

$$\hat{U}(n;\Lambda)\,{}^n\hat{\pi}(X) = {}^{\Lambda n}\hat{\pi}(\Lambda X)\hat{U}(n;\Lambda), \tag{1.21}$$

which can usefully be represented by the commutative diagram

$$\begin{array}{ccc} \mathcal{H}_n & \xrightarrow{\hat{U}(n;\Lambda)} & \mathcal{H}_{\Lambda n} \\ \downarrow {}^n\hat{\phi}(X) & & \downarrow {}^{\Lambda n}\hat{\phi}(\Lambda X) \\ \mathcal{H}_n & \xrightarrow{\hat{U}(n;\Lambda)} & \mathcal{H}_{\Lambda n} \end{array} \tag{1.22}$$

and similarly for the operator ${}^{n}\hat{\pi}(X)$.

These operators $\hat{U}(n;\Lambda):\mathcal{H}_n\to\mathcal{H}_{\Lambda n}$ are expected to give a type of "representation" of the external Lorentz group in the sense that, for all $n\in H_+$ and for all Lorentz transformations Λ, we have

$$\hat{U}(\Lambda n;\Lambda')\hat{U}(n;\Lambda)=\hat{U}(n;\Lambda'\Lambda), \tag{1.23}$$

which is the appropriate analog of the genuine representation Eq. (1.19). The specific form of Eq. (1.23) follows by considering the commutative diagram

$$\begin{array}{ccccc}
 & & \overset{\hat{U}(n;\Lambda)}{\longrightarrow} & & \overset{\hat{U}(\Lambda n,\Lambda')}{\longrightarrow} \\
\mathcal{H}_n & & \mathcal{H}_{\Lambda n} & & \mathcal{H}_{\Lambda'\Lambda n} \\
\downarrow {}^{n}\hat{\phi}(X) & & \downarrow {}^{\Lambda n}\hat{\phi}(\Lambda X) & & \downarrow {}^{\Lambda'\Lambda n}\hat{\phi}(\Lambda'\Lambda X) \\
\mathcal{H}_n & & \mathcal{H}_{\Lambda n} & & \mathcal{H}_{\Lambda'\Lambda n} \\
 & & \underset{\hat{U}(n;\Lambda)}{\longrightarrow} & & \underset{\hat{U}(\Lambda n,\Lambda')}{\longrightarrow}
\end{array} \tag{1.24}$$

whose outer square should equal the diagram

$$\begin{array}{ccc}
 & \overset{\hat{U}(n;\Lambda'\Lambda)}{\longrightarrow} & \\
\mathcal{H}_n & & \mathcal{H}_{\Lambda'\Lambda n} \\
\downarrow {}^{n}\hat{\phi}(X) & & \downarrow {}^{\Lambda'\Lambda n}\hat{\phi}(\Lambda'\Lambda X). \\
\mathcal{H}_n & & \mathcal{H}_{\Lambda'\Lambda n} \\
 & \underset{\hat{U}(n;\Lambda'\Lambda)}{\longrightarrow} &
\end{array} \tag{1.25}$$

We note that Eq. (1.23) is the type of relation that occurs naturally whenever we have a group G that acts on some G-set X, together with a family of operators $U_x(g)$, $x\in X$, defined on vector spaces V_x, $x\in X$, and satisfying the equation [cf. Eq. (1.23)]

$$\hat{U}(gx,g')\hat{U}(x,g)=\hat{U}(x,g'g) \tag{1.26}$$

for all $x\in X$ and g, $g'\in G$. There is also a version of Eq. (1.26) that uses a multiplier, but we shall not need that here.

Mathematically speaking, the appropriate picture [for the specific case of Eq. (1.23)] is a bundle of Hilbert spaces $\mathcal{H}_n$, $n\in H_+$, with base space H_+, in which the action $n\mapsto\Lambda n$ of the external Lorentz group SO(3, 1) on H_+ is lifted to the bundle by the maps $\hat{U}(n,\Lambda):\mathcal{H}_n\to\mathcal{H}_{\Lambda n}$; note that Eq. (1.23) is precisely the statement that the operators $\hat{U}(n,\Lambda)$ "cover" the action of SO(3, 1) on the base space H_+.

Under these circumstances, it is natural to consider the new Hilbert space formed by the *cross-sections* of this vector bundle. However, this Hilbert space is quite different from the individual spaces $\mathcal{H}_n$, $n\in H_+$: in particular, the foliation vector itself becomes an operator under the natural action on a section Ψ as

$$\{\hat{n}^{\mu}\Psi\}(n):=n^{\mu}\Psi(n) \tag{1.27}$$

for all $n\in H_+$.

All this will be discussed properly in Sec. III, but for the moment it suffices to summarize our remarks above by saying that the mathematical formalism for a history quantum field theory developed in Ref. 1 itself suggests a natural way in which the foliation vector could become a quantum operator.

Such a step is also understandable from a more conceptual perspective, for we should recall that the consistent history theory deals with "beables" (albeit contextualized by the choice of a

particular consistent set of histories) not observables. Thus, in quantizing n, we are not saying that the foliation is something that is determined by nature—in particular, something that must be observed—but rather that the existing history QFT formalism depends on the choice of n in such an intrinsic way that it is natural to formulate propositions about things in the context of specifying n. (This also suggests that a topos approach could be useful: we shall make a few remarks about this later on in the article.) And, as we have seen, one way of doing this in a form that is coherent with respect to the action of the external Lorentz group is to let n become a quantum operator.

The challenge now arises of finding a proper theory of a quantized foliation vector, and thereby justifying the rather heuristic ideas presented above. In particular, in the spirit of our approach to history theories, we must find the correct extension of the history field algebra to include an operator $\hat{n}_\mu$ and its conjugate variables.

We will address this issue in Sec. III A by considering the *multi-symplectic* approach to a scalar field theory. There is a relation between multi-symplectic structures and history theory, and—as we shall see—in the case of a scalar field, attempting to quantize the corresponding multi-symplectic structure leads naturally to a quantized foliation vector in the context of a history group whose Lie algebra generators include n and an appropriate set of conjugate variables.

The plan of the article is as follows. We start in Sec. II by summarizing the results in Ref. 1 for constructing the quantum history theory of a free scalar field. Then in Sec. III we study the main problem of quantizing the foliation vector. We base the first few steps in constructing the appropriate history algebra on the discussion in Sec. III A of the multi-symplectic formalism as applied to the relativistic scalar field. The quantization of this formalism is discussed in Sec. III B, and this is completed in Sec. III C, where we apply group-theoretical quantization techniques to a classical system whose configuration space is the set H_+ of all foliation vectors. Then in Sec. IV we discuss the representations of this algebra, and show how a particularly simple one reproduces the heuristic ideas of a Hilbert bundle sketched above.

II. THE QUANTUM HISTORY THEORY OF A SCALAR FIELD

A. The field operators

The starting point for the construction in Ref. 1 of a quantum history version of a free, scalar field is a Fock space $\mathcal{F}$ defined via annihilation and creation operators, $\hat{b}(X)$ and $\hat{b}^\dagger(X)$, respectively, that satisfy the commutation relations:

$$[\hat{b}(X),\hat{b}(X')]=0, \tag{2.1}$$

$$[\hat{b}^\dagger(X),\hat{b}^\dagger(X')]=0, \tag{2.2}$$

$$[\hat{b}(X),\hat{b}^\dagger(X')]=\hbar\,\delta^4(X-X'). \tag{2.3}$$

This bosonic Fock space has (generalized) basis vectors $|X_1,X_2,\ldots,X_k\rangle$ defined by

$$|X_1,X_2,\ldots,X_k\rangle := \hat{b}^\dagger(X_1)\hat{b}^\dagger(X_2)\cdots\hat{b}^\dagger(X_k)|0\rangle \tag{2.4}$$

where $|0\rangle$ is the cyclic "vacuum" state of the Fock space.

On this Fock space $\mathcal{F}$, field operators for each $n\in H_+$ can be defined as

$${}^n\hat{\phi}(X) := \frac{1}{\sqrt{2}}\,{}^n\Gamma^{-1/4}(\hat{b}(X)+\hat{b}^\dagger(X)) \tag{2.5}$$

$${}^n\hat{\pi}(X) := \frac{1}{i\sqrt{2}}\,{}^n\Gamma^{1/4}(\hat{b}(X)-\hat{b}^\dagger(X)), \tag{2.6}$$

where ${}^n\Gamma$ is the elliptic, partial differential operator on $L^2(\mathbb{R}^4)$ defined as

$$ {}^n\Gamma := (\eta^{\mu\nu} - n^\mu n^\nu)\partial_\mu \partial_\nu + m^2, \tag{2.7} $$

where m is the mass parameter in the theory. It is easy to check that, for each foliation vector $n \in H_+$, the fields ${}^n\hat{\phi}(X)$ and ${}^n\hat{\pi}(X)$ defined in Eqs. (2.5) and (2.6) satisfy the history algebra Eqs. (1.14)–(1.16). We note that, as promised, these fields are all defined on the *same* space $\mathcal{F}$ even though the associated representations of the history algebra are unitarily inequivalent for different choices of $n \in H_+$.

The time-averaged energy for each n is represented by the operator

$$ {}^n\hat{H} = \frac{1}{2} : \int d^4X \{ {}^n\hat{\pi}(X)^2 + {}^n\hat{\phi}(X)\, {}^n\Gamma\, {}^n\hat{\phi}(X) \} : \tag{2.8} $$

$$ = \int d^4X \hat{b}^\dagger(X) \sqrt{{}^n\Gamma}\, \hat{b}(X), \tag{2.9} $$

which is a well-defined self-adjoint operator. It is to guarantee the existence of these operators for all $n \in H_+$ that the basic fields ${}^n\hat{\phi}(X)$ and ${}^n\hat{\pi}(X)$ are defined as they are in Eqs. (2.5) and (2.6); see Refs. 5, 6 and 1 for more information on these matters.

B. The external Poincaré group

There is a natural unitary representation of the "external" Poincaré group on the Fock space $\mathcal{F}$. This is defined in the obvious way on the basic vectors $|X_1, X_2, \ldots, X_k\rangle$ as

$$ \hat{U}(\Lambda)|0\rangle := |0\rangle, \tag{2.10} $$

$$ \hat{U}(\Lambda)|X_1, X_2, \ldots, X_k\rangle := |\Lambda X_1, \Lambda X_2, \ldots, \Lambda X_k\rangle, \tag{2.11} $$

$$ \hat{U}(a)|0\rangle := |0\rangle, \tag{2.12} $$

$$ \hat{U}(a)|X_1, X_2, \ldots, X_k\rangle := |X_1 + a, X_2 + a, \ldots, X_k + a\rangle. \tag{2.13} $$

This induces the action on the annihilation operators of

$$ \hat{U}(\Lambda)\hat{b}(X)\hat{U}(\Lambda)^{-1} = \hat{b}(\Lambda X), \tag{2.14} $$

$$ \hat{U}(a)\hat{b}(X)\hat{U}(a)^{-1} = \hat{b}(X + a). \tag{2.15} $$

and similarly for the creation operators $\hat{b}^\dagger(X)$. It is straightforward to show that, as anticipated, the basic field operators ${}^n\hat{\phi}(X)$ and ${}^n\hat{\pi}(X)$ transform as

$$ \hat{U}(\Lambda)\, {}^n\hat{\phi}(X)\hat{U}(\Lambda)^{-1} = {}^{\Lambda n}\hat{\phi}(\Lambda X), \tag{2.16} $$

$$ \hat{U}(\Lambda)\, {}^n\hat{\pi}(X)\hat{U}(\Lambda)^{-1} = {}^{\Lambda n}\hat{\pi}(\Lambda X), \tag{2.17} $$

$$ \hat{U}(a)\, {}^n\hat{\phi}(X)\hat{U}(a)^{-1} = {}^n\hat{\phi}(X + a), \tag{2.18} $$

$$ \hat{U}(a)\, {}^n\hat{\pi}(X)\hat{U}(a)^{-1} = {}^n\hat{\pi}(X + a). \tag{2.19} $$

We note that it is possible to define another set of fields by

$$ \hat{\Phi}(X) := \frac{1}{\sqrt{2}} (\hat{b}(X) + \hat{b}^\dagger(X)), \tag{2.20} $$

$$\hat{\Pi}(X) := \frac{1}{i\sqrt{2}}(\hat{b}(X) - \hat{b}^{\dagger}(X)), \tag{2.21}$$

which satisfy the basic history field algebra Eqs. (1.14)–(1.16). Under the action of the external Poincaré group, we have

$$\hat{U}(\Lambda)\hat{\Phi}(X)\hat{U}(\Lambda)^{-1} = \hat{\Phi}(\Lambda X), \tag{2.22}$$

$$\hat{U}(a)\hat{\Phi}(X)\hat{U}(a)^{-1} = \hat{\Phi}(X + a), \tag{2.23}$$

and similarly for the conjugate variable $\hat{\Pi}(X)$.

The role of these ''covariant'' fields in the theory is intriguing. The relation of $\hat{\Phi}(X)$ to the fields ${}^{n}\hat{\phi}(X)$ suggests strongly that the former should be thought of as the history analog of the *Newton–Wigner* field (which, in standard quantum field theory, creates and annihilates localized *particle* states). However, we note that—in the history theory—$\hat{\Phi}(X)$ is a genuine scalar field, whereas in standard quantum field theory the Newton–Wigner field transforms in a non-covariant way.

The formal explanation of this difference lies in the way the internal and external times interface with each other in the history theory. In particular, the history field $\hat{\Phi}(X)$ is a ''Schrödinger picture'' object in the sense that it does not carry any dynamical information. On the other hand, the remarks above about the standard Newton–Wigner field apply in the Heisenberg picture: in the history case, this would involve invoking the second, internal time.

III. QUANTIZING THE FOLIATION VECTOR

A. The multi-symplectic formalism for a scalar field

One might be tempted to construct the classical history theory for a scalar field by positing the Poisson bracket algebra [cf. Eqs. (1.14)–(1.16)]:

$$\{\phi(X), \phi(X')\} = 0, \tag{3.1}$$

$$\{\pi(X), \pi(X')\} = 0, \tag{3.2}$$

$$\{\phi(X), \pi(X')\} = \delta^4(X - X'), \tag{3.3}$$

which has the advantage of appearing to be manifestly covariant under the action of the external Poincaré group (on the assumption that ϕ and π are scalar fields). However, this covariance is deceptive in the sense that the conjugate variable $\pi(X)$ has no clear *physical* meaning; not least because the actual field momentum for a physical system is manifestly foliation dependent: i.e., it means the momentum along some specified timelike direction n.

This problem is circumscribed in the approach summarized in Sec. II since the *representations* of the quantum algebra Eqs. (1.14)–(1.16) are manifestly n-dependent, and indeed an explicit n-label becomes attached to both the scalar field and its conjugate momentum via Eqs. (2.5) and (2.6). However, these explicit forms are chosen so that the *quantum* average-energy operator ${}^{n}\hat{H}$ exists, and to some extent therefore this leaves open the question of the structure of the underlying *classical* history theory. We shall now address this issue with the aid of some ideas drawn from an, apparently, quite different scheme: namely, the multi-symplectic formalism.

The multi-symplectic formalism arose from attempts to modify the standard classical *canonical* formalism so that it would be manifestly covariant under the appropriate group of space–time transformations.[10] In the case of a scalar field on Minkowski space–time M, the idea is to intro-

duce a pair of space–time fields $\phi(X)$ and $\pi_\mu(X)$ where, physically, for any vector V, $V^\mu\pi_\mu(X)$ can be interpreted as the field momentum along the space–time direction V^μ. Then, for each choice of foliation vector n, there is defined the Poisson bracket

$$\{F,G\}_n(\phi,\pi) := \int_M d^4X \left(\frac{\delta F}{\delta\phi(X)} \frac{\delta G}{\delta\pi_\mu(X)} - \frac{\delta G}{\delta\phi(X)} \frac{\delta F}{\delta\pi_\mu(X)} \right) n_\mu , \tag{3.4}$$

where F and G are functionals of ϕ and π. By this means, a family of symplectic structures is introduced, and the whole system is manifestly covariant under an action of the Poincaré group in which (*i*) ϕ and π_μ transform as genuine space–time objects in the obvious way; and (*ii*) the symplectic structure labeled by a foliation vector n is transformed into that labeled by Λn for all Lorentz transformations Λ.

The nature of this covariance is particularly clear if we look at the basic Poisson brackets that follow from Eq. (3.4):

$$\{\phi(X),\phi(X')\}_n = 0, \tag{3.5}$$

$$\{\pi_\mu(X),\pi_\nu(X')\}_n = 0, \tag{3.6}$$

$$\{\phi(X),\pi_\mu(X')\}_n = n_\mu \delta^4(X-X'), \tag{3.7}$$

where X and X' are points in Minkowski space–time M.

As remarked above, the multi-symplectic formalism was developed in the context of standard canonical theory. However—in so far as they are space–time objects—we could clearly think of ϕ and π_μ as classical *history* fields, and try to develop a history theory based on Eqs. (3.5)–(3.7) instead of Eqs. (3.1)–(3.3). As a mathematical possibility, this makes good sense. However, we should emphasize that, physically speaking, the history interpretation of the multi-symplectic formalism is quite different from the standard one.

For example, a frequent comment in the literature on the multi-symplectic formalism is that the basic Poisson brackets Eqs. (3.5)–(3.7) are not compatible with the equations of motion. But viewed as a history theory, this is no longer the case since the equations of motion are now to be associated with the introduction of the ''internal'' time label. This is closely related to the fact that, from a history perspective, the fields ϕ and π_μ are the classical analogue of *Schrödinger* picture objects, and are used in a temporal logic sense as the carriers of propositions about the history of the system; they are *not* dynamical fields.

B. First steps to the quantum history algebra

We must now address the question of the quantum analog of the parametrized (by n) family of Poisson brackets given in Eqs. (3.5)–(3.7). It is noteworthy that very little has been said in the literature on the multi-symplectic formalism about quantizing such Poisson bracket relations, and by hindsight we can understand why: it is only in the context of a quantum *history* theory—for example, the consistent history theory—that the quantization makes any physical sense.

If we approach quantization in the traditional way of replacing Poisson brackets with operator commutators, then the first issue is how to handle the n-subscript that appears on the left hand side of the equations (3.5)–(3.7). Attaching a subscript to an operator commutator does not have any *a priori* meaning other than, perhaps, to indicate different representations of an algebra, and one is tempted therefore to postulate the simple algebra (from now on we set $\hbar = 1$)

$$[\hat{\phi}(X),\hat{\phi}(X')] = 0, \tag{3.8}$$

$$[\hat{\pi}_\mu(X),\hat{\pi}_\nu(X')] = 0, \tag{3.9}$$

$$[\hat{\phi}(X),\hat{\pi}_\mu(X')] = i n_\mu \delta^4(X-X'), \tag{3.10}$$

with the understanding that the physically appropriate representation may depend on n.

However, the quantity n_μ now appears as a fixed c-number, and the manifest Poincaré covariance is lost. For example, one would like to postulate an action of the external Lorentz group of the form

$$\hat{U}(\Lambda)\hat{\phi}(X)\hat{U}(\Lambda)^{-1}=\hat{\phi}(\Lambda X), \tag{3.11}$$

$$\hat{U}(\Lambda)\hat{\pi}_\mu(X)\hat{U}(\Lambda)^{-1}=\Lambda_\mu^{\ \nu}\hat{\pi}_\nu(\Lambda X), \tag{3.12}$$

but this is incompatible with the right-hand side of Eq. (3.10) because, since n_μ is a c-number, we have $\hat{U}(\Lambda)n_\mu\hat{U}(\Lambda)^{-1}=n_\mu$. The obvious resolution of this problem is to make n_μ itself into an *operator* with modified form

$$[\hat{\phi}(X),\hat{\phi}(X')]=0, \tag{3.13}$$

$$[\hat{\pi}_\mu(X),\hat{\pi}_\nu(X')]=0, \tag{3.14}$$

$$[\hat{\phi}(X),\hat{\pi}_\mu(X')]=i\hat{n}_\mu\delta^4(X-X') \tag{3.15}$$

of the algebra in Eqs. (3.8)–(3.10), and then to augment the transformations Eqs. (3.11) and (3.12) with

$$\hat{U}(\Lambda)\hat{n}_\mu\hat{U}(\Lambda)^{-1}=\Lambda_\mu^{\ \nu}\hat{n}_\nu \tag{3.16}$$

so that the whole set is now compatible.

We now have four main tasks:

(1) Extend Eqs. (3.13)–(3.15) to a complete history theory; in particular we must discuss the form of the conjugate variables to the quantized foliation vector $\hat{n}_\mu$.
(2) Find a physically appropriate representation of the extended algebra.
(3) Show how dynamics is implemented in this scheme. In particular, how the idea arises of a second, ''internal'' time and associated internal Poincaré group.
(4) Give a physical interpretation of the algebra.

Of course, these different issues are closely related. For example, the average-energy operator for the system could be anticipated to be

$$\hat{H}=\frac{1}{2}:\int d^4X\{(\hat{n}^\mu\hat{\pi}_\mu(X))^2+(\hat{n}^\mu\hat{n}^\nu-\eta^{\mu\nu})\partial_\mu\hat{\phi}(X)\partial_\nu\hat{\phi}(X)+m^2\hat{\phi}(X)^2\}: \tag{3.17}$$

which should be compared with the expression in Eq. (2.8) for a fixed n-vector. Note that there is no longer an n-superscript on $\hat{H}$: there is now just a single operator. It is natural, therefore, to seek to fix the representation of the final history algebra by requiring that the expression in Eq. (3.17) exists as a genuine (essentially) self-adjoint operator.

C. Completing the history algebra

1. The conjugate variables to n

The next step is to consider the conjugate variables for the foliation vector. The key observation in this context is that, before quantization, the vector n is timelike, and is of unit length in the sense that

$$n\cdot n:=n^\mu n^\nu\eta_{\mu\nu}=1. \tag{3.18}$$

It seems appropriate that the quantization of n should preserve these constraints, but this requirement is incompatible with the obvious commutator algebra

$$[\hat{p}^{\mu},\hat{n}_{\nu}]=-i\,\delta^{\mu}_{\nu} \tag{3.19}$$

since the conjugate $\hat{p}^{\mu}$ would then generate translations in $\hat{n}_{\mu}$, and these do not preserve the constraints.

What we are faced with is the quantization of a system whose classical configuration space is not a vector space but rather the hyperboloid $H_{+}:=\{n\in\mathbb{R}^4|n^{\mu}n_{\mu}=1,n^0>0\}$ in $\mathbb{R}^4$, which can be viewed as a noncompact version of the three-sphere S^3. The quantization of systems whose configuration spaces are not vector spaces was discussed at length in Ref. 11 which, in particular, contains a detailed description of the quantization of a system whose classical configuration space is an n-sphere. The conclusion was that the appropriate canonical group is not the standard Weyl group (that is associated with the normal canonical commutation relations) but rather the euclidean group $\mathrm{SO}(n+1)\copyright\mathbb{R}^{n+1}$ where © denotes the semi-direct product.

The same general discussion applies in the present case with the hyperboloid H_{+} as configuration space. The result is that the appropriate history group for the foliation variable is the semi-direct product $\mathrm{SO}(3,1)\copyright\mathbb{R}^4$, with the Lie algebra relations

$$[\hat{n}_{\alpha},\hat{n}_{\beta}]=0, \tag{3.20}$$

$$[\hat{p}^{\alpha\beta},\hat{p}^{\gamma\delta}]=i(\eta^{\alpha\gamma}\hat{p}^{\beta\delta}-\eta^{\beta\gamma}\hat{p}^{\alpha\delta}+\eta^{\beta\delta}\hat{p}^{\alpha\gamma}-\eta^{\alpha\delta}\hat{p}^{\beta\gamma}), \tag{3.21}$$

$$[\hat{n}_{\alpha},\hat{p}^{\beta\gamma}]=i(\delta^{\beta}_{\alpha}\hat{n}^{\gamma}-\delta^{\gamma}_{\alpha}\hat{n}^{\beta}), \tag{3.22}$$

where $\hat{p}^{\alpha\beta}=-\hat{p}^{\beta\alpha}$.

We note the following.

(i) Equation (3.20) shows that the variables $\hat{n}_{\alpha}$ span the Lie algebra of the abelian group $\mathbb{R}^4$.
(ii) Equation (3.21) shows that the conjugate variables $\hat{p}^{\alpha\beta}$ satisfy the Lie algebra of the Lorentz group SO(3,1).
(iii) Equation (3.22) reflects the semi-direct structure given by the action of SO(3,1) on $\mathbb{R}^4$.

This group-theoretic scheme works because $\eta^{\mu\nu}\hat{n}_{\mu}\hat{n}_{\nu}$ is a Casimir operator for the algebra in Eqs. (3.20)–(3.22). Hence it is meaningful to look for a representation in which $\eta^{\mu\nu}\hat{n}_{\mu}\hat{n}_{\nu}$ has the constant value 1, thus maintaining compatibility with the classical constraint in Eq. (3.18).

Of course $\mathrm{SO}(3,1)\copyright\mathbb{R}^4$ is nothing but the familiar Poincaré group. But this should not be confused with either the internal or the external Poincaré groups to which we have referred earlier: the present group has arisen as a direct result of quantizing the foliation vector n_{μ}.

2. Completing the history algebra

We must now try to complete the history algebra by considering the cross commutators between the pair $\hat{\phi}(X)$, $\hat{\pi}_{\mu}(X)$, and the pair $\hat{n}_{\mu}$, $\hat{p}^{\alpha\beta}$. As a first step we take the commutator of both sides of Eq. (3.15) with $\hat{p}^{\alpha\beta}$, then use the Jacobi identity on the left-hand side, and the commutator Eq. (3.22) on the right-hand side, to give

$$[\hat{\phi}(X),[\hat{p}^{\alpha\beta},\hat{\pi}_{\mu}(X')]]+[\hat{\pi}_{\mu}(X'),[\hat{\phi}(X),\hat{p}^{\alpha\beta}]]=(\delta^{\alpha}_{\mu}\hat{n}^{\beta}-\delta^{\beta}_{\mu}\hat{n}^{\alpha})\,\delta^4(X-X'). \tag{3.23}$$

It is natural to think of $\hat{\phi}(X)$ and $\hat{n}_{\mu}$ as disjoint configuration variables, which suggests that

$$[\hat{\phi}(X),\hat{n}_{\mu}]=0=[\hat{\pi}_{\alpha}(X),\hat{n}_{\mu}], \tag{3.24}$$

and for this reason it is arguably also natural to assume that $[\hat{\phi}(X),\hat{p}^{\alpha\beta}]=0$. We note that a more general possibility is

$$[\hat{\phi}(X),\hat{p}^{\alpha\beta}]=ia(\hat{n}^{\alpha}\hat{\pi}^{\beta}(X)-\hat{n}^{\beta}\hat{\pi}^{\alpha}(X)) \tag{3.25}$$

for some real constant a. However, this is rather ugly in the sense that the right-hand side of Eq. (3.25) is a nonlinear function of our basic fields, and from now on we shall assume that $a=0$.

We note that, by virtue of Eq. (3.14) and the assumption in Eq. (3.24), even if the commutator in Eq. (3.25) is nonzero, it does not contribute to the left-hand side of Eq. (3.23). Thus, even if $a\neq 0$, the obvious choice for the commutator $[\hat{p}^{\alpha\beta},\hat{\pi}_{\mu}(X)]$ is

$$[\hat{p}^{\alpha\beta},\hat{\pi}_{\mu}(X)]=-i(\delta^{\alpha}_{\mu}\hat{\pi}^{\beta}(X)-\delta^{\beta}_{\mu}\hat{\pi}^{\alpha}(X)). \tag{3.26}$$

In summary, the entire history algebra is postulated to be as follows:

$$[\hat{\phi}(X),\hat{\phi}(X')]=0, \tag{3.27}$$

$$[\hat{\pi}_{\mu}(X),\hat{\pi}_{\nu}(X')]=0, \tag{3.28}$$

$$[\hat{\phi}(X),\hat{\pi}_{\mu}(X')]=i\hat{n}_{\mu}\delta^{4}(X-X'), \tag{3.29}$$

$$[\hat{n}_{\alpha},\hat{n}_{\beta}]=0, \tag{3.30}$$

$$[\hat{p}^{\alpha\beta},\hat{p}^{\gamma\delta}]=i(\eta^{\alpha\gamma}\hat{p}^{\beta\delta}-\eta^{\beta\gamma}\hat{p}^{\alpha\delta}+\eta^{\beta\delta}\hat{p}^{\alpha\gamma}-\eta^{\alpha\delta}\hat{p}^{\beta\gamma}), \tag{3.31}$$

$$[\hat{n}_{\alpha},\hat{p}^{\beta\gamma}]=i(\delta^{\beta}_{\alpha}\hat{n}^{\gamma}-\delta^{\gamma}_{\alpha}\hat{n}^{\beta}), \tag{3.32}$$

$$[\hat{\phi}(X),\hat{n}_{\alpha}]=0, \tag{3.33}$$

$$[\hat{\pi}_{\mu}(X),\hat{n}_{\alpha}]=0, \tag{3.34}$$

$$[\hat{\phi}(X),\hat{p}^{\alpha\beta}]=0, \tag{3.35}$$

$$[\hat{\pi}_{\mu}(X),\hat{p}^{\alpha\beta}]=i(\delta^{\alpha}_{\mu}\hat{\pi}^{\beta}(X)-\delta^{\beta}_{\mu}\hat{\pi}^{\alpha}(X)). \tag{3.36}$$

It is easy to check that the Jacobi identities are satisfied for this algebra.

3. An ansatz for the operator $\hat{\pi}_{\mu}(X)$

At this point we note that Eqs. (3.29) and (3.33) imply that

$$[\hat{\phi}(X),\hat{\pi}_{\mu}(X')-\hat{n}_{\mu}\hat{n}_{\nu}\hat{\pi}^{\nu}(X')]=0 \tag{3.37}$$

in a representation in which $\hat{n}\cdot\hat{n}=1$. For an arbitrary value of this Casimir operator we have instead

$$[\hat{\phi}(X),\hat{n}\cdot\hat{n}\,\hat{\pi}_{\mu}(X')-\hat{n}_{\mu}\hat{n}_{\nu}\hat{\pi}^{\nu}(X')]=0. \tag{3.38}$$

Because of Eq. (3.27), Eq. (3.37) suggests that $\hat{\pi}_{\mu}(X)-\hat{n}_{\mu}\hat{n}_{\nu}\hat{\pi}^{\nu}(X)$ might be a function of $\hat{\phi}(X)$, although from Eq. (3.33) it could also be a function of $\hat{n}_{\mu}$. In any event, clearly one natural possibility is to set

$$\hat{\pi}_{\mu}(X)-\hat{n}_{\mu}\hat{n}_{\nu}\hat{\pi}^{\nu}(X)=0, \tag{3.39}$$

which suggests that $\hat{\pi}_{\mu}(X)$ can be defined using a single "master" field $\hat{\varpi}(X)$ as

$$\hat{\pi}_{\mu}(X):=\hat{n}_{\mu}\hat{\varpi}(X). \tag{3.40}$$

We shall discuss this option at some length below. Note that it is compatible with the supposed commutator $[\hat{\pi}_\mu(X),\hat{\pi}_\nu(X')]=0$ if we postulate that $[\hat{\varpi}(X),\hat{\varpi}(X')]=0$. It is also compatible with the remaining commutators in Eqs. (3.27)–(3.36) that involve $\hat{\pi}_\mu(X)$.

A natural generalization of the definition Eq. (3.40) of the operator $\hat{\pi}_\mu(X)$ in terms of a single $\hat{\varpi}(X)$ is

$$\hat{\pi}_\mu(X) := \hat{n}_\mu \hat{\varpi}(X) + b(\partial_\mu \hat{\phi}(X) - \hat{n}_\mu \hat{n}\cdot\partial\hat{\phi}(X)) \tag{3.41}$$

for some real constant b. Bearing in mind that (assuming that $\hat{n}\cdot\hat{n}=1$)

$$\hat{n}^\mu(\partial_\mu \hat{\phi}(X) - \hat{n}_\mu \hat{n}\cdot\partial\hat{\phi}(X)) \equiv 0, \tag{3.42}$$

we see that Eq. (3.41) can be viewed as the decomposition of $\hat{\pi}_\mu(X)$ into a "longitudinal" part $\hat{n}_\mu\hat{\varpi}(X)$ and a "transverse part" $\partial_\mu\hat{\phi}(X)-\hat{n}_\mu\hat{n}\cdot\partial\hat{\phi}(X)$, with the implication in particular that the transverse part is essentially the spatial derivatives of the field $\hat{\phi}(X)$. There are several attractive features to assuming Eq. (3.41). However, it does have the implication that

$$[\hat{\pi}_\mu(X),\hat{\pi}_\nu(X')] = 2ib(\hat{n}_{(\nu}\partial_{\mu)} - \hat{n}_\mu\hat{n}_\nu\hat{n}\cdot\partial)\,\delta^4(X-X'), \tag{3.43}$$

where the partial derivatives on the right-hand side are with respect to the X label. This would mean making a change in the postulated commutator in Eq. (3.28).

D. The external and internal Poincaré groups

1. The action of the external Poincaré group

There is a natural automorphism of the complete history algebra Eqs. (3.27)–(3.36) by the external Poincaré group, which we might hope could be unitarily implemented as an extension of Eqs. (3.11), (3.12) and (3.16):

$$\hat{U}(\Lambda)\hat{\phi}(X)\hat{U}(\Lambda)^{-1} = \hat{\phi}(\Lambda X), \tag{3.44}$$

$$\hat{U}(\Lambda)\hat{\pi}_\mu\hat{U}(X)\hat{U}(\Lambda)^{-1} = \Lambda_\mu^{\ \nu}\hat{\pi}_\nu(\Lambda X), \tag{3.45}$$

$$\hat{U}(\Lambda)\hat{n}_\mu\hat{U}(\Lambda)^{-1} = \Lambda_\mu^{\ \nu}\hat{n}_\nu, \tag{3.46}$$

$$\hat{U}(\Lambda)\hat{p}^{\alpha\beta}\hat{U}(\Lambda)^{-1} = \Lambda^\alpha{}_\mu\Lambda^\beta{}_\nu\hat{p}^{\mu\nu}, \tag{3.47}$$

and with the translations acting as

$$\hat{U}(a)\hat{\phi}(X)\hat{U}(a)^{-1} = \hat{\phi}(X+a), \tag{3.48}$$

$$\hat{U}(a)\hat{\pi}_\mu(X)\hat{U}(a)^{-1} = \hat{\pi}_\mu(X+a), \tag{3.49}$$

$$\hat{U}(a)\hat{n}_\mu\hat{U}(a)^{-1} = \hat{n}_\mu, \tag{3.50}$$

$$\hat{U}(a)\hat{p}^{\alpha\beta}\hat{U}(a)^{-1} = \hat{p}^{\alpha\beta}. \tag{3.51}$$

2. The internal Poincaré group

The situation with the internal Poincaré group is interesting. As remarked above, we expect the average-energy operator of the system to be

$$\hat{H} = \frac{1}{2}{:}\int d^4X\{(\hat{n}^\mu\hat{\pi}_\mu(X))^2 + (\hat{n}^\mu\hat{n}^\nu - \eta^{\mu\nu})\partial_\mu\hat{\phi}(X)\partial_\nu\hat{\phi}(X) + m^2\hat{\phi}(X)^2\}{:}. \tag{3.52}$$

However, in this situation, $\hat{H}$ is not defined with respect to any *particular* foliation [unlike, for example, the time-averaged energy in Eq. (2.8)], and hence it cannot be identified as the timelike component of a four-vector $\hat{P}_\mu$ in any obvious way.

The resolution of this issue is as follows. In the original form of history quantum field theory, summarized in Sec. II, there is a four-vector operator ${}^n\hat{P}_\mu$ that is related to the associated time-averaged energy operator ${}^n\hat{H}$ by

$$ {}^n\hat{P}_\mu := n_\mu\, {}^n\hat{H} + \int d^4X (\partial_\mu\, {}^n\hat{\phi}(X) - n_\mu n\cdot\partial\, {}^n\hat{\phi}(X))\, {}^n\hat{\pi}(X), \tag{3.53}$$

and where we note that

$$ n^\mu \int d^4X (\partial_\mu\, {}^n\hat{\phi}(X) - n_\mu n\cdot\partial\, {}^n\hat{\phi}(X)) {}^n\hat{\pi}(X) \equiv 0. \tag{3.54}$$

Thus the "*n*-longitudinal" part of ${}^n\hat{P}_\mu$ is ${}^n\hat{H} \equiv n^\mu\, {}^n\hat{P}_\mu$, whereas the "*n*-transverse" part is $\int d^4X (\partial_\mu\hat{\phi}(X) - n_\mu n\cdot\partial\hat{\phi}(X)) {}^n\hat{\pi}(X)$.

In the present case, where n is quantized, the expression in Eq. (3.53) suggests that we define the translation generators of the internal Poincaré group by

$$ {}^{\text{int}}\hat{P}_\mu := \hat{n}_\mu\hat{H} + \int d^4X (\partial_\mu\hat{\phi}(X) - \hat{n}_\mu\hat{n}\cdot\partial\hat{\phi}(X))\hat{n}^\mu\hat{\pi}_\mu(X), \tag{3.55}$$

where $\hat{H}$ is defined in Eq. (3.52). The remaining generators of the internal Poincaré group can be defined in a similar way using the expressions given in Ref. 1 where the foliation vector n is fixed.

We note that, according to Eqs. (3.44) and (3.45), under the action of the external Lorentz group, the generators of the translations of the internal Poincaré group transform as

$$ \hat{U}(\Lambda)\, {}^{\text{int}}\hat{P}_\mu \hat{U}(\Lambda)^{-1} = \Lambda_\mu^{\ \nu}\, {}^{\text{int}}\hat{P}_\nu, \tag{3.56}$$

whereas, for a fixed n, we have

$$ \hat{U}(\Lambda)\, {}^n\hat{P}_\mu \hat{U}(\Lambda)^{-1} = \Lambda_\mu^{\ \nu}\, {}^{\Lambda n}\hat{P}_\nu. \tag{3.57}$$

3. The internal time

In the context of the discussion above of the internal Poincaré group, it is clear that one way in which a second, internal time variable s could enter the formalism is by the definition of a "Heisenberg picture" field $\hat{\phi}(X;s)$ as

$$ \hat{\phi}(X;s) := e^{is\hat{H}}\hat{\phi}(X)e^{-is\hat{H}}. \tag{3.58}$$

We see that, in this approach, there is now a *single* extra time variable s—for each choice of a foliation vector n—and this is not associated with any particular foliation vector. However, it is still true that the interpretation of the formalism should be such that s automatically has the correct meaning in the correct context. (See Ref. 7 for a detailed discussion of the interpretation of the time variable s.)

However, this is not the only option. For example, it is arguably more natural to have a separate internal time variable $s(n)$ for each value of $n \in H_+$, and such that $s(n) \geqslant 0$ for all n. In the quantum case, an operator $s(\hat{n})$ can be defined using the spectral theorem for the self-adjoint operator $\hat{n}$, and then we can define [cf. Eq. (3.52)]

$$ \hat{H}[s] := \frac{1}{2} : \int d^4X s(\hat{n}) \{ (\hat{n}^\mu\hat{\pi}_\mu(X))^2 + (\hat{n}^\mu\hat{n}^\nu - \eta^{\mu\nu})\partial_\mu\hat{\phi}(X)\partial_\nu\hat{\phi}(X) + m^2\hat{\phi}(X)^2 \} : . \tag{3.59}$$

This suggests defining an associated "generalized Heisenberg picture" object $\hat{\phi}(X;s]$ [cf. Eq. (3.58)] as

$$\hat{\phi}(X;s] := e^{i\hat{H}[s]}\hat{\phi}(X)e^{-i\hat{H}[s]}, \tag{3.60}$$

where the brackets in $\hat{\phi}(X;s]$ serve to remind us that $\hat{\phi}$ is a function of the space–time point X, but a *functional* of the function $s: H_+ \to \{0\} \cup \mathbb{R}_+$.

IV. REPRESENTATIONS OF THE HISTORY ALGEBRA

A. The Hilbert bundle construction

From what has been said above, it is clear that one way of satisfying the history algebra Eqs. (3.27)–(3.36) would be to have a single "master" momentum field $\hat{\varpi}(X)$, and then to define

$$\hat{\pi}_\mu(X) := \hat{n}_\mu \hat{\varpi}(X) \tag{4.1}$$

with the assumption that $\hat{n}_\mu$ commutes with $\hat{\varpi}(X)$ so that there are no operator-ordering problems. This gives us the simpler algebra

$$[\hat{\phi}(X), \hat{\phi}(X')] = 0, \tag{4.2}$$

$$[\hat{\varpi}(X), \hat{\varpi}(X')] = 0, \tag{4.3}$$

$$[\hat{\phi}(X), \hat{\varpi}(X')] = i\delta^4(X - X'), \tag{4.4}$$

$$[\hat{n}_\alpha, \hat{n}_\beta] = 0, \tag{4.5}$$

$$[\hat{p}^{\alpha\beta}, \hat{p}^{\gamma\delta}] = i(\eta^{\alpha\gamma}\hat{p}^{\beta\delta} - \eta^{\beta\gamma}\hat{p}^{\alpha\delta} + \eta^{\beta\delta}\hat{p}^{\alpha\gamma} - \eta^{\alpha\delta}\hat{p}^{\beta\gamma}), \tag{4.6}$$

$$[\hat{n}_\alpha, \hat{p}^{\beta\gamma}] = i(\delta^\beta_\alpha \hat{n}^\gamma - \delta^\gamma_\alpha \hat{n}^\beta), \tag{4.7}$$

with all other commutators vanishing. Of course, this is just the direct sum of the field algebra Eqs. (4.2)–(4.4) with the algebra Eqs. (4.5)–(4.7). Note that the commutator $[\hat{\pi}_\mu(X), \hat{p}^{\alpha\beta}] = i(\delta^\alpha_\mu \hat{\pi}^\beta(X) - \delta^\beta_\mu \hat{\pi}^\alpha(X))$ in Eq. (3.36) need no longer be assumed since it is implied now by the commutation relation $[\hat{n}_\alpha, \hat{p}^{\beta\gamma}] = i(\delta^\beta_\alpha \hat{n}^\gamma - \delta^\gamma_\alpha \hat{n}^\beta)$ in Eq. (4.7).

We anticipate that the key average-energy operator (that will eventually be associated with translations along the internal time direction) is [cf. Eq. (3.52)]

$$\hat{H} := \frac{1}{2} : \int d^4X \{\hat{\varpi}(X)^2 + (\hat{n}^\mu \hat{n}^\nu - \eta^{\mu\nu})\partial_\mu \hat{\phi}(X)\partial_\nu \hat{\phi}(X) + m^2 \hat{\phi}(X)^2\} :, \tag{4.8}$$

in which case the main task is to find a representation of the history algebra Eqs. (4.2)–(4.7) in which Eq. (4.8) exists as a genuine self-adjoint operator.

We proceed as follows. For each $n \in H_+$ we construct the Hilbert space $\mathcal{H}_n$ that carries operators ${}^n\hat{\phi}(X)$, ${}^n\hat{\pi}(X)$ that satisfy the history algebra Eqs. (1.14)–(1.16):

$$[{}^n\hat{\phi}(X), {}^n\hat{\phi}(X')] = 0, \tag{4.9}$$

$$[{}^n\hat{\pi}(X), {}^n\hat{\pi}(X)] = 0, \tag{4.10}$$

$$[{}^n\hat{\phi}(X), {}^n\hat{\pi}(X')] = i\delta^4(X - X'), \tag{4.11}$$

and with the property that the average-energy operator in Eq. (2.8),

$$ {}^n\hat{H} := \frac{1}{2} : \int d^4X \{ {}^n\hat{\pi}(X)^2 + (n^\mu n^\nu - \eta^{\mu\nu}) \partial_\mu {}^n\hat{\phi}(X) \partial_\nu {}^n\hat{\phi}(X) + m^2 {}^n\hat{\phi}(X)^2 \} : , \tag{4.12} $$

exists as a genuine self-adjoint operator. The *n*-superscripts on the fields in Eqs. (4.9)–(4.11) serve to indicate that we have chosen the representation of the abstract history algebra Eqs. (1.14)–(1.16) in which this operator ${}^n\hat{H}$ exists. In fact, as we know from the work in Ref. 1, for all $n \in H_+$ these fields can be constructed on the same abstract Fock space even though the corresponding representations of the history field algebra are unitarily inequivalent for different *n*. However, for our present purposes, it is clearer if we continue to refer to the Hilbert space on which ${}^n\hat{H}$ exists as $\mathcal{H}_n$.

We now link up with the heuristic ideas in the Introduction by constructing a Hilbert bundle whose base space is the hyperboloid H_+, and in which the fiber over each $n \in H_+$ is defined to be the Hilbert space $\mathcal{H}_n$. [We note that the SO(3, 1) subgroup of the history group (i.e., the part associated with the $\hat{n}_\mu$ variables) acts transitively on H_+ with stability group SO(3), so that $H_+ \simeq \mathrm{SO}(3,1)/\mathrm{SO}(3)$. Thus we have the principle bundle

$$ \mathrm{SO}(3) \to \mathrm{SO}(3,1) \to \mathrm{SO}(3,1)/\mathrm{SO}(3) \simeq H_+ := \{ n \in \mathbb{R}^4 \,|\, n \cdot n = 1, n^0 > 0 \}. \tag{4.13} $$

This suggests that we could try using a nontrivial representation of SO(3) to ''twist'' the fibers of the Hilbert bundle. However, we shall not explore that option here.] The Hilbert space of our history theory is then defined to be the direct integral

$$ \mathcal{H} := \int_{H_+}^{\oplus} \mathcal{H}_n d\mu(n). \tag{4.14} $$

Here $d\mu(n)$ is the usual SO(3,1)-invariant measure on the hyperboloid H_+: it is just the standard measure used in normal quantum field theory, but now applied to *n*-space rather than momentum space.

The vectors in this direct-integral Hilbert space $\mathcal{H}$ are defined to be the cross-sections of the Hilbert bundle: i.e., maps $\Psi : H_+ \to \cup_{n \in H_+} \mathcal{H}_n$ with the property that $\Psi(n) \in \mathcal{H}_n$ for all $n \in H_+$. The inner product between a pair of such cross-sections Ψ_1 and Ψ_2 is defined as

$$ \langle \Psi_1, \Psi_2 \rangle := \int_{H_+} d\mu(n) \langle \Psi_1(n), \Psi_2(n) \rangle_{\mathcal{H}_n}, \tag{4.15} $$

where $\langle , \rangle_{\mathcal{H}_n}$ denotes the inner product in the Hilbert space fiber $\mathcal{H}_n$.

Of course, if we make the specific identification of each Hilbert space $\mathcal{H}_n$ with the Fock space $\mathcal{F}$, as summarized in Sec. II, then the new Hilbert space $\mathcal{H}$ can be viewed as the vector space of all measurable functions $\Psi : H_+ \to \mathcal{F}$ with the inner product

$$ \langle \Psi_1, \Psi_2 \rangle := \int_{H_+} d\mu(n) \langle \Psi_1(n), \Psi_2(n) \rangle_{\mathcal{F}}. \tag{4.16} $$

Note that there is a natural cyclic ''ground'' state which is defined to be the cross-section Ω such that, for all $n \in H_+$,

$$ \Omega(n) := |0\rangle_n , \tag{4.17} $$

where $|0\rangle_n$ is the ground state of the average-energy operator ${}^n\hat{H}$ in the Hilbert-space $\mathcal{H}_n$.

B. The field and foliation operators

1. The field operators

The next step is to define the history field operators $\hat{\phi}(X)$ and $\hat{\varpi}(X)$ on $\mathcal{H} := \int_{H_+}^{\oplus} \mathcal{H}_n d\mu(n)$ as follows:

$$\{\hat{\phi}(X)\Psi\}(n) := {}^n\hat{\phi}(X)\Psi(n), \tag{4.18}$$

$$\{\hat{\varpi}(X)\Psi\}(n) := {}^n\hat{\pi}(X)\Psi(n) \tag{4.19}$$

for all $n \in H_+$. These equations are meaningful since the vectors $\Psi(n)$, $n \in H_+$, on the right-hand sides belong to the Hilbert space $\mathcal{H}_n$ on which the field operators ${}^n\hat{\phi}(X)$ and ${}^n\hat{\pi}(X)$ are defined. In other words, the maps $n \mapsto {}^n\hat{\phi}(X)$ and $n \mapsto {}^n\hat{\pi}(X)$ define fields of operators over the base space H_+, and are hence well-defined operators on the direct integral $\int_{H_+}^{\oplus} \mathcal{H}_n d\mu(n)$. (Of course, to do this rigorously one needs to discuss the domains of the various operators concerned, but we shall not dwell on such niceties here.)

It is clear that the operators defined by Eqs. (4.18) and (4.19) satisfy the history algebra Eqs. (4.2)–(4.4). For example,

$$\{\hat{\phi}(X)\hat{\varpi}(X')\Psi\}(n) = {}^n\hat{\phi}(X)\{\hat{\varpi}(X')\Psi\}(n) = {}^n\hat{\phi}(X)\,{}^n\hat{\pi}(X')\Psi(n) \tag{4.20}$$

and similarly

$$\{\hat{\varpi}(X')\hat{\phi}(X)\Psi\}(n) = {}^n\hat{\pi}(X')\{\hat{\phi}(X)\Psi\}(n) = {}^n\hat{\pi}(X')\,{}^n\hat{\phi}(X)\Psi(n), \tag{4.21}$$

so that, for all $n \in H_+$,

$$\{[\hat{\phi}(X), \hat{\varpi}(X')]\Psi\}(n) = [{}^n\hat{\phi}(X), {}^n\hat{\pi}(X')]\Psi(n) = i\delta^4(X - X')\Psi(n), \tag{4.22}$$

which means that (modulo subtleties about domains) we have the basic history field commutator $[\hat{\phi}(X), \hat{\varpi}(X')] = i\delta^4(X - X')$.

Note that, if we exploit the fact that the Hilbert spaces can all be identified with the same Fock space $\mathcal{F}$, then using the definitions in Eqs. (2.5) and (2.6), we can further write

$$\{\hat{\phi}(X)\Psi\}(n) := {}^n\hat{\phi}(X)\Psi(n) = \frac{1}{\sqrt{2}}\,{}^n\Gamma^{-1/4}(\hat{b}(X) + \hat{b}^\dagger(X))\Psi(n), \tag{4.23}$$

$$\{\hat{\varpi}(X)\Psi\}(n) := {}^n\hat{\pi}(X)\Psi(n) = \frac{1}{i\sqrt{2}}\,{}^n\Gamma^{1/4}(\hat{b}(X) - \hat{b}^\dagger(X))\Psi(n). \tag{4.24}$$

Here the operator $\hat{b}(X)$ [and similarly for $\hat{b}^\dagger(X)$] is defined as the constant field of operators over H_+ obtained by identifying each fiber of the Hilbert bundle with the Fock space $\mathcal{F}$.

2. The foliation operators

The operators that represent the foliation vector are easy to define in the Hilbert space $\int_{H_+}^{\oplus} \mathcal{H}_n d\mu(n)$. Specifically,

$$\{\hat{n}_\mu\Psi\}(n) := n_\mu\Psi(n) \tag{4.25}$$

and

$$\{\hat{p}^{\alpha\beta}\Psi\}(n) := i\left\{ n_\alpha \frac{\partial}{\partial n_\beta} - n_\beta \frac{\partial}{\partial n_\alpha} \right\} \Psi(n). \tag{4.26}$$

Note that, strictly speaking, if the history states are considered as sections of the Hilbert bundle, then the right-hand side of Eq. (4.26) involves taking the difference between vectors belonging to different Hilbert-space fibers, and hence it is only meaningful if there is a *connection* in the bundle. However, this is not a problem in our case since the fibers $\mathcal{H}_n$, $n \in H_+$, can all be identified with the basic Fock space $\mathcal{F}$, and this is assumed to have been done when writing Eq. (4.26).

3. The time-averaged energy operator

The natural way of defining a time-averaged energy operator is to exploit the fact that, on each Hilbert space fiber $\mathcal{H}_n$, $n \in H_+$, the operator ${}^n\hat{H}$ defined in Eq. (4.12) exists, and represents the time-averaged value of the energy for that particular foliation. Thus we can define an operator $\hat{H}$ by

$$\{\hat{H}\Psi\}(n) := {}^n\hat{H}\Psi(n) \tag{4.27}$$

for all $n \in H_+$. (As usual, to be fully rigorous we should worry about domains of essential self-adjointness for these operators.) Note that, as anticipated in Eq. (4.8), the operator thus defined can be written in terms of the basic history fields as

$$\hat{H} := \frac{1}{2} : \int d^4X \{ \hat{\varpi}(X)^2 + (\hat{n}^\mu \hat{n}^\nu - \eta^{\mu\nu}) \partial_\mu \hat{\phi}(X) \partial_\nu \hat{\phi}(X) + m^2 \hat{\phi}(X)^2 \} : . \tag{4.28}$$

The remaining generators of the internal Poicaré group can be defined in an analogous way.

4. The internal time function

If an internal time function is introduced as in Eq. (3.59), then the action of the operator $\hat{H}[s]$ on a section Ψ of the Hilbert bundle is

$$\{\hat{H}[s]\Psi\}(n) := s(n)\, {}^n\hat{H}\Psi(n), \tag{4.29}$$

which shows clearly the sense in which $s(n)$ is the internal time associated with the foliation vector n.

This suggests an interesting application of the ideas discussed in Ref. 12 of possible uses of topos theory in quantum gravity and quantum theory. In particular, one might try to view the construction above as being, rather than of a bundle, instead of a sheaf of Hilbert spaces over the base space H_+, which is now construed as the category of ''contexts'' in which assertions about the history system are to be made.

By viewing our construction as an object in the topos of sheaves over H_+, we can exploit the existence in any topos of both external and internal views: ''external'' in the sense of how things look from the perspective of normal mathematics, and ''internal'' in the sense of how things look from the perspective of the mathematical structure based on the topos itself. In particular, when viewed externally, the time function $n \mapsto s(n)$ appears precisely as that: i.e., a function. On the other hand, when viewed internally, it corresponds to a real number in the topos of sheaves over H_+. Thus what we have called the ''internal time *function*'' is just a *real number* when viewed internally in the topos. We intend to devote a future paper to the general question of the ways in which topos ideas can be productively applied to history theory.

C. The external Poincaré group

The key step in constructing a representation of the external Lorentz group in the Hilbert space $\mathcal{H}$ of cross-sections is to have a family of intertwining operators $\hat{U}(n;\Lambda):\mathcal{H}_n\to\mathcal{H}_{\Lambda n}$ that satisfy the conditions given in Eq. (1.23):

$$\hat{U}(\Lambda n;\Lambda')\hat{U}(n;\Lambda)=\hat{U}(n;\Lambda'\Lambda). \tag{4.30}$$

Indeed, the conditions in Eq. (4.30) mean precisely that the intertwining operators $\hat{U}(n;\Lambda)$ "cover" (i.e., act coherently with respect to) the action of SO(3,1) on the base space H_+ of the Hilbert bundle.

In these circumstances, for each $\Lambda\in\mathrm{SO}(3,1)$, we can define an operator $\hat{W}(\Lambda):\mathcal{H}\to\mathcal{H}$ by

$$\{\hat{W}(\Lambda)\Psi\}(n):=\hat{U}(\Lambda^{-1}n;\Lambda)\Psi(\Lambda^{-1}n) \tag{4.31}$$

for all $n\in H_+$. This is clearly unitary since

$$\begin{aligned}\langle\hat{W}(\Lambda)\Psi,\hat{W}(\Lambda)\Psi\rangle_{\mathcal{H}}&=\int_{H_+}d\mu(n)\langle\{\hat{W}(\Lambda)\Psi\}(n),\{\hat{W}(\Lambda)\Psi\}(n)\rangle_{\mathcal{H}_n}\\&=\int_{H_+}d\mu(n)\langle\hat{U}(\Lambda^{-1}n;\Lambda)\Psi(\Lambda^{-1}n),\hat{U}(\Lambda^{-1}n;\Lambda)\Psi(\Lambda^{-1}n)\rangle_{\mathcal{H}_n}\\&=\int_{H_+}d\mu(n)\langle\Psi(\Lambda^{-1}n),\Psi(\Lambda^{-1}n)\rangle_{\mathcal{H}_{\Lambda^{-1}n}}\\&=\int_{H_+}d\mu(n)\langle\Psi(n),\Psi(n)\rangle_{\mathcal{H}_n}=\langle\Psi,\Psi\rangle_{\mathcal{H}},\end{aligned} \tag{4.32}$$

where have used (*i*) the assumed unitarity of the intertwining operators $\hat{U}(n;\Lambda):\mathcal{H}_n\to\mathcal{H}_{\Lambda n}$, and (*ii*) the invariance of the measure $d\mu$ on H_+ under the action of SO(3,1).

To see that $\hat{W}(\Lambda)$ defined in Eq. (4.31) satisfies the group law we compute as follows:

$$\begin{aligned}\{\hat{W}(\Lambda_2)\hat{W}(\Lambda_1)\Psi\}(n)&=\hat{U}(\Lambda_2^{-1}n;\Lambda_2)(\{\hat{W}(\Lambda_1)\Psi\}(\Lambda_2^{-1}n))\\&=\hat{U}(\Lambda_2^{-1}n;\Lambda_2)\hat{U}(\Lambda_1^{-1}\Lambda_2^{-1}n;\Lambda_1)\Psi(\Lambda_1^{-1}\Lambda_2^{-1}n).\end{aligned} \tag{4.33}$$

But, from Eq. (4.30) we have

$$\hat{U}(\Lambda_2^{-1}n;\Lambda_2)\hat{U}(\Lambda_1^{-1}\Lambda_2^{-1}n;\Lambda_1)=\hat{U}(\Lambda_1^{-1}\Lambda_2^{-1}n;\Lambda_2\Lambda_1)=\hat{U}((\Lambda_2\Lambda_1)^{-1}n;\Lambda_2\Lambda_1), \tag{4.34}$$

and, hence, for all $n\in H_+$,

$$\{\hat{W}(\Lambda_2)\hat{W}(\Lambda_1)\Psi\}(n)=\hat{U}((\Lambda_2\Lambda_1)^{-1}n;\Lambda_2\Lambda_1)\Psi((\Lambda_2\Lambda_1)^{-1}n)=\{\hat{W}(\Lambda_2\Lambda_2)\Psi\}(n) \tag{4.35}$$

as is required to give a representation of the Lorentz group.

As was mentioned earlier, in our particular case, the existence of intertwining operators $\hat{U}(n;\Lambda):\mathcal{H}_n\to\mathcal{H}_{\Lambda n}$ satisfying Eq. (4.30) is demonstrated rather easily by exploiting the fact that the Hilbert spaces $\mathcal{H}_n$, $n\in H_+$, can all be identified naturally with the same Fock space generated by creation and annihilation operators $\hat{b}(X)^\dagger$ and $\hat{b}(X)$. Indeed, as discussed earlier, we simply get operators $\hat{U}(\Lambda):\mathcal{F}\to\mathcal{F}$ which in themselves give a representation of the external Lorentz group, and which satisfy Eqs. (2.16) and (2.17).

The translation subgroup of the external Poincaré group is easier to define since the translations do not act on H_+. Thus we have the simple definition

$$\{\hat{W}(a)\Psi\}(n) := {}^n\hat{U}(a)\Psi(n) \quad \forall n \in H_+, \tag{4.36}$$

where ${}^n\hat{U}(a)$ denotes the operators of the translation subgroup of the external Poincaré group in $\mathcal{H}_n$.

V. CONCLUSIONS

We have shown how the discussion in Ref. 1 of a history version of scalar quantum field theory can be augmented in such a way as to include the quantization of the unit-length, timelike vector n that determines the Lorentzian foliation of Minkowski space–time. The Hilbert bundle construction that we employed was motivated by (*i*) a heuristic discussion of the role of the external Lorentz group in the existing history quantum field theory,[1] and (*ii*) a more technical discussion of a specific representation of the extended history algebra obtained from the multi-symplectic representation of classical scalar field theory. In the latter context it should be remarked that there exist representations of this algebra other than the simple one given here—the significance of such representations is a subject for future research.

The construction of a Hilbert bundle over $H_+ := \{n \in M | n \cdot n = 1, n^0 > 0\}$ is a natural idea at a technical level, but it is also interesting from a conceptual perspective. For example, the direct integral representation of the history Hilbert space—together with the postulated nondependence of the average energy operator on the variables conjugate to $\hat{n}^\mu$—suggests that we have a type of history analog of what, in ordinary quantum theory, would be regarded as a system with continuous super-selection sectors labeled by $n \in H_+$. But in a 'neo-realist' theory such as consistent histories, the role of super-selection sectors is somewhat different from that which arises in an instrumentalist theory such as standard quantum mechanics.

The specific form of the quantization of the foliation vector presented in this paper is determined by the reduction of the full history algebra Eqs. (3.27)–(3.36) to the simplified algebra Eqs. (4.2)–(4.7) via the ansatz Eq. (4.1). In this situation, we would not expect the quantization of n to generate any physical results that are different from those of the original paper.[1] Of course, it may be possible to find representations of the full history algebra that are *not* generated by representations of the simplified algebra, and it would then be important to see if these have any physical implications. In particular, this would give some physical meaning to the multi-symplectic formalism from which we derived the full history algebra. These issues are a matter for further research.

However, the main motivation behind the present article is to present certain mathematical techniques that can be proved useful when quantizing the space–time foliations that are expected to arise in a history version of general relativity. This important issue in the history approach to quantum gravity is something to which we shall return in a later paper.

(Received 4 February 2002; accepted 31 May 2002)

We show in this article that the Reeh–Schlieder property holds for states of quantum fields on real analytic curved space–times if they satisfy an analytic microlocal spectrum condition. This result holds in the setting of general quantum field theory, i.e., without assuming the quantum field to obey a specific equation of motion. Moreover, quasifree states of the Klein–Gordon field are further investigated in the present work and the (analytic) microlocal spectrum condition is shown to be equivalent to simpler conditions. We also prove that any quasifree ground or KMS state of the Klein–Gordon field on a stationary real analytic space–time fulfills the analytic microlocal spectrum condition. © *2002 American Institute of Physics.*

I. INTRODUCTION

One of the remarkable features of quantum field theory is the ubiquity of fluctuations and, connected with that, the generic appearance of long-range correlations. What is even more remarkable is the fact that, using suitable selective operations and applying them, say, in an arbitrary space–time region to the vacuum, one may produce in this way any given state in any other causally separated space–time region up to arbitrary precision. This is known as the Reeh–Schlieder theorem.[40] Let us recall its statement in the setting of the operator-algebraic approach to quantum field theory. Suppose that we are given a space–time manifold (M,g) (i.e., M is a smooth, n-dimensional manifold, and g is a Lorentzian metric on M) and a family ("local net") $\{\mathcal{A}(O)\}_{O\subset M}$ of von Neumann algebras, all acting on a Hilbert-space $\mathcal{H}$; the family is indexed by the open, relatively compact subsets of M, and is subject to the conditions of isotony and locality:

$$O_1\subset O\Rightarrow\mathcal{A}(O_1)\subset\mathcal{A}(O)\quad\text{and}\quad O_1\subset O^{\perp}\Rightarrow\mathcal{A}(O_1)\subset\mathcal{A}(O)'.$$

Here, $O^{\perp}$ denotes the causal complement of O, i.e., the set of all points in M which cannot be connected to O by any causal curve, and $\mathcal{A}(O)'$ denotes the commutant algebra of $\mathcal{A}(O)$ in $B(\mathcal{H})$. These conditions are the minimal assumptions in order that $\{\mathcal{A}(O)\}_{O\subset M}$ may be viewed as a net of local observable algebras of a (relativistic) physical system situated in M, see Ref. 2 for discussion. One now says that a unit vector $\Omega\in\mathcal{H}$ satisfies the **Reeh–Schlieder property** with respect to the region $O\subset M$ if Ω is cyclic for the algebra $\mathcal{A}(O)$ of observables localized in O, that is, the set of vectors $\mathcal{A}(O)\Omega=\{A\Omega:A\in\mathcal{A}(O)\}$ is dense in $\mathcal{H}$. Moreover, one says that Ω has the

Reeh–Schlieder property if Ω is cyclic for $\mathcal{A}(O)$ for each $O \subset M$ which is open, nonvoid, and relatively compact. By the locality assumption, this then implies that Ω is also separating for all local algebras $\mathcal{A}(O)$ (as long as $O^{\perp}$ contains a nonvoid open set) and this means that $A\Omega = 0 \Rightarrow A = 0$ for all $A \in \mathcal{A}(O)$. (A vector $\Omega \in \mathcal{H}$ which is cyclic and separating for all local algebras $\mathcal{A}(O)$ is sometimes also called a standard vector for the family $\{\mathcal{A}(O)\}_{O \subset M}$.)

The generic occurrence of the Reeh–Schlieder property for large sets of physical states in quantum field theory—as so far known in quantum field theory on manifolds possessing suitable groups of isometries[1,3–9]—is a mathematically precise way of expressing that long-range correlations are a fundamental feature of quantum field theory. Furthermore, the Reeh–Schlieder property plays a very important role in analyzing the mathematical structure of quantum field theory. For instance, it is being used at some stages in the development of charge superselection theory (see Refs. 4 and 10, and references cited there). Another very important aspect of the Reeh–Schlieder property is that one may naturally associate with each von Neumann algebra together with a cyclic and separating vector the so-called Tomita–Takesaki modular objects.[11] In the seminal work of Bisognano and Wichmann[12,13] it has been shown that the Tomita–Takesaki modular objects associated with the vacuum-vector and the von Neumann algebra $\mathcal{A}(W)$ of a ''wedge-region'' (which is actually infinitely extended) in a Wightman-type quantum field theory on Minkowski space–time have a specific geometric significance. This insight has initiated considerable progress in the mathematical development of general quantum field theory on which the recent review by Borchers[14] reports exhaustively; therefore we refer the reader to that reference for further discussion. We limit ourselves to mentioning that quite promising generalized forms of such a ''geometric modular action'' that are applicable to quantum field theories on curved space–times have been suggested and investigated more recently.[15,16] The Reeh–Schlieder property is also responsible for (maximal) violations of Bell's inequalities in quantum field theory,[17] and more recently, Reeh–Schlieder properties have been found to imply various forms of long-range entanglement of states in relativistic quantum field theory;[18–20] see also Refs. 21 and 22 for related discussions. A possible significance of Reeh–Schlieder properties for questions related to cosmology has been proposed in Ref. 23.

As indicated previously, Reeh–Schlieder properties have, either in the model-independent approach or for concrete quantum field models, so far only been established under the assumption that the space–time in which the quantum system is situated possesses a sufficient amount of space–time symmetries. This constitutes a considerable limitation, and the question is if Reeh–Schlieder-like properties can also be established for quantum field theories on space–times not admitting any isometries. This is feasible since the main mathematical argument leading to the Reeh–Schlieder theorem in the case where there are sufficiently many space–time symmetries is an analytical argument of the type of the edge-of-the-wedge-theorem[3] or Schwartz' reflection principle in order to derive a certain global property of a quantum state from local information, and these arguments do not use space–time symmetries (in particular, timelike isometry groups) directly. On the other hand, commonly the analytic properties of correlation functions in quantum field theory are consequences of the relativistic spectrum condition whose formulation requires a form of time-translation symmetry. Time-translation symmetry is also required in order to formulate conditions of thermal equilibrium in relativistic quantum field theory from which Reeh–Schlieder properties may also be deduced.[6]

At any rate, certain analytical properties of correlation functions are prerequisite in order to establish Reeh–Schlieder theorems in quantum field theory and the question arises how to generalize the analyticity properties known to hold, e.g., for ground states or thermal equilibrium states with respect to a time-symmetry group to more general situations. A way to proceed in more general situations may be to follow, and to refine, the approach pioneered by Radzikowski,[24,25] who proved that, for a free scalar quantum field on generic curved space–times, the condition that a quasifree state be a Hadamard state can equivalently be expressed as a condition on the wave front set of the two-point function of that state (see also Refs. 26–28 for related work). Since it can convincingly be argued that Hadamard states are most likely candidates for physical states of quantum fields obeying linear wave-equations,[29] it appears natural to sharpen the condition on the

two-point function of a physical state by demanding that it applies to the analytic wave front set and not only, as in most previous considerations, to the C^∞ wave front set. In order that this makes sense independently of particular coordinates, the underlying space-time manifold ought to be real analytic.

Thus, we will propose a stricter form of the wave front set spectrum condition formulated in Ref. 24, or of the microlocal spectrum condition,[30] for the n-point functions of a generic scalar quantum field on a real analytic space–time in terms of their analytic wave front sets, and we will show that such states possess the Reeh–Schlieder property. In doing so, we will present a transcription of the (analytic) microlocal spectrum condition for a two-point function as a condition on the wave front set of a certain Hilbert-space valued distribution. It turns out that working with wave front sets of Hilbert-space valued distributions has several advantages. One of those is that in terms of Hilbert-space valued distributions the (analytic) microlocal spectrum condition (for two-point functions of free fields) assumes a very simple and elegant form which is, in fact, most reminiscent of the usual spectrum condition in quantum field theory in Minkowski space–time. Part of this analysis appears already in Ref. 31 for the case of the C^∞ wave front set where the calculus of Hilbert space valued distributions is used for the definition of Wick products of free fields. This appeared motivation enough to discuss several aspects of microlocal analysis of Hilbert-space valued distributions more systematically, and that discussion thus forms the first part of the present article in Sec. II.

In Sec. III we summarize some basics on the description of general scalar quantum fields on curved space–times, together with the example of the free scalar Klein–Gordon field.

We recapitulate the definition of the microlocal spectrum condition (''μSC''), referring to the C^∞ wave front sets of n-point functions of quantum fields on manifolds, according to Ref. 30 in Sec. IV. In the same section, we introduce our analytic microlocal spectrum condition (''aμSC'') which will be defined similarly to μSC but now using analytic wave front sets of n-point functions of quantum fields on real analytic manifolds. (We should note that Hollands and Wald[32] have recently also introduced a similar concept of analytic microlocal spectrum condition which refers to a whole class of states, and is used in a different context.)

In Sec. V we will present our main result, which is a Reeh–Schlieder theorem for quantum field states fulfilling the aμSC. Here, we draw on results of Sec. II, and also on a microlocal version of the edge-of-the-wedge theorem, which appears as Theorem 8.5.6′ in Ref. 33.

Finally, in Sec. VI we present the characterization of aμSC and of μSC for two-point functions of a free scalar field on a manifold in terms of a simple conic form of the wave front set of certain Hilbert-space valued distributions. Moreover, we prove that ground and KMS states of the free scalar field on a real analytic stationary space–time obey the aμSC. This shows in particular that the Hartle–Hawking state on the Schwarzschild space–time satisfies the aμSC.

II. MICROLOCAL ANALYSIS FOR HILBERT SPACE VALUED DISTRIBUTIONS

Assume we are given a Hilbert space $\mathcal{H}$ and a smooth manifold M which is second countable and Hausdorff. The space $\mathcal{D}'(M,\mathcal{H})$ of $\mathcal{H}$ valued distributions is defined to be the set of all weakly continuous linear maps

$$C_0^\infty(M)\to\mathcal{H}.$$

Note that due to the nuclearity of $C_0^\infty(M)$ these maps are automatically strongly continuous. If $X\subset\mathbb{R}^n$ is an open subset a linear map $\psi: C_0^\infty(X)\to\mathcal{H}$ is in $\mathcal{D}'(X,\mathcal{H})$ if and only if for each compact subset $K\subset X$ there are constants $C>0$ and $\alpha\in\mathbb{N}_0$ such that

$$\|\psi(f)\|<C\sum_{|k|\leqslant\alpha}\sup_x|(\partial^k f)(x)|, \tag{1}$$

for all $f \in C_0^\infty(K)$. If α can be chosen independently of K, then we say that ψ is of order α and write $\psi \in \mathcal{D}'^{\alpha}(X,\mathcal{H})$. The set of $\psi \in \mathcal{D}'(X,\mathcal{H})$ with compact support in X will be denoted by $\mathcal{E}'(X,\mathcal{H})$. If ψ has compact support then one can easily extend ψ to a linear map $C^\infty(X) \to \mathcal{H}$ and we have for all compact sets K which contain $\mathrm{supp}(\psi)$,

$$\|\psi(f)\| < C \sum_{|k| \leqslant \alpha} \sup_{x \in K} |(\partial^k f)(x)|, \quad \forall f \in C^\infty(X), \tag{2}$$

for some $C > 0, \alpha \in \mathbb{N}_0$. Conversely, if there exists a compact set K such that for a given linear map $\psi: C^\infty(X) \to \mathcal{H}$ the inequality (2) holds for some C and α, then ψ is a distribution with support in K. Therefore, $\mathcal{E}'(X,\mathcal{H})$ can be identified with the set of strongly continuous maps $C^\infty(X) \to \mathcal{H}$. If a subset L of $\mathcal{E}'(X,\mathcal{H})$ is bounded then (2) holds for all $\psi \in L$ and $f \in C^\infty(X)$ with constants C and α independent of ψ. We define $\mathcal{E}'^{\alpha}(X,\mathcal{H}) := \mathcal{E}'(X,\mathcal{H}) \cap \mathcal{D}'^{\alpha}(X,\mathcal{H})$ and obviously $\mathcal{E}'(X,\mathcal{H}) = \cup_\alpha \mathcal{E}'^{\alpha}(X,\mathcal{H})$.

If $\psi \in \mathcal{E}'(\mathbb{R}^n,\mathcal{H})$ one may define the Fourier transform $\hat{\psi}$ in the same way as this is done for ordinary distributions. Namely, the Fourier transform $\hat{\psi}$ is the $\mathcal{H}$ valued function on $\mathbb{R}^n$ given by $\hat{\psi}(k) := \psi(e^{-ik\cdot})$.

Definition 2.1: Let X be open in $\mathbb{R}^n$ and let ψ be in $\mathcal{D}'(X,\mathcal{H})$. Then a point $(x,k) \in X \times (\mathbb{R}^n \backslash \{0\})$ is called regular directed for ψ if the following holds: There exists a function $f \in C_0^\infty(X)$ with $f(x) = 1$ and an open conic neighborhood Γ of k such that for each $N \in \mathbb{N}$ there exists a constant C_N with

$$\sup_{\lambda \in \Gamma} (1 + |\lambda|)^N \|\widehat{f\psi}(\lambda)\| < C_N. \tag{3}$$

The set of regular directed points is open. Its complement in $X \times (\mathbb{R}^n \backslash \{0\})$ is called the wave front set $\mathrm{WF}(\psi)$ *of ψ.*

The following proposition shows that microlocal analysis of Hilbert space valued distributions is analogous to the case of ordinary distributions. See also Ref. 31 for related discussion.

Proposition 2.2: Let X be open in $\mathbb{R}^n$ and let $\psi \in \mathcal{D}'(X,\mathcal{H})$ be a Hilbert space valued distribution.

(1) If (3) *holds for $f \in C_0^\infty(X)$ then it also holds with f replaced by gf for any $g \in C^\infty(X)$.*

(2) If ψ has compact support then $\hat{\psi}$ is polynomially bounded in the norm, i.e., there is a constant C and an integer M, such that

$$\|\hat{\psi}(k)\| < C(1 + |k|)^M. \tag{4}$$

If moreover a subset $L \in \mathcal{E}'(X,\mathcal{H})$ is bounded then (4) *holds for all $\psi \in L$ with C and M independent of ψ.*

(3) If $\mathrm{WF}(\psi)$ *is empty then ψ is smooth in the norm.*

(4) If we define the distribution $w \in \mathcal{D}'(X \times X)$ by $w(f,g) = \langle \psi(\overline{f}), \psi(g) \rangle$, then

$$(x,k) \in \mathrm{WF}(\psi) \Leftrightarrow ((x,-k),(x,k)) \in \mathrm{WF}(w), \tag{5}$$

and moreover, if $(x,k) \notin \mathrm{WF}(\psi)$ with $k \neq 0$, then

$$((x,-k),(x_1,k_1)) \notin \mathrm{WF}(w) \quad \textit{and} \quad ((x_1,k_1),(x,k)) \notin \mathrm{WF}(w), \tag{6}$$

for arbitrary $(x_1,k_1) \in X \times \mathbb{R}^n$.

(5) Under change of coordinates $\mathrm{WF}(\psi)$ *transforms as a subset of the cotangent bundle. Hence,* $\mathrm{WF}(\phi)$ *may be defined for distributions $\phi \in \mathcal{D}'(M,\mathcal{H})$, for a smooth manifold M and* $\mathrm{WF}(\phi) \subset T^*M \backslash 0$. *Here $T^*M \backslash 0$ is the cotangent bundle with zero section removed.*

Proof: The first statement is proved in the same manner as for ordinary distributions (cf. Ref. 33, Lemma 8.1.1). The inequality (2) immediately gives the second statement if $f(x) = e^{-ikx}$. To

see that (3) holds we first note that $\mathrm{WF}(\psi)=\varnothing$ implies that for each point $x\in X$ there is a C_0^∞ function with $f(x)=1$ such that $\|\widehat{f\psi}\|$ is rapidly decreasing. The same arguments as in the complex valued case show that $f\psi$ can be represented by the inverse Fourier transform of $\widehat{f\psi}$, which is a smooth function, i.e., all derivatives in the norm sense exist and are given by $D^\alpha(f\psi)(x)=2\pi((-\mathrm{i}k)^\alpha\widehat{f\psi}(k)(-x)$. (5) is a simple consequence of (4) and it remains to show (4). Assume first that $(x,-k,x,k)$ is regular directed for w. Then there is a function $f_1\in C_0^\infty(X\times X)$ such that $\widehat{f_1 w}$ decays rapidly in a conic neighborhood of $(x,-k,x,k)$. Because of (1) we may choose f_1 to be of the form $f\otimes f$, where $f\in C_0^\infty(X)$ is a positive function. Since

$$\|\widehat{f\psi}(k)\|^2=((\widehat{f\otimes f})w(-k,k), \tag{7}$$

(x,k) is regular directed for ψ. Suppose conversely we knew that (x,k) is regular directed for ψ. By the Cauchy inequality we have

$$|((\widehat{f\otimes g})w(k_1,k_2)|\leqslant\|\psi(\overline{f}(\cdot)e^{\mathrm{i}k_1\cdot})\|\cdot\|\psi(g(\cdot)e^{-\mathrm{i}k_2\cdot})\|. \tag{8}$$

By assumption there is a $g\in C_0^\infty(X)$ with $g(x)=1$ such that in a conic neighborhood of k the second factor is rapidly decreasing. Since the other is polynomially bounded for any $f\in C_0^\infty(X)$, (x_1,k_1,x,k) is a regular directed point for w for any (x_1,k_1). In the same way one shows that $(x,-k,x_1,k_1)$ is regular directed. This concludes the proof. □

The fourth statement in the above-given proposition allows one to take over many results known for ordinary distributions.

Proposition 2.3: If $P:C^\infty(M)\to C^\infty(M)$ is a differential operator and $\psi\in\mathcal{D}'(M,\mathcal{H})$ such that $\psi\circ P^*=0$, where P^* is the formal adjoint of P, then

$$\mathrm{WF}(\psi)\subset\mathrm{char}(P).$$

Here $\mathrm{char}(P)$ *is the characteristic set of P, i.e., the set of points (x,k) in $T^*M\backslash 0$ on which the principal symbol σ_P of P vanishes.*

Proof: We define w as in Proposition 2.2. Note that $((x,-k),(x,k))$ is in the characteristic set of the operator $L:=\overline{P}\otimes P$ if and only if (x,k) is in the characteristic set of P. Moreover, $Lw=0$. The result follows now from the fourth statement in Proposition 2.2. □

One may also define the analytic wave front set of a Hilbert space valued distribution. We follow the definition in Ref. 33 (Definition 8.4.3).

Definition 2.4: Let X be an open subset of $\mathbb{R}^n$ and $\psi\in\mathcal{D}'(X,\mathcal{H})$. We denote by $\mathrm{WF}_A(\psi)$ *the complement in $X\times(\mathbb{R}^n\backslash\{0\})$ of the set of points (x_0,k_0) such that there is a neighborhood $U\subset X$ of x_0, a conic neighborhood Γ of k_0 and a bounded sequence ψ_N of distributions with compact support which is equal to ψ in U, such that there exists a constant C with*

$$\||k|^N\hat{\psi}_N(k)\|\leqslant C(C(N+1))^N, \tag{9}$$

for all $k\in\Gamma$.

The bounded sequence ψ_N can always be chosen to be the product $f_N\psi$, where f_N is a sequence of smooth functions. One has

Lemma 2.5: Let $\psi\in\mathcal{D}'(X,\mathcal{H})$, K a compact subset of X, and let F be a closed cone in $\mathbb{R}^n$ such that $\mathrm{WF}_A(\psi)\cap(K\times F)=\varnothing$. If $f_N\in C_0^\infty(K)$ and for all α

$$|D^{\alpha+\beta}f_N|\leqslant C_\alpha(C_\alpha(N+1))^{|\beta|},\quad |\beta|\leqslant N=1,2,\ldots, \tag{10}$$

then $f_N\psi$ is a bounded sequence and we have

$$\||k|^N\hat{\psi}_N(k)\|\leqslant C(C(N+1))^N, \tag{11}$$

for all $k \in F$. Moreover, if x is a point in the interior of K, there always exists a neighborhood $\mathcal{U}$ of x and a sequence of functions f_N such that (10) is satisfied and $f_N = 1$ on $\mathcal{U}$.

Proof: The proof of this statement is the same as for ordinary distributions (see Ref. 33, Lemma 8.4.4). □

Proposition 2.6: Let X be an open set in $\mathbb{R}^n$ and let $\psi \in \mathcal{D}'(X,\mathcal{H})$ be a Hilbert space valued distribution.

(1) If $\mathrm{WF}_A(\psi)$ is empty then ψ is strongly real analytic.

(2) If we define the distribution $w \in \mathcal{D}'(X \times X)$ by $w(f,g) = \langle \psi(\overline{f}), \psi(g) \rangle$, then

$$(x,k) \in \mathrm{WF}_A(\psi) \Leftrightarrow ((x,-k),(x,k)) \in \mathrm{WF}_A(w), \tag{12}$$

and moreover, if $(x,k) \notin \mathrm{WF}_A(\psi)$ with $k \neq 0$, then

$$((x,-k),(x_1,k_1)) \notin \mathrm{WF}_A(w) \quad \textit{and} \quad ((x_1,k_1),(x,k)) \notin \mathrm{WF}_A(w), \tag{13}$$

for arbitrary $(x_1,k_1) \in X \times \mathbb{R}^n$.

(3) Under analytic change of coordinates $\mathrm{WF}_A(\psi)$ transforms as a subset of the cotangent bundle. Hence, $\mathrm{WF}_A(\phi)$ may be defined for distributions $\phi \in \mathcal{D}'(M,\mathcal{H})$, for a smooth real analytic manifold M and $\mathrm{WF}_A(\phi) \subset T^*M \backslash 0$.

Proof: We start with (2). Assume that $(x,-k,x,k) \notin \mathrm{WF}_A(w)$. We choose a sequence of functions f_N in $C_0^\infty(X)$ which satisfies the inequality (10) and which is equal to 1 in a neighborhood of x. Then the sequence $g_N := \overline{f_N} \otimes f_N \in C_0^\infty(X \times X)$ also satisfies an inequality of the form (10), and hence

$$|(-k_1,k_1)|^N |\widehat{(g_N w)}(-k_1,k_1)| \leq C(C(N+1))^N, \tag{14}$$

for some constant $C > 0$ and all k_1 in a conic neighborhood of k. We have

$$\|\widehat{f_N \psi}(k_1)\|^2 = \widehat{(g_N w)}(-k_1,k_1), \tag{15}$$

and a quick estimate shows that for all k_1 in a conic neighborhood of k we have

$$\| |k_1|^N \widehat{(f_N \psi)}(k_1) \| \leq \widetilde{C}(\widetilde{C}(N+1))^N, \tag{16}$$

for some constant $\widetilde{C}$. Therefore, $(x,k) \notin \mathrm{WF}_A(\psi)$. Suppose conversely that $(x_1,k_1) \notin \mathrm{WF}_A(\psi)$. Hence, there is a sequence ψ_N bounded in $\mathcal{E}'(X,\mathcal{H})$ and equal to ψ in a neighborhood of x_1 such that the inequality (9) holds in a conic neighborhood of k_1. Choose another function g which is equal to 1 in a neighborhood of a point x_2. Then the distribution w_N defined by $w_N(h_1,h_2) := \langle \psi(g \cdot \overline{h_1}), \psi_N(h_2) \rangle$ is bounded in $\mathcal{E}'(X \times X)$. Moreover, an application of the Cauchy inequality shows that

$$|\hat{w}_N(k_2,k)| \leq \|\psi(g e^{\mathrm{i}k_2 \cdot})\| \cdot \|\psi_N(e^{-\mathrm{i}k \cdot})\|. \tag{17}$$

The first factor is bounded by $C_M(1+|k_2|)^M$ for some $M \in \mathbb{N}$ and a simple estimate shows that for all k_2 there is a conic neighborhood Γ of (k_2,k_1) and a $C > 0$ with

$$|(k_2',k)|^N \cdot |\hat{w}_{N+M}(k_2',k)| \leq C(C(N+1))^N, \tag{18}$$

for all $(k_2',k) \in \Gamma$. Since w_N is equal to w in a neighborhood of (x_2,x_1), we get

$$((x_2,k_2),(x_1,k_1)) \notin \mathrm{WF}_A(w).$$

In the same way one shows that

$$((x_1,-k_1),(x_2,k_2)) \notin \mathrm{WF}_A(w).$$

Statement (3) is an immediate consequence of (2) since the analytic wave front set of an ordinary distribution transforms as a subset of the cotangent bundle. The first statement can be shown in the same way as for ordinary distributions (see Ref. 33, Theorem 8.4.5). This concludes the proof.□

Proposition 2.7: If $P:C^\infty(M)\to C^\infty(M)$ *is a differential operator with real analytic coefficients on a real analytic manifold* M *and* $\psi\in\mathcal{D}'(M,\mathcal{H})$ *such that* $\psi\circ P^*=0$, *where* P^* *is the formal adjoint of* P, *then*

$$\mathrm{WF}_A(\psi)\subset\mathrm{char}(P),$$

where $\mathrm{char}(P)$ *is the characteristic set of* P.

Proof: Analogous to the proof of Proposition 2.3. □

Theorem 2.8: *Let* $X\subset\mathbb{R}^n$ *be an open subset and assume* $\psi\in\mathcal{D}'(X,\mathcal{H})$. *Assume that there is a smooth* $\mathcal{H}$*-valued function* $G:I\times X\to\mathcal{H}$, *with* $I=(0,\epsilon)$, *such that*

$\lim_{t\to 0}G(t,\cdot)=\psi$ *in the sense of distributions,*

$(\partial_t G)(t,x_1,\ldots,x_n)=\mathrm{i}(\partial_{x_1}G)(t,x_1,\ldots,x_n)$.

Then $\mathrm{WF}_A(\psi)\subset\{(x_1,\ldots,x_n)\times(y_1,\ldots,y_n)\in X\times\mathbb{R}^n\backslash\{0\};y_1\geqslant 0\}$.

Proof: The proof is a variation of the proof of Theorem 8.4.8 in Ref. 33. Since the statement is local we can assume without loss of generality that $X=X_1\times\cdots\times X_n$ and that ψ. First note that for each given $g\in C_0^\infty(X_2\times\ldots\times X_n)$ the function

$$H(x+\mathrm{i}y):=\int_{X_2\times\cdots\times X_n}G(y,x,y_2,\ldots,y_n)g(y_2,\ldots,y_n)\mathrm{d}y_2\cdots\mathrm{d}y_n \tag{19}$$

is defined on the strip $X_1+\mathrm{i}I$ and is holomorphic. Moreover, it has a distributional boundary value $\psi(\cdot\otimes g)$. We will slightly vary the proof of Theorem 3.1.14 in Ref. 33 to show that the following bound holds:

$$\|H(x+\mathrm{i}y)\|\leqslant C'y^{-m-1} \tag{20}$$

if $(x,y)\in\tilde{X}_1\times I/2$ and $\mathrm{clo}(\tilde{X}_1)\subset X_1$ for some $m>0$. Let $f\in C_0^\infty(X_1\times I)$ be a function with support in $K\times I$, where K is a compact subset of X_1, such that f is equal to 1 in a neighborhood of $\overline{Z}$, where $Z:=\tilde{X}_1\times I/2$. Cauchy's integral formula applied to fH in the set $\Im z>\Im(\zeta/2)$ shows that if $\zeta=\xi+\mathrm{i}\eta\in Z$,

$$\begin{aligned}H(\zeta)=&-\pi^{-1}\int\int_{y>\eta/2}H(x+\mathrm{i}y)\partial f(x,y)/\partial\overline{z}(z-\zeta)^{-1}\mathrm{d}x\,\mathrm{d}y\\&+(2\pi\mathrm{i})^{-1}\int f(x,\eta/2)(x-\xi-\mathrm{i}\eta/2)^{-1}H(x+\mathrm{i}\eta/2)\mathrm{d}x.\end{aligned} \tag{21}$$

An application of the uniform boundedness principle (Banach–Steinhaus theorem) shows that $\|\int_{X_1}H(x+\mathrm{i}y)h(x)\mathrm{d}x\|\leqslant C\Sigma_{\alpha\leqslant m}\sup|\partial^\alpha h|$ for all $h\in C_0^\infty(K)$ with constants C and m independent of y (cf. Ref. 33, Theorem 2.1.8). Therefore, the last integral in (21) can be estimated in the norm by

$$C_1\sum_{\alpha\leqslant m}\sup|\partial_x^\alpha(x,\eta/2)(x-\xi-\mathrm{i}\eta/2)^{-1}|\leqslant C_2|\eta|^{-m-1}. \tag{22}$$

The first integral in (21) is bounded and this proves the inequality (20).

Since the statement of the theorem is local we can always replace X_1 by $\tilde{X}_1$ and I by $I/2$ and we can therefore assume without loss of generality that the bound (20) holds in $X_1\times I$. From Stokes integral formula one gets for y, $Y\in\mathbb{R}_+$ and $N\in\mathbb{N}$ such that $y+Y<\epsilon/2$ the following formula (compare 3.1.19 in Ref. 33) for any $\tilde{\phi}\in C_0^\infty(X)$ with $\tilde{\phi}=\phi\otimes g$:

$$\int_X \tilde{\phi}(\mathbf{x})G(y,\mathbf{x})\mathrm{d}\mathbf{x} = \int_{X_1} \Theta(x,Y)H(x+\mathrm{i}y+\mathrm{i}Y)\mathrm{d}x + (N+1)\int_{X_1}\mathrm{d}x\int_{0<t<1}\mathrm{d}t\, H(x+\mathrm{i}tY+\mathrm{i}y)(\partial^N\phi)(x)\frac{(\mathrm{i}Y)^N}{N!}t^N, \tag{23}$$

where

$$\Theta(x,y) := \sum_{j=0}^{N} \partial^j\phi(x)(\mathrm{i}y)^j/j!. \tag{24}$$

Because of the bound (20) the integrand under the double integral in (23) is uniformly bounded by an integrable function if $N>(m+1)$ and the first term even converges uniformly as $y\to 0$. Therefore, we have for $N>(m+1)$,

$$\psi(\tilde{\phi}) = \int_{X_1}\Theta(x,Y)H(x+\mathrm{i}Y)\mathrm{d}x + (N+1)\int_{X_1}\mathrm{d}x\int_{0<t<1}\mathrm{d}t\, H(x+\mathrm{i}tY)(\partial^N\phi)(x)\frac{(\mathrm{i}Y)^N}{N!}t^N. \tag{25}$$

Now let $\mathbf{x}'=(x_1',\ldots,x_n')$ be a point in X and let ϕ_ν be a sequence of functions on X_1 which are all equal to 1 in a common neighborhood of x_1' such that

$$|\partial^\alpha\phi_\nu| \leqslant (C_1(\nu+1))^\alpha, \quad \alpha\leqslant\nu+1. \tag{26}$$

Assume that g is equal to 1 in a neighborhood of $(x_2',\ldots,x_n')$. With

$$\Theta_\nu(x,y) := \sum_{j=0}^{\nu}\partial^j\phi_\nu(x)(\mathrm{i}y)^j/j! \tag{27}$$

we get from (25) for $\nu>(m+1)$,

$$\widehat{(\phi_\nu\otimes g)}\psi(k) = \int_X G(Y,\mathbf{x})\Theta_\nu(x_1,Y)g(x_2,\ldots,x_n)e^{-\mathrm{i}(\mathbf{x}+\mathrm{i}\mathbf{Y},k)}d\mathbf{x} + (\nu+1)\int_X d\mathbf{x}\int_{0<t<1}dtG(tY,\mathbf{x})e^{-\mathrm{i}(\mathbf{x}+\mathrm{i}t\mathbf{Y},k)}\cdot(\partial^\nu\phi_\nu)(x_1)g(x_2,\ldots,x_n)\frac{(\mathrm{i}Y)^\nu}{\nu!}t^\nu. \tag{28}$$

Here we used the notations $\mathbf{x}=(x_1,\ldots,x_n)$ and $\mathbf{Y}=(Y,0,\ldots,0)$. With $C_2=2e^{C_1Y}$ we have $|\Theta_\nu(x,Y)|\leqslant C_2^{\nu+1}$ and because of the bound (20) we get

$$\|(\phi_\nu\otimes g)\psi(k)\| \leqslant C_3^{\nu+1}(e^{(Y,k)}+(\nu-m-1)!(-\mathbf{Y},k)^{m-\nu}), \quad (\mathbf{Y},k)<0. \tag{29}$$

We define $\psi_\nu := (\phi_{m+\nu}\otimes g)\psi$ and if $(\mathbf{Y},k)<-c|k|$ for a fixed c, we obtain for some C_4,

$$\|\hat{\psi}_\nu(k)\| \leqslant C_4^{\nu+1}\nu!|k|^{-\nu}, \tag{30}$$

since $e^{-c|k|}\leqslant\nu!(c|k|)^{-\nu}$. If we chose ϕ_ν bounded in C_0^∞, then ψ_ν is bounded in $\mathcal{E}'(X,\mathcal{H})$. We have shown that

$$\mathrm{WF}_A(\psi)\subset X\times\{k,(\mathbf{Y},k)\geqslant 0\}.$$

□

An immediate corollary of this theorem is

Corollary 2.9: Let $X\subset\mathbb{R}^n$ be an open subset. Suppose that V is an open cone in $\mathbb{R}^n\backslash\{0\}$ and Z is an open neighborhood of 0 in $\mathbb{R}^n$. Denote by V° the dual cone. (The dual cone V° of an open cone V is defined as the set $V^\circ=\{\xi\in\mathbb{R}^n:\langle v,\xi\rangle\geqslant 0\,\forall\, v\in V\}$, where $\langle\,.\,,.\,\rangle$ denotes the Euclidean scalar product on $\mathbb{R}^n$.) If $\psi\in\mathcal{D}'(X,\mathcal{H})$ is the boundary value in the sense of distributions of a function G which is analytic in $X\times(V\cap Z)$, then $\mathrm{WF}_A(\psi)\subset X\times V^\circ$.

III. QUANTUM FIELD THEORY ON CURVED SPACE–TIMES

By a space–time we mean in the following a connected smooth manifold of dimension $n\geqslant 2$ which is second countable and Hausdorff and which is endowed with a Lorentzian metric g such that M is both oriented and time-oriented. A spacelike hypersurface $\mathcal{C}$ in a space–time M is called Cauchy surface if each inextendible causal curve intersects $\mathcal{C}$ exactly once. In case there exists a Cauchy surface the space–time M is said to be globally hyperbolic (see, e.g., Refs. 34 and 35 for further discussion).

A. Scalar fields on curved space–times

The Borchers–Uhlmann algebra $\mathcal{B}$ of a manifold M is defined to be the topological tensor algebra

$$\mathcal{B}:=\mathbb{C}\oplus\bigoplus_{m=1}^{\infty}\otimes^m C_0^\infty(M) \tag{31}$$

endowed with a star defined by $(f_1\otimes\cdots\otimes f_k)^*=\overline{f_k}\otimes\cdots\otimes\overline{f_1}$. A state ω over $\mathcal{B}$ determines a sequence of distributions $\omega_m\in\mathcal{D}'(M^m)$, the so-called m-point functions, by

$$\omega_m(f_1,\ldots,f_m):=\omega(f_1\otimes\cdots\otimes f_m). \tag{32}$$

If $\mathcal{H}$ is a Hilbert space and D a dense subset we denote by $\mathcal{L}_D^+$ the set of (possibly unbounded) operators A on $\mathcal{H}$ with the properties

$$\mathrm{dom}(A)=D,\quad AD\subset D,\quad \mathrm{dom}(A^*)\supset D,\quad A^*D\subset D. \tag{33}$$

The involution $A^+:=A^*|_D$ and the locally convex topology defined by the seminorms $p_{\phi,\psi}(A):=|\langle\phi,A\psi\rangle|$, $\phi,\psi\in D$ turn $\mathcal{L}_D^+$ into a locally convex topological $*$-algebra.

Each state over the Borchers–Uhlmann algebra $\mathcal{B}$ determines, by the GNS construction, a Hilbert space $\mathcal{H}$ with a dense domain D and an $*$-representation $\pi:\mathcal{B}\to\mathcal{L}_D^+$ with cyclic vector $\Omega\in D$ such that $\pi(\mathcal{B})\Omega=D$. If $M=\mathbb{R}^4$ is the Minkowski space it is well known that Wightman fields can be constructed from states over the Borchers–Uhlmann algebra which satisfy certain requirements like translation invariance or the spectrum condition. The field is, in this case, the operator valued distribution $f\mapsto\Phi(f):=\pi(0\oplus f\oplus 0\oplus\cdots)$. We will think of a quantum field on a curved space–time in the same way, i.e., a quantum field can be defined by a state over the Borchers–Uhlmann algebra of test functions on the underlying space–time. A state is called quasifree if all the odd m-point functions vanish and the even m-point functions can be expressed by

$$\omega_m(f_1,\ldots,f_m)=\sum_P\prod_r\omega_2(f_{(r,1)},f_{(r,2)}), \tag{34}$$

where P denotes a partition of the set $\{1,\ldots,m\}$ into subsets which are pairings of points labeled by r.

For quantum fields on Minkowski space–time one usually requires the properties of Poincaré covariance, spectrum condition, existence of an invariant vacuum vector as well as local commutativity (for observable fields) to hold (see, e.g., Refs. 3 and 2). Due to the lack of an analog of the Poincaré group, only the last requirement can straightforwardly be generalized to curved space–

times. However, as will be seen in Sec. IV, there is a microlocal version of the spectrum condition which can be stated independently of the coordinate system and hence can be applied to quantum fields on curved space–times.

For a field $\Phi(\cdot)$ defined by a state ω over the Borchers–Uhlmann algebra we can associate a net of von Neumann algebras $\{\mathcal{A}(O)\}_{O\subset M}$ in the following way. Let as previously D be the dense domain $\pi(\mathcal{B})\Omega$ arising by the GNS construction from ω. For a subset $S\subset\mathcal{L}_D^+$ the weak commutant S_w' of S is defined to be the set of bounded operators A on $\mathcal{H}$ such that

$$\langle B^*\phi, A\psi\rangle = \langle A^*\phi, B\psi\rangle, \quad \forall \ B\in S, \ \ \phi,\psi\in D. \tag{35}$$

A net of von Neumann algebras $\{\mathcal{A}(O)\}_{O\subset M}$ is then defined by

$$\mathcal{A}(O) := (\{\Phi(f);\ \ \mathrm{supp}(f)\subset O\}_w')'. \tag{36}$$

The requirement of local commutativity may now be formulated by demanding that the von Neumann algebras associated with causally separated regions commute, i.e.,

$$\mathcal{A}(O_1)\subset\mathcal{A}(O)' \quad \text{if} \quad O_1\subset O^\perp.$$

This is a strong form of local commutativity which is to be seen as a selective constraint on the Hilbert-space representation π of the Borchers–Uhlmann algebra $\mathcal{B}$ induced by the state ω, and hence as a constraint on ω itself. It implies in particular spacelike commutativity of field operators, $[\Phi(f),\Phi(h)]=0$ whenever the supports of f and h are causally separated.

B. The Klein–Gordon field on curved space–times

Since the construction of free fields relies heavily on the presence of a Cauchy surface (time-zero formalism) we restrict our considerations of quantum fields on curved space–times to the globally hyperbolic case. The evolution of the free scalar field of mass m and with coupling κ on a globally hyperbolic space–time is described by the Klein–Gordon equation

$$P\phi := (\Box_g + m^2 + \kappa R)\phi = 0, \quad \phi\in C^\infty(M). \tag{37}$$

Here $\Box_g$ is the Laplace operator with respect to the metric and R is the scalar curvature of M. The operator P is a differential operator of second order acting on the smooth functions on M. It has unique advanced and retarded fundamental solutions (see Refs. 36 and 37) $E^\pm: C_0^\infty(M)\to C^\infty(M)$ satisfying

$$PE^\pm = E^\pm P = \mathrm{id} \quad \text{on} \quad C_0^\infty(M),$$

$$\mathrm{supp}(E^\pm f)\subset J^\pm(\mathrm{supp}(f)),$$

where $J^\pm(O)$ denotes the causal future/past of a set O, i.e., the set of points which can be reached by future/past directed causal curves emanating from O. The difference $E := E^+ - E^-$ is the so-called commutator function. It maps $C_0^\infty(M)$ onto the space of smooth solutions to the Klein–Gordon equation which have compactly supported restriction to all Cauchy surfaces. The map $E: C_0^\infty(M)\to C^\infty(M)$ is continuous and hence has a distributional kernel in $\mathcal{D}'(M\times M)$ which we also denote by E, i.e., $E(f,h)=\int_M f(Eh)$ where integration is taken with respect to the Lorentzian metric-volume form. The field algebra $\mathcal{F}$ of the Klein–Gordon field is defined to be the unital $*$-algebra generated by the symbols $\phi(f)$, $f\in C_0^\infty(M)$ and the relations

(1) $f\mapsto\phi(f)$ is complex linear,
(2) $\phi(f)^* = \phi(\overline{f})$,
(3) $\phi(Pf)=0$,
(4) $[\phi(f_1),\phi(f_2)] = \mathrm{i}E(f_1,f_2)$.

Clearly, each state ω over $\mathcal{F}$ with the further property that the $\omega(\phi(\cdot)\cdots\phi(\cdot))$ are distributions defines a state $\tilde{\omega}$ over the Borchers–Uhlmann algebra by

$$\tilde{\omega}(f_1\otimes\cdots\otimes f_m) := \omega(\phi(f_1)\cdots\phi(f_m)). \tag{38}$$

The corresponding quantum field $\Phi: C_0^\infty(M)\to\mathcal{L}_D^+$ satisfies the Klein–Gordon equation

$$\Phi(P\cdot)=0, \tag{39}$$

and the canonical commutation relations

$$[\Phi(f_1),\Phi(f_2)] = \mathrm{i}E(f_1,f_2)\mathbb{I}|_D. \tag{40}$$

Since the commutator function E vanishes for spacelike separation of the arguments the field satisfies the requirement of local commutativity, i.e., $[\Phi(f),\Phi(h)]=0$ if the supports of f and h are spacelike separated. For many states, among them the quasifree states, also the stronger requirement of local commutativity at the level of the net of von Neumann algebras $\{\mathcal{A}(O)\}_{O\subset M}$ in their GNS-representations described previously is fulfilled. In the following we call states over the Borchers–Uhlmann algebra arising in this way states for the Klein–Gordon field.

IV. THE MICROLOCAL SPECTRUM CONDITION

In the investigation of the Klein–Gordon field a crucial role is played by the so-called Hadamard states (see, e.g., Refs. 38–40). They are thought of as the appropriate counterpart of the vacuum in Minkowski space and are characterized by the short distance behavior of their two-point function. The investigation of such states is partially motivated by the result of Wald[29] that the expectation value of the energy momentum tensor $T_{\mu\nu}$ with respect to a Hadamard state can be made sense of in a satisfactory way. This is a very important feature of Hadamard states, since it is this expectation value that appears in the Einstein equations in the semiclassical theory of gravity coupled to the Klein–Gordon field. We will not give the original definition of Hadamard states here, since such states can as well be characterized by the wave front set of their two-point function. This was shown by Radzikowski[24,25] and relies heavily on the work of Duistermaat and Hörmander[41,42] on Fourier integral operators. We first would like to note that the wave front set of the commutator distribution E for the wave operator P on a globally hyperbolic space–time with metric g is given by

$$\begin{aligned}\mathrm{WF}(E)=\{&((x_1,-k_1),(x_2,k_2));(x_1,k_1)\sim(x_2,k_2)\\ &\text{and } g^{\mu\nu}(k_1)_\mu(k_1)_\nu=g^{\mu\nu}(k_2)_\mu(k_2)_\nu=0\},\end{aligned} \tag{41}$$

where $(x_1,k_1)\sim(x_2,k_2)$ means that there is a lightlike geodesic γ connecting x_1 and x_2 such that k_1 is coparallel to the tangent vector of the curve at x_1 and k_2 is the parallel transport of k_1 from x_1 to x_2. Radzikowski's result is that a quasifree state ω for the Klein–Gordon field is a Hadamard state if and only if the wave front set of its two-point function ω_2 is given by

$$\mathrm{WF}(\omega_2)=\{((x_1,-k_1),(x_2,k_2))\in\mathrm{WF}(E);(k_2)_0>0\}, \tag{42}$$

where $(k_2)_0>0$ is shorthand for "k_2 is future-pointing."

The microlocal characterization of Hadamard states has meanwhile led to a rich theory. In fact, it turned out that quasifree Hadamard states allow for a construction of Wick polynomials of field operators[30,32] and a perturbative construction of interacting fields on curved space–times.[31,43] It was shown in Ref. 44 that such states are locally quasiequivalent and therefore (at least locally) distinguish a single folium of states. A passive state for a free quantum field theory on a stationary space–time is always a Hadamard state (see Refs. 45 and 46 for the statement in its full generality). The Hadamard condition can also be formulated almost without change for arbitrary free

quantum fields. Radzikowski's result is known to hold also in these cases.[28] Adiabatic vacuum states satisfy a similar condition with the wave front set replaced by an appropriate Sobolev wave front set as shown in Ref. 47.

Motivated by the observations just mentioned, a microlocal spectrum condition (μSC) that applies to general quantum fields on curved space–times was introduced by Brunetti, Fredenhagen, and Köhler;[30] we shall now summarize its definition. We denote by $\mathcal{G}_k$ the set of all finite graphs with vertices $\{1,\ldots,k\}$ such that for every element $G\in\mathcal{G}_k$ all edges occur in both admissible directions. We write $s(e)$ and $r(e)$ for the source and the target of an edge, respectively. Following Ref. 30 we define an immersion of a graph $G\in\mathcal{G}_k$ into a space–time M an assignment of the vertices ν of G to points $x(\nu)$ in M, and of edges e of G to piecewise smooth curves $\gamma(e)$ in M with source $s(\gamma(e))=x(s(e))$ and range $r(\gamma(e))=x(r(e))$, together with a covariantly constant causal covector field k_e on γ such that

(1) If e^{-1} denotes the edge with opposite direction as e, then the corresponding curve $\gamma(e^{-1})$ is the inverse of $\gamma(e)$.
(2) For every edge e the covector field k_e is directed toward the future whenever $s(e)<r(e)$.
(3) $k_{e^{-1}}=-k_e$.

Definition 4.1 (μSC, Ref. 30)*: A state ω over the Borchers–Uhlmann algebra $\mathcal{B}$ is said to satisfy the microlocal spectrum condition iff its m-point functions $\omega_m\in\mathcal{D}'(M^m)$ satisfy*

$$\mathrm{WF}(\omega_m)\subset\{(x_1,k_1;\ldots;x_m,k_m)\in T^*M^m\setminus 0;\ \ \exists G\in\mathcal{G}_m$$

and an immersion (x,γ,k) of G in, such that

$$x_i=x(i)\quad \forall i=1,\ldots,m \quad and$$

$$k_i=-\sum_{e,\ s(e)=i} k_e(x_i)\}=\Gamma_m .$$

We note here that quasifree Hadamard states of the Klein–Gordon field satisfy the microlocal spectrum condition. For a motivation of this definition and further properties of states satisfying the μSC we refer the reader to Ref. 30. For later purposes we will need the following property of the sets Γ_m which is Lemma 4.2 in Ref. 30.

Proposition 4.2: The sets Γ_m are stable under addition, i.e., $\Gamma_m+\Gamma_m\subset\Gamma_m$. Moreover, if $(x,k)\in\Gamma_m$ then $(x,-k)\notin\Gamma_m$.

V. THE ANALYTIC MICROLOCAL SPECTRUM CONDITION AND THE REEH–SCHLIEDER PROPERTY

In the following we restrict our consideration to the case when M is a real analytic space–time, i.e., M is real analytic as a manifold and the metric g is analytic. Passing from the smooth to the analytic category it seems reasonable to require that the state satisfies a microlocal spectrum condition with the wave front set WF replaced by the analytic wave front set WF_A. (See Ref. 32 for a related concept.)

Definition 5.1 (aμSC)*: A state ω over the Borchers–Uhlmann algebra is said to satisfy the analytic microlocal spectrum condition* (aμSC) *iff its m-point functions satisfy*

$$\mathrm{WF}_A(\omega_m)\subset\Gamma_m ,$$

where the notations of Definition 4.1 are used.

For Wightman fields in Minkowski space–time the spectrum condition is equivalent to the requirement that the m-point functions are boundary values of functions which are analytic in the tube

$$T_m := \{(z_1,\ldots,z_m);\ \Im(z_{j+1}-z_j)\in V_+,\quad j=1,\ldots,m-1\}, \tag{43}$$

where V_+ is the forward lightcone.

Theorem 5.2: *Suppose that M is the n-dimensional Minkowski space–time ($n\geqslant 2$) and let ω be a state over the Borchers–Uhlmann algebra such that its m-point functions are boundary values in the sense of distributions of functions that are analytic in $T_m\cap Z$, where Z is a complex neighborhood of $(\mathbb{R}^n)^m\subset(\mathbb{C}^n)^m$. Then ω satisfies* aμSC.

Proof: Clearly, T_m is of the form $T_m=(\mathbb{R}^n)^m+i\mathcal{C}$, where the cone $\mathcal{C}$ is defined by $\mathcal{C}=\{(k_1,\ldots,k_m);\ k_{j+1}-k_j\in V_+\}$. The dual cone $\mathcal{C}^\circ$ can easily be calculated and the result is

$$\mathcal{C}^\circ=\left\{(k_1,\ldots,k_m);\ k_m,k_{m-1}+k_m,\ldots,\sum_{j=2}^m k_j\in\overline{V}_+,\quad \sum_{j=1}^m k_j=0\right\}. \tag{44}$$

Hence, by Corollary 2.9, the set $\mathrm{WF}_A(\omega_m)$ is contained in $(\mathbb{R}^n)^m\times\mathcal{C}^\circ$. The set

$$\left\{(x_1,k_1;\ldots;x_m,k_m);\ k_m,k_{m-1}+k_m,\ldots,\sum_{j=2}^m k_j\in\overline{V}_+,\quad \sum_{j=1}^m k_j=0\right\}$$

is contained in Γ_m (see, e.g., the proof of Theorem 4.6 in Ref. 30) which concludes the proof.□

This theorem applies to the vacuum state of Wightman fields in Minkowski space–time and, provided that the invariant domain of all field operators includes, e.g., the C^∞-vectors for the energy, it applies also to vector states which are analytic in the energy (in vacuum representation, see, e.g., Chap. 12 in Ref. 4); moreover, it applies also to states which satisfy the relativistic KMS condition proposed by Buchholz and Bros.[48,49] Quasifree states for the Klein–Gordon field on the de Sitter space–time that satisfy the weak spectral condition[50–52] can also be shown to satisfy aμSC.

Let as before $(\pi,\Omega,D,\mathcal{H})$ be the GNS-representation of the state ω and denote by Φ the corresponding quantum field. We will now show that a state that satisfies aμSC has the Reeh–Schlieder property, i.e., the set $\{\Phi(f_1)\cdots\Phi(f_n)\Omega;\ \mathrm{supp}(f_i)\subset O, m\in\mathbb{N}\}$ is total in $\mathcal{H}$ for each nonvoid open set $O\subset M$.

The main technical tool for proving this is a microlocal version of the *edge of the wedge* theorem (Theorem 8.5.6' in Ref. 33).

Proposition 5.3: Let M be a real analytic connected manifold and $u\in\mathcal{D}'(M)$ a distribution with the property that $\mathrm{WF}_A(u)\cap -\mathrm{WF}_A(u)=\varnothing$. Then the following conclusion holds for each nonvoid open subset $O\in M$:

$$u|_O=0\Rightarrow u=0.$$

Proof: For a closed subset $X\subset M$ the exterior normal set $N_e(X)\subset T^*M\setminus 0$ is defined to be the set of all (x,k) such that $x\in X$ and there is a real valued function $f\in C^2(M)$ with $\mathrm{d}f(x)=k\neq 0$ and $f(y)\leqslant f(x)$ for all $y\in X$. The normal set $N(X)$ is the union $N_e(X)\cup -N_e(X)$. Theorem 8.5.6' in Ref. 33 states that $N(\mathrm{supp}(u))\subset\mathrm{WF}_A(u)$ and since $N(\mathrm{supp}(u))=-N(\mathrm{supp}(u))$ the assumption implies that $N(\mathrm{supp}(u))=\varnothing$. Consequently, $N_e(\mathrm{supp}(u))=\varnothing$. Proposition 8.5.8 in Ref. 33 states that the projection of $N_e(X)$ in M is dense in ∂X. Therefore, $\partial(\mathrm{supp}(u))=\varnothing$. Since M is connected this implies that either $\mathrm{supp}(u)=\varnothing$ or $\mathrm{supp}(u)=M$. The latter is excluded by $u|_O=0$. □

Our main result is stated in the following theorem.

Theorem 5.4: *Let ω be a state over the Borchers–Uhlmann algebra on a real analytic space–time and suppose furthermore that ω satisfies* aμSC. *Denote by $(\pi,\Omega,D,\mathcal{H})$ its GNS-representation and by Φ the associated quantum field. Then the set*

$$\{\Omega\}\cup\{\Phi(f_1)\cdots\Phi(f_m)\Omega;\ \mathrm{supp}(f_i)\subset O,\quad m\in\mathbb{N}\}$$

is total in $\mathcal{H}$ for each nonvoid open set $O\subset M$.

Proof: We define a Hilbert space valued distribution $\psi_m \in \mathcal{D}'(M^m, \mathcal{H})$ by

$$\psi_m(f_1,\ldots,f_m) := \Phi(f_1)\cdots\Phi(f_m)\Omega. \tag{45}$$

Note that due to Proposition 2.6 a point $(x,k) \in T^*M^m \setminus 0$ is in $\mathrm{WF}_A(\psi_m)$ if and only if $(x, -k; x, k) \in \mathrm{WF}_A(w_{2m})$, where the distribution $w_{2m} \in \mathcal{D}'(M^{2m})$ is defined by

$$w_{2m}(f_1,\ldots,f_m,g_1,\ldots,g_m) := \omega_{2m}(f_m,\ldots,f_1,g_1,\ldots,g_m). \tag{46}$$

Proposition 4.2 implies that $\mathrm{WF}_A(w_{2m}) \cap -\mathrm{WF}_A(w_{2m}) = \varnothing$ and therefore $\mathrm{WF}_A(\psi_m) \cap -\mathrm{WF}_A(\psi_m) = \varnothing$.

Suppose now that $\phi \in \mathcal{H}$ is orthogonal to the set

$$\{\Omega\} \cup \{\Phi(f_1)\cdots\Phi(f_m)\Omega;\ \mathrm{supp}(f_i) \subset O, \quad m \in \mathbb{N}\}. \tag{47}$$

Then the distributions $v_m(\cdot) = \langle \phi, \psi_m(\cdot)\rangle \in \mathcal{D}'(M^m)$ vanish on O^m and satisfy $\mathrm{WF}_A(v_m) \cap -\mathrm{WF}_A(v_m) = \varnothing$. By Proposition 5.3 we conclude that $v_m = 0$ for all m. Therefore, ϕ is even orthogonal to the set

$$\{\Omega\} \cup \{\Phi(f_1)\cdots\Phi(f_m)\Omega;\ f_i \in C_0^\infty(M), \quad m \in \mathbb{N}\}, \tag{48}$$

which is total in $\mathcal{H}$. We conclude that $\phi = 0$ which proves the theorem. □

An immediate corollary is the Reeh–Schlieder property of the associated net of local algebras.

Corollary 5.5: Let the assumptions of Theorem 5.4 be fulfilled and denote by $\{\mathcal{A}(O)\}_{O \subset M}$ the associated local net of von Neumann algebras. Then $\mathcal{A}(O)\Omega$ is dense in $\mathcal{H}$ for each nonvoid open set O.

Remark 5.6: (a) Clearly, the conclusion of Theorem 5.4 also holds if we impose the weaker condition $\mathrm{WF}_A(\omega_{2m}) \cap -\mathrm{WF}_A(\omega_{2m}) = \varnothing$ on the state instead of the analytic microlocal spectrum condition. Our result is therefore insensitive to the precise form of analytic microlocal spectrum condition as long as an analog of Proposition 4.2 holds.

(b) The same method works for fields with values in an analytic vector bundle. Note that local commutativity is not an assumption of Theorem 5.4 and therefore it applies to fermionic fields as well.

(c) The existence of states fulfilling aμSC *on generic, real analytic, globally hyperbolic space–times remains an open problem, even for free field theories. See our comments at the end of this article on this point.*

VI. QUASIFREE STATES AND THE KLEIN–GORDON FIELD

As indicated in Sec. I the microlocal spectrum condition can be simplified for quasifree states of the Klein–Gordon field using microlocal analysis of Hilbert space valued distributions. This will allow us to give a rather simple proof of the fact that quasifree ground and KMS states for the Klein–Gordon field on (analytic) stationary spacetimes are (analytic) Hadamard states.

Proposition 6.1: Let M be a globally hyperbolic space–time and let ω be a quasifree state for the Klein–Gordon field on M. Let Φ and Ω be as in Sec. V and denote by ψ the Hilbert space valued distribution $\Phi(\cdot)\Omega$. Then the following statements are equivalent.

(1) ω satisfies μSC.

(2) $\mathrm{WF}(\psi) \subset \overline{V}_+$.

(3) $\mathrm{WF}(\psi) = N_+$.

(4) ω is a Hadamard state.

Here $\overline{V}_+$ denotes the set of future directed causal covectors (x,k) and N_+ is the set of future directed non-zero null-covectors.

Proof: We first show that (1)⇒(2). Suppose that $(x,k) \in \mathrm{WF}(\psi)$. Then by Proposition 2.2 we get $(x, -k; x, k) \in \mathrm{WF}(\omega_2)$. By μSC the covector (x,k) must be in $\overline{V}_+$. (2)⇒(3) is a simple consequence of the fact that ψ solves the Klein–Gordon equation and Proposition 2.3. The impli-

cation (4)⇒(1) is Proposition 4.3 in Ref. 30 and it remains to show (3)⇒(4). By Proposition 2.2 we conclude that if $(x_1,k_1;x_2,k_2)\in \mathrm{WF}(\omega_2)$ then $k_2\in \overline{V}_+$ and $k_1\in \overline{V}_-$. Therefore, $\mathrm{WF}(\tilde{\omega}_2)\cap \mathrm{WF}(\omega_2)=\varnothing$ with $\tilde{\omega}_2(f_1,f_2):=\omega_2(f_2,f_1)$. Note that $\tilde{\omega}_2-\omega_2$ is proportional to the commutator function E and consequently $\mathrm{WF}(\omega_2)\cup \mathrm{WF}(\tilde{\omega}_2)=\mathrm{WF}(E)$. This implies Eq. (42) and thus concludes the proof. □

Remark 6.2: It was shown in Ref. 31 that a vector Ω inducing a quasifree Hadamard state is contained in the microlocal domain of smoothness (introduced in the same article), which implies the conclusion (4)⇒(3). *Proposition 6.1 shows that the microlocal domain of smoothness coincides with the set of vectors inducing quasifree Hadamard states.*

A completely analogous statement holds in the analytic category.

Proposition 6.3: Let M be a globally hyperbolic analytic space–time and let ω be a quasifree state for the Klein–Gordon field on M. With the same notation as in Theorem 6.1 the following statements are equivalent.

(1) ω satisfies aμSC.

(2) $\mathrm{WF}_A(\psi)\subset \overline{V}_+$.

(3) $\mathrm{WF}_A(\psi)=N_+$.

(4) ω is an analytic Hadamard state, meaning that (42) is satisfied with WF *replaced by* WF_A.

Proof: Taking into account Propositions 2.6 and 2.7 the proof is identical to that of Proposition 6.1 with WF replaced by WF_A.

A space–time M with metric tensor g is called stationary if there exists a one-parameter group h_t of isometries of M with timelike orbits whose Killing vector fields are (by convention) future pointing. This one-parameter group can be understood as a group of time-translations and it is therefore interesting to investigate passive states with respect to this group action as states which are physically reasonable replacements for the vacuum. For example the Schwarzschild space–time is stationary and the Hartle–Hawking state for the Klein–Gordon field is a KMS state with respect to the group of time translations. Other examples are the Rindler wedge and wedge-like regions in the de Sitter space. We investigate in the following ground and KMS states for the Klein–Gordon field on a stationary space–time. Let us first fix some notation. The push-forward h_{t*} defined by $(h_{t*}f)(x):=f(h_{-t}x)$ acts on the space $C_0^\infty(M)$ and this action lifts uniquely to an action α_t on the Borchers–Uhlmann algebra $\mathcal{B}$ by *-automorphisms. A state ω over $\mathcal{B}$ is called ground state if the function $t\mapsto\omega(A\alpha_t B)$ is bounded for all $A,B\in\mathcal{B}$ and

$$\int_{-\infty}^{+\infty}\hat{f}(t)\,\omega(A\alpha_t(B))\,\mathrm{d}t=0, \tag{49}$$

holds for all $f\in C_0^\infty((-\infty,0))$. A state ω is called KMS state at inverse temperature $\beta>0$ if the function $t\to\omega(A\alpha_t B)$ is bounded for all $A,B\in\mathcal{B}$ and

$$\int_{-\infty}^{+\infty}\hat{f}(t)\,\omega(A\alpha_t(B))\,\mathrm{d}t=\int_{-\infty}^{+\infty}\hat{f}(t+\mathrm{i}\beta)\,\omega(\alpha_t(B)A)\,\mathrm{d}t, \tag{50}$$

for all $f\in C_0^\infty(\mathbb{R})$. Note that ground and KMS states are necessarily invariant, i.e. $\omega(\alpha_t(\cdot))=\omega(\cdot)$.

Theorem 6.4: *Let M be a globally hyperbolic stationary space–time and suppose that ω is a quasifree KMS- or ground-state for the Klein–Gordon field. Then ω satisfies the microlocal spectrum condition. If moreover M is real analytic (as a space–time) and the flow $\mathbb{R}\times M\to M$ induced by h_t is analytic, then ω satisfies the analytic microlocal spectrum condition.*

Proof: Let $(\pi,\Omega,\mathcal{H},D)$ be the GNS representation of ω. Let $\Phi(\cdot)$ be the associated field and define $\psi(\cdot):=\Phi(\cdot)\Omega$. Since ω is invariant there exists a strongly continuous one-parameter group $U(t)=e^{\mathrm{i}t\mathbf{H}}$ on $\mathcal{H}$, such that $U(t)\psi(\cdot)=\psi(h_t\cdot)$ and $U(t)\Omega=\Omega$. If ω is a β-KMS state it follows from the KMS condition that the vectors $\psi(f)$ are in the domain of $e^{-(\beta/2)\mathbf{H}}=U(\mathrm{i}\beta/2)$ for all $f\in C_0^\infty(M)$. If ω is a ground state this is even true for all $\beta>0$. Therefore, we may define the

distribution $G \in \mathcal{D}'((0,\beta/2)\times M,\mathcal{H})$ by $G(t,x)=U(\mathrm{i}t)\psi(x)$. We use a local coordinate system $(x_0,\ldots,x_{n-1})$ such that the vector field ∂_{x_0} generates locally the flow h_t. Then G satisfies the system of equations

$$(\partial_t^2+\partial_{x_0}^2)G=0, \tag{51}$$

$$(\mathrm{id}\otimes P)G=0. \tag{52}$$

This system is elliptic and therefore G is indeed a smooth function satisfying the conditions of Theorem 2.8. It follows that $\mathrm{WF}_A(\psi)$ is a subset of the set $\{(x,k)\in T^*M;k(\partial_{x_0}(x))>0\}$ in this coordinate system. Since ψ solves the Klein–Gordon equation $\mathrm{WF}(\psi)$ is confined to the forward light cone. If M is real analytic and the flow $\mathbb{R}\times M\to M$ induced by h_t is analytic we can choose the local coordinate system to be analytic and therefore $\mathrm{WF}_A(\psi)\subset\overline{V}_+$. □

The part of Theorem 6.4 stating that ground and KMS states on smooth stationary space–times are Hadamard states was shown before in Ref. 46, cf. also Ref. 45. The method we used in our proof is however rather different from the methods employed there. The advantage of our approach is that it applies to the analytic case without any changes.

As a simple consequence of Theorem 6.4 the Hartle–Hawking state on the Schwarzschild space–time is an analytic Hadamard state. On the de Sitter space–time the so-called Euclidian vacuum state (also called Bunch–Davies vacuum) is known to be a KMS state when restricted to certain stationary wedge-like regions (see, e.g., Refs. 53 and 54, and references therein). As a consequence this state satisfies the aμSC. One can also conclude this more directly from the fact that the two-point function of this state is the boundary value of a function holomorphic in a certain complex tuboid.[54]

Whereas the existence of Hadamard states for the Klein–Gordon field on an arbitrary globally hyperbolic space–time is well established a general construction of analytic Hadamard states seems to be a rather difficult task. In the literature there exist two methods of construction of Hadamard states that apply to generic space–time manifolds. The method used by Fulling *et al.*[45] takes advantage of the fact that any globally hyperbolic space–time can be deformed to a space–time that is static in the past of a given Cauchy surface and coincides with the original space–time in its future. Such a C^∞-deformation, however, destroys the analyticity of the metric and thus this method cannot be exploited for the construction of analytic Hadamard states. Another construction of Hadamard states is due to Junker (Ref. 55). His method relies heavily on the calculus of (smooth) pseudodifferential operators and we are so far not aware of a calculus that would allow it to carry over that method to the analytic case.

ACKNOWLEDGMENTS

(Received 11 September 2001; accepted 9 July 2002)

We investigate the covariant Hamiltonian symplectic structure of General Relativity for spatially bounded regions of space–time with a fixed time-flow vector. For existence of a well-defined Hamiltonian variational principle taking into account a spatial boundary, it is necessary to modify the standard Arnowitt–Deser–Misner Hamiltonian by adding a boundary term whose form depends on the spatial boundary conditions for the gravitational field. The most general mathematically allowed boundary conditions and corresponding boundary terms are shown to be determined by solving a certain equation obtained from the symplectic current pulled back to the hypersurface boundary of the space–time region. A main result is that we obtain a covariant derivation of Dirichlet, Neumann, and mixed type boundary conditions on the gravitational field at a fixed boundary hypersurface, together with the associated Hamiltonian boundary terms. As well, we establish uniqueness of these boundary conditions under certain assumptions motivated by the form of the symplectic current. Our analysis uses a Noether charge method which extends and unifies several results developed in recent literature for General Relativity. As an illustration of the method, we apply it to the Maxwell field equations to derive allowed boundary conditions and boundary terms for the existence of a well-defined Hamiltonian variational principle for an electromagnetic field in a fixed spatially bounded region of Minkowski space–time. [DOI: 10.1063/1.1505984]

I. INTRODUCTION

The mathematical structure of General Relativity as a Hamiltonian field theory is well-understood for asymptotically flat space–times. As first shown by Regge and Teitelboim,[1] with asymptotic falloff conditions on the metric, there is a modification of the standard Arnowitt–Deser–Misner (ADM) Hamiltonian[2] whose field equations obtained from the Hamiltonian variational principle yield a $3+1$ split of the Einstein equations. The ADM Hamiltonian itself yields the $3+1$ Einstein equations only if compact support variations of the metric are used in the variational principle. For metric variations satisfying asymptotic falloff conditions, the ADM Hamiltonian does not give a well-defined variational principle since its variation produces asymptotic boundary terms that do not vanish. However, the boundary terms can be canceled by the addition of a surface integral term at spatial infinity to the ADM Hamiltonian. The resulting Regge–Teitelboim Hamiltonian yields a well-defined variational principle for the Einstein equations with asymptotic falloff conditions on the metric. On solutions of the Einstein equations the Hamiltonian reduces to a surface integral expresssion over spatial infinity, which turns out to yield

a)Electronic mail: sanco@brocku.ca
b)Electronic mail: rohtung@phy.ncu.edu.tw

the physically important ADM definition of total energy, momentum, and angular momentum for asymptotically flat space–times. Various modern, covariant formulations of this Hamiltonian structure are known.[3–7]

A natural question to investigate is whether this Hamiltonian structure can be extended to spatially bounded regions of space–time. An important motivation is astrophysical applications where asymptotically flat boundary conditions are not appropriate, e.g., collapse to a black hole, mergers of binary stars, or collision of black holes. Another important application is for numerical solution methods of the Einstein equations. In these situations the spatial boundary is not an actual physical boundary in space–time, but rather is viewed as a mathematically defined timelike hypersurface whose boundary conditions effectively replace the dynamics of the gravitational field in the exterior region.

In this paper and a sequel,[8] we work out the covariant Hamiltonian structure of General Relativity for arbitrary spatially compact regions of space–time $\Sigma\times\mathbb{R}$ whose spacelike slices Σ prossess a closed two-surface boundary $\partial\Sigma$, with a fixed time-flow vector tangent to the timelike boundary hypersurface $\partial\Sigma\times\mathbb{R}$. Rather than start with given boundary conditions on the metric, we instead seek to determine both the most general surface integral term necessary to be added to the ADM Hamiltonian in covariant form together with the most general corresponding boundary conditions on the metric at $\partial\Sigma$ such that the modified Hamiltonian has well-defined variational derivatives. This would yield the most general mathematically allowed variational principle for the Einstein equations with spatial boundary conditions on the metric. To carry out the analysis we employ the covariant Hamiltonian formalism (referred to as the Noether charge method) developed in Refs. 4, 9, and 10.

The main results are that we find Dirichlet and Neumann type boundary conditions for the metric at a spatial boundary two-surface and obtain the associated Hamiltonian surface integrals. Under some natural assumptions motivated by the symplectic structure arising from the ADM Hamiltonian, the most general allowed boundary conditions are shown to be certain types of mixtures of the Dirichlet and Neumann ones. We also investigate the geometrical structure of the Dirichlet and Neumann covariant Hamiltonians. These each turn out to involve an underlying ''energy-momentum'' vector at each point in the tangent space of the space–time at the two-surface. In the Dirichlet case, this vector depends only on the extrinsic geometry of the spatial boundary two-surface. Most strikingly, when the vector is decomposed into tangential and normal parts with respect to the two-surface, the normal part yields a direction in which the two-surface has zero expansion in the spacetime.

In Sec. II we first apply the Noether charge formalism to investigate, as an illustrative example, the covariant Hamiltonian structure of the free Maxwell equations on spatially compact regions of Minkowski space–time. We show that this analysis leads to Dirichlet and Neumann type boundary conditions on the electromagnetic field, corresponding to conductor and insulator type boundaries, as well as mixed type boundary conditions which are linear combinations of the Dirichlet and Neumann ones. We also investigate more general boundary conditions which give rise to a well-defined Hamiltonian variational principle for the Maxwell equations, and we obtain a uniqueness result for the mixed and pure type Dirichlet and Neumann boundary conditions under some assumptions. The associated Dirichlet and Neumann Hamiltonians are shown to reduce to expressions for the total energy of the electromagnetic field, including contributions from surface electric charge and current due to the boundary conditions.

In Sec. III we carry out the corresponding analysis of the covariant Hamiltonian structure of General Relativity for arbitrary spatially compact regions of space–time with a closed two-surface boundary, without matter fields. We make some concluding remarks in Sec. IV. In an Appendix we develop the Noether charge method for general Lagrangian field theories with a time symmetry. This approach extends and unifies some aspects of the covariant Hamiltonian formalism introduced in recent literature.[4,9–11] (Throughout we use the notation and conventions of Ref. 12.)

Inclusion of matter fields and analysis of the geometrical properties of the resulting Dirichlet and Neumann Hamiltonians for General Relativity will be investigated in Ref. 8. It is also left to that paper to discuss the relation between these Hamiltonians and the Regge–Teitelboim Hamil-

tonian in the case when the two-surface boundary is taken in a limit to be spatial infinity in an asymptotically flat space–time.

II. ELECTRODYNAMICS

To illustrate our basic approach and the covariant Hamiltonian (Noether charge) formalism, we consider the free Maxwell field theory in four-dimensional Minkowski space–time $(\mathbb{R}^4, \eta_{ab})$.

We use the standard electromagnetic field Lagrangian, where the field variable is the electromagnetic potential one-form A_a, with the field strength two-form defined as $F_{ab}=\partial_{[a}A_{b]}$. The Lagrangian four-form for the field A_a is given by

$$L_{abcd}(A)=\tfrac{1}{2}\epsilon_{abcd}F_{mn}F^{mn}=3F_{[ab}{*F}_{cd]}, \tag{2.1}$$

where ${*F}_{ab}=\epsilon_{ab}{}^{cd}F_{cd}$ is the dual field strength two-form defined using the volume form ϵ_{abcd}. A variation of this Lagrangian gives

$$\delta L_{abcd}(A)=\partial_{[a}\Theta_{bcd]}(A,\delta A)+6\,\delta A_{[a}(\partial_b {*F}_{cd]}), \tag{2.2}$$

where

$$\Theta_{bcd}(A,\delta A)=6\,\delta A_{[b}{*F}_{cd]} \tag{2.3}$$

defines the symplectic potential three-form. From Eq. (2.2), one obtains the field equations

$$\mathcal{E}_{bcd}(A)=6\,\partial_{[b}{*F}_{cd]}=0, \tag{2.4}$$

or equivalently, after contraction with the volume form,

$$\partial^a F_{ab}=\partial^a\partial_{[a}A_{b]}=0 \tag{2.5}$$

which is the source-free Maxwell equations for A_a.

Let $\xi^a=(\partial/\partial t)^a$ be a timelike isometry of the Minkowski metric, with unit normalization $\xi^a\xi^b\eta_{ab}=-1$, and let Σ be a region contained in a spacelike hyperplane $t=0$ orthogonal to ξ^a with the boundary of the region being a closed two-surface $\partial\Sigma$. Denote the unit outward spacelike normal to $\partial\Sigma$ in Σ by s^a, and denote the metric and volume form on $\partial\Sigma$ by $\sigma_{ab}=\eta_{ab}-s_a s_b+\xi_a\xi_b$ and $\epsilon_{ab}=\epsilon_{abcd}s^c\xi^d$. Let Σ_t and $\partial\Sigma_t$ be the images of Σ and $\partial\Sigma$ under the one-parameter diffeomorphism generated by ξ^a on Minkowski space–time. Denote the metric compatible derivative operator on $\partial\Sigma$ by $\mathcal{D}_a$. Let

$$\mathcal{L}_\xi A_a=\xi^e\partial_e A_a+A_e\partial_a\xi^e=2\,\xi^e\partial_{[e}A_{a]}+\partial_a(\xi^e A_e), \tag{2.6}$$

which is the Lie derivative of A_a with respect to ξ^e.

The Noether current three-form associated with ξ^a is given by

$$J_{abc}(\xi,A)=\Theta_{abc}(A,\mathcal{L}_\xi A)+4\,\xi^d L_{abcd}(A)=6{*F}_{[bc}\mathcal{L}_\xi A_{a]}+12\xi^d F_{[ab}{*F}_{cd]}, \tag{2.7}$$

which simplifies to

$$J_{abc}(\xi,A)=6\,\partial_{[a}({*F}_{bc]}\xi^d A_{d)})+2\,\xi^e\epsilon_{abcd}(\delta^d_e F_{mn}F^{mn}-4F_{en}F^{dn})-\xi^e A_e\mathcal{E}_{abc}(A) \tag{2.8}$$

after use of Eqs. (2.4) and (2.6). Hence, one obtains the Noether current on solutions A_a,

$$J_{abc}(\xi,A)=6\,\partial_{[a}({*F}_{bc]}\xi^d A_{d)})+2\,\xi^e\epsilon_{abcd}(\delta^d_e F_{mn}F^{mn}-4F_{en}F^{dn}). \tag{2.9}$$

(Note, one easily sees that this three-form $J_{abc}(\xi,A)$ is closed but is not exact, i.e., there does not exist a Noether current potential $Q_{bc}(\xi,A)$ satisfying $J_{abc}(\xi,A)=3\partial_{[a}Q_{bc]}(\xi,A)$.) Correspondingly, the Noether charge on solutions A_a is given by

$$Q_\Sigma(\xi)=\int_\Sigma J_{abc}(\xi;A)=\int_\Sigma \epsilon_{abcd}\xi^e(-8F_{en}F^{dn}+2\,\delta^d_e F_{mn}F^{mn})+\oint_{\partial\Sigma}2{*}F_{bc}\xi^d A_d\,. \quad (2.10)$$

This expression simplifies in terms of the electromagnetic stress-energy tensor defined by

$$T_e{}^d(F)=2F_{en}F^{dn}-\tfrac{1}{2}\delta_e{}^d F_{mn}F^{mn}. \quad (2.11)$$

Thus,

$$\tfrac{1}{4}\Omega_\Sigma(\xi)=\int_\Sigma \xi^e\xi^d T_{de}(F)\mathrm{d}^3x+\oint_{\partial\Sigma}\xi^a A_a\xi^d s^e F_{de}\mathrm{d}S, \quad (2.12)$$

where d^3x and $\mathrm{d}S$ denote the coordinate volume elements on Σ and $\partial\Sigma$ obtained from the volume forms $\epsilon_{abcd}\xi^d$ and ϵ_{bc}, respectively.

A. Covariant Hamiltonian formulation

The symplectic current, defined by the antisymmetrized variation of $\Theta_{bcd}(A,\delta A)$, is given by the three-form

$$\tfrac{1}{6}\omega_{bcd}(\delta_1A,\delta_2A)=\delta_1A_{[b}\delta_2{*}F_{cd]}-\delta_2A_{[b}\delta_1{*}F_{cd]}\,. \quad (2.13)$$

Then the presymplectic form on Σ is given by

$$\Omega_\Sigma(\delta_1A,\delta_2A)=\int_\Sigma \omega_{bcd}(\delta_1A,\delta_2A). \quad (2.14)$$

A Hamiltonian conjugate to ξ on Σ is a function $H_\Sigma(\xi;A)=\int_\Sigma \mathcal{H}_{abc}(\xi;A)$ for some locally constructed three-form $\mathcal{H}_{abc}(\xi;A)$ such that

$$\delta H_\Sigma(\xi;A)\equiv H'_\Sigma(\xi;A,\delta A)=\Omega_\Sigma(\delta A,\mathcal{L}_\xi A) \quad (2.15)$$

for arbitrary variations δA_a away from solutions A_a.

From the expression (2.7) for the Noether current, the presymplectic form yields

$$\Omega_\Sigma(\delta A,\mathcal{L}_\xi A)=\int_\Sigma \delta J_{abc}(\xi,A)+4\xi^d\delta A_{[d}\mathcal{E}_{abc]}(A)-\oint_{\partial\Sigma}\xi^c\Theta_{abc}(A,\delta A). \quad (2.16)$$

Hence, for compact support variations δA_a away from solutions A_a, the Noether current gives a Hamiltonian (2.15) with $\mathcal{H}_{abc}(\xi;A)=J_{abc}(\xi,A)$, up to an inessential boundary term. The simplified expression (2.8) for $J_{abc}(\xi,A)$ thereby yields the Hamiltonian

$$H(\xi;A)=4\int_\Sigma \xi^e\xi^d(T_{de}(F)+A_e\partial^cF_{cd})\mathrm{d}^3x. \quad (2.17)$$

On solutions A_a, this Hamiltonian is equal to the total electromagnetic field energy on Σ, $H(\xi;A)=4\int_\Sigma \xi^e\xi^d T_{de}(F)\mathrm{d}^3x$.

To define a Hamiltonian (2.15) for variations δA_a without compact support, it follows that the term $\xi^c\Theta_{abc}(A,\delta A)$ in Eq. (2.16) needs to be a total variation at the boundary $\partial\Sigma$, i.e. there must exist a locally constructed three-form $\tilde{B}_{abc}(A)$ such that one has

$$\xi^c\Theta_{abc}(A,\delta A)|_{\partial\Sigma}=(\xi^c\delta\tilde{B}_{abc}(A)+\partial_{[a}\alpha_{b]}(\xi;A,\delta A))|_{\partial\Sigma}\,, \quad (2.18)$$

where $\alpha_b(\xi;A,\delta A)$ is a locally constructed one-form. This equation holds if and only if, by taking an antisymmetrized variation,[10] one has

$$\epsilon^{bc}\xi^a\omega_{abc}(\delta_1A,\delta_2A)|_{\partial\Sigma}=\mathcal{D}_c\tilde{\beta}^c(\xi;\delta_1A,\delta_2A)|_{\partial\Sigma}, \tag{2.19}$$

where

$$\tilde{\beta}^c(\xi;\delta_1A,\delta_2A)=\epsilon^{cb}\delta_1\alpha_b(\xi;A,\delta_2A)-\epsilon^{cb}\delta_2\alpha_b(\xi;A,\delta_1A) \tag{2.20}$$

is a locally constructed vector, in $T(\partial\Sigma)$, which is skew bilinear in δ_1A, δ_2A. The term involving the symplectic current is given by

$$\epsilon^{bc}\xi^a\omega_{abc}(\delta_1A,\delta_2A)=8s^ch^{de}(\delta_1A_e\delta_2F_{cd}-\delta_2A_e\delta_1F_{cd}) \tag{2.21}$$

with $h_{ab}=\eta_{ab}-s_as_b=\sigma_{ab}-\xi_a\xi_b$. Given a solution of Eq. (2.19), one can then determine $\tilde{B}_{abc}(A)$ from Eq. (2.18) by

$$\epsilon^{ab}\xi^c\tilde{B}_{abc}(A)=\epsilon^{ab}(\xi^c\Theta_{abc}(A,\delta A)-\partial_a\alpha_b(\xi;A,\delta A))=8s^ch^{de}F_{cd}\delta A_e-\mathcal{D}_a\tilde{\alpha}^a(\xi;A,\delta A), \tag{2.22}$$

where

$$\tilde{\alpha}^a(\xi;A,\delta A)=\epsilon^{ab}\alpha_b(\xi;A,\delta A). \tag{2.23}$$

This leads to the following main result.

Proposition 2.1: A Hamiltonian conjugate to ξ^a on Σ exists for variations δA_a with support on $\partial\Sigma$ if and only if

$$8h^{bc}s^a(\delta_1A_b\partial_{[a}\delta_2A_{c]}-\delta_2A_b\partial_{[a}\delta_1A_{c]})|_{\partial\Sigma}=\mathcal{D}_c\tilde{\beta}^c(\xi;\delta_1A,\delta_2A) \tag{2.24}$$

for some locally constructed vector $\tilde{\beta}_a(\xi,\delta_1A,\delta_2A)$, in $T(\partial\Sigma)$, which is skew bilinear in δ_1A, δ_2A. The solutions of Eq. (2.24) of the form $\delta\mathcal{F}_a(A)|_{\partial\Sigma}=0$ give the allowed boundary conditions $\mathcal{F}_a(A)|_{\partial\Sigma}$ for a Hamiltonian formulation of the Maxwell equations in the local space–time region Σ_t, $t\geqslant 0$. For each boundary condition, there is a corresponding Hamiltonian given by the Noether charge plus a boundary term

$$H_\Sigma(\xi;A)=\int_\Sigma J_{abc}(\xi,A)-\oint_{\partial\Sigma}\xi^a\tilde{B}_{abc}(A)\equiv H(\xi;A)+H_B(\xi;A), \tag{2.25}$$

with

$$H(\xi;A)=4\int_\Sigma\xi^e\xi^d(T_{de}(F)+A_e\partial^cF_{cd})\mathrm{d}^3x, \tag{2.26}$$

$$H_B(\xi;A)=\oint_{\partial\Sigma}\xi^a(4A_a\xi^ds^eF_{de}-\tfrac{1}{2}\tilde{B}_a(A))\mathrm{d}S, \tag{2.27}$$

where $\tilde{B}_a(A)=\epsilon^{bc}\tilde{B}_{abc}(A)$ is determined from

$$(\xi^a\tilde{B}_a(A)-8s^ch^{de}F_{cd}\delta A_e)|_{\partial\Sigma}=\mathcal{D}_a\tilde{\alpha}^a(\xi;A,\delta A)|_{\partial\Sigma} \tag{2.28}$$

with $\tilde{\alpha}^a(\xi;A,\delta A)$ given by Eqs. (2.20) and (2.23). Note, $\tilde{B}_a(A)$ is unique up to addition of an arbitrary covector function of the fixed boundary data $\mathcal{F}_a(A)$.

The results in Proposition 2.1 take a more familiar form when expressed in terms of the electric and magnetic fields on Σ defined by $E_a=2\xi^bF_{ab}$, $B_a=\xi^b{*}F_{ab}$, which are vectors in $T(\Sigma)$ (i.e., $\xi^aE_a=\xi^aB_a=0$). A convenient notation now is to write vectors in $T(\Sigma)$ using an

overarrow, and for tensors on M, to denote tangential and normal components with respect to Σ by subscripts $\|$ and $\perp$, and denote components orthogonal to Σ_t by a subscript 0. Then we have

$$\vec{E} = \vec{\partial} A_0 - \partial_0 \vec{A}, \quad \vec{B} = \vec{\partial} \times \vec{A}. \tag{2.29}$$

In this notation, the presymplectic form (2.14) and the Hamiltonian (2.25) reduce to the expressions

$$\begin{aligned} \tfrac{1}{4}\Omega_\Sigma(\delta_1 A, \delta_2 A) &= \int_\Sigma (\delta_2 \vec{A} \cdot \delta_1 \vec{E} - \delta_1 \vec{A} \cdot \delta_2 \vec{E}) \mathrm{d}^3 x \\ &= \int_\Sigma (\delta_1 \vec{A} \cdot (\partial_0 \delta_2 \vec{A} - \vec{\partial} \delta_2 A_0) - \delta_2 \vec{A} \cdot (\partial_0 \delta_1 \vec{A} - \vec{\partial} \delta_1 A_0)) \mathrm{d}^3 x \end{aligned} \tag{2.30}$$

and

$$\tfrac{1}{2} H_\Sigma(\xi; A) = \int_\Sigma \tfrac{1}{2}(\vec{E}^2 + \vec{B}^2) + A_0 \vec{\partial} \cdot \vec{E}_\perp \mathrm{d}^3 x - \oint_{\partial\Sigma} A_0 E_\perp + \tfrac{1}{4} \tilde{B}_0(A) \mathrm{d}S. \tag{2.31}$$

Note that the Hamiltonian field equations obtained from $H_\Sigma(\xi; A)$ are given by the variational principle

$$H'_\Sigma(\xi; A, \delta A) = \Omega_\Sigma(\delta A, \mathcal{L}_\xi A) \tag{2.32}$$

for arbitrary variations $\delta A_a|_\Sigma$. These field equations split into dynamical equations and constraint equations, corresponding to a decomposition of A_a into dynamical and nondynamical components, respectively, $\vec{A}$ and A_0, determined by[4] the degeneracy of the presymplectic form (2.30). In particular, this yields the Gauss-law constraint equation

$$\vec{\partial} \cdot \vec{E} = \Delta A_0 - \partial_0 \vec{\partial} \cdot \vec{A} = 0 \tag{2.33}$$

obtained from $H'_\Sigma(\xi; A, \delta A_0) = 0$ through variation of A_0, and the dynamical Maxwell evolution equation

$$\partial_0 \vec{E} - \vec{\partial} \times \vec{B} = (-\partial_0^2 + \Delta)\vec{A} + \vec{\partial}(\partial_0 A_0 - \vec{\partial} \cdot \vec{A}) = 0 \tag{2.34}$$

obtained from $H'_\Sigma(\xi; A, \delta \vec{A}) = \Omega_\Sigma(\delta \vec{A}, \mathcal{L}_\xi A)$ through variation of $\vec{A}$, where $\Delta = \vec{\partial} \cdot \vec{\partial}$ is the Laplacian on Σ. Thus, the Noether charge (covariant Hamiltonian) formalism here is equivalent to the standard canonical formulation[12] of the Maxwell equations.

B. Dirichlet and Neumann boundary conditions

Two immediate solutions of the determining equation (2.24) with $\tilde{\beta}^a = 0$ are boundary conditions associated with fixing components of A_a or $F_{bc} = \partial_{[b} A_{c]}$ at $\partial\Sigma_t$ for $t \geqslant 0$.

Consider

$$\text{(D)} \quad \sigma_b{}^a \delta A_a|_{\partial\Sigma_t} = 0, \quad \xi^a \delta A_a|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{2.35}$$

or equivalently $\delta \vec{A}_\| = \delta A_0 = 0$, for $t \geqslant 0$, called Dirichlet boundary conditions, i.e.,

$$\mathcal{F}^{\mathrm{D}}_a(A) = h_a{}^b A_b; \tag{2.36}$$

$$\text{(N)} \quad \sigma_b{}^a s^c \delta F_{ac}|_{\partial\Sigma_t} = 0, \ \ s^a \xi^c \delta F_{ac}|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{2.37}$$

or equivalently $\vec{\partial}_\perp \times \delta\vec{A}_\parallel - \vec{\partial}_\parallel \times \delta\vec{A}_\perp = \vec{\partial}_\perp \delta A_0 - \partial_0 \delta\vec{A}_\perp = 0$, for $t \geqslant 0$, called Neumann boundary conditions, i.e.,

$$\mathcal{F}^{\mathrm{N}}_a(A) = h_a{}^b s^c F_{bc}\,. \tag{2.38}$$

Theorem 2.2: *For the boundary conditions* (D) *or* (N), *a Hamiltonian conjugate to* ξ^a *on* Σ, *evaluated on solutions* A_a, *is given by*

$$\tfrac{1}{2} H^{\mathrm{D}}(\xi;A) = 2\int_\Sigma \epsilon_{dabc}(2\xi^e F_{en}F^{dn} - \tfrac{1}{2}\xi^d F_{mn}F^{mn}) + 2\oint_{\partial\Sigma} \epsilon_{bc}\xi^a A_a \xi^d s^e F_{de} \tag{2.39}$$

$$= \tfrac{1}{2}\int_\Sigma \vec{E}^2 + \vec{B}^2 \mathrm{d}^3x - \oint_{\partial\Sigma} A_0 E_\perp \mathrm{d}S, \tag{2.40}$$

$$\tfrac{1}{2} H^{\mathrm{N}}(\xi;A) = 2\int_\Sigma \epsilon_{dabc}(2\xi^e F_{en}F^{dn} - \tfrac{1}{2}\xi^d F_{mn}F^{mn}) + 2\oint_{\partial\Sigma} \epsilon_{bc}\sigma^{bd} A_b s^e F_{de} \tag{2.41}$$

$$= \tfrac{1}{2}\int_\Sigma \vec{E}^2 + \vec{B}^2 \mathrm{d}^3x - \oint_{\partial\Sigma} (\vec{A}\times\vec{B})_\perp \mathrm{d}S. \tag{2.42}$$

Proof: For (D), one has

$$\epsilon^{bc}\xi^a \Theta_{abc}(A, \mathcal{L}_\xi A) = 6\epsilon^{bc}\xi^a \delta A_{[a} * F_{bc]} = 8(\xi^a \delta A_a \xi^d s^e F_{de} - \sigma^{ad}\delta A_a s^e F_{de}) = 0 \tag{2.43}$$

and hence $\tilde{B}_{abc}(A) = 0$, so thus $\xi^a \tilde{B}_a(A) = 0$. For (N), one has

$$\begin{aligned}\epsilon^{bc}\xi^a \Theta_{abc}(A, \mathcal{L}_\xi A) &= 6\epsilon^{bc}\xi^a(\delta A_{[a} * F_{bc]} = 6\epsilon^{bc}\xi^a(\delta(A_{[a} * F_{bc]}) - A_{[a}\delta * F_{bc]}) \\ &= \delta(6\epsilon^{bc}\xi^a A_{[a} * F_{bc]}) + 8(-\xi^a A_a \xi^d s^e \delta F_{de} + A_a \sigma^{ad} s^e \delta F_{de}) \\ &= \delta(\epsilon^{bc}\xi^a \tilde{B}_{abc})\end{aligned} \tag{2.44}$$

with $\tilde{B}_{abc}(A) = 6A_{[a} * F_{bc]}$. Thus,

$$\xi^a \tilde{B}_a(A) = 6\epsilon^{bc}\xi^a A_{[a} * F_{bc]} = 8 s_d A_e F^{de}. \tag{2.45}$$

□

Note that for both boundary conditions (D) and (N), the surface integral terms in the Hamiltonian take the form

$$H_B(\xi;A) = 4\oint_{\partial\Sigma} \xi^a P_a(A)\mathrm{d}S, \tag{2.46}$$

where

$$P^{\mathrm{D}}_a(A) = A_a \xi^b s^c F_{bc}\,, \tag{2.47}$$

$$P^{\mathrm{N}}_a(A) = -\xi_a s^d \sigma^{bc} A_b F_{cd}\,. \tag{2.48}$$

There is simple physical interpretation of the (D) and (N) boundary conditions: (D) involves fixing A_0 and $\vec{A}_\parallel$ at $\partial\Sigma_t$ for $t \geqslant 0$, which means

$$\vec{E}_\parallel = \vec{\partial}_\parallel A_0 - \partial_0 \vec{A}_\parallel\,, \quad \vec{B}_\perp = \vec{\partial}_\parallel \times \vec{A}_\parallel \tag{2.49}$$

are specified data at the boundary surface (analogous to a conductor) as a function of time. Note, consequently, $\vec{E}_\perp$ and $\vec{B}_\parallel$ are left free by the boundary condition (D) and therefore are induced data for solutions A_0, $\vec{A}$ of the Hamiltonian field equations; (N) reverses the role of the induced and fixed data at the boundary surface, so now $\vec{E}_\perp$ and $\vec{B}_\parallel$ are specified as a function of time (analogous to an insulator), while the induced data for solutions A_0, $\vec{A}$ of the Hamiltonian field equations are $\vec{E}_\parallel$ and $\vec{B}_\perp$. Note the fixed data here are gauge-equivalent to specifying the normal derivative of A_0 and $\vec{A}_\parallel$ at $\partial\Sigma_t$ in Σ_t for $t\geqslant 0$,

$$\vec{E}_\perp = \vec{\partial}_\perp(A_0 - \partial_0\chi), \quad \vec{B}_\parallel = \vec{\partial}_\perp \times (\vec{A}_\parallel - \vec{\partial}_\parallel \chi), \tag{2.50}$$

where χ is given by $\vec{\partial}_\perp \chi = \vec{A}_\perp$.

Moreover, the Hamiltonians (2.40) and (2.42) on solutions A_0, $\vec{A}$ have the interpretation as expressions for the total energy of the electromagnetic fields, with the surface integral parts representing the energy contribution[13] from an effective (fictitious) surface charge density in the case (D), and effective (fictitious) surface current density in the case (N), associated with the specified data at the boundary surface. In particular, effective surface charges and currents arise, respectively, when $\vec{E}_\perp$ or $\vec{A}_\parallel$ are left free[13] on the boundary surface.

We remark that similar boundary terms arise in the asymptotic case when the boundary surface is taken to be a two-sphere at spatial infinity on Σ (see Ref. 14).

C. Determination of allowed boundary conditions

The symplectic current component $\epsilon^{bc}\xi^a\omega_{abc}(\delta_1 A, \delta_2 A)$ involves only the field variations $h_a{}^b\delta A_b$, $h_a{}^b s^c \partial_{[b}\delta A_{c]}$. We refer to the components $\sigma_b{}^c A_c$, $\xi^c A_c$, $\sigma_b{}^c s^a F_{ac}$, $\xi^c s^a F_{ac}$, or equivalently $\vec{A}_\parallel$, A_0, $\vec{B}_\parallel$, $\vec{E}_\perp$, as *symplectic boundary data* at $\partial\Sigma$. Hence, in solving the determining equation (2.24) for the allowed boundary conditions on A_a, it is then natural to restrict attention to boundary conditions involving only this data. (Some remarks on more general boundary conditions are made at the end of this section.) To proceed, we suppose that the possible boundary conditions are linear, homogeneous functions of the symplectic boundary data, with coefficients locally constructed out of the geometrical quantities ξ^a, s^a, σ_{bc}, ϵ_{bc} at the boundary surface. We call this type of boundary condition a *symplectic* boundary condition.

Theorem 2.3: *The most general allowed symplectic boundary conditions*

$$\mathcal{F}_b(h_c{}^d A_d, h_c{}^d s^e F_{de}; \xi^c, s^c, \sigma_{de}, \epsilon_{de}) \tag{2.51}$$

for existence of a Hamiltonian conjugate to ξ^a on Σ are given by

$$\mathcal{F}_b = b_0\sigma_b{}^c A_c + a_0\sigma_b{}^c s^a F_{ac} + b_1\xi_b\xi^c A_c + a_1\xi_b\xi^c s^a F_{ca}, \tag{2.52}$$

or equivalently,

$$\sigma_b{}^c(b_0\delta A_c + a_0 s^a \delta F_{ac})|_{\partial\Sigma_t} = 0, \quad t\geqslant 0, \tag{2.53}$$

$$\xi^c(b_1\delta A_c + a_1 s^a \delta F_{ac})|_{\partial\Sigma_t} = 0, \quad t\geqslant 0 \tag{2.54}$$

for any constants a_0, b_0 (not both zero), a_1, b_1 (not both zero).

Proof: First, we show that $\tilde{\beta}^a = 0$ without loss of generality in the determining equation (2.24) for boundary conditions of the form (2.51). Note that the left-hand side of Eq. (2.24) is algebraic in δA_a, $\delta F_{ab} = \partial_{[a}\delta A_{b]}$. Since the right-hand side necessarily involves at least one derivative on δA_a, we must have

$$\tilde{\beta}^a = \delta_1 A_b \delta_2 A_c \beta^{abc} \tag{2.55}$$

for some tensor

$$\beta^{abc} = \sigma_e{}^a \beta^{e[bc]}. \tag{2.56}$$

We substitute expression (2.55) into Eq. (2.24) and collect all terms that do not involve just the symplectic boundary data, namely $s^c A_c$, $\xi^c \sigma_d{}^a F_{ac}$, $\sigma_b{}^c \sigma_d{}^a F_{ac}$, and $\partial_{(a} A_{b)}$. The coefficients of these terms yield algebraic equations

$$s_c \beta^{(ab)c} = 0, \quad s_c \beta^{[ab]c} = 0, \quad s^{[d} \beta^{ab]c} = 0. \tag{2.57}$$

Then, since β^{abc} has the form (2.56), we find that the solution of the equations in (2.57) is

$$\beta^{abc} = 0 \tag{2.58}$$

and so $\tilde{\beta}^a = 0$.

Hence, the determining equation (2.24) reduces to

$$h^{bc} s^a (\delta_1 A_b \partial_{[a} \delta_2 A_{c]} - \delta_1 A_b \partial_{[a} \partial_1 A_{c]})|_{\partial\Sigma} = 0, \tag{2.59}$$

which we are now free to solve as a purely algebraic equation in terms of the variables δA_b and $\delta F_{ac} = \partial_{[a} \delta A_{c]}$, i.e.,

$$h^{bc} s^a (\delta_1 A_b \delta_2 F_{ac} - \delta_1 A_b \delta_2 F_{ac}) = 0. \tag{2.60}$$

It is straightforward to show from the form of Eq. (2.60) that the only solution which is linear, homogeneous in the previous variables is given by

$$\Pi_{1b}{}^c \delta A_c = \Pi_{2b}{}^c s^a \delta F_{ac}, \tag{2.61}$$

where $\Pi_1{}^{bc}$ and $\Pi_2{}^{bc}$ are some symmetric tensors orthogonal to s^a, such that Eq. (2.61) can be solved for either $\xi^b \delta A_b$ or $\xi^b s^a \delta F_{ab}$, and either $\sigma_c{}^b \delta A_b$ or $\sigma_c{}^b s^a \delta F_{ab}$. Since we require the coefficients in the boundary conditions under consideration to be locally constructed out of ξ^a, s^a, σ_{bc}, ϵ_{bc}, we see that

$$\Pi_1{}^{bc} = b_0 \sigma^{bc} + b_1 \xi^b \xi^c, \quad \Pi_2{}^{bc} = a_0 \sigma^{bc} + a_1 \xi^b \xi^c, \tag{2.62}$$

for some constants a_0, a_1, b_0, b_1 with $a_0 \neq 0$ or $b_0 \neq 0$, and $a_1 \neq 0$ or $b_1 \neq 0$. This yields the general solution (2.53) and (2.54) given in the Theorem. □

The boundary conditions given by Theorem 2.3 comprise the following separate types: (i) for $a_0 = a_1 = 0$ or $b_0 = b_1 = 0$, one obtains, respectively, Dirichlet (2.35) and Neumann (2.37) boundary conditions; (ii) for $b_0 = 0 (a_0 \neq 0)$, $b_1 \neq 0$, the boundary conditions yield a one-parameter $a_1/b_1 \equiv c_1$ family of the form

$$\sigma_b{}^c s^a \delta F_{ac}|_{\partial\Sigma_t} = 0, \quad \xi^c \delta A_c|_{\partial\Sigma_t} = -c_1 s^a \xi^c \delta F_{ac}|_{\partial\Sigma_t}, \quad t \geqslant 0, \tag{2.63}$$

or equivalently, $\delta \vec{B}_\parallel = \vec{s} \delta A_0 + c_1 \frac{1}{2} \delta \vec{E}_\perp = 0$, for $t \geqslant 0$; (iii) similarly, for $b_1 = 0 (a_1 \neq 0)$, $b_0 \neq 0$, the boundary conditions yield another one-parameter $a_0/b_0 \equiv c_0$ family of the form

$$\sigma_b{}^c \delta A_c|_{\partial\Sigma_t} = -c_0 s^a \delta F_{ab}|_{\partial\Sigma_t}, \quad \xi^c s^a \delta F_{ac}|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{2.64}$$

or equivalently, $\vec{s} \times \delta \vec{A}_\parallel + c_0 \frac{1}{2} \delta \vec{B}_\parallel = \delta \vec{E}_\perp = 0$, for $t \geqslant 0$; (iv) finally, for $b_0 \neq 0$, $b_1 \neq 0 (a_0 \neq 0, a_1 \neq 0)$, we obtain a two-parameter $a_1/b_1 \equiv c_1$ and $a_0/b_0 \equiv c_0$ family of the boundary conditions

$$\sigma_b{}^c \delta A_c|_{\partial\Sigma_t} = -c_0 s^a \delta F_{ab}|_{\partial\Sigma_t}, \quad \xi^c \delta A_c|_{\partial\Sigma_t} = -c_1 s^a \xi^c \delta F_{ac}|_{\partial\Sigma_t}, \quad t \geqslant 0, \tag{2.65}$$

or equivalently, $\vec{s}\times\delta\vec{A}_\parallel + c_0\tfrac{1}{2}\delta\vec{B}_\parallel = \vec{s}\,\delta A_0 + c_1\tfrac{1}{2}\delta\vec{E}_\perp = 0$, for $t\geqslant 0$.

The fixed data for these boundary conditions (2.63)–(2.65) correspond to specifying, respectively, the field components

$$\vec{s}A_0 + c_1\tfrac{1}{2}\vec{E}_\perp, \quad \vec{B}_\parallel, \quad c_1\neq 0, \tag{2.66}$$

$$\vec{E}_\perp, \quad \vec{s}\times\vec{A}_\parallel + c_0\tfrac{1}{2}\vec{B}_\parallel, \quad c_0\neq 0, \tag{2.67}$$

$$\vec{s}A_0 + c_1\tfrac{1}{2}\vec{E}_\perp, \quad \vec{s}\times\vec{A}_\parallel + c_0\tfrac{1}{2}\vec{B}_\parallel, \quad c_0\neq 0, c_1\neq 0, \tag{2.68}$$

at the boundary surface Σ_t for $t\geqslant 0$. From Proposition 2.1, we readily obtain the Hamiltonian boundary terms corresponding to these boundary conditions (by a proof similar to that for Theorem 2.2).

Theorem 2.4: *For boundary conditions (2.63)–(2.65), there is a respective Hamiltonian (2.25) conjugate to ξ^a on Σ, with boundary terms given by*

$$H_B(\xi;A) = 4\oint_{\partial\Sigma} \epsilon_{bc}(\xi^a A_a \xi^d s^e F_{de} + \sigma^{ad} A_a s^e F_{de} - c_1(\xi^d s^e F_{de})^2)$$

$$= -\oint_{\partial\Sigma} 2(\vec{A}\times\vec{B})_\perp + c_1\vec{E}_\perp{}^2\,\mathrm{d}S, \tag{2.69}$$

$$H_B(\xi;A) = 4\oint_{\partial\Sigma} \epsilon_{bc} c_0 \sigma^{de} s^a F_{ad} s^m F_{me} = \oint_{\partial\Sigma} c_0\vec{B}_\parallel{}^2\mathrm{d}S, \tag{2.70}$$

$$H_B(\xi;A) = 4\oint_{\partial\Sigma} \epsilon_{bc}(\xi^a A_a \xi^d s^e F_{de} - c_1(\xi^d s^e F_{de})^2 + c_0\sigma^{de} s^m F_{md} s^n F_{ne})$$

$$= -\oint_{\partial\Sigma} 2A_0\vec{E}_\perp + c_1 E_\perp{}^2 - c_0\vec{B}_\parallel{}^2\mathrm{d}S. \tag{2.71}$$

Interestingly, among the allowed boundary conditions given by Theorem 2.3, we observe that the Hamiltonian boundary terms vanish identically in one (and only one) case, when $c_0=0$ in boundary condition (2.64), i.e.,

$$\sigma_b{}^c\delta A_c|_{\partial\Sigma_t} = 0, \quad \xi^c s^a \delta F_{ac}|_{\partial\Sigma_t} = 0, \quad t\geqslant 0, \tag{2.72}$$

or equivalently, $\delta\vec{A}_\parallel = \delta\vec{E}_\perp = 0$, for $t\geqslant 0$. The resulting Hamiltonian (2.25) reduces, on solutions A_a, simply to the expression for the total energy of the electromagnetic fields, $H(\xi;A) = 4\int_\Sigma \xi^e\xi^d T_{de}(F)\mathrm{d}^3x = \int_\Sigma \vec{E}^2 + \vec{B}^2\mathrm{d}^3x$. The fixed data corresponding to the boundary condition (2.72) are $\vec{A}_\parallel$ and $\vec{E}_\perp$, which means that the normal components of the electric and magnetic fields at $\partial\Sigma$ are specified for $t\geqslant 0$,

$$\vec{B}_\perp = \vec{\partial}_\parallel\times\vec{A}_\parallel, \quad \vec{E}_\perp = \vec{\partial}_\perp A_0 - \partial_0\vec{A}_\perp. \tag{2.73}$$

Since $\vec{A}_\parallel$ and $\vec{E}_\perp$ are fixed, there are no effective charges and currents associated with the boundary surface. Thus, the total electromagnetic energy involves no surface integral contributions in this case.

D. Remarks

We conclude with some short remarks on the uniqueness of the boundary conditions obtained in Theorem 2.3.

Note that the symplectic boundary conditions (2.53) and (2.54) are linear combinations of the tangential and normal parts of the Dirichlet and Neumann boundary conditions, referred to as mixed boundary conditions. In physical terms, they correspond to specifying $b_0\sigma_b{}^c A_c + a_0 s^a \sigma_b{}^c F_{ac}$ and $b_1 \xi^c A_c + a_1 \xi^c s^a F_{ca}$ as boundary data at $\partial\Sigma_t$ for $t \geqslant 0$. Theorem 2.3 gives a uniqueness result for these mixed boundary conditions under the natural assumption (2.51) about the general type of boundary condition considered on the fields at the boundary surface. If this assumption is loosened, then there exist additional boundary conditions allowed by the determining equation (2.24).

In particular, one can trade off some of the mixed boundary conditions on the symplectic boundary data for boundary conditions involving the symmetrized derivatives of A_a at $\partial\Sigma$. For example, an allowed boundary condition satisfying Eq. (2.24) is given by $\mathcal{F}(A) = (\xi^a A_a, \sigma^{ab}\partial_a A_b, \sigma^{ab} s^c \partial_{(b} A_{c)})$, or equivalently

$$\xi^a \delta A_a|_{\partial\Sigma_t} = 0, \quad \sigma^{ab}\partial_a \delta A_b|_{\partial\Sigma_t} = 0, \quad \sigma^{ab} s^c \partial_{(b}\delta A_{c)}|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{2.74}$$

with $\alpha_a = 8\epsilon_a{}^b A_b s^c \delta A_c$. From Eq. (2.28) one obtains

$$\tfrac{1}{8}\xi^a \tilde{B}_a = s^e \sigma^{cd}(A_c \partial_{(d} A_{e)} - A_e \partial_c A_{d)}) - \tfrac{1}{2} A_d A_e \mathcal{D}^d s^e, \tag{2.75}$$

where $\mathcal{D}_d s_e = \sigma_d{}^m \sigma_e{}^n \partial_m s_n$ is the extrinsic curvature of $\partial\Sigma$ in Σ. Hence the corresponding boundary term in the Hamiltonian is given by Eq. (2.46) with

$$P_a(A) = A_a s^d \xi^e F_{de} - s^e \sigma^{cd}(A_c \partial_{(d} A_{e)} - A_e \partial_c A_{d)}) + \tfrac{1}{2} A_d A_e \mathcal{D}^d s^e. \tag{2.76}$$

III. ANALYSIS OF GENERAL RELATIVITY

We now apply the Noether charge analysis to General Relativity, specifically to the vacuum Einstein equations for the gravitational field in a spatially bounded space–time region with a fixed time-flow vector field. It is straightforward to also include matter fields, as we discuss in Ref. 8.

For General Relativity without matter sources, the starting point is the standard Lagrangian formulation of the Einstein equations with the space–time metric as the field variable. It turns out, however, that the analysis is considerably simplified by introduction of a tetrad (orthonormal frame). Moreover, taking into account local rotations and boosts of the tetrad, the boundary conditions and resulting Hamiltonians that arise in the tetrad formulation are equivalent to those obtained purely using the metric formulation, up to a boundary term in the presymplectic form.

After setting up some preliminary notation and results in Sec. III A, we will first consider a Dirichlet boundary condition as explained in Sec. III B. Then we will carry out details of the Noether charge analysis with the Dirichlet boundary condition using the tetrad formulation of General Relativity in Sec. III C. The resulting covariant Dirichlet Hamiltonian for General Relativity is summarized in Sec. III D where we will discuss the equivalence between the metric and tetrad formulations. In Sec. III E we will investigate a Neumann boundary condition and corresponding Hamiltonian, along with more general boundary conditions and Hamiltonians. The main result will be to establish uniqueness of mixed Dirichlet–Neumann boundary conditions for the existence of a Hamiltonian formulation of General Relativity. Finally, in Sec. III F we will briefly discuss the form of the Dirichlet and Neumann covariant Hamiltonians, and relate these to an analysis of boundary terms for the ADM Hamiltonian using the standard (noncovariant) ADM canonical variables.

A. Preliminaries

On a given smooth orientable four-dimensional space–time manifold M, let g_{ab} be the space–time metric tensor, $\epsilon_{abcd}(g)$ be the volume form normalized with respect to the metric, and ${}^g\nabla_a$ be the covariant (torsion-free) derivative operator determined by the metric.

Now, let ξ^a be a complete, smooth timelike vector field on M, and let Σ be a region contained in a spacelike hypersurface with the boundary of the region being a closed orientable two-surface

$\partial\Sigma$. Let s^a denote the unit outward spacelike normal to $\partial\Sigma$ orthogonal to ξ^a, let t^a denote the unit future timelike normal to $\partial\Sigma$ orthogonal to s^a. Denote the metric tensor and volume form on $\partial\Sigma$ by

$$\sigma_{ab} = g_{ab} - s_a s_b + t_a t_b, \tag{3.1}$$

$$\epsilon_{ab} = \epsilon_{abcd}(g) s^c t^d. \tag{3.2}$$

This yields the decompositions

$$g_{ab} = \sigma_{ab} + s_a s_b - t_a t_b, \tag{3.3}$$

$$\epsilon_{abcd}(g) = 12 t_{[a} s_b \epsilon_{cd]}. \tag{3.4}$$

Note that one has

$$\xi^a = N t^a + N^a, \quad N^a s_a = \xi^a s_a = 0 \tag{3.5}$$

for some scalar function N and vector function N^a on $\partial\Sigma$. It is convenient to extend the previous structures off $\partial\Sigma$ as follows. Let $\mathcal{V}$ be the space–time region foliated by the images of Σ under a one-parameter diffeomorphism on M generated by ξ^a, and let $\mathcal{B}$ be the timelike boundary of $\mathcal{V}$ foliated by the images of $\partial\Sigma$. Fix a time function t which is constant on each of the spacelike slices diffeomorphic to Σ under ξ^a in $\mathcal{V}$ and which is normalized by $\xi^a \partial_a t = 1$, such that $t = 0$ corresponds to Σ. Then $\mathcal{B}$ is a timelike hypersurface in M whose intersection with spacelike hypersurfaces Σ_t given by $t = \text{const}$ in $\mathcal{V}$ consists of spacelike two-surfaces $\partial\Sigma_t$ diffeomorphic to $\partial\Sigma$. Finally, let s^a, t^a, σ_{ab}, ϵ_{ab}, N, N^a be extended to $\partial\Sigma_t$, and let n_a denote the unit future timelike normal to Σ_t parallel to $\partial_a t$.

Note that, by construction, s_a is hypersurface orthogonal to $\mathcal{B}$ and hence

$$s_{[c} \partial_b s_{a]} = 0. \tag{3.6}$$

If t_a is expressed as a linear combination of s_a, $\partial_a t$, then since $\partial_a t$ obviously is hypersurface orthogonal to $\partial\Sigma_t$, it follows that

$$s_{[d} t_c \partial_b t_{a]} = 0. \tag{3.7}$$

In addition, note that $s^a \partial_a t$ measures the extent to which Σ_t fails to be orthogonal to $\mathcal{B}$.

Let $(\mathcal{P}_{\partial\Sigma})_a{}^b$ and $(\mathcal{P}_t)_a{}^b$ be coordinate projection operators onto the respective tangent spaces of the two-surface $\partial\Sigma_t$ and the integral curve of t^a, and let $(\mathcal{P}_{\mathcal{B}})_a{}^b = (\mathcal{P}_{\partial\Sigma})_a{}^b + (\mathcal{P}_t)_a{}^b$, which is the projection operator onto the tangent space of the timelike hypersurface $\mathcal{B}$. Note that these operators are independent of the space–time metric, as they involve only the manifold structure of $\mathcal{B}$ and $\partial\Sigma_t$ in local coordinates in M.

Hereafter we work in terms of an orthonormal frame θ_a^μ (i.e., tetrad) for g_{ab} on M. The frame components of s^a, t^a, n^a, σ_{ab}, ϵ_{ab}, g_{ab}, $\epsilon_{abcd}(g)$ are given by

$$s^\mu = s^a \theta_a^\mu, \quad t^\mu = t^a \theta_a^\mu, \quad n^\mu = n^a \theta_a^\mu, \tag{3.8}$$

$$\sigma^{\mu\nu} = \sigma^{ab} \theta_a^\mu \theta_b^\nu, \quad \epsilon^{\mu\nu} = \epsilon^{ab} \theta_a^\mu \theta_b^\nu, \tag{3.9}$$

$$\eta^{\mu\nu} = g^{ab} \theta_a^\mu \theta_b^\nu, \quad \epsilon^{\alpha\beta\mu\nu} = \epsilon^{abcd}(g) \theta_a^\alpha \theta_b^\beta \theta_c^\mu \theta_c^\nu, \tag{3.10}$$

where $\eta^{\mu\nu} = \sigma^{\mu\nu} + s^\mu s^\nu - t^\mu t^\nu = \text{diag}(-1,1,1,1)$ is the Minkowski frame-metric, with $\sigma^{\mu\nu} = \text{diag}(0,0,1,1)$. This leads to an orthonormal frame for the metric σ_{ab}, given by

$$\sigma_a{}^\mu = \sigma_a{}^b \theta_b^\mu \tag{3.11}$$

satisfying

$$s_\mu \sigma_a{}^\mu = t_\mu \sigma_a{}^\mu = 0. \tag{3.12}$$

Let the inverse orthonormal frame for g_{ab} and for σ_{ab} be denoted by

$$\theta^a_\mu = g^{ab}\theta^\mu_b, \quad \sigma_\mu{}^a = \sigma^{ab}\sigma_b{}^\mu. \tag{3.13}$$

Then, one has the decompositions

$$\theta^\mu_a = \sigma_a{}^\mu + s_a s^\mu - t_a t^\mu, \quad \theta^a_\mu = \sigma_\mu{}^a + s^a s_\mu - t^a t_\mu. \tag{3.14}$$

For later use, we will partially fix the SO(3,1) local gauge freedom in θ^a_μ by choosing the coefficients s_μ, t_μ in the frame decomposition (3.14) to be fixed functions on M, so that under a variation δg_{ab},

$$\delta s_\mu = \delta t_\mu = \delta \sigma_{\mu\nu} = 0 \tag{3.15}$$

and hence, correspondingly,

$$\delta s_a = s_\mu \delta\theta^\mu_a, \quad \delta t_a = t_\mu \delta\theta^\mu_a, \tag{3.16}$$

$$\delta\sigma_{ab} = 2\sigma_{\mu\nu}\theta^\mu_{(a}\delta\theta^\nu_{b)} = 2\sigma_{(a}{}^\mu \delta\sigma_{b)\mu}. \tag{3.17}$$

Similarly, one then also has

$$\delta\epsilon_{abcd}(\theta) = 4\epsilon_{\alpha\beta\mu\nu}\theta^\alpha_{[a}\theta^\beta_b\theta^\mu_c\delta\theta^\nu_{d]} = \epsilon_{abcd}(\theta)\theta^c_\mu\delta\theta^\mu_c, \tag{3.18}$$

$$\delta\epsilon_{ab} = 2\epsilon_{\mu\nu}\theta^\mu_{[a}\delta\theta^\nu_{b]} = \epsilon_{ab}\sigma_\mu{}^c\delta\sigma_c{}^\mu, \tag{3.19}$$

and thus

$$\delta\epsilon_{\mu\nu} = \delta\epsilon_{\alpha\beta\mu\nu} = 0. \tag{3.20}$$

Consequently, some useful identities are given by

$$\delta\theta^\mu_a = \delta\sigma_a{}^\mu + s^\mu\delta s_a - t^\mu\delta t_a, \tag{3.21}$$

$$\delta\theta^a_\mu = -\theta^a_\nu\theta^c_\mu\delta\theta^\nu_c = \delta\sigma_\mu{}^a + s_\mu\delta s^a - t_\mu\delta t^a. \tag{3.22}$$

Now, a variation of the space–time metric δg_{ab} can be decomposed into the parts

$$\delta g_{ab} = \delta\sigma_{ab} + 2s_{(a}\delta s_{b)} - 2t_{(a}\delta t_{b)}. \tag{3.23}$$

By hypersurface orthogonality, one has the identities

$$\delta s_a = s_a s^b \delta s_b, \quad \delta t_a = s_a s^b \delta t_b - t_a t^b \delta t_b \tag{3.24}$$

and

$$\delta\sigma_{ab} = \sigma_a{}^c\sigma_b{}^d\delta\sigma_{cd} + \sigma_a{}^c s_b s^d \delta\sigma_{cd} - \sigma_a{}^c t_b t^d \delta\sigma_{cd}. \tag{3.25}$$

Then, from the relation

$$\delta g^{ab} = \delta\sigma^{ab} + 2s^{(a}\delta s^{b)} - 2t^{(a}\delta t^{b)} = -g^{ac}g^{bd}\delta g_{cd}, \tag{3.26}$$

it straightforwardly follows that

$$\delta\sigma^{ab} = -\sigma^{ac}\sigma^{bd}\delta\sigma_{cd}, \tag{3.27}$$

$$\delta s^a = \sigma_b{}^a \delta s^b + s^a s_b \delta s^b - t^a t_b \delta s^b, \tag{3.28}$$

$$\delta t^a = \sigma_b{}^a \delta t^b - t^a t_b \delta t^b, \tag{3.29}$$

where

$$\sigma_{ab}\delta s^b = -s^b \delta\sigma_{ab}, \quad \sigma_{ab}\delta t^b = -t^b \delta\sigma_{ab}, \tag{3.30}$$

$$s_b \delta s^b = -s^b \delta s_b, \quad t_b \delta s^b = -t^b \delta s_b, \quad t_b \delta t^b = -t^b \delta t_b, \tag{3.31}$$

and again by hypersurface orthogonality,

$$s_a \delta\sigma^{ab} = t_a \delta\sigma^{ab} = 0, \quad s_a \delta t^a = 0. \tag{3.32}$$

Thus, the linearly independent parts of $\delta\theta^\mu_a$, or equivalently of $\delta\theta^a_\mu$, are given by

$$\delta\sigma_\mu{}^a, \sigma_b{}^a \delta s^b, \ \sigma_b{}^a \delta t^b, \ s_b \delta s^b, \ t_b \delta s^b, \ t_b \delta t^b. \tag{3.33}$$

Throughout, the time-flow vector field ξ^a is taken to be fixed, $\delta\xi^a = 0$, under variations of g_{ab}.

B. Dirichlet boundary condition

There is a natural motivation for a Dirichlet boundary condition on the gravitational field in the Einstein equations in analogy with the Maxwell equations where the tangential components of the electromagnetic field potential A_a are specified at the boundary. For General Relativity, similarly, one can introduce a Dirichlet boundary condition given by specifying the tangential components of the space–time metric g_{ab} at the two-surfaces $\partial\Sigma_t$. This boundary condition is expressed equivalently by conditions on the variation of the metric tensor

$$\delta\sigma_{ab}|_{\partial\Sigma_t} = 0, \quad \delta t_a|_{\partial\Sigma_t} = 0, \quad t \geqslant 0. \tag{3.34}$$

Geometrically, this means that the metric given by

$$h_{ab} = \sigma_{ab} - t_a t_b \tag{3.35}$$

on the timelike boundary hypersurface $\mathcal{B}$ is specified data, so it is held fixed under variations of g_{ab},

$$\delta h_{ab} = 0 \ \text{ on } \ \mathcal{B}. \tag{3.36}$$

The geometrical form (3.36) of the Dirichlet boundary condition is often introduced when one considers an action principle for General Relativity on a spacetime manifold with a fixed global timelike boundary hypersurface.[12,15–17] We will see in Sec. III C that this boundary condition in the form (3.34) emerges naturally from the Noether charge analysis for the existence of a Hamiltonian formulation of General Relatively for a spatially bounded local space-time region.

Note that, from the relations (3.27) to (3.31), one can decompose the Dirichlet boundary condition (3.34) into an intrinsic part

$$\delta h^{ab}|_{\partial\Sigma_t} = -h^{ac}h^{bd}\delta h_{cd}|_{\partial\Sigma_t} = 0, \quad t \geqslant 0 \tag{3.37}$$

and an extrinsic part

$$h_{ab}\delta s^b|_{\partial\Sigma_t} = -s^b \delta h_{ab}|_{\partial\Sigma_t} = 0, \quad t \geqslant 0 \tag{3.38}$$

with respect to the timelike hypersurface $\mathcal{B}$. The intrinsic part corresponds to fixing just the metric $\mathcal{P}_{\mathcal{B}}h_{ab}$ restricted to the tangent space of $\mathcal{B}$, where the projection $\mathcal{P}_{\mathcal{B}}$ removes components of the hypersurface metric proportional to s_a. Correspondingly, note that the volume form

$$\epsilon_{abc}(h)=\epsilon_{abcd}(g)s^d=3\epsilon_{[ab}t_{c]} \tag{3.39}$$

on this surface is also fixed, $\delta\epsilon_{abc}(h)=0$ on $\mathcal{B}$, since

$$\delta\epsilon_{abc}(h)=\tfrac{1}{2}\epsilon_{abc}(h)h^{mn}\delta h_{mn}=-\tfrac{1}{2}\epsilon_{abc}(h)h_{mn}\delta h^{mn}. \tag{3.40}$$

The Dirichlet boundary condition has a simple formulation in terms of the orthonormal frame θ_a^μ. It is convenient to introduce a frame for the metric h_{ab} by

$$h_a{}^\mu=h_a{}^b\theta_b^\mu=\sigma_a{}^\mu-t_at^\mu, \tag{3.41}$$

and inverse frame

$$h^{a\mu}=h^{ab}h_b{}^\mu. \tag{3.42}$$

Then the Dirichlet boundary condition (3.34) is equivalent to

$$\delta h_a{}^\mu|_{\partial\Sigma_t}=0,\quad t\geqslant 0, \tag{3.43}$$

with intrinsic part

$$\delta h^{a\mu}|_{\partial\Sigma_t}=0,\quad t\geqslant 0, \tag{3.44}$$

which is equivalent to Eq. (3.37). These equivalences are immediate consequences of the identities $h_{ab}=h_a{}^\mu h_b{}^\nu\eta_{\mu\nu}$ and $h^{ab}=h_\mu{}^a h_\nu{}^b\eta^{\mu\nu}$. From these identities, one also has

$$\delta h_{ab}=2h_{(a}{}^\mu\delta h_{b)\mu}, \tag{3.45}$$

$$\delta\epsilon_{abc}(h)=h_\mu{}^d\delta h_d{}^\mu. \tag{3.46}$$

An additional useful identity is given by

$$\delta h_a{}^c=-(s^c\delta s_a+s_a\delta s^c)=-s_a h_b{}^c\delta s^b \tag{3.47}$$

and therefore $\mathcal{P}_{\mathcal{B}}\delta h_a{}^c=0$.

Finally, note that the intrinsic part of the Dirichlet boundary condition on the frame decomposes into

$$\delta\sigma^{a\mu}|_{\partial\Sigma_t}=0,\quad \delta t^a|_{\partial\Sigma_t}=0,\quad t\geqslant 0. \tag{3.48}$$

The full, extrinsic Dirichlet boundary condition is necessary and sufficient for $\delta h_a{}^c|_{\partial\Sigma_t}=0$, $t\geqslant 0$.

C. Noether charge analysis

We consider the standard tetrad formulation of General Relativity, using an orthonormal frame θ_a^μ for g_{ab} and a frame-connection

$$\Gamma_a{}^{\mu\nu}(\theta)=\theta^{b\mu}\,{}^g\nabla_a\theta_b^\nu=2\theta^{b[\mu}\partial_{[a}\theta_{b]}^{\nu]}-\theta^{b\mu}\theta^{c\nu}\theta_{a\alpha}\partial_{[b}\theta_{c]}^\alpha. \tag{3.49}$$

Here the expression in the second equality is obtained from the relation

$$\theta^\nu_{[b}\Gamma_{a]\nu}{}^\mu(\theta)={}^g\nabla_{[a}\theta^\nu_{b]}=\partial_{[a}\theta^\mu_{b]}. \tag{3.50}$$

The curvature of this connection (3.49) is given by

$$R_{ab}{}^{\mu\nu}(\theta) = 2\partial_{[a}\Gamma_{b]}{}^{\mu\nu}(\theta) + 2\Gamma_{[a}{}^{\mu\sigma}(\theta)\Gamma_{b]\sigma}{}^{\nu}(\theta) = R_{abcd}(g)\,\theta^{c\mu}\theta^{d\nu}, \tag{3.51}$$

related to the Riemann curvature tensor $R_{abcd}(g)$ of g_{ab}.

With θ_a^μ as the field variable, the Lagrangian four-form for General Relativity (without matter sources) is given by

$$L_{abcd}(\theta) = \epsilon_{abcd}(\theta)R(\theta) = 6\,\theta^\mu_{[a}\theta^\nu_b\tilde{R}_{cd]\mu\nu}(\theta), \tag{3.52}$$

where

$$\tilde{R}_{cd}{}^{\mu\nu}(\theta) = R_{cd\alpha\beta}(\theta)\,\epsilon^{\alpha\beta\mu\nu} = 2\partial_{[a}\tilde{\Gamma}_{b]}{}^{\mu\nu} - \Gamma_{[a}{}^{\sigma[\mu}(\theta)\tilde{\Gamma}_{b]\sigma}{}^{\nu]}(\theta) \tag{3.53}$$

in terms of $\tilde{\Gamma}_{a\mu\nu}(\theta) = \Gamma_a{}^{\alpha\beta}(\theta)\epsilon_{\alpha\beta\mu\nu}$. Then the variation of $L_{abcd}(\theta)$ gives, after integration by parts and use of the connection equation (3.50),

$$\tfrac{1}{6}\delta L_{abcd}(\theta) = 2\,\delta\theta^\mu_{[a}(\theta^\nu_b\tilde{R}_{cd]\mu\nu}(\theta)) + \tfrac{1}{6}\partial_{[a}\Theta_{bcd]}(\theta,\delta\theta), \tag{3.54}$$

where

$$\Theta_{bcd}(\theta,\delta\theta) = 12\theta^\mu_{[c}\theta^\nu_d\delta\tilde{\Gamma}_{b]\mu\nu}(\theta) \tag{3.55}$$

defines the symplectic potential three-form. The field equations for θ_a^μ, obtained from the coefficient of $\delta\theta_a^\mu$ in Eq. (3.54), are given by

$$\mathcal{E}^\mu_{bcd}(\theta) = 12\theta^\nu_{[b}\tilde{R}_{cd]\mu\nu}(\theta) = 8\,\epsilon_{bcda}(\theta)(R^{a\mu}(\theta) - \tfrac{1}{2}\theta^{a\mu}R(\theta)) = 0. \tag{3.56}$$

Thus θ_a^μ satisfies $R^{a\mu}(\theta) = 0$, which is equivalent to the vacuum Einstein equations for the space–time metric

$$R_{ab}(g) = 0 \tag{3.57}$$

arising as the stationary points of the action functional $S(g) = \int_M \epsilon_{abcd}(g)R(g)$ under compact support variations of g_{ab}.

The Noether current associated with ξ^a is given by the three-form

$$J_{abc}(\xi,\theta) = \Theta_{abc}(\theta,\mathcal{L}_\xi\theta) + 4\,\xi^d L_{abcd}(\theta) = 12\theta^\mu_{[b}\theta^\nu_c\mathcal{L}_\xi\tilde{\Gamma}_{a]\mu\nu}(\theta) + 24\xi^d\theta^\mu_{[c}\theta^\nu_d\tilde{R}_{ab]\mu\nu}(\theta) \tag{3.58}$$

with the first term obtained from the variation of the frame connection (3.49) after replacement of $\delta\theta_a^\mu$ by the Lie derivative $\mathcal{L}_\xi\theta_a^\mu = \xi^e\partial_e\theta_a^\mu + \theta_e^\mu\partial_a\xi^e$ and use of the fact that Lie derivatives commute with exterior (skew) derivatives. We now simplify the first term in Eq. (3.58) as follows. First we express

$$\mathcal{L}_\xi\Gamma_a{}^{\mu\nu}(\theta) = \partial_a(\xi^e\Gamma_e{}^{\mu\nu}(\theta)) + \xi^e(R_{ea}{}^{\mu\nu}(\theta) - 2\Gamma_{[e}{}^{\mu\sigma}(\theta)\Gamma_{a]\sigma}{}^{\nu}(\theta)). \tag{3.59}$$

Hence we obtain

$$12\theta^\mu_{[b}\theta^\nu_c\mathcal{L}_\xi\tilde{\Gamma}_{a]\mu\nu}(\theta) = \partial_{[a}(12\theta^\mu_b\theta^\nu_{c]}\xi^e\tilde{\Gamma}_{e\mu\nu}(\theta)) - 12\xi^e\theta^\mu_{[b}\theta^\nu_c\tilde{R}_{a]e\mu\nu}(\theta) \tag{3.60}$$

through use of the identity (3.53). Next we combine the second terms in both Eqs. (3.58) and (3.60) to get

$$-12\xi^e\theta^\mu_{[b}\theta^\nu_c\tilde{R}_{a]e\mu\nu}(\theta) + 24\xi^d\theta^\mu_{[c}\theta^\nu_d\tilde{R}_{ab]\mu\nu}(\theta) = \xi^e\epsilon_{abcd}(g)(4\,\delta^d_e R(g) - 8R_e{}^d(g)). \tag{3.61}$$

Thus, one obtains the Noether current

$$J_{abc}(\xi;\theta)=3\partial_{[a}Q_{bc]}(\xi;\theta)-\xi^e\theta_{e\mu}\mathcal{E}^{\mu}_{abc}(\theta), \tag{3.62}$$

where

$$Q_{bc}(\xi;\theta)=4\xi^d\tilde{\Gamma}_{d\mu\nu}(\theta)\theta^{\mu}_b\theta^{\nu}_c \tag{3.63}$$

is the Noether current potential two-form.

On vacuum solutions θ^{μ}_a, the Noether current reduces to an exact three-form

$$J_{abc}(\xi;\theta)=3\partial_{[a}Q_{bc]}(\xi;\theta). \tag{3.64}$$

Therefore, the Noether charge for vacuum solutions is given by the boundary two-surface integral

$$Q_{\Sigma}(\xi)=\int_{\Sigma}J_{abc}(\xi;\theta)=\int_{\partial\Sigma}\epsilon_{bc}4\xi^d\tilde{\Gamma}_{d\mu\nu}(\theta)\epsilon^{\mu\nu}=\int_{\partial\Sigma}8\xi^d\Gamma_{d\mu\nu}(\theta)t^{\mu}s^{\nu}\mathrm{d}S, \tag{3.65}$$

where dS is the volume element on $\partial\Sigma$ corresponding to the volume form ϵ_{bc} in local coordinates.

Now the symplectic current, defined by the antisymmetrized variation of $\Theta_{bcd}(\theta,\delta\theta)$, is given by the three-form

$$\tfrac{1}{24}\omega_{bcd}(\theta,\delta_1\theta,\delta_2\theta)=\theta^{\mu}_{[c}\delta_1\theta^{\nu}_d\delta_2\tilde{\Gamma}_{b]\mu\nu}(\theta)-\theta^{\mu}_{[c}\delta_2\theta^{\nu}_d\delta_1\tilde{\Gamma}_{b]\mu\nu}(\theta). \tag{3.66}$$

Then the presymplectic form on Σ is defined by

$$\Omega_{\Sigma}(\theta,\delta_1\theta,\delta_2\theta)=\int_{\Sigma}\omega_{bcd}(\theta,\delta_1\theta,\delta_2\theta)=24\int_{\Sigma}\theta^{\mu}_{[c}\delta_1\theta^{\nu}_d\delta_2\tilde{\Gamma}_{b]\mu\nu}(\theta)-\theta^{\mu}_{[c}\delta_2\theta^{\nu}_d\delta_1\tilde{\Gamma}_{b]\mu\nu}(\theta). \tag{3.67}$$

A Hamiltonian conjugate to ξ on Σ is a function $H_{\Sigma}(\xi;\theta)=\int_{\Sigma}\mathcal{H}_{abc}(\xi;\theta)$ for some locally constructed three-form $\mathcal{H}_{abc}(\xi;\theta)$ such that

$$\delta H_{\Sigma}(\xi;\theta)\equiv H'_{\Sigma}(\xi;\theta,\delta\theta)=\Omega_{\Sigma}(\delta\theta,\mathcal{L}_{\xi}\theta) \tag{3.68}$$

holds for arbitrary variations $\delta\theta^{\mu}_a$ away from vacuum solutions θ^{μ}_a.

In terms of the Noether current (3.62), the presymplectic form on Σ yields

$$\Omega_{\Sigma}(\theta,\delta\theta,\mathcal{L}_{\xi}\theta)=\int_{\Sigma}J_{abc}(\xi;\theta)-4\xi^d\mathcal{E}^{\mu}_{[abc}(\theta)\delta\theta_{d]\mu}-\int_{\partial\Sigma}\xi^c\Theta_{abc}(\theta,\delta\theta). \tag{3.69}$$

Consequently, for variations $\delta\theta^{\mu}_a$ with compact support on the interior of Σ, the Noether current defines a Hamiltonian conjugate to ξ^a,

$$H(\xi;\theta)=\int_{\Sigma}J_{abc}(\xi;\theta)=8\int_{\Sigma}\xi^e\theta_{e\mu}\mathcal{E}^{\mu}_{abc}(\theta)+\int_{\partial\Sigma}Q_{ab}(\xi;\theta), \tag{3.70}$$

which is equal to the Noether charge (3.65) when θ^{μ}_a is a vacuum solution. Explicitly, from Eqs. (3.56) and (3.63), one has

$$\begin{aligned}H(\xi;\theta)&=8\int_{\Sigma}\epsilon_{dabc}(\xi^e\theta^d_{\mu}R_e{}^{\mu}(\theta)-\tfrac{1}{2}\xi^dR(\theta))+4\int_{\partial\Sigma}\epsilon_{bc}\xi^d\tilde{\Gamma}_{d\mu\nu}(\theta)\epsilon^{\mu\nu}\\&=8\int_{\Sigma}\xi^en_{\mu}(R_e{}^{\mu}(\theta)-\tfrac{1}{2}\theta^{\mu}_eR(\theta))\mathrm{d}\Sigma+8\int_{\partial\Sigma}\xi^d\Gamma_{d\mu\nu}(\theta)t^{\mu}s^{\nu}\,\mathrm{d}S,\end{aligned} \tag{3.71}$$

where $d\Sigma$ is the coordinate volume element on Σ obtained from the volume form $\epsilon_{abcd}n^d$.

To define a Hamiltonian $H_\Sigma(\xi;\theta)$ for variations $\delta\theta^\mu_a$ without compact support, it follows that the term $\xi^c\Theta_{abc}(\theta,\delta\theta)$ in Eq. (3.69) needs to be a total variation at the boundary $\partial\Sigma$, i.e., there must exist a locally constructed three-form $\tilde{B}_{abc}(\theta)$ such that one has

$$\xi^c\Theta_{abc}(\theta,\delta\theta)|_{\partial\Sigma}=(\xi^c\delta\tilde{B}_{abc}(\theta)+\partial_{[a}\alpha_{b]}(\xi;\theta,\delta\theta))|_{\partial\Sigma}, \tag{3.72}$$

where $\alpha_b(\xi;\theta,\delta\theta)$ is a locally constructed one-form. This equation is equivalent to

$$\epsilon^{ab}\xi^c\Theta_{abc}(\theta,\delta\theta)|_{\partial\Sigma}=\epsilon^{ab}\xi^c\delta\tilde{B}_{abc}(\theta,\delta\theta)|_{\partial\Sigma}+\sigma_c{}^d\partial_d\tilde{\alpha}^c(\xi;\theta,\delta\theta)|_{\partial\Sigma}, \tag{3.73}$$

where $\tilde{\alpha}^c(\xi;\theta,\delta\theta)=\epsilon^{cb}\alpha_b(\xi;\theta,\delta\theta)$ and the symplectic potential term is given by

$$\epsilon^{ab}\xi^c\Theta_{abc}(\theta,\delta\theta)=32\xi^c t_{[\alpha}s_{\nu]}\theta^\alpha_c\theta^a_\mu\delta\Gamma_a{}^{\mu\nu}(\theta). \tag{3.74}$$

Hence we now have the following result.

Proposition 3.1: A Hamiltonian conjugate to ξ^a on Σ exists for variations $\delta\theta^\mu_a$ with support on $\partial\Sigma$ if and only if

$$\epsilon^{ab}\xi^c\delta\tilde{B}_{abc}(\theta)|_{\partial\Sigma}=32(\xi^c t_{[\alpha}s_{\nu]}\theta^\alpha_c\theta^a_\mu\delta\Gamma_a{}^{\mu\nu}(\theta))|_{\partial\Sigma}-\sigma_c{}^d\partial_d\tilde{\alpha}^c(\xi;\theta,\delta\theta)|_{\partial\Sigma} \tag{3.75}$$

for some locally constructed three-form $\tilde{B}_{abc}(\theta)$ in $T^*(\Sigma)$ and locally constructed vector $\tilde{\alpha}^c(\xi;\theta,\delta\theta)$ in $T(\partial\Sigma)$. The Hamiltonian is given by the Noether charge plus an additional boundary term

$$\begin{aligned}H_\Sigma(\xi;\theta)&=\int_\Sigma J_{abc}(\xi;\theta)-\int_{\partial\Sigma}\xi^c\tilde{B}_{abc}(\theta)\\&=8\int_\Sigma\xi^e\theta_{e\mu}\mathcal{E}^\mu_{abc}(\theta)+\int_{\partial\Sigma}Q_{ab}(\xi;\theta)-\xi^c\tilde{B}_{abc}(\theta)\\&=8\int_\Sigma\xi^e n_\mu(R_e{}^\mu(\theta)-\tfrac{1}{2}\theta^\mu_e R(\theta))d\Sigma+\int_{\partial\Sigma}\xi^d(8\Gamma_{d\mu\nu}(\theta)t^\mu s^\nu-\tfrac{1}{2}\tilde{B}_d(\theta))dS\end{aligned} \tag{3.76}$$

with $\tilde{B}_d(\theta)=\epsilon^{bc}\tilde{B}_{bcd}(\theta)$.

We now show that equation (3.75) for the existence of a Hamiltonian (3.76) is satisfied for the intrinsic Dirichlet boundary condition on θ^μ_a,

$$\delta h^{a\mu}|_{\partial\Sigma_t}=0,\quad t\geqslant 0, \tag{3.77}$$

and then we derive the corresponding Hamiltonian boundary term. Henceforth we take θ^μ_a to satisfy the gauge conditions (3.15)–(3.17) naturally associated with the boundary hypersurface $\mathcal{B}$.

Consider the left-hand side of Eq. (3.75). The boundary condition (3.77) yields $\delta\sigma^{a\mu}|_{\partial\Sigma}=0$ and hence, from Eq. (3.19), $\delta\epsilon^{ab}=\epsilon^{ab}\sigma_{c\mu}\delta\sigma^{c\mu}|_{\partial\Sigma}=0$. Thus, we have

$$\epsilon^{ab}\xi^c\delta\tilde{B}_{abc}(\theta)|_{\partial\Sigma}=\delta(\epsilon^{ab}\xi^c\tilde{B}_{abc}(\theta))|_{\partial\Sigma}. \tag{3.78}$$

Next consider the right-hand side of Eq. (3.75). We integrate by parts with respect to the variation in the first term to get

$$\xi^c t_{[\alpha}s_{\nu]}\theta^\alpha_c\theta^a_\mu\delta\Gamma_a{}^{\mu\nu}(\theta)=\delta(\xi^c t_{[\alpha}s_{\nu]}\theta^\alpha_c\theta^a_\mu\Gamma_a{}^{\mu\nu}(\theta))-\xi^c t_{[\alpha}s_{\nu]}\Gamma_a{}^{\mu\nu}(\theta)(\theta^a_\mu\delta\theta^\alpha_c+\theta^\alpha_c\delta\theta^a_\mu). \tag{3.79}$$

Then, using orthogonality relations (3.5) and (3.24), we find that the second term in Eq. (3.79) vanishes as follows. First,

$$\xi^c t_{[\alpha} s_{\nu]} \delta\theta^\alpha_c = \tfrac{1}{2}\xi^c (s_\nu \delta t_c - t_\nu \delta s_c) = -s_\nu \xi^c t_c t_b \delta t^b = 0 \tag{3.80}$$

since $\delta t^b|_{\partial\Sigma} = 0$ by the boundary condition (3.77). In addition,

$$\xi^c t_{[\alpha} s_{\nu]} \theta^\alpha_c \delta\theta^a_\mu = \tfrac{1}{2}\xi^c t_c s_\nu (\delta h_\mu{}^a + s_\mu \delta s^a) = -\tfrac{1}{2} N s_\nu s_\mu \delta s^a. \tag{3.81}$$

Hence, the second term in Eq. (3.79) reduces to

$$\tfrac{1}{2} N s_\nu s_\mu \Gamma_a{}^{\mu\nu}(\theta)\, \delta s^a = 0 \tag{3.82}$$

since $\Gamma_a{}^{(\mu\nu)}(\theta) = 0$.

Consequently, returning to Eq. (3.75), we obtain

$$\delta(\xi^c \tilde{B}_c(\theta) - 32 t_{[a} s_{\nu]} \xi^c \theta^\alpha_c \theta^a_\mu \Gamma_a{}^{\mu\nu}(\theta))|_{\partial\Sigma} = -\sigma_c{}^d \partial_d \tilde{\alpha}^c(\xi; \theta, \delta\theta)|_{\partial\Sigma}, \tag{3.83}$$

which obviously is satisfied by

$$\xi^c \tilde{B}_c(\theta) = 32 t_{[\alpha} s_{\nu]} \xi^c \theta^\alpha_c \theta^d_\mu \Gamma_d{}^{\mu\nu}(\theta) \tag{3.84}$$

and $\tilde{\alpha}^c(\xi; \theta, \delta\theta) = 0$. This verifies Proposition 3.1 using the intrinsic Dirichlet boundary condition (3.77).

Finally, from expressions (3.84) for $\xi^c \tilde{B}_c(\theta)$ and (3.63) for $Q_{bc}(\xi, \theta)$, we obtain a Hamiltonian (3.76) with the boundary term given by

$$H_B(\xi, \theta) = \int_{\partial\Sigma} Q_{ab}(\xi, \theta) - \xi^c \tilde{B}_{abc}(\theta, \delta\theta) = 8 \int_{\partial\Sigma} \epsilon_{ab} \xi^c (t_\mu s_\nu \Gamma_c{}^{\mu\nu}(\theta) - 2 t_{[\alpha} s_{\nu]} \theta^\alpha_c \theta^d_\mu \Gamma_d{}^{\mu\nu}(\theta)). \tag{3.85}$$

Hence, the Hamiltonian boundary term takes the form

$$H_B(\xi, \theta) = 8 \int_{\partial\Sigma} \xi^c P_c(\theta) \mathrm{d}S, \tag{3.86}$$

where $P_c(\theta) = t_\mu s_\nu \Gamma_c{}^{\mu\nu}(\theta) - t_c s_\nu \theta^a_\mu \Gamma_a{}^{\mu\nu}(\theta) + s_c t_\nu \theta^a_\mu \Gamma_a{}^{\mu\nu}(\theta)$. This expression is simplified by the identities (3.3) and (3.14), which yield

$$P_c(\theta) = t^a s_\nu \sigma_c{}^{d\ g} \nabla_d \theta^\nu_a - t_c s_\nu \sigma^{bd\ g} \nabla_b \theta^\nu_d + s_c t_\nu \sigma^{bd\ g} \nabla_b \theta^\nu_d. \tag{3.87}$$

Thus, we have the following main result.

Theorem 3.2: *For the intrinsic Dirichlet boundary condition (3.77), a Hamiltonian conjugate to ξ^a on Σ is given by*

$$H_\Sigma(\xi; \theta) = 8 \int_\Sigma \xi^e n_\mu (R_e{}^\mu(\theta) - \tfrac{1}{2} \theta^\mu_e R(\theta)) \mathrm{d}\Sigma + 8 \int_{\partial\Sigma} \xi^c P_c(\theta) \mathrm{d}S. \tag{3.88}$$

On vacuum solutions θ^μ_a, the Hamiltonian reduces to the surface integral (3.86), (3.87).

Note, this Hamiltonian is unique up to adding an arbitrary covector function of the Dirichlet boundary data $h_\mu{}^a$ to $P_c(\theta)$.

D. Dirichlet Hamiltonian

On vacuum solutions of the Einstein equations, the Hamiltonian (3.88) with the Dirichlet boundary condition (3.77) holding on the timelike hypersurface $\mathcal{B}$ bounding a local space–time region $\mathcal{V}$ takes a simple form if the frame θ^μ_a is adapted to the boundary two-surfaces $\partial\Sigma_t$ and ξ^a. Let

$$\vartheta_a^0 = t_a\,, \quad \vartheta_a^1 = s_a\,, \quad \vartheta_{[a}^2 \vartheta_{b]}^3 = \epsilon_{ab}\,, \quad \vartheta_a^2 = \epsilon_a{}^b \vartheta_b^3, \tag{3.89}$$

which defines a preferred orthonormal frame ϑ_a^μ. It follows that

$$t^\nu = t^a \vartheta_a^\nu = -\delta_0^\nu, \quad s^\nu = s^a \vartheta_a^\nu = \delta_1^\nu. \tag{3.90}$$

This choice of frame is unique up to rotations of ϑ_a^2, ϑ_a^3.

Theorem 3.3: *For the Dirichlet boundary condition (3.77), the Hamiltonian (3.88) conjugate to ξ^a on Σ, evaluated in the orthonormal frame (3.89) for vacuum solutions ϑ_a^μ, is given by the surface integral*

$$H^{\mathrm{D}}(\xi;\vartheta) = 8\int_{\partial\Sigma} \xi^c P_c^{\mathrm{D}}(\vartheta)\mathrm{d}S, \tag{3.91}$$

where

$$P_c^{\mathrm{D}}(\vartheta) = t^a \sigma_c{}^{d\,g} \nabla_d s_a - t_c \sigma^{bd\,g} \nabla_b s_d + s_c \sigma^{bd\,g} \nabla_b t_d\,. \tag{3.92}$$

We refer to $H^{\mathrm{D}}(\xi;\vartheta)$ as the *Dirichlet Hamiltonian* for the gravitational field in the local space–time region $\mathcal{V}$, and $P_c^{\mathrm{D}}(\vartheta)$ as the *Dirichlet symplectic vector* associated with the boundary two-surfaces $\partial\Sigma_t$. Note that since ξ^a lies in $\mathcal{B}$, only the first two terms in $P_c^{\mathrm{D}}(\vartheta)$ contribute to $H^{\mathrm{D}}(\xi;\vartheta)$. The significance of the full expression for $P_c^{\mathrm{D}}(\vartheta)$ and its resulting geometrical properties are discussed in Ref. 8.

The general form of the Hamiltonian boundary term (3.86) and (3.87) differs from the special form (3.91) and (3.92) when evaluated in an orthonormal frame not adapted to $\partial\Sigma_t$ and ξ^a. In particular, we obtain the relation

$$P_c(\theta) = P_c^{\mathrm{D}}(\vartheta) - \sigma_c{}^d t^\nu \partial_d s_\nu + t_c \sigma^{b\nu} \partial_b s_\nu - s_c \sigma^{b\nu} \partial_b t_\nu \tag{3.93}$$

and so the general form of the symplectic vector $P_c(\theta)$ differs from $P_c^{\mathrm{D}}(\vartheta)$ by various gradient terms. These terms can be understood by considering a change of orthonormal frame

$$\theta_a^\mu \to U^\mu{}_\nu \theta_a^\nu, \tag{3.94}$$

where $U^\mu{}_\nu$ is a SO(3,1) transformation acting in the frame bundle of the space–time (M,g) at $\partial\Sigma_t$. Such transformations are defined by $U^{-1\mu}{}_\nu = U^\alpha{}_\beta \eta_{\alpha\nu} \eta^{\mu\beta}$ and $\det(U)=1$, where $U^{-1\mu}{}_\nu$ is the inverse of $U^\mu{}_\nu$, given by $U^{-1\mu}{}_\nu U^\nu{}_\alpha = \delta_\alpha^\mu = U^\mu{}_\nu U^{-1\nu}{}_\alpha$.

The transformations (3.94) are a gauge symmetry of the tetrad formulation for General Relativity. Under the change of orthonormal frame, one has

$$\begin{aligned}\Gamma_{a\mu}{}^\nu(\theta) = \theta_\mu^{b\,g} \nabla_a \theta_b^\nu \to \Gamma_{\alpha\mu}{}^\nu(U\theta) &= U^{-1\alpha}{}_\mu \theta_\alpha^b (U^\nu{}_\beta \theta_b^\beta) \\ &= U^{-1\alpha}{}_\mu U^\nu{}_\beta \Gamma_{a\alpha}{}^\beta(\theta) + U^{-1\alpha}{}_\mu \partial_a U^\nu{}_\alpha,\end{aligned} \tag{3.95}$$

and so, through substitution of the transformation (3.95) into the curvature (3.51),

$$R_{ab\mu}{}^\nu(\theta) \to R_{ab\mu}{}^\nu(U\theta) = U^{-1\alpha}{}_\mu U^\nu{}_\beta R_{ab\alpha}{}^\beta(\theta) \tag{3.96}$$

after cancellations of terms. Hence the Lagrangian (3.52) for the field variable θ_a^μ is gauge invariant. As a consequence, it is straightforward to see that the symplectic structure given by the symplectic potential (3.55) and current (3.66) must be gauge invariant. In particular, note that one has $\delta\Gamma_{a\mu}{}^\nu(U\theta) = U^{-1\alpha}{}_\mu U^\nu{}_\beta \delta\Gamma_{a\alpha}{}^\beta(\theta)$ where the gradient term from Eq. (3.95) drops out of the variation since it has no dependence on θ_a^μ. This explicitly establishes the gauge invariance of $\Theta_{abc}(\theta, \delta\theta)$ and hence of $\omega_{abc}(\theta, \delta_1\theta, \delta_2\theta)$.

However, the Noether charge (3.63) fails to be gauge invariant due to its explicit dependence on the frame connection. Consequently, it follows that the gradient terms in the symplectic vector (3.93) originate from a gauge transformation on the frame connection under (3.94) as given by a transformation relating the adapted orthonormal frame to a general orthonormal frame, $\theta^{\mu}_{a} = U^{\mu}{}_{0} t_a + U^{\mu}{}_{1} \sigma_a{}^{1} + U^{\mu}{}_{2} \sigma_a{}^{2} + U^{\mu}{}_{4} s_a$.

The gauge invariance of the symplectic structure arising from the tetrad formulation of the Lagrangian means that the symplectic potential (3.55) and current (3.66) are equivalent to manifestly gauge-invariant expressions derived using the metric formulation of General Relativity with g_{ab} as the field variable. It can be shown that one has

$$\Theta_{abc}(g, \delta g) = \Theta_{abc}(\theta, \delta\theta) + 6\partial_{[c}\psi_{ab]}(g, \delta g), \tag{3.97}$$

where $\psi_{ab}(g, \delta g)$ is a locally constructed two-form, and so the symplectic potentials are equivalent to within an exact three-form. This contributes a boundary term to the presymplectic form obtained from the metric Lagrangian $L_{abcd}(g) = \epsilon_{abcd}(g) R(g)$,

$$\Omega_{\Sigma}(g, \delta g, \mathcal{L}_{\xi} g) = \Omega_{\Sigma}(\theta, \delta\theta, \mathcal{L}_{\xi}\theta) + \int_{\partial\Sigma} \epsilon^{ab} (\delta\psi_{ab}(g, \mathcal{L}_{\xi} g) - \mathcal{L}_{\xi}\psi_{ab}(g, \delta g)) \mathrm{d}S. \tag{3.98}$$

Correspondingly, the Noether charge two-form $Q_{ab}(\xi, g)$ arising in the metric formulation differs from $Q_{ab}(\xi, \theta)$ in the tetrad formulation by the term $2\psi_{ab}(g, \mathcal{L}_{\xi} g)$. Explicitly, using the metric Lagrangian, one finds that[11]

$$\tfrac{1}{4}\epsilon^{ab} Q_{ab}(\xi, g) = -4 t_{[c} s_{d]}{}^{g}\nabla^{c}\xi^{d} = 4\xi^{d} t^{c\,g}\nabla_{c} s_{d} - 2(s^{c}\mathcal{L}_{\xi} t_{c} + t^{c}\mathcal{L}_{\xi} s_{c}). \tag{3.99}$$

Here the first term in Eq. (3.99) is simply the Noether charge (3.63) evaluated in the adapted orthonormal frame (3.89),

$$\epsilon^{ab} Q_{ab}(\xi, \vartheta) = 4\xi^{c}\Gamma_{c}{}^{\mu\nu}(\vartheta)\epsilon^{ab}\epsilon_{abmn}(g)\vartheta^{m}_{\mu}\vartheta^{n}_{\nu} = 16\xi^{c} t_{\mu} s_{\nu}\vartheta^{b\mu\,g}\nabla_{c}\vartheta^{\nu}_{b} = 16\xi^{c} t^{d\,g}\nabla_{c} s_{d} \tag{3.100}$$

since $\mathcal{P}_{\mathcal{B}}({}^{g}\nabla_{[c} s_{d]}) = 0$ by hypersurface orthogonality of s_d. The second term in Eq. (3.99) simplifies through the hypersurface orthogonality relations (3.6) and (3.7), leading to

$$t^{c}\mathcal{L}_{\xi} s_{c} = t^{c}(2\xi^{b\,g}\nabla_{[b} s_{c]} + \partial_{c}(\xi^{b} s_{b})) = 0 \tag{3.101}$$

and

$$s^{c}\mathcal{L}_{\xi} t_{c} = -\xi^{a}\frac{N}{\alpha}\partial_{a}\beta, \tag{3.102}$$

where α, β, N are scalar functions defined by

$$s_{a} = \alpha\partial_{a} s, \quad t_{a} = -N(\partial_{a} t + \beta\partial_{a} s) \tag{3.103}$$

with

$$\mathcal{L}_{\xi} t = \xi^{e}\partial_{e} t = 1, \quad \mathcal{L}_{\xi} s = \xi^{e}\partial_{e} s = 0. \tag{3.104}$$

Hence we obtain the relation

$$\epsilon^{ab} Q_{ab}(\xi, g) = \epsilon^{ab} Q_{ab}(\xi, \vartheta) + 8\xi^{a}\frac{N}{\alpha}\partial_{a}\beta. \tag{3.105}$$

A similar relation can be shown to hold between the respective symplectic vectors arising in the tetrad and metric Hamiltonian formulations of General Relativity. In particular, by direct

calculation with g_{ab} as the field variable, one finds that the full Dirichlet boundary condition (3.34) yields a Hamiltonian conjugate to ξ^a on Σ whose boundary term is given by

$$H^{\mathrm{D}}(\xi;g)=8\int_{\partial\Sigma}\xi^c P_c^{\mathrm{D}}(g)\mathrm{d}S, \tag{3.106}$$

where

$$P_c^{\mathrm{D}}(g)=P_c^{\mathrm{D}}(\vartheta)+\frac{N}{\alpha}\partial_c\beta. \tag{3.107}$$

This differs from the symplectic vector in the tetrad formulation by the same gradient term occurring in the Noether charges (3.105). The extrinsic part (3.38) of the Dirichlet boundary condition is necessary in obtaining this Hamiltonian, because of the boundary term in the presymplectic form (3.98). Interestingly, in the case when ξ^a is orthogonal to Σ_t, then $\beta=0$, and one finds that the weaker, intrinsic Dirichlet boundary condition (3.37) is sufficient for existence of the metric Hamiltonian (3.106) and (3.107). Moreover, in this case the presymplectic form (3.98) and symplectic vector (3.107) are exactly the same as those obtained in the tetrad formulation using the adapted orthonormal frame (3.89).

An expression for the Dirichlet Hamiltonian boundary term (3.106) in terms of the standard ADM canonical variables associated with Σ, and its relation to quasilocal quantities of Brown and York,[16,17] will be derived in Sec. III F.

E. Determination of allowed boundary conditions

A necessary and sufficient condition[10] on variations $\delta\theta_a^\mu$ for the existence of a Hamiltonian (3.76) conjugate to ξ^a on Σ is given by the antisymmetrized variation of the equation (3.72) for the boundary term. This yields

$$\epsilon^{ab}\xi^c\omega_{abc}(\theta,\delta_1\theta,\delta_2\theta)\big|_{\partial\Sigma}=\sigma_a{}^b\partial_b\tilde{\beta}^a(\xi,\gamma;\delta_1\theta,\delta_2\theta)\big|_{\partial\Sigma} \tag{3.108}$$

with

$$\tilde{\beta}^a(\xi,\theta;\delta_1\theta,\delta_2\theta)=\epsilon^{ab}\delta_1\alpha_b(\xi,\theta;\delta_2\theta)-\epsilon^{ab}\delta_2\alpha_b(\xi,\theta;\delta_1\theta). \tag{3.109}$$

To begin, we simplify the expression (3.66) for $\omega_{abc}(\theta,\delta_1\theta,\delta_2\theta)$. First, using Eq. (3.74) for $\Theta_{abc}(\theta,\delta\theta)$ and taking into account the orthogonality $\xi^a s_a=0$, we have

$$\tfrac{1}{16}\epsilon^{ab}\xi^c\Theta_{abc}(\theta,\delta\theta)=\xi^c t_c h_\mu{}^a\delta(s_\nu h^{b\mu g}\nabla_a\theta_b^\nu) \tag{3.110}$$

through the frame decomposition (3.41) and the relation $\Gamma_a{}^{\mu\nu}(\theta)=\theta^{c\mu\,g}\nabla_a\theta_c^\nu=-\theta^{c\nu\,g}\nabla_a\theta_c^\mu$. Now we substitute the identity ${}^g\nabla_a\theta_b^\nu=h_a{}^{c\,g}\nabla_c\theta_b^\nu-s_a s^{c\,g}\nabla_c\theta_b^\nu$ and then use the relations $h^{a\mu}\delta s_a=0$, $h^{a\mu}s_a=0$ to simplify the term

$$h_\mu{}^a\delta(s_\nu s_a h^{b\mu}s^{c\,g}\nabla_c\theta_b^\nu)=0. \tag{3.111}$$

Thus, Eq. (3.110) becomes

$$\tfrac{1}{16}\epsilon^{ab}\xi^c\Theta_{abc}(\theta,\delta\theta)=\xi^c t_c h^{a\mu}\delta(s_\nu h_\mu{}^b h_a{}^{c\ g}\nabla_c\theta_b^\nu). \tag{3.112}$$

Finally, we substitute $\xi^c t_c=\frac{1}{2}\epsilon^{ab}\xi^c\epsilon_{abc}(h)$.

Hence, we obtain

$$\mathcal{P}_{\mathcal{B}}\Theta_{abc}(\theta,\delta\theta)=8\,\epsilon_{abc}(h)h_\mu{}^d\delta K_d{}^\mu, \tag{3.113}$$

where we define

$$K_a{}^\mu = s_\nu h^{b\mu} h_a{}^c{}^g \nabla_c \theta_b^\nu = s_\nu h_a{}^c \Gamma_c{}^{\mu\nu}(\theta). \tag{3.114}$$

Note that $s^a K_a{}^\mu = 0$ and $s_\mu K_a{}^\mu = 0$. From Eq. (3.113), by taking an antisymmetric variation and then using Eq. (3.46) for the variation of $\epsilon_{abc}(h)$, we have

$$\mathcal{P}_{\mathcal{B}} \omega_{abc}(\theta, \delta_1\theta, \delta_2\theta) = 8\epsilon_{abc}(h)((\delta_1 h_\mu{}^d - h_\mu{}^d h_e{}^\nu \delta_1 h_\nu{}^e)\delta_2 K_d{}^\mu - (\delta_2 h_\mu{}^d - h_\mu{}^d h_e{}^\nu \delta_2 h_\nu{}^e)\delta_1 K_d{}^\mu). \tag{3.115}$$

Substitution of this expression into Eq. (3.108) yields the following result.

Theorem 3.4: *A Hamiltonian conjugate to ξ^a on Σ exists for variations $\delta\theta_a^\mu$ with support on $\partial\Sigma$ if and only if*

$$\begin{aligned}&((\delta_1 h_\mu{}^d - h_\mu{}^d h_e{}^\nu \delta_1 h_\nu{}^e)\delta_2 K_d{}^\mu - (\delta_2 h_\mu{}^d - h_\mu{}^d h_e{}^\nu \delta_2 h_\nu{}^e)\delta_1 K_d{}^\mu)\big|_{\partial\Sigma} \\ &\quad = \frac{1}{16N}\sigma_a{}^b \partial_b \tilde{\beta}^a(\xi, \theta; \delta_1\theta, \delta_2\theta)\big|_{\partial\Sigma}\end{aligned} \tag{3.116}$$

for some $\tilde{\beta}^a(\xi, \theta; \delta_1\theta, \delta_2\theta)$ of the form (3.109). The Hamiltonian is given by

$$H_\Sigma(\xi; \theta) = 8\int_\Sigma \xi^e n_\mu (R_e{}^\mu(\theta) - \tfrac{1}{2}\theta_e^\mu R(\theta))\mathrm{d}\Sigma + H_B(\xi; \theta) \tag{3.117}$$

with boundary term

$$H_B(\xi, \theta) = \int_{\partial\Sigma} Q_{ab}(\xi, \theta) - \xi^c \tilde{B}_{abc}(\theta), \tag{3.118}$$

where $\tilde{B}_{abc}(\theta)$ is determined from

$$\xi^c(\mathcal{P}_{\mathcal{B}}\delta\tilde{B}_{abc}(\theta) - 8\epsilon_{abc}(h)h_\mu{}^d \delta K_d{}^\mu) = \mathcal{P}_{\mathcal{B}}\partial_{[a}\alpha_{b]}(\xi, \theta; \delta\theta). \tag{3.119}$$

Thus, equation (3.116) determines the allowed boundary conditions on variations $\delta\theta_a^\mu$ for the existence of a Hamiltonian formulation (3.117) for the vacuum Einstein equations. To proceed, we now parallel the analysis of the similar boundary condition determining equation for the Maxwell equations in Sec. II C.

Two obvious solutions of the determining equation (3.116) with $\tilde{\beta}^a(\xi, \theta; \delta_1\theta, \delta_2\theta) = 0$ are given by $\delta h_\mu{}^a|_{\partial\Sigma_t} = 0$, $t \geqslant 0$, which is the Dirichlet boundary condition (3.77) already considered; and by

$$\delta K_a{}^\mu|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{3.120}$$

which we call the *Neumann boundary condition*. For the boundary condition (3.120), it follows from Eqs. (3.76) and (3.119) that the corresponding Hamiltonian boundary term is given by

$$H^{\mathrm{N}}(\xi; \theta) = 8\int_{\partial\Sigma} \xi^c P_c^{\mathrm{N}}(\theta)\mathrm{d}S, \tag{3.121}$$

where

$$P_c^{\mathrm{N}}(\theta) = t_\mu s_\nu \Gamma_c{}^{\mu\nu}(\theta) = t^a s_\nu{}^g \nabla_c \theta_a^\nu \tag{3.122}$$

by a derivation similar to Eq. (3.87). In the orthonormal frame (3.89) adapted to the boundary two-surfaces $\partial\Sigma_t$, we have

$$P_c^{\mathrm{N}}(\vartheta) = t^{ag}\nabla_c s_a . \tag{3.123}$$

We refer to this as the *Neumann symplectic vector* associated with the boundary two-surfaces $\partial\Sigma_t$. Moreover, in this frame the Neumann boundary condition (3.120) becomes

$$\delta K_a{}^{\mu}|_{\partial\Sigma_t} = \delta(h^{b\mu}K_{ab})|_{\partial\Sigma_t} = 0, \quad t \geqslant 0 \tag{3.124}$$

in terms of

$$K_{ab} = h_a{}^c h_b{}^d \nabla_c s_d , \tag{3.125}$$

which is the extrinsic curvature of the timelike boundary hypersurface $\mathcal{B}$ in (M,g). Thus, geometrically, the Neumann boundary condition corresponds to fixing the frame components of the boundary hypersurface extrinsic curvature,

$$\delta(h^{b\mu}h_a{}^{c\,g}\nabla_c s_b) = 0 \quad \text{on } \mathcal{B}. \tag{3.126}$$

These components measure the rotation and boost of the hypersurface normal s_a with respect to the frame h_a^{μ} under displacement on $\mathcal{B}$.

We now investigate more general boundary conditions. Note that, on the left-hand side of the determining equation (3.116), $\epsilon^{ab}\xi^c\omega_{abc}(\theta,\delta_1\theta,\delta_2\theta)$ involves only the field variations $\mathcal{P}_{\mathcal{B}}\delta h_{\mu}{}^a$ and $\mathcal{P}_{\mathcal{B}}\delta K_a{}^{\mu} = \mathcal{P}_{\mathcal{B}}\delta(s_\nu h_a{}^c \Gamma_a{}^{\mu\nu}(\theta))$. We call $h_{\mu}{}^a$ and $K_a{}^{\mu}$ the *symplectic boundary data* at $\partial\Sigma_t$ and consider boundary conditions of the form

$$\delta\mathcal{F}_a^{\mu}(h_c{}^{\nu}, K_c{}^{\nu})|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{3.127}$$

where $\mathcal{F}_a^{\mu}(h_c{}^{\nu}, K_c{}^{\nu})$ is locally constructed as an algebraic expression in terms of the symplectic boundary data and fixed quantities (including the space–time coordinates). We call (3.127) a *mixed Dirichlet–Neumann* boundary condition if $\mathcal{F}_a^{\mu}(h_c{}^{\nu}, K_c{}^{\nu})$ is a constant-coefficient linear combination of the parts $\mathcal{P}_{\partial\Sigma}h_a{}^{\mu}$, $\mathcal{P}_t h_a{}^{\mu}$, $\mathcal{P}_{\partial\Sigma}K_a{}^{\mu}$, $\mathcal{P}_t K_a{}^{\mu}$ of the Dirichlet and Neumann boundary data in (3.77) and (3.120). Here the projections with respect to $\mathcal{P}_{\partial\Sigma}$ and $\mathcal{P}_t$ remove all components proportional to s_a.

An analysis of the boundary condition determining equation (3.116), given later, leads to the following main results.

Theorem 3.5: *The only allowed mixed Dirichlet–Neumann boundary conditions for the existence of a Hamiltonian (3.76) conjugate to ξ^a on Σ are given by*

$$\mathcal{P}_{\mathcal{B}}(a_0\delta K_a{}^{\mu} + b_0\delta h_a{}^{\mu})|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{3.128}$$

or equivalently

$$\mathcal{F}_a^{\mu}(h_c{}^{\nu}, K_c{}^{\nu}) = a_0 K_a{}^{\mu} + b_0 h_a{}^{\mu} \tag{3.129}$$

for constants a_0, b_0 (and $\beta^a = 0$ in Eq. (3.116)). In the cases $a_0 = 0$ or $b_0 = 0$, respectively Dirichlet or Neumann boundary conditions, the corresponding Hamiltonian boundary terms are given by Eqs. (3.91) and (3.87), and Eqs. (3.121) and (3.122). In the case $a_0 \neq 0$, $b_0 \neq 0$, the corresponding Hamiltonian boundary term is given by

$$H^{\mathrm{DN}}(\xi;\theta) = 8\int_{\partial\Sigma} \xi^c P_c(\theta)\,\mathrm{d}S \tag{3.130}$$

where, now,

$$P_c(\theta) = P_c^{\mathrm{N}}(\theta) + 6\frac{b_0}{a_0}t_c\,. \tag{3.131}$$

(Note, the boundary terms here are unique up to adding an arbitrary covector function of the boundary data (3.129) to $P_c(\theta)$.)

A similar covariant derivation of the pure Dirichlet and Neumann boundary terms is presented in Refs. 18 and 19 from a different perspective. In Theorem 3.5, note that Eq. (3.128) represents a one-parameter a_0/b_0 family of boundary conditions. In particular, in contrast to the two-parameter family of analogous mixed Dirichlet–Neumann boundary conditions (2.52) allowed for the Maxwell equations, here decompositions of the symplectic boundary data with respect to $\mathcal{P}_{\partial\Sigma}$ and $\mathcal{P}_\xi$ do not yield boundary conditions satisfying the determining equation (3.116).

The form of the mixed Dirichlet–Neumann boundary condition (3.128) suggests we also consider boundary conditions specified by a trace part and trace-free part with respect to the boundary hypersurface frame $h_a{}^\mu$:

$$\delta\hat{\mathcal{F}}(h_c{}^\nu, K_c{}^\nu)\big|_{\partial\Sigma_t} = 0, \quad \delta\hat{\mathcal{F}}_a^\mu(h_c{}^\nu, K_c{}^\nu)\big|_{\partial\Sigma_t} = 0, \quad t \geqslant 0 \tag{3.132}$$

with $h_\mu{}^a\hat{\mathcal{F}}_a^\mu(h_c{}^\nu, K_c{}^\nu) = 0$. Taking the trace of the symplectic boundary data variations yields

$$h_\mu{}^a\delta K_a{}^\mu = \delta K + h_\mu{}^b h_\nu{}^a K_a{}^\mu \delta h_b{}^\nu \tag{3.133}$$

and

$$h_\mu{}^a\delta h_a{}^\mu = \delta\ln|h|\,, \tag{3.134}$$

where $K = h_\mu{}^a K_a{}^\mu$ is the trace of $K_a{}^\mu$ and $h = \det(h_a{}^\mu)$ is the determinant of the frame components $h_a{}^\mu$ in local coordinates.

Theorem 3.6: *Allowed boundary conditions (3.132) for the existence of a Hamiltonian (3.76) conjugate to ξ^a on Σ are given by*

$$\mathcal{P}_{\mathcal{B}}\delta(K_a{}^\mu - \tfrac{1}{3}h_a{}^\mu K)\big|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{3.135}$$

$$(a_0\delta K + b_0\delta\ln|h|)\big|_{\partial\Sigma_t} = 0, \quad t \geqslant 0, \tag{3.136}$$

or equivalently

$$\hat{\mathcal{F}}(h,K) = a_0 K + b_0\ln|h|, \quad \hat{\mathcal{F}}_a^\mu(h_c{}^\nu, K_c{}^\nu) = \mathcal{P}_{\mathcal{B}}(K_a{}^\mu - \tfrac{1}{3}h_a{}^\mu K) \tag{3.137}$$

for constants a_0, b_0 (and $\beta^a = 0$ in Eq. (3.116)). The corresponding Hamiltonian boundary term is given by

$$H_B(\xi,\theta) = 8\int_{\partial\Sigma}\xi^c\left(\frac{1}{3}P_c^{\mathrm{D}}(\theta) + \frac{2}{3}P_c^{\mathrm{N}}(\theta) + 4\frac{b_0}{a_0}t_c\right)\mathrm{d}S \tag{3.138}$$

(which is unique up to adding a term depending on an arbitrary covector function of the boundary data (3.137)).

Finally, we remark that the mixed boundary conditions in Theorems 3.5 and 3.6 admit the following two generalizations.

First,

$$\hat{\mathcal{F}}_a^\mu(h_c{}^\nu, K_c{}^\nu) = a(x,K,\ln|h|)\mathcal{P}_{\mathcal{B}}(K_a{}^\mu - \tfrac{1}{3}h_a{}^\mu K), \tag{3.139}$$

$$\hat{\mathcal{F}}(h,K) = b(x,K,\ln|h|), \quad \partial_K b \neq 0 \tag{3.140}$$

for arbitrary functions $a(x,K,\ln|h|)$, $b(x,K,\ln|h|)$.

Second,

$$\mathcal{F}^{\mu}_{a}(h_c{}^{\nu},K_c{}^{\nu}) = a(x,K,\ln|h|)\mathcal{P}_{\mathcal{B}}(K_a{}^{\mu} + b(x,K,\ln|h|)h_a{}^{\mu}), \quad b \neq -\tfrac{1}{3}K \tag{3.141}$$

for an arbitrary function $b(x,K,\ln|h|)$, with the function $a(x,K,\ln|h|)$ now satisfying the linear partial differential equation

$$(\partial_K\hat{b})\partial_{\ln|h|}a + (\hat{b} + \partial_{\ln|h|}\hat{b})\partial_K a = \tfrac{2}{9}(-1 + 3\partial_K\hat{b})a, \quad \hat{b} = b + \tfrac{1}{3}K \tag{3.142}$$

obtained from the determining equation (3.116). The general form of a is given by solving the characteristic ordinary differential equations

$$\frac{\mathrm{d}\ln|h|}{\partial_K\hat{b}} = \frac{\mathrm{d}K}{\hat{b} + \partial_{\ln|h|}\hat{b}} = \frac{\mathrm{d}a}{\frac{2}{9}(-1 + 3\partial_K\hat{b})a} \tag{3.143}$$

in terms of the variables $\ln|h|$, K, a. For instance, if b is taken to be linear homogeneous in K, then one has $b = \lambda K$, $a = f(x,\lambda K\ln|h|)|h|^{(2/3)\lambda/(3\lambda-1)}$, where $\lambda = \text{const}$ and f is an arbitrary function.

Proofs of Theorems: Since any boundary condition locally constructed from the symplectic boundary data is linear homogeneous in $\mathcal{P}_{\mathcal{B}}\delta h_a{}^{\mu}$ and $\mathcal{P}_{\mathcal{B}}\delta K_a{}^{\mu}$, we begin by finding all such solutions of the determining equation (3.116).

First we show that $\tilde{\beta}^a = 0$. The right-hand side of Eq. (3.116) necessarily involves terms with at least one derivative on $\delta\theta^{\mu}_a$, while only first-order derivatives of $\delta\theta^{\mu}_a$ appear on the left-hand side of Eq. (3.116) through

$$\mathcal{P}_{\mathcal{B}}\delta K_a{}^{\mu} = s_{\nu}h_a{}^{c}\delta\Gamma_c{}^{\mu\nu}(\theta) \tag{3.144}$$

due to Eqs. (3.114) and (3.47). Thus, for a balance in numbers of derivatives, we must have

$$\alpha_a = \alpha_{a\mu}{}^{b}(\theta)\,\delta\theta^{\mu}_b \tag{3.145}$$

for some $\alpha_{a\mu}{}^{b}(\theta)$ locally constructed out of θ^{μ}_a and fixed quantities. This yields, for the antisymmetrized variation of α_a,

$$\beta_a = \alpha_{a\mu\nu}{}^{bc}(\theta)\,\delta_1\theta^{\mu}_b\delta_2\theta^{\nu}_c \tag{3.146}$$

where $\alpha_{a\mu\nu}{}^{bc}(\theta) = -\alpha_{a\nu\mu}{}^{cb}(\theta)$ is the curl of $\alpha_{a\mu}{}^{b}(\theta)$ with respect to θ^{ν}_c. Then, using Eqs. (3.109) and (3.50), we collect all the terms on the left-hand side of Eq. (3.116) linearly independent of $\delta h_a{}^{\mu}$, $\delta K_a{}^{\mu}$. Through Eqs. (3.144) and (3.49), the coefficients of these terms yield

$$s_c\tilde{\alpha}^{(be)c}{}_{\mu\nu}(\theta) = 0, \quad s_b\tilde{\alpha}^{[be]c}{}_{\mu\nu}(\theta) = 0, \quad s_c\tilde{\alpha}^{[be]c}{}_{\mu\nu}(\theta) = 0, \tag{3.147}$$

where

$$\tilde{\alpha}^{ebc}{}_{\mu\nu}(\theta) = \epsilon^{ae}\alpha_{a\mu\nu}{}^{bc}(\theta) = -\tilde{\alpha}^{ecb}{}_{\nu\mu}(\theta). \tag{3.148}$$

These algebraic equations are straightforward to solve, leading to

$$\alpha^{abc}{}_{\mu\nu}(\theta) = t^{[b}\alpha_1{}^{c]a}{}_{\mu\nu}(\theta) + \alpha_2{}^{abc}{}_{\mu\nu}(\theta) + t^b t^c\alpha_3{}^{a}{}_{\mu\nu}(\theta) + t^{(b}\alpha_4{}^{c)a}{}_{\mu\nu}(\theta) \tag{3.149}$$

for some

$$\begin{gathered}\alpha_1{}^{ca}{}_{\mu\nu} = \sigma_b{}^{c}\sigma_d{}^{a}\alpha_1{}^{bd}{}_{(\mu\nu)}, \quad \alpha_2{}^{abc}{}_{\mu\nu} = -\sigma_e{}^{a}\sigma_d{}^{b}\sigma_f{}^{c}\alpha_2{}^{edf}{}_{\nu\mu}, \\ \alpha_3{}^{a}{}_{\mu\nu} = \sigma_e{}^{a}\alpha_3{}^{e}{}_{[\mu\nu]}, \quad \alpha_4{}^{ca}{}_{\mu\nu} = \sigma_b{}^{c}\sigma_d{}^{a}\alpha_4{}^{bd}{}_{[\mu\nu]}.\end{gathered} \tag{3.150}$$

Then, returning to Eq. (3.145), we note that $\alpha_{a\mu}{}^{b}(\theta)=\theta_a^{\alpha}\theta^b_{\beta}\alpha^{\beta}_{\mu\alpha}$ for some $\alpha^{\beta}_{\mu\alpha}$ that is locally constructed only from fixed quantities since it is a scalar expression. Thus we immediately obtain

$$\alpha^{abc}_{\mu\nu}(\theta)=\theta^b_{\beta}\theta^c_{\gamma}\theta^{a\alpha}(\alpha^{\beta}_{\nu\mu}\delta^{\gamma}_{\alpha}-\alpha^{\gamma}_{\mu\nu}\delta^{\beta}_{\alpha}-\alpha^{\gamma}_{\alpha\mu}\delta^{\beta}_{\nu}+\alpha^{\beta}_{\alpha\mu}\delta^{\gamma}_{\nu}). \tag{3.151}$$

By equating expressions (3.149) and (3.151), we find that after some algebraic analysis

$$\alpha^{\gamma}_{\nu\mu}=\delta^{\gamma}_{\nu}\alpha_{0\mu} \tag{3.152}$$

for some $\alpha_{0\mu}$. Now, substitution of expression (3.152) back into Eqs. (3.149) and (3.151) easily leads to the result

$$\alpha_{1\mu\nu}{}^{ca}=\alpha_{2\mu\nu}{}^{abc}=\alpha_{3\mu\nu}{}^{a}=\alpha_{4\mu\nu}{}^{ca}=0. \tag{3.153}$$

Hence, from Eq. (3.149), we have $\alpha_{a\mu\nu}{}^{bc}(\theta)=0$ and so $\beta_a=0$. This establishes that $\tilde{\beta}^a=0$.

Consequently, the determining equation (3.116) reduces to

$$(\delta_1 h_{\mu}{}^{d}-h_{\mu}{}^{d}h_e{}^{\nu}\delta_1 h_{\nu}{}^{e})\delta_2 K_d{}^{\mu}-(\delta_2 h_{\mu}{}^{d}-h_{\mu}{}^{d}h_e{}^{\nu}\delta_2 h_{\nu}{}^{e})\delta_1 K_d{}^{\mu}=0, \tag{3.154}$$

which is equivalent to

$$h_{[\nu}{}^{d}h_{\mu]}{}^{e}(\delta_1 h_e{}^{\nu}\delta_2 K_d{}^{\mu}-\delta_2 h_e{}^{\nu}\delta_1 K_d{}^{\mu})=0. \tag{3.155}$$

Then the algebraic solution of Eq. (3.155) in terms of $\mathcal{P}_{\mathcal{B}}\delta h_e{}^{\nu}$ and $\mathcal{P}_{\mathcal{B}}\delta K_d{}^{\mu}$ has the form

$$\Pi_1{}^{\mu b}_{a\nu}\mathcal{P}_{\mathcal{B}}\delta h_b{}^{\nu}+\Pi_2{}^{\mu b}_{a\nu}\mathcal{P}_{\mathcal{B}}\delta K_b{}^{\nu}=0 \tag{3.156}$$

for some coefficient tensors $\Pi^{\mu b}_{a\nu}$ such that

$$\Pi^{\mu b}_{a\nu}h_{[\alpha}{}^{a}h_{\mu]}{}^{c}=\Pi^{\mu c}_{a\alpha}h_{[\nu}{}^{a}h_{\mu]}{}^{b}. \tag{3.157}$$

It is straightforward to show that Eq. (3.157) holds iff

$$\Pi^{\mu b}_{a\nu}=\hat{\Pi}^{\mu b}_{a\nu}-h_a{}^{\mu}\hat{\Pi}^{b}_{\nu}+h_{\nu}{}^{b}\hat{\Pi}^{\mu}_{a}, \tag{3.158}$$

where $\hat{\Pi}^{\mu b}_{a\nu}h_{\alpha}{}^{a}h_{\mu}{}^{c}=\hat{\Pi}^{\mu c}_{a\alpha}h_{\nu}{}^{a}h_{\mu}{}^{b}$ is the symmetric part of $\Pi^{\mu b}_{a\nu}$ in the index pairs (a,μ) and (b,ν), and where $\hat{\Pi}^{b}_{\nu}=h_{\mu}{}^{a}\hat{\Pi}^{\mu b}_{a\nu}$, $\hat{\Pi}^{\mu}_{a}=h_b{}^{\nu}\hat{\Pi}^{\mu b}_{a\nu}$ is the trace part of $\Pi^{\mu b}_{a\nu}$ in the frame $h_a{}^{\mu}$. Thus, we have established the following result.

Lemma 3.7: All solutions of the determining equation (3.116) for allowed boundary conditions that are linear homogeneous in $\mathcal{P}_{\mathcal{B}}\delta h_a{}^{\mu}$ and $\mathcal{P}_{\mathcal{B}}\delta K_a{}^{\mu}$ have the form (3.156) where the coefficient tensors are given by Eq. (3.158).

Now, for mixed Dirichlet–Neumann boundary conditions, we take

$$\Pi_1{}^{\mu b}_{a\nu}=a_1(\mathcal{P}_{\partial\Sigma})_a{}^{b}\sigma_{\nu}{}^{\mu}+a_0(\mathcal{P}_t)_a{}^{b}t_{\nu}t^{\mu}, \tag{3.159}$$

$$\Pi_2{}^{\mu b}_{a\nu}=b_1(\mathcal{P}_{\partial\Sigma})_a{}^{b}\sigma_{\nu}{}^{\mu}+b_0(\mathcal{P}_t)_a{}^{b}t_{\nu}t^{\mu}, \tag{3.160}$$

where a_0, a_1, b_0, b_1 are constants. Then the requirement (3.158) leads directly to

$$a_0=a_1, \quad b_0=b_1. \tag{3.161}$$

Substitution of Eqs. (3.159)–(3.161) into Eq. (3.156) yields the mixed Dirichlet–Neumann boundary conditions (3.128).

Finally, the other boundary conditions (3.135) and (3.136) arise from

$$\Pi_{1a\nu}^{\mu b}=\frac{1}{2}\frac{b_0}{a_0}h_a{}^{\mu}h_{\nu}{}^{b}-\frac{1}{3}Kh_d{}^{e}h_{\nu}{}^{\mu}, \tag{3.162}$$

$$\Pi_{2a\nu}^{\mu b}=h_a{}^{b}h_{\nu}{}^{\mu}, \tag{3.163}$$

which are easily verified to satisfy the requirement (3.158).

This completes the proofs of Theorems 3.5 and 3.6. □

As a concluding remark, we note that Lemma 3.7 yields the following necessary and sufficient determining equations for finding all boundary conditions (3.127).

Lemma 3.8: All allowed boundary conditions of the form $\mathcal{F}_a^{\mu}(h_c{}^{\nu},K_c{}^{\nu})|_{\partial\Sigma}=0$ *for the existence of a Hamiltonian conjugate to* ξ^a *on* Σ *are given by the solutions of*

$$\frac{\partial\mathcal{F}_a^{\mu}}{\partial h_b{}^{\nu}}h_{[\alpha}{}^{a}h_{\mu]}{}^{c}=\frac{\partial\mathcal{F}_a^{\mu}}{\partial h_c{}^{\alpha}}h_{[\nu}{}^{a}h_{\mu]}{}^{b}, \tag{3.164}$$

$$\frac{\partial\mathcal{F}_a^{\mu}}{\partial K_b{}^{\nu}}h_{[\alpha}{}^{a}h_{\mu]}{}^{c}=\frac{\partial\mathcal{F}_a^{\mu}}{\partial K_c{}^{\alpha}}h_{[\nu}{}^{a}h_{\mu]}{}^{b}. \tag{3.165}$$

We will leave a general analysis of the boundary condition determining equations (3.164) and (3.165) for elsewhere.

F. Relation between covariant and canonical Hamiltonians and boundary terms

To conclude this section, we first give a brief discussion of the Hamiltonian field equations for General Relativity using the covariant symplectic structure and Noether charge Hamiltonian in Sec. III C. Then we discuss the boundary terms in the Dirichlet and Neumann Hamiltonians expressed in standard ADM canonical variables.

For a Hamiltonian (3.76) conjugate to ξ^a on Σ, the associated field equations are obtained through the presymplectic form (3.69) by the variational principle

$$\Omega_{\Sigma}(\theta,\delta\theta,\mathcal{L}_{\xi}\theta)-H'_{\Sigma}(\xi;\theta,\delta\theta)=\int_{\Sigma}8\xi^d n_d(R_{\mu}{}^{e}(\theta)-\tfrac{1}{2}\theta_{\mu}^{e})\delta\theta_e^{\mu}\mathrm{d}\Sigma=0 \tag{3.166}$$

for arbitrary variations $\delta\theta_e^{\mu}|_{\Sigma}$. These field equations split into evolution equations and constraint equations with respect to Σ corresponding to a decomposition of θ_a^{μ} into dynamical and nondynamical components determined by[4] the degeneracy of

$$\Omega_{\Sigma}(\theta,\delta_1\theta,\delta_2\theta)=\int_{\Sigma}\omega_{abc}(\theta,\delta_1\theta,\delta_2\theta)=\int_{\Sigma}\tfrac{1}{6}\epsilon^{abcd}n_d\omega_{abc}(\theta,\delta_1\theta,\delta_2\theta)\mathrm{d}\Sigma. \tag{3.167}$$

For this purpose, it is convenient to partially fix the SO(3,1) local gauge freedom in θ_e^{μ} analogously to conditions (3.15)–(3.17) by choosing the frame components $n^{\mu}=n^a\theta_a^{\mu}$ to be fixed constants on M. Then, through a simplification of the symplectic current here similar to Eq. (3.115), we obtain

$$\tfrac{1}{48}\epsilon^{abcd}n_d\omega_{abc}(\theta,\delta_1\theta,\delta_2\theta)=-(\delta_1q_{\mu}{}^{d}-q_{\mu}{}^{d}q_e{}^{\nu}\delta_1q_{\nu}{}^{e})\delta_2p_d{}^{\mu}+(\delta_2q_{\mu}{}^{d}-q_{\mu}{}^{d}q_e{}^{\nu}\delta_2q_{\nu}{}^{e})\delta_1p_d{}^{\mu}, \tag{3.168}$$

where we define

$$q_a{}^{\mu}=\theta_a^{\mu}+n_an^{\mu},\quad p_a{}^{\mu}=n_{\nu}q^{b\mu}q_a{}^{c}\,{}^{g}\nabla_c\theta_b^{\nu}=n_{\nu}q_a{}^{c}\Gamma_c{}^{\mu\nu}(\theta) \tag{3.169}$$

with $q_{ab}=g_{ab}+n_an_b$, which are counterparts of $h_a{}^{\mu}$, $K_a{}^{\mu}$ associated with the spacelike hypersurface Σ. (Geometrically, $q_a{}^{\mu}$ is a frame for the hypersurface metric $q_{ab}=q_a{}^{\mu}q_b{}^{\nu}\eta_{\mu\nu}$, while $p_a{}^{\mu}$

represents the frame components of the hypersurface extrinsic curvature $\mathcal{K}_{ab}=q_a{}^\mu p_b{}^\nu \eta_{\mu\nu} = q_a{}^c\, {}^g\nabla_c n_b$.) Hence, the degeneracy directions of the presymplectic form (3.167) are given by variations $\delta\theta_a^\mu$ satisfying

$$\delta(q_a{}^\mu/|q|) = \delta p_a{}^\mu = 0, \tag{3.170}$$

where $|q| = \det(q_a{}^\mu)$ and $\delta \ln |q| = q_\nu{}^b \delta q_b{}^\nu$. This immediately leads to the following result, analogous to the discussion in Sec. II A for the Maxwell equations.

Proposition 3.9: For a Hamiltonian $H_\Sigma(\xi;\theta)$ conjugate to ξ^a on Σ, let $\theta_{\ker\omega}$ denote the field components of θ_a^μ and $\Gamma_a{}^{\mu\nu}(\theta)$ invariant under the symplectic degeneracy directions (3.170), and let θ_ω denote the remaining field components modulo $\theta_{\ker\omega}$. Then there is corresponding decomposition of the Hamiltonian field equations given by $H'_\Sigma(\xi;\theta,\delta\theta_{\ker\omega})=0$ and $H'_\Sigma(\xi;\theta,\delta\theta_\omega) = \Omega_\Sigma(\theta,\delta\theta_\omega,\mathcal{L}_\xi\theta)$, which, respectively, yield

$$n^a R_a{}^\mu(\theta) - \tfrac{1}{2} n^\mu R(\theta) = 0, \tag{3.171}$$

$$q_a{}^b R_b{}^\mu(\theta) = 0. \tag{3.172}$$

These field equations arise equivalently by variation of $\mathcal{P}_n\theta_a^\mu = -n_a n^\mu$ and $\mathcal{P}_\Sigma\theta_a^\mu = q_a{}^\mu$ in the Lagrangian (3.52).

Equations (3.171) and (3.172) are the frame components of the standard $3+1$ split of the vacuum Einstein equations[12] into constraint equations and time-evolution equations for the hypersurface metric q_{ab}. Thus, the Hamiltonian field equations given by the variational principle (3.166) constitute a covariant formulation of the standard ADM Hamiltonian equations for General Relativity.

With respect to the spacelike hypersurface Σ, one has a decomposition of ξ^a into normal and tangential parts

$$\xi^a = \mathcal{N} n^a + \mathcal{N}^a, \tag{3.173}$$

where $\mathcal{N}^a = \mathcal{P}_\Sigma(\xi^a)$ and $\mathcal{N} = -\xi^a n_a$ define the lapse and shift of the time flow vector field ξ^a. By use of the Gauss–Codacci equations, we straightforwardly see that the volume part of a Hamiltonian (3.76) conjugate to ξ^a on Σ is given by the "pure constraint form" [11]

$$H(\xi;\theta) = 4\int_\Sigma \mathcal{N}(\mathcal{R} + \mathcal{K}^2 - \mathcal{K}_{ab}\mathcal{K}^{ab}) + 2\mathcal{N}^c(\mathcal{D}^b\mathcal{K}_{bc} - \mathcal{D}_c\mathcal{K})\,\mathrm{d}\Sigma, \tag{3.174}$$

where $\mathcal{R}_{ab}$ and $\mathcal{K}_{ab}$ are the Ricci curvature and extrinsic curvature of the metric $\mathcal{P}_{\Sigma g_{ab}} = q_{ab}$, $\mathcal{R} = \mathcal{R}_a{}^a$ and $\mathcal{K} = \mathcal{K}_a{}^a$ are the corresponding scalar curvatures, and $\mathcal{D}_a$ is the derivative operator associated with q_{ab}. (An analogous result holds more generally for any diffeomorphism covariant Lagrangian field theory.[4]) This demonstrates, explicitly, that our covariant analysis of allowed boundary conditions and corresponding boundary terms for General Relativity in Secs. III B and III E is equivalent to a canonical analysis of the ADM Hamiltonian.

Now, consider Dirichlet or Neumann boundary conditions imposed at the two-surfaces $\partial\Sigma_t$, for $t \geqslant 0$. On solutions of the Hamiltonian field equations, the total Hamiltonian $H_\Sigma(\xi;\theta)$ reduces, respectively, to the Dirichlet and Neumann boundary terms (3.91) and (3.121). Let u^a denote the outward unit normal to $\partial\Sigma_t$ in Σ_t. Let $\mathfrak{d}_a^\mu$ be an orthonormal frame adapted to Σ_t given by

$$\mathfrak{d}_a^0 = n_a, \mathfrak{d}_a^1 = u_a, \mathfrak{d}_{[a}^2 \mathfrak{d}_{b]}^3 = \epsilon_{ab}, \mathfrak{d}_a^2 = \epsilon_a{}^b \mathfrak{d}_b^3, \tag{3.175}$$

which is related to the frame ϑ_a^μ adapted to $\mathcal{B}$ by a boost in the normal space $T^\perp(\partial\Sigma_t)$ to the boundary two-surface $\partial\Sigma_t$,

$$t^a = n^a \cosh\chi + u^a \sinh\chi, \quad s^a = u^a \cosh\chi + n^a \sinh\chi. \tag{3.176}$$

Through the corresponding boost relation (3.95) applied to the symplectic vectors (3.92) and (3.123), the Hamiltonian boundary terms take the respective form

$$\xi^c P_c^{\mathrm{D}}(\tilde{\vartheta}) = \xi^c (n^a \sigma_c{}^{d\,g} \nabla_d u_a - n_c \sigma^{bd\,g} \nabla_b u_d + u_c \sigma^{bd\,g} \nabla_b n_d - \sigma_c{}^{d\,g} \nabla_d \chi), \tag{3.177}$$

$$\xi^c P_c^{\mathrm{N}}(\tilde{\vartheta}) = \xi^c (n^{a\,g} \nabla_c u_a - {}^g\nabla_c \chi). \tag{3.178}$$

These expressions can be simplified in terms of the hypersurface metric q_{ab}, extrinsic curvature $\mathcal{K}_{ab}$, and acceleration $a_b = n^{e\,g} \nabla_e n_b$. We find that

$$\xi^c P_c^{\mathrm{D}}(\tilde{\vartheta}) = \mathcal{N}\kappa - \mathcal{N}^a u^b \mathcal{K}_{ab} - \mathcal{N}_\parallel^a \partial_a \chi, \tag{3.179}$$

$$\xi^c P_c^{\mathrm{N}}(\tilde{\vartheta}) = -\mathcal{N} u^b a_b - \mathcal{N}^a u^b \mathcal{K}_{ab} - \mathcal{N}\partial_t \chi - \mathcal{N}_\perp u^a \partial_a \chi - \mathcal{N}_\parallel^a \partial_a \chi, \tag{3.180}$$

where $\mathcal{N}_\parallel^a = \mathcal{P}_{\partial\Sigma}(\mathcal{N}^a)$, $\mathcal{N}_\perp = u_a \mathcal{N}^a$ are the tangential and normal parts of the shift with respect to $\partial\Sigma_t$, and $\kappa = \sigma^{ab\,g} \nabla_a u_b$ is the mean extrinsic curvature of $\partial\Sigma_t$ in Σ_t.

We note that this form of the Dirichlet and Neumann boundary terms (3.179) and (3.180) agrees with the canonical analysis of boundary terms for the ADM Hamiltonian carried out in Refs. 16 and 17. Moreover, in the case when Σ_t is orthogonal to $\mathcal{B}$, i.e., $\chi = 0$, the surface integral $\int_{\partial\Sigma} \xi^c P_c^{\mathrm{D}}(\tilde{\vartheta}) \mathrm{d}S$ for suitable choice of ξ^c reproduces Brown and York's expressions for quasilocal energy, normal momentum, and tangential momentum quantities (respectively, $\mathcal{N}=1$, $\mathcal{N}^a=0$; $\mathcal{N}=0$, $\mathcal{N}_\parallel^a=0$, $\mathcal{N}_\perp=1$; $\mathcal{N}=\mathcal{N}_\perp=0$, $\mathcal{N}_\parallel^a\neq 0$). Further discussion of quasilocal quantities associated with the Dirichlet and Neumann symplectic vectors (3.92) and (3.123) will be left for elsewhere.

IV. CONCLUDING REMARKS

In this paper we have given a mathematical investigation of boundary conditions on the gravitational field required for the existence of a well-defined covariant Hamiltonian variational principle for General Relativity when spatial boundaries are considered, with a fixed time-flow vector field. In particular, a main result is that we obtain a covariant derivation of Dirichlet, Neumann, and mixed type boundary conditions for the gravitational field in any fixed spatially bounded region of space–time. We show that the resulting Dirichlet and Neumann Hamiltonians lead to covariant Hamiltonian field equations which are equivalent to the standard $3+1$ split of the Einstein equations into constraint equations and time-evolution equations. In addition, we obtain a uniqueness result for the allowed boundary conditions based on the covariant symplectic structure associated with the Einstein equations.

However, we do not address the purely analytical issue of whether the boundary-initial value problem for the Einstein equations is well-posed with these boundary conditions (i.e., do there exist solutions of the Einstein equations satisfying the boundary conditions, initial conditions, and constraints). For work in that direction, see e.g. Ref. 20.

A further interesting generalization of our results would be to treat a space–time region whose spatial boundary is dynamical, e.g., a black-hole horizon or Cauchy boundary. We note that boundary conditions for this situation may be investigated by allowing the time-flow vector field to depend on the space–time metric instead of being a fixed quantity. This analysis will be pursued elsewhere.

APPENDIX: NOETHER CHARGE METHOD

First of all, consider in n space–time dimensions a general Lagrangian field theory for a set of fields denoted collectively by ϕ. It will be assumed that these fields are defined as sections of a vector bundle E over the space–time manifold M, using local coordinates on M and E. The theory

will be assumed to be described by a Lagrangian n-form $L(\phi)$ that is locally constructed out of the fields ϕ and their partial derivatives $\partial^k\phi$ to some finite order k (and fixed background structure, if any, on M and E).

The Lagrangian $L(\phi)$ provides a variational principle

$$S(\phi)=\int_M L(\phi), \tag{A1}$$

which yields the field equations $\mathcal{E}(\phi)=0$ obtained as the stationary points of $S(\phi)$,

$$\delta S(\phi)=\int_M \delta L(\phi)=\int_M \mathcal{E}(\phi)\,\delta\phi=0, \tag{A2}$$

under variations $\delta\phi$ of ϕ with compact support on M. For arbitrary variations $\delta\phi$, which are not restricted to have compact support, one then has a variational identity

$$L'(\phi,\delta\phi)\equiv\delta L(\phi)=\mathcal{E}(\phi)\,\delta\phi+d\Theta(\phi,\delta\phi), \tag{A3}$$

where $\Theta(\phi,\delta\phi)$ is an $(n-1)$-form, called the *symplectic potential*, derived through formal integration by parts. This yields a well-defined locally constructed formula for $\mathcal{E}(\phi)$ and $\Theta(\phi,\delta\phi)$ in terms of ϕ, $\delta\phi$, and their partial derivatives to a finite order. The symplectic potential is used to define the *presymplectic form* on a fixed hypersurface Σ,

$$\Omega_\Sigma(\phi,\delta_1\phi,\delta_2\phi)\equiv\int_\Sigma \omega(\phi,\delta_1\phi,\delta_2\phi) \tag{A4}$$

in terms of the *symplectic current* $(n-1)$-form ω given by

$$\omega(\phi,\delta_1\phi,\delta_2\phi)\equiv\delta_1\Theta(\phi,\delta_2\phi)-\delta_2\Theta(\phi,\delta_1\phi). \tag{A5}$$

The symplectic current satisfies $\mathrm{d}\omega(\phi,\delta_1\phi,\delta_2\phi)=\mathcal{E}'(\phi,\delta_2\phi)\,\delta_1\phi-\mathcal{E}'(\phi,\delta_1\phi)\,\delta_2\phi$ with $\mathcal{E}'(\phi,\delta\phi)\equiv\delta\mathcal{E}(\phi)$. Hence, $\omega(\phi,\delta_1\phi,\delta_2\phi)$ is closed for variations on solutions,

$$\mathrm{d}\omega(\Phi,\delta_1\Phi,\delta_2\Phi)=0, \tag{A6}$$

where Φ denotes ϕ restricted to satisfy $\mathcal{E}(\phi)=0$, and $\delta\Phi$ denotes $\delta\phi$ restricted to satisfy $\mathcal{E}'(\Phi,\delta\phi)=0$, i.e., $\delta\Phi$ is, formally, a tangent vector field on the space of solutions. Consequently, $\Omega_\Sigma(\phi,\delta_1\phi,\delta_2\phi)$ is unchanged by deformations of the spacelike surface Σ in any compact region of M.

In the previous constructions, a change of coordinates on M or E leaves $\mathcal{E}(\phi)$ unchanged,[21] while $\Theta(\phi,\delta\phi)$ changes in general by an exact locally constructed $(n-1)$-form $\mathrm{d}\nu(\phi,\delta\phi)$. However, one can show that[4] if the Lagrangian $L(\phi)$ is at most second order in partial derivatives $\partial^k\phi$ $(k\leqslant 2)$ of ϕ, then $\Theta(\phi,\delta\phi)$ is independent of the choice of coordinates on M and E and thus the presymplectic form $\Omega_\Sigma(\phi,\delta_1\phi,\delta_2\phi)$ is then coordinate invariant. Moreover, note that $L(\phi)$ can be freely changed by addition of a locally constructed exact form $\mathrm{d}\mu(\phi)$, without affecting the field equations $\mathcal{E}(\phi)$. This changes $\Theta(\phi,\delta\phi)$ by addition of a locally constructed $(n-1)$-form $\mathrm{d}\delta\mu(\phi)$, but leaves $\Omega_\Sigma(\phi,\delta_1\phi,\delta_2\phi)$ unchanged. Therefore, up to its dependence on Σ, the symplectic structure $\Omega_\Sigma(\phi,\delta_1\phi,\delta_2\phi)$ is uniquely determined by $\mathcal{E}(\phi)$ in this situation.

Now consider a complete, nowhere vanishing vector field ξ on M. It will be assumed that there exists a well-defined Lie derivative acting on ϕ associated with the diffeomorphism generated by ξ on M. Let Σ be a connected region contained in a fixed hypersurface in M with a closed boundary $\partial\Sigma$. (Note, if Σ is simply connected, $\partial\Sigma$ is a closed $n-2$-surface in M bounding Σ. If Σ is multiply connected, then $\partial\Sigma$ is a disjoint union of closed $n-2$-surfaces. Also, if Σ extends to "infinity," then $\partial\Sigma$ contains a corresponding "asymptotic boundary" $n-2$-surface.)

Definition A.1: A Hamiltonian conjugate to ξ *on* Σ *is a function* $H_\Sigma(\xi;\phi)=\int_\Sigma \mathcal{H}(\xi;\phi)$ *for some locally constructed* $(n-1)$*-form* $\mathcal{H}(\xi;\phi)$ *such that, on solutions* Φ,

$$H'_\Sigma(\xi;\Phi,\delta\phi)=\Omega_\Sigma(\Phi,\delta\phi,\mathcal{L}_\xi\Phi), \tag{A7}$$

where $\mathcal{L}_\xi$ *denotes the Lie derivative, and* $H'_\Sigma(\xi;\phi,\delta\phi)\equiv\delta H_\Sigma(\xi;\phi)$.

This is a covariant formulation of the standard Hamiltonian symplectic structure, with the ''time'' direction defined by ξ, called the *time flow* vector field. (In particular, Ref. 4 outlines a construction of a standard phase space and Hamiltonian equations of motion determined from this covariant structure.) Note that a Hamiltonian, if it exists, is automatically conserved along ξ for solutions Φ, i.e., $\mathcal{L}_\xi H_\Sigma(\xi;\Phi)=0$. It will now be shown that when ξ is a ''time symmetry'' of the Lagrangian $L(\phi)$, then a Hamiltonian conjugate to ξ exists and is simply given by the Noether charge associated to ξ.

Given any vector field ζ on M, consider the variation $\delta_\zeta\phi\equiv\mathcal{L}_\zeta\phi$. If this is a symmetry of the Lagrangian, so that

$$\delta_\zeta L(\phi)=L'(\phi,\mathcal{L}_\zeta\phi)=\mathrm{d}(i_\zeta L(\phi))=\mathcal{L}_\zeta L(\phi) \tag{A8}$$

by means of the identity $\mathcal{L}_\zeta L(\phi)=\mathrm{d}(i_\zeta L(\phi))$, then one can define a conserved *Noether current* $(n-1)$-form $J(\zeta;\phi)$ by

$$J(\zeta;\phi)=\Theta(\phi,\mathcal{L}_\zeta\phi)-i_\zeta L(\phi), \tag{A9}$$

where i_ζ is the interior product. Conservation of this current simply means that, on solutions Φ, $J(\zeta;\phi)$ is closed

$$\mathrm{d}J(\zeta;\Phi)=\mathrm{d}\Theta(\Phi,\mathcal{L}_\zeta\Phi)-\mathrm{d}(i_\zeta L(\Phi))=L'(\Phi,\delta\Phi)-\mathcal{L}_\zeta L(\Phi)=0 \tag{A10}$$

through the symmetry condition (A8). The integral of $J(\zeta;\Phi)$ over Σ defines the *Noether charge*

$$Q_\Sigma(\zeta)=\int_\Sigma J(\zeta;\Phi). \tag{A11}$$

One finds that the ''time'' derivative of this charge with respect to ξ is given by

$$\mathcal{L}_\xi Q_\Sigma(\zeta)=\int_\Sigma \mathcal{L}_\xi J(\zeta;\Phi)=\int_\Sigma i_\xi \mathrm{d}J(\zeta;\Phi)+\mathrm{d}(i_\xi J(\zeta;\Phi))=\oint_{\partial\Sigma} i_\xi J(\zeta;\Phi), \tag{A12}$$

where $i_\xi J(\zeta;\phi)$ is called the *flux* of the Noether current. Hence, if the flux vanishes on $\partial\Sigma$, then the charge is conserved for solutions Φ.

Examples of field theories which admit a symmetry $\delta_\zeta\phi=\mathcal{L}_\zeta\phi$ are (i) any generally covariant theory on a fixed, background space–time (M,g) with an isometry vector field ζ (i.e., $\mathcal{L}_\zeta g=0$), where $L(\phi)$ is purely a function of g, ϕ and its metric-covariant derivatives $\nabla\phi$; (ii) any diffeomorphism-covariant theory, whose field variables ϕ include the space–time metric g, where $L(\phi)$ is purely a function of ϕ, curvature tensor of g, and their metric-covariant derivatives.

For a diffeomorphism-covariant theory, $\delta_\zeta\phi$ is a symmetry for all vector fields ζ. Consequently, since $J(\zeta;\phi)$ is locally constructed out of ζ, one can show that in this case[4]

$$J(\zeta;\Phi)=\mathrm{d}Q(\zeta;\Phi) \tag{A13}$$

for some locally constructed $(n-2)$-form $Q(\zeta;\phi)$, called the *Noether current potential*. Then the Noether charge reduces to a surface integral

$$Q_\Sigma(\zeta)=\int_\Sigma J(\zeta;\phi)=\oint_{\partial\Sigma} Q(\zeta;\phi). \tag{A14}$$

In contrast, for a generally covariant theory, $J(\zeta;\Phi)$ is related to the conserved stress-energy tensor $T(\phi)$ defined by considering variations of g,

$$*\delta_g L(\phi) = -\tfrac{1}{2} T(\phi)\,\delta g + *\mathrm{d}\Theta(\phi,\delta g). \tag{A15}$$

One can show that,[9] on solutions Φ,

$$J(\zeta;\Phi) = *i_\zeta T(\Phi) + \mathrm{d}\tau(\zeta;\Phi) \tag{A16}$$

for some locally constructed $(n-2)$-form $\tau(\zeta;\phi)$.

Proposition A2: For any symmetry $\delta_\zeta\phi = \mathcal{L}_\zeta\phi$ admitted by a Lagrangian $L(\phi)$, the field equations and symplectic potential satisfy

$$\delta_\zeta \mathcal{E}(\phi) = \mathcal{L}_\zeta \mathcal{E}(\phi), \tag{A17}$$

$$\delta_\zeta\Theta(\phi,\delta\phi) = \mathcal{L}_\zeta\Theta(\phi,\delta\phi) + \mathrm{d}\psi(\zeta;\phi,\delta\phi), \tag{A18}$$

where $\psi(\zeta;\phi,\delta\phi)$ is some locally constructed $(n-2)$-form.

Proof: Consider an arbitrary variation of the Lagrangian symmetry condition (A8),

$$0 = \delta(\delta_\zeta L(\phi) - \mathcal{L}_\zeta L(\phi)) = \delta_\zeta \delta L(\phi) - \mathcal{L}_\zeta \delta L(\phi). \tag{A19}$$

From Eq. (A3), one has

$$\mathcal{L}_\zeta(\delta L(\phi)) = \mathcal{L}_\zeta(\mathcal{E}(\phi)\,\delta\phi) + \mathcal{L}_\zeta d\Theta(\phi,\delta\phi) = (\mathcal{L}_\zeta\mathcal{E}(\phi))\,\delta\phi + \mathcal{E}(\phi)\,\delta\mathcal{L}_\zeta\phi + d\mathcal{L}_\zeta\Theta(\phi,\delta\phi), \tag{A20}$$

and similarly

$$\delta_\zeta(\delta L(\phi)) = (\delta_\zeta\mathcal{E}(\phi))\,\delta\phi + \mathcal{E}(\phi)\,\delta\mathcal{L}_\zeta\phi + d\,\delta_\zeta\Theta(\phi,\delta\phi), \tag{A21}$$

since $\delta_\zeta\phi = \mathcal{L}_\zeta\phi$. Hence, Eq. (A19) yields

$$(\delta_\zeta\mathcal{E}(\phi) - \mathcal{L}_\zeta\mathcal{E}(\phi))\,\delta\phi = \mathrm{d}(\mathcal{L}_\zeta\Theta(\phi,\delta\phi) - \delta_\zeta\Theta(\phi,\delta\phi)) \tag{A22}$$

holding for all $\delta\phi$. By taking $\delta\phi$ to have compact support and integrating Eq. (A22) over M, one obtains $\int_M(\delta_\zeta\mathcal{E}(\phi) - \mathcal{L}_\zeta\mathcal{E}(\phi))\,\delta\phi = 0$, which immediately yields Eq. (A17). Then Eq. (A22) shows that $\mathcal{L}_\zeta\Theta(\phi,\delta\phi) - \delta_\zeta\Theta(\phi,\delta\phi)$ is a closed $(n-1)$-form holding for all ϕ. Since this expression is locally constructed in terms of ϕ, it follows that[21,22] Eq. (A18) holds. □

From these results, one finds that the variation of the Noether current is given by

$$\begin{aligned} J'(\zeta;\phi,\delta\phi) \equiv \delta J(\zeta;\phi) &= \delta\Theta(\phi,\mathcal{L}_\zeta\phi) - i_\zeta\delta L(\phi) \\ &= \omega(\phi,\delta\phi,\mathcal{L}_\zeta\phi) + \delta_\zeta\Theta(\phi,\delta\phi) - i_\zeta(\mathrm{d}\Theta(\phi,\delta\phi) + \mathcal{E}(\phi)\,\delta\phi) \\ &= \omega(\phi,\delta\phi,\mathcal{L}_\zeta\phi) - i_\zeta(\mathcal{E}(\phi)\,\delta\phi) + \mathrm{d}(i_\zeta\Theta(\phi,\delta\phi) + \psi(\zeta;\phi,\delta\phi)) \end{aligned} \tag{A23}$$

using the identity $i_\zeta(\mathrm{d}\Theta(\phi,\delta\phi)) = \mathcal{L}_\zeta\Theta(\phi,\delta\phi) - \mathrm{d}(i_\zeta\Theta(\phi,\delta\phi))$.

Lemma A.3: On solutions Φ,

$$\Omega_\Sigma(\Phi,\mathcal{L}_\zeta\Phi,\delta\phi) = -\int_\Sigma J'(\zeta;\Phi,\delta\phi) + \oint_{\partial\Sigma} i_\zeta\Theta(\Phi,\delta\phi) + \psi(\zeta;\Phi,\delta\phi). \tag{A24}$$

Thus, for variations $\delta\phi$ with compact support in the interior of Σ, i.e., $\delta\phi|_{\partial\Sigma} = 0$,

$$\Omega_\Sigma(\Phi, \mathcal{L}_\zeta \Phi, \delta\phi) = -\int_\Sigma J'(\zeta; \Phi, \delta\phi). \tag{A25}$$

One can then apply this result to the time flow vector field $\zeta = \xi$ to obtain a Hamiltonian.

Theorem A.4: *The Noether current $J(\xi;\phi)$ yields a Hamiltonian conjugate to ξ on Σ given by $H_\Sigma(\xi;\phi) = \int_\Sigma J(\xi;\phi)$ under compact support variations $\delta\phi$. For solutions Φ, $H_\Sigma(\xi;\Phi) = Q_\Sigma(\xi)$ is the conserved Noether charge associated with ξ.*

For variations $\delta\phi$ without compact support, there exists a Hamiltonian if and only if one can find a locally constructed $(n-2)$-form $B(\xi;\phi)$ such that

$$\oint_{\partial\Sigma} B'(\xi;\Phi,\delta\phi) - i_\xi \Theta(\Phi,\delta\phi) - \psi(\xi;\Phi,\delta\phi) = 0, \tag{A26}$$

where $B'(\xi;\phi,\delta\phi) \equiv \delta B(\xi;\phi)$. If one restricts to variations $\delta\phi = \delta\Phi$, then by considering a second variation and antisymmetrizing in this equation, one obtains the necessary condition

$$\oint_{\partial\Sigma} \delta_1(i_\xi \Theta(\Phi,\delta_2\Phi) + \psi(\xi;\Phi,\delta_2\Phi)) - \delta_2(i_\xi \Theta(\Phi,\delta_1\Phi) + \psi(\xi;\Phi,\delta_1\Phi)) = 0 \tag{A27}$$

for existence of $B(\xi;\phi)$. This condition can also be shown to be sufficient.[10]

Definition A.5: An allowed boundary condition on ϕ is a set of field components $\mathcal{F}(\phi)|_{\partial\Sigma}$ locally constructed from ϕ, partial derivatives $\partial^k\phi$, and space–time quantities associated with ξ, Σ, $\partial\Sigma$, such that for all variations $\delta\phi$ satisfying $\mathcal{F}'(\phi,\delta\phi)|_{\partial\Sigma} = 0$, where $\mathcal{F}'(\phi,\delta\phi) \equiv \delta\mathcal{F}(\phi)$, there exists a Hamiltonian $H_\Sigma(\xi;\phi)$ conjugate to ξ on Σ.

One now has the following main result.

Theorem A.6: *A Hamiltonian conjugate to ξ on Σ exists under variations $\delta\phi$ without compact support if and only if*

$$\oint_{\partial\Sigma} i_\xi \omega(\Phi,\delta_1\Phi,\delta_2\Phi) = \oint_{\partial\Sigma} \psi'(\xi;\Phi,\delta_1\Phi,\delta_2\Phi) \tag{A28}$$

on solutions Φ, where $\psi'(\xi;\phi,\delta_1\phi,\delta_2\phi) \equiv \delta_1\psi(\xi;\phi,\delta_2\psi) - \delta_2\psi(\xi;\phi,\delta_1\phi)$. This determines the allowed boundary conditions $\mathcal{F}(\phi)|_{\partial\Sigma}$ for the field equations to admit a covariant Hamiltonian formulation. Then the Hamiltonian is

$$H_\Sigma(\xi;\phi) = \int_\Sigma J(\xi;\phi) - \mathrm{d}B(\xi;\phi) \tag{A29}$$

with $B(\xi;\phi)$ given by Eq. (A26) up to an arbitrary function of the boundary data $\mathcal{F}(\phi)$ and ξ. Furthermore, under the allowed boundary conditions, the Hamiltonian and symplectic structure are independent of choice of Σ.

The surface integral $\oint_{\partial\Sigma} i_\xi \omega(\Phi,\delta_1\Phi,\delta_2\Phi)$ will be referred to as the *symplectic flux* through $\partial\Sigma$.

For a diffeomorphism-covariant theory, or a generally covariant theory on a background space–time, one can show that $\psi(\xi;\phi,\delta\phi) \equiv 0$. Hence the necessary and sufficient condition for existence of a Hamiltonian becomes

$$\oint_{\partial\Sigma} i_\xi \omega(\Phi,\delta_1\Phi,\delta_2\Phi) = 0 \tag{A30}$$

and, furthermore, from relation (A26) between $\Theta(\Phi,\delta\phi)$ and $B(\xi;\phi)$, it follows that one has

$$B(\xi;\phi)|_{\partial\Sigma} = (i_\xi \tilde{B}(\phi))|_{\partial\Sigma}, \tag{A31}$$

where $\tilde{B}(\phi)$ is a locally constructed $(n-1)$-form. Then on solutions Φ the Hamiltonian takes the following form: in the case of a diffeomorphism-covariant theory,

$$H_B(\xi;\Phi) = \oint_{\partial\Sigma} Q(\xi;\Phi) - i_\xi \tilde{B}(\Phi), \tag{A32}$$

which is a surface integral; and in the case of a generally covariant theory,

$$H(\xi;\Phi) + H_B(\xi;\Phi) = \int_\Sigma * i_\zeta T(\Phi) + \oint_{\partial\Sigma} \tau(\xi;\Phi) - i_\xi \tilde{B}(\Phi), \tag{A33}$$

where $H(\xi;\Phi) = \int_\Sigma * i_\zeta T(\Phi)$ is the canonical energy associated with Φ on Σ, and $H_B(\xi;\Phi)$ is the surface integral term.

To conclude, some further features of the Noether charge Hamiltonian will now be developed.

Definition A.7: The coefficient of an arbitrary compact support variation $\delta\phi|_\Sigma$ in the equation

$$\int_\Sigma \Omega_\Sigma(\phi, \delta\phi, \mathcal{L}_\xi\phi) - H'_\Sigma(\xi;\phi,\delta\phi) \equiv \int_\Sigma \mathcal{E}_H(\xi;\phi)\,\delta\phi = 0 \tag{A34}$$

yields the Hamiltonian field equations for ϕ, $\mathcal{E}_H(\xi;\phi) = 0$.

Theorem A.8: *The Hamiltonian field equations $\mathcal{E}_H(\xi;\phi) = 0$ are equivalent to the Lagrangian field equations $\mathcal{E}(\phi) = 0$.*

Proof: The Hamiltonian (A29) satisfies the variational identity

$$\Omega_\Sigma(\phi, \delta\phi, \mathcal{L}_\xi\phi) - H'_\Sigma(\xi;\phi,\delta\phi) = \int_\Sigma i_\xi(\mathcal{E}(\phi)\,\delta\phi) \tag{A35}$$

derived from Eqs. (A23) and (A26). Hence, for arbitrary compact support variations $\delta\phi|_\Sigma$, $\mathcal{E}(\phi) = 0$ holds if and only if ϕ satisfies $\mathcal{E}_H(\xi;\phi) = 0$. □

A field variation, denoted by $\delta\phi_\mathcal{N}$, is a *symplectic degeneracy direction* if $\Omega_\Sigma(\phi, \delta\phi, \delta\phi_\mathcal{N}) = 0$ holds for arbitrary compact support variations $\delta\phi$. Such degeneracies arise whenever the Lagrangian $L(\phi)$ admits a gauge symmetry (i.e., a symmetry $\delta_\chi\phi$ that is locally constructed from ϕ, partial derivatives $\partial^k\phi$, and that depends linearly on a set of parameters χ freely specifiable as functions on M). Note that the set $\{\delta\phi_\mathcal{N}\}$ of all degeneracy directions is a vector space. Then, a nondegeneracy direction, denoted by $\delta\phi_\mathcal{D}$, is represented as an equivalence class in the vector space of all field variations $\{\delta\phi\}$ quotiented by all symplectic degeneracy directions $\{\delta\phi_\mathcal{N}\}$, namely $\delta\phi_\mathcal{D} = \delta\phi/\delta\phi_\mathcal{N}$. This decomposition yields a break up of the Hamiltonian field equations (A34) into nondynamical constraint equations,

$$H'_\Sigma(\xi;\phi,\delta\phi_\mathcal{N}) = 0, \tag{A36}$$

and dynamical evolution equations,

$$H'_\Sigma(\xi;\phi,\delta\phi_\mathcal{D}) = \Omega_\Sigma(\phi, \delta\phi_\mathcal{D}, \mathcal{L}_\xi\phi), \tag{A37}$$

through arbitrary variations $\delta\phi_\mathcal{N}$, $\delta\phi_\mathcal{D}$ with compact support on Σ.

Since it assumed that the set $\{\phi\}$ of all fields has a linear (vector bundle) structure, the symplectic degeneracy directions $\delta\phi_\mathcal{N}$ can be identified with a corresponding set of field components, denoted $\phi_\mathcal{N}$, which will be called nondynamical with respect to Σ. Similarly, the nondegeneracy directions $\delta\phi_\mathcal{D}$ determine a set of equivalence classes of field components, denoted $\phi_\mathcal{D}$, which will be called dynamical with respect to Σ. (Note these components $\phi_\mathcal{D}$ and $\phi_\mathcal{N}$ are locally constructed from ϕ, partial derivatives $\partial^k\phi$, and space–time quantities associated with Σ.) Then,

from the Hamiltonian variational identity (A35), one can view the constraint equations (A36) and evolution equations (A37) as arising equivalently through the action principle (A1) by variations with respect to $\phi_{\mathcal{N}}$ and $\phi_{\mathcal{D}}$.

In summary, the Noether charge formalism presented here gives a covariant Hamiltonian formulation for Lagrangian field theories in the situation where the underlying time flow is given by a symmetry of the Lagrangian.

(Received 29 November 2001; accepted 10 June 2002)

We determine the maximum dimension of the Lie algebra of inheriting conformal Killing vectors in perfect fluid space–times. For the case of conformally flat space–times the maximum dimension is eight and for the case of nonconformally flat space–times the maximum dimension is found to be five. We illustrate each case with examples. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1509087]

I. INTRODUCTION

We are interested in space–times which admit conformal Killing vector fields and, in particular, fluid space–times which admit inheriting conformal Killing vector fields. A conformal Killing vector field is said to be an inheriting conformal Killing vector field if fluid flow lines **u** are mapped conformally by the conformal Killing vector field (see Sec. II and Coley and Tupper[1]). The motivation for studying inheriting conformal Killing vector fields was discussed in Ref. 1 and inheriting conformal Killing vector fields in perfect fluid space–times were studied in Refs. 2 and 3. For general space–times, from a kinematical description of matter it has been shown[4] that in order for there to be zero entropy production there must exist a conformal Killing vector field parallel to the fluid four-velocity (which is consequently inheriting).

In this article we determine the maximum dimension of the Lie algebra of inheriting conformal Killing vectors in perfect fluid space–times. For the case of conformally flat space–times the maximum dimension is eight and for the case of nonconformally flat space–times the maximum dimension is found to be five.

In Sec. II we define conformal Killing vector fields and state a number of theorems concerning the maximum dimension of Lie algebras of conformal Killing vector fields. We also address the reducibility of a Lie algebra of conformal Killing vector fields (to a Lie algebra of Killing vector fields) with respect to a conformal scaling of the metric. We consider some cases where the inheriting condition is automatically satisfied. In Sec. III we consider the maximum dimension of the inheriting Lie algebra for conformally flat space–times and present the space–times which admit this maximum number. In Sec. IV we determine the maximum dimension of the inheriting

Lie algebra for the nonconformally flat space–times. In Sec. V we discuss the results and outline possible future work.

II. CONFORMAL KILLING VECTORS AND INHERITANCE

Let M be a four-dimensional spacetime manifold with metric tensor $\mathbf{g}$ of Lorentz signature. Any vector field $\mathbf{X}$ which satisfies

$$\mathcal{L}_{\xi}\mathbf{g}=2\psi(x^{\alpha})\mathbf{g} \tag{1}$$

is said to be a *conformal Killing vector* (CKV) of $\mathbf{g}$. If ψ is not constant on M, then ξ is called a *proper conformal Killing vector*; if ψ is constant on M, then ξ is called a *homothetic Killing vector* (HKV); and if ψ is constant and $\psi\neq 0$ on M, then ξ is called *proper homothetic*. If $\psi_{;\alpha\beta}=0$, then ξ is called a *special conformal Killing vector* (SCKV), and if $\psi=0$, then ξ is said to be a Killing vector (KV).

The set of all CKV (respectively, HKV and KV) form a finite dimensional Lie algebra denoted by $\mathcal{C}$ (respectively, $\mathcal{H}$ and $\mathcal{G}$) whose maximum dimension is 15 (respectively, 11 and 10). If $\dim\mathcal{C}=15$, M is conformally flat. If the dimension of $\mathcal{G}$ is 10, then M is of constant curvature. If M is not of constant curvature, then this algebra has dimension at most 7. The algebra of HKV has dimension equal to or at most one greater than that of the KV algebra so that each given space–time admits a basis for $\mathcal{H}$ containing at most one HKV (i.e., all other HKV can be constructed by the addition of a KV). If the algebra $\mathcal{H}$ has its maximum dimension of 11, then M is flat. Any CKV field in a flat space–time is a SCKV and so the maximum dimension of the SCKV algebra is 15. If this occurs, M is flat, while if M is nonflat, its maximum dimension is 8. For details and proofs, see Ref. 5 and references therein (see Ref. 6 for a summary). It will be assumed throughout this article that the space–times considered admit no local (nonglobalizable) conformal Killing vector fields.

We would like to know the maximum dimension of $\mathcal{C}$ in the nonconformally flat case. First, we need to introduce the following terminology. A point $p\in M$ is called a *zero* (or a *fixed point*) of the CKV ξ if $\xi(p)=0$. A zero p of ξ is called *isometric* if $\psi(p)=0$ and *homothetic* if $\psi(p)\neq 0$.

The Petrov type of the Weyl tensor is a statement about the Weyl tensor at a point $p\in M$, and may vary from point to point. If the Petrov type is the same at all points of M, then one can speak of the Petrov type of M.

The following theorem is known,[7–10] but is collected together here for convenience.

Theorem 1: *Let (M,g) be a nonconformally flat space–time and let $\mathcal{C}$ be the conformal algebra of M. Then we have the following.*

(i) *If the Petrov type is N at some $p\in M$, $\dim\mathcal{C}\leqslant 7$.*
(ii) *If the Petrov type is D at some $p\in M$, $\dim\mathcal{C}\leqslant 6$.*
(iii) *If the Petrov type is III at some $p\in M$, $\dim\mathcal{C}\leqslant 5$.*
(iv) *If the Petrov type is I or II at some $p\in M$, $\dim\mathcal{C}\leqslant 4$.*

In fact it can be shown (using theorem 2 below) that part (iii) of theorem 1 may be strengthened by saying that if the Petrov type is III over some non-empty subset of M then $\dim\mathcal{C}(M)\leqslant 4$.

The following theorem is due to Hall and Steele[8] (see also Ref. 11).

Theorem 2: *Let (M,g) be a space–time that admits an r-dimensional conformal algebra $\mathcal{C}$ and suppose that the Petrov type and the dimension and nature of the orbits associated with $\mathcal{C}$ are the same at each $p\in M$ and that M admits no local (nonglobalizable) conformal vector fields. Then for each $p\in M$ there exists an open neighborhood U of p and a function $\sigma: U\mapsto\mathbf{R}$ such that $\mathcal{C}$ (restricted to U) is a Lie algebra of special conformal vector fields on U with respect to the metric $g'=e^{2\sigma}g$ on U. If the Petrov type is not O, the above local scaling function σ can always be chosen such that $\mathcal{C}$ restricts to a Lie algebra of homothetic Killing vector fields with respect to*

g' on U, and, if (M,g) is not locally conformally related to a generalized plane-wave space–time about any $p \in M$, the above local scaling can always be chosen such that $\mathcal{C}$ restricts to a Lie algebra of Killing vector fields with respect to g' on U.

See Ref. 8 for the definition of a *generalized plane wave*. Minkowski space–time admits 15 (special) CKV fields, (admitting a ten-dimensional subalgebra of KV fields) and it follows that the Lie algebra of CKVs of a conformally flat space–time can, in principle, be locally reduced to a corresponding set of special CKVs with a ten-dimensional subalgebra of KVs. For space–times conformal to the (nonconformally flat) pp-wave space–times, the Lie algebra of CKVs can be locally reduced to a Lie algebra of homotheties,[11] that is, if $\dim\mathcal{C}=7$, then $\mathcal{C}$ can be locally reduced to a seven-dimensional homothety Lie algebra (e.g., 6 KV and 1 HKV); if $\dim\mathcal{C}=6$, then $\mathcal{C}$ can be locally reduced to a six-dimensional homothety Lie algebra (e.g., 5 KV and 1 HKV); and if $\dim\mathcal{C}<6$, then $\mathcal{C}$ can be locally reduced to a Lie algebra of KVs.

The energy momentum tensor for a perfect fluid space–time is given by

$$T_{ab}=(\mu+p)u_a u_b+pg_{ab}, \tag{2}$$

where u^a is the normalized fluid four-velocity and μ and p are, respectively, the energy-density and the pressure. A CKV in a perfect fluid space–time is said to be inheriting if fluid flow lines $\mathbf{u}$ are mapped conformally by the CKV ξ, i.e.,

$$\mathcal{L}_\xi \mathbf{u}=-\psi\mathbf{u}. \tag{3}$$

We shall refer to such a CKV as an ICKV. For an HKV or proper CKV which is parallel to the fluid four-velocity vector $\mathbf{u}$, Eq. (3) is automatically true.[1]

We note that the set of ICKVs form a subalgebra $\mathcal{I}$ of the Lie algebra $\mathcal{C}$ and we refer to this as the inheriting algebra. This is proved in Sec. 3.7 of Ref. 12. Thus, the conditions required for a perfect fluid space–time to admit n independent ICKVs are as follows: there must exist n independent vector fields ξ_I, $I=1,\ldots,n$, which satisfy Eqs. (1) and (3). Therefore, in order to determine the maximum dimension of the Lie algebra of ICKV in a space–time, we can either consider the compatibility of these conditions generally or find the answer on a case by case basis.

III. CONFORMALLY FLAT SPACE–TIMES

In the conformally flat (CF) case, in which $\dim\mathcal{C}=15$, it has been shown that the maximum dimension of the inheriting algebra in a perfect fluid space–time is eight (see Sec. 6 in Ref. 13). Since the maximum dimension of the conformal algebra for any non-CF space–time is seven,[7,8] it follows that

$$\mathrm{MAX}(\dim\mathcal{I})=8.$$

In particular, it is known that the Friedmann–Robertson–Walker model with flat spatial geometry admits precisely eight ICKV.[1,2]

Recently, as part of an investigation into the general CKV admitted by CF perfect fluid space–times,[14] all such space–times admitting the maximum eight ICKV and also all admitting seven ICKV have been discovered. Here we present only the results with a brief indication of the calculation that led to the discovery of these space–times.

The CF perfect fluid space–times are all known[15] and fall into two classes, namely the nonexpanding $(\Theta=0)$ generalized Schwarzschild interior solution and the expanding $[\Theta=\Theta(t)\neq 0]$ generalized FRW solution. The space–time metric of each of these classes can be written in the form

$$ds^2=V^{-2}(-F^2dt^2+dx^2+dy^2+dz^2), \tag{4}$$

where $F(t,x,y,z)$ is of the form

$$F(t)=a(t)r^2+b(t)x+c(t)y+d(t)z+e(t), \tag{5}$$

a, b, c, d, e are arbitrary functions of t and $r^2=x^2+y^2+z^2$. For the nonexpanding models, V is given by

$$V=(1+r^2)C/2, \tag{6}$$

where C is a constant and F is of the particular form

$$F=-\tfrac{1}{2}(Cf_4+1)r^2+f_1x+f_2y+f_3z+\tfrac{1}{2}(Cf_4-1), \tag{7}$$

with f_1, f_2, f_3, f_4 arbitrary functions of t. For the expanding models, V is given by

$$V=Hr^2-2Hx_0x-2Hy_0y-2Hz_0z+V_0+Hr_0^2, \tag{8}$$

where H, x_0, y_0, z_0, V_0 are arbitrary functions of t, $r_0^2=x_0^2+y_0^2+z_0^2$ and F is given by

$$F=3\Theta^{-1}\frac{dV}{dt}. \tag{9}$$

In all cases the fluid four-velocity is comoving, i.e., $u^a=VF^{-1}\partial/\partial t$. However, since the condition (3) is conformally invariant, we may consider the ICKV of the underlying space–time

$$d\sigma^2=-F^2dt^2+dx^2+dy^2+dz^2 \tag{10}$$

with four-velocity $u'^a=F^{-1}\partial/\partial t$.

For the space–time (10) the ICKV equations for ξ^a imply that $\xi^0_{,\alpha}=\xi^\alpha_{,0}=0$ ($\alpha=1,2,3$) and lead to

$$\begin{aligned}
\xi^0&=G(t),\\
\xi^1&=\tfrac{1}{2}A(x^2-y^2-z^2)+Bxy+Cxz+Dx-My+Nz+Q,\\
\xi^2&=\tfrac{1}{2}B(-x^2+y^2-z^2)+Ayx+Cyz+Mx+Dy-Pz+R,\\
\xi^3&=\tfrac{1}{2}C(-x^2-y^2+z^2)+Azx+Bzy-Nx+Py+Dz+S,\\
\psi&=Ax+By+Cz+D,
\end{aligned} \tag{11}$$

where A, B, C, D, M, N, P, Q, R, S are constants, together with the set of equations

$$\begin{aligned}
\frac{d}{dt}(Ga)&=\frac{1}{2}(bA+cB+dC-2aD),\\
\frac{d}{dt}(Gb)&=eA+dN-cM-2aQ,\\
\frac{d}{dt}(Gc)&=eB-dP+bM-2aR,\\
\frac{d}{dt}(Gd)&=eC+cP-bN-2aS,\\
\frac{d}{dt}(Ge)&=eD-bQ-cR-dS.
\end{aligned} \tag{12}$$

A. Space–times admitting eight ICKV

To find those space–times admitting the maximum number of ICKV we must find those functions a, b, c, d, e, G which result in the maximum number of nonzero constants A, $B,\ldots,S$. This is found to occur only when $a=b=c=d=0$, $e\neq 0$ or when $b=c=d=e=0$, $a\neq 0$. However, when the appropriate conformal factor V^{-2} is restored, the second case results only in space–times which are coordinate transformed ($r\mapsto 1/r$) versions of those occuring in the first case, which is thus the only one we need to consider. A transformation of the coordinate t enables us to put $e=1$, so the underlying space–time (10) is Minkowski space–time with $u'^a=\partial/\partial t$. Using the notation of Maartens and Maharaj[16] the eight ICKV are then

$$P_a=\frac{\partial}{\partial x^a},\quad H=x^a\frac{\partial}{\partial x^a},\quad M_{\alpha\beta}=x_\alpha\frac{\partial}{\partial x^\beta}-x_\beta\frac{\partial}{\partial x^\alpha}, \tag{13}$$

where $a=0,1,2,3$ and $\alpha,\beta=1,2,3$. From expressions (8) and (9) the corresponding form of V for the expanding case is

$$V=\alpha r^2+\beta x+\gamma y+\delta z+f(t), \tag{14}$$

where α, β, γ, δ are arbitrary constants and $f(t)$ is an arbitrary function of t. Thus the expanding perfect fluid space–times admitting the maximum number of eight ICKV are all of the form

$$ds^2=[\alpha r^2+\beta x+\gamma y+\delta z+f(t)]^{-2}(-dt^2+dx^2+dy^2+dz^2), \tag{15}$$

and the corresponding nonexpanding space–times have V given by (6). There are three cases to consider:

1. Case (i) $\alpha\Theta\neq 0$

A translation of the origin of the form

$$x'=x+\frac{\beta}{2\alpha},\quad y'=y+\frac{\gamma}{2\alpha},\quad z'=z+\frac{\delta}{2\alpha}$$

transforms the metric into

$$ds^2=[f(t)+\alpha r^2]^{-2}(-dt^2+dx^2+dy^2+dz^2), \tag{16}$$

where we have dropped the primes and absorbed the constants into $f(t)$. This is the space–time $S1$ of Ref. 2 with $k=0$ which was shown to admit five proper ICKV, namely P_a and H, together with the three KV of spherical symmetry.

2. Case (ii) $\alpha=0$, $\Theta\neq 0$

A rotation of the spatial axes brings the metric into the form

$$ds^2=[f(t)+kx]^{-2}(-dt^2+dx^2+dy^2+dz^2), \tag{17}$$

where k is an arbitrary constant. This is the plane symmetric model listed under (a) with $k=0$ in Table 1 of in Ref. 3. In addition to the three KV of plane symmetry, this model admits five proper ICKV (a fact not recognized in Ref. 3—see the Appendix), namely P_0, P_1, H, M_{21}, M_{13}. The corresponding conformal scalars ψ are given by

$$(f+kx)\psi=-\frac{df}{dt},\quad -k,\quad f-t\frac{df}{dt},\quad -ky,\quad -kz, \tag{18}$$

respectively. The density of the model is $\mu=3[(df/dt)^2-k^2]$, so we must have $(df/dt)^2>k^2$.

3. Case (iii) $\Theta=0$

For the nonexpanding model, Eq. (6) leads to the metric

$$ds^2=4C^{-2}(1+r^2)^{-2}(-dt^2+dx^2+dy^2+dz^2), \tag{19}$$

i.e., Eq. (7) with $f_1=f_2=f_3=Cf_4+1=0$. This is a special case of the static Schwarzschild interior solution which is known[2] to admit four proper ICKV together with four KV.

The space–times with metrics (16), (17) and (19) are the only perfect fluid space–times admitting the maximum number of eight ICKV.

B. Space–times admitting seven ICKV

Perfect fluid models admitting seven ICKV are found to occur if and only if the functions a, b, c, d, e in Eq. (5) are constant multiples of each other so that, by a redefinition of the time coordinate, we may write the function F in the form

$$F=\alpha r^2+\beta x+\gamma y+\delta z+\epsilon, \tag{20}$$

where α, β, γ, δ, ϵ are constants. For the expanding models, from Eqs. (8) and (9), V is of the form

$$V=K(t)F+\lambda_1 r^2+\lambda_2 x+\lambda_3 y+\lambda_4 z+\lambda_5, \tag{21}$$

where $3dK/dt=\Theta$ and λ_1, λ_2, λ_3, λ_4, λ_5 are constants of integration. For the nonexpanding models V is given by (6). There are three cases to consider:

1. Case (i) $\alpha\Theta\neq 0$

A translation to a new origin, a rotation of the spatial axes and a rescaling of the time coordinate results in the spacetime metric

$$ds^2=[K(t)(1+\alpha r^2)+\omega r^2+\lambda x]^{-2}[-(1+\alpha r^2)^2dt^2+dx^2+dy^2+dz^2], \tag{22}$$

where ω, λ are constants. When $\lambda=0$ these solutions are the spherical symmetric $S1$ models of Ref. 2 with $k\neq 0$. If, in addition, $\omega=0$, these are the $k=\pm 1$ FRW models.

The ICKV of (22) and the corresponding conformal scalars are

$$\xi_{(1)}=\frac{\partial}{\partial t},\quad \psi_{(1)}=-(1+\alpha r^2)V^{-1}\frac{dK}{dt},$$

$$\xi_{(2)}=[\alpha(x^2-y^2-z^2)+1]\frac{\partial}{\partial x}+2\alpha xy\frac{\partial}{\partial y}+2\alpha zx\frac{\partial}{\partial z},\quad \psi_{(2)}=(2\alpha\omega r^2x+\lambda\alpha r^2-\lambda)V^{-1},$$

$$\xi_{(3)}=2\alpha xy\frac{\partial}{\partial x}+[\alpha(-x^2+y^2-z^2)+1]\frac{\partial}{\partial y}+2\alpha zy\frac{\partial}{\partial z},\quad \psi_{(3)}=2\alpha\omega r^2yV^{-1},$$

$$\xi_{(4)}=2\alpha xz\frac{\partial}{\partial x}+2\alpha yz\frac{\partial}{\partial y}+[\alpha(-x^2-y^2+z^2)+1]\frac{\partial}{\partial z},\quad \psi_{(4)}=2\alpha\omega r^2zV^{-1}, \tag{23}$$

$$\xi_{(5)}=-y\frac{\partial}{\partial x}+x\frac{\partial}{\partial y},\quad \psi_{(5)}=\lambda yV^{-1},$$

$$\xi_{(6)}=z\frac{\partial}{\partial x}-x\frac{\partial}{\partial z},\quad \psi_{(6)}=-\lambda zV^{-1},$$

$$\xi_{(7)}=-z\frac{\partial}{\partial y}+y\frac{\partial}{\partial z},\quad \psi_{(7)}=0.$$

No linear combination of $\xi_{(1)}$ to $\xi_{(6)}$ will result in a vanishing or constant conformal scalar, so this model admits six proper ICKV and one KV. Putting $\lambda=0$, we see that the $S1$ models admit four proper ICKV and three KV, as shown in Ref. 3, and putting $\lambda=\omega=0$, we see that the $k=\pm1$ FRW models admit one proper ICKV and six KV, as shown in Ref. 1.

2. Case (ii) $\alpha=0$, $\Theta\neq0$

A translation to a new spatial origin, a rotation of the spatial axes and a rescaling of the time coordinate results in the space–time metric

$$ds^2=[hr^2+L(t)x+m]^{-2}[-x^2dt^2+dx^2+dy^2+dz^2], \tag{24}$$

where h,m are constants and $L(t)$ is an arbitrary function of time. This space–time admits four proper ICKV, namely,

$$\xi_{(1)}=\frac{\partial}{\partial t},\quad \xi_{(2)}=\frac{\partial}{\partial y},\quad \xi_{(3)}=\frac{\partial}{\partial z},\quad \xi_{(4)}=x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}+z\frac{\partial}{\partial z}, \tag{25}$$

and three KV, namely,

$$\begin{aligned}\xi_{(5)}&=-z\frac{\partial}{\partial y}+y\frac{\partial}{\partial z},\\ \xi_{(6)}&=2hxy\frac{\partial}{\partial x}+[m+h(-x^2+y^2-z^2)]\frac{\partial}{\partial y}+2hzy\frac{\partial}{\partial z},\\ \xi_{(7)}&=2hxz\frac{\partial}{\partial x}+2hyz\frac{\partial}{\partial y}+[m+h(-x^2-y^2+z^2)]\frac{\partial}{\partial z}.\end{aligned} \tag{26}$$

When $h=0$, the space–time is plane symmetric and again admits four proper ICKV and three KV.

3. Case (iii) $\Theta=0$

For the nonexpanding model, using Eqs. (6) and (20) together with a rotation of the spatial axes and a rescaling of the time coordinate, we obtain

$$ds^2=4C^{-2}(1+r^2)^{-2}[-(\alpha r^2+\beta x+1)^2dt^2+dx^2+dy^2+dz^2]. \tag{27}$$

This space–time admits three proper ICKV, namely,

$$\begin{aligned}\xi_{(1)}&=[\alpha(x^2-y^2-z^2)+\beta x+1]\frac{\partial}{\partial x}+y(2\alpha x+\beta)\frac{\partial}{\partial y}+z(2\alpha x+\beta)\frac{\partial}{\partial z},\\ \xi_{(2)}&=2\alpha xy\frac{\partial}{\partial x}+[\alpha(-x^2+y^2-z^2)+1]\frac{\partial}{\partial y}+2\alpha yz\frac{\partial}{\partial z},\\ \xi_{(3)}&=2\alpha xz\frac{\partial}{\partial x}+2\alpha yz\frac{\partial}{\partial y}+[\alpha(-x^2-y^2+z^2)+1]\frac{\partial}{\partial z},\end{aligned} \tag{28}$$

and the four KV,

$$\begin{aligned}\xi_{(4)}&=\frac{\partial}{\partial t},\quad \xi_{(5)}=-z\frac{\partial}{\partial y}+y\frac{\partial}{\partial z},\\ \xi_{(6)}&=2y(1-\alpha+\beta x)\frac{\partial}{\partial x}+[\beta(1-x^2+y^2-z^2)+2(\alpha-1)]\frac{\partial}{\partial y}+2\beta yz\frac{\partial}{\partial z},\\ \xi_{(7)}&=2z(1-\alpha+\beta x)\frac{\partial}{\partial x}+2\beta yz\frac{\partial}{\partial y}+[\beta(1-x^2-y^2+z^2)+2(\alpha-1)]\frac{\partial}{\partial z}.\end{aligned} \tag{29}$$

When $\beta=0$, $\xi_{(4)}$ and $\xi_{(5)}$ are KV; the resulting metric is that of the general spherically symmetric Schwarzschild interior solution which is known[2] to admit three proper ICKV and four KV.

The space–times with metrics (22), (24) and (27) are the only CF perfect fluid space–times admitting precisely seven ICKV. Some, but not all, are known admitting precisely six ICKV; none of the known models admit six proper ICKV, thus, so far, the solution (22) is unique in this regard.

IV. NON-CONFORMALLY FLAT SPACE–TIMES

For the case of nonconformally flat space–times, Theorem 1 tells us that $\dim\mathcal{C}\leqslant 7$ and so $\dim\mathcal{I}\leqslant 7$. It is known that the Gödel space–time admits 5 ICKV: This is a perfect fluid homogeneous Petrov type *D* space–time with 5 KVs. Thus, we ask the question: Does there exist a perfect fluid space–time with $\dim\mathcal{I}=7$ or $\dim\mathcal{I}=6$? From Theorem 1, we only need to consider Petrov types *N* and *D*.

First, we give some notation. Let ξ be a CKV. From (1) it follows that $\xi_{a;b}=\psi g_{ab}+F_{ab}$. Now suppose $\xi\not\equiv 0$ but $\xi(p)=0$ for some $p\in M$. Then[9,17] we have the following:

Theorem 3: *(i) If $\psi(p)=0$ (isometric zero), the Petrov type at p is N, D or O. Also, if $F_{ab}(p)=0$, then the Petrov type at p is O. If the Petrov type at p is D, then $F_{ab}(p)\neq 0$ and is a linear combination of the bivectors $l_{[a}n_{b]}$ and $x_{[a}y_{b]}$ where l,n,x,y is a null tetrad ($l_an^a=x_ax^a=y_ay^a=1$, others zero) at p with l and n repeated principle null directions of the Weyl tensor at p. If the Petrov type at p is N, then $F_{ab}(p)\propto l_{[a}x_{b]}$ where l is the repeated principle null direction of the Weyl tensor at p and $l^ax_a=0$.*

(ii) If $\psi(p)\neq 0$ (homothetic zero), the Petrov type at p is III, N or O. If the Petrov type is III or N, $F_{ab}(p)\neq 0$ and timelike.

Corollary: If ξ is a CKV with $\xi\not\equiv 0$ and $\xi(p)=0$ and the Petrov type at p is not O, then $F_{ab}(p)\neq 0$.

Theorem 4: *If ξ is an ICKV and $\xi\not\equiv 0$ and $\xi(p)=0$, then, if u is the fluid flow velocity at p, $F_{ab}u^b=0$ at p (the fluid flow is assumed nowhere zero).*

Proof: Use $\mathcal{L}_\xi u\propto u$ at p and put $\xi(p)=0$.

□

Theorem 5: *If a perfect fluid space–time is not conformally flat, the dimension of the ICKV algebra is at most 5. If such a space–time admits a maximal ICKV algebra (of dimension 5), it must be of Petrov type D with $F_{ab}\propto x_{[a}y_{b]}$.*

Proof: Suppose this dimension is $\geqslant 6$. Then by taking linear combinations of members of the ICKV algebra one can arrange to have ξ, η as two (i.e., 6−4) independent ICKV such that

$$\xi_{a;b}=\psi g_{ab}+F_{ab},\quad \xi(p)=0,\quad \xi\neq 0,\quad \mathcal{L}_\xi u\propto u,\quad F_{ab}u^b=0,$$

$$\eta_{a;b}=\phi g_{ab}+G_{ab},\quad \eta(p)=0,\quad \eta\neq 0,\quad \mathcal{L}_\eta u\propto u,\quad G_{ab}u^b=0$$

hold at any $p\in M$. Also, by taking linear combinations of ξ and η, we can assume that at least one of ψ and ϕ vanishes at p.

Case (a): $\psi(p)=\phi(p)=0$ and $F_{ab}u^b=G_{ab}u^b=0$. Then from Theorem 3 (i) the (necessarily spacelike) blades of F_{ab} and G_{ab} at p must coincide. Hence $F_{ab}=\mu G_{ab}$ at p ($0\neq\mu\in\mathbf{R}$). Now construct $Z=\xi-\mu\eta$ which is not identically zero. Then Z is an ICKV and $Z_{a;b}=(\psi-\mu\phi)g_{ab}+(F_{ab}-\mu G_{ab})$ with $(\psi-\mu\phi)(p)=0$, $(F_{ab}-\mu G_{ab})(p)=0$ which contradicts nonconformal flatness by Theorem 3 (i).

Case (b): $\psi=0$, $\phi\neq 0$. $F_{ab}u^b=0$, $G_{ab}u^b=0$. Theorem 3 (ii) then shows that $G_{ab}(p)$ is nonzero and timelike (contradicting $G_{ab}u^b=0$ at p), i.e., timelike bivectors cannot have a timelike vector annihilating them.

The second assertion of the theorem follows immediately from this proof and Theorem 3, and is due to the fact that the relevant bivectors are necessarily spacelike.

□

Corollary: The maximum dimension of the ICKV algebra for Petrov type N and type III perfect fluid space–times is at most four.

These results also may be obtained by somewhat tedious direct calculations without recourse to the fixed point theorems of Ref. 17.

A. Examples of Petrov type *D* space–times with five ICKV

(a) The Gödel space–time

$$ds^2=a^2[-(dt+e^x dz)^2+dx^2+dy^2+\tfrac{1}{2}e^{2x}dz^2], \tag{30}$$

when considered as a perfect fluid space–time with zero cosmological constant, has energy density μ and pressure p given by $\mu=p=a^{-2}/2$. It admits five ICKV, all of which are KV.

(b) The plane symmetric Kasner type model

$$ds^2=-dt^2+dx^2+t(dy^2+dz^2) \tag{31}$$

admits four KV and one HKV given by

$$\mathbf{H}=t\frac{\partial}{\partial t}+x\frac{\partial}{\partial x}+\frac{y}{2}\frac{\partial}{\partial y}+\frac{z}{2}\frac{\partial}{\partial z}. \tag{32}$$

The four-velocity is comoving, $\mu=p=t^{-2}/4$.

The space–time with metric

$$d\sigma^2=\omega^{-2}ds^2, \tag{33}$$

where ds^2 is the metric (31) and

$$\omega=a(x^2-2t^2)+b, \tag{34}$$

a and b being nonzero constants, is also a perfect fluid space–time. In this case the KV

$$X=\frac{\partial}{\partial x}$$

becomes a proper ICKV with $\psi_X=-2ax/\omega$ and the HKV H given by (32) also becomes a proper ICKV with $\psi_H=-1+2b/\omega$.

(c) The static spherically symmetric model

$$ds^2=-r^{2m}dt^2+(1+2m-m^2)dr^2+r^2(d\theta^2+\sin^2\theta d\phi^2) \tag{35}$$

has $\mu=(1+2m-m^2)^{-1}m(2-m)r^{-2}$ and $p=m(2-m)^{-1}\mu$ and all energy conditions hold for $0<m\leqslant 1$. The space–time admits four KV and one HKV given by

$$\mathbf{H}=(1-m)t\frac{\partial}{\partial t}+r\frac{\partial}{\partial r}. \tag{36}$$

The space–time with metric

$$d\Sigma^2=U^{-2}ds^2, \tag{37}$$

where ds^2 is the metric (35) and $U=a+br^2$, a and b being positive constants, is also a perfect fluid space–time. The four KV of (35) remain as KV but the HKV given by (36) is now a proper ICKV with $\psi=(a-br^2)/(a+br^2)$.

(d) The static spherically symmetric space–time

$$ds^2 = \mathrm{sech}^2\left(\frac{r}{\sqrt{2}}\right)(-dt^2+dr^2+d\theta^2+\sin^2\theta d\phi^2) \tag{38}$$

satisfies the energy conditions. It admits the four KV associated with static spherical symmetry together with the proper ICKV

$$\mathbf{I} = \frac{\partial}{\partial r}.$$

V. DISCUSSION

The results of Secs. III and IV may be summarized in the following theorem:

Theorem 6: *For conformally flat perfect fluid space–times* $\dim\mathcal{I}$ *is at most eight and all such space–times are known. The maximum number of independent proper ICKV is six. For nonconformally flat perfect fluid space–times* $\dim\mathcal{I}$ *is at most five, in which case the space–time is of Petrov type D*.

The example given by (33) and (34) is the only known nonconformally flat perfect fluid solution admitting more than one independent proper ICKV.

It is also of interest to determine the maximum dimension of $\mathcal{I}$ for types *N*, *III*, *II* and *I* separately. From the analysis of Sec. IV we see that for each of those Petrov types $\dim\mathcal{I}\leqslant 4$. The determination of the exact maximum number in each case may require techniques other than the geometrical approach used here.

We would like to thank Michael Capocci and Chris Clarkson for useful discussions. This work was carried out while one of the authors (A.J.K.) was a postdoctoral fellow in the Department of Mathematics and Statistics, Dalhousie University, Halifax, Nova Scotia.

APPENDIX A: ERRATA TO COLEY AND CZAPOR[3]

The result in Sec. III that the plane symmetric CF model given by Eq. (17) admits eight ICKV contradicts Theorem 1 of Ref. 3 which states, in effect, that M_{21} and M_{13} cannot be ICKV (it can be easily checked that they are indeed ICKV). The proof of Theorem 1 in Ref. 3 is correct up to and including Eq. (2.24), but Eq. (2.25) is wrong. In fact, using Eqs. (2.23) and (2.24), Eq. (2.9) becomes (using the notation of Ref. 3)

$$w_x(w_t w_{xt}+w_x w_{tt}-w_{ttx})=0,$$

and, since $w_x\neq 0$, it follows that $w_t w_{xt}+w_x w_{tt}-w_{ttx}=0$; i.e.,

$$(w_t w_x - w_{tx})_x = 0.$$

But Eq. (2.23) states that

$$(w_t w_x - w_{tx})_t = 0,$$

so $w_t w_x - w_{tx} = \text{const}$, which does not contradict the later correct result $w_t w_x = w_{tx}$. [Note Eqs. (2.33a) and (2.33b) are wrong since they are derived from the incorrect Eq. (2.25).] Thus there is no contradiction and solutions do exist for which $\Lambda\neq 0$. Equation (2.37) is correct and substituting this into Eq. (2.9) leads to $w_x^2 w_{xx}+w_{xx}^2-w_x w_{xxx}=0$, and putting $e^{-w}=p(t)+s(x)$ we obtain $s_{xx}^2 = s_x s_{xxx}$. If $s_{xx}=0$, we obtain the solution (18), otherwise we obtain $s=\beta e^{\alpha x}$ which is the first solution in Table I of Ref. 3; i.e., the $k\neq 0$ case. Thus this also admits the "exceptional" ICKV

(using the terminology of Ref. 2) but admits only seven ICKV (4 proper ICKV and 3 KV). Thus the plane symmetric case admits models with the ''exceptional'' ICKV corresponding to those in the spherically symmetric case.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 11 NOVEMBER 2002

Wavefronts, caustic sheets, and caustic surfing in gravitational lensing

Simonetta Frittelli
Department of Physics, Duquesne University, Pittsburgh, Pennsylvania 15282

(Received 1 July 2000; accepted 31 July 2002)

Very little attention has been paid to the properties of optical wavefronts and caustic surfaces due to gravitational lensing. Yet the wavefront-based point of view is natural and provides insights into the nature of the caustic surfaces on a gravitationally lensed lightcone. We derive analytically the basic equations governing the wavefronts, lightcones, caustics on wavefronts, and caustic surfaces on lightcones in the context of weak-field, thin-screen gravitational lensing. These equations are all related to the potential of the lens. In the process, we also show that the standard single-plane gravitational lensing map extends to a new mapping, which we call a wavefront lensing map. Unlike the standard lensing map, the Jacobian matrix of a wavefront lensing map is not symmetric. Our formulas are then applied to caustic ''surfing.'' By surfing a caustic surface, a space–borne telescope can be fixed on a gravitationally lensed source to obtain an observation of the source at very high magnification over an extended time period, revealing structure about the source that could not otherwise be resolved. Using our analytical expressions for caustic sheets, we present a scheme for surfing a caustic sheet of a lensed source in rectilinear motion. Detailed illustrations are also presented of the possible types of wavefronts and caustic sheets due to nonsingular and singular elliptical potentials, and singular isothermal spheres, including an example of caustic surfing for a singular elliptical potential lens. © *2002 American Institute of Physics.*

I. INTRODUCTION

Among relativistic concepts of direct application to gravitational lensing, the observer's past lightcone is perhaps the most fundamental. The lightcone concept unifies the temporal and spatial properties of lensing events in a geometrical manner that makes the multiplicity, magnification, and time delay of the images arise naturally. In this view, gravitational lensing by dark and luminous matter causes the observer's past lightcone to curve into a singular three-dimensional hypersurface that self-intersects and folds sharply. It is the singular ''folding'' of the lightcone that is responsible for most features of interest in gravitational lensing, such as image multiplicity, magnification, and time delay. Additionally, in this view, caustics—so relevant to observational lensing—literally acquire a new dimension, turning into caustic sheets (possibly multiple) contained within the lightcone itself, and carrying a sense of time as well as spatial location. The lightcone concept is most naturally built by imagining an optical wavefront emanating from an observer and traveling out and towards the past or future. At the start, the wavefront is convex and almost perfectly spherical. Upon encountering gravitational lenses, the wavefront becomes nonuniformly retarded, acquiring dents. No matter how small and insignificant these dents in the wavefront are soon after leaving the neighborhood of the lens, in time the normal propagation enhances them, inevitably developing crossings and sharp ridges. The surface traced out in space–time by a wavefront is a (past or future) lightcone. The trace of the wavefront's sharp ridges and

''swallowtail'' points is called a ''comoving caustic surface'' if thought of as embedded in three-space, and a ''caustic surface'' if viewed in space–time. In other words, a caustic surface is built out of caustic sheets with cusp ridges and higher-order singularities (e.g., swallowtails, elliptic umbilics, and hyperbolic umbilics). Remarkably, in spite of the naturalness of this concept, very little attention has been paid to the greater significance of the caustics as sheets or surfaces. As a result, to our knowledge, the properties of optical wavefronts and caustic surfaces in gravitational lensing have not progressed much beyond the generic local classification of caustic singularities of the general theory as developed by Thom, Arnold, and others. Our goal is to initiate a program that investigates optical wavefronts and caustics as they relate to the matter distribution of the gravitational lenses in the space–time.

The vast majority of gravitational lenses can be modeled extremely well using a small-angle approximation of weak-field perturbations of a Friedmann–Lemaître universe, and projecting the deflectors into planes (thin-screen approximation)—see the monographs by Schneider, Ehlers, and Falco[1] and Petters, Levine, and Wambsganss[2] for a detailed treatment. An enormous advantage of weak-field, thin-screen gravitational lensing is that we can obtain explicit analytical expressions for the associated lightcones, optical wavefronts, and caustics on both the wavefronts and lightcones. Indeed, one of the reasons there has been limited progress in the study of quantitative properties of the optical caustic surfaces and wavefronts due to gravitating matter is the lack of computable physical models with observational relevance. Thin-screen, weak-field gravitational lensing provides us with such a setting.

Gravitational lensing from a wavefront perspective was used by Refsdal[3] to relate the Hubble constant to the time delay between lensed images (see Ref. 3, Kayser and Refsdal[4,5] for more). Arnold's singularity theory was used by Petters[6] to treat the local qualitative properties of caustic surfaces (big caustics) in gravitational lensing. Friedrich and Stewart,[7] Stewart,[8] Hasse, Kriele, and Perlick,[9] Low,[10] and Ehlers and Newman[11] also used Arnold's theory to treat wavefronts and caustics in general relativity with varied motivations. In the case of a strong gravitational field, Rauch and Blandford[12] numerically computed the caustic sheets due to the Kerr metric. Wavefronts in the context of liquid droplet lenses have been studied extensively by Berry, Hannay, Nye, Upstill, and others—see Berry and Upstill,[13] Nye,[14] and references therein. Readers may also benefit from the popular article by Nityananda[15] on wavefronts in gravitational lensing.

Our paper calculates explicitly the equations governing the wavefronts and caustic surfaces in gravitational lensing with the standard approximations, and analytically relates the wavefronts and caustic surfaces to the gravitational potential of the lens. This allows us to give a first quantitative treatment of *caustic surfing*, a futuristic notion suggested by Blandford[16] in his millennium essay. The motivation for caustic surfing is to lock a satellite on a gravitationally lensed moving source so as to observe the source at a high magnification over an extended time period. We derive the starting equations for the trajectory to be followed in order to surf the caustic surface. The appeal of caustic surfing lies in its potential as a tool to obtain information about a distant moving source that could not otherwise be resolved.

Our paper is organized as follows. Section II derives an explicit expression for the present optical path length in units of time of light signals that reach the observer in the thin-screen approximation. In Sec. III this expression is used to define a new lensing map in which the sources lie on an instantaneous wavefront, rather than on a lens plane. The caustic surfaces and sheets are related to the wavefront lensing map in Sec. IV. Section V develops some fundamentals of the concept of caustic surfing. Applications to the case of nonsingular and singular elliptical potential models, as well as singular isothermal spheres, are given in Sec. VI. The latter section also gives full classifications of the singularities of the wavefronts and caustic surfaces of the noted lenses, and explicitly illustrates the caustic surfing concept. We conclude in Sec. VII with some remarks and an outlook of future applications. The research reported in this paper extends preliminary results on wavefronts in gravitational lensing first reported by Frittelli and Petters[17] at the Ninth Marcel Grossmann Meeting.

II. THE PRESENT PROPER LENGTH FUNCTION AND LENS EQUATION

We shall calculate the present optical length of gravitationally lensed light rays from a source to the observer using Fermat's principle and coordinates in space. This will include a formula (lensing map) relating the position of a lensed source to the impact positions at the gravitational lens of lensed light rays from the source to observer. For the convenience of readers who are new to gravitational lensing, Secs. II A and II B 1 give an introduction overviewing those aspects of lensing relevant to our wavefront and caustic surface considerations. Readers already familiar with the basics of gravitational lensing can skip to Sec. II B 2, where we cast the lens equation in comoving form.

A. Cosmological model for lensing

We use the usual cosmological setting of gravitational lensing, namely, a weak-field perturbation of a Friedmann–Lemaître space–time. These models are quite robust and fit extremely well with observations. A detailed treatment of the assumptions and approximations used to model most gravitational lensing scenarios is given in Chap. 3 of Ref. 2.

The space–time geometry in the vicinity of a weak-field gravitational lens system [i.e., source, lens(es), observer, and light rays between source and observer] is approximated by the following space–time metric:

$$\mathbf{g}^{\mathsf{K}}_{\mathrm{GL}} = -\left(1+2\frac{\phi}{c^2}\right)c^2\,d\tau^2 + a^2(\tau)\left(1-2\frac{\phi}{c^2}\right)dS^2_{\mathsf{K}} = a^2(\mathsf{t})\left[-\left(1+2\frac{\phi}{c^2}\right)d\mathsf{t}^2 + \left(1-2\frac{\phi}{c^2}\right)dS^2_{\mathsf{K}}\right]. \tag{1}$$

The quantity τ is cosmic time, t is conformal time related to τ by

$$d\mathsf{t} = \frac{c}{a(\tau)}\,d\tau, \tag{2}$$

with $a(\tau)$ a positive function called the *expansion factor* and we use the notation $a(\mathsf{t}) = a(\tau(\mathsf{t}))$. Also ϕ represents the time-independent Newtonian potential of the density perturbation due to the lens(es), and dS^2_{K} the metric of space with constant curvature $\mathsf{K} = -1,0,1$. The weak-field limit is assumed (i.e., $|\phi|/c^2 \ll 1$), so we ignore terms of order greater than ϕ/c^2. Note that the potential ϕ obeys the cosmological Poisson equation—see Sec. II B 2. The weak-field assumption near a gravitational lens ensures that the bending angles $\hat{\alpha}$ of light rays deflected by the lens are small, i.e., $\hat{\alpha} \ll 1$. In addition to the latter assumption, we suppose that the lens is ''thin.'' This means that along the line of sight, the diameter of the matter distribution of the lens or source is very small compared to the distances between lens and observer, and between lens and source. We shall treat the gravitational lens and the point sources as lying on planes—called the *lens plane* and *light source plane*—approximately orthogonal to an axis defined by the observer and some central point on the lens—referred to as the optical axis. All these assumptions allow us to consistently restrict lensing to small observation angles as measured from the optical axis.

Now consider the gravitational lensing metric $\mathbf{g}^{\mathsf{K}}_{\mathrm{GL}}$ in (1). There are coordinates (R,θ,φ) in space, called *comoving coordinates*, such that the Riemannian metric dS^2_{K} becomes

$$dS^2_{\mathsf{K}} = \frac{dR^2}{1-\mathsf{K}R^2} + R^2(d\theta^2 + \sin^2\theta\, d\varphi^2). \tag{3}$$

We assume that the comoving coordinates are dimensionless, the expansion factor $a(\tau)$ has physical dimensions of length, and the potential ϕ has physical dimensions of $[\text{length}]^2/[\text{time}]^2$. The cosmic time τ has dimension of time, while the conformal time t is dimensionless. Away from the neighborhood of the lens, the gravitational lensing metric $\mathbf{g}^{\mathsf{K}}_{\mathrm{GL}}$ is approximated by the Friedmann–Lemaître (FL) metric

$$\mathbf{g}_{\mathrm{FL}}^{\mathsf{K}} = -c^2\, d\tau^2 + a^2(\tau) dS_{\mathsf{K}}^2 = a^2(\mathrm{t})[-d\mathrm{t}^2 + dS_{\mathsf{K}}^2].$$

This employs the assumption that the Newtonian potential ϕ decreases to zero sufficiently fast away from the lens with the lens-source and observer-lens angular diameter distances sufficiently large. In a realistic physical sense, the Newtonian potential of an isolated body decays no faster than r^{-1}. Some plausible ways to justify the use of this metric as intended are discussed in Ref. 18 and references therein. Still, it is not at all clear how to improve on this assumption rigorously. Indeed, there are some unresolved technical mathematical issues with the standard approximations in gravitational lensing, but it is not our intention to address them here.

In this work we will restrict our discussion to a flat cosmological setting. *Henceforth, we shall assume that the gravitational lensing metric* $\mathbf{g}_{\mathrm{GL}}^{\mathsf{K}}$ has $\mathsf{K}=0$. The associated FL metric then reduces to the Einstein–de Sitter metric

$$\mathbf{g}_{\mathrm{Ed}} \equiv \mathbf{g}_{\mathrm{FL}}^{0} = a^2(\mathrm{t}) ds_{\mathrm{flat}}^2, \tag{4}$$

where

$$ds_{\mathrm{flat}}^2 = -d\mathrm{t}^2 + dS_0^2, \quad dS_0^2 = dR^2 + R^2(d\theta^2 + \sin^2\theta\, d\varphi^2) \tag{5}$$

with $0 \leqslant R < \infty$, $0 \leqslant \theta < \pi$, $0 \leqslant \varphi < 2\pi$. Note that for $\mathsf{K}=0$ the comoving coordinates (R,θ,φ) define spherical coordinates in space. The conformal relationship (4) yields that the Minkowski metric ds_{flat}^2 is very important for our study, because $\mathbf{g}_{\mathrm{Ed}}$ and ds_{flat}^2 have the same null geodesics up to an affine parameter. The topology of our space–time with a gravitational lens now takes the form $I \times E$, where I is an open interval of $\mathbf{R}$ and E an open subset of $\mathbf{R}^3$. In most applications of gravitational lensing, we have $E = \mathbf{R}^3 - A$, where A is a finite set of points corresponding to singularities (e.g., point masses) in the lens. These singularities would include points where the density perturbation of the lens or the Newtonian potential ϕ diverge. This yields a lens plane L that is $\mathbf{R}^2$ minus a finite set of points. We call E the *comoving space* and $\tau \times E$ the *proper three-space* at cosmic time τ. Away from the lens, the metrics on E and $\tau \times E$ are the standard Euclidean metric dS_0^2 and metric $a^2(\tau) dS_0^2$, respectively. When we study the caustic surfaces along our past lightcone, we project them into E.

B. The present proper length function and the comoving lens equation

1. Physical setting for present proper length of light rays

We must discuss the basic physical setting needed to determine the present optical length of light rays via Fermat's principle (see pp. 65–76 of Ref. 2 for a detailed treatment). Suppose that a light signal emanates from a source at cosmic time τ_S and arrives at the observer at the present cosmic time τ_0. Assume that the observer is at the origin $\mathbf{0}$ of the spherical coordinate system (R,θ,φ) in the comoving space S and the source at comoving position $p_S = (R_S, \theta_S, \varphi_S)$. Assume that the light ray undergoes deflection by a gravitational lens on some intermediate lens plane L. Since the deflection angle at the lens plane is assumed small, we approximate the light ray's trajectory by an FL piecewise-smooth null geodesic consisting of an FL null geodesic from the source to L and one from L to the observer. Fix an optical axis through an arbitrary comoving point p_L on L (e.g., center of mass of the lens); say, $p_L = (R_L, \theta_L, \varphi_L)$ with (R, θ_L, φ_L) defining the optical axis. Take p_L to be the origin of L. We now consider the set $\mathcal{N}$ of all piecewise-smooth null FL geodesics that left the source at cosmic time τ_S and arrive at the observer at roughly the present cosmic time τ_0 after undergoing deflection at L. The travel time differences between these null rays are assumed to be significantly smaller than the Hubble time $(1/H_0)$ and so the scale factor is assumed to change negligibly during these time differences. In particular, the scale factor is taken to be approximately $a(\tau_0)$ when the different rays arrive. Fixing τ_S and τ_0, the set $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ of null rays can be parametrized by their comoving impact vectors $\mathbf{r}$ on L (relative to the origin of L). The rays in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ will be denoted by $\nu_{\mathbf{r}}$.

But not all the rays in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ represent actual light rays. By Fermat's principle (e.g., pp. 66–67, Ref. 2), the actual physical light rays (within our approximations) are given by the rays in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ whose present proper lengths are stationary with respect to variations of the comoving impact vector $\mathbf{r}$. To characterize the light rays, we first determine a formula for the present proper lengths of the rays in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$. Our space–time with

$$\mathbf{g}_{\mathrm{GL}} \equiv \mathbf{g}_{\mathrm{GL}}^0 = a^2(\mathrm{t})\left[-\left(1+2\frac{\phi}{c^2}\right) d\mathrm{t}^2 + \left(1-2\frac{\phi}{c^2}\right) dS_0^2 \right] \tag{6}$$

can be viewed as an Einstein–de Sitter universe with a medium having the following time-independent refractive index (e.g., p. 54, Ref. 2):

$$n = 1 - \frac{2}{c^2}\phi. \tag{7}$$

Along a null ray $\nu_{\mathbf{r}}(s) = (\tau(s), \hat{\nu}_{\mathbf{r}}(s))$ in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$, where s is a parameter along the ray and $\hat{\nu}_{\mathbf{r}}(s)$ is the spatial path of $\nu_{\mathbf{r}}$ in E, Eq. (6) shows that

$$n(\nu_{\mathbf{r}}(s)) = 1 - \frac{2}{c^2}\phi(\hat{\nu}_{\mathbf{r}}(s)) = \left|\frac{d\mathrm{t}}{d\ell}\right|, \tag{8}$$

where the dimensionless incremental length $d\ell$ along $\hat{\nu}_{\mathbf{r}}(s)$ is relative to the Euclidean metric dS_0^2. The rightmost equality in Eq. (8) uses the assumption that $|\phi|/c^2 \ll 1$ and terms of order higher than ϕ/c^2 are ignored.

The present proper length $L_{\tau_0}(\nu_{\mathbf{r}})$ of a ray $\nu_{\mathbf{r}}$ in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ is then the ray's optical length relative to the refractive medium in the hypersurface $\tau_0 \times E$. In other words,

$$L_{\tau_0}(\nu_{\mathbf{r}}) = \int_{\hat{\nu}_{\mathbf{r}}} n(\hat{\nu}_{\mathbf{r}})\, d\ell_{\tau_0}.$$

Here the increment of length $d\ell_{\tau_0}$ is with respect to the spatial metric $a_0^2\, dS_0^2$ on $\tau_0 \times E$, where

$$a_0 \equiv a(\mathrm{t}(\tau_0)).$$

Note that $d\ell_{\tau_0} = a_0\, d\ell$. Using (7), the present proper length of $\nu_{\mathbf{r}}$ in units of time is

$$\mathcal{T}(\nu_{\mathbf{r}}) = \frac{L_{\tau_0}(\nu_{\mathbf{r}})}{c} = \frac{a_0}{c}\int_{\hat{\nu}_{\mathbf{r}}} \left(1 - \frac{2}{c^2}\phi(\hat{\nu}_{\mathbf{r}})\right) d\ell. \tag{9}$$

Henceforth, we shall refer to $\mathcal{T}$ simply as a present proper length function and assume that its values are in units of time.

By Fermat's principle, the light rays are characterized by those rays in $\nu_{\mathbf{r}}$ for which $\mathcal{T}(\nu_{\mathbf{r}})$ is a stationary value of $\mathcal{T}$. In the next section, we shall obtain an explicit formula that determines these stationary values.

2. Present proper length function and lens equation via comoving coordinates

We shall now provide a practical expression of the present proper length (in units of time) in terms of rectangular coordinates in the comoving space E of our lensing space–time $(I \times E, \mathbf{g}_{\mathrm{GL}})$. First, let's transform the dimensionless spherical coordinates (R, θ, φ) to dimensionless rectangular coordinates (x, y, z) such that the observer is at (0,0,0) and the optical axis (R, θ_L, φ_L) corresponds to the z axis. The lens plane L is the xy plane located at z_l along the positive z axis.

We shall relabel the rectangular coordinates on L as $(\mathbf{r},z_l)$, where $\mathbf{r}=(r_1,r_2)$ and $z_l>0$ is fixed. The source is assumed to be located at $(\mathbf{s},z)$, where $\mathbf{s}=(s_1,s_2)$. When $z>z_l$, the source is behind the lens (and so is gravitationally lensed).

The cosmological Poisson equation at the present cosmic time $\tau=\tau_0$ is

$$\nabla_{\mathsf{x}}^2\phi(\mathsf{x})=4\pi G a_0^2\rho(\mathsf{x}), \tag{10}$$

where $\mathsf{x}=(x,y,z)$, ∇_{x}^2 is the Laplace operator relative to x, G is the gravitational constant, and ρ is the cosmological volume mass density. Here ρ has units of $[\text{mass}]/[\text{length}]^3$. Set

$$\tilde{\rho}\equiv a_0^3\rho, \quad \tilde{\phi}\equiv a_0\phi.$$

Since (10) is solved by

$$\phi(\mathsf{x})=-a_0^2G\int_{\mathbf{R}^3}\rho(\mathsf{x}')\frac{d\mathsf{x}'}{|\mathsf{x}-\mathsf{x}'|},$$

we have

$$\tilde{\phi}(\mathsf{x})=-G\int_{\mathbf{R}^3}\tilde{\rho}(\mathsf{x}')\frac{d\mathsf{x}'}{|\mathsf{x}-\mathsf{x}'|},$$

which has units of $[\text{length}]^3/[\text{time}]^2$. Integrating (10) along the optical axis from the source to the observer, we obtain the cosmological 2D–Poisson equation:

$$\nabla_{\mathbf{r}}^2\Psi(\mathbf{r})=\frac{8\pi G a_0^2}{c^2}\sigma(\mathbf{r}), \tag{11}$$

where

$$\Psi(\mathbf{r})\equiv\frac{2}{c^2}\int_z^0\phi(\mathbf{r},z')a_0\,dz', \quad \sigma(\mathbf{r})\equiv\int_z^0\rho(\mathbf{r},z')a_0\,dz'.$$

Note that $\Psi(\mathbf{r})$ has units of length, while $\sigma(\mathbf{r})$ has units of $[\text{mass}]/[\text{length}]^2$. Let

$$\tilde{\Psi}(\mathbf{r})=\frac{2}{c^2}\int_z^0\tilde{\phi}(\mathbf{r},z')dz', \quad \tilde{\sigma}(\mathbf{r})=\int_z^0\tilde{\rho}(\mathbf{r},z')dz'.$$

It follows that $\tilde{\Psi}=\Psi$ and $\tilde{\sigma}=a_0^2\sigma$. Equation (11) then yields the comoving 2D–Poisson equation

$$\nabla_{\mathbf{r}}^2\tilde{\Psi}(\mathbf{r})=\frac{8\pi G}{c^2}\tilde{\sigma}(\mathbf{r}), \tag{12}$$

where $\tilde{\Psi}$ and $\tilde{\sigma}$ have units of length and mass, respectively. The function $\tilde{\Psi}$ can be expressed formally as a solution of (12) by

$$\tilde{\Psi}(\mathbf{r})=\frac{4G}{c^2}\int_{\mathbf{R}^2}d\mathbf{r}'\,\tilde{\sigma}(\mathbf{r}')\ln\left|\frac{\mathbf{r}'-\mathbf{r}}{\xi_0}\right|,$$

where ξ_0 is an arbitrary, dimensionless, fixed constant.

Equation (9) yields that the present proper length of a null ray $\nu_{\mathbf{r}}$ in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ separates into two terms

$$\mathcal{T}(\nu_{\mathbf{r}}) = \frac{a_0}{c}[L(\hat{\nu}_{\mathbf{r}}) - \hat{\Psi}(\mathbf{r})], \tag{13}$$

where

$$L(\hat{\nu}_{\mathbf{r}}) \equiv \int_{\hat{\nu}_{\mathbf{r}}} d\ell, \quad \hat{\Psi}(\mathbf{r}) \equiv \frac{2}{c^2}\int_{\hat{\nu}_{\mathbf{r}}} \phi(\hat{\nu}_{\mathbf{r}})\, d\ell$$

with $L(\hat{\nu}_{\mathbf{r}})$ the (dimensionless) Euclidean length of $\hat{\nu}_{\mathbf{r}}$. Since bending angles are assumed small, we approximate the line integral of ϕ over $\hat{\nu}_{\mathbf{r}}$ by an integral along the optical axis, i.e.,

$$\hat{\Psi}(\mathbf{r}) = \frac{2}{c^2}\int_z^0 \phi(\mathbf{r}, z')\, dz' = \frac{\tilde{\Psi}(\mathbf{r})}{a_0}.$$

Note that the scaled comoving potential $\hat{\Psi}(\mathbf{r})$ is dimensionless.

The contribution of the term $a_0 L(\hat{\nu}_{\mathbf{r}})/c$ to Eq. (13) is the time due to the present proper length of the light's geometric path relative to the Euclidean metric, while the term $a_0\hat{\Psi}(\mathbf{r})/c$ contributes the relativistic time dilation (Shapiro time delay) due to the gravitational potential ϕ of the lens. We have

$$L(\hat{\nu}_{\mathbf{r}}) = \ell_l + \ell_{ls}, \tag{14}$$

where ℓ_l is the Euclidean length of the segment of $\hat{\nu}_{\mathbf{r}}$ consisting of the straight line from comoving impact vector $\mathbf{r}$ to the observer and ℓ_{ls} the Euclidean length of the straight-line segment from the source to $\mathbf{r}$. Expressing the null ray $\nu_{\mathbf{r}}$ parametrically as $\nu_{\mathbf{r}}(s) = (\tau(s), \hat{\nu}_{\mathbf{r}}(s))$, we obtain

$$0 = \mathbf{g}_{\mathrm{Ed}}\left(\frac{d\hat{\nu}_{\mathbf{r}}}{ds}, \frac{d\hat{\nu}_{\mathbf{r}}}{ds}\right) = -c^2\left(\frac{d\tau}{ds}\right)^2 + a^2(\tau)\left|\frac{d\hat{\nu}_{\mathbf{r}}}{ds}\right|^2,$$

where the squared magnitude of the comoving velocity $d\hat{\nu}_{\mathbf{r}}/ds$ is relative to dS_0^2. This implies

$$\ell_l = \int_{s_L}^{s_0} \left|\frac{d\hat{\nu}_{\mathbf{r}}}{ds}\right| ds = \int_{\tau_L}^{\tau_0} \frac{c}{a(\tau)}\frac{d\tau}{ds}\, ds = \int_{\mathrm{t}_L}^{\mathrm{t}_0} d\mathrm{t} = \mathrm{t}_0 - \mathrm{t}_L,$$

where τ_L is the cosmic time when $\nu_{\mathbf{r}}$ arrives at the lens plane, s_0 and s_L are the respective parameter values corresponding to τ_0 and τ_L, and $\mathrm{t}_0 = \mathrm{t}(\tau_0)$, $\mathrm{t}_L = \mathrm{t}(\tau_L)$. Similarly,

$$\ell_{ls} = \mathrm{t}_L - \mathrm{t}_S,$$

where $\mathrm{t}_S = \mathrm{t}(\tau_S)$ with τ_S the cosmic time when $\nu_{\mathbf{r}}$ left the source. Hence, the present proper length function $\mathcal{T}(\nu_{\mathbf{r}})$ can be expressed in terms of conformal time as

$$\mathcal{T}(\nu_{\mathbf{r}}) = \frac{a_0}{c}[(\mathrm{t}_0 - \mathrm{t}_S) - \hat{\Psi}(\mathbf{r})]. \tag{15}$$

We now express the present proper length function in terms of our comoving rectangular coordinates. In the approximation of small angles, we have

$$\begin{aligned} \ell_l &= \sqrt{z_l^2 + |\mathbf{r}|^2} = z_l + \frac{|\mathbf{r}|^2}{2z_l}, \\ \ell_{ls} &= \sqrt{(z - z_l)^2 + |\mathbf{r} - \mathbf{s}|^2} = z - z_l + \frac{|\mathbf{r} - \mathbf{s}|^2}{2(z - z_l)}. \end{aligned} \tag{16}$$

By (14) and (16), the present proper length of the null ray $\nu_{\mathbf{r}}$ becomes

$$\mathcal{T}(\mathbf{r},\mathbf{s},z)\equiv\mathcal{T}(\nu_{\mathbf{r}})=\frac{a_0}{c^2}\mathsf{T}(\mathbf{r},\mathbf{s},z), \tag{17}$$

where

$$\mathsf{T}(\mathbf{r},\mathbf{s},z)\equiv z+\frac{|\mathbf{r}|^2}{2z_l}+\frac{|\mathbf{r}-\mathbf{s}|^2}{2(z-z_l)}-\hat{\Psi}(\mathbf{r}). \tag{18}$$

Equation (15) implies that the function $\mathsf{t}(\mathbf{r},\mathbf{s},z)$ is the conformal time of the null ray $\nu_{\mathbf{r}}$. Fixing $\mathbf{s}$ and z, Fermat's principle yields that the light rays from source to observer are determined by those null rays in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ with comoving impact vectors $\mathbf{r}$ satisfying

$$\mathrm{grad}_{\mathbf{r}}\,\mathcal{T}(\mathbf{r},\mathbf{s},z)=\mathbf{0}. \tag{19}$$

where $\mathrm{grad}_{\mathbf{r}}$ is the gradient operator in rectangular coordinates $\mathbf{r}$. By (17) and (18), Eq. (19) is equivalent to

$$\mathbf{s}=\frac{z}{z_l}\mathbf{r}-(z-z_l)\hat{\boldsymbol{\alpha}}(\mathbf{r})\equiv\mathbf{s}(\mathbf{r},z), \tag{20}$$

where $\hat{\boldsymbol{\alpha}}(\mathbf{r})\equiv_{\mathbf{r}}\hat{\Psi}(\mathbf{r})$ is the change in direction through which the light signal $\nu_{\mathbf{r}}$ bends at the lens plane, and its magnitude is referred to as the (*comoving*) *bending angle*. Equation (20) is called the (*comoving*) *lens equation*. It determines the comoving impact vectors $\mathbf{r}$ of the light rays from $\mathbf{s}$ to the observer.

For fixed z, Eq. (20) defines a map

$$\mathbf{s}_z:L\to S:\mathbf{s}_z(\mathbf{r})=\mathbf{s}(\mathbf{r},z),$$

called a *(comoving) standard lensing map* from the lens plane L to the *light source plane* S (i.e., the xy plane at position z on the optical axis), and carries no sense of time. This is the comoving version of the cosmological lensing map commonly used in gravitational lensing—see (28). Note that the Jacobian matrix of $\mathbf{s}_z$ is symmetric:

$$(\mathrm{Jac}\,\mathbf{s}_z)(\mathbf{r})=\frac{z}{z_l}\mathbf{I}-(z-z_l)[\mathrm{Hess}_{\mathbf{r}}\hat{\Psi}](\mathbf{r}). \tag{21}$$

Here $\mathbf{I}$ is the 2×2 identity matrix and $\mathrm{Hess}_{\mathbf{r}}\hat{\Psi}$ is the Hessian matrix of $\hat{\Psi}$ relative to $\mathbf{r}=(r_1,r_2)$.

The present proper length of each light ray in $\mathcal{N}_{\tau_S}^{\tau_0}(\mathbf{r})$ depends on the comoving position $\mathbf{s}$ of the source on the source plane. Inserting (20) in (18), we obtain an expression for the present proper length

$$\mathcal{T}(\mathbf{r},z)\equiv\frac{a_0}{c}\mathsf{T}(\mathbf{r},z), \tag{22}$$

where

$$\mathsf{T}(\mathbf{r},z)\equiv\mathsf{T}(\mathbf{r},\mathbf{s}(\mathbf{r},z),z)=z+\frac{1}{2}\left[z\frac{|\mathbf{r}|^2}{z_l^2}+(z-z_l)\left(|\hat{\boldsymbol{\alpha}}(\mathbf{r})|^2-2\frac{\mathbf{r}\cdot\hat{\boldsymbol{\alpha}}(\mathbf{r})}{z_l}\right)\right]-\hat{\Psi}(\mathbf{r}) \tag{23}$$

with $\mathbf{s}(\mathbf{r},z)$ given by (20). *The function $\mathcal{T}(\mathbf{r},z)$ has the convenient property that the source coordinate z appears linearly*. We will take advantage of this fact later in this work.

Notice that though Eqs. (18), (20), and (22) are stated for $z>z_l$, they actually hold for all z if we assume that $\hat{\Psi}(\mathbf{r})\equiv 0$ when $-\infty<z\leqslant z_l$. For example, if $z=0$, then $\mathcal{T}(\mathbf{r},0)=0$. If a light ray starts out from a source at position $(\mathbf{s},z)$ in E with $z_l\leqslant z<\infty$, then $\mathbf{r}$ is the light ray's comoving impact vector on the lens plane L at position z_l. For $0<z<z_l$, the vector $\mathbf{r}$ is the comoving position on L of the light ray's spatial path when extended backward from $(\mathbf{s},z)$ to L. If $-\infty<z<0$, then $\mathbf{r}$ is the ray's impact position on L when the light ray is extended forward from $(\mathbf{s},z)$ to the observer to L. Since the case that is of interest to us is when the wavefront has passed through the lens, *we shall assume, unless stated to the contrary, that* $z\geqslant z_l$.

3. Present proper length function via angular diameter distances, redshifts, and proper vectors

In the majority of the gravitational lensing literature, the comoving coordinates of the preceding sections have not been exploited. In order to make a connection with standard gravitational lensing, we now show that the present proper length function $\mathcal{T}(\mathbf{r},\mathbf{s},z)$ in (17), which uses comoving coordinates, can be expressed in terms of the FL angular diameter distances, redshifts, and proper impact vectors commonly used in gravitational lensing.

Equations (13) and (14) yield

$$\mathcal{T}(\mathbf{r},\mathbf{s},z)=\frac{a_0}{c}[(\ell_l+\ell_{ls}-\ell_s)-\hat{\Psi}(\mathbf{r})]+\frac{a_0\ell_s}{c}. \tag{24}$$

Since $a_0\equiv a(\mathsf{t}(\tau_0))=a(\tau_0)=(1+\mathsf{z}_S)a(\tau_S)$ and the FL angular diameter distance from observer to source is $d_S=a(\tau_S)\ell_s$ for $\mathsf{K}=0$, we get

$$\frac{a_0\ell_s}{c}=\frac{1+\mathsf{z}_S}{c}d_S. \tag{25}$$

The first term on the right-hand side of (24) is the time delay of $\nu_{\mathbf{r}}$ relative to the FL light ray from the source to observer in the absence of the lens. Using the formula for the time delay (e.g., p. 74 of Ref. 2 and p. 146, Ref. 1), we obtain

$$\mathcal{T}(\mathbf{r},\mathbf{s},z)=\frac{1+\mathsf{z}_L}{c}\frac{d_L d_S}{d_{L,S}}\left[\frac{1}{2}\left|\frac{\mathsf{r}}{d_L}-\frac{\mathsf{s}}{d_S}\right|^2-\frac{d_{L,S}}{d_L d_S}\Psi(\mathsf{r})\right]+\frac{1+\mathsf{z}_S}{c}d_S\equiv\mathcal{T}(\mathsf{r},\mathsf{s},d_S), \tag{26}$$

where z_L is the redshift of the lens; d_L is the FL angular diameter distance from observer to lens and $d_{L,S}$ the angular diameter distance from lens to source; $\mathsf{r}=a(\tau_L)\mathbf{r}$ is the proper impact vector of the ray at the lens plane at approximately cosmic time τ_L and $\mathsf{s}=a(\tau_S)\mathbf{s}$ is the proper vector of the source relative to the optical axis at cosmic time τ_S; and $\Psi_L(\mathsf{r})\equiv a_L\hat{\Psi}(\mathbf{r})$ with $a_L=a(\mathsf{t}(\tau_L))$. Note that Ψ_L has units of length and is the two-dimensional cosmological potential at cosmic time $\tau=\tau_L$. Fixing s and d_S, Fermat's principle yields that light rays are determined by $\mathrm{grad}_{\mathsf{r}}\mathcal{T}(\mathsf{r},\mathsf{s},d_S)=\mathbf{0}$. Equation (26) now shows that the latter is equivalent to the usual (cosmological) lens equation:

$$\mathsf{s}=\frac{d_S}{d_L}\mathsf{r}-d_{L,S}\,\mathsf{r}\,\Psi(\mathsf{r}). \tag{27}$$

This induces the standard *cosmological lensing map* in the gravitational lensing literature (e.g., Ref. 2, p. 77):

$$\boldsymbol{\eta}:\mathsf{L}\to\mathsf{S}:\boldsymbol{\eta}(\mathsf{r})=\frac{d_S}{d_L}\mathsf{r}-d_{L,S}\,\mathrm{grad}_{\mathsf{r}}\Psi(\mathsf{r}), \tag{28}$$

where $\mathsf{L}=\{a(\tau_L)\mathbf{r}:\mathbf{r}\in L\}$ and $\mathsf{S}=\{a(\tau_S)\mathbf{s}:\mathbf{r}\in S\}$ are the cosmological lens plane and light source planes, respectively.

III. LIGHTCONES, WAVEFRONTS, AND WAVEFRONT LENSING MAPS

Consider a gravitational lensing situation with an observer receiving light from sources beyond the lens plane where deflectors are located. Even though each light source emits perhaps in all directions, generating their own lightcones, the observer receives only those rays that belong to his past lightcone. Consequently, we shall study the observer's past lightcone, rather than a source's future lightcone. We are also interested in constant-time sections of the observer's past lightcone, which we refer to as wavefronts. In this section, we shall determine parametric equations for the past lightcone and for the wavefronts generating the lightcone.

A. Lensed lightcones

The observer's past lightcone $\mathcal{L}^-$ in the space–time $(I\times E,\mathbf{g}_{\mathrm{GL}})$ is the subset of $I\times E$ consisting of all past-pointing light rays originating from the observer at $(\tau_0,0,0,0)$. Equivalently, the lightcone $\mathcal{L}^-$ is the set of all space–time events in $(I\times E,\mathbf{g}_{\mathrm{GL}})$ from which a light ray arrives at the observer at cosmic time τ_0. To obtain a formula for the points in $\mathcal{L}^-$, consider a light ray $\nu_{\mathbf{r}}$ starting out at event $(\tau_S,\mathbf{s}_s,z_s)$, where z_s may be positive or negative, and arriving at the observer at $(\tau_0,0,0,0)$. Here $\mathbf{r}$ is the light ray's comoving impact position on the lens plane L at z_l, resulting possibly from extending the ray backwards or forwards to L—see discussion at end of Sec. II B 2. Then the (comoving) lens equations (20) and present proper length equation (22), show that $\nu_{\mathbf{r}}$ can be expressed as follows with z as parameter:

$$\nu_{\mathbf{r}}(z)=(\tau_0-\mathcal{T}(\mathbf{r},z),\mathbf{s}(\mathbf{r},z),z), \tag{29}$$

where z varies from z_s to 0, $\mathcal{T}(\mathbf{r},0)=0$, and $\mathbf{s}(\mathbf{r},z_s)=\mathbf{s}_s$. Alternatively, Eq. (29) holds for a light ray from the observer to $(\tau_S,\mathbf{s}_s,z_s)$ by varying z from 0 to z_s. Hence, by allowing z and $\mathbf{r}$ to vary, we obtain the following expression for the observer's past lightcone:

$$\mathcal{L}^-=\{(\tau_0-\mathcal{T}(\mathbf{r},z),\ \mathbf{s}(\mathbf{r},z),\ z):z\in\mathbf{R},\mathbf{r}\in L\}. \tag{30}$$

The set $\mathcal{L}^-$ is a three-dimensional hypersurface in the space–time $(I\times S,\mathbf{g}_{\mathrm{GL}})$ and typically has singularities due to distortions caused by the lens. In Sec. IV, we shall give equations that characterize these singularities. Notice that in the conformally equivalent space–time $(I\times S,\mathbf{g}_{\mathsf{GL}})$, where

$$\mathbf{g}_{\mathsf{GL}}\equiv\frac{\mathbf{g}_{\mathrm{GL}}}{a^2(\mathrm{t})}=-\left(1+2\frac{\phi}{c^2}\right)d\mathrm{t}^2+\left(1-2\frac{\phi}{c^2}\right)dS_0^2,$$

the observer's past lightcone becomes

$$\mathsf{L}^-=\{(\mathsf{T}_0-\mathsf{T}(\mathbf{r},z),\mathbf{s}(\mathbf{r},z),\ z):\ z\in\mathbf{R},\mathbf{r}\in L\}, \tag{31}$$

where $\mathsf{T}_0=c\tau_0/a_0$. The observer's future lightcone $\mathcal{L}^+$ and conformal future lightcone L^+ are given, respectively, as follows:

$$\mathcal{L}^+=\{(\tau_0+\mathcal{T}(\mathbf{r},z),\mathbf{s}(\mathbf{r},z),\ z):\ z\in\mathbf{R},\mathbf{r}\in L\},$$

$$\mathsf{L}^+=\{(\mathsf{T}_0+\mathsf{T}(\mathbf{r},z),\ \mathbf{s}(\mathbf{r},z),\ z):\ z\in\mathbf{R},\mathbf{r}\in L\}.$$

B. Lensed wavefronts and wavefront lensing maps

With fixed z, we saw that Eq. (20) defines a lensing map from the lens plane to the light source plane at z. There is an alternative interpretation of the lensing map stemming from the lightcone point of view. We can consider (20) and (22) jointly with the condition of fixed conformal travel time, instead of fixed z.

We define a *comoving (optical) wavefront* in E as a surface of constant conformal present proper length $\mathsf{T}(\mathbf{r},z)$. One should keep in mind that conformal time flows at a rate different from that of cosmological time—see Eq. (2). However, the surfaces of constant conformal time T are the same as those of constant present proper length $\mathcal{T}$; they are only labeled differently—see (22). Since we are not particularly interested in the specific labels of the wavefronts, which are not observable, we prefer to use the conformal time

$$T \equiv \mathsf{T}(\mathbf{r},z)$$

to describe the wavefronts. We shall refer to T as a conformal present proper length function.

Due to the linearity of (23) in the variable z, we obtain a parametric expression in terms of $(\mathbf{r},T)$ for all the z coordinates of the comoving wavefront by solving for z:

$$z(\mathbf{r},T) = \frac{T - \mathbf{r}\cdot\hat{\boldsymbol{\alpha}}(\mathbf{r}) + \dfrac{z_l}{2}|\hat{\boldsymbol{\alpha}}(\mathbf{r})|^2 + \hat{\Psi}(\mathbf{r})}{1 + \dfrac{|\mathbf{r}|^2}{2z_l^2} + \dfrac{|\hat{\boldsymbol{\alpha}}(\mathbf{r})|^2}{2} - \dfrac{\mathbf{r}\cdot\hat{\boldsymbol{\alpha}}(\mathbf{r})}{z_l}}. \tag{32}$$

The values of $z(\mathbf{r},T)$ are assumed to obey $z(\mathbf{r},T) \geqslant z_l$. In other words, we are interested primarily in the lensed portion of the front, i.e., the portion of the front with z values on the optical axis from the lens plane onward. Note that if we allow $z(\mathbf{r},T) < z_l$, then it is assumed that $\hat{\Psi}(\mathbf{r}) \equiv 0$ in (32)—see the end of Sec. II B 2.

Equation (32) can now be used in (20) to obtain an expression for the points of the wavefront that are on the xy plane at position $z(\mathbf{r},T)$:

$$\mathbf{s}(\mathbf{r},T) \equiv \mathbf{s}(\mathbf{r},z(\mathbf{r},T)) = z(\mathbf{r},T)\left(\frac{\mathbf{r}}{z_l} - \hat{\boldsymbol{\alpha}}(\mathbf{r})\right) + z_l\hat{\boldsymbol{\alpha}}(\mathbf{r}). \tag{33}$$

In other words, the pair $(\mathbf{s},z)$ determined by (33) and (32) defines a chart (possibly with singularities) on the portion of the wavefront that went through the lens plane. Of course, the pair can also be used as a chart for the portion of the front behind the lens plane [e.g., by setting $\hat{\Psi}(\mathbf{r}) \equiv 0$]. The *comoving wavefront* at conformal time T is then given by

$$\mathcal{W}(T) \equiv \{(\mathbf{s}(\mathbf{r},T), z(\mathbf{r},T)) : \mathbf{r} \in L\} \subseteq E, \tag{34}$$

which is a two-dimensional surface that generically has singularities due to lensing. Notice that if we allow $-\infty < z < \infty$ and $0 \leqslant T \leqslant T_0$, then $\mathcal{W}(T)$ traces out the conformal light cone L^- in (31).

For the cosmological present proper length

$$t \equiv \mathcal{T}(\mathbf{r},z),$$

the wavefront is given in the space–time $(I\times E, \mathbf{g}_{\mathrm{GL}})$ at cosmic time τ_0 by

$$\mathcal{W}_0(t) \equiv \{(\tau_0 - t, \mathbf{s}(\mathbf{r},t), z(\mathbf{r},t)) : \mathbf{r} \in L\} \subseteq I\times E,$$

where $\mathbf{s}(\mathbf{r},t) \equiv \mathbf{s}(\mathbf{r},T(t))$ and $z(\mathbf{r},t) \equiv z(\mathbf{r},T(t))$ with $T(t) = ct/a_0$. Equation (30) shows that $\mathcal{W}_0(t)$ is a subset of the past lightcone $\mathcal{L}^-$. The wavefront $\mathcal{W}_0(t)$ is the set of positions of all sources whose light rays left at the same cosmic time $\tau_0 - t$ and arrive at the observer at roughly the present cosmic time τ_0. Most observed lensed light sources are at distances ranging from of

order tens of kiloparsecs (e.g., microlensing) to gigaparsecs (e.g., quasar lensing). The observation time is typically of order weeks to a few years. Consequently, we expect the wavefront $\mathcal{W}_0(t)$ to change negligibly during the observing time, unless the front happens to pass through a higher order singularity during the observation.

The wavefront $\mathcal{W}_0(t)$ lies in the proper space $\{\tau_0-t\}\times E$. Projecting the front into the comoving space, we obtain

$$\mathcal{W}_0^E(t)\equiv\{(\mathbf{s}(\mathbf{r},t),z(\mathbf{r},t)):\mathbf{r}\in L\}\subseteq E,$$

which is a constant cosmic time slice of $\mathcal{L}^-$ (namely, $\tau_0-t=$constant). The wavefront $\mathcal{W}_0^E(t)$ differs from $\mathcal{W}(T)$ in E merely by the label $T=ct/a_0$. The two wavefronts are isometric as singular spaces in the comoving space with the Euclidean metric.

Now for fixed T, the lens Eq. (20) determines a mapping

$$\mathbf{w}_T:L\to\mathcal{W}(T)\subseteq\mathbf{R}^3,$$

called a *comoving wavefront lensing map*, defined by

$$\mathbf{w}_T(\mathbf{r})=(\mathbf{s}(\mathbf{r},T),z(\mathbf{r},T)).$$

By allowing for z values with $z(\mathbf{r},T)<z_l$, the map $\mathbf{w}_T$ can be separated into two single-valued maps

$$\mathbf{w}_T(\mathbf{r})=\begin{cases}\mathbf{w}_T^+(\mathbf{r}) & \text{if } z(\mathbf{r},T)\geqslant z_l,\\ \mathbf{w}_T^-(\mathbf{r}) & \text{if } z(\mathbf{r},T)<z_l\end{cases},$$

where $\mathbf{w}_T^+:L\to\mathcal{W}^+(T)$ and $\mathbf{w}_T^-:L\to\mathcal{W}^-(T)$ with $\mathcal{W}^+(T)$ the subset of $\mathcal{W}(T)$ for which $z\geqslant z_l$, while $\mathcal{W}^-(T)$ is the subset with $z<z_l$. In other words, the map $\mathbf{w}_T$ defines two (possibly singular) coordinate patches on $\mathcal{W}(T)$. Since $\mathcal{W}^-(T)$ did not pass through the lens, it has no singularities and so the map $\mathbf{w}_T^-$ is of little interest for our purposes. Instead, we shall focus primarily on $\mathbf{w}_T$. *Unless stated to the contrary, we shall assume that* $\mathbf{w}_T(\mathbf{r})=\mathbf{w}_T^+(\mathbf{r})$.

It is important to emphasize that rather than the usual mapping from a lens plane to the light source plane (such as given by the comoving and cosmological lensing maps $\mathbf{s}_z:L\to S$ and $\boldsymbol{\eta}:$L $\to$S), *we now have a new mapping—one from the lens plane to a wavefront*. This gives us an alternative interpretation of gravitational lensing where the light source plane is dispensed with and substituted with a wavefront: the locus of points that can be reached in a given time by light signals emitted simultaneously from the observer in all possible directions, after passing through the lens plane. It should also be kept in mind that even though the wavefront as a surface is different from a source plane, in typical lensing scenarios the wavefront surface lies very close to a plane in the region of interest, namely around the optical axis.

IV. CAUSTICS ON WAVEFRONTS AND LIGHTCONES

As a surface in the comoving space $E\subseteq\mathbf{R}^3$, the wavefront $\mathcal{W}^+(T)$ typically develops singularities—called *caustics*—due to the distortions caused by the lens. More precisely, a point $\mathbf{r}$ in the lens plane L is a *critical point* of the wavefront lensing map

$$\mathbf{w}_T:L\to\mathcal{W}^+(T)\subseteq\mathbf{R}^3,\quad \mathbf{w}_T(\mathbf{r})=(\mathbf{s}(\mathbf{r},T),z(\mathbf{r},T))$$

if $\operatorname{rank}[(\operatorname{Jac}\mathbf{w}_T)(\mathbf{r})]<2$, where $\operatorname{Jac}\mathbf{w}_T$ is the Jacobian matrix of $\mathbf{w}_T$ and $z(\mathbf{r},T)\geqslant z_l$. The set of critical points of $\mathbf{w}_T$ will be denoted by $\operatorname{Crit}(\mathbf{w}_T)$. The set of *caustic points* of $\mathbf{w}_T$ or on $\mathcal{W}^+(T)$ is the set

$$\operatorname{Caustics}[\mathcal{W}^+(T)]\equiv\mathbf{w}_T[\operatorname{Crit}(\mathbf{w}_T)]$$

of all critical values of $\mathbf{w}_T$.

The Jacobian matrix of $\mathbf{w}_T$ is the following 3×2 matrix:

$$\operatorname{Jac}\mathbf{w}_T=\begin{bmatrix}\dfrac{\partial \mathbf{s}(\mathbf{r},T)}{\partial \mathbf{r}}\\[2ex] \dfrac{\partial z(\mathbf{r},T)}{\partial \mathbf{r}}\end{bmatrix}, \tag{35}$$

where $z=z(\mathbf{r},T)$ is given by (32) and $\mathbf{s}=\mathbf{s}(\mathbf{r},T)$ by (33). Define a function $f:L\to\mathbf{R}$ by

$$f(\mathbf{r})=z_l+\frac{|\mathbf{r}|^2}{2z_l}-\hat{\Psi}(\mathbf{r}). \tag{36}$$

Note that $f(\mathbf{r})=\ell_l-\hat{\Psi}(\mathbf{r})$ within our approximations [see (16)], so $a_0 f(\mathbf{r})/c$ is the present proper length of a light ray from the point $\mathbf{r}$ on the lens plane to the observer. By (20), we see that

$$\mathbf{s}(\mathbf{r},T)=\mathbf{s}(\mathbf{r},z(\mathbf{r},T))=z(\mathbf{r},T)\nabla_{\mathbf{r}}f(\mathbf{r})+z_l\hat{\boldsymbol{\alpha}}(\mathbf{r}).$$

Consequently, the Jacobian matrix of $\mathbf{s}(\mathbf{r},T)$ relative to $\mathbf{r}$ can then be expressed as

$$\frac{\partial \mathbf{s}}{\partial \mathbf{r}}=\begin{bmatrix} f_1\dfrac{\partial z}{\partial r_1}+zf_{11}+z_l\hat{\Psi}_{11} & f_1\dfrac{\partial z}{\partial r_1}+zf_{12}+z_l\hat{\Psi}_{12}\\[2ex] f_2\dfrac{\partial z}{\partial r_1}+zf_{21}+z_l\hat{\Psi}_{21} & f_2\dfrac{\partial z}{\partial r_2}+zf_{22}+z_l\hat{\Psi}_{22}\end{bmatrix}, \tag{37}$$

where f_i, f_{ij}, and $\hat{\Psi}_{ij}$ denote the usual partial derivatives relative to $\mathbf{r}=(r_1,r_2)$. Note that the Jacobian matrix in (37) is *not* symmetric, unlike the usual Jacobian matrices $\partial \mathbf{s}_z/\partial \mathbf{r}$ and $\partial \boldsymbol{\eta}/\partial \mathbf{r}$ of the comoving and cosmological lensing maps. If z is fixed, then (37) reduces to the usual comoving symmetric case—see Eq. (21),

$$\frac{\partial \mathbf{s}(\mathbf{r},T)}{\partial \mathbf{r}}=\frac{\partial \mathbf{s}_z(\mathbf{r})}{\partial \mathbf{r}}=\frac{z}{z_l}\mathbf{I}-(z-z_l)(\operatorname{Hess}_{\mathbf{r}}\hat{\Psi})(\mathbf{r}).$$

We have $\operatorname{rank}[(\operatorname{Jac}\mathbf{w}_T)(\mathbf{r})]<2$ if and only if every 2-square minor of $\operatorname{Jac}\mathbf{w}_T$ vanishes,

$$\det\frac{\partial \mathbf{s}}{\partial \mathbf{r}}=0, \tag{38}$$

$$\det\begin{bmatrix}\dfrac{\partial s_1}{\partial \mathbf{r}}\\[2ex] \dfrac{\partial z}{\partial \mathbf{r}}\end{bmatrix}=\frac{\partial s_1}{\partial r_1}\frac{\partial z}{\partial r_2}-\frac{\partial s_1}{\partial r_2}\frac{\partial z}{\partial r_1}=0, \tag{39}$$

$$\det\begin{bmatrix}\dfrac{\partial s_2}{\partial \mathbf{r}}\\[2ex] \dfrac{\partial z}{\partial \mathbf{r}}\end{bmatrix}=\frac{\partial s_2}{\partial r_1}\frac{\partial z}{\partial r_2}-\frac{\partial s_2}{\partial r_2}\frac{\partial z}{\partial r_1}=0, \tag{40}$$

where $\mathbf{s}=(s_1,s_2)$. Since the conformal time T is fixed when studying $\mathcal{W}^+(T)$, we have

$$\mathsf{T}(\mathbf{r},\mathbf{s}(\mathbf{r},T),z(\mathbf{r},T))=T=\text{constant},$$

which yields

$$\frac{\partial \mathsf{T}}{\partial \mathbf{r}} + \frac{\partial \mathsf{T}}{\partial \mathbf{s}} \frac{\partial \mathbf{s}}{\partial \mathbf{r}} + \frac{\partial \mathsf{T}}{\partial z} \frac{\partial z}{\partial \mathbf{r}} = \mathbf{0}. \tag{41}$$

By (19), we get

$$\frac{\partial \mathsf{T}}{\partial \mathbf{r}} = \mathbf{0}, \tag{42}$$

while Eq. (18) yields $\partial \mathsf{T}/\partial \mathbf{s} = (\mathbf{s}-\mathbf{r})/(z-z_l)$. The latter vanishes if and only if $\hat{\boldsymbol{\alpha}}(\mathbf{r}) = \mathbf{r}/z_l$ [apply (42) or (20)], which holds if and only if $\mathbf{r}$ is a critical point of the function f in (36). Note that for $\mathbf{r}$ to be a critical point of ξ it must solve

$$\frac{\mathbf{r}}{z_l} - \hat{\boldsymbol{\alpha}}(\mathbf{r}) = \frac{\partial f}{\partial \mathbf{r}}(\mathbf{r}) = \mathbf{0}.$$

Generically, the critical points of f are nondegenerate and so are isolated points (e.g., p. 240, Petters *et al.*[2]). For this reason, *we shall assume—unless stated to the contrary—that* $\mathbf{r} \neq \mathbf{s}$. Consequently,

$$\frac{\partial \mathsf{T}}{\partial \mathbf{s}} = \frac{\mathbf{s}-\mathbf{r}}{z-z_l} \neq \mathbf{0}, \quad \frac{\partial \mathsf{T}}{\partial z} = -\frac{|\mathbf{r}-\mathbf{s}|^2}{2(z-z_l)^2} \neq 0. \tag{43}$$

Equation (41) yields

$$\frac{\partial z}{\partial \mathbf{r}} = \left[\frac{(\partial \mathsf{T}/\partial \mathbf{s})}{(\partial \mathsf{T}/\partial z)}\right] \frac{\partial \mathbf{s}}{\partial \mathbf{r}}, \tag{44}$$

where by (43) the bracketed term is nonzero. Plugging $\partial z/\partial r_1$ and $\partial z/\partial r_2$ from (44) into (39) and (40) implies that

$$\frac{\partial s_1}{\partial r_1}\frac{\partial z}{\partial r_2} - \frac{\partial s_1}{\partial r_2}\frac{\partial z}{\partial r_1} = \left[\frac{(\partial \mathsf{T}/\partial s_2)}{(\partial \mathsf{T}/\partial z)}\right] \det \frac{\partial \mathbf{s}}{\partial \mathbf{r}}, \tag{45}$$

$$\frac{\partial s_2}{\partial r_1}\frac{\partial z}{\partial r_2} - \frac{\partial s_2}{\partial r_2}\frac{\partial z}{\partial r_1} = -\left[\frac{(\partial \mathsf{T}/\partial s_1)}{(\partial \mathsf{T}/\partial z)}\right] \det \frac{\partial \mathbf{s}}{\partial \mathbf{r}}. \tag{46}$$

Equations (38)–(40), (45), (46), along with our assumption in (43), then show that the Jacobian matrix of $\mathbf{w}_T$ has rank below 2 if and only if the Jacobian determinant of $\mathbf{s}$ vanishes. Thus, at the conformal time T the caustics on the wavefront are given by

$$\text{Caustics}[\mathcal{W}(T)] = \{(\mathbf{s}(\mathbf{r},T), z(\mathbf{r},T))\}, \tag{47}$$

where $\mathbf{r} \in L$, $\mathbf{s}(\mathbf{r},T)$ is given by (33) with T fixed, and $\mathbf{s} = \mathbf{s}(\mathbf{r},T)$ is subjected to the constraint

$$\det \frac{\partial \mathbf{s}}{\partial \mathbf{r}}(\mathbf{r},T) = 0. \tag{48}$$

Equation (47) extends to wavefront lensing maps the usual concept of caustics in gravitational lensing, where lensing maps are from a lens plane to a light source plane. Allowing the conformal time T to vary in (47) yields evolving caustics on the wavefront as the front propagates. The caustics on a wavefront trace out a *caustic surface* on the conformal past lightcone L^- is given by

$$\text{Caustics}[\mathsf{L}^-] = \{(T_0 - T(\mathbf{r}), \mathbf{s}(\mathbf{r}, T(\mathbf{r})), z(\mathbf{r}, T(\mathbf{r})))\}, \tag{49}$$

where $T_0 = c\tau_0/a_0$, $\mathbf{r} \in L$, and $\mathbf{s}(\mathbf{r},T)$ obeys (48). Since T varies in the case of a caustic surface, the vanishing-determinant condition (48) forces T to be a function of $\mathbf{r}$, which we have expressed by $T(\mathbf{r})$. Also, note that the caustics lie on the portion of L^- with $z \geqslant z_l$. Projecting Caustics$[\mathsf{L}^-]$ into the comoving space E, we obtain the *comoving caustic surface*

$$\text{Caustics}_E[\mathsf{L}^-] = \{(\mathbf{s}(\mathbf{r},T(\mathbf{r})), z(\mathbf{r},T(\mathbf{r})))\}, \tag{50}$$

where $\mathbf{r} \in L$ and $\mathbf{s}(\mathbf{r},T(\mathbf{r}))$ satisfies (48). In the space–time $(I \times E, \mathbf{g}_{GL})$, the caustic is given by

$$\text{Caustics}[\mathcal{L}^-] = \{(\tau_0 - \tau(\mathbf{r}), \mathbf{s}(\mathbf{r},T(\mathbf{r})), z(\mathbf{r},T(\mathbf{r})))\}, \tag{51}$$

where τ_0 is the present cosmic time and $\tau(\mathbf{r}) \equiv a_0 T(\mathbf{r})/c$, $\mathbf{r} \in L$, and $\mathbf{s}(\mathbf{r},T(\mathbf{r}))$ obeys (48). Projecting Caustics$[\mathcal{L}^-]$ into E yields a surface that is isometric to Caustics$_E[\mathsf{L}^-]$ as singular spaces relative to the Euclidean metric on E. Analogous to Eqs. (49)–(51), the caustics of the future lightcone and their projection into the comoving space are given as follows:

$$\text{Caustics}[\mathcal{L}^+] = \{(\tau_0 + \tau(\mathbf{r}), \mathbf{s}(\mathbf{r},T(\mathbf{r})), z(\mathbf{r},T(\mathbf{r})))\}, \tag{52}$$

$$\text{Caustics}[\mathsf{L}^+] = \{(T_0 + T(\mathbf{r}), \mathbf{s}(\mathbf{r},T(\mathbf{r})), z(\mathbf{r},T(\mathbf{r})))\}, \tag{53}$$

$$\text{Caustics}_E[\mathsf{L}^+] = \{(\mathbf{s}(\mathbf{r},T(\mathbf{r})), z(\mathbf{r},T(\mathbf{r})))\}, \tag{54}$$

where $\mathbf{r} \in L$ and $\mathbf{s}(\mathbf{r},T)$ satisfies (48).

The previous discussion traces out the caustic surfaces of an observer's past lightcone using constant time slices. The caustic surfaces can also be traced out using constant z slices. Slices of the caustic sheet by constant z planes are curves on the light source plane, and coincide with what are commonly referred to in the lensing literature as ''caustics.'' We shall refer to such caustics as *z-sliced caustic curves*. These caustic curves can also have singularities, such as cusps. It is important to add that our discussion shows that points on a z-sliced caustic curve actually occur at different cosmic (or conformal) times. Often times, points on caustic curves are treated in the lensing literature as if they occur at the same cosmic time.

In order to calculate the points on the comoving caustic sheet, we impose the condition that the Jacobian of the lens map be singular—see (50) and (54):

$$\det \frac{\partial \mathbf{s}}{\partial \mathbf{r}} = 0.$$

This condition can be imposed either at constant z or constant T if the intention is to produce the caustic sheet. For constant T, we have that $\mathbf{s}$ is given by the wavefront lensing map (33), i.e., $\mathbf{s} = \mathbf{s}(\mathbf{r},z(\mathbf{r},T))$, while for constant z the function $\mathbf{s}$ is given by the standard lensing map (20), i.e., $\mathbf{s} = \mathbf{s}_z(\mathbf{r})$. In the latter case, we consider the caustics of the mapping $\mathbf{s} = \mathbf{s}_z$ from the lens plane to the light source plane, with the intention of eventually letting the light source plane at z sweep (along the optical axis) the entire range behind the lens.

By Eq. (21)—equivalently, Eq. (37) with z fixed—we see that the Jacobian matrix of $\mathbf{s}_z$ depends linearly on z,

$$\frac{\partial \mathbf{s}_z}{\partial \mathbf{r}} = \begin{bmatrix} 1 + (z - z_l) f_{11} & -(z - z_l)\hat{\Psi}_{12} \\ -(z - z_l)\hat{\Psi}_{21} & 1 + (z - z_l) f_{22} \end{bmatrix}, \tag{55}$$

where f is given by (36). Consequently, the determinant of (55) is a quadratic in z. Explicitly, the vanishing of the Jacobian determinant of $\mathbf{s}_z$ is

$$0 = 1 + (z - z_l)(2z_l^{-1} - \hat{\Psi}_{11} - \hat{\Psi}_{22}) + (z - z_l)^2[(z_l^{-1} - \hat{\Psi}_{11})(z_l^{-1} - \hat{\Psi}_{22}) - \hat{\Psi}_{12}^2]. \tag{56}$$

There are two solutions for z as a function of $\mathbf{r}$, representing the z coordinate of points on the caustic surface,

$$z_{\pm}(\mathbf{r}) \equiv z_l + \frac{\hat{\Psi}_{11} + \hat{\Psi}_{22} - 2z_l^{-1} \pm \sqrt{(\hat{\Psi}_{11} - \hat{\Psi}_{22})^2 + 4\hat{\Psi}_{12}^2}}{2[(z_l^{-1} - \hat{\Psi}_{11})(z_l^{-1} - \hat{\Psi}_{22}) - \hat{\Psi}_{12}^2]}. \tag{57}$$

Evaluating $\mathbf{s}_z = \mathbf{s}(\mathbf{r},z)$ at $z_{\pm}(\mathbf{r})$, we obtain the transverse coordinates of points on the caustic surface:

$$\mathbf{s}_{\pm}(\mathbf{r}) \equiv \mathbf{s}(\mathbf{r}, z_{\pm}(\mathbf{r})) = \frac{z_{\pm}(\mathbf{r})}{z_l}\mathbf{r} - (z_{\pm}(\mathbf{r}) - z_l)\hat{\boldsymbol{\alpha}}(\mathbf{r}). \tag{58}$$

By varying $\mathbf{r}$ across the lens plane, the pair $(\mathbf{s}_{\pm}(\mathbf{r}), z_{\pm}(\mathbf{r}))$ traces out the comoving caustic surface for either the future or past conformal lightcone:

$$\begin{aligned} \mathrm{Caustics}_E[\mathsf{L}^+] &= \{(\mathbf{s}_{\pm}(\mathbf{r}), z_{\pm}(\mathbf{r})) : \ \mathbf{r} \in L\} \\ &= \mathrm{Caustics}_E[\mathsf{L}^-]. \end{aligned} \tag{59}$$

V. SURFING A CAUSTIC SHEET

In his Millennium Essay, Blandford[16] speculated about some possible novel gravitational lensing ways of probing the cosmos. One of these dealt with caustic sheets: ''Our observations need not be passive. ... For example, suppose that we launch an array of robotic telescopes and use three of them to measure the velocity of a caustic sheet (from by a bright source) as it passes Earth; a fourth telescope could be made to ''surf'' the wave and observe the source with considerable magnification for a long time.''

We now apply the results of the previous section to show how a telescope may surf a sheet of a caustic surface. This will be done in two steps.

First, change the point of view by assuming that the telescope is the observer. We shall then consider the past comoving caustic surface of the telescope and the future comoving caustic surface of the source simultaneously, and determine the analytical form of the equations for these surfaces. Assume that the telescope lies somewhere on the future comoving caustic surface of the source (i.e., the source is seen at an extremely high magnification corresponding to being on a caustic). For the time being, we shall also suppose that the source is at rest relative to the lens. The past comoving caustic surface of the telescope is given by an expression of the form

$$S_0(\mathsf{x}) = 0,$$

where $\mathsf{x} = (\mathbf{s},z)$. In principle, one can find S_0 by solving for $\mathbf{r}$ in terms of $\mathbf{s}_{\pm}$ using (58) and inserting those values of $\mathbf{r}$ into (57) to obtain $z_{\pm}$ in terms of $\mathbf{s}_{\pm}$, say, $z_{\pm} = F_{\pm}(\mathbf{s}_{\pm})$. In this case, the past comoving caustic surface of the telescope is given by

$$S_0(\mathsf{x}) \equiv z_{\pm} - F_{\pm}(\mathbf{s}_{\pm}) = 0. \tag{60}$$

Since we are using the small-angle approximation, we can approximate the future comoving caustic surface of the source by (60) if $\mathbf{s}$ and z are transformed as follows:

$$\mathbf{s} \to -\mathbf{s}\frac{\ell_{\mathrm{tl}}}{\ell_{\mathrm{sl}}}, \quad z \to \ell_{\mathrm{tl}} + \ell_{\mathrm{sl}}$$

where ℓ_{tl} and ℓ_{sl} are the telescope-lens and lens-source Euclidean distances, respectively. Hence, we suppose that there is an expression for the future comoving caustic surface of the source of the form

$$S_0(\mathsf{x})=0. \tag{61}$$

Second, suppose that a source moving relative to the lens with slowly varying 3-velocity V in comoving coordinates is observed extremely magnified by a telescope at a given instant of conformal time, say, $\mathsf{t}=0$. Assuming that the telescope lies somewhere on a caustic sheet of the source away from singularities (e.g., cusp ridges, swallowtails, elliptic umbilics, hyperbolic umbilics), what should the subsequent motion of the telescope be in order to track the image of the source at a peak brightness? Suppose that during a time increment $\delta\mathsf{t}$ the source moves keeping the distance to the lens plane approximately the same, and assuming its motion to be relatively slow, the caustic sheet of the source in motion will not differ from that of the source at rest other than by a general translation in the direction of motion, i.e.,

$$S(\mathsf{x},\delta\mathsf{t})=S_0(\mathsf{x}-\mathsf{V}\ \ \delta\mathsf{t})=0.$$

If the telescope lies on the caustic sheet at point x_0 at time $\mathsf{t}=0$, then

$$S(\mathsf{x}_0,0)=0=S_0(\mathsf{x}_0).$$

For the telescope to see a bright image of the source during a length of time $\delta\mathsf{t}$, the telescope needs to move with velocity v to another point on the caustic sheet, i.e., to a point $\mathsf{x}=\mathsf{x}_0+\mathsf{v}\delta\mathsf{t}$ so that

$$S(\mathsf{x},\delta\mathsf{t})=0=S_0(\mathsf{x}_0+(\mathsf{v}-\mathsf{V})\,\delta\mathsf{t}).$$

Taylor expanding to first order in $\delta\mathsf{t}$, this is equivalent to

$$\nabla S_0\cdot(\mathsf{v}-\mathsf{V})=0, \tag{62}$$

where ∇S_0 is evaluated at the original position of the telescope x_0 and $\cdot$ stands for the Euclidean scalar product of the two vectors. This means that the telescope's velocity must differ from that of the source at most by a vector tangent to the caustic sheet. Clearly $\mathsf{v}=\mathsf{V}$ would be one way to stay on the caustic sheet, but it may require more energy than necessary. We want the smallest speed needed to stay on the caustic sheet. In order words, we shall minimize $|\mathsf{v}|^2$ for a fixed spatial position and time subjected to the constraint in (62). This will be valid for the time increment $\delta\mathsf{t}$, i.e., we are considering only the zeroth iterate of caustic surfing. The vanishing gradient of the Lagrangian $\mathcal{L}=v_1^2+v_2^2+v_3^2+\lambda\ \nabla S_0\cdot(\mathsf{v}-\mathsf{V})$ with respect to $\mathsf{v}=(v_1,v_2,v_3)$ and the multiplier λ yields $\lambda=-\mathsf{V}\cdot\nabla S_0/|\nabla S_0|^2$. Hence, we obtain the minimum velocity

$$\mathsf{v}_{\min}=-\lambda\nabla S_0=\frac{\mathsf{V}\cdot\nabla S_0}{|\nabla S_0|^2}\nabla S_0, \tag{63}$$

where ∇S_0 is evaluated at x_0. In other words, the minimum velocity is the projection of V to the normal vector ∇S_0 to the caustic surface at x_0. This is physically the minimum speed since ∇S_0 points along the shortest direction between the caustic sheet at time $\mathsf{t}=0$ and the sheet at $\mathsf{t}=\delta\mathsf{t}$. The speed $|\mathsf{v}_{\min}|$ might be considerably smaller than the source's speed $|\mathsf{V}|$ depending on the circumstances. The normal unit vector to the caustic $\nabla S_0/|\nabla S_0|$ can be calculated either from the expression (61) if available or from the parametric version of the caustic map given by (57) and (58).

In a physically realistic situation the telescope will spend some time to reach this velocity, and one will need to adjust the velocity continuously even if the source is moving at constant speed, due to the curvature of the caustic sheet.

We shall illustrate the caustic surfing concept with a singular-elliptical-potential example in Sec. VI B.

VI. EXAMPLES AND ILLUSTRATIONS

In this section we illustrate explicitly the construction of the wavefronts in some of the most widely used models for the deflection potential in astrophysics. In all the cases that we deal with the expressions for the deflection potentials stated are assumed to hold only in the vicinity of the optical axis. This assumption is maintained in the construction of all the figures.

A. Nonsingular elliptical potential lens

In this section we illustrate the case of an elliptical potential, which has the following form:

$$\hat{\Psi}_{\mathrm{ep}}(\mathbf{r}) \equiv A_0 \sqrt{r_c^2 + (1-\epsilon) r_1^2 + (1+\epsilon) r_2^2}, \tag{64}$$

where A_0 is a dimensionless constant. This potential is often used to model elliptical galaxies with A_0 proportional to the velocity dispersion of the lens, whereas the dimensionless parameters $r_c > 0$ and $\epsilon \geqslant 0$ determine the core radius and ellipticity of the lens. A nonvanishing core radius r_c guarantees a nonsingular surface mass density, which in turn ensures that no light rays are obstructed in their passage through the lens. The bending angle is given by

$$\hat{\boldsymbol{\alpha}}_{\mathrm{ep}}(\mathbf{r}) = \nabla_{\mathbf{r}} \hat{\Psi}_{\mathrm{ep}}(\mathbf{r}) = \frac{A_0((1+\epsilon) r_1, (1-\epsilon) r_2)}{\sqrt{r_c^2 + (1-\epsilon) r_1^2 + (1+\epsilon) r_2^2}}.$$

For fixed parameter values of A_0, r_c, and ϵ, these two explicit expressions for the potential and bending angle can be used in $z(\mathbf{r},T)$ and $\mathbf{s}(\mathbf{r},T)$ to produce plots of the constant-time wavefronts embedded in three-dimensional space beyond the lens plane. At early times beyond the lens plane, the wavefront is essentially spherical, but as it progresses away from the lens plane the central section of the wavefront begins to lag behind the rest of the wavefront, eventually folding and developing multiple sheets. The progression of the wavefront in time shows different regimes, from smooth to various singular types. In the following, we produce a representative surface of each regime, effectively classifying the singularities of the wavefronts of an elliptical lens. This extends the brief summary of such wavefronts given in Ref. 17. Note that formally our treatment is along the future lightcone of the observer, which can be interpreted as the past lightcone in a time coordinate running towards the past, because the space–time is static.

1. Wavefront singularities

We arbitrarily fix the values of the parameters at $A_0 = 1.01, z_l = 90, \epsilon = 0.0002$, and $r_c = 1.001$. These values are chosen for purely pedagogical reasons. Notwithstanding, in making our choice we took care to ensure that the approximation of small angles was met, in order for the plots to be qualitatively representative of lensing problems.

Let T_l be the time at which the ray that passes through the center of the lens (i.e., the origin) reaches the lens plane. With our choice of parameters, it takes the value $T_l = 90$. We find that for times at least as late as $T = T_l + 8900$, the wavefronts are regular on the other side of the lens plane, but sometime before $T = T_l + 9800$ the first singularity occurs in the form of a single point on the wavefront. The time scales in this particular example are irrelevant; in physically accurate lensing situations the time scale should agree with the distance scale to the lens plane in order of magnitude. The time of the first singular wavefront is about $T = T_l + 9699.27$, and is calculated in Sec. VI A 2. After the first singularity, the wavefront successively goes through four more distinct singularity regimes.

The regular regime is illustrated in Fig. 1, which shows a field view of the wavefront. The observer is located to the far right, at (0,0,0) in the plot coordinates. The wavefront is distorted with respect to a sphere, and develops a dent that points toward the observer along the optical axis. The scale of the optical axis is greatly magnified (about 10^4 times) with respect to the transversal axes in order to better show the retardation effect on the wavefront. The ''spike'' has a total length of about 10^{-3} on a sphere of radius about 9×10^3, so the effect is small in the proper scales and

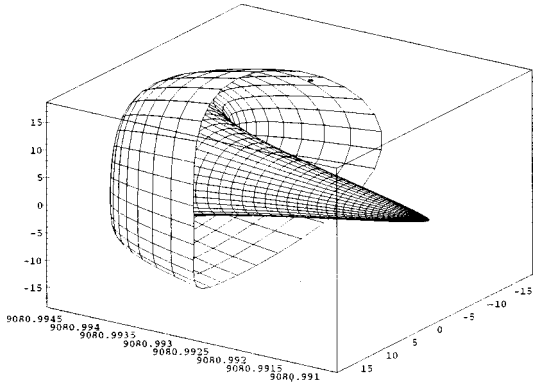

FIG. 1. A portion of the wavefront of an elliptical potential in the regular regime, i.e., early times past the lens plane (in this case, $T=T_l+8900$). The observer is to the right at (0,0,0).

is well within the approximation of small angles. The tip of the ''spike'' is perfectly smooth and presents a convex surface to the observer. There are no singularities anywhere in the wavefront at this time ($T=T_l+8900$).

At a later time, the first singular regime develops, illustrated in Fig. 2. The tip of the spike, which earlier was convex toward the observer, develops a self-intersection and a sharp cuspidal ridge in the form of horizontal ''lips.'' Our use of the term ''lips'' in this context is entirely for descriptive purposes and should not be understood in the technical sense used in Arnold's theory, in which the term ''lips'' refers to the $A_3(+)$ planar caustic metamorphosis (e.g., pp. 375–376, 381 of Ref. 2). The surface of the wavefront that faces the observer is now concave, and limited by the two cuspidal ridges outlining the ''lips.'' The two cuspidal ridges pinch off the back convex

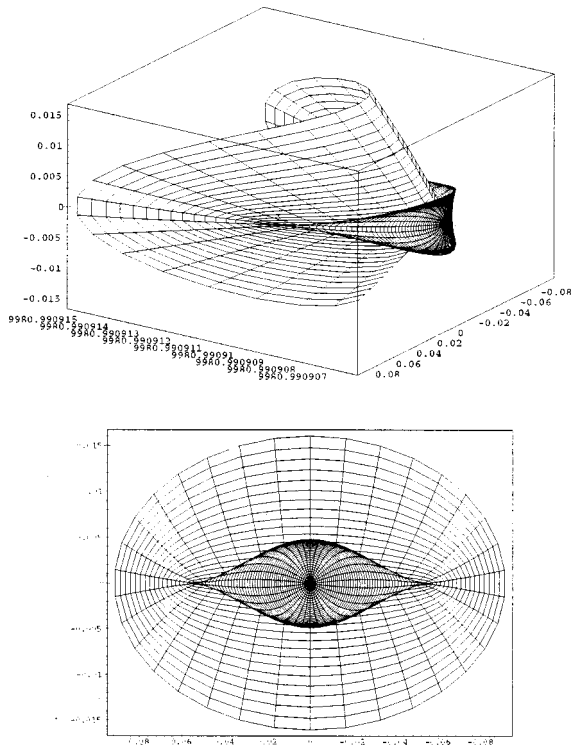

FIG. 2. The single lips regime ($T=T_l+9800$). The bottom panel shows a front view of the lips singularity.

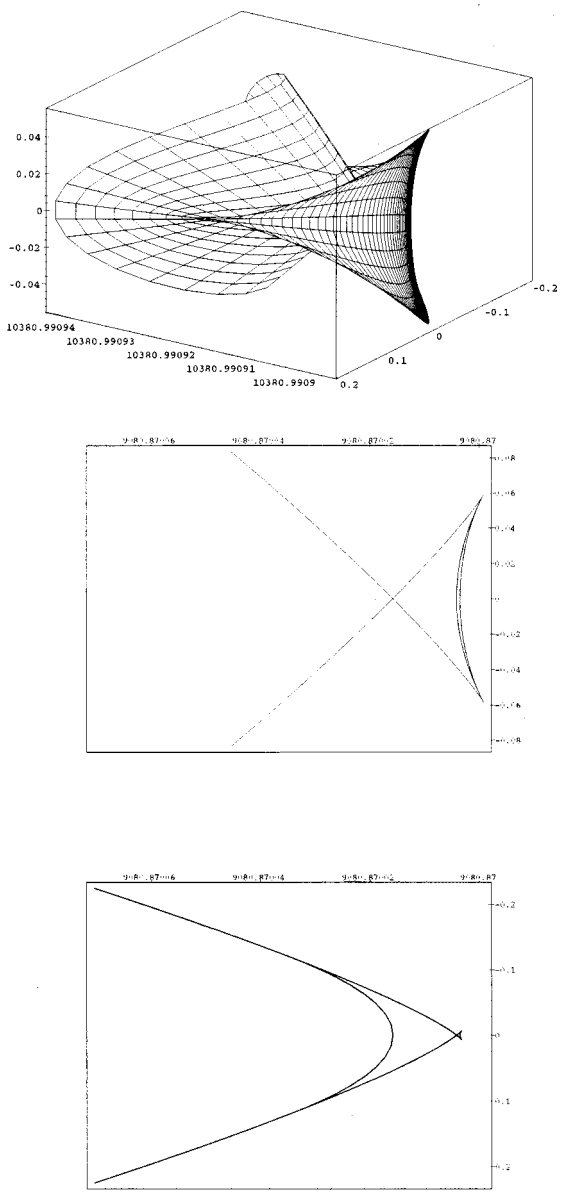

FIG. 3. Typical wavefront in the criss-cross lip regime ($T=T_l+10\,200$), where two nested perpendicular cuspidal ridges are present. The middle panel is a vertical slice of the top panel, while the bottom panel is a horizontal slice. Both slices are through the optical axis.

sheet of the wavefront at two symmetrical swallowtail points. The swallowtails are best appreciated in the top panel, where a side view of the wavefront is shown. The bottom panel shows a front view, where the lip character of the cuspidal ridge can be appreciated. The wavefronts in this regime all have this horizontal lip singularity, but the ''lips'' grow in time continuously after starting out from a single point at the center. The picture shows the wavefront at $T=T_l+9800$, which is still quite early in this regime. One notable fact about this wavefront is that, locally, it is indistinguishable from the early singular wavefronts in the implosion of a triaxial ellipsoid,[18] in which case, the cuspidal lip-ridge lies ''in the outside.'' For the gravitational lensing case that we are illustrating, in a global sense, the cuspidal lip-ridge lies ''inside.''

The next singular regime is illustrated in Fig. 3. The point at the center of the concave sheet of the wavefront facing the observer turns momentarily singular at approximately $T=T_l$

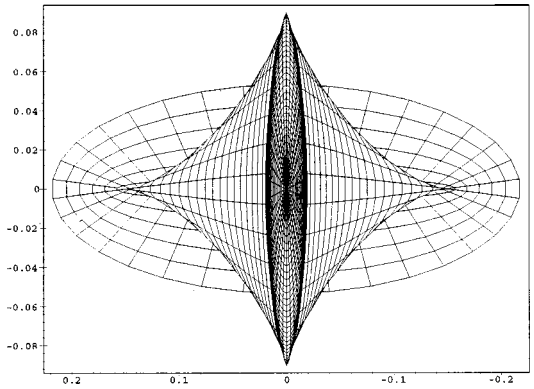

FIG. 4. The critical wavefront ($T=T_l+10\,420$).

$+10\,148.84$, and grows another lips singularity, this time vertically oriented. These vertical ''lips'' ride on top of the now mixed convex–concave section of the wavefront and present a concave surface to the observer, as can be appreciated from the two slices in the middle and bottom panels. The middle panel shows a vertical slice of the wavefront through the optical axis. It may be difficult to appreciate that the foremost sheet pinches off the underlying originally existing sheet well before touching the originally existing cuspidal ridges at the top and bottom. The bottom panel shows an optical-axis horizontal slice, where the cuspidal character of the newly created forefront sheet is evident. The two ends of the vertical ''lips'' are two symmetrical swallowtails. All the wavefronts in this regime have two perpendicular lips, yielding a total of four swallowtails. The perpendicular lips grow continuously in time, but the inner lip starts at the center and grows until it touches the outer lips. This picture shows the wavefront at $T=10\,200$, which is quite late within this regime since the inner lip is about to merge with the outer one.

The next regime consists entirely of a single wavefront at the critical time when the inner lip singularity merges with the outer one. This wavefront is represented in Fig. 4. The singular ridge on the wavefront has the general outline of a football in a vertical position, inscribed in an outer astroid or diamond. The ''football'' outline is the distorted last expression of the inner lip-ridge, whereas the astroid is the distorted last expression of the outer (original) horizontal lips. At this time the two cuspidal ridges merge right before they undergo a permanent change. The wavefront at this critical time has two swallowtails symmetrically located along the horizontal direction, and two singular points symmetrically located along the vertical direction where the two lips merge. In the context of wavefronts, these points have no greater significance than the merger of a cusp ridge and a swallowtail surface. However, their greater significance is that they are indicators of the presence of hyperbolic umbilic points in the caustic sheet, which we describe in the next section. The figure represents the time $T=10\,420$, which is close enough to the critical time at the resolution that we are using.

The last regime comprises all the wavefronts later than the critical time at which the inner ''lips'' merge with the outer ''lips.'' All such late wavefronts have a ''regular'' cuspidal ridge delimiting a concave surface that faces the observer, namely, a cuspidal ridge which is smooth as a curve in three space. Behind the foremost concave cap, the wavefront self-intersects and has another cuspidal ridge with four singular points in the general shape of an astroid or diamond. One such wavefront at time $T=T_l+10\,900$ is shown in Fig. 5. In this front view, the foremost oval cuspidal ridge is clearly distinguishable, as are the two swallowtails in the back. However, there are two other swallowtails completing the diamond, which lie behind the foremost oval cap and are blocked from view in this picture. The qualitative structure of the wavefront in the diamond-ridge neighborhood is shown in the bottom panel of Fig. 6.

A very late wavefront at time $T=T_l+55\,000$ is shown in Fig. 6. It can be seen that as time moves on, the oval and diamond cuspidal ridges remain essentially unchanged except that the oval ridge in the foreground grows at a much faster rate than the diamond-shaped ridge in the back, and

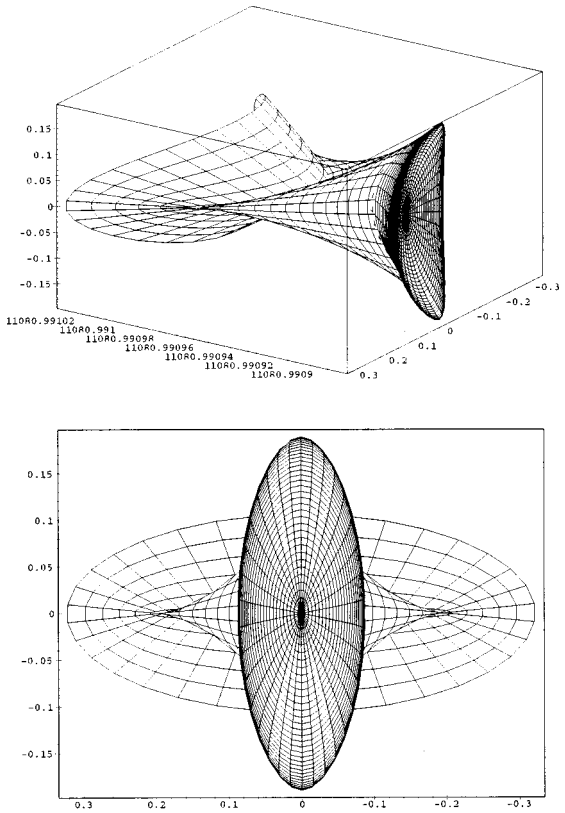

FIG. 5. Typical wavefront early in the late regime ($T=T_I+10\,900$). The bottom panel shows a front view.

the wavefront eventually acquires a shape resembling that of a goblet. The figure shows both a field view of the ''goblet'' and a magnification of the goblet's throat to show the diamond ridge. The diamond ridge structure is almost ubiquitous in wavefront evolutions that are not axisymmetric. For another view of one of these local diamond ridges in wavefronts, we refer the reader to the bottom panel of Fig. 10. The global ''goblet'' wavefront is typical of spherically symmetric regular potentials, with the major difference that the throat of the goblets in the spherically symmetric case degenerates down to a single point, lacking the complicated diamond structure for the case of elliptical symmetry. The diamond ridge represents the nondegenerate version of the throat of the goblet. The goblet's throat has three wavefront sheets, each generically giving rise to an image of the light source.

What we have described in this section are precisely the singularities and metamorphosis of wavefronts in the observer's lightcone in the case of an elliptical potential. In this case, we found that the wavefronts have three types of singularities: cuspidal ridges, swallowtail points, and points of transversal self-intersections. These three singularity types are shared by generic wavefronts in space—see p. 55 of Ref. 19. We also showed that two kinds of metamorphosis occur for the wavefronts due to an elliptical potential. In the first place, we have found two occurrences of the birth of ''lips'' on the wavefront. Second, we have found two hyperbolic umbilic metamorphoses, i.e, the two symmetrical occurrences on the wavefront of the exchange of a swallowtail point from one cuspidal ridge to another. Both metamorphosis are part of Arnold's list of metamorphoses of fronts in space—see, for instance, the first and fourth perestroikas in Fig. 258 on p. 489 of Ref. 20.

2. Caustic sheet

If we think of the family of wavefronts for all times T as spatial slices of the observer's lightcone, then the collection of all the caustic singularities (i.e., cuspidal ridges, swallowtail

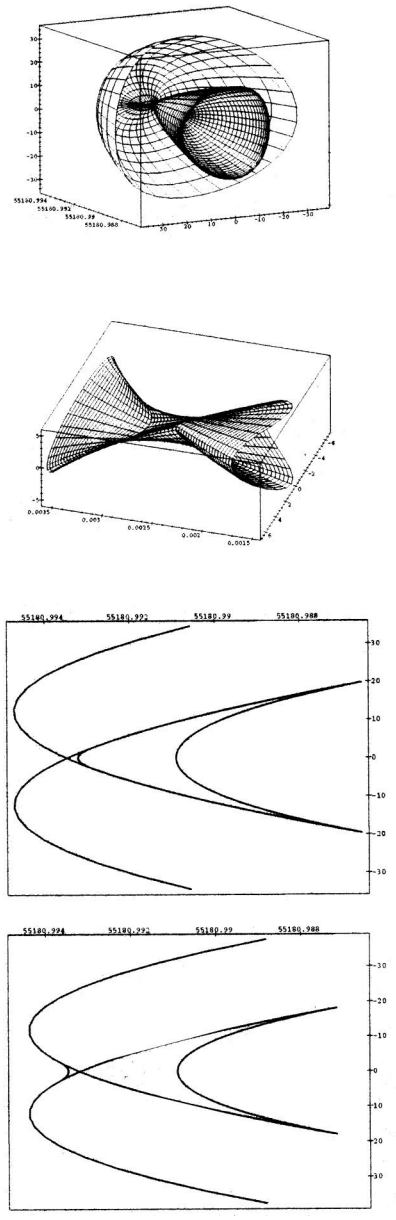

FIG. 6. Typical ''goblet'' wavefront in the very late regime (in this case, $T = T_l + 55\,000$). The middle-top panels shows a magnification of the throat. The middle-bottom and bottom panels show vertical and horizontal slices, respectively.

points) on the instantaneous wavefronts forms a two-surface in space–time. The projection of this two-surface into the comoving space E is referred to as a comoving caustic surface.

As a surface in the three-space E, the caustic surface is traced in time by the caustics of the traveling wavefront as the front moves away from the observer. The metamorphoses of the wavefront's caustics thus build up a picture of the caustic surface's singularities. The generic singularities of a caustic surface in three-space are of five different types: folds, cuspidal ridges, swallowtail points, elliptic umbilic points, and hyperbolic umbilic points.[21]

We showed that the caustic surface on an observer's lightcone is given by Eq. (59). In the particular case of the elliptical potential, the resulting caustic surface is shown in Fig. 7. A significant feature of our caustic surface in three-space is that it consists of two separate intersecting sheets, one for each nontrivial root (57) of the Jacobian determinant in (56). The two bottom

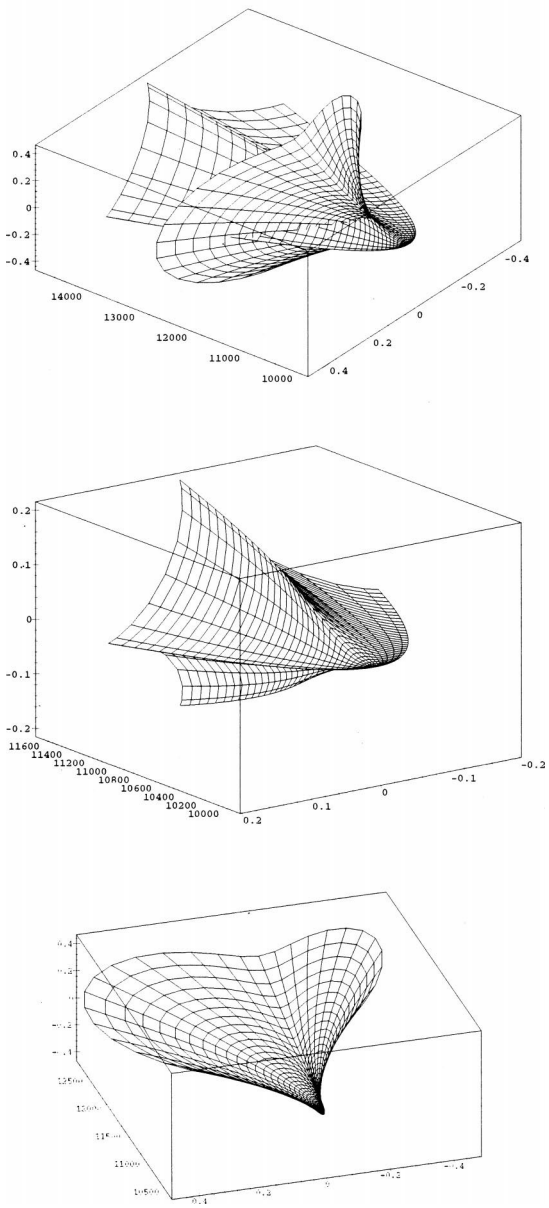

FIG. 7. Caustic sheet of the elliptical potential. The two component sheets are represented separately in the middle and bottom panels.

panels in the figure show the two component sheets. One sheet starts closer to the observer as a horizontal ''beak'' and then develops a diamond cross section. The second sheet starts inside the first one as a vertical ''beak'' and eventually opens up into a smooth surface with an oval cross section. The transitions of both sheets take place at the points where they intersect. The points of intersection where the vertical beak disappears from the second component sheet and the vertical cusp ridge appears on the first component sheet are hyperbolic umbilic points—there are two such points.

We can also at this point give the exact value of the time of the first singular wavefront. This is the smaller of $T(\mathbf{s}_+(\mathbf{0}),z_+(\mathbf{0}))$ and $T(\mathbf{s}_-(\mathbf{0}),z_-(\mathbf{0}))$ since rays passing through the origin have the longest delay (as is evidenced from the spike). For the preceding section, we have

$T(\mathbf{s}_+(\mathbf{0}),z_+(\mathbf{0}))=T_l+9699.27$ and $T(\mathbf{s}_-(\mathbf{0}),z_-(\mathbf{0}))=T_l+10\,148.84$, i.e., the first singular wavefront is the surface at $T=T_l+9699.27$, as anticipated.

By slicing the caustic sheet with constant-z surfaces we obtain a series of planar caustics representing the metamorphosis of the hyperbolic umbilic. These are shown in Fig. 8 and coincide with the well-known caustic curves in the gravitational lensing literature for an elliptical potential—e.g., p. 386 of Ref. 2. Beautiful photographs of caustic metamorphoses are shown in Ref. 14—see p. 68 for the hyperbolic umbilic metamorphosis.

B. Singular elliptical potential lens

We shall illustrate the wavefront singularities and caustic surface due to a singular elliptical potential, namely, the case of vanishing core radius ($r_c=0$). In this case, it is simpler to use polar coordinates (r,ϑ) on the lens plane. We have for the potential,

$$\hat{\Psi}^{\mathrm{sing}}_{\mathrm{ep}}(r,\vartheta)\equiv A_0\sqrt{(1-\epsilon)r_1^2+(1+\epsilon)r_2^2}=A_0 r\sqrt{1+\epsilon\cos(2\vartheta)},$$

and for the associated bending angle,

$$\hat{\boldsymbol{\alpha}}^{\mathrm{sing}}_{\mathrm{ep}}(r,\vartheta)=\frac{A_0}{\sqrt{1+\epsilon\cos(2\vartheta)}}((1+\epsilon)\cos\vartheta,(1-\epsilon)\sin\vartheta),$$

which has no dependence on r. The potential vanishes at the origin $r=0$. This case is singular because the surface mass density associated with the potential blows up at the origin of the lens plane (i.e., $\nabla^2_{\mathbf{r}}\hat{\Psi}^{\mathrm{sing}}_{\mathrm{ep}}(\mathbf{r})\to\infty$ as $\mathbf{r}\to\mathbf{0}$). The center of the lens (i.e., the origin) thus acts as an obstruction to the light rays—see Ref. 22) and p. 544 of Ref. 2 for a detailed treatment of obstruction points. Soon after going through the lens plane, the wavefronts evolve markedly differently from the nonsingular case. For our illustrations, we have used the following values of the lens parameters: $A_0=0.3,\epsilon=0.02,z_l=4000$. As in the regular case, these values are chosen for pedagogical reasons, although taking care to respect the approximations of small angles.

1. Wavefront singularities

Due to the obstruction at the center of the lens (i.e., the origin), all the wavefronts are singular and there are only two regimes. The first regime consists entirely of a single wavefront (the earliest one to make it past the lens plane) with an interior spike pointing towards the observer, as did the wavefronts of the nonsingular elliptical potential. However, in this singular case the spike is conical, and touches the lens plane at the origin. The point at the tip of the spike is removed. This wavefront, $T=T_l=4000$, is shown in Fig. 9. The figure shows both a field view of the wavefront, and a side view of the tip of the spike magnified to make the conical character apparent.

At all times afterwards, the wavefronts resemble a goblet—the second regime. However, these goblets are markedly different from those that resulted at late times in the nonsingular elliptical potential case. There is a single diamond-shaped cuspidal ridge, which lies at the throat of the goblet. The rim of the goblet is removed and acts as a boundary of the wavefront. These goblets lack the interior concave surface facing the observer that characterizes the goblets in the nonsingular case. The throat of the goblet has three sheets, each typically giving rise to an image of the source. One such wavefront in this regime ($T=T_l+1000$) is illustrated in Fig. 10, where a field view evidences the resemblance to a goblet. The bottom panel in the figure shows a magnified view of the throat of the ''goblet'' where the diamond structure is evident.

Two questions relating to this imperfect ''goblet'' wavefront arise. In the first place, do the wavefronts ever detach from the lens plane, or, on the contrary, do they reach out to the obstruction point? As one can appreciate in Fig. 11, where a given portion of the initial wavefront at $T=T_l$ is followed up and plotted again at $T=T_l+1000$, *the wavefront does not remain attached to the lens plane*.

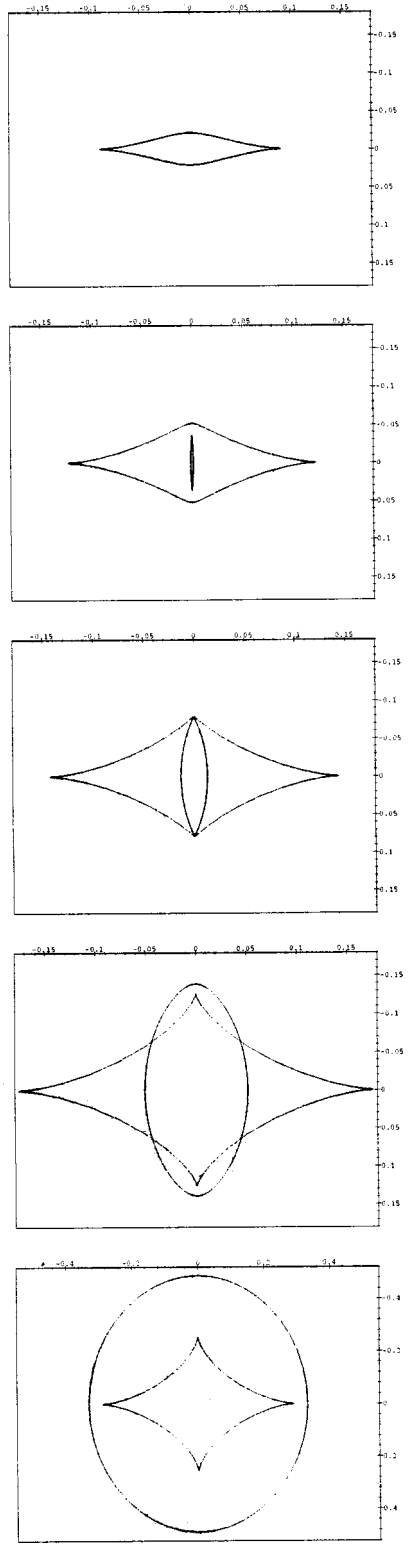

FIG. 8. The metamorphosis of the planar caustics arising from z-plane slices of the caustic surface.

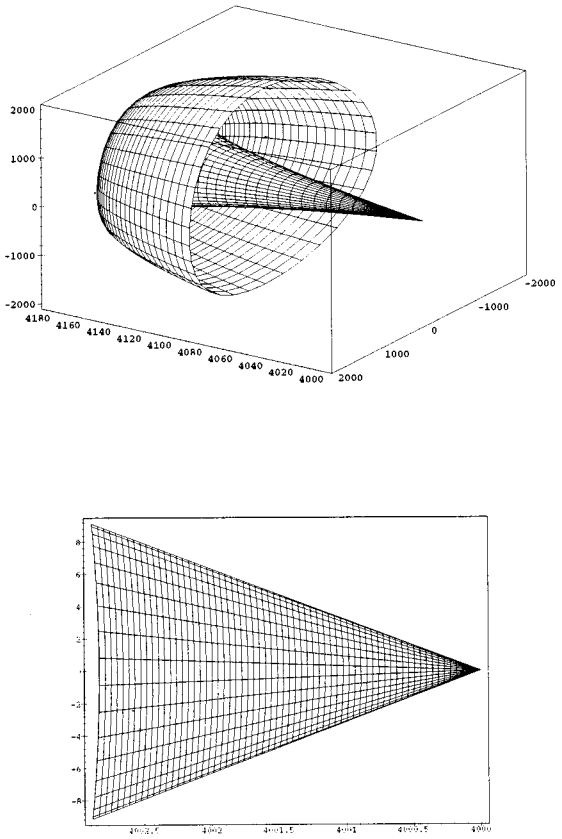

FIG. 9. The unique wavefront in the early regime ($T=T_l$) in the singular case. The bottom panel shows a side view of the tip of the spike.

The second question is whether the rim of the goblet is planar, namely, whether it lies on a constant-z plane. *The answer is no.* The rim of the goblet is a space curve, which is plotted in Fig. 12. It must be kept in mind that the rim is the boundary of the wavefront. This rim is removed because it is the image of the point $r=0$ on the lens plane under the wavefront lensing map, i.e., $\mathbf{w}^{\rm sing}_{T,\rm ep}(0,\vartheta)=(\mathbf{s}(0,\vartheta,T),z(0,\vartheta,T))$, which is a space curve for fixed T. Explicitly, Eqs. (32) and (33) yield that

$$\mathbf{s}(0,\vartheta,T)=\frac{-(T+z_l|\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}(\vartheta)|^2/2)\,\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}(\vartheta)}{1+|\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}(\vartheta)|^2/2}+z_l\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}(\vartheta),$$
$$z(0,\vartheta,T)=\frac{T+z_l|\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}(\vartheta)|^2/2}{1+|\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}(\vartheta)|^2/2}. \tag{65}$$

As is seen from these equations, the ultimate reason why the wavefronts have a whole elliptical curve's worth of boundary points instead of only one point is that the bending angle vector field $\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}$ does not depend on r.

In rectangular coordinates, the map $\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}$ is ill-defined at the origin $\mathbf{r}=\mathbf{0}$. It has a singularity of the type 0/0 since

$$\hat{\boldsymbol{\alpha}}^{\rm sing}_{\rm ep}(\mathbf{r})=\frac{A_0^2((1-\epsilon)r_1,(1+\epsilon)r_2)}{\hat{\Psi}^{\rm sing}_{\rm ep}(\mathbf{r})}.$$

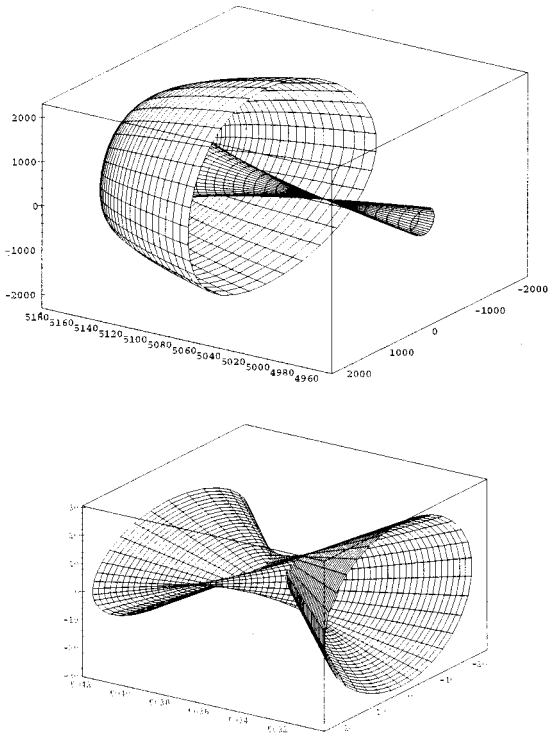

FIG. 10. Typical wavefront in the late regime ($T=T_l+1000$) in the singular case. The bottom panel shows a magnified view of the ''throat'' of the goblet.

One can approach the singular point from different directions in the lens plane and hope that the limit would be the same in all directions. However, the limiting value of the $\hat{\boldsymbol{\alpha}}_{\rm ep}^{\rm sing}(\mathbf{r})$ as $\mathbf{r}\to\mathbf{0}$ is direction dependent, as signaled by the direction-dependent bending angle ϑ in (65). In this atypically singular case, obstructing one light ray (the one that passes through the center of the lens) removes an elliptical curve's worth of points on the wavefront. If a source is outside the rim, then one lensed image is seen of the source, while two images are seen if the source is inside the rim. This phenomenon seems to have been first noted on p. 188 of Ref. 2 for the case of a singular isothermal sphere (i.e., $r_c=\epsilon=0$), where the rim is a circle, as discussed in Sec. VI C.

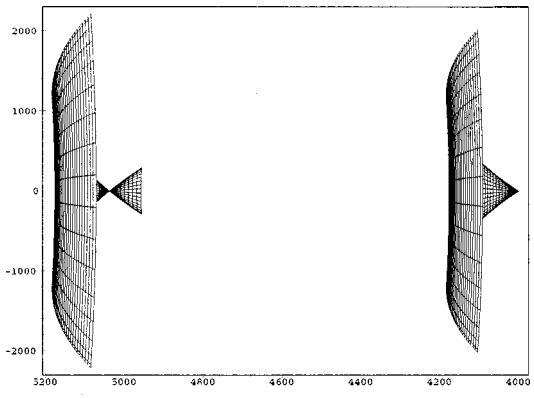

FIG. 11. Progression of a portion of the wavefront in the singular case. The observer is on the right.

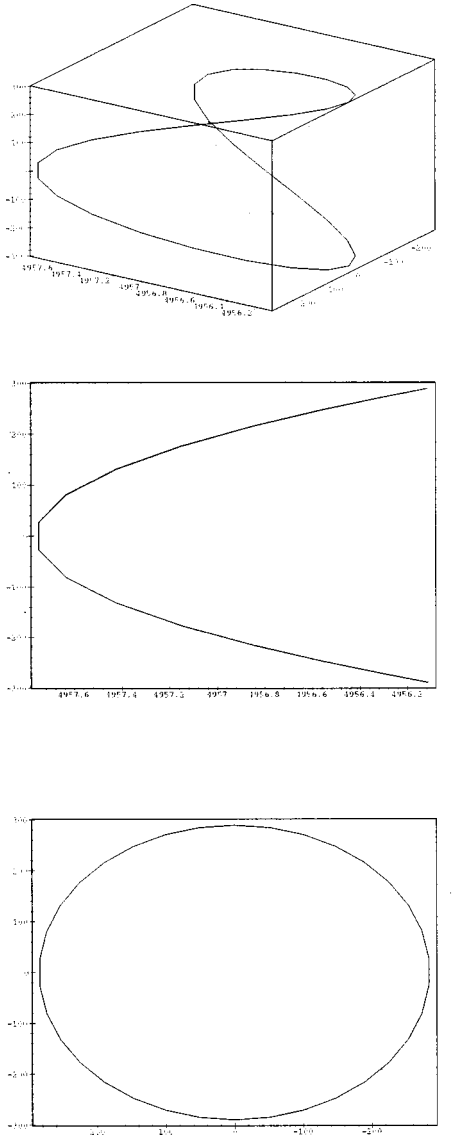

FIG. 12. The boundary of the wavefront in the critical case. Middle and bottom panels show side and front views.

2. Caustic sheet

The caustic sheet in this case is obtained by the same method as in the case of a nonsingular elliptical potential. The use of polar coordinates (r,ϑ) simplifies the calculation. We have

$$\det\frac{\partial \mathbf{s}_z}{\partial \mathbf{r}}=\cos(2\vartheta)\det\frac{\partial \mathbf{s}_z(\mathbf{r})}{\partial(r,\vartheta)}=\cos(2\phi)\left(\frac{\partial x}{\partial r}\frac{\partial y}{\partial \vartheta}-\frac{\partial x}{\partial \vartheta}\frac{\partial y}{\partial r}\right),$$

where x and y are the Cartesian components of the lensing map $\mathbf{s}_z$. In this case, the components reduce to

$$x=\left(\frac{z}{z_l}r-\frac{(z-z_l)A_0(1+\epsilon)}{\sqrt{1+\epsilon\cos(2\vartheta)}}\right)\cos\vartheta,$$

(66)

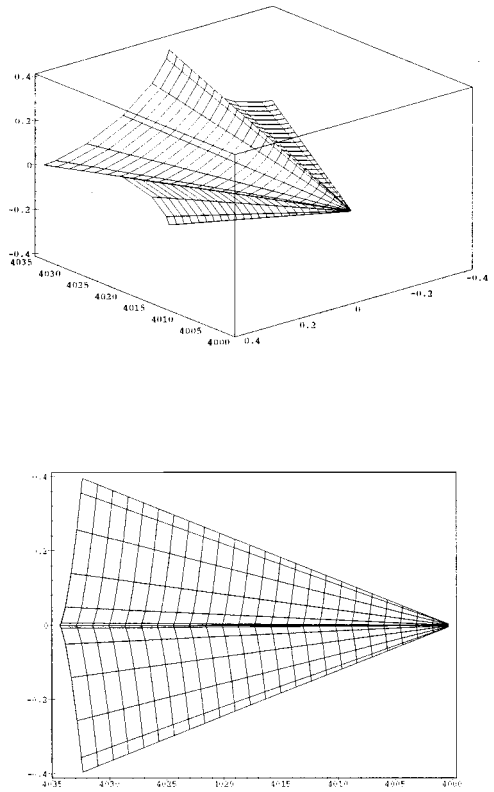

FIG. 13. The caustic sheet in the singular case.

$$y=\left(\frac{z}{z_l}r-\frac{(z-z_l)A_0(1-\epsilon)}{\sqrt{1+\epsilon\cos(2\vartheta)}}\right)\sin\vartheta,$$

and the vanishing of the Jacobian determinant—see Eq. (56)—becomes

$$0=\det\frac{\partial\mathbf{s}_z}{\partial\mathbf{r}}=\frac{z\cos(2\vartheta)}{z_l(1+\epsilon\cos(2\vartheta))^{3/2}}\left[z\left((1+\epsilon\cos(2\vartheta))^{3/2}\frac{r}{z_l}-A_0(1-\epsilon^2)\right)+z_lA_0(1-\epsilon^2)\right].$$

The unphysical root $z=0$, which defines the plane of the observer, is responsible for the absence of a second component caustic sheet, the most notable aspect of the caustic sheet in the singular case. The (one component) caustic sheet is obtained from the nontrivial root, i.e.,

$$z=z_c(r,\vartheta)\equiv-\frac{z_lA_0(1-\epsilon^2)}{(1+\epsilon\cos(2\vartheta))^{3/2}\ r/z_l-A_0(1-\epsilon^2)}. \tag{67}$$

A plot of the caustic sheet is shown in Fig. 13. The surface has four cuspidal ridges with a conical profile, which can clearly be appreciated in the bottom panel of the figure. The tip of the caustic surface lies at the center of the lens (origin) and is removed. Slicing the caustic sheet with constant-z planes we obtain the z-planar caustic curves. The planar caustics are astroid-shaped curves with four cusps, as can be seen in Fig. 14. A source inside the caustic curve has four lensed images, while a source outside has two.

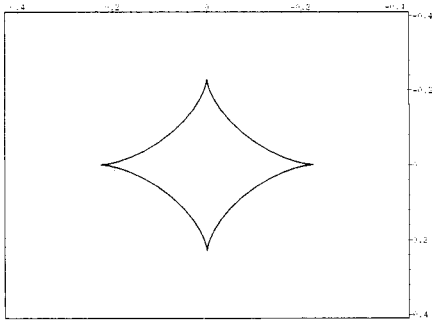

FIG. 14. Typical planar caustic in the singular case.

3. Caustic surfing

The singular elliptical potential provides an excellent opportunity to illustrate the caustic surfing scheme. We start by pointing out that the caustic sheet, which is parametrically given by (66) and (67), can equivalently be given by the following expression:

$$S_0(\mathsf{x}) \equiv ((1+\epsilon)x^2)^{1/3} + ((1-\epsilon)y^2)^{1/3} - (2\epsilon A_0(z-z_l))^{2/3} = 0.$$

This expression assumes that the apex of the lightcone where the caustic lies is at the origin of coordinates, and the lens plane is at a distance z_l from it.

Suppose now that a source is moving on the light source plane with an approximately constant velocity $\mathsf{V}=(V_1,V_2,0)$, carrying its own lightcone with it. Then the caustic on the source's lightcone moves as well, and at any given instant of conformal time t, assuming the motion is sufficiently slow, the caustic surface can be given as $S(\mathsf{x},\mathsf{t}) = S_0(\mathsf{x}-\mathsf{V}\mathsf{t})$. Assume that a space-borne telescope observes at time $\mathsf{t}=0$ an image of the source at peak magnification. From the location of the image, by the (comoving) lens map we can determine the location $\mathbf{s}$ of the source on the source plane. But for our purposes we need to switch the point of view and think of the lightcone of the source instead: The source lies at the origin and the telescope at a location $(x_0,y_0,z_0) = (-\mathbf{s}\ell_{\mathrm{tl}}/\ell_{\mathrm{sl}}, \ell\mathrm{tl}+\ell_{\mathrm{sl}})$, where ℓ_{tl} and ℓ_{sl} are the distance between the telescope and the lens plane, and between the lens plane and the source plane, resp. Because (x_0,y_0,z_0) lies on the comoving future caustic sheet of the source at $\mathsf{t}=0$, we have

$$S_0(\mathsf{x}_0) = 0 = ((1+\epsilon)x_0^2)^{1/3} + ((1-\epsilon)y_0^2)^{1/3} - (2\epsilon A_0 \ell_{\mathrm{tl}})^{2/3}, \tag{68}$$

where we have made the substitution $z_l = \ell_{\mathrm{tl}}$. Now, we calculate the speed $\mathsf{v}_{\min}$ that the telescope needs to stay on the caustic sheet during the time increment $\delta\mathsf{t}$. From our discussion in Sec. V, specifically Eq. (63), we have

$$\mathsf{v}_{\min} = \frac{V_1[(1+\epsilon)/x_0]^{1/3} + V_2[(1-\epsilon)/y_0]^{1/3}}{[(1+\epsilon)/x_0]^{2/3} + [(1-\epsilon)/y_0]^{2/3} + [4\epsilon^2 A_0^2/\ell_{\mathrm{tl}}]^{2/3}} \times \left(\left(\frac{1+\epsilon}{x_0}\right)^{1/3}, \left(\frac{1-\epsilon}{y_0}\right)^{1/3}, -\left(\frac{4\epsilon^2 A_0^2}{\ell_{\mathrm{tl}}}\right)^{1/3} \right).$$

In this expression, all the symbols are known in principle. The values of x_0 and y_0 can be found via the lens mapping at the observation event, as explained above. Clearly, this may be a technically complex procedure, considering that it is only a first step in a iterative scheme to place the telescope on the caustic sheet. Our main purpose is to show that the calculation is feasible in principle.

C. Singular isothermal sphere lens

For a singular isothermal sphere lens, we have $r_c = \epsilon = 0$. The potential and bending angle vector are given respectively as follows:

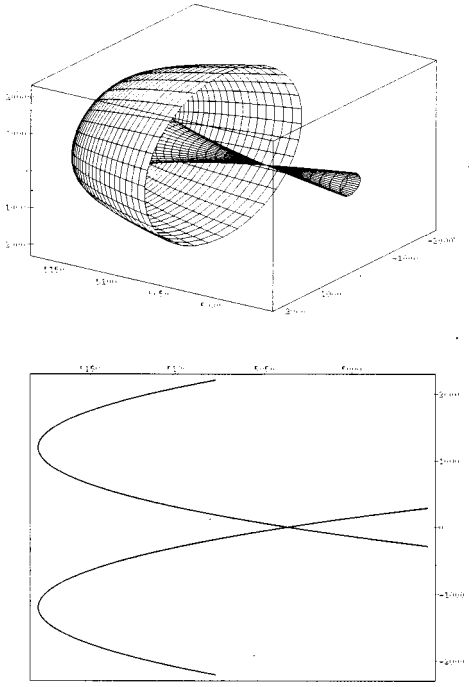

FIG. 15. Wavefront due to a singular isothermal sphere. The top panel shows a field view, and the bottom panel shows a slice or profile of the wavefront. Notice that the wavefront is a surface of revolution around the optical axis.

$$\hat{\Psi}_{ep}^{\mathrm{sis}}(r,\vartheta)=A_0 r, \quad \hat{\boldsymbol{\alpha}}_{\mathrm{ep}}^{\mathrm{sis}}(r,\vartheta)=A_0(\cos\vartheta,\sin\vartheta).$$

The wavefronts are similar to those of the singular elliptical potential, except that the throat of the goblet is a point and the singular rim of the goblet is a circle—see Fig. 15. The caustic surface collapses to a line coinciding with the portion of the optical axis beyond the lens plane (i.e., $z > z_l$). Note the origin on the lens plane, which is a singularity of the lens, is not a part of the caustic line. We have that each z-planar caustic is a point.

VII. CONCLUDING REMARKS AND OUTLOOK

We have shown how to construct a lensing map that takes points on the lens plane into points on a wavefront surface, as opposed to a source plane. This represents a sort of ''instantaneous'' lens map, carrying a sense of constant time. By contrast, the standard lens map carries no sense of time at all. Additionally, the wavefront lensing map has an asymmetric Jacobian matrix. Notice that, barring multiple sheets, the wavefront surface lies very close to a plane in the weak-field case, as illustrated in most of our figures. In the figures the optical axis is magnified several times in order to appreciate the distance between the different sheets in the folded wavefront. Our intial motivation for explicitly constructing a wavefront-lens mapping was inspired by several works (e.g., Refs. 6, 13, 15, 18, and 23). In this respect, it appears that an extension of our constructions in Secs. III and IV beyond the weak field domain is feasible.[24,25]

We took advantage of the conformally flat nature of the flat FL universe in order to make use of a comoving lens equation, which in addition to being comoving is also a conformal lens equation. A conformally related flat space–time exists, of course, in all three types of FL universes, so in principle, our wavefront map could be adapted for interpretation in the open or closed universes. However, in such universes the conformal factor relating the FL universes to the corresponding flat space–time depends on the space point, as well as the time, and the translation of our conformal present proper length function to a cosmological present proper length is not at all as direct as we found it in this work. Some of the subtleties that would be involved in the

translation in the open and closed cases are treated in detail by Frittelli, Kling, and Newman,[26] where the conformally flat lens map and time delay are transformed into the cosmological lensing map and time delay. Nonetheless, we do not need to rely on the conformally related flat space to calculate our present proper length function.

The individual wavefronts for the potentials illustrated proved useful in visualizing the relationship between the location of the source in reference to the caustic, and the number of images observed. Additionally, the wavefronts of the singular potentials helped explain the anomalous counting of images observed by Petters, Levine, and Wambsganss,[2] p. 188. The latter showed that in the case of the singular potentials there is a simple closed curve, that is not a caustic, but that separates regions in the source plane where the number of images differs by one, rather than two. We have here shown that such a curve is the boundary of the wavefront, it is not a caustic, and the number of images differs by one less than in the regular case because one whole sheet of the wavefront is missing due to an obstruction in the lens plane.

Lastly, we have taken a step towards a preliminary scheme for caustic surfing in a meaningful and consistent manner. The form of the subsequent iterations remains an open problem, as does the implementation of the procedure, particularly the measurement of the transverse velocity of the the moving source that one intends to follow. Clearly the caustic surfing proposal depends only on the caustic surface, and not on the method used to obtain it. But the point is that optimal caustic surfing (with the least effort) is achieved only by allowing the telescope to surf the caustic sheet, rather than the planar caustics at fixed distance from the source. One could also imagine scenarios where a telescope may not ride a caustic sheet, but move so as to stay inside certain chambers of the caustic surface (compare with Gaudi and Gould[27]), possibly near higher order singularities. Future studies of the aforementioned issues are clearly warranted.

ACKNOWLEDGMENTS

We are indebted to Scott Gaudi, Marek Kossowki, and Joachim Wambsganss for discussions. We are especially thankful to Jürgen Ehlers for valuable critical feedback on the paper, in particular regarding the difficulties with the validity of the standard approximations in astrophysical gravitational lensing. JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 11 NOVEMBER 2002

Continuum spin foam model for 3d gravity

José A. Zapata[a)]
Instituto de Matemáticas UNAM, Morelia Mich. 58090 México

(Received 9 May 2002; accepted 13 May 2002)

An example illustrating a continuum spin foam framework is presented. This covariant framework induces the kinematics of canonical loop quantization, and its dynamics is generated by a *renormalized* sum over colored polyhedra. Physically the example corresponds to 3d gravity with cosmological constant. Starting from a kinematical structure that accommodates local degrees of freedom and does not involve the choice of any background structure (e.g., triangulation), the dynamics reduces the field theory to have only global degrees of freedom. The result is *projectively* equivalent to the Turaev–Viro model. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1509850]

I. INTRODUCTION

Several TQFTs can be written as a sum over assignments of spins to polyhedra: that is, as spin foam models. A trend in today's research is to try to find a model of a similar type that is related to 4d gravity.[1] Regarding these models as fundamental amounts to postulating that gravity is only effectively a field theory, but fundamentally it has only finitely many degrees of freedom and a privileged polyhedron (or triangulation), comes along with space–time. It has been proposed to get rid of this extra structure with a sum over triangulations.[2] In this article we will explore another route. We will regard the continuum as fundamental and take the diffeomorphism invariance of general relativity as the guiding symmetry. We share this principle with canonical loop quantization.[3]

In this article we present an example. It is defined in the continuum, but it turns out to be equivalent to the Turaev–Viro model.[4] The interest of our example relies on the fact that it is a continuum spin foam model. More precisely, the construction induces the kinematics of q-deformed loop quantization in the spatial slices, and the projector to the space of physical states is constructed as a renormalized sum over colored (by spins) polyhedra.

The construction does not involve the choice of any background structure, and the diffeomorphism group acts faithfully at the kinematical level.

The strategy used to generate this family of examples (one for every value of a deformation parameter) can be adapted to other spin foam models. A ''renormalizability condition'' determines whether the continuum theory exists. The proof that other topological models satisfy the condition proceeds almost in complete parallel to the proof given here. Interestingly, there are reasons to believe that there are other examples corresponding to genuine field theories. In the case of compact QED, the first steps in this direction have already been taken.[5]

In Sec. II we construct the example and prove the equivalence with the Turaev–Viro model. Section III gives an interpretation of the projector as a renormalized sum over quantum geometries.

II. A CONTINUUM SPIN FOAM MODEL

This is the central section of the article. In the beginning we present the construction of the example and show its main properties. With minor modification of the proofs, the construction

a)Electronic mail: zapata@math.unam.mx

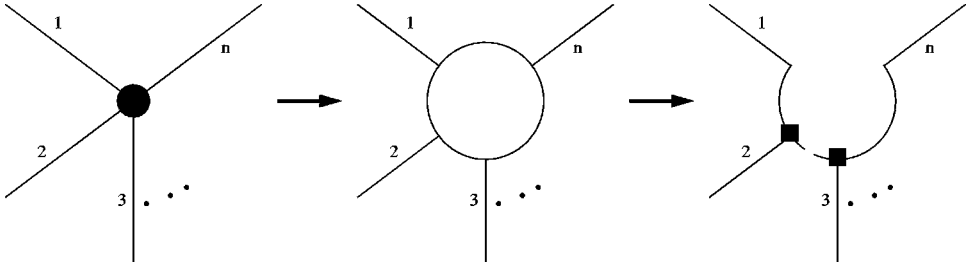

FIG. 1. The construction uses an arbitrary numbering of the edges coming to a vertex. Internal vertices are shown as square dots and internal edges are dashed lines.

applies to other topological spin foam models and the same strategy could apply to other less trivial spin foam models as well. In the last subsection, we prove the projective equivalence with the Turaev–Viro model.

A. Embedded graphs and embedded polyhedra

In this work all the spaces and maps are piecewise linear.

Consider a compact surface without boundary Σ. By an embedded graph Γ we mean a finite one-dimensional CW-complex all of whose vertices have valence two or bigger, together with an embedding into Σ. The set of all graphs embedded into a given surface will be denoted by $G(\Sigma)$. This set has a natural partial order given by inclusion and it is directed.

Similarly, consider a three-manifold with boundary M. By an embedded polyhedron X we mean a finite two-dimensional CW-complex all of whose internal edges have valence two or bigger, together with an embedding into M such that $X\cap\partial M$ denoted by ∂X belongs to $G(\partial M)$. The set of all polyhedra embedded into a given three-manifold will be denoted by $P(M)$. Again, this set is partially ordered and directed.

B. Data from lattice gauge theory

Our construction starts with data generated by ''lattice gauge theory'' on all lattices embedded into given space–times.

For every $\Gamma\in G(\Sigma)$ we are given a complex vector space $C(\Gamma)$ and for every $X\in P(M)$ we are given a linear functional $\Omega_X^n: C(\partial X)\to\mathbb{C}$. Thus, for each surface Σ we get a collection of vector spaces labeled by embedded graphs and for each three-manifold M we get a collection of linear functionals labeled by embedded polyhedra. Our work is based on the compatibility of these collections of structures with the partial order of the labeling sets.

Now we define these objects in the example presented here. We follow the notation of Turaev and Viro[4] as closely as possible as well as their conventions and normalizations.

Fix an integer $r\geqslant 3$ and denote by I the set of spins $\{0,1/2,\ldots,(r-2)/2\}$. A triple of spins is admissible, $(i,j,k)\in adm$, if $i+j+k$ is an integer and

$$i\leqslant j+k,\quad j\leqslant k+i,\quad k\leqslant i+j,\quad i+j+k\leqslant r-2.$$

Given an embedded graph $\Gamma\in G(\Sigma)$ we assign to it an abstract simple graph Γ_s. The vertices of a simple graph are always trivalent; a graph dual to a triangulation is an example of a simple graph.

Γ_s is constructed by blowing up the vertices of Γ as we explain below. To each edge of Γ corresponds one edge in Γ_s and to each vertex of Γ we assign several ''internal vertices'' and ''internal edges'' in Γ_s in the manner indicated by Fig. 1.

A coloring α of Γ is an assignment of spins to its edges and intertwiners to its vertices. An intertwiner is a coloring (with spins) of the internal edges assigned to the vertex. Clearly, a

coloring α of Γ induces a coloring of Γ_s, an assignment of spins to its edges. The coloring is admissible, $\alpha \in adm(\Gamma)$, if at each vertex v of Γ_s the triple $(\alpha(e_1(v)),\alpha(e_2(v)),\alpha(e_3(v))) \in adm$.

Then $C(\Gamma)$ is defined by

$$C(\Gamma)=\mathbb{C}[adm(\Gamma)],$$

where $\mathbb{C}[adm(\Gamma)]$ is the complex vector space freely generated by the elements of $adm(\Gamma)$; in addition, the inner product makes $adm(\Gamma)$ an orthonormal set. A different choice of internal structure in the construction of Γ_s results in an *a priori* different vector space; however, ''recoupling moves'' on the internal edges define an isomorphism between any two spaces generated by different choices. This is reviewed in the Appendix. We identify all these isomorphic vector spaces and call them $C(\Gamma)$.

In the non-q-deformed case, when the set of spins is infinite, the space just constructed is the space of square integrable functions of (generalized) SU(2)-connections,[6] and it is the heart of the kinematics of canonical loop quantum gravity.[3]

X_s, a simple abstract polyhedron, is constructed by blowing up the edges and vertices of $X \in P(M)$ as we explain below. We proceed in complete parallel to the case of graphs. First, we surround every edge by a cylindrical neighborhood and every vertex by a spherical neighborhood; in this way we created an internal (empty) bubble for each edge and vertex of X in analogy with the middle picture of Fig. 1. Then, we will erase one internal face in each internal bubble, as we did in the last picture of Fig. 1, to create X_s. There are only two rules to select the face to be erased from each internal bubble. In the case of edge-bubbles, we erase one of the lateral faces (not a face shared with a vertex-bubble). And in the case of the vertex-bubbles, we erase one of the faces shared with an edge-bubble. Notice that the valence of any edge in X_s is three and that at every vertex of X_s six faces meet.

A coloring φ of X is an assignment of spins to its faces and intertwiners to its edges. An intertwiner is a coloring (with spins) of the internal faces assigned to the edge. The coloring is admissible, $\varphi \in adm(X)$, if at each edge e of X_s the triple $(\varphi(f_1(e)),\varphi(f_2(e)),\varphi(f_3(e))) \in adm$.

Each colored polyhedra is assigned a weight. This assignment is a simple extension of the Turaev and Viro weight to embedded (not necessarily simple) polyhedra. The Turaev–Viro weight is constructed as the product of weights assigned to its vertices and faces (with a correction due to the boundary edges):[4]

$$|X|_\varphi = |X_s|^{TV}_\varphi = w^{-2\chi(X_s)+\chi(\partial X_s)} \prod_{f\in F(X_s)} w^{2\chi(f)}_{\varphi(f)} \prod_{e\in E(X_s)} w^{\chi(e)}_{\partial\varphi(e)} \prod_{v\in V(X_s)} |\hat{T}_v|_\varphi .$$

Here χ denotes Euler characteristic. $w_{\varphi(f)}$ and $w_{\partial\varphi(e)}$ denote the quantum group analog of the dimension of the spin j representation for $j=\varphi(f)$ and $j=\partial\varphi(e)$, respectively. $|\hat{T}_v|_\varphi$ is the quantum $6j$ symbol corresponding to the six-tuple of spins of the faces meeting at vertex v.

Then $\Omega_X : C(\partial(X)) \to \mathbb{C}$ is defined by $\Omega_X(\alpha)=\Sigma_\varphi |X|_\varphi$, where the sum runs over the colorings $\varphi \in adm(X)$ that induce α in the boundary. We will work with the linear functional normalized dividing by the ''vacuum to vacuum amplitude'' $\Omega_X(j=0)$,

$$\Omega^n_X(\alpha)=\frac{\Omega_X(\alpha)}{\Omega_X(j=0)}.$$

Note that $\Omega^n_X(\alpha)$ can also be defined from $\Omega'_X(\alpha)=\Sigma_\varphi |X|'_\varphi$ which is defined from a less refined Turaev–Viro weight $|X|'_\varphi$ in which the normalizing factor $w^{-2\chi(X_s)+\chi(\partial X)}$ is omitted.

The construction of X_s involves a choice of ''internal structure'' on the edges of X. However, the invariance results of Turaev and Viro imply that Ω_X and Ω'_X are independent of this choice. This is reviewed in the Appendix.

The weight assigned to a colored polyhedron is what defines the dynamics of this example. We extended the Turaev–Viro weight in a simple manner, but it is possible to derive a weight assignment for general polyhedra that reduces to the Turaev–Viro weight in the case of simple polyhedra.[7]

C. From lattices to the continuum

Now we will leave single ''lattices'' and go to the continuum.

Consider two embedded graphs $\Gamma_1 \leqslant \Gamma_2$ in $G(\Sigma)$. It is easy to see that $\alpha \in adm(\Gamma_1)$ defines an admissible coloring in Γ_2 by simply extending the coloring with color $j=0$ in the additional edges and extending the intertwiners also coloring with $j=0$ in the additional internal edges. Thus, we can take this natural inclusion for granted and write $C(\Gamma_1) \subset C(\Gamma_2)$. Due to this property we can define $C(\Sigma)$ as the inductive limit or co-limit[8] of the nested spaces labeled by graphs,

$$C(\Sigma) = \text{co-}\lim_{\Gamma \to \Sigma} C(\Gamma).$$

Similarly, for $\alpha \in C(\partial M)$ induced by $\alpha \in adm(\Gamma)$ we define

$$\Omega^n_M(\alpha) = \lim_{X \to M} \Omega^n_X(\alpha), \quad \partial X \geqslant \Gamma. \tag{1}$$

When the limit exists it defines $\Omega^n_M : C(\partial M) \to \mathbb{C}$. In our example we prove its existence in the next subsection. However, the analogous limit in theories constructed from other lattice gauge theories may not exist. The existence of the limit should be interpreted as a renormalizability condition.

Note that the extendibility of colorings from subgraphs implies that $adm(\Sigma)$ and similarly $adm(M)$ can be defined. A coloring in $\alpha \in adm(\Sigma)$ should be thought of as a coloring of all graphs, bigger than a certain minimal graph $\Gamma(\alpha)$, that is compatible with inclusion of graphs. We then have the equivalent definition $C(\Sigma) = \mathbb{C}[adm(\Sigma)]$.

D. Renormalizability and cellular decompositions

A polyhedron $X \in M$ induces a cellular decomposition for (M,Γ), where $\Gamma \in G(\partial M)$, if $\partial X = \Gamma$ and $M - \partial M - X$ is a disjoint union of open balls.

Theorem 1: *Given any polyhedron $X \in P(M)$ there is a finer polyhedron $X' \in P(M)$, $X \leqslant X'$, such that X' induces a cellular decomposition for (M,Γ) for some $\Gamma \geqslant \partial X$.*

Proof: First note that for every manifold with boundary one can find embedded polyhedra inducing cellular decompositions. Take for example the cellular complex dual to any triangulation of the manifold. Once we have one cellular decomposition, we can generate many by subdivision of the induced cells adding faces to the original polyhedron.

Let $X'' \in P(M)$ induce a cellular decomposition that is sufficiently fine in the sense that for each open ball in $\cup_{r=1}^n B_r = M - \partial M - X''$ we have that $B_r - X$ is a finite union of open balls, $B_r - X = \cup_{s=1}^{m_r} B'_{r,s}$.

Since we are working with piecewise-linear spaces, such a X'' can be constructed from an initial cellular decomposition after finitely many refinements.

Let $X' = X'' \cup X$. Then $M - \partial M - X' = \cup_{r=1}^n \cup_{s=1}^{m_r} B'_{r,s}$. □

Theorem 2: *Fix $X \in P(M)$ a polyhedron inducing a cellular decomposition of (M,Γ). For any finer polyhedron $X' \in P(M)$, $X \leqslant X'$, we have*

$$\Omega^n_X = \Omega^n_{X'}|_{C(\partial X)}.$$

The proof of this theorem requires some previous definitions and lemmas presented after the following corollary.

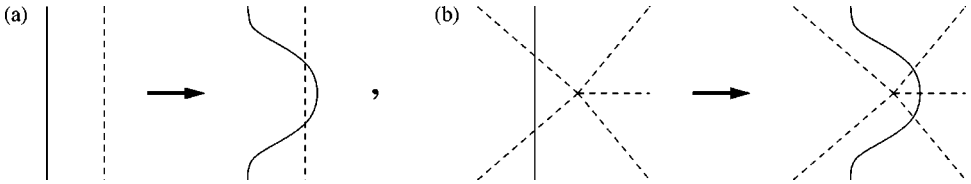

FIG. 2. In each picture the paper corresponds to a set of faces of a portion of the polyhedron. The solid lines indicate edges where one (or more) faces meet the paper from above. The dashed lines correspond to faces that are below the paper. (a) Illustrates a top face(s) sliding through a wedge with bottom face(s). (b) Illustrates a top face(s) sliding through a corner with bottom faces.

Corollary 1 (renormalizability): In the definition

$$\Omega_M^n = \lim_{X \to M} \Omega_X^n$$

the limit exists. In this sense, the theory defined by the collection of linear functionals Ω_X' *is renormalizable*.

We should mention that for the linear functionals Ω_X' and Ω_X the limit does not exist. Only the renormalized functional exists in the continuum.

Wedge and corner moves generalize the lune $\mathcal{L}$ and Matveev $\mathcal{M}$ moves (and their inverses) on simple polyhedra. Wedge moves describe a face of an embedded polyhedron $X \in P(M)$ sliding through a wedge, while in corner moves a face slides through a corner. See Fig. 2.

Lemma 1 (Invariance under wedge and corner moves): Let $X \in P(M)$ *and* $\alpha \in adm(\partial X)$. *Then* $\Omega_X'(\alpha)$ *is invariant under wedge and corner moves*.

Proof: It is clear that a wedge move in X induces a sequence of $\mathcal{L}$ or $\mathcal{L}^{-1}$ moves in X_s. Similarly, a corner move in X induces a sequence of $\mathcal{M}$ and/or $\mathcal{M}^{-1}$ and/or $\mathcal{L}$ and/or $\mathcal{L}^{-1}$ in X_s. Thus, this lemma is a direct consequence of the similar invariance lemmas of Turaev and Viro.[4]□

The following lemma is a well-known consequence of the definition a properties of $|X|_\varphi'$; see Refs. 4 and 9.

Lemma 2 (The color $j=0$ *is invisible): Let* $X \in P(M)$ *and* $\varphi \in adm(X)$. *Construct the polyhedron* $X(\varphi)$ *erasing from* X *the "invisible" two-strata, the ones colored with* $j=0$. *Then*

$$|X(\varphi)|_\varphi' = |X|_\varphi'.$$

Also, for $\alpha \in adm(\partial X)$ *construct* $X(\alpha)$ *erasing from* X *the two-strata meeting* ∂X *in edges colored with* $j=0$. *Then*

$$\Omega_{X(\alpha)}'(\alpha) = \Omega_X'(\alpha).$$

Proof of Theorem 2: Consider a collection of nested polyhedra $\{X_r\}$ such that $X = X_1 \leqslant X_2 \leqslant \cdots \leqslant X_n = X'$ where $X_{r+1} - X_r \subset B_{s(r)}$ for some cell B_s in $\cup_{s=1}^n B_s = M - \partial M - X$ with $B_{s(r)} \neq B_{s(t)}$ if $r \neq t$.

We will show that $\Omega_{X_{r+1}}^n|_{C(\partial X_r)} = \Omega_{X_r}^n$.

Let $\partial B_{s(r)} - \partial M = \cup_{u=1}^m F_u$ with F_u faces of X.

The closures of the faces in $X_{r+1} - X_r$ may intersect several of the faces of $\partial B_{s(r)}$, but we can use wedge and corner moves on X_{r+1} (inside $B_{s(r)}$) until only F_1 (and ∂M if $B_{s(r)}$ is a boundary cell) is intersected. Call the resulting polyhedron Y_{r+1}'. Remove from Y_{r+1}' the two-strata meeting $\partial Y_{r+1}' - \partial X_r$; we call this polyhedron Y_{r+1}.

Let $B \subset M$ be an open ball such that $Y_{r+1} - X_r \subset B$, and $B \cap X_r$ lies in the interior of F_1.

Then

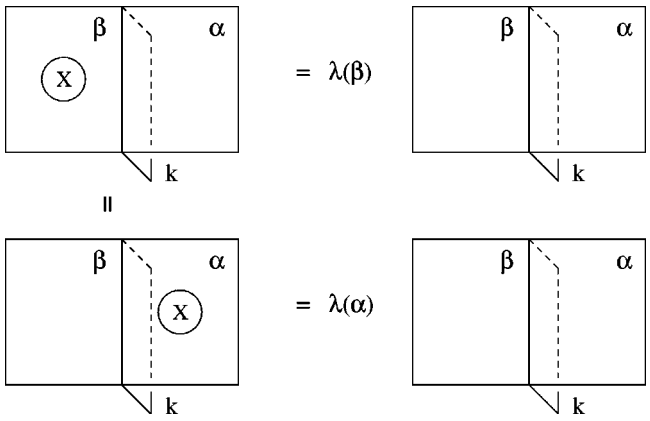

FIG. 3. The pictures should be thought of as Ω' evaluations with the indicated boundary coloring.

$$\Omega'_{X_{r+1}}|_{C(\partial X_r)}(\alpha)=\Omega'_{Y_{r+1}}(\alpha)=\sum_{\beta\in adm(Y_{r+1}\cap\partial B)}\Omega'_{Y_{r+1}\cap B^c}(\alpha\cup\beta)\Omega'_{Y_{r+1}\cap\overline{B}}(\beta)$$

$$=\sum_{\beta\in adm(X_r\cap\partial B)}\Omega'_{X_r\cap B^c}(\alpha\cup\beta)\Omega'_{Y_{r+1}\cap\overline{B}}(\beta)$$

$$=\lambda\sum_{\beta\in adm(X_r\cap\partial B)}\Omega'_{X_r\cap B^c}(\alpha\cup\beta)\Omega'_{X_r\cap\overline{B}}(\beta)=\lambda\Omega'_{X_r}(\alpha),$$

where B^c and $\overline{B}$ denote the complement and the closure of B, respectively. In the first equality Lemmas 1 and 2 were used. In the second and fifth equalities the associativity of Ω' was used. The fourth equality is due to the following lemma.

Lemma 3: The quotient $\Omega'_{Y_{r+1}\cap\overline{B}}(\beta)/\Omega'_{X_r\cap\overline{B}}(\beta)=\lambda$ *is independent of the coloring.*

Proof of the Lemma: Let $(\beta,\alpha,k)\in adm$. The proof follows picture in Fig. 3.

In the upper left picture the face with a circle and an X inside represents $Y_{r+1}\cap\overline{B}$; the rest of the faces play only an auxiliary role. Using wedge moves the X slides through the edge. The result is the picture in the bottom left. There we can again identify the face with a circle and an X with $Y_{r+1}\cap\overline{B}$. From the pictures in the left to the ones in the right we have only used $\Omega'_{Y_{r+1}\cap\overline{B}}(\gamma)=\lambda(\gamma)\Omega'_{X_r\cap\overline{B}}(\gamma)$.

The lemma follows from the fact that the set of spins is adm-connected; given any two spins there is a chain of admissible triples linking them. □

This completes the proof of Theorem 2. □

E. Spaces of physical states and propagators

We will now define adequate spaces of physical states and propagators. To do this cleanly we need to use the language of cobordism theory. A cobordism W is defined by the triple

Corollary 1 (renormalizability): In the definition $W=(M;i_{\Sigma_0}:\Sigma_0\to\partial M,i_{\Sigma_1}:\Sigma_1\to\partial M)$ where M is a three-manifold with boundary, Σ_0 and Σ_1 are compact surfaces without boundary, $\partial M=i_{\Sigma_0}(\Sigma_0)\cup i_{\Sigma_1}(\Sigma_1)$ and $i_{\Sigma_0}(\Sigma_0)\cap i_{\Sigma_1}(\Sigma_1)=\emptyset$. Cobordisms can be composed in an obvious way. Also, there is a special cobordism for each Σ compact surface without boundary, $id_\Sigma=(\Sigma\times I;i_0(p)=(p,0),i_1(p)=(p,1))$.

To every Σ we assign a space of physical states $H(\Sigma)\subset C(\Sigma)^*$ defined by $H(\Sigma)=\Omega^n_{\Sigma\times I}(C(\Sigma))$. In the jargon of the field $\Omega^n_{\Sigma\times I}$ is referred to as the "generalized projector," even though $H(\Sigma)\subset C(\Sigma)^*$. It is useful to note that $H(\Sigma)$ is spanned by vectors $\overline{\alpha}$ defined by

$$\overline{\alpha}[\delta]=\Omega^n_{\Sigma\times I}(i_0^{-1}{}^*\alpha\cup i_1^{-1}{}^*\delta),$$

where $\alpha,\delta\in C(\Sigma)$ and we have used the pull back maps $i_0^{-1}{}^*:adm(\Sigma)\to adm(\partial(\Sigma\times I)_{t=0})$, $i_1^{-1}{}^*:adm(\Sigma)\to adm(\partial(\Sigma\times I)_{t=1})$. The inner product in $H(\Sigma)$ is defined by

$$(\overline{\alpha},\overline{\beta})=\overline{\alpha}(\beta).$$

Now for a general cobordism define the map $\Phi^n_W:H(\Sigma_0)\to C(\Sigma_1)^*$ by

$$\Phi^n_W(\overline{\alpha})[\delta]=\Omega^n_M(i_0^{-1}{}^*\alpha\cup i_1^{-1}{}^*\delta).$$

Theorem 3: $\Phi^n_W(H(\Sigma_0))\subset H(\Sigma_1)$

Proof: Consider a regular neighborhood M'' of $i_{\Sigma_1}\Sigma_1$ in M; it has the $\Sigma_1\times I$ topology. Denote its boundary by $\partial M''=\Sigma_1'\cup\Sigma_1$. Also call $M'=M-M''$; clearly $M'\approx M$ and $\partial M''=\Sigma_0\cup\Sigma_1'$.

We are going to compute $\Phi^n_W(\overline{\alpha})[\delta]$ using the following auxiliary structures: First, two boundary graphs Γ_0,Γ_1 such that $\Gamma_0\geqslant\Gamma(\alpha)$ and $\Gamma_1\geqslant\Gamma(\delta)$; second, $X\in P(M)$ inducing a cellular decomposition of $(M;i_{\Sigma_0}\Gamma_0\cup i_{\Sigma_1}\Gamma_1)$ such that $X|_{M''}\in P(M'')$ induces a cellular decomposition of $(M'';i_{\Sigma_0}\Gamma_0\cup i_{\Sigma_1'}\Gamma_1')$, and $X|_{M'}\in P(M')$ induces a cellular decomposition of $(M';i_{\Sigma_1'}\Gamma_1'\cup i_{\Sigma_1}\Gamma_1)$:

$$\begin{aligned}\Phi^n_W(\overline{\alpha})[\delta]&=\frac{\Omega'_X(\alpha\cup\delta)}{\Omega'_X(j=0)}\\&=\sum_\beta\frac{\Omega'_{X|_{M'}}(\alpha\cup\beta)\Omega'_{X|_{M''}}(\beta\cup\delta)}{\Omega'_X(j=0)}\\&=\left(\frac{\Omega'_{X|_{M'}}(j=0)\Omega'_{X|_{M''}}(j=0)}{\Omega'_X(j=0)}\right)\sum_\beta\ \Omega^n_{M'}(i_{\Sigma_0}^{-1}{}^*\alpha\cup i_{\Sigma_1'}^{-1}{}^*\beta)\Omega^n_{M''}(i_{\Sigma_1'}^{-1}{}^*\beta\cup i_{\Sigma_1}^{-1}{}^*\delta)\\&=\lambda(\Gamma_1')\sum_\beta\ \Omega^n_M(i_{\Sigma_0}^{-1}{}^*\alpha\cup i_{\Sigma_1}^{-1}{}^*\beta)\Omega^n_{\Sigma\times I}(i_0^{-1}{}^*\beta\cup i_1^{-1}{}^*\delta).\end{aligned}\tag{2}$$

The sums are over $\beta\in adm(\Gamma_1')$. In the last equality we used the invariance under homeomorphisms; this property follows from the definitions and will be described in the next subsection. We could have used another cellular decomposition to perform the calculation or another auxiliary surface Σ_1'. The result would have been another expression for the same element of $H(\Sigma)$.

The desired result follows from the above equation. □

Note that the maps assigned to identity cobordisms are identity maps, $\Phi^n_{id_\Sigma}|_{H(\Sigma)}=id_{H(\Sigma)}$. Now we show that Φ^n_W satisfies the projectivized propagator condition.

Theorem 4: *For any two composable cobordisms,* $W_1=(M_1;i_{\Sigma_0},i_{\Sigma_1})$ *and* $W_2=(M_2;i'_{\Sigma_1},i_{\Sigma_2})$, *we have* $\Phi^n_{W_2}\circ\Phi^n_{W_1}=\lambda\Phi^n_{W_2\circ W_1}$.

Proof: The definition of Φ^n_W requires that its argument is written in a canonical form. We use (2). We follow the strategy of the previous theorem's proof: with X an auxiliary polyhedron giving a cellular decomposition for W_1 and Y for W_2, we will write the expression in terms of Ω' to use associativity. Then we will rewrite in terms of the renormalized objects of $X\cup Y$, which is an auxiliary polyhedron giving a cellular decomposition for $W_2\circ W_1$.

$$\Phi^n_{W_2}\circ\Phi^n_{W_1}(\overline{\alpha})(\delta)=\lambda(\Gamma_1')\sum_\beta\ \Omega^n_{M_1}(i_{\Sigma_0}^{-1}{}^*\alpha\cup i_{\Sigma_1}^{-1}{}^*\beta)\Omega^n_{M_2}(i'^{-1}_{\Sigma_1}{}^*\beta\cup i_{\Sigma_2}^{-1}{}^*\delta)$$

$$=\lambda(\Gamma_1')\left(\frac{\Omega'_{X\cup Y}(j=0)}{\Omega'_X(j=0)\Omega'_Y(j=0)}\right)\Omega^n_{X\cup Y}(\alpha\cup\delta)$$

$$=\lambda(\Gamma_1')\Lambda(\Gamma_1)\Phi^n_{W_2\circ W_1}(\overline{\alpha})(\delta).$$

□

Here we proved the last two theorems for the example that we are presenting, but the proofs extend with very little change to the general case in which the renormalizability condition (1) holds.

F. Action of the homeomorphism group

A homeomorphism between two manifolds with boundary $f:M\to N$ induces a map among the spaces of embedded polyhedra. Colorings are pulled back by this map. Similarly, the restriction of the map to the boundaries induces a pull back map among the spaces of colorings which leads to $U_f:C(\partial M)\to C(\partial N)$ defined by the action $U_f(\alpha)=f^{-1}{}^*(\alpha)$. The following identities describe the action of homeomorphisms

$$|X|'_\varphi=|f(X)|'_{f^{-1}{}^*\varphi},\quad \Omega'_X(\alpha)=\Omega'_{f(X)}(f^{-1}{}^*\alpha),\quad \Omega^n_M=\Omega^n_{f(M)}\circ U_f.$$

Note that the action of f is not trivial due to its action in the boundaries. The language of the last subsection already assumes this level of invariance; W is only sensible to M up to a homeomorphism preserving the boundary. By dual action of U_f we have a representation of the modular group (mapping class group) of Σ on $H(\Sigma)$. Indeed, if f and g are two isotopic homeomorphisms, U_f and U_g induce the same map in $H(\Sigma)$. In particular, if f is connected to the identity,

$$U_f|_{H(\Sigma)}=id_{H(\Sigma)}.$$

Thus, for homeomorphisms connected with the identity we have $\Omega^n_{f(M)}=\Omega^n_M$.

In relation with canonical loop quantum gravity we have the following question: *Is it possible to find first the space of homeomorphism invariant states and construct $H(\Sigma)$ from it?* The next section gives a satisfactory affirmative answer to this question. Here we present a preliminary answer.

Define the space of states invariant under homeomorphisms connected with the identity $\mathcal{H}_{hom}(\Sigma)\subset C(\Sigma)^*$ as in Ref. 3. This space is spanned by elements of the type

$$\tilde{\alpha}[\beta]=s(\Gamma(\alpha))\,\delta_{[\Gamma(\alpha)][\Gamma(\beta)]}(\alpha,f_0^{-1}{}^*\beta),$$

where the factor $s(\Gamma(\alpha))$ depends on the symmetry of the graph, and f_0 is a homeomorphism (connected with the identity) on Σ taking $\Gamma(\beta)$ to $\Gamma(\alpha)$.

Clearly, $\tilde{\alpha}=\tilde{\beta}$ only if there is homeomorphism (connected with the identity) f_0 such that $U_{f_0}(\tilde{\beta})=\tilde{\alpha}$. Thanks to the invariance properties stated above, we can define

$$P(\tilde{\alpha})=\overline{\alpha}. \tag{3}$$

In this way the Reisenberger–Rovelli projector, $P(\mathcal{H}_{hom}(\Sigma))=H(\Sigma)$,[10] reconstructs the space of physical states from the space of homeomorphism invariant states.

G. Projective equivalence with the Turaev–Viro model

A particularization of the construction of Turaev and Viro[4] can be described as follows. *To each triangulated surface T assign the vector space $C(T^*)$, where T^* is the graph dual to the triangulation. Similarly, to each cobordism between triangulated surfaces W assign the map $\Phi_W: C(T_0^*) \to C(T_1^*)$ by the formula*

$$\Phi_W(\alpha) = \sum_{\beta} \Omega_{\Delta^*}(i_{T_0}^{-1*}\alpha \cup i_{T_1}^{-1*}\beta)\beta,$$

where α and β are admissible colorings of the graphs dual to the triangulations T_0 and T_1, respectively, and Δ is a triangulation of the interpolating manifold of W.

The structures are then refined to construct a TQFT. The spaces of physical states are $Q(T^*) = C(T^*)/\ker\Phi_{id_T}$ with inner product $([\alpha],[\beta]) = \Omega_{T\times I}(\alpha,\beta)$. The propagators are induced by Φ_W, $\Psi_W: Q(T_0^*) \to Q(T_1^*)$, $\Psi_W[\alpha] = \Sigma_\beta \Omega_{\Delta^*}(\alpha,\beta)[\beta]$.

The invariance result says that two spaces $Q(T)$ constructed from different triangulations of the same surface are isomorphic, and that the map $\Psi_W: Q(T_0^*) \to Q(T_1^*)$ is independent of the triangulation up to conjugacy by the mentioned isomorphisms.

Now we compare the Turaev–Viro model with our construction.

Theorem 5: *For any triangulation T of a surface Σ, the map $\overline{i_{T^*}}: Q(T^*) \to H(\Sigma)$ defined by $\overline{i_{T^*}}([\alpha]) = \overline{\alpha}$ is an isomorphism, and for any cobordism W*

$$\overline{i_{T_1^*}}^{-1} \circ \Phi_W^n \circ \overline{i_{T_0^*}} = \Lambda \Psi_W.$$

Proof: Since the dual of any triangulation of a three-manifold gives a cellular decomposition, it is easy to verify that $\overline{i_{T^*}}$ is a dilatation (a multiple of an isometry) by $\lambda = (\Omega_{\Delta^*_{id_\Sigma}}(j=0))^{-1/2}$ (where Δ_{id_Σ} is a triangulation of $\Sigma \times I$ compatible with T in both boundaries), and that the map taking $\overline{\alpha}$ to $\lambda^2 \Sigma_\beta \overline{\alpha}(\beta)[\beta]$ is its inverse.

$\overline{i_{T_1^*}}^{-1} \circ \Phi_W^n \circ \overline{i_{T_0^*}} = \Lambda \Psi_W$ follows from a simple application of definitions. We obtain $\Lambda = (\Omega_{\Delta^*_{id_{\Sigma_1}}}(j=0)\Omega_{\Delta_W^*}(j=0))^{-1}$, where Δ_W is a triangulation of the interpolating manifold of W compatible with T_0 and T_1. □

III. INTERPRETATION AS A RENORMALIZED SUM OVER QUANTUM GEOMETRIES

A. Preliminaries

Recall that we gave an alternative definition of $C(\Sigma)$ as $\mathbb{C}[adm(\Sigma)]$. Similarly, after having enunciated the "color $j=0$ is invisible" lemma, we can give an equivalent definition of the linear functional Ω'_X:

$$\Omega'_X(\alpha) = \sum_{\varphi} |X(\varphi)|'_\varphi,$$

where the sum runs over colorings $\varphi \in adm(M)$ such that $\partial\varphi = \alpha$ and $X(\varphi) \leqslant X$. That is, X serves only to restrict the set of colorings allowed in Ω'_X.

In this way, we can see Ω_M^n of formula (1) as a renormalized sum over colorings in which the "restricting box" X grows infinitely large.

In particular, *the "generalized projector" $\Omega^n_{\Sigma\times I}$ is a renormalized sum over quantum geometries.*

The term *quantum geometry* means a history in the form of a colored polyhedron because any slice of it defines a quantum geometry in canonical loop quantum gravity. In formal path integral quantization of general relativity the central object is an integral over diffeomorphism classes of metrics. Our quantum geometries are not analogous to diffeomorphism classes of metrics because

they are defined for a fixed embedding. *Is there an interpretation of the "generalized projector" as a sum over knot classes of colored polyhedra?* Below we give an affirmative answer.

B. Summing over knot classes of colorings

Consider $X \in P(M)$, $Y \in [X]$ if and only if there is a homeomorphism $f: M \to M$ such that $f|_{\partial M} = id$ and $f(Y) = X$. The set of such classes will be denoted by $KP(M)$.

There is a natural partial ordering in $KP(M)$ defined by $[X] \leqslant [Y]$ if and only if there are representatives $X \in [X]$, $Y \in [Y]$ satisfying $X \leqslant Y$. It is easy to verify that this defines a partial ordering; in addition, $KP(M)$ is directed with respect to this partial ordering.

Our goal now will be to use $[X]$ as a restricting box for a sum over classes of colorings. Then we will remove the restriction for the renormalized sum.

Recall that a homeomorphism $f: M \to M$ acts on admissible colorings $\varphi \in adm(M)$ by $f^{-1} * \varphi \in adm(M)$. We will denote by $[\varphi]$ the class of colorings with respect to the group of homeomorphisms that restrict to the identity on ∂M. Note that $[X(\varphi)]$ is independent of the representative $\varphi \in [\varphi]$.

Since $|X(f^{-1} * \varphi)|'_{f^{-1} * \varphi} = |X(\varphi)|'_{\varphi}$ we can define $|[\varphi]| = |X(\varphi)|'_{\varphi}$ and for $\alpha \in adm(\partial M)$

$$\Omega'_{[X]}(\alpha) = \sum_{[\varphi]} |[\varphi]|' s([X(\varphi)],[X]),$$

where the sum runs over all classes of colorings such that $\partial[\varphi] = \alpha$ and $[X(\varphi)] \leqslant [X]$. The symmetry factor $s([X(\varphi)],[X])$ counts in how many distinct ways can $[X(\varphi)]$ fit in $[X]$. Then, we have the following interpretative result concerning the central object of this work.

Theorem 6: Ω^n_M, *as defined in Eq. (1), is a renormalized sum over knot classes of colorings. That is,*

$$\Omega^n_M(\alpha) = \lim_{[X] \to M} \Omega^n_{[X]}(\alpha).$$

The same techniques can be applied using the notion of class resulting from the group of homeomorphisms that preserves each connected component of ∂M. The analysis proceeds in complete parallel to the one described above, but the resulting linear functional acts naturally on $\mathcal{H}_{hom}$. In addition, the space of physical states and the projective propagator are naturally isomorphic to the ones constructed here. This construction is of interest to loop quantization because it gives a construction of the Reisenberger–Rovelli projector (3) as a renormalized sum over quantum geometries.

APPENDIX: INDEPENDENCE OF INTERNAL STRUCTURE

A choice of internal structure is needed to construct the simple graph Γ_s from $\Gamma \in G(\Sigma)$. In the next paragraphs we will see that different choices lead to naturally isomorphic vector spaces $C(\Gamma_s)$ which in the main body of the article are denoted collectively by $C(\Gamma)$.

Consider a portion of a graph adjacent to a vertex with valence higher than three; call it $\Gamma(v)$. Use the prescription of Sec. II B (Fig. 1) to generate a simple graph $\Gamma(v)_s$. Fix a coloring α of $\Gamma(v)$'s edges, and define $C(\Gamma(v)_s, \alpha) = \mathbb{C}[adm(\Gamma(v)_s, \alpha)]$ as the complex vector space generated by the admissible colorings of $\Gamma(v)_s$ that are compatible with α.

Construct $\Gamma(v)^3_s$ from $\Gamma(v)_s$ simply by sliding "edge 1" counter clockwise past "edge 3" (see Fig. 1). Continue sliding "edge 1" in the same direction to generate a sequence of graphs $(\Gamma(v)_s, \Gamma(v)^3_s, \Gamma(v)^4_s, \ldots, \Gamma(v)^{n-1}_s)$. Note that $\Gamma(v)^{n-1}_s$ corresponds to the graph $\Gamma(v)_s$ obtained using a different numbering of the edges. With this set of moves we can generate all the graphs $\Gamma(v)_s$ obtained with any counter-clockwise (or clockwise) oriented numbering of edges.

Now we are going to show that the spaces $C(\Gamma(v)_s^i,\alpha)$, $C(\Gamma(v)_s^{i+1},\alpha)$ are naturally isomorphic. After we do so, we will know that any two counter-clockwise (or clockwise) oriented numberings of edges produce different simple graphs $\Gamma(v)_s^a \neq \Gamma(v)_s^b$, but naturally isomorphic vector spaces $C(\Gamma(v)_s^a,\alpha) \approx C(\Gamma(v)_s^b,\alpha)$. Clearly, this implies that different choices of Γ_s for a given Γ lead to naturally isomorphic vector spaces.

Consider the graph $\Gamma(v)_s^i$ described above. Its internal edges can be labeled as $(e_{3,4},e_{4,5},\ldots,e_{i,1},e_{1,i+1},\ldots,e_{n-2,n-1})$. Similarly, the internal edges of the graph $\Gamma(v)_s^{i+1}$ can be labeled as $(e_{3,4},e_{4,5},\ldots,e_{i,i+1},e_{i+1,1},\ldots,e_{n-2,n-1})$. Using an abbreviated notation for the internal edges, we can write the generators of $C(\Gamma(v)i_s,\alpha)$ as $(\ldots,j_{i,1},j_{1,i+1},j_{i+1,i+2}\ldots)_i$. There is one generator for each choice of ''internal spins'' that is compatible with the coloring of the external edges $\alpha=(j_1,j_2,\ldots,j_n)$. In a similar fashion, the generators of $C(\Gamma(v)_s^{i+1},\alpha)$ are denoted by $(\ldots,j_{i,i+1},j_{i+1,1},j_{1,i+2},\ldots)_{i+1}$. The isomorphism is given by the recoupling move,[9] which sends the generator $(\ldots,j_{i,1},j_{1,i+1},j_{i+1,i+2},\ldots)_i$ to

$$\sum_{j_{3,1}} w_{j_{1,i+1}} w_{j_{i+1,1}} \begin{vmatrix} j_{i,1} & j_1 & j_{1,i+1} \\ j_{1,i+2} & j_{i+1} & j_{i+1,1} \end{vmatrix} (\ldots,j_{i,i+1},j_{i+1,1},j_{1,i+2},\ldots)_{i+1}.$$

If we slide back ''edge 1'' to its position in $\Gamma(v)_s^i$ the recoupling move gives us another $6j$ symbol. The resulting sum of products of two $6j$ symbols is just the orthogonality relation, meaning that sliding back ''edge 1'' induces just the inverse transformation. This completes the proof; any two choices of internal structure for $\Gamma \in G(\Sigma)$ lead to naturally isomorphic vector spaces.

Let us now show that Ω'_X is independent of the choice of X_s used to define it. To do it, we will construct a sequence of lune and Matveev moves that interpolates between any two choices of X_s leaving Ω'_X unchanged. We will describe a sequence of moves that changes the internal structure of an edge and a sequence that changes the internal structure of a vertex. Composing these sequences of moves we can generate any of the possible choices of internal structure starting from a particular choice.

We will start describing how to change the internal structure of edges. First take the case of an edge with at least one end in the boundary. In this case the internal structure of the edge is fixed by the structure of the vertex in the boundary; there is no choice of internal structure. (If the edge has two vertices in the boundary, they are assumed to have compatible structures.)

Take now the case of an edge that starts and ends at two distinct vertices that lie in the interior of M. We will change the internal structure of the edge sliding ''face 1'' in the same spirit used to change the internal structure of a vertex in the case of boundary graphs. That is, we will slide ''face 1'' around the lateral faces of the edge-bubble until it is connected to ''face n.'' Iterating this process, we can change the location of the hole in the edge-bubble to be any of the lateral faces. In the next paragraph we describe a sequence of Matveev and lune moves that slides ''face 1'' as we need.

''Face 1'' meets two vertex bubbles, the bubbles corresponding to the vertices at the extremes of the edge. Then we can use Matveev moves to slide ''face 1'' past ''face 3'' on the surface of both vertex-bubbles. Then we simply pull ''face 1'' through the surface of the edge-bubble past ''face 3'' using an inverse lune move. We can iterate this process to slide ''face 1'' until it is connected to ''face n.'' At this point we have moved the position of the hole in the edge-bubble, but we may have not finished our job yet. One of the vertex-bubbles may have had its hole connecting it to the edge-bubble. In this case, the sequence of Matveev moves has made ''face 1'' surround all the internal vertices of the vertex bubble. To finish we have to slide ''face 1'' on the surface of the vertex-bubble past all these vertices using Matveev and inverse Matveev moves.

Finally, consider the case of an edge that closes in itself. ''Face 1'' can be slid using the technique explained above for the case in which the edge ended in two internal vertices. We have described how to change the internal structure of an edge with any location in M. In the next paragraph we explain how to change the internal structure at vertices.

Each vertex-bubble has a hole connecting it to an edge-bubble. We may want to change the location of the hole in a way that connects the vertex-bubble to another edge-bubble. To do it we can simply move the face that occupies the place where we want the hole to be to the old location of the hole. This moving of the face can be achieved by a sequence of Matveev and inverse Matveev moves done inside the vertex-bubble. This finishes the construction; any two choices of internal structure for $X \in P(M)$ are connected by a sequence of lune and Matveev moves (and their inverses). Thus, Ω'_X is independent of any choice.

Generalization of Berry's geometric phase, equivalence of the Hamiltonian nature, quantizability and strong stability of linear oscillatory systems, and conservation of adiabatic invariants

K. Yu. Bliokh[a)]
Institute of Radio Astronomy, 4 Krasnoznamennaya St., Kharkov, 61002, Ukraine

(Received 27 February 2002; accepted 2 July 2002)

A linear set of ordinary differential equations with a matrix depending on a set of adiabatically varying parameters is considered. Its asymptotic solutions are constructed to an arbitrary accuracy in the adiabaticity parameter ε. By extending the phase space of the system not only with the space of parameters, like in the theory of Berry's phase, but also with the space of their derivatives, it proves possible to represent the phase of the solution as a sum of the dynamic phase and a generalized geometric phase (determined by a contour integral in the space of parameters and derivatives). Hence, it is possible to obtain the asymptotic results to any degree of accuracy in ε, while earlier they were obtainable only in the first-order adiabatic approximation. Namely, for linear oscillatory adiabatic systems, the quantizability, parametric stability, and the Hamiltonian nature of the system are equivalent properties. As a consequence, one can obtain the well-known result regarding conservation with accuracy to any power of ε of adiabatic invariants in a Hamiltonian system on a torus. An important point is that the generalized geometric phase can appear, in contrast to Berry's phase, with only one real varying parameter. [DOI: 10.1063/1.1506954]

I. INTRODUCTION

This paper develops the ideas of Refs. 1 and 2 that proposed to analyze nonautonomous dynamic systems with the help of a functional approach. In this case the phase space of a dynamic system is extended not only by adding the dimension of time but also a space of parameters varying with time. As a result, solutions to the equations, changes of variables, etc., are considered as functionals (generally speaking, nonlocal) of the parameters and not just as functions of time. As it occurs, the approach allows one to obtain essential results of considerable interest. For example, the theory of Berry's phases[3] provides a prominent example of the functional approach to nonautonomous dynamic systems.

Note that an essential feature of the functional approach is the possibility to separate coordinate substitutions into local and nonlocal ones. The local substitutions involve only current values of system parameters and their derivatives, and hence cannot result in qualitative distortions of the system's phase portrait. Whereas nonlocal substitutions are, for the most part, integral functionals of parameters containing the system's prior history. Such substitutions always distort the global qualitative phase portrait.[1,2]

Reference 1 was an attempt to develop a consistent theory of linear adiabatic systems from the viewpoint of the functional approach. Special attention was paid to oscillatory systems, i.e., the systems with purely imaginary current eigenvalues. For such systems, adiabatic equivalence was proven (i.e., equivalence to the first order in the adiabatic parameter ε) of the quantizability, strong stability, and Hamiltonian property of the system. It was exactly the functional approach that made

a)Electronic mail: kostya@bliokh.kharkiv.com

the proof possible, and the notion of complex geometric phases was used essentially.

In the present paper we will show that a consistent application of the technique permits extending the formalism up to any order of ε. As a result, the notion of the *generalized geometric phase* is introduced, and the above-mentioned statements of Ref. 1 are proved in a similar way, however to a new accuracy. It is important that the generalized geometric phase, while being described analogously to Berry's phase and representing similar physical effects, can appear under adiabatic changes of only one real parameter. In this paper, some modifications of the strong stability property are introduced for parameter-dependent systems in a more rigorous way than in Ref. 1, namely the parametric stability and strong stability in a class. It is noteworthy that from the formalism introduced and the theorems proved in the paper some well-known results follow immediately. Namely, adiabatic invariants of the Hamiltonian system whose phase trajectories lie, under constant parameters, on an n-dimensional torus, remain unchanged with accuracy to any power of ε.[4–6]

The central idea of this work, allowing an efficient extension of the known results to any degree of accuracy, consists in analyzing the system in a generalized space of parameters that involves not only the dimensions of the parameters but of their derivatives as well.

II. GENERAL FORMALISM

Consider the linear system described by an n-dimensional vector equation in $\mathbf{C}^n$,

$$\mathbf{x}' = \mathbf{A}(\bar{\mu})\mathbf{x}. \tag{1}$$

[Let us note that all conclusions of this paper can be obtained in a similar way for the initial system in $\mathbf{R}^{2n}$. Besides, the results can be derived in an almost identical way for the initial system with the matrix of form $\mathbf{A}=\mathbf{A}(\bar{\mu},\bar{\mu}',\ldots,\bar{\mu}^{(m)})$.] Here $\mathbf{x}=(x_1,\ldots,x_n)$ is the vector-function to be found (its components will be called coordinates), the prime stands for differentiation with respect to the independent real variable t (further referred to as time), $\mathbf{A}(\bar{\mu})$ is a linear operator defined by a square nondegenerate matrix, which is an infinitely differentiable function of the set of s adiabatically varying parameters $\bar{\mu}=(\mu_1,\ldots,\mu_s)$, and $\bar{\mu}$ is a vector from a compact simply connected domain $\wp\subset\mathbf{R}^s$.

The eigenvalues of the matrix $\mathbf{A}(\bar{\mu})$ are assumed to satisfy the following conditions for all values of the parameters:

$$0<|\lambda_j(\bar{\mu})|<\infty, \quad j=1,...,n; \quad \lambda_j(\bar{\mu})\neq\lambda_l(\bar{\mu}) \quad \text{for} \quad j\neq l \tag{1a}$$

The latter requirement is necessary to permit the use of independent adiabatic solutions of (1). [Applicability criteria of the adiabatic approximation for the case when eigenvalues are closing in can be found in Ref. 7.]

The system parameters are subject to an arbitrary adiabatical variation with time:

$$\bar{\mu}=\bar{\mu}(\varepsilon t), \quad \varepsilon\ll 1. \tag{2}$$

Here, ε is the adiabaticity parameter, and the vector-function $\bar{\mu}(\varepsilon t)$ is assumed to be infinitely differentiable. From here on, referring to system (1), we also imply all the above-listed requirements.

Notice that there is no need to require the nonresonance character of the $\bar{\mu}(\varepsilon t)$ dependence as was done in Ref. 1. The point is that even in the presence of parametric resonance in the adiabatic oscillatory system the growth rate is exponentially small,[8,9] being a value of the form $\alpha\exp(-\beta\varepsilon^{-1})$. [In the case of parametric resonance with nonadiabatic sections of the function $\bar{\mu}(t)$, the growth rate generally is of order ε^1, where ε is the reciprocal of the period.[9]] For this reason, parametric resonances are beyond the scope of this paper treating power-series approximations in ε. Furthermore, the statements and theorems discussed here utilize the function $\bar{\mu}(\varepsilon t)$ only as an auxiliary tool. In fact they deal with the system as a whole, i.e., structure of the $\mathbf{A}(\bar{\mu})$ dependence.

To construct asymptotic solutions to system (1) we will use the following idea proposed by Neishtadt.[10] (Compare also with the method of successive diagonalizations in Ref. 4.) Let us bring the parameter-dependent matrix $\mathbf{A}(\overline{\mu})$ to a diagonal form by applying a linear substitution of coordinates. In terms of new coordinates, the matrix of the transformed system will be only slightly nondiagonal (the off-diagonal terms are proportional to the first-order time derivatives of parameters and have the order of ε). Let us further diagonalize the matrix obtained to a first order in ε through the next linear substitution of coordinates. In these coordinates the off-diagonal matrix elements will be small terms of order ε^2 being proportional to second-order time derivatives. This procedure can be similarly reiterated. Thus, the initial system can be reduced, for any finite order in ε, to a diagonal form, for which exact solutions can be easily written. The sequence of recurrence relations to describe the procedure is given in Appendix A.

Equation (1), upon k successive diagonalizations, takes the form

$$\mathbf{x}'_{[k]}=[\mathbf{\Lambda}_{[k]}+\mathbf{\Delta}_{[k]}]\mathbf{x}_{[k]}, \tag{3}$$

where the variables $\mathbf{x}_{[k]}$ are related to the initial ones through a certain reversible local substitution without singularities of the form $\mathbf{x}=\mathbf{B}(\overline{\mu},\overline{\mu}',\ldots,\overline{\mu}^{(k)})\mathbf{x}_{[k]}$; the subscript in the square brackets stands for the diagonalization number; $\mathbf{\Lambda}_{[k]}$ is the diagonal matrix containing terms of order ε^k and under, while the components of the matrix $\mathbf{\Delta}_{[k]}$ are of order ε^{k+1}. The matrix $\mathbf{\Lambda}_{[k]}$ can be written in the form [see (A5)]

$$\mathbf{\Lambda}_{[k]}=\mathbf{\Lambda}+\sum_{j=0}^{k-1}\mathrm{dg}\,\mathbf{\Delta}_{[j]}. \tag{4}$$

Here $|\mathbf{\Delta}_{[j]}|\sim\varepsilon^{j+1}$, the operator dg rejects off-diagonal components of the matrix, and $\mathbf{\Lambda}\equiv\mathbf{\Lambda}_{[0]}=\mathrm{diag}(\lambda_1,\ldots,\lambda_n)$, with the values $\lambda_j=\lambda_j(\overline{\mu})\sim\varepsilon^0$ being current eigenvalues of the matrix $\mathbf{A}(\overline{\mu})$ of the initial equation (1).

Let us determine the form of the matrices $\mathbf{\Delta}_{[j]}$. In view of their proportionality to the corresponding power of ε and with account of Eq. (2), it can be seen that $\mathbf{\Delta}_{[1]}$ is proportional to the first-order time derivative of $\overline{\mu}(\varepsilon t)$ and has the general form like

$$\mathbf{\Delta}_{[0]}=\overline{\mathbf{F}}_{[0]}(\overline{\mu}(\varepsilon t))\overline{\mu}'(\varepsilon t),$$

where $\overline{\mathbf{F}}_{[0]}(\overline{\mu}(\varepsilon t))$ is the matrix field over the $\overline{\mu}$-space of parameters. The nonpotential component of this field gives rise to Berry's geometric phase, or Hannay's angle (see Refs. 1 and 3). Similarly, $\mathbf{\Delta}_{[2]}$ can be written in general form as

$$\mathbf{\Delta}_{[1]}=\overline{\mathbf{F}}_{[1]}(\overline{\mu}(\varepsilon t))\overline{\mu}''(\varepsilon t)+\mathbf{F}_{[1]}(\overline{\mu}(\varepsilon t))(\overline{\mu}'(\varepsilon t))^2,$$

where $\overline{\mathbf{F}}_{[1]}(\overline{\mu}(\varepsilon t))$ also is a matrix field and $\mathbf{F}_{[1]}(\overline{\mu}(\varepsilon t))$ is a scalar (with respect to the $\overline{\mu}$-space) matrix-function.

Continuing the procedure, we see that the diagonal matrix $dg\,\mathbf{\Delta}_{[j]}$ can be represented as a sum of elements that are proportional to different orders of derivatives of $\overline{\mu}(\varepsilon t)$. Besides, in each term, the sum of products of the derivative order by the power it is raised to is equal to $j+1$.

Now we turn to solving Eq. (3). Its solutions can be written as follows:

$$\mathbf{x}_{[k]}(t)\approx\mathbf{x}_{[k]}(0)\exp\left\{\int_0^t\left[\mathbf{\Lambda}+\sum_{j=0}^{k-1}\mathrm{dg}\,\mathbf{\Delta}_{[j]}+O(\varepsilon^{k+1})\right]\mathrm{d}\tau\right\}. \tag{5}$$

From what has been said previously on the form of the matrices in the integrand, it appears that the solution (5) can be written like

$$\mathbf{x}_{[k]}(t)\approx\mathbf{x}_{[k]}(0)\exp\left\{\int_0^t\mathbf{\Lambda}(\overline{\mu}(\varepsilon\tau))\mathrm{d}\tau+\int_0^t\vec{\mathbf{F}}(\vec{M}(\varepsilon\tau))\vec{M}'(\varepsilon\tau)\mathrm{d}\tau\right\}+O(\varepsilon^{k+1}t). \tag{6}$$

Here we have introduced the space $\vec{M}$, which we suggest calling the *generalized parameter space*. Its dimensions are constituted by dimensions of the set of the values $(\overline{\mu}(\varepsilon t),\overline{\mu}'(\varepsilon t),\ldots,\overline{\mu}^{(k-1)}(\varepsilon t))$ (with regard to the properties of this space see Appendix B). The value $\vec{\mathbf{F}}(\vec{M})$ represents a field of diagonal matrices over this space. Finally, similarly to the geometric phase theory, the second term in the integrand of Eq. (6) can be easily transformed into a contour integral in the $\vec{M}$-space:

$$\mathbf{x}_{[k]}(t)\approx\mathbf{x}_{[k]}(0)\exp\left\{\int_0^t\mathbf{\Lambda}(\overline{\mu}(\varepsilon\tau))\mathrm{d}\tau+\int_L\vec{\mathbf{F}}(\vec{M})\mathrm{d}\vec{M}\right\}+O(\varepsilon^{k+1}t), \tag{7}$$

where L is the contour along which the representative point of the system moves in the generalized parameter space.

The solution (7) is fully identical in its form to the known adiabatic solution [Eq. (8) of Ref. 1] that was specified to within ε^1, however its accuracy is ε^k. The first term in Eq. (7) is the standard ''fast'' dynamic phase. The second term is the ''slow'' phase, whose nonlocal part represents the *generalized geometric phase*. It has the form of the standard Berry phase, however written in the generalized parameter space.

Equation (7) can be easily separated by the degrees of freedom of the system in $\mathbf{C}^n$, because it contains diagonal matrices alone. From here on, we will separately consider the projections of the solutions,

$$x_{[k]j}(t)\approx x_{[k]j}(0)\exp\left\{\int_0^t\lambda_j(\overline{\mu}(\varepsilon\tau))\mathrm{d}\tau+\int_L\vec{f}_j(\vec{M})d\vec{M}\right\}+O(\varepsilon^{k+1}t), \tag{8}$$

where $j=1,\ldots,n$ and $\vec{f}_j(\vec{M})\equiv\vec{\mathbf{F}}_{jj}(\vec{M})$.

Let us isolate the potential component of $\vec{f}_j(\vec{M})$, representing the field as

$$\vec{f}_j(\vec{M})=\mathrm{grad}[\varphi_j(\vec{M})]+\vec{f}_j^{(c)}(\vec{M}), \tag{9}$$

where $\varphi_j(\vec{M})$ is a scalar function, while $\vec{f}_j^{(c)}(\vec{M})$ is the nonpotential component of $\vec{f}_j(\vec{M})$. By substituting Eq. (9) into Eq. (8), we obtain

$$x_{[k]j}(t)\approx x_{[k]j}(0)\exp\left\{\int_0^t\lambda_j(\overline{\mu}(\varepsilon\tau))\mathrm{d}\tau+\varphi_j(\vec{M}(\varepsilon t))-\varphi_j(\vec{M}(0))+\int_L\vec{f}_j^{(c)}(\vec{M})\mathrm{d}\vec{M}\right\}+O(\varepsilon^{k+1}t). \tag{10}$$

The contribution of the potential field component $\vec{f}_j(\vec{M})$ to the solutions (8), (10) is *local*. It is determined only by boundary values of the parameters and their derivatives, and is independent of the integration contour in the $\vec{M}$-space. Therefore, it is the component that determines the connection between the slow amplitude of the solution and *current* values of parameters and their derivatives, and is responsible for the construction of adiabatic invariants.

The contribution of the nonpotential component, $\vec{f}_j^{(c)}(\vec{M})$, is, on the contrary, *nonlocal*. It depends essentially on the geometry of the contour L (i.e., on all *prior* values of the parameters), being nonzero even for cyclic variations of the parameters that correspond to closed contours in the $\vec{M}$-space. The last term in the exponent of Eq. (10) is the complex generalized geometric phase.

For the convenience of further consideration we will separate the real and the imaginary part of the generalized geometric phase. Its imaginary part will be called the generalized geometric phase proper,

$$\psi_j(L)=\mathrm{Im}\int_L \vec{f}_j^{(c)}(\vec{M})\mathrm{d}\vec{M}, \tag{11}$$

while its real part will be spoken of as the generalized geometric amplitude,

$$\gamma_j(L)=\mathrm{Re}\int_L \vec{f}_j^{(c)}(\vec{M})\mathrm{d}\vec{M}, \tag{12}$$

since it is exactly its changes that bring forth the variations of the solution amplitude. Note that the $\vec{M}$-space is multidimensional even in the case of only one varying real parameter in the system ($s=1$). For this reason generalized geometric phases and amplitudes may appear even when Berry's phase certainly does not exist (the $\overline{\mu}$-space is one-dimensional).

The potential component of $\vec{f}_j(\vec{M})$ can be easily reduced to zero via the local substitution $x_{[k]j}(t)=\exp[\varphi_j(\vec{M}(\varepsilon t))-\varphi_j(\vec{M}(0))]z_j(t)$. As a result, from (10) we obtain:

$$z_j(t)\approx z_j(0)\exp\left\{\int_0^t \lambda_j(\overline{\mu}(\varepsilon\tau))\mathrm{d}\tau+\int_L \vec{f}_j^{(c)}(\vec{M})\mathrm{d}\vec{M}\right\}+O(\varepsilon^{k+1}t). \tag{13}$$

We will also write the equation corresponding to projections of Eq. (3) in terms of these variables:

$$z_j'=(\lambda_j+\vec{f}_j^{(c)}\vec{M}')z_j+O(\varepsilon^{k+1}t). \tag{14}$$

These expressions coincide in form with those obtained in Ref. 1 [Eqs. (7)–(14) of this work correspond to Eqs. (8), (11), (13)–(16), (20), and (19) of paper Ref. 1]. In what follows we will derive analogous results, therefore in the following discussion we will only write out the fundamental propositions, referring the reader to Ref. 1 for details of the proofs. All one needs to do is to replace the parameter space and geometric terms with their generalized analogs.

III. MAIN RESULTS

A. Global qualitative portrait of the system

Statement I: The generalized geometric terms, together with the current eigenvalues λ_j, *determine the qualitative portrait of a linear adiabatic system.*

Indeed, to describe the system we can introduce, similar to Ref. 1, the efficient eigenvalues corresponding to the solutions (13) over a given time interval,

$$\lambda_j^{\mathrm{eff}}(t)=\frac{\ln z_j(t)-\ln z_j(0)}{t}. \tag{15}$$

By substituting the solutions (13) into Eq. (15), we obtain:

$$\lambda_j^{\mathrm{eff}}(t)=\langle\lambda_j\rangle_t+\frac{\gamma_j+i\psi_j}{t}+O(t^{-1},\varepsilon^{k+1}), \tag{16}$$

where $\langle\lambda_j\rangle_t\equiv(1/t)\int_0^t\lambda_j(\overline{\mu}(\varepsilon\tau))\mathrm{d}\tau$ are average values of the current eigenvalues. The second term in Eq. (16) contains terms of different orders ranging from ε to ε^k and, generally speaking, do not tend to zero together with t^{-1}, since during continuous circulation of the system's representative point in the $\vec{M}$-space the geometric terms increase infinitely. If there is a limit $\tilde{\lambda}_j^{\mathrm{eff}}=\lim_{t\to\infty}\lambda_j^{\mathrm{eff}}(t)$, then the behavior of the solutions for large times (strictly speaking, for times large enough so that $\lambda_j^{\mathrm{eff}}(t)$ does not leave the small vicinity of its limiting value) can be "roughly" (i.e., without account of local deviations) described by the formula $z_j(t)\approx z_j(0)\exp(\tilde{\lambda}_j^{\mathrm{eff}}t)$. For example, under periodic (of period $T\sim\varepsilon^{-1}$) variations of the parameters the value $\lambda_j^{\mathrm{eff}}(t)$ tends asymptotically to the limit

$$\tilde{\lambda}_j^{\text{eff}} = \langle \lambda_j \rangle_T + \frac{\gamma_j(L_T) + i\psi_j(L_T)}{T} + O(\varepsilon^{k+1}),$$

where L_T is the closed contour corresponding to one period. The above-derived solutions as well as the analysis presented are applicable over times $t \ll \varepsilon^{-(k+1)}$. It is significant that the system's portrait analyzed in z-coordinates is qualitatively equivalent to the portrait of the initial system (1). Indeed, we used only local coordinate substitutions that leave the system's fundamental characteristics (current eigenvalues and generalized geometric phases, i.e., efficient eigenvalues) invariant (see Ref. 2 and Appendix B in Ref. 1).

B. Adiabatic and integral invariants

Statement II: A degree of freedom of the system possesses an adiabatic invariant of action, conserved to the order of ε^k, if and only if

$$\begin{aligned} \operatorname{Re} \lambda_j &= 0, \\ \gamma_j &= 0. \end{aligned} \tag{17}$$

Indeed, if the conditions (17) are met, then Eq. (13) yields

$$I_j(t) \equiv |z_j(t)|^2 \approx \text{const}. \tag{18}$$

The values I_j are known as the adiabatic invariants of action. Each I_j corresponds to conservation of the phase flux of the jth degree of freedom in the **z**-space. In terms of the initial coordinates, the adiabatic invariants determine, under given initial conditions, an unambiguous relation between the amplitude of the approximate solution and current values of the parameters. Note that the conditions (17) are equivalent to the requirement that the real part of the effective eigenvalue λ_j^{eff} specified previously, be equal to zero. In other words, this is the requirement of conservation of oscillatory nature of the system movement over large times with adiabatically varying parameters.

Following Ref. 1, it can be easily shown that the existence of Poincaré's first integral invariant is equivalent to the presence in the system of a complete set of n adiabatic invariants (once again, this is true up to the order of ε^k). [It should be noted at this point that we do not consider the case of Hamiltonian systems with $\operatorname{Re} \lambda_j \neq 0$. Such systems also possess Poincaré's integral invariants, however adiabatic invariants are absent. The complex structure suggested here and integral invariants in these systems have different form as compared with Hamiltonian systems on a torus ($\operatorname{Re} \lambda_j = 0$), which mostly are considered in this paper.] In addition, the condition for conservation of the system's phase volume to the accuracy ε^k (Poincaré's nth integral invariant, or Liouville's theorem) are:

$$\begin{aligned} \sum_{j=1}^{n} \operatorname{Re} \lambda_j &= 0, \\ \sum_{j=1}^{n} \gamma_j &= 0. \end{aligned} \tag{19}$$

C. Hamiltonian formalism

We will further consider oscillatory systems, i.e., such systems that

$$\operatorname{Re} \lambda_j = 0, \quad j = 1,...,n. \tag{20}$$

Theorem I: *The system (1) with purely imaginary current eigenvalues [Eq. (20)] coincides, to accuracy* ε^k*, with a Hamiltonian system if and only if all of its generalized geometric amplitudes are equal to zero:*

$$\gamma_j = 0, \quad j = 1,...,n. \tag{21}$$

The Hamiltonian of such a system is represented by the Hamiltonian of a sum of independent oscillators:

$$H(p,q) = \sum_{j=1}^{n} H_j(p_j, q_j) = \frac{1}{2} \sum_{j=1}^{n} \omega_j (p_j^2 + q_j^2), \tag{22}$$

where $i\omega_j = \lambda_j + \vec{f}_j^{(c)} \vec{M}$.

Carrying out the realification of **z**-space, $p_j = \mathrm{Re}\, z_j$ and $q_j = \mathrm{Im}\, z_j$, we obtain from Eq. (14) with account of Eqs. (20) and (21),

$$\begin{aligned} p_j' &= -\,\mathrm{Im}(\lambda_j + \vec{f}_j^{(c)} \vec{M}') q_j + O(\varepsilon^{k+1} t), \\ q_j' &= \mathrm{Im}(\lambda_j + \vec{f}_j^{(c)} \vec{M}') p_j + O(\varepsilon^{k+1} t). \end{aligned} \tag{23}$$

To within the order ε^k, this is a Hamiltonian system with the Hamiltonian (22). Thus, the sufficiency of the condition (21) for the system to be a Hamiltonian one has been proven. The necessity of condition (21) can be proved following Ref. 1 by replacing the parameter space and the geometric values involved with their generalized analogs (also see Appendix B).

Note that points of the unperturbed system trajectory (in the proofs of Theorems I and III) should not belong to the boundary of the considered compact region $\wp$ in the $\overline{\mu}$-space.

D. System quantization

Theorem II: *System (1) with purely imaginary current eigenvalues [Eq. (20)] coincides, to accuracy* ε^k*, with a quantizable system if and only if all of its generalized geometric amplitudes are equal to zero [Eq. (21)].*

The proof can be performed following Ref. 1 by replacing the parameter space and the geometric values involved with their generalized analogs.

E. Strong stability properties

Now we turn to stability properties of the systems considered. In Ref. 1 equivalence of the Hamiltonian nature and quantizability of the system to a special version of strong stability was proven. Here we will introduce the property of a *parametric stability*, which we think is more adequate when discussing parametric systems. Next, we will formulate a strong stability property, which could be more properly referred to as *strong stability in a class*. It will be shown that the parametric stability is a primary property for systems with parameters. The strong stability property can be introduced only for the class of parametrically stable systems.

Definition I: System (1) with a specific (rather than arbitrary) $\overline{\mu}(\varepsilon t)$ *dependence is said to be a realization of system (1).*

In essence, the notion of realization emphasizes that in the functional approach we operate in fact with a set of systems characterized by a variety of $\overline{\mu}(\varepsilon t)$ dependencies, whereas in the temporal approach we consider a single system.

Definition II: Let a realization $\overline{\mu} = \overline{\mu}_0(\varepsilon t)$ *of system (1) with the matrix* $\mathbf{A}(\overline{\mu})$ *be stable, i.e., all of its solutions are bounded, if there exists a* $\delta > 0$*, such that any perturbed realization* $\overline{\mu} = \overline{\mu}_1(\varepsilon t)$ *of the same system satisfying the inequality*

$$|\overline{\mu}_1(\varepsilon t) - \overline{\mu}_0(\varepsilon t)| < \delta, \quad \forall t, \tag{24}$$

is also stable, then the initial realization of the system is called parametrically stable.

The system is parametrically stable if all of its realizations are parametrically stable.

As noted at the beginning of Sec. II, parametric resonances in adiabatic systems go beyond the accuracy of the approximation considered here. Talking of stability here and in the following, we will not consider parametric resonances again, since we operate in the framework of the approximation adopted.

Definition III: Let system (1) with the matrix $\mathbf{A}=\mathbf{A}_0(\overline{\mu})$ *from a certain class* $\aleph$ *be parametrically stable. If there exists a* $\delta>0$, *such that any perturbed system (1) with the matrix* $\mathbf{A}=\mathbf{A}_1(\overline{\mu})$ *from the same class* $\aleph$, *satisfying the inequality*

$$\|\mathbf{A}_1(\overline{\mu})-\mathbf{A}_0(\overline{\mu})\|<\delta, \quad \forall \overline{\mu}\subset\wp, \tag{25}$$

is also parametrically stable, then the initial system is called strongly stable in the class $\aleph$.

In essence, the property of parametric stability reflects the stability of a system against small variations of its parameters. The property of strong stability in a class describes stability under small variations in the system matrix, however, demanding that the matrix does not leave the given class, which is to be determined in every particular problem. Like in Ref. 1, we speak here of strong stability in the class of Hamiltonian oscillatory systems with different eigenvalues. (This kind of stability was proven previously for systems with periodic coefficients.[11–13]) Apparently, small variations in the system matrix that take the system out of that class will readily produce loss of the system's stability. This is the reflection of the fact that Hamiltonian oscillatory systems are *structurally unstable*.[13] More specifically, when the system loses its oscillatory nature, it may become simply *unstable* (parametrically unstable even more so) even for fixed values of its parameters (if $\mathrm{Re}\,\lambda_j>0$). At the same time, if a system leaves the class of Hamiltonian ones, while retaining its oscillatory nature, then the system becomes parametrically unstable (a property opposite to the one of parametric stability).

Remark: If we choose a class in which all the systems are parametrically stable, then they will be also strongly stable in the class.

As a consequence of the Remark, it is the parametric stability property that can be naturally assumed to be primary: it determines the class of systems in which they possess the property of strong stability.

Theorem III: *System (1) with purely imaginary current eigenvalues [Eq. (20)] is parametrically stable to the order of* ε^k *if and only if its generalized geometric amplitudes are all equal to zero [Eq. (21)].*

Once again, the proof is carried out following the pattern of Theorem III in Ref. 1, however replacing the parameter space and the geometric values involved with their generalized analogs (also see Appendix B).

F. Corollaries

By virtue of Eq. (21) representing the necessary and sufficient condition for all of the above-given theorems, the following conclusions can be drawn.

Corollary I: The Hamiltonian nature, parametric stability, and quantizability are equivalent properties with accuracy to any power of ε, *for system (1) with purely imaginary current eigenvalues.*

Also, the property of parametric stability (Theorem III) determines the strong stability class of the oscillatory systems (1):

Corollary II: Systems (1) are strongly stable, with accuracy to any power of ε, *in the class of oscillatory Hamiltonian systems. Moreover, the class of Hamiltonian systems is the complete strong stability class among the oscillatory systems (1), i.e., none of the oscillatory systems not belonging to this set is strongly stable.*

It is clear that the complete class of strongly stable systems (1) represents a union of the set of Hamiltonian systems with $\mathrm{Re}\,\lambda_j=0$, $j=1,...,n$, and the set of systems with a negative real part of current eigenvalues ($\mathrm{Re}\,\lambda_j<0$, $j=1,...,n$). The strong stability in the latter set is clear enough and is not discussed here.

Corollary III: Let the phase curves of a linear Hamiltonian system for fixed values of parameters represent the winding of an n-dimensional torus with various rotation periods. Then n adiabatic invariants exist in the system that are retained during slow variations of the system parameters with accuracy to any power of ε.

Indeed, if the system is a Hamiltonian one and the conditions (20) are met, then its generalized geometric amplitudes are equal to zero (Theorem I) for any k. And hence (Statement II), the system possesses a set of n adiabatic invariants that are conserved to within the accuracy ε^k with arbitrary k.

IV. CONCLUSIONS

The paper considered a linear dynamic system of the general kind, described by the complex vector equation (1) with a nondegenerate matrix possessing different nonzero eigenvalues. The system matrix is assumed to depend on a set of parameters varying adiabatically in time. The principal results reported in the paper are as follows:

(1) A procedure has been suggested for constructing asymptotic solutions (5) that satisfy the system (1) to terms of any given order in ε.

(2) The notion of the generalized parameter space $\vec{M}=(\overline{\mu}(\varepsilon t),\overline{\mu}'(\varepsilon t),\ldots,\overline{\mu}^{(k-1)}(\varepsilon t))$ has been introduced that allows representing asymptotic solutions as an exponential function of the sum of the dynamic phase and the generalized geometric phase. The latter can be represented as a contour integral of some field on the $\vec{M}$-space. Thus the problem has been formally reduced to the case (already considered in Ref. 1) of adiabatic solutions determined with an accuracy of ε. The $\vec{M}$-space is multidimensional even in the case of a single real varying parameter in the system ($s=1$). Hence, generalized geometric phases can appear when Berry's phase is certainly absent. The appearance of such phases may produce interesting effects in physical systems that are similar to the appearance of Berry's phase for higher orders of ε. [In the papers now being prepared for publication the author shows that the generalized geometric phase can appear even in very simple systems, such as an oscillator with a varying eigenfrequency or the rotating polarization plane of light in a one-dimensionally inhomogeneous medium.]

(3) Making use of the analogy with the adiabatic problem already analyzed to within ε, we have shown the generalized geometric terms, along with current eigenvalues, to be fundamental characteristics of the system. They determine its global qualitative portrait over times up to ε^{-k}. The real part of the complex generalized geometric phase, i.e., the generalized geometric amplitude, plays a special role in the system analysis. The geometric amplitudes determine the system's Lyapunov indices.

(4) The necessary and sufficient conditions (17) for constructing the adiabatic invariant for one degree of freedom have been formulated (under the assumption that the invariant is conserved to within ε^k). These are the absence of the generalized geometric amplitude and zero value for the real part of the current eigenvalue for the given degree of freedom. Within the same approximation, Poincaré's first integral invariant is equivalent to the complete set of n adiabatic invariants. In other words, the conditions for its existence are an oscillatory nature of the system and zero values for all geometric amplitudes. The conditions of the Liouville theorem (the nth Poincaré integral invariant) demand that real parts of the current eigenvalues be zeros, as well as the sum of generalized geometric amplitudes.

(5) The central results of the paper are the following equivalence relationships. For the oscillatory systems (1) equivalence has been proved of the Hamiltonian nature of the system, its quantizability, and parametric stability with accuracy to any power of ε. These properties are implemented if and only if the generalized geometric amplitudes of the oscillatory system are all equal to zero.

(6) Particularly discussed have been the properties of parametric stability and strong stability in a class that are modifications of the strong stability property as applied to parametric systems. As has been shown, it is natural to assume the parametric stability as the primary property. It determines the class of strong stability of parametric systems. In the case under consideration, the complete class of strongly stable oscillatory systems (1) is formed by Hamiltonian oscillatory systems.

(7) It is of interest that a direct consequence of the theorems proven here is the known result concerning adiabatic invariants. Namely, a Hamiltonian system with constant-parameter phase trajectories lying on an n-dimensional torus supports a complete set of n adiabatic invariants that are conserved with accuracy to any power of ε.[4–6]

It appears to us that the equivalence relationships proven here and in Ref. 1 do not just have an abstract, mathematical meaning but also possess a physical if not philosophical significance. They show the role of the Hamiltonian nature of our world. It is well known that the principal, elemental oscillatory systems are described by Hamiltonian equations equally in quantum and classical mechanics and in the wave theory. One could think that the form of these equations is somewhat accidental and they might well have different form. However, the results presented in this work offer a clear view of the following fact: if the equations for linear physical oscillators had not been of Hamiltonian nature, then our world would not have been so stable against small perturbations. Besides, it would not have been of quantum nature either, or at least there would have not existed such a correlation between the micro- and macroworld theories.

In conclusion, we stress once again that the derivation of all of these results has become possible exclusively due to the functional approach to nonautonomous systems (see Sec. I and Refs. 1 and 2).

APPENDIX A: CONSTRUCTION OF ASYMPTOTIC SOLUTIONS

Consider in more detail Neishtadt's method of successive diagonalizations proposed in Sec. II (Compare also with method in Ref. 4.). Let upon the kth diagonalization the initial equation (1) take the form

$$\mathbf{x}'_{[k]}=[\mathbf{\Lambda}_{[k]}+\mathbf{\Delta}_{[k]}]\mathbf{x}_{[k]}, \tag{A1}$$

where $|\mathbf{\Delta}_{[k]}|\sim\varepsilon^{k+1}$ and $\mathbf{\Lambda}_{[k]}$ is a diagonal matrix containing the terms up to the order ε^k inclusive. Next let us perform the $(k+1)$th diagonalization. Let us make the substitution

$$\mathbf{x}_{[k]}=\mathbf{D}_{[k]}\mathbf{x}_{[k+1]}, \tag{A2}$$

where

$$\mathbf{D}_{[k]jl}=\frac{\mathbf{\Delta}_{[k]jl}}{(\mathbf{\Lambda}_{[k]jj}-\mathbf{\Lambda}_{[k]ll})}, \quad j\neq l; \quad \mathbf{D}_{[k]jj}=1. \tag{A3}$$

The substitution (A2) always exists and allows inversion, because it is close to the unit matrix (the diagonal elements of $\mathbf{\Lambda}_{[k]}$ are different according to the initial assumptions).

After the substitution (A2), Eq. (A1) will take the form

$$\mathbf{x}'_{[k+1]}=\mathbf{D}^{-1}_{[k]}\{[\mathbf{\Lambda}_{[k]}+\mathbf{\Delta}_{[k]}]\mathbf{D}_{[k]}-\mathbf{D}'_{[k]}\}\mathbf{x}_{[k+1]}. \tag{A4}$$

Then we set in (A4)

$$\mathbf{\Lambda}_{[k+1]}=\mathbf{\Lambda}_{[k]}+\mathrm{dg}\,\mathbf{\Delta}_{[k]}, \tag{A5}$$

(recall that the operator dg denotes rejection of the off-diagonal matrix terms)

$$\mathbf{\Delta}_{[k+1]}=\mathbf{D}_{[k]}^{-1}[\mathbf{\Lambda}_{[k]}+\mathbf{\Delta}_{[k]}]\mathbf{D}_{[k]}-\mathbf{\Lambda}_{[k]}-\mathrm{dg}\,\mathbf{\Delta}_{[k]}-\mathbf{D}_{[k]}^{-1}\mathbf{D}'_{[k]}. \tag{A6}$$

By substituting Eq. (A3) into Eq. (A6) we can easily verify that the components of $\mathbf{\Delta}_{[k+1]}$ are proportional to the derivatives of the $\mathbf{\Delta}_{[k]}$ components, i.e., they are terms of order ε^{k+2}. Finally, by substituting Eqs. (A5) and (A6) into Eq. (A4) we obtain:

$$\mathbf{x}'_{[k+1]}=[\mathbf{\Lambda}_{[k+1]}+\mathbf{\Delta}_{[k+1]}]\mathbf{x}_{[k+1]}. \tag{A7}$$

Thus, we have completely described the recurrent step from Eq. (A1) to Eq. (A7). It only remains to derive the initial equation of the form (A1) to apply the induction.

Since the matrix $\mathbf{A}$ of the initial equation (1) possesses different nonzero eigenvalues, there exists a matrix $\mathbf{D}$ such that $\mathbf{D}^{-1}\mathbf{A}\mathbf{D}=\mathbf{\Lambda}$ (The matrix $\mathbf{\Lambda}$ was introduced in Sec. II.) By carrying out the substitution $\mathbf{x}=\mathbf{D}\mathbf{x}_{[0]}$, we obtain from Eq. (1)

$$\mathbf{x}'_{[0]}=[\mathbf{\Lambda}-\mathbf{D}^{-1}\mathbf{D}']\mathbf{x}_{[0]}.$$

By setting $\mathbf{\Lambda}_{[0]}\equiv\mathbf{\Lambda}$ and $\mathbf{\Delta}_{[0]}\equiv-\mathbf{D}^{-1}\mathbf{D}'$, we obtain Eq. (A1) for $k=0$. Equations (A2)–(A7) allow one to repeat the diagonalization procedure as many times as necessary, reducing the initial equation to a diagonal form with accuracy to any power of ε.

APPENDIX B: ON PROPERTIES OF THE $\vec{M}$-SPACE AND SYSTEM TRAJECTORIES IN IT

It should be noted that the dimensions of the generalized parameter space ($\vec{M}$-space), strictly speaking, are not independent. Indeed, consider, for instance, a closed oriented contour of the system's representative point in the plane (μ_j,μ'_j) (Fig. 1). It is easy to see that the contour shown by a dashed line cannot be realized. Along the sections of decreasing μ_j, the value μ'_j should be negative, and hence this section of the contour should lie in the lower half-plane. The contour depicted in Fig. 1 by a solid line meets the requirement, and thus it can be realized.

By generalizing the example, we can suggest the following requirement, which does not, however, exhaust the relations between the coordinates in the $\vec{M}$-space (certain constraints are also imposed on the trajectories in the planes of $(\mu_j^{(l)},\mu_j^{(l-2)})$ type and others). At the same time, only the relations considered in the following are essential for proving the theorems of this paper.

Statement: Let $\vec{M}=\vec{M}(\tau)$ be some parametrization of a trajectory of the system's representative point in the $\vec{M}$-space. Also, let the τ parameter be a smooth, monotonically increasing function of the real time t $(\mathrm{d}\tau/\mathrm{d}t>0)$. Then the following equality should hold at any point of the trajectory:

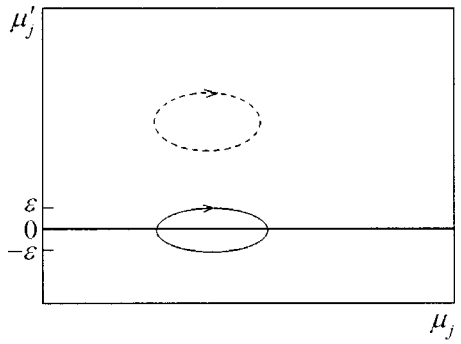

FIG. 1. Realizable (solid line) and nonrealizable (dashed line) contours of the system's representative point in a (μ_j,μ'_j) plane of the $\vec{M}$-space.

$$\operatorname{sign}\frac{d\mu_j^{(l-1)}}{d\tau}=\operatorname{sign}\mu_j^{(l)} \tag{B1}$$

for all components $j=1,...,n$ *and all the derivatives* $l=1,...,k-1$ *used.*

Let us analyze how the constraints (B1) imposed on the coordinates of the $\vec{M}$-space affect the proofs of Theorems I–III. To this end, first note that due to the adiabaticity condition (2) the system trajectories are located in the $\vec{M}$-space near the hyperplane of the $\bar{\mu}$-space. For example, the values μ_j' should be of the order ε. Hence, the trajectory of the system's representative point in the plane shown in Fig. 1 in fact is attached to the band $\mu_j'\in(-\varepsilon,\varepsilon)$ and cannot move far away from it. Similarly, the dimensions of the higher-order derivatives $\mu_j^{(l)}$ are attached to even narrower bands of width ε^l.

Let us turn now to the proof of Theorem I (see Ref. 1). It is clear that the nonperturbed realization of the system used there (an arbitrary point in the considered region of $\vec{M}$-space) is located in the hyperplane of the $\bar{\mu}$-space. The perturbed realization of the system is represented by an arbitrary closed contour around the point considered whose projections are tied to bands $\mu_j^{(l)}\in(-\varepsilon^l,\varepsilon^l)$ in the planes $(\mu_j^{(l)},\mu_j^{(l-1)})$. The admissible closed contour satisfying the conditions (B1) must intersect with the hyperplane $\mu_j^{(l)}=0$ (see Fig. 1), and hence the height of its projection on the plane $(\mu_j^{(l)},\mu_j^{(l-1)})$ is of order ε^l. In terms of μ_j dimensions, no restrictions on the contour geometry are posed, so it can always be chosen arbitrarily small. Meanwhile, in terms of μ_j' dimensions its value is generally bounded both from *above* and from *below* by the order ε. This could prevent us from selecting a sufficiently small arbitrary contour for the perturbed system realization. However, *all* the admissible contours can be made arbitrarily small in the dimensions $\mu_j^{(l)}$, $l\geqslant 1$ by choosing a sufficiently small value of ε. Thus, it only remains to choose the necessarily small shape of the contour in the $\bar{\mu}$-space; its projections onto other dimensions will always be sufficiently small in order to use the theorem on the strong stability of Hamiltonian systems with periodic coefficients. Evidently, the Hamiltonian nature as well as the presence of generalized geometric amplitudes in a system does not depend on the magnitude of ε. So the proof remains valid for any small ε.

The proof of Theorem II does not face any additional difficulties as compared with the one given in Ref. 1. As for the proof of Theorem III, it involves, as in the case of Theorem I, the trajectory of the unperturbed realization of the system, as well as the closely lying trajectory of a perturbed realization, spiraling around the former one. The problem of existence of a sufficiently close perturbed trajectory can be resolved if we follow the logic pattern of the previous paragraph. Any admissible trajectory can be made arbitrarily close (in terms of dimensions $\mu_j^{(l)}$, $l\geqslant 1$) to the initial unperturbed one by choosing a sufficiently small value of ε, then utilizing the fact that the properties in question do not depend on the magnitude of the small ε.

In conclusion, let us note one more interesting point. The theory of Berry's phase is remarkable in that the phase growth in the solution is determined only by the shape of the trajectory of the system's representative point in the $\bar{\mu}$-space, rather than by the explicit time dependence of the parameters. A single trajectory may correspond to an infinitely large number of various realizations of the system. When considering the system trajectories in the generalized $\vec{M}$-space, the freedom in recovering the system's realization (i.e., the $\bar{\mu}(\varepsilon t)$ dependence) is substantially restricted. Indeed, not only the sequence of variations in $\bar{\mu}$ values is specified, but also their derivatives up to the $(k-1)$th order. Still, a single contour corresponds as yet to an infinitely large number of realizations. For example, a closed contour in the $\vec{M}$-space does not necessarily correspond to periodic variations of the parameters: it is quite possible that the contour would be open in further dimensions ($\bar{\mu}^{(k)}$th). However, in the infinite-dimensional space $\vec{M}^{(\infty)}=(\bar{\mu}(\varepsilon t),\bar{\mu}'(\varepsilon t),...,\bar{\mu}^{(k)}(\varepsilon t),...)$, in which all the parameter derivatives are taken into account, the system realization can be recovered unambiguously (if, say, the function $\bar{\mu}(\varepsilon t)$ is analytical) from knowledge of a contour in that space. Closed trajectories in that space correspond to periodic variations in $\bar{\mu}(\varepsilon t)$ values. Moreover, an analytical function $\bar{\mu}(\varepsilon t)$, as well as the corresponding trajectories, can be unambiguously reconstructed from one point on this trajectory. It is readily

seen that the coordinates of this point determine all the coefficients of the Taylor series. The $\vec{M}^{(\infty)}$-space can be regarded as a certain representation of the space of analytic functions. Here every function corresponds to a certain trajectory, and conversely: each point in the $\vec{M}^{(\infty)}$-space corresponds to a unique trajectory containing this point and a function.

Elliptic Ruijsenaars operators and functional equations

Yasushi Komori[a)]

(Received 14 February 2002; accepted 2 July 2002)

We study mutually commutative difference operators introduced by Ruijsenaars, which are regarded as elliptic analogs of Macdonald operators and consist of the Jacobi theta functions and shift operators. These operators are constructed in terms of R-operators due to Shibukawa and Ueno or root algebras introduced by Cherednik, which give rise to a set of functional equations. We investigate solutions of these functional equations for generalizations of elliptic Ruijsenaars operators.
 [DOI: 10.1063/1.1507604]

I. INTRODUCTION

Ruijsenaars introduced a family of mutually commutative operators, whose coefficients consist of theta functions, as a relativistic quantum many-body system in Ref. 10. These operators are regarded as an elliptic analog of Macdonald operators. Since the Macdonald operators are associated with affine root systems, their elliptic analogs are also expected to have generalizations to arbitrary root systems. From this viewpoint, first an analog for the BC-type root system was introduced by van Diejen,[13] and later for arbitrary root systems in Ref. 6. In the latter, the operators are constructed in terms of an algebra called root algebra due to Cherednik,[4] which is a generalization of the Yang–Baxter equation. In this framework, Shibukawa–Ueno's R-operator[12] is regarded as a representation of the root algebras for simply-laced root systems. For the other root systems, we need to construct corresponding elliptic R-operators, which give rise to a set of functional equations and is not yet investigated thoroughly. In this article, we study solutions of these functional equations to find out generalizations of elliptic Ruijsenaars operators.

This article is organized as follows: In Sec. II, we give the notation and definitions, and outline the construction of elliptic Ruijsenaars operators following Ref. 6 as a motivation. In Sec. III, we put four types of equations associated with the root systems of type $A_1\times A_1$, A_2, B_2 and G_2 and set our basic assumption in this article. Since in our setting, the $A_1\times A_1$-type equation gives no functional equation, we first investigate the functional equations of type A_2, in Sec. IV. One of these functional equations coincides with the one of the classical Yang–Baxter equation.[2] Due to their result, we can exhaust all the solutions. It should be noted that a detailed study on R-operators of type A_2 was given in Ref. 11 in a little different setting. In Sec. V, we study the B_2-type equations. Since in affine root systems other than $C_2^{(1)}$, $D_3^{(2)}$ and $A_4^{(2)}$, they are combined with A_2-type equations, the solutions are obtained due to the results in Sec. IV and in Ref. 7. Although general solutions purely subject to the B_2-type equations are not obtained, we present an exceptional solution corresponding to the solution studied in Refs. 8 and 9. The last section is devoted to the G_2-type equations. In this system, the equations are much more complicated than the others, and are not fully investigated. We give partial results and find 22 solutions under an assumption called extensibility.

In this article, we obtain R-operators by solving functional equations. However, it is strongly hoped that they are obtained in a natural way or from smaller algebra as the representation of double affine Hecke algebras in Macdonald theory.[3]

II. AFFINE ROOT SYSTEMS AND ELLIPTIC RUIJSENAARS OPERATORS

We give some well-known facts about affine root systems and affine Weyl groups,[1,4,5] and outline the construction of elliptic Ruijsenaars operators following Ref. 6. In this article we only treat nontwisted root systems for simplicity.

Let $\mathring{V}$ be a real vector space equipped with inner product $(\cdot,\cdot)$. For $\alpha\in V$, define $\alpha^\vee := 2\alpha/(\alpha,\alpha)$. Let $\mathring{\Delta}$ be an irreducible reduced root system, $\mathring{I}=\{1,\ldots,l\}$, $\mathring{\Pi}=\{\alpha_i|i\in\mathring{I}\}$, the set of simple roots and $\mathring{\Pi}^\vee=\{\alpha_i^\vee|i\in\mathring{I}\}$, the set of simple coroots. Let $\mathring{\Lambda}:=\{\lambda_i|i\in\mathring{I}\}$ be a dual basis of $\mathring{\Pi}$. Let $\mathring{Q}^\vee$ and $\mathring{P}^\vee$ be the coroot lattice and the coweight lattice generated by $\mathring{\Pi}$ and $\mathring{\Lambda}$, respectively. Let $V:=\mathring{V}\oplus\mathbb{R}\delta$ with $(\delta,V)=0$. Let $\Delta:=\mathring{\Delta}\times\mathbb{Z}\delta$ be the corresponding nontwisted affine root system. Let $I=\{0,\ldots,l\}$, $\Pi=\{\alpha_i|i\in I\}$ and $\Pi^\vee=\{\alpha_i^\vee|i\in I\}$. Let Δ_+ and Δ_- be the set of positive roots and negative roots, respectively. Then one has the disjoint union $\Delta=\Delta_+\cup\Delta_-$. For $\alpha\in\Delta$, let s_α be a reflection defined by

$$s_\alpha(v):=v-(v,\alpha^\vee)\alpha,\quad v\in V. \tag{2.1}$$

The Weyl group $\mathring{W}$ is generated by the fundamental reflections $\{s_i:=s_{\alpha_i}|i\in\mathring{I}\}$ and the affine Weyl group W is generated by $\{s_i|i\in I\}$. The defining relations are given by $s_i^2=id$ and the Coxeter relations:

$$(s_i\ s_j)^{m_{ij}}=id,\quad \text{for } i\neq j\in I, \tag{2.2}$$

where $m_{ij}=2$ if α_i and α_j are disconnected in the Dynkin diagram and $m_{ij}=3,4,6$ if 1,2,3 lines respectively connect α_i and α_j. For $\mu\in\mathring{V}$, we define endomorphisms τ_μ of the vector space V by

$$\tau_\mu(\lambda):=\lambda-(\lambda,\mu)\delta. \tag{2.3}$$

The actions of s_α, τ_μ are naturally induced on $x\in V^*$ by transposition as follows:

$$s_\alpha(x)=x-\langle x,\alpha\rangle\alpha^\vee, \tag{2.4}$$

$$\tau_\mu(x)=x+\langle x,\delta\rangle\mu, \tag{2.5}$$

where $\langle\cdot,\cdot\rangle$ denotes the pairing of V^* and V, and $\alpha^\vee$, μ are identified with $(\alpha^\vee,\cdot)$, $(\mu,\cdot)$, respectively. For an arbitrary lattice L, we denote by $T(L)$ the corresponding group of translations of L.

Proposition 2.1: The affine Weyl group W is the semidirect product $W=\mathring{W}\ltimes T(\mathring{Q}^\vee)$.

Definition 2.2: The extended affine Weyl group $\hat{W}$ is the semidirect product $\hat{W}:=\mathring{W}\ltimes T(\mathring{P}^\vee)$.

Let Ω be the subgroup of $\hat{W}$ which stabilizes the affine Weyl chamber.

Proposition 2.3: The extended affine Weyl group $\hat{W}$ is isomorphic to the semidirect product $W\rtimes\Omega$.

Definition 2.4: (1) The length $\ell(w)$ of $w\in W$ is the length ℓ of the reduced decomposition:

$$w=s_{i_1}\ldots s_{i_\ell},\quad \text{for}\quad i_k\in I, \tag{2.6}$$

$$\ell(id)=0. \tag{2.7}$$

(2) The length $\ell(\hat{w})$ of $\hat{w}\in\hat{W}$ is the number of the negative roots made positive by $\hat{w}$:

$$\ell(\hat{w}):=|\Delta_{\hat{w}}|,\quad \Delta_{\hat{w}}:=\Delta_+\cap\hat{w}\Delta_-, \tag{2.8}$$

which is equivalent to the definition $\ell(w)$ for $w\in W$. The reduced decomposition of $\hat{w}\in\hat{W}$ is $\hat{w}=w\omega=s_{i_1}\cdots s_{i_\ell}\omega$, where $\omega\in\Omega$ and $\ell=\ell(\hat{w})=\ell(w)$.

The set $\Delta_{\hat{w}}$ is explicitly described as $\Delta_{\hat{w}}=\{\alpha^{(1)}=\alpha_{i_1},\alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\ldots,\alpha^{(\ell)}=ws_{i_\ell}(\alpha_{i_\ell})\}$. By definition, $\Delta_{\hat{w}}$ is independent of reduced expressions.

Definition 2.5: A coweight $\lambda\in\mathring{P}^\vee$ is said to be minuscule if $\Delta_{\tau_{-\lambda}}\subset\mathring{\Delta}_+$.

We shall define the root algebras after Cherednik.[4] Let $\mathcal{T}$ be the tensor algebra over $\mathbb{C}$ generated by independent variables $\{R_\alpha|\alpha\in\Delta\}$. Then the action of $\hat{w}\in\hat{W}$ on Δ induces an action on $\mathcal{T}$ by ${}^{\hat{w}}:R_\alpha\mapsto R_{\hat{w}(\alpha)}$.

Definition 2.6: Let $\mathcal{I}$ be the two-sided ideal in $\mathcal{T}$ which is generated by all the elements of the form for $i\neq j\in I$, and $\hat{w}\in\hat{W}$:

$$\underbrace{{}^{\hat{w}}(R_{\alpha_i}\otimes R_{s_i\alpha_j}\otimes R_{s_is_j\alpha_i}\otimes\cdots)}_{m_{ij}\ \text{factors}}-\underbrace{{}^{\hat{w}}(R_{\alpha_j}\otimes R_{s_j\alpha_i}\otimes R_{s_js_i\alpha_j}\otimes\cdots)}_{m_{ij}\ \text{factors}}. \tag{2.9}$$

The root algebra $\tilde{\mathcal{R}}$ is $\mathcal{T}/\mathcal{I}$. $\{R_\alpha|\alpha\in\Delta\}$ are called the R-matrices.

Because of the $\hat{W}$-invariance of $\mathcal{I}$, the action of $\hat{W}$ is induced on $\tilde{\mathcal{R}}$. For simplicity, we write products in $\tilde{\mathcal{R}}$ in the usual way for associative algebras.

Theorem 2.7 (Cherednik): *(1) There exists a unique set $\{R_{\hat{w}}|\hat{w}\in\hat{W}\}\subset\tilde{\mathcal{R}}$ satisfying the relations*

$$R_{vw}=R_v{}^vR_w,\quad R_{s_i}=R_{\alpha_i}\quad(i\in I),\quad R_\omega=1, \tag{2.10}$$

where $\omega\in\Omega$, $v,w\in\hat{W}$ and $\ell(v\ w)=\ell(v)+\ell(w)$.

(2) We have the R-matrix for $\hat{w}\in\hat{W}$ and its arbitrary reduced decomposition $\hat{w}=w\omega=s_{i_1}\cdots s_{i_\ell}\omega$ as

$$\begin{gathered}R_{\hat{w}}=R_{\alpha^{(1)}}\cdots R_{\alpha^{(\ell)}},\\ \alpha^{(1)}=\alpha_{i_1},\quad \alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\quad\ldots,\quad \alpha^{(\ell)}=ws_{i_\ell}(\alpha_{i_\ell})\in\Delta_{\hat{w}}.\end{gathered} \tag{2.11}$$

Instead of the original root algebra, we use the following extension, where $\tilde{\mathcal{R}}$ is combined with the translation group $T(\mathring{P}^\vee)$:

Definition 2.8: $\mathcal{R}:=\tilde{\mathcal{R}}\rtimes T(\mathring{P}^\vee)$,

$$(R\tau_\lambda)(R'\tau_\mu)=R({}^{\tau_\lambda}R')\tau_{\lambda+\mu}, \tag{2.12}$$

where $R,R'\in\tilde{\mathcal{R}}$ and $\lambda,\mu\in\mathring{P}^\vee$.

Theorem 2.9: *The subalgebra $\mathcal{S}\subset\mathcal{R}$ generated by $\{Y^\lambda:=R_{\tau_\lambda}\ \tau_\lambda|\lambda\in\mathring{P}^\vee_-\}$ forms a commutative algebra and is generated by $\{Y^{-\lambda_i}|i\in\mathring{I}\}$.*

We consider such a representation that R_α acts on the space of the meromorphic functions $\mathcal{M}$ on $\mathbb{C}\otimes V^*$ and takes the form

$$(R_\alpha\ f)(x):=H_\alpha(\langle\alpha,x\rangle,\mu_\alpha)f(x)-H_\alpha(\langle\alpha,x\rangle,(\alpha^\vee,\xi))f(s_\alpha(x)), \tag{2.13}$$

where $\xi\in\mathring{V}$ is a parameter called spectral parameter, $\mu_\alpha\in\mathbb{C}$ is a $\hat{W}$-invariant constant, $f\in\mathcal{M}$ and $H_\alpha(z,\mu)$ is a meromorphic function of z on $\mathbb{C}$. Furthermore, we assume that (2.13) satisfies unitarity:

$$R_{-\alpha}R_\alpha=c_\alpha((\alpha^\vee,\xi)), \tag{2.14}$$

where $c_\alpha(z)$ is a meromorphic function on $\mathbb{C}$ and $c_\alpha(-\mu_\alpha)=0$.

For some $\lambda \in \mathring{P}^\vee_-$, the explicit forms of Y^λ on the space $\mathcal{V}=\mathcal{M}^{\mathring{W}}$ are calculated as follows:

Theorem 2.10: *Let $\xi=-\mathring{\rho}_\mu:=\Sigma_{\alpha\in\mathring{\Delta}}\mu_\alpha\alpha$ and let λ be minuscule. Then we have*

$$Y^{-\lambda}|_{\mathcal{V}}=\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}} w\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\lambda,\alpha)=1}} H_\alpha(\mu_\alpha)\tau_{-\lambda}\right)\Bigg|_{\mathcal{V}}, \tag{2.15}$$

$$Y^{-\theta^\vee}|_{\mathcal{V}}=\frac{1}{|\mathring{W}_{\theta^\vee}|}\sum_{w\in\mathring{W}} w\left(\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\alpha,\theta^\vee)>0}} H_\alpha(\mu_\alpha)\right)(H_{\theta+\delta}(\mu_{\alpha_0})\tau_{-\theta^\vee}-H_{\theta+\delta}(-(\theta^\vee,\mathring{\rho}_\mu)))\right)\Bigg|_{\mathcal{V}}, \tag{2.16}$$

where $H_\alpha(\mu)$ denotes the multiplication operator of $H_\alpha(\cdot,\mu)$ and $\mathring{W}_\nu$ is the stabilizer of ν in $\mathring{W}$.

For an appropriate function H_α, they give actually generalizations of elliptic Ruijsenaars operators. In the following sections, we investigate R-operators in more general settings.

III. FUNCTIONAL EQUATIONS ASSOCIATED WITH ROOT ALGEBRAS

Motivated by the previous section, we will investigate the representation of the root algebras. Following Definition 2.6 in root systems of rank 2, we have the following equations:

$$R_\alpha\ R_\beta = R_\beta\ R_\alpha, \tag{3.1}$$

$$R_\alpha\ R_{\alpha+\beta}\ R_\beta = R_\beta\ R_{\alpha+\beta}\ R_\alpha, \tag{3.2}$$

$$R_\alpha\ R_{\alpha+\beta}\ R_{\alpha+2\beta}\ R_\beta = R_\beta\ R_{\alpha+2\beta}\ R_{\alpha+\beta}\ R_\alpha, \tag{3.3}$$

$$R_\alpha\ R_{\alpha+\beta}\ R_{2\alpha+3\beta}\ R_{\alpha+2\beta}\ R_{\alpha+3\beta}\ R_\beta = R_\beta\ R_{\alpha+3\beta}\ R_{\alpha+2\beta}\ R_{2\alpha+3\beta}\ R_{\alpha+\beta}\ R_\alpha, \tag{3.4}$$

where $|\alpha|\geqslant|\beta|$. In root systems of higher rank, we see that for any two roots α and β, R_α and R_β satisfy one of the equations (3.1)–(3.4). So it is sufficient to consider the above systems.

Let $\mathcal{M}_0$ be the set of meromorphic functions defined in a neighborhood of the origin of $\mathbb{C}$ with a possible pole at the origin. Let $\mathcal{H}_0$ be the set of holomorphic functions defined in a similar manner.

Although we considered the representation of the form (2.13), we relax the condition in the following. Namely, R_α acts on $\mathcal{M}_0$ and takes the form

$$(R_\alpha\ f)(x):=G_\alpha(\langle\alpha,x\rangle)f(x)+H_\alpha(\langle\alpha,x\rangle)f(s_\alpha(x)), \tag{3.5}$$

where $G_\alpha, H_\alpha \in \mathcal{M}_0$.

We study solutions G_α and H_α of (3.1), (3.2), (3.3) or (3.4) such that either G_α or H_α is not identically zero. Since the $A_1\times A_1$-type relation (3.1) does not require any constraint in G_α, H_α, we first investigate general solutions of the A_2-type (3.2).

Define for $\Im\tau>0$

$$\sigma_{a,b}(x,\lambda;\tau):=e^{-2\pi i b\lambda}\frac{\theta_1'(0;\tau)\theta_1(x+a+b\tau-\lambda;\tau)}{\theta_1(x+a+b\tau;\tau)\theta_1(-\lambda;\tau)}, \tag{3.6}$$

where $\theta_1(x;\tau)$ is the Jacobi theta function.

IV. A_2 CASE

A. Functional equations

Proposition 4.1: In the root system of type A_2, *the operators* R_γ *satisfy* (3.2) *if and only if* G_γ *and* H_γ *satisfy, up to an overall factor, the following equations:*

$$G_\alpha(u)=G_{\alpha+\beta}(u)=G_\beta(u), \tag{4.1a}$$

$$H_\alpha(u)H_{\alpha+\beta}(v)+H_{\alpha+\beta}(u+v)H_\beta(-u)-H_\alpha(u+v)H_\beta(v)=0, \tag{4.1b}$$

$$\begin{aligned}G_\alpha(u)G_\alpha(-u)-G_\alpha(v)G_\alpha(-v)&=H_\alpha(u)H_\alpha(-u)-H_\alpha(v)H_\alpha(-v)\\&=H_\beta(u)H_\beta(-u)-H_\beta(v)H_\beta(-v).\end{aligned} \tag{4.1c}$$

Proof: Substituting (3.5) into (3.2), we obtain functional equations as follows:

$$(G_{\alpha+\beta}(v)G_\beta(u+v)-G_{\alpha+\beta}(u+v)G_\beta(v))H_\alpha(u)=0, \tag{4.2a}$$

$$(G_\alpha(u+v)G_{\alpha+\beta}(u)-G_\alpha(u)G_{\alpha+\beta}(u+v))H_\beta(v)=0, \tag{4.2b}$$

$$\begin{aligned}&(G_\alpha(u)G_\beta(-u)-G_\alpha(-v)G_\beta(v))H_{\alpha+\beta}(u+v)+H_\alpha(u)H_{\alpha+\beta}(v)H_\beta(u)\\&-H_\alpha(v)H_{\alpha+\beta}(u)H_\beta(v)=0,\end{aligned} \tag{4.2c}$$

$$\begin{aligned}&G_\beta(u)H_\alpha(u)H_{\alpha+\beta}(v)+G_\alpha(u)H_{\alpha+\beta}(u+v)H_\beta(-u)\\&-G_{\alpha+\beta}(u)H_\alpha(u+v)H_\beta(v)=0,\end{aligned} \tag{4.2d}$$

$$\begin{aligned}&-G_\beta(v)H_\alpha(-v)H_{\alpha+\beta}(u+v)+G_{\alpha+\beta}(v)H_\alpha(u)H_\beta(u+v)\\&-G_\alpha(v)H_{\alpha+\beta}(u)H_\beta(v)=0,\end{aligned} \tag{4.2e}$$

where we have set $u:=\langle x,\alpha\rangle$ and $v:=\langle x,\beta\rangle$. From (4.2a) and (4.2b), since either H_α or H_β is not identically zero, we deduce $G_\alpha(u)=G_{\alpha+\beta}(u)=G_\beta(u)$ without loss of generality and obtain (4.1a). Then (4.2d) and (4.2e) are identical and implies (4.1b). The equation (4.1c) is obtained from (4.2c) by applying (4.1b). □

The equation (4.1b) appears in the classical, i.e., differential, case and was solved in Ref. 2.

Theorem 4.2([2]): *Consider the functional equation*

$$f(u)g(-v)+g(-u-v)h(-u)+h(v)f(u+v)=0. \tag{4.3}$$

(1) The only nontrivial solutions of (4.3) holomorphic around the origin are

$$f(u)=\frac{1}{\lambda}e^{pu},\quad g(u)=-\left(\frac{1}{\lambda+\mu}\right)e^{-(p+q)u},\quad h(u)=\frac{1}{\mu}e^{qu}, \tag{4.4}$$

where $\lambda,\mu,p,q\in\mathbb{C}$ *are arbitrary such that* $\lambda,\mu,\lambda+\mu\neq 0$.

(2) The only nontrivial solutions of (4.3) which have a pole at the origin are

$$\begin{aligned}f(u)&=a\sigma_{0,0}(bu,\lambda;\tau)e^{pu},\\g(u)&=a\sigma_{0,0}(bu,-\lambda-\mu;\tau)e^{-(p+q)u},\\h(u)&=a\sigma_{0,0}(bu,\mu;\tau)e^{qu},\end{aligned} \tag{4.5}$$

where $a,b,\lambda,\mu,p,q\in\mathbb{C}$ *are arbitrary such that* $a,b\neq 0$, $\lambda,\mu,\lambda+\mu\notin\mathbb{Z}+\mathbb{Z}\tau$. *In the above,* ∞ *as a period or a certain limit is also permitted.*[11]

Theorem 4.2 can be applied to $f(u)=H_\alpha(u)$, $g(u)=-H_{\alpha+\beta}(-u)$ and $h(u)=H_\beta(u)$.

B. Holomorphic solutions

Theorem 4.3: *The following functions exhaust all the nontrivial solutions of the equation (4.1) holomorphic around the origin*:

$$H_\alpha(u)=\frac{1}{\lambda}e^{pu},\quad H_{\alpha+\beta}(u)=\left(\frac{1}{\lambda+\mu}\right)e^{(p+q)u},\quad H_\beta(u)=\frac{1}{\mu}e^{qu},\tag{4.6a}$$

$$G_\alpha(u)=G_{\alpha+\beta}(u)=G_\beta(u)=\frac{1}{\nu}\phi(u),\tag{4.6b}$$

where $\lambda,\mu,\nu,p,q\in\mathbb{C}$ *are arbitrary such that* $\lambda,\mu,\nu,\lambda+\mu\neq 0$ *and* $\phi\in\mathcal{M}_0$ *satisfies* $\phi(u)\phi(-u)=1$.

C. Meromorphic solutions

Theorem 4.4: *The following functions exhaust all the nontrivial solutions of the equation (4.1) which has a pole at the origin:*

$$\begin{aligned}H_\alpha(u)&=a\sigma_{0,0}(bu,\lambda;\tau)e^{pu},\\ H_{\alpha+\beta}(u)&=a\sigma_{0,0}(bu,\lambda+\mu;\tau)e^{(p+q)u},\\ H_\beta(u)&=a\sigma_{0,0}(bu,\mu;\tau)e^{qu},\end{aligned}\tag{4.7a}$$

$$G_\alpha(u)=G_{\alpha+\beta}(u)=G_\beta(u)=a\sigma_{0,0}(bu,\nu;\tau)\phi(u),\tag{4.7b}$$

where $a,b,\lambda,\mu,\nu,p,q\in\mathbb{C}$ *such that* $a,b\neq 0$, $\lambda,\mu,\nu,\lambda+\mu\notin\mathbb{Z}+\mathbb{Z}\tau$ *and* $\phi\in\mathcal{M}_0$ *satisfies* $\phi(u)\phi(-u)=1$. *In the above,* ∞ *as a period or a certain limit is also permitted.*

Remark 4.5: The solution in Theorem 4.4 has the following principal part at the origin:

$$H_\alpha(u)=\frac{a}{bu}+\cdots.\tag{4.8}$$

V. B_2 CASE

A. Functional equations

Proposition 5.1: *In the root system of type* B_2, *the operators* R_γ *satisfy (3.3) if and only if* G_γ *and* H_γ *satisfy, up to an overall factor, the following equations:*

$$G_\alpha(u)=G_{\alpha+2\beta}(u),\quad G_{\alpha+\beta}(u)=G_\beta(u),\tag{5.1a}$$

$$H_{\alpha+\beta}(u+v)H_\alpha(-u-2v)+H_\beta(v)H_{\alpha+2\beta}(u)+H_{\alpha+\beta}(-v)H_{\alpha+2\beta}(u+2v)=H_\beta(u+v)H_\alpha(u),\tag{5.1b}$$

$$\begin{aligned}G_\alpha(u)G_\alpha(-u)-G_\alpha(v)G_\alpha(-v)&=H_\alpha(u)H_\alpha(-u)-H_\alpha(v)H_\alpha(-v)\\ &=H_{\alpha+2\beta}(u)H_{\alpha+2\beta}(-u)-H_{\alpha+2\beta}(v)H_{\alpha+2\beta}(-v),\end{aligned}\tag{5.1c}$$

$$G_\beta(u)G_\beta(-u)-G_\beta(v)G_\beta(-v)=H_\beta(u)H_\beta(-u)-H_\beta(v)H_\beta(-v)$$
$$=H_{\alpha+\beta}(u)H_{\alpha+\beta}(-u)-H_{\alpha+\beta}(v)H_{\alpha+\beta}(-v). \tag{5.1d}$$

Proof: Substituting (3.5) into (3.3), we obtain functional equations as follows:

$$(G_{\alpha+\beta}(v)G_\beta(u+v)-G_{\alpha+\beta}(u+v)G_\beta(v))G_{\alpha+2\beta}(u+2v)H_\alpha(u)=0, \tag{5.2a}$$

$$(G_\alpha(u+2v)G_{\alpha+2\beta}(u)-G_\alpha(u)G_{\alpha+2\beta}(u+2v))H_\beta(v)G_{\alpha+\beta}(u+v)=0, \tag{5.2b}$$

$$(G_\alpha(u)G_{\alpha+2\beta}(-u)-G_\alpha(-u)G_{\alpha+2\beta}(u))H_{\alpha+\beta}(u+v)H_\beta(v)$$
$$=(G_{\alpha+\beta}(v)G_\beta(-v)-G_{\alpha+\beta}(-v)G_\beta(v))H_\alpha(u)H_{\alpha+2\beta}(u+2v), \tag{5.2c}$$

$$G_\beta(u+v)G_{\alpha+2\beta}(u)H_{\alpha+\beta}(v)H_\alpha(u)+G_{\alpha+\beta}(u+v)G_\alpha(u)H_\beta(-u-v)H_{\alpha+2\beta}(u+2v)$$
$$+G_\beta(u+v)G_\alpha(u)H_{\alpha+\beta}(u+v)H_{\alpha+2\beta}(-u)$$
$$=G_{\alpha+\beta}(u+v)G_{\alpha+2\beta}(u)H_\beta(v)H_\alpha(u+2v), \tag{5.2d}$$

$$G_\beta(v)G_{\alpha+2\beta}(u+2v)H_{\alpha+\beta}(u+v)H_\alpha(-u-2v)+G_{\alpha+\beta}(v)G_\alpha(u+2v)H_\beta(v)H_{\alpha+2\beta}(u)$$
$$+G_\beta(v)G_\alpha(u+2v)H_{\alpha+\beta}(-v)H_{\alpha+2\beta}(u+2v)$$
$$=G_{\alpha+\beta}(v)G_{\alpha+2\beta}(u+2v)H_\beta(u+v)H_\alpha(u), \tag{5.2e}$$

$$G_\beta(v)G_\alpha(u)G_{\alpha+2\beta}(-u)H_{\alpha+\beta}(u+v)+G_\beta(v)H_{\alpha+\beta}(v)H_\alpha(u)H_{\alpha+2\beta}(u)$$
$$+G_{\alpha+\beta}(v)H_\beta(-v)H_\alpha(u)H_{\alpha+2\beta}(u+2v)$$
$$=G_\beta(v)H_{\alpha+\beta}(-v)H_\alpha(u+2v)H_{\alpha+2\beta}(u+2v)+G_{\alpha+\beta}(v)H_\beta(v)H_\alpha(u+2v)H_{\alpha+2\beta}(u)$$
$$+G_\beta(v)G_\alpha(-u-2v)G_{\alpha+2\beta}(u+2v)H_{\alpha+\beta}(u+v), \tag{5.2f}$$

$$G_{\alpha+2\beta}(u)H_{\alpha+\beta}(v)H_\beta(u+v)H_\alpha(u)+G_\alpha(u)H_{\alpha+\beta}(u+v)H_\beta(u+v)H_{\alpha+2\beta}(-u)$$
$$+G_{\alpha+\beta}(u+v)G_\beta(-u-v)G_\alpha(u)H_{\alpha+2\beta}(u+2v)$$
$$=G_{\alpha+2\beta}(u)H_{\alpha+\beta}(u+v)H_\beta(v)H_\alpha(-u)+G_\alpha(u)H_{\alpha+\beta}(v)H_\beta(v)H_{\alpha+2\beta}(u)$$
$$+G_{\alpha+\beta}(-v)G_\beta(v)G_\alpha(u)H_{\alpha+2\beta}(u+2v), \tag{5.2g}$$

where we have set $u:=\langle x,\alpha\rangle$ and $v:=\langle x,\beta\rangle$. First we see that from (5.2a) and (5.2b), $G_\alpha(u)=G_{\alpha+2\beta}(u)$ and $G_{\alpha+\beta}(u)=G_\beta(u)$, which implies (5.1a). Then (5.2c) vanishes and (5.2d) and (5.2e) result in the same equation as (5.1b). By applying (5.1b) to (5.2f) and (5.2g), we obtain (5.1c) and (5.1d). □

A solution of these equations possesses the duality:

Lemma 5.2: If $\tilde{G}_\gamma$ and $\tilde{H}_\gamma$ are a solution of (5.1), then

$$\begin{aligned} G_\alpha(u)&=\tilde{G}_\beta(u), \quad H_\alpha(u)=\tilde{H}_\beta(u),\\ G_\beta(u)&=\tilde{G}_\alpha(2u), \quad H_\beta(u)=\tilde{H}_\alpha(2u),\\ G_{\alpha+\beta}(u)&=\tilde{G}_{\alpha+2\beta}(2u), \quad H_{\alpha+\beta}(u)=\tilde{H}_{\alpha+2\beta}(2u),\\ G_{\alpha+2\beta}(u)&=\tilde{G}_{\alpha+\beta}(u), \quad H_{\alpha+2\beta}(u)=\tilde{H}_{\alpha+\beta}(u) \end{aligned} \tag{5.3}$$

are also a solution of (5.1).

Proof: This can be checked by a direct calculation. □

In the root systems of type $C_2^{(1)}$, $D_3^{(2)}$ or $A_4^{(2)}$, we have only the equation (3.3) and we actually need the general solution for the equations (5.1). However, it is a very difficult problem to obtain the general solution and we assume that H_α and $H_{\alpha+2\beta}$ are given by Theorem 4.3 or Theorem 4.4, which is not an assumption and is imposed in the other root systems.

B. Solutions associated with holomorphic solutions

We assume that H_α and $H_{\alpha+2\beta}$ are given by Theorem 4.3.

Lemma 5.3: Let

$$H_\alpha(u)=\frac{1}{\lambda}e^{pu},\quad H_{\alpha+2\beta}(u)=\frac{1}{\mu}e^{qu}, \tag{5.4}$$

where $\lambda,\mu\neq 0$. *Then the solution of (5.1b) is*

$$H_\beta(u)=e^{(-p+q)u}(b+\varphi(u)),\quad H_{\alpha+\beta}(u)=e^{(p+q)u}(a+\varphi(u)), \tag{5.5}$$

where $\varphi\in\mathcal{M}_0$ *is an arbitrary odd function and* $a,b\in\mathbb{C}$ *are arbitrary such that* $a(\lambda+\mu)+b(\lambda-\mu)=0$.

Proof: We assume that $\lambda\neq\mu$. By substituting (5.4) and $H_\beta(u)=f(u)e^{(-p+q)u}$ and $H_{\alpha+\beta}(u)=g(u)e^{(p+q)u}$ into the equation (5.1b), we obtain

$$\lambda f(v)-\mu f(u+v)+\lambda g(-v)+\mu g(u+v)=0, \tag{5.6}$$

and thus by setting $u=0$,

$$f(v)=\frac{\lambda g(-v)+\mu g(v)}{-\lambda+\mu}. \tag{5.7}$$

Substituting this into (5.6) and setting $u=0$ after the differentiation by u, we arrive at

$$(g(v)+g(-v))'=0. \tag{5.8}$$

This differential equation yields

$$g(v)=a+\varphi(v), \tag{5.9}$$

where $a\in\mathbb{C}$ is an arbitrary constant and $\varphi\in\mathcal{M}_0$ is an arbitrary odd function. Again substituting this function into (5.6), we can check that they are really a solution of (5.1b). If $\lambda=\mu$, then by exchanging the roles of f and g, the statement follows. □

Theorem 5.4: *Let*

$$H_\alpha(u)=\frac{1}{\lambda}e^{pu},\quad H_{\alpha+2\beta}(u)=\frac{1}{\mu}e^{qu}, \tag{5.10a}$$

$$G_\alpha(u)=G_{\alpha+2\beta}(u)=\frac{1}{\nu}\phi(u), \tag{5.10b}$$

where $\lambda,\mu\neq 0$ *and* $\phi\in\mathcal{M}_0$ *satisfies* $\phi(u)\phi(-u)=1$. *Then the following functions exhaust all the nontrivial solutions of the equation (5.1):*

$$H_\beta(u)=e^{(-p+q)u}(b+\varphi(u)),\quad H_{\alpha+\beta}(u)=e^{(p+q)u}(a+\varphi(u)), \tag{5.11a}$$

$$G_\beta(u)=G_{\alpha+2\beta}(u)=\psi(u)(c+\varphi(u)), \tag{5.11b}$$

where $\varphi \in \mathcal{M}_0$ *is odd and* $a,b,c \in \mathbb{C}$ *are such that* $a(\lambda+\mu)+b(\lambda-\mu)=0$ *and* $\psi \in \mathcal{M}_0$ *satisfies* $\psi(u)\psi(-u)=1$.

C. Solutions associated with meromorphic solutions

We assume that H_α and $H_{\alpha+2\beta}$ are given by Theorem 4.4 and consider the following equation:

$$H_{\alpha+\beta}(v)H_\alpha(u-v)+H_\beta(-u)H_{\alpha+2\beta}(u+v)+H_{\alpha+\beta}(u)H_{\alpha+2\beta}(-u+v) = H_\beta(v)H_\alpha(u+v), \tag{5.1b$'$}$$

which is obtained by replacing u by $u+v$ and v by $-u$ in (5.1b).

Set

$$H_\beta(u)=\sum_{i\geqslant -p} H_\beta^{(i)}u^i, \quad H_{\alpha+\beta}(u)=\sum_{i\geqslant -q} H_{\alpha+\beta}^{(i)}u^i. \tag{5.12}$$

Lemma 5.5: If either H_β *or* $H_{\alpha+\beta}$ *has a pole at the origin, then both* H_β *and* $H_{\alpha+\beta}$ *have a simple pole at the origin and* $H_\beta^{(-1)}=H_{\alpha+\beta}^{(-1)}$.

Proof: We assume H_β has a pole at the origin of order $p>0$. By substituting (5.12) and the Taylor expansions of $H_\alpha(u+v)$, $H_\alpha(u-v)$, $H_{\alpha+2\beta}(u+v)$ and $H_{\alpha+2\beta}(-u+v)$ with respect to u into the equation (5.1b$'$), we see that $H_{\alpha+\beta}$ has the same order as H_β at the origin. Comparing the coefficient of u^{-p}, we have

$$H_{\alpha+\beta}^{(-p)}=(-1)^{-p+1}H_\beta^{(-p)}. \tag{5.13}$$

If $p>1$, we have the following equation by comparing the coefficient of u^{-p+1}:

$$(H_{\alpha+\beta}^{(-p+1)}+(-1)^{-p+1}H_\beta^{(-p+1)})H_{\alpha+2\beta}(v)-2H_{\alpha+\beta}^{(-p)}H'_{\alpha+2\beta}(v)=0, \tag{5.14}$$

where we have used (5.13). Since $H_\beta(v)$ is not of the form ae^{bv}, we have $H_{\alpha+\beta}^{(-p)}=0$, which contradicts to the assumption and implies $p=1$. The case that $H_{\alpha+\beta}$ has a pole at the origin is shown similarly. □

By substituting the form $H_\gamma(u)=\Sigma_{i=-1}^{\infty}H_\gamma^{(i)}u^i$ and $H_\alpha^{(-1)}=H_{\alpha+2\beta}^{(-1)}$ and $H_\beta^{(-1)}=H_{\alpha+\beta}^{(-1)}$, we obtain for all $l,m\geqslant 0$,

$$\begin{aligned}
&-H_\alpha^{(-1)}((-1)^mH_{\alpha+\beta}^{(l+m+1)}+H_\beta^{(l+m+1)})+H_\beta^{(-1)}\Bigg(((-1)^{l+m+1}+(-1)^{m+1})\binom{l+m+1}{m}H_\alpha^{(l+m+1)}\\
&\quad+((-1)^{m+1}-1)\binom{l+m+1}{m+1}H_{\alpha+2\beta}^{(l+m+1)}\Bigg)+\sum_{k=0}^{l}\binom{m+k}{k}((-1)^{m+k}H_{\alpha+\beta}^{(l-k)}H_\alpha^{(m+k)}\\
&\quad-(-1)^mH_\beta^{(l-k)}H_\alpha^{(m+k)})+\sum_{k=0}^{m}\binom{l+k}{k}((-1)^kH_\beta^{(m-k)}H_{\alpha+2\beta}^{(l+k)}+(-1)^{m-k}H_{\alpha+\beta}^{(m-k)}H_{\alpha+2\beta}^{(l+k)})\\
&\quad=0.
\end{aligned} \tag{5.15}$$

Lemma 5.6: H_β *and* $H_{\alpha+\beta}$ *are determined by* $H_\beta^{(-1)}$, $H_\beta^{(0)}$, $H_\beta^{(1)}$ *and* $H_{\alpha+\beta}^{(0)}$.

Proof: In (5.15), by setting $l=n-m-1$ we obtain two equations for $m=0,1$, which are written in the form

$$-H_\alpha^{(-1)}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}\begin{pmatrix}H_\beta^{(n)}\\ H_{\alpha+\beta}^{(n)}\end{pmatrix}=\Phi_n, \tag{5.16}$$

where Φ_n consists of $H_\beta^{(i)}$ and $H_{\alpha+\beta}^{(i)}$ for $-1\leqslant i<n$ and $H_\alpha^{(i)}$ and $H_{\alpha+2\beta}^{(i)}$ for $-1\leqslant i\leqslant n$. Since $H_\alpha^{(-1)}\neq 0$, we see by induction that $H_\beta^{(n)}$ and $H_{\alpha+\beta}^{(n)}$ for $n\geqslant 2$ are determined by $H_\beta^{(-1)}$, $H_\beta^{(0)}$, $H_\beta^{(1)}$, $H_{\alpha+\beta}^{(0)}$, $H_{\alpha+\beta}^{(1)}$, and $H_\alpha^{(i)}$ and $H_{\alpha+2\beta}^{(i)}$ for $i\geqslant -1$. The $l=m=0$ case of (5.15) yields

$$H_\alpha^{(0)}(H_\beta^{(0)}-H_{\alpha+\beta}^{(0)})+H_\alpha^{(-1)}(H_\beta^{(1)}+H_{\alpha+\beta}^{(1)})+2H_\beta^{(-1)}(H_\alpha^{(1)}+H_{\alpha+2\beta}^{(1)})=H_{\alpha+2\beta}^{(0)}(H_\beta^{(0)}+H_{\alpha+\beta}^{(0)}) \tag{5.17}$$

and shows that $H_{\alpha+\beta}^{(1)}$ and thus H_β and $H_{\alpha+\beta}$ are determined by $H_\beta^{(-1)}$, $H_\beta^{(0)}$, $H_\beta^{(1)}$ and $H_{\alpha+\beta}^{(0)}$.□

By Lemma 5.6, we see that $H_\beta^{(-1)}$, $H_\beta^{(0)}$, $H_{\alpha+\beta}^{(0)}$ and $H_\beta^{(1)}$ may be taken arbitrarily as long as the series converges.

Now we return to the whole system (5.1).

Theorem 5.7: *Let*

$$H_\alpha(u)=a\sigma_{0,0}(b\,u,\lambda;\tau)e^{pu},\quad H_{\alpha+2\beta}(u)=a\sigma_{0,0}(b\,u,\mu;\tau)e^{qu}, \tag{5.18a}$$

$$G_\alpha(u)=G_{\alpha+2\beta}(u)=a\sigma_{0,0}(b\,u,\nu;\tau)\phi(u), \tag{5.18b}$$

where $a,b,\lambda,\mu,\nu,p,q\in\mathbb{C}$ *such that* $a,b\neq 0$, $\lambda,\mu,\nu,-\lambda+\mu,\lambda+\mu\notin\mathbb{Z}+\mathbb{Z}\tau$ *and* $\phi\in\mathcal{M}_0$ *satisfies* $\phi(u)\phi(-u)=1$. *Then the following functions exhaust all the nontrivial solutions of the equations (5.1):*

$$H_\beta(u)=\sum_{m,n=0}^{1}a_{m,n}\sigma_{m/2,n/2}(b\,u,-\lambda+\mu;\tau)e^{(-p+q)u},$$

$$H_{\alpha+\beta}(u)=\sum_{m,n=0}^{1}a_{m,n}\sigma_{m/2,n/2}(b\,u,\lambda+\mu;\tau)e^{(p+q)u}, \tag{5.19a}$$

$$G_\beta(u)=G_{\alpha+\beta}(u)=\sum_{m,n=0}^{1}a_{m,n}\sigma_{m/2,n/2}(b\,u,\eta;\tau)\psi(u), \tag{5.19b}$$

where $\eta,a_{m,n}\in\mathbb{C}$ *for* $0\leqslant m,\ n\leqslant 1$ *are arbitrary such that* $\eta\notin\mathbb{Z}+\mathbb{Z}\tau$ *and* $\psi\in\mathcal{M}_0$ *satisfies* $\psi(u)\psi(-u)=1$.

Proof: We know that the equation (5.1b) has at most four free parameters. It is known that for arbitrary $a_{m,n}\in\mathbb{C}$, (5.19a) satisfies the equation (5.1b).[7]

By a direct calculation we have

$$A\begin{pmatrix}a_{0,0}\\ a_{1/2,0}\\ a_{1/2,1/2}\\ a_{0,1/2}\end{pmatrix}=\begin{pmatrix}H_\beta^{(-1)}\\ H_\beta^{(0)}\\ H_{\alpha+\beta}^{(0)}\\ H_\beta^{(1)}\end{pmatrix}, \tag{5.20}$$

where A is a matrix whose determinant is $f(\lambda+\mu,-\lambda+\mu)$ and

$$\begin{aligned}f(x,y)=&-\frac{\theta_1'^{\,3}(0)}{\theta_0(0)\theta_2(0)\theta_3(0)\theta_1(x)\theta_1(y)^2}(-\theta_3(x)\theta_2(y)\theta_0'(y)+\theta_2(x)\theta_3(y)\theta_0'(y)\\&+\theta_3(x)\theta_0(y)\theta_2'(y)-\theta_0(x)\theta_3(y)\theta_2'(y)-\theta_2(x)\theta_0(y)\theta_3'(y)+\theta_0(x)\theta_2(y)\theta_3'(y))\end{aligned} \tag{5.21}$$

$$=\frac{\theta_1((x-y)/2)^2\theta_1((x+y)/2)^2}{\theta_1(x)}g(y), \tag{5.22}$$

with $g(y)$ a meromorphic function which has simple poles at $\mathbb{Z}+\mathbb{Z}\tau$ and no zeros. By the assumption $\lambda,\mu\notin\mathbb{Z}+\mathbb{Z}\tau$, we see that the determinant is always nonzero and A is invertible. □

Remark 5.8: In Theorem 5.7, the $\lambda+\mu\in\mathbb{Z}+\mathbb{Z}\tau$ or $-\lambda+\mu\in\mathbb{Z}+\mathbb{Z}\tau$ case is not investigated.

D. Exceptional solutions

As mentioned before, the general solution of (5.1) is not known. But we found another solution experimentally.

Theorem 5.9: *The following is a solution of the equations (5.1):*

$$\begin{aligned}
H_\alpha(u)&=a\sigma_{0,0}(cu,\lambda;\tau)e^{pu}+b\sigma_{0,0}(cu,2\lambda;2\tau)e^{pu},\\
H_{\alpha+2\beta}(u)&=a\sigma_{0,0}(cu,\mu;\tau)e^{qu}+b\sigma_{0,0}(cu,2\mu;2\tau)e^{qu},\\
H_\beta(u)&=a'\sigma_{0,0}(cu,-\lambda+\mu;\tau)e^{(-p+q)u}+b'\sigma_{0,0}(2cu,-\lambda+\mu;2\tau)e^{(-p+q)u},\\
H_{\alpha+\beta}(u)&=a'\sigma_{0,0}(cu,\lambda+\mu;\tau)e^{(p+q)u}+b'\sigma_{0,0}(2cu,\lambda+\mu;2\tau)e^{(p+q)u},
\end{aligned}\tag{5.23a}$$

$$\begin{aligned}
G_\alpha(u)&=G_{\alpha+2\beta}(u)=a\sigma_{0,0}(cu,\nu;\tau)\phi(u)+b\sigma_{0,0}(cu,2\nu;2\tau)\phi(u),\\
G_\beta(u)&=G_{\alpha+\beta}(u)=a'\sigma_{0,0}(cu,\eta;\tau)\varphi(u)+b'\sigma_{0,0}(2cu,\eta;2\tau)\varphi(u),
\end{aligned}\tag{5.23b}$$

where $a,b,c,a',b',\lambda,\mu,\nu,\eta,p,q$ *are arbitrary complex numbers, and* $\phi,\varphi\in\mathcal{M}_0$ *satisfy* $\phi(u)\phi(-u)=\varphi(u)\varphi(-u)=1$.

Proof: This follows from the linearity of the equation (5.1b), Lemma 5.2 and the following identity. □

Lemma 5.10:

$$\begin{pmatrix}\sigma_{0,0}(2u,\mu;\tau)\\ \sigma_{0,0}(u,\mu;\tau/2)\\ \sigma_{0,0}(2u,2\mu;2\tau)\\ \sigma_{0,0}(u,2\mu;\tau)\end{pmatrix}=\begin{pmatrix}\frac12&\frac12&\frac12&\frac12\\ 0&1&0&1\\ 0&0&\frac12&\frac12\\ 0&0&0&1\end{pmatrix}\begin{pmatrix}\sigma_{1/2,1/2}(u,2\mu;\tau)\\ \sigma_{0,1/2}(u,2\mu;\tau)\\ \sigma_{1/2,0}(u,2\mu;\tau)\\ \sigma_{0,0}(u,2\mu;\tau)\end{pmatrix}.\tag{5.24}$$

Remark 5.11: We can choose a,b,a',b' so that $H_\gamma\in\mathcal{H}_0$. Such a solution indicates that in the B_2 case, holomorphy does not simplify solutions as in the A_2 case. See Theorem 4.3. The solution in Theorem 5.9 corresponds to the system studied in Refs. 8 and 9.

VI. G_2 CASE

In this section, we study the solution related to the G_2 system. The functional equations are much more complicated than the A_2 or the B_2 case and we have not completed the investigation of general solutions.

A. Functional equations

In the following, we make an assumption called extensibility:[4]

$$R_\alpha\ R_{2\alpha+3\beta}\ R_{\alpha+3\beta}=R_{\alpha+3\beta}\ R_{2\alpha+3\beta}\ R_\alpha.\tag{6.1}$$

Then we have the following equivalent condition to (3.4):

Theorem 6.1: *The operators* R_γ *satisfy (3.4) if and only if* G_γ *and* H_γ *satisfy, up to an overall factor, the following equations:*

$$G_{\alpha+\beta}(u)=G_{\alpha+2\beta}(u)=G_\beta(u),\tag{6.2a}$$

$$H_\alpha(u)H_\beta(u+v)-H_\alpha(-2u-3v)H_{\alpha+\beta}(u+v)-H_\beta(v)H_{\alpha+3\beta}(u)-H_{\alpha+2\beta}(-v)H_{\alpha+3\beta}(u+3v)$$
$$-H_{\alpha+2\beta}(u+2v)H_{2\alpha+3\beta}(-u-3v)-H_{\alpha+\beta}(-u-2v)H_{2\alpha+3\beta}(2u+3v)=0, \tag{6.2b}$$

$$G_\beta(u)G_\beta(-u)-G_\beta(v)G_\beta(-v)=H_\beta(u)H_\beta(-u)-H_\beta(v)H_\beta(-v), \tag{6.2c}$$

$$G_\alpha(-u)G_\alpha(u)H_{\alpha+\beta}(u+v)H_{\alpha+2\beta}(v)+G_\alpha(-2u-3v)G_\alpha(2u+3v)H_\beta(-u-v)H_{\alpha+2\beta}(u+2v)$$
$$-G_\alpha(-2u-3v)G_\alpha(2u+3v)H_\beta(v)H_{\alpha+\beta}(u+2v)+G_\beta(-u-v)G_\beta(u+v)$$
$$\times H_{\alpha+3\beta}(-u)H_{2\alpha+3\beta}(2u+3v)+G_\beta(-v)G_\beta(v)H_\alpha(u)H_{2\alpha+3\beta}(u+3v)$$
$$-G_\beta(-v)G_\beta(v)H_\alpha(2u+3v)H_{\alpha+3\beta}(u+3v)+H_\alpha(u)H_{\alpha+\beta}(v)H_{\alpha+2\beta}(u+v)H_{\alpha+3\beta}(-u)$$
$$+H_\alpha(u)H_{\alpha+\beta}(v)H_{\alpha+2\beta}(v)H_{2\alpha+3\beta}(u)+H_\alpha(u)H_{\alpha+\beta}(v)H_\beta(-u-v)H_{\alpha+3\beta}(2u+3v)$$
$$-H_\alpha(2u+3v)H_\beta(v)H_{\alpha+\beta}(-u-v)H_{2\alpha+3\beta}(2u+3v)-H_\alpha(2u+3v)H_\beta(v)H_{\alpha+2\beta}(u+v)$$
$$\times H_{2\alpha+3\beta}(-u)-H_\alpha(2u+3v)H_\beta(v)H_{\alpha+2\beta}(v)H_{\alpha+3\beta}(u)+H_{\alpha+\beta}(u+v)H_{\alpha+2\beta}(u+v)$$
$$\times H_{\alpha+3\beta}(-u)H_{2\alpha+3\beta}(-u)+H_\beta(-u-v)H_{\alpha+\beta}(u+v)H_{\alpha+3\beta}(2u+3v)H_{2\alpha+3\beta}(-u)$$

&+H_{\alpha}(u)H_{\beta}(-v)H_{\alpha+\beta}(v)H_{\alpha+3\beta}(u+3v)H_{2\alpha+3\beta}(u)+H_{\alpha}(u)H_{\beta}(-v)H_{\alpha+2\beta}(-v)\\
&\times H_{\alpha+3\beta}(u+3v)H_{2\alpha+3\beta}(u+3v)-H_{\alpha}(u+3v)H_{\beta}(v)H_{\alpha+2\beta}(v)H_{\alpha+3\beta}(u)H_{2\alpha+3\beta}(u)\\
&-H_{\alpha}(u+3v)H_{\beta}(v)H_{\alpha+\beta}(-v)H_{\alpha+3\beta}(u)H_{2\alpha+3\beta}(u+3v)=0. \qquad (6.2f)
\end{aligned}
$$

We omit the proof, since it is straightforward but lengthy. We remark that the equations (6.2a)–(6.2c) are comparable to the equation (4.1) or (5.1), while the others do not seem to be simplified.

B. Solutions associated with holomorphic solutions

We assume that H_{α}, $H_{2\alpha+3\beta}$ and $H_{\alpha+3\beta}$ are given by Theorem 4.3.

Lemma 6.2: Let

$$
H_{\alpha}(u)=\frac{1}{\lambda}e^{pu},\quad H_{2\alpha+3\beta}(u)=\left(\frac{1}{\lambda+\mu}\right)e^{(p+q)u},\quad H_{\alpha+3\beta}(u)=\frac{1}{\mu}e^{qu}, \qquad (6.3)
$$

where $\lambda,\mu,\lambda+\mu\neq 0$. *Then the solution of (6.2b) is*

$$
\begin{aligned}
H_{\beta}(u)&=e^{(-p+q)u}(a+\varphi(u)),\\
H_{\alpha+2\beta}(u)&=e^{(p+2q)u}(b-\varphi(-u)),\\
H_{\alpha+\beta}(u)&=e^{(2p+q)u}(c+\varphi(u)),
\end{aligned} \qquad (6.4)
$$

where $\varphi\in\mathcal{M}_0$ *and* $a,b,c\in\mathbb{C}$ *are such that*

$$
a(\lambda+\mu)(\lambda-\mu)+b\lambda(\lambda+2\mu)+c\mu(2\lambda+\mu)=0. \qquad (6.5)
$$

Proof: We assume that $\lambda\neq\mu$. By substituting (6.3) and $H_{\beta}(u)=f(u)e^{(-p+q)u}$, $H_{\alpha+\beta}(u)=g(u)e^{(2p+q)u}$ and $H_{\alpha+2\beta}(u)=h(u)e^{(p+2q)u}$ into the equation (6.2b), we obtain

$$
\begin{aligned}
&\lambda(\lambda+\mu)f(v)-\mu(\lambda+\mu)f(u+v)+\mu(\lambda+\mu)g(u+v)\\
&\quad+\lambda(\lambda+\mu)h(-v)+\lambda\mu(g(-u-2v)+h(u+2v))=0,
\end{aligned} \qquad (6.6)
$$

and thus by setting $u=0$,

$$
f(v)=\frac{\lambda\mu g(-2v)+\mu(\lambda+\mu)g(v)+\lambda(\lambda+\mu)h(-v)+\lambda\mu h(2v)}{-\lambda^2+\mu^2}. \qquad (6.7)
$$

Substituting this and $g(v)=c+\varphi(v)$ and $h(v)=a(v)-\varphi(-v)$ into (6.6), we have the following equations for $a(v)$ by setting $u=0$ after the differentiation by u, and $u=-3v$:

$$
(a(-v)+a(2v))'=0, \qquad (6.8)
$$

$$
a(-4v)-2a(-v)+a(2v)=0. \qquad (6.9)
$$

The first equation is solved as

$$a(-v)+a(2v)=2b, \tag{6.10}$$

where $b\in\mathbb{C}$ is an arbitrary constant, and consequently the second as $a(v)=b$. Hence by (6.7), we see that f, g and h should be of the form

$$f(u)=-\frac{c\mu(2\lambda+\mu)+b\lambda(\lambda+2\mu)}{\lambda^2-\mu^2}+\varphi(v), \tag{6.11}$$

$$g(u)=c+\varphi(u), \tag{6.12}$$

$$h(u)=b-\varphi(-u) \tag{6.13}$$

for some $\varphi\in\mathcal{M}_0$. Substituting these functions into (6.6), we can check that they are really a solution of (6.2b) for any $\varphi\in\mathcal{M}_0$. If $\lambda=\mu$, then by exchanging the roles of f and g, the statement follows. □

Theorem 6.3: *Let*

$$H_\alpha(u)=\frac{1}{\lambda}e^{pu},\quad H_{2\alpha+3\beta}(u)=\left(\frac{1}{\lambda+\mu}\right)e^{(p+q)u},\quad H_{\alpha+3\beta}(u)=\frac{1}{\mu}e^{qu}, \tag{6.14a}$$

$$G_\alpha(u)=G_{2\alpha+3\beta}(u)=G_{\alpha+3\beta}(u)=\frac{1}{\nu}\phi(u), \tag{6.14b}$$

where $\lambda,\mu,\nu,\lambda+\mu,2\lambda+\mu,\mu+2\lambda\neq 0$ *and* $\phi\in\mathcal{M}_0$ *satisfies* $\phi(u)\phi(-u)=1$. *Then the following functions exhaust all the nontrivial solutions of the equations (6.2) if* $a\neq -b$:

$$\begin{aligned} H_\beta(u)&=e^{(-p+q)u}(a+\varphi(u)),\\ H_{\alpha+2\beta}(u)&=e^{(p+2q)u}(b-\varphi(-u)), \end{aligned} \tag{6.15a}$$

$$\begin{aligned} H_{\alpha+\beta}(u)&=e^{(2p+q)u}(c+\varphi(u)),\\ G_\beta(u)=G_{\alpha+2\beta}(u)&=G_{\alpha+\beta}(u)=\psi(u)(\kappa+\varphi(u)), \end{aligned} \tag{6.15b}$$

where $a,b,c,\kappa\in\mathbb{C}$ *and*

$$\varphi(u)=\eta/u,\quad \eta\in\mathbb{C}, \tag{6.16a}$$

$$\begin{aligned} &-a(\lambda-\mu)=b(\lambda+2\mu)=c(2\lambda+\mu)\quad \textit{or}\\ &-a(2\nu^2-\lambda\mu-\mu^2)=b(2\nu^2+\lambda\mu),\quad a(2\nu^2-\lambda^2-\lambda\mu)=c(2\nu^2+\lambda\mu), \end{aligned} \tag{6.16b}$$

or

$$\varphi(u)=d\coth(du/\eta),\quad \eta\in\mathbb{C}\backslash\{0\}, \tag{6.17a}$$

$$a(\lambda+\mu)(\lambda-\mu)+b\lambda(\lambda+2\mu)+c\mu(2\lambda+\mu)=0, \tag{6.17b}$$

$$d^2=\frac{ab(\lambda^2+\lambda\mu-2\nu^2)}{\lambda(\lambda+\mu)}-\frac{ac\lambda(\lambda\mu+\mu^2-2\nu^2)}{\mu(\lambda+\mu)}+\frac{bc(\lambda+\mu)(\lambda\mu+2\nu^2)}{\lambda\mu}, \tag{6.17c}$$

and $\psi\in\mathcal{M}_0$ *satisfies* $\psi(u)\psi(-u)=1$.

Proof: Substituting (6.4) with (6.5) into the equation (6.2f), we have

$$(a+b)(\varphi(-u)+\varphi(u)-\varphi(-u-v)-\varphi(u+v))=0, \tag{6.18}$$

where we have used $\lambda,\lambda+2\mu,2\lambda+\mu\neq 0$ and the equation (6.2c). By the proof of Lemma 6.2, we assume without loss of generality that $\varphi(u)$ has no constant term in the Laurent expansion at the origin.

Since we assume $a\neq -b$, then $\varphi(u)$ is an odd function. By the equation (6.2d), we have

$$\varphi(u)\varphi(v)-\varphi(v)\varphi(u+v)-\varphi(u)\varphi(u+v)=d^2, \tag{6.19}$$

where

$$d^2=\frac{ab(\lambda^2+\lambda\mu-2\nu^2)}{\lambda(\lambda+\mu)}-\frac{ac\lambda(\lambda\mu+\mu^2-2\nu^2)}{\mu(\lambda+\mu)}+\frac{bc(\lambda+\mu)(\lambda\mu+2\nu^2)}{\lambda\mu}. \tag{6.20}$$

If $\varphi\in\mathcal{H}_0$, then $\varphi(0)=0$ and thus $\varphi(v)=d=0$ by (6.19). In this case, we have (6.16b) by using (6.5). If $\varphi\in\mathcal{M}_0$ with a pole at the origin, then it should be simple. Replacing $\varphi(u)$ by $1/f(u)$, we have

$$f(u+v)-f(u)-f(v)=d^2f(u)f(v)f(u+v). \tag{6.21}$$

Dividing both sides by u and letting $u\to 0$, we obtain

$$f'(v)-f'(0)=d^2f'(0)f(v)^2. \tag{6.22}$$

This Riccati-type ordinary differential equation has a unique solution:

$$\begin{gathered} f(u)=\tanh(du/\eta)/d, \quad \text{if } d\neq 0, \\ f(u)=u/\eta, \quad \text{if } d=0, \end{gathered} \tag{6.23}$$

for an arbitrary constant $\eta\neq 0$, and it is checked that $\varphi(u)=d\coth(du/\eta)$ or $\varphi(u)=\eta/u$ is actually a solution of (6.19). □

Remark 6.4: If $a=-b$, then by (6.5) we have $b=c$ and the following functional equation is necessary and sufficient for $\gamma(u)=\varphi(u)-b$:

$$\gamma(u-v)\gamma(-v)+\gamma(u)\gamma(v)+\gamma(-u)\gamma(-u+v)=0, \tag{6.24}$$

which is not completely solved yet. However, (6.16a) or (6.17a) is a solution of (6.24).

C. Solutions associated with meromorphic solutions

Similarly to the B_2-type system, the equation (6.2b) has linearity of the solutions for fixed H_α, $H_{2\alpha+3\beta}$ and $H_{\alpha+3\beta}$. Moreover, we can show the following lemma. Set $H_\gamma(u)=\Sigma_{i\geqslant p}H_\gamma^{(i)}u^i$.

Lemma 6.5: *In the equation (6.2b), if one of H_β, $H_{\alpha+2\beta}$ or $H_{\alpha+\beta}$ has a pole at the origin, then all have a simple pole at the origin and $H_\beta^{(-1)}=H_{\alpha+2\beta}^{(-1)}=H_{\alpha+\beta}^{(-1)}$. H_β, $H_{\alpha+\beta}$ and $H_{\alpha+2\beta}$ are determined by $H_\beta^{(-1)}$, $H_\beta^{(0)}$, $H_{\alpha+2\beta}^{(0)}$, $H_{\alpha+\beta}^{(0)}$, $H_\beta^{(1)}$, $H_{\alpha+2\beta}^{(1)}$, $H_\beta^{(2)}$, $H_\beta^{(3)}$ and $H_{\alpha+2\beta}^{(3)}$.*

Theorem 6.6: *Let*

$$\begin{gathered} H_\alpha(u)=a\sigma_{0,0}(bu,\lambda;\tau)e^{pu}, \\ H_{2\alpha+3\beta}(u)=a\sigma_{0,0}(bu,\lambda+\mu;\tau)e^{(p+q)u}, \\ H_{\alpha+3\beta}(u)=a\sigma_{0,0}(bu,\mu;\tau)e^{qu}, \end{gathered} \tag{6.25}$$

where $a,b,\lambda,\mu,p,q\in\mathbb{C}$ *are arbitrary such that* $a,b\neq 0$, $\lambda,\mu,\lambda+\mu,\lambda-\mu,\lambda+2\mu,2\lambda+\mu\notin\mathbb{Z}+\mathbb{Z}\tau$. *Then the following functions are solutions of the equation (6.2b):*

$$\begin{aligned}
H_\beta(u)&=\sum_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(b\,u,-\lambda+\mu;\tau)e^{(-p+q)u},\\
H_{\alpha+2\beta}(u)&=-\sum_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(-b\,u,-\lambda-2\mu;\tau)e^{(p+2q)u},\\
H_{\alpha+\beta}(u)&=\sum_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(b\,u,2\lambda+\mu;\tau)e^{(2p+q)u},
\end{aligned}\tag{6.26}$$

where $a_{m,n}\in\mathbb{C}$ *are arbitrary*.

Remark 6.7: Although the solution in Theorem 6.6 has nine parameters, it is not known whether or not they exhaust all the nontrivial solutions since the same process as in Theorem 5.7 is too complicated to execute.

Theorem 6.8: *Under the same condition as in Theorem 6.6, the following functions are solutions of the equations (6.2):*

$$\begin{aligned}
H_\beta(u)&=\sum_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(b\,u,-\lambda+\mu;\tau)e^{(-p+q)u},\\
H_{\alpha+2\beta}(u)&=-\sum_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(-b\,u,-\lambda-2\mu;\tau)e^{(p+2q)u},\\
H_{\alpha+\beta}(u)&=\sum_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(b\,u,2\lambda+\mu;\tau)e^{(2p+q)u},
\end{aligned}\tag{6.27a}$$

$$G_\beta(u)=G_{\alpha+2\beta}(u)=G_{\alpha+\beta}(u)=\sum_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(b\,u,\eta;\tau)\psi(u),\tag{6.27b}$$

where $\eta\in\mathbb{C}$ *is arbitrary,* $\psi\in\mathcal{M}_0$ *satisfies* $\psi(u)\psi(-u)=1$, *and* $\{a_{m,n}\in\mathbb{C}\}$ *is one of the following:*

	$a_{0,0}$	$a_{0,1}$	$a_{0,2}$	$a_{1,0}$	$a_{1,1}$	$a_{1,2}$	$a_{2,0}$	$a_{2,1}$	$a_{2,2}$
I	1	0	0	0	0	0	0	0	0
II	1	1	1	c	c	c	c^2	c^2	c^2
	1	c	c^2	1	c	c^2	1	c	c^2
	1	c	c^2	c^2	1	c	c	c^2	1
	1	c	c^2	c	c^2	1	c^2	1	c
III	1	c	c^2	0	0	0	0	0	0
IV	1	0	0	c	0	0	c^2	0	0
V	1	0	0	0	c	0	0	0	c^2
VI	1	0	0	0	0	c	0	c^2	0

(6.28)

where c *is one of cubic roots of unity*.

This is checked by comparing the poles and periodicity for the equations (6.2c)–(6.2f).

Remark 6.9: There are 22 solutions and the function $\Sigma_{m,n=0}^{2} a_{m,n}\sigma_{m/3,n/3}(u,3\mu;\tau)$ is simplified up to constant factor as follows except V and VI:

				(6.29)
I		$\sigma_{0,0}(3\mu,u;\tau)$		
II	$\sigma_{0,0}(\mu,3u;\tau)$	$\sigma_{1/3,0}(\mu,3u;\tau)$	$\sigma_{2/3,0}(\mu,3u;\tau)$	
	$\sigma_{0,1/3}(\mu,3u;\tau)$	$\sigma_{1/3,1/3}(\mu,3u;\tau)$	$\sigma_{2/3,1/3}(\mu,3u;\tau)$	
	$\sigma_{0,2/3}(\mu,3u;\tau)$	$\sigma_{1/3,2/3}(\mu,3u;\tau)$	$\sigma_{2/3,2/3}(\mu,3u;\tau)$	
III	$\sigma_{0,0}(\mu,u;\tau/3)$	$\sigma_{1/3,0}(\mu,u;\tau/3)$	$\sigma_{2/3,0}(\mu,u;\tau/3)$	
IV	$\sigma_{0,0}(3\mu,3u;3\tau)$	$\sigma_{0,1/3}(3\mu,3u;3\tau)$	$\sigma_{0,2/3}(3\mu,3u;3\tau)$

(Received 28 February 2002; accepted 29 July 2002)

We introduce the notion of a Lie algebroid structure on an affine bundle whose base manifold is fibered over $\mathbb{R}$. It is argued that this is the framework which one needs for coming to a time-dependent generalization of the theory of Lagrangian systems on Lie algebroids. An extensive discussion is given of a way one can think of forms acting on sections of the affine bundle. It is further shown that the affine Lie algebroid structure gives rise to a coboundary operator on such forms. The concept of admissible curves and dynamical systems whose integral curves are admissible brings an associated affine bundle into the picture, on which one can define in a natural way a prolongation of the original affine Lie algebroid structure. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1510958]

I. INTRODUCTION

There has been a lot of interest recently in the study of dynamical systems which have a Lie algebroid as carrying space (see, e.g., Refs. 1–6). A Lie algebroid is a vector bundle $\pi: V \to M$, which comes equipped with two operators. To begin with, there is a bracket operation on $Sec(\pi)$, the set of sections of π, which provides it with a real Lie algebra structure. Second, there is a linear bundle map $\rho: V \to TM$, called the anchor map, which establishes a Lie algebra homomorphism between $Sec(\pi)$ and the real Lie algebra of vector fields on M and does this in such a way that there is a certain compatibility also with the module structure over $C^\infty(M)$. To be precise, we have

$$[\rho(\sigma),\rho(\eta)]=\rho([\sigma,\eta]) \quad \text{and} \quad n[\sigma,f\eta]=f[\sigma,\eta]+\rho(\sigma)(f)\eta,$$

for all $\sigma,\eta \in Sec(\pi)$ and $f \in C^\infty(M)$.

Weinstein's paper on Lagrangian mechanics and groupoids[6] roused new interest into the field of algebroids and groupoids. Weinstein introduces "Lagrangian systems" on a Lie algebroid by means of a Legendre-type map from V to V^*, associated to a given function L on V. The local coordinate expression of such equations reads

$$\begin{aligned} \dot{x}^i &= \rho^i_\alpha(x)y^\alpha, \\ \frac{d}{dt}\left(\frac{\partial L}{\partial y^\alpha}\right) &= \rho^i_\alpha \frac{\partial L}{\partial x^i} - C^\gamma_{\alpha\beta} y^\beta \frac{\partial L}{\partial y^\gamma}, \end{aligned} \tag{1}$$

where the x^i are coordinates on M, y^α are fiber coordinates on V and the $C^\gamma_{\alpha\beta}$ are structure functions coming from the Lie algebroid structure. Applications for such model equations can be found, e.g., in the theory of systems with symmetries on principal fiber bundles and in rigid body dynamics. Note that, more generally, equations of the form

[a]Electronic mail: willy.sarlet@rug.ac.be

$$\dot{x}^i=\rho^i_\alpha(x)y^\alpha,$$
$$\dot{y}^\alpha=f^\alpha(x,y), \tag{2}$$

were called ''second-order equations on a Lie algebroid'' by Weinstein. They are indeed, to some extent, the analogs of second-order dynamics on a tangent bundle. It is clear, however, that these equations truly are second-order differential equations only when the base manifold and the fibers have the same dimension and ρ is injective. We will therefore rather call them ''pseudo-second-order ordinary differential equations,'' pseudo-SODEs for short. Weinstein also raised the question whether there would be a geometrical way of defining equations of the form (1), much in the line of the geometrical construction of classical Lagrange equations, which makes use of the intrinsic structures living on a tangent bundle.

One of us has recently resolved this issue[5] by introducing a kind of lifted Lie algebroid, where suitable analogs can be introduced of the dilation vector field and the vertical endomorphism on a tangent bundle.

In the present article, we wish to set the stage for an appropriate generalization of this theory to nonautonomous systems of differential equations. We believe that, for example, at the level of pseudo-second-order equations, the right generalization is not just a matter of allowing the functions ρ^i_α and f^α to depend on time, but rather should produce equations of the form

$$\dot{x}^i=\rho^i_\alpha(t,x)y^\alpha+\lambda^i(t,x),$$
$$\dot{y}^\alpha=f^\alpha(t,x,y). \tag{3}$$

The reason for this simply is that we wish the structure of the equations to be invariant under time-dependent coordinate transformations. As for Lagrange-type equations, our only concern at the moment is to have an idea of what a time-dependent generalization of (1) should look like. Now, there is a way of developing a kind of formal calculus of variations approach which leads to equations of the form (1), and in which the first set of equations are treated as constraints. We have shown in Ref. 7 that if such an approach is adopted when the Lagrangian is allowed to depend on time and the constraints are as in (3), one obtains equations of the form

$$\dot{x}^i=\rho^i_\alpha(t,x)y^\alpha+\lambda^i(t,x),$$
$$\frac{d}{dt}\left(\frac{\partial L}{\partial y^\alpha}\right)=\rho^i_\alpha\frac{\partial L}{\partial x^i}-(C^\gamma_{\alpha\beta}y^\beta-C^\gamma_\alpha)\frac{\partial L}{\partial y^\gamma}, \tag{4}$$

where the functions ρ^i_α, λ^i, $C^\gamma_{\alpha\beta}$, C^γ_α satisfy the relations

$$\rho^i_\alpha\frac{\partial\rho^j_\beta}{\partial x^i}-\rho^i_\beta\frac{\partial\rho^j_\alpha}{\partial x^i}=\rho^j_\gamma C^\gamma_{\alpha\beta}, \tag{5}$$

$$\frac{\partial\rho^j_\beta}{\partial t}+\lambda^i\frac{\partial\rho^j_\beta}{\partial x^i}-\rho^i_\beta\frac{\partial\lambda^j}{\partial x^i}=\rho^j_\alpha C^\alpha_\beta. \tag{6}$$

Thus, we want to address the question of explaining the nature of the conditions (5) and (6), which presumably should again have something to do with a Lie algebroid structure.

Inspired by these analytical considerations, we will introduce the notion of a Lie algebroid structure on an affine bundle $\pi:E\to M$, where the base manifold M in addition is assumed to be fibered over $\mathbb{R}$. The assumption about the additional fibration of M is a very natural one to start the development of this new theory, because the canonical example of an affine Lie algebroid (when the anchor map reduces to the identity) should be the model of time-dependent mechanics, which traditionally is described on the first-jet bundle of a manifold fibered over $\mathbb{R}$ (see, e.g., Ref. 8). For

the present paper, we will limit ourselves to a number of basic features of such a theory. In particular, we shall show in Sec. III that our defining relations for an affine Lie algebroid are fully consistent with the expectation of being able to develop an exterior differential calculus of sections of the extended dual of this bundle (and its exterior products). We shall further show in Sec. IV that vector fields on E, whose integral curves are "admissible curves" and which in fact model differential equations of the pseudo-SODE type, can be identified in a natural way with special sections of a kind of prolongation of the original affine bundle. This then brings us to a final test, for this article, of the internal coherence of the newly defined structures: we will verify in Sec. V whether the prolongation of a Lie algebroid, as constructed in Ref. 5 for the vector bundle situation, carries over to the present more general situation.

The final section lists a number of other topics of interest, which will be the subject of forthcoming publications. One of our objectives is to arrive at an intrinsic geometrical construction of the time-dependent Lagrangian equations of type (4). For the time being, however, the conditions (5) and (6) merely serve as benchmarks, to be met by our model of an affine Lie algebroid.

The basic ingredients for our theory are an affine bundle $\pi:E\to M$, where the base manifold M is further fibered over $\mathbb{R}$. In Sec. II, we define the concept of a Lie algebroid on π. In Sec. III, we show that the axioms for such a Lie algebroid structure give rise to a consistent development of an exterior calculus on sections of the extended dual of E. In Sec. IV, we discuss a special class of curves on E, which are said to be admissible by the anchor map, and we look into the concept of dynamical systems whose integral curves all belong to this special class. In Sec. V, we define the prolongation $\pi_1:J^1_\lambda E\to E$ of $\pi:E\to M$ and show that it inherits the Lie algebroid structure from π.

II. AFFINE LIE ALGEBROIDS

Let M be an $(n+1)$-dimensional smooth manifold, which is fibered over $\mathbb{R}$, $\tau:M\to\mathbb{R}$. We denote the first jet bundle of τ by $\tau_1^0:J^1M\to M$. It is an affine bundle modeled on the bundle of tangent vectors to M which are vertical with respect to τ; this vector bundle will be denoted by $\overline{\tau}_1^0:VM\to M$. To fix notations further, if $\pi:E\to M$ is an affine bundle and $\overline{\pi}:V\to M$ its associated vector bundle, sections of π will be denoted by ordinary Greek characters, whereas boldface Greek type will be used for sections of $\overline{\pi}$.

Definition 1: An affine Lie algebroid over M is an affine bundle $\pi:E\to M$, with the following properties:

(1) $Sec(\overline{\pi})$, the set of sections of the vector bundle $\overline{\pi}:V\to M$ on which E is modeled, is equipped with a skew-symmetric and bilinear (over $\mathbb{R}$) bracket $[\cdot,\cdot]$.

(2) The affine space $Sec(\pi)$ acts by derivations on the real algebra $Sec(\overline{\pi})$, that is to say, if the same bracket notation $[\zeta,\boldsymbol{\sigma}]$ is used to denote the way $\zeta\in Sec(\pi)$ acts on $\boldsymbol{\sigma}\in Sec(\overline{\pi})$, we have $[\zeta,\boldsymbol{\sigma}]\in Sec(\overline{\pi})$ and

$$[\zeta,\boldsymbol{\sigma}_1+\boldsymbol{\sigma}_2]=[\zeta,\boldsymbol{\sigma}_1]+[\zeta,\boldsymbol{\sigma}_2],\quad [\zeta+\boldsymbol{\sigma},\boldsymbol{\eta}]=[\zeta,\boldsymbol{\eta}]+[\boldsymbol{\sigma},\boldsymbol{\eta}], \tag{7}$$

$$[\zeta,[\boldsymbol{\sigma},\boldsymbol{\eta}]]=[[\zeta,\boldsymbol{\sigma}],\boldsymbol{\eta}]+[\boldsymbol{\sigma},[\zeta,\boldsymbol{\eta}]]. \tag{8}$$

(3) There exists an affine bundle map $\lambda:E\to J^1M$ (over the identity on M), with corresponding vector bundle homomorphism $\rho:V\to VM$, such that the following compatibility condition holds for all $f\in C^\infty(M)$,

$$[\zeta,f\boldsymbol{\sigma}]=f[\zeta,\boldsymbol{\sigma}]+\lambda(\zeta)(f)\boldsymbol{\sigma}. \tag{9}$$

Both the affine map $\lambda:E\to J^1M$ and its linear part $\rho:V\to VM$ will be called anchor maps.

Note that we make no notational distinction between, on the one hand, the affine and linear anchor maps, regarded as maps between total spaces of bundles, and their action on sections of bundles on the other hand. Needless to say, for the interpretation of the bracket in the left-hand side of (12), both $\lambda(\zeta)$ and $\rho(\boldsymbol{\sigma})$ are regarded as vector fields on M.

Let us derive some further properties which follow from this definition. First of all, if we replace ζ in (8) by $\zeta+\boldsymbol{\xi}$, for an arbitrary $\boldsymbol{\xi}\in Sec(\overline{\pi})$, it follows that $\forall\,\boldsymbol{\xi},\boldsymbol{\sigma},\boldsymbol{\eta}\in Sec(\overline{\pi})$:

$$[\boldsymbol{\xi},[\boldsymbol{\sigma},\boldsymbol{\eta}]]=[[\boldsymbol{\xi},\boldsymbol{\sigma}],\boldsymbol{\eta}]+[\boldsymbol{\sigma},[\boldsymbol{\xi},\boldsymbol{\eta}]]. \tag{10}$$

This means, in view of the first hypothesis, that the bracket on $Sec(\overline{\pi})$ actually provides $Sec(\overline{\pi})$ with a real Lie algebra structure. Second, making the same substitution for ζ in (9), recalling that $\lambda(\zeta+\boldsymbol{\xi})=\lambda(\zeta)+\rho(\boldsymbol{\xi})$, it follows that

$$[\boldsymbol{\xi},f\boldsymbol{\sigma}]=f[\boldsymbol{\xi},\boldsymbol{\sigma}]+\rho(\boldsymbol{\xi})(f)\boldsymbol{\sigma}. \tag{11}$$

This means that the linear anchor map $\rho:V\to VM$ defines a Lie algebra homomorphism from $Sec(\overline{\pi})$ into the real Lie algebra of vertical vector fields on M, and that we have a classical Lie algebroid structure on the vector bundle $\overline{\pi}:V\to M$ (although its image cannot reach the whole of TM). Third, replacing $\boldsymbol{\eta}$ by $f\boldsymbol{\eta}$ in (8) and making use of (9) and (11), one obtains the additional compatibility property

$$[\lambda(\zeta),\rho(\boldsymbol{\sigma})]=\rho([\zeta,\boldsymbol{\sigma}]), \tag{12}$$

from which it further follows that

$$[\rho(\boldsymbol{\xi}),\rho(\boldsymbol{\sigma})]=\rho([\boldsymbol{\xi},\boldsymbol{\sigma}]). \tag{13}$$

Remark: For an alternative and equivalent definition of an affine Lie algebroid, we could impose first the Lie algebra structure (10) of the bracket on $Sec(\overline{\pi})$, together with the compatibility condition (11) for the anchor map ρ, and subsequently require that the properties (7)–(9) hold true for at least one $\zeta\in Sec(\pi)$ and for an affine map $\lambda:E\to J^1M$ whose linear part is ρ. It then follows that such properties hold for all ζ.

We can now further extend the bracket operation to $Sec(\pi)$, as follows.

Definition 2: (i) *For* $\boldsymbol{\sigma}\in Sec(\overline{\pi})$ *and* $\zeta\in Sec(\pi)$, *we put* $[\boldsymbol{\sigma},\zeta]=-[\zeta,\boldsymbol{\sigma}]$. (ii) *For every two sections* $\zeta_1,\zeta_2\in Sec(\pi)$ *with* $\boldsymbol{\zeta}_{12}=\zeta_2-\zeta_1$, $[\zeta_1,\zeta_2]=[\zeta_1,\boldsymbol{\zeta}_{12}]$.

Observe that the extended bracket in (ii) is a map from $Sec(\pi)\times Sec(\pi)$ to $Sec(\overline{\pi})$. As we will show below, it has Lie algebra-type properties, which could justify talking about an ''affine Lie algebra structure,'' were it not that this term is in use already in the literature, with an entirely different meaning. The extended bracket also has Lie algebroid type properties with respect to the anchor maps λ and ρ.

Proposition 1: The bracket $[\,\cdot\,,\cdot\,]:Sec(\pi)\times Sec(\pi)\to Sec(\overline{\pi})$, *has the following properties:*

$$[\zeta_1,\zeta_2+\boldsymbol{\sigma}]=[\zeta_1,\zeta_2]+[\zeta_1,\boldsymbol{\sigma}], \tag{14}$$

$$[\zeta_1,\zeta_2]=-[\zeta_2,\zeta_1], \tag{15}$$

$$[[\zeta_1,\zeta_2],\zeta_3]+[[\zeta_2,\zeta_3],\zeta_1]+[[\zeta_3,\zeta_1],\zeta_2]=\mathbf{0}, \tag{16}$$

$$\rho([\zeta_1,\zeta_2])=[\lambda(\zeta_1),\lambda(\zeta_2)]. \tag{17}$$

Proof: The first property follows immediately from the definition and (7). Next, we have $[\zeta_2,\zeta_1]=[\zeta_2,\boldsymbol{\zeta}_{21}]=-[\zeta_1+\boldsymbol{\zeta}_{12},\boldsymbol{\zeta}_{12}]=-[\zeta_1,\zeta_2]$. For the Jacobi identity, using a simple summation sign to indicate the cyclic sum over the three sections in each summand, we have

$$\sum\,[[\zeta_1,\zeta_2],\zeta_3]=\sum\,[[\zeta_1,\zeta_2],\zeta_2+\boldsymbol{\zeta}_{23}]=\sum\,[[\zeta_1,\zeta_2],\boldsymbol{\zeta}_{23}],$$

in view of the linearity properties and the skew-symmetry of the bracket. Substituting subsequently $\zeta_1+\boldsymbol{\zeta}_{12}$ for ζ_2, we obtain

$$\sum [[\zeta_1,\zeta_2],\zeta_3]=\sum [[\zeta_1,\boldsymbol{\zeta}_{12}],\boldsymbol{\zeta}_{23}],$$

which is zero in view of (8). Finally, the compatibility property (17) easily follows in the same way from the definition of the extended bracket and (12). □

To understand what an affine Lie algebroid structure means in coordinates, let us coordinatize E in the usual way, as follows: t denotes the coordinate on $\mathbb{R}$; $(x^i)_{1\leqslant i\leqslant n}$ are fiber coordinates on M; we further choose a local section e_0 of π to play the role of zero section and a local basis $(\mathbf{e}_\alpha)_{1\leqslant\alpha\leqslant k}$ for $Sec(\overline{\pi})$. Then, if e is a point in the fiber E_m over $m\in M$, it can be written in the form: $e=e_0(m)+y^\alpha\mathbf{e}_\alpha(m)$; (t,x^i,y^α) are coordinates of e $[(t,x^i)$ being the coordinates of $m]$.

We have

$$[\mathbf{e}_\alpha,\mathbf{e}_\beta]=C^\gamma_{\alpha\beta}(t,x)\mathbf{e}_\gamma,\quad [e_0,\mathbf{e}_\alpha]=C^\beta_\alpha(t,x)\mathbf{e}_\beta, \tag{18}$$

for some *structure functions* $C^\gamma_{\alpha\beta}=-C^\gamma_{\beta\alpha}$ and C^β_α on M. The affine map λ and its linear part ρ are fully determined by

$$\lambda(e_0)=\frac{\partial}{\partial t}+\lambda^i(t,x)\frac{\partial}{\partial x^i},\quad \rho(\mathbf{e}_\alpha)=\rho^i_\alpha(t,x)\frac{\partial}{\partial x^i}. \tag{19}$$

The further characterization of the Lie algebroid structure now has the following coordinate translation. The derivation property (8) and the resulting Jacobi identity (10) mean that we have

$$\frac{\partial C^\mu_{\alpha\beta}}{\partial t}+\lambda^i\frac{\partial C^\mu_{\alpha\beta}}{\partial x^i}+C^\gamma_{\alpha\beta}C^\mu_\gamma=C^\mu_{\alpha\gamma}C^\gamma_\beta-C^\mu_{\beta\gamma}C^\gamma_\alpha+\rho^i_\alpha\frac{\partial C^\mu_\beta}{\partial x^i}-\rho^i_\beta\frac{\partial C^\mu_\alpha}{\partial x^i}, \tag{20}$$

$$\sum_{\alpha,\beta,\gamma}\left(\rho^i_\alpha\frac{\partial C^\mu_{\beta\gamma}}{\partial x^i}+C^\mu_{\alpha\nu}C^\nu_{\beta\gamma}\right)=0, \tag{21}$$

where the summation this time refers to a cyclic sum over α, β, γ and also the compatibility conditions (9) and (11) have been invoked. Finally, the properties (12) and (13), for which it is sufficient to express that $[\lambda(e_0),\rho(\mathbf{e}_\alpha)]=\rho([e_0,\mathbf{e}_\alpha])$ and $[\rho(\mathbf{e}_\alpha),\rho(\mathbf{e}_\beta)]=\rho([\mathbf{e}_\alpha,\mathbf{e}_\beta])$, require that

$$\frac{\partial\rho^j_\beta}{\partial t}+\lambda^i\frac{\partial\rho^j_\beta}{\partial x^i}-\rho^i_\beta\frac{\partial\lambda^j}{\partial x^i}=C^\alpha_\beta\rho^j_\alpha, \tag{22}$$

$$\rho^i_\alpha\frac{\partial\rho^j_\beta}{\partial x^i}-\rho^i_\beta\frac{\partial\rho^j_\alpha}{\partial x^i}=C^\gamma_{\alpha\beta}\rho^j_\gamma. \tag{23}$$

These are precisely the relations (5) and (6) we encountered in the Introduction, in the context of Lagrangian equations of type (4).

It is of some interest to look at the way the various structure and anchor map functions transform under coordinate transformations. There are two distinct levels in making a change of coordinates on E, which we will describe separately. First, we could choose a different (local) zero section $\overline{e_0}$ and a different local basis $\overline{\mathbf{e}}_\beta$ for $Sec(\overline{\pi})$: say that $\mathbf{e}_\alpha=A^\beta_\alpha\overline{\mathbf{e}}_\beta$ and $e_0=\overline{e_0}+B^\alpha\overline{\mathbf{e}}_\alpha$. This amounts to making an affine change of coordinates in the fibers of the form $\overline{y^\alpha}=A^\alpha_\beta(t,x)y^\beta+B^\alpha(t,x)$. Putting $[\overline{\mathbf{e}}_\alpha,\overline{\mathbf{e}}_\beta]=\overline{C}^\gamma_{\alpha\beta}\overline{\mathbf{e}}_\gamma$, $[\overline{e_0},\overline{\mathbf{e}}_\alpha]=\overline{C}^\beta_\alpha\overline{\mathbf{e}}_\beta$, and also $\lambda(\overline{e_0})=\partial/\partial t+\overline{\lambda^i}\,\partial/\partial x^i$, $\rho(\overline{\mathbf{e}}_\alpha)=\overline{\rho}^j_\alpha\partial/\partial x^j$, one can verify that the following transformation rules apply:

$$\rho^i_\alpha=A^\beta_\alpha\overline{\rho}^i_\beta,\quad \overline{\lambda^i}=\lambda^i-B^\alpha\overline{\rho}^i_\alpha,$$

and further

$$C^{\gamma}_{\alpha\beta}A^{\mu}_{\gamma}=\overline{C}^{\mu}_{\gamma\nu}A^{\gamma}_{\alpha}A^{\nu}_{\beta}+\rho^{i}_{\alpha}\frac{\partial A^{\mu}_{\beta}}{\partial x^{i}}-\rho^{i}_{\beta}\frac{\partial A^{\mu}_{\alpha}}{\partial x^{i}},$$

$$C^{\gamma}_{\beta}A^{\alpha}_{\gamma}=\overline{C}^{\alpha}_{\mu}A^{\mu}_{\beta}+\overline{C}^{\alpha}_{\gamma\mu}B^{\gamma}A^{\mu}_{\beta}+\frac{\partial A^{\alpha}_{\beta}}{\partial t}+\lambda^{i}\frac{\partial A^{\alpha}_{\beta}}{\partial x^{i}}-\rho^{i}_{\beta}\frac{\partial B^{\alpha}}{\partial x^{i}}.$$

At a different level, one can make a change of coordinates on M, of the form: $t'=t$, $x'^{i}=x'^{i}(t,x)$. This has an effect on the anchor map functions of the form

$$\rho'^{j}_{\alpha}=\rho^{i}_{\alpha}\frac{\partial x'^{j}}{\partial x^{i}},\quad \lambda'^{j}=\frac{\partial x'^{j}}{\partial t}+\lambda^{i}\frac{\partial x'^{j}}{\partial x^{i}}.$$

A general change of adapted coordinates is of course a composition of the two steps described above.

III. EXTERIOR CALCULUS ON AN AFFINE LIE ALGEBROID

We first recall some features of the by now standard theory of Lie algebroids on a vector bundle (see Ref. 9). Considering sections of exterior powers of the dual bundle, one gets a notion of forms on sections of the vector bundle, on which an exterior derivative can be defined which involves the Lie algebroid bracket and the anchor map. It then turns out that the Jacobi identity of the Lie algebroid bracket and the compatibility with the bracket of vector fields via the anchor map are exactly the conditions for this exterior derivative to have the co-boundary property $d^2=0$ (see also Refs. 10, 11, and 5). In our opinion, such a feature in itself gives a strong indication that the generalization from Lie algebra to Lie algebroid is indeed a meaningful step. We shall therefore investigate in this section whether a similar support can be detected for our extension to Lie algebroids on affine bundles.

The extended dual of the affine space E_m is the space of real valued affine functions on E_m and will be denoted by $E^{\dagger}_m$. The union of these spaces over all points $m\in M$ gives us a bundle $\pi^{\dagger}:E^{\dagger}\to M$ say. Although this is in fact a vector bundle, we are interested in the action of its sections (and sections of its exterior powers) on sections of the affine bundle π. This brings some subtleties into the picture which need to be investigated in sufficient detail. We will write $\overline{\pi}^{*}:V^{*}\to M$ for the dual bundle of $\overline{\pi}$ and also use boldface type for its sections (and the sections of its exterior powers). Now, to begin with, if θ is a section of $\pi^{\dagger}$ and $\zeta\in Sec(\pi)$, $\theta(\zeta)$ is a function on M defined by $\theta(\zeta)(m)=\theta_m(\zeta_m)$. θ_m being an affine function on E_m, there exists an associated element $\boldsymbol{\theta}_m\in V^{*}_m$ such that $\forall e_m\in E_m$, $\boldsymbol{\sigma}_m\in V_m$, we have $\theta_m(e_m+\boldsymbol{\sigma}_m)=\theta_m(e_m)+\boldsymbol{\theta}_m(\boldsymbol{\sigma}_m)$. Expressed in slightly different terms and now at the level of sections again, a $\theta\in Sec(\pi^{\dagger})$ is such that there exist a $\theta_0\in Sec(\pi^{\dagger})$ and a $\boldsymbol{\theta}\in Sec(\overline{\pi}^{*})$, such that for all $\zeta\in Sec(\pi)$,

$$\theta(\zeta)=\theta_0(\zeta_0)+\boldsymbol{\theta}(\boldsymbol{\zeta}), \tag{24}$$

where ζ_0 is any section and then $\zeta=\zeta_0+\boldsymbol{\zeta}$. The two composing elements θ_0 (which, in fact, is simply θ itself here) and $\boldsymbol{\theta}$ do not depend on the choice of ζ_0. With sections of $\pi^{\dagger}$ as our notion of one-forms on $Sec(\pi)$, there is of course no linearity with respect to multiplication by functions on M. We can now come in a similar way to the following concept of k-forms on $Sec(\pi)$ [thereby taking for granted that the meaning of a k-form on a vector bundle such as $Sec(\overline{\pi})$ is known].

Definition 3: A k-form on the affine bundle $Sec(\pi)$ $(k\geqslant 1)$ is a map $\omega:Sec(\pi)\times\cdots\times Sec(\pi)\to C^{\infty}(M)$, for which there exists a k-form $\boldsymbol{\omega}$ on the associated vector bundle $Sec(\overline{\pi})$ and a map $\omega_0:Sec(\pi)\times Sec(\overline{\pi})\times\cdots\times Sec(\overline{\pi})\to C^{\infty}(M)$ with the following properties:

(1) ω_0 is skew-symmetric and $C^{\infty}(M)$-linear in its $k-1$ vector arguments;

(2) $\forall\zeta\in Sec(\pi)$ and $\forall\boldsymbol{\sigma},\boldsymbol{\zeta}_j\in Sec(\overline{\pi})$, we have

$$\omega_0(\zeta+\boldsymbol{\sigma},\boldsymbol{\zeta}_1,\ldots,\boldsymbol{\zeta}_{k-1})=\omega_0(\zeta,\boldsymbol{\zeta}_1,\ldots,\boldsymbol{\zeta}_{k-1})+\boldsymbol{\omega}(\boldsymbol{\sigma},\boldsymbol{\zeta}_1,\ldots,\boldsymbol{\zeta}_{k-1}); \tag{25}$$

(3) $\forall \zeta_i \in Sec(\pi)$, *if we choose an arbitrary* $\zeta_0 \in Sec(\pi)$ *and put* $\zeta_i = \zeta_0 + \boldsymbol{\zeta}_i$, *we have*

$$\omega(\zeta_1,\ldots,\zeta_k) = \sum_{i=1}^{k} (-1)^{i-1}\omega_0(\zeta_0,\boldsymbol{\zeta}_1,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\boldsymbol{\zeta}_k) + \boldsymbol{\omega}(\boldsymbol{\zeta}_1,\ldots,\boldsymbol{\zeta}_k). \tag{26}$$

There are a number of properties to be checked to make sure that this definition makes sense. First of all, one can verify that with two different choices of a reference section, ζ_0 and ζ_0', for example, related through $\zeta_0 = \zeta_0' + \boldsymbol{\sigma}$, it follows from the second requirement that

$$\sum_{i=1}^{k} (-1)^{i-1}\omega_0(\zeta_0,\boldsymbol{\zeta}_1,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\boldsymbol{\zeta}_k) + \boldsymbol{\omega}(\boldsymbol{\zeta}_1,\ldots,\boldsymbol{\zeta}_k)$$

$$= \sum_{i=1}^{k} (-1)^{i-1}\omega_0(\zeta_0',\boldsymbol{\zeta}_1',\ldots,\hat{\boldsymbol{\zeta}}_i',\ldots,\boldsymbol{\zeta}_k') + \boldsymbol{\omega}(\boldsymbol{\zeta}_1',\ldots,\boldsymbol{\zeta}_k').$$

Second, the two elements ω_0 and $\boldsymbol{\omega}$ which make up ω are unique. Indeed, assuming there would be a second couple ω_0' and $\boldsymbol{\omega}'$ making up the same ω, it follows by choosing $\zeta_0 = \zeta_1$ (such that $\boldsymbol{\zeta}_1 = 0$) that $\omega_0 = \omega_0'$, after which it is clear that also $\boldsymbol{\omega} = \boldsymbol{\omega}'$. Note finally that the definition implies that ω itself is skew-symmetric in all its arguments.

The set of forms on $Sec(\pi)$, which we will denote by $\Lambda(\pi^\dagger)$, is a module over the ring $C^\infty(M)$, which also constitutes the set of zero-forms. The wedge product of two forms is defined in the usual way. By way of example, if α and β are one-forms, we have

$$(\alpha\wedge\beta)(\zeta_1,\zeta_2) = \alpha(\zeta_1)\beta(\zeta_2) - \alpha(\zeta_2)\beta(\zeta_1),$$

which for every choice of a reference section ζ_0 gives rise to

$$(\alpha\wedge\beta)(\zeta_1,\zeta_2) = \alpha(\zeta_0)\boldsymbol{\beta}(\boldsymbol{\zeta}_2 - \boldsymbol{\zeta}_1) - \beta(\zeta_0)\boldsymbol{\alpha}(\boldsymbol{\zeta}_2 - \boldsymbol{\zeta}_1) + (\boldsymbol{\alpha}\wedge\boldsymbol{\beta})(\boldsymbol{\zeta}_1,\boldsymbol{\zeta}_2). \tag{27}$$

It follows that $\boldsymbol{\alpha}\wedge\boldsymbol{\beta}$ is the two-form on $Sec(\overline{\pi})$ corresponding to $\alpha\wedge\beta$, and

$$(\alpha\wedge\beta)_0(\zeta,\boldsymbol{\sigma}) = \alpha(\zeta)\boldsymbol{\beta}(\boldsymbol{\sigma}) - \beta(\zeta)\boldsymbol{\alpha}(\boldsymbol{\sigma}). \tag{28}$$

Similarly, for the wedge product of three one-forms, we have

$$(\alpha\wedge\beta\wedge\gamma)_0(\zeta,\boldsymbol{\zeta}_1,\boldsymbol{\zeta}_2) = (\alpha(\zeta)(\boldsymbol{\beta}\wedge\boldsymbol{\gamma}) + \beta(\zeta)(\boldsymbol{\gamma}\wedge\boldsymbol{\alpha}) + \gamma(\zeta)(\boldsymbol{\alpha}\wedge\boldsymbol{\beta}))(\boldsymbol{\zeta}_1,\boldsymbol{\zeta}_2). \tag{29}$$

These examples suggest to formalize the representation of k-forms a bit further. As a preliminary remark, it may sometimes be of interest to extend the interpretation of the operator ω_0 in such a way that its single affine section argument need not necessarily be the first. This can simply be achieved by declaring ω_0 to be skew-symmetric in all its arguments [but still $C^\infty(M)$-linear in its vector arguments only]. More importantly, we shall take the sum of ω_0-terms in (26) to define another operator, denoted by ω^0, as follows:

$$\omega^0(\zeta_1,\ldots,\zeta_k) = \sum_{i=1}^{k} (-1)^{i-1}\omega_0(\zeta_0,\boldsymbol{\zeta}_1,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\boldsymbol{\zeta}_k) = \sum_{i=1}^{k} \omega_0(\boldsymbol{\zeta}_1,\ldots,\check{\underset{i}{\zeta}}_0,\ldots,\boldsymbol{\zeta}_k), \tag{30}$$

where the second expression takes the above remark into account and the symbol $\check{\zeta}_{0_i}$then indicates that ζ_0 has been inserted in the ith argument. The other important new convention we will adopt is to regard $\boldsymbol{\omega}$ also as acting on affine sections:

$$\boldsymbol{\omega}(\zeta_1,\ldots,\zeta_k) = \boldsymbol{\omega}(\boldsymbol{\zeta}_1,\ldots,\boldsymbol{\zeta}_k). \tag{31}$$

This way, we can formally write

$$\omega = \omega^0 + \boldsymbol{\omega}, \tag{32}$$

whereby it is to be understood that the two composing terms ω^0 and $\boldsymbol{\omega}$ are not k-forms on $Sec(\pi)$ by themselves. In fact, to compute their value when acting on k sections ζ_i, a reference section ζ_0 has to be chosen, but as argued above, the value of the sum $\omega^0 + \boldsymbol{\omega}$ in the end does not depend on that choice.

The rather formal looking decomposition (32) now greatly facilitates the representation of wedge products and will make the general coordinate representation of a form more transparent. For example, the result (29) means that

$$(\alpha \wedge \beta \wedge \gamma)_0 = \alpha^0 \otimes (\boldsymbol{\beta} \wedge \boldsymbol{\gamma}) + \beta^0 \otimes (\boldsymbol{\gamma} \wedge \boldsymbol{\alpha}) + \gamma^0 \otimes (\boldsymbol{\alpha} \wedge \boldsymbol{\beta}), \tag{33}$$

which then implies from (30) that

$$(\alpha \wedge \beta \wedge \gamma)^0 = \alpha^0 \wedge \boldsymbol{\beta} \wedge \boldsymbol{\gamma} + \boldsymbol{\alpha} \wedge \beta^0 \wedge \boldsymbol{\gamma} + \boldsymbol{\alpha} \wedge \boldsymbol{\beta} \wedge \gamma^0, \tag{34}$$

as expected. More generally, it follows directly from the defining formula for wedge products that for $\omega = \omega^0 + \boldsymbol{\omega}$ and $\rho = \rho^0 + \boldsymbol{\rho}$,

$$\omega \wedge \rho = \omega^0 \wedge \rho^0 + \omega^0 \wedge \boldsymbol{\rho} + \boldsymbol{\omega} \wedge \rho^0 + \boldsymbol{\omega} \wedge \boldsymbol{\rho}, \tag{35}$$

where the sum of the first three terms is $(\omega \wedge \rho)^0$.

Suppose that, for a coordinatization of E, we have chosen a zero section e_0 and a local basis of vector sections $\mathbf{e}_\alpha$. Denote by $\{\mathbf{e}^\beta\}$ the dual basis for $Sec(\overline{\pi}^*)$. There exists a global section of $\pi^\dagger$ which for each m selects in $E_m^\dagger$ the constant function 1. We will call it e^0. The local zero section e_0 of $Sec(\pi)$ can now play the role of the reference section ζ_0 in our general considerations. Writing $\zeta = e_0 + \zeta^\alpha \mathbf{e}_\alpha$ for an arbitrary section ζ, we have for each one-form θ: $\theta(\zeta) = \theta(e_0) + \zeta^\alpha \boldsymbol{\theta}(\mathbf{e}_\alpha)$. Putting $\boldsymbol{\theta}(\mathbf{e}_\alpha) = \theta_\alpha$ and $\theta(e_0) = \theta_0$, we see that θ has the local representation

$$\theta = \theta_0 e^0 + \theta_\alpha \mathbf{e}^\alpha, \tag{36}$$

where, in agreement with the general decomposition (32), $\mathbf{e}^\alpha$ has to be regarded now as acting on $Sec(\pi)$ and $\theta^0 = \theta_0 e^0$. To be precise, putting

$$e_\alpha = e_0 + \mathbf{e}_\alpha, \tag{37}$$

the action of $\mathbf{e}^\beta$ on affine sections, which can be given a meaning only after introducing a reference section, is determined by

$$\mathbf{e}^\beta(e_0) = 0, \quad \mathbf{e}^\beta(e_\alpha) = \delta_\alpha^\beta. \tag{38}$$

There is another slight abuse of notation in (36) since θ_0 could have a double meaning: in (36) it represents a local function on M, whereas it also could refer to the operator introduced in (24) and more generally in Definition 3. We will, however, seldom use the notation θ_0 in the latter sense when dealing with coordinate calculations, so that the meaning will always be clear from the context.

Let us now see how all these notations fit together when we start wedging one-forms. For two one-forms $\alpha = \alpha^0 + \boldsymbol{\alpha}$ and $\beta = \beta^0 + \boldsymbol{\beta}$ we find, for example from (28) and (30), that

$$(\alpha \wedge \beta)^0 = \alpha^0 \wedge \boldsymbol{\beta} - \beta^0 \wedge \boldsymbol{\alpha}. \tag{39}$$

This is in agreement with the general formula (35) since obviously $\alpha^0 \wedge \beta^0 = 0$. Expressing α and β with respect to the basis $(e^0, \mathbf{e}^\alpha)$, we find

$$\alpha \wedge \beta = (\alpha_0 \beta_\gamma - \beta_0 \alpha_\gamma) e^0 \wedge \mathbf{e}^\gamma + \tfrac{1}{2}(\alpha_\gamma \beta_\delta - \alpha_\delta \beta_\gamma) \mathbf{e}^\gamma \wedge \mathbf{e}^\delta. \tag{40}$$

Similarly, for the wedge product of three one-forms with local representations of the form (36), we obtain

$$\alpha\wedge\beta\wedge\gamma=\tfrac{1}{2}(\alpha_0(\beta_\mu\gamma_\nu-\beta_\nu\gamma_\mu)+\beta_0(\gamma_\mu\alpha_\nu-\gamma_\nu\alpha_\mu)+\gamma_0(\alpha_\mu\beta_\nu-\alpha_\nu\beta_\mu))e^0\wedge\mathbf{e}^\mu\wedge\mathbf{e}^\nu+\boldsymbol{\alpha}\wedge\boldsymbol{\beta}\wedge\boldsymbol{\gamma}. \tag{41}$$

It should now be clear without going into any further detail that a general k-form on $Sec(\pi)$ locally has the following representation,

$$\omega=\frac{1}{(k-1)!}\,\omega_{0\mu_1\cdots\mu_{k-1}}\,e^0\wedge\mathbf{e}^{\mu_1}\wedge\cdots\wedge\mathbf{e}^{\mu_{k-1}}+\frac{1}{k!}\,\omega_{\mu_1\cdots\mu_k}\mathbf{e}^{\mu_1}\wedge\cdots\wedge\mathbf{e}^{\mu_k}, \tag{42}$$

where the coefficients are functions on M, which are skew-symmetric in all their indices (including the zero for the first term); we have

$$\omega_{0\mu_1\cdots\mu_{k-1}}=\omega(e_0,e_{\mu_1},\ldots,e_{\mu_{k-1}}), \tag{43}$$

$$\omega_{\mu_1\cdots\mu_k}=\omega(e_{\mu_1},\ldots,e_{\mu_k})-\sum_{i=1}^{k}\omega_{\mu_1\cdots\overset{\check{}}{0}\cdots\mu_k}, \tag{44}$$

where $\overset{\check{}}{0}$ again means that the index μ_i has been replaced by 0.

Before arriving at our main goal, the development of an exterior calculus on forms, we will recall a few generalities about derivations. Derivations on $\Lambda(\pi^\dagger)$ are defined in the usual way. Following the standard work of Frölicher and Nijenhuis,[12] one easily shows that derivations are local operators and that they are completely determined by their action on functions and one-forms. The commutator of two derivations D_i, of degree r_i say, is again a derivation, of degree r_1+r_2, defined by

$$[D_1,D_2]=D_1\circ D_2-(-1)^{r_1r_2}D_2\circ D_1. \tag{45}$$

Perhaps the simplest type of derivation is contraction with a section.

Definition 4: For $\omega\in\Lambda^k(\pi^\dagger)$ and $\zeta\in Sec(\pi)$, $i_\zeta\omega\in\Lambda^{k-1}(\pi^\dagger)$ is defined by

$$i_\zeta\omega(\zeta_1,\ldots,\zeta_{k-1})=\omega(\zeta,\zeta_1,\ldots,\zeta_{k-1}). \tag{46}$$

The proof that this is a derivation of degree -1 is standard and does not depend on the peculiarities of our present theory. But perhaps we have to convince ourselves in the first place that $i_\zeta\omega$ is indeed a form in the sense of Definition 3.

Proposition 2: $i_\zeta\omega$ is a $(k-1)$-form which, in the sense of the general defining relation (26), is determined by an operator $(i_\zeta\omega)_0$ and a k-form $\mathbf{i}_{\boldsymbol{\zeta}}\boldsymbol{\omega}$ on $Sec(\overline{\pi})$, defined as follows: for all $\boldsymbol{\zeta}_i\in Sec(\overline{\pi})$, $\zeta_0\in Sec(\pi)$,

$$(i_\zeta\omega)_0(\zeta_0,\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_{k-1})=-\omega_0(\zeta_0,\boldsymbol{\zeta},\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_{k-1}),\quad \textit{where}\quad \boldsymbol{\zeta}=\zeta-\zeta_0, \tag{47}$$

$$\mathbf{i}_{\boldsymbol{\zeta}}\boldsymbol{\omega}(\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_k)=\omega_0(\zeta,\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_k). \tag{48}$$

We further have the property (with $\boldsymbol{\zeta}_1=\boldsymbol{\zeta}$)

$$i_\zeta\omega(\zeta_2,\ldots,\zeta_k)=\sum_{i=1}^{k}(-1)^{i-1}(i_\zeta\omega_0)(\boldsymbol{\zeta}_1,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\boldsymbol{\zeta}_k). \tag{49}$$

Proof: A direct computation, using (46) and (26), gives

$$
\begin{aligned}
i_{\zeta}\omega(\zeta_2,\ldots,\zeta_k) &= \omega(\zeta,\zeta_2,\ldots,\zeta_k)\\
&= \omega_0(\zeta_0,\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_k)+\sum_{j=1}^{k-1}(-1)^j\omega_0(\zeta_0,\boldsymbol{\zeta},\boldsymbol{\zeta}_2,\ldots,\hat{\boldsymbol{\zeta}}_j,\ldots,\boldsymbol{\zeta}_k)+\boldsymbol{\omega}(\boldsymbol{\zeta},\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_k)\\
&= \sum_{j=1}^{k-1}(-1)^j\omega_0(\zeta_0,\boldsymbol{\zeta},\boldsymbol{\zeta}_2,\ldots,\hat{\boldsymbol{\zeta}}_j,\ldots,\boldsymbol{\zeta}_k)+\omega_0(\zeta,\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_k),
\end{aligned}
$$

from which we are led to introduce $(i_{\zeta}\omega)_0$ and $\mathbf{i}_{\boldsymbol{\zeta}}\boldsymbol{\omega}$ as in (47) and (48). It is then straightforward to verify that these two operators are linked by a property of type (25), so the first statement follows. Observe that, with an obvious meaning for contraction of the operator ω_0 with ζ, we can write $\mathbf{i}_{\boldsymbol{\zeta}}\boldsymbol{\omega}=i_{\zeta}\omega_0$. The somewhat peculiar feature of the additional property is that $i_{\zeta}\omega$ can be completely computed from $i_{\zeta}\omega_0$. To prove this we again start from (26) to write (with $\zeta_1=\zeta$)

$$
i_{\zeta}\omega(\zeta_2,\ldots,\zeta_k)=\sum_{i=1}^{k}(-1)^{i-1}\omega_0(\zeta_0,\boldsymbol{\zeta}_1,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\boldsymbol{\zeta}_k)+\boldsymbol{\omega}(\boldsymbol{\zeta}_1,\ldots,\boldsymbol{\zeta}_k).
$$

This time, we substitute $\zeta_1-\boldsymbol{\zeta}_1$ for ζ_0 and observe that the second part of the sum involving ω_0, in view of (25), then precisely cancels the last term. □

Maintaining the same line of approach requires that also for the exterior derivative $d\omega$, we identify the associated $(d\omega)_0$ and the form $\mathbf{d}\boldsymbol{\omega}$ on $Sec(\overline{\pi})$ in the sense of Definition 3. Before we can introduce $d\omega$, we need to give a meaning also to the value of a k-form ω, when say its first argument is taken to be a vector section.

Definition 5: If ω is a k-form on $Sec(\pi)$, then for $\boldsymbol{\sigma}\in Sec(\overline{\pi})$ and $\zeta_i\in Sec(\pi)$, we put

$$
\omega(\boldsymbol{\sigma},\zeta_2,\ldots,\zeta_k)=\omega(\zeta_1+\boldsymbol{\sigma},\zeta_2,\ldots,\zeta_k)-\omega(\zeta_1,\zeta_2,\ldots,\zeta_k), \tag{50}
$$

where ζ_1 is chosen arbitrarily.

For this to make sense, of course, we need to be sure that the result does not depend on the choice of ζ_1. Now, if we evaluate the right-hand side of the defining relation by using (26), we obtain

$$
\omega(\boldsymbol{\sigma},\zeta_2,\ldots,\zeta_k)=\boldsymbol{\omega}(\boldsymbol{\sigma},\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_k)+\sum_{i=2}^{k}(-1)^{i-1}\omega_0(\zeta_0,\boldsymbol{\sigma},\boldsymbol{\zeta}_2,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\boldsymbol{\zeta}_k). \tag{51}
$$

The right-hand side of this explicit expression makes no mentioning of ζ_1 anymore. It might seem at first sight that we have shifted the problem, because it does depend on the reference section ζ_0. However, we have argued before that (26) does not depend on the choice of such a reference section, whence our newly defined concept makes sense.

The explicit formula (51) further shows that $i_{\boldsymbol{\sigma}}\omega$ is well defined as a $(k-1)$-form, in the sense of Definition 3. The first term on the right identifies its associated form on $Sec(\overline{\pi})$, whereas the second term, upon swapping the first two arguments, reveals that $(i_{\boldsymbol{\sigma}}\omega)_0=i_{\boldsymbol{\sigma}}\omega_0$. As for local computations, it follows from the definition (50) that $e^0(\boldsymbol{\sigma})=0$, whereas the $\mathbf{e}^{\alpha}$ act on $\boldsymbol{\sigma}$ simply as duals of $Sec(\overline{\pi})$.

Definition 6: The exterior derivative of ω, denoted by $d\omega$ is defined by

$$
\begin{aligned}
d\omega(\zeta_1,\ldots,\zeta_{k+1}) &= \sum_{i=1}^{k+1}(-1)^{i-1}\lambda(\zeta_i)(\omega(\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\zeta_{k+1}))\\
&\quad+\sum_{1\leqslant i<j\leqslant k+1}(-1)^{i+j}\omega([\zeta_i,\zeta_j],\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\widehat{\zeta_j},\ldots,\zeta_{k+1}).
\end{aligned} \tag{52}
$$

Note first that we are making use of Definition 5 in the second term on the right, because the bracket of two affine sections is a vector section. It is fairly obvious that $d\omega$ is skew-symmetric in all its arguments. To further justify this definition in the sense of the defining property (26) of forms, note first that we of course have an exterior derivative at our disposal for the k-form $\boldsymbol{\omega}$ on $Sec(\overline{\pi})$ which we denote by d also. We know that $d\boldsymbol{\omega}$ has a property of type (52) (or can be defined that way), with vector sections replacing affine sections and ρ as anchor map instead of λ. It remains to give a meaning to $d\omega_0$.

Definition 7: For $\omega_0 : Sec(\pi)\times Sec(\overline{\pi})\times\cdots\times Sec(\overline{\pi})\to C^\infty(M)$, *we define* $d\omega_0$, *an operator of the same type, but depending on one more vector section, by*

$$\begin{aligned} d\omega_0(\zeta,\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_{k+1}) &= \lambda(\zeta)(\boldsymbol{\omega}(\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_{k+1})) + \sum_{i=2}^{k+1}(-1)^{i-1}\rho(\boldsymbol{\zeta}_i)(\omega_0(\zeta,\boldsymbol{\zeta}_2,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\boldsymbol{\zeta}_{k+1})) \\ &\quad + \sum_{j=2}^{k+1}(-1)^{j+1}\boldsymbol{\omega}([\zeta,\boldsymbol{\zeta}_j],\boldsymbol{\zeta}_2,\ldots,\hat{\boldsymbol{\zeta}}_j,\ldots,\boldsymbol{\zeta}_{k+1}) \\ &\quad - \sum_{2\leqslant i<j\leqslant k+1}(-1)^{i+j}\omega_0(\zeta,[\boldsymbol{\zeta}_i,\boldsymbol{\zeta}_j],\boldsymbol{\zeta}_2,\ldots,\hat{\boldsymbol{\zeta}}_i,\ldots,\hat{\boldsymbol{\zeta}}_j,\ldots,\boldsymbol{\zeta}_{k+1}). \end{aligned} \tag{53}$$

This expression may look rather exotic at first, but it is obtained by formally copying the definition (52) and writing in that process either λ or ρ, and either ω_0 or $\boldsymbol{\omega}$, in such a way that every term in the right-hand side has a proper meaning. There are two important observations to be made here. First of all, the required linearity of $d\omega_0$ in its vector arguments relies on the properties (9) and (11) of our Lie algebroid bracket. Second, replacing the affine section ζ in the definition by $\zeta+\boldsymbol{\sigma}$, we find

$$d\omega_0(\zeta+\boldsymbol{\sigma},\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_{k+1}) = d\omega_0(\zeta,\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_{k+1}) + d\boldsymbol{\omega}(\boldsymbol{\sigma},\boldsymbol{\zeta}_2,\ldots,\boldsymbol{\zeta}_{k+1}). \tag{54}$$

We now know what to expect for the decomposition (26) of $d\omega$ and this is confirmed by the following result.

Proposition 3: We have $(d\omega)_0 = d\omega_0$ *and* $\mathbf{d}\boldsymbol{\omega} = d\boldsymbol{\omega}$.

The proof involves a rather technical but straightforward calculation and therefore is omitted. It is of some interest, however, to work out some simple cases in detail. For a function $f\in C^\infty(M)$, df is defined by

$$df(\zeta) = \lambda(\zeta)(f) = \lambda(\zeta_0)(f) + \rho(\boldsymbol{\zeta})(f), \tag{55}$$

from which we learn that $(df)_0 = df$ (as expected) and $\mathbf{df}(\boldsymbol{\sigma}) = \rho(\boldsymbol{\sigma})(f)$. If θ is a one-form, the defining relation (52) for its exterior derivative reads

$$d\theta(\zeta_1,\zeta_2) = \lambda(\zeta_1)(\theta(\zeta_2)) - \lambda(\zeta_2)(\theta(\zeta_1)) - \boldsymbol{\theta}([\zeta_1,\zeta_2]). \tag{56}$$

Introducing an arbitrary reference section ζ_0, it is easy to verify that this can be rewritten as

$$d\theta(\zeta_1,\zeta_2) = (d\theta)_0(\zeta_0,\boldsymbol{\zeta}_2) - (d\theta)_0(\zeta_0,\boldsymbol{\zeta}_1) + \mathbf{d}\boldsymbol{\theta}(\boldsymbol{\zeta}_1,\boldsymbol{\zeta}_2), \tag{57}$$

where $\mathbf{d}\boldsymbol{\theta} = d\boldsymbol{\theta}$ and

$$(d\theta)_0(\zeta,\boldsymbol{\sigma}) = \lambda(\zeta)(\boldsymbol{\theta}(\boldsymbol{\sigma})) - \rho(\boldsymbol{\sigma})(\theta(\zeta)) - \boldsymbol{\theta}([\zeta,\boldsymbol{\sigma}]). \tag{58}$$

This is in perfect agreement with the results of Proposition 3 and Definition 7.

Concerning derivation properties, it is trivial to verify that for the product of functions: $d(fg) = fdg + gdf$. Also, from (56) applied to $f\theta$ we get

$$d(f\theta)(\zeta_1,\zeta_2)=\lambda(\zeta_1)(f\theta(\zeta_2))-\lambda(\zeta_2)(f\theta(\zeta_1))-f\theta([\zeta_1,\zeta_2])$$
$$=df(\zeta_1)\theta(\zeta_2)-df(\zeta_2)\theta(\zeta_1)+f(\lambda(\zeta_1)(\theta(\zeta_2))-\lambda(\zeta_2)(\theta(\zeta_1))-\theta([\zeta_1,\zeta_2])),$$

from which we conclude that

$$d(f\theta)=fd\theta+df\wedge\theta, \tag{59}$$

i.e., d has the right derivation property for the action on functions and one-forms. Recalling now the general statements about derivations we made before, we can conclude that there is a unique derivation of degree 1 on $\Lambda(\pi^\dagger)$, which coincides with our d on functions and one-forms. Not surprisingly, this is the d we have introduced by (52), but we again omit the rather technical proof of this claim.

We now reach the main question which is about the relationship between d^2 and the compatibility requirements in the definition of an affine Lie algebroid. To appreciate the meaning of the following lemma, we take a step back and assume now that the bracket $[\zeta_i,\zeta_j]$ figuring in the definition (52) of d satisfies the ''Leibniz-type property'' (9) with respect to the module structure of $Sec(\pi)$ [and the resulting property (11)], but no further compatibility or Lie algebra conditions *a priori*. Remember that the property (9) of the bracket was necessary to make sure that $d\omega$ is a form in the first place.

Lemma 1: For all $\omega\in\Lambda^k(\pi^\dagger)$ *and* $\zeta_i\in Sec(\pi)$, *we have*

$$d^2\omega(\zeta_1,...,\zeta_{k+2})=\sum_{1\leqslant i<j\leqslant k+2}(-1)^{i+j}(\rho([\zeta_i,\zeta_j])-[\lambda(\zeta_i),\lambda(\zeta_j)])(\omega(\zeta_1,...,\hat{\zeta}_i,...,\hat{\zeta}_j,...,\zeta_{k+2}))$$
$$+\sum_{1\leqslant i<j<l\leqslant k+2}(-1)^{i+j+l}\omega\Big(\sum_{i,j,l}[\zeta_i,[\zeta_j,\zeta_l]],\zeta_1,.,\hat{\zeta}_i,.,\hat{\zeta}_j,.,\hat{\zeta}_l,.,\zeta_{k+2}\Big) \tag{60}$$

(where the smaller summation sign of course refers again to a cyclic sum over the three indices involved).

In fact this lemma, with suitable adaptations, also has a rather universal validity, though we were unable to find similar statements in the literature. For this reason, we give a sketch of the proof here.

If ω is a k-form, then $d^2\omega$ is a $(k+2)$-form with

$$d^2\omega(\zeta_1,\ldots,\zeta_{k+2})=\sum_{i=1}^{k+2}(-1)^{i-1}\lambda(\zeta_i)(d\omega(\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\zeta_{k+2}))$$
$$+\sum_{1\leqslant i<j\leqslant k+2}(-1)^{i+j}d\omega([\zeta_i,\zeta_j],\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\hat{\zeta}_j,\ldots,\zeta_{k+2}). \tag{61}$$

If we plug in the definition of $d\omega$, the first term on the right will further decompose into two parts, one involving double and the other involving triple sums. After some elementary multiple sum manipulations, it can be written in the form

$$\sum_{1\leqslant i<j\leqslant k+2}(-1)^{i+j}(\lambda(\zeta_j)\lambda(\zeta_i)-\lambda(\zeta_i)\lambda(\zeta_j))(\omega(\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\hat{\zeta}_j,\ldots,\zeta_{k+2}))$$
$$+\sum_{1\leqslant i<j<l\leqslant k+2}(-1)^{i+j+l-1}\sum_{i,j,l}\{\lambda(\zeta_i)(\omega([\zeta_j,\zeta_l]\},\zeta_1,.,\hat{\zeta}_i,.,\hat{\zeta}_j,.,\hat{\zeta}_l,.,\zeta_{k+2})), \tag{62}$$

where the smaller summation sign stands for a cyclic sum, the range of which is delimited by the curly brackets. For the second term on the right in (61), we have to remember that the first argument is a vector section. Using the defining relation (50), applied to $d\omega$, we obtain

$$d\omega(\boldsymbol{\sigma},\zeta_1,\ldots,\zeta_k)=\rho(\boldsymbol{\sigma})(\omega(\zeta_1,\ldots,\zeta_k))+\sum_{i=1}^{k}(-1)^i\lambda(\zeta_i)(\omega(\boldsymbol{\sigma},\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\zeta_k))$$
$$+\sum_{j=1}^{k}(-1)^j\omega([\boldsymbol{\sigma},\zeta_j],\zeta_1,\ldots,\hat{\zeta}_j,\ldots,\zeta_k)$$
$$+\sum_{1\leqslant i<j\leqslant k}(-1)^{i+j}\omega([\zeta_i,\zeta_j],\boldsymbol{\sigma},\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\hat{\zeta}_j,\ldots,\zeta_k). \tag{63}$$

The last line here has two vector arguments, but this is consistent with the application of Definition 5 to a form of type $i_\zeta\omega$. We look at the effect of each of these four terms, when inserted in the second sum of (61). The first one simply gives

$$\sum_{1\leqslant<i<j\leqslant k+2}(-1)^{i+j}\rho([\zeta_i,\zeta_j])(\omega(\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\hat{\zeta}_j,\ldots,\zeta_{k+2})). \tag{64}$$

The second one is easily seen to give rise to terms which cancel exactly the second sum in (62). The third term of (63) gives rise to expressions involving double brackets, which combine to

$$\sum_{1\leqslant i<j<l\leqslant k+2}(-1)^{i+j+l}\omega\left(\sum_{i,j,l}[[\zeta_i,\zeta_j],\zeta_l],\zeta_1,\ldots,\hat{\zeta}_i,\ldots,\hat{\zeta}_j,\ldots,\hat{\zeta}_l,\ldots,\zeta_{k+2}\right). \tag{65}$$

The fourth term of (63) finally creates terms which involve two double sums, and in each of the summands the first two arguments of ω are brackets. One can show by a suitable reshuffling of summations that all terms in this part cancel out. What we are left with in the end is the first term of (62), (64) and (65): they precisely combine to the statement in the lemma.

Proposition 4: The exterior derivative has the property $d^2=0$ if and only if the bracket further satisfies the Jacobi identity (16) [or equivalently (8)].

Proof: If (9) and (16) hold true, we also have (8) and know from previous considerations that (12) then holds as well. The above lemma this way trivially implies $d^2=0$. For the converse, we observe that $d^2f=0$, for $f\in C^\infty(M)$, implies (17), from which it subsequently follows that $d^2\theta=0$, with $\theta\in\Lambda^1(\pi^\dagger)$, implies (16). □

It remains now to list coordinate expressions for the basic exterior derivatives. Let (t,x^i) as before be coordinates on M. For their exterior derivatives we obtain the following: for all $\zeta\in Sec(\pi)$,

$$dt(\zeta)=\lambda(\zeta)(t)=1,\quad dx^i(\zeta)=\lambda(\zeta)(x^i),$$

from which it follows that $\mathbf{dt}=\mathbf{0}$ and $\mathbf{dx}^i(\boldsymbol{\sigma})=\rho(\boldsymbol{\sigma})(x^i)$ [and of course $(dt)_0=dt$, $(dx^i)_0=dx^i$]. In terms of the general representation (36) of a one-form, we thus have

$$dt=e^0, \tag{66}$$

$$dx^i=\lambda^i e^0+\rho^i_\alpha\mathbf{e}^\alpha. \tag{67}$$

Obviously, we have $de^0=0$. We further calculate, making use, for example, of (43) and (44), the general formula (56) and the coordinate expressions (18), that

$$d\mathbf{e}^\alpha=-C^\alpha_\beta e^0\wedge\mathbf{e}^\beta-\frac{1}{2}C^\alpha_{\beta\gamma}\mathbf{e}^\beta\wedge\mathbf{e}^\gamma. \tag{68}$$

It is instructive to verify that expressing the properties $d^2\mathbf{e}^\alpha=0$ and $d^2x^i=0$ is indeed equivalent to the requirements (20) and (21) and (22) and (23), respectively.

To complete the picture of basic derivations on $\Lambda(\pi^\dagger)$, we have a closer look at the analog of the classical Lie derivative.

Definition 8: For every $\zeta\in Sec(\pi)$, the derivation d_ζ of degree zero is defined as

$$d_\zeta=[i_\zeta,d]=i_\zeta\circ d+d\circ i_\zeta. \tag{69}$$

So, since d_ζ is defined as a commutator of derivations, we know that it will itself be a derivation of degree zero:

$$d_\zeta(\omega\wedge\mu)=d_\zeta\omega\wedge\mu+\omega\wedge d_\zeta\mu. \tag{70}$$

Likewise, we can rely on proofs similar to those in the standard theory to conclude that the following commutator properties will hold true:

$$[d_\zeta,i_\eta]=i_{[\zeta,\eta]},\quad [d_\zeta,d]=0,\quad [d_\zeta,d_\eta]=d_{[\zeta,\eta]}. \tag{71}$$

Note, however, that a Lie-type derivation with respect to a vector section turns up in the last property, and this is indeed well defined also as $d_{\boldsymbol{\sigma}}=[i_{\boldsymbol{\sigma}},d]$. It is further natural to extend the action of d_ζ to $Sec(\pi)$ by duality. It then follows, as expected, that for $\eta,\zeta\in Sec(\pi)$,

$$d_\zeta\eta=[\zeta,\eta]. \tag{72}$$

As a result of such an extension, d_ζ has Leibniz-type properties also with respect to the evaluation of forms on the appropriate number of affine (or vector) sections; the following property, which could be verified by a direct computation from the definition of d_ζ, thus becomes self-evident:

$$d_\eta\omega(\zeta_1,\ldots,\zeta_k)=\lambda(\eta)(\omega(\zeta_1,\ldots,\zeta_k))+\sum_{j=1}^{k}(-1)^j\omega([\eta,\zeta_j],\zeta_1,\ldots,\hat{\zeta}_j,\ldots,\zeta_k). \tag{73}$$

In the interest of doing computations, we list the Lie-type derivatives of functions $f\in C^\infty(M)$ and the local basis of one-forms. For $\zeta=e_0+\zeta^\alpha\mathbf{e}_\alpha$,

$$d_\zeta f=\lambda(\zeta)(f),\quad d_\zeta e^0=0,\quad d_\zeta\mathbf{e}^\alpha=C^\alpha_\beta\zeta^\beta e^0-C^\alpha_\beta\mathbf{e}^\beta+C^\alpha_{\beta\gamma}\zeta^\gamma\mathbf{e}^\beta+d\zeta^\alpha.$$

IV. λ-ADMISSIBLE CURVES AND DYNAMICS

As we expressed in the Introduction, the model of affine Lie algebroids we are developing should in the first place offer an environment in which one can accommodate the time-dependent Lagrange-type equations (4). At present, we wish to look in more detail at the geometric nature of the more general dynamical systems, which we call pseudo-second-order equations, and are those described by differential equations of the form (3). For this purpose, in fact, we do not need the full machinery of algebroids: it suffices to assume that E is an affine bundle over M and $\lambda:E\to J^1M$ an affine bundle map over the identity.

Definition 9: A curve ψ in E, which is a section of $\tau\circ\pi$, is said to be λ-admissible, if $\lambda\circ\psi=j^1(\pi\circ\psi)$.

One could say that ψ is the λ-prolongation of a curve in M. In coordinates, we have

$$\psi:t\mapsto(t,x^i(t),y^\alpha(t)),\quad \text{with}\quad \dot{x}^i(t)=\lambda^i(t,x(t))+\rho^i_\alpha(t,x(t))y^\alpha(t).$$

Note in passing that, not unexpectedly, one can characterize λ-admissibility via a concept of contact forms: putting $\Theta^i=\lambda^*\theta^i$, where the θ^i are the contact forms on J^1M, we have that ψ is a λ-admissible curve in E if and only if $\psi^*\Theta^i=0$.

Pseudo-second-order equation fields on E are vector fields whose integral curves all are λ-admissible curves. As in the standard theory of SODEs on a tangent bundle or first jet bundle, however, there is a simple direct characterization of such vector fields.

Definition 10: $\Gamma \in \mathcal{X}(E)$ *is a pseudo-second-order equation field if*

$$T\pi \circ \Gamma = i \circ \lambda,$$

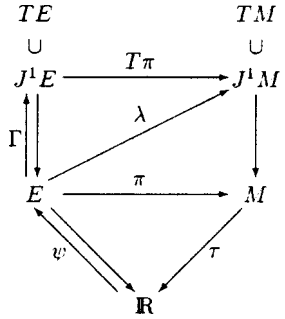
where i *is the injection of* J^1M *into* TM.

Clearly, in coordinates, a pseudo-SODE is of the form

$$\Gamma = \frac{\partial}{\partial t} + (\lambda^i(t,x) + \rho^i_\alpha(t,x)y^\alpha)\frac{\partial}{\partial x^i} + f^\alpha(t,x,y)\frac{\partial}{\partial y^\alpha}, \tag{74}$$

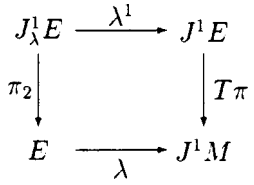
for some functions f^α, and it is obvious that all its integral curves will be λ-admissible.

The following diagram visualizes the notions of λ-admissible curves and pseudo-SODEs.



An important point now, however, is that there is a natural way of interpreting the vector field Γ as section of a different bundle.

From the above definition, it is clear that a pseudo-SODE is actually a section of $(\tau \circ \pi)^0_1 : J^1E \to E$, with the additional property that for all $p \in E$, $T\pi|_{J^1E}(\Gamma(p)) = \lambda(p)$. An equivalent way of saying the same thing, by definition of the concept of a pullback bundle, is that $(p,\Gamma(p))$ is a point of $\lambda^* J^1E$, with J^1E regarded as fibered over J^1M via $T\pi|_{J^1E}$. From now on, we will write $J^1_\lambda E$ for $\lambda^* J^1E$, and denote its two projections as indicated in the following diagram:



If we finally put $\pi_1 = (\tau \circ \pi)^0_1 \circ \lambda^1$, there is yet another way of expressing the characterization of a pseudo-SODE. Indeed, from the trivial observation that $(\tau \circ \pi)^0_1(\Gamma(p)) = p = \pi_2((p,\Gamma(p)))$, it follows that a pseudo-SODE Γ can be regarded also as a section of the bundle $\pi_1 : J^1_\lambda E \to E$, with the property that $\pi_2 \circ \Gamma = \pi_1 \circ \Gamma$.

The various spaces and projections, described in this discussion, are depicted in the diagram of the next section. This diagram immediately suggests the following question: if we put more structure into the scheme by assuming now again that $\pi : E \to M$ carries an affine Lie algebroid structure, is it possible to prolong this structure to the bundle $\pi_1 : J^1_\lambda E \to E$, in such a way of course that λ^1 becomes the anchor map of the induced affine Lie algebroid?

V. PROLONGATION OF AFFINE LIE ALGEBROIDS

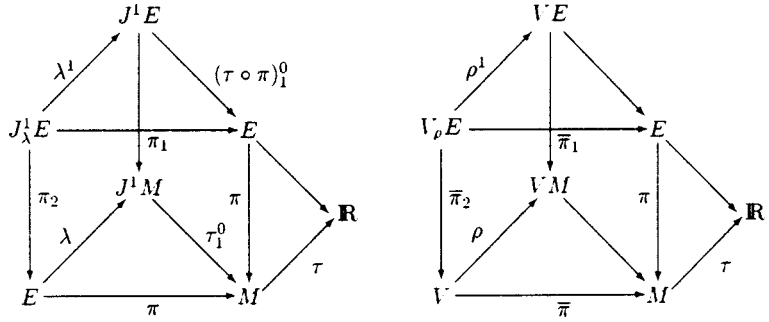
We shall now look in more detail at the bundle $\pi_1 : J^1_\lambda E \to E$. Its total space is the manifold

$$J^1_\lambda E = \lambda^* J^1 E = \{(q,Z) \in E \times J^1 E \,|\, \lambda(q) = T\pi|_{J^1 E}(Z)\},$$

but the fibration we want to focus on is not one of the projections which define $J^1_\lambda E$, but rather the map $\pi_1 = (\tau \circ \pi)^0_1 \circ \lambda^1$. As such, we are looking at an affine bundle, modeled on the vector bundle $\overline{\pi}_1 : V_\rho E \to E$, with total space

$$V_\rho E = \{(\mathbf{v},\mathbf{V}) \in V \times VE \,|\, \rho(\mathbf{v}) = T\pi|_{VE}(\mathbf{V})\}.$$

The affine bundles involved, and their underlying vector bundles, are illustrated below.



A section Z of π_1 is completely determined once we know the maps $\pi_2 \circ Z : E \to E$ and $\lambda^1 \circ Z : E \to J^1 E$. Likewise, vector sections $\mathbf{Z}$ of $\overline{\pi}_1$ are determined by $\overline{\pi}_2 \circ \mathbf{Z}$ and $\rho^1 \circ \mathbf{Z}$. For example, let $e \in E$ be a point with coordinates (t,x^i,y^α), so that (t,x^i) are the coordinates of $\pi(e) \in M$ and e has the representation $e = e_0 + y^\alpha \mathbf{e}_\alpha$. If then Z is a section of π_1, we will have

$$\pi_2 \circ Z: \quad (t,x,y) \mapsto (t,x,z^\alpha(t,x,y)),$$

$$\lambda^1 \circ Z: \quad (t,x,y) \mapsto \left(\frac{\partial}{\partial t} + (\lambda^i + \rho^i_\alpha z^\alpha) \frac{\partial}{\partial x^i} + Z^\alpha \frac{\partial}{\partial y^\alpha} \right)\Bigg|_e,$$

and determining Z in coordinates of course amounts to assigning the functions (z^α, Z^α) on E.

It is worthwhile looking at the representation of such a Z with respect to suitably selected local sections of π_1 and $\overline{\pi}_1$, which will exhibit the affine structure of π_1 and are adapted to the basis which was selected to coordinatize E. To this end, we introduce two sets of local sections $\boldsymbol{\mathcal{X}}_\alpha$ and $\boldsymbol{\mathcal{V}}_\alpha$ of $\overline{\pi}_1$ which will span $Sec(\overline{\pi}_1)$, and select a zero section $\mathcal{E}_0$ as follows. The $\boldsymbol{\mathcal{V}}_\alpha$ span 'vertical sections' and are determined by: $\overline{\pi}_2 \circ \boldsymbol{\mathcal{V}}_\alpha = \mathbf{0}$, while for $e \in E_m$ we let $\rho^1 \circ \boldsymbol{\mathcal{V}}_\alpha(e)$ be the tangent vector to the curve $s \mapsto e + s\mathbf{e}_\alpha(m)$ in E_m. Verticality is an intrinsic property whereas, as usual, there is no intrinsic notion of horizontality. The determination of the $\boldsymbol{\mathcal{X}}_\alpha$ and $\mathcal{E}_0$ will therefore rely on pure coordinate arguments. For the projection onto V we put $\overline{\pi}_2 \circ \boldsymbol{\mathcal{X}}_\alpha = \mathbf{e}_\alpha \circ \pi$ and then, fixing $\rho^1 \circ \boldsymbol{\mathcal{X}}_\alpha$ (as a vector field on E) further requires making a prescription for the vertical components, which we simply take to be zero. Similarly, for the choice of a zero section, we could take any vector field on E which projects under $T\pi$ onto $\lambda(e_0) \in \mathcal{X}(M)$ (and as such defines also a section of π_1), but we will fix it also by taking the vertical components to be zero. Thus we have

$$\boldsymbol{\mathcal{X}}_\alpha(e) = \left(\mathbf{e}_\alpha(\pi(e)), \rho^i_\alpha(t,x) \frac{\partial}{\partial x^i}\Big|_e \right), \quad \boldsymbol{\mathcal{V}}_\alpha(e) = \left(\mathbf{0}(\pi(e)), \frac{\partial}{\partial y^\alpha}\Big|_e \right), \tag{75}$$

and

$$\mathcal{E}_0(e)=\left(e_0(\pi(e)),\left(\frac{\partial}{\partial t}+\lambda^i(t,x)\frac{\partial}{\partial x^i}\right)\Big|_e\right). \tag{76}$$

The general section Z of π_1 then has the local representation

$$Z=\mathcal{E}_0+z^\alpha(t,x,y)\boldsymbol{\mathcal{X}}_\alpha+Z^\alpha(t,x,y)\boldsymbol{\mathcal{V}}_\alpha. \tag{77}$$

Note that pseudo-SODEs, as discussed in the previous section, are precisely those sections Γ of π_1, for which $z^\alpha(t,x,y)=y^\alpha$.

Let now E be equipped with an affine Lie algebroid structure. To be in line with the notations we used in Definition 1, we will from now on also write $\lambda^1(Z)$ instead of $\lambda^1\circ Z$, and likewise for the π_2-projection and the corresponding projections of vector sections.

We wish to establish that there is an induced Lie algebroid structure on the affine bundle π_1. To this end, following the scheme of Definition 1, we have to identify a bracket on $\overline{\pi}_1$ and an action of affine sections on vector sections, such that all the necessary requirements are met. The idea is to define such brackets by requiring roughly that its two projections are determined by the known brackets of the projected sections. But there are some technical complications which we will address now.

For $\mathbf{Z}_1,\mathbf{Z}_2\in Sec(\overline{\pi}_1)$, a preliminary observation is that the Lie bracket of their image under ρ^1 (which gives rise to vector fields on E), belongs to the image of ρ^1. A coordinate calculation can confirm this. Putting

$$\rho^1(\mathbf{Z}_i)=z_i^\alpha\rho_\alpha^j\frac{\partial}{\partial x^j}+Z_i^\alpha\frac{\partial}{\partial y^\alpha},$$

we have

$$[\rho^1(\mathbf{Z}_1),\rho^1(\mathbf{Z}_2)]=(\rho^1(\mathbf{Z}_1)(z_2^\alpha)-\rho^1(\mathbf{Z}_2)(z_1^\alpha))\rho_\alpha^j\frac{\partial}{\partial x^j}+(z_2^\alpha\rho^1(\mathbf{Z}_1)(\rho_\alpha^j)$$

$$-z_1^\alpha\rho^1(\mathbf{Z}_2)(\rho_\alpha^j))\frac{\partial}{\partial x^j}+\cdots\frac{\partial}{\partial y^\alpha}.$$

The first term on the right manifestly belongs to the image of ρ^1, whereas the last term is irrelevant for that purpose. The middle term can be rewritten as

$$z_2^\alpha z_1^\beta\left(\rho_\beta^j\frac{\partial\rho_\alpha^i}{\partial x^j}-\rho_\alpha^j\frac{\partial\rho_\beta^i}{\partial x^j}\right)\frac{\partial}{\partial x^i},$$

which is seen to belong to the image of ρ^1 in view of the property (23). It is therefore natural to impose right away that the bracket $[\cdot,\cdot]^1$ under construction, which of course is required to be skew-symmetric and $\mathbb{R}$-bilinear, should satisfy

$$\rho^1([\mathbf{Z}_1,\mathbf{Z}_2]^1)=[\rho^1(\mathbf{Z}_1),\rho^1(\mathbf{Z}_2)]. \tag{78}$$

This will have for consequence that for $F_i\in C^\infty(E)$,

$$\rho^1([F_1\mathbf{Z}_1,F_2\mathbf{Z}_2]^1)=F_1F_2[\rho^1(\mathbf{Z}_1),\rho^1(\mathbf{Z}_2)]+F_1\rho^1(\mathbf{Z}_1)(F_2)\rho^1(\mathbf{Z}_2)-F_2\rho^1(\mathbf{Z}_2)(F_1)\rho^1(\mathbf{Z}_1).$$

It remains then to make sure that the projection under $\overline{\pi}_2$ can be specified in a compatible way. The above coordinate calculation to some extent illustrates how one should proceed. If we apply $T\pi$ to the preceding equality, we get (pointwise)

$$T\pi(\rho^1([F_1\mathbf{Z}_1,F_2\mathbf{Z}_2]^1))=(F_1F_2)T\pi([\rho^1(\mathbf{Z}_1),\rho^1(\mathbf{Z}_2)])+F_1\rho^1(\mathbf{Z}_1)(F_2)\rho(\overline{\pi}_2(\mathbf{Z}_2))$$
$$-F_2\rho^1(\mathbf{Z}_2)(F_1)\rho(\overline{\pi}_2(\mathbf{Z}_1)).$$

In general, the $\rho(\overline{\pi}_2(\mathbf{Z}_i))$ are vector fields along π for which there is no standard Lie bracket available. If the $\mathbf{Z}_i$ are projectable, however, meaning that there exist $\boldsymbol{\zeta}_i\in Sec(\overline{\pi})$ such that $\overline{\pi}_2\circ\mathbf{Z}_i=\boldsymbol{\zeta}_i\circ\pi$, the vector fields $\rho^1(\mathbf{Z}_i)$ on E are π-related to the vector fields $\rho(\boldsymbol{\zeta}_i)$ on M. Hence, the corresponding brackets are also π-related, meaning that for projectable $\mathbf{Z}_i$, we can put

$$\overline{\pi}_2([\mathbf{Z}_1,\mathbf{Z}_2]^1)=[\overline{\pi}_2(\mathbf{Z}_1),\overline{\pi}_2(\mathbf{Z}_2)], \tag{79}$$

and then the property (13) [which in coordinates gives (23)] ensures that

$$T\pi(\rho^1([\mathbf{Z}_1,\mathbf{Z}_2]^1))=\rho\circ\overline{\pi}_2([\mathbf{Z}_1,\mathbf{Z}_2]^1)$$

as it should. The expression for $T\pi(\rho^1([F_1\mathbf{Z}_1,F_2\mathbf{Z}_2]^1))$ further shows that the $\overline{\pi}_2$ and ρ^1 projections of the bracket under construction will still match up if for projectable $\mathbf{Z}_i$ and for any $F_i\in C^\infty(E)$, we define

$$\overline{\pi}_2([F_1\mathbf{Z}_1,F_2\mathbf{Z}_2]^1)=F_1F_2[\overline{\pi}_2(\mathbf{Z}_1),\overline{\pi}_2(\mathbf{Z}_2)]+F_1\rho^1(\mathbf{Z}_1)(F_2)\overline{\pi}_2(\mathbf{Z}_2)-F_2\rho^1(\mathbf{Z}_2)(F_1)\overline{\pi}_2(\mathbf{Z}_1). \tag{80}$$

It then follows that

$$[F_1\mathbf{Z}_1,F_2\mathbf{Z}_2]^1=F_1F_2[\mathbf{Z}_1,\mathbf{Z}_2]^1+F_1\rho^1(\mathbf{Z}_1)(F_2)\mathbf{Z}_2-F_2\rho^1(\mathbf{Z}_2)(F_1)\mathbf{Z}_1, \tag{81}$$

since both sides have the same $\overline{\pi}_2$ and ρ^1 projections.

The final point to observe now is that sections of $\overline{\pi}_1$ (locally) are finitely generated, over the ring $C^\infty(E)$, by projectable sections. Hence, the defining relations (78) and (80) are sufficient to define the bracket $[\cdot,\cdot]^1$ on vector sections. The property (81) will hold by extension for all vector sections and the bracket will satisfy the Jacobi identity as a result of the Jacobi identity of the Lie algebroid bracket we start from and the same identity for vector fields on E.

To define the action of $Z\in Sec(\pi_1)$ on $\mathbf{V}\in Sec(\overline{\pi}_1)$, we proceed in exactly the same manner. First, one easily verifies that the Lie bracket of $\lambda^1(Z)$ and $\rho^1(\mathbf{V})$ belongs to the image of ρ^1, this time in view of the properties (22) and (23). Hence, it makes sense to put

$$\rho^1([Z,\mathbf{V}]^1)=[\lambda^1(Z),\rho^1(\mathbf{V})], \tag{82}$$

and we of course require the bracket $[\cdot,\cdot]^1$ to have linearity properties of the kind of (7). For projectable sections, we can put

$$\overline{\pi}_2([Z,\mathbf{V}]^1)=[\pi_2(Z),\overline{\pi}_2(\mathbf{V})], \tag{83}$$

and be assured of consistency with the projection (82). Next, still for projectable Z and $\mathbf{V}$ and for any $F\in C^\infty(E)$, we define

$$\overline{\pi}_2([Z,F\mathbf{V}]^1)=F[\pi_2(Z),\overline{\pi}_2(\mathbf{V})]+\lambda^1(Z)(F)\overline{\pi}_2(\mathbf{V}). \tag{84}$$

Sections of π_1 can be written as a projectable zero section, plus a linear combination of projectable vector sections with coefficients in $C^\infty(E)$. In combination with the earlier arguments for vector sections, we are again led to the conclusion that the requirements (82) and (84) are sufficient to define $[Z,\mathbf{V}]^1$ for arbitrary $Z\in Sec(\pi_1)$ and $\mathbf{V}\in Sec(\overline{\pi}_1)$ and that we will have the property

$$[Z,F\mathbf{V}]^1=F[Z,\mathbf{V}]^1+\lambda^1(Z)(F)\mathbf{V}. \tag{85}$$

The final requirement of type (8) then also easily follows, which concludes the construction of the prolonged affine Lie algebroid.

For computational purposes, it remains to list the brackets of the local sections which are used in the general representation of a section of π_1 as in (77). We have

$$[\mathcal{E}_0, \boldsymbol{\mathcal{X}}_\alpha]^1 = C_\alpha^\beta \boldsymbol{\mathcal{X}}_\beta, \quad [\mathcal{E}_0, \boldsymbol{\mathcal{V}}_\alpha]^1 = \mathbf{0},$$

$$[\boldsymbol{\mathcal{X}}_\alpha, \boldsymbol{\mathcal{X}}_\beta]^1 = C_{\alpha\beta}^\gamma \boldsymbol{\mathcal{X}}_\gamma, \quad [\boldsymbol{\mathcal{X}}_\alpha, \boldsymbol{\mathcal{V}}_\beta]^1 = \mathbf{0}, \quad [\boldsymbol{\mathcal{V}}_\alpha, \boldsymbol{\mathcal{V}}_\beta]^1 = \mathbf{0}.$$

It is perhaps worthwhile to repeat hereby that the two projections have to be looked at to verify these statements, although of course they are bound to match up if our new bracket has been defined consistently. Thus we have, for example:

$$\overline{\pi}_2([\mathcal{E}_0, \boldsymbol{\mathcal{X}}_\alpha]^1) = [\pi_2(\mathcal{E}_0), \overline{\pi}_2(\boldsymbol{\mathcal{X}}_\alpha)] = [e_0, \mathbf{e}_\alpha] = C_\alpha^\beta \mathbf{e}_\beta,$$

$$\rho^1([\mathcal{E}_0, \boldsymbol{\mathcal{X}}_\alpha]^1) = [\lambda^1(\mathcal{E}_0), \rho^1(\boldsymbol{\mathcal{X}}_\alpha)] = \left[\frac{\partial}{\partial t} + \lambda^i \frac{\partial}{\partial x^i}, \rho_\alpha^j \frac{\partial}{\partial x^j}\right] = C_\alpha^\beta \rho^1(\boldsymbol{\mathcal{X}}_\beta),$$

where (22) has been used again in the last line.

VI. DISCUSSION AND OUTLOOK FOR FUTURE WORK

The form of equations (4), which we claim to be the appropriate generalization of Lagrangian systems on Lie algebroids to a situation where explicit time dependence is involved, has brought us to the introduction of the new concept of Lie algebroids on affine bundles which are fibered over $\mathbb{R}$. More precisely, the first guidance for developing this concept was provided by the conditions (5) and (6) which the various functions appearing in (4) have to satisfy. Ultimately, of course, we want to arrive at an intrinsic geometrical construction of such Lagrangian systems. There are many aspects to be explored yet, but we have sufficiently paved the way already to be able to predict what the outcome of subsequent studies will bring.

One of us has shown[5] that the prolongation of a Lie algebroid (in the standard situation of vector bundles) provides a platform where there exist analog of the intrinsic structures living on a tangent bundle and these in turn give rise to an intrinsic definition of Lagrangian systems via Poincaré–Cartan-type forms. This is the reason why we were keen to verify immediately that the same notion of prolongation exists in our affine set-up. There is little doubt now that we will find intrinsic objects on such a prolonged affine Lie algebroid, which are analogs of what is known to give rise to an intrinsic definition of time-dependent Lagrangian systems on the first jet bundle of a manifold fibered over $\mathbb{R}$. But there is more to it. Even when there is no Lagrangian for the dynamics under consideration and we are, in other words, talking about pseudo-SODEs on a Lie algebroid, we expect to be able to develop a machinery of associated nonlinear and linear connections, which again is analogous to the standard theory of connections associated to SODEs on a tangent bundle or first jet bundle. A paper on these issues is in preparation.

One of the features we examined in this article as a kind of test for the relevance and internal consistency of the generalized notion of Lie algebroids was the existence of an associated coboundary operator d. But, of course, there are still other interesting properties which standard Lie algebroids are known to exhibit. Let us briefly highlight another one here and show that it also survives our generalization, namely the existence of an associated Poisson structure. Specifically, we want to establish that there exists a canonically defined Poisson structure on the extended dual $E^\dagger$.

Sections of π (respectively $\overline{\pi}$) can be identified with linear functions on $E^\dagger$ (respectively V^*). Explicitly, if $\zeta \in Sec(\pi)$, we consider the function $\hat{\zeta} \in C^\infty(E^\dagger)$ defined by: for each $p \in E^\dagger$, $p \in E_m^\dagger$ say, $\hat{\zeta}(p) = p(\zeta_m)$. Likewise, if $\boldsymbol{\sigma} \in Sec(\overline{\pi})$, we denote by $\hat{\boldsymbol{\sigma}} \in C^\infty(V^*)$ the function defined

by $\hat{\boldsymbol{\sigma}}(\mathbf{p})=\mathbf{p}(\boldsymbol{\sigma}_m)$, where $\mathbf{p}\in V_m^*$. In coordinates, if $\zeta=e_0+\zeta^\alpha \mathbf{e}_\alpha$ and $p\in E^\dagger$ has coordinates (t,x^i,p_0,p_α), then $\hat{\zeta}(p)=p_0+p_\alpha\zeta^\alpha(t,x)$ and similarly for $\hat{\boldsymbol{\sigma}}$. Now, for any two sections $\zeta,\eta \in Sec(\pi)$, we define the function $\{\hat{\zeta},\hat{\eta}\}$ on $E^\dagger$ by

$$\{\hat{\zeta},\hat{\eta}\}(p)=[\widehat{\zeta,\eta}](\mathbf{p}), \tag{86}$$

whereby we recall that $[\zeta,\eta]$ is a section of $\overline{\pi}$ and, for $p\in E_m^\dagger$, $\mathbf{p}$ is the associated element of V_m^*. If further f,g are functions on M and we make no notational distinction for their pullback to $E^\dagger$, internal consistency of (86) for the action of $Sec(\overline{\pi})$ on $Sec(\pi)$ requires that we further put

$$\{\hat{\zeta},f\}=-\{f,\hat{\zeta}\}=\lambda(\zeta)(f),\quad \{f,g\}=0. \tag{87}$$

The construction then uniquely extends to a skew-symmetric, $\mathbb{R}$-bilinear bracket operation on $E^\dagger$ with the required derivation property. This bracket satisfies the Jacobi identity as a result of the Lie algebroid Jacobi identity (16).

The brackets for the coordinate functions on $E^\dagger$ are found to be

$$\{t,t\}=0,\quad \{t,x^i\}=0,\quad \{x^i,x^j\}=0,$$

$$\{p_0,t\}=1,\quad \{p_0,x^i\}=\lambda^i,\quad \{p_0,p_\beta\}=C^\gamma_\beta p_\gamma,$$

$$\{p_\alpha,t\}=0,\quad \{p_\alpha,x^i\}=\rho^i_\alpha,\quad \{p_\alpha,p_\beta\}=C^\gamma_{\alpha\beta}p_\gamma.$$

There is an interesting observation to be made here. Recall that $E^\dagger$ is actually a vector bundle and note now that the bracket we have constructed preserves the subset of functions on $E^\dagger$ which are linear in the fiber coordinates. As a result, we know that there is an induced Lie algebroid structure on the bundle $(E^\dagger)^*\to M$. There are many new insights to be gained from approaching the subject of a Lie algebroid structure on the affine bundle $E\to M$ from this angle; that is to say, by regarding $E\to M$ as an affine subbundle of $(E^\dagger)^*\to M$ and taking an appropriate Lie algebroid structure on $(E^\dagger)^*\to M$ as the starting point. Also this is the subject of a forthcoming paper[13] and is the point of view also in the preprint[14] which came out during the revision process of the present work. One of the main advantages which such an approach offers is that it enables us to get beyond the assumption about the extra fibration of M and thus gives rise to a more general concept of affine Lie algebroids. It further leads to considerable simplifications in proving results about the calculus of forms, as discussed here in Sec. III. We believe, nevertheless, that the present approach preserves its merits mainly for two reasons: one is the repeatedly mentioned motivation coming from time-dependent mechanics; the second one is that the theory of differential forms on sections of an affine bundle $E\to M$, as investigated in Sec. III from a kind of ''internal point of view,'' i.e., without recourse to the larger vector bundle in which E can be imbedded, is something which is being developed here (to the best of our knowledge) for the first time.

On generalizations of the Calogero–Moser–Sutherland quantum problem and WDVV equations

A. P. Veselov[a)]

(Received 26 April 2002; accepted 25 June 2002)

It is proved that if the Schrödinger equation $L\psi=\lambda\psi$ of Calogero–Moser–Sutherland type with $L=-\Delta+\Sigma_{\alpha\in\mathcal{A}_+}[m_\alpha(m_\alpha+1)(\alpha,\alpha)/\sin^2(\alpha,x)]$ has a solution of the product form $\psi_0=\Pi_{\alpha\in\mathcal{A}_+}\sin^{-m_\alpha}(\alpha,x)$, then the function $F(x)=\Sigma_{\alpha\in\mathcal{A}_+}m_\alpha(\alpha,x)^2\log(\alpha,x)^2$ satisfies the generalized WDVV equations. This explains the relation between these equations and the deformed CMS quantum problems observed in an earlier work [Phys. Lett. A **261**, 297 (1999)]. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1505651]

I. INTRODUCTION

Let $\mathcal{A}$ be a finite set of vectors α in the Euclidean space $\mathbf{R}^n$ which generates the space and is invariant under the symmetry $x\to -x$. We assume that $-\alpha$ is the only vector from $\mathcal{A}$ which is proportional to α. Let $\mathcal{A}_+$ be its half positive with respect to some linear form. Let us prescribe to each vector $\alpha\in\mathcal{A}$ a real number (''multiplicity'') m_α such that $m_{-\alpha}=m_\alpha$.

Consider the following Schrödinger operator:

$$L=-\Delta+\sum_{\alpha\in\mathcal{A}_+}\frac{m_\alpha(m_\alpha+1)(\alpha,\alpha)}{\sin^2(\alpha,x)}. \tag{1}$$

When $\mathcal{A}$ is a root system with the multiplicities invariant under the corresponding Weyl group W this is an integrable generalization of the Calogero–Moser–Sutherland (CMS) operator[1,2] suggested by Olshanetsky and Perelomov.[3] As it has been shown in Refs. 4 and 5 there are also nonsymmetric integrable generalizations of this problem. This discovery led to the notion of the locus configurations which play a crucial role in the theory of the Huygens' principle.[6]

It turned out[7,8] that the locus configurations discovered in Refs. 4–6 can be used also to construct new solutions of the generalized Witten–Dijgraaf–Verlinde–Verlinde (WDVV) equations:

$$F_iF_k^{-1}F_j=F_jF_k^{-1}F_i,\quad i,j,k=1,\ldots,n. \tag{2}$$

Here F_m is the $n\times n$ matrix constructed from the third partial derivatives of the unknown function $F=F(x^1,\ldots,x^n)$:

$$(F_m)_{pq}=\frac{\partial^3F}{\partial x^m\partial x^p\partial x^q}. \tag{3}$$

In this form these equations have been written by Marshakov, Mironov and Morozov, who showed that the Seiberg–Witten prepotential in $N=2$ four-dimensional supersymmetric gauge theories

a)Electronic mail: A.P.Veselov@lboro.ac.uk

satisfies this system.[9] Originally these equations have been introduced first in topological field theory as some associativity conditions[10,11] and have been later investigated in this context by Dubrovin.[12]

However, in Ref. 13 we have shown that the relation discovered in Ref. 7 between the locus configurations and WDVV equations does not always work, which raised the question what exactly is the property behind this relation.

The aim of this article is to present the answer to this question. The main result is the following:

Theorem: *If the Schrödinger equation $L\psi=\lambda\psi$ of Calogero–Moser–Sutherland type (1) has a solution of the product form*

$$\psi_0=\prod_{\alpha\in\mathcal{A}_+}\sin^{-m_\alpha}(\alpha,x),$$

then the function

$$F(x)=\sum_{\alpha\in\mathcal{A}_+}m_\alpha(\alpha,x)^2\log(\alpha,x)^2$$

satisfies the generalized WDVV equations.

We should mention that the eigenfunctions of the product form play a special role in the theory of the original CMS problem giving the ground states of the system.[1,2] For the deformed CMS problem this becomes more complicated because these solutions become singular on some hyperplanes, so we can consider these solutions as the eigenfunctions only in the formal sense.

II. SPECIAL CLASS OF SOLUTIONS TO GENERALIZED WDVV EQUATIONS

In this section we essentially follow the analysis of the special solutions to WDVV equations from Refs. 7 and 8.

It is known[9,14] that WDVV equations (2) and (3) are equivalent to the equations

$$F_iG^{-1}F_j=F_jG^{-1}F_i,\quad i,j=1,\ldots,n, \tag{4}$$

where $G=\Sigma_{k=1}^n\eta^kF_k$ is any particular invertible linear combination of F_i with the coefficients, which may depend on x. Introducing the matrices $\check{F}_i=G^{-1}F_i$, one can rewrite (4) as the commutativity relations

$$[\check{F}_i,\check{F}_j]=0,\quad i,j=1,\ldots,n. \tag{5}$$

We will consider the following particular class of the solutions to these equations.

Let V be a real vector space of dimension n, V^* be its dual space consisting of the linear functions on V (covectors), and $\mathfrak{A}$ be a finite set of noncollinear covectors $\alpha\in V^*$ generating V^*.

Consider the following function on V:

$$F^{\mathfrak{A}}=\sum_{\alpha\in\mathfrak{A}}(\alpha,x)^2\log(\alpha,x)^2, \tag{6}$$

where $(\alpha,x)=\alpha(x)$ is the value of covector $\alpha\in V^*$ on a vector $x\in V$. For any basis $e_1,\ldots,e_n$ we have the corresponding coordinates $x^1,\ldots,x^n$ in V and the matrices F_i defined according to (3). In a more invariant form for any vector $a\in V$ one can define the matrix

$$F_a=\sum_{i=1}^n a^iF_i.$$

One can easily check that F_a is the matrix of the following bilinear form on V,

$$F_a^{\mathfrak{A}}=\sum_{\alpha\in\mathfrak{A}}\frac{(\alpha,a)}{(\alpha,x)}\alpha\otimes\alpha,$$

where $\alpha\otimes\beta(u,v)=\alpha(u)\beta(v)$ for any $u,v\in V$ and $\alpha,\beta\in V^*$. Define G as F_x, i.e.,

$$G=\sum_{i=1}^{n}x^iF_i,$$

which is actually the matrix of the bilinear form

$$G^{\mathfrak{A}}=\sum_{\alpha\in\mathfrak{A}}\alpha\otimes\alpha, \tag{7}$$

which does not depend on x. Since the covectors $\alpha\in\mathfrak{A}$ generate V^*, the form $G^{\mathfrak{A}}$ is nondegenerate. This means that the natural linear mapping $\varphi_{\mathfrak{A}}:V\to V^*$ defined by the formula

$$(\varphi_{\mathfrak{A}}(u),v)=G^{\mathfrak{A}}(u,v),\quad u,v\in V,$$

is invertible. We will denote $\varphi_{\mathfrak{A}}^{-1}(\alpha),\alpha\in V^*$, as $\alpha^\vee$. By definition

$$\sum_{\alpha\in\mathfrak{A}}\alpha^\vee\otimes\alpha=Id$$

as an operator in V^* or, equivalently,

$$(\alpha,v)=\sum_{\beta\in\mathfrak{A}}(\alpha,\beta^\vee)(\beta,v), \tag{8}$$

for any $\alpha\in V^*,v\in V$. Now according to (5) the WDVV equations (2) and (3) for the function (6) can be rewritten as

$$[\check{F}_a^{\mathfrak{A}},\check{F}_b^{\mathfrak{A}}]=0 \tag{9}$$

for any $a,b\in V$, where the operators $\check{F}_a^{\mathfrak{A}}$ are defined as

$$\check{F}_a^{\mathfrak{A}}=\sum_{\alpha\in\mathfrak{A}}\frac{(\alpha,a)}{(\alpha,x)}\alpha^\vee\otimes\alpha. \tag{10}$$

Let $G_{\mathfrak{A}}$ be the form on V^* induced by $G^{\mathfrak{A}}$:

$$G_{\mathfrak{A}}(\alpha,\beta)=G^{\mathfrak{A}}(\alpha^\vee,\beta^\vee).$$

Its matrix in the corresponding basis is G^{-1}. A simple calculation shows that (9) can be rewritten as

$$\sum_{\alpha\neq\beta,\alpha,\beta\in\mathfrak{A}}\frac{G_{\mathfrak{A}}(\alpha,\beta)B_{\alpha,\beta}(a,b)}{(\alpha,x)(\beta,x)}\alpha\wedge\beta\equiv 0, \tag{11}$$

where

$$\alpha\wedge\beta=\alpha\otimes\beta-\beta\otimes\alpha$$

and

$$B_{\alpha,\beta}(a,b)=\alpha\wedge\beta(a,b)=\alpha(a)\beta(b)-\alpha(b)\beta(a).$$

One can check that the relations (11) are equivalent to

$$\sum_{\beta\neq\alpha,\beta\in\Pi\cap\mathfrak{A}}\frac{G_{\mathfrak{A}}(\alpha,\beta)B_{\alpha,\beta}(a,b)}{(\beta,x)}\alpha\wedge\beta|_{(\alpha,x)=0}\equiv 0$$

for any $\alpha\in\mathfrak{A}$ and any two-dimensional plane Π containing α, and therefore to

$$\sum_{\beta\neq\alpha,\beta\in\Pi\cap\mathfrak{A}}G_{\mathfrak{A}}(\alpha,\beta)B_{\alpha,\beta}(a,b)=0 \tag{12}$$

for any such α and Π.

Summarizing we have the following result (cf. Refs. 7 and 8).

Proposition 1: The function (6) satisfies the generalized WDVV equations (2) and (3) iff the relations (12) are satisfied for any $\alpha\in\mathfrak{A}$ and any two-dimensional plane Π such that $\alpha\in\Pi$.

Remark: In Refs. 7 and 8 the conditions (12) have been reformulated in geometric terms ($\vee$-conditions). For the purpose of the present article it is more convenient to use these conditions in the original form.

Any Coxeter root system satisfies these conditions, but there are many more examples (see Refs. 7, 8, and 13).

III. MAIN IDENTITY AND PROOF OF THE THEOREM

Let now $\mathcal{A}$ be a finite set of the vectors α in the Euclidean space $\mathbf{R}^n$ with multiplicities m_α. We will assume that this set is invariant under the symmetry $x\to -x$ and that $-\alpha$ is the only vector from $\mathcal{A}$ which is proportional to α. By $\mathcal{A}_+$ we mean the positive half of $\mathcal{A}$:

$$\mathcal{A}_+=\{\alpha\in\mathcal{A}:(\alpha,v)>0\}$$

for some $v\in\mathbf{R}^n$ which is generic in the sense that $(\alpha,v)\neq 0$ for all $\alpha\in\mathcal{A}$.

Consider the Schrödinger equation

$$L\psi=\lambda\psi, \tag{13}$$

where

$$L=-\Delta+\sum_{\alpha\in\mathcal{A}_+}\frac{m_\alpha(m_\alpha+1)(\alpha,\alpha)}{\sin^2(\alpha,x)}.$$

Let us look for the solutions of this equation of the form

$$\psi_0=\prod_{\alpha\in\mathcal{A}_+}\sin^{-m_\alpha}(\alpha,x). \tag{14}$$

By straightforward calculation one can check the following result (cf. Ref. 15).

Lemma 1: The function (14) satisfies the equation (13) for some λ iff the following main identity holds:

$$\sum_{\alpha\neq\beta,\alpha,\beta\in\mathcal{A}_+}m_\alpha m_\beta(\alpha,\beta)(\cot(\alpha,x)\cot(\beta,x)+1)\equiv 0. \tag{15}$$

The eigenvalue λ in that case has a form $\lambda=|\rho(m)|^2$ where $\rho(m)=\Sigma_{\alpha\in\mathcal{A}_+}m_\alpha\alpha$.

Actually, first we have the condition that the sum

$$S=\sum_{\alpha\neq\beta,\alpha,\beta\in\mathcal{A}_+} m_\alpha m_\beta(\alpha,\beta)\cot(\alpha,x)\cot(\beta,x)$$

must be a constant in x. Considering then $x=itv$ with a large positive t and v from the definition of $\mathcal{A}_+$, we see that this constant must be equal to

$$S=-\sum_{\alpha\neq\beta,\alpha,\beta\in\mathcal{A}_+} m_\alpha m_\beta(\alpha,\beta).$$

This leads also to the formula for the eigenvalue λ. It is worthy to note that this formula implies that the vector $\rho(m)$ which depends on the choice of the positive part $\mathcal{A}_+$ (i.e., on the choice of v) has the norm $|\rho(m)|$ independent on this choice.

Remark: The gauged operator $\tilde{L}=\hat{\psi}_0^{-1}L\hat{\psi}_0$, where $\hat{\psi}_0$ is the operator of multiplication by ψ_0, in this case has the form $\tilde{L}=-L^{\mathrm{rad}}+|\rho(m)|^2$,

$$L^{\mathrm{rad}}=\Delta-2\sum_{\alpha\in\mathcal{A}_+} m_\alpha\cot(\alpha,x)\partial_\alpha.$$

When $\mathcal{A}$ is a root system with special multiplicities L^{rad} is the radial part of Laplace–Beltrami operator on some symmetric space.[16] Thus, the property of L we discuss is equivalent to the existence of the "radial gauge." We should mention that the relation between the radial parts of the Laplace operators and quantum many-body problems was first observed [in the case of the symmetric spaces $\mathrm{SU}(n)/\mathrm{SO}(n)$] by Berezin, Pokhil, and Finkelberg[17] and was investigated in details by Olshanetsky and Perelomov in Ref. 15.

The main identity is equivalent to the following identities:

$$\sum_{\beta\in\mathcal{A}_+,\beta\neq\alpha} m_\alpha m_\beta(\alpha,\beta)\cot(\beta,x)|_{(\alpha,x)=k\pi}\equiv 0, \tag{16}$$

for each $\alpha\in\mathcal{A}_+$ and $k\in\mathbf{Z}$. In particular,

$$\sum_{\beta\in\mathcal{A}_+,\beta\neq\alpha} m_\alpha m_\beta(\alpha,\beta)\cot(\beta,x)|_{(\alpha,x)=0}\equiv 0 \tag{17}$$

must be satisfied on all the hyperplanes $(\alpha,x)=0$. It is easy to see that the last identities are equivalent to the set of identities:

$$\sum_{\beta\in\mathcal{A}_+\cap\Pi,\beta\neq\alpha} m_\alpha m_\beta(\alpha,\beta)\cot(\beta,x)|_{(\alpha,x)=0}\equiv 0 \tag{18}$$

hold for any plane Π containing vector $\alpha\in\mathcal{A}_+$.

Let us look now at these two-dimensional identities. Let Π be the plane generated by $\alpha,\beta\in\mathcal{A}_+,\alpha\neq\beta$. We can assume that $(\alpha,\beta)\neq 0$ since otherwise the identity is trivially satisfied. All the vectors $\gamma\in\mathcal{A}_+\cap\Pi$ can be split into equivalence classes $\Gamma_1,\ldots,\Gamma_p$ according to the equivalence relation: $\gamma\sim\gamma'$ if

$$\gamma'=\pm\gamma+\mu\alpha \tag{19}$$

for some μ. I would like to mention that similar equivalence has been considered by M. V. Feigin in the theory of trigonometric locus configurations.[18]

The restrictions of $\cot(\gamma,x)$ and $\cot(\gamma',x)$ on the intersection line of Π with the hyperplane $(\alpha,x)=0$ are the same up to a sign. To take care of this sign let us introduce a skew-symmetric bilinear form $B=B_{a,b}(\alpha,\beta)$ related to a pair of vectors $a,b\in\mathbf{R}^n$ by the formula

$$B_{a,b}(\alpha,\beta)=(\alpha,a)(\beta,b)-(\alpha,b)(\beta,a).$$

It is easy to check that the identity (18) for the plane Π is equivalent to the set of relations

$$\sum_{\gamma\in\Gamma_s,\,\gamma\neq\alpha} m_\alpha m_\gamma(\alpha,\gamma)B(\alpha,\gamma)=0 \tag{20}$$

for all the equivalence classes $\Gamma_1,\ldots,\Gamma_p$. As a corollary we have the same relation on each plane Π:

$$\sum_{\beta\neq\alpha,\beta\in\mathcal{A}_+\cap\Pi} m_\alpha m_\beta(\alpha,\beta)B(\alpha,\beta)=0, \tag{21}$$

and thus in the whole space

$$\sum_{\beta\neq\alpha,\beta\in\mathcal{A}_+} m_\alpha m_\beta(\alpha,\beta)B(\alpha,\beta)=0 \tag{22}$$

for any $\alpha\in\mathcal{A}_+$.

Let us introduce now the operators M_α in $\mathbf{R}^n$ by the relation

$$M_\alpha=m_\alpha\alpha\otimes\alpha,$$

where by definition $\alpha\otimes\beta(x)=(\beta,x)\alpha$. Let M be the sum

$$M=\sum_{\alpha\in\mathcal{A}_+} m_\alpha\alpha\otimes\alpha.$$

Now we need the following natural definition. We will call a configuration $\mathcal{A}$ *irreducible* if it cannot be split into two nontrivial orthogonal parts.

Lemma 2: The main identity (15) implies that all the operators $M_\alpha,\alpha\in\mathcal{A}_+$ commute with M. For irreducible configurations this means that M is a scalar operator: $M=\mu I$ for some μ.

Indeed, the commutator $C_\alpha=[M,M_\alpha]$ is $C_\alpha=[\Sigma_{\beta\in\mathcal{A}_+}m_\beta\beta\otimes\beta,m_\alpha\alpha\otimes\alpha]$ $=-\Sigma_{\beta\neq\alpha,\beta\in\mathcal{A}_+}m_\alpha m_\beta(\alpha,\beta)(\alpha\otimes\beta-\beta\otimes\alpha)$. It is easy to see that the relations (22) are equivalent to $(C_\alpha(a),b)=0$ for arbitrary $a,b\in\mathbf{R}^n$ which imply that $C_\alpha=0$. The commutativity of the operator M with M_α means that any $\alpha\in\mathcal{A}$ is an eigenvector of the (self-adjoint) operator M. If M has two different eigenvalues, then $\mathcal{A}$ can be split into two orthogonal parts which is impossible in the irreducible case. This proves the lemma.

Now everything is ready for the proof of our main result. For a given configuration $\mathcal{A}$ let us define the set $\mathfrak{A}$ in the Euclidean space $V=\mathbf{R}^n\simeq V^*$ by taking all the vectors of the form $\sqrt{m_\alpha}\alpha,\alpha\in\mathcal{A}_+$.

Lemma 3: If $\mathcal{A}$ is irreducible and satisfies the main identity, then $\mathfrak{A}$ satisfies the relations (12) from the previous section.

Indeed, due to Lemma 2 in this case $G^{\mathfrak{A}}=\Sigma_{\alpha\in\mathcal{A}_+}m_\alpha\alpha\otimes\alpha$ is proportional to the scalar product in $\mathbf{R}^n$. The same is obviously true for $G_{\mathfrak{A}}$ so the relations (12) are reduced to (21).

Remark: Strictly speaking we should consider only positive multiplicities in order to stay on reals but one can easily check that the resulting function

$$F(x)=\sum_{\alpha\in\mathcal{A}_+} m_\alpha(\alpha,x)^2\log(\alpha,x)^2$$

is real even in the case of negative multiplicities and all the arguments work in the complex case as well.

Combining these three lemmas with Proposition 1 we have the proof of the theorem in the irreducible case. The reducible case then easily follows.

Now using the results of Refs. 7 and 8 we have the following:

Corollary: For any configuration $\mathcal{A}$ satisfying the main identity the corresponding set $\mathfrak{A}$ is a $\vee$-system in the sense of Ref. 7. In particular the following differential operators of the Knizhnik–Zamolodchikov type,

$$\nabla_a = \partial_a - \sum_{\alpha \in \mathcal{A}_+} m_\alpha \frac{(\alpha,a)}{(\alpha,x)} \alpha \otimes \alpha, \tag{23}$$

commute and therefore define a flat connection in $\mathbf{R}^n$.

As the examples one can consider the following "locus configurations" $A_n(m)$ and $C_{n+1}(m,l)$ which have been introduced in Refs. 4–6. They consist of the following vectors in $\mathbf{R}^{n+1}$:

$$A_n(m) = \begin{cases} e_i - e_j, & 1 \leqslant i < j \leqslant n, \quad \text{with multiplicity } m, \\ e_i - \sqrt{m} e_{n+1}, & i = 1,\ldots,n, \quad \text{with multiplicity } 1, \end{cases}$$

and

$$C_{n+1}(m,l) = \begin{cases} e_i \pm e_j, & 1 \leqslant i < j \leqslant n, \quad \text{with multiplicity } k, \\ 2e_i, & i = 1,\ldots,n, \quad \text{with multiplicity } m, \\ e_i \pm \sqrt{k} e_{n+1}, & i = 1,\ldots,n, \quad \text{with multiplicity } 1, \\ 2\sqrt{k} e_{n+1}, & \text{with multiplicity } l, \end{cases}$$

where $k = (2m+1)/(2l+1)$. The fact that they satisfy the main identity (for all values of the parameters) can be checked by direct calculation. Our theorem thus explains the observation[7] that the corresponding functions F satisfy the generalized WDVV equation.

IV. CONCLUDING REMARKS

We have seen that the main identity is behind the relation between the locus configurations and WDVV equation. Since there are locus configurations without this property this explains also why this relation does not always work.[13] An interesting problem is to classify all locus configurations which satisfy the main identity. The fact that this is true for the series $A_n(m)$ and $C_{n+1}(m,l)$ seems to be very important. In particular, as it follows from our analysis in the previous section these configurations (with integer parameters) are the "vector systems" in the Borcherds' sense.[19] Their role in Borcherds' theory deserves a special investigation.

We have already mentioned the relations with the theory of symmetric spaces and the radial parts of the Laplace operators for the usual root systems. It is interesting that the operators related to $A_n(m)$ and $C_{n+1}(m,l)$ also can be interpreted in a similar way using the Lie superalgebras and symmetric superspaces as it was recently discovered by A. N. Sergeev.[20] This relation gives some new interesting examples of the integrable deformations of Calogero–Sutherland operators satisfying the main identity[21] (and therefore new solutions for the WDVV equation).

(Received 25 March 2002; accepted 20 May 2002)

The problem of scattering of spherical waves by a bounded obstacle is considered. General scattering theorems are proved. These relate the far-field patterns due to scattering of waves from a point source put in any two different locations. The scatterer can have any of the usual properties, penetrable or impenetrable. The optical theorem is recovered as a corollary. Mixed scattering relations are also established, relating the scattered fields due to a point source and a plane wave. [DOI: 10.1063/1.1509089]

I. INTRODUCTION

In classical scattering theory, there are some general results that connect the solutions of two related problems. The most familiar of these is *reciprocity*: the scattered field at A due to a source at B is simply related to the scattered field at B due to a source at A.

There are also internal relations within a single problem. A well-known example is the *optical theorem* for scattering of plane waves: it relates the far-field pattern in the forward direction to a certain integral of the far-field pattern over all directions.

In this article, we derive some general relations for scattering of waves emanating from point sources. Thus, we relate one problem with a point source at A to a similar problem with a point source at B. By setting $A=B$ and then letting A recede to infinity, we recover the optical theorem. If we keep A fixed and let B recede to infinity, we obtain so-called *mixed scattering theorems*, relating plane-wave incidence to point-source incidence. An example of these is the *mixed reciprocity theorem*, which has found much use recently in methods for solving inverse scattering problems.[1]

As Logan[2] points out, Clebsch considered the scattering of elastic waves from a point source by a rigid sphere 140 years ago, a decade before Lord Rayleigh published his solution for the scattering of a plane sound wave by a sphere. Collected results for scattering of point-source fields by simple shapes are given in Ref. 3. More recently, Dassios and his co-workers have studied incident waves generated by a point source in the vicinity of a scatterer; see, for example, Refs. 4–6. There is also some recent work on near-field inverse problems: in addition to the previous papers, we note the work by Coyle[7] and Potthast,[1] as well as recent work by three of the present authors.[8,9] The revival of interest in problems related to point-generated wave fields has several reasons. One is due to the variety of applications coming from the theory of composite materials and of acoustic emission, from the theoretical analysis of biological studies at the cell level, from nondestructive testing and evaluation, from geophysics, from modeling in medicine and health

a)Author to whom correspondence should be addressed. Electronic mail: pamartin@mines.edu

sciences, and from scattering problems connected to environmental data analysis. Another reason is due to the fact that a point-source field is more easily realizable in a laboratory.

We give results for both acoustic and electromagnetic waves, and we permit all the usual kinds of scattering obstacles, penetrable and impenetrable. Extensions to elastic-wave problems are expected.

II. FORMULATION: ACOUSTICS

Let Ω^- be a bounded three-dimensional obstacle with a smooth closed boundary S (the scatterer). The exterior $\mathbb{R}^3\backslash\Omega^- = \Omega$ of the scatterer is an infinite homogeneous isotropic lossless acoustic medium, that is the compressional viscosity δ is zero, and with mass density ρ, phase velocity c, mean compressibility γ and real wave number $k=\omega\sqrt{\gamma\rho}$, ω being the angular frequency. The interior of the scatterer Ω^- is filled with a lossy medium, in general, with corresponding physical parameters δ^-, ρ^-, c^- and γ^-. We consider an incident spherical acoustic wave due to a source located at a point with position vector $\mathbf{a}$. Suppressing the harmonic time dependence $\exp\{-\mathrm{i}\omega t\}$, and following the normalization introduced by Dassios and Kamvyssas,[4] we assume the following form for the incident field:

$$u_a^{\mathrm{i}}(\mathbf{r}) = a\,\mathrm{e}^{-\mathrm{i}ka}\frac{\mathrm{e}^{\mathrm{i}k|\mathbf{r}-\mathbf{a}|}}{|\mathbf{r}-\mathbf{a}|}, \quad \mathbf{r}\neq\mathbf{a}, \tag{1}$$

where $a=|\mathbf{a}|$. We note that when $a\to\infty$, the spherical wave reduces to a plane wave with direction of propagation $-\hat{\mathbf{a}}$, where $\mathbf{a}=a\hat{\mathbf{a}}$.[4] The total field u_a^{t} in the exterior of the scatterer is given by

$$u_a^{\mathrm{t}}(\mathbf{r}) = u_a^{\mathrm{i}}(\mathbf{r}) + u_a^{\mathrm{s}}(\mathbf{r}), \quad \mathbf{r}\in\Omega\backslash\{\mathbf{a}\}, \tag{2}$$

where u_a^{s} is the scattered acoustic field, and solves the Helmholtz equation

$$\nabla^2 u_a^{\mathrm{t}}(\mathbf{r}) + k^2 u_a^{\mathrm{t}}(\mathbf{r}) = 0, \quad \mathbf{r}\in\Omega. \tag{3}$$

The scattered as well as the incident fields are solutions of Helmholtz's equation that satisfy the Sommerfeld radiation condition

$$\hat{\mathbf{r}}\cdot\nabla u(\mathbf{r}) - \mathrm{i}ku(\mathbf{r}) = o(r^{-1}), \quad r\to\infty, \tag{4}$$

uniformly in all directions $\hat{\mathbf{r}}\in S^2$, where S^2 is the unit sphere. We note that u_a^{t} also satisfies the Sommerfeld radiation condition.

In our analysis, we can permit impenetrable or penetrable scatterers. In the former case, we could have Dirichlet ($u_a^{\mathrm{t}}=0$), Neumann ($\partial u_a^{\mathrm{t}}/\partial n=0$) or Robin conditions on S; the Robin (or impedance) condition is

$$\left(\frac{\partial}{\partial n} + \mathrm{i}k\lambda\right) u_a^{\mathrm{t}}(\mathbf{r}) = 0, \quad \mathbf{r}\in S, \tag{5}$$

where λ is a dimensionless real parameter. In the penetrable case, the incident wave is transmitted into the scatterer; let u_a^- be the total acoustic field in Ω^-. Then the following *transmission conditions* must hold on the scatterer's surface

$$u_a^{\mathrm{t}}(\mathbf{r}) = u_a^-(\mathbf{r}) \quad \text{and} \quad \frac{\partial u_a^{\mathrm{t}}(\mathbf{r})}{\partial n} = \beta\frac{\partial u_a^-(\mathbf{r})}{\partial n}, \quad \mathbf{r}\in S, \tag{6}$$

where the constant $\beta=(\rho/\rho^-)(1-\mathrm{i}kc\,\delta^-\gamma^-)$ is complex for a lossy scatterer and real for a lossless scatterer. More details on the physical parameters of the above problems can be found in Ref. 6. The field u_a^- solves the Helmholtz equation in Ω^-,

$$\nabla^2 u_a^-(\mathbf{r}) + \eta^2 k^2 u_a^-(\mathbf{r}), \quad \mathbf{r} \in \Omega^-, \tag{7}$$

where $\eta = (c/c^-)(1 - ikc\gamma^- \delta^-)^{-1/2}$ is the (complex) index of refraction between the two media in Ω and Ω^-. The choice of the branch of the square root is such that $\mathrm{Im}(\eta) \geqslant 0$ and hence $\mathrm{Im}(\eta k) \geqslant 0$.

In addition, in order to cover various cases that arise in applications, we can easily extend our analysis to include an impenetrable core in the interior of the scatterer.

As it is well known, all the above problems are well posed.

The behavior of the scattered wave in the far field is given by

$$u_a^s(\mathbf{r}) = g_a(\hat{\mathbf{r}}) h_0(kr) + O(r^{-2}), \quad r \to \infty, \tag{8}$$

where $h_0(x) = e^{ix}/(ix)$ is the spherical Hankel function of the first kind and order zero. Moreover,

$$g_a(\hat{\mathbf{r}}) = -\frac{ik}{4\pi} \int_S \left[\frac{\partial u_a^s(\mathbf{r}')}{\partial n} + ik(\hat{\mathbf{r}} \cdot \hat{\mathbf{n}}) u_a^s(\mathbf{r}') \right] e^{-ik\hat{\mathbf{r}} \cdot \mathbf{r}'} ds(\mathbf{r}') \tag{9}$$

is the far-field pattern.[5]

III. GENERAL SCATTERING THEOREM

In what follows, we consider two locations for the point source, **a** and **b**, from which the time-harmonic incident spherical waves emanate. Each source generates a corresponding scattered field, u_a^s and u_b^s, respectively. We are interested in relations between these fields.

Let S_r denote a large sphere of radius r, surrounding the points **a** and **b**, and let

$$S_{a,\varepsilon} = \{\mathbf{r} \in \mathbb{R}^3 : |\mathbf{a} - \mathbf{r}| = \varepsilon\}, \tag{10}$$

a small sphere of radius ε, surrounding the point **a**. Then, we introduce the following notation,

$$[u, v]_S = \int_S \left(\overline{u} \frac{\partial v}{\partial n} - v \frac{\partial \overline{u}}{\partial n} \right) ds,$$

where the overbar denotes complex conjugation; in particular, we write $[u, v] \equiv [u, v]_S$.

Lemma 1: Let u_a^i be a point source at **a**. *Let u_b^i be a point source at* **b**, *with corresponding scattered field u_b^s and far-field pattern g_b. Then*

$$\lim_{r \to \infty} [u_a^i, u_b^s]_{S_r} = 2a e^{ika} \int_{S^2} g_b(\hat{\mathbf{r}}) e^{ik\hat{\mathbf{r}} \cdot \mathbf{a}} ds(\hat{\mathbf{r}}) \tag{11}$$

and

$$\lim_{\varepsilon \to 0} [u_a^i, u_b^s]_{S_{a,\varepsilon}} = 4\pi a e^{ika} u_b^s(\mathbf{a}), \tag{12}$$

where S_r is a large sphere of radius r surrounding **a** *and* **b**, *and $S_{a,\varepsilon}$ is the small sphere defined by Eq. (10).*

Proof: For Eq. (11), we use the asymptotic relations

$$|\mathbf{r} - \mathbf{a}| = r - \hat{\mathbf{r}} \cdot \mathbf{a} + O(r^{-1}) \quad \text{and} \quad |\mathbf{r} - \mathbf{a}|^{-1} = r^{-1} + O(r^{-2}), \tag{13}$$

as $r \to \infty$, and obtain

$$u_a^i(\mathbf{r}) = h_0(kr) g_a^i(\hat{\mathbf{r}}) + O(r^{-2}), \quad r \to \infty, \tag{14}$$

where $g_a^{\mathrm{i}}(\hat{\mathbf{r}})=\mathrm{i}ka\exp\{-\mathrm{i}ka(1+\hat{\mathbf{a}}\cdot\hat{\mathbf{r}})\}$ is the far-field pattern of the point-source incident wave. Using Eqs. (8) and (14) gives Eq. (11).

For Eq. (12), we evaluate $\overline{u_a^{\mathrm{i}}}$ and its normal derivative on $S_{a,\varepsilon}$. There, we have $\overline{u_a^{\mathrm{i}}}=(a/\varepsilon)\mathrm{e}^{\mathrm{i}k(a-\varepsilon)}$ and $(\partial/\partial n)\overline{u_a^{\mathrm{i}}}=-(\mathrm{i}k+\varepsilon^{-1})\overline{u_a^{\mathrm{i}}}(\mathbf{r})$, where $\partial/\partial n$ denotes normal differentiation in the outward direction. Using the mean value theorem and letting $\varepsilon\to 0$, Eq. (12) is proved. □

Now, for two point sources, with position vectors **a** and **b**, we define a *spherical far-field pattern generator* for spherical acoustic waves by

$$G_b(\mathbf{a})=\mathrm{i}ka\mathrm{e}^{\mathrm{i}ka}\left[u_b^{\mathrm{s}}(\mathbf{a})-\frac{1}{2\pi}\int_{S^2}g_b(\hat{\mathbf{r}})\mathrm{e}^{\mathrm{i}k\mathbf{a}\cdot\hat{\mathbf{r}}}ds(\hat{\mathbf{r}})\right]. \tag{15}$$

This terminology and definition are appropriate for the following reason [see Eq. (50) later in this work]. When both the point source and the observation point recede to infinity, $G_b(\mathbf{a})$ reduces to the far-field pattern for an incident plane wave propagating in the direction $-\hat{\mathbf{b}}$. Using this notation, the general scattering theorem for spherical waves is formulated as follows.

Theorem 2: *For any two point-source locations in* Ω, **a** *and* **b**, *we have*

$$G_b(\mathbf{a})+\overline{G_a(\mathbf{b})}+\frac{1}{2\pi}\int_{S^2}g_b(\hat{\mathbf{r}})\overline{g_a(\hat{\mathbf{r}})}ds(\hat{\mathbf{r}})=\mathcal{E}_{a,b}, \tag{16}$$

where

$$\mathcal{E}_{a,b}=-\frac{\mathrm{i}k}{4\pi}[u_a^{\mathrm{t}},u_b^{\mathrm{t}}]. \tag{17}$$

The value of $\mathcal{E}_{a,b}$ *depends on the scatterer:*

$$\mathcal{E}_{a,b}=0 \quad \textit{for Dirichlet or Neumann conditions on } S; \tag{18}$$

$$\mathcal{E}_{a,b}=-\frac{k^2\lambda}{2\pi}\int_S u_b^{\mathrm{t}}(\mathbf{r})\overline{u_a^{\mathrm{t}}(\mathbf{r})}ds \quad \textit{for the Robin condition (5) on } S; \tag{19}$$

or

$$\mathcal{E}_{a,b}=-\frac{k}{2\pi}\mathrm{Im}(\beta)\int_{\Omega^-}\nabla\overline{u_a^-(\mathbf{r})}\cdot\nabla u_b^-(\mathbf{r})dv(\mathbf{r}) \quad \textit{for a penetrable scatterer,} \tag{20}$$

where β *is the constant in the transmission conditions (6).*

Proof: Let us first evaluate $\mathcal{E}_{a,b}$ directly. For Dirichlet ($u^{\mathrm{t}}=0$) or Neumann ($\partial u^{\mathrm{t}}/\partial n=0$) conditions, we immediately obtain Eq. (18). Similarly, the Robin condition (5) gives Eq. (19). For a penetrable scatterer, we use the transmission conditions (6), apply Green's first theorem and take into account that $\mathrm{Im}(\beta\eta^2)=0$ (see p. 9 of Ref. 6); this gives Eq. (20).

Next, we give an alternative evaluation of $\mathcal{E}_{a,b}$. Thus, by the relations $u_\alpha^{\mathrm{t}}=u_\alpha^{\mathrm{i}}+u_\alpha^{\mathrm{s}}$ for $\alpha=a,b$ we have

$$[u_a^{\mathrm{t}},u_b^{\mathrm{t}}]=[u_a^{\mathrm{i}},u_b^{\mathrm{i}}]+[u_a^{\mathrm{s}},u_b^{\mathrm{i}}]+[u_a^{\mathrm{i}},u_b^{\mathrm{s}}]+[u_a^{\mathrm{s}},u_b^{\mathrm{s}}]. \tag{21}$$

Since $\overline{u_a^{\mathrm{i}}}$ and u_b^{i} are regular solutions of the Helmholtz equation in Ω^-, Green's second theorem gives

$$[u_a^{\mathrm{i}},u_b^{\mathrm{i}}]=0. \tag{22}$$

For the other terms in Eq. (21), we consider two small spheres, S_{a,ε_1} and S_{b,ε_2}, centered at **a** and **b** with radii ε_1 and ε_2, respectively, with $S_{a,\varepsilon_1}\cap S_{b,\varepsilon_2}=\varnothing$, as well as a large sphere S_R centered

at the origin surrounding the whole system of the scatterer and the two small spheres. Since $\overline{u_a^{\mathrm{i}}}(\mathbf{r})$ and $u_b^{\mathrm{s}}(\mathbf{r})$ are solutions of the Helmholtz equation, for $\mathbf{r}\neq\mathbf{a},\mathbf{b}$, Green's second theorem gives

$$[u_a^{\mathrm{i}},u_b^{\mathrm{s}}]=[u_a^{\mathrm{i}},u_b^{\mathrm{s}}]_{S_R}-[u_a^{\mathrm{i}},u_b^{\mathrm{s}}]_{S_{a,\varepsilon_1}}-[u_a^{\mathrm{i}},u_b^{\mathrm{s}}]_{S_{b,\varepsilon_2}}.$$

The third term is zero because $\overline{u_a^{\mathrm{i}}}$ and u_b^{s} are regular solutions of the Helmholtz equation in the interior of S_{b,ε_2}. Then, letting $R\to\infty$ and $\varepsilon_1\to 0$, using Lemma 1, we obtain

$$[u_a^{\mathrm{i}},u_b^{\mathrm{s}}]=-4\pi a\mathrm{e}^{\mathrm{i}ka}u_b^{\mathrm{s}}(\mathbf{a})+2a\mathrm{e}^{\mathrm{i}ka}\int_{S^2}g_b(\hat{\mathbf{r}})\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}}). \tag{23}$$

As $[u_a^{\mathrm{s}},u_b^{\mathrm{i}}]=-\overline{[u_b^{\mathrm{i}},u_a^{\mathrm{s}}]}$, we easily deduce that

$$[u_a^{\mathrm{s}},u_b^{\mathrm{i}}]=4\pi b\mathrm{e}^{-\mathrm{i}kb}\overline{u_a^{\mathrm{s}}(\mathbf{b})}-2b\mathrm{e}^{-\mathrm{i}kb}\int_{S^2}\overline{g_a(\hat{\mathbf{r}})}\mathrm{e}^{-\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{b}}ds(\hat{\mathbf{r}}). \tag{24}$$

Finally, in view of the regularity of $\overline{u_a^{\mathrm{s}}}$ and u_b^{s} in the region exterior to S, we have

$$[u_a^{\mathrm{s}},u_b^{\mathrm{s}}]=[u_a^{\mathrm{s}},u_b^{\mathrm{s}}]_{S_R}.$$

Then, letting $R\to\infty$, we pass to the radiation zone and thus we can use the asymptotic form (8), giving

$$[u_a^{\mathrm{s}},u_b^{\mathrm{s}}]=\frac{2\mathrm{i}}{k}\int_{S^2}\overline{g_a(\hat{\mathbf{r}})}g_b(\hat{\mathbf{r}})ds(\hat{\mathbf{r}}). \tag{25}$$

Substituting Eqs. (22)–(25) in Eq. (21), making use of Eq. (17) and its evaluation, gives Eq. (16), and the theorem is proved. □

Let us make two remarks. First, if the scatterer is a lossless penetrable obstacle, that is, the physical parameter β is real, then we obtain $\mathcal{E}_{a,b}=0$ in Eq. (16), just as for soft or hard scatterers.

Second, suppose that we have a penetrable scatterer with a core S^- on which $u^-=0$ or $\partial u^-/\partial n=0$. Then, the relation (20) still holds, where, now, Ω^- denotes the part of the scatterer between the surfaces S and S^-.

IV. RECIPROCITY RELATIONS

The proof of Theorem 2 uses two evaluations of $[u_a^{\mathrm{t}},u_b^{\mathrm{t}}]$. If, instead, we start from $[\overline{u_a^{\mathrm{t}}},u_b^{\mathrm{t}}]$, we obtain a reciprocity theorem. This is not surprising, because u_a^{t} can be regarded as the exact Green's function for the scattering problem. The reciprocity theorem can be found on p. 48 of Ref. 6, for example. We quote it here, using our normalizations.

Theorem 3: *For any two point-source locations in* Ω, **a** *and* **b**, *and for any scatterer, we have*

$$h_0(ka)u_a^{\mathrm{s}}(\mathbf{b})=h_0(kb)u_b^{\mathrm{s}}(\mathbf{a}), \tag{26}$$

where $h_0(x)=\mathrm{e}^{\mathrm{i}x}/(\mathrm{i}x)$.

From Eq. (1), we see that the same reciprocity relation holds for the incident fields, as well: $h_0(ka)u_a^{\mathrm{i}}(\mathbf{b})=h_0(kb)u_b^{\mathrm{i}}(\mathbf{a})$. Hence, by Eq. (2) we conclude that the total exterior fields satisfy $h_0(ka)u_a^{\mathrm{t}}(\mathbf{b})=h_0(kb)u_b^{\mathrm{t}}(\mathbf{a})$.

We note that the presence of the multiplicative constant in the above reciprocity relation is due to the form of the modified spherical wave, Eq. (1). If we consider the point sources lying on the same sphere, that is, $a=b$, then we obtain the following results:

$$u_a^{\mathrm{s}}(\mathbf{b})=u_b^{\mathrm{s}}(\mathbf{a}),\quad u_a^{\mathrm{i}}(\mathbf{b})=u_b^{\mathrm{i}}(\mathbf{a}),\quad u_a^{\mathrm{t}}(\mathbf{b})=u_b^{\mathrm{t}}(\mathbf{a}). \tag{27}$$

These relations express the fact that interchanging the excitation with the observation point, the scattered, incident and total fields remain unchanged. From Eq. (26) we cannot have a reciprocity relation for the corresponding spherical far-field patterns, because when the point sources go to infinity the spherical waves reduce to plane waves.

V. THE OPTICAL THEOREM

In Ref. 8, an optical theorem for spherical waves incident upon a soft scatterer has been proved. Now, this theorem as well as optical theorems for scatterers of other types can be derived as corollaries of the general scattering theorem. First we define the scattering cross-section due to a point source at **a** (Ref. 6) as

$$\sigma_a^{\mathrm{s}}=\frac{1}{k^2}\int_{S^2}|g_a(\hat{\mathbf{r}})|^2 ds(\hat{\mathbf{r}}), \tag{28}$$

the absorption cross-section as

$$\sigma_a^{\mathrm{a}}=\frac{1}{k}\,\mathrm{Im}\int_S u_a^{\mathrm{t}}\frac{\partial\overline{u_a^{\mathrm{t}}}}{\partial n}ds, \tag{29}$$

and the extinction cross-section as

$$\sigma_a^{\mathrm{e}}=\sigma_a^{\mathrm{s}}+\sigma_a^{\mathrm{a}}. \tag{30}$$

If we put $\mathbf{a}=\mathbf{b}$ in Theorem 2, we obtain

$$2\,\mathrm{Re}\{G_a(\mathbf{a})\}+\frac{1}{2\pi}\int_{S^2}|g_a(\hat{\mathbf{r}})|^2 ds(\hat{\mathbf{r}})=\mathcal{E}_{a,a}.$$

We can rewrite this equation using Eq. (28) to give

$$\sigma_a^{\mathrm{s}}=-4\pi k^{-2}\,\mathrm{Re}\{G_a(\mathbf{a})\}+2\pi k^{-2}\mathcal{E}_{a,a}. \tag{31}$$

From the definitions (17) and (29), we have

$$\sigma_a^{\mathrm{a}}=\tfrac{1}{2}\mathrm{i}k^{-1}[u_a^{\mathrm{t}},u_a^{\mathrm{t}}]=-2\pi k^{-2}\mathcal{E}_{a,a}. \tag{32}$$

Hence, adding Eqs. (31) and (32), Eq. (30) gives

$$\sigma_a^{\mathrm{e}}=-4\pi k^{-2}\,\mathrm{Re}\{G_a(\mathbf{a})\}. \tag{33}$$

The value of $\mathcal{E}_{a,a}$ is given in Theorem 2. In particular, for a penetrable scatterer, we obtain

$$\sigma_a^{\mathrm{a}}=-\frac{1}{k}\,\mathrm{Im}(\beta)\int_{\Omega^-}|\nabla u_a^-(\mathbf{r})|^2 dv(\mathbf{r}), \tag{34}$$

whereas for an impedance surface, we have

$$\sigma_a^{\mathrm{a}}=\lambda k\int_S|u_a^{\mathrm{t}}|^2 ds.$$

We remark that the absorption cross-section σ_a^{a} provides a measure of the total energy taken from the incident spherical wave and absorbed by the surface of the scatterer in the impedance boundary case, or by the lossy medium occupying Ω^- in the penetrable case. It is clear that $\sigma_a^{\mathrm{a}}=0$ for the soft and hard scatterers and $\sigma_a^{\mathrm{a}}\geqslant 0$ for the other cases.

VI. MIXED SCATTERING RELATIONS

For inverse problems, one effective reconstruction method is the point-source method.[1] One of the main steps of this method is the derivation of mixed reciprocity relations. These relations were introduced in Ref. 10 for sound-soft scatterers, and in Ref. 1 for sound-hard scatterers.

In this section, we allow one of the two point sources considered previously to recede to infinity, so that we have one spherical incident wave and one plane incident wave. We let both sources recede to infinity at the end of this section, and recover known results for plane-wave incidence.

An incident plane wave propagating in the direction of the unit vector $\hat{\mathbf{d}}$ is given by

$$u^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{d}}) = \exp\{\mathrm{i}k\hat{\mathbf{d}}\cdot\mathbf{r}\}. \tag{35}$$

We have already noted that $u_a^{\mathrm{i}}(\mathbf{r}) \to u^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{a}})$ as $a\to\infty$.

For an incident plane wave, Eq. (35), we denote the total field in Ω, the scattered field and the far-field pattern by $u^{\mathrm{t}}(\mathbf{r};\hat{\mathbf{d}})$, $u^{\mathrm{s}}(\mathbf{r};\hat{\mathbf{d}})$ and $g(\hat{\mathbf{r}};\hat{\mathbf{d}})$, respectively, indicating the dependence on the incident direction $\hat{\mathbf{d}}$. We have[4]

$$u_a^{\mathrm{s}}(\mathbf{r}) \to u^{\mathrm{s}}(\mathbf{r};-\hat{\mathbf{a}}), \quad \text{as} \quad a\to\infty \tag{36a}$$

and

$$g_a(\hat{\mathbf{r}}) \to g(\hat{\mathbf{r}};-\hat{\mathbf{a}}), \quad \text{as} \quad a\to\infty. \tag{36b}$$

Now, consider our previous results, involving $\mathbf{a}$ and $\mathbf{b}$, and let $b\to\infty$. Lemma 1 gives the following results.

Lemma 4: Let $u_a^{\mathrm{i}}(\mathbf{r})$ be an incident spherical wave and let $u^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}})$ be an incident plane wave. Then

$$\lim_{r\to\infty}[u_a^{\mathrm{i}}, u^{\mathrm{s}}(\cdot,-\hat{\mathbf{b}})]_{S_r} = 2a\mathrm{e}^{\mathrm{i}ka}\int_{S^2} g(\hat{\mathbf{r}};-\hat{\mathbf{b}})\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}}) \tag{37}$$

and

$$\lim_{\varepsilon\to 0}[u_a^{\mathrm{i}}, u^{\mathrm{s}}(\cdot,-\hat{\mathbf{b}})]_{S_{a,\varepsilon}} = 4\pi a\mathrm{e}^{\mathrm{i}ka}u^{\mathrm{s}}(\mathbf{a};-\hat{\mathbf{b}}). \tag{38}$$

Next, we define a *plane far-field pattern generator* by

$$G(\mathbf{a};-\hat{\mathbf{b}}) = \lim_{b\to\infty} G_b(\mathbf{a}) \tag{39}$$

$$= \mathrm{i}ka\mathrm{e}^{\mathrm{i}ka}\left[u^{\mathrm{s}}(\mathbf{a};-\hat{\mathbf{b}}) - \frac{1}{2\pi}\int_{S^2} g(\hat{\mathbf{r}};-\hat{\mathbf{b}})\mathrm{e}^{\mathrm{i}k\mathbf{a}\cdot\hat{\mathbf{r}}}ds(\hat{\mathbf{r}})\right], \tag{40}$$

where the spherical far-field pattern generator $G_b(\mathbf{a})$ is defined by Eq. (15). We will also require $\lim_{a\to\infty} G_b(\mathbf{a})$; this limit is contained in the following theorem.

Theorem 5: *For two incident spherical waves, u_a^{i} and u_b^{i}, we have*

$$\lim_{a\to\infty} G_b(\mathbf{a}) = g_b(-\hat{\mathbf{a}}) \tag{41}$$

and

$$\lim_{a\to\infty} G(\mathbf{a};-\hat{\mathbf{b}}) = g(-\hat{\mathbf{a}};-\hat{\mathbf{b}}). \tag{42}$$

Proof: We prove Eq. (41); a very similar argument gives Eq. (42).

We choose coordinates so that the point source at $\mathbf{a}$ is on the z-axis. Then, take spherical polar coordinates (θ, φ) on S^2, so that $\hat{\mathbf{a}}\cdot\hat{\mathbf{r}} = \cos\theta$. Hence for $\theta = 0$ we have $\hat{\mathbf{r}} = \hat{\mathbf{a}}$, while for $\theta = \pi$ we have $\hat{\mathbf{r}} = -\hat{\mathbf{a}}$. If we define

$$F_b(\theta) = \int_0^{2\pi} g_b(\hat{\mathbf{r}})\, d\varphi, \tag{43}$$

then we have $F_b(0) = 2\pi g_b(\hat{\mathbf{a}})$ and $F_b(\pi) = 2\pi g_b(-\hat{\mathbf{a}})$. Hence

$$\begin{aligned}\int_{S^2} g_b(\hat{\mathbf{r}})\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}} ds(\hat{\mathbf{r}}) &= \int_0^{\pi} F_b(\theta)\mathrm{e}^{\mathrm{i}ka\cos\theta}\sin\theta\, d\theta \\ &= \frac{\mathrm{i}}{ka}\int_0^{\pi} F_b(\theta)\frac{d}{d\theta}(\mathrm{e}^{\mathrm{i}ka\cos\theta})\, d\theta \\ &= \frac{2\pi\mathrm{i}}{ka}[g_b(-\hat{\mathbf{a}})\mathrm{e}^{-\mathrm{i}ka} - g_b(\hat{\mathbf{a}})\mathrm{e}^{\mathrm{i}ka}] - \frac{\mathrm{i}}{ka}\int_0^{\pi}\mathrm{e}^{\mathrm{i}ka\cos\theta}\frac{dF_b(\theta)}{d\theta}\, d\theta.\end{aligned}$$

From this equation and Eq. (15), we find that

$$G_b(\mathbf{a}) = \mathrm{i}ka\mathrm{e}^{\mathrm{i}ka}u_b^s(\mathbf{a}) + \mathrm{e}^{\mathrm{i}ka}[g_b(-\hat{\mathbf{a}})\mathrm{e}^{-\mathrm{i}ka} - g_b(\hat{\mathbf{a}})\mathrm{e}^{\mathrm{i}ka}] + \frac{\mathrm{e}^{\mathrm{i}ka}}{2\pi}\int_0^{\pi}\mathrm{e}^{\mathrm{i}ka\cos\theta}\frac{dF_b(gv)}{d\theta}\, d\theta. \tag{44}$$

In view of Eq. (8) and taking into account that the integral in Eq. (44) tends to zero as $a\to\infty$, by the Riemann-Lebesgue lemma, we get Eq. (41).

We can now let $b\to\infty$ in the general scattering theorem, Theorem 2; this gives the following results.

Theorem 6: *Let $u_a^{\mathrm{i}}(\mathbf{r})$ be an incident spherical wave and let $u^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}})$ be an incident plane wave. Then*

$$G(\mathbf{a};\hat{\mathbf{b}}) + \overline{g_a(-\hat{\mathbf{b}})} + \frac{1}{2\pi}\int_{S^2} g(\hat{\mathbf{r}};-\hat{\mathbf{b}})\overline{g_a(\hat{\mathbf{r}})}\, ds(\hat{\mathbf{r}}) = \mathcal{M}_a(-\hat{\mathbf{b}}), \tag{45}$$

where $\mathcal{M}_a(-\hat{\mathbf{b}}) = \lim_{b\to\infty}\mathcal{E}_{a,b}$:

$$\mathcal{M}_a(-\hat{\mathbf{b}}) = 0 \quad \textit{for Dirichlet or Neumann conditions on } S; \tag{46}$$

$$\mathcal{M}_a(-\hat{\mathbf{b}}) = -\frac{k^2\lambda}{2\pi}\int_S u^t(\mathbf{r};-\hat{\mathbf{b}})\overline{u_a^t(\mathbf{r})}\, ds(\hat{\mathbf{r}}) \quad \textit{for the Robin condition (5) on } S; \tag{47}$$

or

$$\mathcal{M}_a(-\hat{\mathbf{b}}) = -\frac{k}{2\pi}\mathrm{Im}(\beta)\int_{\Omega^-}\nabla\overline{u_a^-(\mathbf{r})}\cdot\nabla u^-(\mathbf{r};-\hat{\mathbf{b}})\, dv(\mathbf{r}) \quad \textit{for a penetrable scatterer.} \tag{48}$$

The mixed reciprocity principle is contained in the next theorem.

Theorem 7: *Let $u_a^{\mathrm{i}}(\mathbf{r})$ be an incident spherical wave and let $u^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}})$ be an incident plane wave. Then, we have the following reciprocity relation:*

$$g_a(\hat{\mathbf{b}}) = \mathrm{i}ka\,\mathrm{e}^{-\mathrm{i}ka} u^s(\mathbf{a}; -\hat{\mathbf{b}}). \tag{49}$$

Proof: Let $b \to \infty$ in Theorem 3, using Eqs. (8) and (36a). □

This result means that the spherical far-field pattern of the point source at $\mathbf{a}$ in the direction $\hat{\mathbf{b}}$ is proportional to the scattered field at $\mathbf{a}$ due to the incident plane wave with direction of propagation $-\hat{\mathbf{b}}$.

Finally, if we combine Eqs. (36b), (39), (41) and (42), we obtain

$$\lim_{a\to\infty}\lim_{b\to\infty} G_b(\mathbf{a}) = \lim_{b\to\infty}\lim_{a\to\infty} G_b(\mathbf{a}) = g(-\hat{\mathbf{a}}; -\hat{\mathbf{b}}). \tag{50}$$

We can then check that letting both point sources recede to infinity, $a \to \infty$ and $b \to \infty$, yields the known scattering and optical theorems for plane-wave scattering; see Refs. 11–13, 6, and 8.

VII. FORMULATION: ELECTROMAGNETICS

In the remainder of the article, we consider electromagnetic problems. The exterior Ω is an infinite homogeneous medium with electric permittivity ε, magnetic permeability μ, phase velocity c and conductivity $\sigma = 0$. The scatterer Ω^- is filled with a homogeneous medium with corresponding physical parameters ε^-, μ^-, c^- and $\sigma^- \neq 0$.

We consider an incident spherical electromagnetic wave due to a source located at a point with position vector $\mathbf{a}$, with respect to the origin $\mathcal{O}$. This incident wave $(\mathbf{E}_a^{\mathrm{i}}, \mathbf{H}_a^{\mathrm{i}})$ has the form[9]

$$\mathbf{E}_a^{\mathrm{i}}(\mathbf{r}; \hat{\mathbf{p}}) = \frac{a\,\mathrm{e}^{-\mathrm{i}ka}}{\mathrm{i}k} \nabla \times \left(\frac{\mathrm{e}^{\mathrm{i}k|r-a|}}{|\mathbf{r}-\mathbf{a}|} \hat{\mathbf{a}} \times \hat{\mathbf{p}} \right), \tag{51}$$

$$\mathbf{H}_a^{\mathrm{i}}(\mathbf{r}; \hat{\mathbf{p}}) = (\mathrm{i}k)^{-1} (\varepsilon/\mu)^{1/2} \nabla \times \mathbf{E}_a^{\mathrm{i}}(\mathbf{r}; \hat{\mathbf{p}}), \tag{52}$$

where $\hat{\mathbf{p}}$ is a constant unit vector with $\hat{\mathbf{p}} \cdot \hat{\mathbf{a}} = 0$, $k = \omega\sqrt{\varepsilon\mu} > 0$ is the free-space wave number, and $a = |\mathbf{a}|$. Physically, $(\mathbf{E}_a^{\mathrm{i}}, \mathbf{H}_a^{\mathrm{i}})$ represents the field generated by a magnetic dipole with dipole moment $\hat{\mathbf{a}} \times \hat{\mathbf{p}}$; see p. 163 of Ref. 14 or p. 23 of Ref. 6. The coefficient $a\mathrm{e}^{-\mathrm{i}ka}/(\mathrm{i}k)$ in Eq. (51) assures that when the point source tends to infinity the spherical wave reduces to a plane electric wave with direction of propagation $-\hat{\mathbf{a}}$ and polarization $\hat{\mathbf{p}}$. The total electric exterior field $\mathbf{E}_a^{\mathrm{t}}$ is given by

$$\mathbf{E}_a^{\mathrm{t}}(\mathbf{r}; \hat{\mathbf{p}}) = \mathbf{E}_a^{\mathrm{i}}(\mathbf{r}; \hat{\mathbf{p}}) + \mathbf{E}_a^{\mathrm{s}}(\mathbf{r}; \hat{\mathbf{p}}), \quad \mathbf{r} \in \Omega \backslash \{\mathbf{a}\}, \tag{53}$$

where $\mathbf{E}_a^{\mathrm{s}}(\mathbf{r}; \hat{\mathbf{p}})$ is the scattered electric field, which satisfies the Silver-Müller radiation condition

$$\lim_{r\to\infty} (\mathbf{r} \times \nabla \times \mathbf{E}_a^{\mathrm{s}} + \mathrm{i}kr\mathbf{E}_a^{\mathrm{s}}) = \mathbf{0} \tag{54}$$

uniformly in all directions $\hat{\mathbf{r}} \in S^2$, where S^2 is the unit sphere. $\mathbf{E}_a^{\mathrm{t}}$ solves the equation

$$\nabla \times \nabla \times \mathbf{E}_a^{\mathrm{t}} = k^2 \mathbf{E}_a^{\mathrm{t}} \text{ in } \Omega. \tag{55}$$

We note that the incident electric field satisfies the radiation condition (54), and hence the total electric field also satisfies Eq. (54).

The surface of the scatterer may be perfectly conducting, in which case

$$\hat{\mathbf{n}} \times \mathbf{E}_a^{\mathrm{t}} = \mathbf{0} \text{ on } S, \tag{56}$$

or it may be an impedance surface, in which case

$$\hat{\mathbf{n}} \times \nabla \times \mathbf{E}_a^{\mathrm{t}} = -(\mathrm{i}k/Z_s) \hat{\mathbf{n}} \times (\hat{\mathbf{n}} \times \mathbf{E}_a^{\mathrm{t}}) \text{ on } S, \tag{57}$$

where the dimensionless parameter Z_s denotes the surface impedance relative to the characteristic impedance of the medium and may vary on S.

If the scatterer is a dielectric, the incident electromagnetic waves are transmitted into the scatterer. Let $\mathbf{E}_a^-$ be the total electric field in the interior. Then $\mathbf{E}_a^-$ satisfies

$$\nabla\times\nabla\times\mathbf{E}_a^- = \eta^2 k^2 \mathbf{E}_a^- \quad \text{in} \quad \Omega^-, \tag{58}$$

where the complex constant η is the relative index of refraction; on the surface of the scatterer we have the following transmission conditions:

$$\hat{\mathbf{n}}\times\mathbf{E}_a^t = \hat{\mathbf{n}}\times\mathbf{E}_a^- \quad \text{and} \quad \hat{\mathbf{n}}\times\nabla\times\mathbf{E}_a^t = (\mu/\mu^-)\hat{\mathbf{n}}\times\nabla\times\mathbf{E}_a^- \quad \text{on} \quad S.$$

The behavior of the scattered electric field in the radiation zone is given by

$$\mathbf{E}_a^s(\mathbf{r}) = h_0(kr)\mathbf{g}_a(\hat{\mathbf{r}}) + O(r^{-2}), \quad r\to\infty, \tag{59}$$

where $\mathbf{g}_a(\hat{\mathbf{r}})$ is the far-field pattern.

More details on the physical parameters of the above problems can be found in Ref. 6. Each problem has a unique and stable classical solution.[14,15]

VIII. GENERAL SCATTERING THEOREM: ELECTROMAGNETICS

In the sequel, for an incident time-harmonic spherical wave $\mathbf{E}_a^i(\mathbf{r};\hat{\mathbf{p}})$ due to a point source located at $\mathbf{a}$, we will denote the total field in Ω, the scattered field and the far-field pattern by writing $\mathbf{E}_a^t(\mathbf{r};\hat{\mathbf{p}})$, $\mathbf{E}_a^s(\mathbf{r};\hat{\mathbf{p}})$ and $\mathbf{g}_a(\hat{\mathbf{r}};\hat{\mathbf{p}})$, respectively, indicating the dependence on the position $\mathbf{a}$ of the point source and the polarization $\hat{\mathbf{p}}$. Also, the total electric field in Ω^- will be denoted by $\mathbf{E}_a^-(\mathbf{r};\hat{\mathbf{p}})$. We consider a point source at $\mathbf{a}$ with polarization $\hat{\mathbf{p}}_1$ and another point source at $\mathbf{b}$ with polarization $\hat{\mathbf{p}}_2$.

For a shorthand notation, we use

$$\{\mathbf{E},\mathbf{E}'\}_S = \int_S [(\hat{\mathbf{n}}\times\overline{\mathbf{E}})\cdot(\nabla\times\mathbf{E}') - (\hat{\mathbf{n}}\times\mathbf{E}')\cdot(\nabla\times\overline{\mathbf{E}})]ds;$$

in particular, we write $\{\mathbf{E},\mathbf{E}'\}\equiv\{\mathbf{E},\mathbf{E}'\}_S$.

Lemma 8: Let $\mathbf{E}_a^i(\mathbf{r};\hat{\mathbf{p}}_1)$ *be a point source at* $\mathbf{a}$. *Let* $\mathbf{E}_b^i(\mathbf{r};\hat{\mathbf{p}}_2)$ *be a point source at* $\mathbf{b}$, *with corresponding scattered field* $\mathbf{E}_b^s(\mathbf{r};\hat{\mathbf{p}}_2)$ *and far-field pattern* $\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)$. *Then*

$$\lim_{r\to\infty}\{\mathbf{E}_a^i(\cdot;\hat{\mathbf{p}}_1),\mathbf{E}_b^s(\cdot;\hat{\mathbf{p}}_2)\}_{S_r} = 2a\mathrm{e}^{\mathrm{i}ka}\int_{S^2}\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)\cdot(\hat{\mathbf{r}}\times(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1))\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}}) \tag{60}$$

and

$$\lim_{\varepsilon\to 0}\{\mathbf{E}_a^i(\cdot;\hat{\mathbf{p}}_1),\mathbf{E}_b^s(\cdot,\hat{\mathbf{p}}_2)\}_{S_{a,\varepsilon}} = 4\pi\mathrm{i}(a/k)\mathrm{e}^{\mathrm{i}ka}(\nabla\times\mathbf{E}_b^s(\mathbf{a};\hat{\mathbf{p}}_2))\cdot(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1), \tag{61}$$

where S_r *is a large sphere of radius r enclosing* $\mathbf{a}$ *and* $\mathbf{b}$, *and* $S_{a,\varepsilon}$ *is a small sphere surrounding* $\mathbf{a}$, *defined by Eq. (10).*

Proof: For Eq. (60), we use the asymptotic forms (13). These show that the incident electric wave takes the form

$$\mathbf{E}_a^i(\mathbf{r};\hat{\mathbf{p}}_1) = h_0(kr)\mathbf{g}_a^i(\hat{\mathbf{r}};\hat{\mathbf{p}}_1) + O(r^{-2}), \quad r\to\infty, \tag{62}$$

where $\mathbf{g}_a^i(\hat{\mathbf{r}};\hat{\mathbf{p}}_1) = \mathrm{i}ka\exp\{-\mathrm{i}ka(1+\hat{\mathbf{r}}\cdot\hat{\mathbf{a}})\}\ (\hat{\mathbf{r}}\times(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1))$ is the far-field pattern of the point source incident wave. Using Eqs. (59) and (62) we establish Eq. (60). Note that $\hat{\mathbf{r}}\cdot\mathbf{g}_a^i(\hat{\mathbf{r}};\hat{\mathbf{p}}_1) = 0$.

For Eq. (61), some calculations show that

$$\{\mathbf{E}_a^{\mathrm{i}}(\cdot,\hat{\mathbf{p}}_1),\mathbf{E}_b^{\mathrm{s}}(\cdot,\hat{\mathbf{p}}_2)\}_{S_{a,\varepsilon}}=a\mathrm{e}^{\mathrm{i}ka}\Bigg\{\int_{S_{a,\varepsilon}}\hat{\mathbf{n}}\cdot\nabla\times[((\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1)\cdot\overline{\nabla h_0(k|\mathbf{r}-\mathbf{a}|)})\mathbf{E}_b^{\mathrm{s}}]ds$$
$$+\int_{S_{a,\varepsilon}}(\mathrm{i}k+|\mathbf{r}-\mathbf{a}|^{-1})\overline{h_0(k|\mathbf{r}-\mathbf{a}|)}(\nabla\times\mathbf{E}_b^{\mathrm{s}})\cdot(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1)ds$$
$$-k^2\int_{S_{a,\varepsilon}}\hat{\mathbf{n}}\cdot[\mathbf{E}_b^{\mathrm{s}}\times(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1)]\overline{h_0(k|\mathbf{r}-\mathbf{a}|)}ds\Bigg\}.$$

The first integral on the right-hand side vanishes by Stokes's theorem. Applying the mean value theorem on the remaining integrals and letting $\varepsilon\to 0$, we obtain Eq. (61). □

For two incident spherical electric waves, $\mathbf{E}_a^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_1)$ and $\mathbf{E}_b^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_2)$, we define a *spherical far-field pattern generator*, as follows:

$$\mathbf{G}_b(\mathbf{a};\hat{\mathbf{p}}_2)=\mathrm{e}^{\mathrm{i}ka}\mathbf{a}\times\left[\nabla\times\mathbf{E}_b^{\mathrm{s}}(\mathbf{a};\hat{\mathbf{p}}_2)-\frac{\mathrm{i}k}{2\pi}\int_{S^2}\hat{\mathbf{r}}\times\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}})\right]. \tag{63}$$

As we shall see later, when the point sources recede to infinity, $\mathbf{G}_b(\mathbf{a};\hat{\mathbf{p}}_2)$ is reduced to the far-field pattern for an incident plane electric wave propagating in the direction $-\hat{\mathbf{a}}$ and of polarization $\hat{\mathbf{p}}_2$. Using this notation, the general scattering theorem for spherical electric waves is formulated as follows.

Theorem 9: *For any two point-source locations in* Ω, **a** *and* **b**, *and for any polarizations,* $\hat{\mathbf{p}}_1$ *and* $\hat{\mathbf{p}}_2$, *we have*

$$\hat{\mathbf{p}}_1\cdot\mathbf{G}_1(\mathbf{a};\hat{\mathbf{p}}_2)+\hat{\mathbf{p}}_2\cdot\overline{\mathbf{G}_a(\mathbf{b};\hat{\mathbf{p}}_1)}+\frac{1}{2\pi}\int_{S^2}\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)\cdot\overline{\mathbf{g}_a(\hat{\mathbf{r}};\hat{\mathbf{p}}_1)}ds(\hat{\mathbf{r}})=\mathcal{E}_{a,b}(\hat{\mathbf{p}}_1;\hat{\mathbf{p}}_2), \tag{64}$$

where

$$\mathcal{E}_{a,b}(\hat{\mathbf{p}}_1;\hat{\mathbf{p}}_2)=-\frac{\mathrm{i}k}{4\pi}\{\mathbf{E}_a^{\mathrm{t}}(\cdot,\hat{\mathbf{p}}_1),\mathbf{E}_b^{\mathrm{t}}(\cdot,\hat{\mathbf{p}}_2)\}. \tag{65}$$

The value of $\mathcal{E}_{a,b}$ *depends on the scatterer:*

$$\mathcal{E}_{a,b}=0 \quad \textit{for a perfectly conducting surface;} \tag{66}$$

$$\mathcal{E}_{a,b}(\hat{\mathbf{p}}_1;\hat{\mathbf{p}}_2)=-\frac{k^2}{2\pi}\int_S\frac{\mathrm{Re}(Z_S)}{|Z_S|^2}(\hat{\mathbf{n}}\times\overline{\mathbf{E}_a^{\mathrm{t}}(\hat{\mathbf{r}};\hat{\mathbf{p}}_1)})\cdot(\hat{\mathbf{n}}\times\mathbf{E}_b^{\mathrm{t}}(\hat{\mathbf{r}};\hat{\mathbf{p}}_2))ds(\mathbf{r}) \tag{67}$$

for the impedance boundary condition (57); or

$$\mathcal{E}_{a,b}(\hat{\mathbf{p}}_1;\hat{\mathbf{p}}_2)=-\frac{k^3\mu}{2\pi\mu^-}\mathrm{Im}(\eta^2)\int_{\Omega^-}\overline{\mathbf{E}_a^-(\hat{\mathbf{r}};\hat{\mathbf{p}}_1)}\cdot\mathbf{E}_b^-(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)dv \tag{68}$$

for a dielectric scatterer.

Proof: We proceed exactly as in the proof of Theorem 2. First, we evaluate $\mathcal{E}_{a,b}$ directly, using the boundary or transmission conditions on S; for the dielectric scatterer, we have to apply the divergence theorem in Ω^-. This gives the stated expressions for $\mathcal{E}_{a,b}$.

Next, we give an alternative evaluation of $\mathcal{E}_{a,b}$, using the relations $\mathbf{E}_\alpha^{\mathrm{t}}=\mathbf{E}_\alpha^{\mathrm{i}}+\mathbf{E}_\alpha^{\mathrm{s}}$, for $\alpha=a,\ b$. Formally, the calculations proceed as before, with $\{\cdot,\cdot\}$ in place of $[\cdot,\cdot]$. We also use the vector version of Green's second theorem, which gives

$$\{\mathbf{E}_a^{\mathrm{i}},\mathbf{E}_b^{\mathrm{i}}\}=0, \tag{69}$$

$$\{\mathbf{E}_a^{\mathrm{i}},\mathbf{E}_b^{\mathrm{s}}\}=-4\pi\mathrm{i}(a/k)\mathrm{e}^{\mathrm{i}ka}(\nabla\times\mathbf{E}_b^{\mathrm{s}}(\mathbf{a};\hat{\mathbf{p}}_2))\cdot(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1)+2a\mathrm{e}^{\mathrm{i}ka}\int_{S^2}\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)\cdot(\hat{\mathbf{r}}\times(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1))\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}}) \tag{70}$$

and

$$\{\mathbf{E}_a^{\mathrm{s}},\mathbf{E}_b^{\mathrm{s}}\}=\frac{2\mathrm{i}}{k}\int_{S^2}\overline{\mathbf{g}_a(\hat{\mathbf{r}};\hat{\mathbf{p}}_1)}\cdot\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)ds(\hat{\mathbf{r}}). \tag{71}$$

The remaining details are omitted. □

There is also a reciprocity theorem, as $\mathbf{E}_a^{\mathrm{t}}$ is an exact Green's function. It can be found on p. 63 of Ref. 6, for example. With our normalizations, it takes the following form.

Theorem 10: *For any two point-source locations in* Ω, **a** *and* **b**, *for any polarizations,* $\hat{\mathbf{p}}_1$ *and* $\hat{\mathbf{p}}_2$, *and for any scatterer, we have*

$$h_0(ka)(\hat{\mathbf{b}}\times\hat{\mathbf{p}}_2)\cdot(\nabla\times\mathbf{E}_a^{\mathrm{s}}(\hat{\mathbf{b}};\hat{\mathbf{p}}_1))=h_0(kb)(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1)\cdot(\nabla\times\mathbf{E}_b^{\mathrm{s}}(\hat{\mathbf{a}};\hat{\mathbf{p}}_2)). \tag{72}$$

IX. OPTICAL THEOREM: ELECTROMAGNETICS

In Ref. 9, an optical theorem for spherical waves incident upon a perfect conductor has been proved. Here, we generalize this result to other scatterers, using the general scattering theorem.

First we define the scattering cross-section due to a point source at **a** (Ref. 6) as

$$\sigma_a^{\mathrm{s}}=\frac{1}{k^2}\int_{S^2}|\mathbf{g}_a(\hat{\mathbf{r}};\hat{\mathbf{p}})|^2ds(\hat{\mathbf{r}}), \tag{73}$$

the absorption cross-section as

$$\sigma_a^{\mathrm{a}}=\frac{1}{k}\mathrm{Im}\int_S\hat{n}\cdot(\mathbf{E}_a^{\mathrm{t}}\times\nabla\times\overline{\mathbf{E}_a^{\mathrm{t}}})ds \tag{74}$$

and the extinction cross-section, σ_a^{e}, by Eq. (30).

If we put $\mathbf{a}=\mathbf{b}$ and $\hat{\mathbf{p}}_1=\hat{\mathbf{p}}_2=\hat{\mathbf{p}}$ in Theorem 9, we obtain

$$2\,\mathrm{Re}[\hat{\mathbf{p}}\cdot\mathbf{G}_a(a;\hat{\mathbf{p}})]+\frac{1}{2\pi}\int_{S^2}|\mathbf{g}_a(\hat{\mathbf{r}};\hat{\mathbf{p}})|^2ds(\hat{\mathbf{r}})=\mathcal{E}_{a,a}(\hat{\mathbf{p}};\hat{\mathbf{p}}),$$

which we can rewrite as

$$\sigma_a^{\mathrm{s}}=-4\pi k^{-2}\,\mathrm{Re}[\hat{\mathbf{p}}\cdot\mathbf{G}_a(\mathbf{a};\hat{\mathbf{p}})]+2\pi k^{-2}\mathcal{E}_{a,a}(\hat{\mathbf{p}};\hat{\mathbf{p}}). \tag{75}$$

From the definitions (65) and (74), we have

$$\sigma_a^{\mathrm{a}}=\tfrac{1}{2}\mathrm{i}k^{-1}\{\mathbf{E}_a^{\mathrm{t}}(\cdot,\hat{\mathbf{p}}),\mathbf{E}_a^{\mathrm{t}}(\cdot,\hat{\mathbf{p}})\}=-2\pi k^{-2}\mathcal{E}_{a,a}(\hat{\mathbf{p}};\hat{\mathbf{p}}). \tag{76}$$

Hence, adding Eqs. (75) and (76), the definition (30) gives

$$\sigma_a^{\mathrm{e}}=-4\pi k^{-2}\,\mathrm{Re}[\hat{\mathbf{p}}\cdot\mathbf{G}_a(\mathbf{a};\hat{\mathbf{p}})]. \tag{77}$$

The value of $\mathcal{E}_{a,a}(\hat{\mathbf{p}};\hat{\mathbf{p}})$ is given in Theorem 9; it depends on the scatterer's properties.

X. MIXED SCATTERING RELATIONS

Let

$$\mathbf{E}^{\mathrm{i}}(r;\hat{\mathbf{d}},\hat{\mathbf{p}})=\hat{\mathbf{p}}\exp\{\mathrm{i}k\hat{\mathbf{d}}\cdot\mathbf{r}\}. \tag{78}$$

be an incident time-harmonic plane electric wave, where the unit vector $\hat{\mathbf{d}}$ describes the direction of propagation and the unit vector $\hat{\mathbf{p}}$ gives the polarization. We will indicate the dependence of the total field in Ω, the total field in Ω^-, the scattered field and the electric far-field pattern on the incident direction $\hat{\mathbf{d}}$ and the polarization $\hat{\mathbf{p}}$ by writing $\mathbf{E}^{\mathrm{t}}(\mathbf{r};\hat{\mathbf{d}},\hat{\mathbf{p}})$, $\mathbf{E}^{-}(\mathbf{r};\hat{\mathbf{d}},\hat{\mathbf{p}})$, $\mathbf{E}^{\mathrm{s}}(\mathbf{r};\hat{\mathbf{d}},\hat{\mathbf{p}})$ and $\mathbf{g}(\hat{\mathbf{r}};\hat{\mathbf{d}},\hat{\mathbf{p}})$, respectively.

Here, we consider mixed situations, and relate fields due to one spherical electric wave $\mathbf{E}_a^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_1)$ and one plane electric wave $\mathbf{E}^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)$; we do this by letting $b\to\infty$ in our previous results.

Using the asymptotic forms (13), we can easily show that for the spherical electric wave (51) we have

$$\lim_{b\to\infty}\mathbf{E}_b^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}})=\mathbf{E}^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}},\hat{\mathbf{p}}), \tag{79}$$

that is the spherical electric wave, when the point source goes to infinity, reduces to a plane electric wave with direction of propagation $-\hat{\mathbf{b}}$ and polarization $\hat{\mathbf{p}}$. Similarly, we have $\mathbf{E}_b^{\mathrm{t}}(\mathbf{r};\hat{\mathbf{p}})\to\mathbf{E}^{\mathrm{t}}(\mathbf{r};-\hat{\mathbf{b}},\hat{\mathbf{p}})$, $\mathbf{E}_b^{\mathrm{s}}(\mathbf{r};\hat{\mathbf{p}})\to\mathbf{E}^{\mathrm{s}}(\mathbf{r};-\hat{\mathbf{b}},\hat{\mathbf{p}})$ and $\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}})\to\mathbf{g}(\hat{\mathbf{r}};-\hat{\mathbf{b}},\hat{\mathbf{p}})$ as $b\to\infty$.

Next, let $b\to\infty$ in Lemma 8 to give the following result.

Lemma 11: Let $\mathbf{E}_a^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_1)$ *be an incident spherical electric wave and let* $\mathbf{E}^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)$ *be an incident plane electric wave. Then*

$$\lim_{r\to\infty}\{\mathbf{E}_a^{\mathrm{i}}(\cdot;\hat{\mathbf{p}}_1),\mathbf{E}^{\mathrm{s}}(\cdot;-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\}_{S_r}=2a\mathrm{e}^{\mathrm{i}ka}\int_{S^2}\mathbf{g}(\hat{\mathbf{r}};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\cdot(\hat{\mathbf{r}}\times(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1))\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}})$$

and

$$\lim_{\varepsilon\to 0}\{\mathbf{E}_a^{\mathrm{i}}(\cdot;\hat{\mathbf{p}}_1),\mathbf{E}^{\mathrm{s}}(\cdot;-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\}_{S_{a,\varepsilon}}=4\pi\mathrm{i}(a/k)\mathrm{e}^{\mathrm{i}ka}(\nabla\times\mathbf{E}^{\mathrm{s}}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2))\cdot(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1).$$

We define a *plane far-field pattern generator* by the formula

$$\mathbf{G}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)=\lim_{b\to\infty}\mathbf{G}_b(\mathbf{a};\hat{\mathbf{p}}_2)=\mathrm{e}^{\mathrm{i}ka}\mathbf{a}\times\left[\nabla\times\mathbf{E}^{\mathrm{s}}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)-\frac{\mathrm{i}k}{2\pi}\int_{S^2}\hat{\mathbf{r}}\times\mathbf{g}(\hat{\mathbf{r}};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}})\right],$$

where $\mathbf{G}_b(\mathbf{a};\hat{\mathbf{p}}_2)$ is defined by Eq. (63). Other limiting values are given in the next theorem.

Theorem 12: *For two incident point source electric waves,* $\mathbf{E}_a^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_1)$ *and* $\mathbf{E}_b^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_2)$*, we have*

$$\lim_{a\to\infty}\mathbf{G}_b(\mathbf{a};\hat{\mathbf{p}})=\mathbf{g}_b(-\hat{\mathbf{a}};\hat{\mathbf{p}}_2) \tag{80}$$

and

$$\lim_{a\to\infty}\mathbf{G}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)=\mathbf{g}(-\hat{\mathbf{a}};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2). \tag{81}$$

Proof: For Eq. (80), we use spherical polar coordinates (θ, φ) as in the proof of Theorem 5, and define

$$\mathbf{F}_b(\theta)=\int_0^{2\pi}\hat{\mathbf{r}}\times\mathbf{g}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)d\varphi.$$

In particular, we have $\mathbf{F}_b(0)=2\pi\hat{\mathbf{a}}\times\mathbf{g}_b(\hat{\mathbf{a}};\hat{\mathbf{p}}_2)$ and $\mathbf{F}_b(\pi)=-2\pi\hat{\mathbf{a}}\times\mathbf{g}_b(-\hat{\mathbf{a}};\hat{\mathbf{p}}_2)$. Hence

$$\int_{S^2}\hat{\mathbf{r}}\times\hat{\mathbf{g}}_b(\hat{\mathbf{r}};\hat{\mathbf{p}}_2)\mathrm{e}^{\mathrm{i}k\hat{\mathbf{r}}\cdot\mathbf{a}}ds(\hat{\mathbf{r}})=\int_0^{\pi}\mathbf{F}_b(\theta)\mathrm{e}^{\mathrm{i}ka\cos\theta}\sin\theta d\theta$$

$$=\frac{\mathrm{i}}{ka}[\mathbf{F}_b(\pi)\mathrm{e}^{-\mathrm{i}ka}-\mathbf{F}_b(0)\mathrm{e}^{\mathrm{i}ka}]-\frac{\mathrm{i}}{ka}\int_0^{\pi}\mathrm{e}^{\mathrm{i}ka\cos\theta}\frac{d\mathbf{F}_b(\theta)}{d\theta}d\theta$$

$$\sim-\frac{2\pi\mathrm{i}}{ka}\hat{\mathbf{a}}\times[\mathbf{g}_b(-\hat{\mathbf{a}};\hat{\mathbf{p}}_2)\mathrm{e}^{-\mathrm{i}ka}+\mathbf{g}_b(\hat{\mathbf{a}};\hat{\mathbf{p}}_2)\mathrm{e}^{\mathrm{i}ka}]$$

for large a. From this equation and Eq. (63), we arrive at Eq. (80). The proof of Eq. (81) is similar. □

We can now let $b\to\infty$ in the general scattering theorem, Theorem 9.

Theorem 13: *Let* $\mathbf{E}_a^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_1)$ *be an incident spherical electric wave and let* $\mathbf{E}^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)$ *be an incident plane electric wave. Then*

$$\hat{\mathbf{p}}_1\cdot\mathbf{G}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)+\hat{\mathbf{p}}_2\cdot\overline{\mathbf{g}_a(\hat{\mathbf{b}};\hat{\mathbf{p}}_1)}+\frac{1}{2\pi}\int_{S^2}\mathbf{g}(\hat{\mathbf{r}};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\cdot\overline{\mathbf{g}_a(\hat{\mathbf{r}};\hat{\mathbf{p}}_1)}ds(\hat{\mathbf{r}})=\mathcal{M}_a(-\hat{\mathbf{b}};\hat{\mathbf{p}}_1,\hat{\mathbf{p}}_2),$$

where $\mathcal{M}_a(-\hat{\mathbf{b}};\hat{\mathbf{p}}_1,\hat{\mathbf{p}}_2)=\lim_{b\to\infty}\mathcal{E}_{a,b}(\hat{\mathbf{p}}_1;\hat{\mathbf{p}}_2)$:

$$\mathcal{M}_a(-\hat{\mathbf{b}};\hat{\mathbf{p}}_1,\hat{\mathbf{p}}_2)=0 \tag{82}$$

for a perfectly conducting surface;

$$\mathcal{M}_a(-\hat{\mathbf{b}};\hat{\mathbf{p}}_1,\hat{\mathbf{p}}_2)=-\frac{k^2}{2\pi}\int_S\frac{\mathrm{Re}(Z_S)}{|Z_S|^2}(\hat{\mathbf{n}}\times\mathbf{E}^{\mathrm{t}}(\hat{\mathbf{r}};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2))\cdot(\hat{\mathbf{n}}\times\overline{\mathbf{E}_a^{\mathrm{t}}(\hat{\mathbf{r}};\hat{\mathbf{p}}_1)})ds(\hat{\mathbf{r}}) \tag{83}$$

for the impedance boundary condition; or

$$\mathcal{M}_a(-\hat{\mathbf{b}};\hat{\mathbf{p}}_1,\hat{\mathbf{p}}_2)=-\frac{k^3\mu}{2\pi\mu^-}\mathrm{Im}(\eta^2)\int_{\Omega^-}\overline{\mathbf{E}_a^-(\hat{\mathbf{r}};\hat{\mathbf{p}}_1)}\cdot\mathbf{E}^-(\hat{\mathbf{r}};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)dv \tag{84}$$

for a dielectric scatterer.

Proof: The proof is similar to that of Theorem 9. The only substantial difference appears in the formula for $\{\mathbf{E}_a^{\mathrm{s}},\mathbf{E}^{\mathrm{i}}\}$; cf. Eq. (70). Now, using the plane electric wave (78), we find that (see p. 59 of Ref. 6)

$$\{\mathbf{E}_a^{\mathrm{s}}(\cdot;\hat{\mathbf{p}}_1),\mathbf{E}^i(\cdot;-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\}=\hat{\mathbf{p}}_2\cdot\int_S[\hat{\mathbf{n}}\times\nabla\times\overline{\mathbf{E}_a^{\mathrm{s}}(\mathbf{r};\hat{\mathbf{p}}_1)}+\mathrm{i}k\hat{\mathbf{b}}\times(\hat{\mathbf{n}}\times\overline{\mathbf{E}_a^{\mathrm{s}}(\mathbf{r};\hat{\mathbf{p}}_1)})]\mathrm{e}^{-\mathrm{i}k\hat{\mathbf{b}}\cdot\mathbf{r}}ds(\mathbf{r})$$

$$=4\pi\mathrm{i}k^{-1}\hat{\mathbf{p}}_2\cdot\overline{\mathbf{g}_a(-\hat{b},\hat{\mathbf{p}}_1)}.$$

□

The mixed reciprocity relation for perfect conductors is Theorem 2.3.4 in Ref. 1. It is valid more generally, as follows.

Theorem 14: *Let* $\mathbf{E}_a^{\mathrm{i}}(\mathbf{r};\hat{\mathbf{p}}_1)$ *be an incident spherical electric wave and let* $\mathbf{E}^{\mathrm{i}}(\mathbf{r};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)$ *be an incident plane electric wave. Then*

$$\hat{\mathbf{p}}_2\cdot\mathbf{g}_a(\hat{\mathbf{b}},\hat{\mathbf{p}}_1)=\mathrm{e}^{-\mathrm{i}ka}\hat{\mathbf{p}}_1\cdot[(\nabla\times\mathbf{E}^{\mathrm{s}}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2))\times\hat{\mathbf{a}}]. \tag{85}$$

Proof: Working as in the proof of Theorem 10 and taking into account that

$$\{\overline{\mathbf{E}_a^{\mathrm{i}}(\cdot;\hat{\mathbf{p}}_1)},\mathbf{E}^{\mathrm{s}}(\cdot;-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\}=4\pi\mathrm{i}(a/k)\mathrm{e}^{-\mathrm{i}ka}(\nabla\times\mathbf{E}^{\mathrm{s}}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_1))\cdot(\hat{\mathbf{a}}\times\hat{\mathbf{p}}_1)$$

and

$$\{\overline{\mathbf{E}_a^s(\cdot;\hat{\mathbf{p}}_1)},\mathbf{E}^i(\cdot;-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)\}=-4\pi ik^{-1}\hat{\mathbf{p}}_2\cdot\mathbf{g}_a(\hat{\mathbf{b}},\hat{\mathbf{p}}_1),$$

Theorem 14 is proved. □

To conclude, we note that we also have

$$\lim_{a\to\infty}\lim_{b\to\infty}\mathbf{G}_b(\mathbf{a};\hat{\mathbf{p}}_2)=\lim_{b\to\infty}\lim_{a\to\infty}\mathbf{G}_b(\mathbf{a};\hat{\mathbf{p}}_2)=\mathbf{g}(-\hat{\mathbf{a}};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2).$$

This can be used to verify that the known scattering relations for plane-wave incidence[14,6] are recovered when $a\to\infty$ and $b\to\infty$. Furthermore, Eq. (81) and the reciprocity principle for plane waves[6] gives the following limiting property:

$$\lim_{a\to\infty}\hat{\mathbf{p}}_1\cdot\mathbf{G}(\mathbf{a};-\hat{\mathbf{b}},\hat{\mathbf{p}}_2)=\lim_{b\to\infty}\hat{\mathbf{p}}_2\cdot\mathbf{G}(-\mathbf{b};\hat{\mathbf{a}},\hat{\mathbf{p}}_1).$$

In this paper we consider the field equations deduced by the second order approximation of the Born–Infeld Lagrangian density for the electromagnetic field. In particular we prove the existence of finite energy electrostatic fields, both in the case of a point charge and in the case of L^1 charge density. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1508433]

I. INTRODUCTION

A. Classical Maxwell's equations

The classical Maxwell's equations for an electrostatic field $\mathbf{E}$, in the vacuum, with a suitable choice of physical constants, are

$$\nabla \times \mathbf{E} = 0, \tag{1}$$

$$\frac{1}{4\pi} \nabla \cdot \mathbf{E} = \rho, \tag{2}$$

where ρ is the charge density. Standard procedures immediately give the expression of the energy

$$\mathcal{H} = \frac{1}{8\pi} \int |\mathbf{E}|^2 dx.$$

From (1) we deduce

$$\mathbf{E} = -\nabla \phi,$$

then Eq. (2) becomes

$$-\Delta \phi = 4\pi\rho. \tag{3}$$

This classical theory does not cover some physically interesting cases, namely $\rho = \delta$ and $\rho \in L^1(\mathbf{R}^3)$.

(i) If $\rho = \delta$ (point charge), then the solution of (3) is

$$\phi = \frac{1}{|x|},$$

a)Electronic mail: pisani@dm.uniba.it

but the energy

$$\mathcal{H}=\frac{1}{8\pi}\int |\nabla\phi|^2 dx,$$

is infinite;

(ii) if, as it is natural, we assume $\rho\in L^1(\mathbf{R}^3)$ it is not clear if (3) admits solutions such that

$$\mathcal{H}=\frac{1}{8\pi}\int |\nabla\phi|^2 dx<+\infty.$$

Remark 1: By the Sobolev inequality

$$\left(\int |\phi|^6 dx\right)^{1/6}\leqslant c\left(\int |\nabla\phi|^2 dx\right)^{1/2},$$

it is easy to deduce that for any $\rho\in L^{6/5}(\mathbf{R}^3)\simeq(L^6(\mathbf{R}^3))'$ *there exists a unique solution of (3) with finite energy [simply take* ϕ *as test function in (3) and use Hölder inequality].*

If $\rho\in L^1(\mathbf{R}^3)$ *we can give a partial counterexample about the nonexistence of finite energy solutions. Infact consider the charge density*

$$\rho(x)=\frac{1}{|x|^{5/2}+|x|^{7/2}}.$$

Then it is easy to see that $\rho\in L^1(\mathbf{R}^3)\setminus L^{6/5}(\mathbf{R}^3)$ *and Eq. (3) has no radial solutions such that* $\mathcal{H}<+\infty$.

Remark 2: When we consider a bounded domain Ω*, it is well known that (3), with Dirichlet boundary conditions, admits a unique solution* ϕ *such that*

$$\int_\Omega |\nabla\phi|^q dx<+\infty \quad \forall q<\tfrac{3}{2},$$

for any datum $\rho\in L^1(\Omega)$ *[see Ref. 1].*

A way to overcome these difficulties was proposed by Born and Infeld in 1933–34.

The starting point for their theory is the set of Maxwell's equations

$$\nabla\times\mathbf{E}+\frac{\partial\mathbf{B}}{\partial t}=0, \tag{4}$$

$$\nabla\cdot\mathbf{B}=0, \tag{5}$$

$$\nabla\cdot\mathbf{D}=\rho, \tag{6}$$

$$\nabla\times\mathbf{H}-\frac{\partial\mathbf{D}}{\partial t}=\mathbf{J}, \tag{7}$$

where **E** and **H** are, respectively, the electric and the magnetic field, **D** and **B** are, respectively, the electric and the magnetic induction field, ρ and **J** are, respectively, the charge and the current density.

In the vacuum we have the relations

$$\mathbf{D}=\frac{1}{4\pi}\mathbf{E}, \tag{8}$$

$$\mathbf{H}=\frac{1}{4\pi}\mathbf{B}, \tag{9}$$

so we can write the second pair of Maxwell's equations as follows:

$$\frac{1}{4\pi}\nabla\cdot\mathbf{E}=\rho, \tag{10}$$

$$\frac{1}{4\pi}\nabla\times\mathbf{B}-\frac{1}{4\pi}\frac{\partial\mathbf{E}}{\partial t}=\mathbf{J}. \tag{11}$$

If we describe $(\mathbf{E},\mathbf{B})$ by means of the gauge potential $(\phi,\mathbf{A})$

$$\mathbf{E}=-(\mathbf{A}_t+\nabla\phi),$$

$$\mathbf{B}=\nabla\times\mathbf{A},$$

then the first couple of Maxwell's equations (4) and (5) is immediately satisfied.

The other two equations [Eqs. (10) and (11)] are the Euler–Lagrange equations with respect to the Lagrangian density

$$\mathcal{L}_{\mathrm{M}}=\frac{1}{4\pi}\mathcal{I}+\mathbf{J}\cdot\mathbf{A}-\rho\phi, \tag{12}$$

where

$$\mathcal{I}=\tfrac{1}{2}(|\mathbf{E}|^2-|\mathbf{B}|^2).$$

B. The Born–Infeld theory

As we pointed out the electrostatic field of a point charge has infinite energy. In order to overcome this difficulty Born and Infeld[2] (and references therein) proposed to modify equations (10) and (11).

Born and Infeld introduced a parameter $b\gg 1$ and considered the Lagrangian density

$$\mathcal{L}_{\mathrm{BI}}=\frac{b^2}{4\pi}\left(1-\sqrt{1-\frac{2}{b^2}\mathcal{I}}\right)+\mathbf{J}\cdot\mathbf{A}-\rho\phi. \tag{13}$$

If we set

$$\mathbf{D}_{\mathrm{BI}}=\frac{1}{4\pi}\frac{\mathbf{E}}{\sqrt{1-\frac{2}{b^2}\mathcal{I}}}, \tag{14}$$

$$\mathbf{H}_{\mathrm{BI}}=\frac{1}{4\pi}\frac{\mathbf{B}}{\sqrt{1-\frac{2}{b^2}\mathcal{I}}}, \tag{15}$$

then the Euler–Lagrange equations relative to (13) can be written as follows:

$$\nabla\cdot\mathbf{D}_{\mathrm{BI}}=\rho, \tag{16}$$

$$\nabla \times \mathbf{H}_{\mathrm{BI}} - \frac{\partial \mathbf{D}_{\mathrm{BI}}}{\partial t} = \mathbf{J}. \tag{17}$$

These equations, which substitute (10) and (11), are formally identical with the second pair of Maxwell's equations (6) and (7).

In the Born–Infeld theory the electrostatic field of a point charge has finite energy.

In fact consider the electrostatic case, i.e.,

$$\mathbf{B} = 0, \tag{18}$$

$$\frac{\partial \mathbf{E}}{\partial t} = 0, \tag{19}$$

$$\mathbf{J} = 0, \tag{20}$$

and assume

$$\rho = q\,\delta.$$

Equation (17) is immediately satisfied; an explicit solution of (16) is indeed

$$\mathbf{E} = \frac{q}{r_0^2 \sqrt{1 + (|x|/r_0)^4}} \frac{x}{|x|}, \tag{21}$$

where the constant $r_0 = q/b$ can be interpreted as the radius of the electron.

The energy for the Lagrangian density $\mathcal{L}_{\mathrm{BI}}$ is [see Ref. 3]

$$\mathcal{H}_{\mathrm{BI}} = \int T_{00}^{\mathrm{BI}}\, dx,$$

where

$$T_{00}^{\mathrm{BI}} = \frac{\partial \mathcal{L}_{\mathrm{BI}}}{\partial u_t} \cdot u_t - \mathcal{L}_{\mathrm{BI}},$$

and $u_t = (\phi_t, \mathbf{A}_t)$. A direct calculation shows that

$$T_{00}^{\mathrm{BI}} = \frac{1}{4\pi} \left[\frac{|\mathbf{E}|^2}{\sqrt{1 - \frac{2}{b^2}\mathcal{I}}} - b^2 \left(1 - \sqrt{1 - \frac{2}{b^2}\mathcal{I}} \right) \right] - \mathbf{J} \cdot \mathbf{A}. \tag{22}$$

Substituting (21) into (22), and taking into account (18)–(20) we can verify that $\mathcal{H}_{\mathrm{BI}}$ is finite.

Remark 3: As far as we know, it is not clear if the Born–Infeld theory could avoid also the divergence of the energy arising in presence of L^1 charge density (see discussion in Sec. I A).

C. Statement of the results

In the following we propose a slight variation of Born–Infeld theory which also permits us to get a finite energy electrostatic field with L^1 charge density.

Set

$$\beta = \frac{1}{2b^2} \ll 1,$$

then (13) becomes

$$\mathcal{L}_{\mathrm{BI}}=\frac{1}{8\pi\beta}(1-\sqrt{1-4\beta\mathcal{I}})+\mathbf{J}\cdot\mathbf{A}-\rho\phi. \tag{23}$$

We point out that the first order expansion of $\mathcal{L}_{\mathrm{BI}}$, for β small, is $\mathcal{L}_{\mathrm{M}}$ (see 12). In this paper we consider the second order expansion, that is

$$\mathcal{L}^*=\frac{1}{4\pi}(\mathcal{I}+\beta\mathcal{I}^2)+\mathbf{J}\cdot\mathbf{A}-\rho\phi.$$

The Euler–Lagrange equations relative to $\mathcal{L}^*$, which substitute (10) and (11), are

$$\nabla\cdot(1+2\beta\mathcal{I})\mathbf{E}=4\pi\rho, \tag{24}$$

$$\nabla\times(1+2\beta\mathcal{I})\mathbf{B}-\frac{\partial}{\partial t}(1+2\beta\mathcal{I})\mathbf{E}=4\pi\mathbf{J}. \tag{25}$$

Now, if we set

$$\mathbf{D}^*=\frac{1}{4\pi}(1+2\beta\mathcal{I})\mathbf{E}, \tag{26}$$

$$\mathbf{H}^*=\frac{1}{4\pi}(1+2\beta\mathcal{I})\mathbf{B}, \tag{27}$$

then (24) and (25) can be written again as in (6) and (7), namely

$$\nabla\cdot\mathbf{D}^*=\rho,$$

$$\nabla\times\mathbf{H}^*-\frac{\partial\mathbf{D}^*}{\partial t}=\mathbf{J}.$$

A straightforward calculation shows that now the energy is

$$\mathcal{H}^*=\int\left(\frac{\partial\mathcal{L}^*}{\partial u_t}\cdot u_t-\mathcal{L}^*\right)dx=\int\left\{\frac{1}{8\pi}[(|\mathbf{E}|^2+|\mathbf{B}|^2)+\beta\mathcal{I}(3|\mathbf{E}|^2+|\mathbf{B}|^2)]-\mathbf{J}\cdot\mathbf{A}\right\}dx.$$

Now consider the electrostatic situation described by (18)–(20).

Since (5) is obviously satisfied, the first couple of equations (4) and (5) reduces to

$$\nabla\times\mathbf{E}=0. \tag{28}$$

Moreover, since (25) is satisfied the second couple reduces to

$$\nabla\cdot[(1+\beta|\mathbf{E}|^2)\mathbf{E}]=4\pi\rho, \tag{29}$$

with $\beta>0$.

In this case the energy of the solutions is

$$\mathcal{H}^*=\frac{1}{8\pi}\int\left(|\mathbf{E}|^2+\frac{3}{2}\beta|\mathbf{E}|^4\right)dx.$$

The following theorems hold.

Theorem 4: *If we consider a point charge $\rho = q\,\delta$, there exists a solution of (28) and (29) having finite energy.*

We point out that, as well as in case of Born–Infeld equations, we shall give an explicit solution.

Theorem 5: *For every charge density $\rho \in L^1(\mathbf{R}^3)$, there exists a unique solution of (28) and (29) having finite energy.*

In particular, for $\rho = 0$, we have only the trivial solution. Hence the quasi-linear structure does not give rise to an effective source term, as well as in the Born–Infeld theory [see Ref. 4].

II. PROOF OF THEOREM 4

A. Estimate of the energy

Using (28) it easy to see that

$$\nabla \times [(1+\beta|\mathbf{E}|^2)\mathbf{E}] = 0,$$

then

$$(1+\beta|\mathbf{E}|^2)\mathbf{E} = -\nabla v, \tag{30}$$

and (29) becomes

$$-\Delta v = 4\pi q\,\delta,$$

which gives

$$v = \frac{q}{|x|}. \tag{31}$$

(30) and (31) imply

$$|\mathbf{E}| + \beta|\mathbf{E}|^3 = \frac{q}{|x|^2},$$

which gives

$$|\mathbf{E}| \leqslant \frac{q}{|x|^2}, \tag{32}$$

$$|\mathbf{E}| \leqslant \sqrt[3]{\frac{q}{\beta}}\frac{1}{|x|^{2/3}}. \tag{33}$$

From (32) we deduce that $|\mathbf{E}|^2$ and $|\mathbf{E}|^4$ are summable at infinity; from (33) we deduce that $|\mathbf{E}|^4$ and $|\mathbf{E}|^2$ are summable at 0. Hence

$$\mathcal{H}^* = \frac{1}{8\pi}\int_{\mathbf{R}^3}\left(|\mathbf{E}|^2 + \frac{3}{2}\beta|\mathbf{E}|^4\right)dx < +\infty.$$

B. Existence of a solution

For the sake of simplicity assume

$$q = 1.$$

By (28)

$$\mathbf{E} = -\nabla\phi,$$

so we have to solve

$$-\Delta\phi - \beta\Delta_4\phi = 4\pi\delta, \tag{34}$$

where

$$\Delta_p\phi = \mathrm{div}[(|\nabla\phi|^{p-2})\nabla\phi].$$

Since

$$-\mathrm{div}\left(\nabla\frac{1}{|x|}\right) = 4\pi\delta,$$

it is sufficient to solve

$$(1+\beta|\nabla\phi|^2)\nabla\phi = \nabla\frac{1}{|x|} = -\frac{x}{|x|^3}. \tag{35}$$

Let $\varphi:\mathbf{R}\to\mathbf{R}$ denote the inverse function of

$$\psi(t) = t + \beta t^3.$$

Using the asymptotic estimates on φ

$$\varphi(t) \simeq t \quad \text{for } t\to 0,$$

$$\varphi(t) \simeq \sqrt[3]{t/\beta} \quad \text{for } t\to+\infty,$$

we deduce that the integral

$$\int_0^{+\infty} \varphi(1/r^2)\,dr,$$

is convergent; indeed

$$\varphi(1/r^2) \simeq 1/\sqrt[3]{\beta r^2} \quad \text{for } r\to 0,$$

$$\varphi(1/r^2) \simeq 1/r^2 \quad \text{for } r\to+\infty.$$

So we can define

$$\phi(x) = \int_{|x|}^{+\infty} \varphi(1/r^2)\,dr. \tag{36}$$

We claim that ϕ satisfies (35). In fact we have

$$\nabla\phi(x) = -\varphi(1/|x|^2)\frac{x}{|x|},$$

hence

$$|\nabla\phi(x)| = \varphi(1/|x|^2).$$

Therefore

$$(1+\beta|\nabla\phi|^2)\nabla\phi = -(1+\beta\varphi^2(1/|x|^2))\,\varphi(1/|x|^2)\,\frac{x}{|x|}$$

$$= -\psi(\varphi(1/|x|^2))\,\frac{x}{|x|}$$

$$= -\frac{x}{|x|^3}.$$

Remark 6: For $|x|$ large, $\phi(x)$ is asymptotically equivalent to the Coulomb potential $1/|x|$.

Remark 7: We recall that if Ω is a bounded set in $\mathbf{R}^3$, then the solution of $-\Delta_4\phi=\delta$, with Dirichlet boundary data belongs to the Sobolev space $W_0^{1,4}(\Omega)$; so that, in particular

$$\int_\Omega |\nabla\phi|^4 dx < +\infty.$$

Indeed the space of measures on Ω is embedded in the dual space of $W_0^{1,4}(\Omega)$ and so the existence of a solution follows from well-known results on monotone operators in duality [see Ref. 5]. This is not the case for the solution of $-\Delta\phi=\delta$, which is of infinite energy. So the modification of Eq. (3) is used only to control *the energy of the solution near the origin. Note that the operator $-\Delta_4$ can be substituted (always having finite energy solutions) with $-\Delta_p$, for any $p>3$. In this way, however, the equation is no longer obtained as the Euler–Lagrange equation of the second order expansion of $\mathcal{L}_{\mathrm{BI}}$ [defined in (23)] for β near 0.*

III. PROOF OF THEOREM 5

As in the previous section, by (28)

$$\mathbf{E} = -\nabla\phi.$$

So (29) is reduced to

$$-\Delta\phi - \beta\Delta_4\phi = 4\pi\rho.$$

The energy of the solutions is

$$\mathcal{H}^* = \frac{1}{8\pi}\int \left(|\nabla\phi|^2 + \frac{3}{2}\beta|\nabla\phi|^4 \right) dx.$$

Then the natural functional space for finite energy solutions is the closure D of $C_0^\infty(\mathbf{R}^3)$ with respect to this norm

$$\|\phi\|_D = \|\nabla\phi\|_{L^2} + \|\nabla\phi\|_{L^4}.$$

Proposition 8: The Banach space D is continuously embedded in $L^\infty(\mathbf{R}^3)$, that is there exists $M>0$ such that, for every $\phi\in D$

$$\|\phi\|_{L^\infty} \leq M\|\phi\|_D.$$

Proof: It is well known that $D^{1,2}(\mathbf{R}^3)$ is continuously embedded in $L^6(\mathbf{R}^3)$. Consider a family of cubes $Q_k\subset\mathbf{R}^3$ such that

$$|Q_k| = 1$$

$$\bigcup_k Q_k = \mathbf{R}^3.$$

Fixed $\phi \in C_0^\infty(\mathbf{R}^3)$, for every $x \in \mathbf{R}^3$

$$\begin{aligned}|\phi(x)| &\leq \left| \int_{Q_k} \phi dx \right| + M\|\nabla\phi\|_{L^4(Q_k)} \\ &\leq M_1\|\phi\|_{L^6(Q_k)} + M\|\nabla\phi\|_{L^4(Q_k)} \\ &\leq M_1\|\phi\|_{L^6(\mathbf{R}^3)} + M\|\nabla\phi\|_{L^4(\mathbf{R}^3)} \\ &\leq M_2\|\nabla\phi\|_{L^2(\mathbf{R}^3)} + M\|\nabla\phi\|_{L^4(\mathbf{R}^3)}.\end{aligned}$$

Then we easily deduce the thesis. ■

Theorem 5 is a consequence of the following result.

Proposition 9: For every $\rho \in L^1(\mathbf{R}^3)$ there exists a unique $\phi \in D$ such that

$$-\Delta\phi - \beta\Delta_4\phi = \rho. \tag{37}$$

If we call $T(\rho)$ such a solution, the map $T: L^1(\mathbf{R}^3) \to D$ is continuous and bounded, in the sense that it maps bounded sets in bounded sets.

Proof: The solutions of (37) can be characterized as critical points of the functional

$$J(\phi) = \frac{1}{2}\|\nabla\phi\|_{L^2}^2 + \frac{\beta}{4}\|\nabla\phi\|_{L^4}^4 - \int_{\mathbf{R}^3} \phi\rho dx.$$

By Proposition 8 and Hölder inequality, this functional is bounded from below and coercive; furthermore it is weakly lower semicontinuous on D. Then it has a minimizer, which is a solution of (37).

The solution is unique. Indeed observe first that the operator

$$\mathcal{A} = -\Delta - \beta\Delta_4,$$

is monotone; that is, for every $\phi_1, \phi_2 \in D$

$$c(\|\nabla\phi_1 - \nabla\phi_2\|_{L^2}^2 + \|\nabla\phi_1 - \nabla\phi_2\|_{L^4}^4) \leq \langle \mathcal{A}\phi_1 - \mathcal{A}\phi_2, \phi_1 - \phi_2 \rangle, \tag{38}$$

being c a suitable positive constant [see, e.g., Lemma 9 in Ref. 6].

Now if ϕ_1 and ϕ_2 are solutions of (37) in D, then

$$\mathcal{A}\phi_1 - \mathcal{A}\phi_2 = 0.$$

Hence, by (38), $\phi_1 = \phi_2$.

The continuity of the inverse map $T = \mathcal{A}^{-1}$ can be obtained using again (38) and arguments similar to those of Theorem 30 in Benci *et al.*[6]

In order to show that T maps bounded sets in bounded sets we multiply (37) by the solution ϕ. After integration by parts, we obtain, by Proposition 8,

$$\|\nabla\phi\|_{L^2}^2 + \beta\|\nabla\phi\|_{L^4}^4 \leq \|\rho\|_{L^1}\|\phi\|_{L^\infty} \leq M\|\rho\|_{L^1}(\|\nabla\phi\|_{L^2} + \|\nabla\phi\|_{L^4}).$$

Then we easily deduce that, if $\|\rho\|_{L^1}$ is bounded, also $\|\phi\|_D = \|\nabla\phi\|_{L^2} + \|\nabla\phi\|_{L^4}$ is bounded. ■

(Received 15 May 2002; accepted 12 July 2002)

We characterize local behavior, and establish optimal local regularity, for minimizers of the functional $E(\psi)=\int_\Omega|\nabla\psi|^2$ over collections $\mathcal{C}$ that are weakly closed in $H^1(\Omega)$, closed under local smooth domain perturbations, and for which $E(\psi)$ controls $\int_\Omega\psi^2$. Minimizers ψ satisfy a weak magnetohydrodynamic (MHD) equation and correspond to fields in low density ideal plasmas under cylindrical symmetry where the field component in the direction of the axis of symmetry is zero. We prove that $(\partial\psi/\partial x+i\partial\psi/\partial y)^2$ is complex analytic, and locally $\psi=f(\phi)$ for some ϕ, f, with $\Delta\phi=0$ and f Lipschitz continuous with $|f'|=1$ almost everywhere, near points where $\nabla\psi\neq 0$. An analogous but more elaborate characterization is established at points where $\nabla\psi=0$. This characterization forms the basis for a general theory of the existence of current sheets due to imposed topological and boundary constraints. Results carry over to functions that are stationary points of $E(\psi)$ with respect to local smooth domain variations. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1508437]

I. INTRODUCTION

The analysis of current sheets in low density ideal plasmas has important applications in the study of the sun's corona, for instance in understanding the extreme heating that occurs in the corona. We study the problem in cylindrical symmetry, so our results apply to models of solar coronal arcades. Our characterization of local behavior forms the basis for results on existence of current sheets in general boundary value problems with topological constraints that will appear in the companion paper.[8]

Consider a z independent magnetic field B. This can be expressed as

$$B=\left(\frac{\partial\psi}{\partial y},-\frac{\partial\psi}{\partial x},Q\right), \tag{1}$$

where ψ,Q are scalar functions of x,y. We will assume that

$$Q=0. \tag{2}$$

In the context of basic coronal arcade models the condition $Q=0$ corresponds to the case where there is no footpoint motion in the z direction (footpoints being the points where field lines are anchored in the x,z plane, which models the photospheric boundary of the sun's corona). In this setting we avoid the highly nonlinear constraints usually satisfied by Q but retain the conservation of field line topology thought to generate current sheets.

The variational problem, of minimizing the energy

a)Electronic mail: estredul@uwc.edu

$$E(\psi)=\int_{\Omega}|\nabla\psi|^2, \tag{3}$$

over the collection C of functions $\psi=\psi_0(d)$ with ψ_0 a fixed element of $H^1(\Omega)$, and $d:\Omega\to\Omega$ any smooth domain diffeomorphism, models the relaxation of a field to minimum energy constrained by fixed field line topology imposed by ideal MHD. To produce a function ψ that is energy minimizing it is necessary to extract weak limits. Thus it is natural to minimize (3) over the weak closure of C.

To put this problem in historical context note that many examples of current sheets are present in the astrophysics literature. For the most part however these are particular examples generated by explicit mathematical formulas. Although there is a great deal of analysis of one sort or another on the subject, what is lacking is a complete, rigorous theory where current sheets arise in general global energy minimization problems due to prescribed field line topology and boundary data. Such a theory, carried out in settings relevant to solar physics, would substantiate on a rigorous mathematical level an important scientific theory.

Prior to our current results, work of Aly and Amari,[1–3] comes the closest to accomplishing this goal. In Ref. 1 Aly and Amari analyze QPSEs, that is, quasi-potential singular equilibrium states, which are fields B that are solutions of the equations of MHD under the assumption that ψ is harmonic away from a finite union of differentiable (possibly intersecting) curve segments on which ψ is constant and across which $\nabla\psi$ is discontinuous in accord with standard jump conditions. This analysis forms the basis for a careful characterization of what is expected in energy minimizing states that are conjectured to have current sheets. In Refs. 2 and 3 various basic field topologies of interest to solar physics are considered. Integral formulas are given as solutions of general boundary value problems, usually under the assumption of y symmetry in ψ (ψ as above). Except in one basic example, which can be reduced to a consideration of a boundary value problem for harmonic functions, Aly and Amari do not establish that such solutions are energy minimizers, although the solutions are undoubtedly stationary points in a sense we discuss later. In addition the methods are limited to fairly simple geometries due to reliance on integral formulas.

In Refs. 6 and 7 we presented a general existence theory for minimizers of variational problems such as the one described at (3) (also including the $Q\neq 0$ case). In the present paper we characterize local behavior of such minimizers and give an optimal local regularity result. In the companion paper[8] we will apply our general techniques to a model problem first introduced by Low and Wolfson[10] to give the first rigorous proof of the existence of current sheets in energy minimizers of a general boundary value problem with topological constraints, at least for topologies where the problem is not easily reducible to consideration of global harmonic functions. The approach is general in that it easily extends to arbitrarily complex field line topologies.

We now describe more completely the results of the present paper. It is easily seen that a minimizer exists for the variational problem of minimizing (3) over a collection of functions that is weakly closed in H^1, closed under local smooth domain perturbations, and for which (3) controls the H^1 norm, see (9), the latter occurring for example if boundary values are specified. For such a minimizer ψ our first result is that $B^2=(\partial\psi/\partial x+i\partial\psi/\partial y)^2$ is complex analytic, which follows from the Euler equations for the functional (3). Note in Ref. 4 Arnold and Khesin consider the analog of this in the general setting of Riemannian manifolds, however they assume *a priori* that the minimizer is smooth. The analyticity of B^2 also appears for instance in the work of Aly and Amari[1] under the assumption that ψ is harmonic away from a finite union of differentiable curve segments on which ψ is constant and across which $\nabla\psi$ is discontinuous in accord with standard jump conditions. We establish the analyticity here in a much weaker setting where energy minimizers and associated free boundaries can be quite irregular. At first the possibility of highly irregular minimizers is surprising since one is minimizing the simple functional $\int|\nabla\psi|^2$. However note that $|\nabla f(\psi)|=|f'(\psi)\nabla\psi|=|\nabla\psi|$ for Lipschitz continuous functions f satisfying $|f'|=1$ so $\int|\nabla\psi|^2=\int|\nabla f(\psi)|^2$. Thus if ψ is a minimizer of the variational problem described above it can be seen that $f(\psi)$ is a minimizer for a related collection $\mathcal{C}$. Current sheets, i.e., discontinuities in the gradient of a minimizer, can thus occur in general on a dense subset of the domain. Another

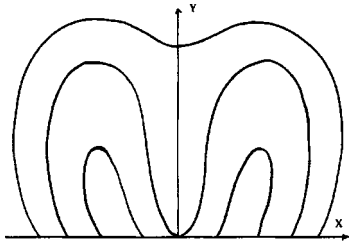

FIG. 1.

perspective is that when one, roughly speaking, takes a square root of $B^2=(\partial\psi/\partial x+i\partial\psi/\partial y)^2$ one gets that $\nabla\psi(p)=s(p)\nabla\phi(p), s(p)=\pm 1$ for some ϕ that is harmonic except possibly on a cut. Intuitively this implies that ψ is locally constant on level curves $\{\phi=c\}$, however, when one moves orthogonally to such a curve the function $s(p)$ possibly introduces wild flips in the direction of $\nabla\psi$.

A corollary of our analyticity result is that $\nabla\psi$ has discontinuities in a subdomain O of Ω if and only if ψ is not harmonic in all of O. This verifies in this weak setting the traditional view that a field must develop currents sheets if it cannot relax to a potential state, due to preservation of field line topology.

A second corollary is that $\nabla\psi$ is locally bounded, so ψ is locally Lipschitz continuous. This is in fact an optimal **local** regularity result due to the observation above relating ψ and $f(\psi)$.

To get a more precise sense of both where ψ is regular, but also where current sheets exist, one must analyze the field line topology, or equivalently the topological structure of levels sets $\{\psi=c\}$. In the setting of $Q=0$ such topology can only be sustained by prescribed boundary conditions. However, boundary conditions are not enough to prescribe such topology. In Ref. 8 we use the results of the present paper, in combination with methods for handling weak topology of level sets introduced in Refs. 6 and 7, to carefully examine a model of a solar coronal arcade first introduce by Low and Wolfson[10] and studied by a number of authors including Aly and Amari.[3] This example involves a topological level set structure that is one of the simplest of relevance to astrophysics in which one expects current sheets to exist (or not exist, depending on imposed boundary values), but that is also complex enough so one cannot trivially reduce the analysis to consideration of a globally harmonic function. In this context we establish a rigorous proof of the existence of currents sheets. In Fig. 1 one sees sample level curves corresponding to an initial field before it relaxes to minimum energy. The level curves correspond to field lines. These are anchored on the x axis, which models the surface of the photosphere. In Fig. 2 we see a typical level curve configuration for the field after it relaxes to minimum energy. In Ref. 10 Low and Wolfson give a specific example of such a field where there is a current sheet in the curve segment shown emanating from the origin up to the point where the level curve moves away from the y axis, the flux function ψ being harmonic away from the current sheet. In Ref. 3 Aly and Amari give an integral formula for such fields for general boundary conditions under the assumption of y symmetry, as well a condition on the boundary values that characterizes whether a current sheet in fact

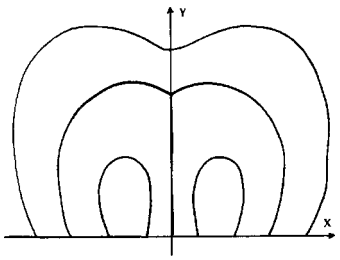

FIG. 2.

occurs or not. They do not prove that such fields are energy minimizing but they do verify that the fields satisfy the correct jump condition, which in this case is that the gradient of ψ has continuous magnitude but reverses direction across the current sheet, which as in the Low, Wolfson example emanates from the origin and lies on the y axis. As before, the flux function ψ associated with the field is harmonic away from the current sheet. In Ref. 8 we use results of the present paper as well as those from Refs. 6 and 7 to prove the existence of energy minimizers in this particular topological class and for general boundary conditions. We show that such minimizers are harmonic away from a current sheet which is an analytic curve emanating from the origin, and across which the gradient has continuous magnitude but changes sign. No symmetry assumption is made on the boundary data. The method handles much more general topological classes, which are discussed more in Sec. III A. The results of Ref. 8 are set in a bounded domain while those of Aly and Amari, and Low and Wolfson are in a half space. In Ref. 9 we will extend our results to unbounded domains.

To properly appreciate these results one must separate them from current sheet examples that arise trivially from field reversal examples created from harmonic functions. Note that if $\phi \in H^1(\mathbb{R}^2)$ is harmonic in a bounded domain Ω and f is Lipschitz continuous with $|f'|=1$ then as mentioned earlier $\int_\Omega |\nabla \phi|^2 = \int_\Omega |\nabla f(\phi)|^2$ so one can show that $\psi = f(\phi)$ is a minimizer over the weak closure of the set of all functions $\psi(d)$ where $d:\Omega \to \Omega$ is any smooth domain diffeomorphism. ψ is thus an energy minimizer of the sort we are discussing which has current sheets at all values of t in the range of ψ where f' has a discontinuity. Such examples are not of great interest because the topological classes associated with these are not of a type that is usually studied in astrophysics. Note, however, that the Low–Wolfson geometry is such that reflections of the type introduced by f cannot reduce ψ to a harmonic function. It is the contrast between these two examples that helps put the results of the present paper in context. In the local theory tackled in the present paper one must cope with the possibility of arbitrarily bad field reversals. It is only in the context of a global problem where boundary values and topology of fields lines are prescribed that one can control where current sheets occur. However, the basic local regularity and structure results of this paper form a foundation for exploiting the global constraints considered in Ref. 8.

We now elaborate on our local characterization results for minimizers of (3). Near points where $\nabla \psi \neq 0$ we prove that $\psi = f(\phi)$ for some ϕ, f with $\Delta \phi = 0$ and f Lipschitz continuous with $|f'|=1$ almost everywhere. Near points p where $\nabla \psi = 0$ (which are isolated) we show for some integer $m \geqslant 3$ that there are analytic curves γ_i, $i=1,2,\ldots,m$ which are asymptotic (as the curves approach p) to m line segments emanating from p at equally spaced angles (relative to p), and a function ϕ that is harmonic, except on γ_1 if m is odd, and zero on $\cup_i \gamma_i$, such that for each $i = 1,2,\ldots,m$ we have $\psi = f_i(\phi)$ near p in the region between γ_i, γ_{i+1}, for Lipschitz continuous functions f_i with $|f_i'|=1$ almost everywhere.

II. INITIAL TECHNICAL DEFINITIONS

Let $B(x,r)=\{y \in \mathbb{R}^2 : |x-y|<r\}$. For any open set $\Omega \subset \mathbb{R}^2$ let $L^1(\Omega)$ be the set of Lebesgue integrable functions defined on Ω, $C(\Omega)$ the set of continuous real valued functions defined on Ω, $C^1(\Omega)$ the subset of $C(\Omega)$ whose elements have continuous first derivatives, $C^\infty(\Omega)$ the set of infinitely differentiable real valued functions defined on Ω, and $C_0^\infty(\Omega)$ the subset of $C^\infty(\Omega)$ whose elements have compact support in Ω. Given the norm $\|u\|_\Omega = [\int_\Omega (|u|^2 + |\nabla u|^2)]^{1/2}$ let $H^1(\Omega)$ be the closure of $\{u \in C^\infty(\Omega) | \|u\|_\Omega < \infty\}$ in $\|\cdot\|_\Omega$, and $H_0^1(\Omega)$ the closure of $C_0^\infty(\Omega)$ in $\|\cdot\|_\Omega$.

For simplicity we follow the convention of treating any two elements of $H^1(\Omega)$ as being equal if they are equal pointwise almost everywhere (that is everywhere except on a set of zero Lebesgue measure). The Lebesgue measure of a set E will be represented by $|E|$. The closure of a set E is denoted by $\overline{E}$.

Given an open set Ω and functions u_n, $u \in H^1(\Omega)$ we say that u_n converges weakly to u in $H^1(\Omega)$ if

$$\int_\Omega u_n v + \nabla u_n \cdot \nabla v \to \int_\Omega uv + \nabla u \cdot \nabla v, \tag{4}$$

for all $v \in H^1(\Omega)$.

A functional $F: H^1(\Omega) \to \mathbb{R}$ is said to be weakly lower semi-continuous if for any sequence $(u_n) \subset H^1(\Omega)$ converging weakly to u in $H^1(\Omega)$ we have

$$\liminf_{n\to\infty} F(u_n) \geqslant F(u). \tag{5}$$

Note that $\int_\Omega |\nabla u|^2$ is weakly lower semicontinuous.

III. GENERAL VARIATIONAL PROBLEM

Definition 1: Given an open bounded set $\Omega \subset \mathbb{R}^2$ let

$$\tilde{\Omega} = \{x + iy \in \mathbb{C} | (x,y) \in \Omega\} \tag{6}$$

and

$$\mathcal{D}(\Omega) = \{d: \Omega \to \Omega | d \text{ is a } C^\infty \text{ diffeomorphism,}$$

$$d = I \text{ in a neighborhood of } \partial\Omega, \det Dd > 0\}, \tag{7}$$

where I is the identity map $I(p) = p$. A collection of functions $\mathcal{C}$ with domain Ω will be said to be closed under smooth domain variations if for all $f \in \mathcal{C}$ and $d \in \mathcal{D}(\Omega)$ we have $f(d) \in \mathcal{C}$.

Recall

$$E(u) = \int_\Omega |\nabla u|^2. \tag{8}$$

Lemma 1: Given an open bounded set $\Omega \subset \mathbb{R}^2$ and a nonempty collection of functions $\mathcal{C} \subset H^1(\Omega)$ that is weakly closed in $H^1(\Omega)$, closed under smooth domain variations, and satisfies the property that for any sequence $(u_n) \subset \mathcal{C}$

$$\{E(u_n) | n = 1,2,\ldots\} \text{ bounded } \Rightarrow \{\|u_n\|_\Omega | n = 1,2,\ldots\} \text{ bounded,} \tag{9}$$

then there exists a function $\psi_1 \in \mathcal{C}$ such that

$$E(\psi_1) \leqslant \inf_{\psi \in \mathcal{C}} (E\psi). \tag{10}$$

For any such ψ_1 the function $(\partial\psi_1/\partial x - i\partial\psi_1/\partial y)^2$ is a complex analytic function on $\tilde{\Omega}$ (after possible redefinition of $\nabla\psi$ on a set of Lebesgue measure zero).

Remark 1: Property (9) holds for instance if functions in $\mathcal{C}$ satisfy a prescribed weak boundary condition, for example if they are restrictions to Ω of functions in $\mathcal{C}' \subset H^1(\mathbb{R}^2)$ with $u = f$ on $\mathbb{R}^2 \backslash \Omega$ for all $u \in \mathcal{C}'$, and some fixed $f \in H^1(\mathbb{R}^2)$. See the next section for more details.

Lemma 2: If $\psi \in H^1(\Omega)$ with $(\partial\psi/\partial x - i\partial\psi/\partial y)^2$ a complex analytic function on $\tilde{\Omega}$ then

$$|\nabla\psi|^4 \text{ is real analytic so } \psi \text{ is locally Lipschitz continuous in } \Omega \tag{11}$$

and

$$\Delta\psi = 0 \text{ in any subdomain of } \Omega \text{ on which } \nabla\psi \text{ is continuous.} \tag{12}$$

Corollary 1: Let ψ be as in Lemma 2 and $O\subseteq\Omega$ be open. If ψ is not harmonic throughout O then $\psi\notin C^1(O)$.

Lemmas 1,2 tell us the nature of a minimizer ψ in regions where ψ is C^1. The following result indicates behavior near points where $\nabla\psi$ may not be continuous.

Theorem 1: *Given a nonconstant ψ as in Lemma 2, if $|\nabla\psi(p)|\neq 0$ then there exist $R>0$, a Lipschitz continuous function $f:\mathbb{R}\to\mathbb{R}$ satisfying*

$$|f'|=1 \ \text{almost everywhere}, \tag{13}$$

and a harmonic function $\phi:B(p,R)\to\mathbb{R}$ such that

$$\psi=f(\phi) \ \text{in} \ B(p,R). \tag{14}$$

Points p where $|\nabla\psi(p)|=0$ are isolated. If $|\nabla\psi(p)|=0$ then for some $R>0$ and some integer $m\geqslant 3$ there are analytic curves $\gamma_i:[0,R]\to\Omega, \gamma_i(0)=p, i=1,2,\ldots,m$ which are asymptotic (as the curves approach p) to m line segments emanating from p at equally spaced angles (relative to p), the set $B(p,R)\setminus(\cup_i\gamma_i([0,R]))$ being the union of m open, pairwise disjoint, simply connected regions $D_i, i=1,2,\ldots,m$ (each bounded by three connected arcs, two being subarcs of γ_i, γ_j for $j=i+1$ unless $i=m$ when $j=1$, and the third a subarc of $\partial B(p,R)$), and a Lipschitz continuous function ϕ which is harmonic in $B(p,R)\setminus\gamma_1$ with $\{\phi=0\}\cap B(0,R)=\cup_i\gamma_i([0,R])$, such that for each $i=1,2,\ldots,m$ there exists a Lipschitz continuous function $f_i:\mathbb{R}\to\mathbb{R}$ satisfying $f_i(p)=\psi(p)$, $|f_i'|=1$ almost everywhere such that

$$\psi=f_i(\phi) \ \text{in the closure of} \ D_i. \tag{15}$$

If m is even then ϕ may be taken to be harmonic in all of $B(p,r)$, while if m is odd one can take $|\nabla\phi|$ to be continuous with $\nabla\phi$ reversing direction across γ_1. Moreover ϕ can be chosen so that the discontinuity in $\nabla\phi$ occurs on any one of the γ_i.

Remark 2: It is fairly easy to see that Theorem 1 is optimal in describing local regularity. Given ψ, p, R, ϕ as in the statement of the theorem, one has $\int_{B(p,R)}|\nabla\psi|^2=\int_{B(p,R)}|\nabla\phi|^2$ in both the $\nabla\psi(p)\neq 0$ and $\nabla\psi(p)=0$ cases (if $f:\mathbb{R}\to\mathbb{R}$ is a Lipschitz continuous function with $|f'|=1$ almost everywhere then $|\nabla(f(\psi))|=|\nabla\psi|$ for $\psi\in H^1(B(p,R))$—see discussion at Lemma 1, in Ref. 6 for technical details beyond the use of the weak chain rule; also $\phi\chi_{D_i}\in H^1(B(p,R)), i=1,\ldots,m$ for ϕ, D_i as above, and $\chi_E(p)=1$ for $p\in E$, $\chi_E(p)=0$ for $p\notin E$). Thus for fixed ϕ one can redefine f or $f_i, i=1,\ldots,m$ arbitrarily (of course maintaining the $|f'|=1, |f_i'|=1$ condition, and taking $f_i(p)$ independent of i), and thus redefine ψ [as in (14), (15)], and ψ is still a minimizer of $\int_{B(p,R)}|\nabla\psi|^2$ over the weak closure of $\{\psi(d)|d\in\mathcal{D}(B(p,R))\}$.

Proof of Lemma 1: The lemma can be deduced from Noether's Theorem (see, for example, Proposition 2, p.168 of Ref. 5; note in Ref. 5 minimizers are assumed to be C^1, but this is used only to justify use of the chain rule which is true much more generally). However, due to the simplicity of the functional we present a self contained elementary proof.

We first verify that there exists a minimizer ψ of the variational problem (10). Recall that $\mathcal{C}\neq\emptyset, \mathcal{C}\subset H^1(\Omega)$ so $\inf_{\psi\in\mathcal{C}}E(\psi)<\infty$, and there exists a sequence $(\psi_n)\subset\mathcal{C}$ such that $E(\psi_n)\to\inf_{\psi\in\mathcal{C}}E(\psi)$ as $n\to\infty$. Such a sequence is bounded in $H^1(\Omega)$ by (9), so one can extract a subsequence that converges weakly in $H^1(\Omega)$ to some $\psi\in H^1(\Omega)$. The weak closedness of $\mathcal{C}$ implies $\psi\in\mathcal{C}$, and the weak lower semi-continuity of E implies that $E(\psi)\leqslant\inf_{\psi\in\mathcal{C}}E(\psi)<\infty$, so ψ is a minimizer.

Given $w\in C_0^\infty(\Omega)\times C_0^\infty(\Omega)$ let $d_t(p)=p+tw(p)$ so there exists $t_0>0$ such that $d_t\in\mathcal{D}(\Omega)$ for $|t|<t_0$. For $|t|<t_0$ let $\psi_t(q)=\psi(d_t^{-1}(q))$ so

$$\nabla\psi_t(q)=\nabla\psi(d_t^{-1}(q))Dd_t^{-1}(q)=\nabla\psi(p)[Dd_t(p)]^{-1}, \tag{16}$$

for $p=d_t^{-1}(q)$.

Note for any 2×2 matrix A that

$$|(x,y)A^{-1}| = \left|A\begin{pmatrix} y \\ -x \end{pmatrix}\right| \Big/ |\det A|, \tag{17}$$

so

$$\int_\Omega |\nabla \psi_t(q)|^2 dq = \int_\Omega |\nabla \psi(p)[Dd_t(p)]^{-1}|^2 \det Dd_t(p) dp, \tag{18}$$

$$= \int_\Omega |Dd_t(p)\begin{pmatrix} \psi_y(p) \\ -\psi_x(p) \end{pmatrix}|^2 \det{}^{-1} Dd_t(p) dp. \tag{19}$$

Also note that

$$Dd_t = I + tDw, \quad \det Dd_t = 1 + t\nabla\cdot w + t^2 \det Dw, \tag{20}$$

so

$$\frac{\partial Dd_t}{\partial t} = Dw, \quad \left.\frac{\partial \det Dd_t}{\partial t}\right|_{t=0} = \nabla\cdot w. \tag{21}$$

Consequently we can differentiate (19) with respect to t and evaluate at $t=0$ to get

$$\int_\Omega 2(\psi_y, -\psi_x) Dw \begin{pmatrix} \psi_y \\ -\psi_x \end{pmatrix} - |\nabla\psi|^2 \nabla\cdot w = 0. \tag{22}$$

Take $w=(-\eta,0)$ to get

$$\int_\Omega (\psi_x^2 - \psi_y^2)\eta_x + 2\psi_y\psi_x\eta_y = 0. \tag{23}$$

Similarly using $w=(0,\eta)$ we get

$$\int_\Omega (\psi_x^2 - \psi_y^2)\eta_y - 2\psi_y\psi_x\eta_x = 0. \tag{24}$$

Note that these are the weak form of the Cauchy–Riemann equations for $(\psi_x^2-\psi_y^2)-2\psi_y\psi_x i$ so we claim, possibly after redefinition of $\nabla\psi$ on a set of measure zero, that

$$(\psi_x^2 - \psi_y^2) - 2\psi_y\psi_x i \ \text{ is complex analytic,} \tag{25}$$

thought of as a function of $z=x+iy$.

To verify the claim let $u=\psi_x^2-\psi_y^2$ and $v=-2\psi_y\psi_x$ so from (23) and (24) we get

$$\int_\Omega u\eta_x - v\eta_y = 0, \int_\Omega u\eta_y + v\eta_x = 0. \tag{26}$$

Take $\eta=\alpha_x$ in the first equation and $\eta=\alpha_y$ in the second to get

$$\int_\Omega u\alpha_{xx} - v\alpha_{xy} = 0, \int_\Omega u\alpha_{yy} + v\alpha_{xy} = 0. \tag{27}$$

Adding the two equation we see that

$$\int_\Omega u\Delta\alpha = 0, \tag{28}$$

so u is a distributional solution of $\Delta u = 0$. Standard results then imply that u is classically harmonic.

A similar calculation implies that v is harmonic, and thus smooth, so using integration by parts in (26) confirms that the classical Cauchy–Riemann equations hold for $u+iv$. Note that the redefinition of u,v on a set of measure zero can be accomplished by redefining $\nabla\psi$ because the equations $u=a^2-b^2$, $v=-ab$ always have a solution.

Proof of Lemma 2: Let $\psi\in H^1(\Omega)$ be such that $a(z)=(\partial\psi/\partial x - i\partial\psi/\partial y)^2$ is a complex analytic function on $\tilde{\Omega}$. Thus $|a(z)|^2=|\partial\psi/\partial x - i\partial\psi/\partial y|^4=|\nabla\psi|^4$ is real analytic, and so is locally bounded in Ω. Consequently ψ is locally Lipschitz in Ω.

Now assume $\psi\in C^1(O)$, O a connected open subset of Ω. Given a point p such that $\nabla\psi(p)\neq 0$ let $B\subset O$ be an open ball centered at p such that $\nabla\psi$ is close to $\nabla\psi(0)$ in B, so for instance $\nabla\psi\neq 0$, but mainly so we can use the complex analytic square root function with cut chosen so that the square root is analytic on the image of B under the map $(\psi_x-\psi_y i)^2$. Thus we can conclude that $\psi_x-\psi_y i$ is analytic. Consequently ψ is harmonic in B due to the Cauchy–Riemann equations.

Next note that complex analytic functions are either constant or have isolated zeros. In the later case the above argument implies that ψ is harmonic in O minus an at most countable set of isolated points. A point is a removable discontinuity for $\Delta\psi=0$ due to $\psi\in H^1$ so in fact ψ is harmonic in all of O.

Proof of Theorem 1: Let ψ be a nonconstant function in $H^1(\Omega)$ such that $a=(\partial\psi/\partial x - i\partial\psi/\partial y)^2$ is a complex analytic function in $\tilde{\Omega}$. Note that a cannot be identically zero otherwise ψ would be constant contrary to assumption.

The following paragraph is strictly for purposes of motivation. The functions q,ϕ will be defined differently in the actual proof. First consider a point $p_0=(x_0,y_0)\in\Omega$ such that $a(z)\neq 0$ in a neighborhood of $z_0=x_0+y_0 i$, and assume $\nabla\psi$ is continuous in a neighborhood of p_0. For $p=(x,y)$, $z=x+yi$ choose a cut for the square root function that avoids $a(z_0)$ and define

$$q(z)=\int_{p_0}^{z}\sqrt{a(w)}\,dw, \quad \phi(x,y)=\mathrm{Re}(q(z)), \tag{29}$$

so $\phi_x-\phi_y i = dq/dz = \pm(\psi_x-\psi_y i)$, $\nabla\phi=\pm\nabla\psi$, and

$$\psi=\psi(p_0)\pm\phi \ \text{ with } \ \Delta\phi=0 \ \text{ near } \ p_0, \tag{30}$$

and so ψ is represented locally in a simple manner in terms of the harmonic function ϕ. We now drop the assumptions that $a(z)\neq 0$ and $\nabla\psi$ is continuous. This makes the analysis more intricate, though we will basically emulate the above construction. Also the sign in (30) will possibly vary with z forcing the introduction of Lipschitz continuous functions f, f_i.

For simplicity we take $z_0=0$. Note that $(\psi_x-\psi_y i)^2=\tilde{c}z^n j(z)$ in a neighborhood of 0 for some complex number $\tilde{c}\neq 0$, integer $n\geq 0$, and analytic function $j(z)$ satisfying $j(0)=1$.

For some $r_0,\beta,0\leq\beta<2\pi$, $\tilde{c}=r_0 e^{i\beta}$. We will define $\tilde{c}^{1/2}=r_0^{1/2}\,e^{i\beta/2}$, but all other fractional exponents will be calculated with respect to the following cut. Let k_0 be the largest integer k such that $\theta_k=((2k+1)\pi-\beta)/(n+2)<0$. Let $\overline{\gamma_k}$ be the half line $r\geq 0$, $\theta=\theta_k$, (r,θ) being the polar coordinates associated with (x,y) with $z=x+iy$. We will use the cut $\overline{\gamma_{k_0}}$ to define z^α for fractional α, except for $\tilde{c}^{1/2}$. More precisely, representing $z=re^{i\theta}$ for $r\geq 0$, $\theta_{k_0}\leq\theta<2\pi+\theta_{k_0}$, define $z^\alpha=r^\alpha e^{i\alpha\theta}$. This particular cut insures that $\mathrm{Re}(\tilde{c}^{1/2}\,z^{(n+2)/2})$ is continuous, which will be important in defining ϕ as a continuous function. In fact note that $\mathrm{Re}(\tilde{c}^{1/2}\,z^{(n+2)/2})=0$ precisely on the sets $\overline{\gamma_k}$, k an integer, of which there are only $m=n+2$ distinct sets. In addition $z=1$ is represented by $\theta=0$, so small neighborhoods of $z=1$ will get mapped to small neighborhoods of 1 by the fractional powers used below.

Let $k(z)=j^{1/2}(z)$, so k is analytic in a small neighborhood of 0 with $k(0)=1$. Thus $k(z)=1+\Sigma_{j=1}^{\infty}c_j z^j$. Note that $\ell(z)=1+\Sigma_{j=1}^{\infty}[(n+2)c_j z^j/(n+2j+2)]$ has the same radius of convergence, so $h(z)=\ell^{2/(n+2)}(z)$ is a well defined analytic function in a small neighborhood of 0, with values close to 1. Define

$$q(z)=\frac{2\tilde{c}^{1/2}}{n+2}(zh(z))^{n+2/2}. \tag{31}$$

Note for $b(z)=zh(z)$ that $db/dz=1$ at $z=0$, thus if $b(z)=u(x,y)+iv(x,y)$, $z=x+iy$, and we define $S(x,y)=(u(x,y),\ v(x,y))$, then the map $S:B(0,R)\to T(B(0,R))$ is an analytic diffeomorphism for small $R>0$, and S approaches the identity map as $R\to 0$. Also let $\gamma_k=b^{-1}(\overline{\gamma_k})$ (with $b^{-1}(z)$ being the inverse function of $b(z)$), so $q(z)$ is analytic in $\tilde{B}(0,R)$ (recall Definition 1) if n is even, and in $\tilde{B}(0,R)\backslash\gamma_{k_0}$ if n is odd.

For small enough R there is a ball $B\subset B(0,R)$, so $B,b(B)$ both lie in the positive quadrant, therefore, in $\tilde{B}$

$$q(z)=\frac{2\tilde{c}^{1/2}}{n+2}z^{n+2/2}\ell(z),\quad \frac{dq}{dz}=\tilde{c}^{1/2}z^{n/2}k(z), \tag{32}$$

due to the explicit power series for $\ell(z)$, thus

$$\left(\frac{dq}{dz}\right)^2=(\phi_x-i\phi_y)^2=(\psi_x-i\psi_y)^2, \tag{33}$$

for

$$\phi(x,y)=\mathrm{Re}(q(z)),z=x+iy. \tag{34}$$

However $(dq/dz)^2$ and $(\psi_x-i\psi_y)^2$ are both analytic in $\tilde{B}(0,R)\backslash\gamma_{k_0}$ (and in $\tilde{B}(0,R)$ if n is even), so (33) holds there as well.

We now characterize the behavior of ψ near 0. First assume $n=0$ so that ϕ is harmonic in $B(0,R)$ and $\nabla\phi(0)\neq 0$. From (33) we see that $\phi_x-i\phi_y=s(x,y)(\psi_x-i\psi_y)$, with $s(x,y)=\pm 1$ for each (x,y), so

$$\nabla\phi=s(x,y)\nabla\psi, \tag{35}$$

which intuitively indicates that ψ is locally constant on level sets of ϕ. To make this rigorous we introduce a change of variables that makes ϕ linear near 0. We can then take advantage of the fact that $H^1(\Omega)$ functions are absolutely continuous along almost all lines, which is enough regularity to compare ψ and ϕ. Choose axes so that $\nabla\phi(0)/|\nabla\phi(0)|=(0,1)$ and note by the implicit function theorem that in a neighborhood of 0 (recall $\phi(0)=0$) there exists a function $l(x,t)$ with $l(0,0)=0$ such that $\phi(x,l(x,t))=t$. Also note that we can assume $T(x,t)=(x,l(x,t))$ is smooth and 1-1 close to 0 so if we define $\overline{\phi}=\phi(T),\overline{\psi}=\psi(T)$ then $\overline{\phi}(x,t)=\phi(x,l(x,t))=t$ so

$$(0,1)=\nabla\overline{\phi}=\nabla\phi(T)DT=s(T)\nabla\psi(T)DT=s(T)\nabla\overline{\psi}, \tag{36}$$

and $\nabla\overline{\psi}=(0,s(T))$. Thus $\partial\overline{\psi}/\partial x=0$, which in conjunction with the fact that $\overline{\psi}$ is absolutely continuous on almost every line (due to $\overline{\psi}\in H^1$), implies that $\overline{\psi}=f(t)$ on almost every line $\mathbb{R}\times\{t\}$ for some function f. However, ψ is continuous so this extends to all t with f continuous. An immediate consequence is that $\psi=f(\phi)$ in a neighborhood of 0. Choosing a line $\{x\}\times\mathbb{R}$ on which $\overline{\psi}$ is absolutely continuous we see that f is absolutely continuous and $\partial\overline{\psi}/\partial t(x,t)=f'(t)$ so $|f'|=1$ almost everywhere due to $\nabla\overline{\psi}=(0,s(T))$.

If $n>0$ then $\nabla\phi(0)=0$. However, isolation of zeros of analytic functions implies that this is the only zero of $\nabla\phi$ in some neighborhood of 0. Thus $\nabla\phi\neq 0$ in each of the open regions $D_i = D_i(R)\subset B(0,R)$, bounded by $\gamma_i, \gamma_{i+1}, \partial B(0,R)$.

Fix i, and recall that the basic idea of the $n=0$ case is that near a point where $\nabla\psi\neq 0$ the identity (35) implies that ψ is constant on level sets of ϕ. This is a local result but it is easily extended to apply to connected components of level sets of ϕ as discussed below. However, that is the best one can do in general. To see this note that in the $n>0$ case $\phi=c$ has several components for many c, each component in a different D_i, as can be seen from the basic example where $k\equiv 1$ [k as defined above (31)]. In such a case it is easy to construct functions ψ satisfying $\nabla\psi=\pm\nabla\phi$ ($\pm$ consistent within each D_i but changing from one D_i to another) such that ψ has opposite signs on two different components of $\{\phi=c\}$. Thus the identity $\psi=f(\phi)$ is not possible because f cannot be defined consistently on all components of $\{\phi=c\}$. Because of this we are forced to analyze the level set structure of ϕ.

Given $c\in\mathbb{R}$ let

$$\overline{\gamma_i}(c)=\left\{ z\in\mathbb{C}\middle|\,\mathrm{Re}\left(\frac{2\tilde{c}^{1/2}}{n+2}z^{(n+2)/2}\right)=c\right\}\cap D_i, \tag{37}$$

which in polar coordinates is described by

$$r=\left(\frac{(n+2)c}{2r_0^{1/2}\cos\left(\dfrac{(n+2)\theta+\beta}{2}\right)}\right)^{2/(n+2)}, \quad \theta_i<\theta<\theta_{i+1}, \tag{38}$$

when c and $\cos([(n+2)\theta+\beta]/2)$ have the same sign, and is empty otherwise.

Thus if $\{\phi=c\}\cap D_i\neq\emptyset$ then for small R it equals $\gamma_i(c)=b^{-1}(\overline{\gamma_i}(c))$, which is a smooth connected curve with no self-intersections, and with endpoints in $\partial B(0,R)$. Let $\gamma:[0,1]\to\mathbb{R}^2$ parameterize $\{\phi=c\}\cap\overline{D_i}$ (where $\overline{D_i}$ is the closure of D_i) with $\gamma(0),\gamma(1)\in\partial B(0,R)$. Let $E=\{t\in[0,1]\,|\,\psi(\gamma(t))=\psi(\gamma(0))\}$. Note that E is closed due to continuity of ψ, γ so we can define $t_0=\max E$. Also the $n=0$ case above tells us that ψ is constant on $\{\phi=c\}$ near $\gamma(t_0)$ which contradicts the definition of t_0 unless $t_0=1$. Thus ψ is constant on $\{\phi=c\}\cap D_i$ so the function $f=f_i$ from the $n=0$ case is consistently defined in $D_i(R)$.

Note that one can take any of the curves $\overline{\gamma_k}$ to use as the cut in defining fractional powers simply by choosing the x,y axes differently. Thus if ϕ_k is the ϕ arising from using the cut $\overline{\gamma_k}$ (after a change of coordinates so we are using one consistent choice of axes for all k), then the above analysis, with ψ replaced by ϕ_j, shows on each D_i that $\phi_j=f_{i,j,k}(\phi_k)$ with $f_{i,j,k}(0)=0, |f'_{i,j,k}|=1$ almost everywhere. However, ϕ_j, ϕ_k are harmonic with nonzero gradient in D_i so $f'_{i,j,k}$ cannot have discontinuities, thus $f'_{i,j,k}$ is identically 1 or identically -1. Therefore, in each D_i either $\phi_j=\phi_k$ or $\phi_j=-\phi_k$. The claims about the discontinuity of $\nabla\phi$ follow directly from comparing $\phi=\phi_{k_0}$ with a ϕ_j corresponding to a different cut, since then ϕ_j is harmonic across γ_{k_0}.

A. Examples of weak classes

Given a function $\psi_0\in H^1(\mathbb{R}^2)$, if $\psi_0\in\mathcal{C}$, with $\mathcal{C}$ a collection as in Lemma 1, then

$$W(\psi_0)=\{\psi_0(d)\,|\,d\in\mathcal{D}(\Omega)\}\subset\mathcal{C}, \tag{39}$$

since $\mathcal{D}$ is closed under smooth domain variations (see Definition 1), and

$$\overline{W}(\psi_0)=\text{Weak Closure of } \{\psi_0(d)\,|\,d\in\mathcal{D}(\Omega)\} \text{ in } H^1(\Omega)\subset\mathcal{C}, \tag{40}$$

since $\mathcal{C}$ is weakly closed (for simplicity, as in the above definition, we will use $\psi_0(d)$ to denote both a function in $H^1(\Omega)$ and a function in $H^1(\Omega')$ for open sets Ω' containing Ω). Therefore it follows from Lemma 3 that $\overline{W}(\psi_0)$ is the smallest collection of the type described in Lemma 1 that contains ψ_0.

Thus our results apply to $\overline{W}(\psi_0)$, however, it is difficult to say much more about the global nature of the discontinuities in the gradients of functions in $\overline{W}(\psi_0)$ due to the fact that the ''topological structure'' of such functions is not explicit. To rectify this deficiency we consider the function classes described after Lemma 3 which very explicitly encode topological structure.

Lemma 3: If $\psi_0 \in H^1(\mathbb{R}^2)$ then $W(\psi_0) \subset H^1(\Omega)$, and $\overline{W}(\psi_0)$ is weakly closed in $H^1(\Omega)$, satisfies (9), and is closed under smooth domain variations, as defined in Definition 1.

Remark 3: Note that one need only assume that $\psi_0 \in H^1(\Omega')$ for some open set Ω' containing the closure of Ω.

Proof: Let $B_r = B(0,r)$, where r is chosen such that $\Omega \subset B_{r/3}$. By multiplying by a smooth cutoff function which equals 1 in $B_{r/2}$, and 0 in $\mathbb{R}^2 \backslash B_r$, one can assume $\psi_0 \in H_0^1(B_r)$.

To confirm the first claim of the lemma take $\psi \in W(\psi_0)$, i.e., $\psi = \psi_0(d)$ for some $d \in \mathcal{D}$. Note that (18), (19) hold with d replacing d_t, thus there is a constant $c(d)$ dependent on d, such that

$$\int_\Omega |\nabla \psi|^2 \leqslant c(d) \int_\Omega |\nabla \psi_0|^2, \tag{41}$$

since Dd is smooth and equals the identity map in a neighborhood of $\partial\Omega$, and thus in addition $\det Dd$ is bounded, and uniformly bounded from zero (with bound dependent on d). However, using the convention above with $\Omega' = B_r$, $\psi = \psi_0$ in $B_r \backslash \Omega$, so

$$\int_{B_r} |\nabla \psi|^2 \leqslant (c(d)+1) \int_{B_r} |\nabla \psi_0|^2, \tag{42}$$

so the first claim follows from the inequality:

$$\int_{B_r} u^2 \leqslant c \int_{B_r} |\nabla u|^2 \tag{43}$$

which holds for all $u \in H_0^1(B_r)$ for some $c = c(r)$.

The second claim of the lemma is clearly true since a weak closure is weakly closed. To confirm (9) holds for $\overline{W}(\psi_0)$ first consider $\psi \in \overline{W}(\psi_0)$. By definition there exists a sequence $(\psi_n) \subset W(\psi_0)$ with $\psi_n \to \psi$ weakly in $H^1(\Omega)$. Thus (ψ_n) is bounded in $H^1(\Omega)$, however $\psi_n = \psi_0$ in $B_r \backslash \Omega$ so ψ_n is bounded in $H_0^1(B_r)$. One can then extract a subsequence which converges weakly in $H_0^1(B_r)$. Weak convergence in $H^1(\Omega)$, or in $H_0^1(B_r)$, implies pointwise convergence almost everywhere on a subsequence, so the later limit must equal ψ in Ω and ψ_0 in $B_r \backslash \Omega$. In summary, any element of $\psi \in \overline{W}(\psi_0)$ can be extended to equal ψ_0 in B_r so that $\psi \in H_0^1(B_r)$.

Now assume $\psi_n \in \overline{W}(\psi_0)$ with $E(\psi_n) \leqslant M$. Extending ψ_n as above we have

$$\int_{B_r} (\psi_n)^2 \leqslant c \int_{B_r} |\nabla \psi_n|^2 \leqslant c \left(\int_{B_r \backslash \Omega} |\nabla \psi_0|^2 + M \right), \tag{44}$$

and (9) is verified.

Finally given $\psi \in \overline{W}(\psi_0), d \in \mathcal{D}$ we need to show that $\psi(d) \in \overline{W}(\psi_0)$. By definition there exist $\psi_n \in W(\psi_0)$ with $\psi_n \to \psi$ weakly in $H^1(\Omega)$. As above we can take ψ, ψ_n equal to ψ_0 in $B_r \backslash \Omega$ with $\psi_n \to \psi$ weakly in $H_0^1(B_r)$ on a subsequence. But $\psi_n = \psi_0(d_n)$ for some $d_n \in \mathcal{D}$ so $\psi_n(d) = \psi_0(d_n(d)) \in W(\psi_0)$ since $d_n(d) \in \mathcal{D}$. Also $E(\psi_n(d)) \leqslant c(d) E(\psi_n)$ as in (41) so

$$\int_{B_r} (\psi_n(d))^2 \leqslant c \int_{B_r} |\nabla(\psi_n(d))|^2 \leqslant c(c(d)+1) \int_{B_r} |\nabla \psi_n|^2, \tag{45}$$

since $\psi_n(d)=\psi_n=\psi_0$ on $B_r\backslash\Omega$. However as before weak convergence of ψ_n in $H^1(\Omega)$ implies (ψ_n) is bounded in $H_0^1(B_r)$ so (45) implies that $(\psi_n(d))$ is bounded in $H_0^1(B_r)$, and so on a subsequence converges weakly in $H_0^1(B_r)$, the limit equaling $\psi(d)$ by pointwise almost everywhere convergence on a subsequence. Thus $\psi(d) \in \overline{W}(\psi_0)$ since $\psi_n(d) \in W(\psi_0)$ and the proof of the lemma is complete.

Next we consider function classes with explicit topological structure. For simplicity assume Ω is a simply connected open set with closure in $B(0,R)$ for some $R>0$. We have strong evidence to indicate that any $\psi \in H_0^1(B(0,R))$ can be decomposed as

$$\psi = \sum_{i \in I} f_i(\psi_i), \tag{46}$$

where I is a finite or countable index set, functions $f_i:\mathbb{R}\to\mathbb{R}$ are Lipschitz continuous with $|f'|=1$ almost everywhere and $f(0)=0$, and functions $\psi_i \in H_0^1(B(0,R)) \cap C(\mathbb{R}^2)$ are "topologically simple" in the sense that $\psi_i \geqslant 0$, and sets $\{\psi_i > t\}$ are simply connected for all t, and in addition ψ_i satisfy 'support conditions' defined in terms of a collection of constants $\{t_{i,j}: i,j \in I, i<j\}$, namely $\psi_i = t_{i,j}$ on $\psi_j > 0$ for all $i<j$.

From methods in Ref. 7, augmented as in Ref. 8, one can prove that the collection of all such functions, with fixed $I, f_i, t_{i,j}$, and with functions ψ_i fixed in $B(0,R)\backslash\Omega$ such that $\max \psi_i = \max_{\partial\Omega} \psi_i$, is weakly closed in $H_0^1(B(0,R))$ (and thus, as in Lemma 3, the collection restricted to Ω is weakly closed in $H^1(\Omega)$). Condition (9) is satisfied due to the inequality $\int_{B(0,R)} \psi^2 \leqslant c \int_{B(0,R)} |\nabla \psi|^2$ which holds due to $\psi \in H_0^1(B(0,R))$. Also it is easy to see that such a collection is closed under smooth domain variations of Ω as in Definition 1. Thus our present results apply so there is a minimizer ψ satisfying various regularity properties. Note the appearance of Lipschitz functions f_i both in Theorem 1 and in the decomposition above. More importantly the decomposition in some sense encodes topological information in that the level sets of ψ can be reconstructed from the level sets of the functions ψ_i, after taking into account the constants $t_{i,j}$ and the "folding" effect of the functions f_i. It remains, however, to analyze the set on which $\nabla\psi$ is discontinuous. This is left to Ref. 8 where a fairly simple example is used to illustrate a general approach to studying discontinuities.

IV. STATIONARY POINTS

Lemma 1 deals with energy minimizers. However, the proof carries over to stationary points of the energy defined in the following manner. Thus all our results carry over to this more general situation.

Definition 2: A function $\psi_0 \in H^1(\Omega)$ is a stationary point of

$$E(\psi) = \int_\Omega |\nabla \psi|^2, \tag{47}$$

with respect to local smooth domain variations if for any $p_0 \in \Omega$ there exists $r, 0<r<\operatorname{dist}(p_0, \partial\Omega)$ such that

$$\frac{d}{dt} E(\psi_t)\bigg|_{t=0} = 0, \tag{48}$$

for all $\psi_t, \psi_t(p,t) = \psi_0(X(p,t))$, X being any smooth map $X:\Omega\times(-\epsilon,\epsilon)\to\Omega$ defined for some $\epsilon>0$ such that $X(\cdot,0)=I$ (I the identity map) and $X(\cdot,t)$ is a diffeomorphism of Ω onto Ω for each t, such that $X(p,t)=p$ for all $p \in \Omega\backslash B(p_0,r)$ and $t \in (-\epsilon,\epsilon)$.

Theorem 2: *If ψ is a stationary point of E then $(\partial\psi/\partial x - i\partial\psi/\partial y)^2$ is a complex analytic function (after possible redefinition of $\nabla\psi$ on a set of Lebesgue measure zero), and consequently Lemma 2, Theorem 1, and Corollary 1 hold for ψ.*

Proof: Given $p_0 \in \Omega$ let r be as in the statement of the theorem. Given $w \in C_0^\infty(B(p_0,r)) \times C_0^\infty(B(p_0,r))$ let $d_t(p) = p + tw(p)$. Thus there exists $\epsilon > 0$ such that for all $|t| < \epsilon$ the map d_t is a smooth diffeomorphism from Ω onto Ω with $\det Dd_t \geqslant c > 1/2$. Consequently $X(\cdot,t) = d_t^{-1}$ satisfies the conditions in Definition 2 so

$$\frac{d}{dt} E(\psi_t)\bigg|_{t=0} = 0, \tag{49}$$

for ψ_t defined by $\psi_t(p,t) = \psi_0(X(p,t))$ for $(p,t) \in \Omega \times (-\epsilon, \epsilon)$. The argument is completed as in the proof of Lemma 1.

(Received 30 May 2002; accepted 8 July 2002)

Using a recently developed image representation for Stokes flow in a half-space bounded by a planar wall [Cichocki and Jones, Physica A **258**, 273 (1998)], the image system is constructed for the flow field produced by a force multipole in the space bounded by two parallel walls. The image singularities are expressed in terms of products of double-reflection matrices, and the expansion is simplified using symmetries of the double-reflection operation. Our analysis yields recurrence relations for the strengths of the image multipoles. The relations are solved explicitly, and a complete image system is obtained for an arbitrary source-force multipole. Applications of our image representation for evaluating the hydrodynamic friction and mobility matrices of particles interacting with two parallel planar walls are indicated. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1508812]

I. INTRODUCTION

Dynamics of particles suspended in a viscous fluid that occupies the space bounded by a planar interface[1–8] or two planar walls[9–15] has recently attracted much attention. Hydrodynamic interactions of particles in such geometries are affected by the flow field reflected from the walls. An important tool for investigating particle motion in wall-bounded systems is the image representation of the reflected flow.[16]

The Stokes flow reflected from a single no-slip wall was originally discussed by Lorentz,[17] and the image of a Stokeslet was derived by Blake.[18] Recently, a complete image representation for a force multipole of an arbitrary order was obtained by Cichocki and Jones.[4] This image representation was used to determine single-particle[4] and many-particle[8] friction and mobility coefficients for the motion of spherical particles near a rigid wall.

In the present article we derive the image representation for a flow field generated by a force multipole between two parallel rigid walls. In an earlier study,[19] the image solution was considered only for a special case of Stokeslet, but a complete multiple-reflection singularity representation was not found. The difficulty of the analysis stems from the form of the one-wall solution: unlike the reflection of an electrostatic charge multipole from a conducting plane, the image of a force multipole of an order l involves a combination of multipoles of orders $l' \neq l$. For this reason, the multiple-reflection series for Stokes flow in a space bounded by two parallel walls involves complicated combinations of image multipoles of different orders and strengths, placed at the positions corresponding to multiple mirror reflections of the source in the bounding planes.

A key ingredient of our analysis is the double-reflection identity that results from a symmetry between the source and the image flows in a system with a single reflection plane. Both of these flows satisfy Stokes equations, and their sum vanishes on the plane; thus, the reflection operation applied twice, first to the source and then to the image flow, yields the original source flow. The double-reflection identities are used to simplify the multiple-reflection sequences in a two-wall system and to derive simple recurrence relations for the strength of the image force multipoles. The recurrence relations are solved explicitly.

This article is organized as follows. In Sec. II, basic notation is introduced, and image singularities are represented in terms of a complete set of Stokes-flow fields. The image representation for a force multipole in a system with a single wall is discussed in Sec. III, where the double-reflection identities are derived. The identities are used in Sec. IV to obtain the image solution for a force multipole between two walls. The results are discussed in Sec. V.

II. FORMULATION

We consider Stokes flow produced by a multipolar force distribution $\mathbf{F}$ located at $\mathbf{r}=0$ in a region bounded by two infinite parallel planar walls (a) and (b) located at

$$z=-h^{(a)}, \quad z=h^{(b)}. \tag{2.1}$$

At the walls, the flow field $\mathbf{u}$ satisfies no-slip boundary conditions.

The incident flow $\mathbf{v}$, produced by the force distribution $\mathbf{F}$ in infinite space, can be expanded in a complete set of basis solutions of Stokes equations. We choose here the representation introduced by Cichocki *et al.*,[20]

$$\mathbf{v}(\mathbf{r})=\sum_{lm\sigma} f_{lm\sigma}\mathbf{v}^{-}_{lm\sigma}(\mathbf{r}), \tag{2.2}$$

where $f_{lm\sigma}$ are the multipole moments of the distribution $\mathbf{F}$, and the basis velocity fields are of the form

$$\mathbf{v}^{-}_{lm\sigma}(\mathbf{r})=\mathbf{V}_{lm\sigma}(\theta,\phi)r^{-(l+\sigma)}. \tag{2.3}$$

Here (r,θ,ϕ) represent vector $\mathbf{r}$ in spherical coordinates, and the indices assume values $l=1,2,\ldots$; $m=-l,\ldots,l$; and $\sigma=0,1,2$. The functions $\mathbf{V}_{lm\sigma}(\theta,\phi)$ are combinations of vector spherical harmonics with angular and azimuthal quantum numbers l and m. This property and the r-dependence in Eq. (2.3) define the functions $\mathbf{v}^{-}_{lm\sigma}(\mathbf{r})$ up to a normalization constant; we use here the same normalization as in Ref. 20. Explicit expressions for the functions $\mathbf{V}_{lm\sigma}(\theta,\phi)$ are listed in Appendix A.

In the presence of the walls, the reflected flow field

$$\mathbf{v}_{\mathrm{s}}=\mathbf{u}-\mathbf{v} \tag{2.4}$$

can be represented in terms of image singularities. In a system with the source singularity at $\mathbf{r}_{\mathrm{s}}=z_{\mathrm{s}}\mathbf{e}_z$ and a single wall at $z=z_{\mathrm{w}}$, the image singularity is at $\mathbf{r}_{\mathrm{i}}=(2z_{\mathrm{w}}-z_{\mathrm{s}})\mathbf{e}_z$, and

$$\mathbf{v}_{\mathrm{s}}(\mathbf{r})=\sum_{lm\sigma} f^{*}_{lm\sigma}\mathbf{v}^{-}_{lm\sigma}(\mathbf{r}-\mathbf{r}_{\mathrm{i}}), \tag{2.5}$$

where $f^{*}_{lm\sigma}$ are the multipole moments of the image, and $\mathbf{e}_z$ is the unit vector in the z direction.

For two walls, the image representation can be obtained from (2.5) in a form of a multiple-reflection sequence. Accordingly,

$$\mathbf{v}_{\mathrm{s}}(\mathbf{r})=\sum_{\alpha=a,b}\sum_{i=1}^{\infty}\mathbf{v}_{\mathrm{s}}^{(i\alpha)}(\mathbf{r}), \tag{2.6}$$

where

$$\mathbf{v}_{\mathrm{s}}^{(i\alpha)}(\mathbf{r})=\sum_{lm\sigma} f^{(i\alpha)}_{lm\sigma}\mathbf{v}^{-}_{lm\sigma}(\mathbf{r}-\mathbf{r}^{(i\alpha)}). \tag{2.7}$$

For the geometry (2.1), the positions of the image singularities are $\mathbf{r}^{(i\alpha)}=H^{(i\alpha)}\mathbf{e}_z$, with

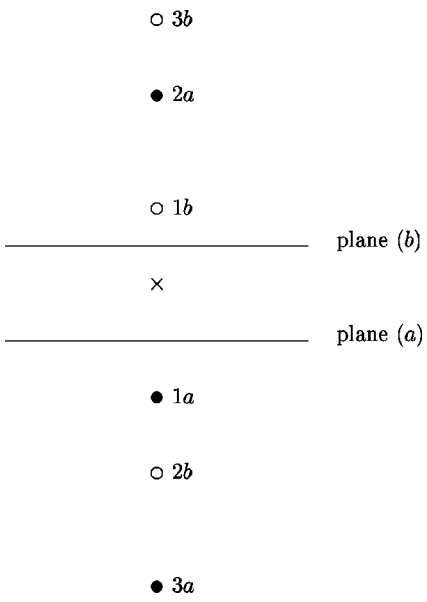

FIG. 1. Positions $\mathbf{r}^{(ia)}$ and $\mathbf{r}^{(ib)}$ $(i=1,2,\ldots)$ of image singularities in two families (a) and (b).

$$\begin{aligned} H^{(2r\,a)}&=2rh, \quad H^{(2r+1\,a)}=-2(h^{(a)}+rh),\\ H^{(2r\,b)}&=-2rh, \quad H^{(2r+1\,b)}=2(h^{(b)}+rh), \end{aligned} \tag{2.8}$$

where $h=h^{(a)}+h^{(b)}$ is the distance between walls, $H^{(0a)}=H^{(0b)}=0$ describes the position of the source singularity, and the index $r=0,1,2...$ characterizes the double-reflection order. The family of images at $\mathbf{r}^{(i\alpha)}$, $i=1,2,\ldots$, corresponds to the multiple-reflection sequence with the initial reflection on the plane (α), as illustrated in Fig. 1. The explicit expressions for the multipole moments $f^{(i\alpha)}_{lm\sigma}$ are derived in the following sections.

III. SINGLE-REFLECTION MATRIX

A. Multipoles of image force

By linearity of Stokes equations, the multipole moments of the source and image force distributions are linearly related,

$$f^{*}_{lm\sigma}=\sum_{l'm'\sigma'} R(H,lm\sigma|l'm'\sigma')f_{l'm'\sigma'}, \tag{3.1}$$

where R is the reflection matrix, and $H=z_{\mathrm{s}}-z_{\mathrm{w}}$ describes the relative position of the source singularity and the wall. The explicit form of the reflection matrix has recently been derived by Cichocki and Jones,[4] and we follow here their notation.

The successive images in the families $\alpha=a,b$ are obtained by a sequence of reflections

$$f^{(i\alpha)}_{lm\sigma}=\sum_{l'm'\sigma'} R(H^{(i-1\alpha)}_{\mathrm{w}},lm\sigma|l'm'\sigma')f^{(i-1\alpha)}_{l'm'\sigma'}, \quad i=1,2,\ldots, \tag{3.2}$$

where

$$H^{(i\alpha)}_{\mathrm{w}}=\tfrac{1}{2}(H^{(i\alpha)}-H^{(i+1\alpha)}). \tag{3.3}$$

The reflection is on the plane α for $i=2r+1$ and at the plane $\beta\neq\alpha$ for $i=2r$.

B. Structure of reflection matrix

Due to the rotational symmetry with respect to the axis z, the matrix R is diagonal in the angular quantum number m,

$$R(H,lm\sigma|l'm'\sigma')=R(H,lm\sigma|l'm\sigma')\,\delta_{mm'}. \tag{3.4}$$

The dependence of $R(H,lm\sigma|l'm'\sigma')$ on the relative coordinate H and the azimuthal quantum numbers l, l' can be derived from the Lorentz's reflection formula[16,17] for the reflected field,

$$\mathbf{v}_s=\hat{\mathrm{P}}(\hat{\mathbf{R}}_0+H\hat{\mathbf{R}}_1+H^2\hat{\mathbf{R}}_2)\cdot\mathbf{v}, \tag{3.5}$$

where

$$\hat{\mathbf{R}}_0=-\mathbf{I}_z-2\bar{z}\boldsymbol{\nabla}\mathbf{e}_z+\bar{z}^2\nabla^2\mathbf{I}, \tag{3.6}$$

$$\hat{\mathbf{R}}_1=-2\boldsymbol{\nabla}\mathbf{e}_z+2\bar{z}\nabla^2\mathbf{I}, \tag{3.7}$$

$$\hat{\mathbf{R}}_2=\nabla^2\mathbf{I}. \tag{3.8}$$

In the above relations, $\bar{z}=z-z_s$ is the coordinate relative to the source position, $\mathbf{I}$ is the identity tensor, $\mathbf{I}_z=\mathbf{I}-2\mathbf{e}_z\mathbf{e}_z$, and $\hat{\mathrm{P}}$ is the reflection operator with respect to the plane $z=z_w$,

$$[\hat{\mathrm{P}}\mathbf{w}](x,y,z)=\mathbf{I}_z\cdot\mathbf{w}(x,y,2z_w-z). \tag{3.9}$$

Since the operators (3.6)–(3.8) can be decomposed into a linear combination of tensor operators with azimuthal quantum numbers $l''\leqslant 2$, the matrix elements (3.4) vanish for $|l-l'|>2$, because of the triangle property of Clebsch–Gordan coefficients.[21] Moreover, operators $\hat{\mathbf{R}}_i$ are homogeneous of the order $-i$ in $\mathbf{r}$, according to Eqs. (3.6)–(3.8). It thus follows from relations (2.3) and (3.5) that

$$\begin{aligned}R(H,n-\sigma\ m\ \sigma|n'-\sigma'\ m\ \sigma')=&R_{n\,n}(\sigma\sigma',m)\,\delta_{n'n}+HR_{n\,n-1}(\sigma\sigma',m)\,\delta_{n'n-1}\\&+H^2R_{n\,n-2}(\sigma\sigma',m)\,\delta_{n'n-2}.\end{aligned} \tag{3.10}$$

The explicit expressions for the matrix elements $R_{n\,n'}(\sigma\sigma',m)$ are listed in Appendix B.

C. Reduced matrix notation

Relations (3.4) and (3.10) allow us to introduce a compact matrix notation. Accordingly, we define a vector space $\mathcal{S}$ of infinite column vectors f with components f_n $(n=1,2,\ldots)$, where each component itself consists of three components $\mathsf{f}_n(\sigma)$ $(\sigma=0,1,2)$. We also define matrices A acting in $\mathcal{S}$: each element $\mathsf{A}_{n\,n'}$ of such a matrix is itself a three-dimensional matrix with the elements $\mathsf{A}_{n\,n'}(\sigma\sigma')$. In the space $\mathcal{S}$, the products Af and AB are defined in a natural way,

$$(\mathsf{Af})_n=\sum_{n'=1}^{\infty}\mathsf{A}_{n\,n'}\mathsf{f}_{n'},\quad (\mathsf{AB})_{n\,n''}=\sum_{n'=1}^{\infty}\mathsf{A}_{n\,n'}\mathsf{B}_{n'n''}, \tag{3.11}$$

where $\mathsf{A}_{n\,n'}\mathsf{f}_{n'}$ and $\mathsf{A}_{n\,n'}\mathsf{B}_{n'n''}$ are the inner products in the corresponding three-dimensional space.

In this notation, the single-reflection matrix (3.10) is represented by the matrix $\mathsf{R}(H)$ with a three-diagonal structure

$$\mathsf{R}_{n\,n-i}(H)=\begin{cases}H^i\bar{\mathsf{R}}_{n\,n-i}, & i=0,1,2,\\ 0, & \text{otherwise},\end{cases} \tag{3.12}$$

where

$$\bar{\mathsf{R}}_{n\,n'}(\sigma\sigma') = R_{n\,n'}(\sigma\sigma', m). \tag{3.13}$$

The arrays of source and image multipoles are represented by the arrays f and f^* with elements

$$\mathsf{f}_n(\sigma) = f_{n-\sigma\,m\,\sigma}, \quad \mathsf{f}^*_n(\sigma) = f^*_{n-\sigma\,m\,\sigma}. \tag{3.14}$$

Taking into account diagonal form (3.4) of the matrix R, relation (3.1) can be rewritten as

$$\mathsf{f}^* = \mathsf{R}(H)\mathsf{f}, \tag{3.15}$$

where, for simplicity, the dependence on the index m is not indicated.

D. Double-reflection identities

The reflection of the image f^* with respect to the plane of the original reflection returns the source force distribution f. This symmetry and Eq. (3.15) imply the double-reflection identity

$$\mathsf{R}(-H)\mathsf{R}(H) = \mathsf{I}^{\mathcal{S}}, \tag{3.16}$$

where $\mathsf{I}^{\mathcal{S}}$ is the unit matrix in the space $\mathcal{S}$. For the individual matrix components (3.12), Eq. (3.16) yields

$$\bar{\mathsf{R}}_{n\,n}\bar{\mathsf{R}}_{n\,n} = \mathsf{I}, \tag{3.17}$$

$$\bar{\mathsf{R}}_{n\,n-1}\bar{\mathsf{R}}_{n-1\,n-1} - \bar{\mathsf{R}}_{n\,n}\bar{\mathsf{R}}_{n\,n-1} = 0, \tag{3.18}$$

$$\bar{\mathsf{R}}_{n\,n-2}\bar{\mathsf{R}}_{n-2\,n-2} - \bar{\mathsf{R}}_{n\,n-1}\bar{\mathsf{R}}_{n-1\,n-2} + \bar{\mathsf{R}}_{n\,n}\bar{\mathsf{R}}_{n\,n-2} = 0, \tag{3.19}$$

$$\bar{\mathsf{R}}_{n\,n-2}\bar{\mathsf{R}}_{n-2\,n-3} - \bar{\mathsf{R}}_{n\,n-1}\bar{\mathsf{R}}_{n-1\,n-3} = 0, \tag{3.20}$$

$$\bar{\mathsf{R}}_{n\,n-2}\bar{\mathsf{R}}_{n-2\,n-4} = 0, \tag{3.21}$$

where I is the identity matrix in three dimensions corresponding to indices σ, σ' in the relation (3.13).

IV. TWO WALL SOLUTION

A. Double-reflection expansion

The double-reflection identities (3.17)–(3.21) can be used to derive explicit expressions for the multipolar moments of the image singularities $f^{(i\alpha)}_{lm\sigma}$ in the two-wall system. The problem is formulated in terms of multiple-reflection matrices $\mathsf{R}^{(i\alpha)}$, which are defined by the linear relation

$$\mathsf{f}^{(i\alpha)} = \mathsf{R}^{(i\alpha)}(h^{(\alpha)}, h)\mathsf{f}, \tag{4.1}$$

where the dependence of R on the wall position (2.1) and the separation of the walls are indicated. The array $\mathsf{f}^{(i\alpha)}$ is related to the elements $f^{(i\alpha)}_{lm\sigma}$ as implied by Eq. (3.14). By invariance with respect to the transformation $z \to -z$, the reflection matrices representing two families of images (a) and (b) are related,

$$\mathsf{R}^{(ib)}(H, h) = \mathsf{R}^{(ia)}(-H, -h). \tag{4.2}$$

In what follows, we thus consider only the family $\alpha = a$, and we set $H = h^{(a)}$.

The structure of matrices $\mathsf{R}^{(ia)}$ is analyzed by factorizing them into a double-reflection sequence. To this end, we introduce abbreviated notation

$$\mathsf{R}^{(2r\,a)}(H,h)=\mathsf{P}^{(r)} \tag{4.3}$$

and

$$\mathsf{R}^{(2r+1\,a)}(H,h)=\tilde{\mathsf{P}}^{(r)}. \tag{4.4}$$

Equations (3.2) and (4.1) imply that the odd-reflection matrices can be obtained from the relation

$$\tilde{\mathsf{P}}^{(r)}=\mathsf{R}(H_r)\mathsf{P}^{(r)}, \tag{4.5}$$

and the even-reflection matrices can be factorized

$$\mathsf{P}^{(r)}=\prod_{i=1}^{r}\mathsf{Q}(H_{i-1}). \tag{4.6}$$

Here

$$H_r=H+2rh \tag{4.7}$$

is the distance between the plane (a) and the image at the position $\mathbf{r}^{(2r\,a)}$, consistent with Eq. (3.3). The double-reflection matrix is defined

$$\mathsf{Q}(H)=\mathsf{R}(-H-h)\mathsf{R}(H), \tag{4.8}$$

and the order of the matrix product is $\Pi_{i=1}^{k}\mathsf{M}_i=\mathsf{M}_k\ldots\mathsf{M}_1$.

B. Simplified form of even-reflection matrices

Definitions (4.6) and (4.8) imply that the even-reflection matrix has the following structure,

$$\mathsf{P}^{(r)}_{n\,n'}=\sum_{\{n_j\}}\left[\alpha(\{n_j\})\prod_{k=1}^{2r}\bar{\mathsf{R}}_{n_k\,n_{k-1}}\right], \tag{4.9}$$

where the summation is over all sets $\{n_j\}$ of integer elements n_j $(j=0,1,\ldots,2r)$ that satisfy relations

$$n_0=n',\quad n_{2r}=n,\quad n_j-n_{j-1}=0,1,2. \tag{4.10}$$

The matrix $\mathsf{P}^{(r)}_{nn'}$ depends on H and h only through the coefficients

$$\alpha(\{n_j\})=\prod_{i=1}^{r}\left[(-h-H_{i-1})^{n_{2i}-n_{2i-1}}H_{i-1}^{n_{2i-1}-n_{2i-2}}\right], \tag{4.11}$$

which can be shown using Eq. (3.12).

Equation (4.9) can be considerably simplified by using the double-reflection identities (3.17)–(3.21). Accordingly, the commutation relations (3.18) and (3.20) are used to shift matrices $\bar{\mathsf{R}}_{k\,k-1}$ to the left; in the resulting formula products $\bar{\mathsf{R}}_{k\,k-1}\bar{\mathsf{R}}_{k-1\,k-2}$ are eliminated using (3.19), and products $\bar{\mathsf{R}}_{k\,k}\bar{\mathsf{R}}_{k\,k}$ and $\bar{\mathsf{R}}_{k\,k-2}\bar{\mathsf{R}}_{k-2\,k-4}$ are reduced using (3.17) and (3.21). Following this procedure, the even-reflection matrices $\mathsf{P}^{(r)}_{n\,n'}$ can be represented as linear combinations

$$\mathsf{P}^{(r)}_{n\,n-2s}=a(r,s)\mathsf{A}_{n\,n-2s}+b(r,s)\mathsf{B}_{n\,n-2s}, \tag{4.12}$$

$$\mathsf{P}^{(r)}_{n\,n-2s-1}=c(r,s)\mathsf{C}_{n\,n-2s-1}+d(r,s)\mathsf{D}_{n\,n-2s-1}, \tag{4.13}$$

where

$$\mathsf{A}_{n\,n}=\mathsf{B}_{n\,n}=\mathsf{I}, \tag{4.14}$$

$$\mathsf{A}_{n\,n-2s}=\prod_{i=n-2s}^{n-2}{}' \ (\bar{\mathsf{R}}_{i+2\,i}\bar{\mathsf{R}}_{i\,i}), \quad s=1,2,\ldots, \tag{4.15}$$

$$\mathsf{B}_{n\,n-2s}=\prod_{i=n-2s}^{n-2}{}' \ (\bar{\mathsf{R}}_{i+2\,i+2}\bar{\mathsf{R}}_{i+2\,i}), \quad s=1,2,\ldots, \tag{4.16}$$

$$\mathsf{C}_{n\,n-2s-1}=\bar{\mathsf{R}}_{n\,n}\bar{\mathsf{R}}_{n\,n-1}\mathsf{A}_{n-1\,n-1-2s}, \quad s=0,1,\ldots, \tag{4.17}$$

$$\mathsf{D}_{n\,n-2s-1}=\bar{\mathsf{R}}_{n\,n-1}\bar{\mathsf{R}}_{n-1\,n-3}\mathsf{B}_{n-3\,n-3-2(s-1)}, \quad s=1,2,\ldots, \tag{4.18}$$

and the remaining elements of $\mathsf{A}_{n\,n'}$, $\mathsf{B}_{n\,n'}$, $\mathsf{C}_{n\,n'}$, $\mathsf{D}_{n\,n'}$ are set equal to zero.

Explicit expressions for the matrices A, B are given in Appendix C; the matrices C and D can be obtained from these results using Eqs. (4.17) and (4.18) and the expressions listed in Appendix B. The scalar coefficients a, b, c, and d are evaluated in the following section.

C. Recurrence relations

To proceed with our analysis, we rewrite Eq. (4.6) in the form

$$\mathsf{P}^{(r+1)}=\mathsf{Q}(H_r)\mathsf{P}^{(r)}, \tag{4.19}$$

which in the component notation yields

$$\mathsf{P}^{(r+1)}_{n\,n-q}=\sum_{p=0}^{4}\mathsf{Q}_{n\,n-p}(H_r)\mathsf{P}^{(r)}_{n-p\,n-q}, \tag{4.20}$$

according to Eqs. (4.8) and (3.12). The elements of the matrix Q are simplified by using the double-reflection identities (3.17)–(3.21). It follows that

$$\mathsf{Q}_{n\,n}(H)=I, \tag{4.21}$$

$$\mathsf{Q}_{n\,n-1}(H)=-h\bar{\mathsf{R}}_{n\,n}\bar{\mathsf{R}}_{n\,n-1}, \tag{4.22}$$

$$\mathsf{Q}_{n\,n-2}(H)=h[(H+h)\bar{\mathsf{R}}_{n\,n-2}\bar{\mathsf{R}}_{n-2\,n-2}-H\bar{\mathsf{R}}_{n\,n}\bar{\mathsf{R}}_{n\,n-2}], \tag{4.23}$$

$$\mathsf{Q}_{n\,n-3}(H)=hH(H+h)\bar{\mathsf{R}}_{n\,n-1}\bar{\mathsf{R}}_{n-1\,n-3}, \tag{4.24}$$

$$\mathsf{Q}_{n\,n-4}(H)=0, \tag{4.25}$$

and all other elements $\mathsf{Q}_{n\,n'}$ vanish. Two pairs of coupled recurrence relations for the coefficients a, b, c, d in Eqs. (4.12) and (4.13) are derived from relation (4.20) by using the above expressions for Q and definitions (4.14)–(4.18),

$$\begin{aligned}a(r+1,s)=a(r,s)-h\,c(r,s-1)+h(h+H_r)[\delta_{s1}+(1-\delta_{s1})a(r,s-1)]\\ +h(h+H_r)\,H_r c(r,s-2),\end{aligned} \tag{4.26}$$

$$c(r+1,s)=c(r,s)-h[\delta_{s0}+(1-\delta_{s0})a(r,s)]-h\,H_r c(r,s-1), \tag{4.27}$$

and

$$b(r+1,s)=b(r,s)-h[d(r,s-1)-rh\delta_{s1}]-h\,H_r[\delta_{s1}+(1-\delta_{s1})b(r,s-1)], \tag{4.28}$$

$$\begin{aligned} d(r+1,s)=&d(r,s)-h(1-\delta_{s0})b(r,s)+h\,(h+H_r)[d(r,s-1)-rh\delta_{s1}]\\ &+h(h+H_r)\,H_r[\delta_{s1}+(1-\delta_{s1})b(r,s-1)]. \end{aligned} \tag{4.29}$$

The initial conditions for the above relations are obtained from the identity

$$\mathsf{P}^{(1)}_{nn'}=\mathsf{Q}_{n\,n'}(H) \tag{4.30}$$

and Eqs. (4.21)–(4.25), which imply

$$\begin{gathered} a(1,0)=1,\quad a(1,1)=h(h+H),\\ b(1,0)=0,\quad b(1,1)=-hH,\\ c(1,0)=-h,\quad c(1,1)=0,\\ d(1,0)=0,\quad d(1,1)=h(h+H)H, \end{gathered} \tag{4.31}$$

and

$$a(1,s)=b(1,s)=c(1,s)=d(1,s)=0,\qquad \text{for}\quad s>1\quad\text{or}\quad s<0. \tag{4.32}$$

We assumed here $a(1,0)=1$; however, because of Eq. (4.14), only $a(1,0)+b(0,1)=1$ is required.

The recurrence relations (4.26)–(4.29) with initial conditions (4.31) and (4.32) can be explicitly solved. It can be verified by induction that the solution is

$$a(r,s)=\frac{(-1)^{s+1}(r+s-1)!}{(2s)!(r-s)!}h^{2s-1}[2sH+(4sr-r-s)h], \tag{4.33}$$

$$b(r,s)=\frac{(-1)^{s}(r+s-1)!}{(2s)!(r-s)!}h^{2s-1}[2sH+(r-s)h](1-\delta_{s0}), \tag{4.34}$$

$$c(r,s)=\frac{(-1)^{s+1}(r+s)!}{(2s+1)!(r-s-1)!}h^{2s+1}, \tag{4.35}$$

$$\begin{aligned} d(r,s)=&\frac{(-1)^{s+1}(r+s-1)!}{(2s+1)!(r-s)!}h^{2s-1}\{2s(2s+1)[H^2+(2r-1)Hh]\\ &+(r-s)(r-s+4rs)h^2\}(1-\delta_{s0}). \end{aligned} \tag{4.36}$$

Using in the above equations the relation $k!=\infty$ for $k=-1,-2,\ldots$, we find

$$a(r,s)=b(r,s)=c(r,s)=d(r,s)=0,\qquad \text{for}\quad s<0,\quad\text{or}\quad s>r, \tag{4.37}$$

which is equivalent to

$$\mathsf{P}^{(r)}_{n\,n-q}=0\qquad \text{for}\quad q<0\quad\text{or}\quad q>2r+1. \tag{4.38}$$

The limit $r\to 0$ yields relations $a(0,0)+b(0,0)=1$ and $c(0,0)=d(0,0)=0$ corresponding to $\mathsf{P}^{(0)}=\mathsf{I}^{\mathcal{S}}$.

D. Odd-reflection matrices

Odd-reflection matrices $\tilde{\mathsf{P}}^{(r)}$ can be evaluated from our solution for the even-reflection problem. By inserting relations (4.12) and (4.13) into (4.5) and using identities (3.17)–(3.21), we find

$$\tilde{\mathsf{P}}^{(r)}_{n\,n-2s}=\tilde{a}(r,s)\bar{\mathsf{R}}_{n\,n}\mathsf{A}_{n\,n-2s}+\tilde{b}(r,s)\bar{\mathsf{R}}_{n\,n-2}\mathsf{B}_{n-2\,n-2s}, \tag{4.39}$$

$$\tilde{\mathsf{P}}^{(r)}_{n\,n-2s-1}=\tilde{c}(r,s)\bar{\mathsf{R}}_{n\,n-1}\mathsf{A}_{n-1\,n-2s-1}+\tilde{d}(r,s)\bar{\mathsf{R}}_{n\,n-1}\mathsf{B}_{n-1\,n-2s-1}, \tag{4.40}$$

where

$$\tilde{a}(r,s)=a(r,s)+H_r c(r,s-1), \tag{4.41}$$

$$\tilde{b}(r,s)=b(r,s)+H_r[d(r,s-1)+c(r,0)\,\delta_{s1}]+H_r^2[b(r,s-1)+\delta_{s1}], \tag{4.42}$$

$$\tilde{c}(r,s)=c(r,s)+H_r a(r,s)+H_r^2 c(r,s-1), \tag{4.43}$$

$$\tilde{d}(r,s)=d(r,s)+H_r b(r,s). \tag{4.44}$$

The above expressions, along with the results (4.12)–(4.18) and (4.33)–(4.36) for $\mathsf{P}^{(r)}$, provide a complete image representation of the flow reflected from the walls.

V. CONCLUSIONS

We have explored the structure of the multiple-reflection series for a Stokes-flow singularity in the space bounded by two parallel planar walls. Explicit expressions for the multipole moments of the images were derived using the symmetry properties of the reflection matrices to simplify the problem.

Accordingly, symmetries of the Lorentz's reflection operator were applied to show that the single-reflection matrix R has a lower-triangular/tri-diagonal structure in a properly chosen basis. The symmetry between the source and image singularities was shown to yield commutation identities for the elements of R. These identities were used to simplify the matrices $\mathsf{P}^{(r)}$ that represent even-order reflections of the flow field from the walls. In this form, $\mathsf{P}^{(r)}$ depends on the position of the source singularity and the reflection order r only through scalar prefactors, which are independent of the multipolar order l of the source. The prefactors were evaluated using recurrence formulas associated with subsequent even-order reflections.

Our image representation can be applied in investigations that involve the motion of particles suspended in a fluid confined between two parallel walls. Such problems include particle dynamics in highly asymmetric colloidal mixtures[22] and suspension flows in slit pores.[9–15] Single- and multi-particle mobility matrices for particles between two walls can be evaluated using the induced-force representation of the particles[23] and our image solution for the flow reflected from the walls. By this approach, the force multipoles induced on the particles are determined using appropriate multipole-expansion algorithms.[8,24] Our image representation can also be used to develop boundary-integral algorithms[25] for the motion of deformable drops between two walls.

Extensions of our work may include derivation of an image solution for a force multipole in a space bounded by two planar surfactant-free[1] or surfactant-covered[5] fluid-fluid interfaces. Such solutions would be useful in investigations of the dynamics of colloidal-particle- or micelle-stabilized thin liquid films.[26,27]

APPENDIX A: FUNDAMENTAL SET OF VELOCITY FIELDS

Following definitions given in Ref. 20, we list expressions for the functions $\mathbf{V}_{lm\sigma}(\theta,\phi)$ that characterize angular dependence of the velocity fields (2.3):

$$\mathbf{V}_{lm0}=\frac{1}{(2l+1)^2}\left[\frac{l+1}{l(2l-1)}\hat{\mathbf{A}}_{lm}-\frac{1}{2}\hat{\mathbf{B}}_{lm}\right], \tag{A1}$$

$$\mathbf{V}_{lm1}=\frac{\mathrm{i}}{l(l+1)(2l+1)}\hat{\mathbf{C}}_{lm}, \tag{A2}$$

$$\mathbf{V}_{lm2}=\frac{l}{(l+1)(2l+1)^2(2l+3)}\hat{\mathbf{B}}_{lm}. \tag{A3}$$

Here

$$\hat{\mathbf{A}}_{lm}=r^{-l+1}\boldsymbol{\nabla}(r^l\hat{Y}_{lm}),\quad \hat{\mathbf{B}}_{lm}=r^{l+2}\boldsymbol{\nabla}(r^{-l-1}\hat{Y}_{lm}),\quad \hat{\mathbf{C}}_{lm}=\hat{\mathbf{A}}_{lm}\times\mathbf{e}_r \tag{A4}$$

(with $r=|\mathbf{r}|$ and $\mathbf{e}_r=\mathbf{r}/r$) are the unnormalized vector spherical harmonics, where

$$\hat{Y}_{lm}=(-1)^m P_l^m(\cos\theta)e^{im\phi} \tag{A5}$$

are the unnormalized scalar spherical harmonics.

APPENDIX B: ELEMENTS OF REFLECTION MATRIX

Here we list expressions for nonzero elements of the reflection matrix $\bar{\mathsf{R}}_{n\,n'}(\sigma\sigma')$, defined by Eqs. (3.10) and (3.13),

$$\bar{\mathsf{R}}_{n\,n}(00)=(-1)^{(n+m+1)}\left[1+\frac{2(n-2)(n+m)(n-m)}{n(2n-1)}\right], \tag{B1}$$

$$\bar{\mathsf{R}}_{n\,n}(01)=(-1)^{(n+m)}\frac{4m(n+m)}{n(n-1)}, \tag{B2}$$

$$\bar{\mathsf{R}}_{n\,n}(02)=(-1)^{(n+m+1)}\frac{4(n-2)(n+m)(n+m-1)}{(n-1)(2n-1)(2n-3)}, \tag{B3}$$

$$\bar{\mathsf{R}}_{n\,n}(10)=(-1)^{(n+m+1)}\frac{2(n-2)m(n-m)}{n(2n-1)}, \tag{B4}$$

$$\bar{\mathsf{R}}_{n\,n}(11)=(-1)^{(n+m+1)}\left[1-\frac{4m^2}{(n-1)n}\right], \tag{B5}$$

$$\bar{\mathsf{R}}_{n\,n}(12)=(-1)^{(n+m+1)}\frac{4(n-2)m(n-1+m)}{(n-1)(2n-3)(2n-1)}, \tag{B6}$$

$$\bar{\mathsf{R}}_{n\,n}(20)=(-1)^{(n+m)}\frac{(n+1)(2n-3)(n-m-1)(n-m)}{n(2n-1)}, \tag{B7}$$

$$\bar{\mathsf{R}}_{n\,n}(21)=(-1)^{(n+m+1)}\frac{2m(n+1)(2n-3)(n-m-1)}{(n-2)(n-1)n}, \tag{B8}$$

$$\bar{\mathsf{R}}_{n\,n}(22)=(-1)^{(n+m+1)}\left[1-\frac{2(n+1)(n-m-1)(n+m-1)}{(n-1)(2n-1)}\right], \tag{B9}$$

$$\bar{\mathsf{R}}_{n\,n-1}(00)=(-1)^{(n+m+1)}2(n+m), \tag{B10}$$

$$\bar{\mathsf{R}}_{n\,n-1}(10)=(-1)^{(n+m+1)}2m, \tag{B11}$$

$$\bar{\mathsf{R}}_{n\,n-1}(20)=(-1)^{(n+m)}4n(n-m-1), \tag{B12}$$

$$\bar{\mathsf{R}}_{n\,n-1}(21)=(-1)^{(n+m+1)}\frac{2m(2n-3)(2n-1)}{(n-2)^2}, \tag{B13}$$

$$\bar{\mathsf{R}}_{n\,n-1}(22)=(-1)^{(n+m)}\frac{2(n-3)(n-1)(2n-1)(n+m-2)}{(2n-5)(n-2)^2}, \tag{B14}$$

$$\bar{\mathsf{R}}_{n\,n-2}(20)=(-1)^{(n+m)}\frac{(n-1)(2n-3)(2n-1)}{n-2}. \tag{B15}$$

In the above expressions we set

$$\bar{\mathsf{R}}_{n\,n'}(\sigma\sigma')=0 \quad \text{for} \quad n'-\sigma'<1. \tag{B16}$$

Equations (B1)–(B15) are equivalent to Eqs. (A20) in Ref. 4.

APPENDIX C: PRODUCTS OF MATRICES $\bar{\mathsf{R}}$

Here we list expressions for nonzero elements of matrices A and B, defined by Eqs. (4.15) and (4.16),

$$\mathsf{A}_{n\,n-2s}=f(n,s)\mathsf{A}'_{n\,n-2s}, \tag{C1}$$

$$\mathsf{B}_{n\,n-2s}=f(n,s)\mathsf{B}'_{n\,n-2s}, \tag{C2}$$

where $s\geqslant 1$, and

$$f(n,s)=(-4)^s\frac{(n-1)(2n-1)(2n-3)}{n-2}\,\frac{(n+m-2)!}{(n+m-2s)!}, \tag{C3}$$

$$\mathsf{A}'_{n\,n-2s}(20)=\frac{1}{4}\left[1+\frac{2(n-2s-2)(n-2s-m)(n-2s+m)}{(2n-4s-1)(n-2s)}\right], \tag{C4}$$

$$\mathsf{A}'_{n\,n-2s}(21)=-\frac{m(m+n-2s)}{(n-2s-1)(n-2s)}, \tag{C5}$$

$$\mathsf{A}'_{n\,n-2s}(22)=\frac{(m+n-2s-1)(m+n-2s)(n-2s-2)}{(2n-4s-3)(2n-4s-1)(n-2s-1)}, \tag{C6}$$

$$\mathsf{B}'_{n\,n-2s}(00)=\frac{(n-2)(m+n)(m+n-1)}{(n-1)(2n-1)(2n-3)}, \tag{C7}$$

$$\mathsf{B}'_{n\,n-2s}(10)=\frac{(n-2)m(m+n-1)}{(n-1)(2n-1)(2n-3)}, \tag{C8}$$

$$\mathsf{B}'_{n\,n-2s}(20)=\frac{1}{4}\left[1-\frac{2(n+1)(n-m-1)(n+m-1)}{(n-1)(2n-1)}\right]. \tag{C9}$$

In the above expressions we set

$$\mathsf{A}_{n\,n'}(\sigma\sigma')=\mathsf{B}_{n\,n'}(\sigma\sigma')=0 \quad \text{for} \quad n'-\sigma'<1. \tag{C10}$$

Relations (C1)–(C10) can be verified by induction using definitions (4.15) and (4.16) and the expressions in Appendix B.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 11 NOVEMBER 2002

Bethe ansatz for the Gaudin model and its relation with Knizhnik–Zamolodchikov equations

Daniela Garajeu[a)]
Centre de Physique Théorique, CNRS-UPR 7061, Luminy, Case 907, F-13288 Marseille, Cedex 9, France

(Received 28 January 2002; accepted 13 May 2002)

We recall the construction of the common eigenvectors of Gaudin Hamiltonians based on the Bethe ansatz. In the case of an arbitrary Lie algebra, this construction can be done either recursively or explicitly and we prove the equivalence of the two methods. We also prove that Bethe vectors are singular only if the Bethe equations are satisfied. In each eigenspace of the spin operator we construct additional common eigenvectors, having the same eigenvalue as the vacuum vector and which can not be obtained by the Bethe ansatz. These eigenvectors are not singular. We also recall the connection between Bethe vectors and integral solutions of the KZ equation. In an analogous way, the additional vectors lead to solutions of KZ equation which are not singular vectors and do not have an integral representation. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1501168]

I. INTRODUCTION

The Gaudin model is an example of a statistical integrable model associated to a quantum interacting system. The prototype of such a model is the system of N spin particles with magnetic interaction. It was formulated as a spin model related to the Lie algebra SL(2). The set of N independent and commuting Hamiltonians which allows us to integrate this model with N degrees of freedom was proposed by Gaudin.[1] For this model two fundamental problems have been discussed. The first one is the integration of the Hamiltonian system by means of the classical methods: construction of action-angle variables, integration of equations of motion.[2] The second one is the diagonalization of the family of Hamiltonians. The present article is concerned with this second problem.

In the simplest case of the Lie algebra SL(2), the problem of the diagonalization of the Hamiltonians was first discussed by Gaudin.[3] Using the method introduced by Bethe,[4] known as the Bethe ansatz, Gaudin constructed common eigenstates for all Hamiltonians (Bethe sums) and obtained the corresponding eigenvalues.

Integrable systems can be associated to any semi-simple complex Lie algebra. For such a system, generalizations of the set of Gaudin Hamiltonians have been constructed.[5] The methods proposed for diagonalization of these Hamiltonians are based on a remarkable connection between integrable models and two dimensional conformal field theories.

In Ref. 5, the structure of the Bethe vectors for the Gaudin model is related to the representation theory of affine Lie algebras. The diagonalization of Gaudin Hamiltonians is based on a concept of invariant functionals (correlation functions) on the tensor product of representations of an affine Lie algebra at the critical level.

Another approach for the problem of diagonalization[6,7] is related to the connection between eigenvectors of the Gaudin Hamiltonians and the solutions[8] of the Knizhnik–Zamolodchikov (KZ) equations.[9] In this approach, the common eigenvectors are constructed inductively, and it is shown that each eigenvector leads to an integral solution of the KZ equations. Conversely, it was proved[10] that, in the quasi-classical limit, the first term of the asymptotic solutions of the KZ equation leads

a)Electronic mail: garajeu@cpt.univ-mrs.fr

to a common eigenvector of Hamiltonians. In this case the Bethe equations for the Gaudin model appear as conditions of critical points.

Another method to construct eigenvectors in statistical models associated to a simple Lie algebra G is to find a sequence of embeddings of Lie algebras into G and to solve inductively the problem of diagonalization of Hamiltonians for each subalgebra.[11]

In the second section we review some aspects concerning the Gaudin model, originally formulated for the Lie algebra SL(2). We recall the expression of the N commuting Hamiltonians, introduced by Gaudin and their common eigenvectors, constructed with the Bethe method. The space Ω of physical states is defined as a tensor product of N finite dimensional highest weight representations of the Lie algebra SL(2). It is decomposed as a direct sum of eigenspaces of the spin operator, i.e., $\Omega=\oplus\mathcal{V}_m$ and we search for common eigenvectors for Hamiltonians in each eigenspace $\mathcal{V}_m$.

With the Bethe ansatz, the number of common eigenvectors obtained in each subspace $\mathcal{V}_m$ is equal to the number of distinct solutions of the Bethe equations. A brief analysis of these equations shows that this constructive method does not provide all the common eigenvectors of Hamiltonians. There is at least one more vector in each subspace $\mathcal{V}_m$, common to all Hamiltonians, which can not be constructed with this method. The expression of such a vector is given as well as its eigenvalue. This result shows that the fundamental state is degenerate.

The third section is devoted to a discussion of the generalized model associated to an arbitrary simple Lie algebra. We recall the generalization of the Gaudin Hamiltonians and we explain how the Bethe ansatz works to construct common eigenvectors for these Hamiltonians. This construction can be done either recursively or explicitly. The main result of this section is the theorem which proves the equivalence of these two methods. The constructive method does not ensure the completeness of the system of eigenvectors. In each eigenspace of the spin operator we construct additional common eigenvectors, corresponding to the same eigenvalue as the vacuum vector and which can not be obtained by the Bethe ansatz.

The Bethe vectors are eigenvectors of the family of Hamiltonians only if the Bethe equations are satisfied and, in this case, we prove that they are also singular vectors in the tensor product representation. This is the main result of Sec. IV. The additional eigenvectors proposed here are not singular.

Section V recalls the connection between Bethe vectors and integral solutions of the KZ equation. In an analogous way, the additional vectors lead to solutions of the KZ equation which do not have an integral representation. Moreover, these solutions are not singular vectors.

Conclusions are presented in Sec. VI.

II. GAUDIN MODEL FOR SL(2) LIE ALGEBRA

In this section we recall the Gaudin model and Bethe ansatz procedure. Consider the Lie algebra SL(2) with generators E, F and H and commutation relations:

$$[E,F]=H;\quad [H,E]=2E;\quad [H,F]=-2F.$$

For this algebra, consider also N finite-dimensional highest weight modules: $V_{\lambda_1},\ldots,V_{\lambda_N}$ with highest weights $\lambda_1,\ldots,\lambda_N$ and highest weight vectors $v_{\lambda_1},\ldots,v_{\lambda_N}$.

The tensor product of these N modules is the space of physical states for a system of N spin particles:

$$\Omega=V_{\lambda_1}\otimes\cdots\otimes V_{\lambda_N}.$$

For each Lie algebra element A consider the following operator on the space Ω:

$$A^{(i)}=1\otimes\cdots\otimes A\otimes\cdots\otimes 1:\Omega\to\Omega,\quad A^{(i)}v_1\otimes\cdots\otimes v_N=v_1\otimes\cdots\otimes Av_i\otimes\cdots\otimes v_N, \qquad (1)$$

which acts as A on the ith module and as the identity operator on all other factors.

The system could be integrated if N independent and commuting Hamiltonians are found. Gaudin proposed a set of N Hamiltonians, which are operators on Ω depending on N distinct, complex parameters $z_1,\ldots,z_N$:

$$\mathcal{H}_i(z_1,\ldots,z_N)=\sum_{j=1,j\neq i}^{N}\frac{1}{z_i-z_j}\left[\frac{1}{2}H^{(i)}H^{(j)}+E^{(i)}F^{(j)}+F^{(i)}E^{(j)}\right],\quad \forall\ i=1,\ldots,N.$$

All these operators commute:

$$[\mathcal{H}_i,\mathcal{H}_j]=0,\quad \forall\ i,j=1,\ldots,N,$$

but they are not independent because $\Sigma_{i=1}^{N}\mathcal{H}_i=0$. We can prove that, up to a constant, this is the only vanishing linear combination of operators $\mathcal{H}_i$ with nonzero coefficients. As a consequence, this family of Hamiltonians is not enough to integrate a system of N spin particles. There is another family of commuting operators $\{H^{(i)}\}_{i=1,\ldots,N}$ introduced by the Cartan generator. Gaudin Hamiltonians do not commute with each $H^{(i)}$, but only with their sum, called the total spin operator:

$$\mathcal{S}=\sum_{i=1}^{N}H^{(i)}\quad\text{and}\quad[\mathcal{H}_i,\mathcal{S}]=0.$$

Then, there is a system of N commuting operators on Ω, which are independent. The problem discussed in this article is to find common eigenvectors for these operators. This can be done using the following ''general constructive procedure.''

Let A and B be two commuting operators on a finite dimensional space Ω. Suppose that for the operator A all the eigenvalues and the complete system of eigenvectors, which form a basis in Ω, are known. Denote by $\{a_n\}_n$ the spectrum of A, by g_n the multiplicity of a_n and by ϕ_{nr}, $r=1,\ldots,g_n$, the eigenvectors, $A\phi_{nr}=a_n\phi_{nr}$, which form a basis of the eigenspace $\mathcal{V}_n$ of A, associated to the eigenvalue a_n. If A and B commute, then $B\phi_{nr}$ is also an eigenvector for A, corresponding to the same eigenvalue a_n:

$$A(B\phi_{nr})=a_nB\phi_{nr}.$$

Therefore, $\mathcal{V}_n$ is an invariant subspace of B and the vector $B\phi_{nr}$, as an element of the eigenspace $\mathcal{V}_n$, has the following expansion:

$$B\phi_{nr}=\sum_{s=1}^{g_n}c_{sr}\phi_{ns}.$$

In the eigenspace $\mathcal{V}_n$ consider now the vector

$$\Phi_n=\sum_{r=1}^{g_n}d_r\phi_{nr}.$$

Then Φ_n is an eigenvector for the operator B, corresponding to an eigenvalue b_n if the coefficients $\{d_r\}_{r=1,g_n}$ satisfy the following system of g_n homogeneous equations:

$$\sum_{r=1}^{g_n}d_rc_{sr}=b_nd_s,\quad s=1,g_n. \tag{2}$$

This system has a nontrivial solution if its determinant is zero:

$$\Delta=\mathrm{Det}|c_{sr}-b_n\delta_{sr}|=0. \tag{3}$$

This is an equation of order g_n for the eigenvalue b_n of B, which has g_n complex roots (not necessarily distinct). For each distinct root b_n^k there is at least one solution $\{d_r^k\}_{r=1,g_n}$ of the system (2) and

$$\Phi_n^k = \sum_{r=1}^{g_n} d_r^k \phi_{nr}$$

is an eigenvector for the operator B with eigenvalue b_n^k and also for the operator A with eigenvalue a_n.

This procedure can be extended to an arbitrary number of commuting operators.

We use this scheme in Sec. II C to prove that the Bethe ansatz does not give all the common eigenvectors and to find an additional eigenvector. The expression of this eigenvector suggests to us how to look for other additional common eigenvectors.

A. Eigenvectors of the spin operator $\mathcal{S}$

The presence of the spin operator $\mathcal{S}$ in the system of commuting operators is important because, for this operator, all the eigenvalues and the complete system of eigenvectors, which form a basis in Ω, are known (see Lemma 1). Then, we look for common eigenvectors of Gaudin Hamiltonians as linear combinations of eigenvectors of $\mathcal{S}$, with some unknown coefficients.

The eigenvectors of $\mathcal{S}$ have a particular form which is explained by the theory of highest weight representations of the Lie algebra SL(2).

The space Ω is a tensor product of N highest weight representations V_λ of SL(2), with highest weight λ. Such a representation is completely determined by a highest weight vector v_λ, on which the action of the algebra is given by

$$Hv_\lambda = \lambda v_\lambda, \quad Ev_\lambda = 0, \quad Fv_\lambda \in \Omega.$$

The representation space V_λ is generated by vectors

$$\{v_n = F^n \; v_\lambda\}_{n \in \mathbb{N}},$$

and the action of the Lie algebra on these vectors is

$$Hv_n = (\lambda - 2n)v_n,$$

$$Ev_n = n(\lambda - n + 1)v_{n-1},$$

$$Fv_n = v_{n+1}.$$

If the highest weight λ is not a positive integer, the representation V_λ is infinite dimensional and irreducible. If $\lambda \in \mathbb{N}$, then in $\{v_n = F^n \; v_\lambda\}_{n \in \mathbb{N}}$ there is an invariant subspace, generated by $\{v_{\lambda+1}, v_{\lambda+2}, \ldots\}$ and the quotient representation is an irreducible, finite dimensional representation, of dimension $\lambda + 1$, generated by vectors $\{v_n = F^n \; v_\lambda\}_{n=0,\ldots,\lambda}$.

We consider Ω as a tensor product of finite dimensional representations, which is completely determined by the vector $v_0 = v_{\lambda_1} \otimes \cdots \otimes v_{\lambda_N}$, called vacuum vector and is generated by vectors $\{v_{n_1 \ldots n_N} = F^{n_1} \otimes F^{n_2} \cdots \otimes F^{n_N} v_0\}_{n_i = 0, \lambda_i;\; i=1,N}$. Remark that a vector $v_{n_1 \ldots n_N}$, with n_i operators F applied on the ith component, can be written as a product of $m = n_1 + n_2 + \cdots + n_N$ operators of type (1), denoted

$$v_m^{(k_1, \ldots, k_m)} = F^{(k_1)} F^{(k_2)} \cdots \; F^{(k_m)} v_0,$$

with $k_1,k_2,\ldots,k_m=1,\ldots,N$. Such a simplified notation is useful for explicit calculations since this model is applied to systems with a very large number N of particles, greater than m, which is related to the Lie algebra representation. Note that for finite dimensional representations, m can vary between 0 and a maximal value $m_{\max}=\Sigma_i^N\lambda_i$.

Knowing the structure of the space Ω, we can determine the eigenvectors and eigenvalues of the spin operator $\mathcal{S}$ on Ω. Obviously, the vacuum state is an eigenstate for the total spin operator and also for all Gaudin Hamiltonians:

$$\mathcal{S}v_0=\left(\sum_{k=1}^{N}\lambda_k\right)v_0,$$

$$\mathcal{H}_iv_0=\left(\frac{1}{2}\sum_{j=1,j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}\right)v_0. \tag{4}$$

Moreover, applying a finite number m of generators F on the vacuum state we get an eigenvector of $\mathcal{S}$:

Lemma 1: For a finite m, the vectors $v_m^{(k_1,\ldots,k_m)}=F^{(k_1)}F^{(k_2)}\cdots F^{(k_m)}v_0$ of the basis of Ω, with $k_1,\ldots,k_m=1,\ldots,N$, are eigenvectors of the total spin operator $\mathcal{S}$:

$$\mathcal{S}F^{(k_1)}F^{(k_2)}\cdots F^{(k_m)}v_0=\left(\sum_{i=1}^{N}\lambda_i-2m\right)F^{(k_1)}F^{(k_2)}\cdots F^{(k_m)}v_0.$$

The eigenvalue $\Sigma_{i=1}^N\lambda_i-2m$ is determined by the number m of operators F. Its eigenspace $\mathcal{V}_m$ is generated by vectors $\{v_m^{(k_1,\ldots,k_m)}=F^{(k_1)}F^{(k_2)}\cdots F^{(k_m)}v_0\}_{k_i=1,\ldots,N}$, called states of spin deviation m.

Since the spin deviation m can take a finite number of positive integer values, $\mathcal{S}$ has a finite number of eigenvalues and the representation space Ω can be written as the direct sum of eigenspaces of spin deviation m: $\Omega=\oplus_{m=0}^{m_{\max}}\mathcal{V}_m$.

The construction of common eigenvectors for Gaudin Hamiltonians is based on the fact that the eigenspaces of the operator $\mathcal{S}$ are invariant subspaces for $\mathcal{H}_i$. Therefore, in each eigenspace $\mathcal{V}_m$ we can look for common eigenvectors for Hamiltonians as expansions on the basis of $\mathcal{V}_m$:

$$\psi_m=\sum_{k_1=1}^{N}\cdots\sum_{k_m=1}^{N}c_{k_1\ldots k_m}F^{(k_1)}\cdots F^{(k_m)}v_0.$$

To determine the coefficients $c_{k_1\ldots k_m}$ one could use the "general constructive procedure," presented at the begining of this section, and solve the system (2) with the condition (3). Another approach is to consider a particular form for these coefficients, as rational complex functions:

$$c_{k_1\ldots k_m}=\frac{1}{w_1-z_{k_1}}\cdots\frac{1}{w_m-z_{k_m}}$$

with some unknown distinct, complex parameters: $w_1,\ldots,w_m$. This approach is essentially known as the Bethe ansatz method.

We present hereafter both approaches.

B. Bethe vectors of spin deviation $m=1$

The eigenspace $\mathcal{V}_1$ is generated by vectors $\{F^{(k)}v_0\}_{k=1,\ldots,N}$. A Bethe vector of spin deviation $m=1$ is defined as an expansion on this basis, with rational coefficients depending on one complex parameter w:

$$\psi_1(w)=\sum_{k=1}^{N}\frac{1}{w-z_k}F^{(k)}v_0.$$

Denote $\mathcal{F}(w)$ the operator on Ω:

$$\mathcal{F}(w)=\sum_{k=1}^{N}\frac{1}{w-z_k}F^{(k)}. \tag{5}$$

Straightforward calculations give the commutator:

$$[\mathcal{H}_i,\mathcal{F}(w)]=\sum_{j=1,j\neq i}^{N}\frac{1}{(w-z_i)(w-z_j)}(H^{(i)}F^{(j)}-F^{(i)}H^{(j)}). \tag{6}$$

Applying this operator on v_0 we obtain

$$[\mathcal{H}_i,\mathcal{F}(w)]v_0=\frac{\lambda_i}{w-z_i}\mathcal{F}(w)v_0-\left(\sum_{k=1}^{N}\frac{\lambda_k}{w-z_k}\right)\frac{F^{(i)}}{w-z_i}v_0. \tag{7}$$

Then the action of a Gaudin Hamiltonian $\mathcal{H}_i$ on $\psi_1(w)$ is

$$\mathcal{H}_i\ \ \psi_1(w)=\left(\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\frac{\lambda_i}{w-z_i}\right)\psi_1(w)-\left(\sum_{k=1}^{N}\frac{\lambda_k}{w-z_k}\right)\frac{F^{(i)}}{w-z_i}v_0$$

and we have the following lemma.

Lemma 2: Given N distinct complex numbers $\{z_i\}_{i=1,\ldots,N}$ *and fixed positive, integer highest weights* $\{\lambda_i\}_{i=1,\ldots,N}$, *the Bethe vector* $\psi_1(w)$ *of spin deviation* $m=1$ *is an eigenvector for all Gaudin Hamiltonians:*

$$\mathcal{H}_i\ \ \psi_1(w)=s_i^1\psi_1(w),\quad \forall\ \ i=1,\ldots,N,$$

if the complex parameter w satisfies the following condition:

$$\sum_{k=1}^{N}\frac{\lambda_k}{w-z_k}=0, \tag{8}$$

called Bethe equation associated to $\mathcal{V}_1$. *The eigenvalue* s_i^1 *of* $\mathcal{H}_i$ *depends on the solution w of this equation:*

$$s_i^1(w)=\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\frac{\lambda_i}{w-z_i}.$$

C. Additional eigenvector in $\mathcal{V}_1$

In the eigenspace $\mathcal{V}_1$ of $\mathcal{S}$, which has dimension N, the Bethe construction gives a number of common eigenvectors equal to the number of distinct solutions of the equation (8). It is a polynomial equation of degree $N-1$ and therefore it has $N-1$ complex solutions (not necessarily distinct). The following lemma gives one more eigenvector in $\mathcal{V}_1$, common to all Hamiltonians, which can not be constructed with the Bethe ansatz (and also from linear combinations of vectors obtained from the Bethe ansatz).

Lemma 3: The vector ψ_1^0 *in* $\mathcal{V}_1$,

$$\psi_1^0=\sum_{k=1}^{N} F^{(k)}v_0,$$

is an eigenvector for each Hamiltonian $\mathcal{H}_i$*:*

$$\mathcal{H}_i\ \ \psi_1^0=\left(\frac{1}{2}\sum_{j=1,j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}\right)\psi_1^0. \tag{9}$$

This vector has equal coefficients, as expansion on the basis of $\mathcal{V}_1$. This possibility is not allowed by the Bethe construction, where these coefficients, chosen in the form $1/(w-z_i)$ with distinct z_i, are necessarily distinct. Remark also that the eigenvalue of this vector is the same as the eigenvalue of the vacuum vector (4).

Finally, remark that the Bethe equation (8) is nothing else that the condition (3) of the ''general constructive procedure,'' presented at the begining of this section, which gives the eigenvalues of the Hamiltonians. To see this let us write the action of a Hamiltonian $\mathcal{H}_i$ on each generator $F^{(k)}v_0$ of $\mathcal{V}_1$:

$$\begin{aligned}
\mathcal{H}_iF^{(i)}v_0&=\left(\sum_{j=1,j\neq i}^{N}\frac{\frac{1}{2}\lambda_i\lambda_j-\lambda_j}{z_i-z_j}\right)F^{(i)}v_0+\sum_{j=1,j\neq i}^{N}\frac{\lambda_i}{z_i-z_j}F^{(j)}v_0,\\
\mathcal{H}_iF^{(k)}v_0&=\left(\frac{1}{2}\sum_{j=1,j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}-\frac{\lambda_i}{z_i-z_k}\right)F^{(k)}v_0+\frac{\lambda_k}{z_i-z_k}F^{(i)}v_0,\quad \forall k\neq i.
\end{aligned} \tag{10}$$

A vector Φ of $\mathcal{V}_1$, $\Phi=\Sigma_{r=1}^{N}d_rF^{(r)}v_0$, is a common eigenvector for all Hamiltonians $\mathcal{H}_i$, corresponding to eigenvalues b_i, $\mathcal{H}_i\Phi=b_i\Phi$, if the set of coefficients $\{d_r\}_{r=1,N}$ is a common solution of the systems of type (2):

$$\sum_{r=1}^{N} d_rc_{sr}^{i}=b_id_s,\quad s=1,\ldots,N \tag{11}$$

(one system for each Hamiltonian $\mathcal{H}_i$), where the coefficients $\{c_{sr}^{i}\}_{s,r=1,\ldots,N}$ are given by (10). The determinant of the ith system, $\Delta_i=\mathrm{Det}(c_{sr}^{i}-b_i\delta_{sr})$, is

$$\Delta_i=\begin{vmatrix}
\tilde{b}-\frac{\lambda_i}{z_i-z_1} & 0 & \ldots & \frac{\lambda_i}{z_i-z_1} & 0 & \ldots & 0\\
0 & \tilde{b}-\frac{\lambda_i}{z_i-z_2} & \ldots & \frac{\lambda_i}{z_i-z_2} & 0 & \ldots & 0\\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \\
\frac{\lambda_1}{z_i-z_1} & \frac{\lambda_2}{z_i-z_2} & \ldots & \tilde{b}-\sum_{j\neq i}^{N}\frac{\lambda_j}{z_i-z_j} & \frac{\lambda_{i+1}}{z_i-z_{i+1}} & \ldots & \frac{\lambda_N}{z_i-z_N}\\
0 & 0 & \ldots & \frac{\lambda_i}{z_i-z_{i+1}} & \tilde{b}-\frac{\lambda_i}{z_i-z_{i+1}} & \ldots & 0\\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots\\
0 & 0 & \ldots & \frac{\lambda_i}{z_i-z_N} & 0 & \ldots & \tilde{b}-\frac{\lambda_i}{z_i-z_N}
\end{vmatrix},$$

where $\tilde{b}=\frac{1}{2}\Sigma_{j=1,j\neq i}^{N}\lambda_i\lambda_j/(z_i-z_j)-b_i$. The determinant can be calculated,

$$\Delta_i=\tilde{b}\left\{\prod_{j=1;j\neq i}^{N}\left(\tilde{b}-\frac{\lambda_i}{z_i-z_j}\right)-\sum_{k=1;k\neq i}^{N}\frac{\lambda_k}{z_i-z_k}\prod_{j=1;j\neq i,k}^{N}\left(\tilde{b}-\frac{\lambda_i}{z_i-z_j}\right)\right\},$$

and gives a polynomial equation of degree N in $\tilde{b}$ with N complex roots.

One of them is $\tilde{b}=0$, which gives the eigenvalue $b_i=\frac{1}{2}\Sigma_{j=1,j\neq i}^{N}\lambda_i\lambda_j/(z_i-z_j)$. In this case the nontrivial common solution of the systems (11) is $d_1=d_2=\cdots=d_N$, which gives, up to a constant, the particular eigenvector ψ_1^0 of Lemma 3, common to all Hamiltonians.

It is more difficult to find the other roots of Δ_i. We can verify that $\lambda_i/(z_i-z_k)$ is not a root of Δ_i for any $k=1,\ldots,N$, $k\neq i$. Then we can choose $\tilde{b}$ as the rational function,

$$\tilde{b}(w)=-\frac{\lambda_i}{w-z_i}$$

depending on the unknown complex variable w, with $w\neq z_k$, for all $k=1,\ldots,N$ and we have

$$\Delta_i=-\left\{\sum_{j=1}^{N}\frac{\lambda_j}{w-z_j}\right\}\left(\frac{\lambda_i}{w-z_i}\right)^{N-1}\prod_{k=1;k\neq i}^{N}\left(\frac{w-z_k}{z_k-z_i}\right).$$

The conditions (3), for each Δ_i, give the same equation:

$$\sum_{j=1}^{N}\frac{\lambda_j}{w-z_j}=0,$$

which is the Bethe equation (8) for the eigenspace $\mathcal{V}_1$. In this case the nontrivial common solution of the systems (11) is $d_k=1/(w-z_k)$, $\forall\ k=1,\ldots,N$, which gives the Bethe eigenvector $\psi_1(w)$, with eigenvalues $b_i=\frac{1}{2}\Sigma_{j=1,j\neq i}^{N}\lambda_i\lambda_j/(z_i-z_j)+\lambda_i(w-z_i)$.

D. States of spin deviation *m*

In the general case of spin deviation m, the eigenspace $\mathcal{V}_m$ is generated by vectors $\{F^{(k_1)}\cdots F^{(k_m)}v_0\}_{1\leqslant k_1\leqslant\ldots\leqslant k_m\leqslant N}$. A Bethe vector of spin deviation m is defined as an expansion on the basis, with coefficients depending on m complex parameters $w_1,\ldots,w_m$:

$$\psi_m(w_1,\ldots,w_m)v_0=\sum_{i_1=1}^{N}\frac{F^{(i_1)}}{w_1-z_{i_1}}\cdots\sum_{i_m=1}^{N}\frac{F^{(i_m)}}{w_m-z_{i_m}}v_0=\mathcal{F}(w_1)\cdots\mathcal{F}(w_m)v_0. \tag{12}$$

The order of the operators $\mathcal{F}$ is not significant because they commute.

The action of a Gaudin Hamiltonian $\mathcal{H}_i$ on this state is calculated by induction on m:

$$\begin{aligned}\mathcal{H}_i\psi_m(w_1,\ldots,w_m)v_0&=\mathcal{H}_i\mathcal{F}(w_m)\psi_{m-1}(w_1,\ldots,\ w_{m-1})v_0\\&=\mathcal{F}(w_m)\mathcal{H}_i\psi_{m-1}(w_1,\ldots,\ w_{m-1})v_0+\psi_{m-1}(w_1,\ldots,\ w_{m-1})\\&\quad\times[\mathcal{H}_i,\mathcal{F}(w_m)]v_0+[[\mathcal{H}_i,\mathcal{F}(w_m)],\psi_{m-1}(w_1,\ldots,\ w_{m-1})]v_0.\end{aligned}$$

The first term is computed from the induction hypothesis, the second from (7), and for the last term we use the commutator formula:

$$[[\mathcal{H}_i,\mathcal{F}(w_1)],\mathcal{F}(w_2)]=\frac{2}{w_1-w_2}\left(\frac{F^{(i)}}{w_1-z_i}\mathcal{F}(w_2)-\frac{F^{(i)}}{w_2-z_i}\mathcal{F}(w_1)\right), \tag{13}$$

which can be obtained from (6). Putting all together it follows:

$$\mathcal{H}_i\psi_m(w_1,\ldots,\ w_m)v_0=\left(\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\sum_{k=1}^{m}\frac{\lambda_i}{w_k-z_i}\right)\psi_m(w_1,\ldots,\ w_m)v_0$$
$$-\sum_{k=1}^{m}\left(\sum_{j=1}^{N}\frac{\lambda_j}{w_k-z_j}+\sum_{l=1;l\neq k}^{m}\frac{2}{w_l-w_k}\right)\frac{F^{(i)}}{w_k-z_i}\psi_{m-1}(\ldots,\widehat{w_k},\ldots)v_0, \tag{14}$$

where $\psi_{m-1}(\ldots,\widehat{w_k},\ldots)$ denotes $\psi_{m-1}(w_1,\ldots,\ w_{k-1},w_{k+1},\ldots,w_m)$. Hence, we obtain the following theorem:

Theorem 4: *The Bethe vector $\psi_m(w_1,\ldots,\ w_m)v_0$ of spin deviation m is a common eigenvector for all Gaudin Hamiltonians:*

$$\mathcal{H}_i\psi_m(w_1,\ldots,\ w_m)v_0=s_i^m\psi_m(w_1,\ldots,\ w_m)v_0,\quad \forall\ \ i=1,\ldots,N,$$

if the complex parameters $w_1,\ldots,w_m$ satisfy the Bethe equations associated to $\mathcal{V}_m$:

$$\sum_{j=1}^{N}\frac{\lambda_j}{w_k-z_j}+\sum_{l=1;l\neq k}^{m}\frac{2}{w_l-w_k}=0,\quad \forall k=1,\ldots,m. \tag{15}$$

The eigenvalues s_i^m depend on the solution of these equations:

$$s_i^m(w_1,\ldots,\ w_m)=\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\sum_{k=1}^{m}\frac{\lambda_i}{w_k-z_i}.$$

E. Additional eigenvector in $\mathcal{V}_m$

As remarked in Ref. 12, the number of distinct solutions of the Bethe equations (15) is at most C_{N+m-2}^m (the standard binomial coefficient), which is less than the dimension of the space $\mathcal{V}_m$:

$$\dim\mathcal{V}_m=\sum_{1\leqslant k_1\leqslant\ldots\leqslant k_m\leqslant N}1=\sum_{1\leqslant j_1\ \ldots\ <j_m\leqslant N+m-1}1=C_{N+m-1}^m.$$

Therefore, the system of Bethe eigenvectors ψ_m is not complete. We can construct one more common vector in $\mathcal{V}_m$, which has equal coefficients and with the same eigenvalues as the vacuum vector (4).

Theorem 5: *The vector $\psi_m^0\in\mathcal{V}_m$,*

$$\psi_m^0=\sum_{k_1=1}^{N}\ \cdots\ \sum_{k_m=1}^{N}F^{(k_1)}\cdots\ F^{(k_m)}v_0 \tag{16}$$

is an eigenvector for each Hamiltonian $\mathcal{H}_i$:

$$\mathcal{H}_i\ \ \psi_m^0=\left(\frac{1}{2}\sum_{j=1,j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}\right)\psi_m^0.$$

The proof follows from (4) and using the fact that $[\mathcal{H}_i,\Sigma_{k=1}^{N}F^{(k)}]=0$.

F. Conclusions

In this section, eigenvalues for Gaudin Hamiltonians are determined and by the Bethe method common eigenvectors for these operators are constructed in each eigenspace of the spin operator. This constructive method does not ensure the completeness of the system of common eigenvec-

tors, but it can be used for large values of spin deviation. On the other hand, the "general constructive procedure," presented at the begining of the section, could give additional common eigenvectors, but it is difficult to apply it, even for $m=2$.

For each value of spin deviation we have constructed one additional common eigenvector which can not be obtained by the Bethe ansatz. From Lemma 3 and Theorem 5 it follows that the eigenvalue $s_0^i=\frac{1}{2}\Sigma_{j=1,j\neq i}^N \lambda_i\lambda_j/(z_i-z_j)$ of the Hamiltonian $\mathcal{H}_i$ is degenerate and its eigenspace contains not only the vacuum state v_0, but all the states ψ_m^0.

Unlike the case $m=1$, where the additional vector ψ_1^0 could complete the system of eigenvectors, if the Bethe equation (8) has distinct solutions, in the case $m>1$ the number of "missing vectors" is greater than one. The additional vector ψ_m^0 is only one of them. An alternative construction, which gives a larger system of eigenvectors, was proposed in Ref. 13.

III. GENERALIZATION OF THE GAUDIN MODEL FOR AN ARBITRARY SIMPLE LIE ALGEBRA *G*

Consider a simple Lie algebra G, of dimension d and rank r. We denote Δ the root system of G, Δ_+ the system of positive roots and Δ_0 the system of simple roots. The Cartan basis of G is formed by the Cartan generators $\{H_i\}_{i=1,r}$, the generators of positive roots $\{E_\alpha\}_{\alpha\in\Delta_+}$ and the generators of negative roots $\{F_\alpha=E_{-\alpha}\}_{\alpha\in\Delta_+}$. The commutation relations are

$$[E_\alpha,F_\alpha]=\frac{2}{\langle\alpha,\alpha\rangle}H_\alpha;\quad [H,E_\alpha]=\alpha(H)E_\alpha;\quad [H,F_\alpha]=-\alpha(H)F_\alpha;$$

$$[E_\alpha,E_\beta]=N_{\alpha,\beta}E_{\alpha+\beta},\quad \forall\,\alpha,\beta\in\Delta \text{ such that } \alpha+\beta\in\Delta.$$

Recall that the Killing form of G defines a symmetrical, G-invariant, bilinear form $\langle,\rangle$ on G. This scalar product allows us to identify the Cartan subalgebra $\mathcal{K}$ of G with its dual $\mathcal{K}^*$ by the isomorphism which associates to each element $\alpha\in\mathcal{K}^*$ one element $H_\alpha\in\mathcal{K}$, defined by $\alpha(H)=\langle H_\alpha,H\rangle$, for all $H\in\mathcal{K}$. The scalar product on $\mathcal{K}$ induces a scalar product on its dual $\mathcal{K}^*$, which is nondegenerate,

$$\langle\alpha,\beta\rangle=\langle H_\alpha,H_\beta\rangle,$$

normalized such that $\langle\alpha_l,\alpha_l\rangle=2$ for a long root α_l.

All generators of G are orthogonal with respect to this scalar product except the pairs (E_α,F_α) and (H_i,H_i), for which we have[14]

$$\langle H_i,H_i\rangle=\frac{1}{2}\chi,\forall i=1,\ldots,r,\quad \langle E_\alpha,F_\alpha\rangle=\frac{2}{\langle\alpha,\alpha\rangle},\forall\alpha\in\Delta_+,$$

where $\chi=\Sigma_{i=1}^r\alpha_l^2(H_i)$ is the square of the length of a long root. Then, for the Cartan basis we can define the dual basis with respect to this scalar product:

$$\tilde{H}_i=\frac{2}{\chi}H_i,\quad \tilde{E}_\alpha=\frac{\langle\alpha,\alpha\rangle}{2}F_\alpha,\quad \tilde{F}_\alpha=\frac{\langle\alpha,\alpha\rangle}{2}E_\alpha,$$

such that $\langle H_i,\tilde{H}_j\rangle=\delta_{ij}$ and $\langle E_\alpha,\tilde{E}_\beta\rangle=\langle F_\alpha,\tilde{F}_\beta\rangle=\delta_{\alpha\beta}$.

For this algebra, consider N finite-dimensional highest weight G-modules: $V_{\lambda_1},\ \ldots,\ V_{\lambda_N}$, with dominant integral highest weights $\lambda_1,\ \ldots,\ \lambda_N$ and highest weight vectors $v_{\lambda_1},\ \ldots,\ v_{\lambda_N}$. The tensor product of these N G-modules is the space of physical states for the system of N spin particles:

$$\Omega=V_{\lambda_1}\otimes\cdots\otimes V_{\lambda_N}.$$

To introduce the Hamiltonian operators on Ω, we consider $\{I_a\}_{a=1,\ldots,d}$ a basis of G and $\{\tilde{I}_a\}_{a=1,\ldots,d}$ its dual with respect to the scalar product. The generalized Gaudin Hamiltonians are defined as

$$\mathcal{H}_i(z_1,\ldots,z_N)=\sum_{j=1,j\neq i}^{N}\frac{1}{z_i-z_j}\sum_{a=1}^{d}I_a^{(i)}\tilde{I}_a^{(j)},\quad \forall i=1,\ldots,N,$$

where $z_1,\ldots,z_N$ are N distinct, complex numbers. A remarkable property of the sum $\Sigma_{a=1}^{d}I_a^{(i)}\tilde{I}_a^{(j)}$ is that it is independent of the choice of the basis.[14] In particular, we can consider the Cartan basis, so that the Hamiltonians are given by

$$\mathcal{H}_i=\sum_{j=1,j\neq i}^{N}\frac{1}{z_i-z_j}\left\{\frac{2}{\chi}\sum_{l=1}^{r}H_l^{(i)}H_l^{(j)}+\sum_{\alpha\in\Delta_+}\frac{\langle\alpha,\alpha\rangle}{2}(E_\alpha^{(i)}F_\alpha^{(j)}+F_\alpha^{(i)}E_\alpha^{(j)})\right\}.$$

All these operators commute:

$$[\mathcal{H}_i,\mathcal{H}_j]=0,\quad \forall i,j=1,\ldots,N,$$

but they are not independent, since $\Sigma_{i=1}^{N}\mathcal{H}_i=0$. There is another family of commuting operators on Ω, introduced by the r Cartan generators:

$$\{H_\alpha^{(i)}\}_{i=1,\ldots,N;\ \alpha\in\Delta_0}.$$

We can define r spin operators $\mathcal{S}_\alpha=\Sigma_{i=1}^{N}H_\alpha^{(i)}$ and Gaudin Hamiltonians commute with each one of them:

$$[\mathcal{H}_i,\mathcal{S}_\alpha]=0,\quad \forall\ \ i=1,\ldots,N;\ \ \forall\ \ \alpha\in\Delta_0.$$

Then, there is a system of $N+r-1$ commuting operators on Ω, which are independent.

Our goal is to find common eigenvectors for these operators.

A. Eigenvectors and eigenvalues for generalized Gaudin Hamiltonians

In this section, we discuss the possibility to generalize the Bethe ansatz to the case of an arbitrary simple Lie algebra G.

The space Ω of physical states is a tensor product of N highest weight representations V_λ of G. Such a representation is completely determined by a highest weight vector v_λ, on which the action of the algebra is given by

$$H_\alpha v_\lambda=\langle\alpha,\lambda\rangle v_\lambda,\quad E_\alpha v_\lambda=0,\quad F_\alpha v_\lambda\in\Omega.$$

As in the SL(2) case, the representation space V_λ is linearly generated by monomials in generators of negative roots:

$$\{v_{\alpha_1\ldots\alpha_l}^{n_1\ldots n_l}=F_{\alpha_1}^{n_1}\cdots F_{\alpha_l}^{n_l}v_\lambda\}_{\alpha_i\in\Delta_+,\ n_i\in\mathbb{N}},$$

but in this case, the monomials are ordered with respect to the roots. The necessity to consider an ordered system of positive roots comes from the Poincaré-Birkhoff-Witt theorem,[15] which gives the basis of the enveloping algebra $\mathcal{U}(G)$ of G.

These vectors are eigenvectors for the Cartan generators:

$$H_\alpha v_{\alpha_1\ldots\alpha_l}^{n_1\ldots n_l}=\left(\langle\alpha,\lambda\rangle-\sum_{\beta\in\Delta_+}n_\beta\langle\alpha,\beta\rangle\right)v_{\alpha_1\ldots\alpha_l}^{n_1\ldots n_l}.$$

We can also compute the action of a positive root generator on monomials $v_\alpha^{n_\alpha}$:

$$E_\alpha v_\alpha^{n_\alpha} = n_\alpha \left(2\frac{\langle \lambda, \alpha \rangle}{\langle \alpha, \alpha \rangle} - n_\alpha + 1 \right) v_\alpha^{n_\alpha - 1}.$$

The dimension of a highest weight representation V_λ of G, with highest weight λ, is related to the notion of dominant integral weight. The set of dominant integral weights is

$$\left\{ \lambda \in \mathcal{K}^* \middle| 2\frac{\langle \lambda, \alpha \rangle}{\langle \alpha, \alpha \rangle} \in \mathbb{N}, \ \ \forall \ \ \alpha \in \Delta_0 \right\}.$$

If the highest weight λ is not a dominant integral weight, then the representation V_λ is infinite dimensional and irreducible. If λ is a dominant integral weight, then, denoting $r_\alpha = 2\langle \lambda, \alpha \rangle / \langle \alpha, \alpha \rangle \in \mathbb{N}$, for all $\alpha \in \Delta_0$, there exists an invariant subspace and the quotient representation is an irreducible, finite dimensional representation of G, generated by ordered monomials:

$$\{ v_{\alpha_1 \dots \alpha_l}^{n_1 \dots n_l} = F_{\alpha_1}^{n_1} \dots F_{\alpha_l}^{n_l} \ v_\lambda \}_{\alpha_j \in \Delta_+, \ n_j = 0, \dots, r_{\alpha_j}}.$$

As in the SL(2) case, we are interested in finite dimensional representations. The space Ω of physical states is then a tensor product of finite dimensional representations, completely determined by the vacuum vector $v_0 = v_{\lambda_1} \otimes \cdots \otimes v_{\lambda_N}$ and generated by vectors $v_{\alpha_1^1 \dots \alpha_l^1}^{n_1^1 \dots n_l^1} \otimes v_{\alpha_1^2 \dots \alpha_l^2}^{n_1^2 \dots n_l^2} \dots \otimes v_{\alpha_1^N \dots \alpha_l^N}^{n_1^N \dots n_l^N}$. To simplify this hard notation, remark that such a vector, which has on the ith component n_1^i operators F_{α_1}, ..., n_l^i operators F_{α_l}, can be written as a product of $m = \Sigma_{i=1}^N \Sigma_{k=1}^l n_k^i$ operators of negative roots of type (1). We denote

$$v_{\alpha_1 \dots \alpha_m}^{(k_1 \dots k_m)} = F_{\alpha_1}^{(k_1)} F_{\alpha_2}^{(k_2)} \dots F_{\alpha_m}^{(k_m)} v_0,$$

with $k_1, k_2, \dots, k_m = 1, \dots, N$. Note that for finite dimensional representations, m can vary between 0 and a maximal value $m_{\max} = \Sigma_{i=1}^N \Sigma_{\alpha \in \Delta_+} r_\alpha^i$.

B. Eigenvectors of the spin operator $\mathcal{S}_\beta$

As in the case of the Lie algebra SL(2), the problem of eigenvectors and eigenvalues for the spin operators $\mathcal{S}_\beta$ on Ω can be completely solved. The vacuum state is an eigenvector for all spin operators and also for all Gaudin Hamiltonians:

$$\mathcal{S}_\beta v_0 = \left(\sum_{k=1}^N \langle \lambda_k, \beta \rangle \right) v_0, \beta \in \Delta_0,$$

$$\mathcal{H}_i v_0 = \left(\sum_{j=1, j \neq i}^N \frac{\langle \lambda_i, \lambda_j \rangle}{z_i - z_j} \right) v_0, \quad i = 1, \dots, N. \tag{17}$$

Moreover, applying a finite number m of generators of negative roots on the vacuum state we get an eigenvector of $\mathcal{S}_\beta$:

Lemma 6: The vectors $v_{\alpha_1 \dots \alpha_m}^{(k_1 \dots k_m)} = F_{\alpha_1}^{(k_1)} F_{\alpha_2}^{(k_2)} \cdots F_{\alpha_m}^{(k_m)} v_0$ *in* Ω, *for all positive roots* $\alpha_1, \dots, \alpha_m \in \Delta_+$ *and* $k_1, \dots, k_m = 1, \dots, N$, *are eigenvectors of the spin operators* $\mathcal{S}_\beta$:

$$\mathcal{S}_\beta \ F_{\alpha_1}^{(k_1)} \cdots \ F_{\alpha_m}^{(k_m)} v_0 = \left(\sum_{i=1}^N \langle \lambda_i, \beta \rangle - \sum_{j=1}^m \langle \alpha_j, \beta \rangle \right) F_{\alpha_1}^{(k_1)} \cdots \ F_{\alpha_m}^{(k_m)} v_0.$$

As in the case of the Lie algebra SL(2), the eigenvalue $\Sigma_{i=1}^{N}\lambda_i(\beta)-\Sigma_{j=1}^{m}\alpha_j(\beta)$ is degenerate but its eigenspace is no more completely determined by the number of operators of negative roots, applied on the vacuum vector. Each eigenspace is determined by the value of the sum of positive roots $\Sigma_{j=1}^{m}\alpha_j$, which can be written as a sum of simple roots, with positive integer coefficients, in a unique way. Then the eigenspaces of $\mathcal{S}_\beta$ will be labeled by a family of simple roots: $\mathcal{V}_{\delta_1\ldots\delta_s}$, with $\delta_1,\ldots,\delta_s\in\Delta_0$ not necessarily distinct and satisfying $\Sigma_{k=1}^{s}\delta_k=\Sigma_{j=1}^{m}\alpha_j$. We call $\mathcal{V}_{\delta_1\ldots\delta_s}$ the subspace of spin deviation $\delta_1,\ldots,\delta_s$.

In view of the discussion concerning the finite dimension of Ω, m can take a finite number of positive integer values and then $\mathcal{S}_\beta$ has a finite number of eigenvalues. Therefore, the tensor product representation space Ω can be written as the direct sum of eigenspaces of $\mathcal{S}_\beta$:

$$\Omega=\bigoplus_{\delta_1,\ldots,\delta_s}\mathcal{V}_{\delta_1\ldots\delta_s},\quad \delta_1,\ldots,\quad \delta_s\in\Delta_0.$$

As in the previous section, for the model related to the Lie algebra SL(2), we search common eigenvectors for all generalized Gaudin Hamiltonians in each eigenspace of the spin operator, as expansions on the basis of eigenvectors of $\mathcal{S}_\beta$. The coefficients of these expansions have a particular form similar to that of the Bethe ansatz.

C. States of spin deviation α

Consider a simple root α. For a spin deviation α, the equation of eigenvectors for a spin operator $\mathcal{S}_\beta$ is

$$\mathcal{S}_\beta F_\alpha^{(k)}v_0=\left(\sum_{i=1}^{N}\lambda_i(\beta)-\alpha(\beta)\right)F_\alpha^{(k)}v_0. \tag{18}$$

The eigenspace $\mathcal{V}_\alpha$ of spin deviation α corresponding to the eigenvalue $\Sigma_{i=1}^{N}\lambda_i(\beta)-\alpha(\beta)$ is generated by vectors $\{F_\alpha^{(k)}v_0\}_{k=1,\ldots,N}$. A Bethe vector of spin deviation α is defined as an expansion on the basis, with rational coefficients depending on one complex parameter w:

$$\psi_1(w,\alpha)=\sum_{i=1}^{N}\frac{F_\alpha^{(i)}}{w-z_i}v_0=\mathcal{F}(w,\alpha)v_0. \tag{19}$$

To give the action of a Hamiltonian $\mathcal{H}_i$ on this vector is useful to calculate the commutator:

$$[\mathcal{H}_i,\mathcal{F}(w,\alpha)]=\mathcal{F}(w,\alpha)\frac{H_\alpha^{(i)}}{w-z_i}-\frac{F_\alpha^{(i)}}{w-z_i}\left(\sum_{j=1}^{N}\frac{H_\alpha^{(j)}}{w-z_j}\right)+\sum_{\beta\in\Delta_+,\beta>\alpha}\frac{\langle\beta,\beta\rangle}{2}N_{\beta,-\alpha}$$
$$\times\left\{\mathcal{F}(w,\beta)\frac{E_{\beta-\alpha}^{(i)}}{w-z_i}-\frac{F_\beta^{(i)}}{w-z_i}\sum_{j=1}^{N}\frac{E_{\beta-\alpha}^{(j)}}{w-z_j}\right\}. \tag{20}$$

Applied on the vacuum vector all the terms of the last sum vanish and then.

$$[\mathcal{H}_i,\mathcal{F}(w,\alpha)]v_0=\frac{\langle\alpha,\lambda_i\rangle}{w-z_i}\mathcal{F}(w,\alpha)v_0-\left(\sum_{j=1}^{N}\frac{\langle\alpha,\lambda_j\rangle}{w-z_j}\right)\frac{F_\alpha^{(i)}}{w-z_i}v_0. \tag{21}$$

Hence, the action of a Gaudin Hamiltonian $\mathcal{H}_i$ on the vector (19) is

$$\mathcal{H}_i\psi_1(w,\alpha)=\left(\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\frac{\langle\alpha,\lambda_i\rangle}{w-z_i}\right)\psi_1(w,\alpha)-\left(\sum_{k=1}^{N}\frac{\langle\alpha,\lambda_k\rangle}{w-z_k}\right)\frac{F_\alpha^{(i)}}{w-z_i}v_0 \tag{22}$$

and we have the following lemma.

Lemma 7: Given N complex numbers $\{z_i\}_{i=1,N}$ and dominant integral highest weights $\{\lambda_i\}_{i=1,N}$, the Bethe vector $\psi_1(w,\alpha)$ of spin deviation α is an eigenvector for all Gaudin Hamiltonians:

$$\mathcal{H}_i\psi_1(w,\alpha)=s_i^1(w,\alpha)\psi_1(w,\alpha), \quad \forall \ i=1,\ldots,N,$$

if the complex parameter w satisfies the Bethe equation

$$\sum_{k=1}^{N}\frac{\langle\alpha,\lambda_k\rangle}{w-z_k}=0. \tag{23}$$

The eigenvalue $s_i^1(w,\alpha)$ of the Hamiltonian $\mathcal{H}_i$ depends on the solution of this equation:

$$s_i^1(w,\alpha)=\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\frac{\langle\alpha,\lambda_i\rangle}{w-z_i}, \quad i=1,\ldots,N.$$

1. Additional eigenvector in $\mathcal{V}_\alpha$

As in the case of the model related to the Lie algebra SL(2), this constructive method does not provide all the common eigenvectors in $\mathcal{V}_\alpha$. In the eigenspace $\mathcal{V}_\alpha$, which has dimension N, the number of common eigenvectors obtained is equal to the number of distinct solutions of the equation (23), which is at most $N-1$. One more common eigenvector, which is not of the form (19), is given by the following lemma.

Lemma 8: The vector $\psi_\alpha^0\in\mathcal{V}_\alpha$,

$$\psi_\alpha^0=\sum_{k=1}^{N}F_\alpha^{(k)}v_0,$$

is an eigenvector for each Hamiltonian $\mathcal{H}_i$:

$$\mathcal{H}_i \ \ \psi_\alpha^0=\left(\sum_{j=1,j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}\right)\psi_\alpha^0. \tag{24}$$

This vector has equal coefficients as an expansion on the basis of $\mathcal{V}_\alpha$ and it has the same eigenvalue as the vacuum vector (17).

2. The case of a nonsimple root α

Lemma 7 is no longer true for a positive root α which is not simple. In this case the action (22) of $\mathcal{H}_i$ on the state $\psi_1(w,\alpha)$ presents a number of additional terms of type

$$\frac{1}{w-z_i}F_\gamma^{(i)}\mathcal{F}(w,F_{\alpha-\gamma})v_0$$

with some numerical coefficients, where $\gamma\in\Delta_+$ are positive roots $\gamma\neq\alpha$ such that $\alpha-\gamma\in\Delta_+$. Such terms exist only if α is not a simple root and they do not vanish for any parameter w. Therefore, $\psi_1(w,\alpha)$ can not be an eigenvector for the Hamiltonians $\mathcal{H}_i$. This fact has the following explanation: If α is not simple, the expression (19) for $\psi_1(w,\alpha)$ has to be modified, because the eigenspace "$\mathcal{V}_\alpha$" is in fact $\mathcal{V}_{\alpha_1\alpha_2\ldots}$ and is generated not only by vectors $F_\alpha^{(i)}v_0$, but also by "higher order" vectors $F_{\alpha_1}^{(i)}F_{\alpha_2}^{(i)}\cdots$ with $\alpha_1+\alpha_2+\cdots=\alpha$ and therefore the expansion (19) is not complete.

In particular, if the nonsimple root α is the sum of two simple roots α_1 and α_2, the action of a Hamiltonian $\mathcal{H}_i$ on the state $\psi_1(w,\alpha)$ presents two additional terms and we have the following formula, which will be useful in the next section, for the case of two spin deviation α_1, α_2:

$$\mathcal{H}_i\psi_1(w,[F_{\alpha_1},F_{\alpha_2}])=\left(\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\frac{\alpha(\lambda_i)}{w-z_i}\right)\psi_1(w,[F_{\alpha_1},F_{\alpha_2}])$$
$$-\left(\sum_{k=1}^{N}\frac{\alpha(\lambda_k)}{w-z_k}\right)\frac{[F_{\alpha_1},F_{\alpha_2}]^{(i)}}{w-z_i}v_0-\langle\alpha_1,\alpha_2\rangle$$
$$\times\left\{\mathcal{F}(w,\alpha_1)\frac{F_{\alpha_2}}{w-z_i}-\frac{F_{\alpha_1}}{w-z_i}\mathcal{F}(w,\alpha_2)\right\}v_0. \tag{25}$$

D. States of spin deviation α_1, α_2

Consider two simple roots α_1 and α_2, which are not necessarily distinct. For spin deviation α_1, α_2, the equation of eigenvectors for the spin operator $\mathcal{S}_\beta$ is

$$\mathcal{S}_\beta F_{\alpha_1}^{(k_1)}F_{\alpha_2}^{(k_2)}v_0=\left(\sum_{i=1}^{N}\lambda_i(\beta)-\alpha_1(\beta)-\alpha_2(\beta)\right)F_{\alpha_1}^{(k_1)}F_{\alpha_2}^{(k_2)}v_0. \tag{26}$$

The eigenspace $\mathcal{V}_{\alpha_1,\alpha_2}$ of spin deviation α_1, α_2, corresponding to the eigenvalue $\Sigma_{i=1}^{N}\lambda_i(\beta)-\alpha_1(\beta)-\alpha_2(\beta)$ is generated by vectors $\{F_{\alpha_1}^{(k_1)}F_{\alpha_2}^{(k_2)}v_0\}_{k_1,k_2=1,\ldots,N;k_1\neq k_2}$ with two generators of negative roots applied on two distinct components of v_0, but also by vectors $\{(F_{\alpha_1}F_{\alpha_2})^{(k)}v_0\}_{k=1,\ldots,N}$ and $\{(F_{\alpha_2}F_{\alpha_1})^{(k)}v_0\}_{k=1,\ldots,N}$ with two generators of negative roots applied on the same component of v_0. A Bethe vector of spin deviation α_1, α_2 is defined as an expansion on all these vectors, with some particular coefficients depending on two complex parameters w_1,w_2:

$$\psi_2(w_1,\alpha_1;w_2,\alpha_2)=\sum_{k_1=1}^{N}\sum_{k_2\neq k_1}^{N}\frac{F_{\alpha_1}^{(k_1)}F_{\alpha_2}^{(k_2)}}{(w_1-z_{k_1})(w_2-z_{k_2})}v_0+\frac{1}{w_1-w_2}\sum_{k=1}^{N}\frac{F_{\alpha_1}^{(k)}F_{\alpha_2}^{(k)}}{w_2-z_k}v_0$$
$$+\frac{1}{w_2-w_1}\sum_{k=1}^{N}\frac{F_{\alpha_2}^{(k)}F_{\alpha_1}^{(k)}}{w_1-z_k}v_0. \tag{27}$$

As an element of the representation space V_{λ_k}, one of the two last terms is not a good ordered monomial and we must write, for instance, $F_{\alpha_2}^{(k)}F_{\alpha_1}^{(k)}=F_{\alpha_1}^{(k)}F_{\alpha_2}^{(k)}+[F_{\alpha_2}^{(k)},F_{\alpha_1}^{(k)}]$. Then this vector can also be written in the following form, using the operators $\mathcal{F}$:

$$\psi_2(w_1,\alpha_1;w_2,\alpha_2)=\mathcal{F}(w_1,\alpha_1)\mathcal{F}(w_2,\alpha_2)v_0+\frac{1}{w_1-w_2}\mathcal{F}(w_1,[F_{\alpha_1},F_{\alpha_2}])v_0.$$

With this construction, the vector ψ_2 is symmetrical in the pairs (w,α):

$$\psi_2(w_1,\alpha_1;w_2,\alpha_2)=\psi_2(w_2,\alpha_2;w_1,\alpha_1).$$

To calculate the action of a Hamiltonian $\mathcal{H}_i$ on the vector ψ_2,

$$\mathcal{H}_i\psi_2(w_1,\alpha_1;w_2,\alpha_2)=[\mathcal{H}_i,\mathcal{F}(w_1,\alpha_1)]\mathcal{F}(w_2,\alpha_2)v_0+\mathcal{F}(w_1,\alpha_1)\mathcal{H}_i\mathcal{F}(w_2,\alpha_2)v_0$$
$$+\frac{1}{w_1-w_2}\mathcal{H}_i\mathcal{F}(w_1,[F_{\alpha_1},F_{\alpha_2}])v_0, \tag{28}$$

we use the result (20) for the first term and (22) for the second term, but not for the third term, because it corresponds to a positive root $\alpha_1+\alpha_2$ which is no longer simple. For this one we apply the formula (25). Then, the action of a Hamiltonian $\mathcal{H}_i$ on the vector ψ_2 is

$$\mathcal{H}_i\psi_2(w_1,\alpha_1;w_2,\alpha_2)=s_i^2(w_1,w_2)\psi_2(w_1,\alpha_1;w_2,\alpha_2)$$
$$-f_1\left(\frac{F^{(i)}_{\alpha_1}}{w_1-z_i}\mathcal{F}(w_2,\alpha_2)+\frac{1}{w_1-w_2}\frac{[F^{(i)}_{\alpha_1},F^{(i)}_{\alpha_2}]}{w_1-z_i}\right)v_0$$
$$-f_2\left(\mathcal{F}(w_1,\alpha_1)\frac{F^{(i)}_{\alpha_2}}{w_2-z_i}+\frac{1}{w_1-w_2}\frac{[F^{(i)}_{\alpha_1},F^{(i)}_{\alpha_2}]}{w_1-z_i}\right)v_0,$$

where

$$s_i^2=\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\frac{\langle\alpha_1,\lambda_i\rangle}{w_1-z_i}+\frac{\langle\alpha_2,\lambda_i\rangle}{w_2-z_i},$$

$$f_1=\sum_{k=1}^{N}\frac{\langle\alpha_1,\lambda_k\rangle}{w_1-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_2-w_1},$$

$$f_2=\sum_{k=1}^{N}\frac{\langle\alpha_2,\lambda_k\rangle}{w_2-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_1-w_2}.$$

Lemma 9 follows from these considerations.

Lemma 9: The Bethe vector $\psi_2(w_1,\alpha_1;w_2,\alpha_2)$ of spin deviation α_1,α_2 is an eigenvector for all Gaudin Hamiltonians

$$\mathcal{H}_i\psi_2(w_1,w_2)=s_i^2\psi_2(w_1,\alpha_1;w_2,\alpha_2)$$

if the parameters w_1,w_2 satisfy the Bethe equations:

$$f_1=\sum_{k=1}^{N}\frac{\langle\alpha_1,\lambda_k\rangle}{w_1-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_2-w_1}=0,$$
$$f_2=\sum_{k=1}^{N}\frac{\langle\alpha_2,\lambda_k\rangle}{w_2-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_1-w_2}=0. \tag{29}$$

Remarks:

(1) As discussed in the previous section, if the roots α_1 and α_2 are not simple the result of the previous lemma is not true and the expression (27) of ψ_2 has to be completed.

(2) The number of distinct solutions of Bethe equations is less than the dimension of the eigenspace $\mathcal{V}_{\alpha_1,\alpha_2}$. Therefore, other common eigenvectors could exist. It can be proved that

$$\psi^0_{\alpha_1,\alpha_2}=\left(\sum_{k_1=1}^{N}F^{(k_1)}_{\alpha_1}\right)\left(\sum_{k_2=1}^{N}F^{(k_2)}_{\alpha_2}\right)v_0 \quad\text{and}\quad \psi^0_{\alpha_1+\alpha_2}=\sum_{k=1}^{N}[F_{\alpha_1},F_{\alpha_2}]^{(k)}v_0$$

are also common eigenvectors of Hamiltonians, with the same eigenvalue as the vacuum vector.

E. States of spin deviation $\alpha_1,\ldots,\alpha_m$

For m simple roots $\alpha_1,\ldots,\alpha_m$, which are not necessarily distinct, the eigenspace $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$ of spin deviation $\alpha_1,\ldots,\alpha_m$, corresponding to the eigenvalue $\Sigma_{i=1}^{N}\lambda_i(\beta)-\Sigma_{l=1}^{m}\alpha_l(\beta)$, is generated by ordered monomials $F^{(k_1)}_{\gamma_1}\cdots F^{(k_n)}_{\gamma_n}v_0$ for all $k_1,\ldots,k_n=1,\ldots,N$ and $\gamma_1,\ldots,\gamma_n$ positive roots with $\Sigma_{i=1}^{n}\gamma_i=\Sigma_{l=1}^{m}\alpha_l$. Common eigenvectors of Hamiltonians are defined as expansions on all the monomials, but, in this general case, a particular form of coefficients (depending on m complex parameters $w_1,\ldots w_m$) can hardly be justified.

It was claimed in Ref. 6 that such a vector can be determined in each subspace $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$ through a recursive procedure in the number m of simple roots:

$$\begin{aligned}&\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)v_0\\&\quad=\psi_{m-1}(w_1,\alpha_1;\ldots;w_{m-1},\alpha_{m-1})\mathcal{F}(w_m,\alpha_m)v_0\\&\qquad+\sum_{j=1}^{m-1}\frac{1}{w_j-w_m}\psi_{m-1}(w_1,\alpha_1;\ldots;w_j,[F_{\alpha_j},F_{\alpha_m}];\ldots;w_{m-1},\alpha_{m-1})v_0,\end{aligned}\tag{30}$$

with $\psi_1(w,\alpha)=\mathcal{F}(w,\alpha)v_0$, and that the action of a Hamiltonian $\mathcal{H}_i$ on the vector $\psi_m v_0$ is

$$\mathcal{H}_i\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)v_0=s_i^m\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)v_0-\sum_{k=1}^{m}f_k^m\overline{\psi}_m^k v_0,\tag{31}$$

where

$$\begin{aligned}s_i^m&=\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\sum_{k=1}^{m}\frac{\langle\alpha_k,\lambda_i\rangle}{w_k-z_i},\\f_k^m&=\sum_{j=1}^{N}\frac{\langle\alpha_k,\lambda_j\rangle}{w_k-z_j}+\sum_{l=1}^{m}\frac{\langle\alpha_k,\alpha_l\rangle}{w_l-w_k},\quad\forall k=1,\ldots,m,\end{aligned}\tag{32}$$

and $\overline{\psi}_m^k v_0$ are some vectors in $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$.

Such a recursive construction of the common eigenvectors seems to be appropriate for inductive calculations. For example, we can verify by induction that the vector ψ_m is symmetrical in the pairs (w,α):

$$\psi_m(\ldots;w_k,\alpha_k;\ldots;w_l,\alpha_l;\ldots)=\psi_m(\ldots w_l,\alpha_l;\ldots;w_k,\alpha_k;\ldots).$$

However, an inductive calculation for the action (31) of Hamiltonians on these vectors is very difficult. As remarked for the case of spin deviation α_1, α_2, the serious problem comes from the presence in (30) of roots which are not simple and therefore the induction step can not be applied.

For the eigenvector ψ_m an explicit form is given by the following theorem (for simplicity F_i denotes F_{α_i})

Theorem 10: *The recursion relation (30) has the following result:*

$$\begin{aligned}&\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)v_0\\&\quad=\sum_{\mathcal{P}_m}\prod_{j=1}^{N}\sum_{\sigma\in\mathcal{S}(I^j)}\frac{(F_{\sigma(i_1^j)}\ldots F_{\sigma(i_{l_j}^j)})^{(j)}}{(w_{\sigma(i_1^j)}-w_{\sigma(i_2^j)})(w_{\sigma(i_2^j)}-w_{\sigma(i_3^j)})\ldots(w_{\sigma(i_{l_j}^j)}-z_j)}v_0.\end{aligned}\tag{33}$$

In this relation the first sum is taken over all N-fold partitions $(I^1,\ldots,I^N)$, $I^1\cup\ldots\cup I^N=\{1,\ldots,m\}$ *of the set of indices* $\{1,\ldots,m\}$ *of the m simple roots* $\alpha_1,\ldots,\alpha_m$. *The partitions are considered with N disjoint subsets, which can be empty, as well:* $I^j=\{i_1^j,\ldots,i_{l_j}^j\}$, *with* $0\leqslant l_j\leqslant m$. *The product is taken over all components* V_{λ_j} *of the tensor product representation* Ω. *The second sum is taken over the set* $\mathcal{S}(I^j)$ *of all permutations in the subset* I^j.

For example, in the case of two simple roots, there are two types of partitions of the set $\{1,2\}$:

$$\text{type } I:\begin{cases}I^k=\{1,2\}\\I^l=\phi\end{cases}\quad\text{together with its permutation}\quad\begin{cases}I^k=\{2,1\}\\I^l=\phi\end{cases}\qquad k,l=1,\ldots,N,l\neq k,$$

$$\text{type } II: \begin{cases} I^k=\{1\} \\ I^l=\{2\} \end{cases} \qquad k,l=1,\ldots,N, l\neq k, \text{ and the others are empty.}$$

Then the sum (33) over these partitions reduces to (27).

Theorem 10 was announced in Ref. 6, where it was also remarked that (33) is exactly the same vector function (45), appearing in the integral solutions of the KZ equation. In Sec. V we will briefly analyze the connection between the problem of common eigenvectors for Gaudin Hamiltonians and the solutions of the KZ equation.

In the rest of the present section we give a proof of Theorem 10 which is based on two lemmas.

Lemma 11: Let $A=\{i_1,i_2,\ldots,i_n\}$ be a set of indices, E an expression depending on these indices and $\mathcal{S}(A)$ the set of permutations of A. Then, for any fixed $i_a\in A$ we have

$$\sum_{\sigma\in\mathcal{S}(A)} E(\sigma(i_1),\ldots,\sigma(i_n)) = \sum_{\sigma'\in\mathcal{S}(A\setminus\{i_a\})}\sum_{q=1}^{n} E(\sigma'(i'_1),\ldots,\sigma'(i'_{q-1}),i_a,\sigma'(i'_q),\ldots,\sigma'(i'_{n-1})),$$

where $\{i'_1,i'_2,\ldots,i'_{n-1}\}=A\setminus\{i_a\}$.

It means that a sum over the permutations of n elements can be rearranged as follows: fix one of these elements, make the sum over the permutations of the resting $n-1$ elements and for each such permutation make the sum of the expressions E in which the fixed element is placed successively on all positions from 1 to n.

The second lemma is a result of straightforward calculations:

Lemma 12: For some distinct complex numbers $w_1,\ldots,w_n,w_\beta,z$, let

$$Q_s(w_1,\ldots,w_n,w_\beta)=\sum_{q=1}^{s}\frac{1}{(w_1-w_2)\cdots(w_{q-1}-w_\beta)(w_\beta-w_q)\cdots(w_{n-1}-w_n)(w_n-z)}, \quad \forall s=1,\ldots,n+1,$$

where the first term (for $q=1$) is $1/[(w_\beta-w_1)(w_1-w_2)\cdots(w_{n-1}-w_n)(w_n-z)]$ and the term for $q=n+1$ is $1/[(w_1-w_2)\cdots(w_{n-1}-w_n)(w_n-w_\beta)(w_\beta-z)]$. Then

$$Q_s(w_1,\ldots,w_n,w_\beta)=\frac{1}{(w_1-w_2)\ldots(w_{n-1}-w_n)(w_n-z)}\frac{1}{(w_\beta-w_s)}, \quad \forall s=1,\ldots,n, \tag{34}$$

$$Q_{n+1}(w_1,\ldots,w_n,w_\beta)=\frac{1}{(w_1-w_2)\ldots(w_{n-1}-w_n)(w_n-z)}\frac{1}{(w_\beta-z)}. \tag{35}$$

Proof of the theorem: In the expression (33) of ψ_m, the sum over the partitions $(J^1,\ldots,J^N)\in\mathcal{P}_m$ of the indices $\{1,2,\ldots,m\}$ is rewritten as the sum over the partitions $(I^1,\ldots,I^N)\in\mathcal{P}_{m-1}$ of the indices $\{1,2,\ldots,m-1\}$, and for each partition in $\mathcal{P}_{m-1}$, the index m is successively placed in each subset $I^k=\{i^k_1,\ldots,i^k_{l_k}\}: J^l=I^l$, $\forall l\neq k$ and $J^k=I^k\cup\{m\}$. It follows

$$\psi_m=\sum_{\mathcal{P}_{m-1}}\sum_{k=1}^{N}\left(\prod_{j=1,j\neq k}^{N}\sum_{\sigma\in\mathcal{S}(I^j)}\frac{(F_{\sigma(i^j_1)}\cdots F_{\sigma(i^j_{l_j})})^{(j)}}{(w_{\sigma(i^j_1)}-w_{\sigma(i^j_2)})\cdots(w_{\sigma(i^j_{l_j})}-z_j)}\right) \times\left(\sum_{\sigma\in\mathcal{S}(J^k)}\frac{(F_{\sigma(i^k_1)}\cdots F_{\sigma(i^k_{l_k})}F_{\sigma(m)})^{(k)}}{(w_{\sigma(i^k_1)}-w_{\sigma(i^k_2)})\cdots(w_{\sigma(i^k_{l_k})}-w_{\sigma(m)})(w_{\sigma(m)}-z_k)}\right). \tag{36}$$

Then we compute the last sum and, to simplify the writing, we leave out the index k. Using Lemma 11 we obtain

$$\sum_{\sigma\in\mathcal{S}(J\setminus\{m\})}\sum_{q=1}^{l+1}\frac{F_{\sigma(i_1)}\cdots F_{\sigma(i_{q-1})}F_mF_{\sigma(i_q)}\cdots F_{\sigma(i_l)}}{(w_{\sigma(i_1)}-w_{\sigma(i_2)})\cdots(w_{\sigma(i_{q-1})}-w_m)(w_m-w_{\sigma(i_q)})\cdots(w_{\sigma(i_l)}-z_k)}. \tag{37}$$

At the numerator, we commute successively F_m, up to the last position:

$$\begin{aligned}&F_{\sigma(i_1)}\cdots F_{\sigma(i_{q-1})}F_mF_{\sigma(i_q)}\cdots F_{\sigma(i_l)}\\&\quad=F_{\sigma(i_1)}\cdots F_{\sigma(i_l)}F_m+\sum_{s=q}^{l}F_{\sigma(i_1)}\cdots F_{\sigma(i_{s-1})}[F_m,F_{\sigma(i_s)}]\cdots F_{\sigma(i_l)},\quad\forall q=1,\ldots,l.\end{aligned}$$

In this relation, the first term does not depend on q and can be factorized out of the sum over q in (37). It multiplies a sum of fractions which forms the sum $Q_l(w_{\sigma(i_1)},\ldots,w_{\sigma(i_l)},w_m)$, given by the relation (35) of Lemma 12.

For the second term we change in (37) the order of the two sums, over s and over q. Then the operator product $F_{\sigma(i_1)}\cdots F_{\sigma(i_{s-1})}[F_m,F_{\sigma(i_s)}]\cdots F_{\sigma(i_l)}$ can also be factorized out of the sum over q and it multiplies the sum $Q_s(w_{\sigma(i_1)},\ldots,w_{\sigma(i_l)},w_m)$, which is given by the relation (34) of Lemma 12, for all $s=1,\ldots,l$. Hence, for (37) we obtain

$$\begin{aligned}\sum_{\sigma\in\mathcal{S}(I)}\Bigg(&\frac{F_{\sigma(i_1)}\ldots F_{\sigma(i_l)}}{(w_{\sigma(i_1)}-w_{\sigma(i_2)})\ldots(w_{\sigma(i_l)}-z_k)}\frac{F_m}{w_m-z_k}\\&+\sum_{s=1}^{l}\frac{1}{w_m-w_{\sigma(i_s)}}\frac{F_{\sigma(i_1)}\ldots F_{\sigma(i_{s-1})}[F_m,F_{\sigma(i_s)}]\ldots F_{\sigma(i_l)}}{(w_{\sigma(i_1)}-w_{\sigma(i_2)})\ldots(w_{\sigma(i_l)}-z_k)}\Bigg).\end{aligned} \tag{38}$$

Replacing the first part of (38) in the expression (36) of ψ_m, we obtain

$$\sum_{\mathcal{P}_{m-1}}\left(\prod_{j=1}^{N}\sum_{\sigma\in\mathcal{S}(I^j)}\frac{(F_{\sigma(i_1^j)}\cdots F_{\sigma(i_{l_j}^j)})^{(j)}}{(w_{\sigma(i_1^j)}-w_{\sigma(i_2^j)})\cdots(w_{\sigma(i_{l_j}^j)}-z_j)}\right)\sum_{k=1}^{N}\frac{F_m^{(k)}}{w_m-z_k}, \tag{39}$$

which is exactly the term $\psi_{m-1}(w_1,\alpha_1;\ldots;w_{m-1},\alpha_{m-1})\mathcal{F}(w_m,\alpha_m)$ of the recursion relation (30).

Using lemma 11, the second part of the relation (38) can be rewritten as

$$\sum_{s=1}^{l}\frac{1}{w_m-w_{i_s}}\sum_{\sigma\in\mathcal{S}(I\setminus\{i_s\})}\sum_{q=1}^{l}\frac{F_{\sigma(j_1)}\ldots F_{\sigma(j_{q-1})}[F_m,F_{i_s}]\ldots F_{\sigma(j_{l-1})}}{(w_{\sigma(j_1)}-w_{\sigma(j_2)})\cdots(w_{\sigma(j_{q-1})}-w_{\sigma(i_s)})(w_{\sigma(i_s)}-w_{\sigma(j_q)})\cdots(w_{\sigma(j_{l-1})}-z_k)},$$

where $\{j_1,\ldots,j_{l-1}\}$ is the subset $I\setminus\{i_s\}$ of I. Applying again Lemma 11, it becomes

$$\sum_{s=1}^{l}\frac{1}{w_m-w_{i_s}}\left\{\sum_{\sigma\in\mathcal{S}(I)}\frac{F_{\sigma(i_1)}\cdots F_{\sigma(i_l)}}{(w_{\sigma(i_1)}-w_{\sigma(i_2)})\cdots(w_{\sigma(i_l)}-z_k)}\right\}_{F_{i_s}\hookrightarrow[F_m,F_{i_s}]},$$

where $\{\text{expr}\}_{F_{i_s}\hookrightarrow[F_m,F_{i_s}]}$ is the expression expr in which the operator F_{i_s} is replaced by the commutator $[F_m,F_{i_s}]$. Replacing this term in the expression (36) of ψ_m, we obtain

$$\sum_{\mathcal{P}_{m-1}} \sum_{k=1}^{N} \sum_{s=1}^{l_k} \frac{1}{w_m - w_{i_s^k}} \left(\prod_{\substack{j=1 \\ j\neq k}}^{N} \sum_{\sigma\in\mathcal{S}(I^j)} \frac{(F_{\sigma(i_1^j)}\cdots F_{\sigma(i_{l_j}^j)})^{(j)}}{(w_{\sigma(i_1^j)} - w_{\sigma(i_2^j)})\cdots} \right)$$
$$\times \left\{ \sum_{\sigma\in\mathcal{S}(I^k)} \frac{(F_{\sigma(i_1^k)}\cdots F_{\sigma(i_{l_k}^k)})^{(k)}}{(w_{\sigma(i_1^k)} - w_{\sigma(i_2^k)})\cdots(w_{\sigma(i_{l_k}^k)} - z_k)} \right\}_{F_{i_s^k}\hookrightarrow[F_m, F_{i_s^k}]}.$$

In this expression, for each partition $(I^1,\ldots,I^N)$ and for each index $r=1,\ldots,m-1$, the factor $1/(w_m - w_r)$ occurs once only. Therefore, this expression can be rearranged in the following form:

$$\sum_{r=1}^{m-1} \frac{1}{w_m - w_r} \sum_{\mathcal{P}_{m-1}} \left(\prod_{\substack{j=1 \\ j\neq k, r\in I^k}}^{N} \sum_{\sigma\in\mathcal{S}(I^j)} \frac{(F_{\sigma(i_1^j)}\cdots F_{\sigma(i_{l_j}^j)})^{(j)}}{(w_{\sigma(i_1^j)} - w_{\sigma(i_2^j)})\cdots} \right)$$
$$\times \left\{ \sum_{\sigma\in\mathcal{S}(I^k)} \frac{(F_{\sigma(i_1^k)}\cdots F_{\sigma(i_{l_k}^k)})^{(k)}}{(w_{\sigma(i_1^k)} - w_{\sigma(i_2^k)})\cdots(w_{\sigma(i_{l_k}^k)} - z_k)} \right\}_{F_r\hookrightarrow[F_m, F_r]},$$

which is exactly the term $\Sigma_{j=1}^{m-1} 1/(w_j - w_m)\, \psi_{m-1}(w_1,\alpha_1;\ldots;w_j,[F_{\alpha_j},F_{\alpha_m}];\ldots;w_{m-1},\alpha_{m-1})$ of the recursion (30).

1. Additional eigenvectors

The recursion relation (30) gives only a part of common eigenvectors. As in the cases of spin deviation α and α_1, α_2, additional eigenvectors can be found:

Lemma 13: For any ordered set of simple roots $\alpha_1,\alpha_2,\ldots,\alpha_m$, the vector

$$\psi^0_{\alpha_1,\ldots,\alpha_m} = \left(\sum_{k_1=1}^{N} F^{(k_1)}_{\alpha_1} \right) \cdots \left(\sum_{k_m=1}^{N} F^{(k_m)}_{\alpha_m} \right) v_0 \tag{40}$$

is an eigenvector of Hamiltonians $\mathcal{H}_i$ corresponding to the same eigenvalue as the vacuum vector:

$$\mathcal{H}_i \psi^0_{\alpha_1,\ldots,\alpha_m} = \left(\sum_{j=1, j\neq i}^{N} \frac{\langle \lambda_i, \lambda_j \rangle}{z_i - z_j} \right) \psi^0_{\alpha_1,\ldots,\alpha_m}.$$

Remark that these vectors of Ω lie in $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$ only if the roots α_i are all simple. The lemma is a consequence of the following property of the operators $\mathcal{H}_i$:

$$\left[\mathcal{H}_i, \sum_{k=1}^{N} F^{(k)}_{\alpha} \right] = 0, \quad \forall \alpha \in \Delta_0.$$

IV. SINGULAR AND NONSINGULAR EIGENVECTORS

In the previous sections we have constructed two types of eigenvectors for the Gaudin Hamiltonians: the Bethe vectors $\psi_m(w_1,\ldots,w_m)v_0$ in (12) and $\psi_m(w_1,\alpha_1,\ldots,w_m,\alpha_m)v_0$ in (33) and the additional eigenvectors ψ^0_m in (16) and $\psi^0_{\alpha_1,\ldots,\alpha_m}$ in (40). In this section we prove that Bethe vectors are singular only if the Bethe equations are satisfied and that the additional eigenvectors are not singular.

A vector v of the tensor product representation Ω is called singular if

$$E_\alpha v=\sum_{i=1}^{N} E_\alpha^{(i)} v=0, \quad \forall \alpha\in\Delta_0 .$$

In the case of the Lie algebra SL(2) the Bethe vectors $\psi_m(w_1,\ldots,w_m)v_0$ given by (12) are singular only for those values of $w_1,\ldots,w_m$ which are solutions of the Bethe equations (15), since

$$E\psi_m(w_1,\ldots,w_m)v_0=\sum_{k=1}^{m}\left(\sum_{j=1}^{N}\frac{\lambda_j}{w_k-z_j}+\sum_{l=1;l\neq k}^{m}\frac{2}{w_l-w_k}\right)\psi_{m-1}(\ldots,\widehat{w_k},\ldots)v_0 .$$

Therefore the Bethe equations (15) appear also as conditions that Bethe vectors be singular vectors of Ω.

Unlike Bethe vectors, the additional eigenvectors ψ_m^0 are not singular, since

$$E\psi_m^0=m\left(\sum_{j=1}^{N}\lambda_j-m+1\right)\psi_{m-1}^0\neq 0, \quad \forall m=1,\ldots,m_{\max}, \quad m_{\max}=\sum_{j=1}^{N}\lambda_j .$$

A similar result holds in the case of an arbitrary Lie algebra G:

Theorem 14: *For any simple root β, the action of the operator E_β on the Bethe vector (33) is given by*

$$E_\beta\psi_m(w_1,\alpha_1,\ldots,w_m,\alpha_m)v_0=\sum_{i=1}^{m}\frac{2\delta_{\beta\alpha_i}}{\langle\alpha_i,\alpha_i\rangle}\left[\sum_{j=1}^{N}\frac{\langle\alpha_i,\lambda_j\rangle}{w_i-z_j}-\sum_{j=1,j\neq i}^{m}\frac{\langle\beta,\alpha_j\rangle}{w_i-w_j}\right]\psi_{m-1}(\ldots,\widehat{w_i,\alpha_i},\ldots)v_0 . \tag{41}$$

Therefore, the Bethe vectors $\psi_m(w_1,\alpha_1,\ldots,w_m\alpha_m)v_0$ are singular only for those values of $w_1,\ldots,w_m$ which are solutions of the Bethe equations $f_j^m=0, \forall j=1,\ldots,m$ in (32).

Proof: Using similar considerations as for Theorem 10, we compute the commutator $[E_\beta,\psi_m]=[\Sigma_{k=1}^{N}E_\beta^{(k)},\psi_m]$, which is

$$\sum_{k=1}^{N}\sum_{\mathcal{P}_m}\left(\prod_{j=1,j\neq k}^{N}\sum_{\sigma\in\mathcal{S}(I^j)}\frac{(F_{\sigma(i_1^j)}\cdots F_{\sigma(i_{l_j}^j)})^{(j)}}{(w_{\sigma(i_1^j)}-w_{\sigma(i_2^j)})\cdots(w_{\sigma(i_{l_j}^j)}-z_j)}\right)\times\left(\sum_{\sigma\in\mathcal{S}(I^k)}\frac{[E_\beta,F_{\sigma(i_1^k)}\cdots F_{\sigma(i_{l_k}^k)}]^{(k)}}{(w_{\sigma(i_1^k)}-w_{\sigma(i_2^k)})\cdots(w_{\sigma(i_{l_k}^k)}-z_k)}\right). \tag{42}$$

Using the relation

$$[E_\beta,F_{\alpha_1}\cdots F_{\alpha_l}]=\sum_{n=1}^{l}\delta_{\beta,\alpha_n}\frac{2}{\langle\alpha_n,\alpha_n\rangle}F_{\alpha_1}\cdots\widehat{F_{\alpha_n}}\cdots F_{\alpha_l}\left(H_{\alpha_n}-\sum_{s=n+1}^{l}\langle\alpha_n,\alpha_s\rangle\right),$$

and applying Lemma 11, the last factor of (42) becomes (for simplicity, we leave out the index k)

$$\sum_{n=1}^{l}\sum_{\sigma\in\mathcal{S}_n}\sum_{q=1}^{l}\frac{2\delta_{\beta,\alpha_{i_n}}}{\langle\alpha_{i_n},\alpha_{i_n}\rangle}\frac{F_{\sigma(i_1)}\cdots F_{\sigma(i_{q-1})}\widehat{F_{i_n}}F_{\sigma(i_q)}\cdots F_{\sigma(i_{l-1})}(H_\beta-\Sigma_{s=q}^{l-1}\langle\beta,\alpha_{\sigma(i_s)}\rangle)}{(w_{\sigma(i_1)}-w_{\sigma(i_2)})\cdots(w_{\sigma(i_{q-1})}-w_{i_n})(w_{i_n}-w_{\sigma(i_q)})\cdots(w_{\sigma(i_{l-1})}-z_k)},$$

where, for each n, $\mathcal{S}_n$ are the permutations of the subset $\{i_1,\ldots,i_{l-1}\}=I\setminus\{i_n\}$ of I. To compute the sum over q we use Lemma 12 and we obtain

$$\sum_{n=1}^{l}\sum_{\sigma\in\mathcal{S}_n}\frac{2\delta_{\beta,\alpha_{i_n}}}{\langle\alpha_{i_n},\alpha_{i_n}\rangle}\frac{F_{\sigma(i_1)}\cdots F_{\sigma(i_{l-1})}}{(w_{\sigma(i_1)}-w_{\sigma(i_2)})\cdots(w_{\sigma(i_{l-1})}-z_k)}\left(\frac{H_\beta}{w_{i_n}-z_k}-\sum_{s=1}^{l-1}\frac{\langle\beta,\alpha_{\sigma(i_s)}\rangle}{w_{i_n}-w_{\sigma(i_s)}}\right).$$

In this expression, since σ is a bijection, it holds

$$\sum_{s=1}^{l-1}\frac{\langle\beta,\alpha_{\sigma(i_s)}\rangle}{w_{i_n}-w_{\sigma(i_s)}}=\sum_{s=1}^{l-1}\frac{\langle\beta,\alpha_{i_s}\rangle}{w_{i_n}-w_{i_s}},$$

and therefore the last parenthesis can be factorized out of the sum over permutations. Replacing this result in (42) we obtain

$$\sum_{\mathcal{P}_m}\sum_{k=1}^{N}\sum_{n=1}^{l_k}\frac{2\delta_{\beta,\alpha_{i_n}}}{\langle\alpha_{i_n},\alpha_{i_n}\rangle}\left(\prod_{\substack{j=1\\ j\neq k}}^{N}\sum_{\sigma\in\mathcal{S}(I^j)}\cdots\right)\sum_{\sigma\in\mathcal{S}_n}\frac{(F_{\sigma(i_1^k)}\cdots F_{\sigma(i_{l-1}^k)})^{(k)}}{(w_{\sigma(i_1^k)}-w_{\sigma(i_2^k)})\cdots(w_{\sigma(i_{l_k-1}^k)}-z_k)}$$
$$\times\left(\frac{H_\beta^{(k)}}{w_{i_n^k}-z_k}-\sum_{s\in I^k\setminus\{i_n^k\}}\frac{\langle\beta,\alpha_s\rangle}{w_{i_n^k}-w_s}\right).$$

For each partition $I^1,\ldots,I^N$ of $\mathcal{P}_m$ and for each index $r=1,\ldots,m$, there is only one index k such that $r\in I^k$. Therefore, in the last expression, there is only one term, containing $2\delta_{\beta,\alpha_r}/\langle\alpha_r,\alpha_r\rangle$. Hence the last expression is

$$\sum_{r=1}^{m}\frac{2\delta_{\beta,\alpha_r}}{\langle\alpha_r,\alpha_r\rangle}\sum_{\mathcal{P}_m}\left(\prod_{j=1,j\neq k}^{N}\sum_{\sigma\in\mathcal{S}(I^j)}\cdots\right)\left(\sum_{\sigma\in\mathcal{S}(I^k\setminus\{r\})}\cdots\right)\left(\frac{H_\beta^{(k)}}{w_r-z_k}-\sum_{s\in I^k\setminus\{r\}}\frac{\langle\beta,\alpha_s\rangle}{w_r-w_s}\right).$$

For each $r=1,\ldots,m$, the sum over the partitions $\mathcal{P}_m$ of the indices is rewritten as the sum over the partitions $(J^1,\ldots,J^N)\in\mathcal{P}_{m-1}$ of the indices $\{1,2,\ldots,m\}\setminus\{r\}$ and the index r is successively placed in each subset J^q. Hence we obtain

$$\sum_{r=1}^{m}\frac{2\delta_{\beta,\alpha_r}}{\langle\alpha_r,\alpha_r\rangle}\sum_{\mathcal{P}_{m-1}}\sum_{q=1}^{N}\left(\prod_{j=1,j\neq q}^{N}\sum_{\sigma\in\mathcal{S}(J^j)}\cdots\right)\left(\sum_{\sigma\in\mathcal{S}(J^q)}\cdots\right)\left(\frac{H_\beta^{(q)}}{w_r-z_q}-\sum_{s\in J^q}\frac{\langle\beta,\alpha_s\rangle}{w_r-w_s}\right).$$

We identify in this expression the vectors $\psi_{m-1}(\ldots,\widehat{w_r,\alpha_r},\ldots)$, given by (33), and we obtain (41).

V. BETHE ANSATZ AND KNIZHNIK–ZAMOLODCHIKOV EQUATION

Knizhnik–Zamolodchikov equations

$$\frac{\partial\Phi}{\partial z_i}(z_1,\ldots,z_N)=\frac{1}{\kappa}\mathcal{H}_i(z_1,\ldots,z_N)\Phi(z_1,\ldots,z_N),\quad i=1,\ldots,N,\tag{43}$$

were first introduced[9] as a system of partial differential equations for correlation functions of primary fields in a WZW model of conformal field theory. The number κ is the sum of the dual Coxeter number of the Lie algebra G and the central charge of the model.

Such a system is defined by N operators:

$$\mathcal{H}_i(z_1,\ldots,z_N)=\sum_{j=1,j\neq i}^{N}\frac{1}{z_i-z_j}\sum_{a=1}^{d}I_a^{(i)}\tilde{I}_a^{(j)},\quad\forall i=1,\ldots,N,$$

on a tensor product representation Ω, which are rational functions of complex variables $z_1,\ldots,z_N$. The ''coefficients'' $\mathcal{H}_i(z_1,\ldots,z_N)$ of this system commute and verify

$$\frac{\partial \mathcal{H}_i}{\partial z_j}=\frac{\partial \mathcal{H}_j}{\partial z_i},$$

which means that the differential form $\Sigma_{i=1}^{N}\mathcal{H}_i\,dz_i$ is closed. Hence the conditions of integrability of the system are fulfilled.

This system is rather difficult to solve, but there is a simple exception in the case of four variables, when the partial differential equation can be reduced to an ordinary differential equation of hypergeometric type. In this case, the four-point correlation functions for a model related to the SL(2) Lie algebra was determined.[16] This has led to the idea that such correlation functions admit representations as generalized hypergeometric integrals (also known as Feigin–Fuchs integrals). For KZ equations associated to arbitrary Lie algebra, Varchenko and Schechtman[17,8] gave a set of solutions in terms of generalized hypergeometric integrals. We present here these solutions.

Consider the KZ equations in the tensor product representation Ω, which is also a graduate space with its weight decomposition $\Omega=\oplus\mathcal{V}_\mu$. In each weight subspace $\mathcal{V}_\mu$, of weight $\mu=\Sigma_{i=1}^{N}\lambda_i-\Sigma_{j=1}^{m}\alpha_j$, a solution of the KZ equations with values in the subspace of singular vectors $\mathrm{Sing}\mathcal{V}_\mu$ is given by

$$\Phi(z_1,\ldots,z_N)=\int_\gamma \chi(z_1,\ldots,z_N;w_1,\ldots,w_m)\,\psi(w_1,\alpha_1;\ldots;w_m,\alpha_m)\,dw_1\cdots dw_m. \tag{44}$$

Here χ is the multivalued complex function:

$$\chi_m(\mathbf{z},\mathbf{w})=\prod_{1\leqslant j<k\leqslant N}(z_j-z_k)^{\langle\lambda_j,\lambda_k\rangle/\kappa}\prod_{j=1}^{N}\prod_{l=1}^{m}(w_l-z_j)^{-\langle\alpha_l,\lambda_j\rangle/\kappa}\prod_{1\leqslant l<n\leqslant m}(w_l-w_n)^{\langle\alpha_l,\alpha_n\rangle/\kappa}$$

with $\mathbf{z}=(z_1,\ldots,z_N)$, $\mathbf{w}=(w_1,\ldots,w_m)$ and γ is a m-cycle in the complement in $\mathbb{C}^{N+m}$ of all hyperplanes

$$z_j-z_k=0;\quad w_l-w_n=0;\quad w_l-z_j=0;\quad \forall j,k=1,\ldots,N;\quad l,n=1,\ldots,m,$$

on which $\chi(\mathbf{z},\mathbf{w})$ is a single-valued function of $\mathbf{w}$. The vector valued function $\psi\in V_\mu$ is a sum of ordered monomials with rational complex coefficients:

$$\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)=\sum_{\mathcal{P}}\prod_{j=1}^{N}\frac{(F_{i_1^j}\cdots F_{i_{l_j}^j})^{(j)}}{(w_{i_1^j}-w_{i_2^j})(w_{i_2^j}-w_{i_3^j})\cdots(w_{i_{l_j}^j}-z_j)}v_0, \tag{45}$$

where the product is taken over all components V_{λ_j} of the tensor product representation Ω and the sum is taken over all ordered partitions $I^1\cup\cdots\cup I^N$ of the set of indices $\{1,\ldots,m\}$ of the m simple roots $\alpha_1,\ldots,\alpha_m$. The ordered partitions are considered with N disjoint subsets, which can be empty, as well: $I^j=\{i_1^j,\ldots,i_{l_j}^j\}$, with $0\leqslant l_j\leqslant m$.

In this form, the solution (44) of KZ equations seems to be rather complicated, but a simple direct calculation can be performed to obtain

$$\kappa\frac{\partial\chi_m}{\partial z_i}(\mathbf{z},\mathbf{w})=\left(\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\sum_{k=1}^{m}\frac{\langle\alpha_k,\lambda_i\rangle}{w_k-z_i}\right)\chi_m=s_i^m(\mathbf{z},\mathbf{w})\chi_m(\mathbf{z},\mathbf{w}),$$

$$\kappa\frac{\partial\chi_m}{\partial w_k}(\mathbf{z},\mathbf{w})=\left(\sum_{l=1;l\neq k}^{m}\frac{\langle\alpha_k,\alpha_l\rangle}{w_k-w_l}-\sum_{j=1}^{N}\frac{\langle\alpha_k,\lambda_j\rangle}{w_k-z_j}\right)\chi_m=-f_k^m(\mathbf{z},\mathbf{w})\chi_m(\mathbf{z},\mathbf{w})$$

for all $i=1,\ldots,N$ and $k=1,\ldots,m$. The particular form of the denominator of (45) allows us to change the derivative of ψ_m with respect to z_i into a sum of derivatives with respect to w_k:

$$\frac{\partial \psi_m}{\partial z_i}(\mathbf{z},\mathbf{w}) = -\sum_{k=1}^{m} \frac{\partial}{\partial w_k} \overline{\psi}_m^{ik}(\mathbf{z},\mathbf{w}), \quad \forall i = 1,\ldots,N,$$

where $\overline{\psi}_m^{ik}$ is also a vector of $\mathcal{V}_\mu$.

Using the last three relations we can formally compute

$$\left(\frac{\partial}{\partial z_i} - \frac{1}{\kappa}\mathcal{H}_i\right)\Phi = \int_\gamma \chi_m(\mathbf{z},\mathbf{w})\left\{\mathcal{H}_i(\mathbf{z})\psi_m(\mathbf{z},\mathbf{w}) - s_i^m(\mathbf{z},\mathbf{w})\psi_m(\mathbf{z},\mathbf{w}) + \sum_{k=1}^{m} f_k^m(\mathbf{z},\mathbf{w})\overline{\psi}_m^{ik}(\mathbf{z},\mathbf{w})\right\} \mathrm{d}\mathbf{w}. \tag{46}$$

To obtain this formula we have supposed that the derivatives $\partial/\partial z_i$ commute with the integral and that it is possible to choose a basis of contours γ such that integrals along them of total derivatives vanish.

It is clear from (46) that the generalized Bethe ansatz and the KZ equations are closely related. If we suppose that we know how to calculate the action of a Hamiltonian $\mathcal{H}_i$ on the vector valued function $\psi_m(\mathbf{z},\mathbf{w})$ given by (45) and if

$$\mathcal{H}_i(\mathbf{z})\psi_m(\mathbf{z},\mathbf{w}) = s_i^m(\mathbf{z},\mathbf{w})\psi_m(\mathbf{z},\mathbf{w}) - \sum_{k=1}^{m} f_k^m(\mathbf{z},\mathbf{w})\overline{\psi}_m^{ik}(\mathbf{z},\mathbf{w}),$$

then the function (44) is a solution of the KZ equation. In particular, this relation holds if all the coefficients $f_k^m(\mathbf{z},\mathbf{w})$ vanish for some $\overline{\mathbf{w}}(\mathbf{z})$ and if $\psi_m(\mathbf{z},\overline{\mathbf{w}}(\mathbf{z}))$ is an eigenvector of $\mathcal{H}_i$ with eigenvalue $s_i^m(\mathbf{z},\overline{\mathbf{w}}(\mathbf{z}))$. In the case of the Lie algebra SL(2), all these suppositions are fulfilled since the vector valued function (45) reduces to the Bethe vector (12) and the action of a Hamiltonian $\mathcal{H}_i$ on it is given by (14).

Conversely, it was proved[17] that (44) is a solution of the KZ equation. It follows from (46) that the integrand is a total derivative with respect to $\mathbf{w}$, but we can not conclude that it vanishes.

A. Additional solutions of KZ equation

All the integral solutions (44) proposed by Varchenko and Schechtman are singular vectors in the tensor product representation Ω. Moreover, in the case of the Lie algebra SL(2), it was proved [17] that, under certain conditions, the family of integral solutions is complete in $\mathrm{Sing}\mathcal{V}_\lambda$. However, other solutions which are not singular vectors may exist.

In this article we have introduced additional eigenvectors ψ_m^0 and $\psi_{\alpha_1,\ldots\alpha_m}^0$. These vectors are not singular. They lead to solutions of the KZ equations which do not have an integral form and which are not singular vectors.

In the case of the Lie algebra SL(2), each vector ψ_m^0 introduces one vector valued function:

$$\Phi_m^0(z_1,\ldots,z_N) = \chi^0(z_1,\ldots,z_N)\psi_m^0,$$

where

$$\chi^0(z_1,\ldots,z_N) = \prod_{1\leqslant j} \prod_{<k\leqslant N} (z_j - z_k)^{\langle \lambda_j,\lambda_k\rangle/\kappa},$$

for which we can verify directly that it is a solution of KZ equations, observing that

$$\kappa\frac{\partial}{\partial z_i}\chi^0 = \left(\sum_{j=1,j\neq i}^{N} \frac{\langle \lambda_i,\lambda_j\rangle}{z_i - z_j}\right)\chi^0 = s_i^0\chi^0.$$

In the case of an arbitrary Lie algebra G, with the same function $\chi^0(z_1,\ldots,z_N)$, for any vector $\psi_{\alpha_1,\ldots\alpha_m}^0$ we can construct in an analogous way solutions of KZ equations:

$$\Phi^0_{\alpha_1,\ldots\alpha_m}(z_1,\ldots,z_N)=\chi^0(z_1,\ldots,z_N)\psi^0_{\alpha_1,\ldots\alpha_m}.$$

VI. CONCLUSIONS

In this article, we recall the construction of the common eigenvectors of generalized Gaudin Hamiltonians based on generalized Bethe ansatz. This constructive method does not ensure the completeness of the system of eigenvectors. In each eigenspace of the spin operator we have constructed common eigenvectors, corresponding to the same eigenvalue as the vacuum vector and which can not be obtained by the Bethe ansatz.

The Bethe vectors are eigenvectors of the family of Hamiltonians only if the Bethe equations are satisfied and in this case they are also singular vectors in the tensor product representation. The additional eigenvectors proposed here are not singular.

We recall also the connection between Bethe vectors and integral solutions of the KZ equations. In an analogous way, the additional vectors lead to solutions of KZ equations which do not have integral representations. Moreover, these solutions are not singular vectors.

(Received 7 August 2001; accepted 8 August 2002)

It is shown that the notion of $\mathcal{W}_\infty$-algebra originally carried out over a (compact) Riemann surface can be extended to n complex dimensional (compact) manifolds within a symplectic geometrical setup. The relationships with the Kodaira–Spencer deformation theory of complex structures are discussed. Subsequently, some field theoretical aspects at the classical level are briefly underlined. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1513653]

I. INTRODUCTION

It is fair to say that the concept of dimensionality plays an important role in Physics. In particular, the developments in quantum field theory as well as in statistical mechanics have greatly enlarged its importance. In renormalization theory, string field models, the concept of dimension is found to be not only a characterization of the background space where the physical phenomena are supposed to take place, but also a physical regularizing parameter. Indeed, a world with a given dimension very often shows merits and faults not found in some others of different dimensions. This led to the search for hyperspaces which could gather together the praises and avoid the imperfections of the theoretical models.

For instance, two-dimensional models show the great relevance of complex structures[1] in quantum field theory. Moreover, this approach produces a dimensional halving, but, in spite of the low dimensionality, the conformal models are described by means of an infinite dimensional algebra.[2]

So, the wide class of these ''new'' symmetries has been supporting the conjecture that life in two dimensions could be easier and more convenient.[3] The so-called $\mathcal{W}$-algebras[4] were a byproduct of this feasibility in two-dimensional spaces. For an extensive review on the various possibilities offered by these kinds of symmetries we refer to Ref. 5. Thus the question of extending this type of symmetries to higher dimensional spaces comes naturally. The extension required the use of the Kodaira–Spencer deformation theory.[6] In particular, chiral symmetries have already been extended from 2D conformal models built on a Riemann surface to models to an n complex dimensional complex manifold.[7–9] Note that Kodaira–Spencer-type deformation theories have already been used to describe $\mathcal{W}_\infty$ in two (or more) dimensions[10–12] in order to study holomorphic properties (chiral splitting) or mirror manifolds of arbitrary complex dimension.[7,8,13–16]. Their cohomologies have been investigated both in Lagrangian field theory models[9] and in more general mathematical aspects in Refs. 17 and 18.

Therefore we shall address in the present paper the extension to n complex dimensions of our

BRS treatment for $\mathcal{W}_\infty$-algebra grounded on a symplectic approach.[19–21] In the latter, the algebra emerges from a ghost realization geometrically constructed from the symplectic approach and as a byproduct the infinite number of chiral ghost fields $\mathcal{C}^{(n)}$, $n=1,2,\ldots$, turn out to be $(-n,0)$-conformal fields and their infinitesimal variations have a well-defined geometrical setting. To be more specific, let us remind how the chiral $\mathcal{W}_\infty$-algebra is recovered in the bidimensional case over a Riemann surface. For any positive integer n, the local variations of the chiral ghosts are

$$\mathcal{S}\mathcal{C}^{(n)}(z,\overline{z})=\sum_{m=1}^{n} m\mathcal{C}^{(m)}(z,\overline{z})\partial_z\mathcal{C}^{(n-m+1)}(z,\overline{z}). \tag{1.1}$$

Introducing by duality to each ghost a local operator $T_{(n)}(z,\overline{z})$ in order to construct the anticommuting functional BRS operator,[22]

$$\delta=\sum_{n\geqslant 1}\int_\Sigma \mathrm{d}\overline{z}\wedge\mathrm{d}z\left(\mathcal{C}^{(n)}(z,\overline{z})T_{(n)}(z,\overline{z})+\mathcal{S}\mathcal{C}^{(n)}(z,\overline{z})\frac{\delta}{\delta\mathcal{C}^{(n)}(z,\overline{z})}\right), \tag{1.2}$$

namely, $\{\delta,\delta\}=0$, leads to the following local commutation relations:

$$\begin{aligned}[T_{(n)}(z,\overline{z}),T_{(m)}(z',\overline{z}')]=&\,n\partial_{z'}\delta^{(2)}(z'-z)T_{(n+m-1)}(z,\overline{z})\\&-m\partial_z\delta^{(2)}(z-z')T_{(n+m-1)}(z',\overline{z}'),\end{aligned} \tag{1.3}$$

which turn out to be a realization of the so-called W_∞-algebra if one goes to the Fourier modes.

We stress that the well-defined ghost realization allows one to write down the extension of the $\mathcal{W}_\infty$-algebra to higher dimensions. Moreover we want to take advantage of the symplectic description for incompressible flows in order to extend to n dimensions the notion of $\mathcal{W}_\infty$-algebra, which in two dimensions is related to area preserving diffeomorphisms, see for instance Ref. 23, and references therein.

The algebra will be described in our approach by means of the Kodaira–Spencer deformation theory of complex structures but reformulated in a symplectic framework. The physical motivation of investigating the subject is connected to the so-called W-gravity and also on the fact that quantizing a conformal gravitational theory would incorporate all the possible configurations of the gravitational fields. By the way, ''well-defined'' gravitational conformal models are fully described by means of the complex structure of the surrounding space. Therefore a complete description just at the classical level of all its possible deformations might be relevant for a successful quantum improvement.

The paper is organized as follows. We shall first briefly introduce, in a nontechnical way, the Kodaira–Spencer deformations, referring the reader to the book by Kodaira[6] for a more complete survey, especially Chaps. 2, 4, and 5. Then Sec. III will give a geometrical setting of symplectomorphisms in a generic n complex dimensional space in order to introduce the BRS formulation of the (infinitesimal) diffeomorphisms of a symplectic space. Furthermore in Sec. IV the specific Kodaira–Spencer deformation of complex structures related to $\mathcal{W}_\infty$-algebra will be presented through a symplectic approach by using a ghost representation. It is recalled that the symplectic treatment of the two-dimensional case for $\mathcal{W}$-algebras[19] provides a well-defined geometrical definition of the ghost fields and their BRS variations as well. In the present paper we avail ourselves of that symplectic approach, in order to address the problem of extending to arbitrary complex dimensions the notion of $\mathcal{W}_\infty$-algebra and its consequences, in particular, for the study of Lagrangians subject to that type of symmetry to which a very brief section will be devoted.

II. A BRIEF ACCOUNT ON THE KODAIRA–SPENCER DEFORMATION

Let M be an n dimensional (compact) complex manifold described in terms of background local complex coordinates:

$$(z^k) := (z^1, z^2, \ldots, z^n), \quad k = 1, \ldots, n \tag{2.1}$$

and the subordinated differentiable structure $(z^k, \overline{z^k})$ turns M into a $2n$ real dimensional manifold.

Its complex structure is determined by the $\overline{\partial} \equiv \Sigma_{i=1}^{n} d\overline{z^i} \overline{\partial_i}$ operator. In order to control the deformation, usually a complex deformation parameter $t = (t_1, \ldots, t_n)$ is introduced. Basically the physical implications of this mathematical field of interest, rises from the primitive idea that a complex manifold is composed of a set of coordinate neighborhoods patched together. Obviously the patching procedure sewing should be irrelevant to the manifold description. In this philosophy a deformation of M is considered to be the sewing of the same patches, through a fit of the parameters t via various identifications. For our purpose the dimension of the parameter space will be exactly equal to that of M. According to Chap. 5 of Ref. 6 one considers a complex family of compact complex manifolds such as a complex manifold $\mathcal{M}$ and a holomorphic map $\varpi: \mathcal{M} \to \mathcal{B}$ where $\mathcal{B}$ is a domain in $\mathbb{C}^n$ such that $\varpi^{-1}(t) = M_t$ is a compact complex manifold. For $\Delta \subset \mathcal{B}$ sufficiently small, $\mathcal{M}_\Delta := \varpi^{-1}(\Delta)$ can be identified as a complex manifold with the complex structure defined on the smooth manifold $M \times \Delta$ since the subordinated smooth structure is always the same and does not depend on t (Ref. 6 Theorem 2.3). Accordingly, local complex coordinates on $\mathcal{M}_\Delta$ will be given by the system of local complex coordinates $(\mathcal{Z}^\alpha((z,\overline{z}),t), t^\alpha)$, $\alpha = 1, \ldots, n$ and for fixed t, M_t is the complex structure of the differentiable manifold M defined by the system of local complex coordinates $(\mathcal{Z}^\alpha((z,\overline{z}),t))$, $\alpha = 1, \ldots, n$ considered as a smooth change of local complex coordinates on M, i.e., the Jacobian does not vanish.

On the other hand, the deformation of complex structure is thus described by the change of the $\overline{\partial}$-operator,[6]

$$\overline{\partial} \to \overline{\partial} - \sum_{\ell=1}^{n} \mu^\ell((z,\overline{z}),t)\partial_\ell, \tag{2.2}$$

the $\mu^\ell((z,\overline{z}),t)$ are unique smooth (0,1)-forms on $M \times \Delta$. In this way, one can describe both infinitesimal and finite deformations. Indeed, by looking for, at fixed t, the local solutions $\mathcal{Z}^\alpha((z,\overline{z}),t)$ of this family of deformed $\overline{\partial}$-operators

$$\left(\overline{\partial} - \sum_{\ell=1}^{n} \mu^\ell((z,\overline{z}),t)\partial_\ell\right)\mathcal{Z}^\alpha((z,\overline{z}),t) = 0, \tag{2.3}$$

then they will patch together holomorphically with respect to the complex structure M_t and thus they will define a new complex structure parametrized by the μ on M.

To be consistent with the deformation philosophy discussed before, the previous equation (2.3) must be coupled (Newlander–Nirenberg integrability theorem)[6] with the Kodaira–Spencer (integrability) equation,

$$\overline{\partial}\mu((z,\overline{z}),t) - \tfrac{1}{2}[\mu((z,\overline{z}),t), \mu((z,\overline{z}),t)] = 0, \tag{2.4}$$

where $\mu((z,\overline{z}),t) = \mu^\ell((z,\overline{z}),t)\partial_\ell$, is a smooth (1,0)-vector field valued (0,1)-form on M and the graded brackets $[,]$ means the commutator of two vector fields and wedging.

To sum up, two solutions of Eq. (2.4) correspond to the same complex structure if they differ by an holomorphic diffeomorphism. Since for $t = 0$ both (z^k) and $(\mathcal{Z}^\alpha(z,0))$ are local complex coordinates on the complex manifold M, then $\mathcal{Z}^\alpha(z,0)$ are holomorphic functions of (z^k), showing that $\mu(z,0) = 0$. The construction of the new local complex coordinates $\mathcal{Z}^\alpha((z,\overline{z}),t)$ for each fixed t will correspond to a smooth change of local complex coordinates $(z^k) \mapsto (\mathcal{Z}^\alpha((z,\overline{z}),t))$. The construction holds in each holomorphic sector in t. Embedding in a symplectic framework generates an infinite sequence of changes of local complex coordinates. It is the signature of their behavior under symplectomorphisms which gives rise to an algebra. The latter extends to higher dimensions the usual $\mathcal{W}_\infty$-algebra (1.3).

For this reason, if we now wish to settle the Kodaira–Spencer deformation in a symplectic framework, we may consider the deformation parameters as the conjugate variables (by symplectic doubling, as it will be better specified later on) to those of the configuration space by identifying locally, as differentiable manifolds, the cotangent space T^*M with $\mathcal{M}_\Delta$ endowed with local smooth coordinates $(z^k,\overline{z^k},t,\overline{t})$. Then all the requirements to perform a Kodaira–Spencer deformation will be satisfied, so that this mathematical artillery will be at our disposal to investigate the possible extension of our symplectic approach to an n complex dimensional manifold and the consequences for physical models, in particular higher spin fields and their sources.

III. SYMPLECTOMORPHISMS IN 2*n* COMPLEX DIMENSIONAL COMPLEX SYMPLECTIC SPACE

Symplectomorphisms describe diffeomorphisms preserving a given symplectic structure on the cotangent bundle T^*M. They can be, respectively, described in terms of local coordinates, namely,

$$\begin{aligned}\mathcal{U}(z,y)&=(z^1\cdots z^n,\overline{z^1}\cdots\overline{z^n};y_1\cdots y_n,\overline{y_1}\cdots\overline{y_n}),\\ \mathcal{U}(Z,\mathcal{Y})&=(Z^1\cdots Z^n,\overline{Z^1}\cdots\overline{Z^n};\mathcal{Y}_1\cdots\mathcal{Y}_n,\overline{\mathcal{Y}_1}\cdots\overline{\mathcal{Y}_n})\end{aligned}\tag{3.1}$$

and, respectively, endowed with the symplectic fundamental two-form which, in full generality, locally writes according to the system of local coordinates—not necessarily Darboux's ones,

$$\Omega_{\mathcal{U}(z,y)}=\sum_{i,j=1}^{n}\omega^i_j\mathrm{d}z^j\wedge\mathrm{d}y_i+\mathrm{c.c.}=\mathrm{d}\theta_{\mathcal{U}(z,y)},\tag{3.2}$$

$$\Omega_{\mathcal{U}(Z,\mathcal{Y})}=\sum_{\alpha,\beta=1}^{n}\omega^\alpha_\beta\,\mathrm{d}Z^\beta\wedge d\mathcal{Y}_\alpha+\mathrm{c.c.}=\mathrm{d}\theta_{\mathcal{U}(Z,\mathcal{Y})}\tag{3.3}$$

with the following local requirements:

$$\det|\omega_{(i,j)}|\neq 0,\quad \det|\omega_{(\beta,\alpha)}|\neq 0,\quad d_z\omega^i_j=d_y\omega^i_j=d_Z\omega^\alpha_\beta=d_{\mathcal{Y}}\omega^\alpha_\beta=0.\tag{3.4}$$

and the invariance of the fundamental two-form is locally expressed by

$$\Omega_{\mathcal{U}(z,y)}=\Omega_{\mathcal{U}(Z,\mathcal{Y})}.\tag{3.5}$$

Locally, this implies on $\mathcal{U}(z,y)\cap\mathcal{U}(Z,\mathcal{Y})\neq\varnothing$ that

$$\theta_{\mathcal{U}(z,y)}-\theta_{\mathcal{U}(Z,\mathcal{Y})}=\mathrm{d}F.\tag{3.6}$$

From now on, we shall work locally in terms of the ''mixed'' local independent coordinates $(z,\mathcal{Y})$,

$$\mathcal{U}(z,\mathcal{Y})=(z^1\cdots z^n,\overline{z^1}\cdots\overline{z^n};\mathcal{Y}_1\cdots\mathcal{Y}_n,\overline{\mathcal{Y}_1}\cdots\overline{\mathcal{Y}_n}),\tag{3.7}$$

where we define the differential operators (from now on the Einstein's convention for summation will be used throughout the paper):

$$d=d_z+\mathrm{d}_{\mathcal{Y}},\quad d_z=\mathrm{d}z^i\frac{\partial}{\partial z^i}+\mathrm{d}\overline{z^i}\frac{\partial}{\partial\overline{z^i}}=\mathrm{d}z^i\partial_i+\mathrm{d}\overline{z^i}\bar{\partial}_i,\quad d_{\mathcal{Y}}=\mathrm{d}\mathcal{Y}_\alpha\frac{\partial}{\partial\mathcal{Y}_\alpha}+\mathrm{d}\overline{\mathcal{Y}_\alpha}\frac{\partial}{\partial\overline{\mathcal{Y}_\alpha}}.\tag{3.8}$$

The corresponding generating function $\Phi(z,\mathcal{Y})$ is obtained through the Legendre transformation

$$d\Phi(z\mathcal{Y}) = d(F + \omega^{\alpha}_{\beta} Z^{\beta}\mathcal{Y}_{\alpha} + \text{c.c.}) = \omega^{i}_{j} y_{i} dz^{j} + \omega^{\alpha}_{\beta} Z^{\beta} d\mathcal{Y}_{\alpha} + \text{c.c.}. \tag{3.9}$$

In the cotangent space T^*M endowed with this system of local coordinates, the mappings:

$$\mathbf{y}_i(z,\mathcal{Y}) \equiv \omega^{j}_{i} y_j = \frac{\partial \Phi(z,\mathcal{Y})}{\partial z^{i}} \equiv \partial_i \Phi(z,\mathcal{Y}), \tag{3.10}$$

$$\mathcal{Z}^{\alpha}(z,\mathcal{Y}) \equiv \omega^{\alpha}_{\beta} Z^{\beta} = \frac{\partial \Phi(z,\mathcal{Y})}{\partial \mathcal{Y}_{\alpha}} \tag{3.11}$$

are canonical and define new canonical variables via the ω matrices.

Several ways can settle this canonical procedure: Poisson brackets (or something similar), flow analysis of hierarchical structures. We shall be concerned with the study of this aspect in a field theoretical language by using the BRS formulation. Moreover we can rewrite:

$$\begin{aligned}\Omega_{\mathcal{U}(z,\mathcal{Y})} &= \partial_i \mathcal{Z}^{\alpha}(z,\mathcal{Y}) dz^{i} \wedge d\mathcal{Y}_{\alpha} + \overline{\partial_i} \mathcal{Z}^{\alpha}(z,\mathcal{Y}) d\overline{z^{i}} \wedge d\mathcal{Y}_{\alpha} + \partial_i \overline{\mathcal{Z}^{\alpha}}(z,\mathcal{Y}) dz^{i} \wedge d\overline{\mathcal{Y}_{\alpha}} + \overline{\partial_i}\,\overline{\mathcal{Z}^{\alpha}}(z,\mathcal{Y}) d\overline{Z^{\alpha}} \wedge d\overline{\mathcal{Y}_{\alpha}} \\ &= \frac{\partial}{\partial \mathcal{Y}_{\alpha}} \mathbf{y}_i(z,\mathcal{Y}) dz^{i} \wedge d\mathcal{Y}_{\alpha} + \frac{\partial}{\partial \mathcal{Y}_{\alpha}} \overline{\mathbf{y}_i}(z,\mathcal{Y}) d\overline{z^{i}} \wedge d\mathcal{Y}_{\alpha} + \frac{\partial}{\partial \overline{\mathcal{Y}_{\alpha}}} \mathbf{y}_i(z,\mathcal{Y}) dz^{i} \wedge d\overline{\mathcal{Y}_{\alpha}} \\ &\quad + \frac{\partial}{\partial \overline{\mathcal{Y}_{\alpha}}} \overline{\mathbf{y}_i}(z,\mathcal{Y}) d\overline{z^{i}} \wedge d\overline{\mathcal{Y}_{\alpha}} = d_z d_{\mathcal{Y}} \Phi(z,\mathcal{Y})\end{aligned} \tag{3.12}$$

from which we get the relations of duality (with their complex conjugate expressions as well):

$$\partial_i \mathcal{Z}^{\alpha}(z,\mathcal{Y}) = \frac{\partial}{\partial \mathcal{Y}_{\alpha}} \mathbf{y}_i(z,\mathcal{Y}), \quad \overline{\partial_i} \mathcal{Z}^{\alpha}(z,\mathcal{Y}) = \frac{\partial}{\partial \mathcal{Y}_{\alpha}} \overline{\mathbf{y}_i}(z,\mathcal{Y}). \tag{3.13}$$

In order to parametrize our space we define[19–21] the Hessian matrix elements by

$$\partial_i \frac{\partial}{\partial \mathcal{Y}_{\alpha}} \Phi(z,\mathcal{Y}) \equiv \lambda^{\alpha}_{i}(z,\mathcal{Y}), \tag{3.14}$$

$$\overline{\partial_j} \frac{\partial}{\partial \mathcal{Y}_{\alpha}} \Phi(z,\mathcal{Y}) \equiv \lambda^{\alpha}_{i}(z,\mathcal{Y}) \mu^{i}_{j}(z,\mathcal{Y}) \equiv \overline{\lambda^{\beta}_{j}}(z,\mathcal{Y}) \overline{\mu^{\alpha}_{\beta}}(z,\mathcal{Y}) \tag{3.15}$$

with $\det|\lambda| \neq 0$ for nonsingularity requirement and also for the complex conjugate expressions. From Eqs. (3.14) and (3.15) we get the following identities:

$$\partial_j \lambda^{\alpha}_{i}(z,\mathcal{Y}) = \partial_i \lambda^{\alpha}_{j}(z,\mathcal{Y}), \quad \frac{\partial}{\partial \mathcal{Y}_{\beta}} \lambda^{\alpha}_{i}(z,\mathcal{Y}) = \frac{\partial}{\partial \mathcal{Y}_{\alpha}} \lambda^{\beta}_{i}(z,\mathcal{Y}), \tag{3.16}$$

$$\overline{\partial_j} \lambda^{\alpha}_{i}(z,\mathcal{Y}) = \partial_i(\lambda^{\alpha}_{r}(z,\mathcal{Y}) \mu^{r}_{j}(z,\mathcal{Y})), \quad \frac{\partial}{\partial \overline{\mathcal{Y}_{\beta}}} \lambda^{\alpha}_{i}(z,\mathcal{Y}) = \frac{\partial}{\partial \mathcal{Y}_{\alpha}}(\overline{\lambda^{\beta}_{r}}(z,\mathcal{Y}) \overline{\mu^{r}_{i}}(z,\mathcal{Y})), \tag{3.17}$$

$$\overline{\partial_j} \lambda^{\alpha}_{i}(z,\mathcal{Y}) = \partial_i(\overline{\lambda^{\alpha}_{j}}(z,\mathcal{Y}) \overline{\mu^{\alpha}_{\alpha}}(z,\mathcal{Y})), \quad \frac{\partial}{\partial \overline{\mathcal{Y}_{\beta}}} \lambda^{\alpha}_{i}(z,\mathcal{Y}) = \frac{\partial}{\partial \mathcal{Y}_{\alpha}}(\lambda^{\sigma}_{i}(z,\mathcal{Y}) \mu^{\beta}_{\sigma}(z,\mathcal{Y})). \tag{3.18}$$

So from Eqs. (3.13) to (3.15) we have the following two main identities which must be viewed within the Kodaira–Spencer spirit of Eq. (2.3):

$$(\overline{\partial_j} - \mu_j^r(z,\mathcal{Y})\partial_r)\mathcal{Z}^\alpha(z,\mathcal{Y}) \equiv \mathcal{L}_j(z,\mathcal{Y})\mathcal{Z}^\alpha(z,\mathcal{Y}) = 0, \tag{3.19}$$

$$\left(\frac{\partial}{\partial\overline{\mathcal{Y}_\alpha}} - \mu_\beta^{\overline{\alpha}}(z,\mathcal{Y})\frac{\partial}{\partial\mathcal{Y}_\beta}\right)\mathbf{y}_r(z,\mathcal{Y}) \equiv \mathcal{L}^{\overline{\alpha}}(z,\mathcal{Y})\mathbf{y}_r(z,\mathcal{Y}) = 0, \tag{3.20}$$

where the role of the parameter t of deformation is presently played by the covariant coordinates $(\mathcal{Y},\overline{\mathcal{Y}})$ in the former or by the background complex coordinates $(z,\overline{z})$ in the latter. The first of the two equations tells us that a local deformation of the complex structure on the base complex manifold M can be implemented by using the symplectic structure on the cotangent bundle T^*M, while the second one governs the vertical deformation. This coincidence justifies our point of view of taking the conjugate variables as the deformation parameter. Hence, the complex family of complex manifolds $M_{\mathcal{Y}}$ is locally recasted as the symplectic cotangent bundle TM when the differentiable structure is considered.

Let us write down the following Pfaff system:

$$\begin{aligned} d_z\mathcal{Z}^\alpha(z,\mathcal{Y}) &= \lambda_i^\alpha(z,\mathcal{Y})(dz^i + \mu_j^i(z,\mathcal{Y})d\overline{z^j}) =: (dz + d\overline{z}\cdot\mu(z,\mathcal{Y}))\cdot\lambda(z,\mathcal{Y}), \\ d_{\mathcal{Y}}\mathbf{y}_i(z,\mathcal{Y}) &= \lambda_i^\alpha(z,\mathcal{Y})(d\mathcal{Y}_\alpha + \mu_\alpha^{\overline{\alpha}}(z,\mathcal{Y})d\overline{\mathcal{Y}_\alpha}). \end{aligned} \tag{3.21}$$

The system serves to define two types of Kodaira–Spencer differentials, namely, $\mu_j^i(z,\mathcal{Y})$ and $\mu_\beta^\alpha(z,\mathcal{Y})$ which parametrize the complex structures on the base space M with background local complex coordinates $(z,\overline{z})$ and the fibers with local coordinates $(\mathcal{Y},\overline{\mathcal{Y}})$, respectively. These complex structures are interlinked by the duality relations Eqs. (3.13)–(3.15)

$$\mu_j^i(z,\mathcal{Y}) = \overline{\partial_j}\mathcal{Z}^\beta(z,\mathcal{Y})[\lambda(z,\mathcal{Y})^{-1}]_\beta^i, \tag{3.22}$$

$$\mu_\beta^{\overline{\alpha}}(z,\mathcal{Y}) = [\overline{\lambda}(z,\mathcal{Y})^{-1}]_\beta^r\partial_r\overline{\mathcal{Z}^\alpha}(z,\mathcal{Y}). \tag{3.23}$$

Inverting the previous formulas (3.21) by matrix inversion

$$\partial_i = \lambda_i^\alpha(z,\mathcal{Y})\partial_\alpha + \overline{\mu_i^j}(z,\mathcal{Y})\overline{\lambda_j^\alpha}(z,\mathcal{Y})\partial_{\overline{\alpha}} = \lambda_i^\alpha(z,\mathcal{Y})(\partial_\alpha + \mu_\alpha^{\overline{\alpha}}(z,\mathcal{Y})\partial_{\overline{\alpha}}), \tag{3.24}$$

where

$$\partial_\alpha = \frac{\partial}{\partial\mathcal{Z}^\alpha(z,\mathcal{Y})},$$

one gets

$$\frac{\partial}{\partial\mathcal{Y}_\alpha} = \lambda_i^\alpha(z,\mathcal{Y})\left(\frac{\partial}{\partial\mathbf{y}_i} + \mu_j^i(z,\mathcal{Y})\frac{\partial}{\partial\overline{\mathbf{y}_j}}\right) \equiv \lambda_i^\alpha(z,\mathcal{Y})\mathcal{D}^i(z,\mathcal{Y}). \tag{3.25}$$

It is now easy to derive from Eqs. (3.15) to (3.25) another description of the Kodaira–Spencer differentials

$$\mu_j^i(z,\mathcal{Y}) = \mathcal{D}^i\partial_{\overline{j}}\Phi(z,\mathcal{Y}), \tag{3.26}$$

where $\mathcal{Y}=\mathcal{Y}(z,y)$ has to be taken into account. The most relevant properties of the $\mathcal{D}^i(z,\mathcal{Y})$ and $\partial/\partial\mathbf{y}_i$ operators can be summarized as

$$[\mathcal{D}^i(z,\mathcal{Y}),\mathcal{D}^j(z,\mathcal{Y})]=0, \quad \left[\frac{\partial}{\partial \mathbf{y}_i},\frac{\partial}{\partial \mathbf{y}_j}\right]=0, \quad \left[\frac{\partial}{\partial \mathbf{y}_i},\frac{\partial}{\partial \overline{\mathbf{y}}_i}\right]=0. \tag{3.27}$$

The third-order derivatives of Φ yield the integrability conditions (2.4) for the deformation of complex structures in the $(z,\overline{z})$ and $(\mathcal{Y},\overline{\mathcal{Y}})$ spaces, written respectively, as

$$\mathcal{L}_{\overline{i}}(z,\mathcal{Y})\mu^s_{\overline{j}}(z,\mathcal{Y})=\mathcal{L}_{\overline{j}}(z,\mathcal{Y})\mu^s_{\overline{i}}(z,\mathcal{Y}), \tag{3.28}$$

$$\lambda^\beta_i(z,\mathcal{Y})\partial_j\mu^{\overline{\alpha}}_{\overline{\beta}}(z,\mathcal{Y})=\lambda^\beta_j(z,\mathcal{Y})\partial_i\mu^{\overline{\alpha}}_{\overline{\beta}}(z,\mathcal{Y}). \tag{3.29}$$

Moreover in the $(\mathcal{Y},\overline{\mathcal{Y}})$ space, the partner of the Kodaira–Spencer equations can be immediately recovered computing $\partial_j(\partial/\partial\overline{\mathcal{Y}}_{\overline{\alpha}})(\partial/\partial\overline{\mathcal{Y}}_{\overline{\beta}})\Phi(z,\mathcal{Y})$,

$$\mathcal{L}^{\overline{\alpha}}(z,\mathcal{Y})\mu^{\overline{\beta}}_{\overline{\lambda}}(z,\mathcal{Y})=\mathcal{L}^{\overline{\beta}}(z,\mathcal{Y})\mu^{\overline{\alpha}}_{\overline{\lambda}}(z,\mathcal{Y}) \tag{3.30}$$

with the consistency conditions:

$$[\mathcal{L}_{\overline{i}}(z,\mathcal{Y}),\mathcal{L}_{\overline{j}}(z,\mathcal{Y})]=0, \quad [\mathcal{L}^{\overline{\alpha}}(z,\mathcal{Y}),\mathcal{L}^{\overline{\beta}}(z,\mathcal{Y})]=0. \tag{3.31}$$

BRS setting of symplectomorphisms in $2n$ *complex dimensions*. As said before the Kodaira–Spencer deformations reparametrize in a consistent way the space of complex structures. Furthermore, we shall study the action of reparametrizations on symplectic space (symplectomorphisms).

The BRS setting for symplectomorphisms can be performed along the lines developed in Ref. 19. Let us define by $\mathcal{S}$ the nilpotent BRS operation associated with the infinitesimal symplectomorphisms. Locally, $\mathcal{S}$ will be represented in $(z,\mathcal{Y})$ coordinates by

$$\mathcal{S}\Phi(z,\mathcal{Y})=\Lambda(z,\mathcal{Y}), \quad \mathcal{S}\Lambda(z,\mathcal{Y})=0. \tag{3.32}$$

The infinitesimal BRS transformation of the deformed coordinate $\mathcal{Z}^\alpha(z,\overline{z})$ can be calculated from its canonical definition Eqs. (3.10) and (3.11),

$$\mathcal{S}\mathcal{Z}^\alpha(z,\mathcal{Y})=\frac{\partial}{\partial\mathcal{Y}_\alpha}\Lambda(z,\mathcal{Y})=\lambda^\alpha_i(z,\mathcal{Y})\mathcal{D}^i(z,\mathcal{Y})\Lambda(z,\mathcal{Y})=\mathcal{C}^i(z,\mathcal{Y})\partial_i\mathcal{Z}^\alpha(z,\mathcal{Y}), \tag{3.33}$$

where the chiral ghost fields $\mathcal{C}^i(z,\mathcal{Y})$ naturally emerge and are related to the ordinary diffeomorphism ghosts $c^i(z,\mathcal{Y})$, $\overline{c^j}(z,\mathcal{Y})$ on T^*M within this symplectic framework by

$$\mathcal{C}^i(z,\mathcal{Y})\equiv\mathcal{D}^i\Lambda(z,\mathcal{Y})=\left(\frac{\partial\Lambda(z,\mathcal{Y})}{\partial\mathbf{y}_i}+\mu^{\overline{i}}_{\overline{j}}(z,\mathcal{Y})\frac{\partial\Lambda(z,\mathcal{Y})}{\partial\overline{\mathbf{y}}_j}\right)=c^i(z,\mathcal{Y})+\mu^{\overline{i}}_{\overline{j}}(z,\mathcal{Y})\overline{c^j}(z,\mathcal{Y}), \tag{3.34}$$

which explicitly corresponds to a change of generators for symplectomorphisms. Their BRS variations read

$$\mathcal{S}\mathcal{C}^i(z,\mathcal{Y})=\mathcal{C}^j(z,\mathcal{Y})\partial_j\mathcal{C}^i(z,\mathcal{Y}), \tag{3.35}$$

$$\mathcal{S}c^i(z,\mathcal{Y})=[c^j(z,\mathcal{Y})\partial_j+\overline{c^j}(z,\mathcal{Y})\overline{\partial_j}]c^i(z,\mathcal{Y}). \tag{3.36}$$

These BRS transformations correspond to an infinitesimal reparametrization of $\mathcal{Z}^\alpha(z,\mathcal{Y})$ due to an infinitesimal shift of the $(z,\overline{z})$ background, keeping $(\mathcal{Y},\overline{\mathcal{Y}})$ fixed.

We can easily derive:

$$\mathcal{S}\lambda^\alpha_i(z,\mathcal{Y})=\partial_i(\lambda^\alpha_j(z,\mathcal{Y})\mathcal{C}^j(z,\mathcal{Y})), \tag{3.37}$$

$$\mathcal{S}(\lambda_r^{\alpha}(z,\mathcal{Y})\mu_j^{r}(z,\mathcal{Y}))=\overline{\partial_j}(\lambda_r^{\alpha}(z,\mathcal{Y})\mathcal{C}^{r}(z,\mathcal{Y})), \tag{3.38}$$

so that

$$\mathcal{S}\mu_j^{i}(z,\mathcal{Y})=\mathcal{C}^{l}(z,\mathcal{Y})\partial_l\mu_j^{i}(z,\mathcal{Y})-\partial_l\mathcal{C}^{i}(z,\mathcal{Y})\mu_j^{l}(z,\mathcal{Y})+\overline{\partial_j}\mathcal{C}^{i}(z,\mathcal{Y}). \tag{3.39}$$

The nonchiral representation of this algebra can be easily given following the lines of Ref. 9, where we have stressed the relevance of the $(z,\overline{z})$ counterpart of the Kodaira–Spencer equation (3.30).

Moreover the ordinary ghosts $c^{i}(z,\mathcal{Y})$ transform as

$$\mathcal{S}c^{i}(z,\mathcal{Y})=(c^{l}(z,\mathcal{Y})\partial_l+\overline{c^{t}}(z,\mathcal{Y})\overline{\partial_l})c^{i}(z,\mathcal{Y}). \tag{3.40}$$

Finally, note the important commutators coming from the combination of the commutators

$$\left[\mathcal{S},\frac{\partial}{\partial\mathcal{Y}_{\alpha}}\right]=0=\left[\partial_i,\frac{\partial}{\partial\mathcal{Y}_{\alpha}}\right]$$

with (3.16) and (3.25):

$$\begin{aligned}[\mathcal{S},\mathcal{D}^{i}(z,\mathcal{Y})]&=-[\lambda(z,\mathcal{Y})^{-1}]_{\alpha}^{i}\partial_i(\lambda_j^{\alpha}(z,\mathcal{Y})\mathcal{C}^{j}(z,\mathcal{Y}))\mathcal{D}^{j}(z,\mathcal{Y})\\&=-\partial_r\mathcal{C}^{i}(z,\mathcal{Y})\mathcal{D}^{r}(z,\mathcal{Y})+\mathcal{C}^{r}(z,\mathcal{Y})[\partial_r,\mathcal{D}^{i}(z,\mathcal{Y})].\end{aligned} \tag{3.41}$$

Conversely, from Eqs. (3.10) and (3.11) we can derive the infinitesimal transformation of $\mathbf{y}_i(z,\mathcal{Y})$ due to an infinitesimal reparametrization on $(\mathcal{Y},\overline{\mathcal{Y}})$ space, keeping the $(z,\overline{z})$ background fixed,

$$\begin{aligned}\mathcal{S}\mathbf{y}_i(z,\mathcal{Y})=\partial_i\Lambda(z,\mathcal{Y})&=\lambda_i^{\alpha}(z,\mathcal{Y})(\partial_{\alpha}+\mu_{\alpha}^{\overline{\alpha}}(z,\mathcal{Y})\partial_{\overline{\alpha}})\Lambda(z,\mathcal{Y})\\&=(\omega_{\alpha}(z,\mathcal{Y})+\mu_{\alpha}^{\overline{\alpha}}(z,\mathcal{Y})\omega_{\overline{\alpha}}(z,\mathcal{Y}))\frac{\partial}{\partial\mathcal{Y}_{\alpha}}\mathbf{y}_i(z,\mathcal{Y})\\&=\mathcal{O}_{\alpha}(z,\mathcal{Y})\frac{\partial}{\partial\mathcal{Y}_{\alpha}}\mathbf{y}_i(z,\mathcal{Y}),\end{aligned} \tag{3.42}$$

where it has been set

$$\omega_{\alpha}(z,\mathcal{Y})=\partial_{\alpha}\Lambda(z,\mathcal{Y}) \tag{3.43}$$

and:

$$\mathcal{S}\mathcal{O}_{\alpha}(z,\mathcal{Y})=\mathcal{O}_{\beta}(z,\mathcal{Y})\frac{\partial}{\partial\mathcal{Y}_{\beta}}\mathcal{O}_{\alpha}(z,\mathcal{Y}). \tag{3.44}$$

Now the generating function $\Phi(z,\mathcal{Y})$ for such canonical transformations will be so chosen in order to view the holomorphic deformation process in the $\mathcal{Y}$ direction as being a canonical transformation.

For this purpose it will be convenient to use a multi-index notation. Let A,B denote multi-indices on the fibers related to Greek indices, while I,J denote multi-indices on M related to Latin indices. For $A=(a_1,\ldots,a_n)$ with positive integers $a_{\alpha}\geqslant 0$, $|A|=\Sigma_{\alpha=1}^{n}a_k$ will be the order of A and one sets $A+1_{\beta}=(a_1,\ldots,a_{\beta-1},a_{\beta}+1,a_{\beta+1},\ldots,a_n)$, $A!=\Pi_{\alpha=1}^{n}a_{\alpha}!$. For the sake of notational completeness, on the base M one will similarly use $I+1_k=(i_1,\ldots,i_{k-1},i_k+1,i_{k+1},\ldots,i_n)$. Now, one *chooses* a $\mathcal{Y}$-holomorphically split generating function

$$\Phi(z,\mathcal{Y})=\sum_{|A|\geqslant 1}\mathcal{Z}^{(A)}(z,\overline{z})\mathcal{Y}_A+\text{c.c.}, \tag{3.45}$$

where for $|A|\geqslant 1$ and $\mathcal{Y}_A:=\Pi_{\alpha=1}^{n}(\mathcal{Y}_\alpha)^{a_\alpha}$, we have set

$$\mathcal{Z}^{(A)}(z,\overline{z}):=\frac{1}{|A|!}\frac{\partial^{|A|}\Phi(z,\mathcal{Y})}{\partial\mathcal{Y}_A}\bigg|_{\mathcal{Y}=0}:=\frac{1}{|A|!}\frac{\partial^{|A|}\Phi(z,\mathcal{Y})}{(\partial\mathcal{Y}_1)^{a_1}\cdots(\partial\mathcal{Y}_n)^{a_n}}\bigg|_{\mathcal{Y}=0} \tag{3.46}$$

for the

$$\frac{(|A|+n-1)!}{|A|!(n-1)!}$$

independent derivatives of order $|A|$. With such a generating function the symplectic two-form (3.12) is locally written as

$$\Omega=\sum_{|A|\geqslant 1}d_z\mathcal{Z}^{(A)}(z,\overline{z})\wedge d_{\mathcal{Y}}\mathcal{Y}_A+\text{c.c.}, \tag{3.47}$$

while the new coordinates defined in (3.10) and (3.11) are, respectively, given by

$$\mathbf{y}_i(z,\mathcal{Y})=\sum_{|A|\geqslant 0}\partial_i\mathcal{Z}^{(A)}(z,\overline{z})\mathcal{Y}_A+\sum_{|B|\geqslant 0}\partial_i\overline{\mathcal{Z}^{(B)}}(z,\overline{z})\overline{\mathcal{Y}_B}, \tag{3.48}$$

$$\begin{aligned}\mathcal{Z}^{\alpha}(z,\mathcal{Y})&=\sum_{|A|\geqslant 0}\sum_{\alpha=1}^{n}(a_\alpha+1)\mathcal{Z}^{(A+1_\alpha)}(z,\overline{z})\mathcal{Y}_A\\&=\mathcal{Z}^{\alpha}(z,\overline{z})+\sum_{|A|\geqslant 1}\sum_{\alpha=1}^{n}(a_\alpha+1)\mathcal{Z}^{(A+1_\alpha)}(z,\overline{z})\mathcal{Y}_A.\end{aligned} \tag{3.49}$$

Note that $\mathcal{Z}^{\alpha}(z,\mathcal{Y})|_{\mathcal{Y}=0}=\mathcal{Z}^{\alpha}(z,\overline{z})$ showing that the complex structure given by the local complex coordinates $\mathcal{Z}^{\alpha}$ is the one which is actually deformed. Recall that the latter are local complex coordinates solutions of (3.19) at $\mathcal{Y}_\alpha=\overline{\mathcal{Y}_{\overline{\alpha}}}=0$ and have already been treated in the context n complex dimensional manifolds in Ref. 9.

As explicitly shown above, the local coefficients $\mathcal{Z}^{(A)}(z,\overline{z})$, $|A|\geqslant 1$ thus describe the response to the deformation of the $\mathcal{Z}^{\alpha}(z,\overline{z})$ complex coordinates. Combining the decomposition (3.47) with the covariance requirement (3.5) leads to an infinite sequence of changes of local complex coordinates $(z^k)\rightarrow(\mathcal{Z}^{(A)}(z,\overline{z}))$ whose algebra of infinitesimal transformations can be derived by means of BRS techniques.

Furthermore, the role of the complex structures involved in the present approach can be deepened. Indeed, the Kodaira–Spencer differentials $\mu^{i}_{\overline{j}}(z,\mathcal{Y})$ reflect the general behavior [see Eq. (3.26)] of the generating function of the canonical transformations. Their infinitesimal behavior in the $(z,\overline{z})$ and $(\mathcal{Y},\overline{\mathcal{Y}})$ spaces are constrained by both Eqs. (3.29) and (3.30). Now the explicit complex deformation will be chosen as a particular case of Ref. 6, according to

$$\mu^{i}_{\overline{j}}(z,\mathcal{Y})=\sum_{|A|\geqslant 0}\mu^{i(A)}_{\overline{j}}(z,\overline{z})\mathcal{Y}_A, \tag{3.50}$$

with

$$\mu^{i(A)}_{\overline{j}}(z,\overline{z})=\frac{1}{|A|!}\frac{\partial^{|A|+1}}{\partial\mathcal{Y}_{A+1_\beta}}(\overline{\partial_j}\Phi(z,\mathcal{Y})[\lambda(z,\mathcal{Y})^{-1}]^{i}_{\beta})\bigg|_{\mathcal{Y}=0}.$$

This series converges in a Holder norm[6] and represents a deformation of the integrable complex structure defined by $\mu_j^{i(0)}$ with the role of deformation parameters played by $\mathcal{Y}$ as already said before. Since the use of this space doubling is to introduce a symplectic structure in order that the smooth local changes of complex coordinates $(z^k)\to(\mathcal{Z}^{(A)}(z,\bar{z}))$ are interpreted as coming from a symplectomorphism symmetry. Recall that the generating function (3.45) for the canonical transformations has been chosen to be compatible with the deformation (3.50). The holomorphic character of the deformations will define, in a BRS framework, a series of infinitesimal symmetry transformations which will reproduce the n complex dimensional extension of the $\mathcal{W}_\infty$-algebra as will be shown in Sec. IV.

The link of the parametrization in Eq. (3.49) with the one of (3.50) is given through (3.15) for $|A|\geqslant 0$ and for each $\alpha=1,\ldots,n$-no summation over α-

$$(a_\alpha+1)\bar{\partial}_j\mathcal{Z}^{(A+1_\alpha)}(z,\bar{z})=\sum_{\substack{|B|,|C|\geqslant 0\\ B+C=A}}(b_\alpha+1)\partial_i\mathcal{Z}^{(B+1_\alpha)}(z,\bar{z})\mu_j^{i(C)}(z,\bar{z}) \tag{3.51}$$

which, in the particular case of $|A|=0$, reduces to the usual Beltrami equations

$$\bar{\partial}_j\mathcal{Z}^\alpha(z,\bar{z})=\partial_r\mathcal{Z}^\alpha(z,\bar{z})\mu_j^{r(0)}(z,\bar{z}), \tag{3.52}$$

which were fully treated in Ref. 9 in the two-dimensional case. In this context the integrability condition (3.28) is transferred on the jet coordinates $\mu_j^{i(A)}(z,\bar{z})$ with $|A|\geqslant 0$, as follows:

$$\bar{\partial}_i\mu_j^{r(A)}(z,\bar{z})-\bar{\partial}_j\mu_i^{r(A)}(z,\bar{z})=\sum_{\substack{|B|,|C|\geqslant 0\\ B+C=A}}(\mu_i^{s(B)}(z,\bar{z})\partial_s\mu_j^{r(C)}(z,\bar{z})-\mu_j^{s(B)}(z,\bar{z})\partial_s\mu_i^{r(C)}(z,\bar{z})). \tag{3.53}$$

For $|A|\geqslant 1$,

$$\bar{\partial}_j\mathcal{Z}^{(A)}(z,\bar{z})=\frac{1}{A!}\frac{\partial^{|A|}}{\partial\mathcal{Y}_A}\bar{\partial}_j\Phi(z,\mathcal{Y})\bigg|_{\mathcal{Y}=0}=\sum_{1\leqslant|I|\leqslant|A|}\mathcal{G}_{(I)}^{(A)}(z,\bar{z})\mu_j^{(I)}(z,\bar{z}), \tag{3.54}$$

where we have set for $|I|\geqslant 1$,

$$\mu_j^{(I)}(z,\bar{z}):=\frac{1}{I!}\mathcal{D}^{(I)}(z,\mathcal{Y})\bar{\partial}_j\Phi(z,\mathcal{Y})\bigg|_{\mathcal{Y}=0}:=\prod_{k=1}^n\left(\frac{1}{i_k!}(\mathcal{D}^k(z,\mathcal{Y}))^{i_k}\right)\bar{\partial}_j\Phi(z,\mathcal{Y})\bigg|_{\mathcal{Y}=0} \tag{3.55}$$

as representing the n-dimensional version for the $\mathcal{W}$-extension of the Beltrami multipliers introduced by Bilal, Fock, and Kogan.[24] It is worthwhile to say that the coefficients $\mathcal{G}_{(I)}^{(A)}(z,\bar{z})$ are very intricate nonlocal expressions depending on the derivatives up to order $|A|$ of $\mathcal{Z}^{(B)}$, with $1\leqslant|B|\leqslant|A|$. Writing (3.54) in more precise terms one has for $|A|\geqslant 1$,

$$\begin{aligned}\bar{\partial}_j\mathcal{Z}^{(A)}(z,\bar{z})&=\mu_j^r(z,\bar{z})\partial_r\mathcal{Z}^{(A)}(z,\bar{z})+\cdots\\ &\quad+\sum_{\alpha=1}^n\sum_{|I^\alpha|=a_\alpha}\frac{(I^1+\cdots+I^n)!}{I^1!\cdots I^n!}\left(\prod_{\beta=1}^n\lambda_{I^\beta}^\beta(z,\bar{z})\right)\mu_j^{(I^1+\cdots+I^n)}(z,\bar{z}),\end{aligned} \tag{3.56}$$

where on the multi-indices $I^\alpha=(i_1^\alpha,\ldots,i_n^\alpha)$ the summand $I=\Sigma_{\alpha=1}^n I^\alpha$ is the linear addition on the monoid of positive integers $\mathbb{N}^n$ while $\lambda_{I^\beta}^\beta(z,\bar{z})=\Pi_{r=1}^n(\partial_r\mathcal{Z}^\beta(z,\bar{z}))^{i_r^\beta}$. Moreover, in the above-given expansion μ_j^r must be identified with $\mu_j^{r(0)}$—see (3.51) and (3.52).

Furthermore, the symplectic structure of the space ought to provide by virtue of (3.50) a recursive construction for the coefficients $\mu_j^{i\,(A)}$ defined in (3.50) for the complex structure in terms of those of Bilal–Fock–Kogan defined in (3.55). This certainly allows one to write

$$\mu_j^i(z,\mathcal{Y})=\sum_{|I|\geqslant 1}\mathcal{F}^i_{(I)}(z,\mathcal{Y})\,\mu_j^{(I)}(z,\overline{z}), \tag{3.57}$$

where the very complicated coefficients $\mathcal{F}^i_{(I)}(z,\mathcal{Y})$ depending on $\mathcal{G}$ carry a well-defined geometrical meaning.

IV. CLASSICAL $\mathcal{W}_\infty$-ALGEBRA IN n-COMPLEX DIMENSIONS

Due to the holomorphically split expansion (3.45), the action of the BRS operator $\mathcal{S}$ on the theory can be parametrized by means of new ghost fields directly obtained from this expansion. These will be intimately related to the $\mathcal{W}_\infty$-algebra. Indeed, since $\mathcal{S}\mathcal{Y}_\alpha=0$, by using (3.46), for $|A|\geqslant 1$, one gets the same combinatorial expansion as (3.54),

$$\mathcal{S}\mathcal{Z}^{(A)}(z,\overline{z})=\frac{1}{A!}\frac{\partial^{|A|}}{\partial\mathcal{Y}_A}\Lambda(z,\mathcal{Y})\bigg|_{\mathcal{Y}=0}=\sum_{1\leqslant|I|\leqslant|A|}\mathcal{G}^{(A)}_{(I)}(z,\overline{z})\mathcal{C}^{(I)}(z,\overline{z}), \tag{4.1}$$

where we have introduced the independent ghost fields

$$\mathcal{C}^{(I)}(z,\overline{z})\coloneqq\frac{1}{I!}\mathcal{D}^{(I)}(z,\mathcal{Y})\Lambda(z,\mathcal{Y})\bigg|_{\mathcal{Y}=0}\coloneqq\prod_{k=1}^{n}\left(\frac{1}{i_k!}(\mathcal{D}^k(z,\mathcal{Y}))^{i_k}\right)\Lambda(z,\mathcal{Y})\bigg|_{\mathcal{Y}=0}. \tag{4.2}$$

Note that from the very definitions, the dependence on the generalized Bilal, Fock, and Kogan pararameters can be isolated and turns out to be coupled to the ghost $\overline{c}^{\overline{I}}\coloneqq\overline{c}^{(0,i)}$,

$$\mathcal{C}^{(I)}(z,\overline{z})=\mu_i^{(I)}(z,\overline{z})\overline{c}^{(0,i)}(z,\overline{z})+\cdots,\quad \overline{c}^{(0,i)}(z,\overline{z})\coloneqq\frac{\partial\Lambda(z,\mathcal{Y})}{\partial\overline{\mathbf{y}}_\mathbf{i}}\bigg|_{\mathcal{Y}=0}, \tag{4.3}$$

the full detailed expression will be given in the following–see (4.10).

Notably, after a tedious combinatorial calculation based upon the commutators (3.41), the BRS variations of the ghosts defined by (4.2) turn out to be local (in the sense that they do not depend on the λ fields), namely, for $|I|\geqslant 1$,

$$\mathcal{S}\mathcal{C}^{(I)}(z,\overline{z})=\sum_{k=1}^{n}(1-\delta_{0i_k})\sum_{J^{(k)}\leqslant I^{(k)}-1_k}\frac{(I-J^{(k)}-1_k+1_r)!}{(I-J^{(k)}-1_k)!}\times\mathcal{C}^{(I-J^{(k)}-1_k+1_r)}(z,\overline{z})\partial_r\mathcal{C}^{(J^{(k)}+1_k)}(z,\overline{z}), \tag{4.4}$$

where the notation $J^{(k)}$ means $J^{(k)}=(j_1,\ldots,j_k,0,\ldots,0)$ (and similarly for $I^{(k)}$), $J\leqslant I$ is a shorthand for $j_k\leqslant i_k$, $k=1,\ldots,n$ and

$$\frac{(I-J^{(k)}-1_k+1_r)!}{(I-J^{(k)}-1_k)!}=\begin{cases} i_r-j_r+1 & \text{if } 1\leqslant r\leqslant k-1\\ i_k-j_k & \text{if } r=k\\ i_r+1 & \text{if } k+1\leqslant r\leqslant n\end{cases}. \tag{4.5}$$

This formula represents the extended version to n complex dimensions of the *chiral* $\mathcal{W}_\infty$-algebra. Indeed, let us consider $n=1$ a complex curve which represents a bidimensional theory built on a Riemann surface. In that case, the multi-index I reduces to a simple index and for $|I|=i_1=m, J^{(1)}=(j_1)=j$, $r=k=1$, the formula (4.4) reduces (with $\ell=m-j$) to that found in Refs. 19 and 20,

$$\mathcal{S}\mathcal{C}^{(m)}(z,\overline{z})=\sum_{\ell=1}^{m}\ \ell\,\mathcal{C}^{(\ell)}(z,\overline{z})\partial\mathcal{C}^{(m-\ell+1)}(z,\overline{z}), \tag{4.6}$$

and recalled in Sec. I—see (1.1). Going back to the general case, at first order $|I|=1$, we refind the usual BRS transformations for the chiral ghosts $\mathcal{C}^i$ under diffeomorphisms of M,[9]

$$\mathcal{S}\mathcal{C}^i(z,\overline{z})=\mathcal{C}^\ell(z,\overline{z})\partial_\ell\mathcal{C}^i(z,\overline{z}), \tag{4.7}$$

showing that diffeomorphisms are actually captured by the $\mathcal{W}_\infty$-symmetry. In order to exemplify once more (4.4), at the second order $|I|=2$, for $1\leqslant i\leqslant j\leqslant n$, the multi-index $I=(0,\ldots,0,1,0,\ldots,0,1,0,\ldots,0)$, where 1 at both the ith and jth places will be shorthandly written as $I=(ij)$ in order to recover a tensorial notation. With this notation, one gets

$$\begin{aligned}\mathcal{S}\mathcal{C}^{(ij)}(z,\overline{z})=&\mathcal{C}^r(z,\overline{z})\partial_r\mathcal{C}^{(ij)}(z,\overline{z})+2\mathcal{C}^{(ii)}(z,\overline{z})\partial_i\mathcal{C}^j(z,\overline{z})+2\mathcal{C}^{(jj)}(z,\overline{z})\partial_j\mathcal{C}^i(z,\overline{z})\\&+\sum_{\substack{r=1\\r\neq i}}^{n}\mathcal{C}^{(ir)}(z,\overline{z})\partial_r\mathcal{C}^j(z,\overline{z})+\sum_{\substack{r=1\\r\neq j}}^{n}\mathcal{C}^{(jr)}(z,\overline{z})\partial_r\mathcal{C}^i(z,\overline{z}),\end{aligned}$$

(no summation on i and j and recall that the independent ghosts are $\mathcal{C}^{(ij)}$). In particular, the case $i=j$ is obtained by dividing both sides of the above equation by the symmetry factor 2,

$$\mathcal{S}\mathcal{C}^{(ii)}(z,\bar{z})=\underbrace{\mathcal{C}^r(z,\bar{z})\partial_r\mathcal{C}^{(ii)}(z,\bar{z})+2\mathcal{C}^{(ii)}(z,\bar{z})\partial_i\mathcal{C}^i(z,\bar{z})}_{\text{as in (4.6) with } m=2}+\sum_{r\neq i}\mathcal{C}^{(ri)}(z,\bar{z})\partial_r\mathcal{C}^i(z,\bar{z})$$

where $I=(ii)$ means 2 at the ith place, a shorthand notation saying that the multi-index entries are $i_k=2\,\delta_{ki}$. Of course, there is the complex conjugate expression to (4.4) as well.

Following the BRS method recalled in Sec. I, the algebra of the $\mathcal{W}_\infty$-generators in the n complex dimensional case will be obtained by duality through the corresponding BRS functional operator (1.2) from the BRS transformations (4.4) of the chiral ghost fields themselves. By performing this construction for the chiral ghosts, one should directly get a generalization to n dimensions of the chiral $\mathcal{W}_\infty$-algebra (1.3).

Accordingly, the BRS variations of the generalized Bilal–Fock–Kogan parameters (3.55) can be directly computed from (4.4) by using a trick related to diffeomorphisms,[25] namely, $\{\mathcal{S},\partial/\partial\overline{c^i}\}=\overline{\partial_i}$,, together with (4.3),

$$\begin{aligned}\mathcal{S}\mu_j^{(I)}(z,\overline{z})=&\overline{\partial_j}\mathcal{C}^{(I)}(z,\overline{z})+\sum_{k=1}^{n}(1-\delta_{0i_k})\sum_{J^{(k)}\leqslant I^{(k)}-1_k}\frac{(I-J^{(k)}-1_k+1_r)!}{(I-J^{(k)}-1_k)!}\\&\times(\mathcal{C}^{(I-J^{(k)}-1_k+1_r)}(z,\overline{z})\partial_r\mu_j^{(J^{(k)}+1_k)}(z,\overline{z})-\mu_j^{(I-J^{(k)}-1_k+1_r)}(z,\overline{z})\partial_r\mathcal{C}^{(J^{(k)}+1_k)}(z,\overline{z})).\end{aligned} \tag{4.8}$$

By using once more the previous trick on (4.8) one ends up with the counterpart of the integrability condition (3.30) in terms of the external fields (3.55) for $|I|\geqslant 1$, and with the aforementioned notation

$$\overline{\partial_i}\mu_j^{(I)}(z,\overline{z})-\overline{\partial_j}\mu_i^{(I)}(z,\overline{z})=\sum_{k=1}^{n}(1-\delta_{0i_k})\sum_{J^{(k)}\leqslant I^{(k)}-1_k}\frac{(I-J^{(k)}-1_k+1_r)!}{(I-J^{(k)}-1_k)!}$$
$$\times(\mu_{\overline{i}}^{(I-J^{(k)}-1_k+1_r)}(z,\overline{z})\partial_r\mu_{\overline{j}}^{(J^{(k)}+1_k)}(z,\overline{z})$$
$$-\mu_{\overline{j}}^{(I-J^{(k)}-1_k+1_r)}(z,\overline{z})\partial_r\mu_{\overline{i}}^{(J^{(k)}+1_k)}(z,\overline{z})). \tag{4.9}$$

The chiral ghost fields $\mathcal{C}^{(I)}$ admit a local decomposition in terms of the fields (3.55) which generalizes the well-known conformal one[26] in two dimensions. The latter has already been extended in Ref. 19 for Riemann surfaces. By definition the promised detailed expression for (4.3) is written as

$$\mathcal{C}^{(I)}(z,\overline{z})=\sum_{|P|,|Q|=0}^{|I|}\overline{Q}!\sum_{\substack{P+a_1J_1+\cdots+a_{|I|}J_{\underline{|I|}}=I\\ a_1+\cdots+a_{|I|}=|Q|}}$$
$$\times\left(\sum_{\substack{\overline{S}_1+\cdots+\overline{S}_{|I|}=\overline{Q}\\ |\overline{S}_k|=a_k,\ k=1,\ldots,|I|}}\prod_{k=1}^{|I|}\left(\frac{1}{\overline{S}_k!}(\mu^{(J_k)}(z,\overline{z}))_{\overline{S}_k}\right)\right)c^{(P,\overline{Q})}(z,\overline{z}), \tag{4.10}$$

where in the second summand a_k enumerates the number of multi-indices identical to J_k, $J_k\neq J_\ell$ for $k\neq\ell$ and $k,\ell=1,\ldots,|I|$, $(0\leqslant a_k\leqslant|I|)$, the sum goes with no repetition, and, for a given multi-index $\overline{S}_k=(\overline{s}_1^{(k)},\ldots,\overline{s}_n^{(k)})$,

$$(\mu^{(J_k)}(z,\overline{z}))_{\overline{S}_k}:=(\mu_{\overline{1}}^{(J_k)}(z,\overline{z}))^{\overline{s}_1^{(k)}}\cdots(\mu_{\overline{n}}^{(J_k)}(z,\overline{z}))^{\overline{s}_n^{(k)}} \tag{4.11}$$

and where new independent ghost fields have been introduced by

$$c^{(P,\overline{Q})}(z,\overline{z}):=\frac{1}{P!\overline{Q}!}\frac{\partial^{|P|}}{\partial\mathbf{y}_P}\frac{\partial^{|\overline{Q}|}}{\partial\overline{\mathbf{y}}_{\overline{Q}}}\Lambda(z,\mathcal{Y})\bigg|_{Y=0}. \tag{4.12}$$

Note that expression (4.10) which expresses a change of generators for the $\mathcal{W}$-symmetry is local. For instance, the case $|I|=1$ gives

$$\mathcal{C}^i(z,\overline{z})=c^{(i,0)}(z,\overline{z})+\mu_{\overline{s}}^i(z,\overline{z})c^{(0,\overline{s})}(z,\overline{z}),$$

which is the expression of the chiral ghost fields in terms of the true ghost fields $c^{(i,0)}$ and $c^{(0,\overline{s})}$ for (infinitesimal) diffeomorphisms of M,[9] while $|I|=2$ yields, respectively, for $I=(ii)$ and $I=(ij)$, $i<j$,

$$\mathcal{C}^{(ii)}(z,\overline{z})=c^{(ii,0)}(z,\overline{z})+\mu_{\overline{s}}^i(z,\overline{z})c^{(i,\overline{s})}(z,\overline{z})+(\mu_{\overline{s}}^i(z,\overline{z}))^2c^{(0,\overline{ss})}(z,\overline{z})+\mu_{\overline{s}}^{(ii)}(z,\overline{z})c^{(0,\overline{s})}(z,\overline{z})$$
$$+\sum_{\underline{r<s}}\mu_{\overline{r}}^i(z,\overline{z})\mu_{\overline{s}}^i(z,\overline{z})c^{(0,\overline{rs})}(z,\overline{z}),$$

$$\mathcal{C}^{(ij)}(z,\overline{z})=c^{(ij,0)}(z,\overline{z})+\mu_{\overline{s}}^i(z,\overline{z})c^{(j,\overline{s})}(z,\overline{z})+\mu_{\overline{s}}^j(z,\overline{z})c^{(i,\overline{s})}(z,\overline{z})+\mu_{\overline{s}}^{(ij)}(z,\overline{z})c^{(0,\overline{s})}(z,\overline{z})$$
$$+2\mu_{\overline{s}}^i(z,\overline{z})\mu_{\overline{s}}^j(z,\overline{z})c^{(0,\overline{ss})}(z,\overline{z})+\sum_{\underline{r<s}}(\mu_{\overline{r}}^i(z,\overline{z})\mu_{\overline{s}}^j(z,\overline{z})+\mu_{\overline{r}}^j(z,\overline{z})\mu_{\overline{s}}^i(z,\overline{z}))c^{(0,\overline{rs})}(z,\overline{z}).$$

The ghosts $c^{(R,\overline{S})}(z,\overline{z})$ satisfy rather elaborate BRS transformations, which generalize formula (4.4) to the nonchiral sectors. They can be obtained either from the very definition Eq. (4.12) or from the combined action of the decomposition Eq. (4.10) and the BRS variations (4.4) and (4.8). For $|P|+|\overline{Q}|\geqslant 1$ the variations look like

$$\begin{aligned}
\mathcal{S}c^{(P,\overline{Q})}(z,\overline{z}) = & \sum_{\overline{S}\leqslant\overline{Q}} \sum_{k=1}^{n} (1-\delta_{0p_k}) \sum_{R^{(k)}\leqslant P^{(k)}-1_k} \frac{(P-R^{(k)}-1_k+1_r)!}{(P-R^{(k)}-1_k)!} \\
& \times c^{(P-R^{(k)}-1_k+1_r,\overline{Q}-\overline{S})}(z,\overline{z})\partial_r c^{(R^{(k)}+1_k,\overline{S})}(z,\overline{z}) \\
& + (1-\delta_{0\overline{Q}}) \frac{(P+1_r)!}{P!} \sum_{\overline{S}\leqslant\overline{Q},|S|\geqslant 1} c^{(P+1_r,\overline{Q}-\overline{S})}(z,\overline{z})\partial_r c^{(0,\overline{S})}(z,\overline{z}) \\
& + \sum_{R\leqslant P} \sum_{k=1}^{n} (1-\delta_{0\overline{q_k}}) \sum_{\overline{S}^{(k)}\leqslant\overline{Q}^{(k)}-\overline{1_k}} \frac{(\overline{Q}-\overline{S}^{(k)}-\overline{1_k}+\overline{1_s})!}{(\overline{Q}-\overline{S}^{(k)}-\overline{1_k})!} \\
& \times c^{(P-R,\overline{Q}-\overline{S^k}-\overline{1_k}+\overline{1_s})}(z,\overline{z})\overline{\partial_s} c^{(R,\overline{S^k}+\overline{1_k})}(z,\overline{z}) \\
& + (1-\delta_{0P}) \frac{(\overline{Q}+\overline{1_s})!}{\overline{Q}!} \sum_{R\leqslant P,|R|\geqslant 1} c^{(P-R,\overline{Q}+\overline{1_s})}(z,\overline{z})\overline{\partial_s} c^{(R,0)}(z,\overline{z}), \qquad (4.13)
\end{aligned}$$

and, according to the BRS technique briefly recalled in Sec. I, give rise to the $\mathcal{W}_\infty$-structure at a nonchiral level. These results provide (in the $(z,\overline{z})$ submanifold characterized by $\mathcal{Y}_\alpha=\overline{\mathcal{Y}_{\overline{\alpha}}}=0$ in the symplectic space) an infinite $\mathcal{W}_\infty$-algebra of which the first step describes the reparametrization invariance $(z,\overline{z})\to(\mathcal{Z}^\alpha(z,\overline{z}),\overline{\mathcal{Z}^\alpha}(z,\overline{z}))$ studied in Ref. 9.

Here, what is left over is the relic of the deformation process for $\mathcal{Y}_\alpha,\overline{\mathcal{Y}_{\overline{\alpha}}}\neq 0$ given by an infinite hierarchy of smooth changes of local complex coordinates $(z,\overline{z})\to(\mathcal{Z}^{(A)}(z,\overline{z}),\overline{\mathcal{Z}^{(A)}}(z,\overline{z}))$ on the base (the $(z,\overline{z})$-space) of the symplectic space. The new $\mathcal{W}_\infty$-algebra really encodes the behavior under symplectomorphisms of this hierarchy.

V. TOWARD A LAGRANGIAN FORMULATION

If we now wish to construct a Lagrangian field theory whose classical limit is invariant under this n-dimensional extension of a $\mathcal{W}_\infty$-algebra, it would retain the imprinting of the infinite expansion from which the algebra is extracted, by reproducing a theory which is badly packed in the $(z,\overline{z})$ space and makes an attempt to get away in the full symplectic space. The ''classical'' fields whose dynamics serve to probe the $\mathcal{Y}_\alpha,\overline{\mathcal{Y}_{\overline{\alpha}}}\neq 0$ sector are the generalized Bilal–Fock–Kogan parameters $\mu_j^{(I)}(z,\overline{z})$ defined in (3.55). Indeed they are the only ''true'' local fields from which the pure gravitational theory would depend on. They are sources related to higher spin fields as in the unidimensional complex case, see, e.g., Ref. 24.

So from the BRS approach an infinite set of Ward operators $\mathcal{W}_{(I)}(z,\overline{z})$ can be obtained and from which a classical action Γ^{Cl} may be defined in the vacuum sector as follows. For $|I|\geqslant 1$,

$$\begin{aligned}
\mathcal{W}_{(I)}(z,\overline{z})\Gamma^{\mathrm{Cl}} = & -\overline{\partial_j}\frac{\delta\Gamma^{\mathrm{Cl}}}{\mu_j^{(I)}(z,\overline{z})} + \sum_{|L|\geqslant 1} ((i_r+\ell_r)(\partial_r\mu_j^{(L)}(z,\overline{z})) + \ell_r\,\mu_j^{(L)}(z,\overline{z})\partial_r)\frac{\delta\Gamma^{\mathrm{Cl}}}{\mu_j^{(I+L-1_r)}(z,\overline{z})} \\
= & 0. \qquad (5.1)
\end{aligned}$$

These encapsulate the first-order case $|I|=|L|=1$ already treated in Ref. 9. Remark also that in order to know the $\overline{\partial}$ divergence of the higher spin current, dual to $\mu_j^{(I)}$, the infinite collection of higher spin fields must be known first.

Using the usual techniques, which in the two-dimensional limit lead from Ward identities to O.P.E. expansion,[24] we can derive a generalization of the ''O.P.E.'' algebra which would promote the present symplectic approach, since an n complex dimensional short-distance product could generally be a difficult task to manage.

For both $|I|$ and $|J|$ greater than 0, one obtains

$$\pi\sum_{j=1}^{n}\int_{\mathbb{C}^{n-1}}\left(\prod_{\substack{\ell=1\\ \ell\neq j}}^{n}\frac{d\overline{w}^{\ell}\wedge dw^{\ell}}{2i(w^{\ell}-z'^{\ell})}\right)\frac{\delta^2\Gamma^{\mathrm{Cl}}}{\delta\mu_j^{(I)}(w^1,\ldots,z'^j,\ldots,w^n,\overline{w}^1,\ldots,\overline{z}'^j,\ldots,\overline{w}^n)\,\delta\mu_k^{(J)}(z,\overline{z})}\Bigg|_{\mu=0}$$
$$+\sum_{r=1}^{n}\left(\frac{i_r+j_r}{(z^r-z'^r)^2}-\frac{i_r}{z^r-z'^r}\right)\left(\prod_{\substack{\ell=1\\ \ell\neq r}}^{n}\frac{1}{z^{\ell}-z'^{\ell}}\right)\frac{\delta\Gamma^{\mathrm{Cl}}}{\delta\mu_j^{(I+J-1_r)}(z,\overline{z})}\Bigg|_{\mu=0}=0. \tag{5.2}$$

leading to a convolution algebra, where the directional properties of the (short) distance limit is taken into account, for the Green functions generated by the generalized Bilal–Fock–Kogan fields. Its two-dimensional limit gives the usual classical O.P.E. expansion.

Anyhow, due to the anomalous character of the diffeomorphism symmetry at the quantum level, we must foresee whether this defect would be transmitted to the residual part of the algebra. Hence quantum corrections would be required to give a meaning to the theoretical model and are still under investigation.

VI. CONCLUSIONS

It has been shown how a symplectic approach gives a strong geometrical way of extending the notion of $\mathcal{W}_\infty$-algebra as a symmetry arising in the one complex dimensional case to a generic n complex dimensional (compact) manifold.

This symmetry appears from consistent deformations of integrable complex structures in the spirit of Kodaira–Spencer deformation. The decomposition in terms of local quantities such as the Bilal–Fock–Kogan coefficients considered as generalized sources for higher spin fields naturally emerges from the construction. However, in this symplectic framework, a truncation process analogous to the one for Riemann surfaces[21] from $\mathcal{W}_\infty$-algebra to a finite $\mathcal{W}$-algebra is still lacking. In particular, the latter could be of some interest in both string and brane theories (see, e.g., Ref. 12) where higher spin fields appear in four real dimensions. In these theories, the fields seem to be related to some finite $\mathcal{W}$-algebra. However theoretical models with explicit higher spin fields still remain to be constructed.

More generally, even if the topic ought to seem, according to the physical context, rather technical and strongly grounded on mathematics, we would emphasize that the important problem of a metric or a complex structure for a physical theory embedded in a gravitational model is far from being understood. So any little step in that direction could be profitable in discovering the role of Nature and the intricacies of geometrical implications within the formulation of physical theories.

Given a pair of holomorphic structures on a complex vector bundle over a complex manifold, Dolbeault cohomological invariants are constructed. The construction is based on the construction of Chern–Simons secondary classes. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1510972]

I. INTRODUCTION

Let E be a C^∞ complex vector bundle over a complex manifold M. Holomorphic structures on E are defined by giving a Dolbeault operator. We recall that a Dolbeault operator is a first order differential operator

$$\overline{\partial}_E : E \to \Omega^{0,1}_M(E)$$

satisfying the Leibniz identity and the integrability condition $\overline{\partial}_E \bigcirc \overline{\partial}_E = 0$. The Leibniz identity says that $\overline{\partial}_E(fs) = f\overline{\partial}_E(s) + s \otimes \overline{\partial} f$, where f is a locally defined smooth function on M and s is a locally defined smooth section of E. The (locally defined) solutions of the operator are the holomorphic sections of the corresponding holomorphic vector bundle.

Let $\overline{\partial}_0$ and $\overline{\partial}_1$ be two Dolbeault operators on E. We construct a differential form $D_k(\overline{\partial}_0, \overline{\partial}_1)$ of degree $2k+1$ on M. This form $D_k(\overline{\partial}_0, \overline{\partial}_1)$ is of Hodge type $(0,2k+1)$ and it is $\overline{\partial}$ closed. Therefore, $D_k(\overline{\partial}_0, \overline{\partial}_1)$ gives a Dolbeault cohomology class in $H^{2k+1}(M, \mathcal{O}_M)$, where $\mathcal{O}_M$ is the coherent analytic sheaf of holomorphic functions.

The construction of $D_k(\overline{\partial}_0, \overline{\partial}_1)$ relies on the construction of secondary classes, and it has some of the properties enjoyed by secondary classes.

If $\overline{\partial}_2$ is a holomorphic structure on E such that $\overline{\partial}_1$ and $\overline{\partial}_2$ lies in the same path connected component in the space of all holomorphic structures on E, then for any $k \geqslant 1$, the Dolbeault cohomology class represented by $D_k(\overline{\partial}_0, \overline{\partial}_1)$ coincides with the one represented by $D_k(\overline{\partial}_0, \overline{\partial}_2)$ (Proposition 3.3).

If $\overline{\partial}_0$ and $\overline{\partial}_1$ are two holomorphic structures on E related by a C^∞ automorphism of E, then the cohomology class represented by $D_k(\overline{\partial}_0, \overline{\partial}_2)$ is contained in the image of the homomorphism

$$H^{2k+1}(M, (2\pi\sqrt{-1})^{k+1}\mathbb{Z}) \to H^{2k+1}(M, \mathcal{O}_M)$$

defined by the obvious inclusion of the constant sheaf $(2\pi\sqrt{-1})^{k+1}\mathbb{Z}$ in the sheaf $\mathcal{O}_M$ of holomorphic functions (Theorem 4.2).

II. SECONDARY INVARIANTS

Let M be a smooth manifold. Let E be a C^∞ complex vector bundle over M. The space of sections of $\mathrm{End}(E) \otimes \wedge T^*M$ has an obvious algebra structure which is defined using the (associative) multiplication of the fibers of $\mathrm{End}(E)$ and the exterior algebra structure of $\wedge T^*M$. The multiplication operation of $\mathrm{End}(E)$-valued forms will also be denoted $\wedge$. There is a natural ho-

a)Electronic mail: indranil@math.tifr.res.in

momorphism $\mathrm{End}(E)\otimes\wedge T^*M\to\wedge T^*M$ of vector bundles that sends any $s\otimes\omega$, where $s\in\mathrm{End}(E_x)$ and $\omega\in\wedge T^*_xM$ are in the fiber over any point $x\in M$, to $\mathrm{trace}(s)\omega$. This homomorphism will be denoted by trace.

Lemma 2.1: Take $\theta_i\in C^\infty(M,\mathrm{End}(E)\otimes\wedge^{n_i}T^*M)$, *where* $i\in[1,d]$. *The identity*

$$\mathrm{trace}(\theta_1\wedge\theta_2\wedge\cdots\wedge\theta_d)=(-1)^{n_1(n_2+n_3+\cdots+n_d)}\mathrm{trace}(\theta_2\wedge\theta_3\wedge\cdots\wedge\theta_d\wedge\theta_1)$$

is valid.

Proof: This is an immediate consequence of the fact that $\mathrm{trace}(AB)=\mathrm{trace}(BA)$, where $A,B\in M(n,\mathbb{C})$.

Let ∇ be a connection on E. The differential operator

$$C^\infty(E\otimes\wedge^iT^*M)\to C^\infty(E\otimes\wedge^{i+1}T^*M),$$

where $i\geqslant 1$, induced by ∇ will also be denoted by ∇. The curvature $\nabla\circ\nabla$ of ∇ will be denoted by K_∇. So $K_\nabla\in C^\infty(\mathrm{End}(E)\otimes\wedge^2T^*M)$. We will often use the notation ∇^2 to denote the curvature of ∇.

Lemma 2.2: If there is a $\mathrm{End}(E)$*-valued one form* θ *on* M *such that*

$$K_\nabla=\theta\wedge\theta,$$

then the $2k$*-form* $\mathrm{trace}((K_\nabla)^k)$ *vanishes identically*.

Proof: Since $(K_\nabla)^k=(\theta\wedge\theta)^k=\theta\wedge\theta^{2k-1}$, by setting $d=2$, $\theta_1=\theta$, and $\theta_2=\theta^{2k-1}$ in Lemma 2.1 we obtain that $\mathrm{trace}((K_\nabla)^k)=-\mathrm{trace}((K_\nabla)^k)$, and hence the lemma follows. □

The Hermitian–Yang–Mills connection on a polystable Higgs bundle is an example of a connection satisfying the condition in Lemma 2.2.[1] Let X be a compact connected Kähler manifold and V a holomorphic vector bundle over X. Let

$$\phi\in H^0(X,\mathrm{End}(V)\otimes\Omega^1_X)$$

be a holomorphic section with $\phi\wedge\phi=0$. Here Ω^1_X is the holomorphic cotangent bundle of X. For notational convenience, the vector bundle $\mathrm{End}(V)\otimes\Omega^1_X$ will be denoted by $\Omega^1_X(\mathrm{End}(V))$. If the pair (V,ϕ), which is called a *Higgs bundle*, is stable and $c_1(E)=0=c_2(E)$, then V admits a unique Hermitian connection satisfying the Yang–Mills equation.[1] If H is a Hermitian metric on V and ∇^H the corresponding Chern connection, then the Yang–Mills equation is the flatness condition

$$(\nabla^H+\phi+\phi^*)^2=0 \tag{2.1}$$

of the connection $\nabla^H+\phi+\phi^*$, where $\phi^*\in C^\infty(M,\Omega^{0,1}_X(\mathrm{End}(V)))$ is the adjoint of ϕ defined using H. It is easy to see that (2.1) is equivalent to the equation $(\nabla^H)^2=-(\phi+\phi^*)^2$. Therefore, a Hermitian–Yang–Mills connection ∇^H satisfies the condition in Lemma 2.2 with $\theta=\sqrt{-1}(\phi+\phi^*)$.

Take two connections ∇_0 and ∇_1 on E. Set $\omega:=\nabla_1-\nabla_0$, which is a $\mathrm{End}(E)$-valued one-form, and for any $t\in[0,1]$, let

$$\nabla_t:=\nabla_0+t\omega$$

be the connection on E. For any $k\geqslant 0$, consider the smooth differential form

$$C_k(\nabla_0,\nabla_1):=\int_0^1\mathrm{trace}(\omega\wedge(\nabla_t^2)^k)\in C^\infty(M,\wedge^{2k+1}T^*M) \tag{2.2}$$

of degree $2k+1$ on M. Note that the integration is defined using the vector space structure of the space of forms. The following lemma is essentially a consequence of Lemma 2.2.

Lemma 2.3: If both ∇_0 and ∇_1 satisfy the condition in Lemma 2.2, then the differential form $C_k(\nabla_0,\nabla_1)$ defined in (2.2) is closed.

Proof: Let $p:M\times[0,1]\to M$ be the projection map. The family of connections ∇_t gives a connection, which we will denote by $\overline{\nabla}$, on p^*E. For each $t\in[0,1]$, the connection induced on $(p^*E)|_{M\times\{t\}}$ by $\overline{\nabla}$ is ∇_t, and for any $x\in M$, the induced connection on $(p^*E)|_{\{x\}\times[0,1]}$ coincides with the natural trivialization of a pullback bundle on a fiber of the projection. These two properties evidently determine $\overline{\nabla}$. The Bianchi identity, says that for a connection ∇' on a vector bundle E', the $\mathrm{End}(E')$-valued three-form $\nabla'\circ\nabla'\circ\nabla'$ vanishes identically. Using the Bianchi identity for $\overline{\nabla}$ it follows that

$$dC_k(\nabla_0,\nabla_1)=\frac{1}{k+1}\int_0^1\frac{d}{dt}\mathrm{trace}((\nabla_t^2)^{k+1})=\frac{\mathrm{trace}((\nabla_1^2)^{k+1})}{k+1}-\frac{\mathrm{trace}((\nabla_0^2)^{k+1})}{k+1}$$

(see Ref. 2, Appendix for details). Now Lemma 2.2 completes the proof. □

For two connections ∇_0 and ∇_1 as in Lemma 2.3 (satisfying the condition in Lemma 2.2), the de Rham cohomology class in $H^{2k+1}(M,\mathbb{C})$ represented by the closed form $C_k(\nabla_0,\nabla_1)$ is an analog of the Chern–Simons secondary invariant for flat connections.[3] See Ref. 4 for construction of secondary invariants of Hermitian–Yang–Mills connections.

Although in the construction of $C_k(\nabla_0,\nabla_1)$ we use the straight-line segment defined by $t\mapsto\nabla_t$ in the affine space of connections on E, the cohomology class represented by the closed form $C_k(\nabla_0,\nabla_1)$ is independent of the choice of path connecting ∇_1 to ∇_0. To prove this, let γ be a smooth map from $[0,1]$ to $\mathrm{Conn}(E)$, the space of connections on E, such that $\gamma(0)=\nabla_0$ and $\gamma(1)=\nabla_1$. Let

$$\Omega_t\in C^\infty(M,\mathrm{End}(E)\otimes\wedge^2T^*M) \tag{2.3}$$

be the curvature of $\gamma(t)$. Now define

$$C_k^\gamma(\nabla_0,\nabla_1):=\int_0^1\mathrm{trace}\left(\frac{d\gamma(t)}{dt}\wedge(\Omega_t)^k\right)dt. \tag{2.4}$$

Note that $d\gamma(t)/dt\in C^\infty(M,\mathrm{End}(E)\otimes T^*M)$.

Proposition 2.4. The form $C_k^\gamma(\nabla_0,\nabla_1)$ is closed. The cohomology class in $H^{2k+1}(M,\mathbb{C})$ represented by it coincides with the one represented by $C_k(\nabla_0,\nabla_1)$ defined in (2.2).

Proof: If $k=0$, then $C_k^\gamma(\nabla_0,\nabla_1)$ and $C_k(\nabla_0,\nabla_1)$ coincide with $\nabla_1-\nabla_0$. So assume $k\geqslant 1$. Let

$$q:M\times[0,1]\times[0,1]\to M$$

be the natural projection map. Consider the map

$$\overline{\gamma}:[0,1]\times[0,1]\to\mathrm{Conn}(E)$$

that sends any (s,t) to $(1-s)\nabla_t+s\gamma(t)$. The map $\overline{\gamma}$ defines a connection on q^*E over $M\times[0,1]\times[0,1]$. The connection on q^*E, which we will denote by $\overline{\nabla}$, is determined by the following two conditions. For any $(s,t)\in[0,1]\times[0,1]$, the restriction of $\overline{\nabla}$ to $(q^*E)|_{M\times\{s\}\times\{t\}}$ coincides with the connection $\overline{\gamma}(s,t)$, and for any $x\in M$, the restriction of $\overline{\nabla}$ to $(q^*E)|_{\{x\}\times[0,1]\times[0,1]}$ coincides with the connection defined by the natural trivialization of $(q^*E)|_{\{x\}\times[0,1]\times[0,1]}$.

The curvature of the connection $\overline{\gamma}(s,t)$ will be denoted by $\Theta(s,t)$. Let ψ denote the one-form on $[0,1]\times[0,1]$ with values in $C^\infty(M,\wedge^{2k+1}T^*M)$ defined by

$$\psi(s,t)(v)=\mathrm{trace}\left(\frac{\partial\overline{\gamma}}{\partial v}(s,t)\wedge\Theta(s,t)^k\right),$$

where $(s,t)\in[0,1]\times[0,1]$, v is a tangent vector to $[0,1]\times[0,1]$ at (s,t) and $\partial/\partial v$ is the directional derivative. So, we have

$$\int_{\partial([0,1]\times[0,1])}\psi = C_k^{\gamma}(\nabla_0,\nabla_1)-C_k(\nabla_0,\nabla_1),$$

where $\partial([0,1]\times[0,1])$ denotes the boundary of $[0,1]\times[0,1]$ with the anticlockwise orientation. Therefore, Stokes' theorem gives

$$C_k^{\gamma}(\nabla_0,\nabla_1)-C_k(\nabla_0,\nabla_1)=\int_{[0,1]\times[0,1]} d\psi.$$

It suffices to show that the form on M defined by the right-hand side is exact.

Let $\overline{\nabla}^2$ be the curvature of the connection $\overline{\nabla}$ on q^*E. Consider the differential form of degree $2k+2$ on $M\times[0,1]\times[0,1]$ defined by $\mathrm{trace}((\overline{\nabla}^2)^{k+1})$. It is straightforward to check that the Künneth component of this form in $\wedge^{2k+1}T^*M\otimes\wedge^1([0,1]\times[0,1])$ coincides with form defined by ψ.

Now it follows that $d\psi$ coincides with the two-form that sends any ordered pair of tangent vectors v_1, $v_2\in T_{(s,t)}[0,1]\times[0,1]$ at any point (s,t) to

$$k\,d\,\mathrm{trace}\left(\frac{\partial\overline{\gamma}}{\partial v_1}(s,t)\wedge\frac{\partial\overline{\gamma}}{\partial v_2}(s,t)(\Theta(s,t))^{k-1}\right).$$

Therefore, $d\psi$ is a two-form on $[0,1]\times[0,1]$ with values in exact $(2k+1)$-forms on M. Consequently, $\int_{[0,1]\times[0,1]}d\psi$ is an exact $(2k+1)$-form on M. This completes the proof of the proposition. □

The Proposition 2.4 has the following consequence. Let ∇_0 and ∇_1 be two connections as in Proposition 2.4 both satisfying the condition in Lemma 2.2. Suppose that ∇_0 and ∇_1 are such that there is a smooth path γ in $\mathrm{Conn}(E)$ connecting ∇_0 with ∇_1 and satisfying the condition that each $\gamma(t)$ is a flat connection, that is each Ω_t in (2.3) vanishes identically. Then the closed form $C_k(\nabla_0,\nabla_1)$ is exact for each $k\geqslant 1$, where $C_k(\nabla_0,\nabla_1)$ is defined in (2.2). Indeed, $C_k(\nabla_0,\nabla_1)$ and $C_k^{\gamma}(\nabla_0,\nabla_1)$ [defined in (2.4)] represent the same cohomology class (Proposition 2.4), and the form $C_k^{\gamma}(\nabla_0,\nabla_1)$ is identically zero for such a path γ provided $k\geqslant 1$.

III. INVARIANTS FOR HOLOMORPHIC BUNDLES

Let M be a complex manifold, and $\overline{\partial}_i$, $i=0,1$, be two holomorphic structures on E. So $\overline{\partial}_i: E\to\Omega_M^{0,1}(E)$ is a first order differential operator satisfying the Leibniz identity

$$\overline{\partial}_i(fs)=f\overline{\partial}_i s+s\otimes\overline{\partial}f,$$

where f is a C^{∞} (local) function and s is a locally defined smooth section of E. In order to be a holomorphic structure, the operator $\overline{\partial}_i$ must satisfy the integrability condition $\overline{\partial}_i\circ\overline{\partial}_i=0$. In other words, such an operator $\overline{\partial}_i$ can be thought of as a flat connection of type (0,1). We denote $\overline{\partial}_1-\overline{\partial}_0$ by ω, which is a section of $\Omega_M^{0,1}(\mathrm{End}(E))$. So ω is a $\mathrm{End}(E)$ valued form of Hodge type (0,1).

For any $t\in[0,1]$, define

$$\overline{\partial}_t=(1-t)\overline{\partial}_0+t\overline{\partial}_1=\overline{\partial}_0+t\omega.$$

The Leibniz identity is clearly satisfied by $\overline{\partial}_t$, but the integrability condition is not necessarily satisfied. Let Θ_t denote $\overline{\partial}_t \circ \overline{\partial}_t$, which is a section of $\Omega_M^{0,2}(\mathrm{End}(E))$. It may be noted that the Bianchi identity $\overline{\partial}_t(\Theta_t)=0$ is satisfied by $\overline{\partial}_t$.

As in (2.2), define

$$D_k(\overline{\partial}_0,\overline{\partial}_1) := \int_0^1 \mathrm{trace}(\omega \wedge (\Theta_t)^k)\,dt \tag{3.1}$$

which is a differential form of Hodge type $(0,2k+1)$ on M.

We have the following analog of Lemma 2.3.

Lemma 3.1: The form $D_k(\overline{\partial}_0,\overline{\partial}_1)$ is $\overline{\partial}$-closed.

We recall that the exterior derivative $d=\partial+\overline{\partial}$. In other words, a smooth differential form ψ of Hodge type $(0,k_0)$ is $\overline{\partial}$ closed if and only if $d\psi$ is of Hodge type $(1,k_0)$. The proof of Lemma 3.1 is identical to that of Lemma 2.3.

So, $D_k(\overline{\partial}_0,\overline{\partial}_1)$ gives an element in the Dolbeault cohomology $H_{\overline{\partial}}^{2k+1}(M)$ of M. Recall that $H_{\overline{\partial}}^{j}(M)$ coincides with $H^j(M,\mathcal{O}_M)$, where $\mathcal{O}_M$ is the structure sheaf of M (the sheaf of holomorphic functions).

For notational convenience, let $\mathrm{Dol}(E)$ denote the space of first order operators

$$\overline{\partial}_E : E \to \Omega_M^{0,1}(E)$$

on E satisfying the Leibniz identity and $\mathrm{Hol}(E)\subset \mathrm{Dol}(E)$ the subset consisting of all those operators that satisfy the integrability condition $\overline{\partial}_E \circ \overline{\partial}_E = 0$. So, $\mathrm{Dol}(E)$ is an affine space for the vector space $C^\infty(M,\Omega_M^{0,1}(\mathrm{End}(E)))$ [the space of $\mathrm{End}(E)$ valued forms of type $(0,1)$].

As in Proposition 2.4, if instead of the line segment in $\mathrm{Dol}(E)$ defined by $t\mapsto\overline{\partial}_t$ we choose a different path smooth γ in $\mathrm{Dol}(E)$ connecting $\overline{\partial}_1$ with $\overline{\partial}_0$, then the corresponding form is also $\overline{\partial}$ closed, and furthermore, the cohomology class in $H_{\overline{\partial}}^{2k+1}(M)$ represented by it coincides with the one represented by $D_k(\overline{\partial}_0,\overline{\partial}_1)$. The proof is exactly identical to Proposition 2.4.

As in Sec. II, we have the following corollary.

Corollary 3.2: If there is a path γ connecting $\overline{\partial}_1$ with $\overline{\partial}_0$ such that each $\gamma(t)$ is an integrable holomorphic structure on E, then the cohomology class in $H_{\overline{\partial}}^{2k+1}(M)$ represented by $D_k(\overline{\partial}_0,\overline{\partial}_1)$ vanishes if $k\geqslant 1$.

Let $\overline{\partial}_2 \in \mathrm{Hol}(E)$ be a third integrable Dolbeault operator. The above corollary has the following generalization.

Proposition 3.3: If there is a path γ connecting $\overline{\partial}_1$ with $\overline{\partial}_2$ such that each $\gamma(t)$ is an integrable holomorphic structure on E, then for any $k\geqslant 1$, the cohomology class in $H_{\overline{\partial}}^{2k+1}(M)$ represented by $D_k(\overline{\partial}_0,\overline{\partial}_2)$ coincides with the one represented by $D_k(\overline{\partial}_0,\overline{\partial}_1)$.

Proof: Since the cohomology class $D_k(\overline{\partial}_0,\overline{\partial}_2)$ does not depend on the choice of the path connecting $\overline{\partial}_0$ to $\overline{\partial}_2$ (see the paragraph before Corollary 3.2) we will compute $D_k(\overline{\partial}_0,\overline{\partial}_2)$ by constructing a path.

Fix a path δ in $\mathrm{Dol}(E)$ connecting $\overline{\partial}_0$ to $\overline{\partial}_2$ that passes through $\overline{\partial}_1$. The path is assumed to pass through $\overline{\partial}_1$ exactly once. Since $\mathrm{Dol}(E)$ is an affine space, such a path exists. Let δ_1 denote the part of δ from $\overline{\partial}_0$ to $\overline{\partial}_1$ and δ_2 the rest, namely the part from $\overline{\partial}_1$ to $\overline{\partial}_2$. Since the integral [as in (3.1)] over δ is the sum of integrals over δ_1 and δ_2, and by Corollary 3.2 the cohomology class represented by the integral over δ_2 is zero, the proof is complete. □

Instead of holomorphic structures on E, we can consider a differential operator

$$\partial_E : E \to \Omega_M^{1,0}(E)$$

satisfying the Leibniz identity $\partial_E(fs)=f\partial_E s+s\partial f$ and the integrability condition $\partial_E\circ\partial_E=0$. If ∂_0 and ∂_1 are two such differential operators, then imitating (3.1) define

$$D'_k(\partial_0,\partial_1):=\int_0^1 \mathrm{trace}((\partial_1-\partial_0)\wedge(\partial_t\circ\partial_t)^k), \tag{3.2}$$

where $\partial_t:=(1-t)\partial_0+t\partial_1$. The $(2k+1,0)$-form $D'_k(\partial_0,\partial_1)$ is ∂ closed, and hence gives a cohomology class in $H^{2k+1}_{\partial}(M)$.

Fix a Hermitian structure on the C^∞ vector bundle E. Given any $\overline{\partial_E}\in\mathrm{Hol}(E)$, there is a unique connection on E, known as the *Chern connection*, determined by the following two conditions: the connection preserves the Hermitian structure and the (0,1) part of the connection coincides with $\overline{\partial_E}$.

The (1,0) part of the Chern connection is a differential operator of the above type. Take $\overline{\partial_i}\in\mathrm{Hol}(E)$, $i=0,1$, and let ∂_i be the (1,0) part of the corresponding Chern connection. It is easy to check that

$$D_k(\overline{\partial_0},\overline{\partial_1})=-\overline{D'_k(\partial_0,\partial_1)},$$

where D_k and D'_k are defined in (3.1) and (3.2), respectively. Indeed, this follows immediately from the fact that if $\partial_2+\overline{\partial_2}$ is a connection on E preserving the Hermitian structure, then the connection $(\partial_2-\beta^*)+(\overline{\partial_2}+\beta)$ on E also preserves the Hermitian structure, where β is any $\mathrm{End}(E)$-valued (0,1)-form.

The construction of the cohomology class $D_k(\overline{\partial_0},\overline{\partial_1})$ can be generalized as follows.

Let T be a compact oriented smooth manifold of dimension $d+1$. The manifold T is assumed to have a boundary. Let $S=\partial T$ be the boundary.

Take a smooth map

$$f:S\to\mathrm{Dol}(E). \tag{3.3}$$

Since $\mathrm{Dol}(E)$ is an affine space, f extends to a smooth map

$$F:T\to\mathrm{Dol}(E).$$

Indeed, any smooth function on S extends to T as a smooth function. Since $\mathrm{Dol}(E)$ is isomorphic to a vector space, this extension property remains valid for functions with values in $\mathrm{Dol}(E)$.

For the Dolbeault operator $F(t)$, the obstruction to integrability, namely $F(t)\circ F(t)$ will be denoted by $F(t)^2$. So, $F(t)^2\in C^\infty(M,\Omega^{0,2}_M(\mathrm{End}(E)))$. Using F, we have a $(d+1)$-form on T, with values in $C^\infty(M,\Omega^{0,2k-l+2}_M)$ which is defined as follows. Take any $t\in T$ and let

$$dF(t):T_tT\to C^\infty(M,\Omega^{0,1}_M(\mathrm{End}(E)))$$

be the differential of the map F. [Recall that $\mathrm{Dol}(E)$ is an affine space for the vector space $C^\infty(M,\Omega^{0,1}_M(\mathrm{End}(E)))$.] Take two integers $k,l\geqslant 0$. Associating to tangent vectors $v_i\in T_tT$, $i\in[1,l]$, the form

$$\mathrm{trace}((dF(t)(v_1)\wedge dF(t)(v_2)\wedge\cdots\wedge dF(t)(v_l))\wedge(F(t)^2)^{k-l+1})\in C^\infty(M,\Omega^{0,2k-l+2}_M)$$

we get a l-form on T with values in $C^\infty(M,\Omega^{0,2k-l+2}_M)$. This form on T will be denoted by Θ_l.

Lemma 3.4: The integral

$$\int_T\Theta_{d+1}\in C^\infty(M,\Omega^{0,2k+1-d}_M)$$

is $\overline{\partial}$ closed. Furthermore, its Dolbeault cohomology class is independent of the extension F. In other words, it depends only on f in (3.3).

Proof: It is a straightforward computation to check that the identity

$$(d\Theta_l)(v_1,v_2,\ldots,v_{l+1})=(k+1-l)\overline{\partial}(\Theta_{l+1}(v_1,v_2,\ldots,v_{l+1})) \tag{3.4}$$

is valid, where $v_i \in T_tT$.

For the inclusion map of S, the pullback of Θ_d to S vanishes identically. Now using (3.4), Stokes' theorem for the form Θ_d on T says that $\int_T \Theta_{d+1}$ is a $\overline{\partial}$-closed form.

Suppose F and F_1 are two extensions of f to T. Set $\overline{T}=T\times[0,1]$ and define

$$\overline{F}:\overline{T}\to \mathrm{Dol}(E)$$

by $\overline{F}(z,s)=(1-s)F(z)+sF_1(z)$, where $z\in T$ and $s\in[0,1]$. Now in (3.4), set $T=\overline{T}$ and $F=\overline{F}$. From Stokes' theorem in (3.4) with $l=d+1$, it follows immediately that $\int_T \Theta_{d+1}$ represents the same cohomology class for both F and F_1. This completes the proof of the lemma.

The identity (3.4) shows that the cohomology class represented by $\int_T \Theta_{d+1}$ does not depend on T. Indeed, let T' be another oriented manifold with boundary such that $\partial T'=S$. Denote $T\cup_S T'$, the gluing of T with T' along S, by T_2. So T_2 is an oriented manifold without boundary. The identity (3.4) says that the form Θ_{d+1} is exact. Consequently,

$$\int_{T_2}\Theta_{d+1}=0.$$

In other words, $\int_T \Theta_{d+1}=\int_{T'}\Theta_{d+1}$. Therefore, we have the following theorem.

Theorem 3.5: *Given any map*

$$f:S\to \mathrm{Dol}(E),$$

where S is a boundary of some smooth oriented manifold, the integral

$$\int_T \Theta_{d+1}\in C^\infty(M,\Omega_M^{0,2k+1-d}),$$

where T is a manifold with boundary given by S, gives a cohomology class in $H_{\overline{\partial}}^{2k+1-d}(M)$ which depends only on f and, in particular, it is independent of the choices of T and the extension of the map f to T.

In the next section, some rigidity properties of the cohomology classes defined in Lemma 2.3 and Lemma 3.1 are described.

IV. RIGIDITY PROPERTIES

Let ∇ be a connections on E whose curvature coincides with θ^2, where θ is a $\mathrm{End}(E)$ valued one-form. Let A be a C^∞ automorphism of E. Set $\nabla_1=A^*\nabla$. Therefore, the curvature of the connection ∇_1 coincides with $(A^*\theta)^2$.

Proposition 4.1: The cohomology class $C_k(\nabla,\nabla_1)\in H^{2k+1}(M,\mathbb{C})$ defined in Lemma 2.3 is contained in the image of $H^{2k+1}(M,(2\pi\sqrt{-1})^{k+1}\mathbb{Z})$.

Proof: Consider the pullback of E to $M\times[0,1]$ using the natural projection to M. Construct the vector bundle $\overline{E}$ over $M\times S^1$ identifying this pullback bundle along $M\times\{0\}$ and $M\times\{1\}$ using the automorphism A of E. Let $\overline{\nabla}$ be the connection on $\overline{E}$ which is $t\nabla+(1-t)\nabla_1$ on $M\times\{t\}$ and coincides with the trivialization in the direction of $[0,1]$. Consider the Künneth decomposition of the Chern character form $(k+1)!\mathrm{Ch}^{k+1}(\overline{E})$ over $M\times S^1$ of the connection $\overline{\nabla}$ over $\overline{E}$. The Künneth component of type $(2k+1,1)$ coincides with the form $C_k(\nabla,\nabla_1)\otimes dt$, where

$C_k(\nabla,\nabla_1)$ is defined in (2.2) and dt is the natural one-form on $S^1=\mathbb{R}/\mathbb{Z}$. Since the cohomology class represented by $(k+1)!\mathrm{Ch}^{k+1}(\overline{E})$ is in the image of $H^{2k+2}(M\times S^1,(2\pi\sqrt{-1})^{k+1}\mathbb{Z})$, each of its Künneth components are also in the image of the cohomology group with values in $(2\pi\sqrt{-1})^{k+1}\mathbb{Z}$. Therefore, the cohomology class represented by $C_k(\nabla,\nabla_1)$ is in the image of $H^{2k+1}(M,(2\pi\sqrt{-1})^{k+1}\mathbb{Z})$ and the proposition is proved. □

We will show that if $\overline{\partial}_0$ and $\overline{\partial}_1$ are two holomorphic structures on a C^∞ vector bundle E related by an automorphism of E, then the cohomology class represented by the form $D_k(\overline{\partial}_0,\overline{\partial}_1)$ is integral.

Let M be a complex manifold. For any $n\geqslant 0$, consider the natural projection

$$\tau(n):C^\infty(M,\wedge^n T^*_{\mathbb{C}}M)\to C^\infty(M,\Omega^{0,n}_M)$$

that sends a complex n form to its component of type $(0,n)$. Here $T^*_{\mathbb{C}}M:=T^*M\otimes_{\mathbb{R}}\mathbb{C}$ is the complexified cotangent bundle. The following diagram of homomorphisms

$$\begin{array}{ccc} C^\infty(M,\wedge^n T^*_{\mathbb{C}}M) & \stackrel{d}{\to} & C^\infty(M,\wedge^{n+1} T^*_{\mathbb{C}}M) \\ \downarrow\tau(n) & & \downarrow\tau(n+1) \\ C^\infty(M,\Omega^{0,n}_M) & \stackrel{\bar\partial}{\to} & C^\infty(M,\Omega^{0,n+1}_M) \end{array}$$

is commutative. Therefore, $\tau(n)$ induces a homomorphism

$$\hat\tau(n):H^n(M,\mathbb{C})\to H^n_{\mathrm{Dol}}(M) \tag{4.1}$$

from the complex de Rham cohomology to the Dolbeault cohomology.

Consider the inclusion map of the constant sheaf $\mathbb{C}$ on M in the structure sheaf $\mathcal{O}_M$. This map induces a homomorphism

$$H^n(M,\mathbb{C})\to H^n(M,\mathcal{O}_M)=H^n_{\mathrm{Dol}}(M)$$

which obviously coincides with $\hat\tau(n)$ constructed in (4.1).

Let E be a holomorphic vector bundle over M defined by a Dolbeault operator $\overline{\partial}_0$. Take a C^∞ automorphism A of E. Set

$$\overline{\partial}_1:=A^{-1}\circ\overline{\partial}_0\circ A$$

to be the new holomorphic structure on E defined by A.

Theorem 4.2: *The Dolbeault cohomology class $D_k(\overline{\partial}_0,\overline{\partial}_1)$ defined in* (3.1) *is in the image of $H^{2k+1}(M,(2\pi\sqrt{-1})^{k+1}\mathbb{Z})$ for the map $\hat\tau(2k+1)$ defined in* (4.1).

Proof: Take a connection ∇ on E such that the (0,1) component of ∇ coincides with $\overline{\partial}_0$. For example, ∇ can be the Chern connection for a Hermitian structure on the holomorphic vector bundle E.

Set $\nabla_1:=A^*\nabla$. Consider the vector bundle $\overline{E}$ over $M\times S^1$ constructed in the proof of Proposition 4.1, and construct the connection $\overline{\nabla}$ on $\overline{E}$ exactly as in the proof of Proposition 4.1.

Let

$$\beta\in H^{2k+1}(M,\mathbb{C})\otimes H^1(S^1,\mathbb{C})$$

be the Künneth component of the Chern character form $(k+1)!\mathrm{Ch}^{k+1}(\overline{E})$ for the connection $\overline{\nabla}$. Using the natural isomorphism $H^1(S^1,\mathbb{C})\cong\mathbb{C}$, the cohomology class β gives an element $\hat\beta\in H^{2k+1}(M,\mathbb{C})$. It was noted in the proof of Proposition 4.1 that $\hat\beta$ is in the image of $H^n(M,(2\pi\sqrt{-1})^{k+1}\mathbb{Z})$.

From the definition of the form $D_k(\overline{\partial}_0, \overline{\partial}_1)$ given in (3.1) it follows immediately that the differential form $\tau(2k+1)(\hat{\beta})$ on M of Hodge type $(0,2k+1)$ coincides with $D_k(\overline{\partial}_0, \overline{\partial}_1)$. This completes the proof of the theorem. □

(Received 28 November 2001; accepted 18 June 2002)

We present a technique to construct a spinor space basis as products of certain nilpotents and projections formed from γ^a for which we only need to know that they obey the Clifford algebra. The technique works for all dimensions and signatures. We use this technique to deliver a concrete choice of γ-matrices and Lorentz group generators for (fundamental representations of) spinors in a rather systematic and transparent way. We further develop the formalism by proposing the corresponding graphic presentation of basic states, which offers an easy way to see all the quantum numbers of states with respect to the generators of the Lorentz group, as well as transformation properties of the states under any element of the Clifford algebra. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1505125]

I. INTRODUCTION

If one wants to work with the Dirac (or the Weyl) spinor states, one *a priori* has the problem that one must choose a certain representation of the γ^a-matrices before writing down in a safe way any state of the spinor. It is therefore often attractive to avoid as long as possible writing down explicit spinor states. In this article, we propose the construction of a basis for spinors made out of products of the formal Clifford algebra objects, presented later in this article. Looking for how the left multiplication with γ^a transforms these formal Clifford algebra objects, we construct representations for the γ^a and accordingly for all the products of γ^a. These technique enables us accordingly to find solutions of the Weyl or the Dirac equation without making a choice of a special representation for γ^a operators.

The technique is built on the property of spinors that eigenstates of a particular member of the Cartan subalgebra of the Lorentz group can be expressed as nilpotents and projectors, expressions which are constructed out of γ^a's as odd and even objects in γ^a's, respectively, and accordingly a spinor basis can be expressed as products of nilpotents and projectors, operating on an (unimportant) ''vacuum state.''

We indeed start by taking γ^a's as abstract objects, fulfilling the Clifford algebra (Sec. II). We then construct a series of the Clifford algebra elements, which can be used as a basis for the representation of the Clifford algebra in the following sense: When multiplying from the left these special Clifford algebra elements, which we call our ''basis,'' with any of the Clifford algebra elements, we get a linear combination of these ''basic'' elements back. In other words, our ''basis'' spans a left ideal. (The reader should see also Chap. 3 of Chevalley's book.[1,2]) We can consider the action of left multiplication by an element of the Clifford algebra on the space spanned by the ''basis'' as a representation of the Clifford algebra. Accordingly we show by this procedure the (well known[3]) fact that the Clifford algebra has an operator representation, which is known as the

[a)]Electronic mail: norma.s.mankoc@ijs.si
[b)]Electronic mail: HBECH@nbivms.nbi.dk

spinor space. So we can consider elements of our special ''basis'' as a proposal for a basis for spinors.

The proposed technique was initiated and developed by one of the authors of this article, when proposing an approach[4–6] in which all the internal degrees of freedom of either spinors or vectors can be described in the space of d-anticommuting (Grassmann) coordinates, if the dimension of ordinary space is also d. In this approach (two kinds of) γ^a operators were defined. One of the two kinds of γ^a's was used to generate nilpotents and projectors—eigenstates of the Cartan subalgebra of the Lorentz group—products of which define, when operating on a vacuum state, basic vectors. These 2^d basic vectors are polynomials of anticommuting coordinates and are orthonormal with respect to the inner product defined as an integral over anticommuting coordinates, with an appropriately chosen weight function. They form an orthonormal basis for spinors.

Both authors of this work then used the results of this approach in the space of differential forms to generalize[7] the approach of Kähler,[8] who defined in the space of differential forms spins of spinors.

We recognized that mapping of ideals to spinor representations can lead either to only one irreducible representation or to ''families'' of representations (Sec. V) (which we have noticed before[5,6]). We investigate the consequence of seeking to keep all the basis spinors corresponding to our basis in the Clifford algebra linearly independent. That of course means that a reducible representation of the Clifford algebra is needed and it is to have for d even $2^{d/2}$ replicas and for d odd $2^{(d+1)/2}$ replicas of the usual irreducible spinor representation. Usually, of course, we deal with only one ''family,'' that is with only one Dirac spinor.

Using this technique, it is then straightforward, for example, to find solutions of the Dirac equation, for either massless or massive spinors, for any dimension d and for any signature (Sec. IX), or to apply any operator to a spin state (Secs. III C and VII), or to find irreducible representations of subgroups of the Lorentz group $\mathrm{SO}(q,d-q)$, where q means the number of timelike coordinates.

We further propose a very simple graphic representation (Sec. VI), which makes the technique transparent by enabling us to easily see all the quantum numbers of states with respect to the generators of the Lorentz group, as well as how states transform when operated on by the operators.

We demonstrate (Sec. VIII) the proposed technique as well as the graphic representation of this technique for $d=3$ and $d=4$ and the Minkowski metric.

In this article, we assume an arbitrary signature of space–time so that our metric tensor η^{ab}, with $a,b \in \{0,1,2,3,5,\ldots\}$, is diagonal with values $\eta^{aa}=\pm 1$, depending on the chosen signature ($+1$ for timelike coordinates and -1 for spacelike coordinates).

II. CLIFFORD AND LORENTZ ALGEBRA

It is well known that there exist for any dimension d and any signature the operators γ^a which fulfill the Clifford algebra. Following the Dirac procedure (a similar procedure with quadratic forms can be found in Ref. 1), one finds the algebra which γ^a's have to fulfill by assuming the equation of motion for a particle, which is called a spinor, to be linear in the momentum p^a. A momentum p^a is a vector in a d-dimensional space, in which the metric tensor η_{ab} (assumed for simplicity diagonal) has q diagonal elements being 1 and $p=d-q$ being -1. For this purpose the operators γ^a, with a vector index a, have to be introduced, which commute with p^a, and operate on some abstract space which is called the spinor space. So, when considering γ^a, we understand that we are making a basis in the vector space marked with the index a.

In order that an equation of motion linear in the momentum p^a and therefore of the form $\gamma_a p^a \psi=0$ for a wave function ψ should lead to the Klein–Gordon equation $p^a \eta_{ab} p^b \psi=0$ (when multiplied from the left by $\gamma_a p^a$, say), it should be required that the operators on the spinor space γ^a should obey the algebra, called the Clifford algebra,

$$\{\gamma^a,\gamma^b\}_+ = I2\,\eta^{ab}, \quad \text{for} \quad a,b \in \{0,1,2,3,5,\ldots,d\}, \tag{1}$$

for any d, even or odd, and with I, which is the unit element in the Cliffird algebra. Here $\{\gamma^a,\gamma^b\}_\pm=\gamma^a\gamma^b\pm\gamma^b\gamma^a$.

In this article, we start by assuming abstract objects γ^a for which we only need to know that they fulfill the Clifford algebra [Eq. (1)]. We do not assume that they are the operators. We deduce that they can be represented by operators operating on a space spanned by a certain basis which we construct out of the Clifford algebra objects γ^a themselves.

We are therefore considering a Clifford algebra $\mathcal{C}$ over a d-dimensional vector space and denote a set of elements corresponding to an orthonormal basis in the vector space for which this Clifford algebra [Eq. (1)] is defined as γ^a $(a\in\{0,1,2,3,5,6,\ldots d-1,d\})$. The quadratic form, for which this Clifford algebra is defined, is taken to be given by the metric $Q(x)=p^a\eta_{ab}p^b$, with p^a being vectors in the d-dimensional vector space.

We can impose an antilinear anti-automorphism for elements A,B,C of the Clifford algebra, which we denote by $(^\dagger)$,

$$\begin{aligned}(AB\cdots C)^\dagger&=C^\dagger\cdots B^\dagger A^\dagger,\\(\alpha A+\beta C)^\dagger&=\alpha^* A^\dagger+\beta^* B^\dagger,\end{aligned}\tag{2}$$

with $(^*)$ meaning complex conjugation. We easily see a possible choice for such an operation $(^\dagger)$ for elements made out of γ^a's by defining the "Hermiticity" property for γ^a's,

$$\gamma^{a\dagger}=\eta^{aa}\gamma^a,\tag{3}$$

in order that γ^a are compatible with (1) and formally unitary, i.e., $\gamma^{a\dagger}\gamma^a=I$, and I is the unity operator.

We also define the Clifford algebra objects

$$S^{ab}=\frac{i}{4}[\gamma^a,\gamma^b]:=\frac{i}{4}(\gamma^a\gamma^b-\gamma^b\gamma^a),\tag{4}$$

which close the Lie algebra of the Lorentz group

$$\{S^{ab},S^{cd}\}_-=i(\eta^{ad}S^{bc}+\eta^{bc}S^{ad}-\eta^{ac}S^{bd}-\eta^{bd}S^{ac})\tag{5}$$

and have the following "Hermiticity" property

$$S^{ab\dagger}=\eta^{aa}\eta^{bb}S^{ab}.\tag{6}$$

We also see that these objects of the Lorentz algebra being imbedded in the Clifford algebra fulfill the relation

$$\{S^{ab},S^{ac}\}_+=\tfrac{1}{2}\eta^{aa}\eta^{bc},\tag{7}$$

which is true only for the Dirac (or the Weyl) spinors (known also as the fundamental representation of the Lorentz group).

We recognize the similarity transformation properties of γ^a's with respect to the Lorentz group

$$e^{i\omega_{cd}S^{cd}}\gamma^a e^{-i\omega_{cd}S^{cd}}=\Lambda^a{}_b(\omega)\gamma^b.\tag{8}$$

Recognizing from Eq. (5) that two Clifford algebra objects S^{ab},S^{cd} with all indices different commute, we readily select the Cartan subalgebra of the algebra of the Lorentz group, which has a basis of

$$m=d/2, \text{ for } d \text{ even},$$

$$m=(d-1)/2, \text{ for } d \text{ odd}, \tag{9}$$

commuting objects.

It is useful also to define one of the Casimirs of the Lorentz group (which will later be used to determine the handedness of an irreducible representation of the Lorentz group). (To see the definition of the operator Γ for any spin in even-dimensional spaces, see Refs. 5, 9–12, and 7.) When once the representation will be built

$$\Gamma: \ =(i)^{d/2}\prod_a \ (\sqrt{\eta^{aa}}\gamma^a), \text{ if } d=2n,$$

$$\Gamma: \ =(i)^{(d-1)/2}\prod_a \ (\sqrt{\eta^{aa}}\gamma^a), \text{ if } d=2n+1, \tag{10}$$

for any integer n. We understand the product of γ^a's in the ascending order with respect to the index a: $\gamma^0\gamma^1\cdots\gamma^d$. Since $(\sqrt{\eta^{aa}}\gamma^a)^\dagger=\sqrt{\eta^{aa}}\gamma^a$ and $(\sqrt{\eta^{aa}}\gamma^a)^2=I$, which is the unit element in the Clifford algebra, then it follows for any choice of the signature η^{aa} that Γ is "Hermitian" in the sense of the antilinear antiautomorphism of Eqs. (2), and (3) and its square is equal to the unity element

$$\Gamma^\dagger=\Gamma,$$

$$\Gamma^2=I. \tag{11}$$

One also finds that in even-dimensional spaces Γ "anticommutes" while in odd-dimensional spaces Γ "commutes." Two formal Clifford objects A and B "commute" or "anticommute," if they fulfill the relation $\{A,B\}_\mp=0$, with $(-)$ and $(+)$, respectively, under the left multiplication, with γ^a's

$$\{\Gamma,\gamma^a\}_+=0, \text{ for } d \text{ even},$$

$$\{\Gamma,\gamma^a\}_-=0, \text{ for } d \text{ odd}. \tag{12}$$

Accordingly, Γ always "commutes" with the generators of the Lorentz algebra S^{ab}.

III. BASIS IN SPINOR SPACE *S*

In this section we are constructing successively a set of 2^d Clifford algebra elements, which if any one of them is multiplied from the left by any of the $d/2$ members S^{ab} of the chosen basis for the Cartan subalgebra of the Lorentz group, Eq. (4) is mapped up to a factor to the same element of the set. We shall start by constructing for each member S^{ab} a set of four of the Clifford algebra elements $(\frac{1}{2})(\gamma^a+ik\gamma^b)$, $(\frac{1}{2})(1+ik\gamma^a\gamma^b)$, with $k^2=\eta^{aa}\eta^{bb}$ and $k=\pm1$ or $\pm i$, depending on the signature η^{aa} and η^{bb}. We shall call two of them "nilpotents" and two of them "projectors," since, when squared, nilpotents map into zero while projectors map into themselves.

We shall then construct the basis for spinors out of $d/2$ factors of these nilpotents and projectors, each member of the Cartan subalgebra being represented by one out of four possibilities. The spinor representation for the Lorentz group will be selected by the application of (all) the elements of the Lorentz algebra on a starting object of $d/2$ factors. A representation will be called the Weyl representation. All the elements of the Clifford algebra will select what we call a Dirac spinor representation. This will lead to the basis for the Clifford algebra elements, which we shall recognize as spinor representation for the Lorentz group. We shall accordingly show that the Clifford algebra objects can be represented as operators acting on these basic states. The procedure

will enable us to construct an explicit matrix representation with concretely constructible matrices representing the γ^a-matrices. These means that we construct the basis in the spinor space from a basis in the vector space M. We shall tell what specifications we need for the construction. The basis in the vector space M used will be taken to be an orthonormal basis so that the different basis vectors are normalized to $Q(e^a)=\pm 1$ according to whether the basic vector in question is space- or timelike.

We shall make our construction formulated for general dimension and signature (i.e., for general index also).

A. Decisions for choosing a basis in spinor space

It is obvious that by specifying whatever properties of a set of spinors, say basis, belong to $\mathcal{S}$ concerning the linear operation of the representatives of the Clifford algebra, say of the γ^a's, we can never specify the overall phase for this set, i.e., if we have a basis ψ_i, $i=1,\ldots,n$, with $n=2^{d/2}$ for d even and $n=2^{(d-1)/2}$ for d odd (the well-known spinor space dimensions will come out also of our formalism below) fulfilling a set of specifications, then so do $e^{i\phi}\psi_i$.

So we only can (and have to) specify the *relative* phase of the various basis spinors, which will also specify phases in the explicit matrix representation of the Clifford algebra. We attempt to make an as simple as possible choice of the basis and its relative phases (putting all phases equal to one) so that the reader can easily remember and reproduce the procedure.

The basis elements for spinors will be chosen as eigenstates under the left multiplication of the chosen basis for the Cartan subalgebra for the Lorentz/orthogonal group $\mathcal{G}$.

B. Eigenstates of Cartan subalgebra elements

We consider the left multiplication with the elements of the Cartan subalgebra. We call ψ an eigenstate of the Cartan subalgebra basis $\{S^{ab},S^{cd},\ldots\}$, if the left multiplication of ψ with the Cartan subalgebra basis maps ψ back to itself up to a complex number. We look for a basis of 2^d eigenstates of the Cartan subalgebra.

According to the algebra of the Lorentz group [Eq. (5)], one can make infinitely many choices of a set [of $d/2$ for d even and $(d-1)/2$ for d odd], commuting elements of the Cartan subalgebra out of $d(d-1)/2$ elements of the Lorentz algebra. In order to be able at the end to present elements of the Clifford algebra as operators—operating on the spinors, which we are constructing successively in this article—in terms of numbers, we make an explicit choice of elements of the Cartan subalgebra.

We shall select elements belonging to the Cartan subalgebra in a given coordinate system as follows,

$$\begin{aligned} &S^{0d},S^{12},S^{35},\ldots,S^{d-2d-1}, \ \text{if} \ d=2n, \\ &S^{12},S^{35},\ldots,S^{d-1d}, \ \text{if} \ d=2n+1, \end{aligned} \tag{13}$$

with raising indices from the left to the right and within each of a chosen element of the Lorentz algebra.

One can easily see that for spinors [Eq. (7)] the element of the Clifford algebra Γ, which will be chosen to determine what we call handedness of eigenstates of the Cartan subalgebra, can for even-dimensional spaces be written in terms of the elements of the Cartan subalgebra as follows:

$$\Gamma=2^{d/2}\prod_a \sqrt{\eta^{aa}}\ S^{0d}S^{12}S^{35}\cdots S^{d-2d-1}, \ \text{if} \ d=2n. \tag{14}$$

For odd-dimension we can write

$$\Gamma=2^{(d-1)/2}\prod_a \sqrt{\eta^{aa}}\ \gamma^0 S^{12}S^{35}\cdots S^{d-1d}, \ \text{if} \ d=2n+1. \tag{15}$$

We can now present a trivial theorem which helps, however, to find eigenstates of the above chosen Cartan subalgebra of the Lorentz group.

Theorem 1a: Let S^{ab} be the element of the Cartan subalgebra of Eq. (9), for which $\eta^{aa}\eta^{bb}=1$. Then elements of the Clifford algebra

$$\overset{ab}{(\pm)} := \frac{1}{2}\left(\gamma^a \pm \frac{\eta^{bb}}{i}\gamma^b\right), \quad \overset{ab}{[\pm]} := \frac{1}{2}(1 \pm i\gamma^a\gamma^b), \tag{16}$$

are eigenstates for the left multiplication with S^{ab} with the eigenvalues $\pm(\frac{1}{2})$ in both cases.

Proof: To prove this theorem we only have to make the left multiplication of $\overset{ab}{(\pm)}$ and $\overset{ab}{[\pm]}$ by $S^{ab}=(i/2)\gamma^a\gamma^b$, $a\neq b$. We easily find the above result.

Theorem 1b: Let S^{ab} be the generator of the Cartan subalgebra of Eq. (9) for which $\eta^{aa}\eta^{bb}=-1$. Then elements of the Clifford algebra

$$\overset{ab}{(\pm i)} := \tfrac{1}{2}(\gamma^a \pm \eta^{bb}\gamma^b), \quad \overset{ab}{[\pm i]} := \tfrac{1}{2}(1 \pm \gamma^a\gamma^b), \tag{17}$$

are eigenstates for the left multiplication with S^{ab} with the eigenvalues $\pm(i/2)$ in both cases.

Proof: The proof follows the proof of Theorem 1a.

According to these two theorems, we can construct states which are eigenstates of all the Cartan subalgebra elements by making products of expressions from Theorems 1a and 1b.

We find that while elements of the Clifford algebra either $\overset{ab}{[\pm]}$ or $\overset{ab}{[\pm i]}$ are idempotent,

$$\overset{ab}{[\pm]}^2 = \overset{ab}{[\pm]}, \quad \overset{ab}{[\pm i]}^2 = \overset{ab}{[\pm i]}, \tag{18}$$

the elements $\overset{ab}{(\pm)}$ and $\overset{ab}{(\pm i)}$ are nilpotent

$$\overset{ab}{(\pm)}^2 = 0, \quad \overset{ab}{(\pm i)}^2 = 0. \tag{19}$$

According to the above theorem, it is straightforward to prove the following theorem.

Theorem 2: For an even dimension $(d=2n)$ the states

$$(\gamma^0 \pm \sqrt{-\eta^{00}\eta^{dd}}\gamma^d)(\gamma^1 \pm \sqrt{-\eta^{11}\eta^{22}}\gamma^2)\cdots(\gamma^{d-2} \pm \sqrt{-\eta^{d-2d-2}\eta^{d-1d-1}}\gamma^{d-1}), \tag{20}$$

or any state which follows from one of the states of Eq. (20) by replacing any of the expressions $(\gamma^a \pm \sqrt{-\eta^{aa}\eta^{bb}}\gamma^b)$ by the corresponding $(1 \pm \sqrt{-\eta^{aa}\eta^{bb}}\gamma^a\gamma^b)$, are the eigenstates of all the elements of the Cartan subalgebra of Eq. (13) for an even dimension, with the eigenvalue of the chosen S^{ab} determined by Theorems 1a and 1b, while the eigenvalue of the element of the Clifford algebra defining handedness [Eq. (10)] can easily be calculated by taking into account Eqs. (14) and (15) and the fact that $\gamma^a\gamma^b=-2iS^{ab}$.

For an odd dimension $(d=2n+1)$ the states

$$(1\pm\Gamma)\gamma^0(\gamma^1 \pm \sqrt{-\eta^{11}\eta^{22}}\gamma^2)(\gamma^3 \pm \sqrt{-\eta^{33}\eta^{55}}\gamma^5)\cdots(\gamma^{d-1} \pm \sqrt{-\eta^{d-1d-1}\eta^{dd}}\gamma^d), \tag{21}$$

or any state which follows from one of the states of Eq. (21) by replacing any of the expressions $(\gamma^a \pm \sqrt{-\eta^{aa}\eta^{bb}}\gamma^b)$ by the corresponding $(1 \pm \sqrt{-\eta^{aa}\eta^{bb}}\gamma^a\gamma^b)$, are the eigenstates of all the elements of the Cartan subalgebra of Eq. (13) of odd dimension, with the eigenvalues of the chosen S^{ab} determined in Theorems 1a and 1b and with the eigenvalue of Γ which follow if taking into account Eq. (10).

The proof for d even or d odd follows from Theorems 1a and 1b and the fact that Γ commutes with all S^{ab}.

It is simple to count the number of basic states, which is 2^d.

C. Irreducible representations of Lorentz group for spinors

In Sec. III B we constructed eigenstates of the basis of the Cartan subalgebra. From Eqs. (14) and (15) one easily sees that they are at the same time also the eigenstates of Γ, which defines handedness of states. We make a choice of one of these states, calling it a ''starting state.'' It is not difficult to prove that one gets an irreducible representation of the Lorentz group by the left multiplication of this state with all the elements of the Lorentz algebra S^{ab}, which do not belong to the Cartan subalgebra [Eq. (13)] [or by the left multiplication of the ''starting state'' by a group element $O(\omega)=\exp(-(i/2)\omega_{ab}S^{ab})$]. (To prove that a set of states, which follows from the ''starting state'' by the application of all the members of the Lorentz algebra, forms an irreducible representation, one only has to count the number of states in this particular set of states [which is for d even $2^{d/2-1}$ and since in the Dirac representation left and right handed states are required one has to multiply this number by 2 and for d odd the number of states is $2^{(d-1)/2}$ (Sec. V)] and then also the number of ''families'' [which is for d even equal to $2^{d/2}$ and for d odd $2^{(d+1)/2}$ (Sec. V)] to see that the number of all the states is equal to 2^d, as it should be.)

We present theorems, which help to find all the irreducible representations of the Lorentz group.

Theorem 3: Let S^{ab} and S^{cd} be the two elements of the Cartan subalgebra. Then the two vectors

$$\begin{aligned}&(\gamma^a+\sqrt{-\eta^{aa}\eta^{bb}}\gamma^b)(\gamma^c+\sqrt{-\eta^{cc}\eta^{dd}}\gamma^d),\\&\left(1+\frac{1}{\eta^{aa}}\sqrt{-\eta^{aa}\eta^{bb}}\gamma^a\gamma^b\right)\left(1+\frac{1}{\eta^{cc}}\sqrt{-\eta^{cc}\eta^{dd}}\gamma^c\gamma^d\right)\end{aligned}\tag{22}$$

belong to the same representation of the left action of the Lorentz algebra.

Proof: To prove the theorem we multiply from the left by $S^{ac}=(i/2)\gamma^a\gamma^c$ (or by S^{ad} or S^{bc} or S^{bd}) the first state

$$\begin{aligned}&\frac{i}{2}\gamma^a\gamma^c(\gamma^a+\sqrt{-\eta^{aa}\eta^{bb}}\gamma^b)(\gamma^c+\sqrt{-\eta^{cc}\eta^{dd}}\gamma^d)\\&\quad=-\frac{i}{2}\eta^{aa}\eta^{cc}\left(1+\frac{1}{\eta^{aa}}\sqrt{-\eta^{aa}\eta^{bb}}\gamma^a\gamma^b\right)\left(1+\frac{1}{\eta^{cc}}\sqrt{-\eta^{cc}\eta^{dd}}\gamma^c\gamma^d\right).\end{aligned}\tag{23}$$

The theorem which follows, generalizes Theorem 3.

Theorem 3a: The generators of the Lorentz transformations which do not belong to the Cartan subalgebra transform a pair of nilpotents (or a pair of a nilpotent and a projector, or a projector and a nilpotent, or two projectors) with the positive eigenvalues of the Cartan subalgebra to a pair of two projectors (or a pair of a projector and a nilpotent, or a nilpotent and a projector, or two nilpotents) with the negative values of the Cartan subalgebra. In resume, the left multiplication of the generators S^{ab} of the Lorentz transformations which do not belong to the Cartan subalgebra leaves all but the two elements, which include indices ab, of a state unchanged, while the two concerned elements change the type (that is each one changes from nilpotency to idempotency or opposite) and the eigenvalues of the corresponding Cartan subalgebra.

Theorem 4: In an odd-dimensional space the two states

$$\begin{aligned}&(1\pm\Gamma)\gamma^0(\gamma^1+\sqrt{-\eta^{11}\eta^{22}}\gamma^2)(\gamma^3+\sqrt{-\eta^{33}\eta^{55}}\gamma^5)\cdots,\\&(1\pm\Gamma)(\gamma^1+\sqrt{-\eta^{11}\eta^{22}}\gamma^2)(\gamma^3+\sqrt{-\eta^{33}\eta^{55}}\gamma^5)\cdots\end{aligned}\tag{24}$$

are proportional to each other.

Proof: We first notice that $\Gamma =: \Gamma^{(d)} = \sqrt{\eta^{00}}\gamma^0\Gamma^{(d-1)}$. The indices (d) and $(d-1)$ were added to point out that $\Gamma^{(d-1)}$ includes all the γ^a's, except the first one with factors which guarantee that either $\Gamma^{(d)}$ or $\Gamma^{(d-1)}$ fulfills the conditions of Eq. (11). Then we see that when $\Gamma^{(d)}$ is applied to the state $\gamma^0(\gamma^1+\sqrt{-\eta^{11}\eta^{22}}\gamma^2)(\gamma^3+\sqrt{-\eta^{33}\eta^{55}}\gamma^5)\cdots$, it gives $\sqrt{\eta^{00}}\eta^{00}\ \varepsilon(\gamma^1+\sqrt{-\eta^{11}\eta^{22}}\gamma^2)\times(\gamma^3+\sqrt{-\eta^{33}\eta^{55}}\gamma^5)\cdots$, where $\varepsilon(=\pm 1)$ is the eigenvalue of $\Gamma^{(d-1)}$ on the chosen state. Then it follows $(1\pm\Gamma)\gamma^0(\gamma^1+\sqrt{-\eta^{11}\eta^{22}}\gamma^2)(\gamma^3+\sqrt{-\eta^{33}\eta^{55}}\gamma^5)\cdots = \pm\varepsilon\,\eta^{00}\sqrt{\eta^{00}}(1\pm\Gamma)(\gamma^1+\sqrt{-\eta^{11}\eta^{22}}\gamma^2)(\gamma^3+\sqrt{-\eta^{33}\eta^{55}}\gamma^5)\cdots$. This completes the proof.

As a consequence of Theorem 4 the following statement follows:

Statement 1: In odd-dimensional spaces γ^a's do not transform one irreducible representation of the Lorentz group into another as they do in even-dimensional spaces.

The proof is self-evident if we take account of Theorem 4 and the fact that $\gamma^0\gamma^a = -2iS^{0a}$. (From Theorems 3 and 4 it follows that by applying to a chosen state the elements $S^{01},S^{03},\ldots,S^{0d-2},S^{13},\ldots,S^{1d-2},\ldots$ for an even d and $S^{01},S^{05},\ldots,S^{0d-1},S^{15},\ldots,S^{1d-1},\ldots$ for an odd d, we obtain all the members of a particular irreducible representation.)

Statement 2a: We find accordingly for d even $2^{d/2-1}$ and for d odd $2^{(d-1)/2}$ basis vectors of an irreducible representation, which is either left (with Γ eigenvalue equal to -1) or right (with Γ eigenvalues equal to $+1$) handed.

We can easily count the number of states in one representation following Theorem 3a just by counting the number of different products, generated by the elements of the Lorentz algebra:

Even case: Since the action of the Lorentz generators (from left multiplication) exchanges both nilpotency-versus-idempotency-character and eigenvalue sign there are in one representation only two combinations for each Cartan algebra generator and thus there can at least be made use of no more than $2^{d/2}$ in the even case, but now it is the even case, so that the S^{cb} generators change two cases at a time and thus say the number of nilpotent factors can only change by an even number as we go along inside the representation. This means that we really only get half as many products needed in the representation. That makes it have $2^{d/2-1}$ dimensions in the even case.

Odd case: In the odd case there is one of the γ^a's for which there is no place in the Cartan subalgebra generators (we made a choice of γ^0). As seen by Theorem 4 the action of this particular γ^0 from the left makes no change—except for a sign—on our products (states) and thus the generators involving this special γ^0 such as $S^{0b}=i/2\gamma^0\gamma^b$ act as a γ^b effectively and change just one of the factors, i.e., an odd number of them. This makes there being no rule guaranteeing an odd number of said nilpotents. Thus the number of products in the representation we can make to close it is $2^{(d-1)/2}$, which is thus the dimension of the found representation in the odd case.

We call these representations the Weyl spinor representations. In Sec. VI we present a graphic way of looking for representations.

Statement 2b: By applying any of the γ^a's to any of the states belonging to the above-obtained irreducible representation of the chosen handedness for an even d, the corresponding Weyl irreducible representation of the opposite handedness follows.

In even-dimensional spaces, left multiplication by γ^a's change the handedness of states, since Γ commutes with S^{ab} and anticommutes with γ^a. The representation we can close under the γ^a's has double dimension relative to the one we found for the Lorentz generators. Two Weyl spinors of the opposite handedness together have $2^{d/2}$ states for even d. We call such a representation the Dirac representation.

In an odd case, multiplication from the left brings according to Theorem 4 no extension compared to the Lorentz algebra representation.

IV. INNER PRODUCT AND SPINOR SPACE $\mathcal{S}_\rho$

Until now we considered the Clifford algebra elements as just abstract objects or elements. We found representations of these elements or the special ones among them being Lorentz generators (or products of Lorentz generators) which form the even part $\mathcal{C}_+$ of the Clifford algebra $\mathcal{C}$. Let us now formally define the (spinor) representation (map) ρ corresponding to the left multiplication

already described. That is to say, we define for any element $v \in \mathcal{C}$, i.e., for v being any linear combination of products of γ^a's, an endomorphism $\rho(v)$, i.e., a linear map $\rho(v)$ of the space $\mathcal{S}$ spanned by those basis vectors in the basis for the Clifford algebra which we have constructed and which correspond to one single representation as we found for γ^a's. For example, we easily saw that if we start from a product with factors only being our nilpotent expressions with eigenvalues of the Cartan subalgebra generators under left multiplication being $+\frac{1}{2}$ or $+i/2$ (for rotation and Lorentz boosts respectively), then we shall get in this representation under left multiplication by γ^a's only the following types of expressions (Theorem 1a and 1b):

$$\begin{aligned}
\overset{ab}{(+)} &= \frac{1}{2}\left(\gamma^a + \frac{\eta^{bb}}{i}\gamma^b\right),\\
\overset{ab}{(+i)} &= \frac{1}{2}(\gamma^a + \eta^{bb}\gamma^b),\\
\overset{ab}{[-]} &= \frac{1}{2}(1 - i\gamma^a\gamma^b),\\
\overset{ab}{[-i]} &= \frac{1}{2}(1 - \gamma^a\gamma^b).
\end{aligned} \tag{25}$$

We denote by $\mathcal{S}$ just the space spanned by these products containing just these mentioned factors. Then we simply define for $\hat{\psi} \in \mathcal{S}$

$$\rho(v)\hat{\psi} = v\hat{\psi}, \tag{26}$$

where the multiplication on the right hand side of the equation (26) $v\hat{\psi}$ is just the product of two Clifford elements. The idea, of course, is to suggest that the space $\mathcal{S}$ is the space of spinors.

We can consider our construction as a realization with an explicit basis of the same spinor space identification with an ideal in the Clifford algebra as used in the book by Chevalley[1] in Sec. III, wherein the spinor space is identified with a minimal left ideal $\mathcal{C}f = \mathcal{C}^N f$ where f is a product of basis vectors in a certain maximally totally singular subspace of the space of d-vectors identified into the Clifford algebra. The subalgebra $\mathcal{C}^N$ is one generated in the Clifford algebra from some other maximally singular subspace of the space M of d-vectors. So really it is the subalgebra $\mathcal{C}^N$ which gets identified with the space of spinors.

Strictly speaking this is not the case since the Lorentz transformation properties usually assigned to spinors only agree with the ones of the elements of $\mathcal{S}$ provided one uses only the left but not also the right multiplication by the Lorentz generators. For states to be identified with spinor states, being the part of the Hilbert space, one would like to define also the inner product. We shall construct an inner product in the next subsection.

A. Inner product and Hilbert space for spinors $\mathcal{S}_\rho$

After we have found that we can use our "basis" of the Clifford algebra elements as a basis on which to represent this algebra, i.e., as the spinor space $\mathcal{S}$, we would like to construct an inner product or Hilbert product on this space, the ideal, spanned by this basis.

It shall turn out that having chosen that the "Hermitian conjugation" operation (†) on the Clifford algebra elements γ^a defined in Sec. II is given by the equation $\gamma^{a\dagger} = \eta^{aa}\gamma^a$ (3) we have essentially specified the inner product in the sense that it only could change by a normalization overall factor.

It is actually easily seen for any pair of "spinors" v, u, (both being linear combinations of our basis vectors for the representation space $\mathcal{S}$) that using the Clifford algebra equipped with (†) have

$$v^\dagger u = c\prod [-]\prod [-i], \tag{27}$$

where c is a complex number. For the space $\mathcal{S}$ it was assumed that we only used those products as basis vectors which could be constructed alone from the expressions $(+),[-],(i),[-i]$ (which is a possible but not at all a unique choice). One can easily prove that any expression resulting when combining various terms in $v^\dagger$ and u gives either zero or a c-number times the product of the expressions $[-]$ and $[-i]$. In fact, one can see that $\overset{ab}{(+)}^\dagger = \eta^{aa}\overset{ab}{(-)}$, $\overset{ab}{(-)}\overset{ab}{(+)}\eta^{aa}\overset{ab}{[-]}$ with the same, and that also $\overset{ab}{[-]}\overset{ab}{[-]}=\overset{ab}{[-]}$ and $\overset{ab}{[-]}^\dagger=\overset{ab}{[-]}$, $\overset{ab}{[-]}\overset{ab}{(+)}=0$ as can be found in Sec. VI in more detailed form, including same relations with $\pm i$ instead of $\pm$.

This formula (27) means that we can propose the c-number c to be identified with the inner product by defining

$$\langle v|u\rangle = c, \quad \text{where} \quad v^\dagger u = c\prod [-]\cdot\prod [-i], \tag{28}$$

or

$$v^\dagger u = \langle v|u\rangle\prod [-]\prod [-i]. \tag{29}$$

Actually we can see that this definition is extremely suggestive if we assumed that we already had a representation, now on a spinor space $\mathcal{S}_\rho$, of the Clifford algebra with $(^\dagger)$ and ρ, i.e., we had

$$\begin{aligned} &\rho(AB)=\rho(A)\rho(B),\\ &\rho(aA+bB)=a\rho(A)+b\rho(B),\\ &\rho(A^\dagger)=\rho(A)^\dagger. \end{aligned} \tag{30}$$

So, for example, $\rho(\gamma^a)$ is the usual γ^a when conceived of as a matrix or operator acting on spinor states. It means accordingly that all the Clifford algebra is mapped into operators and so are our $\overset{ab}{(k)}$ and $\overset{ab}{[k]}$. It further means that we have assumed spinor states $\in\mathcal{S}_\rho$ on which these products of expressions (operators) work. So indeed we can select now one state ψ_0, which we call a ''vacuum state'' and for which we assume, in order to be able to use Eq. (29), that $\rho(\Pi[-]\Pi[-i])\psi_0$ is different from zero. Even having in mind that $\rho([-])$ or $\rho([-i])$ are projectors, we realize that this is indeed a very mild requirement.

After selecting the ''vacuum state'' one can produce the correspondence between the ''spinor states'' $\mathcal{S}$ equal to the left ideal (as Chevalley did in Chap. III in his book) and spinors in $\mathcal{S}_\rho$. The relation is of course

$$u\to\rho(u)\psi_0. \tag{31}$$

If there is an inner product defined on the space of spinors $\mathcal{S}_\rho$ $(\langle\psi_1|\psi_2\rangle_\rho)$, then the corresponding inner product on $\mathcal{S}$ is suggested to be $\langle v|u\rangle=\langle\rho(v)\psi_0|\rho(u)\psi_0\rangle$. Now we have

$$\begin{aligned} \langle\rho(v)\psi_0|\rho(u)\psi_0\rangle_\rho &= \langle\psi_0|\rho(v)^\dagger\rho(u)\psi_0\rangle_\rho = \langle\psi_0|\rho(v^\dagger u)\psi_0\rangle_\rho\\ &= \langle v|u\rangle\cdot\left\langle\psi_0\middle|\rho\left(\prod [-]\prod [-i]\right)\psi_0\right\rangle_\rho, \end{aligned} \tag{32}$$

where $\langle v|u\rangle$ is the expression from Eq. (29). We would now like to justify this inner product on $\mathcal{S}$ as a well chosen definition. To do that we have to evaluate the factor $\langle\psi_0|\rho(\Pi[-]\Pi[-i])\psi_0\rangle_\rho$ from Eq. (32), justifying that it is not important. We assumed already above that $\rho(\Pi[-]\Pi[-i])\psi_0$ is nonzero, which means that the ''vacuum state'' ψ_0 contains spinor states which have the corresponding quantum numbers so that the projector on such a state is nonzero. But since the factor $\langle\psi_0|\rho(\Pi[-]\Pi[-i])\psi_0\rangle_\rho$ does not depend on either u or v it can only be a constant, which goes into normalization. That confirms that the ''vacuum state'' only manifests itself in an overall factor. We conclude that $\langle v|u\rangle$ was a good choice [Eqs. (29) and (27)].

We have the correspondence between the Clifford algebra objects in the left ideal $\mathcal{S}$ spanned by our basis [we made a choice of $(+)(+i)$ as a starting state] and the Hilbert space of spinors $\mathcal{S}_\rho$. Having a set of products in Theorem 3, used for a basis for $\mathcal{S}$, we can now find the corresponding basis in the spinor space $\mathcal{S}_\rho$, just as an example for $d=4$:

$$\begin{aligned}&(\gamma^a+\sqrt{-\eta^{aa}\eta^{bb}}\gamma^b)(\gamma^c+\sqrt{-\eta^{cc}\eta^{dd}}\gamma^d)\psi_0,\\&\left(1+\frac{1}{\eta^{aa}}\sqrt{-\eta^{aa}\eta^{bb}}\gamma^a\gamma^b\right)\left(1+\frac{1}{\eta^{cc}}\sqrt{-\eta^{cc}\eta^{dd}}\gamma^c\gamma^d\right)\psi_0.\end{aligned}\tag{33}$$

These two states belong to one Weyl representation. To get the full basis for the representation $\mathcal{S}_\rho$ for the whole Clifford algebra (two Weyl spinors) one has to add the following two spinor basis states:

$$\begin{aligned}&(\gamma^a+\sqrt{-\eta^{aa}\eta^{bb}}\gamma^b)\left(1+\frac{1}{\eta^{cc}}\sqrt{-\eta^{cc}\eta^{dd}}\gamma^c\gamma^d\right)\psi_0,\\&\left(1+\frac{1}{\eta^{aa}}\sqrt{-\eta^{aa}\eta^{bb}}\gamma^a\gamma^b\right)(\gamma^c+\sqrt{-\eta^{cc}\eta^{dd}}\gamma^d)\psi_0.\end{aligned}\tag{34}$$

One can easily see that these states are orthonormalized provided that the vacuum state ψ_0 is properly normalized, which means in our example

$$\left\langle\psi_0\left|\frac{1}{2}\left(1+\frac{1}{\eta^{aa}}\sqrt{-\eta^{aa}\eta^{bb}}\gamma^a\gamma^b\right)\frac{1}{2}\left(1+\frac{1}{\eta^{cc}}\sqrt{-\eta^{cc}\eta^{dd}}\gamma^c\gamma^d\right)\psi_0\right.\right\rangle=1.\tag{35}$$

In the general case the normalization condition is

$$\left\langle\psi_0\left|\prod\,[-]\prod\,[-i]\psi_0\right.\right\rangle=1.\tag{36}$$

We may realize that only one component along the common eigenstates of the Cartan subalgebra generators $\rho(S^{ab}),\rho(S^{cd})$ matters in our normalization condition Eq. (36).

We conclude the subsection with the statement that each state ${}^h\psi_i$ belonging to a representation of handedness h, is, due to appropriately chosen ''vacuum state,'' orthonormal to any other state $|{}^{h'}\psi_j\rangle$, where ψ_i are basis states of spinors, generated in the way we presented above:

$$\langle{}^h\psi_i|{}^{h'}\psi_j\rangle=\delta^{hh'}\delta^{ij}.\tag{37}$$

V. "FAMILIES"

In the construction of our basis for a left ideal, which at the end got identified with the spinor space $\mathcal{S}$ and mapped into $\mathcal{S}_\rho$, we made at a point a selection of a ''starting object.'' We had chosen for the ''starting object'' the product of $d/2$ for even d [respectively $(d-1)/2$ for odd d] nilpotent

constructions with $+\frac{1}{2}$ or $+i/2$ as the eigenvalues of the left multiplication Cartan algebra generators: $\overset{ab}{(+)}=1/2(\gamma^a+\eta^{aa}/i\gamma^b)$, $\overset{ab}{(+i)}=1/2(\gamma^a+\eta^{bb}\gamma^b)$. By acting on the starting basis with γ^a's we reached other basis elements belonging to our Clifford basis. We ended with a closing involving $2^{d/2}$ for even d (and $2^{(d-1)/2}$ for odd d) basis constructions.

We noticed already that none of the Clifford algebra object can transform $\overset{ab}{(+)}$ into $\overset{ab}{[+]}$ or opposite (Sec. III C), and also not $\overset{ab}{(-)}$ into $\overset{ab}{[-]}$. We see that whenever $\overset{ab}{(+)}$ is replaced by $\overset{ab}{[+]}$ a new ''starting state'' is generated leading to a new representation. We can count the number of different representations, finding $2^{d/2}$ for d even and $2^{(d+1)/2}$ for d odd, respectively. [In the odd d case left and right handed objects transform under the Clifford algebra left multiplication into themselves (Theorem 4), that is, without changing handedness.]

Each of these $2^{d/2}$ (or $2^{(d+1)/2}$ for d odd) different representations leads to a different left ideal and, thus, if we identify the ideals with $\mathcal{S}$, we would get, strictly speaking, different $\mathcal{S}$ in each case. If we let there be, as above, a representation ρ of the Clifford algebra on a spinor space $\mathcal{S}_\rho$, each of these choices of representations, or rather of ideals, would in general lead to a different basis in the space $\mathcal{S}_\rho$. If ρ is an *irreducible* representation, it is well-known that in the even case the dimension of $\mathcal{S}_\rho$ is equal to $2^{d/2}$, which falls into two irreducible representations of the Lorentz group.

Let us remind that we previously showed that when we construct the states (33) and (34) they only extract from the ''vacuum state'' ψ_0 the component along the common eigenspace of the representations $\rho(S^{03})$, $\rho(S^{12})$, etc. of the Cartan algebra generators, namely the one with $-\frac{1}{2}$ or $-i/2$ eigenvalues. If we choose another ideal, belonging to another starting state, the component extracted from ψ_0 will be another one. We find the following rule: (i) If for the Cartan subalgebra generators S^{ab}, in the starting state and accordingly the basis use the pair $\overset{ab}{(+)}$ and $\overset{ab}{[-]}$ is contained, say for $\eta^{aa}=1=\eta^{bb}$, then the extracted component is from a common eigenspace for the Cartan subalgebra generators with the eigenvalue for S^{ab} being $-\frac{1}{2}$. If, however, the pair $\overset{ab}{(-)}$ and $\overset{ab}{[+]}$ is used in the starting state, the extracted component of the common eigenspace will be S^{ab} having the eigenvalue $\frac{1}{2}$. All these different basis states coming from different ideals are independent of the ''vacuum states'' except for normalization. Of course, the basis states in $\mathcal{S}_\rho$, induced by the choice of one ideal, can not be orthogonal to the basis induced by another ideal, when we talk about basis vectors in only one irreducible representation space $\mathcal{S}_\rho$. Actually, the basis vectors in $\mathcal{S}_\rho$, reached by using different representations $\mathcal{S}$, induced by different ideals, are essentially the same. In fact, to get into essentially the same basis vector in $\mathcal{S}_\rho$ from one ideal to another one can use the replacement of $\overset{ab}{(+)}$ into $\overset{ab}{[+]}$ and $\overset{ab}{(-)}$ into $\overset{ab}{[-]}$, because eigenvectors in $\mathcal{S}$ are characterized by their eigenvalues of the Cartan subalgebra generators.

But we could have required that all $2^{d/2}$ different $\mathcal{S}$, belonging to different ideals, should be mapped into $2^{d/2}$ for d even (and similarly for d odd) orthogonal basis vectors in an enlarged $\mathcal{S}_\rho$, which then would be a reducible representation of the Clifford algebra, which would lead to, for instance, block-diagonal representations of blocks of the dimension $2^{d/2}$ in even d case,[4,5]

$$\mathcal{S}_\rho=\sum_i^{N_{gen}} \mathcal{S}_{ir,i}, \tag{38}$$

where N_{gen} is equal $2^{d/2}$ and $\mathcal{S}_{ir,i}$ denotes the ith irreducible representation.

In a generic case, we could have the number of what we call ''families'' greater than one and smaller than $2^{d/2}$ for even d and $2^{(d+1)/2}$ for d odd.

Taking into account the orthogonality of all the 2^d polynomials of the γ^a operators and assuming that these polynomials act on a ''vacuum state'' which assures the orthogonality of all

the obtained states, we find $2^{d/2}$ copies of the two-Weyl spinors (that is, of the Dirac spinor). We count the number of all states, which is for d-dimensional space 2^d, and compare for d even this number with twice the number of states in one Weyl spinor irreducible representation (since we count states of both handedness), which is $2\times 2^{d/2-1}$. For d odd we find accordingly $2^{(d+1)/2}$ copies of the Weyl spinor. We call these $2^{d/2}$ copies for d even and $2^{(d+1)/2}$ copies for d odd ''families'' of spinors. Each ''family'' differs from all the others in the choice of the starting state, on which the irreducible representation is built, and accordingly on all the states.

To achieve the required orthogonality, we make a choice of phases for states belonging to different ''families'' in such a way that, when choosing the ''vacuum state'' $|\psi_0\rangle$ to be the sum of not only all the states in one ''family'' but of all the states of all the ''families,'' each state appearing with the same coefficient, not only the expectation values of the operators S^{ab}, belonging to the Cartan subalgebra, but also the expectation values of γ^a are for such $|\psi_0\rangle$ equal to zero, that is $\langle\psi_0|\gamma^a|\psi_0\rangle=0$, for d even and odd. Given such a choice of the ''vacuum state,'' all states belonging to any ''family'' are orthonormal:

$$\langle {}^a\psi_i|{}^b\psi_j\rangle=\delta^{ab}\delta^{ij}. \tag{39}$$

We use index a or b to numerate a ''family'' and index i or j to numerate states within a ''family.''

VI. GRAPHIC PRESENTATION

We shall present in this section a simple and transparent graphic technique for finding irreducible representations of the Lorentz group for spinors for any dimension—even or odd. We start by introducing the notation (already seen in Theorem 1)

$$\begin{aligned}
\overset{ab}{(k)} &:= \frac{1}{2}\left(\gamma^a+\frac{\eta^{bb}}{i}k\gamma^b\right)=\frac{1}{2}\left(\gamma^a+\frac{\eta^{aa}}{ik}\gamma^b\right),\\
\overset{ab}{[k]} &:= \frac{1}{2}(1+ik\eta^{aa}\eta^{bb}\gamma^a\gamma^b)=\frac{1}{2}\left(1+\frac{i}{k}\gamma^a\gamma^b\right),\\
\overset{+}{\bigcirc} &:= \tfrac{1}{2}(1+\Gamma),\\
\overset{-}{\bullet} &:= \tfrac{1}{2}(1-\Gamma),
\end{aligned} \tag{40}$$

under the assumption that the eigenvalue k of $2S^{ab}$ (supposedly one of the Cartan-algebra generators) being of course restricted by $k^2=\eta^{aa}\eta^{bb}$, since it is real for a and b corresponding both to time or both to space index, while it is purely imaginary for opposite signatures. We see that Theorem 1 above tells us

$$\begin{aligned}
S^{ab}\overset{ab}{(k)} &= \tfrac{1}{2}k\overset{ab}{(k)},\\
S^{ab}\overset{ab}{[k]} &= \tfrac{1}{2}k\overset{ab}{[k]}.
\end{aligned} \tag{41}$$

We have of course for d different from a and b

$$\begin{aligned}
\gamma^d\overset{ab}{(k)} &= -\overset{ab}{(k)}\gamma^d,\\
\gamma^d\overset{ab}{[k]} &= \overset{ab}{[k]}\gamma^d.
\end{aligned} \tag{42}$$

We can easily find

$$\begin{gathered}\overset{ab}{\gamma^a}(k)=\eta^{aa}\overset{ab}{[}-k],\\ \overset{ab}{\gamma^b}(k)=-ik\overset{ab}{[}-k],\\ \overset{ab}{\gamma^a}[k]=\overset{ab}{(}-k),\\ \overset{ab}{\gamma^b}[k]=-ik\,\eta^{aa}\overset{ab}{(}-k).\end{gathered}\tag{43}$$

From Eqs. (42) and (43) it follows that

$$\begin{gathered}\overset{ab\ cd}{S^{ac}}(k)(k)=-\frac{i}{2}\eta^{aa}\eta^{cc}\overset{ab}{[}-k]\overset{cd}{[}-k],\\ \overset{ab\ cd}{S^{ac}}[k][k]=\frac{i}{2}\overset{ab}{(}-k)\overset{cd}{(}-k),\\ \overset{ab\ cd}{S^{ac}}(k)[k]=-\frac{i}{2}\eta^{aa}\overset{ab}{[}-k]\overset{cd}{(}-k),\\ \overset{ab\ cd}{S^{ac}}[k](k)=\frac{i}{2}\eta^{cc}\overset{ab}{(}-k)\overset{cd}{[}-k].\end{gathered}\tag{44}$$

We also find

$$\overset{ab}{(k)}^{\dagger}=\eta^{aa}\overset{ab}{(}-k),\tag{45}$$

$$\overset{ab}{[k]}^{\dagger}=\overset{ab}{[}k],\tag{46}$$

and

$$\begin{gathered}\overset{ab\ ab}{(k)(k)}=0,\quad \overset{ab\ ab}{(k)(}-k)=\eta^{aa}\overset{ab}{[}k],\quad \overset{ab\ ab}{(}-k)(k)=\eta^{aa}\overset{ab}{[}-k],\quad \overset{ab\ ab}{(}-k)(-k)=0,\\ \overset{ab\ ab}{[k][}k]=\overset{ab}{[}k],\quad \overset{ab\ ab}{[k][}-k]=0,\quad \overset{ab\ ab}{[}-k][k]=0,\quad \overset{ab\ ab}{[}-k][-k]=\overset{ab}{[}-k],\\ \overset{ab\ ab}{(k)[}k]=0,\quad \overset{ab\ ab}{[k](}k)=\overset{ab}{(}k),\quad \overset{ab\ ab}{(}-k)[k]=\overset{ab}{(}-k),\quad \overset{ab\ ab}{(}-k)[-k]=0,\\ \overset{ab\ ab}{(k)[}-k]=\overset{ab}{(}k),\quad \overset{ab\ ab}{[k](}-k)=0,\quad \overset{ab\ ab}{[}-k](k)=0,\quad \overset{ab\ ab}{[}-k](-k)=\overset{ab}{(}-k).\end{gathered}\tag{47}$$

According to Eqs. (46) and (47) and discussions in Sec. IV we find

$$\overset{ab\ ab}{(k)^{\dagger}(k)}=\overset{ab}{[}-k],\quad \langle\overset{ab\ ab}{(k)^{\dagger}(k)}\rangle=1,\tag{48}$$

$$\overset{ab}{[k]}{}^{\dagger}\overset{ab}{[k]}=\overset{ab}{[k]}, \quad \langle \overset{ab}{[k]}{}^{\dagger}\overset{ab}{[k]}\rangle = 1. \tag{49}$$

Let us conclude this section by presenting graphically a Weyl spinor irreducible representation for d-dimensional space, with d even and with the handedness [Eq. (14)] Γ equal to $\Pi_a \sqrt{\eta^{aa}}\, \Pi_{\text{Cartan ab}}\, k_{ab}$. The first product runs over all the indices a, while the second product runs over the eigenvectors k_{ab} [Eq. (41)] of the Cartan subalgebra elements [Eq. (9)]. This irreducible representation of the chosen handedness is one out of $2^{d/2}$ possible ones. All the pairs $S^{ab}, S^{cd}, \ldots$ are members of the Cartan subalgebra of the Lorentz group:

$$\begin{aligned}
&\overset{ab}{(k_{ab})}\overset{cd}{(k_{cd})}\overset{ef}{(k_{ef})}\cdots\overset{gh}{(k_{gh})}\cdots\psi_0\\
&\overset{ab}{[-k_{ab}]}\overset{cd}{[-k_{cd}]}\overset{ef}{(k_{ef})}\cdots\overset{gh}{(k_{gh})}\cdots\psi_0\\
&\overset{ab}{[-k_{ab}]}\overset{cd}{(k_{cd})}\overset{ef}{[-k_{ef}]}\cdots\overset{gh}{(k_{gh})}\cdots\psi_0\\
&\qquad\vdots\\
&\overset{ab}{[-k_{ab}]}\overset{cd}{(k_{cd})}\overset{ef}{(k_{ef})}\cdots\overset{gh}{[-k_{gh}]}\cdots\psi_0\\
&\overset{ab}{(k_{ab})}\overset{cd}{[-k_{cd}]}\overset{ef}{[-k_{ef}]}\cdots\overset{gh}{(k_{gh})}\cdots\psi_0\\
&\qquad\vdots
\end{aligned} \tag{50}$$

States, belonging to one multiplet with respect to the group $\mathrm{SO}(q,d-q)$, that is to one irreducible representation, can have any phase. We made a choice of the simplest one, taking all phases equal to one.

What we learn from the above graphic representation is that one obtains all the states of an irreducible Weyl representation by transforming all possible pairs of $\overset{ab}{(k_{ab})}\overset{mn}{(k_{mn})}$ to $\overset{ab}{[-k_{ab}]}\overset{mn}{[-k_{mn}]}$. The procedure gives $2^{(d/2-1)}$ states. We shall use the presented graphical search to find the Weyl spinors for $d=3$ and $d=4$ in the next section.

VII. MATRIX REPRESENTATION OF γ^a AND S^{ab}

In this section we present matrix elements for the Clifford algebra elements γ^a's and for the generators of the Lorentz group S^{ab}.

As we learned in Sec. VI (and can be very easily checked), transforms γ^a the nilpotent $\overset{ab}{(k)} = \frac{1}{2}(\gamma^a + (\eta^{aa}/ik)\,\gamma^b)$ [Eq. (43)] into the projector $\eta^{aa}\overset{ab}{[-k]} = \eta^{aa}\frac{1}{2}(1 - i/k\,\gamma^a\gamma^b)$. A basic state has for a chosen dimension d, $d/2$ factors, which are either nilpotents or projectors, but only one among those nilpotents or projectors has the index ab. We shall therefore first look at the matrix elements between the two states $\overset{ab}{(k)}$ and $\overset{ab}{[-k]}$, for example. The only difference in matrix elements between this case and the case with a general $d/2$ factors in a basic state is in a phase factor, which we shall comment on later.

Following the definition of the inner product in Sec. IV and taking into account Eq. (43) in Sec. VI, one easily finds matrix elements of the Clifford algebra operators γ^a between any two states for any d of what we called the Dirac representation, if we first recognize the relations

$$\langle\psi_0|\overset{ab}{[-k]}^\dagger\gamma^a\overset{ab}{(k)}\psi_0\rangle=\eta^{aa}\langle\psi_0|\overset{ab}{[-k]}^\dagger\overset{ab}{[-k]}\psi_0\rangle=\eta^{aa},$$

$$\langle\psi_0|\overset{ab}{[-k]}^\dagger\gamma^b\overset{ab}{(k)}\psi_0\rangle=-ik_{ab}\langle\psi_0|\overset{ab}{[-k]}^\dagger\overset{ab}{[-k]}\psi_0\rangle=-ik_{ab}, \tag{51}$$

$$\langle\psi_0|\overset{ab}{(k)}^\dagger\gamma^a\overset{ab}{[-k]}\psi_0\rangle=\langle\psi_0|\overset{ab}{(k)}^\dagger\overset{ab}{(k)}\psi_0\rangle=1,$$

$$\langle\psi_0|\overset{ab}{(k)}^\dagger\gamma^b\overset{ab}{[-k]}\psi_0\rangle=ik_{ab}\eta^{aa}\langle\psi_0|\overset{ab}{(k)}^\dagger\overset{ab}{(k)}\psi_0\rangle=ik_{ab}\eta^{aa},$$

where the ''vacuum state'' has to be understood as explained in Sec. IV and k_{ab} means k, which belongs to the nilpotent $\overset{ab}{(k)}$ or to the projector $\overset{ab}{[k]}$, with $k_{ab}^2=\eta^{aa}\eta^{bb}$.

In the space of the two vectors $\overset{ab}{(k)}\psi_0$ and $\overset{ab}{[-k]}\psi_0$ the matrix representations of γ^a and γ^b are

$$\gamma^a=\begin{pmatrix}0 & 1\\ \eta^{aa} & 0\end{pmatrix},\quad \gamma^b=\begin{pmatrix}0 & ik_{ab}\eta^{aa}\\ -ik_{ab} & 0\end{pmatrix}, \tag{52}$$

with k_{ab} belonging to the nilpotent $\overset{ab}{(k)}$ and $-k_{ab}$ belonging to the projector $\overset{ab}{[-k]}$. If γ^{a_k} operates on a state $\overset{a_1a_2}{\{k\}}\cdots\overset{a_ia_j}{\{k\}}\ \overset{a_ka_l}{(k)}\cdots\psi_0$, where $\{k\}$ stands for either nilpotents (k) or for projectors $[k]$, one obtains

$$\gamma^{a_k}\overset{a_1a_2}{\{k\}}\cdots\overset{a_ia_j}{\{k\}}\overset{a_ka_l}{(k)}\cdots\psi_0=(-)^{n_0}\eta^{a_ka_k}\overset{a_1a_2}{\{k\}}\cdots\overset{a_ia_j}{\{k\}}\overset{a_ka_l}{[-k]}\cdots\psi_0, \tag{53}$$

where n_0 means the number of nilpotents among all the $\{k\}$, which γ^{a_k} has to jump over. Accordingly the phase $(-)^{n_0}$ of the new state is either $+$ or $-$ factor, for an even or odd number of nilpotents, respectively. If, in Eq. (53), the state $\overset{a_ka_l}{(k)}$ is replaced by the state $\overset{a_ka_l}{[-k]}$, it follows

$$\gamma^{a_k}\overset{a_1a_2}{\{k\}}\cdots\overset{a_ia_j}{\{k\}}\overset{a_ka_l}{[-k]}\cdots\psi_0=(-)^{n_0}\overset{a_1a_2}{\{k\}}\cdots\overset{a_ia_j}{\{k\}}\overset{a_ka_l}{(k)}\cdots\psi_0, \tag{54}$$

where again n_0 means the number of nilpotents among all the $\{k\}$, which γ^{a_k} has to jump over. By taking into account Eqs. (52)–(54) and accordingly by counting the number of nilpotents, which γ^a's have to jump over, one easily finds the matrix representation for γ^a's for any dimension and any signature.

When looking for matrix representations of $S^{ab}(=(i/4)[\gamma^a,\gamma^b])$, which are not elements of the Cartan subalgebra, the space of at least two factors of nilpotents or projectors has to be considered, since each of γ^a and γ^b transforms one factor as we know from above. In the space of the two vectors $\overset{ab}{(k)}\ \overset{cd}{(k)}\ \psi_0$ and $\overset{ab}{[-k]}\ \overset{cd}{[-k]}\ \psi_0$, for example, one finds the following matrix representations for the generators of the Lorentz group S^{ac}, S^{bd}, S^{ad} and S^{bc},

$$S^{ac}=\frac{1}{2}\begin{pmatrix}0 & i\\ -i\eta^{aa}\eta^{cc} & 0\end{pmatrix},\quad S^{bd}=\frac{1}{2}k_{ab}k_{cd}\begin{pmatrix}0 & -i\eta^{aa}\eta^{cc}\\ i & 0\end{pmatrix},$$

$$S^{ad}=\frac{1}{2}k_{cd}\begin{pmatrix}0 & -\eta^{cc}\\ -\eta^{aa} & 0\end{pmatrix},\quad S^{bc}=\frac{1}{2}k_{ab}\begin{pmatrix}0 & -\eta^{aa}\\ -\eta^{cc} & 0\end{pmatrix}. \tag{55}$$

If $S^{a_k a_p}$ operates on a state $\stackrel{a_1 a_2}{\{k\}}\cdots\stackrel{a_i a_j}{\{k\}}\stackrel{a_k a_l}{(k)}\stackrel{a_m a_n}{\{k\}}\cdots\stackrel{a_p a_r}{(k)}\cdots\psi_0$, where $\{k\}$ stands again for either nilpotents (k) or for projectors $[k]$, one obtains

$$S^{a_k a_p}\stackrel{a_1 a_2}{\{k\}}\cdots\stackrel{a_i a_j a_k a_l a_m a_n}{\{k\}(k)\{k\}}\cdots\stackrel{a_p a_r}{(k)}\cdots\psi_0$$

$$=-(-)^{(n_{0_k}+n_{0_p})}\frac{i}{2}\eta^{a_k a_k}\eta^{a_p a_p}\stackrel{a_1 a_2}{\{k\}}\cdots\stackrel{a_i a_j}{\{k\}}\stackrel{a_k a_l}{[-k]}\stackrel{a_m a_n}{\{k\}}\cdots\stackrel{a_p a_r}{[-k]}\cdots\psi_0, \tag{56}$$

where $\underset{a_k a_l}{n_{0_k}}$ and $\underset{a_p a_r}{n_{0_p}}$ counts the number of nilpotents among all the $\{k\}$ between $S^{a_k a_p}$ and either $\stackrel{a_k a_l}{(k)}$ or $\stackrel{a_p a_r}{(k)}$, respectively.

By taking into account Eqs. (55) and (56) one easily finds matrix elements of all the nondiagonal elements of the Lorentz algebra, while the matrix elements of the Cartan subalgebra very easily follow from Eq. (41).

Up to now we only have paid attention to even dimensions. For odd dimensions, the application of γ^a on a state, if $a\neq 0$, is due to Theorem 4 equivalent to the application of $\gamma^a\gamma^0=2iS^{0a}$ on the state, since Theorem 4 says that $\gamma^a\gamma^0(1\pm\Gamma)\stackrel{a_1 a_2}{\{k\}}\cdots\stackrel{a_i a_j}{\{k\}}\stackrel{a_k a_l}{(k)}\cdots\psi_0=\pm\sqrt{\underset{a_1 a_2}{\eta^{00}}}\eta^{00}\varepsilon(1\pm\Gamma)\gamma^a\stackrel{a_1 a_2}{\{k\}}\cdots\stackrel{a_i a_j}{\{k\}}\stackrel{a_k a_l}{(k)}\cdots\psi_0$, where ε is the handedness of the $(d-1)$-dimensional part $\stackrel{a_1 a_2}{\{k\}}\cdots\stackrel{a_i a_j}{\{k\}}\stackrel{a_k a_l}{(k)}\cdots\psi_0$ of the state, that is, of the even part, which does not include γ^0. We took into account that in odd-dimensional spaces γ^a and Γ commute. The evaluation of γ^a on the rest of the state follows from the above derivations.

We are concluding this section with the statement that the simplest choice of the relative phases (by just taking all the phases equal to one) in Eq. (50) leads for $d=4$ and for the Minkowski metric to the representation known as the chiral representation for spinors. We present matrix representations of γ^a and S^{ab} for $d=3$ and $d=4$ in the next section.

VIII. DEMONSTRATION OF IRREDUCIBLE REPRESENTATIONS OF WEYL SPINORS

In this section we demonstrate what we have learned, on two cases: We look for the irreducible representations of spinors with respect to the Lorentz group for a three-dimensional and a four-dimensional case. In both cases we shall assume the Minkowski metric: $\eta^{00}=-\eta^{ii}$, with $i=1,2$ for $d=3$ and $i=1,2,3$ for $d=4$. The ''vacuum state'' ψ_0 is chosen in such a way that all the 2^d linearly independent polynomials of γ^a are orthonormalized [as explained in Sec. IV].

A. Weyl spinors for $d=3$

There is only one $[(d-1)/2=1]$ operator of the Cartan subalgebra of the Lorentz algebra. According to Eq. (13) we choose S^{12} as the member of the Cartan subalgebra of the Lorentz algebra which the operators S^{01}, S^{02}, S^{12} close. Following Eq. (10) we find $\Gamma=i\gamma^0\gamma^1\gamma^2$. There are 2^3, that is eight, basic states, which we arange to be eigenstates of S^{12}, Γ and γ^0:

$$(\tfrac{1}{2})^2(1\pm\Gamma)(\gamma^1\pm i\gamma^2),\quad (\tfrac{1}{2})^2\gamma^0(1\pm\Gamma)(1\pm i\gamma^1\gamma^2). \tag{57}$$

We find the eigenvalues of the only member of the Cartan subalgebra S^{12} according to Theorem 1 [or by using Eq. (41), since S^{12} commutes with Γ] for the eight states of Eq. (57) to be $\pm\frac{1}{2}$. Using Theorem 4 one easily finds that the eigenvalues of γ^0 are $+1$ for those states, in which both factors appear with the same sign, otherwise they are -1. We arrange these eight orthonormal states into four ''families'' as presented in Table I.

Any of the four ''families'' can be used as the Weyl basis (or the Dirac; for odd dimensions the Weyl and the Dirac basis coincide) when solving the massless or massive Dirac equation, as it will be demonstrated in next section [Sec. IX].

TABLE I. Four "families" of the Lorentz group SO(1,2). All vectors are eigenvectors of S^{12}, γ^0 and Γ. They are orthonormalized according to Sec. IV. The graphical presentation follows the procedure described in Sec. VI. We add also a simplified version of the graphical presentation of states.

a	i	${}^a\psi_i$	S^{12}	γ^0	Γ	Graphic presentation
1	1	$(\frac{1}{2})^2(1+\Gamma)(\gamma^1+i\gamma^2)\psi_0$	$\frac{1}{2}$	1	1	$\overset{+}{\bigcirc}\overset{12}{(+)}$ or $\bigcirc(+)$
1	2	$(\frac{1}{2})^2(1+\Gamma)(1-i\gamma^1\gamma^2)\psi_0$	$-\frac{1}{2}$	-1	1	$\overset{+}{\bigcirc}\overset{12}{[-]}$ or $\bigcirc[-]$
2	1	$(\frac{1}{2})^2(1-\Gamma)(\gamma^1+i\gamma^2)\psi_0$	$\frac{1}{2}$	-1	-1	$\overset{-}{\bullet}\overset{12}{(+)}$ or $\bullet(+)$
2	2	$(\frac{1}{2})^2(1-\Gamma)(1-i\gamma^1\gamma^2)\psi_0$	$-\frac{1}{2}$	1	-1	$\overset{-}{\bullet}\overset{12}{[-]}$ or $\bullet[-]$
3	1	$(\frac{1}{2})^2(1+\Gamma)(1+i\gamma^1\gamma^2)\psi_0$	$\frac{1}{2}$	1	1	$\overset{+}{\bigcirc}\overset{12}{[+]}$ or $\bigcirc[+]$
3	2	$(\frac{1}{2})^2(1+\Gamma)(\gamma^1-i\gamma^2)\psi_0$	$-\frac{1}{2}$	-1	1	$\overset{+}{\bigcirc}\overset{12}{(-)}$ or $\bigcirc(-)$
4	1	$(\frac{1}{2})^2(1-\Gamma)(1+i\gamma^1\gamma^2)\psi_0$	$\frac{1}{2}$	-1	-1	$\overset{-}{\bullet}\overset{12}{[+]}$ or $\bullet[+]$
4	2	$(\frac{1}{2})^2(1-\Gamma)(\gamma^1-i\gamma^2)\psi_0$	$-\frac{1}{2}$	1	-1	$\overset{-}{\bullet}\overset{12}{(-)}$ or $\bullet(-)$

According to Sec. VII we find for the generators of the Lorentz group $S^{0i}(=(i/2)\,\gamma^0\gamma^i)$ for the first (and the third "family"), for $\eta^{00}=1=-\eta^{11}=-\eta^{22}$, just by multiplying γ^0 [which is diagonal with diagonal elements 1 and -1 (by Theorem 4)] and γ^i [from Eq. (52)] the following matrix presentation,

$$S^{01}=\frac{i}{2}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad S^{02}=\frac{i}{2}\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad S^{12}=\frac{1}{2}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \tag{58}$$

which are, up to a factor, just the Pauli matrices $S^{01}=(i/2)\,\sigma_1$, $S^{02}=(i/2)\,\sigma_2$, $S^{12}=\frac{1}{2}\sigma_3$. The matrix γ^0 is equal to $2S^{12}=\sigma_3$. The matrices γ^1 and γ^2 are equal to $-2i\gamma^0S^{01}=i\sigma^2$ and $-2i\gamma^0S^{02}=-i\sigma^1$, respectively. We could, of course, calculate these matrices directly, using Table I. For example, the second element of the first row in S^{01} is equal to

$$\begin{aligned}&\langle\psi_0|((\tfrac{1}{2})^2(1+\Gamma)(1-i\gamma^1\gamma^2))^\dagger S^{01}(\tfrac{1}{2})^2(1+\Gamma)(\gamma^1+i\gamma^2)\psi_0\rangle\\ &\quad=\frac{i}{2}\langle\psi_0|((\tfrac{1}{2})^2(1+\Gamma)(1-i\gamma^1\gamma^2))^\dagger\gamma^0\gamma^1(\tfrac{1}{2})^2(1+\Gamma)(\gamma^1+i\gamma^2)\psi_0\rangle\\ &\quad=-\frac{i}{2}\langle\psi_0|((\tfrac{1}{2})^2(1+\Gamma)(1-i\gamma^1\gamma^2))^\dagger(\tfrac{1}{2})^2\gamma^0(1+\Gamma)(1-i\gamma^1\gamma^2)\psi_0\rangle=\frac{i}{2},\end{aligned} \tag{59}$$

since, due to the Clifford algebra properties, $\{\gamma^a,\gamma^b\}_+=2\,\eta^{ab}$. [The second and the third "families" have $S^{01}=-(i/2)\,\sigma_1$, $S^{02}=-(i/2)\,\sigma_2$, $S^{12}=\frac{1}{2}\sigma_3$ and $\gamma^0=-\sigma_3$.]

B. Weyl spinors for $d=4$

There are two $(d/2=2)$ operators of the Cartan subalgebra of the Lorentz algebra, which is closed by the operators S^{01}, S^{02}, S^{03}, S^{12}, S^{13}, S^{23}. According to Eq. (13) we choose S^{03} and S^{12} as members of the Cartan subalgebra. Following Eq. (10) we find $\Gamma=i\gamma^0\gamma^1\gamma^2\gamma^3$. There are 2^4, that is 16, basic states, all of them being eigenstates of S^{12} and S^{03}:

TABLE II. Four ''families'' of the two Weyl spinors of the Lorentz group SO(1,3). Basic vectors are eigenvectors of the two operators of the Cartan subalgebra S^{12} and S^{03}. The eigenvalues of the operator of handedness $\Gamma=2^2 i S^{03}S^{12}$ are also presented. All the basic states are orthonormalized as discussed in Sec. IV. Two types of graphic presentation are added, a simplified version in addition to the ordinary one. We made the simplest choice of relative phases—assuming all phases to be equal to $+1$, as discussed in Sec. IV.

a	i	${}^a\psi_i$	S^{12}	S^{03}	Γ	Graphic presentation
1	1	$(\frac{1}{2})^2(\gamma^0-\gamma^3)(\gamma^1+i\gamma^2)\psi_0$	$\frac{1}{2}$	$\frac{i}{2}$	-1	$\overset{03}{(+i)}\overset{12}{(+)}$ or $(+i)(+)$
1	2	$(\frac{1}{2})^2(1-\gamma^0\gamma^3)(1-i\gamma^1\gamma^2)\psi_0$	$-\frac{1}{2}$	$-\frac{i}{2}$	-1	$\overset{03}{[-i]}\overset{12}{[-]}$ or $[-i][-]$
2	1	$(\frac{1}{2})^2(1-\gamma^0\gamma^3)(\gamma^1+i\gamma^2)\psi_0$	$\frac{1}{2}$	$-\frac{i}{2}$	1	$\overset{03}{[-i]}\overset{12}{(+)}$ or $[-i](+)$
2	2	$(\frac{1}{2})^2(\gamma^0-\gamma^3)(1-i\gamma^1\gamma^2)\psi_0$	$-\frac{1}{2}$	$\frac{i}{2}$	1	$\overset{03}{(+i)}\overset{12}{[-]}$ or $(+i)[-]$
3	1	$(\frac{1}{2})^2(1+\gamma^0\gamma^3)(1+i\gamma^1\gamma^2)\psi_0$	$\frac{1}{2}$	$\frac{i}{2}$	-1	$\overset{03}{[+i]}\overset{12}{[+]}$ or $[+i][+]$
3	2	$(\frac{1}{2})^2(\gamma^0+\gamma^3)(\gamma^1-i\gamma^2)\psi_0$	$-\frac{1}{2}$	$-\frac{i}{2}$	-1	$\overset{03}{(-i)}\overset{12}{(-)}$ or $(-i)(-)$
4	1	$(\frac{1}{2})^2(\gamma^0+\gamma^3)(1+i\gamma^1\gamma^2)\psi_0$	$\frac{1}{2}$	$-\frac{i}{2}$	1	$\overset{03}{(-i)}\overset{12}{[+]}$ or $(-i)[+]$
4	2	$(\frac{1}{2})^2(1+\gamma^0\gamma^3)(\gamma^1-i\gamma^2)\psi_0$	$-\frac{1}{2}$	$\frac{i}{2}$	1	$\overset{03}{[+i]}\overset{12}{(-)}$ or $[+i](-)$
5	1	$(\frac{1}{2})^2(1+\gamma^0\gamma^3)(\gamma^1+i\gamma^2)\psi_0$	$\frac{1}{2}$	$\frac{i}{2}$	-1	$\overset{03}{[+i]}\overset{12}{(+)}$ or $[+i](+)$
5	2	$(\frac{1}{2})^2(\gamma^0+\gamma^3)(1-i\gamma^1\gamma^2)\psi_0$	$-\frac{1}{2}$	$-\frac{i}{2}$	-1	$\overset{03}{(-i)}\overset{12}{[-]}$ or $(-i)[-]$
6	1	$(\frac{1}{2})^2(\gamma^0+\gamma^3)(\gamma^1+i\gamma^2)\psi_0$	$\frac{1}{2}$	$-\frac{i}{2}$	1	$\overset{03}{(-i)}\overset{12}{(+)}$ or $(-i)(+)$
6	2	$(\frac{1}{2})^2(1+\gamma^0\gamma^3)(1-i\gamma^1\gamma^2)\psi_0$	$-\frac{1}{2}$	$\frac{i}{2}$	1	$\overset{03}{[+i]}\overset{12}{[-]}$ or $[+i][-]$
7	1	$(\frac{1}{2})^2(\gamma^0-\gamma^3)(1+i\gamma^1\gamma^2)\psi_0$	$\frac{1}{2}$	$\frac{i}{2}$	-1	$\overset{03}{(+i)}\overset{12}{[+]}$ or $(+i)[+]$
7	2	$(\frac{1}{2})^2(1-\gamma^0\gamma^3)(\gamma^1-i\gamma^2)\psi_0$	$-\frac{1}{2}$	$-\frac{i}{2}$	-1	$\overset{03}{[-i]}\overset{12}{(-)}$ or $[-i](-)$
8	1	$(\frac{1}{2})^2(1-\gamma^0\gamma^3)(1+i\gamma^1\gamma^2)\psi_0$	$\frac{1}{2}$	$-\frac{i}{2}$	1	$\overset{03}{[-i]}\overset{12}{[+]}$ or $[-i][+]$
8	2	$(\frac{1}{2})^2(\gamma^0-\gamma^3)(\gamma^1-i\gamma^2)\psi_0$	$-\frac{1}{2}$	$\frac{i}{2}$	1	$\overset{03}{(+i)}\overset{12}{(-)}$ or $(+i)(-)$

$$
\begin{aligned}
&(\tfrac{1}{2})^2(\gamma^0\pm\gamma^3)(\gamma^1\pm i\gamma^2), \quad (\tfrac{1}{2})^2(\gamma^0\pm\gamma^3)(1\pm i\gamma^1\gamma^2),\\
&(\tfrac{1}{2})^2(1\pm\gamma^0\gamma^3)(\gamma^1\pm i\gamma^2), \quad (\tfrac{1}{2})^2(1\pm\gamma^0\gamma^3)(1\pm i\gamma^1\gamma^2).
\end{aligned}
\tag{60}
$$

According to Theorem 1, the eigenvalues of the Cartan operator S^{12} for four times four basic states of Eq. (60) are $\pm\frac{1}{2}$ for the $\pm$ sign in the second factor of the states and the eigenvalues of the Cartan operator S^{03} for the four times four basic states are $\mp i/2$ for the $\pm$ sign in the first factor of the states. All 16 basic states are orthonormal.

We arrange these 16 states into four ''families'' as presented in Sec. IV. Each ''family'' includes two Weyl spinors, one left and one right handed. We come from one Weyl spinor, say left, to another, say right, by applying γ^a's to the left one. These four ''families'' are presented in Table II.

Using expressions for basis states from Table II and the orthogonality properties of states we can easily evaluate matrix elements of, say, S^{01}. The second matrix element of the first row for $S^{01}(=(i/2)\,\gamma^0\gamma^1)$, for example, is

$$\left\langle \psi_0 \left| \left(\left(\frac{1}{2}\right)^2 (1-\gamma^0\gamma^3)(1-i\gamma^1\gamma^2) \right)^\dagger S^{01} \left(\frac{1}{2}\right)^2 (\gamma^0-\gamma^3)(\gamma^1+i\gamma^2)\psi_0 \right\rangle \right. \tag{61}$$

$$= -\frac{i}{2} \left\langle \psi_0 \left| \left(\left(\frac{1}{2}\right)^2 (1-\gamma^0\gamma^3)(1-i\gamma^1\gamma^2) \right)^\dagger \left(\frac{1}{2}\right)^2 \gamma^0(\gamma^0-\gamma^3)\gamma^1(\gamma^1+i\gamma^2)\psi_0 \right\rangle \right. = \frac{i}{2}. \tag{62}$$

We present below the matrix representations for the generators of the Lorentz algebra and of the γ^a's for the first family (and the second family):

$$S^{0i}=\frac{i}{2}\begin{pmatrix} \sigma_i & 0 \\ 0 & -\sigma_i \end{pmatrix}, \quad S^{ij}=\sum_k \varepsilon_{ijk}\frac{1}{2}\begin{pmatrix} \sigma_k & 0 \\ 0 & \sigma_k \end{pmatrix}, \quad i\in\{1,2,3\},$$
$$\gamma^o=\begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix} \quad \gamma^i=\begin{pmatrix} 0 & -\sigma_i \\ \sigma_i & 0 \end{pmatrix}, \quad i\in\{1,2,3\}. \tag{63}$$

The above representation is known as the chiral representation for the Lorentz group.

[The matrix representations for the third and the fourth ''families'' differ with respect to Eq. (63) in an overall sign for γ^i, $i=1,2,3$, and accordingly also for S^{0i} but not for S^{ij}.]

Any of the four ''families'' can be used to present the solution of the Dirac equation for a massive spinor, while the massless spinors are either left- or right-handed, so that only half of the space of the massive case is needed to find the solution. We shall present solutions of the Dirac equation for a massless or a massive case in the next section.

IX. SOLUTIONS OF WEYL AND DIRAC EQUATIONS FOR THE THREE- AND FOUR-DIMENSIONAL CASES

We shall demonstrate the usefulness of the presented technique by finding solutions of the Dirac equation for massless and massive cases in three- and four-dimensional spaces with one time ($\eta^{00}=1$) and $(d-1)$ space (η^{ii}, $i=1,..,d-1$) dimensions. We shall work, as one usually does, with only one family, making a choice of the first one in each of the two tables. Looking for solutions of the Dirac equation one proceeds as usual when solving the eigenvalue problem: one makes a superposition of basic states of one ''family'' with unknown coefficients solving the eigenvalue problem for the Dirac equation of the motion operator with the eigenvalue zero, either by taking into account equations from Sec. VI, or by just operating from the left on this superposition by the operator of the Dirac equation and taking into account the Clifford algebra properties of γ^a's.

A. Solution of the Dirac equation for spinors in $d=3$

To find the solution of the Dirac equation (using units in which $c=1=\overline{h}$)

$$(\gamma^a p_a - m=0)\,\psi, \tag{64}$$

we shall use the basic states presented in Table I as the first ''family'' of two basic vectors and find what γ^a does when operating on a linear superposition of basic states. Looking for the solution as a plane wave with a wave vector $p^a=(p^0,p^1,p^2)$ we find that the state

$$\psi=e^{-ip^a x_a}\mathcal{N}\left(\frac{1}{2}\right)^2(1+\Gamma)\left\{(\gamma^1+i\gamma^2)+\frac{p^1+ip^2}{p^0+m}(1-i\gamma^1\gamma^2)\right\}\psi_0, \tag{65}$$

or graphically

$$\psi = e^{-ip^a x_a} \mathcal{N} \left\{ \overset{+}{\circlearrowright}\overset{12}{(+)} + \frac{p^1 + ip^2}{p^0 + m} \overset{+}{\circlearrowright}\overset{12}{[-]} \right\} \psi_0 , \tag{66}$$

solves the Dirac equation for a massive case with $\mathcal{N} = \sqrt{(p^0+m)/(2p^0)}$ and $(p^0)^2 = (p^1)^2 + (p^2)^2 + m^2$. For the massless case we need only to set m equal to zero. Then the normalization factor $\mathcal{N}$ simplifies to $1/\sqrt{2}$. The first state appears with the weight 1 and the second with the weight $(p^1 + ip^2)/p^0$. It is evident that both solutions—for the massless and the massive case—are linear combinations of exactly the same number of basic states.

B. Solution of the Dirac equation for spinors in $d=4$

We shall first look for one of the two solutions of the massless Weyl equation

$$(\gamma^a p_a = 0)|\psi\rangle . \tag{67}$$

Using the first irreducible representation of only left handedness from Table II, we find

$$\psi = e^{-ip^a x_a} \mathcal{N} \left\{ \left(\frac{1}{2}\right)^2 (\gamma^0 - \gamma^3)(\gamma^1 + i\gamma^2) + \frac{p^1 + ip^2}{p^0 + p^3} \left(\frac{1}{2}\right)^2 (1 - \gamma^0\gamma^3)(1 - i\gamma^1\gamma^2) \right\} \psi_0 , \tag{68}$$

or graphically

$$\psi = e^{-ip^a x_a} \mathcal{N} \left\{ \overset{03}{(+i)}\overset{12}{(+)} + \frac{p^1 + ip^2}{p^0 + p^3} \overset{03}{[-i]}\overset{12}{[-]} \right\} \psi_0 , \tag{69}$$

with $\mathcal{N} = \sqrt{(p^0+p^3)/(2p^0)}$ and $(p^0)^2 = (p^1)^2 + (p^2)^2 + (p^3)^2$.

A massive case

$$(\gamma^a p_a - m = 0)|\psi\rangle \tag{70}$$

can only be solved within left and right handed irreducible representations. We find

$$\begin{aligned} \psi = e^{-ip^a x_a} \mathcal{N} \{ & (p^0 + p^3)(\tfrac{1}{2})^2 (\gamma^0 - \gamma^3)(\gamma^1 + i\gamma^2) + (p^1 + ip^2)(\tfrac{1}{2})^2 (1 - \gamma^0\gamma^3)(1 - i\gamma^1\gamma^2) \\ & + m(\tfrac{1}{2})^2 (1 - \gamma^0\gamma^3)(\gamma^1 + i\gamma^2) \} \psi_0 , \end{aligned} \tag{71}$$

or graphically

$$\psi = e^{-ip^a x_a} \mathcal{N} \{ (p^0 + p^3) \overset{03}{(+i)}\overset{12}{(+)} + (p^1 + ip^2) \overset{03}{[-i]}\overset{12}{[-]} + m \overset{03}{[-i]}\overset{12}{(+)} \} \psi_0 , \tag{72}$$

with $\mathcal{N} = 1/\sqrt{(p^0+p^3)(2p^0)}$ and $(p^0)^2 = (p^1)^2 + (p^2)^2 + (p^3)^2 + m^2$.

X. CONCLUSION

In this article we demonstrated a simple technique for finding the representations of the Lorentz group (Weyl spinors) and for Clifford algebra (Dirac spinors) for spinors for any-dimensional space, even or odd, of any signature, solely started from the abstract objects γ^a for which we only needed to know that they fulfill the Clifford algebra: $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}$. We first constructed the basis for the whole Clifford algebra made out, of course, of formal Clifford objects—Clifford algebra elements, each basis vector being a products of two types of objects: nilpotent ones and idempotent ones.

Introducing the ''Hermitian conjugation'' in the space of the Clifford algebra as a formal antiautomorphism specified by the signature $\gamma^{a\dagger} = \eta^{aa}\gamma^a$, we were able to define an inner product.

Introducing the vacuum state, which turned out to be (almost) generic, we were able to map the basis for abstract Clifford objects into the spinor basis forming the Hilbert space and accordingly the abstract Clifford objects into operators.

We further derived a simple and transparent graphic technique, which enables us to easily find matrix elements of all the Clifford operators in our basis—γ^a matrices and generators of the Lorentz transformations S^{ab} in particular.

By formally playing the game, that all 2^d linear independent polynomials of γ^a's, if applied to appropriately chosen "vacuum state," generate 2^d orthogonal states, we get $2^{d/2}$ "families" of twice $2^{d/2-1}$ Weyl spinors for d even and $2^{(d+1)/2}$ families of $2^{(d-1)/2}$ Weyl spinors for d odd. If a "vacuum state" contains the space of only one Dirac spinors, all the polynomials, applied to such a state, generate of course only one Dirac spinor, that is only one "family."

Taking advantage of the fact that the generators of the Lorentz group are binomials of the γ^a operators enables us to find eigenstates of any operator (say the Weyl or the Dirac operator), as well as the application of any operator to a given state, without making a choice of the representation of the operators γ^a.

Except for the orthonormalization procedure, this technique follows Refs. 4–7, 11, 12.

We also present a transparent graphic representation of basic states, as well as the application of operators to these states.

(Received 9 January 2002; accepted 7 July 2002)

We extend the Campbell–Magaard embedding theorem by proving that any n-dimensional semi-Riemannian manifold can be locally embedded in an $(n+1)$-dimensional Einstein space. We work out some examples of application of the theorem and discuss its relevance in the context of modern higher-dimensional spacetime theories. © *2002 American Institute of Physics.*

I. INTRODUCTION

The old idea that our universe is fundamentally higher-dimensional with $n=4+d$ space–time dimensions seems to be gaining grounds very rapidly in recent years. Mathematical schemes by which our ordinary space–time is viewed as a hypersurface embedded in a higher dimensional space have been considered in several different contexts, such as strings,[1] D-branes,[2] Randall-Sundrum[3] models and noncompactified versions of Kaluza–Klein theories.[4]

On the other hand, local isometric embeddings of Riemannian manifolds have long been studied in differential geometry. Of particular interest is a well known theorem which states that if the embedding space is flat, then the minimum number of extra dimensions needed to analytically embed a n-dimensional Riemannian manifold is d, with $0 \leqslant d \leqslant n(n-1)/2$.[5]

It turns out, however, that if the embedding space is allowed to be Ricci-flat, then the minimum number of extra dimensions that are necessary for the embedding falls dramatically to $d=1$. This is the content of a little known but powerful theorem due to Campbell,[6] the proof of which was given by Magaard.[7] Campbell–Magaard's result has acquired fundamental relevance for granting the mathematical consistency of five-dimensional embedding theories and also has been applied to investigate how lower-dimensional theories could be related to $(3+1)$-dimensional vacuum Einstein gravity.[8]

The increasing attention given to the Randall–Sundrum model[3] in which the embedding space, i.e., the bulk, corresponds to an Einstein space, rather than a Ricci-flat one, has led us to wonder whether Campbell–Magaard theorem could be generalized and what sort of generalization could be done. Research in this direction, where a scheme for extending Campbell–Magaard theorem for embedding spaces with a non-null Ricci tensor has been put forward quite recently by Anderson and Lidsey.[9]

The purpose of the present article is to prove that Campbell–Magaard theorem can, indeed, be extended to include Einstein spaces. Our proof is entirely inspired by Magaard's reasoning, although some adaptations to the more general semi-Riemannian character of the spaces had to be made.

The article is organized as follows. Section II is devoted to stating and proving an extension of Campbell–Magaard theorem, in which the embedding manifold is an Einstein space. The proof is rather involved and resorts to auxiliary theorems and lemmas. In Sec. III we apply the general result to some examples and, finally, Sec. 4 contains our conclusion.

II. ISOMETRIC EMBEDDING IN AN EINSTEIN SPACE

The Campbell–Magaard theorem for local isometric embedding in Ricci-flat space refers to Riemannian manifolds, i.e., those endowed with positive-definite metrics. It turns out that for our purposes of generalization this restrictive condition is not essential, so in what follows we shall consider a semi-Riemannian manifold with metrics of indefinite signature instead. First let us introduce some definitions, set the notation and present preliminary theorems and lemmas.

An n-dimensional manifold M^n is termed semi-Riemannian if it is endowed with a metric, i.e., a symmetric and nondegenerated second-rank tensor field of arbitrary signature. (In this article we are considering only manifolds and metrics which are analytic.)

Definition 1: Consider a differential map Φ: $U\subset M^n\rightarrow N^{n+k}$, *where* U *is an open subset of* M^n, *and* N^{n+k} $(k\geqslant 0)$ *is a manifold of dimension* $n+k$. *Then* Φ *is called a local isometric embedding if the following conditions hold:*

(i) $d\Phi_p: T_pM^n\rightarrow T_{\Phi(p)}N^{n+k}$ *is injective for all* $p\in U$.
(ii) $g_p(v,w)=\tilde{g}_{\Phi(p)}(d\Phi(v),d\Phi(w))$ *for all* v, $w\in T_pM^n$, *where* $\tilde{g}$ *denotes the metric of* N^{n+k}.
(iii) Φ *is a homeomorphism onto its image in the induced topology.*

If Φ is of class C^k (*analytic*), then the embedding is said to be of class C^k (*analytic*). Naturally, a local isometric embedding may be characterized in terms of coordinates. For instance, let $\mathbf{x}=\{x^1,\ldots,x^n\}$ and $\mathbf{y}=\{y^1,\ldots,y^{n+k}\}$ denote coordinate patches for $U\subset M^n$ and $V\subset N^{n+k}$, respectively, with $\Phi(p)\in V$. The embedding Φ determines a relation between the coordinates denoted by

$$y^\alpha=\sigma^\alpha(x^1,\ldots,x^n), \tag{1}$$

where $\sigma=\mathbf{y}\circ\Phi\circ\mathbf{x}^{-1}:\mathbf{x}(U)\subset\mathbb{R}^n\rightarrow\mathbb{R}^{n+k}$. (Throughout Latin and Greek indices will run from 1 to n and 1 to $n+k$, respectively.)

In this way the isometric condition leads to

$$g_{ij}=\frac{\partial\sigma^\alpha}{\partial x^i}\frac{\partial\sigma^\beta}{\partial x^j}\tilde{g}_{\alpha\beta}, \tag{2}$$

where the functions g_{ij} and $\tilde{g}_{\alpha\beta}$ are the components of metric with respect to the coordinate bases $\{\partial_{x^i}\}$ and $\{\partial_{y^\alpha}\}$, respectively. We, therefore, say that M^n can be local and isometrically embedded in N^{n+k} if there exist $n+k$ differentiable functions $y^\alpha=\sigma^\alpha(x^1,\ldots,x^n)$, (embedding functions) such that the Jacobian matrix $\partial\sigma^\alpha/\partial x^i$ has rank n and (2) holds.

Given two arbitrary semi-Riemannian manifolds M^n and N^{n+k} it may happen that there exists no isometric embedding between them. Thus, it is of interest to find out conditions assuring or not the existence of embedding, in particular, if the embedding space N^{n+k} is not specified except that its belongs to a collection of manifolds, $\mathcal{M}_\pi$, whose members, say, share a certain geometrical property. For example, π may express a restriction of the following kinds: to be flat, to have constant curvature, to be Ricci-flat, to be an Einstein space, and so forth. This way of formulating the problem motivates the definition below.

Definition 2: We say that a semi-Riemannian manifold M^n *has an embedding in the set* $\mathcal{M}_\pi$, *if there is at least a member of* $\mathcal{M}_\pi$, *say* N^{n+k}, *in which* M^n *is embeddable.*

The following is a theorem which establishes necessary and sufficient conditions for the existence of local isometric embedding of an n-dimensional semi-Riemannian space (M^n,g) in the set $\mathcal{M}_\pi^{n+1}$ of $(n+1)$-dimensional semi-Riemannian spaces $(N^{n+1},\tilde{g})$ that satisfy the (nonspecified) property π. The original version of this theorem is due to Magaard[7] and is restricted to the Riemannian case, though the extension to semi-Riemannian manifold is straightforward.

Theorem 1: *Let* (M^n,g) *constitute a semi-Riemannian manifold,* $\mathcal{M}_\pi^{n+1}=\{(N^{n+1},\tilde{g})$, *which satisfy the property* $\pi\}$ *and* $\mathbf{x}=\{x^1,\ldots,x^n\}$ *a coordinate system covering a neighborhood* U *of* $p\in M^n$. *A necessary and sufficient condition for a local analytical embedding of* M^n *at* p, *with line element*

$$ds^2 = g_{ik}dx^i dx^k, \tag{3}$$

in $\mathcal{M}_\pi^{n+1}$ *is the following.*

(i) There exist analytic functions,

$$\overline{g}_{ik} = \overline{g}_{ik}(x^1,\ldots,x^n,x^{n+1}), \tag{4}$$

$$\overline{\phi} = \overline{\phi}(x^1,\ldots,x^n,x^{n+1}), \tag{5}$$

defined in some open set $D \subset \mathbf{x}(U)\times\mathbb{R}$ *containing the point* $(x_p^1,\ldots,x_p^n,0)$ *and satisfying the conditions*

$$\overline{g}_{ik}(x^1,\ldots,x^n,0) = g_{ik}(x^1,\ldots,x^n) \tag{6}$$

in an open set $A \subset \mathbf{x}(U)$;

$$\overline{g}_{ik} = \overline{g}_{ki}, \tag{7}$$

$$|\overline{g}_{ik}| \neq 0, \tag{8}$$

$$\overline{\phi} \neq 0 \tag{9}$$

in D. ($|\overline{g}_{ik}|$ *denotes the determinant of* $\overline{g}_{ik}$).

(ii) Also,

$$ds^2 = \overline{g}_{ik}dx^i dx^k + \varepsilon\,\overline{\phi}^2 dx^{n+1}dx^{n+1}, \tag{10}$$

where $\varepsilon^2 = +1$, *be a line element in a certain coordinate neighborhood V of some manifold* $N^{n+1} \in \mathcal{M}_\pi^{n+1}$.

The essential idea of this theorem is that there exists a coordinate system ''adapted'' to the embedding in such a manner that the image of the embedding coincide with the hypersurface $x^{n+1}=0$ of the embedding space and the condition of isometry reduces to (6).

While the sufficient condition is easily demonstrated, the proof of the necessary condition of this theorem is very long and will be omitted.[7,10]

We now consider an $(n+1)$-dimensional semi-Riemannian manifold $(N^{n+1},\tilde{g})$ and $\{y^1,\ldots,y^{n+1}\}$ a coordinate system defined in an open set of $V \subset N^{n+1}$. Let $\tilde{g}_{\alpha\beta}$ and $\tilde{R}_{\alpha\beta}$ denote the components of the metric and Ricci tensor, respectively. The manifold $(N^{n+1},\tilde{g})$ is called an Einstein space if

$$\tilde{R}_{\alpha\beta} = \frac{2\Lambda}{1-n}\tilde{g}_{\alpha\beta}, \tag{11}$$

where $n \geqslant 2$ and Λ is a constant. Of course (11) is equivalent to $\tilde{G}_{\alpha\beta} = \Lambda\tilde{g}_{\alpha\beta}$, $\tilde{G}_{\alpha\beta}$ being the components of the Einstein tensor, and for this reason Λ will be occasionally referred to as the cosmological constant.

As is well known, at each point of an arbitrary semi-Riemannian space N^{n+1} there exists a coordinate neighborhood in which the metric has the form

$$ds^2 = \overline{g}_{ik}dy^i dy^k + \varepsilon\,\overline{\phi}^2 (dy^{n+1})^2. \tag{12}$$

Let us now consider the inclusion map $\iota(y^1,\ldots,y^n) = (y^1,\ldots,y^n,0)$. This map determines an embedding of the hypersurface Σ_0, defined by $y^{n+1}=0$, in N^{n+1}. This hypersurface endowed with the induced metric by the inclusion map, which is given by

$$g_{ik}(y^1,\ldots,y^n)=\frac{\partial \iota^\alpha}{\partial y^i}\frac{\partial \iota^\beta}{\partial y^k}\tilde{g}_{\alpha\beta}=\overline{g}_{ik}(y^1,\ldots,y^n,0), \tag{13}$$

constitutes a semi-Riemannian space. The intrinsic curvature of Σ_0 and the curvature of N^{n+1} calculated at Σ_0 are related by the Gauss–Codazzi equations. In the coordinates (12), the Gauss–Codazzi relations can be written in the form[5]

$$R_{mkij}=\tilde{R}_{mkij}+\varepsilon(\Omega_{ik}\Omega_{jm}-\Omega_{jk}\Omega_{im}), \tag{14}$$

$$\nabla_j\Omega_{ik}-\nabla_i\Omega_{jk}=\frac{1}{\phi}\tilde{R}_{(n+1)kij}, \tag{15}$$

where R_{mkij} and $\tilde{R}_{mkij}$ ($R^l_{kij}=\Gamma^l_{ik,j}-\Gamma^l_{jk,i}+\Gamma^l_{jm}\Gamma^m_{ik}-\Gamma^l_{im}\Gamma^m_{jk}$) are the components of the curvature tensor of Σ_0 and of N^{n+1}, respectively, ∇_i denoting the covariant derivative with respect to the metric g_{ik}, and Ω_{ik} (the covariant components of the extrinsic curvature tensor of Σ_0) are given by

$$\Omega_{ik}=-\frac{1}{2\overline{\phi}}\frac{\partial \overline{g}_{ik}}{\partial y^{n+1}}, \tag{16}$$

in the coordinates (12). We are now interested in obtaining the components of the Ricci tensor $R_{\alpha\beta}=g^{\delta\gamma}R_{\delta\alpha\gamma\beta}$ in the coordinates (12). With the help of the Gauss–Codazzi equations and from the expression

$$\tilde{R}^{(n+1)}_{i(n+1)k}=\left(-\frac{\varepsilon}{\phi}\frac{\partial\Omega_{ik}}{\partial y^{n+1}}+\frac{1}{\phi}\nabla_i\nabla_k\phi-\varepsilon g^{jm}\Omega_{jk}\Omega_{im}\right),$$

which can be obtained by a straightforward calculation, we are left with

$$\tilde{R}_{ik}=R_{ik}+\varepsilon g^{jm}(\Omega_{ik}\Omega_{jm}-2\Omega_{jk}\Omega_{im})-\frac{\varepsilon}{\phi}\frac{\partial\Omega_{ik}}{\partial y^{n+1}}+\frac{1}{\phi}\nabla_i\nabla_k\phi, \tag{17}$$

$$\tilde{R}_{i(n+1)}=\phi g^{jk}(\nabla_j\Omega_{ik}-\nabla_i\Omega_{jk}), \tag{18}$$

$$\tilde{R}_{(n+1)(n+1)}=\varepsilon\phi^2 g^{ik}\left(-\frac{\varepsilon}{\phi}\frac{\partial\Omega_{ik}}{\partial y^{n+1}}+\frac{1}{\phi}\nabla_i\nabla_k\phi-\varepsilon g^{jm}\Omega_{jk}\Omega_{im}\right). \tag{19}$$

At this stage, it should be clear that the results just obtained may be carried over to any hypersurface Σ_c defined by $y^{n+1}=c=\text{const}$. Owing to this we shall henceforth introduce a slightly different notation: the metric induced on any Σ_c, i.e., $\overline{g}_{ik}(y^1,\ldots,y^n,c)$, will be denoted simply by $\overline{g}_{ik}$; likewise all quantities associated with $\overline{g}_{ik}$ will be marked with a bar sign. However, for convenience, only the metric induced on Σ_0 may also be denoted by g_{ik} (without the bar).

Now let us turn our attention to the case when the embedding manifold N^{n+1} is an Einstein space. Since we can assume that any point $q\in N^{n+1}$ lies in some hypersurface Σ_c, we can use the equations above for decomposing the Ricci tensor of the embedding manifold in terms of its intrinsic and extrinsic parts with respect to any hypersurface Σ_c, with $c=y^{n+1}_q$. If N^{n+1} is an Einstein space, then it follows from (10) that

$$\tilde{R}_{ik}=\overline{R}_{ik}+\varepsilon\overline{g}^{jm}(\overline{\Omega}_{ik}\overline{\Omega}_{jm}-2\overline{\Omega}_{jk}\overline{\Omega}_{im})-\frac{\varepsilon}{\overline{\phi}}\frac{\partial\overline{\Omega}_{ik}}{\partial y^{n+1}}+\frac{1}{\overline{\phi}}\overline{\nabla}_i\overline{\nabla}_k\overline{\phi}=\frac{2\Lambda}{1-n}\overline{g}_{ik}, \tag{20}$$

$$\tilde{R}_{i(n+1)}=\overline{\phi}\overline{g}^{jk}(\overline{\nabla}_j\overline{\Omega}_{ik}-\overline{\nabla}_i\overline{\Omega}_{jk})=0, \tag{21}$$

$$\tilde{G}^{(n+1)}_{(n+1)} = -\tfrac{1}{2}\overline{g}^{ik}\overline{g}^{jm}(\overline{R}_{ijkm} + \varepsilon(\overline{\Omega}_{ik}\overline{\Omega}_{jm} - \overline{\Omega}_{jk}\overline{\Omega}_{im})) = \Lambda, \tag{22}$$

where in the last equation, from the definition of the Einstein tensor, $\tilde{G}^{(n+1)}_{(n+1)} = \tilde{R}^{(n+1)}_{(n+1)} - 1/2\tilde{R}$, $\tilde{R}$ being the curvature scalar $\tilde{R} = \tilde{g}^{\alpha\beta}\tilde{R}_{\alpha\beta}$.

After writing the equations above let us concentrate on the problem of embedding a semi-Riemannian manifold in an Einstein space. The equations (20)–(22) may be looked upon as a set of partial differential equations for $\overline{g}_{ik}$ and $\overline{\phi}$. At this point, our strategy is to show that if the components $g_{ik}(x^1,\ldots,x^n)$ of a metric of M^n with respect to some coordinate system are given, then there exists an open set of $\mathbb{R}^{n+1}$ where the above-mentioned equations admit a solution $\overline{g}_{ik}(y^1,\ldots,y^n,y^{n+1})$ and $\overline{\phi}(y^1,\ldots,y^n,y^{n+1})$, which satisfies the initial condition $\overline{g}_{ik} = g_{ik}$ at Σ_0. Moreover, it will be shown that the functions $\overline{g}_{ik}$ and $\overline{\phi}$ possess all properties which are necessary to constitute a line element of an $(n+1)$-dimensional semi-Riemannian manifold. Then, as $\overline{g}_{ik}$ and $\overline{\phi}$ satisfy Eqs. (20)–(22), the metric originated by them represents that of an Einstein space. Then, by virtue of Theorem 1, the existence of the embedding will be guaranteed. However, before proceeding to the final demonstration we shall make use of two lemmas. Let us consider the first one.

Lemma 1: Let the functions $\overline{g}_{ik}$ and $\overline{\phi}$ be analytic at $(0,\ldots,0) \in \Sigma_0 \subset \mathbb{R}^{n+1}$ and satisfy the conditions (7)–(9), and the equation (20) in an open set of $\mathbb{R}^{n+1}$ which contains $(0,\ldots,0,0) \in \mathbb{R}^{n+1}$. If, in addition, $\overline{g}_{ik}$ and $\overline{\phi}$ satisfy (21) and (22) at Σ_0, then $\overline{g}_{ik}e\overline{\phi}$ also satisfy (21) and (22) in some open set of $\mathbb{R}^{n+1}$ containing $(0,\ldots, 0, 0)$.

Proof: By assumption $\overline{g}_{ik}$ and $\overline{\phi}$ satisfy (7)–(9), hence the functions $\tilde{g}_{\alpha\beta}$ defined by $\tilde{g}_{ik} = \overline{g}_{ik}$, $\tilde{g}_{n+1n+1} = \overline{\phi}^2$ and $\tilde{g}_{in+1} = 0$ for $i, k = 1,\ldots,n$, may be considered as the components of an $(n+1)$-dimensional metric tensor $\tilde{g}$. The coefficients of the connection and the components of the curvature tensor associated to the metric $\tilde{g}_{\alpha\beta}$ can be calculated as usual. Let us now define the tensor $\tilde{F}_{\alpha\beta} = \tilde{G}_{\alpha\beta} - \Lambda\tilde{g}_{\alpha\beta}$, where $\tilde{G}_{\alpha\beta}$ is the Einstein tensor. Then, as a consequence of Bianchi identities for the curvature tensor, it follows that $\tilde{F}_{\alpha\beta}$ is divergenceless, i.e.,

$$\tilde{\nabla}_\alpha \tilde{F}^\alpha_\beta = 0. \tag{23}$$

This equation can be rewritten as

$$\frac{\partial \tilde{F}^{n+1}_\beta}{\partial y^{n+1}} = -\frac{\partial \tilde{F}^i_\beta}{\partial y^i} - \tilde{\Gamma}^\mu_{\mu\lambda}\tilde{F}^\lambda_\beta + \tilde{\Gamma}^\mu_{\lambda\beta}\tilde{F}^\lambda_\mu. \tag{24}$$

We have assumed that $\overline{g}_{ik}$ and $\overline{\phi}$ satisfy the equations (20)–(22) at Σ_0, hence $\tilde{F}^\alpha_\beta = 0$ at Σ_0. Moreover, $\partial\tilde{F}^i_\beta/\partial y^i\big|_{y^{n+1}=0} = (\partial/\partial y^i)(\tilde{F}^i_\beta\big|_{y^{n+1}=0}) = 0$. Therefore, we conclude from (24) that

$$\left.\frac{\partial \tilde{F}^{n+1}_\beta}{\partial y^{n+1}}\right|_{y^{n+1}=0} = 0. \tag{25}$$

Let us look into Eq. (24) separately for $\beta = n+1$ and $\beta = i$. Taking first $\beta = n+1$ gives

$$\frac{\partial \tilde{F}^{n+1}_{n+1}}{\partial y^{n+1}} = -\frac{\partial \tilde{F}^i_{n+1}}{\partial y^i} - \tilde{\Gamma}^\mu_{\mu\lambda}\tilde{F}^\lambda_{n+1} + \tilde{\Gamma}^{n+1}_{\lambda n+1}\tilde{F}^\lambda_{n+1} + \tilde{\Gamma}^i_{n+1n+1}\tilde{F}^{n+1}_i + \tilde{\Gamma}^i_{kn+1}\tilde{F}^k_i. \tag{26}$$

From the definition of the Einstein tensor we can write $\tilde{G}^i_j = \tilde{R}^i_j - \delta^i_j(\tilde{R}^k_k + \tilde{G}^{n+1}_{n+1})$. By assumption, $\tilde{R}_{ij} = [2\Lambda/(1-n)]\overline{g}_{ij}$ not only at the hypersurface $y^{n+1} = 0$, but also for some open set $V \subset \mathbb{R}^{n+1}$, with $0 \in U$. Thus, the equality $\tilde{F}^k_i = -\delta^k_i\tilde{F}^{n+1}_{n+1}$ holds in V. This implies that

$$\frac{\partial \tilde{F}^{n+1}_{n+1}}{\partial y^{n+1}} = -\frac{\partial \tilde{F}^{i}_{n+1}}{\partial y^{i}} - \tilde{\Gamma}^{\mu}_{\mu\lambda}\tilde{F}^{\lambda}_{n+1} + \tilde{\Gamma}^{n+1}_{\lambda n+1}\tilde{F}^{\lambda}_{n+1} + \tilde{\Gamma}^{i}_{n+1n+1}\tilde{F}^{n+1}_{i} - \tilde{\Gamma}^{i}_{in+1}\tilde{F}^{n+1}_{n+1}. \tag{27}$$

In terms of the components of $\tilde{F}^{n+1}_{n+1}$ and $\tilde{F}^{n+1}_{i}$ the equation above may be written as

$$\frac{\partial \tilde{F}^{n+1}_{n+1}}{\partial y^{n+1}} = -\varepsilon\,\overline{\phi}^{2}\overline{g}^{ij}\frac{\partial \tilde{F}^{n+1}_{i}}{\partial y^{j}} - 2\tilde{\Gamma}^{i}_{in+1}\tilde{F}^{n+1}_{n+1} + \left(-\varepsilon\,\frac{\partial(\overline{\phi}^{2}\overline{g}^{ij})}{\partial y^{j}} - \varepsilon\,\overline{\phi}^{2}\overline{g}^{ij}\tilde{\Gamma}^{k}_{kj} + \tilde{\Gamma}^{i}_{n+1n+1}\right)\tilde{F}^{n+1}_{i}. \tag{28}$$

Analogously for $\beta = i$ we obtain

$$\frac{\partial \tilde{F}^{n+1}_{i}}{\partial y^{n+1}} = \frac{\partial \tilde{F}^{n+1}_{n+1}}{\partial y^{i}} + 2\tilde{\Gamma}^{n+1}_{n+1i}\tilde{F}^{n+1}_{n+1} + (\tilde{\Gamma}^{k}_{n+1i} + \varepsilon\,\overline{\phi}^{2}\overline{g}^{kj}\tilde{\Gamma}^{n+1}_{ij} - \tilde{\Gamma}^{\mu}_{n+1\mu}\delta^{k}_{i})\tilde{F}^{n+1}_{k}. \tag{29}$$

By taking into account (28) and (29) it can be easily shown by mathematical induction that

$$\left.\frac{\partial^{r}\tilde{F}^{n+1}_{\beta}}{\partial (y^{n+1})^{r}}\right|_{y^{n+1}=0} = 0 \tag{30}$$

for any integer $r \geqslant 0$. As a consequence we conclude that $\tilde{F}^{n+1}_{\beta} = 0$ in a neighborhood of the origin. Indeed, as $\overline{g}_{ik}$ and $\overline{\phi}$ are analytic at $0 \in \mathbb{R}^{n+1}$, then there exists such a neighborhood in which $\tilde{F}^{n+1}_{\beta}$ can be expressed as a Taylor series about $0 \in \mathbb{R}^{n+1}$, with each term of this series being null. Since the equation $\tilde{F}^{n+1}_{\beta} = 0$ is equivalent to the equations (21) and (22), then the lemma is proved.

A. The Cauchy–Kowalewski theorem and the existence of the embedding

Although essential to the main result to be presented later, Lemma 1 says nothing about the existence of the solutions $\overline{g}_{ik}$ and $\overline{\phi}$. Thus we have to resort to the following theorem.

Theorem (Cauchy-Kowalewski): *Let us consider the set of partial differential equations:*

$$\frac{\partial^{2}u^{A}}{\partial (y^{n+1})^{2}} = F^{A}\left(y^{\alpha}, u^{B}, \frac{\partial u^{B}}{\partial y^{\alpha}}, \frac{\partial^{2}u^{B}}{\partial y^{\alpha}\partial y^{i}}, \right), \quad A = 1,...,m, \tag{31}$$

where $u^{1},\ldots,u^{m}$ *are* m *unknown functions of the* $n+1$ *variables* $y^{1},\ldots,y^{n},y^{n+1}$, $\alpha = 1,...,n+1$, $i = 1,...,n$, $B = 1,...,m$. *Also, let* $\xi^{1},\ldots,\xi^{m}$, $\eta^{1},\ldots,\eta^{m}$, *functions of the variables* $y^{1},\ldots,y^{n}$, *be analytic at* $0 \in \mathbb{R}^{n}$. *If the functions* F^{A} *are analytic with respect to each of their arguments around the values evaluated at the point* $y^{1} = \cdots = y^{n} = 0$, *then there exists a unique solution of Eqs.* (31) *which is analytic at* $0 \in \mathbb{R}^{n+1}$ *and that satisfies the initial condition*

$$u^{A}(y^{1},\ldots,y^{n},0) = \xi^{A}(y^{1},\ldots,y^{n}), \tag{32}$$

$$\frac{\partial u^{A}}{\partial y^{n+1}}(y^{1},\ldots,y^{n},0) = \eta^{A}(y^{1},\ldots,y^{n}), \quad A = 1,...,m. \tag{33}$$

By using (16), we can rewrite (20) as

$$\frac{\partial^{2}\overline{g}_{ik}}{\partial (y^{n+1})^{2}} = \varepsilon\,\frac{4\Lambda}{1-n}\,\overline{\phi}^{2}\overline{g}_{ik} + \frac{1}{\overline{\phi}}\frac{\partial \overline{\phi}}{\partial y^{n+1}}\frac{\partial \overline{g}_{ik}}{\partial y^{n+1}} - \frac{1}{2}\overline{g}^{jm}\left(\frac{\partial \overline{g}_{ik}}{\partial y^{n+1}}\frac{\partial \overline{g}_{jm}}{\partial y^{n+1}} - 2\,\frac{\partial \overline{g}_{im}}{\partial y^{n+1}}\frac{\partial \overline{g}_{jk}}{\partial y^{n+1}}\right)$$

$$-2\varepsilon\,\overline{\phi}\left(\frac{\partial^{2}\overline{\phi}}{\partial y^{i}\partial y^{k}} - \frac{\partial \overline{\phi}}{\partial y^{j}}\overline{\Gamma}^{j}_{ik}\right) - 2\varepsilon\,\overline{\phi}^{2}\overline{R}_{ik}. \tag{34}$$

Owing to the symmetry condition $\overline{g}_{ik}=\overline{g}_{ki}$, we can express Eq. (34) in terms of the functions $\overline{g}_{ik}$ with $i\leqslant k$. If $\overline{\phi}$ is regarded as a known function, then (34) becomes a set of partial differential equations for the $m=n(n+1)/2$ unknown function $\overline{g}_{ik}(i\leqslant k)$. This set of equations has the same form as (31). We also note that the right-hand side of (34) consists of rational functions of the coordinates y, the functions $\overline{g}_{ik}(i\leqslant k)$ and their derivatives (up to first order with respect to y^{n+1} and up to second order relative to the other coordinates). Therefore, if we take $\overline{\phi}\neq 0$ analytic at $0\in\mathbb{R}^{n+1}$ and if the initial conditions

$$\underset{i\leqslant k}{\overline{g}_{ik}}(y^1,\ldots,y^n,0)=\underset{i\leqslant k}{g_{ik}}(y^1,\ldots,y^n), \tag{35}$$

$$\underset{i\leqslant k}{\frac{\partial\overline{g}_{ik}}{\partial y^{n+1}}}(y^1,\ldots,y^n,0)=-2\,\overline{\phi}(y^1,\ldots,y^n,0)\underset{i\leqslant k}{\Omega_{ik}}(y^1,\ldots,y^n) \tag{36}$$

hold in some neighborhood of the point $0\in\mathbb{R}^n$, where g_{ik} and Ω_{ik} are arbitrary analytic functions with $|g_{ik}|\neq 0$ at the origin, then the right-hand side of (34) will also be analytic at

$$y^1=0\ldots y^{n+1}=0;\quad \underset{i\leqslant k}{\overline{g}_{ik}}\Big|_0\ ;\quad \underset{i\leqslant k}{\frac{\partial\overline{g}_{ik}}{\partial y^1}}\Big|_0\ \cdots\ \underset{i\leqslant k}{\frac{\partial\overline{g}_{ik}}{\partial y^{n+1}}}\Big|_0\ ;\quad \underset{i\leqslant k}{\frac{\partial^2\overline{g}_{ik}}{\partial y^j\partial y^m}}\Big|_0\ . \tag{37}$$

We conclude, then, from the Cauchy–Kowalewski theorem, that Eq. (34) admits a unique solution $\overline{g}_{ik}(y^1,\ldots,y^{n+1})$ which is analytic at $0\in\mathbb{R}^{n+1}$ and also satisfies the given initial conditions. It should be noted that the determinant $|\overline{g}_{ik}|$ (which due to the initial conditions is non-null at the origin) remains non-null in some open set of $\mathbb{R}^{n+1}$ as a consequence of the continuity of the solution. These results may be summed up in the following lemma.

Lemma 2: Let $g_{ik}(y^1,\ldots,y^n)$ and $\Omega_{ik}(y^1,\ldots,y^n)$, for $i,k=1,\ldots,n$, and $\overline{\phi}(y^1,\ldots,y^n,y^{n+1})$, be arbitrary functions which are analytic at $0\in\mathbb{R}^n$ and $0\in\mathbb{R}^{n+1}$, respectively, with $g_{ik}=g_{ki}$, $|g_{ik}|\neq 0$, $\Omega_{ik}=\Omega_{ki}$ in some open set of $\mathbb{R}^n$ containing $0\in\mathbb{R}^n$, and $\overline{\phi}\neq 0$ in some open set of $\mathbb{R}^{n+1}$ containing $0\in\mathbb{R}^{n+1}$. Then there exists a unique set of functions $\overline{g}_{ik}(y^1,\ldots,y^n,y^{n+1})$, which are analytic at $0\in\mathbb{R}^{n+1}$, that satisfy (i) the conditions (7) and (8) and the equation (20) in a neighborhood of $0\in\mathbb{R}^{n+1}$; and (ii) the initial conditions (6) and (36).

Now if we identify the functions g_{ik} of the initial conditions with the components of a semi-Riemannian manifold M^n, then from Lemmas 1 and 2 and Theorem 1 we can prove the following theorem:

Theorem 2: *Let M^n be an n-dimensional semi-Riemannian manifold with metric given by*

$$ds^2=g_{ik}dx^i dx^j,$$

in coordinate system $\{x^i\}$ of M^n. Let $p\in M^n$ have coordinates $x^1_p=\cdots=x^n_p=0$. Then, M^n has a local isometric and analytic embedding (at the point p) in an $(n+1)$-dimensional Einstein space with cosmological constant Λ if and only if there exist functions $\Omega_{ik}(x^1,\ldots,x^n)$ $(i,k=1,\ldots,n)$ that are analytic at $0\in\mathbb{R}^n$ and such that

$$\Omega_{ik}=\Omega_{ki}, \tag{38}$$

$$g^{jk}(\nabla_j\Omega_{ik}-\nabla_i\Omega_{jk})=0, \tag{39}$$

$$g^{ik}g^{jm}(R_{ijkm}+\varepsilon(\Omega_{ik}\Omega_{jm}-\Omega_{jk}\Omega_{im}))=-2\Lambda. \tag{40}$$

Proof: Let $\mathcal{M}_{\Lambda}^{n+1}$ be the collection of all $(n+1)$-dimensional Einstein spaces with cosmological constant Λ. If M^n has a local and analytic embedding in $\mathcal{M}_{\Lambda}^{n+1}$, at the point p, then in accordance with Theorem 1, there exist functions $\overline{g}_{ik}(x^1,\ldots,x^{n+1})$, satisfying (6), and $\overline{\phi}(x^1,\ldots,x^{n+1})$ that are analytic at $0\in\mathbb{R}^{n+1}$ such that

$$ds^2=\overline{g}_{ik}dx^i dx^k+\varepsilon\overline{\phi}^2 dx^{n+1}dx^{n+1} \tag{41}$$

is the line element of some member of $\mathcal{M}_{\Lambda}^{n+1}$ expressed in a conveniently chosen coordinate system. Therefore, this metric satisfies the equations (20)–(22) in a neighborhood of $0\in\mathbb{R}^{n+1}$. In particular, this is true for points lying on the hypersurface $x^{n+1}=0$, where $\overline{g}_{ik}=g_{ik}$, from (6). Thus, if we define $\Omega_{ik}(x^1,\ldots,x^n)=\overline{\Omega}_{ik}(x^1,\ldots,x^n,0)$, then the functions Ω_{ik} necessarily satisfy (38)–(40).

Let us consider the sufficient condition. First, we choose $\overline{\phi}(x^1,\ldots,x^{n+1})\neq 0$ and analytic at $0\in\mathbb{R}^{n+1}$. According to Lemma 2, there exists a unique set of functions $\overline{g}_{ik}(x^1,\ldots,x^{n+1})$ satisfying (6)–(8), (16), and (20) and the condition $\overline{\Omega}_{ik}(x^1,\ldots,x^n,0)=\Omega_{ik}(x^1,\ldots,x^n)$. If Ω_{ik} and g_{ik} satisfy (39) and (40), then, from Lemma 1, the functions $\overline{g}_{ik}(x^1,\ldots,x^{n+1})$ satisfy (20)–(22) in a neighborhood of $0\in\mathbb{R}^{n+1}$, which in turn implies that the line element formed with $\overline{g}_{ik}$ and $\overline{\phi}$ is that of an Einstein space with cosmological constant Λ. Then, Theorem 1 tell us that M^n has a local isometric and analytical embedding in $\mathcal{M}_{\Lambda}^{n+1}$. □

We now want to show that once the functions g_{ik} are given, the equations (38)–(40) always admit a solution for Ω_{ik}. These equations constitute a set of n partial differential equations [Eq. (39)] plus a constraint equation [Eq. (40)] for $n(n+1)/2$ independent functions Ω_{ik}. Except for $n=1$, the number of unknown functions is greater than [or equal to $(n=2)$] the number of equations. Out of the set of functions Ω_{ik} we pick n functions to be regarded as the unknowns. We proceed to put (39) in the form required for application of the Cauchy–Kowalewski (first-order derivative version) theorem to assure the existence of the solution. The detailed proof is a bit laborious, so we shall omit some of its parts.

For the sake of the argument and with no loss of generality we assume that we are using a coordinate system in which $g_{11}\neq 0$ and $g_{1k}=0$, $k=2,\ldots,n$. Thus, $g^{11}=1/g_{11}$ and $g^{1k}=0$. Equation (39) can be written as

$$g^{rs}(\Omega_{sk,r}-\Omega_{rs,k}+\Omega_{rt}\Gamma^t_{sk}-\Omega_{kt}\Gamma^t_{sr})=0. \tag{42}$$

Recalling that $\Omega_{ik}=\Omega_{ki}$, it is not difficult to see that (42) may be put in the form

$$g^{rs}\left(\underset{s\leqslant k}{\Omega_{sk,r}}+\underset{k<s}{\Omega_{ks,r}}-2\underset{r<s}{\Omega_{rs,k}}\right)-g^{rr}\Omega_{rr,k}+g^{rs}\left(\underset{t\leqslant r}{\Omega_{tr}\Gamma^t_{sk}}+\underset{r<t}{\Omega_{rt}\Gamma^t_{sk}}-\underset{t\leqslant k}{\Omega_{tk}\Gamma^t_{sr}}-\underset{k<t}{\Omega_{kt}\Gamma^t_{sr}}\right)=0. \tag{43}$$

Likewise and taking advantage of the special form of the metric we can write Eq. (40) as

$$\begin{aligned}2g^{11}\Omega_{11}\underset{r,s>1}{g^{rs}}\left(\underset{r\leqslant s}{\Omega_{rs}}+\underset{s<r}{\Omega_{sr}}\right)-2g^{11}\underset{r,s>1}{g^{rs}}\,\Omega_{1r}\Omega_{1s}+\underset{r,s,t,u>1}{g^{rs}g^{tu}}\Bigg[&\left(\underset{r\leqslant s}{\Omega_{rs}}+\underset{s<r}{\Omega_{rs}}\right)\left(\underset{t\leqslant u}{\Omega_{tu}}+\underset{u<t}{\Omega_{ut}}\right)\\&-\left(\underset{r\leqslant u}{\Omega_{ru}}+\underset{u<r}{\Omega_{ur}}\right)\left(\underset{s\leqslant t}{\Omega_{st}}+\underset{t<s}{\Omega_{ts}}\right)\Bigg]+\varepsilon R=-2\varepsilon\Lambda.\end{aligned} \tag{44}$$

Our next step is to identify in Eq. (43) the terms containing derivatives of Ω_{ik} with respect to the coordinate x^1. Let us consider first the case $k=1$. Thus, we have

$$g^{rs}\left(\underset{r,s>1}{\Omega_{1s,r}}-2\underset{1<r<s}{\Omega_{rs,1}}\right)-g^{rr}\underset{r>1}{\Omega_{rr,1}}+\underset{r,s>1}{g^{rs}}\left(\underset{t\leqslant r}{\Omega_{tr}\Gamma^t_{s1}}+\underset{r<t}{\Omega_{rt}\Gamma^t_{s1}}-\Omega_{11}\Gamma^1_{sr}-\underset{t<1}{\Omega_{1t}\Gamma^t_{sr}}\right)=0. \tag{45}$$

In order to write (45) in the form specified by Cauchy–Kowalewski (in its first-derivative version) we should decide what among the functions $\Omega_{ik}(i\leqslant k)$ are to be chosen as unknowns. We also

note that since $|g_{ik}|\neq 0$ there exists at least an index $r'>1$ such that $g^{r'n}\neq 0$. We choose $\Omega_{r'n}$ as one of the unknown functions and solve (45) for $\partial\Omega_{r'n}/\partial x^1$. Thus, it is possible to put (45) in the form

$$\frac{\partial\Omega_{r'n}}{\partial x^1}=\frac{1}{g^{r'n}(\delta_{r'n}-2)}\Bigg[-\sum_{r,s>1} g^{rs}\,\Omega_{1s,r}+2\sum_{\substack{1<r<s\\ r,s\neq r',n}} g^{rs}\Omega_{rs,1}+\sum_{\substack{r>1\\ r\neq r'}} g^{rr}\Omega_{rr,1}+g^{r'r'}\Omega_{r'r',1}(1-\delta_{r'n})$$
$$-\sum_{r,s>1} g^{rs}\Bigg(\sum_{t\leqslant r}\Omega_{tr}\Gamma^t_{s1}+\sum_{r<t}\Omega_{rt}\Gamma^t_{s1}-\Omega_{11}\Gamma^1_{sr}-\sum_{t<1}\Omega_{1t}\Gamma^t_{sr}\Bigg)\Bigg], \tag{46}$$

where no sum over r' is implied.

For $k\geqslant 2$ we have

$$\frac{\partial\Omega_{1k}}{\partial x^1}=g_{11}\Bigg[-\sum_{r,s>1} g^{rs}\Bigg(\sum_{s\leqslant k}\Omega_{sk,r}+\sum_{k<s}\Omega_{ks,r}-2\sum_{r<s}\Omega_{rs,k}\Bigg)-g^{11}\Omega_{11,k}-\sum_{r>1} g^{rr}\Omega_{rr,k}$$
$$-g^{rs}\Bigg(\sum_{t\leqslant r}\Omega_{tr}\Gamma^t_{sk}+\sum_{r<t}\Omega_{rt}\Gamma^t_{sk}-\sum_{t\leqslant k}\Omega_{tk}\Gamma^t_{sr}-\sum_{k<t}\Omega_{kt}\Gamma^t_{sr}\Bigg)\Bigg],\quad k\geqslant 2. \tag{47}$$

From (44) we can express Ω_{11} in terms of the other Ω_{ik}. Thus

$$\Omega_{11}=\frac{1}{2g^{11}\sum_{r,s>1} g^{rs}\Big(\sum_{r\leqslant s}\Omega_{rs}+\sum_{s<r}\Omega_{sr}\Big)}\Bigg[2g^{11}\sum_{r,s>1} g^{rs}\,\Omega_{1r}\Omega_{1s}-\sum_{r,s,tu>1} g^{rs}g^{tu}\Bigg[\Big(\sum_{r\leqslant s}\Omega_{rs}+\sum_{s<r}\Omega_{sr}\Big)\Big(\sum_{t\leqslant u}\Omega_{tu}+\sum_{u<t}\Omega_{ut}\Big)$$
$$-\Big(\sum_{r\leqslant u}\Omega_{ru}+\sum_{u<r}\Omega_{ur}\Big)\Big(\sum_{s\leqslant t}\Omega_{st}+\sum_{t<s}\Omega_{ts}\Big)\Bigg]-\varepsilon(R+\Lambda)\Bigg]. \tag{48}$$

Finally, substituting Ω_{11} from (48) into (46) and (47) we obtain a set of partial differential equations for the functions Ω_{ik}, $(i,k)\neq(1,1)$. If we regard the functions $\Omega_{ik}(i\leqslant k)$ with $i>1$ and $(i,k)\neq(r',n)$ as analytic functions already known, then we apply the Cauchy–Kowalewski theorem (first derivative version) to this set of differential equations considering $\Omega_{1k}(k>1)$ and $\Omega_{r'n}$ as the unknown functions. We, then, choose $\Omega_{ik}\,(x^1,\ldots,x^n)$ $[i\leqslant k, i>1, (i,k)\neq(r',n)]$ and the initial conditions $\Omega_{1k}\,(0,x^2,\ldots,x^n)=f_k(x^2,\ldots,x^n)$ $(k>1)$ and $\Omega_{r'n}(0,x^2,\ldots,x^n)=f_1(x^2,\ldots,x^n)$. Of course the chosen functions must be analytic at $0\in\mathbb{R}^n$ and satisfy the condition

$$\sum_{r,s>1} g^{rs}\Big(\sum_{r\leqslant s}\Omega_{rs}+\sum_{s<r}\Omega_{sr}\Big)\Big|_0\neq 0. \tag{49}$$

It should be noted that it is always possible to have functions Ω_{ik} that satisfy the condition above. For instance, if we take $\Omega_{ik}=0$ $[i\leqslant k, i>1, (i,k)\neq(r',n)]$, this condition reduces to $g^{r'n}\Omega_{r'n}|_0\neq 0$. Hence we just choose $\Omega_{r'n}\neq 0$.

Once we have specified the functions $\Omega_{ik}(x^1,\ldots,x^n)$ $[i\leqslant k, i>1, (i,k)\neq(r',n)]$, the right-hand sides of (46) and (47) become a function of the arguments

$$x^1,\ldots,x^n;\quad \sum_{k>1}\Omega_{1k},\Omega_{r'n};\quad \sum_{k,j>1}\Omega_{1k,j},\sum_{j>1}\Omega_{r'n,j}, \tag{50}$$

which is analytic at

$$x^1=0,\ldots,x^n=0;\quad \sum_{k>1}\Omega_{1k}\Big|_0,\Omega_{r'n}|_0;\quad \sum_{k,j>1}\Omega_{1k,j}\Big|_0,\sum_{j>1}\Omega_{r'n,j}\Big|_0. \tag{51}$$

Therefore, the Cauchy–Kowalewski theorem asserts that there exists a unique set of functions $\Omega_{1k}(x^1,x^2,\ldots,x^n)$ $(k>1)$ and $\Omega_{r'n}(x^1,x^2,\ldots,x^n)$, analytic at $0\in\mathbb{R}^{n+1}$ which satisfy the equations (46) and (47). We determine Ω_{11} from (48) by taking the chosen functions $\Omega_{ik}(x^1,\ldots,x^n)$ $[i\leqslant k,i>1,(i,k)\neq(r',n)]$ and the solutions of the system of equations. From (49) and due to the analyticity of g_{ik} and of the solution we conclude that Ω_{11} is analytic at the origin. Therefore, the existence of analytic functions Ω_{ik} satisfying (38)–(40) is demonstrated. The above may be summarized in the following lemma:

Lemma 3: Let $g_{ik}(x^1,\ldots,x^n)$ *and* $\Omega_{ik}(x^1,\ldots,x^n)$ $[i\leqslant k,i>1,(i,k)\neq(r',n)]$ *be analytic functions at the origin* $0\in\mathbb{R}^n$, *with* Ω_{ik} *satisfying the initial conditions* $\Omega_{1k}(0,x^2,\ldots,x^n)=f_k(x^2,\ldots,x^n)$ $(k>1)$ and $\Omega_{r'n}(0,x^2,\ldots,x^n)=f_1(x^2,\ldots,x^n)$, *where* f_k *are analytic at* $0\in\mathbb{R}^n$. *If, in addition, the condition* (49) *is fulfilled, then there exists a unique set of functions* $\Omega_{ik}(x^1,\ldots,x^n)$ $(i,k=1,...,n)$, *analytic at* $0\in\mathbb{R}^{n-1}$, *which satisfy the equations (38)–(40).*

Therefore, according to the lemma above, if we are given a set of analytic functions g_{ik}, then the existence of analytic functions Ω_{ik} which satisfy the equations (38)–(40) is assured. In this way Lemma 3 tell us that the sufficient conditions of Theorem 2 are satisfied, so we can state the final theorem.

Theorem 3: *Let* M^n $(n>1)$ *be a semi-Riemannian space with line element*

$$ds^2=g_{ik}dx^i dx^k,$$

expressed in a coordinate system which covers a neighborhood of a point $p\in M^n$ *whose coordinates are* $x_p^1=\cdots=x_p^n=0$. *If* g_{ik} *are analytic functions at* $0\in\mathbb{R}^n$, *then* M^n *can be embedded at p in some* $(n+1)$*-dimensional Einstein space* $N^{n+1}\in\mathcal{M}_\Lambda$.

Two comments are in order. First, if the $n(n-1)/2-1$ specified arbitrary functions $\Omega_{ik}(x^1,\ldots,x^n)$ $[i\leqslant k,i>1,(i,k)\neq(r',n)]$ obey the conditions

(i) the functions Ω_{ik} $[i\leqslant k,i>1,(i,k)\neq(r',n)]$ are analytic at $0\in\mathbb{R}^n$;
(ii) the n functions $\Omega_{1k}(0,x^2,\ldots,x^n)=f_k(x^2,\ldots,x^n)$ $(k>1)$ and $\Omega_{r'n}(0,x^2,\ldots,x^n)=f_1(x^2,\ldots,x^n)$ are analytic at $0\in\mathbb{R}^{n-1}$, with $g^{rs}_{r,s>1}\,(\Omega_{\substack{rs\\ r\leqslant s}}+\Omega_{\substack{sr\\ s<r}})\big|_0\neq 0$;
(iii) a function $\overline{\phi}(x^1,\ldots,x^{n+1})\neq 0$, analytic at $0\in\mathbb{R}^{n+1}$, is chosen;

then the line element of the embedding space as referred to in Theorem 1 is unique.

Second, if we consider the case $\Lambda=0$, then clearly this theorem reduces to the Campbell–Magaard theorem, which establishes the existence of local analytic embedding of any Riemannian manifold in the set of Ricci-flat spaces. In this sense, Theorem 3 is a generalization of the Campbell–Magaard theorem.

III. APPLICATION OF THE EXTENDED CAMPBELL–MAGAARD THEOREM

Let us consider some cases where (M^n,g) is a Lorentzian manifold of dimension $n=4$. We know from Theorem 3 that there exists at least one Einstein space of dimension $n=5$ in which (M^4,g) can be embedded. In this section, we shall discuss and exhibit explicitly the embedding of four-dimensional Einstein spaces into five-dimensional embedding Einstein spaces.

Let us suppose (M^4,g) is an Einstein space, that is,

$$R_{ik}=-\lambda g_{ik}. \tag{52}$$

Our aim is to find a five-dimensional $(M^5,\tilde{g})$ with a given arbitrary cosmological constant Λ in which (M^4,g) can be embedded.

Let us assume the following *ansatz*,

$$\overline{g}_{ik}=f(u)g_{ik} \tag{53}$$

with $f(0)=1$. Since we now have $R=-4\lambda$, the equation (40) can be satisfied only if $f'(0)=\sqrt{-2\varepsilon\Lambda/3+4\varepsilon\lambda/3}$.

Owing to the fact that $\overline{g}_{ik}$ and g_{ik} are related by a conformal transformation which depends on the extra coordinate u only, it follows that $\overline{R}_{ik}=R_{ik}=-\lambda g_{ik}$. Thus, Eq. (34) is equivalent to

$$f''+\frac{f'^2}{f}+\frac{4\varepsilon\Lambda}{3}f-2\varepsilon\lambda=0. \tag{54}$$

It is not difficult to show that the solution which satisfies the initial conditions imposed on f is given by[9]

$$f(u)=\left[\cosh\left(\sqrt{-\frac{\varepsilon\Lambda}{6}}u\right)+\left(1-2\frac{\lambda}{\Lambda}\right)\sinh\left(\sqrt{-\frac{\varepsilon\Lambda}{6}}u\right)\right]^2. \tag{55}$$

In this way we conclude that the Einstein space (M^4,g) can be embedded in the Einstein space

$$ds^2=f(u)g_{ik}dx^i dx^j+\varepsilon du^2, \tag{56}$$

with $f(u)$ being given by (55).

Let us briefly note that embeddings of Minkowski and Schwarzschild space–times may be easily obtained as a particular case of the example above if we take $\lambda=0$.

IV. CONCLUSION

The recent appearance of physical models which regard the ordinary space–time as a hypersurface embedded in a five-dimensional manifold has naturally raised the question of what kind of mathematical conditions both the embedded and the spaces are subject to. An answer to this question necessarily involves a careful account of the mathematical theory of embedding. Particularly useful and clarifying are the Campbell–Magaard theorem and its extension to the case in which the embedding manifold is an Einstein space. Belonging to the latter kind is the embedding considered in the Randall–Sundrum braneworld. On the other hand, embeddings in Ricci-flat five-dimensional manifolds are crucial for the noncompactified approach to Kaluza–Klein gravity.[4] Of course, if according to some new physical model the five-dimensional surrounding manifolds should obey some field equations, e.g., Einstein field equations, it would be of importance to investigate whether further extensions of Campbell–Magaard theorem could be achieved in order to accommodate these models. We are currently doing some research in this direction.

(Received 24 June 2002; accepted 30 July 2002)

We discuss the (right) eigenvalue equation for $\mathbb{H}$, $\mathbb{C}$ and $\mathbb{R}$ linear quaternionic operators. The possibility to introduce an isomorphism between these operators and real/complex matrices allows us to translate the quaternionic problem into an *equivalent* real or complex counterpart. Interesting applications are found in solving differential equations within quaternionic formulations of quantum mechanics. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1511789]

I. INTRODUCTION

The full understanding of the subtleties of the quaternionic eigenvalue problem still represents an intriguing challenge for mathematicians and physicists. The recent study of the eigenvalue problem for complex linear quaternionic operators[1] played a fundamental role in solving quaternionic differential equations.[2] In the last few years, interesting applications of quaternionic analysis and linear algebra were investigated in quantum mechanics.[3] In particular, the solution of the Schrödinger equation in the presence of quaternionic perturbations was explicitly given for constant potentials and deviations from standard (complex) quantum mechanics discussed.[4] In this article, we aim to complete the study begun in Ref. 1, where preliminary steps in solving the eigenvalue problem for complex linear quaternionic operators were traced. In order to extend to the $\mathbb{R}$-linear case the results obtained for the $\mathbb{H}$- and $\mathbb{C}$-linear quaternionic matrices, we have to introduce a system of *coupled* equations which represents the *new* eigenvalue problem for $\mathbb{R}$ linear quaternionic operators. It is important to observe that no attempt to develop a complete theory of the quaternionic eigenvalue problem has been made here; this exceeds the scope of our article. A satisfactory discussion of the eigenvalue problem for quaternionic operators is at present far from being given. We could have directly investigated the eigenvalue equation in the quaternionic space, but we have preferred a more practical approach and chosen to handle the problem by finding a more familiar real or complex space isomorphic to the quaternionic one. We shall show that the isomorphism between $\mathbb{H}$-, $\mathbb{C}$-, and $\mathbb{R}$-linear quaternionic operators and real/complex matrices immediately allows us to translate the quaternionic (right) eigenvalue problem in a corresponding real or complex counterpart. The study of the new translated problem gives important information about the quaternionic solution. The results obtained are very useful in solving polynomial and differential equations. This could represent a fundamental step in understanding the potentiality of using quaternions in formulating quantum mechanics (by investigating *quaternionic* deviations from the standard theory[3,4]) and gauge theory (by suggesting *new* unification groups[5]).

Throughout the article we shall denote by $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$ the sets of real, complex, and quaternionic numbers, $\mathbb{R}\subset\mathbb{C}\subset\mathbb{H}$, and by $V[n,\mathbb{X}]$ and $M[n,\mathbb{X}]$, respectively, the n-tuples and the $n\times n$ matrices over $\mathbb{X}$. Linear quaternionic operators will be distinguished by their linearity from the

[a)]Electronic mail: deleo@ime.unicamp.br
[b)]Electronic mail: scolarici@le.infn.it
[c)]Electronic mail: solombrino@le.infn.it

right. In what follows, the notation $\mathcal{O}_{\mathbb{X}}$ stands for quaternionic operators linear (from the right) over the field $\mathbb{X}$.

II. QUATERNIONIC ALGEBRA AND LINEAR OPERATORS

We now introduce the quaternionic algebra and some useful properties of $\mathbb{H}$-, $\mathbb{C}$-, and $\mathbb{R}$-linear operators. The (real) quaternionic skew-field $\mathbb{H}$ is an associative (division) algebra of rank 4 over $\mathbb{R}$,

$$q=q_0+iq_1+jq_2+kq_3, \quad q_{0,1,2,3}\in\mathbb{R}, \tag{1}$$

where

$$i^2=j^2=k^2=ijk=-1, \tag{2}$$

endowed with an involutory anti-automorphism (*conjugation*)

$$q\to\overline{q}=q_0-iq_1-jq_2-kq_3.$$

Due to the noncommutative nature of quaternions, we must distinguish between the left and right action of the quaternionic imaginary units i, j, and k. To do it, we introduce the operators

$$L_\mu=(1,L_i,L_j,L_k) \quad \text{and} \quad R_\mu=(1,R_i,R_j,R_k), \quad \mu=0,1,2,3,$$

which act on quaternionic vectors $\psi\in V[n,\mathbb{H}]$ in the following way:

$$L_\mu\psi=h_\mu\psi \quad \text{and} \quad R_\mu\psi=\psi h_\mu, \quad h_\mu=(1,i,j,k).$$

These operators satisfy

$$L_i^2=L_j^2=L_k^2=L_iL_jL_k=R_i^2=R_j^2=R_k^2=R_kR_jR_i=-1, \tag{3}$$

and

$$[L_\mu,R_\nu]=0, \quad \mu,\nu=0,1,2,3. \tag{4}$$

Note that $\mathbb{H}$-linear quaternionic operators acting on a finite n-dimensional quaternionic vector space,

$$\mathcal{O}_{\mathbb{H}}(\psi_1q_1+\psi_2q_2)=(O_{\mathbb{H}}\psi_1)q_1+(O_{\mathbb{H}}\psi_2)q_2, \quad q_{1,2}\in\mathbb{H}, \quad \psi_{1,2}\in V[n,\mathbb{H}],$$

are in one-to-one correspondence with $n\times n$ quaternionic matrices:

$$\mathcal{O}_{\mathbb{H}}\leftrightarrow M_{\mathbb{H}}\in M[n,\mathbb{H}]. \tag{5}$$

Consequently, $\mathbb{R}$- and $\mathbb{C}$-linear quaternionic operators,[6]

$$\mathcal{O}_{\mathbb{R}}(\psi_1r_1+\psi_2r_2)=(\mathcal{O}_{\mathbb{R}}\psi_1)r_1+(\mathcal{O}_{\mathbb{R}}\psi_2)r_2, \quad r_{1,2}\in\mathbb{R}, \quad \psi_{1,2}\in V[n,\mathbb{H}],$$

$$\mathcal{O}_{\mathbb{C}}(\psi_1c_1+\psi_2c_2)=(\mathcal{O}_{\mathbb{C}}\psi_1)c_1+(\mathcal{O}_{\mathbb{C}}\psi_2)c_2, \quad c_{1,2}\in\mathbb{C}, \quad \psi_{1,2}\in V[n,\mathbb{H}],$$

can be represented by $n\times n$ quaternionic matrices $M_{\mathbb{H}}$ and right acting operators R_μ as follows:

$$\mathcal{O}_{\mathbb{R}}\leftrightarrow M_{\mathbb{R}}=\sum_{\mu=0}^{3}M_{\mu,\mathbb{H}}R_\mu \quad \text{and} \quad \mathcal{O}_{\mathbb{C}}\leftrightarrow M_{\mathbb{C}}=\sum_{s=0}^{1}M_{s,\mathbb{H}}R_s. \tag{6}$$

Thus, $\mathbb{R}$-linear quaternionic operators consist of right multiplication by quaternionic numbers ($\mu=0,1,2,3$) whereas $\mathbb{C}$-linear quaternionic operators are restricted to right multiplication by complex numbers ($s=0,1$).

III. THE EIGENVALUE PROBLEM

In this section, we briefly discuss the left and right eigenvalue equation for $\mathbb{H}$-, $\mathbb{C}$-, and $\mathbb{R}$-linear quaternionic operators. As explicitly shown below, the conceptual difficulties which characterize the left eigenvalue problem readily disappear by resorting to right eigenvalues. The need to apply similarity transformations on $\mathbb{H}$-, $\mathbb{C}$-, and $\mathbb{R}$-linear quaternionic matrices introduces *complex* or *real* constraints on the right eigenvalues. The choice of complex or real (right) eigenvalues will be extremely useful in finding a practical method of resolution and manipulating quaternionic matrices.

A. Left eigenvalues

The left eigenvalue problem for $\mathbb{H}$-linear quaternionic operators reads

$$\mathcal{O}_{\mathbb{H}}\psi=q\psi, \quad \psi\in V[n,\mathbb{H}], \quad q\in\mathbb{H}. \tag{7}$$

This problem has been recently studied in the mathematical literature.[7,8] Nevertheless, no systematic way to approach the problem has been given. We point out some difficulties which appear in solving the left eigenvalue equation.

1. Similarity transformations

In finding the solution of Eq. (7), a first difficulty is represented by the impossibility to apply similarity transformations, $S_{\mathbb{H}}\in M[n,\mathbb{H}]$, without losing the formal structure of the left eigenvalue equation. In fact, by observing that $S_{\mathbb{H}}q\neq qS_{\mathbb{H}}$, the quaternionic matrices

$$M_{\mathbb{H}} \quad \text{and} \quad S_{\mathbb{H}}M_{\mathbb{H}}S_{\mathbb{H}}^{-1} \tag{8}$$

do *not* necessarily satisfy the same eigenvalue equation. Consequently, we can have quaternionic matrices with the same left eigenvalue spectrum, but *no* similarity transformation relating them. Explicit examples are found in Ref. 1.

2. Hermitian operators

Let $\mathcal{O}_{\mathbb{H}}$ be a Hermitian quaternionic operator and ψ be the eigenvector corresponding to the eigenvalue q. By using Eq. (7) and denoting by $\langle\varphi|\psi\rangle$ the inner product in $V[n,\mathbb{H}]$, we obtain

$$0=\langle\mathcal{O}_{\mathbb{H}}\psi|\psi\rangle-\langle\psi|\mathcal{O}_{\mathbb{H}}\psi\rangle\Rightarrow 0=\langle q\psi|\psi\rangle-\langle\psi|q\psi\rangle\neq(\overline{q}-q)\langle\psi|\psi\rangle.$$

Consequently, the left eigenvalue problem for Hermitian operators could admit *quaternionic* solutions.[9]

3. Square operators and eigenvalues

As a last difficulty in the use of left eigenvalues, we observe that if ψ is an $\mathcal{O}_{\mathbb{H}}$ eigenvector with eigenvalue q, it will not necessarily be an $\mathcal{O}_{\mathbb{H}}^2$ eigenvector with eigenvalue q^2. In fact,

$$\mathcal{O}_{\mathbb{H}}^2\psi=\mathcal{O}_{\mathbb{H}}q\psi\neq q\mathcal{O}_{\mathbb{H}}\psi=q^2\psi.$$

B. Right eigenvalues

The right eigenvalue equation for $\mathbb{H}$-linear transformations reads

$$\mathcal{O}_{\mathbb{H}}\psi=\psi q, \quad \psi\in V[n,\mathbb{H}], \quad q\in\mathbb{H}. \tag{9}$$

Such an equation can be reduced to a right complex eigenvalue equation rephasing the quaternionic eigenvalues by unitary quaternions u,

$$\mathcal{O}_{\mathrm{H}}\psi u=\psi u\bar{u}qu=\psi uz, \quad z\in\mathbb{C}. \tag{10}$$

This trick obviously fails for complex and real linear transformations. In fact, due to the presence of the operators R_i in $\mathcal{O}_{\mathrm{C}}$ and $\mathbf{R}\equiv(R_i,R_j,R_k)$ in $\mathcal{O}_{\mathbb{R}}$, we cannot apply unitary transformations from the right. Observe that

$$(\mathcal{O}_{\mathbb{R},\mathrm{C}}\psi)u\neq\mathcal{O}_{\mathbb{R},\mathrm{C}}(\psi u), \quad u\in\mathbb{H}. \tag{11}$$

The failure of the *associativity* in Eq. (11) suggests that we should consider *complex* eigenvalue equations for $\mathbb{C}$-linear quaternionic operators,

$$\mathcal{O}_{\mathrm{C}}\psi=\psi z, \quad z\in\mathbb{C}, \tag{12}$$

and *real* eigenvalues for $\mathbb{R}$-linear quaternionic operators,

$$\mathcal{O}_{\mathbb{R}}\psi=\psi r, \quad r\in\mathbb{R}. \tag{13}$$

These equations are formally invariant under $\mathbb{C}$- and $\mathbb{R}$-linear similarity transformations. Moreover, it can easily be proved that

$$\mathcal{O}^n_{\mathrm{H}}\psi=\psi q^n, \quad \mathcal{O}^n_{\mathrm{C}}\psi=\psi z^n, \quad \mathcal{O}^n_{\mathbb{R}}\psi=\psi r^n.$$

It is important to note here that $\mathbb{R}$-linear quaternionic operators admit real eigenvalues only in particular cases. Thus, Eq. (13) has to be generalized. As shown later, a satisfactory discussion of the eigenvalue problem for $\mathbb{R}$-linear quaternionic operators will require the use of a system of *coupled* equations.

IV. CANONICAL FORMS

In this section, following the procedure introduced in the paper of Ref. 1, we discuss the canonical forms for $\mathbb{H}$-, $\mathbb{C}$-, and $\mathbb{R}$-linear quaternionic matrices. The results we will establish find an immediate application in the theory of quaternionic differential operators. In fact, by using the canonical form $J_{\mathbb{X}}$ of a given matrix $M_{\mathbb{X}}$ we can readily obtain the exponential

$$\exp[M_{\mathbb{X}}x]=S_{\mathbb{X}}\exp[J_{\mathbb{X}}x]S^{-1}_{\mathbb{X}}$$

and, consequently, avoiding tedious calculations, solve quaternionic differential equations with constant coefficients.[2]

A. $\mathbb{H}$-linear matrices

While matrices over commutative rings have gained much attention, the literature on matrices with quaternionic entries is often fragmentary. The main difficulty is that, due to the noncommutative nature of quaternions, the standard method of resolution breaks down. Consequently, finding eigenvalues and canonical forms represents a more delicate problem. The recent renewed interest in quaternionic matrix theory[1,10] and its applications[2] shed new light on this intriguing research field. To facilitate access to the individual topics, we recall the main properties of $\mathbb{H}$-linear quaternionic matrices[11–14] and repeat the relevant theorems from Refs. 1, 10, 15, and 16 without proofs, thus making our exposition self-contained.

In approaching the problem of diagonalization we have to consider a right quaternionic eigenvalue equation. In fact, from

$$M_{\mathrm{H}}\psi_k=\psi_k q_k, \quad k=1,\ldots,n, \quad \psi_k\in V[n,\mathbb{H}], \tag{14}$$

in the case $M_{\mathbb{H}}$ is diagonalizable, we immediately get the following matrix equation

$$M_{\mathbb{H}}S_{\mathbb{H}}[\psi_1,\psi_2,\ldots,\psi_n]=S_{\mathbb{H}}[\psi_1,\psi_2,\ldots,\psi_n]D_{\mathbb{H}},$$

where

$$D_{\mathbb{H}}=\mathrm{diag}[q_1,q_2,\ldots,q_n]$$

and $S_{\mathbb{H}}=S_{\mathbb{H}}[\psi_1,\psi_2,\ldots,\psi_n]$ is defined by $Col_k(S_{\mathbb{H}})=\psi_k$.

Consequently, the diagonalization of the matrix $M_{\mathbb{H}}$,

$$M_{\mathbb{H}}=S_{\mathbb{H}}D_{\mathbb{H}}S_{\mathbb{H}}^{-1},$$

is obtained by solving the corresponding right eigenvalue problem. It is important to note here that we have *infinite* ways to diagonalize a quaternionic matrix $M_{\mathbb{H}}$,

$$\mathrm{diag}[u_1,u_2,\ldots,u_n]\mathrm{diag}[q_1,q_2,\ldots,q_n]\mathrm{diag}[\overline{u_1},\overline{u_2},\ldots,\overline{u_n}].$$

Geometrically speaking this means that $\mathrm{Im}[q]$ can arbitrarily be fixed on the sphere of ray $|\mathrm{Im}[q]|$. By a particular choice of the unitary matrix

$$U_{\mathbb{H}}=\mathrm{diag}[u_1,u_2,\ldots,u_n]$$

we can set a preferred space direction, for example the positive i axis, and consequently a *complex* (positive) eigenvalue spectrum.

Let us now briefly recall some properties of the eigenvalue spectrum of $\mathbb{H}$-linear quaternionic matrices. By using the symplectic decomposition of the matrix $M_{\mathbb{H}}$,

$$M_{\mathbb{H}}=M_1+jM_2,\quad M_{1,2}\in M[n,\mathbb{C}],$$

and the symplectic decomposition of the vector ψ,

$$\psi=\psi_1+j\psi_2,\quad \psi_{1,2}\in V[n,\mathbb{C}],$$

we can rewrite Eq. (10) in the following (complex) form:

$$\tilde{M}_{\mathbb{H}}\tilde{\psi}=z\,\tilde{\psi}, \tag{15}$$

where

$$\tilde{M}_{\mathbb{H}}=\begin{pmatrix} M_1 & -M_2^* \\ M_2 & M_1^* \end{pmatrix}\in M[2n,\mathbb{C}]\quad\text{and}\quad \tilde{\psi}=\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}\in V[2n,\mathbb{C}]. \tag{16}$$

The mapping

$$f:M_{\mathbb{H}}\mapsto\tilde{M}_{\mathbb{H}} \tag{17}$$

is an isomorphism of the ring of quaternionic matrices $M_{\mathbb{H}}$ into the ring of the corresponding complex counterparts $\tilde{M}_{\mathbb{H}}$. It is important to observe that this isomorphism do not preserve the inner product of eigenvectors.[9] Nevertheless, the choice of a *complex projection* of quaternionic inner products[17] opens the door to interesting applications in relativistic quantum mechanics.[18] The *complex* orthogonality of quaternionic eigenvectors (instead of a quaternionic orthogonality) implies a doubling of solution in the two-dimensional quaternionic Dirac equation.[17] The *four* (complex) orthogonal quaternionic solutions describe particle/antiparticle with spin up/down. The use of *complex* inner products is also a fundamental ingredient in the formulation of gauge theories by geometric algebras.[5]

The next theorem states the main property of the eigenvalue spectrum of $\mathbb{H}$-linear quaternionic matrices. For a detailed discussion, see Refs. 14–16.

Theorem 1: *Let $\tilde{M}_{\mathrm{H}}$ be the matrix given in Eq. (16). Then, its eigenvalues appear in complex conjugate pairs.*

By using the result of Theorem 1 and the Gram–Schmidt method, we can readily obtain the triangular form for $\mathbb{H}$-linear quaternionic matrices.

Theorem 2: *Every M_{H} is unitarily similar to an upper triangular matrix.*

Moreover, a Jordan form can be given for every $\mathbb{H}$-linear quaternionic matrix.

Theorem 3: *Every $n\times n$ matrix with real quaternion elements is similar under a matrix transformation with real quaternion elements to a matrix in (complex) Jordan normal form with diagonal elements in the complex field.*

To prove Theorem 3, we can use the isomorphism defined in (17). To any $\tilde{M}_{\mathrm{H}}$ corresponds a $2n\times 2n$ matrix B in the (complex) Jordan form $B=B_{\mathrm{H}}\oplus B_{\mathrm{H}}^{*}$, such that $\tilde{M}_{\mathrm{H}}P=PB$, where the (nonsingular) matrix P has the form

$$P=\begin{pmatrix} P_1 & -P_2^{*} \\ P_2 & P_1^{*} \end{pmatrix}.$$

This implies that

$$(P_1+jP_2)^{-1}M_{\mathrm{H}}(P_1+jP_2)=B_{\mathrm{H}}=D_{\mathrm{H}}+N_{\mathrm{H}}, \tag{18}$$

where D_{H} and N_{H} respectively denote the diagonal and the nilpotent parts of B_{H}.

B. $\mathbb{C}$-linear matrices

Let us now consider $\mathbb{C}$-linear transformations. We can associate to any $n\times n$ $\mathbb{C}$-linear quaternionic matrix a $2n$-dimensional complex matrix by the following mapping.

$$M_{\mathrm{C}}=M_{\mathrm{H}}+M'_{\mathrm{H}}R_i\leftrightarrow\tilde{M}_{\mathrm{C}}=f(M_{\mathrm{H}})+if(M'_{\mathrm{H}})=\begin{pmatrix} M_1 & -M_2^{*} \\ M_2 & M_1^{*} \end{pmatrix}+i\begin{pmatrix} M'_1 & -M'^{*}_2 \\ M'_2 & M'^{*}_1 \end{pmatrix}, \tag{19}$$

where f denotes the isomorphism defined in (17). Then the following proposition holds:

Proposition 1: Let M_{C} be a $\mathbb{C}$-linear quaternionic matrix and $\tilde{M}_{\mathrm{C}}$ its complex counterpart [see Eq. (19)]. The mapping

$$g:M_{\mathrm{C}}\mapsto\tilde{M}_{\mathrm{C}} \tag{20}$$

is an isomorphism of the ring of the n-dimensional $\mathbb{C}$-linear matrices into the ring of 2n-dimensional complex matrices.

Indeed, if

$$A_{\mathrm{C}}=A_{0,\mathrm{H}}+A_{1,\mathrm{H}}R_i \quad\text{and}\quad B_{\mathrm{C}}=B_{0,\mathrm{H}}+B_{1,\mathrm{H}}R_i$$

are two $\mathbb{C}$-linear matrices, their corresponding complex counterparts are given by

$$g(A_{\mathrm{C}})=f(A_{0,\mathrm{H}})+if(A_{1,\mathrm{H}}),\quad g(B_{\mathrm{C}})=f(B_{0,\mathrm{H}})+if(B_{1,\mathrm{H}}).$$

Then,

$$\begin{aligned} A_{\mathrm{C}}B_{\mathrm{C}}=C_{\mathrm{C}}&=A_{0,\mathrm{H}}B_{0,\mathrm{H}}+A_{1,\mathrm{H}}R_iB_{0,\mathrm{H}}+A_{0,\mathrm{H}}B_{1,\mathrm{H}}R_i+A_{1,\mathrm{H}}R_iB_{1,\mathrm{H}}R_i \\ &=A_{0,\mathrm{H}}B_{0,\mathrm{H}}-A_{1,\mathrm{H}}B_{1,\mathrm{H}}+(A_{0,\mathrm{H}}B_{1,\mathrm{H}}+A_{1,\mathrm{H}}B_{0,\mathrm{H}})R_i \end{aligned}$$

and

$$g(A_{\mathbb{C}})g(B_{\mathbb{C}})=f(A_{0,\mathbb{H}})f(B_{0,\mathbb{H}})-f(A_{1,\mathbb{H}})f(B_{1,\mathbb{H}})+if(A_{1,\mathbb{H}})f(B_{0,\mathbb{H}})+if(A_{0,\mathbb{H}})f(B_{1,\mathbb{H}})$$
$$=f(A_{0,\mathbb{H}}B_{0,\mathbb{H}}-A_{1,\mathbb{H}}B_{1,\mathbb{H}})+if(A_{0,\mathbb{H}}B_{1,\mathbb{H}}+A_{1,\mathbb{H}}B_{0,\mathbb{H}})=g(C_{\mathbb{C}}).$$

□

By using this isomorphism, the right eigenvalue spectrum of $\mathbb{C}$-linear quaternionic matrices can easily be determined.[1] The following result,

"*A* $\mathbb{C}$*-linear matrix is diagonalizable if the corresponding complex counterpart is diagonalizable,*"

was proven in Ref. 1 (where a preliminary discussion of the eigenvalue problem for $\mathbb{C}$-linear quaternionic matrix operators was given). It is worth pointing out that the converse of the previous statement is, in general, not true. For instance, let us consider the complex matrix

$$\tilde{G}_{\mathbb{C}}=\begin{pmatrix} z_1 & 0 & 1 & 0 \\ 0 & z_2 & 0 & 1 \\ 0 & 0 & z_1 & 0 \\ 0 & 0 & 0 & z_2 \end{pmatrix}. \tag{21}$$

This matrix admits a corresponding *diagonalizable* $\mathbb{C}$-linear quaternionic matrix given by

$$G_{\mathbb{C}}=D_{\mathbb{C}}+N_{\mathbb{C}}=\begin{pmatrix} \mathrm{Re}(z_1)+\mathrm{Im}(z_1)R_i & 0 \\ 0 & \mathrm{Re}(z_2)+\mathrm{Im}(z_2)R_i \end{pmatrix}+\frac{1}{2}\begin{pmatrix} -j+kR_i & 0 \\ 0 & -j+kR_i \end{pmatrix}, \tag{22}$$

where $N_{\mathbb{C}}$ is nilpotent, diagonal, and commutes with $D_{\mathbb{C}}$.

The normal form of a $\mathbb{C}$-linear quaternionic matrix can easily be calculated. Indeed, given any $\mathbb{C}$-linear transformation $M_{\mathbb{C}}$ and its corresponding complex counterpart $\tilde{M}_{\mathbb{C}}$ [see Eq. (19)], from the known properties of the Jordan form of complex matrices, we can immediately obtain

$$\tilde{S}_{\mathbb{C}}^{-1}\tilde{M}_{\mathbb{C}}\tilde{S}_{\mathbb{C}}=\tilde{J}_{\mathbb{C}}=\tilde{D}_{\mathbb{C}}+\tilde{N}_{\mathbb{C}},$$

where $\tilde{D}_{\mathbb{C}}$ is diagonal, $\tilde{N}_{\mathbb{C}}$ is nilpotent, and $[\tilde{D}_{\mathbb{C}},\tilde{N}_{\mathbb{C}}]=0$. Then, the quaternionic $\mathbb{C}$-linear matrices $M_{\mathbb{C}},S_{\mathbb{C}},D_{\mathbb{C}}$, and $N_{\mathbb{C}}$ are uniquely determined by the isomorphism stated in Proposition 1.

C. $\mathbb{R}$-linear matrices

In the n-dimensional quaternionic vector space $V[n,\mathbb{H}]$, the $\mathbb{R}$-linear transformations are represented by

$$M_{\mathbb{R}}=\sum_{\mu=0}^{3} M_{\mu,\mathbb{H}}R_{\mu}, \tag{23}$$

where $M_{\mu,\mathbb{H}}$ represent $\mathbb{H}$-linear quaternionic matrices and R_{μ} are the right acting operators defined

in the second section. Any $M_{\mathbb{R}}$ is then characterized by $16n^2$ real parameters. We can translate $\mathbb{R}$-linear $n\times n$ matrices into equivalent $4n\times 4n$ real matrices, and vice versa, by the following translation rules:

$$R_i \leftrightarrow \mathbf{I} = \begin{pmatrix} 0 & -\mathbf{1}_n & 0 & 0 \\ \mathbf{1}_n & 0 & 0 & 0 \\ 0 & 0 & 0 & \mathbf{1}_n \\ 0 & 0 & -\mathbf{1}_n & 0 \end{pmatrix},$$

$$R_j \leftrightarrow \mathbf{J} = \begin{pmatrix} 0 & 0 & -\mathbf{1}_n & 0 \\ 0 & 0 & 0 & -\mathbf{1}_n \\ \mathbf{1}_n & 0 & 0 & 0 \\ 0 & \mathbf{1}_n & 0 & 0 \end{pmatrix}, \tag{24}$$

$$R_k \leftrightarrow \mathbf{K} = \begin{pmatrix} 0 & 0 & 0 & -\mathbf{1}_n \\ 0 & 0 & \mathbf{1}_n & 0 \\ 0 & -\mathbf{1}_n & 0 & 0 \\ \mathbf{1}_n & 0 & 0 & 0 \end{pmatrix},$$

and

$$M_{\mu,\mathbb{H}} = M_0 + iM_1 + jM_2 + kM_3 \leftrightarrow \hat{M}_{\mu,\mathbb{H}} = \begin{pmatrix} M_0 & -M_1 & -M_2 & -M_3 \\ M_1 & M_0 & -M_3 & M_2 \\ M_2 & M_3 & M_0 & -M_1 \\ M_3 & -M_2 & M_1 & M_0 \end{pmatrix}, \tag{25}$$

where $M_{\mu,\mathbb{H}} \in M[n,\mathbb{H}]$, $M_{0,\ldots,3} \in M[n,\mathbb{R}]$, and $\hat{M}_{\mu,\mathbb{H}} \in M[4n,\mathbb{R}]$. It is easy to verify that $\mathbf{I},\mathbf{J},\mathbf{K}$ commute with $\hat{M}_{\mu,\mathbb{H}}$:

$$[\mathbf{I},\hat{M}_{\mu,\mathbb{H}}] = [\mathbf{J},\hat{M}_{\mu,\mathbb{H}}] = [\mathbf{K},\hat{M}_{\mu,\mathbb{H}}] = 0$$

and

$$\mathbf{I}^2 = \mathbf{J}^2 = \mathbf{K}^2 = \mathbf{KJI} = -\mathbf{1}.$$

The following proposition holds.

Proposition 2: Let $M_{\mathbb{R}}$ be a $\mathbb{R}$-linear matrix and $\hat{M}_{\mathbb{R}}$ its real counterpart. Then the mapping

$$h: M_{\mathbb{R}} = M_{0,\mathbb{H}} + M_{1,\mathbb{H}}R_i + M_{2,\mathbb{H}}R_j + M_{3,\mathbb{H}}R_k \mapsto \hat{M}_{\mathbb{R}} = \hat{M}_{0,\mathbb{H}} + \hat{M}_{1,\mathbb{H}}\mathbf{I} + \hat{M}_{2,\mathbb{H}}\mathbf{J} + \hat{M}_{3,\mathbb{H}}\mathbf{K}$$

is an isomorphism of the ring of the n-dimensional $\mathbb{R}$-linear matrices into the ring of $4n$-dimensional real matrices $\hat{M}_{\mathbb{R}}$.

Observe that $\widehat{M_{\mathbb{H}}M'_{\mathbb{H}}} = \hat{M}_{\mathbb{H}}\hat{M}'_{\mathbb{H}}$. Let

$$A_{\mathbb{R}} = A_{0,\mathbb{H}} + A_{1,\mathbb{H}}R_i + A_{2,\mathbb{H}}R_j + A_{3,\mathbb{H}}R_k \quad \text{and} \quad B_{\mathbb{R}} = B_{0,\mathbb{H}} + B_{1,\mathbb{H}}R_i + B_{2,\mathbb{H}}R_j + B_{3,\mathbb{H}}R_k$$

be two $\mathbb{R}$-linear quaternionic matrices. Their corresponding real counterparts are given by

$$h(A_{\mathbb{R}}) = \hat{A}_{0,\mathbb{H}} + \mathbf{I}\hat{A}_{1,\mathbb{H}} + \mathbf{J}\hat{A}_{2,\mathbb{H}} + \mathbf{K}\hat{A}_{3,\mathbb{H}} \quad \text{and} \quad h(B_{\mathbb{R}}) = \hat{B}_{0,\mathbb{H}} + \mathbf{I}\hat{B}_{1,\mathbb{H}} + \mathbf{J}\hat{B}_{2,\mathbb{H}} + \mathbf{K}\hat{B}_{3,\mathbb{H}}.$$

Then,

$$A_{\mathbb{R}}B_{\mathbb{R}}=C_{\mathbb{R}}=(A_{0,\mathbb{H}}B_{0,\mathbb{H}}-A_{1,\mathbb{H}}B_{1,\mathbb{H}}-A_{2,\mathbb{H}}B_{2,\mathbb{H}}-A_{3,\mathbb{H}}B_{3,\mathbb{H}})+(A_{0,\mathbb{H}}B_{1,\mathbb{H}}+A_{1,\mathbb{H}}B_{0,\mathbb{H}}+A_{2,\mathbb{H}}B_{3,\mathbb{H}}-A_{3,\mathbb{H}}B_{2,\mathbb{H}})R_i+(A_{0,\mathbb{H}}B_{2,\mathbb{H}}+A_{2,\mathbb{H}}B_{0,\mathbb{H}}+A_{3,\mathbb{H}}B_{1,\mathbb{H}}-A_{1,\mathbb{H}}B_{3,\mathbb{H}})R_j+(A_{0,\mathbb{H}}B_{3,\mathbb{H}}+A_{3,\mathbb{H}}B_{0,\mathbb{H}}+A_{1,\mathbb{H}}B_{2,\mathbb{H}}-A_{2,\mathbb{H}}B_{1,\mathbb{H}})R_k$$

and

$$h(A_{\mathbb{R}})h(B_{\mathbb{R}})=(\hat{A}_{0,\mathbb{H}}\hat{B}_{0,\mathbb{H}}-\hat{A}_{1,\mathbb{H}}\hat{B}_{1,\mathbb{H}}-\hat{A}_{2,\mathbb{H}}\hat{B}_{2,\mathbb{H}}-\hat{A}_{3,\mathbb{H}}\hat{B}_{3,\mathbb{H}})+(\hat{A}_{0,\mathbb{H}}\hat{B}_{1,\mathbb{H}}+\hat{A}_{1,\mathbb{H}}\hat{B}_{0,\mathbb{H}}+\hat{A}_{2,\mathbb{H}}\hat{B}_{3,\mathbb{H}}-\hat{A}_{3,\mathbb{H}}\hat{B}_{2,\mathbb{H}})\mathbf{I}+(\hat{A}_{0,\mathbb{H}}\hat{B}_{2,\mathbb{H}}+\hat{A}_{2,\mathbb{H}}\hat{B}_{0,\mathbb{H}}+\hat{A}_{3,\mathbb{H}}\hat{B}_{1,\mathbb{H}}-\hat{A}_{1,\mathbb{H}}\hat{B}_{3,\mathbb{H}})\mathbf{J}+(\hat{A}_{0,\mathbb{H}}\hat{B}_{3,\mathbb{H}}+\hat{A}_{3,\mathbb{H}}\hat{B}_{0,\mathbb{H}}+\hat{A}_{1,\mathbb{H}}\hat{B}_{2,\mathbb{H}}-\hat{A}_{2,\mathbb{H}}\hat{B}_{1,\mathbb{H}})\mathbf{K}=h(C_{\mathbb{R}})$$ □

We now discuss the canonical forms of $\mathbb{R}$-linear matrices. Let $A_{\mathbb{R}}$ be an $\mathbb{R}$-linear transformation, $\hat{A}_{\mathbb{R}}$ its real counterpart, $\{\lambda_1+i\mu_1,\lambda_2+i\mu_2,\ldots,\lambda_s+i\mu_s\}$ the complex eigenvalues of $\hat{A}_{\mathbb{R}}$, and $\{\lambda_{2s+1},\ldots,\lambda_{4n}\}$ the real eigenvalues of $\hat{A}_{\mathbb{R}}$. As is well known,[19,20] there exists a real orthogonal matrix O such that

$$\hat{J}_{\mathbb{R}}=O\hat{A}_{\mathbb{R}}O^T,$$

where

$$\hat{J}_{\mathbb{R}}=\begin{pmatrix} X_1 & & & & & & \\ & X_2 & & & & P & \\ & & \ddots & & & & \\ & & & X_s & & & \\ & 0 & & & \lambda_{2s+1} & & \\ & & & & & \ddots & \\ & & & & & & \lambda_{4n} \end{pmatrix}$$

$$=\begin{pmatrix} X_1 & & & & & & \\ & X_2 & & & & 0 & \\ & & \ddots & & & & \\ & & & X_s & & & \\ & 0 & & & \lambda_{2s+1} & & \\ & & & & & \ddots & \\ & & & & & & \lambda_{4n} \end{pmatrix}+\begin{pmatrix} 0 & & & & & & \\ & 0 & & & & P & \\ & & \ddots & & & & \\ & & & 0 & & & \\ & 0 & & & 0 & & \\ & & & & & \ddots & \\ & & & & & & 0 \end{pmatrix}$$

$$=\hat{D}_{\mathbb{R}}+\hat{N}_{\mathbb{R}}. \tag{26}$$

In the previous equation, X_r represents a 2×2 real matrix with eigenvalues $\lambda_r\pm i\mu_r$. An appropriate choice of O guarantees that

$$X_r=\begin{pmatrix} \lambda_r & -\mu_r \\ \mu_r & \lambda_r \end{pmatrix}. \tag{27}$$

Let us come back to the $\mathbb{R}$-linear transformation $A_{\mathbb{R}}$. By using the translation rules given in Eqs. (24) and (25), we can immediately give its canonical form

$$J_{\mathbb{R}}=D_{\mathbb{R}}+N_{\mathbb{R}}.$$

In particular, the diagonal elements of $D_{\mathbb{R}}$ corresponding to the quaternionic translation of the real blocks

$$\hat{D}_{1,\mathbb{R}}=\begin{pmatrix} \lambda_m & -\mu_m & 0 & 0 \\ \mu_m & \lambda_m & 0 & 0 \\ 0 & 0 & \lambda_{m+1} & -\mu_{m+1} \\ 0 & 0 & \mu_{m+1} & \lambda_{m+1} \end{pmatrix},$$

$$\hat{D}_{2,\mathbb{R}}=\begin{pmatrix} \lambda_m & -\mu_m & 0 & 0 \\ \mu_m & \lambda_m & 0 & 0 \\ 0 & 0 & \lambda_{m+1} & 0 \\ 0 & 0 & 0 & \lambda_{m+2} \end{pmatrix}, \tag{28}$$

$$\hat{D}_{3,\mathbb{R}}=\begin{pmatrix} \lambda_m & 0 & 0 & 0 \\ 0 & \lambda_{m+1} & 0 & 0 \\ 0 & 0 & \lambda_{m+2} & 0 \\ 0 & 0 & 0 & \lambda_{m+3} \end{pmatrix}$$

are respectively given by

$$\begin{aligned} D_{1,\mathbb{R}}&=\tfrac{1}{2}[\lambda_m(1-L_iR_i)+\mu_m(L_i+R_i)+\lambda_{m+1}(1+L_iR_i)+\mu_{m+1}(L_i-R_i)], \\ D_{2,\mathbb{R}}&=\tfrac{1}{2}[\lambda_m(1-L_iR_i)+\mu_m(L_i+R_i)+\tfrac{1}{2}\lambda_{m+1}(1+L_iR_i-L_jR_j+L_kR_k) \\ &\quad+\tfrac{1}{2}\lambda_{m+2}(1+L_iR_i+L_jR_j-L_kR_k)], \\ D_{3,\mathbb{R}}&=\tfrac{1}{4}[\lambda_m(1-L_iR_i-L_jR_j-L_kR_k)+\lambda_{m+1}(1-L_iR_i+L_jR_j+L_kR_k) \\ &\quad+\lambda_{m+2}(1+L_iR_i-L_jR_j+L_kR_k)+\lambda_{m+3}(1+L_iR_i+L_jR_j-L_kR_k)]. \end{aligned} \tag{29}$$

As happens for $\mathbb{C}$-linear quaternionic matrices, an $\mathbb{R}$-linear quaternionic matrix is diagonalizable if the corresponding real counterpart is diagonalizable. The converse is not necessarily true.

V. THE EIGENVALUE PROBLEM FOR $\mathbb{R}$-LINEAR MATRICES

Let us now consider the eigenvalue problem for $\mathbb{R}$-linear quaternionic matrices. Equation (13) is obviously too restrictive. In fact, such an equation sets the real eigenvalue spectrum of $\mathbb{R}$-linear quaternionic operators. No information is given about the remaining eigenvalues. In particular, if the real counterpart $\hat{M}_{\mathbb{R}}$ of the $\mathbb{R}$-linear quaternionic matrix $M_{\mathbb{R}}$ does not have real eigenvalues, Eq. (13) does not admit solution. This is very embarrassing if we consider, for example, $\mathbb{R}$-linear anti-Hermitian quaternionic operators. Thus, we need to modify Eq. (13). The discussion regarding the ''pseudo-triangular'' form of the matrices $\hat{A}_{\mathbb{R}}$ [see Eq. (26)] suggests as a $\mathbb{R}$-linear eigenvalue problem the following system of *coupled* equations:

$$\begin{aligned} M_{\mathbb{R}}\psi&=a\psi+b\varphi, \\ M_{\mathbb{R}}\varphi&=c\varphi+d\psi, \end{aligned} \tag{30}$$

where

$$a,b,c,d\in\mathbb{R}, \quad \psi=\psi_0+i\psi_1+j\psi_2+k\psi_3, \quad \varphi=\varphi_0+i\varphi_1+j\varphi_2+k\varphi_3,$$
$$\psi_{0,\ldots,3},\varphi_{0,\ldots,3}\in V[n,\mathbb{R}].$$

It can be shown that the real coefficients a,b,c,d are related to the real and imaginary parts of the $\hat{M}_{\mathbb{R}}$ eigenvalues. In fact, by translating the system (30) into its real matrix counterpart, we find

$$\begin{pmatrix} \hat{M}_{\mathbb{R}} & 0 \\ 0 & \hat{M}_{\mathbb{R}} \end{pmatrix} \begin{pmatrix} \hat{\psi} \\ \hat{\varphi} \end{pmatrix} = \begin{pmatrix} a\mathbf{1}_{4n} & b\mathbf{1}_{4n} \\ c\mathbf{1}_{4n} & d\mathbf{1}_{4n} \end{pmatrix} \begin{pmatrix} \hat{\psi} \\ \hat{\varphi} \end{pmatrix}, \tag{31}$$

where

$$\hat{\psi} = \begin{pmatrix} \psi_0 \\ \psi_1 \\ \psi_2 \\ \psi_3 \end{pmatrix}, \quad \hat{\varphi} = \begin{pmatrix} \varphi_0 \\ \varphi_1 \\ \varphi_2 \\ \varphi_3 \end{pmatrix} \quad \in V[4n,\mathbb{R}].$$

The matrix equation (31) admits nontrivial solutions if and only if

$$\det\left[\begin{pmatrix} \hat{M}_{\mathbb{R}} - a\mathbf{1}_{4n} & -b\mathbf{1}_{4n} \\ -c\mathbf{1}_{4n} & \hat{M}_{\mathbb{R}} - d\mathbf{1}_{4n} \end{pmatrix} \right] = 0. \tag{32}$$

By rewriting the matrix $\hat{M}_{\mathbb{R}}$ in terms of the similarity matrix $\hat{S}_{\mathbb{R}}$ and of its Jordan form $\hat{J}_{\mathbb{R}}$, i.e.,

$$\hat{M}_{\mathbb{R}} = \hat{S}_{\mathbb{R}} \hat{J}_{\mathbb{R}} \hat{S}_{\mathbb{R}}^{-1},$$

and by using the cyclic property of the determinant, we reduce Eq. (32) to

$$\det\left[\begin{pmatrix} \hat{J}_{\mathbb{R}} - a\mathbf{1}_{4n} & -b\mathbf{1}_{4n} \\ -c\mathbf{1}_{4n} & \hat{J}_{\mathbb{R}} - d\mathbf{1}_{4n} \end{pmatrix} \right] = 0. \tag{33}$$

By simple algebraic manipulations,[20] we obtain

$$\begin{aligned} \det\left[\begin{pmatrix} \hat{J}_{\mathbb{R}} - a\mathbf{1}_{4n} & -b\mathbf{1}_{4n} \\ -c\mathbf{1}_{4n} & \hat{J}_{\mathbb{R}} - d\mathbf{1}_{4n} \end{pmatrix} \right] &= \det[(\hat{J}_{\mathbb{R}} - a\mathbf{1}_{4n})(\hat{J}_{\mathbb{R}} - d\mathbf{1}_{4n}) - bc\mathbf{1}_{4n}] \\ &= \det[\hat{J}_{\mathbb{R}}^2 - (a+d)\hat{J}_{\mathbb{R}} + (ad-bc)\mathbf{1}_{4n}] \\ &= \prod_i [z_i^2 - (a+d)z_i + (ad-bc)] = 0, \end{aligned}$$

where z_i represent the eigenvalues of the real matrix $\hat{M}_{\mathbb{R}}$. The previous equation explicitly shows the relation between the real coefficients a,b,c,d (which appear in the $\mathbb{R}$-linear eigenvalue problem) and the eigenvalues z of the real counterpart of the quaternionic matrix $M_{\mathbb{R}}$. In the case of complex eigenvalues z, we find

$$\Delta = (a+d) - 4(ad-bc) = (a-d)^2 + bc < 0. \tag{34}$$

This condition guarantees that the eigenvalues of the real matrix

$$Z = \begin{pmatrix} a\mathbf{1}_{4n} & b\mathbf{1}_{4n} \\ c\mathbf{1}_{4n} & d\mathbf{1}_{4n} \end{pmatrix}$$

appear in conjugate pairs. Consequently, we can find a real similarity transformation T such that

$$TZT^{-1}=\begin{pmatrix} \lambda \mathbf{1}_{4n} & -\mu \mathbf{1}_{4n} \\ \mu \mathbf{1}_{4n} & \lambda \mathbf{1}_{4n} \end{pmatrix}.$$

Finally, without loss of generality, we can consider the following eigenvalue problem for $\mathbb{R}$-linear transformations

$$\begin{aligned} M_{\mathbb{R}}\psi &= \lambda\psi - \mu\varphi, \\ M_{\mathbb{R}}\varphi &= \lambda\varphi + \mu\psi. \end{aligned} \tag{35}$$

VI. FINAL REMARKS

These final remarks aim to give a concluding discussion on the ''coupled'' eigenvalue problem and a brief summary of mathematical and physical applications motivating our interest in this research. In particular, we are interested to bring together two areas: quaternionic differential operators and quantum mechanics.

A. Coupled eigenvalue equations

In the previous section, we have introduced, for $\mathbb{R}$-linear transformations, the eigenvalue problem (35) which represents the *natural* generalization of (13). In particular, as we observed above, the study of system (35) instead of Eq. (13) allows us to take into account the existence of complex eigenvalues and, consequently, complete the eigenvalue spectrum of $\mathbb{R}$-linear quaternionic operators. Actually, the eigenvalue problem (35) also applies to $\mathbb{H}$- and $\mathbb{C}$-linear transformations. It can be considered as an equivalent formulation of Eqs. (9) and (12). To show that, let us consider the equation

$$M_{\mathbb{C}}\psi = \psi z = \psi\lambda + \psi i\mu. \tag{36}$$

We limit ourselves to discussing $\mathbb{C}$-linear transformations. Obviously, if a preferred complex direction is chosen for the eigenvalues of $\mathbb{H}$-linear quaternionic operators, all the arguments in what follows also hold for $\mathbb{H}$-linear transformations. By using the $\mathbb{C}$-linearity, we find

$$(M_{\mathbb{C}}\psi)i = M_{\mathbb{C}}(\psi i) = \psi i\lambda - \psi\mu.$$

The pair of eigenvector $(\psi, \varphi = \psi i)$, where ψ is solution of Eq. (36), satisfies the coupled equations

$$\begin{aligned} M_{\mathbb{C}}\psi &= \lambda\psi - \mu\varphi, \\ M_{\mathbb{C}}\varphi &= \mu\psi + \lambda\varphi. \end{aligned} \tag{37}$$

Vice versa, let $M_{\mathbb{C}}$ and (37) be respectively a $\mathbb{C}$-linear transformation and the corresponding eigenvalue problem. We denote by (ψ, φ) a solution of the system (37). If ψ satisfies Eq. (36), too, then, comparing Eq. (36) and the first equation in (37), one immediately obtains $\varphi = \psi i$. If, on the contrary, ψ is not a solution of Eq. (36), by using the $\mathbb{C}$-linearity, we obtain

$$M_{\mathbb{C}}(\varphi i) = (M_{\mathbb{C}}\varphi)i = \mu\psi i + \varphi i.$$

Thus,

$$M_{\mathbb{C}}(\psi + \varphi i) = (\psi + \varphi i)z. \tag{38}$$

Hence, it is possible to associate to any solution (ψ, φ) of the system (37) a corresponding eigenvector of $M_{\mathbb{C}}$.

It is worth pointing out that the coupled system (35) can be obtained by solving the eigenvalue problem (13) for *complexified* quaternionic eigenvectors and *complexified* real eigenvalues. In fact, by imposing that

$$\psi \to \Psi = \psi + I\varphi \quad \in \mathbb{H}(1,i,j,k) \otimes \mathbb{C}(1,I),$$

and

$$r \to Z = \lambda + I\mu \quad \in \mathbb{C}(1,I),$$

from the *complexified* eigenvalue problem (13),

$$M_{\mathbb{R}}\Psi = \Psi Z,$$

we immediately get the coupled system (35).

B. Applications

Many physical problems dealing with differential operators are greatly simplified by using the matrix formalism and solving the corresponding eigenvalue problem.

Let us first consider a very simple case, that is, the $\mathbb{H}$-linear second order homogeneous ordinary differential equation

$$\ddot{\psi}(x) - \alpha\dot{\psi}(x) - \beta\psi(x) = 0, \quad \alpha,\beta \in \mathbb{H}, \quad x \in \mathbb{R}. \tag{39}$$

In looking for quaternionic exponential solution $\psi(x) = \exp[qx]$ and observing that the derivative of $\exp[qx]$ with respect to the real variable x is $q\exp[qx]$, we reduce the previous problem to find the solutions of the following quadratic equation

$$q^2 = \alpha q + \beta. \tag{40}$$

This equation can be rewritten in matrix form as follows:

$$M_{\mathbb{H}}\begin{pmatrix} q \\ 1 \end{pmatrix} = \begin{pmatrix} q^2 \\ q \end{pmatrix}, \quad M_{\mathbb{H}} = \begin{pmatrix} \alpha & \beta \\ 1 & 0 \end{pmatrix}. \tag{41}$$

As seen in this article, the $\mathbb{H}$-linear quaternionic matrix $M_{\mathbb{H}}$ satisfies a right (complex) eigenvalue equation

$$M_{\mathbb{H}}\begin{pmatrix} v \\ w \end{pmatrix} = \begin{pmatrix} v \\ w \end{pmatrix} z, \quad z \in \mathbb{C}, \quad v,w \in \mathbb{H}, \quad w\overline{w} = 1. \tag{42}$$

Due to the particular form of $M_{\mathbb{H}}$, the components of the $M_{\mathbb{H}}$-eigenvectors satisfy the following condition

$$v = wz. \tag{43}$$

Multiplying (from the right) Eq. (42) by $\overline{w}$ and using the constraint (43), we obtain

$$M_{\mathbb{H}}\begin{pmatrix} wz\overline{w} \\ 1 \end{pmatrix} = \begin{pmatrix} wz^2\overline{w} \\ wz\overline{w} \end{pmatrix}. \tag{44}$$

Comparing Eq. (41) with Eq. (44), we immediately get

$$q = wz\overline{w}. \tag{45}$$

The problem of finding exponential solutions for a $\mathbb{H}$-linear differential with constant coefficients and, consequently, zeros of $\mathbb{H}$-linear polynomial equations,[21] is thus equivalent to solving the right (complex) eigenvalue problem for the associated matrix. Obviously, the previous considerations also hold for the n-dimensional case.

The solutions of $\mathbb{X}$-linear quaternionic differential equations with constant coefficients

$$\psi^{(n)}(x)-A_{n-1,\mathbb{X}}\psi^{(n-1)}(x)-A_{n-2,\mathbb{X}}\psi^{(n-2)}(x)-\cdots -A_{0,\mathbb{X}}\psi(x)=0, \quad \mathbb{X}=\mathbb{R},\mathbb{C},\mathbb{H}, \tag{46}$$

can be given in terms of the eigenvalues and eigenvectors of the matrix

$$\begin{pmatrix} A_{n-1,\mathbb{X}} & A_{n-2,\mathbb{X}} & \cdots & A_{0,\mathbb{X}} \\ 1 & 0 & \cdots & 0 \\ . & . & \cdots & . \\ . & . & \cdots & . \\ . & . & \cdots & . \\ 0 & 0 & ..1 & 0 \end{pmatrix}.$$

Interesting $\mathbb{C}$-linear differential equations appear in quaternionic quantum mechanics.[3] For example, by studying quaternionic tunneling effects as a candidate to possible phenomenological deviations from the standard (complex) theory, we have to solve the following $\mathbb{H}$-linear Schrödinger equation,

$$\partial_t\Psi(x,t)=\left[\frac{i}{\hbar}\left(\frac{\hbar^2}{2m}\partial_{xx}-iV\right)+\frac{j}{\hbar}W\right]\Psi(x,t), \tag{47}$$

where $(j/\hbar)W$ represents the *new* quaternionic perturbation. The quaternionic stationary state wave function

$$\Psi(x,t)=\psi(x)\exp\left[-\frac{i}{\hbar}Et\right] \tag{48}$$

is a solution of Eq. (47) on the condition that $\psi(x)$ be a solution of the following time-independent $\mathbb{C}$-linear (ordinary) differential equation:

$$i\frac{\hbar^2}{2m}\ddot{\psi}(x)-iV\psi(x)+jW\psi(x)+\psi(x)iE=0. \tag{49}$$

Observe that the choice of the imaginary unit i in the Laplacian operator ∂_{xx}, Eq. (47), and in the time exponential, Eq. (48), is fundamental to recover the standard results in the complex limit. In this formalism, quaternionic potentials are treated as perturbation effects on standard quantum mechanics. We also point out that the right position of the time exponential is fundamental to perform the separation of variables.

The solution of Eq. (49) can be given in terms of the eigenvalues and eigenvectors of the $\mathbb{C}$-linear matrix

$$\begin{pmatrix} 0 & A_{0,\mathbb{C}} \\ 1 & 0 \end{pmatrix},$$

where

$$A_{0,\mathbb{C}}=\frac{2m}{\hbar^2}(V+L_kW+L_iR_iE).$$

A detailed phenomenological discussion of the quaternionic tunneling effect is found in the paper of Ref. 4.

C. Outlooks

As seen in this article, the choice of right (complex) eigenvalues for $\mathbb{H}$- and $\mathbb{C}$-linear operators plays a fundamental role in discussing canonical forms and in finding solutions of polynomial and differential equations. It was shown that the right (complex) eigenvalue problem is equivalent to a ''coupled'' system and this was extremely important to study the eigenvalue problem for $\mathbb{R}$-linear quaternionic matrices, where a pair of real eigenvalues must be introduced. This work was intended as an attempt at motivating the study of $\mathbb{R}$- and $\mathbb{C}$-linear quaternionic operators in view of possible applications in quantum mechanics and gauge theory. It would be desirable to give a complete theory of $\mathbb{X}$-linear quaternionic matrices and differential operators. More realistically, this article touches only a few aspects of the theory and shows how the choice of the right eigenvalue equation seems to be the best to investigate quaternionic formulations of physical theory. It was not our purpose to study here differential operators. The results in this field are far from being conclusive and some questions represent at present intriguing challenges: variations of parameters; order reduction; not invertible higher derivative $\mathbb{R}$- and $\mathbb{C}$-linear constant coefficients; variable coefficients; and integral transforms. Finally, it would be desirable to extend the discussion on the eigenvalue problem by matrix translation to the nonassociative case.[22–24]

ACKNOWLEDGMENTS

The authors wish to express their thanks to Professor N. Cohen and Professor G. Ducati for the helpful discussions during the preparation of the article and for drawing their attention to some interesting applications in matrix and differential operator theory. The authors also thank an anonymous referee for comments, references and suggestions. One of the authors (S.D.L.) gratefully acknowledges the University of Lecce (Department of Physics) and Curitiba (Department of Mathematics) for the hospitality, and the FAEP (State University of Campinas) for financial support.

Matrix models for beta ensembles

Ioana Dumitriu[a] and Alan Edelman[b]
Massachusetts Institute of Technology, Department of Mathematics, 77 Massachusetts Avenue, Cambridge, Massachusetts 02139

(Received 3 December 2001; accepted 3 June 2002)

This paper constructs tridiagonal random matrix models for general ($\beta>0$) β-Hermite (Gaussian) and β-Laguerre (Wishart) ensembles. These generalize the well-known Gaussian and Wishart models for $\beta=1,2,4$. Furthermore, in the cases of the β-Laguerre ensembles, we eliminate the exponent quantization present in the previously known models. We further discuss applications for the new matrix models, and present some open problems. © *2002 American Institute of Physics.*

I. INTRODUCTION

A. Overview

Classical random matrix theory focuses on the random matrix models in the following 3×3 table:

	Real, $\beta=1$	**Complex**, $\beta=2$	**Quaternion**, $\beta=4$
Hermite	GOE	GUE	GSE
Laguerre	Real Wishart	Complex Wishart	(Quaternion Wishart)
Jacobi	Real MANOVA	Complex MANOVA	(Quaternion MANOVA)

The two entries in parentheses (in the third column) correspond to less-studied random matrix models; the others are mainstream and have been extensively researched and publicized. The three columns correspond to Dyson's ''threefold way'' $\beta=1,2$, and 4; the three rows correspond to the weight function associated to the random matrix model. Other weight functions have also been considered (for example, the uniform weight on the unit circle corresponds to the circular ensembles).

Zirnbauer[33] and Ivanov[12] produced a more general taxonomy of random matrix models. Their characterizations (''tenfold,'' and ''twelvefold,'' respectively) are based on symmetric spaces, and include Hermite, Laguerre, and Jacobi cases, and also the circular ensembles (each of their models can be associated with $\beta=1,2$ or 4).

We propose a random matrix program of study that would generalize β beyond the above-mentioned threefold way, thus generalizing the 3×3 Cartesian product to $3\times\infty$, making the leap from discrete characterizations to continuous ones. A step in this direction has been initiated by Forrester,[2,10] who studied the β-ensembles in connection with multivariate orthogonal polynomials and Calogero–Sutherland-type quantum systems. Furthermore, in the case of the classical Laguerre and Jacobi models, our program goes beyond the quantized exponents forced by the classical models, and proposes continuous ones.

For the benefit of the reader we have expanded the 3×3 table with detailed information in Fig. 1.

FIG. 1. Random matrix ensembles. As a guide to MATLAB notation, randn(m,n) produces an $m\times n$ matrix with i.i.d. standard normal entries, conj(X) produces the complex conjugate of the matrix X, and the apostrophe $(')$ operator produces the conjugate transpose of a matrix. Also $[X\ Y;\ Z\ W]$ produces a 2×2 block matrix.

B. Background

The Gaussian (or Hermite) ensembles arise in physics, and are identified by Dyson[7] by the group over which they are invariant: Gaussian Orthogonal or for short GOE (with real entries), Gaussian Unitary or GUE (with complex entries), and Gaussian Symplectic or GSE (with quaternion entries). The Wishart ensembles arise in statistics, and the three corresponding models could be named Wishart real, Wishart complex, and Wishart quaternion.

The three Gaussian ensembles have joint eigenvalue probability density function

$$\text{HERMITE: } f_\beta(\lambda)=c_H^\beta \prod_{i<j} |\lambda_i-\lambda_j|^\beta \exp\left(-\sum_{i=1}^{n} \lambda_i^2/2\right), \tag{1}$$

with $\beta=1$ corresponding to the reals, $\beta=2$ to the complexes, $\beta=4$ to the quaternions, and with

$$c_H^\beta=(2\pi)^{-n/2}\prod_{j=1}^{n}\frac{\Gamma\left(1+\frac{\beta}{2}\right)}{\Gamma\left(1+\frac{\beta}{2}j\right)}. \tag{2}$$

The best references are Mehta[18] and the original paper by Dyson.[7]

Similarly, the Wishart (or Laguerre) models have joint eigenvalue p.d.f.

$$\text{LAGUERRE: } f_\beta(\lambda)=c_L^{\beta,a}\prod_{i<j}|\lambda_i-\lambda_j|^\beta\prod_i \lambda_i^{a-p}\exp\left(\sum_{i=1}^n \lambda_i/2\right), \tag{3}$$

with $a=(\beta/2)\,n$ and $p=1+(\beta/2)\,(m-1)$. Again, $\beta=1$ for the reals, $\beta=2$ for the complexes, and $\beta=4$ for the quaternions. The constant

$$c_L^{\beta,a}=2^{-ma}\prod_{j=1}^m \frac{\Gamma\left(1+\frac{\beta}{2}\right)}{\Gamma\left(1+\frac{\beta}{2}j\right)\Gamma\left(a-\frac{\beta}{2}(m-j)\right)}. \tag{4}$$

Good references are Refs. 21, 8, and 13, and for $\beta=4$, Ref. 17.

To complete the triad of classical orthogonal polynomials, we will mention the β-MANOVA ensembles, which are associated with the multivariate analysis of variance (MANOVA) model. They are better known in the literature as the Jacobi ensembles, with joint eigenvalue p.d.f.

$$\text{JACOBI: } f_\beta(\lambda)=c_J^{\beta,a_1,a_2}\prod_{i<j}|\lambda_i-\lambda_j|^\beta\prod_{j=1}^n \lambda_i^{a_1-p}(1-\lambda_i)^{a_2-p}, \tag{5}$$

with $a_1=(\beta/2)\,n_1$, $a_2=(\beta/2)\,n_2$, and $p=1+(\beta/2)\,(m-1)$. As usual, $\beta=1$ for real and $\beta=2$ for complex; also

$$c_J^{\beta,a_1,a_2}=\prod_{j=1}^m \frac{\Gamma\left(1+\frac{\beta}{2}\right)\Gamma\left(a_1+a_2-\frac{\beta}{2}(m-j)\right)}{\Gamma\left(1+\frac{\beta}{2}j\right)\Gamma\left(a_1-\frac{\beta}{2}(m-j)\right)\Gamma\left(a_2-\frac{\beta}{2}(m-j)\right)}. \tag{6}$$

The MANOVA real and complex cases ($\beta=1$ and 2) have been studied by statisticians (see Ref. 21).

Though ''Gaussian,'' ''Wishart,'' and ''MANOVA'' are the traditional names for the three types of β-ensembles, we prefer the sometimes used and technically more informative names ''Hermite,'' ''Laguerre,'' and ''Jacobi'' ensembles. These technical names reflect the fact that the p.d.f.s for the ensembles correspond to the p.d.f.s $\text{etr}(-A^2/2)$, $\det(A)^{a-p}\text{etr}(-A/2)$, and $\det(A)^{a_1-p}\det(I-A)^{a_2-p}$ over their respective spaces of matrices. In turn, these functions correspond to three sets of orthogonal polynomials (Hermite, Laguerre, Jacobi). Throughout this paper, we will use the term ''general β-Hermite, -Laguerre, -Jacobi ensembles'' for general β in the p.d.f.s (1), (3), (5).

Though it was believed that no other choice of β would correspond to a matrix model constructed with entries from a classical distribution, there have been studies of general β-Hermite ensembles as theoretical eigenvalue distributions. They turn out to have important applications in lattice gas theory (see Refs. 10 and 2).

The general β ensembles appear to be connected to a broad spectrum of mathematics and physics, among which we list lattice gas theory, quantum mechanics, and Selberg-type integrals. Also, the β ensembles are connected to the theory of Jack polynomials (with the correspondence $\alpha=2/\beta$ where α is the Jack parameter), which are currently objects of intensive research (see Refs. 27, 17, and 23).

TABLE I. Random matrix constructions.

Hermite matrix $n \in \mathbb{N}$	$H_\beta \sim \frac{1}{\sqrt{2}} \begin{pmatrix} N(0,2) & \chi_{(n-1)\beta} & & & & \\ \chi_{(n-1)\beta} & N(0,2) & \chi_{(n-2)\beta} & & & \\ & \ddots & \ddots & \ddots & & \\ & & \chi_{2\beta} & N(0,2) & \chi_\beta & \\ & & & \chi_\beta & N(0,2) \end{pmatrix}$
Laguerre matrix $m \in \mathbb{N}$ $a \in \mathbb{R}$ $a > \frac{\beta}{2}(m-1)$	$L_\beta = B_\beta B_\beta^T$, where $B_\beta \sim \begin{pmatrix} \chi_{2a} & & & \\ \chi_{\beta(m-1)} & \chi_{2a-\beta} & & \\ & \ddots & \ddots & \\ & & \chi_\beta & \chi_{2a-\beta(m-1)} \end{pmatrix}$

C. Our results

Dyson's original threefold way is a byproduct of the invariance assumptions as in the ''Invariance'' column of Fig. 1. By necessity, any invariant distribution is generically dense. Further, the invariance approach forces the consideration of the complex and quaternion division algebras.

In this paper, we drop the invariance requirement. What we gain are ''sparse'' models (with only $O(n)$ nonzero parameters) over the reals numbers *only*. As an additional bonus, we go beyond the quantizations of the classical cases $\beta = 1,2,4$ and obtain continuous exponents (see Sec. IV for further discussion of this point).

We provide real tridiagonal random matrix models for all β-Gaussian (or Hermite) and β-Wishart (or Laguerre) ensembles, and we discuss the possibility of constructing a real matrix model for the β-MANOVA (or Jacobi) ensembles.

We obtain our results by extrapolating the classical cases, thereby providing concrete models for what have previously been considered purely theoretical distributions.

In Sec. II we establish results for symmetric tridiagonal matrices, and we use them to construct tridiagonal models for the β-Hermite ensembles. Along the way, we obtain a short proof based on random matrix theory for the Jacobian of the transformation $T \to (q, \lambda)$, where T is a symmetric tridiagonal matrix, λ is its set of eigenvalues, and q is the first row of its eigenvector matrix. In Sec. III we construct tridiagonal models for the β-Laguerre ensembles, by building on the same set of ideas that we use in Sec. II. In Sec. IV we present some immediate applications of the new classes of ensembles and we discuss the β-Jacobi ensembles and other interesting open problems.

We display our random matrix constructions in Table I.

II. THE β-HERMITE (GAUSSIAN) ENSEMBLES

A. Motivation: Tridiagonalizing the GOE, GUE, and GSE

The joint distribution $f_\beta(\lambda)$ of the eigenvalues for the GOE, GUE, and GSE is

$$f_\beta(\Lambda) = c_H^\beta |\Delta(\lambda)|^\beta \exp\left(-\frac{1}{2} \sum_i \lambda_i^2 \right), \tag{7}$$

where $\beta = 1,2,4$.[18] Here the Vandermonde determinant notation $\Delta(\lambda)$ stands for $\Pi_{i \neq j}(\lambda_i - \lambda_j)$, and c_H^β is given by (2).

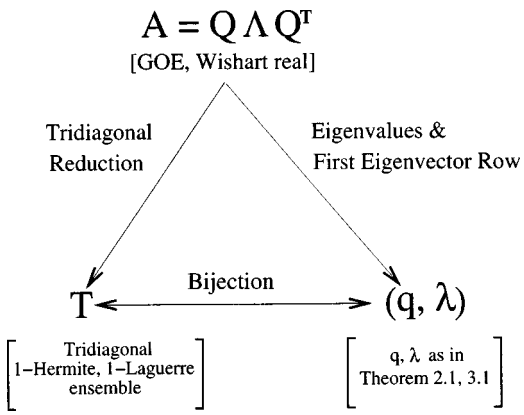

FIG. 2. A dense symmetric matrix A can be tridiagonalized (left-hand side) or diagonalized (right-hand side). In brackets, we provide the distributions starting with that of A (GOE or Wishart real).

We will prove in Sec. II B that the tridiagonal β-Hermite random matrix displayed in Table I has the joint eigenvalue p.d.f. given by general β in (7). For motivation, we will begin with a quick ''back-door'' proof for $\beta=1$ by tridiagonalizing the GOE; then we will extend the result to the GUE and GSE.

To illustrate the proof and help the reader follow it more easily, we have included the diagram of Fig. 2.

Theorem 2.1: *If A is an $n\times n$ matrix from the GOE, then reduction of A to tridiagonal form shows that the matrix T from the 1-Hermite ensemble has joint eigenvalue p.d.f. given by (7) with $\beta=1$.*

Proof: We write $A=\left(\begin{smallmatrix} a_n & x^T \\ x & B \end{smallmatrix}\right)$. Here a_n is a standard Gaussian, x is a vector of $(n-1)$ i.i.d. Gaussians of mean 0 and variance 1/2, and B is an $(n-1)\times(n-1)$ matrix from the GOE; a_n, x and B are all independent from each other.

Let H be any $(n-1)\times(n-1)$ orthogonal matrix (depending only on x) such that

$$Hx=[\|x\|_2\ 0...0]^T\equiv\|x\|_2 e_1,$$

where $e_1=[1,0,\ldots,0]^T$. Then clearly

$$\begin{pmatrix} 1 & 0 \\ 0 & H \end{pmatrix}\begin{pmatrix} a_n & x^T \\ x & B \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & H^T \end{pmatrix}=\begin{pmatrix} a_n & \|x\|_2 e_1^T \\ \|x\|_2 e_1 & HBH^T \end{pmatrix}.$$

Since A is from the GOE and H depends only on x, we can readily identify the distributions of a_n, $\|x\|_2$, and HBH^T (these three quantities are clearly independent). The entry a_n is unchanged and thus a standard normal with variance 1. Being the length of a multivariate Gaussian of mean 0 and entry variance 1/2, $\|x\|_2$ has the distribution $(1/\sqrt{2})\,\chi_{n-1}$. It is worth mentioning that the p.d.f. of $\|x\|_2$ is given by

$$\frac{2}{\Gamma\left(\frac{n-1}{2}\right)}y^{n-2}e^{-y^2}.$$

Finally, by the orthogonal invariance of the GOE, HBH^T is an $(n-1)\times(n-1)$ matrix from the GOE.

Proceeding by induction completes the tridiagonal construction.

Because the only operations we perform on A are orthogonal similarity transformations, which do not affect the eigenvalues, the conclusion of the theorem follows. □

We recall that matrices from the GOE have the following properties:

Property 1: The joint eigenvalue density is $c_H^1|\Delta(\lambda)|\exp(-\frac{1}{2}\Sigma_i\lambda_i^2)$.[18]

Property 2: The first row of the eigenvector matrix is distributed uniformly on the sphere, and it is independent of the eigenvalues.

The second property is an immediate consequence of the fact that the eigenvector matrix of a GOE matrix is independent from the eigenvalues [Ref. 18, (3.1.3) and (3.1.16), pp. 55–58], and has the Haar (uniform) distribution because of the orthogonal invariance.

The following corollary is easily established.

Corollary 2.2: If T is a matrix from the 1-Hermite ensemble, with eigendecomposition $T=Q\Lambda Q^T$, then the first row q of the eigenvector matrix Q is independent of Λ, and is distributed uniformly on the sphere.

Proof: If $A=Q_1\Lambda Q_1^T$ and $T=HAH^T$, then $Q=HQ_1$. Since each one of the reflectors which form H has first row e_1, multiplication by H does not affect the first row of Q_1. The conclusion follows. □

Reduction to tridiagonal form is a familiar algorithm which solves the symmetric eigenvalue problem. The special ''reflector'' matrix H used in practice for a vector $x=[x_1,\ldots,x_{n-1}]^T$ is

$$H=I-2\frac{uu^T}{u^Tu},$$

where $u=x\pm x_1\ e_1$. This special matrix H is known as the ''Householder reflector'' (see Ref. 11, p. 209).

The tridiagonal reduction algorithm can be applied to any real symmetric, complex hermitian, or quaternion self-dual matrix; the resulting matrix is always a real, symmetric tridiagonal. Using the algorithm similarly on a GUE or GSE matrix one gets the following.

Corollary 2.3: When $\beta=2,4$, reduction to tridiagonal form of matrices from the GUE, respectively, GSE, shows that the tridiagonal 2-Hermite, respectively, 4-Hermite, random matrix has the distribution given by (7). Note that β "counts" the number of independent Gaussians in each entry of the matrix.

Remark 2.4: The observation that numerical linear algebra algorithms may be performed statistically is not new; it may be found in the literature (see Trotter—Ref. 31, Silverstein—Ref. 26, and Edelman—Ref. 8).

B. Tridiagonal matrix lemmas

In this section we prove lemmas that will be used in our constructions in Secs. II C and III B.

Given a tridiagonal matrix T defined by the diagonal $a=(a_n,\ldots,a_1)$ and subdiagonal $b=(b_{n-1},\ldots,b_1)$, with all b_i positive, let $T=Q\Lambda Q^T$ be the eigendecomposition of T as in Theorem 2.12. Let q be the first row of Q and $\lambda=\mathrm{diag}(\Lambda)$.

Lemma 2.5: Under the above-given assumptions, starting from q and λ, one can uniquely reconstruct Q and T.

Proof: This is a special case of the more general Theorem 7.2.1 in Parlett.[24] □

Remark 2.6: It follows that, except for sets of measure 0, the map $T\to(q,\lambda)$ is a bijection from the set of tridiagonal matrices of size n with positive subdiagonal, to the set of pairs (q,λ), with q a unit norm n-dimensional vector of positive real entries, and λ a strictly increasingly ordered sequence of n real numbers. Let the bijection's Jacobian be denoted by J

$$J=\left\{\frac{\partial(a,b)}{\partial(q,\lambda)}\right\}.$$

Our next lemma establishes a formula for the Vandermonde determinant of the eigenvalues of a tridiagonal matrix.

Lemma 2.7: The Vandermonde determinant for the ordered eigenvalues of a symmetric tridiagonal matrix with positive subdiagonal $b=(b_{n-1},\ldots,b_1)$ is given by

$$\Delta(\lambda)=\prod_{i<j}(\lambda_i-\lambda_j)=\frac{\Pi_{i=1}^{n-1}b_i^i}{\Pi_{i=1}^{n}q_i},$$

where $(q_1,\ldots,q_n)$ *is the first row of the eigenvector matrix.*

Proof: Let $\lambda_i^{(k)}$, $i=1...k$, be the eigenvalues of the $k\times k$ lower right-corner submatrix of T. Then $P_k(x)=\Pi_{i=1}^{k}(x-\lambda_i^{(k)})$ is the associated characteristic polynomial of that submatrix.

For $k=1,\ldots,n$ we have the three-term recurrence

$$P_k(x)=(x-a_k)P_{k-1}(x)-b_{k-1}^2P_{k-2}(x), \tag{8}$$

and the two-term relation

$$\prod_{\substack{1\leqslant i\leqslant k\\ 1\leqslant j\leqslant k-1}}|\lambda_i^{(k)}-\lambda_j^{(k-1)}|=\prod_{i=1}^{k}|P_{k-1}(\lambda_i^{(k)})|=\prod_{j=1}^{k-1}|P_k(\lambda_j^{(k-1)})|. \tag{9}$$

From (8) we get

$$\left|\prod_{i=1}^{k-1}P_k(\lambda_i^{(k-1)})\right|=b_{k-1}^{2(k-1)}\left|\prod_{i=1}^{k-1}P_{k-2}(\lambda_i^{(k-1)})\right|. \tag{10}$$

By repeatedly applying (8) and (2.9) we obtain

$$\prod_{i=1}^{n-1}|P_n(\lambda_i^{(n-1)})|=b_{n-1}^{2(n-1)}\qquad\prod_{i=1}^{n-2}|P_{n-1}(\lambda_i^{(n-2)})| \tag{11}$$

$$=b_{n-1}^{2(n-1)}\quad b_{n-2}^{2(n-2)}\quad\left|\prod_{i=1}^{n-2}P_{n-3}(\lambda_i^{(n-2)})\right| \tag{12}$$

$$=\ldots \tag{13}$$

$$=\prod_{i=1}^{n-1}b_i^{2i}. \tag{14}$$

Finally, we use the following formula due to Paige, found in Ref. 24, as the more general Theorem 7.9.2:

$$q_i^2=\left|\frac{P_{n-1}(\lambda_i)}{P_n'(\lambda_i)}\right|=\left|\frac{P_{n-1}(\lambda_i^{(n)})}{P_n'(\lambda_i^{(n)})}\right|. \tag{15}$$

It follows that

$$\prod_{i=1}^{n}q_i^2=\frac{\Pi_{i=1}^{n}|P_{n-1}(\lambda_i^{(n)})|}{\Delta(\lambda)^2}=\frac{\Pi_{i=1}^{n-1}b_i^{2i}}{\Delta(\lambda)^2}, \tag{16}$$

which proves the result.

Remark 2.8: The Vandermonde determinant formula of Lemma 2.7 can also be obtained from the Heine formula, as presented in Deift (Ref. 5, p. 44).

The next lemma computes the Jacobian J by relating the tridiagonal and diagonal forms of a GOE matrix, as in Fig. 2.

Lemma 2.9: The Jacobian J can be written as

$$J=\frac{\Pi_{i=1}^{n-1}b_i}{\Pi_{i=1}^{n}q_i}.$$

Proof: To obtain the Jacobian, we will study the transformation from GOE to 1-Hermite ensemble (see Fig. 2). Note that J does *not* depend on β; hence computing the Jacobian for this case is sufficient.

Let T be a 1-Hermite matrix. We know from Sec. II A that the eigenvalues of T are distributed as the eigenvalues of a symmetric GOE matrix A, from which T can be obtained via tridiagonal reduction ($T=HAH^T$ for some orthogonal H, which is the product of the consecutive reflections described in Sec. II A).

The joint element distribution for the matrix T is

$$\mu(a,b)=c_{a,b}\exp\left(-\frac{1}{2}\sum_{i=1}^{n}a_i^2\right)\prod_{i=1}^{n}b_i^{i-1}\exp\left(-\sum_{i=1}^{n}b_i^2\right),$$

where

$$c_{a,b}=\frac{2^{n-1}}{(2\pi)^{n/2}\Pi_{i=1}^{n-1}\Gamma\left(\frac{i}{2}\right)}.$$

Let

$$\mathrm{d}a=\wedge_{i=1}^{n}\mathrm{d}a_i,\quad \mathrm{d}b=\wedge_{i=1}^{n-1}\mathrm{d}b_i,\quad \mathrm{d}\lambda=\wedge_{i=1}^{n}\lambda_i,$$

and $\mathrm{d}q$ be the surface element of the n-dimensional sphere. Let $\mu(a(q,\lambda),b(q,\lambda))$ be the expression for $\mu(a,b)$ in the new variables q,λ. We have that

$$\mu(a,b)\mathrm{d}a\,\mathrm{d}b=J\ \ \mu(a(q,\lambda),b(q,\lambda))\mathrm{d}q\,\mathrm{d}\lambda\equiv\nu(q,\lambda)\ \ \mathrm{d}q\,\mathrm{d}\lambda. \tag{17}$$

We combine Properties 1 and 2 of Sec. II A to get the joint p.d.f. $\nu(q,\lambda)$ of the eigenvalues and first eigenvector row of a GOE matrix, and rewrite it as

$$\nu(q,\lambda)\mathrm{d}q\,\mathrm{d}\lambda=n!c_H^1\frac{2^{n-1}\Gamma\left(\frac{n}{2}\right)}{\pi^{n/2}}\Delta(\lambda)\exp\left(-\frac{1}{2}\sum_i\lambda_i^2\right)\mathrm{d}q\,\mathrm{d}\lambda.$$

We have introduced the $n!$ and removed the absolute value from the Vandermonde, because the eigenvalues are ordered. We have also included the distribution of q (as mentioned in Property 2, it is uniform, but only on the all-positive 2^{-n}th of the sphere because of the condition $q_i\geqslant 0$.)

Since orthogonal transformations do not change the Frobenius norm $\|A\|_F=\Sigma_{i,j=1}^{n}a_{ij}^2$ of a matrix A, from (17), it follows that

$$J=\frac{\nu(q,\lambda)}{\mu(a,b)}=\frac{n!c_H^1\dfrac{2^{n-1}\Gamma\left(\frac{n}{2}\right)}{\pi^{n/2}}}{c_{a,b}}\frac{\Delta(\lambda)}{\Pi_{i=1}^{n}b_i^{i-1}}.$$

All constants cancel, and by Lemma 2.7 we obtain

$$J=\frac{\Pi_{i=1}^{n-1}b_i}{\Pi_{i=1}^{n}q_i}.$$

Note that we have not expressed $\mu(a,b)$ in terms of q and λ in the above, and have thus obtained the expression for the Jacobian neither in the variables q and λ, nor a and b, solely; but rather in a mixture of the two sets of variables. The reason for this is that of simplicity. □

Remark 2.10: Our derivation of the Jacobian is a true random matrix derivation. Alternate derivations of the Jacobian can be obtained either via symplectic maps or through direct calculation.

The last lemma of this section computes one more Jacobian, which will be needed in Sec. III B.

Let B be a bidiagonal matrix with positive diagonal $x=(x_m,\ldots,x_1)$ and positive subdiagonal $y=(y_{m-1},\ldots,y_1)$. Let $T=BB^T$; denote by $a=(a_m,\ldots,a_1)$ and $b=(b_{m-1},\ldots,b_1)$, respectively, the diagonal and the subdiagonal part of T. Since T is a positive definite matrix, the transformation $B\to T$ is a bijection from the set of bidiagonal matrices with positive entries to the set of positive definite tridiagonal matrices.

Lemma 2.11: The Jacobian $J_{(B\to T)}$ is

$$J_{(B\to T)}=\left(2^m x_1\prod_{i=2}^{m} x_i^2\right)^{-1}.$$

Proof: We compute $J_{(B\to T)}$ from the formula

$$\mathrm{d}x\,\mathrm{d}y=J_{(B\to T)}\mathrm{d}a\,\mathrm{d}b,$$

where $\mathrm{d}z=\wedge_i \mathrm{d}z_i$ for all $z\in\{a,b,x,y\}$.

We have that

$$a_m=x_m^2, \tag{18}$$

$$a_i=y_i^2+x_i^2, \tag{19}$$

$$b_i=y_i x_{i+1}, \tag{20}$$

for all $i=m-1,m-2,\ldots,1$.

Hence by computing differentials we get

$$\mathrm{d}a_m=2x_m\,\mathrm{d}x_m$$

$$\mathrm{d}a_i=2(x_i\,\mathrm{d}x_i+y_i\,\mathrm{d}y_i),\quad \forall i=m-1,m-2,\ldots,1$$

$$\mathrm{d}b_i=x_{i+1}\mathrm{d}y_i+y_i\,\mathrm{d}x_{i+1},\quad \forall i=m-1,m-2,\ldots,1,$$

from which the formula follows. □

C. The eigendistribution of the β-Hermite ensemble

Let H_β be a random real symmetric, tridiagonal matrix whose distribution we schematically depict as

$$H_\beta\sim\frac{1}{\sqrt{2}}\begin{pmatrix} N(0,2) & \chi_{(n-1)\beta} & & & & \\ \chi_{(n-1)\beta} & N(0,2) & \chi_{(n-2)\beta} & & & \\ & \ddots & \ddots & \ddots & & \\ & & \chi_{2\beta} & N(0,2) & \chi_\beta & \\ & & & \chi_\beta & N(0,2) & \end{pmatrix}.$$

By this we mean that the n diagonal elements and the $n-1$ subdiagonals are mutually independent, with standard normals on the diagonal, and $1/\sqrt{2}\,\chi_{k\beta}$ on the subdiagonal.

Theorem 2.12: *Let $H_\beta = Q\Lambda Q^T$ be the eigendecomposition of H_β; fix the signs of the first row of Q to be non-negative and order the eigenvalues in increasing order on the diagonal of $\lambda = \mathrm{diag}(\Lambda)$. Then λ and q, the first row of Q, are independent. Furthermore, the joint density of the eigenvalues is*

$$f_\beta(\lambda) = c_H^\beta \prod_{i<j} |\lambda_i - \lambda_j|^\beta \exp\left(-\frac{1}{2}\sum_{i=1}^n \lambda_i^2\right) = c_H^\beta |\Delta(\lambda)|^\beta \exp\left(-\frac{1}{2}\sum_{i=1}^n \lambda_i^2\right),$$

and $q = (q_1,\ldots,q_n)$ is distributed as $(\chi_\beta,\ldots,\chi_\beta)$, normalized to unit length.

Proof of Theorem 2.12: Just as before, we denote by $a = (a_n,\ldots,a_1)$ the diagonal of H_β, and by $b = (b_{n-1},\ldots,b_1)$ the subdiagonal. The differentials $\mathrm{d}a, \mathrm{d}b, \mathrm{d}q, \mathrm{d}\lambda$ are the same as in Lemma 2.9.

For general β, we have that

$$(\mathrm{d}H_\beta) \equiv \mu(a,b)\,\mathrm{d}a\,\mathrm{d}b = c_{a,b} \prod_{k=1}^{n-1} b_k^{k\beta-1} \exp\left(-\frac{1}{2}\|T_1\|_F\right)\mathrm{d}a\,\mathrm{d}b$$

$$= c_{a,b} J \prod_{k=1}^{n-1} b_k^{k\beta-1} \exp\left(-\frac{1}{2}\|T_1\|_F\right)\mathrm{d}q\,\mathrm{d}\lambda,$$

where

$$c_{a,b} = \frac{2^{n-1}}{(2\pi)^{n/2}\prod_{k=1}^{n-1}\Gamma\left(\frac{\beta}{2}k\right)}.$$

With the help of Lemmas 2.7 and 2.9 this identity becomes

$$(\mathrm{d}H_\beta) = c_{a,b}\frac{\prod_{k=1}^{n-1} b_k}{\prod_{k=1}^n q_k} \prod_{k=1}^{n-1} b_k^{k\beta-1} \exp\left(-\frac{1}{2}\|T_1\|_F\right)\mathrm{d}q\,\mathrm{d}\lambda \tag{21}$$

$$= c_{a,b}\frac{\prod_{k=1}^{n-1} b_k^{k\beta}}{\prod_{i=1}^n q_i^\beta} \prod_{i=1}^{n} q_i^{\beta-1} \exp\left(-\frac{1}{2}\sum_i \lambda_i^2\right)\mathrm{d}q\,\mathrm{d}\lambda. \tag{22}$$

Thus

$$(\mathrm{d}H_\beta) = \left(c_q^\beta \prod_{i=1}^n q_i^{\beta-1}\,\mathrm{d}q\right)\left(n!\,c_H^\beta \Delta(\lambda)^\beta \exp\left(-\frac{1}{2}\sum_i \lambda_i^2\right)\mathrm{d}\lambda\right).$$

Since the joint density function of q and λ separates, q and λ are independent. Moreover, once we drop the ordering imposed on the eigenvalues, it follows that the joint eigenvalue density of H_β is $c_H^\beta |\Delta(\lambda)|^\beta \exp(-\frac{1}{2}\Sigma_i \lambda_i^2)$, and q is distributed as $(\chi_\beta,\ldots,\chi_\beta)$, normalized to unit length. From (22), it also follows that

$$c_q^\beta = \frac{2^{n-1}\Gamma\left(\frac{\beta}{2}n\right)}{\left[\Gamma\left(\frac{\beta}{2}\right)\right]^n}. \tag{23}$$

III. THE β-LAGUERRE (WISHART) ENSEMBLES

A. Motivation: Tridiagonalizing the Wishart ensembles

The preceding section gives tridiagonal random matrix models for all β-Hermite ensembles. In the following we define the β-Laguerre ensembles, and give tridiagonal random matrix models for them.

The Wishart ensembles have joint eigenvalue density

$$f_\beta(\lambda)=c_L^{\beta,a}|\Delta(\lambda)|^\beta\prod_{i=1}^m \lambda_i^{a-p}\exp\left(-\sum_{i=1}^m \lambda_i/2\right), \tag{24}$$

again with $a=(\beta/2)\,n$, $p=1+(\beta/2)\,(m-1)$, and with, respectively, $\beta=1$ for real, and $\beta=2$ for complex. Here $c_L^{\beta,a}$ as the same as in (4).

From now on p will always denote the quantity $1+(\beta/2)\,(m-1)$, following the notation of Muirhead for $\beta=1$ (Ref. 21, Chap. 7) and Forrester[10] (Forrester uses $1+(1/\alpha)\,(m-1)$, where $\alpha=2/\beta$ is the Jack parameter). Its presence is implicit in the p.d.f. of all β-Laguerre ensembles; hence we will identify the ensembles by β and by a (we call the latter the ''Laguerre'' parameter, generalizing from the univariate case $\beta=1$, $m=1$).

As in Sec. II A, we will provide the most basic case for our construction: the case $\beta=1$ and Wishart real exponent $(n-m-1)/2$ (also referred to as the case $\beta=1$ and Laguerre parameter $a=n/2$).

Theorem 3.1: *Let G be an $m\times n$ matrix of i.i.d. standard Gaussians; then $W=GG^T$ is a Wishart real matrix. By reducing G to bidiagonal form B one obtains that the matrix $T=BB^T$ from the 1-Laguerre ensemble of Laguerre parameter $a=n/2$ (defined as in Table I) has the joint eigenvalue p.d.f. given by (24).*

Proof: We write

$$G=\begin{pmatrix} x^T \\ G_1 \end{pmatrix},$$

with x^T a row multivariate standard Gaussian of length n and G_1 a $(m-1)\times n$ matrix of i.i.d. standard Gaussians. Let R be a right reflector corresponding to the vector x^T ($R^Tx=\|x\|_2\,e_1^T$) which is independent of G_1. Hence G_1R is a matrix of i.i.d. standard Gaussians.

Write $G_1R=[y,G_2]$, where y is a column multivariate standard Gaussian of length $m-1$ and G_2 is a $(m-1)\times(n-1)$ matrix of i.i.d. standard Gaussians. Let L be a left reflector corresponding to y ($Ly=\|y\|_2\,e_1$) which is independent of G_2. Then we have that

$$\begin{pmatrix} 1 & 0 \\ 0 & L \end{pmatrix} GR=\begin{pmatrix} \|x\|_2 & 0 \\ \|y\|_2\,e_1 & LG_2 \end{pmatrix}.$$

As we have seen before, $\|x\|_2$ is distributed like χ_{n-1}, $\|y\|_2$ is distributed like χ_{m-1}, and LG_2 is a matrix of i.i.d. standard Gaussians (since L and G_2 are independent).

We proceed inductively to finish the bidiagonal construction of B.

Because the operations we have performed on G are orthogonal left and right multiplications, which do not affect the singular values, it follows that the singular values of G and B are the same. Since the squares of the singular values of G and B, respectively, are the eigenvalues of W and T, respectively, the conclusion of the theorem follows. □

Remark 3.2: The bidiagonalization process presented above is part of a familiar numerical linear algebra algorithm for computing the singular values of a matrix.

Corollary 3.3: The same process of bidiagonalization performed on $\tilde{G}$, a matrix of i.i.d. standard complex (standard quaternion) Gaussians, shows that the matrix $\tilde{W}=\tilde{G}\tilde{G}^T$ and the matrix T from the 2-Laguerre (4-Laguerre) ensemble of parameter $a=n$ ($a=2n$) has the joint

eigenvalue p.d.f. given by (24). In all three cases (real, complex, quaternion) we say that T represents the tridiagonalization of the Wishart (real, complex, quaternion) ensemble.

In Sec. III B we prove the general form of the theorem.

B. The Eigendistribution of β-Laguerre ensemble

Let

$$B_\beta \sim \begin{pmatrix} \chi_{2a} & & & \\ \chi_{\beta(m-1)} & \chi_{2a-\beta} & & \\ & \ddots & \ddots & \\ & & \chi_\beta & \chi_{2a-\beta(m-1)} \end{pmatrix},$$

by this we mean that all of the $2m-1$ diagonal and subdiagonal elements are mutually independent with the corresponding χ distribution.

Let $L_\beta = B_\beta B_\beta^T$ be the corresponding tridiagonal matrix.

Theorem 3.4: *Let $L_\beta = Q\Lambda Q^T$ be the eigendecomposition of L_β; fix the signs of the first row of Q to be non-negative and order the eigenvalues increasingly on the diagonal of Λ. Then Λ and the first row q of Q are independent. Furthermore, the joint density of the eigenvalues is*

$$f_\beta(\lambda) = c_L^{\beta,a} |\Delta(\lambda)|^\beta \prod_{i=1}^n \lambda_i^{a-p} \exp\left(-\sum_{i=1}^n \lambda_i/2 \right),$$

where $p = 1 + (\beta/2)(m-1)$, and q is distributed as $(\chi_\beta, \ldots, \chi_\beta)$ normalized to unit length.

Proof of Theorem 3.4: We will use throughout the results of Lemma 2.7, Lemma 2.9, Lemma 2.11, and Remark 2.6, which are true in the context of tridiagonal symmetric matrices with positive subdiagonal entries. By definition, L_β is such a matrix.

We will again use the notations of Lemma 2.9 and 2.11 for the differentials da, db, dq, $d\lambda$, dx, and dy.

We define (dB_β) to be the joint element distribution on B_β

$$(dB_\beta) \equiv \mu(x,y)\,dx\,dy = c_{x,y} \prod_{i=0}^{m-1} x_{m-i}^{a-\beta_i-1} \exp(-x_i^2/2) \prod_{i=1}^{m-1} y_i^{\beta_i-1} \exp(-y_i^2/2)\,dx\,dy.$$

By using Lemma 24 we obtain the joint element distribution on L_β as

$$(dL_\beta) \equiv J_{B\to T}^{-1} \mu(x,y)\,dx\,dy \tag{25}$$

$$= 2^{-m} c_{x,y} x_1^{2a-\beta(m-1)-2} \exp(-x_1^2/2) \prod_{i=0}^{m-2} x_{m-i}^{a-\beta_i-3}$$

$$\times \exp(-x_i^2/2) \prod_{i=1}^{m-1} y_i^{\beta_i-1} \exp(-y_i^2/2)\,dx\,dy, \tag{26}$$

where

$$c_{x,y} = \frac{\Pi_{i=1}^{m-1} \Gamma\left(i\frac{\beta}{2} \right) \Pi_{i=1}^{m} \Gamma\left(a - \frac{\beta}{2}(i-1) \right)}{2^{2m-1}}.$$

We rewrite (26) in terms of x, y, λ, and q:

$$
\begin{aligned}
(dL_\beta) &= 2^{-m} c_{x,y} \exp\left(-\sum_{i=1}^{m} x_i^2/2 \right) \exp\left(-\sum_{i=1}^{m-1} y_i^2/2 \right) \frac{\Pi_{i=1}^{m-1}(x_{i+1}y_i)}{\Pi_{i=1}^{m} q_i} x_1^{2a-\beta(m-1)-2} \\
&\quad \times \prod_{i=0}^{m-2} x_{m-i}^{2a-\beta(m-i)-3} \prod_{i=1}^{m-1} y_i^{\beta_i - 1} \mathrm{d}q \, \mathrm{d}\lambda \\
&= 2^{-m} c_{x,y} \exp\left(-\sum_{i=1}^{m} x_i^2/2 \right) \\
&\quad \times \exp\left(-\sum_{i=1}^{m-1} y_i^2/2 \right) \frac{\Pi_{i=0}^{m-1} x_{m-i}^{2a-\beta(m-i)-2} \Pi_{i=1}^{m-1} y_i^{\beta_i}}{\Pi_{i=1}^{m} q_i} \, \mathrm{d}q \, d\lambda .
\end{aligned}
$$

Since the Vandermonde with respect to b and q and the ordered eigenvalues λ can be written as

$$
\Delta(\lambda) = \frac{\Pi_{i=1}^{m-1} b_i^i}{\Pi_{i=1}^{m} q_i},
$$

it follows that

$$
\Delta(\lambda) = \frac{\Pi_{i=1}^{m-1} (x_{i+1}y_i)^i}{\Pi_{i=1}^{m} q_i}.
$$

This means that we can rewrite

$$
\begin{aligned}
(dL_\beta) &= 2^{-m} c_{x,y} \exp\left(-\sum_{i=0}^{m-1} x_{m-i}^2/2 \right) \exp\left(-\sum_{i=1}^{m-1} y_i^2/2 \right) \frac{\Pi_{i=1}^{m-1}(x_{i+1}y_i)^{\beta_i}}{\Pi_{i=1}^{m} q_i^{\beta}} \\
&\quad \times \prod_{i=1}^{m-1} q_i^{\beta-1} \prod_{i=0}^{m-1} x_{m-i}^{2a-\beta(m-1)-2} \mathrm{d}q \, \mathrm{d}\lambda \\
&= 2^{-m} c_{x,y} \exp\left(-\sum_{i=0}^{m-1} x_{m-i}^2/2 \right) \exp\left(-\sum_{i=1}^{m-1} y_i^2/2 \right) \Delta(\lambda)^{\beta} \\
&\quad \times \prod_{i=1}^{m-1} q_i^{\beta-1} \left(\prod_{i=0}^{m-1} x_{m-i} \right)^{2a-\beta(m-1)-2} \mathrm{d}q \, \mathrm{d}\lambda .
\end{aligned}
$$

The trace and the determinant are invariant under orthogonal similarity transformations, so $\mathrm{tr}(L_\beta) = \mathrm{tr}(\Lambda)$, and $\det(L_\beta) = \det(\Lambda)$. This is equivalent to

$$
\sum_{i=0}^{m-1} x_{m-i}^2 + \sum_{i=1}^{m-1} y_i^2 = \sum_{i=1}^{m} \lambda_i ,
$$

$$
\prod_{i=0}^{m-1} x_{m-i}^2 = \prod_{i=1}^{m} \lambda_i .
$$

Using this, and substituting p for $1 + \beta/2\,(m-1)$, we obtain that

$$
(dL_\beta) = \left(c_q^\beta \prod_{i=1}^{m-1} q_i^{\beta-1} \, \mathrm{d}q \right) \left(m! c_L^{\beta,a} e^{-\sum_{i=1}^{m} \lambda_i/2} \Delta(\lambda)^\beta \prod_{i=1}^{m} \lambda_i^{a-p} \, \mathrm{d}\lambda \right),
$$

where c_q^β is the same as in (23).

From the above we see that q and λ are independent, and once we drop the ordering the joint eigenvalue density is given by the β-Laguerre ensemble of parameter a, while q is distributed like a normalized vector of χ_β's.

This concludes the proof of Theorem 3.4. □

IV. APPLICATIONS AND OPEN PROBLEMS

As we mentioned in Sec. I, we believe that there should be many applications for the new tridiagonal ensembles. Here we illustrate some (in Sec. IV A), in the hope that researchers will find many more. Some of the applications we believe are new results (Applications 1, 3, 5, and 6), and some are simplifications of known results (Applications 2 and 4).

We discuss the open problem of constructing a matrix model for the β-Jacobi ensembles in the beginning of Sec. IV B. To facilitate the finding of new results, we conclude with a few open "general β-ensemble" problems.

A. Applications

1. Interpolating Laguerre exponents

Our β-Laguerre ensembles have "continuous" Laguerre parameters a which, even in the cases $\beta=1,2,4$, interpolate the Wishart parameters. Though β-Laguerre ensembles with general ("continuous") parameter a have been studied by many researchers (Refs. 2, 14, and 21), no nonquantized matrix realizations (i.e., explicit random matrix models) of β-Laguerre ensembles are found in the literature. By "quantized" we mean that the exponent a is either an even integer, an integer, or a half-integer (depending on the value of β). In particular, all models corresponding to a Laguerre (or Jacobi) weight found in Refs. 33 and 12 are quantized.

Thus, our β-Laguerre random matrix constructions extend the pre-existing ones in two ways: through β and through the Laguerre parameter a.

2. The expected characteristic polynomial

The result in the following might be seen as an extension of the classical Heine theorem (see Szegö[25] and Deift[5]) which has $\beta=2$. Note that for $\beta\neq 2$, $\Delta(\lambda)^\beta$ can no longer be written as the determinant of a Vandermonde matrix times its transpose, and the proof cannot be duplicated.

The same result is found in a slightly more general form in Ref. 8, and its Jacobi case was first derived by Aomoto.[1]

Theorem 4.1: *The expected characteristic polynomial $P_n(y)=\det(yI_n-S)$ over S in the β-Hermite and β-Laguerre ensembles, respectively, are proportional to*

$$H_n\left(\frac{y}{\sqrt{2\beta}}\right), \quad L_n^{(2a/\beta)-n}\left(\frac{y}{2\beta}\right).$$

Here H_n and $L_n^{(2a/\beta)-n}$ are, respectively, the Hermite and Laguerre polynomials, and the constant of proportionality accounts for the fact that $P_n(y)$ is monic.

Proof: Both formulas follow immediately from the 3-term recurrence for the characteristic polynomial of a tridiagonal matrix (see formula (8)) and from the independence of the variables involved in the recurrence. □

3. Expected values of symmetric polynomials

Using the three-term recurrence for the characteristic polynomial of a tridiagonal matrix, we obtain Theorem 4.2.

Theorem 4.2: *Let p be any fixed (independent of β) multivariate symmetric polynomial on n variables. Then the expected value of p over the β-Hermite or β-Laguerre ensembles is a polynomial in β.*

We remark that it is difficult to see this from the eigenvalue density.

Proof: The elementary symmetric functions

$$e_i(x_1,x_2,\ldots,x_n)=\sum_{1\leq j_1<\cdots<j_i\leq n} x_{j_1}x_{j_2}\ldots x_{j_i}, \quad i=0,1,\ldots,n,$$

can be used to generate any symmetric polynomial of degree n (in particular p).

The e_i evaluated at the eigenvalues of a matrix are the coefficients of its characteristic polynomial, and hence they can be written in terms of the matrix entries. Thus p can be written as a polynomial of the $n\times n$ tridiagonal matrix entries (which corresponds, respectively, to the Hermite and Laguerre cases).

To obtain the expected value of p over the β-Hermite or β-Laguerre ensemble, one can write p in terms of the corresponding matrix entries, use the symmetry to condense the expression, then replace the powers of the matrix entries by their expected values.

The diagonal matrix entries are either normal random variables in the Hermite case or sums of χ^2 random variables in the Laguerre case. The subdiagonal entries appear only raised at even powers in the e_i and hence in p (this is an immediate consequence of the three-term recurrence for the characteristic polynomial, (8)). Since all even moments of the involved χ distributions are polynomials in $\beta/2$, it follows that the expectation of p will be a polynomial in β. □

As an easy consequence we have the following corollary.

Corollary 4.3: *All moments of the determinant of a β-Hermite matrix are integer-coefficient polynomials in $\beta/2$.*

Proof: Note that even moments of the $\chi_{\beta i}$ distribution are integer-coefficient polynomials in $\beta/2$, and that the determinant is e_n. □

4. A new proof for Hermite and Laguerre forms of the Selberg integral

Here is a quick proof for the Hermite and Laguerre forms of the Selberg integral (Ref. 18), using respectively, the β-Hermite, and β-Laguerre ensembles.

The Hermite Selberg integral is

$$I_H(\beta,n)\equiv\int_{\mathbb{R}^n}|\Delta(\lambda)|^\beta\exp\left(-\sum_{i=1}^n\lambda_i^2/2\right)d\lambda.$$

We have that

$$I_H(\beta,n)=n!\left(\int_{0\leqslant\lambda_1\leqslant\cdots\leqslant\lambda_n<\infty}\Delta(\lambda)^\beta\exp\left(-\sum_{i=1}^n\lambda_i^2/2\right)d\lambda\right)\left(c_q^\beta\int_{S_+^{n-1}}\prod_{i=1}^n q_i^{\beta-1}\,dq\right),$$

where c_q^β is as in (23). We introduce the $n!$ because in the first integral we have ordered the eigenvalues; S_+^{n-1} signifies that all q_i are positive.

Note that c_q^β can easily be computed independently of the β-Hermite ensembles.

Using the formula for the Vandermonde given by Lemma 2.7, the formula for the Jacobian J given in Lemma 2.9, and the fact that the Frobenius norm of a matrix in the tridiagonal 1-Hermite ensemble is the same as the Frobenius norm of its eigenvalue matrix, one obtains

$$I_H(\beta,n)=n!c_q^\beta\int_{\mathbb{R}^n\times(0,\infty)^{n-1}}\frac{\Pi_{i=1}^n q_i}{\Pi_{i=1}^{n-1}b_i}\frac{\Pi_{i=1}^{n-1}b_i^{\beta i}}{\Pi_{i=1}^n q_i^\beta}\prod_{i=1}^n q_i^{\beta-1}\exp\left(-\sum_{i=1}^{n-1}b_i^2-\sum_{i=1}^n a_i^2/2\right)da\,db$$

$$=n!c_q^\beta(2\pi)^{n/2}\prod_{i=1}^{n-1}\int_{(0,\infty)}b_i^{\beta i-1}e^{-b_i^2}db_i=n!\frac{2^{n-1}\Gamma\left(\frac{\beta}{2}n\right)}{\left(\Gamma\left(\frac{\beta}{2}\right)\right)^n}(2\pi)^{n/2}\prod_{i=1}^{n-1}\frac{\Gamma\left(\frac{\beta}{2}i\right)}{2}=\frac{1}{c_H^\beta}.$$

The same reasoning yields the Laguerre Selberg integral formula

$$I_L^{\beta,a,n}=\frac{1}{c_L^{\beta,a}}.$$

5. Moments of the discriminant

The discriminant of a polynomial equation of order m is the square of the Vandermonde determinant of the m zeroes of the equation. Thus, the discriminant of the characteristic polynomial of a β-Hermite or β-Laguerre ensemble matrix is simply $D(\lambda)=\Delta(\lambda)^2$.

A simple calculation shows that the kth moment of $D(\lambda)$ is, respectively,

$$\frac{c_H^{\beta}}{c_H^{\beta+2k}}=\prod_{j=1}^{n}\frac{\left(1+\frac{\beta}{2}j\right)_{kj}}{\left(1+\frac{\beta}{2}\right)_k},$$

$$\frac{c_L^{\beta,a}}{c_L^{\beta+2k,a+k(m-1)}}=2^{km(m-1)}\prod_{j=1}^{m}\frac{\left(1+\frac{\beta}{2}j\right)_{kj}\left(a-\frac{\beta}{2}(m-j)\right)_{k(j-1)}}{\left(1+\frac{\beta}{2}\right)_k},$$

where n and m are, respectively, the matrix sizes for the Hermite and Laguerre cases, and the rising factorial $(x)_k\equiv\Gamma(x+k)/\Gamma(x)$.

Using the Selberg integral, one obtains that the moments of the discriminant for the β-Jacobi case are

$$\frac{c_J^{\beta,a_1,a_2}}{c_J^{\beta+2k,a_1+k(m-1),a2+k(m-1)}}=\prod_{j=1}^{m}\frac{\left(1+\frac{\beta}{2}j\right)_{kj}\left(a_1-\frac{\beta}{2}(m-j)\right)_{k(j-1)}\left(a_2-\frac{\beta}{2}(m-j)\right)_{k(j-1)}}{\left(1+\frac{\beta}{2}\right)_k\left(a_1+a_2-\frac{\beta}{2}(m-j)\right)_{k(m+j-2)}}.$$

6. Software for application 3: Computing eigenvalue statistics for the β-ensembles

Application 3 suggests that integrals of the form

$$E_{\beta}[p]\equiv c_H^{\beta}\int_{\mathbb{R}^n}p(\lambda)|\Delta(\lambda)|^{\beta}\exp\left(-\sum_{i=1}^{n}\lambda_i^2/2\right)d\lambda$$

may be evaluated with software.

One example of this would be computing moments of the determinant over the β-Hermite ensemble. There are explicit formulas for the cases $\beta=1,2$ and 4, due to Mehta[19] and to Delannay and Le Caër,[6] which can be used to evaluate these moments.

In the absence of a closed-form, explicit formula, like the one for $\beta=1$ provided in Ref. 6, the computation of these moments cannot be made polynomial; thus it is inherently slow.

For the general β case, one can compute the moments in terms of a multivariate Hermite polynomial evaluated at 0 (see Refs. 4 and 2). Using this technique, the complexity of the computation might exceed that of symbolically taking the determinant of a tridiagonal matrix, expanding the power, and replacing all powers of the entries by their expected values (which are all known). Writing a Mathematica code to implement this algorithm is an easy exercise, and such a code would allow the author to compute these moments in a reasonable amount of time, provided that the product between the power and the size of the matrix is not very large. A template for a special case when $\beta=1$ can be found in Ref. 9, Appendix A.

B. Open problems

1. β-Jacobi (MANOVA) ensembles

Sections II and III of the paper provide tridiagonal matrix models for the β-Hermite and β-Laguerre ensembles. The natural question is whether such models exist for the last member of the classical triplet, Jacobi. The β-Jacobi ensembles have been intensively studied as theoretical distributions, especially in connection with Selberg-type integrals and Jack (or Jack–Selberg) polynomials (see Refs. 1, 15, 16, and 3). Finding a random matrix model that corresponds to them would be of much interest.

If the two matrix factorization problems that are associated with the Hermite and Laguerre ensembles are the EIG and the SVD, the one associated with the Jacobi should be the QZ (the generalized symmetric eigenvalue problem). This idea is supported by the fact that the MANOVA real and complex distributions, which correspond to the Jacobi $\beta=1,2$ ensembles, are indeed connected to the QZ algorithm. A good reference for QZ is Ref. 11.

Though we have not studied this problem sufficiently, we believe that a concrete (perhaps sparse, perhaps tridiagonal) matrix model may be constructed for the β-Jacobi ensembles.

2. Level densities

The level density of an ensemble is the distribution of a random eigenvalue of that ensemble (and by the Wigner semicircular law we know that the limiting distribution as $n\to\infty$ of such an eigenvalue is semicircular). The three functions found to be the level densities of the Gaussian models depend on the univariate Hermite polynomials.

Recently, Forrester[10] has found a formula for the level densities of the β-Hermite ensembles which works for β an even integer. This formula depends on a multivariate Hermite polynomial.

Finding a unified formula for the general β case would be of interest.

3. Level spacings

The level spacings are the distances between the eigenvalues of an ensemble, usually normalized so that the average consecutive spacing is 1. These spacings have been well-studied in the case of the Gaussian ensembles ($\beta=1,2,4$). The limiting probability density of a random spacing in these cases is known in terms of spheroidal functions (see Ref. 18).

A surprising connection exists between the limiting probability density of a GUE random spacing and the probability density of the zeroes of the Riemann zeta function. Inspired by the theoretical work of Montgomery,[20] Odlyzko[22] has shown experimentally that the two probability densities are very close; the subsequent conjecture that the two probability densities coincide has been named the Montgomery–Odlyzko law.

To the best of our knowledge, the level spacing of the general β-Hermite ensembles has not been investigated.

4. Bulk and edge scaling limits

Finally, a very important application would be the generalization of the bulk and edge scaling limits for the GOE, GUE, and GSE obtained by Tracy and Widom (the latter are known as the Tracy–Widom distributions F_1, F_2, and F_4).

The edge scaling limit refers to the distribution of the largest eigenvalue of a matrix in the ensemble; the bulk scaling limit refers to the distribution of an eigenvalue in the ''bulk'' of the spectrum. See Refs. 29, 30 or 28. The Tracy–Widom distributions are defined in terms of Painlevé functions, which are solutions to certain differential equations, with asymptotics given by Airy functions. For a good treatment of Painlevé equations in relationship with Gaussian (Hermite), Laguerre, and Jacobi random matrix models, see Pierre van Moerbeke's notes (Ref. 32, Sec. 4). Recently, Johnstone[14] has found that the limiting distributions F_1 and F_2 apply to real (respectively, complex) Wishart matrices.

ACKNOWLEDGMENTS

I. INTRODUCTION

A few years ago topologically stable solutions with nonvanishing magnetic flux were constructed[1] in a particular SU(2) gauged $SU(2)\otimes SU(2)$ sigma model. This model differs essentially from the (gauged) Skyrme model[2] because in place of the usual pion-mass potential of the latter, it is characterized by a potential which results in the breaking of the SU(2) symmetry down to U(1), resulting in a monopole charge. The gauging prescription is given by Eq. (6) of Ref. 1 and we employ the constrained field ϕ^a, $a=1,2,3,4$ $[\Sigma_{a=1}^4(\phi^a)^2=1]$, instead of $U=\phi^a\sigma_a$ $U^\dagger=\phi^a\tilde{\sigma}_a$.

Recently, we discovered that the boundary conditions used to solve the axially symmetric equations of the above model are not strong enough to provide continuously differentiable profiles for the ϕ^a fields. In Ref. 1, our inability to specify the boundary conditions satisfactorily stems from our use of an axially symmetric ansatz in which the Skyrme field was represented by two functions in a ''polar parametrization.'' In this corrigendum, to overcome this obstacle, we employ instead a ''vector parametrization'' ansatz. The new results change some of the qualitative conclusions of our results in the case of a vanishing Skyrme term, but also confirm those obtained for the ''full'' system.

The numerical analysis carried out with the new ansatz, however, is unfortunately more limited than that attempted in Ref. 1. We encounter severe difficulties when the coupling constant κ_2 of the quartic (Skyrme) term in Eq. (8) of Ref. 1 is nonvanishing. Thus our main analysis is carried out in the special case of vanishing κ_2. We have, however, presented a heuristic analysis of the $\kappa_2\neq 0$ case, at least for small κ_2, using a simple perturbative prescription.

II. AXIALLY SYMMETRIC ANSATZ

In order to construct axially symmetric solution of the above mentioned model, the following ''polar parametrization'' ansatz was considered in Ref. 1 for the Skyrme field:

$$\phi_4=\cos f, \quad \vec{\phi}=\sin f(\sin g\sin\theta+\cos g\cos\theta)\vec{e}_r^{\,n}+\sin f(\sin g\cos\theta-\cos g\sin\theta)\vec{e}_\theta^{\,n}, \qquad (1)$$

with (e_r^n, e_θ^n) defined in Eq. (34) of Ref. 1 and where f,g are functions of r and θ only. Severe

TABLE I. The energy per winding number E/n, the maximal value of the energy $\mathcal{E}_M$, and the radius x_M of the annulus of the maximal value of the energy density are presented for the gauged skyrmion for winding number $n=1,2,3,4$.

n	1	2	3	4
E/n	2.95	3.05	3.09	3.10
$\mathcal{E}_M$	0.47	0.066	0.031	0.02
x_M	0.0	0.68	0.81	0.86

numerical difficulties using this ansatz had forced us to attempt to construct solutions numerically subject to the boundary conditions for the functions parametrizing the Skyrme field at the origin $(r=0)$:

$$f(r=0,\theta)=\pi, \quad \partial_r g|_{r=0,\theta}=0. \tag{2}$$

Unfortunately, it turned out that these boundary conditions are too weak to ensure the continuity of the partial derivatives of the fields at the origin. We therefore reconsider here the equations by using a ''vector parametrization'' ansatz:

$$\phi_4=\sqrt{1-g_5^2-g_6^2}, \quad \vec{\phi}=g_5\ \vec{e}_r^{\,n}+g_6\ \vec{e}_\theta^{\,n}, \tag{3}$$

where g_5, g_6 are functions of r and θ.

Now, the boundary conditions necessary to ensure regular and finite energy solutions read

$$g_5(r=0,\theta)=0, \quad g_5(r=\infty,\theta)=1, \tag{4}$$

$$g_6(r=0,\theta)=0, \quad g_6(r=\infty,\theta)=0, \tag{5}$$

$$\frac{\partial g_k}{\partial\theta}(r,\theta=0)=0, \quad \frac{\partial g_k}{\partial\theta}\left(r,\theta=\frac{\pi}{2}\right)=0, \ \ k=5,6. \tag{6}$$

III. NUMERICAL RESULTS

With this set of boundary conditions [completed by those for the gauge fields, see Eqs. (35), (37), (39), and (40) in Ref. 1] we succeeded in solving the classical equations numerically for $n=1,2,3,4$. The energy per winding number E/n, the maximal value of the energy density $\mathcal{E}_M$ and the value of the coordinate x_M [represented by means of the compactified coordinate $x \equiv r/(1+r)$] at which the energy density attains its maximum are presented in Table I.

Some features are worth noticing. First we observe that the energy per winding number increases with n, that is to say, at least classically, the solutions for $n>1$ are unstable against decaying into n separate solitons. This contrasts with the case of BPS magnetic monopole where the self-duality equation ensures that the ratio $E(n)/n$ is independent on n. The excess of energy

TABLE II. The energy per winding number E/n, the maximal value of the energy density $\mathcal{E}_M$, and the radius x_M of the annulus of the maximal value of the energy density are presented for the BPS monopoles for winding number $n=1,2,3,4$.

of the $n=2$ gauged skyrmion solution is about 3% of the classical energy of the spherically symmetric soliton. This conclusion is the opposite of what was claimed in Ref. 1.

As a second feature of the axially symmetric solutions we point out that the radius of the annulus (in the plane orthogonal to the symmetry axis, the x,y-plane in our case) increases with n, that is to say, the lump occupies a larger volume in space. We observe that the values of these radii are very close to their corresponding values in the BPS monopole case; this statement can be

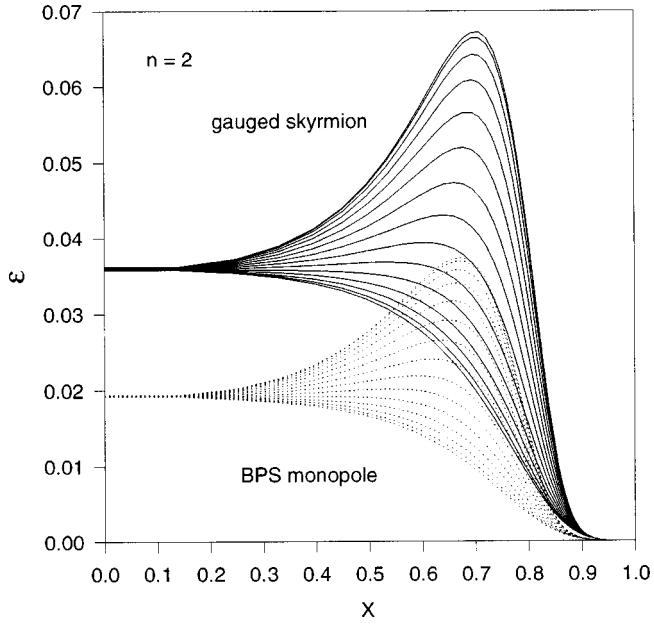

FIG. 2. The profiles of the energy density ε of the gauged skyrmion (solid) and of the BPS monopole (dotted) are shown for $n=2$ and several values of θ between $\theta=0$ and $\theta=\pi/2$. Note that the curve's height increases with θ.

checked easily in Table II which is the counterpart of Table I, for BPS monopoles. The energy densities corresponding to the gauged skyrmion and to the monopole, respectively, are presented in Fig. 1 for the spherically symmetric solutions and in Fig. 2 for the axially symmetric solutions with winding number $n=2$.

A natural question to raise now is whether the addition of a Skyrme term to the model can lead to qualitatively different properties for axially symmetric solutions. We expect that the reinstalment of the Skyrme term should lead to bound states of higher magnetic charges, as is known to be the case for the analogous gauged Higgs models.[3,4] Unfortunately this question leads to severe technical problems in the numerical integrations which we do not have under control at the present. However, we have some heuristic results indicating that, when a nonvanishing Skyrme term [i.e., the term in $\kappa_2^4 \equiv \kappa$ Eqs. (7) and (8) of Ref. 1] is considered, the solutions with $n>2$ become stable for large enough values of κ. The argument is based on the observation that the ''Skyrme term energy,''

$$E_{sk}=\int d^3x \frac{1}{2}|D_{[i}\phi^a D_{j]}\phi^b|^2 \tag{7}$$

evaluated with the solutions constructed for $\kappa=0$, gives

$$E_{sk}\approx 0.368 \quad \text{for} \quad n=1, \quad E_{sk}/2\approx 0.092 \quad \text{for} \quad n=2. \tag{8}$$

This allows us to approximate the total energy with the first order correction:

$$E_a(\kappa)=E+\kappa E_{sk}\,. \tag{9}$$

In the spherically symmetric case we checked that this approximation is correct within 1% up to values of $\kappa\approx 0.2$. Using the values of the energy given in Table I, together with the first order correction to the energy (9), we find the ''binding energy''

$$\Delta(\kappa)\equiv \tfrac{1}{2}E_a(\kappa)|_{n=2}-E_a(\kappa)|_{n=1}\approx 0.1-\kappa 0.278. \tag{10}$$

Equation (10) strongly indicates that Δ decreases for $\kappa>0$ and thus that, at least the $n=2$, solution becomes stable for a large enough value of κ. This kind of approximation, whose validity definitely needs to be confirmed by a direct integration of the full equations, can be justified heuristically as follows. In a two-dimensional system where the charge (vorticity) n solution can be constructed by integrating one-dimensional differential equations, the inclusion of a quartic kinetic term (a Skyrme term) does not result in the numerical difficulties encountered here with two dimensional integrations. Thus a perturbative evaluation of the energy like that used above can be rigorously tested. The heuristic step we have taken here is that we proceed with this perturbative construction in our three-dimensional model, on the justification that it works for two-dimensional models. This approximation gave very good results when applied in the context of the (higher order) Born–Infeld correction to various topological solitons.[5]

(Received 25 June 2002; accepted 27 August 2002)

We propose a Wigner quasiprobability distribution function for Hamiltonian systems in spaces of constant curvature, in this article on hyperboloids, which returns the correct marginals and has the covariance of the Shapiro functions under SO(D,1) transformations. To the free systems obeying the Laplace–Beltrami equation on the hyperboloid, we add a conic-oscillator potential in the hyperbolic coordinate. As an example, we analyze the one-dimensional case on a hyperbola branch, where this conic-oscillator is the Pöschl–Teller potential. We present the analytical solutions and plot the computed results. The standard theory of quantum oscillators is regained in the contraction limit to the space of zero curvature. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1518139]

I. INTRODUCTION

In Hamiltonian systems which a have flat $\mathfrak{R}^D$ configuration space, among the phase space quasiprobability distribution functions the Wigner function[1] is the only one covariant under Euclidean translations of phase space.[2,3] The present article, and others that will follow it, aim to the construction of Wigner functions on configuration spaces that are conic surfaces, hyperboloids and spheres, which transform under the Lorentz and rotation groups respectively, and which reproduce the traditional Wigner function when the conic contracts to the plane. Quantum motion on spaces of constant curvature is of current interest in various fields of theoretical physics, such as quantum gravity and string theory,[4] noncommutative geometry,[5] and quantum chaos.[6] Hamiltonian systems on conic manifolds have a natural kinetic energy given by the Laplace–Beltrami operator, and, moreover, on these conics also a natural oscillator ''potential'' can be proposed. In one dimension, this oscillator turns out to be one of the Pöschl–Teller potentials.[7]

In this article, subtitled I, we propose a Wigner function on the D-dimensional hyperboloid $\mathcal{H}^D_+$, which generalizes the ordinary Wigner function on flat phase space. It displays the correct marginals, and returns the traditional form of the Wigner function under Inönü–Wigner contraction to the zero-curvature limit. The elements and background for this assertion are contained in Sec. II, including the Shapiro solutions $\Phi^{(D)}_{\mathbf{p}}(\mathbf{x})$ to the Laplace–Beltrami equation.[8] In Sec. III we present our proposed definition of Wigner function on the hyperboloid, and verify the properties of marginality and the contraction limit to flat phase space. Covariance remains an issue because the Wigner function that we propose here follows from the covariance of the basis of wavefunctions, between the argument $\mathbf{x}$ and the index $\mathbf{p}$, as if they were canonically conjugate variables. In this context, we reexamine the interpretation of momentum coordinates.

In Sec. IV we exemplify the D-dimensional theory with a one-dimensional *sui generis* oscillator on one branch of a hyperbola. This example may appear to be trivial, because the hyperbola is in most respects equivalent to a straight line. Nevertheless, the resulting Pöschl–Teller potential is of particular interest because the wavefunctions are also the Clebsch–Gordan (Wigner coupling) coefficients for the three-dimensional Lorentz algebra, $\mathrm{so}(2,1)=\mathrm{sp}(2,\mathfrak{R})=\mathrm{su}(1,1)$.[9] We display

[a]Electronic mail: alonso@ce.fis.unam.mx
[b]Permanent address: Laboratory of Theoretical Physics, Joint Institute for Nuclear Research, Dubna, Russia and International Center for Advanced Studies, Yerevan State University, Yerevan, Armenia.

the Wigner functions of some Pöschl–Teller wavefunctions; these have not been examined before. Finally, in Sec. V we recapitulate the aim and offer the present outlook of our program.

II. ELEMENTS OF PHASE SPACE AND HYPERBOLOIDS

In his fundamental article,[1] Wigner proposed a distribution function to represent on phase space the wavefunctions of pure and of mixed states in quantum systems. In this section we recall the definition and properties that we shall generalize from flat to conic spaces, using the Laplace–Beltrami operator and the Shapiro functions.

A. Wigner function on flat phase space

In D-dimensional flat configuration space $\mathbf{x}\in\mathfrak{R}^D$, the generalized Dirac basis of plane waves solves the free-space Schrödinger equation, which is identical to the Helmholtz equation

$$-\Delta\,\phi(\mathbf{x})=p^2\,\phi(\mathbf{x}),\quad \phi_{\mathbf{p}}(\mathbf{x})=\exp(i\mathbf{p}\cdot\mathbf{x}),\quad \mathbf{p}\in\mathfrak{R}^D. \tag{1}$$

When we write $p=+(\mathbf{p}\cdot\mathbf{p})^{1/2}$, $\mathbf{n}=\mathbf{p}/p$, and call $\mathbf{p}=p\mathbf{n}$ the momentum or wavenumber vector, the functions $\phi_{\mathbf{p}}(\mathbf{x})$ represent plane waves in the direction of the unit vector $\mathbf{n}\in\mathcal{S}^{D-1}$ in the $(D-1)$-dimensional sphere manifold. In the quantum model with natural units $\hbar=1$, p has units of inverse length; in the wave optical model, p is the wavenumber of light.

The basis of plane wave functions (1) plays many roles: it provides the Fourier transform kernel which bridges the configuration and momentum realizations, it constitutes a basis for representations of the Euclidean group, and it serves for the construction of the $\mathfrak{R}^{2D}$-Wigner function of wavefields $f(\mathbf{x})$, $g(\mathbf{x})$ through the equivalent expressions

$$W_{\mathfrak{R}^D}(f,g|\mathbf{x},\mathbf{p})=\frac{1}{(2\pi)^D}\int_{\mathfrak{R}^D}d^D\mathbf{z}\,f\left(\mathbf{x}-\frac{1}{2}\mathbf{z}\right)^*e^{-i\mathbf{p}\cdot\mathbf{z}}g\left(\mathbf{x}+\frac{1}{2}\mathbf{z}\right) \tag{2}$$

$$=\frac{1}{(2\pi)^D}\int_{\mathfrak{R}^D}d^D\mathbf{z}\,f\left(\mathbf{x}-\frac{1}{2}\mathbf{z}\right)^*\times e^{+i\mathbf{p}\cdot(\mathbf{x}-(1/2)\mathbf{z})}e^{-i\mathbf{p}\cdot(\mathbf{x}+(1/2)\mathbf{z})}g\left(\mathbf{x}+\frac{1}{2}\mathbf{z}\right)$$

$$=\frac{1}{(2\pi)^D}\int_{\mathfrak{R}^D}d^D\mathbf{x}'\int_{\mathfrak{R}^D}d^D\mathbf{x}''\,f(\mathbf{x}')^*\,g(\mathbf{x}'')\times\phi_{\mathbf{p}}(\mathbf{x}')\,\delta^D\left(\mathbf{x}-\frac{1}{2}(\mathbf{x}'+\mathbf{x}'')\right)\phi_{\mathbf{p}}(\mathbf{x}'')^*. \tag{3}$$

This has the well-known properties of being sesquilinear in the functions, real for $f=g$, with the marginal projections $\int_{\mathfrak{R}^D}d\mathbf{p}W=f(\mathbf{x})^*g(\mathbf{x})$, $\int_{\mathfrak{R}^D}d\mathbf{x}W=\tilde{f}(\mathbf{p})^*\,\tilde{g}(\mathbf{p})$ (the tilde indicates ordinary Fourier transformation, $F:f=\tilde{f}$), and covariant under translations in coordinate and momentum spaces

$$T_{\mathbf{a}}:f(\mathbf{x})=f(\mathbf{x}-\mathbf{a})\Rightarrow W_{\mathfrak{R}^D}(T_{\mathbf{a}}:f,T_{\mathbf{a}}:g|\mathbf{x},\mathbf{p})=W_{\mathfrak{R}^D}(f,g|\mathbf{x}-\mathbf{a},\mathbf{p}), \tag{4}$$

$$\tilde{T}_{\mathbf{b}}:f(\mathbf{x})=e^{i\mathbf{b}\cdot\mathbf{x}}f(\mathbf{x})\Rightarrow W_{\mathfrak{R}^D}(\tilde{T}_{\mathbf{b}}:f,\tilde{T}_{\mathbf{b}}:g|\mathbf{x},\mathbf{p})=W_{\mathfrak{R}^D}(f,g|\mathbf{x},\mathbf{p}-\mathbf{b}), \tag{5}$$

$$F:f(\mathbf{x})=\tilde{f}(\mathbf{x})\Rightarrow W_{\mathfrak{R}^D}(F:f,F:g\,|\mathbf{x},\mathbf{p})=W_{\mathfrak{R}^D}(f,g\,|\mathbf{p},-\mathbf{x}). \tag{6}$$

The last intertwining by the Fourier transform was known when García–Calderón and Moshinsky noticed that the Wigner function is covariant also under the larger group of $\mathrm{Sp}(2D,\mathfrak{R})$ linear canonical transformations of phase space.[10] This is exceptional in the sense that the Heisenberg–Weyl algebra [whose generators are the phase space translations (4) and (5)—and the unit that

generates a commuting phase factor] has the outer automorphism group $\mathrm{Sp}(2D,\Re)$. This accident does not occur for Lorentz algebras, so we should not expect similar covariances of the Wigner function under groups larger than $\mathrm{SO}(D,1)$.

B. Laplace–Beltrami operator on the hyperboloid

The purpose of this article is to generalize the expression of the Wigner function (2) and (3) with functions on a D-dimensional space $\mathbf{x}\in\Re^D$ of constant curvature. This manifold can be seen in an "ambient" space of $D+1$ dimensions as a hyperboloid, with vectors $x=(x_0,\mathbf{x})\in\Re^{D+1}$.

Consider the upper sheet of the two-sheeted hyperboloid $\mathcal{H}_+^D\subset\Re^{D+1}$ of hyperbolic radius $R>0$,

$$|x|^2=x_0^2-\mathbf{x}^2=R^2,\quad \mathbf{x}^2=x_1^2+x_2^2+\cdots+x_D^2. \tag{7}$$

In this ambient Minkowski space, the isometry group is the Poincaré group $\mathrm{ISO}(D,1)_+^{\uparrow}$, in place of the Euclidean group $\mathrm{ISO}(D)_+$ of flat space. The Lie algebra $\mathrm{so}(D,1)$ has then the standard realization

$$M_{j,k}=x_j\partial_{x_k}-x_k\partial_{x_j},\quad M_{0,k}=x_0\partial_{x_k}+x_k\partial_{x_0},\quad j,k=1,2,\ldots,D. \tag{8}$$

The second-order Casimir operator, $\mathcal{C}$, which is an invariant under the group $\mathrm{SO}(D,1)_+^{\uparrow}$, is ($-R^2$ times) the Laplace–Beltrami operator on $\mathcal{H}_+^D$, namely

$$\frac{1}{R^2}\mathcal{C}=-\Delta_{\mathrm{LB}}=\frac{1}{R^2}\left(\sum_{1\leqslant j<k\leqslant D}M_{j,k}^2-\sum_{1\leqslant k\leqslant D}M_{0,k}^2\right). \tag{9}$$

This operator replaces the Laplacian in the Schödinger equation for hyperbolic curved space. Thus, the Schrödinger equation on this space with a potential $V(\mathbf{x})$ is

$$\left(\frac{-1}{2\mu}\Delta_{\mathrm{LB}}+R^2V(\mathbf{x})\right)f(\mathbf{x})=R^2Ef(\mathbf{x}). \tag{10}$$

In quantum mechanics $\mu=m/\hbar^2$, where m is the particle mass. For application in paraxial wave optics, we recall the interpretation where the extra term characterizes the refractive index anomaly of the medium,

$$n(\mathbf{x})=n_\circ-\nu(\mathbf{x}),\quad n_\circ=n(0),\qquad \begin{matrix} n_\circ\leftrightarrow\mu,\\ \nu(\mathbf{x})\leftrightarrow V(\mathbf{x}).\end{matrix} \tag{11}$$

First we consider the case when the potential is identically zero, $V(\mathbf{x})=0$; a nonzero oscillator potential will be introduced in Sec. II E.

For the free case, in the unitary irreducible representation spaces of the D-dimensional Lorentz group belonging to the most degenerate continuous series indicated by p,[11] the operator (9) has a real lower-bound spectrum, as does (1). The wavefunctions of the free system on the hyperboloid are the solutions to the equation

$$\Delta_{\mathrm{LB}}f(\mathbf{x})=-\left[\left(\frac{D-1}{2R}\right)^2+p^2\right]f(\mathbf{x})=-\frac{\lambda(\lambda+D-1)}{R^2}f(\mathbf{x}),$$
$$p\in\Re_0^+=[0,\infty),\quad \lambda=-\frac{1}{2}(D-1)-ipR. \tag{12}$$

Any wavefield of a given wavenumber p is a solution of this equation.

C. Shapiro functions

A privileged basis for the solutions of the Laplace–Beltrami equation (12) was given by Gel'fand, Graev and Shapiro[8] in the form of D-dimensional plane waves of momentum $\mathbf{p}=p\mathbf{n}$, with positive wavenumber p and in the direction of a unit vector on the sphere $\mathbf{n}\in\mathcal{S}^{D-1}$,

$$\Phi_{\mathbf{p}}^{(D)}(x)=\left(\frac{x_0-\mathbf{n}\cdot\mathbf{x}}{R}\right)^{-(1/2)(D-1)-ipR}=(\cosh\chi-\mathbf{n}\cdot\boldsymbol{\xi}\sinh\chi)^{-(1/2)(D-1)-ipR}, \tag{13}$$

where functions $f(x)$ on the hyperboloid $x\in\mathcal{H}_+^D$ $(x^2=R^2)$ will be denoted, according to convenience, by

$$\begin{aligned} &x_0=+\sqrt{R^2+\mathbf{x}^2}=R\cosh\chi\geqslant R,\\ f(x)=f(x_0,\mathbf{x})=f(\mathbf{x}),\qquad &\\ &\mathbf{x}=R\boldsymbol{\xi}\sinh\chi\in\mathfrak{R}^D,\ \ \chi\in\mathfrak{R}_0^+,\ \ \boldsymbol{\xi}\in\mathcal{S}^{D-1}. \end{aligned} \tag{14}$$

The *Shapiro* functions (13) are a Dirac basis for functions on the hyperboloid, which are orthogonal and complete over **x**- and **p**-spaces:

$$\frac{R}{(2\pi)^D}\int_{\mathbf{x}\in\mathfrak{R}^D}\frac{d^D\mathbf{x}}{x_0}\Phi_{\mathbf{p}}^{(D)}(x)^*\,\Phi_{\mathbf{p}'}^{(D)}(x)=N^{(D)}(p)\,\delta^D(\mathbf{p}-\mathbf{p}'), \tag{15}$$

$$\frac{1}{(2\pi)^D}\int_{\mathbf{p}\in\mathfrak{R}^D}\frac{d^D\mathbf{p}}{N^{(D)}(p)}\Phi_{\mathbf{p}}^{(D)}(x)^*\,\Phi_{\mathbf{p}}^{(D)}(x')=\delta^D(x,x'), \tag{16}$$

with the measure and Dirac δ under $\int_{\mathcal{H}_+^D}d^Dx=R\int_{\mathfrak{R}^D}d^D\mathbf{x}/x_0$,

$$N^{(D)}(p)=\left|\frac{\Gamma(ipR)}{\Gamma\left(\frac{1}{2}(D-1)+ipR\right)}\right|^2(pR)^{D-1}, \tag{17}$$

$$\delta^D(x,x')=\frac{x_0}{R}\,\delta^D(\mathbf{x}-\mathbf{x}')=\sqrt{1+\frac{\mathbf{x}^2}{R^2}}\,\delta^D(\mathbf{x}-\mathbf{x}'). \tag{18}$$

In particular, $N^{(1)}(p)=1$, $N^{(2)}(p)=\coth(pR)$, and $N^{(3)}(p)=1$.

The Inönu–Wigner contraction limit of the Lorentz to the Euclidean group $\mathrm{SO}(D,1)_+^\uparrow\to\mathrm{ISO}(D)_+$ is the limit $R\to\infty$ in our expressions for vectors with $x_0\approx R$, $\mathbf{x}^2\ll R^2$, and $\mathbf{p}=p\mathbf{n}$ as before, i.e.,

$$\lim_{R\to\infty}\Phi_{\mathbf{p}}^{(D)}(x)=\lim_{R\to\infty}\left(\frac{x_0-\mathbf{x}\cdot\mathbf{n}}{R}\right)^{-(1/2)(D-1)-ipR}\approx\lim_{R\to\infty}\left(1-\frac{\mathbf{x}\cdot\mathbf{n}}{R}\right)^{-ipR}=\exp(i\mathbf{x}\cdot\mathbf{p}). \tag{19}$$

Correspondingly, $\lim_{R\to\infty}N^{(D)}(p)=1$ and $\delta^D(x,x')\to\delta^D(\mathbf{x}-\mathbf{x}')$.

D. Momentum space for the hyperboloid

The Shapiro functions $\{\Phi_{\mathbf{p}}^{(D)}(\mathbf{x})\}_{\mathbf{p}\in\mathfrak{R}^D}$ in (13) serve as the integral transform kernel between functions of **x** on the hyperboloid, $f(\mathbf{x})$, and conjugate functions of **p**, that has the interpretation of momentum or wavenumber space, and is indicated $\tilde{f}(\mathbf{p})$. Using (14) for $\mathbf{x},\mathbf{p}\in\mathfrak{R}^D$, one writes

$$\tilde{f}(\mathbf{p})=\frac{R}{(2\pi)^{D/2}}\int_{\mathbf{x}\in\mathfrak{R}^D}\frac{d^D\mathbf{x}}{x_0}\Phi_{\mathbf{p}}^{(D)}(\mathbf{x})^*\,f(\mathbf{x}), \tag{20}$$

$$f(\mathbf{x})=\frac{1}{(2\pi)^{D/2}}\int_{\mathbf{p}\in\Re^D}\frac{d^D\mathbf{p}}{N^{(D)}(p)}\Phi_{\mathbf{p}}^{(D)}(\mathbf{x})\,\tilde{f}(\mathbf{p}). \tag{21}$$

This *Shapiro transform* has been used as a relativistic analog of the Fourier transform (the physical context here, though, is **not** that of space–time relativity, as we shall clarify below), and is a vector form of one of the two branches of the bilateral Mellin transform.[12] Here the Shapiro transform replaces the traditional Fourier transform in the definition of a momentum space $\mathbf{p}\in\Re^D$, canonically conjugate with respect to this basis, to a configuration space of constant curvature. The corresponding Parseval relation is

$$R\int_{\mathbf{x}\in\Re^D}\frac{d^D\mathbf{x}}{x_0}f(\mathbf{x})^*\,g(\mathbf{x})=(f,\,g)_{\mathcal{H}_+^D}=\int_{\mathbf{p}\in\Re^D}\frac{d^D\mathbf{p}}{N^{(D)}(p)}\tilde{f}(\mathbf{p})^*\,\tilde{g}(\mathbf{p}). \tag{22}$$

The manifold of momentum $\mathbf{p}=p\mathbf{n}\in\Re^D$ ($p\in\Re^+$ and $\mathbf{n}\in\mathcal{S}^{D-1}$) can be placed also in a $(D+1)$-dimensional "ambient" space, where it occupies the cone $\varpi=(p,\mathbf{p})\in\vee^+$. The momentum thus defined by the Shapiro functions has certain features, however, which do not correspond to those of a standard relativistic momentum vector. If $f(\mathbf{x})$ is a monochromatic wavefield with a definite value of p, this wavenumber will not change under SO(D,1) translations of the hyperboloid ("boosts"), because it is the invariant value of the Casimir operator (9)–(12). Only the direction of momentum, $\mathbf{n}$, can shift over the sphere; it will do so following the well-known Bargmann deformation of the circle,[13] where the colatitude angle "boosts" as $\tan\frac{1}{2}\phi\mapsto e^{-\zeta}\tan\frac{1}{2}\phi$ for rapidity $\zeta\in\Re$. Quotation marks are used for "boost" because here we mean a translation in the hyperboloid, and not the well-known relativistic acceleration.

E. Oscillators on conics

The Laplace–Beltrami equation (9)–(12) provides the free fields (whose energy is purely kinetic) on the hyperboloid. In Eq. (10) we allowed a potential energy term as in the Schrödinger equation of quantum mechanics, by adding a function of position $V(\mathbf{x})$.[7,14,15] A straightforward and useful generalization of the SO(D)-isotropic harmonic oscillator potential from flat to conic D-dimensional configuration space is[14]

$$V(\mathbf{x})=\frac{1}{2}\mu\omega^2R^2\frac{|\mathbf{x}|^2}{x_0^2}=\frac{1}{2}\mu\omega^2R^2\tanh^2\chi=\frac{1}{2}\mu\omega^2R^2\,(1-\operatorname{sech}^2\chi), \tag{23}$$

where $\chi\in\Re_0^+$ is the hyperbolic angle coordinate defined in Eqs. (14). This is the Pöschl–Teller "secant-hyperbolic-squared" trough.

III. WIGNER FUNCTION ON THE HYPERBOLOID

With the Shapiro basis of wavefunctions of the free system, we construct now our proposed Wigner function following the double-integral form in Eq. (3) for two wavefunctions, $f(x)$ and $g(x)$, by means of integrals on two hyperboloids, $|x'|=R$ and $|x''|=R$.

A. Definition

With the measures in Eqs. (15) and the Shapiro functions in (13), we define the Wigner function on the hyperboloid by

$$W_{\mathcal{H}}(f,g|\mathbf{x},\mathbf{p})=\frac{R^2}{(2\pi)^D}\int_{\mathbf{x}'\in\Re^D}\frac{d^D\mathbf{x}'}{x_0'}\int_{\mathbf{x}''\in\Re^D}\frac{d^D\mathbf{x}''}{x_0''}f(x')^*\,g(x'')$$
$$\times\Phi_{\mathbf{p}}^{(D)}(x')\,\Delta^D(x;x',x'')\,\Phi_{\mathbf{p}}^{(D)}(x'')^*, \tag{24}$$

where $\Delta^D(x;x',x'')$ takes the place of the Dirac delta $\delta^D(\mathbf{x}-\frac{1}{2}(\mathbf{x}'+\mathbf{x}''))$ on flat space, Eq. (3), and which will be detailed below.

The crucial property that we must require of this "binding-Δ" in (24) is that it should guarantee that x be the midpoint of the *geodesic* between x' and x'', so that all three points lie on the hyperboloid $\mathcal{H}_+^D$. We achieve this in the following way:[16] given $x \in \mathfrak{R}^{D+1}$ in the upper sheet of a two-sheeted hyperboloid, we build any $y \in \mathfrak{R}^{D+1}$ on a one-sheeted hyperboloid $\tilde{\mathcal{H}}^D$ of the same radius R, such that it be Minkowski-orthogonal to x,

$$y=(y_0,\mathbf{y}), \quad |y|^2=y_0^2-\mathbf{y}^2=-R^2, \quad x_0y_0-\mathbf{x}\cdot\mathbf{y}=0. \tag{25}$$

Then, we can express x' and x'' as vectors obtained from x and y as follows:

$$x'=x\cosh\tfrac{1}{2}\tau-y\sinh\tfrac{1}{2}\tau, \quad x''=x\cosh\tfrac{1}{2}\tau+y\sinh\tfrac{1}{2}\tau, \tag{26}$$

where $x',x'' \in \mathcal{H}_+^D$ for all $\tau \in \mathfrak{R}$. Also, it is easy to show that

$$x_0'x_0''-\mathbf{x}'\cdot\mathbf{x}''=R^2\cosh\tau, \quad x_0x_0'-\mathbf{x}\cdot\mathbf{x}'=x_0x_0''-\mathbf{x}\cdot\mathbf{x}''=R^2\cosh\tfrac{1}{2}\tau, \tag{27}$$

i.e., the geodesic distance between x' and x'' is $R\tau$, while x is at $\frac{1}{2}R\tau$ from both x' and x''. The arguments x' and x'' in the expression (24) thus emulate the arguments $\mathbf{x}\pm\frac{1}{2}\mathbf{z}$ in (2) with the parameter $\frac{1}{2}\tau$.

Using (18) and the parameter τ in (27), we propose the binding-Δ in (24) to be

$$\Delta^D(x;x',x'')=\frac{x_0}{R}\,\delta^D\left(\mathbf{x}-\frac{\mathbf{x}'+\mathbf{x}''}{2\cosh\frac{1}{2}\tau}\right). \tag{28}$$

This will yield the correct marginals (to be seen below) due to its properties

$$\Delta^D(x;x',x')=\frac{x_0}{R}\,\delta^D(\mathbf{x}-\mathbf{x}'), \quad R\int_{\mathbf{x}\in\mathfrak{R}^D}\frac{d^D\mathbf{x}}{x_0}\,\Delta^D(x;x',x'')=1. \tag{29}$$

B. Integral forms

The $2D$-fold integral form of the Wigner function in (24) contains Dirac δ's; it can therefore be brought to a $(D+1)$-fold integral noting that the definition of $y \in \tilde{\mathcal{H}}^D$ leaves the freedom of rotating $\mathbf{y}$ around $\mathbf{x}$ on a sphere $\mathcal{S}^{D-1}$. When we change variables from x' and x'' to x and y according to (26), we reduce the integration to $\mathbf{y}$ and τ while keeping Minkowski-orthogonality. The proposed Wigner function (24) then becomes

$$\begin{aligned} W_{\mathcal{H}}(f,g|\mathbf{x},\mathbf{p})=\frac{R^2}{(2\pi)^D}\int_0^\infty(\sinh\tau)^{D-1}\,d\tau\int_{y\in\tilde{\mathcal{H}}^D}d^D\mathbf{y}\;\delta(x_0y_0-\mathbf{x}\cdot\mathbf{y}) \\ \times f\left(x\cosh\frac{1}{2}\tau-y\sinh\frac{1}{2}\tau\right)^*\,g\left(x\cosh\frac{1}{2}\tau+y\sinh\frac{1}{2}\tau\right) \\ \times\Phi_{\mathbf{p}}^{(D)}\left(x\cosh\frac{1}{2}\tau-y\sinh\frac{1}{2}\tau\right)\Phi_{\mathbf{p}}^{(D)}\left(x\cosh\frac{1}{2}\tau+y\sinh\frac{1}{2}\tau\right)^*. \end{aligned} \tag{30}$$

The Dirac δ remaining in (30) can be used to find a third alternative form of the Wigner function. This is obtained with the parametrization of the ambient-space vectors given by

$$x=(x_0,\mathbf{x})=R(\cosh\chi,\boldsymbol{\xi}\sinh\chi), \quad y=(y_0,\mathbf{y})=R(\sinh\omega,\boldsymbol{\eta}\cosh\omega), \tag{31}$$

where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ are unit vectors on the sphere $\mathcal{S}^{D-1}$ and $\chi,\omega \in \mathfrak{R}_0^+$. The Dirac δ in Eq. (30) is then

$$\delta(x_0 y_0 - \mathbf{x}\cdot\mathbf{y}) = \frac{1}{R^2}\frac{\cosh\Omega}{\cosh\chi}\,\delta(\omega-\Omega), \quad \text{with} \quad \tanh\Omega = \boldsymbol{\xi}\cdot\boldsymbol{\eta}\tanh\chi. \tag{32}$$

The differential $d^D\mathbf{y}$ of the integral in $y\in\tilde{\mathcal{H}}_+^D$ becomes $R^D(\cosh\omega)^{D-1}d\omega\, d^{D-1}\boldsymbol{\eta}$, so the Wigner function (24) becomes a D-fold integral with the structure of (2), viz.,

$$\begin{aligned} W_{\mathcal{H}}(f,g|\mathbf{x},\mathbf{p}) = \frac{1}{(2\pi)^D}\int_0^\infty (\sinh\tau)^{D-1}\,d\tau \int_{\mathcal{S}^{D-1}} \frac{|\mathbf{y}|^D}{\cosh\chi}\,d^{D-1}\boldsymbol{\eta} \\ \times f\left(x\cosh\frac{1}{2}\tau - y\sinh\frac{1}{2}\tau\right)^* g\left(x\cosh\frac{1}{2}\tau + y\sinh\frac{1}{2}\tau\right) \\ \times \Phi_{\mathbf{p}}^{(D)}\left(x\cosh\frac{1}{2}\tau - y\sinh\frac{1}{2}\tau\right)\Phi_{\mathbf{p}}^{(D)}\left(x\cosh\frac{1}{2}\tau + y\sinh\frac{1}{2}\tau\right)^*, \end{aligned} \tag{33}$$

with

$$y = R(\sinh\Omega,\ \ \boldsymbol{\eta}\cosh\Omega) = R\,\frac{(\boldsymbol{\xi}\cdot\boldsymbol{\eta}\tanh\chi,\ \ \boldsymbol{\eta})}{\sqrt{1-(\boldsymbol{\xi}\cdot\boldsymbol{\eta}\tanh\chi)^2}}. \tag{34}$$

C. Marginal projections

The marginal projections obtained by integrating the proposed Wigner function (24) over momentum and configuration space should yield, respectively, $f(\mathbf{x})^* g(\mathbf{x})$ and $\tilde{f}(\mathbf{p})^*\tilde{g}(\mathbf{p})$ as defined in (20) and (21). The two marginals follow from the orthogonality and completeness relations of the Shapiro functions, Eqs. (15) and (16).

The integration of the Wigner function over $\mathfrak{R}^D$ momentum space with the measure $1/N^{(D)}(p)$ in (17) is

$$\begin{aligned} M_{\mathcal{H}}(f,g|\mathbf{x}) &= \int_{\mathbf{p}\in\mathfrak{R}^D}\frac{d^D\mathbf{p}}{N^{(D)}(p)}\,W_{\mathcal{H}}(f,g|\mathbf{x},\mathbf{p}) \\ &= R^2\int_{\mathbf{x}'\in\mathfrak{R}^D}\frac{d^D\mathbf{x}'}{x_0'}\int_{\mathbf{x}''\in\mathfrak{R}^D}\frac{d^D\mathbf{x}''}{x_0''}\,f(x')^*\,g(x'')\,\Delta^D(x;x',x'')\,\delta^D(x',x'') \\ &= R\int_{\mathbf{x}'\in\mathfrak{R}^D}\frac{d^D\mathbf{x}'}{x_0'}\,f(x')^*\,g(x')\,\Delta^D(x;x',x') = f(\mathbf{x})^*\,g(\mathbf{x}), \end{aligned} \tag{35}$$

where we used (16), (18), and the first property of the binding-Δ in (29).

Similarly, the integration over $\mathfrak{R}^D$ configuration space with the measure R/x_0 in (18) is

$$\begin{aligned} M_{\mathcal{H}}(f,g|\mathbf{p}) &= R\int_{\mathbf{x}\in\mathfrak{R}^D}\frac{d^D\mathbf{x}}{\sqrt{R^2+\mathbf{x}^2}}\,W_{\mathcal{H}}(f,g|\mathbf{x},\mathbf{p}) \\ &= \frac{R^2}{(2\pi)^D}\int_{\mathbf{x}'\in\mathfrak{R}^D}\frac{d^D\mathbf{x}'}{x_0'}\,f(x')^*\,\Phi_{\mathbf{p}}^{(D)}(x')\int_{\mathbf{x}''\in\mathfrak{R}^D}\frac{d^D\mathbf{x}''}{x_0''}\,g(x'')\,\Phi_{\mathbf{p}}^{(D)}(x'')^* = \tilde{f}(\mathbf{p})^*\,\tilde{g}(\mathbf{p}), \end{aligned} \tag{36}$$

where we used the second property of the binding-Δ in (29) and the Shapiro transform (20).

Finally, integrating over the whole of phase space with the appropriate measures in the Parseval relation (22), we have the total probability

$$R\int_{\mathbf{x}\in\mathfrak{R}^D}\frac{d^D\mathbf{x}}{x_0}M_{\mathcal{H}}(f,g|\mathbf{x})=(f,g)_{\mathcal{H}_+^D}=\int_{\mathbf{p}\in\mathfrak{R}^D}\frac{d^D\mathbf{p}}{N^{(D)}(p)}M_{\mathcal{H}}(f,g|\mathbf{p}). \tag{37}$$

D. Covariance under rotations and conic translations

Under rotations $\mathbf{R}\in \mathrm{SO}(D)$, wavefunctions $f(x_0,\mathbf{x})$ transform through

$$T(\mathbf{R}):f(x)=f(x_0,\mathbf{R}^{-1}\mathbf{x}). \tag{38}$$

In particular, the basis of Shapiro functions (13) transforms as

$$T(\mathbf{R}):\Phi_{p\,\mathbf{n}}^{(D)}(x_0,\mathbf{x})=\Phi_{p\,\mathbf{n}}^{(D)}(x_0,\mathbf{R}^{-1}\,\mathbf{x})=\Phi_{p\,\mathbf{Rn}}^{(D)}(x_0,\mathbf{x}). \tag{39}$$

Applying rotations $T(\mathbf{R})$ to the wavefields f and g in the Wigner function (24), we next change variables to $\mathbf{x}'=\mathbf{R}\overline{\mathbf{x}'}$ and $\mathbf{x}''=\mathbf{R}\overline{\mathbf{x}''}$ (the ambient x_0-components behave as scalars), then use (39) for $\mathbf{R}^{-1}$, noting that the binding-Δ in (28) is invariant, $\Delta^D(\overline{x};\overline{x}',\overline{x}'')=\Delta^D(x;x',x'')$ for $\overline{\mathbf{x}}=\mathbf{R}^{-1}\mathbf{x}$, and so are the measures $d^D\mathbf{x}'=d^D\overline{\mathbf{x}'}$. It thus follows that the Wigner function (24) is covariant under rotations, fulfilling

$$W_{\mathcal{H}}(T(\mathbf{R}):f,T(\mathbf{R}):g|\mathbf{x},\mathbf{p})=W_{\mathcal{H}}(f,g|\mathbf{R}^{-1}\mathbf{x},\mathbf{R}^{-1}\mathbf{p}). \tag{40}$$

Now consider translations by ζ (''boosts'' of rapidity ζ) $\mathbf{B}_{\mathbf{m}}(\zeta)\in \mathrm{SO}(D,1)_+^{\uparrow}$ in the direction of unit $\mathbf{m}\in\mathcal{S}^{D-1}$, which transform the ambient space vectors preserving the constant-curvature subspaces $x\in\mathcal{H}_+^D$ for each radius $R>0$. We denote by $\mathbf{x}_{\parallel\mathbf{m}}$ and $\mathbf{x}_{\perp\mathbf{m}}$ the projections of $\mathbf{x}$ parallel and perpendicular to the direction of $\mathbf{m}$, so that $\mathbf{x}=\mathbf{x}_{\parallel\mathbf{m}}+\mathbf{x}_{\perp\mathbf{m}}$. Then, wavefunctions on the hyperboloid transform as

$$T(\mathbf{B}_{\mathbf{m}}(\zeta)):f\begin{pmatrix}x_0\\ \mathbf{x}_{\parallel\mathbf{m}}\\ \mathbf{x}_{\perp\mathbf{m}}\end{pmatrix}=f\begin{pmatrix}x_0\cosh\zeta-\mathbf{m}\cdot\mathbf{x}\sinh\zeta\\ \mathbf{x}_{\parallel\mathbf{m}}\cosh\zeta-x_0\,\mathbf{m}\sinh\zeta\\ \mathbf{x}_{\perp\mathbf{m}}\end{pmatrix}. \tag{41}$$

When this transformation is applied to the plane-wave basis of Shapiro functions, their directions $\mathbf{n}$ on the sphere change, and they acquire a multiplier factor:

$$T(\mathbf{B}_{\mathbf{m}}(\zeta)):\Phi_{p\,\mathbf{n}}^{(D)}(x_0,\mathbf{x})=(\cosh\zeta+\mathbf{m}\cdot\mathbf{n}\sinh\zeta)^{-(1/2)(D-1)-ipR}\,\Phi_{p\,\mathbf{n}'}^{(D)}(x_0,\mathbf{x}), \tag{42}$$

where the components of $\mathbf{n}'\in\mathcal{S}^{D-1}$ that are orthogonal and parallel to $\mathbf{m}$ are

$$\mathbf{n}'_{\perp\mathbf{m}}=\frac{\mathbf{n}_{\perp\mathbf{m}}}{\cosh\zeta+\mathbf{n}\cdot\mathbf{m}\sinh\zeta},\quad \mathbf{n}'_{\parallel\mathbf{m}}=\frac{\mathbf{n}\cdot\mathbf{m}\cosh\zeta+\sinh\zeta}{\cosh\zeta+\mathbf{n}\cdot\mathbf{m}\sinh\zeta}\,\mathbf{m}, \tag{43}$$

within the same $\mathrm{SO}(D,1)_+^{\uparrow}$ irreducible representation characterized by the invariant wavenumber, p. If the angle from $\mathbf{m}$ to $\mathbf{n}$ is ϕ, it will transform through the well-known Bargmann SO(2,1) map of the circle.

The expression in the multiplier factor of Eq. (42),

$$\mu(\mathbf{m},\zeta;\mathbf{n})=\cosh\zeta+\mathbf{m}\cdot\mathbf{n}\sinh\zeta, \tag{44}$$

is, not coincidentally, p'/p—if the $(D+1)$-vector $\varpi=(p,\mathbf{p})\in\vee^+$ were allowed to transform as a ''lightlike'' vector in relativity, i.e., without being constrained to its p-sphere. Under the inner product (16), the $\mathrm{SO}(D,1)$ boost with the multiplier (42) is unitary nonetheless, because the measure in $\mathbf{p}$-space is $d^D\mathbf{p}=p^D dp d^{N-1}\mathbf{n}$, and while p is invariant, from (43) it follows that $d^{D-1}\mathbf{n}=\mu(\mathbf{m},\zeta;\mathbf{n})^{D-1}d^{D-1}\mathbf{n}'$. This cancels the absolute square of the multiplier (44) in the

Shapiro functions (41). This type of covariance modulo a multiplier function is determined by the Shapiro function basis; we may call Eqs. (41) and (42) the *Shapiro covariance* between the conjugate transformations in **x** and **p**.

When the wavefields in the Wigner function (24) are translated within the hyperboloid by (41), the ambient vectors x are multiplied by a $(D+1)\times(D+1)$ ('boost') matrix $\mathbf{B_m}(\zeta)$, to $x'\mapsto\overline{x'}=\mathbf{B_m}(\zeta)^{-1}x'$ and $x''\mapsto\overline{x''}=\mathbf{B_m}(\zeta)^{-1}x''$. Under this transformation, the measures are again invariant, $d^D\mathbf{x}'/x_0'=d^D\overline{\mathbf{x}'}/\overline{x_0'}$, etc., and so is $\Delta^D(x;x',x'')=\Delta^D(\overline{x};\overline{x'},\overline{x''})$; hence, $\overline{x}=\mathbf{B_m}(\zeta)^{-1}x$ will appear in the first argument of the transformed Wigner function. But the corresponding transformation of **p** in each of the two Shapiro functions, Eqs. (42) and (44), yields a multiplier factor. The imaginary exponents of $\mu(\mathbf{m},\zeta;\mathbf{n})$ cancel, and there remains a positive net multiplier factor:

$$W_{\mathcal{H}}(T[\mathbf{B_m}(\zeta)]:f,\,T[\mathbf{B_m}(\zeta)]:g|\mathbf{x},p\,\mathbf{n})=(\mu(\mathbf{m},\zeta;\mathbf{n}))^{-D+1}\,W_{\mathcal{H}}(f,g|\mathbf{B}(\zeta)^{-1}:\mathbf{x},\;\; p\,\mathbf{B_m}(\zeta)^{-1}:\mathbf{n}), \tag{45}$$

where $\mathbf{n}'=\mathbf{B_m}(\zeta)^{-1}:\mathbf{n}$ is given by (43). Note that in the $D=1$-dimensional case, the multiplier factor is 1.

Covariance of the Wigner function is usually understood in the simple form it has under rotations, as given by (40). Under these transformations, the hyperboloid in the ambient x-space rotates on its axis, and in the momentum plane the circles **n** of all radii p rotate in synchrony. Translations within the hyperboloid (45), on the other hand, deform the ambient and projected space vectors, x and **x**, through (41); momentum space is concurrently squeezed in the direction of the translation so that its points move on constant-p circles and with a common Bargmann deformation of the angle. Since areas are not conserved in momentum space, a multiplier function of **p** is necessary for the Wigner function to ensure the total conservation of probability (37).

E. Contraction limit

We now show that, when $f(x)$ and $g(x)$ are significantly different from zero only within a small, essentially flat patch of the hyperboloid, the definition of the Wigner function in Eq. (33) reduces to the standard Wigner function for flat space in Eq. (3). In (33), the integrand for $\boldsymbol{\eta}$ [recall Eqs. (31) and (34)] will be significant only when $\mathfrak{R}^D$ norms of the vectors fulfill

$$\left|\mathbf{x}\cosh\frac{1}{2}\tau\pm\mathbf{y}\sinh\frac{1}{2}\tau\right|\ll R\Rightarrow\begin{cases}|\mathbf{x}|\cosh\frac{1}{2}\tau\ll R & \Rightarrow\quad \sinh\chi\ll 1\\ |\mathbf{y}|\sinh\frac{1}{2}\tau\ll R & \Rightarrow\quad \sinh\tau\ll 1\end{cases} \tag{46}$$

$$\Rightarrow x\approx R(1,\chi\,\boldsymbol{\xi}),\quad y\approx R(\chi\,\boldsymbol{\xi}\cdot\boldsymbol{\eta},\boldsymbol{\eta}). \tag{47}$$

Also, using the limit in (19), and approximating $\sinh\tau\approx\tau$ and $\cosh\frac{1}{2}\tau\approx\cosh\chi\approx\cosh\omega\approx 1$, the Wigner function in Eq. (33) reduces to

$$W_{\mathcal{H}}(f,g|\mathbf{x},\mathbf{p})=\frac{R^D}{(2\pi)^D}\int_0^\infty\tau^{D-1}\,d\tau\int_{\mathcal{S}^{D-1}}d^{D-1}\boldsymbol{\eta}$$
$$\times f\left(x_0,\mathbf{x}-\frac{1}{2}R\tau\boldsymbol{\eta}\right)^*\exp(-iR\tau\,\boldsymbol{\eta}\cdot\mathbf{p})\,g\left(x_0,\mathbf{x}+\frac{1}{2}R\tau\boldsymbol{\eta}\right). \tag{48}$$

Finally, changing variables to $\mathbf{z}=R\tau\,\boldsymbol{\eta}$ and noticing that

$$\int_{\mathfrak{R}^D}d^D\mathbf{z}\cdots=R^D\int_0^\infty\tau^{D-1}\,d\tau\int_{\mathcal{S}^{D-1}}d^{D-1}\boldsymbol{\eta}\cdots, \tag{49}$$

we see that (48) reduces to (2).

F. Special case of one dimension

In the case $D=1$, the Wigner function (33) actually coincides in form with the corresponding one-dimensional standard flat space form (2), as we now proceed to show.

First, notice that the unit vectors $\mathbf{n}$ and $\boldsymbol{\xi}$ in Eq. (13) are now the unit scalars $n,\xi=\pm 1$, and that the Shapiro functions become simple exponentials:

$$\Phi_p^{(1)}(R\xi\cosh\chi,R\xi\sinh\chi)=[\exp(-n\xi\chi)]^{-ipR}=\exp(in\xi pR\chi). \tag{50}$$

We can now let $np\mapsto p$ and $\xi\chi\mapsto\chi$ with $p,\chi\in(-\infty,\infty)$, and recognize that (50) is a 1:1 function of only one variable, $x_1\in\mathfrak{R}$,

$$\Phi_p^{(1)}(x_1)=\exp(i\chi pR),\quad x_1=R\sinh\chi. \tag{51}$$

The arguments $x=(x_0,x_1)$ of the functions f and g in (33) then simplify, in components, to

$$x=\begin{pmatrix}x_0\\x_1\end{pmatrix}\mapsto x\cosh\frac{1}{2}\tau\pm y\sinh\frac{1}{2}\tau=R\begin{pmatrix}\cosh(\chi\pm\frac{1}{2}\eta\tau)\\ \sinh(\chi\pm\frac{1}{2}\eta\tau)\end{pmatrix}. \tag{52}$$

For short, we indicate $f(R\cosh\chi,R\sinh\chi)=f(\chi)$. The unit vector $\boldsymbol{\eta}$ in (33) and (34) also becomes a unit scalar, $\eta=\pm 1$, and the integral extends over $y=\eta R(\sinh\chi,\cosh\chi)$, and $\Omega=\eta\chi$ [see Eq. (32)]. Finally, the integral over $\boldsymbol{\eta}$ reduces to a sum over $\eta=\pm 1$, and for $\tau\mapsto\eta\tau\in(-\infty,\infty)$, the Wigner function (33) becomes

$$W_{\mathcal{H}}(f,g|x,p)=\frac{R}{2\pi}\int_{-\infty}^{\infty}d\tau f\left(\chi-\frac{1}{2}\tau\right)^{*}e^{-ipR\tau}g\left(\chi+\frac{1}{2}\tau\right) \tag{53}$$

$$=\frac{1}{2\pi}\int_{-\infty}^{\infty}d\upsilon\tilde{f}\left(p-\frac{1}{2}\upsilon\right)^{*}e^{+iR\upsilon x}\tilde{g}\left(p+\frac{1}{2}\upsilon\right). \tag{54}$$

The last expression is the usual flat-space Wigner function in terms of the conjugate wavefunctions on momentum space. Finally, note that for $D=1$, the net multiplier which appears under "boost" transformations in (45) is unity, so standard and Shapiro covariances coincide.

IV. EXAMPLE: OSCILLATOR ON THE HYPERBOLA

We consider the open one-dimensional space which is the upper branch of a hyperbola of fixed radius $R>0$,

$$\mathcal{H}_{+}^{1}=\{(x_0,x_1)\in\mathfrak{R}^2|x_0^2-x_1^2=R^2\}, \tag{55}$$

parametrized as usual by the hyperbolic angle $\chi\in\mathfrak{R}$.

A. Laplace–Beltrami operator and the oscillator

When the potential $V(\mathbf{x})$ is a constant (corresponding to a homogeneous optical medium), the $D=1$ Schrödinger equation (10) is the free wave equation, and its Shapiro solutions are simply the oscillating exponentials (51), with energy $E=p^2/2\mu\geqslant 0$.

Since the Laplace–Beltrami operator on the hyperbola (55) is $\Delta_{\mathrm{LB}}=R^{-2}d^2/d\chi^2$, the Schrödinger equation for the conic oscillator (23) is

$$\left(\frac{-1}{2\mu}\frac{d^2}{d\chi^2}-R^2E_0\,\mathrm{sech}^2\,\chi\right)f(\chi)=R^2\,(E-E_0)\,f(\chi),\quad E_0=\frac{1}{2}\mu\omega^2R^2, \tag{56}$$

$$V(\chi)=\frac{1}{2}\mu\omega^2R^2\frac{x_1^2}{x_0^2}=\sqrt{s(s+1)}\,(1-\mathrm{sech}^2\chi), \tag{57}$$

$$s=-\tfrac{1}{2}+\sqrt{(\mu\omega R^2)^2+\tfrac{1}{4}}. \tag{58}$$

The bound solutions are[17]

$$\begin{aligned}\psi_n^s(\chi)&=\frac{2^{-(s-n)}}{\Gamma(s-n+1)}\sqrt{\frac{(s-n)\,\Gamma(2s-n+1)}{n!}}\,\mathrm{sech}^{s-n}\chi\,{}_2F_1\left(\begin{matrix}-n,\,2s-n+1\\ s-n+1\end{matrix}\middle|\,\frac{1-\tanh\chi}{2}\right)\\&=\sqrt{\frac{(s-n)\,n!}{\pi\,\Gamma(2s-n+1)}}\,\Gamma\left(s-n+\frac{1}{2}\right)(2\,\mathrm{sech}\,\chi)^{s-n}\,C_n^{s-n+1/2}(\tanh\chi),\end{aligned} \tag{59}$$

where n is a non-negative integer bounded by $s+1$, and $C_n^{\alpha}(\xi)$ are the Gegenbauer (or ultraspherical) polynomials[18] for $\alpha>-\frac{1}{2}$. The corresponding quantized values of the energy are quadratic in n, and counted from the lowest level up by

$$E_n^s=\frac{\mu\omega^2R^2}{2}-\frac{1}{2\mu R^2}(n-s)^2,\quad n=0,1,2,\ldots<s+1. \tag{60}$$

As a check on our concepts, we verify that the contraction limit $R\to\infty$ of this system, when the radius of the hyperbola grows without bound, is the harmonic oscillator on flat space. Since the coefficient s correspondingly grows as $s\approx\mu\omega R^2$, the linear-quadratic spectrum of energies in Eq. (60) becomes the linear spectrum of the quantum harmonic oscillator $E_n=\omega(n+\frac{1}{2})$. To implement this limit on the wavefunctions (59), it is convenient to use the following forms for the Gegenbauer polynomials in $\xi=\tanh\chi$:

$$C_n^{\alpha}(\xi)=\begin{cases}(-1)^{(1/2)\,n}\dfrac{\Gamma(\alpha+\frac{1}{2}\,n)}{(\frac{1}{2}n)!\,\Gamma(\alpha)}\,{}_2F_1\left(\begin{matrix}-\frac{1}{2}n,\,\frac{1}{2}n+\alpha\\ \frac{1}{2}\end{matrix}\middle|\,\xi^2\right), & n\text{ even},\\[2ex](-1)^{(1/2)(n-1)}\dfrac{\Gamma(\alpha+\frac{1}{2}(n+1))}{(\frac{1}{2}(n-1))!\,\Gamma(\alpha)}\,2\xi\,{}_2F_1\left(\begin{matrix}-\frac{1}{2}(n-1),\,\frac{1}{2}(n+1)+\alpha\\ \frac{3}{2}\end{matrix}\middle|\,\xi^2\right), & n\text{ odd}.\end{cases} \tag{61}$$

Then, for $\alpha=s-n+\frac{1}{2}\to\infty$, the hypergeometric polynomials simplify: for n even, ${}_2F_1(-\frac{1}{2}n,\,\alpha;\frac{1}{2};\xi^2)\approx{}_1F_1(-\frac{1}{2}n;\frac{1}{2};\alpha\xi^2)=H_n(\sqrt{\alpha}\xi)$, and similarly for n odd. Replacing this into Eq. (59), with $\xi=\tanh\chi\approx\sinh\chi=x_1/R$ and $\cosh^{-s+n}\chi\approx\exp(-s\tanh^2\frac{1}{2}\chi)$, we obtain the harmonic oscillator wavefunctions on flat space,

$$\frac{1}{\sqrt{R}}\psi_n^s(\chi)\approx\frac{1}{\sqrt{2^n n!\,\sqrt{\pi/\mu\omega}}}\,e^{-\mu\omega x_1^2/2}\,H_n(\sqrt{\mu\omega}\,x_1). \tag{62}$$

The factor $\sqrt{R}$ restores the proper normalization on the x_1 axis.

In addition to the bound states, the sech-trough Pöschl–Teller potential also has free states with energy above the asymptotic value of the potential $\lim_{\chi\to\pm\infty}V(\chi)=\frac{1}{2}\mu\omega^2R^2$. These scattering solutions contain associated Legendre polynomials of imaginary upper index:

$$p = R\sqrt{2\mu E - \mu^2\omega^2 R^2} > 0,$$

$$\psi_p(\chi) = \frac{|\Gamma(1-ip)|}{2\pi} P_\sigma^{ip}(\tanh\chi), \tag{63}$$

$$\sigma = \tfrac{1}{2} \pm \sqrt{\omega^2\mu^2 R^4 + \tfrac{1}{4}}.$$

These wavefunctions are Dirac-orthonormal.

B. Momentum representation of the wavefunctions

The bound wavefunctions of the Pöschl–Teller sech-trough potential in the momentum representation, $\tilde{\psi}_n^s(p)$, are found through the ordinary Fourier transform [Eqs. (20) and (21) for $D=1$ and (51)] of the wavefunctions $\psi_n^s(\chi)$ found in Eq. (59). The result is

$$\tilde{\psi}_n^s(p) = \sqrt{\frac{R}{2\pi}} \int_{-\infty}^{\infty} d\chi \exp(-ipR\chi)\, \psi_n^s(\chi)$$

$$= \frac{R}{2}\sqrt{\frac{\Gamma(2s-n+1)}{\pi(s-n)n!}} \frac{|\Gamma(\frac{1}{2}(s-n-ipR))|^2}{\Gamma(s-n)^2}\, {}_3F_2\left(\begin{matrix} -n,\, 2s-n+1, \frac{1}{2}(s-n-ipR) \\ s-n+1, s-n \end{matrix} \middle| 1 \right) \tag{64}$$

$$= \frac{(-i)^n R}{2\sqrt{\pi}} \frac{\sqrt{(s-n)\,n!\,\Gamma(2s-n+1)}}{\Gamma(s)\,\Gamma(s+1)} \left| \Gamma\left(\frac{1}{2}(s-n-ipR) \right) \right|^2$$

$$\times R_n\left(-\frac{1}{2}ipR; \frac{1}{2}(s-n), \frac{1}{2}(s-n), \frac{1}{2}(s-n), \frac{1}{2}(s-n)+1 \right), \tag{65}$$

where $R_n(z;\alpha,\beta,\gamma,\delta)$ are the continuous Hahn polynomials.[19] On the other hand, the unbound solutions (63) are not square-integrable, so their Fourier transform must be performed allowing for the phase difference between asymptotic incoming and outgoing waves, as determined by the scattering properties of this Pöschl–Teller potential. We shall not further detail the free states here; they can be found in Ref. 9 among the coupling coefficients between the $D^+ \times D^- \to \Sigma D^+ + \int C$ irreducible representations series of SO(2,1).

C. Wigner function for the oscillator eigenstates on the hyperbola

On the one-dimensional hyperbola $\mathcal{H}_+^1$, the Wigner function (24) collapses to (53) and (54), its usual form in Eqs. (2) and (3) for $D=1$.

We are interested in the single-function form $W(f|\mathbf{x},\mathbf{p}) \equiv W(f,f|\mathbf{x},\mathbf{p}) = W(\tilde{f},\tilde{f}|\mathbf{p},-\mathbf{x})$ for the Pöschl–Teller wavefunctions, whose explicit form is in Eq. (59) for $\psi_n^s(x)$, and in Eq. (64) for $\tilde{\psi}_n^s(p)$; we find the latter more amenable to analytic solution. We change the integration to a contour along the imaginary axis, and find

$$W(\psi_n^s|\chi,p) = \frac{R^2}{8\pi^2} \frac{s-n}{n!\,\Gamma(2s-n+1)} \sum_{m,l=0}^{n} \frac{(-n)_m (-n)_l}{\Gamma(s-n+m)\,\Gamma(s-n+l)}$$

$$\times \frac{\Gamma(2s-n+m+1)\,\Gamma(2s-n+l+1)}{\Gamma(s-n+m+1)\,\Gamma(s-n+l+1)} \frac{1}{l!m!} I_n^s(\chi,p), \tag{66}$$

where

$$I_n^s(\chi,p)=-\frac{4i}{R}\int_{-i\infty}^{i\infty}dz\,\Gamma\left(\frac{1}{2}(s-n)-\frac{1}{2}ipR-z\right)\Gamma\left(\frac{1}{2}(s-n)+\frac{1}{2}ipR+z+m\right)$$
$$\times e^{-4\chi z}\,\Gamma\left(\frac{1}{2}(s-n)+\frac{1}{2}ipR-z\right)\Gamma\left(\frac{1}{2}(s-n)-\frac{1}{2}ipR+z+l\right). \tag{67}$$

The last integral can be computed in the complex plane straightforwardly, and leads to a pair of complex conjugate ${}_2F_1$-functions of $e^{-4\chi}$. We thus finally have

$$W(\psi_n^s|\chi,p)=\frac{2R\,(s-n)\,n!\,e^{-2\chi(s-n)}}{\pi\Gamma(2s-n+1)}\sum_{m,l=0}^{n}\frac{\Gamma(2s-n+m+1)\,\Gamma(2s-n+l+1)}{\Gamma(s-n+l+1)\,\Gamma(s-n+m+1)\,\Gamma(s-n+l)}$$
$$\times\frac{(-1)^{l+m}}{l!m!(n-m)!(n-l)!}\,\mathrm{Re}\left\{\Gamma(ipR)\,\Gamma(s-n+l-ipR)\,e^{2ipR\chi}\right.$$
$$\left.\times{}_2F_1\left(\begin{matrix}s-n+m,s-n+l-ipR,\\1-ipR\end{matrix}\middle|\,e^{-4\chi}\right)\right\}. \tag{68}$$

We note that this expression is suitable for numerical computation only for $\chi>0$ because it converges fast, but it holds everywhere analytically, with the reflection symmetries $W(\psi_n^s|\chi,p)=W(\psi_n^s|-\chi,p)=W(\psi_n^s|\chi,-p)$.

The Wigner functions, together with their marginal projections $|\psi_n^s(x)|^2$ and $|\tilde{\psi}_n^s(p)|^2$, are shown in Fig. 1, for $n=0,1,2,3$, and for the potential depth parameter $s=4$ and 30. It can be appreciated that the Wigner function of the most tightly bound states resemble the familiar Gaussian-bell form of the harmonic oscillator ground state. According to (60), for $s=4$ there are only five bound states ($n=0,\ldots,4$), and as the energy of the state approaches the binding energy, the wavefunction stretches in space with ever-smaller momentum in a neighborhood of the classical turning point. The contraction limit can be appreciated in the $s=30$ column, corresponding to a large binding energy; the Wigner functions for the eigenstates in Eq. (59) approach the familiar Laguerre–Gaussian form that corresponds to the Wigner function of the harmonic oscillator wavefunctions on flat space.

V. CONCLUDING REMARKS

We have generalized the Wigner quasiprobability distribution function by replacing the oscillating exponential functions of the standard version, which are Dirac solutions of the free Schrödinger equation on flat space, by the Shapiro functions, because they are solutions to the Laplace–Beltrami equation on a simply connected hyperbolic space, while respecting the midpoint condition through an appropriate Dirac-like $\Delta^D(x;x',x'')$. The role of the Fourier transform in the standard version is transfered by the Shapiro functions to a Mellin-like transform between the position and momentum coordinates of phase space. Indeed, the relation between what were called position and momentum variables is actually defined by the argument and index of the basis of Shapiro functions. Thus built, the proposed Wigner function is covariant under the group SO(D,1) of motions of the hyperbola, with the hyperbolic translations extracting a multiplier factor. The correct marginals are found and the contraction limit to flat space returns the standard Wigner function.

The transformations of the momentum direction under translations of the hyperbola are the (unique) action of SO(D,1) on the sphere $\mathcal{S}^D$.[13] There are several models of Hamiltonian systems where momentum is restricted to a sphere, such as geometric and Helmholtz (monochromatic) optics.[20,21] In the first model, a ''Descartes sphere'' of momentum vectors $\mathbf{p}$, which is of radius $|\mathbf{p}|=n(\mathbf{x})$ (the refractive index), is associated to each point $\mathbf{x}$ in space. This sphere of momentum vectors has been subject to Bargmann's ''boost'' transformation in Ref. 22 (which is unique for Lorentz groups acting on spheres) and here given by (43), with a canonically conjugate transformation of the ray positions at a plane screen. The resulting phenomenon has been called relativ-

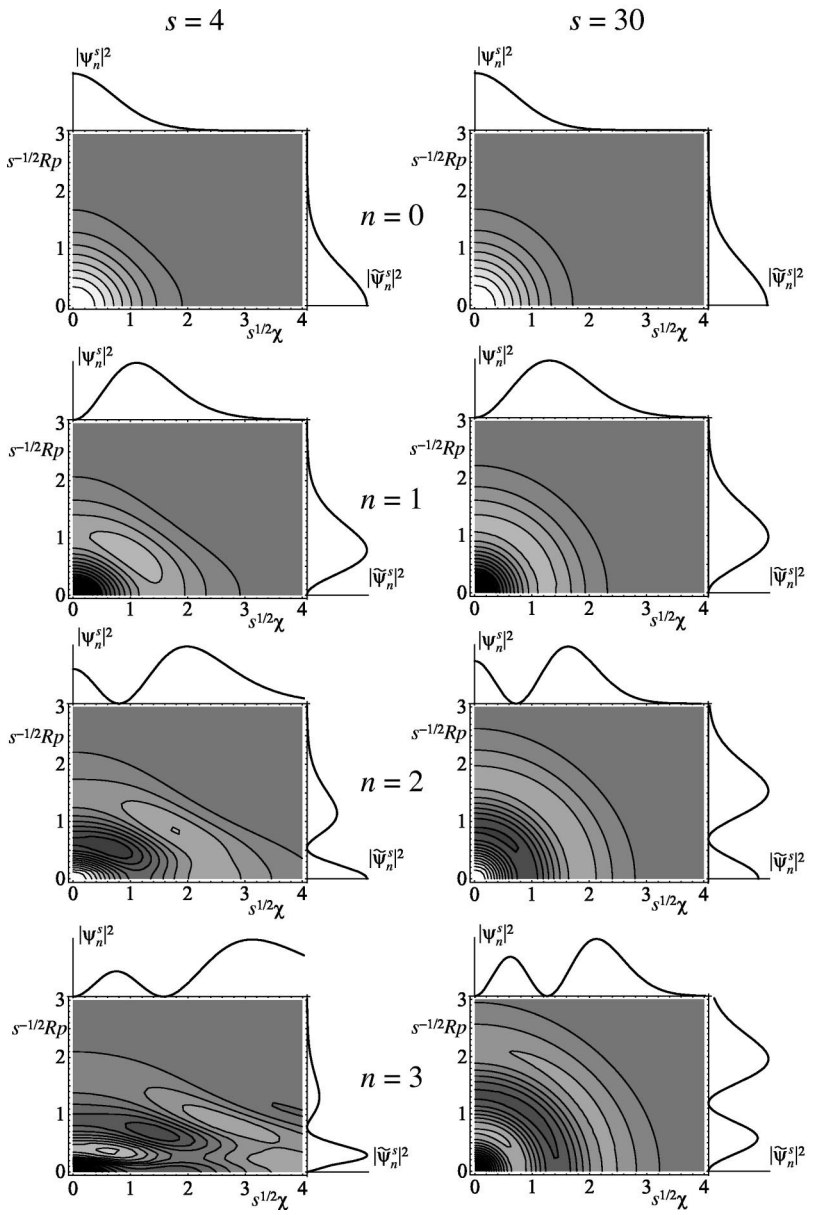

FIG. 1. Wigner functions of the Pöschl–Teller eigenfunctions $\psi_n^s(\chi)$ on a quadrant of phase space (axes are position $\chi\sqrt{s}$ and momentum $pR/\sqrt{s}$; the quadrants have reflection symmetry across the axes). Rows are numbered by the mode $n=0,1,2,3$. Left: $s=4$ (so only five states, $n=0,\ldots,4$, are bound); right: $s=30$ (so states are bound up to $n=30$). White is the maximum, black is the minimum; the shade at the upper right corner corresponds to zero. From each Wigner function we project up the marginal distribution of position $|\psi_n^s(\chi)|^2$, and right the marginal of momentum $|\tilde{\psi}_n^s(p)|^2$.

istic coma, because the aberration in the images projected on moving screens in vacuum is comatic. The Doppler effect is of course absent, so this transformation cannot be called physically relativistic in the Helmholtz case, which involves a configuration space with a nonlocal metric. Indeed, the difference between the various models consists in their space of positions; here, it is the hyperboloid. A Wigner function on spheres will be examined in part II of this title; it is expected to clarify further the use of function bases to define conjugate variables as a simile or substitute for phase space.

The context of this work has a wider significance as a model for phase space with noncom-

mutative geometry, although here the noncommutativity is restricted to momentum space only. In one dimension this argument does not apply, but the example of the one-dimensional Wigner function of Pöschl–Teller wavefunctions is of interest on its own for the traditional quantum mechanical model, and also for the paraxial propagation of light along shallow nonharmonic waveguides whose index of refraction has a sech^2 profile, as given by Eq. (11). One of the manifestations of higher symmetry is the appearance of ''closed-form'' wavefunctions expressed in terms of well-known (and some not-so-well-known) special functions. Generally, the Fourier transforms and Wigner functions of such wavefunctions are again known special functions because symmetry, when it occurs, is displayed in phase space.

(Received 23 August 2002; accepted 2 September 2002)

Quantum operations frequently occur in quantum measurement theory, quantum probability, quantum computation, and quantum information theory. If an operator A is invariant under a quantum operation ϕ, we call A a ϕ-fixed point. Physically, the ϕ-fixed points are the operators that are not disturbed by the action of ϕ. Our main purpose is to answer the following question. If A is a ϕ-fixed point, is A compatible with the operation elements of ϕ? We shall show in general that the answer is no and we shall give some sufficient conditions under which the answer is yes. Our results will follow from some general theorems concerning completely positive maps and injectivity of operator systems and von Neumann algebras. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1519669]

I. INTRODUCTION

Let $\mathcal{H}$ be a Hilbert space and let $\mathcal{B}(\mathcal{H})$ be the set of bounded linear operators on $\mathcal{H}$. We use the notation

$$\mathcal{B}(\mathcal{H})^+ = \{A \in \mathcal{B}(\mathcal{H}) : A \geqslant 0\}, \quad \mathcal{E}(\mathcal{H}) = \{A \in \mathcal{B}(\mathcal{H}) : 0 \leqslant A \leqslant I\},$$

that is, $\mathcal{B}(\mathcal{H})^+$ is the positive cone for $\mathcal{B}(\mathcal{H})$ and $\mathcal{E}(\mathcal{H})$ is the set of **quantum effects**.[1–4] Quantum effects correspond to yes–no quantum measurements that may be unsharp. Denoting the set of trace class operators on $\mathcal{H}$ by $\mathcal{T}(\mathcal{H})$, the set of **states** (or **density operators**) of a quantum system is described by

$$\mathcal{D}(\mathcal{H}) = \{\rho \in \mathcal{T}(\mathcal{H})^+ : \mathrm{tr}(\rho) = 1\}.$$

The probability that an effect A occurs (has a yes answer) in the state ρ is given by $P_\rho(A) = \mathrm{tr}(\rho A)$.

Quantum measurements that have more than two values (not just yes–no) are frequently described by effect-valued measures. In this paper we shall only consider discrete effect-valued measures. These are described by a sequence $E_i \in \mathcal{E}(\mathcal{H})$, $i = 1,2,\ldots$, satisfying $\Sigma E_i = I$, where the sum converges in the strong operator topology. In this case the probability that outcome i occurs in the state ρ is $P_\rho(E_i)$ and the postmeasurement state given that i occurs is $E_i^{1/2}\rho E_i^{1/2}/\mathrm{tr}(\rho E_i)$. Moreover, the resulting state after the measurement is executed but no observation is performed is given by

$$\phi(\rho) = \sum E_i^{1/2}\rho E_i^{1/2}.$$

More general quantum measurements will be discussed later when we consider quantum operations. Notice that ϕ is an affine map from $\mathcal{D}(\mathcal{H})$ into $\mathcal{D}(\mathcal{H})$. Also, ϕ extends to a unital, trace-

preserving, completely positive map on $\mathcal{B}(\mathcal{H})$. (Detailed definitions will be given subsequently.) An important physical question is whether the measurement disturbs the state ρ. The fact that the measurement does not disturb ρ is given mathematically by the equation $\phi(\rho)=\rho$. It is shown in Ref. 5 that $\phi(\rho)=\rho$ if and only if ρ commutes with every E_i, $i=1,2,\ldots$. We then say that ρ is **compatible** with E_i, $i=1,2,\ldots$, and this result is called the generalized Lüders theorem.

In the dual picture, the probability that an effect A occurs in the state ρ given that the measurement was performed is

$$P_{\phi(\rho)}(A)=\mathrm{tr}\left[A\sum\ E_i^{1/2}\rho E_i^{1/2}\right]=\mathrm{tr}\left(\sum\ E_i^{1/2}AE_i^{1/2}\rho\right).$$

If A is not disturbed by the measurement in any state we have

$$\sum\ E_i^{1/2}AE_i^{1/2}=A. \tag{1.1}$$

Again, defining $\phi(A)=\Sigma E_i^{1/2}AE_i^{1/2}$, Eq. (1.1) reduces to $\phi(A)=A$. But, now A may not be in $\mathcal{T}(\mathcal{H})^+$ and the previous proof of the generalized Lüders theorem does not go through. In fact, we shall show that $\phi(A)=A$ does not necessarily imply that A is compatible with E_i, $i=1,2,\ldots$. (This solves an open problem posed in Refs. 5 and 3.) Another way that (1.1) comes about is from the law of total probability, which is given by

$$\mathrm{tr}(\rho A)=P_\rho(A)=\sum\ P_\rho(E_i)P_\rho(A|E_i)=\sum\ \mathrm{tr}(\rho E_i)\frac{\mathrm{tr}(E_i^{1/2}\rho E_i^{1/2}A)}{\mathrm{tr}(\rho E_i)}=\mathrm{tr}\left(\rho\sum\ E_i^{1/2}AE_i^{1/2}\right).$$

If this law holds for every $\rho\in\mathcal{D}(\mathcal{H})$, we again obtain $\phi(A)=A$.

An application of our result can be found in axiomatic quantum field theory. Suppose a measurement $\{E_i:i=1,2,\ldots\}$ is performed in a bounded spacetime region X and $A\in\mathcal{E}(\mathcal{H})$ is a measurement performed in another space–time region Y that is spacelike separated from X. According to Einstein causality, the measurement in X should not disturb A so that $\phi(A)=A$. But, applying our result, A may not be compatible with E_i, $i=1,2,\ldots$. Thus, the axiom of local commutativity does not follow from Einstein causality. We conclude that this axiom may be too strong and it should be replaced by a weaker axiom.

More general measurements are frequently considered in quantum dynamics, quantum computation, and quantum information theory.[1,2,6] Let $A_i\in\mathcal{B}(\mathcal{H})$, $i=1,2,\ldots$, and let $\mathcal{A}=\{A_i,A_i^*:i=1,2,\ldots\}$. Assume for now that $\Sigma A_i^*A_i=I$ (trace preserving) and that $\Sigma A_iA_i^*=I$ (unitality). (The unitality condition is sometimes omitted and the trace-preserving condition is sometimes relaxed to $\Sigma A_i^*A_i\leqslant I$.) For $B\in\mathcal{B}(\mathcal{H})$, define $\phi_\mathcal{A}(B)=\Sigma A_iBA_i^*$. It can be shown that $\phi_\mathcal{A}:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{H})$ is a normal, completely positive map. Moreover, $\phi_\mathcal{A}(I)=I$ (unital) and $\mathrm{tr}[\phi_\mathcal{A}(B)]=\mathrm{tr}(B)$ for all $\mathcal{B}\in\mathcal{T}(\mathcal{H})$ (trace preserving). In fact, if $\mathcal{H}$ is separable, then any map satisfying these conditions has the form $\phi_\mathcal{A}$ for some $\mathcal{A}$.[2] There are various interpretations for $\phi_\mathcal{A}$. For example, $\phi_\mathcal{A}$ can describe a quantum measurement, an interaction of a quantum system with an environment followed by a unitary evolution, a noisy quantum channel, or a quantum error correction map. We call $\phi_\mathcal{A}$ a **quantum operation** and we call $\mathcal{A}$ the set of **operation elements** for $\phi_\mathcal{A}$. Note that our previous examples are a special type of quantum operations. This can be seen by letting $A_i=E_i^{1/2}$.

We say that $B\in\mathcal{B}(\mathcal{H})$ is a $\phi_\mathcal{A}$ **fixed point** if $\phi_\mathcal{A}(B)=B$, and denote the set of $\phi_\mathcal{A}$ fixed points by $\mathcal{B}(\mathcal{H})^{\phi_\mathcal{A}}$. It is clear that the commutant $\mathcal{A}'\subseteq\mathcal{B}(\mathcal{H})^{\phi_\mathcal{A}}$. The main purpose of this paper is to study $\mathcal{B}(\mathcal{H})^{\phi_\mathcal{A}}$ and the question of whether $\mathcal{B}(\mathcal{H})^{\phi_\mathcal{A}}=\mathcal{A}'$. We shall show that in general $\mathcal{B}(\mathcal{H})^{\phi_\mathcal{A}}\neq\mathcal{A}'$ and shall give sufficient conditions under which equality holds. For example, in quantum computation it is assumed that $\dim\mathcal{H}<\infty$. For this case we shall show that $\mathcal{B}(\mathcal{H})^{\phi_\mathcal{A}}=\mathcal{A}'$. Thus, a noisy quantum channel does not disturb a state ρ if and only if ρ is compatible with the operation elements A_i, $i=1,2,\ldots$. Related results and methods may be found in Ref. 7.

II. COMPLETELY POSITIVE MAPS

This section studies completely positive maps on von Neumann algebras. Such maps give a unifying generalization of quantum operations and many of our results will follow from these general considerations.

An **operator system** is a linear subspace of $\mathcal{B}(\mathcal{H})$ that is closed under the involution * and contains the identity operator. Let $\mathcal{M}_k$ be the C^* algebra of $k\times k$ complex matrices which we identify with $\mathcal{B}(\mathbb{C}^k)$. For an operator system $\mathcal{S}\subseteq\mathcal{B}(\mathcal{H})$ we consider $\mathcal{S}\otimes\mathcal{M}_k$ embedded in the C^* algebra $\mathcal{B}(\mathcal{H})\otimes\mathcal{M}_k$. Then, $\mathcal{S}\otimes\mathcal{M}_k$ carries the natural operator norm and the natural operator order. Given operator systems $\mathcal{V}$ and $\mathcal{W}$ and a linear map $\phi:\mathcal{V}\to\mathcal{W}$, for any integer $k\geqslant 1$, there is defined a linear map $\phi_k:\mathcal{V}\otimes\mathcal{M}_k\to\mathcal{W}\otimes\mathcal{M}_k$ given by

$$\phi_k(v)=[\phi(v_{ij})],\quad \text{where}\quad v=[v_{ij}]\in\mathcal{V}\otimes\mathcal{M}_k,\quad i,j=1,\ldots,k.$$

We then have a nondecreasing sequence of operator norms

$$\|\phi\|=\|\phi_1\|\leqslant\|\phi_2\|\leqslant\|\phi_3\|\leqslant\cdots.$$

The map ϕ is called **completely bounded** if

$$\|\phi\|_{\mathrm{cb}}=\sup_{k\geqslant 1}\|\phi_k\|<\infty.$$

It follows that $\|\cdot\|_{\mathrm{cb}}$ is a norm on the linear space $\mathcal{CB}(\mathcal{V},\mathcal{W})$ of completely bounded maps from $\mathcal{V}$ into $\mathcal{W}$. If $\|\phi\|_{\mathrm{cb}}\leqslant 1$, then ϕ is called **completely contractive**. If ϕ_k is positive for all k, then ϕ is called **completely positive**. Any completely positive map ϕ is completely bounded and

$$\|\phi(I)\|=\|\phi\|=\|\phi\|_{\mathrm{cb}}.$$

In particular, if $\phi(I)=I$ then ϕ is completely contractive.[8]

Now, let $\mathcal{V}\subseteq\mathcal{B}(\mathcal{H})$ be an operator system. A map $\psi:\mathcal{V}\to\mathcal{V}$ is **idempotent** if $\psi\circ\psi=\psi$. A completely contractive idempotent map ψ from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{V}$ is called a **projection** onto $\mathcal{V}$. If there exists a projection from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{V}$, then $\mathcal{V}$ is **injective**. A linear map ψ from a C^* subalgebra $\mathcal{M}$ into itself is a **conditional expectation** if ψ is a positive idempotent, its range is a C^* subalgebra $\mathcal{N}$ of $\mathcal{M}$ and $\psi(CB)=\psi(C)B$ and $\psi(BC)=B\psi(C)$ for every $B\in\mathcal{N}$ and $C\in\mathcal{M}$. A C^* algebra $\mathcal{M}\subseteq\mathcal{B}(\mathcal{H})$ is injective if and only if there exists a conditional expectation on $\mathcal{B}(\mathcal{H})$ with range $\mathcal{M}$.[9] A von Neumann algebra $\mathcal{M}$ is injective if and only if $\mathcal{M}'$ is injective.[10,11] A **state** on a C^* algebra $\mathcal{M}$ is a positive linear functional $\omega:\mathcal{M}\to\mathbb{C}$ with norm $\|\omega\|=1$. [If $\mathcal{M}$ has a unit I, the condition $\|\omega\|=1$ is equivalent to $\omega(I)=1$.] We say that ω is **faithful** if $\omega(A^*A)=0$ implies $A=0$.

In the sequel we shall need the following theorem of Choi.[12]

Theorem 2.1: *Suppose that ϕ is a completely contractive and completely positive map from a unital C^* algebra $\mathcal{C}$ into $\mathcal{B}(\mathcal{H})$. Then, $\phi(C)^*\phi(C)\leqslant\phi(C^*C)$ for every $C\in\mathcal{C}$. Moreover, if $\phi(C)^*\phi(C)=\phi(C^*C)$ for some $C\in\mathcal{C}$, then for all $B\in\mathcal{C}$ we have $\phi(BC)=\phi(B)\phi(C)$, $\phi(CB)=\phi(C)\phi(B)$.*

If $\phi:\mathcal{M}\to\mathcal{M}$ is a unital completely positive map and ω is a state on $\mathcal{M}$, then $\omega\circ\phi$ is again a state on $\mathcal{M}$. We say that ω is **ϕ-invariant** of $\omega\circ\phi=\omega$. We say that $A\in\mathcal{M}$ is a **fixed point** of ϕ if $\phi(A)=A$ and denote the set of fixed points of ϕ by $\mathcal{M}^\phi$.[7] Notice that $\mathcal{M}^\phi$ is an operator system. In general, $\mathcal{M}^\phi$ is not an algebra.[7] It is easy to check that

$$\mathcal{I}(\phi)=\{A\in\mathcal{M}:\phi(AB)=A\phi(B),\phi(BA)=\phi(B)A\ \text{ for every }\ B\in\mathcal{M}\}$$

is a C^* algebra in $\mathcal{M}$ and $\mathcal{I}(\phi)\subseteq\mathcal{M}^\phi$. Moreover, if ϕ is weakly continuous, then $\mathcal{I}(\phi)$ is a von Neumann subalgebra of $\mathcal{M}$ and $\mathcal{M}^\phi$ is a weakly closed operator system.

Lemma 2.2: The following statements are equivalent. (a) $\mathcal{M}^\phi=\mathcal{I}(\phi)$. (b) $\mathcal{M}^\phi$ *is a C^* algebra.* (c) If $A\in\mathcal{M}^\phi$, *then* $A^*A\in\mathcal{M}^\phi$.

Proof: (a)⇒(b)⇒(c) is clear. To prove that (c) implies (a) suppose (c) holds and $A \in \mathcal{M}^{\phi}$. Then, $A^*A \in \mathcal{M}^{\phi}$ so that

$$\phi(A)^*\phi(A) = A^*A = \phi(A^*A).$$

It follows from Theorem 2.1 that for every $B \in \mathcal{M}$ we have

$$\phi(AB) = \phi(A)\phi(B) = A\phi(B),$$

and

$$\phi(BA) = \phi(B)\phi(A) = \phi(B)A.$$

Hence, $A \in \mathcal{I}(\phi)$. □

Theorem 2.3: *If ϕ admits a faithful invariant state ω,* then $\mathcal{M}^{\phi} = \mathcal{I}(\phi)$.

Proof: Suppose that $A \in \mathcal{M}^{\phi}$. By Theorem 2.1 we have

$$A^*A = \phi(A)^*\phi(A) \leqslant \phi(A^*A),$$

so that $\phi(A^*A) - A^*A \in \mathcal{M}^{+}$. Since

$$\omega[\phi(A^*A) - A^*A] = \omega \circ \phi(A^*A) - \omega(A^*A) = 0,$$

we conclude that $\phi(A^*A) = A^*A$. Hence, $A^*A \in \mathcal{M}^{\phi}$. Applying Lemma 2.2 we have that $\mathcal{M}^{\phi} = \mathcal{I}(\phi)$. □

For $\phi: \mathcal{M} \to \mathcal{M}$ we denote the map obtained by composing ϕ with itself n times by ϕ^n. If $\psi: \mathcal{M} \to \mathcal{M}$ we denote the composition $\psi \circ \phi$ by $\psi\phi$.

Theorem 2.4: *Let $\phi: \mathcal{M} \to \mathcal{M}$ be a weakly continuous, unital, completely positive map.* (a) *There exists an idempotent, unital, completely positive map $\psi: \mathcal{M} \to \mathcal{M}$ with range* $\mathrm{ran}(\psi) = \mathcal{M}^{\phi}$. (b) $\mathcal{M}^{\phi} = \mathcal{I}(\phi)$ *if and only if ψ is a conditional expectation.* (c) *If $\mathcal{M} = \mathcal{B}(\mathcal{H})$ and $\mathcal{M}^{\phi} = \mathcal{I}(\phi)$, then $\mathcal{I}(\phi)$ is an injective von Neumann algebra.*

Proof: (a) Let $\psi_n: \mathcal{M} \to \mathcal{M}$ be the sequence of Cesàro means

$$\psi_n = \frac{1}{n} \sum_{i=1}^{n} \phi^i.$$

Then, ψ_n, $n = 1,2,\ldots$, are unital completely positive (and hence completely contractive) maps. Since $\mathcal{M}$ has a predual, it follows from the Alaoglu theorem that the closed unit ball of $\mathcal{M}$ is compact in the weak * topology. Hence, the closed unit ball of $\mathcal{CB}(\mathcal{M})$ is compact in the point-weak topology. It follows that there exists a subsequence ψ_{n_k} and a unital completely positive map $\psi: \mathcal{M} \to \mathcal{M}$ such that

$$w\text{-}\lim_{k \to \infty} \psi_{n_k}(A) = \psi(A) \tag{2.1}$$

for every $A \in \mathcal{M}$. For any integer $n \geqslant 1$ we have

$$\|\psi_n - \phi\psi_n\| = \frac{1}{n}\|\phi - \phi^{n+1}\| \leqslant \frac{2}{n}, \tag{2.2}$$

and hence $\psi_n - \phi\psi_n$ converges uniformly to 0. For any $k \geqslant 1$ we have

$$\phi\psi - \psi = (\phi\psi - \phi\psi_{n_k}) + (\phi\psi_{n_k} - \psi_{n_k}) + (\psi_{n_k} - \psi).$$

Note that the point-weak limit of the expression of the right side is 0 as $n_k \to \infty$. Indeed, $\psi_{n_k} - \psi \to 0$ by the definition of ψ, $\psi_{n_k} - \phi\psi_{n_k} \to 0$ by (2.2) and

$$\phi\psi - \phi\psi_{n_k} = \phi(\psi - \psi_{n_k}) \to 0,$$

because ϕ is weakly continuous. In a similar way we have $\psi\phi = \psi$ and thus

$$\phi\psi = \psi\phi = \psi. \tag{2.3}$$

By induction we see that $\phi^k\psi = \psi\phi^k = \psi$ for all $k \geqslant 1$, and hence

$$\psi_{n_k}(\psi(A)) = \psi(A), \tag{2.4}$$

for all $A \in \mathcal{M}$. Taking the weak limit in (2.4) as $k \to \infty$, we conclude that ψ is idempotent. In particular, $\mathrm{ran}(\psi) = \mathcal{M}^{\psi}$. Applying (2.3), we have $\mathrm{ran}(\psi) \subseteq \mathcal{M}^{\phi}$. To prove the converse inclusion, let $A \in \mathcal{M}^{\phi}$. Then $\psi_{n_k}(A) = A$ for all $k \geqslant 1$ and by (2.1) we have $\psi(A) = A$. Hence, $\mathrm{ran}(\psi) = \mathcal{M}^{\phi}$.

(b) If $\mathcal{M}^{\phi} = \mathcal{I}(\phi)$, then $\mathrm{ran}(\psi) = \mathcal{M}^{\phi}$ is a von Neumann subalgebra of $\mathcal{M}$. For $A \in \mathrm{ran}(\psi)$, we have

$$\psi(A)^*\psi(A) = A^*A = \psi(A^*A).$$

Hence, by Theorem 2.1 we obtain

$$\psi(AB) = \psi(A)\psi(B) = A\psi(B),$$

and

$$\psi(BA) = \psi(B)\psi(A) = \psi(B)A$$

for all $B \in \mathcal{M}$. Thus, ψ is a conditional expectation. Conversely, if ψ is a conditional expectation, then $\mathcal{M}^{\phi} = \mathrm{ran}(\psi)$ is a C^* subalgebra of $\mathcal{M}$, so applying Lemma 2.2, we conclude that $\mathcal{M}^{\phi} = \mathcal{I}(\phi)$.

(c) If $\mathcal{M}^{\phi} = \mathcal{I}(\phi)$, then by (b), ψ is a conditional expectation with $\mathrm{ran}(\psi) = \mathcal{I}(\phi)$ so $\mathcal{I}(\phi)$ is an injective von Neumann algebra. □

Corollary 2.5: Let $\phi: \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{H})$ be a weakly continuous, unital, completely positive map. If $\mathcal{I}(\phi)$ is not injective, then $\mathcal{B}(\mathcal{H})^{\phi} \neq \mathcal{I}(\phi)$.

III. QUANTUM OPERATIONS

Let $\mathcal{A}$ be a set of operators $\mathcal{A} = \{A_i, A_i^* : i = 1,2,\ldots\}$, where $A_i \in \mathcal{B}(\mathcal{H})$ satisfy $\Sigma A_i A_i^* \leqslant I$. A map $\phi: \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{H})$ of the form $\phi_{\mathcal{A}}(B) = \Sigma A_i B A_i^*$ is called a **quantum operation**. If $B \geqslant 0$ then this series gives an increasing sequence of positive operators that is bounded above by $\|B\|I$ so it converges in the strong operator topology. It follows that the series converges in the strong operator topology for any $B \in \mathcal{B}(\mathcal{H})$. It is easy to see that a quantum operation is completely positive. If $\phi_{\mathcal{A}}(I) = I$ or equivalently if $\Sigma A_i A_i^* = I$, then $\phi_{\mathcal{A}}$ is **unital**. If $\Sigma A_i^* A_i = I$ then $\phi_{\mathcal{A}}$ is **trace preserving**. If the A_i are self-adjoint then $\phi_{\mathcal{A}}$ is **self-adjoint**. An important example of a self-adjoint quantum operation is **Lüders operation**

$$L_{\mathcal{A}}(B) = \sum A_i^{1/2} B A_i^{1/2},$$

where $A_i \geqslant 0$ and $\Sigma A_i = I$. A quantum operation $\phi_{\mathcal{A}}$ is **faithful** if $\phi_{\mathcal{A}}(B^*B) = 0$ implies that $B = 0$.

Theorem 3.1: *Let $\phi_{\mathcal{A}}$ be a quantum operation.* (a) *$\phi_{\mathcal{A}}$ is a weakly continuous completely positive map.* (b) *If $\phi_{\mathcal{A}}$ is trace preserving then $\phi_{\mathcal{A}}$ is faithful and* $\mathrm{tr}(\phi_{\mathcal{A}}(B)) = \mathrm{tr}(B)$ *for every $B \in \mathcal{T}(\mathcal{H})$.*

Proof: (a) Let ℓ_2 denote the Hilbert space of square summable complex sequences and let $\ell_2(\mathcal{H})=\ell_2\otimes\mathcal{H}$ be the Hilbert space of square summable sequences with elements in $\mathcal{H}$. Let $V:\mathcal{H}\to\ell_2(\mathcal{H})$ be the linear operator defined by

$$Vh=(A_1^*h,A_2^*h,\ldots).$$

Now, $V\in\mathcal{B}(\mathcal{H},\ell_2(\mathcal{H}))$ because

$$\|Vh\|^2=\sum\ \langle A_i^*h,A_i^*h\rangle=\sum\ \langle A_iA_i^*h,h\rangle=\left\langle\sum\ A_iA_i^*h,h\right\rangle\leqslant\|h\|^2.$$

The adjoint $V^*\in\mathcal{B}(\ell_2(\mathcal{H}),\mathcal{H})$ is given by

$$V^*(h_1,h_2,\ldots)=\sum\ A_ih_i.$$

It follows that $\phi_{\mathcal{A}}(B)=V^*(I\otimes B)V$ for all $B\in\mathcal{B}(\mathcal{H})$. Since the map $B\mapsto I\otimes B$ from $\mathcal{B}(\mathcal{H})$ to $\mathcal{B}(\ell_2(\mathcal{H}))$ is weakly continuous[13] and completely positive, it follows that $\phi_{\mathcal{A}}$ is weakly continuous and completely positive.

(b) Suppose that $\phi_{\mathcal{A}}$ is trace preserving. To show $\phi_{\mathcal{A}}$ is faithful, suppose $\phi_{\mathcal{A}}(B^*B)=0$. Then, for every $h\in\mathcal{H}$ we have

$$0=\langle\phi_{\mathcal{A}}(B^*B)h,h\rangle=\left\langle\sum\ A_iB^*BA_i^*h,h\right\rangle=\sum\ \langle BA_i^*h,BA_i^*h\rangle.$$

Hence, $BA_i^*h=0$ for every $h\in\mathcal{H}$ so that $BA_i^*=0$. But, then

$$B=B\sum\ A_i^*A_i=0.$$

Finally, let $B\in\mathcal{T}(\mathcal{H})^+$. Then, the operators $A_iBA_i^*$ and $A_i^*A_iB$ are trace class and

$$\mathrm{tr}\left(\sum_{i=1}^n A_iBA_i^*\right)=\mathrm{tr}\left(\sum_{i=1}^n A_i^*A_iB\right)\leqslant\left\|\sum_{i=1}^n A_i^*A_i\right\|\mathrm{tr}(B)\leqslant\mathrm{tr}(B).$$

Since $\Sigma_{i=1}^n A_iBA_i^*$ is a nondecreasing sequence of positive operators converging strongly to $\phi_{\mathcal{A}}(B)$, and since the trace is continuous with respect to such sequences, we have

$$\mathrm{tr}(\phi_{\mathcal{A}}(B))=\lim_{n\to\infty}\mathrm{tr}\left(\sum_{i=1}^n A_iBA_i^*\right)\leqslant\mathrm{tr}(B).$$

Hence, $\phi_{\mathcal{A}}(B)\in\mathcal{T}(\mathcal{H})^+$. Again by the continuity of trace on bounded nondecreasing sequences we have

$$\mathrm{tr}(\phi_{\mathcal{A}}(B))=\lim_{n\to\infty}\mathrm{tr}\left(\sum_{i=1}^n A_i^*A_iB\right)=\mathrm{tr}\left(\sum_{i=1}^\infty A_i^*A_iB\right)=\mathrm{tr}(B).$$

The result for arbitrary $B\in\mathcal{T}(\mathcal{H})$ now follows. □

Let $\phi_{\mathcal{A}}$ be a unital quantum operation and define the fixed point set $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ as before. We then have the von Neumann algebras $\mathcal{I}(\phi_{\mathcal{A}})$ and $\mathcal{A}'$ as well as the weakly closed operator system $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$, and it is clear that

$$\mathcal{A}'\subseteq\mathcal{I}(\phi_{\mathcal{A}})\subseteq\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}.$$

We are now interested in when these sets coincide; that is, when $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} \subseteq \mathcal{A}'$. The next theorem generalizes a result in Ref. 5 and has essentially the same proof.

Theorem 3.2: *Let $\phi_{\mathcal{A}}$ be a self-adjoint quantum operation. If $B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ is positive and has pure point spectrum which can be totally ordered in decreasing order, then $B \in \mathcal{A}'$.*

Proof: Let h be a unit eigenvector of B corresponding to the largest eigenvalue $\lambda_1 = \|B\|$. Then, $\phi_{\mathcal{A}}(B) = B$ implies that

$$\lambda_1 = \sum \langle BA_i h, A_i h\rangle \leqslant \|B\| \sum \|A_i h\|^2 = \lambda_1 \sum \langle A_i^2 h, h\rangle \leqslant \lambda_1 .$$

Since $\langle BA_i h, A_i h\rangle \leqslant \lambda_1 \langle A_i^2 h, h\rangle$, it follows that

$$\langle (\lambda_1 I - B) A_i h, A_i h\rangle = 0.$$

Hence, $(\lambda_1 I - B) A_i h = 0$ for every eigenvector h corresponding to λ_1. Thus, A_i leaves the λ_1-eigenspace invariant. Letting P_1 be the corresponding spectral projection of B, we have $P_1 A_i P_1 = A_i P_1$, which implies that $A_i P_1 = P_1 A_i$, $i = 1,2,\ldots$. Now, $B = \lambda_1 P_1 + B_1$ where B_1 is a positive operator with a largest eigenvalue. Since

$$\lambda_1 P_1 + B_1 = B = \phi_{\mathcal{A}}(B) = \lambda_1 \phi_{\mathcal{A}}(P_1) + \phi_{\mathcal{A}}(B_1) = \lambda_1 P_1 + \phi_{\mathcal{A}}(B_1),$$

we have $\phi_{\mathcal{A}}(B_1) = B_1$. Proceeding by induction, $B \in \mathcal{A}'$. □

We shall show later that Theorem 3.2 cannot be extended to an arbitrary positive $B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$. Moreover, it cannot be extended to a non-self-adjoint $\phi_{\mathcal{A}}$ even in the case where B is positive with finite spectrum and $\mathcal{A}$ contains only two operation elements. The next result follows from Lemmas 3.1 and 3.3 of Ref. 7. However, we present a simpler and more algebraic proof.

Lemma 3.3: If $\phi_{\mathcal{A}}$ is a unital quantum operation, then the following statements are equivalent. (a) $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$. (b) $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ *is a von Neumann algebra.* (c) $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{I}(\phi_{\mathcal{A}})$. (d) If $B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$, *then* $B^*B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$.

Proof: (a)⇒(b) is clear, (b)⇒(c) follows from Lemma 2.2, and (c)⇒(d) is clear. To show that (d) implies (a) assume that (d) holds and $B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$. Then, $B^*B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$. Notice that

$$\begin{aligned} 0 \leqslant [B,A_i][B,A_i]^* &= (BA_i - A_iB)(A_i^*B^* - B^*A_i^*) \\ &= BA_iA_i^*B^* + A_iBB^*A_i^* - A_iBA_i^*B^* - BA_iB^*A_i^* . \end{aligned}$$

Summing over i yields

$$0 \leqslant \sum [B,A_i][B,A_i]^* = BB^* + \phi_{\mathcal{A}}(BB^*) - \phi_{\mathcal{A}}(B)B^* - B\phi_{\mathcal{A}}(B^*) = \phi_{\mathcal{A}}(BB^*) - BB^* = 0.$$

Hence, $[B,A_i] = 0$ for all $i = 1,2,\ldots$. In a similar way, we have $[B,A_i^*] = 0$. Hence, $B \in \mathcal{A}'$ so that $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$. □

Corollary 3.4: Let $\phi_{\mathcal{A}}$ be a unital quantum operation. If $B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$, then $B \in \mathcal{A}'$ if and only if $B^*B, BB^* \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$.

An operator $W \in \mathcal{T}(\mathcal{H})$ is **faithful** if for any $A \in \mathcal{B}(\mathcal{H})$, $\mathrm{tr}(W^*A^*AW) = 0$ implies $A = 0$.

Theorem 3.5: *Let $\phi_{\mathcal{A}}$ be a trace preserving, unital, quantum operation.*
(a) If $\dim(\mathcal{H}) < \infty$, *then* $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$. (b) *If there exists a faithful operator* $W \in \mathcal{T}(\mathcal{H}) \cap \mathcal{A}'$, *then* $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$. (c) *If* $B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ *and* $B = C + D$ *for* $C \in \mathcal{A}'$, $D \in \mathcal{T}(\mathcal{H})$, *then* $B \in \mathcal{A}'$. (d) $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} \cap \mathcal{T}(\mathcal{H}) = \mathcal{A}' \cap \mathcal{T}(\mathcal{H})$.

Proof: (a) If $\dim(\mathcal{H}) = n < \infty$, then $\omega(B) = \mathrm{tr}(B)/n$ is a faithful ϕ-invariant state. The result follows from Theorem 2.3 and Lemma 3.3. (b) By the proof of Lemma 3.3, if $B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ then

$$\phi_{\mathcal{A}}(B^*B) - B^*B \geqslant 0.$$

Since $W \in \mathcal{T}(\mathcal{H}) \cap \mathcal{A}'$, by Theorem 3.1 (b) we have

$$\text{tr}\,[W^*(\phi_{\mathcal{A}}(B^*B) - B^*B)W] = \text{tr}\,[\phi_{\mathcal{A}}(W^*B^*BW)] - \text{tr}(W^*B^*BW) = 0.$$

Hence, $\phi_{\mathcal{A}}(B^*B) = B^*B$ so that $B^*B \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$. Applying Lemma 3.3 gives $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$. (c) Since

$$C + D = \phi_{\mathcal{A}}(C + D) = \phi_{\mathcal{A}}(C) + \phi_{\mathcal{A}}(D) = C + \phi_{\mathcal{A}}(D),$$

we have $D \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$. Now, $D^*D \in \mathcal{T}(\mathcal{H})$ and by the proof of Lemma 3.3

$$\phi_{\mathcal{A}}(D^*D) - D^*D \geqslant 0.$$

Since $\phi_{\mathcal{A}}$ is trace preserving, we have

$$\text{tr}\,[\phi_{\mathcal{A}}(D^*D) - D^*D] = 0.$$

Hence, $\phi_{\mathcal{A}}(D^*D) = D^*D$ so that $D^*D \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$. Similarly, $DD^* \in \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ so by Corollary 3.4, $D \in \mathcal{A}'$. Hence, $B \in \mathcal{A}'$. (d) follows from (c). □

The next result follows from Theorem 2.4 and Lemma 3.3.

Theorem 3.6: *Let $\phi_{\mathcal{A}}$ be a unital quantum operation.* (a) *There exists an idempotent, unital, completely positive map $\psi: \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{H})$ with* $\text{ran}(\psi) = \mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$. (b) $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$ *if and only if ψ is a conditional expectation.* (c) *If $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$ then $\mathcal{A}'$ is an injective von Neumann algebra.*

IV. EXAMPLE

It follows from Theorem 3.6(c) that if $\mathcal{A}'$ is not injective then $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} \neq \mathcal{A}'$. We can apply this observation to obtain examples for various conjectures. For instance, the following counter-example shows: (a) If $\phi_{\mathcal{A}}(B) = \Sigma A_i^{1/2} B A_i^{1/2}$, $A_i \geqslant 0$, $\Sigma A_i = I$, is a Lüders operation, then $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} \neq \mathcal{A}'$ in general. (This answers a question posed in Refs. 5 and 3.) (b) If $\phi_{\mathcal{A}}(B) = A_1 B A_1^* + A_2 B A_2^*$ is a trace-preserving, unital, quantum operation, then $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} \neq \mathcal{A}'$ in general. (It has been shown that if A_1 and A_2 are positive, then $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}} = \mathcal{A}'$.[5,3])

Example: Let $\mathbb{F}_2$ be the free group on two generators g_1, g_2 with identity e. It is clear that $\mathbb{F}_2$ is countable. Let $\mathcal{H} = \ell_2(\mathbb{F}_2)$ be the separable complex Hilbert space

$$\mathcal{H} = \ell_2(\mathbb{F}_2) = \left\{ f: \mathbb{F}_2 \to \mathbb{C}: \sum |f(x)|^2 < \infty \right\}.$$

For $x \in \mathbb{F}_2$ define $\delta_x: \mathbb{F}_2 \to \mathbb{C}$ by

$$\delta_x(y) = \begin{cases} 1 & \text{if } y = x \\ 0 & \text{if } y \neq x \end{cases}.$$

Then $\{\delta_x : x \in \mathbb{F}_2\}$ is an orthonormal basis for $\mathcal{H}$. Define the unitary operators U_1, U_2 on $\mathcal{H}$ by $U_1 \delta_x = \delta_{g_1 x}$, $U_2 \delta_x = \delta_{g_2 x}$. The von Neumann algebra generated by U_1 and U_2 is denoted by $\mathcal{N} = L(\mathbb{F}_2)$. It is known that $\mathcal{N}$ and hence $\mathcal{N}'$ are not injective.[14,15]

Lemma 4.1: Suppose $B \in \mathcal{B}(\mathcal{H})$ has the form $B\delta_x = \lambda_x \delta_x$, $0 \leqslant \lambda_x \leqslant 1$. Then, $B \in \mathcal{E}(\mathcal{H})$ and if $B \in \mathcal{N}'$, then $B = \lambda_e I$.

Proof: It is clear that $B \in \mathcal{E}(\mathcal{H})$. Now, suppose that $B \in \mathcal{N}'$. Then

$$\lambda_{g_1} \delta_{g_1} = B \delta_{g_1} = B U_1 \delta_e = U_1 B \delta_e = \lambda_e U_1 \delta_e = \lambda_e \delta_{g_1}.$$

Hence, $\lambda_{g_1} = \lambda_e$ and in a similar way

$$\lambda_{g_1^{-1}} = \lambda_{g_2} = \lambda_{g_2^{-1}} = \lambda_e.$$

Now, suppose $x\in\mathbb{F}_2$ has the form $x=g_1y$ for some $y\in\mathbb{F}_2$. Then

$$\lambda_x\delta_x=B\delta_x=B\delta_{g_1y}=BU_1\delta_y=U_1B\delta_y=\lambda_yU_1\delta_y=\lambda_y\delta_{g_1y}=\lambda_y\delta_x.$$

Hence, $\lambda_{g_1y}=\lambda_y$ for every $y\in\mathbb{F}_2$. Similarly

$$\lambda_{g_1^{-1}y}=\lambda_{g_2y}=\lambda_{g_2^{-1}y}=\lambda_y$$

for every $y\in\mathbb{F}_2$. Continuing by induction, we conclude that $\lambda_x=\lambda_e$ for every $x\in\mathbb{F}_2$. Hence, $B=\lambda_eI$. □

Let $A_1=2^{-1/2}U_1$ and $A_2=2^{-1/2}U_2$ and let $\mathcal{A}=\{A_1,A_2\}$. Then, $\mathcal{A}'=\mathcal{N}'$ and

$$A_1A_1^*+A_2A_2^*=A_1^*A_1+A_2^*A_2=I.$$

Thus, $\phi_{\mathcal{A}}$ is a trace-preserving, unital quantum operation. Now, a B of the form in Lemma 4.1 satisfies $B\in\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ if and only if

$$\tfrac{1}{2}\lambda_{g_1^{-1}x}+\tfrac{1}{2}\lambda_{g_2^{-1}x}=\lambda_x \tag{4.1}$$

for all $x\in\mathbb{F}_2$. Define $B\in\mathcal{B}(\mathcal{H})$ by $B\delta_x=\lambda_x\delta_x$ where $\lambda_x=0$ if x ends in g_2^{-1}, $\lambda_x=1$ if x ends in g_1^{-1}, and $\lambda_x=1/2$ otherwise. Then, it is easy to check that (4.1) is satisfied. Hence, $B\in\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ and by Lemma 4.1 $B\notin\mathcal{A}'$. Thus, $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}\neq\mathcal{A}'$.

Theorem 4.2: *There exists a Lüders operation $\phi_{\mathcal{A}}$ on $\mathcal{H}=\ell_2(\mathbb{F}_2)$ such that $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}\neq\mathcal{A}'$. More precisely, there exists a $B\in\mathcal{E}(\mathcal{H})$ such that $B\in\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ but $B\notin\mathcal{A}'$.*

Proof: By taking the real and imaginary parts of $U_1=V_1+iV_2$, $U_2=V_3+iV_4$, we see that $\mathcal{N}$ is generated by four self-adjoint operators V_1,V_2,V_3,V_4. Moreover, $\mathcal{N}$ is generated by the four positive operators $C_i=\|V_i\|I-V_i$, $i=1,2,3,4$. Let $A_i=C_i/4\|C_i\|$, $i=1,2,3,4$, and let $A_5=I-\Sigma_{i=1}^4A_i$. Then, $A_i\in\mathcal{E}(\mathcal{H})$, $i=1,\ldots,5$, $\Sigma A_i=I$ and $\mathcal{A}=\{A_i:i=1,\ldots,5\}$ generates $\mathcal{N}$. Now, $\phi_{\mathcal{A}}$ is a Lüders operation and since $\mathcal{N}'=\mathcal{A}'$ is not injective we have $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}\neq\mathcal{A}'$. Hence, there exists a $B\in\mathcal{B}(\mathcal{H})$ such that $B\in\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}\backslash\mathcal{A}'$. Now, the real part or the imaginary part B_1 of B also satisfies $B_1\in\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}\backslash\mathcal{A}'$. Letting $B_2=\|B_1\|I-B_1$ we see that $B_2\geqslant0$ and that $B_3=B_2/\|B_2\|\in\mathcal{E}(\mathcal{H})$. Moreover, $B_3\in\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}\backslash\mathcal{A}'$. □

Although the B in Theorem 4.2 exists, it appears to be quite difficult to construct a concrete example of such a B.

V. CONCLUDING REMARKS

We have seen that the injectivity of the commutant of the set of operation elements $\mathcal{A}'$ of a Lüders operation $\phi_{\mathcal{A}}$ plays a role in deciding whether the set of fixed points $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ coincides with $\mathcal{A}'$ or not. However, the following question remains: if $\mathcal{A}'$ is injective, does this imply that $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}=\mathcal{A}'$? On the other hand, it has been proved that for a Lüders operation with only two operation elements, we have $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}=\mathcal{A}'$.[5,3] In this case, $\mathcal{A}$ is commutative and it follows that $\mathcal{A}$ and $\mathcal{A}'$ are injective. It is then natural to ask whether the result is true for any commutative set of operation elements $\mathcal{A}$. Finally, we ask the following general question. Is it true that $\mathcal{B}(\mathcal{H})^{\phi_{\mathcal{A}}}$ is an injective envelope of either $\mathcal{A}'$ or $\mathcal{I}(\phi_{\mathcal{A}})$?[8]

ACKNOWLEDGMENT

The second author thanks Laszlo Zsido, University Tor Vergata, Rome, for useful conversations on topics of this paper, as well as for providing bibliographical information on the early research on injectivity of von Neumann algebras.

Classicality criteria

Nuno Costa Dias[a)]
Departamento de Matemática, Universidade Lusófona de Humanidades e Tecnologias, Av. Campo Grande, 376, 1749-024 Lisboa, Portugal

(Received 2 November 2000; accepted 27 August 2002)

We present two possible criteria quantifying the degree of classicality of an arbitrary (finite dimensional) dynamical system. The inputs for these criteria are the classical dynamical structure of the system together with the quantum and the classical data providing the two alternative descriptions of its initial time configuration. It is proved that a general quantum system satisfying the criteria up to some extend displays a time evolution consistent with the classical predictions up to some degree and thus it is argued that the criteria provide a suitable measure of classicality. The features of the formalism are illustrated through two simple examples. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1516626]

I. INTRODUCTION

It is generally accepted that quantum mechanics yields the most fundamental description of all physical systems. Such status requires the theory to provide a suitable description of every day classical like phenomena. However, quantum mechanics faces a considerable number of problems to explain the emergence of a classical domain. In a broad sense, this is called the problem of the semiclassical limit of quantum mechanics.[1–6]

This is a difficult topic not least because there are a variety of different ways of relating classical and quantum mechanics. The standard approach is to take the limit $\hbar \to 0$, or equivalently, the limit of a large number of particles $N \to \infty$. Under some general conditions one can derive the classical evolution from the quantum dynamics.[7] Alternatively, one may start with a set of quantum initial data with minimal spread and show that its quantum time evolution remains very peaked around the classical orbits. Coherent states[8] (and squeezed states[9,10]) have been extensively studied in this context.[11–17] It has been proved, using several different approaches and for a large class of dynamical systems, that coherent states evolve, up to a prescribed error and during a prescribed lapse of time, peaked around the classical paths.[14,16–18] Coherent states methods have also been used to prove that in the limit $\hbar \to 0$ and for times shorter than Eherenfest's time, the quantum and the classical predictions coincide exactly.[10,18–20] Related results have been obtained using the tools of pseudodifferential calculus[21–23] and microlocal analysis.[24–26] These have played an important part in several attempts to understand the semiclassical behavior of classically chaotic systems.[24,27]

Two other significant approaches are the Wigner (or more generally the quasidistributions)[28] and the dechoerent histories[3,4,29] approaches. The aim is to (either by identifying proper quantum phase space distributions, or by coupling the quantum system to a suitable environment) recover the classical statistical predictions from the quantum formulation of the system. All these views are of course not antagonic, but complementary, meaning that the classical behavior can emerge in a variety of different regimes.

Despite the importance of these results there are still several open problems in the field of the semiclassical limit of quantum mechanics. The common view is that classical mechanics is an approximate description of quantum mechanics. This approximation is not always valid. In fact, one expects it to be only valid for some particular set of quantum initial data and even in this case not for all dynamical systems (consider for instance a particle hitting a potential barrier). An

a)Electronic mail: nuno.dias@ulusofona.pt

important question is then what is the degree of validity of the classical approximation? Clearly this question does not have a single answer. It depends on the dynamical structure of the system and on the quantum and also the classical data providing the two alternative descriptions of the initial time configuration. Let us assume that we are given this information. Can we compare the classical and the quantum descriptions of the dynamical system and produce a statement about the degree of validity of the classical description? Or, in other words, can we produce a statement about the degree of classicality of the quantum description? The answer to these questions should be affirmative since we are given all the necessary ingredients. However, and despite the fact that the pertinence of these questions have been recognized by several authors,[3–5] the problem of establishing a measure of classicality is still lacking an unique solution.

Closely related to this topic is the problem of establishing a clear relation between the quantum initial state and the classical like behavior. Very few studies elaborate on this subject. Instead, one typically assumes a particular quantum initial state and works from there to prove the ''classicality'' of the quantum dynamics. A weak point in the procedure is that we are still lacking a precise definition of ''classicality.'' For instance in Refs. 10, 14, and 16 the aim is to provide minimal bounds for the spreading of the time evolution of a specific quantum initial data (typically a coherent or squeezed state). But the questions that remain are: are these results extendable to a wider class of quantum initial states, or more generally, what is the relation between the spreading of the wave function through time and the quantum initial state? And further, how is the spreading of the wave function related to classicality?

In this paper we attempt to provide a partial answer to these questions. In general terms we study the inverse problem of Refs. 10, 14, and 16: we start by imposing the bounds (which will be related to the error margins of the classical time evolution) and attempt to identify those initial quantum states which display a time evolution that satisfies these bounds for all times. In doing so we identify a (possible) set of general conditions an arbitrary, finite dimensional quantum system should satisfy so that it evolves in agreement with the classical predictions. These conditions will be of the form of a sequence of restrictions on the initial quantum state (the higher the classicality the more stringent the conditions) and provide the basic mathematical structure to construct a measure of classicality.

More precisely our approach will be as follows: We work in the context of the standard *Copenhagen* formulation of quantum mechanics[30–33] and consider a general dynamical system with N degrees of freedom. Its initial time configuration might be described by a set of quantum initial data or, alternatively, by a set of classical initial data. The classical description is given by a set of values a_i^0 for a complete set of classical observables a_i $(i=1\cdots 2N)$, together with their associated error margins δ_i. The quantum description is given by the initial time wave function $|\psi\rangle$. Classical mechanics states that the output of a measurement of an observable a_i will belong to the interval $[a_i^0-\delta_i, a_i^0+\delta_i]$. Quantum mechanics, in turn, states that there is some probability $p_i \leqslant 1$ that a measurement of the observable $\hat{a}_i$ yields a value inside the former interval. Clearly the two statements are not equivalent. However, there are a number of fairly intuitive ways by which one can measure the consistency (i.e., the agreement) of the two former descriptions of the initial time configuration. We will propose two such *consistency criteria* in Sec. II.

Unfortunately, the fact that the two descriptions of the initial time configuration are consistent up to some degree does not imply that the classical and the quantum descriptions of a future configuration will also be consistent up to the same degree. Our aim is then to identify the conditions that should be satisfied by the initial time configuration so that the degree of consistency is preserved through time evolution. These conditions are obtained (they are given by a set of relations between the classical initial data (a_i^0, δ_i) and the spreads of the initial wave function $|\psi\rangle$) and used to construct two alternative classicality criteria. Given the classical initial data these conditions constitute a sequence of growing restrictions on the functional form of the initial data wave function. When $|\psi\rangle$ satisfies the n first former conditions we say that $|\psi\rangle$ is *n-order classical*. When $|\psi\rangle$ satisfies the full set of conditions we say that $|\psi\rangle$ is a *classical limit initial data wave function*.

The main property of the classicality criteria is that if the classical and the quantum initial data satisfy the classicality criteria up to some degree then the time evolution of the classical initial data (obtained using classical mechanics) and the time evolution of the quantum initial data (obtained using quantum mechanics) will display a minimum degree of consistency for all times. Hence, the classicality criteria supply a suitable (although clearly not unique) measure of classicality that might be computed, for an arbitrary dynamical system, at the kinematical level.

These results are not limited to some specific type of systems displaying a particular dynamical behavior or having some particular quantum initial data. On the contrary, for an arbitrary dynamical system the classicality criteria can be used to determine the set of quantum initial data that displays a n-order classical time evolution (a quantum time evolution n-order consistent with the classical predictions). This will be done explicitly for the two physical examples presented in Secs. VI and VII.

Further applications of the criteria are given in Refs. 34, 35, and 36.

II. CONSISTENCY CRITERIA

Let us consider a general dynamical system with N degrees of freedom. The phase space T^*M has the structure of the cotangent bundle of the configuration space M, and henceforth will be also assumed to have the structure of a *flat* sympletic manifold. Therefore a global Darboux chart can be defined in T^*M. Let us choose a set of canonical variables $a_i, i=1\cdots 2N$ (where $a_i=q_i, i=1\cdots N$ and $a_i=p_{i-N}, i=N+1\cdots 2N$). They yield the sympletic structure as the 2-form $w=dq_i\wedge dp_i$.

The classical description of a specific time configuration of the system is given by a set of values a_i^0 for the complete set of observables a_i together with the associated error margins δ_i. The classical statement is that a measurement of a_i will yield a value a_i^1 belonging to the classical error interval $I_i=[a_i^0-\delta_i, a_i^0+\delta_i]$.

Alternatively, quantum mechanics describes the same configuration of the system with a wave function $|\psi\rangle$ belonging to the physical Hilbert space $\mathcal{H}$ and the quantum statement is that there is some probability $p(a_i)=\Sigma_k|\langle a_i,k|\psi\rangle|^2$ that a measurement of the observable $\hat{a}_i$ yields the value a_i (where the states $|a_i,k\rangle$ form a complete set of eigenvectors of $\hat{a}_i$ that spans the Hilbert space $\mathcal{H}$, a_i are the associated eigenvalues and k is the degeneracy index). For notational convenience we will assume that $\hat{A}$ displays a discrete spectrum, but all results can be easily rewritten for the continuous case.

A straightforward way of measuring the consistency between the two descriptions is given by the following criterion.

Definition: First consistency criterion. Let us calculate the probabilities p_i—generated by the wave function $|\psi\rangle$ in the representation of each of the observables $\hat{a}_i$, $i=1\cdots 2N$—that a measurement of $\hat{a}_i$ yields a value belonging to the classical error interval $I_i=[a_i^0-\delta_i, a_i^0+\delta_i]$, i.e.,

$$p_i=\sum_{a_i\in I_i,k}|\langle a_i,k|\psi\rangle|^2. \tag{1}$$

The minimum value of the set $\{p_i: i=1\cdots 2N\}$ provides a suitable measure of the consistency between the classical and the quantum descriptions of the configuration of the dynamical system. If this minimum value above is for instance p_0 we say that the classical and the quantum descriptions are p_0-*consistent*. Furthermore, if $p_0=1$ then the two descriptions are fully consistent and $|\psi\rangle$ is named a *classical limit wave function.* □

Another, probably less intuitive, consistency criterion is given by the following definition:

Definition: Second consistency criterion. Let $0\leqslant p<1$ be an arbitrary probability and let $M\in\mathcal{N}$. To each classical observable a_i we associate the set of intervals of the form:

$$I_i(p,M)=\left[a_i^0-\frac{\delta_i}{(1-p)^{1/(2M)}},a_i^0+\frac{\delta_i}{(1-p)^{1/(2M)}}\right]. \tag{2}$$

In each of the former intervals we can calculate the probability p_i generated by the wave function $|\psi\rangle$, in the representation of the corresponding quantum observable $\hat{a}_i$:

$$p_i(p,M)=\sum_{a_i\in I_i(p,M),k}|\langle a_i,k|\psi\rangle|^2. \tag{3}$$

For given values of the classical and quantum data a_i^0, δ_i, and $|\psi\rangle$ this probability is an exclusive function of p and M. The second consistency criterion is defined as follows: The classical and the quantum data, describing a given configuration of the dynamical system, are *M-order consistent* if and only if for all $0\leqslant p<1$ and for all $i=1\cdots 2N$ the condition $p_i(p,M)\geqslant p$ is satisfied, i.e.,

$$\sum_{a_i\in I_i(p,M),k}|\langle a_i,k|\psi\rangle|^2\geqslant p,\quad \forall_{p\in[0,1[},\forall_{i=1\cdots 2N}, \tag{4}$$

where $I_i(p,M)$ is given by (2). If $M=\infty$ the classical and the quantum descriptions are fully consistent, in which case $|\psi\rangle$ is a *classical limit* wave function. □

The former criterion provides a measure of how peaked is the wave function—in the representation of each of the quantum observables—around the classical error margin of the corresponding classical observable. This will became clear in the sequel (16).

As a first remark let us point out that the two alternative definitions of a classical limit wave function (using the first and the second consistency criterion) are, in fact, equivalent, i.e. $p=1\Leftrightarrow M=+\infty$, which in turn, is equivalent to the statement that

$$|\psi\rangle=\sum_{a_i\in I_i,k}\langle a_i,k|\psi\rangle|a_i,k\rangle,\quad \forall_{i=1\cdots 2N}, \tag{5}$$

where, as before $I_i=[a_i^0-\delta_i,a_i^0+\delta_i]$, (a_i^0,δ_i) is the classical data and $|a_i,k\rangle$ is the general eigenstate of the operator $\hat{a}_i$.

As a second remark let us notice that in some cases it is not possible to construct a wave function satisfying Eq. (5) exactly. One should keep in mind that Eq. (5) stands for the limit $M\rightarrow\infty$ or $p\rightarrow 1$ which may, or may not admit an explicit realization in terms of some wave function $|\psi\rangle$.

Some emphasis will be put in the study of the time evolution of a general classical limit initial data wave function. Although, for some systems, we might be unable to write $|\psi\rangle$ [satisfying (5)] explicitly, its time evolution can be obtained, in the Heisenberg picture, using the standard rules of quantum mechanics. This study will prove to be useful allowing us to develop a set of techniques that will later be used to obtain the classicality criteria and, in the sequel, to study physical systems with general initial data.

III. ERROR KET FRAMEWORK

Let us introduce dynamics by specifying a general Hamiltonian H. The quantum time evolution of an arbitrary fundamental observable $\hat{A}$ (with $\hat{A}=\hat{a}_i$ for some $i=1\cdots 2N$) is given by

$$\hat{A}(t)=\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{t}{i\hbar}\right)^n[\cdots[[\hat{A},\hat{H}],\hat{H}]\cdots]. \tag{6}$$

Alternatively, the standard classical treatment of the same system provides the predictions

$$A(t)=\sum_{n=0}^{\infty}\frac{t^n}{n!}\{\cdots\ \{\{A,H\},H\}\cdots\ \},$$

$$\delta_A(t)=\sum_{n=1}^{+\infty}\frac{1}{n!}\sum_{k_1,\ldots,k_n=1}^{2N}\left|\frac{\partial^n A(t)}{\partial a_{k_1}\ldots\partial a_{k_n}}\right|\delta_{k_1}\cdots\ \delta_{k_n}, \tag{7}$$

where the error margins δ_{k_i} are taken at the initial time. Notice that, in general, it is possible to obtain more accurate predictions than those of (7), i.e., with smaller error margins. Such estimates have the disadvantage of requiring a case by case evaluation, while Eq. (7) is valid in general.

To avoid some possible misunderstandings we will, from now on, focus on the case of the second consistency criterion. In Sec. V our results will then be rewritten using the language of the first consistency criterion. Let us then assume that the classical and the quantum initial data are M-consistent. The question we would like to answer is then: which are the conditions that should be satisfied so that the quantum description of the system at a time t—given by the initial data wave function $|\psi\rangle$ in the representation of the observables $\hat{a}_i(t)$ (6)—is also M-consistent with the classical description given by (7)?

This is not an easy task. We start by presenting a framework that will later be used to give a precise answer to this question.

A. Definition and properties of $|E\rangle$ and Δ

Let us start by introducing the relevant definitions. Let $\hat{A}$ be an operator acting on the quantum Hilbert space $\mathcal{H}$. Let $|a,k\rangle$ be a complete set of eigenvectors of $\hat{A}$, with associated eigenvalues a and k being the degeneracy index. This set forms a complete orthogonal basis of $\mathcal{H}$. Finally, let $|\psi\rangle$ be the wave function describing the system.

Definition: Error Ket. We define the nth-order error ket $|E^n(\hat{A},\psi,a^0)\rangle$, as the quantity

$$|E^n(\hat{A},\psi,a^0)\rangle=(\hat{A}-a^0)^n|\psi\rangle, \tag{8}$$

where $n\in\mathcal{N}$, $a^0\in\mathcal{C}$ and $\hat{A}$ does not need to be self-adjoint. The error bra $\langle E^n(\hat{A},\psi,a^0)|$ is defined accordingly to the definition of the error ket.

Let now $\hat{A}_z$, $z=1,...,n$ be a set of operators acting on $\mathcal{H}$. For each value of z let $|a_z,k_z\rangle$ be a complete set of eigenvectors of $\hat{A}_z$, with eigenvalues a_z, and k_z being the degeneracy index. Moreover let $a_z^0\in\mathcal{C}$. The nth-order mixed error ket $|E(\hat{A}_1,\hat{A}_2,\ldots,\hat{A}_n,\psi,a_1^0,a_2^0,\ldots,a_n^0)\rangle$, is defined as the quantity

$$|E(\hat{A}_1,\hat{A}_2,\ldots,\hat{A}_n,\psi,a_1^0,a_2^0,\ldots,a_n^0)\rangle=(\hat{A}_n-a_n^0)\cdots\ (\hat{A}_2-a_2^0)(\hat{A}_1-a_1^0)|\psi\rangle. \tag{9}$$

When there is no risk of confusion we will use the short notations $|E^n\rangle$ or $|E_A^n\rangle$ for the nth-order error ket and $|E_{A_1,A_2,\ldots,A_n}\rangle$ for the mixed error ket. □

We shall now study some of the properties of this quantity.

(a) *Explicit form of the error ket.* Let us start with the 1st-order error ket. We have: $|E(\hat{A},\psi,a^0)\rangle=\Sigma_{a,k}(a-a^0)\langle a,k|\psi\rangle|a,k\rangle$. This result is easily extended to the case of the nth-order mixed error ket $|E_{A_1,A_2,\ldots,A_n}\rangle$:

$$|E_{A_1,A_2,\ldots,A_n}\rangle=\sum_{a_1,k_1}\sum_{a_2,k_2}\ldots\sum_{a_n,k_n}(a_1-a_1^0)(a_2-a_2^0)\cdots\ (a_n-a_n^0)\langle a_1,k_1|\psi\rangle\langle a_2,k_2|a_1,k_1\rangle$$
$$\times\langle a_3,k_3|a_2,k_2\rangle\ldots\langle a_n,k_n|a_{n-1},k_{n-1}\rangle|a_n,k_n\rangle, \tag{10}$$

and if $\hat{A}_1=\hat{A}_2=\cdots\ =\hat{A}_n=\hat{A}$ we have $|E_{A_1,A_2,\ldots,A_n}\rangle=|E_A^n\rangle$ which give us the explicit expression for the nth-order error:

$$|E_A^n\rangle=(\hat{A}-a^0)^n|\psi\rangle=\sum_{a,k}(a-a^0)^n\langle a,k|\psi\rangle|a,k\rangle. \tag{11}$$

(b) *Relation between the n*th*-order error ket and the mean second-order deviation*. Let us calculate the value of $\langle E_A^n|E_A^n\rangle$:

$$\langle E_A^n|_A^n\rangle=\sum_{a,k}((a-a^0)^*(a-a^0))^n|\langle a,k|\psi\rangle|^2, \tag{12}$$

and if $\hat{A}$ is self-adjoint and $a^0=\langle\psi|\hat{A}|\psi\rangle$ then $\langle E_A^n|E_A^n\rangle$ is just the mean $2n$th-order deviation of $\hat{A}$: $(\Delta\hat{A})^{2n}$ (if $n=1$ then $\langle E_A^1|E_A^1\rangle$ is just the mean square deviation).

(c) *N*th*-order error ket of a classical limit initial data wave function*. Let us consider the case in which the initial time configuration of the dynamical system is described by a classical limit initial data wave function $|\psi\rangle$. Let A be a fundamental observable of the system and let the classical initial data associated to A be given by a^0 with error margin δ_A. From Eqs. (5) and (12) it is straightforward to obtain the relation:

$$\langle E_A^n|E_A^n\rangle=\sum_{a,k}|a-a^0|^{2n}|\langle a,k|\psi\rangle|^2\leqslant\delta_A^{2n}\sum_{a,k}|\langle a,k|\psi\rangle|^2=\delta_A^{2n}, \tag{13}$$

which is valid for all $n\in\mathcal{N}$ and for all fundamental observables $A=a_i(i=1\cdots 2N)$.

(d) *Probabilistic distribution function from the n*th*-order error ket*. Let $\hat{A}$ be self-adjoint, let $|\psi\rangle$ be the state of the system and let a^0 be a real number. Given $\langle E^n(\hat{A},\psi,a^0)|E^n(\hat{A},\psi,a^0)\rangle$, to each "quantity of probability" $0\leqslant p<1$ we can associate an interval I_n around a^0, $I_n=[a^0-\Delta_n,a^0+\Delta_n]$, such that the probability of obtaining a value $a\in I_n$ from a measurement of $\hat{A}$ is at least p. The range of the interval I_n is dependent of $\hat{A},\psi$ and a^0 only through the value of $\langle E_A^n|E_A^n\rangle$. The quantity $\Delta_n(\langle E_A^n|E_A^n\rangle,p)$ is named the *n*th*-order spread* of the wave function. Let us show that if $\Delta_n=\Delta_n(\hat{A},\psi,a^0,p)$ is given by

$$\Delta_n(\hat{A},\psi,a^0,p)=\left(\frac{\langle E_A^n|E_A^n\rangle}{1-p}\right)^{1/2n} \tag{14}$$

then the probability of obtaining a value $a\in I_n$ from a measurement of $\hat{A}$ is at least p. From (12), (14) we have

$$(\Delta_n)^{2n}(1-p)=\sum_{k,a}|a-a^0|^{2n}|\langle a,k|\psi\rangle|^2,$$

$$\geqslant\sum_{k,a\notin I_n}|a-a^0|^{2n}|\langle a,k|\psi\rangle|^2\geqslant(\Delta_n)^{2n}\sum_{k,a\notin I_n}|\langle a,k|\psi\rangle|^2, \tag{15}$$

and this implies: $\Sigma_{k,a\notin I_n}|\langle a,k|\psi\rangle|^2\leqslant 1-p$, which is the result we were looking for. If $\hat{A}$ is not self-adjoint the former result can also be obtained, but in this case I_n is a ball of radius Δ_n in the complex plane.

(e) *Corollary of (d)*. A straightforward consequence of the previous result is the following: If for some positive integer M the condition:

$$\langle E^M(\hat{a}_i,\psi,a_i^0)|E^M(\hat{a}_i,\psi,a_i^0)\rangle\leqslant\delta_i^{2M} \tag{16}$$

holds for all $i=1\cdots 2N$ then the classical and the quantum descriptions [given by $(a_i^0,\delta_i,i=1\cdots 2N)$ and $|\psi\rangle$, respectively] are, accordingly to the second consistency criterion, M-order consistent.

B. Time evolution of $|E\rangle$ and Δ

The aim is now to determine the nth-order error ket and the nth-order spread associated to the operator $\hat{A}(t)$ given in (6), as a function of the error kets and spreads associated with the initial time operators. The calculations might seem, in a first reading, complicated and cumbersome. Nevertheless, the final result will be simple and physically appealing.

1. Evolving the error ket

We will start by calculating the 1st-order error ket associated with the sum and with the product of two arbitrary operators $\hat{A}$ and $\hat{B}$ and with the product of an operator by a scalar. Let the state of the system be $|\psi\rangle$, let $|E(\hat{A},\psi,a)\rangle$ and $|E(\hat{B},\psi,b\rangle$ be the first-order error kets associated to $\hat{A}$ and $\hat{B}$ and let $a,b,c\in\mathcal{C}$.

Theorem: The first-order error kets associated to the operators $\hat{A}+\hat{B}$, $c\hat{A}$, and $\hat{A}\hat{B}$ are, respectively,

$$|E(\hat{A}+\hat{B},\psi,a+b)\rangle=|E(\hat{A},\psi,a)\rangle+|E(\hat{B},\psi,b)\rangle, \tag{17}$$

$$|E(c\hat{A},\psi,ca)\rangle=c|E(\hat{A},\psi,a)\rangle, \tag{18}$$

$$|E(\hat{A}\hat{B},\psi,ab)\rangle=a|E(\hat{B},\psi,b)\rangle+b|E(\hat{A},\psi,a)\rangle+|E(\hat{B},\hat{A},\psi,b,a)\rangle. \tag{19}$$

Proof: For the sum of operators we have

$$|E_{A+B}\rangle=(\hat{A}+\hat{B}-(a+b))|\psi\rangle=(\hat{A}-a)|\psi\rangle+(\hat{B}-b)|\psi\rangle=|E_A\rangle+|E_B\rangle. \tag{20}$$

The proof of the product by a scalar and of the product of two operators follows the same lines, this time using the relations $(c\hat{A}-ca)=c(\hat{A}-a)$ and

$$(\hat{A}\hat{B}-ab)=a(\hat{B}-b)+b(\hat{A}-a)+(\hat{A}-a)(\hat{B}-b), \tag{21}$$

that when applied to the state $|\psi\rangle$ provide the desired results. □

Let us now extend these results to the case of several products and sums of fundamental operators. Let $\hat{A}$ be a general hermitian operator displayed as a sum of multiple products of fundamental operators and let A^0 be the classical function that is functionally identical to $\hat{A}$:

$$\hat{A}=\sum_{i=1}^{n} c_i\hat{B}_i=\sum_{i=1}^{n} c_i\prod_{j=1}^{m}\hat{x}_{ij}, \quad A^0=\sum_{i=1}^{n} c_iB_i^0=\sum_{i=1}^{n} c_i\prod_{j=1}^{m} x_{ij}, \tag{22}$$

where $\hat{x}_{ij}$ is one of the fundamental operators ($\hat{x}_{ij}\in\{\hat{I},\hat{q}_1,\ldots,\hat{q}_N,\hat{p}_1,\ldots,\hat{p}_N\}$ where N is the dimension of the classical system), n and m are arbitrary positive integers, c_i are complex numbers and $\hat{B}_i$, B_i are multiple products of the fundamental observables and multiple products of the corresponding classical observables, respectively. The map from $\hat{A}$ to A^0 will be named *unquantization*. Clearly, the procedure (22) is beset by order problems (i.e., if $\hat{A}$ is displayed in different orders we get different A^0). The consequences of this will be discussed later on.

The aim now is to expand $(\hat{A}-A^0)$ in terms of $(\hat{x}_{ij}-x_{ij})$. The first step is to set $(\hat{A}-A^0)=\Sigma_{i=1}^{n}c_i(\hat{B}_i-B_i^0)$. Using Eq. (21) we get

$$\begin{aligned}\hat{B}_i-B_i^0&=\hat{x}_{i1}\prod_{j=2}^{m}\hat{x}_{ij}-x_{i1}\prod_{j=2}^{m}x_{ij}\\&=x_{i1}\left(\prod_{j=2}^{m}\hat{x}_{ij}-\prod_{j=2}^{m}x_{ij}\right)+\prod_{j=2}^{m}x_{ij}(\hat{x}_{i1}-x_{i1})+(\hat{x}_{i1}-x_{i1})\left(\prod_{j=2}^{m}\hat{x}_{ij}-\prod_{j=2}^{m}x_{ij}\right),\end{aligned} \tag{23}$$

and using (21) once again to expand $(\Pi_{j=2}^{m}\hat{x}_{ij}-\Pi_{j=2}^{m}x_{ij})$ in terms of $(\hat{x}_{i2}-x_{i2})$ and $(\Pi_{j=3}^{m}\hat{x}_{ij}-\Pi_{j=3}^{m}x_{ij})$ and so on, after using the relation (21) m times we will obtain

$$\hat{B}_i-B_i^0=\sum_{L=1}^{+\infty}\sum_{j_1<j_2\cdots<j_L=1}^{m}\frac{\partial^L B_i^0}{\partial x_{ij_1}\ldots\partial x_{ij_L}}(\hat{x}_{ij_1}-x_{ij_1})\ldots(\hat{x}_{ij_L}-x_{ij_L}) \tag{24}$$

where the sum in L can be truncated at the mth term. The next step is to multiply each term in i by c_i and after sum in i. We get

$$\hat{A}-A^0=\sum_{L=1}^{+\infty}\sum_{i=1}^{n}\sum_{j_1<j_2\cdots<j_L=1}^{m}\frac{\partial^L A^0}{\partial x_{ij_1}\ldots\partial x_{ij_L}}(\hat{x}_{ij_1}-x_{ij_1})\ldots(\hat{x}_{ij_L}-x_{ij_L}). \tag{25}$$

Notice that this is just a ''Taylor expansion'' of an operator around the classical observable with the same functional form. The sums in the expansions (24) and (25) are taken over $j_1<j_2\cdots<j_L$ to preserve the order in which the operators $\hat{x}_{ij}$ appear in $\hat{B}_i$ since in general $(\hat{x}_{ik}-x_{ik})(\hat{x}_{ij}-x_{ij})\neq(\hat{x}_{ij}-x_{ij})(\hat{x}_{ik}-x_{ik})$. Because of this the analysis of the expansion (25) is tricky. The order in which the classical variables appear in A^0 is relevant. For instance if $\hat{A}=\hat{p}\hat{q}-\hat{q}\hat{p}$ then $A^0=pq-qp$ and this form, and not $A^0=0$, should be the one used to calculate the partial derivatives in (25).

Let us now consider the operator $(\hat{A})_+=\Sigma_{i=1}^{n}c_i(\Pi_{j=1}^{m}\hat{x}_{ij})_+$ obtained from a general hermitian operator $\hat{A}$ (22) by a term by term symmetrization: $(\hat{A})_+=\Sigma_{i=1}^{n}c_i(\hat{B}_i)_+$, where $(\hat{B}_i)_+$ is the completly symmetric operator obtained from $\hat{B}_i$. In general $(\hat{A})_+\neq\hat{A}$ but the classical observables obtained from $\hat{A}$ and $(\hat{A})_+$, given by (22), are identical, i.e., $A^0=(A)_+^0$. For this operator the expansion (25) might be written

$$(\hat{A})_+-A^0=\sum_{L=1}^{+\infty}\frac{1}{L!}\sum_{i=1}^{n}\sum_{j_1,j_2,..,j_L=1}^{m}\frac{\partial^L A^0}{\partial x_{ij_1}\ldots\partial x_{ij_L}}(\hat{x}_{ij_1}-x_{ij_1})\ldots(\hat{x}_{ij_L}-x_{ij_L}) \tag{26}$$

Our next step is to understand under which conditions, if any, is the expansion (26) a valid approximation to the expansion (25). To do this the first step is to define the unquantization map more precisely.

Definition: Unquantization V_0. Let $\mathcal{A}(\mathcal{H})$ be the algebra of linear operators acting on the physical Hilbert space $\mathcal{H}$ and let $\mathcal{A}(T^*M)$ be the algebra of complex functions over the classical phase space T^*M. V_0 is the map:

$$V_0:\mathcal{A}(\mathcal{H})\to\mathcal{A}(T^*M);\quad A^0=V_0(\hat{A}), \tag{27}$$

that satisfies the following *requirements*.

(a) The action of V_0 on a fundamental operator provides the corresponding classical fundamental observable: $V_0(\hat{q}_i)=q_i$ and $V_0(\hat{p}_i)=p_i$, $i=1\cdots N$. Moreover $V_0(\hat{I})=1$.

(b) The action of V_0 on a general operator $\hat{A}$, displayed in an arbitrary order, is given by $V_0(\hat{A})=V_0(\hat{A}_R)$ where $\hat{A}_R=\hat{A}$ but displayed in an order in which (i) $\hat{A}$ is the sum of an hermitian term with an anti-Hermitian term and (ii) all the commutators present in $\hat{A}$ have been resolved ($\hat{A}_R$ does not contain antisymmetric terms).

If $\hat{A}$ is displayed in the required order, $\hat{A}_R$ then

(c) V_0 is linear, i.e., if $\hat{A}_R=b\hat{B}+c\hat{C}$ then $V_0(\hat{A}_R)=bV_0(\hat{B})+cV_0(\hat{C})$; $b,c\in\mathcal{C}$.

(d) The product rule is valid: if $\hat{A}_R=\cdots+\hat{B}\hat{C}+\cdots$ then $V_0(\hat{A}_R)=V_0(\cdots)+V_0(\hat{B})V_0(\hat{C})+V_0(\cdots)$. □

One should notice that the map V_0 is not equivalent to the procedure (22). However, for a general operator $\hat{A}$, all the classical observables $V_0(\hat{A})$ can also be obtained using the procedure

(22) (by displaying $\hat{A}$ in appropriate order). Therefore all the results that were valid for A^0 obtained in (22), are also valid for $A^0=V_0(\hat{A})$. Further properties of the map V_0 will be discussed in Sec. IV.

Let us proceed with the analysis of expansions (25) and (26). We realize that if $\hat{A}$ is displayed in the required order $\hat{A}_R$ then the difference between $\hat{A}$ and $(\hat{A})_+$ is, at the most, proportional to a factor of $\hbar^2$. Since $A^0=V_0(\hat{A})$ is identical to $V_0((\hat{A})_+)$ we conclude that if $A^0=V_0(\hat{A})$ then the difference between the right hand sides of equations (25) and (26) is at the most proportional to a factor of $\hbar^2$ which, in the context of the results of this paper is of negligible magnitude. In conclusion, if $A^0=V_0(\hat{A})$ then the right-hand side of (26) is a valid approximation to $\hat{A}-A^0$.

Let us proceed: since $\hat{x}_{ij}$—in the expansion (26)—is one of the $2N$ fundamental operators the former expansion can be cast in the form

$$\hat{A}-A^0=\sum_{L=1}^{+\infty}\frac{1}{L!}\sum_{j_1,\ldots,j_L=1}^{2N}\frac{\partial^L A^0}{\partial a_{j_1},\ldots,\partial a_{j_L}}(\hat{a}_{j_1}-a_{j_1})\ldots(\hat{a}_{j_L}-a_{j_L}). \tag{28}$$

Finally, if we apply this expansion to the quantum state $|\psi\rangle$, we get

$$|E(\hat{A},\psi,A^0)\rangle=\sum_{L=1}^{+\infty}\frac{1}{L!}\sum_{j_1,\ldots,j_L=1}^{2N}\frac{\partial^L A^0}{\partial a_{j_1}\ldots\partial a_{j_L}}|E_{a_{j1},\ldots,a_{jL}}\rangle. \tag{29}$$

The generalization of the former set of results to the case of the mth-order error ket, $|E_A^m\rangle=(\hat{A}-A^0)^m|\psi\rangle$ can be obtained by exponentiating the expansion (28) to the mth power. Up to the lowest order we get

$$|E_A^m\rangle=(\hat{A}-A^0)^m|\psi\rangle=\sum_{k_1,\ldots,k_m=1}^{2N}\left(\prod_{i=1}^{m}\frac{\partial A^0}{\partial a_{k_i}}\right)|E_{a_{k1},\ldots,a_{km}}\rangle, \tag{30}$$

which is our final result concerning the error ket of an operator $\hat{A}$ functional of the fundamental operators. Notice that the former results are valid in general, irrespectively of the specific functional form of the wave function $|\psi\rangle$.

2. Evolving Δ_m

We shall now concentrate on the case of a system with a classical limit initial data. The aim is to calculate, in the representation of $\hat{A}$ (22), the value of the mth-order spread of a wave function $|\psi\rangle$ satisfying (5). To do this the main point is to calculate the norm of a general error ket: $\langle E_{x_1,\ldots,x_n}|E_{x_1,\ldots,x_n}\rangle$, where $x_1,\ldots,x_n$ is an arbitrary sequence of fundamental observables: $x_i\in\{q_1,\cdots,q_N,p_1,\cdots p_N\}, i=1\cdots n, n\in\mathcal{N}$. The following theorem will do this.

Theorem: If $|\psi\rangle$ is a classical limit initial data wave function then the norm of the error ket $|E(\hat{x}_1,..,\hat{x}_n,\psi,x_1^0,..,x_n^0)\rangle$ satisfies the following relation:

$$\langle E_{x_1,\ldots,x_n}|E_{x_1,\ldots,x_n}\rangle\leqslant\delta_1^2\ldots\delta_n^2, \tag{31}$$

where $(x_i^0,\delta_i), i=1\cdots n$ is the classical initial data associated to the observable x_i.

Proof: This result will be proved by induction:

(i) For $n=1$ and x_1 an arbitrary fundamental observable Eq. (5) immediately implies (result (3.1c): $\langle E_{x_1}|E_{x_1}\rangle\leqslant\delta_1^2$.

(ii) For an arbitrary n we use (10) and write

$$\langle E_{x_1,\ldots,x_n}|E_{x_1,\ldots,x_n}\rangle=\sum_{s,x_n}\langle E_{x_1,\ldots,x_{n-1}}|x_n,s\rangle\langle x_n,s|E_{x_1,\ldots,x_{n-1}}\rangle|(x_n-x_n^0)|^2, \tag{32}$$

where x_n are the eigenvalues of the operator $\hat{x}_n$, with degeneracy index s. We want to show that for all eigenvalues $x_n \notin I_n$, where $I_n=[x_n^0-\delta_n, x_n^0+\delta_n]$, we have

$$\langle x_n,s|E_{x_1,\ldots,x_{n-1}}\rangle=\langle x_n,s|\prod_{i=1}^{n-1}(\hat{x}_i-x_i^0)|\psi\rangle=0, \quad \forall_{x_n\notin I_n}. \tag{33}$$

To prove this let us expand the wave function $|\psi\rangle$ using a second set of eigenstates of $\hat{x}_n$,

$$\langle x_n,s|\prod_{i=1}^{n-1}(\hat{x}_i-x_i^0)|\psi\rangle=\sum_{x_n'\in I_n,s'}\langle x_n,s|\prod_{i=1}^{n-1}(\hat{x}_i-x_i^0)|x_n',s'\rangle\langle x_n',s'|\psi\rangle, \tag{34}$$

where x_n' are eigenvalues of $\hat{x}_n$ with degeneracy index s'. Notice that in the representation of $\hat{x}_n$ the wave function is completely confined to the interval I_n. To prove the result (33) is then sufficient to show that

$$\langle x_n,s|\prod_{i=1}^{j}\hat{x}_i|x_n',s'\rangle=0, \quad \forall_{x_n\notin I_n, x_n'\in I_n}, \forall_{j<n}. \tag{35}$$

Let us then prove the former identity

$$\langle x_n,s|\prod_{i=1}^{j}\hat{x}_i|x_n',s'\rangle=\frac{1}{x_n'}\langle x_n,s|\prod_{i=1}^{j}\hat{x}_i\hat{x}_n|x_n',s'\rangle=\frac{1}{x_n'}\langle x_n,s|\hat{x}_n\prod_{i=1}^{j}\hat{x}_i+\left[\prod_{i=1}^{j}\hat{x}_i,\hat{x}_n\right]|x_n',s'\rangle \tag{36}$$

and if $\langle x_n,s|[\Pi_{i=1}^{j}\hat{x}_i,\hat{x}_n]|x_n',s'\rangle=0$ then

$$\langle x_n,s|\prod_{i=1}^{j}\hat{x}_i|x_n',s'\rangle=\frac{1}{x_n'}\langle x_n,s|\hat{x}_n\prod_{i=1}^{j}\hat{x}_i|x_n',s'\rangle=\frac{x_n}{x_n'}\langle x_n,s|\prod_{i=1}^{j}\hat{x}_i|x_n',s'\rangle. \tag{37}$$

Since $x_n\neq x_n'$ Eq. (37) immediately implies (35) and thus the result (33) is valid. The problem is now reduced to prove that $\langle x_n,s|[\Pi_{i=1}^{j}\hat{x}_i,\hat{x}_n]|x_n',s'\rangle=0$, which in turn, and using the same procedure, will be reduced to prove that $\langle x_n,s|[[\Pi_{i=1}^{j}\hat{x}_i,\hat{x}_n],\hat{x}_n]|x_n',s'\rangle=0$, and so on until we obtain at the most a j-commutator which will always have the value zero (notice that $\hat{x}_i$ are fundamental operators). Inserting the result (33) into (32) we get

$$\begin{aligned}\langle E_{x_1,\ldots,x_n}|E_{x_1,\ldots,x_n}\rangle&=\sum_{s,x_n\in I_n}\langle E_{x_1,\ldots,x_{n-1}}|x_n,s\rangle\langle x_n,s|E_{x_1,\ldots,x_{n-1}}\rangle|(x_n-x_n^0)|^2\\&\leqslant\langle E_{x_1,\ldots,x_{n-1}}|E_{x_1,\ldots,x_{n-1}}\rangle\delta_n^2,\end{aligned} \tag{38}$$

which proves the theorem. □

A straightforward corollary of the former result is the one obtained by using the Schwartz inequality:

$$|\langle E_{x_1,\ldots,x_n}|E_{y_1,\ldots,y_m}\rangle|\leqslant\delta_{x_1}\cdots\delta_{x_n}\delta_{y_1}\cdots\delta_{y_m}, \tag{39}$$

where $x_1,\ldots,x_n$ and $y_1,\ldots,y_m$ are two arbitrary sequences of fundamental observables.

Let us return to the calculation of the m-order spread of the wave function $|\psi\rangle$, satisfying (5), in the representation of $\hat{A}$. The relevant calculation is that of $\langle E_A^m|E_A^m\rangle$. From Eqs. (28) and (39), we get

$$\langle E_A^m|E_A^m\rangle=\langle\psi|(\hat{A}-A^0)^{2m}|\psi\rangle\leqslant\left(\sum_{L=1}^{+\infty}\frac{1}{L!}\sum_{j_1,\ldots,j_L=1}^{2N}\left|\frac{\partial^L A^0}{\partial a_{j_1}\ldots\partial a_{j_L}}\right|\delta_{j_1}\ldots\delta_{j_L}\right)^{2m}=\delta_{A^0}^{2m}, \tag{40}$$

a result that is valid for all $m\in\mathcal{N}$. The m-order spread then reads

$$\Delta_m(\hat{A},\psi,A^0,p)=\left(\frac{\langle E_A^m|E_A^m\rangle}{1-p}\right)^{1/2m}\leqslant\frac{\delta_{A^0}}{(1-p)^{1/2m}}, \tag{41}$$

which, for all $p<1$ converges to the classical error margin δ_{A^0} as $m\to\infty$.

From the results (3.1d) and (41) we can draw the conclusion that the classical limit initial data wave function $|\psi\rangle$, in the representation of an arbitrary observable $\hat{A}$, is completely confined to an interval around A^0 with the range of the classical error margin of A^0, the relation between $\hat{A}$ and A^0 being the one given by (27).

IV. UNQUANTIZATION

In the last section we proved that the wave function $|\psi\rangle$—satisfying (5)—in the representation of a given quantum operator $\hat{A}$, which in the end is to be identified with $\hat{A}(t)$ given in (6), is completely confined to an interval centered at the value of the classical observable A^0 and with the range of the classical error interval of A^0. This implies that the output of a measurement of $\hat{A}$, performed with an experimental apparatus of any resolution, will certainly belong to the previous error interval, which is exactly the classical prediction for the output of a measurement of the classical observable A^0.

However these are not our final results, yet. The reason is straightforward: Let $\hat{A}=\hat{A}(t)$, what remains to be proven is simply that $A^0=V_0(\hat{A}(t))=A(t)$, i.e., that the classical observable A^0, obtained from the quantum observable $\hat{A}(t)$ using the map V_0, coincides with the classical observable $A(t)$ obtained by evolving $A(0)=V_0(\hat{A}(0))$ using the classical theory.

Hence the relevant questions are: Is the map V_0 well defined? And will it map a quantum observable $\hat{A}(t)$ to the classical observable $A(t)$ given by (7)?

Starting with the first question it is easy to see that the map V_0 is not well defined. In general $\hat{A}$ can be displayed in several different functional forms (all of them satisfying the order requirement), each of which will be mapped by V_0 to a *different* (however very similar) classical observable. A simple example will elucidate this point: let $\hat{A}=1/2(\hat{x}\hat{y}\hat{z}+\hat{z}\hat{y}\hat{x})$ with $\hat{x}=\hat{q}_1\hat{p}_2$, $\hat{y}=\hat{p}_1$ and $\hat{z}=\hat{q}_1\hat{q}_2$ where q_1, p_1, q_2, p_2 are the canonical variables of a two dimensional system. Alternatively, $\hat{A}$ might be written as $\hat{A}=1/4(\hat{x}\hat{y}\hat{z}+\hat{z}\hat{y}\hat{x}+\hat{x}\hat{z}\hat{y}+\hat{y}\hat{z}\hat{x})+1/4[\hat{x},[\hat{y},\hat{z}]]$. The first form of $\hat{A}$ is mapped by V_0 to the classical observable $A^0=xyz$ while the second form is mapped to the observable $A^0=xyz-1/4\hbar^2 q_1$. Moreover for each different classical observable obtained we will, in general, also get a different associated error ket and error margin. This does not mean that the former results (30), (41) concerning the error ket and the spread of the wave function are incorrect. These results have been proved to be valid (up to a correction term proportional to $\hbar^2$) for all different orders we may choose for the operator $\hat{A}$, and consequently for all different A^0 obtained from $\hat{A}$, providing the order requirement is satisfied.

Notice however that this ambiguity would be problematic if the difference between two different classical observables, obtained from a single quantum one, had meaningful values. However, one can easily realize that if A_1^0 and A_2^0 are two such observables [i.e., $A_1^0=V_0(\hat{A})$ and also $A_2^0=V_0(\hat{A})$] then $A_1^0-A_2^0$ is proportional to a factor of, at the most $\hbar^2$. An imprecision of this magnitude is not meaningful when compared to the errors associated to the classical observables. That is the predictions A_1^0 and A_2^0 are well within the error interval of each other $|A_1^0-A_2^0|$

$\ll \delta_{A_1^0 \text{or} A_2^0}$. Hence, the two predictions are consistent with each other and we conclude that A_1^0 and A_2^0 are equally valid candidates for a classical description of the quantum observable $\hat{A}$.

This takes us to the second question, which now can be restated as: will the classical observable $A(t)$, given by (7), be one of the images of $V_0(\hat{A}(t))$?

To answer this question let us start by presenting a second proposal for the unquantization map:

Definition: Unquantization V. Using the notation of the previous definition we define the new unquantization V to be the map:

$$V: \mathcal{A}(\mathcal{H}) \to \mathcal{A}(T^*M), \quad A = V(\hat{A}), \tag{42}$$

that satisfies the following requirement: $V \circ \wedge = 1$ where $\wedge$ is the Dirac quantization map.[32,37] That is V is the inverse of the Dirac quantization map $\wedge$. The properties of V follow immediately from the properties of $\wedge$:

(a) $V(\hat{q}_i) = q_i$, $V(\hat{p}_i) = p_i$, $i = 1 \cdots N$, and $V(\hat{I}) = 1$.

(b) $V(1/i\hbar[\hat{A}, \hat{B}]) = \{V_0(\hat{A}), V_0(\hat{B})\}$ for all $\hat{A}$ and $\hat{B}$.

For a general operator $\hat{A}$ displayed in the required order (see definition of V_0):

(c) V is linear: if $\hat{A} = b\hat{B} + \hat{C}$ then $V(\hat{A}) = bV(\hat{B}) + V(\hat{C})$, $b \in \mathcal{C}$.

(d) The product rule is valid: if $\hat{A} = \cdots + \hat{B}\hat{C} + \cdots$ then $V(\hat{A}) = V(\cdots) + V(\hat{B})V(\hat{C}) + V(\cdots)$. □

We should point out that, since the Dirac quantization map $\wedge$ is not injective, the unquantization map V is also nonunivocous. The simple example above—$\hat{A} = 1/2(\hat{x}\hat{y}\hat{z} + \hat{z}\hat{y}\hat{x})$—can also be used here to make this point clear. Being beset by the same type of order problems still V displays an important advantage over V_0: it is straightforward to recognize that when V is applied to the operator $\hat{A}(t)$—given by (6)—yields the classical observable $A(t)$:

$$V(\hat{A}(t)) = V\left[\sum_{n=0}^{\infty} \frac{1}{n!}\left(\frac{t}{i\hbar}\right)^n [\cdots[\hat{A}, \hat{H}], \hat{H}]\cdots\right] = \sum_{n=0}^{\infty} \frac{t^n}{n!}\{\cdots\{A, H\}, H\}\cdots\}. \tag{43}$$

Let us now consider a general operator $\hat{X}$. We want to prove that $V(\hat{X})$ provides a set of classical observables that is included in the set $V_0(\hat{X})$. Clearly the action of the two maps on an operator that does not contain antisymmetric components is identical. Moreover the two commutation relations $1/i\hbar[,]$ and $\{,\}$ have "compatible" algebraic structures, that is we can resolve $1/i\hbar[\hat{A}, \hat{B}]$ and express the result in such an order that when we perform the substitution of the quantum observables by the corresponding classical ones (i.e., when we unquantize $1/i\hbar[\hat{A}, \hat{B}]$ using the map V_0) we get exactly the same final result as if we just compute $\{A, B\}$ (i.e., as if we use the map V to unquantize $1/i\hbar[\hat{A}, \hat{B}]$). Thus, if $\hat{X}$ contains antisymmetric components the classical observable $V(\hat{X})$ might be obtained by displaying $\hat{X}$ in an adequate order and calculating $V_0(\hat{X})$. Hence, it is always possible to obtain the classical observables $V(\hat{X})$ using the map V_0. This is the result we were looking for. It means that expansion (28) and thus all subsequent results are valid for $A^0 = V(\hat{A})$.

Finally, we are able to state that the quantum mechanical predictions for an arbitrary dynamical system with a classical limit initial data wave function are that a measurement of an arbitrary fundamental observable $\hat{A}(t)$ at the time t will yield the value given by (43) with an error margin given by (41) (with $m \to \infty$). These are exactly the predictions of the classical mechanical treatment of the same system.

V. CRITERIA OF CLASSICALITY

In the last section we proved that a dynamical system with a quantum initial data satisfying (5) will evolve *exactly* accordingly to the predictions of classical mechanics, that is the system is ∞-consistent for all times. The main interest of this result is formal since, in most cases we are unable to provide a wave function satisfying the classical limit criterion (5).

To proceed we will now study dynamical systems with general physical initial data. The aim is to use the formalism developed in the previous sections to derive two criteria providing a measure of the degree of classicality of an arbitrary quantum system with arbitrary initial data.

Let then $|\phi\rangle$ be the initial data wave function of a N dimensional dynamical system with canonical variables a_k, $(k=1\cdots 2N)$. Let $\hat{S}_{k_i}=(\hat{a}_{k_1},\hat{a}_{k_2},\ldots,\hat{a}_{k_n})$, $k_i\in\{1\cdots 2N\}$ be a sequence of fundamental operators associated to the n-terms sequence k_i $(i=1\cdots n; n\in\mathcal{N})$. The relevant quantities that we have to calculate will be the n-order mixed error kets associated to the sequences $\hat{S}_{k_i}$:

$$|E_{S_{ki}}\rangle=(\hat{a}_{k_1}-a^0_{k_1})(\hat{a}_{k_2}-a^0_{k_2})\cdots(\hat{a}_{k_n}-a^0_{k_n})|\phi\rangle, \tag{44}$$

where $a^0_{k_i}$ is the classical initial value of the canonical variable a_{k_i}, i.e., $a^0_{k_i}=a_{k_i}(t=0)$.

A. First criterion

The first step is to obtain the time evolution of the canonical variables using the standard classical formulation of the system

$$a_j(t)=\sum_{m=0}^{\infty}\frac{t^m}{m!}\{\ldots\{a_j,H\}\ldots,H\}=F_j(a_k,t). \tag{45}$$

We then consider the sequences S_{k_i} such that

$$\frac{\partial F_j}{\partial S_{k_i}}=\frac{\partial^n F_j}{\partial a_{k_1}\partial a_{k_2}\cdots\partial a_{k_n}}\neq 0, \tag{46}$$

for at least one $j=1\cdots 2N$. For each of these sequences we construct the associated error ket (44). This way we obtain a set of error kets. The first order classicality criterion is given by the following conditions:

$$\langle E_{S_{ki}}|E_{S_{ki}}\rangle\leqslant(\delta_{S_{ki}})^2=(\delta_{k_1}\delta_{k_2}\cdots\delta_{k_n})^2, \tag{47}$$

where the inequalities should hold for all the sequences determined in (46). In (47) δ_{k_i} is the initial data classical error margin associated to the classical observable a_{k_i}, $i=1\cdots n$. If the initial data wave function satisfies the former conditions we say that the dynamical system is *first order classical*.

To proceed we construct the sequences $S^M_{k_i}$ formed by $M\in\mathcal{N}$ original sequences S_{k_i}, that is $S^M_{k_i}=S_{k_i},S_{k_i'},\ldots,S_{k_i''}$, where each of the M former sequences S_{k_i} might be any of the ones determined in (46). Once again, we calculate the values of $\langle E_{S^M_{ki}}|E_{S^M_{ki}}\rangle$ and compare them with $(\delta_{S^M_{ki}})^2$. If the initial data satisfies:

$$\langle E_{S^M_{ki}}|E_{S^M_{ki}}\rangle\leqslant(\delta_{S^M_{ki}})^2, \tag{48}$$

for all possible sequences $S^M_{k_i}$ we say that the dynamical system is M-order classical.

Let us make two remarks: the first one to say that the classification of a given initial data as M-order classical is *dependent* on the scales (error margins δ_k) that characterize the classical description. In particular for $\delta_k=\infty$ all dynamical systems will be ∞-order classical (and will have a classical limit initial data) while for scales smaller than the Planck scale none will even be

first-order classical. The second remark is to point out that if a system is M-order classical then [result (3.1d)] its initial data wave function, in the representation of any of the observables $\hat{a}_k(0)$, will have a minimum probability p in the interval $I_k=[a_k(0)-\delta_k/(1-p)^{1/(2M)},a_k(0)+\delta_k/(1-p)^{1/(2M)}]$, where $a_k(0)$ is the value of the classical observable a_k at the initial time, $t=0$. That is the initial data is M-order consistent. This is because in (46) we always determine the $2N$ single value sequences $S_{k_1}=a_k$, $(k=1\cdots 2N)$.

Furthermore, if the classical and the quantum initial data satisfy the inequalities (48) then we can substitute $\langle E_{S_{ki}^M}|E_{S_{ki}^M}\rangle$ by $(\delta_{S_{ki}^M})^2$ when computing (40) for $A^0=a_j(t)$. The result (41) can then be easily obtained being valid up to the order $m=M$. Hence, using the result (3.1d) we can state that an arbitrary M-order classical system, as defined above, will evolve in such a way that in the representation of $\hat{a}_j(t)$ (for all $j=1\cdots 2N$ and for all t) the initial data wave function has at least a probability p confined to the interval $I_j(t)=[a_j(t)-\delta_j(t)/(1-p)^{1/(2M)},a_j(t)+\delta_j(t)/(1-p)^{1/(2M)}]$ with $a_j(t)$ and $\delta_j(t)$ being the classical time evolution of the canonical variable a_j and associated error margin. According to the second consistency criterion this means that the classical and the quantum data describing the system at the time t are M-order consistent.

We conclude that if M is the order of classicality of a given dynamical system then: first the classical and the quantum data describing the initial time configuration of the system are M-order consistent and, second the degree of consistency is preserved through the time evolution.

Finally, notice that the higher the order of classicality M of the dynamical system the more similar will be the range of $I_j(t)$ and the classical error margin. When M goes to infinity we obtain the classical limit description of the system.

B. Second criterion

A second classicality criterion can be easily devised. Once again the first step is to calculate the time evolution of the canonical variables a_j using the classical formulation of the theory (45). Again we use this result to obtain the sequences of fundamental operators $\hat{S}_{k_i}$ (46) and the associated error kets (44). Using these error kets we can write the second classicality criterion:

$$\langle E_{S_{ki}}|E_{S_{ki}}\rangle \leqslant (\delta_{S_{ki}})^2(1-p_0)=(\delta_{k_1}\delta_{k_2}\ldots\ldots\delta_{k_n})^2(1-p_0), \quad \forall S_{k_i} \quad \text{in (46)}. \tag{49}$$

If the classical and the quantum initial data satisfy the former inequalities for a given p_0 $(0\leqslant p_0<1)$ and for all sequences determined in (46), then we say that the dynamical system is p_0-order classical. A straightforward use of the result (3.1d) will prove that a p_0-order classical system is described by an initial data wave function that, in the representation of any of its fundamental observables $\hat{a}_k(t=0)$, $k=1\cdots 2N$, has at least a probability p_0 confined to the classical error interval $[a_k(0)-\delta_k,a_k(0)+\delta_k]$. That is the initial time configuration is p_0-order consistent (according to the first consistency criterion).

Now, let us concentrate on the dynamical evolution of the former initial data. If the inequalities (49) are satisfied we can perform the substitution of $\langle E_{S_{ki}}|E_{S_{ki}}\rangle$ by $(\delta_{S_{ki}})^2(1-p_0)$ when computing (40) for $m=1$. Notice that there will be an extra factor of $(1-p_0)$ in the final expression in (40). We can then proceed and obtain the result (41) for $\Delta_1(\hat{a}_j(t),\phi,a_j(t),p)$ [which still contains the extra factor $(1-p_0)^{1/2}$]. More precisely we make $p=p_0$ in (41) and get for all $j=1\cdots 2N$:

$$\Delta_1(\hat{a}_j(t),\phi,a_j(t),p_0)=\left(\frac{\langle E_{a_j(t)}|E_{a_j(t)}\rangle}{1-p_0}\right)^{1/2}$$
$$\leqslant \frac{1}{(1-p)^{1/2}}\sum_{L=1}^{+\infty}\frac{1}{L!}\sum_{k_1,\ldots,k_L=1}^{2N}\left|\frac{\partial^L a_j(t)}{\partial a_{k_1}\ldots\partial a_{k_L}}\right|\delta_{k_1}\cdots\delta_{k_L}(1-p_0)^{1/2}=\delta_j(t). \tag{50}$$

The previous result together with (3.1d) implies that in the representation of $\hat{a}_j(t)$ (for all $j=1\cdots 2N$) the initial data wave function has at least a probability p_0 confined to the classical error interval $[a_j(t)-\delta_j(t), a_j(t)+\delta_j(t)]$, i.e., the classical and the quantum descriptions of the configuration of the system at the time t are p_0-order consistent. This result is valid for all times. We conclude that if a dynamical system is p_0-order classical then the classical and the quantum descriptions of the configuration of the system are p_0-order consistent for all times. Once again, when $p_0 \to 1$ we obtain the classical limit description of the system.

VI. EXAMPLE—HARMONIC OSCILLATOR

To illustrate the use of the first classicality criterion (Sec. V A), let us obtain the classicality conditions for the simple example of the harmonic oscillator. The classical Hamiltonian is given by $H=\frac{1}{2}(q^2+p^2)$, where q and p are a pair of canonical variables and, to make it simple we made $w=m=1$. Solving the equations of motion we obtain the classical time evolution of the canonical variables and the corresponding error margins

$$\begin{aligned} &q(t)=q(0)\cos t+p(0)\sin t, \quad \delta_q(t)=|\cos t|\,\delta_q(0)+|\sin t|\,\delta_p(0),\\ &p(t)=q(0)\sin t+p(0)\cos t, \quad \delta_p(t)=|\sin t|\,\delta_q(0)+|\cos t|\,\delta_p(0). \end{aligned} \tag{51}$$

Let $|\phi\rangle$ be the initial data wave function for the quantum harmonic oscillator. Let us then determine the conditions that $|\phi\rangle$ should satisfy so that the quantum system allows for a consistent M-order classical description. Following the general prescription of Sec. V A the first step is to determine the fundamental sequences (46). They are the single value sequences

$$S_1=q \quad \text{and} \quad S_2=p. \tag{52}$$

For a M-order classical system the relevant sequences are arrays of M fundamental sequences:

$$S^M=(z_1,\ldots,z_M), \quad z_i=q\vee p, \quad i=1\cdots M, \tag{53}$$

and the condition of M-order classicality (48) reads

$$\begin{aligned} &\langle E_{S^M}|E_{S^M}\rangle \leqslant \delta^2_{S^M}, \quad \forall S^M \quad \text{in (53)}\\ \Leftrightarrow &\langle\phi|(\hat{z}_1-z_1(0))\ldots(\hat{z}_M-z_M(0))(\hat{z}_M-z_M(0))\ldots(\hat{z}_1-z_1(0))|\phi\rangle \leqslant \delta^2_{z_1}(0)\ldots\delta^2_{z_M}(0). \end{aligned} \tag{54}$$

Given the classical initial data $\{q(0),p(0),\delta_q(0),\delta_p(0)\}$, Eq. (54) constitute a system of inequalities to be satisfied by initial data wave function $|\phi\rangle$. For a first-order classical system the classicality conditions take their simpler form

$$\begin{aligned} &\langle\phi|(\hat{q}-q(0))^2|\phi\rangle \leqslant \delta^2_q(0)\\ &\langle\phi|(\hat{p}-p(0))^2|\phi\rangle \leqslant \delta^2_p(0) \end{aligned} \quad \Leftrightarrow \quad \begin{aligned} &\int (q-q(0))^2|\phi(q)|^2dq \leqslant \delta^2_q(0)\\ &\int (p-p(0))^2|\phi(p)|^2dp \leqslant \delta^2_p(0). \end{aligned} \tag{55}$$

To obtain explicit solutions we may want to consider Gaussian wave packets [notice however that, in general, there are many solutions of (55) which are not Gaussians]:

$$\phi_c(q_0,p_0,\Delta q,q)=\frac{1}{(2\pi(\Delta q)^2)^{1/4}}\exp\left\{-\frac{(q-q_0)^2}{4(\Delta q)^2}+ip_0q/\hbar\right\}, \tag{56}$$

where q_0, p_0 and Δq are parameters and the wave function was displayed in the $\hat{q}$ representation. If we make $q_0=q(0)$ and $p_0=p(0)$ and substitute $\phi_c(q(0),p(0),\Delta q,q)$ in (55) we get the equivalent set of inequalities:

$$\Delta q \leqslant \delta_q(0) \quad \wedge \quad \frac{\hbar}{2^{1/2}\Delta q} \leqslant \delta_p(0). \tag{57}$$

As expected, if $\delta_p(0)\delta_q(0) < \hbar/(2^{1/2})$ there is no coherent state (and actually no wave function) that might satisfy the former inequalities, while for larger values of the classical error margins there are many solutions of (55), including the coherent states with a parameter Δq satisfying (57). We see that the classicality criteria provide a comparative notion of classicality but not an absolute one. In fact the degree of classicality is always relative to the classical description supplied.

The main result of the formalism is that a wave function satisfying (55), and in particular a coherent state satisfying (57) displays a time evolution first order consistent with the classical predictions (51), which means that for all t:

$$\int_{q(t)-\delta_q(t)/(1-P)^{1/2}}^{q(t)+\delta_q(t)/(1-P)^{1/2}} |\phi(q,t)|^2 dq \geqslant P, \quad \wedge \quad \int_{p(t)-\delta_p(t)/(1-P)^{1/2}}^{p(t)+\delta_p(t)/(1-P)^{1/2}} |\phi(p,t)|^2 dp \geqslant P, \quad \forall_{0\leqslant P<1}, \tag{58}$$

where $q(t)$, $p(t)$, $\delta_q(t)$, $\delta_p(t)$ are given by (51), $|\phi(t)\rangle$ is the solution of the Schrödinger equation:

$$i\hbar\,\partial/\partial t|\phi(t)\rangle = 1/2(\hat{q}^2+\hat{p}^2)|\phi(t)\rangle, \quad |\phi(t=0)\rangle = |\phi\rangle,$$

and P is an arbitrary probability. Take for instance $P=0.99$, Eq. (58) states that 99% of the probability of the wave function $|\phi(t)\rangle$, in both the representations of $\hat{q}$ and $\hat{p}$, is confined to the classical intervals $[q(t)-10\delta_q(t), q(t)+10\delta_q(t)]$ and $[p(t)-10\delta_p(t), p(t)+10\delta_p(t)]$, respectively. This statement is valid for all times and, for the case of coherent states can be easily verified by numerical computation of the integrals (58).

To see what happens when the degree of classicality is increased let us consider a 10th-order classical system. In this case the initial data wave function should satisfy the conditions (54) for all $M=10$ sequences (53). If we consider Gaussian type solutions (56) and substitute (56) in (54) we get the following set of inequalities for the parameter Δq:

$$\frac{(2M-1)!}{2^{M-1}((M-1)!)}(\Delta q)^{2M} \leqslant \delta_q^{2M}(0) \quad \wedge \quad \frac{(2M-1)!}{2^{M-1}((M-1)!)}\left(\frac{\hbar}{2^{1/2}\Delta q}\right)^{2M} \leqslant \delta_p^{2M}(0), \tag{59}$$

where $M=10$. Clearly, for the same classical initial data the set of solutions of (59) is just a subset of the set of solutions of (57).

The solutions of (54) with $M=10$ and in particular the coherent states satisfying (59), display a time evolution 10th-order consistent with the classical predictions (Sec. V A). In particular for $P=0.99$ we have $(1-P)^{1/20}=0.79$ and thus

$$\int_{q(t)-1.25\delta_q(t)}^{q(t)+1.25\delta_q(t)} |\phi(q,t)|^2 dq \geqslant 0.99 \quad \wedge \quad \int_{p(t)-1.25\delta_p(t)}^{p(t)+1.25\delta_p(t)} |\phi(p,t)|^2 dp \geqslant 0.99, \tag{60}$$

where $|\phi(t)\rangle$ is the quantum time evolution of a general initial data wave function satisfying (54) for $M=10$. The result is valid for all times and can be checked explicitly for an arbitrary coherent state satisfying (59).

One of the most interesting properties of coherent states is that its quantum time evolution is (in some sense) ''consistent'' with the classical predictions. Because of this coherent states might be seen as ''classical states.'' We see that the classicality criteria provide a systematic procedure to obtain ''classical states'' for an arbitrary dynamical system: by solving the classicality conditions (54) we obtain a large set of classical states (much larger than the coherent states set) for which the quantum time evolution is consistent with the classical predictions. Moreover, and most important, the imprecise notions of ''consistency'' and of ''classical states'' are made fully precise in this formalism.

VII. FURTHER EXAMPLE

To further illustrate the use of the criteria let us consider the two-dimensional system described by the Hamiltonian:

$$H=\frac{P^2}{2M}+\frac{p^2}{2m}+kQp^2, \tag{61}$$

where (Q,P) are the canonical variables of a particle of mass M, (q,p) the ones of the particle of mass m and k is a coupling constant. The classical time evolution is obtained by solving the Hamiltonian equations of motion which yield

$$\begin{aligned} Q(t)&=Q(0)+\frac{P(0)}{M}t-\frac{k}{2M}p(0)^2t^2,\\ P(t)&=P(0)-kp(0)^2t,\\ q(t)&=q(0)+\left\{\frac{p(0)}{m}+2kQ(0)p(0)\right\}t+\frac{k}{M}P(0)p(0)t^2-\frac{k^2}{3M}p(0)^3t^3,\\ p(t)&=p(0) \end{aligned} \tag{62}$$

with error margins (taking into account all orders in the initial time error margins):

$$\begin{aligned} \delta_Q(t)&=\delta_Q(0)+\left|\frac{t}{M}\right|\delta_P(0)+\left|\frac{kp(0)t^2}{M}\right|\delta_p(0)+\left|\frac{kt^2}{2M}\right|\delta_p^2(0),\\ \delta_P(t)&=\delta_P(0)+|2kp(0)t|\,\delta_p(0)+|kt|\,\delta_p^2(0),\\ \delta_q(t)&=\delta_q(0)+\left|\left(\frac{1}{m}+2kQ(0)\right)t+\frac{kP(0)t^2}{M}-\frac{k^2p(0)^2t^3}{M}\right|\delta_p(0)+|2kp(0)t|\,\delta_Q(0)\\ &\quad+\left|\frac{kp(0)t^2}{M}\right|\delta_P(0)+|kt|\,\delta_Q(0)\,\delta_p(0)+\left|\frac{kt^2}{2M}\right|\delta_P(0)\,\delta_p(0)+\left|\frac{k^2p(0)t^3}{M}\right|\delta_p^2(0)+\left|\frac{k^2t^3}{M}\right|\delta_p^3(0),\\ \delta_p(t)&=\delta_p(0). \end{aligned} \tag{63}$$

For this dynamical system the fundamental sequences (46) are (the indexes 1, 2, 3, and 4 refer to the canonical variables q, p, Q, and P, respectively)

$$\begin{aligned} &S_1=q,\quad S_2=p,\quad S_3=Q,\quad S_4=P,\\ &S_{22}=(p,p),\quad S_{23}=(p,Q),\quad S_{24}=(p,P),\quad S_{222}=(p,p,p) \end{aligned} \tag{64}$$

and the first order classicality condition reads

$$\langle E_{S_{ki}}|E_{S_{ki}}\rangle\leqslant\delta_{S_{ki}}^2,\quad \forall S_{k_i}\quad \text{in (64)}. \tag{65}$$

To make the discussion simpler let us consider solutions of the form $|\xi\rangle=|\psi\rangle|\phi\rangle$, where $|\psi\rangle$ is the quantum state of the particle of mass m, and $|\phi\rangle$ is that of the particle of mass M. In the $(\hat{q},\hat{Q})$ representation we have $\xi(q,Q)=\psi(q)\phi(Q)$. To proceed we notice that if the condition (65) is satisfied for the sequences S_1, S_2, S_3 and S_4 then is also satisfied for S_{23} and S_{24}. Furthermore, if it is satisfied for S_{222} is also for S_{22} and S_2. Hence, the system of eight inequalities (65) is reduced to the system of four inequalities: $\langle E_{S_{ki}}|E_{S_{ki}}\rangle\leqslant\delta_{S_{ki}}^2$, $S_{ki}\in\{S_1,S_3,S_4,S_{222}\}$. Moreover, the former system splits into two independent systems:

$$\begin{array}{ll} \langle\psi|(\hat{q}-q(0))^2|\psi\rangle \leqslant \delta_q^2(0) & \langle\phi|(\hat{Q}-Q(0))^2|\phi\rangle \leqslant \delta_Q^2(0) \\ & \text{and} \\ \langle\psi|(\hat{p}-p(0))^6|\psi\rangle \leqslant \delta_p^6(0) & \langle\phi|(\hat{P}-P(0))^2|\phi\rangle \leqslant \delta_P^2(0). \end{array} \tag{66}$$

For Gaussian type solutions $\xi_c(Q_0,P_0,q_0,p_0,\Delta Q,\Delta q,q,Q)=\phi_c(Q_0,P_0,\Delta Q,Q)\psi_c(q_0,p_0,\Delta q,q)$ it reduces to the form

$$\begin{array}{ll} \Delta q \leqslant \delta_q(0) & \Delta Q \leqslant \delta_Q(0) \\ & \text{and} \\ (15)^{1/6}\dfrac{\hbar}{2^{1/2}\Delta q} \leqslant \delta_p(0) & \dfrac{\hbar}{2^{1/2}\Delta Q} \leqslant \delta_P(0), \end{array} \tag{67}$$

where we used Eq. (59) to obtain the second inequality of the first system. Any Gaussian wave function satisfying the former conditions displays a time evolution (solution of the Schrödinger equation: $i\hbar\,\partial/\partial t|\xi(t)\rangle=\hat{H}|\xi(t)\rangle$, $|\xi(0)\rangle=|\xi\rangle$) first order consistent with the classical predictions (62) and (63). This means that for any of the canonical variables $Z=q,p,Q\vee P$ and for all times:

$$\int_w \int_{Z(t)-\delta_Z(t)/(1-P)^{1/2}}^{Z(t)+\delta_Z(t)/(1-P)^{1/2}} |\langle\xi(t)|z,w\rangle|^2 dz dw \geqslant P, \quad \forall_{0\leqslant P<1}, \tag{68}$$

where $|z,w\rangle$ is the general eigenstate of the observable $\hat{Z}$ with associated eigenvalue z and degeneracy index w, P is a probability and $(Z(t),\delta_Z(t))$ are the classical time evolution of the canonical variable Z and its error margin which are given by Eqs. (62) and (63), respectively.

Just like in the example of the harmonic oscillator we can increase the order of classicality of the system by requiring the initial data wave function to satisfy higher order classicality conditions. Likewise, this will increase the degree of consistency between the classical and the quantum predictions.

VIII. CONCLUSIONS

A general procedure leading to the construction of a measure of classicality was presented. The procedure can be summarized in two main steps.

(1) Definition of a consistency criterion. This is a kinematical criterion. It should provide a suitable measure of the degree of agreement between the classical and the quantum descriptions of a single, specific time configuration of the system. Two intuitive definitions of consistency criteria were presented and certainly other, possible more interesting criteria might be defined.

(2) Using the consistency criterion the problem of studying the overall consistency between the classical and the quantum descriptions of a general dynamical system is reduced to a simpler and more precisely formulated problem: that of identifying the conditions that should be satisfied so that the degree of consistency between the classical and the quantum initial data is preserved through time evolution. These conditions were explicitly obtained and used to construct a classicality criterion for each of the consistency criteria proposed at the beginning. We expect that the same general procedure might be used to derive the classicality criterion associated to other proposals of consistency criteria.

Ultimately, the two measures of classicality obtained are arbitrary in nature since they are a direct consequence of the definition of a consistency criterion. Therefore, they should be tested in physical examples to see if they yield sensible results. The criteria of this paper were applied to two simple dynamical systems and yield expected results. Namely, Gaussian wave functions were obtained as ''classical-like states'' (solutions of the classicality conditions).

Further applications of the criteria have been developed in Refs. 34, 35, and 36. Other possible future applications which might be of considerable interest are in the field of nonlinear dynamical systems, where the connection between classical and quantum mechanics becomes more involved.

To finish let us make a few remarks.

(i) The degree of classicality of a given quantum system is always relative to the classical description supplied (more precisely, to the classical initial data supplied). Therefore, the criteria do not provide an absolute classification of classicality but only a comparative one.

(ii) The fully classical behavior (i.e., the complete consistency with the classical predictions) is obtained in the limit case in which the quantum system fully satisfies one of the classicality criteria to all orders or equivalently, if the quantum and the classical initial data are fully consistent. Notice that consistency and classicality, in this case and in general only in this case, are equivalent notions: the results of Sec. III B 2 imply this statement directly.

(iii) The classicality conditions vary from one dynamical system to another. More precisely, once the classical initial data is given the M-order classicality conditions on the quantum initial data are more restrictive for some systems (for instance, the second example) than for others (for instance, the first example). This is not surprising, as neither is the fact that for some dynamical systems, the classicality conditions are so restrictive that there is no wave function that, for typical values of the classical data, might satisfy even the first order classicality conditions (consider for instance the system of a particle in a potential step).

(iv) The classicality criteria provide only a partial answer to the problem of measuring the degree of classicality of a general dynamical system. We were able to prove that a general dynamical system will evolve in agreement with the classical predictions up to some degree if its initial time configuration satisfies the classicality conditions up to some extent. However, these are sufficient but not necessary conditions: the system may very well not satisfy even the first order classicality criterion and still present a fairly classical-like evolution.

(Received 26 June 2002; accepted 26 July 2002)

We consider here the coexistence of first- and third-order integrals of motion in two-dimensional classical and quantum mechanics. We find explicitly all potentials that admit such integrals, and all their integrals. Quantum superintegrable systems are found that have no classical analog, i.e., the potentials are proportional to $\hbar^2$, so their classical limit is free motion. © *2002 American Institute of Physics.*

I. INTRODUCTION

In classical mechanics, an n-dimensional Hamiltonian system is called Liouville integrable if it allows n functionally independent integrals of motion in involution (including the Hamiltonian), that is,

$$\{H,X_i\}=0,$$
$$\{X_i,X_j\}=0,\forall i,j. \tag{1.1}$$

The Hamiltonian $H=H(x_1,\ldots,x_n,p_1,\ldots,p_n)$ and the integrals of motion $X_i=X_i(x_1,\ldots,x_n,p_1,\ldots,p_n)$ must be well defined functions on phase space.[2,13] The system is superintegrable if it allows more than n functionally independent integrals, n of them in involution. The best known superintegrable systems in n dimensions are the harmonic oscillator $V=\omega r^2$ and the Coulomb potential $V=\alpha/r$, both of them allowing $2n-1$ independent integrals of motion, the maximal number possible for an interacting system. Bertrand's theorem[2,3] tells us that these are the only rotationally invariant systems for which all finite trajectories are closed, a fact intimately related to their maximal superintegrability.

In quantum mechanics, a Hamiltonian system is said to be integrable if there exists a set $\{X_i\}$ of n well defined, algebraically independent operators (including the Hamiltonian) that commute pairwise. It is superintegrable if it possesses further independent operators, $\{Y_j\}$ that commute with the Hamiltonian. The Y_j do not necessarily commute with each other, nor with the X_i.

The definition of the independence of quantum operators is not unique, and this may give rise to different types of quantum superintegrability.

A good working definition, which may be appropriate for applications in quantum mechanics, soliton theory and for instance in the study of the Huygens principle, is that operators are considered independent unless one of them can be expressed as a polynomial in the others.[4,5,15,18] The fact that commuting operators can be useful even if they are functionally dependent in the classical limit was clearly demonstrated by Hietarinta.[15–18] This definition is in itself not quite satisfactory

[a)]Electronic mail: graves@magellan.umontreal.ca
[b)]Electronic mail: wintern@crm.umontreal.ca

since it ignores more general polynomial or functional relations between integrals. This may lead to important differences between classical and quantum integrability. Moreover, it is not appropriate for nonpolynomial integrals. Finding an appropriate and rigorous definition of the independence of quantum operators is not an easy problem, but it is worth investigating as wrong or ambiguous definitions may give rise to incorrect results. For a discussion of related problems, see, e.g., Refs. 17 and 30.

Previous systematic searches for superintegrable systems concentrated on integrals of motion of at most second order in momenta.[7–9,12,23,31] This ''quadratic superintegrability'' has been shown to be related to multiseparability of the Schrödinger or Hamilton–Jacobi equations. More recently, it was related to generalized symmetries[27] and exact solvability.[28]

Quadratic superintegrability has been considered in spaces of nonzero constant curvature[22,25] and of nonconstant curvature.[20] For superintegrable systems in n dimensions see Ref. 26.

Our purpose in this article is to start a systematic search for superintegrable systems with higher-order integrals of motion. We consider a two-dimensional real Euclidian space with a one-particle Hamiltonian;

$$H=\frac{1}{2}(p_x^2+p_y^2)+V(x,y).$$

We request the existence of two additional integrals of motion: one of first order in the momenta and the other of third order.

The classical and quantum mechanical cases will be treated separately. When second-order integrals of motion are considered, classical and quantum integrable and superintegrable potentials coincide. For third-order integrals this is no longer the case (as was pointed out by Hietarinta in Ref. 15). For integrable systems with third- or higher-order integrals in classical mechanics, see also Refs. 6, 10, 11, 14, 19, 21, and 24.

II. CONDITIONS FOR THE EXISTENCE OF A THIRD-ORDER INVARIANT IN CLASSICAL MECHANICS

We are looking for a classical integral of motion that is a polynomial in the momenta with coefficients depending on the spatial coordinates, i.e.,

$$X=\sum_{j,k} f_{jk}(x,y)p_1^j p_2^k,$$

that Poisson-commutes with the Hamiltonian;

$$\begin{aligned} 0&=\{H,X\},\\ H&=\frac{p_1^2+p_2^2}{2}+V(x,y). \end{aligned} \tag{2.1}$$

We can simplify our search by using the fact that Eq. (2.1) implies that X is a constant over any trajectory:

$$\frac{dX}{dt}=\frac{\partial X}{\partial q_i}\dot{q}_i+\frac{\partial X}{\partial p_i}\dot{p}_i=0, \tag{2.2}$$

with

$$\begin{aligned} \dot{p}_i&=-V_{q_i}(q_1,q_2),\\ \dot{q}_i&=p_i. \end{aligned} \tag{2.3}$$

If we write explicitly X in (2.2), we find

$$\sum_{j+k=1}^{n}\left(\frac{\partial f_{jk}}{\partial x}p_1^{j+1}p_2^k+\frac{\partial f_{jk}}{\partial y}p_1^j p_2^{k+1}-f_{jk}V_x j p_1^{j-1}p_2^k-f_{jk}V_y k p_1^j p_2^{k-1}\right)=0. \tag{2.4}$$

Since the monomials $p_1^a p_2^b$'s form a basis, the coefficients for each (a,b) must vanish separately, thus (2.4) gives relations between the f_{ij} with odd and even $i+j$ separately. If we are looking for an integral of odd (even) degree in the momenta, the even (odd) terms will play no role and we can without loss of generality consider only integrals that have terms only of odd (even) parity. Moreover, we may notice, in (2.4), that the terms of leading order in the p_i's imply a relation independent of V between the $f_{i,j}$ with $i+j=n$. This allows us to find immediately the form of the leading-order terms, so the integral of motion in the third-order case takes the form

$$\begin{gathered}X=\sum_{i+j+k=3}A_{ijk}L^i p_1^j p_2^k+g_1(x,y)p_1+g_2(x,y)p_2,\\ L=xp_2-yp_1,\end{gathered} \tag{2.5}$$

where the A_{ijk} are arbitrary real constants.

The requirement $dX/dt=0$ and the Hamilton equations (2.3) yield four equations:

$$0=g_1V_x+g_2V_y, \tag{2.6}$$

$$(g_1)_x=3f_1(y)V_x+f_2(x,y)V_y, \tag{2.7}$$

$$(g_2)_y=f_3(x,y)V_x+3f_4(x)V_y, \tag{2.8}$$

$$(g_1)_y+(g_2)_x=2(f_2(x,y)V_x+f_3(x,y)V_y), \tag{2.9}$$

where

$$\begin{gathered}f_1(y)=-A_{300}y^3+A_{210}y^2-A_{120}y+A_{030},\\ f_2(x,y)=3A_{300}xy^2-2A_{210}xy+A_{201}y^2+A_{120}x-A_{111}y+A_{021},\\ f_3(x,y)=-3A_{300}x^2y+A_{210}x^2-2A_{201}xy+A_{111}x-A_{102}y+A_{012},\\ f_4(x)=A_{300}x^3+A_{201}x^2+A_{102}x+A_{003}.\end{gathered}$$

Requiring that Eqs. (2.7), (2.8), and (2.9) be compatible, we obtain a linear compatibility condition for the potential, namely

$$\begin{aligned}0=&-f_3V_{xxx}+(2f_2-3f_4)V_{xxy}+(-3f_1+2f_3)V_{xyy}-f_2V_{yyy}+2(f_{2y}-f_{3x})V_{xx}\\&+2(-3f_{1y}+f_{2x}+f_{3y}-3f_{4x})V_{xy}+2(-f_{2y}+f_{3x})V_{yy}+(-3f_{1yy}+2f_{2xy}-f_{3xx})V_x\\&+(-f_{2yy}+2f_{3xy}-3f_{4xx})V_y.\end{aligned} \tag{2.10}$$

Requiring that all four equations (2.6), (2.7), (2.8), (2.9) be compatible, we obtain further third-order equations for the potential, this time nonlinear ones. They are the limit case (for $\hbar\to 0$) of the corresponding quantum compatibility conditions (3.7)–(3.9) given below.

These conditions, together with (2.10), form an overdetermined system for the potential $V(x,y)$. The solution space will hence be rather restricted. Indeed, in 1935, Drach[6] posed the problem of finding classical Hamiltonian systems with one third-order integral. In a complex Euclidian space $E_2(\mathbf{C})$, he found ten such potentials, each one depending on arbitrary constants, not, however, on arbitrary functions. We recall that in the case of second-order integrals, one

obtains four families of potentials, each of them depending on two arbitrary functions of one variable.[12,31] They are the four most general potentials that allow the separation of variables in Cartesian, polar, parabolic and elliptic coordinates, respectively.

III. CONDITIONS FOR THE EXISTENCE OF A THIRD-ORDER INVARIANT IN QUANTUM MECHANICS

Here we are interested in the existence of third-order operators, i.e.,

$$X=\sum_{i+j=0}^{3} P_{ij}(x,y)p_1^i p_2^j,$$

$$p_1=-i\hbar\partial_x,\quad p_2=-i\hbar\partial_y,$$

that commute with the Hamiltonian. An equivalent way of writing this operator is

$$X=\sum_{i+j=0}^{3} \{P_{ij}(x,y),p_1^i p_2^j\}.$$

Here the bracket means the anticommutator:

$$\{f,p_1^j p_2^k\}=fp_1^j p_2^k+p_1^j p_2^k f.$$

Each of these anticommutators can be expressed as

$$\{f,p_1^j p_2^k\}^+ + i\{f,p_1^j p_2^k\}^- = \{\Re e[f],p_1^j p_2^k\}+i\{\Im m[f],p_1^j p_2^k\}.$$

Hence we can write the operator X in the form

$$X=X^+ + iX^-,$$

where X^+ and X^- are self-adjoint operators. As the Hamiltonian itself is self-adjoint, $X^\dagger = X^+ - iX^-$ must also commute, as well as X^+ and X^-. These two last operators commute under the same conditions, so we may restrict our search without loss of generality to self-adjoint operators. This turns out to be quite useful in view of the following result.

Proposition 3.1: For each self-adjoint integral of motion of order n, there exists one integral of order n with definite parity, i.e.,

$$X_n=\sum_{j=0}^{[n/2]}\sum_{k=0}^{n-2j} \{P_{n-2j,k}(x,y),p_1^k p_2^{n-2j-k}\}, \tag{3.1}$$

where P is a real function.

Proof: This is simply due to the fact that we have a real Hamiltonian and a purely imaginary momentum operator, so terms of even order, which are real, must commute independently of the terms of odd order, which are purely imaginary. □

In the case $n=3$ we restrict ourselves to third-order integrals of the form

$$X_3=\sum_{i+j=3} \{f_{ij}(x,y),p_1^j p_2^k\}+\{g_1(x,y),p_1\}+\{g_2(x,y),p_2\}.$$

Requesting

$$0=[H,X],$$

$$H=\frac{1}{2m}(p_1^2+p_2^2)+V(x,y),$$

we find a set of 15 differential equations, of which the first nine can be explicitly solved to give

$$X=\sum_{\substack{i,j,k\\ i+j+k=3}} A_{ijk}\{L_3^i,p_1^j p_2^k\}+\{g_1(x,y),p_1\}+\{g_2(x,y),p_2\}, \tag{3.2}$$

where the A_{ijk} are arbitrary real constants. So far this is similar to the classical case.

Remark 1: The argument used in demonstrating Proposition 3.1 can be generalized to any expression involving the anticommutators of self-adjoint operators homogeneous in the p_i's, for example, to terms of the form $\{L_3^i,p_1^j p_2^k\}$, as long as the coefficients of the p_i's are real.

We could get rid of the $\hbar$ and m factors by a dilation of the undetermined functions,

$$V(x,y)=\frac{\hbar^2}{2m}\tilde{V}(x,y),$$

$$g_1(x,y)=\hbar^2 g_1'(x,y),$$

$$g_2(x,y)=\hbar^2 g_2'(x,y).$$

This is equivalent to setting $\hbar$ and m equal to one, which we could do, but we prefer to keep track of the dependence on $\hbar$ (while setting $m=1$), in order to see the classical limit.

We are left with a set of 6 equations, two of which are consequences of the other four, so that, as in the classical case, we have to solve four equations:

$$0=g_1V_x+g_2V_y-\frac{\hbar^2}{4}(f_1V_{xxx}+f_2V_{xxy}+f_3V_{xyy}+f_4V_{yyy}+8A_{300}(xV_y-yV_x)$$
$$+2(A_{210}V_x+A_{201}V_y)), \tag{3.3}$$

$$(g_1)_x=3f_1(y)V_x+f_2(x,y)V_y\equiv h_1, \tag{3.4}$$

$$(g_2)_y=f_3(x,y)V_x+3f_4(x)V_y\equiv h_2, \tag{3.5}$$

$$(g_1)_y+(g_2)_x=2(f_2(x,y)V_x+f_3(x,y)V_y)\equiv h_3. \tag{3.6}$$

Equations (3.4) to (3.6) are the same as in the classical case, however, Eq. (3.3) differs from Eq. (2.6) by the terms proportional to $\hbar^2$. Both in the classical and quantum cases we can eliminate g_1 and g_2 and obtain compatibility conditions for the potentials.

We shall write these in a unified manner for both cases. One such compatibility condition is the third-order linear equation (2.10). To write three more conditions we introduce the notation

$$\phi_1=\frac{V_y}{V_x},$$

$$\phi_2=-\hbar^2\frac{(f_1V_{xxx}+f_2V_{xxy}+f_3V_{xyy}+f_4V_{yyy}+8A_{300}(xV_y-yV_x)+2(A_{210}V_x+A_{201}V_y))}{4V_x},$$

and use h_1, h_2 and h_3 introduced in (3.4), (3.5) and (3.6). In the classical case we have $\phi_2=0$. The three (independent) nonlinear compatibility conditions are

$$-\phi_{2x}+\left(\frac{\phi_1(h_3\phi_1+h_2\phi_1^2+\phi_1\phi_{2y}+\phi_{2x}+h_1)}{\phi_{1x}+\phi_1\phi_{1y}}\right)_x=h_1, \tag{3.7}$$

$$\left(\frac{\phi_1^2h_2+\phi_1\phi_{2y}+\phi_1h_3+\phi_{2x}+h_1}{\phi_{1x}+\phi_1\phi_{1y}}\right)_y=-h_2, \tag{3.8}$$

$$\begin{aligned}&h_1(\phi_{1xy}+\phi_{1y}^2)+h_2(\phi_1^2\phi_{1xy}-\phi_{1x}^2-2\phi_1\phi_{1x}\phi_{1y})+h_3(\phi_1\phi_{1xy}-\phi_{1x}\phi_{1y})\\&\quad-(h_{1y}+\phi_1h_{2x})(\phi_{1x}+\phi_1\phi_{1y})\\&\quad=-\phi_{2x}(\phi_{1xy}+\phi_{1y}^2)+\phi_{2y}(\phi_{1x}\phi_{1y}-\phi_{1xy}\phi_1)+\phi_{2xy}(\phi_{1x}+\phi_1\phi_{1y}).\end{aligned} \tag{3.9}$$

In the quantum case these are fifth-order equations for the potential. They can be used to express ϕ_{2xy}, ϕ_{2xx} and ϕ_{2yy} in terms of ϕ_{2x}, ϕ_{2y} and ϕ_2. In the classical case we set $\phi_2=0$, but the equations remain algebraically independent. They can be used to determine ϕ_{1xy}, ϕ_{1xx} and ϕ_{1yy} in terms of ϕ_{1x}, ϕ_{1y} and ϕ_1. The nonlinear equations for $V(x,y)$ are third-order ones in the classical case.

In deriving these equations we have assumed

$$\begin{aligned}\phi_{1x}+\phi_1\phi_{1y}&\neq 0,\\ \phi_{1xy}\phi_1-\phi_{1x}\phi_{1y}&\neq 0.\end{aligned} \tag{3.10}$$

The cases when the above conditions do not hold must be considered separately. This will actually be the case for potentials considered in Sec. IV.

We also mention the interesting fact, already noticed by Hietarinta,[16] that a classical integrable potential is also quantum integrable, if and only if it respects the compatibility condition

$$f_1V_{xxx}+f_2V_{xxy}+f_3V_{xyy}+f_4V_{yyy}+8A_{300}(xV_y-yV_x)+2(A_{210}V_x+A_{201}V_y)=0. \tag{3.11}$$

In that case the equations are invariant under a simultaneous dilation of the potential and the g_i's. Thus any potential that is a solution to both (2.6) to (2.9) and (3.11) can be multiplied by an arbitrary factor, which can be used to "absorb" the $\hbar^2$ factor so the solution does not vanish in the classical limit.

Even if a classical superintegrable potential does not satisfy this relation, there could exist corresponding quantum superintegrable systems. In that case, though, the equations are not invariant under a dilation of the potential as in the previous case, so terms that do not satisfy both (3.11) and (2.6) to (2.9) must be proportional to $\hbar^2$ and vanish in the classical limit.

We will show that condition (3.11) cannot be the consequence of Eqs. (3.4), (3.5) and (3.6) for in that case the classical and quantum integrable potentials would be the same.

IV. SUPERINTEGRABLE SYSTEMS WITH ONE THIRD-ORDER AND ONE FIRST-ORDER INTEGRAL

A. Integral of first order

A potential $V(x,y)$ allows an integral that is of first order in the momenta if and only if it is invariant under either rotations or translations. Thus the potential must satisfy

$$aL_3V+bp_1V+cp_2V=0.$$

Without loss of generality, we can take the potential and first-order integral to be one of the following:

- $a\neq 0$: $\quad V=V(r), \quad X=L_3,$

- $a=0,\ b^2+c^2\neq 0:\ \ V=V(x),\ \ X=p_2.$

B. Quantum and classical superintegrable potentials invariant under rotations

Compatibility conditions obtained from Eqs. (2.6) to (2.9) or (3.3) to (3.6) leave us with only two possibilities, namely,

$$V=\frac{\alpha}{r},$$

$$V=\omega^2 r^2,$$

the Coulomb potential and the harmonic oscillator, which are the best-known superintegrable potentials in any dimension. In addition to angular momentum L_3, the Coulomb potential in E_2 allows two second-order integrals, namely the components of the Laplace–Runge–Lenz vector:

$$X_1^C=\{L_3,p_1\}-\frac{2\alpha y}{r};$$

$$X_2^C=\{L_3,p_2\}+\frac{2\alpha x}{r}.$$

The harmonic oscillator, in addition to angular momentum, allows two second-order integrals which are the components of a quadrupole tensor;

$$X_1^h=-\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+\omega^2x^2-\omega^2y^2;$$

$$X_2^h=-p_1p_2+2\omega^2xy.$$

Commuting (or Poisson commuting) second-order integrals, we in general find third-order integrals.

The third-order integrals obtained for these potentials are indeed direct consequences of integrals at order one and two.

C. Classical superintegrable potentials invariant under translation

In the classical case, the remaining equations are readily solved. If we set $V_y=0$, Eqs. (2.6) to (2.9) simplify to

$$0=g_1,$$

$$0=A_{300}=A_{210}=A_{120}=A_{030},$$

$$(g_2)_y=f_3(x,y)V_x,$$

$$(g_2)_x=2\,f_2(x,y)V_x.$$

We can at once set A_{021} and A_{003} to 0, for they correspond to trivial constants of motion, p_2^3 and Hp_2, that can be subtracted from the constant (2.5).

The compatibility condition between the two last equations forces one of the three following conditions to be satisfied (up to a translation in x):

$$V=ax, \tag{4.1}$$

$$V=\frac{a}{x^2}, \tag{4.2}$$

$$A_{201}=A_{111}=A_{102}=A_{012}=0. \tag{4.3}$$

The first two potentials correspond to superintegrable systems that have one first- and at least one second-order integral. Their third-order integrals can be obtained by commutation of these lower-order ones.

The last conditions forbid the existence of a nontrivial third-order commuting operator for any other potentials than (4.1) and (4.2).

D. Quantum superintegrable potentials invariant under translation

Here the situation is more interesting. Equations (3.3) to (3.6) reduce to

$$0=g_1V_x-\frac{\hbar^2}{4}(f_1V_{xxx}-8yA_{300}V_x+2A_{210}V_x), \tag{4.4}$$

$$(g_1)_x=3f_1(y)V_x, \tag{4.5}$$

$$(g_2)_y=f_3(x,y)V_x, \tag{4.6}$$

$$(g_1)_y+(g_2)_x=2(f_2(x,y)V_x). \tag{4.7}$$

The linear compatibility condition leads to two equations (since coefficients of y^0 and of y^1 must vanish separately), namely,

$$\begin{aligned}0&=(A_{210}x^2+A_{111}x+A_{012})V_{xxx}+4(2A_{210}x+A_{111})V_{xx}+12A_{210}V_x;\\ 0&=(3A_{300}x^2+2A_{201}x+A_{102})V_{xxx}+4(6A_{300}x+2A_{201})V_{xx}+36A_{300}V_x.\end{aligned} \tag{4.8}$$

The two equations are similar and easy to solve, but it turns out their only solutions that also satisfy (4.4) to (4.7) are again the potentials $V=ax$ and $V=a/x^2$. Their third-order integrals in general are direct consequences of lower-order commuting operators, that is, they can be obtained by commuting their second-order integrals. In the $V=a/x^2$ case, we find three third-order integrals:

$$X_1=\{L_3^2,p_2\}+a\left\{2\frac{y^2}{x^2},p_2\right\},$$

$$X_2=\{L_3,p_1p_2\}-a\left\{2\frac{y}{x^2},p_2\right\},$$

$$X_3=2p_1^2p_2+a\left\{\frac{2}{x^2},p_2\right\}.$$

The integrals X_2 and X_3 can be obtained by commuting X_1 with the first-order integral p_2.

In the particular case $V=\hbar^2/x^2$, we find four more integrals, again related to each other by commutation with p_2:

$$X_4=2L_3^3+\hbar^2\left\{\frac{3y^2}{x}+x,p_2\right\}+\hbar^2\left\{\frac{-3y^3}{x^2}-2y,p_1\right\},$$

$$X_5=\{L_3^2,p_1\}-\hbar^2\left\{\frac{2y}{x},p_2\right\}+\frac{\hbar^2}{2}\left\{\frac{6y^2}{x^2}+1,p_1\right\},$$

$$X_6=\{L_3,p_1^2\}+\hbar^2\left\{\frac{1}{x},p_2\right\}+\hbar^2\left\{\frac{-3y}{x^2},p_1\right\},$$

$$X_7=2p_1^3+\hbar^2\left\{\frac{3}{x^2},p_1\right\}.$$

In this case we find nine third-order integrals, two of which are trivial (Hp_2 and p_2^3), and four are purely quantum integrals. In the classical limit they correspond to integrals of the free motion. Only the first three can be associated with the corresponding classical integrals of $V=a/x^2$.

The most interesting potentials are obtained by setting all the A_{ijk} involved in (4.8) equal to 0. The expressions for f_1, f_2, f_3, f_4 greatly simplify and Eqs. (4.4) to (4.7) can be solved directly. The nonlinear compatibility condition for these four equations reduces to

$$\hbar^2V'(x)^2=4V(x)^3+\alpha V(x)^2+\beta V(x)+\gamma, \tag{4.9}$$

where the α, β, γ are arbitrary real integration constants. Equation (4.9) is the well-known equation for elliptic functions which can be rewritten as

$$\hbar^2V'(x)^2=4(V(x)-A_1)(V(x)-A_2)(V(x)-A_3). \tag{4.10}$$

The constants A_i are either all real, or one of them is real and the other two are complex conjugated. If all three constants are real, we obtain either finite or singular potentials of the form

$$V_1=(\hbar\omega)^2k^2sn^2(\omega x,k),$$
$$V_2=\frac{(\hbar\omega)^2}{sn^2(\omega x,k)}, \tag{4.11}$$

respectively.

If we have, e.g., $A_3=A_2^*$ and $\mathrm{Im}\,A_2\neq 0$, we obtain the singular potential

$$V_3=\frac{(\hbar\omega)^2}{2(cn(\omega x,k)+1)}$$

(throughout we have $0\leqslant k\leqslant 1$, $\omega\in\mathbf{R}$).

The special cases with $k=0$ or $k=1$, which arise when two roots coincide, can be expressed in terms of elementary functions. The most interesting example is the ''soliton'' potential,

$$V_{1a}=\frac{(\hbar\omega)^2}{\cosh^2(\omega x)},$$

obtained by setting $k=1$ in V_1. If we set $k=0$, or $k=1$ in V_2, we get a singular periodic, or nonperiodic potential, respectively, namely

$$V_{2a}=\frac{(\hbar\omega)^2}{\sin^2(\omega x)},$$

$$V_{2b}=\frac{(\hbar\omega)^2}{\sinh^2(\omega x)}.$$

For all these potentials ω is an arbitrary constant, hence there exist potentials of arbitrary amplitude for all nonzero values of $\hbar$.

Finally, if all roots coincide, we reobtain the known superintegrable potential,

$$V_4=\frac{\hbar^2}{x^2},$$

which explains the extra integrals found previously for that potential.

The other potentials V_1, V_2, V_3 also satisfy

$$\frac{\hbar^2}{4}\frac{V_{xxx}}{V_x}-3V=-\sigma, \quad \sigma=A_1+A_2+A_3,$$

a consequence of (4.9).

The two nontrivial integrals of motion for all these potentials can be written as

$$X_1=\{L_3,p_1^2\}+\{(\sigma-3V(x))y,p_1\}+\left\{-\sigma x+2xV(x)+\int V(x)dx,p_2\right\},$$
$$X_2=p_1^3+\frac{1}{2}\{3V(x)-\sigma,p_1\}. \tag{4.12}$$

The second integral can be trivially obtained by the commutation of the first one with p_2.

V. CONCLUSION

We have found all potentials in two-dimensional Euclidian space E_2 that allow one first- and at least one third-order integral of motion. In the classical case the result provides no new superintegrable potentials; all the potentials found allow second-order integrals and the third-order integrals are consequences of the second-order ones. In the case of quantum mechanics the result is quite different. Any potential satisfying the elliptic function equation (4.9) will be superintegrable in the above sense, i.e., it will allow the first-order integral p_2 and two nontrivial third-order integrals. All those ''behave well'' in the classical limit, that is, they are proportional to $\hbar^2$ and therefore their classical limit is the (superintegrable) free motion.

No new superintegrable systems are found for rotationally invariant potentials $V(r)$, neither in the classical nor in the quantum case. Thus all potentials found above are of the form $V=V(x)$, i.e., are actually one-dimensional. The problem, however, remains two-dimensional as the kinetic energy and the integrals of motion also involve the y direction.

There is also an interesting link with soliton theory.[1] All new superintegrable potentials obtained above are also translationally invariant solutions of the Korteweg-de Vries equation. The same potentials occur in the rational, trigonometric and elliptic Calogero–Moser–Sutherland models.[29]

The difference between classical and quantum integrable and superintegrable systems with higher-order symmetries makes the systematic search for such systems very interesting. First of all, Drach's study of classical integrable systems should be completed. His systems are really complex ones and most of them do not exist in real Euclidian space. Moreover it is not clear how complete his list is. On the other hand, Rañada[24] has shown that 7 out of 10 Drach potentials are ''reducible'' in the sense that they are superintegrable and allow two second-order integrals. The third-order integral found by Drach is the Poisson commutator of the second-order ones.

The problem of classifying quantum systems with third-order integrals remains open and the conditions of Sec. III provide the means for finding all such systems.

Work is in progress on superintegrable systems in two-dimensional Euclidian space with one second- and one third-order invariant, as well as with two third-order ones.

ACKNOWLEDGMENTS

The authors thank M. B. Sheftel and P. Tempesta who participated in the early stages of this project, and also J. Bérubé for interesting discussions. The final version of this article was written while both authors were visiting the Departemento de Fisica Teorica II of the Universidad Complutense. They thank the Departemento and specially M. A. Rodriguez for hospitality and helpful discussions. S.G. benefited from an NSERC student fellowship. The research of P.W. was partly supported by research grants from NSERC of Canada, FCAR du Québec and NATO.

(Received 29 May 2002; accepted 22 August 2002)

The semirelativistic Hamiltonian $H=\beta\sqrt{m^2+p^2}+V(r)$, where $V(r)$ is a central potential in $\Re^3$, is concave in p^2 and convex in $p\equiv\sqrt{p^2}$. This fact enables us to obtain complementary energy bounds for the discrete spectrum of H. By extending the notion of ''kinetic potential'' we are able to find general energy bounds on the ground-state energy E corresponding to potentials with the form $V=\Sigma_i a_i f^{(i)}(r)$. In the case of sums of powers and the log potential, where $V(r)=\Sigma_{q\neq 0}a(q)\mathrm{sgn}(q)r^q+a(0)\ln(r)$, the bounds can all be expressed in the semiclassical form $E\approx\min_r\{\beta\sqrt{m^2+(1/r^2)}+\Sigma_{q\neq 0}a(q)\mathrm{sgn}(q)(rP(q))^q+a(0)\ln(rP(0))\}$. ''Upper'' and ''lower'' P numbers are provided for $q=-1,1,2$, and for the log potential $q=0$. Some specific examples are discussed, to show the quality of the bounds. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1515381]

I. INTRODUCTION

The Hamiltonian $H=K+V$ for the problems we study has the feature that either the kinetic energy K or the potential energy V is nonlocal. The most important example is the semirelativistic ''spinless-Salpeter'' Hamiltonian[1–4] given by

$$H=K(p)+V(r)=\sqrt{m^2+p^2}+V(r), \tag{1.1}$$

where $r\equiv\|\mathbf{r}\|$, $\mathbf{r}\in\Re^3$, and $p\equiv\|\mathbf{p}\|\equiv\sqrt{\mathbf{p}^2}$. In this form at least $K(p)$ is nonlocal in configuration space and is defined as a multiplicative operator in momentum space. That is to say, $K\psi$ is defined to be what we get when ψ is transformed to momentum space, the multiplicative operator K is applied, and the result is transformed back to coordinate space. Nonlocality is the main source of difficulty for this class of problems. We study the discrete spectra of these Hamiltonians by the use of approaches that make use of convexity and of spectral information already obtained concerning related problems. In an earlier paper[4] we studied the relationship between $H_0=K+h$ and $H=K+g\circ h$, where $g(h(r))$ is a smooth transformation of a 'base' potential $h(r)$. For cases in which g had definite convexity, one could then employ the so-called kinetic-potential[5] formalism and envelope theory[6] to construct upper or lower bounds to the discrete eigenvalues of H by using the known spectrum of H_0.

The present paper has two distinct aspects: we turn our attention firstly to the convexity of K, as a function of p or p^2; and then we look at potentials that are a *sum* of terms $V=\Sigma_i V^{(i)}$. In Sec.

II we extend the kinetic-potential formalism to include more general kinetic-energy operators than the Schrödinger form $K=p^2$ studied earlier.[5] We have already found[7] some implications of the fact that K is *concave* in p^2. The spectral implications of the *convexity* of K in p demand a new analysis. By using Jensen's inequality[8] we are able to construct a framework in Sec. III which accommodates both cases. Although it may not be immediately apparent, the treatment of potential *sums* also leads to an interesting convexity analysis of a completely different type.[9,10] This in turn yields an optimized general lower bound for the bottom of the spectrum expressed in terms of the kinetic potentials generated by 'component' problems $K+V^{(i)}$. We discuss this in general terms in Sec. IV. In the special case in which the component problems are pure-power potentials or the log potential, that is to say

$$V(r)=\sum_{q\neq 0} a(q)\mathrm{sgn}(q)r^q+a(0)\ln(r), \tag{1.2}$$

the lower bound (Sec. V) and also upper bounds obtained by variational methods (Sec. VI) can all be expressed in terms of a semiclassical expression of the form

$$E\approx\min_r\left\{\sqrt{m^2+\frac{1}{r^2}}+\sum_{q\neq 0} a(q)\mathrm{sgn}(q)(rP(q))^q+a(0)\ln(rP(0))\right\}. \tag{1.3}$$

It is the goal of this paper to develop a general theory which leads to such a result and, in particular, to determine P numbers which guarantee that the approximation (1.3) is an upper or lower bound. We shall find the appropriate upper and lower $P(q)$ for the cases $q=-1,1,2$, and for the log potential $q=0$. In Sec. VII we apply our general results to some specific examples.

Although we obtain very concrete results in the end, our study begins with a somewhat abstract viewpoint. We now make a few general remarks that will help motivate these starting considerations. An idea that runs through the work is one well known to those who study nonlinear problems: we try to use transformations to make the most of any soluble problem that is at hand, or, at least, one for which we have a good approximation. The setting for our ideas is geometrical. We suppose that we have an exact solution (or good bounds) for a base problem with Hamiltonian $\alpha p^2+\beta h(r)$, and we are interested in a Hamiltonian of the form $H=k(p^2)+g(h(r))$, where k and g are monotone increasing smooth transformations. It follows that the tangent spaces to H are Schrödinger operators with the general form $H^{(\mathbf{t})}=a+bp^2+ch(r)$, where the parameters $\{a,b,c\}$ depend on the contact vector $\mathbf{t}$. What we look for is a theory that would allow us to deduce spectral information about H from the known spectrum of its tangents $H^{(\mathbf{t})}$. For example, if the transformation functions k and g are both concave, we would expect to obtain upper bounds via the spectral inequality $H<H^{(\mathbf{t})}$. *Mutatis mutandis*, a complimentary theory is possible with operator tangent spaces of the form $H^{(\mathbf{t})}=a+bp+ch(r)$, where $K(p)$ is *convex* in p and $g(h)$ is convex in h: this leads to energy *lower* bounds. Since we have already explored[4] the potential transformation g, the main thrust of the present paper concerns kinetic-energy transformations with base problems, respectively, p^2+h and $p+h$ and to applications of the results when the potential in H is a sum of terms. The more general case in which neither transformation $k(p)$ nor $g(h)$ is the identity follows immediately by combining the present and earlier results; hence we do not need to discuss this natural generalization in detail here. Coulomb components present a special difficulty for a lower bound with kinetic energy p because the operator $p-v/r$ has no discrete eigenvalues. However, for our main concern, the Salpeter Hamiltonian, we are able to make use of the very good Coulomb lower bound of Martin and Roy[11] and so incorporate the Coulomb contribution smoothly into our general formulation.

II. VARIETY OF KINETIC POTENTIALS

The discrete eigenvalues of the self-adjoint operators we study may be characterized variationally. Thus the bottom of the spectrum E of $H=K+V$ is given by $E=\inf(\psi,H\psi)$, where the

infimum is taken over all normalized functions in the domain $\mathcal{D}(H)\subset L^2(\Re^3)$. The idea behind kinetic potentials is to perform the minimization in two stages: we first find the constrained minimum $\overline{V}(K;s)$ of $(\psi,V\psi)$, keeping the mean kinetic energy $(\psi,K\psi)=s$ constant; then, we recover E by minimizing over the kinetic energy $s>0$. Thus we have

$$\overline{V}(K;s)=\inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1\\(\psi,K\psi)=s}}(\psi,V\psi)\ \Rightarrow\ E=\min_{s>0}\{s+\overline{V}(K;s)\}. \tag{2.1}$$

We call the function $\overline{V}(K;s)$ the kinetic potential of V associated with the kinetic-energy operator K; we shall write simply $\overline{V}(s)$, if the kinetic-energy operator K is fixed or is clear from the context. It follows immediately from the definition that the kinetic potentials absorb a positive coupling parameter in the sense that $\overline{cV}(s)=c\overline{V}(s)$. We note also that the elementary

Comparison theorem:

$$\overline{V}^{(1)}(s)<\overline{V}^{(2)}(s)\ \Rightarrow\ E^{(1)}<E^{(2)}$$

follows immediately from (2.1). The arguments we use are not restricted to dimension $N=3$: this choice allows us to illustrate the general results with some explicit well-known examples, without the distraction of the operator dependencies on N.

The reason for using this description of the spectral problem is that it lends itself to some interesting approximations. First, we have shown in the Schrödinger[5] and Salpeter[4] cases that, if $V(r)=g(h(r))$ and g is monotone increasing and has definite convexity, then the approximation $\overline{V}(s)\approx g(\overline{h}(s))$ leads to lower bounds if g is convex and upper bounds if g is concave. In Sec. IV of the present paper we shall extend to general K the result obtained earlier[10] for the Schrödinger case that kinetic potentials are subadditive, that is to say

$$V(r)=h^{(1)}(r)+h^{(2)}(r)\ \Rightarrow\ \overline{V}(s)\geqslant\overline{h}^{(1)}(s)+\overline{h}^{(2)}(s). \tag{2.2}$$

The lower energy bound then immediately follows from the above-mentioned comparison theorem for kinetic potentials. There is more to this result than meets the eye: it generates the optimum of a family of lower bounds; the details will be given in Sec. IV. Extensions to sums with more than two terms (or, further, to mixtures generated by an integral) are immediate. The principal limitation is that each potential term alone, when added to the kinetic energy, must, for large enough coupling, support a discrete eigenvalue. Thus $V(r)=-1/r+r$ is allowed but $V(r)=1/r+r$ is not.

The component kinetic potential $\overline{h}(s)=\overline{h}(K;s)$ can be constructed by use of a Legendre transformation from the eigenvalue function $E=F(v)$, in which $F(v)$ is the bottom of the spectrum of $H=K+vh(r)$, as a function of the coupling v. In the Schrödinger case $H=p^2+vh(r)$ we have shown that $F(v)$ is concave[5] and moreover the kinetic potential for $K=p^2$ is given in terms of $F(v)$ by the transformation

$$s=F(v)-vF'(v),\quad \overline{h}(K;s)=F'(v). \tag{2.3}$$

The concavity of the eigenvalue function $F(v)$ has been proved for the Schrödinger case[5] and the Salpeter case[4] by the application of a simple variational argument. By exactly similar reasoning we can show that the eigenvalue function for the operator $p+vh(r)$ is also concave in v. Moreover, the Legendre transformation (2.3) is generic: it is valid for all kinetic-energy operators K. This is an immediate consequence of the concavity of $F(v)$, as the following equations clearly demonstrate:

$$F(v)=\min_{u>0}\{F(u)-uF'(u)+vF'(u)\}=\min_{s>0}\{s+v\overline{h}(K;s)\}.$$

Our principal assumption concerning K is that it is at once a convex function of p and a concave function of p^2. This convexity is clearly true for our most important example, the relativistic kinetic energy $K=\sqrt{m^2+p^2}$; however, we shall use this specific form only when we need to.

We now turn from the general to some very specific results. We shall need to have at our disposal some component kinetic potentials for the operators $K+v\ \mathrm{sgn}(q)r^q$, where $K=p$, or the Schrödinger case $K=p^2$. By elementary scaling arguments we can show that the dependence of the energy functions on the coupling v are given by

$$p+v\ \mathrm{sgn}(q)r^q \Rightarrow E=F^{(1)}(q;v)=F^{(1)}(q;1)v^{1/(1+q)} \tag{2.4a}$$

and

$$p^2+v\ \mathrm{sgn}(q)r^q \Rightarrow E=F^{(2)}(q;v)=F^{(2)}(q;1)v^{2/(2+q)}. \tag{2.4b}$$

The Legendre transformation $F\leftrightarrow\overline{h}$ given above in (2.3) now allows us to deduce the precise forms of the corresponding kinetic potentials. For convenience we choose to write the kinetic potentials so obtained in a special way. We change variables for the mean kinetic energy s in the two cases, respectively, to $s=1/r$ and $s=1/r^2$. It then follows from (2.3) by straightforward algebraic computations that the kinetic potentials for $h(r)=\mathrm{sgn}(q)r^q$ have similar convenient forms, namely

$$\overline{h}(p;1/r)=\mathrm{sgn}(q)(P^{(1)}(q)r)^q \tag{2.5a}$$

and

$$\overline{h}(p^2;1/r^2)=\mathrm{sgn}(q)(P^{(2)}(q)r)^q, \tag{2.5b}$$

where the P numbers are *defined* in terms of the $v=1$ eigenvalues $E^{(i)}(q)=F^{(i)}(q;1)$, $i=1,2$, respectively, by the explicit formulas

$$K=p \Rightarrow P^{(1)}(q):=\left|\frac{E^{(1)}(q)}{1+q}\right|^{1+1/q}|q|, \quad q>-1, \quad q\neq 0 \tag{2.6a}$$

and

$$K=p^2 \Rightarrow P^{(2)}(q):=\left|\frac{E^{(2)}(q)}{1+q/2}\right|^{1/2+1/q}\left|\frac{q}{2}\right|^{1/2}, \quad q>-2, \quad q\neq 0. \tag{2.6b}$$

The energies are related to the kinetic potentials by specific realizations of the general formula (2.1): for example, we have in this spectral representation

$$p+v\ \mathrm{sgn}(q)r^q \Rightarrow E=\min_{r>0}\left\{\frac{1}{r}+v\ \mathrm{sgn}(q)(P^{(1)}(q)r)^q\right\}, \quad q>-1, \quad q\neq 0. \tag{2.7}$$

One of our side goals is purely esthetic, namely we wish to end up with attractive formulas: after the changes of variable from s to r, the kinetic potentials look like the original power potentials themselves, but with the P factors inserted. We turn now to the base potential $h(r)=\ln(r)$ and find by scaling arguments that

$$p+v\ \ln(r) \Rightarrow F^{(1)}(v)=vF^{(1)}(1)-v\ \ln(v) \tag{2.8a}$$

and

$$p^2+v\ \ln(r) \Rightarrow F^{(2)}(v)=vF^{(2)}(1)-\tfrac{1}{2}v\ \ln(v). \tag{2.8b}$$

TABLE I. Eigenvalues for $v=1$ and corresponding P numbers [given by (2.6) and (2.10)] for the Coulomb, log, linear, and harmonic-oscillator potentials. The eigenvalues have been computed numerically and are rounded so that the $E^{(1)}(q)$ are lower bounds and the $E^{(2)}(q)$ are upper bounds (and similarly for the derived P numbers). The Coulomb lower bound is treated differently because $H=p-1/r$ has no discrete spectrum.

q	$E^{(1)}(q)$	$P^{(1)}(q)$	$E^{(2)}(q)$	$P^{(2)}(q)$
-1			$-\frac{1}{4}$	1
0	1.063 65	1.0657	1.044 3325	1.218 669
1	2.232 25	1.2457	2.338 1075	1.376 084
2	2.338 107	1.366 687	3	$\frac{3}{2}$

Consequently we obtain from the transformation (2.3),

$$\overline{h}(p;1/r)=\ln(P^{(1)}(0)r), \quad \overline{h}(p^2;1/r^2)=\ln(P^{(2)}(0)r), \tag{2.9}$$

where

$$P^{(1)}(0)=\exp(E^{(1)}(0)-1), \quad P^{(2)}(0)=\frac{1}{\sqrt{2}}\exp\left(E^{(2)}(0)-\frac{1}{2}\right). \tag{2.10}$$

For the discussion of examples we shall need to have some specific P values. For the cases $q=-1,0,1,2$ we supply some of these numerical values in Table I. This table has an eigenvalue symmetry because of the operator equivalence $p+r^2\sim p^2+r$; it also has two omissions corresponding to $q=-1$, because $p-1/r$ has no discrete eigenvalues. We offer now a solution to this Coulomb difficulty. As we shall make clear in Sec. IV, viable Coulomb P numbers are needed for *lower* bounds. For our most important application $K=\sqrt{p^2+m^2}$, a lower bound to the bottom of the spectrum of $H=K-v/r$ is provided by the Martin–Roy bound[11]

$$E\geqslant e_L(v)=m\left(\frac{1+\sqrt{1-4v^2}}{2}\right)^{1/2}, \quad v<\frac{1}{2}. \tag{2.11}$$

The condition $v<\frac{1}{2}$ is a little more restrictive than the fundamental operator restriction $v<2/\pi$: it was proved by Herbst[12] that a Friedrichs extension exists for H only if the Coulomb coupling is sufficiently small. The Coulomb lower bound has the same scaling law with respect to m as does the exact energy: although m originates in the Hamiltonian inside the square root of the kinetic-energy term, it appears in the eigenvalue and in its lower approximation simply as an overall factor.[4] Now we construct a v-dependent P representation for this lower bound. We write [as a definition of $P_L(v)$]

$$e_L(v)=\min_r\left\{\sqrt{m^2+\frac{1}{r^2}}-\frac{v}{P_L(v)r}\right\}. \tag{2.12}$$

An elementary calculation then shows that (2.11) and (2.12) imply $P_L(v)=e_L(v)/m$. This serendipitous discovery fills the gaps in Table I, and will allow us to include the Coulomb component in our lower-bound energy formula for sums of potential terms: we must make the substitution

$$-\frac{v}{P^{(1)}(-1)r}=-\frac{v}{P_L(v)r}=-\frac{mv}{e_L(v)r}, \quad v<\frac{1}{2}. \tag{2.13}$$

III. COMPLEMENTARY CONVEXITY: $p+V$ AND p^2+V

The principal result of this section is best expressed in terms of kinetic potentials by the following.

Theorem 1: *If E is the bottom of the spectrum of the Hamiltonian $H=K+V$, and the kinetic-energy operator K is at once convex in p and concave in p^2, then it follows that*

$$\min_{s>0}\{K(s)+\overline{V}(p;s)\}\leqslant E\leqslant\min_{s>0}\{K(s)+\overline{V}(p^2;s^2)\}. \tag{3.1}$$

It makes sense here to speak of $K(p)$ as though p were a real variable since, by definition, the action of the operator K is effected via the Fourier transform. We shall now prove this result by an application of Jensen's inequality[8] and kinetic potentials defined in (2.1). We consider first the left-hand inequality of the theorem. If ψ is a normalized function in the domain $\mathcal{D}(H)$ of $H=K+V$, then, since $K=K(p)$ is convex in p, by Jensen's inequality, we have

$$E=\inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1}}\{(\psi,K(p)\psi)+(\psi,V\psi)\}\geqslant\inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1}}\{K((\psi,p\psi))+(\psi,V\psi)\}.$$

That is to say,

$$E\geqslant\min_{s>0}\inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1\\(\psi,p\psi)=s}}\{K((\psi,p\psi))+(\psi,V\psi)\}=\min_{s>0}\{K(s)+\overline{V}(p;s)\}.$$

The proof of the upper-bound inequality is very similar: we write $K(p)=k(p^2)$, where k is concave; then, setting $t=s^2$, we arrive at the inequality

$$E\leqslant\min_{t>0}\{k(t)+\overline{V}(p^2;t)\}=\min_{s>0}\{K(s)+\overline{V}(p^2;s^2)\},$$

which establishes the theorem. □

This result is an essential ingredient in the proof of the sum approximation in the next section. We now look at an example, namely the Salpeter problem with a linear potential. We have

$$H=\sqrt{m^2+p^2}+V(r),\quad V(r)=vh(r)=vr, \tag{3.2}$$

where v is a positive coupling parameter. In terms of the convenient variable $r>0$ the two kinetic potentials from (2.5) are

$$\overline{h}(p;1/r)=P^{(1)}(1)r,\quad \overline{h}(p^2;1/r^2)=P^{(2)}(1)r, \tag{3.3}$$

where the P numbers are provided in Table I. Theorem 1 then immediately yields the bounds

$$\min_{r>0}\{\sqrt{m^2+r^{-2}}+vP^{(1)}(1)r\}\leqslant E\leqslant\min_{r>0}\{\sqrt{m^2+r^{-2}}+vP^{(2)}(1)r\}. \tag{3.4}$$

In Fig. 1 we plot these bounds as a function of m for the case $v=1$. If we combine Theorem 1 here with Theorem 2 of Ref. 4 (to the effect that $\overline{g\circ h}>g\circ\overline{h}$ when g is convex) we obtain the following class of examples. We suppose that $V(r)$ is monotone increasing and convex in $h(r)=r$ then the two theorems together yield the lower bound

$$E\geqslant\min_{r>0}\left\{\sqrt{m^2+\frac{1}{r^2}}+vV(P^{(1)}(1)r)\right\}. \tag{3.5}$$

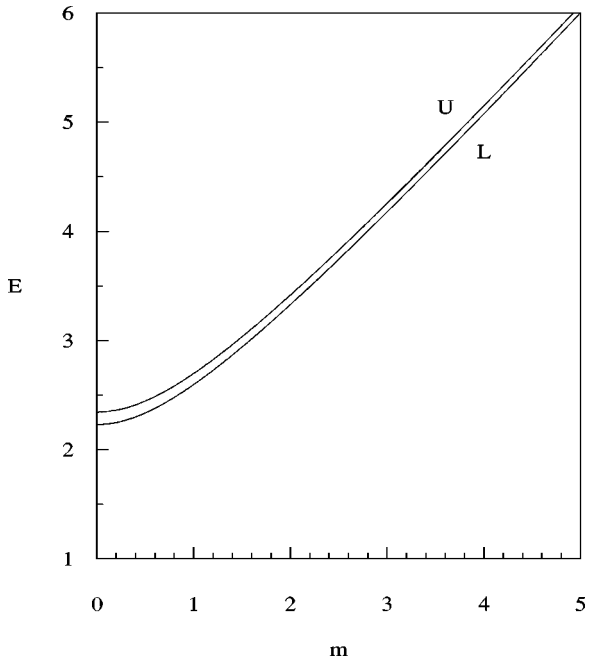

FIG. 1. Complementary upper (U) and lower (L) bounds (3.4) on the lowest eigenvalue $E(m)$ of $H=\sqrt{m^2+p^2}+r$ plotted against m.

Of course, if $V(r)$ is *concave*, then we get an *upper* bound by the same expression provided we use $P^{(2)}(1)$. It is perhaps important to note that with $P=P^{(2)}(r)$ an upper bound would be obtained for every choice of r in the expression on the right-hand side; the expression in (3.5) is however only a lower bound *a priori* at the minimum point.

IV. THE SUM APPROXIMATION: LOWER BOUNDS

Since further generalization easily follows, we first look at the problem of the sum of two potential terms. We assume that each potential $vh^{(i)}(r)$ alone, when added to the kinetic-energy operator K, has a discrete eigenvalue at the bottom of the spectrum for sufficiently large coupling v. We express our result in terms of kinetic potentials and prove the following.

Theorem 2: *If E is the bottom of the spectrum of the Hamiltonian $H=K+V$, and the potential V is the sum $V(r)=h^{(1)}(r)+h^{(2)}(r)$, then it follows that the sum of the component kinetic potentials yields a lower bound to $\overline{V}$, that is to say*

$$\overline{V}(K;s)\geqslant\overline{h^{(1)}}(K;s)+\overline{h^{(2)}}(K;s). \tag{4.1}$$

We shall now prove this theorem, which is in effect an optimized Weyl lower bound;[13–15] this remark will be clarified below, after the proof of the theorem. From the definition (2.1) of kinetic potentials we have

$$\overline{V}(K;s)=\inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1\\(\psi,K\psi)=s}}(\psi,V\psi)=\inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1\\(\psi,K\psi)=s}}(\psi,(h^{(1)}+h^{(2)})\psi).$$

But the latter minimum mean-value is clearly bounded below by the sum of the *separate* minima. Thus we have

$$\overline{V}(K;s) \geqslant \inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1\\(\psi,K\psi)=s}} (\psi,h^{(1)}\psi) + \inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1\\(\psi,K\psi)=s}} (\psi,h^{(2)}\psi) = \overline{h}^{(1)}(K;s) + \overline{h}^{(2)}(K;s),$$

which inequality establishes the theorem. □

Another approach, which would eventually yield an alternative proof of the theorem, exhibits the relationship between Theorem 2 and the classical Weyl lower bound[13–15] for the eigenvalues of the sum of two operators. Let us suppose that Ψ is the exact normalized lowest eigenfunction of $H=K+V$, so that $H\Psi=E\Psi$. If the positive real parameter w is bounded by 1, $0<w<1$, then $E=(\Psi,(K+V)\Psi)$ may be written as follows:

$$E = w\left(\Psi,\left(K+\frac{1}{w}h^{(1)}(r)\right)\Psi\right) + (1-w)\left(\Psi,\left(K+\frac{1}{1-w}h^{(2)}(r)\right)\Psi\right)$$

$$\geqslant w \inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1}}\left(\psi,\left(K+\frac{1}{w}h^{(1)}(r)\right)\psi\right) + (1-w)\inf_{\substack{\psi\in\mathcal{D}(H)\\(\psi,\psi)=1}}\left(\psi,\left(K+\frac{1}{1-w}h^{(2)}(r)\right)\psi\right).$$

That is to say, in terms of component kinetic potentials, we arrive at Weyl's inequality for the lowest eigenvalue of the sum $H=wK+h^{(1)}+(1-w)K+h^{(2)}$:

$$E \geqslant w\min_{s>0}\left\{s+\frac{1}{w}\overline{h}^{(1)}(K;s)\right\} + (1-w)\min_{s>0}\left\{s+\frac{1}{1-w}\overline{h}^{(2)}(K;s)\right\}.$$

Since w is an essentially free parameter in the last expression, we may optimize the Weyl lower bound with respect to the choice of w and this forces the individual values of s at the minima, $\{s_1(w),s_2(w)\}$, to be related. More specifically we find from the individual minimizations over s,

$$E \geqslant \mathcal{E}(w) = ws_1(w) + (1-w)s_2(w) + \overline{h}^{(1)}(K;s_1(w)) + \overline{h}^{(2)}(K;s_2(w)),$$

where

$$w = -\frac{\partial\overline{h}^{(1)}}{\partial s}(K;s_1(w)) \quad \text{and} \quad 1-w = -\frac{\partial\overline{h}^{(2)}}{\partial s}(K;s_2(w)).$$

The critical condition $\mathcal{E}'(w)=0$ for the subsequent maximization of the lower bound over w then yields $s_1(w)=s_2(w)$. Thus the best lower energy bound is given by

$$E \geqslant \min_{s>0}\{s+\overline{h}^{(1)}(K;s)+\overline{h}^{(2)}(K;s)\}.$$

The kinetic-potential inequality of Theorem 2 leads, of course, to the same energy lower bound: the optimization just performed above is therefore seen to be automatically built in by the formalism.

It follows immediately from the above kinetic-potential comparison theorem and coupling-parameter absorption that a lower bound to the lowest energy E of the Hamiltonian $H=K+\Sigma_i c_i h^{(i)}(r)$, $\{c_i>0\}$, is provided by the formula

$$E \geqslant \min_{s>0}\left\{s+\sum_i c_i\overline{h}^{(i)}(K;s)\right\}. \tag{4.2}$$

Similarly we can extend this result to continuous sums such as $V(r)=\int_{t_1}^{t_2}c(t)h^{(t)}(r)dt$.

This general theory becomes practically useful when we have good information concerning the components. More particularly, we must have some exact component kinetic potentials, or

lower bounds to them. Outside the well-explored Schrödinger case $K=p^2$, such analytical results are rather sparse. We look at the interesting class of power-law potentials in the next section.

V. SUMS OF POWERS AND THE LOG POTENTIAL

For power-law potentials and the relativistic kinetic energy $K=\sqrt{m^2+p^2}$ we have discussed some lower bounds in Sec. III and we shall now turn these to our advantage. The link between Theorem 1 and Theorem 2 derives from the observation that the equation $K(s)=\sqrt{m^2+s^2}$ allows us to change the minimization variable $s\to r=1/s$. In the first stage of minimization, we have used Jensen's inequality for the lower bound (see proof of Theorem 1); this allows us to keep $(\psi,p\psi)=s=1/r$ constant at first, and then later minimize over s, or, equivalently, over r. We can also easily accommodate a further positive kinetic-energy parameter β. Thus we immediately arrive at the following.

Theorem 3: *A lower bound to the lowest eigenvalue of the semirelativistic spinless-Salpeter operator*

$$H=\beta\sqrt{m^2+p^2}+\sum_{q\neq 0}a(q)\mathrm{sgn}(q)r^q+a(0)\ln(r),$$

where $\beta>0$ *and the potential coefficients* $a(q)\geqslant 0$ *are not all zero, is given by*

$$E\geqslant\min_{r>0}\left\{\beta\sqrt{m^2+\frac{1}{r^2}}+\sum_{q\neq 0}a(q)\mathrm{sgn}(q)(P^{(1)}(q)r)^q+a(0)\ln(P^{(1)}(0)r)\right\},\tag{5.1}$$

where, for the Coulomb component $q=-1$, *we make the substitution*

$$-\frac{a(-1)}{P^{(1)}(-1)r}=-\frac{\beta^2 mv}{e_L(v)r}=-\frac{\beta v}{r}\left(\frac{2}{1+\sqrt{1-4v^2}}\right)^{1/2},\quad v=\frac{a(-1)}{\beta}<\frac{1}{2}.\tag{5.2}$$

The problem presented for the lower bound by the fact that $p-v/r$ has no discrete spectrum was discussed in Sec. II. We have no simple P-number $P(-1)$ but we could derive a running P (2.13) from the Martin–Roy energy bound (2.11); the positive factor β has been inserted in (5.2) by elementary scaling. We shall look at applications of Theorem 3 in Sec. VII when we also have at our disposal the upper-bound P numbers derived in Sec. VI.

VI. VARIATIONAL UPPER BOUNDS

The lower bound for sums discussed in the preceding two sections has the attractive feature that if the component kinetic potentials are exact and only one term is present, then the result is exact. We are unable to construct a general upper bound with this feature. Instead we use a trial wave function $\phi=c\exp(-\frac{1}{2}\alpha r^\nu)$ with a scale parameter $\alpha>0$ and two other parameters $\{c,\nu\}$, and we apply this wave function to the entire problem. One degree of freedom c is used to guarantee normalization, and the scale parameter $\alpha>0$ is expressed in terms of a new variable $t>0$ chosen in such a way that the scale minimization is of an expression with the same form as the lower bound. Initially we use here t rather than r since, during the discussion, we shall need to refer to the potential function $V(r)$. The choice of the remaining parameter $\nu>0$ is left for later optimization.

If we suppose that c has already been chosen so that $\|\phi\|=1$ and, for computational convenience, we use Jensen's inequality, we then obtain the following upper energy bound:

$$E<\mathcal{E}=\beta\sqrt{m^2+(\phi,p^2\phi)}+\left(\phi,\left\{\sum_{q\neq 0}a(q)\mathrm{sgn}(q)r^q+a(0)\ln(r)\right\}\phi\right).\tag{6.1}$$

Now, for each fixed $\nu>0$, we define a new scale variable $t>0$ by the following:

$$(\phi,p^2\phi)=(\phi,-\Delta\phi)=\alpha^{2/\nu}\left(\frac{\nu}{2}\right)^2\frac{\Gamma\left(2+\frac{1}{\nu}\right)}{\Gamma\left(\frac{3}{\nu}\right)}\equiv\frac{1}{t^2}. \tag{6.2}$$

Using this definition of t, we can go on to define the upper P numbers $\mathcal{P}(\nu,q)$ by the relations

$$(\phi,r^q\phi)=\frac{1}{\alpha^{q/\nu}}\frac{\Gamma\left(\frac{q+3}{\nu}\right)}{\Gamma\left(\frac{3}{\nu}\right)}\equiv(\mathcal{P}(\nu,q)t)^q,\quad q\neq 0, \tag{6.3a}$$

and

$$(\phi,\ln(r)\phi)=\ln(\mathcal{P}(\nu,0)t). \tag{6.3b}$$

If we now rename the scale variable $t=r$, and minimize the upper bound $\mathcal{E}$ with respect to scale, we arrive at

Theorem 4: *For each $\nu>0$, an upper bound to the lowest eigenvalue E of the Salpeter operator*

$$H=\beta\sqrt{m^2+p^2}+\sum_{q\neq 0}a(q)\mathrm{sgn}(q)r^q+a(0)\ln(r),$$

where $\beta>0$ and the potential coefficients $a(q)\geqslant 0$ are not all zero, is given by

$$E\leqslant\min_{r>0}\left\{\beta\sqrt{m^2+\frac{1}{r^2}}+\sum_{q\neq 0}a(q)\mathrm{sgn}(q)(\mathcal{P}(\nu,q)r)^q+a(0)\ln(\mathcal{P}(\nu,0)r)\right\}, \tag{6.4}$$

where the upper P numbers are provided by the formulas

$$\mathcal{P}(\nu,q)=\frac{\nu}{2}\left(\frac{\Gamma\left(2+\frac{1}{\nu}\right)}{\Gamma\left(\frac{3}{\nu}\right)}\right)^{1/2}\left(\frac{\Gamma\left(\frac{q+3}{\nu}\right)}{\Gamma\left(\frac{3}{\nu}\right)}\right)^{1/q},\quad q\neq 0, \tag{6.5a}$$

$$\mathcal{P}(\nu,0)=\frac{\nu}{2}\left(\frac{\Gamma\left(2+\frac{1}{\nu}\right)}{\Gamma\left(\frac{3}{\nu}\right)}\right)^{1/2}\exp\left(\frac{1}{\nu}\psi\left(\frac{3}{\nu}\right)\right), \tag{6.5b}$$

and ψ is the digamma function $\psi(t)=\Gamma'(t)/\Gamma(t)$.

Apart from the special Coulomb considerations pertaining to the lower bound (5.1), that formula is essentially identical to the upper bound (6.4): we simply have to use the correct P numbers in each case.

VII. EXAMPLES

We have now assembled the P numbers for our energy-bound formulas (5.1) and (6.4). We shall use the lower P numbers in Table I, lower running P formula for the Coulomb component

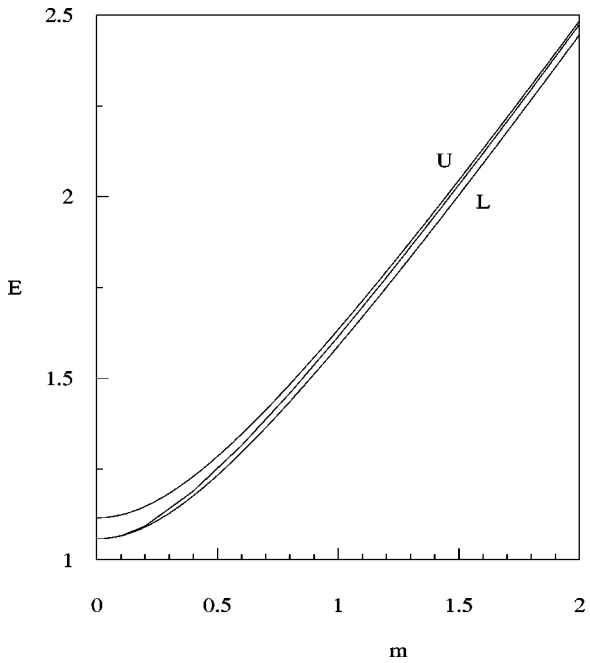

FIG. 2. Lower bounds (L) by (5.1) and upper bounds (U) by (6.4) for the lowest eigenvalue $E(m)$ of $H=\sqrt{m^2+p^2}-0.1/r+0.25r$ plotted against m. The upper bound (U) used the wave-function parameter $\nu=1.6$. The central curve is a very accurate upper bound found by a variational exploration in a 25-dimensional trial space.

(2.13), and the formulas (6.5) for the $\mathcal{P}(\nu,q)$ corresponding to the variational upper bound (6.4). The class of problems we are thus immediately able to consider have the following explicit Hamiltonian form:

$$H=\beta\sqrt{m^2+p^2}-a/r+b\ln(r)+cr+dr^2, \quad a,b,c,d\geqslant 0, \tag{7.1}$$

where $\beta>0$, and the potential parameters $\{a,b,c,d\}$ are not all zero. We look at two examples. In the first, illustrated in Fig. 2, we look at the linear-plus-Coulomb potential $V(r)=-0.1/r+0.25r$ and compare the energy bounds $\{L,U\}$ we find, as functions of the mass m, with some very accurate numerical values (center curve) obtained by minimizing the expectation value of the Hamiltonian in a 25-dimensional trial space. In the next graph, Fig. 3, we plot the energy bounds alone, for the same potential and a wider range of values of the mass m. As a second example we consider the broad linear combination $V(r)=-0.1/r+0.25\ln(r)+0.25r+0.25r^2$ and plot in Fig. 4 the energy bounds as functions of the mass. These illustrations give a clear indication of the quality of the bounds that the theory yields.

VIII. CONCLUSION

The principal theoretical results of this paper are the complementary bounds of Theorem 1, and the sum-approximation lower bound, Theorem 2. In order to arrive at these results we needed first to extend the notion of kinetic potential to allow for more general kinetic-energy operators than the Schrödinger form $K=p^2$. The complementary bounds are based on the assumption that K is a convex function of p and also a concave function of p^2, assumptions clearly satisfied by our prime example and principal motivation, the relativistic kinetic energy $K=\beta\sqrt{m^2+p^2}$. The inequality of Jensen then allows us to learn approximately how special mean values of the problem, the eigenvalues of H, depend on the operator parameters.

By combining Theorem 1 of this paper with Theorem 2 of our earlier paper[4] we obtain a general theory applicable to operator manifolds of the form $H=K(p)+g(h)$ with, on the one

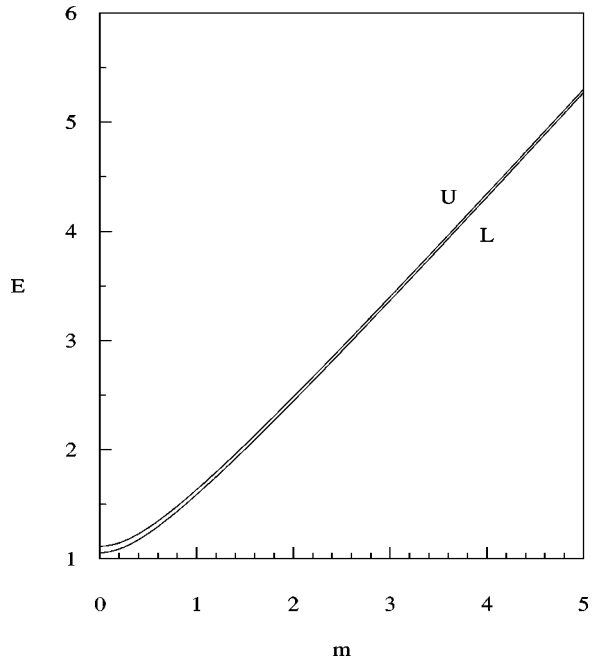

FIG. 3. Lower bounds (L) by (5.1) and upper bounds (U) by (6.4) for the lowest eigenvalue $E(m)$ of $H=\sqrt{m^2+p^2}-0.1/r+0.25r$ plotted against m: this is a continuation of the graph in Fig. 2 to larger m.

hand, tangent spaces spanned by the Schrödinger operators $ap^2+bh(r)+c$, and, on the other, by complementary operators of the form $ap+bh(r)+c$. Given the correct convexities of K and g, energy bounds immediately follow. We looked at one example of this type of problem near the end of Sec. III; and the results were exhibited in Fig. 1.

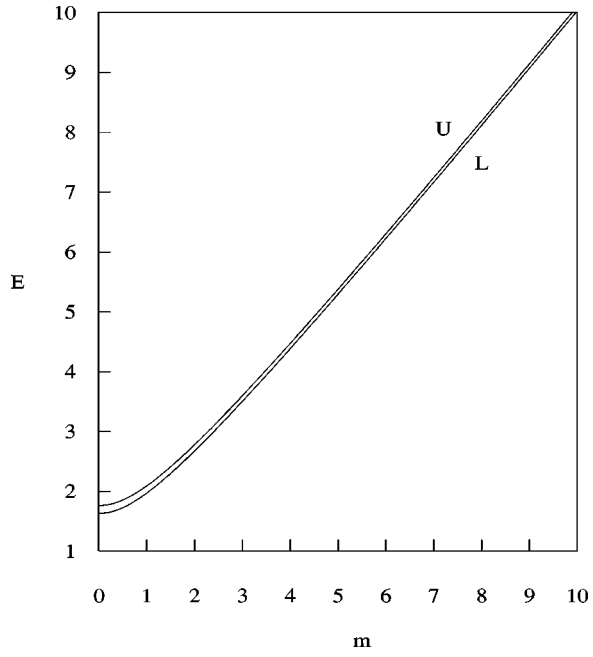

FIG. 4. Lower bounds (L) by (5.1) and upper bounds (U) by (6.4) for the lowest eigenvalue $E(m)$ of $H=\sqrt{m^2+p^2}-0.1/r+0.25\ln(r)+0.25r+0.25r^2$ plotted against m. The upper bound (U) used the wave-function parameter $\nu=1.4$.

A completely different lower bound is provided by Theorem 2, which may be thought of as a spectral expression of the sum structure of the potential, namely the subadditivity of the corresponding kinetic potential, as a sum of components.

In order to make practical use of these theoretical results we need some definite spectral information about component problems. This is provided by the family of pure-power potentials $V(r)=\mathrm{sgn}(q)r^q$. For this family we are able to take advantage of known eigenvalues, or bounds to them, and of simple upper bounds obtained with the aid of Jensen's inequality and a two-parameter family of trial functions. All of our component results can then be expressed in terms of certain P numbers (or, for the lower Coulomb case, $q=-1$, by a P function), which are required by the general lower- and upper-bound formulas of Theorems 3 and 4. These formulas illustrate the effectiveness of the theoretical results and provide recipes for approximate solutions to an interesting class of semirelativistic spectral problems.

Magnetic translation groups in an *n*-dimensional torus and their representations

(Received 7 May 2002; accepted 6 August 2002)

A charged particle in a uniform magnetic field in a two-dimensional torus has a discrete noncommutative translation symmetry instead of a continuous commutative translation symmetry. We study topology and symmetry of a particle in a magnetic field in a torus of arbitrary dimensions. The magnetic translation group (MTG) is defined as a group of translations that leave the gauge field invariant. We show that the MTG in an n-dimensional torus is isomorphic to a central extension of a cyclic group $\mathbf{Z}_{\nu_1}\times\cdots\times\mathbf{Z}_{\nu_{2l}}\times T^m$ by $U(1)$ with $2l+m=n$. We construct and classify irreducible unitary representations of the MTG in a three-torus and apply the representation theory to three examples. We briefly describe a representation theory for a general n-torus. The MTG in an n-torus can be regarded as a generalization of the so-called noncommutative torus. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1513208]

I. INTRODUCTION

Many people have been studying dynamics of an electrically charged particle in a magnetic field for various interests. Landau found that the energy spectrum of an electron becomes discrete when a magnetic field is applied, and explained the diamagnetic property of a metal. The quantum Hall effect looked a peculiar phenomenon when it was first discovered but today it is understood as a universal phenomenon observable in a two-dimensional electron system in a magnetic field. Dynamics of charged particles in a magnetic field is still an active research area.

Here we examine a group-theoretical aspect of the quantum system in a magnetic field. In particular we compare symmetry in a torus with symmetry in a Euclidean space. We would like to understand how the symmetry structure of the dynamical system is affected by the topological structure of the underlying space. It is known that the translation symmetry group becomes noncommutative when a uniform magnetic field is introduced into the Euclidean space. Moreover, the translation symmetry group becomes discrete when the underlying space is replaced by a torus. In this article we consider a vector potential

$$A=\sum_{j,k=1}^{n} x_j\omega_{jk}dx_k+\sum_{j=1}^{n}\alpha_j dx_j \tag{1.1}$$

over an n-dimensional torus $T^n=\mathbf{R}^n/\mathbf{Z}^n$. Here ω_{jk} are arbitrary integers and α_j are real numbers. Then the corresponding magnetic field is given by the two-form

$$B=dA=\sum_{j,k=1}^{n}\frac{1}{2}(\omega_{jk}-\omega_{kj})dx_j\wedge dx_k\,. \tag{1.2}$$

We conclude that the magnetic translation group (MTG) in T^n is

a)Electronic mail: tanimura@kues.kyoto-u.ac.jp

$$S_A=(\mathbf{R}\times_\omega\Omega^n)/(\mathbf{Z}\times_\omega\mathbf{Z}^n), \tag{1.3}$$

where Ω^n is a subgroup of $\mathbf{R}^n$ defined by $\Omega^n=\{v\in\mathbf{R}^n|(\omega-{}^t\omega)v\in\mathbf{Z}^n\}$ and the group operation in $\mathbf{R}\times_\omega\mathbf{R}^n$ is defined by

$$(x_0,x_1,\ldots,x_n)\cdot(y_0,y_1,\ldots,y_n)=\left(x_0+y_0+\sum_{j,k=1}^{n}x_j\omega_{jk}y_k,x_1+y_1,\ldots,x_n+y_n\right). \tag{1.4}$$

This characterization of the magnetic translation symmetry is one of the main results of this article. The MTG is actually a central extension of a cyclic group

$$\mathbf{Z}_{\mu_1}\times\cdots\times\mathbf{Z}_{\mu_l}\times\mathbf{Z}_{\nu_1}\times\cdots\times\mathbf{Z}_{\nu_l}\times T^m\quad(2l+m=n) \tag{1.5}$$

by $S^1=U(1)$. We build a complete set of irreducible representations of the MTG in T^3. We also describe a method to build irreducible representations of the MTG in T^n.

We would like to briefly review studies by other people on a quantum system in a magnetic field. Brown[1] found that the translation symmetry of an electron in a lattice in a uniform magnetic field is noncommutative and that the quantum system obeys a projective representation of the translation group. At the almost same time[2] and later[3] Zak built a representation theory of the lattice translation group in a magnetic field. Ashby and Miller[4] considered a space–time lattice of a finite size in uniform electric and magnetic fields and proposed an electromagnetic translation group. Avron, Herbst, and Simon have been studying spectral problems of the Schrödinger operators in a magnetic field in a series of papers.[5–8] Particularly, in Ref. 6 they examined a system of particles in a uniform magnetic field and characterized a constant of motion analogous to the total momentum. Dubrovin and Novikov[9,10] studied the spectrum of the Pauli operator in a two-dimensional lattice with a periodic magnetic field and intensively analyzed the gap structure above the ground state. Asch, Over, and Seiler[11] clarified how the inequivalent Hamiltonians on a torus in a magnetic field are induced from a Hamiltonian on the universal covering space of the torus. In a series of studies[12–17] Lulek, Florek, Lipinski, and Walcerz established a systematic method to construct central extensions of a finitely generated Abelian group. Their results are equivalent to the MTGs in a lattice. Kuwabara[18,19] is studying relations between the trajectories of a classical particle and the spectra of its quantized system and has obtained many results. Gruber[20] also examined quantization of a particle on a Riemannian manifold in a magnetic field from a view point of geometric quantization.

As reviewed above, a lot of studies on dynamics and symmetry in a magnetic field have been done. Although MTGs in a finite lattice and in an infinite lattice have been much investigated, the MTG in a torus of arbitrary dimensions is not yet fully investigated. Motivated by a recent study[21,22] on extra dimensions of the space–time, Sakamoto *et al.*[23–25] are developing field theoretical models in which the translation symmetry of an extra circle is spontaneously broken by a nontrivial boundary condition in the extra S^1. Moreover, we are developing models[26,27] in which the rotation symmetry of an extra two-sphere is spontaneously broken by a magnetic monopole in the extra S^2. So we would like to understand how a background gauge field in a compact space influences symmetry structure of a quantum system. Hence we decide to investigate symmetry in a magnetic field in a torus.

This article is organized as follows. In Sec. II we shall examine how symmetry of a quantum system in a magnetic field is changed when the underlying two-dimensional Euclidean space is replaced by a two-dimensional torus. In Sec. III we extend our discussion to an n-dimensional torus. We introduce a noncommutative group structure into $\mathbf{R}^{n+1}$ and use it to construct a magnetic fiber bundle, which is a bundle over T^n with a fiber S^1. In Sec. IV we classify topological structures of the bundles. In Sec. V we define connections, which are generalizations of a vector potential, and classify them. In Sec. VI we define a magnetic translation group as a group of lifted translations that leave the connection invariant. In Sec. VII we build a representation theory of the MTG for T^3 and illustrate the theory by a few examples. In Sec. VIII we describe an outline of the

representation theory of the MTG for a general T^n. Section IX is devoted to conclusions and discussions. To reach the main result quickly the reader may read only Secs. III, V, and VI.

II. SYMMETRIES IN A MAGNETIC FIELD

This section is devoted to exercises to get ideas about the problem. The reader may skip this section and restart from Sec. III without missing the main course of the article.

A. Euclidean space

Let us begin our discussion by examining symmetry of quantum mechanics of a particle in the uniform magnetic field in $\mathbf{R}^2$. It is a well-known system and becomes a starting point to explore further nontrivial systems.

A uniform magnetic field $Bdx\wedge dy=dA$ is derived from a vector potential $A=Bx\ dy$. The Schrödinger equation is

$$H\psi=\left[-\frac{1}{2}\left(\frac{\partial}{\partial x}\right)^2-\frac{1}{2}\left(\frac{\partial}{\partial y}-iBx\right)^2\right]\psi(x,y)=E\psi. \tag{2.1}$$

Then the operators

$$\tilde{P}_x:=-i\frac{\partial}{\partial x}-By, \quad P_y:=-i\frac{\partial}{\partial y} \tag{2.2}$$

commute with H. These generate unitary transformations

$$(U_x(a)\psi)(x,y)=e^{-i\tilde{P}_x a}\psi(x,y)=e^{iBay}\psi(x-a,y), \tag{2.3}$$

$$(U_y(b)\psi)(x,y)=e^{-iP_y b}\psi(x,y)=\psi(x,y-b). \tag{2.4}$$

It is to be noted that $U_x(a)$ is a combination of a translation in the x-direction by the length a and a gauge transformation. It is also to be noted that the translation in the x-direction and the one in the y-direction do not commute but satisfy

$$U_x(a)U_y(b)(U_x(a))^{-1}(U_y(b))^{-1}=e^{iBab}. \tag{2.5}$$

The momentum generates a continuous symmetry and enables us to separate the variables. For example, if we put the eigenvalue of P_y as k, the wave function is factorized as

$$\psi(x,y)=e^{iky}\phi(x). \tag{2.6}$$

Then the Schrödinger equation (2.1) is rewritten as

$$H\psi=e^{iky}\left[-\frac{1}{2}\left(\frac{\partial}{\partial x}\right)^2+\frac{1}{2}(k-Bx)^2\right]\phi(x)=e^{iky}E\phi(x) \tag{2.7}$$

and is reduced to the equation of a harmonic oscillator. Hence the energy eigenvalues are given by

$$E=|B|(n+\tfrac{1}{2}) \quad (n=0,1,2,\ldots) \tag{2.8}$$

and are called the Landau levels. Each eigenvalue is infinitely degenerated with respect to $-\infty<k<\infty$.

B. Torus

Next we turn to a two-dimensional torus. The two-torus T^2 is defined as the quotient space $\mathbf{R}^2/\mathbf{Z}^2$. Namely, the points in $\mathbf{R}^2$,

$$(x,y)\sim(x+1,y)\sim(x,y+1), \tag{2.9}$$

are identified as a single point in T^2. If we impose a pseudoperiodic condition

$$\psi(x+1,y)=e^{iBy}\psi(x,y), \quad \psi(x,y+1)=\psi(x,y), \tag{2.10}$$

on the wave function, the Schrödinger equation (2.1) is well defined over T^2. In other words, on the space of functions satisfying the pseudoperiodic condition, the operator H becomes self-adjoint. To make the two conditions in (2.10) compatible each other we need to have

$$\psi(x+1,y+1)=e^{iB(y+1)}\psi(x,y+1)=e^{iB}e^{iBy}\psi(x,y)=\psi(x+1,y)=e^{iBy}\psi(x,y). \tag{2.11}$$

Hence we should have $e^{iB}=1$. Namely, in the magnetic field strength

$$B=2\pi\nu, \tag{2.12}$$

ν must be an integer. We call ν the magnetic flux number of the torus.

The operators $\tilde{P}_x$ and P_y in (2.2) commute with H defined in (2.1). However, when they act on a wave function satisfying the pseudoperiodic condition (2.10), they do not give back a function satisfying the pseudoperiodic condition but instead give

$$P_y\psi(x+1,y)=e^{iBy}(P_y+B)\psi(x,y), \tag{2.13}$$

$$\tilde{P}_x\psi(x,y+1)=(\tilde{P}_x-B)\psi(x,y). \tag{2.14}$$

Hence, the actions of these operators are not closed in the space of pseudoperiodic functions. Thus we get a lesson that *the generator of infinitesimal translation does not exist in the torus*. However, it is still possible to construct operators for finite translations. We let the finite translation operators (2.3) and (2.4) act on a pseudoperiodic function (2.10), and examine whether the resultant functions satisfy the pseudoperiodic condition. Using the flux quantization (2.12) we get

$$\begin{aligned}(U_x(a)\psi)(x,y+1)&=e^{iBa(y+1)}\psi(x-a,y+1)\\&=e^{iBa}e^{iBay}\psi(x-a,y)\\&=e^{2\pi i\nu a}(U_x(a)\psi)(x,y),\end{aligned} \tag{2.15}$$

$$\begin{aligned}(U_y(b)\psi)(x+1,y)&=\psi(x+1,y-b)\\&=e^{iB(y-b)}\psi(x,y-b)\\&=e^{-iBb}e^{iBy}\psi(x,y-b)\\&=e^{-2\pi i\nu b}e^{iBy}(U_y(b)\psi)(x,y).\end{aligned} \tag{2.16}$$

Therefore, the transformed wave functions, $U_x(a)\psi$ and $U_y(b)\psi$, satisfy the pseudoperiodic condition (2.10) if and only if

$$\nu a,\nu b\in\mathbf{Z}. \tag{2.17}$$

Consequently, the lengths of shifts, a and b, are restricted to integral multiples of $1/\nu$. Moreover, on a pseudoperiodic function the shifts by the unit length act as

$$(U_x(1)\psi)(x,y)=e^{iBy}\psi(x-1,y)=\psi(x,y), \tag{2.18}$$

$$(U_y(1)\psi)(x,y)=\psi(x,y-1)=\psi(x,y). \tag{2.19}$$

Hence $U_x(1)$ and $U_y(1)$ are identity operators. Thus the operators $U_x(1/\nu)$ and $U_y(1/\nu)$ generate a cyclic group $\mathbf{Z}_\nu=\mathbf{Z}/\nu\mathbf{Z}$ of the order ν. However, as seen in (2.5) their commutator produces a nontrivial phase factor. Thus we conclude that the symmetry of the quantum system in the torus magnetic field is described by a projective representation of $\mathbf{Z}_\nu\times\mathbf{Z}_\nu$.

The group of translations of the quantum system in the magnetic field is called a magnetic translation group (abbreviated as MTG). A more precise definition of the MTG will be given in Sec. VI. In the torus the MTG becomes discrete and finite. Its representation is constructed as follows. Let $\{|0\rangle,|1\rangle,\ldots,|\nu-1\rangle\}$ be a basis of the representation space. Then we define the action of the translation operators by

$$U_x(n_x/\nu)|q\rangle=e^{2\pi i n_x q/\nu}|q\rangle, \tag{2.20}$$

$$U_y(n_y/\nu)|q\rangle=|q+n_y(\mathrm{mod}\ \ \nu)\rangle, \tag{2.21}$$

for $n_x,n_y\in\mathbf{Z}$. We can easily verify that they satisfy

$$U_x(n_x/\nu)U_y(n_y/\nu)(U_x(n_x/\nu))^{-1}(U_y(n_y/\nu))^{-1}|q\rangle=e^{i(2\pi\nu)(n_x/\nu)(n_y/\nu)}|q\rangle, \tag{2.22}$$

which is homomorphic to the commutator (2.5). This representation is irreducible and its dimension is ν. Hence each energy eigenvalue (2.8) is degenerated by ν folds.

C. Three-torus

Let us examine the case of a three-dimensional torus briefly to motivate further discussion. With real constants (b_1,b_2,b_3) a vector potential

$$A=b_1x_2dx_3+b_2x_3dx_1+b_3x_1dx_2 \tag{2.23}$$

gives rise to a magnetic field

$$B=dA=b_1dx_2\wedge dx_3+b_2dx_3\wedge dx_1+b_3dx_1\wedge dx_2. \tag{2.24}$$

The Hamiltonian is then given by

$$H\psi=-\frac{1}{2}\left[\left(\frac{\partial}{\partial x_1}-ib_2x_3\right)^2+\left(\frac{\partial}{\partial x_2}-ib_3x_1\right)^2+\left(\frac{\partial}{\partial x_3}-ib_1x_2\right)^2\right]\psi(x_1,x_2,x_3). \tag{2.25}$$

On the three-torus the wave function must satisfy a set of conditions

$$\begin{aligned}\psi(x_1+1,x_2,x_3)&=e^{ib_3x_2}\psi(x_1,x_2,x_3),\\ \psi(x_1,x_2+1,x_3)&=e^{ib_1x_3}\psi(x_1,x_2,x_3),\\ \psi(x_1,x_2,x_3+1)&=e^{ib_2x_1}\psi(x_1,x_2,x_3),\end{aligned} \tag{2.26}$$

which is a generalization of the the pseudoperiodic condition (2.10) of the two-torus.

We would like to find a complete set of translation operators that commute with H and are compatible with the pseudoperiodic condition (2.26). Of course, if the magnetic field is parallel to one of the axes, the system is reduced to the two-torus as has been discussed by Zak.[3] For example, if $(b_1,b_2,b_3)=(0,0,B)$, the Hamiltonian (2.25) and the condition (2.26) are reduced to (2.1) and (2.10), respectively. However, it is a highly nontrivial and not yet fully solved problem to find a complete symmetry group for an inclined magnetic field (b_1,b_2,b_3). Thus we decide to develop a more systematic method to construct the translation symmetry group for a generic magnetic field in the n-torus.

III. MAGNETIC FIBER BUNDLE

We shall extend the previous consideration on the two-dimensional torus to arbitrary dimensions. What we will do in the rest of this article is to construct $U(1)$ principal fiber bundles over an n-dimensional torus T^n, to classify the bundles, to introduce $U(1)$ connections with constant curvatures over T^n, to define the MTG as the stability group of each connection, and to construct the representations of the MTGs. Throughout this article we are identifying S^1 with $U(1)$.

Let us begin with construction of S^1 principal fiber bundles over T^n. For this purpose we introduce a noncommutative group structure into $\mathbf{R}^{n+1}$ as follows. Take an $n\times n$ matrix ω which consists of integers, $\omega_{jk}\in\mathbf{Z}$ $(j,k=1,\ldots,n)$. The matrix ω is not necessarily antisymmetric. Define a product of $(x_0,x_1,\ldots,x_n),(y_0,y_1,\ldots,y_n)\in\mathbf{R}^{n+1}$ by

$$(x_0,x_1,\ldots,x_n)\cdot(y_0,y_1,\ldots,y_n):=\left(x_0+y_0+\sum_{j,k=1}^{n}x_j\omega_{jk}y_k,x_1+y_1,\ldots,x_n+y_n\right). \tag{3.1}$$

In the following we abbreviate the notation of the vectors as $x=(x_1,\ldots,x_n)\in\mathbf{R}^n$. We write the inner product of vectors as $xy=\Sigma_{j=1}^{n}x_j\,y_j$ and the bilinear form as $x\omega y=\Sigma_{j,k=1}^{n}x_j\omega_{jk}y_k$. It is easily verified that the set $\mathbf{R}^{n+1}$ becomes a group with this product operation; the associativity is satisfied as

$$\begin{aligned}((x_0,x)\cdot(y_0,y))\cdot(z_0,z)&=(x_0+y_0+x\omega y,x+y)\cdot(z_0,z)\\&=(x_0+y_0+z_0+x\omega y+(x+y)\omega z,(x+y)+z)\\&=(x_0+y_0+z_0+x\omega y+x\omega z+y\omega z,x+y+z)\\&=(x_0+y_0+z_0+x\omega(y+z)+y\omega z,x+(y+z))\\&=(x_0,x)\cdot((y_0,y)\cdot(z_0,z)),\end{aligned} \tag{3.2}$$

the unit element is given by $(0,0)\in\mathbf{R}\times\mathbf{R}^n$, and the inverse element of $(x_0,x)\in\mathbf{R}\times\mathbf{R}^n$ is given by

$$(x_0,x)^{-1}=(-x_0+x\omega x,-x). \tag{3.3}$$

The set $\mathbf{R}^{n+1}$ equipped with this group structure is denoted by $\mathbf{R}\times_\omega\mathbf{R}^n$. A commutator is calculated as

$$\begin{aligned}(x_0,x)\cdot(y_0,y)\cdot(x_0,x)^{-1}\cdot(y_0,y)^{-1}&=(x_0+y_0+x\omega y,x+y)\cdot(-x_0+x\omega x,-x)\cdot(-y_0+y\omega y,-y)\\&=(y_0+x\omega y+x\omega x-(x+y)\omega x,y)\cdot(-y_0+y\omega y,-y)\\&=(x\omega y+x\omega x-(x+y)\omega x+y\omega y-y\omega y,0)=(x\omega y-y\omega x,0),\end{aligned} \tag{3.4}$$

and therefore $\mathbf{R}\times_\omega\mathbf{R}^n$ is Abelian if and only if ω is a symmetric matrix. The natural projection map $\mathbf{R}\times_\omega\mathbf{R}^n\to\mathbf{R}^n$ becomes a group homomorphism. As its kernel $\mathbf{R}\times_\omega\{0\}$ is contained in the center of $\mathbf{R}\times_\omega\mathbf{R}^n$, the group $\mathbf{R}\times_\omega\mathbf{R}^n$ is a central extension of $\mathbf{R}^n$ by $\mathbf{R}$.

The subset $\mathbf{Z}\times_\omega\mathbf{Z}^n=\{(m_0,m_1,\ldots,m_n)|m_0,m_j\in\mathbf{Z}\}$ is also a subgroup of $\mathbf{R}\times_\omega\mathbf{R}^n$ but it is not isomorphic to the standard Abelian group $\mathbf{Z}^{n+1}$. The subgroup $\mathbf{Z}\times_\omega\mathbf{Z}^n$ acts freely on $\mathbf{R}\times_\omega\mathbf{R}^n$ from the left via the group operation. Hence the space of orbits

$$P_\omega^{n+1}:=(\mathbf{Z}\times_\omega\mathbf{Z}^n)\backslash(\mathbf{R}\times_\omega\mathbf{R}^n) \tag{3.5}$$

becomes a smooth manifold.

The group operation also induces action of the group $\mathbf{R}\times_\omega\mathbf{R}^n$ on the space P_ω^{n+1} from the right. The subgroups $\mathbf{Z}\times_\omega\{0\}\subset\mathbf{R}\times_\omega\{0\}$ are contained in the center of $\mathbf{R}\times_\omega\mathbf{R}^n$ and hence their actions from the right are equivalent to those from the left. The subgroups $\mathbf{R}\times_\omega\{0\}$ and $\mathbf{Z}$

$\times_\omega\{0\}$ are isomorphic to $\mathbf{R}$ and $\mathbf{Z}$, respectively. Thus $\mathbf{R}$ acts on P_ω^{n+1} but its subgroup $\mathbf{Z}$ acts trivially on P_ω^{n+1} since $\mathbf{Z}$ is contained in the dividing group $\mathbf{Z}\times_\omega\mathbf{Z}^n$ of the quotient space (3.5). Therefore the action of $\mathbf{R}$ is reduced to the effective action of $S^1=\mathbf{R}/\mathbf{Z}$ on P_ω^{n+1}. The space of orbit P_ω^{n+1}/S^1 is diffeomorphic to a torus T^n. Consequently we obtain a principal fiber bundle with the canonical projection map $\pi_\omega: P_\omega^{n+1}\to T^n$ with a structure group S^1. We call this fiber bundle a *magnetic fiber bundle twisted by the matrix* ω. The procedure to construct the magnetic fiber bundle is summarized by the following commutative diagram:

$$\begin{array}{ccccc} \mathbf{Z}\times_\omega\{0\} & \to & \mathbf{Z}\times_\omega\mathbf{Z}^n & \to & \mathbf{Z}^n \\ \downarrow & & \downarrow & & \downarrow \\ \mathbf{R}\times_\omega\{0\} & \to & \mathbf{R}\times_\omega\mathbf{R}^n & \to & \mathbf{R}^n \\ \downarrow & & \downarrow & & \downarrow \\ S^1 & \to & P_\omega^{n+1} & \underset{\pi_\omega}{\to} & T^n \end{array}. \tag{3.6}$$

A function $f: P_\omega^{n+1}\to\mathbf{C}$ is identified with a function $f:\mathbf{R}\times_\omega\mathbf{R}^n\to\mathbf{C}$ that is invariant under action of $\mathbf{Z}\times_\omega\mathbf{Z}^n$ from the left as

$$f(m_0+x_0+m\omega x, m+x)=f(x_0,x), \quad (m_0,m)\in\mathbf{Z}\times_\omega\mathbf{Z}^n. \tag{3.7}$$

Moreover, when the function $f: P_\omega^{n+1}\to\mathbf{C}$ satisfies

$$f(x_0+t,x)=e^{-2\pi it}f(x_0,x), \quad t\in\mathbf{R}, \tag{3.8}$$

it is called an equivariant function on P_ω^{n+1}. Hence the equivariant function f has the property

$$f(x_0,x+m)=e^{2\pi im\omega x}f(x_0,x), \quad m\in\mathbf{Z}^n. \tag{3.9}$$

This is a generalization of the pseudoperiodic condition (2.10),

$$\psi(x+1,y)=e^{2\pi i\nu y}\psi(x,y), \quad \psi(x,y+1)=\psi(x,y). \tag{3.10}$$

In fact, if we take the matrix

$$\omega=\begin{pmatrix} 0 & \nu \\ 0 & 0 \end{pmatrix}, \tag{3.11}$$

the general condition (3.9) of T^n is reduced to the specific one (3.10) of T^2.

IV. EQUIVALENT MAGNETIC BUNDLES

In the above construction each magnetic fiber bundle is specified by an integral matrix ω. However, it can happen that different matrices ω and ω' give rise to equivalent fiber bundles. In this section we prove that ω and ω' induce equivalent fiber bundles if and only if the difference $\omega'-\omega$ is a symmetric integral matrix. Therefore, we may choose a representative matrix ω such that $\omega_{jk}=0$ for $j\geqslant k$. Namely, the upper triangle matrix

$$\omega=\begin{pmatrix} 0 & \omega_{12} & \omega_{13} & \cdots & \omega_{1,n-1} & \omega_{1n} \\ 0 & 0 & \omega_{23} & \cdots & \omega_{2,n-1} & \omega_{2n} \\ 0 & 0 & 0 & \cdots & \omega_{3,n-1} & \omega_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & \omega_{n-1,n} \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix} \tag{4.1}$$

with integers ω_{jk} can be taken as a standard form of the matrix ω. The reader will not miss the main result of the article even if he skips this section and restarts from Sec. V.

Here we introduce three kinds of isomorphisms that convert a bundle specified by a matrix ω to a bundle specified by another matrix ω'.

Let us introduce the first kind of bundle isomorphism. When a symmetric matrix σ of integral elements, $\sigma_{jk}=\sigma_{kj}\in\mathbf{Z}$, satisfies

$$\sum_{j,k=1}^{n} m_j\sigma_{jk}m_k\in 2\mathbf{Z} \tag{4.2}$$

for any $m=(m_1,\ldots,m_n)\in\mathbf{Z}^n$, we call σ an even symmetric matrix. This requirement for σ is equivalent to demanding that the off-diagonal elements σ_{jk} are integers and that the diagonal elements σ_{jj} are even integers. Here we will show that two magnetic bundles P_{ω}^{n+1} and $P_{\omega+\sigma}^{n+1}$ are isomorphic each other for any even symmetric matrix σ. For this purpose let us define a map $\phi_\sigma:\mathbf{R}\times_\omega\mathbf{R}^n\to\mathbf{R}\times_{\omega+\sigma}\mathbf{R}^n$ by

$$\phi_\sigma(x_0,x):=(x_0+\tfrac{1}{2}x\sigma x,x). \tag{4.3}$$

Existence of the inverse map is obvious; it is given by $\phi_\sigma^{-1}(x_0,x)=(x_0-\frac{1}{2}x\sigma x,x)$. It is easily verified that the map ϕ_σ is a group isomorphism as

$$\begin{aligned}\phi_\sigma((x_0,x)\cdot_\omega(y_0,y)) &= \phi_\sigma(x_0+y_0+x\omega y,x+y)\\ &=(x_0+y_0+x\omega y+\tfrac{1}{2}(x+y)\sigma(x+y),x+y)\\ &=(x_0+y_0+\tfrac{1}{2}x\sigma x+\tfrac{1}{2}y\sigma y+x(\omega+\sigma)y,x+y)\\ &=(x_0+\tfrac{1}{2}x\sigma x,x)\cdot_{\omega+\sigma}(y_0+\tfrac{1}{2}y\sigma y,y)\\ &=\phi_\sigma(x_0,x)\cdot_{\omega+\sigma}\phi_\sigma(y_0,y),\end{aligned} \tag{4.4}$$

where we have distinguished the product operation of $\mathbf{R}\times_{\omega+\sigma}\mathbf{R}^n$ from that of $\mathbf{R}\times_\omega\mathbf{R}^n$. The map ϕ_σ sends the integer subgroup $\mathbf{Z}\times_\omega\mathbf{Z}^n$ to $\mathbf{Z}\times_{\omega+\sigma}\mathbf{Z}^n$, since σ is even as required in (4.2). Therefore, ϕ_σ induces a diffeomorphism

$$(\phi_\sigma)_*:(\mathbf{Z}\times_\omega\mathbf{Z}^n)\backslash(\mathbf{R}\times_\omega\mathbf{R}^n)\to(\mathbf{Z}\times_{\omega+\sigma}\mathbf{Z}^n)\backslash(\mathbf{R}\times_{\omega+\sigma}\mathbf{R}^n). \tag{4.5}$$

Moreover, since ϕ_σ is the identity map when it is restricted on $\mathbf{R}\times_\omega\{0\}$,

$$\phi_\sigma((t,0)\cdot_\omega(x_0,x))=\phi_\sigma(t,0)\cdot_{\omega+\sigma}\phi_\sigma(x_0,x)=(t,0)\cdot_{\omega+\sigma}\phi_\sigma(x_0,x), \tag{4.6}$$

thus $(\phi_\sigma)_*$ is equivariant with respect to the action of S^1. It is also clear that $\pi_\omega=\pi_{\omega+\sigma}\circ(\phi_\sigma)_*$. Thus we conclude that the map $(\phi_\sigma)_*$ is an isomorphism between the principal fiber bundles P_{ω}^{n+1} and $P_{\omega+\sigma}^{n+1}$.

Next we shall introduce the second kind of bundle isomorphism. We identify a diagonal matrix $\Delta=\mathrm{diag}(\Delta_1,\Delta_2,...,\Delta_n)$ with a vector $\Delta=(\Delta_1,\Delta_2,\ldots,\Delta_n)\in\mathbf{Z}^n$. Then we define a map $\phi_\Delta:\mathbf{R}\times_\omega\mathbf{R}^n\to\mathbf{R}\times_{\omega+\Delta}\mathbf{R}^n$ by

$$\phi_\Delta(x_0,x):=\left(x_0+\frac{1}{2}x\Delta x+\frac{1}{2}\Delta x,x\right)=\left(x_0+\frac{1}{2}\sum_{j=1}^{n}(x_j\Delta_jx_j+\Delta_jx_j),x\right). \tag{4.7}$$

It is also easily verified that ϕ_Δ is a group isomorphism as

$$\begin{aligned}\phi_\Delta((x_0,x)\cdot_\omega(y_0,y)) &= \phi_\Delta(x_0+y_0+x\omega y,x+y)\\ &= (x_0+y_0+x\omega y+\tfrac{1}{2}(x+y)\Delta(x+y)+\tfrac{1}{2}\Delta(x+y),x+y)\\ &= (x_0+y_0+\tfrac{1}{2}x\Delta x+\tfrac{1}{2}\Delta x+\tfrac{1}{2}y\Delta y+\tfrac{1}{2}\Delta y+x(\omega+\Delta)y,x+y)\\ &= (x_0+\tfrac{1}{2}x\Delta x+\tfrac{1}{2}\Delta x,x)\cdot_{\omega+\Delta}(y_0+\tfrac{1}{2}y\Delta y+\tfrac{1}{2}\Delta y,y)\\ &= \phi_\Delta(x_0,x)\cdot_{\omega+\Delta}\phi_\Delta(y_0,y). \end{aligned} \tag{4.8}$$

Note that when x_j is an integer, $x_j^2+x_j=x_j(x_j+1)$ is always an even integer and hence $\frac{1}{2}\Delta_j(x_j^2+x_j)$ is an integer. Therefore the map ϕ_Δ sends the integer subgroup $\mathbf{Z}\times_\omega\mathbf{Z}^n$ to $\mathbf{Z}\times_{\omega+\Delta}\mathbf{Z}^n$. Moreover, ϕ_Δ sends $\mathbf{R}\times_\omega\{0\}$ to $\mathbf{R}\times_{\omega+\Delta}\{0\}$ identically. Thus the induced map $(\phi_\Delta)_*$ becomes an isomorphism between the principal fiber bundles P_ω^{n+1} and $P_{\omega+\Delta}^{n+1}$.

There is the third kind of bundle isomorphism, which will be used when we classify connections later. For each $\varepsilon=(\varepsilon_1,\varepsilon_2,\ldots,\varepsilon_n)\in\mathbf{Z}^n$ we define a map $\phi_\varepsilon:\mathbf{R}\times_\omega\mathbf{R}^n\to\mathbf{R}\times_\omega\mathbf{R}^n$ by

$$\phi_\varepsilon(x_0,x):=(x_0+\varepsilon x,x)=\left(x_0+\sum_{j=1}^n\varepsilon_j x_j,x\right). \tag{4.9}$$

It is also easily verified that ϕ_ε is a group isomorphism as

$$\begin{aligned}\phi_\varepsilon((x_0,x)\cdot_\omega(y_0,y)) &= \phi_\varepsilon(x_0+y_0+x\omega y,x+y)\\ &= (x_0+y_0+x\omega y+\varepsilon(x+y),x+y)\\ &= (x_0+\varepsilon x+y_0+\varepsilon y+x\omega y,x+y)\\ &= (x_0+\varepsilon x,x)\cdot_\omega(y_0+\varepsilon y,y)=\phi_\varepsilon(x_0,x)\cdot_\omega\phi_\varepsilon(y_0,y). \end{aligned} \tag{4.10}$$

The map ϕ_ε sends the integer subgroup $\mathbf{Z}\times_\omega\mathbf{Z}^n$ to $\mathbf{Z}\times_\omega\mathbf{Z}^n$. Moreover, ϕ_ε sends $\mathbf{R}\times_\omega\{0\}$ to $\mathbf{R}\times_\omega\{0\}$ identically. Thus the group isomorphism ϕ_ε induces an automorphism $(\phi_\varepsilon)_*$ of the principal fiber bundle P_ω^{n+1}.

As a summary, we write down a combined isomorphism of the three kinds of maps

$$(\phi_\varepsilon\circ\phi_\Delta\circ\phi_\sigma)(x_0,x):=(x_0+\tfrac{1}{2}x(\sigma+\Delta)x+\tfrac{1}{2}\Delta x+\varepsilon x,x). \tag{4.11}$$

By adding an integral diagonal matrix Δ to an even symmetric matrix σ, we can make any integral symmetric matrix $\sigma'=\sigma+\Delta$. Therefore, by combining the first and second kinds of isomorphisms, ϕ_σ and ϕ_Δ, we can establish an isomorphism between P_ω^{n+1} and $P_{\omega+\sigma'}^{n+1}$ for any integral symmetric matrix σ'. In other words, the set of magnetic fiber bundles has a one-to-one correspondence with $\mathrm{Mat}(n,\mathbf{Z})/\mathrm{Sym}(n,\mathbf{Z})$, where the quotient is taken in the sense of additive groups.

V. CONNECTION

In this section we define the vector potentials that yield uniform magnetic fields in an n-dimensional torus. We use the words, a vector potential, a gauge field, and a connection, to describe the same notion. Magnetic field strength and curvature are an identical notion.

Let us define a differential one-form A on $\mathbf{R}\times_\omega\mathbf{R}^n$ by

$$A:=-dx_0+\sum_{j,k=1}^n x_j\omega_{jk}dx_k+\sum_{j=1}^n\alpha_j dx_j=-dx_0+x\omega dx+\alpha dx \tag{5.1}$$

with a real vector $\alpha\in\mathbf{R}^n$. These parameters $\alpha=(\alpha_1,\ldots,\alpha_n)$ characterize the Aharonov–Bohm effect. The action of $(m_0,m)\in\mathbf{Z}\times_\omega\mathbf{Z}^n$ from the left of $\mathbf{R}\times_\omega\mathbf{R}^n$ defines a map $\varphi:(x_0,x)\mapsto(m_0+x_0+m\omega x,m+x)$. Note that the one-form A is invariant under the transformation by φ as

$$\varphi^*A=-(dx_0+m\omega dx)+(m+x)\omega dx+\alpha dx=A. \tag{5.2}$$

Thus A can be regarded as a one-form on $P_\omega^{n+1}=(\mathbf{Z}\times_\omega\mathbf{Z}^n)\backslash(\mathbf{R}\times_\omega\mathbf{R}^n)$. It is also obvious that A is invariant under a transformation $(x_0,x)\mapsto(x_0+t,x)$ for any $t\in\mathbf{R}$. Moreover, A satisfies

$$\left\langle\frac{\partial}{\partial x_0},A\right\rangle=-1 \tag{5.3}$$

by the definition. In the above equation, $\langle\cdot,\cdot\rangle$ denotes the pairing of a vector and a one-form. Thus A satisfies the axiom of a connection form of the principal bundle $\pi_\omega:P_\omega^{n+1}\to T^n$.

We can classify the connections using isomorphism maps introduced in the last section. The connection $A_{\omega,\alpha}$ defined by (5.1) is parametrized by an integral matrix $\omega\in\mathrm{Mat}(n,\mathbf{Z})$ and a real vector $\alpha\in\mathbf{R}^n$. For any even symmetric matrix $\sigma\in\mathrm{EvenSym}(n,\mathbf{Z})$ and integral vectors $\Delta,\varepsilon\in\mathbf{Z}^n$, the combined isomorphism (4.11) induces a transformation

$$\begin{aligned}
&(\phi_\varepsilon\circ\phi_\Delta\circ\phi_\sigma)^*A_{\omega+\sigma+\Delta,\alpha+1/2\,\Delta+\varepsilon}\\
&\quad=-d(x_0+\tfrac{1}{2}x(\sigma+\Delta)x+\tfrac{1}{2}\Delta x+\varepsilon x)+x(\omega+\sigma+\Delta)dx+(\alpha+\tfrac{1}{2}\Delta+\varepsilon)dx\\
&\quad=-dx_0-x(\sigma+\Delta)dx-\tfrac{1}{2}\Delta dx-\varepsilon dx+x(\omega+\sigma+\Delta)dx+(\alpha+\tfrac{1}{2}\Delta+\varepsilon)dx\\
&\quad=-dx_0+x\omega dx+\alpha dx\\
&\quad=A_{\omega,\alpha}
\end{aligned} \tag{5.4}$$

via pullback. Thus the connections are classified by the equivalence relation

$$(\omega,\alpha)\sim(\omega+\sigma+\Delta,\alpha+\tfrac{1}{2}\Delta+\varepsilon),\quad \sigma\in\mathrm{EvenSym}(n,\mathbf{Z});\Delta,\varepsilon\in\mathbf{Z}^n \tag{5.5}$$

among $(\omega,\alpha)\in\mathrm{Mat}(n,\mathbf{Z})\times\mathbf{R}^n$.

Next we define a covariant derivative of the equivariant function f by

$$Df:=df-2\pi iAf. \tag{5.6}$$

Of course, on the right-hand side, $i=\sqrt{-1}$. The curvature form F is defined by

$$F:=dA=\sum_{j,k=1}^{n}\omega_{jk}dx_j\wedge dx_k=\sum_{j,k=1}^{n}\frac{1}{2}(\omega_{jk}-\omega_{kj})dx_j\wedge dx_k, \tag{5.7}$$

which gives a constant magnetic field. Hence the first Chern class is uniquely specified by the integral antisymmetrized matrix $(\omega-{}^t\omega)$. It is known[28] that an S^1-fiber bundle has a one-to-one correspondence with the first Chern class. Therefore, by choosing $\omega\in\mathrm{Mat}(n,\mathbf{Z})$ appropriately, we can construct any principal fiber bundles over T^n with the fiber S^1.

VI. MAGNETIC TRANSLATION GROUP

Now we shall examine translation symmetry of the vector potential A of the uniform magnetic field. In this section we shall give a precise definition of the MTG in T^n and express the MTG in a more concrete form. We will prove that the MTG is

$$S_A=(\mathbf{R}\times_\omega\Omega^n)/(\mathbf{Z}\times_\omega\mathbf{Z}^n), \tag{6.1}$$

where Ω^n is a subgroup of $\mathbf{R}^n$ defined by $\Omega^n=\{v\in\mathbf{R}^n|(\omega-{}^t\omega)v\in\mathbf{Z}^n\}$ and the group operation is taken in the sense of (3.1). This is one of the main results of this article.

We begin by defining the MTG. A vector $v\in\mathbf{R}^n$ generates a translation of T^n by

$$\tau_v : T^n \to T^n, \quad x \mapsto x+v. \tag{6.2}$$

When a map $\tilde{\tau}_v : P_\omega^{n+1} \to P_\omega^{n+1}$ satisfies the commutative diagram

$$\begin{array}{ccc} & S^1 & \\ \swarrow & & \searrow \\ P_\omega^{n+1} & \overset{\tilde{\tau}}{\to} & P_\omega^{n+1} \\ \pi_\omega \downarrow & & \downarrow \pi_\omega \\ T^n & \overset{\tau}{\to} & T^n \end{array} \tag{6.3}$$

the map $\tilde{\tau}_v$ is called a lift of the translation τ_v. The lifted translations that leave the connection A invariant form a group

$$S_A := \{\tilde{\tau}_v : P_\omega^{n+1} \to P_\omega^{n+1} | v \in \mathbf{R}^n, \pi_\omega \circ \tilde{\tau}_v = \tau_v \circ \pi_\omega ; \ \tilde{\tau}_v^* A = A\}. \tag{6.4}$$

We call it the stability group of A, or the magnetic translation group (MTG).

Let us write down the lifted translation in a more explicit form. We use $(x_0, x) \in \mathbf{R}^{n+1}$ as a coordinate of P_ω^{n+1}. Since $\pi_\omega \circ \tilde{\tau}_v = \tau_v \circ \pi_\omega$, the lift $\tilde{\tau}_v$ of (6.2) must have the form

$$\tilde{\tau}_v : (x_0, x) \mapsto (x_0 + \theta(x_0, x, v), x+v). \tag{6.5}$$

To make $\tilde{\tau}_v$ commutative with the action of $e^{2\pi i w_0} \in S^1$ the function θ must satisfy

$$x_0 + w_0 + \theta(x_0 + w_0, x, v) = x_0 + \theta(x_0, x, v) + w_0, \tag{6.6}$$

namely, θ must satisfy

$$\theta(x_0 + w_0, x, v) = \theta(x_0, x, v) \tag{6.7}$$

for any $w_0 \in \mathbf{R}$. Therefore, the function θ is independent of x_0. To become a map of P_ω^{n+1}, the map $\tilde{\tau}_v$ must send an orbit of the left-action of $\mathbf{Z} \times_\omega \mathbf{Z}^n$ to an orbit of the same group. In other words, for any $(m_0, m) \in \mathbf{Z} \times_\omega \mathbf{Z}^n$ there must exist an element $(m_0', m') \in \mathbf{Z} \times_\omega \mathbf{Z}^n$ that satisfies

$$\tilde{\tau}_v((m_0, m) \cdot (x_0, x)) = (m_0', m') \cdot \tilde{\tau}_v(x_0, x). \tag{6.8}$$

The above equation is rewritten as

$$(m_0 + x_0 + m\omega x + \theta(m+x, v), m+x+v) = (m_0' + x_0 + \theta(x, v) + m'\omega(x+v), m'+x+v),$$

which is equivalent to a set of equations

$$m = m', \tag{6.9}$$

$$m_0 + m\omega x + \theta(m+x, v) = m_0' + \theta(x, v) + m'\omega(x+v). \tag{6.10}$$

The last equation implies that

$$\theta(m+x, v) - \theta(x, v) - m\omega v = m_0' - m_0 \in \mathbf{Z} \tag{6.11}$$

for any $m \in \mathbf{Z}^n$. In reverse order, any function $\theta(x, v)$ satisfying the condition (6.11) defines a lifted translation $\tilde{\tau}_v$ by (6.5). The lifted translation $\tilde{\tau}_v$ is actually a combination of a spatial shift by v with a gauge transformation by θ. Hence, we finish characterizing the lifted translations.

Let the lifted translation $\tilde{\tau}_v$ act on the connection form A of (5.1) via pull-back. Then it gives

$$\tilde{\tau}_v^* A = -(dx_0 + d\theta) + (x+v)\omega d(x+v) + \alpha d(x+v) = A - d\theta + v\omega dx. \tag{6.12}$$

Hence, to leave the connection invariant as $\tilde{\tau}_v^* A = A$, the function θ must satisfy a differential equation $d\theta = v\omega dx$. Thus we have

$$\theta(x,v) = v\omega x + v_0 \tag{6.13}$$

with a constant $v_0 \in \mathbf{R}$. To make $\tilde{\tau}_v$ a map of P_ω^{n+1}, the function θ must satisfy the condition (6.11), which requires that

$$\theta(m+x,v) - \theta(x,v) - m\omega v = v\omega m - m\omega v = -m(\omega - {}^t\omega)v \in \mathbf{Z} \tag{6.14}$$

for any $m \in \mathbf{Z}^n$. Therefore, the vector $v \in \mathbf{R}^n$ is required to satisfy

$$(\omega - {}^t\omega)v \in \mathbf{Z}^n. \tag{6.15}$$

We call the vector v satisfying (6.15) a magnetic shift. A set of the magnetic shifts is denoted by

$$\Omega^n := \{v \in \mathbf{R}^n \mid (\omega - {}^t\omega)v \in \mathbf{Z}^n\}. \tag{6.16}$$

The set Ω^n becomes an additive subgroup of $\mathbf{R}^n$. When the antisymmetrized matrix $(\omega - {}^t\omega)$ is nondegenerated, Ω^n is discrete. The lifted translation $\tilde{\tau}_v$ defined by (6.5) with (6.13) becomes

$$\tilde{\tau}_v : (x_0,x) \mapsto (x_0 + \theta(x_0,x,v), x+v) = (x_0 + v\omega x + v_0, x+v) = (v_0,v)\cdot(x_0,x), \tag{6.17}$$

and therefore the action of $\tilde{\tau}_v$ is identified with the action of $(v_0,v) \in \mathbf{R} \times_\omega \Omega^n$ on P_ω^{n+1} from the left. However, the subgroup $\mathbf{Z} \times_\omega \mathbf{Z}^n \subset \mathbf{R} \times_\omega \Omega^n$ acts on P_ω^{n+1} trivially. Thus the stability group S_A of the connection A is identified as

$$S_A = (\mathbf{R} \times_\omega \Omega^n)/(\mathbf{Z} \times_\omega \mathbf{Z}^n). \tag{6.18}$$

This is one of the main results of this article. Note that S_A is a central extension of a compact Abelian group $\Omega^n/\mathbf{Z}^n$ by $S^1 = \mathbf{R}/\mathbf{Z}$.

Actually, there is another way to characterize the group S_A. The group $\mathbf{R} \times_\omega \Omega^n$ is a normalizer of $N = \mathbf{Z} \times_\omega \mathbf{Z}^n$ in $G = \mathbf{R} \times_\omega \mathbf{R}^n$. In other words, the subgroup H defined by

$$H := \{h \in G \mid \forall n \in N, hnh^{-1} \in N\} \tag{6.19}$$

coincides with $\mathbf{R} \times_\omega \Omega^n$. The above statement is easily proved as follows. A straightforward calculation yields

$$(x_0,x)\cdot(m_0,m)\cdot(x_0,x)^{-1} = (m_0 + x(\omega - {}^t\omega)m, m). \tag{6.20}$$

Therefore the necessary and sufficient condition for $(x_0,x) \in \mathbf{R} \times_\omega \mathbf{R}^n$ to bring the above element into $N = \mathbf{Z} \times_\omega \mathbf{Z}^n$ is that $(\omega - {}^t\omega)x \in \mathbf{Z}^n$, or that $x \in \Omega^n$. Thus $N = \mathbf{Z} \times_\omega \mathbf{Z}^n$ is a normal subgroup of $H = \mathbf{R} \times_\omega \Omega^n$, and hence the quotient group $S_A = H/N$ is well defined.

VII. REPRESENTATIONS OF THE MTG IN A THREE-TORUS

A unitary representation theory of the MTG is significant for spectral analyses of the Laplace operator and the Dirac operator in a background gauge field. In this section we examine a three-dimensional torus and construct a complete set of representations. This is another main result of this article. In the next section we will discuss an outline of the representation theory of the MTG for arbitrary dimensions.

A. Method

The MTG was identified as $S_A=(\mathbf{R}\times_\omega\Omega^n)/(\mathbf{Z}\times_\omega\mathbf{Z}^n)$ at (6.18). We would like to express the MTG in terms of generators and relations. Here we concentrate on the three-dimensional torus. Let us take the matrix

$$\omega=\begin{pmatrix}0 & b_3 & -b_2\\ 0 & 0 & b_1\\ 0 & 0 & 0\end{pmatrix} \tag{7.1}$$

with positive integers b_1, b_2, and b_3. Then antisymmetrization of ω yields

$$\omega-{}^t\omega=\begin{pmatrix}0 & b_3 & -b_2\\ -b_3 & 0 & b_1\\ b_2 & -b_1 & 0\end{pmatrix}. \tag{7.2}$$

The characteristic equation of $(\omega-{}^t\omega)$ is

$$\det(\lambda-(\omega-{}^t\omega))=\lambda(\lambda^2+b_1^2+b_2^2+b_3^2). \tag{7.3}$$

Hence, its eigenvalues are

$$\lambda=0,\pm iB \tag{7.4}$$

with $B:=\sqrt{b_1^2+b_2^2+b_3^2}$. We assume that $B\neq 0$. The eigenspace for $\lambda=0$ is spanned by

$$b=\begin{pmatrix}b_1\\ b_2\\ b_3\end{pmatrix}. \tag{7.5}$$

The action of $(\omega-{}^t\omega)$ on a vector $v\in\mathbf{R}^3$ is equivalent to the vector product $(\omega-{}^t\omega)v=v\times b$. The magnetic shift group (6.16) now becomes

$$\Omega^3=\{v\in\mathbf{R}^3|(\omega-{}^t\omega)v\in\mathbf{Z}^3\}. \tag{7.6}$$

The linear subspace $\mathbf{R}b$ spanned by b of (7.5) is a subgroup of Ω^3. Let us define a generator e_0 by

$$D_0:=\mathrm{GCD}\{b_1,b_2,b_3\}, \tag{7.7}$$

$$e_0:=\frac{1}{D_0}\begin{pmatrix}b_1\\ b_2\\ b_3\end{pmatrix}. \tag{7.8}$$

Here the GCD is an abbreviation of the greatest common divisor while the LCM is an abbreviation of the least common multiple. It is obvious that e_0 is in $\mathbf{Z}^3$ and that $(\omega-{}^t\omega)e_0=0$. The vector e_0 is a minimal integral vector in the sense that there is no real number s such that $0<s<1$ and $se_0\in\mathbf{Z}^3$. There exist other vectors e_1, e_2, $\in\mathbf{Q}^3$ that generate Ω^3 as

$$\Omega^3=\mathbf{R}e_0\oplus\mathbf{Z}e_1\oplus\mathbf{Z}e_2. \tag{7.9}$$

Here $\mathbf{Q}$ is the whole set of rational numbers. From (7.6) these generators e_1 and e_2 must satisfy

$$(\omega-{}^t\omega)e_1,(\omega-{}^t\omega)e_2\in\mathbf{Z}^3. \tag{7.10}$$

These vectors $\{e_1,e_2\}$ are minimal magnetic shifts in the sense that there is no real number s such that

$$0<s<1, \quad s(\omega-{}^t\omega)e_i\in\mathbf{Z}^3, \tag{7.11}$$

for each $i=1,2$. Moreover, there are positive integers ν_1 and ν_2 such that

$$\nu_1 e_1, \nu_2 e_2\in\mathbf{Z}^3. \tag{7.12}$$

We demand that the integers $\{\nu_1,\nu_2\}$ are the smallest cycles in the sense that there is no integer m such that

$$0<m<\nu_i, \quad me_i\in\mathbf{Z}^3, \tag{7.13}$$

for each $i=1,2$. Consequently, the decomposition (7.9) yields

and

$$\Omega^3/\mathbf{Z}^3=(\mathbf{R}/\mathbf{Z})\oplus(\mathbf{Z}/\nu_1\mathbf{Z})\oplus(\mathbf{Z}/\nu_2\mathbf{Z}). \tag{7.14}$$

Thus an arbitrary element g of $S_A=(\mathbf{R}\times_\omega\Omega^3)/(\mathbf{Z}\times_\omega\mathbf{Z}^3)$ is parametrized as

$$g=(s,te_0+n_1e_1+n_2e_2), \quad s,t\in\mathbf{R}/\mathbf{Z};n_1\in\mathbf{Z}/\nu_1\mathbf{Z};n_2\in\mathbf{Z}/\nu_2\mathbf{Z}. \tag{7.15}$$

Let us examine the commutator (3.4). It is clear that the element $(s,0)$ commutes with any element. Since $(\omega-{}^t\omega)e_0=0$, the element $(0,te_0)$ also commutes with any element. On the other hand, $(0,e_1)$ and $(0,e_2)$ produce a nonvanishing commutator

$$(0,e_1)\cdot(0,e_2)\cdot(0,e_1)^{-1}\cdot(0,e_2)^{-1}=(\gamma,0) \tag{7.16}$$

with

$$\gamma:=e_1(\omega-{}^t\omega)e_2=e_1\cdot(e_2\times b). \tag{7.17}$$

From (7.10) and (7.12) we can see that

$$\nu_1\gamma,\nu_2\gamma\in\mathbf{Z}. \tag{7.18}$$

Hence γ is a rational number. Let d be the greatest common divisor of ν_1 and ν_2. If we put $\nu_1=dp_1$ and $\nu_2=dp_2$, then p_1 and p_2 are mutually prime. The above equation (7.18) implies that $d\gamma$ is an integer. So we have

$$d:=\mathrm{GCD}\{\nu_1,\nu_2\}, \quad \ell:=d\gamma\in\mathbf{Z}. \tag{7.19}$$

Before constructing the representation of the MTG, we need to know how the generators generate an arbitrary element of the MTG. From the multiplication rule of the group $\mathbf{R}\times_\omega\mathbf{R}^n$ we deduce that for $x,y\in\mathbf{R}^n$

$$\begin{aligned}(\tfrac{1}{2}x\omega x,x)\cdot(\tfrac{1}{2}y\omega y,y)&=(\tfrac{1}{2}x\omega x+\tfrac{1}{2}y\omega y+x\omega y,x+y)\\&=(\tfrac{1}{2}x\omega y-\tfrac{1}{2}y\omega x+\tfrac{1}{2}(x+y)\omega(x+y),x+y)\\&=(\tfrac{1}{2}x(\omega-{}^t\omega)y,0)\cdot(\tfrac{1}{2}(x+y)\omega(x+y),x+y)\end{aligned} \tag{7.20}$$

and

$$(\tfrac{1}{2}x\omega x,x)^{-1}=(\tfrac{1}{2}x\omega x,-x). \tag{7.21}$$

Iteration of (7.20) yields

$$(\tfrac{1}{2}x\omega x,x)^n=(\tfrac{1}{2}n^2x\omega x,nx),\quad n\in\mathbf{Z}. \tag{7.22}$$

Furthermore, (7.20) implies

$$(\tfrac{1}{2}s^2x\omega x,sx)\cdot(\tfrac{1}{2}t^2x\omega x,tx)=(\tfrac{1}{2}(s+t)^2x\omega x,(s+t)x),\quad s,t\in\mathbf{R}. \tag{7.23}$$

By a tedious calculation we can show

$$(s,x+y+z)=(s-X,0)\cdot(\tfrac{1}{2}x\omega x,x)\cdot(\tfrac{1}{2}y\omega y,y)\cdot(\tfrac{1}{2}z\omega z,z) \tag{7.24}$$

with

$$X=\tfrac{1}{2}(x+y+z)\omega(x+y+z)+\tfrac{1}{2}x(\omega-{}^t\omega)y+\tfrac{1}{2}x(\omega-{}^t\omega)z+\tfrac{1}{2}y(\omega-{}^t\omega)z. \tag{7.25}$$

Thus an arbitrary element of the MTG is expressed as

$$\begin{aligned}g&=(s,te_0+n_1e_1+n_2e_2)\\&=(s-\tfrac{1}{2}(te_0+n_1e_1+n_2e_2)\omega(te_0+n_1e_1+n_2e_2)-\tfrac{1}{2}\gamma n_1n_2,0)\\&\quad\cdot(\tfrac{1}{2}t^2e_0\omega e_0,te_0)\cdot(\tfrac{1}{2}e_1\omega e_1,e_1)^{n_1}\cdot(\tfrac{1}{2}e_2\omega e_2,e_2)^{n_2}\\&=\phi(s-X)\cdot g_0(t)\cdot(g_1)^{n_1}\cdot(g_2)^{n_2},\end{aligned} \tag{7.26}$$

which is a product of the generators

$$\phi(s):=(s,0), \tag{7.27}$$

$$g_0(t):=(\tfrac{1}{2}t^2e_0\omega e_0,te_0), \tag{7.28}$$

$$g_1:=(\tfrac{1}{2}e_1\omega e_1,e_1), \tag{7.29}$$

$$g_2:=(\tfrac{1}{2}e_2\omega e_2,e_2). \tag{7.30}$$

These generators satisfy the relations

$$\phi(s)\cdot\phi(t)=\phi(s+t), \tag{7.31}$$

$$\phi(1)=1, \tag{7.32}$$

$$g_0(s)\cdot g_0(t)=g_0(s+t), \tag{7.33}$$

$$g_0(1)=\phi(\tfrac{1}{2}z_0), \tag{7.34}$$

$$(g_1)^{\nu_1}=\phi(\tfrac{1}{2}z_1), \tag{7.35}$$

$$(g_2)^{\nu_2}=\phi(\tfrac{1}{2}z_2), \tag{7.36}$$

$$g_1\cdot g_2\cdot g_1^{-1}\cdot g_2^{-1}=\phi(\gamma) \tag{7.37}$$

and other trivial commutators. Here we have defined $\{z_0,z_1,z_2\}$ by

$$z_0 := e_0 \omega e_0 = \left(\frac{1}{D_0}\right)^2 b_1 b_2 b_3, \tag{7.38}$$

$$z_1 := \nu_1^2 e_1 \omega e_1, z_2 := \nu_2^2 e_2 \omega e_2. \tag{7.39}$$

Because e_0 is an integral vector and ω is an integral matrix, z_0 is an integer. Furthermore, (7.12) implies that z_1 and z_2 are also integers.

In reverse order, the generators $\{\phi(s), g_0(t), g_1, g_2\}$ and their relations (7.31)–(7.37) determine the MTG uniquely. These generators with the relations form the MTG in a constructive manner. Consequently, the MTG in T^3 is completely characterized by the set of parameters $(z_0, z_1, z_2, \nu_1, \nu_2, \gamma)$, where $\{z_0, z_1, z_2, \nu_1, \nu_2\}$ are integers and γ is a rational number constrained by the condition (7.18).

Now we discuss the representation theory of the MTG exhaustively. The space of functions $\{f: \mathbf{R}^{n+1} \to \mathbf{C}\}$ provides the regular representation of the group $\mathbf{R} \times_\omega \mathbf{R}^n$ via

$$\begin{aligned} U(v_0, v) f(x_0, x) &:= f((v_0, v)^{-1} \cdot (x_0, x)) \\ &= f((-v_0 + v\,\omega v, -v) \cdot (x_0, x)) \\ &= f(x_0 - v_0 + v\,\omega v - v\,\omega x, x - v). \end{aligned} \tag{7.40}$$

We restrict the representation U on the space of equivariant functions, which are constrained by (3.7) and (3.8). Then we have

$$U(v_0, v) f(x_0, x) = e^{2\pi i (v_0 - v\,\omega v + v\,\omega x)} f(x_0, x - v), \tag{7.41}$$

which reproduces the unitary transformations (2.3) and (2.4) when the twisting matrix (3.11) is taken. Particularly $(v_0, 0)$ is represented by

$$U(v_0, 0) f(x_0, x) = e^{2\pi i v_0} f(x_0, x). \tag{7.42}$$

Hence the representation U induces an isomorphism of (7.31) and (7.32) by

$$U(\phi(s)) = e^{2\pi i s}. \tag{7.43}$$

Moreover, if we put

$$U_0(t) := U(g_0(t)), \quad U_1 := U(g_1), \quad U_2 := U(g_2), \tag{7.44}$$

they satisfy

$$U_0(s) U_0(t) = U_0(s + t), \tag{7.45}$$

$$U_0(1) = e^{\pi i z_0}, \tag{7.46}$$

$$(U_1)^{\nu_1} = e^{\pi i z_1}, \tag{7.47}$$

$$(U_2)^{\nu_2} = e^{\pi i z_2}, \tag{7.48}$$

$$U_1 U_2 U_1^{-1} U_2^{-1} = e^{2\pi i \gamma}, \tag{7.49}$$

since U is a homomorphism of the relations (7.33)–(7.37).

An irreducible representation of $U_0(t)$ is labeled by an integer q_0 and defined by

$$U_0(t) |q_0\rangle = e^{2\pi i (q_0 + (1/2) z_0) t} |q_0\rangle. \tag{7.50}$$

On the other hand, to construct a representation of the algebra generated by U_1 and U_2, we introduce a set of orthogonal vectors $\{|q_1,q_2\rangle | q_1 \in \mathbf{Z}/\nu_1\mathbf{Z}, q_2 \in \mathbf{Z}/\nu_2\mathbf{Z}\}$. We assume identification $|q_1,q_2\rangle = |q_1+k_1\nu_1, q_2+k_2\nu_2\rangle$ for any $k_1,k_2 \in \mathbf{Z}$. Let the operators U_1 and U_2 act on them by

$$U_1|q_1,q_2\rangle = e^{2\pi i(q_1+(1/2)z_1)/\nu_1}|q_1,q_2\rangle, \tag{7.51}$$

$$U_2|q_1,q_2\rangle = e^{2\pi i(q_2+(1/2)z_2)/\nu_2}|q_1+\nu_1\gamma,q_2\rangle. \tag{7.52}$$

The step of q_1 generated by U_2 is

$$\Delta q_1 := \nu_1\gamma = dp_1\frac{\ell}{d} = p_1\ell. \tag{7.53}$$

Then the fundamental relations, (7.47)–(7.49), are satisfied as

$$(U_1)^{\nu_1}|q_1,q_2\rangle = e^{2\pi i(q_1+(1/2)z_1)}|q_1,q_2\rangle = e^{2\pi i(1/2)z_1}|q_1,q_2\rangle, \tag{7.54}$$

$$\begin{aligned}(U_2)^{\nu_2}|q_1,q_2\rangle &= e^{2\pi i(q_2+(1/2)z_2)}|q_1+\nu_1\nu_2\gamma,q_2\rangle \\ &= e^{2\pi i(1/2)z_2}|q_1,q_2\rangle \quad \text{(because } \nu_2\gamma \text{ is an integer)},\end{aligned} \tag{7.55}$$

$$\begin{aligned}U_1U_2U_1^{-1}U_2^{-1}|q_1,q_2\rangle &= U_1U_2U_1^{-1}e^{-2\pi i(q_2+(1/2)z_2)/\nu_2}|q_1-\nu_1\gamma,q_2\rangle \\ &= U_1U_2e^{-2\pi i(q_1-\nu_1\gamma+(1/2)z_1)/\nu_1}e^{-2\pi i(q_2+(1/2)z_2)/\nu_2}|q_1-\nu_1\gamma,q_2\rangle \\ &= U_1\,e^{-2\pi i(q_1-\nu_1\gamma+(1/2)z_1)/\nu_1}|q_1,q_2\rangle = e^{2\pi i\gamma}|q_1,q_2\rangle.\end{aligned} \tag{7.56}$$

Thus the basis $\{|q_1,q_2\rangle\}$ spans a representation space of the algebra generated by U_1 and U_2. This representation space is reducible generally. We can see that the action of U_2 is cyclic. Namely, if we put

$$c := \frac{\mathrm{LCM}\{\Delta q_1,\nu_1\}}{\Delta q_1} = \frac{\mathrm{LCM}\{p_1\ell,p_1d\}}{p_1\ell} = \frac{\mathrm{LCM}\{\ell,d\}}{\ell} = \frac{d}{\mathrm{GCD}\{\ell,d\}}, \tag{7.57}$$

then

$$c\Delta q_1 = \mathrm{LCM}\{\Delta q_1,\nu_1\} \tag{7.58}$$

is an integral multiple of ν_1 and therefore the U_2 action (7.52) iterated by c times gives

$$(U_2)^c|q_1,q_2\rangle = e^{2\pi i(q_2+(1/2)z_2)c/\nu_2}|q_1+c\Delta q_1,q_2\rangle = e^{2\pi i(q_2+(1/2)z_2)c/\nu_2}|q_1,q_2\rangle. \tag{7.59}$$

Moreover,

$$\frac{\nu_1}{c} = \frac{\nu_1\mathrm{GCD}\{\ell,d\}}{d} = \frac{dp_1\mathrm{GCD}\{\ell,d\}}{d} = p_1\mathrm{GCD}\{\ell,d\}, \tag{7.60}$$

$$\frac{\nu_2}{c} = \frac{\nu_2\mathrm{GCD}\{\ell,d\}}{d} = \frac{dp_2\mathrm{GCD}\{\ell,d\}}{d} = p_2\mathrm{GCD}\{\ell,d\} \tag{7.61}$$

are integers. Therefore, each choice of $q_1 \in \mathbf{Z}$ modulo $(\nu_1/c)\mathbf{Z}$ and $q_2 \in \mathbf{Z}$ modulo $(\nu_2/c)\mathbf{Z}$ specifies one of inequivalent irreducible representations. Consequently, the dimension of the irreducible representation is

$$\text{dimension} = c = \frac{d}{\mathrm{GCD}\{d,\ell\}}. \tag{7.62}$$

On the other hand, the number of inequivalent representations for a fixed q_0 is

$$\#\text{inequivalent irreducible representations} = \frac{\nu_1}{c}\cdot\frac{\nu_2}{c} = p_1 p_2 (\mathrm{GCD}\{d,\ell\})^2. \tag{7.63}$$

These numbers give a number

$$(\text{dimension})^2 \times (\#\text{inequivalent irreducible representations}) = c^2 \times \frac{\nu_1\nu_2}{c^2} = \nu_1\nu_2, \tag{7.64}$$

which coincides with the dimension of the algebra generated by U_1 and U_2, as required by the Peter–Weyl theory on group representation.[29] Thus we have obtained the complete set of irreducible representations of the algebra.

In summary, an irreducible representation of the MTG in the three-dimensional torus is specified by

$$\chi = (q_0,[q_1],[q_2]) \in \mathbf{Z}\times\mathbf{Z}_{(\nu_1/c)}\times\mathbf{Z}_{(\nu_2/c)}. \tag{7.65}$$

Using the decomposition (7.26) we have

$$\begin{aligned} &U(s,te_0+n_1e_1+n_2e_2)|q_0,q_1,q_2\rangle \\ &\quad = e^{2\pi i(s-X)}U_0(t)(U_1)^{n_1}(U_2)^{n_2}|q_0,q_1,q_2\rangle \\ &\quad = e^{2\pi i\{(s-X)+(q_0+(1/2)z_0)t+(q_1+\gamma\nu_1 n_2+(1/2)z_1)n_1/\nu_1+(q_2+(1/2)z_2)n_2/\nu_2\}}|q_0,q_1+\gamma\nu_1 n_2,q_2\rangle \end{aligned} \tag{7.66}$$

with X evaluated as

$$X = \tfrac{1}{2}(te_0+n_1e_1+n_2e_2)\omega(te_0+n_1e_1+n_2e_2)+\tfrac{1}{2}\gamma n_1 n_2. \tag{7.67}$$

B. Examples in the three-dimensional torus

Here we apply the previous method of representation of the MTG to three examples of magnetic fields in T^3.

The first example is a magnetic field parallel to the x_3-axis,

$$b = \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ \nu \end{pmatrix} \tag{7.68}$$

with a positive integer ν. The generators (7.9) of the MTG are chosen as

$$e_0 = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \quad e_1 = \frac{1}{\nu}\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad e_2 = \frac{1}{\nu}\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}. \tag{7.69}$$

The vectors $\{e_1,e_2\}$ reproduce the discrete magnetic shifts (2.17) in the plane perpendicular to the magnetic field. The cycles (7.12) of e_1 and e_2 are found to be

$$\nu_1 = \nu, \quad \nu_2 = \nu, \tag{7.70}$$

respectively. Using them we evaluate the parameters of the MTG as

$$d=\mathrm{GCD}\{\nu_1,\nu_2\}=\mathrm{GCD}\{\nu,\nu\}=\nu, \tag{7.71}$$

$$\gamma=e_1(\omega-{}^t\omega)e_2=e_1\cdot(e_2\times b)=\frac{1}{\nu}, \tag{7.72}$$

$$\ell=d\gamma=\nu\frac{1}{\nu}=1, \tag{7.73}$$

$$z_0=z_1=z_2=0. \tag{7.74}$$

The size and the number of irreducible representations are

$$\text{dimension}=c=\frac{d}{\mathrm{GCD}\{\ell,d\}}=\frac{\nu}{\mathrm{GCD}\{1,\nu\}}=\frac{\nu}{1}=\nu, \tag{7.75}$$

$$\#\text{inequivalent irreducible representations}=\frac{\nu_1\nu_2}{c^2}=\frac{\nu^2}{\nu^2}=1. \tag{7.76}$$

In this case (7.51) and (7.52) reproduce the representations (2.20) and (2.21) in T^2.

The second example is a magnetic field perpendicular to the x_1-axis and lying in the middle of the x_2- and x_3-axes,

$$b=\begin{pmatrix}b_1\\b_2\\b_3\end{pmatrix}=\begin{pmatrix}0\\\nu\\\nu\end{pmatrix}, \tag{7.77}$$

with a positive integer ν. The generators of the MTG are chosen as

$$e_0=\begin{pmatrix}0\\1\\1\end{pmatrix},\quad e_1=\frac{1}{\nu}\begin{pmatrix}0\\0\\1\end{pmatrix},\quad e_2=\frac{1}{\nu}\begin{pmatrix}1\\0\\0\end{pmatrix}. \tag{7.78}$$

The cycles of e_1 and e_2 are

$$\nu_1=\nu,\quad \nu_2=\nu, \tag{7.79}$$

and other parameters of the MTG are also evaluated as

$$d=\nu,\ \gamma=\frac{1}{\nu},\ \ell=1,\ z_0=z_1=z_2=0, \tag{7.80}$$

$$\text{dimension}=c=\nu, \tag{7.81}$$

$$\#\text{inequivalent irreducible representations}=\frac{\nu_1\nu_2}{c^2}=1. \tag{7.82}$$

The third example is a magnetic field in the direction of (1,1,1),

$$b=\begin{pmatrix}b_1\\b_2\\b_3\end{pmatrix}=\begin{pmatrix}\nu\\\nu\\\nu\end{pmatrix} \tag{7.83}$$

with a positive integer ν. A calculation similar to the previous ones gives a series of parameters. Here we show only the results

$$e_0=\begin{pmatrix}1\\1\\1\end{pmatrix},\quad e_1=\frac{1}{\nu}\begin{pmatrix}1\\0\\0\end{pmatrix},\quad e_2=\frac{1}{\nu}\begin{pmatrix}0\\1\\0\end{pmatrix}, \tag{7.84}$$

$$\nu_1=\nu,\ \nu_2=\nu,\ d=\nu,\ \gamma=\frac{1}{\nu},\ \ell=1, z_0=\nu, z_1=z_2=0, \tag{7.85}$$

$$\text{dimension}=c=\nu, \tag{7.86}$$

$$\#\text{inequivalent irreducible representations}=\frac{\nu_1\nu_2}{c^2}=1. \tag{7.87}$$

VIII. REPRESENTATION THEORY OF THE MTG IN AN *n*-TORUS

Here we describe how to characterize the MTGs in an n-dimensional torus. We can choose generators $\{e_1,e_2,\ldots,e_l,f_1,f_2,\ldots,f_l,g_1,g_2,\ldots,g_m\}$ $(2l+m=n)$ of the magnetic shift group Ω^n such that

$$e_i,f_i\in\mathbf{Q}^n,\quad(\omega-{}^t\omega)e_i,(\omega-{}^t\omega)f_i\in\mathbf{Z}^n,\quad e_i(\omega-{}^t\omega)f_j=\gamma_i\delta_{ij}\quad(i,j=1,\ldots,l), \tag{8.1}$$

$$g_k\in\mathbf{Z}^n,\quad(\omega-{}^t\omega)g_k=0\quad(k=1,\ldots,m), \tag{8.2}$$

with nonzero rational numbers $\gamma_i\in\mathbf{Q}$. The vectors $\{g_1,\ldots,g_m\}$ are demanded to be minimal integral vectors in the sense that there is no real number s satisfying

$$0<s<1,\quad sg_k\in\mathbf{Z}^n, \tag{8.3}$$

for each $k=1,\ldots,m$. Let $\{\mu_i,\nu_i\}(i=1,\ldots,l)$ be smallest positive integers such that

$$\mu_ie_i,\nu_if_i\in\mathbf{Z}^n \tag{8.4}$$

and that there are no integers $\{m_i,n_i\}$ satisfying

$$0<m_i<\mu_i,\quad m_ie_i\in\mathbf{Z}^n, \tag{8.5}$$

$$0<n_i<\nu_i,\quad n_if_i\in\mathbf{Z}^n. \tag{8.6}$$

Equations (8.1) and (8.4) imply that $\gamma_i\mu_i$ and $\gamma_i\nu_i$ are integers. Thus, by putting

$$d_i:=\mathrm{GCD}\{\mu_i,\nu_i\}, \tag{8.7}$$

we can see that γ_id_i is an integer. Consequently, the group of translations (6.16) is decomposed as

$$\Omega^n=\mathbf{Z}e_1\oplus\cdots\oplus\mathbf{Z}e_l\oplus\mathbf{Z}f_1\oplus\cdots\oplus\mathbf{Z}f_l\oplus\mathbf{R}g_1\oplus\cdots\oplus\mathbf{R}g_m \tag{8.8}$$

and the MTG (6.18) is expressed as

$$S_A\cong S^1\times_\omega(\mathbf{Z}_{\mu_1}\times\cdots\times\mathbf{Z}_{\mu_l}\times\mathbf{Z}_{\nu_1}\times\cdots\times\mathbf{Z}_{\nu_l}\times T^m). \tag{8.9}$$

Finally, we describe an outline of the representation theory of the MTG's in an n-dimensional torus. Let us define integers x_i,y_i,z_j by

$$x_i:=\mu_i^2e_i\omega e_i, \tag{8.10}$$

$$y_i:=\nu_i^2f_i\omega f_i\quad(i=1,\ldots,l), \tag{8.11}$$

$$z_k := g_k \omega g_k \quad (k=1,\ldots,m). \tag{8.12}$$

Generators of the MTG (8.9) are represented by a set of unitary operators

$$T(s) := U(s,0), \quad s \in \mathbf{R}, \tag{8.13}$$

$$U_i := U(\tfrac{1}{2} e_i \omega e_i, e_i), \tag{8.14}$$

$$V_i := U(\tfrac{1}{2} f_i \omega f_i, f_i), \tag{8.15}$$

$$W_k(t) := U(\tfrac{1}{2} t^2 g_k \omega g_k, t g_k), \quad t \in \mathbf{R}. \tag{8.16}$$

They satisfy the equations

$$T(s)T(t) = T(s+t), \tag{8.17}$$

$$T(1) = 1, \tag{8.18}$$

$$(U_i)^{\mu_i} = T(x_i/2), \tag{8.19}$$

$$(V_i)^{\nu_i} = T(y_i/2), \tag{8.20}$$

$$U_i V_i U_i^{-1} V_i^{-1} = T(\gamma_i), \tag{8.21}$$

$$W_k(s) W_k(t) = W_k(s+t), \tag{8.22}$$

$$W_k(1) = T(z_k/2), \tag{8.23}$$

and other trivial commutators. These equations for the n-torus are generalization of the equations (7.31)–(7.37) for the three-torus. A representation space is spanned by the basis vectors

$$|\lambda, p, q, r\rangle = |\lambda, p_1, p_2, \ldots, p_l, q_1, q_2, \ldots, q_l, r_1, r_2, \ldots, r_m\rangle \tag{8.24}$$

labeled by $\lambda \in \mathbf{Z}$, $p_i \in \mathbf{Z}_{\mu_i}$, $q_i \in \mathbf{Z}_{\nu_i}$, and $r_k \in \mathbf{Z}$. The generators act on the basis vectors according to

$$T(s)|\lambda, p, q, r\rangle = e^{2\pi i \lambda s} |\lambda, p, q, r\rangle, \tag{8.25}$$

$$U_i |\lambda, p, q, r\rangle = e^{\pi i \lambda (2p_i + x_i)/\mu_i} |\lambda, p, q, r\rangle, \tag{8.26}$$

$$V_i |\lambda, p, q, r\rangle = e^{\pi i \lambda (2q_i + y_i)/\nu_i} |\lambda, p_1, \ldots, p_i + \gamma_i \mu_i, \ldots, p_l, q, r\rangle, \tag{8.27}$$

$$W_k(t) |\lambda, p, q, r\rangle = e^{\pi i \lambda (2r_k + z_k) t} |\lambda, p, q, r\rangle. \tag{8.28}$$

These are generalization of (7.43) and (7.50)–(7.52). The cycle of V_i is given by

$$c_i := \frac{\mathrm{LCM}\{\gamma_i \mu_i, \mu_i\}}{\gamma_i \mu_i} = \frac{\mathrm{LCM}\{\gamma_i d_i, d_i\}}{\gamma_i d_i} = \frac{d_i}{\mathrm{GCD}\{\gamma_i d_i, d_i\}}. \tag{8.29}$$

Hence an irreducible representation is labeled by

$$\chi = (\lambda, [p_1], \ldots, [p_l], [q_1], \ldots, [q_l], r_1, \ldots, r_m) \in \mathbf{Z} \times \mathbf{Z}_{(\mu_1/c_1)} \times \cdots \times \mathbf{Z}_{(\mu_l/c_l)} \times \mathbf{Z}_{(\nu_1/c_1)} \times \cdots \times \mathbf{Z}_{(\nu_l/c_l)} \times \mathbf{Z}^m. \tag{8.30}$$

The dimension of the irreducible representation is

$$\text{dimension}=\prod_{i=1}^{l} c_i, \tag{8.31}$$

and the number of inequivalent representations is

$$\#\text{inequivalent irreducible representations}=\prod_{i=1}^{l} \frac{\mu_i \nu_i}{c_i^2} \tag{8.32}$$

for fixed $(\lambda, r_1, \ldots, r_m) \in \mathbf{Z}^{m+1}$.

IX. CONCLUSION

Let us summarize our discussions. We began this article with a discussion on symmetry of a charged particle in a uniform magnetic field. We saw that the quantum system in T^2 has a discrete noncommutative translation symmetry. The symmetry is characterized by a central extension of a cyclic group.

In the following part of this article we introduced a noncommutative product into $\mathbf{R}^{n+1}$. Using the group structure, we defined the magnetic fiber bundles P_ω^{n+1}, which is a fiber bundle over T^n with a fiber S^1. Then we showed that the set of magnetic fiber bundles is classified by the quotient space of integral matrices $\mathrm{Mat}(n,\mathbf{Z})/\mathrm{Sym}(n,\mathbf{Z})$. We introduced connections into the fiber bundles and classified them by $\mathrm{Mat}(n,\mathbf{Z})\times\mathbf{R}^n/\mathrm{Sym}(n,\mathbf{Z})\times\mathbf{Z}^n$ as shown in (5.5). The lifted translations leaving the connection invariant form the magnetic translation group of (6.4). We characterized the MTG by (6.18) with (6.16). This characterization of the MTG is one of main results of this article. We found that the magnetic shift group Ω^n is discrete when the characteristic matrix $(\omega - {}^t\omega)$ is nondegenerated.

In the rest of the article we discussed the representation theory of the MTG for T^3 in detail and applied it to a few examples. The dimensions of an irreducible unitary representation is given by c in (7.62) and each irreducible representation is labeled by χ in (7.65). These results may be useful for application to the electron system in a lattice in an inclined magnetic field. We briefly described the representation theory of the MTG for T^n and summarized the result in (8.30) and (8.31).

Here we would like to mention remaining problems. It is desirable to apply the representation theory of the MTG to spectral analyses of the Laplace and Dirac operators. Originally the spectral problem of the quantum mechanics in a torus motivated this study. For this application the Peter–Weyl theory on group representation will play an essential role. In the next study we would like to pursue the analysis of the Laplace operator in the torus with a magnetic field. Moreover, an equilateral torus admits discrete transformations that exchange vertices of the torus and that leave the metric and the magnetic field invariant. It is also desirable to include such discrete transformations into the MTG for the complete spectral analysis.

By developing the theory of the MTG we will find its applications to physics. Inclusion of the supersymmetry into the MTG is an interesting direction for the future development. Sakamoto, Tachibana, and Takenaga[30,31] have pointed out that breaking of the translation symmetry causes breaking of the supersymmetry because the supersymmetry includes the translation symmetry. Hence the magnetic field may trigger supersymmetry breaking. On the other hand, the MTG in an n-torus is regarded as a generalization of the noncommutative torus, which attracted much attention recently in the string theory.[32] The B-field in a compactified space naturally induces a noncommutative structure, which is described by the MTG. Jackiw[33] also showed that how the noncommutative structure emerges in physical situations. If we turn our attention to solid state physics, we find another interesting application of the MTG also in this area. Tranquada[34] observed spontaneous formation of a charge density wave at a nonzero wave number in a copper-

oxide superconductor. This ordered state is called the stripe phase, in which the translation symmetry is broken. A similar stripe phase occurs commonly in a quantum Hall system.[35] Application of the MTG may help understanding of the stripe phases.

Note added in proof. After acceptance for publication of this article we obtained more strong results on the magnetic translation group in n dimensions. As concerns γ_i in (8.1) and μ_i, ν_i in (8.4), we proved that $\mu_i=\nu_i=1/\gamma_i$. Consequently, the definition (8.7) means simply that $d_i=\nu_i$. Eq. (8.29) is also simplified as $c_i=\nu_i$. In (8.31) the dimension of the irreducible representation becomes $\Pi_{i=1}^{l}\nu_i$. Finally, the number of inequivalent reprenentations (8.32) is reduced to one. As a corollary, we can show that $\nu_1=\nu_2=d=c=1/\gamma$ and hence $\ell=d\gamma=1$ in Sec. VII. More strongly, we can prove that $\nu_1=\mathrm{GCD}\{b_1,b_2,b_3\}$ for the three-deimensional magnetic field. Proofs of these statements are to be published elsewhere.

(Received 17 May 2002; accepted 30 August 2002)

The theory of interaction at one point is developed for the one-dimensional Schrödinger equation. In analog with the three-dimensional case, the resulting interaction is referred to as the Fermi pseudo-potential. The dominant feature of this one-dimensional problem comes from the fact that the real line becomes disconnected when one point is removed. The general interaction at one point is found to be the sum of three terms, the well-known delta-function potential and two Fermi pseudo-potentials, one odd under space reflection and the other even. The odd one gives the proper interpretation for the $\delta'(x)$ potential, while the even one is unexpected and more interesting. Among the many applications of these Fermi pseudo-potentials, the simplest one is described. It consists of a superposition of the delta-function potential and the even pseudo-potential applied to two-channel scattering. This simplest application leads to a model of the quantum memory, an essential component of any quantum computer. © *2002 American Institute of Physics.*

I. INTRODUCTION

There are several interrelated motivations for the present investigation. These are discussed in the following.

It was realized several years ago that there are significant differences between scattering in one channel and scattering in two or more coupled channels.[1] For this reason, it may be useful to gain some experience in dealing with coupled channels in general.

The first question is: What is the simplest scattering problem in the case of coupled channels? Once this simplest problem is understood, it is reasonable to expect that many of its features hold also for more general situations. Clearly, for this simplest problem, the number of channels should be chosen to be the smallest, namely two, and the number of spatial dimensions should also be chosen this way, namely one. Thus the scattering problem under consideration, in the time-independent case, deals with the coupled Schrödinger equations

$$\begin{aligned} -\frac{d^2\psi_1(x)}{dx^2}+V_{11}(x)\psi_1(x)+V_{12}(x)\psi_2(x)&=k^2\psi_1(x),\\ -\frac{d^2\psi_2(x)}{dx^2}+V_{21}(x)\psi_1(x)+V_{22}(x)\psi_2(x)&=k^2\psi_2(x), \end{aligned} \tag{1.1}$$

where the 2×2 matrix potential

[a)]Electronic mail: ttwu@deas.harvard.edu
[b)]Present address: Applied Materials, Inc., 3050 Bowers Ave., Santa Clara, CA 95054.

$$V(x)=\begin{bmatrix} V_{11}(x) & V_{12}(x) \\ V_{21}(x) & V_{22}(x) \end{bmatrix} \tag{1.2}$$

is such that it cannot be diagonalized simultaneously for all x.

What is the simplest possible choice for this $V(x)$? In the case of one channel, the simplest potential is the one that is proportional to the Dirac delta-function $\delta(x-x_0)$. This potential is localized at the one point x_0, and the corresponding Schrödinger equation is easy to solve. For two coupled channels, it is equally desirable to have the potential localized at one point, say at $x=0$. However, it is not allowed to take $V(x)$ to be the product of $\delta(x)$ and a constant 2×2 matrix because the diagonalization of this constant matrix decouples the channels.

What is needed, therefore, is another one-dimensional potential that is localized at one point. With a linear combination of $\delta(x)$ and this new potential, the 2×2 matrix $V(x)$ can be easily chosen such that it cannot be diagonalized and, hence, the two channels do not decouple.

There are many practical applications of the two-channel scattering problem in one dimension. In this article, let us restrict ourselves to one such application that is of current interest. The coupled channels can be used as a model for quantum memory; a natural approach to resetting, reading, and writing on a quantum memory is to use scattering from such a quantum memory.

In trying to find this second potential that is localized at one point, it is not necessary to study the coupled Schrödinger equations (1.1); it is sufficient to return to the simpler case of the one-channel Schrödinger equation

$$\left[-\frac{d^2}{dx^2}+V(x)\right]\psi(x)=k^2\psi(x). \tag{1.3}$$

A natural first guess for this second potential is the derivative of the Dirac delta-function, i.e., $\delta'(x)$. However, the presence of this $\delta'(x)$ term in Eq. (1.3) implies that the wave function must be discontinuous at this point $x=0$. But the product of $\delta'(x)$ and a function discontinuous at $x=0$ is not well defined. Furthermore, even if this $\delta'(x)$ potential is well defined, it is not suitable for the first application to quantum memory. The reason for this will be discussed later in this article.

A more powerful method is needed to find this desired potential. It is useful here to recall the concept of the Fermi pseudo-potential in three dimensions, which can be written in the form

$$\delta^3(r)\frac{\partial}{\partial r}r, \tag{1.4}$$

as given by Blatt and Weisskopf.[2] The most far-reaching application of this Fermi pseudo-potential is to the study of many-body systems, as initiated by Huang and Yang.[3] For the ground-state energy per particle of a Bose system of hard spheres, the low-density expansion is known to be

$$4\pi a\rho\left[1+\frac{128}{15\sqrt{\pi}}(\rho a^3)^{1/2}+8\left(\frac{4\pi}{3}-\sqrt{3}\right)\rho a^3\ln(\rho a^3)+O(\rho a^3)\right]. \tag{1.5}$$

In this expansion, the second term was first obtained by Lee and Yang[4] using the method of binary collision, but the derivation by Lee, Huang and Yang[5] using the Fermi pseudo-potential is somewhat simpler; the third term, which involves the logarithm, was first obtained by using the Fermi pseudo-potential.[6] In the derivation of the third term, it was found inconvenient to use the form (1.4), and thus a limiting process was reintroduced. This point will be of importance in this article. Thus a great deal is known about the Fermi pseudo-potential in three dimensions.

A further motivation for this article is to develop the Fermi pseudo-potential for one-dimensional scattering. In many cases, once a theory has been developed for three dimensions, it

is straightforward to repeat the development for one dimension. In the present case of the Fermi pseudo-potential, this is not the case. Furthermore, the result for one dimension seems qualitatively different from that for three dimensions.

For clarity of presentation, this article is organized into two parts: part A for the theory of the Fermi pseudo-potential in one dimension, and part B for its application to quantum computing. Needless to say, these two parts are closely related to each other. The sections are numbered consecutively throughout the paper.

PART A: THEORY OF ONE-DIMENSIONAL FERMI PSEUDO-POTENTIAL

II. INTERACTION AT ONE POINT

In the absence of V, the Hamiltonian of Eq. (1.3) is

$$H_0 = -\frac{d^2}{dx^2} \tag{2.1}$$

for real x, where the right-hand side is suitably interpreted so that it is self-adjoint. Let k be purely imaginary; define a real, positive κ by

$$\kappa = -ik. \tag{2.2}$$

For such a k, the Green's function, or resolvent, for this H_0 satisfies the differential equation

$$\left(-\frac{d^2}{dx^2} + \kappa^2\right) R_\kappa^{(0)}(x,x') = \delta(x-x'), \tag{2.3}$$

and is given explicitly by

$$R_\kappa^{(0)}(x,x') = (2\kappa)^{-1} e^{-\kappa|x-x'|}. \tag{2.4}$$

Let a potential V be added to this H_0 to give

$$H = H_0 + V, \tag{2.5}$$

which is also self-adjoint. Again for κ positive, the Green's function, or resolvent, for this H satisfies, similar to Eq. (2.3),

$$(H+\kappa^2) R_\kappa(x,x') = \delta(x-x'). \tag{2.6}$$

The interaction V is said to be at the one point x_0 if Eq. (2.6) implies that Eq. (2.3), with $R_\kappa^{(0)}(x,x')$ replaced by $R_\kappa(x,x')$, is satisfied for all x except $x = x_0$.

Because of translational symmetry, this x_0 is chosen to be 0 throughout this article. It is a consequence of Eq. (2.4) and the symmetry of the Green's function that this definition of an interaction at one point implies

$$R_\kappa(x,x') = \frac{1}{2\kappa}[e^{-\kappa|x-x'|} - f(\kappa;\mathrm{sg}x,\mathrm{sg}x') e^{-\kappa(|x|+|x'|)}], \tag{2.7}$$

where sg$x$ and sgx' mean the sign of x and the sign of x', respectively.

Since Eq. (2.7) is the starting point for the present paper, this is the appropriate place to add the following comments.

(1) In the present case of one dimension, the real line with the point $x=0$ removed is not connected. This is a qualitative difference between one dimension and higher dimensions.

(2) It is because of this property that the f in Eq. (2.7) can depend on the signs of x and x'.

(3) In the three-dimensional case, the Fermi pseudo-potential can be obtained in the following way: Take the self-adjoint Hamiltonian $-\nabla^2$, where ∇^2 is the three-dimensional Laplacian, and restrict it to functions that are zero at $\mathbf{r}=0$; the self-adjoint extensions[7] of this restricted operator give the Fermi pseudo-potential, i.e., these self-adjoint extensions can be written as the sum of $-\nabla^2$ and (1.4) multiplied by a constant. Such a procedure applied to the case of one dimension does not give Eq. (2.7).

It is useful to write out explicitly the f of Eq. (2.7) as

$$f(\kappa;\mathrm{sg}x,\mathrm{sg}x')=\begin{cases} f_1(\kappa), & \text{for } x>0,\ x'>0,\\ f_2(\kappa), & \text{for } x<0,\ x'>0,\\ f_3(\kappa), & \text{for } x<0,\ x'<0,\\ f_4(\kappa), & \text{for } x>0,\ x'<0, \end{cases} \tag{2.8}$$

following the four quadrants in the $x-x'$ plane. Note that all of these f's are dimensionless.

III. RESOLVENT EQUATION

In view of Eq. (2.7), it is most convenient to study the resolvent equation in coordinate representation:

$$R_{\kappa_1}(x,x')-R_{\kappa_2}(x,x')+(\kappa_1^2-\kappa_2^2)\int_{-\infty}^{\infty}dx''R_{\kappa_1}(x,x'')R_{\kappa_2}(x'',x')=0, \tag{3.1}$$

where κ_1 and κ_2 are two values of κ.

The substitution of Eq. (2.7) into this resolvent equation (3.1) gives, after a lengthy calculation,

$$\frac{1}{\kappa_1-\kappa_2}f(\kappa_1;\mathrm{sg}x,\mathrm{sg}x')+\frac{1}{\kappa_1+\kappa_2}f(\kappa_1;\mathrm{sg}x,-\mathrm{sg}x')-\frac{1}{\kappa_1-\kappa_2}f(\kappa_2;\mathrm{sg}x,\mathrm{sg}x')+\frac{1}{\kappa_1+\kappa_2}f(\kappa_2;$$
$$-\mathrm{sg}x,\mathrm{sg}x')-\frac{1}{\kappa_1+\kappa_2}[f(\kappa_1;\mathrm{sg}x,-)f(\kappa_2;-,\mathrm{sg}x')+f(\kappa_1;\mathrm{sg}x,+)f(\kappa_2;+,\mathrm{sg}x')]=0 \tag{3.2}$$

for $\kappa_1\neq\kappa_2$. This is the resolvent equation for the interaction at the point $x=0$ as defined in Sec. II.

Equation (3.2) has the following symmetry properties besides space reflection.

(1) Since $f(\kappa;\mathrm{sg}x,\mathrm{sg}x')$ is dimensionless, there is no scale for κ. Thus, Eq. (3.2) is invariant under the scale change

$$\kappa_1\to\lambda\kappa_1 \quad \text{and} \quad \kappa_2\to\lambda\kappa_2. \tag{3.3}$$

Note that λ is positive since the κ's are positive.

(2) There is an additional symmetry

$$f(\kappa;\mathrm{sg}x,\mathrm{sg}x')\to-\mathrm{sg}x\,\mathrm{sg}x'f\left(\frac{1}{\kappa};\mathrm{sg}x,\mathrm{sg}x'\right). \tag{3.4}$$

This discrete symmetry is going to play an important role in this article. In terms of the $f_j(\kappa)$ defined in Eq. (2.8), this symmetry is

$$\kappa\to\frac{1}{\kappa},$$

$$f_1 \to -f_1, \quad f_3 \to -f_3, \tag{3.5}$$

$$f_2 \to f_2, \quad f_4 \to f_4.$$

The next task is to solve the resolvent equation (3.2) for $f(\kappa;\mathrm{sg}x,\mathrm{sg}x')$. Since differential equations are easier to deal with than difference equations, it is convenient to take the limit $\kappa_1 \to \kappa_2$. In this limit, Eq. (3.2) reduces to

$$\frac{d}{d\kappa} f(\kappa;\mathrm{sg}x,\mathrm{sg}x') + \frac{1}{2\kappa}[f(\kappa;\mathrm{sg}x,-\mathrm{sg}x') + f(\kappa;-\mathrm{sg}x,\mathrm{sg}x')]$$

$$- \frac{1}{2\kappa}[f(\kappa;\mathrm{sg}x,-)f(\kappa;-,\mathrm{sg}x') + f(\kappa;\mathrm{sg}x,+)f(\kappa;+,\mathrm{sg}x')] = 0. \tag{3.6}$$

In terms of the $f_j(\kappa)$ of Eq. (2.8), this differential equation (3.6) consists of the following four equations by taking various signs for x and x':

$$f_1'(\kappa) + \frac{1}{2\kappa}[f_2(\kappa)+f_4(\kappa)] - \frac{1}{2\kappa}[f_2(\kappa)f_4(\kappa)+f_1(\kappa)^2] = 0, \tag{3.7a}$$

$$f_2'(\kappa) + \frac{1}{2\kappa}[f_1(\kappa)+f_3(\kappa)] - \frac{1}{2\kappa}[f_2(\kappa)f_3(\kappa)+f_1(\kappa)f_2(\kappa)] = 0, \tag{3.7b}$$

$$f_3'(\kappa) + \frac{1}{2\kappa}[f_2(\kappa)+f_4(\kappa)] - \frac{1}{2\kappa}[f_3(\kappa)^2+f_2(\kappa)f_4(\kappa)] = 0, \tag{3.7c}$$

$$f_4'(\kappa) + \frac{1}{2\kappa}[f_1(\kappa)+f_3(\kappa)] - \frac{1}{2\kappa}[f_3(\kappa)f_4(\kappa)+f_1(\kappa)f_4(\kappa)] = 0. \tag{3.7d}$$

An examination of these four differential equations shows the important role played by the combination $f_1(\kappa)+f_3(\kappa)$, which appears twice in Eq. (3.7b) and twice in Eq. (3.7d). Define $F(\kappa)$ up to an additive constant by

$$F'(\kappa) = \frac{1}{2\kappa}[f_1(\kappa)+f_3(\kappa)]. \tag{3.8}$$

In terms of this $F(\kappa)$, Eqs. (3.7b) and (3.7d) take the form

$$f_2'(\kappa) + F'(\kappa) - f_2(\kappa)F'(\kappa) = 0; \quad f_4'(\kappa) + F'(\kappa) - f_4(\kappa)F'(\kappa) = 0. \tag{3.9}$$

Integration of Eqs. (3.9) gives $f_2(\kappa)$ and $f_4(\kappa)$ in terms of $F(\kappa)$:

$$f_2(\kappa) = 1 + c_2 e^{F(\kappa)}, \quad f_4(\kappa) = 1 + c_4 e^{F(\kappa)}, \tag{3.10}$$

where c_2 and c_4 are two arbitrary constants of integration. Similarly, subtracting Eq. (3.7c) from Eq. (3.7a) gives

$$\frac{d}{d\kappa}[f_1(\kappa)-f_3(\kappa)] = \frac{1}{2\kappa}[f_1(\kappa)^2 - f_3(\kappa)^2] = F'(\kappa)[f_1(\kappa)-f_3(\kappa)], \tag{3.11}$$

or

$$f_1(\kappa) - f_3(\kappa) = 2c_3 e^{F(\kappa)}, \tag{3.12}$$

where c_3 is another arbitrary constant of integration.

It remains to determine $F(\kappa)$, which satisfies the second-order ordinary differential equation obtained from adding Eqs. (3.7a) and (3.7c):

$$2\kappa\frac{d}{d\kappa}\kappa\frac{d}{d\kappa}F(\kappa)=\left[\kappa\frac{d}{d\kappa}F(\kappa)\right]^2-1+(c_3^2+c_2c_4)e^{2F(\kappa)}. \tag{3.13}$$

The solution of this equation is straightforward but somewhat lengthy and is thus relegated to Appendix A.

The results are as follows:

$$f_1(\kappa)=\frac{-\sqrt{c_3^2+c_2c_4-c_1^2}\,[c_0\kappa+(c_0\kappa)^{-1}]-2c_3}{\sqrt{c_3^2+c_2c_4-c_1^2}\,[c_0\kappa-(c_0\kappa)^{-1}]+2c_1}, \tag{3.14a}$$

$$f_2(\kappa)=1-\frac{2c_2}{\sqrt{c_3^2+c_2c_4-c_1^2}\,[c_0\kappa-(c_0\kappa)^{-1}]+2c_1}, \tag{3.14b}$$

$$f_3(\kappa)=\frac{-\sqrt{c_3^2+c_2c_4-c_1^2}\,[c_0\kappa+(c_0\kappa)^{-1}]+2c_3}{\sqrt{c_3^2+c_2c_4-c_1^2}\,[c_0\kappa-(c_0\kappa)^{-1}]+2c_1}, \tag{3.14c}$$

$$f_4(\kappa)=1-\frac{2c_4}{\sqrt{c_3^2+c_2c_4-c_1^2}\,[c_0\kappa-(c_0\kappa)^{-1}]+2c_1}, \tag{3.14d}$$

when

$$c_3^2+c_2c_4-c_1^2>0. \tag{3.15}$$

Similarly,

$$f_1(\kappa)=\frac{-\sqrt{c_1^2-c_3^2-c_2c_4}\,[c_0\kappa-(c_0\kappa)^{-1}]-2c_3}{\sqrt{c_1^2-c_3^2-c_2c_4}\,[c_0\kappa+(c_0\kappa)^{-1}]+2c_1}, \tag{3.16a}$$

$$f_2(\kappa)=1-\frac{2c_2}{\sqrt{c_1^2-c_3^2-c_2c_4}\,[c_0\kappa+(c_0\kappa)^{-1}]+2c_1}, \tag{3.16b}$$

$$f_3(\kappa)=\frac{-\sqrt{c_1^2-c_3^2-c_2c_4}\,[c_0\kappa-(c_0\kappa)^{-1}]+2c_3}{\sqrt{c_1^2-c_3^2-c_2c_4}\,[c_0\kappa+(c_0\kappa)^{-1}]+2c_1}, \tag{3.16c}$$

$$f_4(\kappa)=1-\frac{2c_4}{\sqrt{c_1^2-c_3^2-c_2c_4}\,[c_0\kappa+(c_0\kappa)^{-1}]+2c_1}, \tag{3.16d}$$

when

$$c_3^2+c_2c_4-c_1^2<0. \tag{3.17}$$

In Eqs. (3.14) and (3.16), $c_0>0$ and all square roots are also positive. Although there are five constants c_0, c_1, c_2, c_3 and c_4, effectively there are four because all the quantities do not change under

$$c_j\to\lambda c_j \tag{3.18}$$

for $j=1, 2, 3, 4$, and $\lambda>0$.

It remains to discuss briefly the case

$$c_3^2+c_2c_4-c_1^2=0. \tag{3.19}$$

This case, which was in fact the first case worked out and also the most important one as discussed in Sec. IV, can be recovered by taking the limit $c_3^2+c_2c_4-c_1^2\to 0$ together with either $c_0\to 0$ or $c_0\to\infty$. These two limiting cases are to be considered separately. For definiteness, they are applied to Eqs. (3.16).

(1) $c_3^2+c_2c_4-c_1^2\to 0$ and $c_0\to 0$, such that

$$\gamma=c_0^{-1}\sqrt{c_1^2-c_3^2-c_2c_4} \tag{3.20}$$

is fixed; $\gamma>0$. In this limit,

$$f_1(\kappa)=\frac{\gamma-2c_3\kappa}{\gamma+2c_1\kappa}, \tag{3.21a}$$

$$f_2(\kappa)=1-\frac{2c_2\kappa}{\gamma+2c_1\kappa}, \tag{3.21b}$$

$$f_3(\kappa)=\frac{\gamma+2c_3\kappa}{\gamma+2c_1\kappa}, \tag{3.21c}$$

$$f_4(\kappa)=1-\frac{2c_4\kappa}{\gamma+2c_1\kappa}. \tag{3.21d}$$

(2) $c_3^2+c_2c_4-c_1^2\to 0$ and $c_0\to\infty$, such that

$$\gamma=c_0\sqrt{c_1^2-c_3^2-c_2c_4} \tag{3.22}$$

is fixed; $\gamma>0$. In this limit,

$$f_1(\kappa)=\frac{-\gamma\kappa-2c_3}{\gamma\kappa+2c_1}, \tag{3.23a}$$

$$f_2(\kappa)=1-\frac{2c_2}{\gamma\kappa+2c_1}, \tag{3.23b}$$

$$f_3(\kappa)=\frac{-\gamma\kappa+2c_3}{\gamma\kappa+2c_1}, \tag{3.23c}$$

$$f_4(\kappa)=1-\frac{2c_4}{\gamma\kappa+2c_1}. \tag{3.23d}$$

Note that Eqs. (3.21) and (3.23) are related by the discrete symmetry (3.5) provided that the sign of c_3 is reversed. The same results also follow from Eqs. (3.14).

IV. INTERACTION POTENTIALS

Naively, one would expect it to be straightforward to determine the potential when the Green's function (resolvent) is known. It does not turn out to be so straightforward, and this section is devoted to solving this problem.

The substitution of Eqs. (2.1) and (2.5) into Eq. (2.6) gives

$$V(x)R_\kappa(x,x')=\delta(x-x')-\left(-\frac{d^2}{dx^2}+\kappa^2\right)R_\kappa(x,x'), \tag{4.1}$$

or

$$V(x)R_\kappa(x,x')=-\left(-\frac{d^2}{dx^2}+\kappa^2\right)[R_\kappa(x,x')-R_\kappa^{(0)}(x,x')], \tag{4.2}$$

with the last term defined by Eq. (2.3) or (2.4). This should determine $V(x)$; that this $V(x)$ does not depend on κ is a consequence of $R_\kappa(x,x')$ satisfying the resolvent equation.

More generally, the left-hand side of Eq. (4.2) may be an integral, and this equation takes the form

$$\int_{-\infty}^{\infty}dx''V(x,x'')R_\kappa(x'',x')=-\left(-\frac{d^2}{dx^2}+\kappa^2\right)[R_\kappa(x,x')-R_\kappa^{(0)}(x,x')]. \tag{4.3}$$

If $V(x)$ exists, then

$$V(x,x')=V(x)\,\delta(x-x'). \tag{4.4}$$

Since Eq. (4.2) is simpler than Eq. (4.3), it is useful to study Eq. (4.2) first even though it is less general. The substitution of Eq. (2.7) into Eq. (4.2) gives

$$V(x)R_\kappa(x,x')=\frac{1}{2\kappa}\left(-\frac{d^2}{dx^2}+\kappa^2\right)f(\kappa;\mathrm{sg}x,\mathrm{sg}x')e^{-\kappa(|x|+|x'|)}. \tag{4.5}$$

The difficulty is to give a proper interpretation to this equation. The right-hand side contains a term

$$f(\kappa;\mathrm{sg}x,\mathrm{sg}x')\,\delta(x)e^{-\kappa|x'|}, \tag{4.6}$$

obtained by applying the differential operator to the exponential. As seen from Eqs. (3.14) for example, this expression (4.6) is in general the product of $\delta(x)$ and a function discontinuous at $x=0$. The only reasonable interpretation of such a product is

$$\alpha(x)\,\delta(x)=\frac{1}{2}\left[\left(\lim_{x\to 0+}+\lim_{x\to 0-}\right)\alpha(x)\right]\delta(x). \tag{4.7}$$

As mentioned above, there are effectively four parameters in the solutions as given by either Eqs. (3.14) or Eqs. (3.16). Since the symmetry of the Green's function implies that $c_2=c_4$, the number of parameters is reduced by 1. Therefore, the potential $V(x,x')$ depends on *three* parameters. That there are three parameters instead of two is a major surprise, and this fact is to play a central role in part B of this article, where this interaction potential is applied to study certain aspects of quantum computing.

The three pieces of $V(x,x')$ are of different levels of complication. They are studied in the following three subsections.

A. $\delta(x)$ potential

The simplest piece is the well-known $\delta(x)$ potential, where

$$V_1(x)=g_1\,\delta(x), \tag{4.8}$$

and

$$V_1(x,x')=g_1\,\delta(x)\,\delta(x-x'), \tag{4.9}$$

or equivalently

$$V_1(x,x')=g_1\delta(x)\delta(x'). \tag{4.10}$$

For this potential, the differential equation (2.6) is well defined. Its solution is

$$R_\kappa(x,x')=\frac{1}{2\kappa}\left[e^{-\kappa|x-x'|}-\frac{g_1}{2\kappa+g_1}e^{-\kappa(|x|+|x'|)}\right]. \tag{4.11}$$

Comparison with Eq. (2.7) gives

$$f(\kappa;\mathrm{sg}x,\mathrm{sg}x')=\frac{g_1}{2\kappa+g_1}, \tag{4.12}$$

independent of the signs of x and x'. By Eq. (2.8), this is

$$f_1(\kappa)=f_2(\kappa)=f_3(\kappa)=f_4(\kappa)=\frac{g_1}{2\kappa+g_1}. \tag{4.13}$$

This is a special case of Eqs. (3.21) with

$$c_1=c_2=c_4=\frac{\gamma}{g_1} \quad \text{and} \quad c_3=0. \tag{4.14}$$

It is instructive to recover Eq. (4.8) from Eq. (4.12) by using Eq. (4.5). Since $f(\kappa;\mathrm{sg}x,\mathrm{sg}x')$ does not depend on the signs of x and x', Eq. (4.5) gives

$$V(x)=\left[\frac{g_1}{2\kappa+g_1}\delta(x)e^{-\kappa|x'|}\right]\Bigg/\left\{\frac{1}{2\kappa}\left[e^{-\kappa|x-x'|}-\frac{g_1}{2\kappa+g_1}e^{-\kappa(|x|+|x'|)}\right]\right\}=g_1\delta(x). \tag{4.15}$$

This $V(x)$ is even in x.

B. $\delta'(x)$ potential

As already discussed in Sec. I, the potential $\delta'(x)$ is not acceptable because, in the Schrödinger equation, there is a product of $\delta'(x)$ and a function discontinuous at $x=0$. While $\delta(x)$ is a potential, $\delta'(x)$ has to be understood as a Fermi pseudo-potential in much the same way as the expression (1.4) in three dimensions.

Since $\delta'(x)$ is odd in x, the resolvent must satisfy

$$f_1(\kappa)=-f_3(\kappa) \quad \text{and} \quad f_2(\kappa)=f_4(\kappa). \tag{4.16}$$

Next, consider the *formal* Eq. (2.6) with this $\delta'(x)$ potential

$$\left[-\frac{d^2}{dx^2}+g_2\delta'(x)+\kappa^2\right]R_\kappa(x,x')=\delta(x-x'). \tag{4.17}$$

Since every term on the left-hand side is of dimension x^{-2} times that of $R_\kappa(x,x')$, the resolvent $R_\kappa(x,x')$ must be of the form

$$\kappa^{-1} \text{ function of } \kappa x \text{ and } \kappa x'.$$

A comparison with Eq. (2.7) then shows that $f(\kappa;\mathrm{sg}x,\mathrm{sg}x')$ is independent of κ. This is satisfied with

$$f_1(\kappa)=\alpha, \quad f_3(\kappa)=-\alpha, \quad \text{and} \quad f_2(\kappa)=f_4(\kappa)=-\beta, \tag{4.18}$$

with

$$2\beta+\alpha^2+\beta^2=0. \tag{4.19}$$

With the resolvent known, it is now possible to define the Fermi pseudo-potential

$$V_2(x)=g_2\delta_p'(x). \tag{4.20}$$

Omitting the argument κ in f, Eq. (4.5) takes the form

$$g_2\delta_p'(x)R_\kappa(x,x')=\frac{1}{2\kappa}\left(-\frac{d^2}{dx^2}+\kappa^2\right)f(\mathrm{sg}x,\mathrm{sg}x')e^{-\kappa(|x|+|x'|)}. \tag{4.21}$$

Let x' be positive. Then

$$\left(-\frac{d^2}{dx^2}+\kappa^2\right)f(\mathrm{sg}x,\mathrm{sg}x')e^{-\kappa|x|}=-(f_1-f_2)\delta'(x)+\kappa(f_1+f_2)\delta(x). \tag{4.22}$$

This expression has not only a $\delta'(x)$ term, but also a $\delta(x)$ term. For the left-hand side of Eq. (4.21), it is necessary to evaluate, using Eq. (4.7),

$$\begin{aligned}R_\kappa(x,x')|_{x=0}&=[e^{-\kappa(x'-x)}-f(\mathrm{sg}x,+)e^{-\kappa(|x|+x')}]_{x=0}\\&=e^{-\kappa x'}[1-\tfrac{1}{2}(\lim_{x\to 0+}+\lim_{x\to 0-})f(\mathrm{sg}x,+)e^{-\kappa|x|}]=e^{-\kappa x'}[1-\tfrac{1}{2}(f_1+f_2)]\end{aligned} \tag{4.23}$$

and

$$\begin{aligned}\frac{d}{dx}[e^{-\kappa(x'-x)}-f(\mathrm{sg}x,+)e^{-\kappa(|x|+x')}]_{x=0}&=\kappa[e^{-\kappa(x'-x)}+(\mathrm{sg}x)f(\mathrm{sg}x,+)e^{-\kappa(|x|+x')}]_{x=0}\\&=\kappa e^{-\kappa x'}[1+\tfrac{1}{2}(\lim_{x\to 0+}+\lim_{x\to 0-})(\mathrm{sg}x)f(\mathrm{sg}x,+)e^{-\kappa|x|}]\\&=\kappa e^{-\kappa x'}[1+\tfrac{1}{2}(f_1-f_2)].\end{aligned} \tag{4.24}$$

Suppose the $\delta_p'(x)$ on the left-hand side of Eq. (4.21) is replaced by $\delta'(x)$. Then a comparison of Eq. (4.22) with Eqs. (4.23) and (4.24) gives

$$g_2[1-\tfrac{1}{2}(f_1+f_2)]=f_1-f_2; \quad g_2[1+\tfrac{1}{2}(f_1-f_2)]=f_1+f_2, \tag{4.25}$$

where the identity $x\delta'(x)=-\delta(x)$ has been used. These are the conditions for $x'>0$; similar conditions for $x'<0$ are

$$g_2[1-\tfrac{1}{2}(f_4+f_3)]=f_4-f_3; \quad g_2[-1+\tfrac{1}{2}(f_4-f_3)]=f_4+f_3. \tag{4.26}$$

Solving Eqs. (4.25) and (4.26) gives

$$f_1=\frac{g_2}{1+g_2^2/4}; \quad f_3=\frac{-g_2}{1+g_2^2/4}; \quad f_2=f_4=\frac{g_2^2/2}{1+g_2^2/4}. \tag{4.27}$$

This is consistent with the previous Eqs. (4.18) and (4.19).

Where is the difficulty explained in Sec. I? Another way of asking the same question is: How does $\delta_p'(x)$ differ from $\delta'(x)$?

The answer is to be found in the first step of Eq. (4.24). In differentiating the quantity on the left-hand side of Eq. (4.24), the factor $f(\mathrm{sg}x,+)$ is not differentiated. In other words, the term with $(d/dx)f(\mathrm{sg}x,+)$ has been omitted; if this term were not omitted, there would be a $\delta(x)$, precisely the difficulty explained in Sec. I.

The situation is therefore entirely similar to the Fermi pseudo-potential in three dimensions, where the operator (1.4) performs the function of removing a term proportional to $1/r$. Here, what $\delta_p'(x)$ does is

$$\delta_p'(x)g(x)=\delta'(x)\tilde{g}(x), \tag{4.28}$$

where

$$\tilde{g}(x)=\begin{cases} g(x)-\lim\limits_{x\to 0+} g(x), & \text{for } x>0, \\ g(x)-\lim\limits_{x\to 0-} g(x), & \text{for } x<0. \end{cases} \tag{4.29}$$

This removes the discontinuity of $g(x)$ at $x=0$, which is precisely what is needed.

C. Third potential

At the beginning of this investigation it was thought that, in one dimension, there was one potential (Sec. IV A) and one pseudo-potential (Sec. IV B). But the detailed analysis of the resolvent equation in Sec. III shows that there are three independent parameters in the resolvent, and hence there is an independent third potential, or a second pseudo-potential in one dimension.

This third potential is most easily understood through the discrete symmetry (3.4). Let $c=2/g_1$. Then, from Eq. (4.13), the resolvent for the $\delta(x)$ potential is given by

$$f_1(\kappa)=f_2(\kappa)=f_3(\kappa)=f_4(\kappa)=\frac{1}{1+c\kappa}. \tag{4.30}$$

Application of the discrete symmetry (3.4) to Eq. (4.30) gives the result that the resolvent for the third potential is expressed by

$$f_1(\kappa)=f_3(\kappa)=\frac{-\kappa}{\kappa+c}; \quad f_2(\kappa)=f_4(\kappa)=\frac{\kappa}{\kappa+c}. \tag{4.31}$$

In particular, similar to the resolvent of the first pseudo-potential as given by Eq. (4.27), this resolvent is also not continuous. The relation between the resolvents as expressed by Eqs. (4.30) and (4.31) is a special case of that between Eqs. (3.21) and (3.23).

It remains to determine the potential, or more precisely the pseudo-potential, from Eq. (4.31), which can be written more succinctly as

$$f(\kappa;\mathrm{sg}x,\mathrm{sg}x')=-\frac{\kappa}{\kappa+c}\mathrm{sg}x\,\mathrm{sg}x'. \tag{4.32}$$

Therefore, for the present case of the third potential $V_3(x,x')$, Eq. (4.3) takes the form

$$\int_{-\infty}^{\infty} dx'' V_3(x,x'')\left[e^{-\kappa|x''-x'|}+\frac{\kappa}{\kappa+c}\,\mathrm{sg}x''\mathrm{sg}x' e^{-\kappa(|x''|+|x'|)}\right]$$
$$=\frac{\kappa}{\kappa+c}\left(-\frac{d^2}{dx^2}+\kappa^2\right)[\mathrm{sg}x\mathrm{sg}x' e^{-\kappa(|x|+|x'|)}]. \tag{4.33}$$

Differentiation of the right-hand side gives

$$\frac{d}{dx}[\mathrm{sg}x e^{-\kappa|x|}]=2\delta(x)-\kappa e^{-\kappa|x|},$$

and hence

$$\left(-\frac{d^2}{dx^2}+\kappa^2\right)[\mathrm{sg}x e^{-\kappa|x|}]=-2\delta'(x). \tag{4.34}$$

Thus Eq. (4.33) for $V_3(x,x')$ is explicitly

$$\int_{-\infty}^{\infty} dx'' V_3(x,x'')\left[e^{-\kappa|x''-x'|}+\frac{\kappa}{\kappa+c}\,\mathrm{sg}x''\mathrm{sg}x' e^{-\kappa(|x''|+|x'|)}\right]=-\frac{2\kappa}{\kappa+c}\,\delta'(x)\mathrm{sg}x' e^{-\kappa|x'|}. \tag{4.35}$$

The task is to make sense of this equation and to determine $V_3(x,x')$.

That the resolvent equation is satisfied means that Eq. (4.35), properly understood, does lead to a $V_3(x,x')$. By Eqs. (4.28) and (4.29), the $\delta'(x)$ on the right-hand side of Eq. (4.35) can be replaced by $\delta_p'(x)$, because it is not multiplied by a discontinuous function of x. Therefore, $V_3(x,x')$ is expected to be proportional to $\delta_p'(x)$; that $\delta_p'(x)$ is used instead of $\delta'(x)$ is due to the development in Sec. IV B. With these considerations, an examination of Eq. (4.35) indicates that

$$V_3(x,x')=g_3\delta_p'(x)\delta_p'(x'). \tag{4.36}$$

See also Eq. (4.20).

It remains to substitute Eq. (4.36) into Eq. (4.35) to find the relation between the two constants g_3 and c:

$$g_3\int_{-\infty}^{\infty} dx''\delta_p'(x'')\left[e^{-\kappa|x''-x'|}+\frac{\kappa}{\kappa+c}\,\mathrm{sg}x''\mathrm{sg}x' e^{-\kappa(|x''|+|x'|)}\right]=-\frac{2\kappa}{\kappa+c}\,\mathrm{sg}x' e^{-\kappa|x'|}. \tag{4.37}$$

The evaluation of the first integral is straightforward because $e^{-\kappa|x''-x'|}$ is continuous:

$$\int_{-\infty}^{\infty} dx''\delta_p'(x'')e^{-\kappa|x''-x'|}=\int_{-\infty}^{\infty} dx''\delta'(x'')e^{-\kappa|x''-x'|}=-\kappa\mathrm{sg}x' e^{-\kappa|x'|}. \tag{4.38}$$

After the removal of the common factor

$$\kappa\mathrm{sg}x' e^{-\kappa|x'|},$$

Eq. (4.37) reduces to

$$g_3\left[-1+\frac{1}{\kappa+c}\int_{-\infty}^{\infty} dx''\delta_p'(x'')\mathrm{sg}x'' e^{-\kappa|x''|}\right]=-\frac{2}{\kappa+c}. \tag{4.39}$$

This integral can be evaluated using Eqs. (4.28) and (4.29):

$$\int_{-\infty}^{\infty} dx'' \delta_p'(x'') \mathrm{sg}x'' e^{-\kappa|x''|} = -\int_{-\infty}^{\infty} dx'' \delta(x'') \mathrm{sg}x'' \frac{d}{dx''} e^{-\kappa|x''|} = \kappa. \tag{4.40}$$

Therefore, Eq. (4.39) is simply

$$g_3\left[-1+\frac{\kappa}{\kappa+c}\right] = -\frac{2}{\kappa+c} \quad \text{or} \quad g_3 = \frac{2}{c}. \tag{4.41}$$

This is the desired relation.

It is merely a matter of terminology whether this pseudo-potential $V_3(x,x')$ as given by Eq. (4.36) is called a local potential or not. It is a local potential if the definition is used that the support is the same before and after operating with $V_3(x,x')$.

In summary, the three potentials V_1, V_2, and V_3 are given by Eqs. (4.8), (4.20), and (4.36). Thus the most general Fermi pseudo-potential for the interaction at one point in one dimension is

$$\begin{aligned} V(x,x') &= V_1(x,x') + V_2(x,x') + V_3(x,x') \\ &= g_1 \delta(x)\delta(x-x') + g_2 \delta_p'(x)\delta(x-x') + g_3 \delta_p'(x)\delta_p'(x'). \end{aligned} \tag{4.42}$$

From the above experience of working with $\delta_p'(x)$ and the fact that the product of $\delta'(x)$ and a function discontinuous at $x=0$ is not meaningful, from here on the convention will be adopted that $\delta'(x)$ always means $\delta_p'(x)$. With this convention, Eq. (4.42) is written as

$$V(x,x') = g_1 \delta(x)\delta(x-x') + g_2 \delta'(x)\delta(x-x') + g_3 \delta'(x)\delta'(x'). \tag{4.43}$$

Equation (4.43) can be rewritten in a prettier form as follows. Since

$$\delta(x)\delta(x-x') = \delta(x)\delta(x')$$

and

$$\delta'(x)\delta(x-x') = \delta'(x)\delta(x'-x) = \delta'(x)[\delta(x') - x\delta'(x')] = \delta'(x)\delta(x') + \delta(x)\delta'(x'), \tag{4.44}$$

where use has been made of the identity $\delta'(x)x = -\delta(x)$, a general Fermi pseudo-potential (4.43) can be written as

$$V(x,x') = g_1 \delta(x)\delta(x') + g_2[\delta'(x)\delta(x') + \delta(x)\delta'(x')] + g_3 \delta'(x)\delta'(x'). \tag{4.45}$$

As already mentioned, the first and last terms are even while the middle term is odd. That is, under space inversion

$$x \to -x \quad \text{and} \quad x' \to -x', \tag{4.46}$$

the coupling constants transform as

$$g_1 \to g_1; \quad g_2 \to -g_2; \quad g_3 \to g_3. \tag{4.47}$$

V. SOLVING THE SCHRÖDINGER EQUATION

In applying the Fermi pseudo-potential to various problems, such as the one to be treated in part B of this article, the resolvent equation is difficult to use and it is much more convenient to employ the prescription of Sec. IV to the Schrödinger equation.

This section is devoted to studying the equation

$$\left(-\frac{d^2}{dx^2}+\kappa^2\right)R_\kappa(x,x')+\int_{-\infty}^{\infty}dx''V(x',x'')R_\kappa(x'',x')=\delta(x-x'), \tag{5.1}$$

where $V(x,x')$ is the Fermi pseudo-potential as given by Eq. (4.42). On the one hand, this is an equation for this $V(x,x')$. On the other hand, the procedure of this section is directly applicable to the Schrödinger equation, which differs from Eq. (5.1) only in the absence of the $\delta(x-x')$ term on the right-hand side.

This section serves two distinct purposes. First, the parameters in the known resolvent of Sec. III, especially Eqs. (3.14) and (3.16), are to be related to the coupling constants g_1, g_2, and g_3 in Eq. (4.42). This will give an explicit verification of consistency of the prescriptions given in Sec. IV. Second, the procedure to be followed here serves as a useful introduction to the slightly more complicated problem of the next section, where a two-channel scattering by a Fermi pseudo-potential is taken to be a model for a quantum memory.

The solution $R_\kappa(x,x')$ is given, as in the general case, by Eq. (2.7). The substitution of Eq. (2.7) into Eq. (5.1) gives

$$\left(-\frac{d^2}{dx^2}+\kappa^2\right)\left[-\frac{1}{2\kappa}f(\kappa;\mathrm{sg}x,\mathrm{sg}x')e^{-\kappa(|x|+|x'|)}\right]+\int_{-\infty}^{\infty}dx''V(x,x'')R_\kappa(x'',x')=0. \tag{5.2}$$

Since the first term has been evaluated by Eq. (4.22), Eq. (5.2) can be written alternatively as

$$2\kappa\int_{-\infty}^{\infty}dx''V(x,x'')R_\kappa(x'',x')$$

$$=e^{-\kappa|x'|}\begin{cases}\{-[f_1(\kappa)-f_2(\kappa)]\delta'(x)+\kappa[f_1(\kappa)+f_2(\kappa)]\delta(x)\}, & \text{for } x'>0\\ \{-[f_4(\kappa)-f_3(\kappa)]\delta'(x)+\kappa[f_4(\kappa)+f_3(\kappa)]\delta(x)\}, & \text{for } x'<0.\end{cases} \tag{5.3}$$

Using the knowledge gained from Sec. IV, a fairly lengthy calculation gives more explicitly

$$\begin{aligned}&[g_1\delta(x)+g_2\delta'(x)]e^{-\kappa|x'|}\begin{cases}\{1-\frac{1}{2}[f_1(\kappa)+f_2(\kappa)]\}, & \text{for } x'>0\\ \{1-\frac{1}{2}[f_4(\kappa)+f_3(\kappa)]\}, & \text{for } x'<0\end{cases}\\ &+[g_2\delta(x)+g_3\delta'(x)]\kappa e^{-\kappa|x'|}\begin{cases}\{-1+\frac{1}{2}[-f_1(\kappa)+f_2(\kappa)]\}, & \text{for } x'>0\\ \{1+\frac{1}{2}[-f_4(\kappa)+f_3(\kappa)]\}, & \text{for } x'<0\end{cases}\\ &=e^{-\kappa|x'|}\begin{cases}\{-[f_1(\kappa)-f_2(\kappa)]\delta'(x)+\kappa[f_1(\kappa)+f_2(\kappa)]\delta(x)\}, & \text{for } x'>0\\ \{-[f_4(\kappa)-f_3(\kappa)]\delta'(x)+\kappa[f_4(\kappa)+f_3(\kappa)]\delta(x)\}, & \text{for } x'<0,\end{cases}\end{aligned} \tag{5.4}$$

where Eq. (4.45) has been used. In Eq. (5.4), all dependences on x' cancel out. It therefore only remains to identify the coefficients of $\delta(x)$ and $\delta'(x)$. The results are

$$g_1\{1-\tfrac{1}{2}[f_1(\kappa)+f_2(\kappa)]\}+\kappa g_2\{-1+\tfrac{1}{2}[-f_1(\kappa)+f_2(\kappa)]\}=\kappa[f_1(\kappa)+f_2(\kappa)], \tag{5.5a}$$

$$g_2\{1-\tfrac{1}{2}[f_1(\kappa)+f_2(\kappa)]\}+\kappa g_3\{-1+\tfrac{1}{2}[-f_1(\kappa)+f_2(\kappa)]\}=-[f_1(\kappa)-f_2(\kappa)], \tag{5.5b}$$

$$g_1\{1-\tfrac{1}{2}[f_4(\kappa)+f_3(\kappa)]\}+\kappa g_2\{1+\tfrac{1}{2}[-f_4(\kappa)+f_3(\kappa)]\}=\kappa[f_4(\kappa)+f_3(\kappa)], \tag{5.5c}$$

$$g_2\{1-\tfrac{1}{2}[f_4(\kappa)+f_3(\kappa)]\}+\kappa g_3\{1+\tfrac{1}{2}[-f_4(\kappa)+f_3(\kappa)]\}=-[f_4(\kappa)-f_3(\kappa)]. \tag{5.5d}$$

Solving Eqs. (5.5) gives

$$f_1(\kappa)=D^{-1}[-g_3\kappa+2g_2-g_1\kappa^{-1}], \tag{5.6a}$$

$$f_3(\kappa)=D^{-1}[-g_3\kappa-2g_2-g_1\kappa^{-1}], \tag{5.6b}$$

$$f_2(\kappa)=f_4(\kappa)=1+D^{-1}\tfrac{1}{2}(4+g_1g_3-g_2^2), \tag{5.6c}$$

where

$$D=g_3\kappa-\tfrac{1}{2}(4-g_1g_3+g_2^2)-g_1\kappa^{-1}. \tag{5.7}$$
