Equations (5.6) are to be compared with Eqs. (3.14) and (3.16). First, this gives a deeper understanding why there are the two distinct cases (3.14) and (3.16). Equations (3.14) correspond to the situation where g_1 and g_3 have the same sign, while Eqs. (3.16) correspond to g_1 and g_3 having opposite signs. Second, in both cases, it is seen immediately from Eqs. (5.6) that $c_2=c_4$, a fact that has been used before. The results of expressing the five c's in terms of the three g's are the following:

$$c_0=\sqrt{|g_3/g_1|}, \tag{5.8}$$

$$c_1=\tfrac{1}{4}(4-g_1g_3+g_2^2), \tag{5.9a}$$

$$c_2=c_4=\tfrac{1}{4}(4+g_1g_3-g_2^2), \tag{5.9b}$$

$$c_3=g_2. \tag{5.9c}$$

Here use has been made of the scale invariance (3.18). [Strictly speaking, the right-hand sides of the three Eqs. (5.9a)–(5.9c) should all be multiplied by the factor $\mathrm{sg}g_3$. This factor has been omitted because it has no consequences.]

For completeness and also for later use, let the scattering matrix be written down. This involves returning to the more familiar variable k through Eq. (2.2) and then letting $x'\to\pm\infty$. After analytic continuation to positive values of k, the S-matrix is a 2×2 matrix,

$$S=\begin{bmatrix} S_{++} & S_{+-} \\ S_{-+} & S_{--} \end{bmatrix}, \tag{5.10}$$

where $+$ denotes propagation in the $+x$ direction, and $-$ in the $-x$ direction. For any interaction at the point $x=0$, it follows from Eqs. (2.7) and (2.8) that

$$S=\begin{bmatrix} 1-f(-ik;+,-) & -f(-ik;-,-) \\ -f(-ik;+,+) & 1-f(-ik;-,+) \end{bmatrix}=\begin{bmatrix} 1-f_4(-ik) & -f_3(-ik) \\ -f_1(-ik) & 1-f_2(-ik) \end{bmatrix}. \tag{5.11}$$

Equations (5.6) and (5.7) then give explicitly

$$S=[ig_3k+\tfrac{1}{2}(4-g_1g_3+g_2^2)+ig_1k^{-1}]^{-1}\begin{bmatrix} \tfrac{1}{2}(4+g_1g_3-g_2^2) & ig_3k-2g_2-ig_1k^{-1} \\ ig_3k+2g_2-ig_1k^{-1} & \tfrac{1}{2}(4+g_1g_3-g_2^2) \end{bmatrix}, \tag{5.12}$$

which is unitary.

An interesting special case is that with $g_2=0$; in this case, the pseudo-potential is even and there is left–right symmetry. Explicitly, in this case $g_2=0$, the S-matrix is

$$S=[ig_3k+\tfrac{1}{2}(4-g_1g_3)+ig_1k^{-1}]^{-1}\begin{bmatrix} \tfrac{1}{2}(4+g_1g_3) & ig_3k-ig_1k^{-1} \\ ig_3k-ig_1k^{-1} & \tfrac{1}{2}(4+g_1g_3) \end{bmatrix}. \tag{5.13}$$

This special case $g_2=0$, generalized to the case of coupled channels, is going to play a central role in part B of this article.

This completes the present discussion of the theory of Fermi pseudo-potential in one dimension. Attention is now turned to the first application of this theory.

PART B: APPLICATION OF ONE-DIMENSIONAL FERMI PSEUDO-POTENTIAL

VI. MODEL FOR QUANTUM MEMORY

There are many possible applications of the Fermi pseudo-potential in one dimension. As an example, it is intriguing to ask under what conditions Bethe's hypothesis[8,9] still holds when the delta-function potential is replaced by the $V(x,x')$ of Eq. (4.42). As a first application, however, it is more desirable to begin with a case where the Fermi pseudo-potential is used in a relatively simple situation of current interest.

For decades, computer components have become smaller and smaller, and this trend is expected to continue.[10] When some of the components become sufficiently small, as to be expected in the not-too-distant future, they need to be described in general by quantum mechanics. No matter how quantum computing is to develop in the future, one important component is necessarily the quantum memory, sometimes called the quantum register. The main function of any quantum memory is to store a quantum state.

In order for a quantum memory to be useful, it must be possible to alter the quantum state in the memory in a controlled way. This can only be accomplished by sending a signal from outside of the memory. In other words, the quantum state in the memory is to be controlled by a scattering process.[11]

It is the purpose of Sec. VI to propose a simple model for quantum memory. First, in order to have scattering processes, at least one space dimension is necessary. Otherwise there is no possibility of interference between the incident wave and the scattered wave. As perhaps to be expected, this interference is of central importance. Since the state in the memory must include at least two independent quantum states, it is simplest to describe the quantum memory using the coupled Schrödinger equations for two channels. This is essentially Eq. (1.1) in the Introduction.

It remains to make the simplest choice for the 2×2 matrix potential $V(x)$ of Eq. (1.2). This simplest choice, the Fermi pseudo-potential in one dimension, has been investigated systematically in part A of this article, the general result being given by Eq. (4.42).

The symmetry properties of this $V(x,x')$ under space inversion have been discussed at the end of Sec. IV. In particular, it is symmetrical if $g_2=0$. In order for the model to be suitable for quantum memory, it is essential to concentrate on this special case. The reason is that, only in this case, do the even wave $\cos kx$ and the odd wave $\sin kx$ not mix. This is also the basis for the comment in the Introduction, after Eq. (1.3), why the $\delta'(x)$ potential is not suitable for quantum memory. That this absence of mixing is important is discussed further in Sec. VII for a more general setting.

With this understanding and choice, the present model for the quantum memory is described by the one-dimensional coupled Schrödinger equations

$$\begin{aligned} -\frac{d^2\psi_1(x)}{dx^2}+\int_{-\infty}^{\infty}dx'[V_{11}(x,x')\psi_1(x')+V_{12}(x,x')\psi_2(x')]=k^2\psi_1(x),\\ -\frac{d^2\psi_2(x)}{dx^2}+\int_{-\infty}^{\infty}dx'[V_{21}(x,x')\psi_1(x')+V_{22}(x,x')\psi_2(x')]=k^2\psi_2(x), \end{aligned} \tag{6.1}$$

with the 2×2 matrix potential

$$V(x,x')=\begin{bmatrix} V_{11}(x,x') & V_{12}(x,x') \\ V_{21}(x,x') & V_{22}(x,x') \end{bmatrix}=\begin{bmatrix} g_3\delta'(x)\delta'(x') & g_1\delta(x)\delta(x') \\ g_1\delta(x)\delta(x') & -g_3\delta'(x)\delta'(x') \end{bmatrix}. \tag{6.2}$$

A more elegant way to write this potential is

$$V(x,x')=g_1\delta(x)\delta(x')\sigma_1+g_3\delta'(x)\delta'(x')\sigma_3, \tag{6.3}$$

where the σ's are the Pauli matrices.

When $g_2=0$, the potential $g_1\delta(x)\delta(x')$ does not act on the odd wave, and similarly the potential $g_3\delta'(x)\delta'(x')$ does not act on the even wave. The first part of this claim is easy to obtain, and the second part follows from the definition (4.28) of $\delta'_p(x)$. Alternatively, they can be seen from Eq. (5.13), where $S_{++}=S_{--}$ and $S_{+-}=S_{-+}$. For the even wave, the scattering phase shift is given by

$$S_{++}+S_{+-}=\frac{2k-ig_1}{2k+ig_1} \tag{6.4}$$

independent of g_3, while, for the odd wave, it is

$$S_{++}-S_{+-}=\frac{2-ig_3k}{2+ig_3k} \tag{6.5}$$

independent of g_1. Therefore, for the present case of two coupled channels as described by Eqs. (6.1) and (6.2), the S-matrix for the even and odd cases can be expressed in terms of these quantities as follows. Consider first the case for the odd wave; since the g_1 term does not contribute and can be neglected, the $V(x,x')$ of Eq. (6.2) effectively reduces to

$$V(x,x')=\begin{bmatrix} g_3\delta'(x)\delta'(x') & 0 \\ 0 & -g_3\delta'(x)\delta'(x') \end{bmatrix}, \tag{6.6}$$

which is diagonal, meaning that $\psi_1(x)$ and $\psi_2(x)$ do not couple. Since the behaviors of the two channels differ only in the sign of g_3, the S-matrix for this odd case is given by Eq. (6.5), or more explicitly

$$S_-(k)=\begin{bmatrix} \dfrac{2-ig_3k}{2+ig_3k} & 0 \\ 0 & \dfrac{2+ig_3k}{2-ig_3k} \end{bmatrix}. \tag{6.7}$$

It is instructive to rewrite this expression in terms of σ_3:

$$S_-(k)=\frac{(4-g_3^2k^2)-4ig_3k\sigma_3}{4+g_3^2k^2}=\exp\left[-i\sigma_3\left(2\tan^{-1}\frac{g_3k}{2}\right)\right]. \tag{6.8}$$

For the even wave, it is merely necessary to replace the right-hand side of Eq. (6.5) by that of Eq. (6.4), and also σ_3 by σ_1. Therefore Eq. (6.8) leads to

$$S_+(k)=\frac{(4k^2-g_1^2)-4ig_1k\sigma_1}{4k^2+g_1^2}=\exp\left[-i\sigma_1\left(2\tan^{-1}\frac{g_1}{2k}\right)\right] \tag{6.9}$$

or

$$S_+(k)=\begin{bmatrix} \dfrac{4k^2-g_1^2}{4k^2+g_1^2} & \dfrac{-4ig_1k}{4k^2+g_1^2} \\ \dfrac{-4ig_1k}{4k^2+g_1^2} & \dfrac{4k^2-g_1^2}{4k^2+g_1^2} \end{bmatrix}. \tag{6.10}$$

When neither g_1 nor g_3 is zero, any given element S of SU(2) can be expressed as a finite product of $S_+(k)$ and $S_-(k)$, i.e.,

$$S=S(k_1)S(k_2)\cdots S(k_m), \tag{6.11}$$

where each $S(k_i)$ is suitably chosen as $S_+(k_i)$ or $S_-(k_i)$.

In the language of scattering theory, the meaning of $S_+(k)$ is as follows. [The meaning of $S_-(k)$ is similar.] The in field is

$$\Psi^{\text{in}}=\begin{bmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{bmatrix} e^{-ik|x|}, \tag{6.12}$$

while the out field is

$$\Psi^{\text{out}}=\begin{bmatrix} a_1^{\text{out}} \\ a_2^{\text{out}} \end{bmatrix} e^{ik|x|}. \tag{6.13}$$

Then

$$\begin{bmatrix} a_1^{\text{out}} \\ a_2^{\text{out}} \end{bmatrix} = S_+(k) \begin{bmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{bmatrix}. \tag{6.14}$$

In other words, the quantum state in the memory is $\left[\begin{smallmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{smallmatrix}\right]$ before scattering, and $\left[\begin{smallmatrix} a_1^{\text{out}} \\ a_2^{\text{out}} \end{smallmatrix}\right]$ after scattering. These states before and after scattering are related by Eq. (6.14).

For any memory, classical or quantum, the basic operations are *write*, *read*, and *reset*. Of these three operations, writing is the simplest: Given the initial state $\left[\begin{smallmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{smallmatrix}\right]$ and the desired final state $\left[\begin{smallmatrix} a_1^{\text{out}} \\ a_2^{\text{out}} \end{smallmatrix}\right]$, there is a desired S-matrix S. Express this particular S by Eq. (6.11) as a finite product; then the writing is accomplished by a sequence of these m scatterings.

The question may be asked: While the final state $\left[\begin{smallmatrix} a_1^{\text{out}} \\ a_2^{\text{out}} \end{smallmatrix}\right]$ is the desired state to be stored in the quantum memory, how can one know what the initial state $\left[\begin{smallmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{smallmatrix}\right]$ is? This is where the idea of a standard state s is needed. ''Resetting'' means changing the content of the quantum memory, whatever it is, to the standard state s. For writing, the initial state is the standard state, i.e.,

$$\begin{bmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{bmatrix} = s. \tag{6.15}$$

In other words, before writing on a quantum memory, it is first reset so that Eq. (6.15) is satisfied. The standard state can be chosen to be any quantum state; however, once chosen, the choice is rarely altered.

Since scattering from a quantum memory leads to a unitary transformation of the quantum state in the memory, resetting cannot be accomplished without first finding out the content of the quantum memory. In other words, the first step of ''resetting'' is ''reading.'' After the content of

the quantum memory is known, say $\left[\begin{smallmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{smallmatrix}\right]$, "resetting" involves finding a sequence of scattering $S(k_j)$, $j=1,2,\ldots,m$, via Eq. (6.11) such that the resulting S has the property

$$S\begin{bmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{bmatrix} = s. \tag{6.16}$$

In summary, if "reading" can be accomplished, then so can "resetting;" if "resetting" can be accomplished, so can "writing."

The main task here is therefore to discuss, within the present model, the operation of reading a quantum memory. More precisely, what is involved is the following. When the quantum state in a memory, $\left[\begin{smallmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{smallmatrix}\right]$, is not known, find a suitably chosen sequence of incident waves $\cos k_i x$ or $\sin k_i x$ such that the knowledge about the field can be used to determine the values of a_1^{in} and a_2^{in}. After this determination, the quantum memory is returned to the initial state $\left[\begin{smallmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{smallmatrix}\right]$. (The last step is similar to the classical case in which a core memory is read from an initial state and then returned to it.)

Let the quantum state in the memory be $\left[\begin{smallmatrix} a_1 \\ a_2 \end{smallmatrix}\right]$; the problem is to determine the values of a_1 and a_2 by scattering from this state. Suppose an odd wave is used for the first scattering; then the two-component wave function for $x>0$ is given explicitly by

$$\psi(x) = \begin{bmatrix} \psi_1(x) \\ \psi_2(x) \end{bmatrix} = \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} e^{-ikx} + \begin{bmatrix} a_1 e^{i\phi_-} \\ a_2 e^{-i\phi_-} \end{bmatrix} e^{ikx}, \tag{6.17}$$

where, by Eq. (6.8),

$$\phi_- = -2\tan^{-1}\tfrac{1}{2}g_3 k. \tag{6.18}$$

In particular,

$$\psi(x)^\dagger \psi(x) = 2[1+\cos 2kx\cos\phi_- - (|a_1|^2-|a_2|^2)\sin 2kx\sin\phi_-], \tag{6.19}$$

because $|a_1|^2+|a_2|^2=1$. Therefore, this scattering process gives, through the interference term, the quantity

$$A_1 = |a_1|^2 - |a_2|^2. \tag{6.20}$$

Similarly, if the quantum state in the memory is first returned to the original state by a suitable scattering, then a second scattering with an even wave gives, again through the interference term, the second quantity

$$A_2 = \tfrac{1}{2}[|a_1+a_2|^2+|a_1-a_2|^2] = 2\,\text{Re}\,a_1^* a_2. \tag{6.21}$$

These two quantities, A_1 and A_2, are sufficient to determine the values of the complex numbers a_1 and a_2, except for a common phase. In order to determine this common phase, it is simplest to use the known standard state s. For example, a further interference with this standard state using, say, the odd wave gives a third quantity

$$A_3 = |a_1+s_1|^2 - |a_2+s_2|^2. \tag{6.22}$$

Since s_1 and s_2 are known, these three quantities A_1, A_2 and A_3 determine a_1 and a_2. Returning once more to the original quantum state presents no problem.

This completes the description of the present model of the quantum memory, including the operations of writing, reading, and resetting.

The advantages of this model, based on the Fermi pseudo-potential in one dimension, are its simplicity and its being completely explicit. On the one hand, such an explicit model plays an essential role in the initial understanding of some aspects of a new problem. On the other hand, the usefulness of such a model really lies in the possibility of opening a line of inquiry into these aspects. This is to be discussed in some detail in the next section. That is, in Sec. VII an attempt is to be made to present a general picture concerning the quantum memory, emphasizing the operations of writing, reading, and resetting, all accomplished by repeated scattering.

Some simplifying assumptions introduced in the model of this section are clearly not needed in the general setting of the next section. An example is the choice of using the Fermi pseudo-potential $V(x,x')$ of Eq. (6.2); another one is the use of the Schrödinger equation (6.1) in one dimension. Thus the generalization to the Schrödinger equation in three dimensions with a more general potential is immediate but the results are less explicit. The further generalization to renormalized quantum field theory also does not present any obstacle.

What is less clear, and most important, is the role played by the condition $g_2=0$, used throughout this section. This condition is closely related to, and makes it possible to use, the even waves and the odd waves. In order to appreciate this point, take instead the incoming wave as, say, from the direction of the $-x$ axis, i.e.,

$$\Psi^{\text{in}}=\begin{bmatrix} a_1^{\text{in}} \\ a_2^{\text{in}} \end{bmatrix} e^{-ikx}. \tag{6.23}$$

This is a superposition of an even wave and an odd wave. Since the Schrödinger equation is linear, the even part is operated on by the $S_+(k)$ of Eq. (6.10), and the odd part by the $S_-(k)$ of Eq. (6.7). Since g_1 and g_3 are not zero and thus these $S_+(k)$ and $S_-(k)$ are not equal, the quantum state in the memory for an outgoing wave in the $+x$ direction is different from that for an outgoing wave in the $-x$ direction. In other words, in order to determine the quantum state in the memory after scattering with the Ψ^{in} of Eq. (6.23), it is necessary to detect the direction of the outgoing wave.

In order for a quantum memory to behave as a memory, i.e., as the storage for a quantum state, it is essential that what is in the memory does not depend on the behavior of the scattered wave. Indeed, from the point of view of scattering theory, this characterizes quantum memories. Therefore, for the present model with the Fermi pseudo-potential, some incident waves, such as the even wave and the odd wave, are acceptable or ''admissible,'' while many others, such as e^{-ikx} of Eq. (6.23), are not ''admissible.''

This concept of admissible incident waves is central, not only for the present model but also in general. This is the first topic to be discussed in the next section.

VII. GENERALIZATION

It is the purpose of this section to give a general description of quantum memories. This is to be accomplished by extracting the dominant features from the model of Sec. VI on the basis of the Fermi pseudo-potential in one dimension.

In order to extract the dominant features, consider first the following two generalizations, the first one obvious and the second one less so.

First, that the potential is the Fermi pseudo-potential is not necessary. In other words, the matrix potential $V(x,x')$ of Eq. (6.2) can take a fairly general form. That g_2 is zero translates into the condition that this $V(x,x')$ is symmetrical, i.e.,

$$V(-x,-x')=V(x,x')$$

in general.

Second, that the model is one-dimensional is not essential. For example, the model can be a two-channel scattering in three-dimensional space. In this case, the $V(x,x')$ is replaced by another 2×2 matrix potential $V(\mathbf{r},\mathbf{r}')$, while the symmetry of the $V(x,x')$ becomes the condition that this $V(\mathbf{r},\mathbf{r}')$ is rotationally symmetrical.

While this rotational symmetry is probably not necessary, this symmetry does play an important role. In the one-dimensional case studied in detail in Sec. VI, the symmetry of the $V(x,x')$, coming from $g_2=0$, makes it possible to use the even wave and the odd wave. Similarly, in three dimensions, the rotational symmetry of $V(\mathbf{r},\mathbf{r}')$ makes it possible to use partial waves: the various partial waves do not couple so that each partial in wave leads to only the corresponding partial out wave.

Consider now the more general setting. Let the quantum memory be in a pure state $\Sigma_j a_j|j\rangle$, where $|j\rangle$ is a complete set of linearly independent states for the memory. The standard state s is a particular linear combination of these $|j\rangle$. Let ψ denote the wave function sent in from the outside to interact with the quantum memory; then the in field for the scattering process on the memory is

$$\Psi^{\text{in}}=\left(\sum_j a_j^{\text{in}}|j\rangle\right)\psi^{\text{in}}. \tag{7.1}$$

An example of Ψ^{in} is given by Eq. (6.23). It should be emphasized that ψ^{in} is at our disposal to accomplish whatever the purpose of this scattering is.

It is the fundamental characteristic of the scattering from a quantum memory that not only is the in field Ψ^{in} of the form of Eq. (7.1), but also the out field is of a similar form,

$$\Psi^{\text{out}}=\left(\sum_j a_j^{\text{out}}|j\rangle\right)\psi^{\text{out}}. \tag{7.2}$$

For the special model of Sec. VI, this important point has been discussed near the end of that section. For the present generalization, it is worked out in detail in Appendix B. As already seen in Sec. VI, Eq. (7.2) puts strong conditions on ψ^{in}. More precisely, a ψ^{in} is defined to be *admissible* if, for all $\Sigma_j a_j^{\text{in}}|j\rangle$, the corresponding Ψ^{out} is given by Eq. (7.2).

It should be added parenthetically that this definition of being admissible can be easily generalized by restricting the $\Sigma_j a_j^{\text{in}}|j\rangle$ to certain subsets. This generalization is expected to be useful in future investigations, but is not needed for this article.

In order to perform the operations of writing, reading, and resetting a quantum memory, it is necessary to have a sufficiently large collection of admissible ψ^{in}. This has been verified to be the case for the model of Sec. VI, and will be assumed to be so in this section. Let

$$\psi^{\text{in}}\left(\sum_j a_j^{\text{in}}|j\rangle\rightarrow\sum_j a_j^{\text{out}}|j\rangle\right) \tag{7.3}$$

denote a ψ^{in} with the property that, if Eq. (7.1) holds for this ψ^{in}, then Eq. (7.2) holds. It is assumed that, given any a_j^{in} and a_j^{out}, there is at least one such ψ^{in}. It is possible that there is more than one such ψ^{in}. It has been seen from the model of Sec. VI that this ψ^{in} may actually involve a sequence of ψ^{in}'s; see especially Eq. (6.11). However, for simplicity of notation, the expression (7.3) will be retained.

The operations of writing, reading, and resetting are now to be described in this order. For the purpose of writing after the quantum memory has been reset to the standard state s, it is sufficient to use any one of the $\psi^{\text{in}}(s\rightarrow\Sigma_j a_j|j\rangle)$, where $\Sigma_j a_j|j\rangle$ is the desired quantum state to be put in the memory.

Reading from a quantum memory is more complicated. Let a quantum memory be in a state $\Sigma_j a_j^{\text{in}}|j\rangle$; it is desired to determine the values of these a_j^{in} by interrogating this memory, i.e., by sending a suitably chosen sequence of admissible ψ^{in}'s,

$$\psi^{\text{in}(1)},\ \psi^{\text{in}(2)},\ \psi^{\text{in}(3)},\ldots,\psi^{\text{in}(N)}, \tag{7.4}$$

and scattering them successively by this quantum memory. More precisely, consider the successive scattering processes

$$
\begin{aligned}
&\sum_j a_j^{\mathrm{in}}|j\rangle\psi^{\mathrm{in}(1)}\to\sum_j a_j^{\mathrm{out}(1)}|j\rangle\psi^{\mathrm{out}(1)}\to a_j^{\mathrm{out}(1)}=a_j^{\mathrm{in}(2)}\\
&\to\sum_j a_j^{\mathrm{in}(2)}|j\rangle\psi^{\mathrm{in}(2)}\to\sum_j a_j^{\mathrm{out}(2)}|j\rangle\psi^{\mathrm{out}(2)}\to a_j^{\mathrm{out}(2)}=a_j^{\mathrm{in}(3)}\\
&\to\sum_j a_j^{\mathrm{in}(3)}|j\rangle\psi^{\mathrm{in}(3)}\to\sum_j a_j^{\mathrm{out}(3)}|j\rangle\psi^{\mathrm{out}(3)}\to a_j^{\mathrm{out}(3)}=a_j^{\mathrm{in}(4)}\\
&\to\cdots\\
&\to\sum_j a_j^{\mathrm{in}(N)}|j\rangle\psi^{\mathrm{in}(N)}\to\sum_j a_j^{\mathrm{out}(N)}|j\rangle\psi^{\mathrm{out}(N)}.
\end{aligned}
\tag{7.5}
$$

Corresponding to the list (7.4), there is a list of ψ^{out}'s,

$$
\psi^{\mathrm{out}(1)},\ \psi^{\mathrm{out}(2)},\ \psi^{\mathrm{out}(3)},\ \ldots,\ \psi^{\mathrm{out}(N)}. \tag{7.6}
$$

From the quantities given in (7.4) and (7.6) together with their interference, the values of a_j^{in} are obtained. This has been demonstrated explicitly in Sec. VI for the model there, and it is also shown there that a further interference with the standard state s may be needed to determine the overall phase. The importance of interference cannot be overemphasized.

Once the a_j^{in} are known, the values of $a_j^{\mathrm{out}(N)}$ of the process (7.5) can be obtained. An additional scattering using any one of the admissible $\psi^{\mathrm{in}}(\Sigma_j a_j^{\mathrm{out}(N)}|j\rangle\to\Sigma_j a_j^{\mathrm{in}}|j\rangle)$ returns the quantum memory to its initial state.

With the above process of reading a quantum memory, resetting is now straightforward. Resetting a quantum memory in the initial state $\Sigma_j a_j^{\mathrm{in}}|j\rangle$ to the standard state s consists of the following two steps.

(i) Read the memory to determine a_j^{in}. Note that, after the process of reading is performed, the memory is in the original initial state $\Sigma_j a_j^{\mathrm{in}}|j\rangle$.
(ii) Apply an additional scattering using any one of the admissible $\psi^{\mathrm{in}}(\Sigma_j a_j^{\mathrm{in}}|j\rangle\to s)$.

This completes the description of the quantum memory together with writing, reading, and resetting, all performed through scattering from the memory.

It may be worthwhile to emphasize that the concept of the quantum memory introduced and described here is quite general. In particular, the scattering process

$$
\Psi^{\mathrm{in}}=\left(\sum_j a_j^{\mathrm{in}}|j\rangle\right)\psi^{\mathrm{in}}\to\Psi^{\mathrm{out}}=\left(\sum_j a_j^{\mathrm{out}}|j\rangle\right)\psi^{\mathrm{out}} \tag{7.7}
$$

does not have many restrictions, and may or may not be linear. Also, the linearly independent states $|j\rangle$ are allowed to depend on time, and may or may not be the eigenstates of an operator.

VIII. COMPARISON WITH AN EARLIER MODEL

The idea of quantum computing was first discussed by Benioff in 1980.[12] In this pioneering paper, spatial dependence was retained, although not in the form of the Schrödinger equation. Since then, quantum computing and quantum information have become popular subjects with a vast literature.[13] However, in the majority of the theoretical papers on quantum computing, spatial dependence is omitted entirely. Therefore the usual model for quantum memory consists of a spin system or its generalization, and the operations on the quantum memory consist of applying unitary matrices. This prevailing model for the quantum memory has led to a number of important results.

In the present article, as a first application of the Fermi pseudo-potential in one dimension, an alternative model for the quantum memory is proposed. This model differs from the previous one mainly in the reintroduction of the spatial variables, much in the spirit of the original work of Benioff.[12] From the point of view of physics, the spatial variables are clearly present, whether one wants them or not. Instead of saying that a unitary matrix is applied mathematically to the content of the quantum memory, here the content of the quantum memory is altered in a controlled way by applying suitably chosen scatterings to the memory.

This is much more than a change of language. While the previous model has the advantage of simplicity, which is important because quantum computing is a difficult subject, the present model with the spatial variable or variables may be considered to be desirable from the following two points of view. First, it offers a closer description of the experimental situation. Since a quantum memory is necessarily small in size, for practical reasons scattering is the simplest means of modifying the content of a quantum memory. Second, the presence of the spatial dimensions allows more possibilities of analyzing the quantum memory. It is also worth mentioning that the theory of scattering has been developed over many decades and is well understood, in the context of both quantum mechanics and quantum field theory. It is often advantageous to be able to make use of existing knowledge to study a new subject.

In both the previous model and the present model, the content of a quantum memory is given as a pure state. This content is altered by applying a unitary transformation, directly in the previous model and indirectly through scattering in the present model. The incident, scattered, and total wave functions have no analog in the previous model. In general, the phase shift[2] of scattering is determined from the total wave function, and the analysis of the explicit model in Sec. VI is actually an especially simple application of the usual phase-shift analysis, including the prominent role played by interference. The point is that, while in the definition of an admissible ψ^{in} in Sec. VII both Ψ^{in} [Eq. (7.1)] and Ψ^{out} [Eq. (7.2)] are unentangled so far as the memory and the interrogating wave are concerned, this is not true of the total wave function, which is for example

$$\psi(x)=\begin{bmatrix}\psi_1(x)\\ \psi_2(x)\end{bmatrix}$$

for the model of Sec. VI.

There are many interesting open questions for the present model. The analysis of these questions is beyond the scope of the present article. Nevertheless, here are two examples of such open questions.

(a) In Sec. VII, it is explicitly assumed that there is a sufficiently large class of admissible ψ^{in} of the form (7.3). In the model of Sec. VI, such a large class indeed exists in the form of even waves and odd waves. On the other hand, when $g_2\neq 0$, no such large class exists. What is needed is a more general discussion as to the conditions under which such a sufficiently large class of admissible ψ^{in} is actually available.

Even though examples where such a large class is available are known both in one dimension and in three dimensions, the three-dimensional case seems rather difficult to achieve experimentally. If this observation is true in general, then there may well be significant advantages to connecting the various components of a quantum computer, including quantum memories, by single-mode optical fibers. In particular, sending signals through space rather than fibers may lead to unexpected problems.

(b) Another especially challenging and interesting question for the present model of quantum memory concerns the issue of the so-called no-cloning theorem. This has been derived in the context of the previous model, but such derivations do not seem to be applicable directly to the present model. This is again related to the fact that here there is not only an S-matrix but also the incident, scattered, and total wave functions.

Preliminary analysis indicates that whether the no-cloning theorem holds for the present

model of quantum memory may depend on subtle aspects of the Schrödinger equation. If this is indeed the case, then the no-cloning theorem may need to be stated properly and precisely before it can be derived within the present model of quantum memory.

IX. DISCUSSIONS

The present investigation began as an attempt to understand the $\delta'(x)$ potential in the context of the one-dimensional Schrödinger equation. When simple attempts failed, the powerful method of the resolvent equation was used. The surprise is that, not only can the resolvent equation be solved in general in terms of rational functions, but also the solution yields, in addition to the well-known δ-function potential, not one but *two* linearly independent Fermi pseudo-potentials in one dimension. One of the pseudo-potentials is odd under space reflection and is the proper interpretation of the $\delta'(x)$ potential. The other one is originally unexpected and is even under space reflection.

It is likely that there are many applications of these pseudo-potentials to one-dimensional problems. A possible use in statistical mechanics connected with the Bethe ansatz[8,9] has already been mentioned in Sec. VI. In this article, only the simplest application is discussed. This has nothing to do with the proper interpretation of the $\delta'(x)$ potential, but depends critically on the unexpected, even pseudo-potential. By combining this even pseudo-potential with the δ-function potential, an elegant special case is found for the scattering in two coupled channels. Even though the two channels cannot be decoupled, it is easy to write down the complete solution from the known one-channel case.

In spite of the mathematical simplicity of this application of the Fermi pseudo-potential in one dimension, this example gives a model for the quantum memory (sometimes called the quantum register). While this model is completely explicit, its more important function is to point out a way to gain a general picture concerning the quantum memory.

More generally, the time-independent Schrödinger equation for n coupled channels with interaction at only the one point $x=0$ is

$$-\frac{d^2\psi(x)}{dx^2}+\int_{-\infty}^{\infty}dx'\,V(x,x')\,\psi(x')=k^2\psi(x) \tag{9.1}$$

with

$$\psi(x)=\begin{bmatrix}\psi_1(x)\\ \psi_2(x)\\ \vdots\\ \psi_n(x)\end{bmatrix} \tag{9.2}$$

and

$$V(x,x')=C_1\delta(x)\,\delta(x')+C_2[\,\delta_p'(x)\,\delta(x')+\delta(x)\,\delta_p'(x')\,]+C_3\delta_p'(x)\,\delta_p'(x'). \tag{9.3}$$

Here C_1, C_2 and C_3 are three numerical Hermitian $n\times n$ matrices, while $\delta_p'(x)$ is similar to $\delta'(x)$ and is defined in Sec. IV. For a given k and a given incident wave $\psi_0(x)$ with n components, the solution of Eq. (9.1) takes the form, for $j=1,2,\ldots,n$,

$$\psi_j(x)=\psi_{0j}(x)+\begin{cases}F_{j+}e^{ikx}, & \text{for } x>0,\\ F_{j-}e^{-ikx}, & \text{for } x<0,\end{cases} \tag{9.4}$$

analogous to Eq. (2.7), where the F's are $2n$ coefficients that depend on ψ_{0j} and k. The substitution of Eq. (9.4) into Eq. (9.1) shows that these $2n$ F's satisfy $2n$ linear equations. Indeed, it is the power of the Fermi pseudo-potential that Schrödinger equations reduce to linear algebraic equations. It will be interesting to study the structure of these algebraic equations. Even more

generally, the pseudo-potential (9.3) at $x=0$ may be replaced by a linear superposition of a finite number of such pseudo-potentials at $x=x_1,x_2,\ldots$. The number of coefficients in the solution increases but remains finite, leading to more simultaneous algebraic equations that are still linear. The Green's functions can be treated in a very similar manner.

Needless to say, the range of integration in Eq. (9.1) for x' can be replaced by a semi-infinite or finite interval, and the $V(x,x')$ may contain additional terms such as those from step potentials. A more interesting problem is to apply the Fermi pseudo-potentials to first-order differential equations.

In summary, the theory of the Fermi pseudo-potential in one dimension has been worked out here together with the simplest nontrivial application to a problem of current interest.

APPENDIX A: SOLUTION FOR EQUATION (3.13)

A possible way to solve Eq. (3.13) for $F(\kappa)$ is as follows. Because of the exponential function in the last term, let

$$x=e^{F(\kappa)} \tag{A1}$$

and

$$y=\ln\kappa. \tag{A2}$$

[This x of Eq. (A1) of course has nothing to do with the space variable in the Schrödinger equation (1.1), for example.] In view of Eq. (3.3), Eq. (3.13) is translationally invariant in y. It is therefore desirable to use x as the independent variable and y as the dependent variable, leading to a first-order ordinary differential equation for

$$z=\frac{dy}{dx}. \tag{A3}$$

This first-order equation is

$$-\frac{2}{x^2z^3}\left[x\frac{dz}{dx}+z\right]=\frac{1}{x^2z^2}-1+(c_3^2+c_2c_4)x^2. \tag{A4}$$

Let

$$u=\frac{1}{x^3z^2}. \tag{A5}$$

Then, after some algebra,

$$\frac{du}{dx}=-\frac{1}{x^2}+(c_3^2+c_2c_4). \tag{A6}$$

Integration yields

$$u=\frac{1}{x}+2c_1+(c_3^2+c_2c_4)x, \tag{A7}$$

where c_1 is the fourth arbitrary constant of integration. The expression for z follows from Eqs. (A5) and (A7):

$$z=\pm x^{-1}[1+2c_1x+(c_3^2+c_2c_4)x^2]^{-1/2}, \tag{A8}$$

where the $\pm$ sign comes from taking the square root of z^2. It is, of course, related to the fact that every term in Eq. (A4) is even in z. In the following, there are many $\pm$ and $\mp$ signs; it is to be understood that these signs are used as a shorthand for two equations, one with the upper sign everywhere and a second one with the lower sign everywhere.

From Eqs. (A3) and (A8), y is given by

$$y=\mp\int\frac{dx'}{\sqrt{(c_3^2+c_2c_4)+2c_1x'+x'^2}}, \tag{A9}$$

where $x'=1/x$. It is fortunate that this integral is elementary. For definiteness, consider the case

$$c_3^2+c_2c_4-c_1^2>0. \tag{A10}$$

In this case, the explicit integration of the right-hand side of Eq. (A9) gives

$$y=\mp\left[\sinh^{-1}\frac{1+c_1x}{\sqrt{c_3^2+c_2c_4-c_1^2}x}+\text{const}\right]. \tag{A11}$$

The rest of the calculation is straightforward although lengthy, and the results are

$$f_1(\kappa)=\frac{-\sqrt{c_3^2+c_2c_4-c_1^2}[c_0\kappa+(c_0\kappa)^{-1}]\mp 2c_3}{\sqrt{c_3^2+c_2c_4-c_1^2}[c_0\kappa-(c_0\kappa)^{-1}]\pm 2c_1}, \tag{A12}$$

$$f_2(\kappa)=1\mp\frac{2c_2}{\sqrt{c_3^2+c_2c_4-c_1^2}[c_0\kappa-(c_0\kappa)^{-1}]\pm 2c_1}, \tag{A13}$$

$$f_3(\kappa)=\frac{-\sqrt{c_3^2+c_2c_4-c_1^2}[c_0\kappa+(c_0\kappa)^{-1}]\pm 2c_3}{\sqrt{c_3^2+c_2c_4-c_1^2}[c_0\kappa-(c_0\kappa)^{-1}]\pm 2c_1}, \tag{A14}$$

$$f_4(\kappa)=1\mp\frac{2c_4}{\sqrt{c_3^2+c_2c_4-c_1^2}[c_0\kappa-(c_0\kappa)^{-1}]\pm 2c_1}. \tag{A15}$$

Since c_1, c_2, c_3 and c_4 are arbitrary constants of integration, their signs can be changed simultaneously. This change then removes all the $\pm$ and $\mp$ signs, and Eqs. (A12)–(A15) reduce to Eqs. (3.14).

The other case, where $c_3^2+c_2c_4-c_1^2<0$, can be treated in an entirely similar manner, leading to Eq. (3.16).

APPENDIX B: DERIVATION OF EQUATION (7.2)

In this Appendix B, the reasoning is given that leads to Eq. (7.2).

Just as the Ψ^{in} of Eq. (7.1) contains information about the initial state of the quantum memory and the behavior of the incoming wave ψ^{in} before scattering, the Ψ^{out} contains information about the final state of the quantum memory and the behavior of the outgoing wave after scattering.

Later the outgoing wave moves away from the memory and the information about this outgoing wave is no longer available. This means that the final state of the memory is given by Ψ^{out} *averaged* over this outgoing wave. This average can be written schematically as

$$M = \int \Psi^{\text{out}} \Psi^{\text{out}\dagger}. \tag{B1}$$

This M is the density matrix for the quantum memory. Here the $\int$ indicates integration and summation over all degrees of freedom associated with the outgoing wave or particle, but not those of the quantum memory. The corresponding differential symbol is omitted: It is $d^3\mathbf{r}$ if the wave is described by the three-dimensional Schrödinger equation; it is $d^3\mathbf{r}$ together with a summation over the spin in the case of the Dirac equation; and it is a functional differential such as $\mathcal{D}A_\mu$ in the context of quantum field theory.

In order for the quantum memory to function, the final state must be a pure state $\Sigma_j a_j^{\text{out}}|j\rangle$, just like the initial state. Therefore, the above M must also be given by

$$M = \sum_j a_j^{\text{out}}|j\rangle \sum_i a_i^{\text{out}*}\langle i|. \tag{B2}$$

Equating the two formulas for M gives

$$\sum_j a_j^{\text{out}}|j\rangle \sum_i a_i^{\text{out}*}\langle i| = \int \Psi^{\text{out}} \Psi^{\text{out}\dagger}. \tag{B3}$$

It remains to derive Eq. (7.2) from Eq. (B3).

Since the $|j\rangle$ form a complete set, Ψ^{out} can always be written in the form

$$\Psi^{\text{out}} = \sum_j |j\rangle \psi_j^{\text{out}}. \tag{B4}$$

The substitution of Eq. (B4) into Eq. (B3) gives

$$a_j^{\text{out}} a_i^{\text{out}*} = \int \psi_j^{\text{out}} \psi_i^{\text{out}\dagger} \tag{B5}$$

for all i and j. For $i \neq j$, define the integral

$$I_{ji} = \int (a_i^{\text{out}} \psi_j^{\text{out}} - a_j^{\text{out}} \psi_i^{\text{out}})(a_i^{\text{out}*} \psi_j^{\text{out}\dagger} - a_j^{\text{out}*} \psi_i^{\text{out}\dagger}). \tag{B6}$$

This I_{ji} is non-negative, and is zero only if

$$a_i^{\text{out}} \psi_j^{\text{out}} - a_j^{\text{out}} \psi_i^{\text{out}} = 0. \tag{B7}$$

But the substitution of Eq. (B5) into Eq. (B6) gives immediately that

$$I_{ji} = 0. \tag{B8}$$

Thus, Eq. (B7) holds for all i and j.

The desired Eq. (7.2) is just Eq. (B4) with Eq. (B7).

(Received 6 May 2002; accepted 9 August 2002)

We consider the problem of consistence between the Bethe ansatz (BA) wave function and the multiparticle (more than two) scattering in one-dimensional δ-function interacting SU(4) fermions, which the approach of BA does not explicitly take into account. We find the scattering conditions of three and four particles located at the same position and show that the conditions can be fulfilled by the two-particle connection conditions of the BA wave function. So the definition of the BA wave function can be exactly extended to those cases with multiple occupancies. The inconsistence between the BA and multiparticle interacting on a same site in the degenerate Hubbard model, which makes the BA fail for the model, is shown to vanish in the limit of small site spacing. A correspondence relation of the BA equation and SU(4) symmetry of the system is also indicated for the fermions. The degeneracy of state with BA eigenenergy is given. Singlet lies in the case when there are equal numbers of particles in each inner component. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1515380]

I. INTRODUCTION

Since the Bethe ansatz (BA) approach was proposed to solve exactly the Heisenberg model,[1] it has been applied to many integrable systems such as one-dimensional δ-function interacting bosons[2,3] and spin-1/2 fermions,[4] Hubbard model,[5] Kondo model,[6] spin ladder,[7] etc., and recently there has been much interest in extending the BA to the study of degenerate electrons systems.[8–14] As is well known, the coordinate BA wave functions for N-particle systems are defined on separated regions denoted by $x_{Q_1} < \cdots < x_{Q_N}$ where Q is a permutation of the particles and x_{Q_i} is the coordinate of the Q_ith particle, the connection boundaries between two adjacent regions are those cases in which two (and no more than two) particles interact at the same position, and the two-particle scattering matrices solve the boundary conditions. The matrices transferring amplitudes in the BA wave function from one region to another factorize into products of two-particle S matrices. The diagonalization of the N-particle transfer matrices with periodic conditions leads to the BA equations that determine the whole solutions. So the original BA, as a matter of fact, does not involve the boundaries with more than two particles scattering at the same position or take into account the corresponding scattering conditions. If the scattering conditions of multiple occupations, which are required by models of the degenerate or multicomponent particle systems, cannot be consistently met by the BA wave function, the BA wave function will not be the solutions of the systems. Such a problem of consistence has been encountered in the degenerate Hubbard model, the BA fails to solve the model at configurations with more than two particles on one site,[10] and the theoretical work in the framework of the BA for degenerate Hubbard model has

a)Electronic mail: zjying@zimp.zju.edu.cn

been based on the exclusion of such multiply occupied configurations.[11–14] Therefore, whether the BA wave functions are exactly valid for the degenerate systems is still unconfirmed if the consistency between the BA wave function and multiparticle scattering conditions has not been definitely verified.

In the present paper we shall investigate explicitly the problem of consistence between the BA and the multiparticle scattering conditions for one-dimensional δ-function interacting SU(4) fermions which is a spatially continuous system instead of a lattice model. We work out explicitly the scattering boundary conditions of three and four particles located at the same spatial point. We prove that the multiparticle scattering conditions can be fulfilled by the two-particle connection conditions of the BA wave function. Therefore we can extend exactly the definition of the BA wave function to the configurations with multiple occupancies and, unlike in lattice models, the BA is valid for the spatially continuous model without the exclusion of more than two particles interacting at the same position. The inconsistency in the BA for the degenerate Hubbard model is shown to vanish in the limit of small site spacing. An interesting correspondence between the SU(4) symmetry and the BA equation is also pointed out for the δ-function interacting fermions. The states relating to a BA eigenenergy are degenerate, and the degeneracy can be calculated in terms of the highest weight vector of the corresponding SU(4) multiplet.

II. TWO-PARTICLE SCATTERING AND THE BETHE ANSATZ WAVE FUNCTION

The Schrödinger equation of the N-fermion system we shall consider reads

$$\left(-\frac{1}{2}\sum_{i}^{N}\frac{\partial^2}{\partial x_i^2} + c\sum_{i<j}\delta(x_i - x_j)\right)\psi = E\psi. \tag{1}$$

We define the BA wave function in the form of

$$\psi^{(Q)}_{a_1\cdots\ a_N}(x_1,\cdots,x_N) = \sum_{P\in S_N} A^{(Q)}_{a_1\cdots\ a_N}(k_{P_1}\cdots\ k_{P_N})e^{i\Sigma_j k_{P_j}x_j}, \tag{2}$$

where a_j labels the four components of the jth fermions. The inner degree of freedom can be spin–orbital double. Other forms of BA wave function are equivalent, our further proof holds as long as the solution is BA wave function. The BA wave function is defined in the region sector

$$R_Q : x_{Q_1} < \cdots < x_{Q_N}.$$

The wave function (2) surely solves the eigenequation

$$-\frac{1}{2}\sum_{i}^{N}\frac{\partial^2}{\partial x_i^2}\psi^{(Q)} = E_{\mathrm{BA}}\psi^{(Q)} \tag{3}$$

in R_Q with the eigenenergy

$$E_{\mathrm{BA}} = \frac{1}{2}\sum_{i}^{N} k_i^2 . \tag{4}$$

Let $(Q_1\cdots ij\cdots Q_N)$ denote a sector with $Q_r = i$ and $Q_{r+1} = j$ for some r. The two-particle connection condition across the barrier $x_i = x_j$ is given by

$$\left(\frac{\partial}{\partial x_i} - \frac{\partial}{\partial x_j}\right)\psi^{(Q_1\cdots ji\cdots Q_N)}_{a_1\cdots\ a_N}\Big|_{x_j = x_i -} - \left(\frac{\partial}{\partial x_i} - \frac{\partial}{\partial x_j}\right)\psi^{(Q_1\cdots ij\cdots Q_N)}_{a_1\cdots\ a_N}\Big|_{x_j = x_i +} = 2c\,\psi^{(Q_1\cdots ij\cdots Q_N)}_{a_1\cdots\ a_N}\Big|_{x_i = x_j}, \tag{5}$$

which can be obtained by integrating of the eigenequation over a Gauss box at the hyperplane $x_i=x_j$. And on the right-hand side of Eq. (5) the $\psi^{(Q_1\cdots ij\cdots Q_N)}|_{x_j=x_i}$ can be replaced by $\psi^{(Q_1\cdots ji\cdots Q_N)}|_{x_j=x_i}$ because of the continuity of the wave function. Combining the above condition with the uniqueness of the wave function on the two-particle connection boundary, one can find the two-particle S-matrix,[4]

$$S^{ij}=\frac{(k_{P_i}-k_{P_j})I^{ij}+icP^{ij}}{(k_{P_i}-k_{P_j})+ic}, \quad S^{ij}A^{(Q_1\cdots\ ij\cdots\ Q_N)}_{(k_{P_1}\cdots\ k_{P_i}\cdots\ k_{P_j}\cdots\ k_{P_N})}=A^{(Q_1\cdots\ ji\cdots\ Q_N)}_{(k_{P_1}\cdots\ k_{P_i}\cdots\ k_{P_j}\cdots\ k_{P_N})}, \tag{6}$$

where P^{ij} exchanges inner components a_i,a_j and

$$\begin{aligned}
&P^{ij}A^{(Q_1\cdots\ ij\cdots\ Q_N)}_{a_1\cdots\ a_i\cdots\ a_j\cdots\ a_N}(k_{P_1}\cdots\ k_{P_i}\cdots\ k_{P_j}\cdots\ k_{P_N})\\
&\quad=A^{(Q_1\cdots\ ij\cdots\ Q_N)}_{a_1\cdots\ a_j\cdots\ a_i\cdots\ a_N}(k_{P_1}\cdots\ k_{P_i}\cdots\ k_{P_j}\cdots\ k_{P_N})\\
&\quad=-A^{(Q_1\cdots\ ji\cdots\ Q_N)}_{a_1\cdots\ a_i\cdots\ a_j\cdots\ a_N}(k_{P_1}\cdots\ k_{P_j}\cdots\ k_{P_i}\cdots\ k_{P_N}),
\end{aligned}$$

where the minus sign in the second equation comes from the antisymmetry of fermions.

It should be noted that $\psi^{(Q_1\cdots ij\cdots Q_N)}|_{x_j=x_i-}$ and $\psi^{(Q_1\cdots ji\cdots Q_N)}|_{x_j=x_i+}$ in (5) are, respectively, in two regions $(Q_1\cdots ij\cdots Q_N)$ and $(Q_1\cdots ji\cdots Q_N)$ which are neighbor sectors. The transfer matrices for regions not adjacent are products of the two-particle S-matrices. The S-matrices satisfy the Yang–Baxter relations.[4] The diagonalization of the N-particle transfer matrices combined with periodic conditions

$$\psi(\cdots\ x_j\ \cdots\ )=\psi(\cdots\ x_j+L\cdots\ )$$

results in the BA equations by means of the methods in Refs. 15 and 16

$$\begin{aligned}
e^{ik_jL}&=\prod_{\alpha=1}^{M}\frac{k_j-\lambda_\alpha+ic/2}{k_j-\lambda_\alpha-ic/2},\\
1&=-\prod_{j=1}^{N}\frac{\lambda_\alpha-k_j-ic/2}{\lambda_\alpha-k_j+ic/2}\prod_{\alpha'=1}^{M}\frac{\lambda_\alpha-\lambda_{\alpha'}+ic}{\lambda_\alpha-\lambda_{\alpha'}-ic}\prod_{\beta=1}^{M'}\frac{\lambda_\alpha-\mu_\beta-ic/2}{\lambda_\alpha-\mu_\beta+ic/2},\\
1&=-\prod_{\alpha=1}^{M}\frac{\mu_\beta-\lambda_\alpha-ic/2}{\mu_\beta-\lambda_\alpha+ic/2}\prod_{\beta'=1}^{M'}\frac{\mu_\beta-\mu_{\beta'}+ic}{\mu_\beta-\mu_{\beta'}-ic}\prod_{\gamma=1}^{M''}\frac{\mu_\beta-\nu_\gamma-ic/2}{\mu_\beta-\nu_\gamma+ic/2},\\
1&=-\prod_{\beta=1}^{M'}\frac{\nu_\gamma-\mu_\beta-ic/2}{\nu_\gamma-\mu_\beta+ic/2}\prod_{\gamma'=1}^{M''}\frac{\nu_\gamma-\nu_{\gamma'}+ic}{\nu_\gamma-\nu_{\gamma'}-ic},
\end{aligned} \tag{7}$$

which determine the whole solution in the BA approach. The total particle numbers N_1,N_2,N_3,N_4 with inner components 1,2,3,4 are, respectively,

$$\begin{aligned}
&N_1=N-M, \quad N_2=M-M',\\
&N_3=M'-M'', \quad N_4=M''.
\end{aligned} \tag{8}$$

Here we do not intend to discuss the corresponding ground states, excitations or thermodynamics. In the following we shall consider the relation of the BA wave function and the system symmetry as well as the state's degeneracy.

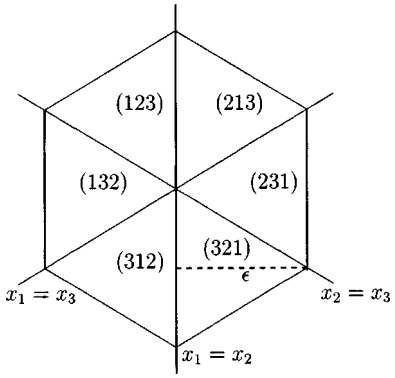

FIG. 1. A cross section of the hexagonal prism in the three-dimensional subspace of x_1, x_2, and x_3. The center axis of the prism is along the intersecting line $x_1=x_2=x_3$, and labels of the three interacting particles ijk have been set to be 123.

As one can see from the above procedure, the BA treatment is built up on the basis of solving the separate noninteracting regions R_Q and the two-particle boundaries which are connections of *two* neighbor regions. The BA indeed does not take into account the multiple-occupancy (more than two) boundaries which are joint boundary of *three* or *four* regions, and the corresponding multiparticle scattering conditions become additional ones; what these conditions are is not explicit and whether they are solved by BA remains to be answered. In fact, it is just by examining this kind of multiparticle scattering that Choy and Haldane found the failure of the BA in the degenerate Hubbard model.[10] In the following we shall explicitly investigate the consistence between the BA and those multiparticle scattering out of the consideration of the BA for the four-component fermions (1).

III. THREE-PARTICLE SCATTERING

With the help of the continuity of the wave function at two-particle scattering boundary, which has been used in the Bethe ansatz, it is easy to prove the single valueness of the wave function for three and four particles at the same point. Without guarantee of the wave function single valueness, further discussion on the problem of consistence would be unnecessary since it had been inconsistent here.

To investigate the consistence between the BA and the three-particle scattering we have to obtain the corresponding scattering boundary condition which is not obvious or explicit to write out. Let us consider three particles i, j, and k at the boundary $x_i=x_j=x_k$. We integrate the eigenequation (1) over an arbitrarily shaped volume through which the intersecting line $x_i=x_j=x_k$ is located in the three-dimensional subspace of x_i, x_j, and x_k. The arbitrarily shaped volume can be cut into an ϵ-sized hexagonal prism of which a cross section is shown in Fig. 1. The integration of the eigenequation over the cutoff part cancels automatically, which is a natural result of (3) and (5), respectively, in the sectors and on the two-particle connecting hyperplanes. Therefore, it's sufficient to consider only the prism left.

Set ϵ to be infinitesimal, carry out the expansion of the Gaussian integral in orders of ϵ and keep the lowest order, we find the three-particle condition to be

$$\left(\frac{\partial}{\partial x_1}-\frac{\partial}{\partial x_2}\right)\left(\psi^{(Q_1\cdots 231\cdots Q_N)}-\psi^{(Q_1\cdots 132\cdots Q_N)}\right)\Big|_{x_1=x_2=x_3}+\left(\frac{\partial}{\partial x_2}-\frac{\partial}{\partial x_3}\right)\left(\psi^{(Q_1\cdots 312\cdots Q_N)}\right.$$
$$\left.-\psi^{(Q_1\cdots 213\cdots Q_N)}\right)\Big|_{x_1=x_2=x_3}+\left(\frac{\partial}{\partial x_3}-\frac{\partial}{\partial x_1}\right)\left(\psi^{(Q_1\cdots 123\cdots Q_N)}-\psi^{(Q_1\cdots 321\cdots Q_N)}\right)\Big|_{x_1=x_2=x_3}$$
$$=12c\,\psi^{(Q_1\cdots 123\cdots Q_N)}\big|_{x_1=x_2=x_3}, \tag{9}$$

where we have set the three particles to be 123 for the sake of clarity, and the infinitesimal notations as in $\psi^{(Q_1\cdots 231\cdots Q_N)}|_{x_1=x_3^+,x_2=x_3^-}$ have been dropped since it has been indicated in the corresponding label Q of region sector. Also on the right-hand side of the above relations, $\psi^{(Q_1\cdots 123\cdots Q_N)}|_{x_1=x_2=x_3}$ can be replaced by wave function with other permutation of the particles 123, while the positions of other particles remain unchanged. On the left-hand side of (9), it should be noted that the pairs of wave functions in a bracket are not in neighbor sectors as those of Eq. (5).

We find the condition (9) can be satisfied in terms of the two-particle connection condition (5). As one knows in the BA, the two-particle S-matrices provide to cancel the amplitudes of a same exponential $\exp(i\Sigma_j k_{P_j} x_j)$, the amplitudes $A^{(Q)}_{k_{P_1}\cdots\ k_{P_N}}$ are independent of the particles coordinates, so it does not affect the cancellation of the amplitudes in (5) when we set the position of a third adjacent particle to be the same as the two particles on the connection boundary and keep all the permutation notation Q's in the amplitudes unchanged. Hence, Eq. (5) still holds at $x_{Q_1}<\cdots<x_i=x_j=x_k<\cdots<x_{Q_N}$,

$$\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}\right)(\psi^{(Q_1\cdots jik\cdots Q_N)}-\psi^{(Q_1\cdots ijk\cdots Q_N)})|_{x_i=x_j=x_k}=2c\,\psi^{(Q_1\cdots ijk\cdots Q_N)}|_{x_i=x_j=x_k},$$
$$\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}\right)(\psi^{(Q_1\cdots kji\cdots Q_N)}-\psi^{(Q_1\cdots kij\cdots Q_N)})_{x_i=x_j=x_k}=2c\,\psi^{(Q_1\cdots kij\cdots Q_N)}|_{x_i=x_j=x_k}. \tag{10}$$

Also note that the wave functions on the left-hand sides are defined on neighbor regions as in (5). We split the differential operation $\partial/\partial x_1-\partial/\partial x_2$ to be $(\partial/\partial x_1-\partial/\partial x_3)+(\partial/\partial x_3-\partial/\partial x_2)$ and similarly for others, thus the left-hand side of (9) becomes

$$\begin{aligned}&\left(\left(\frac{\partial}{\partial x_1}-\frac{\partial}{\partial x_3}\right)+\left(\frac{\partial}{\partial x_3}-\frac{\partial}{\partial x_2}\right)\right)(\psi^{(Q_1\cdots 231\cdots Q_N)}-\psi^{(Q_1\cdots 132\cdots Q_N)})|_{x_1=x_2=x_3}\\&\quad+\left(\left(\frac{\partial}{\partial x_2}-\frac{\partial}{\partial x_1}\right)+\left(\frac{\partial}{\partial x_1}-\frac{\partial}{\partial x_3}\right)\right)(\psi^{(Q_1\cdots 312\cdots Q_N)}-\psi^{(Q_1\cdots 213\cdots Q_N)})|_{x_1=x_2=x_3}\\&\quad+\left(\left(\frac{\partial}{\partial x_3}-\frac{\partial}{\partial x_2}\right)+\left(\frac{\partial}{\partial x_2}-\frac{\partial}{\partial x_1}\right)\right)(\psi^{(Q_1\cdots 123\cdots Q_N)}-\psi^{(Q_1\cdots 321\cdots Q_N)})|_{x_1=x_2=x_3}\end{aligned}$$

which, as a result of (10), equals to $12c\,\psi^{(Q)}|_{x_1=x_2=x_3}$, exactly the right-hand side of (9). Therefore we have proved that the scattering condition of three particles at a same position can be fulfilled by the two-particle connection conditions in the BA solution.

IV. FOUR-PARTICLE SCATTERING

Now let us consider the case of four particles interacting at the same point. For simplicity we omit the notations of other particles. Similar to the three-particle scattering, it is also sufficient to calculate the integral of the eigenequation over an ϵ-sized Gaussian box at the axis $x_1=x_2=x_3=x_4$. A vector in the sector of (1234) can be built on another set of orthonormal basis

$$\mathbf{r}_{1234}\equiv x_1\mathbf{e}_1+x_2\mathbf{e}_2+x_3\mathbf{e}_3+x_4\mathbf{e}_4=\omega\alpha_{1234}+h\gamma+y\beta_{1234}+y'\beta'_{1234}, \tag{11}$$

where the basis vectors are

$$\alpha_{1234}=-\frac{3\mathbf{e}_1+\mathbf{e}_2-\mathbf{e}_3-3\mathbf{e}_4}{\sqrt{20}},\quad \gamma=\frac{\mathbf{e}_1+\mathbf{e}_2+\mathbf{e}_3+\mathbf{e}_4}{2},$$
$$\beta_{1234}=\frac{\mathbf{e}_1-\mathbf{e}_2-\mathbf{e}_3+\mathbf{e}_4}{2},\quad \beta'_{1234}=\frac{\mathbf{e}_1-3\mathbf{e}_2+3\mathbf{e}_3-\mathbf{e}_4}{\sqrt{20}}. \tag{12}$$

γ is the direction vector along the center axis $x_1=x_2=x_3=x_4$. The connecting boundary $x_i=x_j$ can be expressed in terms of α_{1234}, γ, β_{1234}, and β'_{1234} according to the above relations. In the (1234) sector the inwards normals of the intersecting hyperplanes $x_1=x_2$, $x_2=x_3$ and $x_3=x_4$ are, respectively, $\mathbf{n}_{21}=\mathbf{e}_2-\mathbf{e}_1$, $\mathbf{n}_{32}=\mathbf{e}_3-\mathbf{e}_2$, and $\mathbf{n}_{43}=\mathbf{e}_4-\mathbf{e}_3$. It is easy to see $\alpha_{1234}\cdot\mathbf{n}_{21}=\alpha_{1234}\cdot\mathbf{n}_{32}=\alpha_{1234}\cdot\mathbf{n}_{43}$. Setting $\omega=\epsilon$, we have a hyperplane which can be the side surface of the Gaussian box in the (1234) region, α_{1234} is the outwards normal direction vector. Other sectors are similar with the subscripts permuted correspondingly. We also set the size parameter ϵ to be infinitesimal, carry out the expansion in the orders of ϵ and keep the lowest order in the integration of the eigenequation. After a careful calculation we find the scattering condition of four particles at one point to be

$$-\frac{1}{2}\sum_{Q\in S_4}\left(3\frac{\partial}{\partial x_{Q_1}}+\frac{\partial}{\partial x_{Q_2}}-\frac{\partial}{\partial x_{Q_3}}-3\frac{\partial}{\partial x_{Q_4}}\right)\psi^{(Q)}(x,x,x,x)=120c\,\psi(x,x,x,x). \tag{13}$$

As we show below, the above four-particle scattering condition is also fulfilled by the two-particle conditions.

Relations in (10) are similarly extended to

$$\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}\right)(\psi^{(Q_1\cdots jikl\cdots Q_N)}-\psi^{(Q_1\cdots ijkl\cdots Q_N)})|_{x_i=x_j=x_k=x_l}=2c\,\psi^{(Q_1\cdots ijkl\cdots Q_N)}|_{x_i=x_j=x_k=x_l},$$
$$\left(\frac{\partial}{\partial x_j}-\frac{\partial}{\partial x_k}\right)(\psi^{(Q_1\cdots ikjl\cdots Q_N)}-\psi^{(Q_1\cdots ijkl\cdots Q_N)})|_{x_i=x_j=x_k=x_l}=2c\,\psi^{(Q_1\cdots ijkl\cdots Q_N)}|_{x_i=x_j=x_k=x_l}, \tag{14}$$
$$\left(\frac{\partial}{\partial x_k}-\frac{\partial}{\partial x_l}\right)(\psi^{(Q_1\cdots ijlk\cdots Q_N)}-\psi^{(Q_1\cdots ijkl\cdots Q_N)})|_{x_i=x_j=x_k=x_l}=2c\,\psi^{(Q_1\cdots ijkl\cdots Q_N)}|_{x_i=x_j=x_k=x_l}.$$

And by means of the following trick:

$$\left(3\frac{\partial}{\partial x_{Q_1}}+\frac{\partial}{\partial x_{Q_2}}-\frac{\partial}{\partial x_{Q_3}}-3\frac{\partial}{\partial x_{Q_4}}\right)=\left(3\left(\frac{\partial}{\partial x_{Q_1}}-\frac{\partial}{\partial x_{Q_2}}\right)+4\left(\frac{\partial}{\partial x_{Q_2}}-\frac{\partial}{\partial x_{Q_3}}\right)+3\left(\frac{\partial}{\partial x_{Q_3}}-\frac{\partial}{\partial x_{Q_4}}\right)\right), \tag{15}$$

the differential operations are changed to be of neighbor particles pairs on the left-hand side of (13). To use (14) we note the relation

$$\sum_{Q\in S_4}\left(\frac{\partial}{\partial x_{Q_1}}-\frac{\partial}{\partial x_{Q_2}}\right)\psi^{(Q)}(x,x,x,x)=\frac{1}{2}\sum_{Q\in S_4}\left(\frac{\partial}{\partial x_{Q_1}}-\frac{\partial}{\partial x_{Q_2}}\right)(\psi^{(Q)}(x,x,x,x)-\psi^{(Q')}(x,x,x,x)), \tag{16}$$

where $Q'=(Q_2Q_1Q_3Q_4)$, and the similar relations for the cases of $(\partial/\partial x_{Q_2}-\partial/\partial x_{Q_3})$ and $(\partial/\partial x_{Q_3}-\partial/\partial x_{Q_4})$ with Q' replaced, respectively, by $(Q_1Q_3Q_2Q_4)$ and $(Q_1Q_2Q_4Q_3)$. Applying (14)–(16), we find the four-particle condition (13) is also satisfied. The general case for any four scattering particles among the total N particles can be directly generalized from the results we have obtained.

The configurations with more than four particles at one point are excluded by the Pauli principle (extended to four components), the antisymmetric wave function vanishes in such cases. Thus we have covered all kinds of occupancies and explicitly proven the consistence between the BA and the multiparticle scattering boundary conditions.

V. NARROW-SITES LIMITING IN THE DEGENERATE HUBBARD MODEL

In the above sections we have proven explicitly the consistence between the multiparticle scattering and the BA solution in spatially continuous case. Now let us turn to the lattice case and investigate the limiting process of small site spacing in the Hubbard model. As one knows the Hubbard model, in the limit of small site distance d, approaches to the model of electrons with δ-function interaction which is spatially continuous. The single-band Hubbard model was solved by the SU(2) BA.[5] But the direct generalization of SU(2) BA solution of the single-band Hubbard model to the degenerate SU(N) case for the degenerate Hubbard model fails due to the multiparticle same-site interacting case. In Ref. 10 it is found that there appears to be an unhermition extra interacting term for three bosons occupying the same site in the BA wave function which was proposed with an attempt to solve the boson Hubbard model. This unhermition term extra to the Hubbard on-site interaction $3U$, with the form of

$$\frac{U^2/t}{\cos(k_1+k_2)\cos(k_2+k_3)\cos(k_3+k_1)}, \tag{17}$$

where U is the Hubbard on-site interaction and t is the hopping constant and k_1, k_2, and k_3 are momenta of the interacting bosons, breaks the validity of the BA for boson Hubbard model. The similar thing will happen for degenerate electrons or fermions and the inconsistent extra term has the same form as (17) except a sign difference. According to our explicit proof of consistence between the BA and the multiparticle interacting for δ-function interacting fermions, the inconsistent term should come to vanish in the limit process of site distance going to zero, since the Hubbard model approaches to the model of electrons with δ-function interaction. Let us pick up the site distance d which is usually taken to be unit, and the S-matrix for the Hubbard model is

$$S^{ij}=\frac{(\sin k_s d-\sin k_t d)I^{ij}+iU/2tP^{ij}}{(\sin k_s d-\sin k_t d)+iU/2t} \tag{18}$$

where the notations of P_s, P_t, and P^{ij} are the same as in (6) and $\sin k_s d$ is originated from the discreteness in space coordinate for lattice sites. The above S-matrix becomes

$$\frac{(k_s d-k_t d)I^{ij}+iU/2tP^{ij}}{(k_s d-k_t d)+iU/2t}=\frac{(k_s-k_t)I^{ij}+iU/2tdP^{ij}}{(k_s-k_t)+iU/2td} \tag{19}$$

for small d.

One may mention the large momentum case in which $k_j d$ may not be small. This is true indeed if we have definite total site number. But the problem is naturally solved when we take into account the increasing site number in the limiting process. In fact, the one-dimensional space of the fermions should have a finite length L. So the total site number $N_s=L/d$ should increase with the decreasing d in the limiting process. The momenta are inversely proportional to the site number and site spacing

$$k_j \propto \frac{2\pi}{N_s d}$$

and

$$k_j d \propto \frac{2\pi}{N_s} = \frac{2\pi d}{L} \to 0, \tag{20}$$

where the space length L is definite constant. Thus we still have the limiting result (19).

Besides L, another important parameter

$$c = U/2td$$

should remain to be constant as $d \to 0$ and the S-matrix (19) becomes the same as the S-matrix (6) of δ-function interacting fermions. So we have

$$\frac{U}{t} = 2cd, \tag{21}$$

which means that U/t is proportional to the decreasing site distance d. Therefore the extra term (17) will vanish with the d and inconsistency arising in the lattice case diminishes and disappears in the limiting process to spatially continuous case.

VI. SU(4) SYMMETRY OF THE SYSTEM

Since we have proven that the BA is exactly valid for all occupancies in the four-component fermions with δ-function interactions, we would like to mention an interesting correspondence between the BA equations and system symmetry and then consider the degeneracy of the eigenstates. The system of the four-component fermions, with the second-quantized Hamiltonian

$$H = -\frac{1}{2}\int dx \sum_a \psi_a^*(x)\frac{\partial^2}{\partial x^2}\psi_a(x) + \frac{c}{2}\int dx \sum_{a\neq a'} n_a(x) n_{a'}(x),$$

where $\psi_a^*(x)$ creates a fermion with internal component a at position x and $n_a(x) = \psi_a^*(x)\psi_a(x)$ is the particle number operator, possesses the SU(4) symmetry

$$\mathrm{SU}(4): \{D_m, \quad E_{aa'} | m = 1,2,3; \;\; a, a' = 1,2,3,4, \;\; a \neq a'\}, \tag{22}$$

where the generators are

$$E_{aa'} = \int dx\, \psi_a^*(x)\psi_{a'}(x),$$

$$D_m = N_m - N_{m+1}, \quad N_m = \int dx \psi_m^*(x)\psi_{m'}(x),$$

and a, m label the inner components. The commutation relations are

$$\begin{aligned} [E_{ss'}, E_{tt'}] &= \delta_{s',t}E_{st'} - \delta_{s,t'}E_{ts'}, \\ [D_m, E_{ss'}] &= (\delta_{m,s} - \delta_{m,s'} - \delta_{m+1,s} + \delta_{m+1,s'})E_{ss'} \end{aligned} \tag{23}$$

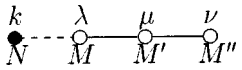
and $\{D_m\}$ forms the commuting Cardan subalgebra of rank 3. As the system is spatially continuous instead of lattice, the symmetry involving pairing creation and annihilation operators as in the simple Hubbard model[17] and spin–orbital case[18,19] does not exist.

The BA equations (7) rewritten as

$$e^{ik_j L} = \prod_{\alpha=1}^{M} \Xi_{1/2}(k_j - \lambda_\alpha),$$

$$
\begin{aligned}
1 &= -\prod_{j=1}^{N} \Xi_{-1/2}(\lambda_\alpha - k_j) \prod_{\alpha'=1}^{M} \Xi_1(\lambda_\alpha - \lambda_{\alpha'}) \prod_{\beta=1}^{M'} \Xi_{-1/2}(\lambda_\alpha - \mu_\beta), \\
1 &= -\prod_{\alpha=1}^{M} \Xi_{-1/2}(\mu_\beta - \lambda_\alpha) \prod_{\beta'=1}^{M'} \Xi_1(\mu_\beta - \mu_{\beta'}) \prod_{\gamma=1}^{M''} \Xi_{-1/2}(\mu_\beta - \nu_\gamma), \\
1 &= -\prod_{\beta=1}^{M'} \Xi_{-1/2}(\nu_\gamma - \mu_\beta) \prod_{\gamma'=1}^{M''} \Xi_{-1/2}(\nu_\gamma - \nu_{\gamma'}),
\end{aligned}
\tag{24}
$$

where $\Xi_n(x) = (x + inc)/(x - inc)$ is easy to remember by means of the Dynkin diagram of A_3 Lie algebra



where the dark dot is added to represent the charge rapidity k_j which takes an angle of 120° relative to the first simple root r_1. The subscripts of $\Xi_n(x)$ in the above form of BA equations correspond, respectively, to the covariant components of the simple roots which are chosen as nonorthogonal basis, $r_1 = (-1/2, 1, -1/2, 0)$, $r_2 = (0, -1/2, 1, -1/2)$, $r_3 = (0, 0, -1/2, 1)$. This connection exists because the system has the above SU(4) symmetry, the generators of which constitute an A_3 Lie algebra. Such a connection was noticed for correlated electrons with twofold orbital degeneracy in SU(4) lattice case[14] and the electrons with spin–exchange interactions in $\mathrm{SU}(2) \times \mathrm{SU}(2)$ case.[20]

The BA eigenstates are the SU(4) highest weight state. Let us assume the highest weight is $w^h = (w_1^h, w_3^h, w_3^h)$ which labels an irreducible representation of the SU(4) group. We obtain the expression

$$
\begin{aligned}
w_1^h &= N_1 - N_2 = N - 2M + M', \\
w_2^h &= N_2 - N_3 = M - 2M' + M'', \\
w_3^h &= N_3 - N_4 = M' - 2M'',
\end{aligned}
\tag{25}
$$

from the Cartan operators and the relations (8) of N_m and M, M', M''. The lower weight states in the SU(4) representation can be obtained by the lowering operators $E_{-\alpha}$ acting on the highest weight state $|w^h\rangle = |\psi_{\mathrm{BA}}\rangle$,

$$
|w^h - \alpha\rangle = E_{-\alpha}|w^h\rangle, \tag{26}
$$

where the lowering operator $E_{-\alpha}$ is a product of the SU(4) generators $E_{ss'}$ which commute with the Hamiltonian. The obtained lower-weight states are also the eigenstates of the system

$$
H|w^h - \alpha\rangle = E_{-\alpha} H|w^h\rangle = E_{-\alpha} E_{\mathrm{BA}}|w^h\rangle = E_{\mathrm{BA}}|w^h - \alpha\rangle \tag{27}
$$

with the same eigenenergy E_{BA} as the BA solution. Therefore the state with energy E_{BA} is degenerate with degeneracy

$$
n_{w^h} = \tfrac{1}{12}(w_1^h + 1)(w_2^h + 1)(w_3^h + 1)(w_1^h + w_2^h + 2)(w_2^h + w_3^h + 2)(w_1^h + w_2^h + w_3^h + 3) \tag{28}
$$

which corresponds to the total weight number and dimension of the SU(4) representation. The only possible nondegenerate case is

$$
w_1^h = w_2^h = w_3^h = 0 \tag{29}
$$

which requires

$$M=\frac{3N}{4},\quad M'=\frac{N}{2},\quad M''=\frac{N}{4},$$

$$N_1=N_2=N_3=N_4=\frac{N}{4}, \tag{30}$$

and the total particle number N should be the integer times 4, i.e., there are an equal number of particles in each state $a=1,2,3,4$. If the condition (30) is not satisfied, all the states will be degenerate including the BA ground state.

VII. BRIEF SUMMERY

In this paper, we have worked out the boundary conditions of three and four particles interacting at the same spatial point for the δ-function interacting SU(4) fermions and shown that they can be solved by the two-particle connection boundary conditions in the BA. Therefore we have explicitly proven the consistence of the BA with the multiparticle scattering boundary conditions and that the BA is valid for all multiple occupancies. Unlike the lattice degenerate Hubbard model, the definition of the BA wave function for the spatially continuous system can be extended to those cases with more than two particles occupying the same positions. We also show that the inconsistence of BA in the degenerate Hubbard model vanishes in the limit of small-site spacing. An interesting correspondence between the BA equations and the system SU(4) symmetry is indicated. The degeneracy is generally given for the state with BA eigenenergy. Singlet exists in the case that there are equal number of particles in each inner component. Our proof for consistence of the BA and the multiparticle scattering is also valid for the δ-function interacting bosons.[2,3] In that case one needs to show the consistency for all the multiple occupancies.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 12 DECEMBER 2002

Results on the Wess–Zumino consistency condition for arbitrary Lie algebras

A. Barkallil, G. Barnich,[a] and C. Schomblond
Physique Théorique et Mathématique, Université Libre de Bruxelles, Campus Plaine C.P. 231, B-1050 Bruxelles, Belgium

(Received 30 May 2002; accepted 8 August 2002)

The so-called covariant Poincaré lemma on the induced cohomology of the space–time exterior derivative in the cohomology of the gauge part of the BRST differential is extended to cover the case of arbitrary, nonreductive Lie algebras. As a consequence, the general solution of the Wess–Zumino consistency condition with a nontrivial descent can, for arbitrary (super) Lie algebras, be computed in the small algebra of the one-form potentials, the ghosts and their exterior derivatives. For particular Lie algebras that are the semidirect sum of a semisimple Lie subalgebra with an ideal, a theorem by Hochschild and Serre is used to characterize more precisely the cohomology of the gauge part of the BRST differential in the small algebra. In the case of an Abelian ideal, this leads to a complete solution of the Wess–Zumino consistency condition in this space. As an application, the consistent deformations of $2+1$ dimensional Chern–Simons theory based on $iso(2,1)$ are rediscussed. © *2002 American Institute of Physics.*

I. INTRODUCTION

The algebraic problem that is central for the renormalization of Yang–Mills theory is the computation of $H^{0,n}(s|d)$ and $H^{1,n}(s|d)$, the cohomology of the BRST differential modulo the exterior space–time differential d in ghost number 0 and 1 in the space of fields, external sources (called antifields below) and their derivatives[1] (see also, e.g., Refs. 2–4 for reviews).

So far, local BRST cohomology groups for Yang–Mills and Chern–Simons theories have been investigated exclusively in the context of reductive Lie algebras, i.e., Lie algebras that are the direct sum of a semisimple and Abelian factors. In this case, the invariant metric used in the construction of the actions is necessarily the Killing metric for the semisimple factor (up to an overall constant), complemented by an arbitrary metric for the Abelian factors. Recently, there has been a lot of interest in nonreductive Lie algebras that nevertheless possess an invariant metric,[5] as it is then still possible to construct Wess–Zumino–Witten models and Chern–Simons and Yang–Mills theories (see Ref. 6 and references therein). In particular, the associated Yang–Mills theories have remarkable renormalization properties. This motivates the study of the local BRST cohomology groups for such theories.

An important intermediate step in this study is the computation of the local BRST cohomology $H(\gamma|d)$ of the gauge part γ of the BRST differential in the algebra $\mathcal{A}$ generated by the space–time forms, the gauge potentials, ghosts and a finite number of their derivatives. This computation in turn relies crucially on the so-called covariant Poincaré lemma.[7–9] In the reductive case, the covariant Poincaré lemma states that the cohomology $H(d,H(\gamma,\mathcal{A}))$ is generated by the invariant polynomials in the curvature two-forms F^a and invariant polynomials in the ghosts C^a. The proof of this lemma uses the fact that for reductive Lie algebras, the (Chevalley–Eilenberg) Lie algebra cohomology[10] with coefficients in a finite dimensional module V is isomorphic to the

[a]Author to whom correspondence should be addressed. Research Associate of the National Fund for Scientific Research (Belgium). Electronic mail: gbarnich@ulb.ac.be

tensor product of the invariant subspace of the module (Whitehead's theorem) and the Lie algebra cohomology with coefficients in $\mathbb{R}$, which is itself generated by the primitive elements (see, e.g., Ref. 11 and 12 and also Ref. 13). The consequence for the computation of $H(\gamma|d)$ is that all the solutions of the Wess–Zumino consistency condition[14] with a nontrivial descent can be computed in the small algebra $\mathcal{B}$ generated by the one-form potentials, the ghosts and their exterior derivatives, thus providing an a posteriori justification of the assumptions of Refs. 15–18 (see also Refs. 19–22 for related considerations).

The central result of the present article is the generalization of the covariant Poincaré lemma to arbitrary Lie algebras for which the Lie algebra cohomology is not necessarily explicitly known. In order to do so, we will use a standard decomposition according to the homogeneity in the fields. From the proof, it will also be obvious that the result extends to the case of super/graded Lie algebras.

For particular Lie algebras $\mathcal{G}$ that admit an ideal $\mathcal{J}$ such that the quotient $\mathcal{G}/\mathcal{J}$ is semisimple, we use a theorem by Hochschild and Serre[23] that states that the Lie algebra cohomology of $\mathcal{G}$ with coefficients in V reduces to the tensor product of the Lie algebra cohomology of the semisimple factor $\mathcal{G}/\mathcal{J}$ with coefficients $\mathbb{R}$ and the invariant cohomology of the ideal $\mathcal{J}$ with coefficients in V. As this result is not as widely known as the standard results on reductive Lie algebra cohomology, we will rederive it using ''ghost'' language, i.e., by writing the cochains with coefficients in V as polynomials in the Grassmann odd generators C^a with coefficients in V and by writing the Chevalley–Eilenberg differential as a first order differential operator acting in this space. As a direct application, we explicitly compute $H(\gamma,\mathcal{B})$ for the three dimensional Euclidian and Poincaré algebras $iso(3)$ and $iso(2,1)$.

In the case where the ideal $\mathcal{J}$ is abelian, this leads to a complete characterization of $H(\gamma|d,\mathcal{B})$, allowing us in particular to give exhaustive results for $iso(3)$ and $iso(2,1)$. The covariant Poincaré lemma allows us to extend these results to $H(\gamma|d,\mathcal{A})$.

Finally, we explicitly rediscuss the local BRST cohomology, and more particularly the consistent deformations, of $iso(2,1)$ Chern–Simons theory, whose physical relevance is due to its relation with $2+1$ dimensional gravity.[24,25]

II. GENERALITIES AND CONVENTIONS

We take space–time to be n-dimensional Minkowski space with $n \geqslant 3$ and $\mathcal{A}$ to be either the algebra of form valued polynomials or the algebra of form valued formal power series in the potentials A^a_μ, the ghosts C^a (collectively denoted by ϕ^i) and their derivatives. The algebra $\mathcal{A}$ can be decomposed into subspaces of definite ghost number g, by assigning ghost number 1 to the ghosts and their derivatives and ghost number zero to x^μ, dx^μ, the gauge potentials and their derivatives. Let $\mathcal{B}$ be either the algebra of polynomials or of formal power series generated by A^a, C^a, dA^a, dC^a, with $d = dx^\mu \partial_\mu$ and ∂_μ denoting the total derivative. Let f^c_{ab} be the structure constants of a Lie algebra $\mathcal{G}$. The action of the gauge part γ of the BRST differential is defined by

$$\gamma A^a_\mu = \partial_\mu C^a + f^a_{bc} A^b_\mu C^c, \gamma C^a = -\tfrac{1}{2} f^a_{bc} C^b C^c, \tag{2.1}$$

$$\gamma x^\mu = \gamma dx^\mu = 0, [\gamma, \partial_\mu] = \{\gamma, d\} = 0. \tag{2.2}$$

Let $F^a_{\mu\nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu + f^a_{bc} A^b_\mu A^c_\nu$ so that $\gamma F^a_{\mu\nu} = f^a_{bc} F^b_{\mu\nu} C^c$. In $\mathcal{B}$, the action of γ reads

$$\gamma A^a = -DC^a, \tag{2.3}$$

$$\gamma C^a = -\tfrac{1}{2}[C,C]^a. \tag{2.4}$$

The field strength two-form $F^a = dA^a + \frac{1}{2}[A,A]^a$ satisfies

$$\gamma F^a=[F,C]^a,\quad DF^a=0, \tag{2.5}$$

with $D=d+[A,\cdot]$.

In the following, the algebra $\mathcal{E}$ stands for either $\mathcal{A}$ or $\mathcal{B}$. Under the above assumptions, the cohomology of d is known to be trivial in $\mathcal{E}$.[7,26–35] More precisely, in form degree 0, the cohomology of d is exhausted by the constants, and in particular it is trivial in strictly positive ghost numbers. It is also trivial in form degrees $0<p<n$.

A standard technique for computing $H(\gamma|d,\mathcal{E})$ is to use so-called descent equations. As a consequence of the acyclicity of the exterior differential d, the cocyle condition $\gamma\omega^p+d\omega^{p-1}=0$ implies that $\gamma\omega^{p-1}+d\omega^{p-2}=0$. Iterating the descent, there necessarily exists an equation which reads $\gamma\omega^{p-l}=0$ because the form degree cannot be lower than zero. One then tries to compute $H(\gamma|d,\mathcal{E})$ by starting from the last equation. The systematics of this strategy can be captured by the exact couple

$$\mathcal{C}=\langle H(\gamma|d,\mathcal{E}),H(\gamma,\mathcal{E}),\mathcal{D},l^{\#},i^{\#}\rangle, \tag{2.6}$$

$$\begin{array}{ccc} H(\gamma|d,\mathcal{E}) & \overset{\mathcal{D}}{\longrightarrow} & H(\gamma|d,\mathcal{E}) \\ & {\scriptstyle i^{\#}}\nwarrow \quad \swarrow{\scriptstyle l^{\#}} & \\ & H(\gamma,\mathcal{E}) & \end{array} \tag{2.7}$$

and the associated spectral sequence[16] (see also Refs. 36 and 37 for reviews). The various maps are defined as follows: $i^{\#}$ is the map which consists in regarding an element of $H(\gamma,\mathcal{E})$ as an element of $H(\gamma|d,\mathcal{E})$, $i^{\#}:H(\gamma,\mathcal{E})\to H(\gamma|d,\mathcal{E})$, with $i^{\#}[\omega]=[\omega]$. It is well defined because every γ cocycle is a γ cocycle modulo d and every γ coboundary is a γ coboundary modulo d. The descent homomorphism $\mathcal{D}:H^{k,l}(\gamma|d,\mathcal{E})\to H^{k+1,l-1}(\gamma|d,\mathcal{E})$ with $\mathcal{D}[\omega]=[\omega']$, if $\gamma\omega+d\omega'=0$ is well defined because of the triviality of the cohomology of d in form degree $p\leqslant n-1$ (and ghost number $\geqslant 1$). Finally, the map $l^{\#}:H^{k+1,l-1}(\gamma|d,\mathcal{E})\to H^{k+1,l}(\gamma,\mathcal{E})$ is defined by $l^{\#}[\omega]=[d\omega]$. It is well defined because the relation $\{\gamma,d\}=0$ implies that it maps cocycles to cocycles and coboundaries to coboundaries. The differential associated to the exact triangle is $d^{\#}=l^{\#}\circ i^{\#}$.

The exactness of the couple (2.7) implies that

$$H(\gamma,\mathcal{E})\simeq H(d^{\#},H(\gamma,\mathcal{E}))\oplus d^{\#}\mathcal{N}_{\mathcal{E}}\oplus\mathcal{N}_{\mathcal{E}}, \tag{2.8}$$

$$H(\gamma|d,\mathcal{E}))=i^{\#}H(\gamma,\mathcal{E})\oplus\mathcal{D}^{-1}\mathcal{D}H(\gamma|d,\mathcal{E}), \tag{2.9}$$

where $\mathcal{N}_{\mathcal{E}}$ is the subspace of $H(\gamma,\mathcal{E}))$ which cannot be lifted, i.e., $[c]\in\mathcal{N}_{\mathcal{E}}$ if $\gamma c=0$ with $dc+\gamma\omega=0\Rightarrow c=\gamma\omega'$.

In the following, $\omega,a,A\in\mathcal{A}$ and $\varpi,b,B\in\mathcal{B}$.

III. THE FIRST LIFT IN THE SMALL ALGEBRA

In $\mathcal{B}$, the change of generators from A^a,dA^a,C^a,dC^a to $A^a,F^a,C^a,-DC^a$ allows us to isolate the contractible pairs $A^a,-DC^a$ and the cohomology of γ can be computed in the polynomial algebra generated by F^a,C^a. In other words, $\gamma b=0\Leftrightarrow b=P(F,C)+\gamma b'$ with $\gamma P(F,C)=0$, while $P(F,C)=\gamma b'\Rightarrow P(F,C)=\gamma P'(F,C)$. Let us first prove the following lemma:

Lemma 1: Every element of $H(\gamma,\mathcal{B})$ can be lifted at least once and, furthermore, no element of $H(\gamma,\mathcal{B})$ is an obstruction to a lift of an element of $H(\gamma,\mathcal{B})$:

$$H^p(d^{\#},H(\gamma,\mathcal{B}))\simeq H^p(\gamma,\mathcal{B}),\quad \text{for } 0\leqslant p\leqslant n, \tag{3.1}$$

i.e.,

$$\gamma b^p = 0 \Rightarrow d b^p + \gamma \varpi = 0, \tag{3.2}$$

together with

$$\left.\begin{array}{c} b^p = d\bar{b} + \gamma b', \\ \gamma \bar{b} = 0 \end{array}\right\} \Rightarrow b^p = \gamma \varpi'. \tag{3.3}$$

Proof: In terms of the new generators, we have

$$\gamma = -DC^a \frac{\partial}{\partial A^a} + [F,C]^a \frac{\partial}{\partial F^a} - \frac{1}{2}[C,C]^a \frac{\partial}{\partial C^a}, \tag{3.4}$$

$$d = \left(F - \frac{1}{2}[A,A]\right)^a \frac{\partial}{\partial A^a} - [A,F]^a \frac{\partial}{\partial F^a} + (DC - [A,C])^a \frac{\partial}{\partial C^a} + ([F,C] - [A,DC])^a \frac{\partial}{\partial DC^a}. \tag{3.5}$$

Let us introduce the operator[7,38]

$$\lambda = A^a \frac{\partial}{\partial C^a} - \left(F^a - \frac{1}{2}[A,A]^a\right) \frac{\partial}{\partial DC^a}. \tag{3.6}$$

We get

$$d = [\lambda, \gamma]. \tag{3.7}$$

It follows that

$$db + \gamma \lambda b = 0, \tag{3.8}$$

if $\gamma b = 0$. Furthermore, if $b = d\bar{b} + \gamma \varpi$ with $\gamma \bar{b} = 0$, we get $b = \gamma(\varpi - \lambda \bar{b})$.

If $\gamma b = 0$, we also get

$$d\lambda b + \gamma \tfrac{1}{2} \lambda^2 b = \tau b, \tag{3.9}$$

with

$$\tau = \frac{1}{2}[d,\lambda] = F^a \frac{\partial}{\partial C^a}, \tag{3.10}$$

$$\tau^2 = 0, \ \{\tau, \gamma\} = 0. \tag{3.11}$$

It follows that the potential obstructions to lifts of elements of $H(\gamma,\mathcal{B})$ are controlled by the differential τ.

IV. COVARIANT POINCARÉ LEMMA FOR GENERIC (SUPER)-LIE ALGEBRAS

A. Formulation

Theorem 1 (Covariant Poincaré lemma): *The following isomorphism holds:*

$$H^p(d^{\#}, H(\gamma,\mathcal{A})) \simeq H^p(\gamma,\mathcal{B}), \ \ 0 \leqslant p < n. \tag{4.1}$$

Explicitly, this means that

$$\left.\begin{array}{c} \gamma a^p = 0, \\ d a^p + \gamma \omega = 0, \ \ 0 \leqslant p < n \end{array}\right\} \Leftrightarrow \left\{\begin{array}{c} a^p = b^p + d a'^p + \gamma \omega', \\ \gamma b^p = 0 = \gamma a'^p, \end{array}\right. \tag{4.2}$$

together with

$$\left.\begin{array}{c} b^p + da'^p + \gamma\omega' = 0, \\ \gamma b^p = 0 = \gamma a'^p, \quad 0 \leqslant p < n \end{array}\right\} \Rightarrow b^p = \gamma\varpi. \tag{4.3}$$

In fact, we will prove that (4.3) also holds in form degree $p=n$.

B. Associated structure of $\mathcal{D}H(\gamma|d,\mathcal{A})$

As a direct consequence of the covariant Poincaré lemma, the descent homomorphism in $\mathcal{A}$ reduces to that in $\mathcal{B}$.

Corollary 1: The isomorphism (4.1) *implies*

$$(\mathcal{D}H)^p(\gamma|d,\mathcal{A}) \simeq (\mathcal{D}H)^p(\gamma|d,\mathcal{B}), \quad 0 \leqslant p < n. \tag{4.4}$$

More precisely, (4.1) *for* $0 \leqslant p \leqslant m (< n)$ *implies* (4.4) *for* $0 \leqslant p \leqslant m (< n)$.

This last isomorphism is equivalent to

$$\left.\begin{array}{c} \gamma A^p + dA'^{p-1} = 0, \\ dA^p + \gamma\omega = 0, \quad 0 \leqslant p < n, \end{array}\right\} \Leftrightarrow \left\{\begin{array}{c} A^p = B^p + \gamma\omega' + d\omega'', \\ \gamma B^p + dB'^{p-1} = 0, \\ dB^p + \gamma B'' = 0, \end{array}\right. \tag{4.5}$$

together with

$$\left.\begin{array}{c} B^p + \gamma\omega' + d\omega'' = 0, \\ dB^p + \gamma B'' = 0, \quad 0 \leqslant p < n, \end{array}\right\} \Rightarrow B^p = \gamma\varpi + d\varpi'. \tag{4.6}$$

Proof: That the condition (4.5) is necessary ($\Leftarrow$) follows directly from the properties of γ cocycles in the small algebra proved in Sec. III and the fact that d and γ anticommute.

The proof that the condition (4.5) is also sufficient, and the proof of (4.6) proceeds by induction on the form degree. In form degree 0, (4.5) and (4.6) hold, because (4.5) coincides with (4.2), while (4.6) coincides with (4.3). Suppose (4.5) and (4.6) hold in form degree $0 \leqslant p \leqslant m-1$.

For (4.5), it follows by induction that $A'^{m-1} = B'^{m-1} + \gamma\omega'' + d(\ )$. This implies $\gamma(A^m - d\omega'') + dB'^{m-1} = 0$. This gives $dB'^{m-1} + \gamma\overline{B}^m = 0$ and then $A^m = B^m + \overline{a}^m + d\omega''$ with $\gamma\overline{a}^m = 0$. The assumption on A^m implies that $d\overline{B}^m + d\overline{a}^m + \gamma\omega = 0$. From (4.3), we then deduce that $d\overline{B}^m + \gamma\overline{B}'' = 0$, and also that $d\overline{a}^m + \gamma(\omega - \overline{B}'') = 0$. Using (4.2), we get $\overline{a}^m = b^m + da' + \gamma(\ )$. Hence, because of (3.2), the right hand side (4.5) holds with $B^m = \overline{B}^m + b^m$.

For (4.6), we note that the assumptions imply that $\gamma B^m + dB'^{m-1} = 0$. Furthermore, $d(B'^{m-1} + \gamma\omega'') = 0$, so that $B'^{m-1} + \gamma\omega'' + d(\ ) = 0$. By induction, this means that $B'^{m-1} = \gamma\varpi' + d\varpi''$. This implies that $\gamma(B^m - d\varpi') = 0$ so that $B^m = d\varpi' + b^m$. The assumption that B^m can be lifted in the small algebra then gives $db^m = -\gamma B''$. Using (3.3), this implies that $b^m = \gamma\varpi$ so that the r.h.s. of (4.6) holds in form degree m.

C. Associated structure of $H(\gamma,\mathcal{A})$ and $H(\gamma|d,\mathcal{A})$

Taking (4.1) into account, the decomposition (2.8) for $\mathcal{E}=\mathcal{A}$ becomes

$$H^p(\gamma,\mathcal{A}) \simeq H^p(\gamma,\mathcal{B}) \oplus d^{\#}\mathcal{N}_{\mathcal{A}}^{p-1} \oplus \mathcal{N}_{\mathcal{A}}^{p}, \quad 0 \leqslant p < n, \tag{4.7}$$

$$H^n(\gamma,\mathcal{A}) \simeq \mathcal{F}^n \oplus d^{\#}\mathcal{N}_{\mathcal{A}}^{n-1}, \tag{4.8}$$

with $\mathcal{F}^n \simeq H^n(\gamma,\mathcal{A})/d^{\#}\mathcal{N}_{\mathcal{A}}^{n-1}$. This is equivalent to

$$\gamma a^p = 0,\ \ 0 \leqslant p < n \Leftrightarrow \begin{cases} a^p = b^p + d\tilde{a}^{p-1} + \tilde{a}'^p + \gamma\omega, \\ \gamma b^p = 0 = \gamma\tilde{a}^{p-1} = \gamma\tilde{a}'^p, \end{cases} \tag{4.9}$$

together with

$$\left.\begin{matrix} b^p + d\tilde{a}^{p-1} + \tilde{a}'^p + \gamma\omega = 0,\ \ 0 \leqslant p < n, \\ \gamma b^p = 0 = \gamma\tilde{a}^{p-1} = \gamma\tilde{a}'^p \end{matrix}\right\} \Rightarrow \begin{cases} b^p = \gamma\varpi, \\ \tilde{a}^{p-1} = \gamma\omega', \\ \tilde{a}'^p = \gamma\omega'', \end{cases} \tag{4.10}$$

in form degrees $0 \leqslant p < n$ and to

$$\gamma a^n = 0 \Leftrightarrow \begin{cases} a^n = \hat{a}^n + d\tilde{a}^{n-1} + \gamma\omega, \\ \gamma\hat{a}^n = 0 = \gamma\tilde{a}^{n-1}, \end{cases} \tag{4.11}$$

together with

$$\left.\begin{matrix} \hat{a}^n + d\tilde{a}^{n-1} + \gamma\omega = 0, \\ \gamma\hat{a}^n = 0 = \gamma\tilde{a}^{n-1} \end{matrix}\right\} \Rightarrow \begin{cases} \hat{a}^n = \gamma\omega, \\ \tilde{a}^{n-1} = \gamma\omega', \end{cases} \tag{4.12}$$

in form degree n.

Finally, using (4.7) and (4.4), the decomposition (2.9) for $\mathcal{E} = \mathcal{A}$ becomes

$$H^p(\gamma|d,\mathcal{A}) \simeq i^{\#}H^p(\gamma,\mathcal{B}) \oplus \mathcal{N}^p_{\mathcal{A}} \oplus \mathcal{D}^{-1}(\mathcal{D}H)^{p-1}(\gamma|d,\mathcal{B}), 0 \leqslant p < n. \tag{4.13}$$

$$H^n(\gamma|d,\mathcal{A}) \simeq \mathcal{F}^n \oplus \mathcal{D}^{-1}(\mathcal{D}H)^{n-1}(\gamma|d,\mathcal{B}), \tag{4.14}$$

which is equivalent to

$$\gamma A^p + dA'^p = 0,\ \ 0 \leqslant p < n \Leftrightarrow \begin{cases} A^p = \tilde{a}^p + b^p + B^p + \gamma\omega + d\omega', \\ \gamma\tilde{a}^p = 0 = \gamma b^p = \gamma B^p + dB'^{p-1}, \\ d\tilde{a}^p + \gamma\omega'' = 0 \Rightarrow \tilde{a}^p = \gamma\omega''', \\ B'^{p-1} = \gamma\varpi + d\varpi' \Rightarrow B^p = \gamma\varpi'' + d\varpi, \end{cases} \tag{4.15}$$

together with

$$\left.\begin{matrix} \tilde{a}^p + b^p + B^p + \gamma\omega + d\omega' = 0,\ \ 0 \leqslant p < n \\ \gamma\tilde{a}^p = 0 = \gamma b^p = \gamma B^p + dB'^{p-1}, \\ d\tilde{a}^p + \gamma\omega'' = 0 \Rightarrow \tilde{a}^p = \gamma\omega''', \\ B'^{p-1} = \gamma\varpi + d\varpi' \Rightarrow B^p = \gamma\varpi'' + d\varpi \end{matrix}\right\} \Rightarrow \begin{cases} \tilde{a}^p = \gamma\omega^4, \\ b^p = dB''^{p-1} + \gamma\varpi''', \\ B^p = \gamma\varpi''' + d\varpi^4, \end{cases} \tag{4.16}$$

in form degrees $0 \leqslant p < n$, and

$$\gamma A^n + dA'^{n-1} = 0 \Leftrightarrow \begin{cases} A^n = \hat{a}^n + B^n + \gamma\omega + d\omega', \\ \gamma\hat{a}^n = 0 = \gamma B^n + dB'^{n-1}, \\ \left.\begin{matrix} \hat{a}^n + d\tilde{a}^{n-1} + \gamma\omega'' = 0, \\ \gamma\tilde{a}^{n-1} = 0, \end{matrix}\right\} \Rightarrow \begin{cases} \hat{a}^n = \gamma\omega''', \\ \tilde{a}^{n-1} = \gamma\omega^4, \end{cases} \\ B'^{n-1} = \gamma\varpi + d\varpi' \Rightarrow B^n = \gamma\varpi'' + d\varpi, \end{cases} \tag{4.17}$$

together with

$$\left.\begin{matrix} \hat{a}^n + B^n + \gamma\omega + d\omega' = 0, \\ \gamma\hat{a}^n = 0 = \gamma B^n + dB'^{n-1}, \\ B'^{n-1} = \gamma\varpi + d\varpi' \Rightarrow B^n = \gamma\varpi'' + d\varpi \end{matrix}\right\} \Rightarrow \begin{cases} \hat{a}^n = dB''^{n-1} + \gamma\omega''', \\ \gamma B''^{n-1} + dB'''^{p-2} = 0, \\ B^n = \gamma\varpi''' + d\varpi^4, \end{cases} \tag{4.18}$$

in form degree n.

D. Proof of theorem 1

That the condition (4.2) is necessary ($\Leftarrow$) is again direct.

1. Decomposition according to homogeneity and change of variables

If one decomposes the space of polynomials or formal power series into monomials of definite homogeneity, the differential γ splits accordingly into a piece that does not change the homogeneity and a piece that increases the homogeneity by one, $\gamma=\gamma_0+\gamma_1$. Consider the change of variables from A_μ, C^a and their derivatives to

$$y^\alpha \equiv \partial_{(\mu_k}\cdots\partial_{\mu_2}A^a_{\mu_1)}, \tag{4.19}$$

$$z^\alpha \equiv \partial_{\mu_k}\cdots\partial_{\mu_1}C^a, \tag{4.20}$$

$$C^a, F^{0a}_\Delta \equiv \partial_{(\mu_{k-1}}\cdots\partial_{\mu_3}F^{0a}_{\mu_2)\mu_1}, \tag{4.21}$$

with $F^{0a}_{\mu\nu}=\partial_\mu A^a_\nu-\partial_\nu A^a_\mu$. In the new variables,

$$\gamma_0 = z^\alpha\frac{\partial}{\partial y^\alpha}. \tag{4.22}$$

This implies that

$$a(y^\alpha,z^\alpha,F^{0a}_\Delta,C^a)=a(0,0,F^{0a}_\Delta,C^a)+\{\gamma_0,\rho\}a, \tag{4.23}$$

$$\rho\cdot=\int_0^1\frac{dt}{t}\left[y^\alpha\frac{\partial}{\partial z^\alpha}\cdot\right](ty^\alpha,tz^\alpha,F^{0a}_\Delta,C^a). \tag{4.24}$$

Suppose that $\gamma_0 a=0$. It follows that

$$\gamma_0 a=0\Leftrightarrow a=I+\gamma_0\omega, \tag{4.25}$$

for some form valued polynomials $I(x^\mu,dx^\mu,F^{0a}_\Delta,C^a)$. Furthermore,

$$I+\gamma_0\omega=0\Rightarrow I=0. \tag{4.26}$$

2. Properties of γ_1 and γ_0

Let $\mathcal{I}^0$ be the algebra of form valued polynomials or formal power series that do not depend on y^α,z^α, but only on C^a,F^{0a}_Δ, with elements denoted below by I,J and $\mathcal{P}^0$ be the algebra of polynomials or formal power series that depend only on F^{0a},C^a, with elements denoted by P,Q. Polynomials which depend only on the ghosts are denoted by R.

Let us introduce the operator

$$\sigma=\gamma_1-C^a\delta_a, \tag{4.27}$$

where δ_a denotes the representation under which the object transforms. We have

$$\sigma A^a_\mu=0,\ \ \sigma C^a=\tfrac{1}{2}[C,C]^a,\ \ \sigma^2=0,\ \ [\sigma,\partial_\mu]=[\partial_\mu C,\cdot],\ \ \{\sigma,\gamma_0\}=0. \tag{4.28}$$

The point about σ is that when it acts on any expression that depends only on A^a_μ and its derivatives, the result does not involve undifferentiated ghosts. More precisely, $(\sigma f[A^a_\mu])|_{z=0}=0$. We have $\gamma_0\sigma\partial_{\nu_k}\cdots\partial_{\nu_2}F^{0a}_{\nu_1\mu}=0$. It follows that

$$\sigma\partial_{\nu_k}\cdots\partial_{\nu_2}F^{0a}_{\nu_1\mu}=\gamma_0\rho\sigma\partial_{\nu_k}\cdots\partial_{\nu_2}F^{0a}_{\nu_1\mu}. \tag{4.29}$$

Symmetrizing over the ν indices, one gets

$$\sigma F^{0a}_{\Delta} = \gamma_0(\rho\sigma) F^{0a}_{\Delta}. \tag{4.30}$$

3. The differential γ^R

For later use, let us also establish that if

$$\gamma^R J = -[C, F^0_{\Delta}]^a \frac{\partial J}{\partial F^{0a}_{\Delta}} - \frac{1}{2}[C,C]^a \frac{\partial J}{\partial C^a}, \tag{4.31}$$

and

$$v = (\rho\sigma F^{0a}_{\Delta}) \frac{\partial}{\partial F^{0a}_{\Delta}}, \tag{4.32}$$

then

$$\gamma_1 J = \gamma_0(vJ) + \gamma^R J. \tag{4.33}$$

Lemma 2:

$$H(\gamma_1, H(\gamma_0)) \simeq H(\gamma^R, \mathcal{I}^0). \tag{4.34}$$

Proof: The lemma means that

$$\left.\begin{array}{c} \gamma_0 a = 0, \\ \gamma_1 a + \gamma_0 b = 0, \end{array}\right\} \Leftrightarrow \left\{\begin{array}{c} a = J + \gamma_0(\ ), \\ \gamma^R J = 0, \end{array}\right. \tag{4.35}$$

and

$$\left.\begin{array}{c} J = \gamma_1 a' + \gamma_0(\ ), \\ \gamma_0 a' = 0, \end{array}\right\} \Rightarrow J = \gamma^R J'. \tag{4.36}$$

Indeed, the result follows directly from (4.33).

Suppose now that the decomposition of the space of polynomials or of formal power series into monomials of homogeneity M has been made (see the Appendix for notations and more details). Then one has the following:

Lemma 3:

$$H(\gamma, \mathcal{A}) \simeq \oplus_{M \geqslant 0} H_M(\gamma^R, \mathcal{I}^0), \tag{4.37}$$

$$H(\gamma, \mathcal{B}) \simeq \oplus_{M \geqslant 0} H_M(\gamma^R, \mathcal{P}^0). \tag{4.38}$$

Proof: Let us first show that every element $[I_M] \in H(\gamma^R, \mathcal{I}^0)$ can be completed to a γ cocycle. Indeed, let us denote by I^M the expression obtained by replacing in I_M the variables F^{0a}_{Δ} by their non-Abelian counterparts,

$$F^a_{\Delta} \equiv D_{(\mu_{k-1}} \cdots D_{\mu_3} F^a_{\mu_2)\mu_1}, \tag{4.39}$$

where $F^a_{\mu\nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu + f^a_{bc} A^b_\mu A^c_\nu$, and $D_\mu = \partial_\mu + A^b_\mu \delta_b$ and the covariant derivatives of $F^a_{\mu\nu}$ transform in the coadjoint representation. Hence, $I^M = I_M|$ where the vertical bar denotes the operation of substitution. Because $\gamma F^a_{\Delta} = -[C, F_{\Delta}]^a$, it follows that

$$\gamma I^M = (\gamma^R I_M)| = 0. \tag{4.40}$$

Similarily,

$$(\gamma^R J_M)| = \gamma J^M. \tag{4.41}$$

Note that if $I_M, J_M \in \mathcal{P}^0$, then $I^M \equiv b^M \in \mathcal{B}$ and $J^M \equiv \varpi^M \in \mathcal{B}$.

Suppose $\gamma a^M = 0$. The equations in homogeneity M and $M+1$ imply that a_M is a cocycle of $H(\gamma_1, H(\gamma_0))$. According to the previous lemma, $a_M = I_M + \gamma_0 \eta_M$ where I_M is a cocycle of $H(\gamma^R, \mathcal{I}^0)$.

Suppose that $a^M = \gamma \omega^{M-B}$. In particular, to orders $\leqslant M$, we have

$$\begin{aligned} a_M = \gamma_0 \omega_M \quad &+ \quad \gamma_1 \omega_{M-1}, \\ \gamma_0 \omega_{M-1} \quad &+ \quad \gamma_1 \omega_{M-2} = 0, \\ &\vdots \\ \gamma_0 \omega_{M-B+1} \quad &+ \quad \gamma_1 \omega_{M-B} = 0, \\ \gamma_0 \omega_{M-B} = 0. & \end{aligned} \tag{4.42}$$

If $B > 1$, the equations for ω_{M-B} imply that $\omega_{M-B} = J_{M-B} + \gamma_0 \eta_{M-B}$ with $\gamma^R J_{M-B} = 0$. The redefinition $\omega^{M-B} \to \omega^{M-B} - \gamma \eta_{M-B}$, which does not affect a^M allows to absorb η_{M-B}. One can then replace ω^{M-B} by $\omega^{M-B+1} = \omega^{M-B} - J^{M-B}$, without affecting a^M. This can be done until $B = 1$, where one finds $I_M = \gamma^R J_{M-1}$. This proves that the map $[a^M] \in H(\gamma) \mapsto [I_M] \in H(\gamma^R, \mathcal{I}^0)$ is well defined. The map is surjective because as shown above, every γ^R cocycle I_M can be extended to a γ cocycle I^M. It is also injective, because as also shown above, if $I_M = \gamma^R J_{M-1}$, then $I^M = \gamma J^{M-1}$, so that $a^M - \gamma(J^{M-1} - \eta_M) = a^{M+1}$ starts at homogeneity $M+1$.

4. $H(\gamma)$ and split of variables adapted to the non-Abelian differential γ

If one is not interested in proving the covariant Poincaré lemma, one can avoid the detour of using the split of variables adapted to the Abelian differential γ_0 given in (4.19)–(4.21) for the characterization of $H(\gamma)$. One can use instead directly the variables

$$Y^\alpha \equiv \partial_{(\mu_k} \cdots \partial_{\mu_2} A^a_{\mu_1)}, \tag{4.43}$$

$$Z^\alpha \equiv \partial_{(\mu_k} \cdots \partial_{\mu_2} D_{\mu_1)} C^a, \tag{4.44}$$

$$C^a, F^a_\Delta \equiv D_{(\mu_{k-1}} \cdots D_{\mu_3} F^a_{\mu_2)\mu_1}, \tag{4.45}$$

with $F^a_{\mu\nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu + f^a_{bc} A^b_\mu A^c_\nu$ adapted to the non-Abelian differential γ, which reads

$$\gamma = Z^\alpha \frac{\partial}{\partial Y^\alpha} + \gamma^S, \tag{4.46}$$

$$\gamma^S = C^a \delta_a - \frac{1}{2}[C,C]^a \frac{\partial}{\partial C^a}, \tag{4.47}$$

$$\delta_a = -f^c_{ab} F^b_\Delta \frac{\partial}{\partial F^c_\Delta}. \tag{4.48}$$

The usual argument then shows that $H(\gamma, \mathcal{A})$ and $H(\gamma, \mathcal{B})$ are isomorphic to $H(\gamma^S, \mathcal{I})$, respectively $H(\gamma^S, \mathcal{P})$, where $\mathcal{I}$ is the algebra of form valued polynomials or formal power series that do not depend on Y^α, Z^α, but only on C^a, F^a_Δ, and $\mathcal{P}$ is the algebra of polynomials or formal power series that depend only on F^a, C^a.

5. Exterior derivative and contracting homotopy for the gauge potentials

Let us introduce the total derivative that does not act on the ghosts,

$$\overline{\partial}_\mu = \partial_\mu - \partial_{(\nu)\mu} C^a \frac{\partial}{\partial \partial_{(\nu)} C^a}, \tag{4.49}$$

and also the associated exterior derivative and contracting homotopy,[39]

$$\overline{d} = dx^\mu \overline{\partial}_\mu, \tag{4.50}$$

$$\overline{\rho}\omega^p = \int_0^1 dt \frac{|\lambda|+1}{n-p+|\lambda|+1} \overline{\partial}_{(\lambda)} \left(A^a_\mu \left[\frac{\overline{\delta}}{\delta \partial_{(\lambda)\nu} A^a_\mu} \frac{\partial \omega^p}{\partial dx^\nu} \right] [x, dx, C, tA] \right), \tag{4.51}$$

$$\omega^p[x,dx,C,A] = \omega^p[x,dx,C,0] + \{\overline{\rho}, \overline{d}\}\omega^p, 0 \leqslant p < n, \tag{4.52}$$

where $\overline{\delta}/\delta \partial_{(\lambda)\nu} A^a_\mu$ are the higher order Euler operators with respect to the dependence on A^a_μ only (see Ref. 40, Appendix A for conventions). In the old variables A^a_μ, C^a and their derivatives, consider the split

$$\gamma_1 = \gamma^R + \gamma^{\partial C}, \gamma^R = [\partial_{(\nu)} A_\mu, C]^a \frac{\partial}{\partial \partial_{(\nu)} A^a_\mu} - \frac{1}{2}[C,C]^a \frac{\partial}{\partial C^a}. \tag{4.53}$$

This is consistent with (4.31) when acting on functions that depend only on F^{0a}_Δ, C^a. We have

$$\{\gamma^R, \overline{d}\} = 0 = \{\gamma^R, \overline{\rho}\} = 0. \tag{4.54}$$

The first relation is obvious, while the second follows from the fact that γ^R just rotates all the A^a_μ and their derivatives in the internal space without changing the derivatives, while $\overline{\rho}$ only involves the various derivatives and does not act in the internal space. It can be proved directly using the explicit expression (4.51) for $\overline{\rho}$.

6. Core of the proof

Lemma 4:

$$\left.\begin{array}{c} \gamma a^M = 0, \\ d a^M + \gamma \omega^{M-B} = 0, \end{array}\right\} \Rightarrow \left\{\begin{array}{c} \gamma^R I_M = 0, \\ \overline{d} I_M + \gamma^R J_{M-1} = 0. \end{array}\right. \tag{4.55}$$

Proof: In (4.55), one can assume without loss of generality that $B=1$. This can be shown in the same way as in the corresponding part of the proof of Lemma 3. We then have $a_M = I_M + \gamma_0 \eta_M$ with $\gamma^R I_M = 0$, and $\omega_{M-1} = J_{M-1}$, with $\gamma^R J_{M-1} = 0$. To order M, the l.h.s. of (4.55) then gives the r.h.s. of (4.55).

Lemma 5: In form degree $<n$,

$$\left.\begin{array}{c} \gamma^R I_M = 0, \\ \overline{d} I_M + \gamma^R J_{M-1} = 0, \end{array}\right\} \Leftrightarrow \left\{\begin{array}{c} I_M = P_M + \overline{d} I'_M + \gamma^R J'_{M-1}, \\ \gamma^R P_M = 0 = \gamma^R I'_M. \end{array}\right. \tag{4.56}$$

Proof: That the condition is necessary ($\Leftarrow$) is direct. In order to show that it is sufficient, we are first going to show that

$$\overline{d} I_{N a_1 \ldots a_k} + \gamma^R_k J_{N-1 a_1 \ldots a_k} = 0 \Rightarrow I_{N a_1 \ldots a_k} = P_{N a_1 \ldots a_k} + \overline{d} I'_{N a_1 \ldots a_k} + \gamma^R_k J'_{N-1 a_1 \ldots a_k}, \tag{4.57}$$

where $\gamma^R_k J_{a_1 \ldots a_k} = -\Sigma_{l=1}^k C^b f^c_{b a_l} J_{a_1 \ldots a_{l-1} c a_{l+1} \ldots a_k} + \gamma^R J_{a_1 \ldots a_k}$.

Indeed, in form degree 0, the algebraic Poincaré lemma for $\overline{d}$ implies that $I_{Na_1 \ldots a_k} = R_{Na_1 \ldots a_k} + \overline{\rho}\overline{d} I_{Na_1 \ldots a_k}$. Using the l.h.s. of (4.57) and the fact γ^R_k anticommutes with $\overline{\rho}$, one gets the desired result by putting the y^α to zero.

Suppose now that the result is true in form degrees $<p$ and that $I_{Na_1 \ldots a_k}$ has form degree p. The algebraic Poincaré lemma for $\overline{d}$ implies that $I_{Na_1 \ldots a_k} = \overline{\rho}\overline{d} I_{Na_1 \ldots a_k} + \overline{d}\overline{\rho} I_{Na_1 \ldots a_k}$. Using the l.h.s. of (4.57), we get $I_{Na_1 \ldots a_k} = \gamma^R_k \overline{\rho} J_{N-1 a_1 \ldots a_k} + \overline{d}\overline{\rho} I_{Na_1 \ldots a_k}$. We have $\overline{\rho} I_{Na_1 \ldots a_k} = y^\alpha I_{N-1 \alpha a_1 \ldots a_k} + I'_{Na_1 \ldots a_k}$ and $\overline{\rho} J_{N-1 a_1 \ldots a_k} = y^\beta J_{N-2 \beta a_1 \ldots a_k} + J'_{N-1 a_1 \ldots a_k}$ so that

$$I_{Na_1 \ldots a_k} - \overline{d} I'_{Na_1 \ldots a_k} - \gamma^R_k J'_{N-1 a_1 \ldots a_k} = \overline{d}(y^\alpha I_{N-1 \alpha a_1 \ldots a_k}) + \gamma^R_k (y^\beta J_{N-2 \beta a_1 \ldots a_k}). \tag{4.58}$$

The action of γ^R only rotates the y^β in the internal space; its action on an expression that is linear and homogeneous in the y^β reproduces an expression that is linear and homogeneous in y^β. Supposing that the term in $y^\alpha I_{N-1 \alpha a_1 \ldots a_k}$ with the highest number of derivatives on y^α is

$$A^a_{(\mu, \nu_1 \ldots \nu_m)} I^{(\mu \nu_1 \ldots \nu_m)}_{N-1 a a_1 \ldots a_k},$$

we get, for the term linear in y^α with the highest number of derivatives on y^α, that $dx^\sigma A^a_{(\mu, \nu_1 \ldots \nu_m \sigma)} I^{(\mu \nu_1 \ldots \nu_m)}_{N-1 a a_1 \ldots a_k} + \gamma^R_k (A^a_{(\mu, \nu_1 \ldots \nu_m \sigma)} J^{(\mu \nu_1 \ldots \nu_m \sigma)}_{N-2 a a_1 \ldots a_k}) = 0$. This implies that $J^{(\mu \nu_1 \ldots \nu_m \sigma)}_{N-2 a a_1 \ldots a_k} = dx^{(\sigma} J^{\mu \nu_1 \ldots \nu_m)}_{N-2 a a_1 \ldots a_k}$ and that

$$I^{(\mu \nu_1 \ldots \nu_m)}_{N-1 a a_1 \ldots a_k} = dx^{(\nu_m} I^{(\mu \nu_1 \ldots \nu_{m-1}))}_{N-1 a a_1 \ldots a_k} - \gamma^R_{k+1} J^{(\mu \nu_1 \ldots \nu_m)}_{N-2 a a_1 \ldots a_k}.$$

The redefinition,

$$\begin{aligned} y^\alpha I_{N-1 \alpha a_1 \ldots a_k} \to y^\alpha I_{N-1 \alpha a_1 \ldots a_k} &- \overline{d}(A^a_{(\mu, \nu_1 \ldots \nu_{m-1})} I^{(\mu \nu_1 \ldots \nu_{m-1})}_{N-1 a a_1 \ldots a_k}) \\ &+ \gamma^R_k (A^a_{(\mu, \nu_1 \ldots \nu_m)} J^{(\mu \nu_1 \ldots \nu_m)}_{N-2 a a_1 \ldots a_k}), \end{aligned} \tag{4.59}$$

$$y^\beta J_{N-2 \beta a_1 \ldots a_k} \to y^\beta J_{N-2 \beta a_1 \ldots a_k} + \overline{d}(A^a_{(\mu, \nu_1 \ldots \nu_m)} J^{(\mu \nu_1 \ldots \nu_m)}_{N-2 a a_1 \ldots a_k}), \tag{4.60}$$

does not change the equation (4.58) and allows it to absorb the term linear in y^α with the highest number of derivatives on y^α. These redefinitions can be done until there are no derivatives on the y^α left, so that $y^\alpha I_{N-1 \alpha a_1 \ldots a_k} = A^a I_{N-1 a a_1 \ldots a_k}$, $y^\beta J_{N-2 \beta a_1 \ldots a_k} = A^a J_{N-2 a a_1 \ldots a_k}$. The vanishing of the term proportional to A^a in (4.58) then implies that $\overline{d} I_{N-1 a a_1 \ldots a_k} + \gamma^R_{k+1} J_{N-2 a a_1 \ldots a_k} = 0$. Because this is the l.h.s. of (4.57) in form degree $<p$, we have by induction that $I_{N-1 a a_1 \ldots a_k} = P_{N-1 a a_1 \ldots a_k} + \overline{d} I'_{N-1 a a_1 \ldots a_k} + \gamma^R_{k+1} J'_{N-2 a a_1 \ldots a_k}$. Injecting into (4.58) gives the desired result:

$$\begin{aligned} &I_{Na_1 \ldots a_k} - \overline{d} I'_{Na_1 \ldots a_k} - \gamma^R_k J'_{N-1 a_1 \ldots a_k} \\ &\quad = F^a P_{N-1 a a_1 \ldots a_k} + \overline{d}(F^a I'_{N-1 a a_1 \ldots a_k}) + \gamma^R_k (F^a J'_{N-2 a a_1 \ldots a_k}). \end{aligned} \tag{4.61}$$

The first line on the right hand side of (4.56) then follows as a particular case of (4.57). Applying now γ^R, one gets $\gamma^R P_M - \overline{d} \gamma^R I'_M = 0$. Restriction to the small algebra $\mathcal{B}$ then implies that $\gamma^R P_M = 0 = \overline{d} \gamma^R I'_M$ because $\overline{d}(\gamma^R I'_M)|_{\mathcal{B}} = 0$. We have $I'_M = R'_M + \overline{d}\overline{\rho} I'_M + \overline{\rho}\overline{d} I'_M$. One can then set the variables y^α to zero on the r.h.s. without changing the l.h.s., $I'_M = R'_M + (\overline{d}\overline{\rho} I'_M)|_{y=0}$

$+(\overline{\rho d} I'_M)_{y=0}$. Appling the same reasoning as above then gives $(\overline{d\rho} I'_M)|_{y^\alpha=0} = P'''_M + \overline{d} J''_M$, so that $I'_M = P''_M + \overline{d} J''_M + (\overline{\rho d} I'_M)|_{y=0}$. Because the first two terms do not contribute to $\overline{d} I'_M$, we can assume without loss of generality that $I'_M = (\overline{\rho d} I'_M)|_{y=0}$. For such an I'_M, the relation $\overline{d}\gamma^R I'_M = 0$ implies $\gamma^R I'_M = 0$ by using (4.54).

Completing the proof of (4.2): According to (4.40), we can complete $P^M = P_M|$, $I'^M = (I'_M)|$ such that $\gamma P^M = 0 = \gamma I'^M$, and according to (4.41) $\gamma^R J'_{M-1} = \gamma J'^{M-1} + O(M+1)$. Hence,

$$a^M - P^M - dI'^M - \gamma\left(\eta_M + A^a \frac{\partial I'_M}{\partial C^a} + J'^{M-1}\right) = a^{M+1}. \tag{4.62}$$

Because all the individual terms on the left hand side satisfy the l.h.s. of (4.2), so does a^{M+1}.

Lemma 6:

$$\left.\begin{array}{c} b^M + da'^{M-B} + \gamma\omega'^{M-C} = 0, \\ \gamma b^M = 0 = \gamma a'^{M-B}, \end{array}\right\} \Rightarrow \left\{\begin{array}{c} P_M + \overline{d} I'_M + \gamma^R J'_{M-1} = 0, \\ \gamma^R P_M = 0 = \gamma^R I'_M. \end{array}\right. \tag{4.63}$$

Proof: Proceeding again as in the proof of Lemma 3, one can assume without loss of generality that $C = B+1 \geqslant 1$ by suitably modifying ω'^{M-C}. If $B \geqslant 1$, we have by assumption at the lowest orders

$$\begin{gathered} da'_{M-B} + \gamma_1 \omega'_{M-B-1} + \gamma_0 \omega'_{M-B} = 0, \\ \gamma_0 \omega'_{M-B-1} = 0 = \gamma_0 a'_{M-B} = \gamma_1 a'_{M-B} + \gamma_0 a'_{M-B+1}. \end{gathered} \tag{4.64}$$

We thus have $\omega'_{M-B-1} = J'_{M-B-1} + \gamma_0(\ )$. The γ_0 exact term can be assumed to be absent by a further modification of ω'^{M-B-1} by a γ exact term that does not affect the equations. Because $a'_{M-B} = I'_{M-B} + \gamma_0 \eta_{M-B}$, we get

$$\left\{\begin{array}{c} \overline{d} I'_{M-B} + \gamma^R J'_{M-B-1} = 0, \\ \gamma^R I'_{M-B} = 0. \end{array}\right. \tag{4.65}$$

According to (4.56), this implies

$$\begin{gathered} I'_{M-B} = P'_{M-B} + \overline{d} I''_{M-B} + \gamma^R J''_{M-B-1}, \\ \gamma^R P'_{M-B} = 0 = \gamma^R I''_{M-B}. \end{gathered} \tag{4.66}$$

As in the reasoning leading to (4.62), we get

$$a'^{M-B} - P'^{M-B} - dI''^{M-B} - \gamma\left(\eta_{M-B} + A^a \frac{\partial I'_{M-B}}{\partial C^a} + J''^{M-B-1}\right) = a'^{M-B+1}, \tag{4.67}$$

with $\gamma P'^{M-B} = 0 = \gamma I''^{M-B}$. Because $dP'^{M-B} + \gamma(\ ) = 0$, we can replace on the l.h.s. of (4.63) a'^{M-B} by a'^{M-B+1} by suitably modifying ω'^{M-C}. This can be done until $B = 0$ by the same reasoning as in the beginning of this proof. For $B = 0$, we get the r.h.s. of (4.63), with $b_M = P_M + \gamma_0 \varpi_M$.

Lemma 7: In form degree $\leqslant n$,

$$\left.\begin{array}{c} P_M + \overline{d} I'_M + \gamma^R J'_{M-1} = 0, \\ \gamma^R P_M = 0 = \gamma^R I'_M, \end{array}\right\} \Rightarrow P_M = \gamma^R Q_{M-1}. \tag{4.68}$$

Proof: By restricting to the small algebra $\mathcal{B}$, we get $P_M + \overline{d}(I'_M|_{\mathcal{B}}) + \gamma^R(J'_{M-1}|_{\mathcal{B}}) = 0$. This gives directly the result because $\overline{d}(I'_M|_{\mathcal{B}}) = 0$.

Note that because of the first relation of (4.54), the map

$$\begin{aligned} &\overline{d}^{\#}: H(\gamma^R, \mathcal{I}^0) \to H(\gamma^R, \mathcal{I}^0), \\ &[I] \mapsto [\overline{d} I], \end{aligned} \tag{4.69}$$

is well defined. Lemmas 5 and 7 (for $p<n$) can then be summarized by the following corollary.

Corollary 2:

$$H^p(\overline{d}^{\#}, H(\gamma^R, \mathcal{I}^0)) \simeq H^p(\gamma^R, \mathcal{P}^0), \quad p<n. \tag{4.70}$$

Completing the proof of (4.3): According to (4.41), the expression $Q^{M-1}=Q_{M-1}|$ satisfies $\gamma^R Q_{M-1} = \gamma Q^{M-1} + O(M+1)$ so that $b^M - \gamma(\varpi_M + Q^{M-1}) = b^{M+1}$. This implies that b^{M+1} obeys again the l.h.s. of (4.3).

7. Convergence in the space of polynomials

As they stand, the proofs are valid in the space of formal power series. In order that they apply to the case of polynomials, one needs to be sure that if the l.h.s. of (4.2) and (4.3) are polynomials, i.e., if the degrees of homogeneity of all the elements are bounded from above, then the same holds for the elements that have been constructed on the r.h.s. of these equations. This can be done by controlling the number of derivatives on the A^a_μ and the C^a's. Let

$$K = (|\nu| - 1)\partial_{(\nu)} C^a \frac{\partial}{\partial \partial_{(\nu)} C^a} + |\nu| \partial_{(\nu)} A^a_\mu \frac{\partial}{\partial \partial_{(\nu)} A^a_\mu}. \tag{4.71}$$

Suppose that a^M is a polynomial $a^M = a_M + \ldots + a_{M+L}$. It follows that the K degree of a^M is bounded from above by some k. We will say that a^M is of order k. Note that γ_0 does not modify the order, while γ_1 decreases the order by 1. It follows that the γ_0 exact term and J in (4.35) can be assumed to be of order k as well, while J' in (4.36) can be assumed to be of order $k+1$. The important point is that $I^M - I_M$ and $\gamma J^M - \gamma^R J_M$ are of order $k-1$ if I_M, respectively $\gamma^R J_M$, are of order k.

Since $\overline{d}$ increases the order by 1, I_M and J_{M-1} in (4.55) can be assumed to be of order k, respectively $k+2$, while I'_M can be assumed to be of order $k-1$. It follows that J'_{M-1} in (4.56) can be assumed to be of order $k+1$. This implies that in the recursive construction (4.62) of a^M, after $M+L+1$ steps, i.e., after all of the original $a_M + \ldots + a_{M+L}$ have been absorbed, the order strictly decreases at each step. Since the order is bounded from below, the construction necessarily finishes after a finite number of steps, so that one stays inside the space of polynomials.

Similarily, if b^M on the l.h.s. (4.63) is of order k, P_M, I'_M and J'_{M-1} on the right hand side of (4.63) can be assumed to be of order k, $k-1$ and $k+1$, respectively. It follows that on the r.h.s. of (4.68), Q_{M-1} can be assumed to be of order $k+1$. In the recursive construction of b^M, once the original b^M has been completely absorbed, the order strictly decreases at each step, so that the construction again finishes after a finite number of steps.

8. The case of super or graded Lie algebras

In the case of super or graded Lie algebras, some of the gauge potentials become fermionic, while some of the ghosts become bosonic. By taking due care of sign factors and using graded commutators everywhere, the same proof as above of the covariant Poincaré lemma goes through.

V. $H(\gamma)$ FOR $\mathcal{G}/\mathcal{J}$ SEMISIMPLE

A. Formulation of a theorem by Hochschild and Serre

As shown in the digression in Sec. IV D 4, $H(\gamma, \mathcal{A}) \simeq H(\gamma^S, \mathcal{I})$, respectively $H(\gamma, \mathcal{B}) \simeq H(\gamma^S, \mathcal{P})$. By identifying the ghosts C^a as generators of $\wedge(\mathcal{G}^*)$, the spaces $\mathcal{I}$ and $\mathcal{P}$ can be

identified with $C(\mathcal{G},V^{\mathcal{I}})$, respectively $C(\mathcal{G},V^{\mathcal{P}})$, the spaces of cochains with values in the module $V^{\mathcal{I}}$, respectively $V^{\mathcal{P}}$. Here, $V^{\mathcal{I}}$ is the module of form valued polynomials or formal power series in the F^a_Δ, while $V^{\mathcal{P}}$ is the module of polynomials or formal power series in the F^a. The differential γ^S defined in (4.48) can then be identified with the Chevalley–Eilenberg Lie algebra differential with coeffcients in the module $V^{\mathcal{I}}$, respectively $V^{\mathcal{P}}$. The module $V^{\mathcal{P}}$ decomposes into the direct sum of finite dimensional modules $V^{\mathcal{P}}_M$ of monomials of homogeneity M in the F^a. The module $V_{\mathcal{I}}$ decomposes into the direct sum of modules $\Omega(M)\otimes V^{\mathcal{I}}_M$ of form valued monomials of homogeneity M in the F^a_Δ. The space–time forms can be factorized because the representation does not act on them, and the module $V^{\mathcal{I}}_M$ is finite dimensional.

As mentioned in the Introduction, it is at this stage that, for reductive Lie algebras, one can use standard results on Lie algebra cohomology with coefficients in a finite dimensional module (see, e.g., Ref. 12). But even for non reductive Lie algebras, there exist some general results. We will now review one of these results due to Hochschild and Serre.[23] In order to be self-contained, a simple proof of their theorem in ''ghost'' language is given.

Theorem 2: *Let $\mathcal{G}$ be a real Lie algebra and $\mathcal{J}$ an ideal of $\mathcal{G}$ such that $\mathcal{G}/\mathcal{J}$ is semi-simple. Let V be a finite dimensional $\mathcal{G}$-module. Then the following isomorphism holds,*

$$H(\mathcal{G},V)\simeq H(\mathcal{G}/\mathcal{J},\mathbb{R})\otimes H^{\mathcal{G}}(\mathcal{J},V), \tag{5.1}$$

where $H^{\mathcal{G}}$ means the $\mathcal{G}$-invariant cohomology space.

B. Proof

The above hypothesis implies that there is a semi-simple subalgebra $\mathcal{K}$ of $\mathcal{G}$ isomorphic to $\mathcal{G}/\mathcal{J}$ such that

$$\mathcal{G}=\mathcal{K}\ltimes\mathcal{J}. \tag{5.2}$$

Let $\{e_A,h_\alpha\},(A=1,\ldots,p),(\alpha=1,\ldots,q)$ denote a basis of $\mathcal{G}$, among which the e_A's form a basis of $\mathcal{K}$ and the h_α's a basis of $\mathcal{J}$: the fundamental brackets are given by

$$[e_A,e_B]=f_{AB}^{C}e_C,\quad [h_\alpha,h_\beta]=f_{\alpha\beta}^{\gamma}h_\gamma,\quad [e_A,h_\beta]=f_{A\beta}^{\gamma}h_\gamma. \tag{5.3}$$

If $C^a\equiv(\eta^A,C^\alpha)$, the coboundary operator γ^T can be cast into the form

$$\gamma^T=\eta^A\rho(e_A)+\eta^A\rho_C(e_A)-\frac{1}{2}\eta^A\eta^B f_{AB}^{C}\frac{\partial}{\partial\eta^C}+C^\alpha\rho(h_\alpha)-\frac{1}{2}C^\alpha C^\beta f_{\alpha\beta}^{\gamma}\frac{\partial}{\partial C^\gamma}. \tag{5.4}$$

Here, $\rho_C(e_A)$ is the extension to $\wedge(C)$ of the coadjoint representation of the semi-simple $\mathcal{K}$,

$$\rho_C(e_A)=-f_{A\beta}^{\gamma}C^\beta\frac{\partial}{\partial C^\gamma}, \tag{5.5}$$

while ρ denotes the representation of $\mathcal{G}$ in V. Let

$$N_\eta=\eta^A\frac{\partial}{\partial\eta^A},\quad N_C=C^\alpha\frac{\partial}{\partial C^\alpha}, \tag{5.6}$$

be the counting operators for the η's and C's and the associated gradings gh_η and gh_C on $V\otimes\wedge(C,\eta)$. According to the gh_C–grading, γ^T is the sum

$$\gamma^T=\gamma_0^T+\gamma_1^T,\quad (\gamma^T)^2=(\gamma_0^T)^2=(\gamma_1^T)^2=0,\quad \{\gamma_0^T,\gamma_1^T\}=0, \tag{5.7}$$

with γ_1^T explicitly given by

$$\gamma_1^T = C^\alpha \rho(h_\alpha) - \frac{1}{2} C^\alpha C^\beta f_{\alpha\beta}{}^\gamma \frac{\partial}{\partial C^\gamma} \tag{5.8}$$

and which obey

$$[N_C, \gamma_0^T] = 0, \quad [N_C, \gamma_1^T] = \gamma_1^T, \tag{5.9}$$

which means that γ_0^T conserves the number of C's while γ_1^T increases this number by one. At this stage, γ_0^T can already be identified with the coboundary operator of the Lie algebra cohomology of the semi-simple subalgebra $\mathcal{K}$ with coefficients in the $\mathcal{K}$-module $V \otimes \wedge(C)$, the corresponding representation being defined as $\rho^T(e_A) = \rho(e_A) \otimes \mathbb{I}_C + \mathbb{I}_V \otimes \rho_C(e_A)$. An element $a \in V \otimes \wedge(C, \eta)$ of total ghost number g can be decomposed according to its gh_C components,

$$a = a_0 + a_1 + \cdots + a_g, \quad gh_C a_k = k. \tag{5.10}$$

The cocycle condition $\gamma^T a = 0$ generates the following tower of equations,

$$\gamma_0^T a_0 = 0, \tag{5.11}$$

$$\gamma_1^T a_0 + \gamma_0^T a_1 = 0, \tag{5.12}$$

$$\gamma_1^T a_1 + \gamma_0^T a_2 = 0, \tag{5.13}$$

$$\vdots$$

$$\gamma_1^T a_g = 0, \tag{5.14}$$

and the coboundary condition reads

$$a_0 = \gamma_0^T \omega_0, \tag{5.15}$$

$$a_1 = \gamma_1^T \omega_0 + \gamma_0^T \omega_1, \tag{5.16}$$

$$\vdots$$

$$a_g = \gamma_1^T \omega_{g-1}. \tag{5.17}$$

The above mentioned results on reductive Lie algebra cohomology imply that the general solution of Eq. (5.11) can be written as

$$a_0 = v_0^j \Theta_j + \gamma_0^T \omega_0, \tag{5.18}$$

$$\rho^T(e_A) v_0^j = 0, \tag{5.19}$$

where the $\Theta_j(\eta)$'s form a basis of the cohomology $H(\mathcal{K}, \mathbb{R})$, which is generated by the primitive elements. Furthermore, all $\mathcal{K}$-invariant polynomials v^j, obeying $v^j \Theta_j + \gamma_0^T \omega = 0$ for some ω, have to vanish, $v^j = 0$.

The term $\gamma_0^T \omega_0$ can be absorbed by subtracting $\gamma^T \omega_0$ from a and modifying a_1 appropriately. Injecting then (5.18) in (5.12), one gets, since γ_1^T does not act on the η's,

$$(\gamma_1^T v_0^j) \Theta_j + \gamma_0^T a_1 = 0. \tag{5.20}$$

Now, from $[\rho^T(e_A), \gamma_1^T] = 0$, one sees that $\gamma_1^T v_0^j \in V \otimes \wedge(C)$ is still invariant under $\rho^T(e_A)$. Accordingly, one must have

$$\gamma_1^T v_0^j = 0 \quad \text{and} \quad \gamma_0^T a_1 = 0. \tag{5.21}$$

Again, the general solution of the last equation (5.21) is

$$a_1 = v_1^j \Theta_j + \gamma_0^T \omega_1 \tag{5.22}$$

with $\rho^T(e_A)v_1^j = 0$; subtraction of $\gamma^T\omega_1$ and injection in Eq. (5.13) gives

$$(\gamma_1^T a_1^j)\Theta_j + \gamma_0^T a_2 = 0, \tag{5.23}$$

implying

$$\gamma_1^T v_1^j = 0 \quad \text{and} \quad \gamma_0^T a_2 = 0. \tag{5.24}$$

The same procedure can be repeated until (5.14).

Every γ^T-cocycle is thus of the form

$$a = \sum_{k=0}^{g} v_k^j \Theta_j + \gamma^T \omega, \tag{5.25}$$

with

$$\rho^T(e_A)v_k^j = 0 \Rightarrow v_k^j \in [V \otimes \wedge(C)]^{\mathcal{K}}, \tag{5.26}$$

$$\gamma_1^T v_k^j = 0. \tag{5.27}$$

Let us now analyze the coboundary condition. To order 0, we find

$$v_0^j = 0 \quad \text{and} \quad \gamma_0^T \omega_0 = 0. \tag{5.28}$$

The last equation implies $\omega_0 = w_0^j \Theta_j + \gamma_0^T(\ )$. The γ_0^T exact term can be absorbed by subtracting the corresponding γ^T exact term from ω. To order 1, we then find

$$v_1^j = \gamma_1^T w_0^j \quad \text{and} \quad \gamma_0^T \omega_1 = 0. \tag{5.29}$$

Going on in the same way gives

$$v_k^j = \gamma_1^T w_{k-1}^j, \quad k = 1, \ldots, g. \tag{5.30}$$

In other words,

$$H(\mathcal{G}, V) \simeq H(\mathcal{G}/\mathcal{J}, \mathbb{R}) \otimes H(\gamma_1^T, (V \otimes \wedge(C))^{\mathcal{K}}). \tag{5.31}$$

From $\{\gamma_1^T, \partial/\partial C^\alpha\} = \rho^T(h_\alpha)$, it follows that the elements $[v_k^j]$ of the second space are invariant under the action of $\mathcal{J}$,

$$\rho^T(h_\alpha)v_k^j = \gamma_1^T \frac{\partial}{\partial C^\alpha} v_k^j \Rightarrow (\rho^T(h_\alpha))^{\#}[v_k^j] = 0, \tag{5.32}$$

where $\rho^T(h_\alpha) = \rho(h_\alpha) \otimes \mathbb{I}_C + \mathbb{I}_V \otimes \rho_C(h_\alpha)$. Hence,

$$H(\gamma_1^T, (V \otimes \wedge(C))^{\mathcal{K}}) = H^{\mathcal{G}}(\mathcal{J}, V), \tag{5.33}$$

as required.

C. Explicit computation of $H(\gamma,\mathcal{B})$ for $\mathcal{G}=iso(3)$ or $iso(2,1)$

1. Applicability of the theorem

As a concrete application, we consider the case where $\mathcal{G}=iso(3)$, the three dimensional Euclidian algebra, or $\mathcal{G}=iso(2,1)$, the three dimensional Poincaré algebra. Both of these Lie algebras fulfill the hypothesis of the Hochschild–Serre theorem with $\mathcal{J}$ being the Abelian translation algebra.

Denoting by $\{h_a=P_a, e_a=J_a\}$ a basis of $\mathcal{G}$ where P_a represent the translation generators and J_a represent the rotation (resp. Lorentz) generators, their brackets can be written as

$$[P_a,P_b]=0,\ [J_a,J_b]=\epsilon_{abc}J^c,\ [J_a,P_b]=\epsilon_{abc}P^c. \tag{5.34}$$

The indices are lowered or raised with the Killing metric g_{ab} of the semi-simple subalgebra $\mathcal{K}=so(3)$ or $so(2,1)$.

In the so-called universal algebra, (see Refs. 16 and 37 for more details) the space of polynomials in the F^a, the Abelian curvature two-form associated to the translations, and the G^a, the non-Abelian curvature two-form associated to the rotations/boosts, can be identified with the module $V=S(\mathcal{G}^*)$ transforming under the extension of the coadjoint representation, so that

$$H(\gamma,\mathcal{B}))\simeq H(\gamma^R,\mathcal{P})\equiv H(\mathcal{G},S(\mathcal{G}^*)). \tag{5.35}$$

The coboundary operator γ^R acts on $V\otimes\wedge(C,\eta)$ through

$$\gamma^R=\eta^a\epsilon_{abc}\left[F^c\frac{\partial}{\partial F_b}+G^c\frac{\partial}{\partial G_b}-\frac{1}{2}\eta^b\frac{\partial}{\partial\eta_c}-C^b\frac{\partial}{\partial C_c}\right]+C^a\epsilon_{abc}G^c\frac{\partial}{\partial F_b}. \tag{5.36}$$

As mentioned above, the Lie algebra cohomology $H(\mathcal{K},\mathbb{R})$ is generated by particular ghost polynomials $\Theta_i(\eta)$ representing the primitive elements which are in one-to-one correspondence with the independent Casimir operators. In the particular cases considered here, there is but one primitive element given by

$$\theta_1=\frac{1}{3!}\epsilon_{abc}\eta^a\eta^b\eta^c=(-)^\sigma\hat{\eta}^3, \tag{5.37}$$

where $\sigma=0,1$ for the Euclidean respectively Minkowskian case. The elements of the set $\{1,\theta_1\}$ provide a basis of this cohomology.

2. Invariants, cocycles, coboundaries

a. Order zero. In $gh_C=0$, the invariant space $V^{\mathcal{K}}$ is generated by the following quadratic invariants:

$$f_1=g_{ab}G^aG^b,\ f_2=g_{ab}F^aF^b,\ f_3=g_{ab}F^aG^b. \tag{5.38}$$

An element $a_0\in V^{\mathcal{K}}$ is a polynomial in the three variables

$$a_0=Q(f_1,f_2,f_3). \tag{5.39}$$

To fulfill the cocycle condition $\gamma_1^Ra_0=0$, Q has to obey

$$\epsilon_{abc}G^c\frac{\partial}{\partial F_b}Q=0=\epsilon_{abc}G^c\left[2F^b\frac{\partial}{\partial f_2}+G^b\frac{\partial}{\partial f_3}\right]Q, \tag{5.40}$$

which implies

$$\frac{\partial}{\partial f_2}Q=0. \tag{5.41}$$

The γ_1^R-cocycles of $gh_C=0$ are thus of the form

$$a_0=Q(f_1,f_3). \tag{5.42}$$

Using the following decomposition,

$$Q(f_1,f_2,f_3)=Q(f_1,0,f_3)+f_2\tilde{Q}(f_1,f_2,f_3), \tag{5.43}$$

the coboundaries of $gh_C=1$ are given by

$$t_1=\gamma_1^R[f_2\tilde{Q}(f_1,f_2,f_3)]=2C^a\epsilon_{abc}G^cF^b\frac{\partial}{\partial f_2}[f_2\tilde{Q}(f_1,f_2,f_3)]. \tag{5.44}$$

b. Order one. In $gh_C=1$, the elements of $[V\otimes\wedge(C)]^{\mathcal{K}}$ can be written as

$$\omega_1=C^b\omega_b, \tag{5.45}$$

where the $\omega_b\in S(\mathcal{G}^*)$ transform under $\mathcal{K}$ as the components of a vector. They are of the form

$$C^b\omega_b=C^b[G_bQ(f_k)+F_bR(f_k)+\epsilon_{bcd}G^cF^dS(f_k)]. \tag{5.46}$$

According to (5.44), the last term is γ_1^R-exact. For the other terms, the cocycle condition $\gamma_1^Ra_1=0$ implies

$$C^aC^b\epsilon_{amn}G^n\left[2G_bF^m\frac{\partial Q}{\partial f_2}+\delta_b^mR+2F_bF^m\frac{\partial R}{\partial f_2}\right]=0, \tag{5.47}$$

and imposes

$$R=0 \quad \text{and} \quad \frac{\partial Q}{\partial f_2}=0. \tag{5.48}$$

Hence, the nontrivial $gh_C=1$ cocycles are given by

$$a_1=C^bG_bQ(f_1,f_3). \tag{5.49}$$

The $gh_C=2$ coboundaries are given by

$$t_2=\gamma_1^RC^b[G_bf_2\tilde{Q}(f_k)+F_bR(f_k)], \tag{5.50}$$

or equivalently by

$$t_2=[(GC^2)f_3-(FC^2)f_1]\frac{\partial f_2\tilde{Q}}{\partial f_2}+(GC^2)R+[(GC^2)f_2-(FC^2)f_3]\frac{\partial R}{\partial f_2} \tag{5.51}$$

due to the identities

$$2(C^aG_a)(C^b\epsilon_{bcd}G^cF^d)=(GC^2)f_3-(FC^2)f_1, \tag{5.52}$$

$$2(C^aF_a)(C^b\epsilon_{bcd}G^cF^d)=(GC^2)f_2-(FC^2)f_3, \tag{5.53}$$

in which $(FC^2)=C^aC^b\epsilon_{abc}F^c$ and $(GC^2)=C^aC^b\epsilon_{abc}G^c$.

One deduces from (5.51) that, for all integers L,M,N, the following equalities between γ_1^R equivalences classes hold:

$$[(GC^2)f_1^L f_2^M f_3^{N+1}]=[(FC^2)f_1^{L+1}f_2^M f_3^N], \tag{5.54}$$

$$[(GC^2)f_1^L f_2^M f_3^N]=\left[\frac{M}{M+1}(FC^2)f_1^L f_2^{M-1}f_3^{N+1}\right], \tag{5.55}$$

from which one infers that the elements of the form $(GC^2)U(f_k)$ are equivalent to elements of the form $(FC^2)V(f_k)$ and, furthermore, that all monomials of the form $(FC^2)f_1^L f_2^M f_3^N$ with $L>M$ are coboundaries, while those which have $L\leqslant M$ can be replaced by monomials not containing f_1 according to

$$[(FC^2)f_1^L f_2^M f_3^N]=\left[(FC^2)\frac{(M-L+1)}{M+1}f_2^{M-L}f_3^{N+2L}\right]. \tag{5.56}$$

c. Order two. The $gh_C=2$ elements of $[V\otimes\wedge(C)]^{\mathcal{K}}$ can be written as

$$\omega_2=C^aC^b\omega_{ab}. \tag{5.57}$$

The most general element is of the type

$$\omega_2=C^aC^b\epsilon_{abc}[G^cU(f_k)+F^cV(f_k)+\epsilon^{cmn}G_mF_nW(f_k)], \tag{5.58}$$

but, according to our preceding results, through the addition of an appropriate coboundary, we can remove the U-part and suppose V not depending on f_1. The cocycle condition $\gamma_1^R a_2=0$ then reads

$$C^dC^aC^b\epsilon_{def}G^f\epsilon_{abc}\frac{\partial}{\partial F_e}[F^cV(f_2,f_3)+\epsilon^{cmn}G_mF_nW(f_k)]=0. \tag{5.59}$$

It does not further restrict V but requires $W=0$. The nontrivial $gh_C=2$ cocycles are thus given by

$$a_2=(FC^2)V(f_2,f_3). \tag{5.60}$$

In order to characterize the $gh_C=3$ coboundaries, we use the following identity,

$$\gamma_1^R(F\times G)C^2f_1^Lf_2^Mf_3^N=C^1C^2C^3(4(M+1)f_1^{L+1}f_2^Mf_3^N-4Mf_1^Lf_2^{M-1}f_3^{N+2}), \tag{5.61}$$

from which we infer that all monomials of the form $C^1C^2C^3f_1^Lf_2^Mf_3^N$ for $L>M$ are coboundaries, while those with $L\leqslant M$ are equivalent to monomials involving powers of f_2 and f_3 only.

d. Order three. The $gh_C=3$ invariants are of the form

$$\omega_3=C^1C^2C^3Q(f_1,f_2,f_3). \tag{5.62}$$

All of them are cocycles since $\mathcal{J}$ is of dimension 3, but only those of the form

$$a_3=C^1C^2C^3Q(f_2,f_3) \tag{5.63}$$

are nontrivial.

e. Summary. The nontrivial cocycles of $H(\gamma_1^R,[V\otimes\wedge(C)]^{\mathcal{K}})$ are summarized in Table I, where $\hat{C}^3=C^1C^2C^3$, $CG=C^aG_a$. They provide a basis of $H(\gamma_1^R,[V\otimes\wedge(C)]^{\mathcal{K}})$ as a vector space.

The associated basis of $H(\gamma,\mathcal{B})\simeq H(\gamma_1^R,\mathcal{P})$ is given by

$$\{Q_0(f_1,f_3),CGR_0(f_1,f_3),FC^2S_0(f_2,f_3),\hat{C}^3T_0(f_2,f_3),$$

$$\hat{\eta}^3Q_1(f_1,f_3),\hat{\eta}^3CGR_1(f_1,f_3),\ \hat{\eta}^3FC^2S_1(f_2,f_3),\ \hat{\eta}^3\hat{C}^3T_1(f_2,f_3)\}. \tag{5.64}$$

VI. $H(\gamma|d)$ FOR $\mathcal{G}/\mathcal{J}$ SEMISIMPLE AND $\mathcal{J}$ ABELIAN

Let $\mathcal{K}$ be a semi-simple Lie algebra and $\mathcal{G}=\mathcal{K}\ltimes\mathcal{J}$ with $\mathcal{J}$ an Abelian ideal. This means that, with respect to Sec. V, the additional assumption $[h_\alpha,h_\beta]=0$ holds. In other words, the only possibly nonvanishing structure constants are given by f_{AB}^C and $f_{A\beta}^\gamma$.

A. $H(\gamma|d,\mathcal{B})$

1. General results

Let B^A and η^A the gauge field one-forms and ghosts associated to $\mathcal{K}$ and A^α and C^α the gauge fields one-forms and ghosts associated to $\mathcal{J}$. The curvature two-form decomposes as $G^A=dB^A+\frac{1}{2}[B,B]^A$ and $F^\alpha=dA^\alpha+[B,A]^\alpha$. Let us consider the algebra $\mathcal{B}$ using the variables C^α, $DC^\alpha=dC^\alpha+[B,C]^\alpha$, A^α, F^α, B^A, G^A, η^A, $D\eta^A=d\eta^A+[B,\eta]^A$. Applying the results of Sec. III, we have

$$d=[\lambda,\gamma]. \tag{6.1}$$

As in Sec. III, if $\gamma b=0$, one has

$$db+\gamma\lambda b=0, \tag{6.2}$$

and

$$d\lambda b+\gamma\tfrac{1}{2}\lambda^2 b=\tau b, \tag{6.3}$$

with

$$\tau=\frac{1}{2}[d,\lambda]=F^\alpha\frac{\partial}{\partial C^\alpha}+G^A\frac{\partial}{\partial\eta^A}, \tag{6.4}$$

$$\tau^2=0,\ \{\tau,\gamma\}=0. \tag{6.5}$$

Furthermore, if

$$\sigma=C^\alpha\frac{\partial}{\partial F^\alpha}, \tag{6.6}$$

$$\sigma^2=0,\ \{\tau,\sigma\}=N_{C,F}, \tag{6.7}$$

$$\{\sigma,\gamma\}=0. \tag{6.8}$$

It is in order for this last relation to hold that one needs the assumption that $\mathcal{J}$ is Abelian. Indeed, in this case, because

$$\gamma = -DC^\alpha \frac{\partial}{\partial A^\alpha} - D\eta^A \frac{\partial}{\partial B^A} + ([F,\eta]+[G,C])^\alpha \frac{\partial}{\partial F^\alpha}$$
$$+[G,\eta]^A \frac{\partial}{\partial G^A} - [\eta,C]^\alpha \frac{\partial}{\partial C^\alpha} - \frac{1}{2}[\eta,\eta]^A \frac{\partial}{\partial \eta^A}, \tag{6.9}$$

the absence of the term $[F,C]^\alpha \partial/\partial F^\alpha$ guarantess that (6.8) holds.

According to (5.25), we can assume $b = v^j \Theta_j$, where $v^j = v^j(F,G,C)$ with

$$\rho^T(e_A) v^j = 0 = \gamma v^j, \tag{6.10}$$

$$\rho^T(e_A) = -f^\gamma_{A\beta} F^\beta \frac{\partial}{\partial F^\gamma} - f^C_{AB} G^B \frac{\partial}{\partial G^C} - f^\gamma_{A\beta} C^\beta \frac{\partial}{\partial C^\gamma}, \tag{6.11}$$

$$\gamma v^j = -[C,G]^\alpha \frac{\partial}{\partial F^\alpha} v^j. \tag{6.12}$$

Applying (6.2) and (6.3), we get

$$dv^j + \gamma \lambda v^j = 0, \tag{6.13}$$

$$d\lambda v^j + \gamma \tfrac{1}{2}\lambda^2 v^j = \tau v^j. \tag{6.14}$$

Furthermore, because $\mathcal{K}$ is semi-simple, there exist $\hat{\Theta}_j$ and $\hat{\hat{\Theta}}_j$ such that

$$d\Theta_j + \gamma \hat{\Theta}_j = 0, \tag{6.15}$$

$$d\hat{\Theta}_j + \gamma \hat{\hat{\Theta}}_j = 0. \tag{6.16}$$

It follows that

$$\gamma(v^j \Theta_j) = 0, \tag{6.17}$$

$$d(v^j \Theta_j) + \gamma((\lambda v^j)\Theta_j + v^j \hat{\Theta}_j) = 0, \tag{6.18}$$

$$d((\lambda v^j)\Theta_j + v^j \hat{\Theta}_j) + \gamma((\tfrac{1}{2}\lambda^2 v^j)\Theta_j + (\lambda v^j)\hat{\Theta}_j + v^j \hat{\hat{\Theta}}_j) = (\tau v^j)\Theta_j. \tag{6.19}$$

The necessary and sufficient condition that $v^j \Theta_j$ "can be lifted twice," i.e., that $[v^j \Theta_j] \in \mathrm{Ker}\, d_1$, with

$$d_1 : H(d, H(\gamma, \mathcal{B})) \to H(d, H(\gamma, \mathcal{B})),$$

$$[v^j \Theta_j] \mapsto d_1[v^j \Theta_j] = [d((\lambda v^j)\Theta_j + v^j \hat{\Theta}_j)],$$

is

$$d((\lambda v^j)\Theta_j + v^j \hat{\Theta}_j) = db' + \gamma(\ ), \tag{6.20}$$

with $\gamma b' = 0$. Because $db' + \gamma(\ ) = 0$, it follows by using (6.19) that this necessary and sufficient condition is

$$(\tau v^j)\Theta_j + \gamma(\ ) = 0. \tag{6.21}$$

Because τ commutes with $\rho^T(e_a)$ and anticommutes with γ, it follows from (5.30) that the condition reduces to

$$(\tau v^j)+\gamma w^j=0,\ \rho^T(e_A)w^j=0, \tag{6.22}$$

for some w^j. Let us decompose v^j as a sum of terms of definite $N_{F,C}$ degree k, $v^j=v_0^j+\Sigma_{k=1}v_k^j$. Using (6.7), this can be rewritten as

$$v^j=v_0^j+\sum_{k=1}\ (\sigma t_k^j+\tau s_k^j), \tag{6.23}$$

where $t_k^j=1/k\ \tau v_k^j$ and $s_k^j=1/k\ \sigma v_k^j$. This decomposition is direct and induces a well defined decomposition in cohomology because γ and τ, respectively σ, anticommute. Furthermore,

$$\tau v_0^j=0,\ \tau(\tau s_k^j)=0, \tag{6.24}$$

$$\tau\sigma t_k^j+\gamma w_k^j=0\Rightarrow\tau v_k^j+\gamma w_k^j=0\Rightarrow\sigma t_k^j=\gamma\frac{1}{k}\sigma w_k^j=0. \tag{6.25}$$

This implies for the decomposition $H(\gamma,\mathcal{B})=E_2\oplus d_1F_1\oplus F_1$, with Ker $d_1=E_2\oplus d_1F_1$, that

$$\text{Ker } d_1=\left\{v_0^j\Theta_j+\sum_{k=1}\ [\tau s_k^j]\,\Theta_j\right\}, \tag{6.26}$$

$$d_1F_1=\left\{\sum_{k=1}\ [\tau s_k^j]\,\Theta_j\right\}, \tag{6.27}$$

$$F_1=\left\{\sum_{k=1}\ [\sigma t_k^j]\,\Theta_j\right\}, \tag{6.28}$$

$$E_2=\{v_0^j\,\Theta_j\}. \tag{6.29}$$

Here, $[\tau s_k^j]$ and $[\sigma t_k^j]$ denote equivalence classes of $\rho^T(e_A)$ invariant cocycles that are τ, respectively σ, exact, up to coboundaries of $\rho^T(e_a)$ invariant elements that are also τ, respectively σ, exact.

Let

$$\lambda^{\#}:F_1\to H(\gamma|d,B),$$

$$[\sigma t_k^j]\Theta_j\mapsto[(\lambda\sigma t_k^j)\Theta_j+\sigma t_k^j\hat{\Theta}_j]. \tag{6.30}$$

That the map is well defined follows from (6.18) and $\lambda\gamma(\sigma w_k^j)\Theta_j+\gamma(\sigma w_k^j)\hat{\Theta}_j=d(\sigma w_k^j\Theta_j+\gamma(\lambda\sigma w_k^j\Theta_j+\sigma w_k^j\hat{\Theta}_j)$ due to (6.1).

Let $\mathcal{B}_\mathcal{K}$ be the restriction of $\mathcal{B}$ to the generators associated to $\mathcal{K}$. Because $E_2\simeq H(\gamma,\mathcal{B}_\mathcal{K})$, we have

$$H(\gamma,\mathcal{B}_\mathcal{G})\simeq H(\gamma,\mathcal{B}_\mathcal{K})\oplus d_1F_1\oplus F_1. \tag{6.31}$$

Furthermore, the general analysis of the exact triangle associated to the descent equations[16] (see also, e.g., Ref. 36) implies that

$$H(\gamma|d,\mathcal{B}_\mathcal{G})\simeq H(\gamma|d,\mathcal{B}_\mathcal{K})\oplus\lambda^{\#}F_1\oplus F_1. \tag{6.32}$$

TABLE II. Nontrivial solutions of the consistency condition in the small algebra.

gh	$H(\gamma\|d,\mathcal{B})$			
0	1	$GAR_0(f_1,f_3)$	0	$\hat{\eta}^0 Q_1(f_1)$
1	$GCR_0(f_1,f_3)$	0	$\hat{\eta}^1 Q_1(f_1)$	0
2	0	$\hat{\eta}^2 Q_1(f_1)+\frac{1}{2}AC^2T_1(f_2,f_3)$	0	0
3	$\hat{\eta}^3 Q_1(f_1)+\hat{C}^3T_0(f_2,f_3)$	$(\hat{\eta}^2 GC+\hat{\eta}^3 GA)R_1(f_1,f_3)$	0	0
4	$\hat{\eta}^3 GCR_1(f_1,f_3)$	0	0	0
5	0	$(\hat{\eta}^2\hat{C}^3+\frac{1}{2}\hat{\eta}^3AC^2)T_1(f_2,f_3)$	0	0
6	$\hat{\eta}^3\hat{C}^3T_1(f_2,f_3)$	0	0	0

This solves the problem because the classification of $H(\gamma|d,\mathcal{B}_\mathcal{K})$ and the associated decomposition of $H(\gamma,\mathcal{B}_\mathcal{K})$ for semi-simple $\mathcal{K}$ has been completely solved[16] (see, e.g., Ref. 37 for a review).

2. Application to $\mathcal{G}=iso(3)$ or $iso(2,1)$

By applying the analysis of the previous subsubsection to the particular case of $iso(3)$, respectively $iso(2,1)$, with $H(\gamma,\mathcal{B})$ given by (5.64), it follows that

$$F_1=\{GC\,R_0(f_1,f_3),\ \hat{C}^3\,T_0(f_2,f_3),\ \hat{\eta}^3\,GC\,R_1(f_1,f_3),\ \hat{C}^3\hat{\eta}^3\,T_1(f_2,f_3)\}, \tag{6.33}$$

$$d_1F_1=\{f_3\,\tilde{Q}_0(f_1,f_3),\ FC^2\,S_0(f_2,f_3),\ \hat{\eta}^3\,f_3\,\tilde{Q}_1(f_2,f_3),\ \hat{\eta}^3\,S_1(f_2,f_3)\}, \tag{6.34}$$

$$E_2=\{Q_0(f_1),\hat{\eta}^3\,Q_1(f_1)\}. \tag{6.35}$$

Furthermore, the general analysis of the semi-simple case applied to $so(3)$, respectively $so(2,1)$, gives

$$E_2=1\oplus d_3F_3\oplus F_3, \tag{6.36}$$

with

$$F_3=\{\hat{\eta}^3\,Q_1(f_1)\}, \tag{6.37}$$

$$d_3F_3=\{f_1\,\tilde{Q}_0(f_1)\}. \tag{6.38}$$

The associated elements of $H(\gamma|d,\mathcal{B})$ are listed in Table II, which involves the following new shorthand notations

$$\hat{\eta}^2=-\tfrac{1}{2}\epsilon_{abc}\,\eta^a\eta^bB^c, \tag{6.39}$$

$$\hat{\eta}^1=\eta^a\,(G_a-\tfrac{1}{2}\,\epsilon_{abc}B^bB^c), \tag{6.40}$$

$$\hat{\eta}^0=B^bG_b-\frac{1}{3!}\,\epsilon_{abc}B^aB^bB^c=g_{ab}B^adB^b+\frac{1}{3}\,\epsilon_{abc}B^aB^bB^c. \tag{6.41}$$

B. $H(\gamma|d,\mathcal{A})$

Using (4.13), respectively (4.14), we have, for $0\leqslant p<n$,

$$H^p(\gamma|d,\mathcal{A})\simeq i_0 H^p(\gamma,\mathcal{B}_\mathcal{K})\oplus F_1\oplus\mathcal{N}^p_\mathcal{A}\oplus\mathcal{D}^{-1}(\mathcal{D}H)^{p-1}(\gamma|d,\mathcal{B}_\mathcal{K})\oplus\lambda^\# F^n_1. \tag{6.42}$$

and in form degree n,

$$H^n(\gamma|d,\mathcal{A})\simeq\mathcal{F}^n\oplus\mathcal{D}^{-1}(\mathcal{D}H)^{n-1}(\gamma|d,\mathcal{B}_\mathcal{K})\oplus\lambda^\# F^n_1, \tag{6.43}$$

with $\mathcal{F}^n\simeq H^n(\gamma,\mathcal{A})/d_0\mathcal{N}^{n-1}_\mathcal{A}$.

VII. APPLICATION TO THE CONSISTENT DEFORMATIONS OF 2+1 DIMENSIONAL GRAVITY

A. Generalities

$2+1$ dimensional gravity with vanishing cosmological constant λ is equivalent to a Chern–Simons theory based on the gauge group $ISO(2,1)$.[24,25]

The Lie algebra $iso(2,1)$ is not reductive and its Killing metric $G_{AB}=f^D_{AC}f^C_{BD}$ is degenerate,

$$G_{AB}=\begin{pmatrix} g_{ab} & 0\\ 0 & 0\end{pmatrix}, \tag{7.1}$$

where g_{ab} is the Killing metric of the semi-simple $so(2,1)$ subalgebra. However, in this case, another invariant, symmetric and nondegenerate metric $\Omega^{(0)}_{AB}$ exists which allows for the construction of the CS Lagrangian. The invariant quadratic form of interest is

$$\Omega^{(0)}_{AB}=\begin{pmatrix}\langle J_a,J_b\rangle & \langle J_a,P_b\rangle\\ \langle P_a,J_b\rangle & \langle P_a,P_b\rangle\end{pmatrix}=\begin{pmatrix}0 & g_{ab}\\ g_{ab} & 0\end{pmatrix}. \tag{7.2}$$

Locally, the relation between $2+1$ dimensional gravity and the Chern–Simons theory is based on the $iso(2,1)$ Lie algebra valued one-form

$$\mathcal{A}_\mu=A^A_\mu T_A=e^a_\mu P_a+\omega^a_\mu J_a \tag{7.3}$$

built from the dreibein fields e^a_μ and the spin connection $\omega^a_\mu=\frac{1}{2}\epsilon^a_{bc}\omega^{bc}_\mu$ of three dimensional Minkowski space–time $\mathcal{M}$ with metric that we choose of signature $(-,+,+)$. In terms of these variables, the Chern–Simons action takes the form of the $2+1$ dimensional Einstein–Hilbert action in vielbein formulation:

$$\begin{aligned} S^{(0)}_{CS}&=\int_\mathcal{M}\Omega^{(0)}_{AB}\left[\frac{1}{2}A^A\,dA^B+\frac{1}{6}A^A\,f^B{}_{CD}\,A^C\,A^D\right]\\ &=\int_\mathcal{M}\frac{1}{2}(e^a\,d\omega_a+\omega^a\,de_a+\epsilon_{abc}\,e^a\,\omega^b\,\omega^c), \qquad (7.4)\\ &=\int_\mathcal{M}e^a\,G_a+\frac{1}{2}d(e^a\,\omega_a). \qquad (7.5)\end{aligned}$$

The gauge transformations are parametrized by two zero-forms ϵ^a and τ^a,

$$\varepsilon=\varepsilon^A T_A=\epsilon^a P_a+\tau^a J_a. \tag{7.6}$$

Explicitly,

$$\delta_\epsilon e^a = -d\epsilon^a - \epsilon^a{}_{bc}(\omega^b \epsilon^c + e^b \tau^c), \tag{7.7}$$

$$\delta_\epsilon \omega^a = -d\tau^a - \epsilon^a{}_{bc}\omega^b \tau^c, \tag{7.8}$$

and are equivalent, on shell, to local diffeomorphisms and local Lorentz rotations. The classical equations of motion express the vanishing of the field strenghts two-forms

$$F_a = \tfrac{1}{2}F_{\mu\nu a}dx^\mu dx^\nu = de_a + \epsilon_{abc}\omega^b e^c, \tag{7.9}$$

$$G_a = \tfrac{1}{2}G_{\mu\nu a}dx^\mu dx^\nu = d\omega_a + \tfrac{1}{2}\epsilon_{abc}\omega^b \omega^c, \tag{7.10}$$

where

$$\mathcal{F}_{\mu\nu} = \mathcal{F}^A_{\mu\nu} T_A = F^a_{\mu\nu} P_a + G^a_{\mu\nu} J_a . \tag{7.11}$$

For invertible dreibeins, the equation $F^a = 0$ can be algebraically solved for ω^a as a function of the e^a's; when substituted into the remaining equation it tells that the space–time Riemann curvature vanishes, which in three dimensions implies that space–time is locally flat.

Our aim is to study systematically all consistent deformations of $2+1$ dimensional gravity. By consistent, we mean deformations of the action by local functionals and simultaneous deformations of the gauge transformations such that the deformed action is invariant under the deformed gauge transformations.

The problem of such consistent deformations can be reformulated[41] (for a review, see Ref. 42) as the problem of deformations of the solution of the master equation and is controlled to first order by the cohomology $H^{0,3}(s|d)$.

B. Results on local BRST cohomology

The analysis of $H(s|d)$ for the Chern–Simons case (see, e.g., Ref. 37, Sec. 14) implies that the cohomology $H(s|d)$ is essentially given by the bottoms $[\frac{1}{2}\hat{\eta}^3]$, $[\hat{C}^3]$, $[\frac{1}{2}\hat{\eta}^3\hat{C}^3]$ of $H(\gamma,\mathcal{B})$ and by their lifts, which are all nontrivial and unobstructed. (The only additional classes correspond to the above bottoms multiplied by nonexact space–time forms.)

It follows that $H^{0,3}(s|d)$ is obtained from the lift (associated to s) of the elements $[\frac{1}{2}\hat{\eta}^3]$ and $[\hat{C}^3]$ of $H^{3,0}(s)$. The former element can be lifted to $\frac{1}{2}\hat{\eta}^0$ with $\hat{\eta}^0$ given in (6.41). It corresponds to the Chern–Simons action built on $so(2,1)$. The results on $H(\gamma|d,\mathcal{B})$ (see Table II) imply that the lift of $\hat{C}^3$ in $H(s|d)$ cannot been done without a nontrivial dependence on the antifields, and hence without a nontrivial deformation of the gauge transformations. Following again, Ref. 37, this lift is given by

$$\epsilon_{abc}[\tfrac{1}{6}e^a e^b e^c + e^a \star\omega^{*b} C^c + \tfrac{1}{2}\star\eta^{*a} C^b C^c], \tag{7.12}$$

where $\star\omega^{*a} = \frac{1}{2}dx^\mu dx^\nu \epsilon_{\mu\nu\rho}\omega^{*a\rho}$ and $\star\eta^*_a = d^3x\,\eta^*_a$. The antifield independent part gives the deformation of the original action.

Note also that $H^{1,3}(s|d)$ is trivial, which implies that there can be no anomalies in a perturbative quantization of $2+1$ dimensional gravity. Furthermore, the starting point Lagrangian three-form eG is trivial, $[eG]=[0]\in H^{0,3}(s|d)$, which is the reason why we do not introduce a separate coupling constant for this term.

C. Maximally deformed 2+1 dimensional gravity

Introducing coupling constants μ and λ (the cosmological constant) for the two first order deformations, they can be easily shown to extend to all orders by introducing a $\lambda\mu$ dependent term in the action. The associated completely deformed theory can be written as a Chern–Simons theory in terms of the deformed invariant metric

$$\Omega^{\lambda,\mu}_{AB}=\Omega^{(0)}_{AB}+G^{\mu,\lambda}_{AB}, \tag{7.13}$$

$$G^{\mu,\lambda}_{AB}=\mu\begin{pmatrix} g_{ab} & 0 \\ 0 & \lambda\, g_{ab}\end{pmatrix}, \tag{7.14}$$

and the deformed structure constants $f^{A(\lambda)}_{BC}$ given by

$$[J_a,J_b]=\epsilon_{abc}\,J^c,[J_a,P_b]=\epsilon_{abc}\,P^c,[P_a,P_b]=\lambda\,\epsilon_{abc}\,J^c. \tag{7.15}$$

For $\lambda>0$, these structure constants are those of the semi-simple Lie algebra $so(2,1)\oplus so(2,1)$. The deformed Chern–Simons action reads explicitly

$$S^{\lambda,\mu}=\int_{\mathcal{M}}\Omega^{\lambda,\mu}_{AB}\left[\frac{1}{2}A^A\,dA^B+\frac{1}{6}A^A\,f^{B(\lambda)}_{CD}\,A^C A^D\right] \tag{7.16}$$

$$=\int_{\mathcal{M}}\left[e^a G_a+\mu\left[\frac{1}{2}\,\omega^a\,d\omega_a+\frac{1}{6}\,\epsilon_{abc}\,\omega^a\,\omega^b\,\omega^c\right]\right.$$

$$\left.+\lambda\,\frac{1}{3!}\,\epsilon_{abc}\,e^a\,e^b\,e^c+\lambda\mu\left[\frac{1}{2}\,e^a\,de_a+\frac{1}{2}\,\epsilon_{abc}\,e^a\,e^b\,\omega^c\right]\right], \tag{7.17}$$

while the deformed gauge transformations read

$$\delta_\epsilon\,e^a=-d\,\epsilon^a-\epsilon^a{}_{bc}(\omega^b\,\epsilon^c+e^b\,\tau^c), \tag{7.18}$$

$$\delta_\epsilon\,\omega^a=-d\,\tau^a-\epsilon^a{}_{bc}(\omega^b\,\tau^c+\lambda\,e^b\,\epsilon^c). \tag{7.19}$$

Thus, our analysis shows that there are no other consistent deformations of $2+1$ dimensional gravity than those already discussed in Ref. 25.

Note added in proof: Two remarks concerning the proof of lemma 5 are in order. (1) The homotopy formula (4.52) has been used in the form $\{\overline{p},d\}=1$. This supposes that the forms on which it applies vanish when the variables A^a_μ and their derivatives are put to zero. In order to complete the reasoning, one should separate each form in such a part and a part that does not depend on those variables, but only on C^a, x^μ and dx^μ. This last part can be treated easily by using the homotopy of the standard Poincaré lemma. The final result, Eq. (4.61) is unchanged. (2) The proof on the top of page 12 that $\gamma^R I'_M=0$ is incorrect. The correct proof proceeds again by induction. More precisely, one shows that if $I_{Na_1\ldots a_k}$ in the l.h.s. of (4.57) is γ^R_k closed, then the $I'_{Na_1\ldots a_k}$ that has been constructed in the r.h.s of (4.57) can be chosen to be γ^R_k closed as well.

ACKNOWLEDGMENTS

The authors want to thank M. Henneaux for suggesting the problem and for useful discussions. U. Leuven.

APPENDIX: DESCENTS AND DECOMPOSITION ACCORDING TO HOMOGENEITY

The space $\mathcal{E}$ can be decomposed into monomials of definite homogeneity M in the fields and their derivatives, $\mathcal{E}=\oplus_{M=0}\mathcal{E}_M$, and one can define the spaces of polynomials of homogeneity greater or equal to M, $\mathcal{E}^M=\oplus_{N\geq M}\mathcal{E}_N$.

If

$$\mathcal{C}^M=\langle H(\gamma|d,\mathcal{E}^M),H(\gamma,\mathcal{E}^M),\mathcal{D}^M,l^{\#^M},i^{\#^M}\rangle, \tag{A1}$$

$$\mathcal{C}_M=\langle H(\gamma_0|d,\mathcal{E}_M),H(\gamma_0,\mathcal{E}_M),\mathcal{D}_M,l_M^{\#},i_M^{\#}\rangle, \tag{A2}$$

are the exact couples that describe the descents of γ in $\mathcal{E}^M$, respectively of γ_0 in $\mathcal{E}_M$, one can define mappings between exact couples (see, e.g., Ref. 43) through

$$I_{M+1}=(j_{M+1},k_{M+1}):\mathcal{C}^{M+1}\to\mathcal{C}^M, \tag{A3}$$

$$P_M=(\pi_M,\psi_M):\mathcal{C}^M\to\mathcal{C}_M, \tag{A4}$$

$$G_M=(m_M,n_M):\mathcal{C}_M\to\mathcal{C}^{M+1}. \tag{A5}$$

The map j_{M+1} consists in the natural injection of elements of $H(\gamma|d,\mathcal{E}^{M+1})$ in $H(\gamma|d,\mathcal{E}^M)$ and similarily k_{M+1} consists in the injection of elements of $H(\gamma,\mathcal{E}^{M+1})$ as elements of $H(\gamma,\mathcal{E}^M)$, with

$$\mathcal{D}^M\circ j_{M+1}=j_{M+1}\circ\mathcal{D}^{M+1}, \tag{A6}$$

$$l^{\#^M}\circ j_{M+1}=k_{M+1}\circ l^{\#^{M+1}}, \tag{A7}$$

$$i^{\#^M}\circ k_{M+1}=j_{M+1}\circ i^{\#^{M+1}}. \tag{A8}$$

The map $\pi_M:H(\gamma|d,\mathcal{E}^M)\to H(\gamma_0|d,\mathcal{E}_M)$ is defined by $\pi_M[A^M]=[A_M]$, while $\psi_M:H(\gamma,\mathcal{E}^M)\to H(\gamma_0,\mathcal{E}_M)$ is defined by $\psi_M[a^M]=[a_M]$. Again, the various maps commute,

$$\mathcal{D}_M\circ\pi_M=\pi_M\circ\mathcal{D}^M, \tag{A9}$$

$$l_M^{\#}\circ\pi_M=\psi_M\circ l^{\#^M}, \tag{A10}$$

$$i_M^{\#}\circ\psi_M=\pi_M\circ i^{\#^M}. \tag{A11}$$

Both the maps $m_M:H(\gamma_0|d,\mathcal{E}_M)\to H(\gamma|d,\mathcal{E}^{M+1})$ and $n_M:H(\gamma_0,\mathcal{E}_M)\to H(\gamma,\mathcal{E}^{M+1})$ are defined by the induced action of $\gamma_1:m_M[a_M]=[\gamma_1 a_M]$ and $n_M[a_M]=[\gamma_1 a_M]$, with

$$\mathcal{D}^{M+1}\circ m_M=m_M\circ\mathcal{D}_M, \tag{A12}$$

$$l^{\#^{M+1}}\circ m_M=n_M\circ l_M^{\#}, \tag{A13}$$

$$i^{\#^{M+1}}\circ n_M=m_M\circ i_M^{\#}. \tag{A14}$$

Finally, the triangles

$$\begin{array}{ccc} H(\gamma|d,\mathcal{E}^{M+1}) & \overset{j_{M+1}}{\to} & H(\gamma|d,\mathcal{E}^M) \\ & {\scriptstyle m_M}\nwarrow \quad \swarrow{\scriptstyle \pi_M} & \\ & H(\gamma_0|d,\mathcal{E}_M), & \end{array} \tag{A15}$$

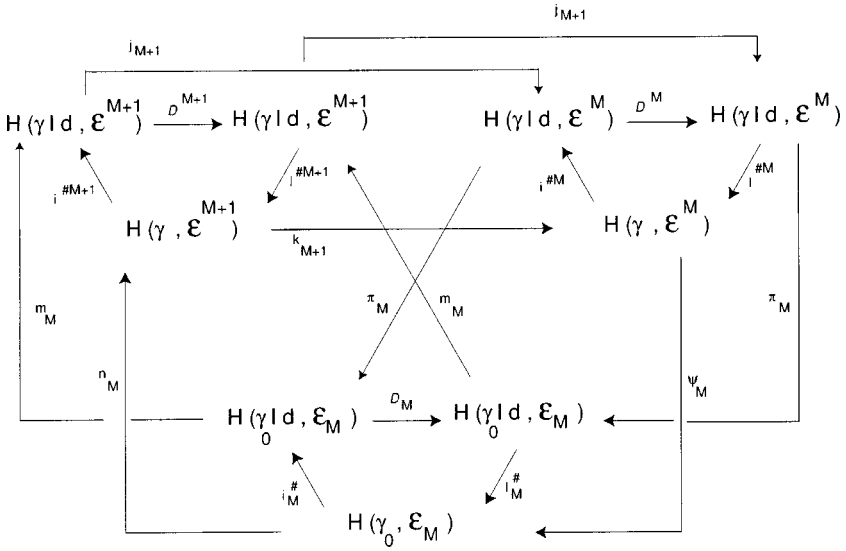

FIG. 1. Exact triangle of exact triangles.

$$
\begin{array}{ccc}
 & & H(\gamma,\mathcal{E}^{M+1}) \\
 & \overset{k_{M+1}}{\nearrow} & \downarrow \\
H(\gamma,\mathcal{E}^{M+1}) & & H(\gamma,\mathcal{E}^{M}) \\
 & {\scriptstyle n_M}\nwarrow \quad \swarrow{\scriptstyle \psi_M} & \\
 & H(\gamma_0,\mathcal{E}_M), &
\end{array}
\tag{A16}
$$

are exact at all corners, implying, if $j_0=1=k_0$, that

$$H(\gamma|d,\mathcal{E})=\oplus_{M=0}^{\infty} j_0 \ldots j_M \pi_M^{-1}\mathrm{Ker}\ \ m_M, \tag{A17}$$

$$H(\gamma,\mathcal{E})=\oplus_{M=0}^{\infty} k_0 \ldots k_M \psi_M^{-1}\mathrm{Ker}\ \ n_M. \tag{A18}$$

All this can be summarized by the commutative diagram of Fig. 1. The corners of the big triangle are itself given by exact triangles and the large triangles obtained by taking a group at the same position of each small triangle are also exact.

(Received 16 November 2001; accepted 12 August 2002)

Black p-brane solutions for a wide class of intersection rules and Ricci-flat ''internal'' spaces are considered. They are defined up to moduli functions H_s obeying nonlinear differential equations with certain boundary conditions imposed. A new solution with intersections corresponding to the Lie algebra C_2 is obtained. The functions H_1 and H_2 for this solution are polynomials of degree 3 and 4. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1513654]

I. INTRODUCTION

The discovery of various extended objects (D-branes, p-branes, etc.)[1] in superstring theories leads to a new stage in the development of superstring paradigm, e.g., to a notion of M-theory.[2] These extended objects (branes) play a very important role in the description of superstrings in the strong coupling limit and the explanation of dual relations between different superstring theories.

The brane objects may be described as classical solutions in supergravitational models (see, for example, Ref. 3 and references therein). They have BPS properties (i.e., they preserve partial supersymmetry) and are protected from quantum corrections. These solutions lead to extremal black hole solutions after a suitable compactifications of extra dimensions.

Other important objects are non-extremal black brane solutions.[4–6] In the extremal limit they (usually) lead to BPS brane configurations. Nonextremal black branes give also a remarkable microscopical explanation of black hole entropy,[7,8] being a nice polygon for application of different quantum methods (for toy quantum analogues of black branes see Ref. 9).

This paper is devoted to intersecting black-brane solutions with (next to) arbitrary intersections (see Sec. II).[10–13] These black-brane solutions are governed by moduli functions $H_s = H_s(R)$ obeying a set of second order nonlinear differential equations with some boundary relations imposed.

Some general features of the black-brane solutions were investigated earlier (see Ref. 14). More general spherically symmetric (and cosmological solutions) were obtained in Ref. 15 using the sigma-model approach and the Lagrange representation from Refs. 16–18.

In Ref. 10 the following conjecture was suggested (see Sec. III): the moduli functions H_s are polynomials when intersection rules correspond to semisimple Lie algebras. This conjecture was confirmed by special black-brane ''block-orthogonal'' solutions considered earlier in Refs. 14, 19–22 (Sec. III A). It was verified also for A_m and C_m series of Lie algebras in Refs. 11 and 12. An analogue of this conjecture for extremal black holes was considered earlier in Ref. 23.

An example of black brane solution corresponding to Lie algebra $A_2 = \mathrm{sl}(3)$ was considered earlier in Refs. 10 and 11, where some dyonic configurations (e.g., in 11-dimensional supergrav-

[a]Electronic mail: mag@gravi.phys.msu.su
[b]Electronic mail: ivas@rgs.phys.msu.su
[c]Electronic mail: sungwon@mm.ewha.ac.kr

ity) were considered. The A_2 solution is governed by two polynomials H_1 and H_2 of degree 2. The coefficients of polynomials and charges are functions of some parameters P_1 and P_2 and have a rather simple form (Sec. III A). It seems that A_2 solution is the only one that may be obtained "by hands:" the search of solutions for other Lie algebras needs computer calculations.

Here we present a first nontrivial result of such calculations, i.e., a new solution corresponding to the Lie algebra C_2 governed by polynomials of degree 3 and 4 (Sec. III C). The coefficients of polynomials exhibit a nontrivial dependence upon parameters P_1 and P_2, namely: a nontrivial term Δ, that is a square root of a polynomial of degree 4, appears.

II. *p*-BRANE BLACK HOLE SOLUTIONS

Consider a model governed by the action

$$S=\int d^D x\sqrt{|g|}\left\{R[g]-h_{\alpha\beta}g^{MN}\partial_M\varphi^\alpha\partial_N\varphi^\beta-\sum_{a\in\triangle}\frac{\theta_a}{n_a!}\exp[2\lambda_a(\varphi)](F^a)^2\right\}, \tag{1}$$

where $g=g_{MN}(x)dx^M\otimes dx^N$ is a metric, $\varphi=(\varphi^\alpha)\in\mathbb{R}^l$ is a vector of scalar fields, $(h_{\alpha\beta})$ is a constant symmetric nondegenerate $l\times l$ matrix ($l\in\mathbb{N}$), $\theta_a=\pm 1$,

$$F^a=dA^a=\frac{1}{n_a!}F^a_{M_1\cdots M_{n_a}}dz^{M_1}\wedge\cdots\wedge dz^{M_{n_a}} \tag{2}$$

is a n_a-form ($n_a\geqslant 1$), λ_a is a 1-form on $\mathbb{R}^l$: $\lambda_a(\varphi)=\lambda_{\alpha a}\varphi^\alpha$, $a\in\triangle$, $\alpha=1,\ldots,l$. In (1) we denote $|g|=|\det(g_{MN})|$, $(F^a)^2_g=F^a_{M_1\cdots M_{n_a}}F^a_{N_1\cdots N_{n_a}}g^{M_1N_1}\cdots g^{M_{n_a}N_{n_a}}$, $a\in\triangle$. Here $\triangle$ is some finite set. In the models with one time all $\theta_a=1$ when the signature of the metric is $(-1,+1,\ldots,+1)$.

Let us consider (black-brane) solutions to field equations corresponding to the action (1) from Refs. 10–12. These solutions are defined on the manifold

$$M=(R_0,+\infty)\times(M_1=S^{d_1})\times(M_2=\mathbb{R})\times\cdots\times M_n, \tag{3}$$

and have the following form:

$$g=\left(\prod_{s\in S}H_s^{2h_s d(I_s)/(D-2)}\right)\left\{f^{-1}\,dR\otimes dR+R^2\,d\Omega^2_{d_1}-\left(\prod_{s\in S}H_s^{-2h_s}\right)f\,dt\otimes dt\right.$$
$$\left.+\sum_{i=3}^{n}\left(\prod_{s\in S}H_s^{-2h_s\delta_{iI_s}}\right)g^i\right\}, \tag{4}$$

$$\exp(\varphi^\alpha)=\prod_{s\in S}H_s^{h_s\chi_s\lambda^\alpha_{a_s}}, \tag{5}$$

$$F^a=\sum_{s\in S}\delta^a_{a_s}\mathcal{F}^s, \tag{6}$$

where $f=1-2\mu/R^{\overline{d}}$,

$$\mathcal{F}^s=-\frac{Q_s}{R^{d_1}}\left(\prod_{s'\in S}H_{s'}^{-A_{ss'}}\right)dR\wedge\tau(I_s),\quad s\in S_e, \tag{7}$$

$$\mathcal{F}^s=Q_s\tau(\overline{I_s}),\quad s\in S_m. \tag{8}$$

Here $Q_s \neq 0$ $(s \in S)$ are charges, $R_0 > 0$, $R_0^{\overline{d}} = 2\mu > 0$, $\overline{d} = d_1 - 1$. In (4) $g^i = g^i_{m_i n_i}(y_i) dy_i^{m_i} \otimes dy_i^{n_i}$ is a Ricci-flat metric on M_i, $i = 3,\ldots,n$ and $\delta_{iI} = \Sigma_{j \in I} \delta_{ij}$ is the indicator of i belonging to I: $\delta_{iI} = 1$ for $i \in I$ and $\delta_{iI} = 0$ otherwise. Here $g^2 = -dt \otimes dt$, and $g^1 = d\Omega_{d_1}$ be a canonical metric on unit sphere $M_1 = S^{d_1}$,

The p-brane set S is by definition

$$S = S_e \cup S_m, \quad S_v = \cup_{a \in \triangle} \{a\} \times \{v\} \times \Omega_{a,v}, \tag{9}$$

$v = e,m$ and $\Omega_{a,e}, \Omega_{a,m} \subset \Omega$, where $\Omega = \Omega(n)$ is the set of all nonempty subsets of $\{2,\ldots,n\}$, i.e., all p-branes do not "live" in M_1.

Any p-brane index $s \in S$ has the form $s = (a_s, v_s, I_s)$, where $a_s \in \triangle$, $v_s = e,m$ and $I_s \in \Omega_{a_s,v_s}$. The sets S_e and S_m define electric and magnetic p-branes, correspondingly. In (5) $\chi_s = +1,-1$ for $s \in S_e, S_m$, respectively. All p-branes contain the time manifold $M_2 = \mathbb{R}$, i.e.,

$$2 \in I_s, \quad \forall s \in S. \tag{10}$$

All manifolds M_i, $i > 2$, are oriented and connected and

$$\tau_i \equiv \sqrt{|g^i(y_i)|} dy_i^1 \wedge \cdots \wedge dy_i^{d_i}, \tag{11}$$

are volume d_i forms, where $d_i = \dim M_i$, $i = 1,\ldots,n$, with $d_1 > 1$ and $d_2 = 1$. For any $I = \{i_1,\ldots,i_k\} \in \Omega$, $i_1 < \cdots < i_k$, we denote

$$\tau(I) \equiv \tau_{i_1} \wedge \cdots \wedge \tau_{i_k}, \quad d(I) = \sum_{i \in I} d_i. \tag{12}$$

The forms $\mathcal{F}^s$ correspond to electric and magnetic p-branes for $s \in S_e, S_m$, respectively. In (8) we use the notation $\overline{I} = \{1,\ldots,n\} \setminus I$.

The parameters h_s appearing in the solution satisfy the relations: $h_s = (B_{ss})^{-1}$, where

$$B_{ss'} = d(I_s \cap I_{s'}) + \frac{d(I_s) d(I_{s'})}{2 - D} + \chi_s \chi_{s'} \lambda_{\alpha a_s} \lambda_{\beta a_{s'}} h^{\alpha\beta}, \tag{13}$$

$s, s' \in S$, with $(h^{\alpha\beta}) = (h_{\alpha\beta})^{-1}$ and $D = 1 + \Sigma_{i=1}^n d_i$. Here we assume that (i) $B_{ss} \neq 0$, $s \in S$ and (ii) $\det(B_{ss'}) \neq 0$, i.e., the matrix $(B_{ss'})$ is a nondegenerate one.

Let us consider the matrix

$$(A_{ss'}) = (2B_{ss'}/B_{s's'}). \tag{14}$$

Here some ordering in S is assumed.

The functions $H_s = H_s(z) > 0$, $z = 2\mu/R^{\overline{d}} \in (0,1)$, obey the equations

$$\frac{d}{dz}\left(\frac{(1-z)}{H_s} \frac{dH_s}{dz} \right) = B_s \prod_{s' \in S} H_{s'}^{-A_{ss'}}, \tag{15}$$

equipped with the boundary conditions

$$H_s(1-0) = H_{s0} \in (0,+\infty), \tag{16}$$

$$H_s(+0) = 1, \tag{17}$$

$s \in S$. Here $B_s = B_{ss} \epsilon_s Q_s^2 / (2\overline{d}\mu)^2$ and

$$\epsilon_s = (-\epsilon[g])^{(1-\chi_s)/2} \epsilon(I_s) \theta_{a_s}, \tag{18}$$

$s \in S$, $\epsilon[g] \equiv \operatorname{sign}\det(g_{MN})$. More explicitly Eq. (18) reads $\epsilon_s = \epsilon(I_s)\theta_{a_s}$ for $v_s = e$ and $\epsilon_s = -\epsilon[g]\epsilon(I_s)\theta_{a_s}$, for $v_s = m$.

Equations (16) are equivalent to Toda-type equations. The first boundary condition guarantees the existence of a regular horizon at $R^d = 2\mu$. The second condition (17) ensures an asymptotical flatness (for $R \to +\infty$) of the $(2+d_1)$-dimensional section of the metric.

Due to Eqs. (7) and (8), the dimension of p-brane world volume $d(I_s)$ is defined by relations $d(I_s) = n_{a_s} - 1$, $d(I_s) = D - n_{a_s} - 1$, for $s \in S_e, S_m$, respectively. For a p-brane we use a standard notation $p = p_s = d(I_s) - 1$.

The solutions are valid if the following restriction on the sets $\Omega_{a,v}$ is imposed. This restriction guarantees the block-diagonal structure of the stress-energy tensor. We denote $w_1 \equiv \{i | i \in \{2, \ldots, n\},\ d_i = 1\}$ and $n_1 = |w_1|$ (i.e., n_1 is the number of one-dimensional spaces among M_i, $i = 2, \ldots, n$). It is clear, that $2 \in w_1$.

Restriction. Let $(1a)$ $n_1 \leqslant 1$ *or* $(1b)$ $n_1 \geqslant 2$ *and for any* $a \in \Delta$, $v \in \{e, m\}$, $i, j \in w_1$, $i \neq j$, *there are no* $I, J \in \Omega_{a,v}$ *such that* $i \in I$, $j \in J$ *and* $I \backslash \{i\} = J \backslash \{j\}$.

This restriction is satisfied in the noncomposite case: $|\Omega_{a,e}| + |\Omega_{a,m}| = 1$ (i.e., when there are no two p-branes with the same color index a, $a \in \Delta$). The restriction forbids certain intersections of two p-branes with the same color index for $n_1 \geqslant 2$.

The solution under consideration describes a set of charged (by forms) overlapping black p-branes "living" on submanifolds of $M_2 \times \cdots \times M_n$.

III. EXAMPLES OF SOLUTIONS

A. "Block-orthogonal" solutions

The simplest polynomial solutions occur in orthogonal case,[18,24–27] when

$$B_{ss'} = 0, \tag{19}$$

for $s \neq s'$, $s, s' \in S$. In this case $(A_{ss'}) = \operatorname{diag}(2, \ldots, 2)$ is a Cartan matrix for semisimple Lie algebra $A_1 \oplus \cdots \oplus A_1$ and

$$H_s(z) = 1 + P_s z, \tag{20}$$

with $P_s \neq 0$, satisfying

$$P_s(P_s + 1) = -B_s, \tag{21}$$

$s \in S$. For positive parameters $P_s > 0$ we get negative $B_s < 0$.

In Refs. 19, 20, and 22 this solution was generalized to the "block-orthogonal" case,

$$S = S_1 \cup \cdots \cup S_k, \quad S_i \cap S_j = \varnothing, \quad i \neq j, \tag{22}$$

$S_i \neq \varnothing$, i.e., the set S is a union of k nonintersecting (nonempty) subsets $S_1, \ldots, S_k$, and relation (19) is satisfied for all $s \in S_i$, $s' \in S_j$, $i \neq j$; $i, j = 1, \ldots, k$. In this case Eq. (20) is modified as follows:

$$H_s(z) = (1 + P_s z)^{b^s}, \tag{23}$$

where

$$b^s = 2 \sum_{s' \in S} A^{ss'}, \tag{24}$$

$(A^{ss'})=(A_{ss'})^{-1}$ and parameters P_s are coinciding inside blocks, i.e., $P_s=P_{s'}$ for $s,s'\in S_i$, $i=1,\ldots,k$. Parameters $P_s\neq 0$ satisfy the relations (21) and parameters B_s are also coinciding inside blocks, i.e., $B_s=B_{s'}$ for $s,s'\in S_i$, $i=1,\ldots,k$.

Let $(A_{ss'})$ be a Cartan matrix for a finite-dimensional semisimple Lie algebra $\mathcal{G}$. In this case all powers in (24) are natural numbers coinciding with the components of twice the dual Weyl vector in the basis of simple roots,[28] and hence, all functions H_s are polynomials, $s\in S$.

Conjecture (Ref. 10). Let $(A_{ss'})$ be a Cartan matrix for a semisimple finite-dimensional Lie algebra $\mathcal{G}$. Then the solution to Eqs. (15)–(17) (if exists) is a polynomial

$$H_s(z)=1+\sum_{k=1}^{n_s} P_s^{(k)} z^k, \tag{25}$$

where $P_s^{(k)}$ are constants, $k=1,\ldots,n_s$, the integers $n_s=b^s$ are defined in (24) and $P_s^{(n_s)}\neq 0$, $s\in S$.

This conjecture was verified for A_n and C_n series of Lie algebras.[11,12] In the extremal case $\mu=+0$ an a analogue of this conjecture was suggested previously in Ref. 23.

B. Solution for A_2 algebra

Here we present the polynomial solution from Refs. 10 and 11 corresponding to the Lie algebra $A_2=sl(3)$ with the Cartan matrix

$$(A_{ss'})=\begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}. \tag{26}$$

The moduli polynomials read in this case as follows:

$$H_s=1+P_s z+P_s^{(2)} z^2, \tag{27}$$

where $P_s=P_s^{(1)}$ and $P_s^{(2)}\neq 0$ are constants and

$$P_s^{(2)}=\frac{P_s P_{s+1}(P_s+1)}{2(P_1+P_2+2)}, \tag{28}$$

$$B_s=-\frac{P_s(P_s+1)(P_s+2)}{P_1+P_2+2}, \tag{29}$$

$s=1,2$. Here $P_1+P_2+2\neq 0$.

In the A_2-case the solution is described by relations (4)–(8) with $S=\{s_1,s_2\}$ and intersection rules following from (13), (14), and (26):

$$d(I_{s_1}\cap I_{s_2})=\frac{d(I_{s_1})d(I_{s_2})}{D-2}-\chi_{s_1}\chi_{s_2}\lambda_{a_{s_1}}\cdot\lambda_{a_{s_2}}-\frac{1}{2}K, \tag{30}$$

$$d(I_{s_i})-\frac{(d(I_{s_i}))^2}{D-2}+\lambda_{a_{s_i}}\cdot\lambda_{a_{s_i}}=K, \tag{31}$$

where $K\neq 0$ and functions $H_{s_i}=H_i$ are defined by relations (27)–(29) with $z=2\mu R^{-\bar{d}}$, $i=1,2$. Here and in what follows $\lambda\cdot\lambda'=\lambda_\alpha\lambda'_\beta h^{\alpha\beta}$.

C. Solutions for C_2 algebra

Now we present the solution related to the Lie algebra $C_2=\mathrm{so}(5)$ with the Cartan matrix

$$(A_{ss'})=\begin{pmatrix} 2 & -1 \\ -2 & 2 \end{pmatrix}. \tag{32}$$

According to "Conjecture" we seek the solution to Eqs. (15)–(17) in the following form:

$$H_1(z)=1+P_1z+P_1^{(2)}z^2+P_1^{(3)}z^3, \tag{33}$$

$$H_2(z)=1+P_2z+P_2^{(2)}z^2+P_2^{(3)}z^3+P_2^{(4)}z^4, \tag{34}$$

where $P_s=P_s^{(1)}$ and $P_s^{(k)}$ are constants, $s=1,2$.

Here we outline the result. For B_s parameters we get the following relations:

$$2B_1=-\Delta+(2P_1+3)(2+P_2), \tag{35}$$

$$B_2=\Delta-2-2P_1(P_1+3)-(2+P_2)^2, \tag{36}$$

and for parameters $P_s^{(k)}$ we obtain

$$4P_1^{(2)}=6+3P_2-\Delta+2P_1(3+P_1+P_2), \tag{37}$$

$$\begin{aligned}12P_1^{(3)}=&-\Delta(2+P_1+P_2)+12+18P_1+2P_1^3+3P_2(4+P_2)\\&+2P_1^2(5+P_2)+P_1P_2(11+2P_2),\end{aligned} \tag{38}$$

$$2P_2^{(2)}=-6-2P_1(3+P_1)-3P_2+\Delta, \tag{39}$$

$$\begin{aligned}6P_2^{(3)}=&\Delta(2+2P_1+P_2)-12-24P_1-4P_1^3-3P_2(4+P_2)\\&-2P_1P_2(7+P_2)-2P_1^2(8+P_2),\end{aligned} \tag{40}$$

$$\begin{aligned}24P_2^{(4)}=&\Delta[2P_1^2+(3+P_2)(2+2P_1+P_2)]-4P_1^4-3(2+P_2)^2(3+P_2)\\&-2P_1(3+P_2)^2(4+P_2)-4P_1^3(6+P_2)-P_1^2(60+30P_2+4P_2^2),\end{aligned} \tag{41}$$

where

$$\Delta=\sqrt{4(3+P_1(3+P_1))^2+(3+2P_1)^2P_2(4+P_2)}. \tag{42}$$

It may be verified that $B_1<0$ and $B_2<0$ for $P_1>0$, $P_2>0$.

The C_2 black-brane solution is described by relations (4)–(8), with $S=\{s_1,s_2\}$, and intersection rules following from (13), (14), and (32):

$$d(I_{s_1}\cap I_{s_2})=\frac{d(I_{s_1})d(I_{s_2})}{D-2}-\chi_{s_1}\chi_{s_2}\lambda_{a_{s_1}}\cdot\lambda_{a_{s_2}}-K, \tag{43}$$

$$d(I_{s_1})-\frac{(d(I_{s_1}))^2}{D-2}+\lambda_{a_{s_1}}\cdot\lambda_{a_{s_1}}=K, \tag{44}$$

$$d(I_{s_2})-\frac{(d(I_{s_2}))^2}{D-2}+\lambda_{a_{s_2}}\cdot\lambda_{a_{s_2}}=2K, \tag{45}$$

where $K \neq 0$ and functions $H_{s_i} = H_i$ are defined by relations (33) and (34) with $z = 2\mu R^{-\bar{d}}$, $i = 1,2$.

A simple test for verification of the relations for H_s-functions is to set $P_1 = 3P$ and $P_2 = 4P$ with $P > 0$. In this case we a get a special "block-orthogonal" solution

$$H_1(z) = (1+Pz)^3, \quad H_2(z) = (1+Pz)^4, \tag{46}$$

in agreement with the relations (23) and (24).

IV. CONCLUSIONS

In this paper we presented a new black-brane solution with two branes and intersection rule corresponding to the Lie algebra C_2. The solutions is governed by polynomials of degree 3 and 4 and the coefficients of polynomials exhibit a nontrivial dependence upon the parameters P_1 and P_2, due to appearance of the nontrivial term Δ [see (42)]. The C_2 solution differs drastically from the A_2 one, that has a rather simple analytical structure. This means that the polynomial solutions for other A_n algebras ($n > 2$) should be also nontrivial. Indeed, the C_2 solution may be extended to a special A_3 one, if we impose a restriction on the moduli polynomials H_1, H_2, H_3 of the following form: $H_1 = H_3$. (Thus, here we obtained by product a special A_3 black-brane solution.) It should be noted that A,D,E (or simply laced) Lie algebras are of much interest, since they appear for p-brane intersection rules in supergravitational models.[18] Other topics of interest are related to black-brane thermodynamics (e.g., relations for the entropy, the Hawking temperature, etc.) and analysis of post-Newtonian effects. On this way one may expect to clarify the appearance of the function Δ in the solution. But the main (mathematical) problem here is to find the polynomial solutions for all Lie algebras. This problem seems to be a very difficult one and may be of interest for mathematicians dealing with polynomials (e.g., appearing in nonlinear ordinary and partial differential equations), Lie algebras, number theory, etc.

Cluster properties in relativistic quantum mechanics of *N*-particle systems

W. N. Polyzou[a)]
Department of Physics and Astronomy, The University of Iowa, Iowa City, Iowa 52242

(Received 21 May 2002; accepted 25 August 2002)

A general technique is presented for constructing a quantum theory of a finite number of interacting particles satisfying Poincaré invariance, cluster separability, and the spectral condition. Irreducible representations and Clebsch–Gordan coefficients of the Poincaré group are the central elements of the construction. A different realization of the dynamics is obtained for each basis of an irreducible representation of the Poincaré group. Unitary operators that relate the different realizations of the dynamis are constructed. This technique is distinguished from other solutions [S. N. Sokolov, Dokl. Akad. Nauk USSR **233**, 575 (1977); F. Coester and W. N. Polyzou, Phys. Rev. D **26**, 1348 (1982)] of this problem because it does not depend on the kinematic subgroups of Dirac's forms [P. A. M. Dirac, Rev. Mod. Phys. **21**, 392 (1949)] of dynamics. Special basis choices lead to kinematic subgroups. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1516627]

I. INTRODUCTION

This article illustrates a general method for constructing a relativistic quantum theory of N-interacting particles. The theory has a dynamical unitary representation of the Poincaré group, satisfies cluster separability, and has a four-momentum operator with spectrum in the future-pointing cone. These are the minimal elements of any physically motivated axioms of relativistic quantum theory.

Relativistic quantum theory of particles falls between nonrelativistic quantum theory and local relativistic quantum field theory. It is interesting because it provides a mathematically well-defined framework for realizing the symmetry of special relativity in quantum theories. This makes it useful for applications to systems of a few strongly interacting particles.

The relativistic quantum theory constructed in this article has many properties of local relativistic quantum field theory.[1] Both are quantum theories satisfying Poincaré invariance, cluster separability, and the spectral condition. The most significant distinction between the two theories is that local relativistic quantum field theory satisfies a microscopic locality constraint, which requires an infinite number of degrees of freedom.

The absence of theories that are simultaneously consistent with the axioms of local quantum field theory and applicable to realistic systems suggests that mathematically well-behaved alternatives might be well-suited to applications involving strongly interacting particles.

The essential features of quantum theory of particles are as follows:

(1) The model Hilbert space is the finite tensor product of single-particle Hilbert spaces. This defines the degrees of freedom of the model.

(2) There is a unitary representation of the Poincaré group $\hat{U}(\Lambda, Y)$ on the model Hilbert space. This ensures that the quantum probabilities are independent of inertial frame. This representation necessarily contains the dynamics.

a)Electronic mail: polyzou@uiowa.edu

(3) The four-momentum operators, which are the infinitesimal generators of the space–time translation subgroup of $\hat{U}(\Lambda,Y)$, have a spectrum in the future-pointing light cone. This ensures the stability of the theory.
(4) The operator $\hat{U}(\Lambda,y)$ can be approximated by a tensor product of $\hat{U}_i(\Lambda,y)$'s on vectors describing subsets of particles in asymptotically separated regions. This justifies experiments on isolated subsystems and provides the relation between few- and many-body systems.
(5) The scattering operator is unitary and Poincaré invariant.

While relativistic quantum theory of particles is useful, independent of a relation to local quantum field theory, any local field theory should be well approximated by a quantum theory of particles when it is applied to reactions involving a finite number of particles. Because the defining requirements of relativistic quantum theory of particles are a subset of the axioms of local relativistic quantum field theory, the consequences of these requirements on the structure of the models of interacting particles are the same in both theories.

The Poincaré symmetry makes the problem of constructing a dynamical theory difficult. Poincaré covariance of the dynamics involves nonlinear constraints. The requirement that these constraints are preserved when the system is separated into isolated subsystems introduces additional nonlinear constraints. These difficulties were recognized by Dirac[2] and have been pointed out in a recent text by Weinberg.[3]

The essential role of unitary representations of the Poincaré group in relativistic quantum theory was first emphasized by Wigner[4] in 1939. Most applications to finite systems of interacting particles cite Dirac's[2] 1949 paper, which identified the essential difficulty and introduced kinematic subgroups associated with different ''forms of dynamics.'' These subgroups, which reduce the number of constraints on the interactions, have played a role in all subsequent theoretical development.

The problem of constructing interacting unitary representations of the Poincaré group was first solved for the two-particle system by Bakamjian and Thomas[5] in 1953. A three-particle solution satisfying S-matrix clustering was given by Coester in 1965.[6] The first complete solution of the problem for N particles was given by Sokolov in 1977.[7] A general solution in all of Dirac's forms of dynamics appears in Refs. 8 and 9.

Relativistic quantum theory of particles is a practical framework for applications to few-hadron[10–17] and few-quark systems.[18–22] All of these application are formulated in one of Dirac's forms of dynamics; they are limited to systems where cluster properties can be trivially realized.

The construction in this article is directly motivated by Wigner's 1939 paper and makes essential use of irreducible representations of the Poincaré group. It generalizes the two-body construction of Ref. 23 and leads to a relativistic N-body dynamics satisfying cluster properties and the spectral condition. Groups of unitary transformations that preserve the S-matrix and cluster properties are constructed. In the general construction all of the Poincaré generators may be interaction dependent. The kinematic subgroup symmetries can be implemented by imposing additional constraints on the general construction.

The resulting dynamics has interactions in between three and ten of the Poincaré generators. Unitary operators that preserve the S-matrix and cluster properties redistribute the interactions in ways that may be advantageous for different applications. These unitary operators are elements of a C^* algebra of asymptotic constants, which is relevant for identifying physically equivalent theories.

This article is organized as follows. Section II contains a brief account of Wigner's formulation of relativistic quantum mechanics, which is central to the construction in this paper. Sections III–VI summarize the group theory that is needed to construct the required representations. These sections discuss inhomogeneous $SL(2,C)(ISL(2,C))$, which is the covering group of the Poincaré group, irreducible representations of $ISL(2,C)$, and Clebsch–Gordan coefficients of $ISL(2,C)$. Section VII provides an introduction to relativistic scattering theory, which is used in the general construction. This formulation of scattering theory does not assume the existence of a kinematic

subgroup. Section VIII introduces the cluster separability condition. Section IX introduces the C^* algebra of asymptotic constants and its unitary elements, which are called scattering equivalences. This algebra provides a functional calculus of noncommuting operators that is used to establish cluster properties. Section X introduces the Möbius and Zeta function of the lattice of partitions. These combinatoric tools, which generalize standard Ursell cumulant expansions, are used extensively in the construction of the N-body dynamics. Section XI contains the general solution of the two-body problem, which is the starting point of the recursive construction, and Sec. XII contains the recursive N-body construction. Section XIII constructs scattering and cluster equivalences that relate dynamical models that utilize different bases. Section XIV has conclusions. Technical aspects of the construction are included in the four appendices.

II. RELATIVITY IN QUANTUM MECHANICS

In 1939 Wigner[4] showed that the relativistic invariance of all quantum probabilities

$$P_{\psi\phi} := |\langle \psi | \phi \rangle|^2 \tag{1}$$

is equivalent to the existence of a unitary representation of the Poincaré group. This was refined by Bargmann in 1954,[24] who observed that the dynamics could be realized by a single valued unitary representation of the covering group, $ISL(2,C)$, of the Poincaré group. The central problem of relativistic quantum mechanics is to construct a unitary representation $\hat{U}[\Lambda,Y]$ of $ISL(2,C)$ which implements the dynamics.

III. INHOMOGENEOUS $SL(2,C)$

In this section $ISL(2,C)$ is defined and related to the Poincaré group. Elements of $ISL(2,C)$ consist of ordered pairs of complex 2×2 matrices (Λ,Y), where Λ has determinant 1 and Y is Hermitian. The group product is

$$(\Lambda_2,Y_2)(\Lambda_1,Y_1)=(\Lambda_2\Lambda_1,\Lambda_2 Y_1 \Lambda_2^\dagger + Y_2). \tag{2}$$

The relation to four-dimensional Poincaré transformations follows by representing four vectors x^μ by 2×2 Hermitian matrices X:

$$X := x^\mu \sigma_\mu, \quad x^\mu = \tfrac{1}{2}\mathrm{Tr}(X\sigma_\mu) \tag{3}$$

where σ_0 is the identity and σ_i are the Pauli matrices. In this matrix representation $ISL(2,C)$ transformations are affine transformations of the form

$$X' = \Lambda X \Lambda^\dagger + Y. \tag{4}$$

Any Poincaré transformation continuously connected to the identity can be represented in the form (4).

Elements of $ISL(2,C)$ can be parametrized by three components of a rotation vector $\vec{\theta}$, three components of a rapidity vector $\vec{\rho}$, and a space–time translation four vector y^μ:

$$\Lambda(\vec{\theta},\vec{\rho}) = e^{-(i/2)(\vec{\theta}+i\vec{\rho})\cdot\vec{\sigma}}, \quad Y(y) := y^\mu \sigma_\mu. \tag{5}$$

Thus, the relativistic quantum dynamics, $\hat{U}[\Lambda,Y]$, satisfies

$$\hat{U}^\dagger[\Lambda,Y] = \hat{U}^{-1}[\Lambda,Y] = \hat{U}[\Lambda^{-1}, -\Lambda^{-1}Y(\Lambda^{-1})^\dagger] \tag{6}$$

and

$$\hat{U}[\Lambda_2,Y_2]\hat{U}[\Lambda_1,Y_1] = \hat{U}[\Lambda_2\Lambda_1, \Lambda_2 Y_1 \Lambda_2^\dagger + Y_2]. \tag{7}$$

IV. $ISL(2,C)$ GENERATORS

The infinitesimal generators of $\hat{U}[\Lambda,Y]$ are defined. These operators are used to identify a maximal set of commuting self-adjoint operators. For structureless particles the eigenvalues of these commuting operators label the state of the particle. The spectrum of these operators is determined by the eigenvalues of the invariant mass and spin operators, which define an irreducible subspace, and group theoretic considerations. The single-particle Hilbert space is the space of square integrable functions of these eigenvalues.

The ten parameters $y^\mu, \vec{\theta}, \vec{\rho}$ have the property that if any nine of them are set to zero, the group becomes a one-parameter unitary group with respect to the remaining parameter. These unitary one-parameter groups necessarily have the form $\hat{U}(\lambda)=e^{-i\lambda\hat{G}}$ for a self-adjoint operator $\hat{G}$.[25] Thus a unitary representation $\hat{U}[\Lambda,Y]$ of $ISL(2,C)$ can be parametrized as

$$\hat{U}[\Lambda(\vec{\theta},\vec{\rho}),I]=e^{-i(\vec{\theta}\cdot\hat{\vec{J}}+\vec{\rho}\cdot\hat{\vec{K}})}, \tag{8}$$

$$\hat{U}[I,Y(y)]=e^{i(\vec{y}\cdot\hat{\vec{P}}-y^0\hat{H})}, \tag{9}$$

with self-adjoint generators $\hat{H},\hat{\vec{P}},\hat{\vec{J}}$ and $\hat{\vec{K}}$.

The commutation relations of the generators follow from the group representation property (7) and the definition (8) and (9) of the generators.[26] The commutation relations are consistent with $\hat{P}^\mu:=(\hat{H},\hat{\vec{P}})$ transforming as a four-vector operator

$$\hat{U}[\Lambda,0]\hat{P}^\mu\hat{U}^\dagger[\Lambda,0]=\hat{P}^\nu\Lambda^\mu_\nu, \tag{10}$$

and

$$\hat{J}^{\mu\nu}:=\begin{pmatrix} 0 & \hat{K}^1 & \hat{K}^2 & \hat{K}^3 \\ -\hat{K}^1 & 0 & \hat{J}^3 & -\hat{J}^2 \\ -\hat{K}^2 & -\hat{J}^3 & 0 & \hat{J}^1 \\ -\hat{K}^3 & \hat{J}^2 & -\hat{J}^1 & 0 \end{pmatrix} \tag{11}$$

transforming as a rank-two antisymmetric tensor operator:

$$\hat{U}[\Lambda,0]\hat{J}^{\mu\nu}\hat{U}^\dagger[\Lambda,0]=\hat{J}^{\alpha\beta}\Lambda^\mu_\alpha\Lambda^\nu_\beta. \tag{12}$$

The Pauli–Lubanski vector $\hat{W}^\mu$ is a four-vector valued function of $\hat{P}^\mu$ and $\hat{J}^{\mu\nu}$:

$$\hat{W}^\mu:=\tfrac{1}{2}\epsilon^{\mu\alpha\beta\gamma}\hat{P}_\alpha\hat{J}_{\beta\gamma} \tag{13}$$

satisfying

$$[\hat{J}^j,\hat{W}^k]_-=i\epsilon^{jkl}\hat{W}^l, \quad [\hat{J}^j,\hat{W}^0]_-=0, \tag{14}$$

$$[\hat{K}^j,\hat{W}^k]_-=-i\delta^{jk}\hat{W}^0, \quad [\hat{K}^j,\hat{W}^0]_-=-i\hat{W}^j, \tag{15}$$

$$[\hat{P}^\mu,\hat{W}^\nu]_-=0, \tag{16}$$

$$[\hat{W}^\mu,\hat{W}^\nu]_-=i\epsilon^{\mu\nu\rho\eta}\hat{W}_\rho\hat{P}_\eta, \quad \hat{W}^\mu\hat{P}_\mu=0. \tag{17}$$

The scalar operators

$$\hat{M}^2 = -\hat{P}^\mu \hat{P}_\mu \tag{18}$$

and

$$\hat{W}^2 = \hat{W}^\mu \hat{W}_\mu \tag{19}$$

are the two independent invariant polynomial functions of the generators[27] of $ISL(2,C)$.

When the spectrum of the mass operator is positive, the spin-squared operator is defined by

$$\hat{j}^2 := \frac{\hat{W}^2}{\hat{M}^2}. \tag{20}$$

V. IRREDUCIBLE REPRESENTATIONS OF $ISL(2,C)$

The Hilbert space for an N-particle system is the tensor product of single particle Hilbert spaces. Single particle Hilbert spaces are irreducible representation spaces of $ISL(2,C)$. The irreducible representations are labeled by the mass and spin of a particle. Eigenvalues of additional commuting self-adjoint functions of the $ISL(2,C)$ generators are needed to specify the state of the particle. Simultaneous eigenstates of the commuting self-adjoint operators define a basis in the irreducible representation space. The single particle Hilbert space is the space of square integrable functions of the eigenvalues.

The irreducible representations of the $ISL(2,C)$ were classified by Wigner.[6,28,29,5] The displacement $x_a^\mu - x_b^\mu$ between events a and b can be classified into six invariant classes depending on whether this displacement is zero, lightlike positive time, lightlike negative time, spacelike, timelike positive time, or timelike negative time.

The irreducible representations corresponding to massive particles are the timelike positive-time representations. These irreducible representations of $ISL(2,C)$ are labeled by the invariant eigenvalues of the mass (18) and spin operators (20). For a particle the mass eigenvalue m is discrete and the spin operator has the eigenvalue $j(j+1)$ where j is the spin of the particle.

The state of a structureless particle of mass m and spin j is determined by specifying the eigenvalues of a maximal set of commuting self-adjoint operators. These operators are the invariant mass $\hat{M}$, the spin $\hat{j}^2$ and four independent functions, $\hat{F}^i = F^i(\hat{P}^\mu, \hat{J}^{\mu\nu})$, of the $ISL(2,C)$ generators. The operators $\hat{F}^j$ cannot be invariant. They are arbitrary independent functions of the $ISL(2,C)$ generators subject to the constraints:

$$\hat{F}^i = (\hat{F}^i)^\dagger, \quad [\hat{F}^i, \hat{F}^j] = 0, \tag{21}$$

$$[\hat{F}^i, \hat{M}] = [\hat{F}^i, \hat{j}^2] = 0. \tag{22}$$

For particles with structure, additional invariant degeneracy operators are needed to get a maximal set of commuting operators.

The traditional choice for the operators $\hat{F}^i$ are the three components of the linear momentum $\hat{\vec{P}}$ and the z-component of the canonical[26] spin $\hat{z} \cdot \hat{\vec{j}}_c$. In some applications it is advantageous to use the four velocity, the light-front components of the four momentum, or their conjugate variables. The helicity or light-front spin is sometimes used instead of the canonical spin. Any of the spin observables could be replaced by a component of the Pauli–Lubanski operator. These special cases are treated in Appendix A. Each choice of $\hat{F}^i$ corresponds to a single particle basis. In this article the operators $\hat{F}^i$ are assumed to have a spectrum independent of the mass eigenvalue. This condition is not very restrictive and holds for all conventional choices.

The Hilbert space for a particle of mass m and spin j can be represented as the space of square integrable functions of the eigenvalues of the operators $\hat{F}^i$:

$$\mathcal{H}_{mj}=\left\{\langle f|\psi\rangle\left|\int d\mu(f)|\langle f|\psi\rangle|^2\right.\right\}<\infty, \tag{23}$$

where $f=\{f^1\cdots f^4\}$ and $\int d\mu(f)$ indicates a sum over the discrete eigenvalues and an integral over the continuous eigenvalues of $\hat{F}^i$.

Basis vectors have the form

$$|f\rangle:=|f;m,j\rangle:=|f^1,f^2,f^3,f^4;m,j\rangle. \tag{24}$$

The normalization convention is

$$\langle f|f'\rangle=\delta[f,f'], \tag{25}$$

where $\delta[f,f']$ is the product of Dirac or Kronecker delta functions in the variables f^i.

Irreducibility requires the transformation property:

$$\hat{U}[\Lambda,Y]|f;m,j\rangle=\int|f';m,j\rangle d\mu(f')\mathcal{D}^{m,j}_{f',f}[\Lambda,Y], \tag{26}$$

where

$$\mathcal{D}^{m,j}_{f',f}[\Lambda,Y]\delta_{m'm}\delta_{j'j}:=\langle f';m',j'|\hat{U}[\Lambda,Y]|f;m,j\rangle \tag{27}$$

is the mass m, spin j irreducible representation of $ISL(2,C)$ in the basis $\hat{F}^j$. The $\mathcal{D}$-function includes δ-functions that eliminate the integrals over the continuous spectrum in (26). Unitarity of the group representation property requires

$$\mathcal{D}^{m,j}_{f',f}[\Lambda,Y]=(\mathcal{D}^{m,j}_{f,f'}[\Lambda^{-1},-\Lambda Y\Lambda^{\dagger}])^* \tag{28}$$

and

$$\int\mathcal{D}^{m,j}_{f',f''}[\Lambda_2,Y_2]d\mu(f'')\mathcal{D}^{m,j}_{f'',f}[\Lambda_1,Y_1]=\mathcal{D}^{m,j}_{f',f}[\Lambda_2\Lambda_1,\Lambda_2Y_1\Lambda_2^{\dagger}+Y_2]. \tag{29}$$

The restriction on the spectrum of $\hat{F}^i$ implies that range of values of f in $\mathcal{D}^{m,j}_{f',f}[\Lambda,Y]$ is independent of m.

Explicit representations for the $ISL(2,C)$ Wigner $\mathcal{D}$-functions corresponding to different $\hat{F}^i$ are given in Appendix A. The form of the $\mathcal{D}$-functions is basis dependent.

Irreducible representations in a basis of simultaneous eigenstates of a different set of commuting self-adjoint functions, $\hat{G}^i$, of the generators are related to the representations in the basis $\hat{F}^i$ by

$$\mathcal{D}^{m,j}_{g,g'}[\Lambda,Y]=\int\langle g|f\rangle d\mu(f)\mathcal{D}^{m,j}_{f,f'}[\Lambda,Y]d\mu(f')\langle f'|g'\rangle, \tag{30}$$

where

$$\langle f|g\rangle\delta_{mm'}\delta_{jj'}:=\langle f;m,j|g;m',j'\rangle. \tag{31}$$

The coefficient functions $\langle f|g\rangle$ can depend parametrically on the mass or spin. This parametric dependence on the mass is responsible for the dynamical differences that arise with different basis choices.

VI. CLEBSCH–GORDAN COEFFICIENTS

In this section Clebsch–Gordan coefficients[8,26,28,29] and Racah coefficients of $ISL(2,C)$ are defined. These are used to expand tensor products of irreducible representation as linear superpositions of irreducible representations and to transform between irreducible bases with different degeneracy quantum numbers.

The tensor product of irreducible representations of $ISL(2,C)$ is reducible. The $ISL(2,C)$ generators for a tensor product of two irreducible representations are

$$\hat{P}^\mu = \hat{P}_1^\mu \otimes \hat{I}_2 + \hat{I}_1 \otimes \hat{P}_2^\mu, \tag{32}$$

$$\hat{J}^{\mu\nu} = \hat{J}_1^{\mu\nu} \otimes \hat{I}_2 + \hat{I}_1 \otimes \hat{J}_2^{\mu\nu}. \tag{33}$$

These operators act on the space

$$\mathcal{H} = \mathcal{H}_{m_1 j_1} \otimes \mathcal{H}_{m_2 j_2}. \tag{34}$$

The operators $\hat{F}^i = F^i(\hat{P}^\mu, \hat{J}^{\mu\nu})$, $\hat{M} = M(\hat{P}^\mu, \hat{J}^{\mu\nu})$, and $\hat{j}^2 = j^2(\hat{P}^\mu, \hat{J}^{\mu\nu})$ are commuting self-adjoint operators on $\mathcal{H}$. Because the tensor product is reducible, these operators do not define a maximal set of commuting self-adjoint operators. There are additional $ISL(2,C)$ invariant degeneracy operators $\hat{D}^j$ that distinguish multiple copies of the same irreducible representation. The degeneracy operators $\hat{D}^i$ normally include the invariant operators $\hat{M}_1$, $\hat{j}_1$, $\hat{M}_2$, $\hat{j}_2$ of the factors of the tensor product and additional operators, $\hat{R}_{12}$, that distinguish multiple copies of the m,j representation in the tensor product of the m_1,j_1 and m_2,j_2 representations.

The operators $\hat{D}^j$ are invariant, self-adjoint functions of the single particle generators. The operators $\hat{M}$, $\hat{j}^2$, $\hat{F}^1,\ldots,\hat{F}^4$, $\hat{D}^1,\ldots,\hat{D}^6$ form a maximal set of commuting self-adjoint operators on $\mathcal{H}$. Examples are given in the Appendix B.

The (f,d) basis is the $ISL(2,C)$-irreducible basis for the tensor product space defined in terms of simultaneous eigenstates, $|f,d;m,j\rangle$ of

$$\{\hat{F}^i, \hat{D}^k; \hat{M}, \hat{j}^2\}. \tag{35}$$

It follows that

$$\hat{U}_1[\Lambda,Y] \otimes \hat{U}_2[\Lambda,Y] |f,d;m,j\rangle = \int |f',d;m,j\rangle d\mu(f') \mathcal{D}^{m,j}_{f',f}[\Lambda,Y], \tag{36}$$

where $\mathcal{D}^{m,j}_{f',f}[\Lambda,Y]$ is the irreducible representation matrix for a single particle of mass m and spin j. The $\mathcal{D}$-function is independent of the invariant degeneracy parameters, d.

The coefficients

$$\langle f_1;m_1,j_1:f_2;m_2,j_2|f,d;m,j\rangle \tag{37}$$

are Clebsch–Gordan coefficients of the Poincaré group in the (f,d) basis. They are the kernel of the unitary transformation that relates tensor products of $ISL(2,C)$ irreducible representations to direct integrals of irreducible representations. The $ISL(2,C)$ Clebsch–Gordan coefficients have similar properties to $SU(2)$ Clebsch–Gordan coefficients:

$$\int \mathcal{D}^{m_1,j_1}_{f_1,f_1'}[\Lambda,Y] \mathcal{D}^{m_2,j_2}_{f_2,f_2'}[\Lambda,Y] d\mu(f_1') d\mu(f_2') \langle f_1';m_1,j_1:f_2';m_2,j_2|f,d;m,j\rangle$$
$$= \int \langle f_1;m_1,j_1:f_2;m_2,j_2|f',d;m,j\rangle d\mu(f') \mathcal{D}^{m,j}_{f',f}[\Lambda,Y]. \tag{38}$$

The new feature is that the irreducible representations are labeled by two Casimir operators and the mass operator has a continuous spectrum.

It is sometimes useful to replace the mass operator $\hat{M}$ of the tensor product of two irreducible representations by the invariant relative momentum $\hat{q}^2$, which has absolutely continuous spectrum, $[0,\infty)$:

$$\hat{q}^2 = q^2(\hat{M}^2,\hat{M}_1^2,\hat{M}_2^2) := \frac{\hat{M}^4+\hat{M}_1^4+\hat{M}_2^4-2\hat{M}_1^2\hat{M}_2^2-2\hat{M}^2\hat{M}_1^2-2\hat{M}^2\hat{M}_2^2}{4\hat{M}^2}. \tag{39}$$

The Clebsch–Gordan coefficients have different forms in different bases. If $(f,d)\rightarrow(g,k)$, then the Clebsch–Gordan coefficients in the (f,d) basis are related to the Clebsch–Gordan coefficients in the (g,k) basis by

$$\begin{aligned}&\langle g_1;m_1,j_1:g_2;m_2,j_2|g,k;m,j\rangle\\ &\quad=\int \langle g_1|f_1'\rangle\langle g_2|f_2'\rangle d\mu(f_1')d\mu(f_2')\langle f_1';m_1,j_1:f_2';m_2,j_2|f',d';m,j\rangle d\mu(f',d')\\ &\qquad\times\langle f',d'|g,k\rangle,\end{aligned} \tag{40}$$

where

$$\langle g_i|f_i'\rangle\delta_{j_ij_i'}\delta_{m_im_i'} := \langle g_i;m_i,j_i|f_i';m_i',j_i'\rangle \tag{41}$$

and

$$\delta_{jj'}\delta(m-m')\langle f,d|g',k'\rangle := \langle f,d;m,j|g',k';m',j'\rangle. \tag{42}$$

The Hilbert space for a system of N-particles is the N-fold tensor product of single particle Hilbert spaces:

$$\mathcal{H}=\mathcal{H}_{m_1j_1}\otimes\cdots\otimes\mathcal{H}_{m_Nj_N}. \tag{43}$$

The noninteracting representation of $ISL(2,C)$ on $\mathcal{H}$ is defined by

$$\hat{U}_0[\Lambda,Y] := \hat{U}_1[\Lambda,Y]\otimes\cdots\otimes\hat{U}_N[\Lambda,Y], \tag{44}$$

where the 0 subscript is used to denote the noninteracting system. It follows that

$$\hat{U}_0[\Lambda,Y]|f_1;m_1,j_1\cdots f_N;m_N,j_N\rangle=\int |f_1';m_1,j_1:\cdots f_N';m_N,j_N\rangle d\mu(f_1'\cdots f_N')\prod_{i=1}^{N}\mathcal{D}_{f_i',f_i}^{m_i,j_i}[\Lambda,Y]. \tag{45}$$

As in the case of $SU(2)$, the tensor product of N irreducible representation spaces can be decomposed into a direct integral of irreducible representation spaces using successive pairwise coupling. The invariant degeneracy operators depend on the order of the coupling. It is also possible to use a simultaneous coupling scheme based on Mackey's[30] theory of induced representations[9] which leads to a symmetric coupling.

Successive pairwise coupling is illustrated for the three-particle system:

$$|f,d_{((12)3)};m,j\rangle = \int |f_1;m_1,j_1:f_2;m_2,j_2:f_3;m_3,j_3\rangle d\mu(f_1)d\mu(f_2)$$
$$\times\langle f_1;m_1,j_1:f_2;m_2,j_2|f_{12},d_{12};m_{12},j_{12}\rangle d\mu(f_{12})d\mu(f_3)d\mu(m_{12},j_{12})$$
$$\times\langle f_{12};m_{12},j_{12}:f_3;m_3,j_3|f,d_{12,3};m,j\rangle, \tag{46}$$

where the invariant degeneracy parameters are

$$d_{12,3}=\{d_{12},m_{12},j_{12},m_3,j_3,r_{12,3}\} \tag{47}$$

with

$$d_{12}=\{m_1,j_1,m_2,j_2,r_{12}\}. \tag{48}$$

Changing the ordering of the coupling from ((12)3) to ((23)1) changes the degeneracy parameters from $\{r_{12},j_{12},m_{12},r_{12,3}\}$ to $\{r_{23},j_{23},m_{23},r_{23,1}\}$, leaving the operators $\hat{M},\hat{j}^2$ and $\hat{F}^i$ unchanged. The overlap coefficients have the general form

$$\langle f,d_{ab,c}(m,j)|f',d'_{ef,g}(m',j')\rangle = \delta[f,f']\delta_{jj'}\delta(m-m')R^{m,j}_{d_{a,bc},d'_{e,fg}}. \tag{49}$$

The invariant quantities $R^{m,j}_{d_{a,bc},d'_{e,fg}}$ are Racah coefficients for $ISL(2,C)$. They are the kernel of the unitary transformation that changes the choice of degeneracy labels in subspaces corresponding the same mass, spin, and vector labels f. They are independent of f.

The Racah coefficients are important for performing computations because, as in the case of rotations, some operators have a simple form when the couplings are done in a specific order. Since many of the operators are defined in specific representations, the Racah coefficients are needed for the evaluation of the abstract operator expressions.

The term Racah coefficient is used to indicate any change of irreducible basis with matrix elements of the form (49). Examples of Racah coefficients in representative bases are given in Appendix B.

VII. RELATIVISTIC SCATTERING THEORY

Relativistic scattering theory is formulated in this section. A kinematic subgroup is not assumed. The two-Hilbert space formulation[6,8,31] is used to treat multichannel scattering theory. The notation of this section follows Ref. 8. Conditions on the interactions that are sufficient for a sensible relativistic scattering theory are discussed. Relativistic two-Hilbert-space wave operators are essential elements of the general construction.

In this section the dynamical representation $\hat{U}[\Lambda,Y]$ of $ISL(2,C)$ is assumed to be given. The construction of $\hat{U}[\Lambda,Y]$ is the main topic of the remainder of this article.

The first step in formulating relativistic scattering theory is to determine the bound states of $\hat{U}[\Lambda,Y]$; subsystem bound states are needed to formulate the asymptotic conditions in multichannel scattering.

Bound states are associated with point eigenvalues of the mass and spin. For each bound-state channel α_b there is an irreducible subspace of $\mathcal{H}$. Vectors in the bound state subspace can be expressed as linear superpositions of simultaneous eigenstates of $\hat{M},\hat{j}^2,\hat{F}^i$:

$$|\phi_{\alpha_b}\rangle = \int |f;m_\alpha,j_\alpha\rangle d\mu(f)\langle f|\chi\rangle, \tag{50}$$

where in this expression $\hat{F}^i=F^i(\hat{P}^\mu,\hat{J}^{\mu\nu})$ are functions of the generators of $\hat{U}[\Lambda,Y]$.

The channel eigenstate $|f;m_{\alpha_b},j_{\alpha_b}\rangle$ can be considered as a mapping, $\hat{\Phi}_{\alpha_b}$, from the channel Hilbert space $\mathcal{H}_{\alpha_b}$,

$$\mathcal{H}_{\alpha_b}=\left\{\langle f|\chi_\alpha\rangle\middle|\int\langle f|\chi_\alpha\rangle|^2 d\mu(f)<\infty\right\}, \tag{51}$$

to the invariant bound-state subspace of the Hilbert space $\mathcal{H}$,

$$\hat{\Phi}_{\alpha_b}|\chi_\alpha\rangle:=|\phi_{\alpha_b}\rangle=\int|f;m_\alpha,j_\alpha\rangle d\mu(f)\langle f|\chi_\alpha\rangle. \tag{52}$$

For each bound channel α_b there is a channel injection operator $\hat{\Phi}_{\alpha_b}$ and a channel Hilbert space $\mathcal{H}_{\alpha_b}$. Since the bound channel spaces are irreducible representation spaces with respect to $\hat{U}[\Lambda,Y]$, the channel eigenstates transform irreducibly

$$\hat{U}[\Lambda,Y]|f;m_{\alpha_b},j_{\alpha_b}\rangle=\int|f';m_{\alpha_b},j_{\alpha_b}\rangle d\mu(f')\mathcal{D}^{m_{\alpha_b},j_{\alpha_b}}_{f',f}[\Lambda,Y]. \tag{53}$$

Equation (53) can be expressed in terms of the channel injection operator as

$$\hat{U}[\Lambda,Y]\hat{\Phi}_{\alpha_b}=\hat{\Phi}_{\alpha_b}\hat{U}_{\alpha_b}[\Lambda,Y]. \tag{54}$$

Scattering states are solutions of the time-dependent Schrödinger equation that look like mutually noninteracting bound or elementary subsystems in the asymptotic past or future. To formulate the asymptotic condition let a denote a partition of N particles into n_a disjoint nonempty clusters. Denote the ith cluster by a_i and the number of particles in the i-th cluster by n_{a_i}.

For any partition a, the N-particle Hilbert space can be factored into a tensor product of subsystem Hilbert spaces $\mathcal{H}_{a_i}$:

$$\mathcal{H}=\otimes_{i=1}^{n_a}\mathcal{H}_{a_i}, \tag{55}$$

$$\mathcal{H}_{a_i}=\otimes_{l\in a_i}\mathcal{H}_{m_l j_l}. \tag{56}$$

A partition a has a scattering channel α if the subsystem dynamics

$$\hat{U}_{a_i}[\Lambda,Y]:\mathcal{H}_{a_i}\to\mathcal{H}_{a_i} \tag{57}$$

associated with each cluster of a is either a one particle cluster or has a bound state.

For each bound subsystem channel, α_i, there is an injection operator, an asymptotic Hilbert space,

$$\hat{\Phi}_{\alpha_i}:\mathcal{H}_{\alpha_i}\to\mathcal{H}_{a_i}, \tag{58}$$

and an irreducible asymptotic representation $\hat{U}_{\alpha_i}[\Lambda,Y]$ of $ISL(2,C)$ on $\mathcal{H}_{\alpha_i}$ satisfying

$$\hat{U}_{a_i}[\Lambda,Y]\hat{\Phi}_{\alpha_i}=\hat{\Phi}_{\alpha_i}\hat{U}_{\alpha_i}[\Lambda,Y]. \tag{59}$$

These relations hold trivially for the one particle clusters. The asymptotic Hilbert space for the scattering channel α is defined as the tensor product of the bound channel subspaces for the subsystems:

$$\mathcal{H}_\alpha=\otimes_{i=1}^{n_a}\mathcal{H}_{\alpha_i}. \tag{60}$$

The channel injection operator

$$\hat{\Phi}_\alpha : \mathcal{H}_\alpha \to \mathcal{H} \tag{61}$$

is defined by

$$\hat{\Phi}_\alpha := \otimes_{i=1}^{n_a} \hat{\Phi}_{\alpha_i}. \tag{62}$$

It follows from (59) that $\hat{\Phi}_\alpha$ satisfies the intertwining relation

$$\hat{U}_a[\Lambda, Y]\hat{\Phi}_\alpha = \hat{\Phi}_\alpha \hat{U}_\alpha[\Lambda, Y], \tag{63}$$

where

$$\hat{U}_a[\Lambda, Y] := \otimes_{i=1}^{n_a} \hat{U}_{a_i}[\Lambda, Y] \tag{64}$$

and

$$\hat{U}_\alpha[\Lambda, Y] := \otimes_{i=1}^{n_a} \hat{U}_{\alpha_i}[\Lambda, Y]. \tag{65}$$

In this notation a scattering state is a solution

$$|\psi_\alpha^\pm(t)\rangle = \hat{U}[I,T]|\psi_\alpha^\pm\rangle, \quad T := t\sigma_0 \tag{66}$$

of the time-dependent Schrödinger equation satisfying the asymptotic condition

$$\lim_{t\to\pm\infty} \| |\psi_\alpha^\pm(t)\rangle - \hat{U}_a[I,T]\hat{\Phi}_\alpha|\chi_\alpha\rangle \| \tag{67}$$

for $|\chi_\alpha\rangle \in \mathcal{H}_\alpha$.

Equation (63) can be used to express the asymptotic condition as

$$\lim_{t\to\pm\infty} \| |\psi_\alpha^\pm\rangle - \hat{U}[I,-T]\hat{\Phi}_\alpha \hat{U}_\alpha[I,T]|\chi_\alpha\rangle \| = 0, \tag{68}$$

which is identically satisfied by the bound-state channels.

Equation (68) can be expressed as

$$|\psi_\alpha^\pm\rangle := \hat{\Omega}_{\alpha\pm}|\chi_\alpha\rangle, \tag{69}$$

where the channel wave operators

$$\hat{\Omega}_{\alpha\pm} : \mathcal{H}_\alpha \to \mathcal{H} \tag{70}$$

are defined by the strong limits

$$\hat{\Omega}_{\alpha\pm} := \lim_{t\to\pm\infty} \hat{U}(I,-T)\hat{\Phi}_\alpha \hat{U}_\alpha(I,T). \tag{71}$$

A sufficient condition for the existence of the channel wave operators is the Cook condition:[32]

$$\int_{t_c}^{\infty} \| \hat{V}_\alpha \hat{U}_\alpha(I, \pm T)|\chi\rangle \| dt < \infty, \tag{72}$$

where t_c is any constant and

$$\hat{V}_\alpha := \hat{H}\hat{\Phi}_\alpha - \hat{\Phi}_\alpha \hat{H}_\alpha . \tag{73}$$

The scattering operator for scattering from channel α to channel β is the mapping from $\mathcal{H}_\alpha \to \mathcal{H}_\beta$ defined by

$$\hat{S}_{\beta\alpha} := \hat{\Omega}^\dagger_{\beta+} \hat{\Omega}_{\alpha-} . \tag{74}$$

This can be expressed compactly in a two-Hilbert-space notation, where the asymptotic Hilbert space, $\mathcal{H}_\mathcal{A}$, is the orthogonal direct sum of all of the channel spaces, including the bound state channel spaces:

$$\mathcal{H}_\mathcal{A} = \oplus_\alpha \mathcal{H}_\alpha . \tag{75}$$

A two-Hilbert-space injection operator $\hat{\Phi}_\mathcal{A}$,

$$\hat{\Phi}_\mathcal{A} : \mathcal{H}_\mathcal{A} \to \mathcal{H}, \tag{76}$$

is defined as the sum of the channel injection operators

$$\hat{\Phi}_\mathcal{A} = \sum_\alpha \hat{\Phi}_\alpha , \tag{77}$$

where it is understood that each $\hat{\Phi}_\alpha$ acts on the channel subspace $\mathcal{H}_\alpha$ of $\mathcal{H}_\mathcal{A}$.

There is a natural unitary representation of $ISL(2,C)$ on $\mathcal{H}_\mathcal{A}$ which transforms the particles or bound states as tensor products of irreducible representations:

$$\hat{U}_\mathcal{A}[\Lambda, Y] = \sum_\alpha \hat{U}_\alpha[\Lambda, Y], \tag{78}$$

where $\hat{U}_\alpha[\Lambda, Y] : \mathcal{H}_\alpha \to \mathcal{H}_\alpha$.

The bound state solutions and the scattering asymptotic conditions can be replaced by one two-Hilbert-space equation:

$$\Omega_\pm(\hat{H}, \hat{\Phi}_\mathcal{A}, \hat{H}_\mathcal{A}) = \lim_{t \to \pm\infty} \hat{U}[I, -T] \hat{\Phi}_\mathcal{A} \hat{U}_\mathcal{A}[I, T], \tag{79}$$

where the limit is a strong limit. The wave operators $\Omega_\pm(\hat{H}, \hat{\Phi}_\mathcal{A}, \hat{H}_\mathcal{A})$ are mappings from $\mathcal{H}_\mathcal{A} \to \mathcal{H}$.

The scattering operator $\hat{S}$ is a mapping from $\mathcal{H}_\mathcal{A} \to \mathcal{H}_\mathcal{A}$ defined by

$$\hat{S} := \Omega^\dagger_+(\hat{H}, \hat{\Phi}_\mathcal{A}, \hat{H}_\mathcal{A}) \Omega_-(\hat{H}, \hat{\Phi}_\mathcal{A}, \hat{H}_\mathcal{A}). \tag{80}$$

The dynamics is asymptotically complete if the two-Hilbert space wave operators $\Omega_\pm(\hat{H}, \hat{\Phi}_\mathcal{A}, \hat{H}_\mathcal{A})$, which include all bound state channels, are unitary mappings from $\mathcal{H}_\mathcal{A}$ to $\mathcal{H}$. In all that follows the two-Hilbert-space wave operators are assumed exist and to be unitary. These properties can be proved using the same methods used in nonrelativistic scattering theory.

Fong and Sucher[8,33–35] showed that relativistic invariance of the scattering operator does not follow from the existence of $\hat{U}[\Lambda, Y]$. This is because the $ISL(2,C)$ transformations must commute with the limiting operations that are used to construct the scattering operator.

Invariance of $\hat{S}$ is equivalent to the condition

$$[\hat{U}_\mathcal{A}[\Lambda, Y], \hat{S}]_- = 0. \tag{81}$$

The following theorem provides a sufficient condition on $\hat{U}[\Lambda,Y]$ for the $ISL(2,C)$ invariance of the S-matrix:

Theorem 1: Let $\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})$ be asymptotically complete two-Hilbert-space wave operators. A sufficient condition for $\hat{S}$ to be $ISL(2,C)$ invariant is that for all Λ and Y

$$\lim_{t\to\pm\infty}(\hat{\Phi}_{\mathcal{A}}-\hat{U}^{\dagger}[\Lambda,Y]\hat{\Phi}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[\Lambda,Y])\hat{U}_{\mathcal{A}}[I,T]=0, \tag{82}$$

and for any Y of the form $Y=\vec{y}\cdot\vec{\sigma}$

$$\lim_{t\to\pm\infty}(\hat{\Phi}_{\mathcal{A}}-\hat{U}^{\dagger}[I,Yt]\hat{\Phi}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[I,Yt])\hat{U}_{\mathcal{A}}[I,T]=0. \tag{83}$$

The limits above are strong limits. They must hold for both time directions.

Theorem 1 provides sufficient conditions on the interactions in the generators for a sensible relativistic scattering theory. The proof of this theorem is given in Appendix C.

The proof of Theorem 1 has a number of useful corollaries:

Corollary 1: If the conditions of Theorem 1 are satisfied, then

$$\hat{U}[\Lambda,Y]\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[\Lambda,Y]. \tag{84}$$

This intertwining property ensures the $ISL(2,C)$ invariance of S.

Corollary 2: If the conditions of Theorem 1 are satisfied, then

$$\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\Omega_{\pm}(\hat{P}\cdot y,\hat{\Phi}_{\mathcal{A}},\hat{P}_{\mathcal{A}}\cdot y), \tag{85}$$

where y is any future-pointing timelike four-vector.

This means that all future pointing timelike directions are equivalent for the purpose of formulating the asymptotic condition.

Corollary 3: If the conditions of Theorem 1 are satisfied, then

$$\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\Omega_{\pm}(\hat{M},\hat{\Phi}_{\mathcal{A}},\hat{M}_{\mathcal{A}}). \tag{86}$$

This shows that in applications the Hamiltonian can be replaced by the mass operator in the wave operators. Both representations of the two-Hilbert-space wave operators are used in the remainder of this article.

Theorem 1 and its corollaries define conditions on the interactions that ensure that the dynamics is consistent with naive expectations for a relativistic scattering theory. In all that follows it is assumed that the two-Hilbert-space wave operators exist, are complete, and the dynamical operators satisfy (82) and (83).

VIII. CLUSTER PROPERTIES

Cluster properties provide the essential connection between the few- and many-body problem. The cluster property requires that few-body interactions in the few-body problem are identical to the few-body interactions in the many-body problem. This establishes the justification for performing experiments on few-body systems.

The difficulty in satisfying cluster properties is that the interactions that appear in the $ISL(2,C)$ generators are uniquely determined by cluster properties up to an N-body interaction. Unfortunately, the $ISL(2,C)$ commutation relations put nonlinear constraints on the N-body interactions which cannot be satisfied by setting these interactions to zero.

To formulate cluster properties let a be a partition of the N-particle systems into n_a disjoint clusters. Let $\hat{U}_{a_i}[\Lambda,Y]$ be the subsystem representation of $ISL(2,C)$ for the particles in the ith cluster of a. Define the cluster translation operator $\hat{T}_a(Y_1,\ldots,Y_{n_a})$ on $\mathcal{H}$ by

$$\hat{T}_a[Y_1,\ldots,Y_{n_a}] := \otimes \hat{U}_{a_i}[I,Y_i]. \tag{87}$$

The dynamical representation of the Poincaré group satisfies strong cluster properties if for all partitions a and all $|\chi\rangle \in \mathcal{H}$

$$\lim_{\min(y_i-y_j)^2\to+\infty} \|(\hat{U}[\Lambda,Y]-\otimes_{i=1}^{n_a}\hat{U}_{a_i}[\Lambda,Y])\hat{T}_a[Y_1,\ldots,Y_{n_a}]|\chi\rangle\| = 0. \tag{88}$$

Cluster properties will hold if (a)

$$\hat{U}[\Lambda,Y]\to U_a[\Lambda,Y] = \otimes_{i=1}^{n_a}\hat{U}_{a_i}[\Lambda,Y], \tag{89}$$

when the interactions involving particles in different clusters of a are set to zero and (b) all of the interactions in each generator $\hat{G}$ satisfy

$$\lim_{\min(y_i-y_j)^2\to+\infty} \|(\hat{G}-\hat{G}_a)\hat{T}_a[Y_1,\ldots,Y_{n_a}]|\chi\rangle\| = 0, \tag{90}$$

where $\hat{G}$ and $\hat{G}_a$ are the $ISL(2,C)$ generators associated with $\hat{U}[\Lambda,Y]$ and $U_a[\Lambda,Y]$, respectively.

Condition (a) is called the algebraic cluster property.[8] It puts the nonlinear constraints on the interactions of a relativistic quantum theory. It ensures that once the interactions between particles in different clusters are turned off, the remainder is a tensor product. This condition is nontrivial because it must hold for every possible clustering.

The condition (b) is related to the range of the interaction. If the operators satisfy algebraic cluster properties, the proof of the short range condition is similar to the nonrelativistic proof[36] of cluster properties. In all that follows the interaction terms are assumed to satisfy condition (b).

When $\hat{U}[\Lambda,Y]$ does not satisfy algebraic cluster properties the limit (88) may not exist. A typical consequence is that the cluster limit eliminates interactions between particles in the *same* cluster.[26]

The cluster condition (88) is a strong form of the cluster condition. It is also possible to formulate a weaker form of the cluster condition that applies only to the scattering matrix.[8] The stronger form is needed for the recursive construction in Secs. XII and XIII.

IX. SCATTERING EQUIVALENCES

There is a large class of dynamical models with the same S-matrix. These models are called scattering equivalent models.[37] The freedom to transform between scattering equivalent models with different properties is an important tool for realizing cluster properties. What separates scattering equivalent models from unitary equivalent models is that scattering equivalent models do not change the description of free particles. They provide a parametrization of the freedom that is created by restricting the class of physical observables to asymptotic quantities ($t\to\pm\infty$).

While scattering equivalences necessarily preserve cluster properties of the S-matrix, they do not preserve cluster properties of the representation $\hat{U}[\Lambda,Y]$. Because of this property, scattering equivalences can be used to restore cluster properties of the dynamics.

The key to understanding scattering equivalences is to understand the algebra of operators that are asymptotically zero. A bounded operator $\hat{Z}$ on the N-particle Hilbert space is asymptotically zero if the following strong limits vanish:

$$\lim_{t\to\pm\infty} \hat{Z}\hat{U}_0[I,T]|\psi\rangle = 0, \tag{91}$$

$$\lim_{t\to\pm\infty}\hat{Z}^\dagger\hat{U}_0[I,T]|\psi\rangle=0, \tag{92}$$

for *both* time limits, where

$$T=t\sigma_0. \tag{93}$$

The subset of bounded operators that are asymptotically zero are denoted by $\mathcal{Z}$. It is straightforward to show that for $\hat{Z}_n\in\mathcal{Z}$ and α complex that

$$\alpha\hat{Z}_1+\hat{Z}_2\in\mathcal{Z}, \tag{94}$$

$$\hat{Z}_1\hat{Z}_2\in\mathcal{Z}, \tag{95}$$

$$\hat{Z}_1^\dagger\in\mathcal{Z}, \tag{96}$$

$$\|\hat{Z}_n-\hat{Z}\|\to 0\Rightarrow\hat{Z}\in\mathcal{Z}. \tag{97}$$

Including the identity makes a C^* algebra, which we call the algebra of asymptotic constants, $\mathcal{C}$.

A scattering equivalence $\hat{A}$ is a unitary member of $\mathcal{C}$ that is asymptotically equal to the identity $\hat{I}$:

$$\lim_{t\to\pm\infty}(\hat{A}-\hat{I})\hat{U}_0[I,T]|\psi\rangle=0; \tag{98}$$

$$\lim_{t\to\pm\infty}(\hat{A}^\dagger-\hat{I})\hat{U}_0[I,T]|\psi\rangle=0. \tag{99}$$

The relation of these operators to scattering is through the following theorems:

Theorem 2: Let $\hat{A}$ be a scattering equivalence. Let $\Omega_\pm(\hat{H},\hat{\Phi}_\mathcal{A},\hat{H}_\mathcal{A})$ be asymptotically complete two-Hilbert-space wave operators. Let $\hat{H}'=\hat{A}\hat{H}\hat{A}^\dagger$ and $\hat{\Phi}'_\mathcal{A}=\hat{A}\hat{\Phi}_\mathcal{A}$. Then $\Omega_\pm(\hat{H}',\hat{\Phi}'_\mathcal{A},\hat{H}_\mathcal{A})$ exist, are asymptotically complete, and give the same S matrix as $\Omega_\pm(\hat{H},\hat{\Phi}_\mathcal{A},\hat{H}_\mathcal{A})$.

The proof follows from the identity

$$\hat{A}\Omega_\pm(\hat{H},\hat{\Phi}_\mathcal{A},\hat{H}_\mathcal{A})=\Omega_\pm(\hat{H}',\hat{\Phi}'_\mathcal{A},\hat{H}_\mathcal{A}). \tag{100}$$

While the structure of the injection operator $\hat{\Phi}_\mathcal{A}$ depends on the representation of the subsystem bound states, it must become the identity in the scattering channel, $(\alpha=\alpha_0)$, corresponding to N free particles. Note that $\hat{\Phi}'_{\alpha_0}=\hat{A}\hat{I}=\hat{I}+\hat{Z}\neq\hat{I}$ where $\hat{Z}$ is asymptotically zero. This ensures that $\hat{\Phi}'_\mathcal{A}$ can be replaced by another injection operator, $\hat{\Phi}''_\mathcal{A}$, with $\hat{\Phi}''_{\alpha_0}=\hat{I}$:

$$\hat{\Phi}''_\mathcal{A}=\hat{\Phi}'_\mathcal{A}-\delta_{\alpha\alpha_0}\hat{Z}. \tag{101}$$

It follows that

$$\Omega_\pm(\hat{H}',\hat{\Phi}'_\mathcal{A},\hat{H}_{\alpha_0})=\Omega_\pm(\hat{H}',\hat{\Phi}''_\mathcal{A},\hat{H}_{\alpha_0}), \tag{102}$$

where $\hat{\Phi}''_{\alpha_0}=\hat{I}$.

Scattering equivalences are naturally constructed from pairs of wave operators that give the same S-matrix.

Theorem 3: Let $\hat{\Omega}_{\pm} := \Omega_{\pm}(\hat{H}, \hat{\Phi}_{\mathcal{A}}, \hat{H}_{\mathcal{A}})$ and $\hat{\Omega}'_{\pm} := \Omega_{\pm}(\hat{H}', \hat{\Phi}'_{\mathcal{A}}, \hat{H}_{\mathcal{A}})$ be asymptotically complete wave operators that give the same scattering matrix. Then there is a scattering equivalence $\hat{A}$ satisfying $\hat{H}' = \hat{A}\hat{H}\hat{A}^{\dagger}$.

To prove Theorem 3 note that the assumptions imply

$$S = \hat{\Omega}_{+}^{\dagger}\hat{\Omega}_{-} = \hat{\Omega}_{+}'^{\dagger}\hat{\Omega}'_{-}. \tag{103}$$

Asymptotic completeness implies

$$\hat{A} := \hat{\Omega}'_{+}\hat{\Omega}_{+}^{\dagger} = \hat{\Omega}'_{-}\hat{\Omega}_{-}^{\dagger}. \tag{104}$$

This definition and the intertwining relations[36] for the Hamiltonian give

$$\hat{A}\hat{H}\hat{A}^{\dagger} = \hat{\Omega}'_{+}\hat{H}_{\mathcal{A}}\hat{\Omega}_{+}^{\dagger}\hat{A}^{\dagger} = \hat{H}'\hat{\Omega}'_{+}\hat{\Omega}_{+}^{\dagger}\hat{A}^{\dagger} = \hat{H}'. \tag{105}$$

Equations (104) and (105) imply

$$\Omega_{\pm}(\hat{H}', \hat{\Phi}'_{\mathcal{A}}, \hat{H}_{\mathcal{A}}) = \hat{A}\Omega_{\pm}(\hat{H}, \hat{\Phi}_{\mathcal{A}}, \hat{H}_{\mathcal{A}}) = \Omega_{\pm}(\hat{H}', \hat{A}\hat{\Phi}_{\mathcal{A}}, \hat{H}_{\mathcal{A}}). \tag{106}$$

The equality of the first and last terms gives the strong limit

$$\lim_{t \to \pm\infty} (\hat{\Phi}'_{\mathcal{A}} - \hat{A}\hat{\Phi}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[I,T] = 0. \tag{107}$$

Unitarity of $\hat{A}$ gives

$$\lim_{t \to \pm\infty} (\hat{A}^{\dagger}\hat{\Phi}'_{\mathcal{A}} - \hat{\Phi}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[I,T] = 0; \tag{108}$$

restricting to the α_0 channel, using $\hat{\Phi}_{\alpha_0} = \hat{\Phi}'_{\alpha_0} = \hat{I}$ and $\hat{U}_{\alpha_0}[I,T] = \hat{U}_0[I,T]$ gives

$$\lim_{t \to \pm\infty} (\hat{A} - \hat{I})\hat{U}_0[I,T] = 0 \tag{109}$$

and

$$\lim_{t \to \pm\infty} (\hat{A}^{\dagger} - \hat{I})\hat{U}_0[I,T] = 0, \tag{110}$$

which establishes that $\hat{A}$ is a scattering equivalence.

This shows that if two asymptotically complete wave operators give the same scattering matrix, then the Hamiltonians are related by a scattering equivalence. Since $\hat{A}$ is unitary it follows that

$$\hat{U}'[\Lambda, Y] := \hat{A}\hat{U}[\Lambda, Y]\hat{A}^{\dagger} \tag{111}$$

is a scattering equivalent representation of $ISL(2,C)$.

The important property of the scattering equivalences is that they are the unitary elements of the C^* algebra of asymptotic constants. The C^* algebra can be used to construct functions of the noncommuting scattering equivalences. When these functions are unitary and can be expressed as uniform limits of elements of this algebra, they are scattering equivalences. This provides the mechanism for constructing scattering equivalences with specialized properties.

X. BIRKHOFF LATTICES:

The construction of operators satisfying cluster properties requires a significant amount of algebra involving cluster expansions of operators. The theory of Birkhoff lattices[8,38–41] facilitates the required algebra. It provides closed-form expressions relating different standard cluster expansions of operators.

Let $\mathcal{P}$ denote the set of all possible partitions of N-particles into disjoint nonempty clusters. There is a natural partial ordering on $\mathcal{P}$ given by

$$a \supseteq b \tag{112}$$

if and only if every pair of particles in the same cluster of b is in the same cluster of a. This means that b can be obtained from a by breaking up clusters.

The Zeta and Möbius functions[38,41] for this partial ordering are integer valued functions on $\mathcal{P}\times\mathcal{P}$ defined by

$$\zeta(a \supseteq b) = \begin{cases} 1, & a \supseteq b, \\ 0, & \text{otherwise}, \end{cases} \tag{113}$$

and

$$\mu(a \supseteq b) = \zeta^{-1}(a \supseteq b) = \begin{cases} (-)^{n_a} \prod_{i=1}^{n_a} (-)^{n_{b_i}} (n_{b_i}-1)!, & a \supseteq b, \\ 0, & \text{otherwise}, \end{cases} \tag{114}$$

where n_{b_i} are the number of clusters of b in the ith cluster of a. Note that both $\zeta(a \supseteq b)$ and $\mu(a \supseteq b)$ vanish unless $a \supseteq b$.

Intersections and unions, $a \cap b$ and $a \cup b$, of two partitions a and b are defined as the greatest lower bound and least upper bound with respect to this partial ordering.

It follows from the definitions that

$$\zeta((a \cap b) \supseteq c) = \zeta(a \supseteq c)\zeta(b \supseteq c), \tag{115}$$

$$\zeta(a \supseteq (b \cup c)) = \zeta(a \supseteq b)\zeta(a \supseteq c). \tag{116}$$

The set of partitions with the operations $\cup$ and $\cap$ form a semimodular lattice,[38] called a partition or Birkhoff lattice. It provides a convenient means for keeping track of interactions. Let $\mathcal{O}$ be an operator that is a function of the physical $ISL(2,C)$ infinitesimal generators. Imagine putting a parameter λ_i in front of each interaction that appears in the physical $ISL(2,C)$ generators. The operator $\mathcal{O}_a$ is defined to be the result of turning off the interactions between particles in different clusters of a. In general the operator $\mathcal{O}_a$ will include the contributions of operators in $\mathcal{O}_b$ for all $a \supset b$. These can be recursively subtracted to construct truncated contributions $[\mathcal{O}]_b$ to $\mathcal{O}_a$. The truncated operators $[\mathcal{O}]_a$ vanish whenever interactions involving particles in *any* cluster of a are turned off. Then the Möbius function can be used to generate closed form expressions for the truncated operators in terms of the untruncated $\mathcal{O}_a$'s:

$$[\mathcal{O}]_a := \sum_b \mu(a \supseteq b)\mathcal{O}_b. \tag{117}$$

This can be inverted using the Zeta function to get

$$\mathcal{O}_a := \sum_b \zeta(a \supseteq b)[\mathcal{O}]_b. \tag{118}$$

If this is applied to the case where a is the one-cluster partition, this becomes

$$\mathcal{O}=\sum_b [\mathcal{O}]_b . \tag{119}$$

While this generates the standard relations between ordinary multipoint functions and truncated multipoint functions based on cluster expansion methods, use of the lattice structure, and specifically the underlying partial ordering, has advantages that are useful in the recursive construction described in Secs. XII and XIII.

XI. TWO-BODY PROBLEM

The construction of two-body models follows.[23] The two-body Hilbert space is the tensor product of single particle spaces

$$\mathcal{H}=\mathcal{H}_{m_1 j_1}\otimes\mathcal{H}_{m_2 j_2}. \tag{120}$$

Choose a basis (f,d) and use the Clebsch–Gordan coefficient,

$$\langle f_1;m_1,j_1:f_2;m_2,j_2|f,d;m,j\rangle, \tag{121}$$

to construct an irreducible free-particle basis. The states

$$|f,d;m,j\rangle \tag{122}$$

transform as mass m, spin j irreducible representations of $ISL(2,C)$ with respect to the noninteracting representation

$$\hat{U}_0[\Lambda,Y]:=\hat{U}_1[\Lambda,Y]\otimes\hat{U}_2[\Lambda,Y]. \tag{123}$$

Using the $ISL(2,C)$ transformation properties it is possible to construct operators $\Delta\hat{F}_0^i$ that change the value of f^i, holding the values of f^j $(j\neq i)$ constant. If $\hat{F}_0^i$ has a continuous spectrum, these operators are proportional to partial derivatives

$$\Delta\hat{F}_0^j=i\frac{\partial}{\partial f^j} \tag{124}$$

holding $f^k;k\neq j$ constant. If F_0^j has discrete eigenvalues, a suitable $\Delta\hat{F}_0^j$ can typically be expressed in terms of a raising or lowering operators.

The operators $\hat{M}_0$, $\hat{j}_0^2$, $\hat{F}_0^i$, $\Delta\hat{F}_0^i$ are functions of the free particle generators. Expression for the generators in terms of these operator can be constructed using the $ISL(2,C)$ $\mathcal{D}$-functions:

$$\langle f,d;m,j|\vec{K}_0|f',d';m,s\rangle:=i\frac{\partial}{\partial\vec{\rho}}\mathcal{D}^{m,j}_{f,f'}[\Lambda(\theta=0,\rho),0]\delta[d,d']\delta(m-m')\delta_{jj'}, \tag{125}$$

$$\langle f,d;m,j|\vec{J}_0|f',d';m,j\rangle:=i\frac{\partial}{\partial\vec{\theta}}\mathcal{D}^{m,j}_{f,f'}[\Lambda(\theta,\rho=0),0]\delta[d,d']\delta(m-m')\delta_{jj'}, \tag{126}$$

$$\langle f,d;m,j|P_0^\mu|f',d';m,j\rangle:=-i\frac{\partial}{\partial y_\mu}\mathcal{D}^{m,j}_{f,f'}[I,Y(y)]\delta[d,d']\delta(m-m')\delta_{jj'}, \tag{127}$$

where all derivatives are computed at 0.

The chain rule gives explicit expressions for the $ISL(2,C)$ generators in terms of the operators $\hat{M}_0,\hat{j}_0^2,\hat{F}_0^i,\Delta\hat{F}_{i0}$:

$$\hat{P}_0^\mu = \hat{P}^\mu(\hat{M}_0, \hat{j}_0, \hat{F}_0^i, \Delta\hat{F}_0^i), \tag{128}$$

$$\hat{J}_0^{\mu\nu} = \hat{J}^{\mu\nu}(\hat{M}_0, \hat{j}_0, \hat{F}_0^i, \Delta\hat{F}_0^i). \tag{129}$$

These expressions can be inverted to express $\hat{M}_0, \hat{j}_0^2, \hat{F}_0^i, \Delta\hat{F}_{i0}$ in terms of the $ISL(2,C)$ generators:

$$\hat{M}_0 = M(\hat{P}_0^\mu, \hat{J}_0^{\mu\nu}), \tag{130}$$

$$\hat{j}_0^2 = j_0(\hat{P}_0^\mu, \hat{J}_0^{\mu\nu}), \tag{131}$$

$$\hat{F}_0^i = F^j(\hat{P}_0^\mu, \hat{J}_0^{\mu\nu}), \tag{132}$$

$$\Delta\hat{F}_{i0} = \Delta F^j(\hat{P}_0^\mu, \hat{J}_0^{\mu\nu}). \tag{133}$$

Examples of these operators for specific basis choices are computed in Appendix A to illustrate the general procedure.

Since $\hat{M}_0^2$ is a Casimir operator for $ISL(2,C)$, it necessarily commutes with $\hat{j}_0^2$, $\hat{F}_0^i$, and $\Delta\hat{F}_0^i$. The $ISL(2,C)$ commutation relations follow as consequences of the commutation relations of $\hat{M}_0$, $\hat{j}_0^2$, $\hat{F}_0^i$, and $\Delta\hat{F}_0^i$.

It follows that in order to construct a dynamical representation of $ISL(2,C)$ it is enough to replace $\hat{M}_0$ by an operator $\hat{M} = \hat{M}_0 + \hat{V}$ which also commutes with $\hat{j}_0^2$, $\hat{F}_{i0}$, and $\Delta\hat{F}_{i0}$. With this choice of interaction it follows that the operators

$$\hat{P}_0^\mu \to \hat{P}^\mu = \hat{P}^\mu(\hat{M}, \hat{j}_0^2, \hat{F}_0^i, \Delta\hat{F}_0^i), \tag{134}$$

$$\hat{J}_0^{\mu\nu} \to \hat{J}^{\mu\nu} = \hat{J}^{\mu\nu}(\hat{M}, \hat{j}_0^2, \hat{F}_0^i, \Delta\hat{F}_0^i) \tag{135}$$

automatically satisfy the $ISL(2,C)$ Lie algebra.

Cluster properties are satisfied for sufficiently short-range interactions. For the interaction to be nontrivial it should also satisfy

$$[\hat{M}, \hat{M}_0] \neq 0 \tag{136}$$

and the spectral condition, $\hat{M}_0 > \hat{V}$. In general the interaction can be treated as a perturbation of different functions of $\hat{M}_0$, such as $\hat{M}_0^2$. In all cases the interactions can be put in the form $\hat{M} = \hat{M}_0 + \hat{V}$ by defining $\hat{V} := \hat{M} - \hat{M}_0$, independent of how $\hat{M}$ is constructed. The spectral condition constrains the interaction.

In the free particle irreducible basis an interaction $\hat{V}$ commuting with $\hat{j}_0^2$, $\hat{F}_0^i$, and $\Delta\hat{F}_0^i$ has a kernel with the structure

$$\langle f,d;m,j|\hat{V}|f',d';m',j'\rangle = \delta[f,f']\delta_{jj'}\langle d,m\|\hat{V}_j\|d',m'\rangle. \tag{137}$$

The dynamical generators are given by (134) and (135) with $\hat{M} = \hat{M}_0 + \hat{V}$. If the expression for a generator in (134) or (135) has an explicit mass dependence, the corresponding operator will be interaction dependent. Depending on the choice of basis (f,d) between three and ten generators will have an explicit interaction dependence. Dirac's forms of dynamics result from specific basis choices. A generic choice will not have a kinematic subgroup.

While it is straightforward to derive explicit expressions for the generators in terms of the $\hat{F}^i$'s, (see Appendix A) it is easier to directly solve for the dynamics in the free particle basis $|f,d;m,j\rangle$.

In this basis $\hat{M}$, $\hat{F}_0^i$, $\hat{j}_0$ can be simultaneously diagonalized:

$$\langle f',d';m',j'|f;m,j\rangle = \delta[f,f']\delta_{jj'}\phi_m^j(d',m'), \tag{138}$$

where $\phi_m^j(d',m')$ is the solution of the mass eigenvalue equation

$$(m-m')\phi_m^j(d',m') = \sum \int dm''dd''\langle d',m'\|\hat{V}_j\|d''m''\rangle\phi_m^j(d'',m''). \tag{139}$$

For suitable interactions $\hat{M}$ will be self-adjoint and the eigenstates $|f,d;m,j\rangle$ will define a complete set of simultaneous eigenstates of $\hat{M}$, $\hat{F}_0^i$, $\hat{j}_0^2$. Solving equation (139) is of comparable difficulty to solving the time-independent nonrelativistic Schrödinger equation. It is assumed that the eigenstates include two-body bound states and scattering states satisfying incoming and outgoing wave asymptotic conditions.

Since the expressions (125)–(127) for the $ISL(2,C)$ generators were derived by evaluating the infinitesimal transformations in an irreducible basis, and $\{\hat{M}_0,\hat{F}_0^i,\Delta\hat{F}_0^i,\hat{j}_0\}$ and $\{\hat{M},\hat{F}_0^i,\Delta\hat{F}_0^i,\hat{j}_0\}$ have the same commutation relations, the action of the dynamical representation of $ISL(2,C)$ on the eigenstates $|f;m,j\rangle$ has the same form as the free dynamics on $|f,d;m_0,j\rangle$, with the eigenvalue of $\hat{M}_0$ replaced by the eigenvalue of $\hat{M}$. It follows that

$$\hat{U}[\Lambda,Y]|f;m,j\rangle = |f';m,j\rangle d\mu(f')\mathcal{D}^{m,j}_{f',f}[\Lambda,Y]. \tag{140}$$

Since the states $|f;j,m\rangle$ are complete, this defines $\hat{U}[\Lambda,Y]$ on $\mathcal{H}$. Since m is the eigenvalue of a dynamical operator, all of the mass dependent parts of $\mathcal{D}^{mj}_{f'f}[\Lambda,Y]$ are interaction dependent.

This construction gives (1) an explicit expressions for the interaction dependent $ISL(2,C)$ Lie algebra, (2) a solution of the two-body dynamics expressed as a direct integral of irreducible representations of $ISL(2,C)$, and (3) and an explicit unitary representation of $ISL(2,C)$ on $\mathcal{H}$.

This construction can be done in any irreducible basis. Consider the same construction in two bases (f,d) and (g,d) where, for simplicity, the degeneracy operators in both bases are assumed to have the same spectrum. In one model the interaction commutes with $\hat{F}^i$, while in the other the interaction commutes with $\hat{G}^i$. Because $\hat{M}$ does not commute with $\hat{M}_0$, if the relation between the (f,d) and (g,d) bases involves the mass, these two interactions cannot be the same.

Nevertheless, the form of the dynamical equation (139) is identical in both cases. Both will give the same bound state masses and scattering matrix elements. It follows, using Theorem 3, that the dynamical models constructed using the free particle bases

$$(\hat{F},\hat{d},\hat{M}_1) \quad \text{and} \quad (\hat{G},\hat{d},\hat{M}_2) \tag{141}$$

are scattering equivalent and are related by

$$\hat{A} = \Omega_{\pm}(\hat{M}_1,\hat{\Phi}_1,\hat{M}_{\mathcal{A}})\Omega_{\pm}^{\dagger}(\hat{M}_2,\hat{\Phi}_2,\hat{M}_{\mathcal{A}}). \tag{142}$$

The transformation $\hat{A}$ is not simply a change of basis; it is interaction dependent and changes the nature of the interactions. This illustrates the relation of the basis choice to the structure of the dynamics.

To understand the nature of the interaction dependence of $\hat{A}$ note that both wave operators in (142) need to be computed in the same basis. This leads to an expression of the form

$$\langle f|\hat{A}|f'\rangle = \int \langle f|\Omega_{\pm}(\hat{M}_f,\hat{\Phi}_f,\hat{M}_{\mathcal{A}})|f''\rangle d\mu(f'')\langle f''|g''\rangle_{\mathcal{A}} d\mu(g'')$$
$$\times\langle g''|\Omega_{\pm}^{\dagger}(\hat{M}_g,\hat{\Phi}_g,\hat{M}_{\mathcal{A}})|g'\rangle d\mu(g')\langle g'|f'\rangle. \tag{143}$$

If the change of basis $f \leftrightarrow g$ involves the mass parametrically, then $\langle f|g\rangle_{\mathcal{A}}$ will involve the physical mass eigenvalues while $\langle g|f\rangle$ involves the noninteracting masses. The interaction dependence is due to having the interacting mass in one of these expressions and the free mass in the inverse expression. In the limit that the interactions are turned off, this becomes the identity.

This completes the construction of the two-body dynamics. The construction provides a relativistic two-body model for any choice of basis and $ISL(2,C)$ Clebsch–Gordan coefficient.

To illustrate the structure of the dynamical equation in a familiar basis consider the case (see Appendix B) that $\hat{F}=\{\hat{\vec{P}},\hat{j}_{cz}\}$, corresponding to the linear momentum and z-component of the canonical spin, and $\hat{D}^i=\{j_1,m_1,j_2,m_2,\hat{l},\hat{s}\}$ where $\hat{l},\hat{s}$ are two-body orbital and spin angular momenta. The matrix elements of $\hat{V}=\hat{M}-\hat{M}_0$ have the form

$$\langle p,\mu,l,s;m,j|\hat{V}|p',\mu',l',s';m',j'\rangle=\delta(\vec{p}-\vec{p}')\,\delta_{\mu\mu'}\,\delta_{jj'}\langle l,s,m\|\hat{V}^j\|l',s',m\rangle. \tag{144}$$

If m is replaced by the kinematic momentum q defined by

$$m=\sqrt{q^2+m_1^2}+\sqrt{q^2+m_2^2}, \tag{145}$$

the matrix element (144) has the same structure as the corresponding nonrelativistic interaction. The eigenvalue equation (139) becomes:

$$\begin{aligned}(m-\sqrt{q^2+m_1^2}+\sqrt{q^2+m_2^2})\,\phi^j_m(l,s,q)&\\ =\sum_{l'=0}^{\infty}\sum_{s'=|j-l|}^{|j+l|}\int_0^\infty q'^2 dq'\langle l,s,q\|\hat{V}^j\|l',s',q'\rangle\,\phi^j_m(l',s',q').&\end{aligned} \tag{146}$$

XII. THE *N*-BODY PROBLEM

The formulation of the N-body problem is by induction. The construction follows.[7–9] What is different is that the notion of ''form of the dynamics'' is replaced by a choice (f,d) of basis for $ISL(2,C)$ irreducible representation spaces and associated Clebsch–Gordan coefficients.

The construction of the N-body dynamics exploits the scattering equivalence of two representations of $ISL(2,C)$. One representation satisfies algebraic cluster properties and the other has a kinematic spin, which is useful for the $ISL(2,C)$ invariant addition of interactions.

The construction begins with the decomposition of the system into interacting subsystems, which are obtained by turning off the interactions between particles in different clusters of a partition a. The tensor product of the subsystem representations define unitary representation of $ISL(2,C)$ on the N-body Hilbert space. These representations are reducible and have interactions in both the N-body mass and spin operators. As a runs over all partitions these representations contain all interactions except the N-body interactions. Because the mass and spin operators for different decompositions into subsystems do not all commute, these tensor product representations are not suited to $ISL(2,C)$ invariant addition of interactions.

In order to facilitate the invariant addition of interactions, scattering equivalences are introduced that transform each of the tensor product representations into scattering equivalent representations of $ISL(2,C)$ where $\hat{j}^2$, $\hat{F}^j$, and $\Delta\hat{F}^j$ are free of interaction. In these representations all of the interactions are in the mass operators. Linear combinations of the mass operators for different decompositions into subsystems can be used to construct an overall N-body mass operator $\overline{M}$ that still commutes with the noninteracting operators j_0^2, $\hat{F}_0^j$, and $\Delta\hat{F}_0^j$.

The existence of the required scattering equivalences follows by induction from properties of the two-body solution. This is different than the solution presented in Ref. 8 where the kinematic subgroup and the $\vec{p}=0$ condition played a central role in establishing the required scattering equivalences.

The properties of $\overline{M}$ guarantee that $ISL(2,C)$ generators expressed as functions of $\overline{M}$, j_0^2, $\hat{F}_0^j$, and $\Delta\hat{F}_0^j$ satisfy the $ISL(2,C)$ commutation relations. The associated unitary representation of

$ISL(2,C)$, which is constructed using the same method used in the two-body construction, does not satisfy algebraic cluster properties for $N>2$. Cluster properties are restored by constructing a suitable scattering equivalence, which introduces additional many-body interactions and introduces a non-trivial interaction dependence in the spin.

The induction begins with the two-body dynamics formulated in the previous section. The dynamical two-body representation, $\hat{U}[\Lambda,Y]$, of $ISL(2,C)$ satisfies the following:

(i) It becomes the tensor product of two one-body representations when the interaction is set to zero:

$$\hat{U}_{(12)}[\Lambda,Y]\rightarrow\hat{U}_1[\Lambda,Y]\otimes\hat{U}_2[\Lambda,Y]. \tag{147}$$

(ii) The two-body mass operator commutes with the noninteracting $\hat{F}^j$, $\Delta\hat{F}^j$, and $\hat{j}^2$:

$$[\hat{M}_{(12)},\hat{F}^j_0]=[\hat{M}_{(12)},\Delta\hat{F}^j_0]=[\hat{M}_{(12)},\hat{j}^2_0]=0. \tag{148}$$

These conditions cannot be simultaneously satisfied for systems of more than two particles. They are replaced by the following induction assumption, which reduces to the above condition when $N=2$:

(i) For each proper subsystem s of the N-body system, there is a dynamical representation $\hat{U}_s[\Lambda,Y]:\mathcal{H}_s\rightarrow\mathcal{H}_s$ with short-range interactions satisfying algebraic cluster properties. This means that if the interactions between particles in different clusters of the subsystem s are set to zero, then

$$\hat{U}_s[\Lambda,Y]\rightarrow\otimes_i\hat{U}_{a_i}[\Lambda,Y]. \tag{149}$$

(ii) For each proper subsystem there is a scattering equivalence $\hat{C}_s$ satisfying

$$\hat{C}_s\hat{U}_s[\Lambda,Y]\hat{C}_s^\dagger=\overline{U}_s[\Lambda,Y] \tag{150}$$

with the property that the mass operator $\overline{M}_s$ of the $\overline{U}_s[\Lambda,Y]$ representation commutes with $\hat{F}^i_s$, $\hat{j}^2_s$, $\Delta\hat{F}^i_s$ of the noninteracting subsystem, s.

These conditions are trivially satisfied by the two-body construction of the previous section for $\hat{C}_s=\hat{I}$ on each single particle Hilbert space.

First we show that if these conditions hold for all proper subsystems, then they hold for any nontrivial partitioning of the N-body system.

The theorem below ensures the scattering equivalence of tensor products of subsystem representations that satisfy (150) to representations with a non-interacting $\hat{j}^2$, $\hat{F}^i$, and $\Delta\hat{F}^i$.

Theorem 4: Let a be a partition of the N-particle system into n_a disjoint mutually noninteracting subsystems, a_i. Assume that each subsystem has a dynamical representation $\hat{U}_{a_i}[\Lambda,Y]$ of $ISL(2,C)$ with an asymptotically complete scattering theory. Assume that each of the representations $\hat{U}_{a_i}[\Lambda,Y]$ is scattering equivalent to a representation that has $\hat{F}^j_{a_i}=\hat{F}^j_{0a_i}$, $\Delta\hat{F}^j_{a_i}=\Delta\hat{F}^j_{0a_i}$, $\hat{j}^2_{a_i}=\hat{j}^2_{0a_i}$. Let

$$\hat{U}_a[\Lambda,Y]:=\otimes_{i=1}^{n_a}\hat{U}_{a_i}[\Lambda,Y] \tag{151}$$

be the tensor product of subsystem representations of $ISL(2,C)$. Then $\hat{U}_a[\Lambda,Y]$ is scattering equivalent to a representation $\overline{U}_a[\Lambda,Y]$ that has $\hat{F}^j_a=\hat{F}^j_0$, $\Delta\hat{F}^j_a=\Delta\hat{F}^j_0$, $\hat{j}_a=\hat{j}_0$.

This states that if the subsystem mass operators are scattering equivalent to the subsystem mass operator with kinematic $\hat{F}^j_{a_i}$, $\Delta\hat{F}^j_{a_i}$, $\hat{j}_{a_i}$ then the tensor product of the subsystems has a mass operator that is scattering equivalent to a mass operator with kinematic $\hat{F}^j$, $\Delta\hat{F}^j$, and $\hat{j}$.

The induction assumptions (150) and (149) and the application of Theorem 4 imply that for every partition a with at least two nonempty clusters there are representations $\hat{U}_a[\Lambda,Y]$, and $\overline{U}_a[\Lambda,Y]$, related by a scattering equivalence $\hat{B}_a$. The proof of Theorem 4 as well as the construction of $\hat{B}_a$ is given in Appendix D.

To establish algebraic cluster properties let $\hat{X}$ be an operator valued function of the interactions. Assume that a coupling constant λ_b is put in front of all interactions involving particles in different clusters of a partition b. Let $(\hat{X})_b$ denote the operator obtained from $\hat{X}$ by setting λ_b to 0.

Theorem 4 implies the following relation:

$$\overline{U}_a[\Lambda,Y]=\hat{B}_a\hat{U}_a[\Lambda,Y]\hat{B}_a^\dagger. \tag{152}$$

Turning off interactions between particles in different clusters of b in (152) gives, using (149) and (151),

$$(\overline{U}_a[\Lambda,Y])_b=(\hat{B}_a)_b\hat{U}_{a\cap b}[\Lambda,Y](\hat{B}_a^\dagger)_b, \tag{153}$$

when $b\cap a$ is a refinement of a.

Applying Theorem 4 directly to the partition $c=b\cap a$ gives

$$\overline{U}_{a\cap b}[\Lambda,A]=\hat{B}_{a\cap b}\hat{U}_{a\cap b}[\Lambda,Y]\hat{B}_{a\cap b}^\dagger. \tag{154}$$

This gives distinct scattering equivalences $\hat{B}_{a\cap b}$ and $(\hat{B}_a)_b$ relating $\hat{U}_{a\cap b}[\Lambda,Y]$ to different representations that commute with $\hat{F}_0^j$, $\Delta\hat{F}_0^j$, and $\hat{j}_0^2$. An illustration of this ambiguity in the four-body system occurs for $a=(123)(4)$, $b=(12)(34)$ and $c=(12)(3)(4)$.

It is desirable that the scattering equivalence obtained by turning off interactions agrees with the scattering equivalence constructed directly by applying Theorem 4 to the tensor products. This can be achieved by recursively replacing the operators $\hat{B}_a$ of Theorem 4 with operators $\hat{A}_a$ that satisfy $(\hat{A}_a)_b=\hat{A}_{a\cap b}$. This replacement involves a redefinition of the $\overline{M}_a$'s.

For $N-1$ cluster partitions define

$$\hat{A}_a:=\hat{B}_a. \tag{155}$$

Because $N-1$ cluster interactions only have two-body interactions, both $\hat{A}_a$ and $\hat{B}_a$ become the identity when the interaction is turned off:

$$(\hat{A}_a)_b=\hat{A}_{a\cap b}=\hat{I}. \tag{156}$$

In this case any nontrivial refinement of a gives N free particles.

Next consider a partition a with k clusters. By induction assume that scattering equivalences $\hat{A}_c$ have have been defined for all partitions c with more than k clusters and that these operators satisfy $(\hat{A}_c)_d=\hat{A}_{c\cap d}$ for $n_c>k$.

Let b be a partition such that $a\cap b$ has more than k clusters. Note that

$$\hat{A}_{a\cap b}(\hat{B}_a^\dagger)_b \tag{157}$$

is defined and commutes with $\hat{F}_0^j$, $\Delta\hat{F}_0^j$, and $\hat{j}_0$.

Define

$$\hat{A}_a:=\left(\frac{\hat{I}-i\hat{\alpha}_a}{\hat{I}+i\hat{\alpha}_a}\right)\hat{B}_a, \tag{158}$$

where

$$\hat{\alpha}_a := -\sum_{b\neq a} \mu(a\supset b)\hat{\alpha}_{a,b} \tag{159}$$

and

$$\hat{\alpha}_{a,b} := i\frac{\hat{I}-\hat{A}_b(\hat{B}_a^\dagger)_b}{\hat{I}+\hat{A}_b(\hat{B}_a^\dagger)_b}. \tag{160}$$

Note that $a\cap b=b$ was used in (160). These expressions utilize Cayley transforms to construct unitary functions of scattering equivalences. The resulting unitary operators will be scattering equivalences provided their Cayley transforms are in the algebra of asymptotic constants. This is not entirely trivial, because the algebra $\mathcal{C}$ is uniformly closed, but not strongly closed. $\hat{A}_a$ will be a scattering equivalence if the Cayley transforms $\hat{\alpha}_{a,b}$ are bounded. This will be assumed in all that follows.

The restriction $b\neq a$ means that the b's appearing in the sum are proper refinements of a and necessarily have more than k clusters. By induction the $\hat{A}_b$'s satisfy $(\hat{A}_b)_c=\hat{A}_{b\cap c}$. It follows for $c\cap a\neq a$ that

$$(\hat{\alpha}_{a,b})_c := i\frac{\hat{I}-\hat{A}_{b\cap c}(\hat{B}_a^\dagger)_{b\cap c}}{\hat{I}+\hat{A}_{b\cap c}(\hat{B}_a^\dagger)_{b\cap c}} = \hat{\alpha}_{a,b\cap c}, \tag{161}$$

which gives

$$(\hat{\alpha}_a)_c = -\sum_{b\neq a} \mu(a\supset b)\hat{\alpha}_{a,b\cap c} = -\sum_{b\neq a} \mu(a\supset b)\zeta((b\cap c)\supset d)\mu(d\supset e)\hat{\alpha}_{a,e}. \tag{162}$$

Using (115) gives

$$-\sum_{b\neq a} \mu(a\supset b)\zeta(b\supset d)\zeta(c\supset d)\mu(d\supset e)\hat{\alpha}_{a,e}. \tag{163}$$

The b sum gives $\mu(a\supset a)\zeta(a\supset d)-\delta_{ad}=\zeta(a\supset d)-\delta_{ad}$. Using this in the above sum and observing that $\zeta(c\supset a)=0$ gives

$$\sum_{d,e} \zeta(a\supset d)\zeta(c\supset d)\mu(d\supset e)\hat{\alpha}_{a,e} = \sum_{d,e} \zeta(a\cap c\supset d)\mu(d\supset e)\hat{\alpha}_{a,e} = \hat{\alpha}_{a,a\cap c}. \tag{164}$$

It follows that

$$(\hat{A}_a)_c = \left(\frac{\hat{I}-i\hat{\alpha}_{a,c}}{\hat{I}+i\hat{\alpha}_{a,c}}\right)(\hat{B}_a)_c = \hat{A}_{a\cap c}(\hat{B}_a^\dagger)_c(\hat{B}_a)_c = \hat{A}_{a\cap c}. \tag{165}$$

This shows that if the result holds for more than k clusters, it holds for k clusters.

This process can be continued recursively until $n_a=2$. The result is a set of scattering equivalences, $\hat{A}_a$, and representations

$$\hat{U}_a[\Lambda,Y], \overline{\hat{U}}_a[\Lambda,Y] \tag{166}$$

with the properties

$$\overline{U}_a[\Lambda,Y]=\hat{A}_a\hat{U}_a[\Lambda,Y]\hat{A}_a^\dagger, \tag{167}$$

$$\hat{U}_a[\Lambda,Y]=\otimes_{i=1}^{n_a}\hat{U}_{a_i}[\Lambda,Y], \tag{168}$$

$$\hat{A}_a\to\hat{A}_{a\cap b}, \tag{169}$$

and

$$\overline{F}_a^i=\hat{F}_0^i, \quad \Delta\overline{F}_a^i=\Delta\hat{F}_0^i, \quad \overline{j}_a^2=\hat{j}_0^2. \tag{170}$$

The final step is to complete the construction of the dynamics. For each partition a of the N-particle system with at least two clusters let $\hat{M}_a$ be the mass operator for the tensor product representation $\hat{U}_a[\Lambda,Y]$. Note that

$$\overline{M}_a=\hat{A}_a\hat{M}_a\hat{A}_a^\dagger \tag{171}$$

is scattering equivalent to $\hat{M}_a$ and commutes with $\hat{F}_0^j$, $\Delta\hat{F}_0^j$, and $\hat{j}_0^2$.

Define

$$\overline{M}:=-\sum_{a\neq 1}\mu(1\supseteq a)\overline{M}_a+[\overline{M}]_N=-\sum_{a\neq 1}\mu(1\supseteq a)\hat{A}_a\hat{M}_a\hat{A}_a^\dagger+[\overline{M}]_N, \tag{172}$$

where $[\overline{M}]_N$ is a possible additional N-body interaction that commutes $\hat{F}_0^j$, $\Delta\hat{F}_0^j$, and $\hat{j}_0^2$. By construction $\overline{M}$ commutes with $\hat{F}_0^j$, $\Delta\hat{F}_0^j$, and $\hat{j}_0^2$. This expansion is equivalent to the cluster expansion of $\overline{M}$. By the induction assumption, turning off the interactions between particles in different clusters of partition b gives

$$\begin{aligned}(\overline{M})_b&:=-\sum_{a\neq 1}\mu(1\supseteq a)(\overline{M}_a)_b=-\sum_{a\neq 1}\mu(1\supseteq a)\hat{A}_{a\cap b}\hat{M}_{a\cap b}\hat{A}_{a\cap b}^\dagger\\&=-\sum_{a\neq 1}\mu(1\supseteq a)\zeta((a\cap b)\supseteq d)\mu(d\supseteq e)\hat{A}_e\hat{M}_e\hat{A}_e^\dagger\\&=-\sum_{a\neq 1}\mu(1\supseteq a)\zeta(a\supseteq d)\zeta(b\supseteq d)\mu(d\supseteq e)\hat{A}_e\hat{M}_e\hat{A}_e^\dagger.\end{aligned} \tag{173}$$

The a sum gives $(1-\delta_{1d})\hat{I}$. Inserting this into (173) gives

$$(\overline{M})_b=\hat{A}_b\hat{M}_b\hat{A}_b^\dagger \tag{174}$$

or

$$(\overline{M})_b=\overline{M}_b. \tag{175}$$

This is not the mass operator $\hat{M}_b$ corresponding to the tensor product of the subsystems associated with the clusters of b. To correct this define the scattering equivalence

$$\hat{A}:=\frac{I+i\hat{\alpha}}{I-i\hat{\alpha}} \tag{176}$$

with

$$\hat{\alpha}=-\sum_{a\neq 1}\mu(1\supseteq a)\hat{\alpha}_a, \tag{177}$$

$$\hat{\alpha}_a:=i\frac{\hat{I}-\hat{A}_a}{\hat{I}+\hat{A}_a}. \tag{178}$$

Using the same algebra used to show that $(\overline{M})_b=\overline{M}_b$, it follows that

$$(\hat{A})_b=\hat{A}_b. \tag{179}$$

Since $\hat{A}$ is a scattering equivalence define

$$\hat{M}:=\hat{A}^\dagger\overline{M}\hat{A}. \tag{180}$$

Since $\overline{M}$ commutes with the kinematic operators $\hat{F}_0^j$, $\Delta\hat{F}_0^j$, and $\hat{j}_0^2$, simultaneous eigenstates of $\overline{M}$, $\hat{F}_0^j$, and $\hat{j}_0^2$ define a complete set of states that transform irreducibly. This can be used to construct a representation $\overline{U}[\Lambda,Y]$ of the $ISL(2,C)$. The scattering equivalence $\hat{A}$ defines a scattering equivalent representation

$$\hat{U}[\Lambda,Y]:=\hat{A}^\dagger\overline{U}[\Lambda,Y]\hat{A} \tag{181}$$

with the property that

$$(\hat{U}[\Lambda,Y])_b:=\hat{A}_b^\dagger\overline{U}_b[\Lambda,Y]\hat{A}_b=\hat{U}_b[\Lambda,Y]=\otimes_{i=1}^{n_b}\hat{U}_{b_i}[\Lambda,Y]. \tag{182}$$

The generators have the form

$$\hat{P}^\mu=\hat{A}^\dagger P^\mu(\overline{M},\hat{j}_0^2,\hat{F}_0^i,\Delta\hat{F}_0^i)\hat{A} \tag{183}$$

and

$$\hat{J}^{\mu\nu}=\hat{A}^\dagger J^{\mu\nu}(\overline{M},\hat{j}_0^2,\hat{F}_0^i,\Delta\hat{F}_0^i)\hat{A}. \tag{184}$$

This completes the proof of the induction.

The operator $\hat{U}[\Lambda,Y]$ defined in (181) is the desired N-body representation of $ISL(2,C)$ that is consistent with the dynamics and satisfies algebraic cluster separability. The effect of the transformation $\hat{A}$ is to cancel the $\hat{A}_a$'s from the subsystems. It generates new many-body interactions that are necessary for the algebraic cluster properties of $\hat{U}[\Lambda,Y]$.

To summarize this construction, tensor products of subsystem dynamics are transformed to scattering equivalent representations where the operators $\hat{F}^j$, $\Delta\hat{F}^j$, and $\hat{j}$ are free of interactions. The transformed mass operators are combined to construct a mass operator for a unitary representation of $ISL(2,C)$ with kinematic $\hat{F}^j,\Delta\hat{F}^j$, and $\hat{j}$. This representation is transformed to a scattering equivalent representation satisfying cluster properties.

The construction, while complex, leads to a simple structure. All of the $ISL(2,C)$ generators can be expressed as sums of one, two, three, ..., N-body interactions. For any $ISL(2,C)$ generator, the k-body interaction in the k-body problem is identical to the k-body interaction in the many-body problem. At each stage of the construction the subsystem interactions remain unchanged. What is new is that cluster properties generate new many-body interactions. These do not change when they are imbedded in systems with more than N particles. The spin, which is a nonlinear function of these generators, is an interaction dependent quantity given by

$$\hat{j}^2 = \hat{A}^\dagger \hat{j}_0^2 \hat{A}. \tag{185}$$

The scattering equivalence $\hat{A}$ is an interaction dependent operator that becomes the identity when the interactions are switched off. While there is freedom to include many-body interactions, there is a class of many-body interactions that cannot be removed without violating cluster properties.

XIII. CLUSTER EQUIVALENCE

The dynamical unitary representation of $ISL(2,C)$ constructed in the previous section satisfies algebraic cluster properties. With suitable short-ranged interactions it will satisfy cluster properties (88) and the spectral condition. The choice of basis (f,d) was an important element of this construction. In this section, this representation is shown to be scattering equivalent to a representation based on a different choice of basis, (g,h). This representation also satisfies algebraic cluster properties.

This illustrates the existence of a subgroup of the group of scattering equivalences that relates the constructions based on different irreducible representation basis choices and preserves algebraic cluster properties. This subgroup will be called the group of cluster equivalences.

It follows that the choice of irreducible basis used in the construction has no fundamental physical significance. This generalizes the equivalence of choices of kinematic subgroups in two ways. First, it extends the result to the general setting of this article where the form of dynamics is replaced by the basis choice (f,d). Second, it shows that this equivalence respects cluster properties.

To illustrate the nature of the required scattering equivalence, first let $\hat{U}^f[\Lambda,Y]$ denote the representation constructed in the previous section using the (f,d) basis. Turning off interactions between particles in different clusters of the partition a gives

$$\hat{U}^f[\Lambda,Y] \to \hat{U}_a^f[\Lambda,Y] = \hat{A}_a^{f\dagger} \overline{U}_a^f[\Lambda,Y] \hat{A}_a^f, \tag{186}$$

where $\hat{A}_a^f$ are the scattering equivalences constructed in the previous section. The superscript f indicates that the (f,d) basis was used in the construction.

Algebraic cluster properties give the relations

$$\begin{aligned}\hat{U}^f[\Lambda,Y] \to \hat{U}_a^f[\Lambda,Y] &= \otimes_{i=1}^{n_a} \hat{U}_{a_i}^f[\Lambda,Y] = \otimes_{i=1}^{n_a} (\hat{A}_{a_i}^{f\dagger} \overline{U}_{a_i}^f[\Lambda,Y] \hat{A}_{a_i}^f) \\ &= (\otimes_{i=1}^{n_a} \hat{A}_{a_i}^{f\dagger})(\otimes_{j=1}^{n_a} \overline{U}_{a_j}^f[\Lambda,Y])(\otimes_{k=1}^{n_a} \hat{A}_{a_k}^f), \end{aligned} \tag{187}$$

where the $\hat{A}_{a_i}^f$ are the $\hat{A}^f$ operators for the subsystem consisting of the particles in the ith cluster of a.

It is useful to introduce the operators

$$\tilde{U}_a^f[\Lambda,Y] := \otimes_{i=1}^{n_a} \overline{U}_{a_i}^f[\Lambda,Y], \tag{188}$$

which are related to $\hat{U}_a^f[\Lambda,Y]$ by the scattering equivalence

$$\hat{B}_a^f := \otimes_{i=1}^{n_a} \hat{A}_{a_i}^f. \tag{189}$$

The construction of the previous section defined $\hat{U}_a^f[\Lambda,Y] := \tilde{U}_a^f[\Lambda,Y]$ for $n_a = N-1$. All of the $\hat{U}_a^f[\Lambda,Y]$'s were recursively constructed from the $n_a = N-1$ cluster representations.

Any of the representations $\overline{U}_a^f[\Lambda,Y]$ are scattering equivalent to a $\overline{U}_a^g[\Lambda,Y]$ representation. This scattering equivalence is realized by making the following replacements in the kernel of the barred mass operators:

$$\langle f,d(m_0,j_0)|\overline{M}^f|f',d'(m_0',j_0')\rangle=\delta[f;f']\delta_{j_0,j_0'}\langle m_0,d||\overline{M}^{j_0}||m_0',d'\rangle \tag{190}$$

by

$$\langle g,h(m_0,j_0)|\overline{M}^g|g',h'(m_0',j_0')\rangle=\delta[g;g']\delta_{j_0,j_0'}\langle m_0,h||\overline{M}^{j_0}||m_0',h'\rangle, \tag{191}$$

where the reduced kernel $\langle m_0,h||\overline{M}^{j_0}||m_0',h'\rangle$ is defined in terms of the reduced kernel $\langle m_0,d||\overline{M}^{j_0}||m_0',d'\rangle$ by a variable change $d\to h$ implemented by kinematic $ISL(2,C)$–Racah coefficients. This means abstract reduced mass operators are identical. The operators $\overline{M}^g$ and $\overline{M}^f$ differ because of the delta functions in f or g, but both operators manifestly give the same S matrix elements and bound-state observables. The operators $\overline{M}^f$ and $\overline{M}^g$ define scattering equivalent representations of $ISL(2,C)$ with the noninteracting $\hat{F}^i,\Delta\hat{F}^i$ or $\hat{G}^i,\Delta\hat{G}^i$, respectively. The scattering equivalence is denoted by $\hat{C}^{gf}$:

$$\hat{C}^{gf}\overline{U}^f[\Lambda,Y]\overline{C}^{gf\dagger}=\overline{U}^g[\Lambda,Y]. \tag{192}$$

Since this equivalence is valid for systems or subsystems, for each partition a the following representations are scattering equivalent:

$$\hat{U}_a^f[\Lambda,Y],\quad \overline{U}_a^f[\Lambda,Y],\quad \tilde{U}_a^f[\Lambda,Y],\quad \overline{U}_a^g[\Lambda,Y],\quad \tilde{U}_a^g[\Lambda,Y]. \tag{193}$$

These representations have the property that $\hat{U}_a^f[\Lambda,Y]=\tilde{U}_a^f[\Lambda,Y]$ for $N-1$ cluster partitions and $\hat{U}_a^f[\Lambda,Y]$ is scattering equivalent to $\overline{U}_a^f[\Lambda,Y]$ for the one-cluster partition.

The goal is to find a $\hat{U}^g[\Lambda,a]$ that is scattering equivalent to $\overline{U}^g[\Lambda,Y]$ and $\overline{U}^f[\Lambda,Y]$ and also satisfies algebraic cluster properties, with $\hat{U}_a^g[\Lambda,Y]=\tilde{U}_a^g[\Lambda,Y]$ for $n_a=N-1$.

The first step is to define

$$\hat{U}_a^g[\Lambda,Y]=\tilde{U}_a^g[\Lambda,Y] \tag{194}$$

for $n_a=N-1$. Following the construction of the previous section, this gives scattering equivalences $\hat{A}_a^g$ relating $\hat{U}_a^g[\Lambda,Y]$ to $\overline{U}_a^g[\Lambda,Y]$ for $n_a=N-1$.

Next, assume by induction that $\hat{U}_a^g[\Lambda,Y]$ has been defined for partitions with more than K clusters satisfying algebraic cluster properties and is scattering equivalent to $\overline{U}_a^g[\Lambda,Y]$. The $\overline{U}_a^g[\Lambda,Y]$ for K-cluster partitions is defined by (192). Its mass operator, $\overline{M}_a^g$, is related to $\overline{M}_a^f$ by replacing delta functions in f by delta functions in g. Since $(\overline{M}_a^f)_b=\overline{M}_{a\cap b}^f$ it follows that $(\overline{M}_a^g)_b=\overline{M}_{a\cap b}^g$ because the kernel of the two operators only differ by delta functions in the overall kinematic operators f or g.

This means that $\overline{M}_a^g$ differs from the cluster expansion

$$\overline{M}_a^{g0}=-\sum_{b\neq a}\mu(a\supseteq b)\overline{M}_b^g \tag{195}$$

by at most an a-connected interaction term, $[\overline{M}]_a^g$. In order to construct the desired representation it is enough to define

$$\hat{U}_a^g[\Lambda,Y]:=\hat{A}_a^{g\dagger}\overline{U}_a^g[\Lambda,Y]\hat{A}_a^g, \tag{196}$$

where

$$\hat{A}^g_a = \frac{I + i\hat{\alpha}^g_a}{I - i\hat{\alpha}^g_a}, \tag{197}$$

$$\hat{\alpha}^g_a := -\sum_{b \neq a} \mu(a,b)\hat{\alpha}^g_b, \tag{198}$$

$$\hat{\alpha}^g_b = i\frac{I + \hat{A}^g_b}{I - \hat{A}^g_b}. \tag{199}$$

Following the algebra used in (173) $\hat{\alpha}^g_a$ has the property that

$$(\hat{\alpha}^g_a)_b = \hat{\alpha}^g_b, \quad b \subset a, \tag{200}$$

and

$$(\hat{U}^g_a)_b[\Lambda, Y] := \hat{A}^{g\dagger}_{a\cap b}\overline{U}^g_{a\cap p}[\Lambda, Y]\hat{A}^g_{a\cap b} = \hat{U}^g_{a\cap b}[\Lambda, Y]. \tag{201}$$

This differs from the result of a direct construction in the (g,h) basis because of the difference $[\overline{M}]^g_a$ between $\overline{M}^g_a$ and $\overline{M}^{g0}_a$. This introduces additional many-body interactions that are needed to maintain the scattering equivalence at each stage of the recursion. Note that in this construction the factor $\mu(a \supseteq b)$ ensures that only the b satisfying $b \subset a$ appear in the sum. These partitions have more than K-clusters. This construction can be continued until $K = 1$, where

$$\hat{U}^g[\Lambda, Y] = \hat{U}^g_1[\Lambda, Y] = \hat{A}^g\overline{U}^g_1\hat{A}^{g\dagger} \tag{202}$$

is the desired representation based on the (g,h) representation. The relevant scattering equivalence is

$$\hat{U}^g[\Lambda, Y] = \hat{A}^{g\dagger}\hat{C}^{gf}\hat{A}^f\hat{U}^f[\Lambda, Y]\hat{A}^{f\dagger}\hat{C}^{gf\dagger}\hat{A}^g. \tag{203}$$

It follows that $\hat{A}^{g\dagger}\hat{C}^{gf}\hat{A}^f$ is the desired scattering equivalence connecting the construction of $\hat{U}[\Lambda, Y]$ using the (f,d) representation to a dynamics satisfying cluster properties based on the (g,h) representation.

It is important to emphasize that the $\hat{A}^g$ constructed in this manner are not identical to the corresponding operators that would have been constructed if one began with the (g,h) basis. This is due to the presence of additional many-body interactions that are determined by the difference between the operators $\overline{M}^{g0}_a$ and $\overline{M}^g_a$ for each a. These differences account for the dynamical differences that occur when the many-body dynamics is formulated with different basis choices, or using different forms of dynamics.

The cluster equivalences transform $ISL(2,C)$ generators in one representation to physically equivalent generators in another representation. In each representation the interactions are distributed differently among the generators. Specific representation have computational advantages.

XIV. SUMMARY AND CONCLUSION

This article provides a general construction of a unitary representation $\hat{U}[\Lambda, Y]$ of $ISL(2,C)$ for a system of N-interacting particles based on the representation theory of $ISL(2,C)$. For suitable interactions the representation satisfies cluster properties and the spectral condition. The representation defines a nontrivial relativistic quantum theory of interacting particles. Unitary operators that preserve the S-matrix and cluster properties, called cluster equivalences, relate the different constructions.

Relativistic quantum theory of N-particles can be applied to model systems of strongly interacting particles. This framework has many features of nonrelativistic quantum mechanics and local relativistic quantum field theory. Like nonrelativistic quantum mechanics, it is a mathematically well behaved theory where exact numerical calculations are possible. Like quantum field theory, it is a quantum theory with an exact $ISL(2,C)$ symmetry that satisfies cluster properties and the spectral condition.

The generality of the construction suggests that any quantum theory dominated by a finite number of particle degrees of freedom which is consistent with Poincaré invariance, cluster properties, and the spectral condition will be related to a theory of the type discussed in this article by a cluster equivalence.

The cluster equivalences introduced in Sec. XIII relate physically equivalent representations of the same model. Cluster equivalent models have the same bound state observables and S-matrix elements. In each representation free particles are represented as tensor products of irreducible representations. The unitary representation of $ISL(2,C)$ that defines the dynamics clusters into tensor products of subsystems representations with the same properties. Cluster equivalence is a stronger condition than unitary equivalence or scattering equivalence. Scattering equivalences were shown to be unitary elements of the C^* algebra of asymptotic constants. Cluster equivalences were shown to be a subgroup of the scattering equivalences.

The practical need to understand the relationship between different formulations of relativistic quantum theory suggests that it would be useful to have an abstract definition of a relativistic quantum theory of particles. The situation is different than the quantum field theory case, where there are several sets of axioms[1] that are designed to define a suitable local field theory, with an absence of examples of realistic theories consistent with these axioms. In relativistic quantum theory there are many applications that claim to be relativistic quantum theories, with no universally accepted criteria of what it means to be a relativistic quantum theory of particles. The absence of an acceptable definition of what constitutes a relativistic quantum theory of particles makes comparison difficult. The construction of this article, which focuses on mathematical formulation of observable physical properties, and how they can be realized in models, suggest minimal elements that need to be included in a set of axioms:

(A1) The Hilbert space $\mathcal{H}$ is the tensor product of irreducible representation spaces of $ISL(2,C)$ associated with the mass and spins of the constituent particles.

(A2) There is a unitary representation $\hat{U}[\Lambda,Y]$ of $ISL(2,C)$ on $\mathcal{H}$ with a positive mass and energy spectrum.

(A3) The Hilbert space can be factored into a tensor product of subsystem spaces, with each one supporting a subsystem unitary representation $\hat{U}_i[\Lambda,Y]$ of $ISL(2,C)$. For each partition a into subsystems a_i the operator $\hat{U}[\Lambda,Y]$ satisfies cluster property (88).

(A4) The dynamics $\hat{U}[\Lambda,Y]$ has an asymptotically complete, $ISL(2,C)$ invariant S-matrix.

These requirements can be used to formulate a precise relationship between different formulations of relativistic quantum theory when they are applied to systems with finite energy and number of degrees of freedom.

The construction in Sec. XII points to some of the general features of relativistic quantum theory of particles. In the physical representations of $ISL(2,C)$ the scattering equivalence $\hat{A}$, which is an interaction dependent operator, normally generates interaction dependent terms in all of the operators using the relations

$$\hat{F}^i=\hat{A}^\dagger\hat{F}_0^i\hat{A}, \tag{204}$$

$$\Delta\hat{F}^i=\hat{A}^\dagger\Delta\hat{F}_0^i\hat{A}, \tag{205}$$

$$j^2=\hat{A}^\dagger j_0^2\hat{A}, \tag{206}$$

$$P^\mu = P^\mu(M, j^2, \hat{F}^i, \Delta\hat{F}^i) = \hat{A}^\dagger P^\mu(\overline{M}, j_0^2, \hat{F}_0^i, \Delta\hat{F}_0^i)\hat{A}, \tag{207}$$

$$J^{\mu\nu} = J^{\mu\nu}(M, j^2, \hat{F}^i, \Delta\hat{F}^i) = \hat{A}^\dagger J^{\mu\nu}(\overline{M}, j_0^2, \hat{F}_0^i, \Delta\hat{F}_0^i)\hat{A}. \tag{208}$$

While the construction begins with representations having kinematic j^2, $\hat{F}^i$, and $\Delta\hat{F}^i$, all of these operators acquire an interaction dependence in the physical representation.

Tensor and spinor operator densities also play an important role in relativistic quantum mechanics. For example, the hadronic electroweak current operators provide the coupling of the hadronic dynamics to electroweak probes. In one-boson exchange approximations these current operators must transform as four-vector densities with respect to $ISL(2,C)$:

$$\hat{U}[\Lambda, Y] I^\mu[X] \hat{U}^\dagger[\Lambda, Y] = I^\nu[\Lambda X \Lambda^\dagger + Y]\Lambda^\mu_\nu. \tag{209}$$

Because $\hat{U}[\Lambda, Y]$ is an interaction dependent operator, the covariance condition (209) requires the existence of many-body contributions to the current.

This is understood by considering covariance condition

$$\langle f; m, j | I^\mu[X] | f'; m', j' \rangle = \int d\mu(f'') d\mu(f''') \langle f''; m, j | I^\nu[\Lambda X \Lambda^\dagger + Y] | f'''; m', j' \rangle \times \mathcal{D}^{*m,j}_{f'',f}[\Lambda, Y] \mathcal{D}^{m',j'}_{f''',f'}[\Lambda, Y]\Lambda^\mu_\nu. \tag{210}$$

In this expression the m and m' in the $\mathcal{D}$-functions are physical mass eigenvalues. This expression fixes a general matrix elements in terms of a set of independent current matrix elements and interaction (m) dependent coefficients. This is essentially the Wigner–Eckart theorem for $ISL(2,C)$. In this interpretation the interaction dependence arises because the Clebsch–Gordan coefficients depend on the physical mass eigenvalues. This means that the operators $\hat{I}^\mu(X)$ necessarily have interaction dependent terms that depend on the specific representation.

The result is that the representation of tensor and spinor densities is related to the representation of the dynamics. Changing the representation of the dynamics by a cluster equivalence changes the representation of the interaction dependent parts of the tensor and spinor densities. This has important implications for modeling electromagnetic probes of hadronic systems.

Dirac's forms of dynamics are obtained for special basis choices. Specifically, if the $ISL(2,C)$ Wigner $\mathcal{D}$ functions, $\mathcal{D}^{m,j}_{f,f'}[\Lambda, Y]$, do not depend explicitly on m for a subgroup $\mathcal{G}$ of $ISL(2,C)$, there are no interactions in the generators of the subgroup. This depends on the choice of commuting operators $\hat{F}^i$ that are used to label vectors in $ISL(2,C)$ irreducible subspaces. Cluster equivalences can be used to relate a general model to an equivalent models in any of Dirac's forms of dynamics.

APPENDIX A: $ISL(2,C)$ IRREDUCIBLE REPRESENTATIONS: EXAMPLES

Examples of positive mass positive energy irreducible representations of $ISL(2,C)$ are constructed. The construction presented below is not as general as the abstract construction given in Sec. V, but it is general enough to include all of the representations that are commonly used in the literature.

Let $f^i(\vec{p}, m)$, $i = 1,2,3$, be three independent real valued functions of the three momentum and the mass. Since the $\hat{M}$ and $\hat{\vec{P}}$ commute, these three functions become commuting self-adjoint

operators when m and $\vec{p}$ are replaced by operators. Independence means that these functions can be uniquely inverted to express $\vec{p}=\vec{P}(f,m)$ where f denotes the three functions f^i. By the implicit function theorem this will be true provided the Jacobian matrix

$$\frac{\partial f^i}{\partial p^j} \tag{A1}$$

is invertible for any $\vec{p}$ and any m in the spectrum of $\hat{M}$.

Define the operators

$$\hat{F}^i=f^i(\hat{\vec{P}},\hat{M}) \tag{A2}$$

for $i=1$ to 3. Let $L(p)$ be an arbitrary but fixed $SL(2,C)$ valued function of $p=(\sqrt{m^2+\vec{p}^2},\vec{p})$ with properties

$$L(p)L^\dagger(p)=\frac{1}{m}\sigma_\mu p^\mu, \tag{A3}$$

$$L(p_0)L^\dagger(p_0)=\sigma_0, \quad p_0:=(m,0,0,0). \tag{A4}$$

These equations mean that $L(p)$ is an $SL(2,C)$ representation of a Lorentz boost. In general it can differ from the canonical (rotationless boost) by a p-dependent rotation, $R(p)\in SU(2)$:

$$L(p)=L_c(p)R(p), \quad R(p_0)=I. \tag{A5}$$

Given the function $L(p)$ it is possible to define the $SL(2,C)$ valued matrix of operators $L(\hat{P})$ which is obtained by replacing p by the commuting operators $(\hat{\vec{P}},\hat{M})$.

For a given $L(p)$ define the l-spin by

$$\hat{\vec{j}}_l:=\frac{1}{2\hat{M}}\mathrm{Tr}[\vec{\sigma}L(\hat{P})\hat{W}^\mu\sigma_\mu L^\dagger(\hat{P})], \tag{A6}$$

where $\hat{W}^\mu$ is the Pauli Lubanski vector. Since $\hat{W}^\mu$ commutes with $\hat{P}^\nu$, all components of $\hat{\vec{j}}_l$ commute with $\hat{F}^1,\hat{F}^2,\hat{F}^3$. In addition, for any choice of $L(p)$ the components of $\hat{\vec{j}}_l$ satisfy $SU(2)$ commutation relations with $\hat{j}_l^2=\hat{j}^2=\hat{W}^2/\hat{M}^2$. Let $\hat{F}^4=\hat{z}\cdot\hat{\vec{j}}_l$. The operators $\hat{F}^1,\ldots,\hat{F}^4,\hat{M},\hat{j}^2$ define a complete set of commuting self-adjoint operators.

Let $f_0^1=f^1(p_0)$, $f_0^2=f^2(p_0)$, and $f_0^3=f^3(p_0)$. By construction f_0^1,f_0^2,f_0^3 is invariant under rotations, although f does not transform like an $SO(3)$ vector. Let $\vec{f}$ denote the eigenvalues of $\hat{F}^1$, $\hat{F}^2$, and $\hat{F}^3$ and μ denote the eigenvalue of $\hat{F}^4$. Define $f_\Lambda:=f(\vec{p}_\Lambda,m)$, where $p_\Lambda^\mu=\Lambda^\mu_\nu p^\nu$. For fixed Λ, f_Λ is a function of f and m.

Let $|f_0,\mu;j,m\rangle$ denote a rest eigenstate of $\hat{F}^i,\hat{M},\hat{j}^2$ and let R be an $SU(2)$ rotation. Define rotations and translations on the rest states by

$$\hat{U}[R,0]|f_0,\mu;j,m\rangle:=\sum_{\nu=-j}^{j}|f_0,\nu;j,m\rangle D^j_{\nu\mu}(R), \tag{A7}$$

$$\hat{U}[I,Y]|f_0,\mu;j,m\rangle:=e^{-imy^0}|f_0,\mu;j,m\rangle. \tag{A8}$$

Define states of arbitrary $\hat{F}$ by

$$|f,\mu;j,m\rangle := \hat{U}[L(f),0]|f_0,\mu;j,m\rangle \sqrt{\left|\frac{\partial f_0}{\partial f}\right|}. \tag{A9}$$

The expressions for $\hat{U}[R,0]$ and $\hat{U}[I,Y]$ are manifestly unitary. The factor $\sqrt{|\partial f_0/\partial f|}$ assures $\hat{U}[L(f),0]$ unitarity for states with a delta-function normalization. These elementary relations determine a unitary representation $\hat{U}[\Lambda,Y]$ on any state by using the decomposition

$$\hat{U}[\Lambda,Y] = \hat{U}[I,Y]\hat{U}[L(f_\Lambda),0]\hat{U}[R_{wl}(\Lambda,f),0]\hat{U}[L^{-1}(f),0], \tag{A10}$$

where

$$R_{wl}(\Lambda,f) := L^{-1}(f_\Lambda)\Lambda L(f) \tag{A11}$$

is the l-spin Wigner rotation and $L(f)$ is obtained from $L(p)$ by replacing p by $p(f,m)$.

The irreducible representation in this basis follows as a consequence of the above relations:

$$\hat{U}[\Lambda,Y]|f,\mu;j,m\rangle = \sum_{\nu=-j}^{j} |f_\Lambda,\nu;j,m\rangle e^{ip(\vec{f}_\Lambda,m)\cdot y}\left|\frac{\partial f_\Lambda}{\partial f}\right|^{1/2} D^j_{\nu\mu}[R_{wl}(\Lambda,f)]. \tag{A12}$$

Taking matrix elements give the $ISL(2,C)$ $\mathcal{D}$-function

$$\mathcal{D}^{mj}_{f'f}[\Lambda,Y] = e^{ip(\vec{f}',m)\cdot y} D^j_{\mu'\mu}[R_{wl}(\Lambda,f)]\left|\frac{\partial f_\Lambda}{\partial f}\right|^{1/2} \delta^3(f'-f_\Lambda). \tag{A13}$$

The infinitesimal generators of $ISL(2,C)$ in this representation can be computed using (125)–(127). The results are

$$\hat{P}^\mu = p^\mu(\vec{f},m), \tag{A14}$$

$$\hat{j}^j = i\epsilon^{jkl}\frac{\partial f^m}{\partial p^k}\frac{\partial}{\partial f^m}\hat{p}^l + (\hat{c}_1^{jk}(p) + i\epsilon_{jlm}\hat{c}_2^{lk}(p)\hat{p}^m)\hat{j}^k, \tag{A15}$$

$$\hat{K}^j = -\frac{1}{2}\frac{\partial f^m}{\partial \hat{p}^k}[\Delta f^m,\hat{H}]_+ + i(\hat{c}_1^{jk}(p) - H\hat{c}_2^{jk}(p))\hat{j}^k, \tag{A16}$$

where

$$\hat{c}_1^{jk}(p) = \tfrac{1}{2}\mathrm{Tr}(L^{-1}(\hat{p})\sigma_j L(\hat{p})\sigma_k), \tag{A17}$$

$$\hat{c}_2^{jk}(p) = \mathrm{Tr}\left(L^{-1}(\hat{p})\frac{\partial}{\partial p^j}L(\hat{p})\sigma_k\right). \tag{A18}$$

These equations can be inverted to obtain explicit expressions (133) for $\Delta\hat{f}^k$ in terms of the generators

$$\Delta\hat{f}^k = -\frac{i}{2\hat{H}}\frac{\partial\hat{H}}{\partial f^k} - \frac{1}{\hat{H}}\left[\frac{\partial p^j}{\partial f^k}(\hat{K}^j - i(\hat{c}_1^{jm}(p) - \hat{H}\hat{c}_2^{jm}(p))\hat{j}^m)\right] \tag{A19}$$

for $k=1$, 2, or 3. This expression reduces[23] to the Newton–Wigner position operator when $f^i = p^i$ and the l-spin is the canonical spin. The l-spin is given as a function of the infinitesimal generators by (A6). The partial derivatives in this expression are computed with functions which are replaced by the appropriate operators after the differentiation is performed.

The Δf^4 for the spins are the raising and lowering operators

$$\hat{j}_{l\pm} := \hat{j}_{lx} \pm i\hat{j}_{ly}. \tag{A20}$$

This shows explicitly the equivalence between

$$\{\hat{H},\vec{\hat{P}},\vec{\hat{J}},\vec{\hat{K}}\} \quad \text{and} \quad \{\hat{M},\hat{j}^2,\vec{\hat{F}},\Delta\vec{\hat{F}}\}. \tag{A21}$$

The basis choices illustrated above, while restrictive, include all of the basis choices that lead to Dirac's forms of dynamics. The general construction yields a Dirac instant form of dynamics if f^i are taken as the three components of the linear momentum and $L_l(p)$ is a canonical (rotationless) boost. Dirac's point-form dynamics is obtained if f^i is taken as the three components of the four velocity and $L_l(p)$ is the canonical boost. A front form dynamics is obtained if f^i is taken as the three generators of translations tangent to a light front and L_l is taken as corresponding the light front boost. Infinitely many other choices of f^i and $L_l(p)$ are possible.

APPENDIX B: *ISL*(2,*C*) CLEBSCH-GORDAN AND RACAH COEFFICIENTS

The Clebsch–Gordan coefficients for the representations in Appendix A can be computed from the tensor product representation using the same methods that were used to construct the single irreducible representations. The first step is to decompose the tensor product representation of the ''rest state'' into irreducible representation of $SU(2)$. This requires generalized Melosh rotations to ensure that all of the spins undergo the same rotations. The irreducible representation are then boosted with the appropriate l-boost. This generally leads to Wigner rotations. The general result is derived in Ref. 26. The resulting Clebsch–Gordan coefficients for this basis are

$$\begin{aligned}\langle \vec{f}_1,\mu_1,\vec{f}_2,\mu_2|\vec{f},\mu;m,j,l,s\rangle = {} & \delta(\vec{f}-\vec{f}(\vec{f}_1,\vec{f}_2))\,\delta(m-m(\vec{f}_1,\vec{f}_2,m_1,m_2))\left|\frac{\partial(f,k)}{\partial(f_1,f_2)}\right|^{1/2}\frac{1}{k}\frac{\partial k}{\partial m}\\ & \times D^{j_1}_{\mu_1\mu_1'}[R_{wl}(p,k_1)R_{ml}(k_1)]D^{j_2}_{\mu_2\mu_2'}[R_{wl}(p,k_2)R_{ml}(k_2)]\\ & \times Y^l(\hat{k}_1(f_1,f_2))\langle j_1,\mu_1,j_2,\mu_2|s,\mu_s\rangle\langle s,\mu_s,l,\mu_l|j,\mu\rangle,\end{aligned}$$

where $L_c(p)$ is the canonical boost and $L_l(p)$ is a l-boost,

$$k_i = \tfrac{1}{2}\mathrm{Tr}(L_l^{-1}(p)p_i^\mu\cdot\sigma_\mu(L_l^{-1}(p))^\dagger) \tag{B1}$$

and

$$R_{wl}(p,k_i) := L_l^{-1}(p_i)L_l(p)L_l(k_i), \tag{B2}$$

$$R_{mlc}(k_i) := L_l^{-1}(k_i)L_c(k_i). \tag{B3}$$

These are the Wigner and Melosh rotations associated with the l-boost.

The Racah coefficient for this choice of basis can be computed in terms of four Clebsch–Gordan coefficients. It is simplest to compute the invariant part of this coefficient by choosing $p=(m,0,0,0)$ and integrating the result over $SU(2)$. The Racah coefficients for the couplings $((12)(3))\to((23)(1))$ become

$$
\begin{aligned}
&\langle \vec{f}',\mu';m',j',(12,3)|\vec{f},\mu;m,j,(23,1)\rangle \\
&\quad=\delta_{j'j}\delta_{\mu'\mu}\delta(\vec{f}'-\vec{f})\,\delta(m-m')\,\frac{1}{2j+1} \\
&\qquad\times\sum_{\mu_f}\left[\frac{8\pi^2 m_{12}m_{23}\omega_2(q_3'+q_1)}{k_1'k_2q_3'q_1\omega_1(k_1')\omega_2(k_1')\omega_2(k_2)\omega_3(k_2)\omega_{12}(q_3)\omega_{23}(q_1)}\right] \\
&\qquad\times\left[\left|\frac{\partial(f_{12}',f_3')}{\partial(f',q_3')}\right|\left|\frac{\partial(f_{12}',k_1')}{\partial(f_1',f_2')}\right|\left|\frac{\partial(f_{23},k_2)}{\partial(f_2,f_3)}\right|\left|\frac{\partial(f_{23},f_1)}{\partial(f,q_1)}\right|\right]^{1/2} \\
&\qquad\times\langle j,\mu_f|L',\mu_L',S',\mu_S'\rangle\langle S',\mu_S'|j_{12}',\mu_{12}',j_3',\mu_3'\rangle \\
&\qquad\times D^{j_{12}}_{\mu_{12}'\mu_{12}}[R_{mcl}(-q_3')]Y^{L'*}_{\mu_L'}(\hat{q}_3')\langle j_{12}',\mu_{12}|l',\mu_l',s',\mu_s'\rangle\langle s',\mu_s'|j_1',\mu_1',j_2',\mu_2'\rangle Y^{l'*}_{\mu_l'}(\hat{k}_1') \\
&\qquad\times D^{j_3}_{\mu_3'\mu_3}[R_{mcl}(q_3')R_{wl}(-q_1,k_3)R_{mlc}(k_3)]D^{j_1}_{\mu_1\mu_1'}[R_{mcl}(k_1')R_{wl}^{-1}(-q_3',q_1')R_{ml}(q_1)] \\
&\qquad\times D^{j_2}_{\mu_2\mu_2'}[R_{mcl}(k_2')R_{wl}^{-1}(-q_3',q_2')R_{wl}(-q_1,k_2)R_{mlc}(k_2)]Y^{l*}_{\mu_l'}(\hat{k}_2)\langle j_2\mu_2 j_3\mu_3|s\mu_s\rangle \\
&\qquad\times\langle l,\mu_l,s,\mu_s|j_{23}\mu_{23}\rangle Y^{L}_{\mu_L}(\hat{q}_1) \\
&\qquad\times D^{j_{23}}_{\mu_{23}\mu_{23}'}[R_{ml}(-q_1)]\langle j_{23}\mu_{23}j_1\mu_1|S\mu_S\rangle\langle L,\mu_L,S,\mu_S|j\mu_f\rangle,
\end{aligned}
$$

where m is the three-body invariant mass, m_{ij} are the invariant masses of the ij and jk subsystems, $w(k)$ are energies, and q_i are the operators

$$\hat{q}_i := L_l^{-1}(\hat{p})\hat{p}_i\,. \tag{B4}$$

APPENDIX C: PROOF OF THEOREM 1

To prove Theorem 1 first note that condition (82) implies

$$\lim_{t\to\pm\infty}\|\hat{U}[I,-T](\hat{\Phi}_{\mathcal{A}}-\hat{U}^{\dagger}[\Lambda,Y]\hat{\Phi}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[\Lambda,Y])\hat{U}_{\mathcal{A}}[I,T]|\psi\rangle\|=0, \tag{C1}$$

which is equivalent to

$$\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\Omega_{\pm}(\hat{H},\hat{U}^{\dagger}[\Lambda,Y]\hat{\Phi}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[\Lambda,Y],\hat{H}_{\mathcal{A}}). \tag{C2}$$

Since the Hamiltonian commutes with the linear and angular momentum operators, it follows that if (Λ,A) is a rotation or translation, this becomes

$$\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\hat{U}^{\dagger}[R,0]\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[R,0] \tag{C3}$$

and

$$\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\hat{U}^{\dagger}[I,Y]\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[I,Y]. \tag{C4}$$

For the case of a rotationless Lorentz transformation condition (C2) implies

$$\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\Omega_{\pm}(\hat{H},\hat{U}^{\dagger}[\Lambda,0]\hat{\Phi}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[\Lambda,0],\hat{H}_{\mathcal{A}}). \tag{C5}$$

The commutation relations imply

$$\hat{U}^{\dagger}[\Lambda,0]\hat{H}\hat{U}[\Lambda,0]=\Lambda^0_\mu\hat{P}^\mu, \tag{C6}$$

$$\hat{U}^{\dagger}_{\mathcal{A}}[\Lambda,0]\hat{H}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[\Lambda,0]=\Lambda^0_\mu\hat{P}^\mu_{\mathcal{A}}. \tag{C7}$$

It follows that

$$\begin{aligned}\hat{U}^{\dagger}[\Lambda,0]\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[\Lambda,0]&=\hat{U}^{\dagger}[\Lambda,0]\Omega_{\pm}(\hat{H},\hat{U}[\Lambda,0]\hat{\Phi}_{\mathcal{A}}\hat{U}^{\dagger}_{\mathcal{A}}[\Lambda,0],\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[\Lambda,0]\\&=\Omega_{\pm}(\Lambda^0_\mu\hat{P}^\mu,\hat{\Phi},\Lambda^0_\mu\hat{P}^\mu_{\mathcal{A}}),\end{aligned} \tag{C8}$$

which can be expressed as

$$\Omega_{\pm}(\Lambda^0_\mu\hat{P}^\mu,\hat{\Phi}_{\mathcal{A}},\Lambda^0_\mu\hat{P}^\mu_{\mathcal{A}})=\lim_{t\to\pm\infty}e^{i\hat{H}\Lambda^0_0t+i\Lambda^0_i\hat{P}_it}\hat{\Phi}_{\mathcal{A}}e^{-i\hat{H}_{\mathcal{A}}\Lambda^0_0t+i\Lambda^0_i\hat{P}_{\mathcal{A}i}t}. \tag{C9}$$

Since $\Lambda^0_0>0$ it is possible to redefine $t\to t'=\Lambda^0_0t$ so the limit $t\to\pm\infty$ is equivalent to the limit the $t'\to\pm\infty$. This gives

$$\lim_{t'\to\pm\infty}e^{i\hat{H}t'}\hat{U}[I,At']\hat{\Phi}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[I,At']e^{-i\hat{H}_{\mathcal{A}}t'}, \tag{C10}$$

where

$$A=\frac{\Lambda^0_i}{\Lambda^0_0}\sigma_i. \tag{C11}$$

Condition (83) then gives

$$\lim_{t'\to\pm\infty}e^{i\hat{H}t'}\hat{U}[I,At]\hat{\Phi}_{\mathcal{A}}\hat{U}_{\mathcal{A}}[I,At']e^{-i\hat{H}_{\mathcal{A}}t'}=\Omega_{\pm}(\hat{H},\hat{\Phi},\hat{H}_{\mathcal{A}}). \tag{C12}$$

Combining (C8) and (C12) gives

$$\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\hat{U}^{\dagger}[\Lambda,0]\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[\Lambda,0]. \tag{C13}$$

To complete the proof of Theorem 1 note that (C3) and (C13) imply

$$\hat{U}[\Lambda,Y]\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\Omega_{\pm}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[\Lambda,Y], \tag{C14}$$

which is the intertwining relation of Corollary 1. Corollary 2 follows by identifying (C9) and (C12).

It follows that

$$\begin{aligned}\hat{U}^{\dagger}_{\mathcal{A}}[\Lambda,Y]\hat{S}\hat{U}_{\mathcal{A}}[\Lambda,Y]&=\hat{U}^{\dagger}_{\mathcal{A}}[\Lambda,Y]\Omega^{\dagger}_{+}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\Omega_{-}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}_{\mathcal{A}}[\Lambda,Y]\\&=\Omega^{\dagger}_{+}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})\hat{U}^{\dagger}[\Lambda,Y]\hat{U}[\Lambda,Y]\Omega_{-}(\hat{H},\hat{\Phi}_{\mathcal{A}},\hat{H}_{\mathcal{A}})=\hat{S}.\end{aligned} \tag{C15}$$

This completes the proof of Theorem 1.

To prove Corollary 3 note that Eq. (86) is equivalent to

$$s-\lim_{s\to\pm\infty}[e^{-i\hat{M}s}\Omega_{\pm}(\hat{H},\hat{\Phi},\hat{H}_{\mathcal{A}})-\hat{\Phi}e^{-i\hat{M}_{\mathcal{A}}s}]=0. \tag{C16}$$

The intertwining properties that follow from Theorem 1 give the strong limit:

$$s-\lim_{s\to\pm\infty}[(\Omega_{\pm}(\hat{H},\hat{\Phi},\hat{H}_{\mathcal{A}})-\hat{\Phi})]e^{-i\hat{M}_{\mathcal{A}}s}=0. \tag{C17}$$

The proof that this holds on the dense set of asymptotic states with bounded momentum follows the proof of theorem IX.23 of Ref. 36 (see also Refs. 42 and 43). The extension to the strong limit follows the argument in Ref. 8.

APPENDIX D: PROOF OF THEOREM 4

To prove Theorem 4 let $\hat{C}_{a_i}$ be the scattering equivalence that maps $\hat{U}_{a_i}[\Lambda,Y]$ to the representation $\tilde{U}_{a_i}[\Lambda,Y]$ with kinematic $\hat{F}^i_{a_j}$, $\Delta\hat{F}^i_{a_j}$, $\hat{j}_{a_j}$. Define

$$\hat{C}_a:=\otimes_{i=1}^{n_a}\hat{C}_{a_i} \tag{D1}$$

and

$$\tilde{U}_a[\Lambda,Y]:=\hat{C}_a\hat{U}_a[\Lambda,Y]\hat{C}_a^{\dagger}=\otimes_{i=1}^{n_a}(\hat{C}_{a_i}\hat{U}_{a_i}[\Lambda,Y]\hat{C}_{a_i}^{\dagger}). \tag{D2}$$

By assumption, the representations $\hat{U}_a[\Lambda,A]$ and $\tilde{U}_a[\Lambda,A]$ have the same scattering matrix elements, which are products of the single cluster scattering matrix elements. In addition, because

$$(\hat{I}-\hat{C}_a)\hat{U}_0[I,T]=\otimes_{i=1}^{n_a}(I_{a_i}-\hat{C}_{a_i})\hat{U}_{0a_i}[I,T], \tag{D3}$$

it follows that

$$\lim_{t\to\pm\infty}(\hat{I}-\hat{C}_a)\hat{U}_0[I,T]=0, \tag{D4}$$

which shows that $\hat{C}_a$ is a scattering equivalence on the N-body Hilbert space.

The representation $\tilde{U}_a[\Lambda,Y]$ does not have kinematic $\hat{F}_i$, $\Delta\hat{F}_i$, or $\hat{j}$, even though each factor of the tensor product has this property. The advantage of the representation $\tilde{U}_a[\Lambda,Y]$ is that it is scattering equivalent to a representation $\overline{U}_a[\Lambda,Y]$ that has a kinematic $\hat{F}^i$, $\Delta\hat{F}^i$ and $\hat{j}$.

To show this consider the structure of the single cluster $\tilde{H}_{a_i}$ and $\tilde{M}_{a_i}$. The Hamiltonian $\tilde{H}_a$ of the representation $\tilde{U}_a[\Lambda,Y]$ is

$$\tilde{H}_a:=\sum_{i=1}^{n_a}\tilde{H}_{a_i}\otimes\hat{I}_i, \tag{D5}$$

where $\hat{I}_i$ is the identity on the remaining factors in the tensor product. The mass operator $\tilde{M}_a$ is a function of the commuting operators $\tilde{M}_{a_i}\otimes\hat{I}_i$ and $\tilde{\vec{P}}_{a_i}\otimes\hat{I}_i$. Corollary 3 of Theorem 1 give mild conditions on the interactions for $\tilde{H}_a$ and $\tilde{M}_a$ to lead to the same S-matrix.

The matrix elements of $\tilde{M}_{a_i}\otimes\hat{I}_i$ in the tensor product of n_a free particle irreducible representations have the form

$$\begin{aligned}&\langle\otimes_j(f_j,d_j;m_j,j_j)|\tilde{M}_{a_i}\otimes\hat{I}_i|\otimes_k(f'_k,d'_k;m'_k,j'_k)\rangle\\&=\delta[f_i,f'_i]\delta_{j_ij'_i}\langle d_i,m_i\|\tilde{M}^{j_i}_{a_i}\|d'_i,m'_i\rangle\prod_{k\neq i}\delta[f_k,f'_k]\delta[d_k,d'_k]\delta_{j_kj'_k}\delta(m_k-m'_k).\end{aligned} \tag{D6}$$

An irreducible free particle basis for the N-body system can be constructed by successive use of the $ISL(2,C)$ Clebsch–Gordan coefficients to decompose the basis $|\otimes_j(f_j,d_j;m_j,j_j)\rangle$ into a

direct integral of irreducible representations. What is relevant for the proof of this theorem is that the variables m_i, d_i, and j_i that appear in the kernel $\langle d_i, m_i \| \tilde{M}_{a_i}^{j_i} \| d_i', m_i' \rangle$ of $\tilde{M}_{a_j}$ are degeneracy parameters in this representation.

In order to be precise assume that the irreducible free particle basis is obtained by successively coupling clusters in the order $(\cdots(((12)3)4)\cdots n_a)$. In addition, at each stage in the coupling define $\hat{q}_i$ as the solution to

$$\hat{M}_{0(\cdots(12))3)\cdots i+1)} = \sqrt{\hat{q}_i^2 + \hat{M}_{0(i+1)}^2} + \sqrt{\hat{q}_i^2 + \hat{M}_{0(\cdots(12))3)\cdots i)}^2}. \tag{D7}$$

The operators $\hat{q}_i$ are alternate labels for the kinematic invariant masses $\hat{M}_{0(\cdots(12))3)\cdots i)}$.

Define the single cluster mass operators $\overline{M}_{a_i}$ in this irreducible representation,

$$\langle f,d;m,j|\overline{M}_{a_i}|f',d';m',j'\rangle = \delta[f,f']\delta[j,j']\delta_{j_i j_i'}\langle d_i, m_i \| \tilde{M}_{a_i}^{j_i} \| d_i', m_i' \rangle \times JJ' \prod_{k\neq i} \delta_{j_k j_k'} \delta(m_k - m_k') \prod_{l=1}^{n_a} (q_l - q_l') \delta_{r_l r_l'}, \tag{D8}$$

where the q_l's are considered functions of the kinematic invariant masses, the r_l are degeneracy parameters that result when particle l is coupled to the irreducible $(1\cdots l-1)$ system, and J and J' are Jacobians

$$J = \left| \frac{\partial(q_1 \cdots q_{n_a-1})}{\partial(m_{(12)} \cdots m_{0(\cdots((12)\cdots(n_a)))})} \right|^{1/2}. \tag{D9}$$

The three important observations about this definition are the following.

(i) The nontrivial part of this kernel is identical to the nontrivial part of the kernel of $\tilde{M}_{a_i}$ in the tensor product representation (D6).

(ii) Each $\overline{M}_{a_j}$ commutes with $\hat{F}_0^i$, $\Delta\hat{F}_0^i$, $\hat{j}_0$.

(iii) $[\overline{M}_{a_i}, \overline{M}_{a_j}] = 0$.

The relations (D7) can be inverted to express the free mass as a function of the free single cluster mass operators and the q_i's:

$$\hat{M}_0 = M(\hat{M}_{01}, \ldots, \hat{M}_{0n_a}, \hat{q}_1, \ldots, \hat{q}_{n_a-1}). \tag{D10}$$

The commutation relations allow the definition

$$\overline{M}_a := M(\tilde{M}_{a_1}, \ldots, \tilde{M}_{a_{n_a}}, \hat{q}_1, \ldots, \hat{q}_{n_a-1}), \tag{D11}$$

where the $\hat{q}_i$'s in (D11) are identical to the non-interacting $\hat{q}_i$'s in (D10). By construction $\overline{M}_a$ commutes with $\hat{F}_0^i$, $\Delta\hat{F}_0^i$, $\hat{j}_0$. Simultaneous eigenstates of $\overline{M}_a$, $\hat{F}_0^i$, and j_0 transform as mass $\overline{M}_a$ spin j_0 irreducible representations of $ISL(2,)$. This defines the representation $\overline{U}_a[\Lambda, Y]$.

In order to construct a scattering theory we need to define a suitable injection operator to the asymptotic Hilbert space for $\hat{M}_a$. The channel injection operator for the representation $\tilde{U}_a[\Lambda, Y]$ is the tensor product of irreducible eigenstates

$$\tilde{\Phi}_\alpha = |f_1, \alpha_1, \ldots, f_{n_a}, \alpha_1\rangle. \tag{D12}$$

The corresponding channel injection operator for the representation $\overline{U}_a[\Lambda,A]$ is defined as the simultaneous eigenstates of $\overline{M}_a$, $\hat{j}_0^2$, $\hat{F}_0^j$, $\hat{q}_{i0}$, $\hat{r}_i$, and $\tilde{M}_{a_i}$ corresponding the same bound states of the $\tilde{M}_{a_i}$:

$$\overline{\Phi}_\alpha = |f, j_0, q_1, \ldots, q_{n_a-1}, r_1, \ldots, r_{n_a-1}, \alpha_1 \ldots \alpha_{n_a}\rangle. \tag{D13}$$

These differ by the delta functions that multiply the cluster eigenfunctions.

With this definition it follows that

$$\overline{\Omega}_{a\pm} := \Omega_\pm(\overline{M}_a, \overline{\Phi}_{\mathcal{A}a}, H_{\mathcal{A}a}) \tag{D14}$$

exist and are complete. The scattering operator

$$\overline{S}_a = \overline{\Omega}_{a+}^\dagger \overline{\Omega}_{a-} = \delta_{j_0 j_0'} \delta[f, f'] \prod_{i=1}^{n_a-1} \delta(q_i - q_i') \delta[r_i, r_i'] \prod_i \delta_{j_i j_i'} \hat{S}_{a_i} \tag{D15}$$

is identical to $\tilde{S}_a$ if the Clebsch–Gordan coefficients are used to replace the irreducible spectator variables by the single cluster f_i, j_i's. The equivalence follows because the S-matrix elements are determined by the single cluster mass operators, which have identical reduced kernels in representations (D6) and (D8).

This establishes that the representations $\tilde{U}_a[\Lambda,Y]$ and $\overline{U}_a[\Lambda,Y]$ give the same scattering matrix elements. By Theorem 3 they are scattering equivalent. Let $\hat{D}_a$ be the scattering equivalence that relates these two representations:

$$\overline{U}_a[\Lambda,Y] = \hat{D}_a \tilde{U}_a[\Lambda,Y] \hat{D}_a^\dagger. \tag{D16}$$

It follows from (D2) and (D16) that

$$\overline{U}_a[\Lambda,Y] = \hat{B}_a \hat{U}_a[\Lambda,Y] \hat{B}_a^\dagger, \tag{D17}$$

where

$$\hat{B}_a := \hat{D}_a \hat{C}_a. \tag{D18}$$

The operator $\hat{B}_a$ is a scattering equivalence since it is a product of scattering equivalences. This completes the proof of Theorem 4.

(Received 12 January 2001; accepted 13 August 2002)

We discuss the quantum Hamiltonian $H_{\underline{\underline{G}}}$ describing a δ-sphere interaction introduced in [J. Math. Phys **30**, 2275 (1989)] and formally given by $H_{\underline{\underline{G}}}=H_D+\underline{\underline{G}}\,\delta(|x|-R)$, where H_D is the Dirac Hamiltonian and $\underline{\underline{G}}$ is a real 4×4 matrix defined by $\underline{\underline{G}}=\left(\begin{smallmatrix}A & 0\\ 0 & B\end{smallmatrix}\right)$. We obtain a series of new results for this model, in particular the resolvent equation, the spectral properties, the nonrelativistic limit and the various quantities related to the scattering theory. These results are generalized to the case of an asymmetric δ-sphere interaction and a δ-sphere plus Coulomb interaction, respectively. © *2002 American Institute of Physics.*

I. INTRODUCTION

In the last two decades, a lot of research has been carried out on point and sphere interactions in quantum mechanics, both from the mathematical point of view and for their applications in physics.[1–15]

For a long time, this research focused on nonrelativistic interactions. The first paper providing a rigorous mathematical analysis of relativistic δ-sphere interactions was published in 1989 by Dittrich *et al.*[7] Using the theory of self-adjoint extensions of symmetric closed operators in Hilbert spaces, Ref. 7 defines the quantum Hamiltonian corresponding to the formal expression:

$$H_{\underline{\underline{G}}}=H_D+\underline{\underline{G}}\,\delta(|x|-R),\quad x\in\mathbb{R}^3,\quad R\in\mathbb{R}, \tag{1}$$

where $\underline{\underline{G}}$ is a real 4×4 matrix of the form $\underline{\underline{G}}=\left(\begin{smallmatrix}A & 0\\ 0 & B\end{smallmatrix}\right)$, H_D is the Dirac Hamiltonian and R is the radius of a sphere in $\mathbb{R}^3$ centered at the origin. Ref. 7 also provides a detailed discussion of the spectral properties of $H_{\underline{\underline{G}}}$.

In Ref. 12, the above results were extended to the case of a δ sphere plus a Coulomb interaction. In Ref. 12, the authors also provide a numerical analysis of the point spectrum and compare the definition of $H_{\underline{\underline{G}}}$ used in Refs. 7 and 12 with an alternative definition proposed by Dominguez-Adame.[8]

More recently, Hounkonnou and Avossevou published a series of papers in which they claim to provide rigorous mathematical definitions and to perform a systematic study of the δ, δ' and finitely many δ-sphere interactions in the particular cases when $A\neq0$, $B=0$ and $A=0$, $B\neq0$.[16–19] Unfortunately, a comparison with Refs. 7 and 12 shows that the boundary conditions used in Refs. 17 and 19 do not correspond to any of the above-mentioned δ-sphere interactions. Actually these boundary conditions do not define any self-adjoint operator. Therefore, the conditions required for

[a)]On leave of absence from University of Burundi, Faculty of Science, BP 2700 Bujumbura, Burundi. Electronic mail: j.shabani@unesco.org
[b)]Electronic mail: vyabandi@hotmail.com

the application of the Krein formula and the Weyl theorem for the computation of the resolvent equation and the analysis of spectral properties of $H_{\underline{\underline{G}}}$ are not fulfilled which means that all the results presented in Refs. 17–19 are not correct.

The aim of this paper is to provide new results on the relativistic δ-sphere interaction in the general case $A\neq 0$ and $B\neq 0$.

The paper covers several areas which were not considered in Refs. 7 and 12 and therefore provides new insights in the understanding of relativistic δ-sphere interactions. As an example, the nonrelativistic limit leads to a new two-parameters family of nonrelativistic δ-sphere interactions. As in the case of point and nonrelativistic δ-sphere interactions, these results were obtained by applying rigorous concepts and techniques of functional analysis and differential operators.

The applications of point and sphere interactions in physics are greatly facilitated by the fact these interactions are exactly solvable. Point and nonrelativistic δ-sphere interactions are extensively used since the 1930s in order to develop mathematical models in nuclear, solid state, and molecular physics [(see Refs. 2 and 3) and references therein]. More recently, nonrelativistic δ-sphere interactions were used to define a mathematical model of heavy quarkonia mesonic decays.[13] Since relativistic δ-sphere interactions are also exactly solvable, it is anticipated that a better understanding of these interactions will stimulate research on their applications in various areas of physics.

In Sec. II, we define the quantum Hamiltonian describing the interaction, compute the resolvent equation, derive the spectral properties and obtain the nonrelativistic limit of the Hamiltonian. We also discuss the stationary scattering theory for the pair $(h_{jl,G_{jl}};h_D)$ where $h_{jl,G_{jl}}$ and h_D are defined by Eqs. (38) and (42), respectively. In Sec. III, we discuss the generalization of $H_{\underline{\underline{G}}}$ to the so-called asymmetric δ-sphere interactions while in Sec. IV we provide a generalization of the results obtained in Sec. II to the case of a δ-sphere plus a Coulomb interaction.

The special cases $A\neq 0$, $B=0$ and $A=0$, $B\neq 0$ yield the relativistic δ-sphere interactions of the first and second type, respectively. Indeed, as indicated in Sec. II D, the nonrelativistic limits of the Hamiltonians corresponding to these interactions converge in the norm resolvent topology to the Hamiltonians describing the nonrelativistic δ-sphere interactions of the first and second type, respectively.[2,4,5]

In a series of forthcoming papers,[20] we extend the results presented in this publication to the case of a δ' and finitely many sphere interactions and discuss the approximation of $H_{\underline{\underline{G}}}$ by local scaled short range and momentum cutoff Hamiltonians.

II. THE δ-SPHERE INTERACTION

A. Definition of the Hamiltonian

In this section, using the theory of self-adjoint extensions of symmetric closed operators in Hilbert spaces, we provide the mathematical definition of a quantum Hamiltonian describing a relativistic δ-sphere interaction formally given by

$$H_{\underline{\underline{G}}}=H_D+\underline{\underline{G}}\,\delta(|x|-R);\quad x\in\mathbb{R}^3,\quad R\in\mathbb{R}, \tag{2}$$

where $\underline{\underline{G}}$ is a real 4×4 matrix of the form

$$\underline{\underline{G}}=\begin{pmatrix} A & 0\\ 0 & B\end{pmatrix}. \tag{3}$$

1. The radial operators

Consider in the state Hilbert space $\mathcal{H}=L^2(\mathbb{R}^3)\otimes\mathbb{C}^4$ the Dirac Hamiltonian H_D defined by

$$\begin{aligned} H_D&=-\mathrm{i}\underline{\underline{\alpha}}\nabla+\underline{\underline{\beta}}\frac{c^2}{2},\\ \mathcal{D}(H_D)&=H^{1,2}(\mathbb{R}^3)\otimes\mathbb{C}^4, \end{aligned} \tag{4}$$

where we have used the following definitions and notations:

(i) c is the velocity of the light,
(ii) $H^{m,n}(\Omega)$ is the Sobolev space of indices (m,n),
(iii) $\underline{\underline{\alpha}}$ and $\underline{\underline{\beta}}$ are 4×4 Dirac matrices given by

$$\underline{\underline{\alpha}}=\begin{pmatrix}0 & \sigma\\ \sigma & 0\end{pmatrix},\quad \underline{\underline{\beta}}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{5}$$

Here σ are Pauli's spin matrices defined by

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0 & -\mathrm{i}\\ \mathrm{i} & 0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{6}$$

Consider in $L^2(\mathbb{R}^3)\otimes\mathbb{C}^4$ the symmetric closed operator $\overline{H}_D$ defined by

$$\overline{H}_D=H_D,$$

$$D(\overline{H}_D)=\{\psi\in H^{1,2}(\mathbb{R}^3)\otimes\mathbb{C}^4/\psi(S_R)=0\}, \tag{7}$$

where $S_R=\{x\in\mathbb{R}^3:|x|=R\}$ is the sphere of radius R in $\mathbb{R}^3$ centered at the origin.

As indicated in Ref. 7, the operator $\overline{H}_D$ admits a large number of self-adjoint extensions. In this paper, we consider those extensions of $\overline{H}_D$ which correspond to $H_{\underline{\underline{G}}}$.

For this purpose, we restrict ourselves to those extensions of $\overline{H}_D$ which are rotationally and space-reflection symmetric. With these assumptions, one may decompose the space $\mathcal{H}$ in the following way:

$$\mathcal{H}=\bigoplus_{j=1/2}^{\infty}\ \bigoplus_{l=j-1/2}^{j+1/2}\ \bigoplus_{\mu=-j}^{j}\mathcal{H}_{jl\mu}, \tag{8}$$

where we have used the following definitions and notations:

(i)
$$\mathcal{H}_{jl\mu}=\left\{\psi\in\mathcal{H}\,\middle|\,\psi(r,n)=\begin{pmatrix}f(r)\Omega_{jl\mu}(n)\\ g(r)\Omega_{jl'\mu}(n)\end{pmatrix};f,g\in L^2((0,\infty),r^2dr)\right\}, \tag{9}$$

(ii) $\Omega_{jl\mu}$ are spherical spinors defined by[21]

$$\Omega_{jl\mu}(\theta,\varphi)=\begin{pmatrix}\sqrt{\dfrac{j+\mu}{2l+1}}Y_{l,\mu-1/2}(\theta,\varphi)\\ \sqrt{\dfrac{j-\mu}{2l+1}}Y_{l,\mu+1/2}(\theta,\varphi)\end{pmatrix}\quad \text{for } l=j-\frac{1}{2}, \tag{10}$$

$$\Omega_{jl\mu}(\theta,\varphi)=\begin{pmatrix}-\sqrt{\dfrac{j-\mu+1}{2l+1}}Y_{l,\mu-1/2}(\theta,\varphi)\\ \sqrt{\dfrac{j+\mu+1}{2l+1}}Y_{l,\mu+1/2}(\theta,\varphi)\end{pmatrix}\quad \text{for } l=j+\frac{1}{2}, \tag{11}$$

(iii) $l'=j\mp\frac{1}{2}$ for $l=j\pm\frac{1}{2}$.

Next we introduce the isomorphisms U_{jl} defined by

$$U_{jl}:L^2((0,\infty);r^2dr)\otimes\mathbb{C}^2\to\tilde{\mathcal{H}}\equiv L^2((0,\infty);dr)\otimes\mathbb{C}^2, \tag{12}$$

$$(U_{jl}\psi)(r)=\begin{pmatrix} rf(r) \\ (-1)^{j-l-1/2}rg(r)\end{pmatrix} \tag{13}$$

which enable us to represent $\mathcal{H}$ in the form

$$\mathcal{H}=\bigoplus_{j=1/2}^{\infty}\bigoplus_{l=j-1/2}^{j+1/2}\bigoplus_{\mu=-j}^{j}[U_{jl}^{-1}\tilde{\mathcal{H}}]\otimes[\Omega_{jl\mu}(\theta,\varphi)], \tag{14}$$

where $[\Omega_{jl\mu}(n)]$ stands for the vector space generated by the spherical spinors.

With respect to the decomposition (14), $\overline{H}_D$ reads

$$\overline{H}_D=\bigoplus_{j=1/2}^{\infty}\bigoplus_{l=j-1/2}^{j+1/2}[U_{jl}^{-1}h_{jl}U_{jl}]\otimes\mathbb{1}. \tag{15}$$

The operators h_{jl} in $L^2((0,\infty))\otimes\mathbb{C}^2$ are given by

$$h_{jl}=\begin{pmatrix} \dfrac{c^2}{2} & -c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} \\ c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} & -\dfrac{c^2}{2}\end{pmatrix}\equiv\tau, \tag{16}$$

$$\kappa_{jl}=(-1)^{j-l+1/2}(j+\tfrac{1}{2}), \tag{17}$$

$$\begin{aligned} D(h_{jl})=\{&\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\,|\,\psi\in \mathrm{AC}_{\mathrm{loc}}((0,\infty));\quad \psi(R\pm)=0;\\ &\tau\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\},\end{aligned} \tag{18}$$

where $\mathrm{AC}_{\mathrm{loc}}(\Omega)$ denotes the set of locally absolutely continuous functions on Ω and

$$\psi(x\pm)=\lim_{\epsilon\to 0+}\psi(x\pm\epsilon).$$

The adjoint h_{jl}^* of h_{jl} reads

$$h_{jl}^*=\tau,$$

$$\begin{aligned} D(h_{jl}^*)=\{&\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\,|\,\psi\in \mathrm{AC}_{\mathrm{loc}}((0,\infty)\setminus\{R\}),\\ &\tau\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\}.\end{aligned} \tag{19}$$

2. The self-adjoint extensions of h_{jl}

Consider the equation

$$(h_{jl}^*-z)\psi=0,\quad \psi\in\mathcal{D}(h_{jl}^*),\quad z\in\mathbb{C}-\left\{\left(-\infty,-\frac{c^2}{2}\right]\cup\left[\frac{c^2}{2},\infty\right)\right\} \tag{20}$$

which may be written in the form

$$\psi_1''+\left[k(z)^2-\frac{\kappa_{jl}(\kappa_{jl}+1)}{r^2}\right]\psi_1=0,$$
$$\psi_2''+\left[k(z)^2-\frac{\kappa_{jl}(\kappa_{jl}-1)}{r^2}\right]\psi_2=0, \tag{21}$$

where

$$k(z)=\frac{1}{c}\sqrt{z^2-\frac{c^4}{4}}\equiv k. \tag{22}$$

A straightforward computation shows that Eq. (20) has two linearly independent solutions

$$\psi^{(1)}_{jl,z}(r)=\begin{cases}\begin{pmatrix}F_{jl}(z,r)\\ \tilde{F}_{jl}(z,r)\end{pmatrix}, & r<R,\\ \begin{pmatrix}0\\0\end{pmatrix}, & r>R,\end{cases} \tag{23}$$

$$\psi^{(2)}_{jl,z}(r)=\begin{cases}\begin{pmatrix}0\\0\end{pmatrix}, & r<R,\\ \begin{pmatrix}G_{jl}(z,r)\\ \tilde{G}_{jl}(z,r)\end{pmatrix}, & r<R,\end{cases} \tag{24}$$

where

$$F_{jl}(z,r)=\left(\frac{k(z)}{2}\right)^{-\kappa_{jl}-1/2}\Gamma\left(\kappa_{jl}+\frac{3}{2}\right)r^{1/2}J_{\kappa_{jl}+1/2}(k(z)r), \tag{25}$$

$$\tilde{F}_{jl}(z,r)=\frac{1}{c}\left(\frac{1}{2}\right)^{-\kappa_{jl}-1/2}k(z)^{-\kappa_{jl}+1/2}\Gamma\left(\kappa_{jl}+\frac{3}{2}\right)r^{1/2}J_{\kappa_{jl}-1/2}(k(z)r), \tag{26}$$

$$G_{jl}(z,r)=\mathrm{i}\frac{\pi}{2}\left(\frac{k(z)}{2}\right)^{\kappa_{jl}+1/2}\Gamma\left(\kappa_{jl}+\frac{3}{2}\right)^{-1}r^{1/2}H^{(1)}_{\kappa_{jl}+1/2}(k(z)r), \tag{27}$$

$$\tilde{G}_{jl}(z,r)=\mathrm{i}\frac{\pi}{2c}\left(\frac{1}{2}\right)^{\kappa_{jl}+1/2}k(z)^{\kappa_{jl}+3/2}\Gamma\left(\kappa_{jl}+\frac{3}{2}\right)^{-1}r^{1/2}H^{(1)}_{\kappa_{jl}-1/2}(k(z)r),\quad \mathrm{Im}\,k(z)>0. \tag{28}$$

$J_\nu(.)$ is the Bessel function and $H^{(1)}_\nu(.)$ the Hankel function of the first type of order ν.

The solutions (23) and (24) have been normalized in such a way that

$$\det\begin{bmatrix}G_{jl}(z,r) & F_{jl}(z,r)\\ \tilde{G}_{jl}(z,r) & \tilde{F}_{jl}(z,r)\end{bmatrix}=\frac{1}{c}. \tag{29}$$

Therefore, h_{jl} has deficiency indices (2,2) and consequently, all self-adjoint(sa) extensions of h_{jl} are given by a four-parameter family of self-adjoint operators.[22] Since the matrix G in Eq. (34) depends on two parameters, it follows that the sa extension $h_{jl,G}$ of h_{jl} corresponding to the interaction $V(r)=G\,\delta(r-R)$ is a special two-parameters family of sa extensions of h_{jl}.

The relation $h_{jl,G}\subset h^*_{jl}$ implies that the domain $\mathcal{D}(h_{jl,G})$ contains those functions $\psi\in\mathcal{D}(h^*_{jl})$ which satisfy suitable boundary conditions at $r=R$.

Theorem 2.1 (Ref. 7): Any self-adjoint extension $\hat{h}_{jl}$ of h_{jl} reads

$$\hat{h}_{jl}=\begin{pmatrix} \frac{c^2}{2} & -c\frac{d}{dr}+c\frac{\kappa_{jl}}{r} \\ c\frac{d}{dr}+c\frac{\kappa_{jl}}{r} & -\frac{c^2}{2} \end{pmatrix},$$

$$\mathcal{D}(\hat{h}_{jl})=\{\psi\in\mathcal{D}(h_{jl}^{*})/\psi \text{ satisfies } \mathrm{cond}_1 \text{ or } \mathrm{cond}_2\}, \tag{30}$$

$$\mathrm{cond}_1:\psi(R-)=e^{i\theta}\hat{A}\psi(R_+),\quad \theta\in[0,\pi), \tag{31}$$

and $\hat{A}$ is a 2×2 matrix with $\det\hat{A}=1$;

$$\mathrm{cond}_2:\begin{pmatrix} c_1 & c_2 \\ 0 & 0 \end{pmatrix}\psi(R-)+\begin{pmatrix} 0 & 0 \\ d_1 & d_2 \end{pmatrix}\psi(R+)=0, \tag{32}$$

where c_1, c_2, d_1, and d_2 are real and both matrices are nonzero. Conversely, any operator of this form is self-adjoint extension of h_{jl}.

Theorem 2.2 (Ref. 7): The general form of boundary conditions (31) and (32) reads

$$C\psi(R-)+D\psi(R+)=0, \tag{33}$$

where C and D are 2×2 matrices such that the 2×4 matrix (C,D) has rank 2.

Let us now construct the self-adjoint extension corresponding to the radial Dirac operator with the potential

$$V(r)=G_{jl}\delta(r-R),$$

$$G_{jl}=\begin{pmatrix} A_{jl} & 0 \\ 0 & B_{jl} \end{pmatrix},\quad A_{jl},B_{jl}\in\mathbb{R}.$$

Suppose that ψ satisfies the equation

$$[\tau+G_{jl}\delta(r-R)]\psi=z\psi, \tag{34}$$

$$\tau=\begin{pmatrix} \frac{c^2}{2} & -c\frac{d}{dr}+c\frac{\kappa_{jl}}{r} \\ c\frac{d}{dr}+c\frac{\kappa_{jl}}{r} & -\frac{c^2}{2} \end{pmatrix},$$

$$G_{jl}=\begin{pmatrix} A_{jl} & 0 \\ 0 & B_{jl} \end{pmatrix},\quad A_{jl},\ B_{jl}\in\mathbb{R}, \tag{35}$$

and the limits $f(R\pm)$ exist. Integrating Eq. (34) over $(R-\epsilon,R+\epsilon)$, and taking the limit $\epsilon\to0$ we get[7]

$$\left(1-\tau_0\frac{G_{jl}}{2c}\right)\psi(R+)-\left(1+\tau_0\frac{G_{jl}}{2c}\right)\psi(R-)=0, \tag{36}$$

where

$$\tau_0=\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \tag{37}$$

We will accept only those matrices G for which Eq. (36) is compatible with Eqs. (31) and (32). As indicated in Ref. 7 the boundary condition (36) defines a self-adjoint extension of h_{jl} iff $G=G^{+}$.

Consider in $L^2((0,\infty))\otimes\mathbb{C}^2$ the operator $h_{jl,G_{jl}}$ defined by

$$h_{jl,G_{jl}}=\begin{pmatrix} \dfrac{c^2}{2} & -c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} \\ c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} & -\dfrac{c^2}{2} \end{pmatrix}\equiv\tau,$$

$$D(h_{jl,G_{jl}})=\left\{\psi\in\mathcal{D}(h_{jl}^{*})\middle|\left(1-\tau_0\frac{G_{jl}}{2c}\right)\psi(R+)-\left(1+\tau_0\frac{G_{jl}}{2c}\right)\psi(R-)=0\right\}, \tag{38}$$

$$l\in[j-\tfrac{1}{2},j+\tfrac{1}{2}],\quad j\in[\tfrac{1}{2},\infty).$$

The boundary condition (38) may be written in the form

$$C\psi(R-)+D\psi(R+)=0 \tag{39}$$

with

$$C=-\begin{pmatrix} 1 & -\dfrac{B_{jl}}{2c} \\ \dfrac{A_{jl}}{2c} & 1 \end{pmatrix},\quad D=\begin{pmatrix} 1 & \dfrac{B_{jl}}{2c} \\ -\dfrac{A_{jl}}{2c} & 1 \end{pmatrix}. \tag{40}$$

Therefore, according to theorem 2.2, the operator $h_{jl,G_{jl}}$ is a self-adjoint extension of h_{jl}.

By construction, the operator $h_{jl,G_{jl}}$ provides the mathematical definition of the formal expression

$$h_{G_{jl}}=h_D+G_{jl}\delta(r-R), \tag{41}$$

where h_D is the radial Dirac Hamiltonian defined by

$$h_D=\begin{pmatrix} \dfrac{c^2}{2} & -c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} \\ c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} & -\dfrac{c^2}{2} \end{pmatrix},$$

$$\mathcal{D}(h_D)=\{\psi\in\mathcal{D}(h_{jl}^{*})\,|\,\psi(R+)=\psi(R-)\}\quad l\in[j-\tfrac{1}{2},j+\tfrac{1}{2}],j\in[\tfrac{1}{2},\infty). \tag{42}$$

The case $G_{jl}=0$ in Eq. (38) yields the radial Dirac Hamiltonian $h_{jl,0}\equiv h_D$. The case $A_{jl}\neq 0$, $B_{jl}=0$ in Eq. (38) gives the δ-sphere interaction of the first type defined by[23]

$$h_{jl,A_{jl}}=\tau,$$

$$\mathcal{D}(h_{jl,A_{jl}})=\left\{\psi=\begin{pmatrix} f \\ g \end{pmatrix}\in\mathcal{D}(h_{jl}^{*})\middle|\, f(R-)=f(R+)\equiv f(R),\ \ g(R+)-g(R-)=\frac{A_{jl}}{c}f(R)\right\}. \tag{43}$$

The case $A_{jl}=0$, $B_{jl}\neq 0$ leads to a δ-sphere interaction of the second type defined by[23]

$$h_{jl,B_{jl}}=\tau,$$
$$\mathcal{D}(h_{jl,B_{jl}})=\left\{\psi=\begin{pmatrix} f \\ g\end{pmatrix}\in\mathcal{D}(h_{jl}^{*})\,\middle|\, g(R-)=g(R+)\equiv g(R),\ \ f(R+)-f(R-)=-\frac{B_{jl}}{c}g(R)\right\}. \tag{44}$$

Let $\underline{\underline{G}}=\{G_{jl}\};\ j-\frac{1}{2}\leqslant j+\frac{1}{2};\ \frac{1}{2}\leqslant j<\infty$. The decomposition (15), implies that the operator $H_{\underline{\underline{G}}}$ in $L^2(\mathbb{R}^3)\otimes\mathbb{C}^4$ defined by

$$H_{\underline{\underline{G}}}=\bigoplus_{j=1/2}^{\infty}\ \bigoplus_{l=j-1/2}^{j+1/2} U_{jl}^{-1}h_{jl,G_{jl}}U_{jl}\otimes\mathbb{I} \tag{45}$$

provides the mathematical formulation of the formal expression (2). Actually, $H_{\underline{\underline{G}}}$ in Eq. (45) provides a slight generalization of Eq. (2) since $\underline{\underline{G}}$ may depend on j and l.

The case $\underline{\underline{G}}=0$, i.e., $G_{jl}=0$ for all j and l yields the Dirac Hamiltonian H_D defined by Eq. (4).

B. The resolvent equation

Theorem 2.3: The resolvent of $h_{jl,G_{jl}}$ is given by

$$(h_{jl,G_{jl}}-z)^{-1}=(h_D-z)^{-1}+\vartheta_{jl}(z,A_{jl},B_{jl})\left\{(\overline{\hat{M}_{jl,z}^{(2)}(.)},.)\left[A_{jl}\hat{M}_{jl,z}^{(2)}(.)+\frac{A_{jl}B_{jl}}{2c}\tilde{M}_{jl,z}^{(1)}(.)\right]\right.$$
$$\left.+(\overline{\tilde{M}_{jl,z}^{(2)}(.)},.)\left[B_{jl}\tilde{M}_{jl,z}^{(2)}(.)-\frac{A_{jl}B_{jl}}{2c}\hat{M}_{jl,z}^{(1)}(.)\right]\right\},$$
$$z\in\rho(h_{jl,G_{jl}}),\quad \operatorname{Im}k(z)>0,\quad l\in\left[j-\frac{1}{2},j+\frac{1}{2}\right],\quad j\in\left[\frac{1}{2},\infty\right) \tag{46}$$

[$\rho(.)$ is the resolvent set],
where $(h_D-z)^{-1}$, $\operatorname{Im}k(z)>0$ is the radial Dirac resolvent with kernel

$$G^{(jl)}(z,r,r')=\begin{pmatrix} G_{11}^{(jl)}(z,r,r') & G_{12}^{(jl)}(z,r,r') \\ G_{21}^{(jl)}(z,r,r') & G_{22}^{(jl)}(z,r,r')\end{pmatrix}, \tag{47}$$

where

$$G_{11}^{(jl)}(z,r,r')=\begin{cases} G_{jl}(z,r')F_{jl}(z,r), & r<r', \\ F_{jl}(z,r')G_{jl}(z,r), & r>r', \end{cases} \tag{48}$$

$$G_{12}^{(jl)}(z,r,r')=\begin{cases} \tilde{G}_{jl}(z,r')F_{jl}(z,r), & r<r' \\ \tilde{F}_{jl}(z,r')G_{jl}(z,r), & r>r', \end{cases} \tag{49}$$

$$G_{21}^{(jl)}(z,r,r')=\begin{cases} G_{jl}(z,r')\tilde{F}_{jl}(z,r), & r<r' \\ F_{jl}(z,r')\tilde{G}_{jl}(z,r), & r>r', \end{cases} \tag{50}$$

$$G_{22}^{(jl)}(z,r,r')=\begin{cases} \tilde{G}_{jl}(z,r')\tilde{F}_{jl}(z,r), & r<r' \\ \tilde{F}_{jl}(z,r')\tilde{G}_{jl}(z,r), & r>r', \end{cases} \tag{51}$$

and

$$\vartheta_{jl}(z,A_{jl},B_{jl})=-\left[1-\frac{A_{jl}B_{jl}}{4c^2}+B_{jl}\tilde{F}_{jl}(z,R)\tilde{G}_{jl}(z,R)+A_{jl}F_{jl}(z,R)G_{jl}(z,R)\right]^{-1}, \tag{52}$$

$$\hat{M}^{(m)}_{jl,z}(r)=\begin{cases} G^{(jl)}(z,r,R)\begin{pmatrix}1\\0\end{pmatrix}, & r<R,\\ (-1)^m G^{(jl)}(z,r,R)\begin{pmatrix}1\\0\end{pmatrix}, & r>R, m=1,2,\end{cases} \tag{53}$$

$$\tilde{M}^{(m)}_{jl,z}(r)=\begin{cases} G^{(jl)}(z,r,R)\begin{pmatrix}0\\1\end{pmatrix}, & r<R,\\ (-1)^m G^{(jl)}(z,r,R)\begin{pmatrix}0\\1\end{pmatrix}, & r>R, m=1,2\end{cases} \tag{54}$$

with $F_{jl}(z,r)$, $\tilde{F}_{jl}(z,r)$, $G_{jl}(z,r)$, $\tilde{G}_{jl}(z,r)$, and $k(z)$ defined by (25)–(28) and (22), respectively.

Proof: According to Krein's resolvent formula,[22] we have

$$(h_{jl,G_{jl}}-z)^{-1}=(h_D-z)^{-1}+\sum_{n,m=1}^{2}\lambda_{mn}(z)(\overline{\psi^{(n)}_{jl,z}(.)},.)\psi^{(m)}_{jl,z}(.),\quad z\in\rho(h_{jl,G_{jl}}),\quad \mathrm{Im}\,k(z)>0, \tag{55}$$

where $\psi^{(m)}_{jl,z}(r)$, $m=1,2$ are given by (23) and (24), respectively.

Let $\phi=\binom{\phi_1}{\phi_2}\in L^2((0,\infty))\otimes\mathbb{C}^2$ and define the function $\chi_{jl}(z,r)$ by

$$\chi_{jl}(z,r)=((h_{jl,G_{jl}}-z)^{-1}\phi)(r). \tag{56}$$

Since $\chi_{jl}=\binom{\chi_{jl,1}}{\chi_{jl,2}}\in\mathcal{D}(h_{jl,G_{jl}})$, it follows that χ_{jl} satisfies the boundary conditions in (38).

The implementation of these boundary conditions provides the constants $\lambda_{mn}(z)$. Inserting the λ_{mn} [z into (55) we obtain Eq. (46)].

Remarks:

(i) The resolvent of H_G may be obtained from Eq. (46) and the decomposition (45).

(ii) In the cases $A_{jl}\neq 0$, $B_{jl}=0$ and $A_{jl}=0$, $B_{jl}\neq 0$, the resolvent Eq. (46) simplifies, respectively, to

$$(h_{jl,A_{jl}}-z)^{-1}=(h_D-z)^{-1}+A_{jl}\vartheta_{jl}(z,A_{jl},0)(\overline{\hat{M}^{(2)}_{jl,z}(.)},.)\hat{M}^{(2)}_{jl,z}(.),$$

$$z\in\rho(h_{jl,A_{jl}}),\quad \mathrm{Im}\,k(z)>0,\ \ l\in[;j-\tfrac{1}{2},j+\tfrac{1}{2}],\quad j\in[\tfrac{1}{2},\infty] \tag{57}$$

and

$$(h_{jl,B_{jl}}-z)^{-1}=(h_D-z)^{-1}+B_{jl}\vartheta_{jl}(z,0,B_{jl})(\overline{\tilde{M}^{(2)}_{jl,z}(.)},.)\tilde{M}^{(2)}_{jl,z}(.),$$

$$z\in\rho(h_{jl,B_{jl}}),\quad \mathrm{Im}\,k(z)>0,\ \ l\in[j-\tfrac{1}{2},j+\tfrac{1}{2}],\quad j\in[\tfrac{1}{2},\infty]. \tag{58}$$

C. Spectral properties

Theorem 2.4: For $A_{jl},B_{jl}\in(-\infty,\infty)$, $l\in[j-\frac{1}{2},j+\frac{1}{2}]$, $j\in[\frac{1}{2},\infty)$, the essential spectrum of $h_{jl,G_{jl}}$ is purely absolutely continuous and coincides with $(-\infty,-c^2/2]\cup[c^2/2,\infty)$. Its singularly continuous and residual spectra are empty. Furthermore, $h_{jl,G_{jl}}$ has at most two eigenvalues (with account of multiplicity in $[-c^2/2,c^2/2]$.

Proof:

See, e.g., Ref. 7, Proposition 6.1 and theorem 6.2.

The resonances of $h_{jl,G_{jl}}$ are defined as poles of the resolvent equation (46) in the unphysical sheet $\mathrm{Im}\,k(z)<0$.

D. The nonrelativistic limit

Following the strategy of Gesztesy *et al.*[1,24] in the case of point interactions, one can discuss the nonrelativistic limit of $h_{jl,G_{jl}}$ as $c\to\infty$.

Theorem 2.5: For spin-$\frac{1}{2}$ particules, the operator $h_{jl,G_{jl}}-(c^2/2)$ converges in norm resolvent sense to the Schrödinger operator $h_{l,\hat{\alpha}_l}$ times the projector onto $\tilde{\mathcal{H}}_+=L^2((0,\infty))$:

$$n.\lim_{c\to\infty}\left(h_{jl,G_{jl}}-\frac{c^2}{2}-z\right)^{-1}=(h_{l,\hat{\alpha}_l}-z)^{-1}\otimes\begin{pmatrix}1&0\\0&0\end{pmatrix},\quad z\in\mathbb{C}\backslash\mathbb{R},\tag{59}$$

where $h_{l,\hat{\alpha}_l}$ is defined by

$$h_{l,\hat{\alpha}_l}=-\frac{d^2}{dr^2}+\frac{l(l+1)}{r^2},$$

$$\mathcal{D}(h_{l,\hat{\alpha}_l})=\{f\in L^2((0,\infty))\,|\,f,f'\in \mathrm{AC}_{loc}((0,\infty)\backslash\{R\}),\quad f(0+)=0\quad \text{if } l=0,$$

$$f(R+)-f(R-)=\frac{\beta_l}{2}[f'(R+)+f'(R-)],$$

$$f'(R+)-f'(R-)=\frac{\alpha_l}{2}[f(R+)+f(R-)],\quad -f''+l(l+1)r^{-2}f\in L^2((0,\infty))\},$$

$$\hat{\alpha}=\{\beta_l,\alpha_l\};-\infty<\beta_l,\alpha_l\leqslant\infty;\ \ l\in\mathbb{N}_0.\tag{60}$$

One can prove that if $\alpha_l\beta_l-4=0,\alpha_l,\beta_l\in\mathbb{R}$, then the boundary conditions in (60) define a self-adjoint extension of the radial Schrödinger operator $\dot{h}_l$ defined by

$$\dot{h}_l=-\frac{d^2}{dr^2}+\frac{l(l+1)}{r^2},$$

$$\mathcal{D}(\dot{h}_l)=\{f\in L^2((0,\infty))\,|\,f,f'\in \mathrm{AC}_{loc}((0,\infty));f(0+)=0\ \text{ if }\ l=0;\ \ f(R\pm)=f'(R\pm)=0-f''+l(l+1)r^{-2}f\in L^2((0,\infty))\}\quad l\in\mathbb{N}_0.\tag{61}$$

Proof:

One may follow step by step[1,24] where a similar result was obtained in the case of the point interactions.

To the best of our knowledge, the Hamiltonian $h_{l,\hat{\alpha}_l}$ defines a new exactly solvable model of nonrelativistic δ-sphere interactions. The cases $\alpha_l\neq 0$, $\beta_l=0$ and $\alpha_l=0$, $\beta_l\neq 0$ in Eq. (60) lead to nonrelativistic δ-sphere interactions of the first and second type, respectively. These interactions have been extensively discussed in Refs. 2, 4, 5, and 15.

E. Scattering theory for the pair $(h_{jl,G_{jl}};h_D)$

Let us define for $k(z)>0$, the function

$$\begin{pmatrix} F_{G_{jl},1}(z,r) \\ F_{G_{jl},2}(z,r) \end{pmatrix} = \begin{pmatrix} F_{jl}(z,r) \\ \tilde{F}_{jl}(z,r) \end{pmatrix} + \vartheta_{jl}(z,A_{jl},B_{jl}) \Bigg\{ G^{(jl)}(z,r,R) \Bigg[A_{jl} \begin{pmatrix} F_{jl}(z,R) \\ 0 \end{pmatrix} + B_{jl} \begin{pmatrix} 0 \\ \tilde{F}_{jl}(z,R) \end{pmatrix} \Bigg] + \frac{A_{jl}B_{jl}}{2c} \hat{G}^{(jl)}(z,r,R) \Bigg[\begin{pmatrix} 0 \\ F_{jl}(z,R) \end{pmatrix} - \begin{pmatrix} \tilde{F}_{jl}(z,R) \\ 0 \end{pmatrix} \Bigg] \Bigg\}, \tag{62}$$

where

$$\hat{G}^{(jl)}(z,r,R) = \begin{cases} G^{(jl)}(z,r,R) & r<R, \\ -G^{(jl)}(z,r,R), & r>R, \end{cases} \tag{63}$$

$G^{(jl)}(z,r,R)$ is the Green matrix of the radial Dirac Hamiltonian defined by the Eq. (47) and the functions $F_{jl}(z,r)$, $\tilde{F}_{jl}(z,r)$, and $\vartheta_{jl}(z,A_{jl},B_{jl})$ are defined by (25), (26), and (52), respectively. A straightforward calculation shows that $\binom{F_{G_{jl},1}(z,r)}{F_{G_{jl},2}(z,r)}$ are the scattering wave functions of $h_{jl,G_{jl}}$. In the particular cases $A_{jl}\neq 0$ and $B_{jl}=0$ and $A_{jl}=0$, $B_{jl}\neq 0$ Eq. (62) simplies, respectively, to

$$\begin{pmatrix} F_{A_{jl},1}(z,r) \\ F_{A_{jl},2}(z,r) \end{pmatrix} = \begin{pmatrix} F_{jl}(z,r) \\ \tilde{F}_{jl}(z,r) \end{pmatrix} + A_{jl}\vartheta_{jl}(z,A_{jl},0) G^{(jl)}(z,r,R) \begin{pmatrix} F_{jl}(z,R) \\ 0 \end{pmatrix} \tag{64}$$

and

$$\begin{pmatrix} F_{B_{jl},1}(z,r) \\ F_{B_{jl},2}(z,r) \end{pmatrix} = \begin{pmatrix} F_{jl}(z,r) \\ \tilde{F}_{jl}(z,r) \end{pmatrix} + B_{jl}\vartheta_{jl}(z,0,B_{jl}) G^{(jl)}(z,r,R) \begin{pmatrix} 0 \\ \tilde{F}_{jl}(z,R) \end{pmatrix}. \tag{65}$$

Equations (64) and (65) define the scattering wave functions corresponding to the Hamiltonians $h_{jl,A_{jl}}$ and $h_{jl,B_{jl}}$ describing relativistic δ-sphere interactions of the first and second type, respectively.

The asymptotic behavior of $\binom{F_{G_{jl},1}(z,r)}{F_{G_{jl},2}(z,r)}$ as $r\to\infty$ yields[25,26]

$$\begin{aligned} \begin{pmatrix} F_{G_{jl},1}(z,r) \\ F_{G_{jl},2}(z,r) \end{pmatrix} &\xrightarrow[r\to\infty]{k(z)>0} \begin{pmatrix} \hat{A}_{jl}(z)\sin\left[kr-\kappa_{jl}\frac{\pi}{2}\right] \\ \hat{B}_{jl}(z)\sin\left[kr-(\kappa_{jl}-1)\frac{\pi}{2}\right] \end{pmatrix} + \vartheta_{jl}(z,A_{jl},B_{jl})\{A_{jl}F_{jl}^2(z,R) \\ &\quad + B_{jl}\tilde{F}_{jl}^2(z,R)\} \begin{pmatrix} \hat{C}_{jl}(z)\exp -i\left[kr-\kappa_{jl}\frac{\pi}{2}\right] \\ \hat{O}_{jl}(z)\exp -i\left[kr-(\kappa_{jl}-1)\frac{\pi}{2}\right] \end{pmatrix} \\ &= \begin{pmatrix} [A_1^2(z)+A_2^2(z)]^{1/2}\sin\left[kr-\kappa_{jl}\frac{\pi}{2}+\delta_{G_{jl}}(z)\right]+0(1) \\ [A_3^2(z)+A_4^2(z)]^{1/2}\sin\left[kr-(\kappa_{jl}-1)\frac{\pi}{2}+\delta_{G_{jl}}(z)\right]+0(1) \end{pmatrix}, \end{aligned} \tag{66}$$

where $\hat{A}_{jl}(z)$, $\hat{C}_{jl}(z)$, $\hat{B}_{jl}(z)$, $\hat{O}_{jl}(z)$ are given by

$$\hat{A}_{jl}(z) = 2^{-\kappa_{jl}}k(z)^{-\kappa_{jl}-1}\Gamma(2\kappa_{jl}+2)\Gamma(\kappa_{jl}+1)^{-1}, \tag{67}$$

$$\hat{C}_{jl}(z) = 2^{\kappa_{jl}}k(z)^{\kappa_{jl}}\Gamma(2\kappa_{jl}+2)^{-1}\Gamma(\kappa_{jl}+1), \tag{68}$$

$$\hat{B}_{jl}(z)=\frac{1}{c}2^{-\kappa_{jl}}k(z)^{-\kappa_{jl}}\Gamma(2\kappa_{jl}+2)\Gamma(\kappa_{jl}+1)^{-1}, \tag{69}$$

$$\hat{O}_{jl}(z)=\frac{1}{c}2^{\kappa_{jl}}k(z)^{\kappa_{jl}+1}\Gamma(2\kappa_{jl}+2)^{-1}\Gamma(\kappa_{jl}+1). \tag{70}$$

The phase shifts corresponding to $h_{jl,G_{jl}}$ are defined as

$$\delta_{G_{jl}}(z)=-\arctan\frac{A_2(z)}{A_1(z)}=-\arctan\frac{A_4(z)}{A_3(z)}=-\arctan\frac{\hat{C}_{jl}(z)\vartheta'_{jl}(z)}{\hat{A}_{jl}(z)-\mathrm{i}\hat{C}_{jl}(z)\vartheta'_{jl}(z,A_{jl},B_{jl})}, \tag{71}$$

where

$$\vartheta'_{jl}(z)=\vartheta_{jl}(z,A_{jl},B_{jl})[A_{jl}F_{jl}(z,R)F_{jl}(z,R)+B_{jl}\tilde{F}_{jl}(z,R)\tilde{F}_{jl}(z,R)]. \tag{72}$$

The elements of the on-shell scattering matrix are given by

$$S_{G_{jl}}(z)=\exp[2\mathrm{i}\delta_{G_{jl}}(z)]. \tag{73}$$

The partial wave scattering amplitude is given by

$$f_{G_{jl}}(z)=\frac{\exp[2\mathrm{i}\delta_{G_{jl}}(z)]-1}{2\mathrm{i}k}. \tag{74}$$

III. THE ASYMMETRIC δ-SPHERE INTERACTION

Consider in dimension $n=3$, the quantum Hamiltonian describing the so-called asymmetric δ-sphere interaction formally given by:[7]

$$H_{\underline{\underline{G}}^{(a)}}=H_D+\underline{\underline{G}}\,\delta_a(|x|-R), \quad a\in\mathbb{C}, \tag{75}$$

where $\underline{\underline{G}}$ is a 4×4 matrix given by $\underline{\underline{G}}=\left(\begin{smallmatrix}A & 0\\ 0 & B\end{smallmatrix}\right)$ and δ_a is defined by

$$\int_{R-\epsilon}^{R+\epsilon}\delta_a(r-R)\psi(r)dr=a\,\psi(R+)+(1-a)\psi(R-). \tag{76}$$

Following the strategy used for the construction of $h_{jl,G_{jl}}$ in Eq. (38), one can show that the self-adjoint extension corresponding to the radial Dirac operator with the potential

$$V_a(r)=G_{jl}\delta_a(r-R);a\in\mathbb{C}, \quad G_{jl}=\begin{pmatrix}A_{jl} & 0\\ 0 & B_{jl}\end{pmatrix}, \quad A_{jl},B_{jl}\in\mathbb{R} \tag{77}$$

is given by

$$h_{jl,G_{jl}^{(a)}}=\begin{pmatrix}\dfrac{c^2}{2} & -c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r}\\ c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} & -\dfrac{c^2}{2}\end{pmatrix}\equiv\tau,$$

$$\mathcal{D}(h_{jl,G_{jl}^{(a)}})=\{g\in\mathcal{D}(h_{jl}^{*})|(1-a\tilde{B})g(R+)-(1+b\tilde{B})g(R-)=0\},$$

$$l\in[j-\tfrac{1}{2},j+\tfrac{1}{2}], \quad j\in[\tfrac{1}{2},\infty), \tag{78}$$

where we have used the following definitions and notations:

$$\tilde{B}=\tau_0 c^{-1}G_{jl}, \quad b=1-a, \quad a\in\mathbb{C} \tag{79}$$

and $G_{jl}-G_{jl}^{+}=(1-2\,\mathrm{Re}\,a)c^{-1}G_{jl}^{+}\tau_0 G_{jl}$.

The case $a=\frac{1}{2}$ gives $h_{jl,G_{jl}}$ defined by Eq. (38). Obviously, all the results obtained in Sec. II may be extended to the case of asymmetric δ-sphere interactions.

IV. THE δ-SPHERE PLUS COULOMB INTERACTION

A. Definition of the Hamiltonian

Now the Hamiltonian of the system is formally given by[12]

$$H_{\gamma,\underline{\underline{G}}}=H_D+\frac{\gamma}{|x|}+\underline{\underline{G}}\,\delta(|x|-R), \quad x\in\mathbb{R}^3, \quad R>0, \tag{80}$$

where $\underline{\underline{G}}$ is a real 4×4 matrix of the form

$$\underline{\underline{G}}=\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}. \tag{81}$$

Consider the decomposition (15) and introduce in $L^2((0,\infty))\otimes\mathbb{C}^2$ the operator

$$\overline{H}_{\gamma,\underline{\underline{G}}}=\bigoplus_{j=1/2}^{\infty}\bigoplus_{l=j-1/2}^{j+1/2}[U_{jl}^{-1}h_{jl,\gamma}U_{jl}]\otimes\mathbb{1}, \tag{82}$$

where $h_{jl,\gamma}$ is given by

$$h_{jl,\gamma}=\begin{pmatrix} \dfrac{c^2}{2}+\dfrac{\gamma}{r} & -c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} \\ c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} & -\dfrac{c^2}{2}+\dfrac{\gamma}{r} \end{pmatrix}\equiv\tau_\gamma, \tag{83}$$

$$D(h_{jl,\gamma})=\{\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\,|\,\psi\in\mathrm{AC}_{loc}((0,\infty)), \quad \psi(R\pm)=0;$$
$$\tau_\gamma\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\}. \tag{84}$$

κ_{jl} is defined by Eq. (17).

The adjoint $\overline{H}^{*}_{\gamma,\underline{\underline{G}}}$ of $\overline{H}_{\gamma,\underline{\underline{G}}}$ is defined by

$$\overline{H}^{*}_{\gamma,\underline{\underline{G}}}=\bigoplus_{j=1/2}^{\infty}\bigoplus_{l=j-1/2}^{j+1/2}[U_{jl}^{-1}h^{*}_{jl,\gamma}U_{jl}]\otimes\mathbb{1}, \tag{85}$$

$$h^{*}_{jl,\gamma}=\begin{pmatrix} \dfrac{c^2}{2}+\dfrac{\gamma}{r} & -c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} \\ c\dfrac{d}{dr}+c\dfrac{\kappa_{jl}}{r} & -\dfrac{c^2}{2}+\dfrac{\gamma}{r} \end{pmatrix}\equiv\tau_\gamma, \tag{86}$$

$$D(h^{*}_{jl,\gamma})=\{\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\,|\,\psi\in\mathrm{AC}_{loc}((0,\infty)\backslash\{R\});$$
$$\tau_\gamma\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\}. \tag{87}$$

The self-adjoint extension of $h_{jl,\gamma}$: Consider the equation

$$(h^*_{jl,\gamma}-z)\psi=0,\psi=\begin{pmatrix} f \\ g \end{pmatrix}\in D(h^*_{jl,\gamma}),z\in\mathbb{C}-\left\{\left(-\infty,-\frac{c^2}{2}\right]\left[\frac{c^2}{2},\infty\right)\right\} \tag{88}$$

and introduce the following notations

$$k(z)=\frac{1}{c}\sqrt{z^2-\frac{c^4}{4}}\equiv k, \tag{89}$$

$$\xi=(\kappa_{jl}^2c^2-\gamma^2)^{1/2}, \tag{90}$$

$$\tilde{\xi}=\frac{1}{c}\xi, \tag{91}$$

$$\tilde{\gamma}=\frac{2z\gamma}{c^2}. \tag{92}$$

A straightforward computation shows that the equation (88) has two linearly independent solutions[25]

$$\psi^{(1)}_{\gamma,z}(r)=\begin{cases} \begin{pmatrix} f_{\gamma,1}(z,r) \\ f_{\gamma,2}(z,r) \end{pmatrix}, & r<R, \\ \begin{pmatrix} 0 \\ 0 \end{pmatrix}, & r>R, \end{cases} \tag{93}$$

$$\psi^{(2)}_{\gamma,z}(r)=\begin{cases} \begin{pmatrix} 0 \\ 0 \end{pmatrix}, & r<R, \\ \begin{pmatrix} g_{\gamma,1}(z,r) \\ g_{\gamma,2}(z,r) \end{pmatrix}, & r>R, \end{cases} \tag{94}$$

where

$$f_{\gamma,1}(z,r)=\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}\left[F_{jl,\gamma}(z,r)-\frac{\gamma}{\kappa_{jl}c+\xi}\tilde{F}_{jl,\gamma}(z,r)\right], \tag{95}$$

$$f_{\gamma,2}(z,r)=\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}\left[\tilde{F}_{jl,\gamma}(z,r)-\frac{\gamma}{\kappa_{jl}c+\xi}F_{jl,\gamma}(z,r)\right], \tag{96}$$

$$g_{\gamma,1}(z,r)=\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}\left[G_{jl,\gamma}(z,r)-\frac{\gamma}{\kappa_{jl}c+\xi}\tilde{G}_{jl,\gamma}(z,r)\right], \tag{97}$$

$$g_{\gamma,2}(z,r)=\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}\left[\tilde{G}_{jl,\gamma}(z,r)-\frac{\gamma}{\kappa_{jl}c+\xi}G_{jl,\gamma}(z,r)\right], \tag{98}$$

with

$$F_{jl,\gamma}(z,r)=r^{\tilde{\xi}+1}e^{-\mathrm{i}k(z)r}{}_1F_1\left(\tilde{\xi}+1-\mathrm{i}\frac{\tilde{\gamma}}{2k(z)},2\tilde{\xi}+2,2\mathrm{i}k(z)r\right), \tag{99}$$

$$G_{jl,\gamma}(z,r)=\Gamma(2\tilde{\xi}+2)^{-1}\Gamma\left(\tilde{\xi}+1-\frac{\mathrm{i}\tilde{\gamma}}{2k(z)}\right)(2\mathrm{i}k(z))^{2\tilde{\xi}+1}r^{\tilde{\xi}+1}e^{-\mathrm{i}k(z)r}$$
$$\times U\left(\tilde{\xi}+1-\mathrm{i}\frac{\tilde{\gamma}}{2k(z)},2\tilde{\xi}+2,2\mathrm{i}k(z)r\right), \tag{100}$$

$$\tilde{F}_{jl,\gamma}(z,r)=\frac{\tilde{\xi}}{c}(2\tilde{\xi}+1)\left|\Gamma\left(\tilde{\xi}+\frac{\mathrm{i}\tilde{\gamma}}{2k(z)}\right)\right|\left|\Gamma\left(\tilde{\xi}+1+\frac{\mathrm{i}\tilde{\gamma}}{2k(z)}\right)\right|^{-1}r^{\tilde{\xi}}e^{-\mathrm{i}k(z)r}$$
$$\times{}_1F_1\left(\tilde{\xi}-\mathrm{i}\frac{\tilde{\gamma}}{2k(z)},2\tilde{\xi},2\mathrm{i}k(z)r\right), \tag{101}$$

$$\tilde{G}_{jl,\gamma}(z,r)=\frac{\tilde{\xi}^{-1}}{c}(2\tilde{\xi}+1)^{-1}\Gamma(2\tilde{\xi})^{-1}\Gamma\left(\tilde{\xi}+\frac{\mathrm{i}\tilde{\gamma}}{2k(z)}\right)\left|\Gamma\left(\tilde{\xi}+\frac{\mathrm{i}\tilde{\gamma}}{2k(z)}\right)\right|^{-1}$$
$$\times\left|\Gamma\left(\tilde{\xi}+1+\frac{\mathrm{i}\tilde{\gamma}}{2k(z)}\right)\right|k(z)^2(2\mathrm{i}k(z))^{2\tilde{\xi}-1}r^{\tilde{\xi}}e^{-\mathrm{i}k(z)r}U\left(\tilde{\xi}-\mathrm{i}\frac{\tilde{\gamma}}{2k(z)},2\tilde{\xi},2\mathrm{i}k(z)r\right), \tag{102}$$

${}_1F_1(a,b,r)$ ($U(a,b,r)$) denotes the regular (respectively, irregular) confluent hypergeometric functions.[27] The functions $f_{\gamma,n}(z,r),g_{\gamma,n}(z,r),n=1,2$ are normalized in such a way that

$$\det\begin{bmatrix} g_{\gamma,1}(z,r) & f_{\gamma,1}(z,r) \\ g_{\gamma,2}(z,r) & f_{\gamma,2}(z,r)\end{bmatrix}=\frac{1}{c}. \tag{103}$$

We note that the limit $\gamma\to 0+$, yields[26]

$$\begin{pmatrix} f_{\gamma,1}(z,r) \\ f_{\gamma,2}(z,r)\end{pmatrix}\xrightarrow[\gamma\to 0+]{}\begin{pmatrix} F_{jl}(z,r) \\ \tilde{F}_{jl}(z,r)\end{pmatrix}, \tag{104}$$

$$\begin{pmatrix} g_{\gamma,1}(z,r) \\ g_{\gamma,2}(z,r)\end{pmatrix}\xrightarrow[\gamma\to 0+]{}\begin{pmatrix} G_{jl}(z,r) \\ \tilde{G}_{jl}(z,r)\end{pmatrix}, \tag{105}$$

where $F_{jl}(z,r)$, $\tilde{F}_{jl}(z,r)$, $G_{jl}(z,r)$, and $\tilde{G}_{jl}(z,r)$ are defined by (25)–(27) and (28).

The operator $h_{jl,\gamma}$ has deficiency indices (2,2) and consequently all its self-adjoint extensions may be parametrised by a four-parameter family of self-adjoint operators. As in Sec. II A, we consider the following two-parameters family of self-adjoint extensions of $h_{jl,\gamma}$

$$h_{jl,\gamma,G_{jl}}=\begin{pmatrix} \frac{c^2}{2}+\frac{\gamma}{r} & -c\frac{d}{dr}+c\frac{\kappa_{jl}}{r} \\ c\frac{d}{dr}+c\frac{\kappa_{jl}}{r} & -\frac{c^2}{2}+\frac{\gamma}{r}\end{pmatrix}\equiv\tau_\gamma,$$

$$D(h_{jl,\gamma,G_{jl}})=\left\{\psi=\begin{pmatrix} f \\ g\end{pmatrix}\in\mathcal{D}(h^*_{jl,\gamma})\middle|\left(1-\tau_0\frac{G_{jl}}{2c}\right)\psi(R+)-\left(1+\tau_0\frac{G_{jl}}{2c}\right)\psi(R-)=0\right\},$$
$$A_{jl},B_{jl}\in\mathbb{R};\quad l\in[j-\tfrac{1}{2},j+\tfrac{1}{2}];\quad j\in[\tfrac{1}{2},\infty). \tag{106}$$

Following Sec. II A, one can show that the operator $h_{jl,\gamma,G_{jl}}$ gives the mathematical definition of the formal expression

$$h_{\gamma,G_{jl}}=h_D+\frac{\gamma}{r}+G_{jl}\delta(r-R). \tag{107}$$

The case $G_{jl}=0$ in Eq. (106) gives the radial Dirac–Coulomb Hamiltonian $h_{jl,\gamma,0}\equiv h_{\gamma,D}$,

$$h_{\gamma,D}=h_D+\frac{\gamma}{r}\equiv\tau_\gamma,$$

$$\mathcal{D}(h_{\gamma,D})=\{\psi\in\mathcal{D}(h^*_{jl,\gamma})\,|\,\psi(R+)=\psi(R-)\};\quad l\in[j-\tfrac{1}{2},j+\tfrac{1}{2}],\quad j\in[\tfrac{1}{2},\infty). \tag{108}$$

The cases $A_{jl}\neq 0$, $B_{jl}=0$ and $A_{jl}=0$, $B_{jl}\neq 0$ in Eq. (106) yields the δ-sphere plus Coulomb interaction of the first and second types, respectively.

The model (80) is defined in $L^2(\mathbb{R}^3)\otimes\mathbb{C}^4$ by

$$H_{\gamma,\underline{\underline{G}}}=\bigoplus_{j=1/2}^{\infty}\bigoplus_{l=j-1/2}^{j+1/2}U_{jl}^{-1}h_{jl,\gamma,G_{jl}}U_{jl}\otimes\mathbb{1}. \tag{109}$$

The case $\underline{\underline{G}}=0$ for all j and l leads to the Dirac–Coulomb Hamiltonian $H_{\gamma,D}$,

$$H_{\gamma,D}=H_D+\frac{\gamma}{|x|},\quad \mathcal{D}(H_{\gamma,D})=H^{1,2}(\mathbb{R}^3)\otimes\mathbb{C}^4. \tag{110}$$

B. The resolvent equation

Theorem 4.1: The resolvent of $h_{jl,\gamma,G_{jl}}$ is given by

$$\begin{aligned}(h_{jl,\gamma,G_{jl}}-z)^{-1}=(h_{\gamma,D}-z)^{-1}+\vartheta_{jl,\gamma}(z,A_{jl},B_{jl})\Bigg\{&(\overline{\hat{M}^{(2)}_{jl,z,\gamma}(.)},.)\left[A_{jl}\hat{M}^{(2)}_{jl,z,\gamma}(.)+\frac{A_{jl}B_{jl}}{2c}\tilde{M}^{(1)}_{jl,z,\gamma}(.)\right]\\&+(\overline{\tilde{M}^{(2)}_{jl,z,\gamma}(.)},.)\left[B_{jl}\tilde{M}^{(2)}_{jl,z,\gamma}(.)-\frac{A_{jl}B_{jl}}{2c}\hat{M}^{(1)}_{jl,z,\gamma}(.)\right]\Bigg\},\\ z\in\rho(h_{jl,\gamma,G_{jl}}),\ \ \mathrm{Im}\,k(z)>0,\ \ l\in[j-\tfrac{1}{2},j+\tfrac{1}{2}],\ \ j\in[\tfrac{1}{2},\infty)\end{aligned} \tag{111}$$

[$\rho(.)$ is the resolvent set] where $(h_{\gamma,D}-z)^{-1}$, $\mathrm{Im}\,k(z)>0$ is the radial Dirac–Coulomb resolvent with kernel

$$G^{(jl,\gamma)}(z,r,r')=\begin{pmatrix}G^{(jl,\gamma)}_{11}(z,r,r') & G^{(jl,\gamma)}_{12}(z,r,r')\\ G^{(jl,\gamma)}_{21}(z,r,r') & G^{(jl,\gamma)}_{22}(z,r,r')\end{pmatrix}, \tag{112}$$

where

$$G^{(jl,\gamma)}_{11}(z,r,r')=\begin{cases}g_{\gamma,1}(z,r')f_{\gamma,1}(z,r), & r<r',\\ f_{\gamma,1}(z,r')g_{\gamma,1}(z,r), & r>r',\end{cases} \tag{113}$$

$$G^{(jl,\gamma)}_{12}(z,r,r')=\begin{cases}g_{\gamma,2}(z,r')f_{\gamma,1}(z,r), & r<r',\\ f_{\gamma,2}(z,r')g_{\gamma,1}(z,r), & r>r',\end{cases} \tag{114}$$

$$G^{(jl,\gamma)}_{21}(z,r,r')=\begin{cases}g_{\gamma,1}(z,r')f_{\gamma,2}(z,r), & r<r',\\ f_{\gamma,1}(z,r')g_{\gamma,2}(z,r), & r>r',\end{cases} \tag{115}$$

$$G_{22}^{(jl,\gamma)}(z,r,r')=\begin{cases} g_{\gamma,2}(z,r')f_{\gamma,2}(z,r), & r<r', \\ f_{\gamma,2}(z,r')g_{\gamma,2}(z,r), & r>r', \end{cases} \tag{116}$$

and

$$\vartheta_{jl,\gamma}(z,A_{jl},B_{jl})=-\left[1-\frac{B_{jl}A_{jl}}{4c^2}+A_{jl}f_{\gamma,1}(z,R)g_{\gamma,1}(z,R)+B_{jl}f_{\gamma,2}(z,R)g_{\gamma,2}(z,R)\right]^{-1}, \tag{117}$$

$$\hat{M}_{jl,z,\gamma}^{(m)}(r)=\begin{cases} G^{(jl,\gamma)}(z,r,R)\begin{pmatrix}1\\0\end{pmatrix}, & r<R, \\ (-1)^m G^{(jl,\gamma)}(z,r,R)\begin{pmatrix}1\\0\end{pmatrix}, & r>R, m=1,2, \end{cases} \tag{118}$$

$$\tilde{M}_{jl,z,\gamma}^{(m)}(r)=\begin{cases} G^{(jl,\gamma)}(z,r,R)\begin{pmatrix}0\\1\end{pmatrix}, & r<R, \\ (-1)^m G^{(jl,\gamma)}(z,r,R)\begin{pmatrix}0\\1\end{pmatrix}, & r>R, m=1,2, \end{cases} \tag{119}$$

where Green matrix for the radial Dirac-Coulomb operator defined by the equation (111).

Proof:

One may follow step by step the proof of theorem 2.3.

Remark 1: As in the case of Sec. II B, the resolvent of $H_{\gamma,\underline{G}}$ may be obtained from Eq. (111) and the decomposition (82).

C. Spectral properties

Theorem 4.2: For $A_{jl},B_{jl}\in(-\infty,\infty)$, $l\in[j-\frac{1}{2},j+\frac{1}{2}]$, $j\in[\frac{1}{2},\infty)$ and $\gamma\in\mathbb{R}$, the essential spectrum of $h_{jl,\gamma,G_{jl}}$ is purely absolutely continuous and coincide with $(\infty,-c^2/2]\cup[c^2/2,\infty)$. Its singular continuous and residual spectra are empty.[12] The bound states of $h_{jl,\gamma,G_{jl}}$ in the gap $(-c^2/2,c^2/2)$ coincide with the poles of the resolvent equation (111) in $\mathrm{Im}\,k>0$.

D. The nonrelativistic limit

Theorem 4.3: For spin-$\frac{1}{2}$ particles, i.e., $l=j+\frac{1}{2}$, one obtain

$$n.\lim_{c\to\infty}\left(h_{jl,\gamma,G_{jl}}-\frac{c^2}{2}-z\right)^{-1}=(h_{l,\gamma,\hat{\beta}_l}-z)^{-1}\otimes\begin{pmatrix}1&0\\0&0\end{pmatrix}, \quad z\in\mathbb{C}\backslash\mathbb{R}, \tag{120}$$

where $h_{l,\gamma,\hat{\beta}_l}$ is defined by

$$h_{l,\gamma,\hat{\beta}_l}=-\frac{d^2}{dr^2}+\frac{l(l+1)}{r^2}+\frac{\gamma}{r},$$

$$\mathcal{D}(h_{l,\gamma,\hat{\beta}_l})=\Bigg\{f\in L^2((0,\infty))\Bigg|\, f,f'\in \mathrm{AC}_{loc}((0,\infty)\backslash\{R\});f(0+)=0 \text{ if } l=0;$$

$$f'(R+)-f'(R-)=\frac{\alpha_l}{2}[f(R+)+f(R-)];$$

$$f(R+)-f(R-)=\frac{\beta_l}{2}[f'(R+)+f'(R-)]-f''+l(l+1)r^{-2}f+\gamma r^{-1}f\in L^2((0,\infty))\Bigg\},$$

$$-\infty<\alpha_l,\beta_l\leqslant\infty;\ \ l\in\mathbb{N}_0,\ \ \gamma\in\mathbb{R}. \tag{121}$$

If $\alpha_l\beta_l-4=0,\alpha_l,\beta_l\in\mathbb{R}$, then one can show that the boundary conditions in (121) define a self-adjoint extension of $\dot{h}_{l,\gamma}$ defined by

$$\dot{h}_{l,\gamma}=-\frac{d^2}{dr^2}+\frac{l(l+1)}{r^2}+\frac{\gamma}{r}$$

$$\mathcal{D}(\dot{h}_{l,\gamma})=\{f\in L^2((0,\infty))|f,f'\in \mathrm{AC}((0,\infty));f(0+)=0 \text{ if } l=0;f(R\pm)=f'(R\pm)=0;$$
$$-f''+l(l+1)r^{-2}f+\gamma r^{-1}f\in L^2((0,\infty))\},\quad \gamma\in\mathbb{R},l=0. \tag{122}$$

The Hamiltonian $h_{l,\gamma,\hat{\beta}_l}$ provides a generalization of the nonrelativistic δ-sphere interaction of the first and second kind plus a Coulomb interaction discussed in Ref. 2.

E. Scattering theory for the pair $(h_{jl,\gamma,G_{jl}};h_{\gamma,D})$

For $k(z)>0$, we define the function

$$\begin{pmatrix}F_{\gamma,G_{jl},1}(z,r)\\F_{\gamma,G_{jl},2}(z,r)\end{pmatrix}=\begin{pmatrix}f_{\gamma,1}(z,r)\\f_{\gamma,2}(z,r)\end{pmatrix}+\vartheta_{jl,\gamma}(z,A_{jl},B_{jl})\Bigg\{G^{(jl,\gamma)}(z,r,R)\Bigg[A_{jl}\begin{pmatrix}f_{\gamma,1}(z,R)\\0\end{pmatrix}$$
$$+B_{jl}\begin{pmatrix}0\\f_{\gamma,2}(z,R)\end{pmatrix}\Bigg]+\frac{A_{jl}B_{jl}}{2c}\hat{G}^{(jl,\gamma)}(z,r,R)\Bigg[\begin{pmatrix}0\\f_{\gamma,1}(z,R)\end{pmatrix}-\begin{pmatrix}f_{\gamma,2}(z,R)\\0\end{pmatrix}\Bigg]\Bigg\}, \tag{123}$$

where

$$\hat{G}^{(jl,\gamma)}(z,r,R)=\begin{cases}G^{(jl,\gamma)}(z,r,R), & r<R,\\ -G^{(jl,\gamma)}(z,r,R), & r>R,\end{cases} \tag{124}$$

$G^{(jl,\gamma)}(z,r,R)$ is the Green matrix of the radial Dirac–Coulomb operator defined by the equation (112) and the functions $f_{\gamma,1}(z,r)$, $f_{\gamma,2}(z,r)$, and $\vartheta_{jl,\gamma}(z,A_{jl},B_{jl})$ are defined by (95), (96), and (117), respectively.

A straightforward computation shows that $\binom{F_{\gamma,G_{jl},1}(z,r)}{F_{\gamma,G_{jl},2}(z,r)}$ is the wave scattering function of $h_{jl,\gamma,G_{jl}}$.

The particular cases $A_{jl}\neq 0,B_{jl}=0$ and $A_{jl}=0;\ B_{jl}\neq 0$ in Eq. (123) yield

$$\begin{pmatrix}F_{\gamma,A_{jl},1}(z,r)\\F_{\gamma,A_{jl},2}(z,r)\end{pmatrix}=\begin{pmatrix}f_{\gamma,1}(z,r)\\f_{\gamma,2}(z,r)\end{pmatrix}+A_{jl}\vartheta_{jl,\gamma}(z,A_{jl},0)G^{(jl,\gamma)}(z,r,R)\begin{pmatrix}f_{\gamma,1}(z,R)\\0\end{pmatrix} \tag{125}$$

and

$$\begin{pmatrix}F_{\gamma,B_{jl},1}(z,r)\\F_{\gamma,B_{jl},2}(z,r)\end{pmatrix}=\begin{pmatrix}f_{\gamma,1}(z,r)\\f_{\gamma,2}(z,r)\end{pmatrix}+B_{jl}\vartheta_{jl,\gamma}(z,0,B_{jl})G^{(jl,\gamma)}(z,r,R)\begin{pmatrix}0\\f_{\gamma,2}(z,R)\end{pmatrix}. \tag{126}$$

Equations (125) and (126) define the wave functions corresponding to the δ-sphere plus Coulomb interactions of the first and second type, respectively.

The asymptotic behavior of $\binom{F_{G_{jl},1}(z,r)}{F_{G_{jl},2}(z,r)}$ as $r\to\infty$ is given by[26]

$$\begin{pmatrix}F_{G_{jl},1}(z,r)\\F_{G_{jl},2}(z,r)\end{pmatrix}\xrightarrow[r\to\infty]{k(z)>0}\begin{pmatrix}V_1(z)\sin[x_1+\delta^0_{\xi}(z)]+V_2(z)\cos[x_1+\delta^0_{\xi}(z)]\\V_3(z)\sin[x_2+\delta^0_{\xi-1}(z)]+V_4(z)\cos[x_2+\delta^0_{\xi-1}(z)]\end{pmatrix}$$

$$= \begin{pmatrix} [V_1^2(z)+V_2^2(z)]^{1/2} \sin[x_1+\delta^0_{\tilde{\xi}}(z)+\delta^C_{\gamma,G_{jl},1}(z)] \\ [V_3^2(z)+V_4^2(z)]^{1/2} \sin[x_2+\delta^0_{\tilde{\xi}-1}(z)+\delta^C_{\gamma,G_{jl},2}(z)] \end{pmatrix}, \tag{127}$$

where

$$x_1 = k - \frac{\tilde{\gamma}}{2k}\ln(2kr) - \tilde{\xi}\frac{\pi}{2}, \tag{128}$$

$$x_2 = k - \frac{\tilde{\gamma}}{2k}\ln(2kr) - (\tilde{\xi}-1)\frac{\pi}{2}, \tag{129}$$

and

$$\delta^0_{\tilde{\xi}}(z) = \delta^0_{\tilde{\xi}-1}(z) + \arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right), \tag{130}$$

$$\delta^0_{\tilde{\xi}}(z) = \arg\Gamma\left(\tilde{\xi}+1+\mathrm{i}\frac{\tilde{\gamma}}{2k}\right). \tag{131}$$

The Coulomb modified phase shift $\delta^C_{\gamma,G_{jl}}(z)$ corresponding to $h_{jl,\gamma,G_{jl}}$ is given by

$$\delta^C_{\gamma,G_{jl}}(z) = \begin{pmatrix} \delta^C_{\gamma,G_{jl},1}(z) \\ \delta^C_{\gamma,G_{jl},2}(z) \end{pmatrix}, \tag{132}$$

where

$$\delta^C_{\gamma,G_{jl},1}(z) = -\arctan\frac{V_2(z)}{V_1(z)}, \tag{133}$$

$$\delta^C_{\gamma,G_{jl},2}(z) = -\arctan\frac{V_4(z)}{V_3(z)}. \tag{134}$$

The constants $V_i (i=1,\ldots,4)$ are defined by

$$V_1(z) = d_1(z) + [d_2(z) - \mathrm{i}\vartheta'_{jl,\gamma}(z)d_4(z)]\sin\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right] - \mathrm{i}\vartheta'_{jl,\gamma}(z)d_3(z)$$
$$- \vartheta'_{jl,\gamma}(z)d_4(z)\cos\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right], \tag{135}$$

$$V_2(z) = [d_2(z) - \mathrm{i}\vartheta'_{jl,\gamma}(z)d_4(z)]\cos\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right] + \vartheta'_{jl,\gamma}(z)d_3(z)$$
$$+ \vartheta'_{jl,\gamma}(z)d_4(z)\sin\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right], \tag{136}$$

$$V_3(z)=\left[-\frac{\gamma}{\kappa_{jl}c+\xi}d_1(z)+\mathrm{i}\vartheta'_{jl,\gamma}(z)\frac{\gamma}{\kappa_{jl}c+\xi}d_3(z)\right]\sin\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]-\left(\frac{\gamma}{\kappa_{jl}c+\xi}\right)^{-1}d_2(z)$$
$$-\vartheta'_{jl,\gamma}(z)\frac{\gamma}{\kappa_{jl}c+\xi}d_3(z)\cos\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]+\mathrm{i}\vartheta'_{jl,\gamma}(z)\left(\frac{\gamma}{\kappa_{jl}c+\xi}\right)^{-1}d_4(z), \tag{137}$$

$$V_4(z)=\left[-\frac{\gamma}{\kappa_{jl}c+\xi}d_1(z)+\mathrm{i}\vartheta'_{jl,\gamma}(z)\frac{\gamma}{\kappa_{jl}c+\xi}d_3(z)\right]\cos\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]$$
$$-\vartheta'_{jl,\gamma}(z)\frac{\gamma}{\kappa_{jl}c+\xi}d_3(z)\sin\left[\arctan\left(\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]-\vartheta'_{jl,\gamma}(z)\left(\frac{\gamma}{\kappa_{jl}c+\xi}\right)^{-1}d_4(z) \tag{138}$$

with $\vartheta'_{jl}(z,A_{jl},B_{jl})$ defined by

$$\vartheta'_{jl}(z)=\vartheta_{jl}(z,A_{jl},B_{jl})[A_{jl}f_{\gamma,1}(z,R)f_{\gamma,1}(z,R)+B_{jl}f_{\gamma,2}(z,R)f_{\gamma,2}(z,R)]. \tag{139}$$

The constants $d_i(z)(i=1,\ldots,4)$ are given by

$$d_1(z)=\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}2^{-\tilde{\xi}}(k)^{-\tilde{\xi}-1}\Gamma(2\tilde{\xi}+2)$$
$$\times\left|\Gamma\left(\tilde{\xi}+1+\mathrm{i}\frac{\tilde{\gamma}}{2k}\right)\right|^{-1}e^{\pi(\tilde{\gamma}/4k)}, \tag{140}$$

$$d_2(z)=-\frac{\gamma}{c(\kappa_{jl}c+\xi)}\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}2^{-\tilde{\xi}}(k)^{-\tilde{\xi}}$$
$$\times\Gamma(2\tilde{\xi}+2)\left|\Gamma\left(\tilde{\xi}+1+\mathrm{i}\frac{\tilde{\gamma}}{2k}\right)\right|^{-1}e^{\pi(\tilde{\gamma}/4k)}, \tag{141}$$

$$d_3(z)=\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}2^{\tilde{\xi}}(k)^{\tilde{\xi}}$$
$$\times\Gamma(2\tilde{\xi}+2)^{-1}\left|\Gamma\left(\tilde{\xi}+1+\mathrm{i}\frac{\tilde{\gamma}}{2k}\right)\right|e^{-\pi(\tilde{\gamma}/4k)}, \tag{142}$$

$$d_4(z)=-\frac{\gamma}{c(\kappa_{jl}c+\xi)}\left(1-\frac{\gamma^2}{(\kappa_{jl}c+\xi)^2}\right)^{-1/2}\left[\cos\left(\arctan\frac{\tilde{\gamma}}{2k\tilde{\xi}}\right)\right]^{-1/2}2^{\tilde{\xi}}(k)^{\tilde{\xi}+1}$$
$$\times\Gamma(2\tilde{\xi}+2)^{-1}\left|\Gamma\left(\tilde{\xi}+1+\mathrm{i}\frac{\tilde{\gamma}}{2k}\right)\right|e^{-\pi(\tilde{\gamma}/4k)}. \tag{143}$$

The limit $\gamma\to 0+$, in (133) and (134) yields

$$\lim_{\gamma\to 0+}\delta^C_{\gamma,G_{jl},1}(z)=\lim_{\gamma\to 0+}\delta^C_{\gamma,G_{jl},2}(z)=\delta_{G_{jl}}(z), \tag{144}$$

where $\delta_{G_{jl}}(z)$ is defined by (71).

The Coulomb modified on-shell scattering matrix is given by

$$S^{C}_{\gamma,G_{jl},n}(z)=e^{2i\delta^{C}_{\gamma,G_{jl},n}(z)},\quad n=1,2. \tag{145}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 12 DECEMBER 2002

Boundary states, extended symmetry algebra, and module structure for certain rational torus models

Ioannis Smyrnakis[a)]
Department of Applied Mathematics, University of Crete, L. Knosou-Ambelokipi, 71409 Iraklio Crete, Greece

(Received 23 May 2002; accepted 20 August 2002)

The massless bosonic field compactified on the circle of rational R^2 is reexamined in the presense of boundaries. A particular class of models corresponding to $R^2 = 1/2k$ is distinguished by demanding the existence of a consistent set of Neumann boundary states. The boundary states are constructed explicitly for these models and the fusion rules are derived from them. These are the ones prescribed by the Verlinde formula from the S-matrix of the theory. In addition, the extended symmetry algebra of these theories is constructed, which is responsible for the rationality of these theories. Finally, the chiral space of these models is shown to split into a direct sum of irreducible modules of the extended symmetry algebra. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1517168]

I. INTRODUCTION

The massless bosonic field compactified on the circle has been particularly useful for studying the moduli space of $c=1$ theories.[1,2] In this case, there are two continuous families of theories corresponding to the torus and the Z_2 orbifold models. Theories in each family are connected by marginal operator deformations. In both cases there is a duality that identifies the model with radius R with the model with radius $1/2R$. Also the theory corresponding to $R=\sqrt{2}$ for the torus models is identified with the $R=1/\sqrt{2}$ theory for the orbifold models. For the self-dual radius $R=1/\sqrt{2}$ the theory possesses an extended $SU(2)\times SU(2)$ symmetry. By dividing this symmetry by the three special discrete subgroups of $SU(2)$, the tetrahedral, octahedral, and icosahedral,[1] we constructed three more theories that are not connected to the others by marginal operator deformations. This list of $c=1$ theories has been shown to be complete in the case where the partition function is a linear combination of toroidal partition functions by Ref. 2. However the partition functions of these theories contain an infinite sum of products of holomorphic times antiholomorphic Virasoro characters, as predicted by a theorem of Ref. 3. In the particular case where R^2 is rational, these products group into a finite sum of holomorphic times antiholomorphic blocks. Furthermore this is the complete list of $c=1$ theories possessing this property as proven in Ref. 4.

Next we consider conformal field theory on surfaces with boundaries.[5] On the finite cylinder it is possible to construct a partition function in two ways: either through a closed string propagating between two boundary states or through an open string satisfying corresponding boundary conditions propagating around a loop. Compatibility between these two points of view gives two conditions on the boundary states. One is the Ishibashi condition[6] arising from the restriction of the conformal field theory to the upper half plane (necessary in the open string picture) and the other is the Cardy condition,[7,8] which arises from the representational compatibility of the two constructions. Cardy, in particular, showed that given the Verlinde formula and a complete set of Ishibashi states it is possible to construct a consistent set of boundary states for diagonal theories. In the particular case where the representation space of the theory splits into a direct sum of irreducible representations of an extended $\widehat{su}(2)$ chiral algebra, the Ishibashi states have been constructed in Ref. 6. The case of the Z_2 orbifold model at radius 1 has been considered in Ref. 9.

a)Electronic mail: smyrnaki@tem.uoc.gr

In this case boundary states have been derived that do not correspond to bulk operators.

In this work we study the rational torus models from the boundary CFT point of view. We distinguish a particular class of models ($R=1/\sqrt{2k}$) which posesses a consistent set of Neumann boundary states (or dually Dirichlet boundary states) in the sense of Ref. 7. These boundary states have been constructed explicitly. Next the extended symmetry algebra of these theories has been written down. Finally the infinite direct sum of Fock modules, which constitutes the chiral representation space of this particular set of torus models, is shown to decompose into a finite sum of irreducible extended algebra modules.

II. TORUS MODELS REVISITED

These models correspond to a free massless real bosonic field compactified on a circle of radius R. The action in this case is

$$S=\frac{1}{2\pi}\int \partial X\bar{\partial}X. \tag{1}$$

The partition function for these models turns out to be

$$Z(\beta)=\sum_{m,n}\frac{q^{(1/2)(m/2R+nR)^2}}{\eta(q)}\frac{\bar{q}^{(1/2)(m/2R-nR)^2}}{\eta(\bar{q})}. \tag{2}$$

Here $q=e^{2\pi i\tau}=e^{-2\pi\beta}$, $\beta=-i\tau$, and $\eta(q)$ is the Jacobi eta function. The representation space for these models can be read of from the partition function to be

$$H=\bigoplus_{n,m\epsilon Z} F_{\alpha_{m,n}}\otimes F_{\bar{\alpha}_{m,n}}, \tag{3}$$

where the possible charges are $\alpha_{m,n}=m/2R-nR$ and $\bar{\alpha}_{m,n}=m/2R-nR$.

In the particular case $R^2=p/p'$ the partition function becomes a finite sum of holomorphic times antiholomorphic parts:

$$Z(q)=\sum_{r=0}^{2p-1}\sum_{s=0}^{2p'-1} f_{r,s}(q)f_{r,-s}(\bar{q}), \tag{4}$$

where

$$f_{r,s}(q)=\sum_{n\epsilon Z}\frac{q^{2pp'(n+(r/4p)+(s/2p'))^2}}{\eta(q)}. \tag{5}$$

Now consider the free field more closely. We can view our field as describing an open string propagating along a strip periodic in the horizontal direction but with boundary conditions along the end point lines of the string. What we really have in this way is an open string propagating along the sides of a cylinder, while it obeys boundary conditions on the end point circles. The length of the circumference will be taken to be β, while the height of the cylinder will be 1/2. This one loop open string diagram is equivalent to a closed string propagating along the cylinder from one boundary to the other. The boundaries of the closed string are to be interpreted as states. Following the closed string picture we will take time to be the vertical direction. The free field admits now the following expansion into oscillator modes:

$$\phi(\sigma,t)=\hat{x}+\frac{2\pi}{\beta}R\hat{w}\sigma+\frac{\pi}{\beta}\hat{p}t+\frac{1}{2}i\sum_{n\neq 0}\left(\frac{a_n}{n}\exp\left(-\frac{2\pi i}{\beta}n(t+\sigma)\right)+\frac{\tilde{a}_n}{n}\exp\left(-\frac{2\pi i}{\beta}n(t-\sigma)\right)\right). \tag{6}$$

This splits into left and right modes according to

$$\phi(\sigma,t)=\phi_L(x^+)+\phi_R(x^-), \tag{7}$$

where $x^+=t+\sigma$ and $x^-=t-\sigma$. Here

$$\begin{aligned}\phi_L(x^+)&=\frac{\hat{x}}{2}+\frac{\pi}{\beta}a_0x^+ +\frac{1}{2}i\sum_{n\neq 0}\frac{a_n}{n}\exp\left(-\frac{2\pi i}{\beta}nx^+\right),\\ \phi_R(x^-)&=\frac{\hat{x}}{2}+\frac{\pi}{\beta}\tilde{a}_0x^- +\frac{1}{2}i\sum_{n\neq 0}\frac{\tilde{a}_n}{n}\exp\left(-\frac{2\pi i}{\beta}nx^-\right),\end{aligned} \tag{8}$$

where $a_0=\hat{p}/2+R\hat{w}$ and $\tilde{a}_0=\hat{p}/2-R\hat{w}$. The Hamiltonian in the closed string picture turns out to be

$$H_\beta=\frac{2\pi}{\beta}\left[(R\hat{w})^2+(\hat{p}/2)^2+\sum_{n=1}^{\infty}a_{-n}a_n+\sum_{n=1}^{\infty}\tilde{a}_{-n}\tilde{a}_n-1/12\right]. \tag{9}$$

Using the oscillator mode representation of the Virasoro generators

$$\begin{aligned}L_m&=\frac{1}{2}\sum_{-\infty}^{\infty}:a_{m-n}a_n:,\\ \overline{L}_m&=\frac{1}{2}\sum_{-\infty}^{\infty}:\tilde{a}_{m-n}\tilde{a}_n:,\end{aligned} \tag{10}$$

we have that

$$H_\beta=\frac{2\pi}{\beta}(L_0+\overline{L}_0-1/12). \tag{11}$$

The boundary states of the closed string have to satisfy the Ishibashi condition[6]:

$$(L_n-\overline{L}_{-n})|B\rangle=0. \tag{12}$$

This is certainly satisfied if

$$(a_m\pm\tilde{a}_{-m})|B\rangle=0. \tag{13}$$

The plus sign corresponds to Neumann boundary conditions in the open string picture while the minus sign corresponds to Dirichlet boundary conditions.[9] Solving the conditions (13) we get the following Ishibashi states:

$$\begin{aligned}|\iota^N_{nR}\rangle&=\exp\left(-\sum_{n=1}^{\infty}\frac{a_{-n}\tilde{a}_{-n}}{n}\right)|p=0,\quad w=nR\rangle,\\ |\iota^D_{m/2R}\rangle&=\exp\left(\sum_{n=1}^{\infty}\frac{a_{-n}\tilde{a}_{-n}}{n}\right)\left|\frac{p}{2}=\frac{m}{2R},\quad w=0\right\rangle.\end{aligned} \tag{14}$$

Note that in the Neumann case the zero mode condition demands that there is no momentum while in the Dirichlet case it demands that there is no winding. Now we have the following lemma:

Lemma 1: The Ishibashi states (14) give rise to the following inner products:

$$\langle \iota^N_{nR}|e^{-H_{\beta/2}}|\iota^N_{mR}\rangle = \frac{\tilde{q}^{R^2n^2/2}}{\eta(\tilde{q})}\delta_{n,m},$$

$$\langle \iota^D_{n/2R}|e^{-H_{\beta/2}}|\iota^D_{m/2R}\rangle = \frac{\tilde{q}^{n^2/8R^2}}{\eta(\tilde{q})}\delta_{n,m}, \tag{15}$$

$$\langle \iota^N_{nR}|e^{-H_{\beta/2}}|\iota^D_{m/2R}\rangle = \tilde{q}^{-1/24}\prod_{n=1}^{\infty}\frac{1}{1+\tilde{q}^n}\delta_{n,0}\delta_{m,0} = \frac{\Sigma_{n\epsilon Z}(-1)^n\tilde{q}^{n^2}}{\eta(\tilde{q})}\delta_{n,0}\delta_{m,0},$$

where $\tilde{q}=e^{-2\pi/\beta}$.

The proof of this lemma is a simple free field calculation. Note that it is possible to interchange the Neumann and Dirichlet Ishibashi states by interchanging the directions of t and σ.

There is however another condition that must be satisfied by the boundary states.[7] This states that if $|X_A\rangle$ are the boundary states, then

$$Z_{AB}(\beta)=\langle X_A|e^{-H_{\beta/2}}|X_B\rangle=\sum_i n^i_{AB}\chi_i(q) \tag{16}$$

for some integers n^i_{AB} where $q=e^{-2\pi i\beta}$. In particular there is a special vacuus state $|X_0\rangle$ for which $n^i_{0j}=\delta_{i,j}$. This condition arises from the possibility to see $Z_{AB}(\beta)$ as an one loop amplitude of an open string satisfying the boundary conditions A,B on the boundary circles.

Now let us restrict ourselves to the Neumann sector. Consider the case R^2 is rational, and let us demand that there is a Neumann vacuum boundary state

$$|X^N_0\rangle=\sum_{n\epsilon Z} C_n|\iota^N_{nR}\rangle. \tag{17}$$

Of course demanding a Dirichlet vacuum boundary state is completely equivalent because of the t, σ interchange duality. Consider the partition function on the cylinder with two vacuum boundary states at the boundary circles:

$$Z_{00}(\beta)=\langle X^N_0|e^{-H_{\beta/2}}|X^N_0\rangle=\sum_{n\epsilon Z}|C_n|^2\frac{\tilde{q}^{R^2n^2/2}}{\eta(\tilde{q})}. \tag{18}$$

According to the Cardy condition,[7] $Z_{00}(\beta)$ must be equal to the vacuum character. To change the variable from $\tilde{q}$ to q, we need to use the Poisson resummation formula, which in this case takes the form:

$$\sum_{n\epsilon Z}\frac{\tilde{q}^{A(n+b)^2}}{\eta(\tilde{q})}=\frac{1}{\sqrt{2A}}\sum_{n\epsilon Z}\frac{q^{(n^2/4A)}e^{2\pi inb}}{\eta(q)}. \tag{19}$$

In the case of the rational theories and in order to be able to get the identity character after use of formula (19) there must exist a minimum integer m such that the constants C_n in the classes $n=r \bmod m$ are equal. This gives rise to the following partition function:

$$Z_{00}(\beta)=\sum_{r=0}^{m-1}|C_r|^2\sum_{n\epsilon Z}\frac{\tilde{q}^{(m^2R^2/2)(n+(r/m))^2}}{\eta(\tilde{q})}=\sum_{r=0}^{m-1}\frac{|C_r|^2}{mR}\sum_{n\epsilon Z}\frac{q^{(n^2/2m^2R^2)\rangle}e^{2\pi in(r/m)}}{\eta(q)}. \tag{20}$$

Now letting $n=mn'+s$ we get

$$Z_{00}(\beta)=\sum_{r,s=0}^{m-1}\frac{|C_r|^2}{mR}e^{2\pi irs/m}\sum_{n'\epsilon Z}\frac{q^{[(n'+s/m)^2/2R^2]}}{\eta(q)}. \tag{21}$$

Since $s/m<1$, the power $q^{1/2R^2}$ appears only when $s=0$, and taking into account that in the vacuum character only integer powers of q appear and that

$$\sum_{r=0}^{m-1}\frac{|C_r|^2}{mR}\neq 0$$

we have that

$$R^2=\frac{1}{2k}. \tag{22}$$

These are the values of the radius that we are going to analyze further. For these values the closed string partition function regroups to

$$Z(\beta)=\sum_{s=0}^{2k-1}\chi_s(q)\chi_{-s}(\overline{q}), \tag{23}$$

where

$$\chi_s(q)=\sum_{n\epsilon Z}\frac{q^{k(n+s/2k)^2}}{\eta(q)}. \tag{24}$$

The vacuum character must be a partial sum of $\chi_0(q)$. Comparing this with $Z_{00}(\beta)$ we get that $s=0$, which in turn means that $\chi_0(q)$ itself is the vacuum character. Furthermore it is necessary that all $|C_r|$ are equal, so that the value $s=0$ is the only one that survives the sum over r. So, without loss of generality we can assume that $m=1$. In this case we have

$$Z_{00}(\beta)=\frac{|C|^2}{R}\sum_{n\epsilon Z}\frac{q^{kn^2}}{\eta(q)}. \tag{25}$$

Equality with $\chi_0(q)$ demands that $|C|=\sqrt{R}=1/\sqrt[4]{2k}$. So the corresponding vacuum state is

$$|X_0^N\rangle=\frac{1}{\sqrt[4]{2k}}\sum_{n\epsilon Z}|\iota^N_{n/\sqrt{2k}}\rangle=\frac{1}{\sqrt[4]{2k}}\sum_{l=0}^{2k-1}\sum_{n\epsilon Z}|\iota^N_{\sqrt{2k}(n+l/2k)}\rangle. \tag{26}$$

Now it is necessary (because of the Cardy condition) that

$$Z_{0m}(\beta)=\chi_m(q)=\frac{1}{\sqrt{2k}}\sum_{l=0}^{2k-1}\exp\left(\frac{2\pi ilm}{2k}\right)\chi_l(\tilde{q}). \tag{27}$$

This demands that the other boundary states are

$$|X_m^N\rangle=\frac{1}{\sqrt[4]{2k}}\sum_{l=0}^{2k-1}\exp\left(\frac{2\pi ilm}{2k}\right)\sum_{n\epsilon Z}|\iota^N_{\sqrt{2k}(n+l/2k)}\rangle. \tag{28}$$

It is not too difficult to check that

$$Z_{m_1 m_2}=\frac{1}{2k}\sum_{l,m=0}^{2k-1}\exp\left(2\pi i l\frac{(m_2-m_1+m)}{2k}\right)\chi_m(q)=\chi_{m_1-m_2}(q). \tag{29}$$

This is certainly an integer sum of characters so the Cardy condition is satisfied. It is worth mentioning that since the construction of the boundary states is based on the modular properties of the characters the Verlinde formula gives integer fusion rules as was necessary. In particular we can read from (27) that

$$S_l^j=\frac{1}{\sqrt{2k}}\exp\left(\frac{2\pi i j l}{2k}\right)$$

and from the Verlinde formula

$$\sum_{i=0}^{2k-1} S_i^j N_{k'l}^i=S_k'^j S_l^j/S_0^j \tag{30}$$

we can read the fusion rules

$$N_{k'l}^i=\delta_{(i,k'+l)\bmod 2k}. \tag{31}$$

III. EXTENDED SYMMETRY ALGEBRA

We will now try to find which extended symmetry gives rise to the characters $\chi_m(q)$ for each k. Consider first the identity character

$$\chi_0(q)=\frac{\Sigma_{n\epsilon Z}q^{kn^2}}{\eta(q)}=q^{-1/24}\frac{1+2q^k+2q^{4k}+\cdots+2q^{n^2k}+\cdots}{(1-q)(1-q^2)\cdots(1-q^k)(1-q^{k+1})\cdots}. \tag{32}$$

Expanding in q we get

$$\begin{aligned}\chi_0(q)=q^{-1/24}([1+P(1)q+P(2)q^2+\cdots+P(k-1)q^{k-1}]+q^k[[P(k)+2]+[P(k+1)\\ +2P(1)]q+\cdots+[P(4k-1)+2P(3k-1)]q^{3k-1}]+\cdots+q^{n^2k}[[P(n^2k)+\cdots+2]\\ +\cdots+[P((n+1)^2k-1)+\cdots+2P((2n+1)k-1)]q^{(2n+1)r-1}]+\cdots).\end{aligned} \tag{33}$$

Here $P(n)$ is the number of partitions of n. Now the Fock module built on the zero charge vacuum, F_0, has $P(n)$ linearly independent states at level n. From the above-given expansion we see that at level k we have two extra linearly independent states that are orthogonal to F_0, and since they are the first such states they have to be killed by all a_n for n positive. So they can be taken to be the highest weight Fock states of charge $\alpha_{nm}=\pm\sqrt{2k}$ because the L_0 eigenvalue $h_{nm}=k$. They are generated by the spin k currents

$$J^{\pm}(z)=e^{\pm i\sqrt{2k}\phi(z)}. \tag{34}$$

Here we have taken $\phi(z)=2\phi_L(x^+)$ and $z=e^{2\pi i x^+/\beta}$. Clearly, $J^{\pm}$ adds charge $\pm\sqrt{2k}$ on the states it acts on. There is of course another current, of spin 1, the $U(1)$ current, which we take to be

$$J^0(z)=\frac{1}{\sqrt{2k}}i\partial\phi(z). \tag{35}$$

Now we have the following lemma:

Lemma 2: The modes of the above currents generate the space $\oplus_{n\epsilon Z}F_{n\sqrt{2k}}$.

Proof: To prove this consider the mode expansion of the $J^+(z)$ current acting on the zero charge vacuum:

$$\sum_{n\epsilon Z} J_n^+ z^{-n-k}|0\rangle = \exp\left(\sqrt{2k}\sum_{n>0}\frac{a_{-n}}{n}z^n\right)|\sqrt{2k}\rangle, \tag{36}$$

where by $|\sqrt{2k}\rangle$ we denote the vacuum state of charge $\sqrt{2k}$. From this relation we see that

$$J_0^+|0\rangle = 0, \quad J_{-1}^+|0\rangle = 0,\cdots, \quad J_{-k+1}^+|0\rangle = 0, \quad J_{-k}^+|0\rangle = |\sqrt{2k}\rangle. \tag{37}$$

Similarly we get that $J_{-k}^-|0\rangle = |-\sqrt{2k}\rangle$. These are the extra states at level k. Of course since the modes of $J^0(z)$ can act on those states all the Fock descendents of the states $|\pm\sqrt{2k}\rangle$ are generated by the current modes. If we move to level $k+r$ then the number of them is $2P(r)$. Together with the descendents of $|0\rangle$ we have overall $P(k+r)+2P(r)$ states. This takes account of the second bracket in (33). But at level $4k$ there are again two more states. To take account of them consider the product

$$J^+(z)J_{-k}^+|0\rangle = J^+(z)|\sqrt{2k}\rangle = z^{2k}\exp\left(\sqrt{2k}\sum_{n>0}\frac{a_{-n}}{n}z^n\right)|2\sqrt{2k}\rangle. \tag{38}$$

This means that we have

$$J_0^+J_{-k}^+|0\rangle = 0, \quad J_{-1}^+J_{-k}^+|0\rangle = 0,\cdots, \quad J_{-3k+1}^+J_{-k}^+|0\rangle = 0, \quad J_{-3k}^+J_{-k}^+|0\rangle = |2\sqrt{2k}\rangle. \tag{39}$$

Considering also $J_{-3k}^-J_{-k}^-|0\rangle$ we get the extra two states at level $4k$. Again at level $4k+r$ we have all the Fock descendents of $|0\rangle$, $J_{-k}^\pm|0\rangle = |\pm\sqrt{2k}\rangle$, and $J_{-3k}^\pm J_{-k}^\pm|0\rangle = |\pm 2\sqrt{2k}\rangle$. The number of these states is $P(4k+r)+2P(3k+r)+2P(r)$. Continuing in this fashion we get two extra states appearing at every level of the form n^2k, as indicated by (32). They are of the form

$$J_{-(2n-1)k}^\pm\cdots J_{-3k}^\pm J_{-k}^\pm|0\rangle = |\pm n\sqrt{2k}\rangle. \tag{40}$$

Of course all the Fock descendents of these states are created by the J^0 modes so we have that the current modes generate completely the direct sum $\oplus_{n\epsilon Z}F_{n\sqrt{2k}}$. This ends the proof of the lemma.

The next question is what are the OPEs satisfied by these high spin currents. This is not too difficult to obtain. These are the following:

$$\begin{aligned} J^0(z)J^\pm(w) &= \pm\frac{1}{z-w}J^\pm(w)+\text{reg}, \\ J^+(z)J^-(w) &= \frac{1}{(z-w)^{2k}}\exp n_{O(2k-1)}e^{i\sqrt{2k}(\phi(z)-\phi(w))}+\text{reg}. \end{aligned} \tag{41}$$

The second operator product has to be expressed in terms of the currents. This is possible by expanding $\phi(z)$ near w:

$$\begin{aligned} J^+(z)J^-(w) = \frac{1}{(z-w)^{2k}}\exp n_{O(2k-1)}\exp\Bigg(2k\Bigg[&(z-w)J^0(w)+\cdots \\ &+\frac{(z-w)^{2k-1}}{(2k-1)!}\partial^{2k-2}J^0(w)\Bigg]\Bigg)+\text{reg}. \end{aligned} \tag{42}$$

Here by $\exp n_{O(2k-1)}$ we mean expansion up to and including terms of order $(z-w)^{2k-1}$. At this point it is worth mentioning that our product $J^+(z)J^-(w)$ is a bilocal field in the sense of Ref. 10. There it was remarked that for $k=1/2$ (unaccepted value for us) this product is the generating

function for the $W_{1+\infty}$ algebra. Here however we will restrict our attention to integer values of k. Now, the product (42) can be expanded in terms of Schur polynomials. In general the Schur polynomials are defined by

$$\exp\left(\sum_{k=1}^{\infty} t_k z^k\right)=\sum_{N=0}^{\infty} z^N S_N(t_1,t_2,\ldots,t_k,\ldots) \tag{43}$$

and they turn out to be

$$S_N(t_1,t_2,\ldots,t_k,\ldots)=\sum_{n_1,\ldots,n_k,\ldots}^{\Sigma_{k=1}^{\infty} k n_k=N} \frac{t_1^{n_1}\cdots t_k^{n_k}\cdots}{n_1!\cdots n_k!\cdots}. \tag{44}$$

Let us now define, following Ref. 10, the associated polynomials:

$$f^l(\partial^i J^0(z))=(l)!:S_l\left(J^0(z),\frac{\partial J^0(z)}{2!},\cdots,\frac{\partial^{l-1}J^0(z)}{l!}\right):. \tag{45}$$

They satisfy the following recurrence relation:

$$f^{l+1}(\partial^i J^0(z))=(J^0(z)+\partial)f^l(\partial^i J^0(z))=\cdots=(J^0(z)+\partial)^l J^0(z). \tag{46}$$

Now using these new definitions we have

$$\begin{aligned} J^+(z)J^-(w)&=\frac{1}{(z-w)^{2k}}\left(\sum_{N=0}^{2k-1} S_N(2kJ^0(w),\ldots,2k\partial^{2k-2}J^0(w)/(2k-1)!)(z-w)^N\right)+\text{reg}\\ &=\sum_{N=0}^{2k-1}\frac{f^N(2k\partial^i J^0(w))}{N!}(z-w)^{N-2k}+\text{reg}. \end{aligned} \tag{47}$$

The next question is what is the algebra satisfied by the modes of the currents $J^+(z)$, $J^-(z)$. This can be read from the OPEs:

$$[J_n^+,J_m^-]=\oint_0\frac{dw}{2\pi i}\oint_w\frac{dz}{2\pi i}z^{n+k-1}w^{m+k-1}J^+(z)J^-(w), \tag{48}$$

where the left integral is around the origin and the right is around w. Expanding the product of currents as above we get

$$[J_n^+,J_m^-]=\sum_{N=0}^{2k-1}\frac{\Gamma(n+k)}{\Gamma(2k-N)\Gamma(N+n-k+1)}\oint_0\frac{dw}{2\pi i}w^{n+m+N-1}\frac{f^N(2k\partial^i J^0(w))}{N!}. \tag{49}$$

This suggests the following definition:

$$V^k_{m+n,N}=\oint_0\frac{dw}{2\pi i}w^{n+m+N-1}f^N(2k\partial^i J^0(w))=\oint_0\frac{dw}{2\pi i}w^{n+m+N-1}(2kJ^0(w)+\partial)^{N-1}2kJ^0(w), \tag{50}$$

where we have made use of the recurrence relation (46). In this notation (49) becomes

$$[J_n^+,J_m^-]=\sum_{N=0}^{2k-1}\frac{\Gamma(n+k)}{\Gamma(2k-N)\Gamma(N+n-k+1)\Gamma(N+1)}V^k_{n+m,N}. \tag{51}$$

Following the same procedure for the remaining commutators we get

$$[J_n^0, J_m^0] = \frac{n}{2k}\delta_{n+m}, \quad [J_n^0, J_m^\pm] = \pm J_{m+n}^\pm, \tag{52}$$

while the other commutators are 0.

Note that in particular if $k=1$ then $V_{m+n,0}^1 = \delta_{m+n}$ and $V_{m+n,1}^1 = 2J_{m+n}^0$, so in this case the commutator (51) becomes

$$[J_n^+, J_m^-] = n\delta_{m+n} + 2J_{m+n}^0 \tag{53}$$

giving rise to the $\widehat{su}(2)$ current algebra. Nevertheless it is only for $k=1$ that this algebra closes so nicely. In general the operators V_{m+n}^k belong to the universal enveloping algebra of the U(1) current.

IV. PRIMARY FIELDS

Now that we have the extended symmetry algebra, the next question is what are the primary fields with respect to this algebra. To answer this we need to consider the characters $\chi_m(q)$. Under $q \to e^{2\pi i} q$ we pick a phase $\exp(2\pi i((m^2/4k) - (1/24)))$. So the conformal dimension of the corresponding field is $h_m = m^2/4k$, $0 \leqslant m \leqslant 2k-1$. There are two Virasoro primary fields with this conformal dimension, the fields

$$V_m^\pm(z) = \exp\left(\pm i \frac{m}{\sqrt{2k}} \phi(z) \right). \tag{54}$$

Observe that for $m = 2k$ we get the two currents.

These primary fields satisfy the following operator product expansions:

$$J^0(z) V_m^\pm(w) = \pm \frac{m}{2k} \frac{V_m^\pm(w)}{z-w} + \text{reg},$$

$$\begin{aligned} J^+(z) V_m^-(w) = \frac{1}{(z-w)^m} :V_{2k-m}^+(w) \exp\Bigg(& 2k(z-w)J^0(w) + 2k\frac{(z-w)^2}{2!}\partial J^0(w) + \cdots \\ & + 2k\frac{(z-w)^{m-1}}{(m-1)!}\partial^{m-2} J^0(w) \Bigg) : + \text{reg}, \end{aligned} \tag{55}$$

$$\begin{aligned} J^-(z) V_m^+(w) = \frac{1}{(z-w)^m} :V_{2k-m}^-(w) \exp\Bigg(& -2k(z-w)J^0(w) - 2k\frac{(z-w)^2}{2!}\partial J^0(w) - \cdots \\ & - 2k\frac{(z-w)^{m-1}}{(m-1)!}\partial^{m-2} J^0(w) \Bigg) : + \text{reg}, \end{aligned}$$

where the remaining OPEs are trivial. Note that we can take the fields $V_m^+(z) = e^{i(m/\sqrt{2k})\,\phi(z)}$, $0 \leqslant m \leqslant 2k-1$ as a complete set of primary fields, since they are related to the $V_m^-(z)$ through the last of the relations (55).

V. MODULE STRUCTURE

The primary fields $V_m^+(z)$ add charge $m/\sqrt{2k}$ to the vacuum so we have

$$V_m^+(0)|0\rangle = \left| \frac{m}{\sqrt{2k}} \right\rangle. \tag{56}$$

Recall now that the chiral Fock space associated with the partition function was $H=\oplus_{n,m\epsilon Z}F_{\alpha_{nm}}$, where $\alpha_{nm}=n\sqrt{2k}+m/\sqrt{2k}$. The currents now can only add charges that are multiples of $\sqrt{2k}$. So it is natural to decompose the space H into the sum

$$H=\bigoplus_{m=0}^{2k-1}\mathcal{H}_m, \tag{57}$$

where

$$\mathcal{H}_m=\bigoplus_{n\epsilon Z}F_{m/\sqrt{2k}+n\sqrt{2k}} \tag{58}$$

is the space that is generated by the currents from $V_m^+(0)|0\rangle=|m/\sqrt{2k}\rangle$.

Let us examine now more closely what is the action of the currents on $\mathcal{H}_m$. Again by expanding the character $\chi_m(q)$ as a power series in q we see that there is one extra state appearing at the levels $n^2k-nm+m^2/4k$ and $n^2k+nm+m^2/4k$ for all positive integers n. Considering the product $J^+(z)|m/\sqrt{2k}\rangle$ we get

$$\sum_{n\epsilon Z}J_{-n}^+z^{n-k}|m/\sqrt{2k}\rangle=z^m\exp\left(\sqrt{2k}\sum_{n>0}\frac{a_{-n}}{n}z^n\right)|\sqrt{2k}+m/\sqrt{2k}\rangle. \tag{59}$$

This implies that

$$J_{-(k+m)}^+|m/\sqrt{2k}\rangle=|\sqrt{2k}+m/\sqrt{2k}\rangle \tag{60}$$

and $J_{-r}^+|m/\sqrt{2k}\rangle=0$ for all $r<k+m$. Applying $J^+(z)$ on this new state a number of times we eventually get that

$$J_{-((2n-1)k+m)}^+\cdots J_{-(3k+m)}^+J_{-(k+m)}^+|m/\sqrt{2k}\rangle=|n\sqrt{2k}+m/\sqrt{2k}\rangle. \tag{61}$$

These states account for the extra states at the levels $n^2k+nm+m^2/4k$. Applying $J^-(z)$ similarly a number of times on the state $m/\sqrt{2k}$ we get

$$J_{-((2n-1)k-m)}^-\cdots J_{-(3k-m)}^-J_{-(k-m)}^-|m/\sqrt{2k}\rangle=|-n\sqrt{2k}+m/\sqrt{2k}\rangle \tag{62}$$

and these states account for the extra states at levels $n^2k-nm+m^2/4k$.

Suppose now that the space $\mathcal{H}_m$ is reducible, as a module of our current algebra. Then there must be a state $|v_m\rangle$ other than $|m/\sqrt{2k}\rangle$ such that

$$J_n^\pm|v_m\rangle=0,\quad n>0 \tag{63}$$

and

$$J_n^0|v_m\rangle=0,\quad n>0. \tag{64}$$

Equation (64) forces us to consider the highest weight Fock states. Such states in the module $\mathcal{H}_m$ are the states $|m/\sqrt{2k}+n\sqrt{2k}\rangle$ for n integer. Suppose now that $n>0$. Applying $J^-(z)$ we get

$$\sum_{l\epsilon Z}J_l^-z^{-l-k}|m/\sqrt{2k}+n\sqrt{2k}\rangle=z^{-(m+2nk)}\exp\left(-\sqrt{2k}\sum_{l>0}\frac{a_{-l}}{l}z^l\right)|m/\sqrt{2k}+(n-1)\sqrt{2k}\rangle \tag{65}$$

and this in turn implies that

$$J_{m+(2n-1)k}^-|m/\sqrt{2k}+n\sqrt{2k}\rangle\neq 0. \tag{66}$$

Since $m+(2n-1)k$ is positive for positive n, $J_r^-|m/\sqrt{2k}+n\sqrt{2k}\rangle$ cannot be 0 for all positive r. If now $n=-n'<0$ then we need to apply $J^+(z)$. In this case we get

$$J^+_{-m+(2n'-1)k}|m/\sqrt{2k}-n'\sqrt{2k}\rangle=|m/\sqrt{2k}-(n'-1)\sqrt{2k}\rangle\neq 0. \tag{67}$$

Since $-m+(2n'-1)k$ is positive for positive n' (negative n), $J_r^+|m/\sqrt{2k}+n\sqrt{2k}\rangle$ cannot be 0 for all positive r. So $\mathcal{H}_m$ cannot be reducible. Hence we have the following theorem:

Theorem 1: *The space* $H=\oplus_{n,m\epsilon Z}F_{\alpha_{nm}}$ *where* $\alpha_{nm}=n\sqrt{2k}+m/\sqrt{2k}$ *admits the decomposition* $H=\oplus_{m=0}^{2k-1}\mathcal{H}_m$ *into irreducible modules of the algebra generated by the modes of the spin k currents* $J^{\pm}(z)$ *and the spin 1 current* $J^0(z)$. *In terms of Fock modules we have* $\mathcal{H}_m=\oplus_{n\epsilon Z}F_{m/\sqrt{2k}+n\sqrt{2k}}$.

VI. CONCLUSIONS

What we have achieved in this work is to single out a family of rational torus models by demanding the existence of a consistent set of Newmann (dually Dirichlet) boundary states. For these models we have written down the extended symmetry algebra which restricts the number of blocks to a finite number. Furthermore it is shown that the space of these torus models, which is an infinite sum of Fock modules, splits into a direct sum of a finite number of irreducible extended algebra modules.

The extended symmetry algebra that has appeared is a W-type algebra since it contains high spin currents. It should be thought of as a generalization of the SU(2) current algebra at level one, a theory which corresponds to $k=1$ in our list of theories. It is of interest to identify the algebras corresponding to the general level, in this way getting theories that may not possess free field representations. Some work in this direction has been done in the context of W-algebras in Ref. 11. A study of the representation theory of such algebras may give new examples of rational conformal field theories.

(Received 29 March 2002; accepted 6 September 2002)

Global properties of vacuum static, spherically symmetric configurations are studied in a general class of scalar-tensor theories (STTs) of gravity in various dimensions. The conformal mapping between the Jordan and Einstein frames is used as a tool. Necessary and sufficient conditions are found for the existence of solutions admitting a conformal continuation (CC). The latter means that a singularity in the Einstein-frame manifold maps to a regular surface $\mathbb{S}_{\text{trans}}$ in the Jordan frame, and the solution is then continued beyond this surface. $\mathbb{S}_{\text{trans}}$ can be an ordinary regular sphere or a horizon. In the second case, $\mathbb{S}_{\text{trans}}$ connect two epochs of a Kantowski-Sachs type cosmology. It is shown that the list of possible types of global causal structure of vacuum space–times in any STT, with any potential function $U(\phi)$, is the same as in general relativity with a cosmological constant. This is even true for conformally continued solutions. A traversable wormhole is shown to be one of the generic structures created as a result of CC. Two explicit examples are presented: the known solution for a conformal field in general relativity, illustrating the emergence of singularities and wormholes due to CC, and a nonsingular three-dimensional model with an infinite sequence of CCs. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1519667]

I. INTRODUCTION

Scalar fields with various potentials are of great significance in various branches of theoretical physics and cosmology: it is sufficient to mention, e.g., the Higgs field in particle theory and numerous quintessence models in modern cosmology. It is thus highly desirable to know which kinds of gravitationally self-bound configurations can be formed by such fields.

This article continues the study of global properties of static, spherically symmetric scalar-vacuum configurations of arbitrary dimension in various theories of gravity begun in Refs. 1–3. We will here consider scalar-tensor theories (STTs) belonging to the Bergmann–Wagoner–Nordtvedt family, where the Lagrangian depends on two essential arbitrary functions of the scalar field. It can be mentioned that STTs are among the viable alternatives to general relativity (GR), and their different versions emerge in the field limits of the candidate ''theories of everything.''

The field equations of an arbitrary STT are reduced by a conformal mapping to the equations of GR with a scalar field possessing a certain potential (the so-called Einstein frame). This article will pay special attention to the properties of such mappings. The point is that, when a manifold $\mathbb{M}[g]$ is conformally mapped to another manifold $\overline{\mathbb{M}}[\overline{g}]$ (relating the metrics by $g_{\mu\nu} = F(x)\overline{g}_{\mu\nu}$), the global properties of both manifolds are the same as long as the conformal factor F is everywhere smooth and finite. It can happen, however, that a singular surface in $\overline{\mathbb{M}}$ maps to a regular surface $\mathbb{S}_{\text{trans}}$ in $\mathbb{M}$ due to a singularity in the conformal factor F. Then $\mathbb{M}$ can be continued in a regular manner through this surface, and the global properties of $\mathbb{M}$ can be considerably richer than those of $\overline{\mathbb{M}}$: in the new region one can possibly find, e.g., new horizons or another spatial infinity. A known example of this phenomenon, to be called *conformal continua-*

a)Electronic mail: kb@rgs.mccme.ru

tion, is provided by the properties of the static, spherically symmetric solution for a conformally coupled scalar field in GR[4,5] as compared with the corresponding solution for a minimally coupled scalar field—see Sec. VI.

The Einstein-frame action for vacuum configurations in STT reads

$$S_{\mathrm{E}}=\int d^{D}x\sqrt{g}[\mathcal{R}_{\mathrm{E}}+(\partial\psi)^{2}-2V(\psi)], \tag{1}$$

i.e., coincides with the action of GR with a minimally coupled real scalar field ψ possessing a potential $V(\psi)$.

The field equations due to (1) with nontrivial potentials can be integrated explicitly in very few cases, even for highly symmetric configurations such as cosmological or static, spherically symmetric ones. Nevertheless, rather much can be said about the nature of the solutions. Examples of such general statements for non-negative potentials V are the no-hair theorems[6] discarding nontrivial scalar field for asymptotically flat black holes and the generalized Rosen theorem[7] claiming that an asymptotically flat solution with a positive mass cannot have a regular center.

It is also of interest what can happen if the asymptotic flatness and/or $V\geqslant 0$ assumptions are abandoned. Both assumptions are frequently violated in modern studies. Negative potential energy densities, in particular, the cosmological constant $V=\Lambda<0$ giving rise to the anti-de Sitter (AdS) solution or AdS asymptotic, do not lead to catastrophes (if bound below), are often treated in various aspects and quite readily appear from quantum effects like vacuum polarization.

Our previous papers[1,2] have provided some essential restrictions on the possible behavior of solutions of the theory (1) with arbitrary $V(\psi)$ in D dimensions. It has been shown, in particular, that, whatever is the potential and irrespective of the asymptotic conditions, the variable scalar field adds nothing to the list of causal structures known for $\psi=\mathrm{const}$. In the latter case V becomes a cosmological constant, and the corresponding exact solutions are well known (Schwarzschild, Schwarzschild–de Sitter, Schwarzschild–anti-de Sitter and their multidimensional analogs) along with their causal structures.

The possibility of regular configurations without a center (wormholes and horns) was also ruled out.

As was shown in Refs. 1 and 2, the above results can be extended to (i) generalized scalar field Lagrangians in GR, with an arbitrary dependence on the ψ field and its gradient squared, and (ii) to multiscalar field theories of sigma-model type in GR. To scalar-tensor theories, as is clear from the aforesaid, the same results can be extended only partly and only in the absence of conformal continuation (CC). This phenomenon is of particular interest since it widens the set of possible configurations. A study of possible CCs in the Jordan frames of STT was begun in Ref. 3 and is continued here more systematically and in more detail. Moreover, we will discuss the global properties of conformally continued space–times.

We will here avoid a detailed discussion of which conformal frame (Jordan or Einstein) in STT should be regarded as the physical one, refering to Ref. 8 and references therein. Only one comment is in order: when an STT emerges in a weak-field or low-energy limit of some more fundamental theory, its Lagrangian generally contains the scalar curvature with a ϕ-dependent factor, thus leading to one of numerous possible Jordan frames (e.g., the string metric in models of string origin). So, by origin, it is this formulation of the theory that should be used for studying such fundamental issues as topology, singularities, causal properties, etc., although a comparison with observations may require a different formulation.

The paper is organized as follows. Section II presents the field equations. In Sec. III we review the known results on scalar vacuum structures in GR and configurations described by generic STT solutions. We begin with a brief description of purely vacuum structures in D-dimensional GR with a cosmological constant and then reproduce the no-go theorems of Refs. 1 and 2 on the properties of scalar vacuum in GR and mention some other known theorems and examples. Two theorems, providing the necessary and sufficient conditions under which a given STT contains a CC, are formulated and proved in Sec. IV. In Sec. V we discuss the global properties of Jordan-

frame space–times in the presence of CCs. It turns out, in particular, that even the presence of CCs does not enlarge the number of possible horizons and hence the above list of global causal structures. It is shown that one of the generic structures created by CCs is a traversable wormhole. The whole space–time is then globally regular and static. Some particular kinds of singularities can also be created beyond a CC surface. Section VI contains two explicit examples of STT solutions with CCs. One of them represents the well-known solution for a conformally coupled scalar field in GR, which, in addition to singular cases, contains a family of traversable wormhole solutions.[5,9] The other is a nonsingular model containing an infinite sequence of CCs in three-dimensional gravity with a conformally coupled scalar field having a certain non-negative potential.

To sum up, with all theorems and examples at hand, we now have, even without solving the field equations, rather a clear picture of what can and what cannot be expected from static scalar-vacuum configurations in a general class of STT of gravity with various scalar field potentials.

Throughout the article all relevant functions are assumed to be sufficiently smooth, unless otherwise indicated. The symbol $\sim$, as usual, connects quantities of the same order of magnitude. The ends of theorem proofs are marked with $\square$.

II. FIELD EQUATIONS

The general STT action in a D-dimensional pseudo-Riemannian manifold $\mathbb{M}_J[g]$ is

$$S_{\rm STT}=\int d^D x\sqrt{g}[f(\phi)\mathcal{R}+h(\phi)(\partial\phi)^2-2U(\phi)+L_m], \tag{2}$$

where $g_{\mu\nu}$ is the metric, $\mathcal{R}=\mathcal{R}[g]$ is the scalar curvature, $g=|\det g_{\mu\nu}|$, f, h and U are functions of the real scalar field ϕ, $(\partial\phi)^2=g^{\mu\nu}\partial_\mu\phi\partial_\nu\phi$, and L_m is the matter Lagrangian. The manifold $\mathbb{M}_J[g]$ with the metric $g_{\mu\nu}$ comprises the so-called Jordan conformal frame. The vacuum ($L_m=0$) field equations due to (2) read

$$\nabla_\alpha(h\nabla^\alpha)\phi-\tfrac{1}{2}\mathcal{R}f_\phi=-dU/d\phi, \tag{3}$$

$$f(\phi)(\mathcal{R}_\mu^{\ \nu}-\tfrac{1}{2}\delta_\mu^\nu\mathcal{R})=h(\phi)(-\phi_{,\mu}\phi^{,\nu}+\tfrac{1}{2}\delta_\mu^\nu\phi^{,\alpha}\phi_{,\alpha})-\delta_\mu^\nu U(\phi)-(\nabla_\mu\nabla^\nu-\delta_\mu^\nu\square)f-T^\nu_{\mu({\rm m})}, \tag{4}$$

where $\square=\nabla^\alpha\nabla_\alpha$ is the d'Alembert operator, $\mathcal{R}_\mu^{\ \nu}$ is the Ricci tensor, and the last term in (4) is the energy-momentum tensor of matter. (The usual constant factor $8\pi G$, where G is the gravitational constant, can be restored by proper redefinition of the variables.)

The standard transition to the Einstein frame, which generalizes Wagoner's[10] four-dimensional transformation,

$$g_{\mu\nu}=F(\psi)\overline{g}_{\mu\nu},\quad F=|f|^{-2/(D-2)}, \tag{5}$$

$$\frac{d\psi}{d\phi}=\pm\frac{\sqrt{|l(\phi)|}}{f(\phi)},\quad l(\phi)\overset{\rm def}{=}fh+\frac{D-1}{D-2}\left(\frac{df}{d\phi}\right)^2, \tag{6}$$

removes the nonminimal scalar-tensor coupling expressed in the ϕ-dependent coefficient before $\mathcal{R}$. Putting $L_m=0$ (vacuum), one can write the action (2) in the new manifold $\mathbb{M}_E[\overline{g}]$ with the new metric $\overline{g}_{\mu\nu}$ and the new scalar field ψ as follows (up to a boundary term):

$$S_{\rm E}=\int d^D x\sqrt{\overline{g}}\{{\rm sign}f[\overline{\mathcal{R}}+({\rm sign}l)(\partial\psi)^2]-2V(\psi)\}, \tag{7}$$

where the determinant $\overline{g}$, the scalar curvature $\overline{\mathcal{R}}$ and $(\partial\psi)^2$ are calculated using $\overline{g}_{\mu\nu}$ and

$$V(\psi)=|f|^{-D/(D-2)}(\psi)\,U(\phi). \tag{8}$$

Note that $\mathrm{sign}\,l=-1$ corresponds to the so-called anomalous STT, with a wrong sign of scalar field kinetic energy, while $\mathrm{sign}\,f=-1$ means that the effective gravitational constant in the Jordan frame (which can be defined as $1/f$ up to a constant factor) is negative. So the normal choice of signs is $\mathrm{sign}\,l=\mathrm{sign}\,f=1$, when the scalar-vacuum action takes the form (1). We will adhere to theories with $l>0$ in the whole paper, but we shall see that the continuations to be discussed in Secs. IV–VI lead to $f<0$ in some regions of $\mathbb{M}_{\mathrm{J}}$.

Among the three functions of ϕ entering into (2) only two are independent since there is a freedom of transformations $\phi=\phi(\phi_{\mathrm{new}})$. We assume $h\geqslant 0$ and use this freedom, choosing in what follows $h(\phi)\equiv 1$. {Another standard parametrization is to put $f(\phi)=\phi$ and $h(\phi)=\omega(\phi)/\phi$ [the Brans–Dicke parametrization of the general theory (2)].}

From the viewpoint of the field equations, the transformation (5) and (6) is merely a simplifying substitution. Instead of Eqs. (3) and (4) (assuming $f>0$), we deal in $\mathbb{M}_{\mathrm{E}}$ with simpler equations due to (1):

$$\overline{\Box}\psi+dV/d\psi=0, \tag{9}$$

$$\overline{\mathcal{R}}{}^{\nu}_{\mu}-\tfrac{1}{2}\delta^{\nu}_{\mu}\overline{\mathcal{R}}=-\psi_{,\mu}\psi^{,\nu}+\tfrac{1}{2}\delta^{\nu}_{\mu}(\partial\psi)^2-\delta^{\nu}_{\mu}V(\psi), \tag{10}$$

with the Ricci tensor $\overline{\mathcal{R}}{}^{\nu}_{\mu}$ and the d'Alembert operator $\overline{\Box}$ corresponding to $\overline{g}_{\mu\nu}$.

Consider static, spherically symmetric configurations, so that the metric in $\mathbb{M}_{\mathrm{E}}$ is written as

$$ds^2_{\mathrm{E}}=A(\rho)dt^2-\frac{d\rho^2}{A(\rho)}-r^2(\rho)d\Omega^2_{\overline{d}}, \tag{11}$$

where $d\Omega^2_{\overline{d}}$ is the linear element on the sphere $\mathbb{S}^{\overline{d}}$ of unit radius, and the scalar field is $\psi=\psi(\rho)$.

Then Eq. (9) and some combinations of the Einstein equations (10) have the form

$$(Ar^{\overline{d}}\psi')'=r^{\overline{d}}V_{\psi}; \tag{12}$$

$$(A'r^{\overline{d}})'=-(4/\overline{d})r^{\overline{d}}V; \tag{13}$$

$$\overline{d}r''/r=-\psi'^2; \tag{14}$$

$$A(r^2)''-r^2A''+(\overline{d}-2)r'(2Ar'-A'r)=2(\overline{d}-1); \tag{15}$$

$$\overline{d}(\overline{d}-1)(1-Ar'^2)-\overline{d}A'rr'=-Ar^2\psi'^2+2r^2V, \tag{16}$$

where the prime denotes $d/d\rho$. Only three of these five equations are independent: the scalar equation (12) follows from the Einstein equations, while Eq. (16) is a first integral of the others. Given a potential $V(\psi)$, this is a determined set of equations for the unknowns r, A, ψ.

This choice of the radial coordinate according to the condition $\overline{g}_{tt}\overline{g}_{\rho\rho}=-1$ is preferable for considering Killing horizons, which correspond to zeros of the function $A(\rho)$, since such zeros are regular points of Eqs. (12)–(16), and therefore one can jointly consider regions at both sides of a horizon; moreover, in a close neighborhood of a horizon, the coordinate ρ defined in this way varies (up to a positive constant factor) like manifestly well-behaved Kruskal-like coordinates used for an analytic continuation of the metric.[11] Therefore this coordinate frame can be called *quasiglobal*.

The corresponding metric in $\mathbb{M}_{\mathrm{J}}$ reads

$$ds_J^2 = F(\psi)\left[A(\rho)dt^2 - \frac{d\rho^2}{A(\rho)} - r^2 d\Omega_{\bar{d}}^2\right] = \mathcal{A}(q)dt^2 - \frac{dq^2}{\mathcal{A}(q)} - R^2 d\Omega_{\bar{d}}^2, \tag{17}$$

where we have introduced the quasiglobal coordinate q in $\mathbb{M}_J$, similar to ρ in (11), such that $g_{tt}g_{\rho\rho} = -1$. The quantities in (17) and (11) are related by

$$\pm dq = F d\rho, \quad \mathcal{A}(q) = FA(\rho), \quad R(q) = \sqrt{F} r(\rho). \tag{18}$$

With our convention $h(\phi) \equiv 1$, three independent field equations in $\mathbb{M}_J$ can be written as follows:

$$f\left(\mathcal{A}_{qq} + \bar{d}\mathcal{A}_q \frac{R_q}{R}\right) + \frac{D}{\bar{d}}\mathcal{A}_q f_q + 2\mathcal{A}\frac{R_q}{R} f_q + \frac{2}{\bar{d}}\mathcal{A} f_{qq} + \frac{4}{\bar{d}}U = 0, \tag{19}$$

$$\bar{d} f \frac{R_{qq}}{R} + \phi_q^2 + f_{qq} = 0, \tag{20}$$

$$\frac{f}{R^2}\left[-(\bar{d}-1) + \mathcal{A}RR_{qq} + \mathcal{A}R_q^2 - \frac{1}{2}R^2\mathcal{A}_{qq} + \frac{1}{2}(\bar{d}-2)R_q(2\mathcal{A}R_q - R\mathcal{A}_q)\right] + \left(\frac{\mathcal{A}R_q}{R} - \frac{\mathcal{A}_q}{2}\right) f_q = 0, \tag{21}$$

where the subscript q denotes d/dq.

III. PROPERTIES OF GENERIC STT SOLUTIONS

A. Some known results for the Einstein frame

Let us enumerate some consequences of Eqs. (12)–(16) valid in $\mathbb{M}_E$.

The first important restriction is the nonexistence of regular configurations having no center ($r = 0$), namely, wormholes, horns and flux tubes.[1,2]

For the metric (11), a (traversable, Lorentzian) *wormhole* is, by definition, a configuration with two asymptotics at which $r(\rho) \to \infty$, hence with $r(\rho)$ having at least one regular minimum. A *horn* is a region where, as r tends to some finite value, $g_{tt} = A$ remains finite whereas the length integral $l = \int d\rho/\sqrt{A}$ diverges. In other words, a horn is a configuration ending with a regular, infinitely long $(\bar{d}+1)$-dimensional "tube" of finite radius. Such "horned particles" were discussed as possible remnants of black hole evaporation.[12] Lastly, a *flux tube* is a configuration with $r = \text{const}$, a "cylindrical" space.

Theorem 1: *The field equations due to (1) for $D \geqslant 4$ do not admit (i) solutions where the function $r(\rho)$ has a regular minimum, (ii) solutions describing a horn, and (iii) flux-tube solutions with $\psi \neq \text{const}$.*

The formulation of the theorem and its proof,[1,2] which essentially rests on Eq. (14), do not refer to any kind of asymptotic, therefore wormhole throats or horns are absent in solutions having any large r behavior—flat, de Sitter or any other, or having no large r asymptotic at all.

For $D = 3$ items (*i*) and (*iii*) of Theorem 1 hold, but solutions with a horn can exist; though, a horn can only appear at a maximum of $r(\rho)$, so that horned configurations have no spatial asymptotic.

The global causal structure of space–time is unambiguously determined (up to identification of isometric surfaces, if any) by the disposition of static ($A > 0$) and nonstatic, homogeneous ($A < 0$) regions, separated by horizons.[13–16] The following two theorems severely restrict such possible dispositions.

Theorem 2: *Consider solutions of the theory (1), $D \geqslant 4$, with the metric (11) and $\psi = \psi(\rho)$. Let there be a static region $a < \rho < b \leqslant \infty$. Then:*

(i) all horizons are simple;
(ii) no horizons exist at $\rho<a$ and at $\rho>b$.

Theorem 2a: *A static, circularly symmetric configuration in the theory (1), $D=3$, has either no horizon or one simple horizon.*

The proof of these theorems[1,2] employs the properties of Eq. (15), which can be rewritten in the form

$$r^4B''+(\bar{d}+2)r^3r'B'=-2(\bar{d}-1), \tag{22}$$

where $B(\rho)=A/r^2$. This equation shows that B cannot have a regular minimum, therefore, having once become negative while moving to the left or to the right along the ρ axis, $B(\rho)$ [and hence $A(\rho)$] cannot return to zero or positive values.

Theorems 2 and 2a show that the possible disposition of zeros of the function $A(\rho)$ is the same as in the case of vacuum with a cosmological constant. Therefore the list of possible global causal structures is also the same.

Let us, for reference purposes, enumerate these structures. The metric satisfying Eqs. (13)–(16) with $\psi'=0$, $V=\Lambda=\text{const}$ is

$$ds^2=A(r)dt^2-\frac{dr^2}{A(r)}-r^2d\Omega_{\bar{d}}^2 \tag{23}$$

[it is (11) with $\rho\equiv r$] where

$$A(r)=1-\frac{2m}{r^{\bar{d}-1}}-\frac{2\Lambda r^2}{\bar{d}(\bar{d}+1)}. \tag{24}$$

This is the multidimensional Schwarzschild–de Sitter solution. Its special cases correspond to the Schwarzschild ($\bar{d}=2$, $\Lambda=0$) and Tangherlini (any $\bar{d}$, $\Lambda=0$) solutions and the de Sitter solution in arbitrary dimension when $m=0$, called anti-de Sitter (AdS) in the case $\Lambda<0$.

Different qualitative behaviors of $A(r)$ for different values of Λ and m correspond to the following structures:[17]

(1) $\Lambda=0$, $m\leqslant 0$: curves 1a and 1b in Fig. 1, diagram 1 in Fig. 2 (Minkowski and $m<0$ Schwarzschild, respectively).
(2) $\Lambda<0$, $m\leqslant 0$: curves 2a and 2b in Fig. 1, diagram 2 in Fig. 2 (AdS and $m<0$ Schwarzschild–AdS).
(3) $\Lambda<0$, $m>0$: curve 3 in Fig. 1, diagram 3 in Fig. 2 (Schwarzschild–AdS).
(4) $\Lambda=0$, $m>0$: curve 4 in Fig. 1, diagram 4 in Fig. 2 (Schwarzschild).
(5) $\Lambda>0$, $m\leqslant 0$: curves 5a and 5b in Fig. 1, diagram 5 in Fig. 2 (de Sitter and $m<0$ Schwarzschild–de Sitter).
(6) $\Lambda>0$, $m>0$: curves 6a, 6b and 6c in Fig. 1, and the corresponding diagrams in Fig. 2 (Schwarzschild–de Sitter in case 6a and Kantowski–Sachs homogeneous cosmologies in cases 6b and 6c).

The center $r=0$ is regular for $m=0$ and singular for $m\neq 0$.

In case 6, given a particular value of $\Lambda>0$, the solution behavior depends on the mass parameter m. When m is smaller than the critical value

$$m_{\text{cr}}=\frac{1}{\bar{d}+1}\left[\frac{\bar{d}(\bar{d}-1)}{2\Lambda}\right]^{(\bar{d}-1)/2}, \tag{25}$$

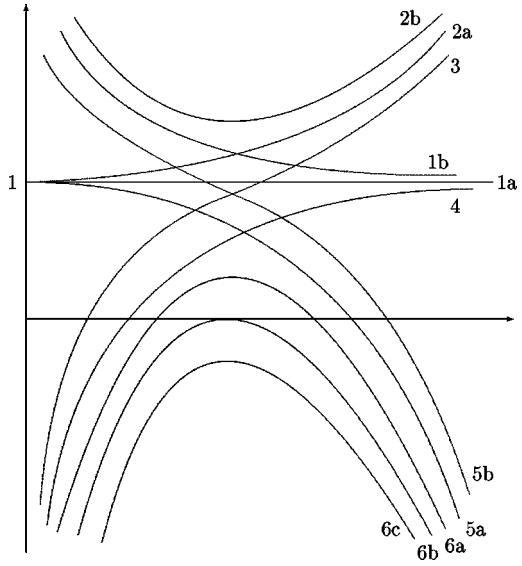

FIG. 1. The behavior of $A(r)$, Eq. (24), for different values of m and Λ.

there are two horizons, the smaller one being interpreted as a black hole horizon and the greater one as a cosmological horizon. If $m=m_{\rm cr}$, the two horizons merge, and one has two homogeneous T regions separated by a double horizon. Lastly, the solution with $m>m_{\rm cr}$ is purely cosmological and has no Killing horizon.

In $(2+1)$-dimensional gravity ($\bar{d}=1$), according to Theorem 2a, the list is even shorter: the structures corresponding to the curves 6a and 6b are absent.

Let us also mention, for completeness, some results known for $D=4$ and most probably admitting a generalization to other dimensions.

No-hair theorems state that (1) if $V\geqslant 0$, an asymptotically flat black hole cannot have a nontrivial scalar field;[6,18,19] and (2) if $V\geqslant 0$ and $d^2V/d\psi^2\geqslant 0$ (a convex potential), an asymptotically anti-de Sitter black hole cannot have a nontrivial scalar field.[20]

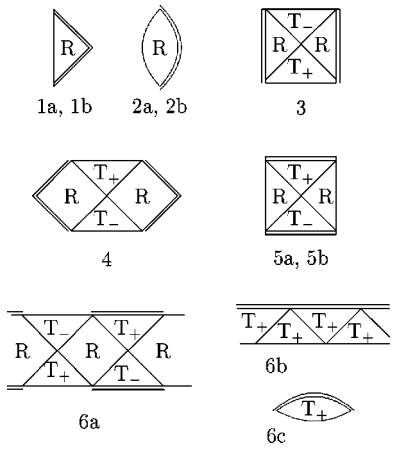

FIG. 2. Carter–Penrose diagrams for different cases of the metric (23) and (24), labeled according to Fig. 1. The R and T letters correspond to R and T space–time regions; T_+ and T_- denote expanding and contracting T region (i.e., with r increasing and decreasing with time, respectively). Single lines on the border of the diagrams denote $r=0$, double lines—$r=\infty$. Diagrams 6b and 6c are drawn for the case of expanding Kantowski–Sachs cosmologies; to obtain diagrams for contracting models, one should merely interchange $r=0$ and $r=\infty$ and replace T_+ with T_-. Diagrams 6a and 6b admit identification of isometric timelike sections.

The generalized Rosen theorem states that, provided $V \geqslant 0$, a particlelike solution with a regular center, a flat asymptotic and positive mass does not exist.[7]

These theorems cannot be directly extended to STT in the Jordan frame and will not be discussed any more, though an attempt to formulate additional conditions able to provide such extensions may be of interest.

Explicit examples have been obtained, confirming the existence of some kinds of solutions admitted by the above theorems. Thus, there exist (1) black holes possessing nontrivial scalar fields (scalar hair), with $V \geqslant 0$, but with nonflat and non-de Sitter asymptotics;[21] (2) black holes with scalar hair and flat asymptotics, but partly negative potentials;[2] and (3) configurations with a regular center, a flat asymptotic and positive mass, but also with partly negative potentials.[2]

Thus black holes with scalar hair are not excluded in general, but such objects as regular black holes,[22] possessing a regular center and a global structure coinciding with that of Reissner–Nordstrom or Reissner–Nordstrom–de Sitter space–time, are ruled out.

B. Generic solutions in the Jordan frame

It should be, above all, noted that when a space–time manifold $\mathbb{M}_{\mathrm{E}}[\overline{g}]$ (the Einstein frame) with the metric (11) is conformally mapped into another manifold $\mathbb{M}_{\mathrm{J}}[g]$ (the Jordan frame), equipped with the same coordinates, according to the law

$$g_{\mu\nu} = F(\rho)\overline{g}_{\mu\nu}, \tag{26}$$

it is easily verified that a horizon $\rho = h$ in $\mathbb{M}_{\mathrm{J}}$ passes into a horizon of the same order in $\mathbb{M}_{\mathrm{E}}$, a center ($r = 0$) and an asymptotic ($r \to \infty$) in $\mathbb{M}_{\mathrm{J}}$ pass into a center and an asymptotic, respectively, in $\mathbb{M}_{\mathrm{E}}$ if the conformal factor $F(\rho)$ is regular (i.e., finite, at least C^2-smooth and positive) at the corresponding values of ρ. A regular center passes to a regular center and a flat asymptotic to a flat asymptotic under evident additional requirements.

The validity of Theorems 1, 2 and 2a in the Jordan frame depends on the nature of the conformal mapping (5) that connects $\mathbb{M}_{\mathrm{J}}[g]$ with $\mathbb{M}_{\mathrm{E}}[\overline{g}]$). There are four variants:

I. $\mathbb{M}_{\mathrm{J}} \leftrightarrow \mathbb{M}_{\mathrm{E}}$,

II. $\mathbb{M}_{\mathrm{J}} \leftrightarrow (\mathbb{M}'_{\mathrm{E}} \subset \mathbb{M}_{\mathrm{E}})$,

III. $(\mathbb{M}'_{\mathrm{J}} \subset \mathbb{M}_{\mathrm{J}}) \leftrightarrow \mathbb{M}_{\mathrm{E}}$,

IV. $(\mathbb{M}'_{\mathrm{J}} \subset \mathbb{M}_{\mathrm{J}}) \leftrightarrow (\mathbb{M}'_{\mathrm{E}} \subset \mathbb{M}_{\mathrm{E}})$,

where $\leftrightarrow$ is a diffeomorphism preserving the metric signature. The last three variants are possible if the conformal factor F vanishes or blows up at some values of ρ, which then mark the boundary of $\mathbb{M}'_{\mathrm{J}}$ or $\mathbb{M}'_{\mathrm{E}}$.

A situation of the kind III or IV can be called a *conformal continuation* (CC) from $\mathbb{M}_{\mathrm{E}}$ into $\mathbb{M}_{\mathrm{J}}$.

One can notice that such continuations can only occur for special solutions: to admit a CC, the singularity in $\mathbb{M}_{\mathrm{E}}$ should be removable by a conformal factor, i.e., be, in a sense, isotropic. Moreover, the factor F should have precisely the behavior needed to remove it.

Thus generic situations are I and II, the latter meaning that the factor F "spoils" the geometry and creates a singularity. In these cases Theorem 2 (or 2a for $D = 3$) on horizon dispositions is obviously valid in $\mathbb{M}_{\mathrm{J}}$.

The manifolds $\mathbb{M}_{\mathrm{J}}$ then cannot have other causal structures than those depicted in Fig. 2. This is manifestly true for STT with $f(\phi) > 0$.

Theorem 1 cannot be directly transferred to $\mathbb{M}_{\mathrm{J}}$ in any case except the trivial one, $F = \mathrm{const}$. In particular, minima of $g_{\theta\theta}$ (wormhole throats) can appear. It is only possible to assert without specifying $F(\psi)$ that wormholes as global entities are impossible in $\mathbb{M}_{\mathrm{J}}$ in case I if the conformal factor F is finite in the whole range of ρ, including the boundary values. Indeed, if we suppose that

there is such a wormhole, it will immediately follow that there are two large r asymptotics and a minimum of $r(\rho)$ between them even in $\mathbb{M}_E$, in contrast to Theorem 1 which is valid there. Wormholes are also absent in case II since we then have a singularity instead of at least one of the asymptotics.

The above-mentioned examples of black holes with scalar hair when the potential is not positive-definite or the asymptotic is nonflat are also directly transferred to $\mathbb{M}_J$ provided $F(\psi)$ is regular at least outside the horizon. Given a particlelike solution in $\mathbb{M}_E$, with a regular center and positive mass, the condition that a solution with similar properties occurs in $\mathbb{M}_J$ can also be easily formulated, but we will not concentrate on this question here.

Conformal continuations, if any, can in principle lead to other, maybe more complex structures. In what follows we will try to answer two questions: (1) under which conditions the mapping (26) creates a conformal continuation in STT and (2) what can be the nature of conformally continued solutions in the Jordan frame.

IV. CONFORMAL CONTINUATION CONDITIONS

A. Preliminaries

A CC from $\mathbb{M}_E$ into $\mathbb{M}_J$ can occur at such values of the scalar field ϕ that the conformal factor F in the mapping (5) is singular while the functions f, h and U in the action (2) are regular. This means that at $\phi=\phi_0$, corresponding to a possible transition surface $\mathbb{S}_{\text{trans}}$, the function $f(\phi)$ has a zero of a certain order n. We then have in the transformation (6) near $\phi=\phi_0$ in the leading order of magnitude

$$f(\phi)\sim\Delta\phi^n, \quad n=1,2,\ldots, \quad \Delta\phi\equiv\phi-\phi_0. \tag{27}$$

One can notice, however, that $n>1$ leads to $l(\phi_0)=0$ [recall that by our convention $h(\phi)\equiv 1$]. This generically leads to a curvature singularity in $\mathbb{M}_J$, as can be seen from the trace of Eqs. (4):

$$l(\phi)\mathcal{R}=-\left(1+2\frac{D-1}{D-2}f_{\phi\phi}\right)\phi^\alpha\phi_\alpha+\frac{2}{D-2}[DU+(D-1)f_\phi U_\phi] \tag{28}$$

(the subscript ϕ denotes $d/d\phi$). If the right-hand side of (28) is nonzero at $\phi=\phi_0$ at which $l=0$, the scalar curvature $\mathcal{R}$ is infinite. There can be special choices of f and U such that this singularity is avoided, but we will ignore this possibility and simply assume $l>0$ at $\mathbb{S}_{\text{trans}}$.

Thus, according to (6), we have near $\mathbb{S}_{\text{trans}}(\phi=\phi_0)$,

$$f(\phi)\sim\Delta\phi\sim e^{-\psi\sqrt{d/(d+1)}}, \tag{29}$$

where without loss of generality we choose the sign of ψ so that $\psi\to\infty$ as $\Delta\phi\to 0$.

In the CC case, the metric $\overline{g}_{\mu\nu}$ specified by (11) is singular on $\mathbb{S}_{\text{trans}}$ while $g_{\mu\nu}=F(\psi)\overline{g}_{\mu\nu}$ is regular. There are two opportunities. The first one, to be called CC-I for short, is that $\mathbb{S}_{\text{trans}}$ is an *ordinary regular surface* in $\mathbb{M}_J$, where both $g_{tt}=\mathcal{A}=FA$ and $-g_{\theta\theta}=R^2=\underline{F}r^2$ (squared radius of $\mathbb{S}_{\text{trans}}$) are finite. (Here θ is one of the angles that parametrize the sphere $\mathbb{S}^d$.) The second variant, to be called CC-II, is that $\mathbb{S}_{\text{trans}}$ is a *horizon* in $\mathbb{M}_J$. In the latter case only $g_{\theta\theta}$ is finite, while $g_{tt}=0$. We will consider these two kinds of CC separately.

In both cases some necessary conditions for CC are easily obtained using the field equations in $\mathbb{M}_E$, but these equations describe the system only on one side of $\mathbb{S}_{\text{trans}}$. Another Einstein frame may be built for the region beyond $\mathbb{S}_{\text{trans}}$, but in this case there arises the problem of matching the solutions obtained in two nonintersecting regions. Therefore to prove sufficient conditions for the existence of solutions in $\mathbb{M}_J$, which are regular on and near $\mathbb{S}_{\text{trans}}$, we have to deal with the field equations in $\mathbb{M}_J$.

B. Continuation through an ordinary sphere (CC-I)

Given a metric $\overline{g}_{\mu\nu}$ of the form (11) in $\mathbb{M}_{\rm E}$, a CC-I can occur if

$$F(\psi)=|f|^{-2/\overline{d}}\sim 1/r^2\sim 1/A \tag{30}$$

as $\psi\to\infty$, while the behavior of f is specified by (29). The surface $\mathbb{S}_{\rm trans}$, being regular in the Jordan frame, is singular in $\mathbb{M}_{\rm E}$ ($r^2\sim A\to 0$): it is either a singular center if the continuation occurs in an R-region, or a cosmological singularity in the case of a T-region.

The following theorem is valid:

Theorem 3: *Consider scalar-vacuum configurations with the metric (17) and $\phi=\phi(q)$ in the theory (2) with $h(\phi)\equiv 1$ and $l(\phi)>0$. Suppose that $f(\phi)$ has a simple zero at some $\phi=\phi_0$, and $|U(\phi_0)|<\infty$. Then*

(i) there exists a solution in $\mathbb{M}_{\rm J}$, smooth in a neighborhood of the surface $\mathbb{S}_{\rm trans}$ ($\phi=\phi_0$), which is an ordinary regular surface in $\mathbb{M}_{\rm J}$; and

(ii) in this solution the ranges of ϕ are different on different sides of $\mathbb{S}_{\rm trans}$.

Proof: Let us begin with item (ii): given a CC-I, we will show that $d\phi/dq\neq 0$ at $\phi=\phi_0$, so that ϕ_0 is not a maximum or minimum of $\phi(q)$.

Indeed, it can be deduced from the conditions (29) and (30) and Eq. (14) that near $\mathbb{S}_{\rm trans}$

$$r(\rho)\sim(\rho-\rho_0)^{1/D}, \tag{31}$$

where $\rho=\rho_0$ is the location of $\mathbb{S}_{\rm trans}$. It then follows that $q_0=q(\rho_0)$ is finite on $\mathbb{S}_{\rm trans}$ and both $\Delta\phi$ and $q-q_0$ behave as $r^{\overline{d}}$ in its neighborhood, hence $d\phi/dq$ is finite.

With this necessary condition, we can prove item (i), seeking a solution to Eqs. (19)–(21) in an appropriate form. Here, the unknowns are $\mathcal{A}(q)$, $R(q)$, $\phi(q)$, while $f(\phi)$ and $U(\phi)$ are prescribed by the choice of the theory. However, since $f(\phi_0)=0$ and $df/d\phi\neq 0$ at $\phi=\phi_0$, we can treat $\phi(f)$ as a known function in a certain neighborhood of $f=0$ and consider $f(q)$ as an unknown instead of $\phi(q)$.

Let $\mathbb{S}_{\rm trans}$ be located (without loss of generality) at $q=0$. It is sufficient to find a solution in the form of a power series in q near $q=0$. Since R and A should be finite at $\mathbb{S}_{\rm trans}$, while $f=0$ and $df/dq\neq 0$, we seek a solution in the form

$$\mathcal{A}(q)=\sum_{n=0}^{\infty}A_n q^n/n!=A_0+A_1 q+\frac{1}{2}A_2 q^2+\ldots,$$

$$R(q)=\sum_{n=0}^{\infty}R_n q^n/n!=R_0+R_1 q+\frac{1}{2}R_2 q^2+\ldots, \tag{32}$$

$$f(q)=\sum_{n=1}^{\infty}f_n q^n/n!=f_1 q+\frac{1}{2}f_2 q^2+\ldots,$$

with nonzero A_0, R_0, f_1.

Substituting (32) into the equations, we see that in the senior order of magnitude, $O(1)$, the coefficients A_1, R_1, f_2 are expressed in terms of A_0, R_0, f_1 and $U(\phi_0)$. Next powers of q express the further expansion factors in terms of the previous ones. Namely, in every order of magnitude $O(q^n)$, $n>0$, Eq. (20) gives

$$(n-1)\overline{d}R_n/R_0+f_{n+1}/f_1=\cdots, \tag{33}$$

where the dots on the right mean various combinations of coefficients of the previous orders as well as power expansion factors of the known functions $U(\phi)$ and $\phi(f)$. Then, excluding f_{n+1} from the other two equations in the order $O(q^n)$, we obtain a set of two linear algebraic equations for A_n/A_0 and R_n/R_0:

$$A_n/A_0 - 2R_n/R_0 = \cdots,$$
$$(n\overline{d}+2)A_n/A_0 - 2\overline{d}(n-2)R_n/R_0 = \cdots, \tag{34}$$

whose determinant is equal to $4(\overline{d}+1)$ for any n. We conclude that all the expansion factors in (32) are uniquely expressed in terms of A_0, R_0, f_1 and the expansion factors of the known functions. This proves the existence of the solution in $\mathbb{M}_J$ near $\mathbb{S}_{trans}$. □

The order of smoothness of the solution obtained depends on the smoothness of the original functions f, h, U. If they are C^∞, as is natural for a field theory, then the metric functions and ϕ are also C^∞.

The existence of such a solution automatically implies the existence of the corresponding solutions on different sides of $\mathbb{S}_{trans}$ in two different Einstein frames. These solutions are special, being restricted by Eq. (30). As follows from the proof, the solution in $\mathbb{M}_J$, and hence its counterparts in both $\mathbb{M}_E$, contain two essential integration constants (R_0 and f_1, whereas A_0 determines the time scale on $\mathbb{S}_{trans}$ and can be chosen arbitrarily).

It is of interest that, under the CC-I conditions, the potential $V(\psi)$ in $\mathbb{M}_E$ (although it may even blow up) is inessential: the solution is close to Fisher's scalar-vacuum solution[23] for $D=4$ or its modification in other dimensions.

In case $D=3$, as follows from Eq. (15), a necessary condition for CC is $A/r^2 = \text{const}$.

One can also notice that no restriction other than regularity is imposed on the potential U, in particular, U may vanish in some region or in the whole space. [The conclusion that $U(\phi)=0$ on $\mathbb{S}_{trans}$, obtained in Ref. 3, appeared there due to an additional assumption on the form of the expansion of $A(\rho)$ in powers of ρ. An inspection shows that this assumption is unnecessary.] The latter case will be used as an explicit example of CC in Sec. VI A.

C. Continuation through a horizon in $\mathbb{M}_J$ (CC-II)

Let us suppose that in the metric (17) a certain value of q (without loss of generality, $q=0$) corresponds to a horizon of order $k \geqslant 1$. This means that $q=0$ is a zero of order k of the function $\mathcal{A}(q)$.

Suppose now that this horizon is $\mathbb{S}_{trans}$, a transition sphere in a CC. In other words, in the vicinity of $q=0$, $f(\phi) \sim \Delta\phi$. One can directly verify that the corresponding value ρ_0 of the coordinate ρ in the Einstein-frame metric (11) is finite, and we can choose for convenience $\rho_0 = 0$. We thus have near $q=0$

$$\mathcal{A}(q) = AF \sim q^k, \quad R^2(q) = Fr^2 = O(1). \tag{35}$$

Now, the question is: under which requirements to the original theory a horizon in $\mathbb{M}_J$, described by (35), can be a transition sphere $\mathbb{S}_{trans}$. An answer is given by the following theorem.

Theorem 4: *Consider scalar-vacuum configurations with the metric (17) and $\phi=\phi(q)$ in the theory (2) with $h(\phi)\equiv 1$ and $l(\phi)>0$. Suppose that $f(\phi)$ has a simple zero at some $\phi=\phi_0$. There exists a solution in $\mathbb{M}_J$, smooth in a neighborhood of the surface $\mathbb{S}_{trans}$ ($\phi=\phi_0$), which is a Killing horizon in $\mathbb{M}_J$,* **if and only if**

(**a**) $D \geqslant 4$,

(**b**) *ϕ_0 is a simple zero of $U(\phi)$, and*

(**c**) *$dU/df > 0$ at $\phi=\phi_0$.*

Then, in addition,

(**d**) *$\mathbb{S}_{trans}$ is a second-order horizon, connecting two T-regions in $\mathbb{M}_J$; and*

(**e**) *the ranges of ϕ are different on the two sides of $\mathbb{S}_{trans}$.*

Proof: Necessity: Given a CC-II, we will prove items (a)–(e).

Let us use Eqs. (13)–(15) in $\mathbb{M}_{\mathrm{E}}$. In particular, Eq. (15), which contains only $A(\rho)$ and $r(\rho)$, can be rewritten in the form

$$[r^D(A/r^2)']' + 2(\overline{d}-1)r^{\overline{d}-2} = 0. \tag{36}$$

Suppose CC-II at $\rho = 0$ $(q=0)$, which is a horizon of order k in $\mathbb{M}_{\mathrm{J}}$. Let us put $\overline{d} > 1$ and assume for certainty, without generality loss, that $q > 0$ as $\rho \to +0$. We have $dq/d\rho \sim F \sim 1/r^2$ and $A/r^2 \sim q^k$. Therefore the first term in (36) at small ρ behaves as

$$(\text{sign } A)\ [r^{\overline{d}} q^{k-1}]'.$$

Since both $r(\rho)$ and q are growing functions of ρ, this derivative is non-negative, whereas the second term in (36) is manifestly positive. The only way to satisfy (36) is to put $A < 0$. In other words, the horizon is approached from a T-region, where we deal with a Kantowski-Sachs type cosmological model.

Such a reasoning applies to approaching the surface $q=0$ from either side, therefore the horizon $\mathbb{S}_{\mathrm{trans}}$ connects two T-regions and is thus of even order.

We must also ascertain that the orders of magnitude of the two terms in (36) are the same. This is only true if $k=2$, as can be easily verified using (31), which now reads $r \sim \rho^{1/D}$. So item (d) is proved.

Equations (29) and (31) can be used to show that the derivative $d\phi/dq$ is finite at $q=0$, leading to item (e).

The behavior of $U(\phi)$ can be determined using Eq. (13), taking into account the relation (8) between U and V and the conditions (35) with $k=2$. We find in this way that $U(\phi) \sim \Delta\phi$ (i.e., the potential has a first-order zero) and that $dU/df > 0$ at $\phi = \phi_0$, so items (b) and (c) hold.

It remains to rule out $\overline{d}=1$ (three-dimensional gravity). In this case (36) leads to $(A/r^2) = c_1/r^3$, $c_1 = \text{const}$. The value $c_1 = 0$ is excluded since we must have $A/r^2 \sim q^k$. For $c_1 \neq 0$ we obtain $(q^k)' = kq^{k-1}dq/d\rho$, where due to (35) $q^{k-1} \sim 1/r \to \infty$, whereas $q \to 0$ and $k \geqslant 1$. This contradiction proves item (a).

Sufficiency: As in Theorem 3, the existence of a solution in $\mathbb{M}_{\mathrm{E}}$, smoothly continued across $\mathbb{S}_{\mathrm{trans}}$, is proved using Eqs. (19)–(21) and a power expansion for a sought-for solution. It is again convenient to treat $\phi(f)$ as a known function and $f(q)$ as an unknown, so again the unknowns are $\mathcal{A}(q)$, $R(q)$ and $f(q)$.

Seeking solutions to Eqs. (19)–(21) as series in q, we use again the expansions (32), but, under the present necessary conditions, we put there $A_0 = A_1 = 0$ and suppose nonzero A_2, R_0, f_1. With these expansions substituted, the equations again lead to a chain of recurrent relations for the coefficients, slightly more involved than in Theorem 3.

In the orders $O(1)$ and $O(q)$, Eq. (19) leads to

$$U(\phi_0) = 0, \quad (\overline{d}+D)A_2 + 4U_{f0} = 0$$

(where $U_{f0} = dU/df|_{f=0}$), hence $U_{f0} > 0$, in agreement with the necessary conditions. Equation (20) $[O(1)]$ expresses f_2 in terms of f_1 and $d\phi/df(f=0)$. Equation (21) $[O(1)]$ gives $A_2 = -(\overline{d}-1)/R_0^2$. Furthermore, Eqs. (19) $[O(q^2)]$ and (21) $[O(q)]$ yield two equations determining R_1 and A_3:

$$\begin{gathered}(3\overline{d}+2)A_3/A_2 + 2\overline{d}(\overline{d}+1)R_1/R_0 = \cdots, \\ 3A_3/A_2 + 2(\overline{d}-1)R_1/R_0 = \cdots,\end{gathered} \tag{37}$$

where the dots on the right replace combinations of previously known constants. The determinant of this set of linear equations with respect to A_3/A_2 and R_1/R_0 is $-4(2\overline{d}+1)<0$ for $\overline{d}>0$. We thus know the coefficients up to R_1, f_2, A_3. Further coefficients are determined recursively from further orders of magnitude in all three equations:

$$(n+D/\overline{d})a_n+n(n-1)(\overline{d}+1)b_n+(n-1)(n+D)c_n/D=\cdots,$$

$$(n+2)\overline{d}b_n+c_n=\cdots, \tag{38}$$

$$(n+1)a_n+n(-n^2+\overline{d}n-\overline{d}+9)b_n+(n-1)c_n=\cdots,$$

where $n\geqslant 3$ and

$$a_n=A_{n+1}/A_2, \quad b_n=R_{n-1}/R_0, \quad c_n=f_n/f_1.$$

The determinant of Eqs. (38) with respect to a_n, b_n, c_n is a multiple (with a nonzero coefficient) of

$$n[\overline{d}(n^2-2n-7)+n^2-9]. \tag{39}$$

This quantity is nonzero for all values of $\overline{d}$ and n of interest: it is negative for $n=3$ and positive for $n>3$. Therefore Eqs. (38) can be consecutively solved for all n, leading to a C^∞ solution to the field equations (19)–(21). The proof is completed. □

Thus the only kind of STT configurations admitting CC-II is a $D\geqslant 4$ Kantowski–Sachs cosmology consisting of two T-regions (in fact, epochs, since ρ is a temporal coordinate), separated by a second-order horizon. The qualitative behavior of the metric function $\mathcal{A}(q)$ is shown by the curve 6b in Fig. 1, and the Carter–Penrose diagram is 6b in Fig. 2. We shall see in the next section that this conclusion does not change even if the same solution undergoes one more CC.

Unlike CC-I, the present case requires specific properties of the potential U. It cannot vanish everywhere, but must behave as const$\cdot(\phi-\phi_0)$ near ϕ_0.

Moreover, when these requirements are satisfied, the solution that realizes a CC-II is even more special than in CC-I. Indeed, in the above series expansion, only the constant f_1 is arbitrary, whereas A_2 and R_0 are expressed via U_{f0}, a constant depending on the potential in the theory chosen.

V. GLOBAL PROPERTIES OF CONFORMALLY CONTINUED SOLUTIONS

A. Horizon dispositions

A solution to the STT equations may *a priori* undergo a number of CCs, so that each region of $\mathbb{M}_\mathrm{J}$ between adjacent surfaces $\mathbb{S}_\mathrm{trans}$ is conformally equivalent to some $\mathbb{M}_\mathrm{E}$. However, the global properties of $\mathbb{M}_\mathrm{J}$ with CCs turn out to be not so diverse as one might expect. The main restriction is that Theorems 2 and 2a on horizon dispositions, which have been proved for $\mathbb{M}_\mathrm{E}$, actually hold in $\mathbb{M}_\mathrm{J}$.

A key point for proving this is the observation that the quantity $B=A/r^2=\mathcal{A}/R^2$ is insensitive to conformal mappings and is thus common to $\mathbb{M}_\mathrm{J}$ and $\mathbb{M}_\mathrm{E}$ equivalent to a given part of $\mathbb{M}_\mathrm{J}$. We have here presented B in terms of the metrics (11) and (17), respectively, so that it may be treated as a function of the quasiglobal coordinates ρ in $\mathbb{M}_\mathrm{E}$ or q in $\mathbb{M}_\mathrm{J}$.

A horizon of order k in $\mathbb{M}_\mathrm{J}$ is evidently a zero of the same order of the function $B(q)$, and between zeros (if more than one) there must be maxima and minima. Theorem 2 rests on the fact that $B(\rho)$ cannot have a regular minimum in $\mathbb{M}_\mathrm{E}$ due to Eq. (22). Hence it follows that $B(q)$ cannot have a regular minimum in any region of $\mathbb{M}_\mathrm{J}$ equivalent to a particular $\mathbb{M}_\mathrm{E}$. A minimum can thus take place only on a transition surface $\mathbb{S}_\mathrm{trans}$ between two such regions. Consider Eq. (21) rewritten in terms of $B(q)$ [an analogue of (22) in $\mathbb{M}_\mathrm{J}$]:

$$f[R^4 B_{qq} + (\overline{d}+2)R^3 R_q B_q + 2(\overline{d}-1)] + R^4 f_q B_q = 0. \tag{40}$$

Assuming that $q=0$ is $\mathbb{S}_{\text{trans}}$ and simultaneously an extremum of $B(q)$ and taking into account Theorems 3 and 4, we can suppose that the Taylor expansions of B, f, R near $q=0$ begin with the terms

$$\begin{aligned} B &= B_0 + \tfrac{1}{2} B_2 q^2 + \cdots, \\ f &= f_1 q + \cdots, \\ R &= R_0 + R_1 q + \cdots, \end{aligned} \tag{41}$$

with nonzero f_1 and R_0. Substituting (41) into (40), we find in the senior order of magnitude $O(q)$:

$$B_2 = -(\overline{d}-1)/R_0^4. \tag{42}$$

Thus $q=0$ is a maximum of $B(q)$—in particular, if $B_0=0$, we are dealing with CC-II, and $\mathbb{S}_{\text{trans}}$ separates two T-regions.

The lack of minima of $B(q)$ means that there can be at most two simple zeros, with $B>0$ between them, or one double zero outside which $B<0$.

We thus obtain the following theorem, extending Theorem 2 to Jordan frames of arbitrary STT:

Theorem 5: *In the theory (2), $D \geqslant 4$, under the conditions $l(\phi)>0$ and $h(\phi)>0$, configurations with the metric (17) and the field $\phi=\phi(q)$ can have at most two simple horizons (and there is then an* R*-region between them), or one double horizon separating two* T*-regions.*

There certainly can be a single simple horizon, as in the Schwarzschild or de Sitter space–times, or no horizons at all. Theorem 5 means that, precisely as in GR, the list of possible causal structures of scalar-vacuum configurations in STT is exhausted by the list presented in Sec. III for systems with a cosmological constant in D-dimensional GR.

The situation is still simpler for $D=3$: in this case a CC (more precisely, CC-I) is only possible under the condition $B=\text{const}\neq 0$, which excludes horizons. A single horizon can exist, but there is then no CC.

B. Multiple CCs, singularities and wormholes

A full classification of STT solution behaviors is beyond the scope of this article; we will instead outline some new features appearing in STT formulated in $\mathbb{M}_{\text{J}}$ as compared with GR or with the Einstein-frame formulation of STT, in particular, in connection with conformal continuations. For simplicity, we will use the STT parametrization such that $h\equiv 1$.

A singularity in $\mathbb{M}_{\text{J}}$ can emerge due to the behavior of the conformal factor $F=|f|^{-2/\overline{d}}$ at points where $\mathbb{M}_{\text{E}}$ is regular. The most evident case is that $f\to\infty$ at some value of ϕ, then $F\to 0$, and we obtain both $\mathcal{A}=g_{tt}\to 0$ and $R^2=g_{\theta\theta}\to 0$.

Two kinds of singularities can appear in an ''anti-gravitational'' region where $f<0$, that is, beyond a CC surface. The first one occurs if ϕ blows up while ψ is finite. Using the relation (6) between ϕ and ψ, one easily finds that this is only possible when, at large $|\phi|$,

$$f(\phi) \approx -\frac{D-2}{4(D-1)}\phi^2, \tag{43}$$

i.e., when the ϕ field is asymptotically conformally coupled to the curvature. The singularity is then again connected with $F\to 0$ that leads to zero $A(q)$ and $R(q)$.

Another kind of singularity is more generic and occurs where

$$l(\phi)=f+\frac{D-1}{D-2}\left(\frac{df}{d\phi}\right)^2\to 0. \tag{44}$$

Recall that we adhere to the assumption $l>0$ in the whole article. In the case (44), the conformal factor F is finite provided $f\neq 0$ but its derivatives generically blow up:

$$\frac{dF}{du}=-\frac{2}{\overline{d}\sqrt{l(\phi)}}\frac{df}{d\phi}\frac{d\psi}{du}$$

(u is any admissible coordinate in $\mathbb{M}_{\rm E}$), which can only be finite if $d\psi/du\to 0$ at the same u. So, a value of ϕ where $l\to 0$ is generically a singular sphere of finite radius. Recall also Eq. (28) showing that, again generically, the scalar curvature $\mathcal{R}$ is infinite where $l=0$. Special solutions where such a sphere is regular are not completely excluded but are not considered here.

Under the assumption $l>0$, *there cannot be more than two values of* ϕ *where CCs are possible*, i.e., those where $f=0$ and $df/d\phi\neq 0$; if they do exist, one has $f>0$ between them. Indeed, if the function $f(\phi)<0$ between two zeros, it has to pass a minimum where $df/d\phi=0$, hence $l<0$, contrary to our assumption.

This does not mean, however, that a STT solution cannot contain more than two CCs. The point is that ϕ as a function of the radial coordinate is not necessarily monotonic, so there can be two or more CCs corresponding to the same value of ϕ; see the second example in Sec. VI. But there can be no more than one CC-II due to Theorem 5: other CCs in the same solution, if any, belong to type CC-I and occur in a T-region.

Though, multiple CCs can appear in rather special (if not artificial) situations since the very existence of a CC imposes restrictions on the solution parameters, such as (30) for CC-I. A transition surface $\mathbb{S}_{\rm trans}\in\mathbb{M}_{\rm J}$ corresponds to a singularity $r=0$ in $\mathbb{M}_{\rm E}$, therefore an Einstein-frame manifold $\mathbb{M}_{\rm E}$, describing a region between two transitions, should contain ''two centers,'' more precisely, two values of the radial coordinate (say, ρ) at which $r(\rho)=0$. This property, resembling that of a closed cosmological model, is quite generic due to $r''\leqslant 0$ in Eq. (14), but a special feature is that the conditions (30) should hold at both centers.

Another generic (and more usual) behavior of $\mathbb{M}_{\rm E}$ is that r varies from zero to infinity. Let there be a family of such static solutions and an STT with $f(\phi)$ having a simple zero. Then, by Theorem 3, there is a subfamily of solutions admitting CC-I. A particular solution from this subfamily can come beyond $\mathbb{S}_{\rm trans}$ either to one of the above-mentioned types of singularities, or, if ''everything is quiet,'' to another spatial asymptotic and will then describe a static, traversable wormhole. Each of the asymptotics can be either flat [if $U(\phi)\to 0$], or anti-de Sitter [if $U(\phi)\to$const<0]. Thus wormholes are among generic structures that emerge due to conformal continuations.

VI. EXAMPLES

We will present two explicit examples of configurations with CC-I. The first example is well known and is given here to illustrate the generic character of wormholes appearing due to CC. The second one is a three-dimensional periodic structure with an infinite sequence of CCs.

A. Conformal scalar field in GR

Conformal scalar field in GR can be viewed as a special case of STT, such that, in Eq. (2), $D=4$ and

$$f(\phi)=1-\phi^2/6,\quad h(\phi)=1,\quad U(\phi)=0. \tag{45}$$

After the transformation (5) $g_{\mu\nu}=F(\psi)\overline{g}_{\mu\nu}$ with

$$\phi=\sqrt{6}\tanh(\psi+\psi_0)/\sqrt{6}),\quad \psi_0=\text{const},$$
$$F(\psi)=\cosh^2[(\psi+\psi_0)/\sqrt{6}], \tag{46}$$

we obtain the action (1) with $D=4$ and $V\equiv 0$, describing a minimally coupled massless scalar field in GR. The corresponding static, spherically symmetric solution is well known: it is the Fisher solution.[23] In terms of the harmonic radial coordinate $u\in\mathbb{R}_+$, specified by the condition $g_{uu}=-g_{tt}(g_{\theta\theta})^2$, the solution is[5]

$$ds_{\mathrm{E}}^2=\mathrm{e}^{-2mu}dt^2-\frac{k^2\mathrm{e}^{2mu}}{\sinh^2(ku)}\left[\frac{k^2du^2}{\sinh^2(ku)}+d\Omega^2\right],$$
$$\psi=Cu, \tag{47}$$

where $d\Omega^2=d\theta^2+\sin^2\theta d\varphi^2$, m (the mass), C (the scalar charge), $k>0$ and u_0 are integration constants, and k is expressed in terms of m and C:

$$k^2=m^2+C^2/2. \tag{48}$$

In the case $C=0$, $k=m$ we recover the Schwarzschild solution, as is easily verified using the coordinate $\rho=2k/(1-\mathrm{e}^{-2ku})$. The metric (47) takes the form (11) with $A(\rho)=(1-2k/\rho)^{m/k}$ and $r^2(\rho)=\rho^2(1-2k/\rho)^{1-m/k}$.

Another convenient form of the solution is obtained in isotropic coordinates: with $y=\tanh(ku/2)$, Eqs. (47) are converted to

$$ds_{\mathrm{E}}^2=A(y)dt^2-\frac{k^2(1-y^2)^2}{y^4A(y)}(dy^2+y^2d\Omega^2),$$
$$A(y)=\left|\frac{1-y}{1+y}\right|^{2m/k},\quad \psi=\frac{C}{k}\ln\left|\frac{1+y}{1-y}\right|. \tag{49}$$

The solution is asymptotically flat at $u\to 0$ ($y\to 0$), has no horizon when $C\neq 0$ (as should be the case according to the no-hair theorem) and is singular at the center ($u\to\infty$, $y\to 1-0$, $\psi\to\infty$).

A feature of importance is the invariance of (49) under the inversion $y\mapsto 1/y$, noticed probably for the first time by Mitskevich.[24] Due to this invariance, the solution (49) considered in the range $y>1$ describes quite a similar configuration, but now $y\to\infty$ is a flat asymptotic and $y\to 1+0$ is a singular center. An attempt to unify the two ranges of y is meaningless due to the singularity at $y=1$. We shall see that such a unification, leading to a wormhole, is achieved when the singularity is smoothed out in $\mathbb{M}_{\mathrm{J}}$ in case $C=\sqrt{6}m$ due to the conformal factor.

The Jordan-frame solution for (45) is described by the metric $ds^2=F(\psi)ds_{\mathrm{E}}^2$ and the ϕ field according to (46). It is the conformal scalar field solution,[4,25] its properties are more diverse and can be described as follows (putting, for definiteness, $m>0$ and $C>0$):

(**1**) $C<\sqrt{6}m$. The metric behaves qualitatively as in the Fisher solution: it is flat at $y\to 0$ ($u\to 0$), and both g_{tt} and $r^2=|g_{\theta\theta}|$ vanish at $y\to 1$ ($u\to\infty$)—a singular attracting center. A difference is that here the scalar field is finite: $\phi\to\sqrt{6}$.

(**2**) $C>\sqrt{6}m$. Instead of a singular center, at $y\to 1$ ($u\to\infty$) one has a repulsive singularity of infinite radius: $g_{tt}\to\infty$ and $r^2\to\infty$. Again $\phi\to\sqrt{6}$.

(**3**) $C=\sqrt{6}m$, $k=2m$. Now the metric and ϕ are regular at $y=1$; this is $\mathbb{S}_{\mathrm{trans}}$, and the coordinate y provides a continuation. The solution acquires the form

$$ds^2=\frac{(1+yy_0)^2}{1-y_0^2}\left[\frac{dt^2}{(1+y)^2}-\frac{m^2(1+y)^2}{y^4}(dy^2+y^2d\Omega^2)\right],$$
$$\phi=\sqrt{6}\,\frac{y+y_0}{1+yy_0}, \tag{50}$$

where $y_0=\tanh(\psi_0/\sqrt{6})$. The range $u\in\mathbb{R}_+$, describing the whole manifold $\mathbb{M}_E$ in the Fisher solution, corresponds to the range $0<y<1$, describing only a region $\mathbb{M}_J'$ of the manifold $\mathbb{M}_J$ of the solution (50). The properties of the latter depend on the sign of y_0.[5] In all cases, $y=0$ corresponds to a flat asymptotic, where $\phi\to\sqrt{6}y_0$, $|y_0|<1$.

(**3a**) $y_0<0$. The solution is defined in the range $0<y<1/|y_0|$. At $y=1/|y_0|$, there is a naked attracting central singularity: $g_{tt}\to 0$, $r^2\to 0$, $\phi\to\infty$. Such singularities have been mentioned in Sec. V B as a characteristic feature of solutions for conformally and asymptotically conformally coupled scalar fields, see Eq. (43).

(**3b**) $y_0>0$. The solution is defined in the range $y\in\mathbb{R}_+$. At $y\to\infty$, we find another flat spatial infinity, where $\phi\to\sqrt{6}/y_0$, $r^2\to\infty$ and g_{tt} tends to a finite limit. This is a *wormhole solution*, found for the first time in Ref. 5 and recently discussed by Barcelo and Visser.[9]

(**3c**) $y_0=0$, $\phi=\sqrt{6}y$, $y\in\mathbb{R}_+$. In this case it is helpful to pass to the conventional coordinate r, substituting $y=m/(r-m)$. The solution

$$ds^2=(1-m/r)^2dt^2-\frac{dr^2}{(1-m/r)^2}-r^2d\Omega^2,$$
$$\phi=\sqrt{6}m/(r-m) \tag{51}$$

is the well-known BH with a conformal scalar field.[4,25] The infinite value of ϕ at the horizon $r=m$ does not make the metric singular since, as is easily verified, the energy-momentum tensor remains finite there. This solution turns out to be unstable under radial perturbations.[26]

Case 3 belongs to variant III in the classification of Sec. III B, and the whole manifold $\mathbb{M}_J$ can be represented as the union

$$\mathbb{M}_J=\mathbb{M}_J'\cup\mathbb{S}_{\rm trans}\cup\mathbb{M}_J'', \tag{52}$$

where $\mathbb{M}_J'$ is the region $y<1$, which is, according to (46), in one-to-one correspondence with the manifold $\mathbb{M}_E$ of the Fisher solution (47). The "antigravitational" [$f(\phi)<0$] region $\mathbb{M}_J''$ ($y>1$) is in similar correspondence with another "copy" of the Fisher solution, where, instead of (46),

$$\phi=\sqrt{6}\coth(\psi/\sqrt{6}),\quad F(\psi)=\sinh^2(\psi/\sqrt{6}). \tag{53}$$

Static wormhole solutions have also been found[9] for more general nonminimally coupled massless scalar fields in GR, represented as STT where

$$f(\phi)=1-\xi\phi^2,\quad h(\phi)=1,\quad U(\phi)=0 \tag{54}$$

with $\xi=\text{const}>0$. In full agreement with the observations of Sec. V B, there appear wormholes similar to (50), but, in the case $\xi<\frac{1}{6}$, some of the conformally continued solutions possess singularities connected with $l(\phi)=1-\xi(1-6\xi)\phi^3\to 0$. In the case $\xi>\frac{1}{6}$ all continued solutions describe wormholes.

All the wormhole solutions mentioned in this section prove to be unstable under radial perturbations,[27] which seems to be a common feature of transitions to regions with $f<0$, where the effective gravitational constant becomes negative. This problem deserves further study. A similar instability was pointed out by Starobinsky[28] for cosmological models with conformally coupled scalar fields.

B. A solution with multiple CCs

Trying to obtain a simple analytical solution, we choose $D=3$ and the functions $f(\phi)$ and $h(\phi)$ in the action (2) corresponding to conformal coupling:

$$f(\phi)=1-\phi^2/8, \quad h(\phi)\equiv 1. \tag{55}$$

The $\phi-\psi$ connection according to (6) (with a proper choice of the integration constant) and the conformal factor $F(\psi)$ in (5) may be written as

$$\begin{gathered}\phi=\sqrt{8}\tanh(\psi/\sqrt{8}),\\ F(\psi)=\cosh^2(\psi/\sqrt{8}) \quad \text{for} \quad \phi^2<8,\end{gathered} \tag{56}$$

$$\begin{gathered}\phi=\sqrt{8}\coth(\psi/\sqrt{8}),\\ F(\psi)=\sinh^2(\psi/\sqrt{8}) \quad \text{for} \quad \phi^2>8.\end{gathered} \tag{57}$$

A solution in $\mathbb{M}_{\mathrm{J}}$, including regions with $|\phi|$ larger and smaller than $\sqrt{8}$, is built from solutions in different $\mathbb{M}_{\mathrm{E}}$ with CC through the surfaces $\mathbb{S}_{\mathrm{trans}}$ on which $\phi^2=8$.

Let us first construct a solution in the Einstein frame, to be put into correspondence to any of the regions (56) and (57) in $\mathbb{M}_{\mathrm{J}}$, in such a way as to avoid $\psi=0$, since otherwise we shall encounter a singularity due to $F(\psi)=0$ in the region (57). We will use the metric in the form (11) and Eqs. (13)–(15) with $\overline{d}=1$.

As follows from the aforesaid, to provide a CC we must choose a solution to (15) in the form

$$A(\rho)=c_A r^2(\rho), \quad c_A=\text{const}, \tag{58}$$

where $c_A>0$ and $c_A<0$ correspond to static and cosmological solutions, respectively.

By (31), near $\mathbb{S}_{\mathrm{trans}}$ ($\rho=\rho_c$) the function $r(\rho)$ behaves as $(\rho-\rho_c)^{1/D}$. Accordingly, let us choose this function as follows:

$$\begin{gathered}r(\rho)=r_0(1-x^4)^{1/3}, \quad x=\rho/\rho_0,\\ \rho_0=\text{const}>0.\end{gathered} \tag{59}$$

Thus a CC-I can occur at $x=\pm 1$.

Now, Eq. (14) makes it possible to find $\psi(\rho)$, or equivalently $\psi(x)$:

$$\pm 3\frac{d\psi}{dx}=\frac{2x\sqrt{9-x^4}}{1-x^4}. \tag{60}$$

Choosing the plus sign and integrating, we find

$$\psi(x)=-\frac{\sqrt{2}}{3}\ln(1-x^2)+\psi_1(x)+\psi_0, \tag{61}$$

where ψ_0 is an integration constant while the function ψ_1 is analytic and finite for all $|x|\leqslant 1$:

$$\psi_1(x)=\arcsin(x^2/3)+\sqrt{2}\ln\frac{(1+x^2)[9-x^2+\sqrt{8(9-x^4)}]}{9+x^2+\sqrt{8(9-x^4)}}. \tag{62}$$

The potential $V(\psi)$ as a function of x is found from (13):

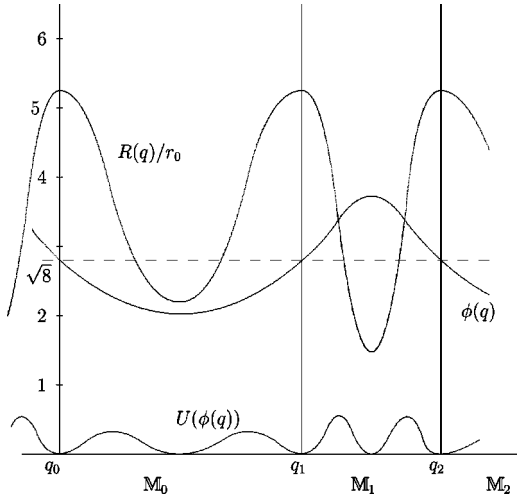

FIG. 3. The behavior of $\phi(q)$, $R(q)$, $U(\phi(q))$ in the model of Sec. VI B with multiple CCs, in the case $\psi_0=\sqrt{8}$, on a segment of the infinite sequence of regions $\mathbb{M}_i$. The latter are separated by vertical lines $q=q_i$ corresponding to the surfaces $\mathbb{S}_{\text{trans}}$. The potential $U(\phi)$ is shown in an arbitrary scale.

$$V(\psi)=2\,\frac{c_A r_0^2}{\rho_0^2}\,\frac{x^2}{(1-x^4)^{1/3}}. \tag{63}$$

This completes the solution in $\mathbb{M}_{\text{E}}$, specified in the range $-1<x<1$. All the constituent functions are even. The potential $V(\psi)$ is well-defined due to monotonicity of $\psi(x)$ in each half-range $0<|x|<1$. At possible CCs, $x=\pm 1$, $\psi\to\infty$, and the minimum value of ψ is $\psi(0)=\psi_0$; assuming $\psi_0>0$, we make sure that $\psi>0$ everywhere.

The corresponding solutions in the Jordan frame are different for $\phi<\sqrt{8}$ and $\phi>\sqrt{8}$, according to (56) and (57) where we put for certainty $\phi>0$.

The solution in $\mathbb{M}_{\text{J}}$ for $\phi<\sqrt{8}$, obtained from $\mathbb{M}_{\text{E}}$ using (56), occupies in $\mathbb{M}_{\text{J}}$ a certain region $\mathbb{M}_0$ parametrized by $x\in(-1.+1)$. The solution can be continued through the surface, say, $x=1$ to $\phi>\sqrt{8}$; to do that one can, i.e., consider the metric coefficients as functions of ϕ and analytically continue them beyond the value $\phi=\sqrt{8}$. However, one cannot do that explicitly since the transcendental equation (61) cannot be resolved with respect to x.

In the new region $\mathbb{M}_1$, which can again be parametrized by $x\in(-1,+1)$, another ''copy'' of the Einstein-frame solution (58)–(63) is valid. To make sure that this is the same solution as the one used in $\mathbb{M}_0$, let us consider the transition between them and recall the proof of Theorem 3 (sufficiency). Namely, there is a unique solution in $\mathbb{M}_{\text{J}}$ near $\mathbb{S}_{\text{trans}}$ (in the form of a power series in q) if the functions $f(\phi)$ and $U(\phi)$ and the constants A_0, R_0 and f_1 are specified. In our case $f(\phi)$ is given, and $U(\phi)$ is not known explicitly but its existence follows from the existence of the analytic continuation in terms of ϕ. So it is sufficient to show that the constants A_0, R_0 and f_1, calculated as the limiting values of $\mathcal{A}=AF$, $R=r\sqrt{F}$ and df/dq, respectively, from the two solutions, are finite and coincide with each other. A direct inspection shows that this is indeed the case if all the parameters of the solutions are the same, including ψ_0.

In $\mathbb{M}_1$ the field ϕ reaches its maximum at $x=0$,

$$\phi_{\max}=\sqrt{8}\,\coth(\psi_0/\sqrt{8}), \tag{64}$$

and returns to the value $\sqrt{8}$ on the other end of the region. One more CC leads to one more region M_2 with $\phi<\sqrt{8}$ and so on. The same happens starting from $x=-1$ of the initial region $\mathbb{M}_0$. We obtain *an infinite sequence of regions* M_i, $i\in\mathbb{Z}$, where adjacent regions are connected by CCs. In

regions with even and odd numbers i, one has $\phi<\sqrt{8}$ and $\phi>\sqrt{8}$, respectively. Each region $\mathbb{M}_i \in \mathbb{M}_J$ corresponds to its own Einstein-frame manifold $\mathbb{M}_{Ei}$, described by the solution (58)–(63) with singularities at $x \to \pm 1$.

The whole manifold $\mathbb{M}_J$ can be parametrized by a unique "radial" coordinate: it can be, e.g., the quasiglobal coordinate q used in Theorem 3, or the proper length $\ell = \int dq/\sqrt{\mathcal{A}}$; both quantities take finite values on the transition surfaces from $\mathbb{M}_i$ to $\mathbb{M}_{i+1}$ and change monotonically inside $\mathbb{M}_i$.

The manifold $\mathbb{M}_J$ is thus nonsingular and has the topology $\mathbb{R}\times\mathbb{R}\times\mathbb{S}^1$: an infinitely long static tube with a periodically changing diameter. This is true if $c_A>0$, when we deal with a static model. One can identify any two $\mathbb{M}_i$ with the numbers i of equal parity, and this leads to the topology $\mathbb{R}\times\mathbb{S}^1\times\mathbb{S}^1$, in other words, two-torus times the time axis. If $c_A<0$, then q is a temporal coordinate, ℓ becomes proper time, and the solution describes a $(2+1)$-dimensional cosmology with a periodically and isotropically (since $A \propto R^2$) changing scale factor. The spatial section is $\mathbb{R}\times\mathbb{S}^1$, but any two points on the t axis (t is now spacelike) may be identified, and we obtain a periodically "breathing" two-torus.

The properties of the model are illustrated in Fig. 3.

(Received 31 May 2002; accepted 20 July 2002)

A large class of nonlocal equations and nonlocal charges for the Harry Dym hierarchy is exhibited. They are obtained from nonlocal Casimirs associated with its bi-Hamiltonian structure. The Lax representation for some of these equations is also given. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1512974]

I. INTRODUCTION

The following nonlinear partial differential equation,

$$w_t=(w^{-1/2})_{xxx}, \tag{1}$$

is known as the Harry Dym equation (see Ref. 1 for a review). It can also be written in the following equivalent forms:

$$v_t=\tfrac{1}{4}v^3v_{xxx},$$

$$u_t=(u_{xx}^{-1/2})_x,$$

for $v=-2^{1/3}w^{-1/2}$ and $u_{xx}=w$, respectively. This equation was obtained by Harry Dym and Martin Kruskal as an evolution equation solvable by a spectral problem based on the string equation instead of the Schrödinger equation. This result was reported in Ref. 2 and rediscovered independently in Refs. 3 and 4. The Harry Dym equation shares many of the properties typical of the soliton equations. It is a completely integrable equation which can be solved by the inverse scattering transform.[5–7] It has a bi-Hamiltonian structure and an infinite number of conservation laws and infinitely many symmetries.[8,9]

The nonlinear hyperbolic equation, which we call the Hunter–Zheng equation,

$$(u_t+uu_x)_{xx}=\tfrac{1}{2}(u_x^2)_x,$$

or the nonlocal version

$$w_t=-(\partial^{-2}w)w_x-2(\partial^{-1}w)w \tag{2}$$

for $u_{xx}=w$, has the same bi-Hamiltonian structure as the Harry Dym equation. The complete integrability of (2) was established in Ref. 10 as well its connection with the Camassa–Holm equation;[11] the former is the high-frequency limit of the latter. Due to the presence of the antiderivative ∂^{-1} the Hunter–Zheng equation (2) is nonlocal.

[a)]Electronic mail: brunelli@fsc.ufsc.br
[b)]Electronic mail: gatcosta@mtm.ufsc.br

As we will describe the Harry Dym equation (1) and the Hunter–Zheng equation (2) belong to the same hierarchy of flows, which we will call the Harry Dym hierarchy. The Hunter–Zheng equation is a member of the positive order equations in this hierarchy while the Harry Dym belongs to the negative order equations. Hierarchies of negative order equations were considered previously through the use of the negative powers of the recursion operator.[12–14] Usually, while the positive order equations are local the negative order ones are nonlocal. For the Harry Dym hierarchy we have the opposite situation, all the positive order equations are nonlocal.

We will show the existence of two new hierarchies of integrable nonlocal equations associated with the Harry Dym hierarchy besides the Hunter–Zheng one. In fact the existence of two nonlocal Casimirs operators implies some sort of degeneracy for the positive order equations.

The paper is organized as follows. In Sec. II we review the bi-Hamiltonian formulation of integrable evolution equations emphasizing the role played by the Casimirs or distinguished functionals of the Hamiltonian operators. We find one more nonlocal Casimir for the modified Kortweg–de Vries equation. In Sec. III we obtain new nonlocal equations as well nonlocal charges for the Harry Dym hierarchy. In Sec. IV we discuss the Lax representation of these equations. The conclusions are given in Sec. V.

II. Bi-HAMILTONIAN SYSTEMS AND CASIMIRS

Central to our discussion is the concept of the bi-Hamiltonian formulation of an integrable evolution equation[8,9]

$$u_t = K_1[u] = \mathcal{D}_1 \frac{\delta H_2}{\delta u} = \mathcal{D}_2 \frac{\delta H_1}{\delta u}.$$

Whenever $\mathcal{D}_1$ and $\mathcal{D}_2$ are compatible this implies the existence of an infinite hierarchy of higher order commuting bi-Hamiltonian systems,

$$u_t^{(n)} = K_n[u] = \mathcal{D}_1 \frac{\delta H_{n+1}}{\delta u} = \mathcal{D}_2 \frac{\delta H_n}{\delta u} \quad \text{with} \quad n \in \mathbb{Z}, \tag{3}$$

where the higher order conservation laws $H_n[u]$ are shared by all members of the hierarchy. This hierarchy of equations can be generated by the recursion operator

$$R = \mathcal{D}_2 \mathcal{D}_1^{-1},$$

since

$$K_{n+1} = R K_n.$$

Also, using

$$\frac{\delta H_{n+1}}{\delta u} = R^{\dagger} \frac{\delta H_n}{\delta u}, \tag{4}$$

where $R^{\dagger} = \mathcal{D}_1^{-1} \mathcal{D}_2$ is the adjoint of R, as a recursion scheme we can obtain the higher Hamiltonians H_n.

We call any functional $H_C[u]$ a Casimir (or distinguished functional) of the Hamiltonian operator $\mathcal{D}$ if

$$\mathcal{D} \frac{\delta H_C}{\delta u} = 0.$$

As a consequence any Hamiltonian system having $\mathcal{D}$ as a Hamiltonian operator,

$$u_t = \mathcal{D}\frac{\delta H}{\delta u},$$

has H_C as a conserved charge. In fact

$$\dot{H}_C = \{H_C, H\} = \int \mathrm{d}x \int \mathrm{d}y \, \frac{\delta H_C}{\delta u(x,t)} \{u(x,t), u(y,t)\} \frac{\delta H}{\delta u(y,t)} = -\int \mathrm{d}x \left(\mathcal{D}\frac{\delta H_C}{\delta u} \right) \frac{\delta H}{\delta u} = 0.$$

When one of the conservation laws in (3) is a Casimir, let us say of $\mathcal{D}_1$, the hierarchy of equations stops except if the Hamiltonian operator $\mathcal{D}_2$ has at least one Casimir.

The Kortweg–de Vries (KdV) equation

$$u_t = u_{xxx} + 3uu_x$$

has the following series of conservation laws:

$$H_0 = \int \mathrm{d}x \, u,$$

$$H_1 = \int \mathrm{d}x \, \frac{1}{2}u^2,$$

$$H_2 = \int \mathrm{d}x \, \frac{1}{2}(u^3 - u_x^2),$$

$$\vdots,$$

and the two compatible Hamiltonian operators

$$\begin{aligned} \mathcal{D}_1 &= \partial, \\ \mathcal{D}_2 &= \partial^3 + u\partial + \partial u. \end{aligned} \tag{5}$$

From (3) we get

$$u_t^{(0)} = \mathcal{D}_1\frac{\delta H_1}{\delta u} = \mathcal{D}_2\frac{\delta H_0}{\delta u} = u_x,$$

$$u_t^{(1)} = \mathcal{D}_1\frac{\delta H_2}{\delta u} = \mathcal{D}_2\frac{\delta H_1}{\delta u} = u_{xxx} + 3uu_x,$$

$$u_t^{(2)} = \mathcal{D}_1\frac{\delta H_3}{\delta u} = \mathcal{D}_2\frac{\delta H_2}{\delta u} = u_{xxxxx} + 5uu_{xxx} + 10u_xu_{xx} + \frac{15}{2}u^2u_x,$$

$$\vdots$$

and apparently we cannot extend this recursion procedure for negatives values of n in (3) since H_0 is a Casimir of $\mathcal{D}_1$ and $\mathcal{D}_2$ appears to have only trivial local distinguished functionals [see Eq. (9)]. Now, the modified KdV equation (mKdV)

$$u_t = u_{xxx} + \tfrac{3}{2}u^2u_x$$

has the following bi-Hamiltonian form:

$$u_t = \mathcal{D}_1 \frac{\delta H_2}{\delta u} = \mathcal{D}_2 \frac{\delta H_1}{\delta u},$$

where

$$\begin{aligned} \mathcal{D}_1 &= \partial, \\ \mathcal{D}_2 &= \partial^3 + \partial u \partial^{-1} u \partial, \end{aligned} \tag{6}$$

and

$$H_1 = \int \mathrm{d}x \frac{1}{2} u^2,$$

$$H_2 = \int \mathrm{d}x \left(\frac{1}{8} u^4 - \frac{1}{2} u_x^2 \right).$$

Of course, $H_0 = \int \mathrm{d}x\, u$ is the Casimir of $\mathcal{D}_1$, however $\mathcal{D}_2$ in (6) admits a nontrivial nonlocal Casimir,[15]

$$H_C = \int \mathrm{d}x \cos(\partial_x^{-1} u).$$

Here we will define the skew-adjoint antiderivative ∂^{-1} acting on functions u, which satisfy $u \to 0$ as $|x| \to \infty$, by

$$(\partial_x^{-1} u) \equiv (\partial^{-1} u)(x) = \int_{-\infty}^{+\infty} \mathrm{d}y\, \epsilon(x-y) u(y), \tag{7}$$

where

$$\epsilon(x-y) = \begin{cases} 1/2 & \text{for } x > y, \\ -1/2 & \text{for } x < y. \end{cases}$$

From now on we will omit the x subscript in (7). It is easy to verify that for functions A and B of u we have the property

$$\int \mathrm{d}x\, A(\partial^{-1} B) = -\int \mathrm{d}x (\partial^{-1} A) B.$$

Now

$$\frac{\delta H_C}{\delta u} = \partial^{-1}(\sin(\partial^{-1} u))$$

and it is easy to show that $\mathcal{D}_2(\delta H_C / \delta u) = 0$. From (3) we get, for $n = -1, -2, \ldots$, a hierarchy of negative order equations

$$
\begin{aligned}
u_t^{(0)} &= \mathcal{D}_1 \frac{\delta H_1}{\delta u} = \mathcal{D}_2 \frac{\delta H_0}{\delta u} = u_x, \\
u_t^{(-1)} &= \mathcal{D}_1 \frac{\delta H_0}{\delta u} = \mathcal{D}_2 \frac{\delta H_{-1}}{\delta u} = 0, \\
u_t^{(-2)} &= \mathcal{D}_1 \frac{\delta H_{-1}}{\delta u} = \mathcal{D}_2 \frac{\delta H_{-2}}{\delta u} = \sin(\partial^{-1} u), \\
&\vdots
\end{aligned}
\tag{8}
$$

where $H_{-1} \equiv H_C$. Introducing the potential function $\psi_x = u$ the last equation in (8) is the sine-Gordon equation

$$\psi_{xt} = \sin \psi.$$

Besides H_0 and H_C we have found that the Hamiltonian operator $\mathcal{D}_2$ also has the following nonlocal Casimir:

$$H_C' = \int \mathrm{d}x \sin(\partial^{-1} u)(\partial^{-1} \cos(\partial^{-1} u)),$$

which will generate another negative order hierarchy of equations.

Returning to the KdV equation, if we set

$$u = -2 \psi^{-1} \psi_{xx},$$

the second Hamiltonian structure in (5) can be written as

$$\mathcal{D}_2 = \psi^{-2} \partial \psi^2 \partial \psi^2 \partial \psi^{-2},$$

and it follows that

$$\psi^2, \quad \psi^2(\partial^{-1} \psi^{-2}), \quad \psi^2 \partial^{-1}(\psi^{-2}(\partial^{-1} \psi^{-2})) \tag{9}$$

are non trivial kernels of $\mathcal{D}_2$. We will not discuss this system here but the Casimirs associated with (9) will give rise to nonlocal KdV hierarchies of equations (see Refs. 12–14, and references therein) and nonlocal charges. Instead, we will perform this analysis in a systematic way for the Harry Dym hierarchy in Sec. III.

III. THE HARRY DYM HIERARCHY

The Harry Dym equation (1) is a completely integrable bi-Hamiltonian system[8,9]

$$w_t = \mathcal{D}_1 \frac{\delta H_{-1}}{\delta w} = \mathcal{D}_2 \frac{\delta H_{-2}}{\delta w},$$

where

$$
\begin{aligned}
\mathcal{D}_1 &= \partial^3, \\
\mathcal{D}_2 &= w \partial + \partial w,
\end{aligned}
\tag{10}
$$

and

$$H_{-1}=\int \mathrm{d}x(2w^{1/2}),$$

$$H_{-2}=\int \mathrm{d}x\left(\frac{1}{8}w^{-5/2}w_x^2\right).$$

It is well known that H_{-1} is a Casimir of $\mathcal{D}_2$ and that

$$H_0=-\int \mathrm{d}x\, w \tag{11}$$

is a Casimir of $\mathcal{D}_1$. So, we can consider equations going ''up'' and ''down'' in Eq. (3). However, we also have the following nonlocal Casimirs for $\mathcal{D}_1$:

$$\begin{aligned} H_0^{(1)}&=\int \mathrm{d}x(\partial^{-1}w),\\ H_0^{(2)}&=\int \mathrm{d}x(\partial^{-2}w). \end{aligned} \tag{12}$$

In this way (3) gets degenerated for $n>0$,

$$\vdots$$

$$\begin{aligned} w_t^{(2,\alpha)}&=\mathcal{D}_1\frac{\delta H_2^{(\alpha)}}{\delta w}=\mathcal{D}_2\frac{\delta H_1^{(\alpha)}}{\delta w},\\ w_t^{(1,\alpha)}&=\mathcal{D}_1\frac{\delta H_1^{(\alpha)}}{\delta w}=\mathcal{D}_2\frac{\delta H_0^{(\alpha)}}{\delta w},\\ w_t^{(0)}&=\mathcal{D}_1\frac{\delta H_0^{(\alpha)}}{\delta w}=\mathcal{D}_2\frac{\delta H_{-1}}{\delta w}=0,\\ w_t^{(-1)}&=\mathcal{D}_1\frac{\delta H_{-1}}{\delta w}=\mathcal{D}_2\frac{\delta H_{-2}}{\delta w}=(w^{-1/2})_{xxx},\\ &\vdots, \end{aligned} \tag{13}$$

where $\alpha=0$, 1, 2 and $H_0^{(0)}=H_0$.

Using (4) and (13) as a recursion scheme we can obtain, after a straightforward but tedious calculation, the first few Hamiltonian functionals and flows for the Harry Dym hierarchy equations. For $n\leqslant 0$ the first conserved charges, some of them already calculated in Ref. 10, are

$$H_0=H_0^{(0)}=\int \mathrm{d}x(-w),$$

$$H_{-1}=\int \mathrm{d}x\, 2w^{1/2},$$

$$H_{-2}=\int \mathrm{d}x\,\frac{1}{8}w^{-5/2}w_x^2,$$

$$H_{-3}=\int \mathrm{d}x\,\frac{1}{16}\left(\frac{35}{16}w^{-11/2}w_x^4-w^{-7/2}w_{xx}^2\right), \tag{14}$$

$$H_{-4}=\int \mathrm{d}x\,\frac{1}{32}\left(\frac{5005}{128}w^{-17/2}w_x^6-\frac{231}{8}w^{-13/2}w_x^2w_{xx}^2+5w^{-11/2}w_{xx}^3+w^{-9/2}w_{xxx}^2\right),$$

$$\vdots$$

and the first flows are

$$w_t^{(0)}=0,$$

$$w_t^{(-1)}=(w^{-1/2})_{xxx},$$

$$w_t^{(-2)}=\tfrac{1}{4}(\tfrac{5}{4}w^{-7/2}w_x^2-w^{-5/2}w_{xx})_{xxx}, \tag{15}$$

$$w_t^{(-3)}=\tfrac{1}{16}(\tfrac{1155}{32}w^{-13/2}w_x^4-\tfrac{231}{4}w^{-11/2}w_x^2w_{xx}+\tfrac{21}{2}w^{-9/2}w_{xx}^2+14w^{-9/2}w_{xxx}w_x-2w^{-7/2}w_{xxxx})_{xxx},$$

$$\vdots.$$

For $n>0$ we have to consider the three cases $\alpha=0$, 1, 2 separately. So, for $\alpha=0$ we get the nonlocal conserved charges

$$H_1^{(0)}=\int \mathrm{d}x\,\frac{1}{2}(\partial^{-1}w)^2,$$

$$H_2^{(0)}=\int \mathrm{d}x\,\frac{1}{2}(\partial^{-2}w)(\partial^{-1}w)^2,$$

$$H_3^{(0)}=\int \mathrm{d}x\left[\frac{1}{4}(\partial^{-2}w)^2(\partial^{-1}w)^2+\frac{1}{8}(\partial^{-1}(\partial^{-1}w)^2)^2\right], \tag{16}$$

$$H_4^{(0)}=\int \mathrm{d}x\left[\frac{1}{12}(\partial^{-2}w)^3(\partial^{-1}w)^2-\frac{1}{4}(\partial^{-1}w)^2\partial^{-2}((\partial^{-2}w)(\partial^{-1}w)^2)\right.$$
$$\left.-\frac{1}{8}(\partial^{-2}w)(\partial^{-1}(\partial^{-1}w)^2)^2\right],$$

$$H_5^{(0)}=\int \mathrm{d}x\Big[\frac{1}{48}(\partial^{-2}w)^4(\partial^{-1}w)^2-\frac{1}{8}(\partial^{-2}w)^2(\partial^{-1}w)^2(\partial^{-2}(\partial^{-1}w)^2)$$
$$-\frac{1}{16}(\partial^{-2}w)^2(\partial^{-1}(\partial^{-1}w)^2)^2+\frac{1}{16}(\partial^{-2}(\partial^{-1}w)^2)^2(\partial^{-1}w)^2$$
$$+\frac{1}{16}(\partial^{-1}w)^2(\partial^{-2}(\partial^{-1}(\partial^{-1}w)^2)^2)+\frac{1}{8}(\partial^{-1}((\partial^{-1}w)\partial^{-1}(\partial^{-1}w)^2))^2\Big],$$
$$\vdots,$$

and the first flows are

$$\begin{gathered} w_t^{(1,0)}=-w_x, \\ w_t^{(2,0)}=-(\partial^{-2}w)w_x-2(\partial^{-1}w)w, \\ w_t^{(3,0)}=-\tfrac{1}{2}(\partial^{-2}w)^2w_x-2(\partial^{-2}w)(\partial^{-1}w)w+\tfrac{1}{2}(\partial^{-2}(\partial^{-1}w)^2)w_x+w(\partial^{-1}(\partial^{-1}w)^2), \\ \vdots. \end{gathered} \tag{17}$$

Note that the flow $w_t^{(2,0)}$ is the Hunter–Zheng equation (2).

From (10) we can construct the recursion operator

$$R=\mathcal{D}_2\mathcal{D}_1^{-1}=2w\partial^{-2}+w_x\partial^{-3}, \tag{18}$$

and since

$$(\partial w+w\partial)^{-1}=\tfrac{1}{2}w^{-1/2}\partial^{-1}w^{-1/2}$$

we have

$$R^{-1}=\tfrac{1}{2}\partial^3w^{-1/2}\partial^{-1}w^{-1/2}.$$

The flows (15) and (17) can now be expressed as the action of powers of R acting on the seed equation $w_t^{(1,0)}=\mathcal{D}_2\,(\delta H_0^{(0)}/\delta w)=-w_x$,

$$w_t^{(n)}=R^{n-1}(-w_x), \quad n=0,-1,-2,..., \tag{19}$$

$$w_t^{(n,0)}=R^{n-1}(-w_x), \quad n=1,2,3,.... \tag{20}$$

To be able to perform the steps in the iteration given in (19) and (20) we must point out that for any function $f(x,t)$ we can use instead of (7) the representation[16,12,13,14]

$$(\partial^{-1}f)(x,t)=\int_{-\infty}^{+\infty}\mathrm{d}y\;\epsilon(x-y)f(y,t)+c(t),$$

where $c(t)$ is a function of t. Here we set $c=0$ for any f, except $f=0$ where we use $c=2$. In this way,

$$w_t^{(0)}=R^{-1}(-w_x)=0$$

and

$$w_t^{(-1)}=R^{-2}(-w_x)=\tfrac{1}{2}\partial^3w^{-1/2}\partial^{-1}0=(w^{-1/2})_{xxx},$$

resulting in the Harry Dym equation.

For $n>0$ and $\alpha=1, 2$ we have the seed equations

$$w_t^{(1,1)}=\mathcal{D}_2\frac{\delta H_0^{(1)}}{\delta w}=-2w-xw_x,$$
$$w_t^{(1,2)}=\mathcal{D}_2\frac{\delta H_0^{(2)}}{\delta w}=2xw+\frac{x^2}{2}w_x, \tag{21}$$

where we have used $(\partial^{-n}1)=x^n/n$, for $n>0$. The respective flows follow from the analog of (20) and they read for $\alpha=1$,

$$w_t^{(1,1)}=-2w-xw_x,$$
$$w_t^{(2,1)}=-2wx(\partial^{-1}w)-w_x(\partial^{-1}(x(\partial^{-1}w))),$$
$$w_t^{(3,1)}=(2w+w_x\partial^{-1})\left(\frac{x}{2}\partial^{-1}(\partial^{-1}w)^2-(\partial^{-1}w)\partial^{-1}(x(\partial^{-1}w))\right), \tag{22}$$
$$\vdots$$

and for $\alpha=2$,

$$w_t^{(1,2)}=2xw+\frac{x^2}{2}w_x,$$
$$w_t^{(2,2)}=2w(\tfrac{1}{2}x^2(\partial^{-1}w)-(\partial^{-3}w))+w_x\partial^{-1}(\tfrac{1}{2}x^2(\partial^{-1}w)-(\partial^{-3}\omega)),$$
$$w_t^{(3,2)}=(2w+w_x\partial^{-1})\left(\frac{1}{2}\partial^{-1}(\partial^{-2}w)^2+\frac{1}{2}\partial^{-3}(\partial^{-2}w)^2-(\partial^{-4}w)(\partial^{-1}w)-\frac{x^2}{4}\partial^{-1}(\partial^{-1}w)^2\right.$$
$$\left.+\frac{1}{2}(\partial^{-1}w)\partial^{-1}(x^2(\partial^{-1}w))\right), \tag{23}$$
$$\vdots.$$

Again using (4) and (13) recursively we obtain the nonlocal conserved charges

$$H_1^{(1)}=-\frac{1}{2}\int \mathrm{d}x\,\partial^{-1}(\partial^{-1}w)^2,$$
$$H_2^{(1)}=\frac{1}{2}\int \mathrm{d}x\,\partial^{-1}((\partial^{-1}w)\partial^{-1}(\partial^{-1}w)^2),$$
$$H_3^{(1)}=-\frac{1}{2}\int \mathrm{d}x\,\partial^{-1}\left[\frac{1}{4}(\partial^{-1}(\partial^{-1}w)^2)^2+(\partial^{-1}w)\partial^{-1}((\partial^{-1}w)\partial^{-1}(\partial^{-1}w)^2)\right], \tag{24}$$
$$\vdots$$

and

$$H_1^{(2)}=-\frac{1}{2}\int \mathrm{d}x[(\partial^{-2}w)^2+(\partial^{-2}(\partial^{-1}w)^2)],$$

$$H_2^{(2)}=\frac{1}{2}\int \mathrm{d}x\left[\frac{1}{3}(\partial^{-2}w)^3+\partial^{-2}((\partial^{-1}w)(\partial^{-1}(\partial^{-1}w)^2))+(\partial^{-4}w)(\partial^{-1}w)^2\right],$$

$$H_3^{(2)}=-\frac{1}{2}\int \mathrm{d}x\left[\frac{1}{12}(\partial^{-1}w)^4+\frac{1}{4}(\partial^{-2}(\partial^{-1}w)^2)^2+\frac{1}{4}\partial^{-2}(\partial^{-1}(\partial^{-1}w)^2)^2\right.$$
$$+\frac{1}{2}(\partial^{-1}w)^2\partial^{-2}(\partial^{-2}w)^2-(\partial^{-1}w)^2\partial^{-1}((\partial^{-4}w)(\partial^{-1}w))$$
$$\left.+\partial^{-2}((\partial^{-1}w)\partial^{-1}((\partial^{-1}w)(\partial^{-1}(\partial^{-1}w)^2)))\right], \tag{25}$$

$$\vdots.$$

These hierarchies of integrable equations become extremely nonlocal as we proceed further in the recursion. $w_t^{(2,1)}$ and $w_t^{(2,2)}$ are equations of the Hunter–Zheng type. It is interesting to note that Eqs. (17), (22), and (23) are in the positive direction (positive flows) of recursion while the Harry Dym equations (15) are in the negative direction (negative flows). Of course this is due to the fact that the recursion operator (18) is completely nonlocal. That is to be compared with the usual situation we have for the KdV recursion operator $R=\partial^2+2u+u_x\partial^{-1}$.

After obtaining Eqs. (22) and (23) we became aware of Refs. 17 and 18 where these equations are given implicitly in a recursion form. However, we have shown here their origin from the Casimirs (11) and (12).

IV. LAX PAIRS

The equations in the Harry Dym hierarchy are integrable since they are bi-Hamiltonian. Therefore we hope to find a Lax representation for all of them. In fact, the Lax pair for the Harry Dym equation (1) is given by[1,19,20]

$$L=\frac{1}{w}\partial^2, \tag{26}$$

$$B=-2w^{-3/2}\partial^3+\tfrac{3}{2}w^{-5/2}w_x\partial^2,$$

$$\frac{\partial L}{\partial t}=[B,L]. \tag{27}$$

Calculating the square-root of L (aided by a computer algebra program) we obtain

$$L^{1/2}=\beta\partial+a_0+a_1\partial^{-1}+a_2\partial^{-2}+a_3\partial^{-3}+a_4\partial^{-4}+a_5\partial^{-5}+O(\partial^{-6}),$$

where

$$\beta=w^{-1/2},$$

$$a_0=-\tfrac{1}{2}\beta_x,$$

$$a_1=\frac{1}{2^2}\beta_{xx}-\frac{1}{2^3}\beta_x^2\beta^{-1},$$

$$a_2=-\frac{1}{2^3}\beta_{xxx}-\frac{3}{2^4}\beta_x^3\beta^{-2}+\frac{3}{2^3}\beta_x\beta_{xx}\beta^{-1},$$

$$a_3=\frac{1}{2^4}\beta_{xxxx}-\frac{3}{2^3}\beta_x\beta_{xx}\beta^{-1}+\frac{37}{2^5}\beta_x^2\beta_{xx}\beta^{-2}-\frac{61}{2^7}\beta_x^4\beta^{-3}-\frac{13}{2^5}\beta_{xx}^2\beta^{-1},$$

$$a_4=-\frac{1}{2^5}\beta_{(5)}+\frac{5\cdot 7}{2^5}\beta_{xx}\beta_{xxx}\beta^{-1}+\frac{5}{2^4}\beta_x\beta_{xxxx}\beta^{-1}-\frac{3\cdot 5\cdot 7}{2^6}\beta_x^2\beta_{xxx}\beta^{-2}-\frac{3\cdot 5\cdot 13}{2^6}\beta_x\beta_{xx}^2\beta^{-2}$$
$$+\frac{3^2\cdot 5\cdot 7}{2^6}\beta_x^3\beta_{xx}\beta_{-3}-\frac{3\cdot 5\cdot 29}{2^8}\beta_x^5\beta^{-4},$$

$$a_5=\frac{1}{2^6}\beta_{(6)}-\frac{7\cdot 17}{2^7}\beta_{xxx}^2\beta^{-1}-\frac{19}{2^4}\beta_{xx}\beta_{xxxx}\beta^{-1}+\frac{43}{2^2}\beta_{xx}\beta_{xxx}\beta_x\beta^{-2}-\frac{3\cdot 5}{2^6}\beta_x\beta_{(5)}\beta^{-1}$$
$$+\frac{241}{2^7}\beta_x^2\beta_{xxxx}\beta^{-2}-\frac{569}{2^6}\beta_x^3\beta_{xxx}\beta^{-3}+\frac{413}{2^7}\beta_{xx}^3\beta^{-2}-\frac{3\cdot 1973}{2^8}\beta_x^2\beta_{xx}^2\beta^{-3}$$
$$+\frac{3\cdot 4493}{2^9}\beta_x^4\beta_{xx}\beta^{-4}-\frac{7\cdot 17\cdot 67}{2^{10}}\beta_x^6\beta^{-5},$$

where $\beta_{(n)}=\mathrm{d}^n\beta/\mathrm{d}x^n$. Now it can be easily recognized that

$$B=-2(L^{3/2})_{\geqslant 2},$$

and $(\ )_{\geqslant 2}$ stands for the differential part of the pseudodifferential operator with terms ∂^n, $n\geqslant 2$. In this way (27) assumes the nonstandard Lax representation

$$\frac{\partial L}{\partial t}=-2[(L^{3/2})_{\geqslant 2},L]. \tag{28}$$

Similarly the whole negative hierarchy of Eq. (15) can be obtained from

$$\frac{\partial L}{\partial t}=-2^n[(L^{(2n+1)/2})_{\geqslant 2},L],\quad n=0,1,2,\ldots. \tag{29}$$

The charges (14) (except by multiplicative constant factors) follow from

$$H_{-(n+1)}=\mathrm{Tr}L^{(2n-1)/2},\quad n=1,2,3,..., \tag{30}$$

where ''Tr'' is the usual Adler trace.[21] We have used (29) and (30) to perform a check of Eq. (15) and charges (14), respectively.

Through ''gauge transformations'' [22] the Lax representation for the Harry Dym hierarchy (27) and (28) can be brought in other forms. For instance, the Harry Dym equation also follows from

$$L'=\partial L\partial^{-1},$$

with the nonstandard Lax representation

$$\frac{\partial L'}{\partial t}=-2[(L'^{3/2})_{\geqslant 1},L'], \tag{31}$$

or even from a standard Lax representation

$$\frac{\partial L''}{\partial t} = -2[(L''^{3/2})_{\geqslant 0}, L''],$$

with

$$L'' = w^{1/2} L w^{-1/2}.$$

So, for the negative flows of the Harry Dym hierarchy we have a complete Lax representation. However, for the positive flows the Lax representation picture is not so complete. It is easy to check that the Lax operator (26) with

$$\frac{\partial L}{\partial t} = -2[B^{(i,\alpha)}, L], \quad i = 1,2,3,\ldots, \quad \alpha = 0,1,2, \tag{32}$$

yields the first equations $w^{(1,\alpha)}$, for the positive flows (17), (22), and (23), if we choose

$$B^{(1,0)} = \tfrac{1}{2}\partial,$$

$$B^{(1,1)} = -\tfrac{1}{4} + \tfrac{1}{2} x \partial,$$

$$B^{(1,2)} = \tfrac{1}{4} x - \tfrac{1}{4} x^2 \partial,$$

respectively. For the equations $w^{(2,\alpha)}$ in (17), (22), and (23) we have obtained, for $i=2$ in (32), the operators

$$B^{(2,0)} = \tfrac{1}{4}(\partial^{-2} w)\partial + \tfrac{1}{4}\partial^{-1}(\partial^{-2} w)\partial^2,$$

$$B^{(2,1)} = \tfrac{1}{4}(\partial^{-1}(x\partial^{-1} w))\partial + \tfrac{1}{4}\partial^{-1}(\partial^{-1}(x\partial^{-1} w))\partial^2 - \tfrac{1}{4}\partial^{-1}(\partial^{-1} w),$$

$$B^{(2,2)} = \tfrac{1}{4}(\partial^{-1}(\tfrac{1}{2}x^2\partial^{-1} w - \partial^{-3} w))\partial + \tfrac{1}{4}\partial^{-1}(\partial^{-1}(\tfrac{1}{2}x^2\partial^{-1} w - \partial^{-3} w))\partial^2 - \tfrac{1}{4}\partial^{-1} x(\partial^{-1} w) + \tfrac{1}{4}\partial^{-1}(\partial^{-2} w) + \tfrac{1}{8}\partial^{-2} x w.$$

In fact $B^{(2,0)}$ was first obtained in Ref. 10 but in the nonstandard Lax representation (31). An interesting question is how, if possible at all, $B^{(i,\alpha)}$ in (32) and the nonlocal charges $H_n^{(\alpha)}$ in (16), (24), and (25) can be obtained from the same Lax operator (26), i.e., what are the analogs of Eqs. (29) and (30) for the positive Harry Dym flows? In the literature we can find Lax representations for equations obtained by the inverse recursion operator,[23,24] such as of the Harry Dym type. However, these Lax representations are not given only in terms of L and use some sort of ansatz. Also, the authors do not try to obtain the relation between the nonlocal charges and the Lax operator. These intriguing points are under investigation and will appear elsewhere.

V. CONCLUSION

We have given a unified picture of the Harry Dym hierarchy of equations which includes local as well a series of three nonlocal hierarchies of equations. We have shown, using the bi-Hamiltonian formulation of integrable models, how the nonlocal Casimirs lead to these nonlocal equations and also to three series of nonlocal charges. Some of the nonlocal equations and nonlocal charges obtained in this way are new. This procedure can also be applied for the KdV and mKdV equations since both equations, in accordance with the discussion in Sec. II, also have three Casimirs associated with the third-order Hamiltonian operator $\mathcal{D}_2$. We believe that the treatment given here for the Harry Dym hierarchy unifies, within the bi-Hamiltonian formulation of the integrable models, some of the results scattered in the literature. We have also tried to understand these nonlocal equations and charges from a Lax representation. Even though we have found explicitly Lax pairs for some of the positive flows a unique Lax representation is still missing.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 12 DECEMBER 2002

Infinite symmetries and conservation laws

V. Rosenhaus[a)]
Department of Mathematics and Statistics, California State University, Chico, California 95929

(Received 13 December 2001; accepted 2 September 2002)

We will consider partial differential equations of a variational problem whose symmetry group generators contain arbitrary function(s) of one or more independent variables. Unlike the Second Noether Theorem we will be interested in the case of arbitrary functions of not all base variables. We will study the relations between infinite symmetries and local conservation laws. We will demonstrate that infinite symmetries may lead to a finite number of conservation laws through appropriate boundary conditions, or to a set of additional constraints for the function and its derivatives. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1517394]

I. INTRODUCTION

The problem of the relationship between symmetries and conservation laws has a long history starting from the famous work by Emmy Noether.[1] A thorough study of the Noether theory with many references can be found in Ref. 2; see also Refs. 3, 4 and references therein, and the paper by Lanczos.[5] Numerous applications of the Noether Theorem are presented in Ref. 6.

In this paper we will discuss a problem somewhat intermediate between the First and the Second Noether Theorems:[1] the correspondence between infinite-dimensional symmetries and conservation laws. We consider differential equations in R^n that admit infinite symmetry algebras with operators depending on an arbitrary function of independent variables, as well as its derivatives. We will be interested in systems corresponding to a well defined variational (action) functional, where symmetries of the functional (variational or Noether symmetries) are at the same time symmetries of our differential system (see, e.g., Ref. 2). Our goal is to generate conservation laws associated with infinite symmetries through the Noether mechanism. By a conservation law, we will mean such a continuity equation, which leads to nonvanishing conserved (in time) quantity. We will consider a general situation of an arbitrary function of $k<n$ independent variables, or their combinations, for a differential equation with a Lagrangian of any order, and will follow the ideology of Ref. 7 where the case of an arbitrary function of one variable: x or t was studied for first order Lagrangians. We will demonstrate that considered infinite symmetries do not lead to an infinite number of conservation laws. We will also show that boundary conditions determine the existence of a finite number of conservation laws.

The paper is organized as follows.

In Sec. II we review the First and Second Noether Theorems. We point out the essential difference between the case of arbitrary functions of all independent variables of the base space and arbitrary functions of some of the base variables.

In Sec. III we consider the case of an arbitrary function of one independent variable, and introduce a ''strict'' boundary condition as a necessary condition for the existence of conservation laws.

In Sec. IV we analyze the correspondence between infinite symmetries and conservation laws for Lagrangian differential equations of the second order associated with one-dimensional infinite symmetries.

In Sec. V a special situation of an arbitrary function of time is considered and the role of boundary conditions for the generation of conservation laws is discussed.

[a)]Electronic mail: vrosenhaus@csuchico.edu

In Sec. VI we deal withthe correspondence between infinite symmetries and conservation laws for higher order differential equations.

In Sec. VII the generalizations for arbitrary functions of several variables are discussed.

II. FIRST AND SECOND NOETHER THEOREMS

Let

$$S=\int L(x^i,u,u_i,\ldots)d^nx, \tag{1}$$

be the action functional, where L is the Lagrangian density, $x^i=(x,y,\ldots,t)$, $i=1,...,n$ are independent variables and u is a dependent variable, $u_i\equiv\partial u/\partial x^i$, $u_{ij}\equiv\partial^2 u/\partial x^i\,\partial x^j$. Then

$$E(L)\equiv\omega(x,u,u_i,u_{ij},\ldots)=0 \tag{2}$$

is the equation of motion, where E is the Euler–Lagrange operator,

$$E=\frac{\partial}{\partial u}-D_i\frac{\partial}{\partial u_i}+\sum_{i\leqslant j}D_iD_j\frac{\partial}{\partial u_{ij}}+\cdots. \tag{3}$$

Consider an infinitesimal transformation of the form (see, e.g., Ref. 2)

$$\begin{aligned} x'^i&=x^i+\varepsilon\xi^i(x,u,u_j,\ldots)+O(\varepsilon^2),\\ u'&=u+\varepsilon\eta(x,u,u_j,\ldots)+O(\varepsilon^2), \end{aligned} \tag{4}$$

where ε is a small parameter. The operator corresponding to this transformation is

$$X=\xi^i\frac{\partial}{\partial x^i}+\eta\frac{\partial}{\partial u}+\zeta^i\frac{\partial}{\partial u_i}+\cdots. \tag{5}$$

Instead of X, we consider a canonical operator X_α with $\alpha=\eta-\xi^iu_i$:

$$\begin{aligned} X_\alpha&=\alpha\frac{\partial}{\partial u}+\sum_i(D_i\alpha)\frac{\partial}{\partial u_i}+\sum_{i\leqslant j}(D_iD_j\alpha)\frac{\partial}{\partial u_{ij}}+\cdots,\\ &i,j=1,...,m+1. \end{aligned} \tag{6}$$

In the future we will make use of the Noether identity (see Ref. 8 or Ref. 4, or Ref. 9 for a version used here):

$$X_\alpha=\alpha E+\sum_{i=1}D_iR_{\alpha i}, \tag{7}$$

where

$$\begin{aligned} R_{\alpha i}=&\alpha\frac{\partial}{\partial u_i}+\left\{\sum_{k\geqslant i}(D_k\alpha)-\alpha\sum_{k\leqslant i}D_k\right\}\frac{\partial}{\partial u_{ik}}\\ &+\left\{\sum_{k\geqslant j\geqslant i}(D_jD_k\alpha)-\sum_{k\leqslant i\leqslant j}(D_j\alpha)D_k+\alpha\sum_{j\leqslant k\leqslant i}D_JD_k\right\}\frac{\partial}{\partial u_{ijk}}+\cdots. \end{aligned} \tag{8}$$

Variation of the functional S under a transformation (4) with the symmetry vector α and operator X_α is

$$\delta S = \int [X_\alpha L + D_i(\xi^i L)] d^n x. \tag{9}$$

Let the canonical transformation X_α be a variational (Noether) symmetry,

$$X_\alpha L = D_i M_i . \tag{10}$$

The application of Noether identity (7) to L gives

$$X_\alpha L = \alpha\omega + D_i(R_{\alpha i} L). \tag{11}$$

Combining (11) with (10) we will obtain

$$D_i(M_i - R_{\alpha i} L) = \alpha\omega, \tag{12}$$

meaning that on the solution manifold ($\omega = 0$, $D_i\omega = 0, \ldots$) we get a continuity equation

$$D_i(M_i - R_{\alpha i} L) \doteq 0. \tag{13}$$

Thus, any variational symmetry α (in case of a finite Lie group) leads to a corresponding conservation law (continuity equation) (13); which is a statement of the First Noether Theorem.[1]

Consider now a case of an infinite group where the symmetry vector α is of the form

$$\alpha = a p(x) + b_i D_i p(x) + c_{ij} D_i D_j p(x) + \cdots, \tag{14}$$

with an *arbitrary function* $p(x)$. Applying the Noether identity (7) to L,

$$X_\alpha L = \alpha^b E^b(L) + D_i(R_{\alpha i} L), \tag{15}$$

and transforming the rhs of (15) we obtain

$$\begin{aligned} \alpha^b E^b(L) &= (a^b p + b_i^b D_i p + c_{ij}^b D_i D_j p + \cdots)\omega^b \\ &= p a^b \omega^b + D_i(b_i^b \omega^b p) - p D_i(b_i^b \omega^b) + \cdots \\ &= p(x)\{a^b \omega^b - D_i(b_i^b \omega^b) + D_i D_j(c_{ij}^b \omega^b) + \cdots\} + D_i(b_i^b \omega^b p + \cdots). \end{aligned} \tag{16}$$

Thus,

$$\alpha^b E^b(L) = p(x)\tilde{a}(\omega, D_i\omega, \ldots) + D_i K_i , \tag{17}$$

where $K_i \sim p(x), D_k p(x), \ldots,$ and

$$\tilde{a} = a^b \omega^b - D_i(b_i^b \omega^b) + D_i D_j(c_{ij}^b \omega^b) + \cdots . \tag{18}$$

Since α is a variational symmetry using (10), (15) and (17) we obtain

$$D_i M_i = p(x)\tilde{a} + D_i K_i + D_i(R_{\alpha i} L), \tag{19}$$

or

$$D_i T_i = p(x)\tilde{a}, \tag{20}$$

where $T_i = M_i - K_i - R_{\alpha i} L \sim p(x), D_k p(x), \ldots$. Equation (20) has the form of a continuity equation, but in general for arbitrary $p(x)$ it does not imply a conservation law. Let us integrate (20) over the whole space in R^n and apply the Gauss theorem:

$$\int_D D_i T_i \, dV = \int_{\partial D} T_i n_i \, d\sigma = \int_D p(x) \tilde{a} dV. \tag{21}$$

Consider the following cases.

(I) $p = p(x^1, x^2, \ldots, x^n)$, *where* $p(x)$ *is an arbitrary function of all variables in* R^n.

In this case it is possible to choose the function $p(x)$ such that it vanishes on the boundary together with its derivatives,

$$p(x)|_{\partial D} = D_k p(x)|_{\partial D} = \cdots = 0. \tag{22}$$

Then $T_i|_{\partial D} = 0$. From Eq. (21) using arbitrariness of V we can write

$$D_i T_i = 0, \tag{23}$$

and from (20) we conclude that

$$\tilde{a}(\omega, D_i \omega, \ldots) = 0. \tag{24}$$

Therefore,

$$a^b \omega^b - D_i(b_i^b \omega^b) + D_i D_j (c_{ij}^b \omega^b) + \cdots = 0, \tag{25}$$

where $a^b, b_i^b, c_{ij}^b, \ldots,$ are components of the symmetry α (14). Equation (25) expresses the Second Noether Theorem, which states that in case of an infinite variational symmetry group not all equations of the original differential system are independent.[1]

As an interesting example of the Second Noether Theorem in action, let us consider a consequence of local gauge invariance for the Yang–Mills functional,

$$S = \frac{1}{4} \int G_{\mu\nu}^a G^{a\mu\nu} d^4 x, \tag{26}$$

where

$$G_{\mu\nu}^a = A_{\nu,\mu}^a - A_{\mu,\nu}^a + g g^{abc} A_\mu^b A_\nu^c, \quad A_\mu^a = A_\mu^a(x_\nu), \quad \mu, \nu = 1, \ldots, 4, \quad a, b, c = 1, \ldots, N;$$

g is a coupling constant, g_{abc} are structure constants of the (simple) gauge group H of dimension N [for $H = \mathrm{SU}(2)$: $g_{abc} = \varepsilon_{abc}$; we are using the adjoint representation of H]. The Yang–Mills equations $\omega^{a\mu} \equiv E^{a\mu}(L) = 0$ take the form

$$d_\rho G^{a\mu\rho} + g g^{abc} A_\rho^b G^{c\mu\rho} = 0, \tag{27}$$

or

$$D_\rho G^{a\mu\rho} = 0, \tag{28}$$

where

$$D_\rho = d_\rho + g[A_\rho, \ ] = d_\rho + g g^{abc} A_\rho^b \tag{29}$$

is the covariant derivative operator, and $d_\rho \equiv d/dx^\rho$. The Yang–Mills equations (27) are invariant under a local gauge transformation,

$$A_\mu^a \to A_\mu^a - \frac{1}{g} \partial_\mu \varphi^a(x) + g^{abc} \varphi^b A_\mu^c \tag{30}$$

(in infinitesimal form) with arbitrary functions $\varphi^a=\varphi^a(x)$. As was shown in Ref. 10 the gauge transformations (30) can be extended to potentials A^a_μ and their derivatives to give rise to generalized symmetries (Lie–Bäcklund tangent transformation group) with the following operator:

$$X_\varphi=\alpha^a_\mu\frac{\partial}{\partial A^a_\mu}+(d_\rho\alpha^a_\mu)\frac{\partial}{\partial A^a_{\mu,\rho}}+\cdots, \tag{31}$$

where

$$\alpha^a_\mu=-\frac{1}{g}d_\mu\varphi^a+g^{abc}\varphi^bA^c_\mu \tag{32}$$

and $\varphi^a=\varphi^a(x,A^a_\mu,A^a_{\mu,\alpha},A^a_{\mu,\alpha\beta},\ldots)$ are arbitrary functions of all variables. For the coefficients of the symmetry vector α (14) we can write

$$\alpha^a_\mu=a^a_{\mu b}\varphi^b+b^{a\nu}_{\mu b}d_\nu(\varphi^b),\quad a^a_{\mu b}=g^a_{bc}A^c_\mu,\quad b^{a\nu}_{\mu b}=-\frac{1}{g}\delta^a_b\delta^\nu_\mu. \tag{33}$$

Thus, the Second Noether theorem (25) takes the form

$$a^a_{\mu b}\omega^{a\mu}-d_\nu(b^{a\nu}_{\mu b}\omega^{a\mu})=0, \tag{34}$$

which together with Eq. (33) gives rise to the equation

$$D_\mu D_\rho G^{b\mu\rho}=0. \tag{35}$$

The expression (35) is a known identity, which was noted to be related to the Second Noether Theorem.[11] Here we aimed to show how the direct application of the Second Noether Theorem to a gauge invariant functional leads to the condition showing that the set of Yang–Mills equations is under-determined; quite important for the quantization of the gauge fields fact.[11]

(II) $p=p(\theta_1,\theta_2,\ldots,\theta_k)$, where $\theta_i=\theta_i(x)$, $i=1,\ldots,k$, $x\in R^n$, $k<n$ are some independent combinations of $x^1,x^2,\ldots,x^n$, and $p(\theta)$ is arbitrary.

In this case we generally cannot choose $p(x)$ such that it would vanish on the boundary together with its derivatives. Therefore, $T_i\sim p(x)\not\to 0$ as $x_i\to\partial D$ and we can no longer conclude that $\tilde{a}=0$. We will start consideration of this situation with a case $k=1$ (Ref. 7) when generators of a variational symmetry group contain an arbitrary function of one of independent variables or their combination.

III. INFINITE SYMMETRY ALGEBRA WITH ARBITRARY FUNCTION(S) OF ONE VARIABLE. NOETHER AND "STRICT" BOUNDARY CONDITIONS

Let us consider functions $u=u(x)$ defined on a region D of $(m+1)$-dimensional space–time $D\subset R^{m+1}$, $x=(x^1,x^2,\ldots,x^m,t)$. Consider a Noether symmetry α of the form

$$\begin{gathered}\alpha=a\gamma(\theta)+b\gamma'(\theta)+c\gamma''(\theta)+\cdots+h\gamma^{(l)}(\theta),\\ \theta=\theta(x).\end{gathered} \tag{36}$$

We have

$$\delta S=\int\limits_D\int\delta L\,d^{m+1}x=\int\limits_D\int(X_\alpha L)d^{m+1}x=\int\limits_D\int\sum_{i=1}^{m+1}(D_iM_i)d^{m+1}x=0. \tag{37}$$

Therefore,

$$\int\int \sum_{i=1}^{m+1} M_i\Big|_{x_i\to\partial D} d^m x=0, \tag{38}$$

and it follows from (37) that the following conditions for M_i should be satisfied:

$$M_i(x,u,\ldots)|_{x_i\to\partial D}=0, \quad \forall i=1,\ldots,m+1. \tag{39}$$

We will call Eqs. (39) the *Noether boundary conditions*. Equations (39) are usually satisfied for a "regular" asymptotic behavior, $u,u_i\to 0$ as $x\to\pm\infty$, or for periodic solutions.

Let us consider now another type of boundary condition related to the existence of local conserved quantities. Integrating Eq. (12) over the space $(x^1,x^2,\ldots,x^m)$, and restricting ourselves to the solution manifold, we get

$$\int\int dx^1\,dx^2\ldots dx^m \sum_{j=1}^{m+1} D_j(M_j-R_{\alpha j}L)\doteq 0, \tag{40}$$

or

$$\int\int dx^1\,dx^2\ldots dx^m\, D_t(M_t-R_{\alpha t}L)\doteq \int\int dx^1\,dx^2\cdots dx^{i-1}\,dx^{i+1}\cdots dx^m \sum_{i=1}^{m} D_i(R_{\alpha i}L-M_i). \tag{41}$$

Since α is a Noether symmetry, we can apply the Noether boundary condition (39). Requiring also that the lhs of (41) vanishes on the solution manifold[7] we obtain

$$R_{\alpha 1}L|_{x^1\to\partial D}=R_{\alpha 2}L|_{x^2\to\partial D}=\cdots R_{\alpha m}L|_{x^m\to\partial D}=0. \tag{42}$$

We will call Eqs. (42) "*strict*" *boundary conditions*.[6] Thus, in order for the system to possess (Noether) local conserved quantities, conditions (39) and (42) have to be satisfied. Note that in case $L=L(x,u,u_j)$ (second order PDE's) strict boundary conditions (32) take a simple form,

$$\alpha\frac{\partial L}{\partial u_i}\Big|_{x^i\to\partial D}=0, \quad \forall i=1,\ldots,m. \tag{43}$$

If both Noether (39) and strict boundary conditions (42) are satisfied the Noether conservation laws will take a form

$$\int\int dx^1\,dx^2\cdots dx^m\, D_t(M_t-R_{\alpha t}L)\doteq 0. \tag{44}$$

Let us look at the structure of possible Noether conservation laws (44) corresponding to an infinite Lie group on the example of the case $L=L(x^i,u,u_i)$.

IV. CONSERVATION LAWS FOR EQUATIONS WITH FIRST ORDER LAGRANGIANS. NONSINGULAR SPATIAL TRANSFORMATION

Writing M_t as

$$\begin{gathered} M_t=A\gamma(\theta)+B\gamma'(\theta)+C\gamma''(\theta)+\cdots+H\gamma^{(l)}(\theta), \\ \theta=\theta(x^1,\ldots,x^m,t), \end{gathered} \tag{45}$$

and using Eqs. (44) and (36) we obtain

$$D_t\int\int dx^1\,dx^2\cdots dx^m\left[\gamma\left(A-a\frac{\partial L}{\partial u_t}\right)+\gamma'\left(B-b\frac{\partial L}{\partial u_t}\right)+\cdots+\gamma^{(l)}\left(H-h\frac{\partial L}{\partial u_t}\right)\right]\doteq 0. \quad (46)$$

Let us rewrite Eq. (46) in the form

$$D_t\int\int dx^1\,dx^2\cdots dx^m[a_0\gamma(\theta)+a_1\gamma'(\theta)+a_2\gamma''(\theta)+\cdots+a_l\gamma^{(l)}(\theta)]\doteq 0, \quad (47)$$

where

$$a_0=A-a\frac{\partial L}{\partial u_t},\quad a_1=B-b\frac{\partial L}{\partial u_t},\cdots,a_l=H-h\frac{\partial L}{\partial u_t}. \quad (48)$$

Let us go over to new integration variables $(x^1,x^2,\ldots,x^m)\overset{\psi}{\to}(x^1,x^2,\ldots,x^{p-1},\theta,x^{p+1},\ldots,x^m)$, corresponding to the transformation $\tilde{\psi}$ of the whole space R^{m+1}, $(x^1,x^2,\ldots,x^m,t)\overset{\tilde{\psi}}{\to}(x^1,x^2,\ldots,x^{p-1},\theta,x^{p+1},\ldots,x^m,t)$. In case of a nonsingular one-to-one transformation ψ, we can invert the functional relation $\theta=\theta(x^1,x^2,\ldots,x^p,\ldots,x^m,t)$: $x^p=\varphi^p(x^1,x^2,\ldots,x^{p-1},\theta,x^{p+1},\ldots,x^m,t)$ and obtain the Jacobian of the transformation ψ, $J=\partial\varphi^p/\partial\theta$. From (47) we get

$$D_t\int\int d\theta\,dx^1\,dx^2\cdots dx^{p-1}\,dx^{p+1}\cdots dx^m[\overline{a_0}\gamma(\theta)+\overline{a_1}\gamma'(\theta)+\overline{a_2}\gamma''(\theta)+\cdots+\overline{a_l}\gamma^{(l)}(\theta)]\doteq 0, \quad (49)$$

where

$$\overline{a_i}=a_i\frac{\partial\varphi^p}{\partial\theta},\quad \text{for } i=0,\ldots,l,\ p=1,\ldots,m. \quad (50)$$

For the integral (49) we use integration by parts and either choose an arbitrary function $\gamma(\theta)$ to vanish on the boundary along with all its derivatives up to the order $l-1$,

$$\gamma(\theta)|_{\theta\to\partial D}=\gamma'(\theta)|_{\theta\to\partial D}=\gamma''(\theta)|_{\theta\to\partial D}=\cdots=\gamma^{(l-1)}(\theta)|_{\theta\to\partial D}=0, \quad (51a)$$

or impose an *additional boundary condition*,

$$\partial_\theta^i\overline{a_k}|_{\theta\to\partial D}=0,\quad \forall i=0,\ldots,k-1,\quad k=1,\ldots,l, \quad (51b)$$

where $\partial_\theta\equiv\partial/\partial\theta$. Then we get

$$D_t\int\int d\theta\,dx^1\,dx^2\cdots dx^{p-1}\,dx^{p+1}\cdots dx^m\,\gamma(\theta)[\overline{a_0}-\partial_\theta\overline{a_1}+\partial_\theta^2\overline{a_2}+\cdots+(-1)^l\partial_\theta^l\overline{a_l}]\doteq 0. \quad (52)$$

Since $\gamma(\theta)$ is arbitrary we can use a known theorem of analysis (see, e.g., Ref. 12): if $\alpha(x),p(x)$ are continuous functions on $[a,b]$ and $\int_a^b\alpha(x)p(x)dx=0$ for arbitrary $p(x)$ such that $p(a)=p(b)=0$ then $\alpha(x)=0$ for all x in $[a,b]$.

Therefore,

$$D_t\int\int dx^1\,dx^2\cdots dx^{p-1}\,dx^{p+1}\cdots dx^m[\overline{a_0}-\partial_\theta\overline{a_1}+\partial_\theta^2\overline{a_2}+\ldots+(-1)^l\partial_\theta^l\overline{a_l}]\doteq 0. \quad (53)$$

Equation (53) gives an expression of a conserved quantity corresponding to an infinite symmetry α of the form (36) where $\overline{a_i}$, $i=0,\ldots,l$ are determined by coefficients of the symmetry vector α

and Eqs. (48), (50), and all Noether (39), strict (43) and additional boundary conditions (51a) or (51b) are satisfied. In case additional boundary conditions (51b) are not satisfied, symmetries with arbitrary functions $\gamma(\theta)$ whose derivatives do not vanish on the boundary may lead according to (49) only to the following "conservation statements" (which in fact may impose additional constraints on the system instead of producing any conserved quantities):

$$D_t \int \int dx^1\, dx^2 \cdots dx^{p-1}\, dx^{p+1} \cdots dx^m\, \overline{a_i} \doteq 0, \quad i=0,\ldots,l. \tag{54}$$

Thus, an infinite symmetry group with an arbitrary function of independent variables (36) in case of a nonsingular transformation $(x^1,x^2,\ldots,x^m) \overset{\psi}{\rightarrow} (x^1,x^2,\ldots,x^{p-1},\theta,x^{p+1},\ldots,x^m)$, leads to just one conservation law (53) provided that additional boundary conditions (51a) or (51b) are satisfied.

Let us consider a special case when $\theta = x^p$ and α is a Noether symmetry of the form[6]

$$\alpha = aq(x^p) + bq'(x^p) + cq''(x^p) + \cdots + hq^{(l)}(x^p), \tag{55}$$

and

$$M_t = Aq(x^p) + Bq'(x^p) + Cq''(x^p) + \cdots + Hq^{(l)}(x^p). \tag{56}$$

In accordance with Eqs. (53) if either conditions (51a) or (51b) are satisfied we will obtain the following conservation law:

$$D_t \int \int dx^1 \cdots dx^{p-1}\, dx^{p+1} \cdots dx^m \left\{ \left(A - a\frac{\partial L}{\partial u_t} \right) - D_{x^p}\left(B - b\frac{\partial L}{\partial u_t} \right) + \cdots + (-1)^l D_{x^p}^l \left(H - h\frac{\partial L}{\partial u_t} \right) \right\} \doteq 0. \tag{57}$$

In the case for which additional conditions (51b) are satisfied,

$$\left(B - b\frac{\partial L}{\partial u_t} \right)\Big|_{x^p \to \pm\infty} = \left(C - c\frac{\partial L}{\partial u_t} \right)\Big|_{x^p \to \pm\infty} = D_{x^p}\left(C - c\frac{\partial L}{\partial u_t} \right)\Big|_{x^p \to \pm\infty} = \cdots = \left(H - h\frac{\partial L}{\partial u_t} \right)\Big|_{x^p \to \pm\infty}$$
$$= D_{x^p}\left(H - h\frac{\partial L}{\partial u_t} \right)\Big|_{x^p \to \pm\infty} = \cdots = D_{x^p}^{l-1}\left(H - h\frac{\partial L}{\partial u_t} \right)\Big|_{x^p \to \pm\infty} = 0, \tag{58}$$

the conservation law (53) takes a simple form,

$$D_t \int \int dx^1 \cdots dx^{p-1}\, dx^{p+1} \cdots dx^m \left(A - a\frac{\partial L}{\partial u_t} \right) \doteq 0. \tag{59}$$

According to (54) if conditions (51b) [or (58)] are not satisfied then the symmetry (55) with $q(x^p)$ such that its derivatives do not vanish on the boundary $(x^p \to \pm\infty)$ may lead only to the relations

$$D_t \int dy \left(A - a\frac{\partial L}{\partial u_t} \right) \doteq D_t \int dy \left(B - b\frac{\partial L}{\partial u_t} \right) \doteq \cdots \doteq D_t \int dy \left(H - h\frac{\partial L}{\partial u_t} \right) \doteq 0 \tag{60}$$

$(dy \equiv dx^1 \cdots dx^{p-1} dx^{p+1} \cdots dx^m)$. Obviously some relations in (60) imply additional constraints on the function and its derivatives rather than conservation laws.

As an example let us consider the following differential equation:

$$\omega = 2u_{xt} + u_t u_{tt} - u_{yy} = 0, \tag{61}$$

with the Lagrangian

$$L=-u_x u_t-\frac{1}{6}u_t^3+\frac{1}{2}u_y^2. \tag{62}$$

A symmetry transformation for the equation (61) is

$$X=\beta(x)\frac{\partial}{\partial t}+[2\beta'(x)t+2\beta''(x)y^2]\frac{\partial}{\partial u}. \tag{63}$$

We will consider a canonical form of this transformation,

$$\begin{gathered}X_\alpha=\alpha\frac{\partial}{\partial u}+(D_i\alpha)\frac{\partial}{\partial u_i}+\sum_{i\leqslant j}(D_iD_j\alpha)\frac{\partial}{\partial u_{ij}}+\cdots,\\ \alpha=2\beta'(x)t+2\beta''(x)y^2-\beta(x)u_t,\end{gathered} \tag{64}$$

where $\beta(x)$ is an arbitrary function. Calculating $X_\alpha L$ we can see that transformation (64) is a divergence symmetry,

$$X_\alpha L=D_iM_i, \tag{65}$$

$$M_x=-2\beta'(x)u,\quad M_y=4\beta''(x)yu,\quad M_t=-\beta(x)L-2\beta'''(x)y^2u-2t\beta''(x)u.$$

Transformation (64) is a Noether symmetry ($\delta S=0$) if the following (Noether) boundary conditions are satisfied [see (39)]:

$$\beta'(x)u(x,y,t)\Big|_{x\to-\infty}^{x\to\infty}=0,\quad yu(x,y,t)\Big|_{y\to-\infty}^{y\to\infty}=0,\quad u_i\Big|_{t\to-\infty}^{t\to\infty}=tu\Big|_{t\to-\infty}^{t\to\infty}=0, \tag{66}$$

or

$$u(x,y,t)\Big|_{x\to-\infty}^{x\to\infty}=yu(x,y,t)\Big|_{y\to-\infty}^{y\to\infty}=u_i(x,y,t)\Big|_{t\to-\infty}^{t\to\infty}=tu(x,y,t)\Big|_{t\to-\infty}^{t\to\infty}=0. \tag{67}$$

"Strict" boundary conditions (43) take the form

$$[2\beta'(x)t+2\beta''(x)y^2-\beta(x)u_t]u_t\Big|_{x\to-\infty}^{x\to\infty}=[2\beta'(x)t+2\beta''(x)y^2-\beta(x)u_t]u_y\Big|_{y\to-\infty}^{y\to\infty}=0, \tag{68}$$

and for a function $\beta(x)$ vanishing on the boundary along with its first and second derivatives, we get

$$u_t\Big|_{x\to-\infty}^{x\to\infty}=y^2u_y\Big|_{y\to-\infty}^{y\to\infty}=0. \tag{69}$$

Thus, for the equation (61) with symmetry transformation (64) we have [see (65), (55), (56)]

$$a=-u_t,\quad b=2t,\quad c=2y^2,\quad d=0, \tag{70}$$

$$A=u_xu_t+u_t^3/6-u_y^2/2,\quad B=0,\quad C=-2tu,\quad D=-2y^2u.$$

The conservation law (53) corresponding to the symmetry (64) will have the form

$$D_t\int dy\left\{-\left(\frac{u_t^3}{3}+\frac{u_y^2}{2}\right)-(2tu_x+tu_t^2)_x+(-2tu+2y^2u_x+y^2u_t^2)_{xx}-2y^2u_{xxx}\right\}\doteq 0. \tag{71}$$

In case the additional boundary conditions (58) are satisfied,

$$t(2u_x+u_t^2)|_{x\to\pm\infty}=(-2tu+2y^2u_x+y^2u_t^2)|_{x\to\pm\infty}=(-2tu+2y^2u_x+y^2u_t^2)_x|_{x\to\pm\infty}$$
$$=(-2y^2u)|_{x\to\pm\infty}=(-2y^2u_x)|_{x\to\pm\infty}=(-2y^2u_{xx})|_{x\to\pm\infty}=0,$$

or

$$u,u_x,u_t,u_{xx},u_{xt}\Big|_{x\to\pm\infty}=0, \tag{72}$$

the conservation law (71) will take the form

$$D_t\int\int dx\,dy\left(\frac{u_t^3}{3}+\frac{u_y^2}{2}\right)\doteq 0. \tag{73}$$

Note that (73) is the energy conservation law for Eq. (61). This observation is the reflection of a more general rule for Noether symmetries X of the form (55) with an arbitrary function of x^p. When additional boundary conditions (58) are satisfied the conservation law (59) associated with this symmetry will be the energy conservation law, if it belongs in the equivalence class with time translation: $X\sim\partial/\partial t$; or momentum conservation law, if $X\sim\partial/\partial x$. Obviously, these two special cases do not cover the whole variety of different situations. In case the additional boundary conditions (71) are not satisfied, and derivatives of the function $\beta(x)$ do not vanish on the boundary the symmetry (55) may lead only to the relations (60)

$$D_t\int dy\left[\frac{u_t^3}{3}+\frac{u_y^2}{2}\right]\doteq D_t\int dy[2tu_x+tu_t^2]\doteq D_t\int dy[-2tu+2y^2u_x+y^2u_t^2]\doteq D_t\int dy[-y^2u]\doteq 0. \tag{74}$$

It is easy to see that Eqs. (74) imply additional constraints on the function u and its derivatives instead of determining a system of conservation laws, and in this case infinite symmetries do not lead to any local conserved quantities.

Consider a situation when transformation ψ is singular. If $\partial\theta/\partial x^p=0$, but $\exists k\in(1,\ldots,m)$: $\partial\theta/\partial x^k\neq 0$, we can change $x^p\leftrightarrow x^k$, and generate a corresponding conservation law (57) or (59). If $\partial\theta/\partial x^p=0\ \forall p\in(1,\ldots,m)$ then $\theta=t$; this is a case of an arbitrary function of time in the generators of the symmetry group. This case is considered in the next section.

V. INFINITE SYMMETRY ALGEBRA WITH ARBITRARY FUNCTION OF TIME. LAGRANGIAN OF THE FIRST ORDER

Let $x^i=(x^1,x^2,\ldots,x^m,t)$. Consider a Noether symmetry α of the form

$$\alpha=a\,\gamma(t)+b\,\gamma'(t)+c\,\gamma''(t)+\cdots+h\,\gamma^{(l)}(t) \tag{79}$$

for a differential equation with the Lagrangian function $L=L(x^i,u,u_i)$. As earlier, [see (37)] we have

$$\delta S=\int\int\delta L\,d^{m+1}x=\int\int X_\alpha L\,d^{m+1}x=\int\int D_iM_i\,d^{m+1}x=0. \tag{80}$$

Assuming that the Noether and strict boundary conditions (39) and (43) are satisfied we will obtain the corresponding Noether conservation law in the form

$$\int\int dx^1\,dx^2\cdots dx^m\,D_t(M_t-R_{\alpha t}L)\doteq 0. \tag{81}$$

Let us demonstrate that for the symmetry (79) the equation (81) does not lead to an infinite number of conservation laws.[7] In fact, we will show that symmetry with an *arbitrary* function of time does not correspond to any conservation law. As earlier, writing M_t as

$$M_t = A\gamma(t) + B\gamma'(t) + C\gamma''(t) + \cdots + H\gamma^{(l)}(t), \tag{82}$$

and using Eq. (79), we obtain from Eq. (81)

$$D_t \int\int dx^1\, dx^2 \cdots dx^m \left[\gamma(t)\left(A - a\frac{\partial L}{\partial u_t}\right) + \gamma'(t)\left(B - b\frac{\partial L}{\partial u_t}\right) + \cdots + \gamma^{(l)}(t)\left(H - h\frac{\partial L}{\partial u_t}\right)\right] \doteq 0. \tag{83}$$

Since $\gamma(t)$ is an arbitrary function we get

$$\begin{aligned}
&\gamma(t): \quad \int\int dx^1\, dx^2 \cdots dx^m D_t\left(A - a\frac{\partial L}{\partial u_t}\right) \doteq 0,\\
&\gamma'(t): \quad \int\int dx^1\, dx^2 \cdots dx^m \left\{ A - a\frac{\partial L}{\partial u_t} + D_t\left(B - b\frac{\partial L}{\partial u_t}\right)\right\} \doteq 0,\\
&\gamma''(t): \quad \int\int dx^1\, dx^2 \cdots dx^m \left\{ B - b\frac{\partial L}{\partial u_t} + D_t\left(C - c\frac{\partial L}{\partial u_t}\right)\right\} \doteq 0,\\
&\qquad\qquad \cdots\cdots\\
&\gamma^{(l+1)}(t): \quad \int\int dx^1\, dx^2 \cdots dx^m \left\{ H - h\frac{\partial L}{\partial u_t}\right\} \doteq 0.
\end{aligned} \tag{84}$$

The system (84) can be written in the form

$$\begin{aligned}
\int\int dx^1\, dx^2 \cdots dx^m \left\{ A - a\frac{\partial L}{\partial u_t}\right\} &\doteq \int\int dx^1\, dx^2 \cdots dx^m \left\{ B - b\frac{\partial L}{\partial u_t}\right\}\\
&\doteq \ldots \doteq \int\int dx^1\, dx^2 \cdots dx^m \left\{ H - h\frac{\partial L}{\partial u_t}\right\} \doteq 0.
\end{aligned} \tag{85}$$

Obviously, Eqs. (85) in general determine not a system of conservation laws but additional constraints. Thus, Noether symmetries (empowered by strict boundary conditions) with arbitrary functions of time instead of conservation laws lead to a set of additional constraints imposed on the function u and its derivatives. Therefore the satisfaction of the strict boundary conditions (43) [or more general conditions (42)] becomes critical in the sense of avoiding additional constraints (85). Correspondingly, we have three possible situations.

(1) Strict boundary conditions (43) (or (42) can be satisfied for an arbitrary function $\gamma(t)$. Then the system (85) as a consequence of an infinite symmetry (79) provides additional constraints that the function u and its derivatives must satisfy. No conservation laws are associated with the symmetry. This situation can obviously be materialized for the cases when the system (85) is not overly restrictive.
(2) Strict boundary conditions (43) can be satisfied for some particular functions $\gamma(t)$. In this case the (finite) symmetry (79) will lead to the Noether conservation law (83) in agreement with the First Noether Theorem. Additional constraints (85) will not appear in this picture.

(3) Strict boundary conditions cannot be satisfied for any functions $\gamma(t)$. In this case a consequence of an infinite symmetry will be the fact that the solutions of the original differential equation with the strict boundary conditions (43) do not exist.

As an example of the system with one-dimensional infinite symmetry algebra, let us consider the equation of nonstationary transonic gas flows,[13]

$$2u_{xt}+u_xu_{xx}-u_{yy}=0, \tag{86}$$

with Lagrangian

$$L=-u_xu_t-\frac{u_x^3}{6}+\frac{u_y^2}{2}. \tag{87}$$

The Lie point symmetry group for the equation (86) was studied in Ref. 14. An infinite set of conservation laws for this equation is presented in Ref. 6. The symmetry group of the equation (86) includes a number of infinite subgroups:

$$(1) \qquad X=n(t)\frac{\partial}{\partial u}, \tag{88}$$

where $n(t)$ is arbitrary. We have

$$\begin{gathered}\alpha=n(t), \quad X_\alpha L=n'(t)\frac{\partial L}{\partial u_t}=D_x(-n'(t)u), \quad M_x=-n'(t)u, \quad M_y=M_z=0,\\ a=1, \ b=c=0, \ A=B=C=0.\end{gathered} \tag{89}$$

The Noether boundary condition (39) here reads as

$$u(x,y,t)\Big|_{x\to-\infty}^{x\to\infty}=0. \tag{90}$$

The strict boundary conditions (43) have the form

$$n(t)(u_t+u_x^2/2)\Big|_{x\to-\infty}^{x\to\infty}=0, \quad n(t)u_y\Big|_{y\to-\infty}^{y\to\infty}=0. \tag{91}$$

Conditions (91) are easy to satisfy for all $n(t)$. Therefore we are dealing with case (1) and no conservations laws are associated with this symmetry. Equation (85) takes the form

$$\int\int dx\,dy\,u_x\doteq 0. \tag{92}$$

Obviously, Eq. (92) does not imply any ''additional'' constraint on the function u and is automatically satisfied for all Noether symmetries (88) [see the Noether boundary condition (90)]:

$$(2) \qquad X=m(t)y\frac{\partial}{\partial u}, \tag{93}$$

where $m(t)$ is arbitrary. We have

$$\begin{gathered}\alpha=ym(t), \quad X_\alpha L=ym'(t)\frac{\partial L}{\partial u_t}+m(t)\frac{\partial L}{\partial u_y}=D_x(-m'(t)yu)+D_y(m(t)u),\\ M_x=-m'(t)u, \quad M_y=m(t)u, \quad M_z=0,\\ a=y, \ b=c=0, \quad A=B=C=0.\end{gathered} \tag{94}$$

The Noether boundary conditions are

$$u(x,y,t)\Big|_{x\to-\infty}^{x\to\infty}=u(x,y,t)\Big|_{y\to-\infty}^{y\to\infty}=0. \tag{95}$$

The strict boundary conditions are

$$ym(t)(u_t+u_x^2/2)\Big|_{x\to-\infty}^{x\to\infty}=0,\quad ym(t)u_y\Big|_{y\to-\infty}^{y\to\infty}=0. \tag{96}$$

Conditions (96) can be satisfied for any $m(t)$. No conservation laws are associated with given symmetry transformation. The additional constraint,

$$\int\int dx\,dy y u_x \doteq 0, \tag{97}$$

is fulfilled for any Noether symmetry [see (95)]:

$$(3)\qquad X=\gamma(t)\frac{\partial}{\partial x}+(2\gamma'(t)x+2\gamma''(t)y^2)\frac{\partial}{\partial u}, \tag{98}$$

$\gamma(t)$ is arbitrary. We have

$$\begin{gathered}\alpha=2\gamma' x+2\gamma'' y^2-\gamma u_x,\ \ M_x=-\gamma L-2xu\gamma''-2y^2u\gamma''',\ \ M_y=4yu\gamma'',\\ M_t=-2u\gamma',\ \ a=-u_x,\ \ b=2x,\ \ c=2y^2,\quad A=C=0,\ \ B=-2u.\end{gathered} \tag{99}$$

In this case the form of Noether and strict boundary conditions depends on the function $\gamma(t)$.

(a) $\gamma(t)$ *is arbitrary:*

Noether conditions are

$$u_i \xrightarrow[x\to\pm\infty]{} 0,\ \ xu \xrightarrow[x\to\pm\infty]{} 0,\quad yu \xrightarrow[y\to\pm\infty]{} 0,\ \ u \xrightarrow[t\to\pm\infty]{} 0. \tag{100}$$

Strict conditions are

$$xu_t, xu_x^2 \xrightarrow[x\to\pm\infty]{} 0,\ \ y^2u_y \xrightarrow[y\to\pm\infty]{} 0. \tag{101}$$

No local conservation laws are associated with the Noether transformation (98). The additional constraints (85) take the form

$$\int\int u_x^2\,dx\,dy=\int\int(2xu_x-2u)dx\,dy=\int\int 2y^2u_x dx\,dy\doteq 0. \tag{102}$$

Conditions (102) lead only to a trivial solution ($u=ay$). Situation (1) does not materialize.

Let us consider now some specific forms of $\gamma(t)$ [situation (2)] for which we can weaken our "strict" boundary conditions (96) in order to avoid restrictions (102).

(b) $\gamma'(t)=0,\ \gamma(t)=c=\text{const.}$:

Noether conditions are

$$u_i \xrightarrow[x_i\to\pm\infty]{} 0. \tag{103}$$

For "strict" boundary conditions in addition to (103) we have

$$u_x u_y \xrightarrow[y\to\pm\infty]{} 0. \tag{104}$$

According to (83) we will get the following conservation law (conservation of momentum):

$$D_t \int\int u_x^2 dx\, dy \doteq 0, \tag{105}$$

or

$$\int\int u_x^2 dx\, dy \doteq \text{const.} \tag{106}$$

As could be expected, the conservation of momentum corresponds to standard boundary conditions (103)–(104).

(c) $\gamma''(t)=0,\ \gamma(t)=at,\ a=\text{const.}$:

Noether conditions are

$$u_i \xrightarrow[x_i\to\pm\infty]{} 0, \quad u \xrightarrow[t\to\pm\infty]{} 0. \tag{107}$$

For "strict" boundary conditions in addition to (107) we have

$$xu_t, xu_x^2 \xrightarrow[x\to\pm\infty]{} 0, \quad u_y \xrightarrow[y\to\pm\infty]{} 0. \tag{108}$$

The conservation law (83) corresponding to the boundary conditions (107)–(108) has the form

$$D_t \int\int [2(xu_x - u) - tu_x^2] dx\, dy \doteq 0. \tag{109}$$

As we can see strict boundary conditions (108) determined a nontrivial conservation law.

(d) $\gamma''(t)\neq 0$: In this case we will get the same boundary conditions (100)–(101) as in (a) and the same additional constraints (102) which do not leave any nontrivial solutions.

Let us note that the transonic gas equation (86) can be obtained from the equation (61) with the interchange $x\leftrightarrow t$. The analysis above illustrates the difference in conservation laws between these two systems. The strict boundary conditions (42), critical for the derivation of conservation laws, clearly distinguish between x and t. However, in the situation when boundary conditions take a "standard" form: (72) or (103)–(104), the conservation laws for both systems may correspond to similar continuity equations. For example, it can be shown that the conserved densities (73) and (106) are dual in the sense that their corresponding continuity equations transform into each other by the interchange $x\leftrightarrow t$. A full analysis of other infinite subgroups of the symmetry group of the nonstationary transonic gas equation (86), along with corresponding conservation laws, will be given elsewhere. Another interesting application of the above approach for finding conservation laws and asymptotic behavior for systems that admit invariance transformations with arbitrary functions of time, would be the equation of "short waves."[4]

VI. CONSERVATION LAWS FOR EQUATIONS WITH HIGHER ORDER LAGRANGIANS

Let us now consider the more general case of equation of the order $(N+1)$,

$$L = L(x^i, u, u_j, u_{j_1 j_2}, \ldots, u_{j_1 j_2 \ldots j_N}), \tag{110}$$

in R^{m+1}: $u=u(x^1,x^2,\ldots,x^m,x^{m+1}\equiv t)$ with the Noether symmetry vector,

$$\alpha = b_0\gamma(\theta) + b_1\gamma'(\theta) + b_2\gamma''(\theta) + \cdots + b_l\gamma^{(l)}(\theta),$$

$$\theta=\theta(x^j),\quad j=1,\ldots,m+1. \tag{111}$$

As earlier,

$$X_\alpha L=D_i M_i, \tag{112}$$

and since $L=L(\ldots,u_{j_1 j_2 \ldots j_N})$, then according to formula (6),

$$M_t=A_0\gamma(\theta)+A_1\gamma'(\theta)+A_2\gamma''(\theta)+\cdots+A_{N+l}\gamma^{(N+l)}(\theta). \tag{113}$$

As in Sec. III, if both Noether (39) and strict boundary conditions (42) are satisfied, corresponding Noether conservation laws (if any) will take the form (44)

$$\int\int dx^1\,dx^2\ldots dx^m\,D_t(M_t-R_{\alpha t}L)\doteq 0. \tag{114}$$

Let us derive the expression for $R_{\alpha t}L$. We start with the definition (6),

$$X_\alpha L=\alpha\frac{\partial L}{\partial u}+\sum_{i=1}^{m+1}(D_i\alpha)\frac{\partial L}{\partial u_i}+\sum_{i_1\leqslant i_2}(D_{i_1}D_{i_2}\alpha)\frac{\partial L}{\partial u_{i_1 i_2}}+\sum_{i_1\leqslant i_2\leqslant i_3}(D_{i_1}D_{i_2}D_{i_3}\alpha)$$
$$\times\frac{\partial L}{\partial u_{i_1 i_2 i_3}}+\cdots+\sum_{i_1\leqslant i_2\leqslant\ldots\leqslant i_N}(D_{i_1}D_{i_2}\cdots D_{i_N}\alpha)\frac{\partial L}{\partial u_{i_1 i_2\ldots i_N}}, \tag{115}$$

and use integration by parts,

$$\sum_{i=1}^{m+1}(D_i\alpha)\frac{\partial L}{\partial u_i}=\sum_{i=1}^{m+1}D_i\left(\alpha\frac{\partial L}{\partial u_i}\right)-\sum_{i=1}^{m+1}\alpha\left(D_i\frac{\partial L}{\partial u_i}\right),$$

$$\begin{aligned}\sum_{i_1\leqslant i_2}(D_{i_1}D_{i_2}\alpha)\frac{\partial L}{\partial u_{i_1 i_2}}&=\sum_{i_1\leqslant i_2}D_{i_1}\left((D_{i_2}\alpha)\frac{\partial L}{\partial u_{i_1 i_2}}\right)-\sum_{i_1\leqslant i_2}(D_{i_2}\alpha)\left(D_{i_1}\frac{\partial L}{\partial u_{i_1 i_2}}\right)\\&=\sum_{i_1\leqslant i_2}D_{i_1}\left((D_{i_2}\alpha)\frac{\partial L}{\partial u_{i_1 i_2}}\right)-\sum_{i_1\leqslant i_2}D_{i_2}\left(\alpha D_{i_1}\frac{\partial L}{\partial u_{i_1 i_2}}\right)\\&\quad+\sum_{i_1\leqslant i_2}\alpha\left(D_{i_2}D_{i_1}\frac{\partial L}{\partial u_{i_1 i_2}}\right)\\&=\sum_{i_1\leqslant i_2}D_{i_1}\left((D_{i_2}\alpha)\frac{\partial L}{\partial u_{i_1 i_2}}\right)-\sum_{i_1\geqslant i_2}D_{i_1}\left(\alpha D_{i_2}\frac{\partial L}{\partial u_{i_{21} i_1}}\right)\\&\quad+\sum_{i_1\leqslant i_2}\alpha\left(D_{i_2}D_{i_1}\frac{\partial L}{\partial u_{i_1 i_2}}\right),\end{aligned} \tag{116}$$

$$\sum_{i_1\leqslant i_2\leqslant i_3}(D_{i_1}D_{i_2}D_{i_3}\alpha)\frac{\partial L}{\partial u_{i_1 i_2 i_3}}$$
$$=\sum_{i_1\leqslant i_2\leqslant i_3}D_{i_1}\left((D_{i_2}D_{i_3}\alpha)\frac{\partial L}{\partial u_{i_1 i_2 i_3}}\right)+\sum_{i_1\leqslant i_2\leqslant i_3}D_{i_3}\left(\alpha D_{i_2}D_{i_1}\frac{\partial L}{\partial u_{i_1 i_2 i_3}}\right)$$
$$-\sum_{i_2\leqslant i_1\leqslant i_3}D_{i_1}\left((D_{i_3}\alpha)D_{i_2}\frac{\partial L}{\partial u_{i_2 i_1 i_3}}\right)-\sum_{i_1\leqslant i_2\leqslant i_3}\alpha(D_{i_3}D_{i_2}D_{i_1})\frac{\partial L}{\partial u_{i_1 i_2 i_3}}.$$

.....

The sum of the last terms in each expression gives rise to $\alpha E(L)$, in agreement with (7),

$$X_\alpha L = \alpha E(L) + D_i(R_{\alpha i} L). \tag{117}$$

Terms with D_t have the form ($t \equiv x^{m+1}$):

$$\begin{aligned}
&D_t\left(\alpha \frac{\partial L}{\partial u_t}\right) + D_t\left((D_t\alpha)\frac{\partial L}{\partial u_{tt}} - \sum_{j\leqslant t}\alpha\left(D_j \frac{\partial L}{\partial u_{jt}}\right)\right)\\
&\quad + D_t\left((D_t^2\alpha)\frac{\partial L}{\partial u_{ttt}} - (D_t\alpha)\sum_{j\leqslant t} D_j \frac{\partial L}{\partial u_{jtt}} - \sum_{i\leqslant j}\alpha\left(D_j D_i \frac{\partial L}{\partial u_{ijt}}\right)\right) + \cdots\\
&\quad = D_t\Bigg\{\alpha\Bigg[\frac{\partial L}{\partial u_t} - \sum_{j=1}^{m+1} D_j \frac{\partial L}{\partial u_{jt}} + \sum_{j_1\leqslant j_2} D_{j_2}D_{j_1}\frac{\partial L}{\partial u_{j_1 j_2 t}}\\
&\qquad - \sum_{j_1\leqslant j_2\leqslant j_3} D_{j_3}D_{j_2}D_{j_1}\frac{\partial L}{\partial u_{j_1 j_2 t}} - \cdots\Bigg] + (D_t\alpha)\Bigg[\frac{\partial L}{\partial u_{tt}} - \sum_{j=1}^{m+1} D_j \frac{\partial L}{\partial u_{jtt}}\\
&\qquad + \sum_{j_1\leqslant j_2} D_{j_2}D_{j_1}\frac{\partial L}{\partial u_{j_1 j_2 tt}} - \sum_{j_1\leqslant j_2\leqslant j_3} D_{j_3}D_{j_2}D_{j_1}\frac{\partial L}{\partial u_{j_1 j_2 tt}} - \cdots\Bigg]\\
&\qquad + (D_t^2\alpha)\Bigg[\frac{\partial L}{\partial u_{ttt}} - \sum_{j=1}^{m+1} D_j \frac{\partial L}{\partial u_{jttt}} + \sum_{j_1\leqslant j_2} D_{j_2}D_{j_1}\frac{\partial L}{\partial u_{j_1 j_2 ttt}}\\
&\qquad - \sum_{j_1\leqslant j_2\leqslant j_3} D_{j_3}D_{j_2}D_{j_1}\frac{\partial L}{\partial u_{j_1 j_2 ttt}} - \cdots\Bigg] + \cdots\Bigg\}.
\end{aligned} \tag{118}$$

Thus, using (115) and (117) we get

$$\begin{aligned}
R_{\alpha t} L = \sum_{k=0}^{N-1} (D_t^k\alpha)\Bigg\{&\frac{\partial L}{\partial \underbrace{u_{tt\ldots t}}_{k+1}} - \sum_{j=1}^{m+1} D_j \frac{\partial L}{\partial \underbrace{u_{jtt\ldots t}}_{k+1}} + \sum_{j_1\leqslant j_2} D_{j_2}D_{j_1}\frac{\partial L}{\partial u_{j_1 j_2}\underbrace{{}_{tt\ldots t}}_{k+1}} - \cdots\\
&+ (-1)^n \sum_{j_1\leqslant j_2\leqslant\ldots\leqslant j_n} D_{j_n}D_{j_{n-1}}\ldots D_{j_1}\frac{\partial L}{\partial u_{j_1\ldots j_n}\underbrace{{}_{tt\ldots t}}_{k+1}} + \cdots\Bigg\},
\end{aligned} \tag{119}$$

where

$$j_1, j_2, \ldots, j_n = 1, \ldots, m+1,$$

and, obviously,

$$n_{\max} = N - k - 1.$$

Let us analyze the structure of the ''conservation law'' (114). Following the logic of Sec. IV, we can rewrite the equation (114) in the form

$$D_t \int\int dx^1\, dx^2 \ldots dx^m [a_0\gamma(\theta) + a_1\gamma'(\theta) + a_2\gamma''(\theta) + \cdots + a_{N+l}\gamma^{(N+l)}(\theta)] \doteq 0, \tag{120}$$

with corresponding coefficients a_j, determined by coefficients b_j, A_j from (111), (113) and L. As in Sec. IV, we can introduce new integration variables θ and make use of the transformation ψ: $(x^1, x^2, \ldots, x^m) \overset{\psi}{\to} (x^1, x^2, \ldots, x^{p-1}, \theta, x^{p+1}, \ldots, x^m)$. Conservation law (120) can be given the form

$$D_t\int\int d\theta\, dx^1\, dx^2\cdots dx^{p-1}\, dx^{p+1}\cdots dx^m[\overline{a}_0\gamma(\theta)+\overline{a}_1\gamma'(\theta)+\cdots+\overline{a}_{N+l}\gamma^{(N+l)}(\theta)]\doteq 0, \tag{121}$$

where

$$\overline{a}_i=a_i\frac{\partial\varphi^p}{\partial\theta},\text{for}\quad i=0,...,N+l. \tag{122}$$

Like in the case of Eq. (49) for the integral (121), we use integration by parts and either choose an arbitrary function $\gamma(\theta)$ to vanish on the boundary along with all its derivatives up to the order of $N+l-1$ or impose additional boundary conditions (51). We will get

$$D_t\int\int d\theta\, dx^1\, dx^2\cdots dx^{p-1}\, dx^{p+1}\cdots dx^m\,\gamma(\theta)[\overline{a}_0-\partial_\theta\overline{a}_1+\partial_\theta^2\overline{a}_2+\ldots+(-1)^{N+l}\partial_\theta^{N+l}\overline{a}_{N+l}]\doteq 0. \tag{123}$$

Using arbitrariness of the function $\gamma(\theta)$ as in the derivation of (53) we obtain

$$D_t\int\int dx^1\, dx^2\cdots dx^{p-1}\, dx^{p+1}\cdots dx^m[\overline{a}_0-\partial_\theta\overline{a}_1+\partial_\theta^2\overline{a}_2+\cdots+(-1)^{N+l}\partial_\theta^{N+l}\overline{a}_{N+l}]\doteq 0. \tag{124}$$

Equation (124) is an expression for a conserved quantity corresponding to an infinite symmetry α of the form (111), and $\overline{a}_i$, $i=0,\ldots,N+l$ are determined by coefficients of symmetry vector α and M_t. Thus, an infinite symmetry group with an arbitrary function of independent variables in case of a nonsingular one-to-one transformation ψ [if additional boundary conditions (51) are satisfied] leads to just one conservation law (124).

In case additional boundary conditions are not satisfied, symmetries with arbitrary functions $\gamma(\theta)$ whose derivatives do not vanish on the boundary may lead according to (121) only to the following ''conservation statements'' (which in fact may impose additional constraints on the system instead of producing any conserved quantities; in this case infinite symmetries do not lead to any local conserved quantities):

$$D_t\int\int dx^1\, dx^2\cdots dx^{p-1}\, dx^{p+1}\cdots dx^m\,\overline{a}\doteq 0,\quad i=0,\ldots,N+l. \tag{125}$$

Let us analyze the structure of the conservation law (114) for the case of infinite symmetry (111) with $\theta=t$,

$$\int\int dx^1\, dx^2\cdots dx^m\, D_t(M_t-R_{\alpha t}L)\doteq 0. \tag{126}$$

Using (119) we can write

$$R_{\alpha t}L=\sum_{k=0}^{N-1}(D_t^k\alpha)\{S_k\}, \tag{127}$$

where S_k is determined by L; see (119). From (111) we have

$$D_t^k\alpha=D_t^k\sum_{\mu=0}^{l}b_\mu\gamma^{(\mu)}(t)=\sum_{\mu=0}^{l}\sum_{q=0}^{k}C_k^q(D_t^{k-q}b_\mu)\gamma^{(\mu+q)}(t), \tag{128}$$

where C_p^q is the number of combinations of q from p. Using (127), (128) and (113) the ''conservation law'' (114) can be given for

$$D_t\int\int dx^1\,dx^2\ldots dx^m\left[\sum_{\mu=0}^{l}\sum_{k=0}^{N-1}\sum_{q=0}^{k}C_k^q(D_t^{k-q}b_\mu)\{S_k\}\gamma^{(\mu+q)}(t)-\sum_{\mu=0}^{N+l}A_{\bar{\mu}}\gamma^{(\bar{\mu})}(t)\right]\doteq 0. \tag{129}$$

Let us rewrite the equation (129) in the form

$$D_t\int\int dx^1\,dx^2\ldots dx^m\left[\sum_{k=0}^{N-1}\sum_{q=0}^{k}\sum_{r=q}^{q+l}C_k^q(D_t^{k-q}b_{r-q})\{S_k\}\gamma^{(r)}(t)-\sum_{\nu=0}^{N+l}A_\nu\gamma^{(\nu)}(t)\right]\doteq 0, \tag{130}$$

or

$$D_t\int\int dx^1\,dx^2\ldots dx^m\sum_{\nu=0}^{N+l}B_\nu\gamma^{(\nu)}(t)\doteq 0, \tag{131}$$

where coefficients B_ν are determined from the equation (130). Since the function $\gamma(t)$ is arbitrary, similar to (84) we obtain the following system:

$$\begin{aligned}
&\gamma(t): && \int\int dx^1\,dx^2\cdots dx^m D_tB_0\doteq 0,\\
&\gamma'(t): && \int\int dx^1\,dx^2\cdots dx^m\{B_0+D_tB_1\}\doteq 0,\\
&\gamma''(t): && \int\int dx^1\,dx^2\ldots dx^m\{B_1+D_tB_2\}\doteq 0,\\
&&&\cdots\\
&\gamma^{(N+l)}(t): && \int\int dx^1\,dx^2\ldots dx^m\{B_{N+l-1}+D_tB_{N+l}\}\doteq 0,\\
&\gamma^{(N+l+1)}(t): && \int\int dx^1\,dx^2\ldots dx^m B_{N+l}\doteq 0,
\end{aligned} \tag{132}$$

which is equivalent to the system

$$\int\int dx^1\,dx^2\ldots dx^m B_j\doteq 0,\ \ \forall j=1,\ldots,N+l. \tag{133}$$

Equations (133) determine, in general, additional constraints imposed on the function u and its derivatives rather than conservation laws. Similar to the situation with the first order Lagrangian functions, the fact of whether or not the strict boundary conditions (42) can be satisfied is critical in order to avoid additional constraints (133). Again, we have three possible situations.

(1) Strict boundary conditions (42) can be satisfied for the arbitrary function $\gamma(t)$. The system (133) provides the additional constraints the function u and its derivatives must satisfy. No conservation laws are associated with the symmetry. This situation can be materialized for the cases when the system (133) is not overly restrictive.

(2) Strict boundary conditions can be satisfied for some particular functions $\gamma(t)$. In this case the ''finite'' symmetry (111) will lead to the Noether conservation law (130) in agreement with the First Noether Theorem. Additional constraints (133) will not appear.

(3) Strict boundary conditions cannot be satisfied for any functions $\gamma(t)$. Solutions of the original differential equation with the strict boundary conditions (42) do not exist.

An interesting example of the equation with infinite symmetry algebra and a higher (third) order Lagrangian is the potential Kadomtsev–Petviashvili equation; see, e.g., Ref. 15.

VII. ARBITRARY FUNCTION OF TWO OR MORE VARIABLES

Let us consider now a case when the Noether symmetry vector of the equation with a Lagrangian (110) has an arbitrary function of two or more variables:

$$\alpha = b^0 \gamma(\theta_1,\theta_2,\ldots,\theta_k) + \sum_{q=1}^{k} b^1_q \partial_q \gamma(\theta_1,\theta_2,\ldots,\theta_k) + \sum_{q_1,q_2=1}^{k} b^2_{q_1q_2} \partial_{q_1q_2}\gamma(\theta_1,\theta_2,\ldots,\theta_k)$$
$$+\cdots+\sum_{q_i=1}^{k} b^l_{q_1q_2\ldots q_l}\partial_{q_1q_2\ldots q_l}\gamma(\theta_1,\theta_2,\ldots,\theta_k), \tag{134}$$

where

$$\theta=\theta(x^j),\quad j=1,\ldots,m+1,\quad l=1,\ldots,k,\quad k<m+1,$$

and

$$\partial_q=\frac{\partial}{\partial\theta_q},\quad \partial_{q_1q_2}=\frac{\partial^2}{\partial\theta_{q_1}\partial\theta_{q_2}},\ldots,\quad \partial_{q_1q_2\ldots q_l}=\frac{\partial^l}{\partial\theta_{q_1}\partial\theta_{q_2}\ldots\partial\theta_{q_l}}. \tag{135}$$

As earlier,

$$X_\alpha L = D_i M_i, \tag{136}$$

and since $L=L(\ldots,u_{j_1j_2\ldots j_N})$, then similarly to the formula (113) we get

$$M_t = A^0\gamma(\theta_1,\theta_2,\ldots,\theta_k) + \sum_{q=1}^{k} A^1_q\partial_q\gamma(\theta_1,\theta_2,\ldots,\theta_k) + \sum_{q_1,q_2=1}^{k} A^2_{q_1q_2}\partial_{q_1q_2}\gamma(\theta_1,\theta_2,\ldots,\theta_k)$$
$$+\cdots+\sum_{q_i=1}^{k} A^{N+l}_{q_1q_2\ldots q_{N+l}}\partial_{q_1q_2\ldots q_{N+l}}\gamma(\theta_1,\theta_2,\ldots,\theta_k). \tag{137}$$

If the Noether and strict boundary conditions, (39) and (42), are satisfied the corresponding Noether conservation laws (if any) take the form of (114),

$$\int\int dx^1\,dx^2\ldots dx^m\, D_t(M_t - R_{\alpha t}L)\doteq 0. \tag{138}$$

We can rewrite the equation (138) in the form

$$D_t\int\int dx^1\,dx^2\cdots dx^m\Bigg[a^0\gamma(\theta_1,\theta_2,\ldots,\theta_k)+\sum_{q=1}^{k} a^1_q\partial_q\gamma+\sum_{q_i,q_2=1}^{k} a^2_{q_1q_2}\partial_{q_1q_2}\gamma(\theta_1,\theta_2,\ldots,\theta_k)$$
$$+\cdots+\sum_{q_i=1}^{k} a^{N+l}_{q_1q_2\cdots q_{N+l}}\partial_{q_1q_2\cdots q_{N+l}}\gamma(\theta_1,\theta_2,\ldots,\theta_k)\Bigg]\doteq 0, \tag{139}$$

with corresponding coefficients a^j, determined by coefficients b^i, A^j from (134), (137) and L.

Introduce new integration variables θ_i, $i=1,\ldots,k$ and consider a transformation ψ, $(x^1,x^2,\ldots,x^m)\overset{\psi}{\to}(x^1,x^2,\ldots,x^{p_i-1},\theta_i,x^{p_i+1},\ldots,x^m)$ with k inserts $x^{p_i}\to\theta_i\ \forall i=1,\ldots,k$, correspond-

ing to the transformation $\tilde{\psi}$ of the whole space R^{m+1}, $(x^1,x^2,\ldots,x^m,t) \overset{\tilde{\psi}}{\to} (x^1,x^2,\ldots,x^{p_i-1},\theta_i,x^{p_i+1},\ldots,x^m,t)$. In case of a nonsingular one-to-one transformation ψ we get

$$D_t \int\int d\theta_1\, d\theta_2 \cdots d\theta_k\, dx^1\, dx^2 \cdots dx^{p_1-1}\, dx^{p_1+1} \cdots dx^{p_k-1}\, dx^{p_k+1} \cdots dx^m \times \left[\overline{a}^0 \gamma(\theta_1,\theta_2,\ldots,\theta_k) + \sum_{q=1}^{k} \overline{a}^1_q\, \partial_q \gamma + \sum_{q_i,q_2=1}^{k} \overline{a}^2_{q_1q_2}\, \partial_{q_1q_2} \gamma(\theta_1,\theta_2,\ldots,\theta_k) + \cdots + \sum_{q_i=1}^{k} \overline{a}^{N+l}_{q_1q_2\cdots q_{N+l}}\, \partial_{q_1q_2\cdots q_{N+l}} \gamma(\theta_1,\theta_2,\ldots,\theta_k) \right] \doteq 0, \tag{140}$$

where coefficients $\overline{a^j}$ are determined by a^j and the Jacobian of the transformation $\overline{\psi}$. As earlier for the integral (140) we will use integration by parts and either choose an arbitrary function $\gamma(\theta_1,\theta_2,\ldots,\theta_k)$ to vanish on the boundary along with all its derivatives up to the order of $N+l-1$ or impose *additional boundary conditions*:

$$\overline{a}^j_q|_{\theta_q \to \partial D} = 0, \quad j = 1,\ldots,N+l. \tag{141}$$

We get

$$D_t \int\int d\theta_1\, d\theta_2 \cdots d\theta_k\, dx^1\, dx^2 \cdots dx^{p_1-1}\, dx^{p_1+1} \cdots dx^{p_k-1}\, dx^{p_k+1} \cdots dx^m \gamma(\theta_1,\theta_2,\ldots,\theta_k) \times \left[\overline{a}_0 - \sum_{q=1}^{k} \partial_q \overline{a}^1_q + \sum_{q_i,q_2=1}^{k} \partial_{q_1q_2} (\overline{a}^2_{q_1q_2}) + \cdots + (-1)^{N+l} \sum_{q_i=1}^{k} \partial_{q_1q_2\cdots q_{N+l}} (\overline{a}^{N+l}_{q_1q_2\cdots q_{N+l}}) \right] \doteq 0. \tag{142}$$

Using arbitrariness of the function $\gamma(\theta_1,\theta_2,\ldots,\theta_k)$ as in derivation of (53) we obtain

$$D_t \int\int dx^1\, dx^2 \cdots dx^{p_1-1}\, dx^{p_1+1} \cdots dx^{p_k-1}\, dx^{p_k+1} \cdots dx^m \left[\overline{a}^0 - \sum_{q=1}^{k} \partial_q \overline{a}^1_q + \sum_{q_i,q_2=1}^{k} \partial_{q_1q_2} (\overline{a}^2_{q_1q_2}) + \cdots + (-1)^{N+l} \sum_{q_i=1}^{k} \partial_{q_1q_2\cdots q_{N+l}} (\overline{a}^{N+l}_{q_1q_2\cdots q_{N+l}}) \right] \doteq 0. \tag{143}$$

Equation (143) gives an expression of a conserved quantity corresponding to an infinite symmetry α of the form (111) where $\overline{a^j}$, $j=0,\ldots,N+l$ are determined by coefficients of symmetry vector α and M_t, with the aid of Eqs. (134), (137), knowing the specific form of transformation Ψ. Noether strict and additional boundary conditions are assumed satisfied.

Thus, again an infinite symmetry group with an arbitrary function of several independent variables in the case of a nonsingular one-to-one transformation ψ (if additional boundary conditions are satisfied) leads to just one conservation law (143). In case additional boundary conditions (141) are not satisfied, symmetries with arbitrary functions $\gamma(\theta_1,\theta_2,\ldots,\theta_k)$ whose derivatives do not vanish on the boundary may lead according to (140) only to the following "conservation statements" (which in fact may impose additional constraints on the system instead of producing any conserved quantities; in this case infinite symmetries do not lead to any local conserved quantities):

$$D_t \int\int d\theta_1\, d\theta_2 \cdots d\theta_k\, dx^1\, dx^2 \cdots dx^{p-1}\, dx^{p+1} \cdots dx^m\, \overline{a^j} \doteq 0, \quad j = 0,\ldots,N+l. \tag{144}$$

Let us discuss now the situation when transformation ψ is singular. Since we naturally assume all θ_i to be independent, the interesting case to consider is $\theta_r=t$, $1\leqslant r\leqslant k$. Let $\theta_k=t$. Then $\gamma=\gamma(\theta_1,\theta_2,\ldots,\theta_{k-1},t)$ and analogously to (140), we get

$$D_t\int\int d\theta_1\,d\theta_2\ldots d\theta_{k-1}\,dx^1\,dx^2\cdots dx^{p_1-1}\,dx^{p_1+1}\cdots dx^{p_k-1}$$
$$\times dx^{p_k+1}\ldots dx^m\Bigg[\overline{a}^0\gamma(\theta_1,\theta_2,\ldots,\theta_{k-1},t)$$
$$+\sum_{q=1}^{k}\overline{a}^1_q\,\partial_q\gamma+\sum_{q_i,q_2=1}^{k}\overline{a}^2_{q_1q_2}\,\partial_{q_1q_2}\gamma(\theta_1,\theta_2,\ldots,\theta_{k-1},t)+\cdots$$
$$+\sum_{q_i=1}^{k}\overline{a}^{N+l}_{q_1q_2\cdots q_{N+l}}\,\partial_{q_1q_2\cdots q_{N+l}}\gamma(\theta_1,\theta_2,\ldots,\theta_{k-1},t)\Bigg]\doteq 0. \tag{145}$$

As with the integral (140) we can use integration by parts and either choose an arbitrary function $\gamma(\theta_1,\theta_2,\ldots,\theta_{k-1},t)$ to vanish on the boundary along with all its spatial derivatives up to the order of $N+l-1$ or impose additional boundary conditions (141) with $q=1,\ldots,k-1$ to get

$$D_t\int\int dx^1\,dx^2\cdots dx^{p_1-1}\,d\theta_1\,dx^{p_1+1}\cdots dx^{p_2-1}\,d\theta_2\,dx^{p_2+1}\cdots dx^{p_{k-1}-1}$$
$$\times d\theta_{k-1}\,dx^{p_{k-1}+1}\cdots dx^m\sum_{\nu=0}^{N+l}B_\nu(x^j)\,\partial_t^\nu\gamma(\theta_1,\theta_2,\ldots,\theta_{k-1},t)\doteq 0, \tag{146}$$

with some coefficients B_ν determined from (140). As in the case with the equation (121) arbitrariness of the function γ (and its time derivatives) leads us to the system

$$D_t\int\int dx^1\,dx^2\cdots dx^{p_1-1}\,d\theta_1\,dx^{p_1+1}\cdots dx^{p_{k-1}-1}\,d\theta_{k-1}\,dx^{p_{k-1}+1}\cdots dx^m B_\nu(x^j)\doteq 0. \tag{147}$$

As earlier, the system (147) is a system of additional constraints rather than conservation laws. If the strict boundary conditions (42) are satisfied for arbitrary γ, no conservation law is associated with the given symmetry. However, the case when conditions (42) can be satisfied only for some functions γ may lead to local conserved quantities. Every such situation when a function γ satisfying (42) still preserves arbitrariness with respect to other variables $\theta_1,\theta_2,\ldots,\theta_{k-1}$ (but not t), according to the analysis above, may lead to one conservation law.

Note 1. Conclusions made in Secs. III–VI cover two- and higher-dimensional equations. One-dimensional theories, like mechanics or quantum mechanics fall under the Second Noether Theorem (see, e.g., Sec. II).

Note 2. Arbitrary functions of dependent variables and their derivatives were not considered in the paper.

VIII. CONCLUSIONS

We have shown that infinite symmetries with arbitrary functions of not all independent variables lead to a finite number of conservation laws. The set of Noether, ''strict'' and additional boundary conditions determines the existence of associated nontrivial conservation laws. An arbitrary function of spatial variables, or any combination of independent variables with a nonzero spatial part, may lead to one (nontrivial) conservation law. Arbitrary functions of time in general do not correspond to conservation laws; instead they generate a system of additional constraints imposed on the function and its derivatives. However, the system of boundary conditions may determine specific form(s) of arbitrary functions that may lead to a finite number of local conser-

vation laws. The difference in roles of arbitrary functions of spatial variables and time is, obviously related to our understanding of (local) conservation laws as those continuity equations that result in conserved in time quantities $D_t \int \int dx^1\, dx^2 \ldots dx^m\, P_t \doteq 0$. The observation that a differential system possesses infinite symmetries corresponding to (at most) a finite number of conservation laws could be an indication of the fact that our description of such a system is ''richer'' than the very system.

(Received 20 June 2002; accepted 20 July 2002)

In this work we study second and third order approximations of water wave equations of the Korteweg–de Vries (KdV) type. First we derive analytical expressions for solitary wave solutions for some special sets of parameters of the equations. Remarkably enough, in all these approximations, the form of the solitary wave and its amplitude-velocity dependence are identical to the sech^2 formula of the one-soliton solution of the KdV. Next we carry out a detailed numerical study of these solutions using a Fourier pseudospectral method combined with a finite-difference scheme, in parameter regions where soliton-like behavior is observed. In these regions, we find solitary waves which are stable and behave like solitons in the sense that they remain virtually unchanged under time evolution and mutual interaction. In general, these solutions sustain small oscillations in the form of radiation waves (trailing the solitary wave) and may still be regarded as stable, provided these radiation waves do not exceed a numerical stability threshold. Instability occurs at high enough wave speeds, when these oscillations exceed the stability threshold already at the outset, and manifests itself as a sudden increase of these oscillations followed by a blowup of the wave after relatively short time intervals.
 [DOI: 10.1063/1.1514387]

I. INTRODUCTION

As is well known, the Korteweg–de Vries (KdV) equation represents a first order approximation in the study of long wavelength, small amplitude waves of inviscid and incompressible fluids. Furthermore, if one allows the appearance of higher order terms, more complicated wave equations can be obtained. Such an equation, including second and third order corrections, was proposed in Ref. 1 and was examined, in its second order form, analytically and numerically in Refs. 2, 3, and 4. It was found that, although it is nonintegrable in general, it still possesses solitary wave solutions, which, for small values of parameters, behave like pure solitons.

One problem mentioned in Ref. 4 was that the solitary waves of this second order equation generally possess a nonzero background and thus might be unphysical.

In this work, we study in more detail this second order equation, as well as its third order counterpart proposed in Ref. 1, as approximations for water wave propagation. We first apply the Pickering algorithm[5,6] and introduce an additional arbitrary constant, which allows us to construct zero background solitary waves for both of these equations. Thus we demonstrate the remarkable fact that all these solutions have the same sech^2 form and the same amplitude dependence on the velocity as the one-soliton solution of the KdV.

We then proceed to conduct a numerical study and show that a range of parameters exists for which these solitary waves possess soliton-like behavior, in the sense that they interact nearly elastically with each other and are stable under small perturbations. We also demonstrate that all these results continue to hold in the case of the third order approximation of water wave propagation, for an even larger set of parameters.

Let us consider the famous KdV equation

$$\frac{\partial u}{\partial t}+\frac{\partial u}{\partial x}+\alpha u\frac{\partial u}{\partial x}+\beta\frac{\partial^3 u}{\partial x^3}=0 \tag{1}$$

which constitutes a first approximation of unidirectional wave motion on the surface of a thin layer of an inviscid and incompressible fluid. The function $u(x,t)$ represents the amplitude of the fluid surface with respect to its level at rest, while α and β characterize, respectively, the long wavelength and short amplitude of the waves, compared with the depth of the layer.

In order to obtain a more physically realistic form of (1) one may include second order terms in α and β as suggested in Ref. 1

$$\frac{\partial u}{\partial t}+\frac{\partial u}{\partial x}+\alpha u\frac{\partial u}{\partial x}+\beta\frac{\partial^3 u}{\partial x^3}+\alpha^2\rho_1 u^2\frac{\partial u}{\partial x}+\alpha\beta\left(\rho_2 u\frac{\partial^3 u}{\partial x^3}+\rho_3\frac{\partial u}{\partial x}\frac{\partial^2 u}{\partial x^2}\right)=0, \tag{2}$$

where ρ_1,ρ_2,ρ_3 are considered, for the time being, as free parameters. This equation holds for $\alpha,\beta\ll 1$, obeying $O(\beta)<O(\alpha)$, as, e.g., $\beta\approx\alpha^2$.[1] In Ref. 1 it was also observed that (2) can be transformed—up to terms of second order in α, β—to a completely integrable partial differential equation (pde), through a nonlinear local change of the dependent variable.

As mentioned in Refs. 2 and 3, Eq. (2) is, in general, nonintegrable in the sense that some of its ordinary differential equation (ode) reductions do not possess the Painlevé property and a Lax pair does not seem to exist. However, it was still found to possess the traveling wave solution:[3,4]

$$u(x,t)=K+\frac{3\beta k(A^2-2k)(2\rho_2+\rho_3)\operatorname{sech}^2[\sqrt{k}(x-Ct-x_0)/\sqrt{2}]}{\alpha\rho_1(A-\sqrt{2k}\tanh[\sqrt{k}(x-Ct-x_0)/\sqrt{2}])^2}, \tag{3}$$

where

$$K=\frac{2\rho_1-2\rho_2-\rho_3}{2\alpha\rho_1(\rho_2+\rho_3)}-\frac{\beta(2\rho_2+\rho_3)k}{\alpha\rho_1}, \tag{4}$$

$$C=\frac{4\rho_1-1}{4\rho_1}+\frac{(\rho_2-2\rho_1)^2}{4\rho_1(\rho_2+\rho_3)^2}+\frac{\beta^2\rho_3(2\rho_2+\rho_3)k^2}{\rho_1}, \tag{5}$$

and A,k,x_0 are arbitrary constants.

These waves were studied numerically in Ref. 4 and were found to possess, for small values of β and k, properties of true solitons: i.e., they are stable under small perturbations and interact elastically with each other. However, they also possess a generally nonzero ''background,'' given by (4), which means that they may be thought of as unphysical, since they have infinite energy (when integrated over the full real line).

As we show in this paper, however, this need not be true, since there are particular choices of the ρ_i parameters which make $K=0$ and thus restore to the solitary wave (3) its proper physical meaning. To establish this we use a method due to Pickering[5,6] and introduce an extra free parameter which helps us choose the ρ_i so that (3) finally becomes identical to the sech^2-profile of the KdV one-soliton solution.

Entirely analogous results are obtained if we allow third order terms in (2) and study solitary wave solutions of the pde

$$\frac{\partial u}{\partial t}+\frac{\partial u}{\partial x}+\alpha u\frac{\partial u}{\partial x}+\beta\frac{\partial^3 u}{\partial x^3}+\alpha^2\rho_1 u^2\frac{\partial u}{\partial x}+\alpha\beta\left(\rho_2 u\frac{\partial^3 u}{\partial x^3}+\rho_3\frac{\partial u}{\partial x}\frac{\partial^2 u}{\partial x^2}\right)$$
$$+\alpha^3\rho_4 u^3\frac{\partial u}{\partial x}+\alpha^2\beta\left(\rho_5 u^2\frac{\partial^3 u}{\partial x^3}+\rho_6 u\frac{\partial u}{\partial x}\frac{\partial^2 u}{\partial x^2}+\rho_7\left(\frac{\partial u}{\partial x}\right)^3\right)=0, \tag{6}$$

where $\rho_1,\ldots,\rho_7$ are again considered free parameters. This equation is also found to be valid for $O(\beta)<O(\alpha)$,[1] as e.g., $\beta\approx\alpha^2$, with $0<\alpha\leqslant 1$.

In fact, as we show in Sec. II, (6) possesses a solitary wave that has exactly the sech^2-form of the KdV soliton, for certain choices of the values of the parameters $\rho_1,\ldots,\rho_7$. These solitary wave solutions are obtained at ρ_i values which are different than the ones needed to derive (6) from the pair of pdes of bidirectional wave propagation given by first principles.[1] However, this does not mean that solitary waves cannot be found by other analytical or numerical methods and for other parameter values than those identified in this paper.

We then proceed, in Sec. III, to carry out a detailed numerical investigation of the stability of our solutions, using a combination of a Fourier pseudospectral method in space and a finite difference scheme in time with various step sizes Δt. Establishing first as maximum tolerance for numerical stability, $E=(\Delta t)^2$, we regard a solitary wave as stable if the small radiation waves, occurring due to numerical errors, do not exceed in amplitude this threshold.

Thus, we find regions of parameters for which such stable solutions exist, exhibiting small oscillations that remain bounded for all times. However, when the amplitude of these oscillations exceeds E they are seen to exhibit a sharp increase after relatively short times, leading eventually to blowup of the wave. In Sec. III we also study the interaction of three such stable solitary waves and show that they remain unchanged before and after collision, demonstrating thus their soliton-like character. Finally in Sec. IV we summarize our conclusions and list some open questions for future investigation.

II. ANALYTICAL EXPRESSIONS OF SOLITARY WAVE SOLUTIONS

In order to obtain explicit expressions for solitary wave solutions we shall employ Pickering's algorithm,[5,6] which was also used in Ref. 3 for the derivation of the solution (3)–(5). As can be seen in (4), however, for specific values of $\rho_i\alpha$ and β, K becomes zero only for one value of k. This means that such solutions would exist only for one particular velocity, which is inconsistent with what one finds for the soliton solutions of the KdV. It is possible, however, to obtain a zero background for a wider set of k values by introducing an additional arbitrary constant in (4), as follows:

If we consider a truncated expansion of the solution of (2) of the form

$$u(x,t)=\frac{u_0}{z^2}+\frac{u_1}{z}+u_2+u_3z+u_4z^2, \tag{7}$$

where the u_i's are constants and $z=z(x,t)$ satisfies the equations

$$z_x=1-Az-Bz^2,$$

$$z_t=-C+ACz+BCz^2 \tag{8}$$

with A, B, and C also free constants, we can allow one of the u_i to be arbitrary. This happens, for example, if

$$\rho_1=0 \quad \text{and} \quad \rho_3=-2\rho_2, \tag{9}$$

in which case u_0 is arbitrary and

$$u_1=-Au_0, \quad u_2=\frac{1}{12}(A^2-8B)u_0-\frac{au_0+12b}{12ab\rho_2}, \quad u_3=u_4=0.$$

Substituting relation (7) in (2) and using (8) we finally obtain

$$u(x,t)=K-\frac{B_1(A^2-4B_1)u_0\,\mathrm{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2}$$

(where we have set $B_1=B+\frac{1}{4}A^2$) with

$$K=-\frac{1}{\alpha\rho_2}+\frac{1}{12}\left(4B_1-\frac{1}{\beta\rho_2}\right)u_0,$$

$$C=\frac{\rho_2-1}{\rho_2}-\frac{\alpha u_0}{12\beta\rho_2}+\frac{4}{3}\alpha\beta B_1^2\rho_2 u_0,$$

x_0 being the arbitrary location of the ''center'' of the wave. We can now force the background to be zero ($K=0$) by choosing

$$u_0=\frac{12\beta}{\alpha(4\beta\rho_2B_1-1)} \tag{10}$$

(hence u_0 is no longer arbitrary) and conclude with the solution

$$R3U_0:\ u(x,t)=-\frac{B_1(A^2-4B_1)u_0\,\mathrm{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2}, \tag{11}$$

where

$$C=1+4\beta B_1$$

is the velocity of the traveling wave.

Observe that (11) can in fact be written in the form of the well-known sech^2-soliton solution of the KdV (1) by a simple transformation: Writing

$$\cosh\theta=\frac{A}{\sqrt{A^2-4B_1}}\quad\text{and}\quad\sinh\theta=\frac{2\sqrt{B_1}}{\sqrt{A^2-4B_1}}\quad\text{for}\ A^2>4B_1$$

and shifting x_0 appropriately, (11) is easily seen to take the form

$$u(x,t)=-\frac{3(C-1)}{\alpha(-1+(C-1)\rho_2)}\,\mathrm{sech}^2\left[\frac{1}{2}\sqrt{\frac{C-1}{\beta}}(x-Ct-x_0)\right]$$

which is exactly the one-soliton solution of the KdV if $\rho_2=0$ in which case (2) reduces exactly to (1).

In the expansion (7) of the Pickering algorithm we may alternatively consider u_2 as an arbitrary constant, by setting

$$\rho_2=2\rho_1\quad\text{and}\quad\rho_3=-2\rho_1 \tag{12}$$

and thus obtain explicit solutions of (3) even in the case $\rho_1\neq0$. Conditions (12) then lead to the solution

$$u(x,t)=K+\frac{12\beta B_1(A^2-4B_1)\mathrm{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{\alpha(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2},$$

where

$$K=\frac{3\beta(A^2-4B_1)}{\alpha}+u_2,$$

$$C=1+3A^2\beta-8\beta B_1+\alpha u_2+\rho_1(3A^2\beta-12\beta B_1+\alpha u_2)(3A^2\beta-4\beta B_1+\alpha u_2),$$

and A,B_1,x_0 are again arbitrary constants. Zero background is obtained by setting

$$u_2=-\frac{3\beta(A^2-4B_1)}{\alpha}, \tag{13}$$

whence we arrive at the expression

$$R3U2:\ u(x,t)=\frac{12\beta B_1(A^2-4B_1)\operatorname{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{\alpha(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2}, \tag{14}$$

where the velocity of the wave is again $C=1+4\beta B_1$.

It is worth remarking here that if, instead of applying Pickering's approach, we were to consider the traveling wave reductions of (2), $u(x,t)=f(x-Ct)$, for the choice of parameters (12), we can integrate the resulting ode and discover, by a simple phase plane analysis, that it possesses a separatrix along which the solution is

$$u(x,t)=\frac{3(C-1)}{\alpha}\operatorname{sech}^2\left[\frac{1}{2}\sqrt{\frac{C-1}{\beta}}(x-Ct-x_0)\right]. \tag{15}$$

This is exactly the same as the sech^2-soliton solution of KdV (1) for all ρ_1 and also coincides with (14), for $C=1+4\beta B_1$ if we shift x_0 appropriately, as explained below (11).

Finally, let us turn to the third order equation (6). Here it is important to point out that a traveling wave reduction and a derivation of the solitary wave form as done above appears to be quite difficult, as the associated odes are too cumbersome to integrate exactly. Thus we need to turn to the application of Pickering's algorithm and show, as before, that u_0, A, and B remain arbitrary iff ρ_i satisfy the following relations:

$$\rho_3=2(\rho_1-\rho_2),\quad \rho_4=0,\quad \rho_5=2\rho_1(\rho_2-2\rho_1),$$

$$\rho_6=6\rho_1(2\rho_1-\rho_2),\quad \rho_7=3\rho_1(\rho_2-2\rho_1), \tag{16}$$

whence the corresponding solution takes the form

$$u(x,t)=K-\frac{B_1(A^2-4B_1)u_0\operatorname{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2},$$

where K and C depend on the parameters of the equation and the arbitrary constants u_0, A, and B_1. The zero background solution $(K=0)$ arises if we set

$$u_0=\frac{12\beta}{\alpha(4\beta B_1\rho_2-8\beta B_1\rho_1-1)}, \tag{17}$$

whence we finally obtain

$$R7U0:\ u(x,t)=-\frac{B_1(A^2-4B_1)u_0\operatorname{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2} \tag{18}$$

with $C=1+4\beta B_1$ again the velocity of the wave. Note that, with $\rho_1=0$, solution (18) with (17) coincides exactly with (11) and (10).

In the same way, as with the second order equations, we may also consider u_2 arbitrary and derive the following ρ_i relations:

$$\rho_2=2\rho_1, \quad \rho_3=-2\rho_1, \quad \rho_5=3\rho_4, \quad \rho_6=-6\rho_4, \quad \rho_7=3\rho_4, \tag{19}$$

whence the corresponding solution is

$$u(x,t)=K+\frac{12\beta B_1(A^2-4B_1)\operatorname{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{\alpha(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2},$$

where K and C depend again on the parameters of the equation and the arbitrary constants u_2, A and B_1. The zero background solution $(K=0)$ now requires

$$u_2=-\frac{3\beta(A^2-4B_1)}{\alpha} \tag{20}$$

and we finally obtain

$$R7U2: \quad u(x,t)=\frac{12\beta B_1(A^2-4B_1)\operatorname{sech}^2[\sqrt{B_1}(x-Ct-x_0)]}{\alpha(A-2\sqrt{B_1}\tanh[\sqrt{B_1}(x-Ct-x_0)])^2}, \tag{21}$$

where the velocity is $C=1+4\beta B_1$, as in all the cases above. Again here (21) also becomes identical to the KdV soliton (15), with the appropriate shift of the constant x_0, even though it is the solution of a much more complicated pde.

It is important, however, to remark that the ρ_i parameter values, (16) or (19), determined by our approach, are quite different from the ones found in Ref. 1, by the reduction to unidirectional flow from a pair of pdes describing bidirectional wave propagation. The reasons for this difference remains an open question, which clearly requires further investigation.

III. NUMERICAL STABILITY ANALYSIS

The numerical scheme used in the current study is the same as the one employed in Ref. 4 and is based on a combination of finite differences and a Fourier pseudospectral method. In order to demonstrate the application of our algorithm we first describe it on the KdV equation

$$u_t+u_x+\alpha u u_x+\beta u_{xxx}=0 \tag{22}$$

with the initial condition $u(x,0)=f(x)$. The time derivative in (22) is discretized using a finite difference approximation, in terms of central differences

$$u^{n+1}=u^{n-1}-2\Delta t(u_x^n+\alpha u^n u_x^n+\beta u_{xxx}^n)=0. \tag{23}$$

According to the pseudospectral method, we introduce the approximate solution

$$u(x,t)=\sum_{k=0}^{N}\alpha_k(t)\Phi_k(x), \tag{24}$$

where $\Phi_k(x)=e^{ikx}$ are the Fourier exponentials, and $\alpha_k(t)$ are coefficients to be determined, for $k=0,1,...,N$.

The steps used to advance the solution from time step n to $n+1$ are[7]

(i) Given $u_j^n=u(x_j,t_n)$ evaluate $\alpha_k^n=\alpha_k(t_n)$ from (24).
(ii) Given α_k^n evaluate the derivatives, e.g., $[\partial^2 u/\partial x^2]_j^n$ from (24).

(iii) Evaluate the nonlinear terms, e.g., $u_j^n[\partial u/\partial x]_j^n$.
(iv) Evaluate u_j^{n+1} from (23), at $x=x_j$, $t=t_{n+1}$.

Step (i) is the transformation from physical space to spectral space. This transformation is achieved by the use of a fast Fourier transform (FFT) described in Refs. 7 and 8 with a number of operations $(5/2)N\log_2 N$ (N being the number of polynomials), in contrast to the $2N^2$ operations required for a matrix-vector multiplication.[9] Step (ii) occurs in spectral space and the evaluation of the nonlinear term in step (iii) is in physical space, thus avoiding the expensive multiplication of all coefficients in the expansions of the form (24). Step (iv) occurs again in physical space.

The accuracy of our numerical scheme for the time variable t is $O((\Delta t)^2)$, due to central differences and for the space variable x, where we use the pseudospectral method, $O(e^{-qN})$, where q is a constant.[8] Numerical calculations were carried out for various numbers of polynomials $N=128$, 256, 512, and 1024 and time steps $\Delta t=0.0001$ to 0.002, while the spatial step was chosen to be $\Delta x=1$.

We should mention here that, for the time propagation of such types of problems, where the spatial discretization is extremely accurate, the most commonly used method is the fourth order Runke–Kutta integration scheme. Even though this method provides satisfactory results, it may fail because of sensitivity to the initial conditions and inherent instabilities. Thus, since the stability of the waves propagating in time is of more interest than the accuracy, a more stable, central differencing is used for the discretization in time.

In Ref. 4 we carried out several calculations to verify the efficiency of our numerical code. For the KdV equation (1) at $t=0$ with $\alpha=1$, $\beta=0.1$, $x_0=20$ and $c=1.1$, we took as initial condition the well-known exact solitary wave solution

$$u(x,t)=\frac{3(c-1)}{\alpha}\,\mathrm{sech}^2\left[\frac{1}{2}\sqrt{\frac{c-1}{\beta}}(x-ct-x_0)\right], \tag{25}$$

where c is the propagation speed and x_0 is an arbitrary constant.[10,11] We observed that our wave moves along the spatial direction retaining its initial profile for a very long time period of at least $t=2.5\times10^6$ time units with time step $\Delta t=0.01$. A three-soliton interaction was also studied and the results were as expected from the soliton solutions of the KdV, i.e., the waves interact elastically and remain unchanged before and after their interaction. These results were obtained for various time steps and numbers of polynomials N mentioned above, which demonstrates that our code reproduces accurately the fundamental properties of the KdV.

The plethora of free parameters entering into Eqs. (2) and (6) makes the study of the wave solutions, obtained in Sec. II, not a very easy task. However, if we impose the zero background for our solutions, much of the redundancy is removed and our ρ_i's begin to have a more specific meaning. Thus, we investigate the wave solution (11) for Eq. (2), with u_0 given by (10) and for ρ_i, $i=1,2,3$ satisfying (9). This solution is referred to as $R3U0$. For the same equation we also study the solution (14) for u_2 given by (13) and ρ_i, $i=1,2,3$ satisfying (12), which is referred to as $R3U2$. Similarly we name $R7U0$ the solution (18) of Eq. (6) with u_0 given by (17) and for ρ_i, $i=1,...,7$ satisfying (16) and $R7U2$ the solution (21) of the same equation with u_2 given by (20) and for ρ_i, $i=1,...,7$ satisfying (19).

The free parameters now present in the solutions $R3U0$ and $R3U2$ are only α, β, B_1, and ρ_2 for $R3U0$ or ρ_1 for $R3U2$. Therefore, we will first study how they affect the stability of the above-mentioned wave solutions, and then proceed to study the $R7U0$ and $R7U2$ waves, using similar α and β, plus ρ_1 for $R7U0$ and ρ_4 for $R7U2$.

A. A stability criterion

Our ultimate goal, of course, is to examine the values of the parameters in our higher order KdV equations (2) and (6), for which the solitary wave solutions mentioned above preserve their shape and are stable under evolution. By the term ''stable'' we mean that a wave solution, when

substituted in an equation, retains its initial profile for long times, albeit with some smaller oscillations present as radiation waves, due to unavoidable numerical errors produced under time evolution.

Thus, in order to check stability, one way is to track the residual of the solution in time. For the case of KdV, for example, if $\overline{u}$ is an exact solution of (1) it will satisfy

$$\overline{u}_t+\overline{u}_x+\alpha\overline{u}\overline{u}_x+\beta\overline{u}_{xxx}=0. \tag{26}$$

If the approximate solution (24), computed numerically, is substituted into (26) it will not, of course, give zero. Thus we write for it

$$u_t+u_x+\alpha u u_x+\beta u_{xxx}=R,$$

where R is called the residual of the equation. It is expected that R is a continuous function of x and t and if N is sufficiently large then, in principle, the coefficients $\alpha_k(t)$ can be chosen so that R is as small as we wish over the computational domain. In our case we evaluate $R=R_i$ at each x_i, $i=1,...,N$ grid point at specific time moments t_n.

Due to the fact that the wave solutions are computed for sufficiently large values of N (128 to 1024), the spatial error of the pseudospectral method is in agreement with the $O(e^{-qN})$ estimate mentioned above, and is practically zero. The maximum absolute residual, which we refer to as the error, $E=\max_i|R_i|$, will increase due to the central differencing in time, but cannot be greater than $O((\Delta t)^2)$. Several tests have been made for the wave solution (25) of the KdV verifying that for various values of N (128 to 1024) and time step $\Delta t=0.0001$ to 0.02, $E<(\Delta t)^2$ at least for a time period of 10^6 time units.

Therefore, a practical way to verify that a wave solution is stable is to check if the error remains, for long times, less than $O((\Delta t)^2)$. If E increases above this value already from the outset, oscillations will soon grow and become unbounded after relatively short times, not only because of the numerical scheme, but also due to the nonlinear nature of the equations, suggesting that the initial wave solution has become unstable. *This is also supported by the fact that blowup occurs nearly at the same times, irrespective of the values of the Δx and Δt step sizes used in the numerical scheme.*

B. Solutions *R3U0* and *R3U2*

Let us now proceed to the study of $R3$ solutions. In all that follows B_1 satisfies the relations $B_1>0$ and $A>\sqrt{2B_1}$ which are vital in order to have a bounded wave solution. The parameter A does not affect the stability of the wave and in all cases is taken $A=3$.

One way to examine the stability of solutions under investigation is to set α, β fixed and start to increase B_1, the velocity of the wave, by a quantity ΔB_1. Each time we increase B_1, we track the error E for a period of time: If it remains below $(\Delta t)^2$, we consider that the wave is stable for this period, and proceed to increase B_1 by another ΔB_1 until E becomes greater than $(\Delta t)^2$. Once this happens, we set $\Delta B_1=\Delta B_1/2$, decrease B_1 by ΔB_1 and track the error again. In that way, we determine, up to an accuracy ϵ ($\Delta B_1<\varepsilon$), the maximum value of B_1 (speed), $B_1^{\max}$, for which the solitary wave is stable.

The period of time used in the current study is 500 time units, with time step $\Delta t=0.001$ and accuracy $\varepsilon=0.001$. Several tests have been made, e.g., with the KdV, using cases where the exact solution is known to be stable, and as expected, the value of $B_1^{\max}$, estimated in the above way, depends neither on the time step Δt, nor on the number of points N we use.

Figure 1 shows the variation of $B_1^{\max}$ with α for various values of β. The parameter ρ_2 is fixed equal to 1. It is observed that as α increases $B_1^{\max}$ is increasing for small values of β. The variation of $B_1^{\max}$ with α is smaller as β increases and finally no significant changes are observed when $\beta>0.2$. Thus, it can be concluded that α has a stabilizing effect on the solutions, especially for low

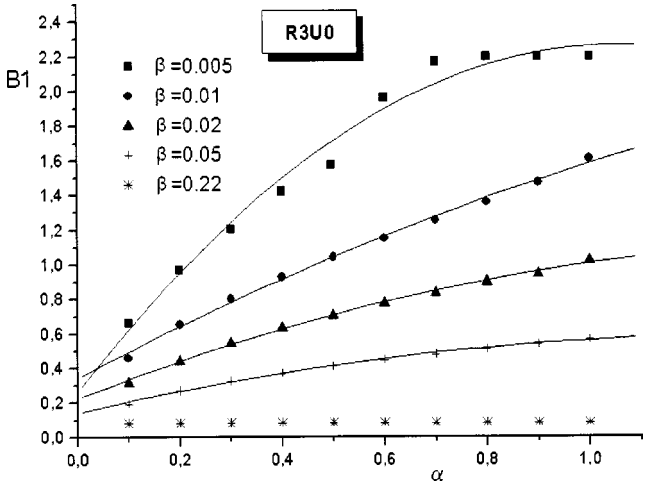

FIG. 1. Variation of $B_1^{\max}$ of solution $R3U0$ with α.

values of β, since its increase makes the range of velocities larger for stable soliton-like waves (in the range of $0<\beta\leqslant 0.1$). The region below each curve (plotted by interpolation) is the region of stability of the wave solution for the corresponding values of parameters.

The variation of the $B_1^{\max}$ with β for various values of α is shown in Fig. 2. Unlike what was observed for α in Fig. 1, we find that $B_1^{\max}$ decays exponentially with the increase of β, and the region where the wave solution is stable is larger for greater values of α. Thus we conclude that increasing β has a destabilizing effect on the solitary waves. The parameter ρ_2 is again kept equal to 1. The variation of $B_1^{\max}$ for the solution $R3U2$ with α or β is qualitatively the same as that for $R3U0$, and any quantitative differences with Figs. 1 and 2 are insignificant.

Similar results were also observed for the $R7U0$ and $R7U2$ solutions. However, because of the additional ρ_i parameters present in these cases, a direct comparison with the $R3$ solutions is not easy to demonstrate pictorially.

It is important to note that these findings are in good agreement with the conditions of the validity of (2) and (6), i.e., that $O(\beta)<O(\alpha)$.[1] In fact, using $\beta\approx\alpha^2$ is seen to yield optimal results in terms of the size of stability regions of our solitary wave solutions.

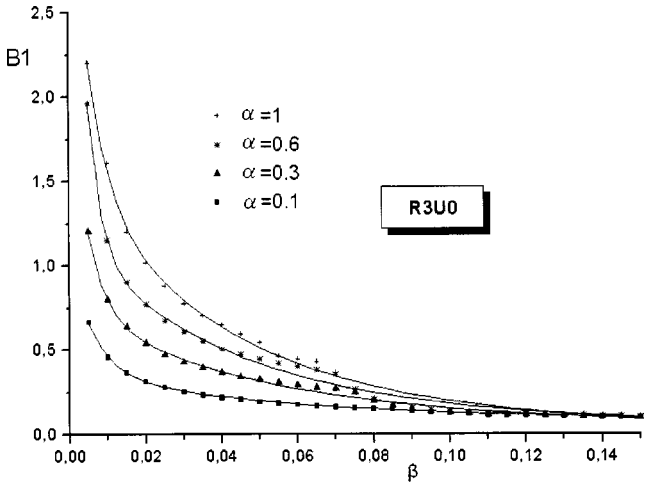

FIG. 2. Variation of $B_1^{\max}$ of solution $R3U0$ with β.

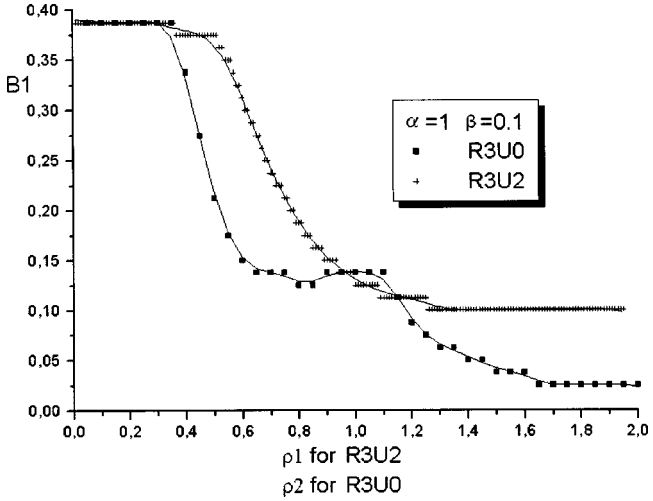

FIG. 3. Variation of $B_1^{\max}$ with ρ_2 for $R3U0$ and ρ_1 for $R3U2$.

In order to examine the effect of ρ_2 on $R3U0$ or ρ_1 on $R3U2$ we can set $\alpha=1$, $\beta=0.1$ and find $B_1^{\max}$ while varying the corresponding ρ_i. Figure 3 shows this variation of $B_1^{\max}$ with ρ_2 for $R3U0$ and ρ_1 for $R3U2$ solitary wave solutions. It is found that for an increase of the corresponding ρ_i up to 0.4 there are no significant changes. When the ρ_i increase beyond 0.4 a rapid decrease of $B_1^{\max}$ takes place. This decrease stops at $\rho_1 \approx 1.2$ for the $R3U2$ solution, while, in the case of $R3U0$ it continues until ρ_2 reaches the value of approximately 1.7.

It is worth mentioning that the results plotted in Figs. 1–3 using $\Delta t=0.001$ and $N=128$, are also obtained for time steps 0.0001, 0.002, and number of points 256 and 512.

C. Error behavior during wave propagation

Before proceeding to the $R7$ solutions, let us discuss some results concerning the error criterion of Sec. III A, in order to understand how wave solutions propagate in time and which of them are considered as stable. The results described below were obtained for the $R7U0$ solution, but are similar to what is observed for $R7U2$.

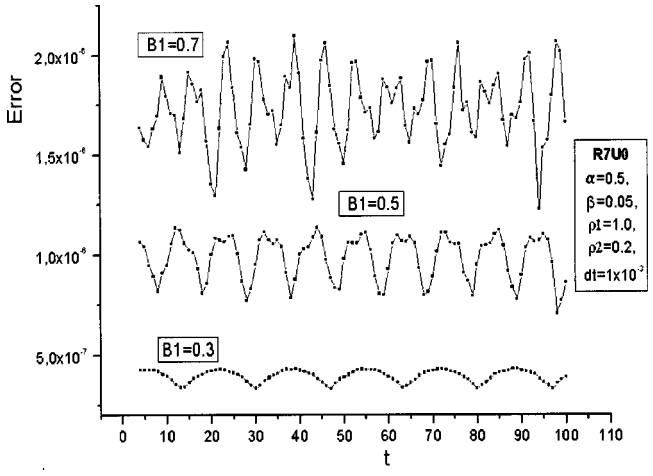

FIG. 4. Error variation with time for three different values of B_1. The case $B_1=0.5$ lies just above the boundary of the stability region $E \leqslant (\Delta t)^2$.

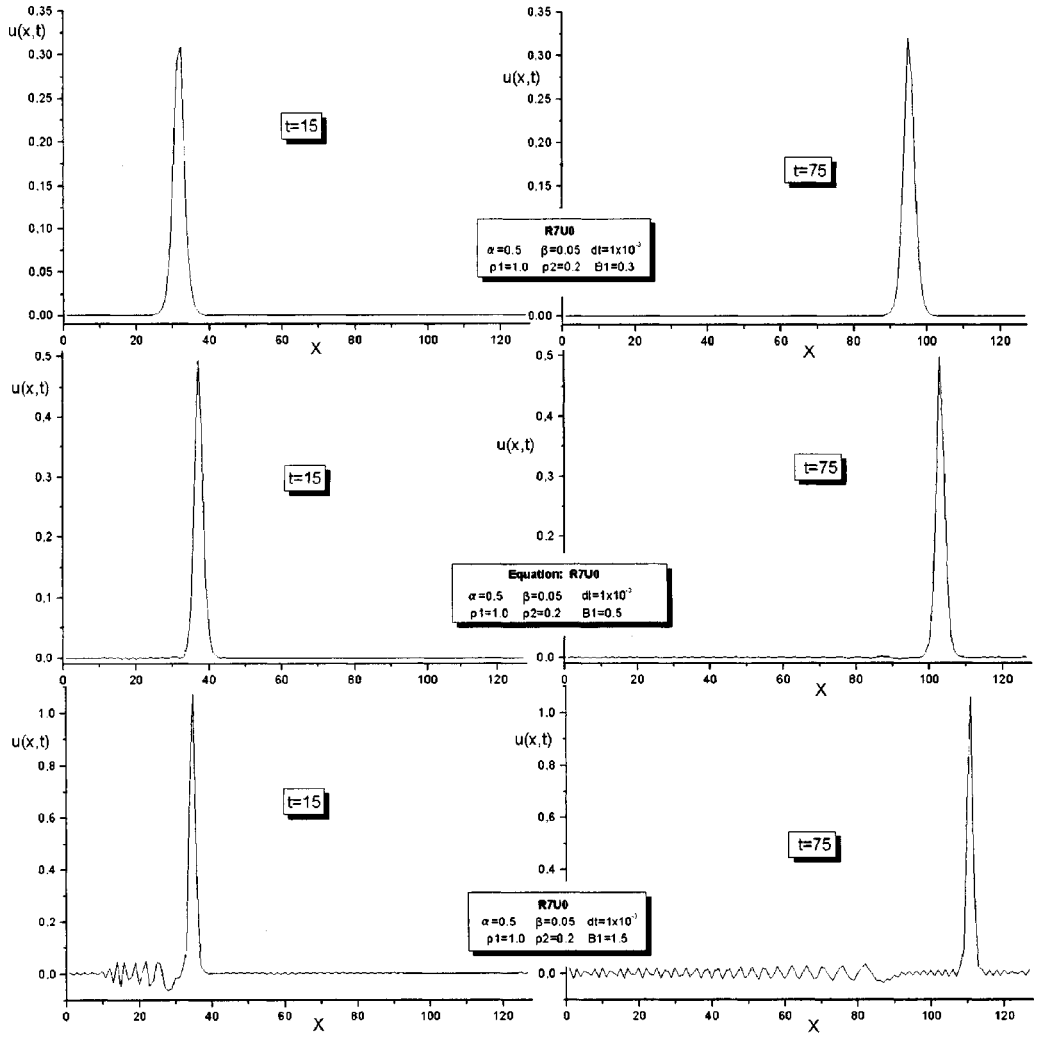

FIG. 5. Evolution of $R7U0$ in time for $B_1=0.3$, 0.5, and 1.5, respectively.

We set $\alpha=0.5$, $\beta=0.05$, $\rho_1=1$, $\rho_2=0.2$ and track the error of $R7U0$ for a period of time of 100 time units, with time step $\Delta t=0.001$, and three different values of B_1, namely 0.3, 0.5, and 0.7. The variation of the errors for these cases are shown in Fig. 4. Note that the error for $B_1=0.3$ is less than $(\Delta t)^2=1\times10^{-6}$.

Figure 5 shows the $R7U0$ solution propagating in time for B_1 equal to 0.3, 0.5 and 1.5, respectively, for the same values of the other parameters as above. It is observed that for $B_1=0.3$ the wave remains virtually unchanged in time and is therefore considered stable, with its radiation waves remaining smaller than $(\Delta t)^2$ for very long times. On the other hand, in the case $B_1=0.5$, bounded oscillations appear where the error slightly exceeds $(\Delta t)^2$. We call this solution unstable, because its radiation waves grow as time increases and become unbounded after a relatively short time. Similarly, for $B_1=1.5$, where these oscillations are even larger at the beginning, blowup occurs after a much shorter time interval. We remark once more that analogous results are obtained for different time steps, and also for the same time step and greater values of N.

It is important to mention that for small $\beta(\beta<0.1)$ and large $\alpha(\alpha\approx1)$ oscillations appear, even when the error E does not exceed $(\Delta t)^2$. These oscillations remain almost the same for a time period comparable to the one used to test the stability of the solutions of KdV. Moreover,

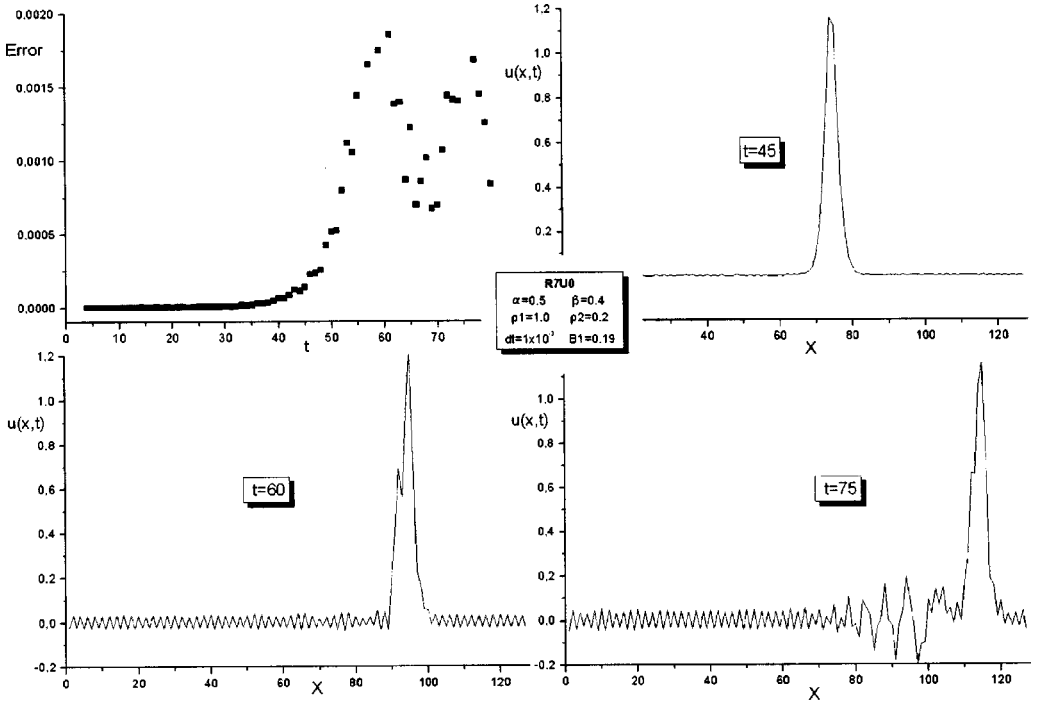

FIG. 6. Evolution of $R7U0$ in time for $B_1=0.19$.

even when $E\approx(\Delta t)^2$ (and β small enough) oscillations can persist over long time intervals as seen in Fig. 5, with $\beta=0.05$, where the oscillations occurring for $B_1=1.5$ remain unchanged and bounded well beyond value of $t=75$ shown in the figure.

However, if the error grows sharply at some point in time, this implies that the oscillation will become unbounded soon thereafter leading to a blowup of the solution. Figure 6 shows the propagation of $R7U0$ for $\alpha=0.5$, $\beta=0.4$, $\rho_1=1$ and $\rho_2=0.2$. In this case, $B_1^{\max}\approx 0.156$, as estimated by the method described above. Consequently, if we set $B_1=0.19$ error oscillations suddenly explode at $t\approx 50$ causing the wave amplitude to increase while at $t\approx 80$ the solution blows up. The same behavior is observed for Δt varying from 0.0001 to 0.002 and N from 128 to 512 indicating that this is not a numerical blowup.

As in the case of $R7U0$ shown in Fig. 6, we have also observed from numerous tests, that if the wave is to blow up, the error will suddenly increase by 2–3 orders of magnitude within the first 200 time units. In some examples, blowup occurs after thousands of time units, but is predicted by our error analysis already within the first 200 time units. Thus, for the calculation of stability results, we adopt the time period of 500 time units of numerical integration.

In order to investigate the stability of the $R7$ solutions we keep the values of α and β fixed at $\alpha=1$, $\beta=0.1$. Moreover, we consider $\rho_1=0.2$ and $\rho_2=0.2$ for $R7U2$ and $R7U0$, respectively. Consequently, the independent parameters are ρ_1 for $R7U0$ and ρ_4 for $R7U2$. The variation of $B_1^{\max}$ with ρ_1 for $R7U0$ and ρ_4 with $R7U2$ is shown in Fig. 7. It is found that the growth of ρ_1 in $R7U0$ results in an increase of $B_1^{\max}$, whereas increasing ρ_4 in $R7U2$ solution results in a decrease of $B_1^{\max}$. For relatively large values of the corresponding ρ_i the stability regions differ considerably and for values greater than unity the corresponding $B_1^{\max}$ can be 4 times greater for $R7U0$ than that of $R7U2$.

D. Elastic three wave interactions

In Ref. 4 a three-wave interaction was performed with Eq. (2), using its solution (3) as initial condition for the three solitary waves. It was reported that due to the different backgrounds of the

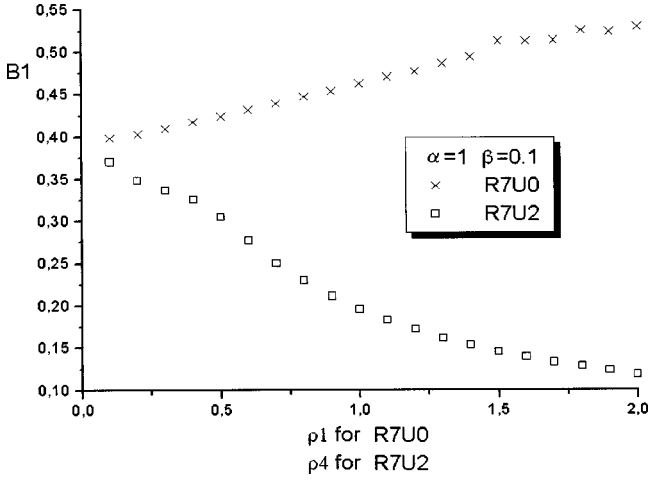

FIG. 7. Variation of the $B_1^{\max}$ with ρ_1, for $R7U0$ and ρ_4 for $R7U2$.

waves a slight displacement of each solution by a constant had to be applied. This can now be avoided using the zero background wave solutions we have obtained here. Thus, we study here the interactions of solitary waves of the form (15), using the third order KdV equation (6).

A preliminary investigation of the $R7$ solutions suggests using the $R7U0$ solitary wave, since its stability region increases with increasing ρ_1, provided we keep the difference between ρ_1 and ρ_2 small. The reason is that the additional nonlinear terms in $R7U0$ are multiplied by $\rho_4,\ldots,\rho_7$ values which are smaller than those of $R7U2$, and thus lead to a larger area of stability.

The next step is to specify values for the α and β parameters. As was shown in Sec. II, the wave speed of propagation is $C=1+4\beta B_1$. Thus, the relative speed between two waves is $4\beta(B_1-B_1')$, where $C'=1+4\beta B_1'$ is the velocity of the second wave. Consequently, we have to use relatively large values of β to see an interaction within a reasonable time. Furthermore, we have to avoid using large α so as to reduce the bounded oscillations described in the preceding section. Therefore, taking into account all these considerations we choose $\alpha=0.4$, $\beta=0.1$, $\rho_1=0.25$, and $\rho_2=0.1$.

For the values of the remaining parameters we set $x_1=10$, $x_2=28$, $x_3=55$ and $B_{11}=0.30$, $B_{12}=0.20$, $B_{13}=0.06$, where x_i and B_{1i} correspond, for $i=1,2,3$, to the first (fastest), second (middle), and third (slowest) wave. The interaction of these solitary waves, as shown in Fig. 8, is seen to occur in exactly the same way as for the KdV equation. No radiation is observed and no differences are found in the shape of the solitary waves (before and after collision) as far as we could determine numerically (with $\Delta t=0.01$ and $N=1024$). These results strongly indicate the existence of wave solutions which ''behave'' as true solitons in water wave equations which represent higher order approximations to the KdV equation.

IV. CONCLUDING REMARKS

In this paper, we have studied the existence and stability of solitary wave solutions of pdes representing second and third order approximations of unidirectional water wave propagation, in the short amplitude, $0<\alpha=a/h\ll 1$, and long wavelength limit, $0<\beta=(h/l)^2\ll 1$ (h is the depth of the fluid layer). To first order in α and β, these pdes reduce to the famous KdV equation, which is completely integrable and possesses solitary waves that interact perfectly elastically with each other and are called solitons.

Our original motivation was the fact that these higher order KdV equations have been shown to be equivalent to completely integrable pdes, by a local nonlinear transformation, at the same order of approximation in α and β.[1] The question therefore naturally arises if these higher order KdV approximations also possess solitary waves exhibiting soliton-like dynamics.

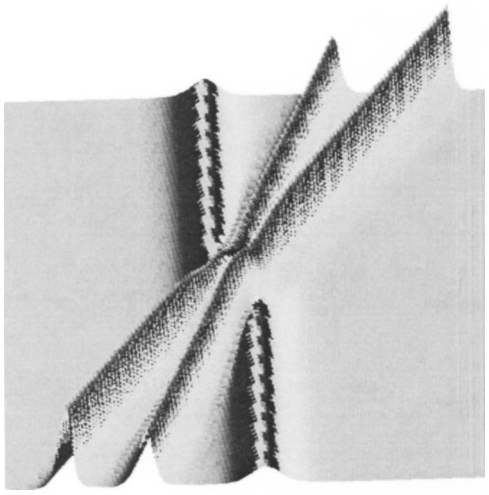

FIG. 8. Elastic interaction of three $R7U0$ solitary waves of Eq. (6).

Adopting the assumption $O(\alpha)<O(\beta)$ (e.g., $\beta\approx\alpha^2$), which eliminates some dispersive terms with higher order derivatives,[1,12] we derive exact, closed form expressions for the solitary waves valid to second and third order in α and β using Pickering's algorithm.[5,6] Choosing then specific values for the free parameters, we force these solutions to have zero background and demonstrate the remarkable fact that they all have the same sech^2 form and velocity dependence as the simple, one-soliton solution of the KdV.

Proceeding to a numerical study of their stability, we use a Fourier pseudospectral method combined with finite difference in time (with step size Δt) and establish a threshold of numerical error tolerance $E=(\Delta t)^2$. Thus we call a solitary wave stable if the small oscillations trailing the wave have amplitude smaller than E and remain bounded for very long times ($\leqslant$500 units).

However, as the speed of the wave increases, these ''radiation'' oscillations also increase and when their amplitude exceeds E, already at the beginning of their evolution, turn out to exhibit a dramatic growth over relatively short times ($\leqslant$200 units) leading eventually to blowup of the wave and characterizing the solution as unstable. Our results are entirely consistent with what is observed for the KdV equation and also agree with the assumption that $O(\beta)<O(\alpha)$ in these pdes.

A number of open questions remain for future investigation: What is the ''physical'' meaning of the values of the free parameters, which we have chosen so that the solitary waves of these pdes have zero background? Why are these values different from those obtained by the reduction of the original water wave equations to unidirectional motion?[1] In fact, we have recently observed that the ode that gives traveling wave solutions for the second order approximation (2) can be easily integrated once and then numerically studied by phase plane analysis to give homoclinic orbits, which correspond to solitary waves for many other ρ_i parameters than the ones identified here.

Can such integrations be carried out also for the third order equation (6) to yield solitary waves, exhibiting similar behavior and reducing to the KdV soliton, as α and β go to zero? Finally, among all these choices, which ρ_i fit best the physical realization of a solitary water wave?

Another question concerns the mathematical form of the solitary waves we have obtained in this paper: Could their simple sech^2 expressions (identical for the second and third order case) imply that they also hold in higher order approximations? Finally, is their presence related to the fact that the corresponding approximation can be transformed to a pde which is completely integrable to the same order in α, β?

In conclusion, we believe that water wave motion still remains an open and fascinating topic of great mathematical and physical interest and hope to be able to answer some of the above questions in a future publication.

ACKNOWLEDGMENTS

(Received 14 March 2002; accepted 9 August 2002)

We present a class of time-dependent potentials in R^n that can be integrated by separation of variables: by embedding them into so-called cofactor pair systems of higher dimension, we are led to a time-dependent change of coordinates that allows the time variable to be separated off, leaving the remaining part in separable Stäckel form. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1514833]

I. INTRODUCTION

Newton's law of force in mechanics leads to second order ordinary differential equations $\ddot{q}=M(q,\dot{q},t)$, where $q=(q^1,\ldots,q^n)$ are coordinates on some manifold Q, the configuration space of the system. Often the force M is derived from a potential $V(q,t)$ and the equations can be written in Lagrangian form

$$\frac{\partial L}{\partial q^i}-\frac{d}{dt}\frac{\partial L}{\partial \dot{q}^i}=0, \quad L(q,\dot{q},t)=\frac{1}{2}g_{ij}\dot{q}^i\dot{q}^j-V(q,t),$$

or, via the Legendre transformation, in Hamiltonian form

$$\dot{q}^i=\frac{\partial H}{\partial p_i}, \quad \dot{p}_i=-\frac{\partial H}{\partial q^i}, \quad H(q,p,t)=\frac{1}{2}g^{ij}p_ip_j+V(q,t).$$

Here g_{ij} is the metric tensor on Q, with inverse g^{ij}, and (q^i,p_j) are (adapted) coordinates on the cotangent bundle T^*Q.

Powerful techniques have been developed for solving such equations; in particular the well-known Hamilton–Jacobi method, where one tries to find new coordinates $u=u(q)$ on Q, in terms of which the Hamilton–Jacobi equation corresponding to H can be solved by separation of variables. If this succeeds, the mechanical system can be integrated by quadratures.

We will restrict ourselves to Euclidean n-space, i.e., $Q=R^n$ and $g_{ij}=\delta_{ij}$. The coordinates will be written with lower indices in this case, and regarded as a column vector $q=(q_1,\ldots,q_n)^T$, the T denoting matrix transposition.

Consider a Newton system which does not contain time t or velocity $\dot{q}$ explicitly,

$$\ddot{q}=M(q).$$

If there is a potential, the system takes the form

$$\ddot{q}=-\nabla V(q), \quad \nabla=\frac{\partial}{\partial q}=\left(\frac{\partial}{\partial q_1},\ldots,\frac{\partial}{\partial q_n}\right)^T,$$

a)Electronic mail: lundmark@math.usask.ca
b)Electronic mail: strau@mai.liu.se

and then the energy $E=\frac{1}{2}\dot{q}^T\dot{q}+V(q)$ is conserved ($\dot{E}=0$). The separability theory for such time-independent potentials in Euclidean space is highly developed. It is known that separation of the corresponding Hamilton–Jacobi equation can only take place in so-called generalized elliptic coordinates or some degeneration thereof.[4] There even exists an effective algorithm for determining whether or not a given potential $V(q)$, expressed in Cartesian coordinates, is separable, and if so, in which coordinate system.[10]

Less is known in the time-dependent case. One of the aims of this paper is to show how certain Newton systems in R^n with time-dependent potential can be integrated by viewing them as driven systems in R^N, with $N>n$, as the following example illustrates.

Example 1: Consider the time-dependent potential

$$V(x_1,x_2,t)=\frac{1}{x_1x_2-t} \tag{1}$$

and the corresponding Newton system in R^2:

$$\begin{aligned}\ddot{x}_1&=-\frac{\partial V}{\partial x_1}=\frac{x_2}{(x_1x_2-t)^2},\\ \ddot{x}_2&=-\frac{\partial V}{\partial x_2}=\frac{x_1}{(x_1x_2-t)^2}.\end{aligned} \tag{2}$$

In order to integrate this system, we introduce the following auxiliary Newton system in R^3, where the first equation drives the other two:

$$\begin{aligned}\ddot{q}_1&=0,\\ \ddot{q}_2&=\frac{q_3}{(q_2q_3-q_1)^2},\\ \ddot{q}_3&=\frac{q_2}{(q_2q_3-q_1)^2}.\end{aligned} \tag{3}$$

We think of the q coordinates as partitioned into *driving* coordinates y and *driven* coordinates x:

$$\begin{pmatrix} q_1\\ \hline q_2\\ q_3\end{pmatrix}\equiv\begin{pmatrix} y\\ \hline x_1\\ x_2\end{pmatrix}.$$

The particular solution $y(t)\equiv q_1(t)=t$ clearly gives rise to the system (2) under the identification $x_1=q_2$, $x_2=q_3$. The Newton system (3) in R^3 is what we call a *cofactor system* (see Sec. II), which means that it has the form

$$\ddot{q}=-A(q)^{-1}\nabla W(q)=-\frac{1}{\det G(q)}G(q)\nabla W(q),$$

where $A=\operatorname{cof}G=(\det G)G^{-1}$ is the cofactor matrix of a symmetric matrix $G(q)$ of the form

$$G_{ij}(q)=\alpha q_iq_j+\beta_iq_j+\beta_jq_i+\gamma_{ij}.$$

Equivalently, $\frac{1}{2}\dot{q}^TA(q)\dot{q}+W(q)$ is an integral of motion (of *cofactor type*) for the system.

In this specific case, as is easily verified, the system (3) can be written as $\ddot{q}=-G\nabla W/(\det G)$ with

$$G(q)=\begin{pmatrix} 2q_1 & q_2 & q_3 \\ q_2 & 0 & 1 \\ q_3 & 1 & 0 \end{pmatrix}, \quad W(q)=-\frac{q_2^2+q_3^2}{q_2q_3-q_1}.$$

According to the general theory to be developed in this paper, such a driven cofactor system can be integrated using a time-dependent change of coordinates

$$u_1=\lambda_1(t,x_1,x_2),$$

$$u_2=\lambda_2(t,x_1,x_2),$$

where $\lambda_1(q)$ and $\lambda_2(q)$ are the roots of the equation $\det(G(q)-\lambda\tilde{G})=0$, with $\tilde{G}=\mathrm{diag}(0,1,1)$.

It turns out that by defining corresponding momenta s_1 and s_2 appropriately, the equations of motion for (u_1,u_2) can be put in Hamiltonian form with a time-dependent *separable* Hamiltonian. Consequently, $u_1(t)$ and $u_2(t)$ can be found using a variant of the Hamilton–Jacobi method. Changing back to old coordinates, we find $x_1(t)$ and $x_2(t)$, and the problem is solved.

We will fill in the details of this example in Sec. V, after explaining the method in general.

II. QUASIPOTENTIAL NEWTON SYSTEMS OF COFACTOR TYPE

The general framework in which we are working was developed in Refs. 9, 6, and 7. It has been extended[2] to cover also the case of Riemannian manifolds, but here we will restrict ourselves to Euclidean space. We will now quote the definitions and results needed here, some of which have already been hinted at above.

We use the shorthand $\partial_i=\partial/\partial q_i$. The notation $\mathrm{cof}\,X$ means the cofactor matrix of a square matrix X. If X is nonsingular, then $\mathrm{cof}\,X=(\det X)X^{-1}$.

Proposition 2: The "energy-like" function

$$E(q,\dot{q})=\frac{1}{2}\sum_{i,j=1}^{n}A_{ij}(q)\dot{q}_i\dot{q}_j+W(q)=\frac{1}{2}\dot{q}^TA(q)\dot{q}+W(q), \tag{4}$$

with $A(q)$ a symmetric $n\times n$ matrix, is an integral of motion of the Newton system $\ddot{q}=M(q)$ in R^n if and only if

(1) The matrix entries $A_{ij}(q)$ satisfy the cyclic conditions

$$\partial_iA_{jk}+\partial_jA_{ki}+\partial_kA_{ij}=0, \quad i,j,k=1,\ldots,n. \tag{5}$$

[*The general solution of these equations is a subspace, of dimension $\frac{1}{12}n(n+1)^2(n+2)$, of the vector space of symmetric matrices whose entries are polynomials of degree at most two in $q_1,\ldots,q_n$.*]

(2) The force $M(q)$ satisfies $A(q)M(q)+\nabla W(q)=0$.

Definition 3 (quasipotential system): A Newton system of the form

$$\ddot{q}=-A(q)^{-1}\nabla W(q),$$

where the matrix A satisfies the cyclic conditions (5), is called a *quasipotential* system. By the proposition above, $E=\frac{1}{2}\dot{q}^TA\dot{q}+W$ is an integral of motion for the system, and it is said to generate the system, since the system is completely determined by $A(q)$ and $W(q)$, and hence by E. (Special case: if $A=I$ is the identity matrix, then W is a potential for the system and E is the usual energy.)

Definition 4 (elliptic coordinates matrix G): A symmetric matrix of the form

$$G_{ij}(q)=\alpha q_i q_j+\beta_i q_j+\beta_j q_i+\gamma_{ij}, \quad i,j=1,\ldots,n, \tag{6}$$

is called an *elliptic coordinates matrix.* Using matrix multiplication, $G(q)$ can be written

$$G(q)=\alpha qq^T+\beta q^T+q\beta^T+\gamma, \tag{7}$$

with α a scalar, q and β column vectors, and γ a symmetric matrix.

Set briefly, the eigenvalues $u_1(q),\ldots,u_n(q)$ of $G(q)$ give the change of coordinates from Cartesian coordinates q to elliptic coordinates $u=u(q)$. See Ref. 6 for a more detailed explanation.

Definition 5 (associated vector N): To a given elliptic coordinate matrix G we associate the column vector $N=\alpha q+\beta=\frac{1}{2}\nabla \operatorname{tr} G$.

Proposition 6: If G is an elliptic coordinates matrix, N the associated vector, and $A=\operatorname{cof} G$, then

$$\nabla \det G=2AN. \tag{8}$$

The preceding proposition is frequently useful. It implies, for example, that $A=\operatorname{cof} G$ satisfies

$$(\det G)\partial_k A_{ij}=2[AN]_k A_{ij}-[AN]_i A_{kj}-[AN]_j A_{ik}, \tag{9}$$

from which the following remarkable property of elliptic coordinates matrices follows.

Proposition 7: If $G(q)$ is an elliptic coordinates matrix, then $A(q)=\operatorname{cof} G(q)$ satisfies the cyclic conditions (5).

Corollary 8: If $G(q)$ and $\tilde{G}(q)$ are elliptic coordinates matrices, then the matrices $A^{(0)}(q),\ldots,A^{(n-1)}(q)$ defined by the generating function

$$\operatorname{cof}(G+\mu\tilde{G})=\sum_{k=0}^{n-1} A^{(k)}\mu^i \tag{10}$$

all satisfy the cyclic conditions (5).

Remark 9: Note that $A^{(0)}=\operatorname{cof} G$ and $A^{(n-1)}=\operatorname{cof}\tilde{G}$.

We will also need a proposition that does not occur in Ref. 6.

Proposition 10: With G, N, and $A=\operatorname{cof} G$ as above,

$$\nabla(N^TAN)=2\alpha AN. \tag{11}$$

Proof: Equation (9) implies that $\Sigma_{i,j}(\partial_k A_{ij})N_iN_j=0$, from which the statement follows easily. □

Definition 11 (cofactor system): A *cofactor system* is a quasipotential Newton system of the special form

$$\ddot{q}=-A(q)^{-1}\nabla W(q)=-\frac{1}{\det G(q)}G(q)^{-1}\nabla W(q),$$

where $A=\operatorname{cof} G$, and G is a nonsingular elliptic coordinates matrix. The integral of motion $E=\frac{1}{2}\dot{q}^TA\dot{q}+W=\frac{1}{2}\dot{q}^T(\operatorname{cof} G)\dot{q}+W$ is said to be of cofactor type.

Definition 12 (cofactor pair system): A *cofactor pair system* is a Newton system which has two independent integrals of motion of cofactor type,

$$E=\tfrac{1}{2}\dot{q}^T(\operatorname{cof} G)\dot{q}+W \quad \text{and} \quad \tilde{E}=\tfrac{1}{2}\dot{q}^T(\operatorname{cof}\tilde{G})\dot{q}+\tilde{W}.$$

Equivalently, it is a system which can be written as

$$\ddot{q}=-A^{-1}\nabla W=-\tilde{A}^{-1}\nabla\tilde{W}, \tag{12}$$

where $A=\operatorname{cof} G$ and $\tilde{A}=\operatorname{cof}\tilde{G}$.

Theorem 13 (two implies *n*): *A cofactor pair system $\ddot{q}=M(q)$ in R^n has n integrals of motion*

$$E^{(k)}=\tfrac{1}{2}\dot{q}^T A^{(k)}\dot{q}+W^{(k)}, \quad k=0,\ldots,n-1, \tag{13}$$

where the matrices $A^{(k)}$ are given by (10) and the quasipotentials $W^{(k)}$ are determined (up to irrelevant additive constants) by $\nabla W^{(k)}=-A^{(k)}M$.

Remark 14: Note that the original integrals of motion $E=E^{(0)}$ and $\tilde{E}=E^{(n-1)}$ of cofactor type sit at either end of this ''cofactor chain'' of integrals.

Remark 15: It is sometimes convenient to handle the integrals of motion using a generating function

$$E_\mu=\sum_{k=0}^{n-1} E^{(k)}\mu^k=\frac{1}{2}\dot{q}^T\operatorname{cof}(G+\mu\tilde{G})\dot{q}+W_\mu, \tag{14}$$

where $W_\mu=\Sigma_{k=0}^{n-1}W^{(k)}\mu^k$.

Remark 16: For W to be well defined by $\nabla W=-AM$, the compatibility conditions $\partial_i[AM]_j=\partial_j[AM]_i$ have to be satisfied for all i and j. This, of course, is the reason that not every Newton system $\ddot{q}=M(q)$ has a potential V, and also that not every Newton system has a quasipotential W, even though by allowing $A(q)\neq I$ we enlarge the class of systems under consideration.

Now, for $\ddot{q}=M(q)$ to be a cofactor pair system, two sets of compatibility conditions need to be satisfied simultaneously; $\partial_i[AM]_j=\partial_j[AM]_i$ and $\partial_i[\tilde{A}M]_j=\partial_j[\tilde{A}M]_i$. For given G and $\tilde{G}$, this is a rather strong restriction on M. In fact, according to the theorem, it is so strong that if $\partial_i[A^{(k)}M]_j=\partial_j[A^{(k)}M]_i$ holds for $A^{(0)}=A=\operatorname{cof} G$ and $A^{(n-1)}=\tilde{A}=\operatorname{cof}\tilde{G}$, then it must hold for *all* the matrices $A^{(k)}$.

Definition 17 (fundamental equations): The *fundamental equations* associated to a pair $(G,\tilde{G})$ of elliptic coordinates matrices is the following set of $\binom{n}{2}$ second order linear PDEs:

$$\begin{aligned}0=&\sum_{r,s=1}^{n}(G_{ir}\tilde{G}_{js}-G_{jr}\tilde{G}_{is})\partial_{rs}K+3\sum_{r=1}^{n}(G_{ir}\tilde{N}_j+\tilde{G}_{jr}N_i-G_{jr}\tilde{N}_i-\tilde{G}_{ir}N_j)\partial_r K\\&+6(N_i\tilde{N}_j-N_j\tilde{N}_i)K, \quad i,j=1,\ldots,n.\end{aligned} \tag{15}$$

Here $N=\alpha q+\beta$ is the vector associated to G, with the same parameters α and β as in $G=\alpha qq^T+\beta q^T+q\beta^T+\gamma$, and similarly for $\tilde{N}$.

Theorem 18: *Let*

$$\ddot{q}=-(\operatorname{cof} G)^{-1}\nabla W=-(\operatorname{cof}\tilde{G})^{-1}\nabla\tilde{W} \tag{16}$$

be a cofactor pair system. Then the functions $K_1=W/\det G$ and $K_2=\tilde{W}/\det\tilde{G}$, while in general different, both satisfy the fundamental equations (15) associated to the pair $(G,\tilde{G})$.

Conversely, if K satisfies (15) and we set $W=K\det G$, then there is a function $\tilde{W}$ such that (16) holds. And if we set $\tilde{W}=K\det\tilde{G}$, then there is a function W such that (16) holds (but these W and $\tilde{W}$ are in general not the same as those in the previous sentence).

Remark 19: Once again, this is all about compatibility conditions. If G, $\tilde{G}$, and W are given, then $\tilde{W}$ is well defined by (16) if and only if

$$\partial_i[(\operatorname{cof}\tilde{G})(\operatorname{cof} G)^{-1}\nabla W]_j=\partial_j[(\operatorname{cof}\tilde{G})(\operatorname{cof} G)^{-1}\nabla W]_i$$

for all i and j. This is a system of $\binom{n}{2}$ second order linear PDEs for W, with coefficients depending in a complicated way on G and $\widetilde{G}$. Substituting $K=W/\det G$ and forming suitable linear combinations of the equations simplifies this system to precisely the fundamental equations (15). These being completely antisymmetric with respect to coefficients with and without the tilde, the result is the same if we go the other way around, interchanging the roles of W and $\widetilde{W}$.

Remark 20: This theorem leads to a recursive procedure for explicitly constructing infinite families of cofactor pair systems. See Ref. 6 for details.

In Ref. 6 it was shown, using the theory of bi-Hamiltonian systems, that cofactor pair systems generically are completely integrable, but it was not clear if they admit some kind of separation of variables. The special case $\widetilde{G}=I$ corresponds to conservative systems with an extra integral of motion of cofactor type. Such systems are precisely those with potentials separable in the elliptic (or parabolic) coordinates given by the eigenvalues of $G(q)$, so in that case we have a concrete method of integration. Reference 8, which appeared recently, deals with separation of variables for generic cofactor pair systems, with both G and $\widetilde{G}$ nonsingular (and nonconstant, in general). Here, we study the very degenerate case of cofactor pair systems with $\widetilde{G}=\mathrm{diag}(0,\ldots,0,1,\ldots,1)$. As we will see in the next section, these systems admit a somewhat nonstandard integration by separation of variables, and there is a surprising connection with time-dependent potentials.

III. DRIVEN SYSTEMS

From now on we fix positive integers m and n, and let $N=m+n$. Hopefully there is no risk of confusing this integer N with the vector $N(q)$ associated to an elliptic coordinates matrix $G(q)$. Let us begin by defining some notation.

Definition 21 (block notation): If X is an $N\times N$ matrix, with $N=m+n$, then we use arrow subscripts to denote blocks in X, as follows:

$$X=\begin{pmatrix} X_{\nwarrow} & X_{\nearrow} \\ X_{\swarrow} & X_{\searrow} \end{pmatrix} \quad \text{with sizes} \quad \begin{bmatrix} m\times m & m\times n \\ n\times m & n\times n \end{bmatrix}. \tag{17}$$

Similarly, if Y is a column vector in R^N, then

$$Y=\begin{pmatrix} Y_{\uparrow} \\ Y_{\downarrow} \end{pmatrix} \quad \text{with sizes} \quad \begin{bmatrix} m \\ n \end{bmatrix}. \tag{18}$$

So, for instance, $[X_{\nearrow}]_{ij}=X_{i,m+j}$.

We will consider *driven* Newton systems in R^N, where $N=m+n$. By this we mean that the first m equations depend only on the first m variables, so that they form a Newton system in R^m on their own:

$$\begin{gathered} \ddot{q}_1=M_1(q_1,\ldots,q_m), \\ \vdots \\ \ddot{q}_m=M_m(q_1,\ldots,q_m), \\ \ddot{q}_{m+1}=M_{m+1}(q_1,\ldots,q_m;q_{m+1},\ldots,q_{m+n}), \\ \vdots \\ \ddot{q}_{m+n}=M_{m+n}(q_1,\ldots,q_m;q_{m+1},\ldots,q_{m+n}). \end{gathered} \tag{19}$$

This notion is not new; for example Kossowski and Thompson[5] use tangent bundle geometry to study *submersive* systems, which are second order ODEs on manifolds, containing a subsystem depending on fewer variables (possibly after a change of coordinates).

Here, however, our purpose is to investigate what happens when a system is at the same time a driven system and a cofactor system. In this initial stage of investigation we have restricted ourselves to Euclidean space and assume that the systems splits as above in Cartesian coordinates. We hope that further research will clarify the relation between our present results and the geometric picture of Refs. 5 and 2.

Definition 22 (vectors x and y): Since we will consider the time evolution of $q_\uparrow$ and $q_\downarrow$ separately, we write $y=q_\uparrow$ and $x=q_\downarrow$ to simplify the notation.

With this definition, the system (19) can be written as

$$\begin{aligned} \ddot{y} &= M_\uparrow(y), \\ \ddot{x} &= M_\downarrow(y,x). \end{aligned} \tag{20}$$

As in example 1, $(y_1,\ldots,y_m)$ are called *driving* variables and $(x_1,\ldots,x_n)$ are called *driven* variables. The system $\ddot{y}=M_\uparrow(y)$ is called the *driving* system, since its solution $y=y(t)$, when fed into $\ddot{x}=M_\downarrow(y(t),x)$, drives the evolution of the x variables.

An important observation is that if

$$G=\alpha qq^T+\beta q^T+q\beta^T+\gamma$$

is an $N\times N$ elliptic coordinates matrix, then

$$G_{\nwarrow}=\alpha yy^T+\beta_\uparrow y^T+y(\beta_\uparrow)^T+\gamma_{\nwarrow},$$

so that $G_{\nwarrow}(y)$ is an $m\times m$ elliptic coordinates matrix in the y variables. [Similarly for $G_{\searrow}(x)$, but we will not use that here.]

The major part of this paper is devoted to proving the following theorem.

Theorem 23 (driven cofactor systems): *Suppose that a driven Newton system in R^{m+n} is of cofactor type*

$$\ddot{q}=\begin{pmatrix} M_\uparrow(y) \\ M_\downarrow(y,x) \end{pmatrix}=-(\operatorname{cof} G(q))^{-1}\frac{\partial W}{\partial q}(q). \tag{21a}$$

Suppose also that G is not constant (i.e., that α and β are not both zero), that $\det G_{\nwarrow}\neq 0$, *and that there is a potential $V(y,x)$, with y occuring parametrically, such that*

$$M_\downarrow(y,x)=-\frac{\partial V}{\partial x}(y,x). \tag{21b}$$

Then the driving system is a cofactor system in R^m. Namely, there is a function $w(y)$ such that

$$\ddot{y}=-(\operatorname{cof} G_{\nwarrow}(y))^{-1}\frac{\partial w}{\partial y}(y). \tag{22}$$

Moreover, for any given solution $y=y(t)$ of the driving system $\ddot{y}=M_\uparrow(y)$, the system

$$\ddot{x}=M_\downarrow(y(t),x)=-\frac{\partial V}{\partial x}(y(t),x), \tag{23}$$

given by the time-dependent potential $V(y(t),x)$, has n (time-dependent) integrals of motion. Under some technical assumptions, stated in definition 28, its solution $x(t)$ can be found by quadratures.

The proof is quite lengthy, so we have divided it into subsections labeled A through F. First we show that a driven cofactor system can be viewed as a degenerate form of cofactor pair system, with $\tilde{G}=\mathrm{diag}(0,\ldots,0,1,\ldots,1)$. The integrals of motion are given by a cofactor chain that terminates prematurely. We introduce a new system of coordinates, which is given by the m driving Cartesian coordinates together with the n roots of the equation $\det(G(q)-u\tilde{G})=0$. This is similar to defining elliptic coordinates implicitly as the eigenvalues of G. When the integrals of motion are transformed into these new coordinates, which is the most technical part of this paper, it turns out that they take a form similar to that known from classical separability theory (Stäckel systems). This suggests that the system should be solvable by separation of variables. We show that this is indeed the case, since the equations of motion are Hamiltonian and the variables can be separated in the time-dependent Hamilton–Jacobi equation. Perhaps surprisingly, the Hamiltonian does not involve the potential $V(y,x)$ in any direct way, but is instead given by one of the integrals of motion in the cofactor chain, divided by the determinant $\det G$, all expressed in new coordinates.

A. Driven cofactor systems as cofactor pair systems

Definition 24 (matrix J): Let J denote the $N\times N$ diagonal matrix

$$J=\mathrm{diag}(0,\ldots,0,1,\ldots,1), \tag{24}$$

with m zeros and n ones along the diagonal ($N=m+n$).

Proposition 25: A system of the form (21) is a cofactor pair system with

$$\tilde{G}(q)=\lambda G(q)+J=:\tilde{G}_\lambda(q), \tag{25}$$

for any λ such that $\det\tilde{G}_\lambda\neq 0$. Conversely, any such cofactor pair system has the form (21).

We note that since G is assumed nonsingular by the definition of cofactor system, $\det(\lambda G(q)+J)$ cannot vanish identically, so there are λ such that $\det\tilde{G}_\lambda\neq 0$. The reason for taking $\tilde{G}=\tilde{G}_\lambda$ instead of just $\tilde{G}=J$ is that the theorems we use about cofactor pair systems require both G and $\tilde{G}$ to be nonsingular. However, many of the results will be the same as if applying the theorems formally with $\tilde{G}=J$ directly, so we will regard such systems as cofactor pair systems associated with the pair (G,J).

The proof of proposition 25 uses the following lemma, which follows from the algebraic properties of an elliptic coordinates matrix G.

Lemma 26: If $M=-(\det G)^{-1}G\nabla W$, then

$$-\partial_j M_i=\sum_{r=1}^{N} G_{ir}\partial_{rj}K+3N_i\partial_j K \quad (i\neq j),$$

where $K(q)=W(q)/\det G(q)$.

Proof: Proposition 6 implies that $-M=G\nabla(K\det G)/\det G=2KN+G\nabla K$. Differentiating $-M_i=2KN_i+\sum_{r=1}^{N}G_{ir}\partial_r K$ we obtain the result immediately, since for $j\neq i$ we have $\partial_j G_{ir}=\delta_{jr}N_i$ and $\partial_j N_i=0$. □

Proof of proposition 25: By construction, the given cofactor system

$$\ddot{q}=M(q)=-(\mathrm{cof}\,G)^{-1}\nabla W=-(\det G)^{-1}G\nabla W,$$

has an integral of motion of cofactor type $E=\frac{1}{2}\dot{q}^T(\mathrm{cof}\,G)\dot{q}+W$. Now fix some constant λ such that $\det\tilde{G}_\lambda\neq 0$. Theorem 18 says that the system is a cofactor *pair* system with $\tilde{G}=\tilde{G}_\lambda$, i.e., admits an additional integral of motion of cofactor type

$$\tilde{E}_\lambda=\tfrac{1}{2}\dot{q}^T(\mathrm{cof}\,\tilde{G}_\lambda)\dot{q}+\tilde{W}_\lambda,$$

if and only if $K=W/\det G$ satisfies the fundamental equations (15) associated to the pair $(G,\tilde{G}_\lambda)$.

The antisymmetry of the fundamental equations shows that any pair $(G,\lambda G+J)$ gives rise to the same fundamental equations as the pair (G,J), so we simply plug $\tilde{G}=J$ into the fundamental equations (15) (with n replaced by $m+n$). To begin with, since J is diagonal and constant (so that $\tilde{N}=0$), we obtain

$$0=\sum_{r=1}^{m+n} G_{ir}J_{jj}\partial_{rj}K-\sum_{r=1}^{m+n} G_{jr}J_{ii}\partial_{ri}K+3(J_{jj}N_i\partial_j K-J_{ii}N_j\partial_i K),\quad i,j=1,\ldots,m+n. \tag{26}$$

Now $J_{ii}=0$ or 1 as $i\leqslant m$ and $i>m$, respectively. From this it is immediate that (26) is identically satisfied if $i,j\leqslant m$. Using lemma 26 to express the remaining equations (26) for K in terms of $M=-(\det G)^{-1}G\nabla(K\det G)$ gives $0=\partial_j M_i$ for $i\leqslant m<j$, and $0=\partial_i M_j-\partial_j M_i$ for $m<i,j$. Clearly, these equations are equivalent to M having the block structure

$$M(q)=\begin{pmatrix} M_\uparrow(y) \\ M_\downarrow(y,x)\end{pmatrix}$$

and (at least locally) a "partial potential" V such that $M_\downarrow=-\partial V/\partial x$. □

B. Integrals of motion

Proposition 27: The system (21) has $n+1$ integrals of motion $E^{(0)},\ldots,E^{(n)}$ given by the generating function

$$E_\mu=\sum_{k=0}^{n} E^{(k)}\mu^k=\sum_{k=0}^{n}\left(\frac{1}{2}\dot{q}^T A^{(k)}\dot{q}+W^{(k)}\right)\mu^k=\frac{1}{2}\dot{q}^T\operatorname{cof}(G+\mu J)\dot{q}+W_\mu \tag{27}$$

for some functions $W^{(k)}$. The integral $E^{(n)}$ has the form

$$E^{(n)}(y,\dot{y})=\tfrac{1}{2}\dot{y}^T\operatorname{cof}G_{\diagdown}(y)\dot{y}+w(y), \tag{28}$$

and is an integral of motion of the driving system $\ddot{y}=M_\uparrow(y)$, of cofactor type in the y variables.

Proof: According to theorem 13, our cofactor pair system should have a chain of $N=m+n$ integrals of motion. Here, however, that number is reduced since some of them will be linearly dependent. More specifically, for arbitrary λ such that $\det\tilde{G}_\lambda\neq 0$, theorem 13 gives us integrals $E_\lambda^{(0)},\ldots,E_\lambda^{(N-1)}$ which we write using a generating function

$$E_{\lambda,\mu}=\sum_{k=0}^{m+n-1} E_\lambda^{(k)}\mu^k=\frac{1}{2}\dot{q}^T\operatorname{cof}(G+\mu\tilde{G}_\lambda)\dot{q}+W_{\lambda,\mu} \tag{29}$$

as in (14). By construction, $\dot{E}_{\lambda,\mu}=0$ for all values of μ and all λ such that $\det\tilde{G}_\lambda\neq 0$. But $E_{\lambda,\mu}$ depends polynomially on λ and μ, since $\operatorname{cof}(G+\mu\tilde{G}_\lambda)=\operatorname{cof}(G+\mu(\lambda G+J))=\operatorname{cof}((1+\mu\lambda)G+\mu J))$ does. Hence, $\dot{E}_{\lambda,\mu}=0$ identically. In particular, if we set $\lambda=0$ we extract the constant term with respect to λ, which is just the E_μ of (27), a polynomial in μ whose coefficients are integrals of motion.

The reason why E_μ is only of degree n (instead of $m+n-1$) is that the matrix J has so few nonzero elements that the expansion of $\operatorname{cof}(G+\mu J)$ in powers of μ terminates "prematurely" (the details in this expansion are explained below, after the proof):

$$\operatorname{cof}(G+\mu J)=\operatorname{cof} G + \cdots + \begin{pmatrix} A^{(n-1)}_{\nwarrow} & -(\operatorname{cof} G_{\nwarrow})G_{\nearrow} \\ -((\operatorname{cof} G_{\nwarrow})G_{\nearrow})^T & (\det G_{\nwarrow})I_{n\times n}\end{pmatrix}\mu^{n-1}+\begin{pmatrix}\operatorname{cof} G_{\nwarrow} & 0_{m\times n}\\ 0_{n\times m} & 0_{n\times n}\end{pmatrix}\mu^n$$
$$=:\sum_{k=0}^{n} A^{(k)}\mu^k. \tag{30}$$

All the coefficients in the generating function $E_{\lambda,\mu}$ in (29) are linear combinations of these $n+1$ basic integrals $E^{(0)},\ldots,E^{(n)}$, so even though one can obtain a seemingly longer chain (with $N=m+n$ integrals) by taking $\lambda\neq 0$, it would not contain any essentially new integrals of motion. (Note also that the polynomial E_μ is what we would have obtained by applying theorem 13 formally with the singular matrix $\tilde{G}=J$ instead of $\tilde{G}_\lambda$.)

The integral $E^{(n)}$ has the form

$$E^{(n)}=\frac{1}{2}(\dot{y}^T \quad \dot{x}^T)\begin{pmatrix}\operatorname{cof} G_{\nwarrow}(y) & 0_{m\times n}\\ 0_{n\times m} & 0_{n\times n}\end{pmatrix}\begin{pmatrix}\dot{y}\\ \dot{x}\end{pmatrix}+W^{(n)}(y,x)=\frac{1}{2}\dot{y}^T\operatorname{cof} G_{\nwarrow}(y)\dot{y}+w(y), \tag{31}$$

where clearly $W^{(n)}=w(y)$ cannot depend on x if $E^{(n)}$ is to be an integral of motion. Consequently, $E^{(n)}(y,\dot{y})$ must be an integral of motion of the driving system $\ddot{y}=M_\uparrow(y)$, and it is of cofactor type in the y variables. □

In (30) we have written out some blocks in the matrices $A^{(n-1)}$ and $A^{(n)}$ for future reference (in the proof of proposition 36). These can be found either by analyzing the cofactor expansion directly or by writing the identity

$$(G+\mu J)\operatorname{cof}(G+\mu J)=\det(G+\mu J)I_{N\times N}$$

as

$$JA^{(n)}\mu^{n+1}+(JA^{(n-1)}+GA^{(n)})\mu^n+\cdots=(0\,\mu^{n+1}+(\det G_{\nwarrow})\mu^n+\ldots)I_{N\times N}$$

and identifying coefficients block-wise at μ^{n+1} and μ^n, using that the matrices $A^{(i)}$ are symmetric. The block $A^{(n-1)}_{\nwarrow}$ does not enter into this identity until at the power μ^{n-1}, and depends on G in a more complicated way. Fortunately, the only information about $A^{(n-1)}_{\nwarrow}$ that we will need is that $A^{(n-1)}$ satisfies the cyclic conditions (5) which connect derivatives of $A^{(n-1)}_{\nwarrow}$ to derivatives of the other blocks, which are known explicitly.

We have now completed the proof of the first statement of theorem 23, namely, that the driving system is a cofactor system in the y variables.

Moreover, for any given solution $y=y(t)$ of the driving system, we can consider $E^{(0)},\ldots,E^{(n-1)}$ as functions of $(x,\dot{x},t)$, and these constitute n time-dependent integrals of motion of the driven system (23) given by the time-dependent potential $V(y(t),x)$. These are the integrals referred to at the end of theorem 23.

C. Separation coordinates

Our remaining task (which is much more complicated) is to show how to integrate the driven system $\ddot{x}=-(\partial V/\partial x)(y(t),x)$, given a solution $y(t)$ of the driving system $\ddot{y}=M_\uparrow(y)$. This will be accomplished using a change of variables $(y,x)\mapsto(v,u)$ on R^{m+n} defined as follows:

Definition 28 (variables u and v, roots λ): Let $v_i=y_i$ *for* $i=1,\ldots,m$. *Let* $u_j=\lambda_j(y,x)$ *for* $j=1,\ldots,n$, *where* $\lambda_1,\ldots,\lambda_n$ *are the roots of the n*th *degree polynomial equation*

$$\det(G(y,x)-\lambda J)=0. \tag{32}$$

(We assume that this really defines a coordinate system. This requires, to begin with, that all the roots λ_j are nonconstant as functions of q. Moreover, the gradients of the v_i and u_j must be linearly independent. Because of lemma 31 below, this holds at least in a neighborhood of any point where all $\lambda_j(q)$ are distinct.)

Definition 29 [polynomial $U(\mu)$]. Let

$$U(\mu)=(u_1-\mu)(u_2-\mu)\cdots(u_n-\mu). \tag{33}$$

It follows from the definition of the u_k as roots of the polynomial $\det(G-\mu J)$, which has the leading term $(-\mu)^n \det G_{\nwarrow}$, that

$$\det(G-\mu J)=U(\mu)\det G_{\nwarrow}. \tag{34}$$

Our aim is to express the integrals of motion $E^{(0)},\ldots,E^{(n)}$ in terms of the new coordinates v and u, and likewise for the equations of motion for the system [although for that purpose we view $x\mapsto u=\lambda(y(t),x)$, where $y(t)$ is a given solution of the driving system, as a time-dependent change of variables in R^n; more about that later]. The remainder of this subsection contains technical preparations for these tasks.

Definition 30 (matrix Ψ): Let Ψ denote the $N\times N$ matrix of partial derivatives of v and u with respect to y and x, arranged so that the columns of Ψ are the gradients of v and u with respect to $q=\binom{y}{x}$:

$$\Psi=(\nabla v_1\cdots\nabla v_m \;\; \nabla u_1\cdots\nabla u_n)=(e_1\cdots e_m \;\; \nabla\lambda_1\cdots\nabla\lambda_n), \tag{35}$$

where e_i is the column vector with 1 in position i and 0 elsewhere. [In the block notation of (17), $\Psi_{\nwarrow}=I_{m\times m}$ and $\Psi_{\swarrow}=0_{n\times m}$.]

With this definition we have

$$\begin{pmatrix}\dot v\\ \dot u\end{pmatrix}=\Psi^T\dot q, \quad \dot q=\frac{1}{\det\Psi}(\operatorname{cof}\Psi^T)\begin{pmatrix}\dot v\\ \dot u\end{pmatrix}, \tag{36}$$

and also

$$\nabla=\begin{pmatrix}\partial/\partial y\\ \partial/\partial x\end{pmatrix}=\Psi\begin{pmatrix}\partial/\partial v\\ \partial/\partial u\end{pmatrix}. \tag{37}$$

(Note that $\partial/\partial y\neq\partial/\partial v$ even though $y=v$, hence the need for the different names.)

The following lemma will give us information about the last n columns in the matrix Ψ (or, equivalently, about the blocks $\Psi_{\nearrow}$ and $\Psi_{\searrow}$).

Lemma 31 (eigenvalues and eigenvectors): Let $G(q)$ and $\tilde G(q)$ be elliptic coordinates matrices. If $\lambda=\lambda(q)$ is a simple root of $\det(G-\lambda\tilde G)=0$, then $\nabla\lambda(q)$ is the corresponding "eigenvector:"

$$(G(q)-\lambda(q)\tilde G(q))\nabla\lambda(q)=0. \tag{38}$$

If λ_1 and λ_2 are two different such roots, then

$$(\nabla\lambda_1)^T\tilde G\nabla\lambda_2=0. \tag{39}$$

Proof: Let $G_r=G-r\tilde G$ and $p(r)=\det G_r$. For each r, G_r is an elliptic coordinates matrix, with associated vector $N_r=N-r\tilde N$, where $N=\alpha q+\beta$ and $\tilde N=\tilde\alpha q+\tilde\beta$. If we apply proposition 6 to G_r we get $\nabla p(r)=2(\operatorname{cof}G_r)N_r$. Now compute the gradient of $p(\lambda(q))\equiv 0$:

$$0=(\nabla p)(\lambda(q))+p'(\lambda(q))\nabla\lambda(q)=2\operatorname{cof}(G-\lambda(q)\tilde G)(N-\lambda(q)\tilde N)+p'(\lambda(q))\nabla\lambda(q). \tag{40}$$

Multiplying this by $G-\lambda(q)\tilde{G}$ yields, since $\det(G-\lambda(q)\tilde{G})=0$ by definition of λ,

$$0=p'(\lambda(q))\,(G-\lambda(q)\tilde{G})\nabla\lambda(q).$$

But $p'(\lambda(q))\neq 0$ since $\lambda(q)$ is assumed to be a simple root of p. The first statement follows.

The second statement comes from the simple observation that if $GX_1=\lambda_1\tilde{G}X_1$ and $GX_2=\lambda_2\tilde{G}X_2$, then, since G and $\tilde{G}$ are symmetric,

$$0=(GX_1)^TX_2-X_1^T(GX_2)=(\lambda_1-\lambda_2)X_1^T\tilde{G}X_2.$$

□

Lemma 31, with $\tilde{G}=J$, says that

$$G\nabla u_k=u_kJ\nabla u_k, \tag{41}$$

and that $\nabla u_1,\ldots,\nabla u_n$ (which are the last n columns of Ψ) are "J-orthogonal,"

$$(\nabla u_j)^TJ\,(\nabla u_k)=0, \quad \text{if } j\neq k. \tag{42}$$

Thus, the columns $(\nabla u_j)_\downarrow$ of the lower right $n\times n$ block $\Psi_\searrow$ in Ψ are orthogonal in R^n in the ordinary Euclidean sense, with squared lengths $\Delta_1,\ldots,\Delta_n$, where

$$\Delta_k=((\nabla u_k)_\downarrow)^T(\nabla u_k)_\downarrow=\sum_{i=1}^{n}(\Psi_{n+i,n+k})^2. \tag{43}$$

Consequently, since the first m columns in Ψ are just $e_1,\ldots,e_m$, the interpretation of an $n\times n$ determinant as a volume in R^n shows that

$$(\det\Psi)^2=\Delta_1\Delta_2\cdots\Delta_n. \tag{44}$$

It also follows that, with $\Delta=\mathrm{diag}(\Delta_1,\ldots,\Delta_n)$ and $\mathcal{U}=\mathrm{diag}(u_1,\ldots,u_n)$,

$$\Psi^TJ\,\Psi=\begin{pmatrix}0_{m\times m} & 0_{m\times n}\\ 0_{n\times m} & \Delta\end{pmatrix} \tag{45}$$

and

$$\Psi^TG\,\Psi=\begin{pmatrix}G_\nwarrow & 0_{m\times n}\\ 0_{n\times m} & \mathcal{U}\Delta\end{pmatrix}. \tag{46}$$

D. Integrals of motion in separation coordinates

Now we will transform the integrals of motion $E^{(0)},\ldots,E^{(n)}$ given by (27) to the new coordinates (v,u).

Kinetic part: We begin with the "kinetic" part $\dot{q}^T\,\mathrm{cof}(G+\mu J)\dot{q}$. Write $G_\mu=G+\mu J$ for simplicity. Equation (36) gives

$$\dot{q}^T(\mathrm{cof}\,G_\mu)\dot{q}=\frac{1}{(\det\Psi)^2}(\dot{v}^T\ \ \dot{u}^T)\mathrm{cof}(\Psi^TG_\mu\Psi)\begin{pmatrix}\dot{v}\\ \dot{u}\end{pmatrix}.$$

Equations (45) and (46) show that

$$\Psi^TG_\mu\Psi=\begin{pmatrix}G_\nwarrow & 0_{m\times n}\\ 0_{n\times m} & \mathcal{U}_\mu\Delta\end{pmatrix},$$

where

$$\mathcal{U}_\mu = \mathcal{U} + \mu I_{n\times n} = \mathrm{diag}(u_1+\mu,\ldots,u_n+\mu). \tag{47}$$

This, together with (44), gives

$$\frac{1}{(\det\Psi)^2}\,\mathrm{cof}(\Psi^T G_\mu \Psi) = \begin{pmatrix} \det\mathcal{U}_\mu\,\mathrm{cof}G_{\nwarrow} & 0_{m\times n} \\ 0_{n\times m} & (\det G_{\nwarrow})\Delta^{-1}\,\mathrm{cof}\,\mathcal{U}_\mu \end{pmatrix}.$$

Sandwiching this between $(\dot v^T\ \dot u^T)$ and $\binom{\dot v}{\dot u}$, we finally obtain

$$\dot q^T(\mathrm{cof}\,G_\mu)\dot q = (\det\mathcal{U}_\mu)\dot v^T(\mathrm{cof}\,G_{\nwarrow})\dot v + (\det G_{\nwarrow})\dot u^T(\Delta^{-1}\mathrm{cof}\,\mathcal{U}_\mu)\,\dot u. \tag{48}$$

Note that $\det\mathcal{U}_\mu = \Pi_1^n(u_i+\mu)$ is the generating function for the elementary symmetric polynomials in the n variables $\{u_1,\ldots,u_n\}$, while the kth entry in the diagonal matrix $\mathrm{cof}\,\mathcal{U}_\mu$ generates the elementary symmetric polynomials in the $n-1$ variables $\{u_1,\ldots,u_n\}\setminus\{u_k\}$.

Structure of Δ_k: Next we prove a statement about how Δ_k, defined by (43), depends on u and v. This result is important for showing separability later.

Proposition 32: The quantities $\Delta_1,\ldots,\Delta_n$ satisfy

$$\Delta_k(u,v)\,U'(u_k)\det G_{\nwarrow}(v) = f_k(u_k), \quad k=1,\ldots,n, \tag{49}$$

where each of the functions $f_1,\ldots,f_n$ depends on one variable only, as indicated. [But $U'(u_k)$, which is just the derivative of $U(\mu)=\Pi(u_i-\mu)$ evaluated at $\mu=u_k$, depends on all the variables u_i.]

Proof: Recall that $\Delta=\mathrm{diag}(\Delta_1,\ldots,\Delta_n)=(\Psi_{\searrow})^T\Psi_{\searrow}$, by (45). Since the columns ∇u_k make up the blocks $\Psi_{\nearrow}$ and $\Psi_{\searrow}$, the "upper part" of (41) shows that

$$G_{\nwarrow}\Psi_{\nearrow} + G_{\nearrow}\Psi_{\searrow} = 0_{m\times n}. \tag{50}$$

Recall from (34) that

$$\det(G-\mu J) = U(\mu)\det G_{\nwarrow} = \det G_{\nwarrow}\left((-\mu)^n + (-\mu)^{n-1}\left(\sum u_i\right) + \cdots\right).$$

By proposition 6,

$$\nabla\det(G-\mu J) = 2\,\mathrm{cof}(G-\mu J)\,N = 2((-\mu)^n A^{(n)} + (-\mu)^{n-1}A^{(n-1)} + \cdots)\,N.$$

(Note that N is the vector associated to $G-\mu J$ as well as to G, since J is constant.) Hence, in particular,

$$2\,A^{(n-1)}N = \nabla\left((\det G_{\nwarrow})\sum u_i\right).$$

Now, $(\nabla\det G_{\nwarrow})_{\downarrow}=0$ since $G_{\nwarrow}$ depends only on the y variables, and consequently

$$2\,(A^{(n-1)}N)_{\downarrow} = (\det G_{\nwarrow})\sum (\nabla u_i)_{\downarrow} = (\det G_{\nwarrow})\Psi_{\searrow}1_n,$$

where $1_n\in R^n$ is the column vector with all ones. If we use what we know from (30) about the block structure of $A^{(n-1)}$ and divide by $\det G_{\nwarrow}$, this takes the form

$$2\begin{pmatrix} -G_{\nwarrow}^{-1}G_{\nearrow} \\ I_{n\times n}\end{pmatrix}^T N = \Psi_{\searrow}1_n. \tag{51}$$

Combining (50) and (the transpose of) (51), we find

$$2\,N^T\begin{pmatrix}\Psi_{\nearrow}\\ \Psi_{\searrow}\end{pmatrix}=2\,N^T\begin{pmatrix}-G^{-1}_{\nwarrow}G_{\nearrow}\Psi_{\searrow}\\ \Psi_{\searrow}\end{pmatrix}=(\Psi_{\searrow}1_n)^T\Psi_{\searrow}=1_n^T\Delta=(\Delta_1\quad\Delta_2\ldots\Delta_n).$$

In other words,

$$\Delta_k=2\,N^T\nabla u_k,\quad k=1,\ldots,n. \tag{52}$$

As a special case of (40), with $\tilde{G}=J$, $\tilde{N}=0$, $p(\mu)=\det(G-\mu J)=U(\mu)\det G_{\nwarrow}$, and $\lambda=u_k$, we have

$$U'(u_k)\,(\det G_{\nwarrow})\nabla u_k=-2\,\mathrm{cof}(G-u_kJ)\,N, \tag{53}$$

which, because of (52), when multiplied from the left by $2\,N^T$ yields

$$U'(u_k)\,(\det G_{\nwarrow})\,\Delta_k=-4\,N^T\,\mathrm{cof}(G-u_kJ)\,N, \tag{54}$$

The left-hand side here is what we claim depends on u_k only, and we will prove this by showing that the gradient of the right hand side is proportional to ∇u_k. [Clearly, a function $f(v,u)$ depends on u_k alone iff $(\partial f/\partial u_k)\nabla u_k$ is the only contribution when computing ∇f with the chain rule.]

Proposition 10, applied to $G-\mu J$ (which has the same α and N as G), shows that

$$\nabla(N^T\mathrm{cof}(G-\mu J)\,N)=2\,\alpha\mathrm{cof}(G-\mu J)\,N.$$

Hence, by the chain rule,

$$\nabla(N^T\,\mathrm{cof}(G-u_kJ)\,N)=2\,\alpha\,\mathrm{cof}(G-u_kJ)\,N+\frac{d}{d\mu}[N^T\mathrm{cof}(G-\mu J)\,N]_{\mu=u_k}\nabla u_k\,.$$

It is manifest that the second term is proportional to ∇u_k, and so is in fact also the first term, because of (53). This finishes the proof of proposition 32. □

Remark 33: In all the examples we have computed, it turns out that $f_i(q_i)=f(q_i)$ for a single function f, but we have no proof that this is always true. In any case, it is not needed for proving separability here.

Solution of the fundamental equations: We previously (in the proof of proposition 25) investigated the fundamental equations associated to the pair (G,J):

$$0=\frac{\partial M_i}{\partial q_j}\quad\text{for } i\leqslant m<j, \tag{55}$$

$$0=\frac{\partial M_i}{\partial q_j}-\frac{\partial M_j}{\partial q_i}\quad\text{for } m<i,j, \tag{56}$$

where

$$M=-\frac{G\,\nabla(K\det G)}{\det G}$$

is the right-hand side in the cofactor pair system $\ddot{q}=M(q)$ generated by $E^{(0)}=\frac{1}{2}\dot{q}^T(\mathrm{cof}\,G)\dot{q}+K\det G$.

Proposition 34: In terms of the separations coordinates (v,u), the general solution of the fundamental equations(55) and (56) is

$$K(v,u)=\frac{1}{\det G_{\nwarrow}(v)}\left(w(v)+\sum_{k=1}^{n}\frac{g_k(u_k)/u_k}{U'(u_k)}\right), \tag{57}$$

where $g_1(u_1),\ldots,g_n(u_n)$ are arbitrary functions of one variable, and $U'(u_k)$ is as in proposition 32.

Proof: Recall from (37) that

$$\nabla\equiv\begin{pmatrix}\partial_y\\ \partial_x\end{pmatrix}=\Psi\begin{pmatrix}\partial_v\\ \partial_u\end{pmatrix},$$

while (34) shows that $\det G=u_1\ldots u_n\det G_{\nwarrow}(v)$. Hence,

$$-M=G\Psi\begin{pmatrix}\partial_v(K\det G)\\ \partial_u(K\det G)\end{pmatrix}/\det G=\frac{\begin{pmatrix}G_{\nwarrow} & 0\\ G_{\swarrow} & \Psi_{\searrow}\mathcal{U}\end{pmatrix}\begin{pmatrix}u_1\cdots u_n\,\partial_v(K\det G_{\nwarrow})\\ (\det G_{\nwarrow})\partial_u(u_1\cdots u_nK)\end{pmatrix}}{u_1\ldots u_n\det G_{\nwarrow}}$$

$$=\begin{pmatrix}\dfrac{G_{\nwarrow}\partial_v(K\det G_{\nwarrow})}{\det G_{\nwarrow}}\\ \dfrac{G_{\swarrow}\partial_v(K\det G_{\nwarrow})}{\det G_{\nwarrow}}+\Psi_{\searrow}\begin{pmatrix}\partial_{u_1}(u_1K)\\ \vdots\\ \partial_{u_n}(u_nK)\end{pmatrix}\end{pmatrix},$$

where $G\Psi$ was computed using (41). Equation (55) says that the upper part

$$M_{\uparrow}=-\frac{G_{\nwarrow}\partial_v(K\det G_{\nwarrow})}{\det G_{\nwarrow}}$$

depends only on the y (or v) variables, which happens if and only if

$$K\det G_{\nwarrow}=w(v)+F(u).$$

The function $w(y)$ here is the same as in theorem 23, since the driving system $\ddot{y}=M_{\uparrow}$ is generated by $E^{(n)}=\frac{1}{2}\dot{y}^T(\operatorname{cof}G_{\nwarrow})\dot{y}+w(y)$.

The function $F(u)$ is then determined by (56), which obviously is only interesting if $i\neq j$. In this case, if we set $i=m+k$ and $j=m+l$, the first term in

$$M_i=M_{m+k}=-\frac{[G_{\swarrow}]_{\text{row }k}\,\partial_v(K\det G_{\nwarrow})}{\det G_{\nwarrow}}-[\Psi_{\searrow}]_{\text{row }k}\begin{pmatrix}\partial_{u_1}(u_1K)\\ \vdots\\ \partial_{u_n}(u_nK)\end{pmatrix}$$

does not depend on $q_j=x_l$, since row k of $G_{\swarrow}$ depends on x_k and y only. Then, since by the definition of Ψ

$$[\Psi_{\searrow}]_{\text{row }k}=\begin{pmatrix}\dfrac{\partial u_1}{\partial x_k} & \dfrac{\partial u_2}{\partial x_k}\cdots\dfrac{\partial u_n}{\partial x_k}\end{pmatrix},$$

we find

$$\frac{\partial M_i}{\partial q_j}=-\frac{\partial}{\partial x_l}\sum_{s=1}^{n}\frac{\partial u_s}{\partial x_k}\partial_{u_s}(u_sK)=-\sum_{s=1}^{n}\frac{\partial^2u_s}{\partial x_l\partial x_k}\partial_{u_s}(u_sK)-[\Psi_{\searrow}]_{\text{row }k}\frac{\partial}{\partial x_l}\begin{pmatrix}\partial_{u_1}(u_1K)\\ \vdots\\ \partial_{u_n}(u_nK)\end{pmatrix}.$$

In the second term we substitute $K=(w(v)+F(u))/\det G_{\nwarrow}(v)$ and plug what we have into (56). The first term cancels out in the subtraction, leaving

$$0=\frac{\partial M_i}{\partial q_j}-\frac{\partial M_j}{\partial q_i}=-\frac{1}{\det G_{\nwarrow}}\left([\Psi_{\searrow}]_{\text{row }k}\frac{\partial}{\partial x_l}\begin{pmatrix}\partial_{u_1}(u_1F)\\ \vdots\\ \partial_{u_n}(u_nF)\end{pmatrix}-[\Psi_{\searrow}]_{\text{row }l}\frac{\partial}{\partial x_k}\begin{pmatrix}\partial_{u_1}(u_1F)\\ \vdots\\ \partial_{u_n}(u_nF)\end{pmatrix}\right).$$

Now, since $\partial_x=\Psi_{\searrow}\partial_u$, this shows that

$$0=[\Psi_{\searrow}]_{\text{row }l}\,\Omega\,[\Psi^T_{\searrow}]_{\text{column }k}-[\Psi_{\searrow}]_{\text{row }k}\,\Omega\,[\Psi^T_{\searrow}]_{\text{column }l},$$

where Ω (temporarily) denotes the $n\times n$ matrix with entries $\Omega_{ab}=\partial_{u_a}\partial_{u_b}(u_bF)$. In other words, $0=\Psi_{\searrow}(\Omega-\Omega^T)\Psi^T_{\searrow}$, or, finally,

$$\frac{\partial^2}{\partial u_a\partial u_b}((u_a-u_b)F(u))=0,\quad a,b=1,\ldots,n. \tag{58}$$

This equation occurs in classical separability theory in connection with separation in elliptic and parabolic coordinates. It is known to have the general solution

$$F(u)=\sum_{k=1}^{n}\frac{F_k(u_k)}{\prod\limits_{\substack{j=1\\ j\neq k}}^{n}(u_k-u_j)},$$

with arbitrary functions $F_1(u_1),\ldots,F_n(u_n)$ depending on one variable each (see Lemma 1 and Lemma 2 in Ref. 3). Hence, we have the general solution

$$K(v,u)=\frac{1}{\det G_{\nwarrow}(v)}\left(w(v)+\sum_k\frac{F_k(u_k)}{\Pi_{j\neq k}(u_k-u_j)}\right). \tag{59}$$

For our purposes, it turns out to be most convenient to write this in the form (57). □

Potential part: It remains to investigate the form of the "potential" parts $W^{(0)},\ldots,W^{(n)}$ in the (v,u) coordinates.

Proposition 35: The functions $W^{(0)},\ldots,W^{(n-1)}$ take the following form when expressed in the (v,u) coordinates:

$$W^{(a)}(v,u)=\sigma_{n-a}(u)\,w(v)+\sum_{k=1}^{n}\frac{\sigma_{n-a-1}(\check{u}_k)\,g_k(u_k)}{U'(u_k)}, \tag{60}$$

where $\sigma_b(u)$ denotes the elementary symmetric polynomial of degree b in the n variables $\{u_1,\ldots,u_n\}$, and $\sigma_b(\check{u}_k)$ denotes the elementary symmetric polynomial of degree b in the $n-1$ variables $\{u_1,\ldots,u_n\}\backslash\{u_k\}$. As above, $g_1(u_1),\ldots,g_n(u_n)$ are functions of one variable, and $U'(u_k)$ is as in proposition 32.

In particular, the function $W^{(n)}$ depends on the v coordinates only:

$$W^{(n)}=w(v). \tag{61}$$

Proof: We have seen that $W^{(n)}=w(y)$ depends only on y in the original coordinates, hence also $W^{(n)}=w(v)$. We also know that $K=W^{(0)}/\det G$ is a solution of the fundamental equations, so according to (57)

$$W^{(0)}(v,u)=\frac{\det G(v,u)}{\det G_{\nwarrow}(v)}\left(w(v)+\sum_{k=1}^{n}\frac{g_k(u_k)/u_k}{U'(u_k)}\right)=u_1\cdots u_n\,w(v)+\sum_{k=1}^{n}\frac{\sigma_{n-1}(\check{u}_k)\,g_k(u_k)}{U'(u_k)}. \tag{62}$$

With M determined by $W^{(0)}$, the remaining $W^{(a)}$ are determined (up to irrelevant additive constants) by the relation $\nabla W^{(a)}=-A^{(a)}M$, or

$$\nabla W_\mu=\sum_{a=0}^{n}\nabla W^{(a)}\mu^a=-\left(\sum_{a=0}^{n}A^{(a)}\mu^a\right)M=\operatorname{cof}(G+\mu J)\frac{G}{\det G}\nabla W^{(0)}.$$

We multiply by $(\det G)\Psi^T(G+\mu J)$ from the left and use (37), (45), and (46) to obtain the equivalent condition

$$(\det G)\begin{pmatrix}G_{\nwarrow} & 0\\ 0 & (\mathcal{U}+\mu I)\Delta\end{pmatrix}\begin{pmatrix}\partial_v W_\mu\\ \partial_u W_\mu\end{pmatrix}=\det(G+\mu J)\begin{pmatrix}G_{\nwarrow} & 0\\ 0 & \mathcal{U}\Delta\end{pmatrix}\begin{pmatrix}\partial_v W^{(0)}\\ \partial_u W^{(0)}\end{pmatrix}.$$

It is a tedious but fairly straightforward calculation, which we omit, to verify that this is satisfied by

$$W_\mu=\left(\prod_{i=1}^{n}(u_i+\mu)\right)w(v)+\sum_{k=1}^{n}\left(\prod_{\substack{j=1\\ j\neq k}}^{n}(u_j+\mu)\right)\frac{g_k(u_k)}{U'(u_k)},$$

from which $W^{(a)}$ can be read off as the coefficient of μ^a. □

Summary: We have now determined the form of the integrals of motion in separation coordinates (v,u). We have seen that

$$E^{(n)}=\tfrac{1}{2}\dot{v}^T(\operatorname{cof}G_{\nwarrow}(v))\dot{v}+w(v) \tag{63}$$

depends only on v, while the form of $E^{(0)},\ldots,E^{(n-1)}$ is obtained from (48) and (60):

$$E^{(a)}=\sigma_{n-a}(u)\,E^{(n)}+\sum_{k=1}^{n}\sigma_{n-a-1}(\check{u}_k)\left(\frac{1}{2}(\det G_{\nwarrow})\frac{\dot{u}_k^2}{\Delta_k}+\frac{g_k(u_k)}{U'(u_k)}\right). \tag{64}$$

If we let $s_k=\dot{u}_k/\Delta_k$ and use proposition 32, we can write this as

$$E^{(a)}=\sigma_{n-a}(u)\,E^{(n)}+\sum_{k=1}^{n}\frac{\sigma_{n-a-1}(\check{u}_k)}{U'(u_k)}\left(\frac{1}{2}f_k(u_k)\,s_k^2+g_k(u_k)\right). \tag{65}$$

Note in particular that

$$E^{(n-1)}=\left(\sum_{k=1}^{n}u_k\right)E^{(n)}+\sum_{k=1}^{n}\left(\frac{f_k(u_k)\,s_k^2+g_k(u_k)}{U'(u_k)}\right). \tag{66}$$

E. The equations of motion are Hamiltonian

Given some solution $y=y(t)$ [or $v=v(t)$] of the driving system, we now consider $u=u(y(t),x)$ as a time-dependent change of variables in R^n. We want to express the driven system $\ddot{x}=-(\partial V/\partial x)(y(t),x)$ in terms of the u variables. Note that since $E^{(n)}$ is an integral of motion for the driving system, it can from now on be treated as simply a constant, the value of which is determined by which solution $y(t)$ is taken.

Proposition 36: The equations of motion for the u variables can be put into canonical Hamiltonian form

$$\dot{u} = \frac{\partial h}{\partial s}(u,s,t),$$

$$\dot{s} = -\frac{\partial h}{\partial u}(u,s,t),$$

with momenta $s_1,\ldots,s_n$ *defined by*

$$s_k = \frac{\dot{u}_k}{\Delta_k} \tag{67}$$

(Δ_i *as in proposition 32*), *and with the time-dependent Hamiltonian*

$$h(u,s,t) = \frac{1}{\det G_{\diagdown}(y(t))}\left(\left(\sum_{k=1}^{n} u_k\right)E^{(n)} + \sum_{k=1}^{n}\left(\frac{f_k(u_k)\,s_k^2 + g_k(u_k)}{U'(u_k)}\right)\right). \tag{68}$$

Proof: First we see from (66) that h is simply $E^{(n-1)}/\det G_{\diagdown}$, expressed in terms of u, s, and t. Now, with $p=\dot{x}$ the system $\ddot{x} = -(\partial V/\partial x)(y(t),x)$ has a canonical Hamiltonian formulation

$$\dot{x} = \frac{\partial H}{\partial p}(x,p,t),$$

$$\dot{p} = -\frac{\partial H}{\partial x}(x,p,t),$$

where $H(x,p,t) = \frac{1}{2}p^T p + V(y(t),x)$. Consider the extended phase space R^{2n+1} with coordinates (x,p,t). With $T=t$, the variables (u,s,T) constitute a different coordinate system on this space. The vector field in extended phase space that corresponds to the canonical phase flow is encoded in the 1-form $p^T\,dx - H\,dt$ (by spanning the kernel of its exterior derivative). It follows that the equations of motion are canonical in the new coordinates, with Hamiltonian h, if the two 1-forms,

$$p^T\,dx - H\,dt \quad \text{and} \quad s^T\,du - h\,dT,$$

have the same exterior derivative (see Sec. 45 in Ref. 1). Here we view dx and du as column vectors of 1-forms dx_i and du_i, in order to be consistent with our previous matrix notation. Since here we have $dT = dt$, the proof amounts to showing that

$$d(p^T\,dx - s^T\,du + (h-H)\,dt) = 0. \tag{69}$$

The computations will be performed in the (x,p,t) coordinates, and whenever we write y we mean the given function $y(t)$. Note also that since $G_{\diagdown}$ depends only on the y variables, it too will be a function of t only. In particular, $\det G_{\diagdown}$ is a function of t only.

We need to express $s^T\,du$ and h in terms of the (x,p,t) coordinates. Recall that by the definition 30 of the matrix Ψ we have

$$(\nabla u_1,\ldots,\nabla u_n) = \begin{pmatrix} \Psi_{\nearrow} \\ \Psi_{\searrow} \end{pmatrix}.$$

Since

$$du_i = \sum_{k=1}^{m}\frac{\partial u}{\partial y_k}\dot{y}_k\,dt + \sum_{k=1}^{n}\frac{\partial u}{\partial x_k}dx_k$$

we obtain

$$du=(\Psi_{\nearrow})^T\dot{y}\,dt+(\Psi_{\searrow})^T\,dx,$$

that is,

$$\dot{u}=(\Psi_{\nearrow})^T\dot{y}+(\Psi_{\searrow})^T\dot{x}.$$

If we transpose and multiply from the right by $\Delta^{-1}=\mathrm{diag}(\Delta_k^{-1})$, we get

$$s^T=\dot{y}^T\Psi_{\nearrow}\Delta^{-1}+p^T\Psi_{\searrow}\Delta^{-1}.$$

Now we define an $m\times n$ matrix Ξ by

$$\Xi=\Psi_{\nearrow}(\Psi_{\searrow})^{-1}. \tag{70}$$

Since $\Delta=(\Psi_{\searrow})^T\Psi_{\searrow}$, it follows that

$$\Psi_{\searrow}\Delta^{-1}(\Psi_{\nearrow})^T=\Xi^T,$$

$$\Psi_{\nearrow}\Delta^{-1}(\Psi_{\nearrow})^T=\Xi\,\Xi^T.$$

Consequently,

$$s^T\,du=p^T\,dx+(\dot{y}^T\Xi\,\Xi^T\dot{y}+\dot{y}^T\Xi p)dt+\dot{y}^T\Xi\,dx. \tag{71}$$

Furthermore, (50) shows that $G_{\nearrow}=-G_{\nwarrow}\Xi$, so that the expression for the block $A^{(n-1)}_{\nearrow}$ from (30) can be written as

$$A^{(n-1)}_{\nearrow}=-(\mathrm{cof}\,G_{\nwarrow})G_{\nearrow}=(\det G_{\nwarrow})\Xi. \tag{72}$$

Hence, since from (30) we also have $A^{(n-1)}_{\searrow}=(\det G_{\nwarrow})I$, we find the following expression for h:

$$h=\frac{E^{(n-1)}}{\det G_{\nwarrow}}=\frac{1}{\det G_{\nwarrow}}\left(\frac{1}{2}(\dot{y}^T\ \ p^T)A^{(n-1)}\begin{pmatrix}\dot{y}\\ p\end{pmatrix}+W^{(n-1)}\right)=\frac{1}{2}p^Tp+\dot{y}^T\Xi p+\frac{\frac{1}{2}\dot{y}^TA^{(n-1)}_{\nwarrow}\dot{y}+W^{(n-1)}}{\det G_{\nwarrow}}. \tag{73}$$

So far we have

$$p^T\,dx-s^T\,du+(h-H)\,dt=\left(\frac{\frac{1}{2}\dot{y}^TA^{(n-1)}_{\nwarrow}\dot{y}+W^{(n-1)}}{\det G_{\nwarrow}}-V-\dot{y}^T\Xi\,\Xi^T\dot{y}\right)dt-\dot{y}^T\Xi\,dx,$$

and the exterior derivative of this is zero iff

$$\frac{\partial}{\partial x}\left(\frac{\frac{1}{2}\dot{y}^TA^{(n-1)}_{\nwarrow}\dot{y}+W^{(n-1)}}{\det G_{\nwarrow}}-V-\dot{y}^T\Xi\,\Xi^T\dot{y}\right)+\frac{\partial}{\partial t}(\Xi^T\dot{y})=0.$$

Now $(\partial/\partial t)\,(\Xi^T\dot{y})=(\partial\Xi^T/\partial t)\dot{y}+\Xi^T\ddot{y}$, and from $\ddot{q}=-[A^{(n-1)}]^{-1}\nabla W^{(n-1)}$ it follows that

$$\frac{\partial W^{(n-1)}}{\partial x}=-[A^{(n-1)}\ddot{q}]_{\downarrow}=-(A^{(n-1)}_{\nearrow})^T\ddot{y}+A^{(n-1)}_{\searrow}\frac{\partial V}{\partial x}=(\det G_{\nwarrow})\left(-\Xi^T\ddot{y}+\frac{\partial V}{\partial x}\right),$$

so it remains to show that

$$\frac{\partial}{\partial x}\left(\frac{\frac{1}{2}\dot{y}^TA^{(n-1)}_{\nwarrow}\dot{y}}{\det G_{\nwarrow}}-\dot{y}^T\Xi\,\Xi^T\dot{y}\right)+\frac{\partial\Xi^T}{\partial t}\dot{y}=0.$$

To simplify the notation for this final computation, write

$$\det G_{\nwarrow} = D, \quad A^{(n-1)}_{\nwarrow} = (a_{ij}), \quad \text{and } A^{(n-1)}_{\nearrow} = (b_{ij}).$$

Then $(b_{ij}) = -(\operatorname{cof} G_{\nwarrow}) G_{\nearrow} = D\Xi$, by (72). In this notation, what we must show is

$$\frac{1}{2D}\sum_{i,j=1}^{m} \frac{\partial a_{ij}}{\partial x_k}\dot{y}_i\dot{y}_j - \frac{1}{D^2}\sum_{i,j=1}^{m}\sum_{l=1}^{n} \frac{\partial(b_{il}b_{jl})}{\partial x_k}\dot{y}_i\dot{y}_j + \sum_{i=1}^{m}\frac{\partial}{\partial t}\left(\frac{b_{ik}}{D}\right)\dot{y}_i = 0. \tag{74}$$

To begin with, since $G_{\nwarrow}$ is independent of x and $G_{\nearrow}$ is linear in x, we see that b_{ij} is linear in x. More precisely, since

$$\frac{\partial [G_{\nearrow}]_{rj}}{\partial x_k} = \frac{\partial G_{r,m+j}}{\partial q_{m+k}} = \delta_{jk} N_r,$$

applying proposition 6 with y instead of q gives

$$\frac{\partial b_{ij}}{\partial x_k} = -\sum_{r=1}^{m} [\operatorname{cof} G_{\nwarrow}]_{ir}(\delta_{jk}N_r) = -\delta_{jk}[(\operatorname{cof} G_{\nwarrow})N_{\uparrow}]_i = -\frac{\delta_{jk}}{2}\frac{\partial D}{\partial y_i}.$$

Furthermore,

$$\sum_{i=1}^{m}\frac{\partial}{\partial t}\left(\frac{b_{ik}}{D}\right)\dot{y}_i = \sum_{i,j=1}^{m}\frac{\partial}{\partial y_j}\left(\frac{b_{ik}}{D}\right)\dot{y}_i\dot{y}_j.$$

Finally, since $A^{(n-1)}$ satisfies the cyclic conditions,

$$\frac{\partial a_{ij}}{\partial x_k} = \frac{\partial A^{(n-1)}_{ij}}{\partial q_{m+k}} = -\frac{\partial A^{(n-1)}_{j,m+k}}{\partial q_i} - \frac{\partial A^{(n-1)}_{m+k,i}}{\partial q_j} = -\frac{\partial b_{jk}}{\partial y_i} - \frac{\partial b_{ik}}{\partial y_j}.$$

Plugging all this into (74), it is easy to verify that everything cancels out, which completes the proof. □

F. Separation of the time-dependent Hamilton–Jacobi equation

The time-dependent Hamilton–Jacobi equation corresponding to the Hamiltonian $h(u,s,t)$ of proposition 36 is

$$h\left(u, \frac{\partial F}{\partial u}, t\right) + \frac{\partial F}{\partial t} = 0. \tag{75}$$

A complete solution $F(u,\alpha,t)$ can be obtained by separation of variables, as we will now show. We number the parameters $\alpha_0,\ldots,\alpha_{n-1}$ since they will in fact be just the values of the integrals of motion $E^{(0)},\ldots,E^{(n-1)}$, as will be clear by comparing (78) below with (65).

To begin with, since the time variable t appears in K only in the overall multiplicative factor $1/(\det G_{\nwarrow})$, it can be separated off by assuming a solution for F of the form

$$F(u,\alpha,t) = S(u,\alpha) - \alpha_{n-1}\int \frac{1}{\det G_{\nwarrow}(y(t))}\,dt. \tag{76}$$

With the explicit expression for h from proposition 36 we get the following equation for $S(u,\alpha)$:

$$\left(\sum_{k=1}^{n} u_k\right)E^{(n)} + \sum_{k=1}^{n}\left(\frac{\frac{1}{2}f_k(u_k)(\partial S/\partial u_k)^2 + g_k(u_k)}{U'(u_k)}\right) = \alpha_{n-1}. \tag{77}$$

In order to find a complete solution, depending on all the parameters α_i, we will use Stäckel's method. Consider the n equations

$$\sum_{k=1}^{n} \frac{\sigma_{n-a-1}(\breve{u}_k)}{U'(u_k)} \left(\frac{1}{2} f_k(u_k) \left(\frac{\partial S}{\partial u_k} \right)^2 + g_k(u_k) \right) = \alpha_a - \sigma_{n-a}(u) E^{(n)}, \tag{78}$$

where $a=0,\ldots,n-1$. If we can find a solution of this system, it will be a complete solution of (77), since it will depend on all α_i. [Of course it will solve (77) which is just the last equation of the system, corresponding to $a=n-1$.]

Now (78) is a linear system of equations for the expression in parentheses, and the matrix of coefficients is the inverse of a Stäckel matrix (similar to the one occuring when separating in elliptic or parabolic coordinates). In fact, the matrix can be inverted using known properties of symmetric polynomials, resulting in

$$\frac{1}{2} f_k(u_k) \left(\frac{\partial S}{\partial u_k} \right)^2 + g_k(u_k) = -P(-u_k), \quad k=1,\ldots,n, \tag{79}$$

where the polynomial P is given by

$$P(z) = \alpha_0 + \alpha_1 z + \cdots + \alpha_{n-1} z^{n-1} + E^{(n)} z^n. \tag{80}$$

It is now clear that the additive Ansatz

$$S(u,\alpha) = S_1(u_1,\alpha) + \ldots + S_n(u_n,\alpha)$$

yields a separated solution, provided that each function S_k satisfies the separation ODE

$$\frac{1}{2} \left(\frac{dS_k}{du_k} \right)^2 = \frac{-g_k(u_k) - P(-u_k)}{f_k(u_k)}. \tag{81}$$

Consequently,

$$F(u,\alpha,t) = \sum_{k=1}^{n} \int \sqrt{-2 \frac{g_k(u_k) + P(-u_k)}{f_k(u_k)}}\, du_k - \alpha_{n-1} \int \frac{1}{\det G_{\nwarrow}(y(t))}\, dt \tag{82}$$

is a complete solution, and in the usual way it generates a canonical transformation to variables (β,α), where $\beta_i = \partial F / \partial \alpha_i$. These new variables will be constant during the motion, with values determined by the initial condition. One can then (at least in principle) solve for $u=u(\beta,\alpha,t)$, and hence $x=x(\beta,\alpha,t)$. This finishes the proof of theorem 23.

IV. THE CASE OF ONE DRIVEN EQUATION

The case when only the last equation is driven by the other ones is easier to handle, since it does not require the Hamilton–Jacobi method, as we shall soon see. Specializing our previous results to this case by setting $n=1$, we find the following. If a system of the form

$$\begin{aligned} \ddot{y}_1 &= M_1(y_1,\ldots,y_m), \\ &\vdots \\ \ddot{y}_m &= M_m(y_1,\ldots,y_m), \\ \ddot{x} &= -\frac{\partial V}{\partial x}(y_1,\ldots,y_m;x) \end{aligned} \tag{83}$$

has an integral of motion $E^{(0)}$ of cofactor type, then it must have an extra integral of motion $E^{(1)}=\frac{1}{2}\dot{y}^T \operatorname{cof} G_{\nwarrow}(y)\dot{y}+w(y)$ depending only on the variables y. We change to new coordinates $(v_1,\ldots,v_m,u)$, where $v=y$ and u is the zero of the first degree polynomial $\det(G-\lambda J)$. Here $J=\operatorname{diag}(0,\ldots,0,1)$, so $\det(G-\lambda J)=\det G-\lambda \det G_{\nwarrow}$, hence

$$u=\frac{\det G(y,x)}{\det G_{\nwarrow}(y)}.$$

In the new variables, $E^{(1)}$ remains unchanged (with v instead of y), while $E^{(0)}$ takes the form given by (64),

$$E^{(0)}=uE^{(1)}+\frac{1}{2}\frac{\det G_{\nwarrow}(v)}{\Delta}\dot{u}^2+g(u),$$

where, according to (43) and proposition 32,

$$\Delta=\left(\frac{\partial u}{\partial x}\right)^2=\frac{f(u)}{\det G_{\nwarrow}(v)}$$

for some function $f(u)$. Hence,

$$E^{(0)}=uE^{(1)}+\frac{1}{2}\frac{(\det G_{\nwarrow}(v))^2}{f(u)}\dot{u}^2+g(u). \tag{84}$$

Now, for a given solution $v(t)=y(t)$ of the driving system, we write this as

$$\left(\det G_{\nwarrow}(v(t))\frac{du}{dt}\right)^2=2\,f(u)(E^{(0)}-uE^{(1)}-g(u)),$$

or

$$\frac{du}{\sqrt{2\,f(u)(E^{(0)}-uE^{(1)}-g(u))}}=\frac{dt}{\det G_{\nwarrow}(v(t))},$$

which can be integrated by quadrature, since u and t are separated.

This procedure can be applied recursively to ''triangular'' systems, as in the following proposition. Note that for an arbitrary triangular system all we can do in general is to solve the first equation for $q_1(t)$. It is quite surprising that the existence of an integral of motion of cofactor type is enough to allow us to solve the system completely.

Proposition 37 (triangular cofactor systems): Suppose that the "triangular" Newton system

$$\begin{aligned}
\ddot{q}_1&=M_1(q_1),\\
\ddot{q}_2&=M_2(q_1,q_2),\\
\ddot{q}_3&=M_3(q_1,q_2,q_3),\\
&\vdots\\
\ddot{q}_N&=M_N(q_1,q_2,q_3,\ldots,q_N),
\end{aligned} \tag{85}$$

is of cofactor type. Suppose also that no upper left $k\times k$ block in G is constant or singular ($k=1,\ldots,N-1$). Then the system can be integrated by quadratures.

Proof: The whole system is of the type considered above (driven, with $n=1$), so it can be integrated provided that the driving system, consisting of the $N-1$ first equations, can be integrated. By what we said above, the driving system must have an integral of motion of cofactor type, so it is itself a triangular cofactor system, of one dimension less. Since the first equation can be integrated (being one dimensional), the statement follows by induction. □

In each step of the integration procedure one new variable $u=u_k$ is introduced. Denoting the determinant of the upper left $k\times k$ block in G by $D_k(q_1,\ldots,q_k)$, we can write the separation variables $(u_1,\ldots,u_N)$ as

$$u_1=q_1 \quad \text{and} \quad u_i=\frac{D_i}{D_{i-1}}, \quad i=2,\ldots,N.$$

V. EXAMPLES

Example 38 (example 1 continued): We can now fill in the missing details in our first example. We had

$$M(q)=\frac{1}{(q_2q_3-q_1)^2}\begin{pmatrix}0\\ q_3\\ q_2\end{pmatrix}.$$

With

$$G(q)=\begin{pmatrix}2q_1 & q_2 & q_3\\ q_2 & 0 & 1\\ q_3 & 1 & 0\end{pmatrix}, \quad J=\begin{pmatrix}0 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix},$$

we find from $A_\mu=\operatorname{cof}(G+\mu J)$ that

$$A^{(0)}=\operatorname{cof} G=\begin{pmatrix}-1 & q_3 & q_2\\ q_3 & -q_3^2 & q_2q_3-2q_1\\ q_2 & q_2q_3-2q_1 & -q_2^2\end{pmatrix},$$

$$A^{(1)}=\begin{pmatrix}0 & -q_2 & -q_3\\ -q_2 & 2q_1 & 0\\ -q_3 & 0 & 2q_1\end{pmatrix}, \quad A^{(2)}=\begin{pmatrix}1 & 0 & 0\\ 0 & 0 & 0\\ 0 & 0 & 0\end{pmatrix}.$$

The relation $\nabla W^{(k)}=-A^{(k)}M$ then yields

$$W^{(0)}=-\frac{q_2^2+q_3^2}{q_2q_3-q_1}, \quad W^{(1)}=\frac{2q_1}{q_2q_3-q_1}, \quad W^{(2)}=0.$$

We introduce new variables (v,u_1,u_2), where $v=q_1$ and $u_{1,2}$ are the roots of

$$0=\det(G-uJ)=2(q_2q_3-q_1)+(q_2^2+q_3^2)u+(2q_1)u^2.$$

With (y,x_1,x_2) instead of (q_1,q_2,q_3), we see that $u_1+u_2=-(x_1^2+x_2^2)/2y$ and $u_1u_2=2(x_1x_2-y)/2y$, so that

$$\left(\frac{x_1+x_2}{\sqrt{2}}\right)^2 = v(1-u_1)(1-u_2),$$
$$\left(\frac{x_1-x_2}{\sqrt{2}}\right)^2 = -v(1+u_1)(1+u_2). \tag{86}$$

Except for the factor v, the new variables (u_1,u_2) are elliptic coordinates aligned along axes that are rotated $\pi/4$ relative to the Cartesian coordinates (x_1,x_2). With $u_1<-1<u_2<1$, the coordinate curves are ellipses (for u_1) and hyperbolas (for u_2). The example (2) is obtained by taking the particular solution $y(t)=v(t)=q_1(t)=t$ of the driving equation $\ddot{q}_1=0$, and in this case we get a factor t with the effect of expanding the entire coordinate web as time increases, so these coordinates might be called "expanding elliptic coordinates."

We can express (u_1,u_2) in terms of (y,x_1,x_2) as

$$u_{1,2}=\frac{-1}{4y}(x_1^2+x_2^2\pm\sqrt{(x_1^2+x_2^2)^2-16y(x_1x_2-y)}),$$

and then a straightforward computation gives the quantities

$$\Delta_{1,2}=\left(\frac{\partial u_{1,2}}{\partial x_1}\right)^2+\left(\frac{\partial u_{1,2}}{\partial x_2}\right)^2=\frac{1}{2y^2}\left(x_1^2+x_2^2\pm\frac{(x_1^2+x_2^2)^2-8yx_1x_2}{\sqrt{(x_1^2+x_2^2)^2-16y(x_1x_2-y)}}\right).$$

With $U(\mu)=(u_1-\mu)(u_2-\mu)$ we find that $(\det G_{\nwarrow})U'(u_1)\Delta_1=2y(u_1-u_2)\Delta_1=4(1-u_1^2)$ and $(\det G_{\nwarrow})U'(u_2)\Delta_2=2y(u_2-u_1)\Delta_1=4(1-u_2^2)$ depend only on one variable, as predicted by Proposition 32. So in this case we have $f_1=f_2=f$, where $f(u)=4(1-u^2)$.

The functions $W^{(k)}$, expressed in the new variables, take the form

$$W^{(0)}=2\frac{u_1+u_2}{u_1u_2}=u_2\frac{-2/u_1}{U'(u_1)}+u_1\frac{-2/u_2}{U'(u_2)},$$
$$W^{(1)}=\frac{2}{u_1u_2}=\frac{-2/u_1}{U'(u_1)}+\frac{-2/u_2}{U'(u_2)},$$
$$W^{(2)}=0,$$

in accordance with proposition 35.

We can now write down the integrals of motion $E^{(k)}=\frac{1}{2}\dot{q}^TA^{(k)}\dot{q}+W^{(k)}$ in terms of the variables (v,u_1,u_2). With $s_i=\dot{u}_i/\Delta_i$, we find

$$E^{(2)}=\frac{\dot{v}^2}{2},$$
$$E^{(1)}=(u_1+u_2)E^{(2)}+\frac{4(1-u_1^2)\frac{s_1^2}{2}-\frac{2}{u_1}}{U'(u_1)}+\frac{4(1-u_2^2)\frac{s_2^2}{2}-\frac{2}{u_2}}{U'(u_2)},$$
$$E^{(0)}=u_1u_2E^{(2)}+u_2\frac{4(1-u_1^2)\frac{s_1^2}{2}-\frac{2}{u_1}}{U'(u_1)}+u_1\frac{4(1-u_2^2)\frac{s_2^2}{2}-\frac{2}{u_2}}{U'(u_2)}.$$

The new Hamiltonian is $h=E^{(1)}/\det G_{\nwarrow}(v(t))$, or, with $v(t)=t$,

$$h(u,s,t)=\frac{1}{2t}\left(\frac{u_1+u_2}{2}+\frac{4(1-u_1^2)\dfrac{s_1^2}{2}-\dfrac{2}{u_1}}{U'(u_1)}+\frac{4(1-u_2^2)\dfrac{s_2^2}{2}-\dfrac{2}{u_2}}{U'(u_2)}\right).$$

The time-dependent Hamilton–Jacobi equation $h(u,\partial F/\partial u,t)+\partial F/\partial t=0$ admits a separated complete solution of the form

$$F(u_1,u_2,\alpha_1,\alpha_2,t)=S_1(u_1,\alpha_0,\alpha_1)+S_2(u_2,\alpha_0,\alpha_1)-\frac{\alpha_1}{2}\ln|t|,$$

where S_1 and S_2 satisfy the separation equations

$$\frac{1}{2}\left(\frac{dS_1}{du_1}\right)^2=\frac{\dfrac{2}{u_1}-\alpha_0+\alpha_1u_1-\dfrac{u_1^2}{2}}{4(1-u_1^2)},$$

$$\frac{1}{2}\left(\frac{dS_2}{du_2}\right)^2=\frac{\dfrac{2}{u_2}-\alpha_0+\alpha_1u_2-\dfrac{u_2^2}{2}}{4(1-u_2^2)}.$$

From $\beta_k=\partial F/\partial\alpha_k$ we finally obtain

$$\beta_1(u_1,u_2,t,\alpha_0,\alpha_1)=\int^{u_1}\frac{x}{2R}dx+\int^{u_2}\frac{x}{2R}dx-\frac{1}{2}\ln|t|,$$

$$\beta_0(u_1,u_2,t,\alpha_0,\alpha_1)=\int^{u_1}\frac{-1}{2R}dx+\int^{u_2}\frac{-1}{2R}dx,$$

where

$$R(x,\alpha_1,\alpha_2)=\sqrt{2(1-x^2)\left(\frac{2}{x}-\alpha_0+\alpha_1x-\frac{x^2}{2}\right)}.$$

This gives the solution $u(\beta,\alpha,t)$ in implicit form.

Example 39 (a triangular system): An interesting example of a triangular cofactor system appears when applying the recursive method for constructing cofactor pair systems given in Ref. 6 to the matrices

$$G=\begin{pmatrix}0&-1&q_1\\-1&0&q_2\\q_1&q_2&2q_3\end{pmatrix},\quad \tilde{G}=\begin{pmatrix}0&0&1\\0&1&0\\1&0&0\end{pmatrix}.$$

Starting with $W^{(0)}=W^{(1)}=0$ and $W^{(2)}=-1$, one obtains after four steps the system

$$\begin{aligned}\ddot{q}_1&=-4q_1,\\ \ddot{q}_2&=6q_1^2-4q_2,\\ \ddot{q}_3&=-10q_1^3+12q_1q_2-4q_3,\end{aligned}\tag{87}$$

which is a cofactor pair system with respect to the given matrices G and $\tilde{G}$. Since the third equation is driven by the first two, the system is also a cofactor pair system with respect to G and $J=\mathrm{diag}(0,0,1)$. In fact, the most general matrix G for which the system has an integral of motion of the form $\frac{1}{2}\dot{q}^T(\mathrm{cof}\,G)\dot{q}+W(q)$ is

$$c_1\begin{pmatrix} 0 & -1 & q_1 \\ -1 & 0 & q_2 \\ q_1 & q_2 & 2q_3 \end{pmatrix}+c_2\begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}+c_3\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}+c_4\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

so it might be called a ''cofactor quadruple system.'' [The third matrix comes from the fact that there is a function $U(q)$ such that $M_2=\partial_3 U$ and $M_3=\partial_2 U$.] Anyway, we know from Sec. IV that the driving system is a cofactor system with respect to

$$G_{\nwarrow}=\begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix}.$$

Since this matrix is constant, we cannot use it for integrating the driving system, but it so happens that the driving system is a cofactor system with respect to any matrix of the form

$$c_1\begin{pmatrix} -1 & q_1 \\ q_1 & 2q_2 \end{pmatrix}+c_2\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}+c_3\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

So, forgetting about (87) for the moment, we consider the two-dimensional driving system

$$\ddot{q}=\begin{pmatrix} -4q_1 \\ 6q_1^2-4q_2 \end{pmatrix}=-\frac{g\nabla w}{\det g}, \tag{88}$$

where now

$$g=\begin{pmatrix} -1 & q_1 \\ q_1 & 2q_2 \end{pmatrix}, \quad w=\tfrac{3}{2}q_1^4+2q_1^2q_2-2q_2^2.$$

[In this example, we use lowercase letters for quantities referring to the two-dimensional system (88).] In the new variables $v=q_1$ and $u=\det g/\det g_{\nwarrow}=q_1^2+2q_2$, we have the integrals of motion

$$e^{(1)}=\tfrac{1}{2}\dot{q}_1^2+2q_1^2=\tfrac{1}{2}\dot{v}^2+2v^2$$

from the first equation, and (after a short calculation)

$$e^{(0)}=\frac{1}{2}\dot{q}^T(\mathrm{cof}\,g)\dot{q}+w(q)=ue^{(1)}-\frac{\dot{u}^2}{8}-\frac{u^2}{2}.$$

The function $v(t)=q_1(t)$ is just a harmonic oscillation, whose amplitude determines the numerical value of $e^{(1)}$ (or the other way around):

$$q_1(t)=\sqrt{\frac{e^{(1)}}{2}}\sin 2(t-t_1). \tag{89}$$

The value of $e^{(0)}$ is determined by the initial conditions for q_1 and q_2. Then $u(t)$, and hence $q_2(t)=(u(t)-v(t)^2)/2$, can be found from the separable ODE

$$\frac{du}{dt}=\sqrt{8\left(ue^{(1)}-\frac{u^2}{2}-e^{(0)}\right)}.$$

This gives

$$u(t)=\sqrt{(e^{(1)})^2-2e^{(0)}}\sin 2(t-t_2)+e^{(1)},$$

so that

$$q_2(t)=\tfrac{1}{2}\left(\sqrt{(e^{(1)})^2-2e^{(0)}}\sin 2(t-t_2)+e^{(1)}\left(1-\tfrac{1}{2}\sin^2 2(t-t_1)\right)\right). \tag{90}$$

Having found $q_1(t)$ and $q_2(t)$, we return to the three-dimensional system (87):

$$\ddot{q}=\begin{pmatrix} -4q_1 \\ 6q_1^2-4q_2 \\ -10q_1^3+12q_1q_2-4q_3 \end{pmatrix}=-\frac{G\nabla W}{\det G},$$

where

$$G=\begin{pmatrix} 0 & -1 & q_1 \\ -1 & 0 & q_2 \\ q_1 & q_2 & 2q_3 \end{pmatrix}, \quad W=6q_1^2q_2^2-4q_1^4q_2+4q_1q_2q_3-2q_3^2-4q_1^3q_3.$$

Here we take new variables $v_1=q_1$, $v_2=q_2$, and $u=\det G/\det G_{\nwarrow}=2(q_1q_2+q_3)$. The integrals of motion turn out to be

$$E^{(1)}=\frac{1}{2}\dot{v}^T\operatorname{cof}\begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix}\dot{v}+4v_1v_2-2v_1^3$$

and

$$E^{(0)}=\frac{1}{2}\dot{q}^T(\operatorname{cof}G)\dot{q}+W(q)=uE^{(1)}-\frac{\dot{u}^2}{8}-\frac{u^2}{2},$$

so the equation for $u(t)$ can again be separated (in exactly the same way as above). After finding $u(t)$, we finally obtain $q_3(t)=u(t)/2-q_1(t)q_2(t)$, that is

$$q_3(t)=\tfrac{1}{2}\left(\sqrt{E^{(1)}-2E^{(0)}}\sin 2(t-t_3)+E^{(1)}\right)-q_1(t)q_2(t). \tag{91}$$

By inserting the expressions for $q_1(t)$ and $q_2(t)$ into the expression for $E^{(1)}$ we find that it depends on the previous integration constants $e^{(0)}$, $e^{(1)}$, t_1, t_2 through the equation

$$E^{(1)}=\sqrt{2e^{(1)}}\sqrt{e^{(1)}-2e^{(0)}}\cos 2(t_2-t_1).$$

On the other hand, $E^{(0)}$ and t_3 are independent of the previous integration constants.

Example 40 (construction of driven systems): Given a cofactor system

$$\ddot{y}=M_{\uparrow}(y)=-(\operatorname{cof}g(y))^{-1}\frac{\partial w}{\partial y}(y),$$

how can it be extended to a driven system

$$\ddot{q}=\begin{pmatrix} M_{\uparrow}(y) \\ M_{\downarrow}(y,x) \end{pmatrix}=-(\operatorname{cof}G(q))^{-1}\frac{\partial W}{\partial q}(q)$$

of the type considered in this paper? First of all, the restriction that the elliptic coordinates matrix $G(q)$ must have $g(y)=G_{\nwarrow}(y)$ as its upper left block fixes α, $\beta_{\uparrow}$ and $\gamma_{\nwarrow}$. The remaining entries of β and γ can be chosen at will (as long as G is nonsingular). Then we want to find some

extension $M_{\downarrow}$ of the right-hand side which is compatible with the chosen matrix G [i.e., so that $W(q)$ exists]. In separation coordinates, this amounts to specifying the functions $g_k(u_k)$ in the corresponding solution of the fundamental equations (proposition 34), the function $w(v)=w(y)$ already being determined by the driving system. One can find a family of possible $M_{\downarrow}$ in Cartesian coordinates directly by using the recursion formula from Ref. 6. As it stands, this formula requires $\widetilde{G}$ to be nonsingular, but taking $\widetilde{G}=J$ can be justified like in the proof of proposition 27 (however, it only makes sense in the ''downwards'' recursion formula). We then find that if a driven system has integrals of motion given by the generating function $E_\mu=\frac{1}{2}\dot{q}^T A_\mu \dot{q}+W_\mu$ as in (27), then we obtain another driven system with integrals of motion $\frac{1}{2}\dot{q}^T A_\mu \dot{q}+U_\mu$ by setting

$$U_\mu=\frac{1}{\mu}\left(\frac{\det(G+\mu J)}{\det G}W^{(0)}-W_\mu\right). \tag{92}$$

It is clear that U_μ is a polynomial in μ of degree $n-1$, not n, which means that the new system (and any system obtained by iterating this process) is driven in the trivial way ($\ddot{y}=0$). They correspond to solutions (57) of the fundamental equations with $w(y)=0$. Adding

$$\frac{\det(G+\mu J)}{\det G_{\nwarrow}}w(y)$$

to U_μ gives a system with any $w(y)$ desired.

As an example, consider the two-dimensional Garnier potential $V=(q_1^2+q_2^2)^2-(\lambda_1 q_1^2+\lambda_2 q_2^2)$. We will demonstrate how to find G and M_3 such that the system

$$\begin{aligned}\ddot{q}_1&=-\partial_1 V(q_1,q_2),\\ \ddot{q}_2&=-\partial_2 V(q_1,q_2),\\ \ddot{q}_3&=M_3(q_1,q_2,q_3)\end{aligned} \tag{93}$$

is of cofactor type $\ddot{q}=-(G/\det G)\nabla W$. With $G_{\nwarrow}=\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$, corresponding to $w=V$, we have $\alpha=\beta_1=\beta_2=0$, so we choose, for example, $\beta_3=1$ and extend γ with zeros to get

$$G=\begin{pmatrix}1&0&q_1\\0&1&q_2\\q_1&q_2&2q_3\end{pmatrix}.$$

Applying (92) with $W_\mu=1+0\mu$ and $J=\mathrm{diag}(0,0,1)$ gives $U_\mu=(\det G)^{-1}$, corresponding to the trivially driven system

$$\ddot{q}=-\frac{G}{\det G}\nabla\left(\frac{1}{\det G}\right)=\frac{2}{(2q_3-q_1^2-q_2^2)^2}\begin{pmatrix}0\\0\\1\end{pmatrix}.$$

To keep things simple we stop the recursion after this first step, and let

$$E_\mu=\frac{1}{2}\dot{q}^T\,\mathrm{cof}(G+\mu J)\dot{q}+(\det G)^{-1}+\frac{\det(G+\mu J)}{\det G_{\nwarrow}}V(q_1,q_2),$$

which then generates an extended system of the desired form

$$\ddot{q}=-\frac{G}{\det G}\nabla((\det G)^{-1}+(\det G)V)=\begin{pmatrix}-\partial_1 V\\-\partial_2 V\\2(2q_3-q_1^2-q_2^2)^{-2}-2V\end{pmatrix}. \tag{94}$$

Since the Garnier potential is separable in elliptic coordinates it admits an extra integral of motion of cofactor type. This gives us the possibility to instead take

$$G_{\nwarrow} = \begin{pmatrix} \lambda_1 - q_1^2 & -q_1 q_2 \\ -q_1 q_2 & \lambda_2 - q_2^2 \end{pmatrix},$$

corresponding to

$$w = \lambda_2 q_1^4 + \lambda_1 q_2^4 + (\lambda_1 + \lambda_2) q_1^2 q_2^2 - \lambda_1 \lambda_2 (q_1^2 + q_2^2).$$

Here $\alpha = -1$ and $\beta_{\uparrow} = 0$, and we can for example extend $G_{\nwarrow}$ to

$$G = \begin{pmatrix} \lambda_1 - q_1^2 & -q_1 q_2 & -q_1 q_3 \\ -q_1 q_2 & \lambda_2 - q_2^2 & -q_2 q_3 \\ -q_1 q_3 & -q_2 q_3 & \lambda_3 - q_3^2 \end{pmatrix}.$$

In a similar way as above we get in this case (after some computation) the extended system

$$\begin{aligned} \ddot{q} &= -\frac{G}{\det G} \nabla \left(\frac{\det G_{\nwarrow}}{\det G} + \frac{\det G}{\det G_{\nwarrow}} w \right) \\ &= \begin{pmatrix} -\partial_1 V \\ -\partial_2 V \\ \lambda_1 \lambda_2 q_3 \left(\dfrac{2w(q_1, q_2)}{(\det G_{\nwarrow})^2} - \dfrac{2}{(\det G)^2} + \dfrac{q_1 (\partial_1 V)/\lambda_1 + q_2 (\partial_2 V)/\lambda_2}{\det G_{\nwarrow}} \right) \end{pmatrix}, \end{aligned} \tag{95}$$

where $\det G = \lambda_1 \lambda_2 \lambda_3 (1 - q_1^2/\lambda_1 - q_2^2/\lambda_2 - q_3^2/\lambda_3)$ and $\det G_{\nwarrow} = \lambda_1 \lambda_2 (1 - q_1^2/\lambda_1 - q_2^2/\lambda_2)$.

Uniqueness in MHD in divergence form: Right nullvectors and well-posedness

Maurice H. P. M. van Putten[a)]
Massachusetts Institute of Technology, Room 2-388, Cambridge, Massachusetts 02139

(Received 30 August 2001; accepted 21 July 2002)

Magnetohydrodynamics in divergence form describes a hyperbolic system of covariant and constraint-free equations. It comprises a linear combination of an algebraic constraint and Faraday's equations. Here, we study the problem of well-posedness, and identify a preferred linear combination in this divergence formulation. The limit of weak magnetic fields shows the slow magnetosonic and Alfvén waves to bifurcate from the contact discontinuity (entropy waves), while the fast magnetosonic wave is a regular perturbation of the hydrodynamical sound speed. These results are further reported as a starting point for characteristic based shock capturing schemes for simulations with ultra-relativistic shocks in magnetized relativistic fluids. © *2002 American Institute of Physics.*

I. INTRODUCTION

Highly relativistic astrophysical fluids have been observed as highly energetic outflows, e.g., jets in active galactic nuclei, including a few optical radio-jets such as 3C273 (Pearson *et al.*, 1981; Thomson *et al.*, 1993; Bahcall *et al.*, 1995), 3C346 (Dey and van Breugel, 1994), M87 (Biretta *et al.*, 1995) and PKS 1229-21 (Le Brun *et al.*, 1997), microquasars in our galaxy (Hjellming and Rupen, 1995; Mirabel and Rodriguez, 1995; Levinson and Blandford, 1996), pulsar winds (Kennel and Coroniti, 1984), and fireballs in recent models of γ-ray bursts (Rees and Meszaros, 1994). These flows are generally time-dependent, or have been produced in a strongly time-variable episode, and hence are relativistically shocked fluid flows. In most cases, shocks are responsible for brightest emission features at the highest energies.

The evolution of strongly magnetized flows can be markedly different from unmagnetized flows. This is already apparent from small amplitude wave-motion in ideal magnetohydrodynamics compared with hydrodynamics, and their distinct shock structures. The nonlinear development of large scale morphology of strongly magnetized jets can result in features such as the formation of a nose cone (Clarke *et al.*, 1986), which is absent in hydrodynamical evolution. Of particular interest is the role of magnetic fields in the large scale, three-dimensional stability of jets and their knotted structures.

Time-dependent simulations may provide the link between the observed emission features and the internal structure such as magnetized field distribution, and boundary conditions at the source. It is hoped that simulations ultimately provide constraints on the flow parameters, perhaps also derived from stability criteria. Higher dimensional simulations of jets are performed by a number of groups in the approximation of relativistic hydrodynamics (van Putten, 1993b; Duncan and Hughes 1994; Martí *et al.*, 1995; Martí *et al.*, 1997) and relativistic magnetohydrodynamics (van Putten 1994a, b, 1996; Nishikawa *et al.*, 1997; Koide *et al.*, 1996, 1998).

The earliest approach for time-dependent simulations on shocked relativistic magnetohydrodynamic flows with dynamically significant magnetic fields uses the equations of magnetohydrodynamics (MHD) in divergence form (van Putten 1991, 1993a). The divergence technique obtains hyperbolic systems from partial differential-algebraic systems of equations, and applies more

a)Electronic mail: mvp@schauder.mit.edu

generally to the case of Yang-Mills magnetohydrodynamics in SU(N) (van Putten 1994c, d; Choquet-Bruhat 1994a, b), and general relativity (van Putten and Eardley, 1996). A linear smoothing method has been used as a shock capturing scheme for this formulation (van Putten 1993a, 1994a b, 1995). Both one- and two-dimensional simulations on astrophysical jets are performed (van Putten, 1993b, 1996; Levinson and van Putten, 1997). This method is accurate and stable, and generally performs well for relativistic shocked fluid flow with up to moderately strong shock strengths (van Putten, 1993a), and preserves divergence free magnetic fields to within machine round-off error (van Putten, 1995). A smoothing method, therefore, is appropriate for simulations on the large scale morphology of astrophysical jets.

Advanced shock capturing schemes are commonly based on characteristics, however, such as Roe's method (1981) and its extensions. These methods are generally more stable than smoothing methods for flows with ultra-relativistic shocks, such as in calculations of fire-balls for γ-ray bursts (Rees and Meszaros 1994; Wen *et al.*, 1997). It is therefore of interest to explore applications of these shock capturing schemes to relativistic MHD. Here, we describe a first step in this direction given by studying the computational stability of normalized right nullvectors (i.e., the right eigenvectors) of the characteristic matrix.

The divergence technique incorporates a constraint $c=0$ into a divergence equation of a two-form, $\nabla^a \omega_{ab}=0$, as in Faraday's equation, through the linear combination

$$\nabla^a(\omega_{ab}+\lambda g_{ab}c)=0, \quad \lambda \neq 0. \tag{1}$$

In the context of a Cauchy problem, (1) conserves $c=0$ in the future domain of dependence of the initial hypersurface with physical Cauchy data (van Putten 1991).

In this article, we identify a preferred linear combination in (1), i.e., a choice of λ and overall sign of (1) in its application to the equations of ideal MHD. This follows from two separate analyses: a derivation of the right nullvectors of the characteristic matrix and well-posedness. Somewhat remarkably, both analyses agree in their preferred linear combinations. This suggests to consider this preferred linear combination in future applications in characteristic based methods to MHD in divergence form.

The problem of linearized perturbations in relativistic MHD has been considered previously by Anile (1989) and that of Alfvén waves by Komissarov (1997). The well-posedness proof uses an extension to the Friedrichs–Lax symmetrization procedure from earlier work on Yang–Mills magnetohydrodynamics (van Putten, 1994c, d).

In Sec. II we describe nonuniqueness in the original version of the divergence technique. In Sec. III, a new derivation of the right nullvectors is given. Section IV briefly summarizes well-posedness obtained by embedding of physical solutions in a symmetric hyperbolic system of equations.

II. MHD IN DIVERGENCE FORM

Ideal MHD describes an inviscid, perfectly conductive plasma in a single fluid description with velocity four-vector, u^b $(u^c u_c=-1)$. It is given by energy-momentum conservation, $\nabla_a T^{ab}=0$, where T^{ab} is the stress-energy tensor of both the fluid and the electromagnetic field, Faraday's equations, $\nabla_a(u^{[a}h^{b]})=0$ subject to the algebraic constraint $u^c h_c=0$, and conservation, $\nabla_a(ru^a)=0$, of baryon number, r. For a polytropic equation of state with polytropic index γ, we have $T^{ab}=(r+[\gamma/(\gamma-1)](P/r)+h^2)u^a u^b+(P+h^2/2)g^{ab}-h^a h^b$, P is the hydrostatic pressure and g^{ab} is the metric tensor. The theory of relativistic magnetohydrodynamics is contained in the conservation laws of energy-momentum, $\nabla_a T^{ab}=0$, and baryon number, $\nabla_a(ru^a)=0$, together with Faraday's equations and a constraint,

$$\nabla_a(h^{[a}u^{b]})=0, \quad u^c h_c=0. \tag{2}$$

The divergence technique considers a constraint-free formulation by taking a linear combination

$$\nabla_a(h^{[a}u^{b]}+\lambda u^c h_c)=0. \tag{3}$$

Provided $\lambda \neq 0$, (3) preserves $u^c h_c = 0$ during dynamical evolution in response to physical initial data (van Putten, 1991), and no constraint violating wave-motion occurs.

Algebraically, the linear combination (3) establishes a rank-one update to its Jacobian, and hence of that of the full equations of MHD. Clearly, symmetry conditions of the Jacobian may enter a particular choice of λ. Below, we consider the choice

$$\lambda = 1, \tag{4}$$

so that

$$\begin{gathered} \nabla_a T^{ab} = 0, \\ -\nabla_a (h^{[a} u^{b]} + g^{ab} u^c h_c) = 0, \\ \nabla_a (r u^a) = 0, \\ \nabla_a (\xi^a (u^2 + 1)) = 0, \end{gathered} \tag{5}$$

where ξ is any timelike vector field and $U = (u^b, h^b, r, P)$. The minus sign in front of the present linear combination is chosen also in regards to the structure of the Jacobian of (5). This will be made explicit below.

Upon expansion, (5) obtains the system

$$A^a \partial_a U + \cdots = 0, \tag{6}$$

where the matrices $A^{aA}_B = A^{aA}_B(U) = \partial F^{aA} / \partial U^B$ are 10 by 10, and the dots refer coupling terms to the Christoffel symbols. The infinitesimal wave-structure is given by characteristic wave-fronts at given U (since the A^a are coordinate independent). The simple wave ansatz $U = U(\phi)$ obtains

$$A^a \partial_a \phi U' + \cdots = 0. \tag{7}$$

The wave-fronts are characteristic surfaces, whenever the matrix $A^a \partial_a \phi$ is singular. The directions $\nu_a = \partial_a \phi$ then are the normals to these surfaces. The small amplitude perturbations in these simple waves are given by the right nullvectors of $A^a \nu_a$. Stated differently, the small amplitude perturbations are right eigenvectors, R, of $(A^t)^{-1} A^x \nu_x$, when the wave moves along the x direction, following

$$((A^t)^{-1} A^x - v) R = 0, \tag{8}$$

where v is the velocity of propagation.

The divergence technique provides an embedding of the theory of ideal MHD in a system of ten equations. Physical initial data are properly propagated by it, without exiting nonphysical wave-modes. The physical waves (entropy waves, Alfvén and magnetohydrodynamic waves) are all contained within the light cone. Here, adding $g^{ab} u^c h_c$ (or a multiple thereof) to Faraday's equations provides a rank-one update to the characteristic matrix $A^c \nu_c$. On the light cone, however, $\nu^2 = 0$, and this linear combination no longer regularizes the characteristic determinant. (This results from insisting on covariance in the divergence formulation.) Kommissarov (1997) attempts to discuss MHD in divergence form outside the context of the initial value problem with physical initial data, and hence erroneously concludes the presence of nonphysical wave-modes.

III. THE CHARACTERISTIC MATRIX

We have

$$A^{aA}(U) = \frac{\partial F^{aA}}{\partial U^B} \nu_a = \frac{\partial F^{aA} \nu_a}{\partial U^B}; \tag{9}$$

with $\rho = r + [\gamma/(\gamma-1)]P + h^2 = rf + h^2$, we have

$$F^{cA}\nu_c = \begin{cases} \rho(u^c\nu_c)u^a + (P + h^2/2)\nu^a - (h^c\nu_c)h^a, \\ -\{(h^c\nu_c)u^a - (u^c\nu_c)h^a + \nu^a u^c h_c\}, \\ r(u^c\nu_c), \\ (\xi^c\nu_c)(u^2+1). \end{cases} \tag{10}$$

The system of 10×10 equations for $U^B = (u^b, h^b, r, P)$ can be reduced to 8×8 in the variables $V^B = (v^s, h^b, r)$ by expressing u^b in terms of the spatial three-velocity $u^b = \Gamma(1, v^s)$, $\Gamma = 1/\sqrt{1-v^2}(1, v^s)$, $s = 1,2,3$, noting that linearized wave-motion conserves entropy, so that $\mathrm{d}P = \gamma(P/r)\mathrm{d}r$. In V^B, the equation of energy conservation, $\nabla_a T^{at} = 0$ and the last equation of (5) are automatically satisfied, whence they can be ignored. In what follows, A^a shall denote the resulting 8×8 matrix, obtained from the original 10×10 matrix by deletion of the first and last row, addition of the last column (multiplied by $\gamma P/r$) to the one-but last column (associated with r), followed by deletion of the first and last columns.

The linearized wave-structure is given by the characteristic problem

$$A^c\nu_c z = 0 \tag{11}$$

for the right null-vectors $z = U'$. Without loss of generality, (11) can be studied in a co-moving frame, in which $u^b = (1,0,0,0)$. In this event, $\Gamma = 1$ and $\partial\Gamma/\partial v^s = 0$. Furthermore, the x-axis of the local coordinate system can be aligned with the magnetic field, so that $h^b = (0,H,0,0)$. Given the two orientations u^s and h^b, the wave-structure is rotationally symmetric about the x axis, and hence ν_y and ν_z act symmetrically as $\sqrt{\nu_y^2 + \nu_z^2}$; we will put $\nu_z = 0$. For $A^c\nu_c$, we have

$$\begin{bmatrix} \rho\nu_1 & 0 & 0 & -\nu_1 H & -H\nu_2 & -H\nu_3 & 0 & \dfrac{\gamma P\nu_2}{r} \\ 0 & \rho\nu_1 & 0 & 0 & H\nu_3 & -H\nu_2 & 0 & \dfrac{\gamma P\nu_3}{r} \\ 0 & 0 & \rho\nu_1 & 0 & 0 & 0 & -H\nu_2 & 0 \\ \nu_1 H & 0 & 0 & -\nu_1 & -\nu_2 & -\nu_3 & 0 & 0 \\ -H\nu_2 & H\nu_3 & 0 & \nu_2 & \nu_1 & 0 & 0 & 0 \\ -H\nu_3 & -H\nu_2 & 0 & \nu_3 & 0 & \nu_1 & 0 & 0 \\ 0 & 0 & -H\nu_2 & 0 & 0 & 0 & \nu_1 & 0 \\ r\nu_2 & r\nu_3 & 0 & 0 & 0 & 0 & 0 & \nu_1 \end{bmatrix}. \tag{12}$$

Note that the lower diagonal block is ν_1 times the 4×4 indentity matrix. *This results from the sign choice in the given combination of Faraday's equations and the constraint in (5) and (10).* Furthermore, notice that the third and seventh rows and columns act independently to give rise to the Alfvén waves. The remaining waves are described by the reduced problem

$$(A^c\nu_c)'z' = 0, \tag{13}$$

where $(A^c\nu_c)'$ is obtained from $A^c\nu_c$ by deleting the third and seventh rows and columns, thereby obtaining a problem in the six-dimensional variable z'. Introducing

$$z' = \begin{pmatrix} x \\ y \end{pmatrix}, \tag{14}$$

(11) takes the form of a coupled system of 3×3 equations

$$\nu_1 Z x + X y = 0, \quad Y x + \nu_1 y = 0, \tag{15}$$

in which

$$Z=\begin{bmatrix}\rho & 0 & -H\\ 0 & \rho & 0\\ H & 0 & -1\end{bmatrix},$$

$$X=\begin{bmatrix}-H\nu_2 & -H\nu_3 & \dfrac{\gamma P\nu_2}{r}\\ H\nu_3 & -H\nu_2 & \dfrac{\gamma P\nu_3}{r}\\ -\nu_2 & -\nu_3 & 0\end{bmatrix}, \tag{16}$$

$$Y=\begin{bmatrix}-H\nu_2 & H\nu_3 & \nu_2\\ -H\nu_3 & -H\nu_2 & \nu_3\\ r\nu_2 & r\nu_3 & 0\end{bmatrix}.$$

This obtains a *single* 3×3 eigenvalue problem in x, given by

$$XYx=\nu_1^2 Zx\Leftrightarrow Z^{-1}XYx=\nu_1^2 x. \tag{17}$$

Here, $Z^{-1}XY-\nu_1^2$ is given by the matrix

$$\begin{bmatrix}W_{1,1} & W_{1,2} & 0\\ W_{2,1} & W_{2,2} & 0\\ \dfrac{H(\gamma P\nu_2^2-rf\nu_2^2-rf\nu_3^2)}{rf} & \dfrac{H\gamma P\nu_2\nu_3}{rf} & \nu_2^2+\nu_3^2-\nu_1^2\end{bmatrix}, \tag{18}$$

where the upper diagonal 2×2 matrix W is given by

$$W=\begin{bmatrix}\dfrac{\gamma P\nu_2^2}{rf}-\nu_1^2 & \dfrac{\gamma P\nu_2\nu_3}{rf}\\ \dfrac{\gamma P\nu_2\nu_3}{rf+H^2} & \dfrac{H^2\nu_3^2+H^2\nu_2^2+\gamma P\nu_3^2}{rf+H^2}-\nu_1^2\end{bmatrix}. \tag{19}$$

The two zeros in the third column of (18) result from $\lambda=1$. Upon substitution $\nu_3^2=\nu^2+\nu_1^2-\nu_2^2$, the determinant assumes the covariant expression

$$\rho\det W=(rf-\gamma P)(u^c\nu_c)^4-(h^2+\gamma P)\nu^2(u^c\nu_c)^2+\frac{\gamma P}{rf}(h^c\nu_c)^2\nu^2. \tag{20}$$

Alfvén waves. The eigenvalues for the Alfvén waves are given by

$$\nu_1=\pm\frac{|h^c\nu_c|}{\sqrt{\rho}} \tag{21}$$

with null-vector

$$z=(0,0,H\nu_2,0,0,0,\rho\nu_1,0)^T, \tag{22}$$

associated with Alfvén waves; covariantly,

$$U^A=(v^a,\pm\sqrt{\rho}v^a,0,0)^T, \tag{23}$$

where v_a may be taken to be

$$H(0,0,\nu_4,-\nu_3)=\epsilon_{abcd}u^b h^c \nu^d \equiv v_a . \tag{24}$$

Thus, the Alfvén wave is transversal in which h^2 is conserved (δh^b is orthogonal to h^b).

Magnetohydrodynamic waves. The eigenvalues for the magnetohydrodynamic waves are given by the roots of the characteristic determinant (20). Writing

$$n^b=\nu^b+(u^c\nu_c)u^c, \tag{25}$$

we have $\nu^2=-t^2+n^2$, $t=u^c\nu_c$, $n^2=n^c n_c$. Let $\alpha=rf/\gamma P$ and $\beta=h^2/\gamma P$. Then

$$\frac{(h^c\nu_c)^2}{rfn^2}=\frac{\beta}{\alpha}\frac{(h^c n_c)^2}{h^2 n^2}\equiv\frac{\beta}{\alpha}\cos^2\phi. \tag{26}$$

Consequently, (20) becomes

$$(\alpha-1)v^4-(1+\beta)v^2(1-v^2)+\beta\alpha^{-1}\cos^2\phi(1-v^2)=0, \tag{27}$$

where $v^2=t^2/n^2$. Equation (27) has real solutions v for any given n^b, whenever

$$(\alpha+\beta)v^4-(1+\beta+\beta\alpha^{-1})v^2+\beta\alpha^{-1}=0 \tag{28}$$

has real solutions v. But (28) has discriminant

$$D=(\alpha+\beta-\alpha\beta)^2\geqslant 0. \tag{29}$$

Weak magnetic fields are described by small β expansions as follows.

Proposition 3.1: Fast magnetosonic waves are a regular perturbation of sound waves in pure hydrodynamics, while the Alfvén and slow magnetosonic waves bifurcate from entropy waves (contact discontinuities), whose propagation velocities satisfy

$$v_f^2/v_h^2\sim 1+\beta\frac{\alpha-1}{\alpha}\sin^2\phi+O(\beta^2),$$

$$v_A^2/v_h^2\sim\beta\cos^2\phi[1-\beta\alpha^{-1}+O(\beta^2)], \tag{30}$$

$$v_s^2/v_h^2\sim\beta\cos^2\phi\left[1-\beta\left(1-\frac{\alpha-1}{\alpha}\cos^2\phi\right)+O(\beta^2)\right],$$

where $v_h^2=\alpha^{-1}$ *is the square of the hydrodynamical velocity, and which obey the inequalities*

$$v_s^2\leqslant v_A^2\leqslant v_f^2 . \tag{31}$$

Inequalities (31) remain valid for general β (e.g., Bazer and Ericson, 1959; Lichnerowicz, 1967; Anile, 1989).

IV. RIGHT NULLVECTORS

Inspection of (19), together with (15), shows the null-vector

$$z=\begin{pmatrix} \nu_1\nu_2\nu_3^2 \\ -\nu_1\nu_3(\nu_2^2-\alpha\nu_1^2) \\ 0 \\ H\nu_1\nu_2\nu_3^2 \\ H\nu_3^2(\nu_2^2-\alpha\nu_1^2) \\ -H\nu_2\nu_3(\nu_2^2-\alpha\nu_1^2) \\ 0 \\ -\alpha r\nu_3^2\nu_1^2 \end{pmatrix}. \tag{32}$$

Of course, (32) can be stated covariantly by noting that $H^2=h^2$, $H\nu_2=h^c\nu_c$, $\nu_1=u^c\nu_c$,

$$H^2(\nu_2^2-\alpha\nu_1^2)=(h^c\nu_c)^2-\alpha h^2(u^c\nu_c)^2\equiv h^2k_1, \tag{33}$$

and introducing

$$H(0,\nu_4^2+\nu_3^2,-\nu_2\nu_3,-\nu_2\nu_4)^T=\epsilon_{abcd}u^b\nu^cv^d\equiv w_a. \tag{34}$$

Since $-\alpha r\nu_3^2\nu_1^2$ is a scalar, ν^3 is to be treated as

$$H^2(\nu_3^2+\nu_4^2)=h^2n^2-(h^c\nu_c)^2\equiv h^2k_2, \tag{35}$$

where $n_a=\nu_a+(u^c\nu_c)u_a$. Note that

$$k_1=n^2(\cos^2\phi-\alpha v^2),\quad k_2=n^2\sin^2\phi, \tag{36}$$

where $v=v_s$, v_f. Clearly, z is formed from

$$\begin{aligned} \delta u^b&=-t(k_1n^b-(k_2+k_1)(\hat{h}^cn_c)\hat{h}^b), \\ \delta h^b&=k_1w^b+k_2t(h^cn_c)u^b, \\ \delta r&=-\alpha rk_2t^2, \\ \delta P&=-rfk_2t^2, \end{aligned} \tag{37}$$

where $\hat{h}^b=h^b/|h|$, and

$$v_a=\epsilon_{abcd}u^bh^c\nu^d,\quad w_a=\epsilon_{abcd}u^b\nu^cv^d. \tag{38}$$

We thus have the following.

Proposition 3.2: Given a unit vector n^b orthogonal to u^b, and a root $\nu^b=n^b+vu^b$, $v=u^c\nu_c$ of (28), the right nullvectors for the hydrodynamical waves of (11), $U^A=(\delta u^b,\delta h^b,\delta r,\delta P)$, are

$$\begin{aligned} \delta u^b&=v[\sin^2\phi n^b-(1-\alpha v^2)(n^b-\cos\phi\,\hat{h}^b)], \\ \delta h^b&=|h|[(\cos^2\phi-\alpha v^2)\tilde{w}^b+v\sin^2\phi\cos\phi u^b], \\ \delta r&=-v^2\alpha r\sin^2\phi, \\ \delta P&=-v^2rf\sin^2\phi. \end{aligned} \tag{39}$$

where $\tilde{w}^b = w^b/|h|$.

Anile (1989) gives a different form of these right nullvectors. By Proposition 3.1, our weak magnetic field limits show that

$$\cos^2\phi - \alpha v_f^2 < 0 \tag{40}$$

for fast magnetosonic waves, while

$$\cos^2\phi - \alpha v_s^2 > 0 \tag{41}$$

for slow magnetosonic waves. Inspection of (34) shows that therefore the tangential component of the magnetic field is strengthened in fast magnetosonic waves, while it is weakened in slow magnetosonic waves. This distinguishing aspect of fast and slow magnetosonic waves was first noted by Bazer and Ericson (1959) in their analysis of shocks in nonrelativistic MHD.

The limit of small β is of particular interest to computation. For example, in various settings a magnetized fluid streams into a nearly unmagnetized environment. A characteristics based scheme must therefore reliably treat a large dynamic range in β. Clearly, a full set of nullvectors (including those of contact discontinuities) obtains for nonzero β. However, the behavior of these nullvectors is somewhat nontrivial as β becomes small. In what follows, we consider the small β limit, in the sense of small $|h|/\sqrt{\gamma P}$, while keeping the direction $\hat{h}^b$ constant. In this limit,

$$\begin{aligned} 1-\alpha v^2 &\sim -\beta\frac{\alpha-1}{\alpha}\sin^2\phi + O(\beta^2), \\ 1-\alpha v^2 &\sim 1 + O(\beta) \end{aligned} \tag{42}$$

for the fast and slow magnetosonic speeds, respectively.

Corollary 4.1: In the limit of low magnetic field strength, the fast magnetosonic waves are described by the right nullvectors

$$\begin{aligned} \delta u^b &= v_f n^b + \beta\frac{\alpha-1}{\alpha}(n^b - \cos\phi\hat{h}^b)v_f + O(\beta^2), \\ \delta h^b &= |h|(-\tilde{w}^b + v_f\cos\phi u^b) + \beta\frac{\alpha-1}{\alpha}w^b + O(\beta^2), \\ \delta r &= -v_f^2\alpha r, \\ \delta P &= -v_f^2 r f, \end{aligned} \tag{43}$$

and the slow magnetosonic waves by

$$\begin{aligned} \delta u^b &= \cos\phi(\hat{h}^b - \cos\phi n^b) + O(\beta), \\ \delta h^b &= \sqrt{\gamma P}(\cos\phi\tilde{w}^b + v_s\sin^2\phi u^b) + O(\beta), \\ \delta r &= -v_s\alpha r\sin^2\phi, \\ \delta P &= -v_s\alpha r f\sin^2\phi. \end{aligned} \tag{44}$$

The small β limit of the nullvectors can now be normalized.

A. Bifurcations from entropy waves

The behavior of the nullvectors in the limit of weak magnetic fields can be derived from (23) and Corollary 4.1. To this end, note that

$$v^a = |h|\tilde{v}^a = \sin\phi |h|\hat{v}^a, \tag{45}$$

where $\hat{v}^c\hat{v}_c = 1$, and ϕ denotes the angle between n^c and h^c,

$$n^b = \cos\phi \hat{h}^b + \sin\phi y^b, \tag{46}$$

$y^c u_c = h^c y_c = 0$, $y^c y_c = 1$ (n^b is normalized to be unit, as in the assumptions of Proposition 3.2). It follows that the Alfvén nullvectors may be normalized to

$$\delta\hat{U}^A = (\hat{v}^a, \pm\sqrt{\rho}\hat{v}^a, 0, 0). \tag{47}$$

In the limit of vanishingly small β, the pair of slow magnetosonic waves collapse to the single normalized nullvector

$$\delta\hat{U}^A = (y^b, \sqrt{\gamma P}y^b, 0, 0). \tag{48}$$

Note that $y^c\hat{v}_c = 0$, so that (47) and (48) are independent. Division by $\sin\phi$ thus provides a normalization of the original expressions (23) and (44).

The nullvector associated with entropy waves ($u^c\nu_c = 0$) is

$$\delta U^A = (0, 0, \delta r, 0) \tag{49}$$

if $h^c\nu_c \neq 0$, and

$$(0, \delta h^c, \delta r, \delta P), \quad (\delta u^c, 0, 0, 0) \tag{50}$$

if $h^c\nu_c = 0$, subject to

$$\delta P + h_c\delta h^c = 0, \quad \nu_c\delta h^c = 0, \quad \nu_c\delta u^c = 0. \tag{51}$$

The second case refers to transverse MHD for which continuity must hold of total pressure, zero orthogonal magnetic field and transverse velocity. Note that transverse MHD has two nullvectors, and corresponds to the case of pure hydrodynamics. With the exception of transverse MHD, therefore, the contact discontinuity provides one nullvector.

Transverse MHD or pure hydrodynamics allows for shear along contact discontinuities, which is responsible for the two independent nullvectors. Whenever magnetic field lines cross a contact discontinuity, however, the persistent coupling to the magnetic field lines in ideal MHD prohibits shear. In ideal MHD, the response to the original two-dimensional degree of freedom in shear is two new wave-modes. These wave-modes are the Alfvén wave and the slow magnetosonic wave. These two wave-modes are indeed different, as (47) and (48) show. The Alfvén and slow magnetosonic wave may be regarded as one pair, bifurcating from the contact discontinuity. This has been illustrated in Fig. 6 of van Putten (1993a). Indeed, *the limit of vanishing β recovers the two shear modes from the independent Alfvén and slow magnetosonic waves*. Of course, the Alfvén wave is purely rotational, while the slow magnetosonic wave is slightly helical, including a longitudinal variation of $\pm v_s\sin^2\phi = \pm\beta\sin^2\phi\cos\phi$. The fast magnetosonic wave remains a regular perturbation of the ordinary sound wave.

The weak magnetic field limit thus obtains two nullvectors from the fast magnetosonic waves, two from the Alfvén waves, one from the slow magnetosonic waves and generally one from the contact discontinuity, a total of six. This leaves an apparent degeneracy of one.

The degeneracy stems from the neighboring to order v_s of the two nullvectors of the slow magnetosonic waves. This would suggest ill-posedness to this order in projections. However,

characteristic based methods consider the product of the projections on the nullvectors *and* the associated eigenvectors. In the present case, therefore, the order of the degeneracy is precisely cancelled by multiplication with the eigenvalue v_s, which is computationally stable. The limit of arbitrarily small β *in the application of characteristic based methods* is computationally well-posed.

V. WELL-POSEDNESS

The theory of ideal relativistic MHD was first shown to be well-posed by Friedrichs (1974), using the Friedrichs–Lax symmetrization procedure. The problem of constraints was circumvented by a reduction of variables. The symmetrization procedure of Fredrichs and Friedrichs and Lax (1971) applies to hyperbolic systems of equations of the form

$$\nabla_a F^{aB} = f^B, \tag{52}$$

which satisfy a certain convexity condition. The presence of conserved constraints, however, can be treated also by an extension of the Friedrichs–Lax symmetrization procedure, with no need for an additional reduction of variables, developed in earlier work on Yang–Mills magnetohydrodynamics in SU(N) (van Putten, 1994c, d). Once in symmetric hyperbolic form, well-posedness results from standard energy arguments (e.g., Fisher and Marsden, 1972). The main arguments of symmetrization in the presence of constraints are briefly recalled here, to highlight the same linear combination of (5), now from the point of view of well-posedness.

A. Symmetrization with constraints

Variations δV^A of (u^b, h^b, r, P) can be unconstraint (with respect to all ten degrees of freedom), and constraint, i.e., those obeying the constraints. For example, $\delta c \neq 0$ results from a total variation, while $\delta c = 0$ is a constraint variation. Symmetrization in the presence of constraints follows if there exists a vector field W_A which produces a total derivative in the modified main dependency relation

$$\text{YI:} \quad W_A \delta F^{aA} \equiv \delta z^a, \tag{53}$$

and which obtains constraint positive definiteness in

$$\text{YII:} \quad \delta W_A \delta F^{aA} \xi_a > 0 \tag{54}$$

for some timelike vector ξ^a. Of course, the source terms f^B must satisfy the consistency condition

$$W_A f^A = 0 \tag{55}$$

whenever the constraints are satisfied. Allowing a possible nonzero total derivative in YI defines an extension (van Putten, 1994c, d) to the Friedrichs–Lax (1971) symmetrization procedure.

Differentiation by V^C of the unconstraint identity YI obtains

$$\frac{\partial W_A}{\partial V^C} \frac{\partial F^{aA}}{\partial V^D} \nabla_a V^D + \frac{W_A \partial^2 F^{aA}}{\partial V^C \partial V^D} \nabla_a V^D = \frac{\partial^2 z}{\partial V^C \partial V^D} \nabla_a V^D. \tag{56}$$

This establishes symmetry of the matrices

$$A^a_{CD} = \frac{\partial W_A}{\partial V^C} \frac{\partial F^{aA}}{\partial V^D}. \tag{57}$$

Also,

$$\delta V^C A^a_{CD} \xi_a \delta V^D = \left(\delta V^C \frac{\partial W_A}{\partial V^C} \right) \left(\frac{\partial F^{aA} \xi_a}{\partial V^D} \delta V^D \right) = \delta W_A \delta F^{aA} \xi_a > 0 \tag{58}$$

for all constraint variations δV^A. Of course, given V^A, the constraint variations δV^A define a linear subspace $\mathcal{V}$ of dimension $N-m$, where m is the number of constraints $c=0$, each giving rise to

$$0=\delta c=\frac{\partial c}{\partial V^A}\,\delta V^A. \tag{59}$$

We have the following construction (van Putten, 1994c, d).

Lemma 5.1: Given a real-symmetric $A\epsilon\mathcal{L}(\mathrm{R}^n,\mathrm{R}^n)$ which is positive definite on a linear subspace $\mathcal{V}\subset\mathrm{R}^n$, there exists a real-symmetric, positive definite $A^*\epsilon\mathcal{L}(\mathrm{R}^n,\mathrm{R}^n)$ such that

$$A^*y=Ay \quad (y\epsilon\mathcal{V}). \tag{60}$$

This may be seen as follows. Consider $A^*=A+\mu x^Tx$, where x is a unit element from $V^\perp$. Then A^* is symmetric positive definite on $V'=\{z=y+\lambda x|y\epsilon V,\lambda\epsilon R\}$: $z^TA^Tz\geqslant c'\|z\|^2=c'(\|y\|^2+\lambda^2\|x\|^2)$ with $c'>0$ upon choosing $\mu>M$, where $M=\|A\|$ denotes the norm of A. This construction may be repeated until $V^\perp$ is exhausted, leaving A^* symmetric positive definite on R^n as an embedding of A on V.

The real-symmetric matrix $A^a_{CD}\xi_a$ is positive definite on the subspace of constraint variations $\mathcal{V}$; let $(A^a_{CD}\xi_a)^*$ be the positive definite, symmetric matrix obtained from the lemma. It follows that solutions to (52) (and its constraints) satisfy the *symmetric positive definite* system of equations

$$-(A^{aAB})^*\xi_a(\xi^c\nabla_c)V_A+A^{aAB}(\nabla_\Sigma)_aV_A=f^B, \tag{61}$$

where

$$\nabla_a=-\xi_a(\xi^c\nabla_c)+(\nabla_\Sigma)_a\,. \tag{62}$$

It remains to show that ideal MHD satisfies properties YI and YII.

B. Symmetrization of hydrodynamics

Relativistic hydrodynamics has been shown to be symmetrizable by Friedrichs (1974), Ruggeri and Strumia (1981), and Anile (1989). This uses the equations in the form

$$\nabla_aF^{aA}_f=\begin{cases}\nabla_a(rfu^au^b+Pg^{ab})=0,\\ \nabla_a(ru^a)=0,\\ \nabla_a(rSu^a)=0\end{cases} \tag{63}$$

away from entropy generating shocks. Then $W^f_A=(u_a,f-TS,T)$ and $V^f_C=(v_\alpha,T,f)$ with a reduction of variables on the velocity four-vector by $u^b=\Gamma(1,v^\alpha)$, where Γ is the Lorentz factor. With F^{aA}_f denoting the fluid dynamical equations $\nabla_aT^{ab}_f=0$, $T^{ab}_f=rfu^au^b+Pg^{ab}$ with f the specific enthalpy, and $\nabla_a(ru^a)=0$, it has been shown that (Ruggeri and Strumia, 1981; Anile, 1989)

$$W^f_A\delta F^{aA}_f\equiv 0, \quad Q_f=\delta W_A\delta F^{aA}_f\xi_a>0, \tag{64}$$

provided that the free enthalpy $G(T,P)=f-TS-1$ is concave, and the sound velocity is less than the speed of light. Under these conditions, the hydrodynamical equations alone, therefore, satisfy YI and YII, and in fact the original Friedrichs–Lax conditions CI and CII of Friedrichs and Lax (1971), so that they satisfy a symmetric hyperbolic system of equations.

C. Symmetrization of ideal MHD

In what follows, we set

$$\omega_{ab}=h^a u^b-u^a h^b+g^{ab}u^c h_c,$$
$$T_m^{ab}=h^2 u^a u^b+\tfrac{1}{2}h^2 g^{ab}-h^a h^b. \tag{65}$$

We then have the expansions

$$\begin{aligned} u_b\delta T_m^{ab}&=u_b(h^2u^a\delta u^b+h^2u^b\delta u^a+2u^a u^b h_c\delta h^c+g^{ab}h_c\delta h^c-h^a\delta h^b-h^b\delta h^a)\\ &=-h^2\delta u^a-u^a(h_c\delta h^c)-h^a(u_c\delta h^c)-c\,\delta h^a,\\ h_b\delta\omega^{ab}&=h_b(h^a\delta u^b+u^b\delta h^a-h^b\delta u^a-u^a\delta h^b+g^{ab}\delta c)\\ &=h^a(h_c\delta u^c)+c\,\delta h^a-h^2\delta u^a-u^a(h_c\delta h^c)+h^a\delta c. \end{aligned} \tag{66}$$

We hereby arrive at the identity

$$u_b\delta T_m^{ab}-h_b\delta\omega^{ab}\equiv\delta z^a, \tag{67}$$

where $z^a=-2h^a c$. *The total derivative in (67) follows by the unique linear combination* $\omega^{ab}=h^a u^b-h^b u^a+g^{ab}c$, *as in (5).* With $W_A=(u_a,h_a,f-TS,S)$ and F^{aA} given by (5) [rewritten according to (63)], it follows that

$$W_A\delta(F_f^{aA}+F_m^{aA})\equiv\delta z^a. \tag{68}$$

A similar calculation (van Putten, 1994c, d) shows that quadratic of constraint variations Q_m given by

$$\delta u_b\delta T_m^{ab}\xi_a-\delta h_b\delta\omega^{ab}\xi_a=(u^c\xi_c)[h^2(\delta u)^2+(\delta h)^2]+2[(\xi_c\delta u^c)(h_c\delta h^c)-(h^c\xi_c)(\delta u_c\delta h^c)] \tag{69}$$

is positive definite (for $\delta h^a\neq 0$). Therefore, the sum

$$Q=\delta W_A\delta F^{aA}\xi_a=Q_f+Q_m \tag{70}$$

is constraint positive definite, whenever Q_f is such (with respect to the fluid dynamical variables). It follows that both YI and YII are satisfied [with $W_A=(u_a,h_a,f-TS,S)$ and $V_A=(v_\alpha,h_a,T,f)$], and hence physical solutions to (5) satisfy the symmetric hyperbolic system (61) with $f^B=0$.

(Received 8 May 2002; accepted 25 June 2002)

In this article we study the four-particle decay of the Bethe–Salpeter (B-S) kernel for the high-temperature Ising model. We use the hyperplane decoupling method [T. Spencer, Commun. Math. Phys. **44**, 143 (1975); R. S. Schor, Nucl. Phys. B **222**, 71 (1983)] to prove exponential decay in a set of variables particularly adapted to the methods of Spencer and Zirilli [Commun. Math. Phys. **49**, 1 (1976)] for the analysis of scattering and bound states in QFT, transcribed to lattice theories by Auil and Barata [Ann. Henri Poincare **2**, 1065 (2001)]. We study arbitrary derivatives of the general n-point correlation functions with respect to the interpolating variables, and we are able to obtain, in some cases, information about the third derivatives of the B-S kernel. As a later consequence, we have two-body asymptotic completeness for the (massive) Euclidean lattice field theory implemented by this model. This allows us to analyze the Ornstein–Zernike behavior of four-point functions, related to the specific heat of the model. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1510176]

I. INTRODUCTION AND MAIN RESULT

The exponential decay properties of the Bethe–Salpeter (B-S) kernel are used in the analysis of the energy-momentum (e-m) spectrum in the low energy range for weakly coupled models. The methods employed to prove these decay properties are basically lattice analogous of the techniques originally introduced in Euclidean QFT. The work of Spencer[1] introduced new procedures, namely, the decoupling of hyperplane method, then used, in the sequel, in a program about the investigation of the e-m spectrum of $P(\phi)_2$ models.[2–7] The hyperplane decoupling method was introduced in lattice theories in Ref. 8. Several results have been developed recently along the same ideas to analyze e-m spectrum for a wide class of lattice models. Those results focalize basically the existence (or not) of bound states[9–14] and two-body asymptotic completeness (a.c.)[15] in Euclidean lattice theories.

In the present article we verify the four-particle exponential decay, in the sense of Spencer,[1] of the B-S kernel for the ferromagnetic Ising model (IM) at high-temperatures ($\beta \ll 1$). Our analysis is mainly based in polymer expansion and the ''hyperplane decoupling'' method, following closely Ref. 1. Using the results of Ref. 15, this decay property actually proves the two-particle a.c. of the model, because Gaussian domination inequalities hold in this case and exclude bound states from the spectrum, as remarked in Ref. 12. One relevant fact for the standpoint of statistical mechanics is that two-particle a.c. allows us to study the Ornstein–Zernike behavior of four-point functions related to the specific heat of the model. In fact, the exponent in the polynomial correction to the exponential decay is twice that in the presence of bound states, as we remark below in more detail.

We give a more precise description of the method and the model. In the lattice of integers in $d+1$ dimensions $\mathbb{Z}^{d+1}$, with $d \geqslant 1$, the sites will be denoted by $x=(x_0,x_1,\ldots,x_d)$ or $(x_0,\mathbf{x})$ for short. Finite subsets of sites will be denoted generically by Λ. The decoupling method is applicable to hyperplanes perpendicular to any fixed direction parallel to the coordinate axis. To fix

a)Electronic mail: auil@fma.if.usp.br

ideas, and for sake of brevity, here we consider only the x_0 direction, but it is important to have in mind that the method and all results below are equally applicable to the other directions independently. For this aim, we introduce the IM with an anisotropy in the x_0 direction; the boundary conditions are free. Explicitly, the local states are given by

$$\mu_\Lambda(f) := \frac{\Sigma_{\sigma\in S^\Lambda} f(\sigma)\exp(\beta\Sigma_{\langle ij\rangle} J_{ij}\sigma(i)\sigma(j))}{\Sigma_{\sigma\in S^\Lambda}\exp(\beta\Sigma_{\langle ij\rangle} J_{ij}\sigma(i)\sigma(j))}, \tag{1.1}$$

for functions f on the configurations $S^\Lambda=\{\sigma/\sigma:\Lambda\to\{-1,+1\}\}$, where the sum in the exponents is over all the nearest-neighbor, or bounds, and

$$J_{ij} := \begin{cases} J & \text{if } \{i,j\}=\{(n,\mathbf{x}),(n,\mathbf{y})\}, \\ J_m & \text{if } \{i,j\}=\{(m,\mathbf{x}),(m+1,\mathbf{x})\}; \end{cases}$$

being J and J_m strictly positive numbers. The first of them gives the coupling between nearest-neighbor lying in the same hyperplane defined by $x_0=\text{const}=n$, while the J_m's give the coupling between nearest-neighbor lying in two different of such hyperplanes. The isotropic ferromagnetic IM is obtained taking $J_m=J$, $\forall m\in\mathbb{Z}$. In our study we consider the J_{ij}'s as being complex variables and, for convenience, it is useful to introduce a new variable g_{ij} given by g_{ij} $:=\tanh(\beta J_{ij})$. Just for reference, the g_{ij}'s will be called the *interpolating variables*. The correlations, or (local) n-point Euclidean, functions are given by

$$\mathcal{S}_n^\Lambda(x_1,\ldots,x_n) := \frac{\Sigma_{\sigma\in S^\Lambda}\sigma(x_1)\cdots\sigma(x_n)\Pi_{\langle ij\rangle}e^{\beta J_{ij}\sigma(i)\sigma(j)}}{\Sigma_{\sigma\in S^\Lambda}\Pi_{\langle ij\rangle}e^{\beta J_{ij}\sigma(i)\sigma(j)}}. \tag{1.2}$$

The limit $\mathcal{S}_n(x_1,\ldots,x_n) := \lim_{\Lambda\uparrow\mathbb{Z}^{d+1}}\mathcal{S}_n^\Lambda(x_1,\ldots,x_n)$ exists and is translation invariant. As we deal with a model without bound states, we could expect to be compelled to the analysis of derivatives of higher order than in the case of models exhibiting bound states. In our approach, we consider arbitrary derivatives of the n-point correlation functions with respect to the interpolating variables g_{ij}, providing general results and considering lately its particularization for two- and four-point functions. Joining our different particular results, we are able to obtain, in some cases, information about the third (and lower) derivatives of the B-S kernel; see Lemma 4.10 later in this work. Higher derivatives of the two-point function were also considered in Refs. 16 and 17.

We define the connected part of the truncated four-point function as

$$\mathcal{D}(x_1,x_2,x_3,x_4) := \mathcal{S}_4(x_1,x_2,x_3,x_4) - \mathcal{S}_2(x_1,x_2)\mathcal{S}_2(x_3,x_4), \tag{1.3}$$

and the unconnected part as

$$\mathcal{D}_0(x_1,x_2,x_3,x_4) := \mathcal{S}_2(x_1,x_3)\mathcal{S}_2(x_2,x_4) + \mathcal{S}_2(x_1,x_4)\mathcal{S}_2(x_2,x_3). \tag{1.4}$$

We introduce the Bethe–Salpeter (B-S) equation on the lattice

$$\mathcal{D}(x_1,x_2,x_3,x_4) = \mathcal{D}_0(x_1,x_2,x_3,x_4) - \sum_{y_1,y_2,y_3,y_4\in\mathbb{Z}^{d+1}} \mathcal{D}_0(x_1,x_2,y_1,y_2)\mathcal{N}(y_1,y_2,y_3,y_4)\mathcal{D}(y_3,y_4,x_3,x_4), \tag{1.5}$$

or symbolically $\mathcal{D}=\mathcal{D}_0-\mathcal{D}_0\mathcal{N}\mathcal{D}$ for short. Here, the B-S kernel $\mathcal{N}$ is self-defined by this equation. The B-S equation has the formal solution $\mathcal{D}=\mathcal{D}_0(\mathbb{1}+\mathcal{N}\mathcal{D}_0)^{-1}$, provided this inverse exists. Taking formally inverses in this last relation we get $\mathcal{N}=\mathcal{D}^{-1}-\mathcal{D}_0^{-1}$, a convenient expression for the B-S kernel. In fact, this expression allows us to define rigorously the B-S kernel as an operator on the space $\ell_s^2 := \{\{a_{ij}\}_{i,j\in\mathbb{Z}^{d+1}}\in\ell^2(\mathbb{Z}^{d+1}\times\mathbb{Z}^{d+1}): a_{ij}=a_{ji}\}$ of symmetrical quadratically summable se-

quences indexed by pairs of sites. In this space, the inverse $\mathcal{D}_0^{-1}$ is explicitly given by expression (4.1); see Lemma 4.5(c). The inverse $\mathcal{D}^{-1}$ exists and is well-defined as consequence of Lemma 4.7(a) and Lemma 4.8(b); see also expression (4.3).

For sites $i=(i_0,i_1,\ldots,i_d)\in\mathbb{Z}^{d+1}$ we denote $\|i\|=\Sigma_{k=0}^{d}|i_k|$. We can now state our main result as follows.

Theorem 1.1: *For the IM with β sufficiently small there exist $m=m(\beta)$ and $C=C(\beta)$ such that*

$$|\mathcal{N}(i,j,k,l)|\leqslant C\mathrm{e}^{-m(\|i-j\|+\|k-l\|+2\|i+j-k-l\|)}, \tag{1.6}$$

for all $i,j,k,l\in\mathbb{Z}^{d+1}$. □

Note the particular combination of the sites at the exponent in the relation (1.6), becoming analogous to the property proved in Ref. 1 for some $P(\phi)_2$ models in QFT. Theorem 1.1 has the following consequence: the B-S kernel in momentum space $K(k,p,q)$ is analytic in the region

$$|\mathrm{Im}\,k_0|<2m,\quad |\mathrm{Im}\,p_i|<m,\quad |\mathrm{Im}\,q_i|<m\quad (i=0,1,\ldots,d);$$

where K is defined by $\check{K}(i+j-k-l,i-j,k-l)=\mathcal{N}(i,j,k,l)$; see Refs. 15 and 18. As we remark above, these analyticity properties plus the absence of bound states and the upper and lower mass gap imply the two-particle a.c. for the model; see Ref. 15 for details. (See the last remark at the end of Sec. III.)

To state the Ornstein–Zernike behavior of the four-point functions implied by the a.c. condition we introduce before a few definitions. In terms of the new variables

$$\xi:=x_1-x_2,\quad \eta:=x_3-x_4,\quad \tau:=x_1+x_2-(x_3+x_4), \tag{1.7}$$

and expressing, by the translation invariance, the two- and four-point functions in terms of the difference variables $\mathcal{S}_n(x_1,\ldots,x_n)=S_n(x_1-x_n,\ldots,x_{n-1}-x_n)$, we get

$$\mathcal{D}(x_1,x_2,x_3,x_4)=S_4\left(\frac{\tau+\xi+\eta}{2},\frac{\tau-\xi+\eta}{2},\eta\right)-S_2(\xi)S_2(\eta)=:D(\tau,\xi,\eta). \tag{1.8}$$

The change of variables given by (1.7) requires certain care in the lattice context. Here, we remark that for each of the new variables τ, ξ and η are allowed to vary freely in the whole lattice $\mathbb{Z}^{d+1}$ if we redefine D, introduced in (1.8), by D times the characteristic function of the image of the transformation (1.7). The details were extensively discussed in Ref. 15, Appendix A. Denoting by $\hat{}$ the Fourier transform, define $R(k,p,q):=\hat{D}(k,p,q)$, and consider it as a family of integral operators indexed by k, acting as $[R(k)f](p)=\int_{\mathbb{T}^{d+1}}R(k,p,q)f(q)dq$. For fixed f belonging to a suitable set, denote the map $k_0\mapsto\langle f,R(k)f\rangle$ by R, for abuse of notation, and $D=\check{R}$. From the a.c. condition and under suitable hypothesis on the dispersion curve, it is possible to establish (see Ref. 19) the following Ornstein–Zernike behavior for $|D(\tau)|$:

$$|D(\tau)|\leqslant k_1\mathrm{e}^{-m|\tau_0|}\left[\frac{1}{|\tau_0|^d}+O^*(|\tau_0|^{-(d+1)/2})\right]+k_2\mathrm{e}^{-m''|\tau_0|}, \tag{1.9}$$

for $\tau_0\to\infty$, where k_1, k_2 are positive constants and $m''>m$. Here, $O^*(K^{-p})$ means $O(K^{-p+\delta})$ for all $\delta>0$. Note that the τ coordinate in (1.7) is *twice* the center of mass coordinate, so the exponential decay in (1.9) is the expected for a four-point function. The relation (1.9) is valid under reasonably general hypothesis, and not exclusively for the IM. As remarked in Ref. 19, a relation analogous to (1.9) can be derived assuming the existence of two-particle bound states, but in this case with the exponential decay corrected by $|\tau_0|^{-d/2}$ instead of $|\tau_0|^{-d}$. This last situation is like the case of the two-point function.[20] As the four-point functions are related to the specific heat of the model, we could expect that a.c. condition may have, apparently, some influence on the

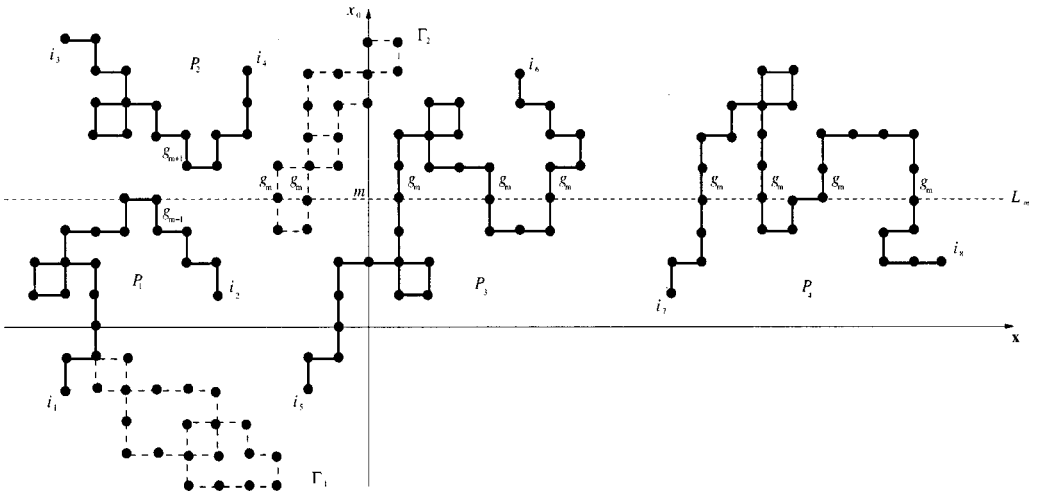

FIG. 1. The P_i's are examples of paths. The Γ_i's are examples of polymers, where Γ_1 is incompatible with the path P_1.

statistical properties of the models. The opposite question could be raised, i.e., to go from Ornstein–Zernike behavior to e-m spectral properties, but this is not our subject here.

This article is organized as follows. In Sec. II we introduce the polymer expansions and prove a general result for arbitrary derivatives of the $2n$-point functions with respect to the interpolating variables g_{ij}, giving a particularization for the case of the first and second derivatives. In Sec. III we perform a detailed study of the two-point function and its convolution inverse. Some of these later results (and main consequences) are known in the literature, but our approach is rather general. In Sec. IV we perform a detailed study of the connected and unconnected parts of the truncated four-point function and its respective inverses, concluding with the proof of Theorem 1.1 in Sec. IV C.

II. HIGH-TEMPERATURE POLYMER EXPANSION

The polymer expansion provides an alternative way to write the the general $2n$-point function (1.2) for the IM. Specifically,

$$\mathcal{S}_{2n}^{\Lambda}(i_1,\ldots,i_{2n})=\sum_{M\in \mathrm{conn}(i_1,\ldots,i_{2n})}\left(\prod_{L\in M} g_L\right)\exp\sum_{\substack{\Gamma\in\mathcal{G}'(\Lambda)\\ \Gamma\not\sim M}} c_\Gamma \mu^\Gamma. \tag{2.1}$$

An element M of $\mathrm{conn}(i_1,\ldots,i_{2n})$ is by definition a set of n paths joining different pairs of sites taken from the set $\{i_1,\ldots,i_{2n}\}$ (a path P is a connected set of bounds, such that an even number of bounds meets at every site except for the initial and final sites, see Fig. 1). The index L denote bounds. The sum in the exponent is basically over the family of set of polymers (i.e., connected sets of bounds, see Fig. 1) with at least one polymer in the set being incompatible with M. Here, c_Γ is a numerical constant and μ^Γ is of the form $\Pi_{\gamma\mathrm{polymer}}(\Pi_{L\in\gamma} g_L)^{n_\gamma}$, where $n_\gamma\in\mathbb{N}\cup\{0\}$. It can be proved that the series in the exponent in (2.1) is absolutely convergent if $|\mu|$ $:=\sup_{\gamma\mathrm{polymer}}|\Pi_{L\in\gamma} g_L|^{1/|\gamma|}$ is sufficiently small; see Refs. 21–23. Note that $|\mu|=|g|$ for the isotropic IM. Polymer expansion allows us to prove that $\mathcal{S}_{2n}(i_1,\ldots,i_{2n})$ is the limit of a convergent net of analytic functions of each g, g_m in a neighborhood of $0\in\mathbb{C}$. For our present aims, the relevant feature about expression (2.1) rests on the fact that it is a sum of a product of two factors $A\mathrm{e}^B$, being A and B products of powers of g_L's.

Denoting $L_m:=\{(x_0,x_1,\ldots,x_d)\in\mathbb{Z}^{d+1}: x_0=m\}$, see Fig. 1, polymer expansions allow to prove the following general result for the $2n$-point functions

Lemma 2.1: Assume that the hyperplane L_m divides the set of sites $\{i_1,\ldots,i_{2n}\}$ in two subsets, let's say $\{i_{k_1},\ldots,i_{k_r}\}$ and $\{i_{k_{r+1}},\ldots,i_{k_{2n}}\}$ (one of them might be eventually empty), in the sense that $\{i_{k_1},\ldots,i_{k_r}\}\subset\{(x_0,x_1,\ldots,x_d)\in\mathbb{Z}^{d+1}:x_0\leqslant m\}$ and $\{i_{k_{r+1}},\ldots,i_{k_{2n}}\}\subset\{(x_0,x_1,\ldots,x_d)\in\mathbb{Z}^{d+1}:x_0\geqslant m+1\}$. Then, we have the following

(a) If r is even, let's say $r=2l$, then $\mathcal{S}_{2n}(i_1,\ldots,i_{2n})|_{g_m=0}$ factorizes as

$$\mathcal{S}_{2n}(i_1,\ldots,i_{2n})|_{g_m=0}=\mathcal{S}_{2l}(i_{k_1},\ldots,i_{k_{2l}})|_{g_m=0}\mathcal{S}_{2n-2l}(i_{k_{2l+1}},\ldots,i_{2n})|_{g_m=0}.$$

For $n\in\mathbb{N}\cup\{0\}$, we have the following.

(b) If r is odd, then $\partial_{g_m}^{2n}\mathcal{S}_{2n}(i_1,\ldots,i_{2n})|_{g_m=0}=0$.

(c) If r is even, then $\partial_{g_m}^{2n+1}\mathcal{S}_{2n}(i_1,\ldots,i_{2n})|_{g_m=0}=0$. □

Proof: For part (a), note that, evaluating $\mathcal{S}_{2n}(i_1,\ldots,i_{2n})$ at $g_m=0$, in the sum in (2.1), only the paths $M\in\mathrm{conn}(i_1,\ldots,i_{2n})$ contribute which are independent of g_m. If there exists an even number of sites lying on both sides of L_m, such paths are the paths joining pairs of sites lying on the same side of the hyperplane and not crossing L_m, as P_1 and P_2 in Fig. 1 (otherwise, the path could lie across L_m and then g_m appears at least one time as a factor, given zero contribution at $g_m=0$). In this case the $2n$-point function factorizes, because the polymers appearing in the exponent in (2.1) are incompatible with at least one of the paths not crossing L_m. [There exists also the case of polymers lying across the hyperplane, as Γ_2 in Fig. 1, but their activities depend on g_m (actually, on g_m^2 or higher even powers, because the connectedness of Γ) and then evaluating at $g_m=0$ their contribution in the exponent is zero, i.e., contribute with a factor 1.] For parts (b) and (c), by (2.1) we have to derivate a sum of a product of two factors. Even derivatives have the form

$$\partial_{g_m}^{2n}\mathcal{S}_{2n}(i_1,\ldots,i_{2n})=\sum_{M\in\mathrm{conn}(i_1,\ldots,i_{2n})}A_1+A_2.$$

Here, A_1 is a sum of terms of the form

$$\text{const}\,\partial_{g_m}^{(\text{even})}\left(\prod_{L\in M}g_L\right)\partial_{g_m}^{(\text{even})}\exp\sum_{\substack{\Gamma\in\mathcal{G}'(\Lambda)\\ \Gamma\not\supset M}}c_\Gamma\mu^\Gamma. \tag{2.2}$$

If there exists an odd number of sites lying on both sides of L_m, then there exists at least one path joining sites lying on different sides of the hyperplane, as P_3 in Fig. 1. Furthermore, such paths would cross L_m an odd number of times and there would exist an odd number of such paths. Thus, in this case, the factor in parentheses in (2.2) depends on odd powers of g_m, and then its derivative vanishes at $g_m=0$, therefore implying $A_1=0$. On the other hand, A_2 is a sum of terms of the form

$$\text{const}\,\partial_{g_m}^{(\text{odd})}\left(\prod_{L\in M}g_L\right)\partial_{g_m}^{(\text{odd})}\exp\sum_{\substack{\Gamma\in\mathcal{G}'(\Lambda)\\ \Gamma\not\supset M}}c_\Gamma\mu^\Gamma$$

that vanish also, because the exponent depends on even powers of g_m since the polymers are connected. Analogously, for part (c) we have

$$\partial_{g_m}^{2n+1}\mathcal{S}_{2n}(i_1,\ldots,i_{2n})=\sum_{M\in\mathrm{conn}(i_1,\ldots,i_{2n})}B_1+B_2.$$

Here, B_1 is a sum of terms of the form

$$\text{const}\,\partial_{g_m}^{(\text{odd})}\left(\prod_{L\in M} g_L\right)\partial_{g_m}^{(\text{even})}\exp\sum_{\substack{\Gamma\in\mathcal{G}'(\Lambda)\\ \Gamma\neq M}} c_\Gamma \mu^\Gamma. \tag{2.3}$$

The paths not crossing the hyperplane are independent of g_m, with a vanishing derivative. The paths that cross L_m joining sites lying on the same side of the hyperplane would cross L_m an even number of times, as P_4 in Fig. 1. The paths that cross L_m joining sites lying on different sides of the hyperplane would cross L_m an odd number of times, as P_3 in Fig. 1, but if r is even, there exists an even number of such paths. So, in both cases, the factor in parentheses in (2.3) depends on even powers of g_m and then its derivative vanishes at $g_m=0$, therefore implying $B_1=0$. On the other hand, B_2 is a sum of terms of the form

$$\text{const}\,\partial_{g_m}^{(\text{even})}\left(\prod_{L\in M} g_L\right)\partial_{g_m}^{(\text{odd})}\exp\sum_{\substack{\Gamma\in\mathcal{G}'(\Lambda)\\ \Gamma\neq M}} c_\Gamma \mu^\Gamma,$$

which vanish also, by the same argument used to prove the vanishing of A_2 above. ■

Lemma 2.2:

$$\partial_{g_m}\mathcal{S}_n(i_1,\ldots,i_n)\big|_{g_m=0}=\sum_{\mathbf{x}\in\mathbb{Z}^d}\mathcal{S}_{n+2}(i_1,\ldots,i_n,(m,\mathbf{x}),(m+1,\mathbf{x}))\big|_{g_m=0}, \tag{2.4}$$

$$\begin{aligned}\partial_{g_m}^2\mathcal{S}_n(i_1,\ldots,i_n)\big|_{g_m=0}=&\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_{n+4}(i_1,\ldots,i_n,(m,\mathbf{x}),(m+1,\mathbf{x}),(m,\mathbf{y}),(m+1,\mathbf{y}))\big|_{g_m=0}\\ &-\mathcal{S}_n(i_1,\ldots,i_n)\big|_{g_m=0}\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_2((m,\mathbf{x}),(m,\mathbf{y}))\big|_{g_m=0}\\ &\mathcal{S}_2((m+1,\mathbf{x}),(m+1,\mathbf{y}))\big|_{g_m=0}.\end{aligned} \tag{2.5}$$

□

Proof: Recalling that $g_m=\tanh(\beta J_m)$, note that $J_m=(1/\beta)\operatorname{arctanh} g_m$ and therefore $\partial_{g_m}\mathcal{S}_n=(\mathrm{d}J_m/\mathrm{d}g_m)\partial_{J_m}\mathcal{S}_n=[\beta^{-1}/(1-g_m^2)]\partial_{J_m}\mathcal{S}_n$. Using this observation, differentiate (1.2), evaluate at $g_m=0$, and then use Lemma 2.1 to get (2.4). The proof of (2.5) is analogous, differentiating twice (1.2) and using (2.4) to simplify some expressions. ■

III. THE TWO-POINT FUNCTION AND ITS INVERSE

Particularizing the general results of the last section for the case of the two-point function, we have the following lemma.

Lemma 3.3: Consider $i,j\in\mathbb{Z}^{d+1}$ such that $i_0<j_0$ and $n\in\mathbb{N}\cup\{0\}$.

(a) If $i_0\leqslant m<j_0$, then $\partial_{g_m}^{2n}\mathcal{S}_2(i,j)\big|_{g_m=0}=0$.

(b) If $m<i_0$, then

$$\begin{aligned}\partial_{g_m}^2\mathcal{S}_2(i,j)\big|_{g_m=0}=&\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_2((m,\mathbf{x}),(m,\mathbf{y}))\big|_{g_m=0}\mathcal{S}_4((m+1,\mathbf{x}),(m+1,\mathbf{y}),i,j)\big|_{g_m=0}\\ &-\mathcal{S}_2(i,j)\big|_{g_m=0}\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_2((m,\mathbf{x}),(m,\mathbf{y}))\big|_{g_m=0}\mathcal{S}_2((m+1,\mathbf{x}),(m+1,\mathbf{y}))\big|_{g_m=0}.\end{aligned}$$

(c) If $j_0\leqslant m$, then

$$\partial_{g_m}^2 \mathcal{S}_2(i,j)\big|_{g_m=0} = \sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d} \mathcal{S}_4(i,j,(m,\mathbf{x}),(m,\mathbf{y}))\big|_{g_m=0} \mathcal{S}_2((m+1,\mathbf{x}),(m+1,\mathbf{y}))\big|_{g_m=0}$$

$$- \mathcal{S}_2(i,j)\big|_{g_m=0} \sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d} \mathcal{S}_2((m,\mathbf{x}),(m,\mathbf{y}))\big|_{g_m=0} \mathcal{S}_2((m+1,\mathbf{x}),(m+1,\mathbf{y}))\big|_{g_m=0}.$$

(d) If $m<i_0$ or $j_0\leqslant m$, then $\partial_{g_m}^{2n+1}\mathcal{S}_2(i,j)\big|_{g_m=0}=0$.

(e) If $i_0\leqslant m<j_0$, then

$$\partial_{g_m}\mathcal{S}_2(i,j)\big|_{g_m=0} = \sum_{\mathbf{x}\in\mathbb{Z}^d} \mathcal{S}_2(i,(m,\mathbf{x}))\big|_{g_m=0} \mathcal{S}_2((m+1,\mathbf{x}),j)\big|_{g_m=0}. \tag{3.1}$$

On other hand, when $i_0=j_0$, we have

(f) $\partial_{g_m}^{2n+1}\mathcal{S}_2(i,j)\big|_{g_m=0}=0$, $\forall m$. □

Lemma 3.3(a) has the following well known consequence: for the high-temperature IM the two-point function decays exponentially with the separation of its arguments, i.e., if β is sufficiently small, there exist $m=m(\beta)$ and $C=C(\beta)$ such that $|\mathcal{S}_2(i,j)|\leqslant C\mathrm{e}^{-m|i_0-j_0|}$ (see, e.g., Refs. 24–27). This fact has relevant corollaries, among them the uniqueness of ground state, the existence of a lower mass gap and the analyticity of the Fourier transform of the two-point function in momentum space (see, e.g., Refs. 28, 18, and 24, and cf. Refs. 29 and 30).

The two-point function considered as a linear operator in $\ell^2(\mathbb{Z}^{d+1})$, via

$$[\mathcal{S}_2(\{a_j\}_{j\in\mathbb{Z}^{d+1}})]_i := \sum_{j\in\mathbb{Z}^{d+1}} \mathcal{S}_2(i,j)a_j,$$

is well defined and exists $\mathcal{S}_2^{-1}=:\Gamma$ (see Ref. 25, p. 606 and Lemma A2, pp. 605–606). Moreover, as a consequence of Lemma 3.3(a), for a given $m\in\mathbb{Z}$, $\mathcal{S}_2\big|_{g_m=0}$ leaves invariant each of the subspaces

$$\ell^2_{\leqslant m} := \{\{a_j\}_{j\in\mathbb{Z}^{d+1}}\in\ell^2(\mathbb{Z}^{d+1}) : a_j=0 \quad \text{if } j_0>m\};$$

$$\ell^2_{>m} := \{\{a_j\}_{j\in\mathbb{Z}^{d+1}}\in\ell^2(\mathbb{Z}^{d+1}) : a_j=0 \quad \text{if } j_0\leqslant m\}.$$

Therefore, $\mathcal{S}_2\big|_{g_m=0}$ is a direct sum of two operators acting separately in each of these subspaces and the same follows for Γ. Note also that Γ is symmetrical, i.e., $\Gamma(i,j)=\Gamma(j,i)$.

Lemma 3.4: Consider $i,j\in\mathbb{Z}^{d+1}$ such that $i_0<j_0$.

(a) If $i_0\leqslant m<j_0$, then $\Gamma(i,j)\big|_{g_m=0}=0$.

(b)

$$\partial_{g_m}\Gamma(i,j)\big|_{g_m=0} = \begin{cases} 0 & \text{if } j_0\leqslant m, \\ 0 & \text{if } i_0\leqslant m<j_0 \text{ when } |i_0-j_0|\geqslant 2, \\ 0 & \text{if } m<i_0. \end{cases}$$

On the other hand, when $i_0=j_0$ we have

(c) $\partial_{g_m}\Gamma(i,j)\big|_{g_m=0}=0$, $\forall m$.

Consider now $i,j\in\mathbb{Z}^{d+1}$ arbitrary. If $n\in\mathbb{N}\cup\{0\}$, then

(d) n even $\Rightarrow \partial_{g_m}^n\Gamma(i,j)\big|_{g_m=0}=0 \forall i_0\leqslant m<j_0$ if $i_0<j_0$;

n odd $\Rightarrow \partial_{g_m}^n\Gamma(i,j)\big|_{g_m=0}=0$ if $m<i_0$ or $j_0\leqslant m$ when $i_0<j_0$ or $\forall m$ when $i_0=j_0$.

□

Proof: Note first that for every $n\in\mathbb{N}$ we have the following simple identity

$$\partial_{g_m}^n \Gamma = -\Gamma(\partial_{g_m}^n(\mathcal{S}_2\Gamma) - \mathcal{S}_2\partial_{g_m}^n\Gamma). \tag{3.2}$$

Although formally trivial (since $\Gamma = \mathcal{S}_2^{-1}$), this expression is useful for the *iterative* computation of the nth derivative of Γ, because the right side of (3.2) contains only derivatives of Γ of order $n-1$ at most. Now, part (a) is a consequence of the invariance of $\ell^2_{>m}$ and $\ell^2_{\leqslant m}$ under Γ, using *reductio ad absurdum*. For part (b) in the case of $i_0 \leqslant m < j_0$, using (3.2) with $n=1$ and Lemma 3.3(d–f) we have

$$\begin{aligned}
\partial_{g_m}\Gamma(i,j)|_{g_m=0} &= -\sum_{a,b\in\mathbb{Z}^{d+1}} \Gamma(i,a)|_{g_m=0}\partial_{g_m}\mathcal{S}_2(a,b)|_{g_m=0}\Gamma(b,j)|_{g_m=0} \\
&= -\sum_{a,b\in\mathbb{Z}^{d+1}} \sum_{\mathbf{x}\in\mathbb{Z}^d} \Gamma(i,a)|_{g_m=0}\mathcal{S}_2(a,(m,\mathbf{x}))|_{g_m=0} \\
&\quad \mathcal{S}_2((m+1,\mathbf{x}),b)|_{g_m=0}\Gamma(b,j)|_{g_m=0} \\
&= -\sum_{\mathbf{x}\in\mathbb{Z}^d} \delta_{i(m,\mathbf{x})}\delta_{(m+1,\mathbf{x})j},
\end{aligned} \tag{3.3}$$

where the last expression is equal to zero if $|i_0 - j_0| \geqslant 2$. The other cases of parts (b) and (c) follow using (3.2) analogously, adding the part (a) already proved and Lemma 3.3(b) and (c). The proof of part (d) is done by induction in n. The case $n=0$ is given in part (a) and the case $n=1$ is given in parts (b) and (c), already proved. Assume that statement of part (d) is valid for every i such that $i \leqslant n-1$. From (3.2) we have

$$\partial_{g_m}^n\Gamma(i,j)|_{g_m=0} = -\sum_{a,b\in\mathbb{Z}^{d+1}} \sum_{k=0}^{n-1} \binom{n}{k} \Gamma(i,a)|_{g_m=0}\partial_{g_m}^{n-k}\mathcal{S}_2(a,b)|_{g_m=0}\partial_{g_m}^k\Gamma(b,j)|_{g_m=0}. \tag{3.4}$$

If n is even with $i_0 < j_0$ and $i_0 \leqslant m < j_0$, then, by part (a), the factor $\Gamma(i,a)|_{g_m=0}$ in (3.4) vanishes unless a lays into or below L_m.

(i) Now, when the index k of the second sum in (3.4) is even, the inductive hypothesis implies that the factor $\partial_{g_m}^k\Gamma(b,j)|_{g_m=0}$ in (3.4) vanishes unless b lays above L_m. But in this case $n-k$ is even also and, therefore, by Lemma 3.3(a), the factor $\partial_{g_m}^{n-k}\mathcal{S}_2(a,b)|_{g_m=0}$ vanishes if $a_0 \leqslant m < b_0$.

(ii) On the other hand, when the index k is odd, the inductive hypothesis implies that the factor $\partial_{g_m}^k\Gamma(b,j)|_{g_m=0}$ in (3.4) vanishes unless b lays into or below L_m. But in this case $n-k$ is odd also and, therefore, by Lemma 3.3(b) and (c), the factor $\partial_{g_m}^{n-k}\mathcal{S}_2(a,b)|_{g_m=0}$ vanishes if $a_0,\ b_0 \leqslant m$.

If n is odd with $i_0 < j_0$ and $m < i_0$ (resp. $j_0 \leqslant m$), the proof is analogous, using part (a) and relation (3.4). The case of n odd with $i_0 = j_0$ is also proved analogously, considering the subcases $m < i_0 = j_0$ and $i_0 = j_0 \leqslant m$ separately. ■

Parts (a) and (b) and (d) (with $n=2$) of Lemma 3.4 have the following well known consequence: for the high-temperature IM, if $|i_0 - j_0| \geqslant 2$, then $|\Gamma(i,j)| \leqslant \text{const}\, e^{-3m|i_0-j_0|}$ (see, e.g., Refs. 24–27). [Cf. Remark (1) following Lemma 2.2 in Ref. 25, p. 600.] This fact has as a corollary the analyticity property in momentum space for Γ and allows us to prove for the high-temperature IM the existence of lower and upper mass gaps (or existence of "one-particle states"), i.e., the analogy of Theorem 2.5 in Ref. 24 relative to the Fourier transform of the two-point function.

FIG. 2. *Left:* The top, middle, bottom, border and outside parts are shown in this example of type 1 configuration. *Right:* In the column at left an example of each configuration type. In the columns at right are the configurations obtained from the first at left of the respective row by the application of the operations shown in the top line.

IV. THE FOUR-POINT FUNCTIONS

Given four sites $i,j,k,l \in \mathbb{Z}^{d+1}$ such that $i_0<j_0<k_0<l_0$, the four-tuple $(i_0,j_0,k_0,l_0) \in \mathbb{Z}^4$ will be called the *configuration* determined by these sites. To simplify the statement and proofs of some results, we introduce the following definitions. The sets

$$\{m \in \mathbb{Z}: k_0 \leqslant m < l_0\}, \quad \{m \in \mathbb{Z}: j_0 \leqslant m < k_0\}, \quad \text{and } \{m \in \mathbb{Z}: i_0 \leqslant m < j_0\}$$

will be called respectively the *top*, the *middle* and the *bottom* of the configuration. The complement of the union of these sets will be called the *outside*, and the union of the top and the bottom will be called the *border*. We say that a configuration is of type 1 if the sites i and j are both in the top or in the bottom; see Fig. 2. Analogously, we say that a configuration is of type 2 if the sites i and l are both in the top or in the bottom. Finally, we say that a configuration is of type 3 if the sites i and k are both in the top or in the bottom. See Fig. 2. The configurations of types 1–3, will be relevant for some results, because any statement relative to one of them in the middle is automatically valid for all the others of the same type. In $\ell^2 := \ell^2(\mathbb{Z}^{d+1} \times \mathbb{Z}^{d+1})$ we define the symmetrical and antisymmetrical subspaces respectively by

$$\ell^2_s := \{\{a_{ij}\}_{i,j \in \mathbb{Z}^{d+1}} \in \ell^2 : a_{ij} = a_{ji}\}, \quad \ell^2_a := \{\{a_{ij}\}_{i,j \in \mathbb{Z}^{d+1}} \in \ell^2 : a_{ij} = -a_{ji}\}.$$

A. The unconnected part of truncated four-point function $\mathcal{D}_0$

As a simple consequence of the definition (1.4), we have the following.

Lemma 4.5: (a) $\mathcal{D}_0$ is invariant under the operations $A_1 :=$ exchange $i \leftrightarrow j$,

$$A_2 := \text{exchange } k \leftrightarrow l, \quad B := \text{simultaneous exchange } i \leftrightarrow k \text{ and } j \leftrightarrow l.$$

(b) As an operator in ℓ^2, $\mathcal{D}_0$ vanishes in the antisymmetric space ℓ^2_a.

(c) Considering $\mathcal{D}_0$ as an operator in the symmetric space ℓ^2_s, we have

$$\mathcal{D}_0^{-1}(i,j,k,l) = \tfrac{1}{2}\Gamma(i,k)\Gamma(j,l). \tag{4.1}$$

(d) $\mathcal{D}_0^{-1}$ has the same symmetry properties of part (a) plus the additional symmetry

$$A_3 := \text{exchange } j \leftrightarrow l.$$

□

Note that the set of type 1 configurations is invariant for any of the operations A_1, A_2, A_1A_2, B, A_1B, A_2B and A_1A_2B. In this sense, we say that such configurations are *equivalent*. The union of type 2 and 3 configurations is a set of equivalent configurations also; see Fig. 2. Equivalence of configurations reflects the symmetry properties of $\mathcal{D}_0$ in the following sense: If the value $V_{i,j,k,l}$ of $\mathcal{D}_0(i,j,k,l)$ is known when the sites i,j,k,l determine a given configuration, the value of $\mathcal{D}_0(i,j,k,l)$ when the sites determine another configuration obtained from the original by the application of some of the symmetry operations $C=A_r$, B $(r=1,2,3)$ is given by $V_{C(i,j,k,l)}$. The same considerations apply to derivatives of $\mathcal{D}_0$ with respect to g_m, the inverse $\mathcal{D}_0^{-1}$, and the derivatives of the inverse. Note also that a configuration is of type 2 if and only if it is equivalent to one of type 1 by the application of A_3. Thus, by Lemma 4.5(d), for the study of $\mathcal{D}_0^{-1}$ configurations of types 1 and 2 will be equivalent.

Lemma 4.6: For any configuration we have the following.

(a) $\partial_{g_m}^{2n}\mathcal{D}_0^{-1}(i,j,k,l)|_{g_m=0}=0$ *in the border. Furthermore, in the cases* $n=0,1$ *the corresponding derivative also vanishes in the middle of configuration 1.*

(b) $\partial_{g_m}^{2n-1}\mathcal{D}_0^{-1}(i,j,k,l)|_{g_m=0}=0$ *in the middle. Furthermore, in the case* $n=1$ *the derivative also vanishes in the border of any configuration.* □

Proof: For part (a), by (4.1) we have $\partial_{g_m}^{2n}\mathcal{D}_0^{-1}(i,j,k,l)|_{g_m=0}=A_1+A_2$, where A_1 and A_2 are sums of terms proportional to

$$\partial_{g_m}^{(\text{even})}\Gamma(i,k)|_{g_m=0}\partial_{g_m}^{(\text{even})}\Gamma(j,l)|_{g_m=0} \quad \text{and} \quad \partial_{g_m}^{(\text{odd})}\Gamma(i,k)|_{g_m=0}\partial_{g_m}^{(\text{odd})}\Gamma(j,l)|_{g_m=0},$$

respectively. Using Lemma 3.4(d) such terms have the values

A_1	1 and 2	3
top	0	0
middle	0	A_1
bottom	0	0

and

A_2	1 and 2	3
top	0	0
middle	A_2	0
bottom	0	0

respectively (here, numbers in the first line indicate the configuration type). Note that $A_2=0$ in the case $n=0$ (i.e., without derivative) and that in the case $n=1$ (i.e., the second derivative) the odd derivatives in A_2 are at most of first order, and all are equal to zero from Lemma 3.4(b). For part (b) we have $\partial_{g_m}^{2n-1}\mathcal{D}_0^{-1}(i,j,k,l)|_{g_m=0}=B_1+B_2$, where B_1 and B_2 are sums of terms proportional to

$$\partial_{g_m}^{(\text{odd})}\Gamma(i,k)|_{g_m=0}\partial_{g_m}^{(\text{even})}\Gamma(j,l)|_{g_m=0} \quad \text{and} \quad \partial_{g_m}^{(\text{even})}\Gamma(i,k)|_{g_m=0}\partial_{g_m}^{(\text{odd})}\Gamma(j,l)|_{g_m=0},$$

respectively, both equal to zero in the middle by Lemma 3.4(d). ■

B. The connected part of the truncated four-point function $\mathcal{D}$

It is easy to verify that Lemma 4.5(a) and (b) is also valid for $\mathcal{D}$. The next result is a direct consequence of Definition (1.3) and the general the results of Sec. II plus Lemma 3.3. For part (c) in the following lemma, we assume that the subindexed sites i_{k_m} pertain to the set $\{i,j,k,l\}$ and also we use the following convention: $\widehat{i_{k_m}}$ indicates that site i_{k_m} has to be omitted.

Lemma 4.7: (a) $\mathcal{D}(i,j,k,l)|_{g_m=0}$ *takes the following values*

	1	2	3
top	0	0	0
middle	0	$\mathcal{S}_2(i,l)|_{g_m=0}\mathcal{S}_2(k,j)|_{g_m=0}$	$\mathcal{S}_2(i,k)|_{g_m=0}\mathcal{S}_2(j,l)|_{g_m=0}$
bottom	0	0	0

(b) $\partial_{g_m}\mathcal{D}(i,j,k,l)\big|_{g_m=0}$ *takes the value*

$$\sum_{\mathbf{x}\in\mathbb{Z}^d}\mathcal{S}_4(i_{k_1},\ldots,\widehat{i_{k_r}},\ldots,i_{k_4},(m,\mathbf{x}))\big|_{g_m=0}\mathcal{S}_2((m+1,\mathbf{x}),i_{k_r})\big|_{g_m=0}$$
$$-\mathcal{S}_2(i_{k_1},i_{k_2})\big|_{g_m=0}\partial_{g_m}\mathcal{S}_2(i_{k_3},i_{k_4})\big|_{g_m=0}$$

in the top of any configuration such that $i_{k_r}\in\{i_{k_3},i_{k_4}\}$ *and* $(i_{k_r})_0=\max\{i_0,j_0,k_0,l_0\}$*, and the value*

$$\sum_{\mathbf{x}\in\mathbb{Z}^d}\mathcal{S}_2(i_{k_r},(m,\mathbf{x}))\big|_{g_m=0}\mathcal{S}_4((m+1,\mathbf{x}),i_{k_1},\ldots,\widehat{i_{k_r}},\ldots,i_{k_4})\big|_{g_m=0}$$
$$-\partial_{g_m}\mathcal{S}_2(i_{k_1},i_{k_2})\big|_{g_m=0}\mathcal{S}_2(i_{k_3},i_{k_4})\big|_{g_m=0}$$

in the bottom of any configuration such that $i_{k_r}\in\{i_{k_1},i_{k_2}\}$ *and* $(i_{k_r})_0=\min\{i_0,j_0,k_0,l_0\}$.

(c) In the middle of configuration 1, $\partial_{g_m}^2\mathcal{D}(i,j,k,l)\big|_{g_m=0}$ *is equal to*

$$\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{D}(i,j,(m,\mathbf{x}),(m,\mathbf{y}))\big|_{g_m=0}\mathcal{D}((m+1,\mathbf{x}),(m+1,\mathbf{y}),k,l)\big|_{g_m=0}. \tag{4.2}$$

(d) Even derivatives vanish in the border of any configuration.

(e) Odd derivatives vanish in the middle and in the outside of any configuration. □

For a given $m\in\mathbb{Z}$, we define the subspaces

$$\ell^2_{>m}:=\{\{a_{ij}\}_{i,j\in\mathbb{Z}^{d+1}}\in\ell^2: a_{ij}=0 \text{ if } i_0 \text{ or } j_0\leqslant m\},$$

$$\ell^2_{\leqslant m}:=\{\{a_{ij}\}_{i,j\in\mathbb{Z}^{d+1}}\in\ell^2: a_{ij}=0 \text{ if } i_0 \text{ or } j_0> m\},$$

$$\ell^2_{\div m}:=\{\{a_{ij}\}_{i,j\in\mathbb{Z}^{d+1}}\in\ell^2: a_{ij}=0 \text{ if } i_0,j_0\leqslant m \text{ or } i_0,j_0> m\}.$$

Lemma 4.8: (a) *Each of the subspaces above is invariant by* $\mathcal{D}$*, and therefore also under* $\mathcal{D}^{-1}$.

(b) In $\ell^2_{\div m}\cap\ell^2_s$ *we have*

$$\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}=\tfrac{1}{4}[\Gamma(i,k)\big|_{g_m=0}\Gamma(j,l)\big|_{g_m=0}+\Gamma(i,l)\big|_{g_m=0}\Gamma(j,k)\big|_{g_m=0}]. \tag{4.3}$$

(c) In the middle of configuration 1 we have

$$[(\partial_{g_m}\mathcal{D})\mathcal{D}^{-1}\partial_{g_m}\mathcal{D}](i,j,k,l)\big|_{g_m=0}=\partial_{g_m}^2\mathcal{D}(i,j,k,l)\big|_{g_m=0}.$$

□

Proof: Part (a) follows from Lemma 4.7(a), using *reductio ad absurdum*. Part (b) can be proved by direct substitution. For part (c), $(\partial_{g_m}\mathcal{D})\mathcal{D}^{-1}\partial_{g_m}\mathcal{D}\big|_{g_m=0}$ evaluated at (i,j,k,l) is equal to

$$\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\partial_{g_m}\mathcal{D}(i,j,a,b)\big|_{g_m=0}\mathcal{D}^{-1}(a,b,c,d)\big|_{g_m=0}\partial_{g_m}\mathcal{D}(c,d,k,l)\big|_{g_m=0}. \tag{4.4}$$

From Lemma 4.7(e), the third factor in (4.4) considered as a function of index c and d only is in $\ell^2_{\div m}$. Therefore, each term of the summatory in (4.4) vanishes unless the hyperplane L_m separates the pair $\{c,d\}$. Also from Lemma 4.7(e), in the middle of configuration 1 the first factor in (4.4) vanishes unless L_m separates the pair $\{a,b\}$. Thus, we have four cases, depending on the positions of both pairs $\{c,d\}$ and $\{a,b\}$ with respect to the hyperplane L_m. Assume, to fix ideas, that b and d are above L_m and that a and c lie into or below L_m. In any case, sites i,j,a,b determine

configurations with a or b in the top, and the sites c,d,k,l determine configurations with c or d in the bottom. Using Lemma 4.7(b) and (4.3) [note that in this case the second term at right in (4.3) vanishes from Lemma 3.4(a)], expression (4.4) is given by

$$\begin{aligned}
&\frac{1}{4}\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_4(i,j,a,(m,\mathbf{x}))\big|_{g_m=0}\mathcal{S}_2((m+1,\mathbf{x}),b)\big|_{g_m=0}\Gamma(a,c)\big|_{g_m=0}\\
&\quad\times\Gamma(b,d)\big|_{g_m=0}\mathcal{S}_2(c,(m,\mathbf{y}))\big|_{g_m=0}\mathcal{S}_4((m+1,\mathbf{y}),d,k,l)\big|_{g_m=0}\\
&\quad-\frac{1}{4}\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_4(i,j,a,(m,\mathbf{x}))\big|_{g_m=0}\mathcal{S}_2((m+1,\mathbf{x}),b)\big|_{g_m=0}\Gamma(a,c)\big|_{g_m=0}\\
&\quad\times\Gamma(b,d)\big|_{g_m=0}\partial_{g_m}\mathcal{S}_2(c,d)\big|_{g_m=0}\mathcal{S}_2(k,l)\big|_{g_m=0}\\
&\quad-\frac{1}{4}\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_2(i,j)\big|_{g_m=0}\partial_{g_m}\mathcal{S}_2(a,b)\big|_{g_m=0}\Gamma(a,c)\big|_{g_m=0}\Gamma(b,d)\big|_{g_m=0}\\
&\quad\times\mathcal{S}_2(c,(m,\mathbf{y}))\big|_{g_m=0}\mathcal{S}_4((m+1,\mathbf{y}),d,k,l)\big|_{g_m=0}\\
&\quad+\frac{1}{4}\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{y}\in\mathbb{Z}^d}\mathcal{S}_2(i,j)\big|_{g_m=0}\partial_{g_m}\mathcal{S}_2(a,b)\big|_{g_m=0}\Gamma(a,c)\big|_{g_m=0}\Gamma(b,d)\big|_{g_m=0}\\
&\quad\times\partial_{g_m}\mathcal{S}_2(c,d)\big|_{g_m=0}\mathcal{S}_2(k,l)\big|_{g_m=0}.
\end{aligned}$$

Using (3.1) to replace the derivatives of the two-point functions in the last three terms above, we get $\frac{1}{4}$ times expression (4.2). The remaining three cases are analogous and give the same result.■

Lemma 4.9: (a) $\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}=0$ *in the border of any configuration and in the middle of the configuration 1. Furthermore,* $\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}=\mathcal{D}_0^{-1}(i,j,k,l)\big|_{g_m=0}$ *in the middle of configurations 2 and 3.*

(b) If $|i_0-j_0|\geqslant 2$ *and* $|k_0-l_0|\geqslant 2$, *then* $\partial_{g_m}\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}=0$ *in the bottom (with* $i_0<m$*), middle, top (with* $m<l_0-1$*) and outside of any configuration.*

(c) $\partial_{g_m}^2\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}=\partial_{g_m}^2\mathcal{D}_0^{-1}(i,j,k,l)\big|_{g_m=0}$ *in the middle of configuration 1.*

If $n\in\mathbb{N}\cup\{0\}$, *then*

(d) n *even* $\Rightarrow\partial_{g_m}^n\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}=0$ *in the border of any configuration.*

n *odd* $\Rightarrow\partial_{g_m}^n\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}$

$=0$ *in the middle and the outside of any configuration.*

□

Proof: Part (a) follows from Lemma 4.7(a) in analogy with the proof Lemma 3.4(a) [note that the second claim of part (a) in $\ell^2_{\div m}\cap\ell^2_s$ follows also from (4.1) and (4.3)]. Once part (b) is proved, the proof of part (d) can be done by induction on n in analogy with the proof of Lemma 3.4(d). To prove (b), using a formula analogous to (3.2) we have that $\partial_{g_m}\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}$ is equal to

$$-\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\mathcal{D}^{-1}(i,j,a,b)\big|_{g_m=0}\partial_{g_m}\mathcal{D}(a,b,c,d)\big|_{g_m=0}\mathcal{D}^{-1}(c,d,k,l)\big|_{g_m=0}. \tag{4.5}$$

Consider first the case of a configuration with $i_0=\min\{i_0,j_0,k_0,l_0\}$. In the bottom, the first factor in (4.5) vanishes, by part (a), unless the hyperplane L_m separates the pair $\{a,b\}$, and by the same argument the third factor vanishes unless the pair $\{c,d\}$ lies above L_m. Thus, with regards to the second factor in (4.5), we are in the bottom of some configuration having a or b in the bottom.

Note that there exist two cases, depending on the positions of a and b with respect to the hyperplane L_m. Assume that b is above and a lies into or below L_m (the argument for the opposite case will be analogous). Note also that by the same argument above, the product of the last two factors in (4.5) considered as a function of a and b only is in $\ell^2_{\div m}$. Using Lemmas 4.8(b) and 4.7(b) to replace the first and second factors in (4.5), respectively, we have that (4.5) can be written as the sum of

$$
\begin{aligned}
&-\frac{1}{4}\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{x}\in\mathbb{Z}^d}\Gamma(i,a)\big|_{g_m=0}\Gamma(j,b)\big|_{g_m=0}\mathcal{S}_2(a,(m,\mathbf{x}))\big|_{g_m=0}\\
&\quad\mathcal{S}_4((m+1,\mathbf{x}),b,c,d)\big|_{g_m=0}\mathcal{D}^{-1}(c,d,k,l)\big|_{g_m=0}\\
&\quad=-\frac{1}{4}\sum_{b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{x}\in\mathbb{Z}^d}\delta_{i(m,\mathbf{x})}\Gamma(j,b)\big|_{g_m=0}\\
&\quad\mathcal{S}_4((m+1,\mathbf{x}),b,c,d)\big|_{g_m=0}\mathcal{D}^{-1}(c,d,k,l)\big|_{g_m=0},
\end{aligned}
$$

which vanishes if $i_0<m$, plus

$$
\begin{aligned}
&\frac{1}{4}\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{x}\in\mathbb{Z}^d}\Gamma(i,a)\big|_{g_m=0}\Gamma(j,b)\big|_{g_m=0}\mathcal{S}_2(a,(m,\mathbf{x}))\big|_{g_m=0}\\
&\quad\mathcal{S}_2((m+1,\mathbf{x}),b)\big|_{g_m=0}\mathcal{S}_2(c,d)\big|_{g_m=0}\mathcal{D}^{-1}(c,d,k,l)\big|_{g_m=0}\\
&\quad=\frac{1}{4}\sum_{c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{x}\in\mathbb{Z}^d}\delta_{i(m,\mathbf{x})}\delta_{j(m+1,\mathbf{x})}\mathcal{S}_2(c,d)\big|_{g_m=0}\mathcal{D}^{-1}(c,d,k,l)\big|_{g_m=0},
\end{aligned}
$$

which vanishes if $|i_0-j_0|\geqslant 2$. In the middle we consider two cases separately.

(1) j lie into or below L_m.
From part (a), the first factor in (4.5) vanishes unless the pair $\{a,b\}$ is below L_m, and by the same argument the third factor vanishes unless the pair $\{c,d\}$ is above L_m. But then the second factor vanishes from Lemma 4.7(e).

(2) j lie above L_m.
From part (a), the first factor in (4.5) vanishes unless L_m separates the pair $\{a,b\}$, and by the same argument the third factor vanishes unless L_m separates the pair $\{c,d\}$. But then the second factor vanishes by Lemma 4.7(e).

In the top the analysis is analogous to the bottom part. In the lower (resp. upper) outside part, from part (a) the first and third factors vanish unless the pairs $\{a,b\}$ and $\{c,d\}$ are above (resp. below) L_m. But then the second factor vanishes by Lemma 4.7(e). The proofs for the remainder configurations are analogous.

For part (c), using a formula analogous to (3.2) with $n=1,2$, we have

$$
\partial_{g_m}\mathcal{D}^{-1}=-\mathcal{D}^{-1}[(\partial_{g_m}\mathcal{D})\mathcal{D}^{-1}], \tag{4.6}
$$

$$
\partial^2_{g_m}\mathcal{D}^{-1}=-\mathcal{D}^{-1}[(\partial^2_{g_m}\mathcal{D})\mathcal{D}^{-1}+2(\partial_{g_m}\mathcal{D})(\partial_{g_m}\mathcal{D}^{-1})], \tag{4.7}
$$

respectively. Replacing $\partial_{g_m}\mathcal{D}^{-1}$ in (4.7) by the expression in (4.6), we get

$$
\partial^2_{g_m}\mathcal{D}^{-1}=-\mathcal{D}^{-1}[\partial^2_{g_m}\mathcal{D}-2(\partial_{g_m}\mathcal{D})\mathcal{D}^{-1}\partial_{g_m}\mathcal{D}]\mathcal{D}^{-1}.
$$

As in the proof of part (b), from part (a) each term vanishes unless the sites a,b,c,d determine a type 1 configuration with a and b in the bottom. Evaluating at $g_m=0$ and using Lemma 4.8(c) and (4.2) we have

$$\begin{aligned}\partial_{g_m}^2\mathcal{D}^{-1}(i,j,k,l)\big|_{g_m=0}&=\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\mathcal{D}^{-1}(i,j,a,b)\big|_{g_m=0}\partial_{g_m}^2\mathcal{D}(a,b,c,d)\big|_{g_m=0}\mathcal{D}^{-1}(c,d,k,l)\big|_{g_m=0}\\&=\sum_{a,b,c,d\in\mathbb{Z}^{d+1}}\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\mathcal{D}^{-1}(i,j,a,b)\big|_{g_m=0}\mathcal{D}(a,b,(m,\mathbf{x}),(m,\mathbf{y}))\big|_{g_m=0}\\&\quad\times\mathcal{D}((m+1,\mathbf{x}),(m+1,\mathbf{y}),c,d)\big|_{g_m=0}\mathcal{D}^{-1}(c,d,k,l)\big|_{g_m=0}\\&=\sum_{\mathbf{x},\mathbf{y}\in\mathbb{Z}^d}\delta_{i(m,\mathbf{x})}\delta_{j(m,\mathbf{y})}\delta_{(m+1,\mathbf{x})k}\delta_{(m+1,\mathbf{y})l}\\&=\left(-\sum_{\mathbf{x}\in\mathbb{Z}^d}\delta_{i(m,\mathbf{x})}\delta_{(m+1,\mathbf{x})k}\right)\left(-\sum_{\mathbf{y}\in\mathbb{Z}^d}\delta_{j(m,\mathbf{y})}\delta_{(m+1,\mathbf{y})l}\right)\\&=\partial_{g_m}\Gamma(i,k)\big|_{g_m=0}\partial_{g_m}\Gamma(j,l)\big|_{g_m=0}=\partial_{g_m}^2\mathcal{D}_0^{-1}(i,j,k,l)\big|_{g_m=0}.\end{aligned}$$

In the last line above, we have used (3.3) for the first equality and (4.1) and Lemma 3.4(a) for the second. ■

C. The Bethe–Salpeter kernel

As $\mathcal{N}=\mathcal{D}^{-1}-\mathcal{D}_0^{-1}$, from Lemmas 4.6 and 4.9 we have the following.

Lemma 4.10: (a) If $k=0,1,2,3$, *then* $\partial_{g_m}^k\mathcal{N}(i,j,k,l)\big|_{g_m=0}=0$ *in the middle of configuration 1.*

(b) If $|i_0-j_0|\geq 2$, $|k_0-l_0|\geq 2$ *and* $k=0,1,2$, *then* $\partial_{g_m}^k\mathcal{N}(i,j,k,l)\big|_{g_m=0}=0$ *in the border* (*with* $i_0<m$ *and* $m<l_0-1$) *of all configurations.*

(c) If $k=0,1$, *then* $\partial_{g_m}^k\mathcal{N}(i,j,k,l)\big|_{g_m=0}=0$ *in the middle of configurations 2 and 3.* □

Proof of Theorem 1.1: Consider first the case of configuration 1. From Lemma 4.10 we have

$$\mathcal{N}(i,j,k,l)=(g_{i_0+1}g_{i_0+2}\cdots g_{j_0-1})^3(g_{j_0}g_{j_0+1}\cdots g_{k_0-1})^4(g_{k_0}g_{k_0+1}\cdots g_{l_0-2})^3F(g,g_m),$$

where F is an analytic function. In particular, for the isotropic IM model we have

$$\mathcal{N}(i,j,k,l)=g^{3|j_0-i_0-1|}g^{4|j_0-k_0|}g^{3|l_0-k_0-1|}F(g)=\mathrm{e}^{-m(3|j_0-i_0-1|+4|j_0-k_0|+3|l_0-k_0-1|)}F(g),$$

where $m:=-\ln g>0$ if $0<g<1$. Therefore,

$$|\mathcal{N}(i,j,k,l)|\leq C_1\mathrm{e}^{-m(3|j_0-i_0-1|+4|j_0-k_0|+3|l_0-k_0-1|)}. \tag{4.8}$$

Note that for $a,b\in\mathbb{R}$ we have $|a-b|\leq|a-b-1|+1$, or $|a-b-1|\geq|a-b|-1$. Therefore,

$$3|j_0-i_0-1|+4|j_0-k_0|+3|l_0-k_0-1|\geq 3|i_0-j_0|+4|j_0-k_0|+3|k_0-l_0|-6. \tag{4.9}$$

Note also that $|i_0+j_0-k_0-l_0|\leq|i_0-j_0|+2|j_0-k_0|+|k_0-l_0|$, and, therefore,

$$3|i_0-j_0|+4|j_0-k_0|+3|k_0-l_0|\geq|i_0-j_0|+|k_0-l_0|+2|i_0+j_0-k_0-l_0|. \tag{4.10}$$

Combining (4.8)–(4.10) we have

$$|\mathcal{N}(i,j,k,l)|\leq C_2\mathrm{e}^{-m(|i_0-j_0|+|k_0-l_0|+2|i_0+j_0-k_0-l_0|)}. \tag{4.11}$$

For configuration 2, from Lemma 4.10 we have analogously

$$|\mathcal{N}(i,j,k,l)| \leqslant C_1 \mathrm{e}^{-m(3|l_0-i_0-1|+2|l_0-j_0|+3|k_0-j_0-1|)}, \tag{4.12}$$

and (4.11) follows in this case combining the inequalities

$$3|l_0-i_0-1|+2|l_0-j_0|+3|k_0-j_0-1| \geqslant 3|l_0-i_0|+2|l_0-j_0|+3|k_0-j_0|-6,$$

$$|i_0-l_0|+|j_0-k_0| \geqslant |i_0+j_0-k_0-l_0|,$$

$$|i_0-l_0|+|l_0-j_0| \geqslant |i_0-j_0|,$$

$$|l_0-j_0|+|j_0-k_0| \geqslant |l_0-k_0|.$$

The case of configuration 3 is analogous to this latter case. Finally, Theorem 1.1 follows by the observation that the hyperplane decoupling method is equally applicable in each direction independently. ■

(Received 7 January 2002; accepted 7 August 2002)

In a region above the Almeida–Thouless line, where we are able to control the thermodynamic limit of the Sherrington–Kirkpatrick model and to prove replica symmetry, we show that the fluctuations of the overlaps and of the free energy are Gaussian, on the scale $1/\sqrt{N}$, for large N. The method we employ is based on the idea we recently developed of introducing quadratic coupling between two replicas. The proof makes use of the cavity equations and of concentration of measure inequalities for the free energy. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1515109]

I. INTRODUCTION

We consider the mean-field spin glass model, introduced by Sherrington and Kirkpatrick in Refs. 1 and 2, in the regime of high temperature or, equivalently, of large magnetic field. On physical grounds, it is known that in this region the replica symmetric solution holds, as shown for example in Ref. 3, and references quoted therein. However, due to the very large fluctuations present in the model, it is difficult to give a mathematically rigorous description of this region. Rigorous works on this subject include Refs. 4–8. For other rigorous results concerning the model, we refer to Refs. 9–13.

The method developed in Ref. 8 by Talagrand is particularly interesting. The starting point is the very deep physical idea that the phenomenon of replica symmetry breaking can be understood by studying the properties of the model under the application of auxiliary interactions, which explicitly break replica symmetry. In Ref. 8, this idea is employed to prove that the replica symmetric solution holds in a region, which (*probably*) coincides with that found in the theoretical physics literature,[3] i.e., up to the Almeida–Thouless critical line.

Recently,[14] we proposed a different strategy, which consists of coupling two replicas of the system by means of a term proportional to the square of the deviation of the overlap from its replica symmetric value. In this way, we proved that replica symmetry holds in a region above the Almeida–Thouless line. In the same region, we obtained a control of the two-replica system, provided that the coupling parameter is small enough, and we showed that the fluctuations of the overlap are at most of order $1/\sqrt{N}$. In the present paper we prove that, in the same region of parameters, the fluctuations of overlaps and free energy, when suitably rescaled, have a Gaussian distribution when $N\to\infty$. The main ingredients of the proof are the control of the thermodynamic limit obtained in Ref. 14 and concentration of measure techniques inspired by Talagrand's works. Then, by means of the cavity method, one can write self-consistent linear equations for the characteristic functions of the fluctuation variables, which can be easily solved.

b)Electronic mail: f.toninelli@sns.it

Previous results concerning limit theorems for fluctuations in the high temperature region of mean-field spin glass models include Refs. 4, 6, 15, 9, and 16.

This work is organized as follows: In Sec. II, we recall the main definitions of the model and introduce the overlap distribution structure. In Sec. III, we state the main results. Two useful tools, i.e., exponential inequalities and the cavity method, are briefly outlined in Secs. IV and V. In Secs. VI and VII, we prove the central limit theorem for overlap and free energy fluctuations, respectively. Finally, Sec. VIII is dedicated to a short outlook about open problems and further developments.

II. THE MODEL

The generic configuration of the Sherrington–Kirkpatrick (SK) model is determined by the N Ising variables $\sigma_i = \pm 1$, $i = 1,2,\ldots,N$, and the Hamiltonian is

$$H_N(\sigma,h;J) = -\frac{1}{\sqrt{N}} \sum_{(i,j)} J_{ij}\sigma_i\sigma_j - h\sum_i \sigma_i, \tag{1}$$

where the sum $\Sigma_{(i,j)}$ runs over all the $N(N-1)/2$ distinct couples of sites. The J_{ij}'s (quenched noise) are independent centered unit Gaussian variables $\mathcal{N}(0,1)$. The first term in (1) is a long-range random two-body interaction, while the second represents the interaction with a fixed external magnetic field h. For a given temperature $1/\beta$ we can introduce the disorder dependent partition function

$$Z_N(\beta,h;J) = \sum_{\{\sigma\}} \exp(-\beta H_N(\sigma,h;J)), \tag{2}$$

and the auxiliary function

$$\alpha_N(\beta,h) = \frac{1}{N} E \ln Z_N(\beta,h;J), \tag{3}$$

where E denotes the average with respect to the external noise J. Note that $\alpha_N(\beta,h)$ is the quenched average of the free energy per spin, apart from the multiplicative factor $-1/\beta$.

For later convenience, it is useful to generalize the model (1) by introducing a quenched random external magnetic field, which at every site is an independent Gaussian variable of strength $x>0$. In other words, the Boltzmann factor of the system becomes

$$\exp\left(\sqrt{\frac{t}{N}} \sum_{(i,j)} J_{ij}\sigma_i\sigma_j + \sum_i (\beta h + \sqrt{x}J_i)\sigma_i \right), \tag{4}$$

where J_i are i.i.d. $\mathcal{N}(0,1)$ random variables, independent of the J_{ij}'s. We let $t=\beta^2$ in the two-body term. In the following, we always regard the system as depending on the parameters $t,x,\beta h$. In analogy with Eqs. (2) and (3), we define the disorder-dependent partition function $Z_N(t,x,h;J)$ and the auxiliary function

$$\alpha_N(t,x,h) = \frac{1}{N} E \ln Z_N(t,x,h;J).$$

Here, E denotes averaging with respect to J_{ij} and J_i. For simplicity of notations, here and in the following we write the argument h instead of βh.

Let us consider a countably infinite number of independent copies (replicas) of the system, whose spin variables σ_i^a are distributed, for fixed J, according to the product state

$$\Omega_J = \Omega_J^1 \Omega_J^2 \ldots,$$

where $\Omega_J \equiv \Omega_J^{N,t,x,h}$ denotes the Gibbs state associated with the Boltzmann factor (4). Each replica is subject to the same quenched noise. The "real replica" approach has already been exploited in a number of papers.[17–20]

The overlap between two replicas a,b is defined as

$$q_{ab}(\sigma^a,\sigma^b)=\frac{1}{N}\sum_i \sigma_i^a\sigma_i^b,$$

with the obvious bounds

$$-1\leqslant q_{ab}\leqslant 1.$$

For a generic smooth function F of the overlaps, we define the $\langle . \rangle$ average as

$$\langle F(q_{12},q_{13},\ldots)\rangle = E\Omega_J(F(q_{12},q_{13},\ldots)).$$

Note that the average over disorder introduces correlations between different groups of replicas, which would be independent under the Boltzmann average Ω_J. For example,

$$\Omega_J(q_{12}q_{34})=\Omega_J(q_{12})\Omega_J(q_{34}),$$

but

$$\langle q_{12}q_{34}\rangle \neq \langle q_{12}\rangle\langle q_{34}\rangle.$$

III. THE HIGH TEMPERATURE REGION AND THE MAIN RESULTS

In this section, we recall the results of Ref. 14 and state limit theorems for fluctuations, in the region where we prove that replica symmetry holds, i.e.,

$$\lim_{N\to\infty}\alpha_N(t,x,h)=\overline{\alpha}(t,x,h).$$

$\overline{\alpha}(t,x,h)$ is the replica-symmetric free energy[1,2]

$$\overline{\alpha}(t,x,h)=\ln 2+\int \ln\cosh(\beta h+z\sqrt{t\overline{q}+x})d\mu(z)+\frac{t}{4}(1-\overline{q})^2,$$

where $\overline{q}$ is the Sherrington–Kirkpatrick order parameter, defined as the unique[17] solution of

$$\overline{q}=\overline{q}(t,x,h)=\int \tanh^2(\beta h+z\sqrt{t\overline{q}+x})d\mu(z),$$

and $d\mu(z)$ is the centered unit Gaussian measure.

In Ref. 14 we proved the following: Consider the auxiliary function $\tilde{\alpha}_N$, dependent on the parameter $\lambda\geqslant 0$

$$\tilde{\alpha}_N(t,x,h;\lambda)=\alpha_N(t,x,h)+\frac{1}{2N}E\ln\Omega_{t,x,h}(e^{N(\lambda/2)(q_{12}-\overline{q})^2})$$

and the trajectory in the (t,x) plane

$$\Gamma=(t',x_{t'})\equiv(t',x+\overline{q}(t-t'))\equiv(t',x_0-\overline{q}t'),\quad 0\leqslant t'\leqslant t \tag{5}$$

where $x_0=x+\overline{q}t$ and $\overline{q}=\overline{q}(t,x,h)=\overline{q}(t',x_{t'},h)$. Notice that $\tilde{\alpha}_N$ equals α_N for $\lambda=0$. Given x_0,h there exists a value $t_c(x_0,h)$, such that

$$|\overline{\alpha}(t',x_{t'},h)-\tilde{\alpha}_N(t',x_{t'},h;\lambda)|\leqslant\frac{k}{N} \tag{6}$$

for some constant k, uniformly in the triangular region

$$0\leqslant t'+\lambda\leqslant\overline{t}<t_c(x_0,h). \tag{7}$$

In the same region, the overlaps self-average around the value $\overline{q}$

$$\langle(q_{ab}-\overline{q})^2\rangle\leqslant\frac{k}{N}. \tag{8}$$

The critical value $t_c(x_0,h)$ is determined in the following way:[14] Let

$$\Delta(x_0,h,\lambda_0)\equiv\frac{1}{2}\max_{\rho\in\mathbb{R}}\left(\int \ln(\cosh\rho+\tanh^2(\beta h+z\sqrt{x_0})\sinh\rho)d\mu(z)-\rho\overline{q}-(\rho^2/2\lambda_0)\right),$$

where $\lambda_0\geqslant 0$. Then, we define $t_c(x_0,h)$ such that, for any $\lambda_0\leqslant t_c(x_0,h)$, one has

$$\Delta(x_0,h,\lambda_0)=0.$$

In the case of vanishing external field $x=h=0$, then also $x_0=\overline{q}=0$ and $t_c=1$, the correct critical value. As discussed in Ref. 14, the region defined by (7) falls short of the Almeida–Thouless line, which is the expected critical line.

In this paper, we investigate more precisely the behavior of fluctuations of physical quantities around the replica symmetric value. First of all, we give a central limit-type theorem for the rescaled overlaps

$$\xi_{ab}^N=\sqrt{N}(q_{ab}-\overline{q}),$$

showing that they behave as centered Gaussian variables characterized by a nondiagonal correlation matrix. Notice that, thanks to (8), one has the following bound for the second moment of the rescaled overlap fluctuations:

$$\langle(\xi_{ab}^N)^2\rangle\leqslant k. \tag{9}$$

Theorem 1: *If $t<t_c(x_0,h)$, the rescaled overlaps ξ_{ab}^N tend in distribution, for $N\to\infty$, to jointly Gaussian variables ξ_{ab}, with covariances*

$$\langle\xi_{ab}^2\rangle=A(t,x,h),$$

$$\langle\xi_{ab}\xi_{ac}\rangle=B(t,x,h),$$

$$\langle\xi_{ab}\xi_{cd}\rangle=C(t,x,h),$$

where a, b, c, d are all different. A, B, and C are explicitly given by

$$A(t,x,h)=(1+2R+4R^2)Y+c_0R^2, \tag{10}$$

$$B(t,x,h)=(1+4R)RY+c_0R^2, \tag{11}$$

$$C(t,x,h)=4R^2Y+c_0R^2, \tag{12}$$

where

$$Y(t,x,h)=\frac{1}{Y_0^{-1}-t},$$

$$R(t,x,h)=\frac{d_0}{Y_0^{-1}+2d_0-t},$$

and $Y_0(x_0,h), c_0(x_0,h)$, *and* $d_0(x_0,h)$ *are chosen in such a way that* A,B,C *satisfy the initial conditions*

$$A(0,x_0,h)=1-\overline{q}^2,$$

$$B(0,x_0,h)=\overline{q}-\overline{q}^2,$$

$$C(0,x_0,h)=\int \tanh^4(z\sqrt{x_0}+\beta h)d\mu(z)-\overline{q}^2.$$

In particular, one has

$$Y_0=\int \cosh^{-4}(z\sqrt{t\overline{q}+x}+\beta h)d\mu(z). \tag{13}$$

Recently, an analogous result was proved independently by Talagrand,[16] who computed the $N\to\infty$ limit for all moments of the ξ variables.

The expressions for $A,B,$ and C were first given by Guerra in Ref. 17. For $h=x=0$, the limit Gaussian variables are not correlated and have variance $1/(1-t)$, which is a well-known result.[4,6]

Let us consider now free-energy fluctuations. Aizenman, Lebowitz, and Ruelle[4] proved that in the case of zero external field and $t<1$, the variable

$$\ln Z_N-\ln EZ_N$$

tends to a shifted Gaussian random variable whose variance diverges at $t=1$. In the general case the situation is quite different and the following theorem holds:

Theorema 2: *Let*

$$\hat{f}_N(t,x,h;J)\equiv\sqrt{N}\left(\frac{\ln Z_N(t,x,h;J)}{N}-\overline{\alpha}(t,x,h)\right).$$

If $t<t_c(x_0,h)$ *then*

$$\hat{f}_N(t,x,h;J)\overset{d}{\to}\mathcal{N}(0,\sigma^2(t,x,h)),$$

where

$$\sigma^2(t,x,h)=Var(\ln\cosh(z\sqrt{t\overline{q}+x}+\beta h))-\frac{\overline{q}^2t}{2}.$$

Here, $Var(.)$ *denotes the variance of a random variable and* $z=\mathcal{N}(0,1)$.

Notice that fluctuations of the extensive free energy $\ln Z_N$ are of order 1 at zero external field and of order $\sqrt{N}$ otherwise.

IV. EXPONENTIAL SUPPRESSION OF OVERLAP FLUCTUATIONS

General arguments based on concentration of measure[9,21,22] show that the fluctuations of the free energy $1/N \ln Z_N$ around its mean value α_N are exponentially suppressed as N grows. Indeed, one has the following:[9]

Theorem 3: *For any* $u>0$,

$$P\left(\left|\frac{1}{N}\ln Z_N(t,x,h;J)-\alpha_N(t,x,h)\right|\geqslant u\right)\leqslant \exp(-NKu^2), \tag{14}$$

where

$$K=\frac{1}{t+2x}.$$

This, in connection with the results of Ref. 14, allows us to obtain a strong control on the fluctuations of the overlaps (we learned this nice argument in Ref. 8): First of all, the same argument leading to Theorem 3 shows that

$$P\left(\left|\frac{1}{2N}\ln \Omega_{t,x,h}(e^{N(\lambda/2)(q_{12}-\bar{q})^2})-\tilde{\alpha}_N(t,x,h,\lambda)+\alpha_N(t,x,h)\right|\geqslant 2u\right)\leqslant \exp(-NKu^2).$$

Therefore, thanks to Eq. (6), with probability at least $1-\exp(-NKu^2)$ one has

$$\Omega_{t,x,h}(e^{(\lambda/2)\,N(q_{12}-\bar{q})^2})\leqslant e^{4Nu+2C}$$

for $\lambda\leqslant\bar{\lambda}<t_c(x_0,h)-t$. Then, by Tchebysheff's inequality

$$\Omega_{t,x,h}(\chi_{\{|q_{12}-\bar{q}|\geqslant v\}})\leqslant e^{-(\bar{\lambda}/2)\,Nv^2}\Omega_{t,x,h}(e^{(\bar{\lambda}/2)\,N(q_{12}-\bar{q})^2})\leqslant e^{N(4u-(\bar{\lambda}/2)\,v^2)+2C}$$

and, choosing $u=\bar{\lambda}v^2/16$, one has

$$\Omega_{t,x,h}(\chi_{\{|q_{12}-\bar{q}|\geqslant v\}})\leqslant e^{-N(v^2\bar{\lambda}/4)+2C}.$$

The estimate we are looking for easily follows

$$E\Omega_{t,x,h}(\chi_{\{|q_{12}-\bar{q}|\geqslant v\}})\leqslant e^{-N(v^2\bar{\lambda}/4)+2C}+e^{-NK(\bar{\lambda}^2v^4/256)}. \tag{15}$$

Of course, this is much more than just self-averaging of the overlaps.

V. THE CAVITY METHOD

The cavity method allows expression of thermal averages of quantities defined on the N-spin system as functions of averages on the system with $N-1$ spins, at a slightly different temperature. This method has been widely applied both in the theoretical physics literature[3] and in the mathematical physics one (see, for instance, Refs. 5, 16, 10, and 18).

Introduce the following definitions:

$$t'=t(1-N^{-1})$$

$$\sigma^a=(\eta^a,\epsilon^a),\quad \eta^a\in\{-1,1\}^{N-1},\quad \epsilon^a=\sigma_N^a=\pm 1$$

$$J=J_N$$

$$g_i=J_{N\ i},\quad i=1,\ldots,N-1$$

$$\Omega'(.)=\Omega_{N-1}^{t'}(.).$$

The cavity equations consist of the identity

$$\Omega_N^{t,x,h}(f(\sigma^1,\ldots,\sigma^k))=\frac{\Omega'(Av\quad f(\eta^1,\epsilon^1,\ldots,\eta^k,\epsilon^k)\Psi^{(k)})}{\Omega'(Av\quad \Psi^{(k)})},\tag{16}$$

where Av denotes the average over the spin variables ϵ^a and

$$\Psi^{(k)}\equiv\exp\sum_{a=1}^{k}\epsilon^a(\sqrt{t/N}g\,\eta^a+\sqrt{x}J+\beta h).\tag{17}$$

$g\,\eta^a$ denotes the scalar product $\Sigma_{i=1}^{N-1}g_i\eta_i^a$.

VI. LIMIT THEOREM FOR OVERLAP FLUCTUATIONS

To prove Theorem 1, it suffices[23] to show that for any integer s, the characteristic function

$$\phi_N^t(u)=\langle\exp i\quad u\xi^N\rangle\equiv\left\langle\exp i\sum_{(a,b)}u_{ab}\xi_{ab}^N\right\rangle,\quad 1\leqslant a<b\leqslant s$$

converges for $N\to\infty$ to

$$\phi^t(u)=\exp\{-\tfrac{1}{2}(\hat{L}u,u)\},\tag{18}$$

where $(\ldots)$ denotes scalar product and $\hat{L}$ is the $s(s-1)/2\times s(s-1)/2$ dimensional matrix of elements

$$L_{(ab),(ab)}=A(t,x,h),$$

$$L_{(ab),(ac)}=B(t,x,h),$$

$$L_{(ab),(cd)}=C(t,x,h).$$

The idea of the proof is to obtain a set of closed linear differential equations for $\phi_N^t(u)$, which determines uniquely the solution as (18), for $N\to\infty$. Some of the calculations involved in the proof are quite long, although straightforward, and are therefore just sketched.

First of all, we explain how the cavity equations (16) and (17) can be simplified in the region where (15) holds. Following Ref. 10, we introduce some notations, letting $\Omega(.)\equiv\Omega_N^{t,x,h}(.)$ and $\Omega'(.)\equiv\Omega_{N-1}^{t',x,h}(.)$. Moreover, we define

$$b=\Omega'(\eta)\in\mathbb{R}^{N-1},$$

$$\dot{\eta}^a=\eta^a-b,$$

$$X=\sqrt{t/N}gb+\sqrt{x}J+\beta h,$$

$$\Psi_0^{(k)}=\exp\left(X\sum_{a=1}^{k}\epsilon^a\right),$$

$$f(\sigma^1,\ldots,\sigma^k)=f(\eta^1,\epsilon^1,\ldots,\eta^k,\epsilon^k).$$

Then, the following holds:[10]

Theorem 4:

$$E\Omega(f(\sigma^1,\ldots,\sigma^k))=E\frac{1}{\cosh^k X}\Omega'(Av\,f\Psi_0^{(k)}) \tag{19}$$

$$+tE\frac{1}{\cosh^k X}\Omega'\left(Av\,f\Psi_0^{(k)}\sum_{1\leqslant a<c\leqslant k}\epsilon^a\epsilon^c\frac{\dot\eta^a\dot\eta^c}{N}\right) \tag{20}$$

$$+tE\frac{1}{\cosh^k X}\Omega'\left(Av\,f\Psi_0^{(k)}\sum_{1\leqslant a\neq c\leqslant k}\epsilon^a\epsilon^c\frac{\dot\eta^c b}{N}\right) \tag{21}$$

$$-ktE\frac{\tanh X}{\cosh^k X}\Omega'\left(Av\,f\Psi_0^{(k)}\sum_{a=1}^{k}\epsilon^a\frac{\dot\eta^a b}{N}\right)+S, \tag{22}$$

and the "error term" S can be estimated as

$$|S|\leqslant w_k(t,x,h)E\Omega'\left(Av|f|\left(\sum_{a=1}^{k+1}\left(\frac{\dot\eta^a b}{N}\right)^2+\sum_{1\leqslant a<c\leqslant k+2}\left(\frac{\dot\eta^a\dot\eta^c}{N}\right)^2\right)\right),$$

where w is a smooth function of its arguments, independent of N.

Note that, with respect to Theorem 3.2 in Ref. 10, the last sum on the right-hand side is performed on $a<c$ instead of $a\leqslant c$. However, the proof of Theorem 4 proceeds exactly as in Ref. 10.

Theorem 4 is a sort of Taylor expansion of the cavity equations around $\eta^a=b$. This turns out to be particularly useful in the region where Eq. (15) holds, since in this case $\dot\eta_a$ is small with large probability, and S vanishes for $N\to\infty$, as we explain in the following.

In order to prove Theorem 1, we first exploit symmetry between sites to write

$$\partial_{u_{rr'}}\phi_N^t(u)=i\langle\xi_{rr'}^N e^{iu\xi^N}\rangle=i\sqrt{N}\langle(\sigma_N^r\sigma_N^{r'}-\overline{q})e^{iu\xi^N}\rangle, \tag{23}$$

$$\varphi_N^{(a)t}(u)\equiv i\langle\xi_{a,s+1}^N e^{iu\xi^N}\rangle=i\sqrt{N}\langle(\sigma_N^a\sigma_N^{s+1}-\overline{q})e^{iu\xi^N}\rangle, \tag{24}$$

$$\psi_N^t(u)\equiv i\langle\xi_{s+1,s+2}^N e^{iu\xi^N}\rangle=i\sqrt{N}\langle(\sigma_N^{s+1}\sigma_N^{s+2}-\overline{q})e^{iu\xi^N}\rangle, \tag{25}$$

and then employ the cavity equations to express these quantities as functions of ϕ,φ,ψ themselves. For instance, apply Theorem 4 to the right-hand side of Eq. (23) and consider the term arising from (19). After averaging on the dichotomic variables ϵ, one is left with

$$\begin{aligned}
&i\left(\sqrt{N}-i\sum_{(a,b)}u_{ab}\overline{q}\right)E\{(\tanh^2 X-\overline{q})\Omega'\exp(iu'\xi^{N-1})\}\\
&\quad-u_{rr'}E\{(1-\overline{q}\tanh^2 X)\Omega'\exp(iu'\xi^{N-1})\}\\
&\quad-(1-\overline{q})\sum_{a\neq r,r'}(u_{ar}+u_{ar'})E\{\tanh^2 X\Omega'\exp(iu'\xi^{N-1})\}\\
&\quad-\sum_{(c,d)c,d\neq r,r'}u_{cd}E\{\tanh^2 X(\tanh^2 X-\overline{q})\Omega'\exp(iu'\xi^{N-1})\}+o(1),
\end{aligned} \tag{26}$$

where $u'=u\sqrt{1-1/N}$. The term $o(1)$ arises when $\exp(iu/\sqrt{N})$ is expanded around $u=0$ and the terms of order u^2 or higher are neglected. Indeed, one has

$$\left|\sqrt{N}\left\langle (\sigma_N^r\sigma_N^{r'}-\overline{q})e^{iu'\xi^{N-1}}\left(e^{i\Sigma_{(a,b)}(u_{ab}/\sqrt{N})(\sigma_N^a\sigma_N^b-\overline{q})}-1-i\sum_{(a,b)}\frac{u_{ab}}{\sqrt{N}}(\sigma_N^a\sigma_N^b-\overline{q})\right)\right\rangle\right|$$

$$\leqslant 2\sqrt{N}\left|e^{i\Sigma_{(a,b)}(u_{ab}/\sqrt{N})(\sigma_N^a\sigma_N^b-\overline{q})}-1-i\sum_{(a,b)}\frac{u_{ab}}{\sqrt{N}}(\sigma_N^a\sigma_N^b-\overline{q})\right|=O(N^{-1/2}).$$

Now, rewrite E as $E\,E_g$, where E_g denotes the average only with respect to the random variables J and $g_i, i=1,\ldots,N-1$, and notice that J, g_i do not appear in the thermal average Ω'. Computation of $E_g(\ldots)$ would be simpler if, instead of X, there were

$$\overline{X}\equiv\sqrt{t/N}g\overline{b}+\sqrt{x}J+\beta h,$$

where

$$\overline{b}\equiv\frac{b}{||b||}\sqrt{N\overline{q}}.$$

Of course, one has

$$\overline{X}\overset{d}{=}z\sqrt{t\overline{q}+x}+\beta h,$$

where z is a standard unit Gaussian variable and equality holds in distribution so that, for instance,

$$E_g\tanh^2\overline{X}=\overline{q}.$$

The idea is, therefore, to expand around $X=\overline{X}$. As a preliminary fact, notice that the second moment of the random variable $(b-\overline{b})$ is bounded uniformly in N. Indeed,

$$E||b-\overline{b}||^2=E(||b||-\sqrt{N\overline{q}})^2\leqslant\frac{1}{\overline{q}N}E(||b||^2-N\overline{q})^2 \tag{27}$$

$$=\frac{1}{\overline{q}}E\Omega'(\xi_{12}^{N-1}\xi_{34}^{N-1})+O(1/N)=O(1), \tag{28}$$

thanks to Eq. (9). As an example, let us examine in detail the first term in (26), that is,

$$i\sqrt{N}EE_g(\tanh^2 X)\Omega'\exp(iu'\xi^{N-1})-i\overline{q}\sqrt{N}E\Omega'\exp(iu'\xi^{N-1}). \tag{29}$$

By a simple second-order Taylor expansion and an integration by parts on the Gaussian noise g, one finds

$$E_g\tanh^2 X=E_g\tanh^2\overline{X}+\frac{t}{N}(b-\overline{b})\overline{b}E_g\partial_x^2\tanh^2 x|_{x=\overline{X}} \tag{30}$$

$$+\frac{t}{2N}E_g\,\partial_x^2\tanh^2 x|_{x=\overline{X}+\theta(X-\overline{X})}(g(b-\overline{b}))^2 \tag{31}$$

$$=\overline{q}+\frac{t}{2N}(b-\overline{b})(b+\overline{b})E_g\partial_x^2\tanh^2\overline{X} \tag{32}$$

$$+\frac{t}{2N}||b-\overline{b}||^2E_g(\partial_x^2\tanh^2 x|_{x=\overline{X}+\theta(X-\overline{X})}-\partial_x^2\tanh^2\overline{X}) \tag{33}$$

$$+\frac{t^2}{2N^2}E_g\,\partial_x^4\tanh^2 x|_{x=\overline{X}+\theta(X-\overline{X})}[(b-\overline{b})(\overline{b}+\theta(b-\overline{b}))]^2, \tag{34}$$

where $0\leqslant\theta\leqslant 1$. Analyze each term separately. Recalling the definitions of b and $\overline{b}$, the second term in (32) equals

$$\frac{t}{2N}\Omega'(\eta^{s+1}\eta^{s+2}-N\overline{q})\int d\mu(z)\,\partial_x^2\tanh^2(\beta h+z\sqrt{t\overline{q}+x}) \tag{35}$$

$$=\frac{t}{\sqrt{N}}\Omega'(\xi^{N-1}_{s+1,s+2})(3Y_0+2\overline{q}-2)+O(1/N), \tag{36}$$

where Y_0 was defined in (13). Another application of Taylor's expansion and integration by parts, together with Cauchy–Schwarz inequality and the fact that the derivatives of the function $\tanh^2(x)$ are bounded, shows that the terms (33) and (34) can be bounded by

$$\frac{k}{N}||b-\overline{b}||^2.$$

Therefore, using the estimate (28), the expression (29) reduces to

$$it(3Y_0+2\overline{q}-2)E\Omega'[\xi_{s+1,s+2}\exp(iu'\xi^{N-1})]+O(N^{-1/2}),$$

and

$$i\sqrt{N}E\{(\tanh^2 X-\overline{q})\Omega'\exp(iu'\xi^{N-1})\}=t(2\overline{q}-2+3Y_0)\psi'+o(1),$$

where

$$\psi'\equiv\psi^{t'}_{N-1}(u').$$

The other terms in (26) are much simpler than (29), and can be dealt with in the same way. Finally, the whole expression (26) can be rewritten as

$$t(2\overline{q}-2+3Y_0)\psi'-u_{rr'}(1-\overline{q}^2)\phi'-(\overline{q}-\overline{q}^2)\sum_{a\neq r,r'}(u_{ar}+u_{ar'})\phi'$$

$$-(Y_0-(1-\overline{q})^2)\sum_{(c,d)c,d\neq r,r'}u_{cd}\phi'+o(1). \tag{37}$$

The steps leading to expression (37) can be repeated with minor changes for the remaining terms (20) to (22). These terms, although they look more complicated than (19) at first sight, are actually simpler to treat, since a first- (instead of second) order Taylor expansion around $X=\overline{X}$ is sufficient. This is due to the presence of terms like $\dot{\eta}_a\dot{\eta}_b/N$ or $\dot{\eta}_a b/N$, which are with large probability small, thanks to (9). Also in this case, one finds that terms (20) to (22) give quantities linear in $\phi',\partial\phi',\varphi',\psi'$, apart from terms of order $o(1)$. As for the "error term" S which appears in Theorem 4, one can easily check that it vanishes in the thermodynamic limit. This is a consequence of the exponential decay of overlap fluctuations, as expressed by (15).

Next, we show that terms like $\phi^{t'}_{N-1}(u')$ or $\psi^{t'}_{N-1}(u')$ can be substituted by the same functions calculated at N,t,u, apart from negligible error terms. Indeed, for instance

$$\phi^t_N(u)=\langle\exp(iu'\xi^{N-1}+iu(\sigma^1_N\sigma^2_N-\overline{q})/\sqrt{N})\rangle_t=\langle\exp iu'\xi^{N-1}\rangle_t(1+o(1))=\phi'+o(1).$$

In the last step, we used Theorem 4 in order to substitute t with t'. Therefore, Eq. (23) reduces to a linear relation between ϕ,φ, and ψ, apart from a remainder which becomes irrelevant in the thermodynamic limit. In the same way, one sees also that Eqs. (24), (25) yield linear equations for ϕ,φ,ψ. Putting everything together, in the thermodynamic limit one has a set of coupled linear differential equations of the form

$$\mathbf{\Phi}^t(u) = \phi^t(u)\mathbf{v}(u) + t\hat{M}\mathbf{\Phi}^t(u), \tag{38}$$

where $\mathbf{\Phi}^t(u)$ is the vector

$$\mathbf{\Phi}^t(u) = (\partial_{u_{12}}\phi^t(u),\ldots,\partial_{u_{s-1,s}}\phi^t(u),\varphi^{(1)\,t}(u),\ldots,\varphi^{(s)\,t}(u),\psi^t(u)).$$

$\mathbf{v}(u)$ is a vector whose components are homogeneous linear functions of the variables u, while $\hat{M}$ is a real square matrix with elements depending on $\overline{q}, Y_0$ alone. We do not report here the explicit expressions of $\mathbf{v}(u)$ and $\hat{M}$, which are quite complicated. However, it is instructive to check that, for instance, the term (37) is in agreement with this structure. In fact, the coefficient of ϕ' is a homogeneous linear function of the u variables, while the coefficient of ψ' is linear in t and depends only on Y_0 and $\overline{q}$. As will be clear in the following, only the structure (38), and not the specific form of $\mathbf{v}$ and $\hat{M}$, are needed to conclude the proof of the theorem.

Assume at first that the matrix $(1-t\ \hat{M})$ is invertible, which in principle can fail only for a finite number of values of t, since $\hat{M}$ is finite dimensional. In this case, Eq. (38) can be reduced to a first-order differential system in normal form

$$\mathbf{\Phi}^t(u) = \phi^t(u)(1-t\ \ \hat{M})^{-1}\mathbf{v}(u), \tag{39}$$

which can be easily integrated. The most general solution for $\phi^t(u)$, compatible with the initial condition

$$\phi^t(0) = 1,$$

is of the form

$$\phi^t(u) = \exp\{-\tfrac{1}{2}(\hat{K}u,u) + (p,u)\}, \tag{40}$$

where p is some $s(s-1)/2$ dimensional u-independent vector, and $\hat{K}$ is a $s(s-1)/2 \times s(s-1)/2$ real symmetric positive definite matrix. The symmetry and non-negativity of $\hat{K}$ derive from the obvious property of symmetry among replicas, and from the bound

$$|\phi^t(u)| \leqslant 1,$$

which holds for any characteristic function. The quadratic dependence on u of the exponent of $\phi^t(u)$ stems from the linear dependence of the components of $\mathbf{v}(u)$. Clearly, Eq. (40) means that the random variables $\{\xi_{ab}^N\}$ converge to some Gaussian process $\{\xi_{ab}\}$. Moreover, it turns out that the identification

$$p = 0$$

and

$$\hat{K} = \hat{L}$$

are straightforward. Indeed, it was shown by Guerra in Ref. 17 that, if the limit process is Gaussian, then it is centered and its covariance function is exactly $\hat{L}$.

In order to conclude the proof, it remains to show convergence of the characteristic function for those possible values $\tilde{t}$ where $(1-t\,\hat{M})$ is singular. For any $\delta>0$ one can write

$$\phi_N^{\tilde{t}}(u)=\phi_N^{\tilde{t}-\delta}(u)+\delta\partial_t\phi_N^t|_{t=\tilde{t}-\theta_N\delta},$$

where $0<\theta_N<1$. After a straightforward computation, one finds that

$$\partial_t\phi_N^t=\frac{1}{2}\left\langle e^{iu\xi^N}\left(\sum_{(a,b)}(\xi_{ab}^N)^2-s\sum_{a=1}^{s}(\xi_{a,s+1}^N)^2+\frac{s(s+1)}{2}(\xi_{s+1,s+2}^N)^2\right)\right\rangle.$$

By exploiting the uniform bound (9) and the arbitrariness of δ, one finds therefore that the theorem holds also for $t=\tilde{t}$. □

VII. FLUCTUATIONS OF THE FREE ENERGY

In order to prove Theorem 2, we show that the characteristic function of $\hat{f}_N$ converges to that of $\mathcal{N}(0,\sigma^2(t,x,h))$, i.e.,

$$\lim_{N\to\infty}Ee^{iu\hat{f}_N(t,x,h)}=e^{-(u^2/2)\,\sigma^2(t,x,h)}.$$

Define

$$\overline{\alpha}(t')=\overline{\alpha}(t',x_{t'},h)$$

$$\zeta_N(t')=\frac{\ln Z_N(t',x_{t'},h;J)}{N},$$

where $x_{t'}$ is defined in Eq. (5). The characteristic function of $\hat{f}_N$ can be written as

$$Ee^{iu\hat{f}_N(t,x,h)}=Ee^{iu\hat{f}_N(0,x_0,h)}+iuE\int_0^t e^{iu\hat{f}_N(t',x_{t'},h)}\frac{d}{dt'}\hat{f}_N(t',x_{t'},h)dt'. \tag{41}$$

Since

$$\frac{d}{dt'}\overline{\alpha}(t')=\frac{1}{4}(1-\overline{q})^2,$$

$$\frac{d}{dt'}\zeta_N(t')=\frac{1}{2\sqrt{t'}N^{3/2}}\sum_{(i,j)}J_{ij}\Omega_{t'}(\sigma_i\sigma_j)-\frac{\overline{q}}{2N\sqrt{x_{t'}}}\sum_i J_i\Omega_{t'}(\sigma_i),$$

one finds through integration by parts that

$$E\left\{e^{iu\zeta_N(t')}\frac{d}{dt'}\zeta_N(t')\right\}=\frac{1}{4}E\{e^{iu\zeta_N(t')}[1-\Omega_{t'}(q_{12}^2)-2\overline{q}(1-\Omega_{t'}(q_{12}))]\}$$
$$+\frac{iu}{4N}E\{e^{iu\zeta_N(t')}[\Omega_{t'}(q_{12}^2)-2\overline{q}\Omega_{t'}(q_{12})-N^{-1}]\}. \tag{42}$$

By using (42) in Eq. (41), one finds

$$Ee^{iu\hat{f}_N(t,x,h)}=Ee^{iu\hat{f}_N(0,x_0,h)}+\frac{u^2\overrightarrow{q}^2}{4}E\int_0^t e^{iu\hat{f}_N(t')}dt'-\frac{u^2}{4N}\int_0^t Ee^{iu\hat{f}_N(t')}(\Omega_{t'}(\xi_{12}^2)-1)dt'$$

$$-\frac{iu}{4\sqrt{N}}\int_0^t Ee^{iu\hat{f}_N(t')}\Omega_{t'}(\xi_{12}^2)dt'. \tag{43}$$

At $t=0$, all sites are decoupled and the central limit theorem for i.i.d. random variables implies that

$$\hat{f}_N(0,x,h)\overset{d}{\to}\mathcal{N}(0,\sigma^2(0,x,h)). \tag{44}$$

The last two terms in Eq. (43) clearly vanish for $N\to\infty$. For instance,

$$N^{-1/2}|Ee^{iu\hat{f}_N(t')}\Omega_{t'}(\xi_{12}^2)|\leqslant N^{-1/2}E\Omega_{t'}(\xi_{12}^2)=O(N^{-1/2}),$$

since

$$E\Omega_{t'}(\xi_{12}^2)=O(1)$$

for $t'<t_c$. Therefore, Eq. (43) yields the following linear integral equation for the characteristic function:

$$Ee^{iu\hat{f}_N(t,x,h)}=Ee^{iu\hat{f}_N(0,x_0,h)}+\frac{u^2\overrightarrow{q}^2}{4}E\int_0^t e^{iu\hat{f}_N(t',x_{t'},h)}dt'+o(1),$$

whose solution is, keeping into account the initial condition (44)

$$Ee^{iu\hat{f}_N(t,x,h)}=e^{-(u^2/2)\,\sigma^2(t,x,h)}+o(1).$$

□

Before concluding this section, we wish to note that from Eq. (43) one can also obtain in a very simple way a well-known result for free-energy fluctuations at zero external field and $t<1$,[4,6] i.e.,

$$\eta_N^t\equiv\ln Z_N(t)-N\left(\ln 2+\frac{t}{4}\right)\overset{d}{\to}\hat{Y}_t-\frac{1}{4}\ln\frac{1}{1-t}, \tag{45}$$

where Y_t is a centered Gaussian random variable of variance

$$\frac{1}{2}\left(\ln\frac{1}{1-t}-t\right).$$

Indeed, setting $u=\sqrt{N}s$ and $x=h=0$ in Eq. (43), one obtains the equation

$$Ee^{is\eta_N^t}=1-\frac{u^2}{4}\int_0^t Ee^{is\eta_N^{t'}}(\Omega_{t'}(\xi_{12}^2)-1)dt'-\frac{iu}{4}\int_0^t Ee^{is\eta_N^{t'}}\Omega_{t'}(\xi_{12}^2)dt'. \tag{46}$$

Since Theorem 1 implies, for vanishing external field and $t<1$,

$$E(\Omega_t(\xi_{12}^2)-\langle\xi_{12}^2\rangle)^2=\langle\xi_{12}^2\xi_{34}^2\rangle-\langle\xi_{12}^2\rangle^2=o(1),$$

Eq. (46) yields

$$Ee^{is\eta_N^t}=1-\frac{u^2}{4}\int_0^t Ee^{is\eta_N^{t'}}\left(\frac{1}{1-t'}-1\right)dt'-\frac{iu}{4}\int_0^t Ee^{is\eta_N^{t'}}\frac{1}{1-t'}dt'+o(1),$$

from which the result (45) easily follows.

VIII. CONCLUSIONS AND OUTLOOK

We have employed the cavity method to prove a central limit theorem for the fluctuations of overlaps and free energy, in a region above the Almeida–Thouless line. The key ingredient was provided by the control of the coupled two replica system. The open question remains to understand whether and how our method can be extended to the entire physically expected high temperature region.

In the case of vanishing external field, our method can be employed to obtain very detailed information on the system in proximity of the critical point. In particular, one can obtain lower and upper bounds on the overlap fluctuations, at $\beta=1$. We plan to report on this soon.[24]

We find the exotic matrix bialgebras which correspond to the two nontriangular nonsingular 4×4 R-matrices in the classification of Hietarinta, namely, $R_{S0,3}$ and $R_{S1,4}$. We find two new exotic bialgebras $S03$ and $S14$ which are not deformations of the classical algebras of functions on GL(2) or GL(1|1). With this we finalize the classification of the matrix bialgebras which unital associative algebras generated by four elements. We also find the corresponding dual bialgebras of these new exotic bialgebras and study their representation theory in detail. We also discuss in detail a special case of $R_{S1,4}$ in which the corresponding algebra turns out to be a special case of the two-parameter quantum group deformation $\mathrm{GL}_{p,q}(2)$. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1516845]

I. INTRODUCTION

Until now there was no complete list of the matrix bialgebras which are unital associative algebras generated by four elements. Naturally, since the co-product relations are the classical ones we first mention the two related to GL(2), namely, the standard $\mathrm{GL}_{pq}(2)$ (Ref. 1) and nonstandard (Jordanian) $\mathrm{GL}_{gh}(2)$ (Ref. 2) two-parameter deformations. For the supergroup GL(1|1) there are also two: the standard $\mathrm{GL}_{pq}(1|1)$ (Refs. 3–5) and the hybrid (standard–nonstandard) $\mathrm{GL}_{qh}(1|1)$ (Ref. 6) two-parameter deformations. Recently, in Ref. 7 it was shown that there are no more deformations of GL(2) or GL(1|1). In particular, it was shown that these four deformations match the distinct triangular 4×4 R-matrices from the classification of Ref. 8 which are deformations of the trivial R-matrix [corresponding to undeformed GL(2)].

Naturally, there are matrix bialgebras generated by four elements, which are not deformations of the classical algebra of functions over the group GL(2) or the supergroup GL(1|1). Those should correspond to 4×4 R-matrices which are not deformations of the trivial R-matrix. Studying the classification of Ref. 8 we noticed altogether five nonsingular such R-matrices. The triangular ones were introduced in Ref. 7 and their duals were found and studied in detail in Ref. 9. In the latter paper we called these bialgebras exotic.

In the present article we finalize the explicit classification of the matrix bialgebras generated by four elements, by studying those that correspond to the two nontriangular nonsingular 4×4 R-matrices of Ref. 8, namely, $R_{S0,3}$ and $R_{S1,4}$ which also are not deformations of the trivial R-matrix.

The article is organized as follows. Section II just introduces general notation. In Sec. III we study the matrix bialgebra $S03$ which corresponds to $R_{S0,3}$. We find the dual bialgebra $s03$ and study the representation theory of $s03$ in detail. In Secs. IV and V we study the matrix bialgebras $S14$ and $S14o$ which correspond to $R_{S1,4}$ for two distinctive regions of the deformation parameter q: $q^2\neq1$ and $q^2=1$, respectively. In both cases we find the corresponding dual bialgebras and their representation theory. In Sec. VI we present our conclusions and outlook.

II. GENERALITIES

In this article we consider matrix bialgebras which are unital associative algebras generated by four elements a,b,c,d. The co-product and co-unit relations are the classical ones:

$$\delta\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} a\otimes a+b\otimes c & a\otimes b+b\otimes d \\ c\otimes a+d\otimes c & c\otimes b+d\otimes d \end{pmatrix}, \tag{2.1a}$$

$$\varepsilon\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{2.1b}$$

However, the bialgebras under consideration are not Hopf algebras, except one. This shall be discussed separately in each case.

It shall be convenient to make the following change of generators:

$$\tilde a=\tfrac12(a+d),\quad \tilde d=\tfrac12(a-d),\quad \tilde b=\tfrac12(b+c),\quad \tilde c=\tfrac12(b-c). \tag{2.2}$$

With the new generators we have

$$\delta\begin{pmatrix} \tilde a & \tilde b \\ \tilde c & \tilde d \end{pmatrix}=\begin{pmatrix} \tilde a\otimes\tilde a+\tilde b\otimes\tilde b-\tilde c\otimes\tilde c+\tilde d\otimes\tilde d & \tilde a\otimes\tilde b+\tilde b\otimes\tilde a-\tilde c\otimes\tilde d+\tilde d\otimes\tilde c \\ \tilde a\otimes\tilde c+\tilde c\otimes\tilde a-\tilde b\otimes\tilde d+\tilde d\otimes\tilde b & \tilde a\otimes\tilde d+\tilde d\otimes\tilde a-\tilde b\otimes\tilde c+\tilde c\otimes\tilde b \end{pmatrix},$$
$$\varepsilon\begin{pmatrix} \tilde a & \tilde b \\ \tilde c & \tilde d \end{pmatrix}=\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}. \tag{2.3}$$

III. ALGEBRA $S03$

A. Bialgebra relations

In this section we consider the matrix bialgebra $S03$. We obtain it by applying the RTT relations of Ref. 10:

$$RT_1T_2=T_2T_1R, \tag{3.1}$$

where $T_1=T\otimes\mathbf{1}_2$, $T_2=\mathbf{1}_2\otimes T$, for the case when $R=R_{S0,3}$, where

$$R_{S0,3}\equiv\begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & -1 & 0 \\ -1 & 0 & 0 & 1 \end{pmatrix}. \tag{3.2}$$

This R-matrix is given in Ref. 8.

The relations which follow from (3.1) and (3.2) are

$$\begin{gathered} b^2+c^2=0, \quad a^2-d^2=0, \\ cd=ba, \quad dc=-ab, \\ bd=ca, \quad db=-ac, \\ da=ad, \quad cb=-bc. \end{gathered} \tag{3.3}$$

In terms of the generators $\tilde{a},\tilde{b},\tilde{c},\tilde{d}$ we have

$$\begin{gathered} \tilde{b}^2=\tilde{c}^2=0, \quad \tilde{a}\tilde{d}=\tilde{d}\tilde{a}=0, \\ \tilde{a}\tilde{b}=0, \quad \tilde{b}\tilde{d}=0, \\ \tilde{d}\tilde{c}=0, \quad \tilde{c}\tilde{a}=0. \end{gathered} \tag{3.4}$$

In view of the above relations we conclude that this bialgebra has no PBW basis. Indeed, the ordering following from (3.4) is cyclic:

$$\tilde{a}>\tilde{c}>\tilde{d}>\tilde{b}>\tilde{a}. \tag{3.5}$$

Thus, the basis consists of building blocks like $\tilde{a}^k\tilde{c}\tilde{d}^\ell\tilde{b}$ and cyclic. Explicitly the basis can be described by the following monomials:

$$\tilde{a}^{k_1}\tilde{c}\tilde{d}^{\ell_1}\tilde{b}\cdots\tilde{a}^{k_n}\tilde{c}\tilde{d}^{\ell_n}\tilde{b}\tilde{a}^{k_{n+1}}, \quad n,k_i,\ell_i\in\mathbb{Z}_+, \tag{3.6a}$$

$$\tilde{d}^{\ell_1}\tilde{b}\tilde{a}^{k_1}\tilde{c}\cdots\tilde{d}^{\ell_n}\tilde{b}\tilde{a}^{k_n}, \quad n,k_i,\ell_i\in\mathbb{Z}_+, \tag{3.6b}$$

$$\tilde{a}^{k_1}\tilde{c}\tilde{d}^{\ell_1}\tilde{b}\cdots\tilde{a}^{k_n}\tilde{c}\tilde{d}^{\ell_n}, \quad n,k_i,\ell_i\in\mathbb{Z}_+, \tag{3.6c}$$

$$\tilde{d}^{\ell_1}\tilde{b}\tilde{a}^{k_1}\tilde{c}\cdots\tilde{d}^{\ell_n}\tilde{b}\tilde{a}^{k_n}\tilde{c}\tilde{d}^{\ell_{n+1}}, \quad n,k_i,\ell_i\in\mathbb{Z}_+. \tag{3.6d}$$

We shall call the elements of the basis ''words.'' The one-letter words are the generators $\tilde{a},\tilde{b},\tilde{c},\tilde{d}$; they are obtained from (3.6a), (3.6b), (3.6c), (3.6d), respectively, for $n=0,k_1=1$, $n=1,k_1=\ell_1=0$, $n=1,k_1=\ell_1=0$, $n=0,\ell_1=1$, respectively The unit element $1_{\mathcal{A}}$ is obtained from (3.6b) or (3.6c) for $n=0$.

B. Dual algebra

Two bialgebras $\mathcal{U}$, $\mathcal{A}$ are said to be *in duality*[11] if there exists a doubly nondegenerate bilinear form

$$\langle,\rangle:\mathcal{U}\times\mathcal{A}\to\mathbb{C},\langle,\rangle:(u,a)\mapsto\langle u,a\rangle, u\in\mathcal{U}, a\in\mathcal{A}, \tag{3.7}$$

such that, for $u,v\in\mathcal{U},a,b\in\mathcal{A}$,

$$\langle u,ab\rangle=\langle\delta_{\mathcal{U}}(u),a\otimes b\rangle,\langle uv,a\rangle=\langle u\otimes v,\delta_{\mathcal{A}}(a)\rangle, \tag{3.8a}$$

$$\langle 1_{\mathcal{U}},a\rangle=\varepsilon_{\mathcal{A}}(a),\langle u,1_{\mathcal{A}}\rangle=\varepsilon_{\mathcal{U}}(u). \tag{3.8b}$$

Two Hopf algebras $\mathcal{U}$, $\mathcal{A}$ are said to be *in duality*[11] if they are in duality as bialgebras and if

$$\langle\gamma_{\mathcal{U}}(u),a\rangle=\langle u,\gamma_{\mathcal{A}}(a)\rangle. \tag{3.9}$$

It is enough to define the pairing (3.7) between the generating elements of the two algebras. The pairing between any other elements of $\mathcal{U}$, $\mathcal{A}$ follows then from relations (3.8) and the standard bilinear form inherited by the tensor product.

The duality between two bialgebras or Hopf algebras may be used also to obtain the unknown dual of a known algebra. For that it is enough to give the pairing between the generating elements of the unknown algebra with arbitrary elements of the basis of the known algebra. Using these initial pairings and the duality properties one may find the unknown algebra. One such possibility is given in Ref. 10. However, their approach is not universal. In particular, it is not enough for the algebras considered here (as will become clear), and will be used only as a consistency check.

Another approach was initiated by Sudbery.[12] He obtained $\mathrm{U}_q(\mathrm{sl}(2))\otimes\mathrm{U}(\mathrm{u}(1))$ as the algebra of tangent vectors at the identity of $\mathrm{GL}_q(2)$. The initial pairings were defined through the tangent vectors at the identity. However, such calculations become very difficult for more complicated algebras. Thus, in Ref. 13 a generalization was proposed in which the initial pairings are postulated to be equal to the classical undeformed results. This generalized method was applied in Ref. 13 to the standard two-parameter deformation $\mathrm{GL}_{p,q}(2)$, (where also Sudbery's method was used), then in Ref. 14 to the multiparameter deformation of $\mathrm{GL}(n)$, in Ref. 15 to the matrix quantum Lorentz group of Ref. 16, in Ref. 17 to the Jordanian two-parameter deformation $\mathrm{GL}_{g,h}(2)$, in Ref. 6 to the hybrid two-parameter deformation of the superalgebra $\mathrm{GL}_{q,h}(1|1)$, in Ref. 18 to the multiparameter deformation of the superalgebra $\mathrm{GL}(m|n)$, and in Ref. 9 to the first discussed three exotic bialgebras. [We note that the dual of $\mathrm{GL}_{p,q}(2)$ was obtained also in Ref. 19 by methods of q-differential calculus.]

Let us denote by $s03$ the unknown yet dual algebra of $S03$, and by $\tilde{A},\tilde{B},\tilde{C},\tilde{D}$ the four generators of $s03$. Like in Ref. 13 we define the pairing $\langle Z,f\rangle$, $Z=\tilde{A},\tilde{B},\tilde{C},\tilde{D}$, f is from (3.6), as the classical tangent vector at the identity:

$$\langle Z,f\rangle\equiv\varepsilon\left(\frac{\partial f}{\partial y}\right), \tag{3.10}$$

where $(Z,y)=(\tilde{A},\tilde{a})$, $(\tilde{B},\tilde{b})$, $(\tilde{C},\tilde{c})$, $(\tilde{D},\tilde{d})$. Explicitly, we get

$$\langle\tilde{A},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{a}}\right)=\begin{cases}k & \text{for } f=\tilde{a}^k,\\ 0 & \text{otherwise,}\end{cases} \tag{3.11a}$$

$$\langle\tilde{B},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{b}}\right)=\begin{cases}1 & \text{for } f=\tilde{b}\tilde{a}^k,\\ 0 & \text{otherwise,}\end{cases} \tag{3.11b}$$

$$\langle\tilde{C},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{c}}\right)=\begin{cases}1 & \text{for } f=\tilde{a}^k\tilde{c},\\ 0 & \text{otherwise,}\end{cases} \tag{3.11c}$$

$$\langle\tilde{D},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{d}}\right)=\begin{cases}1 & \text{for } f=\tilde{d},\\ 0 & \text{otherwise.}\end{cases} \tag{3.11d}$$

Using the above we obtain the following proposition.

Proposition 1: The generators $\tilde{A},\tilde{B},\tilde{C},\tilde{D}$ introduced above obey the following relations:

$$[\tilde{A},Z]=0,\quad Z=\tilde{B},\tilde{C}, \tag{3.12a}$$

$$\tilde{A}\tilde{D}=\tilde{D}\tilde{A}=\tilde{D}^3=\tilde{B}^2\tilde{D}=\tilde{D}\tilde{B}^2=\tilde{D}, \tag{3.12b}$$

$$[\tilde{B},\tilde{C}]=-2\tilde{D}, \tag{3.12c}$$

$$\tilde{D}\tilde{B} = -\tilde{B}\tilde{D} = \tilde{C}\tilde{D}^2 = \tilde{D}^2\tilde{C}, \tag{3.12d}$$

$$\{\tilde{C},\tilde{D}\} = 0, \tag{3.12e}$$

$$\tilde{B}^2 + \tilde{C}^2 = 0, \tag{3.12f}$$

$$\tilde{B}^3 = \tilde{B}, \tag{3.12g}$$

$$\tilde{C}^3 = -\tilde{C}, \tag{3.12h}$$

$$\tilde{B}^2\tilde{A} = \tilde{A}; \tag{3.12i}$$

$$\delta_{\mathcal{U}}(\tilde{A}) = \tilde{A}\otimes 1_{\mathcal{U}} + 1_{\mathcal{U}}\otimes\tilde{A}, \tag{3.13a}$$

$$\delta_{\mathcal{U}}(\tilde{B}) = \tilde{B}\otimes 1_{\mathcal{U}} + (1_{\mathcal{U}} - \tilde{B}^2)\otimes\tilde{B}, \tag{3.13b}$$

$$\delta_{\mathcal{U}}(\tilde{C}) = \tilde{C}\otimes(1_{\mathcal{U}} - \tilde{B}^2) + 1_{\mathcal{U}}\otimes\tilde{C}, \tag{3.13c}$$

$$\delta_{\mathcal{U}}(\tilde{D}) = \tilde{D}\otimes(1_{\mathcal{U}} - \tilde{B}^2) + (1_{\mathcal{U}} - \tilde{B}^2)\otimes\tilde{D}, \tag{3.13d}$$

$$\varepsilon_{\mathcal{U}}(Z) = 0, \quad Z = \tilde{A},\tilde{B},\tilde{C},\tilde{D}. \tag{3.13e}$$

$\tilde{A}$, $\tilde{B}^2 = -\tilde{C}^2$ and $\tilde{D}^2$ are Casimir operators. The bialgebra $s03$ is not a Hopf algebra.

Proof: Using the assumed duality the algebraic relations (3.12) are shown by calculating their pairings with the basis monomials f from (3.6). In particular, we have (giving only the nonzero pairings)

$$\langle\tilde{A}\tilde{B},f\rangle = \langle\tilde{B}\tilde{A},f\rangle = k+1, \quad \text{for } f = \tilde{b}\tilde{a}^k, \tag{3.14a}$$

$$\langle\tilde{A}\tilde{C},f\rangle = \langle\tilde{C}\tilde{A},f\rangle = k+1, \quad \text{for } f = \tilde{a}^k\tilde{c}, \tag{3.14b}$$

$$\langle\tilde{A}\tilde{D},f\rangle = \langle\tilde{D}\tilde{A},f\rangle = \langle\tilde{D}^3,f\rangle = \langle\tilde{B}^2\tilde{D},f\rangle = \langle\tilde{D}\tilde{B}^2,f\rangle = -\langle\tilde{B}\tilde{C},f\rangle = \langle\tilde{C}\tilde{B},f\rangle = \langle\tilde{D},f\rangle = 1, \quad \text{for } f = \tilde{d} \tag{3.14c}$$

$$\langle\tilde{B}\tilde{C},f\rangle = \langle\tilde{C}\tilde{B},f\rangle = 1, \quad \text{for } f = \tilde{b}\tilde{a}^k\tilde{c}, \tag{3.14d}$$

$$\langle\tilde{D}\tilde{B},f\rangle = -\langle\tilde{B}\tilde{D},f\rangle = \langle\tilde{C}\tilde{D}^2,f\rangle = \langle\tilde{D}^2\tilde{C},f\rangle = 1, \quad \text{for } f = \tilde{c}, \tag{3.14e}$$

$$\langle\tilde{D}\tilde{C},f\rangle = -\langle\tilde{C}\tilde{D},f\rangle = 1, \quad \text{for } f = \tilde{b}, \tag{3.14f}$$

$$\langle\tilde{B}^2,f\rangle = -\langle\tilde{C}^2,f\rangle = 1, \quad \text{for } f = \tilde{a}^k, \tag{3.14g}$$

$$\langle\tilde{B}^3,f\rangle = \langle\tilde{B},f\rangle = 1, \quad \text{for } f = \tilde{b}\tilde{a}^k, \tag{3.14h}$$

$$\langle -\tilde{C}^3,f\rangle = \langle\tilde{C},f\rangle = 1, \quad \text{for } f = \tilde{a}^k\tilde{c}, \tag{3.14i}$$

$$\langle\tilde{B}^2\tilde{A},f\rangle = \langle\tilde{A},f\rangle = k, \quad \text{for } f = \tilde{a}^k. \tag{3.14j}$$

For the proof of (3.14h) and (3.14j), (3.14g) is used. The facts that $\tilde{A}$, $\tilde{B}^2=-\tilde{C}^2$ and $\tilde{D}^2$ are Casimir operators follow easily from (3.12) having in mind also (3.14g) and (3.14j) and that $\langle \tilde{D}^2,\tilde{a}\rangle=1$ is the only nonzero pairing of $\tilde{D}^2$. For the proof of (3.13a)–(3.13d) we use the duality property (3.8a):

$$\langle Z,f_1f_2\rangle=\langle \delta_{\mathcal{U}}(Z),f_1\otimes f_2\rangle$$

for every generator Z of $s03$ and for every $f_1,f_2\in S03$, then we calculate separately the lhs and rhs and compare the results. We also use that

$$\tilde{B}^2Z=Z\ , \quad \text{for } Z=\tilde{A},\tilde{B},\tilde{C},\tilde{D}. \tag{3.15}$$

This is contained in (3.12) except for $Z=\tilde{C}$ for which we use that $\langle \tilde{B}^2\tilde{C},\tilde{a}^k\tilde{c}\rangle=1$ is the only nonzero pairing of $\tilde{B}^2\tilde{C}$. Formulas (3.13e) follow from $\varepsilon_{\mathcal{U}}(Z)=\langle Z,1_{\mathcal{A}}\rangle$, cf. (3.8b), and the defining relations (3.11). To show that $s03$ is not a Hopf algebra we suppose that it is, i.e., there should exist an antipode γ. Then we use one of the Hopf algebra axioms:

$$m\circ(\mathrm{id}\otimes\gamma)\circ\delta=i\circ\varepsilon \tag{3.16}$$

as maps $s03\to s03$, where m maps to the usual product in the algebra: $m(Y\otimes Z)=YZ$, $Y,Z\in s03$ and i is the natural embedding of the number field $\mathbb{C}$ into $s03$: $i(\mu)=\mu 1_{\mathcal{U}},\mu\in\mathbb{C}$. Applying this to the generator $\tilde{B}$ we would get

$$\tilde{B}+(1_{\mathcal{U}}-\tilde{B}^2)\gamma(\tilde{B})=0,$$

which is a contradiction, since $1_{\mathcal{U}}-\tilde{B}^2$ is zero when multiplied by anything except by $1_{\mathcal{U}}$, and in the latter case the product is not equal to $-\tilde{B}$. From this we see that γ can not be defined on $\tilde{C}$ and $\tilde{D}$ since their coproducts involve $\tilde{B}$. The antipode may be introduced only if we restrict to the subalgebra generated by $\tilde{A}$, but the bialgebra $s03$ as a whole is not a Hopf algebra. ■

Corollary 1: The algebra generated by the generator $\tilde{A}$ is a sub-bialgebra of $s03$. The algebra $s03'$ generated by the generators $\tilde{B},\tilde{C},\tilde{D}$ is a nine-dimensional sub-bialgebra of $s03$ with PBW basis:

$$1_{\mathcal{U}},\tilde{B},\tilde{C},\tilde{D},\tilde{B}\tilde{C},\tilde{B}\tilde{D},\tilde{D}\tilde{C},\tilde{B}^2,\tilde{D}^2. \tag{3.17}$$

Proof: The statement follows immediately from relations (3.12) and (3.13). We comment on only the PBW basis of the subalgebra $s03'$. Indeed, a priori it has a PBW basis:

$$\tilde{B}^k\tilde{D}^\ell\tilde{C}^m\ , \quad k,\ell\leqslant 2,\ m\leqslant 1, \tag{3.18}$$

the restrictions following from (3.12b), (3.12f), and (3.12g). Furthermore, it is easy to see that there are no cubic (and consequently higher order) elements of the basis. For some of the cubic elements this is clear from (3.12). For the rest we have

$$\tilde{B}\tilde{D}\tilde{C}=-\tilde{D}^2\tilde{C}^2=\tilde{D}^2\tilde{B}^2=\tilde{D}^2, \tag{3.19a}$$

$$\tilde{B}^2\tilde{C}=-\tilde{C}^3=\tilde{C}, \tag{3.19b}$$

$$\tilde{B}\tilde{D}^2=-\tilde{C}\tilde{D}^3=\tilde{D}\tilde{C}, \tag{3.19c}$$

also using (3.12). Thus, the basis is given by (3.17); the algebra is indeed nine-dimensional. ■

Remark 1: The algebra $s03$ is not the direct sum of the two subalgebras described in the preceding Corollary since both subalgebras have nontrivial action on each other, e.g., $\tilde{B}^2\tilde{A}=\tilde{A}$,

$\tilde{A}\tilde{D}=\tilde{D}$. The algebra $s03$ is a nine-dimensional associative algebra over the central algebra generated by $\tilde{A}$. ■

C. Regular representation

We start with the study of the left regular representation (LRR) of the subalgebra $s03'$. For this we need the left multiplication table:

	1	$\tilde{B}$	$\tilde{C}$	$\tilde{B}^2$	$\tilde{B}\tilde{C}$	$\cdots$
$\tilde{B}$	$\tilde{B}$	$\tilde{B}^2$	$\tilde{B}\tilde{C}$	$\tilde{B}$	$\tilde{C}$	$\cdots$
$\tilde{C}$	$\tilde{C}$	$\tilde{B}\tilde{C}+2\tilde{D}$	$-\tilde{B}^2$	$\tilde{C}$	$-\tilde{B}+2\tilde{D}\tilde{C}$	$\cdots$
$\tilde{D}$	$\tilde{D}$	$-\tilde{B}\tilde{D}$	$\tilde{D}\tilde{C}$	$\tilde{D}$	$-\tilde{D}^2$	$\cdots$

	$\cdots$	$\tilde{D}$	$\tilde{D}^2$	$\tilde{B}\tilde{D}$	$\tilde{D}\tilde{C}$
$\tilde{B}$	$\cdots$	$\tilde{B}\tilde{D}$	$\tilde{D}\tilde{C}$	$\tilde{D}$	$\tilde{D}^2$
$\tilde{C}$	$\cdots$	$-\tilde{D}\tilde{C}$	$-\tilde{B}\tilde{D}$	$\tilde{D}^2$	$\tilde{D}$
$\tilde{D}$	$\cdots$	$\tilde{D}^2$	$\tilde{D}$	$-\tilde{D}\tilde{C}$	$-\tilde{B}\tilde{D}$

The LRR hence contains the subrepresentation generated as a vector space by $\{\tilde{D},\tilde{D}^2,\tilde{B}\tilde{D},\tilde{D}\tilde{C}\}$, which decomposes into two two-dimensional irreps:

$$v_0^1=\tilde{D}+\tilde{D}^2, \quad v_1^1=\tilde{B}\tilde{D}+\tilde{D}\tilde{C}, \tag{3.20}$$

$$\tilde{B}\begin{pmatrix} v_0^1 \\ v_1^1 \end{pmatrix}=\begin{pmatrix} v_1^1 \\ v_0^1 \end{pmatrix}, \quad \tilde{C}\begin{pmatrix} v_0^1 \\ v_1^1 \end{pmatrix}=\begin{pmatrix} -v_1^1 \\ v_0^1 \end{pmatrix}, \quad \tilde{D}\begin{pmatrix} v_0^1 \\ v_1^1 \end{pmatrix}=\begin{pmatrix} v_0^1 \\ -v_1^1 \end{pmatrix}, \tag{3.21}$$

and

$$v_0^2=\tilde{B}\tilde{D}-\tilde{D}\tilde{C}, \quad v_1^2=\tilde{D}-\tilde{D}^2, \tag{3.22}$$

$$\tilde{B}\begin{pmatrix} v_0^2 \\ v_1^2 \end{pmatrix}=\begin{pmatrix} v_1^2 \\ v_0^2 \end{pmatrix}, \quad \tilde{C}\begin{pmatrix} v_0^2 \\ v_1^2 \end{pmatrix}=\begin{pmatrix} -v_1^2 \\ v_0^2 \end{pmatrix}, \quad \tilde{D}\begin{pmatrix} v_0^2 \\ v_1^2 \end{pmatrix}=\begin{pmatrix} v_0^2 \\ -v_1^2 \end{pmatrix}. \tag{3.23}$$

These two irreps are isomorphic by the map $(v_0^1,v_1^1)\to(v_0^2,v_1^2)$. On both of them the Casimirs $\tilde{B}^2$, $\tilde{D}^2$ take the value 1. (Also the Casimir $\tilde{A}$ of $s03$ has the value 1.)

The LRR contains also the trivial one-dimensional representation generated by the vector $v=\tilde{B}^2-1_{\mathcal{U}}$. On this vector all Casimirs and, moreover, all generators of $s03$ take the value 0.

The quotient of the LRR by the above three submodules has the following multiplication table:

	1	$\tilde{B}$	$\tilde{C}$	$\tilde{B}\tilde{C}$
$\tilde{B}$	$\tilde{B}$	$\tilde{B}^2$	$\tilde{B}\tilde{C}$	$\tilde{C}$
$\tilde{C}$	$\tilde{C}$	$\tilde{B}\tilde{C}$	$-\tilde{B}^2$	$-\tilde{B}$
$\tilde{D}$	0	0	0	0

Thus the quotient decomposes into a direct sum of four one-dimensional representations, generated as vector spaces by

$$v_{\epsilon,\epsilon'}=\tilde{B}+\epsilon 1_{\mathcal{U}}-i\epsilon\epsilon'\tilde{C}-i\epsilon'\tilde{B}\tilde{C},\quad \epsilon,\epsilon'=\pm. \tag{3.24}$$

On the latter vectors we have the following action:

$$\tilde{B}v_{\epsilon,\epsilon'}=\epsilon v_{\epsilon,\epsilon'},\quad \tilde{C}v_{\epsilon,\epsilon'}=i\epsilon' v_{\epsilon,\epsilon'},\quad \tilde{D}v_{\epsilon,\epsilon'}=0. \tag{3.25}$$

Obviously, on all of them the Casimirs $\tilde{B}^2$, $\tilde{D}^2$ take the values 1,0, respectively. However, these four representations are not isomorphic to each other.

To summarize, there are seven irreps of $s03'$ which are obtained from the LRR:

(i) one-dimensional trivial (all generators act by zero),
(ii) two-dimensional with both Casimirs $\tilde{B}^2$, $\tilde{D}^2$ having value 1, and
(iii) four one-dimensional with Casimir values 1,0 for $\tilde{B}^2$, $\tilde{D}^2$, respectively.

Turning to the algebra $s03$ we note that it inherits the representation structure of its subalgebra $s03'$. On the representations (3.20) and (3.22) the Casimir $\tilde{A}$ has the value 1, while on the trivial irrep generated by $v=\tilde{B}^2-1_{\mathcal{U}}$ the Casimir $\tilde{A}$ has the value 0. However, on the one-dimensional irreps generated by (3.24) the Casimir $\tilde{A}$ has no fixed value. Thus, the list of the irreps of $s03$ arising from the LRR is

(i) one-dimensional trivial,
(ii) two-dimensional with all Casimirs $\tilde{A}$, $\tilde{B}^2$, $\tilde{D}^2$ having value 1, and
(iii) four one-dimensional with Casimir values μ,1,0 for $\tilde{A}$, $\tilde{B}^2$, $\tilde{D}^2$, respectively, $\mu\in\mathbb{C}$.

Finally, we note that we could have studied also the right regular representation of $s03$. The list of irreps would be the same as the one obtained above.

D. Weight representations

Here we consider *weight representations*. These are representations which are built from the action of the algebra on a *weight vector* with respect to one of the generators. We start with a weight vector v_0 such that

$$\tilde{D}\,v_0=\lambda\,v_0, \tag{3.26}$$

where $\lambda\in\mathbb{C}$ is the weight. As we shall see, the cases $\lambda\neq 0$ and $\lambda=0$ are very different.

We start with $\lambda \neq 0$. In that case from $\tilde{D}^3 = \tilde{D}$ follows that $\lambda^2 = 1$, while from $\tilde{B}^2\tilde{D} = \tilde{D}$ follows that $\tilde{B}^2 v_0 = v_0$. Thus, acting with the elements of $s03$ on v_0 we obtain a two-dimensional representation:

$$v_0, \ \tilde{B}\, v_0, \ \tilde{C}\, v_0, \ \tilde{B}\tilde{C}\, v_0. \tag{3.27}$$

This representation is *irreducible*. The action is given as follows:

	v_0	$\tilde{B}v_0$	$\tilde{C}v_0$	$\tilde{B}\tilde{C}v_0$
$\tilde{B}$	$\tilde{B}v_0$	v_0	$\tilde{B}\tilde{C}v_0$	$\tilde{C}v_0$
$\tilde{C}$	$\tilde{C}v_0$	$(\tilde{B}\tilde{C}+2\lambda)v_0$	$-v_0$	$-(\tilde{B}+2\lambda\tilde{C})v_0$
$\tilde{D}$	λv_0	$-\lambda\tilde{B}v_0$	$-\lambda\tilde{C}v_0$	$\lambda\tilde{B}\tilde{C}v_0$

Both Casimirs $\tilde{B}^2$, $\tilde{D}^2$ take the value 1.

Let now $\lambda = 0$. In this case acting with the elements of $s03$ on v_0 we obtain a five-dimensional representation:

$$v_0, \ \tilde{B}\, v_0, \ \tilde{C}\, v_0, \ \tilde{B}\tilde{C}\, v_0, \ \tilde{B}^2\, v_0. \tag{3.28}$$

This representation is *reducible*. It has a one-dimensional subrepresentation spanned by the vector $w = v\, v_0 = (\tilde{B}^2 - 1_{\mathcal{U}})v_0$. This is the trivial representation since all generators act by zero on it. After we factor out this representation the factor representation splits into four one-dimensional representations spanned by the following vectors, $w_{\epsilon,\epsilon'} = v_{\epsilon,\epsilon'}\, v_0$, where $v_{\epsilon,\epsilon'}$ are from (3.24) and the action of the generators is as given in (3.25). Thus, these irreps are as those obtained from the LRR.

To summarize, there are six irreps of $s03'$ which are obtained as weight irreps of the generator $\tilde{D}$:

(i) one-dimensional trivial,
(ii) one two-dimensional with both Casimirs $\tilde{B}^2$, $\tilde{D}^2$ having value 1, and
(iii) four one-dimensional with Casimir values 1,0 for $\tilde{B}^2$, $\tilde{D}^2$, respectively.

Turning to the algebra $s03$ we note that it inherits the representation structure of its subalgebra $s03'$; however, the value of the Casimir $\tilde{A}$ is not fixed except on the trivial irrep. Thus, the list of the irreps of $s03$ which are obtained as weight irreps of the generator $\tilde{D}$ is

(i) one-dimensional trivial,
(ii) one two-dimensional with Casimir values μ,1,1 for $\tilde{A}$, $\tilde{B}^2$, $\tilde{D}^2$, respectively, $\mu \in \mathbb{C}$, and
(iii) four one-dimensional with Casimir values μ,1,0 for $\tilde{A}$, $\tilde{B}^2$, $\tilde{D}^2$, respectively, $\mu \in \mathbb{C}$.

Finally, we note that it is not possible to construct weight representations w.r.t. generator $\tilde{B}$ (or $\tilde{C}$).

E. Representations of *s*03 on *S*03

Here we shall study the representations of $s03$ obtained by the use of its right regular action (RRA) on the dual bialgebra $S03$. The RRA is defined as follows:

$$\pi_R(Z)f \equiv f_{(1)}\langle Z, f_{(2)}\rangle, \quad Z \in s03, \quad Z \neq 1_{\mathcal{U}}, \quad f \in S03, \tag{3.29a}$$

$$\pi_R(1_{\mathcal{U}})f \equiv f, \quad f \in S03, \tag{3.29b}$$

where we use Sweedler's notation for the co-product: $\delta(f)=f_{(1)}\otimes f_{(2)}$. [Note that we can not use the left regular action since that would be given by the formula $\pi_L(Z)f=\langle \gamma_{\mathcal{U}}(Z), f_{(1)}\rangle f_{(2)}$, and we do not have an antipode.] More explicitly, for the generators of $s03$ we have

$$\pi_R(\tilde{A})\begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix} = \begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix}, \tag{3.30a}$$

$$\pi_R(\tilde{B})\begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix} = \begin{pmatrix} \tilde{b} & \tilde{a} \\ \tilde{d} & \tilde{c} \end{pmatrix}, \tag{3.30b}$$

$$\pi_R(\tilde{C})\begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix} = \begin{pmatrix} -\tilde{c} & \tilde{d} \\ \tilde{a} & -\tilde{b} \end{pmatrix}, \tag{3.30c}$$

$$\pi_R(\tilde{D})\begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix} = \begin{pmatrix} \tilde{d} & -\tilde{c} \\ -\tilde{b} & \tilde{a} \end{pmatrix}, \tag{3.30d}$$

$$\pi_R(Z)\,1_{\mathcal{A}} = 1_{\mathcal{A}}\langle Z, 1_{\mathcal{A}}\rangle = 1_{\mathcal{A}}\,\varepsilon_{\mathcal{U}}(Z) = 0, \quad Z=\tilde{A},\tilde{B},\tilde{C},\tilde{D}. \tag{3.30e}$$

For the action on the elements (words) of $S03$ we use a corollary of (3.29):

$$\pi_R(Z)fg = \pi_R(\delta_{\mathcal{U}}(Z))(f\otimes g), \tag{3.31}$$

where f,g are arbitrary words from (3.6). Further, we shall need the notion of the "length" $\ell(f)$ of the word f. It is defined naturally as the number of the letters of f; in addition we set $\ell(1_{\mathcal{A}})=0$. Now we obtain from (3.31)

$$\pi_R(\tilde{A})\,f = \ell(f)\,f, \tag{3.32a}$$

$$\pi_R(\tilde{B})\,f\cdot g = (\pi_R(\tilde{B})f)\cdot g, \tag{3.32b}$$

$$\pi_R(\tilde{C})\,f\cdot g = f\cdot(\pi_R(\tilde{C})g), \tag{3.32c}$$

$$\pi_R(\tilde{D})\,f = 0, \quad \text{if } \ell(f)>1. \tag{3.32d}$$

From (3.32b) and (3.32c) it is obvious that the only nonzero action of $\tilde{B}$, $\tilde{C}$ actually is

$$\pi_R(\tilde{B})\begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix}\cdot f = \begin{pmatrix} \tilde{b} & \tilde{a} \\ \tilde{d} & \tilde{c} \end{pmatrix}\cdot f, \tag{3.33a}$$

$$\pi_R(\tilde{C})\,f\cdot\begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix} = f\cdot\begin{pmatrix} -\tilde{c} & \tilde{d} \\ \tilde{a} & -\tilde{b} \end{pmatrix}. \tag{3.33b}$$

From (3.32a) it is obvious that we can classify the irreps by the value μ_A of the Casimir $\tilde{A}$ which runs over the non-negative integers. For fixed μ_A the basis of the corresponding representations is spanned by the words f such that $\ell(f)=\mu_A$. Thus, we have the following.

(i) $\mu_A=0$: This is the one-dimensional trivial representation spanned by the unit element $1_{\mathcal{A}}$ on which all generators of $s03$ have zero action.

(ii) $\mu_A=1$: This representation is four-dimensional spanned by the four generators $\tilde{a}$, $\tilde{b}$, $\tilde{c}$, $\tilde{d}$ of $S03$. It is reducible and decomposes in two two-dimensional irreps with basis vectors:

$$v_0^1=\tilde{a}+\tilde{d}=a, \quad v_1^1=\tilde{b}+\tilde{c}=b, \tag{3.34a}$$

and

$$v_0^2=\tilde{b}-\tilde{c}=c, \quad v_1^2=\tilde{a}-\tilde{d}=d. \tag{3.34b}$$

The RRA of $\tilde{B}$, $\tilde{C}$, $\tilde{D}$ on these vectors is as (3.21) and (3.23):

$$\pi_R(\tilde{B})\begin{pmatrix} v_0^k \\ v_1^k \end{pmatrix}=\begin{pmatrix} v_1^k \\ v_0^k \end{pmatrix}, \quad \pi_R(\tilde{C})\begin{pmatrix} v_0^k \\ v_1^k \end{pmatrix}=\begin{pmatrix} -v_1^k \\ v_0^k \end{pmatrix}, \quad \pi_R(\tilde{D})\begin{pmatrix} v_0^k \\ v_1^k \end{pmatrix}=\begin{pmatrix} v_0^k \\ -v_1^k \end{pmatrix}. \tag{3.35}$$

These two irreps are isomorphic by the map $(v_0^1,v_1^1)\to(v_0^2,v_1^2)$. On both of them the Casimirs $\tilde{B}^2$, $\tilde{D}^2$ take the value 1.

(iii) $\mu_A=2$: This representation is eight-dimensional spanned by $\tilde{a}^2$, $\tilde{a}\tilde{c}$, $\tilde{b}\tilde{a}$, $\tilde{b}\tilde{c}$, $\tilde{c}\tilde{b}$, $\tilde{c}\tilde{d}$, $\tilde{d}^2$, $\tilde{d}\tilde{b}$. It is reducible and decomposes in eight one-dimensional irreps with basis vectors:

$$v^1_{\epsilon,\epsilon'}=(\tilde{a}+\epsilon\tilde{b})(\tilde{a}+i\epsilon'\tilde{c}), \tag{3.36a}$$

$$v^2_{\epsilon,\epsilon'}=(\tilde{d}+\epsilon\tilde{c})(\tilde{d}+i\epsilon'\tilde{b}), \tag{3.36b}$$

$$\epsilon,\epsilon'=\pm.$$

The RRA of $\tilde{B}$, $\tilde{C}$, $\tilde{D}$ on these vectors is as (3.25):

$$\pi_R(\tilde{B})v^k_{\epsilon,\epsilon'}=\epsilon v^k_{\epsilon,\epsilon'}, \quad \pi_R(\tilde{C})v^k_{\epsilon,\epsilon'}=i\epsilon' v^k_{\epsilon,\epsilon'}, \quad \pi_R(\tilde{D})v^k_{\epsilon,\epsilon'}=0. \tag{3.37}$$

The irrep with vector $v^1_{\epsilon,\epsilon'}$ is isomorphic to the irrep with vector $v^2_{\epsilon,\epsilon'}$. Thus, there are only four distinct irreps parametrized by ϵ,ϵ'. On all of them the Casimirs $\tilde{B}^2$, $\tilde{D}^2$ take the values 1,0, respectively.

(iv) $\mu_A=N>2$: These representations are reducible and decompose in one-dimensional irreps with basis vectors:

$$v^1_{\epsilon,\epsilon'}=(\tilde{a}+\epsilon\tilde{b})\cdot f_1\cdot(\tilde{a}+i\epsilon'\tilde{c}), \tag{3.38a}$$

$$v^2_{\epsilon,\epsilon'}=(\tilde{d}+\epsilon\tilde{c})\cdot f_2\cdot(\tilde{d}+i\epsilon'\tilde{b}), \tag{3.38b}$$

$$v^3_{\epsilon,\epsilon'}=(\tilde{a}+\epsilon\tilde{b})\cdot f_3\cdot(\tilde{d}+i\epsilon'\tilde{b}), \tag{3.38c}$$

$$v^4_{\epsilon,\epsilon'}=(\tilde{d}+\epsilon\tilde{c})\cdot f_4\cdot(\tilde{a}+i\epsilon'\tilde{c}), \tag{3.38d}$$

$$\epsilon,\epsilon'=\pm, \quad \ell(f_k)=N-2.$$

The RRA of $\tilde{B}$, $\tilde{C}$, $\tilde{D}$ on these vectors is as exactly as (3.25). The irrep with vector $v^k_{\epsilon,\epsilon'}$ is isomorphic to the irrep with vector $v^n_{\epsilon,\epsilon'}$. Thus, there are only four distinct irreps as in the case above. On all of them the Casimirs $\tilde{B}^2$, $\tilde{D}^2$ take the values 1,0, respectively.

To summarize the list of irreps of $s03'$ is the same as given in Sec. III C. The list of irreps of $s03$ here is smaller since the Casimir $\tilde{A}$ can take only non-negative integer values. Thus, the list of the irreps of $s03$ using the dual bialgebra $S03$ as carrier space is

(i) one-dimensional trivial,
(ii) two-dimensional with all Casimirs $\tilde{A}$, $\tilde{B}^2$, $\tilde{D}^2$ having value 1, and
(iii) four one-dimensional with Casimir values μ,1,0 for $\tilde{A}$, $\tilde{B}^2$, $\tilde{D}^2$, respectively, $\mu \in \mathbb{N}+1$.

The difference in the two lists is natural since here more structure (the co-product) is involved. Speaking more loosely, the irreps here may be looked upon as ''integrals'' of the irreps obtained in Sec. III C.

IV. ALGEBRA *S*14

A. Bialgebra relations

In this section we consider the matrix bialgebra $S14$. We obtain it by applying the RTT relations (3.1) for the case $R=R_{S1,4}$, when $q^2\neq 1$ where

$$R_{S1,4}\equiv\begin{pmatrix} 0 & 0 & 0 & q \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ q & 0 & 0 & 0 \end{pmatrix}. \tag{4.1}$$

This R-matrix is given in Ref. 8.

The relations which follow from (3.1) and (4.1) when $q^2\neq 1$ are

$$\begin{aligned} &b^2-c^2=0, \quad a^2-d^2=0, \\ &ab=ba=0, \quad ac=ca=0, \\ &bd=db=0, \quad cd=dc=0. \end{aligned} \tag{4.2}$$

In terms of the generators $\tilde{a}$, $\tilde{b}$, $\tilde{c}$, $\tilde{d}$,

$$\begin{aligned} &\tilde{b}\tilde{c}+\tilde{c}\tilde{b}=0, \quad \tilde{a}\tilde{d}+\tilde{d}\tilde{a}=0, \\ &\tilde{a}\tilde{b}=\tilde{b}\tilde{a}=0, \quad \tilde{a}\tilde{c}=\tilde{c}\tilde{a}=0, \\ &\tilde{b}\tilde{d}=\tilde{d}\tilde{b}=0, \quad \tilde{c}\tilde{d}=\tilde{d}\tilde{c}=0. \end{aligned} \tag{4.3}$$

From the above relations it is clear that the PBW basis of $S14$ is

$$\tilde{a}^k\tilde{d}^\ell, \quad \tilde{b}^k\tilde{c}^\ell. \tag{4.4}$$

B. Dual algebra

Let us denote by $s14$ the unknown yet dual algebra of $S14$, and by $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, $\tilde{D}$ the four generators of $s14$. We define the pairing $\langle Z,f\rangle$, $Z=\tilde{A}$, $\tilde{B}$, $\tilde{C}$, $\tilde{D}$, f is from (4.4), as (3.10). Explicitly, we obtain

$$\langle \tilde{A}, \ f\rangle=\varepsilon\left(\frac{\partial f}{\partial \tilde{a}}\right)=\begin{cases} k\delta_{\ell 0}, & f=\tilde{a}^k\tilde{d}^\ell, \\ 0, & f=\tilde{b}^k\tilde{c}^\ell, \end{cases} \tag{4.5a}$$

$$\langle \tilde{B}, \ f\rangle=\varepsilon\left(\frac{\partial f}{\partial \tilde{b}}\right)=\begin{cases} 0, & f=\tilde{a}^k\tilde{d}^\ell, \\ \delta_{k1}\delta_{\ell 0}, & f=\tilde{b}^k\tilde{c}^\ell, \end{cases} \tag{4.5b}$$

$$\langle \tilde{C},\ f\rangle = \varepsilon\left(\frac{\partial f}{\partial \tilde{c}}\right) = \begin{cases} 0, & f = \tilde{a}^k \tilde{d}^\ell, \\ \delta_{k0}\delta_{\ell 1}, & f = \tilde{b}^k \tilde{c}^\ell, \end{cases} \tag{4.5c}$$

$$\langle \tilde{D},\ f\rangle = \varepsilon\left(\frac{\partial f}{\partial \tilde{d}}\right) = \begin{cases} \delta_{\ell 1}, & f = \tilde{a}^k \tilde{d}^\ell, \\ 0, & f = \tilde{b}^k \tilde{c}^\ell. \end{cases} \tag{4.5d}$$

We shall need (as in Ref. 9) the auxilliary operator E such that

$$\langle E, f\rangle = \begin{cases} 1 & \text{for } f = 1_{\mathcal{A}}, \\ 0 & \text{otherwise.} \end{cases} \tag{4.6}$$

Using the above we obtain the following.

Proposition 2: The generators $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, $\tilde{D}$ introduced above obey the following relations:

$$\tilde{C} = \tilde{D}\tilde{B} = -\tilde{B}\tilde{D}, \tag{4.7a}$$

$$[\tilde{A}, \tilde{D}] = 0, \tag{4.7b}$$

$$\tilde{A}\tilde{B} = \tilde{B}\tilde{A} = \tilde{D}^2\tilde{B} = \tilde{B}^3 = \tilde{B}, \tag{4.7c}$$

$$EZ = ZE = 0, \quad Z = \tilde{A}, \tilde{B}, \tilde{D}; \tag{4.7d}$$

$$\delta_{\mathcal{U}}(\tilde{A}) = \tilde{A} \otimes 1_{\mathcal{U}} + 1_{\mathcal{U}} \otimes \tilde{A}, \tag{4.8a}$$

$$\delta_{\mathcal{U}}(\tilde{B}) = \tilde{B} \otimes E + E \otimes \tilde{B}, \tag{4.8b}$$

$$\delta_{\mathcal{U}}(\tilde{D}) = \tilde{D} \otimes K + 1_{\mathcal{U}} \otimes \tilde{D}, \quad K \equiv (-1)^{\tilde{A}}, \tag{4.8c}$$

$$\delta(E) = E \otimes E; \tag{4.8d}$$

$$\varepsilon_{\mathcal{U}}(Z) = 0, \quad Z = \tilde{A}, \tilde{B}, \tilde{D}, \tag{4.9a}$$

$$\varepsilon_{\mathcal{U}}(E) = 1. \tag{4.9b}$$

$\tilde{A}$, $\tilde{B}^2$ and $\tilde{D}^2$ are Casimir operators. The bialgebra $s14$ is not a Hopf algebra.

Proof: Using the assumed duality the algebraic relations (4.7) are shown by calculating their pairings with the basis monomials f from (4.4). In particular, we have (giving only the nonzero pairings)

$$\langle \tilde{D}\tilde{B},\ f\rangle = -\langle \tilde{B}\tilde{D},\ f\rangle = \langle \tilde{C},\ f\rangle = 1, \quad \text{for } f = \tilde{c}, \tag{4.10a}$$

$$\langle \tilde{A}\tilde{D},\ f\rangle = \langle \tilde{D}\tilde{A},\ f\rangle = k+1, \quad \text{for } f = \tilde{a}^k\tilde{d}, \tag{4.10b}$$

$$\langle \tilde{A}\tilde{B},\ f\rangle = \langle \tilde{B}\tilde{A},\ f\rangle = \langle \tilde{D}^2\tilde{B},\ f\rangle = \langle \tilde{B}^3,\ f\rangle = \langle \tilde{B},\ f\rangle = 1, \quad \text{for } f = \tilde{b}. \tag{4.10c}$$

The facts that $\tilde{A}$, $\tilde{B}^2$ and $\tilde{D}^2$ are Casimir operators follow easily from (4.7). The proof of (4.8) is done as the proof of (3.13). We also use that

$$\langle \tilde{A}^n,\ \tilde{a}^k\tilde{d}^\ell\rangle = k^n \delta_{\ell 0}, \tag{4.11}$$

and hence

$$\langle K,\ \tilde{a}^k\tilde{d}^\ell\rangle=(-1)^k\delta_{\ell 0}. \tag{4.12}$$

There is no antipode for the bialgebra $s14$. Indeed, suppose that there was such. Then, by applying the Hopf algebra axiom (3.16) to the operator E, we would get

$$E\ \gamma(E)=1_{\mathcal{U}},$$

which would lead to contradiction after multiplication from the left with $Z=\tilde{A},\ \tilde{B},\ \tilde{D}$ (we would get $0=Z$). From this follows also that the generator $\tilde{B}$ does not have an antipode, since from (3.16) to the $\tilde{B}$ we would get

$$\tilde{B}\ \gamma(E)+E\ \gamma(\tilde{B})=0.$$

Thus, the bialgebra $s14$ is not a Hopf algebra. ■

Corollary 2: The algebra generated by the generator $\tilde{A}$ is a sub-bialgebra of $s14$. The algebra $s14'$ generated by $\tilde{B},\tilde{D}$ is a subalgebra of $s14$, but is not a sub-bialgebra [cf. (4.8b) and (4.8c)]. It has the following PBW basis:

$$\tilde{B},\ \tilde{B}^2,\ \tilde{D}\tilde{B},\ \tilde{D}\tilde{B}^2,\ \tilde{D}^\ell,\quad \ell=0,1,2,\ldots, \tag{4.13}$$

where we use the convention $\tilde{D}^0=1_{\mathcal{U}}$. ■

C. Regular representation

We start with the study of the right regular representation of the subalgebra $s14'$. For this we use the right multiplication table:

	$\tilde{B}$	$\tilde{B}^2$	$\tilde{D}\tilde{B}$	$\tilde{D}\tilde{B}^2$	$\tilde{D}^{2k}$	$\tilde{D}^{2k+1}$
$\tilde{B}$	$\tilde{B}^2$	$\tilde{B}$	$\tilde{D}\tilde{B}^2$	$\tilde{D}\tilde{B}$	$\tilde{B}$	$\tilde{D}\tilde{B}$
$\tilde{D}$	$-\tilde{D}\tilde{B}$	$\tilde{D}\tilde{B}^2$	$-\tilde{B}$	$\tilde{B}^2$	$\tilde{D}^{2k+1}$	$\tilde{D}^{2k+2}$

From the above table follows that there is a four-dimensional subspace spanned by $\tilde{B},\tilde{B}^2,\tilde{D}\tilde{B},\tilde{D}\tilde{B}^2$. It is reducible and decomposes into four one-dimensional representations spanned by

$$v_{\epsilon,\epsilon'}=\tilde{B}+\epsilon\tilde{B}^2-\epsilon'\tilde{D}\tilde{B}+\epsilon\epsilon'\tilde{D}\tilde{B}^2. \tag{4.14}$$

The action of $\tilde{B},\tilde{D}$ on these vectors is

$$\tilde{B}v_{\epsilon,\epsilon'}=\epsilon v_{\epsilon,\epsilon'},\quad \tilde{D}v_{\epsilon,\epsilon'}=\epsilon' v_{\epsilon,\epsilon'}. \tag{4.15}$$

The value of the Casimirs $\tilde{B}^2,\tilde{D}^2$ on these vectors is 1.

The quotient of the RRR by the above submodules has the following multiplication table:

	$\tilde{D}^{2k}$	$\tilde{D}^{2k+1}$
$\tilde{B}$	0	0
$\tilde{D}$	$\tilde{D}^{2k+1}$	$\tilde{D}^{2k+2}$

This representation is reducible. It contains an infinite set of nested submodules $V^n \supset V^{n+1}$, $n=0,1,\ldots$, where V^n is spanned by $\tilde{D}^{n+\ell}$, $\ell=0,1,\ldots$. Correspondingly there is an infinite set of one-dimensional irreducible factor-modules $F^n \equiv V^n/V^{n+1}$, (generated by $\tilde{D}^n$) which are all isomorphic to the trivial representation since the generators $\tilde{B},\tilde{D}$ act as zero on them. Thus there are five irreps arising from the RRR of $s14'$:

(i) one-dimensional trivial and
(ii) four one-dimensional with both Casimirs $\tilde{B}^2,\tilde{D}^2$ having value 1.

Turning to the algebra $s14$ we note that it inherits the representation structure of its subalgebra $s14'$. On the representations (4.14) the Casimir $\tilde{A}$ has the value 1. However, on the one-dimensional irreps F^n the Casimir $\tilde{A}$ has no fixed value. Thus, the list of the irreps arising from the RRR of $s14$ is

(i) one-dimensional with Casimir values $\mu,0,0$ for $\tilde{A},\tilde{B}^2,\tilde{D}^2$, respectively, $\mu \in \mathbb{C}$, and
(ii) four one-dimensional with all Casimirs $\tilde{A},\tilde{B}^2,\tilde{D}^2$ having value 1.

D. Weight representations

Here we study weight representations, first w.r.t. $\tilde{D}$, as in (3.26). The resulting representation of $s14'$ is three-dimensional:

$$v_0,\ \tilde{B}v_0,\tilde{B}^2v_0. \tag{4.16}$$

It is reducible and contains one one-dimensional and one two-dimensional irrep:

(i) One-dimensional:

$$w_0=(\tilde{B}^2-1_{\mathcal{U}})v_0, \tag{4.17}$$

$$\tilde{B}w_0=0,\quad \tilde{D}w_0=\lambda w_0, \tag{4.18}$$

$\lambda \in \mathbb{C}$.

(ii) Two-dimensional:

$$\{v_0,v_1=\tilde{B}v_0\}, \tag{4.19}$$

$$\tilde{B}\begin{pmatrix} v_0 \\ v_1 \end{pmatrix}=\begin{pmatrix} v_1 \\ v_0 \end{pmatrix},\quad \tilde{D}\begin{pmatrix} v_0 \\ v_1 \end{pmatrix}=\lambda\begin{pmatrix} v_0 \\ -v_1 \end{pmatrix}, \tag{4.20}$$

with $\lambda=\pm 1$.

Turning to the algebra $s14$ we note that it inherits the representation structure of its subalgebra $s14'$. On the one-dimensional irrep (4.17) the Casimir $\tilde{A}$ has no fixed value since $\tilde{B}$ is trivial, and $[\tilde{A},\tilde{D}]=0$. On the two-dimensional irrep (4.19) the Casimir $\tilde{A}$ has the value 1 since $\tilde{A}\tilde{B}=\tilde{B}$.

Thus, there are the following irreps of $s14$ which are obtained as weight irreps of the generator $\tilde{D}$:

(i) one-dimensional with Casimir values $\mu,0,\lambda^2$ for $\tilde{A},\tilde{B}^2,\tilde{D}^2$, respectively, $\mu,\lambda\in\mathbb{C}$, and
(ii) two two-dimensional with all Casimirs $\tilde{A},\tilde{B}^2,\tilde{D}^2$ having the value 1.

Next we consider weight representations w.r.t. $\tilde{B}$:

$$\tilde{B}\ v_0=\nu\ v_0, \tag{4.21}$$

with $\nu\in\mathbb{C}$. From $\tilde{B}^3=\tilde{B}$ follows that $\nu=0,\pm 1$. Acting with the generators we obtain the following representation vectors: $v_\ell=\tilde{D}^\ell v_0$. We have that $\tilde{D}v_\ell=v_{\ell+1}$.

Further, we consider first the case $\nu^2=1$. Then we apply the relation $\tilde{D}^2\tilde{B}=\tilde{B}$ to v_ℓ and we get

$$\tilde{D}^2\tilde{B}v_\ell=(-1)^\ell\nu v_{\ell+2}=\tilde{B}v_\ell=(-1)^\ell\nu v_\ell$$

from which follows that we have to identify $v_{\ell+2}$ with v_ℓ. Thus the representation is given as follows:

$$\{v_0,v_1=\tilde{D}v_0\}, \tag{4.22}$$

$$\tilde{B}\begin{pmatrix}v_0\\v_1\end{pmatrix}=\nu\begin{pmatrix}v_0\\-v_1\end{pmatrix},\quad \tilde{D}\begin{pmatrix}v_0\\v_1\end{pmatrix}=\begin{pmatrix}v_1\\v_0\end{pmatrix}. \tag{4.23}$$

On this irrep both Casimirs $\tilde{B}^2,\tilde{D}^2$ have value 1 ($\nu^2=1$).

Further, we consider the case $\nu=0$. This representation is reducible. It contains an infinite set of nested submodules $V^n\supset V^{n+1}$, $n=0,1,\ldots$, where V^n is spanned by $\tilde{D}^{n+\ell}v_0$, $\ell=0,1,\ldots$. Correspondingly, there is an infinite set of one-dimensional irreducible factor-modules $F^n\equiv V^n/V^{n+1}$ (generated by $\tilde{D}^n v_0$), which are all isomorphic to the trivial representation since the generators $\tilde{B},\tilde{D}$ act as zero on them.

Turning to the algebra $s14$ we note that it inherits the representation structure of its subalgebra $s14'$, with the value of the Casimir $\tilde{A}$ being not fixed if $\tilde{B}$ acts trivially, and being 1, if $\tilde{B}$ acts nontrivially.

Thus, there are the following irreps of $s14$ which are obtained as weight irreps of the generator $\tilde{B}$:

(i) one-dimensional with Casimir values $\mu,0,0$ for $\tilde{A},\tilde{B}^2,\tilde{D}^2$, respectively, $\mu\in\mathbb{C}$, and
(ii) two two-dimensional with all Casimirs $\tilde{A},\tilde{B}^2,\tilde{D}^2$ having the value 1.

E. Representations of $s14$ on $S14$

Here we shall study the representations of $s14$ obtained by the use of its right regular action (RRA) on the dual bialgebra $S14$. The RRA is defined as in (3.29). For the generators of $s14$ we have

$$\pi_R(\tilde{A})\begin{pmatrix}\tilde{a}&\tilde{b}\\\tilde{c}&\tilde{d}\end{pmatrix}=\begin{pmatrix}\tilde{a}&\tilde{b}\\\tilde{c}&\tilde{d}\end{pmatrix}, \tag{4.24a}$$

$$\pi_R(\tilde{B})\begin{pmatrix}\tilde{a}&\tilde{b}\\\tilde{c}&\tilde{d}\end{pmatrix}=\begin{pmatrix}\tilde{b}&\tilde{a}\\\tilde{d}&\tilde{c}\end{pmatrix}, \tag{4.24b}$$

$$\pi_R(\tilde{D})\begin{pmatrix}\tilde{a} & \tilde{b}\\ \tilde{c} & \tilde{d}\end{pmatrix}=\begin{pmatrix}\tilde{d} & -\tilde{c}\\ -\tilde{b} & \tilde{a}\end{pmatrix}, \tag{4.24c}$$

$$\pi_R(E)\begin{pmatrix}\tilde{a} & \tilde{b}\\ \tilde{c} & \tilde{d}\end{pmatrix}=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix}, \tag{4.24d}$$

$$\pi_R(Z)1_{\mathcal{A}}=1_{\mathcal{A}}\langle Z,1_{\mathcal{A}}\rangle=1_{\mathcal{A}}\varepsilon_{\mathcal{U}}(Z)=\begin{cases}0, & Z=\tilde{A},\tilde{B},\tilde{D},\\ 1, & Z=E.\end{cases} \tag{4.24e}$$

For the action on the basis of $S14$ we use formula (3.31). We obtain

$$\pi_R(A)\tilde{a}^n\tilde{d}^k=(n+k)\tilde{a}^n\tilde{d}^k,\quad \pi_R(A)\tilde{b}^n\tilde{c}^k=(n+k)\tilde{b}^n\tilde{c}^k, \tag{4.25a}$$

$$\pi_R(B)\tilde{a}^n\tilde{d}^k=\delta_{k0}\delta_{n1}\tilde{b}+\delta_{n0}\delta_{k1}\tilde{c},\quad \pi_R(B)\tilde{b}^n\tilde{c}^k=\delta_{k0}\delta_{n1}\tilde{a}+\delta_{n0}\delta_{k1}\tilde{d}, \tag{4.25b}$$

$$\pi_R(D)\tilde{a}^k\tilde{d}^\ell=(-1)^{\ell+1}\ell\tilde{a}^{k+1}\tilde{d}^{\ell-1}+(-1)^\ell k\tilde{a}^{k-1}\tilde{d}^{\ell+1}, \tag{4.25c}$$

$$\pi_R(D)\tilde{b}^k\tilde{c}^\ell=(-1)^\ell\ell\tilde{b}^{k+1}\tilde{c}^{\ell-1}+(-1)^{\ell+1}k\tilde{b}^{k-1}\tilde{c}^{\ell+1}. \tag{4.25d}$$

We see that similarly to Sec. III E, the Casimir $\tilde{A}$ acts as the length of the elements of $S14$, i.e., (3.30) holds. Thus, also here we classify the irreps by the value μ_A of the Casimir $\tilde{A}$ which runs over the non-negative integers. For fixed μ_A the basis of the corresponding representations is spanned by the elements f such that $\ell(f)=\mu_A$. The dimension of each such representation is

$$\dim(\mu_A)=\begin{cases}2(\mu_A+1) & \text{for } \mu_A\geqslant 1,\\ 1 & \text{for } \mu_A=0.\end{cases} \tag{4.26}$$

The classification goes as follows:

(i) $\mu_A=0$: This is the one-dimensional trivial representation spanned by $1_{\mathcal{A}}$.

(ii) $\mu_A=1$: This representation is four-dimensional spanned by the four generators $\tilde{a},\tilde{b},\tilde{c},\tilde{d}$ of $S14$. It decomposes in two two-dimensional, isomorphic to each other irrep with basis vectors as in (3.34)—this is due to the fact that the action (4.24b) and (4.24c) is the same as the action (3.30). The value of the Casimirs $\tilde{B}^2,\tilde{D}^2$ is 1.

(iii) Each representation for fixed $\mu_A\geqslant 2$ is reducible and decomposes in two isomorphic representations: one built on the basis $\tilde{a}^k\tilde{d}^\ell$, and the other built on the basis $\tilde{b}^k\tilde{c}^\ell$, each of dimension μ_A+1. Thus, for $\mu_A\geqslant 2$ we shall consider only the representations built on the basis $\tilde{a}^k\tilde{d}^\ell$. These representations are also reducible and they all decompose in one-dimensional irreps. Further, the action of $\tilde{B}$ is zero, thus, we speak only about the action of $\tilde{D}$.

(iv) $\mu_A=2n$, $n=1,2,\ldots$: For fixed n the representation decomposes into $2n+1$ one-dimensional irreps. On one of these, which is spanned by the element

$$w_0=\sum_{k=0}^{n}\binom{n}{k}\tilde{a}^{2n-2k}\tilde{d}^{2k}, \tag{4.27}$$

the generator $\tilde{D}$ acts by zero. The rest of the irreps are enumerated by the parameters $\pm$, τ, where $\tau=2,4,\ldots,2n=\mu_A$, and are spanned by the vectors

$$u_\tau^\pm=u_0\pm\pi u_1,$$

$$u_0=\sum_{k=0}^{n}\alpha_k\tilde{a}^{2n-2k}\tilde{d}^{2k},\quad \alpha_0=1, \tag{4.28}$$

$$u_1=\sum_{k=0}^{n-1}\beta_k\tilde{a}^{2n-2k-1}\tilde{d}^{2k+1},\quad \beta_0=1,$$

on which $\tilde{D}$ acts by

$$\pi_R(\tilde{D})u_\tau^{\pm}=\pm\tau u_\tau^{\pm}, \tag{4.29}$$

which follows from

$$\pi_R(\tilde{D})\begin{pmatrix}u_0\\u_1\end{pmatrix}=\begin{pmatrix}\tau^2u_1\\u_0\end{pmatrix}. \tag{4.30}$$

Note that the value of the Casimir $\tilde{D}^2$ is equal to τ^2. The coefficients α_k,β_k depend on τ and are fixed from the two recursive equations which follow from (4.30):

$$\tau^2\beta_k=2(n-k)\alpha_k-2(k+1)\alpha_{k+1},\quad k=0,\ldots,n-1, \tag{4.31a}$$

$$\alpha_k=(2k+1)\beta_k-(2n-2k+1)\beta_{k-1},\quad k=0,\ldots,n, \tag{4.31b}$$

where we set $\beta_{-1}\equiv 0$, $\beta_n\equiv 0$.

(v) $\mu_A=2n+1$, $n=1,2,\ldots$: For fixed n the representation is $(2n+2)$-dimensional and decomposes into $2n+2$ irreps which are enumerated by two parameters: $\pm$, τ, where $\tau=1,3,5,\ldots,2n+1=\mu_A$, and are spanned by the vectors

$$w_\tau^{\pm}=w_0\pm\tau w_1,$$

$$w_0=\sum_{k=0}^{n}\alpha_k'\tilde{a}^{2n-2k+1}\tilde{d}^{2k},\quad \alpha_0'=1, \tag{4.32}$$

$$w_1=\sum_{k=0}^{n}\beta_k'\tilde{a}^{2n-2k}\tilde{d}^{2k+1},\quad \beta_0'=1,$$

on which $\tilde{D}$ acts by (4.29). Note that the value of the Casimir $\tilde{D}^2$ is equal to τ^2. The coefficients α_k',β_k' are fixed from the two recursive equations which follow from (4.29):

$$\tau^2\beta_k'=(2n-2k+1)\alpha_k'-2(k+1)\alpha_{k+1}',\quad k=0,\ldots,n, \tag{4.33}$$

$$\alpha_k'=(2k+1)\beta_k'-2(n-k+1)\beta_{k-1}',\quad k=0,\ldots,n, \tag{4.34}$$

where we set $\alpha_{n+1}'\equiv 0$, $\beta_{-1}'\equiv 0$.

To summarize the list of irreps of $s14$ on $S14$ is

(i) one-dimensional trivial;

(ii) two two-dimensional with all Casimirs $\tilde{A},\tilde{B}^2,\tilde{D}^2$ having the value 1;

(iii) one-dimensional enumerated by $n=1,2,\ldots$, which for fixed n have Casimir values $2n,0,0$ for $\tilde{A},\tilde{B}^2,\tilde{D}^2$, respectively;

(iv) pairs of one-dimensional irreps enumerated by $n=1,2,\ldots$, $\tau=2,4,\ldots,2n$, which have Casimir values $2n,0,\tau^2$ for $\tilde{A},\tilde{B}^2,\tilde{D}^2$, respectively; and

(v) pairs of one-dimensional irreps enumerated by $n=1,2,\ldots$, $\tau=1,3,\ldots,(2n+1)$, which have Casimir values $2n+1,0,\tau^2$ for $\tilde{A},\tilde{B}^2,\tilde{D}^2$, respectively.

Finally, we note in the irreps of $s14$ on $S14$ all Casimirs can take only non-negative integer values.

V. ALGEBRA *S*14*o*

A. Bialgebra relations

In this section we consider the matrix bialgebra $S14o$. We obtain it by applying the RTT relations (3.1) for the case $R=R_{S1,4}$, cf. (4.1), when $q^2=1$. We shall consider the case $q=1$ (the case $q=-1$ is equivalent, cf. below). For $q=1$ the relations following from (3.1) and (4.1) are

$$a^2=d^2,\ \ b^2=c^2=0,\quad ab=ba=ac=ca=bd=db=cd=dc=0, \tag{5.1}$$

or, in terms of the generators $\tilde{a},\tilde{b},\tilde{c},\tilde{d}$,

$$\tilde{b}\tilde{a}=\tilde{a}\tilde{b},\ \ \tilde{c}\tilde{a}=-\tilde{a}\tilde{c},\ \ \tilde{d}\tilde{a}=-\tilde{a}\tilde{d},\ \ \tilde{c}\tilde{b}=-\tilde{b}\tilde{c},\ \ \tilde{d}\tilde{b}=-\tilde{b}\tilde{d},\ \ \tilde{d}\tilde{c}=\tilde{c}\tilde{d}. \tag{5.2}$$

(The case $q=-1$ is obtained from the above through the exchange $\tilde{b}\leftrightarrow\tilde{c}$.)

From the above relations it is clear that we can choose any ordering of the PBW basis. For definiteness we choose for the PBW basis of $S14o$

$$\tilde{a}^k\tilde{b}^\ell\tilde{c}^m\tilde{d}^n. \tag{5.3}$$

B. Dual algebra

Let us denote by $s14o$ the unknown yet dual algebra of $S14o$, and by $\tilde{A},\tilde{B},\tilde{C},\tilde{D}$ the four generators of $s14o$. We define the pairing $\langle Z,f\rangle$, $Z=\tilde{A},\tilde{B},\tilde{C},\tilde{D}$, f is from (5.3), as (3.10). Explicitly, we obtain

$$\langle\tilde{A},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{a}}\right)=\begin{cases}k & \text{for } f=\tilde{a}^k,\\ 0 & \text{otherwise,}\end{cases} \tag{5.4a}$$

$$\langle\tilde{B},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{b}}\right)=\begin{cases}1 & \text{for } f=\tilde{a}^k\tilde{b},\\ 0 & \text{otherwise,}\end{cases} \tag{5.4b}$$

$$\langle\tilde{C},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{c}}\right)=\begin{cases}1 & \text{for } f=\tilde{a}^k\tilde{c},\\ 0 & \text{otherwise,}\end{cases} \tag{5.4c}$$

$$\langle\tilde{D},f\rangle=\varepsilon\left(\frac{\partial f}{\partial\tilde{d}}\right)=\begin{cases}1 & \text{for } f=\tilde{a}^k\tilde{d},\\ 0 & \text{otherwise.}\end{cases} \tag{5.4d}$$

Using the above we obtain the following proposition.

Proposition 3: The generators $\tilde{A},\tilde{B},\tilde{C},\tilde{D}$ introduced above obey the following relations:

$$[\tilde{A},Z]=0,\quad Z=\tilde{B},\tilde{C},\tilde{D}, \tag{5.5a}$$

$$[\tilde{B},\tilde{C}]=-2\tilde{D},\quad [\tilde{B},\tilde{D}]=-2\tilde{C},\quad [\tilde{C},\tilde{D}]=-2\tilde{B}, \tag{5.5b}$$

$$\delta_{\mathcal{U}}(\tilde{A})=\tilde{A}\otimes 1_{\mathcal{U}}+1_{\mathcal{U}}\otimes\tilde{A}, \tag{5.6a}$$

$$\delta_{\mathcal{U}}(\tilde{B})=\tilde{B}\otimes 1_{\mathcal{U}}+1_{\mathcal{U}}\otimes\tilde{B}, \tag{5.6b}$$

$$\delta_{\mathcal{U}}(\tilde{C})=\tilde{C}\otimes K+1_{\mathcal{U}}\otimes\tilde{C},\quad K=(-1)^{\tilde{A}}, \tag{5.6c}$$

$$\delta_{\mathcal{U}}(\tilde{D})=\tilde{D}\otimes K+1_{\mathcal{U}}\otimes\tilde{D}, \tag{5.6d}$$

$$\varepsilon_{\mathcal{U}}(Z)=0, \quad Z=\tilde{A},\tilde{B},\tilde{C},\tilde{D}, \tag{5.7}$$

$$\gamma_{\mathcal{U}}(\tilde{A})=-\tilde{A}, \gamma_{\mathcal{U}}(\tilde{B})=-\tilde{B}, \quad \gamma_{\mathcal{U}}(\tilde{C})=-\tilde{C}K, \quad \gamma_{\mathcal{U}}(\tilde{D})=-\tilde{D}K. \tag{5.8}$$

Proof: The proof of (5.5) goes as the standard duality between the classical U(gl(2)) and GL(2), cf. e.g., Ref. 13. The proof of (5.6)–(5.8) is also standard, except the factor K which appears while calculating:

$$\langle \tilde{C},\tilde{c}\tilde{a}^k\rangle=(-1)^k\langle \tilde{C},\tilde{a}^k\tilde{c}\rangle=(-1)^k,$$

which on the other hand is equal to (supposing an unknown yet K)

$$\langle \delta_{\mathcal{U}}(\tilde{C}),\tilde{c}\otimes\tilde{a}^k\rangle=\langle \tilde{C}\otimes K+1_{\mathcal{U}}\otimes\tilde{C},\tilde{c}\otimes\tilde{a}^k\rangle=\langle K,\tilde{a}^k\rangle.$$

Comparing the two rhs's we conclude that $K=(-1)^{\tilde{A}}$. The same follows from calculating $\langle \tilde{D},\tilde{d}\tilde{a}^k\rangle$. ■

Corollary 3: The auxiliary generator $K=(-1)^{\tilde{A}}$ is central and $K^{-1}=K$. Its co-algebra relations are

$$\delta_{\mathcal{U}}(K)=K\otimes K, \quad \varepsilon_{\mathcal{U}}(K)=1, \quad \gamma_{\mathcal{U}}(K)=K. \tag{5.9}$$

■

Corollary 4: The algebra generated by the generator $\tilde{A}$ is a Hopf subalgebra of $s14o$. The algebra $s14o'$ generated by $\tilde{B},\tilde{C},\tilde{D}$ is a subalgebra of $s14o$, but is not a Hopf subalgebra because of the operator K in the co-algebra structure. The algebras $s14o,s14o'$ are isomorphic to U(gl(2)),U(sl(2)), respectively. The latter is seen from the following:

$$X^{\pm}\equiv\tfrac{1}{2}(\tilde{D}\mp\tilde{C}), \tag{5.10a}$$

$$[\tilde{B},X^{\pm}]=\pm 2X^{\pm}, \quad [X^{+},X^{-}]=\tilde{B}. \tag{5.10b}$$

Indeed the last line presents the standard sl(2) commutation relations. However, the generators $X^{\pm}$ inherit the K dependence in the coalgebra operations:

$$\delta_{\mathcal{U}}(X^{\pm})=X^{\pm}\otimes K+1_{\mathcal{U}}\otimes X^{\pm}, \tag{5.11a}$$

$$\varepsilon_{\mathcal{U}}(X^{\pm})=0, \tag{5.11b}$$

$$\gamma_{\mathcal{U}}(X^{\pm})=-X^{\pm}K. \tag{5.11c}$$

The algebra $s14o$ is graded:

$$\deg\ X^{\pm}=\pm 1, \quad \deg\ \tilde{A}=\deg\ \tilde{B}=0, \quad (\Rightarrow \deg\ K=0). \tag{5.12}$$

■

Based on the above corollary we are able to make the following important observation. The algebra $s14o$ may be identified with a special case of the Hopf algebra $\mathcal{U}_{p,q}$ which was found in Ref. 13 as the dual of $\mathrm{GL}_{p,q}(2)$. To make direct contact with Ref. 13 we need to replace their $(p^{1/2},q^{1/2})\to(p,q)$, then set $q=p^{-1}$, and at the end set $p=-1$. [The necessity to set values in such order is clear from, e.g., the formula for the co-product in (5.21) of Ref. 13]. The generators from Ref. 13 $K,p^{K},H,X^{\pm}$ correspond to $\tilde{A},K,\tilde{B},X^{\pm}$ in our notation.

More than this, it turns out that the corresponding algebras in duality, namely, $S14o$ and $\mathrm{GL}_{p,q}(2)$, may be identified setting q,p as above. To make this evident we make the following change of generators:

$$\hat{a}=\tilde{a}+\tilde{b},\quad \hat{b}=\tilde{d}-\tilde{c},\quad \hat{c}=\tilde{c}+\tilde{d},\quad \hat{d}=\tilde{a}-\tilde{b}. \tag{5.13}$$

For these generators the commutation relations are

$$\hat{b}\hat{a}=-\hat{a}\hat{b},\quad \hat{c}\hat{a}=-\hat{a}\hat{c},\quad \hat{d}\hat{a}=\hat{a}\hat{d},\quad \hat{c}\hat{b}=\hat{b}\hat{c},\quad \hat{b}\hat{d}=-\hat{d}\hat{b},\quad \hat{c}\hat{d}=-\hat{d}\hat{c}, \tag{5.14}$$

i.e., exactly those of $\mathrm{GL}_{p,q}(2)$ (cf. Ref. 1) for $p=q=-1$. Furthermore, the co-product and co-unit are as for $\mathrm{GL}_{p,q}(2)$ or $\mathrm{GL}(2)$, i.e., as in (2.1). For the antipode we have to suppose that the determinant $ad-p^{-1}bc$ from Ref. 1, which here becomes (cf. $p=-1$)

$$\omega=\hat{a}\hat{d}+\hat{b}\hat{c}, \tag{5.15}$$

is invertible, or that $\omega\neq 0$, and we extend the algebra by an element ω^{-1} so that

$$\omega\omega^{-1}=\omega^{-1}\omega=1_{\mathcal{A}},\quad \delta_{\mathcal{U}}(\omega^{\pm 1})=\omega^{\pm 1}\otimes\omega^{\pm 1},\ \ \varepsilon_{\mathcal{U}}(\omega^{\pm 1})=1,\ \ \gamma_{\mathcal{U}}(\omega^{\pm 1})=\omega^{\mp 1}. \tag{5.16}$$

Then the antipode is given by

$$\gamma_{\mathcal{U}}\begin{pmatrix}\hat{a} & \hat{b}\\ \hat{c} & \hat{d}\end{pmatrix}=\omega^{-1}\begin{pmatrix}\hat{d} & \hat{b}\\ \hat{c} & \hat{a}\end{pmatrix}, \tag{5.17}$$

or in a more compact notation

$$\gamma_{\mathcal{U}}(M)=M^{-1}. \tag{5.18}$$

Indeed, we have

$$\begin{pmatrix}\hat{a} & \hat{b}\\ \hat{c} & \hat{d}\end{pmatrix}\begin{pmatrix}\hat{d} & \hat{b}\\ \hat{c} & \hat{a}\end{pmatrix}=\begin{pmatrix}\hat{d} & \hat{b}\\ \hat{c} & \hat{a}\end{pmatrix}\begin{pmatrix}\hat{a} & \hat{b}\\ \hat{c} & \hat{d}\end{pmatrix}=\omega\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}. \tag{5.19}$$

This relation between $s14o$, $S14o$ and $\mathcal{U}_{p,q}$, $\mathrm{GL}_{p,q}(2)$ was not anticipated since the corresponding R-matrices $R_{S1,4}$ and $R_{S2,1}$ are listed in Ref. 8 as different and, furthermore, nonequivalent. It turns out that this is indeed the case, except in the case we have stumbled upon. To show this we first recall

$$R_{S2,1}=\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & p & 1-pq & 0\\ 0 & 0 & q & 0\\ 0 & 0 & 0 & 1\end{pmatrix}, \tag{5.20}$$

which for $q=p^{-1}=-1$ becomes

$$R_0\equiv(R_{S2,1})_{q=p^{-1}=-1}=\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & -1 & 0 & 0\\ 0 & 0 & -1 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}. \tag{5.21}$$

Further, we need

$$R_{\pm}\equiv(R_{S1,4})_{q=\pm 1}=\begin{pmatrix} 0 & 0 & 0 & \pm 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ \pm 1 & 0 & 0 & 0 \end{pmatrix}. \tag{5.22}$$

Now we can show that $R_{\pm}$ can be transformed by "gauge transformations" to R_0. Namely, we have

$$R_0=(U_{\pm}\otimes U_{\pm})R_{\pm}(U_{\pm}\otimes U_{\pm})^{-1}, \tag{5.23a}$$

$$U_{+}=\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}, \quad U_{-}=\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix}. \tag{5.23b}$$

In accord with this we have

$$\hat{T}\equiv\begin{pmatrix} \hat{a} & \hat{b} \\ \hat{c} & \hat{d} \end{pmatrix}, \quad T\equiv\begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad \hat{T}=U_{+}T(U_{+})^{-1} \tag{5.24}$$

$$\Rightarrow \quad \begin{aligned} &\hat{a}=\tfrac{1}{2}(a+b+c+d), \quad \hat{b}=\tfrac{1}{2}(a-b+c-d), \\ &\hat{c}=\tfrac{1}{2}(a+b-c-d), \quad \hat{d}=\tfrac{1}{2}(a-b-c+d), \end{aligned} \tag{5.25}$$

which is equivalent to substituting (2.2) in (5.13).

The use of U_{-} would lead to different relations between hatted and unhatted generators, which, however, would not affect the algebra relations. Indeed,

$$\hat{T}'\equiv\begin{pmatrix} \hat{a}' & \hat{b}' \\ \hat{c}' & \hat{d}' \end{pmatrix}, \quad T'\equiv\begin{pmatrix} a' & b' \\ c' & d' \end{pmatrix}, \quad \hat{T}'=U_{-}T'(U_{-})^{-1} \tag{5.26}$$

$$\Rightarrow \quad \begin{aligned} &\hat{a}'=\tfrac{1}{2}(a'-ib'+ic'+d'), \quad \hat{b}'=\tfrac{1}{2}(-ia'+b'+c'+id'), \\ &\hat{c}'=\tfrac{1}{2}(ia'+b'+c'-id'), \quad \hat{d}'=\tfrac{1}{2}(a'+ib'-ic'+d'). \end{aligned} \tag{5.27}$$

But this becomes equivalent to (5.25) with the changes

$$(\hat{a}',i\hat{b}',-i\hat{c}',\hat{d}')\mapsto(\hat{a},\hat{b},\hat{c},\hat{d}), \quad (a',-ib',ic',d')\mapsto(a,b,c,d), \tag{5.28}$$

while the (inverse) changes (5.28) do not affect (5.14) and (5.1).

C. Representations of *s*14*o* on *S*14*o*

The regular representation of $s14o$ ($s14o'$) on itself and its weight representations are the same as those of $U(gl(2))$ ($U(sl(2))$) due to (5.10). The situation is different for the representations of $s14o$ on $S14o$ since these involve the coalgebra structure. However, the deviation from the trivial coalgebra structure is only via the sign operator K, and as we shall see in some representations there remains no trace of this.

In treating the representations of $s14o$ on $S14o$ we shall use the known construction for the induced representations of $\mathcal{U}_{p,q}$ on $\mathrm{GL}_{p,q}(2)$ from Ref. 20 and the relation between $s14o$,$S14o$

and $\mathcal{U}_{p,q}$, $\mathrm{GL}_{p,q}(2)$ that we established in the previous subsection. For the comparison with Ref. 20 we should note the parametrization used there: $p=ts^{1/2}$, $q=ts^{-1/2}$. Thus, using $q=p^{-1}$, $p=-1$ we need to substitute $t\to 1$, $\sqrt{s}\mapsto -1$. Further, one should substitute the operator h from Ref. 20 with $t^{\tilde{B}/2}$, and expand in order to get the action of $\tilde{B}$. Finally, one should substitute the operator r from Ref. 20 with $\sqrt{s}^{\tilde{A}}=(-1)^{\tilde{A}}=K$. In fact, it is easier to derive the necessary formulas directly, which we shall proceed to do in a compact way.

Here we shall employ both the left action and the right action. We start by calculating the left action using

$$\pi_L(Z)f\equiv\langle \gamma_{\mathcal{U}}(Z),f_{(1)}\rangle f_{(2)},\quad Z\in s14,\ Z\neq 1_{\mathcal{U}},\quad f\in S14, \tag{5.29a}$$

$$\pi_L(1_{\mathcal{U}})f\equiv f,\quad f\in S14, \tag{5.29b}$$

using for the PBW basis

$$\hat{a}^j\hat{d}^k\hat{b}^\ell\hat{c}^n. \tag{5.30}$$

For the left action on the elements of $S14o$ we use a corollary of (5.29):

$$\pi_L(Z)fg=\pi_L(\delta'_{\mathcal{U}}(Z))(f\otimes g), \tag{5.31}$$

where is used the *opposite comultiplication* $\delta'_{\mathcal{U}}\equiv\sigma\circ\delta_{\mathcal{U}}$, where σ is the permutation in $\mathcal{U}\otimes\mathcal{U}$. We find

$$\pi_L(A)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=-k\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}, \tag{5.32a}$$

$$\pi_L(K)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=(-1)^k\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}, \tag{5.32b}$$

$$\pi_L(B)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=k\begin{pmatrix}-\hat{a}^k & -\hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}, \tag{5.32c}$$

$$\pi_L(X^+)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=k\begin{pmatrix}(-1)^{k-1}\hat{a}^{k-1}\hat{c} & \hat{d}\hat{b}^{k-1}\\ 0 & 0\end{pmatrix}, \tag{5.32d}$$

$$\pi_L(X^-)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=k\begin{pmatrix}0 & 0\\ \hat{a}\hat{c}^{k-1} & (-1)^{k-1}\hat{d}^{k-1}\hat{b}\end{pmatrix}, \tag{5.32e}$$

$$\pi_L(K)1_{\mathcal{A}}=1,\quad \pi_L(Z)1_{\mathcal{A}}=0,\quad Z=\tilde{A},\tilde{B},\tilde{C},\tilde{D}. \tag{5.32f}$$

(We give also the action of K though it follows from that of $\tilde{A}$.)

Next we calculate the right action as in (3.29) to find

$$\pi_R(A)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=k\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}, \tag{5.33a}$$

$$\pi_R(K)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=(-1)^k\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}, \tag{5.33b}$$

$$\pi_R(B)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=k\begin{pmatrix}\hat{a}^k & -\hat{b}^k\\ \hat{c}^k & -\hat{d}^k\end{pmatrix}, \tag{5.33c}$$

$$\pi_R(X^+)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=k\begin{pmatrix}0 & (-1)^{k-1}\hat{a}\hat{b}^{k-1}\\ 0 & \hat{d}^{k-1}\hat{c}\end{pmatrix}, \tag{5.33d}$$

$$\pi_R(X^-)\begin{pmatrix}\hat{a}^k & \hat{b}^k\\ \hat{c}^k & \hat{d}^k\end{pmatrix}=k\begin{pmatrix}\hat{a}^{k-1}\hat{b} & 0\\ (-1)^{k-1}\hat{d}\hat{c}^{k-1} & 0\end{pmatrix}, \tag{5.33e}$$

$$\pi_R(K)1_{\mathcal{A}}=1,\quad \pi_R(Z)1_{\mathcal{A}}=0,\quad Z=\tilde{A},\tilde{B},\tilde{C},\tilde{D}. \tag{5.33f}$$

By (5.29) and (5.33) we have defined left and right actions of $s14o$ on $S14o$. As in the classical case the left and right actions commute, and we shall use the right action to reduce the left regular representation. Following Ref. 21 we would like the right action to mimic some properties of a lowest weight module, i.e., annihilation by the lowering (negative grade) generator X^- and scalar action by the (exponent of the) Cartan (zero grade) generators $\tilde{A}$ (or K) and $\tilde{B}$. Such action is the reason we call these representations induced. We start with functions which are formal power series in the PBW basis:

$$f=\sum_{j,k,\ell,m\in\mathbb{Z}_+}\mu_{j,k,\ell,m}\hat{a}^j\hat{d}^k\hat{b}^\ell\hat{c}^m. \tag{5.34}$$

The right-action conditions we mentioned are

$$\pi_R(X^-)f=0, \tag{5.35a}$$

$$\pi_R(\tilde{A})f=\rho f,\quad \pi_R(\tilde{B})f=-\nu f. \tag{5.35b}$$

From (5.35a) follows that our functions would not depend on $\hat{a}$ and $\hat{c}$, except through the determinant ω, since $\pi_R(X^-)\omega=0$. We also have

$$\pi_R(\tilde{A})\omega^n=2n\omega^n,\quad \pi_R(K)\omega^n=\omega^n,\quad \pi_R(B)\omega^n=0,\quad \pi_R(X^\pm)\omega^n=0. \tag{5.36}$$

Thus, we continue with

$$f=\sum_{\substack{k,\ell,n\in\mathbb{Z}_+\\ n\in\mathbb{Z}}}\mu_{k,\ell}\hat{d}^k\hat{b}^\ell\omega^n, \tag{5.37}$$

on which conditions (5.35b) lead to $k+\ell+2n=\rho\in\mathbb{Z}$, $k+\ell=\nu\in\mathbb{Z}_+$, $\rho-\nu\in2\mathbb{Z}$, and the summation becomes single:

$$f=\sum_{\ell\in\mathbb{Z}_+}\mu_\ell u_\ell,\quad u_\ell\equiv\hat{b}^\ell\hat{d}^{\nu-\ell}\omega^{(\rho-\nu)/2}, \tag{5.38}$$

(where we changed the ordering since this would give simpler formulas for the action). Now if neither $\hat{b}$ nor $\hat{d}$ has an inverse the representations will be finite-dimensional, in contrast to the classical case. However, these finite-dimensional representations we shall obtain also if we suppose that either $\hat{b}$ or $\hat{d}$ has an inverse (see below), and at the same time we shall have infinite-dimensional representations. Thus, further, we shall suppose that $\hat{d}$ has an inverse. This means that we can allow k in (5.38) to take any integer values, and then the same is true for ν.

Now we shall work out the representation (left) action for the basis u_ℓ for which we need first the left action on ω:

$$\pi_L(A)\omega^n=-2n\omega^n,\quad \pi_L(K)\omega^n=\omega^n,\quad \pi_L(B)\omega^n=0,\quad \pi_L(X^\pm)\omega^n=0. \tag{5.39}$$

We also remark that the action on $\hat{d}^k$, ω^n for negative k, n is given again by (5.32) and (5.39). [This can be checked, e.g., by calculating $\pi_L(Z)\hat{d}^{-k}\hat{d}^k=\pi_L(Z)1_{\mathcal{A}}$ in two different ways: (5.31) for the lhs, and (5.32) for the rhs.] Then the rules are

$$\pi_{\nu,\rho}(\tilde{A})u_\ell=-\rho u_\ell, \tag{5.40a}$$

$$\pi_{\nu,\rho}(\tilde{B})u_\ell=(\nu-2\ell)u_\ell, \tag{5.40b}$$

$$\pi_{\nu,\rho}(X^+)u_\ell=(-1)^{\ell-1}\ell u_{\ell-1}, \tag{5.40c}$$

$$\pi_{\nu,\rho}(X^-)u_\ell=(-1)^{\ell+1}(\ell-\nu)u_{\ell+1}, \tag{5.40d}$$

where $\pi_{\nu,\rho}$ denotes π_L with the parameter dependence made explicit.

Thus, we have obtained infinite-dimensional representations of $s14o$ parametrized by two integers ν, ρ. We shall denote by $\mathcal{C}_{\nu,\rho}$ the corresponding representation space. Note that these representations are highest weight representations since we have $\pi_L(X^+)u_0=0$. If the parameter ν is non-negative, $\nu\in\mathbb{Z}_+$, then the corresponding representation is reducible, due to the fact that $\pi_L(X^-)u_\nu=0$. Thus, the vectors $u_0,\ldots,u_\nu$ form an invariant subspace, of dimension $\nu+1$, which shall denote by $\mathcal{E}_{\nu,\rho}$, $\nu\in\mathbb{Z}_+$. Thus, if $\nu\in\mathbb{Z}_+$ we have two irreducible representations with representation spaces isomorphic to $\mathcal{E}_{\nu,\rho}$ and to $\mathcal{C}_{\nu,\rho}/\mathcal{E}_{\nu,\rho}$ (the latter is infinite-dimensional). If $\nu\notin\mathbb{Z}_+$ the representation $\mathcal{C}_{\nu,\rho}$ is irreducible.

From the above we are prompted to use the variable $\eta\equiv\hat{b}\hat{d}^{-1}$. This is also related to the following Gauss decomposition of $S14o$:

$$\begin{pmatrix}\hat{a} & \hat{b}\\ \hat{c} & \hat{d}\end{pmatrix}=\begin{pmatrix}1 & \hat{b}\hat{d}^{-1}\\ 0 & 1\end{pmatrix}\begin{pmatrix}\omega\hat{d}^{-1} & 0\\ 0 & \hat{d}\end{pmatrix}\begin{pmatrix}1 & 0\\ \hat{d}^{-1}\hat{c} & 1\end{pmatrix}, \tag{5.41}$$

i.e., from here the natural variables are η, $\hat{d}$, ω. Thus, we use also the functions

$$\varphi=\sum_{\ell\in\mathbb{Z}_+}\alpha_\ell v_\ell,\quad v_\ell\equiv\eta^\ell\hat{d}^\nu\omega^{(\rho-\nu)/2}. \tag{5.42}$$

The action of the generators on the variable η is

$$\begin{pmatrix}\tilde{A} & K\\ \tilde{B} & X^\pm\end{pmatrix}\eta^\ell=\begin{pmatrix}0 & \eta^\ell\\ -2\ell\,\eta^\ell & \pm\ell\,\eta^{\ell\mp1}\end{pmatrix}, \tag{5.43}$$

and the action on the basis is as for u_ℓ except for $X^\pm$:

$$\pi_{\nu,\rho}(X^+)v_\ell=\ell v_{\ell-1}, \tag{5.44a}$$

$$\pi_{\nu,\rho}(X^-)v_\ell=(\nu-\ell)v_{\ell+1}. \tag{5.44b}$$

Thus, in this basis there is no trace of the nontriviality of the co-product of $X^\pm$. More than this we can reduce the representations directly to the classical U(gl(2)) if we introduce the restricted functions $\hat{\varphi}(\eta)$ by the operators

$$\hat{A}_{\nu,\rho}:\mathcal{C}_{\nu,\rho}\to\hat{C}_{\nu,\rho},\quad \hat{\varphi}(\eta)=(\hat{A}_{\nu,\rho}\varphi)(\eta)\equiv\varphi(\eta,1_{\mathcal{A}},1_{\mathcal{A}}),$$
$$\hat{A}^{-1}_{\nu,\rho}:\hat{C}_{\nu,\rho}\to\mathcal{C}_{\nu,\rho},\quad \varphi(\eta,\hat{d},\omega)=(\hat{A}^{-1}_{\nu,\rho}\hat{\varphi})(\eta,\hat{d},\omega)\equiv\hat{\varphi}(\eta)\hat{d}^{\nu}\omega^{(\rho-\nu)/2}. \tag{5.45}$$

We denote the representation space of $\hat{\varphi}(\eta)$ by $\hat{C}_{\nu,\rho}$ and the representation acting in $\hat{C}_{\nu,\rho}$ by $\hat{\pi}_{\nu,\rho}$. The properties of $\hat{C}_{\nu,\rho}$ follow from the intertwining requirements:[21]

$$\hat{\pi}_{\nu,\rho}\circ\hat{A}_{\nu,\rho}=\hat{A}_{\nu,\rho}\circ\pi_{\nu,\rho},\quad \pi_{\nu,\rho}\circ\hat{A}^{-1}_{\nu,\rho}=\hat{A}^{-1}_{\nu,\rho}\circ\hat{\pi}_{\nu,\rho}. \tag{5.46}$$

In particular, the representation action of $\hat{\pi}_{\nu,\rho}$ on η^{ℓ} is given by the same formulas as the action of $\pi_{\nu,\rho}$ on v_{ℓ}.

At this moment, we should note that since we have functions of one variable η we can treat it as complex variable z. In these terms we recover from the action of $\hat{\pi}_{\nu,\rho}$ the classical vector-field representation of gl(2) (with $\partial_z\equiv d/dz$):

$$\tilde{A}\hat{\varphi}=-\rho\hat{\varphi},\quad \tilde{B}\hat{\varphi}=(\nu-2z\partial_z)\hat{\varphi},\quad X^{+}\hat{\varphi}=\partial_z\hat{\varphi},\quad X^{-}\hat{\varphi}=(\nu z-z^2\partial_z)\hat{\varphi}. \tag{5.47}$$

Of course, the importance of the nontrivial co-product for $X^{\pm}$ will be felt in the construction of the tensor products of the representations.

VI. CONCLUSIONS AND OUTLOOK

In this article we have found the exotic matrix bialgebras which correspond to the two nontriangular nonsingular 4×4 R-matrices of Ref. 8, namely, $R_{S0,3}$ and $R_{S1,4}$, which are not deformations of the trivial R-matrix. We study three bialgebras denoted by $S03$, $S14$, $S14o$, the latter two cases corresponding to $R_{S1,4}$ for deformation parameter $q^2\neq1$ and $q^2=1$, respectively. We have found the corresponding dual bialgebras $s03$, $s14$, $s14o$, and studied their representation theory.

For the bialgebras $s03$ and $s14$ we have studied the regular representation (the algebra acting on itself), the weight representations, and the representations in which the algebra acts on the dual matrix bialgebra. The representation theory is degenerate: the irreps are finite-dimensional of maximal dimension 4 and 2 for $s03$ and $s14$, respectively. For future use we shall say that the bialgebras $s03$, $S03$ and $s14$, $S14$ are *exotic* (adding to the list of exotic bialgebras termed so in Ref. 9).

The algebras $s14o$, $S14o$ turned out to be Hopf algebras and to be special cases of the two-parameter deformations $\mathcal{U}_{p,q}$, $\mathrm{GL}_{p,q}(2)$, namely, they would be obtained from the latter by setting $q=p^{-1}$ and then $p=-1$. This was not anticipated since the corresponding R-matrices were different and seemingly nonequivalent cases of the classification of Ref. 8. Thus, this became a case study important methodologically, and so we have made the exposition according to the way we proceeded. In fact, the algebra $s14o$ is equivalent even to U(gl(2)), and the only nontriviality is in the Hopf algebra structure. Thus, the regular and weight representations are as those of U(gl(2)). The induced representations of $s14o$ on $S14o$ could also be extracted from the equivalence with the two-parameter p, q deformations, but their consideration is also important methodologically.

To conclude, we should stress that with this article we finalize the explicit classification of the matrix bialgebras generated by four elements. There are altogether *nine* such bialgebras, four of which are quantum groups and are deformations of the classical algebras of functions on GL(2) and GL(1|1) (two in each case), and the other five bialgebras, which we call exotic, are not such deformations.

Further, we would like to study the spectral decomposition and Baxterization of these exotic algebras and associated noncommutative geometries, cf. Ref. 22.

Note added in proof: Note that the four-dimensional representation of Sec. III D, formula (3.27), actually reduces to a two-dimensional one, since $\tilde{C}v_0=-\lambda\tilde{B}v_0$.

(Received 17 June 2002; accepted 13 August 2002)

We consider the Laplacian in a strip $\mathbb{R}\times(0,d)$ with the boundary condition which is Dirichlet except at the segment of a length $2a$ of one of the boundaries where it is switched to Neumann. This operator is known to have a non-empty and simple discrete spectrum for any $a>0$. There is a sequence $0<a_1<a_2<\cdots$ of critical values at which new eigenvalues emerge from the continuum when the Neumann window expands. We find the asymptotic behavior of these eigenvalues around the thresholds showing that the gap is in the leading order proportional to $(a-a_n)^2$ with an explicit coefficient expressed in terms of the corresponding threshold-energy resonance eigenfunction. © *2002 American Institute of Physics.*

I. INTRODUCTION

Spectra of Dirichlet Laplacians in infinitely stretched regions such as planar strips or layers with local perturbations were studied recently in numerous papers. The motivation for this work came from applications in condensed matter physics, and also from the fact that it was itself an interesting mathematical problem.

One of the simplest systems of this type is a free quantum particle confined to a pair of straight parallel strips with Dirichlet boundary conditions coupled laterally by a window in the common boundary. If they are of the same width d, one can employ the mirror symmetry and concentrate on the nontrivial part which is equivalent to the analysis of the Laplacian in a single strip with the Dirichlet boundary condition switched to Neumann at a finite segment of one of the boundaries.

Such a system has at least one bound state for any ''window'' length $2a>0$ as it was found in Ref. 1 and independently in Ref. 2. The discrete spectrum is simple, the eigenvalues $\lambda_n, n=0,1,\ldots,$ are continuously decreasing as functions of a and their number is linear in a up to an error term as the window is widening.[1] These properties follow from a simple bracketing argument which allows to squeeze the eigenvalues between those of a box covering the ''coupled'' part with Dirichlet and Neumann conditions at $x_1=\pm a$. It shows, in particular, that there are critical values a_n, $n=0,1,\ldots,$ at which new eigenvalues emerge from the continuum. By Refs. 1 and 2 we have $a_0=0$ while generally we know only that

$$a_n\in\left(\frac{nd}{\sqrt{3}},\frac{(n+1)d}{\sqrt{3}}\right),\quad n=1,2,\ldots\ . \tag{1.1}$$

[b)]Electronic mail: exner@ujf.cas.cz
[c)]Electronic mail: gadylshin@bspu.ru

This tells us nothing about the behavior of the eigenvalues around the critical points.

The weak coupling asymptotics was studied for the ground state. A variational method of Ref. 3 yields for small a a two-sided estimate of $\lambda_0(a)$ between two multiples of a^4. This is indeed the leading term: using the matching method of Refs. 4 and 5 Popov derived in Ref. 6 the expansion

$$\lambda_0(a)=\left(\frac{\pi}{d}\right)^2-\left(\frac{\pi^3}{2d^3}\right)^2 a^4+\mathcal{O}(a^5). \tag{1.2}$$

While his argument is not fully rigorous because an estimate of the error term is missing, the formula itself raises no doubts, in particular, because of its excellent agreement with the numerical result of Ref. 1. The result is subtle: recall that (1.2) differs substantially from the asymptotics corresponding to a local change in *mixed* boundary conditions, where the Birman–Schwinger technique is applicable and the leading term is a multiple of the window width *squared*.[7]

In the present paper we address the question about the behavior of the higher eigenvalues λ_n, $n=1,2,\ldots$, in the vicinity of the critical points a_n. It is a natural counterpart of the coupling constant threshold problem of Ref. 8. Our main result is that the gap between an eigenvalue λ_n and the continuum is proportional to $(a-a_n)^2$ with a coefficient given explicitly in terms of the corresponding threshold-energy resonance eigenfunction. This fits well into the analogy between our problem and spectral properties of one-dimensional Schrödinger operators. The latter extends to higher dimensions, but the argument becomes more complicated and we leave that to another paper.

To finish the introduction, let us say something about the method. We deal with a perturbative problem with respect to the parameter ε defined as the excess of the window halfwidth a over the critical value a_n. Since the latter is positive for $n\geqslant 1$, the problem in question is a regular one. This fact makes it possible to map the problem into an equivalent one with a small and local perturbation of the equation and the boundary condition fixed, i.e., independent of ε. This is what we are going to do. We employ the technique introduced in Ref. 9 for calculations of the eigenfunctions for one-dimensional perturbed Schrödinger operator; its advantage is that we arrive at the sought asymptotic formula in a straightforward and reasonably simple way.

II. THE MAIN RESULT

To formulate the result we need first to introduce some notation and recall a few simple facts about the problem in question. We employ Cartesian coordinates, $x=(x_1,x_2)$, in which $\Sigma=\{x:0<x_2<d\}$. The upper strip boundary is $\Gamma=\{x:x_2=d\}$, while the lower decomposes into the union of $\gamma^a=\{x:|x_1|<a,x_2=0\}$ and $\Gamma^a=\{x:|x_1|>a,x_2=0\}$. The operator H_a we are going to consider is the Laplacian, $H_a\psi=-\Delta\psi$, in $L^2(\Sigma)$ with the Dirichlet boundary condition on $\Gamma^a\cup\Gamma$ and Neumann on γ^a; it is a well-defined self-adjoint operator, cf. Ref. 10, Chap. 7.[11]

Proposition 2.1: The discrete part of $\sigma(H_a)$ is simple and the eigenvalues $\lambda_n(a):(\pi/2d)^2<\lambda_0(a)<\lambda_1(a)<\cdots<(\pi/d)^2$ are continuous and monotonously decreasing with respect to a. There are numbers $0=a_0<a_1<a_2<\cdots$ satisfying (1.1) such that (a) for $a\in(a_{n-1},a_n]$ the operator H_a has exactly n eigenvalues, (b) for $a>a_n$ we denote $\varepsilon:=a-a_n$, then the eigenfunction $\psi_n^{(\varepsilon)}$ associated with $\lambda_n(a)$ has a definite parity with respect to x_1, namely

$$\psi_n^{(\varepsilon)}(-x_1,x_2)=(-1)^n\psi_n^{(\varepsilon)}(x_1,x_2),$$

(c) for $a=a_n$ the equation $-\Delta\psi=(\pi/d)^2\psi$ with given boundary conditions has a solution $\psi_n^{(0)}\in H^1_{\mathrm{loc}}(\Sigma)$, unique up to a multiplicative constant, which behaves like

$$\psi_n^{(0)}(x)=c_1(\pm 1)^n\sin\left(\frac{\pi x_2}{d}\right)+\mathcal{O}(\mathrm{e}^{-\delta|x_1|}) \tag{2.1}$$

as $x_1\to\pm\infty$, where $\delta:=\pi\sqrt{3}/d$ (in what follows we set $c_1:=\sqrt{2/\pi}$ for the sake of definiteness).

Proof: Most part was demonstrated in Ref. 1, it remains to check the claim (c). Any solution can be expanded in terms of the transverse eigenfunction bases

$$\chi_j(x_2) := \sqrt{\frac{2}{d}}\sin\left(\frac{\pi j x_2}{d}\right),$$

$$\phi_j(x_2) := \sqrt{\frac{2}{d}}\sin\left(\frac{\pi(2j-1)(d-x_2)}{d}\right)$$

with $j=1,2,\ldots$. Since the problem has a mirror symmetry with respect to $x_1=0$, it is sufficient to discuss the halfstrip part, $x_1\geq 0$, with the appropriate boundary condition at $x_1=0$. Let us consider the even case. A solution of energy $\epsilon(\pi/d)^2$ expresses as

$$\begin{aligned}\psi(x) &= \sum_{j=1}^{\infty} c_j e^{q_j(a-x_1)}\chi_j(x_2),\\ \psi(x) &= \sum_{j=1}^{\infty} b_j \frac{\cosh(p_j x_1)}{\cosh(p_j a)}\phi_j(x_2)\end{aligned} \tag{2.2}$$

for $|x_1|\geq a$ and $|x_1|\leq a$, respectively, where $q_j := (\pi/d)\sqrt{j^2-\epsilon}$ and $p_j := (\pi/d)\sqrt{(j-\frac{1}{2})^2-\epsilon}$. The coefficients in the above relation are determined by the requirement of smoothness of ψ at the segment $x_1=a$; we have

$$\begin{aligned}c_j &= \sum_{k=1}^{\infty} b_k(\chi_j,\phi_k),\\ (\chi_j,\phi_k) &= \frac{(-1)^{j-k}}{\pi}\frac{2j}{j^2-(k-\frac{1}{2})^2},\end{aligned} \tag{2.3}$$

and $b=\{b_j\}$ is given as solution of an infinite system of equations which can be written concisely in the operator form

$$Cb=0 \tag{2.4}$$

with

$$C_{jk} := [q_j + p_k\tanh(p_k a)](\chi_j,\phi_k).$$

The odd case is similar, just cosh and tanh are replaced by sinh and coth, respectively. The allowed values of ϵ are those for which a solution to the system (2.4) exists.

We know from Ref. 1 that the sequence corresponding to an isolated eigenvalue of H_a, i.e., $\epsilon\in(1/4,1)$, belongs to $\ell^2(j^{-r})$ for any $r\geq 1$, and that $C=C(a,\epsilon)$ is Hilbert–Schmidt on $\ell^2(j^{-r})$ with r large enough independently of a and ϵ. Choosing such an r it is straightforward to check that $(a,\epsilon)\mapsto C(a,\epsilon)$ is jointly continuous in the corresponding Hilbert–Schmidt norm. Take $a>a_n$ and $\epsilon_n(a) := (d/\pi)^2\lambda_n(a)$, clearly $\epsilon_n(a)\to 1$ as $a\to a_n+$. The said continuity implies that the equation (2.4) has for $C(a_n,1)$ a unique solution in $\ell^2(j^{-r})$, and by (2.3) it determines a sequence $b\in\ell^2(j^{-r})$. Together they yield the sought threshold resonance solution for $a=a_n$ with the asymptotics (2.1) following from the first one of the relations (2.2). ■

Remark 2.2: The function $\psi_n^{(0)}$ described in Proposition 2.1 has the following smoothness properties. It is infinitely differentiable everywhere in $\overline{\Sigma}$ except the endpoints of the segment γ^{a_n}. At these points the asymptotic formula

$$\psi_n^{(0)}(x)=(\pm 1)^n \alpha_n r_\pm^{1/2} \sin\frac{\theta_\pm}{2}+\mathcal{O}(r_\pm), \quad r_\pm\to 0, \tag{2.5}$$

is valid, where $(r_\pm,\theta_\pm)$ are polar coordinates associated with the variables $(\pm x_1-a_n,x_2)$ and α_n is a some number (a unique one provided we fix c_1). These asymptotics formulas can be verified in two easy steps. First, one should extend the function $\psi_n^{(0)}$ to the mirrored strip $\{x:-d<x_2<0\}$ in the even way. This leads to solution of the equation $-\Delta\psi_n^{(0)}=(\pi/d)^2\psi_n^{(0)}$ in the double strip $\{x:|x_2|<d\}\backslash\{x:|x_1|>a,x_2=0\}$ with the Dirichlet boundary condition at the outer boundary and at the cut $\{x:|x_1|>a,x_2=\pm 0\}$, and it is sufficient to employ the results established in Ref. 12 for such elliptic problems.

Now we can state our main result:

Theorem 2.3: *The eigenvalue $\lambda_n(a)$ of H_a with $n\geqslant 1$ has the following asymptotic behavior,*

$$\lambda_n(a)=\left(\frac{\pi}{d}\right)^2-\mu_n^2(a-a_n)^2+\mathcal{O}((a-a_n)^3) \tag{2.6}$$

as $a\to a_n+$, where the coefficient is given by

$$\mu_n:=\frac{1}{a_n}\int_\Sigma\left|\frac{\partial\psi_n^{(0)}}{\partial x_1}\right|^2 dx_1\,dx_2, \tag{2.7}$$

or alternatively by

$$\mu_n:=\frac{\pi\alpha_n^2}{4}, \tag{2.8}$$

where α_n is the number appearing in (2.5). The associated eigenfunction $\psi_n^{(\varepsilon)}$ can be normalized in such a way that it satisfies the relation

$$\psi_n^{(\varepsilon)}=\psi_n^{(0)}+\mathcal{O}(\varepsilon), \tag{2.9}$$

in $H^1((-R,R)\times(0,d))$ for any $R>0$ behaving asymptotically as

$$\psi_n^{(\varepsilon)}(x)=c_1(\pm 1)^n e^{-\varepsilon\mu_n|x_1|}\sin\left(\frac{\pi x_2}{d}\right)+\mathcal{O}(\mathrm{e}^{-\delta|x_1|}) \tag{2.10}$$

when $x_1\to\pm\infty$, with δ defined in Proposition 2.1.

Remark 2.4: The function $\psi_n^{(\varepsilon)}$ belongs, of course, to $L^2(\Sigma)$, but it does not have a limit in this space as $\varepsilon\to 0+$ since the norm $\|\psi_n^{(\varepsilon)}\|_{L^2(\Sigma)}$ explodes in the limit. Furthermore, α_n is nonzero for any $n\geqslant 1$. This fact can be easily deduced from the assertion (2.7). Indeed, the assumption $\alpha_n=0$ implies immediately that $\psi_n^{(0)}$ is independent on x_1. However, this contradicts to the boundary value problems that $\psi_n^{(0)}$ satisfies to. The coefficient α_n being nonzero, the formula (2.8) shows that the asymptotics of each λ_n is nontrivial in the leading order.

III. PROOF OF THEOREM 2.2

The rest of the paper is devoted to the proof of Theorem 2.3. With the scaling behavior of the spectrum in mind we can put $d=\pi$ without loss of generality in the following. Furthermore, the mirror symmetry with respect to $x_1=0$ makes it possible to consider the half-strip problem with the Dirichlet or Neumann condition at the cut.

We need to introduce some notations. Let $\mathbb{R}^2_+=\{x:x_1>0\}$ be the open right half-plane. As indicated above, we will work in the half-strip $\Pi:=\Sigma\cap\mathbb{R}^2_+$, similarly we introduce γ_ε

$:=\gamma^{a_n+\varepsilon}\cap\mathbb{R}^2_+$, $\Gamma_+:=\Gamma\cap\mathbb{R}^2_+$, and $\Gamma_\varepsilon:=\Gamma^{a_n+\varepsilon}\cap\mathbb{R}^2_+$. Moreover, we need a symbol for the cut at the symmetry axis, $\gamma:=\{x:x_1=0,\ 0<x_2<\pi\}$. Since we consider a fixed eigenvalue, we shall omit the index n when there is no danger of misunderstanding.

Let us outline the strategy of the proof. In the first step we are going to analyze the problem

$$\begin{gathered}(\Delta+1)u=m^2u+f,\quad x\in\Pi,\\ l_xu=0,\quad x\in\gamma,\\ u=0,\quad x\in\Gamma_0\cup\Gamma_+,\\ \frac{\partial u}{\partial x_2}=0,\quad x\in\gamma_0,\end{gathered}\tag{3.1}$$

with a fixed function f at the right-hand side of the equation. The trace operator l_x in the boundary conditions is defined as $(l_xu)(x_1,x_2)=u(0,x_2)$ if n is odd and $(l_xu)(x_1,x_2)=(\partial u/\partial x_1)(0,x_2)$ if n is even. The parameter m is assumed to be complex and to lie in a (sufficiently small) neighborhood of zero (we indicate this neighborhood by $\mathcal{D}$). We also suppose that f is an arbitrary function from $L^2(\Pi)$ with a compact support. We will construct a solution of the problem (3.1), meromorphic with respect to m, with the following asymptotic behavior far from the cut of the half-strip:

$$u(x,m)=c(m)e^{-mx_1}\sin x_2+\mathcal{O}(e^{-\sqrt{3+m^2}x_1}),\quad x_1\to+\infty,\tag{3.2}$$

where $c(m)$ is a constant determined by the function f. In the second step we will transform the original boundary value problem for the eigenfunction $\psi^{(\varepsilon)}$ to another one with an equation the coefficients of which depend smoothly on ε and the boundary condition is independent of ε. What is important is that the reformulated problem will be of the form (3.1) with a particular right-hand side $f=f_\varepsilon$ for which we deduce a sufficient explicit representation. Combining the latter with properties of the solution to (3.1) will finally obtain the announced results concerning λ_ε and $\psi^{(\varepsilon)}$. Since the proof of Theorem 2.3 divides in this way naturally into two steps, we shall discuss them separately in the following two sections.

A. Solution of the problem (3.1)

As we have indicated our aim is to construct a solution of (3.1) which is meromorphic in $m\in\mathcal{D}$. Let us say more explicitly what we mean by that. It is easy to see that there is a unique solution for $m\in\mathcal{D}\cap\{m:\mathrm{Re}\,m>0\}$ which decays as $x_1\to\infty$. We shall check that as a function of m it is analytic in $\mathcal{D}\cap\{m:\mathrm{Re}\,m>0\}$ and extend it to the remaining part of $\mathcal{D}$. The extension will be for $\mathrm{Re}\,m<0$ again a solution to (3.1) with the asymptotics (3.2), and in addition, it will be meromorphic in $m\in\mathcal{D}$ with just one simple pole at $m=0$. Of course, the extension will be bounded at large distances if $\mathrm{Re}\,m=0$ and will be increasing for $\mathrm{Re}\,m<0$. Speaking about solutions everywhere in the following we mean always such analytic continuations.

Recall that a function F with values in some Banach space X is said to be holomorphic in $\mathcal{D}$ if it is differentiable (in the sense of the norm of X) at each point $m\in\mathcal{D}$. If this function is holomorphic in $\mathcal{D}$ everywhere except a discrete set of points which are poles of F, i.e., Laurent's series of F at such a point has at most a finite number of negative terms, then F is said to be meromorphic.

We introduce some notations. Let $\mathcal{L}(X,Y)$ be the Banach space of bounded linear operators from a Banach space X into a Banach space Y. We will use the symbol $\mathcal{H}(X)$ for the class of functions with values in X which are holomorphic with respect to $m\in\mathcal{D}$, and $\mathcal{M}(X)$ for the class of meromorphic on $m\in\mathcal{D}$ functions with values in X. For the sake of brevity we also introduce the notations $\mathcal{H}(X,Y):=\mathcal{H}(\mathcal{L}(X,Y))$, $\mathcal{M}(X,Y):=\mathcal{M}(\mathcal{L}(X,Y))$.

We will treat the problem (3.1) by the technique introduced in Ref. 13, Sec. XVI.4. Let R be a fixed number larger than a_n, $\Pi_R := \Pi \cap \{x : x_1 < R\}$, and g a function from $L^2(\Pi_R)$ which can be also regarded as an element of $L^2(\Pi)$ if we set it equal to zero for $x_1 > R$. The problem

$$(\Delta + 1)v = m^2 v + g, \quad x \in \Pi, \quad v = 0, \quad x \in \partial\Pi, \tag{3.3}$$

can be easily solved by separation of variables, the solution being

$$\begin{gathered} v(x,m) = -\sum_{k=1}^{\infty} \frac{1}{\pi M_k} \int_{\Pi} G_k(x,t,m) g(t) d^2 t, \\ G_k(x,t,m) = (e^{-M_k|x_1 - t_1|} - e^{-M_k(x_1 + t_1)}) \sin kt_2 \sin kx_2, \end{gathered} \tag{3.4}$$

where $M_1 = m$ and $M_k = \sqrt{k^2 - 1 + m^2}$ for $k \geqslant 2$. For the sake of brevity we use the notation $d^2 t = dt_1\, dt_2$. Obviously, the formula (3.4) is valid for all $m \in \mathcal{D}$, not only for $\operatorname{Re} m > 0$. The function v can be represented as $v = T_1(m) g$, where $T_1(m) : L^2(\Pi_R) \to H^2(\Pi_{\tilde{R}})$ is a bounded linear operator for any positive $\tilde{R}$. It is straightforward to check that $v \in \mathcal{H}(H^2(\Pi_{\tilde{R}}))$ and $T_1(\cdot) \in \mathcal{H}(L^2(\Pi_R), H^2(\Pi_{\tilde{R}}))$ in $\mathcal{D}$ for any positive $\tilde{R}$.

In the next step we consider another boundary value problem for an unknown function w, namely

$$\begin{gathered} \Delta w = \Delta v, \quad x \in \Pi_R, \\ w = 0, \quad x \in (\Gamma_+ \cup \Gamma_0) \cap \partial\Pi_R, \\ w = v, \quad x_1 = R, \\ \frac{\partial w}{\partial x_2} = 0, \quad x \in \gamma_0, \\ l_x w = 0, \quad x \in \gamma. \end{gathered} \tag{3.5}$$

Since $v \in H^2(\Pi_R)$ we have $\Delta v \in L^2(\Pi_R)$, and thus the problem (3.5) has a unique solution $w \in H^1(\Pi_R)$, see, e.g., Ref. 14, Sec. 2.5, Rem. 5.1. Using the standard theorem on smoothness of solutions of elliptic boundary value problems we can conclude that $w \in H^2(\Pi_{R,s})$ holds for each $s > 0$, where $\Pi_{R,s} := \Pi_R \setminus D_s$ with $D_s := \{x : x_2 > 0, (x_1 - a_n)^2 + x_2^2 < s^2\}$. Hence we can define the linear operator T_2 by $w =: T_2 v$ which is a linear bounded map from $H^2(\Pi_R)$ into $H^1(\Pi_R)$, and from $H^2(\Pi_R)$ into $H^2(\Pi_{R,s})$ for each fixed s.

Let $\chi_R(x_1)$ be an infinitely differentiable mollifier function equal to one for $x_1 \leqslant R - 1$ and vanishing for $x_1 \geqslant R$. We take the two functions considered above and construct u as a smooth interpolation between them,

$$u(x,m) := \chi_R(x_1) w(x,m) + (1 - \chi_R(x_1)) v(x,m). \tag{3.6}$$

Since $w(x,m) = T_2 T_1(m) g$, we have $w \in \mathcal{H}(H^1(\Pi_R)) \cap \mathcal{H}(H^2(\Pi_{R,s}))$ as a function of m for each $s > 0$. Thus we can introduce the operator $T_3(m)$ which maps a function $g \in L^2(\Pi_R)$ to the function u determined by (3.6), where v and w are the solutions of (3.3) and (3.5), respectively, for this g. It easy to see that $T_3(\cdot) \in \mathcal{H}(L^2(\Pi_R), H^1(\Pi_{\tilde{R}}))$ and $T_3(\cdot) \in \mathcal{H}(L^2(\Pi_R), H^2(\Pi_{\tilde{R},s}))$ in $\mathcal{D}$ for any pair of positive $\tilde{R}$, s.

According to the definition of v and w, the function u satisfies all the boundary condition of (3.1). Applying the operator $(\Delta + 1 - m^2)$ to this function, we obtain

$$(\Delta + 1 - m^2) u = g + (w - v)(\Delta + 1 - m^2)\chi_R + 2(\nabla_x \chi_R, \nabla_x (w - v))_{\mathbb{R}^2},$$

where we have used in the calculation the equations which v and w satisfy. This result shows that the function u solves the problem (3.1) if and only if g satisfies the following equation:

$$g+T_4(m)g=f, \tag{3.7}$$

where

$$T_4(m)g:=(w-v)(\Delta+1-m^2)\chi_R+2(\nabla_x\chi_R,\nabla_x(w-v))_{\mathbb{R}^2};$$

recall that both w and v are obtained from g by actions of the operators specified above.

Proposition 3.1: The operator $T_4(m)$ is compact for any $R>0$ as an element of $\mathcal{L}(L^2(\Pi_R),L^2(\Pi_R))$ and the function $m\mapsto T_4(m)$ belongs to $\mathcal{H}(L^2(\Pi_R),L^2(\Pi_R))$ in $\mathcal{D}$.

Proof: We denote

$$T_{41}(m)g:=(w-v)(\Delta+1-m^2)\chi_R,$$

$$T_{42}(m)g:=2(\nabla_x\chi_R,\nabla_x(w-v))_{\mathbb{R}^2}+(w-v)\Delta\chi_R.$$

Using the described properties of $T_1(m)$ and T_2 it is easy to see that $T_{41}(m)$ is a bounded linear map from $L^2(\Pi_R)$ into $H^1(\Pi_R)$. The operator-valued function $T_{41}(\cdot)$ belongs to $\mathcal{H}(L^2(\Pi_R),H^1(\Pi_R))$. The function χ_R' is smooth and its support lies in $\Pi_R\backslash\overline{\Pi}_{R-1}$. Using this together with the fact that the function $w-v$ belongs to $H^2(\Pi_R\backslash\overline{\Pi}_{R-1})$, we conclude that $T_{42}(m):L^2(\Pi_R)\to H^1(\Pi_R)$ is a linear bounded operator belonging to $\mathcal{H}(L^2(\Pi_R),H^1(\Pi_R))$ as a function of m. Hence $T_4(\cdot)=T_{41}(\cdot)+T_{42}(\cdot)\in\mathcal{H}(L^2(\Pi_R),H^1(\Pi_R))$, and therefore $T_4(m)$ is compact when considered as an operator from $L^2(\Pi_R)$ to $L^2(\Pi_R)$, belonging to $\mathcal{H}(L^2(\Pi_R),L^2(\Pi_R))$ with respect to m. ■

Proposition 3.1 shows that Eq. (3.7) can be studied using Fredholm theorems. This will help us to solve our original problem: to construct the solution of (3.1) we have to solve the equation (3.7), then by the procedure described above its solution gives rise to the solution u of the boundary value problem (3.1): $u=T_3(m)g$.

Proposition 3.2: The problems (3.7) and (3.1) are equivalent: to each solution g of (3.7) there is a unique solution $u=T_3(m)g$ of (3.1), and vice versa, for each solution of (3.1) there exists a unique g solving (3.7) such that $u=T_3(m)g$. The equivalence holds for any $m\in\mathcal{D}$.

Proof: The first part has been proved above, it remains to check invertibility of the operator T_3. Let u be a solution of the problem (3.1). Notice that the function u is infinitely differentiable outside the support of f since there it is a solution of a homogeneous equation. We have to construct the solution g of (3.7) such that $u=T_3g$. Let us first determine the functions v and w. By U we denote a solution of the following problem:

$$\begin{aligned}&\Delta U=0, \quad x\in\Pi_R,\\ &U=0, \quad x\in\partial\Pi_R\backslash\overline{\gamma_0\cup\gamma},\\ &U=u, \quad x\in\gamma_0\cup\gamma,\end{aligned} \tag{3.8}$$

which is unique in $H^1(\Pi_R)$, and moreover, it belongs to $C^\infty(\Pi_R)$ by a standard result on the smoothness of solutions of elliptic equations. We set

$$v(x,m):=u(x,m)-\chi_R(x_1)U(x,m),$$

$$w(x,m):=u(x,m)+(1-\chi_R(x_1))U(x,m).$$

One checks easily that the functions $u=\chi_Rw+(1-\chi_R)v$, w and v satisfy all the required boundary conditions and that $\Delta w=\Delta v$ holds in Π_R. Now it suffices to use the equation of the problem (3.3) to determine the function g by

$$g(x,m) := (\Delta + 1 - m^2)v(x,m) = (\Delta + 1 - m^2)(u(x,m) - \chi_R(x_1)U(x,m))$$
$$= f(x) - (\Delta + 1 - m^2)(\chi_R(x_1)U(x,m)).$$

Let us check that this g solves (3.7). Using the definition of U, v, and w, we compute directly the action of $T_4(m)$ on g obtaining

$$T_4(m)g = U(\Delta + 1 - m^2)\chi_R + 2(\nabla_x \chi_R, \nabla_x U)$$
$$= U(\Delta + 1 - m^2)\chi_R + 2(\nabla_x \chi_R, \nabla_x U) + \chi_R \Delta U = (\Delta + 1 - m^2)(\chi_R U).$$

The last two relations show that g is a solution of Eq. (3.7). Let us check the uniqueness: suppose that there are two solutions g_1 and g_2 of (3.7) leading to the same function $u^{(1)} = u^{(2)}$. Then $g := g_1 - g_2 \neq 0$ gives rise to $u := u^{(1)} - u^{(2)} = 0$. Let v and w be the solutions of (3.3) and (3.5), respectively, associated with u, and set $U := w - v$. Then it easy to see that this U solves (3.8), where the boundary condition on $\gamma_0 \cup \gamma$ is homogeneous. Such a solution of (3.8) is unique, $U = 0$. Thus $w = v = u = 0$ holds in Π_R, and therefore $g = (\Delta + 1 - m^2)v = 0$ in Π_R, which is a contradiction. ■

The solution of Eq. (3.7) depends on m, i.e., $g = g(x,m)$. Our next aim is to clarify a nature of this dependence and to look what this implies for the solution of the problem (3.1). We employ the following result borrowed from Ref. 13, Sec. XV.7:

Theorem 3.3: *Let $\mathcal{D}$ be an open connected domain of the complex plane of the variable m and $\{T(m): m \in \mathcal{D}\}$ be a bounded holomorphic family of compact operators from the Banach space X into itself. Moreover, assume that there exists a point $m_* \in D$ such that $(I + T(m_*))^{-1} \in \mathcal{L}(X,X)$. Then $m \mapsto (I + T(m))^{-1}$ is a meromorphic function in $\mathcal{D}$ with values in $\mathcal{L}(X,X)$.*

In our case the Banach space mentioned in Theorem 3.3 is $L^2(\Pi_R)$ and $T(m) = T_4(m)$. The existence of m_* is easy to establish: since the equation (3.7) is equivalent to the boundary-value problem (3.1) by Proposition 3.2, it is sufficient to prove the existence of m_* for which the problem (3.1) has no nontrivial solution for $f = 0$ and $m = m_*$ with the asymptotics (3.2). This is true for $m_* > 0$ which is sufficiently small, because assuming the contrary would lead us to the conclusion that H_{a_n} has the eigenvalue $(1 - m_*^2)$, and this in turn would contradict to the claims (a) and (c) of Proposition 2.1. The compactness of $T_4(m)$ and its holomorphic dependence on m follow from Proposition 3.1.

Thus we may apply Theorem 3.3 to the equation (3.7). We imply that $(I + T_4(m))^{-1}$ exists and it is meromorphic as an operator-valued function in $\mathcal{D}$, $(I + T_4(\cdot))^{-1} \in \mathcal{M}(L^2(\Pi_R), L^2(\Pi_R))$. Poles of this function are the values of m for which the equation (3.7) with the vanishing right-hand side has a nontrivial solution. The value $m_0 := 0$ has this property as it follows from the claim (c) of Proposition 2.1. Let ϕ_0 be a solution of the equation (3.7) for $f = 0$ and $m = m_0$. The function ϕ_0 is unique up to a multiplicative constant, the uniqueness being implied by Proposition 2.1(c) and Proposition 3.1. The remaining ambiguity is removed if we set $\psi^{(0)} = T_3(0)\phi_0$. Making the domain $\mathcal{D}$ smaller if necessary we can achieve that zero is the only pole of the function $(I + T_4(\cdot))^{-1}$ contained in $\mathcal{D}$. In such a case the solution $g = (I + T_4(m))^{-1}$ of the equation (3.7) can be for any nonzero $m \in \mathcal{D}$ represented as

$$g = g(m) = \frac{g_{-k}}{m^k} + \tilde{g}(m), \tag{3.9}$$

where the integer $k \geqslant 1$ is the order of the pole, the functions $g_{-k}, \tilde{g}(m)$ belong to $L^2(\Pi_R)$ for nonzero $m \in \mathcal{D}$, and $\tilde{g}(\cdot) \in \mathcal{M}(L^2(\Pi_R))$ may have a pole at zero of order not exceeding $k - 1$.

Let us stress that Theorem 3.3 says nothing about the order of this pole. Next we are going to prove that the pole in (3.9) is simple, i.e., $k = 1$. Substituting (3.9) into (3.7) and comparing the leading terms in m we see that $g_{-k} = K_0[f]\phi_0$, where $K_0[f]$ is a constant depending on f. The representation (3.9) in turn yields the following expression for u:

$$u = T_3(m)g = \frac{K_0[f]\psi^{(0)}}{m^k} + \tilde{u}(m). \tag{3.10}$$

Here $\tilde{u}(\cdot)$ is a function belonging to $\mathcal{M}(H^1(\Pi_{\tilde{R}})) \cap \mathcal{M}(H^2(\Pi_{\tilde{R},s}))$ for any positive $\tilde{R}$, s which again may have pole at zero of order not exceeding $k-1$. Multiplying the equation in the problem (3.1) by $\psi^{(0)}$ and integrating by parts we see that

$$\int_{\Pi_{\tilde{R}}} f\psi^{(0)}\, d^2x = -m^2 \int_{\Pi_{\tilde{R}}} \psi^{(0)} u\, d^2x + \int_0^\pi \left(\psi^{(0)} \frac{\partial u}{\partial x_1} - u \frac{\partial \psi^{(0)}}{\partial x_1} \right)\Bigg|_{x_1=\tilde{R}} dx_2. \tag{3.11}$$

For d sufficiently large we have

$$u|_{x_1=\tilde{R}} = \sum_{j=1}^{\infty} C_j(m) \sin jx_2, \quad \psi^{(0)}|_{x_1=\tilde{R}} = \sum_{j=1}^{\infty} c_j \sin jx_2,$$

$$\frac{\partial u}{\partial x_1}\bigg|_{x_1=\tilde{R}} = -\sum_{j=1}^{\infty} \sqrt{j^2-1+m^2}\, C_j(m) \sin jx_2,$$

$$\frac{\partial \psi^{(0)}}{\partial x_1}\bigg|_{x_1=\tilde{R}} = -\sum_{j=2}^{\infty} c_j \sqrt{j^2-1}\, \sin jx_2,$$

where the functions C_j in view of (3.10) behave as

$$C_j(m) = \frac{K_0[f]c_j}{m^k} + \mathcal{O}(m^{-k+1}).$$

Combining the above relations and using the normalization condition $c_1 = \sqrt{2/\pi}$ we deduce that

$$\int_0^\pi \left(\psi^{(0)} \frac{\partial u}{\partial x_1} - u \frac{\partial \psi^{(0)}}{\partial x_1} \right)\Bigg|_{x_1=\tilde{R}} dx_2 = -\frac{K_0[f]}{m^{k-1}} + \mathcal{O}(m^{-k+2}).$$

The first integral on the right-hand side of (3.11) behaves as

$$-m^2 \int_{\Pi_{\tilde{R}}} \psi^{(0)} u\, d^2x = -\frac{K_0[f]}{m^{k-2}} \int_{\Pi_{\tilde{R}}} |\psi^{(0)}|^2 d^2x + \mathcal{O}(m^{-k+3})$$

in the limit $m \to 0$. Substituting the expressions obtained above into (3.11) and comparing the coefficients at the powers of m, we conclude that $k=1$, and furthermore, that

$$K_0[f] = -\int_{\Pi_{\tilde{R}}} f\psi^{(0)}\, d^2x = -\int_{\Pi} f\psi^{(0)}\, d^2x. \tag{3.12}$$

To get the last relation we have used the fact that f has a compact support by assumption which therefore lies in $\Pi_{\tilde{R}}$ for $\tilde{R}$ sufficient large.

Next we denote $A(m) = T_3(m)(I + T_4(m))^{-1}$. It follows from the relations (3.10) and (3.12) that

$$\begin{aligned} u = A(m)f =: A_0(m)f + A_1(m)f = K_0[f]\frac{\psi^{(0)}}{m} + A_1(m)f, \\ A_1(\cdot) \in \mathcal{H}(L^2(\Pi_R), \mathcal{H}(H^1(\Pi_{\tilde{R}})) \cap \mathcal{H}(L^2(\Pi_R), H^2(\Pi_{\tilde{R},s})), \end{aligned} \tag{3.13}$$

where $\tilde{R}$ and s are arbitrary positive.

It is convenient to summarize all the conclusions made above in a single theorem which represents the main result of this subsection.

Theorem 3.4: *Let $f\in L^2(\Pi_R)$, and assume that $\tilde{R}$, s are arbitrary positive numbers, $m\in\mathcal{D}$. Then for $m\in\mathcal{D}\backslash\{0\}$ there exists a unique solution of the boundary value problem (3.1) given by $u=A(m)f$. As a function on m this solution belongs to $\mathcal{M}(H^1(\Pi_{\tilde{R}}))\cap\mathcal{M}(H^2(\Pi_{\tilde{R},s}))$. The neighborhood $\mathcal{D}$ can be chosen in such a way that the function $A(\cdot)\in\mathcal{M}(L^2(\Pi_R),H^1(\Pi_{\tilde{R}}))\cap\mathcal{M}(L^2(\Pi_R),H^2(\Pi_{\tilde{R},s}))$ has just one pole $m_0=0$ which is simple. The operator $A(m)$ can be decomposed into the sum $A(m)=A_0(m)+A_1(m)$, where the operators $A_i(m)$ are defined by (3.13). Finally, the relation (3.12) holds true.*

B. The asymptotic analysis

To find the behavior of the quantity $\lambda_n(a)$ around the threshold we will analyze m_ε defined as $m_\varepsilon^2:=1-\lambda_n(a_n+\varepsilon)$, which satisfies $m_\varepsilon\to 0$ as $\varepsilon\to 0$. Let $y=(y_1,y_2)$ be the Cartesian coordinates of a point in the strip. The boundary value problem for the eigenfunction $\psi^{(\varepsilon)}$ can be then written as

$$\begin{gathered}(\Delta_y+1)\psi^{(\varepsilon)}=m_\varepsilon^2\psi^{(\varepsilon)},\quad y\in\Pi,\\ l_y\psi^{(\varepsilon)}=0,\quad y\in\gamma,\\ \psi^{(\varepsilon)}=0,\quad y\in\Gamma_\varepsilon\cup\Gamma_+,\\ \frac{\partial\psi^{(\varepsilon)}}{\partial y_2}=0,\quad y\in\gamma_\varepsilon.\end{gathered}\tag{3.14}$$

As we have announced, we want to get rid of the ε-dependent boundary condition passing to one independent on ε, while the corresponding equation will have coefficients which depend smoothly on ε. To construct the appropriate transformation we use an infinitely differentiable mollifier function χ of the variable y_1 which is equal to one for $y_1\in[\beta_2,\beta_3]$ and vanishes for $y_1\leqslant\beta_1$ and $y_1\geqslant\beta_4$. Here β_i, $i=1,\ldots,4$, are positive constants, $\beta_1<\beta_2<\beta_3<\beta_4$, such that $\beta_2<a_n+\varepsilon<\beta_3$ holds for all ε from a fixed neighborhood of zero. We consider the function $x_1:\mathbb{R}_+\to\mathbb{R}_+$ defined as

$$x_1: x_1(y_1,\varepsilon)=y_1-\varepsilon\ \chi(y_1).$$

It is easy to see, in particular, that $x_1=a_n$ as $y_1=a_n+\varepsilon$. Taking the first two derivatives we get

$$\frac{dx_1}{dy_1}=1-\varepsilon\chi'(y_1),\quad \frac{d^2x_1}{dy_1^2}=-\varepsilon\chi''(y_1)$$

from where it follows that for all sufficiently small ε the first derivative of x_1, with respect to y_1, is nonzero everywhere in $\mathbb{R}_+$. Thus the map x_1 is bijective and can be used to define a change of the variable, $y_1\mapsto x_1(y_1,\varepsilon)$. The problem (3.14) expressed in the variables $x=(x_1,x_2)$, $x_2:=y_2$, becomes

$$\begin{gathered}(\Delta_x+\varepsilon L_\varepsilon+1)\psi^{(\varepsilon)}=m_\varepsilon^2\psi^{(\varepsilon)},\quad x\in\Pi,\\ l_x\psi^{(\varepsilon)}=0,\quad x\in\gamma,\\ \psi^{(\varepsilon)}=0,\quad x\in\Gamma_0\cup\Gamma_+,\end{gathered}\tag{3.15}$$

$$\frac{\partial\psi^{(\varepsilon)}}{\partial x_2}=0, \quad x\in\gamma_0.$$

The operator L_ε appearing in the transformed equation is defined by

$$L_\varepsilon := b_{11}(x_1,\varepsilon)\frac{\partial^2}{\partial x_1^2}+b_1(x_1,\varepsilon)\frac{\partial}{\partial x_1},$$

$$b_{11}(x_1,\varepsilon) := -2\chi'(y_1(x_1,\varepsilon))+\varepsilon(\chi'(y_1(x_1,\varepsilon)))^2, \tag{3.16}$$

$$b_1(x_1,\varepsilon) := -\chi''(y_1(x_1,\varepsilon)).$$

The functions b_{11} and b_1 are obviously infinitely differentiable, they vanish for $y_1\notin[\beta_1,\beta_2]\cup[\beta_3,\beta_4]$ and satisfy in the limit $\varepsilon\to 0$ the asymptotic formulas

$$b_{11}(x_1,\varepsilon)=-2\chi'(x_1)+\mathcal{O}(\varepsilon), \quad b_1(x_1,\varepsilon)=-\chi''(x_1)+\mathcal{O}(\varepsilon)$$

uniformly in the variable x_1.

Now we can proceed to the calculation of m_ε and $\psi^{(\varepsilon)}$. Proposition 2.1 ensures that the eigenfunction and eigenvalue exist. The function $\psi^{(\varepsilon)}$ decays as $|x_1|\to\infty$ and $\lambda_n(a_n+\varepsilon)$ is real. These two facts imply that m_ε is real and positive. It is obvious that $\psi^{(\varepsilon)}$ solves the problem (3.1) for $m=m_\varepsilon$ and $f=-\varepsilon L_\varepsilon\psi^{(\varepsilon)}$. This allows us to seek for the solution of (3.15) in the form

$$\psi^{(\varepsilon)}=A(m_\varepsilon)f_\varepsilon, \tag{3.17}$$

where the function f_ε is assumed to an unknown element of $L^2(\Pi_R)$ with $R>\beta_4$. This may appear strange at a glance, because we know that $f_\varepsilon=-\varepsilon L_\varepsilon\psi^{(\varepsilon)}$, however, we want to obtain another formula for f_ε not involving $\psi^{(\varepsilon)}$. The function $\psi^{(\varepsilon)}$ defined by (3.17) satisfies all the boundary condition of the problem (3.15). In order to be a solution of (3.15), it is necessary and sufficient for $\psi^{(\varepsilon)}$ to be a solution of the corresponding equation. Substituting into the latter the formula for $\psi^{(\varepsilon)}$, we arrive at the equation for f_ε which reads

$$(I+\varepsilon L_\varepsilon A(m_\varepsilon))f_\varepsilon=0. \tag{3.18}$$

In view of (3.13) we have

$$A(m_\varepsilon)f_\varepsilon=K_0[f_\varepsilon]\frac{\psi^{(0)}}{m_\varepsilon}+A_1(m_\varepsilon)f_\varepsilon. \tag{3.19}$$

We substitute this representation for $A(m_\varepsilon)f_\varepsilon$ into (3.18) obtaining

$$f_\varepsilon+\frac{\varepsilon}{m_\varepsilon}K_0[f_\varepsilon]L_\varepsilon\psi^{(0)}+\varepsilon L_\varepsilon A_1(m_\varepsilon)f_\varepsilon=0. \tag{3.20}$$

It is clear that $L_\varepsilon A_1(\cdot)\in\mathcal{H}(L^2(\Pi_R),L^2(\Pi_R))$ and as a function of (m,ε) the operator $L_\varepsilon A_1(m)$ is jointly continuous. Thus for sufficiently small ε the inverse operator $B(m,\varepsilon)=(I+\varepsilon L_\varepsilon A_1(m))^{-1}:L^2(\Pi_R)\to L^2(\Pi_R)$ exists and converges to the identity map as $\varepsilon\to 0$ uniformly in m. It is also obvious that $B(\cdot,\varepsilon)\in\mathcal{H}(L^2(\Pi_R),L^2(\Pi_R))$. Applying now $B(m_\varepsilon,\varepsilon)$ to the equation (3.20) we find

$$f_\varepsilon+\frac{\varepsilon}{m_\varepsilon}K_0[f_\varepsilon]B(m_\varepsilon,\varepsilon)L_\varepsilon\psi^{(0)}=0. \tag{3.21}$$

Applying further K_0 to (3.21), we get one more equation,

$$K_0[f_\varepsilon]+\frac{\varepsilon}{m_\varepsilon}K_0[f_\varepsilon]K_0[B(m_\varepsilon,\varepsilon)L_\varepsilon\psi^{(0)}]=0.$$

Notice that $K_0[f_\varepsilon]$ cannot be zero, because otherwise (3.21) would imply $f_\varepsilon=0$ which yields $\psi^{(\varepsilon)}=0$. The last equation induces the relation

$$m_\varepsilon=-\varepsilon K_0[B(m_\varepsilon,\varepsilon)L_\varepsilon\psi^{(0)}], \tag{3.22}$$

which can be regarded as an equation for m_ε. It is easy to see that $B(\cdot,\varepsilon)L_\varepsilon\psi^{(0)}\in\mathcal{H}(L^2(\Pi_R))$ and the function $(m,\varepsilon)\mapsto B(m,\varepsilon)L_\varepsilon\psi^{(0)}$ is jointly continuous. This immediately implies that $K_0[B(m,\varepsilon)L_\varepsilon\psi^{(0)}]$ is a holomorphic with respect to m and jointly continuous as a function of (m,ε). Consequently, for all ε small enough the estimate

$$\varepsilon|[K_0[B(m,\varepsilon)L_\varepsilon\psi^{(0)}]|<|\ m|,\quad m\in\partial\mathcal{D},$$

holds true. Using this inequality in combination with the Rouché theorem we conclude that the functions $h_1:h_1(m)=m$ and $h_2:h_2(m)=m+[K_0[B(m,\varepsilon)L_\varepsilon\psi^{(0)}]$ have the same numbers of zeroes inside $\mathcal{D}$. This means that the equation (3.22) has a unique solution in $\mathcal{D}$ for all sufficient small ε. On the other hand, due to Proposition 2.1 we know that there is a root of equation (3.22) that converges to zero, namely

$$m_\varepsilon=\sqrt{\lambda_n(a_n+\varepsilon)-1}>0.$$

Consequently, it is the only root of (3.22). Thus the function

$$f_\varepsilon=-\varepsilon B(m_\varepsilon,\varepsilon)L_\varepsilon\psi^{(0)}, \tag{3.23}$$

where m_ε is the solution of (3.22), solves the equation (3.18). It means that the function f_ε defined by (3.23) gives rise to the eigenfunction $\psi^{(\varepsilon)}=A(m_\varepsilon)f_\varepsilon$ corresponding to the eigenvalue $\lambda_n(a_n+\varepsilon)=1-m_\varepsilon^2$. In fact, we have also proved that there is just one value of $m=m_\varepsilon$ tending to zero as $\varepsilon\to0$, for which the boundary value problem (3.14) has a nontrivial solution. This solution decays as $|x_1|\to\infty$, i.e., there are no nondecaying or even increasing solutions.

The equation (3.22) allows us to calculate the asymptotic expansion for m_ε. Since $B(m,\varepsilon)L_\varepsilon\psi^{(0)}$ is holomorphic with respect to m and jointly continuous in (m,ε), and since m_ε tends to zero as $\varepsilon\to0$, then by the equation (3.22) we have

$$m_\varepsilon=\varepsilon\mu+O(\varepsilon m_\varepsilon),\quad \varepsilon\to0,$$

$$\mu=-K_0[L_0\psi^{(0)}],$$

$$L_0=-2\chi'(x_1)\frac{\partial^2}{\partial x_1^2}-\chi''(x_1)\frac{\partial}{\partial x_1}.$$

Combining these relations, we can rewrite the error term as follows:

$$m_\varepsilon=\varepsilon\mu+O(\varepsilon^2),\quad \varepsilon\to0. \tag{3.24}$$

Next we want to express the coefficient μ,

$$\mu=-\int_\Pi\psi^{(0)}\left(2\chi'(x_1)\frac{\partial^2}{\partial x_1^2}+\chi''(x_1)\frac{\partial}{\partial x_1}\right)\psi^{(0)}\,d^2x. \tag{3.25}$$

Using the equation which the function $\psi^{(0)}$ satisfies we find

$$\left(2\chi'(x_1)\frac{\partial^2}{\partial x_1^2}+\chi''(y_1)\frac{\partial}{\partial x_1}\right)\psi^{(0)}=(\Delta+1)\left(\chi(x_1)\frac{\partial\psi^{(0)}}{\partial x_1}\right).$$

Integrating then by parts and taking into account properties of $\psi^{(0)}$ together with the definition of the mollifier χ we have

$$\mu=-\lim_{s\to 0}\int_{\Pi\setminus D_s}\psi^{(0)}(\Delta+1)\left(\chi(x_1)\frac{\partial\psi^{(0)}}{\partial x_1}\right)d^2x=\lim_{s\to 0}\int_{\partial D_s}\left(\psi^{(0)}\frac{\partial^2\psi^{(0)}}{\partial r\,\partial x_1}-\frac{\partial\psi^{(0)}}{\partial x_1}\frac{\partial\psi^{(0)}}{\partial r}\right)ds.$$

In order to evaluate the last integral along ∂D_s we replace $\psi^{(0)}$ by its asymptotics (2.5) and pass to limit $s\to 0$ obtaining

$$\mu=\frac{1}{2}\alpha^2\int_0^\pi\sin^2\frac{\theta_+}{2}\,d\theta_+=\frac{\pi\alpha^2}{4},$$

which proves (2.8) with $\mu=\mu_n$. In the same way we get

$$0=\int_\Pi x_1\frac{\partial\psi_n^{(0)}}{\partial x_1}(\Delta+1)\psi_n^{(0)}d^2x=a_n\frac{\pi\alpha^2}{4}+2\int_\Pi\psi_n^{(0)}\frac{\partial^2\psi_n^{(0)}}{\partial x_1^2}d^2x=a_n\mu_n-2\int_\Pi\left|\frac{\partial\psi_n^{(0)}}{\partial x_1}\right|^2d^2x,$$

which yields the representation (2.7) for μ,

$$\mu_n=\frac{2}{a_n}\int_\Pi\left|\frac{\partial\psi_n^{(0)}}{\partial x_1}\right|^2d^2x=\frac{1}{a_n}\int_\Sigma\left|\frac{\partial\psi_n^{(0)}}{\partial x_1}\right|^2d^2x.$$

In the last relation we employed the fact that $\psi_n^{(0)}$ has a definite parity.

Let us finally pass to discussion of the eigenfunction. In view of (3.19), (3.23) we find that $\psi^{(\varepsilon)}$ is equal to

$$A(m_\varepsilon)f_\varepsilon=-\frac{\varepsilon K_0[B(m_\varepsilon,\varepsilon)L_\varepsilon\psi^{(0)}]}{m_\varepsilon}\psi^{(0)}-\varepsilon A_1(m_\varepsilon)B(m_\varepsilon,\varepsilon)L_\varepsilon\psi^{(0)}.$$

Using now the equation (3.22) together with the fact that the function $A_1(m)B(m,\varepsilon)L_\varepsilon\psi^{(0)}$ is holomorphic and continuous as a function of the respective variables, we conclude that the relation

$$\psi^{(\varepsilon)}=\psi^{(0)}-\varepsilon A_1(m_\varepsilon)B(m_\varepsilon,\varepsilon)L_\varepsilon\psi^{(0)}$$

is valid in $H^1(\Pi_R)$ for each R. This yields the relation (2.9) and the asymptotic behavior (2.10) concluding thus the proof of Theorem 2.3.

We construct Wigner's continuous spin representations of the Poincaré algebra for massless particles in higher dimensions. The states are labeled both by the length of a spacelike translation vector and the Dynkin indices of the *short little group* $\mathrm{SO}(d-3)$, where d is the space–time dimension. Continuous spin representations are in one-to-one correspondence with representations of the short little group. We also demonstrate how combinations of the bosonic and fermionic representations form supermultiplets of the super-Poincaré algebra. If the light-cone translations are nilpotent, these representations become finite dimensional, but contain zero or negative norm states, and their supersymmetry algebra contains a central charge in four and ten dimensions. © *2002 American Institute of Physics.*

I. INTRODUCTION

The Poincaré group is an essential ingredient of relativistic quantum field theories. Its representations in four space–time dimensions were first studied by E. Wigner.[1] Some of its representations describe quantum states found in local field theory: massless particles of fixed helicity and massive particles with or without spin. In string theory, the ''front form'' construction of the Poincaré group generators[2,3] has been particularly useful in describing the 26-dimensional bosonic string.[4]

Other representations do not seem to be realized by nature. One is the tachyon representation with negative mass-squared which appears in theories as indicator of instabilities, for instance in spontaneous symmetry breaking. The others are the ''continuous spin representations'' (CSRs), which describe a massless object with an infinity number of helicities. Wigner himself has argued[5] against their use in physics since they lead to infinite heat capacity of the vacuum. All attempts to associate these representations with physical systems have failed. Several authors[6,7] have shown their naive quantization implies either nonlocality or a breakdown of causality. More recently, Zoller[8] showed how they could arise from a higher-derivative Lagrangian such as the length of the acceleration. In addition, massless theories with helicities greater than two have special problems,[9,10] unless perhaps for theories with an infinite number of degrees of freedom. Not surprisingly, these representations have been forgotten.

Yet, the idea of an infinite number of massless spins has some attractions. Indeed, Vasiliev[11] among others has argued for the existence of such theories. A particular lure is the zero tension (infinite slope) limit of string theories which suggests (classically) an infinite number of massless states with unbounded helicities.

The object of this article is to study these representations in higher dimensions, and show that they can be assembled in representations of supersymmetry.

II. THE POINCARÉ ALGEBRA

The Poincaré generators satisfy the commutation relations,

$$[P^\mu,P^\nu]=0,$$

$$[M^{\mu\nu},P^\sigma]=i(\eta^{\mu\sigma}P^\nu-\eta^{\nu\sigma}P^\mu),$$

$$[M^{\mu\nu},M^{\alpha\beta}]=i(\eta^{\mu\alpha}M^{\nu\beta}+\eta^{\alpha\nu}M^{\beta\mu}+\eta^{\nu\beta}M^{\mu\alpha}+\eta^{\beta\mu}M^{\alpha\nu}),$$

where $\eta_{\mu\nu}=(-1,1,\ldots,1)$. Its representations are characterized by the values of the Casimir operators which are the squared mass $P_\mu P^\mu$, and the squares of the Pauli–Lubanski forms built out of the Levi-Civitá symbols. In d space–time dimensions, the Pauli–Lubanski n-forms are,

$$W_{\mu_1\cdots\mu_n}=\frac{\epsilon_{\mu_1\cdots\mu_n\mu_{n+1}\cdots\mu_d}P^{\mu_d}M^{\mu_{n+1}\mu_{n+2}}\cdots M^{\mu_{d-2}\mu_{d-1}}}{\sqrt{n!2^{(d-n+1)/2}((d-n-1)/2)((d-n-1)/2)!}},\tag{1}$$

where $n=1,3,\ldots,(d-3)$ for d even and $n=0,2,\ldots,(d-3)$ for d odd.

It is convenient to express the Poincaré generators in Dirac's[2] front form, derived long ago for spin in four dimensions by Bacry and Chang.[3] For a particle of mass m, the Poincaré generators are expressed in terms of transverse positions and momenta

$$[x^i,p^j]=i\delta^{ij},\quad i,j=1,2,\ldots,d-2;\quad [x^-,p^+]=-i,\tag{2}$$

and

$$x^\pm=\frac{1}{\sqrt{2}}(x^0\pm x^{d-1}),\quad p^\pm=\frac{1}{\sqrt{2}}(p^0\pm p^{d-1}).\tag{3}$$

The translations are given by

$$P^-=\frac{p^ip^i+m^2}{2p^+},\quad P^+=p^+,\quad P^i=p^i,\tag{4}$$

where P^- is the light-cone Hamiltonian. The Lorentz generators break up into those which transform the transverse plane into itself, and those which transform out of that plane (called ''kinematic'' and ''Hamiltonian,'' respectively by Dirac). The kinematic generators are given by

$$M^{+i}=-x^ip^+,\quad M^{+-}=-x^-p^+,\quad M^{ij}=x^ip^j-x^jp^i+S^{ij},\tag{5}$$

where S^{ij} obey the SO$(d-2)$ Lie algebra of the transverse little group

$$[S^{ij},S^{kl}]=i(\delta^{ik}S^{jl}+\delta^{jl}S^{ik}-\delta^{il}S^{jk}-\delta^{jk}S^{il}).\tag{6}$$

The Hamiltonian-like boosts are

$$M^{-i}=x^-p^i-\frac{1}{2}\{x^i,P^-\}+\frac{1}{p^+}(T^i-p^jS^{ij}),\tag{7}$$

where the T^i transform as SO$(d-2)$ vectors

$$[S^{ij},T^k]=i\delta^{ik}T^j-i\delta^{jk}T^i,\tag{8}$$

and satisfy

$$[T^i,T^j]=im^2S^{ij}.\tag{9}$$

When $m\neq 0$, T^i/m are the generators of $\mathrm{SO}(d-1)/\mathrm{SO}(d-2)$, which, together with S^{ij}, complete the massive little group $\mathrm{SO}(d-1)$.

When $m=0$, the T^i commute with one another, acting as light-cone translations, and the algebra can be satisfied in two ways:

(i) $T^i=0$. This corresponds to the familiar massless representations which describe particles with a finite number of degrees of freedom, realized on states that satisfy

$$T^i|p^+,p^i;(a_1,\ldots,a_r)\rangle=0, \tag{10}$$

where $(a_1,\ldots,a_r)$ are the Dynkin labels of $\mathrm{SO}(d-2)$ representations and r is the rank of the little group. These label the different helicity states of the massless particle. In four dimensions, the Pauli–Lubanski vector is lightlike.

(ii) $T^i\neq 0$. In this case, T^i are the c-number components of a transverse vector. The states on which the Poincaré algebra is realized are

$$T^i|p^+,p^i;\xi^i,(a_1,\ldots,a_r)\rangle=\xi^i|p^+,p^i;\xi^i,(a_1,\ldots,a_r)\rangle, \tag{11}$$

which have additional labels, in the form of a little group vector ξ^i. There is an important difference from the previous case, since $(a_1,\ldots,a_r)$ now labels the $\mathrm{SO}(d-3)$ subgroup of the transverse little group $\mathrm{SO}(d-2)$. In four dimensions, there is no such group and the states are simply labeled by an additional spacelike vector of constant magnitude. These span two distinct representations, called ''continuous spin representations'' by Wigner in his original work.[1] They are characterized by a spacelike Pauli–Lubanski vector, and describe a massless state with an infinite number of integer-spaced helicities.

In the following, we construct these representations in higher dimensions, as well as their supersymmetric generalizations.

A. Continuous spin representations

These representations are characterized by the fact that the light-cone translations T^i do not vanish, even though $m=0$. It follows that a finite boost creates an infinite number of integer-spaced helicities. To see this, consider a ket that represents a state with lightlike momentum aligned along the z direction. In $(3+1)$-dimensions, a rotation in the transverse plane yields

$$e^{i\phi M^{12}}|p^+,p^i=0;\Xi,\alpha\rangle=|p^+,p^i=0;\Xi,\alpha+\phi\rangle, \tag{12}$$

where Ξ is the length of the transverse light-cone translation vector with components

$$\xi^1=\Xi\cos\alpha,\quad \xi^2=\Xi\sin\alpha,$$

which enables us to set

$$S^{12}=-i\frac{\partial}{\partial\alpha}.$$

Since $[S^{12},\xi^i]\neq 0$ for $i=1,2$, S^{12} (helicity) is no longer a good quantum number; instead it acts on periodic or antiperiodic functions of the angle α

$$|\alpha\rangle=\sum_{\lambda} e^{2\pi i\lambda\alpha}|f_\lambda\rangle,$$

where λ are either integer-spaced integers or half-odd integers. Another way to see the infinite number of helicities is to apply the infinitesimal boost M^{-i} on any state

$$M^{-i}|p^+,p^i=0;\Xi,\alpha\rangle=\frac{T^i}{p^+}|p^+,p^i=0;\Xi,\alpha\rangle, \tag{13}$$

which produces a state which has picked up plus or minus one unit of helicity. In a finite boost, this action is repeated an infinite amount, resulting in states with possible helicities ranging from minus to plus infinity in integer steps. There are (in four dimensions only) two types of representations, those with all integer (single-valued) and those with all half-odd integer (double-valued) helicities. The square of the Pauli–Lubanski vector (Casimir) is the squared length of the translation vector

$$W^\mu W_\mu = \vec{T}\cdot\vec{T} = \Xi^2. \tag{14}$$

As we have stated in the Introduction, the CSRs have no obvious physical applications, explicitly in local field theories, but the appearance of an infinite number of states may indicate a connection with nonlocal theories of extended objects. This motivates their study in more general contexts. We explicitly construct these representations in higher dimensions, then proceed to show that they sustain supersymmetry and build continuous spin representations of supersymmetry. Finally, we show that if the light-cone translations are nilpotent, the CSRs become finite-dimensional, but at the expense of negative or zero-norm state, and the supersymmetric generalizations yield central charges for these massless representations.

1. Higher dimensions

The front-form of the Poincaré generators shows that CSRs in any dimensions correspond to representations of the Galilean little group

$$[T^i, T^j] = 0, \quad [S^{ij}, T^k] = i\delta^{ik}T^j - i\delta^{jk}T^i, \tag{15}$$

where the T^i *do not vanish* and the S^{ij} generate the light-cone little group SO$(d-2)$. Consider $(4+1)$-dimensions, where the light-cone little group is SO(3). In the frame $p^- = \vec{p} = 0$, the Pauli–Lubanski two-form is

$$W_{ij} = \frac{1}{\sqrt{2}}\epsilon_{ijk}T^k,$$

so that one Casimir is

$$W_{ij}W_{ij} = \Xi^2, \tag{16}$$

as in the four-dimensional case. The other Casimir is the Pauli–Lubanski zero-form

$$W = \frac{1}{\sqrt{2}}\epsilon_{ijk}T^iS^{jk},$$

which is the projection of the generator S^{jk} along T^i. The vector T^i then acts as a "quantization axis," along which W assumes the values

$$\frac{W}{\sqrt{2}\Xi} = 0, \pm\frac{1}{2}, \pm 1, \pm\frac{3}{2}, \cdots. \tag{17}$$

It follows that there are two types of representations corresponding to integer and half-odd integer values of $W/\sqrt{2}\Xi$. For each value of $W/\sqrt{2}\Xi$, there corresponds one infinite-dimensional representation. Unlike $(3+1)$-dimensions, there are infinite numbers of CSRs in higher dimensions. The states are no longer characterized by the light-cone little group but by its subgroup orthogonal to T^i, which we call the short little group, SO(2) in this case. Each CSR is labeled by a value of SO(2) (integer or half-odd integer) as well as by the length of T^i.

It is straightforward to find the CSR representations in terms of $|j,m\rangle$, the eigenstates of SO(3), the full little group. Its states are required to be eigenstates of $\vec{T}$, the SO(2) rotations about it, and of the Casimir $\epsilon_{ijk}T^iS^{jk}$. As the action of T^i on each $|j,m\rangle$ yields a linear combination of $j=j,j\pm1$ states, its eigenstates are infinite linear combinations of eigenstates of the full little group SO(3). To see this in detail, take the light-cone vector in the z direction, so that $\vec{T}$ is like the tensor operator $T^1_0\equiv Y^1_0$,

$$T^1_0|j,m\rangle=\alpha^{(jm)}_+|j+1,m\rangle+\alpha^{(jm)}_0|j,m\rangle+\alpha^{(jm)}_-|j-1,m\rangle,$$

where the α's are proportional to Clebsch–Gordan (C-G) coefficients

$$\alpha^{(jm)}_0=\Xi\sqrt{(j+m)(j-m+1)},\quad -j<m<j,$$

$$\alpha^{(jm)}_\pm=\Xi\sqrt{(j'+m)(j'-m+1)},\quad j'=j\pm1,\quad -j'<m<j'.$$

The state of the form

$$|F\rangle=\sum_{j=|M|}^{\infty}f^{(M)}_j|j,M\rangle$$

is an eigenstate of the Casimir

$$\tfrac{1}{2}\epsilon_{ijk}T^iS^{jk}|F\rangle=\Xi M|F\rangle,\quad M=0,\pm\tfrac{1}{2},\pm1,\ldots,$$

and of T^3, as long as the coefficients satisfy the recursion relations

$$\alpha^{(|M|+p,M)}_-f^{(M)}_{|M|+p}+\alpha^{(|M|+p-2,M)}_+f^{(M)}_{|M|+p-2}+(\alpha^{(|M|+p-1,M)}_0-\Xi)f^{(M)}_{|M|+p-1}=0,$$

with $p=2,3,\ldots$ and

$$\alpha^{(|M|+1,M)}_-f^{(M)}_{|M|+1}+(\alpha^{(|M|,M)}_0-\Xi)f^{(M)}_{|M|}=0,$$

since $f^{(M)}_{|M|-1}=0$. The other states of the CSR are determined by acting the SO(3) raising and lowering operators on $|F\rangle$. Unlike the usual case, their action does not terminate, producing an infinite number of SO(3) representations. This is similar to Wigner's CSR which contains an infinite number of integer spaced helicities. The difference in higher dimensions is that there is an infinite number of CSRs, each labeled by M.

In $(5+1)$-dimensions the light-cone little group is SO(4), and there are two Pauli–Lubanski forms,

$$\text{one-form:}\quad W_i=\frac{1}{\sqrt{2}}\epsilon_{ijkl}T^jS^{kl},$$

$$\text{three-form:}\quad W_{ijk}=\frac{1}{\sqrt{6}}\epsilon_{ijkl}T^l.$$

The square of the highest form is Ξ^2, a general feature in any dimensions. The square of the one-form is the other Casimir,

$$W_iW_i=-\Xi^2S^2_\perp,$$

where $S^{ij}_\perp$ are the generators of the SO(3) subgroup of SO(4) perpendicular to T^i, and $S^2_\perp\equiv S^{kl}_\perp S^{lk}_\perp(k,l=1,2,3)$ is its Casimir operator. Thus

$$W_i W_i = \Xi^2 j(j+1), \quad j = 0, \tfrac{1}{2}, 1, \tfrac{3}{2}, \cdots . \tag{18}$$

There are an infinite number of distinct CSRs, one for each value of j. The states of the CSR can be labeled by finite rotations of SO(3) and vector $\vec{T}$ characterized by length, Ξ, and three angles,

$$|p^+, p^i = 0; \Xi, \Omega_3; j, m\rangle,$$

where m ranges from $-j$ to $+j$ in integer steps.

In $(6+1)$-dimensions the little group is SO(5) and the Pauli–Lubanski forms are

$$\text{zero-form:} \quad W = \frac{1}{2\sqrt{2}} \epsilon_{ijklm} T^i S^{jk} S^{lm},$$

$$\text{two-form:} \quad W_{ij} = \frac{1}{2} \epsilon_{ijklm} T^k S^{lm},$$

$$\text{four-form:} \quad W_{ijkl} = \frac{1}{2\sqrt{6}} \epsilon_{ijklm} T^m.$$

The two Casimirs of the short little group $\mathrm{SO}(4) \approx \mathrm{SU}(2) \times \mathrm{SU}(2)$ are given by

$$W^2_{(\text{two-form})} = -\Xi^2 S_\perp^2, \tag{19}$$

where here $S_\perp^{ij}$ are the generators of the SO(4) subgroup of SO(5) which leave $\vec{T}$ invariant, and the zero-form which gives the projection of the vector $\epsilon_{ijklm} S^{jk} S^{lm}$ along $\vec{T}$. The CSR states, characterized by four angles Ω_4, and the (j_1, j_2) representations of $\mathrm{SU}(2) \times \mathrm{SU}(2)$, are of the form

$$|p^+, p^i; \Xi, \Omega_4; j_1, m_1; j_2, m_2\rangle,$$

where $-j_{1(2)} \leqslant m_{1(2)} \leqslant j_{1(2)}$. There are an infinite number of CSRs, each labeled by j_1 and j_2.

The pattern is now clear: the CSRs are labeled by the length of a vector and by the irreps of the short little group $\mathrm{SO}(d-3)$ which leaves it invariant. Its Casimirs are directly related to the squares of the Pauli–Lubanski n-forms and the zero-form. There are infinitely many such representations, fermionic and bosonic.

The case of 11 space–time dimensions is particularly interesting because of M-theory and supergravity. Its CSRs are labeled by SO(8), with its magic triality property which acts on its vector representation, $\mathbf{8}_v$, and two inequivalent spinor representations, $\mathbf{8}_s$ and $\mathbf{8}_s'$.

We conclude this section by writing the general expressions for the Casimir operators of the Poincaré algebra in terms of those of the short little group. The Pauli–Lubanski n-form for the light-cone little group $\mathrm{SO}(d-2)$ is given by Eq. (1),

$$W_{i_1 \cdots i_n} = \frac{\epsilon_{i_1 \cdots i_n i_{n+1} \cdots i_{d-2}} T^{i_{d-2}} S^{i_{n+1} i_{n+2}} \cdots S^{i_{d-4} i_{d-3}}}{\sqrt{n! 2^{(d-n-3)/2} ((d-n-3)/2)!}}.$$

The Casimir operators are simplest to calculate in a frame where only $T^{i_{d-2}} \neq 0$, and the square of the highest form is the squared length of the vector $\vec{T}$. The Casimir operators for $n \geqslant 1$ are given by the following.

(i) For little group SO(6) and SO(7),

$$W^2_{i_1 \cdots i_n} = \Xi^2 \{ (S_\perp^2)^{(d-n-3)/2} - 2(S_\perp^{(d-n-3)}) \}; \quad 5 \geqslant d-n-2 > 1.$$

(ii) For little group SO(8) and SO(9),

$$W^2_{i_1\cdots i_n}=\Xi^2\begin{cases}(S_\perp^2)^{(d-n-3)/2}-2(S_\perp^{(d-n-3)}); & 1<d-n-2<7,\\ -(S_\perp^2)^3+2S_\perp^2S_\perp^4-2S_\perp^6; & d-n=9.\end{cases}$$

(*iii*) In general for the little group SO(d),

$$W^2_{i_1\cdots i_n}=\Xi^2\sum_{p=0}^{k}(A_{2p}S_\perp^{2p}S_\perp^{2(k-p)}+B_{2p}(S_\perp^2)^k+C_{2p}(S_\perp^2)^pS_\perp^{2(k-p)}),$$

where $k=\frac{1}{2}(d-n-3)$, and A_{2p}, B_{2p} and C_{2p}'s are numerical constants. In the above, $S_\perp^{ij}$ are the generators of SO($d-3$) subgroup of SO($d-2$) perpendicular to $T^{i_{d-2}}$ and

$$S_\perp^m\equiv S_\perp^{i_1i_2}S_\perp^{i_2i_3}\cdots S_\perp^{i_{m-1}i_m}S_\perp^{i_mi_1}.$$

In odd dimensions, the extra Casimir operator is provided by the Pauli–Lubanski zero-form

$$W=\frac{1}{\sqrt{2^{(d-3)/2}((d-3)/2)!}}\epsilon_{ijk\cdots mn}T^iS_\perp^{ij}\cdots S_\perp^{mn}.$$

In higher dimensions, the CSR states are labeled by Ξ and the solid angle in $(d-3)$-dimensions, Ω_{d-3}, which give the length and direction of $\vec{T}$, respectively, as well as by $(a_1,\ldots,a_r)$, the Dynkin labels of SO($d-3$),

$$|p^+,p^i;\Xi,\Omega_{d-3};(a_1,\ldots,a_r)\rangle.$$

These differ from the usual massless representations in that they are characterized by a spacelike vector, and contain an infinite number of states.

III. SUPER-POINCARÉ ALGEBRA

A. Super-charges in light-cone form

The continuous spin representations can be generalized to include supersymmetry. Indeed, Wigner originally found two CSRs, one single-valued with integer helicities, the other double-valued with half-odd integer helicities. As we shall see, they are related by supersymmetry.

The super-Poincaré algebra includes the spinor generators which satisfy

$$[Q_A,p^\mu]=0, \tag{20}$$

$$[M^{\mu\nu},Q_A]=-\tfrac{1}{2}(\Sigma^{\mu\nu}Q)_A, \tag{21}$$

$$\{Q_A,Q_B^\dagger\}=(\gamma^\mu p_\mu\gamma^0)_{AB}, \tag{22}$$

where A,B are spinor indices. In the above,

$$\Sigma^{\mu\nu}=-\frac{i}{2}[\gamma^\mu,\gamma^\nu],$$

where the γ matrices satisfy the anticommutation relation,

$$\{\gamma^\mu,\gamma^\nu\}=2\eta^{\mu\nu};\quad \mu,\nu=0,\ldots,d.$$

We first consider these relations in four space–time dimensions. The supercharges do not commute with the Pauli–Lubanski vector, as

$$[W_\mu, Q_A] = \frac{i}{2} p^\nu (\Sigma_{\mu\nu}\gamma_5 Q)_A,$$

using

$$\tfrac{1}{2}\epsilon_{\mu\nu\rho\sigma}\Sigma^{\rho\sigma} = -i\Sigma_{\mu\nu}\gamma_5,$$

and $\gamma^5 = -i\gamma^0\gamma^1\gamma^2\gamma^3$ is the chirality matrix. The supercharges can be realized linearly using Grassmann variables and their derivatives as[12]

$$Q_A = \partial_A + \tfrac{1}{2}(\gamma^\mu p_\mu \gamma^0)_{AB}\overline{\theta^B}, \tag{23}$$

and its conjugate as

$$Q_C^\dagger = \overline{\partial_C} + \tfrac{1}{2}(\gamma^\mu p_\mu \gamma^0)_{DC}\theta^D, \tag{24}$$

where we used

$$\gamma^0\gamma^{\mu\dagger}\gamma^0 = \gamma^\mu,$$

and $\partial_A = \partial/\partial\theta^A$, $\overline{\partial_A} = \partial/\partial\overline{\theta^A}$, and $\overline{\theta_A}$ is the complex conjugate of θ_A with $A,\ldots,D$ running over the spinor indices. θ, $\overline{\theta}$, ∂ and $\overline{\partial}$ are anticommuting Grassmann parameters. We use the light-cone projectors to split the supercharge into two-component spinors,

$$Q = Q_+ + Q_-, \quad \text{where} \quad Q_\pm \equiv \mathcal{P}_\pm Q,$$

with $\mathcal{P}_\pm = \frac{1}{2}\gamma^\mp\gamma^\pm$. In the Weyl representation, from Eqs. (22)–(24), we can now read off the various anticommutation relations, namely,

$$\{Q_{+a}, Q_{+b}^\dagger\} = \sqrt{2}p^+\delta_{ab},$$

$$\{Q_{-a}, Q_{-b}^\dagger\} = \sqrt{2}p^-\delta_{ab} \equiv \sqrt{2}\frac{p\overline{p}}{p^+}\delta_{ab},$$

$$\{Q_{-1}, Q_{+1}^\dagger\} = -\sqrt{2}\overline{p}, \quad \{Q_{+1}, Q_{-1}^\dagger\} = -\sqrt{2}p,$$

$$\{Q_{+2}, Q_{-2}^\dagger\} = \sqrt{2}\overline{p}, \quad \{Q_{-2}, Q_{+2}^\dagger\} = \sqrt{2}p,$$

where $p(\overline{p}) = (1/\sqrt{2})(p^1 \pm ip^2)$ and $a,b = 1,2$, all other anticommutators being zero. This shows that the supercharge splits up into two disconnected sets of anticommutators, corresponding to the left and right projections $[\mathcal{P}_{L,R} = \frac{1}{2}(1 \pm \gamma_5)]$

$$\mathcal{Q}_\pm^R \equiv \mathcal{P}_R Q_\pm, \quad \mathcal{Q}_\pm^L \equiv \mathcal{P}_L Q_\pm. \tag{25}$$

One could also think of these as representing $N = 2$ supersymmetry.

There is further reducibility, indicated by the fact that the supercharge anticommutes with the covariant derivative

$$\mathcal{D}_A = \partial_A - \tfrac{1}{2}(\gamma^\mu p_\mu \gamma^0)_{AB}\overline{\theta^B}, \tag{26}$$

and their Hermitian conjugates, which give the following relations,

$$\mathcal{Q}_-^L = -\frac{\overline{p}}{p^+}\mathcal{Q}_+^L, \quad \mathcal{Q}_-^R = \frac{p}{p^+}\mathcal{Q}_+^R, \tag{27}$$

together with their conjugates

$$\mathcal{Q}_-^{L\dagger}=-\frac{p}{p^+}\mathcal{Q}_+^{L\dagger},\quad \mathcal{Q}_-^{R\dagger}=\frac{\overline{p}}{p^+}\mathcal{Q}_+^{R\dagger},\tag{28}$$

without affecting the anticommutation relations. From now on we concentrate on the right-handed projections of the algebra. On (right-handed) superfields, the constraint becomes

$$\mathcal{P}_R\mathcal{D}\Phi=0,\tag{29}$$

and after using mass-shell condition, we are left with only one supercharge, $\mathcal{Q}_+$ (henceforth we drop the superscript R). It is expressed in terms of one Grassmann variable $\theta_3\equiv\theta$ and its conjugate, as we can drop the θ_4 variable altogether since its derivative is now expressed in terms of the derivative with respect to θ_3. Hence

$$\mathcal{Q}_+=\frac{\partial}{\partial\theta}+\frac{1}{\sqrt{2}}p^+\overline{\theta},\quad \mathcal{Q}_+^\dagger=\frac{\partial}{\partial\overline{\theta}}+\frac{1}{\sqrt{2}}p^+\theta.\tag{30}$$

Since

$$[M^{+-},\mathcal{Q}_\pm]=\pm\frac{i}{2}\mathcal{Q}_\pm,\tag{31}$$

we must extend the Bacry–Chang representation of M^{+-} to

$$M^{+-}=-x^-p^+-\frac{i}{2}\left(\theta\frac{\partial}{\partial\theta}+\overline{\theta}\frac{\partial}{\partial\overline{\theta}}\right).\tag{32}$$

In order to satisfy the other commutation relations,

$$[M^{+i},M^{-j}]=i\delta^{ij}M^{+-}-iM^{ij},\quad [M^{12},\mathcal{Q}_\pm]=\mp\tfrac{1}{2}\mathcal{Q}_\pm,\tag{33}$$

the generators M^{12} and M^{-i} now include the θ-dependent terms,

$$M^{12}=x^1p^2-x^2p^1+\hat{S}^{12},\tag{34}$$

as well as

$$M^{-i}=x^-p^i-\frac{1}{2}\{x^i,P^-\}+\frac{1}{p^+}(T^i-p^j\hat{S}^{ij})+i\frac{p^i}{2p^+}\left(\theta\frac{\partial}{\partial\theta}+\overline{\theta}\frac{\partial}{\partial\overline{\theta}}\right),\tag{35}$$

where now

$$\hat{S}^{12}=S^{12}+\frac{1}{2}\left(\theta\frac{\partial}{\partial\theta}-\overline{\theta}\frac{\partial}{\partial\overline{\theta}}\right).\tag{36}$$

The generator M^{+i} remains unchanged. The other relevant commutators in light-cone form are

$$[M^{\pm i},\mathcal{Q}_\pm]=0.\tag{37}$$

In the frame where $p^i=0$, we have

$$\mathcal{Q}_-=0,\quad M^{-i}=T^i/p^+,\tag{38}$$

so that the commutators

$$[M^{-1},\mathcal{Q}_+]=-\frac{i}{\sqrt{2}}\mathcal{Q}_-,\quad [M^{-2},\mathcal{Q}_+]=-\frac{1}{\sqrt{2}}\mathcal{Q}_-, \tag{39}$$

$$[M^{+1},\mathcal{Q}_-]=-\frac{i}{\sqrt{2}}\mathcal{Q}_+,\quad [M^{+2},\mathcal{Q}_-]=\frac{1}{\sqrt{2}}\mathcal{Q}_+, \tag{40}$$

imply that

$$[T^i,\mathcal{Q}_+]=0. \tag{41}$$

Since the vector that characterizes the CSRs commutes with the supercharge, we can implement supersymmetry on the continuous spin representations without having to change the supercharges.

Thus in $(3+1)$-dimension, we obtain the *unique* representation of supersymmetry which contains all integer and half-odd integer helicities. This of course does not alleviate the problems associated with the CSRs.

B. Higher dimensions

In higher dimensions, Eqs. (20)–(24) still hold, but the number and nature of independent Grassmann parameters, i.e., whether these are Dirac, Weyl or Majorana type, depend on the number of space-time dimensions.[13] In d-dimensions, there are $2^{d/2}(2^{(d-1)/2})$ complex spinor components for d even(odd). Using the anticommutativity between supercharge and covariant derivative, these numbers can be further reduced by a factor of 2. Let a, b run over the independent spinor indices, i.e., $a,b=1,2,\ldots,2^{d/2-m}(2^{(d-1)/2-m})$, for d even(odd), respectively, where m is the number of independent constraints. Using all reducibility conditions, we can always express the super-Poincaré algebra in the light-cone form,

$$M^{ij}=x^ip^j-x^jp^i+\hat{S}^{ij}, \tag{42}$$

$$M^{+-}=-x^-p^++S^{+-}, \tag{43}$$

$$M^{-i}=x^-p^i-\frac{1}{2}\{x^i,P^-\}+\frac{1}{p^+}(T^i-p^j\hat{S}^{ij})-\frac{p^i}{p^+}S^{+-}, \tag{44}$$

where

$$\hat{S}^{ij}=S^{ij}+(\tfrac{1}{2}\theta^a(\gamma^{ij})_{ab}\partial^b+\text{c.c.}), \tag{45}$$

$$S^{+-}=(\tfrac{1}{2}\theta^a(\gamma^{+-})_{ab}\partial^b+\text{c.c.}), \tag{46}$$

and γ^{ij} and γ^{+-} are the reduced Dirac submatrices consistent with the constraints. M^{+i} remain the same as before. The indices i, j run over transverse space. The supercharges can be irreducibly expressed as

$$\mathcal{Q}^a_+=\frac{\partial}{\partial\theta^a}+\frac{1}{\sqrt{2}}p^+\overline{\theta^a},\quad \mathcal{Q}^{\dagger a}_+=\frac{\partial}{\partial\overline{\theta^a}}+\frac{1}{\sqrt{2}}p^+\theta^a, \tag{47}$$

and $\mathcal{Q}^a_-$ can be expressed in terms of $\mathcal{Q}^a_+$. To illustrate this construction, we now show how supersymmetric CSRs arise in 5 and 11 dimensions.

1. (4+1)*-dimensions*

In five dimensions, the spinors have four complex components which can be reduced to two using the covariant derivative constraint. Using the light-cone projectors, $\mathcal{P}_{\pm}=-\frac{1}{2}\gamma^{\mp}\gamma^{\pm}$ in the representation,

$$\gamma^0=i\sigma^1\otimes I,\quad \gamma^i=\sigma^3\otimes\sigma^i,\quad i=1,2,3;\quad \text{and}\quad \gamma^4=\sigma^2\otimes I, \tag{48}$$

and Eq. (22), we find

$$\{\mathcal{Q}_{+a},\mathcal{Q}^{\dagger}_{+b}\}=\sqrt{2}p^{+}\delta_{ab}, \tag{49}$$

$$\{\mathcal{Q}_{-a},\mathcal{Q}^{\dagger}_{-b}\}=\sqrt{2}p^{-}\delta_{ab}=\frac{\vec{p}\cdot\vec{p}}{\sqrt{2}p^{+}}\delta_{ab}, \tag{50}$$

$$\{\mathcal{Q}_{+a},\mathcal{Q}^{\dagger}_{-b}\}=i(\vec{\sigma}\cdot\vec{p})_{ab}, \tag{51}$$

$$\{\mathcal{Q}_{-a},\mathcal{Q}^{\dagger}_{+b}\}=-i(\vec{\sigma}\cdot\vec{p})_{ab}, \tag{52}$$

where $a,b=1,2$ and also we used the on-shell condition $p^{-}=p^{i}p^{i}/2p^{+}$. From Eq. (26) and $\mathcal{D}\Phi=0$, we find

$$\frac{\partial}{\partial\theta^{2+a}}=-i\left(\frac{\vec{\sigma}\cdot\vec{p}}{\sqrt{2}p^{+}}\right)_{ab}\frac{\partial}{\partial\theta^{b}},$$

and similarly for their complex conjugates, allowing us to set $(\theta^3,\theta^4)=0$. The supercharges, Eqs. (23) and (24), reduce to the irreducible form as in Eq. (47) with $a,b=1,2$, and

$$Q_{-a}=-i\left(\frac{\vec{\sigma}\cdot\vec{p}}{\sqrt{2}p^{+}}Q_{+}\right)_{a}\quad\text{and hence}\quad Q^{\dagger}_{-a}=i\left(Q^{\dagger}_{+}\frac{\vec{\sigma}\cdot\vec{p}}{\sqrt{2}p^{+}}\right)_{a}. \tag{53}$$

The Lorentz generators remain the same as in Eqs. (42)–(44) with the following irreducible representations of S^{ij} and S^{+-} [in Eqs. (45) and (46)],

$$S^{+-}=-\frac{i}{2}\left(\theta\frac{\partial}{\partial\theta}+\overline{\theta}\frac{\partial}{\partial\overline{\theta}}\right), \tag{54}$$

$$\hat{S}^{ij}=S^{ij}+\frac{1}{2}\epsilon^{ijk}\left(\theta\sigma^{k}\frac{\partial}{\partial\theta}+\text{c.c.}\right), \tag{55}$$

where $\theta=(\theta^1,\theta^2)$ and $\partial/\partial\theta=(\partial/\partial\theta^1,\partial/\partial\theta^2)$. The supercharges transform as SO(3) spinors,

$$[M^{ij},\mathcal{Q}_{+a}]=-\tfrac{1}{2}\epsilon^{ijk}(\sigma^{k}\mathcal{Q}_{+})_{a}. \tag{56}$$

These charges can be made to act on the CSRs, for which the relevant group is that of the short little group SO(2) which leaves the light-cone translation vector invariant. Aligning $\vec{T}$ along the z-axis, the supercharges split into two components, $\mathcal{Q}_{+1}$ and $\mathcal{Q}^{\dagger}_{+2}$, that lower the value of M^{12} by half a unit, and two components, $\mathcal{Q}_{+2}$ and $\mathcal{Q}^{\dagger}_{+1}$ that raise it.

In terms of M, the eigenvalue of $\hat{S}^{12}$, the supermultiplet consists of

$$|M\rangle_{\text{CSR}}\sim|M\rangle_{\text{CSR}},$$

$$\mathcal{Q}_{+1}|M\rangle_{\text{CSR}},\quad \mathcal{Q}^{\dagger}_{+2}|M\rangle_{\text{CSR}}\sim|M-\tfrac{1}{2}\rangle_{\text{CSR}},$$

$$\mathcal{Q}_{+1}\mathcal{Q}^{\dagger}_{+2}|M\rangle_{\mathrm{CSR}} \sim |M-1\rangle_{\mathrm{CSR}}.$$

It contains two bosonic and two fermionic CSRs, with the same structure as the ordinary ($\vec{T}=0$) massless $N=2$ supermultiplet in four dimensions. The important difference is that it contains not only the ordinary states but their copies under the boosts proportional to $\vec{T}$. This yields as usual an infinite number of SO(3) polarization states. The action of supersymmetry is the same as in the normal case, but the CSR supermultiplets contain an infinite number of ordinary massless supermultiplets of ever-increasing spin.

2. (10+1)*-dimensions*

The case of 11 dimensions is particularly interesting because it is shrouded in mystery, as it contains not only local supergravity but also the elusive M-theory. What we know of M-theory is that its compactifications to lower dimensions yields supersymmetric theories and that its long distance limit is the supergravity theory.

In 11 dimensions, the spinors have 32 complex components, which, upon using the Majorana condition and the covariant derivative constraint, reduce to 16 real components. The supercharge splits as

$$Q=\begin{pmatrix} Q^A \\ Q^{16+A}\end{pmatrix} \equiv \begin{pmatrix} Q^A_+ \\ Q^A_-\end{pmatrix}, \quad A=1,\ldots,16.$$

The Majorana condition implies,

$$Q^A_+ = Q^{\dagger A}_+ \quad \text{and} \quad Q^A_- = -Q^{\dagger A}_-.$$

In the representation

$$\gamma^0 = i\sigma^1\otimes I, \quad \gamma^i = \sigma^3\otimes\tilde{\gamma}^i, \quad \gamma^{10}=\sigma^2\otimes I, \tag{57}$$

where $i=1,\ldots,9$ and $\tilde{\gamma}^i$'s are 16×16 and real, symmetric matrices which satisfy the following algebra

$$\{\tilde{\gamma}^i,\tilde{\gamma}^j\}=2\delta^{ij},$$

the super-Poincaré algebra becomes

$$\{Q^A_+,Q^B_+\}=\sqrt{2}p^+\delta^{AB},$$

$$\{Q^A_-,Q^B_-\}=-\sqrt{2}p^-\delta^{AB}=-\frac{\vec{p}\cdot\vec{p}}{\sqrt{2}p^+}\delta^{AB},$$

$$\{Q^A_+,Q^B_-\}=-i\tilde{\gamma}^{AB}_i p^i,$$

$$[M^{ij},Q^A_\pm]=\frac{i}{2}(\tilde{\gamma}_{ij}Q_\pm)^A,$$

$$[M^{+-},Q^A_\pm]=\pm\frac{i}{2}Q^A_\pm,$$

$$[M^{\pm i},Q^A_\pm]=0, \quad [M^{\pm i},Q^A_\mp]=\pm\frac{i}{\sqrt{2}}(\tilde{\gamma}_i Q_\pm)^A.$$

Using $\mathcal{D}\Phi=0$ and Eq. (26), we find

$$\frac{\partial}{\partial\theta^{16+A}}=-i\left(\frac{\tilde{\gamma}^i p^i}{\sqrt{2}p^+}\frac{\partial}{\partial\theta}\right)_A,$$

allowing us to set $\theta^{16+A}=0$ for $A=1,\ldots,16$. The remaining real Q_+^A's can be expressed in terms of 16 real Grassmann parameters,

$$Q_+^A=\frac{\partial}{\partial\theta^A}+\frac{1}{\sqrt{2}}p^+\theta^A \quad \text{and} \quad Q_-^A=-i\left(\frac{\tilde{\gamma}^i p^i}{\sqrt{2}p^+}Q_+\right)^A.$$

Similarly, in this representation, Eqs. (45) and (46) reduce to

$$S^{+-}=-\frac{i}{2}\theta^A\frac{\partial}{\partial\theta^A},$$

$$\hat{S}^{ij}=S^{ij}-\frac{i}{2}\theta^A\tilde{\gamma}^{ij}_{AB}\frac{\partial}{\partial\theta^B},$$

which together with Eqs. (42)–(44) give the Lorentz generators, where $\tilde{\gamma}^{ij}=\tilde{\gamma}^i\tilde{\gamma}^j$ for $i\neq j$ and zero otherwise.

We can let these charges act onto CSRs, remembering that they are labeled by the short little group SO(8) that leaves the light-cone translation vector $\vec{T}$ invariant. We decompose the supercharges into two eight-component supercharges, $\mathcal{Q}_+^a$ and $\mathcal{Q}_+^{\dot{a}}$, by the SO(8) chirality matrix,

$$Q_+^A=\begin{pmatrix}\mathcal{Q}_+^a\\ \mathcal{Q}_+^{\dot{a}}\end{pmatrix}, \quad a=1,\ldots,8,$$

where

$$\mathcal{Q}_+^a=\tfrac{1}{2}(1+\tilde{\gamma}^{(9)}) \quad \text{and} \quad \mathcal{Q}_+^{\dot{a}}=\tfrac{1}{2}(1-\tilde{\gamma}^{(9)}),$$

and the chirality matrix of SO(8) subgroup is

$$\tilde{\gamma}^{(9)}\equiv\tilde{\gamma}^1\tilde{\gamma}^2\tilde{\gamma}^3\tilde{\gamma}^4\tilde{\gamma}^5\tilde{\gamma}^6\tilde{\gamma}^7\tilde{\gamma}^8.$$

These two eight-component supercharges furnish two inequivalent spinor representations of SO(8), $\mathbf{8}_s$ and $\mathbf{8}_s'$, characterized by opposite SO(8) chirality and $\mathcal{Q}_+^a\sim\mathbf{8}_s$, $\mathcal{Q}_+^{\dot{a}}\sim\mathbf{8}_s'$.

The (16×16) $\tilde{\gamma}^i$ matrices can be written in terms of 8×8 block form

$$\tilde{\gamma}^i=\begin{pmatrix}0 & \tilde{\gamma}^i_{a\dot{a}}\\ \tilde{\gamma}^i_{\dot{b}b} & 0\end{pmatrix},$$

where $\tilde{\gamma}^i_{a\dot{a}}$ is the transpose of $\tilde{\gamma}^i_{\dot{a}a}$. The Clifford algebra for $\tilde{\gamma}^i$ is satisfied if

$$\tilde{\gamma}^i_{a\dot{a}}\tilde{\gamma}^j_{\dot{a}b}+\tilde{\gamma}^j_{a\dot{a}}\tilde{\gamma}^i_{\dot{a}b}=2\,\delta^{ij}\delta_{ab}, \quad \text{for } i,j,a,b=1,\ldots,8,$$

and similarly with undotted and dotted indices interchanged. We also define

$$\tilde{\gamma}^{ij}_{ab}=\tfrac{1}{2}(\tilde{\gamma}^i_{a\dot{a}}\tilde{\gamma}^j_{\dot{a}b}-\tilde{\gamma}^j_{a\dot{a}}\tilde{\gamma}^i_{\dot{a}b}),$$

and similarly for $\tilde{\gamma}^{ij}_{\dot{a}\dot{b}}$. The (8×8) $\tilde{\gamma}^i_{a\dot{a}}$ matrices couple the vector and spinor representations. In this chiral subspace, the supercharges, $\hat{S}^{ij}$ and S^{+-} take the following irreducible forms

$$\mathcal{Q}_+^a = \frac{\partial}{\partial \theta^a} + \frac{1}{\sqrt{2}} p^+ \theta^a, \tag{58}$$

$$\mathcal{Q}_+^{\dot{a}} = \frac{\partial}{\partial \theta^{\dot{a}}} + \frac{1}{\sqrt{2}} p^+ \theta^{\dot{a}},$$

$$\mathcal{Q}_-^a = -\frac{ip^i}{\sqrt{2}p^+} \tilde{\gamma}^i_{a\dot{a}} \mathcal{Q}_+^{\dot{a}}, \tag{59}$$

$$\mathcal{Q}_-^{\dot{a}} = -\frac{ip^i}{\sqrt{2}p^+} \tilde{\gamma}^i_{\dot{a}a} \mathcal{Q}_+^a,$$

as well as

$$S^{+-} = -\frac{i}{2} \theta^a \frac{\partial}{\partial \theta^a}, \quad \hat{S}^{ij} = S^{ij} - \frac{i}{2} \theta^a \tilde{\gamma}^{ij}_{ab} \frac{\partial}{\partial \theta^b}. \tag{60}$$

We have two supersymmetries, each transforming as a different SO(8) spinor, and the basic supermultiplet is of the form $(\mathbf{8}_v + \mathbf{8}_s)_{\mathrm{CSR}} \times (\mathbf{8}_v + \mathbf{8}'_s)_{\mathrm{CSR}}$, with 128 bosonic and 128 fermionic states,

$$(\mathbf{8}_v + \mathbf{8}_s)_{\mathrm{CSR}} \times (\mathbf{8}_v + \mathbf{8}'_s)_{\mathrm{CSR}} = (\mathbf{1} + \mathbf{28} + \mathbf{35} + \mathbf{8} + \mathbf{56})_{v,\mathrm{CSR}} + (\mathbf{8}' + \mathbf{56}' + \mathbf{8} + \mathbf{56})_{s,\mathrm{CSR}}. \tag{61}$$

This supermultiplet (without CSR) is of course that of the massless states of IIA string theory, obtained by dimensional reduction from 11-dimensional supergravity.

As we found in the five-dimensional case, there is a one-to-one correspondence between the labels of the ordinary massless representation for $N=2$ supersymmetry in ten dimensions and those of the massless CSR for $N=1$ supersymmetry in 11 dimensions. However, the CSR supermultiplet contains the states of $N=1$ supergravity as well as an infinite number of massless supermultiplets obtained by boosting along $\vec{T}$.

C. Dimensional reduction

The characteristic feature of the CSRs is the transverse space vector T^i. A nonzero value implies an infinite number of polarization states while a zero value requires a finite number of polarizations. In covariant terms, this vector is written in terms of the Pauli–Lubanski $(d-3)$-form, its magnitude unchanged by Poincaré transformations.

This suggests several ways in which CSRs might play a role in physics. One is to enlarge the invariance group to include transformations capable of changing the length. The other is to view the CSR in the context of dimensional reduction by limiting transformations to rotations perpendicular to $\vec{T}$.

The former approach requires a study of the representations of the larger groups. Of prime interest are the conformal group (since we are dealing with massless representations) and perhaps the de Sitter groups. In particular we need to identify how CSRs and normal massless representations reside in unitary irreducible representations of these groups.

In physical terms we may view the length as an order parameter (as in the Higgs mechanism with a vector representation). For this we need to give it a dynamical meaning and couple it to an external field; it is amusing to note that in 11 dimensions it naturally couples to an eight-form, which is dual to a three-form.

As we let the length tend to zero, we cannot *a priori* determine which normal representation will be singled out in the transition. This is reminiscent of Dashen's theorem in chiral theories where an external additional tag is required; otherwise it points to a first-order phase transition.

In the context of dimensional reduction, the translation vector $\vec{T}$ naturally singles out a subspace perpendicular to its direction. It follows that group operations restricted to that subspace span normal representations of the Poincaré and super-Poincaré algebras. Thus it might be possible to start with a problematic theory and dimensionally reduce it to a well-defined one.

D. Nilpotent light-cone translations

We have seen that CSRs necessarily contain massless states of unbounded spins related by finite boosts, raising many objections for their use in the description of pointlike objects. On the other hand, the extension of Poincaré invariance to supersymmetry introduces nilpotent Grassmann variables, which suggests the construction of the light-cone translations out of these Grassmann parameters. The translations would be nilpotent, and therefore generate a finite number of helicities with finite boosts.

In $(3+1)$-dimensions, we need two complex Grassmann variables, θ_1, θ_2, in order to build an SO(2) vector. We set

$$T^1+iT^2=\sqrt{2}\overline{z}p^+\theta_1\theta_2, \quad T^1-iT^2=\sqrt{2}zp^+\overline{\theta_1}\,\overline{\theta_2}, \tag{62}$$

where z is a complex variable, and we have added the appropriate power of p^+ to ensure proper commutation with M^{+-}. S^{12} now becomes

$$\hat{S}^{12}\equiv S^{12}+\tfrac{1}{2}(\theta^a\partial_a-\overline{\theta}^a\overline{\partial}_a), \tag{63}$$

and the Poincaré Casimir operator is now a nilpotent Grassmann number,

$$W^2=W^\mu W_\mu=-2|z|^2(p^+)^2\theta_1\theta_2\overline{\theta}_1\overline{\theta}_2. \tag{64}$$

With two Grassmann variables, we can construct two supercharges, corresponding to $N=2$ supersymmetry. The kinematic supersymmetries are unaltered

$$\mathcal{Q}^a_+=\frac{\partial}{\partial\theta_a}+\frac{1}{\sqrt{2}}p^+\overline{\theta}_a; \quad \mathcal{Q}^{a\dagger}_+=\frac{\partial}{\partial\overline{\theta}_a}+\frac{1}{\sqrt{2}}p^+\theta_a, \tag{65}$$

where $a=1,2$. However, the light-cone translations no longer commute with these supercharges. To restore the super-Poincaré algebra, the dynamic supersymmetries must be altered to the new form

$$\mathcal{Q}^a_-=\frac{p}{p^+}\mathcal{Q}^a_+-i\overline{z}\epsilon^{ab}\theta_b, \quad \mathcal{Q}^{a\dagger}_-=\frac{\overline{p}}{p^+}\mathcal{Q}^{a\dagger}_++iz\epsilon^{ab}\overline{\theta}_b, \tag{66}$$

which ensures the commutation relations of $\mathcal{Q}^a_+$ with the boosts M^{-i}. The resulting supersymmetry algebra,

$$\{\mathcal{Q}^a_+,\mathcal{Q}^b_-\}=i\epsilon^{ab}\overline{z}, \quad \{\mathcal{Q}^{a\dagger}_+,\mathcal{Q}^{b\dagger}_-\}=-i\epsilon^{ab}z, \tag{67}$$

acquires central charges, even though we are in a massless representation.

This leads to zero or negative norm states. The positive norm states are of the form $|\cdots\rangle$, and $\mathcal{Q}^{a\dagger}_+|\cdots\rangle$, and $\mathcal{Q}^{1\dagger}_+\mathcal{Q}^{2\dagger}_+|\cdots\rangle$, where $|\cdots\rangle$ is annihilated by $\mathcal{Q}^a_+$. However, with central charges, in the frame where only $p^+\neq 0$,

$$\langle\cdots|\mathcal{Q}^1_+\mathcal{Q}^2_-|\cdots\rangle=iz\langle\cdots|\cdots\rangle, \tag{68}$$

and a similar argument with 1,2 interchanged, which shows that the states $\mathcal{Q}^a_-|0\rangle$ do not vanish. Yet from

$$\{\mathcal{Q}_-^a, \mathcal{Q}_-^{b\dagger}\} = 0, \tag{69}$$

their norms must satisfy

$$|\mathcal{Q}_-^a|\cdots\rangle|^2 + |\mathcal{Q}_-^{a\dagger}|\cdots\rangle|^2 = 0, \tag{70}$$

for $a=1,2$, implying that one is negative, or both are zero. This reproduces general arguments[13] based on the absence of negative or zero norm states, which show that central charges are limited to massive representations. In the frame where only $p^+ \neq 0$, the dynamic generators of massless supersymmetry anticommute with one another. If they do not, negative or zero-norm states are generated.

This construction does not seem to generalize to odd dimensions. We have shown this explicitly in 11 dimensions by starting with $\vec{T}$ quadratic in the Grassmann numbers. There a quadratic product of a Grassmann spinor transforms as two- and three-forms, so that to make a vector we need some c-number tensors, either a one- or two-form, but the commutation with the supercharge does not have the right form.

On the other hand, the construction in $(9+1)$-dimensions is straighforward. We consider two supercharges

$$\mathcal{Q}_+^{(1)} = \frac{\partial}{\partial\theta} + \frac{1}{\sqrt{2}} p^+ \theta; \quad \mathcal{Q}_+^{(2)} = \frac{\partial}{\partial\eta} + \frac{1}{\sqrt{2}} p^+ \eta,$$

where $\theta \sim \mathbf{8}_s$, $\eta \sim \mathbf{8}_s'$. We take the light-cone translation vector to be

$$T^i = i p^+ z\, \theta \tilde{\gamma}^i \eta \sim \mathbf{8}_v, \quad z \text{ real},$$

so that this corresponds to type IIA supersymmetry. The dynamic boosts are

$$S^{-i} = i z\, \theta \tilde{\gamma}^i \eta - \frac{p^j}{p^+} \hat{S}^{ij} - \frac{p^i}{p^+} S^{+-},$$

with

$$\hat{S}^{ij} = S^{ij} - \frac{i}{2}\left(\theta \tilde{\gamma}^{ij} \frac{\partial}{\partial\theta} + \eta \tilde{\gamma}^{ij} \frac{\partial}{\partial\eta} \right), \quad \text{and} \quad S^{+-} = -\frac{i}{2}\left(\theta \frac{\partial}{\partial\theta} + \eta \frac{\partial}{\partial\eta} \right).$$

The dynamic supercharges are now

$$\mathcal{Q}_-^{(2)} = -\frac{i p^i}{\sqrt{2} p^+} \tilde{\gamma}^i \mathcal{Q}_+^{(2)} + i\sqrt{2} z\, \theta,$$

$$\mathcal{Q}_-^{(1)} = -\frac{i p^i}{\sqrt{2} p^+} \tilde{\gamma}^i \mathcal{Q}_+^{(1)} - i\sqrt{2} z\, \eta.$$

The resulting supersymmetry algebra now includes central charge

$$\{\mathcal{Q}_+^{(1)}, \mathcal{Q}_-^{(2)}\} = -\{\mathcal{Q}_+^{(2)}, \mathcal{Q}_-^{(1)}\} = i\sqrt{2} z.$$

We have seen that our construction leads to supersymmetry but the representations necessarily contain negative and zero-norm states. Although it is interesting to note that central charges occur naturally whenever the light-cone translations are built out of the Grassmann variables, the representations contain negative and zero-norm states; at best they could be used as ghost compensators of some unknown theory.

IV. CONCLUSION

In this article, we considered nonzero light-cone translations to construct the continuous spin representations of both Poincaré and super-Poincaré algebra. We started with the Poincaré algebra in four space–time dimensions and generalized it to higher dimensions. The light-cone translation vector, $\vec{T}$, is represented by spherical harmonics in $(d-2)$-dimensions for the light-cone little group $\mathrm{SO}(d-2)$. We find that the states can be represented by p^+, the length Ξ and $(d-3)$ number of angles of the $\mathrm{SO}(d-2)$ spherical harmonics, and the Dynkin labels $(a_1,\ldots,a_r)$ of $\mathrm{SO}(d-3)$ the short little group, with r being the rank. There is one CSR for each representation $(a_1,\ldots,a_r)$.

If $\vec{T}$ is nilpotent, a finite number of states are generated by the light-cone boost, instead of infinite number of states, but the resulting CSR contains zero or negative norm states, and its supersymmetric extension (in four and ten dimensions) has a central charge. The nilpotent construction of T^i in higher dimensions is not so evident. These CSRs may be useful in conjunction with theories where the invariances force overcounting, as in ghost states in gauge theories.

(Received 26 July 2002; accepted 26 August 2002)

An algebraic routine for the evaluation of analytical expressions for isoscalar factors (ISFs) of $S_f \supset S_{f-1}$ is formulated based on the linear equation method (LEM) and the analytical continuation of the rank f. As examples, ISFs of $S_f \supset S_{f-1}$ for the coupling $[f-1,1]\cdot[f-1,1]$, $[f-1,1]\cdot[f-2,2]$, $[f-2,1,1]\cdot[f-2,1,1]$ are tabulated. The results demonstrate that the number of ISF tables can be greatly reduced compared with corresponding numerical results produced using other methods. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1517169]

I. INTRODUCTION

Clebsch–Gordan Coefficients (CGCs) of the symmetric groups S_f are very important. First of all, by definition, they are transformation coefficients between uncoupled basis vectors of two irreducible representations (irreps) and a coupled inner product irrep of those two irreps.[1] Next, it has been shown[2–5] that the CGCs of S_f can be used to evaluate coupling coefficients for the $U(mn)\supset U(m)\times U(n)$, $SU(mn)\supset SU(m)\times SU(n)$ coefficients of fractional parentage (CFP), and so on, due to the Schur–Weyl duality relation between the symmetric group S_f and the unitary group $U(n)$.

There are many different ways to evaluate the CGCs of S_f.[6–11] Vanagas studied an extension of the tensor algebraic approach to the symmetric groups.[6] In this approach, one- and two-body operators are expressed in terms of irreducible tensor operators of symmetric groups. Hence, the Wigner–Racah tensor operator technique can be applied for evaluating matrix elements of the operators with CGCs and Racah coefficients of S_f. Analytical expressions of the isoscalar factors (ISFs) for the inner product $[f-1]\cdot[f-1]$ were derived based on this method. However, this approach is not practical for deriving analytical expressions of other ISFs due to the fact that the order of the symmetric group S_f increases dramatically with f and more complex Young shapes. As a consequence, numerical algorithms have been developed based on various routines for $f \leqslant 6$. The Schindler and Mirman method for computing the CGCs of S_f is based on the fact that the CG vectors of S_f are the simultaneous eigenvectors of the two-cycle class operators of its subgroups.[10,11] Chen *et al.* proposed the eigenfunction method,[7,8] and pointed out that the CG vectors of S_f can be much more easily obtained by diagonalizing a single matrix rather than by diagonalizing simultaneously the $f-1$ representation matrices of the $f-1$ two-cycle class operators used by Schindler and Mirman. Based on these considerations, two sets of tables of CGCs of S_f for $f \leqslant 6$ have been published; one was generated using the Schindler and Mirman algorithm,[11] while another was produced by Chen *et al.* based on the eigenfunction method.[7,8] Very recently, ISFs of $S_f \supset S_{f-1}$ for $f \leqslant 6$ have been calculated[12] based on Hamermesh's recursion relation.[1]

CGCs or ISFs of the symmetric groups calculated by any of these methods quickly become intractable with increasing rank f. Furthermore, these methods only yield CGCs and ISFs for a specific f, implying the need for a large number of tables. But, upon close examination of the results one finds that many of the tables have common structures, suggesting that an analytical continuation in the rank f may be possible.

In this paper, the linear equation method (LEM) is used to evaluate ISFs of $S_f \supset S_{f-1}$. The LEM has proven to be an effective method for dealing with coupling and recoupling coefficients of Hecke, Brauer, and Birman–Wenzl algebras in analytical form.[13–17] In Ref. 17, tensor product reduction coefficients of Hecke algebras $H_f(q)$ are also discussed within the LEM framework. The tensor product reduction coefficients reduce to CGCs of S_f when $q \to 1$. In Sec. II, the LEM for evaluating ISFs of $S_f \supset S_{f-1}$ will be outlined. Analytical expressions of ISFs of $S_f \supset S_{f-1}$ for the coupling $[f-1,1]\cdot[f-1,1]$, $[f-1,1]\cdot[f-2,2]$, $[f-2,1,1]\cdot[f-2,1,1]$ are tabulated in Sec. III.

II. THE LINEAR EQUATION METHOD

The symmetric group S_f can be defined by $f-1$ generators $\{g_i;\ i=1,2,\ldots,f-1\}$, which are nothing but adjacent permutations that satisfy the following relations:

$$g_i g_{i+1} g_i = g_{i+1} g_i g_{i+1},$$
$$g_i g_j = g_j g_i \quad \text{for} \quad |i-j| \geqslant 2, \tag{1}$$

and the constraint

$$g_i^2 = 1. \tag{2}$$

Consider two symmetric groups of the same rank $S_f^{(k)}$, $k=1,2$. The inner product $S_f^{(1)} \cdot S_f^{(2)}$ can be defined in terms of the generators of $g_i^{(k)} \in S_f^{(k)}$ with

$$G_i = g_i^{(1)} g_i^{(2)} \quad \in S_f^{(1)} \cdot S_f^{(2)}, \tag{3}$$

where $i=1,2,\ldots,f-1$. It can be verified easily that the new generators G_i with $i=1,2,\ldots,f-1$ satisfy (1) and (2). Therefore, the $\{G_i\}$ generate the symmetric group S_f.

The reduction, or CG series of the symmetric group, is designated

$$[\nu_1]\cdot[\nu_2] = \sum_{\nu} \{\nu_1 \nu_2 \nu\}[\nu], \tag{4}$$

where $[\nu_1]$ and $[\nu_2]$ are irreps of $S_f^{(1)}$ and $S_f^{(2)}$, respectively, $[\nu]$ is an irrep of S_f, and $\{\nu_1 \nu_2 \nu\}$ is multiplicity of $[\nu]$ in the reduction.

Let $|Y_{m_k}^{[\nu_k]}\rangle$ with $k=1$, 2 be basis vectors of the symmetric groups S_f^k. Then, uncoupled basis vectors of $S_f^1 \cdot S_f^2$ can be denoted as

$$|Y_{m_1}^{[\nu_1]}\rangle |Y_{m_2}^{[\nu_2]}\rangle, \tag{5}$$

where $Y_m^{[\nu]}$ denotes a standard Young tableau and the $|Y_m^{[\nu]}\rangle$ orthogonal basis vectors, that is, the $|Y_m^{[\nu]}\rangle$ satisfy $\langle Y_m^{[\nu]} | Y_{m'}^{[\nu]} \rangle = \delta_{mm'}$, $[\nu] \equiv [\nu_1 \nu_2 \cdots \nu_f]$ with $\nu_1 \geqslant \nu_2 \geqslant \cdots \geqslant \nu_f$ and $\Sigma_i \nu_i = f$. Here, f denotes an irrep of S_f, and the Yamanouchi basis $[\nu]m$ operates on the indices of the basis vectors in the so-called decreasing page order of the Yamanouchi symbol.[13] There exist unitary transformations between the uncoupled basis vectors (5) and basis vectors for an irrep $[\nu]$ of S_f, namely

$$|Y_m^{[\nu]}; \tau\rangle = \sum_{m_1 m_2} C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2} |Y_{m_1}^{[\nu_1]}\rangle |Y_{m_2}^{[\nu_2]}\rangle, \tag{6}$$

where τ is a multiplicity label needed in the decomposition $S_f^{(1)}\cdot S_f^{(2)}\downarrow S_f$. The coefficients $C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}$ appearing in (6) are the CGCs of $S_f^{(1)}\cdot S_f^{(2)}\downarrow S_f$. The CGCs satisfy unitary conditions

$$\sum_{m_1m_2} C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}C^{[\nu']m';\tau'}_{[\nu_1]m_1;[\nu_2]m_2}=\delta_{\nu\nu'}\delta_{mm'}\delta_{\tau\tau'}, \tag{7a}$$

$$\sum_{m\tau} C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}C^{[\nu]m;\tau}_{[\nu_1]m_1';[\nu_2]m_2'}=\delta_{m_1m_1'}\delta_{m_2m_2'}, \tag{7b}$$

and the following symmetry property:

$$C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}=\epsilon(\nu_1\nu_2\nu)C^{[\nu]m;\tau}_{[\nu_2]m_2;[\nu_1]m_1}, \tag{8}$$

where $\epsilon(\nu_1\nu_2\nu)$ is a phase factor that will be determined later.

We can use the linear equation method (LEM),[17] i.e., the intertwining relations among the CGCs derived from generators of S_f, to evaluate the CGCs of $S_f\cdot S_f\downarrow S_f$. Let $g_iY_m^{[\nu]}$ be the Young tableau obtained by interchanging the numbers i and $i+1$ in $Y_m^{[\nu]}$. It is understood that if the resultant tableau is not a standard one, the corresponding basis vector $|g_iY_m^{[\nu]}\rangle$ is set to zero. First of all, the results of generators $\{g_i^{(k)},\ i=1,2,\ldots,f-1;\ k=1,2\}$ acting on the uncoupled basis vectors $|Y^{[\nu_1]}_{m_1}\rangle|Y^{[\nu_2]}_{m_2}\rangle$ can be known directly from the standard results of the symmetric group given by

$$g_i|Y_m^{[\nu]}\rangle=\frac{1}{d_i}|Y_m^{[\nu]}\rangle+\left(\frac{(d_i+1)(d_i-1)}{d_i^2}\right)^{1/2}|(g_iY_m^{[\nu]})\rangle, \tag{9}$$

where d_i is the axial distance from the box i to the box $i+1$ in the Young tableau $Y_m^{[\lambda]}$ with movement upward and to the right being counted as positive.

Applying $G_i=g_i^{(1)}g_i^{(2)}$ with $i=1,2,\ldots,f-1$ to (6), the left-hand side of (6) becomes

$$\sum_{m';m_1'm_2'}(G_i)^{[\nu]}_{m'm}C^{[\nu]m';\tau}_{[\nu_1]m_1';[\nu_2]m_2'}|Y^{[\nu_1]}_{m_1'}\rangle|Y^{[\nu_2]}_{m_2'}\rangle, \tag{10}$$

where $(G_i)_{m'm}$ is a matrix element of G_i in the standard basis given by (9). On the other hand, the right-hand side of (6) becomes

$$\sum_{m_1m_2m_1'm_2'}C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}(g_i^{(1)})_{m_1'm_1}(g_i^{(2)})_{m_2'm_2}|Y^{[\nu_1]}_{m_1'}\rangle|Y^{[\nu_2]}_{m_2'}\rangle, \tag{11}$$

where $(g_i^{(k)})_{m_i'm_i}$ with $k=1,2$ are matrix elements of $g_i^{(k)}$ in the standard basis vectors of $S_f^{(k)}$, which can also be obtained by using Eq. (9). Combining (10) and (11), we can establish linear relations among the CGCs $C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}$

$$\sum_{m'}(G_i)^{[\nu]}_{m'm}C^{[\nu]m';\tau}_{[\nu_1]m_1';[\nu_2]m_2'}=\sum_{m_1m_2}C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}(g_i^{(1)})_{m_1'm_1}(g_i^{(2)})_{m_2'm_2}. \tag{12}$$

These relations, together with unitary conditions (7), are sufficient to determine the $C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}$ up to an overall phase factor, which can be fixed by requiring that the CGCs with smallest m and m_1 be positive

$$(C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2})\big|_{(m,m_1)=\min}\rangle 0, \tag{13}$$

where $(m,m_1)=\min$ means taking the index m as small as possible followed by taking m_1 as small as possible for which the CGC $C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2}$ is nonzero. Then, it can easily be seen that

$$\epsilon(\nu_1\nu_2\nu)=\mathrm{Sign}((C^{[\nu]m;\tau}_{[\nu_1]m_1;[\nu_2]m_2})|_{(m_2,m_1)=\min}). \tag{14}$$

Using this method, one can easily deduce the following simple results.

(1) If both $[\nu_1]$ and $[\nu_2]$ are symmetric, $[\nu_1]=[\nu_2]=[\nu]$,

$$C^{[\nu]}_{[\nu][\nu]}=1, \tag{15a}$$

(2) If $[\nu_1]$ is symmetric, while $[\nu_2]$ is neither symmetric nor antisymmetric

$$C^{[\nu]m}_{[\nu_1][\nu_2]m_2}=\delta_{\nu\nu_2}\delta_{mm_2}, \tag{15b}$$

(3) If $[\nu_1]$ is antisymmetric, while $[\nu_2]$ is symmetric

$$C^{[\nu]}_{[\nu_1][\nu_2]}=\delta_{\nu\nu_1}. \tag{15c}$$

The LEM stated above, however, can only be used to evaluate CGCs of S_f for specific f. According to the Racah factorization lemma,[18,19] the CGCs of S_f can be written as

$$C^{[\nu]\tau m}_{[\nu_1]m_1;[\nu_2]m_2}=\sum_{\tau'}\left\langle\begin{matrix}[\nu_1] & [\nu_2]\\ [\nu_1'] & [\nu_2']\end{matrix}\middle|\begin{matrix}\tau[\nu]\\ \tau'[\nu']\end{matrix}\right\rangle C^{\tau'[\nu']m'}_{[\nu_1']m_1';[\nu_2']m_2'}, \tag{16}$$

where $[\nu_1']$, $[\nu_2']$, and $[\nu']$, are possible irreps occurring in the reductions $[\nu_1]\downarrow[\nu_1']$, $[\nu_2]\downarrow[\nu_2']$, and $[\nu]\downarrow[\nu']$ of $S_f\supset S_{f-1}$, respectively,

$$\left\langle\begin{matrix}[\nu_1] & [\nu_2]\\ [\nu_1'] & [\nu_2']\end{matrix}\middle|\begin{matrix}\tau[\nu]\\ \tau'[\nu']\end{matrix}\right\rangle$$

is the ISF of $S_f\supset S_{f-1}$ and $C^{\tau'[\nu']m'}_{[\nu_1']m_1';[\nu_2']m_2'}$ is the CGCs of S_{f-1}, similar to S_f, $[\nu_1']m_1'$, $[\nu_2']m_2'$, $[\nu']m'$ denote Yamanouchi basis of S_{f-1}, and τ' is the multiplicity label for the inner product $[\nu_1']\cdot[\nu_2']\downarrow[\nu']$. In the multiplicity-free case, the multiplicity labels τ and τ' are redundant; one simply gets

$$C^{[\nu]m}_{[\nu_1]m_1;[\nu_2]m_2}=\left\langle\begin{matrix}[\nu_1] & [\nu_2]\\ [\nu_1'] & [\nu_2']\end{matrix}\middle|\begin{matrix}[\nu]\\ [\nu']\end{matrix}\right\rangle C^{[\nu']m'}_{[\nu_1']m_1';[\nu_2']m_2'}. \tag{17}$$

The ISFs of $S_f\supset S_{f-1}$ satisfy the unitary conditions

$$\sum_{\nu_1'\nu_2'\tau'}\left\langle\begin{matrix}[\nu_1] & [\nu_2]\\ [\nu_1'] & [\nu_2']\end{matrix}\middle|\begin{matrix}\tau[\nu]\\ \tau'[\nu']\end{matrix}\right\rangle\left\langle\begin{matrix}[\nu_1] & [\nu_2]\\ [\nu_1'] & [\nu_2']\end{matrix}\middle|\begin{matrix}\overline{\tau}[\overline{\nu}]\\ \tau'[\nu']\end{matrix}\right\rangle=\delta_{\nu\overline{\nu}}\delta_{\tau\overline{\tau}}, \tag{18a}$$

$$\sum_{\tau\nu}\left\langle\begin{matrix}[\nu_1] & [\nu_2]\\ [\nu_1'] & [\nu_2']\end{matrix}\middle|\begin{matrix}\tau[\nu]\\ \tau'[\nu']\end{matrix}\right\rangle\left\langle\begin{matrix}[\nu_1] & [\nu_2]\\ [\overline{\nu}_1'] & [\overline{\nu}_2']\end{matrix}\middle|\begin{matrix}\tau[\nu]\\ \overline{\tau}'[\nu']\end{matrix}\right\rangle=\delta_{\overline{\nu}_1'\nu_1'}\delta_{\overline{\nu}_2'\nu_2'}\delta_{\tau'\overline{\tau}'}. \tag{18b}$$

Our method for evaluating analytical expressions of the ISFs of $S_f\supset S_{f-1}$ can be summarized as follows. First, we use linear relations among the CGCs of S_f provided by (12) for inner product $[\nu_1]\cdot[\nu_2]\downarrow[\nu]$ with smallest f, as long as the irreps $[\nu_1]$, $[\nu_2]$, and $[\nu]$ exist. For example, irreps $[f]$, $[f-1,1]$ exist when $f\geqslant 2$, while irrep $[f-2,1,1]$ only exists when $f\geqslant 3$, and $[f-2,2]$ only exists when $f\geqslant 4$. Then, in the multiplicity-free cases, we use (17) together with (12) to get linear

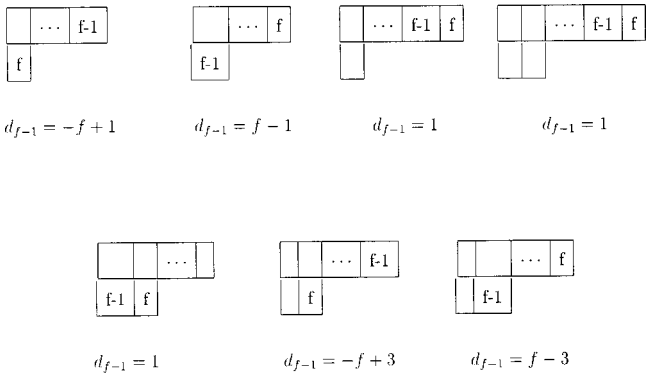

FIG. 1. Axial distance d_{f-1} for $[f-1,1]$ and $[f-2,2]$ with different possible locations of the final two numbers $f-1$ and f in the corresponding Young tableau.

relations of the corresponding ISFs of $S_f \supset S_{f-1}$. The ISFs of $S_f \supset S_{f-1}$ are f-dependent. One can replace the ISFs of $S_f \supset S_{f-1}$ for the specific f by those with general f. Actually, it can be shown that the relations among the ISFs of the same coupling are the same for any f value. Therefore, one can get analytical expressions for ISFs of $S_f \supset S_{f-1}$ from those for specific f. To do this, one has to use analytical expressions of the axial distance d_{f-1} in (12). Values of d_{f-1} for some irreps with different reductions of $S_f \supset S_{f-1}$ are shown in Fig. 1. Finally, one can use the linear relations obtained together with the unitary condition

$$\sum_{\nu_1' \nu_2'} \left\langle \begin{matrix} [\nu_1] & [\nu_2] \\ [\nu_1'] & [\nu_2'] \end{matrix} \middle| \begin{matrix} [\nu] \\ [\nu'] \end{matrix} \right\rangle^2 = 1, \tag{19}$$

to derive all ISFs involved in these linear relations up to an overall phase. The phase convention used here is consistent with that chosen for the CGCs of S_f shown in Ref. 20. We will use the symbol $[\nu]_p$ to denote $[\nu][\nu']$ for the reduction $[\nu]\downarrow[\nu']$ of $S_f \supset S_{f-1}$, where p denotes the last number f in the pth row of the Young diagram $[\nu]$. For example, $[f-1,1][f-1] \equiv [f-1,1]_2$, $[f-1,1][f-2,1] \equiv [f-1,1]_1$, etc. This labeling scheme greatly simplifies the final results. In the following, we give an example to show how the method works.

A. Example 1. Deriving ISFs of $S_f \supset S_{f-1}$ for the inner product $[f-1,1]\cdot[f-1,1]\downarrow[f]_1$

In this case, we need to work with $f=3$ because there are two reductions in $S_f \supset S_{f-1}$ for irrep $[f-1,1]$, namely $[f-1,1]\downarrow[f-2,1]$ and $[f-1]$, and the smallest f allowed for $[f-2,1]$ is $f \geqslant 3$. Hence, we need to consider the following expansion:

$$|[3]_1\rangle = \sum_{m_1 m_2} C^{[3]_1}_{m_1 m_2} |Y^{[21]}_{m_1} Y^{[21]}_{m_2}\rangle. \tag{20a}$$

Step 1. Acting with $G_1 = g_1^{(1)} g_1^{(2)}$ on (20a), one gets

$$|[3]_1\rangle = c_1 |Y^{[21]}_1 Y^{[21]}_1\rangle + c_2 |Y^{[21]}_2 Y^{[21]}_2\rangle. \tag{20b}$$

Other CGCs are obviously zero in this case according to the linear relations obtained from the results of the G_1 action.

Step 2. We need first to extend $[3] \to [f]$, and $[21] \to [f-1,1]$. Hence, (20b) becomes

$$|[f]_1\rangle = c_1 |[f-1,1]_1 [f-1,1]_1\rangle + c_2 |[f-1,1]_2 [f-1,1]_2\rangle. \tag{20c}$$

Step 3. By acting with $G_2 \to G_{f-1}$ on (20c), the left-hand side of (20c) is

$$c_1|[f-1,1]_1[f-1,1]_1\rangle+c_2|[f-1,1]_2[f-1,1]_2\rangle, \tag{20d}$$

while the right-hand side of (20c) becomes

$$\begin{aligned}
&c_1\Bigg(\frac{1}{(f-1)^2}|[f-1,1]_1[f-1,1]_1\rangle+\frac{f(f-2)}{(f-1)^2}|[f-1,1]_2[f-1,1]_2\rangle\\
&\quad+\frac{\sqrt{f(f-2)}}{(f-1)^2}(|[f-1,1]_1[f-1,1]_2\rangle+|[f-1,1]_2[f-1,1]_1\rangle\Bigg)\\
&\quad+c_2\Bigg(\frac{1}{(f-1)^2}|[f-1,1]_2[f-1,1]_2\rangle+\frac{f(f-2)}{(f-1)^2}|[f-1,1]_1[f-1,1]_1\rangle\\
&\quad-\frac{\sqrt{f(f-2)}}{(f-1)^2}(|[f-1,1]_1[f-1,1]_2\rangle+|[f-1,1]_2[f-1,1]_1\rangle\Bigg).
\end{aligned} \tag{20e}$$

Combining (20d) and (20e), we obtain

$$c_1=c_2. \tag{20f}$$

Because of analyticity, (20f) should hold for $f\geqslant 3$. Hence, for general f, (20c) should be written as

$$\begin{aligned}
|[f]_1\rangle&=C_f|[f-1,1]_2[f-1,1]_2\rangle+C_f\sum_{m_1m_2}|Y^{[f-1,1]_1}_{m_1}Y^{[f-1,1]_1}_{m_2}\rangle\\
&=C_f|[f-1,1]_2[f-1,1]_2\rangle+\frac{C_f}{C_{f-1}}(|[f-1,1]_1[f-1,1]_1\rangle)^{[f]_1},
\end{aligned} \tag{20g}$$

where

$$C_f=c_1=\langle[f-1,1]_2[f-1,1]_2|[f]_1\rangle,\quad c_2=\frac{C_f}{C_{f-1}}=\langle[f-1,1]_1[f-1,1]_1|[f]_1\rangle \tag{21}$$

are the ISFs involved in the coupling.

Step 4. Finally, using the unitary condition (19), we obtain the recursion relation for C_f^2 with

$$C_f^2=\frac{C_{f-1}^2}{C_{f-1}^2+1}. \tag{22}$$

Starting with $C_2^2=1$, we finally get

$$\langle[f-1,1]_2[f-1,1]_2|[f]_1\rangle=+\sqrt{\frac{1}{f-1}},\quad \langle[f-1,1]_1[f-1,1]_1|[f]_1\rangle=+\sqrt{\frac{f-2}{f-1}}, \tag{23}$$

where the overall phase is fixed with $C_f>0$ which is consistent with the phase convention for the CGCs of S_f set in Ref. 20. ISFs of $[f-1,1]\cdot[f-1,1]\downarrow[f-1,1]_2$ can be obtained by the unitary condition

$$\sum_{[\nu]_p}\langle[\nu_1]_{p_1}[\nu_2]_{p_2}|[\nu]_p\rangle^2=1 \tag{24}$$

or by the similar procedure. The results are shown in Table III.

TABLE I. Some inner product reduction rules of S_f.

$$
\begin{aligned}
&[f-1,1]\cdot[f-1,1]=[f]+[f-1,1]+[f-2,1,1]+[f-2,2]\\
&[f-1,1]\cdot[f-2,2]=[f-1,1]+[f-2,2]+[f-2,1,1]\\
&\qquad\qquad+[f-3,3]+[f-3,2,1]\\
&[f-2,1,1]\cdot[f-1,1]=[f-1,1]+[f-2,2]+[f-2,1,1]\\
&\qquad\qquad+[f-3,2,1]+[f-3,1^3]\\
&[f-2,2]\cdot[f-2,2]=[f]+[f-1,1]+2[f-2,2]+[f-2,1,1]\\
&\qquad\qquad+[f-3,3]+2[f-3,2,1]+[f-3,1^3]\\
&\qquad\qquad+[f-4,4]+[f-4,3,1]+[f-4,2,2]\\
&[f-2,1,1]\cdot[f-2,2]=[f-1,1]+[f-2,2]+2[f-2,1,1]\\
&\qquad\qquad+[f-3,3]+2[f-3,2,1]+[f-3,1^3]\\
&\qquad\qquad+[f-4,3,1]+[f-4,2,1^2]\\
&[f-2,1,1]\cdot[f-2,1,1]=[f]+[f-1,1]+2[f-2,2]+[f-2,1,1]\\
&\qquad\qquad+[f-3,3]+2[f-3,2,1]+[f-3,1^3]\\
&\qquad\qquad+[f-4,2,2]+[f-4,2,1^2]+[f-4,1^4]
\end{aligned}
$$

B. Example 2. Deriving ISFs of $S_f \supset S_{f-1}$ for the inner product $[f-1,1]\cdot[f-1,1]\downarrow[f-1,1]_1$

In this example, we choose to work with $f=4$. After acting with $G_1=g_1^{(1)}g_1^{(2)}$ on an expansion similar to (20a), we get

$$
\left|\begin{matrix}124\\3\end{matrix}\right\rangle = a_1\left|\begin{matrix}124\\3\end{matrix}\right\rangle\left|\begin{matrix}123\\4\end{matrix}\right\rangle + a_2\left|\begin{matrix}123\\4\end{matrix}\right\rangle\left|\begin{matrix}124\\3\end{matrix}\right\rangle + a_3\left(-\sqrt{\frac{1}{f-2}}\left|\begin{matrix}134\\2\end{matrix}\right\rangle\left|\begin{matrix}134\\2\end{matrix}\right\rangle + \sqrt{\frac{f-3}{f-2}}\left|\begin{matrix}124\\3\end{matrix}\right\rangle\left|\begin{matrix}124\\3\end{matrix}\right\rangle\right), \tag{25}
$$

where $C^{[21]_1}_{[21]_1[21]_1}$ and $C^{[21]_1}_{[21]_2[21]_2}$ have been replaced by $C^{[f-1,1]_1}_{[f-1,1]_1[f-1,1]_1}$ and $C^{[f-1,1]_1}_{[f-1,1]_2[f-1,1]_2}$, respectively, of which the analytical expressions derived in the example 1 are used, and

$$
a_1=\langle[f-1,1]_1[f-1,1]_2|[f-1,1]_1\rangle,\quad a_2=\langle[f-1,1]_2[f-1,1]_1|[f-1,1]_1\rangle,
$$

$$
a_3=\langle[f-1,1]_1[f-1,1]_1|[f-1,1]_1\rangle \tag{26}
$$

are the corresponding ISFs. Similarly, we have

$$
\left|\begin{matrix}123\\4\end{matrix}\right\rangle = \sqrt{\frac{f-2}{f-1}}\left|\begin{matrix}123\\4\end{matrix}\right\rangle\left|\begin{matrix}123\\4\end{matrix}\right\rangle - \sqrt{\frac{1}{(f-1)(f-2)}}\left|\begin{matrix}124\\3\end{matrix}\right\rangle\left|\begin{matrix}124\\3\end{matrix}\right\rangle - \sqrt{\frac{f-3}{(f-1)(f-2)}}\left|\begin{matrix}134\\2\end{matrix}\right\rangle\left|\begin{matrix}134\\2\end{matrix}\right\rangle. \tag{27}
$$

By acting with $G_3\to G_{f-1}=g_{f-1}^{(1)}g_{f-1}^{(2)}$ on (25), the left-hand side of (25) becomes

TABLE II. Dimensions of some irreps of S_f.

$$
\begin{aligned}
&\dim([f])=1\\
&\dim([f-1,1])=f-1\\
&\dim([f-2,2])=f(f-3)/2\\
&\dim([f-2,1^2])=(f-1)(f-2)/2\\
&\dim([f-3,2,1])=f(f-2)(f-4)/3\\
&\dim([f-3,1^3])=(f-1)(f-2)(f-3)/6\\
&\dim([f-3,3])=f(f-1)(f-5)/6\\
&\dim([f-4,4])=f(f-1)(f-2)(f-7)/24\\
&\dim([f-4,2,1^2])=f(f-2)(f-3)(f-5)/8\\
&\dim([f-4,2^2])=f(f-1)(f-4)(f-5)/12\\
&\dim([f-4,3,1])=f(f-1)(f-3)(f-6)/8\\
&\dim([f-4,1^4])=(f-1)(f-2)(f-3)(f-4)/24
\end{aligned}
$$

TABLE III. ISFs of $[f-1,1]\cdot[f-1,1]\downarrow[f]+[f-1,1]$.

	$[f]_1$	$[f-1,1]_2$
$[f-1,1]_2[f-1,1]_2$	$\sqrt{\frac{1}{f-1}}$	$\sqrt{\frac{f-2}{f-1}}$
$[f-1,1]_1[f-1,1]_1$	$\sqrt{\frac{f-2}{f-1}}$	$-\sqrt{\frac{1}{f-1}}$

$$G_{f-1}\left|\begin{matrix}124\\3\end{matrix}\right\rangle=\frac{1}{f-1}\left|\begin{matrix}124\\3\end{matrix}\right\rangle+\sqrt{\frac{f(f-2)}{(f-1)^2}}\left|\begin{matrix}123\\4\end{matrix}\right\rangle, \tag{28}$$

while the right-hand side of (25) becomes

$$\begin{aligned}&\left(-\frac{a_1}{(f-1)^2}+a_2\frac{f(f-2)}{(f-1)^2}+a_3\sqrt{\frac{f(f-3)}{(f-1)^4}}\right)\left|\begin{matrix}124\\3\end{matrix}\right\rangle\left|\begin{matrix}123\\4\end{matrix}\right\rangle\\&\quad+\left(a_1\frac{f(f-2)}{(f-1)^2}-\frac{a_2}{(f-1)^2}+a_3\sqrt{\frac{f(f-3)}{(f-1)^4}}\right)\left|\begin{matrix}123\\4\end{matrix}\right\rangle\left|\begin{matrix}124\\3\end{matrix}\right\rangle\\&\quad+\left(-a_1\sqrt{\frac{f(f-2)}{(f-1)^4}}-a_2\sqrt{\frac{f(f-2)}{(f-1)^4}}+a_3\frac{\sqrt{f(f-2)(f-3)}}{(f-1)^2}\right)\left|\begin{matrix}123\\4\end{matrix}\right\rangle\left|\begin{matrix}123\\4\end{matrix}\right\rangle\\&\quad+\left(a_1\sqrt{\frac{f(f-2)}{(f-1)^4}}+a_2\sqrt{\frac{f(f-2)}{(f-1)^4}}+\frac{a_3}{(f-1)^2}\sqrt{\frac{f-3}{f-2}}\right)\left|\begin{matrix}124\\3\end{matrix}\right\rangle\left|\begin{matrix}124\\3\end{matrix}\right\rangle-a_3\sqrt{\frac{1}{f-2}}\left|\begin{matrix}134\\2\end{matrix}\right\rangle\left|\begin{matrix}134\\2\end{matrix}\right\rangle.\end{aligned} \tag{29}$$

Combining (25) and (27)–(29), we get

$$a_1=a_2=-\sqrt{\frac{1}{(f-1)(f-2)}},\quad a_3=\sqrt{\frac{f(f-3)}{(f-1)(f-2)}}. \tag{30}$$

Using this procedure, one can obtain all the ISFs of $S_f\supset S_{f-1}$ with smallest f as long as the couplings and the reductions exist with the specific f value. In the evaluation, the unitary condition for the ISFs given in (24) and

$$\sum_{p_1p_2}\langle[\nu_1]_{p_1}[\nu_2]_{p_2}|[\nu]_p\rangle^2=1 \tag{31}$$

are always helpful. Some examples will be given in the next section.

TABLE IV. ISFs of $[f-1,1]\cdot[f-1,1]\downarrow[f-1,1]+[f-2,2]+[f-2,1,1]$.

III. SOME MULTIPLICITY-FREE ISFS OF $S_f \supset S_{f-1}$

In this section, ISFs of $S_f \supset S_{f-1}$ for the inner products $[f-1,1]\cdot[f-1,1]$, $[f-1,1]\cdot[f-2,2]$, and $[f-2,1,1]\cdot[f-1,1]$, all of which are multiplicity-free, will be tabulated using the procedure outlined in Sec. II. Actually, we do not need the inner product reduction rule of (4) in the calculation because the LEM will automatically generate the product irreps. Some inner product reduction rules of S_f are listed in Table I. One can check their validity by using the dimension formulas shown in Table II. The ISFs are tabulated in Tables III–IX. It should be noted that Table III should be evaluated with $f=3$ and the f-continuation by the LEM; Tables IV and V should be evaluated with $f=4$; Tables VI–IX with $f=5$; and Table X with $f=6$. The phase is chosen to be consistent with that of the CGCs of S_f given in Ref. 20. It is clear that one needs to work with higher rank cases for most other irreps. For example, one needs to work with $f=7$ for the inner product reduction $[f-2,2]\cdot[f-2,2]\downarrow[f-4,3,1]$, and with $f=8$ for $[f-2,2]\cdot[f-2,2]\downarrow[f-4,4]$. For any $f\geqslant 3$, one can always derive some ISFs of $S_f \supset S_{f-1}$ analytically by using the LEM outlined in Sec. II. Some trivial ISFs involved in the inner product reduction considered are

$$\langle[f-1,1]_1[f-1,1]_1|[f-2,2]_1\rangle=1,\quad \langle[f-1,1]_1[f-1,1]_1|[f-2,1,1]_1\rangle=1,$$

$$\langle[f-1,1]_1[f-2,2]_2|[f-1,1]_2\rangle=1,\quad \langle[f-1,1]_1[f-2,2]_1|[f-3,3]_1\rangle=1,$$

$$\langle[f-1,1]_1[f-2,2]_1|[f-3,2,1]_1\rangle=1,\quad \langle[f-2,1,1]_3[f-1,1]_1|[f-1,1]_2\rangle=-1,$$

$$\langle[f-2,1,1]_1[f-1,1]_1|[f-3,2,1]_1\rangle=1,\quad \langle[f-2,1,1]_1[f-1,1]_1|[f-3,1,1]_1\rangle=1.$$

IV. CONCLUSIONS

In this paper, an algebraic routine for the evaluation of analytical expressions for isoscalar factors (ISFs) of $S_f \supset S_{f-1}$ is formulated based on the linear equation method (LEM) and the analytical continuation of the rank f. As examples, ISFs of $S_f \supset S_{f-1}$ for the coupling $[f-1,1]\cdot[f-1,1]$, $[f-1,1]\cdot[f-2,2]$ and $[f-2,1,1]\cdot[f-2,1,1]$ are tabulated. It is obvious that the number of ISF tables is greatly reduced in comparison with numerical results calculated using other

TABLE X. $[f-1,1]\cdot[f-2,2]\downarrow[f-2,2]+[f-3,3]+[f-3,2,1]$.

$[f-1,1]_1[f-2,2]_1$	$\sqrt{\frac{f(f-5)(f-2)^2}{(f-1)^2(f-3)(f-4)}}$	$\sqrt{\frac{8(f-2)}{3(f-1)(f-3)(f-4)}}$	$\sqrt{\frac{f-5}{3(f-1)^2(f-3)}}$

methods. Though the method is only illustrated for multiplicity-free cases, the method can also be applied to cases with multiplicity. Similar to the LEM applied to the Hecke algebra case,[13] the same linear relation given by (12) hold for ISFs with different multiplicity labels in the case with multiplicity. The ISFs of $S_f \supset S_{f-1}$ with different multiplicity labels should be chosen to be orthogonal to each other. Therefore, the solution to the ISFs of $S_f \supset S_{f-1}$ will not be unique and depends on the phase convention and symmetry properties imposed on the ISFs.[13,20] However, one can use the procedure with smallest f and f-continuation outlined in this paper to derive the ISFs with multiplicity. It can be seen from Table I that the multiplicity case occurs for $f \geqslant 6$. Hence, one needs to work at least with $f \geqslant 6$ for ISFs with multiplicity, which will be studied in our next paper.

(Received 22 October 2001; accepted 1 September 2002)

Using the frame formalism we determine some possible metrics and metric-compatible connections on the noncommutative differential geometry of the real quantum plane. By definition, a metric maps the tensor product of two 1-forms into a ''function'' on the quantum plane. It is symmetric in a modified sense, namely in the definition of symmetry one has to replace the permutator map with a deformed map σ fulfilling some suitable conditions. Correspondingly, also the definition of the Hermitian conjugate of the tensor product of two 1-forms is modified (but reduces to the standard one if σ coincides with the permutator). The metric is real with respect to such modified $*$-structure. © *2002 American Institute of Physics.*

I. INTRODUCTION AND NOTATION

It is an old idea[1,2] that a noncommutative modification of the algebraic structure of space–time could provide a regularization of the divergences of quantum field theory, because the representations of noncommutative ''spaces'' have a lattice-like structure. The main aim of noncommutative geometry[3] is to endow such an algebra with additional structures (starting from a differential calculus), so as to build a bridge between the algebra and its ''geometrical'' interpretation. Since there is no unique prescription how to do this, it is useful to test possible prescriptions first on simpler models.

In this paper we choose as a noncommutative space(time) algebra model the so-called real quantum or Manin plane,[4] and as a differential calculus upon it the so-called Wess–Zumino calculus.[5,6] The latter is charaterized by the property that the relations defining the module of 1-forms are covariant under the action of the quantum group $SL_q(2)$ and homogeneous in the generators. We adopt the noncommutative geometry formalism of Refs. 7–11.

We start with a brief description of the latter. Let $\mathcal{A}$ be an algebra with differential calculus $\{\Omega^*(\mathcal{A}),d\}$[3] [here, $\Omega^*(\mathcal{A})$ denotes the algebra of differential forms on $\mathcal{A}$ and d the exterior derivative acting on the latter] and suppose that the calculus has a *frame*,[7,10] i.e., a basis of 1-forms θ^i $(i=1,2,\ldots,n)$ which commutes with the elements of the algebra

$$\theta^i f = f\theta^i. \tag{1.1}$$

The relation

$$df = \theta^i e_i f \tag{1.2}$$

(with $f \in \mathcal{A}$) defines a set of derivations e_i dual to θ^i, from which it follows that the module structure of $\Omega^1(\mathcal{A})$ is given by

$$f\,dg = \theta^i f e_i g, \quad dg\,f = \theta^i (e_i g) f.$$

We see that the $\mathcal{A}$-bimodule $\Omega^1(\mathcal{A})$ is free of rank n as a left or right module. It can therefore be identified with the direct sum

$$\Omega^1(\mathcal{A}) = \bigoplus_1^n \mathcal{A}, \tag{1.3}$$

of n copies of $\mathcal{A}$. In this representation θ^i is given by the element of the direct sum with the unit in the ith position and zero elsewhere. We shall refer to the integer n as the dimension of the geometry.

The wedge product π in $\Omega^*(\mathcal{A})$ fulfills relations of the form

$$\theta^i \theta^j \equiv \pi(\theta^i \otimes_{\mathcal{A}} \theta^j) = P^{ij}_{kl} \theta^k \theta^l \tag{1.4}$$

(we omit the symbol $\wedge$ of the wedge product), where P is a projector

$$P^{ij}_{mn} P^{mn}_{kl} = P^{ij}_{kl}, \tag{1.5}$$

with entries $P^{ij}_{kl} \in \mathcal{Z}(\mathcal{A})$. If in particular the wedge product is such that the θ^i anticommute, then P is the antisymmetric projector

$$P^{ij}_{kl} = \tfrac{1}{2}(\delta^i_k \delta^j_l - \delta^j_k \delta^i_l).$$

From (1.3) it follows immediately that the algebra and its differential calculus are related in a simple manner. Let $\wedge^*_P$ be the exterior algebra over $\mathbb{C}^n$ with the wedge product defined by (1.4). Then, with the identification (1.3) it follows that one can write

$$\Omega^*(\mathcal{A}) = \mathcal{A} \otimes \wedge^*_P. \tag{1.6}$$

Since the exterior derivative of θ^i is a 2-form, it can necessarily be written as

$$d\theta^i = -\tfrac{1}{2} C^i_{jk} \theta^j \theta^k,$$

where, because of (1.4), the structure elements can be chosen to satisfy the constraints

$$C^i_{jk} P^{jk}_{lm} = C^i_{lm}.$$

It will also be convenient to introduce the quantities

$$C^{ij}_{kl} = \delta^i_k \delta^j_l - 2P^{ij}_{kl}. \tag{1.7}$$

Then, from (1.5) we find that

$$C^{ij}_{kl} C^{kl}_{mn} = \delta^i_m \delta^j_n. \tag{1.8}$$

For simplicity, we shall further assume that the e_i are inner derivations: $e_i f = [\lambda_i, f]$, $\lambda_i \in \mathcal{A}$. From the θ^i we can construct a 1-form

$$\theta = -\lambda_i \theta^i \tag{1.9}$$

in $\Omega^1(\mathcal{A})$ which plays the role of a Dirac operator[3]

$$df = -[\theta, f]. \tag{1.10}$$

One can show that from the general consistency of the differential calculus it follows that

$$2P^{ij}_{kl}\lambda_i\lambda_j - F^i_{kl}\lambda_i - K_{kl} = 0, \tag{1.11}$$

for some array of elements $F^i_{jk}, K_{kl} \in \mathcal{Z}(\mathcal{A})$. In the cases which interest us here, the latter vanish.

In order to consistently define a covariant derivative, we need to introduce[8] a flip σ, i.e., a $\mathcal{A}$-bilinear map

$$\Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}) \overset{\sigma}{\to} \Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}). \tag{1.12}$$

In the case of the De-Rham calculus on the commutative algebra of functions on an ordinary manifold, it reduces to $\sigma(\omega \otimes_{\mathcal{A}} \omega') = \omega' \otimes_{\mathcal{A}} \omega$. In terms of the frame it is given by $S^{ij}_{kl} \in \mathcal{Z}(\mathcal{A})$, defined by

$$\sigma(\theta^i \otimes_{\mathcal{A}} \theta^j) = S^{ij}_{kl}\theta^k \otimes_{\mathcal{A}} \theta^l.$$

A covariant derivative on the module $\Omega^1(\mathcal{A})$ is a map

$$\Omega^1(\mathcal{A}) \overset{D}{\to} \Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}), \tag{1.13}$$

satisfying both a left and a right Leibniz rule. We use the ordinary left Leibniz rule and define the right Leibniz rule as

$$D(\xi f) = \sigma(\xi \otimes_{\mathcal{A}} df) + (D\xi) f, \tag{1.14}$$

for arbitrary $f \in \mathcal{A}$ and $\xi \in \Omega^1(\mathcal{A})$. The connection 1-form $\omega^i_k \equiv \omega^i_{jk}\theta^j$ is defined by

$$D\theta^i = \omega^i_k \otimes_{\mathcal{A}} \theta^k. \tag{1.15}$$

We shall impose the condition

$$\pi \circ (\sigma + 1) = 0, \tag{1.16}$$

so that the antisymmetric part of a symmetric tensor vanishes. This can be considered as a condition on the product or on the flip. In ordinary geometry it is the definition of π; a 2-form can be considered as an antisymmetric tensor. Because of this condition the torsion is a bilinear map.[11] The most general solution can be written in the form

$$1 + \sigma = (1 - \pi) \circ \tau, \tag{1.17}$$

where τ is an an arbitrary $\mathcal{A}$-bilinear map. Suppose that τ is invertible. Then, because of the identity

$$1 = \pi + (1 + \sigma) \circ \tau^{-1},$$

one can identify the second term on the right-hand side as the projection onto the symmetric part of the tensor product. The choice $\tau = 2$ yields the value $\sigma = 1 - 2\pi$. If τ is not invertible there arises the possibility that part of the tensor product is neither symmetric nor antisymmetric. Condition (1.16) applied to the tensor product $\theta^i \otimes_{\mathcal{A}} \theta^j$ becomes

$$P^{ij}_{lm} + S^{ij}_{hk}P^{hk}_{lm} = 0. \tag{1.18}$$

If the flip is such that in (1.11) $F^i_{jk} = K_{kl} = 0$, one possible linear connection is

$$\omega^i_{jk} = \lambda_l (S^{il}_{jk} - \delta^l_j \delta^i_k). \tag{1.19}$$

The corresponding connection 1-form is given by

$$\omega^i_k = \lambda_l S^{il}_{jk} \theta^j + \delta^i_k \theta. \tag{1.20}$$

The curvature of the covariant derivative D defined in (1.19) can be readily calculated. One finds the expression

$$\tfrac{1}{2} R^i_{jkl} = S^{im}_{rn} S^{np}_{sj} P^{rs}_{kl} \lambda_m \lambda_p . \tag{1.21}$$

This can also be written in the form

$$\tfrac{1}{2} R^i_{jkl} = - S^{im}_{rn} S^{np}_{sj} S^{rs}_{uv} P^{uv}_{kl} \lambda_m \lambda_p .$$

In complete analogy with the commutative case, a metric g can be defined as an $\mathcal{A}$-bilinear, nondegenerate map[11]

$$\Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}) \overset{g}{\to} \mathcal{A}, \tag{1.22}$$

and as such it can[12] be used to define a ''distance'' between ''points.'' It is important to notice here that the bilinearity is an alternative way of expressing locality. In ordinary differential geometry, if ξ and η are 1-forms then the value of $g(\xi \otimes \eta)$ at a given point depends only on the values of ξ and η at that point. Bilinearity

$$g(f\xi \otimes_{\mathcal{A}} \eta h) = f\, g(\xi \otimes_{\mathcal{A}} \eta)\, h \quad \forall f, h \in \mathcal{A},$$

is an exact expression of this fact. In general the algebra introduces a certain amount of nonlocality via its nontrivial commutation relations, and it is important to assure that all geometric quantities be just that nonlocal and not more. Without the bilinearity condition it is not possible to distinguish, for example, in ordinary space–time a metric which assigns a function to a vector field in such a way that the value at a given point depends only on the vector at that point from one which is some sort of convolution over the entire manifold.

We define frame components of the metric by

$$g^{ij} = g(\theta^i \otimes_{\mathcal{A}} \theta^j).$$

They lie necessarily in the center $\mathcal{Z}(\mathcal{A})$ of the algebra. The condition that (1.19) be metric-compatible can be written as[10]

$$S^{im}_{ln} g^{np} S^{jk}_{mp} = g^{ij} \delta^k_l . \tag{1.23}$$

As a way to remember this seemingly odd condition, introduce a ''covariant derivative'' $D_i X^j$ of a ''vector'' X^j. The covariant derivative $D_i(X^j Y)$ of the product of X^j by a ''field'' Y must then be defined as

$$D_i(X^j Y) = D_i X^j Y + S^{jl}_{im} X^m D_l Y,$$

since there is a ''flip'' as the index on the derivation crosses the index on the first ''vector.'' If we apply this rule again to $Y = Y^k Z$, with Y^k also a vector and Z another field, we find

$$D_i(X^j Y^k Z) = D_i(X^j Y^k) Z + S^{jl}_{im} X^m Y^p S^{kn}_{lp} D_n Z.$$

Since g^{jk} is a ''tensor,'' the ''crossing rule'' is the same as for $X^j Y^k$

$$D_i(g^{jk}Z)=(D_i g^{jk})Z+S_{im}^{jl}g^{mp}S_{lp}^{kn}D_n Z.$$

Therefore, (1.23) is equivalent to the usual condition

$$D_i g^{jk}=0,$$

that the connection be compatible with the metric.

We shall require that the metric be symmetric in the sense

$$g\circ\pi=0, \tag{1.24}$$

that it annihilates the 2-forms. This condition applied to the tensor product $\theta^i\otimes_{\mathcal{A}}\theta^j$ becomes

$$P_{lm}^{ij}g^{lm}=0. \tag{1.25}$$

Let us now briefly summarize the additional conditions which arise from the requirement of existence of $*$-structures. Assume $\mathcal{A}$ is a $*$-algebra. If[13,14] the $*$-structure of $\mathcal{A}\equiv\Omega^0(\mathcal{A})$ can be extended to a $*$-structure of $\Omega^*(\mathcal{A})$, and

$$(df)^*=df^*, \tag{1.26}$$

the differential calculus is said to be real. A sufficient condition for (1.26) to hold[15] is that the λ_i are anti-Hermitian (with respect to the $*$ of $\mathcal{A}$) and the θ^i are Hermitian [with respect to the extension of $*$ to $\Omega^*(\mathcal{A})$], so that the ''Dirac operator'' θ is anti-Hermitian.

To obtain a real covariant derivative it is necessary first of all that the flip σ satisfies a reality constraint (see Ref. 15), which takes the simple form

$$(S_{kl}^{ji})^*S_{mn}^{lk}=\delta_m^i\delta_n^j, \tag{1.27}$$

if $(\theta^i)^*=\theta^i$. Moreover, the connection 1-form ω_k^i and the flip σ must satisfy a condition[15] involving both, which we do not report here because it is automatically satisfied in the case of the connection (1.19). In order to define a real metric, one has to use σ to impose the reality condition of Ref. 15, which takes the simple form

$$S_{kl}^{ij}g^{kl}=(g^{ji})^*, \tag{1.28}$$

in the case of a real frame. This is a combination of a ''twisted'' symmetry condition and the ordinary condition of reality on a complex matrix. It can also be written as an ordinary condition of symmetry and a twisted definition of reality. The map σ is also involved[15] in the reality condition for the curvature or for the covariant derivative acting on tensor powers of $\Omega^1(\mathcal{A})$. The latter implies the former, and takes the form of the braid equation

$$S_{12}S_{23}S_{12}=S_{23}S_{12}S_{23}, \tag{1.29}$$

where

$$(S_{12})_{def}^{abc}:=S_{de}^{ab}\delta_f^c, \quad (S_{23})_{def}^{abc}:=\delta_d^a S_{ef}^{bc}.$$

The ''infinitesimal distance'' ds corresponding to the metric g is introduced through the relation

$$ds^2=g_{ij}\theta^i\otimes_{\mathcal{A}}\theta^j, \tag{1.30}$$

where $g_{ij}\in\mathcal{A}$ are the matrix elements of the inverse matrix of $\|g^{ij}\|$. Every representation of $\mathcal{A}$ yields a distance between ''points'' because of (1.6). Let $dt=\xi_i\theta^i\in\Omega^1(\mathcal{A})$ be an exact form, which we can think of as an infinitesimal displacement along an axis t, and suppose that $|p\rangle$ is a

common eigenvector of all the ξ_i: $\xi_i|p\rangle=\tilde{\xi}_i|p\rangle$. This would be the case, for example, if only one of them is not equal to zero. We define the element of distance δs along the "coordinate" t at the state $|p\rangle$ by the equation

$$(\delta s)^2=\langle p|ds^2|p\rangle=g^{ij}\tilde{\xi}_i\tilde{\xi}_j.$$

Let $\hbar$ be the length scale at which points become fuzzy and K^{-1} the scale at which the curvature effects become important. The definition of g which we have given is unambiguous but the interpretation of the norm $|\delta s|^2$ of an infinitesimal displacement as a distance can be only made within the range

$$\hbar\ll|\delta s|^2\ll K^{-1}.$$

If the displacement is too small then the points are not defined; if it is too large then an integral must be taken. The second problem was solved by Leibniz/Newton; the first is a feature, not a bug, of noncommutative geometry. We are especially interested in the region $|\delta s|^2\simeq\hbar$ where the noncommutative effects become of interest.

There exist other definitions of distance. One proposal[16–18] uses the Dirac operator to define distance on the space of pure states. Several authors[19,20] do not consider the bilinearity condition we have imposed as important and several[21–27] consider the invariance under the coaction of a quantum group as essential.

It is sometimes convenient to write the metric as a sum

$$g^{ij}=g_S^{ij}+g_A^{ij},$$

of a symmetric and an antisymmetric part (in the usual sense of the word). The inverse matrix we write as a sum

$$g_{ij}=\eta_{ij}+B_{ij},$$

of a symmetric and an antisymmetric term. We shall choose as normalization when possible the condition that η_{ij} be the standard Minkowski or Euclidean form.

II. THE WESS–ZUMINO CALCULUS

The extended real quantum plane is the $*$-algebra $\mathcal{A}$ generated by Hermitian elements $(x^i)=(x,y)$

$$x^*=x \quad y^*=y, \tag{2.1}$$

together with their inverses, fulfilling the relation

$$xy=\tilde{q}yx, \tag{2.2}$$

with $|\tilde{q}|=1$ and $q\neq\pm1$, as well as the usual relations between inverses. We call it *extended* because in the original version[4] the inverses x^{-1},y^{-1} were not included; the word *real* refers to the $*$-structure (2.1). The center of $\mathcal{A}$ is trivial, $\mathcal{Z}(\mathcal{A})=\mathbb{C}$. We now show how the Wess–Zumino calculus[5] fits in the scheme described in the previous section. We define, for $\tilde{q}^4\neq1$

$$\lambda_1=-\epsilon_1\frac{\tilde{q}^4}{\tilde{q}^4-1}x^{-2}y^2, \quad \lambda_2=\epsilon_2\frac{\tilde{q}^2}{\tilde{q}^4-1}x^{-2}.$$

There is an ambiguity in this definition due to the fact that the defining relations (2.2) are homogeneous and which we reduce to a sign: $\epsilon_a = \pm 1$. The extra minus is a "historical convenience." The important fact is that the λ_a are singular in the limit $\tilde{q} \to 1$ and that they are anti-Hermitian if $\tilde{q}$ is of unit modulus, as we are assuming. We find for $\tilde{q}^2 \neq -1$

$$e_1 x = \epsilon_1 \frac{\tilde{q}^2}{(\tilde{q}^2+1)} x^{-1} y^2, \quad e_1 y = \epsilon_1 \frac{\tilde{q}^4}{\tilde{q}^2+1} x^{-2} y^3,$$
$$e_2 x = 0, \quad e_2 y = -\epsilon_2 \frac{\tilde{q}^2}{\tilde{q}^2+1} x^{-2} y. \tag{2.3}$$

These derivations are again extended to arbitrary polynomials in the generators by the Leibniz rule. Using them and (1.9), (1.10), we find

$$dx = \frac{\tilde{q}^2}{(\tilde{q}^2+1)} x^{-1} y^2 \epsilon_1 \theta^1, \quad dy = \frac{\tilde{q}^2}{\tilde{q}^2+1} x^{-2} y (\tilde{q}^2 y^2 \epsilon_1 \theta^1 - \epsilon_2 \theta^2), \tag{2.4}$$

and solving for the θ^i we obtain

$$\epsilon_1 \theta^1 = (\tilde{q}^2+1) x y^{-2} dx, \quad \epsilon_2 \theta^2 = -(\tilde{q}^2+1) x (x y^{-1} dy - dx).$$

The module structure which follows from the condition (1.1) that the θ^i commute with the elements of the algebra is equivalent to the Wess–Zumino relations[5]

$$x dx = \tilde{q}^2 dx\, x, \quad x\, dy = \tilde{q}\, dy\, x + (\tilde{q}^2 - 1) dx\, y,$$
$$y dx = \tilde{q}\, dx\, y, \quad y\, dy = \tilde{q}^2 dy\, y. \tag{2.5}$$

One can show that they are invariant under the coaction of the quantum group $SL_q(2,\mathbb{C})$. This invariance was encoded in the choice of λ_a.

Consider the elements

$$u := \epsilon_2 \tilde{q}^{-2} x^2, \quad v := \epsilon_1 x^2 y^{-2}. \tag{2.6}$$

We shall see that each of the four possible choices of sign pairs corresponds to an identification of x and y as the coordinates of one of the four regions on $\mathbb{R}^2$ defined by the light cone of a metric with Minkowski signature. The u, v fulfill the quadratic commutation relation

$$uv = qvu, \tag{2.7}$$

where $q := \tilde{q}^{-4}$. They and their inverses generate a slightly smaller algebra than $\mathcal{A}$. One also finds that (2.5) becomes

$$u du = q^{-1} du u, \quad u dv = q dv u,$$
$$v du = q^{-1} du v, \quad v dv = q dv v. \tag{2.8}$$

In terms of the new generators, the θ^i become

$$\theta^1 = q^{-1} v u^{-1} du, \quad \theta^2 = u v^{-1} dv. \tag{2.9}$$

What we have done in fact is use the λ_a^{-1} as generators of the algebra and the differential calculus; otherwise, nothing has been changed. The form θ is most conveniently expressed in terms of the λ_a. Since

$$\lambda_1=\frac{1}{1-q^{-1}}v^{-1},\quad \lambda_2=-\frac{1}{1-q^{-1}}u^{-1}, \tag{2.10}$$

we find that

$$\theta=\frac{1}{1-q}(u^{-1}du-qv^{-1}dv).$$

It is an anti-Hermitian closed form with vanishing square

$$d\theta=0,\quad (\theta)^2=0. \tag{2.11}$$

The volume element is a product of two exact forms

$$\theta^1\theta^2=du\,dv.$$

The structure of the exterior algebra is given by the relations

$$(\theta^1)^2=0,\quad (\theta^2)^2=0,\quad \theta^1\theta^2+q\theta^2\theta^1=0. \tag{2.12}$$

This can be written in the form (1.4) with

$$P=\tfrac{1}{2}\begin{pmatrix}0&0&0&0\\0&1&-q&0\\0&-q^{-1}&1&0\\0&0&0&0\end{pmatrix}. \tag{2.13}$$

If we reorder the indices $(11,12,21,22)=(1,2,3,4)$, then the C^{ij}_{kl} introduced in (1.7) is given by the expression

$$C=\begin{pmatrix}1&0&0&0\\0&0&q&0\\0&q^{-1}&0&0\\0&0&0&1\end{pmatrix}.$$

That is, $C^{12}_{21}=q$ and $C^{21}_{12}=q^{-1}$.

The reality of the differential implies that the structure elements must satisfy the conditions

$$((C^i_{jk})^*+C^i_{jk})P^{jk}_{lm}=0,$$

from which it follows that

$$(C^i_{21})^*=-C^i_{12}=q^{-1}C^i_{21},\quad (C^i_{12})^*=-C^i_{21}=qC^i_{12}.$$

More precisely, the independent coefficients are given by

$$C^1_{12}=(q^{-1}-1)\lambda_2,\quad C^2_{12}=(q^{-1}-1)\lambda_1. \tag{2.14}$$

The C^i_{jk} do not depend on the sign ambiguities. With the generators

$$t=\frac{1}{\sqrt{2}}(u+v),\quad r=\frac{1}{\sqrt{2}}(u-v), \tag{2.15}$$

the four possible sign combinations can be written as

$$\epsilon_1=\epsilon_2:\quad \mathrm{sgn}(t)=\epsilon_1,\quad \epsilon_1=-\epsilon_2:\quad \mathrm{sgn}(r)=\epsilon_2.$$

We shall later in Sec. V introduce a light-cone and interpret these relations in terms of space-like and time-like.

Introduce the notation

$$X=\begin{pmatrix} t \\ r \end{pmatrix},\quad \Xi=\begin{pmatrix} dt \\ dr \end{pmatrix},\quad Q=\begin{pmatrix} \cos(\pi\gamma) & i\sin(\pi\gamma) \\ i\sin(\pi\gamma) & \cos(\pi\gamma) \end{pmatrix}\quad q=e^{2\pi i\gamma}.$$

Then, Q is unitary. The commutation relations in $\Omega^*(\mathcal{A})$ can be written in the form

$$X^t(Q\sigma_2)X=0,\quad X\Xi^t=\Xi(Q^2X)^t,\quad \Xi^tQ\Xi=0. \tag{2.16}$$

The σ_2 is the second Pauli matrix.

There are alternative $*$-structures which require a real q. One can impose the conditions $u^*=v$, $v^*=u$. In terms of the original variables x and y, this implies that

$$x^*=\pm\tilde{q}^{1/2}xy^{-1},\quad y^*=y.$$

It follows that the frame satisfies

$$(\theta^1)^*=\theta^2,\quad (\theta^1)^*=\theta^2,$$

and so one can introduce a real frame by taking the real and imaginary parts or consider the resulting structure as a q-deformed complex line. This is better with the change of generators

$$t=\frac{1}{\sqrt{2}}(u+v),\quad r=\frac{i}{\sqrt{2}}(u-v). \tag{2.17}$$

It is equivalent to a replacement $\gamma\mapsto i\gamma$ in the formula (2.16).

III. REPRESENTATIONS

An extensive discussion of the $*$-representations of the algebra $\mathcal{A}$ for $|\tilde{q}|=1$ and $q\neq\pm1$ has been given.[28] We recall parts of it to illustrate our interpretation of the geometry. It is easy to see that there can be no normed basis with u or v diagonal. Suppose in fact that there is a basis with $v|j\rangle=v_j|j\rangle$. Since v is Hermitian the eigenvalue $v_j\in\mathbb{R}$. Using the commutation relations one sees that $v(u|j\rangle)=q^{-1}v_j(u|j\rangle)$, and so $u|j\rangle$ is also an eigenvector with eigenvalue $q^{-1}v_j\notin\mathbb{R}$. One concludes, therefore, that $u|j\rangle\notin\mathcal{H}$. More specifically, one can consider $\mathcal{H}=L^2(\mathbb{R})$ with the plane-wave basis $|k\rangle=e^{ikx}$. The operator $u=-i\partial_x$ is Hermitian on a dense subspace of $\mathcal{H}$ and diagonal: $u|k\rangle=k|k\rangle$. We can formally set

$$v|k\rangle=|qk\rangle=e^{-iqkx}$$

in order to have the correct commutation relations, but u is not properly defined on the plane-wave basis.

As solution to this problem we restrict our representation space to the positive real line $\mathbb{R}^+$ with free boundary condition at $x=0$. The Laplace transform replaces the Fourier transform and so we choose as basis $|k\rangle=e^{-kx}$ for $k\in\mathbb{C}$ with $\Re k>0$. We need in fact represent only one (at a time) of the four regions defined by the light "cone" and we choose the one defined by $\epsilon_1=\epsilon_2=1$. Our sign conventions were partly dictated by the desire that this be the forward light cone. We choose[28] then two positive real numbers α and β with $\alpha\beta=\gamma$, and we define on the Hilbert space $L^2(\mathbb{R}^+)$

$$(uf)(x)=f(x+i\beta),\quad (vf)(x)=e^{-2\pi\alpha x}f(x).$$

Both u and v are formally Hermitian and bounded. It is more convenient to express them in terms of the Laplace transform, which we recall is given by

$$F(k)=(Lf)(k)=\int_0^\infty f(x)e^{-kx}dx, \quad f(x)=(L^{-1}F)(x)=\frac{1}{2\pi i}\int_{a+i\infty}^{a-i\infty}F(k)e^{kx}dk,$$

where a depends on the growth rate of the function. We have then

$$(uF)(k)\equiv(L(uf))(k)=e^{i\beta k}F(k), \quad (vF)(k)\equiv(L(vf))(k)=F(k+2\pi\alpha).$$

In particular, these transformation formulas are valid on the basis $|k\rangle=e^{-kx}$. The operators u and v are well-defined and positive for $\Re k>0$.

IV. THE METRICS AND THEIR CONNECTIONS

We now determine some possible metrics and metric-compatible connections on the real quantum plane. We require them to fulfill all or at least part of the conditions listed in Sec. I, namely (1.18), (1.29), (1.25), (1.23), (1.27), (1.28).

To shorten the notation, we shall often perform the following change of index notation: $(11,12,21,22)\to(1,2,3,4)$. Then, the condition (1.23) can be written in the matrix form

$$\begin{pmatrix} S_1^1 & S_2^1 & S_3^1 & S_4^1 \\ S_1^2 & S_2^2 & S_3^2 & S_4^2 \\ S_1^3 & S_2^3 & S_3^3 & S_4^3 \\ S_1^4 & S_2^4 & S_3^4 & S_4^4 \end{pmatrix}\times(S_{(g)})=\begin{pmatrix} g^1 & 0 & g^3 & 0 \\ 0 & g^1 & 0 & g^3 \\ g^2 & 0 & g^4 & 0 \\ 0 & g^2 & 0 & g^4 \end{pmatrix}, \tag{4.1}$$

where we have introduced the matrix $S_{(g)}$ defined by

$$S_{(g)}=\begin{pmatrix} S_1^1g^1+S_2^1g^3 & S_3^1g^1+S_4^1g^3 & S_1^3g^1+S_2^3g^3 & S_3^3g^1+S_4^3g^3 \\ S_1^1g^2+S_2^1g^4 & S_3^1g^2+S_4^1g^4 & S_1^3g^2+S_2^3g^4 & S_3^3g^2+S_4^3g^4 \\ S_1^2g^1+S_2^2g^3 & S_3^2g^1+S_4^2g^3 & S_1^4g^1+S_2^4g^3 & S_3^4g^1+S_4^4g^3 \\ S_1^2g^2+S_2^2g^4 & S_3^2g^2+S_4^2g^4 & S_1^4g^2+S_2^4g^4 & S_3^4g^2+S_4^4g^4 \end{pmatrix}. \tag{4.2}$$

Using the expression (2.13) for P, the condition (1.25) becomes

$$g^2=qg^3. \tag{4.3}$$

The consistency condition (1.16) is equivalent to the conditions

$$S_3^1=qS_2^1, \quad S_3^2=q(S_2^2+1), \quad S_3^3=qS_2^3-1, \quad S_3^4=qS_2^4. \tag{4.4}$$

The equations to be solved then are Eqs. (4.1), (4.3), and (4.4). We are especially interested in real solutions, which satisfy therefore also (1.27) and (1.28). We have found that there are several types of solutions, four of which we shall describe in the following subsections. One can show that there are no solutions with $\tau=2$. A complete classification has been given[29] of the solutions to the braid equation as well[30,31] as of those which satisfy a weaker modified equation.

If one considers locality as of importance only in the commutative limit, then there is no restriction on the coefficients of the metric, except that they be local functions in this limit. If one considers locality as of importance even before the limit but is willing to accept a metric which is real and symmetric only in the commutative limit, then the most general line element one can write is of the form

$$ds^2=g_{ij}\theta^i\otimes\theta^j.$$

The g_{ij} is a real symmetric matrix (in the sense we have defined it) and the moving frame θ^i is defined by

$$\theta^1 = v u^{-1} du, \quad \theta^2 = u v^{-1} dv.$$

The line element (1.30) then becomes

$$ds^2 = g_1 v^2 u^{-2}\, du^2 + 2 g_2 du\, dv + g_4 u^2 v^{-2}\, dv^2. \tag{4.5}$$

The product here is the symmetrized tensor product; not the exterior product.

The associated metric connection is given by the structure functions

$$C^1_{12} = u^{-1}, \quad C^2_{12} = -v^{-1}.$$

If we interpret the matrix g_{ij} as the components of the Killing metric on $SO(2)$ or $SO(1,1)$ then we can use it to calculate the connection form. The result will be of the form

$$\omega^i_j = A^i_{jk} u^{-1} \theta^k + B^i_{jk} v^{-1} \theta^k,$$

with $g_{ik}\omega^k_j$ antisymmetric in the two indices. The Gaussian curvature K is a second-order homogeneous polynomial in the variables u^{-1} and v^{-1}

$$K = \kappa_{11} u^{-2} + 2\kappa_{12} u^{-1} v^{-1} + \kappa_{22} v^{-2}.$$

A. Solution I

A one-parameter family of solutions of conditions (1.18), (1.25), (1.23), can be found with a Minkowski-signature metric. For the particular value $\zeta = 0$ of the parameter also the braid relation (1.29) and the reality conditions (1.27), (1.28) are fulfilled. These are the most interesting solutions.

With the convenient normalization of the metric so that $g^3 = q^{-1/2}$ the flip is given by the matrix

$$S = \begin{pmatrix} q & -q^{-1/2}\zeta & -q^{1/2}\zeta & q^{-1}(q^2-1)^{-1}\zeta^2(q^2+1) \\ 0 & 0 & q & -q^{-1/2}\zeta \\ 0 & q^{-1} & 0 & q^{-3/2}\zeta \\ 0 & 0 & 0 & q^{-1} \end{pmatrix},$$

where $\zeta \in \mathbb{C}$. It tends to the ordinary flip as $q \to 1$ if $\zeta = 0$; only for $\zeta = 0$ it is a solution to the braid equation (1.29). The corresponding metric is given by

$$g^{ij} = \begin{pmatrix} (q-1)^{-1}\zeta & q^{1/2} \\ q^{-1/2} & 0 \end{pmatrix}. \tag{4.6}$$

From (4.3) one sees that it is σ-symmetric for all g^1 and real if $g^1 = 0$ (i.e., $\zeta = 0$). In this case S is given by

$$S = \begin{pmatrix} q & 0 & 0 & 0 \\ 0 & 0 & q & 0 \\ 0 & q^{-1} & 0 & 0 \\ 0 & 0 & 0 & q^{-1} \end{pmatrix}. \tag{4.7}$$

The σ and π are related as in (1.17) with $T^{ij} := \tau(\theta^i \otimes_{\mathcal{A}} \theta^j)$

$$T=\begin{pmatrix} 1+q & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 1+q^{-1} \end{pmatrix}. \tag{4.8}$$

The fact that T is not proportional to the identity is due to the fact that the map $(1+\sigma)/2$ is not a projector and that we would like it to act as such and be the complement to π. The metric matrix is of indefinite signature and in ''light-cone'' coordinates. If we use the expression $q=e^{2\pi i\eta}$, we find that

$$g_S^{ij}=\cos(\pi\eta)\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad g_A^{ij}=i\sin(\pi\eta)\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{4.9}$$

The inverse metric components are defined by the equation

$$g_{ij}g^{jk}=\delta_i^k.$$

This matrix also can be split. If we rescale so that the symmetric part is of the standard form, we find

$$(\eta_{ij})=\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad (B_{ij})=i\tan(\pi\zeta)\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

For the choice (4.7) of the flip (i.e., for $\zeta=0$) the metric connection (1.20) is given by

$$(\omega_j^i)=(1-q)\begin{pmatrix} 1 & 0 \\ 0 & -q^{-1} \end{pmatrix}\theta,$$

and has vanishing curvature, because of the identities (2.11) and (1.29). This can be shown by an argument already used in Refs. 32 and 33. In other words, in this case the quantum plane is flat. In the commutative limit the line element is given by

$$ds^2=g_{ij}\theta^i\otimes\theta^j=2\,\theta^1\otimes\theta^2=2\,du\otimes dv=dt^2-dr^2.$$

The frame is singular along the light cone through the origin [see (2.9)]. Suppose $\epsilon_1=\epsilon_2=1$. If in a representation one forces x and y to be Hermitian, then the u and v must be positive operators. One concludes then that $t>|r|$; the geometry describes only the forward light cone through the origin. The other three regions are given by the other three possible combinations of signs.

B. Solution II

A family of solutions defined by flips which are solutions to (1.18), (1.27), but not to the braid equation (1.29) is given by

$$S=\begin{pmatrix} -q^2 & 0 & 0 & 0 \\ 0 & 0 & q & 0 \\ 0 & -q^{-2} & -1-q^{-1} & 0 \\ 0 & 0 & 0 & q^{-1} \end{pmatrix}. \tag{4.10}$$

The metric is given again by (4.6) with $\zeta=0$, and fulfills (1.23), (1.25), but not (1.28). The metric connection (1.20) is

$$(\omega_j^i)=(1+q^2)\begin{pmatrix}1 & 0\\ 0 & q^{-2}\end{pmatrix}\quad\theta+(1+q^{-1})\begin{pmatrix}0 & 0\\ -1 & 0\end{pmatrix}\quad\lambda_1\theta^2+(q+1)\begin{pmatrix}q & 0\\ 0 & q^{-2}\end{pmatrix}\quad\lambda_2\theta^2.$$

The curvature is equal to

$$\Omega_j^i=-(q^2-1)q^{-3}(1+q+q^2)\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}(\lambda_1)^2\theta^1\theta^2.$$

It diverges as $(q-1)^{-1}$ when $q\to 1$. This is then the case of a regular metric which has a singular metric connection.

C. Solution III

A third family

$$S=\frac{1}{q^2+1}\begin{pmatrix}2q & 0 & 0 & 1-q^2\\ 0 & 1-q^2 & 2q & 0\\ 0 & 2q & q^2-1 & 0\\ q^2-1 & 0 & 0 & 2q\end{pmatrix},\tag{4.11}$$

$$g^{ij}=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},$$

fulfills (1.18), (1.25), (1.23), the reality condition (1.27) but not the one (1.28) nor the braid relation (1.29). The latter are fulfilled for $q=\pm 1$. For $q=-1$ this means the connection form is imaginary in the usual sense of the word (since so are the λ_i).

The compatible connection (1.20) form is

$$(\omega_j^i)=\frac{(q-1)^2}{q^2+1}\delta_j^i\theta+\frac{q^2-1}{q^2+1}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\quad(\lambda_2\theta^1+\lambda_1\theta^2).$$

The curvature 2-form is

$$(\Omega_j^i)=\frac{(q^2-1)}{(q^2+1)^2}\left\{-q^{-1}(q^2-1)^2\delta_j^i\lambda_1\lambda_2+2(q-1)\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\quad((\lambda_1)^2+(\lambda_2)^2)\right\}\theta^1\theta^2.$$

In the limit $q\to 1$ this becomes

$$(\Omega_j^i)=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\quad(u^{-2}+v^{-2})\theta^1\theta^2.$$

D. The $\hat{R}$-matrix "solution"

Finally, one might ask whether one can find a solution (S,g) using the formalism of Faddeev *et al.*,[34] as has been done[32,33] for the q-Euclidean spaces $\mathbb{R}_q^n$ with $n>2$. This would imply an S proportional to the braid matrix $\hat{R}$ of $SL_q(2)$ or to its inverse. One can show that there is a solution only if one admits nonsymmetry metrics.

We recall that the braid matrix which defines the Hopf algebra $SL_q(2)$

$$\hat{R}_q=\begin{pmatrix} q & 0 & 0 & 0 \\ 0 & q-q^{-1} & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & q \end{pmatrix},$$

fulfills the braid relation, admits the projector decomposition

$$\hat{R}_q=qP_{s,q}-q^{-1}P_{a,q},$$

and fulfills the (1.29) relations

$$\hat{R}_q^{\pm 1}{}^{ij}_{hk}\varepsilon_q^{kl}\hat{R}_q^{\pm 1}{}^{rs}_{jl}=q^{\mp 1}\varepsilon_q^{ir}\delta_h^s, \quad \hat{R}_q^{\pm 1}{}^{ij}_{hk}\varepsilon_q^{hk}=-q^{\mp 1}\varepsilon_q^{ij}, \tag{4.12}$$

where ε_q^{ij} is the q-deformed epsilon tensor

$$\varepsilon_q^{ij}=\begin{pmatrix} 0 & -q^{-1/2} \\ q^{1/2} & 0 \end{pmatrix}.$$

So, one finds

$$P^{ij}_{a,qhk}=(\varepsilon^{lm}\varepsilon_{lm})^{-1}(\varepsilon^{ij}\varepsilon_{hk})=\frac{1}{q+q^{-1}}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & q^{-1} & -1 & 0 \\ 0 & -1 & q & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

By a straightforward computation, one can check that (2.12) can be given the form (1.4) by setting

$$P=P_{a,q^{-1}}.$$

The first relation in (4.12) suggests that we make the ansatz $S\propto\hat{R}^{\pm 1}_{q^{-1}}$, $g^{ij}\propto\varepsilon^{ij}_{q^{-1}}$, so that we can fulfill (1.23) at least up to a conformal factor. Equation (1.16) fixes the first proportionality constant to be either

$$S=q^{-1}\hat{R}_{q^{-1}} \quad \text{or} \quad S=q(\hat{R}_{q^{-1}})^{-1},$$

which respectively implies that

$$S^{im}_{ln}g^{np}S^{jk}_{mp}=q^{-1}g^{ij}\delta^k_l, \quad S^{im}_{ln}g^{np}S^{jk}_{mp}=qg^{ij}\delta^k_l, \tag{4.13}$$

i.e., we indeed fulfill (1.23) only up to a conformal factor $q^{\pm 1}$, and

$$S^{ij}_{hk}g^{hk}=-g^{ij}. \tag{4.14}$$

This ''antisymmetry'' relation is to be contrasted with Eq. (1.24), which, with the above choice of S, amounts to replacing at the right-hand side of (4.14) -1, respectively, by q^{-2} or q^2, as can be seen writing P as a combination of S and of the identity matrix. Using the fact that $|q|=1$ and $\hat{R}^{ij}_{q^{-1}hk}=\hat{R}_q^{-1}{}^{ji}_{kh}$,[34] one can easily see that the reality conditions (1.27) and (1.28) are satisfied. The curvature (1.21) can easily be calculated to be zero using the conditions $K^{ij}=0$ and $F^h_{ij}=0$ as well as the fact that P_q is a polynomial in S, which it turn fulfills the braid equation.

E. Other "solutions"

There are a certain number of partial solutions which are unsatisfactory for some reason or other. As an example, to underline the possibility of exotic metrics which are both symmetric and antisymmetric according to our definitions, we consider σ defined by the matrix

$$S=\begin{pmatrix} 0 & 0 & 0 & \zeta \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ \zeta^{-1} & 0 & 0 & 0 \end{pmatrix},$$

where $\zeta \in \mathbb{R}$ is a parameter. This value of S is a solution to the braid equation. The σ and π are related as in (1.17) with (using the same conventions)

$$\mathbf{1}+S=T=\begin{pmatrix} 1 & 0 & 0 & \zeta \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \zeta^{-1} & 0 & 0 & 1 \end{pmatrix}. \tag{4.15}$$

This means that τ is not invertible and the case is degenerate. The unpleasant thing here is that $(1+\sigma)/2$ and π do not add up to the identity map. The metric is given by

$$g^{ij}=i\begin{pmatrix} 1 & 0 \\ 0 & -\zeta^{-1} \end{pmatrix}. \tag{4.16}$$

One has $\tau=1+\sigma$ and the flip is degenerate. Instead of interchanging g^2 and g^3, as does the ordinary flip, it interchanges g^1 and g^4. It also changes the sign, which accounts for the i in the metric components. Also, $g\bigcirc(1+\sigma)=0$ so in a certain sense the metric has vanishing symmetric as well as antisymmetric parts. We refer to σ nonetheless as a flip because it satisfies (1.16).

The linear connection (1.19) is given by

$$\omega^i_j=\delta^i_j\theta+\begin{pmatrix} 0 & 1 \\ -\zeta^{-1} & 0 \end{pmatrix} \quad (\zeta\lambda_1\theta^2-\lambda_2\theta^1).$$

The curvature is given by

$$\Omega^i_j=q^{-1}(q^2-1)\,\delta^i_j\lambda_1\lambda_2\theta^1\theta^2.$$

The connection is singular in the commutative limit as is the curvature. Because of (1.24) it cannot be satisfied for any curvature which is proportional to the metric.

V. JORDANIAN DEFORMATION

It has been shown recently (See, for example, Aneva *et al.*[31]) that the Jordanian deformation is a singular limit of a family of q deformations. The transformation from the set of generators of one algebra to the other has also been studied in some detail.[35] We can now discuss to what extent the limit can be understood in a geometric manner. We recall that the Jordanian deformation is defined using a parameter h and that the generators (x',y') satisfy the commutation relations $[x',y']=hy'^2$. The differential calculus is given by two elements λ'_a similar to the λ_a which satisfy the $SL(2,\mathbb{R})$ relation $[\lambda'_1,\lambda'_2]=\lambda'_1$, a relation which is not quadratic. This must be compared with the quadratic relation $\lambda_1\lambda_2=q^{-1}\lambda_2\lambda_1$ satisfied by the elements (2.10). We must find a smooth map from one algebra into the other, that is, one which respects the commutation relations between the elements which define the derivations dual to the frame. Consider[35] the map

$$\lambda_1' = h_0^{-1}\lambda_1, \quad \lambda_2' = h_0^{-1}\lambda_2 - \frac{1}{2}h^{-1}h_0, \quad h_0 = \frac{2h}{1-q}. \tag{5.1}$$

This change defines a deformation of the differential calculus. From the commutation relations of the λ_i, we deduce that

$$[\lambda_1', \lambda_2'] = h_0^{-2}[\lambda_1, \lambda_2] = h_0^{-2}(1-q)\lambda_1\lambda_2 = \lambda_1' + (1-q)\lambda_1'\lambda_2'.$$

In the (singular) limit when $q \to 1$ the differential calculus tends to that of the Jordanian deformation.

The relations between the two calculi can be written in terms of a diagram

$$\begin{array}{ccc} (x,\ y) & \to & (u,\ v) = (\epsilon_2 q^{1/2} x^2,\ \epsilon_1 x^2 y^{-2}). \\ \downarrow & & \downarrow \\ (x',\ y') & \to & (u',\ v') = (x' y'^{-1} + \frac{1}{2}h,\ y'^{-2}). \end{array} \tag{5.2}$$

The two horizontal arrows are changes of generators. The two vertical ones define a map between the two deformations. In terms of the generators u and v and their analogs[36] u' and v' for the Jordanian deformation, the map (5.1) can be written as

$$u' = qu^{-1} - h_0, \quad v' = -qv^{-1}$$

with $h_0 \to \infty$. It has been shown[36] that the local metric on the Jordanian deformation is that of Lobachevsky. This must be a limit of one of the family of metrics (4.5). The Lobachevsky metric can be described with the line element $ds'^2 = v'^{-2}(du'^2 + dv'^2)$. To compare, we write (4.5) in the primed variables

$$ds^2 = (u' + h_0)^{-2} v'^{-2}[q^2 g_1 du'^2 - 2g_2 du'\, dv' + q^{-2} g_4 dv'^2].$$

We see then that we must choose $g_2 = 0$ and let $g_1, g_4 \to \infty$ with the constraint

$$g_1 h_0^{-2} = g_4 h_0^{-2} = 1.$$

The quantum-plane metric belongs to the family III. Another interesting metric obtained in the same limit is with $g_1 = g_4 = 0$ and $g_2 \to \infty$ so that $g_2 h_0^{-2} = 1$

$$ds^2 = -2v'^{-2} du'\, dv' = -2du'\, dv.$$

This solution belongs to the family I.

VI. PATCHING

Let us consider now the solutions *I* found in Sec. IV A. To each of the four regions defined by the light cone through the origin in two dimensions we have associated an algebra, a differential calculus, and a metric, but none is complete as ''manifold.'' From the form of the metric we see that this can be done using the generators (t,r) or (u,v), but that the generators (x,y) are singular on the cone.

The patching is done[28] by extending the domain of definition of u for example to negative eigenvalues. The frame θ^i is also singular on the cone, but the equivalent frame du^i is quite regular. We can write $\theta^i = \Lambda^i_j\, du^j$, where

$$\Lambda^i_j = \sqrt{q}\begin{pmatrix} vu^{-1} & 0 \\ 0 & uv^{-1} \end{pmatrix}$$

is a local Lorentz transformation in the commutative limit.

VII. DISCUSSION

We have given a partial classification of the solutions to the three conditions of metric compatibility (1.23), symmetry (1.24), and the consistency condition (1.16), as well as the reality conditions (1.27), (1.28), and the braid relation (1.29), without due regard to quantum covariance. In fact, we could show that there was no solution which respected a coaction of the quantum group. A similar problem was found by Cotta-Ramusino and Rinaldi in trying to construct holonomy groups.[37] Written in terms of the components in the frame basis, one sees that S^{ij}_{kl} has 16 unknowns and g^{ij} has 4 unknowns. The condition (1.16) gives 4 equations and metric compatibility gives 16 equations. So, a naive computation would say that the solution is unique up to a rescaling of g^{ij}, which is not fixed by the equation. We have indeed found a finite set of solutions.

Another conclusion concerns the uniqueness of the vacuum. It has been claimed[38] that within the context of the present formalism there is essentially a unique differential calculus which has associated with it a given metric, unique that is up to a choice of norm on the frame. This statement needs qualification since we have shown here that the quantum plane is naturally endowed with the Lorentz-signature flat metric and it is known that the same is true of the Heisenberg algebra with its natural differential calculus.

N coupled nonlinear Schrödinger equations: Special set and applications to *N*=3

F. T. Hioe[a)]
Department of Physics, St. John Fisher College, Rochester, New York 14618

(Received 16 July 2002; accepted 12 September 2002)

Analytic solutions for a special set of N coupled nonlinear Schrödinger equations characterized by 2^N interaction types are presented for $N=1-3$. They provide an overview of the important role played by nonlinear couplings. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1521238]

I. INTRODUCTION

There are many physical processes that are described by the nonlinear Schrödinger equations. Because of problems of mathematical interest and a growing interest in nonlinear phenomena in optical fibers,[1] systems of coupled nonlinear Schrödinger (CNLS) equations involving two and generally N components have attracted a great deal of attention. The complex wavefunction $\phi_m(z,t)$ of the mth component as a function of position z and time t is assumed to satisfy the following N CNLS equations:

$$i\phi_{mz}+\varepsilon_m\phi_{mtt}+\kappa_m\phi_m+\left(\sum_{j=1}^{N}\lambda_{mj}|\phi_j|^2\right)\phi_m=0, \quad m=1,\ldots,N, \tag{1}$$

where ε_m, κ_m and λ_{mj} are real parameters characteristic of the medium and interaction, and where the subscripts in z and t denote derivatives with respect to z and t, and the subscript m is for different components. Although the term $\kappa_m\phi_m$ can be eliminated by a substitution $\phi_m \rightarrow \phi_m e^{i\kappa_m z}$, we shall keep the term for the purpose of ordering the N equations that will become clear later.

Soliton[1–4] and solitary-wave solutions[4–6] have been presented for special sets of parameters ε_m, κ_m and λ_{mj}. In particular, Lakshmanan and his collaborators[7] have studied a special set of ''mixed'' interaction cases using the Painlevé analysis.

In a recent paper, Hioe and Salter[8] showed that there is a special set that can be characterized by 2^N specific arrays of interaction parameters for which the N CNLS equations possess special analytic solutions. For this special set, the N components of the CNLS equations can be expressed in terms of N Lamé functions,[9] and every Lamé function of order $n \leqslant N$ is a solution for one or more components for one or more interaction types of this special set. In particular, they presented simple rules that (a) identify a given combination of Lamé functions to be a solution to one or more specific interaction types, and (b) give all the possible combinations of Lamé functions as solutions of a specific interaction type. These CNLS equations that have these Lamé functions as solutions were called the L-set. It was pointed out that the L-set coincides with the set of CNLS equations that pass the Painlevé test identified by Radhakrishnan *et al.*[7] In a separate development, Hioe and Carroll[10] showed that N coupled Gross–Pitaevskii (CGP) equations in D-dimensions with a square-well and Coulomb potential can be transformed into N CNLS equations, and solutions in terms of same or different Lamé functions can be used to suggest possible ways of making multiple Bose–Einstein condensates overlap each other or separate.

In this article, we first review briefly the L-set and the subsets of it that consist of what are called the weakly and strongly mixed interaction types. We then present and consider analytic

a)Electronic mail: hioe@sjfc.edu

solutions particularly for $N=3$. The use of two or three coupled waves can play a very important role in optical communication with unexpected results. For example, a wave that cannot be solitary by itself when it propagates through an anomalous group-velocity dispersion (GVD) region[1] can be made to do so when it is coupled to a second appropriate wave, and two waves that cannot be solitary by themselves when they propagate through an anomalous GVD region can be made to do so when they are coupled to a third appropriate wave. For the many analytic solutions presented in this article, besides their theoretical and mathematical interest, the true test of their practical usefulness could be realized if and when a general recognizable pattern would emerge that would strongly suggest the robustness of certain combinations of waveforms.

II. THE L-SET FOR *N* CNLS EQUATIONS

We first review the L-set for a general value of N. The L-set of N CNLS equations (1) is defined to be a special subset of Eq. (1) given by the following,[8]

$$i\phi_{mz}\pm\beta_m\phi_{mtt}+\kappa_m\phi_m\pm\left(\sum_{j=1}^{N}\beta_m\beta_j|\phi_j|^2\right)\phi_m=0,\quad m=1,\ldots,N, \tag{2}$$

where $\beta_j=+1$ or -1, for $j=1,\ldots,N$. That is, the L-set of N CNLS equations (1) has those coefficients ε_m and λ_{mj} which are expressible as in Eq. (2).

Consider the stationary-wave solution of the form

$$\phi_m(z,t)=\psi_m(t)\exp(i\omega z), \tag{3}$$

where ω is a real constant and $\psi_m(t)$'s are real functions of t only. Substitution of Eq. (3) into Eq. (2) gives the following N equations for $\psi_m(t)$:

$$\psi_{mtt}+c_m\psi_m+\left(\sum_{j=1}^{N}\beta_j\psi_j^2\right)\psi_m=0,\quad m=1,\ldots,N, \tag{4}$$

where

$$c_m=\pm\beta_m(\kappa_m-\omega). \tag{5}$$

To eliminate the permutation symmetry, Eq. (4) is arranged such that

$$c_1\geqslant c_2\geqslant\cdots\geqslant c_N, \tag{6}$$

so that only one of the two choices (the upper or lower sign) in Eq. (2) gives Eq. (4). The traveling waves, if required, can be constructed by substituting the solutions ψ_m from Eq. (4) into Eq. (2), and replacing $\phi_m(z,t)$ by $\phi_m(z,t-z/v)\exp\{i[t-z/(2v)]/(2v)\}$, where v is the common velocity of the waves.

The interaction parameters of Eq. (2) [and Eq. (4)] are now characterized by the array $(\beta_1,\beta_2,\ldots,\beta_N)$, where $\beta_j=+1$ or -1, and each of the 2^N arrays is referred to as an interaction type. The two special cases are the normal GVD region characterized by $(--\ldots-)$ and the anomalous GVD region characterized by $(++\ldots+)$. Note that the 2^N interaction types constitute only a subset of the symmetric λ_{mn} that can take on values $+1$ or -1, because the λ_{mn}'s are constrained to be only those given by $\lambda_{mn}=+\beta_m\beta_n$ or $-\beta_m\beta_n$. This special set of CNLS equations that consists of the 2^N interaction types is the L-set.

A Lamé equation of order n can be written in the form[9]

$$d^2f/d\tau^2+[h-n(n+1)k^2sn^2(\tau,k)]f=0. \tag{7}$$

Only the polynomial solutions of the Lamé equation are used here and are referred to as Lamé functions, and the $2n+1$ Lamé functions of order n, $f_1^{(n)},f_2^{(n)},\ldots,f_{2n+1}^{(n)}$, are numbered in the

order of numbering their corresponding eigenvalues $h_m^{(n)}$ arranged in descending order $h_1^{(n)} > h_2^{(n)} > \cdots > h_{2n+1}^{(n)}$. These Lamé functions and their corresponding eigenvalues, which will be needed later for our analytic solutions, are given in Appendix A for $n=1-3$. An N-combination $(f_{p_1}^{(n)}, f_{p_2}^{(n)}, \ldots, f_{p_N}^{(n)})$ that gives an analytic solution for the N components $(\psi_1, \psi_2, \ldots, \psi_N)$ will be represented simply by $(p_1, p_2, \ldots, p_N)_n$, where Eq. (6) implies $p_1 \leqslant p_2 \leqslant \cdots \leqslant p_N$. The $2n+1$ eigenvalues of the Lamé equation $h_1^{(n)}, h_2^{(n)}, \ldots, h_{2n+1}^{(n)}$ are renumbered as $h_1^{(n)}, h_2^{(n)}, h_{2'}^{(n)}, \ldots, h_{n+1}^{(n)}, h_{(n+1)'}^{(n)}$, and the corresponding Lamé functions $f_1^{(n)}$, $f_2^{(n)}$, $\ldots$, $f_{2n+1}^{(n)}$ as $f_1^{(n)}, f_2^{(n)}, f_{2'}^{(n)}, \ldots, f_{n+1}^{(n)}, f_{(n+1)'}^{(n)}$, i.e., they are grouped in pairs except the first one. The use of Lamé function ansatz described in Ref. 4 gives the required specific values for the c_m of Eq. (4) and the amplitude C_m for the mth component, thus giving, for combination $(p_1, p_2, \ldots, p_N)_n$, the solution

$$\psi_m(t) = C_m f_{p_m}^{(n)}(t), \quad m = 1, \ldots, N. \tag{8}$$

Two separate cases of representing the solutions in terms of Lamé functions may be distinguished: case (I) is in terms of Lamé functions of order $n=N$, and case (II) in terms of Lamé functions of order $n<N$.

(I) For $n=N$, the N Lamé functions for the N components must necessarily be different Lamé functions. The number of N combinations that can be chosen from $2n+1$ distinct Lamé functions of order $n=N$, with no repetition allowed, is $M=\binom{2n+1}{N}$.

Every one of the M combinations is a solution of one and only one particular interaction type, and every interaction type has one or more combinations as solutions. More specifically,

(a) Combination $(p_1, p_2+1, p_3+2, \ldots, p_N+N-1)_n$ is a solution of interaction type $((-1)^{p_1}, (-1)^{p_2}, (-1)^{p_3}, \ldots, (-1)^{p_N})$, and

(b) an interaction type $((-1)^{p_1}, (-1)^{p_2}, (-1)^{p_3}, \ldots, (-1)^{p_N})$ has solutions given by all possible combinations $(m_1, m_2, m_3, \ldots, m_N)_n$, that can be obtained by setting $m_1 = p_1$, $m_2 = p_2+1$, $m_3 = p_3+2, \ldots$, $m_N = p_N+N-1$, and by increasing or decreasing m_j by any multiple of 2 subject to the condition that $m_1 < m_2 < m_3 < \cdots < m_N$, where m_j can take on values $1, 2, 2', 3, 3', \ldots, n+1, (n+1)'$ with the understanding that $r < r'$.

(II) For $n<N$, two or more of the Lamé functions for the N components may be the same function. The number of N combinations that can be chosen from $2n+1$ distinct Lamé functions of order $n<N$ each of which may appear from 0 to N times is $M' = \binom{2n+N}{N}$.

A total of M' combinations $(m_1, m_2, \ldots, m_N)_n$ are possible where $m_1 \leqslant m_2 \leqslant m_3 \leqslant \ldots \leqslant m_N$ can be chosen, with repetition allowed, from 1, 2, 2′, 3, 3′, $\ldots$, $n+1$, $(n+1)'$, and in general, these combinations are possible solutions for each of the 2^N interaction types, but with a number of exceptions, some specific and some general. The following restrictions apply generally:

(a) A combination $(m_1, m_2, \ldots, m_N)_n$ must have at least n distinct m's for it to be a solution; and

(b) combination $(m_1, m_2, \ldots, m_N)_n$ is disallowed for interaction type $((-1)^{m_1+n}, (-1)^{m_2+n}, \ldots, (-1)^{m_N+n})$.

III. COMBINATIONS AND INTERACTION TYPES

For the case of $N>n$ for which combinations with repetitions are allowed, a combination in which two or more of the m's in the combination $(m_1, m_2, \ldots, m_N)_n$ are equal is referred to as a degenerate combination, and one in which all the m's are distinct as a nondegenerate combination.

For the case of $n=N$, all combinations must be nondegenerate (for $0<k^2<1$) to be solutions of N CNLS equations (4). It is useful to divide the $M=\binom{2n+1}{N}$ combinations of Lamé functions that can be obtained from $2n+1$ Lamé functions of order n (with no repetition allowed) into two kinds: the degenerative combination is one in which at least two of the m's in the combination $(m_1, m_2, \ldots, m_N)_n$ involve a pair p and p', where p is one of the numbers from 2 to $n+1$; the

nondegenerative combination is one that is not degenerative. Of the M combinations, the number of degenerative combinations is $M_d = n(2n-1)!/\{(N-2)!(2n-N+1)!\}$ and the number of nondegenerative combinations is $M_{nd} = M - M_d$.

The 2^N interaction types are divided into two subsets: (1) the interaction types in which all the $-$'s precede the $+$'s belong to the "weakly" mixed type or subset that includes the "pure" type in which the signs are all $-$'s or all $+$'s, as two special cases; and (2) the interaction types in which the $-$'s that appear before *and* after the $+$'s belong to the "strongly" mixed type or subset. The weakly mixed subset consists of $N+1$ interaction types, and the strongly mixed subset consists of the remaining $2^N - N - 1$ interaction types.

The nondegenerative combinations are found to be solutions of only the weakly mixed interaction type. The degenerative combinations can be solutions of the strongly mixed as well as the weakly mixed interaction types excepting the pure type. Division into degenerative and nondegenerative combinations aside, every one of the M possible combinations (for $n=N$) of Lamé functions is a solution to one and only one of the 2^N interaction types.

In Appendix B, we present, for $N=1-3$, the combinations of Lamé functions that give analytic solutions for each of the 2^N interaction types, the Lamé functions being those given in Appendix A. The grouping can be verified to be in agreement with the rules given above. To complete the analytic solutions, we need the explicit expressions for the amplitudes C's for Eq. (8) and the required c's for Eq. (4). Some solutions given previously[6,11–13] were for the pure type only. For $N=1$ and 2, the solutions for the entire set were given in Ref. 14. For $N=3$, the number of possible combinations for $n=3$ alone is 35, and there are many combinations that are solutions for $n=1$ and 2. We present, in Appendix C, the complete analytic solutions for five specific combinations, pure and mixed, with examples from $n=1$, 2 and 3, for which the Lamé functions given in Appendix A are used and Eq. (8) applies.

The complete analytic solutions for $N=3$ for the case of $k^2=1$, for which the $2n+1$ Lamé functions of order n coalesce into $n+1$ associated Legendre functions of order n, will be presented later. Indeed, for the case $k^2=1$, two special cases allow very compact expressions for a general N which we shall discuss in the next section.

The division of combinations into degenerative and nondegenerative is consistent with consideration of Lamé functions as k^2 becomes equal to 1. In that case, the $2n+1$ eigenvalues, except for the first one, become pairwise degenerate, i.e., $h_2^{(n)} = h_{2'}^{(n)}, h_3^{(n)} = h_{3'}^{(n)}, \ldots, h_{n+1}^{(n)} = h_{(n+1)'}^{(n)}$, and the corresponding Lamé functions of order n become $n+1$ associated Legendre functions of order n, $P_n^m(x)$, $m=0,1,2,\ldots,n$, where $x=\tanh(\alpha t)$. These (unnormalized) Legendre functions are presented in Appendix D.

IV. ANALYTIC SOLUTIONS FOR $k^2=1$

We shall present in this section all analytic solutions for $N=1-3$ for $k^2=1$ for all 2^N interaction types. For the weakly mixed interaction type, we have compact closed-form expressions of analytic solutions for a general value of N for two special cases that are derived from studying the equations obtained with the use of the ansatz.[5]

We first define our normalized associated Legendre functions $P_n^m(x)$ as follows:

$$P_n^m(x) = (1-x^2)^{m/2} d^m P_n(x)/dx^m,$$

where $P_n(x) = (2^{-n}/n!) d^n (x^2-1)^n / dx^n$.

Consider the following $(N+1)$ CNLS equations involving ψ_j, $j=1,2,\ldots,N+1$:

$$\psi_{mtt} + c_m \psi_m + \left(\sum_{j=1}^{s} - \psi_j^2 + \sum_{j=s+1}^{N+1} \psi_j^2 \right) \psi_m = 0, \quad m = 1, \ldots, N+1, \tag{9}$$

where s can take the value from 0 to $N+1$. It can be verified that the following analytic solution for ψ_j satisfies Eq. (9):

$$\psi_j = C_j P_N^{j-1}(\tanh \alpha t), \quad j=1,\ldots,N+1, \tag{10}$$

$$C_1 = \pm c_1, \quad + \text{for } s \geqslant 1, \quad - \text{for } s=0,$$

$$C_j = \pm\{[(N-j+1)!][c_1 - 2(j-1)^2\alpha^2]/(N+j-1)!\}^{1/2},$$

where $+$ for $j=2,...,s$, $s \geqslant 2$, $-$ for $j=s+1,\ldots,N+1$, $N \geqslant s$,

$$c_j = c_1 - (j-1)^2\alpha^2, \quad j=1,\ldots,N+1,$$

$$c_1 < 0 \quad \text{for } s=0,$$

$$2s^2\alpha^2 > c_1 > 2(s-1)^2\alpha^2 \quad \text{for } N+1 > s \geqslant 1,$$

$$c_1 > 2N^2\alpha^2 \quad \text{for } s=N+1.$$

We now consider the above $(N+1)$ CNLS equations involving ψ_j, $j=1,2,\ldots,N+1$ with $j=r$ missing (or $\psi_r=0$), where r can be any one of the $N+1$ components. Written explicitly, we have the following equations:

$$\psi_{mtt} + c_m\psi_m + \left(\sum_{j=1}^{r-1} -\psi_j^2 + \sum_{j=r+1}^{N+1} \psi_j^2\right)\psi_m = 0, \quad m=1,\ldots,N+1. \tag{11}$$

We find the following analytic solutions ψ_j with amplitudes C_j and the required c_j given by

$$\psi_j = C_j P_N^{j-1}(\tanh \alpha t), \quad j=1,\ldots,N+1, \quad j \neq r, \tag{12}$$

$$C_1 = [2(r-1)^2]^{1/2}\alpha,$$

$$C_j = \{4[(N-j+1)!]|(r-1)^2 - (j-1)^2|/(N+j-1)!\}^{1/2}\alpha, \quad \text{for } j>1,$$

$$c_j = [2(r-1)^2 - (j-1)^2]\alpha^2, \quad j=1,\ldots,N+1, \quad j \neq r,$$

where the specification $j \neq r$ is not really necessary since setting $j=r$ would give C_j and c_j equal to zero anyway. However, the specification $j \neq r$ is a reminder that there are N and not N+1 coupled components of CNLS equations considered.

Equation (12) gives a compact expression for the analytic solution for the L-set of N CNLS equations for the weakly mixed interaction type in terms of a combination of (different) associated Legendre functions of order $n=N$. It can be checked that for $r=1$, i.e., when the nonlinear coupling parameters in Eq. (11) are all equal to $+1$, the above results coincide with those given previously in Refs. 4–6, and for $r=N+1$, i.e., when the nonlinear coupling parameters are all equal to -1, the above results coincide with those given previously in Ref. 12. Thus our above results given by Eq. (12) generalize the previous results to the weakly mixed type where the first $r-1$ of the β's in Eqs. (11) are equal to -1, and the remaining β's are equal to $+1$. It may be noted that the ''generalized'' dark solitary wave is $P_n^0(\tanh \alpha t)$ and the ''generalized'' bright solitary wave is $P_n^n(\tanh \alpha t)$; they become the familiar dark solitary wave $\tanh \alpha t$ and the familiar bright solitary wave $\operatorname{sech} \alpha t$, respectively, for $n=1$. The generalized dark solitary waves $P_n^0(\tanh \alpha t)$, unlike the rest of the set $P_n^m(\tanh \alpha t)$, $m=1,\ldots,n$, do not become zero when $t \to \pm\infty$.

By replacing N by $N-1$, Eq. (10) can be seen to provide a compact expression for a particular analytic solution for the L-set of N CNLS equations for the weakly mixed interaction type in terms of N different associated Legendre functions of order $n=N-1$. Unlike the analytic solution given by Eq. (12) for Eq. (11) which is the only analytic solution in terms of associated Legendre

functions of order $n=N$, there is generally more than one analytic solution in terms of Legendre functions of order $n=N-1$ for $n<N$ generally: the other possibilities include combinations in which the same Legendre functions represent different components.

For the strongly mixed interaction type, the ansatz and procedure given in Ref. 5 are used to obtain the analytic solutions. The complete analytic solutions for $N=1-3$ in terms of associated Legendre functions of order $n\leqslant N$ are presented in Appendix E for all 2^N interaction types. To use these results, the solution of Eq. (4) for N CNLS equations characterized by the interaction type $(\beta_1,\ldots,\beta_N)$ for combination $(p_1,\ldots,p_N)$ is expressed in the form

$$\psi_m(t)=C_m f_{p_m}^{(n)}(x), \quad m=1,\ldots,N, \tag{13}$$

where the associated Legendre functions f's used are those given in Appendix D, the C's for Eq. (13) and the required c's for Eq. (4) are given in Appendix E, and where $x\equiv\tanh(\alpha t)$, α being a scaling parameter. Note that the $f_q^{(n)}(x)$ used for Eq. (13) differs from the normalized associated Legendre function $P_n^{(q-1)}(x)$ used for Eqs. (10) and (12) by a normalization constant. The solutions for $\psi_m(t)$ obtained from Eqs. (13) must of course be the same as those obtained from Eqs. (10) or (12) for the corresponding cases. Notice that combinations of associated Legendre functions of order $n=N$ are absent for the strongly mixed interaction type for $k^2=1$, which can be understood from the rules described in Secs. II and III (see also Appendix B for $0<k^2<1$).

The important role played by coupling a wave to another wave or to two other waves can now be seen in full view in Appendix E. For example, the wave $f_1^{(1)}$ that can by itself be a solitary wave only in the normal GVD region $[(1)_1$ in $(-)]$ can be a solitary wave in the anomalous GVD region if it is coupled with another wave $f_2^{(1)}$ $[(1,2)_1$ in $(++)]$; and the coupled waves $f_1^{(2)}$ and $f_2^{(2)}$ that can be a solitary-wave pair only in the normal GVD region $[(1,2)_2$ in $(--)]$ can be made into solitary waves in the anomalous GVD region if the pair is coupled to a third wave $f_3^{(2)}$ $[(1,2,3)_2$ in $(+++)]$.

V. SUMMARY

We have reviewed the L-set for N CNLS equations that possess analytic solutions in terms of N combinations of Lamé functions of order $n\leqslant N$ for 2^N interaction types. That every combination of Lamé functions of order $n=N$ is a solution for *one and only one* interaction type, and that every interaction type has *at least one* combination of Lamé functions of order $n=N$ as solution, as were first presented in Ref. 8, clearly tie the Lamé functions of order $n=N$ very intimately with the L-set for N CNLS equations, and may indicate a relationship of a deeper significance to be uncovered. The relationship between the weakly mixed interaction type and the nondegenerative combinations of Lamé functions order $n=N$ is another curiously interesting result.

For $k^2=1$, the weakly mixed interaction type allows the analytic solution in a combination of associated Legendre functions of order $n=N$ to be expressed in a compact closed-form expression for a general N, and likewise for a combination of associated Legendre functions of order $n=N-1$. Generally for $0<k^2\leqslant 1$ and every possible interaction type, however, the analytic solutions must be obtained individually, for which the ansatz and procedure prescribed in Ref. 5 can be used efficiently.

The complete analytic solutions presented for $N=1-3$ in Appendix E for $k^2=1$, for combinations of associated Legendre functions of order $n\leqslant N$, and for all 2^N interaction types, provide an excellent overview of the important role played by nonlinear couplings. For example, it enables one to easily see that coupling another wave or two other waves to a given wave can make all partners propagate as solitary waves in certain GVD regions when the individual waves cannot propagate as solitary waves by themselves. The robustness of the combinations must await experimental testing which hopefully will be used also to discover the required general pattern for certain combinations to be robust and practically useful. There is another useful application of our results. As presented in a recent communication,[10] they provide the analytic forms of stationary distributions of coupled Bose–Einstein condensates that can be used to suggest possible ways of making condensates overlap each other (i.e., same functions appearing in the combination) or

separated (i.e. different functions in the combination). The mixed interaction types, which make the L-set complete in terms of its relationship to Lamé functions of order $n=N$, are clearly important mathematically, but their physical applications still await experimental explorations.

APPENDIX A: LAMÉ FUNCTIONS FOR $n=1-3$

The $2n+1$ Lamé functions $f_m^{(n)}(\tau)$ and their eigenvalues $h_m^{(n)}$ satisfy the Lamé equations (7), and we list them for $n=1-3$ according to the subscript $m=1,2,2',3,3',\ldots,n+1,(n+1)'$ in the following.

1. $n=1$

$$h_1^{(1)}=1+k^2,\quad h_2^{(1)}=1,\quad h_{2'}^{(1)}=k^2,$$

$$f_1^{(1)}=sn(\tau),\quad f_2^{(1)}=cn(\tau),\quad f_{2'}^{(1)}=dn(\tau).$$

2. $n=2$

$$h_{1,3'}^{(2)}=2(1+k^2)\pm 2\sqrt{1-k^2+k^4},$$

$$h_2^{(2)}=4+k^2,\quad h_{2'}^{(2)}=1+4k^2,\quad h_3^{(2)}=1+k^2,$$

$$f_{1,3'}^{(2)}=\frac{1}{3}(1+k^2\mp\sqrt{1-k^2+k^4})-k^2sn^2(\tau),$$

$$f_2^{(2)}=sn(\tau)cn(\tau),\quad f_{2'}^{(2)}=sn(\tau)dn(\tau),\quad f_3^{(2)}=cn(\tau)dn(\tau).$$

3. $n=3$

$$h_{1,3'}^{(3)}=5(1+k^2)\pm 2\sqrt{4-7k^2+4k^4},$$

$$h_{2,4}^{(3)}=5+2k^2\pm 2\sqrt{4-k^2+k^4},$$

$$h_{2',4'}^{(3)}=2+5k^2\pm 2\sqrt{1-k^2+4k^4},$$

$$h_3^{(3)}=4(1+k^2),$$

$$f_{1,3'}^{(3)}=sn(\tau)\{1-a_{1,3'}sn^2(\tau)\},$$

$$f_{2,4}^{(3)}=cn(\tau)\{1-a_{2,4}sn^2(\tau)\},$$

$$f_{2',4'}^{(3)}=dn(\tau)\{1-a_{2',4'}sn^2(\tau)\},$$

$$f_3^{(3)}=sn(\tau)cn(\tau)dn(\tau),$$

where

$$a_{1,3'}=\frac{1}{3}[2+2k^2\pm\sqrt{4-7k^2+4k^4}],$$

$$a_{2,4}=2+k^2\pm\sqrt{4-k^2+k^4},$$

$$a_{2',4'}=1+2k^2\pm\sqrt{1-k^2+4k^4}.$$

APPENDIX B: COMBINATIONS AND INTERACTION TYPES FOR $N=1-3$

A collection of N Lamé functions $(f^{(n)}_{m_1},f^{(n)}_{m_2},\ldots,f^{(n)}_{m_N})$ or $(m_1,m_2,\ldots,m_N)_n$ chosen from $2n+1$ Lamé functions $f^{(n)}_m$ of order n that can serve as an analytic solution for the N components ψ_m, $m=1,\ldots,N$, of Eqs. (4) is referred to as a combination. In this Appendix, we list, for every one of the 2^N possible interaction types $(\beta_1,\beta_2,\ldots,\beta_N)$, where β_j can be $+1$ or -1, for Eq. (4), all the possible combinations for Lamé functions of order $n=N$, for $N=1-3$ [the subscript n in the combination $(m_1,m_2,\ldots,m_N)_n$ is dropped as it is understood that $n=N$]. The total number M of possible combinations for $N=1,2,3$ are 3, 10, and 35, respectively.

We list only the ''principal'' combinations with the number of total possible combinations that can be obtained from them by changing, say, 2 to $2'$, 3 to $3'$, etc., given in the square brackets that follow, remembering the restriction that for any combination $(m_1,m_2,\ldots,m_N)_n$ for the case $n=N$, $m_1<m_2<\ldots<m_N$. For example, (2)[2] represents two combinations $(2)_1$ and $(2')_1$, and (1,2,3)[4] represents four combinations $(1,2,3)_3$, $(1,2,3')_3$, $(1,2',3)_3$ and $(1,2',3')_3$.

Interaction type	Combination
$N=1$	
$(-)$	(1)[1]
$(+)$	(2)[2]
$N=2$	
$(--)$	(1,2)[2]
$(-+)$	(1,3)[2],(3,3′)[1]
$(+-)$	(2,2′)[1]
$(++)$	(2,3)[4]
$N=3$	
$(---)$	(1,2,3)[4]
$(--+)$	(1,2,2′)[1],(1,2,4)[4],(1,4,4′)[1], (3,4,4′)[2]
$(-+-)$	(1,3,3′)[1]
$(-++)$	(1,3,4)[4],(3,3′,4)[2]
$(+--)$	(2,2′,3)[2]
$(+-+)$	(2,2′,4)[2],(2,4,4′)[2]
$(++-)$	(2,3,3′)[2]
$(+++)$	(2,3,4)[8]

APPENDIX C: SOLUTIONS FOR FIVE COMBINATIONS FOR $N=3$

In this Appendix, we give some representative examples of analytic solutions for $N=3$ of Eq. (4) for various interaction types: three combinations consist of Lamé functions of order 3, and one combination each consists of Lamé functions of orders 1 and 2. For combination $(p_1,p_2,p_3)_n$, the analytic solution is $\psi_m=C_m f^{(n)}_{p_m}$, $m=1,2,3$, where f's are given in Appendix A, and C's and the required c's for Eq. (4) are given in this Appendix.

1. *N*=3

(*i*) Combination $(1,2,3)_3$ for interaction type $(---)$.

$$C_j=(\Delta_j/\Delta)^{1/2},$$

where

$$\Delta_1=108k^2\alpha^2(8-k^2+4\sqrt{4-k^2+k^4}),$$

$$\Delta_2=12k^2\alpha^2\{8-3k^2-3k^4+8k^6+2(2+k^2+2k^4)\sqrt{4-7k^2+4k^4}\},$$

$$\Delta_3=12k^4\alpha^2\{-80+57k^2+18k^4+16k^6+(-50+26k^2+16k^4)\sqrt{4-k^2+k^4}+(50+16k^2+8k^4)\sqrt{4-7k^2+4k^4}+(20+8k^2)\sqrt{(4-7k^2+4k^4)(4-k^2+k^4)}\},$$

$$\Delta=32-90k^2+78k^4-16k^6+4(5-11k^2+8k^4)\sqrt{4-k^2+k^4}+2(-10+16k^2-4k^4)\sqrt{4-7k^2+4k^4}+8(-1+2k^2)\sqrt{(4-7k^2+4k^4)(4-k^2+k^4)},$$

$$c_j=\Delta_j/\Delta+h_j^{(3)}\alpha^2.$$

(*ii*) Combination $(1,3,3')_3$ for interaction type $(--+)$.

$$C_{1,3}=\sqrt{3}k'^{-2}k\alpha\left(2+k^2+2k^4\mp\frac{(1+k^2)(8-11k^2+8k^4)}{2\sqrt{4-7k^2+4k^4}}\right)^{1/2},$$

$$C_2=\sqrt{30}k'^{-2}k\alpha,$$

$$c_{1,3}=\{5(1+k^2)\pm2\sqrt{4-7k^2+4k^4}\}\alpha^2,\quad c_2=4(1+k^2)\alpha^2.$$

(*iii*) Combination $(2,3,4)_3$ for interaction type $(+++)$.

$$C_{1,3}=\sqrt{3}k\alpha\left(2\mp\frac{8-k^2}{2\sqrt{4-k^2+k^4}}\right)^{1/2},\quad C_2=\sqrt{30}k^2\alpha,$$

$$c_{1,3}=\{5(1-2k^2)\pm2\sqrt{4-k^2+k^4}\}\alpha^2,\quad c_2=4(1-2k^2)\alpha^2.$$

(*iv*) Combination $(1,2,3)_2$ for interaction type $(\beta_1,\beta_2,\beta_3)$, excluding $(-+-)$ and $(+-+)$.

$$C_1=(D_1/D)^{1/2},\quad C_2=(D_2/D)^{1/2}+6k^4\alpha^2,\quad C_3=(D_3/D)^{1/2}+6k^2\alpha^2,$$

where

$$D_1=9\beta_1\{-c_1+[2(1-2k^2)+2\sqrt{1-k^2+k^4}]\alpha^2\},$$

$$D_2=3\beta_2k^4(1+k^2+2\sqrt{1-k^2+k^4})\{-c_1+[2(1-2k^2)+2\sqrt{1-k^2+k^4}]\alpha^2\},$$

$$D_3=3\beta_3k^2(-2+k^2+2\sqrt{1-k^2+k^4})\{-c_1+[2(1-2k^2)+2\sqrt{1-k^2+k^4}]\alpha^2\},$$

$$D=2-5k^2+5k^4-2(1-2k^2)\sqrt{1-k^2+k^4},$$

$$c_1-c_2=-2+k^2+2\sqrt{1-k^2+k^4},\quad c_1-c_3=1+k^2+2\sqrt{1-k^2+k^4}.$$

(v) Combination $(1,2,2)_1$ for interaction type $(\beta_1,\beta_2,\beta_3)$, excluding $(+--)$.

$$C_1=\beta_1\{-c_1+(1-k^2)\alpha^2\},$$

$$\beta_2C_2^2+\beta_3C_3^2=-c_1+(1+k^2)\alpha^2,$$

$$c_1-c_2=k^2\alpha^2, \quad c_2=c_3,$$

$$\text{and for } \beta_1=+1, \quad c_1<(1-k^2)\alpha^2,$$

$$\text{and for } \beta_1=-1, \quad c_1>(1-k^2)\alpha^2.$$

APPENDIX D: ASSOCIATED LEGENDRE FUNCTIONS FOR $n=1-3$

In this Appendix, we list the $n+1$ associated Legendre functions of order $n=1-3$ that are to be used for Eq. (13) in conjunction with Appendix E.

1. $n=1$

$$f_1^{(1)}=\tanh(\alpha t)\equiv x, \quad f_2^{(1)}=\operatorname{sech}(\alpha t)=(1-x^2)^{1/2}.$$

2. $n=2$

$$f_1^{(2)}=\operatorname{sech}^2(\alpha t)-\frac{2}{3}=\frac{1}{3}-x^2,$$

$$f_2^{(2)}=\tanh(\alpha t)\operatorname{sech}(\alpha t)=x(1-x^2)^{1/2},$$

$$f_3^{(2)}=\operatorname{sech}^2(\alpha t)=1-x^2.$$

3. $n=3$

$$f_1^{(3)}=\tanh(\alpha t)\left\{\operatorname{sech}^2(\alpha t)-\frac{2}{5}\right\}=x\left(\frac{3}{5}-x^2\right),$$

$$f_2^{(3)}=\operatorname{sech}(\alpha t)\left\{\operatorname{sech}^2(\alpha t)-\frac{4}{5}\right\}=(1-x^2)^{1/2}\left(\frac{1}{5}-x^2\right),$$

$$f_3^{(3)}=\tanh(\alpha t)\operatorname{sech}^2(\alpha t)=x(1-x^2),$$

$$f_4^{(3)}=\operatorname{sech}^3(\alpha t)=(1-x^2)^{3/2}.$$

APPENDIX E: SPECIAL SOLUTIONS FOR $N=1-3$

In this Appendix, we give all analytic solutions of Eq. (4) for 2^N interaction types in terms of combinations of associated Legendre functions given in Appendix D, for $N=1-3$. See Eq. (13) for applications of the parameters given here.

1. $N=1$

$\underline{(-)}$ $(1)_1$ $C_1=\sqrt{2}\alpha, \quad c_1=2\alpha^2.$

$\underline{(+)}$ $(2)_1$ $C_1=\sqrt{2}\alpha, \quad c_1=-\alpha^2.$

2. *N*=2

$(--)$

$(1,2)_2 \quad C_1=C_2=3\sqrt{2}\alpha, \quad c_1=8\alpha^2, \quad c_2=7\alpha^2.$

$(1,1)_1 \quad C_1^2+C_2^2=2\alpha^2, \quad c_1=c_2=2\alpha^2.$

$(1,2)_1 \quad C_1^2=c_1, \quad C_2^2=c_1-2\alpha^2, \quad c_1-c_2=\alpha^2, \quad c_1>2\alpha^2.$

$(-+)$

$(1,3)_2 \quad C_1=C_2=3\sqrt{2}\alpha/2, \quad c_1=2\alpha^2, \quad c_2=-2\alpha^2.$

$(1,1)_1 \quad C_1^2-C_2^2=2\alpha^2, \quad c_1=c_2=2\alpha^2.$

$(1,2)_1 \quad C_1^2=c_1, \quad C_2^2=-c_1+2\alpha^2, \quad c_1-c_2=\alpha^2, \quad 2\alpha^2>c_1>0.$

$(2,2)_1 \quad -C_1^2+C_2^2=2\alpha^2, \quad c_1=c_2=-\alpha^2.$

$(+-)$

$(1,1)_1 \quad -C_1^2+C_2^2=2\alpha^2, \quad c_1=c_2=2\alpha^2.$

$(2,2)_1 \quad C_1^2-C_2^2=2\alpha^2, \quad c_1=c_2=-\alpha^2.$

$(++)$

$(2,3)_2 \quad C_1=C_2=\sqrt{6}\alpha, \quad c_1=-\alpha^2, \quad c_2=-4\alpha^2.$

$(1,2)_1 \quad C_1^2=-c_1, \quad C_2^2=-c_1+2\alpha^2, \quad c_1-c_2=\alpha^2, \quad c_1<0.$

3. *N*=3

$(---)$

$(1,2,3)_3 \quad C_1=15\sqrt{2}\alpha/2, \quad C_2=5\sqrt{6}\alpha, \quad C_3=5\sqrt{6}\alpha/2, \quad c_1=18\alpha^2, \quad c_2=17\alpha^2, \quad c_3=14\alpha^2.$

$(1,1,2)_2 \quad C_1^2+C_2^2=C_3^2=18\alpha^2, \quad c_1=c_2=8\alpha^2, \quad c_3=7\alpha^2.$

$(1,2,2)_2 \quad C_1^2=C_2^2+C_3^2=18\alpha^2, \quad c_1=8\alpha^2, \quad c_2=c_3=7\alpha^2.$

$(1,2,3)_2 \quad C_1^2=9c_1/4, \quad C_2^2=3(c_1-2\alpha^2), \quad C_3^2=3(c_1-8\alpha^2)/4, \quad c_1>4\alpha^2,$

$c_2=c_1-\alpha^2, \quad c_3=c_1-4\alpha^2.$

$(1,1,1)_1 \quad C_1^2+C_2^2+C_3^2=2\alpha^2, \quad c_1=c_2=c_3=2\alpha^2.$

$(1,1,2)_1 \quad C_1^2+C_2^2=c_1, \quad C_3^2=c_1-2\alpha^2, \quad c_1>2\alpha^2, \quad c_1=c_2, \quad c_1-c_3=\alpha^2.$

$(1,2,2)_1 \quad C_1^2=c_1, \quad C_2^2+C_3^2=c_1-2\alpha^2, \quad c_1>2\alpha^2.$

$(--+)$

$(1,2,4)_3 \quad C_1=5\sqrt{2}\alpha, \quad C_2=15\alpha/2, \quad C_3=5\alpha/2, \quad c_1=8\alpha^2, \quad c_2=7\alpha^2, \quad c_3=-\alpha^2.$

$(1,1,3)_2 \quad C_1^2+C_2^2=C_3^2=9\alpha^2/2, \quad c_1=c_2=2\alpha^2, \quad c_3=-2\alpha^2.$

$(1,2,2)_2 \quad C_1^2=C_2^2-C_3^2=18\alpha^2, \quad c_1=8\alpha^2, \quad c_2=c_3=7\alpha^2.$

$(1,2,3)_2 \quad C_1^2=9c_1/4, \quad C_2^2=3(c_1-2\alpha^2), \quad C_3^2=3(-c_1+8\alpha^2)/4, \quad 8\alpha^2>c_1>2\alpha^2,$

$c_2=c_1-\alpha^2, \quad c_3=c_1-4\alpha^2.$

$(1,3,3)_2 \quad C_1^2=-C_2^2+C_3^2=9\alpha^2/2, \quad c_1=2\alpha^2, \quad c_2=c_3=-2\alpha^2.$

$(1,1,1)_1 \quad C_1^2+C_2^2-C_3^2=2\alpha^2, \quad c_1=c_2=c_3=2\alpha^2.$

De Rham–Wu decomposition of holomorphic Riemannian manifolds

Peter R. Law[a)]
1 Mack Place, Monroe, New York 10950

(Received 22 July 2002; accepted 13 August 2002)

It is shown that a de Rham–Wu decomposition for holomorphic Riemannian manifolds is obtained easily from the underlying real geometry of holomorphic Riemannian manifolds by appealing to H. Wu's extension to pseudo-Riemannian manifolds of de Rham's decomposition theorem. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1515110]

I. INTRODUCTION

A holomorphic Riemannian manifold is a complex manifold M, of complex dimension n say, together with a holomorphic tensor field h that is a complex scalar product (i.e., nondegenerate, symmetric, **C**-bilinear form) on each holomorphic tangent space T'_pM, $p \in M$.

Holomorphic Riemannian geometry has many formal analogies with pseudo-Riemannian geometry and so has not required special study to elaborate its basic features. Nevertheless, it has attracted considerable interest in the context of general relativity, arising initially from the fact that the Hodge star operator provides a complex structure J on $\Lambda^2(\mathbf{R}^{1,3})$ so that the notion of self-duality in Lorentzian geometry involves complex-valued objects. In fact, $\Lambda^2(\mathbf{R}^{1,3}) \cong \mathbf{R}^{3,3}$ and the Hodge star operator is an *anti*-orthogonal complex structure J with respect to the neutral scalar product g on $\Lambda^2(\mathbf{R}^{1,3})$. Defining $\mu(\ ,\ ) := g(J\ ,\ )$, then $g - i\mu$ defines a complex scalar product on $(\Lambda^2(\mathbf{R}^{1,3}), J)$. This linear algebra plays a role in the well-known Petrov classification and underlies the associated proof that $\mathbf{SO}^+(\mathbf{1},\mathbf{3}) \cong \mathbf{SO}(\mathbf{3},\mathbf{C})$, (cf., Ref. 10). Complex geometry also occurs in general relativity in the form of complex space–times, i.e., four-(complex-)dimensional holomorphic Riemannian manifolds, of special interest in Penrose's twistor theory and Newman's theory of $\mathcal{H}$-space, cf., e.g., Ref. 7. Specifically, half-flat complex space–times provide a nonlinear analog of (anti-)self-dual objects in the linear theory. These applications inspired further work on complex Riemannian geometry itself, e.g., Ref. 6.

Typically, holomorphic Riemannian geometry is regarded as arising most naturally via complexification of real analytic Riemannian geometry. But, as in the linear theory, holomorphic Riemannian geometry possesses an underlying real geometry consisting of a pseudo-Riemannian metric of neutral signature for which the (integrable) almost complex structure tensor is anti-orthogonal. The latter approach is more natural in a geometrical setting, can include the weaker case of almost complex manifolds, and also indicates the significance of neutral signature amongst the various indefinite signatures. Rózga[9] and Woodhouse[11] appear to be have been the first to employ the real geometry of complex space–times, in applications to real slices of complex space–time. Recently, Robinson[8] has employed the real geometry to study half-flat complex space–times. The real geometry of holomorphic Riemannian manifolds has also been considered for its own sake, e.g., Ref. 2.

Much differential geometry of a holomorphic Riemannian manifold (M,h) may be developed simply by analogy with pseudo-Riemannian geometry. The notion of holonomy, however, would appear to be an exception. One approach is to utilize the underlying real geometry of (M,h). In this paper, I employ this approach to formulate for (M,h) an analog of Wu's[12–14] generalization to pseudo-Riemannian geometry of the de Rham decomposition theorem of Riemannian geometry,

a)Electronic mail: prldb@member.ams.org

see, e.g., Ref. 4. This result further demonstrates the utility of the real geometric approach to holomorphic Riemannian manifolds, not only for elucidating the holomorphic Riemannian geometry but also for suggesting how to adapt concepts (such as holonomy) from the real to the complex context.

II. HOLOMORPHIC RIEMANNIAN GEOMETRY

Briefly, consider a real, orientable, $2n$-dimensional manifold M, equipped with a neutral metric g, i.e., a pseudo-Riemannian metric of signature type (n,n), and an almost complex structure J which is compatible with g in the sense that J acts as an anti-orthogonal transformation of each tangent space T_pM:

$$g(J(v),J(w))=-g(v,w),$$

$v,\ w\in T_pM$. Extend g $\mathbf{C}$-bilinearly and J $\mathbf{C}$-linearly to the complexified tangent space $\mathbf{C}T_pM$. As usual, let $T_p^{1,0}M$ and $T_p^{0,1}M$ be, respectively, the eigenspaces of the eigenvalues i and $-i$ of J acting on $\mathbf{C}T_pM$. The compatability of J with g entails that $\mathbf{C}T_pM=T_p^{1,0}M\oplus T_p^{0,1}M$ is an orthogonal decomposition with respect to g. Moreover, the restriction, h, of g to $T_p^{1,0}M$ is a complex scalar product. If the Levi-Civita connection ∇_g of g is almost complex, $\nabla_g J=0$, then it turns out that J is integrable and h is holomorphic, i.e., (M,h) is a holomorphic Riemannian manifold. Conversely, every holomorphic Riemannian manifold can be seen to arise in this manner. Thus, one may refer to such (M,g,J) as a holomorphic Riemannian manifold. Note that one defines $\mu(\ ,\ ):=g(J\ ,\ )$ (by analogy with the Kähler form in Hermitian geometry), which is another neutral metric on M. Then ∇_g is almost complex iff $\nabla_g=\nabla_\mu$, where the latter is the Levi-Civita connection of μ. These results appear in Woodhouse[11] and Robinson[8] and are easy analogs of familiar results in Hermitian/Kähler geometry. Indeed, one may now develop holomorphic differential geometry in purely real terms by analogy with the development of Hermitian and Kähler geometry in, for example, Ref. 5, Chap. IX.

Let U be a holomorphic chart domain for a holomorphic Riemannian manifold $(M,h)=(M,g,J)$ equipped with holomorphic coordinates $\{z_1,\ldots,z_n\}$ and write $Z^i:=\partial/\partial z_i$ so that $\{Z_1,\ldots,Z_n\}$ is a basis for $T_p^{1,0}$, $p\in U$. Adopting the notation of Ref. 5, Chap. IX, Sec. 5, $\{Z_A:A=1,\ldots,n,\overline{1},\ldots,\overline{n}\}=\{Z_\alpha,Z_{\overline{\alpha}}:\alpha=1,\ldots,n\}$ denotes the associated basis of the complexified tangent space $\mathbf{C}T_pM$. Introduce Christoffel symbols as follows:

$$\nabla_{Z_B}Z_C=\Gamma_{BC}^A Z_A,$$

where ∇ is the $\mathbf{C}$-linear extension of ∇_g to $\mathbf{C}TM$. As ∇_g is almost complex and torsion free, then (cf., Ref. 5, p. 156)

$$\Gamma_{\beta\gamma}^{\alpha}=\Gamma_{\gamma\beta}^{\alpha},\quad \Gamma_{\beta\overline{\gamma}}^{\overline{\alpha}}=\overline{\Gamma_{\beta\gamma}^{\alpha}}\quad \text{all other } \Gamma_{BC}^A \text{ vanish.}$$

Hence, $\nabla_{Z_\beta}Z_\gamma=\Gamma_{\beta\gamma}^{\alpha}Z_\alpha$. Adaptation of a standard argument shows that

$$\Gamma_{BC}^A=\tfrac{1}{2}g^{DA}(\partial_B g_{DC}+\partial_C g_{DB}-\partial_D g_{BC}),$$

where $g_{AB}:=g(Z_A,Z_B)$, and g^{AB} are the entries of the matrix inverse to (g_{AB}). With $h_{\alpha\beta}:=h(Z_\alpha,Z_\beta)$, and $h^{\alpha\beta}$ the entries of the matrix inverse to the matrix $(h_{\alpha\beta})$, one finds

$$\Gamma_{\beta\gamma}^{\alpha}=\tfrac{1}{2}h^{\delta\alpha}(\partial_\beta h_{\delta\gamma}+\partial_\gamma h_{\delta\beta}-\partial_\delta h_{\beta\gamma}),$$

i.e., the Christoffel symbols of h with respect to the coordinates $\{z_\alpha\}$ are just $\Gamma_{\beta\gamma}^{\alpha}$. In a similar fashion, one may, for example, obtain the holomorphic Riemann curvature tensor of h from the (complexification) of the Riemann curvature tensor of g.

Turning to the matter of holonomy, it turns out that ∇_g is almost complex iff the Levi-Civita connection, as a connection on the frame bundle, reduces to the bundle of complex frames (analog of Ref. 5, (4.8), p. 152). Thus, taking the holonomy for (M,h) to be that of the connection ∇_g yields holonomy in

$$\mathbf{O}(\mathbf{n};\mathbf{C}) = \mathbf{GL}(\mathbf{n};\mathbf{C}) \cap \mathbf{O}(\mathbf{n},\mathbf{n}),$$

as is appropriate. The holonomy of neutral metrics is the subject of Refs. 1 and 3 though with an emphasis upon the four (real)-dimensional case.

III. THE DE RHAM–WU DECOMPOSITION

The possibility of obtaining a de Rham-like decomposition theorem for (M,h), when M is simply connected, is now accessible through Wu's[12–14] extension to pseudo-Riemannian geometry of de Rham's result by applying Wu's result directly to (M,g).

Let $\Psi(p)$ be the linear holonomy group of ∇_g at $p \in M$ acting on T_pM, and T_0 the subspace of tangent vectors fixed under this action. Suppose T_0 is nondegenerate, which I shall refer to as *Wu's condition*. Then, there is a decomposition $T_pM = \oplus_{i=0}^{k} T_i$ into mutually g-orthogonal, $\Psi(p)$-invariant, weakly irreducible (i.e., no nontrivial, nondegenerate, $\Psi(p)$-invariant subspaces) subspaces T_i. The decomposition is unique up to order and $\Psi(p)$ is a direct product $\Psi_0 \times \cdots \times \Psi_k$ of normal subgroups, with Ψ_i acting trivially on T_j, $j \neq i$, and weakly irreducibly on T_i, and $\Psi_0 = \langle 1 \rangle$. The subspaces T_i may be parallely propagated to yield involutive distributions.

If M is complete, one obtains a global decomposition: M is isometric to a product $M_0 \times \cdots \times M_k$, where each factor M_i is a simply connected, complete pseudo-Riemannian manifold with weakly irreducible holonomy Ψ_i, and is totally geodesic as a submanifold of M. Furthermore, M_0 is flat (in fact pseudo-Euclidean since it is a simply connected space form). Call such a decomposition a *de Rham–Wu decomposition*.

Given a de Rham–Wu decomposition of a manifold with neutral metric, then presumably the factors need not, in general, be neutral. Nevertheless, one still has:

Theorem: Let (M,g,J) be a simply connected, complete, holomorphic Riemannian manifold of real dimension $2n$ satisfying Wu's condition. Then M has a de Rham–Wu decomposition $M_0 \times \cdots \times M_k$, where each factor is holomorphic Riemannian in a natural manner and the isometry $M \simeq M_0 \times \cdots \times M_k$ is biholomorphic. $M_0 \simeq \mathbf{R}^{m,m}$, some $m \leqslant n$.

Proof: The essentials of the argument of Ref. 5, Theorem 8.1, p. 172, carry over to the present circumstances. In particular, the argument there establishes that J restricts to each T_i as an anti-orthogonal complex structure, whence each factor *is* neutral. The remainder of the argument in Ref. 5, Theorem 8.1 confirms the assertions in the theorem.

Completeness in the Theorem refers to the geodesics of g, but it is clear from the discussion of complex geodesics in Ref. 6 that the obvious notion of *completeness* for the complex geodesics of h is equivalent to completeness of the geodesics of g.

Note that the notion of nondegeneracy introduced on p. 173 of Ref. 5 is not relevant to holomorphic Riemannian manifolds as J, being anti-orthogonal, cannot belong to $\Psi(x)$.

Pseudo-Hermiticity for a class of nondiagonalizable Hamiltonians

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University,
Rumelifeneri Yolu, 80910 Sariyer, Istanbul, Turkey

(Received 8 July 2002; accepted 12 August 2002)

We give two characterization theorems for pseudo-Hermitian (possibly nondiagonalizable) Hamiltonians with a discrete spectrum that admit a block-diagonalization with finite-dimensional diagonal blocks. In particular, we prove that for such an operator H the following statements are equivalent: (1) H is pseudo-Hermitian; (2) the spectrum of H consists of real and/or complex-conjugate pairs of eigenvalues and the geometric multiplicity and the dimension of the diagonal blocks for the complex-conjugate eigenvalues are identical; (3) H is Hermitian with respect to a positive-semidefinite inner product. We further discuss the relevance of our findings for the merging of a complex-conjugate pair of eigenvalues of diagonalizable pseudo-Hermitian Hamiltonians in general, and the PT-symmetric Hamiltonians and the effective Hamiltonian for a certain closed FRW minisuperspace quantum cosmological model in particular. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1514834]

I. INTRODUCTION

In Refs. 1–5 we developed the notion of a pseudo-Hermitian operator and investigated its various consequences in particular in connection with PT-symmetric quantum systems[6] and two-component formulation of the FRW minisuperspace quantum cosmology.[7] Since the announcement of the results of Ref. 1 several authors have explored the implications of pseudo-Hermiticity.[8] The main results reported in Refs. 1–5 were, however, based on the assumption that the Hamiltonian of the system is diagonalizable and has a discrete spectrum. As demonstrated in Ref. 5, the latter condition can be easily relaxed. Moreover, in Ref. 9 we showed, without making any assumption about the diagonalizability of the Hamiltonian or discreteness of its spectrum, that the results of Refs. 1 and 3 generalized to the class of all PT-symmetric standard Hamiltonians having $\mathbb{R}$ as their configuration space. This suggests that these results may be valid under more general conditions. Our purpose in the present article is to generalize the results of Ref. 1 to the class of possibly nondiagonalizable Hamiltonians that admit a block-diagonalization with finite-dimensional diagonal blocks. This, in particular, includes all the matrix Hamiltonians. It is also relevant to the accidental loss of diagonalizability due to the pseudo-Hermiticity-preserving variations of diagonalizable pseudo-Hermitian Hamiltonians that lead to the merging of complex-conjugate pairs of eigenvalues.

The organization of the article is as follows. In Sec. II, we discuss the basic properties of the class of the Hamiltonians admitting a block-diagonalization with finite-dimensional diagonal blocks. In Sec. III, we present two characterization theorems for pseudo-Hermitian Hamiltonians belonging to this class. In Sec. IV, we study general 2×2 matrix Hamiltonians. In Sec. V, we discuss an application of our results in quantum cosmology. Finally, in Sec. VI, we present our concluding remarks.

II. BLOCK-DIAGONALIZABLE HAMILTONIANS WITH FINITE-DIMENSIONAL DIAGONAL BLOCKS

Consider a linear operator $H:\mathcal{H}\to\mathcal{H}$ acting in a (separable) Hilbert space $\mathcal{H}$ and having a discrete spectrum. Suppose that for every eigenvalue E_n, there are positive integers $g_n, p_n \in \mathbb{Z}^+$ such that for all $l \in \mathbb{Z}^+$,

$$d_{n,l} := \dim[\ker(H-E_n 1)^l] = g_n, \text{ if and only if } l \geqslant p_n. \tag{1}$$

This in particular means that

$$d_{n,1} \leqslant d_{n,2} \leqslant \cdots \leqslant d_{n,p_n-1} \leqslant d_{n,p_n} = g_n. \tag{2}$$

The integer $d_{n,1}$ is just the degree of degeneracy or the geometric multiplicity of E_n. In what follows, we shall use the abbreviated notation d_n for $d_{n,1}$ and denote the degeneracy labels $1,2,\ldots,d_n$ by the letters from the beginning of the Latin alphabet.

The integer g_n is called the algebraic multiplicity of E_n. The condition (1) means that all the eigenvalues of H have finite algebraic multiplicity. Throughout this paper we shall assume that this condition is satisfied and that there is a basis of the Hilbert space in which H is block-diagonal with diagonal blocks being finite-dimensional. In this case, we can always find a basis in which the diagonal blocks have the canonical Jordan form,[10] i.e., there is an invertible operator $A:\mathcal{H}\to\mathcal{H}$ and an orthonormal basis $\{|n,a,i\rangle\}$ with n being the spectral label, $a \in \{1,2,\ldots,d_n\}$, $i \in \{1,2,\ldots,p_{n,a}\}$, and $p_{n,a} \in \mathbb{Z}^+$, such that

$$A^{-1}HA = H_b := \sum_n \sum_{a=1}^{d_n} \left(E_n \sum_{i=1}^{p_{n,a}} |n,a,i\rangle\langle n,a,i| + \sum_{i=1}^{p_{n,a}-1} |n,a,i\rangle\langle n,a,i+1| \right). \tag{3}$$

Alternatively, letting

$$|\psi_n,a,i\rangle := A|n,a,i\rangle, \quad |\phi_n,a,i\rangle := A^{-1\dagger}|n,a,i\rangle, \tag{4}$$

we have

$$\langle \psi_n,a,i|\phi_m,b,j\rangle = \delta_{mn}\delta_{ab}\delta_{ij}, \quad \sum_i \sum_{a=1}^{d_n} \sum_{i=1}^{p_{n,a}} |\psi_n,a,i\rangle\langle\phi_n,a,i| = 1, \tag{5}$$

$$H = AH_bA^{-1} = \sum_n \sum_{a=1}^{d_n} \left(E_n \sum_{i=1}^{p_{n,a}} |\psi_n,a,i\rangle\langle\phi_n,a,i| + \sum_{i=1}^{p_{n,a}-1} |\psi_n,a,i\rangle\langle\phi_n,a,i+1| \right). \tag{6}$$

Note that according to Eqs. (5) and (6), $\{|\psi_n,a,i\rangle, |\phi_n,a,i\rangle\}$ is a complete biorthonormal system for the Hilbert space and

$$H|\psi_n,a,1\rangle = E_n|\psi_n,a,1\rangle, \tag{7}$$

$$H^\dagger|\phi_n,a,p_{n,a}\rangle = E_n^*|\phi_n,a,p_{n,a}\rangle. \tag{8}$$

Hence $|\psi_n,a,1\rangle$ are the eigenvectors of H and $|\phi_n,a,p_{n,a}\rangle$ are the eigenvectors of $H^\dagger$.

The numbers $p_{n,a}$ represent the dimension of the Jordan block associated with the spectral label n and the degeneracy label a. We shall refer to them as the Jordan dimensions. For a given eigenvalue E_n, the number of the corresponding Jordan blocks (which is equal to the geometric multiplicity of E_n) and the Jordan dimensions are uniquely determined by the integers $d_{n,l}$ of (1) up to the permutations of the degeneracy labels.[10] Note also that the algebraic multiplicity is the sum of the Jordan dimensions, $g_n := \sum_{a=1}^{d_n} p_{n,a}$.

III. CONSEQUENCES OF PSEUDO-HERMITICITY

Theorem 1: Let $H:\mathcal{H}\to\mathcal{H}$ be a linear operator acting in a (separable) Hilbert space $\mathcal{H}$. Suppose that the spectrum of H is discrete, its eigenvalues have finite algebraic multiplicity, and that (6) holds. Then, H is pseudo-Hermitian if and only if the eigenvalues of H are either real or come in complex-conjugate pairs and the geometric multiplicity and the Jordan dimensions of the complex-conjugate eigenvalues coincide.

Proof: Suppose that H is pseudo-Hermitian. Then, by definition,[1] there is a Hermitian automorphism (linear bijection mapping $\mathcal{H}$ onto $\mathcal{H}$) $\eta:\mathcal{H}\to\mathcal{H}$ such that $H^\dagger=\eta H\eta^{-1}$. Now let E_n be an arbitrary element of the spectrum of H. Then, by virtue of Eqs. (7) and (8), for each $a\in\{1,2,\ldots,d_n\}$, $|\psi_n,a,1\rangle$ is an eigenvector of H with eigenvalue E_n and $|\phi_n,a,p_{n,a}\rangle$ is an eigenvector of $H^\dagger$ with eigenvalue E_n^*. This in turn implies $H\eta^{-1}|\phi_n,a,p_{n,a}\rangle=\eta^{-1}H^\dagger|\phi_n,a,p_{n,a}\rangle=E_n^*\eta^{-1}|\phi_n,a,p_{n,a}\rangle$. As η^{-1} is an invertible operator, $\eta^{-1}|\phi_n,a,p_{n,a}\rangle\neq 0$. Hence E_n^* also belongs to the spectrum of H. Next, note that because the eigenvalues of H and consequently $H^\dagger$ have finite algebraic multiplicity, for every $l\in\mathbb{Z}^+$, $\text{kernel}(H-E_n)^l$, $\text{kernel}(H-E_n^*)^l$, and $\text{kernel}(H^\dagger-E_n^*)^l$ are finite-dimensional subspaces of $\mathcal{H}$. Clearly, as a result of (6), H and $H^\dagger$ have essentially the same Jordan block-diagonalization. In particular, the geometric multiplicity and the Jordan dimensions of E_n^* as an eigenvalue of $H^\dagger$ is the same as the geometric multiplicity and the Jordan dimensions of E_n as an eigenvalue of H. This implies that $\text{kernel}(H^\dagger-E_n^*)^l$ and $\text{kernel}(H-E_n)^l$ have the same dimension. Thus they are isomorphic. Furthermore, using the fact that η is an automorphism, $\text{kernel}(H^\dagger-E_n^*)^l$ is also isomorphic to

$$\text{kernel}[\,\eta^{-1}(H^\dagger-E_n^*)^l\eta]=\text{kernel}(\,\eta^{-1}H^\dagger\eta-E_n^*)^l=\text{kernel}(H-E_n^*)^l.$$

Therefore, for every $l\in\mathbb{Z}^+$, $\text{kernel}(H-E_n)^l$ and $\text{kernel}(H-E_n^*)^l$ are isomorphic and consequently have the same dimension. This in turns implies that the number of the Jordan blocks associated with E and their dimensions are identical with those of E_n^*, i.e., E_n and E_n^* have the same geometric multiplicity, and up to permutations of the degeneracy labels they have identical Jordan dimensions as well. Conversely, suppose that the eigenvalues of H are either real or come in complex-conjugate pairs and the geometric multiplicity d_n and the Jordan dimensions $p_{n,a}$ of the complex conjugate pairs of eigenvalues are identical. We shall set $n=\nu_0,\nu,\nu-$ depending on whether imaginary part of E_n is zero, positive, or negative. Then $E_{\nu-}=E_\nu^*$, $d_{\nu-}=d_\nu$, for all $a\in\{1,2,\ldots,d_n\}$, $p_{\nu-,a}=p_{\nu,a}$, and Eq. (6) takes the form

$$\begin{aligned}H=&\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}\Bigg(E_{\nu_0}\sum_{i=1}^{p_{\nu_0,a}}|\psi_{\nu_0},a,i\rangle\langle\phi_{\nu_0},a,i|+\sum_{i=1}^{p_{\nu_0,a}-1}|\psi_{\nu_0},a,i\rangle\langle\phi_{\nu_0},a,i+1|\Bigg)\\&+\sum_{\nu}\sum_{a=1}^{d_\nu}\Bigg[\sum_{i=1}^{p_{\nu,a}}(E_\nu|\psi_\nu,a,i\rangle\langle\phi_\nu,a,i|+E_\nu^*|\psi_{\nu-},a,i\rangle\langle\phi_{\nu-},a,i|)\\&+\sum_{i=1}^{p_{\nu,a}-1}(|\psi_\nu,a,i\rangle\langle\phi_\nu,a,i+1|+|\psi_{\nu-},a,i\rangle\langle\phi_{\nu-},a,i+1|)\Bigg].\end{aligned}\tag{9}$$

Next, let

$$\begin{aligned}\eta(x,\xi):=&\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}\sum_{i=1}^{p_{\nu_0,a}}\sum_{j=p_{\nu_0,a}+1-i}^{p_{\nu_0,a}}x_{\nu_0,a,i+j}|\phi_{\nu_0},a,i\rangle\langle\phi_{\nu_0},a,j|\\&+\sum_{\nu}\sum_{a=1}^{d_\nu}\sum_{i=1}^{p_{\nu,a}}\sum_{j=p_{\nu,a}+1-i}^{p_{\nu,a}}(\xi_{\nu,a,i+j}|\phi_\nu,a,i\rangle\langle\phi_{\nu-},a,j|+\xi_{\nu,a,i+j}^*|\phi_{\nu-},a,j\rangle\langle\phi_\nu,a,i|),\end{aligned}\tag{10}$$

where $x_{\nu_0,a,k}\in\mathbb{R}$, $\xi_{\nu,a,k}\in\mathbb{C}$,

$$x_{\nu_0,a,p_{\nu_0,a}+1}\neq 0\neq \xi_{\nu,a,p_{\nu,a}+1}, \tag{11}$$

and x and ξ, respectively, stand for the sequences $\{x_{\nu_0,a,k}\}$ and $\{\xi_{\nu,a,k}\}$. It is not difficult to check that, for all $n=\nu_0,\nu,\nu-$, $m=\mu_0,\mu,\mu-$, and the corresponding degeneracy labels a,b and Jordan block labels i,j,

$$\langle\psi_{\nu_0},a,i|\,\eta(x,\xi)\,|\psi_{\mu_0},b,j\rangle=\begin{cases}\delta_{\nu_0,\mu_0}\delta_{ab}x_{\nu_0,a,i+j}, & \text{for } i+j>p_{\nu_0,a}\\ 0, & \text{otherwise;}\end{cases}$$

$$\begin{aligned}\langle\psi_{\nu},a,i|\,\eta(x,\xi)\,|\psi_{\mu-},b,j\rangle&=\langle\psi_{\mu-},a,i|\,\eta(x,\xi)\,|\psi_{\nu},b,j\rangle^*\\&=\begin{cases}\delta_{\nu,\mu}\delta_{ab}\xi_{\nu,a,i+j}, & \text{for } i+j>p_{\nu,a}\\ 0, & \text{otherwise;}\end{cases}\end{aligned} \tag{13}$$

and that the other matrix elements of $\eta:=\eta(x,\xi)$, in the basis $\{|\psi_n,a,j\rangle\}$, vanish. In view of Eqs. (12), (13), and (11), η is a Hermitian automorphism. Furthermore, using Eqs. (5) and (9)–(11), one can check that it satisfies $\eta H=H^\dagger\eta$. Hence, $H^\sharp:=\eta^{-1}H^\dagger\eta=H$, and H is η-pseudo-Hermitian.□

An immediate consequence of this theorem is the following

Corollary 1: Let H be as in Theorem 1. Then the pseudo-Hermiticity of H is a necessary condition for the reality of its spectrum.

Note that (10) is not the most general expression for an η with respect to which H is η-pseudo-Hermitian. One can obtain more general expressions by performing appropriate basis transformations. (These are the transformations that mix the basis vectors with different degeneracy labels a but identical spectral label n and the Jordan dimension $p_{n,a}$). Similarly to the diagonalizable case,[4] one can also perform a change of basis to set $x_{\nu_0,a,k}=\pm 1$ and $\xi_{\nu,a,k}=1$. This is, however not the simplest choice for η. It is not difficult to check that the following simpler choice works as well:

$$x_{\nu_0,a,k}=\begin{cases}\pm 1, & \text{for } k=p_{\nu_0,a}+1,\\ 0, & \text{otherwise,}\end{cases}\qquad \xi_{\nu,a,k}=\begin{cases}1, & \text{for } k=p_{\nu,a}+1,\\ 0, & \text{otherwise.}\end{cases} \tag{14}$$

In this way one obtains the following set of simple canonical automorphisms with respect to which H is η-pseudo-Hermitian:

$$\begin{aligned}\eta(\sigma):=&\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}\sigma_{\nu_0,a}\left(\sum_{i=1}^{p_{\nu_0,a}}|\phi_{\nu_0},a,i\rangle\langle\phi_{\nu_0},a,p_{\nu_0,a}+1-i|\right)\\&+\sum_{\nu}\sum_{a=1}^{d_\nu}\sum_{i=1}^{p_{\nu,a}}(|\phi_\nu,a,i\rangle\langle\phi_{\nu-},a,p_{\nu,a}+1-i|+|\phi_{\nu-},a,p_{\nu,a}+1-i\rangle\langle\phi_\nu,a,i|),\end{aligned} \tag{15}$$

with $\sigma:=\{\sigma_{\nu_0,a}\}$ being a sequence of signs. A straightforward calculation shows that

$$\begin{aligned}\eta(\sigma)^{-1}:=&\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}\sigma_{\nu_0,a}\left(\sum_{i=1}^{p_{\nu_0,a}}|\psi_{\nu_0},a,i\rangle\langle\psi_{\nu_0},a,p_{\nu_0,a}+1-i|\right)\\&+\sum_{\nu}\sum_{a=1}^{d_\nu}\sum_{i=1}^{p_{\nu,a}}(|\psi_\nu,a,i\rangle\langle\psi_{\nu-},a,p_{\nu,a}+1-i|+|\psi_{\nu-},a,p_{\nu,a}+1-i\rangle\langle\psi_\nu,a,i|).\end{aligned} \tag{16}$$

If H is diagonalizable, $p_{n,a}=1$ and (15) yields the expression for the canonical automorphisms given in Ref. 4. Again choosing all the signs $\sigma_{\nu_0,a}$ to be positive yields a positive-semidefinite (non-negative) η and a positive-semidefinite inner product,

$$\langle\langle\psi,\phi\rangle\rangle_\eta := \langle\psi|\,\eta\,|\phi\rangle. \tag{17}$$

However, even if the complex eigenvalues are absent this choice does not lead to a positive-definite inner product on the Hilbert space unless H is diagonalizable. This is because in general there are defective (real) eigenvalues E_{ν_0}; at least one of the Jordan dimensions $p_{\nu_0,a}$ is greater than 1; and according to (12) and (13), $\langle\langle\psi_{\nu_0},a,1|\psi_{\nu_0},a,1\rangle\rangle_\eta=\langle\psi_{\nu_0},a,1|\,\eta\,|\psi_{nu_0},a,1\rangle=0$. Hence the corresponding eigenvector $|\psi_{\nu_0},a,1\rangle$ is null, and the inner product (17) is not positive-definite.

Theorem 2: Let H be as in Theorem 1. Then H is pseudo- Hermitian if and only if it is Hermitian with respect to a positive-semidefinite inner product $\langle\langle\,,\rangle\rangle:\mathcal{H}^2\to\mathbb{C}$, i.e., for all $\phi,\psi\in\mathcal{H}$, $\langle\langle\phi,H\psi\rangle\rangle=\langle\langle H\phi,\psi\rangle\rangle$.

Proof: Suppose H is pseudo-Hermitian, then according to Theorem 1 it has real and/or complex-conjugate pairs of eigenvalues with identical geometric multiplicity and Jordan dimensions. According to the proof of this theorem, this implies that H is pseudo-Hermitian with respect to the automorphism (15) with $\sigma_{\nu_0,a}=1$ for all ν_0 and $a\in\{1,2,\ldots,d_{\nu_0}\}$. The latter yields the positive-semidefinite inner product (17) which satisfies, for all $\psi,\phi\in\mathcal{H}$,

$$\langle\langle\phi,H\psi\rangle\rangle_\eta=\langle\phi|\,\eta H\,|\psi\rangle=\langle\phi|H^\dagger\,\eta\,|\psi\rangle=\langle H\phi|\,\eta\,|\psi\rangle=\langle\langle H\phi,\psi\rangle\rangle_\eta.$$

Hence H is Hermitian with respect to the inner product (17). Conversely, let H be Hermitian with respect to a positive-semidefinite inner product $\langle\langle\,,\rangle\rangle$. Let $\eta:\mathcal{H}\to\mathcal{H}$ be defined in terms of its matrix elements according to, for all $\psi,\phi\in\mathcal{H}$,

$$\langle\psi|\,\eta\,|\phi\rangle := \langle\langle\psi,\phi\rangle\rangle.$$

Then, because $\langle\langle\,,\rangle\rangle$ is a sesquilinear, Hermitian, nondegenerate quadratic form,[11] η is a linear, Hermitian, automorphism. Furthermore, because H is Hermitian with respect to $\langle\langle\,,\rangle\rangle$ we have, for all $\psi,\phi\in\mathcal{H}$,

$$\langle\phi|\,\eta H\psi\rangle=\langle\langle\phi,H\psi\rangle\rangle=\langle\langle H\phi,\psi\rangle\rangle=\langle H\phi|\,\eta\,|\psi\rangle=\langle\phi|H^\dagger\,\eta\psi\rangle.$$

Therefore, $\eta H=H^\dagger\,\eta$ or $H^\sharp:=\eta^{-1}H^\dagger\,\eta=H$, i.e., H is pseudo-Hermitian. □

IV. 2×2 MATRIX HAMILTONIANS

In Ref. 3, we showed that the pseudo-Hermiticity of a diagonalizable Hamiltonian is equivalent to the presence of antilinear symmetries. The PT-symmetry studied in the literature[6] is a primary example. In general, such a Hamiltonian depends on certain continuous parameters whose variation does not destroy the symmetry but changes the spectrum. In particular, it is possible that under such variations complex-conjugate pairs of eigenvalues merge and produce real eigenvalues or a real eigenvalue splits into a complex-conjugate pair of eigenvalues. This is a generic behavior observed in the numerical studies of PT-symmetric Hamiltonians[6] and naturally applies in the case of general pseudo-Hermitian Hamiltonians. Now consider a diagonalizable pseudo-Hermitian Hamiltonian with a discrete spectrum that undergoes a continuous pseudo-Hermiticity-preserving perturbation. In general, such a perturbation may not preserve the diagonalizability of the Hamiltonian.[12] In particular, at the critical values of the perturbation parameter when two nondegenerate complex-conjugate eigenvalues merge to produce a real eigenvalue, there is no guarantee that the resulting eigenvalue is doubly degenerate. This observation underlies the importance of the results of Sec. III in the study of the behavior of diagonalizable pseudo-Hermitian operators undergoing arbitrary pseudo-Hermiticity-preserving perturbations.

Consider the case that under such a perturbation a pair of complex-conjugate nondegenerate eigenvalues cross while no other level-crossing occurs. In the vicinity of this level-crossing, one can approximate the behavior of the Hamiltonian by a traceless 2×2 matrix Hamiltonian. In Ref. 4, we have studied the properties of general complex, traceless, diagonalizable, pseudo-Hermitian 2×2 matrix Hamiltonians. A traceless 2×2 matrix H with two nondegenerate eigenvalues is pseudo-Hermitian if its determinant is a nonzero real number.[4] As we explain below the converse of this statement is also true. In particular, $\det(H)<0$ or $\det(H)>0$ depending on whether the eigenvalues are real or imaginary. This means that the moduli space $\mathcal{M}$ of traceless pseudo-Hermitian 2×2 matrices with two nondegenerate eigenvalues is a 5-dimensional subspace of the 8-dimensional space $M(2,\mathbb{C})$ of all complex 2×2 matrices. The latter has the manifold structure of $\mathbb{C}^4=\mathbb{R}^8$. If we, respectively, denote the subsets of complex traceless 2×2 matrices, complex traceless pseudo-Hermitian 2×2 matrices, and traceless Hermitian 2×2 matrices by M_0, $\mathcal{M}'$, and $\mathcal{M}_0$, we have

$$\begin{array}{ccccccccc} \mathcal{M}_0 & \subset & \mathcal{M} & \subset & \mathcal{M}' & \subset & M_0 & \subset & M(2,\mathbb{C}) \\ || & & & & & & || & & || \\ \mathbb{R}^3 & & & & & & \mathbb{R}^6 & & \mathbb{R}^8. \end{array}$$

We can identify $\mathcal{M}$ with the inverse image of $\mathbb{R}-\{0\}\subset\mathbb{R}^2=\mathbb{C}$ under the continuous function $\det: M(2,\mathbb{C})\to\mathbb{C}=\mathbb{R}^2$. Noting that $\mathbb{R}^+$ and $\mathbb{R}^-$ are disjoint, open, connected subsets of $\mathbb{C}$ and det is continuous, we infer that $\mathcal{M}$ consists of two open connected components, namely

$$\mathcal{M}^{\pm}:=\{H\in\mathcal{M}|\det H\in\mathbb{R}^{\pm}\}.$$

This in turn implies that at a critical point of the parameters of H where a level-crossing happens, H fails to stay in $\mathcal{M}$. This is also easily seen by realizing that because H is traceless, a level-crossing can occur only if $\det H$ vanishes. Therefore, at the level-crossing either $H=0$ or it is nondiagonalizable.

In fact, it is not difficult to see that an element $X_{\pm}$ of $\mathcal{M}^{\pm}$ has the general form

$$X_{\pm}=\sqrt{\pm 1}Eg^{-1}\sigma_3 g, \tag{18}$$

where E is a nonzero real number, g is an element of the special linear group $SL(2,\mathbb{C})$, and σ_3 is the diagonal Pauli matrix $\mathrm{diag}(1,-1)$. The form (18) indicates that the moduli spaces $\mathcal{M}^+$ and $\mathcal{M}^-$ have the manifold structure of $F\times(\mathbb{R}-\{0\})$ where F is the 4-dimensional homogeneous space:

$$F:=SL(2,\mathbb{C})/U_{\mathbb{C}}(1),$$

and

$$U_{\mathbb{C}}(1):=\{e^{z\sigma_3}|z\in\mathbb{C}\}=\left\{\left(\begin{array}{cc} w & 0 \\ 0 & w^{-1}\end{array}\right)\middle| w\in\mathbb{C}-\{0\}\right\}.$$

Furthermore, according to (18) the group elements g that are uniquely parametrized by the points of F play the same role for both X_+ and X_-. It is the factor $\sqrt{\pm 1}\,E$ in (18) that differentiates X_+ and X_-. This suggests that we can identify $\mathcal{M}^{\pm}$ by $F\times L^{\pm}$, where

$$L^+:=\{z\in\mathbb{C}-\{0\}|\mathrm{Re}(z)=0\}=\text{imaginary axis in the complex plane with 0 removed,}$$

$$L^-:=\{z\in\mathbb{C}-\{0\}|\mathrm{Im}(z)=0\}=\text{real axis in the complex plane with 0 removed,}$$

and ''Re'' and ''Im'' stand for the ''real'' and the ''imaginary'' part of the corresponding complex variable, respectively.

The above picture of $\mathcal{M}$ confirms our earlier remark that at a level-crossing a traceless pseudo-Hermitian 2×2 matrix,

$$H=\begin{pmatrix} a & b \\ c & -a \end{pmatrix}, \tag{19}$$

either vanishes identically:

$$a=b=c=0, \tag{20}$$

or becomes nondiagonalizable:

$$a=\pm i\sqrt{bc}, \quad |a|^2+|b|^2+|c|^2\neq 0, \tag{21}$$

where $i:=\sqrt{-1}$. In the latter case, according to (6), H has the form $H=|\psi_1\rangle\langle\phi_2|$ where $\{|\psi_a\rangle,|\phi_a\rangle\}$ with $a=\{1,2\}$ is a complete biorthonormal system in $\mathbb{C}^2$. In particular, we have the following.

Proposition 1: Every traceless nondiagonalizable 2×2 matrix H is pseudo-Hermitian.

Proof: Because H is both traceless and nondiagonalizable, zero is the only eigenvalue of H. Hence according to Theorem 1, it must be pseudo-Hermitian. □

Theorem 3: A traceless 2×2 matrix H is pseudo-Hermitian if and only if it has a real determinant, i.e.,

$$\mathcal{M}'=\{H\in M_0|\det H\in\mathbb{R}\}.$$

Proof: If H is not diagonalizable, then according to Proposition 1 it is pseudo-Hermitian, and the statement of Theorem 3 is trivially satisfied. If H is diagonalizable, it is either identically zero, in which case it is pseudo-Hermitian and has a real (zero) determinant, or it has two nondegenerate eigenvalues. In the latter case, in view of a proposition proven in Ref. 4, the reality of the determinant of H implies its pseudo-Hermiticity. The converse is also true. For if H is pseudo-Hermitian, then its eigenvalues are either both real or they are complex-conjugate of one another. Because H has a vanishing trace, in the latter case the eigenvalues must be imaginary. This in turn implies that in both cases the determinant of H is real. □

In light of Theorem 3, the possibility (20) that at a level-crossing a traceless pseudo-Hermitian 2×2 matrix Hamiltonian remains diagonalizable corresponds to a single point in the uncountably infinite set of traceless nondiagonalizable pseudo-Hermitian 2×2 matrices $\mathcal{M}'-\mathcal{M}$. To make this observation more transparent, consider the pseudo-Hermitian matrix Hamiltonians (19) corresponding to the choice $c=0$. Then $\det H=-a^2$, $a\in L^{\pm}$, and $H\in\mathcal{M}^{\pm}$. Now suppose that a and b are analytic functions of a real perturbation parameter λ and that a level-crossing occurs at $\lambda=0$. Then at the vicinity of the level-crossing, i.e., for $|\lambda|<\epsilon$ for some sufficiently small $\epsilon\in\mathbb{R}^+$,

$$a(\lambda)\approx\begin{cases} a_{\rm r}\lambda, & \text{for} \quad -\epsilon<\lambda\leqslant 0 \\ ia_{\rm i}\lambda, & \text{for} \quad 0\leqslant\lambda<\epsilon \end{cases}, \quad b(\lambda)\approx b_0+b_1\lambda,$$

where $a_{\rm r}$ and $a_{\rm i}$ are nonzero real constants, and b_0 and b_1 are complex constants. At $\lambda=0$, H vanishes identically provided that $b_0=b(0)=0$. This is the only way in which H can maintain its diagonalizability. Clearly, for $b_0\neq 0$, H becomes nondiagonalizable at $\lambda=0$. In both cases $a(0)=0\in\mathbb{R}$ is the only eigenvalue (alternatively $\det H=0$). Hence, according to Corollary 1 (respectively, Theorem 3), H remains pseudo-Hermitian at $\lambda=0$. This example clearly shows that the loss of diagonalizability at the crossing of the complex-conjugate eigenvalues is a generic behavior.

V. APPLICATION

Consider the Wheeler–DeWitt equation for the closed FRW minisuperspace model with a real massive scalar field,

$$\left[-\frac{\partial^2}{\partial\alpha^2}+\frac{\partial^2}{\partial\varphi^2}+e^{4\alpha}-m^2e^{6\alpha}\varphi^2\right]\psi(\alpha,\varphi)=0, \tag{22}$$

where $\alpha:=\ln a$, "a" is the scale factor, φ is a real scalar field of mass m, and we have chosen a particularly simple factor ordering and the natural units.[13,14] The Wheeler–DeWitt equation (22) can be written in the Schrödinger form $i\dot{\Psi}=H\Psi$ where Ψ is the two-component wave function,[7]

$$\Psi:=\frac{1}{\sqrt{2}}\begin{pmatrix}\psi+i\dot{\psi}\\ \psi-i\dot{\psi}\end{pmatrix},$$

H is the effective Hamiltonian,

$$H:=\frac{1}{2}\begin{pmatrix}1+D & -1+D\\ 1-D & -1-D\end{pmatrix}, \tag{23}$$

a dot means a derivative with respect to α, and

$$D:=-\frac{\partial^2}{\partial\varphi^2}+m^2e^{6\alpha}\varphi^2-e^{4\alpha}. \tag{24}$$

The eigenvalue problem for the Hamiltonian (23) may be easily solved.[7] The eigenvectors $\Psi_{n\pm}$ and the corresponding eigenvalues $E_{n\pm}$ have the form

$$\Psi_{n\pm}=\frac{1}{\sqrt{2}}\begin{pmatrix}1+E_{n\pm}\\ 1-E_{n\pm}\end{pmatrix}\phi_n,\quad E_{n\pm}=\pm\sqrt{me^{3\alpha}(2n+1)-e^{4\alpha}}=\pm a\sqrt{a[m(2n+1)-a]}, \tag{25}$$

where $n=0,1,2,\ldots$, $\phi_n:=N_nH_n(m^{1/2}e^{3\alpha/2}\varphi)e^{-me^{3\alpha}\varphi^2/2}$, H_n are Hermite polynomials, and $N_n:=[me^{3\alpha}/(\pi 2^{2n}n!^2)]^{1/4}$ are normalization constants.

As seen from (25), for $a\leqslant m$ the spectrum of H is real, and for $a>m$ it consists of real and complex-conjugate pairs of eigenvalues. In general H is pseudo-Hermitian, because $H^\dagger=\sigma_3H\sigma_3$. For $a\neq(2n+1)m$, it is also diagonalizable. But at the critical values $a=(2n+1)m$ where a real (namely the zero) eigenvalue splits into a complex-conjugate pair of eigenvalues or the converse happens, H fails to be diagonalizable. The situation is precisely like the one discussed in Sec. IV. Here the perturbation parameter has the form $\lambda:=a-(2n+1)m$. At the vicinity of a level-crossing where $\lambda\to0$, the operator D and its eigenvectors do not undergo any discontinuous changes. Therefore, one can approximate the span of the eigenvectors Ψ_{n-} and Ψ_{n+} for $\lambda\neq0$ with the span of the vectors,

$$|1\rangle=\begin{pmatrix}\phi_n\\ 0\end{pmatrix},\quad |2\rangle=\begin{pmatrix}0\\ \phi_n\end{pmatrix},$$

where ϕ_n is evaluated at $\alpha=\ln a=\ln[(2n+1)m]$, i.e., $\lambda=0$. Clearly, we can study the level-crossing by confining our attention to this subspace. The above approximation becomes exact in the limit $\lambda\to0$. In the subspace spanned by $|1\rangle$ and $|2\rangle$ the operator D is identically zero. Therefore, we can approximate D by a constant that tends to zero as $\lambda\to0$. Therefore, the Hamiltonian (23) takes the form of the matrix Hamiltonian (19) with $a=(1+D)/2$,$b=(-1+D)/2$, and $c=(1-D)/2$. In the limit $\lambda\to0$, D approaches zero, and the conditions (21) hold. Hence, as expected, H becomes nondiagonalizable at the level-crossing.

The above argument implies that in general H is diagonalizable for all values of the scale factor except the critical values $a=(2n+1)m$. At these values H becomes nondiagonalizable as one of its eigenvalues, namely the zero eigenvalue, becomes defective. The algebraic multiplicity of this eigenvalue is two. In fact, the effective Hamiltonian (23) belongs to the class of block-diagonalizable Hamiltonians discussed in Secs. II and III. Its canonical Jordan form consists of a 2×2 Jordan block corresponding to the zero eigenvalue and an infinite number of trivial (1×1) blocks corresponding to nonzero eigenvalues. The fact that this Hamiltonian is pseudo-Hermitian for all values of the scale factor, its spectrum consists of real and complex- conjugate eigenvalues, and its complex eigenvalues are not defective is consistent with the general results of Sec. III.

VI. SUMMARY AND CONCLUSION

In this article we generalized our earlier results on diagonalizable pseudo-Hermitian Hamiltonians to a broad class of nondiagonalizable Hamiltonians. We showed that if a pseudo-Hermitian Hamiltonian may be mapped to a block-diagonal operator with finite-dimensional blocks via a similarity transformation, then the characterization theorems of Ref. 1 apply provided that the number and size of the Jordan blocks for the complex-conjugate pairs of eigenvalues are identical.

We also discussed the implications of our findings for the phenomenon of the loss of diagonalizability at the crossing of the complex-conjugate pairs of eigenvalues of diagonalizable pseudo-Hermitian Hamiltonians. For the latter, pseudo-Hermiticity is known to be equivalent to the presence of an antilinear symmetry.[3] This in particular means that our results are relevant in the description of the PT-symmetric systems that are diagonalizable except in the case of level-crossings of the complex-conjugate eigenvalues due to perturbations of the Hamiltonian. If at the critical values of the perturbation parameter each level-crossing involves a finite number of levels, then our results apply generally. This seems to be the case for various PT-symmetric models studied in the literature. Specifically, at the critical values of the parameters of the PT-symmetric systems that undergo a spontaneous PT-symmetry breaking, a pair of real eigenvalues merge and a loss of diagonalizability similar to the one discussed in Sec. V occurs.

As a final note, we wish to emphasize that the results of this paper rely on the basic assumption that the quantum system has a genuine separable Hilbert space in which the Hamiltonian acts. For many PT-symmetric Hamiltonians the (inner product) structure of the function space in which one solves for the eigenfunctions is not clear. In this context, the assumption of considering non-Hermitian Hamiltonians acting in a separable Hilbert space may seem too restrictive. Nevertheless, we believe that this assumption provides a framework for exploring some of the intriguing properties of a class of non-Hermitian Hamiltonians. This class includes many PT-symmetric Hamiltonians as well as all the matrix Hamiltonians and the non-Hermitian Hamiltonians appearing in the two-component formulation of the Klein–Gordon and Wheeler–DeWitt equations.

ACKNOWLEDGMENTS

I wish to thank the anonymous referee(s) of Refs. 3 and 4, who emphasized that the diagonalizability assumption made in these papers might be a serious limitation, and M. Znojil who convinced me that a loss of diagonalizability occured in certain PT-symmetric models. Finally I would like to acknowledge the support of the Turkish Academy of Sciences through the Young Researcher Award Program (GEBIP).

(Received 22 April 2002; accepted 25 June 2002)

A grading of a Lie algebra is called fine if it cannot be further refined. Fine gradings provide basic information about the structure of the algebra. There are eight fine gradings of the simple Lie algebra of type A_3 over the complex number field. One of them (root decomposition) is the main tool of the theory and applications in working with A_3 and with its representations; one other has also been used in the literature, and the rest have apparently not been recognized so far. An explicit description of all the fine gradings of A_3 is given in terms of the four-dimensional [sl(4, $\mathbb{C}$)] and six-dimensional orthogonal [o(6, $\mathbb{C}$)] representations of the algebra. These results should be useful generally for choosing bases which reflect structural properties of the Lie algebra, for defining various sets of additive quantum numbers for systems with such symmetries, and for systematic study of grading preserving contractions of this Lie algebra. © *2002 American Institute of Physics.*

I. INTRODUCTION

Decomposition of a Lie algebra, considered as a linear space, into the direct sum of subspaces of lower dimension is a simple problem which obviously has many solutions. However, if in addition one requires that such a decomposition is a grading, severe limitations are imposed on the possible decompositions so that the problem of classification of all the gradings becomes a difficult task. Its solution has not been published for any simple Lie algebra of rank >1. Indeed, grading is a requirement involving the multiplication (i.e., commutation) in the algebra. It is natural to consider two decompositions (grading or not) equivalent if one can be transformed into the other by an automorphism of the Lie algebra.

A finite dimensional Lie algebra can be decomposed into a finite number of nonempty subspaces. (We disregard the decompositions which would introduce additional subspaces of dimension 0.) A coarse grading decomposes the Lie algebra into a small number of grading subspaces. The coarsest trivial one leaves the Lie algebra in one subspace. The coarsest nontrivial gradings decompose the algebra into two subspaces. Every simple Lie algebra over $\mathbb{C}$ admits several gradings of this kind. It is well known that the real forms of the algebra are in one-to-one correspondence with such gradings.

The *fine grading* was introduced in Ref. 1 as a grading which decomposes the Lie algebra into a maximal number of subspaces. By definition such a decomposition cannot be further refined while remaining a grading. The best known example of a fine grading of simple Lie algebra over $\mathbb{C}$ is the root (also called Cartan) decomposition. There a Lie algebra of rank r and dimension rk is decomposed into the r-dimensional Cartan subalgebra and $r(k-1)$ one-dimensional root spaces. There is no grading which would further split the Catran subalgebra.

The present article is very similar to Ref. 2, where an explicit description of fine gradings of a rank two Lie algebra of type B_2 [equivalently sp(4, $\mathbb{C}$) and o(5, $\mathbb{C}$)] is given. There are eight nonequivalent fine gradings of the simple Lie algebra A_3.[3] Their description is provided in this article for the first time. More precisely, we consider the lowest representations of A_3 of dimension 4 and 6, calling them respectively sl(4, $\mathbb{C}$) and o(6, $\mathbb{C}$), and present the eight gradings in both representations. Only one of them is well known (root decomposition) and one other for each representation can also be found in the literature. We refer to Ref. 2 also for general motivation for studying fine gradings of semisimple Lie algebras. Let us point out here only the following: A fine grading goes a long way in defining a basis of the Lie algebra (up to a normalization). A graded basis exploits structural properties of the Lie algebra such as the simplicity of commutation relations of the generators. The most difficult step in describing all the gradings of an algebra is to find its fine gradings. Many important properties of simple Lie algebras and computing tools are related to their root systems. Therefore it is natural to ask whether the grading labels of other fine gradings could possibly play an analogous role. In particular, an important class of subalgebras are the regular ones. They are all displayed by the root decomposition. Other fine gradings display other subalgebras.

Consider a simple Lie algebra L with complex parameters. In Ref. 3 maximal subgroups of the automorphism group Aut L with Abelian diagonalizable action on L were classified (so called MAD-groups). Decomposition of L into eigenspaces of a given MAD-group is a fine grading. The eigenspaces (grading subspaces) of such a decomposition are naturally labeled by the eigenvalues of the elements of the MAD-group. Practically a small number of elements of the MAD-group provides enough eigenvalues to label the subspaces. Choice of the labeling elements is far from unique but the grading subspaces of a fine grading do not depend on that choice. In physics the eigenvalues labeling the grading subspaces are interpreted as maximal sets of simultaneously admissible quantum numbers describing a system with the symmetry of the Lie algebra L. Different choices of the labeling elements reflect the fact that there are several possible choices of quantum numbers describing the systems with the same symmetry algebra L.

Once the explicit fine gradings are written down, it is easy to verify that among them there are no equivalent pairs. Indeed, one can proceed, for example, as follows: (i) Compare the dimensions of grading subspaces. If they do not coincide, gradings are not equivalent. It there are coincidences, then (ii) compare the number of one-dimensional grading subspaces which consist of semisimple and nilpotent elements. Again, if those numbers do not coincide, the two gradings are not equivalent. Finally, if previous tests failed to provide a definite answer, (iii) compare the number of commuting pairs of one-dimensional grading subspaces. The three simple criteria above may not be sufficient for all the simple Lie algebras, but they suffice to verify the nonequivalence of the eight gradings of sl(4, $\mathbb{C}$). It is taken from Ref. 3 that there are precisely eight such gradings. One of the motivations for the present article is the fact that the way from the MAD-groups to actual gradings is rather laborious and that the properties of the fine gradings are not easily detectable from its MAD-group.

In this article we say that a subalgebra L' of a Lie algebra L is *displayed* by a grading of L, if L' consists of several grading subspaces of the grading decomposition. There are four maximal reductive subalgebras in sl(4, $\mathbb{C}$), namely the following ones:

$$\mathrm{sp}(4,\mathbb{C}),\quad \mathrm{o}(4,\mathbb{C})\simeq\mathrm{sl}(2,\mathbb{C})\times\mathrm{sl}(2,\mathbb{C}),\quad \mathrm{gl}(3,\mathbb{C})\simeq\mathrm{sl}(3,\mathbb{C})\times\mathrm{u}(1),\quad \mathrm{sl}(2,\mathbb{C})\times\mathrm{sl}(2,\mathbb{C})\times\mathrm{u}(1). \tag{1}$$

Here we have noted the well known isomorphisms; u(1) stands for a one-dimensional ideal of the subalgebra. The presence of a displayed maximal reductive subalgebra for each of the fine gradings is pointed out in the article. There is an inherent ambiguity in the traditional notations for subalgebras (1). Thus, for example, the two subalgebras denoted sl(2, $\mathbb{C}$)$\times$sl(2, $\mathbb{C}$) are very different [see (6) in Sec. II].

In Sec. II preliminary useful information is recalled and some notations are fixed. Section III contains a description of the fine gradings of sl(4, $\mathbb{C}$) in terms of 4×4 matrices. Maximal reductive subalgebras of A_3 are described in Sec. IV. The fine gradings of o(6, $\mathbb{C}$) are presented in Sec. V in terms of 6×6 matrices. The last section contains comments and conclusions.

II. PRELIMINARIES

Since the task we have set forth in this article is to describe eight rather complicated cases in two versions each, it makes sense to collect in this section common notations, facts, and as much as possible of the repetitive pertinent properties, besides the introductory mathematics that one typically expects here. The economy of space one gains in this way does not come without a price: the section becomes a collection of little connected and/or motivated facts which need to be frequently consulted later on.

(1) The defining or natural representation of the simple Lie algebra sl(4, $\mathbb{C}$) has 15 complex valued parameters which are denoted by $a,b,\ldots,p$. Thus the (complex) dimension of the algebra is 15:

$$\mathrm{sl}(4,\mathbb{C})=\{X\in\mathbb{C}^{4\times4}|\mathrm{tr}X=0\}=\left\{X=\begin{pmatrix} a & b & c & d\\ e & f & g & h\\ j & k & l & m\\ n & o & p & -a-f-l\end{pmatrix}\middle|\, a,\ldots,p\in\mathbb{C}\right\}. \tag{2}$$

In a number of applications one needs to consider only the Lie algebras of orthogonal transformations. It is one of the coincidences which happen among small rank simple Lie algebras, that sl(4, $\mathbb{C}$) of (2) is isomorphic to the Lie algebra o(6, $\mathbb{C}$):

$$\mathrm{o}(6,\mathbb{C})=\{X\in\mathbb{C}^{6\times6}|XK+KX^T=0\},\quad K=K^T,\quad \det K=1. \tag{3}$$

Different choices of the matrix K define equivalent representations of the algebra. The two following representations are widely used:

$$K=\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0\\ 0 & 1 & 0 & 0 & 0 & 0\\ 0 & 0 & 1 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 0 & 0\\ 0 & 0 & 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 0 & 0 & 1\end{pmatrix}:$$

$$\mathrm{o}(6,\mathbb{C})=\left\{\begin{pmatrix} 0 & a & b & c & d & e\\ -a & 0 & f & g & h & j\\ -b & -f & 0 & k & l & m\\ -c & -g & -k & 0 & n & o\\ -d & -h & -l & -n & 0 & p\\ -e & -j & -m & -o & -p & 0\end{pmatrix}\middle|\, a,\ldots,p\in\mathbb{C}\right\}, \tag{4}$$

$$K=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}:$$

$$\mathrm{o}(6,\mathbb{C})=\left\{ \begin{pmatrix} a & b & c & d & e & 0 \\ f & g & h & j & 0 & -e \\ k & l & m & 0 & -j & -d \\ n & o & 0 & -m & -h & -c \\ p & 0 & -o & -l & -g & -b \\ 0 & -p & -n & -k & -f & -a \end{pmatrix} \middle| \; a,\ldots,p\in\mathbb{C} \right\}. \tag{5}$$

One simple way how to choose a basis, also called the generators, of the Lie algebra, is to put one parameter equal to 1 and all others equal to 0. The bases chosen in this way from (2) and (4) or (5) are in no particular correspondence. In our study of gradings, the normalization of the generators is of no importance, therefore we are often being guided by the simplicity of the corresponding matrices.

In general, the equality of the normalizations in (2) and (4), (5) can be fixed by using the Killing form with the second indices of the representations involved. More precisely, suppose $\phi(x)$ and $\psi(x)$ represent the element $x\in A_3$ in two different representations, say ϕ and ψ. Denoting the second indices of the representations respectively by l_ϕ and l_ψ, one has the Killing form (x,y) given (up to a suitable constant) by

$$(x,y)=l_\phi \mathrm{tr}(\phi(x)\phi(y))=l_\psi \mathrm{tr}(\psi(x)\psi(y)),$$

which fixes the relative normalization in the representations ϕ and ψ. In particular, let ϕ and ψ stand for the representations (2) and (3), respectively. Then we have

$$\mathrm{tr}(\phi(x)\phi(y))=2\,\mathrm{tr}(\psi(x)\psi(y)).$$

The values of the indices can be found, for example, in Ref. 4 for many representations.

(2) Grading of a Lie algebra L implies that, as a linear space, the algebra can be decomposed into the direct sum of several nontrivial subspaces, $L=\oplus_{k\in\mathcal{I}}L_k$ in such a way that for every choice of $x\in L_k$ and $y\in L_j$ we have $[x,y]\in L_{k+j}$. Symbolically we note this property as

$$0\neq[L_k,L_j]\subseteq L_{k+j}. \tag{6}$$

If $j+k\notin\mathcal{I}$ for some $j,k\in\mathcal{I}$, then necessarily the subspaces L_j, L_k commute.

The grading labels $k,j,\ldots$ are far from uniquely defined. However, the decomposition into the direct sum of subspaces is determined up to an automorphism of L. Natural requirements of simplicity reduce the wide choice of grading labels to a very few. In general the grading labels are multi-component.

A grading is determined if a basis for each subspace L_k is given. Practically a grading is obtained as an eigenspace decomposition of suitably chosen elements of the automorphism group $Aut\ L$ of L. It follows that the grading subspaces are orthogonal with respect to the Killing form.

The result that we present in this article is the list of all nonequivalent *fine* gradings of the Lie algebra sl(4, $\mathbb{C}$). A grading $L=\oplus_{k\in\mathcal{I}}L_k$ of a Lie algebra is called fine when none of its subspaces L_k can be further split into several nontrivial subspaces in such a way that the new decomposition would still be a grading of L.

It is useful to introduce two operations on gradings of a Lie algebra L, namely *refinement* and *coarsening* of a grading. A given grading $L=\oplus_{k\in\mathcal{I}}L_k$ is refined when some of its subspaces L_k are split and the resulting decomposition is a grading. Thus a fine grading is an end of the process of successive refinements of a grading. In the opposite direction, the ultimate end of coarsening a grading is the whole Lie algebra forming just one grading subspace.

(3) For a simple Lie algebra $L/\ \mathbb{C}$ there is a one-to-one correspondence between fine gradings of L and maximal Abelian groups of diagonalizable automorphisms on L (so-called MAD-groups). The list of MAD-groups used in this article was obtained from Ref. 3.

In order to obtain all the nonequivalent fine gradings of sl(4, $\mathbb{C}$) we first rewrite the pertinent MAD-groups of Ref. 3 as subgroups of the group of automorphisms Aut sl(4, $\mathbb{C}$). Subsequently, we have to use also the MAD-groups of Aut o(6, $\mathbb{C}$). They are described in Sec. V. The correspondence between the two sets of MAD-groups is not entirely obvious.

We use the Lie group SL(4, $\mathbb{C}$)$=\{A\in\ \mathbb{C}^{4\times4}|\det A=1\}$ to describe the set $\mathcal{A}ut$ sl(4, $\mathbb{C}$) of all automorphisms on sl(4, $\mathbb{C}$). In general, $\mathcal{A}ut$ sl(4, $\mathbb{C}$) contains both inner and outer automorphisms. These act on an element X of the Lie algebra sl(4, $\mathbb{C}$) in the following way:

$$\text{inner automorphism}\quad Ad_A:\ Ad_AX=A^{-1}XA, \tag{7}$$

$$\text{outer automorphism}\quad Out_C:\ Out_CX=-(C^{-1}XC)^T. \tag{8}$$

Notice that for any $\alpha\neq0$ the description for $Ad_{\alpha A}$ and Ad_A coincide. Therefore the condition $\det A=1$ can be released to $\det A\neq0$. A compact description of the set $\mathcal{A}ut$ sl(4, $\mathbb{C}$) is then

$$\mathcal{A}ut\ \text{sl}(4,\mathbb{C})=\{Ad_A|\det A\neq0\}\cup\{Out_C|\det C\neq0\}.$$

(4) Two of the MAD-groups of Aut sl(4, $\mathbb{C}$) consist of inner automorphisms only, the remaining six involve also outer automorphisms. In our list of the MAD-groups we always characterize a MAD-group $\mathcal{G}$ by the set G_{Ad} of matrices A of the inner automorphisms Ad_A and by the set G_{Out} of matrices C for outer automorphisms Out_C. Actually when G_{Out} is nonempty, we mention only one of its elements denoted C, because all other elements F of G_{Out} can be written as $F=AC$, where $A\in G_{Ad}$. The outer automorphism $Out_F=Out_{AC}$ is just a composition of Out_C and Ad_A, respectively: $Out_{AC}=Out_C\circ Ad_A$.

The list of MAD-groups $\mathcal{G}_1,\ldots,\mathcal{G}_8$ in Aut sl(4, $\mathbb{C}$) is found in Table I. The symbols σ_k, $k=0,1,2,3$, stand for 2×2 Pauli matrices:

$$\sigma_0=\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad \sigma_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0&1\\-1&0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

Our convention as to how the tensor product $\otimes$ is understood is explained by the following example, where A is an arbitrary matrix:

$$\sigma_1\otimes A=\begin{pmatrix}0&1\\1&0\end{pmatrix}\otimes A=\begin{pmatrix}0&A\\A&0\end{pmatrix}.$$

(5) It is convenient to introduce the constant $n\times n$ matrices E_{jk}, M_{jk}, and N_{jk}, and to recall their commutation rules:

$$(E_{jk})_{lm}=\delta_{jl}\delta_{km},\quad M_{jk}=E_{jk}-E_{kj},\quad N_{jk}=E_{jk}-E_{(n+1-k)(n+1-j)}, \tag{9}$$

$$[E_{jk},E_{lm}]=\delta_{kl}E_{jm}-\delta_{jm}E_{lk}, \tag{10}$$

$$[M_{jk},M_{lm}]=\delta_{kl}M_{jm}-\delta_{jm}M_{lk}-\delta_{jl}M_{km}+\delta_{km}M_{lj}, \tag{11}$$

$$[N_{jk},N_{lm}]=\delta_{kl}N_{jm}-\delta_{jm}N_{lk}-\delta_{j(n+1-l)}N_{(n+1-k)m}+\delta_{k(n+1-m)}N_{l(n+1-j)}. \tag{12}$$

TABLE I. The full list of nonconjugate maximal Abelian groups of diagonalizable automorphisms (MAD-groups) on sl(4, $\mathbb{C}$).

	G_{Ad}	G_{Out}
$\mathcal{G}_1$	$\{A=\mathrm{diag}(d_1,d_2,d_3,1),\ d_j\in\mathbb{C}, d_j\neq 0\}$	$\emptyset$
$\mathcal{G}_2$	$\left\{A=P^jQ^k, j,k=0,1,2,3, P=\begin{pmatrix}0&1&0&0\\0&0&1&0\\0&0&0&1\\1&0&0&0\end{pmatrix},\ Q=\mathrm{diag}(1,i,-1,-i)\right\}$	$\emptyset$
$\mathcal{G}_3$	$\{A=\mathrm{diag}(\varepsilon_1,\varepsilon_2,\varepsilon_3,1),\ \varepsilon_i=\pm 1\}$	$C=I_4$
$\mathcal{G}_4$	$\{A=\mathrm{diag}(1,\varepsilon,\alpha,\alpha^{-1}),\ \varepsilon=\pm 1,\alpha\in\mathbb{C},\alpha\neq 0\}$	$C=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix}$
$\mathcal{G}_5$	$\{A=\mathrm{diag}(\alpha,\alpha^{-1},\beta,\beta^{-1}),\ \alpha,\beta\in\mathbb{C},\alpha,\beta\neq 0\}$	$C=\begin{pmatrix}0&1&0&0\\1&0&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix}$
$\mathcal{G}_6$	$\{A=\sigma_j\otimes\mathrm{diag}(\alpha,\alpha^{-1}),\ \alpha\in\mathbb{C},\alpha\neq 0, j=0,1,2,3\}$	$C=\begin{pmatrix}0&1&0&0\\1&0&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix}$
$\mathcal{G}_7$	$\{A=\sigma_j\otimes\sigma_k,\ j,k=0,1,2,3\}$	$C=I_4$
$\mathcal{G}_8$	$\left\{A\in(G_0\otimes I_2)\cup(RG_0\otimes\sigma_3)\cup(G_0\otimes\sigma_1)\cup(RG_0\otimes\sigma_2),\ G_0=\left\{\begin{pmatrix}1&0\\0&1\end{pmatrix},\begin{pmatrix}1&0\\0&-1\end{pmatrix}\right\}, R=\begin{pmatrix}1&0\\0&i\end{pmatrix}\right\}$	$C=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix}$

(6) A simple way to avoid the ambiguity of traditional notations for maximal reductive subalgebras (1) is to provide the branching rule for one of the representations, usually of very low dimension. In this article we encounter three irreducible representations of A_3. Therefore it is useful to provide the corresponding branching rules. For that we use the notations of Ref. 4 for representations of the semisimple algebras (by their highest weight relative to the basis of fundamental weights). Irreducible representations of u(1) are all one-dimensional. The nonequivalent ones are labeled by an integer (positive and negative). In order to distinguish the representations of u(1), we write them as $[k]$.

Branching rules for the four-dimensional representation (1,0,0) of A_3:

$$(1)(1) \quad \text{for} \quad \mathrm{o}(4,\mathbb{C})\simeq\mathrm{sl}(2,\mathbb{C})\times\mathrm{sl}(2,\mathbb{C}), \tag{13}$$

$$(1,0) \quad \text{for} \quad \mathrm{sp}(4,\mathbb{C}), \tag{14}$$

$$(1,0)[1]+(0,0)[-3] \quad \text{for} \quad \mathrm{gl}(3,\mathbb{C})\simeq\mathrm{sl}(3,\mathbb{C})\times\mathrm{u}(1), \tag{15}$$

$$(1)(0)[1]+(0)(1)[-1] \quad \text{for} \quad \mathrm{sl}(2,\mathbb{C})\times\mathrm{sl}(2,\mathbb{C})\times\mathrm{u}(1). \tag{16}$$

Branching rules for the six-dimensional representation (0,1,0) of A_3:

$$(2)(0)+(0)(2) \quad \text{for } o(4,\mathbb{C})\simeq sl(2,\mathbb{C})\times sl(2,\mathbb{C}), \tag{17}$$

$$(1,0)+(0,0) \quad \text{for } sp(4,\mathbb{C}), \tag{18}$$

$$(1,0)[-2]+(0,1)[2] \quad \text{for } gl(3,\mathbb{C})\simeq sl(3,\mathbb{C})\times u(1), \tag{19}$$

$$(1)(1)[0]+(0)(0)[2]+(0)(0)[-2] \quad \text{for } sl(2,\mathbb{C})\times sl(2,\mathbb{C})\times u(1). \tag{20}$$

Branching rules for the 15-dimensional representation (1,0,1) of A_3:

$$(2)(2)+(2)(0)+(0)(2) \quad \text{for } o(4,\mathbb{C})\simeq sl(2,\mathbb{C})\times sl(2,\mathbb{C}), \tag{21}$$

$$(2,0)+(0,1) \quad \text{for } sp(4,\mathbb{C}), \tag{22}$$

$$(1,1)[0]+(0,1)[-4]+(1,0)[4] \quad \text{for } gl(3,\mathbb{C})\simeq sl(3,\mathbb{C})\times u(1), \tag{23}$$

$$(1)(1)[2]+(1)(1)[-2]+(2)(0)[0]+(0)(2)[0]+(+(0)(0)[0] \text{ for } sl(2,\mathbb{C})\times sl(2,\mathbb{C})\times u(1). \tag{24}$$

(7) *Example*. Consider an example of the automorphism $g(X)=F^{-1}XF$ of a general 4×4 matrix X [an element of gl(4, $\mathbb{C}$)]. Let the automorphism be realized by the diagonal matrix $F=\mathrm{diag}(\omega^3,\omega,\omega^{-1},\omega^{-3})$, where $\omega=\exp 2\pi i/8$. Corresponding eigenspace decomposition of gl(4, $\mathbb{C}$) is a grading by the cyclic group of order four generated by $g=Ad_F$. The adjoint action of this group is of order 4 while F is of order eight. Indeed, the equation $F^{-1}XF=\lambda X$ has four eigenvalues $\pm1,\pm i$ and four eigenspaces,

$$L_0=\begin{pmatrix} a & 0 & 0 & 0\\ 0 & f & 0 & 0\\ 0 & 0 & l & 0\\ 0 & 0 & 0 & q \end{pmatrix}, \quad L_1=\begin{pmatrix} 0 & b & 0 & 0\\ 0 & 0 & g & 0\\ 0 & 0 & 0 & m\\ n & 0 & 0 & 0 \end{pmatrix}, \quad L_2=\begin{pmatrix} 0 & 0 & c & 0\\ 0 & 0 & 0 & h\\ j & 0 & 0 & 0\\ 0 & o & 0 & 0 \end{pmatrix},$$

$$L_3=\begin{pmatrix} 0 & 0 & 0 & d\\ e & 0 & 0 & 0\\ 0 & k & 0 & 0\\ 0 & 0 & p & 0 \end{pmatrix}, \tag{25}$$

which we are labeling additively (subscripts read mod 4), rather than multiplicatively by the eigenvalues. Clearly the grading property (6) is satisfied. The grading decomposition gl(4, $\mathbb{C}$) $=L_0+L_1+L_2+L_3$ displays two subalgebras: L_0 of dimension 4 and L_0+L_2 of dimension 8. The latter subalgebra consists of four ideals, thus it can be written as a direct sum of four commuting subspaces. The ideals can be given by the generic 4×4 matrices which represent them:

$$\begin{pmatrix} a & 0 & c & 0\\ 0 & 0 & 0 & 0\\ j & 0 & -a & 0\\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 & 0 & 0\\ 0 & f & 0 & h\\ 0 & 0 & 0 & 0\\ 0 & o & 0 & -f \end{pmatrix}, \quad \begin{pmatrix} b & 0 & 0 & 0\\ 0 & -b & 0 & 0\\ 0 & 0 & b & 0\\ 0 & 0 & 0 & -b \end{pmatrix}, \quad \begin{pmatrix} l & 0 & 0 & 0\\ 0 & l & 0 & 0\\ 0 & 0 & l & 0\\ 0 & 0 & 0 & l \end{pmatrix}. \tag{26}$$

Note that the ideals are not displayed by the grading (25) Indeed, the subspace L_0 is split between all four ideals. Consequently, the four ideals could not be displayed in any refinement of the grading (25).

Putting $q=-a-f-l$, one restricts gl(4, $\mathbb{C}$) in this example to sl(4, $\mathbb{C}$) considered in this article. With that additional restriction, L_0 becomes three-dimensional, the last of the ideals (26) is eliminated, so that the remaining three ideals then form the subalgebra sl(2, $\mathbb{C}$)$\times$sl(2, $\mathbb{C}$) $\times$u(1). In the branching rule (24) the subalgebra is shown as its adjoint representation, namely $(2)(0)[0]+(0)(2)[0]+(0)(0)[0]$, corresponding to the first three ideals in (26). The remaining two terms of (24) are two irreducible representations of dimension 4 each which differ just by the representation of u(1). Again one could investigate whether the representations are displayed by the grading. The answer is negative in this example. The two representations are found within L_1+L_3 but not within L_1 or L_3 separately. Using the three diagonal generators of the subalgebra (one from each ideal) and remembering that their spectrum is either $\pm1,\pm1,2$ or $\pm1,\pm1,-2$ on the two representations, respectively, one finds directly the generic matrices of the two representations:

$$(1)(1)[2]\Leftrightarrow\begin{pmatrix}0&b&0&d\\0&0&0&0\\0&k&0&m\\0&0&0&0\end{pmatrix},\quad (1)(1)[-2]\Leftrightarrow\begin{pmatrix}0&0&0&0\\e&0&g&0\\0&0&0&0\\n&0&p&0\end{pmatrix}.$$

III. FINE GRADINGS OF THE COMPLEX LIE ALGEBRA sl(4, $\mathbb{C}$)

In this section we list all nonequivalent fine gradings of the Lie algebra sl(4, $\mathbb{C}$). Corresponding results for o(6, $\mathbb{C}$) are found in Sec. V.

A fine grading is a decomposition of the Lie algebra into eigenspaces (grading subspaces) of a MAD-group. It suffices to characterize a fine grading using a small subset of the MAD-group whose elements provide enough eigenvalues so that one can distinguish the eigenspaces–subspaces of the grading. There is a table shown for each fine grading. In this table one finds the eigenspaces (grading subspaces) labeled additively, the eigenvalues, and a basis for each subspaces. If the eigenvalues turn out to be functions of continuous parameters, we show as well their fixed values used for the grading.

A. Fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_1$

In order to produce the grading, we just take a generic element of $\mathcal{G}_1$, namely the automorphism Ad_A with $A=\mathrm{diag}(d_1,d_2,d_3,1)$. It decomposes sl(4, $\mathbb{C}$) into 13 subspaces: one three-dimensional (Cartan subalgebra) and 12 one-dimensional (root) subspaces. Results of this case are summarized in Table II.

The eigenvectors $X_1,\ldots,X_{15}$ of Ad_A are given in terms of matrices E_{jk} of (9):

$$\begin{gathered}X_1=E_{11}-E_{22},\quad X_2=E_{22}-E_{33},\quad X_3=E_{33}-E_{44},\\ X_4=E_{23},\quad X_5=E_{12},\quad X_6=E_{13},\\ X_7=E_{34},\quad X_8=E_{24},\quad X_9=E_{41},\\ X_{10}=E_{14},\quad X_{11}=E_{42},\quad X_{12}=E_{43},\\ X_{13}=E_{31},\quad X_{14}=E_{21},\quad X_{15}=E_{32}.\end{gathered}\tag{27}$$

In Table II we identify the grading subspaces L_j by their basis vectors X_k and by the corresponding eigenvalues. Two sets of eigenvalues are shown. The first one involves continuous parameters d_1,d_2,d_3. In the second set the values of the parameters are fixed to take some convenient values. Clearly there are many ways this could be done.

This grading is the well known root or Cartan decomposition of sl(4, $\mathbb{C}$). The grading group $\mathcal{G}_1$ is a fixed maximal torus of the Lie group SL(4, $\mathbb{C}$). The three-dimensional grading space L_0, spanned by X_1,X_2,X_3, is the Cartan subalgebra, the remaining 12 one-dimensional grading spaces

TABLE II. $\mathcal{G}_1$: The correspondence between eigenvectors X_k from (27) and the eigenvalue λ of Ad_A. Fixing the values of $d_1=\omega^6$, $d_2=\omega^8$, and $d_3=\omega^9$, where $\omega=\exp(2\pi i/13)$, the maximal torus is restricted to its cyclic subgroup $\mathbb{Z}_{13}$.

	Eigenvector	$\lambda=\lambda(d_1,d_2,d_3)$	$\lambda=\lambda(\omega^6,\omega^8,\omega^9)$
L_0	X_1	1	
	X_2	1	ω^0
	X_3	1	
L_1	X_4	$\frac{d_3}{d_2}$	ω^1
L_2	X_5	$\frac{d_2}{d_1}$	ω^2
L_3	X_6	$\frac{d_3}{d_1}$	ω^3
L_4	X_7	$\frac{1}{d_3}$	ω^4
L_5	X_8	$\frac{1}{d_2}$	ω^5
L_6	X_9	d_1	ω^6
L_7	X_{10}	$\frac{1}{d_1}$	ω^7
L_8	X_{11}	d_2	ω^8
L_9	X_{12}	d_3	ω^9
L_{10}	X_{13}	$\frac{d_1}{d_3}$	ω^{10}
L_{11}	X_{14}	$\frac{d_1}{d_2}$	ω^{11}
L_{12}	X_{15}	$\frac{d_2}{d_3}$	ω^{12}

are the root spaces of that decomposition. Let $\alpha_1,\alpha_2,\alpha_3$ denote the three simple roots. Matrices representing the root spaces can be chosen, for example, as follows: $E_{\alpha_1}=E_{12}$, $E_{\alpha_2}=E_{23}$, $E_{\alpha_3}=E_{34}$, $E_{\alpha_1+\alpha_2}=E_{13}$, $E_{\alpha_2+\alpha_3}=E_{24}$, $E_{\alpha_1+\alpha_2+\alpha_3}=E_{14}$. Then for the negative roots one has $E_{-\alpha_1}=E_{21}$, $E_{-\alpha_2}=E_{32}$, $E_{-\alpha_3}=E_{43}$, $E_{-\alpha_1-\alpha_2}=E_{31}$, $E_{-\alpha_2-\alpha_3}=E_{42}$, $E_{-\alpha_1-\alpha_2-\alpha_3}=E_{41}$.

Any further decomposition of sl(4, $\mathbb{C}$), which can split the Cartan subalgebra into lower dimensional subspaces while preserving the root spaces, is not a grading.

B. The fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_2$

Inner automorphisms Ad_{A_1} and Ad_{A_2}, where

$$A_1=Q=\begin{pmatrix}1&0&0&0\\0&i&0&0\\0&0&-1&0\\0&0&0&-i\end{pmatrix},\quad A_2=P=\begin{pmatrix}0&1&0&0\\0&0&1&0\\0&0&0&1\\1&0&0&0\end{pmatrix},$$

decompose the Lie algebra sl(4, $\mathbb{C}$) into 15 one-dimensional subspaces. Results of this case are summarized in Table III. The eigenvectors $X_1,\ldots,X_{15}$ can be given as powers of P and Q:

$$X_1=P^0Q^3,\quad X_2=P^0Q^2,\quad X_3=P^0Q^1,$$

TABLE III. $\mathcal{G}_2$: The correspondence between eigenvectors X_k from (28) and the eigenvalues λ_1,λ_2 of $Ad_{A_1}=Ad_Q$, $Ad_{A_2}=Ad_P$.

	Eigenvector	λ_1	λ_2
$L_{(0,1)}$	X_1	1	i
$L_{(0,2)}$	X_2	1	-1
$L_{(0,3)}$	X_3	1	$-i$
$L_{(1,0)}$	X_4	i	1
$L_{(1,1)}$	X_5	i	i
$L_{(1,2)}$	X_6	i	-1
$L_{(1,3)}$	X_7	i	$-i$
$L_{(2,0)}$	X_8	-1	1
$L_{(2,1)}$	X_9	-1	i
$L_{(2,2)}$	X_{10}	-1	-1
$L_{(2,3)}$	X_{11}	-1	$-i$
$L_{(3,0)}$	X_{12}	$-i$	1
$L_{(3,1)}$	X_{13}	$-i$	i
$L_{(3,2)}$	X_{14}	$-i$	-1
$L_{(3,3)}$	X_{15}	$-i$	$-i$

$$\begin{aligned} &X_4=P^1Q^0, \quad X_5=P^1Q^3, \quad X_6=P^1Q^2, \quad X_7=P^1Q^1,\\ &X_8=P^2Q^0, \quad X_9=P^2Q^3, \quad X_{10}=P^2Q^2, \quad X_{11}=P^2Q^1,\\ &X_{12}=P^3Q^0, \quad X_{13}=P^3Q^3, \quad X_{14}=P^3Q^2, \quad X_{15}=P^3Q^1. \end{aligned} \tag{28}$$

In terms of subspaces $L_{(j,k)}$ denoted by indices from the additive group $\mathbb{Z}_4\times\mathbb{Z}_4$ this can be briefly written as $L_{(j,k)}=\mathbb{C}(P^jQ^{-k})$, and the pair (λ_1,λ_2) of eigenvalues of elements from $L_{(j,k)}$ is equal to $(\lambda_1,\lambda_2)=(i^j,i^k)$.

Properties of the associative algebra generated by $n\times n$ matrices analogous to P and Q have been noted a long time ago.[5] The corresponding grading of $\mathrm{sl}(n,\mathbb{C})$ was studied in Ref. 6.

C. The fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_3$

Results of this case are summarized in Table IV. Using $A_1=\mathrm{diag}(-1,1,1,1)$, $A_2=\mathrm{diag}(-1,-1,1,1)$, $A_3=\mathrm{diag}(-1,-1,-1,1)$ for Ad_A and $C=I_4$ for Out_C the Lie algebra

TABLE IV. $\mathcal{G}_3$: The correspondence between eigenvectors X_k from (29) and the eigenvalues $\lambda_0,\lambda_1,\lambda_2,\lambda_3$ of $Out_C, Ad_{A_1}, Ad_{A_2}, Ad_{A_3}$. Indices of the subspaces $L_{(j,k,l,m)}$ are elements of the additive group $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$.

	Eigenvector	λ_0	λ_1	λ_2	λ_3
$L_{(1,1,1,1)}$	X_1	-1	-1	-1	-1
$L_{(0,1,1,1)}$	X_2	1	-1	-1	-1
$L_{(1,0,1,1)}$	X_3	-1	1	-1	-1
$L_{(0,0,1,1)}$	X_4	1	1	-1	-1
$L_{(1,0,0,1)}$	X_5	-1	1	1	-1
$L_{(0,0,0,1)}$	X_6	1	1	1	-1
$L_{(1,1,1,0)}$	X_7	-1	-1	-1	1
$L_{(0,1,1,0)}$	X_8	1	-1	-1	1
$L_{(1,0,1,0)}$	X_9	-1	1	-1	1
$L_{(0,0,1,0)}$	X_{10}	1	1	-1	1
$L_{(1,1,0,0)}$	X_{11}	-1	-1	1	1
$L_{(0,1,0,0)}$	X_{12}	1	-1	1	1
$L_{(1,0,0,0)}$	X_{13}	-1	1	1	1
	X_{14}	-1	1	1	1
	X_{15}	-1	1	1	1

TABLE V. $\mathcal{G}_4$: The correspondence between eigenvectors X_k from (30) and the eigenvalues λ_0, λ_1 of Out_C, Ad_A. Denoting $\eta = \exp(2\pi i/8)$ and appointing the value $\alpha = \eta$ to the parameter α, the indices of subspaces become elements of $\mathbb{Z}_2 \times \mathbb{Z}_8$.

	Eigenvector	λ_0	$\lambda_1 = \lambda_1(\alpha)$	$\lambda_1 = \lambda_1(\eta)$
$L_{(0,0)}$	X_1	1	1	η^0
$L_{(1,0)}$	X_2	-1	1	η^0
	X_3	-1	1	
$L_{(0,1)}$	X_4	1	α	η^1
$L_{(1,1)}$	X_5	-1	α	η^1
$L_{(1,2)}$	X_6	-1	α^2	η^2
$L_{(0,3)}$	X_7	1	$-\alpha^{-1}$	η^3
$L_{(1,3)}$	X_8	-1	$-\alpha^{-1}$	η^3
$L_{(0,4)}$	X_9	1	-1	η^4
$L_{(1,4)}$	X_{10}	-1	-1	η^4
$L_{(0,5)}$	X_{11}	1	$-\alpha$	η^5
$L_{(1,5)}$	X_{12}	-1	$-\alpha$	η^5
$L_{(1,6)}$	X_{13}	-1	α^{-2}	η^6
$L_{(0,7)}$	X_{14}	1	α^{-1}	η^7
$L_{(1,7)}$	X_{15}	-1	α^{-1}	η^7

sl(4, $\mathbb{C}$) is decomposed into one three-dimensional and 12 one-dimensional subspaces which are described by simultaneous eigenvectors $X_1, \ldots, X_{15}$:

$$\begin{gathered} X_1 = E_{14} + E_{41}, \quad X_2 = E_{14} - E_{41}, \quad X_3 = E_{24} + E_{42}, \quad X_4 = E_{24} - E_{42}, \\ X_5 = E_{34} + E_{43}, \quad X_6 = E_{34} - E_{43}, \quad X_7 = E_{13} + E_{31}, \quad X_8 = E_{13} - E_{31}, \\ X_9 = E_{23} + E_{32}, \quad X_{10} = E_{23} - E_{32}, \quad X_{11} = E_{12} + E_{21}, \quad X_{12} = E_{12} - E_{21}, \\ X_{13} = E_{11} - E_{22}, \quad X_{14} = E_{22} - E_{33}, \quad X_{15} = E_{33} - E_{44}. \end{gathered} \tag{29}$$

One can see that the present grading is not conjugate to the root decomposition, e.g., because all grading subspaces are spanned by semisimple elements of the Lie algebra, as opposed to the root decomposition, where only the Cartan subalgebra consists of such elements.

Clearly the six skew-symmetric matrices in this grading display the subalgebra o(4, $\mathbb{C}$). The simplest way to examine the grading is the following: Consider the four subalgebras which consist of the subspaces of the form $L_{(0,*,*,*)}$, $L_{(*,0,*,*)}$, $L_{(*,*,0,*)}$, $L_{(*,*,*,0)}$. Here $*$ stands for any admissible value of the corresponding label. Then identify each subalgebra. In this way one finds here respectively o(4, $\mathbb{C}$), gl(3, $\mathbb{C}$), sl(2, $\mathbb{C}$) $\times$ sl(2, $\mathbb{C}$) $\times$ u(1), and gl(3, $\mathbb{C}$).

D. The fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_4$

Results of this case are summarized in Table V. To obtain a fine grading by $\mathcal{G}_4$ one only needs to use the inner automorphism Ad_A with matrix $A = \mathrm{diag}(1, -1, \alpha, \alpha^{-1})$ and the outer automorphism Out_C with

$$C = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

TABLE VI. $\mathcal{G}_5$: The correspondence between eigenvectors X_k from (31) and the eigenvalues λ_0, λ_1 of Out_C, Ad_A. In order to embed the index set into the additive group $\mathbb{Z}_2 \times \mathbb{Z}_9$ we put $\alpha = \nu^2$ and $\beta = \nu^8$, where $\nu = \exp(2\pi i/9)$.

	Eigenvector	λ_0	$\lambda_1 = \lambda_1(\alpha, \beta)$	$\lambda_1 = \lambda_1(\nu^2, \nu^8)$
$L_{(0,0)}$	X_1	1	1	ν^0
	X_2	1	1	
$L_{(1,0)}$	X_3	-1	1	ν^0
$L_{(0,1)}$	X_4	1	$\alpha\beta$	ν^1
$L_{(1,1)}$	X_5	-1	$\alpha\beta$	ν^1
$L_{(1,2)}$	X_6	-1	β^{-2}	ν^2
$L_{(0,3)}$	X_7	1	$\alpha\beta^{-1}$	ν^3
$L_{(1,3)}$	X_8	-1	$\alpha\beta^{-1}$	ν^3
$L_{(1,4)}$	X_9	-1	α^2	ν^4
$L_{(1,5)}$	X_{10}	-1	α^{-2}	ν^5
$L_{(0,6)}$	X_{11}	1	$\alpha^{-1}\beta$	ν^6
$L_{(1,6)}$	X_{12}	-1	$\alpha^{-1}\beta$	ν^6
$L_{(1,7)}$	X_{13}	-1	β^2	ν^7
$L_{(0,8)}$	X_{14}	1	$\alpha^{-1}\beta^{-1}$	ν^8
$L_{(1,8)}$	X_{15}	-1	$\alpha^{-1}\beta^{-1}$	ν^8

There are one two-dimensional and 13 one-dimensional subspaces, and we list them in terms of eigenvectors $X_1, \ldots, X_{15}$:

$$
\begin{gathered}
X_1 = E_{33} - E_{44}, \quad X_2 = E_{11} + E_{22} - E_{33} - E_{44}, \quad X_3 = E_{11} - E_{22}, \\
X_4 = E_{13} - E_{41}, \quad X_5 = E_{13} + E_{41}, \quad X_6 = E_{43}, \\
X_7 = E_{24} - E_{32}, \quad X_8 = E_{24} + E_{32}, \quad X_9 = E_{12} - E_{21}, \\
X_{10} = E_{12} + E_{21}, \quad X_{11} = E_{23} - E_{42}, \quad X_{12} = E_{23} + E_{42}, \\
X_{13} = E_{34}, \quad X_{14} = E_{14} - E_{31}, \quad X_{15} = E_{14} + E_{31}.
\end{gathered} \tag{30}
$$

The presence of the parameter α indicates that a one-parametric subgroup of the torus remains a part of the grading group. It can be identified with the subgroup $\mathrm{SL}(2, \mathbb{C}) \subset \mathrm{SL}(4, \mathbb{C})$ corresponding to one of the simple roots of $\mathrm{sl}(4, \mathbb{C})$. This decomposition of $\mathrm{sl}(4, \mathbb{C})$ displays $\mathrm{sl}(2, \mathbb{C})$ spanned by $\{X_1, X_6, X_{13}\}$. Equivalently one may identify it as one of the $\mathrm{sl}(2, \mathbb{C})$ ideals in $\mathrm{sl}(2, \mathbb{C}) \times \mathrm{sl}(2, \mathbb{C}) \times \mathrm{u}(1)$. Indeed, the exponents of α in Table V are the weights of the $\mathrm{sl}(2, \mathbb{C})$-representation. Thus one obtains the direct sum of one three-dimensional, four two-dimensional, and four one-dimensional representations. That is what one finds from (24) when it is reduced further to the subalgebra $\mathrm{sl}(2, \mathbb{C}) \subset \mathrm{sl}(2, \mathbb{C}) \times \mathrm{sl}(2, \mathbb{C}) \times \mathrm{u}(1)$.

E. The fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_5$

Results of this case are summarized in Table VI. Here, again, we only need one (general) inner automorphism $Ad_A \in \mathcal{G}_5$ with $A = \mathrm{diag}(\alpha, \alpha^{-1}, \beta, \beta^{-1})$ and the outer automorphism Out_C,

$$
C = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.
$$

TABLE VII. $\mathcal{G}_6$: The correspondence between eigenvectors X_k from (32) and the eigenvalues $\lambda_0,\lambda_1,\lambda_2$ of $Out_C, Ad_{A_1}, Ad_{A_2}$. With the choice of $\alpha = \xi^{1/2}$, where $\xi = \exp(2\pi i/6)$, the additive group for subspace indices is $\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_6$.

	Eigenvector	λ_0	λ_1	$\lambda_2=\lambda_2(\alpha)$	$\lambda_2=\lambda_2(\xi^{1/2})$
$L_{(0,0,0)}$	X_1	1	1	1	ξ^0
$L_{(0,1,0)}$	X_2	1	−1	1	ξ^0
$L_{(1,1,0)}$	X_3	−1	−1	1	ξ^0
$L_{(1,0,1)}$	X_4	−1	1	α^2	ξ^1
$L_{(1,1,1)}$	X_5	−1	−1	α^2	ξ^1
$L_{(0,1,2)}$	X_6	1	−1	$-\alpha^{-2}$	ξ^2
$L_{(1,0,2)}$	X_7	−1	1	$-\alpha^{-2}$	ξ^2
$L_{(0,0,3)}$	X_8	1	1	−1	ξ^3
$L_{(0,1,3)}$	X_9	1	−1	−1	ξ^3
$L_{(1,0,3)}$	X_{10}	−1	1	−1	ξ^3
$L_{(1,1,3)}$	X_{11}	−1	−1	−1	ξ^3
$L_{(0,1,4)}$	X_{12}	1	−1	$-\alpha^2$	ξ^4
$L_{(1,0,4)}$	X_{13}	−1	1	$-\alpha^2$	ξ^4
$L_{(1,0,5)}$	X_{14}	−1	1	α^{-2}	ξ^5
$L_{(1,1,5)}$	X_{15}	−1	−1	α^{-2}	ξ^5

The Lie algebra sl(4, $\mathbb{C}$) is decomposed into one two-dimensional and 13 one-dimensional subspaces, whose bases are given in terms of vectors E_{jk}:

$$
\begin{gathered}
X_1=E_{11}-E_{22}, \quad X_6=E_{34}, \quad X_{11}=E_{13}-E_{42}, \\
X_2=E_{33}-E_{44}, \quad X_7=E_{24}-E_{31}, \quad X_{12}=E_{13}+E_{42}, \\
X_3=E_{11}+E_{22}-E_{33}-E_{44}, \quad X_8=E_{24}+E_{31}, \quad X_{13}=E_{43}, \\
X_4=E_{23}-E_{41}, \quad X_9=E_{21}, \quad X_{14}=E_{14}-E_{32}, \\
X_5=E_{23}+E_{41}, \quad X_{10}=E_{12}, \quad X_{15}=E_{14}+E_{32}.
\end{gathered}
\tag{31}
$$

The parameters α and β indicate that a two-parametric subgroup of the maximal torus belongs to the grading group. The parameters can be identified with two orthogonal simple roots of sl(4, $\mathbb{C}$). Hence the grading displays two commuting sl(2, $\mathbb{C}$) subalgebras spanned by $\{X_1,X_9,X_{10}\}$ and $\{X_2,X_6,X_{13}\}$.

F. The fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_6$

Results of this case are summarized in Table VII. This time it is necessary to use two inner automorphisms Ad_A, e.g., those with matrices $A_1=\sigma_1\otimes\mathrm{diag}(1,1)$, $A_2=\sigma_3\otimes\mathrm{diag}(\alpha,\alpha^{-1})$, and also the outer automorphism Out_C,

$$
C=\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.
$$

We obtain a decomposition into 15 one-dimensional subspaces—linear hulls of eigenvectors $X_1,\ldots,X_{15}$:

TABLE VIII. $\mathcal{G}_7$: The correspondence between eigenvectors X_k from (33) and the eigenvalues $\lambda_1,\lambda_2,\lambda_3,\lambda_4$ of $Ad_{A_1},Ad_{A_2},Ad_{A_3},Ad_{A_4}$. The additive group is $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$.

	Eigenvector	λ_1	λ_2	λ_3	λ_4
$L_{(0,0,0,1)}$	X_1	1	1	1	−1
$L_{(0,0,1,0)}$	X_2	1	1	−1	1
$L_{(0,0,1,1)}$	X_3	1	1	−1	−1
$L_{(0,1,0,0)}$	X_4	1	−1	1	1
$L_{(0,1,0,1)}$	X_5	1	−1	1	−1
$L_{(0,1,1,0)}$	X_6	1	−1	−1	1
$L_{(0,1,1,1)}$	X_7	1	−1	−1	−1
$L_{(1,0,0,0)}$	X_8	−1	1	1	1
$L_{(1,0,0,1)}$	X_9	−1	1	1	−1
$L_{(1,0,1,0)}$	X_{10}	−1	1	−1	1
$L_{(1,0,1,1)}$	X_{11}	−1	1	−1	−1
$L_{(1,1,0,0)}$	X_{12}	−1	−1	1	1
$L_{(1,1,0,1)}$	X_{13}	−1	−1	1	−1

$L_{(1,1,1,1)}$	X_{15}	−1	−1	−1	−1

$$
\begin{gathered}
X_1=E_{11}-E_{22}+E_{33}-E_{44},\quad X_2=E_{11}-E_{22}-E_{33}+E_{44},\\
X_3=E_{11}+E_{22}-E_{33}-E_{44},\quad X_4=E_{21}+E_{43},\\
X_5=E_{21}-E_{43},\quad X_6=E_{14}-E_{32},\\
X_7=E_{14}+E_{32},\quad X_8=E_{13}-E_{24}+E_{31}-E_{42},\\
X_9=E_{13}+E_{24}-E_{31}-E_{42},\quad X_{10}=E_{13}+E_{24}+E_{31}+E_{42},\\
X_{11}=E_{13}-E_{24}-E_{31}+E_{42},\quad X_{12}=E_{23}-E_{41},\\
X_{13}=E_{23}+E_{41},\quad X_{14}=E_{12}+E_{34},\\
X_{15}=E_{12}-E_{34}.
\end{gathered}
\tag{32}
$$

The single parameter here cannot be identified with a root of sl(2, $\mathbb{C}$) as in the previous cases. Nevertheless, its presence identifies a one-parametric subgroup of the sl(2, $\mathbb{C}$)-torus and hence an sl(2, $\mathbb{C}$) subalgebra of sl(4, $\mathbb{C}$). The simple root of the subalgebra divides the angle between the two orthogonal roots of sl(4, $\mathbb{C}$) and it is $\sqrt{2}$ shorter than the roots of sl(4, $\mathbb{C}$). Practically it amounts to putting $\alpha=\beta$ in the previous grading.

G. The fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_7$

Results of this case are summarized in Table VIII. To reach the complete decomposition of sl(4, $\mathbb{C}$) by the MAD-group $\mathcal{G}_7$, four inner automorphisms Ad_A must be used. The outer automorphism does not supply any of them, so we do not use it this time although it belongs to the MAD-group.

The matrices A for the inner automorphisms are the following: $A_1=\sigma_3\otimes\sigma_3$, $A_2=\sigma_0\otimes\sigma_3$, $A_3=\sigma_2\otimes\sigma_2$, and $A_4=\sigma_2\otimes\sigma_3$. Those 15 one-dimensional subspaces $L_{(j,k,l,m)}$ are linear hulls of eigenvectors $X_1,\ldots,X_{15}$; the set of indices is equal to the additive group $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$; the subspace $L_{(0,0,0,0)}$ is empty:

TABLE IX. $\mathcal{G}_8$: The correspondence between eigenvectors X_k from (34) and the eigenvalues $\lambda_0,\lambda_1,\lambda_2$ of $Out_C, Ad_{A_1}, Ad_{A_2}$. The additive group in this case is $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_4$.

	Eigenvector	λ_0	λ_1	λ_2
$L_{(0,1,0)}$	X_1	1	−1	1
$L_{(1,0,0)}$	X_2	−1	1	1
$L_{(1,1,0)}$	X_3	−1	−1	1
$L_{(0,0,1)}$	X_4	1	1	i
$L_{(0,1,1)}$	X_5	1	−1	i
$L_{(1,0,1)}$	X_6	−1	1	i
$L_{(1,1,1)}$	X_7	−1	−1	i
$L_{(0,1,2)}$	X_8	1	−1	−1
$L_{(1,0,2)}$	X_9	−1	1	−1
	X_{10}	−1	1	−1
$L_{(1,1,2)}$	X_{11}	−1	−1	−1
$L_{(0,0,3)}$	X_{12}	1	−1	$-i$
$L_{(0,1,3)}$	X_{13}	1	−1	$-i$
$L_{(1,0,3)}$	X_{14}	−1	1	$-i$
$L_{(1,1,3)}$	X_{15}	−1	1	$-i$

$$
\begin{aligned}
&X_1=E_{11}-E_{22}-E_{33}+E_{44}, \quad X_2=E_{11}-E_{22}+E_{33}-E_{44},\\
&X_3=E_{11}+E_{22}-E_{33}-E_{44}, \quad X_4=E_{14}+E_{23}+E_{32}+E_{41},\\
&X_5=E_{14}-E_{23}-E_{32}+E_{41}, \quad X_6=E_{14}-E_{23}+E_{32}-E_{41},\\
&X_7=E_{14}+E_{23}-E_{32}-E_{41}, \quad X_8=E_{13}+E_{24}-E_{31}-E_{42},\\
&X_9=E_{13}-E_{24}+E_{31}-E_{42}, \quad X_{10}=E_{13}-E_{24}-E_{31}+E_{42},\\
&X_{11}=E_{13}+E_{24}+E_{31}+E_{42}, \quad X_{12}=E_{12}+E_{21}-E_{34}-E_{43},\\
&X_{13}=E_{12}-E_{21}+E_{34}-E_{43}, \quad X_{14}=E_{12}-E_{21}-E_{34}+E_{43},\\
&X_{15}=E_{12}+E_{21}+E_{34}+E_{43}.
\end{aligned}
\tag{33}
$$

The eigenvectors $X_j, j=1,\ldots,15$, can be written as $\sigma_k\otimes\sigma_l$, where $k,l\in\{0,1,2,3\}$, except for $k=l=0$.

H. The fine grading of sl(4, $\mathbb{C}$) corresponding to $\mathcal{G}_8$

Results of this case are summarized in Table IX. To obtain a fine grading by $\mathcal{G}_8$, one outer and two inner automorphisms are used, namely those with $A_1=I_2\otimes\sigma_1$, $A_2=R\otimes\sigma_3$ for Ad_A, and

$$
C=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix}
$$

for Out_C. The fine grading of sl(4, $\mathbb{C}$) consists of one two-dimensional and 13 one-dimensional subspaces, which are described by the following set of eigenvectors:

TABLE X. Subalgebra gl(3, $\mathbb{C}$) displayed by fine gradings of sl(4, $\mathbb{C}$).

X_{11} = E_{34} - E_{43}, \quad X_{12} = E_{14} + E_{23} - E_{31} - E_{42}, \\
X_{13} = E_{14} - E_{23} - E_{31} + E_{42}, \quad X_{14} = E_{14} + E_{23} + E_{31} + E_{42}, \\
X_{15} = E_{14} - E_{23} + E_{31} - E_{42}.
\end{gathered}
\tag{34}
$$

IV. MAXIMAL SUBALGEBRAS OF sl(4, $\mathbb{C}$) DISPLAYED BY THE FINE GRADINGS OF sl(4, $\mathbb{C}$)

Recall that a subalgebra is said to be displayed by a grading if it is a sum of several grading subspaces of the grading (cf. example in Sec. II). Having described the fine gradings, it is curious to know which of the maximal subalgebras of A_3 are preferred by each grading. The root grading displays so called regular subalgebras. (A subalgebra of L is regular if its roots can be chosen as a subset of roots of L.)

We are interested here in the four maximal reductive subalgebras (1) of sl(4, $\mathbb{C}$). There are ways how to characterize the subalgebras in a representation independent way, but our aim is to be as specific as possible. Hence we describe the subalgebras by explicit 4×4 matrices.

A. gl(3, $\mathbb{C}$) as a subalgebra of sl(4, $\mathbb{C}$)

The subalgebra gl(3, $\mathbb{C}$) $\subset$ sl(4, $\mathbb{C}$) spans a nine-dimensional subspace in (2). It can be realized as the set of matrices

$$
\text{gl}(3, \mathbb{C}) = \begin{pmatrix} a & b & c & 0 \\ e & f & g & 0 \\ j & k & l & 0 \\ 0 & 0 & 0 & -a-f-l \end{pmatrix}. \tag{35}
$$

There are just three MAD-groups in $\mathcal{A}ut$ sl(4, $\mathbb{C}$) providing fine gradings of sl(4, $\mathbb{C}$) which display the subalgebra gl(3, $\mathbb{C}$). These are the MAD-groups $\mathcal{G}_1$, $\mathcal{G}_3$, and $\mathcal{G}_4$. In each of these cases the subalgebra gl(3, $\mathbb{C}$) can be picked out as an eigensubspace of $Ad_A \in \mathcal{G}_j$ corresponding to the eigenvalue $+1$. [$A = \text{diag}(-1,-1,-1,1)$ for $\mathcal{G}_1$ and $\mathcal{G}_3$, $A = \text{diag}(1,-1,-1,-1)$ for $\mathcal{G}_4$.] Table X depicts the subspaces L_k of fine gradings by $\mathcal{G}_1, \mathcal{G}_3, \mathcal{G}_4$ that make up the subalgebra gl(3, $\mathbb{C}$).

TABLE XI. Gradings of o(4, $\mathbb{C}$) displayed by fine gradings of sl(4, $\mathbb{C}$). These gradings are all fine, with the only exception of the one by $\mathcal{G}_5$.

MAD-group on sl(4, $\mathbb{C}$)	Grading of o(4, $\mathbb{C}$) in terms of $L_k \subset$ sl(4, $\mathbb{C}$)
$\mathcal{G}_3$	$L_{(0,1,1,1)} \oplus L_{(0,0,1,1)} \oplus L_{(0,0,0,1)} \oplus L_{(0,1,1,0)} \oplus L_{(0,0,1,0)} \oplus L_{(0,1,0,0)}$
$\mathcal{G}_4$	$L_{(0,0)} \oplus L_{(0,1)} \oplus L_{(0,3)} \oplus L_{(0,4)} \oplus L_{(0,5)} \oplus L_{(0,7)}$
$\mathcal{G}_5$	$L_{(0,0)} \oplus L_{(0,1)} \oplus L_{(0,3)} \oplus L_{(0,6)} \oplus L_{(0,8)}$
$\mathcal{G}_6$	$L_{(0,0,0)} \oplus L_{(0,1,0)} \oplus L_{(0,1,2)} \oplus L_{(0,0,3)} \oplus L_{(0,1,3)} \oplus L_{(0,1,4)}$
$\mathcal{G}_7$	$L_{(0,1,1,0)} \oplus L_{(0,1,1,1)} \oplus L_{(1,0,0,0)} \oplus L_{(1,0,1,0)} \oplus L_{(1,1,0,1)} \oplus L_{(1,1,1,0)}$
$\mathcal{G}_8$	$L_{(0,1,0)} \oplus L_{(0,0,1)} \oplus L_{(0,1,1)} \oplus L_{(0,1,2)} \oplus L_{(0,0,3)} \oplus L_{(0,1,3)}$

B. o(4, $\mathbb{C}$) subalgebra of sl(4, $\mathbb{C}$)

This is the six-dimensional subalgebra which is most simply realized in sl(4, $\mathbb{C}$) as the subset of all matrices antisymmetric with respect to transposition (skew-symmetric). A general definition is the following:

$$\mathrm{o}(n, \mathbb{C}) = \{X \in \mathbb{C}^{n\times n} | XK + KX^T = 0\}, \quad K \in \mathbb{C}^{n\times n}, \det K = 1, K = K^T. \tag{36}$$

[With $K = I$, o(n, $\mathbb{C}$) is the set of all skew-symmetric matrices.]

A simple rule to decide whether a particular fine grading of sl(n, $\mathbb{C}$) displays o(n, $\mathbb{C}$) is found in Ref. 3.

Theorem 4.1: (*I*) *Let* $\mathcal{G} = \{Ad_A | A \in G_{Ad}\} \cup \{Out_C | C \in G_{Out}\}$ *be a MAD-group on* sl(n, $\mathbb{C}$). *A fine grading of* sl(n, $\mathbb{C}$) *produced by the MAD-group* $\mathcal{G}$ *(i.e., consisting of simultaneous eigensubspaces of automorphisms from* $\mathcal{G}$*) displays the subalgebra* o(n, $\mathbb{C}$) *iff there exists a matrix* $A \in G_{Ad}$ *such that* AC *is symmetric.*

If such $A \in G_{Ad}$ *exists, then* $\{Ad_A | A \in G_{Ad}\}$ *is a MAD-group on the displayed subalgebra* o(n, $\mathbb{C}$).

(*II*) *A MAD-group* $\mathcal{H}$ on sl(n, $\mathbb{C}$) *which does not contain any outer automorphism* Out_C *does not display the subalgebra* o(n, $\mathbb{C}$).

Once we have found the matrix $A \in G_{Ad}$ such that AC is symmetric, we put $K = AC$, and then pick out all the subspaces L_k that are eigensubspaces corresponding to eigenvalue $+1$ for Out_{AC}. These subspaces build up the subalgebra o(n, $\mathbb{C}$). Indeed, for an element X fulfilling $Out_{AC}X = X$ one can write

$$X = Out_{AC}X = -((AC)^{-1}X(AC))^T = -(K^{-1}XK)^T,$$

$$-X^T = K^{-1}XK,$$

$$-KX^T = XK,$$

$$0 = XK + KX^T.$$

The matrix $K = AC$ is symmetric (i.e., $K = K^T$), and $\det K = \det(AC) = \det A \cdot \det C = 1 \cdot 1 = 1$ [since $A, C \in$ SL(4, $\mathbb{C}$)], so matrices from the extracted subspaces correspond to the definition (36) of o(n, $\mathbb{C}$).

According to part II of Theorem 4.1, the MAD-groups $\mathcal{G}_1$ and $\mathcal{G}_2$ do not come into consideration any more. But all the remaining MAD-groups $\mathcal{G}_3, \ldots, \mathcal{G}_8$ contain an outer automorphism Out_C, even with C symmetric (i.e., AC is symmetric for $A = I$). So, each of the fine gradings of sl(4, $\mathbb{C}$) produced by MAD-groups $\mathcal{G}_3, \ldots, \mathcal{G}_8$ displays the subalgebra o(4, $\mathbb{C}$) in the following way (see Table XI):

$$\mathrm{o}(4, \mathbb{C}) = \{X \in \mathbb{C}^{4\times 4} | XC + CX^T = O\} \tag{37}$$

$$o(4,\mathbb{C}) = \oplus_{k\in\mathcal{S}} L_k, \tag{38}$$

where $\mathcal{S}=\{j|(\forall X\in L_j)(Out_C X = X)\}$, with $Out_C \in \mathcal{G}_j$, $j=3,\ldots,8$.

But not only it holds that the fine gradings by $\mathcal{G}_3,\ldots,\mathcal{G}_8$ display the subalgebra o(4, $\mathbb{C}$). The sum (38) is a fine grading of o(4, $\mathbb{C}$) for all $j=3,4,6,7,8$. For $j=5$ the subspace $L_{(0,0)}$ can be split into two to get a fine grading. In this way each fine grading of o(4, $\mathbb{C}$) is displayed by exactly one fine grading of sl(4, $\mathbb{C}$) by $\mathcal{G}_j$, $j=3,\ldots,8$. [Indeed, the algebra o(4, $\mathbb{C}$) has six fine gradings.]

Note the zero value in the first index of all the subspaces L_k (with the exception of the grading by $\mathcal{G}_7$). It stands for the eigenvalue $+1$ of Out_C. In the $\mathcal{G}_7$-grading we did not use the eigenvalues of Out_C in the indices.

The Lie algebra o(4, $\mathbb{C}$) is isomorphic to sl(2, $\mathbb{C}$)$\times$sl(2, $\mathbb{C}$). Suppose one has $C=I$. Then, according to (37) o(4, $\mathbb{C}$) is formed by 4×4 skew-symmetric matrices. In that case the two commuting sl(2, $\mathbb{C}$)-subalgebras can be written in the form

$$\begin{pmatrix} 0 & a & b & c \\ -a & 0 & c & -b \\ -b & -c & 0 & a \\ -c & b & -a & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & f & e & d \\ -f & 0 & -d & e \\ -e & d & 0 & -f \\ -d & -e & f & 0 \end{pmatrix}. \tag{39}$$

Again, this is just one of the basis dependent forms of the subalgebra o(4, $\mathbb{C}$)$\simeq$sl(2, $\mathbb{C}$)$\times$sl(2, $\mathbb{C}$). Therefore, even if the subalgebra is displayed by a grading, it may not be displayed in the form of (39)

In order to get the subalgebra o(4, $\mathbb{C}$) in terms of skew-symmetric matrices one only needs to introduce a change of coordinates: $\tilde{X}=S^{-1}XS$, with $S=\left(\begin{smallmatrix}1 & 0\\ 0 & 1\end{smallmatrix}\right)\oplus\left(\begin{smallmatrix}1/2 & -i/2\\ 1 & i\end{smallmatrix}\right)$ for the cases of $\mathcal{G}_4$, $\mathcal{G}_8$, and $S=\left(\begin{smallmatrix}1/2 & -i/2\\ 1 & i\end{smallmatrix}\right)\oplus\left(\begin{smallmatrix}1/2 & -i/2\\ 1 & i\end{smallmatrix}\right)$ for the cases $\mathcal{G}_5$, $\mathcal{G}_6$. The fine gradings by $\mathcal{G}_3$ and $\mathcal{G}_7$ already display o(4, $\mathbb{C}$) as skew-symmetric matrices (because here $C=I$).

C. sp(4, $\mathbb{C}$) subalgebra of sl(4, $\mathbb{C}$)

The ten-dimensional Lie algebra sp(4, $\mathbb{C}$) can be realized as the complex vector space of matrices

$$\begin{aligned} sp(4,\mathbb{C}) &= \left\{ X \,\middle|\, X\begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix} X^T = 0 \right\} \\ &= \begin{pmatrix} a & b & c & d \\ e & -a & g & h \\ -h & d & l & m \\ g & c & p & -l \end{pmatrix}. \end{aligned} \tag{40}$$

But also here it is useful to write down the general definition:

$$sp(n,\mathbb{C}) = \{X\in \mathbb{C}^{n\times n} | XK + KX^T = 0\}, \quad K\in \mathbb{C}^{n\times n}, \det K = 1, K = -K^T. \tag{41}$$

In particular, with $n=4$,

$$K = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix},$$

one arrives at (40).

As well as in the case of o(4, $\mathbb{C}$), theory from Ref. 3 provides us with a tool to decide whether a fine grading of sl(4, $\mathbb{C}$) displays sp(4, $\mathbb{C}$) or not. Actually one just replaces o(n, $\mathbb{C}$) with sp(n, $\mathbb{C}$),

TABLE XII. Fine gradings of sp(4, $\mathbb{C}$) displayed by fine gradings of sl(4, $\mathbb{C}$).

MAD-group on sl(4, $\mathbb{C}$)	Fine grading of sp(4, $\mathbb{C}$) in terms of $L_k \subset$ sl(4, $\mathbb{C}$)
$\mathcal{G}_5$	$L_{(0,0)} \oplus L_{(1,1)} \oplus L_{(1,2)} \oplus L_{(0,3)} \oplus L_{(1,4)} \oplus L_{(1,5)} \oplus L_{(0,6)} \oplus L_{(1,7)} \oplus L_{(1,8)}$
$\mathcal{G}_6$	$L_{(0,0,0)} \oplus L_{(0,1,0)} \oplus L_{(1,0,1)} \oplus L_{(1,1,1)} \oplus L_{(1,0,2)} \oplus L_{(0,0,3)} \oplus L_{(0,1,3)} \oplus L_{(1,0,4)} \oplus L_{(1,0,5)} \oplus L_{(1,1,5)}$
$\mathcal{G}_7$	$L_{(0,0,0,1)} \oplus L_{(0,0,1,0)} \oplus L_{(0,1,0,0)} \oplus L_{(0,1,1,0)} \oplus L_{(1,0,0,0)} \oplus L_{(1,0,0,1)} \oplus L_{(1,1,0,0)} \oplus L_{(1,1,0,1)} \oplus L_{(1,1,1,0)} \oplus L_{(1,1,1,1)}$

and AC symmetric with AC skew-symmetric in Theorem 4.1. Fine gradings by $\mathcal{G}_1$ and $\mathcal{G}_2$ are again out of discussion, and so we restrict ourselves to $\mathcal{G}_3,\ldots,\mathcal{G}_8$, more precisely to matrices AC, $A \in G_{Ad}$. And again, once we find such a matrix $A \in G_{Ad}$ that AC is skew-symmetric, $Out_C \in \mathcal{G}_j$, the same reasoning as for o(4, $\mathbb{C}$) leads to the conclusion that the subalgebra sp(4, $\mathbb{C}$) displayed by the fine grading of sl(4, $\mathbb{C}$) is the eigensubspace of Out_{AC} corresponding to the eigenvalue $+1$. (Dimension of such an eigensubspace is 10.) Since the Lie algebra sp(4, $\mathbb{C}$) is simple, it is guaranteed by the sp(n, $\mathbb{C}$)-modification of Theorem 4.1 that this subalgebra displayed by a fine grading of sl(4, $\mathbb{C}$) is already in the form of its fine grading. All fine gradings of sp(4, $\mathbb{C}$) have been described in Ref. 2 and they are all displayed by exactly one fine grading of sl(4, $\mathbb{C}$)—see Table XII. [Indeed, the Lie algebra sp(4, $\mathbb{C}$) has three fine gradings.] All the fine gradings by $\mathcal{G}_j, j=5,6,7$ display sp(4, $\mathbb{C}$) in the form described in (40).

D. sl(2, $\mathbb{C}$)×sl(2, $\mathbb{C}$)×u(1) subalgebra of sl(4, $\mathbb{C}$)

There is another maximal reductive subalgebra in sl(4, $\mathbb{C}$). It has dimension 7 and can be realized as follows:

$$\mathrm{sl}(2,\mathbb{C})\times\mathrm{sl}(2,\mathbb{C})\times\mathrm{u}(1)=\begin{pmatrix} a+g & b & 0 & 0 \\ c & -a+g & 0 & 0 \\ 0 & 0 & d-g & e \\ 0 & 0 & f & -d-g \end{pmatrix}. \tag{42}$$

Here u(1) denotes a one-dimensional subalgebra, its parameter is denoted by g. The semisimple part sl(2, $\mathbb{C}$)×sl(2, $\mathbb{C}$) of the subalgebra is not maximal among semisimple subalgebras of sl(4, $\mathbb{C}$). Indeed, one has sl(2, $\mathbb{C}$)×sl(2, $\mathbb{C}$)⊂sp(4, $\mathbb{C}$)⊂sl(4, $\mathbb{C}$).

The algebra sl(2, $\mathbb{C}$)×sl(2, $\mathbb{C}$)×u(1) is displayed by five fine gradings of sl(4, $\mathbb{C}$), namely by those corresponding to MAD-groups $\mathcal{G}_j$, $j=1,3,4,5,8$. Fine gradings produced by MAD-groups $\mathcal{G}_2$, $\mathcal{G}_6$, and $\mathcal{G}_7$ do not display sl(2, $\mathbb{C}$)×sl(2, $\mathbb{C}$)×u(1). Table XIII gives the list of subspaces that form the subalgebra sl(2, $\mathbb{C}$)×sl(2, $\mathbb{C}$)×u(1) in terms of subspaces of the fine gradings of sl(4, $\mathbb{C}$).

V. FINE GRADINGS OF THE LIE ALGEBRA o(6, $\mathbb{C}$)

In this section we consider the analogous objects, MAD-groups, gradings, eigenvalues and eigenvectors, as in Sec. III. The difference here is that the Lie algebra A_3 is represented by 6×6 matrices and called traditionally o(6, $\mathbb{C}$). It is useful because in a number of applications one works only with the Lie algebra of the orthogonal group O(6, $\mathbb{C}$), and because the correspondence between the two representations is not always straightforward. Indeed, take for example the center of SL(4, $\mathbb{C}$) which is of order 4. In the six-dimensional representation, half of it coalesces, so that the center of O(6, $\mathbb{C}$) is of order 2.

The list of MAD-groups $\mathcal{H}_1,\ldots,\mathcal{H}_8$ in Aut o(6, $\mathbb{C}$) follows in Table XIV [they are ordered in such a way that $\mathcal{H}_j$ produces a fine grading of o(6, $\mathbb{C}$) which is isomorphic to the fine grading of sl(4, $\mathbb{C}$) by $\mathcal{G}_j$ in Sec. III]. Note, however, that the generators are generally not normalized to the same values. Within grading subspaces of dimension greater than 1, the basis is chosen by convenience, no particular correspondence between the four- and six-dimensional representations is maintained.

A. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_1$

In this case the MAD-group is the maximal torus of the Lie group represented by 6×6 matrices. Its generic element is A,

$$A=\begin{pmatrix}\cos\varphi_1 & \sin\varphi_1\\ -\sin\varphi_1 & \cos\varphi_1\end{pmatrix}\oplus\begin{pmatrix}\cos\varphi_2 & \sin\varphi_2\\ -\sin\varphi_2 & \cos\varphi_2\end{pmatrix}\oplus\begin{pmatrix}\cos\varphi_3 & \sin\varphi_3\\ -\sin\varphi_3 & \cos\varphi_3\end{pmatrix}.$$

Using A and (4) in (7) the Lie algebra o(6, $\mathbb{C}$) is decomposed into 13 subspaces: one three-dimensional (Cartan subalgebra) and 10 one-dimensional (root) subspaces.

The eigenvectors $Z_1,\ldots,Z_{15}$ are given in terms of matrices M_{jk} of (9):

$$
\begin{gathered}
Z_1=M_{34}-M_{56}, \quad Z_2=M_{12}-M_{34}, \\
Z_3=M_{34}+M_{56}, \quad Z_4=(M_{13}+M_{24})+i(M_{14}-M_{23}), \\
Z_5=(M_{35}+M_{46})+i(M_{36}-M_{45}), \quad Z_6=(M_{15}+M_{26})+i(M_{16}-M_{25}), \\
Z_7=(M_{35}-M_{46})+i(-M_{36}-M_{45}), \quad Z_8=(M_{15}-M_{26})+i(-M_{16}-M_{25}), \\
Z_9=(M_{13}-M_{24})+i(M_{14}+M_{23}), \quad Z_{10}=(M_{13}-M_{24})+i(-M_{14}-M_{23}), \\
Z_{11}=(M_{15}-M_{26})+i(M_{16}+M_{25}), \quad Z_{12}=(M_{35}-M_{46})+i(M_{36}+M_{45}), \\
Z_{13}=(M_{15}+M_{26})+i(-M_{16}+M_{25}), \quad Z_{14}=(M_{35}+M_{46})+i(-M_{36}+M_{45}), \\
Z_{15}=(M_{13}+M_{24})+i(-M_{14}+M_{23}).
\end{gathered}
\tag{43}
$$

The eigenvalues of Z_j coincide with those of X_j of $\mathcal{G}_1$ (Table II), after the values d_1, d_2, d_3 are replaced by $\exp(-i(\varphi_1+\varphi_2))$, $\exp(-i(\varphi_1+\varphi_3))$, and $\exp(-i(\varphi_2+\varphi_3))$. Clearly the additive group is again $\mathbb{Z}_{13}$. The Cartan subalgebra is spanned by the generators Z_1, Z_2, and Z_3.

Rather complicated expressions for the nilpotent generators of the root spaces $Z_4, \ldots, Z_{13}$ are the result of our choice of $\{M_{jk}\}$ of (9) as the basis of o(6, $\mathbb{C}$), in which we write the basis $\{Z_m\}$. Had we started with the representation (5) of o(6, $\mathbb{C}$), the expressions for $\{Z_m\}$ would have been simpler in terms of N_{jk} (see Table XVI).

B. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_2$

With $A_1=D^{-1}(TU\otimes\sigma_2)D, A_2=D^{-1}(T\otimes\sigma_3)D$ the Lie algebra o(6, $\mathbb{C}$) is decomposed into 15 one-dimensional subspaces—linear hulls of the eigenvectors Z_j:

$$
\begin{gathered}
Z_1=(M_{35}-M_{46})+i(M_{36}-M_{45}), \quad Z_2=M_{12}, \\
Z_3=(M_{35}-M_{46})+i(-M_{36}+M_{45}), \quad Z_4=M_{13}+iM_{24}, \\
Z_5=(M_{15}+M_{25})+i(M_{16}-M_{26}), \quad Z_6=M_{14}+iM_{23}, \\
Z_7=(M_{15}-M_{25})+i(-M_{16}-M_{26}), \quad Z_8=M_{56}, \\
Z_9=(M_{35}+M_{46})+i(M_{36}+M_{45}), \quad Z_{10}=M_{34}, \\
Z_{11}=(M_{35}+M_{46})+i(-M_{36}-M_{45}), \quad Z_{12}=M_{13}-iM_{24}, \\
Z_{13}=(M_{15}-M_{25})+i(M_{16}+M_{26}), \quad Z_{14}=M_{14}-iM_{23}, \\
Z_{15}=(M_{15}+M_{25})+i(-M_{16}+M_{26}).
\end{gathered}
\tag{44}
$$

The additive group ($\mathbb{Z}_4\times\mathbb{Z}_4$) and the table of eigenvalues are the same as for $\mathcal{G}_2$ (Table III).

C. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_3$

With $A_1=\sigma_0\otimes\mathrm{diag}(1,1,-1)$, $A_2=\sigma_3\otimes\mathrm{diag}(1,1,1)$, $A_3=\sigma_2\otimes\mathrm{diag}(1,1,-1)$, and $A_4=\sigma_1\otimes\mathrm{diag}(1,-1,1)$ the Lie algebra o(6, $\mathbb{C}$) is decomposed into one three-dimensional and 12 one-dimensional subspaces whose bases consist of the eigenvectors Z_j:

TABLE XV. $\mathcal{H}_3$: The correspondence between eigenvectors Z_k from (45) and the eigenvalues $\lambda_1,\lambda_2,\lambda_3,\lambda_4$ of $Ad_{A_1},Ad_{A_2},Ad_{A_3},Ad_{A_4}$.

	Eigenvector	λ_1	λ_2	λ_3	λ_4
$L_{(0,0,0,1)}$	Z_1	1	1	1	−1
$L_{(0,0,1,0)}$	Z_2	1	1	−1	1
$L_{(0,1,0,0)}$	Z_3	1	−1	1	1
$L_{(0,1,0,1)}$	Z_4	1	−1	1	−1
	Z_5	1	−1	1	−1
	Z_6	1	−1	1	−1
$L_{(0,1,1,1)}$	Z_7	1	−1	−1	−1
$L_{(1,0,0,0)}$	Z_8	−1	1	1	1
$L_{(1,0,0,1)}$	Z_9	−1	1	1	−1
$L_{(1,0,1,0)}$	Z_{10}	−1	1	−1	1
$L_{(1,0,1,1)}$	Z_{11}	−1	1	−1	−1
$L_{(1,1,0,0)}$	Z_{12}	−1	−1	1	1
$L_{(1,1,0,1)}$	Z_{13}	−1	−1	1	−1
$L_{(1,1,1,0)}$	Z_{14}	−1	−1	−1	1
$L_{(1,1,1,1)}$	Z_{15}	−1	−1	−1	−1

$$
\begin{gathered}
Z_1=M_{12}+M_{45},\quad Z_2=M_{12}-M_{45},\quad Z_3=M_{15}+M_{24},\quad Z_4=M_{36},\\
Z_5=M_{25},\quad Z_6=M_{14},\quad Z_7=M_{15}-M_{24},\quad Z_8=M_{23}-M_{56},\\
Z_9=M_{13}-M_{46},\quad Z_{10}=M_{13}+M_{46},\quad Z_{11}=M_{23}+M_{56},\quad Z_{12}=M_{16}-M_{34},\\
Z_{13}=M_{26}-M_{35},\quad Z_{14}=M_{26}+M_{35},\quad Z_{15}=M_{16}+M_{34}.
\end{gathered}
\tag{45}
$$

The table of eigenvalues follows (Table XV); and the indices of eigensubspaces are elements of $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$.

D. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_4$

With

$$
A_1=\sigma_1\otimes\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix},\quad A_2=\sigma_2\otimes\begin{pmatrix}1&0&0\\0&\cos\varphi&\sin\varphi\\0&-\sin\varphi&\cos\varphi\end{pmatrix}
$$

the Lie algebra o(6, $\mathbb{C}$) is decomposed into one two-dimensional and 13 one-dimensional subspaces. The eigenvectors $Z_1,\ldots,Z_{15}$ describing the subspaces are

$$
\begin{gathered}
Z_1=M_{23}+M_{56},\quad Z_2=M_{14},\\
Z_3=M_{25}+M_{36},\quad Z_4=(M_{12}+M_{45})+i(-M_{13}-M_{46}),\\
Z_5=(M_{15}+M_{24})+i(-M_{16}-M_{34}),\quad Z_6=(M_{25}-M_{36})+i(-M_{26}-M_{35}),\\
Z_7=(M_{15}-M_{24})+i(M_{16}-M_{34}),\quad Z_8=(M_{12}-M_{45})+i(M_{13}-M_{46})\\
Z_9=M_{26}-M_{35},\quad Z_{10}=M_{23}-M_{56}\\
Z_{11}=(M_{15}-M_{24})+i(-M_{16}+M_{34}),\quad Z_{12}=(M_{12}-M_{45})+i(-M_{13}+M_{46}),\\
Z_{13}=(M_{25}-M_{36})+i(M_{26}+M_{35}),\quad Z_{14}=(M_{12}+M_{45})+i(M_{13}+M_{46}),\\
Z_{15}=(M_{15}+M_{24})+i(M_{16}+M_{34}).
\end{gathered}
\tag{46}
$$

As in the case of $\mathcal{G}_4$, the set of indices is a subset of $\mathbb{Z}_2\times\mathbb{Z}_8$. The eigenvalues are the same as in Table V with $\alpha=\exp(i\varphi)$.

E. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_5$

Using the two matrices

$$A_1=\mathrm{diag}(1,-1)\oplus\begin{pmatrix}-1&0\\0&-1\end{pmatrix}\oplus\begin{pmatrix}1&0\\0&1\end{pmatrix},$$

$$A_2=\mathrm{diag}(1,1)\oplus\begin{pmatrix}\cos\varphi_1&\sin\varphi_1\\-\sin\varphi_1&\cos\varphi_1\end{pmatrix}\oplus\begin{pmatrix}\cos\varphi_2&\sin\varphi_2\\-\sin\varphi_2&\cos\varphi_2\end{pmatrix}$$

for Ad_A, the Lie algebra o(6, $\mathbb{C}$) is decomposed into 13 one-dimensional and one two-dimensional subspaces with bases consisting of eigenvectors $Z_1,\ldots,Z_{15}$:

$$\begin{gathered}
Z_1=M_{34},\quad Z_2=M_{56},\\
Z_3=M_{12},\quad Z_4=M_{15}-iM_{16},\\
Z_5=M_{25}-iM_{26},\quad Z_6=(M_{35}+M_{46})+i(M_{36}-M_{45}),\\
Z_7=M_{23}-iM_{24},\quad Z_8=M_{13}-iM_{14},\\
Z_9=(M_{35}-M_{46})+i(-M_{36}-M_{45}),\quad Z_{10}=(M_{35}-M_{46})+i(M_{36}+M_{45}),\\
Z_{11}=M_{23}+iM_{24},\quad Z_{12}=M_{13}+iM_{14},\\
Z_{13}=(M_{35}+M_{46})+i(-M_{36}+M_{45}),\quad Z_{14}=M_{15}+iM_{16},\\
Z_{15}=M_{25}+iM_{26}.
\end{gathered}\tag{47}$$

Replacing α with $\exp((i/2)(\varphi_1+\varphi_2))$ and β with $\exp((i/2)(-\varphi_1+\varphi_2))$ in Table VI we get the pairs of eigenvalues of Ad_{A_1} and Ad_{A_2}; these are then embedded into the additive group $\mathbb{Z}_2\times\mathbb{Z}_9$.

F. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_6$

Three inner automorphisms Ad_A, $A_1=\mathrm{diag}(1,1,-1,1,-1,-1)$, $A_2=\mathrm{diag}(1,-1,-1,1,1,1)$, and

$$A_3=\mathrm{diag}(1,1,-1,-1)\oplus\begin{pmatrix}\cos\varphi&\sin\varphi\\-\sin\varphi&\cos\varphi\end{pmatrix},$$

split the Lie algebra o(6, $\mathbb{C}$) into 15 one-dimensional subspaces—linear hull of matrices Z_j:

$$\begin{gathered}
Z_1=M_{56},\quad Z_2=M_{12},\quad Z_3=M_{34},\quad Z=M_{15}-iM_{16},\\
Z_5=M_{25}-iM_{26},\quad Z_6=M_{35}+iM_{36},\quad Z_7=M_{45}+iM_{46},\quad Z_8=M_{14},\\
Z_9=M_{24},\quad Z_{10}=M_{23},\quad Z_{11}=M_{13},\quad Z_{12}=M_{35}-iM_{36},\\
Z_{13}=M_{45}-iM_{46},\quad Z_{14}=M_{15}+iM_{16},\quad Z_{15}=M_{25}+iM_{26}.
\end{gathered}\tag{48}$$

The table of eigenvalues (elements of $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_6$) can be obtained from Table VII, just with the value $\exp(i\varphi/2)$ in the place of α.

G. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_7$

With four specimen of $A=\mathrm{diag}(1,\varepsilon_1,\varepsilon_2,\varepsilon_3,\varepsilon_4,\varepsilon_5)$, namely $A_1=\mathrm{diag}(1,1,-1,-1,-1,-1)$, $A_2=\mathrm{diag}(1,-1,1,-1,-1,-1)$, $A_3=\mathrm{diag}(1,-1,-1,1,-1,-1)$, and $A_4=\mathrm{diag}(1,-1,-1,-1,1,-1)$, the Lie algebra o(6, $\mathbb{C}$) is decomposed into 15 one-dimensional subspaces, whose bases are the eigenvectors Z_j:

$$\begin{gathered}Z_1=M_{56},\quad Z_2=M_{46},\quad Z_3=M_{45},\quad Z_4=M_{36},\\ Z_5=M_{35},\quad Z_6=M_{34},\quad Z_7=M_{12},\quad Z_8=M_{26},\\ Z_9=M_{25},\quad Z_{10}=M_{24},\quad Z_{11}=M_{13},\quad Z_{12}=M_{23},\\ Z_{13}=M_{14},\quad Z_{14}=M_{15},\quad Z_{15}=M_{16}.\end{gathered}\tag{49}$$

See Table VIII for the eigenvalues $(j,k,l,m)\in\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$.

H. The fine grading of o(6, $\mathbb{C}$) corresponding to $\mathcal{H}_8$

Using $A_1=E^{-1}(I_3\otimes\sigma_3)E$, $A_2=E^{-1}(\mathrm{diag}(1,-1,1)\otimes\sigma_0)E$, and $A_3=E^{-1}(I_3\otimes\sigma_1)E$ in Ad_A, the Lie algebra o(6, $\mathbb{C}$) is decomposed into fourteen subspaces, one being two-dimensional and the rest one-dimensional. The eigenvectors $Z_1,\ldots,Z_{15}$ are again given in terms of M_{ij}:

$$\begin{gathered}Z_1=M_{13}+M_{24},\quad Z_2=M_{56},\quad Z_3=M_{14}+M_{23},\quad Z_4=M_{15}+iM_{26},\\ Z_5=M_{35}+iM_{46},\quad Z_6=M_{16}-iM_{25},\quad Z_7=M_{36}-iM_{45},\quad Z_8=M_{13}-M_{24},\\ Z_9=M_{12},\quad Z_{10}=M_{34},\quad Z_{11}=M_{14}-M_{23},\quad Z_{12}=M_{15}-iM_{26},\\ Z_{13}=M_{35}-iM_{46},\quad Z_{14}=M_{16}+iM_{25},\quad Z_{15}=M_{36}+iM_{45}.\end{gathered}\tag{50}$$

The grading subspaces generated by $Z_1,\ldots,Z_{12}$ are labeled by the eigenvalues of $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_4$ given in Table IX.

VI. CONCLUDING REMARKS

Having seen the eight fine gradings of A_3 in this article, the four fine gradings of A_2 in Ref. 3, the two such gradings of A_1 (the root decomposition and the grading spanned by the Pauli matrices), as well as the four fine gradings of the simple Lie algebra $C_2\simeq B_2$ in Ref. 2, it appears unlikely that it will ever be practical to describe all fine gradings of sl(n, $\mathbb{C}$) or other simple Lie algebras for much higher ranks in an explicit way similarly as it is done in this article. There are, however, other interesting questions one may want to address, once particular fine gradings are known or can be found. Let us mention some of them.

(i) There are many intermediate gradings of a Lie algebra between the two grading extremes, the finest gradings (which we call fine) and the coarsest one. It would be useful to know them. Indeed, our original motivation for studying fine gradings came from the need to know the intermediate ones in order to use them for contractions of Lie algebras which preserve a chosen grading (cf. Ref. 7 and references therein). Typically in physics applications one requires that a subalgebra L' of L should be left intact, while contractions of the rest of L are admitted. An appropriate grading for such a problem would have L' displayed.

The most difficult part in finding all the nonequivalent gradings is to determine the fine ones. One can visualize information about all gradings of a given algebra, for example, as

a graph with nodes, representing different gradings, ordered by levels which are given by the number of grading subspaces in each grading, and with edges linking nodes/gradings related by a minimal refinement/coarsening. A complete list of gradings is simple to make for A_1, but it is considerably more difficult for all higher rank algebras. In fact, a description of all nonequivalent gradings is not available even for rank two algebras.

(ii) In this article we have introduced the notion of a subalgebra $L' \subset L$ which is displayed by a grading of L. In general, such a grading may not be a fine one. It is unlikely that for any $L' \subset L$ one can find a grading of L which would display L'. An interesting problem is to recognize the subalgebras which are displayed by some grading of L. We have seen in this article that all maximal reductive subalgebras are displayed by some grading, usually more than one. That includes the subalgebras o(4, $\mathbb{C}$) and sp(4, $\mathbb{C}$) which are of rank 2 and which are not displayed by the root grading.

(iii) Besides the fine gradings by the maximal torus, well known for all simple Lie algebras, there is also another family of fine gradings of all sl(n, $\mathbb{C}$). The corresponding MAD-group $\mathcal{P}_n$ is finite, is of order n^3, and is generated by the $n \times n$ Pauli matrices.[6] In this article such a grading is produced by the MAD-group $\mathcal{G}_2$ in four dimensions and by $\mathcal{H}_2$ in six dimensions.

Furthermore, for each sl(n, $\mathbb{C}$) with $n = n_1 \times n_2$, where the factors n_1 and n_2 have a nontrivial common divisor, there is another MAD-group $\mathcal{P}_{n_1} \times \mathcal{P}_{n_2}$ containing the tensor products of Pauli matrices $n_1 \times n_1$ and $n_2 \times n_2$. It is the case of MAD-groups $\mathcal{G}_7$ for $n_1 = n_2 = 2$ in this article. The group $\mathcal{H}_7$ is a six-dimensional representation of $\mathcal{G}_7$. If n_1 and n_2 have no common divisor, $\mathcal{P}_{n_1} \times \mathcal{P}_{n_2}$ is isomorphic to $\mathcal{P}_n$.

(iv) The fine gradings of the real forms of A_3 and the maximal reductive subalgebras they display are considered in our subsequent paper. Given the classification of the corresponding MAD-groups,[8] it is a natural continuation of this work.

(v) The Lie algebra A_3 has two independent Casimir operators, of degree 2 and 3. The degree 2 operator and its eigenvalues on irreducible representations are well known for simple Lie algebras of all types. The operator of degree 3 was written for all sl(n, $\mathbb{C}$) by I. M. Gelfand some 50 years ago. Its eigenvalues apparently were never given in a closed form for all irreducible representations.

It would be interesting to write the operators in terms of other bases than that given by the root decomposition. It is conceivable that an easier description of their eigenvalues would then be possible.

(vi) Ubiquity of the weight decomposition of the representations of simple Lie algebras, which is the decomposition of the representation spaces into eigenspaces of the maximal torus, is well known as the workhorse of the applications of the standard representation theory of these Lie algebras.

Eigenspace decomposition of representation spaces of A_3 by other MAD-groups is a well defined problem which would be interesting to consider even before a fine grading turns out to be particularly useful: Such a decomposition may suggest useful applications of the grading. There is a technical complication arising in all but the root decomposition. It is related to the fact that the MAD-groups involve automorphisms of finite order. Such automorphisms, in general, behave differently in representations belonging to different congruence classes.[9] Their order may be different in representations belonging to different congruence classes.

(vii) Finally, let us point out an interesting new application of the fine gradings outside the Lie theory proper. The well known Drinfeld–Jimbo quantum algebra is a q-deformation of the universal enveloping algebra U(so(n)) in the basis given by the root decomposition. In Refs. 10 and 11 a new deformation of U(so(n)) is based on another fine grading of so(n), namely on the grading generated by the MAD-group $\mathcal{G} = \{Ad_A | A = \mathrm{diag}(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n), \varepsilon_i = \pm 1\}$. This new deformation is nonisomorphic to the Drifeld–Jimbo deformation. It is quite natural to ask the question about q-deformations for every fine grading of so(n), not only for the two mentioned in Ref. 10.

TABLE XVI. Matrices representing the root spaces e_{α_1}, e_{α_2}, e_{α_3} of A_3 in terms of matrices E_{jk}, N_{jk}, and M_{jk} defined in (9), and normalized so that corresponding structure constants coincide.

	sl(4, $\mathbb{C}$)	o(6, $\mathbb{C}$)	
e_{α_1}	E_{12}	N_{23}	$\frac{1}{2}[(M_{35}+M_{46})+i(M_{36}-M_{45})]$
e_{α_2}	E_{23}	N_{12}	$\frac{1}{2}[(M_{13}+M_{24})+i(M_{14}-M_{23})]$
e_{α_3}	E_{34}	N_{24}	$\frac{1}{2}[(M_{35}-M_{46})-i(M_{36}+M_{45})]$

(viii) Occasionally one needs bases/generators of the Lie algebra chosen in different representations in such a way that the corresponding structure constants coincide. In Table XVI one finds such a choice of the matrices representing the root vectors of the three simple roots e_{α_1}, e_{α_2}, and e_{α_3} in the four- and six-dimensional representations of A_3. For the latter we show them in both realizations (4) and (5). The root vectors of the negative simple roots roots, $e_{-\alpha_j}, j=1,2,3$, are obtained from the positive ones by matrix transposition in the cases (2) and (5): $e_{-\alpha_j}=e_{\alpha_j}^T$, whereas for o(6, $\mathbb{C}$), represented by skew-symmetric matrices (4), one uses Hermitian conjugation (transposition and complex conjugation): $e_{-\alpha_j}=\overline{e_{\alpha_j}^T}=\overline{-e_{\alpha_j}}$. From the six root vectors $e_{\pm\alpha_j}, j=1,2,3$, the rest of the basis is generated by repeated commutations. In all three cases the structure constants are the same.

In this note, we show that the definitions proposed in J. Math. Phys. **41**, 24 (2000); **41**, 1718 (2000); **41**, 1735 (2000) for the description of relativistic δ-sphere interactions and its various generalizations are not correct. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1518786]

I. INTRODUCTION

In the last two decades, several researchers were attracted by the study of δ-sphere interactions in quantum mechanics both from the mathematical point of view and for their applications in modelling various physical phenomena.

For a long time, most of the studies were focusing on nonrelativistic interactions. The first rigorous mathematical definition and analysis of relativistic δ-sphere interactions were provided in Refs. 1 and 2.

More recently, Hounkonnou and Avossevou[3–5] published a series of papers on relativistic δ, δ' and finitely many δ-sphere interactions in quantum mechanics. Although they refer to Refs. 1 and 2, the definitions proposed in Refs. 3–5 for the description of relativistic δ-sphere interactions are not correct. Furthermore, the papers contain several other mistakes related to a misunderstanding of some basic concepts of the theory of self-adjoint extensions of symmetric operators in Hilbert spaces.

The purpose of this note is to show that the definitions proposed in Refs. 3–5 do not correspond to any relativistic δ-sphere interaction.

In Secs. II and III we review the definitions proposed in Refs. 1 and 2 and 3–5, respectively, and in Sec. IV we carry out a comprehensive critical analysis of the boundary conditions of the models introduced in Refs. 3–5.

II. THE DEFINITION OF DITTRICH, EXNER, AND SEBA (Ref. 1)

Using the theory of self-adjoint extensions of symmetric operators in Hilbert spaces, Dittrich *et al.*[1] introduced the Dirac Hamiltonian with a δ-sphere interaction, formally given in three dimensions by

$$H_{\underline{\underline{G}}} = H_D + \underline{\underline{G}}\,\delta(|x|-R); \quad x \in \mathbb{R}^3, \quad R \in (0,\infty), \tag{1}$$

where H_D is the free Dirac Hamiltonian and $\underline{\underline{G}}$ is a real 4×4 matrix of the form $\underline{\underline{G}} = \left(\begin{smallmatrix} A & 0 \\ 0 & B \end{smallmatrix}\right)$.

[a)]On leave of absence from University of Burundi, Faculty of Science, BP 2700 Bujumbura, Burundi. Electronic mail: j.shabani@unesco.org
[b)]Electronic mail: vyabandi@hotmail.com

For the construction of the self-adjoint operator corresponding to $H_{\underline{G}}$ the authors proceed as follows. First, they consider the operator

$$H = H_D,$$
$$\mathcal{D}(H) = C_0^\infty(\mathbb{R}^3 \backslash \{S_R\}) \otimes \mathbb{C}^4, \tag{2}$$

where S_R is the closed ball of radius R centered at the origin in $\mathbb{R}^3$ and look for those self-adjoint extensions of H which are rotationally and space reflection symmetric.

Next they decompose the state Hilbert space $L^2(\mathbb{R}^3) \otimes \mathbb{C}^4$ with respect to radial and angular variables and introduce a unitary operator in order to remove the weight factor r^2 from the integration measure.

With these transformations, the analysis of $H_{\underline{G}}$ in Eq. (1) is reduced to that of the radial Dirac Hamiltonian h_D with a δ-interaction formally given by

$$h_G = h_D + G\,\delta(r-R), \tag{3}$$

where G is a real 2×2 matrix of the form $G = \left(\begin{smallmatrix} A & 0 \\ 0 & B \end{smallmatrix}\right)$ and

$$h_D = \begin{pmatrix} \dfrac{c^2}{2} & -c\dfrac{d}{dr} + c\dfrac{\kappa_{jl}}{r} \\ c\dfrac{d}{dr} + c\dfrac{\kappa_{jl}}{r} & -\dfrac{c^2}{2} \end{pmatrix} \equiv \tau, \quad \mathcal{D}(h_D) = H^{1,2}((0,\infty)) \otimes \mathbb{C}^2. \tag{4}$$

In Eq. (4), c denotes the velocity of the light, $H^{1,2}((0,\infty))$, the Sobolev space of indices (1,2) and $\kappa_{jl} = (-1)^{j-l+\frac{1}{2}}(j+\frac{1}{2})$.

The construction of the self-adjoint operator corresponding to h_G is performed as follows. Fisrt, one considers the closure of the radial part of the operator H which is defined by

$$h_{jl} = \tau,$$
$$D(h_{jl}) = \{\psi \in L^2((0,\infty)) \otimes \mathbb{C}^2 \,|\, \psi \in \mathrm{AC}_{\mathrm{loc}}((0,\infty)), \psi(R\pm) = 0;$$
$$\tau\psi \in L^2((0,\infty)) \otimes \mathbb{C}^2\}, \tag{5}$$

where $\mathrm{AC}_{\mathrm{loc}}(\Omega)$ denotes the set of locally absolutely continuous functions on Ω and

$$\psi(x\pm) = \lim_{\epsilon \to 0+} \psi(x \pm \epsilon).$$

The adjoint h_{jl}^* of h_{jl} reads

$$h_{jl}^* = \tau,$$
$$D(h_{jl}^*) = \{\psi \in L^2((0,\infty)) \otimes \mathbb{C}^2 \,|\, \psi \in \mathrm{AC}_{\mathrm{loc}}((0,\infty) \backslash \{R\}),$$
$$\tau\psi \in L^2((0,\infty)) \otimes \mathbb{C}^2\}. \tag{6}$$

The following theorem was proved in Ref. 1

Theorem 1:

Any self-adjoint extension $\hat{h}_{jl}$ of h_{jl} reads

$$\hat{h}_{jl} = \tau,$$
$$\mathcal{D}(\hat{h}_{jl}) = \{\psi \in \mathcal{D}(h_{jl}^*) \,|\, C\psi(R-) + D\psi(R+) = 0\}, \tag{7}$$

where C and D are 2×2 matrices such that the 2×4 matrix (C,D) has rank 2.

Conversely any operator of this form is a self-adjoint extension of h_{jl}.

Definition:

According to Ref. 1, Eqs. (4.3) and (4.6), the operator h_G in Eq. (3) is defined in $L^2((0,\infty))\otimes\mathbb{C}^2$ by

$$h_G=\tau,$$

$$D(h_G)=\left\{\psi\in\mathcal{D}(h_{jl}^*)\left|\begin{pmatrix}1 & \frac{B}{2c}\\ -\frac{A}{2c} & 1\end{pmatrix}\psi(R+)-\begin{pmatrix}1 & -\frac{B}{2c}\\ \frac{A}{2c} & 1\end{pmatrix}\psi(R-)=0\right.\right\}. \tag{8}$$

The particular cases $A\neq0$, $B=0$ and $A=0$, $B\neq0$ yield the relativistic δ-sphere interactions of the first and second type, respectively, with the domains

$$\mathcal{D}(h_A)=\left\{\psi=\begin{pmatrix}f\\ g\end{pmatrix}\in\mathcal{D}(h_{jl}^*)\left|f(R-)=f(R+)\equiv f(R),g(R+)-g(R-)=\frac{A}{c}f(R)\right.\right\}, \tag{9}$$

$$\mathcal{D}(h_B)=\left\{\psi=\begin{pmatrix}f\\ g\end{pmatrix}\in\mathcal{D}(h_{jl}^*)\left|g(R-)=g(R+)\equiv g(R),f(R+)-f(R-)=-\frac{B}{c}g(R)\right.\right\}. \tag{10}$$

III. THE DEFINITIONS OF HOUNKONNOU AND AVOSSEVOU (Refs. 3–5)

Recently, Hounkonnou and Avossevou published a series of papers on relativistic δ-interactions of the type

$$h_\alpha=h_D+\alpha\,\delta(r-R), \tag{11}$$

$$h_{\alpha,\{R\}}=h_D+\sum_{m=1}^{N}\alpha_m\delta(r-R_m), \tag{12}$$

$$\tilde{h}_{\alpha,\{R\}}=h_D+\sum_{m=1}^{N}\tilde{\alpha}_m\delta'(r-R_m), \tag{13}$$

where h_D is the radial Dirac Hamiltonian defined by Eq. (4).

The authors define these interactions in Ref. 3, Eqs. (2.21)–(2.25), Ref. 5, Eqs. (2.21)–(2.24), and Ref. 4, Eqs. (2.18)–(2.21), respectively.

In this note we focus our analysis on the model given by Eq. (11). Our argumentation applies as well to the models defined by Eqs. (12) and (13).

The following two definitions were proposed in Ref. 3, Eqs. (2.21)–(2.25) for the formal expression (11),

(i)

$$h_{\alpha,1}=\tau,$$

$$\mathcal{D}(h_{\alpha,1})=\left\{\psi=\begin{pmatrix}f\\ g\end{pmatrix}\in L^2((0,\infty))\otimes\mathbb{C}^2\left|f'(R+)=f'(R-),\right.\right.$$

$$g'\in\mathrm{AC}_{\mathrm{loc}}((0,\infty)\backslash\{R\}),g'(R+)-g'(R-)$$

$$\left.\left.=\frac{\alpha}{c}f'(R)+\tilde{A},\quad \tau\psi\in L^2((0,\infty))\otimes\mathbb{C}^2,\quad \tilde{A}\neq0,-\infty<\alpha\leqslant+\infty\right\}; \right. \tag{14}$$

(ii)

$$h_{\alpha,2}=\tau,$$

$$\mathcal{D}(h_{\alpha,2})=\left\{\psi=\begin{pmatrix} f \\ g \end{pmatrix}\in L^2((0,\infty))\otimes\mathbb{C}^2 \,\middle|\, g'(R+)=g'(R-),\right.$$

$$f'\in \mathrm{AC}_{loc}((0,\infty)\backslash\{R\}), f'(R+)-f'(R-)$$

$$\left.=-\frac{\alpha}{c}g'(R)+\tilde{B}, \tau\psi\in L^2((0,\infty))\otimes\mathbb{C}^2, \tilde{B}\neq 0, -\infty<\alpha\leqslant+\infty\right\}. \tag{15}$$

IV. DISCUSSION

In this section we carry out a comprehensive critical analysis of the model introduced in Ref. 3. As indicated in Sec. III, our argumentation applies as well to the models discussed in Refs. 4 and 5.

(1) Obviously the operators defined by Eqs. (14) and (15) are different from the operators h_A and h_B given by Eqs. (9) and (10). Therefore (14) and (15) do not define any relativistic δ-sphere interaction.

Moreover, since H_β and H_γ in Ref. 3, Eqs. (2.22) and (2.25) are defined through Eqs. (14) and (15), it follows that they do not correspond to the relativistic δ-sphere interaction given by Ref. 3, Eq. (2.1). Furthermore, since the operator $h_{\alpha,\{R\}}$ in Eq. (12) is defined through h_α, it follows that $h_{\alpha,\{R\}}$ does not correspond to any radial Dirac Hamiltonian with finitely many δ-sphere interactions supported by concentric spheres.

(2) The boundary conditions given in Eqs. (14) and (15) cannot be written in the form

$$C\psi(R-)+D\psi(R+)=0. \tag{16}$$

Therefore, according to theorem 1, the corresponding operators are not self-adjoint and consequently the conditions required for the application of Krein's formula and Weyl's theorem for the computation of the resolvent equation and the analysis of spectral properties of the Hamiltonians are not fulfilled.

Furthemore, the domain $\mathcal{D}(h_{\alpha,1})$ is not a linear manifold unless the quantity $\tilde{A}$ entering the boundary conditions in (14) is a linear functional on $\mathcal{D}(h_{jl}^*)$. Since this assumption was not explicitely stated, it follows that $h_{\alpha,1}$ is not a linear operator.

(3) The paper contains several other mistakes related to a misunderstanding of some basic concepts of the theory of self-adjoint extensions of symmetric operators in Hilbert spaces. In this note we just point out the following mistakes.

(i) The domain $\mathcal{D}(\dot{h}_{jl})$ in Ref. 3, Eq. (2.13) should read

$$D(\dot{h}_{jl})=\{\psi\in L^2((0,\infty))\otimes\mathbb{C}^2 | \psi\in \mathrm{AC}_{loc}((0,\infty)), \psi(R\pm)=0;$$

$$\tau\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\}. \tag{17}$$

Moreover, contrary to the statement following Ref. 3, Eq. (2.11), $\dot{h}_{jl}$ is not a self-adjoint operator.

(ii) The operator $\dot{h}_{jl}^*$ in Ref. 3, Eq. (2.14) has not been introduced. Since the definition of $\dot{h}_{jl}$ in Ref. 3, Eq. (2.13) is wrong, we assume that the definition of $\dot{h}_{jl}^*$ in Ref. 3, Eq. (2.14) is also wrong.

(iii) In Ref. 3, Eq. (2.21), the case $\beta_{jl}=0$ leads to the boundary conditions $f'_{jl}\in \mathrm{AC_{loc}}((0,\infty))$ and $g'_{jl}(k,R+)-g'_{jl}(k,R-)=\tilde{A}$. These boundary conditions do not define the radial Dirac Hamiltonian given by (4).

(iv) In Ref. 3, Eq. (2.11) the boundary conditions are defined on $(0,\infty)$. Therefore the case $\beta_{jl}=\infty$ can not lead to any boundary condition on the sphere S_R in $\mathbb{R}^3$. Furthemore, the case

$\beta_{jl}=\infty$ leads to the boundary condition $g'_{jl}(R)=0$ and not $g'_{jl}(k,R+)-g'_{jl}(k,R-)=0$. Therefore, $\beta_{jl}=\infty$ does not coincide with the radial Dirac Hamiltonian with a Neumann boundary condition at R.

(v) The definition of H_{γ_0} in Ref. 3, Eq. (3.2) is wrong. H_{γ_0} should read

$$H_{\gamma_0}=H_D+\frac{\gamma_0}{|x|};\quad x\in\mathbb{R}^3. \tag{18}$$

Moreover, as in the case $\gamma_0=0$, one can show that Ref. 3, Eq. (3.5) is wrong and that Ref. 3, Eqs. (3.11)–(3.13) do not define any relativistic δ-sphere plus a Coulomb interaction.

Erratum: "Symmetric tensor spherical harmonics on the *N*-sphere and their application to the de Sitter group *SO*(*N*,1)" [J. Math. Phys. 28, 1553 (1987)]

Atsushi Higuchi
Department of Mathematics, University of York,
Heslington, York, YO10 5DD, United Kingdom

[DOI: 10.1063/1.1515382]

The second line of Eq. (7.22a) should read "$\times(l-q)(l+q+N-3)$" and the second line of Eq. (7.22b) should read "$\times(l-q+1)(l+q+N-2)$."

The first line of the right-hand side of Eq. (7.24a) should read

$$\frac{(l-r)(l+1)}{(l-m)(l-m+1)}$$

and that of Eq. (7.24b) should read

$$-\frac{(l+N+r-2)(l+N-3)}{(l+N+m-2)(L+N+m-3)}.$$

In the line between Eqs. (8.12) and (8.13) "replacing r, L, l, and N by m, l, q, and $N-1$" should read "replacing m, l, q, and $N-1$ by r, L, l, and N."

In Eqs. (9.12) and (9.17), the factor of π should be replaced by 2.
