Proof: To show (i), it suffices to check the relations (2.7)–(2.20) in Proposition 2.1. Relations (2.7)–(2.10) are satisfied since $\mathcal{V}$ is originally U_ε-module. Relations (2.11)–(2.18) are obtained from Lemma 5.1. We have (2.19), $t^{l}_{i}=1$ on $\mathcal{V}$ and then (2.20) from Proposition 5.3. Thus, $\mathcal{V}$ becomes a $U^{\mathrm{fin}}_{\varepsilon}$-module of type **1**.

C. Proof of irreducibility

In order to show the irreducibility of $L(\lambda)$, we need the following:

Proposition 5.6: Any finite dimensional $U^{\mathrm{fin}}_{\varepsilon}$*-module contains a primitive vector.*

To prove this proposition, we shall show the following lemma

Lemma 5.7: Let $L>0$ *be a sufficiently large integer. For any* $i_1,i_2,\ldots,i_L\in I$ *we have in* $U^{\mathrm{fin}}_{\varepsilon}$,

$$e_{i_L}\cdots e_{i_2}e_{i_1}=0. \tag{5.10}$$

Proof: We define a **Z**-gradation on $(U^{\mathrm{fin}}_{\varepsilon})^{+}$ by the following way: As we have seen in Proposition 2.2, $(U^{\mathrm{fin}}_{\varepsilon})^{+}$ has the basis

$$\{e^{r_N}_{\beta_N}e^{r_{N-1}}_{\beta_{N-1}}\cdots e^{r_1}_{\beta_1}\}_{0\leqslant r_1,\ldots r_N<l}.$$

Using this, we define

$$(U^{\mathrm{fin}}_{\varepsilon})^{+}_{d}:=\bigoplus_{r_1\,ht(\beta_1)+\cdots+r_N\,ht(\beta_N)=d}\mathbf{C}e^{r_N}_{\beta_N}e^{r_{N-1}}_{\beta_{N-1}}\cdots e^{r_1}_{\beta_1}, \tag{5.11}$$

where $ht(\beta)$ is the height of a root $\beta\in\Delta_+$. We have

$$(U^{\mathrm{fin}}_{\varepsilon})^{+}=\bigoplus_{d}(U^{\mathrm{fin}}_{\varepsilon})^{+}_{d}.$$

Since all the relations in $(U_\varepsilon^{\mathrm{fin}})^+$, that is, (2.11), (2.13), (2.14), (2.15), and (2.19) are homogeneous, this gradation is well-defined. We call an element in $(U_\varepsilon^{\mathrm{fin}})_d^+$ a *homogeneous element of degree d*. We have $(U_\varepsilon^{\mathrm{fin}})_d^+(U_\varepsilon^{\mathrm{fin}})_e^+ \subset (U_\varepsilon^{\mathrm{fin}})_{d+e}^+$ for $d, e \in \mathbf{Z}_{\geqslant 0}$ and then $e_{i_L}\cdots e_{i_2}e_{i_1}$ is a homogeneous element of degree L. It immediately follows from Proposition 2.2 that the maximum degree is $(l-1)\ \Sigma_{i=1}^N \mathrm{ht}(\beta_i) := J$, which implies that if $L>J$, $(U_\varepsilon^{\mathrm{fin}})_L^+ = 0$. Thus, if L is sufficiently large, a homogeneous element $e_{i_L}\ldots e_{i_2}e_{i_1}$ must vanish. □

Proof of Proposition 5.6: Suppose that a finite dimensional $U_\varepsilon^{\mathrm{fin}}$-module V does not have any primitive vector. So for any nonzero $v \in V$ there exists an infinite sequence $i_1, i_2, \ldots, i_k, \ldots (i_j \in I)$ such that all vectors v, $e_{i_1}v$, $e_{i_2}e_{i_1}v, \ldots, e_{i_k}\cdots e_{i_2}e_{i_1}v, \ldots$ never vanish. But this contradicts to Lemma 5.7. Therefore, V contains a primitive vector. □

Proof of Theorem 5.5 (ii): Let W be a nonzero submodule of $L(\lambda)$. By Proposition 5.6, W contains a primitive vector. By the uniqueness of the primitive vector in $\mathcal{V}$ (Proposition 4.2), W has to contain $u_0^{\sim}$. Therefore, $W = L(\lambda)$ and then $L(\lambda)$ is the unique irreducible submodule in $\mathcal{V}$. Here we completed the proof of Theorem 5.5(ii). □

By Theorem 3.6 (ii), for "l-restricted weight" $\lambda \in P_+$, the $U_\varepsilon^{\mathrm{res}}$-module $V_\varepsilon^{\mathrm{res}}(\lambda)$ (see Sec. III B) is identified with the irreducible $U_\varepsilon^{\mathrm{fin}}$-module, which is isomorphic to $L(\lambda)$. Accordingly, by Theorem 5.5 we realize the irreducible highest weight $U_\varepsilon^{\mathrm{res}}$-module $V_\varepsilon^{\mathrm{res}}(\lambda)$ with the l-restricted highest weight λ in the vector space $\mathcal{V}$.

In Ref. 14, for the B_n, C_n, and D_n cases the analogous presentations of the maximal cyclic representations are given explicitly. Thus, we can apply the procedure adopted here to them and might hope to obtain the irreducible $U_\varepsilon^{\mathrm{fin}}(B_n)$ $(U_\varepsilon^{\mathrm{fin}}(C_n), U_\varepsilon^{\mathrm{fin}}(D_n))$-modules, which will be discussed elsewhere.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 4 APRIL 2002

The real geometry of holomorphic four-metrics

D. C. Robinson
Mathematics Department, King's College London, Strand, London WC2R 2LS, United Kingdom

(Received 25 October 2001; accepted for publication 15 January 2002)

The real geometry of holomorphic four-metrics is investigated. The almost product and complex structures, associated with the real eight-metrics corresponding to the real and imaginary parts of the holomorphic metrics, are studied. It is shown that half-flat holomorphic metrics, and the corresponding real eight-metrics, are associated with integrable almost product, complex and hyper-Kähler structures. Real and complex local coordinate descriptions are presented. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1456947]

I. INTRODUCTION

In the approximately 25 years since the original work by Newman, Penrose and Plebánski on holomorphic half-flat four-metrics,[1–3] there have been many developments of their results.[4–6] There have also been numerous applications of this and related work to real four-metrics of Riemannian and neutral (Kleinian or ultrahyperbolic) signature.[7–9] However, the extension of the original ideas to real four-metrics of Lorentzian signature and Ricci-flat Lorentzian four-metrics remains to be fully realized, although some interesting results have been obtained. There have been promising developments in both the twistorial approach to this problem,[10,11] and in the approach of Newman and his collaborators.[12,13] There have also been some isolated results on combining self-dual and anti-self-dual solutions to obtain Ricci flat and real metrics by using Plebánski's formalism.[14–18] More references to aspects of these various lines of research can be found in a recent review.[19] This article aims to provide further background for research into the construction of real metrics from holomorphic ones by exploring, in greater detail than previously, certain aspects of the real geometry associated with holomorphic four-metrics on complex four-manifolds.

The focus in this article is on the geometry of the underlying eight dimensional real manifold and the two real eight-metrics defined by the real and imaginary parts of holomorphic four-metrics. Most research on such four-metrics focuses on their holomorphic properties. While this is clearly the natural thing to do, different and interesting insights can be obtained from the study of the geometry on the real eight-manifold. Investigations of this type were initiated in the 1970s by Rozga and Woodhouse.[20,21] This article includes an extension of that line of work, with particular attention being paid to half-flat holomorphic four-metrics and the important real structures and geometry which are related to them.

The content of the article is as follows. The Sec. II is devoted to a discussion of the complex and almost complex structures associated with a holomorphic four-metric, g, on a complex four-manifold M. All the real metrics discussed explicitly in this article will have indefinite signature, but in the interests of simplicity the term ''pseudo-'' as in, for example ''pseudo-Kähler'' will be avoided. Here, where complex four dimensional (eight real dimensional) manifolds and holomorphic four-metrics g are considered, the real metrics, $h=\mathrm{Re}\,g$ and $k=\mathrm{Im}\,g$, have neutral signature (4,4) and this simplification in terminology is unambiguous. Some previously obtained results[21–23] are included in this section for the sake of completeness. Examples are the exhibition of the anti-Kähler structure of the real metrics, h and k, and the fact that these real metrics may inherit the Einstein property of a holomorphic Einstein metric g. In the particular case of four complex dimensions being considered here, additional structures occur naturally. The real metrics, h and k, obtained from a holomorphic metric g are almost hyper-Kähler, in two distinct ways. That is, there

are two sets of three almost complex structures, which are compatible with the real metrics, so they are, in fact, almost Hermitian structures with respect to h and k, and which also satisfy quaternionic relations. These structures are determined from the holomorphic metric, certain bases of self-dual (respectively anti self-dual) holomorphic two-forms, and their complex conjugates. Together with the complex structure of the complex four-manifold these almost complex structures also determine two sets of almost product structures satisfying related, but different, algebraic relations. These almost hyper-Kähler and almost product structures, together with the real metrics, encode certain of the information contained in the holomorphic metric. Further aspects of the latter are exposed when differential, in addition to algebraic, relations are considered. In the third section half-flat holomorphic four-metrics are investigated. Since these are necessarily Ricci flat the corresponding real metrics h and k are also Ricci flat. In addition, each self-dual or anti-self-dual holomorphic metric determines bases (respectively anti-self-dual and self-dual) of three holomorphic two-forms with zero covariant exterior derivative. Hence, in the half-flat case there are triples of (covariantly constant) complex structures satisfying quaternionic relations and h and k are in fact hyper-Kähler. Furthermore, there are now triples of almost product structures which are integrable. Unified real descriptions of these structures are presented. The particular case that is dealt with focuses on anti-self-dual metrics and their real parts. However, analogous constructions apply to the imaginary parts of anti-self-dual metrics and the real or imaginary parts of self-dual four-metrics.

In Sec. IV local coordinates, adapted to an integrable almost product metric structure, (P,h), of the type discussed in Sec. III, are introduced. This coordinate formulation is like a real version of the standard local coordinate description of a Kähler metric. Next an integrable and compatible almost complex structure I is added, the system (P,h,I) is described in adapted complex coordinates, and a holomorphic metric g is naturally defined. When the condition of Ricci flatness is imposed on h, the description of g is seen to coincide with a description of half-flat holomorphic four-metrics introduced by Plebánski.[3] Hence an alternative approach to holomorphic four-metrics, via the structure (P,h,I). is provided here.

An appendix contains a brief outline of the relationship between the construction of twistor spaces for the real hyper-Kahler eight-metrics on M,[24,25] and holomorphic half-flat four-metrics.

Lower case, Latin indices $a, b, c,\ldots,i, j, k\ldots$ range and sum from 1 to 4; barred indices $\overline{a},\overline{b}, \overline{c},\ldots$ from $4+1$ to $4+4$; bold lower case Latin indices, **i**, **j**, **k** from 1 to 3; Greek indices from 1 to 8; upper-case Latin indices A,B,... from 1 to 2 and barred upper case Latin indices $\overline{A},\overline{B},\ldots$ from $2+1$ to $2+2$. Complex conjugates (c.c.) are denoted with a bar over the kernel letter. Geometrical considerations are essentially local.

II. HOLOMORPHIC FOUR-METRICS

Let M be a complex manifold with $\dim_{\mathbb{C}} M$ equal to four, and let g be a holomorphic metric on M, with line element given in complex coordinates z^i by

$$ds^2 = g_{ij}\, dz^i \otimes dz^j, \tag{1}$$

with $\partial g_{ij}/\partial \overline{z}^{\overline{k}} = 0$.

Let I denote the (real) complex structure tensor satisfying $I^2 = -1$ and $I dz^i = i dz^i$. Then

$$g(IX, IY) = -g(X, Y) \tag{2}$$

for all vector fields X and Y tangent to M.[26,27] Since $g(X,Y)$ is zero whenever X or Y is a (0,1) vector field, the metric g is degenerate. Nevertheless, when the holomorphic category only is considered, it determines in the usual way, a unique torsion free metric connection, the holomorphic Levi-Civita connection with holomorphic curvature. It is convenient here to present this metric geometry in terms of the holomorphic Cartan structure equations, using conventions which will be used later when real Lorentzn metrics are considered. These conventions are naturally adapted to two component spinor and anti-self-dual formulations.[28]

Let χ^a be a basis of holomorphic one-forms, a Cartan co-frame for g, so that the line element for g is given by

$$ds^2 = \eta_{ab}\chi^a \otimes \chi^b, \tag{3}$$

where

$$\eta_{ab} = \begin{bmatrix} 0 & \epsilon_{AB} \\ -\epsilon_{AB} & 0 \end{bmatrix}, \qquad \epsilon_{AB} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}. \tag{4}$$

The complex volume element is given by

$$V = i\chi^1 \wedge \chi^2 \wedge \chi^3 \wedge \chi^4. \tag{5}$$

The first and second Cartan structure equations are given by

$$d\chi^a - \chi^b \wedge A^a_b = 0, \qquad A_{ab} + A_{ba} = 0, \tag{6}$$

and

$$dA^a_b + A^a_c \wedge A^c_b = -\tfrac{1}{2} F^a_{bcd} \chi^c \wedge \chi^d. \tag{7}$$

Here A^a_b denotes the holomorphic Levi-Civita connection one-form (with covariant derivative ∇), and F^a_{bcd} are the components of its curvature two-form F^a_b. The structure group is SO(4,C) and the connection and curvature forms, which take values in the Lies algebra so(4,C), can be written as the sum of their self-dual and anti-self-dual parts, ${}^+A^a_b, {}^-A^a_b, {}^+F^a_b, {}^-F^a_b$, respectively. Here, $*{}^+F^a_b = i\,{}^+F^a_b$, $*{}^-F^a_b = -i\,{}^-F^a_b$. In 4×4 matrix form

$${}^+A^a_b = \begin{bmatrix} \varpi^{0'}_{0'} 1 & \varpi^{0'}_{1'} 1 \\ \varpi^{1'}_{0'} 1 & -\varpi^{0'}_{0'} 1 \end{bmatrix}, \tag{8}$$

where here 1 is the unit 2×2 matrix and $\varpi^{0'}_{0'}$, $\varpi^{0'}_{1'}$, $\varpi^{1'}_{0'}$ denote the independent components of ${}^+A^a_b$. Similarly,

$${}^-A^a_b = \begin{bmatrix} \omega^A_B & 0 \\ 0 & \omega^A_B \end{bmatrix}, \tag{9}$$

where the trace of the 2×2 matrix (ω^A_B) is zero. Other self-dual and anti-self-dual objects can be written similarly, for instance,

$${}^-F^a_b = \begin{bmatrix} \Omega^A_B & 0 \\ 0 & \Omega^A_B \end{bmatrix}, \tag{10}$$

where

$$\Omega^A_B = d\omega^A_B + \omega^A_C \wedge \omega^C_B. \tag{11}$$

The structure group SO(4,C) is isomorphic to $\{\mathrm{SL}(2,\mathrm{C})_L \times \mathrm{SL}(2,\mathrm{C})_R\}/Z_2$. The self-dual connection and curvature take values in the Lie algebra $\mathrm{sl}(2,C)_R$ and the anti-self-dual connection and curvature take values in the Lie algebra $\mathrm{sl}(2,\mathrm{C})_L$.

The basis of self-dual holomorphic two-forms, given by

$$
\begin{aligned}
{}^{+}\Sigma^{\mathbf{1}} &= \chi^2 \wedge \chi^1 + \chi^4 \wedge \chi^3, \\
{}^{+}\Sigma^{\mathbf{2}} &= i(\chi^1 \wedge \chi^4 + \chi^3 \wedge \chi^2), \\
{}^{+}\Sigma^{\mathbf{3}} &= i(\chi^1 \wedge \chi^2 + \chi^4 \wedge \chi^3),
\end{aligned}
\tag{12}
$$

defines three holomorphic tensor fields ${}^{+}\mathbb{J}^{\mathbf{i}}$ by

$$
g(X, {}^{+}\mathbb{J}^{\mathbf{i}}(Y)) = {}^{+}\Sigma^{\mathbf{i}}(X,Y) \tag{13}
$$

for any holomorphic vector fields X and Y. It is a straightforward matter to show that

$$
({}^{+}\mathbb{J}^{\mathbf{1}})^2 = ({}^{+}\mathbb{J}^{\mathbf{2}})^2 = ({}^{+}\mathbb{J}^{\mathbf{3}})^2 = -\mathbb{I}, \tag{14}
$$

where $\mathbb{I}$ is the unit operator, and

$$
{}^{+}\mathbb{J}^{\mathbf{1}} {}^{+}\mathbb{J}^{\mathbf{2}} = {}^{+}\mathbb{J}^{\mathbf{3}}, \quad {}^{+}\mathbb{J}^{\mathbf{2}} {}^{+}\mathbb{J}^{\mathbf{3}} = {}^{+}\mathbb{J}^{\mathbf{1}}, \quad {}^{+}\mathbb{J}^{\mathbf{3}} {}^{+}\mathbb{J}^{\mathbf{1}} = {}^{+}\mathbb{J}^{\mathbf{2}}, \tag{15}
$$

$$
g({}^{+}\mathbb{J}^{\mathbf{1}}X, {}^{+}\mathbb{J}^{\mathbf{1}}Y) = g({}^{+}\mathbb{J}^{\mathbf{2}}X, {}^{+}\mathbb{J}^{\mathbf{2}}Y) = g({}^{+}\mathbb{J}^{\mathbf{3}}X, {}^{+}\mathbb{J}^{\mathbf{3}}Y) = g(X,Y), \tag{16}
$$

for all holomorphic vector fields X and Y. The basis of anti-self-dual holomorphic two-forms given by

$$
\begin{aligned}
{}^{-}\Sigma^{\mathbf{1}} &= \chi^3 \wedge \chi^1 + \chi^4 \wedge \chi^2, \\
{}^{-}\Sigma^{\mathbf{2}} &= i(\chi^4 \wedge \chi^1 + \chi^3 \wedge \chi^2), \\
{}^{-}\Sigma^{\mathbf{3}} &= i(\chi^2 \wedge \chi^4 + \chi^3 \wedge \chi^1),
\end{aligned}
\tag{17}
$$

define, as above, three holomorphic tensor fields, ${}^{-}\mathbb{J}^{\mathbf{i}}$, by

$$
g(X, {}^{-}\mathbb{J}^{\mathbf{i}}(Y)) = {}^{-}\Sigma^{\mathbf{i}}(X,Y), \tag{18}
$$

and these satisfy equations of the same form as Eqs. (14)–(16).

The real and imaginary parts, h and k, of the holomorphic metric $g = h + ik$ are two real metrics on the real eight dimensional manifold M. In terms of the complex co-frame of eight one-forms $(\chi^a, \overline{\chi}^a)$ on M, the line element of h is given by

$$
{}_h ds^2 = \tfrac{1}{2}\, \eta_{ab}(\chi^a \otimes \chi^b + \overline{\chi}^a \otimes \overline{\chi}^b), \tag{19}
$$

and the line element of k is given by

$$
{}_k ds^2 = \frac{i}{2}\, \eta_{ab}(-\chi^a \otimes \chi^b + \overline{\chi}^a \otimes \overline{\chi}^b). \tag{20}
$$

The two real metrics have Kleinian (neutral or ultrahyperbolic) signatures (4,4). The covariant derivatives corresponding to the Levi-Civita connections of h and k, ${}_h\nabla$ and ${}_k\nabla$, respectively, are each determined by the same connection one-forms[21]

$$
\begin{bmatrix} A^a_b & 0 \\ 0 & \overline{A}^a_b \end{bmatrix}. \tag{21}
$$

When g is Einstein, that is, when

$$F^{a}_{bad} = \tfrac{1}{4} F \eta_{bd}\,, \tag{22}$$

then h is Einstein if and only if $\mathrm{Im}\, F$ is zero and k is Einstein if and only if $\mathrm{Re}\, F$ is zero, cf. Refs. 22 and 23.

Both real metrics are anti-Hermitian with respect to the complex structure I, that is, for all real vector fields X and Y on M,

$$h(IX,IY) = -h(X,Y); k(IX,IY) = -k(X,Y). \tag{23}$$

Moreover, since

$${}_h\nabla I = {}_k\nabla I = 0, \tag{24}$$

the two real metrics are, in fact, anti-Kähler[21–23] with respect to the complex structure I. They are, of course, related, with the metric k in the anti-Kähler case replacing the two-form of the Kähler case; for any two real vector fields X and Y

$$k(X,Y) = -h(IX,Y). \tag{25}$$

The holomorphic tensor fields ${}^{+}\mathbb{J}^{\mathbf{i}}$ and ${}^{-}\mathbb{J}^{\mathbf{i}}$ defined above can be naturally extended to real tensor fields which satisfy relations like those in Eqs. (14)–(16) above. Define the real tensor fields ${}^{+}J^{\mathbf{i}}$ by

$$h(X, {}^{+}J^{\mathbf{i}}(Y)) = \tfrac{1}{2}({}^{+}\Sigma^{\mathbf{i}} + {}^{+}\overline{\Sigma^{\mathbf{i}}})(X,Y) \tag{26}$$

for X and Y any vector fields tangent to M. Here, and in the following, ${}^{+}\overline{\Sigma^{\mathbf{i}}}$ denotes the complex conjugate of ${}^{+}\Sigma^{\mathbf{i}}$. Then, if α and X are, respectively, a real one-form and vector field on M, with (1,0) parts denoted respectively by $\alpha_{(1,0)}$ and $X_{(1,0)}$, so that $\alpha = \alpha_{(1,0)} + \text{c.c.}$ and $X = X_{(1,0)} + \text{c.c.}$,

$${}^{+}J^{\mathbf{i}}(\alpha, X) = {}^{+}\mathbb{J}^{\mathbf{i}}(\alpha_{(1,0)}, X_{(1,0)}) + \text{c.c.} \tag{27}$$

When h is replaced by k in the left hand side of Eq. (25) the result is the following equation:

$$k(X, {}^{+}J^{\mathbf{i}}(Y)) = \frac{i}{2}(-{}^{+}\Sigma^{\mathbf{i}} + {}^{+}\overline{\Sigma^{\mathbf{i}}})(X,Y). \tag{28}$$

The holomorphic tensor fields ${}^{-}\mathbb{J}^{\mathbf{i}}$ can be extended to the real tensor fields ${}^{-}J^{\mathbf{i}}$ in a similar way.

Both ${}^{+}J^{\mathbf{i}}$ and ${}^{-}J^{\mathbf{i}}$ are triplets of almost complex structures and both h and k are Hermitian with respect to each of these almost complex structures. Furthermore, the almost complex structures satisfy a quaternionic algebra; that is, each of the triplets ${}^{+}J^{\mathbf{i}}$ and ${}^{-}J^{\mathbf{i}}$ separately satisfies the set of equations

$$\begin{gathered}
(J^{\mathbf{1}})^2 = (J^{\mathbf{2}})^2 = (J^{\mathbf{3}})^2 = -1, \\
J^{\mathbf{1}}J^{\mathbf{2}} = J^{\mathbf{3}}, \quad J^{\mathbf{2}}J^{\mathbf{3}} = J^{\mathbf{1}}, \quad J^{\mathbf{3}}J^{\mathbf{1}} = J^{\mathbf{2}}, \\
h(J^{\mathbf{1}}X, J^{\mathbf{1}}Y) = h(J^{\mathbf{2}}X, J^{\mathbf{2}}Y) = h(J^{\mathbf{3}}X, J^{\mathbf{3}}Y) = h(X,Y), \\
k(J^{\mathbf{1}}X, J^{\mathbf{1}}Y) = k(J^{\mathbf{2}}X, J^{\mathbf{2}}Y) = k(J^{\mathbf{3}}X, J^{\mathbf{3}}Y) = k(X,Y).
\end{gathered} \tag{29}$$

In other words, the eight dimensional real manifold M is almost quaternion and each of $(M,h,J^{\mathbf{i}})$ and $(M,k,J^{\mathbf{i}})$ are almost quaternionic metric structures.[27,29]

By interchanging h and k in Eqs. (26) and (28) a second set of real tensor fields, ${}^{+}P^{\mathbf{i}}$ and ${}^{-}P^{\mathbf{i}}$ which are almost product, almost anti-Hermitian structures, rather than almost complex, almost-Hermitian structures, can be defined. Let ${}^{+}P^{\mathbf{i}}$ be defined by

$$k(X,{}^{+}P^{\mathbf{i}}(Y))=\tfrac{1}{2}({}^{+}\Sigma^{\mathbf{i}}+{}^{+}\overline{\Sigma}^{\mathbf{i}})(X,Y) \tag{30}$$

or, equivalently,

$${}^{+}P^{\mathbf{i}}(\alpha,X)=i\,{}^{+}J^{\mathbf{i}}(\alpha_{(1,0)},X_{(1,0)})+\text{c.c.} \tag{31}$$

with the notation as above. It then follows, analogously to Eq. (28), that

$$h(X,{}^{+}P^{i}(Y))=\frac{i}{2}({}^{+}\Sigma^{\mathbf{i}}-{}^{+}\overline{\Sigma}^{\mathbf{i}})(X,Y). \tag{32}$$

Here ${}^{-}P^{\mathbf{i}}$ can be defined in a similar way and satisfies equations parallel to Eqs. (30)–(32). In terms of their components with respect to the co-frame $(\chi^{a},\chi^{\overline{a}})$ and its dual basis of vector fields, these operators are given by

$$I=i\begin{bmatrix}\delta^{a}_{b} & 0\\ 0 & -\delta^{a}_{b}\end{bmatrix},\quad {}^{+}J^{\mathbf{i}}=\begin{bmatrix}{}^{+}\mathbb{J}^{\mathbf{i}} & 0\\ 0 & {}^{+}\overline{\mathbb{J}^{\mathbf{i}}}\end{bmatrix},\quad {}^{+}P^{i}=i\begin{bmatrix}{}^{+}\mathbb{J}^{\mathbf{i}} & 0\\ 0 & -{}^{+}\overline{\mathbb{J}^{\mathbf{i}}}\end{bmatrix}, \tag{33}$$

and similarly for ${}^{-}J^{\mathbf{i}}$ and ${}^{-}P^{\mathbf{i}}$. The algebraic relationships between these real tensors, for short I, $J^{\mathbf{i}}$ and $P^{\mathbf{i}}$, can be summarized in the following equations,

$$\begin{gathered}IJ^{\mathbf{i}}=J^{\mathbf{i}}I=P^{\mathbf{i}},\\ IP^{\mathbf{i}}=-J^{\mathbf{i}},\\ J^{\mathbf{i}}P^{\mathbf{j}}=P^{\mathbf{i}}J^{\mathbf{j}}=-I\delta^{\mathbf{ij}}+\varepsilon^{\mathbf{ijk}}P^{\mathbf{k}},\end{gathered} \tag{34}$$

where in each equation $J^{\mathbf{i}}$ and $P^{\mathbf{i}}$ are both self-dual or both anti-self-dual. The self-dual and anti-self-dual operators commute. Both ${}^{+}P^{\mathbf{i}}$ and ${}^{-}P^{\mathbf{i}}$ are almost product rather than almost complex structures,[27] and satisfy algebraic equations which are generalizations of the quaternionic equations. They also satisfy almost anti-Hermitian rather than almost-Hermitian relations with the real metrics; altogether

$$\begin{gathered}(P^{\mathbf{1}})^{2}=(P^{\mathbf{2}})^{2}=(P^{\mathbf{3}})^{2}=1,\\ P^{1}P^{\mathbf{2}}=IP^{\mathbf{3}},\quad P^{\mathbf{2}}P^{\mathbf{3}}=IP^{\mathbf{1}},\quad P^{\mathbf{3}}P^{\mathbf{1}}=IP^{\mathbf{2}},\\ h(P^{\mathbf{1}}X,P^{\mathbf{1}}Y)=h(P^{\mathbf{2}}X,P^{\mathbf{2}}Y)=h(P^{\mathbf{3}}X,P^{\mathbf{3}}Y)=-h(X,Y),\\ k(P^{\mathbf{1}}X,P^{\mathbf{1}}Y)=k(P^{\mathbf{2}}X,P^{\mathbf{2}}Y)=k(P^{\mathbf{3}}X,P^{\mathbf{3}}Y)=-k(X,Y).\end{gathered} \tag{35}$$

Since g is a *four-metric*, it always follows that

$$\nabla\,{}^{+}\mathbb{J}^{\mathbf{1}}=-{}^{+}\mathcal{A}^{\mathbf{1}}_{\mathbf{i}}\,{}^{+}\mathbb{J}^{\mathbf{i}},\quad \nabla\,{}^{+}\mathbb{J}^{\mathbf{2}}=-{}^{+}\mathcal{A}^{\mathbf{2}}_{\mathbf{i}}\,{}^{+}\mathbb{J}^{\mathbf{i}},\quad \nabla\,{}^{+}\mathbb{J}^{\mathbf{3}}=-{}^{+}\mathcal{A}^{\mathbf{3}}_{\mathbf{i}}\,{}^{+}\mathbb{J}^{\mathbf{i}}, \tag{36}$$

where the so(3,C) -valued one-form ${}^{+}\mathcal{A}^{\mathbf{i}}_{\mathbf{j}}$, is the so(3,C)-valued representation of the self-dual part of the Levi-Civita spin connection. Similar equations holds for the anti-self-dual objects. From these equations it follows that, for $\mathbf{i}=1,2,3$ separately,

$${}_{h}\nabla_{\gamma}({}^{+}J^{\mathbf{i}\alpha}_{\beta})={}_{k}\nabla_{\gamma}({}^{+}J^{\mathbf{i}\alpha}_{\beta})=\begin{bmatrix}-{}^{+}\mathcal{A}^{\mathbf{i}}_{\mathbf{j}\gamma}\,{}^{+}\mathbb{J}^{\mathbf{j}a}_{b} & 0\\ 0 & \text{c.c.}\end{bmatrix} \tag{37}$$

[in components with respect to the complex bases and where c.c. denotes the complex conjugate of $-({}^{+}\mathcal{A}^{\mathbf{i}}_{\mathbf{j}\gamma}\ {}^{+}\mathbb{J}^{\mathbf{j}a}_{b})$]. Similar results hold in the anti-self-dual case. Hence when a gauge can be found in which the components of ${}^{+}\mathcal{A}^{\mathbf{i}}_{\mathbf{j}}$ are real (and hence constant) so that ${}^{+}\mathcal{A}^{\mathbf{i}}_{\mathbf{j}}$ takes values in so(3,R), the triples (M, h, ${}^{+}J^{\mathbf{i}}$) and (M, k, ${}^{+}J^{\mathbf{i}}$) constitute a quaternion Kähler structure and the metrics are Einstein metrics.[29,30] Similar results hold, of course, when the anti-self-dual case is considered.

III. HALF-FLAT ANTI-SELF-DUAL FOUR-METRICS

In this section half-flat, anti-self-dual four-metrics, g, on M will be considered. (In both the self-dual and the anti-self-dual case, the Levi-Civita connection of the corresponding real metrics h and k is determined by the real so(1,3) connection given by twice the real part of the holomorphic Levi-Civita connection of g. There is only one real connection.) Since the self-dual part of the curvature of a holomorphic half-flat anti-self-dual metric is zero, ${}^{+}F^{a}_{b}=0$, a co-frame can be chosen in which ${}^{+}A^{a}_{b}=0$. In this gauge $d^{+}\Sigma^{\mathbf{i}}=0$, and the tensors, defined by Eq. (13), are covariantly constant,

$$\nabla^{+}\mathbb{J}^{\mathbf{i}}=0. \tag{38}$$

It then follows from Eqs. (36) and (37), and then (24) and (34), that the real tensors, defined by Eqs. (26) and (30), are covariantly constant with respect to the Levi-Civita covariant derivatives of the Ricci flat eight-metrics h and k. Relationships between the various structures discussed in this section can be summarized in three propositions which it is a straightforward matter to prove. The first is due to Woodhouse.[21–23]

Proposition 1: Let h be a real eight-metric of signature (4,4) on a real eight dimensional manifold M. Let h be anti-Hermitian with respect to an almost complex structure I. Then I is a complex structure and the tensor g given by the equation

$$g(X,Y)=h(X,Y)-ih(IX,Y)$$

is holomorphic (a holomorphic metric) with respect to the complex structure I if and only if ${}_{h}\nabla I=0$.

Proposition 2: If the conditions and conclusions of Lemma 1 hold, and in addition there is a hyper-Kähler structure (M, h, $J^{\mathbf{i}}$) with $IJ^{\mathbf{i}}=J^{\mathbf{i}}I$, then

(a) $J^{\mathbf{i}}=\mathbb{J}^{\mathbf{i}j}_{k}\partial/\partial z^{j}\otimes dz^{k}+$c.c., for some complex $\mathbb{J}^{\mathbf{i}j}_{k}$, where $I\partial/\partial z^{j}=i\partial/\partial z^{j}$.
(b) For each $\mathbf{i}=1,2,3$, ${}_{g}\nabla\mathbb{J}^{\mathbf{i}}=0$, and $g(\mathbb{J}^{\mathbf{i}}\partial/\partial z^{j},\mathbb{J}^{\mathbf{i}}\partial/\partial z^{k})=g(\partial/\partial z^{j},\partial/\partial z^{k})$.
(c) The holomorphic metric g is half-flat.
(d) (M, $k=\mathrm{Im}\,g$,$J^{\mathbf{i}}$) is also hyper-Kähler, $\nabla_{k}J^{\mathbf{i}}=0$.
(e) The hyper-Kähler structures are Ricci flat.

The results of Proposition 2 can be reformulated in terms of three almost product structures $P^{\mathbf{i}}$.

Proposition 3: If the conditions and conclusions of Lemma 1 hold, and in addition there are three almost product structures $P^{\mathbf{i}}$ which satisfy the conditions $P^{\mathbf{i}}P^{\mathbf{j}}=\epsilon^{\mathbf{ijk}}IP^{\mathbf{k}}$, $h(P^{\mathbf{i}}X,P^{\mathbf{i}}Y)=-h(X,Y)$, $\nabla_{h}P^{\mathbf{i}}=0$ and $IP^{\mathbf{i}}=P^{\mathbf{i}}I$, then the tensors $J^{\mathbf{i}}=-IP^{\mathbf{i}}$ satisfy the conditions of Lemma 2 and hence determine a holomorphic half-flat metric g and Ricci-flat hyper-Kähler structures (M, h, $J^{\mathbf{i}}$) and (M, k, $J^{\mathbf{i}}$) on the eight dimensional real manifold M.

Results from this and the previous section will be used later and it is useful to summarize them in a convenient form, which starts here with the almost product structures. For the sake of explicitness structures arising from anti-self-dual half-flat holomorphic metrics, $g=h+ik$, will be given, but there are similar equations for self-dual holomorphic metrics.

First consider the almost product structures ${}^{+}P^{\mathbf{i}}$, with components given in Eq. (33),

$$ {}^{+}P^{\mathbf{i}} = i\begin{bmatrix} {}^{+}\mathbb{J}^{\mathbf{i}} & 0 \\ 0 & -\overline{{}^{+}\mathbb{J}^{\mathbf{i}}} \end{bmatrix}. \tag{39} $$

Let P denote the almost product structure (strictly the two complex parameter family of almost product structures)

$$ P = i\begin{bmatrix} a_{\mathbf{i}}{}^{+}\mathbb{J}^{\mathbf{i}} & 0 \\ 0 & -\overline{a_{\mathbf{i}}{}^{+}\mathbb{J}^{\mathbf{i}}} \end{bmatrix} \tag{40} $$

for any *complex* numbers $a_{\mathbf{i}}$ satisfying the equation

$$ (a_{\mathbf{1}})^2 + (a_{\mathbf{2}})^2 + (a_{\mathbf{3}})^2 = 1. \tag{41} $$

Then the results given in the propositions above for almost product structures ${}^{+}P^{\mathbf{i}}$, and complex structure I, associated with an anti-self-dual holomorphic half-flat metric g, can be summarized by the equations

$$ (P)^2 = 1, \tag{42} $$

$$ h(PX,PY) = -h(X,Y), \quad k(PX,PY) = -k(X,Y), \tag{43} $$

$$ {}_{h}\nabla P = 0, \quad {}_{k}\nabla P = 0, \tag{44} $$

$$ (I)^2 = -1, \quad PI = IP, \tag{45} $$

$$ h(IX,IY) = -h(X,Y), \quad k(IX,IY) = -k(X,Y), \tag{46} $$

$$ {}_{h}\nabla I = 0, \quad {}_{k}\nabla I = 0, \tag{47} $$

where X and Y are any vectors tangent to M. Furthermore, h and k are Ricci flat. Conversely, Eqs. (42)–(47) imply that the complex metric $g = h + ik$ is a holomorphic four-metric and half-flat, and the eight-metrics h and k are Ricci flat. A local coordinate description of the geometry determined by a single triple consisting of an almost product structure P, an almost complex structure I and a metric h, satisfying Eqs. (42)–(47), will be given in Sec. IV.

It follows from Eqs. (42)–(47) that the almost complex structure J (here strictly a two complex parameter family) defined by

$$ J = -IP, \tag{48} $$

satisfies the equations

$$ \begin{gathered} J^2 = -1, \\ JP = PJ, \quad JI = IJ, \\ h(JX,JY) = h(X,Y), \quad k(JX,JY) = k(X,Y), \\ {}_{h}\nabla J = 0, \quad {}_{k}\nabla J = 0. \end{gathered} \tag{49} $$

A two complex parameter family of Kähler structures, (J,h), so defined, determines the hyper-Kähler structures mentioned above. These results, with the parameters $a_{\mathbf{i}}$ real, are used in the twistor construction reviewed in the Appendix.

Finally, it is interesting to note that all Eqs. (42)–(49) can be rewritten in terms of a four real parameter family of tensors $T(\alpha_{\mathbf{i}},\beta_{\mathbf{j}})$. Define this family of real tensors by

$$T \equiv (\alpha_{\mathbf{i}} + \beta_{\mathbf{i}} I) J^{\mathbf{i}}, \tag{50}$$

where $\alpha_{\mathbf{i}}$ and $\beta_{\mathbf{i}}$ are real parameters satisfying the conditions

$$\alpha_{\mathbf{i}} \beta_{\mathbf{j}} \delta^{\mathbf{ij}} = 0,$$

$$\varepsilon \equiv \alpha_{\mathbf{i}} \alpha_{\mathbf{j}} \delta^{\mathbf{ij}} - \beta_{\mathbf{i}} \beta_{\mathbf{j}} \delta^{\mathbf{ij}},$$

for fixed ε, or, equivalently, the conditions

$$\text{if } a_{\mathbf{i}} = \alpha_{\mathbf{i}} + i \beta_{\mathbf{i}}, \text{ then} (a_{\mathbf{1}})^2 + (a_{\mathbf{2}})^2 + (a_{\mathbf{3}})^2 = \varepsilon. \tag{51}$$

Equations (41)–(49) imply, for all vector fields X and Y, that

$$\begin{gathered} T^2 = -\varepsilon, \\ h(TX, TY) = \varepsilon h(X, Y), \\ k(TX, TY) = \varepsilon k(X, Y), \\ {}_h\nabla T = 0, \quad {}_k\nabla T = 0. \end{gathered} \tag{52}$$

It follows from these equations that, when ε is nonzero, that

$$\begin{gathered} I = -\varepsilon^{-1} T(\alpha_{\mathbf{i}}, \beta_{\mathbf{j}}) T(-\beta_{\mathbf{i}}, \alpha_{\mathbf{j}}), \\ \text{for each } \mathbf{i}\text{: } J^{\mathbf{i}} = T(\alpha^{\mathbf{i}} = 1, \beta^{\mathbf{i}} = 0) = -IT(\alpha^{\mathbf{i}} = 0, \beta^{\mathbf{i}} = 1). \end{gathered} \tag{53}$$

Structures of similar types have been considered by Dunajski.[31,32]

IV. LOCAL COORDINATE DESCRIPTION OF A STRUCTURE (P, h, I)

In this section local coordinate descriptions are given of the geometry represented by a *single* triple (P, h, I) which satisfies Eqs. (42)–(47) of Sec. III. It is shown that when the Ricci tensor of h is zero, such a geometry defines a holomorphic half-flat metric. The aim here is to show, using local coordinates, the effect of a sequential introduction of these structures and the implementation of the equations. Equations (42)–(44) are used first to introduce coordinates adapted to the almost product structure P, and to derive a description of the integrable almost product structure P, and the eight-metric h, in these coordinates. Equations (45)–(47) are then used to introduce complex coordinates adapted to both P and I, and then the triple (P, h, I) is expressed in terms of these coordinates. (Similar calculations could be carried out using the metric k and/or the parallel results associated with self-dual holomorphic metrics.) Finally, a holomorphic half-flat metric is identified.

Equation (44), the vanishing of the covariant derivative of the almost product structure P, implies that the Nijenhuis tensor of P is also zero.[27,33] Hence P is integrable. Standard arguments, analogous to those which can be used for Kähler metrics, can now be applied to construct a local coordinate system adapted to the geometrical structure determined by Eqs. (42)–(44). First, it follows from Eqs. (42) that the eigenvalues of P are 1 or -1. At each point of M the eigenvectors corresponding respectively to the eigenvalues 1 and -1 span complementary distributions, D_1 and D_2, of dimensions d_1 and d_2 say, where $d_1 + d_2 = \dim \mathrm{M}$. The dimensions of the two distributions can be different but here it suffices to consider the case where they are equal. The ideas then apply to even dimensional manifolds but here of course dim M equal eight. Let $(e_\alpha) = (e_a, e_{\bar{a}})$ be a basis of real tangent vectors to M, adapted to the almost product structure so that (e_a) span D_1 and $(e_{\bar{a}})$ span D_2; lower case barred Latin indices range and sum over $4+1$ to $4+4$. It follows from Eqs. (42) and (43) that a real two-form, Π, is defined by the equations

$$\Pi(X,Y)=h(X,PY), \tag{54}$$

for all vector fields X and Y, and that the components of h, with respect to the basis of vector fields $(e_a,e_{\bar a})$, are given by

$$h=\begin{bmatrix} 0 & h_{a\bar b} \\ h_{\bar a b} & 0 \end{bmatrix} \tag{55}$$

where $h_{\bar a b}=h_{b\bar a}$. The vanishing of the Nijenhuis tensor of P is equivalent to integrability of the two complementary distributions,[27,33] D_1 and D_2. Hence adapted local coordinates $u^\alpha=(u^a,u^{\bar a})$ can be introduced on M and the adapted bases chosen to be coordinate bases so that $e_a=\partial/\partial u^a$ and $e_{\bar a}=\partial/\partial u^{\bar a}$. The vanishing of the covariant derivative of P implies that Π is closed and therefore a local potential function, H, exists such that

$$h_{a\bar b}=\partial^2 H/\partial u^a \partial u^{\bar b}\equiv H_{,a\bar b}. \tag{56}$$

Consequently, the line element of h is given, in these coordinates, by

$${}_h ds^2=h_{\alpha\beta}du^\alpha\otimes du^\beta=H_{,a\bar b}(du^a\otimes du^{\bar b}+du^{\bar b}\otimes du^a). \tag{57}$$

Neither the coordinates nor the potential are unique. In these coordinates

$$\Pi=-2H_{,a\bar b}du^a\wedge du^{\bar b}, \tag{58}$$

and

$$P^\alpha_\beta=\begin{bmatrix} \delta^a_b & 0 \\ 0 & -\delta^{\bar a}_{\bar b} \end{bmatrix}. \tag{59}$$

It is a straightforward matter to compute the curvature tensor of the metric given by Eq. (57). Here it is convenient to employ the first and second sets of Cartan structure equations using the adapted coordinate basis of one-forms $du^\alpha=(du^a,du^{\bar a})$. The first set of Cartan structure equations,

$$\begin{aligned} \Gamma^\alpha_{\beta\gamma}du^\gamma&=\Gamma^\alpha_{\gamma\beta}du^\gamma, \\ dh_{\alpha\beta}&=h_{\alpha\sigma}\Gamma^\sigma_\beta+h_{\sigma\beta}\Gamma^\sigma_\alpha, \end{aligned} \tag{60}$$

reduces to the equation

$$dh_{a\bar b}=h_{c\bar b}\Gamma^c_a+h_{a\bar c}\Gamma^{\bar c}_{\bar b}, \tag{61}$$

and the only nonzero Levi-Civita connection one-forms are

$$\begin{aligned} \Gamma^a_b&=\Gamma^a_{bc}du^c=h^{a\bar d}H_{,bc\bar d}du^c, \\ \Gamma^{\bar a}_{\bar b}&=\Gamma^{\bar a}_{\bar b c}du^{\bar c}=h^{d\bar a}H_{,d\bar b\bar c}du^{\bar c}. \end{aligned} \tag{62}$$

Here $h^{a\bar d}=h^{\bar d a}$, and $h^{a\bar d}h_{\bar d b}=\delta^a_b$, $h^{d\bar a}h_{\bar b d}=\delta^{\bar a}_{\bar b}$.

The second set of Cartan structure equations,

$$d\Gamma^\alpha_\beta+\Gamma^\alpha_\sigma\wedge\Gamma^\sigma_\beta=-\tfrac{1}{2}R^\alpha_{\beta\gamma\delta}du^\gamma\wedge du^\delta, \tag{63}$$

reduces to

$$d\Gamma^a_b+\Gamma^a_c\wedge\Gamma^c_b=-R^a_{bc\bar{d}}du^c\wedge du^{\bar{d}},$$
$$d\Gamma^{\bar{a}}_{\bar{b}}+\Gamma^{\bar{a}}_{\bar{c}}\wedge\Gamma^{\bar{c}}_{\bar{b}}=-R^{\bar{a}}_{\bar{b}c\bar{d}}du^{\bar{c}}\wedge du^d. \tag{64}$$

The nonzero components of the curvature tensor in this basis are given by

$$R^a_{bc\bar{d}}=-R^a_{b\bar{d}c}=\Gamma^a_{bc,\bar{d}},$$
$$R^{\bar{a}}_{\bar{b}c\bar{d}}=-R^{\bar{a}}_{\bar{b}d\bar{c}}=\Gamma^{\bar{a}}_{\bar{b}\bar{c},d}. \tag{65}$$

The only components of the Ricci tensor, $R_{\beta\delta}=R^\alpha_{\beta\alpha\delta}$, of this curvature tensor which are not identically zero are

$$R_{b\bar{d}}=R^a_{ba\bar{d}}=[h^{a\bar{c}}(H,_{a\bar{c}b})],_{\bar{d}}=[\ln|\det(H,_{a\bar{c}})|],_{b\bar{d}},$$
$$R_{\bar{b}d}=R^{\bar{a}}_{\bar{b}a\bar{d}}=[h^{\bar{a}d}(H,_{\bar{a}d\bar{b}})],_d=[\ln|\det(H,_{a\bar{c}})|],_{d\bar{b}}. \tag{66}$$

In the Ricci flat case the function H must satisfy a Monge–Ampère equation, $\det(H,_{a\bar{b}})=\exp[B(u^{\bar{a}})+C(u^a)]$, where B and C are arbitrary functions of their arguments. By choice of coordinates the right hand side can be set equal to a constant so that the condition of Ricci flatness of the metric h becomes

$$\det(H,_{a\bar{b}})=\text{const.} \tag{67}$$

It should be noted that the condition that the covariant derivative of P be zero is now also satisfied.

[It is also interesting to note, as an aside, the following. Let N be a four dimensional real submanifold of M, given locally by the level sets $u^a-u^{\bar{a}}=0$. It follows from Eqs. (60) that the connection one-forms Γ^a_b and $\Gamma^{\bar{a}}_{\bar{b}}$ both pull back to define symmetric affine connections on N. When the holonomy group of the pulled-back connections is contained in $\mathrm{SO}(p,q)$, the connections are the Levi-Civita connections of four-metrics on N of signature (p,q).[34] Furthermore, Eqs. (64)–(66), and the appropriate pullbacks to N, imply that these connections are Ricci flat when h is Ricci flat. In the special cases where H is a function only of the four real variables $u^a+u^{\bar{a}}$, that is, h has four Killing vector fields, $\partial/\partial u^a-\partial/\partial u^{\bar{a}}$, and h is also Ricci flat, the eight-metric h pulls back to four-metrics on N given, in local coordinates u^a on N, by ${}_hds^2_N=(\partial^2H/\partial u^a\partial u^b)(du^a\otimes du^b+du^b\otimes du^a)$, where $\det(\partial^2H/\partial u^a\partial u^b)$ is a constant which can be chosen to be one. Such four-metrics belong to a class first considered by Calabi,[35,36] and are formally similar to a class of metrics which are of interest in stochastic geometry.[37] In general, they will not be Ricci flat.]

So far only Eqs. (42)–(44) have been used in the main discussion in this section. Now consider the implementation of Eqs. (45)–(47). It follows from Eq. (45) that, in adapted local coordinates, the almost complex structure I must have components of the form

$$I^\alpha_\beta=\begin{bmatrix} I^a_b & 0 \\ 0 & I^{\bar{a}}_{\bar{b}} \end{bmatrix}, \tag{68}$$

where $I^a_bI^b_c=-\delta^a_c$ and $I^{\bar{a}}_{\bar{b}}I^{\bar{b}}_{\bar{c}}=-\delta^{\bar{a}}_{\bar{c}}$. It follows from Eq. (46) that $h_{\alpha\gamma}I^\gamma_\beta=I_{\alpha\beta}=I_{\beta\alpha}$, where

$$I_{\alpha\beta}=\begin{bmatrix} 0 & I^c_ah_{c\bar{b}} \\ I^{\bar{c}}_{\bar{a}}h_{\bar{c}b} & 0 \end{bmatrix}. \tag{69}$$

Equations (47) now imply that the four dimensional integral manifolds of D_1 and D_2 each admit integrable complex structures I_1 and I_2 with components given respectively by I^a_b and $I^{\bar{a}}_{\bar{b}}$. In fact, Eqs. (47) take the form

$$\begin{aligned} &\partial_c I^a_b - I^a_s \Gamma^s_{bc} + I^s_b \Gamma^a_{sc} = 0, \quad \partial_{\bar{c}} I^a_b = 0, \\ &\partial_{\bar{c}} I^{\bar{a}}_{\bar{b}} - I^{\bar{a}}_{\bar{s}} \Gamma^{\bar{s}}_{\bar{b}\bar{c}} + I^{\bar{s}}_{\bar{b}} \Gamma^{\bar{b}}_{\bar{s}c} = 0, \quad \partial_c I^{\bar{a}}_{\bar{b}} = 0. \end{aligned} \tag{70}$$

Hence the four coordinates on each of D_1 and D_2 can respectively be chosen to be pairs of complex coordinates, $(z^A, \overline{z^{A'}})$ and $(z^{\bar{A}}, \overline{z^{\bar{A}'}})$, where $I_1 \partial/\partial z^A = i\partial/\partial z^A$ and $I_2 \partial/\partial z^{\bar{A}} = i\partial/\partial z^{\bar{A}}$, and $\overline{z^{A'}}$ and $\overline{z^{\bar{A}'}}$ denote the complex conjugate of z^A and $z^{\bar{A}}$ respectively. In order to fully satisfy Eqs. (42)–(47), Eqs. (69) and (70) must now be completely implemented. Equation (69) and the requirement that the matrix $(I_{\alpha\beta})$ be symmetric imply that

$$H_{,A\bar{B}'} = H_{,A'\bar{B}} = 0. \tag{71}$$

It follows that, without loss of generality in this context, the function H can be taken to be of the form

$$H = \mathbb{H} + \text{c.c.}, \tag{72}$$

where $\mathbb{H}$ is a holomorphic function of z^A and $z^{\bar{A}}$ only. In these adapted complex coordinates, the metric h can now be written

$${}_h ds^2 = \mathbb{H}_{,A\bar{B}} (dz^A \otimes dz^{\bar{B}} + dz^{\bar{B}} \otimes dz^A) + \text{c.c.}, \tag{73}$$

and the components of the complex structure I take the form

$$I^\alpha_\beta = \begin{bmatrix} i\delta^A_B & 0 & 0 & 0 \\ 0 & -i\delta^{A'}_{B'} & 0 & 0 \\ 0 & 0 & i\delta^{\bar{A}}_{\bar{B}} & 0 \\ 0 & 0 & 0 & -i\delta^{\bar{A}'}_{\bar{B}'} \end{bmatrix}. \tag{74}$$

It follows from Eq. (70) that, in these complex coordinates, the only nonzero components of the Christoffel symbols Γ^a_{bc} and $\Gamma^{\bar{a}}_{\bar{b}c}$ are the respective pairs of components $(\Gamma^A_{BC}, \Gamma^{A'}_{B'C'})$ and $(\Gamma^{\bar{A}}_{\bar{B}\bar{C}}, \Gamma^{\bar{A}'}_{\bar{B}'\bar{C}'})$, where

$$\begin{aligned} \Gamma^A_B &= h^{A\bar{D}} \mathbb{H}_{,B\bar{D}C} dz^C, \\ \Gamma^{\bar{A}}_{\bar{B}\bar{C}} &= h^{\bar{A}D} \mathbb{H}_{,\bar{B}D\bar{C}} dz^{\bar{C}}, \\ h^{A\bar{D}} \mathbb{H}_{,B\bar{D}} &= \delta^A_B, \quad h^{\bar{A}D} \mathbb{H}_{,D\bar{B}} = \delta^{\bar{A}}_{\bar{B}}, \end{aligned} \tag{75}$$

and similarly for the complex conjugates $\overline{\Gamma^{A'}_{B'C'}}$ and $\overline{\Gamma^{\bar{A}'}_{\bar{B}'\bar{C}'}}$. The curvature of the connection can be simply computed from these expressions as in Eqs. (64)–(66).

Since, by Eq. (25), the components of the metric k, $k_{\alpha\beta}$, are equal to $-I_{\alpha\beta}$, the metric k is given by

$$_k ds^2 = -i\mathbb{H}_{,A\bar{B}}(dz^A \otimes dz^{\bar{B}} + dz^{\bar{B}} \otimes dz^A) + \text{c.c.}, \tag{76}$$

and $g = h + ik$ is a holomorphic metric with line element

$$ds^2 = 2\mathbb{H}_{,A\bar{B}}(dz^A \otimes dz^{\bar{B}} + dz^{\bar{B}} \otimes dz^A). \tag{77}$$

When the condition of Ricci flatness, Eq. (67), is imposed on the metric h, it follows that

$$\det(\mathbb{H}_{,A\bar{B}}) = \text{const.} \tag{78}$$

Hence, as expected, g is also Ricci flat. In fact, the last two equations correspond to a description of holomorphic half-flat four-metrics given by Plebanski.[3] Therefore, it follows that a triple (P,h,I) which satisfies Eqs. (42)–(47) and the condition of Ricci flatness of h imply that the metric $g = h + ik$ is a holomorphic half-flat four-metric.

Finally, here, note the description of the Kähler structure $(J = -IP, h)$, implied by the structure (P,h,I), in these complex coordinates. It follows from Eqs. (59) and (74) that the components of J are given by

$$J^{\alpha}_{\beta} = \begin{bmatrix} -i\delta^{A}_{B} & 0 & 0 & 0 \\ 0 & i\delta^{A'}_{B'} & 0 & 0 \\ 0 & 0 & i\delta^{\bar{A}}_{\bar{B}} & 0 \\ 0 & 0 & 0 & -i\delta^{\bar{A}'}_{\bar{B}'} \end{bmatrix}. \tag{79}$$

Consequently, the Kähler two-form is given by $[i(\mathbb{H}_{,A\bar{B}} dz^A \wedge dz^{\bar{B}}) + \text{c.c.}]$; the metric h is given by Eq. (73).

ACKNOWLEDGEMENTS

The author thanks Maciej Dunajski and Pawel Nurowski for a number of very helpful comments.

APPENDIX: TWISTOR SPACES

In this appendix the relation between twistor spaces for hyper-Kähler metrics eight-metrics on M and half-flat holomorphic metrics on M is outlined.

Salamon's generalization of Penrose's nonlinear graviton construction[24] (see also Ref. 25) to hyper-Kähler structures can be used to encode the hyper-Kähler structures presented in Sec. III in the complex structure of a twistor space, Z, where $\dim_{\mathbb{C}} Z$ is five. As a real manifold Z is $\mathrm{M} \times \mathrm{S}^2$. In the case of the real or imaginary parts of the anti-self-dual half-flat metrics on M, considered above, the complex structure on the corresponding twistor space Z_{ASD} is given by

$$I_{ASD} = (a_{\mathbf{i}}({}^{+}J^{\mathbf{i}}),\ I_0),$$

$$(a_{\mathbf{1}})^2 + (a_{\mathbf{2}})^2 + (a_{\mathbf{3}})^2 = 1,$$

and, following Refs. 24 and 25, $\{a_{\mathbf{i}}\} \in \mathbb{R}$ here.

Here the tangent space at the point (m,ς) in Z_{ASD} has been expressed as the direct sum $T_m \oplus T_\varsigma$, and I_0 is the operation of multiplication by i on the tangent space T_ς of $\varsigma \in \mathrm{S}^2$. Furthermore, S^2 is identified with CP^1, with local complex coordinate ζ, so that at $(a_{\mathbf{1}},a_{\mathbf{2}},a_{\mathbf{3}}) \in \mathrm{S}^2$, $(a_{\mathbf{1}},a_{\mathbf{2}},a_{\mathbf{3}}) = ((1-\varsigma\bar{\varsigma})/(1+\varsigma\bar{\varsigma}), (\varsigma+\bar{\varsigma})/(1+\varsigma\bar{\varsigma}), i(\varsigma-\bar{\varsigma})/(1+\varsigma\bar{\varsigma}))$. It is shown in detail in Refs. 24 and 25 that the integrability conditions for the tensor I_{ASD} to define a complex structure

on $M\times S^2$ are indeed satisfied, and furthermore, that the hyper-Kähler structure on M can be recovered from the holomorphic properties of Z_{ASD}. The twistor space Z_{ASD} can also be identified with the primed projective spin bundle over M.

In a similar way, now using $^{-}J^{\mathbf{i}}$, the hyper-Kahler structures associated with any half-flat self-dual holomorphic metric on M can be encoded in, and extracted from, a complex structure, I_{SD} say on $M\times S^2$ (this time the unprimed projective spin bundle over M), and the holomorphic properties of the resulting twistor space, Z_{SD}. As before, the latter can be extracted from the former.

Although the results contained in Refs. 24 and 25 enable real hyper-Kähler metrics to be derived from the structure of a twistor space Z, this is not quite the same as deriving a holomorphic half-flat metric g from the properties of a twistor space of the above type. An additional complex structure on M satisfying certain properties is also required, as was noted in Propositions 1 and 2 of Sec. III. In summary, the holomorphic structure on the five complex dimensional twistor space Z [which determines a hyper-Kähler structure, say, $(M,J^{\mathbf{i}},h)$], and a complex structure I, on the four complex dimensional manifold M, which together satisfy the compatibility relations $h(IX,IY)=-h(X,Y)$, ${}_h\nabla I=0$ and $IJ^i=J^{\mathbf{i}}I$, determine a half-flat holomorphic metric g. Hence they also determine the real metric k and the hyper-Kähler structure $(M,J^{\mathbf{i}},k)$.

By using results from Sec. III these statements can be reexpressed in terms of (integrable) almost product structures.

Quantum enveloping superalgebras and link invariants

R. B. Zhang[a)]
School of Mathematics and Statistics, The University of Sydney, Sydney, New South Wales 2006, Australia

(Received 15 September 2000; accepted for publication 30 November 2001)

Corresponding to each finite dimensional simple basic classical Lie superalgebra, a new quantum enveloping superalgebra is introduced, which has the structure of a braided quasi-Hopf superalgebra. In the case of $\mathfrak{osp}(1|2n)$, this quantum enveloping superalgebra is shown to be isomorphic to the standard Drinfeld–Jimbo quantum superalgebra $U_q(\mathfrak{osp}(1|2n))$ as braided quasi Hopf superalgebras. The new quantum enveloping superalgebras are applied to construct link invariants, from which Vassiliev invariants can be readily extracted. This, in particular, provides a useful construction for the Vassiliev invariants associated with $U_q(\mathfrak{osp}(1|2n))$. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1436564]

I. INTRODUCTION

The Drinfeld–Jimbo quantum superalgebras[1–3] were introduced in the early 1990s to describe supersymmetries exhibited by statistical mechanics models such as the Perk–Schultz models. By now a considerable body of theory for the quantum superalgebras[2,4] and the associated quantum supergroups[5,6] exists, and their applications to integrable models[1,7] and low dimensional topology[8–10] have been extensively explored. It has also long been known[11] that there is a deep connection between quantum supergroups and noncommutative geometry. This has been further explored lately and applied to the study of the representation theory,[5] leading to Borel–Weil type theorems for induced representations of quantum $SL(m|n)$ and $OSP(1|2n)$.

A Drinfel–Jimbo quantum superalgebra is a quasi-triangular Hopf superalgebra, which is a deformation (in the sense of Gerstenhaber[12]) of the corresponding enveloping superalgebra.[13] Deformation theory thus lies at the foundation of the theory of quantum superalgebras and quantum supergroups. The broad aim of the article is to develop the deformation theory of enveloping superalgebras following the general strategy of Ref. 14, and to explore its applications in low dimensional topology.

As we have already alluded to, low dimensional topology is one of the areas where quantum superalgebras have major applications. There exists a supersymmetric version[8] of the Reshetikhin–Turaev theory,[15,16] which provides a powerful machinery for generating topological invariants of links and three-manifolds using the representation theory[4] of quantum superalgebras.[1–3] Due to the vast difference between the representations of Lie algebras and Lie superalgebras in the quantum setting,[4] invariants arising from the supersymmetric Reshetikhin–Turaev theory exhibit very different features from those constructed from ordinary quantum algebras.

We may formally regard a quantum superalgebra invariant ν_q of links at generic $q=\exp(h)$ as a power series in h: $\nu_q=\Sigma_{i=0}^{\infty}h^i\nu^{(i)}$. Following the strategy of Birman and Lin,[17] one can show that *each coefficient* $\nu^{(k)}$ *is a Vassiliev invariant*[18,19] *of degree less than or equal to* k. However, it is very difficult to gain any understanding of such Vassiliev invariants within the framework of the Drinfeld–Jimbo superalgebras. Also, there exists no satisfactory quantum Chern–Simons theory formulation[20] for the quantum superalgebra invariants of links and three-manifolds, thus

a)Electronic mail: rzhang@maths.usyd.edu.au

perturbative techniques of quantum field theory are not useful for studying the Vassiliev invariants arising from quantum superalgebras. As we shall see later, deformation theory provides a way to the problem at hand.

Let us now briefly describe the main results of this article. Corresponding to each finite dimensional simple basic classical Lie superalgebra,[13] we introduce a new quantum enveloping superalgebra with braiding (i.e., with a universal R-matrix), which is a quasi-Hopf superalgebra with a nontrivial associator. The underlying algebraic structure of the new quantum enveloping superalgebra is identical to that of the corresponding enveloping superalgebra over the power series ring $\mathbb{C}[[h]]$. Its universal R-matrix takes a particularly simple form and is explicitly given. The associator, however, is a highly complicated object, which is constructed by using a Knizhnik–Zamolodchikov equation following the work of Drinfeld.[14] In the case of the Lie superalgebra $\mathfrak{osp}(1|2n)$, we prove, using results of Ref. 21 that the new quantum enveloping superalgebra is isomorphic to the Drinfeld–Jimbo superalgebra as braided quasi-Hopf superalgebras.

The Reshetikhin–Turaev functor[15,16] from the category $\mathcal{H}$ of colored ribbon graphs to the module category of a ribbon Hopf superalgebra is generalized to a functor from $\mathcal{H}$ to the module category of a ribbon quasi-Hopf superalgebra. It is then applied to the new quantum enveloping superalgebras to construct topological invariants of (framed) links. The advantage of the resulting invariants is that the associated Vassiliev invariants (i.e., the coefficients in their power series expansions) can, in principle, be extracted, as the universal R-matrix and the associator are known. This enables us to construct large classes of Vassiliev invariants. This in particular provides us with a practical construction of the Vassiliev invariants associated with $\mathrm{U}_q(\mathfrak{osp}(1|2n))$.

The organization of the article is as follows. In Sec. II we discuss general properties of quasi-Hopf superalgebras. In Sec. III we introduce the new class of quantum enveloping algebras with braiding. In Sec. IV we prove the isomorphism (as quasi-Hopf superalgebras with braiding) between the new quantum enveloping algebra and the standard Drinfeld–Jimbo quantum superalgebra in the special case of $\mathfrak{osp}(1|2n)$. Section V studies link invariants.

This article makes extensive use of results in Refs. 14 and 22 and Kassel's book.[23]

Before closing this Introduction, we mention that there is no systematic study of deformations (e.g., within the category of braided quasi-Hopf superalgebras) of enveloping superalgebras except in the case $\mathfrak{osp}(1|2n)$. Even the relationship among the different Drinfeld–Jimbo quantum superalgebras associated with Weyl group inequivalent simple root systems of a given simple basic classical Lie superalgebra (see Subsec. III A 2) has not been studied in any depth. We hope to give a thorough treatment of the deformation theory of enveloping superalgebras in a future publication.

II. QUASI-HOPF SUPERALGEBRAS

A. Quasi-Hopf superalgebras

We explain the notion of quasi Hopf superalgebras here. In the fundamental paper[24] by Milnor and Moore, a version of graded quasi-Hopf algebras was introduced. Such algebras are similar to graded Hopf algebras but with the coassociativity requirement on the comultiplications removed altogether. In the earlier 1990s, Drinfeld[14] reignited the subject quite independently of Ref. 24 aiming at applications to quantum groups. He arrived at a notion of quasi-Hopf algebras which is more restrictive than that of Ref. 24, but structurally more interesting in that the comultiplications are quasi-coassociative. We shall consider $\mathbb{Z}_2$-graded generalizations of Drinfeld quasi-Hopf algebras here.

Let A be a $\mathbb{Z}_2$-graded associative algebra, i.e., an associative superalgebra, over a commutative ring $\mathbb{K}$, which admits two algebra homomorphisms, $\Delta: A \to A \otimes A$ and $\epsilon: A \to \mathbb{K}$. These homomorphisms will be called the comultiplication and counit, respectively. The algebra A will be called a $\mathbb{Z}_2$-graded quasi-bi-algebra, or a quasi-bi-superalgebra, if there exists an invertible even element $\Phi \in A \otimes A \otimes A$, called the associator, satisfying the following relations:

$$(\mathrm{id}\otimes\Delta)\Delta(x)=\Phi(\Delta\otimes\mathrm{id})\Delta(x)\Phi^{-1},$$

$$(\epsilon\otimes\mathrm{id})\Delta(x)=x,$$

$$(\mathrm{id}\otimes\epsilon)\Delta(x)=x,\quad \forall x\in A, \tag{2.1}$$

$$(\mathrm{id}\otimes\mathrm{id}\otimes\Delta)(\Phi)(\Delta\otimes\mathrm{id}\otimes\mathrm{id})(\Phi)=\Phi_{234}(\mathrm{id}\otimes\Delta\otimes\mathrm{id})(\Phi)\Phi_{123},$$

$$(\mathrm{id}\otimes\epsilon\otimes\mathrm{id})\Phi=1.$$

Here the second to last equation is usually referred to as the pentagon relation.

We use the following notation for $\Delta(x)$,

$$\Delta(x)=\sum_{(x)} x_{(1)}\otimes x_{(2)},\quad x\in A,$$

which will not lead to confusion, even though the standard Sweedler notation becomes ambiguous for $(\Delta\otimes\mathrm{id})\Delta$ and $(\mathrm{id}\otimes\Delta)\Delta$. A quasi-bi-superalgebra A will be called a $\mathbb{Z}_2$-graded quasi-Hopf algebra, or a quasi-Hopf superalgebra, if there exist invertible even elements $\alpha,\beta\in A$, and an algebra anti-automorphism S satisfying the following relations:

$$\sum_{(x)} S(x_{(1)})\alpha x_{(2)}=\epsilon(x)\alpha,\quad \sum_{(x)} x_{(1)}\beta S(x_{(2)})=\epsilon(x)\beta,\quad \forall x\in A,$$

$$\sum_t X_t\beta S(Y_t)\alpha Z_t=1=\sum_t S(\overline{X}_t)\alpha\overline{Y}_t\beta S(\overline{Z}_t), \tag{2.2}$$

where

$$\Phi=\sum_t X_t\otimes Y_t\otimes Z_t,\quad \Phi^{-1}=\sum_t \overline{X}_t\otimes\overline{Y}_t\otimes\overline{Z}_t.$$

Similar to the case of Hopf superalgebras, (S,α,β) will be called the antipode. It immediately follows from the definition that

$$\epsilon(\alpha)\epsilon(\beta)=1,\quad \epsilon S=\epsilon.$$

Note the following freedom in the definition of the antipode: Let (S,α,β) be an antipode of A. Then for any invertible element $g\in A$, the conditions (2.2) are also satisfied by $(\tilde{S},\tilde{\alpha},\tilde{\beta})$, where

$$\tilde{S}(a)=gS(a)g^{-1},\quad \tilde{\alpha}=g\alpha,\quad \tilde{\beta}=\beta g^{-1}. \tag{2.3}$$

Lemma 2.1: If (S,α,β) *and* $(\tilde{S},\tilde{\alpha},\tilde{\beta})$ *are antipodes of the quasi-Hopf superalgebra* A*, then there exists a unique invertible* $g\in A$ *transforming* (S,α,β) *to* $(\tilde{S},\tilde{\alpha},\tilde{\beta})$ *through (2.3).*

The antipode enables one to turn the dual $V^*=\mathrm{Hom}_{\mathbb{K}}(V,\mathbb{K})$ of a left A-module V into a left A-module, with the action

$$A\otimes V^*\to V^*,\quad x\otimes v^*\mapsto xv^*,$$

defined for homogeneous elements by

$$xv^*(w)=v^*((-1)^{[x][v^*]}S(x)w),\quad \forall w\in V,$$

and extending to inhomogeneous elements by linearity. Here $[x]=0$ if x is even, and $[x]=1$ if odd, and $[v^*]$ is similarly defined. However, it should be observed that while the following linear map defines a module homomorphism,

$$V^*\otimes V\to\mathbb{K},\quad v^*\otimes w\mapsto v^*(\alpha w),$$

even though the natural dual space pairing $v^*\otimes w\mapsto v^*(w)$ is no longer a module map if $\alpha\neq 1$.

A quasi-Hopf superalgebra A is called braided if there exists an even and invertible element $R\in A\otimes A$, called the universal R-matrix, which satisfies the following relations

$$R\Delta(x)=\Delta'(x)R,\quad \forall x\in A,$$

$$(\mathrm{id}\otimes\Delta)R=(\Phi_{231})^{-1}R_{13}\Phi_{213}R_{12}(\Phi_{123})^{-1}, \tag{2.4}$$

$$(\Delta\otimes\mathrm{id})R=\Phi_{312}R_{13}(\Phi_{132})^{-1}R_{23}\Phi_{123}.$$

Here $\Delta'=\tau\Delta$, with $\tau: A\otimes A\to A\otimes A$ being the flip $x\otimes y\mapsto(-1)^{[x][y]}y\otimes x$. It immediately follows from the defining relations of the universal R-matrix that we have the following generalized Yang–Baxter equation

$$R_{12}\Phi_{312}R_{13}(\Phi_{132})^{-1}R_{23}\Phi_{123}=\Phi_{321}R_{23}(\Phi_{231})^{-1}R_{13}\Phi_{213}R_{12}. \tag{2.5}$$

Write $R=\Sigma_r a_r\otimes b_r$, and let

$$u=\sum_{r,t}(-1)^{[\overline{X}_t]}S(b_r\overline{Y}_t\beta S(\overline{Z}_t))\alpha a_r\overline{X}_t.$$

Then u is invertible and for all $x\in A$,

$$S^2(x)=uxu^{-1}.$$

Furthermore, $uS(u)=S(u)u$ belongs to the center of A. We shall call A a ribbon quasi-Hopf superalgebra if there exists an even v belonging to the center of A such that

$$v^2=uS(u). \tag{2.6}$$

In studying deformation quantizations of enveloping superalgebras, we will work on the power series ring $\mathbb{C}[[h]]$. The quasi Hopf superalgebras encountered are topological in the sense that the underlying $\mathbb{C}[[h]]$-modules are completed with respect to the h-adic topology, and the structure maps are continuous.

B. Gauge transformations

Let $(A,m,\Delta,\epsilon,\Phi,S,R,\alpha,\beta)$ be a braided quasi-Hopf superalgebra, where m denotes the multiplication of A. Let $F\in A\otimes A$ be an invertible even element $F\in A\otimes A$ satisfying

$$(\epsilon\otimes\mathrm{id})F=(\mathrm{id}\otimes\epsilon)F=1. \tag{2.7}$$

Write $F=\Sigma f_i\otimes g_i$, $F^{-1}=\Sigma\overline{f}_i\otimes\overline{g}_i$, and set

$$\Delta_F=F\cdot\Delta\cdot F^{-1}: A\to A\otimes A,\quad x\mapsto F\Delta(x)F^{-1};$$

$$\Phi_F=F_{23}(\mathrm{id}\otimes\Delta)(F)\Phi(\Delta\otimes\mathrm{id})(F^{-1})F_{12}^{-1}$$

$$R_F=F_{21}RF^{-1}, \tag{2.8}$$

$$\alpha_F=\sum_i S(\overline{f_i})\alpha\overline{g_i},$$

$$\beta_F=\sum_i f_i\beta S(g_i).$$

Lemma 2.2: $(A,m,\Delta_F,\epsilon,\Phi_F,S,R_F,\alpha_F,\beta_F)$ *is a braided quasi-Hopf superalgebra.*

Equation (2.8) is called a gauge transformation by F on the braided quasi-Hopf superalgebra $(A,m,\Delta,\epsilon,\Phi,S,R,\alpha,\beta)$.

Let

$$\mathbf{A}=(A,m^{(A)},\Delta^{(A)},\epsilon^{(A)},\Phi^{(A)},S^{(A)},R^{(A)},\alpha^{(A)},\beta^{(A)}),$$

$$\mathbf{B}=(B,m^{(B)},\Delta^{(B)},\epsilon^{(B)},\Phi^{(B)},S^{(B)},R^{(B)},\alpha^{(B)},\beta^{(B)})$$

be braided quasi Hopf superalgebras. A homomorphism $(f,F):\mathbf{A}\to\mathbf{B}$ between them consists of an algebra homomorphism $f:(A,m^{(A)})\to(B,m^{(B)})$ and a gauge transformation $F\in B\otimes B$ such that

$$(f\otimes f)\Delta^{(A)}=F\cdot(\Delta^{(B)}f)\cdot F^{-1},$$

$$\{F_{23}(\mathrm{id}\otimes\Delta^{(B)})(F)\}(f\otimes f\otimes f)(\Phi^{(A)})=\Phi^{(B)}F_{12}(\Delta^{(B)}\otimes\mathrm{id})F,$$

$$(f\otimes f)R^{(A)}=F_{21}R^{(B)}F^{-1}.$$

If f is an algebra isomorphism, then (f,F) is called an isomorphism between the braided quasi-Hopf superalgebras **A** and **B**. An isomorphism of braided quasi-Hopf superalgebras strictly preserves the algebraic structure, but only preserves the coalgebraic structure, the associator and the braiding up to a gauge transformation. If $(f,F):\mathbf{A}\to\mathbf{B}$ is an isomorphism, then it follows from Lemma 2.1 that there exists a unique invertible $g\in B$ such that

$$f\circ S^{(A)}\circ f^{-1}=g\circ S^{(B)}\circ g^{-1},$$

$$f(\alpha^{(A)})=g\alpha_F^{(B)},$$

$$f(\beta^{(A)})=\beta_F^{(B)}g^{-1}.$$

We mention that the category of left A-modules has the structure of a braided tensor category, where Φ provides the associativity constraint, and the universal R-matrix gives the braiding. If two braided quasi-Hopf superalgebras are isomorphic, then their module categories are equivalent as braided tensor categories

C. Associative tensor product

Let $(A,m,\Delta,\epsilon,\Phi,S,R,\alpha,\beta)$ be a quasi-Hopf superalgebra. Tensor products of A-modules are not strictly associative, but for any A-modules U, V, and W, there exists the module isomorphism

$$\begin{aligned}&(U\otimes V)\otimes W\to U\otimes(V\otimes W),\\&(u\otimes v)\otimes w\mapsto\Phi((u\otimes v)\otimes w)=u\otimes(v\otimes w),\end{aligned}\tag{2.9}$$

where Φ is the associator of A. The nonassociativity of tensor products is a cause of inconvenience in applications of quasi-Hopf superalgebras, but there is a way to get around the problem (See Remark XI.1.4, p. 496 of Ref. 16 and Section XI.5 of Ref. 23).

Let $\mathbf{V}=\{V_1,V_2,\ldots,V_m\}$ be a sequence of A-modules. We denote

$$(\mathbf{V})=(\ldots((V_1\otimes V_2)\otimes V_3)\otimes\ldots\otimes V_{n-1})\otimes V_n.$$

All the tensor products of the V_i's in this order but with parentheses positioned in different ways are isomorphic to $(\mathbf{V})$. Let us introduce the subsequences

$$\mathbf{V}_r^{(k)}=\{V_1,V_2,\ldots,V_k\},$$

$$\mathbf{V}_l^{(k)}=\{V_k,V_{k-1},\ldots,V_m\}.$$

If $\mathbf{W}=\{W_1,W_2,\ldots,W_n\}$ is also a sequence of A-modules, by joining $\mathbf{V}$ with $\mathbf{W}$ we obtain another sequence $\{V_1,V_2,\ldots,V_m,W_1,W_2,\ldots,W_n\}$. We denote by $(\mathbf{V},\mathbf{W})$ the tensor product $(\{V_1,V_2,\ldots,V_m,W_1,W_2,\ldots,W_n\})$.

Now we introduce a new tensor product $\odot$ for A-modules defined by

$$(\mathbf{V})\odot(\mathbf{W})=(\mathbf{V},\mathbf{W}). \tag{2.10}$$

This is clearly associative. The problem is to find an associative tensor product of maps consistent with this tensor product of A-modules. Consider linear maps

$$f:(\mathbf{V})\to(\mathbf{S}),\quad g:(\mathbf{W})\to(\mathbf{T}).$$

Let $J_{(\mathbf{V}),(\mathbf{W})}:(\mathbf{V})\odot(\mathbf{W})\to(\mathbf{V})\otimes(\mathbf{W})$ be the natural A-module isomorphism

$$J_{(\mathbf{V}),(\mathbf{W})}=(\Phi^{-1}_{(\mathbf{V}),(\mathbf{W}_r^{(1)}),W_2}\otimes\mathrm{id}_{W_3}\otimes\ldots\otimes\mathrm{id}_{W_n})(\Phi^{-1}_{(\mathbf{V}),(\mathbf{W}_r^{(2)}),W_3}\otimes\mathrm{id}_{W_4}\otimes\ldots\otimes\mathrm{id}_{W_n})$$
$$\ldots\Phi^{-1}_{(\mathbf{V}),(\mathbf{W}_r^{(n-1)}),W_n}.$$

Similarly we have the A-module isomorphism $J_{(\mathbf{S}),(\mathbf{T})}:(\mathbf{S})\odot(\mathbf{T})\to(\mathbf{S})\otimes(\mathbf{T})$. An associative tensor product, also denoted by $\odot$, of the maps consistent with the associative tensor product of A-modules is then given by the composition

$$(\mathbf{V})\odot(\mathbf{W})\xrightarrow{J_{(\mathbf{V}),(\mathbf{W})}}(\mathbf{V})\otimes(\mathbf{W})\xrightarrow{f\otimes g}(\mathbf{S})\otimes(\mathbf{T})\xrightarrow{J^{-1}_{(\mathbf{S}),(\mathbf{T})}}(\mathbf{S})\odot(\mathbf{T}).$$

Explicitly, we have

$$f\odot g=J^{-1}_{(\mathbf{S}),(\mathbf{T})}(f\otimes g)J_{(\mathbf{V}),(\mathbf{W})}.$$

More formally, one can always turn the tensor category $\mathrm{Mod}(A)$ of A-modules into a strict tensor category $\mathrm{Mod}_s(A)$ with objects being the $(\mathbf{V})$ for all finite sequences of A-modules, and the morphisms $(\mathbf{V})\to(\mathbf{V}')$ being $\mathrm{Hom}((\mathbf{V}),(\mathbf{V}'))$. The strictly associative tensor product is the $\odot$ just defined above.

D. Gauge transformations on modules

Let $(A,m,\Delta,\epsilon,\Phi,S,\alpha,\beta)$ be a quasi-Hopf superalgebra. Let $V_1,\ldots,V_n$ be A-modules. Denote by $(\mathbf{V})$ the ordered tensor product of the modules. For convenience we shall only consider gauge transformations on ordered tensor product of modules and their homomorphisms. Because of the isomorphism (2.9), the discussions below also apply to the nonassociative tensor product.

Let $\Delta^{(k)}$ be defined inductively by

$$\Delta^{(k)}=(\Delta\otimes\mathrm{id}^{\odot(n-1)})\Delta.$$

Under a gauge transformation $F=\Sigma f_i\otimes g_i$ as defined by (2.8), Δ is transformed to $\Delta_F=F\Delta F^{-1}$, and $\Delta^{(k)}$ to $\Delta_F^{(k)}$, which is defined in exactly the same way as $\Delta^{(k)}$ but with Δ replaced by Δ_F.

Let $(\mathbf{V}_F)$ be the A-module with the same underlying $\mathbb{K}$-module as the A-module $(\mathbf{V})$, but with the A-action defined by

$$x\otimes\mathbf{v}_F\mapsto\Delta_F^{(n)}(x)\mathbf{v}_F, \quad x\in A, \ \mathbf{v}_F\in(\mathbf{V}_F).$$

There exists an A-module isomorphism $(\mathbf{V})\to(\mathbf{V}_F)$ defined by

$$\mathbf{v}\mapsto F^{(n)}\mathbf{v}, \quad \mathbf{v}\in(\mathbf{V}),$$

where

$$F^{(n)}=\sum_{i_2,\ldots,i_n}(\cdots((F\Delta(f_{i_2})\otimes g_{i_2})\Delta^{(2)}(f_{i_3})\otimes g_{i_3})\cdots)\Delta^{(n-1)}(f_{i_n})\otimes g_{i_n}.$$

This is indeed an A-module isomorphism as confirmed by the following relation:

$$\Delta_F^{(n)}(x)(F^{(n)}\mathbf{v})=F^{(n)}\Delta^{(n)}(x)\mathbf{v}, \quad \mathbf{v}\in(\mathbf{V}).$$

Let $W_1,\ldots,W_m$ be another set of A-modules. Assume we have the linear map $\psi:(\mathbf{V})\to(\mathbf{W})$. Then F transforms ψ to $\psi_F:(\mathbf{V}_F)\to(\mathbf{W}_F)$, which is defined by the following commutative diagram

$$\begin{array}{ccc}(\mathbf{V})&\to&(\mathbf{W})\\ \downarrow&&\downarrow\\ (\mathbf{V}_F)&\to&(\mathbf{W}_F).\end{array} \tag{2.11}$$

Consider also the transformation (2.3) on the antipode. It affects only the definition of dual modules. Let V be an A-module, and denote by V_S^* and $V_{\tilde{S}}^*$ the dual A-modules defined by using S and $\tilde{S}$, respectively. Then we have the following A-module isomorphism

$$S^{-1}(g):V_{\tilde{S}}^*\to V_S^*.$$

For $\epsilon_i\in\{1,-1\}$, let $V_i^{\epsilon_i}$ be V_i if $\epsilon_i=1$ and $V_i^{\epsilon_i}=V_i^*$ if $\epsilon_i=-1$. Let $(\mathbf{V}^{\epsilon})=(\{V_1^{\epsilon_1},\ldots,V_n^{\epsilon_n}\})$. The isomorphism $G:(\mathbf{V}_S^{\epsilon})\to(\mathbf{V}_{\tilde{S}}^{\epsilon})$ then is given by

$$G=(\ldots((S^{-1}(g^{(1-\epsilon_1)/2})\otimes S^{-1}(g^{(1-\epsilon_2/2)}))\otimes S^{-1}(g^{(1-\epsilon_3/2)}))\otimes\ldots)\otimes S^{-1}(g^{(1-\epsilon_n/2)}).$$

Let $(\mathbf{W}_{\tilde{S}}^{\epsilon'})$ be another A-module and assume we have the linear map $\psi:(\mathbf{V}_S^{\epsilon})\to(\mathbf{W}_S^{\epsilon'})$. Then the antipode transformation changes ψ to $\tilde{\psi}:(\mathbf{V}_{\tilde{S}}^{\epsilon})\to(\mathbf{W}_{\tilde{S}}^{\epsilon'})$, which is defined by the following commutative diagram:

$$\begin{array}{ccc}(\mathbf{V}_S^{\epsilon})&\to&(\mathbf{W}_S^{\epsilon'})\\ \downarrow&&\downarrow\\ (\mathbf{V}_{\tilde{S}}^{\epsilon})&\to&(\mathbf{W}_{\tilde{S}}^{\epsilon'})\end{array}. \tag{2.12}$$

To summarize, tensor product functors $\odot:\mathrm{Mod}_s(A)\times\mathrm{Mod}_s(A)\to\mathrm{Mod}_s(A)$ defined with respect to gauge equivalent comultiplications of A are naturally isomorphic, and so are also the duality functors of $\mathrm{Mod}_s(A)$ defined with respect to gauge equivalent antipodes of A.

III. QUANTUM ENVELOPING SUPERALGEBRAS

In this section we shall work over the power series ring $\mathbb{C}[[h]]$ exclusively. All superalgebras and quasi-Hopf superalgebras should be understood as topological. The main result is contained in Sec. III B, where a new type of quantum enveloping superalgebras with braiding are constructed. For the purpose of studying the relationship amongst different deformations of enveloping superalgebras, we also discuss the standard Drinfeld–Jimbo quantum superalgebras.[1–3] In the next section, we shall show that the new quantum enveloping superalgebra is isomorphic to the Drinfeld–Jimbo quantum superalgebra in the case of $\mathfrak{osp}(1|2n)$.

A. Drinfeld–Jimbo quantum superalgebras

1. Drinfeld-Jimbo quantum superalgebras

The Drinfeld–Jimbo quantum superalgebras[1–3] were studied quite extensively in the last decade. Here we shall summarize some of their main properties.

Let $\mathfrak{g}$ be a simple basic classical Lie superalgebra[13] (all such Lie superalgebras are assumed to be finite dimensional.). Denote by H^* the dual of its Cartan subalgebra with the nondegenerate symmetric bilinear form $(\ ,\ )$. Let $\phi=\{\alpha_i|i=1,2,\ldots,r\}$ be a chosen simple root system. Denote the set of the even simple roots by ϕ_0 and that of the odd simple roots by ϕ_1. Set

$$[\alpha_i]=\begin{cases}0, & \alpha_i\in\phi_0,\\ 1, & \alpha_i\in\phi_1.\end{cases}$$

If $(\alpha_i,\alpha_i)\neq 0$, we define $a_{ij}=2(\alpha_i,\alpha_j)/(\alpha_i,\alpha_i)$ for all j. If $(\alpha_i,\alpha_i)=0$, and this can only happen if $\alpha_i\in\phi_1$, we set

$$a_{ij}=\begin{cases}-1, & (\alpha_i,\alpha_j)\neq 0,\\ 0, & (\alpha_i,\alpha_j)=0.\end{cases}$$

Corresponding to the given data, a Drinfeld–Jimbo quantum superalgebra $\mathrm{U_q}(\mathfrak{g})$ has been introduced. We shall work in the Drinfeld setting, where $\mathrm{U_q}(\mathfrak{g},\phi)$ is a Hopf superalgebra over the power series ring $\mathbb{C}[[h]]$ completed with respect to the h-adic topology. As is well known, $\mathrm{U_q}(\mathfrak{g},\phi)$ is a deformation of the enveloping superalgebra $\mathrm{U}(\mathfrak{g})[[h]]$.

Now we describe $\mathrm{U_q}(\mathfrak{g},\phi)$ in terms of generators and relations. Recall that $\mathrm{U_q}(\mathfrak{g})$ is generated by the identity and the elements e_i,f_i,h_i, $i=1,2,\ldots,r$, subject to the relations

$$[h_i,h_j]=0,$$

$$[h_i,e_j]=(\alpha_i,\alpha_j)e_j,$$

$$[h_i,f_j]=-(\alpha_i,\alpha_j)f_j,$$

$$[e_i,f_j]=\delta_{ij}(q^{h_i}-q^{-h_i})/(q_i-q_i^{-1}),$$

$$(e_s)^2=(f_i)^2=0,\quad (\alpha_s,\alpha_s)=0,$$

$$ad_{e_i}^{1-a_{ij}}(e_j)=0,\quad i\neq j,$$

$$ad_{f_i}^{1-a_{ij}}(f_j)=0,\quad i\neq j,$$

plus higher order Serre-relations.

The higher order Serre relations can be found in Ref. 2 and thus will not be spelled out explicitly here. It suffices to mention that they depend very much on the Lie superalgebra $\mathfrak{g}$ itself and also on the chosen simple root system ϕ.

Some explanations are now in order. Here q is the power series $q=\exp(h)$, and

$$q_i=\begin{cases} q^{(\alpha_i,\alpha_i)/2}, & (\alpha_i,\alpha_i)\neq 0, \\ q, & (\alpha_i,\alpha_i)=0. \end{cases}$$

The $\mathbb{Z}_2$-gradation of the superalgebra is defined in such a way that all h_i and e_j, f_j with $[\alpha_j]=0$ are even, while all e_s, f_s with $[\alpha_s]=1$ are odd. For a homogeneous element $x\in \mathrm{U_q}(\mathfrak{g},\phi)$, we set $[x]=0$ if x is even and $[x]=1$ if x is odd. Then the graded bracket is defined by $[x,y]=xy-(-1)^{[x][y]}yx$. The notation $ad_{e_i}(x)$ and $ad_{f_i}(x)$ are defined by

$$ad_{e_i}(x)=e_ix-(-1)^{[e_i][x]}q^{h_i}xq^{-h_i}e_i,$$

$$ad_{f_i}(x)=f_ix-(-1)^{[f_i][x]}q^{-h_i}xq^{h_i}f_i.$$

Finally, we note that if $(\alpha_s,\alpha_s)=0$ and $a_{sj}\neq 0$, then the relations $(ad_{e_s})^{1-a_{sj}}(e_j)=(ad_{f_s})^{1-a_{sj}}(f_j)=0$ are implied by $e_s^2=f_s^2=0$.

The $\mathrm{U_q}(\mathfrak{g},\phi)$ has the structures of a Hopf superalgebra, with the coassociative comultiplication

$$\Delta_q(h_i)=h_i\otimes 1+1\otimes h_i,$$

$$\Delta_q(e_i)=e_i\otimes q^{h_i}+1\otimes e_i,$$

$$\Delta_q(f_i)=f_i\otimes 1+q^{-h_i}\otimes f_i,$$

counit

$$\epsilon_q(h_i)=\epsilon_q(e_i)=\epsilon_q(f_i)=0,$$

and antipode

$$S_q(h_i)=-h_i,$$

$$S(e_i)=-e_iq^{-h_i},$$

$$S(f_i)=-q^{h_i}f_i.$$

Let 2ρ be the sum of the even positive roots minus the sum of the odd positive roots of $\mathfrak{g}$. Let $2h_\rho$ denote the linear combination of the h_i such that $[h_\rho,e_i]=(\rho,\alpha_i)e_i$ for all i. Set

$$K=q^{2h_\rho}.$$

Then it can be immediately shown that

$$S^2(x)=KxK^{-1},\quad \forall x\in \mathrm{U_q}(\mathfrak{g},\phi).$$

We shall regard $\mathrm{U_q}(\mathfrak{g},\phi)$ as a quasi-Hopf superalgebra with

$$\Phi=1\otimes 1\otimes 1,\quad \alpha=\beta=1.$$

One of the most important properties of $\mathrm{U_q}(\mathfrak{g},\phi)$ is its braiding, that is, the existence of a universal R-matrix R_q.[3] The explicit form of R_q in terms of the generators of $\mathrm{U_q}(\mathfrak{g},\phi)$ is, in principle, known. However, for the purpose of studying the Vassiliev invariants arising from quantum superalgebras, we are interested in the expansion of R_q into a power series in h. The coefficients of this expansion are in $\mathrm{U}(\mathfrak{g})$ as $\mathrm{U_q}(\mathfrak{g},\phi)$ is a deformation of $\mathrm{U}(\mathfrak{g})$. It is easy to see that

$$R_q = 1 \otimes 1 + h r_c + o(h^2), \tag{3.1}$$

where r_c is the classical r-matrix discussed in Ref. 25. However, there exists no method, even in principle, for computing the higher order terms.

2. The choice of simple root systems

We consider very briefly the dependence of the quantum superalgebra $U_q(\mathfrak{g}, \phi)$ on the chosen simple root system ϕ. Recall that a Lie superalgebra in general admits Weyl group inequivalent simple root systems. The quantum superalgebra $U_q(\mathfrak{g}, \phi)$ is defined in terms of simple and Cartan generators subject to some defining relations. The simple roots thus play a special role. One expects $U_q(\mathfrak{g}, \phi)$ to depend on ϕ nontrivially. This is indeed true, even in the simplest case of $\mathfrak{sl}(2|1)$.

The two simple root systems for $\mathfrak{sl}(2|1)$ are, in terms of Dynkin diagrams,

$$\phi: \bigcirc - - - \otimes, \quad \phi': \otimes - - - \otimes.$$

It is known that the definitions of $U_q(\mathfrak{sl}(2|1), \phi)$ and $U_q(\mathfrak{sl}(2|1), \phi')$ do not involve higher order Serre relations. Now it is a simple matter to check that the square of the antipode of $U_q(\mathfrak{sl}(2|1), \phi)$ is nontrivial, while that of $U_q(\mathfrak{sl}(2|1), \phi')$ is the identity map. This immediately shows that the two Hopf superalgebras are not isomorphic,[26] although it is known that the underlying algebraic structures of $U_q(\mathfrak{sl}(2|1), \phi)$ and $U_q(\mathfrak{sl}(2|1), \phi')$ are the same.[21]

B. Braided structure for enveloping superalgebras

Let $U(\mathfrak{g})$ be the enveloping superalgebra of the Lie superalgebra $\mathfrak{g}$ defined over the complex field. Let $U(\mathfrak{g})[[h]]$ be the $\mathbb{C}[[h]]$-module consisting of formal power series in h with coefficients in $U(\mathfrak{g})$. By $\mathbb{C}[[h]]$-linearly extending the structure maps of the complex Hopf superalgebra $U(\mathfrak{g})$ to $U(\mathfrak{g})[[h]]$, one obtains a natural Hopf superalgebra structure on $U(\mathfrak{g})[[h]]$. We denote the multiplication by m, the comultiplication by Δ, the counit by ϵ, and the antipode by S. Then

$$\begin{aligned} \Delta(X) &= X \otimes 1 + 1 \otimes X, \\ \epsilon(X) &= 0, \\ S(X) &= -X, \quad \forall X \in \mathfrak{g}. \end{aligned} \tag{3.2}$$

Let C denote the quadratic Casimir operator of $\mathfrak{g}$, that is, the central element of $U(\mathfrak{g})$ which takes the eigenvalue $(\lambda + 2\rho, \lambda)$ in any irreducible $U(\mathfrak{g})$-module with highest weight λ. Set

$$t = \tfrac{1}{2}(\Delta(C) - C \otimes 1 - 1 \otimes C).$$

The following results are straightforward to prove, but will be of crucial importance for the remainder of this section.

Lemma 3.1:

$$\begin{aligned} (\mathrm{id} \otimes \Delta) t &= t_{12} + t_{13}, \\ (\Delta \otimes \mathrm{id}) t &= t_{13} + t_{23}, \\ [t_{12}, \; t_{13} + t_{23}] &= 0. \end{aligned}$$

The last equation will be referred to as the "four-term relation."

Now we introduce a braided structure on $U(\mathfrak{g})[[h]]$. We shall take as the universal R-matrix the following power series

$$R = \exp(ht/2). \tag{3.3}$$

As $U(\mathfrak{g})[[h]]$ is cocommutative and t belongs to the commutant of $\Delta(U(\mathfrak{g})[[h]])$, we immediately see that

$$R\Delta(x)=\Delta'(x)R, \quad \forall x\in U(\mathfrak{g})[[h]].$$

However, R requires a nontrivial associator Φ to satisfy the defining relations of a universal R-matrix.

Because of Lemma 3.1, Cartier's work[22] on infinitesimal symmetric categories applies to the problem at hand. This in particular tells us that Drinfeld's construction (second paper of Ref. 14) of associators for enveloping algebras of semi-simple Lie algebras can be generalized to the present context to construct the desired associator. Consider the following differential equation on $\mathbb{C}\backslash\{0,1\}$,

$$\frac{dG(z)}{dz}=\frac{h}{2\pi i}\left(\frac{t_{12}}{z}+\frac{t_{23}}{z-1}\right) \tag{3.4}$$

for the analytic function $G:\mathbb{C}\backslash\{0,1\}\to U(\mathfrak{g})^{\otimes 3}[[h]]$. This is a special case of the celebrated Knizhnik–Zamolodchikov equations, which first arose in the context of Wess–Zumino–Witten models of two dimensional conformal quantum field theory. The classical theory of Fuchsian differential equations guarantees the existence and uniqueness of solutions G_0 and G_1 of the Knizhnik–Zamolodchikov equation with the asymptotics

$$G_0(z)\cong z^{ht_{12}/2\pi i}, \quad z\to 0,$$

$$G_1(z)\cong (1-z)^{ht_{23}/2\pi i}, \quad z\to 1.$$

Furthermore, the two solutions can only differ by a z independent factor

$$\Phi_{KZ}:=(G_0(z))^{-1}G_1(z). \tag{3.5}$$

Φ_{KZ} can be expressed as a power series in h with coefficients being linear combinations of Lie words in t_{12} and t_{23}, where the coefficients involve Chen's iterated integrals. We refer to Ref. 27 by Le and Murakami for details.

It follows from Lemma 3.1 and Cartier's work[22]

Theorem 3.1: *Φ_{KZ} satisfies the relations (2.1) and (2.4), and thus yields the desired associator.*

Furthermore, we can also show that for the given comultiplication Δ and universal R-matrix $R=\exp(ht/2)$, Φ_{KZ} is the unique associator.

The complete quasi-Hopf superalgebra structure of $U(\mathfrak{g})[[h]]$ includes α and β. The relationship between α and β with the antipode S requires both of them be central, while the relationship with the associator Φ involves $\alpha\beta$ only. Therefore, we have the freedom to choose $\alpha=1$. Then

$$\beta^{-1}=m(m\otimes \mathrm{id})(\mathrm{id}\otimes S\otimes \mathrm{id})\Phi_{KZ},$$

where m is the multiplication of $U(\mathfrak{g})[[h]]$.

Remark: A natural question is how the Drinfeld–Jimbo superalgebras are related to the new quantum enveloping superalgebras. More generally, we want to classify all quantisations of the enveloping superalgebras. We will address the problem for the superalgebra $\mathfrak{osp}(1|2n)$ in the next section, and results are used in the study of the Vassiliev invariants associated with $U_q(\mathfrak{osp}(1|2n))$.

IV. THE CASE OF $\mathfrak{osp}(1|2n)$

We now consider the Lie superalgebra $\mathfrak{osp}(1|2n)$. We shall set

$$\mathfrak{g}=\mathfrak{osp}(1|2n)$$

in this section.

Recall that all simple root systems of $\mathfrak{osp}(1|2n)$ are equivalent under the Weyl group, thus we can drop ϕ from the notation of the quantum superalgebra of $\mathfrak{osp}(1|2n)$.[28] $\mathrm{U}_q(\mathfrak{osp}(1|2n))$ is the best studied[28] among all the quantum superalgebras. Its finite dimensional representations at generic q are thoroughly understood. This quantum superalgebra also has an unexpected but very interesting application[29] to the study of a Duflo theorem for $\mathrm{U}(\mathfrak{osp}(1|2n))$ at the classical level.

For $\mathrm{U}(\mathfrak{g})[[h]]$, the structure maps m,Δ,ϵ,S are the standard ones of the universal enveloping superalgebra; the associator Φ_{KZ} is that constructed from the KZ equation; $R=\exp(ht/2)$, and $\alpha=1$, $\beta^{-1}=m(m\otimes\mathrm{id})(\mathrm{id}\otimes S\otimes\mathrm{id})\Phi_{KZ}$.

One of the main results of this section is the following theorem.

Theorem 4.1: $(\mathrm{U}_q(\mathfrak{g}),m_q,\Delta_q,\epsilon_q,S_q,R_q)$ *and* $(\mathrm{U}(\mathfrak{g})[[h]],m,\Delta,\epsilon,\Phi_{KZ},S,\alpha,\beta,R)$ *are isomorphic as braided quasi-Hopf superalgebras on* $\mathbb{C}[[h]]$ *in the case* $\mathfrak{g}=\mathfrak{osp}(1|2n)$.

We break the proof of Theorem 4.1 into a series of lemmas and propositions. Recall that $\mathfrak{osp}(1|2n)$ has many remarkable properties not shared by the other Lie superalgebras. We mention in particular that an analog of Whitehead's lemma holds,[21] i.e., for any finite dimensional $\mathfrak{osp}(1|2n)$-module V, the Lie superalgebra cohomology groups $H^1(\mathfrak{g},V)$ and $H^2(\mathfrak{g},V)$ are trivial. The vanishing of $H^1(\mathfrak{g},V)$ for all finite dimensional $\mathfrak{g}$-modules implies that all such modules are completely reducible.

The universal enveloping algebra $\mathrm{U}(\mathfrak{g})$ forms an $\mathfrak{osp}(1|2n)$-module under the adjoint action. Furthermore, it can be decomposed into a direct sum of finite dimensional $\mathfrak{osp}(1|2n)$-modules. Similarly, $\mathrm{U}(\mathfrak{g})\otimes\mathrm{U}(\mathfrak{g})$ as an $\mathfrak{osp}(1|2n)$-module can also be decomposed into a direct sum of finite dimensional modules. Therefore,[21]

$$H^1(\mathfrak{g},\mathrm{U}(\mathfrak{g})\otimes\mathrm{U}(\mathfrak{g}))=0,\quad H^2(\mathfrak{g},\mathrm{U}(\mathfrak{g}))=0. \tag{4.1}$$

Let M be a two-sided $\mathrm{U}(\mathfrak{g})$-module. Then M forms a left $\mathfrak{g}$-module under the action

$$X\otimes v\mapsto Xv-(-1)^{[X][v]}vX. \tag{4.2}$$

Denote by $H_H^k(\mathrm{U}(\mathfrak{g}),M)$ the kth Hochschild cohomology group of $\mathrm{U}(\mathfrak{g})$ with coefficients in M. It can be shown that there exist vector space embeddings

$$H_H^k(\mathrm{U}(\mathfrak{g}),M)\to H^k(\mathfrak{g},M),\quad k=1,2.$$

Combining these results we have the following.

Lemma 4.1:

$$H_H^1(\mathrm{U}(\mathfrak{g}),\mathrm{U}(\mathfrak{g})\otimes\mathrm{U}(\mathfrak{g}))=0,$$

$$H_H^2(\mathrm{U}(\mathfrak{g}),\mathrm{U}(\mathfrak{g}))=0.$$

Observe that $\mathrm{U}_q(\mathfrak{g})$ in the Drinfeld setting is a deformation of $\mathrm{U}(\mathfrak{g})$ in the sense of Gerstenhaber.[12] The deformations of $\mathrm{U}(\mathfrak{g})$ as an associative superalgebra are classified, up to obstructions, by the even part of the Hochschild cohomology group $H^2(\mathrm{U}(\mathfrak{g}),\mathrm{U}(\mathfrak{g}))$. The vanishing of $H_H^2(\mathrm{U}(\mathfrak{g}),\mathrm{U}(\mathfrak{g}))$ thus implies the following.

Proposition 4.1: The algebraic structure of $\mathrm{U}(\mathfrak{g})$ *is rigid, that is, all Gerstenhaber type deformations of* $\mathrm{U}(\mathfrak{g})$ *are isomorphic to* $\mathrm{U}(\mathfrak{g})[[h]]$ *as associative superalgebras over* $\mathbb{C}[[h]]$.

In particular, as associative superalgebras $\mathrm{U}_q(\mathfrak{g})$ and $\mathrm{U}(\mathfrak{g})[[h]]$ are isomorphic. We denote by $H_h:\mathrm{U}_q(\mathfrak{g})\to\mathrm{U}(\mathfrak{g})[[h]]$ the isomorphism. Define

$$\tilde{\Delta}_q=(H_h\otimes H_h)\circ\Delta_q\circ H_h^{-1},$$

$$\tilde{S}_q=H_h\circ S_q\circ H_h^{-1},$$

$$\tilde{\epsilon}_q = \epsilon_q \circ H_h^{-1},$$

$$\tilde{R}_q = (H_h \otimes H_h) R_q.$$

Consider the Drinfeld operator $v_q \in \mathrm{U_q}(\mathfrak{g})$. Its image under H_q gives rise to a central element $\tilde{v}$ of $\mathrm{U}(\mathfrak{g})[[h]]$, which can be expanded into a power series

$$\tilde{v} = 1 + h\tilde{v}_1 + h^2\tilde{v}_2 + \cdots,$$

where each $\tilde{v}_i$ belongs to the center of $\mathrm{U}(\mathfrak{g})$. If V is an irreducible highest weight $\mathrm{U}(\mathfrak{g})$-module, we denote by $\chi_V(C)$ the eigenvalue of C on V. Then $\tilde{v}$ takes the eigenvalue $\exp(h\chi_V(C))$ on the $\mathrm{U}(\mathfrak{g})[[h]]$-module $V[[t]]$. By using Harish–Chandra's homomorphism for the Lie superalgebra $\mathfrak{g}$, one obtains $\tilde{v}_n = C^n/n!$, i.e., the following lemma.

Lemma 4.2: $\tilde{v} = \exp(hC)$.

Also by using $\Delta_q(v_q^{-1}) = R_{21}R(v_q^{-1} \otimes v_q^{-1})$, one obtains

$$(\tilde{R}_q)_{21}\tilde{R}_q = (\tilde{v} \otimes \tilde{v})\tilde{\Delta}_q(\tilde{v}).$$

For any $w = 1^{\otimes n} + hw_1 + h^2w_2 + h^3w_3 + \cdots$ in $\mathrm{U}(\mathfrak{g})^{\otimes n}[[h]]$, we define $w^{1/2}$ to be the power series $x = 1^{\otimes n} + hx_1 + h^2x_2 + \cdots$ such that $x^2 = w$. Then $w^{1/2}$ is uniquely defined. From the above equation, we obtain

$$((\tilde{R}_q)_{21}\tilde{R}_q)^{1/2} = (\tilde{v}^{1/2} \otimes \tilde{v}^{1/2})\tilde{\Delta}_q(\tilde{v}^{-1/2}). \tag{4.3}$$

Now

$$\tilde{A}_q = (\mathrm{U}(\mathfrak{g})[[h]], m, \tilde{\Delta}_q, \tilde{\epsilon}_q, \tilde{S}_q, \tilde{R}_q)$$

forms a braided Hopf superalgebra isomorphic to A_q.

Proposition 4.2: There exists a gauge transformation $F = 1 \otimes 1 + o(h)$ *such that*

$$\Delta = F\tilde{\Delta}_q F^{-1},$$

$$R = F_{21}\tilde{R}_q F^{-1},$$

$$\Phi_{KZ} = F_{23}(\mathrm{id} \otimes \tilde{\Delta}_q)(F)(\tilde{\Delta}_q \otimes \mathrm{id})(F^{-1})F_{12}^{-1},$$

where Δ *is the standard comultiplication for enveloping superalgebras,* $R = \exp(ht/2)$ *and* Φ_{KZ} *is given by (3.5).*

Proof: The deformations of the coalgebraic structure of $\mathrm{U}(\mathfrak{g})$ within the category of quasi-Hopf superalgebras are determined by $H_H^1(\mathrm{U}(\mathfrak{g}), \mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g}))$. Since for $\mathfrak{g} = \mathfrak{osp}(1|2n)$, $H_H^1(\mathrm{U}(\mathfrak{g}), \mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g})) = 0$, one can always find an $f = 1 \otimes 1 + o(h) \in (\mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g}))[[h]]$ with $(\epsilon \otimes \mathrm{id})f = (\mathrm{id} \otimes \epsilon)f = 1$ such that

$$f\tilde{\Delta}_q f^{-1} = \Delta.$$

Then $R^{(f)} = f_{21}\tilde{R}_q f^{-1}$ commutes with $\Delta(\mathrm{U}(\mathfrak{g})[[h]])$. Let

$$f' = (R^{(f)}(R_{21}^{(f)}R^{(f)})^{-1/2})^{1/2}.$$

It is easy to show that $(f'_{21})^2(f')^2 = 1$. Thus it follows from the uniqueness of the square root that $f'_{21} = (f')^{-1}$. Set

$$F = f'f.$$

We claim that F provides the desired gauge transformation.

Consider the effect of the further gauge transformation f' after f. The comultiplication Δ remains unchanged. The transformed R-matrix reads

$$R^{(F)}=f'_{21}R^{(f)}(f')^{-1}.$$

One can show that

$$R^{(F)}_{21}=R^{(F)}=f'(R^{(f)}_{21}R^{(f)})^{1/2}(f')^{-1}.$$

Thus $R^{(F)}$ is symmetric, and

$$(R^{(F)})^2=R^{(F)}_{21}R^{(F)}=f'R^{(f)}_{21}R^{(f)}(f')^{-1}=\Delta(\tilde{v}^{-1})(\tilde{v}\otimes\tilde{v}).$$

Upon taking the square root, we obtain $R^{(F)}=R$. Obviously

$$\Phi=F_{23}(\mathrm{id}\otimes\tilde{\Delta}_q)(F)(\tilde{\Delta}_q\otimes\mathrm{id})(F^{-1})F^{-1}_{12}$$

provides the associator for the braided quasi-Hopf superalgebra $\mathrm{U}(\mathfrak{g})[[h]]$ with the comultiplication Δ and universal R-matrix $\exp(ht/2)$. But with Δ and $R=\exp(ht/2)$ given, Φ_{KZ} is the unique associator, hence we must have $\Phi=\Phi_{KZ}$.

Finally we consider the antipode. Let

$$\alpha_F=m(\tilde{S}_q\otimes id)F^{-1},$$

$$\beta_F=m(id\otimes\tilde{S}_q)F,$$

$$A'_h=(\mathrm{U}(\mathfrak{g})[[h]],\Delta,\epsilon,R,\Phi_{KZ},\tilde{S}_q,\alpha_F,\beta_F).$$

Needless to say, $(\tilde{S}_q,\alpha_F,\beta_F)$ defines an antipode for A'_h. Applying Lemma 2.1 with $g=\alpha_F^{-1}$, we arrive at the antipode $(S,\alpha=1,\beta)$ with $\beta^{-1}=m(m\otimes\mathrm{id})(\mathrm{id}\otimes S\otimes\mathrm{id})\Phi_{KZ}$.

V. FRAMED LINK INVARIANTS

A. Colored ribbon graphs

We briefly discuss colored ribbon graphs here. Standard references on the subject are Refs. 15 and 16. Note that each (0,0) ribbon graph gives rise to a framed oriented link and vice versa.

By a ribbon we mean the square $[0,1]\times[0,1]$ smoothly embedded in $\mathbf{R}^3$. The images of $[0,1]\times 0$ and $[0,1]\times 1$ are the bases, and that of $\frac{1}{2}\times[0,1]$ is called the core of the ribbon. Similarly an annulus is the cylinder $S^1\times[0,1]$ embedded in $\mathbf{R}^3$, and the image of $S^1\times\frac{1}{2}$ under the embedding is called the core of the annulus. Ribbons and annuli are oriented as surfaces and their cores are directed.

Given k, $l\in\mathbb{Z}_+$. A (k,l) ribbon graph is an oriented surface consisting of ribbons and annuli such that ribbons and annuli never meet, and this surface intersects $(\mathbf{R}^2\times 0)\cup(\mathbf{R}^2\times 1)$ in the bases of the ribbons, where the collection of these bases are the collection of segments

$$\{[i-\tfrac{1}{4},i+\tfrac{1}{4}]\times 0\times 0|i=1,2,\ldots,k\}\cup\{[j-\tfrac{1}{4},j+\tfrac{1}{4}]\times 0\times 1|j=1,2,\ldots,l\}.$$

For simplicity, we will represent a ribbon or an annulus by its directed core.

Remark: Our notion of ribbon graphs is more restrictive than that of Refs. 15 and 16 in that coupons are not allowed.

We introduce two operations, composition and juxtaposition, to manufacture new ribbon graphs from given ones. Given (k,l) graph Γ_1, (l,m) graph Γ_2, and (k',l') graph Γ_3, the composition of $\Gamma_1\circ\Gamma_2$ is defined in the following way: shift Γ_2 by the vector (0,0,1) into

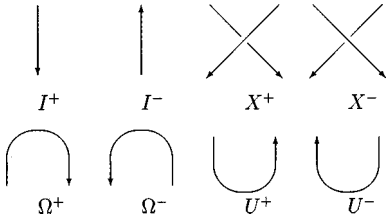

FIG. 1. Generators of ribbon graphs.

$\mathbf{R}^2\times[1,2]$, glue the bottom end of Γ_2 to the top end of Γ_1 in such a way that the core of the ribbons glued together should have the same direction as the core of the resultant ribbon (if this is not possible, then the composition is not defined), then reduce the size of the resultant picture by a factor of 2, leading to a (k, m) graph. The juxtaposition $\Gamma_1\otimes\Gamma_3$ is to position Γ_3 on the right of Γ_1, leading to a $(k+k', l+l')$ graph.

By repeatedly applying these two operations to the set of ribbon graphs depicted in Fig. 1, we can generate all the ribbon graphs.

We associate to each (k,l) graph Γ two sequences $\epsilon_*(\Gamma)=(\epsilon_1,\epsilon_2,\ldots,\epsilon_k)$ and $\epsilon^*(\Gamma)=(\epsilon^1,\epsilon^2,\ldots,\epsilon^l)$, ϵ^i, $\epsilon_j\in\{1,-1\}$, in the following way. For a ribbon of Γ with a base $[i-\frac{1}{4},i+\frac{1}{4}]\times 0\times 0$ (resp. $[j-\frac{1}{4},j+\frac{1}{4}]\times 0\times 1$), if its core is directed towards this base, then $\epsilon_i=1$ (resp. $\epsilon^j=-1$), and $\epsilon_i=-1$ (resp. $\epsilon^j=1$) otherwise.

Let $I=\{1,2,\ldots,N\}$ be a finite index set. We introduce the set $\mathcal{N}$ consisting of finite sequences of the form $((i_1,\epsilon_1),(i_2,\epsilon_2),\ldots,(i_k,\epsilon_k))$, $i_k\in I$, $k\in\mathbb{Z}_+$, $\epsilon_t\in\{1,-1\}$. A coloring of a ribbon graph Γ is a map associating with each ribbon or annulus of Γ an index $i\in I$. The category $\mathcal{H}$ of ribbon graphs is defined to have as objects the elements of $\mathcal{N}$, and as morphisms the ribbon graphs, where we require that if the ribbon graph Γ is a morphism $\eta\to\eta'$, $\eta,\eta'\in\mathcal{N}$, then the sequences of colors and directions of cores of the bottom and top ribbons must be equal to η and η', respectively. $\mathcal{H}$ is provided with a tensor product structure $\otimes:\mathcal{H}\times\mathcal{H}\to\mathcal{H}$, such that the tensor product of objects η and η' is to position the latter on the right of η to form one sequence, and the tensor product of morphism is simply the juxtaposition of ribbon graphs defined earlier.

B. Generalized Reshetikhin–Turaev functor

In Ref. 30, Altschuler and Coste extended the construction of Reshetikhin and Turaev[15,16] to braided quasi-Hopf algebras, obtaining a covariant functor from the category of colored ribbon graphs to the module category (with the strictly associative tensor product) of any ribbon quasi-Hopf algebra. Their result can be directly extended to the supersymmetric setting, leading to the following generalization of Theorem 1 of Ref. 8.

Theorem 5.1: *Let A be a ribbon quasi-Hopf superalgebra. Let $\{V_i|i\in I\}$ be a set of A-modules, which are free $\mathbb{K}$-modules of finite ranks. There exists a unique covariant functor F from the category $\mathcal{H}$ of colored ribbon graphs to the module category of A with the strictly associative tensor product such that*

(1) F transforms any object $\eta=((i_1,\epsilon_1),(i_2,\epsilon_2),\ldots,(i_k,\epsilon_k))$ of $\mathcal{H}$ into the A-module $(\mathbf{V}(\eta))=(\cdots(V_{i_1}^{\epsilon_1}\otimes V_{i_2}^{\epsilon_2})\otimes\cdots)\otimes V_{i_k}^{\epsilon_k}$, where $V_i^{+1}=V_i$, $V_i^{-1}=V_i^*$, and if $k=0$, then $V(\eta)$ is defined as the trivial A module.

(2) For any two colored ribbon graphs Γ and Γ',

$$F(\Gamma\otimes\Gamma')=F(\Gamma)\odot F(\Gamma'), \tag{5.1}$$

that is, F preserves the tensor product $\odot$.

(3) Color the bottom left ribbons of X^+ and X^- by i and the bottom right ones by j, and denote the resultant colored ribbon graphs by X_{ij}^+ and X_{ij}^- respectively. Then

$$F(X_{ij}^{+})=\tau R:\quad V_i\odot V_j\to V_j\odot V_i,$$
$$F(X_{ij}^{-})=R^{-1}\tau:\quad V_i\odot V_j\to V_j\odot V_i, \tag{5.2}$$

where R is the universal R matrix of A, and τ is the flipping map. Similarly, we have

$$F(I_i^{+})=id:V_i\to V_i,$$
$$F(I_i^{-})=id:V_i^{*}\to V_i^{*},$$
$$F(\Omega_i^{+}):V_i^{*}\odot V_i\to\mathbb{K},$$
$$x^{*}\otimes y\mapsto x^{*}(\alpha y),$$
$$F(\Omega_i^{-}):V_i\odot V_i^{*}\to\mathbb{K},$$
$$x\otimes y^{*}\mapsto(-1)^{[x]}y^{*}(S(\alpha)uv^{-1}x),$$
$$F(U_i^{+}):\mathbb{K}\to V_i\odot V_i^{*},$$
$$c\mapsto c\sum_t \beta b_t\otimes b_t^{*},$$
$$F(U_i^{-}):\mathbb{K}\to V_i^{*}\odot V_i,$$
$$c\mapsto c\sum_t (-1)^{[b_t]}b_t^{*}\otimes u^{-1}vS(\beta)b_t, \tag{5.3}$$

where $\{b_t\}$ is a basis for V_i, and $\{b_t^{*}\}$ a basis for V_i^{*}, which are dual to each other in the sense that $b_s^{*}(b_t)=\delta_{st}$.

Let $\eta=((i_1,\epsilon_1),(i_2,\epsilon_2),\ldots,(i_k,\epsilon_k))$. Consider the (k,k) colored ribbon graph $\Gamma_c:\eta\to\eta$. We joint the top and bottom right-most ends to get the following $(k-1,k-1)$ colored ribbon graph

$$(I^{\epsilon_1}\otimes\cdots\otimes I^{\epsilon_{k-1}}\otimes U^{\epsilon_k})(\Gamma_c\otimes I^{-\epsilon_k})(I^{\epsilon_1}\otimes\cdots\otimes I^{\epsilon_{k-1}}\otimes\Omega^{-\epsilon_k}).$$

Iterating this process we will arrive at the (0,0) colored ribbon graph $\hat{\Gamma}_c$, which we call the closure of Γ_c. Now $F(\Gamma_c)$ is a module map from $(\mathbf{V}(\eta))=V_{i_1}^{\epsilon_1}\odot\cdots\odot V_{i_k}^{\epsilon_k}$ to itself, and

$$F(\hat{\Gamma}_c)=\mathrm{str}[\beta S(\alpha)uv^{-1}F(\Gamma_c)],$$

where the supertrace is taken over $(\mathbf{V}(\eta))$. In particular, for a (1,1) graph Γ_c with the open strand colored by an A-module V, there exists a central element γ of A such that

$$F(\Gamma_c)=\gamma:V\to V.$$

If we assume that the A-module V admits central characters, i.e., all central elements of A act by scalars, then

$$F(\Gamma_c)=\chi_V(\gamma)\,\mathrm{id}_V:V\to V,$$
$$F(\hat{\Gamma}_c)=\chi_V(\gamma)SD_q(V),$$

where $\chi_V(\gamma)$ is the eigenvalue of γ in V, and $SD_q(V)=\mathrm{str}_V(\beta S(\alpha)uv^{-1})$ is the quantum superdimension of V. It follows that for any (0,0) graph, if any of its components is colored with an A-module (on which central elements of A act on as scalars), which has a vanishing quantum superdimension, then the Reshetikhin–Turaev functor yields zero when applied to the ribbon graph.

For any colored ribbon graph Γ_c, consider the A-module homomorphism $F(\Gamma_c)$. Under a gauge transformation as defined by (2.8), $F(\Gamma_c)$ transforms according to (2.11). Under a transformation (2.3) on the antipode, $F(\Gamma_c)$ transforms as (2.12). In particular, if Γ_c is a (0,0) colored ribbon graph, $F(\Gamma_c)$ is an A-module map $\mathbb{K}\to\mathbb{K}$. In this case, (2.11) and (2.12) dictate that $F(\Gamma_c)$ is not changed. We state this observation as follows.

Lemma 5.1: For any (0,0) *colored ribbon graph* Γ_c, $F(\Gamma_c)$ *remains intact under gauge transformations and antipode transformations*.

C. Drinfeld–Jimbo quantum superalgebras versus braided enveloping superalgebras

For convenience, we set

$$A_q=(\mathrm{U_q}(\mathfrak{g}),m_q,\Delta_q,\epsilon,S_q,R_q,v_q),$$

$$A[[h]]=(\mathrm{U}(\mathfrak{g})[[h]],m,\Delta,\epsilon,S,\Phi=\Phi_{KZ},R,\alpha,\beta,v),$$

where v is the Drinfeld operator defined by (2.6). For $A[[h]]$, $\alpha=1$ and $v=u$.

Equipped with Theorem 5.1, we can easily construct link invariants from the new braided enveloping superalgebras $A[[h]]$. Such link invariants should be closely related to the link invariants obtained by using the standard Drinfeld–Jimbo quantum superalgebras A_q. We shall formulate a conjecture on their relationship and prove it in the case of $\mathfrak{osp}(1|2n)$.

Consider a set of non-isomorphic $\mathrm{U_q}(\mathfrak{g},\phi)$-modules, $\{V_i[[h]]=V_i\otimes_{\mathbb{C}}\mathbb{C}[[h]]|i\in I\}$, which satisfies the following conditions:

(1) all $V_i[[h]]$ are free $\mathbb{C}[[h]]$-modules of finite ranks;
(2) as $\mathrm{U_q}(\mathfrak{g},\phi)$-modules, the $V_i[[h]]$ are indecomposable and
(3) admit central characters, i.e., the central elements of $\mathrm{U_q}(\mathfrak{g},\phi)$ act on each $V_i[[h]]$ by scalar multiplications; and
(4) for each $i\in I$, there exists a unique $i^*\in I$ such that $V_{i*}[[h]]=(V_i[[h]])^*$.

Now we can use $\{V_i[[h]]|i\in I\}$ to color ribbon graphs, and to construct the RT functor following the general procedure of subsection V.B, but with $\Phi=1\otimes 1\otimes 1$ and $\alpha=\beta=1$. This reproduces the result of Theorem 1 of Ref. 8.

Let Γ be a ribbon graph with m components labeled by the integers $1,2,\ldots,m$. For each k, we color the kth component of the ribbon graph with the $\mathrm{U_q}(\mathfrak{g},\phi)$-module $V_{i_k}[[h]]$, and denote the resultant colored ribbon graph by Γ_c. Applying the generalized RT functor to the colored ribbon graph leads to a $\mathrm{U_q}(\mathfrak{g},\phi)$-module homomorphism

$$F_{A_q,\{V_i[[h]]|i\in I\}}(\Gamma_c):\mathbb{C}[[h]]\to\mathbb{C}[[h]].$$

Each $\mathrm{U_q}(\mathfrak{g})$-module $V_i[[h]]$ gives rise to a finite dimensional $\mathrm{U}(\mathfrak{g})$-module

$$V_i=V_i[[h]]/hV_i[[h]]$$

over $\mathbb{C}$. We assume that as $\mathrm{U}(\mathfrak{g})$-modules, the V_i, $i\in I$, are non-isomorphic and have the following properties: (a) the V_i are indecomposable and (b) admit central characters; and (c) for each $i\in I$, there exists a unique $i^*\in I$ such that $V_{i*}=V_i^*$.

Remark: There always exist $\mathrm{U_q}(\mathfrak{g})$-modules $V_i[[h]]$, $i\in I$, satisfying the conditions (1)–(4), such that the associated $\mathrm{U}(\mathfrak{g})$-modules V_i, $i\in I$, meet the conditions (a)–(c).

Now $V_i\otimes_{\mathbb{C}}\mathbb{C}[[h]]$ admits a $U(\mathfrak{g})[[h]]$-module structure in the obvious way. As $V_i[[h]]$ is free over $\mathbb{C}[[h]]$, we have $V_i[[h]]=V_i\otimes_{\mathbb{C}}\mathbb{C}[[h]]$. We shall apply the construction of Sec. V B to the braided quasi-Hopf superalgebra $A[[h]]$ with the set $\{V_i[[h]]|i\in I\}$ of $U(\mathfrak{g})[[h]]$-modules. Because of the special forms of α and v in the present context, Eq. (5.3) is considerably simplified.

For a (0,0) ribbon graph Γ with m components labeled by the integers $1,2,\ldots,m$, we color its kth component by the $U(\mathfrak{g})[[h]]$-module $V_{i_k}[[h]]$ for each k, and denote by Γ_c the resultant colored ribbon graph. Applying the generalized RT functor to the colored ribbon graph leads to a $U(\mathfrak{g})[[h]]$-module homomorphism

$$F_{A[[h]],\{V_i[[h]]|i\in I\}}(\Gamma_c):\mathbb{C}[[h]]\to\mathbb{C}[[h]].$$

It is important for the purpose of studying link invariants to understand the relationship between $F_{A_q,\{V_i[[h]]|i\in I\}}(\Gamma_c)$ and $F_{A[[h]],\{V_i[[h]]|i\in I\}}(\Gamma_c)$. We conjecture that

$$F_{A_q,\{V_i[[h]]|i\in I\}}(\Gamma_c)=F_{A[[h]],\{V_i[[h]]|i\in I\}}(\Gamma_c) \tag{5.4}$$

for all the simple basic classical Lie superalgebras but a few exceptions. We do not have a proof at hand (A proof probably requires a thorough understanding of the Drinfeld–Jimbo quantum superalgebras from a deformation theoretical point of view.) However, we can show the following.

Theorem 5.2: *Equation (5.4) holds when* $\mathfrak{g}=\mathfrak{osp}(1|2n)$.

Proof: Let $\mathfrak{g}=\mathfrak{osp}(1|2n)$ in the proof. Consider the A_q-module $V_i[[h]]$. The inverse of the Hopf superalgebra isomorphism H_h induces a natural $\tilde{A}_q$-module structure on $V_i[[h]]$, defined by

$$\tilde{A}_q\otimes V_i[[h]]\to V_i[[h]],$$

$$\tilde{x}\otimes v\mapsto H_h^{-1}(\tilde{x})v.$$

Clearly, $F_{A_q,\{V_i[[h]]|i\in I\}}(\Gamma_c)=F_{\tilde{A}_q,\{V_i[[h]]|i\in I\}}(\Gamma_c)$.

As we have shown in the last section, a gauge transformation turns the ribbon Hopf superalgebra $\tilde{A}_q$ into a ribbon quasi-Hopf superalgebra A_h'. Under this gauge transformation, $F_{\tilde{A}_q,\{V_i[[h]]|i\in I\}}(\Gamma_c)$ transforms to $F_{A_h',\{V_i[[h]]|i\in I\}}(\Gamma_c)$. Because Γ_c is a (0,0) colored ribbon graph, it follows Lemma 5.1 that

$$F_{\tilde{A}_q,\{V_i[[h]]|i\in I\}}(\Gamma_c)=F_{A_h',\{V_i[[h]]|i\in I\}}(\Gamma_c).$$

Finally we consider the transformation $g=\alpha_F^{-1}$ on the antipode $(\tilde{S}_q,\alpha_F,\beta_F)$ of A_h'. This transformation also turns $F_{A_h',\{V_i[[h]]|i\in I\}}(\Gamma_c)$ to $F_{A[[h]],\{V_i[[h]]|i\in I\}}(\Gamma_c)$. Using Lemma 5.1 again we have

$$F_{A_h',\{V_i[[h]]|i\in I\}}(\Gamma_c)=F_{A[[h]],\{V_i[[h]]|i\in I\}}(\Gamma_c).$$

This proves the theorem.

D. Vassiliev invariants

Each framed link can be represented as a (0,0)-ribbon graph Γ. Let us color all the components of Γ by the same finite dimensional indecomposable A_q-module $V[[h]]$. Then $F_{A_q,\{V_i[[h]]|i\in I\}}$ gives rise to a framed link invariant, which we denote by ν_q. We may formally regard ν_q as a power series in h,

$$\nu_q=\sum_{k=0}^{\infty}h^k\nu^{(k)}, \tag{5.5}$$

where $\nu^{(k)}:\{\text{framed links}\}\to\mathbb{C}$ are framed link invariants themselves. As we have already mentioned, each $\nu^{(k)}$ is a Vassiliev invariant of degree $\leqslant k$. We now explain this point following Birman and Lin.[17] A framed link invariant ν can be extended to an invariant of singular framed links in the following way. If L is a singular framed link, we may replace any one of its double point by an over crossing to get L_+, or by an under crossing to get L_-. Then $\nu(L)$ is defined inductively by

$$\nu(L)=\nu(L_+)-\nu(L_-).$$

It is easy to see that the definition is independent of the order in which the singular points are resolved. A (framed) link invariant is a Vassiliev invariant of degree $\leqslant k$ if it vanishes on all singular (framed) links with more than k double points.

Consider ν_q applied to a singular framed link L with $(k+1)$ double points. Because of (3.1),

$$\nu_q(L)\in h^{k+1}\mathbb{C}[[h]].$$

Therefore, $\nu^{(i)}(L_c)=0$, $\forall i\leqslant k$.

Remark: Equation (5.5) is of little use for computing the Vassiliev invariants $\nu^{(k)}$, as there is no known way to expand the universal R-matrix R_q into a power series in h.

On the other hand, we may use the $A[[h]]$-module $V[[h]]$ to color all the components of Γ to obtain a framed link invariant from $F_{A[[h]],\{V_i[[h]]|i\in I\}}$, which we will denote by $\mu[[h]]$. Clearly, $\mu[[h]]$ is a powers series in h,

$$\mu[[h]]=\sum_{k=0}^{\infty}h^k\mu^{(k)},$$

and each $\mu^{(k)}$ is a Vassiliev invariant of framed links. Now both the associator and R-matrix of $A[[h]]$ are known as power series in h, thus the $\mu^{(k)}$ are computable.

Thus we have the following from Theorem 5.4 that

Corollary 5.1. In the case of $\mathfrak{osp}(1|2n)$, $\nu^{(k)}=\mu^{(k)}$, *for all* k.

This provides us with a more accessible construction of the Vassiliev invariants $\nu^{(k)}$ associated with the Drinfeld–Jimbo quantum superalgebra $\mathrm{U}_q(\mathfrak{osp}(1|2n))$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 5 MAY 2002

Controllability of quantum mechanical systems by root space decomposition of $\mathfrak{su}(N)$

Claudio Altafini[a)]
SISSA-ISAS, International School for Advanced Studies, via Beirut 2-4, 34014 Trieste, Italy

(Received 24 October 2001; accepted for publication 4 February 2002)

The controllability property of the unitary propagator of an N-level quantum mechanical system subject to a single control field is described using the structure theory of semisimple Lie algebras. Sufficient conditions are provided for the vector fields in a generic configuration as well as in a few degenerate cases. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467611]

I. INTRODUCTION

The question of controllability for a finite level quantum system, see Dahlen *et al.* (1996), Schirmer *et al.* (2001a), Turinici and Rabitz (2001) is studied in this paper by analyzing the structure of the semisimple Lie algebra of its time evolution operator. The system dynamics is determined by its internal Hamiltonian and by an external Hamiltonian describing the interaction with a control field. Of the several different aspects of controllability that can be defined for a closed system of such type [overviewed in Albertini and D'Alessandro (2001); Schirmer *et al.* (2001b)] we consider here the more direct and important in practical applications, namely the controllability of its unitary propagator which, in control terms, is governed by a bilinear system with drift and a single control input and evolves on $\mathrm{SU}(N)$. For a compact semisimple Lie group like $\mathrm{SU}(N)$, the testing of global controllability is the simplest of all noncommutative Lie groups. In fact, compactness implies that the accessibility property collapses into (global) controllability and semisimplicity implies that almost all pairs of vector fields span the corresponding Lie algebra. The first property means that purely algebraic tools, like the *Lie algebra rank condition* normally used in control theory provides necessary and *sufficient* conditions for controllability, while the second property affirms that controllability is generically verified even in the single control case. The main scope of this paper is to give the interpretation of these properties in terms of structure theory of semisimple Lie algebras, see Cornwell (1997), Gilmore (1974), Sattinger (1986), and to provide alternative tests to the exhaustive computation of commutators that the Lie algebra rank condition requires. So genericity is interpreted in terms of regularity of the roots of the Lie algebra $\mathfrak{su}(N)$ and another property, regularity along the control vector field, immediately follows. Replacing the Lie algebra rank condition means seeking alternative conditions that guarantee the maximal nonintegrability of the pair of vector fields. The main tool we use, together with the regularity of the roots, is the connectivity of the graph of the control vector field. Both properties were classically used to analyze controllability of vector fields on semisimple Lie algebras (especially the noncompact ones, see Jurdjevic and Kupka (1981), Gauthier and Bonnard (1982), El Assoudi *et al.* (1995), Silva Leite and Crouch (1988). For the same type of problem as ours, the properties of the graph were recently used also in Turinici *et al.* (2001). The conditions we obtain, based only on the *a priori* knowledge of the two vector fields, are only sufficient but they allow us to avoid any computation of Lie brackets. From the generic case, physically representing a quantum system with all different transition values between its (nondegenerate) energy levels, these tools carry on to the singular case, where some of these levels might be equispaced.

The paper is organized as follows: the structure theory of semisimple Lie algebras is recalled

a)Electronic mail: altafini@sissa.it

in Sec. II and it is applied to the quantum system in Sec. III, where all the needed control concepts are given. The sufficient conditions for a generic pair of vector fields are given in Sec. IV, while in Sec. V the simplest among the singular cases are analyzed.

II. ROOT SPACE DECOMPOSITION FOR $\mathfrak{su}(N)$

Consider the classical Lie algebra A_{N-1}, complexification of $\mathfrak{su}(N)$ according to Cartan's notation. The subindex $N-1$ is the rank of the *Cartan subalgebra* $\mathfrak{h}$ of A_{N-1}, i.e., of the maximal Abelian subalgebra such that the endomorphism ad_H of A_{N-1} is semisimple for all $H \in \mathfrak{h}$.

Definition 1: An element $H \in A_{N-1}$ is said to be regular if the multiplicity of the zero eigenvalue of ad_H *is equal to the rank of A_{N-1}, i.e.,* $\dim(\ker \mathrm{ad}_H) = \mathrm{rank}\, A_{N-1} = N-1$.

The set of regular elements H is open and dense in A_{N-1}. Choose one such H and consider the corresponding Cartan subalgebra $\mathfrak{h} = \mathfrak{g}_0(H) = \{B \in A_{N-1} | \mathrm{ad}_H B = 0\}$.

The *roots* of A_{N-1} are the functionals α on $\mathfrak{h}$ such that, for $H \in \mathfrak{h}$, $\mathrm{ad}_H B = \alpha(H)B$, $B \in A_{N-1}$, i.e., α give the eigenvalues of ad_H for each choice of H. Denote by Δ the set of nonzero roots of A_{N-1} with respect to $\mathfrak{h}$, by Δ^+ the subset of positive roots with respect to the lexicographic order on the dual of $\mathfrak{h}$, and by Φ the set of *fundamental roots*, i.e., the set of positive roots that cannot be written as sums of two other positive roots.

We need a stronger version of the regularity property, see Jurdjevic (1996)—p. 187.

Definition 2: A regular $H \in A_{N-1}$ is said to be strongly regular if all nonzero eigenvalues $\alpha(H)$ are distinct and have multiplicity 1.

Also the set of strongly regular elements is open and dense in A_{N-1}. For all strongly regular H, the decomposition induced by the roots has the same structure: A_{N-1} can be written as a direct sum of *root spaces* $\mathfrak{g}_\alpha = \{B \in A_{N-1} | \mathrm{ad}_H B = \alpha(H)B\}$:

$$A_{N-1} = \mathfrak{h} + \bigoplus_{\alpha \in \Delta} \mathfrak{g}_\alpha .$$

Each $\mathfrak{g}_\alpha$ is invariant for ad_H and satisfies $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] = \mathfrak{g}_{\alpha+\beta}$ where $\mathfrak{g}_{\alpha+\beta} = 0$ if $\alpha + \beta \notin \Delta$. Furthermore, calling K the Killing form, i.e., the bilinear form $K : A_{N-1} \times A_{N-1} \to \mathbb{R}$, $X, Y \mapsto \mathrm{trace}(\mathrm{ad}_X \mathrm{ad}_Y)$, the restriction of K to $\mathfrak{h}$ is nondegenerate and for each root $\alpha \in \Delta$ there exists a unique $H_\alpha \in \mathfrak{h}$ such that $\alpha(H) = K(H, H_\alpha)$, so that $\alpha(H_\alpha) = K(H_\alpha, H_\alpha) \neq 0$. If $\alpha \in \Delta$, so does $-\alpha$ and for $X \in \mathfrak{g}_\alpha$ and $Y \in \mathfrak{g}_{-\alpha}$ $[X, Y] = K(X, Y)H_\alpha$. Therefore, by normalizing, we can choose *root vectors* $E_\alpha \in \mathfrak{g}_\alpha$ such that

$$[H, E_\alpha] = \alpha(H)E_\alpha \quad \text{for } H \in \mathfrak{h},$$

$$[E_\alpha, E_{-\alpha}] = H_\alpha ,$$

$$[E_\alpha, E_\beta] = \begin{cases} 0 & \text{if } \alpha + \beta \notin \Delta \\ N_{\alpha\beta} E_{\alpha+\beta} & \text{if } \alpha + \beta \in \Delta, \end{cases} \tag{1}$$

where $N_{\alpha\beta}$ are real constants and $N_{\alpha\beta} = -N_{(-\alpha)(-\beta)}$ From (1), one obtains a *Weyl basis* for A_{N-1}:

$$\{H_\alpha, \alpha \in \Phi\} \cup \{E_\alpha, \alpha \in \Delta\}. \tag{2}$$

Since $\{\mathrm{ad}_H \mid H \in \mathfrak{h}\}$ is a commuting family of semisimple operators, there is a basis of A_{N-1} in which these operators are simultaneously diagonalizable. Fix $\overline{H} \in \mathfrak{h}$ to be one such $N \times N$ diagonal traceless matrices, $\overline{H} = \mathrm{diag}(\lambda_1, \ldots, \lambda_N)$ such that $\Sigma_{i=1}^N \lambda_i = 0$ where the λ_i are assumed to be ordered: $\lambda_1 > \ldots > \lambda_N$. Let E_{ij} be the matrix with 1 in the (ij) slot and 0 elsewhere. Since $\mathrm{ad}_{\overline{H}} E_{ij} = (\lambda_i - \lambda_j)E_{ij}$, the E_{ij} are the root vectors and the roots are the functionals α_{ij} such that

$\alpha_{ij}(\overline{H})=\lambda_i-\lambda_j$. The sum $\alpha_{ij}+\alpha_{kl}$ is a root if and only if $j=k$ or $i=l$ (if both, then it is the zero root). In fact, from $E_{ij}E_{kl}=\delta_{jk}E_{il}$ where δ_{ij} is the Kroneker delta, $[E_{ij},E_{kl}]=\delta_{jk}E_{il}-\delta_{li}E_{kj}$, i.e.,

$$[E_{ij},E_{kl}]=\begin{cases}0 & \text{if } j\neq k \text{ and } i\neq l\\ E_{il} & \text{if } j=k\\ -E_{kj} & \text{if } i=l\\ E_{ii}-E_{jj} & \text{if } j=k \text{ and } i=l.\end{cases} \tag{3}$$

The roots α_{ij} are real and such that if α_{ij} is a root so is $-\alpha_{ij}$. $\overline{H}$ is a strongly regular element if $\alpha_{ij}\neq\alpha_{kl}$, for indexes i, j, k, l such that $(i,j)\neq(k,l)$, $i\neq j$ and $k\neq l$. Thus $\overline{H}$ is strongly regular if and only if $\lambda_i-\lambda_j\neq\lambda_k-\lambda_l$. The fundamental roots are α_{12}, $\alpha_{23},\ldots,\alpha_{N-1,N}$ and a basis of A_{N-1} corresponding to (2) is given by

$$\{H_i=E_{ii}-E_{i+1,i+1},i=1,\ldots,N-1\}\cup\{E_{ij},i,j=1,\ldots,N,i\neq j\} \tag{4}$$

$\mathfrak{su}(N)$ is the *compact real form* of A_{N-1} since it corresponds to a negative definite Killing form. The basis of $\mathfrak{su}(N)$ corresponding to (2) is

$$\{iH_\alpha,\alpha\in\Phi\}\cup\{X_\alpha=E_\alpha-E_{-\alpha},\alpha\in\Delta^+\}\cup\{Y_\alpha=i(E_\alpha+E_{-\alpha}),\alpha\in\Delta^+\} \tag{5}$$

or, after diagonalization of the Cartan subalgebra

$$\{iH_i,i=1,\ldots,N-1\}\cup\{X_{ij}=E_{ij}-E_{ji},\ 1\leqslant i<j\leqslant N\}\cup\{Y_{ij}=i(E_{ij}+E_{ji}),\ 1\leqslant i<j\leqslant N\}. \tag{6}$$

Indeed, this skew-Hermitian basis forms a real Lie algebra as all the structure constants are real:

$$\begin{aligned}
[X_{ij},X_{kl}]&=\delta_{jk}X_{il}+\delta_{il}X_{jk}+\delta_{jl}X_{ki}+\delta_{ik}X_{lj},\\
[Y_{ij},Y_{kl}]&=\delta_{jk}X_{li}+\delta_{il}X_{kj}+\delta_{jl}X_{ki}+\delta_{ik}X_{lj},\\
[X_{ij},Y_{kl}]&=\delta_{jk}Y_{il}-\delta_{il}Y_{kj}+\delta_{jl}Y_{ik}-\delta_{ik}Y_{lj},\\
[iH_i,X_{jk}]&=\delta_{ij}Y_{ik}-\delta_{ik}Y_{ji}-\delta_{i+1,j}Y_{i+1,k}+\delta_{k,i+1}Y_{j,i+1},\\
[iH_i,Y_{jk}]&=\delta_{ij}X_{ki}+\delta_{ik}X_{ji}+\delta_{i+1,j}X_{i+1,k}+\delta_{k,i+1}X_{i+1,j}.
\end{aligned} \tag{7}$$

The basis (5) corresponds to the direct sum, orthogonal with respect to the Killing form:

$$\mathfrak{su}(N)=\bigoplus_{\alpha\in\Phi}i\mathbb{R}H_\alpha\bigoplus_{\alpha\in\Delta^+}\mathbb{R}X_\alpha\bigoplus_{\alpha\in\Delta^+}\mathbb{R}Y_\alpha. \tag{8}$$

If A is in the Cartan subalgebra of $\mathfrak{su}(N)$, then $A=iH$ with $H\in\mathfrak{h}$. Since the values of the roots at H, $\alpha(H)$, are real, $\alpha(A)$ will be imaginary and, from (7),

$$\begin{aligned}
\mathrm{ad}_A X_\alpha&=\alpha(H)Y_\alpha,\\
\mathrm{ad}_A Y_\alpha&=-\alpha(H)X_\alpha,
\end{aligned} \tag{9}$$

thus the vector space $\mathfrak{f}_\alpha=\mathbb{R}X_\alpha+\mathbb{R}Y_\alpha$ is invariant for ad_A. Furthermore, the vector spaces corresponding to the fundamental roots are enough to generate all the α-strings and therefore

Lemma 1: $\{\oplus_{\alpha\in\Phi}\mathfrak{f}_\alpha\}_{L.A.}=\mathfrak{su}(N)$

Proof: Similar to (3), in the basis (6) we obtain [using (7)]:

$$[\mathfrak{f}_{ij},\mathfrak{f}_{kl}]=\begin{cases}\varnothing & \text{if } j\neq k \quad \text{and } i\neq l\\ \mathfrak{f}_{il} & \text{if } j=k\\ \mathfrak{f}_{kj} & \text{if } i=l\\ \in\mathfrak{h} & \text{if } j=k \quad \text{and } i=l.\end{cases} \tag{10}$$

Thus from $\{\oplus_{\alpha\in\Phi}\mathfrak{f}_\alpha\}$ it is possible to generate $\{\oplus_{\alpha\in\Delta^+}\mathfrak{f}_\alpha\}$. Moreover, $[X_{i,i+1},Y_{i,i+1}]=2iH_i$, $i=1,\ldots,N-1$, therefore also $i\mathfrak{h}$ is generated. ■

On the other hand, a proper subset of fundamental roots cannot generate $\mathfrak{su}(N)$.

Lemma 2: If $\Phi'\subsetneq\Phi$ *then* $\{\oplus_{\alpha\in\Phi'}\mathfrak{f}_\alpha\}_{L.A.}\subsetneq\mathfrak{su}(N)$.

Proof: Trivial since by its very definition a fundamental root cannot be written as a sum of other positive roots, therefore if $\overline{\alpha}$ is a missing fundamental root, $\nexists\ \alpha,\beta\in\Phi$ such that $[E_\alpha,E_\beta]=N_{\alpha,\beta}E_{\overline{\alpha}}$. Thus $X_{\overline{\alpha}}$ and $Y_{\overline{\alpha}}$ are not spanned by any bracket. ■

III. QUANTUM CONTROL SYSTEM

Consider a finite level quantum system described by a state $|\psi\rangle$ evolving according to the time-dependent Schrödinger equation

$$i\hbar|\dot{\psi}(t)\rangle=(\hat{H}_0+u(t)\hat{H}_1)|\psi(t)\rangle, \tag{11}$$

where the traceless Hermitian matrices $\hat{H}_0$ and $\hat{H}_1$ are, respectively, the internal (or free) Hamiltonian and the external Hamiltonian, the latter representing the interaction of the system with a single control field $u(t)$. In the N-level approximation, the state $|\psi\rangle$ is expanded with respect to a basis of N orthonormal eigenstates $|\varphi_i\rangle$: $|\psi\rangle=\Sigma_{i=1}^N c_i|\varphi_i\rangle$ where the c_i are complex coefficients that satisfy the normalization condition $\Sigma_{i=1}^N|c_i|^2=1$. If we write the initial condition of (11) as $|\psi_0\rangle=\Sigma_{i=1}^N c_{0i}|\varphi_i\rangle$, then also the vector $c=[c_1\cdots c_N]^T$ satisfies a differential equation similar to (11):

$$\begin{gathered}i\hbar\dot{c}(t)=(\tilde{H}_0+u(t)\tilde{H}_1)c(t),\\ c(0)=c_0,\end{gathered} \tag{12}$$

where now the traceless Hermitian matrix $\tilde{H}_0$ is diagonal. The real coefficients $\mathcal{E}_i$, $\mathcal{E}_1\leqslant\cdots\leqslant\mathcal{E}_N$, appearing along the diagonal of $\tilde{H}_0$ are eigenvalues, $\tilde{H}_0|\varphi_i\rangle=\mathcal{E}_i|\varphi_i\rangle$, and represent the energy levels of the system. If $\mathcal{E}_i=\mathcal{E}_j$ for some $i\neq j$, then the system is said to be *degenerate*. If, instead, some of the levels are equispaced, $\mathcal{E}_i-\mathcal{E}_j=\mathcal{E}_k-\mathcal{E}_l$ for $(i,j)\neq(k,l)$, $i\neq j$, $k\neq l$, then the system is said to have *degenerate transitions* (or resonances). The solution of (12) is $c(t)=X(t)c(0)$ with the unitary matrix $X(t)$ representing the time evolution operator. If we use atomic units ($\hbar=1$), then instead of (12) we can study the right invariant bilinear control system evolving on the Lie group SU(N) and characterized by the skew-Hermitian vector fields $A=-i\tilde{H}_0$ and $B=-i\tilde{H}_1$:

$$\begin{gathered}\dot{X}(t)=(A+u(t)B)X(t),\quad X(t)\in SU(N),\quad A,B\in\mathfrak{su}(N),\\ X(0)=I.\end{gathered} \tag{13}$$

The system (13) is said to be (globally) *controllable* if the reachable set

$$\mathcal{R}_{\{A,B\}}=\{\overline{X}\in SU(N)|\ \text{there exists an admissible input } u(\cdot) \text{ such that the integral curve of (13) satisfies } X(0)=I,\ X(t)=\overline{X} \text{ for some } t\geqslant 0\}$$

is all of the Lie group: $\mathcal{R}_{\{A,B\}}=\mathrm{SU}(N)$. Given (any) $A,B\in\mathfrak{su}(N)$, call $\{A,B\}_{L.A.}$ the Lie algebra generated by A and B with respect to the Lie bracket. The literature on the subject of quantum control, see D'Alessandro (2001), Ramakrishna *et al.* (1995), Albertini and D'Alessandro (2001), has relied essentially on the condition of the following Theorem [originally due to Jurdjevic and Sussmann (1972)]:

Theorem 1: *The system (13) is controllable if and only if* $\{A,B\}_{L.A.}=\mathfrak{su}(N)$.

Theorem 1 is a consequence of the following Lemma, which affirms that subsemigroups of compact groups are always subgroups:

Lemma 3: [Lemma 1, Chap. 6 of Jurdjevic (1996)]: *For the compact semisimple Lie group* $\mathrm{SU}(N)$,

$$\mathrm{cl}(\exp(tA,t<0))\subset\mathrm{cl}(\exp(tA,t\geqslant 0)),\quad \forall A\in\mathfrak{su}(N),$$

where $\exp:\mathfrak{su}(N)\rightarrow\mathrm{SU}(N)$ *is the Lie group exponential map (and* cl *means closure*).

Consequently, the drift vector field A of (13) is not hampering controllability on the large and thus Theorem 1 follows. Since the controllability in this case is obtained for ''large times'' the situation would be different if ''small time local controllability'' were of interest, see D'Alessandro (2001). Furthermore, the semisimple character of $\mathfrak{su}(N)$ implies the following:

Lemma 4: [Theorem 12, Chap. 6 of Jurdjevic (1996)]: *The set of pairs* $A,B\in\mathfrak{su}(N)$ *such that* $\{A,B\}_{L.A.}=\mathfrak{su}(N)$ *is open and dense in* $\mathfrak{su}(N)$.

Putting together Theorem 1 and Lemma 4 then we have:

Corollary 1: The system (13) is controllable for almost all pairs $A,B\in\mathfrak{su}(N)$.

In spite of the above mentioned generic result, there is still some interest in the controllability problem, especially

(1) characterizing the algebraic set in which controllability may fail,

(2) determining alternative procedures for testing controllability, other than exhaustive computation of Lie brackets,

(3) finding sufficient conditions for controllability based on the *a priori* knowledge of the vector fields A and B.

This paper is dedicated to the last two items of the list.

Roots and graphs. B is expressed in terms of the components of the $\mathfrak{su}(N)$ basis (5) as

$$B=B_0+\sum_{\alpha\in\Gamma^+\subseteq\Delta^+}(b_\alpha^{\Re}X_\alpha+b_\alpha^{\Im}Y_\alpha),\tag{14}$$

where $B_0\in i\mathfrak{h}$, $b_\alpha^{\Re}$ and $b_\alpha^{\Im}$ are real and $\Gamma^+\subseteq\Delta^+$ is the subset of roots ''touched'' by B.

In this case, it is possible to use the connectivity properties of the graph of B to draw conclusions about controllability in the same spirit as is done in Gauthier and Bonnard (1982), Silva Leite and Crouch (1988) for *normal* (or *split*) *real forms* and, more recently, in Turinici and Rabitz (2001) for the same quantum control problem. Consider the *graph* $\mathcal{G}_B$ associated with a square matrix $B=[b_{ij}]$, i.e., the pair $\mathcal{G}_B=(\mathcal{N}_B,\mathcal{C}_B)$ where $\mathcal{N}_B$ represents a set of N ordered nodes $\mathcal{N}_B=\{1,\ldots,n\}$ and $\mathcal{C}_B$ the set of oriented arcs joining the nodes: $\mathcal{C}_B=\{(i,j)|b_{ij}\neq 0\}$. The graph $\mathcal{G}_B$ is said to be *strongly connected* if for all pairs of nodes in $\mathcal{N}_B$ there exists an oriented path in $\mathcal{C}_B$ connecting them. A matrix P is said to be a permutation matrix if it has elements that are 0 or 1, see Varga (1962). $\mathcal{G}_B$ is strongly connected if and only if B is permutation-irreducible (P-irreducible), i.e., there exists no permutation matrix P such that

$$P^{-1}BP=\begin{bmatrix}B_1 & *\\ 0 & B_2\end{bmatrix}.$$

A square matrix is P-irreducible if and only if its graph does not contain any strongly disconnected subgraph. As long as we consider matrices B that are Hermitian or skew-Hermitian, the adjective ''strong'' (referring to the path being oriented) is irrelevant since $b_{ij}\neq 0$ if and only if $b_{ji}\neq 0$.

Remark 1: For B Hermitian or skew-Hermitian, $\mathcal{G}_B$ *connected*$\Leftrightarrow\mathcal{G}_B$ *strongly connected.*

This is not anymore true if B belongs to a noncompact real form. Working with the complexification A_{N-1} and considering the graphs associated with the elements E_α, $\alpha\in\Delta^+$, of the Weyl basis (4), a unique $\mathcal{G}_{E_\alpha}$ is associated with each positive root. $\mathcal{G}_{E_\alpha}$ are called *elementary root graphs*. If $b_\alpha=b_\alpha^{\Re}+ib_\alpha^{\Im}$, rewriting B as

$$B=B_0+B_1=B_0+\sum_{\alpha\in\Gamma^+}(b_\alpha E_\alpha-b_\alpha^* E_{-\alpha}), \tag{15}$$

where the asterisk is complex conjugate, then the (positive) *root graph* of B is $\mathcal{G}_B^+=\cup_{\alpha\in\Gamma^+}\mathcal{G}_{E_\alpha}$ and $\mathcal{G}_{B-B_0}$ is "twice" $\mathcal{G}_B^+$.

For the quantum system on $\mathfrak{su}(N)$, the roots admit the interpretation of transitions between energy levels of the system. According to our definitions, $\lambda_i=-\mathcal{E}_i$ and the roots are $\alpha_{ij}=\mathcal{E}_j-\mathcal{E}_i$ $(i<j\Rightarrow\alpha_{ij}\geqslant 0)$.

The concepts of regular and strongly regular roots correspond to those of degenerate system and of system with degenerate transitions in the following way:

(i) if a system is degenerate then it has nonregular roots;
(ii) if a system is nondegenerate but has degenerate transitions then it has regular but not all strongly regular roots;
(iii) if a system is nondegenerate and has no degenerate transitions then it has only strongly regular roots.

In the basis (6), $b_\alpha=b_{ij}$, $1\leqslant i<j\leqslant N$ and B_0 is simply the diagonal

$$B_0=\sum_{k=1}^{N} b_{kk}E_{kk}=\sum_{k=1}^{N-1}\left(\sum_{j=1}^{k} ib_{jj}\right)(iH_K) \tag{16}$$

since $B_0\in\mathfrak{su}(N)$ has to be traceless. The b_{jj} (which must be purely imaginary) correspond to loops on $\mathcal{G}_B$, i.e., to arcs beginning and ending on the same node. Thus they are irrelevant for the connectivity property. In the basis (6), A and B are

$$A=\sum_{k=1}^{N-1}\left(\sum_{j=1}^{k}\mathcal{E}_j\right)(iH_k), \tag{17}$$

$$B=B_0+\sum_{(i,j)\in\mathcal{C}_B^+}(b_{ij}^{\Re}X_{ij}+b_{ij}^{\Im}Y_{ij}). \tag{18}$$

The following lemma is the adaptation to our situation of Theorem 2 and Corollary 2 of Silva Leite and Crouch (1988).

Lemma 5: B is P-irreducible $\Leftrightarrow$ $\{\mathfrak{f}_\alpha,\alpha\in\Gamma^+\}_{L.A.}=\mathfrak{su}(N)$

Proof: If B is P-irreducible, then $B-B_0$ is P-irreducible and $\mathcal{G}_B^+$ is connected. Therefore, every pair of nodes (i,j), $i\neq j$, can be joined by a path made up of elementary root graphs belonging to $\mathcal{G}_B^+$, or, in terms of roots, each positive root of A_{N-1}, $\alpha_{ij}\in\Delta^+$, can be written as a sum of the roots of Γ^+: $\alpha_{ij}=\Sigma_{(k,l)\in\mathcal{C}_B^+}\lambda_{k,l}\alpha_{k,l}$ for positive rationals λ_{kl}. The situation is specular for negative roots. From the commutation relations (10), for some vector spaces $\mathfrak{f}_{k_i,l_i}$ of indexes $(k_i,l_i)\in\mathcal{C}_B^+$ we have

$$[\mathfrak{f}_{k_1,l_1},[\mathfrak{f}_{k_2,l_2},\ldots[\mathfrak{f}_{k_{m-1},l_{m-1}},\mathfrak{f}_{k_m,l_m}]\ldots]=\mathfrak{f}_{i,j}. \tag{19}$$

Then also the Cartan subalgebra can be generated, see (7), and the result follows. On the other direction, $\{\mathfrak{f}_\alpha,\alpha\in\Gamma^+\}_{L.A.}=\mathfrak{su}(N)$ means that repeated brackets like (19) span all the subspaces

$\mathfrak{f}_{ij}$, $1 \leqslant i < j \leqslant N$, and therefore touch all the roots $\alpha_{ij} \in \Delta$. But this is equivalent to $\mathcal{G}_B$ connected. ■

Lemma 1 and Lemma 2 tell us that the condition of Lemma 5 is "minimally" satisfied by a set of fundamental roots, although due to the nonuniqueness of the selection of the fundamental roots, not all the $\alpha \in \Phi$ have to be in Γ^+ for $\mathcal{G}_B$ to be connected.

Corollary 2: If $\Phi \subseteq \Gamma^+$ then B is P-irreducible.

IV. SUFFICIENT CONDITIONS FOR CONTROLLABILITY IN THE GENERIC CASE

Considerations similar to those used in the controllability analysis of normal real forms of classical Lie algebras [see Jurdjevic and Kupka (1981), Gauthier and Bonnard (1982), El Assoudi *et al.* (1995), Silva Leite and Crouch (1988)] can be employed for our compact real form as well. In the case of free Hamiltonian of diagonal type, the connectivity property of the graph of the forced term B can replace the Lie algebraic rank condition, see Gauthier (1982).

Lemma 6: If A is diagonal, a necessary condition for controllability is that $\mathcal{G}_B$ connected.

Proof: If B is P-reducible, then there exist nontrivial invariant subspaces of $\mathfrak{su}(N)$ that are simultaneously A-invariant and B-invariant. Thus the system cannot be controllable. ■

In the case of $\mathcal{G}_B$ disconnected, the quantum system is decomposable into noninteracting subsystems. In Turinici *et al.* (2001) it is required that $\tilde{H}_1$ is off-diagonal. The interpretation in terms of root decomposition offered here shows that this assumption is irrelevant for controllability: the diagonal terms of $\tilde{H}_1$ belong to the Cartan subalgebra and as such they commute with A.

The equivalence between $\{A,B\}_{L.A.} = \mathfrak{su}(N)$ and $\mathcal{G}_B$ connected is not exact: while $\mathcal{G}_B$ connected is a necessary condition for controllability, alone it is not a sufficient condition, but requires extra assumptions to be made on the diagonal matrix A. The simplest case corresponds to the drift term A being strongly regular and corresponds to all nondegenerate transitions.

Theorem 2: *Given A and B as in (17) and (18), assume that $\mathcal{G}_B$ is connected. If A is strongly regular, then the system (13) is controllable.*

Proof: Since ad_A is invariant on each $\mathfrak{f}_\alpha$, $\alpha \in \Delta^+$, the level one bracket $C = \mathrm{ad}_A \Sigma_{\alpha \in \Gamma^+}(b_\alpha^{\Re} X_\alpha + b_\alpha^{\Im} Y_\alpha)$ allows one to reach $\oplus_{\alpha \in \Gamma^+} \mathfrak{f}_\alpha$ as $b_\alpha = b_\alpha^{\Re} + i b_\alpha^{\Im} \neq 0$ for all $\alpha \in \Gamma^+$. Using an argument similar to the proof of Theorem 3 in Silva Leite and Crouch (1988), we compute as many "A-brackets" (like $[A,B]$, $[A,[A,B]]$, etc.) as the number of roots in Γ^+, say $2m$ (with $m \geqslant N-1$). For simplicity of bookkeeping, it is convenient to number roots α and coefficients b_α cardinally from 1 to $2m$: $\{\alpha_1,\ldots,\alpha_{2m}\} = \Gamma^+$, $b_\alpha = b_i$, $i = 1,\ldots,2m$ and $E_\alpha = E_i$, $i = 1,\ldots,2m$,

$$\begin{bmatrix} \mathrm{ad}_A B \\ \mathrm{ad}_A^2 B \\ \vdots \\ \mathrm{ad}_A^{2m} B \end{bmatrix} = \begin{bmatrix} \alpha_1 b_1 & \alpha_2 b_2 & \cdots & \alpha_m b_m & \alpha_1 b_1^* & \cdots & \alpha_m b_m^* \\ \alpha_1^2 b_1 & \alpha_2^2 b_2 & \cdots & \alpha_m^2 b_m & -\alpha_1^2 b_1^* & \cdots & -\alpha_m^2 b_m^* \\ \alpha_1^3 b_1 & \alpha_2^3 b_2 & \cdots & \alpha_m^3 b_m & \alpha_1^3 b_1^* & \cdots & \alpha_m^3 b_m^* \\ & & & \vdots & & & \\ & & & \vdots & & & \\ \alpha_1^{2m} b_1 & \alpha_2^{2m} b_2 & \cdots & \alpha_m^{2m} b_m & -\alpha_1^{2m} b_1^* & \cdots & -\alpha_m^{2m} b_m^* \end{bmatrix} \begin{bmatrix} E_1 \\ E_2 \\ \vdots \\ E_m \\ E_{-1} \\ \vdots \\ E_{-m} \end{bmatrix}$$

$$= M \begin{bmatrix} E_1 \\ E_2 \\ \vdots \\ E_m \\ E_{-1} \\ \vdots \\ E_{-m} \end{bmatrix}. \tag{20}$$

M can be written as

$$M=S_1\left[\begin{array}{ccc|ccc} \alpha_1 & \cdots & \alpha_m & \alpha_1 & \cdots & \alpha_m \\ \alpha_1^3 & \cdots & \alpha_m^3 & \alpha_1^3 & \cdots & \alpha_m^3 \\ \alpha_1^{2m-1} & \cdots & \alpha_m^{2m-1} & \alpha_1^{2m-1} & \cdots & \alpha_m^{2m-1} \\ \hline \alpha_1^2 & \cdots & \alpha_m^2 & 0 & \cdots & 0 \\ \alpha_1^4 & \cdots & \alpha_m^4 & 0 & \cdots & 0 \\ \alpha_1^{2m} & \cdots & \alpha_m^{2m} & 0 & \cdots & 0 \end{array}\right] S_2\left[\begin{array}{ccc|ccc} b_1 & & & & & \\ & \ddots & & & & \\ & & b_m & & & \\ \hline & & & b_1^* & & \\ & & & & \ddots & \\ & & & & & b_m^* \end{array}\right]$$

with

$$S_1=\left[\begin{array}{ccc|ccc} 1 & & & -1 & & \\ & \ddots & & & \ddots & \\ & & 1 & & & -1 \\ \hline & & & 2 & & \\ & & & & \ddots & \\ & & & & & 2 \end{array}\right],\quad S_2=\left[\begin{array}{cccc|ccc} 1 & 0 & & & 0 & & \\ 0 & 0 & & & 1 & 0 & \\ 0 & 1 & 0 & & 0 & 0 & \\ 0 & 0 & 0 & & 0 & 1 & \\ 0 & 0 & 1 & & 0 & 0 & \\ & & & \ddots & & & \ddots \\ & & & 1 & & & 0 \\ & & & 0 & & & 1 \end{array}\right].$$

Straightforward computations give the determinant of M:

$$\det M=(-1)^{m+1}2^m\prod_{i=1}^{m}\alpha_i^m\prod_{1\leqslant i<j\leqslant m}(\alpha_j^2-\alpha_i^2)^2\prod_{i=1}^{m}|b_i|^2\neq 0.$$

Therefore $\{A,B\}_{L.A.}\supseteq\{\mathfrak{f}_\alpha,\alpha\in\Gamma^+\}_{L.A.}$, and controllability follows from P-irreducibility of B (Lemma 5). ■

A weaker property than strong regularity is B-strong regularity, introduced in Silva Leite and Crouch (1988).

Definition 3: Given B as in (14), *A is said to be B*-strongly regular *if the elements* $\alpha(\tilde{H}_0)$, $\alpha\in\Gamma^+$, *are nonzero and distinct.*

Unlike strong regularity, which requires all roots of Δ to be non-null and distinct when computed in A, B-strong regularity requires the root decomposition determined by A to be strongly regular only along the roots Γ^+ entering into the decomposition of B: $\alpha_{ij}(\tilde{H}_0)=\mathcal{E}_j-\mathcal{E}_i\neq 0$ if $b_{ij}\neq 0$. Obviously, A strongly regular means A is B-strongly regular for all B.

Theorem 2 is a particular case of the following:

Theorem 3: *Given A and B as in (17) and (18), assume that* $\mathcal{G}_B$ *is connected. If A is B-strongly regular, then the system (13) is controllable.*

Proof: The only difference with Theorem 2 is that ad_A is invariant only on $\mathfrak{f}_\alpha$, $\alpha\in\Gamma^+$ (rather than Δ^+). However, Lemma 5 is true regardless of this assumption (as it is concerned with B alone) and, using the same construction of the proof of Theorem 2, $\det M\neq 0$ still holds true. ■

An alternative extension of Theorem 2 is mentioned in Turinici and Rabitz (2001). If Π_A^+ is the set of positive roots $\alpha(\tilde{H}_0)$ that are strongly regular for A, call $\Theta_A^+=\Gamma^+\cap\Pi_A^+$ the subset of positive strongly regular roots of Γ^+ when computed in A and Ω_A^+ the corresponding complementary set in Γ^+ (i.e., the set of nonstrongly regular roots of Γ^+): $\Omega_A^+=\Gamma^+\backslash\Theta_A^+$. So B splits into $B=B_r+B_s$ with $B_r=B_0+\Sigma_{\alpha\in\Theta_A^+}(b_\alpha^{\Re}X_\alpha+b_\alpha^{\Im}Y_\alpha)$, the intersection of B with the strongly regular roots, and $B_s=\Sigma_{\alpha\in\Omega_A^+}(b_\alpha^{\Re}X_\alpha+b_\alpha^{\Im}Y_\alpha)$.

Theorem 4: *Given A and B as in* (17) *and* (18), *assume that* $\mathcal{G}_B$ *is connected. If* $\mathcal{G}_{B_r}$ *is connected, then the system* (13) *is controllable.*

Proof: The pair A, B_r is such that A is B_r-strongly regular. If $\mathcal{G}_{B_r}$ is connected, Theorem 3 applies to the pair (A,B_r). We can use an argument similar to the proof of Theorem 2. If $m_r \geqslant N$ are the strongly regular roots and m_s the degenerate ones, instead of the ordering of the root vector used in (20) $E=[E_1\cdots E_m E_{-1}\cdots E_{-m}]^T$ we can use a splitting corresponding to strongly regular and degenerate roots $E=[E^{rt}E^{sT}]^T=[E^r_1\cdots E^r_{m_r}E^r_{-1}\cdots E^r_{-m_r}E^s_1\cdots E^s_{m_s}E^s_{-1}\cdots E^s_{-m_s}]^T$. Then

$$\begin{bmatrix} \mathrm{ad}_A B \\ \mathrm{ad}_A^2 B \\ \vdots \\ \mathrm{ad}_A^{2m_r} B \end{bmatrix} = \begin{bmatrix} \mathrm{ad}_A B_r \\ \mathrm{ad}_A^2 B_r \\ \vdots \\ \mathrm{ad}_A^{2m_r} B_r \end{bmatrix} + \begin{bmatrix} \mathrm{ad}_A B_s \\ \mathrm{ad}_A^2 B_s \\ \vdots \\ \mathrm{ad}_A^{2m_r} B_s \end{bmatrix} = [M_r \;\; 0]E + [0 \;\; M_s]E = M_r E^r + M_s E^s,$$

where the $2m_r\times 2m_r$ matrix M_r is nonsingular and M_s is a rectangular matrix of dimensions $2m_r\times 2m_s$. Since $\det M_r \neq 0$, we have

$$E^r = M_r^{-1}\left(\begin{bmatrix} \mathrm{ad}_A B \\ \vdots \\ \mathrm{ad}_A^{2m_r} B \end{bmatrix} - M_s E^s \right),$$

i.e., the Lie algebra generated by A and B contains a complete set of generators. Thus the statement again follows from Lemma 5 and the B_s part of B is not influencing the controllability property. ■

For controllability, it is sufficient that Θ_A^+ contains the fundamental roots, as in this case $\mathcal{G}_{B_r}$ is connected by Corollary 2.

Corollary 3: If $\Phi\subseteq\Theta_A^+$, *then the system (13) is controllable*.

Notice that the condition of Theorem 2 is the one traditionally used in the literature to show that a generic pair of vector fields on compact semisimple Lie algebras are generating, see Kuranishi (1951), Boothby (1975), Bonnard *et al.* (1980). For this purpose, given A strongly regular, B is constructed such that ad_A is cyclic on $\oplus_{\alpha\in\Delta^+}\mathfrak{f}_\alpha$, for example by having $b_\alpha\neq 0 \;\; \forall\alpha\in\Delta^+$. This means that $\oplus_{\alpha\in\Delta^+}\mathfrak{f}_\alpha$ can be spanned by ''A-brackets'' and thus all $\mathfrak{su}(N)$ is generated by adding the elements of the Cartan subalgebra [bracketing according to the last row of (10)]. However, here the method is not directly applicable because some of the b_{ij} elements of B are allowed to be zero. In this case, from $\oplus_{\alpha\in\Gamma^+}\mathfrak{f}_\alpha$, the missing subspaces must be reached by means of ''B-brackets'' $[C,B]$, $[[C,B],B]$, etc., and then their span completed by single ''A-brackets'' $[A,[C,B]]$, $[A,[[C,B],B]]$, etc.

V. SUFFICIENT CONDITIONS FOR CONTROLLABILITY IN A FEW SINGULAR CASES

The use of ''B-brackets'' is the *leitmotif* of all other sufficient conditions which are based on properties weaker than the strong regularity and B-strong regularity of the diagonal vector field A. These conditions belong to the first two cases of the classification of Sec. III and, from Corollary 3, they correspond to at least a pair of fundamental roots being equal. If new diagonal terms can be provided to compensate for the degenerate transitions, then controllability can be recovered. From (15), writing C as $C=\Sigma_{\Gamma^+}\alpha(A)(b_\alpha E_\alpha + b_\alpha^* E_{-\alpha})$, the level two bracket $[C,B]$ is

$$
\begin{aligned}
D=[C,B]&=[C,B_0]+[C,B_1]\\
&=\left[\sum_{\Gamma^+}\alpha(A)b_\alpha E_\alpha,B_0\right]+\left[\sum_{\Gamma^+}\alpha(A)b_\alpha^* E_{-\alpha},B_0\right]+\left[\sum_{\Gamma^+}\alpha(A)b_\alpha E_\alpha,\sum_{\Gamma^+}b_\alpha E_\alpha\right]\\
&\quad+\left[\sum_{\Gamma^+}\alpha(A)b_\alpha^* E_{-\alpha},\sum_{\Gamma^+}b_\alpha E_\alpha\right]-\left[\sum_{\Gamma^+}\alpha(A)b_\alpha E_\alpha,\sum_{\Gamma^+}b_\alpha^* E_{-\alpha}\right]\\
&\quad-\left[\sum_{\Gamma^+}\alpha(A)b_\alpha^* E_{-\alpha},\sum_{\Gamma^+}b_\alpha^* E_{-\alpha}\right].
\end{aligned}
\tag{21}
$$

If B_0 is non-null and linearly independent from A, it constitutes the simplest candidate to provide the missing fundamental roots. From (16), the fundamental roots at B_0, $\alpha(B_0)$, are equal to $\beta_{i,i+1}=b_{ii}-b_{i+1,i+1}$ when expressed in the basis (6). Restricting to the case (ii) of Sec. III A, i.e., assuming that the system is nondegenerate but with possibly degenerate transitions, equivalent versions of Theorems 2 and 3 hold for B_0 and C instead of A and B.

Theorem 5: *If A is regular and $\mathcal{G}_B$ connected, then either of the following conditions is sufficient for controllability of (13):*
(1) B_0 is strongly regular,
(2) B_0 is C-strongly regular.

Proof: A regular means $\mathcal{E}_i\neq\mathcal{E}_j$ for $i\neq j$, i.e., $\alpha_{ij}\neq 0\ \forall 1\leqslant i<j\leqslant N$. Then in case of $\mathcal{G}_B$ connected also $\mathcal{G}_C$ is connected. Therefore, B_0 strongly regular or C-strongly regular satisfy, respectively, Theorems 2 and 3 for the pair (B_0,C). Since $B=B_0+B_1$ (not B_0) is the available vector field, in order to complete the proof one has to verify that the (B_1,C) pair is not spoiling the maximal nonintegrability property of (B_0,C), i.e., $A\oplus\{B_0,C\}_{L.A.}=A\oplus\{B,C\}_{L.A.}=\mathfrak{su}(N)$ (neglecting the trivial case of A and B_0 linearly dependent). But this follows from Eq. (21): while $[B_0,C]\in\{\mathfrak{f}_\alpha,\alpha\in\Gamma^+\}$, whenever $\Gamma^+\subsetneq\Delta^+$, $[B_1,C]\in\{\mathfrak{f}_\alpha,\alpha\in\tilde{\Gamma}^+\supseteq\Gamma^+\}$ because components along $E_{\pm\alpha\pm\beta}$, $\alpha,\beta\in\Gamma^+$ are produced by the last four terms of (21) [see (1)]. If $\tilde{\Gamma}^+\subsetneq\Gamma^+$, then $[B_0,C]$ and $[B_1,C]$ are automatically linearly independent. If, instead, $\tilde{\Gamma}^+=\Gamma^+$, then from (21) it has to be $\alpha+\beta\in\Gamma^+$ for all roots $\alpha,\beta\in\Gamma^+$ such that $\alpha+\beta$ is a root and $\alpha b_\alpha^* E_{-\alpha}b_\beta E_\beta-\beta b_\beta E_\beta b_\alpha^* E_{-\alpha}=0$ for all $\alpha,\beta\in\Gamma^+$ such that $\alpha-\beta\in\Delta$, $\alpha-\beta\notin\Gamma$. But the only case of roots $\alpha,\beta\in\Gamma^+$ with $\alpha-\beta\in\Delta$ and satisfying $(\alpha-\beta)b_\alpha^* b_\beta[E_{-\alpha},E_\beta]=0$ is the case of all equal (and non-null since A regular) roots. Linear independence of $[B_0,C]$ and $[B_1,C]$ then follows from the fact that $[B_1,C]$ has terms on the diagonal which are certainly non-null for the case of all equal roots [they are computed in detail in the following, see Eqs. (22) and (23)], while $[B_0,C]$ is off-diagonal. Thus, in both cases, the basis elements obtained from $[B_0,C]$, $[B_0,[B_0,C]]$, etc., are not canceled by the remaining parts of the brackets $[B_1,C]$, $[B_0,[B_1,C]]+[B_1,[B_0,C]]+[B_1,[B_1,C]]$, etc. ■

One can think of weakening further the hypothesis of Theorem 5 by combining together strongly regular pieces from both A and B_0. To this end, analogously to what was done for the diagonal matrix A, call Θ_B^+ the set of positive strongly regular roots $\alpha(B_0)$ of Γ^+ and C_r the corresponding part of C: $C_r=\Sigma_{\Theta_B^+}\alpha(A)(b_\alpha E_\alpha+b_\alpha^* E_{-\alpha})$.

Theorem 6: *Assume A regular and $\mathcal{G}_B$ connected. If $\mathcal{G}_{B_r}\cup\mathcal{G}_{C_r}$ is connected then the system (13) is controllable.*

Proof: In this case it is necessary to use both "A-brackets" for the pair $[A,B]$ and "B-brackets" for $[B_0,C]$. Since "A-brackets" and "B-brackets" yield independent new generators, the proof follows by combining the arguments used in proving Theorem 4 and Theorem 5. ■

As last, we treat the case of Cartan subalgebras from level two brackets of A and B. Since C is off-diagonal, the only useful bracket in this respect is $[C,B]$. By looking at the commutators for the Weyl basis (1), new diagonal terms appear only on the fourth and fifth terms of the expression (21) for D. By isolating them

$$D_0=-2\sum_{\Gamma^+}\alpha(A)|b_\alpha|^2[E_\alpha,E_{-\alpha}]=-2\sum_{\Gamma^+}\alpha(A)|b_\alpha|^2H_\alpha$$

or, in terms of the basis (6)

$$D_0=-2\sum_{(i,j)\in\mathcal{C}_B^+}\alpha_{ij}(A)|b_{ij}|^2(H_i+H_{i+1}+\cdots+H_{j-1}).$$

Thus $D=[C,B]=D_0+D_1$ with D_0 diagonal and D_1 off-diagonal. It is convenient to sum over Δ^+ rather than Γ^+ (if $(i,j)\notin\mathcal{C}_B^+$ then $b_{ij}=0$):

$$\begin{aligned}D_0&=-2\sum_{i=1}^{N-1}\sum_{j=i+1}^{N}\alpha_{ij}(A)|b_{ij}|^2(E_{ii}-E_{jj})\\&=2\sum_{k=1}^{N}\left(\sum_{i=1}^{k-1}\alpha_{ik}|b_{ik}|^2-\sum_{i=k+1}^{N}\alpha_{ki}|b_{ki}|^2\right)E_{kk}\\&=\sum_{k=1}^{N}d_kE_{kk},\end{aligned}\tag{22}$$

where it is intended that $\Sigma_{i=1}^{k-1}\alpha_{ik}|b_{ik}|^2=0$ if $k=1$ and $\Sigma_{i=k+1}^{N}\alpha_{ki}|b_{ki}|^2=0$ if $k=N$. The diagonal elements d_k of D_0 can be expressed in terms of the energy levels $\mathcal{E}_k$ of the quantum system (11) as

$$\begin{aligned}d_k=&2\mathcal{E}_k(|b_{1,k}|^2+\cdots+|b_{k-1,k}|^2+|b_{k,k+1}|^2+\cdots+|b_{k,N}|^2)\\&-2(\mathcal{E}_1|b_{1,k}|^2+\cdots+\mathcal{E}_{k-1}|b_{k-1,k}|^2+\mathcal{E}_{k+1}|b_{k,k+1}|^2+\cdots+\mathcal{E}_N|b_{k,N}|^2)\end{aligned}\tag{23}$$

from which it is straightforward to check that $\Sigma_{k=1}^{N}d_k=0$ (thus that $D_0\in\mathfrak{su}(N)$).

Now we can reformulated Theorem 5 with D_0 replacing B_0.

Theorem 7: *If A is regular and $\mathcal{G}_B$ connected, then any of the following conditions is sufficient for controllability of (13):*
(1) D_0 is strongly regular,
(2) D_0 is B-strongly regular,
(3) D_0 is C-strongly regular.

Proof: The proof is completely analogous to that of Theorem 5, with the extra simplification that now D_1, when $\neq 0$, is linearly independent from both B and C regardless of the regularity of the roots computed in A and B, respectively. ■

The practical situations in which Theorems 5–7 apply are when the system has resonant modes [which, again, corresponds to the case (ii) in the classification of Sec. III]. The extreme case is when $\mathcal{E}_{i+1}-\mathcal{E}_i=\text{const}\ \forall\ i=1,\ldots,n-1$ (nondegenerate system with all equally spaced energy levels).

Often a case-by-case analysis provides less strict sufficient conditions than those discussed in this paper. As an example, consider the completely harmonic system mentioned previously. If $b_{i,j}=0$ for $j\neq i\pm1$ (dipole approximation) and $b_{i,i\pm1}=b_{i,i\pm1}^{\mathfrak{I}}$, we are exactly in the situation described in Fu *et al.* (2001)—Sec. 2.3 (since $\Gamma^+=\Phi^+$, such pair of vector fields A and B is minimal among the generating pairs, in the sense of Lemma 2, which implies that methods like Theorem 4 are inapplicable). In this case, all the fundamental roots are equal, $\alpha_{i,\,i+1}=\mu, i=1,\ldots,N-1$, $B=\Sigma_{i=1}^{N-1}b_{i,i+1}Y_{i,i+1}$ $(B_0=0)$ and $C=\mu\Sigma_{i=1}^{N-1}b_{i,i+1}X_{i,i+1}$. Thus $D=-2\mu\Sigma_{i=1}^{N-1}b_{i,i+1}^2(iH_i)$ and the "new fundamental roots" are $-2\mu(b_{i,\,i+1}^2-b_{i+1,\,i+2}^2)$, which are not necessarily distinct for $i=1,\ldots,N-1$. Thus Theorem 7 needs not be verified. For the same system, Theorem 3 of Fu *et al.* (2001) provides an alternative sufficient condition that is

weaker than any of the items of Theorem 7, obtained by making use of the special structure of the system to compute a full set of generating brackets explicitly. The drawback of this method is that whenever the structure of B or the values of the fundamental roots are modified, the algorithm needs to be redesigned.

(Received 8 October 2001; accepted for publication 31 January 2002)

States which minimize the Schrödinger–Robertson uncertainty relation are constructed as eigenstates of an operator which is an element of the $h(1)\oplus su(2)$ algebra. The relations with supercoherent and supersqueezed states of the supersymmetric harmonic oscillator are given. Moreover, we are able to compute general Hamiltonians which behave like the harmonic oscillator Hamiltonian or are related to the Jaynes–Cummings Hamiltonian. © *2002 American Institute of Physics.*

I. INTRODUCTION

Minimum uncertainty states (MUSs) are usually understood through the minimization of the Heisenberg uncertainty relation (HUR). These states are well-known[1] since they are long associated with the so-called coherent states (CSs)[2] and squeezed states (SSs)[3]. But, it has been observed[4–6] that a more accurate uncertainty relation may be used to construct generalized CSs and SSs. Indeed, this relation known as the Schrödinger–Robertson uncertainty relation (SRUR)[7] can be minimized and gives rise to new classes of CSs and SSs which have received different names in the literature, such as correlated states[4] or intelligent states.[5] There are two main reasons to consider such last states. First, when the two Hermitian operators entering in the SRUR are noncanonical operators, i.e., their commutator is not a multiple of the identity, the HUR could be redundant while the SRUR not. Second, the MUSs that minimize the SRUR are shown to be eigenstates of a linear combination of the two Hermitian operators entering in the SRUR.

Recently[8] a connection has been made with the CS and SS based on group theoretic approaches[9] and the concept of algebra eigenstates (AESs). In particular, AESs have been constructed for the algebras su(2) and su(1,1). This concept constitutes a unification of different definitions of CS and SS.

In this article, we give a general construction of AESs based on the direct sum $h(1)\oplus su(2)$. The Heisenberg algebra $h(1)$ being relevant for the problem of the harmonic oscillator and the algebra su(2) for particles with spin, we have a procedure to find general CSs and SSs for supersymmetric systems, for example. These are clearly MUSs for which the dispersions of corresponding operators may be calculated easily. We show finally how to use these states in the construction of particularly relevant Hamiltonians and in the calculation of their dispersions.

In Sec. II, we put the emphasis on the SRUR and its relevancy with respect to the determination of MUSs. The application to the position and momentum operators MUS leads to the well-known CS and SS of the harmonic oscillator while when the angular momentum operators MUS are considered we have in mind the su(2) CS and SS. These particular applications are given to bring a new light on these states and also to facilitate the treatement of the $h(1)\oplus su(2)$ CS and SS. In Sec. III, we construct the AES based on the $h(1)\oplus su(2)$ algebra and show how this gives CSs and SSs which generalize the supercoherent and supersqueezed states obtained in other approaches.[10,11] Finally, in Sec. IV, we construct general Hamiltonians similar to the one of the

a)Electronic mail: hussin@dms.umontreal.ca

harmonic oscillator but where the so-called annihilation operator is now an element of the algebra $h(1)\oplus su(2)$. This permits us to use our CS and SS to compute the mean value and the dispersions of the corresponding energies. We show also how the well-known Jaynes–Cummings Hamiltonian enters in this scheme.

II. COHERENT AND SQUEEZED STATES AS MINIMUM UNCERTAINTY STATES

This section will be concerned by the general definition and properties of MUS (Sec. II A). They are explicitly constructed when the usual position and momentum operators are considered (Sec. II B) as well as when the angular momentum operators are taken (Sec. II C). The connection is made with already known results.

A. Minimum uncertainty relation

It is well-known[7] that, for two Hermitian operators A and B such that the commutator is

$$[A,B]=iC, \quad C\neq 0, \tag{2.1}$$

the HUR

$$(\Delta A)^2(\Delta B)^2\geqslant \frac{\langle C\rangle^2}{4} \tag{2.2}$$

is satisfied. The mean value and dispersion of a given operator X are defined, as usual, by

$$\langle X\rangle=\langle\psi|X|\psi\rangle, \quad (\Delta X)^2=\langle X^2\rangle-\langle X\rangle^2, \tag{2.3}$$

for a normalized state $|\psi\rangle$ describing the evolution of a quantum system. As observed by Puri,[6] for noncanonical operators, i.e., such that C is not a multiple of the identity I, we can have $\langle C\rangle=0$ and the relation (2.2) is then redundant. The SRUR[1,7] is never redundant and writes

$$(\Delta A)^2(\Delta B)^2\geqslant \tfrac{1}{4}(\langle C\rangle^2+\langle F\rangle^2), \tag{2.4}$$

where $\langle F\rangle$ is a measure of the correlation between A and B. The operator F is Hermitian and given by

$$F=\{A-\langle A\rangle I, B-\langle B\rangle I\}, \tag{2.5}$$

where $\{\ ,\ \}$ denotes the anticommutator. If there is no correlation between the operators A and B, i.e., if $\langle F\rangle=0$, the SRUR reduces to the usual HUR.

We are interested here in the description of states which minimize the SRUR (2.4). A necessary and sufficient condition to get them is to solve the eigenvalues equation:

$$[A+i\lambda B]|\psi\rangle=\beta|\psi\rangle, \tag{2.6}$$

where

$$\beta=[\langle A\rangle+i\lambda\langle B\rangle], \quad \lambda\in\mathbb{C}, \ \lambda\neq 0. \tag{2.7}$$

Note that, if $\mathrm{Re}\,\lambda\neq 0$, once we know the value of β, this last relation may be inverted to give the mean values

$$\langle A\rangle=\mathrm{Re}\,\beta+\frac{\mathrm{Im}\,\lambda}{\mathrm{Re}\,\lambda}\mathrm{Im}\,\beta, \quad \langle B\rangle=\frac{\mathrm{Im}\,\beta}{\mathrm{Re}\,\lambda} \tag{2.8}$$

and, if $\mathrm{Re}\,\lambda=0$, we get

$$\langle A\rangle=\mathrm{Re}\,\beta+\mathrm{Im}\,\lambda\langle B\rangle. \tag{2.9}$$

As a consequence of (2.6), one has

$$(\Delta A)^2=|\lambda|\Delta, \quad (\Delta B)^2=\frac{1}{|\lambda|}\Delta, \tag{2.10}$$

with

$$\Delta=\tfrac{1}{2}\sqrt{\langle C\rangle^2+\langle F\rangle^2}. \tag{2.11}$$

So the states $|\psi\rangle$ satisfying (2.6) with $|\lambda|=1$ will be called **coherent** because they satisfy

$$(\Delta A)^2=(\Delta B)^2=\Delta, \tag{2.12}$$

i.e., the dispersions in A and B are the same and minimized in the sense of SRUR. The states $|\psi\rangle$ satisfying (2.6) with $|\lambda|\neq 1$ will be called **squeezed** because if $|\lambda|<1$, we have $(\Delta A)^2<\Delta<(\Delta B)^2$ and if $|\lambda|>1$, we have $(\Delta B)^2<\Delta<(\Delta A)^2$.

Some other relations are also useful for our considerations. The direct computation of $(\Delta A)^2$ and $(\Delta B)^2$ is usually complicated but in the MUSs that satisfy (2.6), we can write

$$(\Delta A)^2=\tfrac{1}{2}|\mathrm{Re}\,\lambda\langle C\rangle+\mathrm{Im}\,\lambda\langle F\rangle|, \tag{2.13}$$

$$(\Delta B)^2=\frac{1}{2|\lambda|^2}|\mathrm{Re}\,\lambda\langle C\rangle+\mathrm{Im}\,\lambda\langle F\rangle|, \tag{2.14}$$

with

$$\mathrm{Im}\,\lambda\langle C\rangle=\mathrm{Re}\,\lambda\langle F\rangle. \tag{2.15}$$

For $\mathrm{Re}\,\lambda=0$, we have $\langle C\rangle=0$, which corresponds to the case where the HUR is redundant. The MUSs satisfy the minimum SRUR (MSRUR)

$$(\Delta A)^2(\Delta B)^2=\Delta^2, \tag{2.16}$$

with

$$(\Delta A)^2=\frac{1}{2}|\mathrm{Im}\,\lambda\langle F\rangle|, \quad (\Delta B)^2=\frac{1}{2}\left|\frac{\langle F\rangle}{\mathrm{Im}\,\lambda}\right| \tag{2.17}$$

and

$$\Delta=\tfrac{1}{2}|\langle F\rangle|. \tag{2.18}$$

For $\mathrm{Re}\,\lambda\neq 0$, from (2.15), we have

$$\langle F\rangle=\frac{\mathrm{Im}\,\lambda}{\mathrm{Re}\,\lambda}\langle C\rangle. \tag{2.19}$$

Moreover, from (2.13) and (2.14), we get

$$(\Delta A)^2=\left|\frac{|\lambda|^2}{2\,\mathrm{Re}\,\lambda}\langle C\rangle\right|, \quad (\Delta B)^2=\left|\frac{1}{2\,\mathrm{Re}\,\lambda}\langle C\rangle\right|, \tag{2.20}$$

and, then,

$$\Delta = \left| \frac{|\lambda|}{2 \operatorname{Re} \lambda} \langle C \rangle \right|. \tag{2.21}$$

In this case, it is sufficient to compute the mean value of C to deduce that of F and the dispersions. The particular case where $\operatorname{Im} \lambda = 0$ corresponds to the fact that the MSUR coïncides with the minimum HUR (MHUR).

B. Position and momentum coherent and squeezed states

Let us apply the preceding considerations to the special case of the usual position x and momentum p operators of a given quantum system. The canonical commutation relation (if $\hbar = 1$) being

$$[x,p] = iI, \tag{2.22}$$

the SRUR writes

$$(\Delta x)^2 (\Delta p)^2 \geqslant \tfrac{1}{4}(1 + \langle F \rangle^2). \tag{2.23}$$

The MUSs $|\psi, \lambda, \beta\rangle$ satisfy the eigenvalues equation:

$$[x + i\lambda p]|\psi, \lambda, \beta\rangle = \beta |\psi, \lambda, \beta\rangle. \tag{2.24}$$

If we introduce the usual creation $a^\dagger$ and annihilation a operators,

$$a^\dagger = \frac{x - ip}{\sqrt{2}}, \quad a = \frac{x + ip}{\sqrt{2}}, \tag{2.25}$$

such that $[a, a^\dagger] = I$, the equation (2.24) becomes

$$\frac{1}{\sqrt{2}}[(1-\lambda)a^\dagger + (1+\lambda)a]|\psi, \lambda, \beta\rangle = \beta |\psi, \lambda, \beta\rangle. \tag{2.26}$$

The general resolution of Eq. (2.26) is obtained by expressing the state $|\psi, \lambda, \beta\rangle$ as a superposition of the energy eigenstates $\{|n\rangle, n = 0,1,2, \ldots\}$ of the usual harmonic oscillator Hamiltonian

$$H_0 = w(a^\dagger a + \tfrac{1}{2}). \tag{2.27}$$

Let us recall that these eigenstates satisfy

$$a|n\rangle = \sqrt{n}|n-1\rangle, \quad a^\dagger |n\rangle = \sqrt{n+1}|n+1\rangle \tag{2.28}$$

and we can write them as

$$|n\rangle = \frac{a^{\dagger n}}{\sqrt{n!}}|0\rangle, \quad n = 0,1,2, \ldots . \tag{2.29}$$

So, if we insert

$$|\psi, \lambda, \beta\rangle = \sum_{n=0}^{\infty} C_{\lambda,\beta,n}|n\rangle, \quad C_{\lambda,\beta,n} \in \mathbb{C}, \tag{2.30}$$

in Eq. (2.26), using the expressions (2.28), we get the recurrence system

$$\frac{1}{\sqrt{2}}[\sqrt{n}(1-\lambda)C_{\lambda,\beta,n-1}+\sqrt{n+1}(1+\lambda)C_{\lambda,\beta,n+1}]=\beta C_{\lambda,\beta,n},\quad n=1,2,3,\ldots,$$
$$\frac{(1+\lambda)}{\sqrt{2}}C_{\lambda,\beta,1}=\beta C_{\lambda,\beta,0}. \tag{2.31}$$

The case $\lambda=-1$ does not give any solution and must be eliminated. If we set

$$\left(\frac{1-\lambda}{1+\lambda}\right)=\delta e^{i\phi},\quad \delta\in \mathrm{R}_+,\phi\in\left[-\frac{\pi}{2},\frac{3\pi}{2}\right[, \tag{2.32}$$

the resolution of the recurrence system (2.31) leads to the general solution of Eq. (2.26):

$$|\psi,\lambda,\beta\rangle=C_{\lambda,\beta,0}\exp\left(-\delta e^{i\phi}\frac{a^{\dagger 2}}{2}\right)\exp\left(\frac{\beta}{\sqrt{2}}(1+\delta e^{i\phi})a^{\dagger}\right)|0\rangle. \tag{2.33}$$

The special case $\lambda=1$ corresponds to $\delta=0$ and gives rise to the usual expression of the CS of the harmonic oscillator. These states (2.33) can also be obtained as the action of two unitary operators on the fundamental state. The first one[9] is the usual displacement operator D associated with an irreducible representation of the Heisenberg–Weyl group $H(1)$ with algebra $h(1)=\{a,a^{\dagger},I\}$. The second one is the squeezed operator S associated with an irreducible representation of SU(1,1) with algebra $su(1,1)=\{a^2,(a^{\dagger})^2,aa^{\dagger}+a^{\dagger}a\}$. This is a known fact[12] when squeezed states of the harmonic oscillator are studied. We have explicitly

$$|\psi,\lambda,\beta\rangle=S(\chi(\delta,\phi))D(\eta)|0\rangle, \tag{2.34}$$

where

$$D(\eta)=\exp(\eta a^{\dagger}-\overline{\eta}a)\ \text{ and }\ S(\chi)=\exp\left(\chi\frac{a^{\dagger 2}}{2}-\overline{\chi}\frac{a^2}{2}\right) \tag{2.35}$$

with

$$\eta=\frac{\beta}{\sqrt{2}}\frac{(1+\delta e^{i\phi})}{\sqrt{1-\delta^2}}\ \text{ and }\ \chi(\delta,\phi)=-\tanh^{-1}(\delta)e^{i\phi}. \tag{2.36}$$

The condition for having normalizable states is that $0\leqslant\delta<1$. Let us insist here on the fact that these SSs already obtained in the literature as eigenstates of a linear combination of a and $a^{\dagger}$ are also MUSs such that $(\Delta x)^2(\Delta p)^2=\Delta^2=(1+\langle F\rangle^2)/4$. From Eq. (2.19) and the fact that $\langle C\rangle=1$, we get

$$\langle F\rangle=\frac{\mathrm{Im}\,\lambda}{\mathrm{Re}\,\lambda}=\frac{-2\delta\sin\phi}{(1-\delta^2)} \tag{2.37}$$

and the factor Δ is

$$\Delta(\delta,\phi)=\sqrt{\frac{1}{4}(1+\langle F\rangle^2)}=\sqrt{\frac{1}{4}+\frac{\delta^2\sin^2\phi}{(1-\delta^2)^2}}. \tag{2.38}$$

Moreover, from (2.13) and (2.14), the dispersions are

$$(\Delta x)^2=\frac{|\lambda|^2}{2|\mathrm{Re}\,\lambda|}=\frac{(1-2\delta\cos\phi+\delta^2)}{2(1-\delta^2)} \tag{2.39}$$

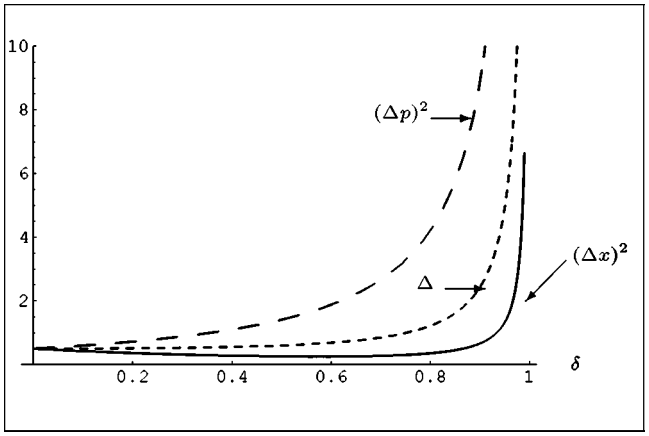

FIG. 1. Graphs of the dispersions $(\Delta x)^2$, $(\Delta p)^2$ and the Δ factor as functions of δ for $\phi=\pi/6$.

and

$$(\Delta p)^2=\frac{1}{2|\mathrm{Re}\,\lambda|}=\frac{(1+2\delta\cos\phi+\delta^2)}{2(1-\delta^2)}. \tag{2.40}$$

Let us recall now that the CSs are not only the one for $\lambda=1$ but also all the states where $|\lambda|=1$. From the relation (2.32), we deduce that

$$\lambda=\frac{1-\delta e^{i\phi}}{1+\delta e^{i\phi}}=\frac{(1-\delta^2)-2i\delta\sin\phi}{(1+2\delta\cos\phi+\delta^2)} \tag{2.41}$$

and then

$$|\lambda|^2=\frac{1-2\delta\cos\phi+\delta^2}{1+2\delta\cos\phi+\delta^2}. \tag{2.42}$$

This means that CSs occur also for $\phi=-\pi/2$ or $\phi=\pi/2$ and $\delta\neq 0$. The other values of λ describe x-squeezed states when $\phi\in\,]-\pi/2,\pi/2[$ and p-squeezed states when $\phi\in\,]\pi/2,3\pi/2[$. On the other hand, for fixed values of ϕ the expression (2.38) attains its minimum value $\frac{1}{2}$ when $\delta=0$ and when $\phi=0$ and $\phi=\pi$ for fixed values of δ. In the first of these cases, we have $\lambda=1$ and we are in the standard CSs of the harmonic oscillator, i.e., eigenstates of the a operator. In the second case, λ is a positive real quantity equal to $(1-\delta)/(1+\delta)\leqslant 1$ if $\phi=0$ and to $(1+\delta)/(1-\delta)\geqslant 1$ if $\phi=\pi$. We are in the special SSs that are eigenstates of the $(a+\delta a^\dagger)$ and $(a-\delta a^\dagger)$ operators, respectively.

Figure 1 shows the behavior of $(\Delta x)^2$, $(\Delta p)^2$ and Δ as functions of δ for $\phi=\pi/6$. In this region $(\Delta x)^2[(\Delta p)^2]$ is always less (greater) than Δ, as expected. For $\delta=0$, the three curves coïncide, and the intersection point corresponds to the CS $|\psi,1,\beta\rangle$. The value of $\Delta=(2.38)$ when $\delta=0$ is also the minimum value $\frac{1}{2}$ which corresponds to the MHUR. Figure 2 shows the behavior of the same quantities as functions of ϕ for $\delta=0.5$. The points where the three curves intersect are the CS.

C. Angular momentum coherent and squeezed states

Let us now take the angular momentum operators J_k for $k=1,2,3$, which satisfy the usual su(2) commutations relations

$$[J_k,J_l]=i\varepsilon_{klm}J_m,\quad k,l,m=1,2,3. \tag{2.43}$$

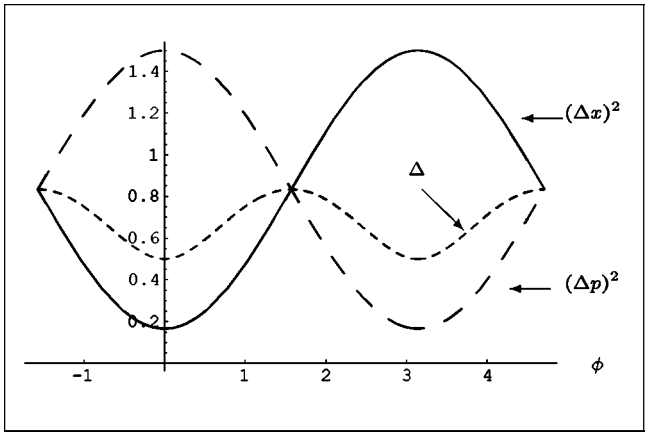

FIG. 2. Graphs of the dispersions $(\Delta x)^2$, $(\Delta p)^2$ and the Δ factor as functions of ϕ for $\delta=0.5$.

Here we want to solve the eigenvalues equation

$$(J_1+i\lambda J_2)|\psi,\lambda,\beta\rangle=\beta|\psi,\lambda,\beta\rangle, \tag{2.44}$$

where $\beta=[\langle J_1\rangle+i\lambda\langle J_2\rangle]$. On the contrary of the preceding example where the HUR is never redundant (because x and p are canonical), here the commutator of J_1 and J_2 is not a multiple of the identity and then $\langle J_3\rangle$ may be equal to zero for some special cases. Some of these cases have been discussed elsewhere.[6,13–15] Here we give the general solution of the equation (2.44), for all possible values of λ and β.

It would be better to work with the operators $J_\pm=J_1\pm iJ_2$ instead of J_1 and J_2, so that the equation (2.44) becomes

$$\tfrac{1}{2}[(1+\lambda)J_+ +(1-\lambda)J_-]|\psi,\lambda,\beta\rangle=\beta|\psi,\lambda,\beta\rangle. \tag{2.45}$$

Using the usual complete set of angular momentum states $\{|j,r\rangle\}$, j integer or half-odd integer and $r\in\{-j,-(j-1),\ldots,j-1,j\}$, we know that

$$J^2|j,r\rangle=(J_1^2+J_2^2+J_3^2)|j,r\rangle=j(j+1)|j,r\rangle, \tag{2.46}$$

$$J_3|j,r\rangle=r|j,r\rangle \tag{2.47}$$

and

$$J_\pm|j,r\rangle=\sqrt{(j\mp r)(j\pm r+1)}|j,r\pm1\rangle. \tag{2.48}$$

This means that for each j fixed, the eigenstates $|\psi,\lambda,\beta\rangle^j$ of Eq. (2.45) may be written as

$$|\psi,\lambda,\beta\rangle^j=\sum_{r=-j}^{j} C^j_{\lambda,\beta,r}|j,r\rangle, \quad C^j_{\lambda,\beta,r}\in\mathbb{C}, \tag{2.49}$$

where the coefficients $C^j_{\lambda,\beta,r}$ satisfy a recurrence system of the form

$$(1+\lambda)\sqrt{(j+r)(j-r+1)}C^j_{\lambda,\beta,r-1}+(1-\lambda)\sqrt{(j-r)(j+r+1)}C^j_{\lambda,\beta,r+1}=2\beta C^j_{\lambda,\beta,r}, \tag{2.50}$$

for $r=-j,\ldots,j$ and $C^j_{\lambda,\beta,j+1}=C^j_{\lambda,\beta,-(j+1)}=0$.

For $\lambda=\pm1$, the unique eigenstates are $|\psi,\pm1,0\rangle^j=|j,\pm j\rangle$. For $\lambda\neq\pm1$ and $\beta=0$, the recurrence relation (2.50) is solved to give

$$|\psi,\lambda,0\rangle^j = C^j_{\lambda,0,j} e^{i(j\phi/2)} \sum_{k=0}^{j} (-1)^k \frac{\binom{j}{k}}{\sqrt{\binom{2j}{2k}}} \delta^k e^{-i(j-2k)\phi/2} |j, j-2k\rangle, \quad j \text{ integer}, \tag{2.51}$$

where we have used the formula (2.32) to express λ in terms of the δ and ϕ. It is again possible to express such a state from the action of unitary operators associated with an irreducible representation of a group which is here SU(2). Indeed, we have

$$|\psi,\lambda,0\rangle^j = C^j_{\lambda,0} \exp[-\tfrac{1}{2}\ln(\delta) J_3] U |j,0\rangle, \tag{2.52}$$

where

$$U = \exp\left(-\frac{\pi}{4}(e^{-i\phi/2} J_+ - e^{i\phi/2} J_-) \right). \tag{2.53}$$

For the general case $\lambda \neq \pm 1$, the analysis of the system (2.50) shows that for each j, there exist $(2j+1)$ possible values for the eigenvalue β, which are

$$\beta^j_m = m\sqrt{1-\lambda^2}, \quad m = -j, \ldots, j. \tag{2.54}$$

If we use the relation

$$[J_1 + i\lambda J_2][\exp(-\tfrac{1}{2}\ln(\delta) J_3) U] = [\exp(-\tfrac{1}{2}\ln(\delta) J_3) U][\sqrt{1-\lambda^2} J_3], \tag{2.55}$$

we see immediately that the corresponding eigenstate $|\psi,\lambda,\beta^j_m\rangle^j$ is

$$|\psi,\lambda,\beta^j_m\rangle^j \equiv |\psi,\lambda,m\rangle^j = C^j_{\lambda,m} \exp[-\tfrac{1}{2}\ln(\delta) J_3] U |j,m\rangle, \quad m = -j, \ldots, j, \tag{2.56}$$

where $U \equiv (2.53)$. They can be written in terms of the Jacobi polynomials as

$$\begin{aligned} |\psi,\lambda,m\rangle^j = {} & C^j_{\lambda,m} \\ & \times \exp\left(-\frac{1}{2}\ln(\delta) J_3 \right) e^{im\phi/2} e^{-i(\phi/2)J_3} \\ & \times \sum_{r=-j}^{j} 2^r \sqrt{\frac{(j+r)!(j-r)!}{(j-m)!(j+m)!}} P^{-r+m,-r-m}_{j+r}(0) |j,r\rangle. \end{aligned} \tag{2.57}$$

In these last states, we want to compute now the mean values and dispersions of some operators in order to exhibit their behavior in the CS and SS.

If $\mathrm{Re}\,\lambda \neq 0$, the mean values of J_1 and J_2 in the states (2.57) are obtained using (2.8) and (2.54). In terms of δ and ϕ as defined by (2.32), we get

$$\langle J_1 \rangle^j_m = 2m \frac{\delta^{1/2}}{(\delta+1)} \cos\left(\frac{\phi}{2}\right), \quad \langle J_2 \rangle^j_m = 2m \frac{\delta^{1/2}}{(\delta+1)} \sin\left(\frac{\phi}{2}\right). \tag{2.58}$$

The relations (2.19)–(2.21) applied to our case tell us that $(\Delta J_1)^2$, $(\Delta J_2)^2$, Δ and $\langle F \rangle$ are all obtained from the mean value of J_3, i.e.,

$$((\Delta J_1)^2)^j_m=\frac{|\lambda|^2}{2\,\mathrm{Re}\,\lambda}\langle J_3\rangle^j_m,\quad ((\Delta J_2)^2)^j_m=\frac{1}{2\,\mathrm{Re}\,\lambda}\langle J_3\rangle^j_m,$$
$$\Delta^j_m=\frac{|\lambda|}{2\,\mathrm{Re}\,\lambda}\langle J_3\rangle^j_m,\quad \langle F\rangle^j_m=\frac{\mathrm{Im}\,\lambda}{\mathrm{Re}\,\lambda}\langle J_3\rangle^j_m. \tag{2.59}$$

The mean values of J_3 in the states (2.57) or equivalently in the states (2.56) are given by

$$\langle J_3\rangle^j_m=-\frac{\partial}{\partial q}\ln(\langle j,m|U^\dagger e^{-qJ_3}U|j,m\rangle), \tag{2.60}$$

where $q=\ln\delta$. After some computations, we get

$$\langle J_3\rangle^j_m=-|m|\tanh\left(\frac{q}{2}\right)-\frac{1}{2}\sinh(q)(j+|m|+1)\,\frac{P^{1,1+2|m|}_{j-|m|-1}(\cosh q)}{P^{0,2|m|}_{j-|m|}(\cosh q)}. \tag{2.61}$$

Inserting (2.61) into the expression (2.59), we get

$$((\Delta J_1)^2)^j_m=(1-2\delta\cos\phi+\delta^2)\Lambda^j_m(\delta),\quad ((\Delta J_2)^2)^j_m=(1+2\delta\cos\phi+\delta^2)\Lambda^j_m(\delta), \tag{2.62a}$$

$$(\Delta)^j_m=\sqrt{1-2\delta^2\cos(2\phi)+\delta^4}\,\Lambda^j_m(\delta),\quad \langle F\rangle^j_m=-4\delta\sin\phi\Lambda^j_m(\delta), \tag{2.62b}$$

where

$$\Lambda^j_m(\delta)=\left[\frac{|m|}{2(1+\delta)^2}+\frac{(j+|m|+1)}{8\delta}\,\frac{P^{1,1+2|m|}_{j-|m|-1}((1+\delta^2)/2\delta)}{P^{0,2|m|}_{j-|m|}((1+\delta^2)/2\delta)}\right]. \tag{2.63}$$

The case $\mathrm{Re}\,\lambda=0$ may be obtained as the limit case of the preceding one by taking $\delta=1$ in the expressions (2.62a), (2.62b) and (2.63). Let us recall that it corresponds to $\langle J_3\rangle=0$ and $\lambda=-i\tan\phi/2$. We get

$$((\Delta J_1)^2)^j_m=\frac{1}{2}[j(j+1)-m^2]\sin^2\left(\frac{\phi}{2}\right),\quad ((\Delta J_2)^2)^j_m=\frac{1}{2}[j(j+1)-m^2]\cos^2\left(\frac{\phi}{2}\right), \tag{2.64a}$$

$$(\Delta)^j_m=\frac{1}{4}[j(j+1)-m^2]|\sin\phi|\ \text{ and }\ \langle F\rangle^j_m=-\frac{1}{2}[j(j+1)-m^2]\sin\phi, \tag{2.64b}$$

using the fact that

$$P^{\alpha,\beta}_n(1)=\frac{(\alpha+1)(\alpha+2)\cdots(\alpha+n)}{n!}. \tag{2.65}$$

These are exactly the results given by Puri.[6]

To illustrate these considerations by a concrete example, let us take the "spin–$\frac{1}{2}$" case, i.e., $j=\frac{1}{2}$. The expressions (2.62a) and (2.62b) thus reduce to

$$((\Delta J_1)^2)_\pm=\frac{(1-2\delta\cos\phi+\delta^2)}{4(1+\delta)^2},\quad ((\Delta J_2)^2)_\pm=\frac{(1+2\delta\cos\phi+\delta^2)}{4(1+\delta)^2} \tag{2.66}$$

and

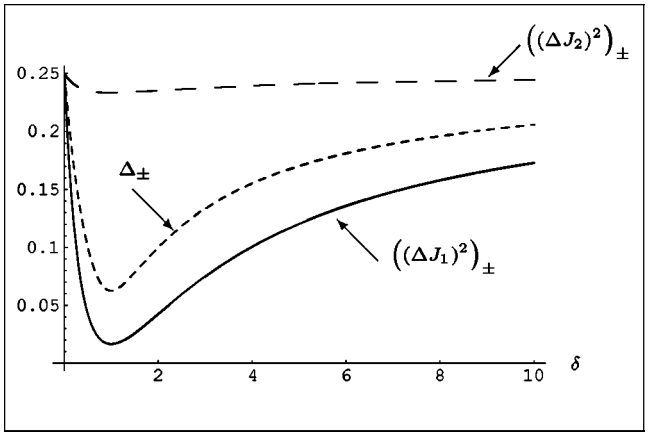

FIG. 3. Graphs of the dispersions $((\Delta J_1)^2)_\pm$, $((\Delta J_2)^2)_\pm$ and the $\Delta_\pm$ factor as functions of δ for $\phi=\pi/6$ and $j=\frac{1}{2}$.

$$\Delta_\pm(\delta,\phi)=\frac{1}{4}\sqrt{1+4\left(\frac{\delta^2\sin^2\phi-\delta(1+\delta)^2}{(1+\delta)^4}\right)}, \tag{2.67}$$

where we have used the $\pm$ sign for the values of $m=\pm\frac{1}{2}$. The MSRUR thus writes

$$((\Delta J_1)^2)_\pm((\Delta J_2)^2)_\pm=(\Delta_\pm)^2(\delta,\phi)=\frac{1}{16}\left[1+4\left(\frac{\delta^2\sin^2\phi-\delta(1+\delta)^2}{(1+\delta)^4}\right)\right]. \tag{2.68}$$

For fixed values of $\phi\neq 0$ and π, the expression (2.67) attains its minimum value $|\sin\phi|/8$ when $\delta=1$. On the other hand, for fixed values of δ such that $\delta\in[0,1[\cup]1,\infty]$, the minimum of (2.67) is $(\frac{1}{4})\sqrt{[1-(4\delta)/(1+\delta)^2]}$ when $\phi=0$ or $\phi=\pi$. In the first case we have $\lambda=-i(\sin\phi)/(1+\cos\phi)$, which means that we have some special classes of SSs from which we recognize CSs with $\lambda=-i$ (eigenstates of the J_1+J_2 operator) and with $\lambda=i$ (eigenstates of the J_1-J_2 operator). In the second case, we have $\lambda=(1-\delta)/(1+\delta)\leqslant 1$ if $\phi=0$ and $\lambda=(1+\delta)/(1-\delta)\geqslant 1$ if $\phi=\pi$, i.e., the minimum $\Delta_\pm(\delta,0)=\Delta_\pm(\delta,\pi)$ values occur for the special states which are eigenstates of the operators $(J_+\pm\delta J_-)$ and $(J_+-\delta J_-)$, respectively. Let us recall that the CSs with $\lambda=1$ occur when $\delta=0$ and those with $\lambda=-1$ when $\delta\mapsto\infty$. They correspond to the eigenstates of J_+ and J_- operators, respectively. For such states, according to Eq. (2.68), we have $((\Delta J_1)^2)_\pm=((\Delta J_2)^2)_\pm=(\Delta_\pm(0,\phi))^2=\lim_{\delta\mapsto\infty}(\Delta_\pm(\delta,\phi))^2=\frac{1}{4}$.

Figure 3 shows the behavior of the dispersions $((\Delta J_1)^2)$, $((\Delta J_2)^2)$ and Δ as functions of δ for $\phi=\pi/6$ and $j=\frac{1}{2}$. The minimum value of $\Delta_\pm$ is here 0,0625. In Fig. 4, we see that the graphs as a function of ϕ are very similar to ones for the preceding example of x and p.

III. ALGEBRA EIGENSTATES ASSOCIATED TO $h(1)\oplus su(2)$

This section begins (Sec. III A) with a review of the SUSY harmonic oscillator and its super-coherent states (SCSs) studied by Aragone and Zypman.[10] We follow (Sec. III B) by the general construction of AES based on the algebra $h(1)\oplus su(2)$. These states are defined as eigenstates of an arbitrary linear combination of the generators of the considered algebra.[8] Then we consider special solutions to CSs and SSs for the so-called super-position and super-momentum operators (Sec. III C).

A. The SUSY harmonic oscillator and its super-coherent states

Let us recall that the quantum SUSY harmonic oscillator is defined as a combination of a bosonic and a fermionic oscillators. Its Hamiltonian is given by

$$H_{\mathrm{SUSY}}=w(a^\dagger a-f^\dagger f), \tag{3.1}$$

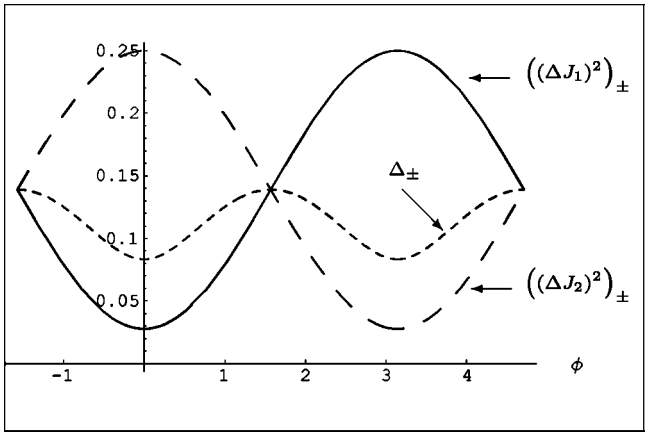

FIG. 4. Graphs of the dispersions $((\Delta J_1)^2)_\pm$, $((\Delta J_2)^2)_\pm$ and the $\Delta_\pm$ factor as functions of ϕ for $\delta=0.5$ and $j=\frac{1}{2}$.

where the bosonic creation and annihilation operators $a^\dagger$ and a are defined as in (2.25) and the corresponding fermionic operators $f^\dagger$ and f are defined as

$$f^\dagger=\sigma_+=\tfrac{1}{2}(\sigma_1+i\sigma_2),\quad f=\sigma_-=\tfrac{1}{2}(\sigma_1-i\sigma_2), \tag{3.2}$$

(the σ_i, $i=1,2$, being the usual Pauli matrices) for the spin $\frac{1}{2}$ fermion. We can thus write

$$H_{\mathrm{SUSY}}=w\left(a^\dagger a-\frac{1}{2}\right)-\frac{w}{2}\sigma_3. \tag{3.3}$$

The representation space we are working with in this context is nothing else than the direct product

$$\begin{aligned}\mathcal{F}=\mathcal{F}_b\otimes\mathcal{F}_f&=\{|n\rangle,n=0,1,2,\ldots\}\otimes\left\{\left|\frac{1}{2},\frac{1}{2}\right\rangle=|+\rangle,\left|\frac{1}{2},\frac{-1}{2}\right\rangle=|-\rangle\right\}\\&=\{|n,+\rangle,|n,-\rangle,n=0,1,2,\ldots\}.\end{aligned} \tag{3.4}$$

Following Aragone and Zypman,[10] SCSs may be constructed as eigenstates of a SUSY annihilation operator $[\sqrt{2}(a+\sigma_+)]$. They are shown to be given as a linear combination of the following normalized pure states:

$$|\psi\rangle_+=D\left(\frac{z}{\sqrt{2}}\right)|0,+\rangle \tag{3.5}$$

and

$$|\psi\rangle_-=D\left(\frac{z}{\sqrt{2}}\right)\frac{[a^\dagger|0,+\rangle-|0,-\rangle]}{\sqrt{2}}, \tag{3.6}$$

in terms of the displacement operator D given in (2.35) and where we recognize in (3.5) the usual CS of the harmonic oscillator. A discussion[10,11] of the properties of such states has led to the observation that, except for the state $|\psi_+\rangle\equiv$ (3.5), no other linear combination of (3.5) and (3.6) will minimize the usual HUR. This means that these states satisfy $(\Delta x)^2(\Delta p)^2\geqslant\frac{1}{4}$, the equality between the position x and the momentum p being realized only for $|\psi_+\rangle\equiv$(3.5).

Such a fact can be clarified from our discussion of Sec. II A. The SCSs (3.5) and (3.6) are in fact MUS for the SRUR (2.4) with

$$A=\frac{1}{\sqrt{2}}[(a^{\dagger}+a)+\sigma_1]=\left[x+\frac{\sigma_1}{\sqrt{2}}\right] \quad \text{and} \quad B=\frac{1}{\sqrt{2}}[i(a^{\dagger}-a)+\sigma_2]=\left[p+\frac{\sigma_2}{\sqrt{2}}\right], \tag{3.7}$$

these operators being different from x and p. The SCSs are coherent in the sense that they satisfy Eq. (2.6) with $\lambda=1$.

Clearly, in such a context, through the group theory level, we are combining the information coming from both the Heisenberg–Weyl $h(1)$ and the su(2) algebras realized in terms of the Pauli matrices in the spin $\frac{1}{2}$ case. It is then natural to ask the questions of determining the general CS and SS for the direct sum $h(1)\oplus \mathrm{su}(2)$ which will indeed include the special SCS we just discussed.

B. Algebra eigenstates

We are working with the $h(1)\oplus \mathrm{su}(2)$ algebra generated by $\{a,a^{\dagger},I;J_+,J_-,J_3\}$ as defined in the preceding sections. The AESs[8] for this algebra are defined as eigenstates corresponding to a complex combination of the associated generators. A general Hermitian operator A constructed from a combination of these generators is

$$A=A_1a+\overline{A}_1a^{\dagger}+A_2I+A_3J_+ +\overline{A}_3J_-+A_4J_3, \quad A_2,A_4\in\mathbb{R}, \ A_1,A_3\in\mathbb{C}. \tag{3.8}$$

Two such operators, called A and B, satisfy the commutation relation (2.1) with

$$C=[i(\overline{A}_1B_1-A_1\overline{B}_1)I+2i(B_3\overline{A}_3-\overline{B}_3A_3)J_3+i(A_3B_4-A_4B_3)J_+ +i(A_4\overline{B}_3-\overline{A}_3B_4)J_-]. \tag{3.9}$$

Once we search for states satisfying (2.6), i.e., for eigenstates of $A+i\lambda B$ ($\lambda\in\mathbb{C},\lambda\neq 0$), we are in fact considering AESs and we know from Sec. II A that they minimize the SRUR (2.4). Let us then study the solutions of such a general eigenstate equation (2.6) for A and B on the form (3.8).

It is convenient to rewrite this equation as

$$[\alpha_-a+\alpha_+a^{\dagger}+\alpha_3I+\beta_-J_+ +\beta_+J_- +\beta_3J_3]|\psi\rangle=z|\psi\rangle, \tag{3.10}$$

where

$$\begin{aligned} &\alpha_-=A_1+i\lambda B_1, \quad \alpha_+=\overline{A}_1+i\lambda\overline{B}_1, \quad \alpha_3=A_2+i\lambda B_2,\\ &\beta_-=A_3+i\lambda B_3, \quad \beta_+=\overline{A}_3+i\lambda\overline{B}_3, \quad \beta_3=A_4+i\lambda B_4. \end{aligned} \tag{3.11}$$

To solve (3.10), we express $|\psi\rangle$ as a superposition of fundamental states $|n;j,m\rangle$ which constitute a generalization of the Fock space (3.4) for spin j. We write

$$|\psi\rangle^j=\sum_{m=-j}^{j}\sum_{n=0}^{\infty}C_{n,m}^{j}|n;j,m\rangle, \tag{3.12}$$

for fixed j, integer or half-odd integer. Let us recall that we have

$$\begin{aligned} a|n;j,m\rangle&=\sqrt{n}|n-1;j,m\rangle,\\ a^{\dagger}|n;j,m\rangle&=\sqrt{n+1}|n+1;j,m\rangle,\\ J_{\pm}|n;j,m\rangle&=\sqrt{(j\mp m)(j\pm m+1)}|n;j,m\pm 1\rangle, \end{aligned} \tag{3.13}$$

with

$$\langle n;j,m|l;j,r\rangle=\delta_{nl}\delta_{mr}. \tag{3.14}$$

Inserting (3.12) into (3.10) and taking into account the relations (3.13) and (3.14), we get a recurrence system which becomes more and more complicated as j increases. We also notice that the case where $\alpha_-=0$ with $\alpha_+\neq 0$ does not give any solution and must be eliminated. Here two ways of solving it completely are presented. The first one uses the results obtained in Sec. II B and Appendix A where AESs of su(2) are explicitly constructed. It is described explicitly in this section using operators acting on a fundamental state. The second one is based on the method of resolution of a first order system of linear differential equations and is described in Appendix B.

With respect to the discussion in Appendix A, we have mainly two types of eigenvalues for z. The first type is given by

$$z=\rho_m^j+\alpha_3+mb, \quad \rho_m^j\in\mathbb{C}, \tag{3.15}$$

for fixed j and where $m=-j,\ldots,j$ and

$$b=\sqrt{4\beta_+\beta_-+\beta_3^2}\neq 0. \tag{3.16}$$

If we compare equations (2.26) and (A5) and their respective solutions (2.33) and (A15), we find the set of solutions

$$|\psi\rangle_m^j=(C_m^j)^{-1/2}\exp\left[-\frac{\alpha_+}{2\alpha_-}a^{\dagger 2}+\frac{\rho_m^j}{\alpha_-}a^\dagger\right]T_{\text{eff}}|0;j,m\rangle, \tag{3.17}$$

when $\alpha_-\neq 0$. Here T_{eff} is given by (A14) when $\{\beta_+\neq 0,\beta_-\neq 0\}$, (A18) when $\{\beta_+=0,\beta_3\neq 0\}$, (A20) when $\{\beta_-=0,\beta_3\neq 0\}$ and finally the identity when $\{\beta_-=\beta_+=0,\beta_3\neq 0\}$.

The second type corresponds to the so-called degenerate case ($b=0$) where $z=\rho+\alpha_3$. The sets of independent solutions are now given by

$$\begin{aligned}|\psi\rangle_m^j=(C_m^j)^{-1/2}&\exp\left[-\frac{\alpha_+}{2\alpha_-}a^{\dagger 2}+\frac{\rho}{\alpha_-}a^\dagger\right]\\&\times\sum_{k=0}^{j-m}(-1)^k\binom{j-m}{k}\frac{(2j-k)!}{(2j)!}(a^\dagger)^{j-m-k}\left(\frac{\alpha_-J_-}{\beta_-}\right)^k|0;j,j\rangle\end{aligned} \tag{3.18}$$

when $\beta_+=\beta_3=0$,

$$\begin{aligned}|\psi\rangle_m^j=(C_m^j)^{-1/2}&\exp\left[-\frac{\alpha_+}{2\alpha_-}a^{\dagger 2}+\frac{\rho}{\alpha_-}a^\dagger\right]\\&\times\sum_{k=0}^{j-m}(-1)^k\binom{j-m}{k}\frac{(2j-k)!}{(2j)!}(a^\dagger)^{j-m-k}\left(\frac{\alpha_-J_+}{\beta_+}\right)^k|0;j,-j\rangle\end{aligned} \tag{3.19}$$

when $\beta_-=\beta_3=0$, and

$$\begin{aligned}|\psi\rangle_m^j=(C_m^j)^{-1/2}&\exp\left[-\frac{\alpha_+}{2\alpha_-}a^{\dagger 2}+\frac{\rho}{\alpha_-}a^\dagger\right]\\&\times\left[\sum_{k=0}^{j-m}(-1)^k\binom{j-m}{k}\frac{(2j-k)!}{(2j)!}(a^\dagger)^{j-m-k}\left(\frac{\alpha_-}{\beta_+}\right)^k\frac{d^k e^{\vartheta J_+}}{d\vartheta^k}\right]|0;j,-j\rangle\end{aligned} \tag{3.20}$$

when β_+,β_- and β_3 are different from zero and for $\vartheta=\beta_3/(2\beta_+)=-2\beta_-/\beta_3$.

C. Coherent and squeezed states for the super-position and super-momentum operators

Let us consider the eigenstates of Eq. (3.10) corresponding to the following special values of the parameters

$$A_4=B_4=A_2=B_2=0,\quad A_1=iB_1=\frac{\mu}{\sqrt{2}},\quad (\mu\neq 0),\quad A_3=iB_3=\frac{\tau}{\sqrt{2}}, \tag{3.21}$$

so that A will be called the super-position operator denoted by X and B the super-momentum operator denoted by P. We have

$$X=\frac{1}{\sqrt{2}}[(\mu a+\overline{\mu}a^{\dagger})+(\tau J_{+}+\overline{\tau}J_{-})],\quad P=\frac{i}{\sqrt{2}}[(\overline{\mu}a^{\dagger}-\mu a)+(\overline{\tau}J_{-}-\tau J_{+})]. \tag{3.22}$$

We see that the operators (3.7) associated to the SCS are then a special case where $\mu=\overline{\mu}=\tau=\overline{\tau}=1$ in the spin-$\frac{1}{2}$ case.

The eigenstate equation (3.10) now writes

$$[X+i\lambda P]|\psi\rangle=z|\psi\rangle \tag{3.23}$$

and the operator C in (3.9) is diagonal and takes the form

$$C=|\mu|^2I+2|\tau|^2J_3. \tag{3.24}$$

Since we have

$$\begin{aligned}&\alpha_{-}=\frac{\mu(1+\lambda)}{\sqrt{2}},\quad \alpha_{+}=\frac{\overline{\mu}(1-\lambda)}{\sqrt{2}},\quad \alpha_3=0,\\ &\beta_{-}=\frac{\tau(1+\lambda)}{\sqrt{2}},\quad \beta_{+}=\frac{\overline{\tau}(1-\lambda)}{\sqrt{2}},\quad \beta_3=0,\end{aligned} \tag{3.25}$$

and finally

$$b=\sqrt{2}|\tau|\sqrt{1-\lambda^2}, \tag{3.26}$$

we can use the preceding solutions to give all the solutions of Eq. (3.23).

For $\lambda=1$, we have $\alpha_{+}=\beta_{+}=b=0$ and the eigenstate equation is

$$[\mu a+\tau J_{+}]|\psi\rangle=\frac{z}{\sqrt{2}}|\psi\rangle. \tag{3.27}$$

The normalized solutions are obtained from (3.18) and take the form

$$|\psi\rangle_m^j=(C_m^j(\mu,\tau))^{-1/2}D\left(\frac{z}{\mu\sqrt{2}}\right)\left[\sum_{k=0}^{j-m}(-1)^k\binom{j-m}{k}\frac{(2j-k)!}{(2j)!}(a^{\dagger})^{j-m-k}\left(\frac{\mu J_{-}}{\tau}\right)^k\right]|0;j,j\rangle, \tag{3.28}$$

where the normalization constant is given by

$$C_m^j(\mu,\tau)=(j-m)!\left[\sum_{k=0}^{j-m}\binom{j-m}{k}\frac{(2j-k)!}{(2j)!}\left(\frac{|\mu|^2}{|\tau|^2}\right)^k\right]. \tag{3.29}$$

Let us recall that in this case we have CSs for which

$$(\Delta X)=(\Delta P)=\Delta=\tfrac{1}{2}\langle C\rangle. \tag{3.30}$$

The mean value of C is easy to compute and we have

$$\langle C\rangle_m^j=|\mu|^2+2|\tau|^2\left[j+|\tau|^2\frac{\partial}{\partial|\tau|^2}\ln(C_m^j(\mu,\tau))\right]. \tag{3.31}$$

In the special case $j=\frac{1}{2}$, we find the normalized and orthogonal states

$$|\psi\rangle^+=D\left(\frac{z}{\mu\sqrt{2}}\right)|0;+\rangle,\quad |\psi\rangle^-=D\left(\frac{z}{\mu\sqrt{2}}\right)\frac{|\tau|}{\sqrt{|\mu|^2+|\tau|^2}}\left[a^\dagger|0;+\rangle-\frac{\mu}{\tau}|0;-\rangle\right], \tag{3.32}$$

where D is again given by (2.35). In those states, we have

$$\langle C\rangle^+=|\mu|^2+|\tau|^2,\quad \langle C\rangle^-=\left[(|\mu|^2+|\tau|^2)-\frac{2|\mu|^2|\tau|^2}{(|\mu|^2+|\tau|^2)}\right]. \tag{3.33}$$

This is clearly a generalization of SCSs considered by Aragone and Zypman[10] and recalled in (3.5) and (3.6).

From (3.33), we see that the dispersions of ΔX and ΔP given by (3.30) computed in the CS $|\psi\rangle^-$ are smaller than in the states $|\psi\rangle^+$. The states $|\psi\rangle^-$ thus are the closest to classical states for the SUSY harmonic oscillators (this means with respect to the super-position and the super-momentum) while $|\psi\rangle^+$ are indeed the ones closest to classical states of the standard harmonic oscillator (i.e., they minimize the HUR for X and P). Let us mention that if we take $\mu=1$, we see that $\langle C\rangle^+$ has its minimum value equal to 1 for $\tau\mapsto 0$ and in this case $X=x$ and $P=p$. For the same value of μ, we see that $\langle C\rangle^-$ takes the form

$$\langle C\rangle^-=\frac{1+|\tau|^4}{1+|\tau|^2}, \tag{3.34}$$

which has a minimum value $\langle C\rangle^-_{\min}=2(\sqrt{2}-1)<1$ for $|\tau|^2=\sqrt{2}-1$.

For $\lambda\neq\pm 1$, from Eq. (3.17) and $T_{\text{eff}}\equiv$ (A13), using also (2.35) and (2.36), we get the states

$$\begin{aligned}|\psi\rangle_m^j=&(C_m^j)^{-1/2}S(\chi(\delta,\phi-2\phi_u))D(\eta_m(z,\delta,\phi,\mu,\tau))\\&\times\exp\left(\frac{-\tau\delta^{-1/2}e^{-i\phi/2}}{|\tau|}J_+\right)\exp\left(\frac{\bar{\tau}\delta^{1/2}e^{i\phi/2}}{2|\tau|}J_-\right)|0;j,m\rangle,\end{aligned} \tag{3.35}$$

where

$$\eta_m(z,\delta,\phi,\mu,\tau)=\frac{1}{\mu}\left\{\frac{z(1+\delta e^{i\phi})}{\sqrt{2}}-2m|\tau|\delta^{1/2}e^{i\phi/2}\right\},\quad \mu=|\mu|e^{i\phi_u} \tag{3.36}$$

and where we have used instead of λ the parameters δ and ϕ as given in (2.32). Let us mention that this general expression (3.35) clearly shows the presence of the unitary operators D and S associated with $h(1)$ and su(1,1), respectively, which is the contribution of the bosonic part of our SUSY model. Moreover, the fermionic contribution appears through the action of a unitary operator associated with su(2).

Now these states satisfy the MUR

$$(\Delta X)_m^j(\Delta P)_m^j=\Delta_m^j=\frac{1}{2}\sqrt{1+\frac{4\delta^2\sin^2\phi}{(1-\delta^2)^2}}|\langle C\rangle_m^j|. \tag{3.37}$$

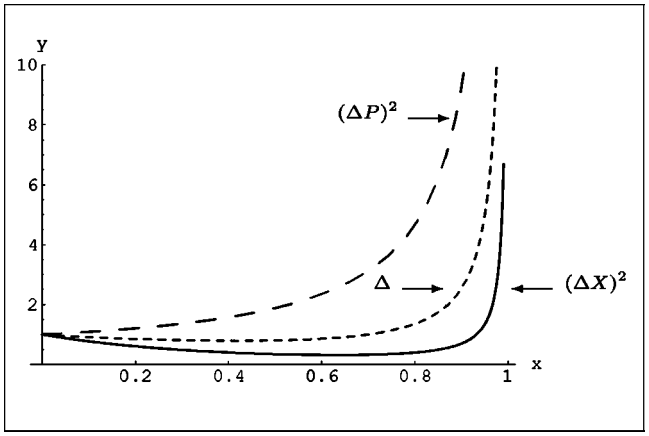

FIG. 5. Graphs of the dispersions $(\Delta X)^2$, $(\Delta P)^2$ and the factor Δ as functions of $x \equiv \delta$ for $\phi = \pi/6$. $|\tau| = |\mu| = 1$, $j = \frac{1}{2}$.

The mean value of C is

$$\langle C \rangle_m^j = |\mu|^2 + 2|\tau|^2 \frac{(1-\delta)}{(1+\delta)} \left(j - \frac{4(j+|m|)\delta}{(1+\delta)^2} \Omega \right), \tag{3.38}$$

where Ω is expressed in terms of Jacobi polynomials (see Appendix A),

$$\Omega = \frac{P_{j-|m|-1}^{(-2j,1)}(1-(8\delta/(1+\delta)^2))}{P_{j-|m|}^{(-2j-1,0)}(1-(8\delta/(1+\delta)^2))}, \tag{3.39}$$

for $m = -j+1, \ldots, j-1$ and $\Omega = 0$ for $m = \pm j$. In fact, we see that in these last cases, we have

$$\langle C \rangle_{\pm j}^j = |\mu|^2 + 2j|\tau|^2 \frac{(1-\delta)}{(1+\delta)}. \tag{3.40}$$

It is now interesting to examine the behavior of the dispersions ΔX and ΔP in these states for the spin $\frac{1}{2}$ case. Using (2.20) with (3.40) for $j = \frac{1}{2}$, we get

$$\begin{aligned} ((\Delta X)^2)_\pm &= \frac{(1-2\delta\cos\phi+\delta^2)}{2(1-\delta^2)} \left[|\mu|^2 + |\tau|^2 \frac{(1-\delta)}{(1+\delta)} \right], \\ ((\Delta P)^2)_\pm &= \frac{(1+2\delta\cos\phi+\delta^2)}{2(1-\delta^2)} \left[|\mu|^2 + |\tau|^2 \frac{(1-\delta)}{(1+\delta)} \right], \end{aligned} \tag{3.41}$$

with

$$\Delta_\pm = \frac{\sqrt{(1-\delta^2)^2 + 4\delta^2 \sin^2\phi}}{2(1-\delta^2)} \left[|\mu|^2 + |\tau|^2 \frac{(1-\delta)}{(1+\delta)} \right]. \tag{3.42}$$

If we take $\delta = 0$ (i.e., $\lambda = 1$) in these last expressions, we find only the values of the dispersions of X and P in the usual coherent states $|\psi\rangle^+$ as given by (3.32) and not the ones in the CS $|\psi\rangle^-$, which is the reason why that case has been treated separately.

Figures 5 and 6 show the behavior of $((\Delta X)^2)_\pm$ and $((\Delta P)^2)_\pm$ and $\Delta_\pm$ as functions of δ for $\phi = \pi/6$ and as functions of ϕ for $\delta = 0.5$, respectively. We notice a similar behavior as for the position and momentum operators.

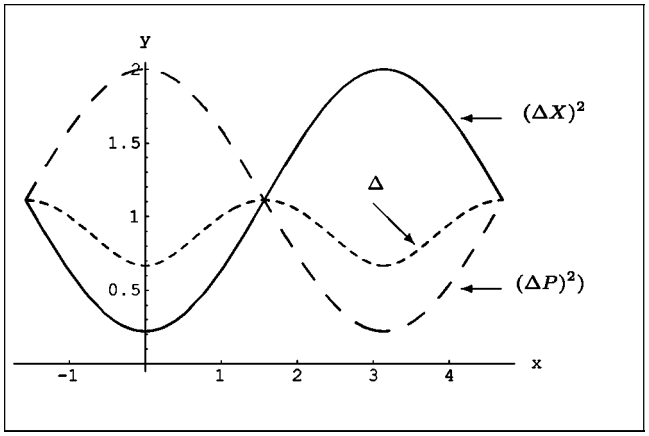

FIG. 6. Graphs of the dispersions $(\Delta X)^2$, $(\Delta P)^2$ and the factor Δ as functions of $x\equiv\phi$, $\delta=0.5$, $|\tau|=|\mu|=1$, $j=\frac{1}{2}$.

IV. CONSTRUCTION OF $h(1)\oplus su(2)$ HAMILTONIANS

An application of our CS and SS based on the algebra $h(1)\oplus su(2)$ will be the study of possible Hamiltonians which can be written as $\mathcal{H}=w\mathcal{A}^\dagger\mathcal{A}$, where $\mathcal{A}$ is a linear combination of the generators of $h(1)\oplus su(2)$. It is clear that the usual harmonic oscillator Hamiltonian will enter in the scheme as a special case (Sec. IV A) but also the Jaynes–Cummings[16] one in the strong coupling limit (Sec. IV B and C).

Moreover, since the CSs and SSs already constructed in the preceding section are in fact eigenstates of the operator $\mathcal{A}$, we would be able to find easily some properties of the mean value and the dispersion of the associated energies in those states.

A. Isospectral $h(1)\oplus su(2)$ harmonic oscillator Hamiltonians

We are interested in systems for which the Hamiltonian is expressed in the form

$$\mathcal{H}=w\mathcal{A}^\dagger\mathcal{A}, \tag{4.1}$$

where

$$\mathcal{A}=\alpha_- a+\alpha_+ a^\dagger+\alpha_3 I+\beta_- J_+ +\beta_+ J_- +\beta_3 J_3, \quad \alpha_-\neq 0, \tag{4.2}$$

is an element of the $h(1)\oplus su(2)$ algebra. The commutator of the operators $\mathcal{A}$ and $\mathcal{A}^\dagger$ is

$$[\mathcal{A},\mathcal{A}^\dagger]=(|\alpha_-|^2-|\alpha_+|^2)I+(|\beta_-|^2-|\beta_+|^2)J_3+(\beta_3\overline{\beta}_+-\overline{\beta}_3\beta_-)J_+ +(\overline{\beta}_3\beta_+-\beta_3\overline{\beta}_-)J_- . \tag{4.3}$$

If $|Z\rangle$ is an eigenstate of the operator $\mathcal{A}$ with eigenvalue z, i.e.,

$$\mathcal{A}|Z\rangle=z|Z\rangle, \tag{4.4}$$

then the mean value of the energy in this state will always be given by

$$\langle Z|\mathcal{H}|Z\rangle=w|z|^2 \tag{4.5}$$

and the dispersion by

$$(\Delta\mathcal{H})^2=w^2|z|^2\langle Z|[\mathcal{A},\mathcal{A}^\dagger]|Z\rangle. \tag{4.6}$$

First, let us consider the special case where

$$[\mathcal{A},\mathcal{A}^{\dagger}]=I. \tag{4.7}$$

This imposes the following conditions on the parameters:

$$|\alpha_-|^2-|\alpha_+|^2=1, \quad |\beta_-|=|\beta_+| \quad \text{and} \quad \beta_3\overline{\beta}_+-\overline{\beta}_3\beta_-=0, \tag{4.8}$$

i.e.,

$$\alpha_-=\cosh\alpha e^{i\theta_-}, \quad \alpha_+=\sinh\alpha e^{i\theta_+}, \quad \beta_\pm=\beta e^{i\varphi_\pm}, \tag{4.9}$$

and

$$\beta_3=\begin{cases} re^{i(\varphi_++\varphi_-)/2}, r\in\mathbb{R}_+\cup\{0\}, & \text{if } \beta\neq 0, \\ re^{i\varphi_3}, r\in\mathbb{R}_+\cup\{0\}, & \text{if } \beta=0. \end{cases} \tag{4.10}$$

When $\beta\neq 0$, the operator $\mathcal{A}$ then takes the form

$$\mathcal{A}=\cosh\alpha e^{i\theta_-}a+\sinh\alpha e^{i\theta_+}a^{\dagger}+\alpha_3 I+\beta(e^{i\varphi_-}J_++e^{i\varphi_+}J_-)+re^{i(\varphi_++\varphi_-)/2}J_3. \tag{4.11}$$

The parameter b given in (3.16) becomes $b=\sqrt{4\beta^2+r^2}e^{i(\varphi_++\varphi_-)/2}$ and is different from zero. Therefore in this case, according to the equation (3.17), the normalized solutions of the eigenstate equation (4.4) are given by

$$|Z\rangle_m^j=S(\Lambda)D(\zeta_m(\alpha_3,1))TD(ze^{-i\theta_-})|0;j,m\rangle, \tag{4.12}$$

where

$$\Lambda=-\alpha e^{i(\theta_+-\theta_-)}, \quad \zeta_m(\alpha_3,\epsilon)=-[\alpha_3+\epsilon m\sqrt{4\beta^2+r^2}e^{i(\varphi_++\varphi_-)/2}]e^{-i\theta_-}, \tag{4.13}$$

and

$$T=\exp\left(-\frac{\tilde{\theta}}{2}[e^{-i(\varphi_+-\varphi_-)/2}J_+-e^{i(\varphi_+-\varphi_-)/2}J_-]\right), \tag{4.14}$$

with

$$\frac{\tilde{\theta}}{2}=\tan^{-1}\left(\sqrt{1-\frac{r}{2\beta^2}(\sqrt{4\beta^2+r^2}-r)}\right). \tag{4.15}$$

This means that T is a unitary operator.

We remark that, if we define the new operator

$$\begin{aligned}\mathcal{A}_0&=D^{\dagger}(-\alpha_3e^{-i\theta_-})S^{\dagger}(\Lambda)\mathcal{A}S(\Lambda)D(-\alpha_3e^{-i\theta_-})\\&=e^{i\theta_-}a+\beta(e^{i\varphi_-}J_++e^{i\varphi_+}J_-)+re^{i(\varphi_++\varphi_-)/2}J_3,\end{aligned} \tag{4.16}$$

which is simpler than the original $\mathcal{A}$, then the new Hamiltonian $\mathcal{H}_0=w\mathcal{A}_0^{\dagger}\mathcal{A}_0$ is isospectral to the Hamiltonian $\mathcal{H}\equiv$ (4.1).

The dispersion of $\mathcal{H}$ calculated on the states (4.12) is, from (4.6) and (4.7), given by $(\Delta\mathcal{H})^2=w^2|z|^2$ and is the same as the one of $\mathcal{H}_0$ calculated on the states $D(\zeta_m(-z,1))T|0;j,m\rangle$. This value is exactly the dispersion of the harmonic oscillator in the usual CS.

On the other hand, due to (4.7) we have $[\mathcal{H},\mathcal{A}]=-w\mathcal{A}$, so we have a complete analogy with the harmonic oscillator. The CSs associated to the Hamiltonian $\mathcal{H}$, called generalized harmonic oscillator, are those given by the equation (4.12) and, thus, one can write them in the form

$$|Z\rangle_m^j = \mathcal{D}(z)|\tilde{0}\rangle_m^j, \quad \text{where} \quad \mathcal{D}(z) = \exp(z\mathcal{A}^\dagger - \bar{z}\mathcal{A}) \tag{4.17}$$

and $|\tilde{0}\rangle_m^j$, $m=-j,\ldots,j$, are the fundamental states of the system $\mathcal{H}$, that is, the eigenstates of $\mathcal{H}$ corresponding to the $(2j+1)$ degenerate eigenvalue 0. They are also eigenstates of $\mathcal{A}$ corresponding to the eigenvalue 0. So, they can be written

$$|\tilde{0}\rangle_m^j = S(\Lambda)D(\zeta_m(\alpha_3,1))T|0;j,m\rangle. \tag{4.18}$$

Furthermore, the SSs associated with $\mathcal{H}$ are given by

$$|\tilde{\psi}\rangle_m^j = \mathcal{S}(\chi)\mathcal{D}(z)|\tilde{0}\rangle_m^j, \tag{4.19}$$

where the super-squeezed operator $\mathcal{S}(\chi)$ is given by $\exp(\chi\mathcal{A}^{\dagger 2}/2 - \bar{\chi}\mathcal{A}^2/2)$ and the super-displacement operator $\mathcal{D}(z)$ is given in (4.17). If we define $\mathcal{X}=(\mathcal{A}+\mathcal{A}^\dagger)/\sqrt{2}$ and $\mathcal{P}=i(\mathcal{A}^\dagger - \mathcal{A})/\sqrt{2}$, these states (4.19) minimize the SRUR $(\Delta\mathcal{X})^2(\Delta\mathcal{P})^2=(1+\langle F\rangle^2)/4$, i.e., they are solutions of the eigenstate equation $[(1-\lambda)\mathcal{A}^\dagger+(1+\lambda)\mathcal{A}]|\psi\rangle=\sqrt{2}|\psi\rangle$.

The eigenstates of $\mathcal{H}$ corresponding to the $(2j+1)$ degenerate energy eigenvalue $E_n=nw$ are now given by

$$|\tilde{n}\rangle_m^j = \frac{\mathcal{A}^{\dagger n}}{\sqrt{n!}}|\tilde{0}\rangle_m^j. \tag{4.20}$$

These states may be obtained as the action of a unitary operator on the states $|n;j,m\rangle$. Indeed, if we introduce the unitary operator

$$U_n^m = e^{-in\theta_-}S(\Lambda)D(\zeta_m(\alpha_3,1))T, \tag{4.21}$$

we see that, from (4.20), we have

$$\begin{aligned}
|\tilde{n}\rangle_m^j &= \frac{e^{in\theta_-}}{\sqrt{n!}}(\mathcal{A}^\dagger)^n U_n^m|0;j,m\rangle, \\
&= \frac{e^{in\theta_-}}{\sqrt{n!}}U_n^m((U_n^m)^\dagger\mathcal{A}^\dagger U_n^m)^n|0;j,m\rangle, \\
&= \frac{e^{in\theta_-}}{\sqrt{n!}}U_n^m(e^{-i\theta_-}a^\dagger + \sqrt{4\beta^2+r^2}e^{-i(\varphi_+ + \varphi_-)/2}(J_3-m))^n|0;j,m\rangle.
\end{aligned} \tag{4.22}$$

Since we have $(J_3-m)|0;j,m\rangle=0$, we finally find

$$|\tilde{n}\rangle_m^j = U_n^m|n;j,m\rangle. \tag{4.23}$$

In the case $\beta=0$, the operator $\mathcal{A}$ is given by

$$\mathcal{A} = \cosh\alpha e^{i\theta_-}a + \sinh\alpha e^{i\theta_+}a^\dagger + \alpha_3 I + re^{i\varphi_3}J_3. \tag{4.24}$$

Then, if $r\neq 0$, one has the same results as above, except that it is necessary to replace T by I and b by $\beta_3=re^{i\varphi_3}$. If $r=0$, $\mathcal{A}$ is an element of the algebra $h(1)$ and then the results are the ones obtained in Sec. II A for the standard harmonic oscillator after applying the unitary transformation $S(\Lambda)D(-\alpha_3 e^{-i\theta_-})$.

B. Strong-coupling limit of the Jaynes–Cummings Hamiltonian as limit of $h(1)\oplus su(2)$ Hamiltonians

We are going to consider now the case where

$$[\mathcal{A},\mathcal{A}^\dagger]=I+2xJ_3, \quad x\in\mathbb{R}. \tag{4.25}$$

This imposes the following conditions on the parameters:

$$|\alpha_-|^2-|\alpha_+|^2=1, \quad |\beta_-|^2-|\beta_+|^2=x \quad \text{and} \quad \beta_3\overline{\beta}_+-\overline{\beta}_3\beta_-=0. \tag{4.26}$$

We already know the results when $x=0$. When $x\neq 0$, the conditions (4.26) imply

$$\alpha_-=\cosh\alpha e^{i\theta_-}, \quad \alpha_+=\sinh\alpha e^{i\theta_+}, \quad \beta_3=0, \tag{4.27}$$

and

$$\beta_-=\begin{cases} x^{1/2}\cosh\beta e^{i\varphi_-}, & \text{if } x>0,\\ |x|^{1/2}\sinh\beta e^{i\varphi_-}, & \text{if } x<0,\end{cases} \tag{4.28}$$

$$\beta_+=\begin{cases} x^{1/2}\sinh\beta e^{i\varphi_+}, & \text{if } x>0,\\ |x|^{1/2}\cosh\beta e^{i\varphi_+}, & \text{if } x<0.\end{cases} \tag{4.29}$$

The parameter $b\equiv$ (3.16) becomes $b=|x|^{1/2}\sqrt{2\sinh(2\beta)}e^{i(\varphi_++\varphi_-)/2}$. This means that $b=0$ if and only if $\beta=0$.

In the case $\beta\neq 0$, according to the equations (3.17), (A7), (A11), and (A12), the normalized eigenstates of the operator $\mathcal{A}$ are given by

$$|Z(x)\rangle_m^j=(C_m^j(x))^{-1/2}S(\Lambda)D(-\alpha_3e^{-i\theta_-})D(\eta_m(z,x))\exp\left[-\frac{x}{2|x|}\ln(\tanh\beta)J_3\right]U|0;j,m\rangle, \tag{4.30}$$

where

$$\eta_m(z,x)=[z-m|x|^{1/2}\sqrt{2\sinh(2\beta)}e^{i(\varphi_++\varphi_-)/2}]e^{-i\theta_-}, \tag{4.31}$$

$$U=\exp\left[-\frac{\pi}{4}(e^{-i(\varphi_+-\varphi_-)/2}J_+-e^{i(\varphi_+-\varphi_-)/2}J_-)\right] \tag{4.32}$$

and

$$\begin{aligned} C_m^j(x)&=\langle j,m|U^\dagger\exp\left[-\frac{x}{|x|}\ln(\tanh\beta)J_3\right]U|j,m\rangle\\ &=\left(\frac{1+\tanh\beta}{2\sqrt{\tanh\beta}}\right)^{\mp 2m}P_{j\pm m}^{0;\mp 2m}\left(\frac{1+\tanh^2\beta}{2\tanh\beta}\right). \end{aligned} \tag{4.33}$$

From (4.6) and (4.25), the dispersion of the $\mathcal{H}\equiv$ (4.1) in the states (4.30) can be calculated explicitly. We get

$$(\Delta\mathcal{H})^2)_m^j=w^2|z|^2(1+2x_m^j\langle Z(x)|J_3|Z(x)\rangle_m^j). \tag{4.34}$$

In the last expression, the mean value of J_3 is obtained in a similar way then to get (2.61). The result is

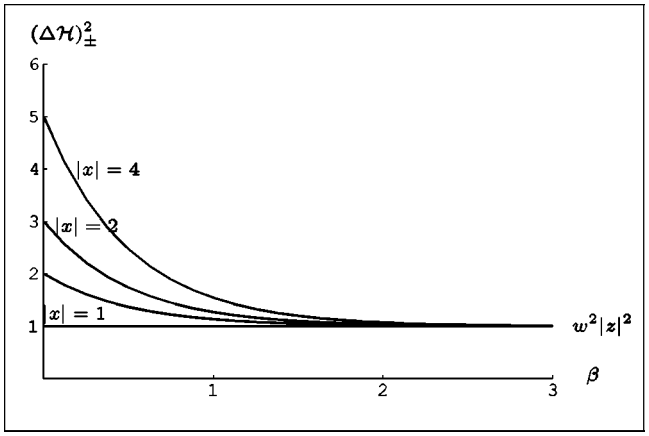

FIG. 7. Graphs of the dispersions $((\Delta\mathcal{H})^2)_{\pm} \equiv$ (4.37) as functions of $\beta>0$ for $|x|=0,1,2,4$.

$$ {}^{j}_{m}\langle Z(x)|J_3|Z(x)\rangle^{j}_{m} = \frac{x}{|x|}\left\{ |m|e^{-2\beta} + \frac{(j+|m|+1)}{2\sinh(2\beta)} \frac{P^{1;2|m|}_{j-|m|-1}(\coth(2\beta))}{P^{0;2|m|}_{j-|m|}(\coth(2\beta))} \right\}. \tag{4.35} $$

If we take $m=\pm j$, the dispersion of $\mathcal{H}$ is

$$ ((\Delta\mathcal{H})^2)^{j}_{\pm j} = w^2|z|^2(1+2j|x|e^{-2\beta}), \tag{4.36} $$

and, in particular, when $j=\frac{1}{2}$, we get

$$ ((\Delta\mathcal{H})^2)_{\pm} = w^2|z|^2(1+|x|e^{-2\beta}). \tag{4.37} $$

Figure 7 shows the graphs of $((\Delta\mathcal{H})^2)_{\pm}$ as functions of β for different values of $|x|$ when $w^2|z|^2$ is taken equal to 1.

Let us compute the new operator $\mathcal{A}_0$ defined as (4.16). We get

$$ \mathcal{A}_0 = \begin{cases} e^{i\theta_-}a + x^{1/2}\cosh\beta e^{i\varphi_-}J_+ + x^{1/2}\sinh\beta e^{i\varphi_+}J_-, & \text{if } x>0, \\ e^{i\theta_-}a + |x|^{1/2}\sinh\beta e^{i\varphi_-}J_+ + |x|^{1/2}\cosh\beta e^{i\varphi_+}J_-, & \text{if } x<0, \end{cases} \tag{4.38} $$

and a new Hamiltonian $\mathcal{H}_0 = w\mathcal{A}_0^{\dagger}\mathcal{A}_0$ isospectral to the Hamiltonian $\mathcal{H}$ which takes the form

$$ \begin{aligned} \mathcal{H}_0 = w\{ & a^{\dagger}a + |x|[\sinh^2(\beta)J_-J_+ + \cosh^2(\beta)J_+J_-] + |x|^{1/2}\cosh\beta[e^{i(\varphi_+-\theta_-)}a^{\dagger}J_- \\ & + e^{-i(\varphi_+-\theta_-)}aJ_+] + |x|^{1/2}\sinh\beta[e^{i(\varphi_--\theta_-)}a^{\dagger}J_+ + e^{-i(\varphi_--\theta_-)}aJ_-] \\ & + |x|\sinh\beta\cosh\beta[e^{i(\varphi_+-\varphi_-)}J_-^2 + e^{-i(\varphi_+-\varphi_-)}J_+^2]\}, \end{aligned} \tag{4.39} $$

if $x<0$. If $x>0$, we get a similar expression except that we must make the change $\sinh\beta \leftrightarrow \cosh\beta$.

In the spin-$\frac{1}{2}$ representation, we have

$$ J_-^2 = J_+^2 = 0, \quad J_+J_- = \frac{I}{2} + J_3 \quad \text{and} \quad J_-J_+ = \frac{I}{2} - J_3, \tag{4.40} $$

hence (4.39) becomes

$$\mathcal{H}_0 = w\left\{\left(a^\dagger a + \frac{I}{2}\right) - xJ_3 + |x|^{1/2}\cosh\beta[e^{i(\varphi_+ - \theta_-)}a^\dagger J_- + e^{-i(\varphi_+ - \theta_-)}aJ_+] \right.$$
$$\left. + |x|^{1/2}\sinh\beta[e^{i(\varphi_- - \theta_-)}a^\dagger J_+ + e^{-i(\varphi_- - \theta_-)}aJ_-] + (|x|\cosh(2\beta) - 1)\frac{I}{2}\right\} \quad (4.41)$$

and a similar expression when $x>0$, making the literal change $\sinh\beta \leftrightarrow \cosh\beta$. If we take $x = -w_0/w$, $\varphi_+ = \theta_-$ and the limit $\beta \mapsto 0$, then $\mathcal{H}_0 \equiv$ (4.41) becomes

$$\mathcal{H}_0 = w\left(a^\dagger a + \frac{1}{2}\right) + w_0 J_3 + \sqrt{ww_0}(a^\dagger J_- + aJ_+) + \frac{w - w_0}{2}I, \quad (4.42)$$

which is the Jaynes–Cummings Hamiltonian[16] up to a constant term and for a coupling constant given by $\kappa = \sqrt{ww_0}$. Let us recall that this Hamiltonian describes the interaction of a cavity mode (with frequency w) with a two level-system (w_0 being the atomic frequency). When $x=-1$, i.e., for $w=w_0$, (4.42) becomes the strong-coupling limit of the Jaynes–Cummings Hamiltonian.

In the case $\beta=0$, the new operator $\mathcal{A}_0 \equiv$ (4.16) reduces now to

$$\mathcal{A}_0(x) = \begin{cases} e^{i\theta_-}a + |x|^{1/2}e^{i\varphi_+}J_-, & \text{if } x<0, \\ e^{i\theta_-}a + |x|^{1/2}e^{i\varphi_-}J_+, & \text{if } x>0. \end{cases} \quad (4.43)$$

As we have here $b=0$, according to the expressions (3.18) and (3.19), the orthonormalized eigenstates of $\mathcal{A}_0$ are given by

$$|Z(x)\rangle_m^j = (\tilde{C}_m^j(x))^{1/2}D(ze^{-i\theta_-}) \times \sum_{k=0}^{j-m}(-1)^k\binom{j-m}{k}\frac{(2j-k)!}{(2j)!}(e^{-i\theta_-}a^\dagger)^{j-m-k}\left(J_\mp\frac{e^{-i\varphi_\mp}}{\sqrt{|x|}}\right)^k\left|0;j,\frac{x}{|x|}j\right\rangle, \quad (4.44)$$

where the $-$ sign refers to $x>0$ and the sign $+$ to $x<0$ and

$$\tilde{C}_m^j(x) = (j-m)!\sum_{k=0}^{j-m}\binom{j-m}{k}\frac{(2j-k)!}{(2j)!}\left(\frac{1}{|x|}\right)^k. \quad (4.45)$$

Since, in this case, we have

$${}_m^j\langle Z(x)|J_3|Z(x)\rangle_m^j = \frac{x}{|x|}\left[j + |x|\frac{\partial}{\partial|x|}\ln(\tilde{C}_m^j(x))\right], \quad (4.46)$$

the dispersion of $\mathcal{H}_0 = w\mathcal{A}_0^\dagger\mathcal{A}_0$ in the states (4.44) is given by

$$((\Delta\mathcal{H}_0)^2)_m^j = w^2|z|^2\left[1 + 2|x|j + 2|x|^2\frac{\partial}{\partial|x|}\ln(\tilde{C}_m^j(x))\right]. \quad (4.47)$$

When $m=j$, we have $\tilde{C}_m^j(x)=1$, so that we get

$$((\Delta\mathcal{H}_0)^2)_j^j = w^2|z|^2(1 + 2|x|j). \quad (4.48)$$

For example, when $j=\frac{1}{2}$, the dispersion corresponding to $m=\frac{1}{2}$ is given by

$$((\Delta\mathcal{H}_0)^2)_+ = w^2|z|^2(1 + |x|) \quad (4.49)$$

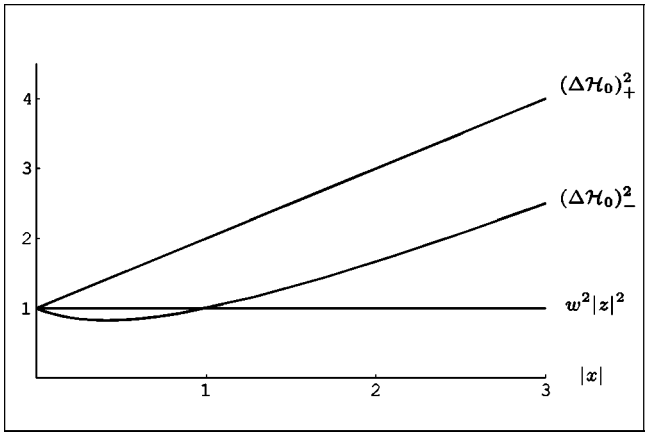

FIG. 8. Graphs of the dispersions $((\Delta\mathcal{H}_0)^2)_\pm$ as given by (4.49) and (4.50) as functions of $|x|$.

and one obtains the same result as in the preceding case when we take the limit $\beta\mapsto 0$. On the other hand, for $m=-1/2$, we get

$$((\Delta\mathcal{H}_0)^2)_-=w^2|z|^2\left[1+|x|\frac{(|x|-1)}{(|x|+1)}\right] \tag{4.50}$$

and it is always smaller than $((\Delta\mathcal{H}_0)^2)_+$. In this last case, we see that if $|x|>1$, the dispersion is bigger than $w^2|z|^2$, while if $|x|<1$ it is smaller than $w^2|z|^2$, and if $|x|=1$, it is equal to $w^2|z|^2$. Furthermore, the dispersion reaches its minimum $0.83w^2|z|^2$ when $|x|=(\sqrt{2}-1)$. Figure 8 shows the behavior of dispersions $((\Delta\mathcal{H}_0)^2)_\pm$ as function of $|x|$.

Let us finally mention that the Hamiltonian $\mathcal{H}_0$ in this case and for $j=\frac{1}{2}$ corresponds to (4.41) when $\beta=0$. A special case is again the Jaynes–Cummings Hamiltonian (4.42) so we get eigenstates of $\mathcal{A}_0\equiv$ (4.43) such that the dispersion of this Hamiltonian is minimized and lower than $w^2|z|^2$.

C. Generalized $h(1)\oplus su(2)$ noncanonical commutation relation

In the case where we have

$$[\mathcal{A},\mathcal{A}^\dagger]=I+\gamma J_+ +\overline{\gamma}J_-, \quad \gamma\in\mathbb{C}, \quad \gamma\neq 0. \tag{4.51}$$

According to (4.3), the necessary conditions on the original parameters are

$$|\alpha_-|^2-|\alpha|_+{}^2=1, \quad |\beta_-|=\beta_+, \quad \beta_3\overline{\beta}_+-\overline{\beta}_3\beta_-=\gamma=\rho e^{i\nu}, \tag{4.52}$$

where $\rho\in\mathbb{R}_+$. A suitable choice of the parameters is

$$\alpha_-=\cosh\alpha e^{i\theta_-}, \quad \alpha_+=\sinh\alpha e^{i\theta+}, \quad \beta_\pm=\beta e^{i\varphi_\pm}, \quad \beta_3=re^{i\varphi_3}, \quad \beta\neq 0, \ r\neq 0, \tag{4.53}$$

such that

$$r\beta[e^{i(\varphi_3-\varphi_+)}-e^{-i(\varphi_3-\varphi_+)}]=\rho e^{i\nu}. \tag{4.54}$$

Equation (4.54) implies that

$$\rho=2r\beta\left|\sin\left(\varphi_3-\frac{(\varphi_++\varphi_-)}{2}\right)\right| \tag{4.55}$$

and the following conditions on the phases: $\varphi_3 \neq (\varphi_+ + \varphi_-)/2$, $\varphi_3 \neq (\varphi_+ + \varphi_-)/2 + \pi$ and $\varphi_+ - \varphi_- = \pi - 2\nu, \nu \in [0, 3\pi/2]$ or $\varphi_+ - \varphi_- = 3\pi - 2\nu$, $\nu \in [\pi/2, 2\pi]$. Thus, the operator $\mathcal{A}$ compatible with all the previous conditions is

$$\mathcal{A} = \cosh \alpha e^{i\theta_-} a + \sinh \alpha e^{i\theta_+} a^\dagger + \alpha_3 I + e^{i(\varphi_- - \nu)} \left[\beta (e^{i\nu} J_+ - e^{-i\nu} J_-) + \frac{\rho}{2\beta |\cos\theta|} e^{i\theta} J_3 \right], \tag{4.56}$$

where

$$\theta = \varphi_3 - (\varphi_- - \nu), \quad -\frac{\pi}{2} < \theta < 3\frac{\pi}{2}. \tag{4.57}$$

The new operator $\mathcal{A}_0$ defined in (4.16) is then given by

$$\mathcal{A}_0 = e^{i\theta_-} a + e^{i(\varphi_- - \nu)} \left[-\beta (e^{i\nu} J_+ - e^{-i\nu} J_-) + \frac{\rho}{2\beta |\cos\theta|} e^{i\theta} J_3 \right]. \tag{4.58}$$

The parameter $b \equiv$ (3.16) is now $b = i\sqrt{16\beta^2 \cos^2(\theta) - \rho^2 e^{2i\theta}} e^{i(\varphi_- - \nu)}/(2\beta|\cos\theta|)$, i.e., $b = 0$ if and only if $\beta = \sqrt{\rho}/2$ and $\theta = \pi$.

Here we can proceed as before, that is, when $b = 0$, find, by means of the equation (3.20) the eigenstates of $\mathcal{A}_0$ and, when $b \neq 0$, find the solutions by means of the equation (3.17) and then calculate the dispersions of $\mathcal{H}_0$.

But, we will follow another treatment which teaches us about the similarities between the canonical and the noncanonical cases. Indeed, seen in another perspective, the commutation relation (4.51) can be expressed in the form

$$[\mathcal{A}_0, \mathcal{A}_0^\dagger] = I + 2\rho \mathbb{J}_3, \tag{4.59}$$

where we have set

$$\mathbb{J}_3 = \frac{(e^{i\nu} J_+ + e^{-i\nu} J_-)}{2}. \tag{4.60}$$

Thus, when $b = 0$, $\mathcal{A}_0$ becomes

$$\mathcal{A}_0 = e^{i\theta_-} a + \sqrt{\rho} e^{i(\varphi_- - \nu)} \mathbb{J}_+, \tag{4.61}$$

with

$$\mathbb{J}_\pm = \pm \frac{(e^{i\nu} J_+ - e^{-i\nu} J_-)}{2} - J_3. \tag{4.62}$$

The operators $\mathbb{J}_3$, $\mathbb{J}_\pm$ satisfy the su(2) algebra and let us denote by $|J, M\rangle$ the eigenstates of both $\mathbb{J}^2$ and $\mathbb{J}_3$. We have again

$$\mathbb{J}_3 |J, M\rangle = M |J, M\rangle, \quad \mathbb{J}_\pm |J, M\rangle = \sqrt{(J \mp M)(J \pm M + 1)} |J, M\rangle. \tag{4.63}$$

Now, it is clear that the resolution of the problem to find the eigenstates of $\mathcal{A}_0$ is similar to the canonical case. Indeed, the normalized eigenstates of $\mathcal{A}_0$ are given by

$$|Z(\rho)\rangle_M^J=(\tilde{C}_M^J(\rho))^{1/2}D(ze^{-i\theta_-})\times\sum_{k=0}^{J-M}(-1)^k\binom{J-M}{k}\frac{(2J-k)!}{(2J)!}(e^{-i\theta_-}a^\dagger)^{J-M-k}\left(\frac{\mathbb{J}_-e^{-i(\varphi_--\nu)}}{\sqrt{\rho}}\right)^k|0;J,J\rangle, \tag{4.64}$$

where $\tilde{C}_M^J(\rho)$ is given as in (4.45).

As before, the dispersion of $\mathcal{H}_0$ in the states (4.64) is given by

$$((\Delta\mathcal{H}_0)^2)_M^J=w^2|z|^2\left[1+2J\rho+2\rho^2\frac{\partial}{\partial\rho}\ln(\tilde{C}_M^J(\rho))\right]. \tag{4.65}$$

For example, when $J=\frac{1}{2}$, we have

$$((\Delta\mathcal{H}_0)^2)_+=w^2|z|^2(1+\rho),\quad((\Delta\mathcal{H}_0)^2)_-=w^2|z|^2\left[1+\rho\frac{(\rho-1)}{(\rho+1)}\right]. \tag{4.66}$$

Evidently, the behavior of these dispersions as functions of ρ is identical to that described in the last paragraph of the previous section.

In the general case where $b\neq0$, $\mathcal{A}_0$ can be expressed in the form

$$\mathcal{A}_0=e^{i\theta_-}a+e^{i(\varphi_--\nu)}\left\{\left[\frac{4\beta^2|\cos\theta|-\rho e^{i\theta}}{4\beta|\cos\theta|}\right]\mathbb{J}_+-\left[\frac{4\beta^2|\cos\theta|+\rho e^{i\theta}}{4\beta|\cos\theta|}\right]\mathbb{J}_-\right\}. \tag{4.67}$$

From (3.17), we see that the eigenstates of $\mathcal{A}_0$ are

$$|Z\rangle_M^J=(C_m^j)^{-1/2}D(ze^{-i\theta_-})T_{\text{eff}}|0;J,M\rangle, \tag{4.68}$$

where

$$T_{\text{eff}}=e^{\Phi_-\mathbb{J}_+}e^{\Phi_+\mathbb{J}_-}, \tag{4.69}$$

with

$$\Phi_-=i\frac{[4\beta^2|\cos\theta|-\rho e^{i\theta}]}{R^{1/2}e^{i\tilde{\varphi}/2}},\quad\Phi_+=i\frac{[4\beta^2|\cos\theta|+\rho e^{i\theta}]}{2R^{1/2}e^{i\tilde{\varphi}}/2}. \tag{4.70}$$

The dispersion of $\mathcal{H}_0$ in these states is

$$((\Delta\mathcal{H}_0)^2)_M^J=w^2|z|^2[1+2\rho_M^J\langle Z|\mathbb{J}_3|Z\rangle_M^J], \tag{4.71}$$

where[17]

$${}_M^J\langle Z|\mathbb{J}_3|Z\rangle_M^J=M\left(\frac{1-|\Phi_-|^2}{1+|\Phi_-|^2}\right)+\frac{(J-M+1)}{2}\frac{P_{J+M-1}^{1,-2M+1}(\Lambda)}{P_{J+M}^{0,-2M}(\Lambda)}\tilde{\Lambda}, \tag{4.72}$$

with

$$\Lambda=1+2|\Phi_-+\bar{\Phi}_+(1+|\Phi_-|^2)|^2 \tag{4.73}$$

and

$$\tilde{\Lambda}=2[|\Phi_-|^2(1+\Phi_-\Phi_++\bar{\Phi}_-\bar{\Phi}_+)+|\Phi_+|^2(|\Phi_-|^4-1)]. \tag{4.74}$$

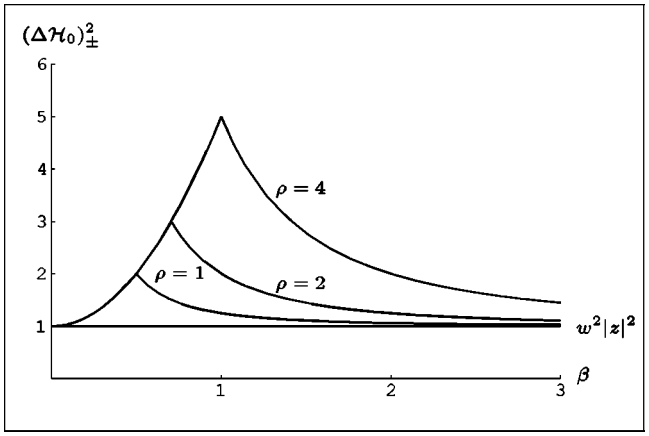

FIG. 9. Graphs of the dispersions $((\Delta\mathcal{H}_0)^2)_\pm \equiv$ (4.76) as functions of $\beta>0$, $\theta=\pi$ and $\rho=1,2,4$.

Thus, in the spin-$\frac{1}{2}$ representation, we get

$$ {}_\pm\langle Z|\mathbb{J}_3|Z\rangle_\pm = \frac{1}{2}\left(\frac{|\Phi_-|^2-1}{1+|\Phi_-|^2}\right). \tag{4.75}$$

Finally, by direct computation, we find

$$((\Delta\mathcal{H}_0)^2)_\pm = w^2|z|^2\left[1+\rho\frac{[16\beta^4\cos^2(\theta)+\rho^2-8\rho\beta^2\cos\theta|\cos\theta|]-R}{[16\beta^4\cos^2(\theta)+\rho^2-8\rho\beta^2\cos\theta|\cos\theta|]+R}\right], \tag{4.76}$$

where

$$R=\sqrt{[16\beta^4\cos^2(\theta)-\rho^2\cos(2\theta)]^2+\rho^4\sin^2(2\theta)}. \tag{4.77}$$

We see that, for fixed value of ρ, Eq. (4.76) as a function of β is symmetric around $\theta=\pi$.

Figure 9 shows the behavior of the dispersions (4.76) as functions of $\beta>0$ when $\theta=\pi$ and for different values of parameter ρ. Let us notice the similarity between these curves starting from a certain value of β and the curves for the canonical case showed in Fig. 7.

Figure 10 shows the behavior of the same functions as functions of $\beta>0$, for different values

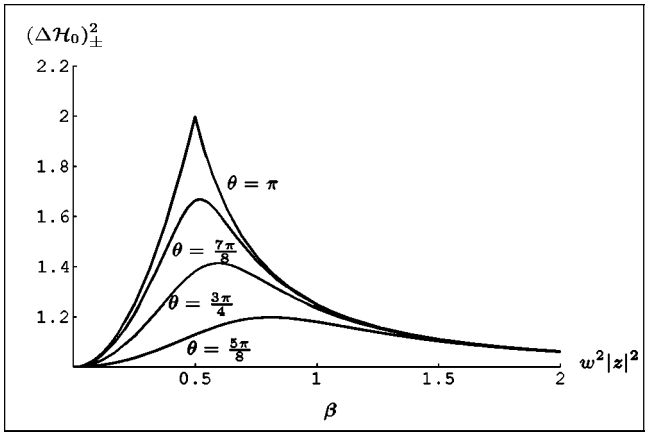

FIG. 10. Graphs of the dispersions $((\Delta\mathcal{H}_0)^2)_\pm \equiv$ (4.76) as functions of $\beta>0$ for $\rho=1$. $\theta=5\pi/8$, $3\pi/4$, $7\pi/8$ and π.

of θ when $\rho=1$. We observe that when the angle θ is different from π the curves have a continuous derivative with respect to β but, when the angle $\theta=\pi$, the derivative of the curve at the point $\beta=0.5=\sqrt{\rho}/2$ is not continuous.

APPENDIX A: ALGEBRA EIGENSTATES ASSOCIATED TO su(2)

In this appendix we want to solve the eigenvalue equation

$$[\vec{\beta}\cdot\vec{J}]|\psi\rangle=[\beta_1 J_1+\beta_2 J_2+\beta_3 J_3]|\psi\rangle=\Gamma|\psi\rangle,\quad \beta_1,\beta_2,\beta_3\in\mathbb{C}, \tag{A1}$$

where J_1, J_2 and J_3 are the su(2) generators which have already been given in Sec. II C. The eigenvalue equation (A1) can also be written as

$$[\beta_- J_+ +\beta_+ J_- +\beta_3 J_3]|\psi\rangle=\Gamma|\psi\rangle, \tag{A2}$$

where J_1 and J_2 have been expressed in terms of the usual operators $J_\pm$ and

$$\beta_\pm=\frac{\beta_1\pm i\beta_2}{2}. \tag{A3}$$

We see that Eq. (2.45) is just a particular case of Eq. (A2). The eigenvalue equation (A2) has already been solved by Brif[8] by expanding the state $|\psi\rangle$ in the standard coherent-state basis[9], introducing in this way analytic functions and asking for solving a first order differential equation. Here, we consider a different method based on the operator algebra technique.

For j fixed, we can show that (A2) admits the eigenvalues

$$\Gamma^j_m=mb, \tag{A4}$$

with $m=-j,\ldots,j$ and $b=\sqrt{\beta_1^2+\beta 0_2^2+\beta_3^2}=\sqrt{4\beta_+\beta_-+\beta_3^2}$. We then solve

$$[\beta_- J_+ +\beta_+ J_- +\beta_3 J_3]|\psi\rangle^j_m=\Gamma^j_m|\psi\rangle^j_m, \tag{A5}$$

by using

$$|\psi\rangle^j_m=(N^j_m)^{-1/2}T|j,m\rangle, \tag{A6}$$

where the N^j_m are normalization constants and T is an operator that has to be determined. We take it as

$$T=\exp\left(-\frac{\tilde{\theta}}{2}[e^{-i\tilde{\phi}}J_+ -e^{i\tilde{\phi}}J_-]\right),\quad \tilde{\phi},\tilde{\theta}\in\mathbb{C}. \tag{A7}$$

Inserting (A6) with (A7) into (A5) leads to

$$[\vec{\beta}\cdot\vec{J}]T|j,m\rangle=mbT|j,m\rangle. \tag{A8}$$

Using the usual decomposition

$$T=\exp\left(-e^{-i\tilde{\phi}}\tan\left(\frac{\tilde{\theta}}{2}\right)J_+\right)\quad \exp\left(\ln\sec^2\left(\frac{\tilde{\theta}}{2}\right)J_3\right)\quad \exp\left(e^{i\tilde{\phi}}\tan\left(\frac{\tilde{\theta}}{2}\right)J_-\right) \tag{A9}$$

and the relations

$$e^{\eta J_3} J_\pm e^{-\eta J_3} = e^{\pm \eta} J_\pm, \quad e^{\eta J_\pm} J_3 e^{-\eta J_\pm} = J_3 \mp \eta J_\pm, \quad e^{\eta J_\pm} J_\mp e^{-\eta J_\pm} = J_\mp \pm 2\eta J_3 - \eta^2 J_\pm, \tag{A10}$$

we can show that, for $\beta_+ \neq 0$, $\beta_- \neq 0$ and $b \neq 0$, we have

$$e^{i\tilde{\phi}} = \sqrt{\frac{\beta_+}{\beta_-}}, \tag{A11}$$

and

$$\frac{\tilde{\theta}}{2} = \arctan\left(\sqrt{\frac{b-\beta_3}{b+\beta_3}} \right). \tag{A12}$$

Inserting the results (A11) and (A12) in (A9), we obtain

$$T = \exp\left(-\frac{2\beta_-}{b+\beta_3} J_+ \right) \exp\left(\ln\left(\frac{2b}{b+\beta_3} \right) J_3 \right) \exp\left(\frac{2\beta_+}{b+\beta_3} J_- \right). \tag{A13}$$

The original form (A7) of the T operator allows us to look easily for the special cases studied in Refs. 6, and 9 and in the preceding sections while the form (A13) allows us to calculate directly the explicit form of the eigenstates (A6). Indeed, the first relation (A10) allows us to pass the exponential term $\exp(\ln(2b/(b+\beta_3))J_3)$ to the right in (A13) and this without changing essentially the operator action on the pure states $|j,m\rangle$ because $|j,m\rangle$ is an eigenstate of the operator J_3. Thus, in Eq. (A6), we can replace the operator T by the operator

$$T_{\text{eff}} = \left(\frac{b}{\beta_+} \right)^{j+m} \sqrt{\frac{(j+m)!(j-m)!}{(2j)!}} \exp\left(-\frac{2\beta_-}{b+\beta_3} J_+ \right) \exp\left(\frac{\beta_+}{b} J_- \right), \tag{A14}$$

such that

$$|\psi\rangle_m^j = (\tilde{N}_m^j)^{-1/2} T_{\text{eff}} |j,m\rangle, \tag{A15}$$

where $\tilde{N}_m^j$ are new normalization constants. Redefining the summation indices, we get

$$|\psi\rangle_m^j = (\tilde{N}_m^j)^{-1/2} \sum_{u=-j}^{j} \sqrt{\frac{(j+u)!(j-u)!}{(2j)!}} \left(\frac{b}{\beta_+} \right)^{j+u} \frac{(j+m)!}{(j-u)!} \times \sum_{n=0}^{j+u} (-1)^n \frac{(j-u+n)!}{n!(m-u+n)!(j+u-n)!} \left(\frac{(1-\beta_3/b)}{2} \right)^n |j,u\rangle. \tag{A16}$$

We also have an expression in terms of the Jacobi polynomials (see Ref. 18):

$$|\psi\rangle_m^j = (\tilde{N}_m^j)^{-1/2} \sum_{u=-j}^{j} \sqrt{\frac{(j+u)!(j-u)!}{(2j)!}} \left(\frac{b}{\beta_+} \right)^{j+u} P_{j+u}^{-u+m,-u-m} \left(\frac{\beta_3}{b} \right) |j,u\rangle, \tag{A17}$$

which is the result obtained by Brif.[8]

For the special case where $\beta_+ = 0$, $\beta_3 \neq 0$ so that, in connection with (A4), we have $b = \beta_3$, we find the operator

$$T_{\text{eff}} = \exp\left(-\frac{\beta_-}{\beta_3} J_+ \right). \tag{A18}$$

The eigenstates are

$$|\psi\rangle_m^j=(C_m^j)^{-1/2}\sum_{u=m}^{j}\sqrt{\frac{(j+u)!}{(j-u)!}}\frac{1}{(u-m)!}\left(-\frac{\beta_-}{\beta_3}\right)^{u-m}|j,u\rangle, \tag{A19}$$

and become the standard CS of SU(2) (Ref. 9) when $m=-j$.

For the special case where $\beta_-=0$, $\beta_3\neq 0$, we have similar results. Indeed, the new operator T_{eff} is

$$T_{\text{eff}}=\exp\left(\frac{\beta_+}{\beta_3}J_-\right) \tag{A20}$$

and the eigenstates write

$$|\psi\rangle_m^j=(C_m^j)^{-1/2}\sum_{u=-j}^{m}\sqrt{\frac{(j-u)!}{(j+u)!}}\frac{1}{(m-u)!}\left(\frac{\beta_+}{\beta_3}\right)^{u-m}|j,u\rangle, \tag{A21}$$

which become the standard CS of SU(2) (Ref. 9) when $m=j$.

Now, for the case $\beta_+=0$ and $\beta_3=0$ ($\beta_-=0$ and $\beta_3=0$), the only normalizable solution is $|j,-j\rangle$ ($|j,j\rangle$). For $\beta_+=\beta_-=0$ and $\beta_3\neq 0$, the AES are evidently the pure states $|j,m\rangle$.

Finally, the degenerate case $b=0$ leads to the solution $|\psi\rangle_{-j}^j=(C_{-j}^j)^{-1/2}T_{\text{eff}}|j,-j\rangle$ with $T_{\text{eff}}=\exp(-2(\beta_-/\beta_3)J_+)$, that is the standard CS of SU(2).

The mean value of J_3 in the states (A17) has already been calculated by Brif.[8] We have

$$\langle J_3\rangle_m^j=\frac{jY+m(S_+-S_-)}{S_+S_-}-\frac{(j+|m|)Yt}{S_+^2S_-^2}\Omega, \tag{A22}$$

where

$$S_\pm=1+\left|\frac{2\beta_-}{\beta_3\mp b}\right|^2,\quad t=\left|\frac{b}{\beta_+}\right|^2,\quad Y=S_+S_--S_+-S_- \tag{A23}$$

and

$$\Omega=\frac{P_{j-|m|-1}^{(-2j,1)}(1-(2t/S_+S_-))}{P_{j-|m|}^{(-2j-1,0)}(1-(2t/S_+S_-))},\quad \text{if } |m|<j;\quad \Omega=0,\quad \text{if } |m|=j. \tag{A24}$$

APPENDIX B: RESOLUTION OF A FIRST ORDER SYSTEM OF DIFFERENTIAL EQUATIONS

Let us recall that a realization[9] of the Fock space $\mathcal{F}_b=\{|n\rangle,n=0,1,2,\dots\}$ of energy eigenstates of the harmonic oscillator as a space $\mathcal{H}$ of analytic functions $f(\zeta)$ is obtained by expanding this function in the basis of analytic functions $\{\varphi_n(\zeta)=\zeta^n/\sqrt{n!},n=0,1,2,\dots\}$, that is,

$$f(\zeta)=\sum_{n=0}^{\infty}c_n\varphi_n(\zeta)=\sum_{n=0}^{\infty}c_n\frac{\zeta^n}{\sqrt{n!}},\quad \zeta\in\mathbb{C}. \tag{B1}$$

The scalar product is

$$(f_1,f_2)=\int_C\overline{f_1}(\zeta)f_2(\zeta)e^{-|\zeta|^2}\frac{d\zeta\,d\overline{\zeta}}{2\pi i},\quad \forall f_1,f_2\in\mathcal{H}, \tag{B2}$$

the integral being extended to the complex plane. The action of the creation $a^\dagger$ and annihilation a operators on the $\mathcal{H}$ space is then given by

$$a^\dagger \equiv \zeta, \quad a \equiv \frac{d}{d\zeta}. \tag{B3}$$

The eigenvalue equation (2.26) thus becomes a first order differential equation

$$\frac{1}{\sqrt{2}}\left((1+\lambda)\frac{d}{d\zeta}+(1-\lambda)\zeta\right)f(\zeta)=\beta f(\zeta), \tag{B4}$$

for which normalized solutions are obtained for $\lambda \neq -1$. The general solution of (B4) is

$$f(\zeta)=f(0)\exp\left(\frac{2\sqrt{2}\beta\zeta-(1-\lambda)\zeta^2}{2(1+\lambda)}\right). \tag{B5}$$

With respect to the scalar product (B2), the normalization constant $f(0)$ is computed by imposing

$$\int_C |f(\zeta)|^2 e^{-|\zeta|^2}\frac{d\zeta\, d\overline{\zeta}}{2\pi i}=1, \tag{B6}$$

and we find the normalized solution of (B4) as

$$f(\zeta)=(1-|\eta_1|^2)^{1/4}\exp\left(-\frac{1}{2}\left[\frac{|\eta_2|^2-\mathrm{Re}(\overline{\eta}_1\eta_2^2)}{1-|\eta_1|^2}\right]\right)\exp\left(\eta_2\zeta-\frac{\eta_1}{2}\zeta^2\right), \tag{B7}$$

with

$$\eta_1=\frac{(1-\lambda)}{(1+\lambda)}=\delta e^{i\phi} \quad \text{and} \quad \eta_2=\frac{\sqrt{2}\beta}{(1+\lambda)}=\frac{\beta}{\sqrt{2}}(1+\delta e^{i\phi}). \tag{B8}$$

This corresponds to the states (2.33) after normalization.

Now we are concerned with the algebra eigenstates satisfying the equation (3.10) in the Fock space $\mathcal{F}\equiv$ (3.4). A realization of $\mathcal{F}$ can be easily given from the preceding considerations and the expression (3.12) of a state $|\psi\rangle$ for a fixed j. Indeed, we have

$$\psi^j_m(\zeta)=\langle \zeta; j,m|\psi\rangle \tag{B9}$$

and the eigenvalue equation (3.10) then becomes a system of first order differential equations

$$\begin{aligned}\left(\alpha_- \frac{d}{d\zeta}+\alpha_+\zeta+\alpha_3\right)\psi^j_m(\zeta)+[\beta_-\sqrt{(j-m+1)(j+m)}\,\psi^j_{m-1}(\zeta)\\ +\beta_+\sqrt{(j+m+1)(j-m)}\,\psi^j_{m+1}(\zeta)+\beta_3 m\,\psi^j_m(\zeta)]=\beta\psi^j_m(\zeta),\end{aligned} \tag{B10}$$

where j is fixed but m takes the values $-j,\ldots,j$. Let us now solve this system by first introducing the differential operator

$$L=\alpha_-\frac{d}{d\zeta}+\alpha_+\zeta+\alpha_3-\beta \tag{B11}$$

and, second, defining the vector

$$\Psi=\begin{pmatrix}\psi^j_{-j}\\ \psi^j_{-j+1}\\ \vdots\\ \psi^j_{j-1}\\ \psi^j_j\end{pmatrix}. \tag{B12}$$

The system (B10) thus becomes a matrix differential system

$$L\Psi=-A\Psi, \tag{B13}$$

with A a $(2j+1)\times(2j+1)$ matrix given by

$$A=\begin{pmatrix}
-j\beta_3 & \sqrt{2j}\beta_+ & 0 & 0 & \cdots & 0\\
\sqrt{2j}\beta_- & (-j+1)\beta_3 & \sqrt{(2j-1)2}\beta_+ & 0 & \cdots & 0\\
0 & \sqrt{(2j-1)2}\beta_- & (-j+2)\beta_3 & \sqrt{(2j-2)3}\beta_+ & \cdots & 0\\
\vdots & \vdots & \vdots & \ddots & \cdots & \vdots\\
0 & 0 & \sqrt{(2j-2)3}\beta_- & (j-2)\beta_3 & \sqrt{(2j-1)2}\beta_+ & 0\\
0 & 0 & 0 & \sqrt{(2j-1)2}\beta_- & (j-1)\beta_3 & \sqrt{2j}\beta_+\\
0 & 0 & 0 & 0 & \sqrt{2j}\beta_- & j\beta_3
\end{pmatrix}. \tag{B14}$$

If we can find a nonsingular matrix S that diagonalizes A on the form $D=S^{-1}AS$ where

$$D=\mathrm{diag}(\lambda^j_{-j},\lambda^j_{-j+1},\cdots,\lambda^j_j), \tag{B15}$$

the system (B13) will reduce to

$$L\tilde{\Psi}=-D\tilde{\Psi},\quad \tilde{\Psi}=S^{-1}\Psi. \tag{B16}$$

Thus, for $\alpha_-\neq 0$, the direct integration of (B16) will lead to

$$\tilde{\psi}^j_m=\tilde{\psi}^j_m(0)\exp\left(\frac{\beta-\alpha_3-\lambda^j_m}{\alpha_-}\zeta-\frac{\alpha_+}{2\alpha_-}\zeta^2\right) \tag{B17}$$

and the general solution Ψ will be obtained as

$$\begin{pmatrix}\psi^j_{-j}\\ \psi^j_{-j+1}\\ \vdots\\ \psi^j_{j-1}\\ \psi^j_j\end{pmatrix}=S\begin{pmatrix}\tilde{\psi}^j_{-j}\\ \tilde{\psi}^j_{-j+1}\\ \vdots\\ \tilde{\psi}^j_{j-1}\\ \tilde{\psi}^j_j\end{pmatrix}=\sum_{m=-j}^{j}\tilde{\psi}^j_m(0)\exp\left(\frac{\beta-\alpha_3-\lambda^j_m}{\alpha_-}\zeta-\frac{\alpha_+}{2\alpha_-}\zeta^2\right)\begin{pmatrix}S_{-j,m}\\ S_{-j+1,m}\\ \vdots\\ S_{j-1,m}\\ S_{j,m}\end{pmatrix}, \tag{B18}$$

where S is assumed to be of the form

$$S=\begin{pmatrix} S_{-j,-j} & S_{-j,-j+1} & \cdots & S_{-j,j-1} & S_{-j,j} \\ S_{-j+1,-j} & S_{-j+1,-j+1} & \cdots & S_{-j+1,j-1} & S_{-j+1,j} \\ \vdots & \vdots & \cdots & \vdots & \vdots \\ S_{j-1,-j} & S_{j-1,-j+1} & \cdots & S_{j-1,j-1} & S_{j-1,j} \\ S_{j,-j} & S_{j,-j+1} & \cdots & S_{j,j-1} & S_{j,j} \end{pmatrix}. \tag{B19}$$

Computing the eigenvalues of A, we find that we have to distinguish two cases, i.e., the one with $b=\sqrt{4\beta_+\beta_-+\beta_3^2}\neq 0$ and the one with $b=0$. For the first case $b\neq 0$, all eigenvalues are different and given by

$$\lambda_m^j=mb, \quad m=-j,\cdots,j. \tag{B20}$$

The system is diagonalizable and the general solution is given by (B18) with

$$S_{u,m}=\sqrt{\frac{(j+u)!(j-u)!}{(2j)!}}\left(\frac{b}{\beta_+}\right)^{j+u}P_{j+u}^{-u+m,-u-m}\left(\frac{\beta_3}{b}\right), \quad u=-j,\cdots,j, \tag{B21}$$

when $\beta_-\neq 0$, $\beta_+\neq 0$ and $\beta_3\neq 0$,

$$S_{u,m}=\sqrt{\frac{(j-u)!}{(j+u)!}}\frac{1}{(m-u)!}\left(\frac{\beta_+}{\beta_3}\right)^{u-m}, \quad -j\leqslant u\leqslant m, \quad S_{u,m}=0, \quad m<u\leqslant j, \tag{B22}$$

when $\beta_-=0$, $\beta_+\neq 0$ and $\beta_3\neq 0$ and

$$S_{u,m}=\sqrt{\frac{(j+u)!}{(j-u)!}}\frac{1}{(u-m)!}\left(-\frac{\beta_-}{\beta_3}\right)^{u-m}, \quad m\leqslant u\leqslant j, \quad S_{u,m}=0, \quad -j\leqslant u<m, \tag{B23}$$

when $\beta_-\neq 0$, $\beta_+=0$ and $\beta_3\neq 0$.

In the Fock space representation, the solutions (B18) with (B21), (B22) and (B23) correspond, apart from a superfluous change of notation, exactly to the states (3.17) with T_{eff} given by (A14), (A18), and (A20), respectively.

For the second case $b=0$, the matrix A can not be diagonalized. We could use the Jordan form or start from the differential equation system again and include this condition. Taking the second way, we can express the $\psi_m^j(\zeta)$ components in the form

$$\psi_m^j(\zeta)=\exp\left[-\frac{\alpha_+}{2\alpha_-}\zeta^2+\frac{(\beta-\alpha_3-m\beta_3)}{\alpha_-}\zeta\right]\tilde{\psi}_m^j(\zeta), \tag{B24}$$

and insert these in Eq. (B10). We get to the following system:

$$\alpha_-\frac{d}{d\zeta}\tilde{\psi}_m^j(\zeta)+\beta_-\sqrt{(j-m+1)(j+m)}e^{\beta_3\zeta/\alpha_-}\tilde{\psi}_{m-1}^j(\zeta) + \beta_+\sqrt{(j+m+1)(j-m)}e^{-\beta_3\zeta/\alpha_-}\tilde{\psi}_{m+1}^j(\zeta)=0, \tag{B25}$$

when $m=-j,\ldots,j$. By handling these equations suitably we can, for example, obtain an ordinary differential equation of the $2j+1$ order for $\tilde{\psi}_{-j}^j(\zeta)$, namely

$$\left[\prod_{-j}^{j}\left(\frac{d}{d\zeta}-\mu_m^j\right)\right]\tilde{\psi}_{-j}^j(\zeta)=0, \tag{B26}$$

where

$$\mu_m^j = -j\frac{\beta_3}{\alpha_-} + m\frac{b}{\alpha_-}. \tag{B27}$$

When $b=0$, we have $2j+1$ equal roots. This means that the solutions for $\tilde{\psi}^j_{-j}(\zeta)$ take the form:

$$\tilde{\psi}^j_{-j}(\zeta) = \exp\left(\frac{-j\beta_3\zeta}{\alpha_-}\right)\sum_{q=0}^{2j} A_q\zeta^q. \tag{B28}$$

Then, we can insert (B28) in (B25) and thus obtain, in an iterative way, all solutions $\tilde{\psi}^j_m(\zeta)$ and, thereafter, using (B24), all solutions $\psi^j_m(\zeta)$.

For example, in the case $\beta_+=\beta_3=0$ and $\beta_-\neq 0$, we have

$$\tilde{\psi}^j_{-j}(\zeta) = \psi^j_{-j}(0), \tag{B29}$$

i.e., a constant and, consequently, by integrating one by one the equations of the system (B25), we obtain

$$\tilde{\psi}^j_m(\zeta) = \sum_{k=0}^{j+m}\left(-\frac{\beta_-}{\alpha_-}\right)^k\frac{\zeta^k}{k!}\sqrt{\frac{(j+m)!(j-m+k)!}{(j-m)!(j+m-k)!}}\,\psi^j_{m-k}(0), \tag{B30}$$

when $m=-j,\ldots,j$. The general solution (B12) is then given by

$$\Psi = \exp\left[-\frac{\alpha_+}{2\alpha_-}\zeta^2 + \frac{(\beta-\alpha_3)}{\alpha_-}\zeta\right]\sum_{m=-j}^{j}\psi^j_m(0)$$
$$\times\left[\sum_{k=0}^{j-m}\frac{(-1)^k}{k!}\sqrt{\frac{(j-m)!(j+m+k)!}{(j-m-k)!}}\left(\frac{\beta_-}{\alpha_-}\right)^k\zeta^k\begin{pmatrix}0\\ \vdots\\ 0\\ 1\\ 0\\ \vdots\\ 0\end{pmatrix}\right], \tag{B31}$$

where, in each sum, the 1 in the vector column is placed in the $(j+m+k+1)$ row. We thus obtain the $(2j+1)$ independent solutions of the system of differential equations.

In the Fock space representation, we can show that the independent solutions given by Eq. (B31) correspond, apart from a superfluous change of notation, to the states (3.18). In the case $\beta_-=\beta_3=0$ with $\beta_+\neq 0$, following a similar procedure, one finds the expression (3.19).

Finally, when β_+, β_-, $\beta_3\neq 0$, by inserting (B28) in (B25) and ordering the independent solutions with respect to the arbitrary constants A_q, one finds

$$\Psi(\zeta) = \exp\left[-\frac{\alpha_+}{2\alpha_-}\zeta^2 + \frac{(\beta-\alpha_3)}{\alpha_-}\zeta\right]\sum_{q=0}^{2j}A_q$$
$$\times\left[\sum_{k=0}^{q}(-1)^k\binom{q}{k}\frac{(2j-k)!}{(2j)!}\zeta^{q-k}\left(\frac{\alpha_-}{\beta_+}\right)^k\left[\frac{d^k}{d\vartheta^k}\sum_{r=0}^{2j}\sqrt{\frac{(2j)!}{(2j-r)!r!}}\,\vartheta^r\right]\begin{pmatrix}0\\ \vdots\\ 1\\ \vdots\\ 0\end{pmatrix}\right], \tag{B32}$$

where $\vartheta=\beta_3/2\beta_+=-2\beta_-/\beta_3$ and, in each sum, the 1 in the vector column is placed in the $r+1$ row. In the Fock space representation, these solutions, with a slight change of notation, correspond to Eq. (3.20).

Reversing quantum dynamics with near-optimal quantum and classical fidelity

H. Barnum[a] and E. Knill[b]
Los Alamos National Laboratories, Los Alamos, New Mexico 87545

(Received 23 May 2001; accepted for publication 24 January 2002)

We consider the problem of reversing quantum dynamics, with the goal of preserving an initial state's quantum entanglement or classical correlation with a reference system. We exhibit an approximate reversal operation, adapted to the initial density operator and the ''noise'' dynamics to be reversed. We show that its error in preserving either quantum or classical information is no more than twice that of the optimal reversal operation. Applications to quantum algorithms and information transmission are discussed. © *2002 American Institute of Physics.*

I. INTRODUCTION

Counteracting the effects on quantum systems of noise generated by interaction with an environment is a central problem for the emerging field of quantum information processing. Its solution can be expected to have applications in quantum computation, precision measurement, and information transmission. In this paper we exhibit a reversal operation which takes account of both the noise and the initial density operator, to achieve near-optimal preservation of the initial density operator's quantum entanglement or classical correlation with a reference system. We work throughout with finite-dimensional systems although we expect that the results generalize to infinite-dimensional ones, at least those with separable Hilbert spaces.

Section II reviews some of the theory of completely positive (CP) linear maps on spaces of operators on finite-dimensional Hilbert spaces. When these are trace-nonincreasing, they are also known in the quantum information/computation community as ''quantum operations.'' Readers familiar with these matters may wish to skip Sec. II, or skim it for notation. [The only notation not standard in quantum information theory is our writing $\mathcal{A}\sim\{A_i\}$ to indicate that a CP-map acts as $\mathcal{A}(\rho)=\Sigma_i A_i\rho A_i^\dagger$.] Section III reviews measures of fidelity commonly used in quantum information theory to quantify the effect of noise and information-processing operations on a system's state, or an ensemble of system states. In addition, it motivates the particular measures we use, and indicates their connection to fidelity measures used in classical information-transmission theory. It also explains why, although our measures of quantum fidelity concentrate on preserving the correlation or entanglement of a mixed state, subjected to noise, with a reference system, it is relevant to the preservation of an ensemble of pure states as well. This section includes several formal definitions required in the rest of the paper. Sections IV and VI are the core of the paper, containing the two main results. In Sec. IV the near-optimal reversal operation is defined, and we prove one of our main results: that its error is no worse than twice that of the optimal reversal operation, for either quantum or classical information. Section V discusses the relationship of the reversal operation to a known near-optimal method of recovering classical information encoded in an ensemble of density operators, the ''pretty good measurement.'' When the noise can be viewed as encoding classical information in a completely decohered ensemble of density operators, our reversal operation can be viewed as performing the pretty-good measurement to distinguish these density operators. But when the noise operation may be viewed as encoding classical information

[a]Electronic mail: barnum@lanl.gov
[b]Electronic mail: knill@lanl.gov

into these density operators in a way which leaves some coherence between them, our reversal operation writes a nearly optimal estimate of the density operator into a set of orthogonal states *without* decohering these states as a measurement would. Section VI proves the other main result of the paper: a useful lower bound on the fidelity with which the reversal operation recovers classical information. This bound can be more tractable than the reversal operation's fidelity itself, and has proven useful, for example, in discovering upper bounds on quantum query complexity. This and other applications are touched on in the concluding section.

II. QUANTUM NOISE OPERATIONS

We model quantum noise in a system Q by the most general dynamics that can arise via a unitary interaction U^{QE} with an environment E initially independent of the system, in the sense that the initial joint density matrix of system and environment is a product $\rho^Q \otimes \sigma^E$. We also model operations performed on a system in an attempt to counteract noise by such dynamics. For our purposes, where we ultimately care about the effect of operations on the system, and perhaps on its entanglement with systems other than the environment, we may model these with the environment starting in a pure state because the effect *on the system* of interaction with a mixed state σ of E via U^{QE} can be replicated by an interaction $U^{QE_1} \otimes I^{E_2}$ with a pure state $|0\rangle$ of an environment $E = E_1 \otimes E_2$, whose partial trace onto E_1 is equal to σ.

The dynamics thus obtained are trace-preserving completely positive maps $\mathcal{A}: \rho \mapsto \Sigma_i A_i \rho A_i^\dagger$, on the space of linear operators on Q. They are also trace-preserving; equivalently, $\Sigma_i A_i^\dagger A_i = I$. Here

$$A_i := \langle i^E | U^{QE} | 0^E \rangle \tag{1}$$

are the ''operator matrix elements'' of the unitary interaction, between the environment initial state and states $|i^E\rangle$ forming an orthonormal basis for the environment. It should be clear what this means, but to be explicit, we define the operator matrix element $\langle \chi^A | O^{AB} | \psi^{AB} \rangle$ of an operator O^{AB} on the tensor product space $A \otimes B$. Let the matrix elements of O in some tensor product basis $|i^A\rangle |j^B\rangle$ be $O_{ij,i'j'}$, and let χ_i and ψ_i be the components of $|\chi\rangle$ and $|\psi\rangle$ in the basis $|i^A\rangle$. Then the operator matrix element just mentioned is the operator X on B whose matrix elements in the basis $|j^B\rangle$ are given by

$$\langle j | X | j' \rangle = \sum_{i,i'} \chi_i^* \psi_{i'} O_{ij,i'j'}. \tag{2}$$

$A_i |\psi\rangle$ is what is often called the (unnormalized) ''relative state'' of the system Q—relative, that is, to the environment basis state $|i^E\rangle$. The overall evolution of system and environment is $|\psi^Q\rangle |0^E\rangle \to U^{QE} |\psi^Q\rangle |0^E\rangle = \Sigma_i A_i^Q |\psi^Q\rangle |i^E\rangle$. The fact that the overall state remains normalized (so that the density matrix's trace is preserved) results in the requirement $\Sigma_i A_i^\dagger A_i = I$ on a trace-preserving quantum operation.

If the environment were considered as a measuring apparatus, and the states of the basis $|i^E\rangle$ the ''pointer variable'' of that apparatus, so that each value of $|i\rangle$ corresponded to a different measurement result, then $A_i |\psi\rangle$ would be the state of the system conditional on the measurement outcomes i, and their squared norms, the probabilities of the measurement outcomes. The overall operation $\mathcal{A}$ represents the dynamics of the measurement, averaged over measurement results. Of course, a trace-preserving operation need not arise from a measurement in this manner, but it may always be viewed this way, in terms of averaging over a notional readout of the environment in some ''pointer basis,'' if desired.

The A_i are said to form a *decomposition* of $\mathcal{A}$, for which we use the notation $\mathcal{A} \sim \{A_i\}$. Using a different orthonormal ''pointer basis'' [1] for the environment in (1) results in a different decomposition of the same operation. Two such pointer bases are related by a unitary transformation. The corresponding decompositions of the operation are related by the complex conjugate of that unitary (taken in either of the bases):

$$B_i = \sum_j (U_{ij})^* A_j , \tag{3}$$

where U takes the pointer basis used to define the A_j to that used to define the B_i.

III. QUANTIFYING THE EFFECTS OF NOISE

Let us consider how to quantify the effects of a "noise" operation on information which we consider to be contained in a quantum system, using the classical Shannon theory of information transmission as a guide. The information we have about a set of classical alternatives indexed by i of a local system T is usually measured by the entropy of the probabilities we ascribe to the alternatives: $H(\mathbf{p}) := -\Sigma_i p_i \log p_i$. Suppose we want to be able to transmit or store the states i, which will be presented to us with the probabilities p_i. We encode them on a system T, while keeping a reference copy with us, on a system R. T is then affected by noise. We might define perfect success as the preservation of the initial perfect correlation between R and T. In terms of the probability measures, we want the initial and final joint *mixed* states of reference R and system T both to be $p(i^R, j^T) = p_i \delta_{iRjT}$. If our actual, noise-affected transmission results in the state $q(i^R, j^T)$, we could measure how well we have succeeded by looking at the distance between $p(i^R, j^T)$ and $q(i^R, j^T)$ using some standard measure of distance between probability distributions. To give examples of such distances, let $\mathbf{r} = [r_1, \ldots, r_n]$, $\mathbf{s} = [s_1, \ldots, s_n]$ be probabilities on a common set of classical alternatives labeled $1, \ldots, n$. We might, for example, measure the distance between $\mathbf{r}$ and $\mathbf{s}$ by the Bhattacharyya distance $B(\mathbf{r}, \mathbf{s}) := 1 - (\Sigma_k r_k^{1/2} s_k^{1/2})^2$. The L_1-norm distance (also called total variation or Kolmogorov distance) would be another reasonable choice. We will assume $q(i,j) = p_i t(j|i)$, where $t(j|i)$ is a stochastic matrix of transition probabilities describing the noise. Using the Bhattacharyya distance to measure how well the original correlation has been preserved in the above-given example

$$1 - \left(\sum_{i,j} \delta_{ij} p_i^{1/2} q(i,j)^{1/2} \right)^2 = 1 - \left(\sum_i p_i^{1/2} q(i,i)^{1/2} \right)^2 = 1 - \left(\sum_i p_i t(i|i)^{1/2} \right)^2 . \tag{4}$$

Using the L_1-norm distance gives

$$(1/2) \sum_{ij} |\delta_{ij} p_i - \delta_{ij} p_i t(j|i)| = (1/2) \sum_i p_i |1 - t(i|i)| = \sum_i p(R = i \& T \neq i). \tag{5}$$

This is the familiar "error probability" criterion for channel transmission: the average, over messages i, of the probability that i is sent but a different message is received. This is an average pure-state fidelity, but we have shown that it can be rewritten as the fidelity for a *mixed* state representing perfect initial correlation. The measure defined using the Bhattacharyya distance, while not identical to error probability, is equivalent to it as an error criterion for use in Shannon-type block coding theorems. (It goes to zero with the error probability, and with similar speed and dimensional dependence.)

We have gone through this analysis to indicate that there is a classical analog of the approach we here take to quantum as well as classical fidelity: investigating the effects of noise on a channel, which we may want to use to transmit *pure* states, by looking at its effect on a state whose marginal distribution on the noise-affected system is a *mixed* state corresponding to the ensemble of possible pure-state messages. Thus an approach which might if incompletely understood be viewed as perversely concerned with the fidelity of mixed states, provides a good fidelity criterion for the problem of transmitting pure states which are supplied to the channel with probabilities p_i, in terms of the idea of preservation of correlation with a (possibly notional) reference system. And this is not a bit of peculiarly quantum weirdness: the approach can be taken in the classical case, too.

We now present our similar approach to the problem of transmitting *quantum* information, or more generally of evaluating the fidelity with which a given operation preserves quantum infor-

mation. We resume consideration of the trace-preserving completely positive "noise" operation $\mathcal{A}$ which is the analog of the classical stochastic channel matrix $t(i|j)$ presented earlier. But now, rather than preservation of the noise-affected system's correlation with a reference system, we require preservation of its *entanglement*. Just as the classical reference system could be completely notional, introduced because high-fidelity preservation of correlation with a notional reference system implies high-fidelity preservation of states on the noise-affected system when they are supplied to the channel with the marginal distribution p_i, so the quantum reference system may also be taken to be completely notional. When $\mathcal{A}$ acts on Q, an entangled state $|\psi_0^{RQ}\rangle := \Sigma_i \sqrt{p_i}|i^R\rangle|i^Q\rangle$ of Q with a reference system R evolves as

$$|\Psi_0\rangle := \sum_i \sqrt{p_i}|i^R\rangle|i^Q\rangle|0^E\rangle \rightarrow |\Psi_f\rangle := \sum_{ij} \sqrt{p_i}|i^R\rangle A_j|i^Q\rangle|j^E\rangle. \tag{6}$$

The entanglement fidelity $F_e(\rho,\mathcal{A})$ is defined as $||P_0|\Psi_f\rangle||^2$, where $P_0 := |\psi_0^{RQ}\rangle\langle\psi_0^{RQ}| \otimes I^E$.[2] Thus F_e is the squared norm of the projection of the final state in (6) onto the subspace associated with the initial entangled state $|\psi_0^{RQ}\rangle$. It depends only on $\rho := \Sigma_i p_i|i^Q\rangle\langle i^Q|$, and is given by $\Sigma_i|\mathrm{tr}\, A_i\rho|^2$. When $\rho = |\psi\rangle\langle\psi|$, it is equal to the input–output fidelity $\langle\psi|\mathcal{A}(|\psi\rangle\langle\psi|)|\psi\rangle$, that is, the fidelity of the final state of Q to its inital state.

As in the classical case for correlation, so in the quantum case we argue that this approach does not reflect a perverse fixation on entanglement, but also provides an appropriate fidelity criterion even when it is preservation of pure states on the system Q that we are concerned with, and no entangled system R in fact exists. For the entanglement fidelity $F_e(\rho^Q,\mathcal{A})$ is a lower bound on the average input–output fidelity $\Sigma_i q_i\langle\psi_i|\mathcal{A}(|\psi_i\rangle\langle\psi_i|)|\psi\rangle$ for *any* pure-state ensemble on Q having density operator ρ^Q.

While this is a good lower bound to the input–output fidelities of pure-state ensembles, there is not a tight lower bound on the input–output fidelity in terms of the entanglement fidelity. Thus if one is really interested only in the effect of a quantum channel on a particular ensemble, one might get fidelities much higher than the entanglement fidelity suggests. We will be interested in one such case, the input–output fidelity for an orthonormal set of states, related to the ability to preserve essentially *classical* information coded in a quantum channel. In order to treat this case simultaneously with entanglement fidelity, we introduce a notion which generalizes both: average entanglement fidelity.

For an ensemble $E = \{p_i, \rho_i\}$ (where state ρ_i occurs with probability p_i), we define the *average entanglement fidelity* by $\overline{F_e}(E,\mathcal{A}) := \Sigma_i p_i F_e(\rho_i,\mathcal{A})$. A special case is

$$F_{\mathrm{cl}}(\rho,\mathcal{A}) := \sum_i p_i\langle i|\mathcal{A}(|i\rangle\langle i|)|i\rangle = \overline{F_e}(\{p_i, |i\rangle\langle i|\},\mathcal{A}), \tag{7}$$

where the $|i\rangle$ form an eigenbasis of ρ and $\rho = \Sigma_i p_i|i\rangle\langle i|$. This is the *classical fidelity* for the classical information [quantified by $S(\rho)$] of the ensemble of orthogonal eigenstates of the input density operator ρ. Another special case is an ensemble consisting of a single density operator ρ. In this case $\overline{F_e}$ is just $F_e(\rho,\mathcal{A})$ and may be viewed as the fidelity for transmission of the amount $S(\rho)$ of *quantum* information.

The average entanglement fidelity can equivalently be defined as the norm squared of the projection of the overall final state onto the subspace in which entangled states $|\psi_i^{RQ}\rangle$ representing the initial ensemble are correctly correlated with orthogonal states of an additional reference system S:

$$\begin{aligned}\overline{F_e} &= ||P_c \otimes I^E|\Psi_f\rangle||^2 \\ &= \mathrm{tr}\, P_c(\mathcal{I}^{RS} \otimes \mathcal{A})|\psi_0^{RQS}\rangle\langle\psi_0^{RQS}|,\end{aligned} \tag{8}$$

where $P_c := \Sigma_i |i^S\rangle\langle i^S| \otimes |\psi_i^{RQ}\rangle\langle\psi_i^{RQ}|$. The initial state of RQS may be $|\psi_0^{RQS}\rangle := \Sigma_i \sqrt{p_i}|i^S\rangle|\psi_i^{RQ}\rangle$, with the ensemble of entangled states in RQ produced by entanglement with S. Alternatively, the initial state of RQS may be mixed, with perfect classical correlation rather than entanglement, between the states of a basis of S and the different entangled states of RQ. In this case $|\psi_0^{RQS}\rangle\langle\psi_0^{RQS}|$ is given by $\Sigma_i p_i |i^S\rangle\langle i^S| \otimes |\psi_i^{RQ}\rangle\langle\psi_i^{RQ}|$. The average entanglement measure (8) is insensitive to whether entanglement, or merely classical correlation, exists between S and RQ.

For example, consider the special case of F_{cl}. Here the reference system R plays no role as the ρ_i are pure. After suppressing R, $P_c = \Sigma_i |i^S\rangle|i^Q\rangle\langle i^Q|\langle i^S|$. S contains a record of the classical information sent. S and Q may be supposed to be either entangled or classically correlated, with $\rho_0^{SQ} = \Sigma_{i,j}\sqrt{p_i p_j}|i^S\rangle\langle j^S| \otimes |i^Q\rangle\langle j^Q|$ or $\rho_0^{SQ} = \Sigma_i p_i |i^S\rangle\langle i^S| \otimes |i^Q\rangle\langle i^Q|$, for orthonormal system and reference bases $|i\rangle$, where the system basis is the eigenbasis of ρ. In either case, computing the probability $\mathrm{tr}(P_c \rho_f^{SQ})$ that the final system-reference state falls into the subspace in which system and reference exhibit perfect classical correlation in the desired bases, gives the classical fidelity $F_{\mathrm{cl}}(\rho, \mathcal{A})$.

IV. THE REVERSAL OPERATION

We motivate the definition of the near-optimal reversal operation $\mathcal{R}_{\mathcal{A},\rho}$ by considering operations $\mathcal{A}$ that are perfectly reversible on a "code" subspace C. Let P_C be the projector onto C. Perfectly reversible operations have a decomposition A_i for which $A_i P_C = \sqrt{p_i} W_i$, where the W_i are isometries from C into orthogonal subspaces, which means that $W_i^\dagger W_j = \delta_{ij} P_C$.[3,4] (Intuitively, this means that as far as its action on the code subspace is concerned, the operation just maps the state isometrically ("unitarily") into one of a set of mutually orthogonal subspaces.) Without loss of generality, assume that the ranges of the W_i span the state space. The reversal operation has a decomposition consisting of the operators $W_i^\dagger = P_C A_i^\dagger / \sqrt{p_i}$. (Intuitively, it may be thought of as measurement of which of the subspaces the state was mapped isometrically to, followed by the inverse of that isometry to put it correctly back into the code space.) This resembles the adjoint [defined using the Hilbert–Schmidt inner product $(A,B) := \mathrm{tr}\, A^\dagger B$ on operators] $\mathcal{A}_C^\dagger$ of the restriction $\mathcal{A}_C$ of $\mathcal{A}$ to C, which is given by $\mathcal{A}_C^\dagger \sim \{P_C A_i^\dagger\} = \{\sqrt{p_i} W_i^\dagger\}$. To get the reversal operation, the $\sqrt{p_i}$ need to be removed, which also makes the operation trace preserving. The general definition of $\mathcal{R}_{\mathcal{A},\rho}$ is also based on the adjoint, suitably corrected to ensure that it is trace preserving [and continuous in the density operator when, as we assume, $\mathcal{A}(\rho)$'s support is the entire Hilbert space]:

$$\mathcal{R}_{\mathcal{A},\rho} \sim \{\rho^{1/2} A_i^\dagger \mathcal{A}(\rho)^{-1/2}\}. \tag{9}$$

If we apply this definition to an operation $\mathcal{A}$ perfectly reversible on a code, using as our input ρ any state supported precisely on the code, it is a simple but useful exercise to verify that we get the reversal operation for codes described previously.

The notation $\mathcal{R}_{\mathcal{A},\rho}$ is justified by:

Lemma 1: The definition of the reversal operation $\mathcal{R}_{\mathcal{A},\rho}$ is independent of the decomposition $\{A_i\}$ of $\mathcal{A}$.

Proof: Let $\mathcal{A} \sim \{B_i\}$ be another decomposition. By adding null operators to one of the two decompositions, we can ensure that both have the same number of operators. Note that adding null operators to $\{A_i\}$ does not change the action of $\mathcal{R}_{\mathcal{A},\rho}$. Then there exist u_{ij} such that $B_i = \Sigma_j u_{ij} A_j$, where the matrix u defined by u_{ij} is unitary. The decomposition of $\mathcal{R}_{\mathcal{A},\rho}$ given in (9) transforms via the coefficients of $u^\dagger$ into a decomposition given in terms of the $B_i^\dagger$. As $u^\dagger$ is also unitary, the result is another decomposition of the same operation. ■

A simple but important property of $\mathcal{R}_{\mathcal{A},\rho}$ is easily verified directly from the definition:

Proposition 1: $\mathcal{R}_{\mathcal{A},\rho}(\rho) = \rho$.

The operation $\mathcal{R}_{\mathcal{A},\rho}$ is near-optimal in the sense given by the following theorem.

Theorem 2: Let $E=\{p_i,\rho_i\}$ be an ensemble of commuting density matrices, and let $\rho := \Sigma_i p_i\rho_i$. Then for any trace-preserving completely positive map $\mathcal{R}$, $\overline{F}_e(E,\mathcal{R}_{\mathcal{A},\rho}\mathcal{A}) \geqslant \overline{F}_e(E,\mathcal{R}\mathcal{A})^2$.

As a corollary, if $\overline{F}_e(E,\mathcal{R}\mathcal{A})=1-\eta$, then $\overline{F}_e(E,\mathcal{R}_{\mathcal{A},\rho}\mathcal{A})\geqslant(1-\eta)^2\geqslant 1-2\eta$. That is, $\mathcal{R}_{\mathcal{A},\rho}$'s error (defined as one minus the entanglement fidelity) is never greater than twice that of the best reversal operation.

Proof: Without loss of generality, assume that $\mathcal{R}\sim\{R_i\}$'s domain is the algebra of operators on $\mathrm{supp}(\mathcal{A}(\rho))$ and its range is $\mathrm{supp}(\rho)$. Allowing more general reversal operations cannot increase entanglement fidelity. Then there exist operators B_i such that

$$R_i=\rho^{1/2}B_i^\dagger\mathcal{A}(\rho)^{-1/2}, \tag{10}$$

namely those defined by $B_i^\dagger := \rho^{-1/2}R_i\mathcal{A}(\rho)^{1/2}$. (Generalized inverses are to be understood here.) Let $\mathcal{B}\sim\{B_i\}$. We have

$$\overline{F}_e(E,\mathcal{R}\mathcal{A})=\sum_l p_l\sum_{ij}|\mathrm{tr}\,\rho^{1/2}B_i^\dagger\mathcal{A}(\rho)^{-1/2}A_j\rho_l|^2. \tag{11}$$

Define $X^l_{ij} := \mathrm{tr}\,\rho^{1/2}B_i^\dagger\mathcal{A}(\rho)^{-1/2}A_j^\dagger\rho_l$. By proper ($l$-dependent) choice of operator decompositions $\mathcal{B}\sim\{B_i^l\}$ and $\mathcal{A}\sim\{A_i^l\}$ (corresponding to singular value decompositions—cf. Ref. 5, Sec. 7.3—of the matrices X^l), we may obtain the same expression, but with the inner sum having just one index. Then applying the cyclicity of the trace, the fact that $[\rho,\rho_l]=0$, and defining $X_{li} := p_l^{1/4}\mathcal{A}(\rho)^{-1/4}A_i^l\rho^{1/4}\rho_l^{1/2}$, $Y_{li} := p_l^{1/4}\mathcal{A}(\rho)^{-1/4}B_i^l\rho^{1/4}\rho_l^{1/2}$, gives

$$\begin{aligned}
\overline{F}_e(E,\mathcal{R}\mathcal{A})&=\sum_l p_l\sum_i|\mathrm{tr}\,\rho^{1/2}B_i^{l\dagger}\mathcal{A}(\rho)^{-1/2}A_i^l\rho_l|^2\\
&=\sum_{il}|\mathrm{tr}\,Y_{li}^\dagger X_{li}|^2\leqslant\sum_{il}\mathrm{tr}\,X_{li}^\dagger X_{li}\mathrm{tr}\,Y_{li}^\dagger Y_{li}\\
&\leqslant\left(\sum_{il}|\mathrm{tr}\,X_{li}^\dagger X_{li}|^2\sum_{i'l'}|\mathrm{tr}\,Y_{l'i'}^\dagger Y_{l'i'}|^2\right)^{1/2}\\
&\leqslant\left(\sum_{il}|\mathrm{tr}\,X_{li}^\dagger X_{li}|^2\right)^{1/2}\leqslant\left(\sum_{ijl}|\mathrm{tr}\,X_{li}^\dagger X_{lj}|^2\right)^{1/2}\\
&=\left(\sum_l p_l\sum_{ij}|\mathrm{tr}\,\rho^{1/2}A_i^{l\dagger}\mathcal{A}(\rho)^{-1/2}A_j^l\rho_l|^2\right)^{1/2}\\
&=\overline{F}_e(E,\mathcal{R}_{\mathcal{A},\rho}\mathcal{A})^{1/2}.
\end{aligned} \tag{12}$$

Here the first two inequalities are Schwarz inequalities, the third uses the fact that

$$\sum_i|\mathrm{tr}\,\rho^{1/2}B_i^\dagger\mathcal{A}(\rho)^{-1/2}B_i\rho_l|^2\leqslant F_e(\rho,\mathcal{R}\mathcal{B})\leqslant 1, \tag{13}$$

the fourth just adds positive terms inside the square root. The last identity depends on Lemma 1. Since $\mathcal{B}$ is not necessarily trace-preserving, (13) is not immediate, but from (11) and the trace-preserving condition on $\mathcal{R}$,

$$\sum_i R_i^\dagger R_i=\sum_i\mathcal{A}(\rho)^{-1/2}B_i\rho B_i^\dagger\mathcal{A}(\rho)^{-1/2}=I. \tag{14}$$

It follows that $\mathcal{B}(\rho)=\mathcal{A}(\rho)$, a normalized density operator. Let $|\psi_0^{RQ}\rangle$ be a purification of ρ. Then the states $(\mathcal{I}^R\otimes\mathcal{B}^Q)(|\psi_0^{RQ}\rangle\langle\psi_0^{RQ}|)$ and $(\mathcal{I}^R\otimes\mathcal{R}^Q\mathcal{B}^Q)(|\psi_0^{RQ}\rangle\langle\psi_0^{RQ}|)$ are also normalized density matrices, whence $F_e(\rho,\mathcal{RB})=\mathrm{tr}\,P_0(\mathcal{I}^R\otimes\mathcal{R}^Q\mathcal{B}^Q)(|\psi_0^{RQ}\rangle\langle\psi_0^{RQ}|)\leqslant 1$. ■

Important special cases of Theorem 2 are noted in:

Corollary 2: For any trace-preserving completely positive $\mathcal{R}$, $F_{\mathrm{cl}}(\rho,\mathcal{RA})\leqslant\sqrt{F_{\mathrm{cl}}(\rho,\mathcal{R}_{\mathcal{A},\rho}\mathcal{A})}$ and $F_e(\rho,\mathcal{RA})\leqslant\sqrt{F_e(\rho,\mathcal{R}_{\mathcal{A},\rho}\mathcal{A})}$.

When the members of the input ensemble ρ_i do not commute, we do not know whether $\mathcal{R}_{\mathcal{A},\rho}$, for $\rho:=\Sigma_i p_i\rho_i$, is still near-optimal.

V. RELATIONSHIP TO THE "PRETTY GOOD MEASUREMENT"

The above-presented analysis of the fidelity of reversal makes it clear that $\mathcal{R}_{\mathcal{A},\rho}$ provides a method for distinguishing, with close to optimal average error, density matrices from the ensemble $\{p_j,\hat{\rho}_j\}$, where $\hat{\rho}_j:=\mathcal{A}(|j\rangle\langle j|)$, and $\rho=\Sigma_j p_j|j\rangle\langle j|$. This provides a near-optimal method for distinguishing density matrices in an arbitrary ensemble, for any ensemble $\{p_j,\hat{\rho}_j\}$ may be constructed by an operation

$$\mathcal{A}\sim\{\sqrt{\lambda_{ij}}|v_{ij}\rangle\langle j|\},\tag{15}$$

where $\hat{\rho}_j=\Sigma_i\lambda_{ij}|v_{ij}\rangle\langle v_{ij}|$ are the spectral decompositions of the density matrices to be distinguished. The operation $\mathcal{A}$ may be thought of as measuring in the orthogonal basis $|j\rangle$, and then producing the corresponding $\hat{\rho}_j$, for example by randomly applying, with probabilities λ_{ij}, unitary rotations taking $|j\rangle$ to $|v_{ij}\rangle$. With $\mathcal{A}$ as defined previously,

$$\mathcal{R}_{\mathcal{A},\rho}\sim\{R_{ij}\}=\{\sqrt{p_j}\sqrt{\lambda_{ij}}|j\rangle\langle v_{ij}|\rho_{\mathrm{out}}^{-1/2}\}.\tag{16}$$

The "pretty good measurement" (PGM) was introduced by Holevo[6] (the term "pretty good measurement" is from Ref. 7) for the case of linearly independent pure states, in which case the PGM is a measurement of orthogonal projectors, and as Holevo showed, the optimal such measurement. For an ensemble of unnormalized density matrices $\rho_j:=p_j\hat{\rho}_j$, where $\rho_{\mathrm{out}}:=\Sigma_j\rho_j$ is a normalized density operator, the PGM is defined by the set of operators consisting of the

$$X_j:=\rho_{\mathrm{out}}^{-1/2}\rho_j\rho_{\mathrm{out}}^{-1/2}.\tag{17}$$

For pure $\rho_j\propto|j\rangle\langle j|$, these are just the operators corresponding to the "ρ-distorted"[8] states $\rho_{\mathrm{out}}^{-1/2}|j\rangle$. Note that for a doubly indexed ensemble of unnormalized states ρ_{ij}, $\Sigma_i X_{ij}=X_j$, where the X_j are the PGM for the $\rho_j:=\Sigma_i\rho_{ij}$. The operation (16) may be viewed, via the given representation, as performing the PGM for the ensemble of unnormalized states $\sqrt{p_j}\sqrt{\lambda_{ij}}|v_{ij}\rangle$, and returning $|j\rangle$ when the measurement result ij is obtained. Indeed, for that ensemble $R_{ij}^\dagger R_{ij}=X_{ij}$, and therefore $\Sigma_i R_{ij}^\dagger R_{ij}=X_j$. Thus the operation may also be viewed as doing the PGM for the ρ_j, and returning $|j\rangle\langle j|$ when the measurement result is j. (Since $|j\rangle$ are orthogonal, this is "classical information:" the value of j is viewed as the estimate of which j was input.) However, a given ensemble ρ_j may in general arise from orthogonal states $|j\rangle$ by actions of channels different from the "classicizing" one (15), which completely decoheres the orthogonal states $|j\rangle$ before producing $\hat{\rho}_j$. For example, if the $\hat{\rho}_j$ are orthogonal and pure they may be produced either by measurement in the basis $|j\rangle$ followed by an appropriate unitary operator U, or by applying U without prior measurement. In the first case quantum coherence is completely destroyed, while in the second case it is perfectly preserved. When the channel producing the $\hat{\rho}_j$ is not of the form (15), the reversal operation $\mathcal{R}_{\mathcal{A},\rho}$ will be different from (16). Although (16) still gives near-optimal classical fidelity, it will not necessarily give good entanglement fidelity, since in some sense it decoheres the states $\hat{\rho}_j$. $\mathcal{R}_{\mathcal{A},\rho}$, however, will have near-optimal entanglement fidelity while retaining near-optimal classical fidelity. $\mathcal{R}_{\mathcal{A},\rho}$ thus takes advantage of whatever coherence remains between the $\hat{\rho}_j$; it avoids decohering the $\hat{\rho}_j$ if the channel has not decohered them already.

VI. A BOUND ON THE CLASSICAL FIDELITY OF REVERSAL

To bound a fidelity of reversal it is sufficient to bound the fidelity for the near optimal reversal operation and apply Theorem 2. Here we have a look at such bounds for classical fidelities of reversal for $\mathcal{A}$ of the form (15). In this case, the classical fidelities are average probabilities of success for measurements that attempt to infer which of the eigenprojectors $|j\rangle\langle j|$ of the input state $\rho=\Sigma_j p_j|j\rangle\langle j|$ was actually transmitted. The expression for the PGM gives the following bound on the optimal probability of success F_{cl} (with the definitions of Sec. V):

$$\begin{aligned} F_{\mathrm{cl}}^2 &\geqslant F_{\mathrm{cl}}(\rho,\mathcal{R}_{\mathcal{A},\rho}\mathcal{A}) \\ &= \sum_j \mathrm{tr}\,(\rho_{\mathrm{out}}^{-1/2}\rho_j\rho_{\mathrm{out}}^{-1/2}\rho_j) \\ &= 1-\sum_{i,j:i\neq j} \mathrm{tr}(\rho_{\mathrm{out}}^{-1/2}\rho_i\rho_{\mathrm{out}}^{-1/2}\rho_j), \end{aligned} \tag{18}$$

where we used the identity $\Sigma_{i,j}\,\mathrm{tr}(\rho_{\mathrm{out}}^{-1/2}\rho_i\rho_{\mathrm{out}}^{-1/2}\rho_j)=1$. Thus the probability of error E_{cl} is bounded above by $2\Sigma_{i,j:i\neq j}\,\mathrm{tr}(\rho_{\mathrm{out}}^{-1/2}\rho_i\rho_{\mathrm{out}}^{-1/2}\rho_j)$, which is a multiple of the sum of the Hilbert–Schmidt inner products of the different $\rho_{\mathrm{out}}^{-1/4}\rho_j\rho_{\mathrm{out}}^{-1/4}$. When ρ_{out} is uniform (proportional to a projection), this sum can be easy to estimate. An often used measure of overlap between density matrices is the Bures–Uhlmann fidelity.[9,10] This measure depends only on the pair of density matrices, and is defined by $F_{\mathrm{BU}}(\sigma_1,\sigma_2):=\mathrm{tr}\sqrt{\sigma_1^{1/2}\sigma_2\sigma_1^{1/2}}$. The expression for the optimal reversal given in (16) can be used to derive a bound on the probability of error in terms of the Bures–Uhlmann fidelities.

Theorem 3:

$$F_{\mathrm{cl}}^2 \geqslant 1-\sum_{i,j:i\neq j}\sqrt{p_ip_j}F_{\mathrm{BU}}(\hat{\rho}_i,\hat{\rho}_j). \tag{19}$$

Proof: Let A_j be the matrix whose ith column is $\sqrt{p_j}\sqrt{\lambda_{ij}}|v_{ij}\rangle$, and A the matrix obtained by placing the A_j in a row. Then $AA^\dagger=\rho_{\mathrm{out}}$. Let R_j be the matrix whose ith row is $\sqrt{p_j}\sqrt{\lambda_{ij}}\langle v_{ij}|\rho_{\mathrm{out}}^{-1/2}$ and R the matrix obtained by placing the R_j in a column. R is simply an explicit matrix form of $\mathcal{R}_{\mathcal{A},\rho}$. Since $R=A^\dagger(AA^\dagger)^{-1/2}$, R is a matrix with the property that RA is positive semidefinite. (In fact, this gives an alternative approach to defining $\mathcal{R}_{\mathcal{A},\rho}$). The matrix RA has a natural block structure that mirrors that used to define R and A. It is readily verified that F_{cl} for $\mathcal{R}_{\mathcal{A},\rho}$ is given by the sum of the squared Frobenius norms $|(RA)_{jj}|_2^2:=\mathrm{tr}(RA)_{jj}^\dagger(RA)_{jj}$ of the diagonal blocks. Since $|RA|_2^2$ is one, it suffices to estimate the sum of the squared Frobenius norms of the off-diagonal blocks to bound the optimal F_{cl}. To do so, observe that $(RA)^2=A^\dagger A$. The block at block position l,k in $B:=A^\dagger A$ is given by $B_{lk}=A_l{}^\dagger A_k$. Since $A_lA_l{}^\dagger=\rho_l$,

$$\begin{aligned} B_{lk}{}^\dagger B_{lk} &= A_k{}^\dagger\rho_lA_k \\ &= U\rho_k^{1/2}\rho_l\rho_k^{1/2}U^\dagger \end{aligned}$$

(by polar decomposition of A_k) for some unitary operator U. Consequently, the L_1-norm of B_{lk}, defined by $|B_{lk}|_1:=\mathrm{tr}\sqrt{B_{lk}{}^\dagger B_{lk}}$ is given by $\sqrt{p_lp_k}F_{\mathrm{BU}}(\hat{\rho}_l,\hat{\rho}_k)$. It therefore suffices to relate the Frobenius norms of the off-diagonal blocks of a positive semidefinite matrix to the L_1 norms of the off-diagonal blocks of its square, via the following lemma.

Lemma 4: Let

$$M=\begin{pmatrix} a & b^\dagger \\ b & c \end{pmatrix}$$

be positive semidefinite, with a,b,c matrices. Write

$$M^{1/2}=\begin{pmatrix} x & y^{\dagger} \\ y & z \end{pmatrix}$$

with the same block structure. Then $|y|_2^2 \leq |b|_1$.

Proof of Lemma 4: Without loss of generality, assume that y is non-negative diagonal. Otherwise, with a block-diagonal unitary

$$U=\begin{pmatrix} u & 0 \\ 0 & v \end{pmatrix}$$

with u and v chosen to implement the singular value decomposition of y, we may transform M and $M^{1/2}$ so that y is a diagonal matrix with non-negative diagonal entries (for rectangular y, the upper or left-hand square portion is diagonalized). This does not affect the norms, since U transforms blocks independently and the L_1 and Frobenius norms are both unitarily invariant. Let y_i be the diagonal entries of y. Note that $b=yx+zy$ and $|b|_1 \geq \mathrm{tr}\, b$ (cf. Ref. 5, p. 432). Now tr $(yx+zy)=\Sigma_i y_i(x_{ii}+z_{ii})$. By the positivity of $M^{1/2}$, $y_i^2 \leq x_{ii}z_{ii}$, so y_i is less than at least one of x_{ii}, z_{ii}. Thus $|y|_2^2=\Sigma_i y_i^2 \leq \mathrm{tr} b \leq |b|_1$, as desired. ■

To complete the proof of Theorem 3, consider first the block decomposition of RA and B determined by B_{11}. By Lemma 4, the squared Frobenius norm of the first block row and column excluding $(RA)_{11}$ is bounded by the sum of the L_1 norms of the corresponding block row and column in B_{11}. By subadditivity of the norm, this is at most $\Sigma_{i>1}(|B_{1i}|_1+|B_{i1}|_1)$. After a suitable permutation, the same argument applies to the row and column determined by B_{ii}, for each i. The proof of the theorem then follows by summing over the resulting inequalities and noting that each off-diagonal block occurs twice on both sides. ■

VII. EXAMPLES AND APPLICATIONS

By a slight extension of an example already given, $\mathcal{R}_{\mathcal{A},\rho}$ is optimal for $\mathcal{A}$ perfectly reversible on some code subspace, when ρ is a state with no support outside the code. Applications to reversing other simple quantum operations may be instructive. For instance, for a depolarizing channel $\mathcal{A} \sim \{(1-p)^{1/2}I, (p/3)^{1/2}\sigma_i\}_{i=1,2,3}$ acting on $\rho=I/d$, $\mathcal{R}_{\mathcal{A},\rho}$ is another application of the depolarizing channel, whereas the optimal reversal is to do nothing. (This case saturates the inequality of Theorem 3.)

Due to its near optimality, the reversal operation $\mathcal{R}_{\mathcal{A},\rho}$ can be used in any situation where classical or quantum information has been corrupted by noise with known behavior. $\mathcal{R}_{\mathcal{A},\rho}$ has a simple definition, but whether it or a good approximation can be implemented efficiently depends on the details of the situation. Whether or not it can be efficiently implemented, because its error is at most twice the optimum, it can be used as a theoretical tool to obtain upper bounds on the achievable fidelities in a given situation. The upper bounds can then be compared to the fidelity achieved by simpler algorithms. An example of this occurs in the use of stabilizer codes for quantum error-correction. When the noise model is independent and depolarizing, classical coding theory immediately suggests a combinatorially straightforward error-correction algorithm based on maximum likelihood error syndrome decoding. Comparing this method to $\mathcal{R}_{\mathcal{A},\rho}$ suggests itself as a fruitful path of investigation with applications to asymptotic bounds in quantum coding theory.[11,12] More generally, for any encoding scheme capable of transmitting quantum information through a given channel at a given rate when appropriate decoding is used, $\mathcal{R}_{\mathcal{A},\rho}$ may be used to provide such a decoding (with $\mathcal{A}$ taken to be the concatenation of encoding and noise).

Another application is to query complexity for quantum oracles. Here we are given a quantum black box implementing an unknown quantum operation from some set. A simple method for attempting to determine which operation we are given is to apply it to copies of some input state and attempt to distinguish the output state. A bound on the probability of success can then be obtained by using bounds such as the one of Theorem 3. This was how the fact that the hidden subgroup problem has low query complexity was first realized.[13]

(Received 19 October 2001; accepted for publication 23 January 2002)

We apply the techniques of control theory and of sub-Riemannian geometry to laser-induced population transfer in two- and three-level quantum systems. The aim is to induce complete population transfer by one or two laser pulses minimizing the pulse fluences. Sub-Riemannian geometry and singular-Riemannian geometry provide a natural framework for this minimization, where the optimal control is expressed in terms of geodesics. We first show that in two-level systems the well-known technique of "π-pulse transfer" in the rotating wave approximation emerges naturally from this minimization. In three-level systems driven by two resonant fields, we also find the counterpart of the "π-pulse transfer." This geometrical picture also allows one to analyze the population transfer by adiabatic passage. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1465516]

I. INTRODUCTION: PHYSICAL CONTEXT

A. Generalities

Design of external laser fields (amplitudes and frequencies) to reach a selected state of a quantum system is of primary importance for the control of quantum dynamics. The techniques for this state-selectivity that have been developed are essentially based on (i) adiabatic passage (see, e.g., the recent works[1–4]), (ii) multiphoton quasiresonant pumping[5] by "generalized π-pulses,"[6] and (iii) optimal control theory (see, e.g., Refs. 7 and 8).

Adiabatic passage has the advantage of robustness in the sense that significant deviations of the fields do not significantly modify the final result. On the other hand, optimal control is a systematic framework to design the field parameters (or control variables) to reach selectivity in maximizing or minimizing a quantity (the cost) depending functionally on the state and control variables. This design is in general not robust, in contrast with standard adiabatic passage. Since the robustness is difficult to quantify as a cost, we do not expect in general the adiabatic passage to emerge from an optimal control solution. This has been discussed for specific simple systems.[9,10] However optimality for adiabatic passages has been characterized in Ref. 11.

The success of these coherent laser-induced processes requires, in general, use of as short as possible external pulses, to minimize incoherent effects of relaxation (through spontaneous emission, collisions, etc.). It is essential that the total time of the pulse is shorter than the characteristic times of the incoherent losses. Coherent transfers also need as low as possible pulse intensities in order to (i) minimize incoherent phenomena induced by strong fields such as ionization for atoms or molecules, and (ii) avoid involving other energy levels, that are not included in the models. Otherwise the population is spread among these levels and the transfer becomes inefficient.

Depending on the concrete physical setting there are several possible choices of the cost functional. One choice, which has been studied in Ref. 12, is to minimize the total time of the control process. However, the total time minimization presented in Ref. 12 assumes that arbitrarily large laser intensities can be used. The relations between our results and the results of Ref. 12 will be made clear in Sec. II C.

In this paper we address the two- and three-level problem from the geometric control theory point of view. We consider several functionals to be minimized, which are geometrically very natural, and that physically reflect the practical constraints mentioned previously [fluence, see formula (5) for the two-level case and formula (7) for the three-level case, or transfer time with bounded controls, etc.]. The choice of these costs will be discussed in Sec. II C. We will also use the classical tracking technique, often used in in geometric control theory (see Ref. 13), that will allow in particular achievement of adiabatic transfer.

Remark 1: In the choice of the cost to be minimized, it is useful to consider optimal problems that are independent of time reparametrization. Indeed, in that case, very slowly varying solutions, comparable with the ones used in experiments, can be obtained just by time reparametrization. This point will be taken into account in the following, in particular see Sec. II C. But we will also consider problems that do not have this feature.

B. Content of the paper

In this work we apply geometric control theory in two- and three-level systems, which we briefly describe in the following. Moreover we make the connection with the adiabatic passage.

1. The two-level case

We first study the population transfer in a two-level quantum system (of energies E_1 and E_2) driven by an external field of arbitrary time-dependent shape, starting at t_0 and ending at t_1. The dynamics is governed by the time-dependent Schrödinger equation (in a system of units such that $\hbar=1$):

$$i\frac{\mathrm{d}\psi(t)}{\mathrm{d}t}=H\psi(t), \tag{1}$$

$\psi(.):\mathbb{R}\to\mathbb{C}^n$, $n=2$, where

$$H=\begin{pmatrix} E_1 & \Omega(t) \\ \Omega^*(t) & E_2 \end{pmatrix}. \tag{2}$$

is the Hamiltonian of the system (we have assumed no diagonal coupling). We choose the most general situation where the off-diagonal element is complex: $\Omega(t):\mathbb{R}\to\mathbb{C}$.

In the two-level system (2), complete controllability (on spheres) is obvious (see the following for the precise definition of controllability). We show that the natural optimal control problem of minimizing the integral of the laser amplitude:

$$\mathcal{C}=\int_{t_0}^{t_1}|\Omega|\ \mathrm{d}t \tag{3}$$

has the following features.

(a) After some transformations the problem can be formulated as a problem of Sub-Riemannian geometry (see Remark 3).

(b) The optimal control solution has the expected resonance property, i.e., Ω can be written as

$$\Omega(t)=b(t)e^{i[(E_2-E_1)t+\alpha]}, \tag{4}$$

where α is an arbitrary constant, $b(.):\mathbb{R}\to\mathbb{R}^+$ is a real function with compact support $[t_0,t_1]$.

(c) The optimal amplitude $b(t)$ satisfies

$$\int_{t_0}^{t_1} b(t)=\pi/2.$$

Remark 2: We thus recover the well-known strategy of "π-pulse transfer" of a resonant pulse in the rotating wave approximation,[14] which gives complete transfer with $\Omega(t)=\mu\mathcal{F}(t)e^{i\phi(t)}/2$, $\dot{\phi}(t)=E_2-E_1$, and $\not{\ell}=|\mu|\int_{t_0}^{t_1}\mathcal{F}(t)\mathrm{d}t/2=\pi/2$. Here μ is the intrinsic coupling between the two levels and $\mathcal{F}(t)$ the external pulsed field. This shows in particular that an additional controllable time-dependent frequency ("chirping," see, e.g., Ref. 15) does not improve the minimization with respect to this cost. We thus show that in the model of the rotating wave approximation, the "π-pulse transfer" corresponding to the minimum pulse area to achieve the complete transfer is a consequence of purely geometric considerations.

(d) The solution is independent of time reparametrization, i.e., derivatives of controls can be made as small as required simply by choosing an appropriate time parametrization. Moreover, with an adequate choice of the parametrization it minimizes the *fluence* for fixed transfer time t_1-t_0:

$$\mathcal{E}=\int_{t_0}^{t_1}|\Omega|^2(t)\mathrm{d}t=\int_{t_0}^{t_1}b^2(t)\mathrm{d}t, \tag{5}$$

or equivalently the transfer time, with the constraint on the amplitude $|b(t)|\leqslant 1$. More details about the relations between these costs are given in Sec. II C.

Remark 3: A control problem is called *distributional* if the set of admissible velocities is a *distribution*, i.e., a nonintegrable field of planes. It is called *contact* if the distribution is a *contact distribution*, i.e., if the field of planes is defined as the kernel of the one-form ω, then $\mathrm{d}\omega$ is nondegenerate when restricted to $\mathrm{Ker}(\omega)$. A control problem is said to be *sub-Riemannian* if additionally one gives a Riemannian metric on the distribution, and one minimizes the Riemannian length. For sub-Riemannian geometry we refer to Refs. 16–18.

In fact, as we shall see, the two-level problem reduces to a three-dimensional contact sub-Riemannian problem, with a special feature: it has a symmetry, transverse to the distribution. It is a standard fact that such a sub-Riemannian problem is in fact an isoperimetric problem (in the sense of the calculus of variations) on the quotient by the symmetry. Such isoperimetric contact three-dimensional sub-Riemannian problems have been studied in detail at the local level in Ref. 19, for instance. In fact, the above-given statement is nothing but the (trivial) solution of the classical isoperimetric problem (or Dido problem) on the Riemannian sphere.

The study of this two-level case is described in Sec. III.

2. The three-level case

For three-level systems, labeled 1, 2, and 3, of respective energies E_1, E_2, and E_3, driven by two resonant monochromatic fields of respective envelopes $\mathcal{F}_j(t)$, $j=1,2$ and of frequencies ω_1 and ω_2, the Hamiltonian, in the rotating wave approximation (RWA), reads

$$H=\begin{pmatrix} E_1 & u_1(t)e^{i\omega_1 t} & 0 \\ u_1(t)e^{-i\omega_1 t} & E_2 & u_2(t)e^{i\omega_2 t} \\ 0 & u_2(t)e^{-i\omega_2 t} & E_3 \end{pmatrix}, \tag{6}$$

where

$$\omega_1 := E_2 - E_1, \quad u_1(.):\mathbb{R}\to\mathbb{R},$$

$$\omega_2 := E_3 - E_2, \quad u_2(.):\mathbb{R}\to\mathbb{R}.$$

The controls $u_j(t)$, $j=1,2$ are connected to the physical parameters by $u_j(t)=\mu_j\mathcal{F}_j(t)/2$, with the couplings μ_j, intrinsic to the quantum system, that we have restricted to couple only levels j and $j+1$ by pairs. We allow the control variables, starting at t_0 and ending at t_1, to have any shape.

Controllability. For a control system, the *accessibility set* of a point x_0 in the configuration space is the set of points that can be joined from x_0 by a trajectory of the system. A control system is said to be *controllable* if the accessible set of every x_0 is the whole configuration space. For an analytic distributional system, it is known that the configuration space is foliated by accessible sets, called *orbits* in that case. These orbits are exactly the Hermann–Nagano orbits (see the Hermann–Nagano Theorem in the following and Ref. 22 for details).

In the following we first prove that this three-level system reduces to a distributional problem which is not controllable, since the orbits under consideration are two-dimensional spheres. Then we show that on each of these spheres the control problem reduces to a singular-Riemannian problem. The ''relevant locus,'' which is the union of all the orbits (spheres) passing through state number 1, has an interesting nontrivial geometric description. It is the only nonorientable sphere-bundle over S^1 (see Sec. IV A).

Optimal solutions. In this case we first consider the problem of minimizing the fluence for fixed transfer time t_1-t_0 (which is a parametrization-dependent cost):

$$\mathcal{E}=\int_{t_0}^{t_1}(u_1^2+u_2^2)\mathrm{d}t. \tag{7}$$

Again let us notice that minimization of the functional:

$$\ell=\int_{t_0}^{t_1}\sqrt{u_1^2+u_2^2}\mathrm{d}t, \tag{8}$$

leads to the same motion in the space state, parametrized in any way. Moreover, minimizing the functional $\mathcal{E}$ is equivalent to minimizing the transfer-time for controls bounded in the following way:

$$u_1^2+u_2^2\leqslant 1. \tag{9}$$

This will be explained in detail in Sec. II C.

For the three-level system (6), the main known ways to completely populate state 3 from the initial condition in state 1 are the following:

(i) application of two successive π-pulses (without overlap), giving $\ell=\pi$ in the system (6);
(ii) interaction with two completely overlapping control variables: $u_1(t)=u_2(t)$ (with two different pulses assuming that the couplings between 1 and 2 and between 2 and 3 are different), giving also $\ell=\pi$;[20]
(iii) adiabatic passage by delayed pulses (of the same shape) such that $u_2(t)$ starts before $u_1(t)$ (known as ''counterintuitive'' pulse sequence).[1] This way of transferring the population is energetically expensive since it requires $\ell\gg\pi$.

For this three-level system, we show that the cost ℓ can be significantly reduced, finding its minimum value

$$\ell = \frac{\sqrt{3}}{2}\pi \approx 0.866\pi,$$

corresponding to the singular-Riemannian geodesic. This is also the minimum transfer time under the constraint (9).

The minimum value for the functional $\mathcal{E}$ is

$$\mathcal{E} = \frac{3}{4}\pi^2 \frac{1}{t_1 - t_0}$$

[where $(t_1 - t_0)$ is the fixed interaction time]. These results are described by Theorem 4 of Sec. IV.

We show that the associated pulse sequence is such that $u_1(t)$ starts before $u_2(t)$ (''intuitive'' sequence) and we construct symmetric smooth pulses of the same shape giving this minimum. We compute the geodesic joining the initial state to the final state, and we give some examples of time reparametrized optimal controls. The results thus show very natural control strategies that do not look like the standard strategy in this type of problem. This study is the content of Sec. IV.

Tracking. In Sec. V we construct for the three-level problem a geometric representation of adiabatic passage and compare it with the strategies of optimal control. This allows one to reformulate the adiabatic passage as explicitly fixing the trajectory leading from state 1 to state 3 and in controlling the rate of transient population in the intermediate state 2. This procedure improves on the standard adiabatic passage in that it exactly reaches the target state. This tracking technique is standard in control theory. A solution of this type is generated by a counterintuitive sequence of controls, in the adiabatic approximation.[1]

II. PRELIMINARIES, ELIMINATION OF THE DRIFT, AND CHOICE OF THE COST

A. Preliminaries

We start with a quantum system with finite number of (distinct) levels in interaction with a time-dependent external field such that the Hamiltonian reads:

$$\begin{aligned} H &= \begin{pmatrix} E_1 & \Omega_1(t) & 0 & \cdots & 0 \\ \Omega_1^*(t) & E_2 & \Omega_2(t) & \ddots & \vdots \\ 0 & \Omega_2^*(t) & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & E_{n-1} & \Omega_{n-1}(t) \\ 0 & \cdots & 0 & \Omega_{n-1}^*(t) & E_n \end{pmatrix} \\ &= D + \begin{pmatrix} 0 & \Omega_1(t) & 0 & \cdots & 0 \\ \Omega_1^*(t) & 0 & \Omega_2(t) & \ddots & \vdots \\ 0 & \Omega_2^*(t) & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 0 & \Omega_{n-1}(t) \\ 0 & \cdots & 0 & \Omega_{n-1}^*(t) & 0 \end{pmatrix}, \end{aligned} \tag{10}$$

with $D := \mathrm{diag}(E_1, \ldots, E_n)$ and the energies of the system states appearing on the diagonal. Time-dependent elements $\Omega_j(.): \mathbb{R} \to \mathbb{C}$, $j = 1, \ldots, n-1$ are different from zero only between times t_0 and t_1. They couple the states by pairs. The term D is called *drift*. Section II B is devoted to the elimination of D via a unitary transformation.

The state-vector $\psi(t)$, solution of the time-dependent Schrödinger equation (1), can be expanded in the canonical basis of $\mathbb{C}^n$, formed by elements $\varphi_1=(1,0,\ldots,0)$, $\varphi_2=(0,1,\ldots,0),\ldots\ \varphi_n=(0,,0,\ldots,1)$: $\psi(t)=c_1(t)\varphi_1+c_2(t)\varphi_2+\cdots+c_n(t)\varphi_n$, with $|c_1(t)|^2+|c_2(t)|^2+\cdots+|c_n(t)|^2=1$. For $t<t_0$ and $t>t_1$, $|c_i(t)|^2$ is the probability of measuring energy E_i. Notice that

$$\frac{\mathrm{d}}{\mathrm{d}t}|c_i(t)|^2=0 \quad \text{for } t<t_0 \text{ and } t>t_1.$$

Our problem can be stated in the following way: Assuming $|c_1(t)|^2=1$ for $t<t_0$, we want to determine suitable interaction functions $\Omega_i(.)$, $i=1,\ldots,n-1$, such that $|c_j(t)|^2=1$ for time $t>t_1$ and some chosen $j\in\{2,\ldots,n\}$, requiring that they minimize the cost (8).

Remark 4: This problem is a control problem on the real $2n$-1 dimensional sphere in $\mathbb{R}^{2n}$ (or on the complex sphere in $\mathbb{C}^n$). Standard considerations from control theory allow one to conclude on the controllability on the sphere [even with arbitrarily small bounds on the controls $\Omega_i(.)$], i.e., it is possible to drive the system from any initial condition to any terminal condition on the sphere. Also, control problems of this type have finite dimensional Lie-algebra: the reductive Lie algebra $su(n)\times\mathbb{R}$. They can be lifted to left-invariant control problems on the compact Lie group $\mathrm{SU}(n)\times S^1$ (S^1, the circle), and the controllability of the lifted control system also holds.

We will also consider the "real resonant case" in which the controls Ω_i correspond to lasers that are in resonance:

$$\Omega_i(t)=u_i(t)e^{i\omega_i t}, \quad \omega_i=E_{i+1}-E_i,$$

$$i=1,\ldots,n-1, \quad u_i(.):\mathbb{R}\to\mathbb{R}. \tag{11}$$

Notice that in this case we consider real controls which always leads to lack of controllability.

In the following we treat the $n=2$ and $n=3$ cases. The $n=2$ case is treated in the most general setting, in the sense that we control both the amplitude and the phase of the laser pulses. We obtain that the optimal strategy is realized with an external pulse in resonance in the rotating wave form. The $n=3$ case is treated directly with pulses in resonance in the rotating wave approximation.

In the $n=3$ case, it is an open question if it is possible to reduce the value of the cost (8), when controlling both amplitude and phase of the lasers.

In the following, to compute the orbits of the control systems under consideration, we will make use of the standard Hermann–Nagano theorem. Moreover to compute optimal trajectories we will use the well-known Pontryagin Maximum Principle.[21] For convenience we recall these two theorems in the following. Proofs can be found for instance in Ref. 22.

Theorem (Hermann–Nagano): *Let M be an analytic manifold and $\mathcal{F}$ a family of analytic vector fields on M. Then:*

(1) each orbit of $\mathcal{F}$ is an analytic submanifold of M,
(2) if $\mathcal{O}(\mathbf{x}_0)$ is an orbit containing the point $\mathbf{x}_0$, then the tangent space of $\mathcal{O}(\mathbf{x}_0)$ at $\mathbf{x}$ is given by $\mathrm{Lie}_{\mathbf{x}}(\mathcal{F})$. In particular the dimension of $\mathrm{Lie}_{\mathbf{x}}(\mathcal{F})$ is constant as $\mathbf{x}$ varies over $\mathcal{O}(\mathbf{x}_0)$.

Theorem (Pontryagin Maximum Principle): *Consider a control system of the form $\dot{x}=f(x,u)$ with a cost of the form $\int_0^T f^0(x,u)\mathrm{d}t$, where x belongs to a manifold M and $u\in U\subset\mathbb{R}^m$. Assume moreover that M,f,f^0 are smooth. If the couple $(u(.),x(.)):[0,T]\subset\mathbb{R}\to U\times M$ is optimal, then there exists a never vanishing field of covectors along $x(.)$, that is an absolutely continuous function $(p(.),p^0):t\in[0,T]\mapsto p(t)\in T^*_{x(t)}M\times\mathbb{R}$ (where $p_0\leqslant 0$ is a constant) such that:*

(i) $\dot{x}(t)=\partial\mathcal{H}/\partial p\,(x(t),p(t),u(t))$,
(ii) $\dot{p}(t)=-\partial\mathcal{H}/\partial x\,(x(t),p(t),u(t))$,

where by definition

$$\mathcal{H}(x,p,u) := <p, f(x,u)> + p_0 f^0(x,u). \tag{12}$$

Moreover:

(iii) $\mathcal{H}(x(t),p(t),u(t)) = \mathcal{H}_M(x(t),p(t))$, *for a.e.* $t \in [0,T]$,

where $\mathcal{H}_M(x(t),p(t)) := \max_{v \in U} \mathcal{H}(x(t),p(t),v)$.

The real-valued map on $T^*M \times U$, defined in (12), is called Hamiltonian. The couples $(u(.),x(.))$ satisfying conditions (i)–(iii) with $p_0 = 0$ are called *abnormal extremals*.

B. Elimination of the drift term

In both cases (2) and (6) we show how to eliminate the drift term [i.e., diag(E_1,E_2) and diag(E_1,E_2,E_3) respectively] from the Hamiltonian. In case (6) this elimination will be made just by a unitary change of coordinates that at the same time eliminates the explicit dependence on the time. In case (2) it will moreover require a unitary change of controls. This difference is simply a consequence of the fact that in the three-level case we start with ''real controls in resonance,'' while in the two-level case we use general complex controls.

Assume that $\psi(t)$ satisfies the Schrödinger equation (1). Let $U(t)$ be a unitary time-dependent matrix and set $\psi(t) = U(t)\psi'(t)$ (interaction representation). Then $\psi'(t)$ satisfies the Schrödinger equation:

$$i\frac{d\psi'(t)}{dt} = H'(t)\psi'(t),$$

with the new Hamiltonian:

$$H' = U^{-1}HU - iU^{-1}\frac{dU}{dt}. \tag{13}$$

Here we consider the Hamiltonian (10), and we choose

$$U = \mathrm{diag}(e^{-iE_1 t}, e^{-iE_2 t}, \ldots, e^{-iE_n t}).$$

We get:

$$H' = \begin{pmatrix} 0 & \Omega_1(t)e^{-i(E_2-E_1)t} & 0 & \cdots & 0 \\ \Omega_1^*(t)e^{i(E_2-E_1)t} & 0 & \Omega_2(t)e^{-i(E_3-E_2)t} & \ddots & \vdots \\ 0 & \Omega_2^*(t)e^{i(E_3-E_2)t} & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 0 & \Omega_{n-1}(t)e^{-i(E_n-E_{n-1})t} \\ 0 & \cdots & 0 & \Omega_{n-1}^*(t)e^{i(E_n-E_{n-1})t} & 0 \end{pmatrix}. \tag{14}$$

As a consequence, if we write $\psi(t) = c_1(t)\varphi_1 + c_2(t)\varphi_2 + \cdots + c_n(t)\varphi_n$, and $\psi'(t) = c_1'(t)\varphi_1 + c_2'(t)\varphi_2 + \cdots + c_n'(t)\varphi_n$, then $|c_i(t)|^2 = |c_i'(t)|^2$, $i = 1,2,\ldots,n$, that is H and H' have the same population distribution.

For the three-level system (6), this leads to (dropping the prime)

$$H = \begin{pmatrix} 0 & u_1(t) & 0 \\ u_1(t) & 0 & u_2(t) \\ 0 & u_2(t) & 0 \end{pmatrix}. \tag{15}$$

For the two-level system (2), redefining

$$u(t) := e^{-i(E_2-E_1)t}\ \Omega(t), \tag{16}$$

we get (dropping the prime)

$$H=\begin{pmatrix} 0 & u(t) \\ u^*(t) & 0 \end{pmatrix}, \tag{17}$$

In the following we set $u(t)=u_1(t)+iu_2(t)$, where $u_1(.)$ and $u_2(.)$ are two real functions.

Remark 5: Notice that the unitary transformations on the states and on the controls preserve the cost and the probabilities. As a consequence they preserve the initial and final conditions $|c_1(t_0)|^2=1$, $|c_j(t_1)|^2=1$.

Remark 6: This reduction procedure can be easily extended to the case where the drift term in (10) is time-dependent:

$$D=\mathrm{diag}(E_1(t),\ldots,E_n(t)). \tag{18}$$

The key point is that the couplings have to be only between successive levels. For the two-level case, this requirement is obviously met. The elimination of the drift (18) in (10) requires the matrix

$$U=\mathrm{diag}\left(\exp\left(-i\int_{t_0}^{t}E_1(s)\mathrm{d}s\right),\exp\left(-i\int_{t_0}^{t}E_2(s)\mathrm{d}s\right),\ldots,\exp\left(-i\int_{t_0}^{t}E_n(s)\mathrm{d}s\right)\right).$$

In this case the new Hamiltonian has the form (14) with $i(E_{i+1}-E_i)t$ replaced by $i\int_{t_0}^{t}(E_{i+1}(s)-E_i(s))\mathrm{d}s$ and the resonance condition (11) becomes

$$\Omega_i(t)=u_i(t)\exp\left(i\int_{t_0}^{t}(E_{i+1}(s)-E_i(s))\mathrm{d}s\right),\quad i=1,\ldots,n-1,\quad u_i(.):\mathbb{R}\to\mathbb{R}.$$

C. Choice of different costs and relation between them

1. Minimizing length and energy

As we will show, both the $n=2$ and $n=3$ problems can be stated as control problems that are linear with respect to the controls (i.e., ''distributional control problems''):

$$\dot{\mathbf{x}}=u_1F_1+u_2F_2, \tag{19}$$

where $\mathbf{x}\in S^3$ for $n=2$ and $\mathbf{x}\in S^5$ for $n=3$, with F_1 and F_2 two vector fields on the d-dimensional sphere S^d. It is thus natural to treat this problem as a sub-Riemannian problem (in the three-level case it is in fact singular-Riemannian problem on S^2, see Sec. IV), to which is associated the length

$$\ell=\int_{t_0}^{t_1}\sqrt{u_1^2+u_2^2}\mathrm{d}t. \tag{20}$$

This length represents the cost, i.e., the quantity that has to be minimized in our problem. This cost is time-reparametrization invariant. Thus, with such a cost one can always reparametrize the time of the optimal solution in order to obtain controls with slow variation (i.e., with $\dot{u}_1$ and $\dot{u}_2$ small), that are closer to realistic pulses in practice.

Standard considerations show that it is equivalent to minimize the fluence for fixed transfer time t_1-t_0:

$$\mathcal{E}=\int_{t_0}^{t_1}(u_1^2+u_2^2)dt, \tag{21}$$

instead of the length ℓ (20). Indeed a curve minimizes the cost $\mathcal{E}$ among all curves joining the points q_0 and q_1 in time t_1-t_0 if:

(a) it minimizes the length ℓ among all curves joining q_0 to q_1, and
(b) it is a curve parametrized by a multiple of the arclength.

Once we have a curve minimizing $\mathcal{E}$, we can then change the parametrization to have derivatives of controls as small as required.

Remark 7: Notice that, if we do not fix the time, the minimum of the cost $\mathcal{E}$ is zero and it is not attained.

2. Minimizing the time

Reparametrizing the geodesics of the control system (19), (20) by the arclength, i.e., setting

$$\mathrm{d}s=\sqrt{u_1^2+u_2^2}\mathrm{d}t,$$

we get the control problem:

$$\dot{\mathbf{x}}=u_1F_1+u_2F_2, \quad u_1^2+u_2^2=1, \tag{22}$$

and the question is to minimize the transfer time, from the initial to the terminal condition.

Taking into account the homogeneity of the problem (22), it is clear that it is the same as to minimize the transfer time for the system $\dot{\mathbf{x}}=u_1F_1+u_2F_2$, with the constraint

$$u_1^2+u_2^2\leqslant 1.$$

It follows that, for the control system (19), the problem of minimizing the cost (20), using a parametrization with arclength [that is using the cost (21), with t_1-t_0 equal to the total length], is equivalent to minimizing the time under the constraint on the controls $u_1^2+u_2^2\leqslant 1$.

Remark 8: Notice that the transformation on the controls necessary to eliminate the drift does not affect the conditions $u_1^2+u_2^2\leqslant 1$, $u_1^2+u_2^2=1$.

Remark 9: The problem of minimizing the transfer time for the system (19) under the constraint $u_1^2+u_2^2\leqslant 1$, makes sense by itself. However, notice that if we drop the condition $u_1^2+u_2^2\leqslant 1$, then by the Hermann–Nagano theorem, the minimizing time between any two initial and terminal conditions is zero.

In a recent article[12] some related questions in the control of spin systems were discussed. The problem is, however, distinctly different from the ones considered here. The authors also consider a quantum system with a drift:

$$\dot{\mathbf{x}}=X_0(\mathbf{x})+\sum_{i=1}^{p} u_iX_i(\mathbf{x}),$$

left invariant on some compact group G. But, in their case, all vector fields $X_i(x)$ belong to $\mathbf{k}$, a Lie subalgebra of the Lie algebra $\mathbf{g}$ of G. They consider a Cartan decomposition $\mathbf{g}=\mathbf{k}\oplus\mathbf{p}$, with the standard Cartan's commutation relations, and hence, the Lie algebra generated by the X_i's, $i>1$, is not equal to $\mathbf{g}$ (it is only $\mathbf{k}$). Therefore in their case, to move from a point in a coset $K\cdot x_0$ to another point in a coset $K\cdot x_1$ requires the use of the drift X_0 and hence requires a bounded speed.

This implies that, in their case, even for unbounded controls there is a minimum time, which is strictly larger than zero (and not attained in general). As mentioned previously, if we relax the constraint $u_1^2+u_2^2\leqslant 1$, in our case, the minimum time is zero (also not attained in general).

3. Conclusions on the choice of the costs

There are three costs under consideration:

(a) The length (20). In the two–level case it is the sub-Riemannian length and coincides with the integral of the absolute value of the amplitude. In the three-level case it is a singular-Riemannian length.
(b) The fluence (21), for fixed transfer time t_1-t_0.
(c) The time under the constraint $u_1^2+u_2^2\leqslant 1$.

Only the first of these costs is parametrization invariant, but all cases (a), (b), (c) lead to the same trajectories in the phase space.

III. THE TWO-LEVEL SYSTEM

In this section, we study a two-level quantum system in interaction with a laser for which we control both the amplitude and the phase. The Hamiltonian becomes after elimination of the drift

$$H=\begin{pmatrix} 0 & u(t) \\ u^*(t) & 0 \end{pmatrix}. \tag{23}$$

Our aim is to transfer all the population from level E_1 to level E_2 minimizing (here we set $t_0=0$)

$$\int_0^{t_1}|\Omega(t)|\mathrm{d}t=\int_0^{t_1}|u(t)|\mathrm{d}t. \tag{24}$$

Writing $\psi(t)=c_1(t)\varphi_1+c_2(t)\varphi_2$, where $\varphi_1=(1,0)$, $\varphi_2=(0,1)$, we start from any point satisfying $|c_1(0)|^2=1$, and our target is defined by $|c_2(t_1)|^2=1$.

Remark 10: This new Hamiltonian clearly gives rise to a driftless (or ''distributional'') control system, while the original Hamiltonian (2) had a drift term. Notice that since we have assumed $\Omega\in\mathbb{C}$, this simplification works without any additional hypothesis on Ω. The fact that the optimal strategy has the laser in resonance [i.e., $\Omega(t)=b(t)e^{i[\omega t+\alpha]}$, $\omega=E_2-E_1$, $\alpha\in\mathbb{R}$, $b(.)$ real function] will be obtained as a consequence.

The Schrödinger equation corresponding to the Hamiltonian given by formula (23) is equivalent to the system of ordinary differential equations (ODE) for the c_i's:

$$\begin{cases} \dot{c}_1=-iu(t)c_2, \\ \dot{c}_2=-iu^*(t)c_1. \end{cases} \tag{25}$$

Setting $c_1=x_1+ix_2$, $c_2=x_3+ix_4$, $u=u_1+iu_2$, Eq. (25) becomes

$$\dot{\mathbf{x}}=u_1F_1+u_2F_2,$$

where

$$\mathbf{x}=\begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix}, \quad F_1=\begin{pmatrix} x_4 \\ -x_3 \\ x_2 \\ -x_1 \end{pmatrix}, \quad F_2=\begin{pmatrix} x_3 \\ x_4 \\ -x_1 \\ -x_2 \end{pmatrix}. \tag{26}$$

and the functional (24) to be minimized is now

$$\int_0^{t_1}\sqrt{u_1^2+u_2^2}\mathrm{d}t. \tag{27}$$

In these new variables the condition $|c_1(t)|^2+|c_2(t)|^2=1$ is $\Sigma_{i=1}^4 x_i^2(t)=1$, so in fact $\mathbf{x}\in S^3$. The initial condition is now one point on the circle $S^1_{in}:=\{\mathbf{x}\in S^3\colon x_1^2+x_2^2=1\}$ and the target is the circle $S^1_{\text{fin}}:=\{\mathbf{x}\in S^3\colon x_3^2+x_4^2=1\}$. These targets are preserved by the transformations eliminating the drift. The problem of minimizing (27) is a classical sub-Riemannian problem on S^3, which is contact, as we shall see immediately.

The Lie algebra of the distribution. Let us compute the Lie algebra of the distribution. By setting $F_3=[F_1,F_2]$, we have

$$F_3=2\begin{pmatrix} x_2\\ -x_1\\ -x_4\\ x_3\end{pmatrix} \quad \text{and} \quad \begin{cases} [F_1,F_2]=F_3,\\ [F_2,F_3]=4F_1,\\ [F_3,F_1]=4F_2,\end{cases} \quad \text{so Lie}(\mathcal{F})=su(2)\sim so(3). \tag{28}$$

A. Controllability and minimizers

Let $\mathcal{F}:=\{F_1,F_2\}$. Since $\mathcal{F}$ is an analytic family of vector fields on an analytic manifold, we can use the Hermann–Nagano theorem (see Sec. I). In this case, $\text{Lie}_{\mathbf{x}_0}(\mathcal{F})$ is the vector space having $F_1(x)$, $F_2(x)$, and $F_3(x)$ as base vectors. The Hermann–Nagano theorem says that the orbit is an analytic submanifold of S^3 of dimension given by $\text{Lie}_{\mathbf{x}}(\mathcal{F})$, where $\mathbf{x}$ is any point of the orbit. Let $n(\mathbf{x}),\mathbf{x}\in S^3$ be the rank of the distribution. We have:

$$n(\mathbf{x}):=\text{rank}_{\mathbf{x}}(F_1,F_2,F_3)=\text{rank}_{\mathbf{x}}\begin{pmatrix} x_4 & x_3 & 2x_2\\ -x_3 & x_4 & -2x_1\\ x_2 & -x_1 & -2x_4\\ -x_1 & -x_2 & 2x_3\end{pmatrix}=3.$$

It follows:

Proposition 1: The control system (26) is completely controllable.

Remark 11: This controllability property, using only the first bracket, is equivalent, in the three-dimensional case, to the fact that the distribution is contact.

Remark 12: The sub-Riemannian problem is not generic at all: first as we shall see, it is isoperimetric (it has a symmetry). Second, even among isoperimetric sub-Riemannian problems, it is non generic in the sense that the main basic sub-Riemannian invariant vanishes (see Refs. 19, 23, and 24).

Remark 13: The control system (26) is invariant under the following transformation:

$$\begin{pmatrix} x_1\\ x_2\\ x_3\\ x_4\end{pmatrix}\to\begin{pmatrix} \cos(\alpha) & \sin(\alpha) & 0 & 0\\ -\sin(\alpha) & \cos(\alpha) & 0 & 0\\ 0 & 0 & \cos(\alpha) & \sin(\alpha)\\ 0 & 0 & -\sin(\alpha) & \cos(\alpha)\end{pmatrix}\begin{pmatrix} x_1\\ x_2\\ x_3\\ x_4\end{pmatrix}. \tag{29}$$

This means that all the initial conditions $\mathbf{x}_0\in S_{\text{in}}$ are equivalent. Notice that transformation (29) is generated by the Lie bracket $[F_1,F_2]=F_3$.

Minimizing geodesics. We will be able to find optimal trajectories joining our boundary conditions without making any computation. In fact F_1 and F_2 are two orthogonal vectors for the standard metric of S^3:

$$F_1\cdot F_2=\sum_{i=1}^4 (F_1)_i(F_2)_i=0.$$

Hence, the length of an admissible curve is just its standard Riemannian length on S^3. Therefore, if we find an admissible trajectory going from state 1 to state 2, which is a minimizing geodesic

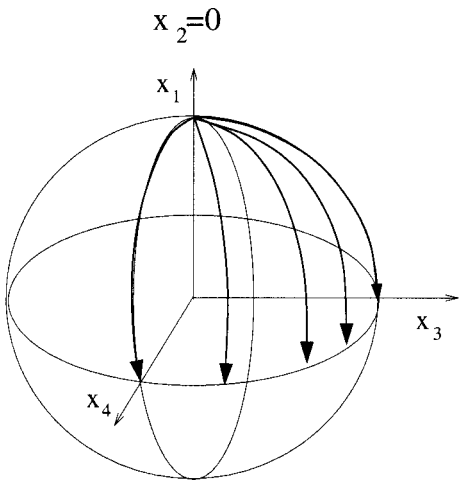

FIG. 1. The sphere S^3 and the geodesics from $x_1=1$ in the space $x_2=0$.

for the Riemannian metric on S^3, then it is also a minimizer for our sub-Riemannian problem. Now, each integral curve of the vector field $b(\cos(\alpha)F_1+\sin(\alpha)F_2)$ $(b\in\mathbb{R},\alpha\in[0,2\pi])$ are such admissible trajectories. It follows that:

Theorem 1: *Every constant control of the form:*

$$\begin{cases} u_1=b\cos(\alpha) \\ u_2=b\sin(\alpha) \end{cases}, \quad b\in\mathbb{R}, \quad \alpha\in[0,2\pi] \tag{30}$$

is optimal and the target is reached at time $t_1=(\pi/2)(1/b)$. *Moreover if* $\mathbf{x}_0\in S_{\text{in}}$ *is defined by* $x_1=\cos(\beta)$, $x_2=\sin(\beta)$, *then the equations of the geodesics corresponding to the controls (30) are:*

$$\begin{cases} x_1=\cos(\beta)\cos(bt), \\ x_2=\sin(\beta)\cos(bt), \\ x_3=-\sin(\alpha-\beta)\sin(bt), \\ x_4=-\cos(\alpha-\beta)\sin(bt). \end{cases} \tag{31}$$

The second part of Theorem 1 is easily checked.

Now since the functional (27) is invariant under time reparametrizations, one can take b to be a function of the time so that every optimal control has the form given by

$$\Omega(t)=b(t)e^{i[(E_2-E_1)t+\alpha]},$$

where α is an arbitrary constant, $b(.):\mathbb{R}\to\mathbb{R}^+$ is a real function with compact support $[0,t_1]$ and satisfying $\int_0^{t_1} b(t)=\pi/2$. In Fig. 1 are shown the geodesics issued from the point $x_1=1$ in the space $x_2=0$.

B. Another interpretation: The Hopf fibration and the Isoarea problem

The Hopf fibration (see, e.g., Ref. 18), $\pi:S^3\to S^2$ is defined by the following map. Let S^3 be described by the variables (x_1,x_2,x_3,x_4), $\Sigma x_i^2=1$ and S^2 by the variables (z_1,z_2,z_3), $\Sigma z_i^2=1/4$. We have:

$$(z_1,z_2,z_3)=\pi(x_1,x_2,x_3,x_4):=(\tfrac{1}{2}(x_1^2+x_2^2-x_3^2-x_4^2),x_1x_3-x_2x_4,x_2x_3+x_1x_4). \tag{32}$$

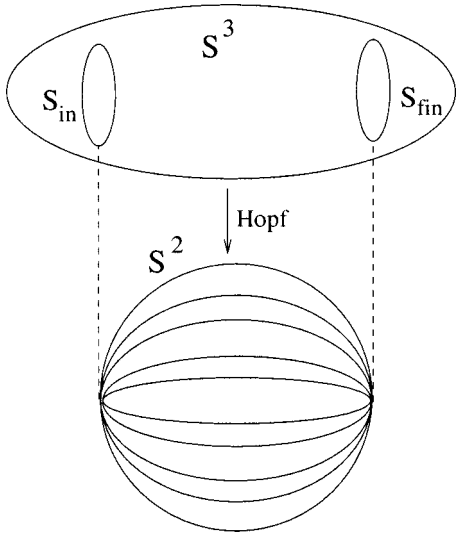

FIG. 2. Schematic representation of the Hopf fibration $\pi: S^3 \to S^2$. The geodesics given by Theorem 1 are also drawn.

The Hopf fibration gives to S^3 the structure of a principal bundle with base S^2 and fiber $S^1 \sim U(1)$. The following proposition (that one easily checks) shows why the Hopf fibration is connected to our problem:

Proposition 2: Let $F_3 := [F_1, F_2]$ *[see formula (28)], and* π *the Hopf fibration defined above. Then* $F_3 \in Ker(d\pi)$.

Notice that F_3 is the generator of the symmetry that "transports" along S_{in} and S_{fin} (cf. Remark 13) that means the following. If $\mathbf{x}_0 \in S_{\text{in}}$ (respectively, $\mathbf{x}_0 \in S_{\text{fin}}$) then the orbit $\mathcal{O}(x_0)$ of F_3 coincides with S_{in} (respectively, S_{fin}). From Proposition 2 it follows that S_{in} and S_{fin} shrink into two points through π. In particular these points are, respectively, the opposite points $(z_1, z_2, z_3) = (\pm \frac{1}{2}, 0, 0)$. The situation is illustrated by Fig. 2. Notice that we have a one parameter family of geodesics connecting S_{in} and S_{fin}, since their images under π are opposite points on S^2.

In fact, the sub-Riemannian problem we have, is as follows: The distribution (transversal to the fibers of the Hopf fibration) defines a connection over this (circle) principal bundle. It is easily seen that the curvature form of this connection is just the pull back (by the bundle projection) of the volume form of the Euclidean metric on S^2.

As a consequence (see Ref. 19), our sub-Riemannian problem corresponds to the "isoarea problem" on the Riemannian sphere S^2: given two points (antipodal on S^2 in our case), and any fixed curve $x(.)$ joining these two points, find another curve $y(.)$, joining also the two points, such that the length of $y(.)$ is minimal, and the area encircled by the curves $x(.), y(.)$ has a given value.

Corollary: There is no other minimizing curve [than the circle (31)] joining S_{in} and S_{fin}.

Proof: Assume that $\gamma: [0, t_1] \to S^3$ is such a minimizing curve. Then it has length $\pi/2$, and its projection on S^2 is one of the circles in Fig. 2. Now each of these circles is lifted in a unique way, via the connection, in one of the curves (31), once the initial point is chosen in S_{in}. Hence γ is one of the circles (31). ■

Our (very special) solutions exhibited previously are in fact geodesics of the Euclidean metric on S^2: they correspond to the choice of geodesics for the curve $x(.)$, and to the zero value of the area.

IV. THE THREE-LEVEL RESONANT PROBLEM

Statement of the Problem. In this section, we study a three-level quantum system, with only neighboring levels coupled, controlled by two laser pulses in resonance, i.e., with frequencies $\omega_1 = E_2 - E_1$, $\omega_2 = E_3 - E_2$; E_1, E_2, E_3 being the three energy levels.

The aim is to transfer all the population from the state with energy E_1 to the state with energy E_3 minimizing (again we set $t_0=0$)

$$\int_0^{t_1}\sqrt{u_1^2+u_2^2}\mathrm{d}t. \tag{33}$$

Writing $\psi(t)=c_1(t)\varphi_1+c_2(t)\varphi_2+c_3(t)\varphi_3$, where $\varphi_1=(1,0,0)$, $\varphi_2=(0,1,0)$, $\varphi_3=(0,0,1)$, we start from one point satisfying $|c_1(0)|^2=1$, and our target is defined by $|c_3(t_1)|^2=1$.

Remark 14: As in Sec. III, this new Hamiltonian gives rise to a driftless autonomous control system, while the control system corresponding to the old Hamiltonian (6) was time dependent and with drift. But in this case (i.e., with real controls), to obtain this strong simplification it is essential to use lasers in resonance.

The Control System. The Schrödinger equation corresponding to the Hamiltonian given by formula (15) is equivalent to the system of ODE for the c_i:

$$\begin{cases}\dot c_1=-iu_1(t)c_2,\\ \dot c_2=-i(u_1(t)c_1+u_2(t)c_3),\\ \dot c_3=-iu_2(t)c_2.\end{cases} \tag{34}$$

Setting $c_1=x_1+ix_2$, $c_2=x_4-ix_3$, $c_3=x_5+ix_6$, Eq. (34) becomes

$$\dot{\mathbf{x}}=u_1F_1+u_2F_2$$

where

$$x=\begin{pmatrix}x_1\\x_2\\x_3\\x_4\\x_5\\x_6\end{pmatrix},\quad F_1=\begin{pmatrix}-x_3\\-x_4\\x_1\\x_2\\0\\0\end{pmatrix},\quad F_2=\begin{pmatrix}0\\0\\x_5\\x_6\\-x_3\\-x_4\end{pmatrix}. \tag{35}$$

Here, the notations are such that the real parts (respectively, imaginary parts) of c_1,c_2,c_3 are x_1,x_4,x_5 (respectively $x_2,-x_3,x_6$). This convention will be very convenient later on.

In these new variables the condition $|c_1(t)|^2+|c_2(t)|^2+|c_3(t)|^2=1$ is $\Sigma_{i=1}^6x_i^2(t)=1$, so in fact $\mathbf{x}\in S^5$. The initial condition is now one point on the circle $S^1_{\text{in}}:=\{\mathbf{x}\in S^5: x_1^2+x_2^2=1\}$ and the target is $S^1_{\text{fin}}:=\{\mathbf{x}\in S^5: x_5^2+x_6^2=1\}$. With the choice (33) of the functional to be minimized, our problem looks like a classical sub-Riemannian problem on S^5, but, as we shall see, it is very degenerate.

The Lie algebra of the distribution. Let us compute the Lie algebra of the distribution. By setting $F_3=[F_1,F_2]$, we have

$$F_3=\begin{pmatrix}x_5\\x_6\\0\\0\\-x_1\\-x_2\end{pmatrix},\quad \begin{cases}[F_1,F_2]=F_3,\\ [F_2,F_3]=F_1,\\ [F_3,F_1]=F_2,\end{cases}$$

so $\mathrm{Lie}(\mathcal{F})=su(2)\sim so(3)$.

A. General properties of the orbit

Let $n(\mathbf{x})$, $\mathbf{x}\in S^5$ be the rank of the distribution. We have

$$n(\mathbf{x}):=\mathrm{rank}_{\mathbf{x}}(F_1,F_2,F_3)=\mathrm{rank}_{\mathbf{x}}\begin{pmatrix} -x_3 & 0 & x_5 \\ -x_4 & 0 & x_6 \\ x_1 & x_5 & 0 \\ x_2 & x_6 & 0 \\ 0 & -x_3 & -x_1 \\ 0 & -x_4 & -x_2 \end{pmatrix}=\begin{cases} 2 & \text{if } \mathbf{x}\in Q \\ 3 & \text{if } \mathbf{x}\in S^5\backslash Q, \end{cases} \tag{36}$$

where Q is the subset of S^5 defined by

$$x_3x_6-x_4x_5=0, \tag{37}$$

$$x_1x_6-x_2x_5=0, \tag{38}$$

$$x_3x_2-x_4x_1=0. \tag{39}$$

Notice that if x_1,x_3,x_5 are all different from zero, Eqs. (37), (38), and (39) are equivalent to

$$\frac{x_2}{x_1}=\frac{x_4}{x_3}=\frac{x_6}{x_5}. \tag{40}$$

Now since every initial condition lies in Q (i.e., $S^1_{\mathrm{in}}\in Q$), from the Hermann–Nagano theorem it follows:

Proposition 3: For each $\mathbf{x}_0\in S^1_{\mathrm{in}}$, *the orbit* $\mathcal{O}(\mathbf{x}_0)$ *is an analytic two-dimensional submanifold of* S^5.

More precisely defining $\mathbf{x}_0(\alpha)$ as the initial condition corresponding to

$$\begin{cases} x_1(0)=\cos(\alpha), \\ x_2(0)=\sin(\alpha), \end{cases} \tag{41}$$

where $\alpha\in[0,2\pi[$, we get the following:

Theorem 2: *The orbit* $O(\mathbf{x}_0(\alpha))$, $\alpha\in[0,2\pi[$ *is the two-dimensional sphere of equation* $x'^2_1+x'^2_3+x'^2_5=1$ *where*

$$\begin{pmatrix} x_1' \\ x_2' \\ x_3' \\ x_4' \\ x_5' \\ x_6' \end{pmatrix}=\begin{pmatrix} \cos(\alpha) & \sin(\alpha) & 0 & 0 & 0 & 0 \\ -\sin(\alpha) & \cos(\alpha) & 0 & 0 & 0 & 0 \\ 0 & 0 & \cos(\alpha) & \sin(\alpha) & 0 & 0 \\ 0 & 0 & -\sin(\alpha) & \cos(\alpha) & 0 & 0 \\ 0 & 0 & 0 & 0 & \cos(\alpha) & \sin(\alpha) \\ 0 & 0 & 0 & 0 & -\sin(\alpha) & \cos(\alpha) \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \end{pmatrix}. \tag{42}$$

Proof: Assume first $\alpha=0$. This means that the initial condition is defined by $x_1(0)=1$ and the variables with the prime coincide with those without the prime.

In Eq. (35) the variables x_1,x_3,x_5 are decoupled from the other (in fact, we have a product system, of two subsystems on $\mathbb{R}^3$). It follows $\mathcal{O}(\mathbf{x}_0(\alpha))\subset\{\mathbf{x}\in S^5: x_1^2+x_3^2+x_5^2=1\}$. But all the points of this sphere belong to the orbit since they can be reached by using a control of the form:

$$(u_1(t),u_2(t))=\begin{cases} (1,0) & \text{for } t\in[0,t_a] \\ (0,1) & \text{for } t\in[t_a,t_b] \end{cases}$$

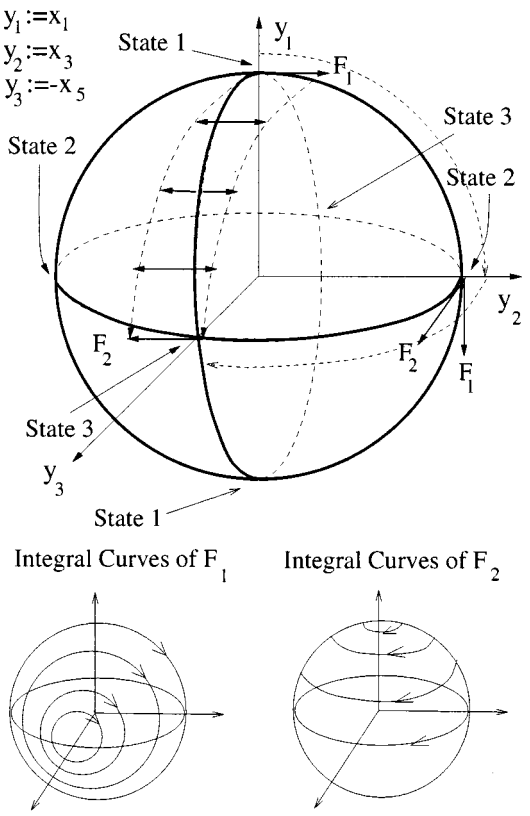

FIG. 3. The vector fields F_1 and F_2 on the sphere.

for some $t_a, t_b > 0$. In fact, in the (x_1, x_3, x_5) space, each integral curve of F_1 (respectively, F_2) is a circle that lies in the plane $x_5 = \text{const}$ (respectively, $x_1 = \text{const}$) and the center of which belongs to the x_5 (respectively, x_1) axis, see Fig. 3. At time t_a one reaches the point:

$$\begin{cases} x_1(t_a) = \cos(t_a), \\ x_3(t_a) = \sin(t_a), . \\ x_5(t_a) = 0. \end{cases}$$

At time t_b one reaches the point:

$$\begin{cases} x_1(t_b) = \cos(t_a), \\ x_3(t_b) = \sin(t_a)\cos(t_b), \\ x_5(t_b) = -\sin(t_b). \end{cases}$$

So all the points of the sphere $x_1^2 + x_3^2 + x_5^2 = 1$ can be reached for suitable t_a and t_b. The Theorem is proved for $\alpha = 0$.

Assume now that we start from the point $\mathbf{x}_0(\alpha)$ for an arbitrary α. Making the change of coordinates given by formula (42), one is back to the situation $\alpha = 0$ for the variables with the prime. This concludes the proof. ■

Notice that, for fixed $\mathbf{x}_0(\alpha)$, one can reach only two points of the final target. For instance if $\alpha = 0$, i.e., $x_1(0) = 1$, we can reach S^1_{fin} only in the two points $x_5 = \pm 1$. The situation is illustrated by Fig. 4.

More precisely as a consequence of the symmetry given by formula (42) we have the following:

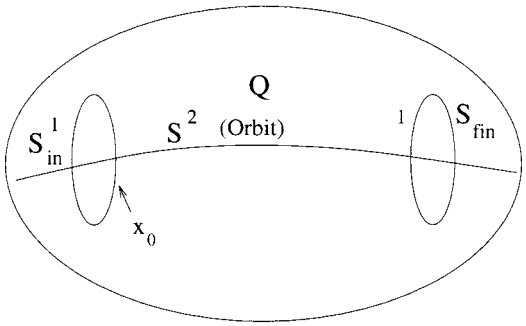

FIG. 4. The foliation of Q.

Corollary of Theorem 2: Fix $\alpha\in[0,2\pi]$, *let* $\mathbf{x}=(x_1,\ldots,x_6)\in\mathcal{O}(\mathbf{x}_0(\alpha))$, *and define* $\alpha_{12}(\mathbf{x})$, $\alpha_{34}(\mathbf{x})$, $\alpha_{56}(\mathbf{x})$ *to be the angles (illustrated in Fig. 5) such that*

$$\begin{cases} x_1=\sqrt{x_1^2+x_2^2}\cos(\alpha_{12}(\mathbf{x})),\\ x_2=\sqrt{x_1^2+x_2^2}\sin(\alpha_{12}(\mathbf{x})),\end{cases}$$

$$\begin{cases} x_3=\sqrt{x_3^2+x_4^2}\cos(\alpha_{34}(\mathbf{x})),\\ x_4=\sqrt{x_3^2+x_4^2}\sin(\alpha_{34}(\mathbf{x})),\end{cases}$$

$$\begin{cases} x_5=\sqrt{x_5^2+x_6^2}\cos(\alpha_{56}(\mathbf{x})),\\ x_6=\sqrt{x_5^2+x_6^2}\sin(\alpha_{56}(\mathbf{x})).\end{cases}$$

Then, for each such $\mathbf{x}$, *there exist* $n_{12}(\mathbf{x}),n_{34}(\mathbf{x}),n_{56}(\mathbf{x})\in\{0,\pm1\}$ *such that*

$$\alpha_{12}(\mathbf{x})=\alpha\pm n_{12}\pi \quad \textit{if} \quad \alpha_{12} \textit{ is defined } (\textit{i.e., } x_1,x_2 \textit{ not both vanishing}), \tag{43}$$

$$\alpha_{34}(\mathbf{x})=\alpha\pm n_{34}\pi \quad \textit{if} \quad \alpha_{34} \textit{ is defined } (\textit{i.e., } x_3,x_4 \textit{ not both vanishing}), \tag{44}$$

$$\alpha_{56}(\mathbf{x})=\alpha\pm n_{56}\pi \quad \textit{if} \quad \alpha_{56} \textit{ is defined } (\textit{i.e., } x_5,x_6 \textit{ not both vanishing}). \tag{45}$$

Moreover at least one of the three angles $\alpha_{12},\alpha_{34},\alpha_{56}$ *is defined.*

The Structure of Q. Let us now study the structure of Q. From the Hermann–Nagano theorem we have

$$Q\supseteq\bigcup_{\mathbf{x}_0\in S^1_{\text{in}}}\mathcal{O}_{\mathbf{x}_0}$$

but in fact this equation holds with equality as a consequence of the fact that relations (37), (38), and (39) defining Q are equivalent to Eqs. (43), (44), (45), that hold on the orbit. More precisely let $\overline{\mathbf{x}}=(\overline{x_1},\ldots,\overline{x_6})$ be a point of Q and $\overline{\alpha}$ the angle between $\overline{x_1}$ and $\overline{x_2}$ measured counterclockwise, if defined. If not $\overline{\alpha}$ will be the angle between the variables $\overline{x_3}$ and $\overline{x_4}$, or between the

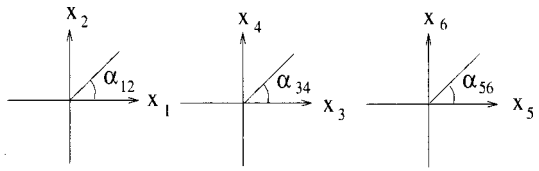

FIG. 5. The definition of the angles $\alpha_{12}(\mathbf{x})$, $\alpha_{34}(\mathbf{x})$, $\alpha_{56}(\mathbf{x})$.

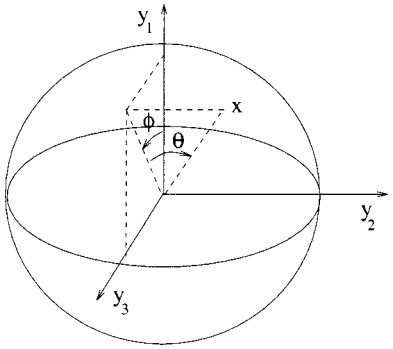

FIG. 6. The angles θ and ϕ.

variables $\overline{x_5}$ and $\overline{x_6}$ (in the spirit of the Corollary of Theorem 2). Because of (40), $\overline{\alpha}$ can be actually defined in this way. One clearly has $\overline{x} \in \mathcal{O}(\mathbf{x}_0(\overline{\alpha}))$. Hence we have proved the following:

Proposition 4: We have $Q = \cup_{\mathbf{x}_0 \in S^1_{\text{in}}} \mathcal{O}_{\mathbf{x}_0}$.

Let σ be the antipodal involution of $S^1 \times S^2$, that is, $\sigma(\alpha, p) = (\alpha + \pi, -p)$. The involution σ has no fixed point, and is orientation reversing. Also, clearly, by Theorem 2, our orbits are σ stable. Hence: $Q = (S^1 \times S^2)/\sim$ where $\mathbf{x} \sim \mathbf{x}'$ if $\sigma(x) = \sigma(\mathbf{x}')$. Therefore, it is not hard to see that:

Theorem 3: *Q is the (only) nonorientable sphere-bundle over* S^1.

B. Geodesic equations on the sphere

Due to the invariance under the transformation (42) all the points of S_{in} can be considered equivalently. In the following we will study the optimal control problem on the orbit $\mathcal{O}(\mathbf{x}_0)$, where $\mathbf{x}_0$ is defined by $x_1 = 1$. Then $\mathcal{O}(\mathbf{x}_0)$ is the sphere of equation $x_1^2 + x_3^2 + x_5^2 = 1$. In what follows, we will keep the notation F_1 and F_2 for the restrictions of F_1 and F_2 to this sphere.

In order to get labels for coordinates corresponding to quantum states, and in order to have F_2 pointing in the positive direction from the point $x_3 = 1$, we define $y_1 = x_1$, $y_2 = x_3$, $y_3 = -x_5$. The control system under consideration is then

$$\begin{pmatrix} \dot{y}_1 \\ \dot{y}_2 \\ \dot{y}_3 \end{pmatrix} = u_1 F_1 + u_2 F_2,$$

where

$$F_1 = \begin{pmatrix} -y_2 \\ y_1 \\ 0 \end{pmatrix}, \quad F_2 = \begin{pmatrix} 0 \\ -y_3 \\ y_2 \end{pmatrix}.$$

The vector fields are plotted in Fig. 3. The initial condition is the point $y_1 = 1$. The state number 1 (respectively, 2, 3) correspond to the points $y_1 = \pm 1$ (respectively, $y_2 = \pm 1$, $y_3 = \pm 1$). State 2 can be reached from state 1 using only F_1 and state 3 can be reached from state 2 using only F_2 (dotted lines). However, state 3 cannot be reached from state 1 using a trajectory contained in the circle of equation:

$$y_2 = 0 \quad (\text{i.e., } y_1^2 + y_3^2 = 1), \tag{46}$$

since no piece of this circle is an admissible trajectory. This is due to the fact that F_1 is collinear to F_2 on the circle (46), and not tangent to this circle.

A new orthogonal frame. Let us describe the orbit in spherical coordinates (see Fig. 6):

$$\begin{cases} y_1 = \cos(\theta)\cos(\phi), \\ y_2 = \sin(\theta), \\ y_3 = \cos(\theta)\sin(\phi). \end{cases} \tag{47}$$

We have

$$\begin{pmatrix} F_1 \\ F_2 \end{pmatrix} = R \begin{pmatrix} G_1 \\ G_2 \end{pmatrix},$$

where

$$R := \begin{pmatrix} \cos(\phi) & \sin(\phi) \\ -\sin(\phi) & \cos(\phi) \end{pmatrix}, \quad \begin{cases} G_1 = \partial_\theta \\ G_2 = \tan(\theta)\partial_\phi . \end{cases}$$

Since $R \in \mathrm{SO}(2)$, the couple (G_1, G_2) is a new orthonormal frame for the singular-Riemannian length. For this new frame the control system is then

$$\begin{pmatrix} \dot{\theta} \\ \dot{\phi} \end{pmatrix} = v_1 G_1 + v_2 G_2, \tag{48}$$

and the functional to be minimized is $\int_0^{t_1} \sqrt{v_1^2 + v_2^2}\,dt$. The relation between u_1, u_2 and v_1, v_2 is obtained from $u_1 F_1 + u_2 F_2 \equiv v_1 G_1 + v_2 G_2$:

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = R \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}. \tag{49}$$

The metric defined by the frame (G_1, G_2) is a singular metric. Indeed when $\theta = 0$ we have $G_2 = 0$, that is exactly on the circle (46). Notice that the singularity of the metric for $\theta = \pi/2$ is only due to the choice of the coordinates system.

The Hamiltonian. Let us compute the geodesics using the Maximum Principle. Here, for standard reasons, we use as cost the fluence (21). The final time is fixed by requiring the parametrization by arclength that is $v_1^2 + v_2^2 = 1$ (this means to normalize $\mathcal{H}_M = 1/2$, see the Pontryagin Maximum Principle in Sec. I for the definition of $\mathcal{H}_M$). Notice that from formula (49) we have

$$v_1^2 + v_2^2 = u_1^2 + u_2^2.$$

As explained in Sec. II C 2 this corresponds to minimizing the time under the constraint $u_1^2 + u_2^2 \leqslant 1$. Let $P = (P_\theta, P_\phi) \in T^*_{\theta,\phi} M$. By definition the Hamiltonian is

$$\begin{aligned} \mathcal{H}(\theta, \phi, P_\theta, P_\phi, v_1, v_2) &= \langle P, v_1 G_1 + v_2 G_2 \rangle + p_0 (v_1^2 + v_2^2) \\ &= v_1 P_\theta + v_2 P_\phi \tan(\theta) + p_0 (v_1^2 + v_2^2). \end{aligned} \tag{50}$$

It is easily checked that, as for the Riemannian case, we can always assume $p_0 \neq 0$ (there are no abnormal extremals) and we can normalize $p_0 = -\frac{1}{2}$. Extremal controls are computed from the maximum condition:

$$\frac{\partial \mathcal{H}}{\partial v_1} = 0, \quad \frac{\partial \mathcal{H}}{\partial v_2} = 0, \quad \Rightarrow v_1 = P_\theta, \quad v_2 = P_\phi \tan(\theta). \tag{51}$$

Hence, we obtain that the extremals are projections on the (θ, ϕ) space of integral curves of the Hamiltonian vector field corresponding to the following Hamiltonian:

$$\mathcal{H}_M = \tfrac{1}{2} (P_\theta^2 + (\tan(\theta) P_\phi)^2). \tag{52}$$

The Hamiltonian equations are

$$\dot{\theta}=\frac{\partial \mathcal{H}_M}{\partial P_\theta}=P_\theta,$$

$$\dot{\phi}=\frac{\partial \mathcal{H}_M}{\partial P_\phi}=P_\phi \tan^2(\theta),$$

$$\dot{P}_\theta=-\frac{\partial \mathcal{H}_M}{\partial \theta}=-P_\phi^2 \tan(\theta)(1+\tan^2(\theta)),$$

$$\dot{P}_\phi=-\frac{\partial \mathcal{H}_M}{\partial \phi}=0.$$

Setting $a:=P_\phi$ finally we have

$$\dot{\theta}=P_\theta, \quad \dot{\phi}=a\tan^2(\theta), \quad \dot{P}_\theta=-a^2\tan(\theta)(1+\tan^2(\theta)). \tag{53}$$

This Hamiltonian system is Liouville integrable since we have two independent and commuting constants of the motion $\mathcal{H}_M$ and $P_\phi=a$.

1. Minimizing the length

Let us find the geodesic without the parametrization, i.e., a relation between θ and ϕ. We have

$$\frac{d\phi}{d\theta}=\frac{\dot{\phi}}{\dot{\theta}}=\frac{\dot{\phi}}{P_\theta}=\pm\frac{a\tan^2(\theta)}{\sqrt{1-a^2\tan^2(\theta)}}, \tag{54}$$

where we have expressed P_θ using relation (52) and normalized $\mathcal{H}_M=1/2$. So we have the two families of solutions parametrized by the value of a:

$$\begin{aligned}\phi_a^{\pm}(\theta)&=\pm\int_0^\theta \frac{a\tan^2(s)}{\sqrt{1-a^2\tan^2(s)}}ds\\ &=\pm\left[\arctan\left(\frac{a}{\Xi(\theta,a)}\sin(\theta)\right)-\frac{a}{\sqrt{1+a^2}}\arctan\left(\frac{\sqrt{1+a^2}}{\Xi(\theta,a)}\sin(\theta)\right)\right],\end{aligned} \tag{55}$$

where $\Xi(\theta,a):=\sqrt{\frac{1}{2}(1-a^2+(1+a^2)\cos(2\theta))}$.

To fix the ideas, let us consider only the family ϕ_a^+ with $a>0$ and suppose $\theta\geqslant 0$, the other cases being symmetric. Let us call this family $\phi_a(\theta)$. Expression (55) defines $\phi_a(\theta)$ in the interval $[0,\overline{\theta}_a[$ where $\overline{\theta}_a$ is the value of θ at which the denominator of formula (54) vanishes:

$$\overline{\theta}_a:=\arctan\left(\frac{1}{a}\right). \tag{56}$$

Notice that $\lim_{\theta\to\overline{\theta}_a}\Xi[\theta,a]=0$ so

$$\lim_{\theta\to\overline{\theta}_a}\phi_a(\theta)=\frac{\pi}{2}\left(1-\frac{a}{\sqrt{1+a^2}}\right). \tag{57}$$

In the following we consider $\phi_a(\theta)$ defined in $[0,\overline{\theta}_a]$ where by definition $\phi_a(\overline{\theta}_a)$ is the value given by formula (57). Indeed, from the symmetries of the system, we have to consider two branches (illustred in Fig. 7) to describe the whole relation between θ and ϕ:

$$\phi_a^1(\theta)=\phi_a(\theta),$$

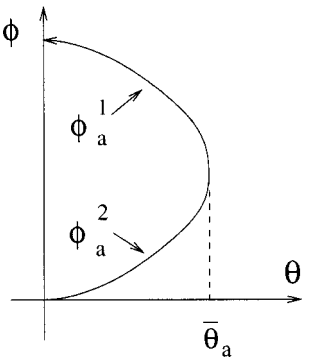

FIG. 7. The geodesic curve as a relation between θ and ϕ.

$$\phi_a^2(\theta)=2\phi_a(\overline{\theta}_a)-\phi_a(\theta).$$

The geodesic reaching the target is the one satisfying $\phi_a(\overline{\theta}_a)=\pi/4$. From Eq. (57) we get $a:=1/\sqrt{3}$.

Remark 15: By considering both signs in formula (55) (or equivalently a positive and negative) and $\theta\in[-\pi,\pi]$ one gets four equivalent optimal trajectories reaching the state 3 (see Fig. 8). Moreover the set of geodesics parametrized by a allows one to easily compute an optimal synthesis for the problem.

A smooth parametrization of the geodesic. To get an explicit expression of the controls (as function of the time) reaching the final point $\theta=0$, $\phi=\pi/2$, one should first fix a parametrization $\theta(t)$ in such a way that:

(1) $\theta(0)=\theta(t_1)=0$,

(2) for some $\overline{t}\in]0,t_1[$ it holds:

$$\begin{cases}\theta(\overline{t})=\overline{\theta}_{1/\sqrt{3}}=\pi/3,\\ \theta(t) \quad \text{is increasing for } t\in[0,\overline{t}],\\ \theta(t) \quad \text{is decreasing for } t\in[\overline{t},t_1].\end{cases}$$

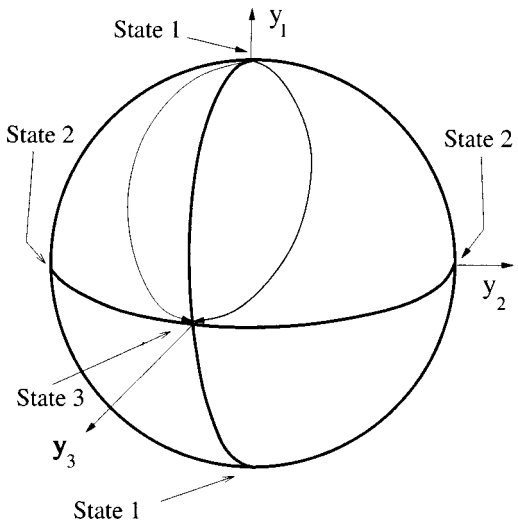

FIG. 8. The four geodesics reaching the state 3. Two are on the other side and reach the point $y_3=-1$.

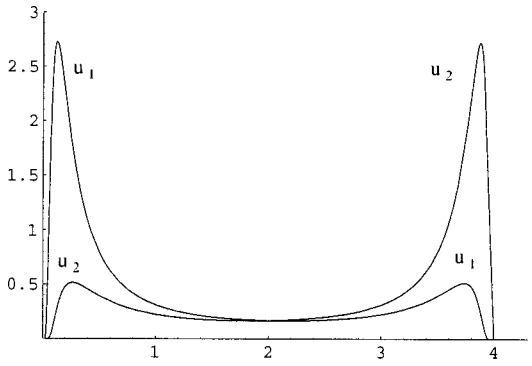

FIG. 9. Example 1: $\mathcal{C}^\infty$ optimal controls.

The best choice is of course a sufficiently regular symmetric function. In this case we have $\bar{t}=t_1/2$ and

$$\phi(t)=\begin{cases}\phi_{1/\sqrt{3}}(\theta(t)) & \text{if } t\in[0,t_1/2[,\\ 2\phi_{1/\sqrt{3}}(\theta(t_1/2))-\phi_{1/\sqrt{3}}(\theta(t_1-t)) & \text{if } t\in[t_1/2,t_1].\end{cases} \tag{58}$$

The controls $v_1(t)$ and $v_2(t)$ can be obtained from the relation $\dot{\theta}(t)\partial_\theta+\dot{\phi}(t)\partial_\phi=v_1(t)\partial_\theta+v_2(t)\tan(\theta(t))\partial_\phi$ from which we have

$$v_1(t)=\dot{\theta}(t),\quad v_2(t)=\frac{\dot{\phi}(t)}{\tan(\theta(t))}. \tag{59}$$

Remark 16: Notice that relations (59) coincide with relations (51) only in the case in which the curve $(\theta(t),\phi(t))$ is parametrized with constant velocity.

Finally the amplitudes of the lasers are obtained with formula (49).

Example 1: Consider the $\mathcal{C}^\infty$ function:

$$\theta(t)=\begin{cases}0 & \text{if } t<0 \text{ or } t>t_1\\ \dfrac{\pi}{3}e^{1/(t_1-t)(-t)} & \text{otherwise.}\end{cases} \tag{60}$$

The corresponding laser amplitudes $u_1(t)$ and $u_2(t)$ (for $t_1=4$) are shown in Fig. 9.

Example 2: Consider the function:

$$\theta(t)=\begin{cases}0 & \text{if } t<0 \text{ or } t>t_1\\ \dfrac{(-1+e^{-36t(t-t_1)/t_1^2})\pi}{3(-1+e^9)} & \text{otherwise.}\end{cases} \tag{61}$$

The corresponding laser amplitudes $u_1(t)$ and $u_2(t)$ (for $t_1=4$) are shown in Fig. 10.

2. Minimizing either the fluence or the time for constrained controls

To minimize the fluence, one should also get the parametrization from the Hamiltonian equations. From the equation (after fixing $a=1/\sqrt{3}$):

$$\dot{\theta}=P_\theta=\sqrt{1-a^2\tan^2(\theta)},$$

we have

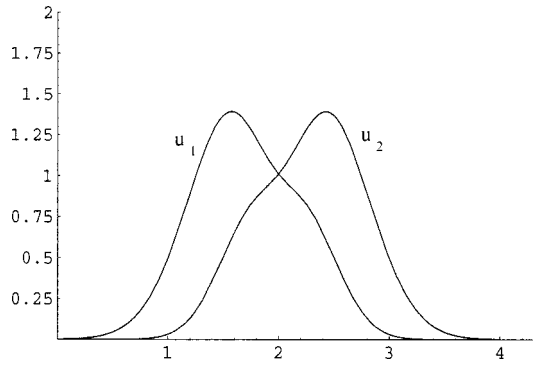

FIG. 10. Example 2: a possible choice of optimal controls.

$$t(\theta)=\frac{\arctan\left(\dfrac{2\sin(\theta)}{\sqrt{1+2\cos(2\theta)}}\right)\sqrt{1+2\cos(2\theta)}\sec(\theta)}{2\sqrt{1-\tan(\theta)^2/3}}.$$

Using the inverse function theorem, this formula permits one to describe $\theta(t)$ in the interval $[0,\bar{t}]$ where

$$\bar{t}:=\lim_{\theta\to\bar{\theta}_a} t(\theta)=\frac{\sqrt{3}}{4}\pi.$$

By symmetry this is exactly half of the final time. Finally $\dot{\phi}(t)$ can be obtained integrating the equation $\dot{\phi}(t)=a\ \tan^2(\theta(t))$. Controls $u_1(t)$ and $u_2(t)$ can be obtained with formulas (59) and (49) and they are shown in Fig. 11.

Remark 17: Notice that these controls are not smooth at $t=0$ and at the final time $2\bar{t}=(\sqrt{3}/2)\ \pi$.

From this analysis we get the values of the costs for the optimal trajectory:

Theorem 4: *For the three costs described in Sec. II C, the following relations hold.*

(a) Length:

$$\mathrm{Min}\left(\int_0^{t_1}\sqrt{u_1^2+u_2^2}\,\mathrm{d}t\right)=\frac{\sqrt{3}}{2}\pi.$$

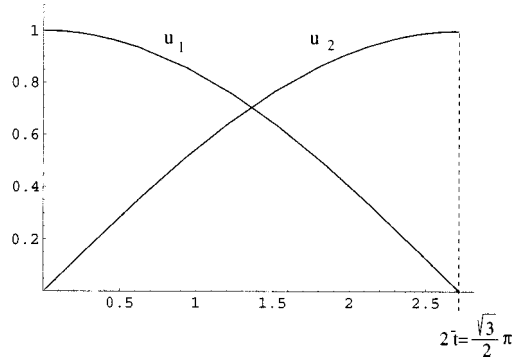

FIG. 11. Optimal controls minimizing fluence or time.

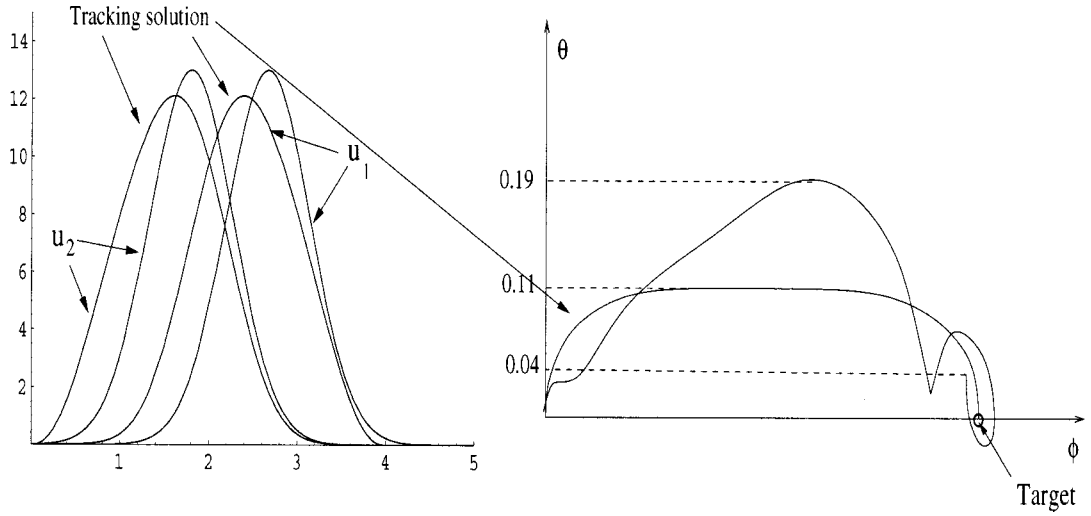

FIG. 12. Usual-adiabatic and tracking solutions.

(b) Fluence, with fixed transfer time T:

$$\mathrm{Min}\left(\int_0^T (u_1^2+u_2^2)\,\mathrm{d}t \right) = \frac{3}{4}\pi^2 \frac{1}{T}. \tag{62}$$

(c) Time under the constraint $u_1^2+u_2^2 \leqslant 1$,

$$T_{\min} = \frac{\sqrt{3}}{2}\pi. \tag{63}$$

V. THE TRACKING COUNTERINTUITIVE SOLUTIONS

For practical applications, trajectories joining state 1 to state 3, that take as small as possible the population of state 2 [i.e., with $\theta(t)$ closed to zero], are also interesting. We recall that the nonadmissible trajectory is contained in the circle (46). In this section we study a trajectory in which $\phi(t)$ is monotonously increasing between 0 and $\pi/2$, and

$$\theta(t) \leqslant \varepsilon, \quad \text{for every } t \in [0,t_1], \tag{64}$$

for some small $\varepsilon>0$ fixed. This means that the population in state 2 $[0,t_1]$ is always small, less or equal than $\sin^2(\varepsilon)=\varepsilon^2+O(\varepsilon^4)$ [see formula (47)].

It is well known[1,25] that the nonadmissible trajectory can be approximated using controls $u_1(t)$ and $u_2(t)$ in the so-called "counterintuitive" sequence: (see Fig. 12 for such a sequence). In the following we show how to build a trajectory satisfying condition (64) and connecting exactly the points P_1 defined by $(\phi,\theta)=(0,0)$ and P_2 defined by $(\phi,\theta)=(\pi/2,0)$.

The idea is to track a trajectory connecting these two points taking care of the constraints that we have on the derivatives at P_1 and P_2. More precisely we should find a function $\theta(\phi)$ such that the following holds. Let $\phi^1(\theta)$ (respectively, $\phi^2(\theta)$) be the inverse function of $\theta(\phi)$ in a neighborhood of P_1 (respectively, P_2). Since F_1 and F_2 vanish, respectively, at points P_1 and P_2, we must have

$$\left.\frac{\mathrm{d}\phi^1}{\mathrm{d}\theta}\right|_{\theta=0} = 0, \tag{65}$$

$$\left.\frac{\mathrm{d}\phi^2}{\mathrm{d}\theta}\right|_{\theta=0}=0. \tag{66}$$

A possible choice is the symmetric function is

$$\theta(\phi)=\varepsilon\frac{4}{\pi}\sqrt{\phi\left(\frac{\pi}{2}-\phi\right)}, \tag{67}$$

which reaches the value ε only at the point $\phi=\pi/4$, as shown in Fig. 12.

Now we have to choose a parametrization $(\theta(t),\phi(t))$. To have continuous controls satisfying $u_1(0)=0$, $u_2(0)=0$, $u_1(t_1)=0$, $u_2(t_1)=0$ we must have

$$\dot{\theta}^1(t)|_0=0,$$

$$\dot{\theta}^2(t)|_{t_1}=0.$$

From Eqs. (65), (66) we get

$$\ddot{\phi}^1(t)|_0=0,$$

$$\ddot{\phi}^2(t)|_{t_1}=0.$$

To get controls having zero derivative at the initial and final points, we can use the following function:

$$\phi(t)=\frac{6006\pi}{t_1^{13}}\left(\frac{t^{13}}{13}-\frac{t^{12}t_1}{2}+\frac{15t^{11}t_1^2}{11}-2\,t^{10}t_1^3+\frac{5t^9t_1^4}{3}-\frac{3t^8t_1^5}{4}+\frac{t^7t_1^6}{7}\right). \tag{68}$$

Notice that this function satisfies $\phi^1(\overline{t})=\phi^2(\overline{t})=\phi^3(\overline{t})=\phi^4(\overline{t})=\phi^5(\overline{t})=\phi^6(\overline{t})=0$ for $\overline{t}=0,t_1$. The corresponding controls are computed with relations (59) and (49).

Remark 18: Let us use a parametrization $\phi(t)$ with $\phi^{(i)}(t)|_{t=0}=0$, $\phi^{(i)}(t)|_{t=t_1}=0)$, $i=1,\ldots,n$, $n\geqslant 2$, then the following holds:

(1) if $n=2$ then $u_1(0)=u_2(0)=0$, $\lim_{t\to t_1}\dot{u}_1(t)=-\infty$, $\lim_{t\to 0}\dot{u}_2(t)=\infty$,

(2) if $n=3$ then $u_1(0)=u_2(0)=0$, $0>\dot{u}_1(t_1)>-\infty$, $0<\dot{u}_2(0)<\infty$,

(3) if $n\geqslant 4$ then $u_1(0)=u_2(0)=0$,
$u_1^{(i)}(0)=u_2^{(i)}=0$ for $i=1,\ldots,n-3$. So if ϕ is $\mathcal{C}^n$, in $]-\delta,t_1+\delta[$ $(\delta>0,\quad \phi(t)=0$ in $]-\delta,0]\cup[t_1,t_1+\delta[)$ then u_1 and u_2 are $\mathcal{C}^{n-3}$ in $]-\delta,t_1+\delta[$.

Notice that for very small values of ε one gets very big values of the controls. We would like to stress the fact that the trajectory obtained with this tracking reaches exactly the final target for any fixed value of ε. While in the ''counterintuitive'' strategies used in literature, if ε_c is the maximum value reached by θ, then the final target is reached with an error smaller than ε_c but different from zero.

In the last picture the tracking solution corresponding to the expression of (68), for $\varepsilon=2/19$, and $t_1=4$ and a typical strategy used in literature:

$$\begin{cases} u_1(t)=\dfrac{-5}{e^{16}}+\dfrac{13}{e^{(-4+1.5\,t)^2}}, \\ u_2(t)=\dfrac{-5}{e^{9}}+\dfrac{13}{e^{(-2.7+1.5\,t)^2}} \end{cases} \tag{69}$$

are compared. Notice that the pulses have similar area. Moreover, notice that the trajectory corresponding to the controls (69) (obtained integrating numerically the Schrödinger equation) reaches negative values of θ.

VI. CONCLUSION

In summary, we have shown how optimal controls for two- and three-level models can be constructed on the basis of geometric arguments. For the two-level modes we recover the well-known ''π-pulse'' strategy, and obtain the corresponding generalization for the resonant three-level model. The optimal trajectories appear as geodesics (Riemannian or singular-Riemannian) on two-dimensional spheres. Furthermore, besides the optimal control strategies, the standard tracking technique from geometric control theory allows us to analyze a method of adiabatic control used in recent experiments. It leads to an improvement that allows one to reach the target state precisely. The extension of these results to the treatment of more general N-level systems will be presented in forthcoming work.

(Received 20 September 2001; accepted for publication 1 February 2002)

As an extension of the intertwining operator idea, an algebraic method which provides a link between supersymmetric quantum mechanics and quantum (super)integrability is introduced. By realization of the method in two dimensions, two infinite families of superintegrable and isospectral stationary potentials are generated. The method makes it possible to perform Darboux transformations in such a way that, in addition to the isospectral property, they acquire the superintegrability preserving property. Symmetry generators are second and fourth order in derivatives and all potentials are isospectral with one of the Smorodinsky–Winternitz potentials. Explicit expressions of the potentials, their dynamical symmetry generators, and the algebra they obey as well as their degenerate spectra and corresponding normalizable states are presented. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1463217]

I. INTRODUCTION

A Hamiltonian system of N degrees of freedom is said to be completely integrable, in the Liouville–Arnold sense, if it possesses functionally independent globally defined and single-valued N integrals of motion in involution.[1,2] It is called superintegrable if it admits more than N integrals of motion. Not all the integrals of the superintegrable system can be in involution, but they must be functionally independent otherwise the extra invariants are trivial. In analogy to the classical mechanics, a quantum mechanical system described in N-dimensional (ND) Euclidean space by a stationary Hamiltonian operator H is called completely integrable if there exists a set of $N-1$ (together with H,N) algebraically independent linear operators $X_i, i=1,2,\ldots,N-1$ commuting with H and among each other.[3–11] If there exist k additional operators $Y_j, j=1,2,\ldots,k$ where $0<k\leqslant N-1$, commuting with H it is said to be superintegrable. The superintegrability is said to be minimal if $k=1$ and maximal if $k=N-1$.

Classical and quantum mechanical examples of the maximally superintegrable systems for any finite N are the Kepler-Coulomb problem, the harmonic oscillator with rational frequency ratio, the Calogero–Moser system in a harmonic well, and the Winternitz (or, Smorodinsky–Winternitz) system. The first two are known, for $N=3$, since the time of Laplace and the superintegrability of the last two systems were established for the first time, respectively, by Wojciechowski[5] and by Evans.[6] The first systematic search for other possible superintegrable

[d]Electronic mail: vercin@science.ankara.edu.tr

systems was begun by Winternitz and co-workers. They first found four independent two-dimensional (2D) potentials that are separable in more than one coordinate system,[3] and then they extended this to $N=3$.[4] This approach is based on two assumptions; (1) Hamiltonians are of potential form; (2) integrals of motion are at most quadratic in momenta (or, in derivatives). The Winternitz program has been completed in Ref. 7 where a complete list consisting of, up to the equivalence of linear transformations, thirteen different three-dimensional potentials with four or five independent integrals of motion is given. Winternitz potentials have also been considered by different formulations such as path integral formulation,[8] Lagrangian formalism,[9] and evolutionary vector fields formalism.[10]

In this paper we report an infinite family of 2D potentials which are not only superintegrable, but at the same time isospectral. We shall give explicit expressions of the potentials, their dynamical symmetry generators and the algebra they obey, as well as their degenerate spectrum and corresponding normalizable states. We achieve this goal by following an algebraic method which is based on and, in fact, is an extension of intertwining operator idea. This is closely connected with the supersymmetric (SUSY) methods such as the Darboux transformation, and Schrödinger factorization which deal with pairs of Hamiltonians having the same energy spectra but different eigenstates.[12–15] It turns out that each member of this infinite family is a triplet of potentials one of which is the same for entire family and the other two change from member to member. Hence, we have, in fact, two different infinite families of superintegrable and isospectral potentials. The fixed potential turns out to be one of 2D Winternitz potentials and determines the spectra of both families and the other two are intertwined to it by Darboux-type transformations. The generators of these transformations depend on eigenfunctions of two associated solvable one-dimensional problems that result from the separation of the Winternitz potential in different coordinates. We should emphasize that our approach makes it possible to apply Darboux transformations simultaneously to potential and to its symmetry generators in such a way that superintegrability property is preserved.

Formal aspects of our method together with a brief review of the main points of the intertwining operator idea will be given in Sec. II. Sections III–V are devoted to explicit realization of our method. In Sec. IV we present the most general form of 2D integrable and isospectral potentials in the plane polar coordinates. Two subfamilies of superintegrable and isospectral potentials and then their general forms are presented in Secs. VI and VII. Section VIII contains a review of bound states of the associated one-dimensional (1D) problems and the above-mentioned Winternitz potential. After investigating the symmetry generators and their algebra in Sec. IX, the normalizable states of the generated superintegrable and isospectral potentials are given in Sec. X.

II. MULTIPLE INTERTWINING METHOD

The object of the intertwining method is to construct a linear differential operator $\mathcal{L}$ which intertwines two Hamiltonian operators H_0 and H_1 such that $\mathcal{L}H_0=H_1\mathcal{L}$. Two important facts that immediately follow from this relation are as follows. (i) If ψ^0 is an eigenfunction of H_0 with eigenvalue of E^0 then $\psi^1=\mathcal{L}\psi^0$ is an (unnormalized) eigenfunction of H_1 with the same eigenvalue E^0. (ii) When H_0 and H_1 are self-adjoint (on some common function space) $\mathcal{L}^\dagger$ intertwines in the other direction $H_0\mathcal{L}^\dagger=\mathcal{L}^\dagger H_1$ and this in turn implies that $[H_0,\mathcal{L}^\dagger\mathcal{L}]=0=[\mathcal{L}\mathcal{L}^\dagger,H_1]$, where the dagger (†) and $[,]$ stand for Hermitian conjugation and commutator. The first property shows that $\mathcal{L}$ transforms one solvable problem into another, and the second one means that two hidden dynamical symmetries of H_0 and H_1 are immediately constructed in terms of $\mathcal{L}$. These are dimension and form independent general properties of this method.[16,17] In the context of 1D systems where $\mathcal{L}$ is taken to be the first-order differential operator and Hamiltonians are of the potential forms two additional properties arise: (i) every eigenfunction of H_0 (without regard to boundary conditions or normalizability) can be used to generate a transformation to a new solvable problem; (ii) a direct connection to a SUSY algebra can be established.[18] The first property is a manifestation of the celebrated Darboux transformation and its generalization (Crum transformation). The second property enables us to express in a compact algebraic form of the spectral equivalence of the intertwined systems.

Now suppose that there are three self-adjoint Hamiltonian operators H_0, H_1, H_2 which are intertwined as

$$\mathcal{L}_{10}H_0 = H_1\mathcal{L}_{10}, \quad \mathcal{L}_{21}H_1 = H_2\mathcal{L}_{21}. \tag{1}$$

The subscripts of the intertwining operators are used to distinguish them and to denote the intertwined Hamiltonians. Equation (1) immediately implies that $\mathcal{L}_{20} \equiv \mathcal{L}_{21}\mathcal{L}_{10}$ will intertwine H_0 and H_2 as follows:

$$\mathcal{L}_{20}H_0 = H_2\mathcal{L}_{20}. \tag{2}$$

Equations (1) and (2) can be unified into the following diagram:

$$\begin{array}{ccc} H_0 & \rightarrow & H_1 \\ & \searrow\downarrow & \\ & H_2 & \end{array}, \tag{3}$$

which must be understood in the sense described by (1) and (2).

Adjoints of (1) and (2) yield

$$\mathcal{L}_{21}^{\dagger}H_2 = H_1\mathcal{L}_{21}^{\dagger}, \quad \mathcal{L}_{10}^{\dagger}H_1 = H_0\mathcal{L}_{10}^{\dagger}, \quad \mathcal{L}_{20}^{\dagger}H_2 = H_0\mathcal{L}_{20}^{\dagger}. \tag{4}$$

That is, the adjoints of the intertwining operators will intertwine in the reverse directions and this can be represented by a diagram the same as (3) with reversed directions of arrows. Making use of (1)–(4) it is easy to show that each of H_0, H_1, H_2 has two dynamical symmetry generators respectively given by

$$\begin{aligned} X_0 &= \mathcal{L}_{10}^{\dagger}\mathcal{L}_{10}, \quad Y_0 = \mathcal{L}_{20}^{\dagger}\mathcal{L}_{20}, \\ X_1 &= \mathcal{L}_{10}\mathcal{L}_{10}^{\dagger}, \quad Y_1 = \mathcal{L}_{21}^{\dagger}\mathcal{L}_{21}, \\ X_2 &= \mathcal{L}_{21}\mathcal{L}_{21}^{\dagger}, \quad Y_2 = \mathcal{L}_{20}\mathcal{L}_{20}^{\dagger}. \end{aligned} \tag{5}$$

The subscripts of X_j, Y_j indicate the Hamiltonians they belong to. Throughout this paper we assume that the domains of definition of Hamiltonians and intertwining operators are some linear subspaces of a common Hilbert space $\mathcal{H} = L^2(\Omega)$ with the standard sesquilinear inner product. $L^2(\Omega)$ is the space of all square-integrable functions (and distributions) defined on a subspace Ω of ND Euclidean space R^N.[19–21]

For all $N \geqslant 2$, diagram (3) implies a triplet of isospectral Hamiltonians such that each has two dynamical symmetries. By construction, all the symmetry operators obtained in this manner will be factorized, and have even orders depending on the order of intertwining operators. They will be of the same order only for H_1. According to the von Neumann theorem (see Ref. 19, p. 141 and Ref. 20, p. 275) $\mathcal{L}_{ij}\mathcal{L}_{ij}^{\dagger}$ (and $\mathcal{L}_{ij}^{\dagger}\mathcal{L}_{ij}$) are self-adjoint and non-negative if $\mathcal{L}_{ij}$ are closed with dense domains of definition. Otherwise there may exist states in which they have negative expectation values (see Sec. X). If $\mathcal{L}_{10}$ and $\mathcal{L}_{21}$ are taken to be algebraically independent, the independence of X_i, Y_i pairs will be guaranteed from the outset. Extensions of these ideas to higher dimensions will be, generically, called multiple intertwining method. A simple observation that this work initiated from is that, in the particular case of $N = 2$, diagram (3) guarantees the superintegrability of the three Hamiltonians. In the case of $N = 3$ such a diagram will imply, provided that symmetry generators are commutative, the integrability of the potentials.

The rest of the paper is devoted to explicit realization of these formal observations for 2D systems. First we will determine the most general form of the potentials and the first-order intertwining operator for two Hamiltonians. We then construct the intertwinings $H_0 \rightarrow H_1$ and $H_1 \rightarrow H_2$ by special forms of the intertwining operator. We end this section by explaining our use

of the adjective ''isospectral.'' Two Hamiltonians are said to be isospectral if they have the same eigenvalue spectrum.[18,22,23] In this sense two linearly intertwined Hamiltonians are always formally isospectral except for the eigenvalues corresponding to the kernel of the intertwining operator. Even for these exceptional cases one can construct eigenfunctions corresponding to these eigenvalues at least for 1D and 2D systems by appealing to the Liouville formula and its 2D version.[14] However, due to physical requirements, in the case of the bound states mainly due to normalizability conditions, some eigenvalues of one of the partner potentials are to be discarded. For higher dimensional systems also the degree of degeneracy of a common eigenvalue may be different (see Sec. X). These will just mean that a finite number of eigenvalues are to be disregarded for they are not physically admissible.

III. INTERTWINING IN TWO DIMENSIONS

We start by considering a pair of 2D one-particle systems characterized by the Hamiltonian operators of potential form

$$H_i=-\nabla^2+V_i, \quad H_f=-\nabla^2+V_f, \tag{6}$$

where the potentials V_i, V_f (and eigenvalues of H_i, H_f) are expressed in terms of $2m/\hbar^2$ and

$$\nabla^2=\partial_r^2+\frac{1}{r}\partial_r+\frac{1}{r^2}\partial_\theta^2$$

is the Laplace operator in the plane polar coordinates (r,θ). m is the mass of the particle and $\hbar$ denotes the Planck constant. Here and in the following we use the notation ∂_x for partial derivative $\partial/\partial x$ and the subindexes ''i,'' ''f'' as the shorthands for the ''initial'' and ''final.'' We suppose that the Hamiltonians are intertwined by

$$\mathcal{L}_{fi}H_i=H_f\mathcal{L}_{fi} \tag{7}$$

and propose the ansatz that $\mathcal{L}_{fi}$ is the most general first-order linear operator

$$\mathcal{L}_{fi}=L_0+L_d=L_0+L_1\partial_r+L_2\partial_\theta, \tag{8}$$

where $L_d=L_1\partial_r+L_2\partial_\theta$ will be referred to as the differential part of $\mathcal{L}_{fi}$. The potentials and L_0, L_1, L_2 are some real functions of (r,θ) which are to be determined from consistency equations of the intertwining relation (7).

In view of (6) and (8) the relation (7) explicitly reads as

$$[\nabla^2,L_d]=-[\nabla^2,L_0]+[V_i,L_d]+P\mathcal{L}_{fi}, \tag{9}$$

where $P=V_f-V_i$. The second-order derivatives come, together with some first-order derivatives, only from

$$\begin{aligned}[\nabla^2,L_d]=&\left(\nabla^2L_1+\frac{1}{r^2}L_1\right)\partial_r+(\nabla^2L_2)\partial_\theta\\&+2\left(\frac{1}{r^2}\partial_\theta L_1+\partial_r L_2\right)\partial_\theta\partial_r+2(\partial_r L_1)\partial_r^2+\frac{2}{r^3}(L_1+r\partial_\theta L_2)\partial_\theta^2,\end{aligned} \tag{10}$$

and by setting their coefficients to zero we obtain

$$\partial_\theta L_1+r^2\partial_r L_2=0, \quad \partial_r L_1=0, \quad L_1+r\partial_\theta L_2=0.$$

It is straightforward to show that the general solutions of these equations are

$$L_1 = A\sin(\theta+\phi), \quad L_2 = B + \frac{A}{r}\cos(\theta+\phi), \tag{11}$$

where A,B, and ϕ are integration constants. Since $\nabla^2 L_1 = -L_1/r^2$, and $\nabla^2 L_2 = 0$, we have from (10) $[\nabla^2, L_d] = 0$. As a result of this the relation (9) simplifies to

$$[\nabla^2, L_0] = -L_1\partial_r V_i - L_2\partial_\theta V_i + P(L_0 + L_d). \tag{12}$$

By substituting

$$[\nabla^2, L_0] = \nabla^2 L_0 + 2(\partial_r L_0)\partial_r + \frac{2}{r^2}(\partial_\theta L_0)\partial_\theta,$$

into (12), and then by equating the coefficients of the first and zeroth powers of derivatives we obtain

$$2\partial_r L_0 = PL_1, \tag{13}$$

$$2\partial_\theta L_0 = r^2 PL_2, \tag{14}$$

$$(-\nabla^2 + P)L_0 = L_1\partial_r V_i + L_2\partial_\theta V_i. \tag{15}$$

These three partial differential equations, the first two of which are linear and the third is nonlinear, constitute a reduced form of the consistency conditions for three unknown functions L_0, V_i, and V_f.

IV. GENERAL FORM OF 2D INTEGRABLE ISOSPECTRAL POTENTIALS IN POLAR COORDINATES

Equations (11), (13), and (14) and the compatibility condition $\partial_r\partial_\theta L_0 = \partial_\theta\partial_r L_0$ imply that

$$2\nabla^2 L_0 = L_d P, \quad ZL_0 = 0, \quad ZP = 2BrP,$$

where $Z = L_1\partial_\theta - r^2 L_2\partial_r$. From the second and third of these equations [or, from (13) and (14)] we have $L_0 = f(w)$, and $P = -2A^2 f'(w)/r^2 L_1^2$, where f is an arbitrary function of

$$w = B\cot(\theta+\phi) + \frac{A}{r\sin(\theta+\phi)}.$$

Prime stands for derivative with respect to the argument and when there is no risk of confusion the argument will be suppressed. By combining $2\nabla^2 L_0 = L_d P$ with (15) and using the found L_0 and P we obtain an inhomogeneous equation from the general solution of which the general form of potentials are found to be

$$V_i = h(\kappa) + \frac{\mathcal{V}_-(w)}{\kappa^2}, \quad V_f = h(\kappa) + \frac{\mathcal{V}_+(w)}{\kappa^2}. \tag{16}$$

Here h is an arbitrary function of $\kappa = [A^2 + B^2 r^2 + 2ABr\cos(\theta+\phi)]^{1/2}$ such that $L_d h = 0$ and

$$\mathcal{V}_\pm(w) = f^2(w) \mp (w^2 + B^2) f'(w). \tag{17}$$

Equation (16) represents the most general form of the 2D integrable and isospectral potentials in polar coordinates.

Let us define the operators

$$T_1=\cos\theta\partial_r-\frac{1}{r}\sin\theta\partial_\theta,\quad T_2=\sin\theta\partial_r+\frac{1}{r}\cos\theta\partial_\theta,\quad J=\partial_\theta, \tag{18}$$

which close in the defining relations of the Euclidean Lie algebra $e(2)$ in two dimensions

$$[J,T_1]=-T_2,\quad [J,T_2]=T_1,\quad [T_1,T_2]=0. \tag{19}$$

Now L_d can be rewritten as

$$L_d=A\sin\phi T_1+A\cos\phi T_2+BJ, \tag{20}$$

which shows that the differential part of $\mathcal{L}_{fi}$ is an element of $e(2)$. In terms of the Cartesian coordinates $x=r\cos\theta, y=r\sin\theta$ we have $T_1=\partial_x, T_2=\partial_y, J=x\partial_y-y\partial_x$, and $T_i^\dagger=-T_i, J^\dagger=-J$. These relations can also be verified from (18) by noting that $(\partial_r)^\dagger=-(r^{-1}+\partial_r), (\partial_\theta)^\dagger=-\partial_\theta$. Now from (5) and (17) the symmetry generators of H_i and H_f are

$$\mathcal{L}_{fi}^\dagger\mathcal{L}_{fi}=\mathcal{V}_--L_d^2,\quad \mathcal{L}_{fi}\mathcal{L}_{fi}^\dagger=\mathcal{V}_+-L_d^2,$$

where L_d^2 is at most quadratic operator in generators of $e(2)$.

V. CONSTRUCTION OF THE INTERTWINING OPERATORS

We shall construct the legs of the diagram (3) by adopting particular forms of (20) as the differential parts of $\mathcal{L}_{10}$ and $\mathcal{L}_{21}$. In doing that we shall make use of the orbit structure of $e(2)$ under the adjoint action of the Euclidean group $E(2)$ in two dimensions.[24]

Under a unitary similarity transformation, generated by

$$U=e^{a_0J}e^{a_1T_1+a_2T_2},\quad U^\dagger=U^{-1}=e^{-(a_1T_1+a_2T_2)}e^{-a_0J}, \tag{21}$$

where a_i's are real parameters and U^{-1} stands for the inverse of $U\in E(2)$, relation (7) transforms into $\overline{\mathcal{L}}_{fi}\overline{H}_i=\overline{H}_f\overline{\mathcal{L}}_{fi}$, where $\overline{X}=UXU^\dagger$. Since $\nabla^2=T_1^2+T_2^2$ is the Casimir invariant of $e(2)$, only V_i, V_f, and $\mathcal{L}_{fi}$ will change under this $E(2)$ action. Now suppose that L_d is of the form (20). Making use of the well-known operator identity

$$e^{bK}Me^{-bK}=M+b[K,M]+\frac{b^2}{2!}[K,[K,M]]+\cdots,$$

where b is a constant and K,M are two arbitrary operators, one can easily show that

$$\overline{L}_d=BJ+e^{a_0J}[T_1(A\sin\phi-a_2B)+T_2(A\cos\phi+a_1B)]e^{-a_0J}.$$

Hence, if $B\neq0$ we can take $\overline{L}_d=BJ$ by choosing $a_1=-A\cos\phi/B, a_2=A\sin\phi/B$. On the other hand, if $B=0, A\neq0$ we get $\overline{L}_d=AT_1$ (or, $\overline{L}_d=AT_2$) for the choice $a_0=\phi$ (or, $a_0=-\phi$). Therefore, under the adjoint action of $E(2)$, $e(2)$ has two orbits represented by J and T_2. Since L_d and cL_d belong to the same orbit for $c\neq0$, we can choose $L_d=J$ for $\mathcal{L}_{10}$ and $L_d=T_2$ for $\mathcal{L}_{21}$. In such a case the potentials and L_0 will be specified up to the adjoint action of $E(2)$.

For the first leg $H_0\rightarrow H_1$ of (3) we take $A=0, B=1$ in Eq. (11) and redefine the Hamiltonians as $H_i=H_0$ and $H_f=H_1$. Hence $L_1=0, L_2=1$ and Eqs. (13) and (14) imply that $L_0=f(\theta)$ and

$$\mathcal{L}_{10}=f(\theta)+\partial_\theta,\quad P=V_1-V_0=\frac{2}{r^2}f'(\theta), \tag{22}$$

where f is an arbitrary differentiable function of θ. Noting that $\nabla^2L_0=f''(\theta)/r^2$ we obtain from (15) and (22)

$$V_0 = h(r) + \frac{V_-(\theta)}{r^2}, \quad V_1 = h(r) + \frac{V_+(\theta)}{r^2}, \tag{23}$$

where h is an arbitrary differentiable function of r and

$$V_\pm(\theta) = f^2(\theta) \pm f'(\theta). \tag{24}$$

As a result the first $H_0 \to H_1$ leg of the diagram (3) has been constructed.

For the second leg we take $B=0, A=1$, fix the form of H_1 and denote it as $H_i = H_1$. We then look for $H_f = H_2$ such that $\mathcal{L}_{21} H_1 = H_2 \mathcal{L}_{21}$ and $\mathcal{L}_{21} = L_0 + \sin\phi T_1 + \cos\phi T_2$. In that case from Eqs. (13) to (14) we get $L_0 = g(u)$ and

$$\mathcal{L}_{21} = g(u) + \sin(\theta+\phi)\partial_r + \frac{1}{r}\cos(\theta+\phi)\partial_\theta, \tag{25}$$

$$P = V_2 - V_1 = 2g'(u), \tag{26}$$

where g is an arbitrary differentiable function of $u = r\sin(\theta+\phi)$. It only remains to solve the nonlinear equation (15) which now takes the form

$$\partial_u[g^2(u) - g'(u)] = \sin(\theta+\phi)h'(r) + \frac{1}{r^3}[\cos(\theta+\phi)V'_+(\theta) - 2\sin(\theta+\phi)V_+(\theta)], \tag{27}$$

where we have made use of $\nabla^2 L_0 = g''(u)$ and of the second equation of (23). Note that we could have chosen $\phi = 0$, but since it costs almost nothing we keep ϕ in our formulas in order to see that action of $E(2)$.

Since it further restricts the three arbitrary functions specifying the potentials, Eq. (27) is the main equation which determines the final form of the potentials. As a consistency condition the right-hand side of Eq. (27) must be only a function of u. Nevertheless this requirement provides us with many possibilities for f, g, and h, which are investigated in Secs. VI and VII. Note that for any solutions of Eq. (27) the potentials will be connected to each other as follows:

$$V_0 = V_1 - \frac{2}{r^2}f'(\theta), \quad V_2 = V_1 + 2g'(u), \quad V_0 = V_2 - 2\left[g'(u) + \frac{f'(\theta)}{r^2}\right]. \tag{28}$$

VI. TWO SUBFAMILIES OF POTENTIALS

We construct the simplest family of potentials by taking, in (24) and (27), $h = (\lambda_1/r^2) + a, V_+ = -\lambda_1$. These lead us to

$$f^2 + f' = -\lambda_1, \quad g^2 - g' = -\lambda_2, \tag{29}$$

where a, λ_1, λ_2 are some arbitrary constants. Then, by Eqs. (23) and (24) and (26), we obtain

$$V_0 = \frac{2}{r^2}(f^2 + \lambda_1) + a, \quad V_1 = a, \quad V_2 = 2(g^2 + \lambda_2) + a. \tag{30}$$

The general solution of $g^2 - g' = -\lambda_2$ is

$$g = \begin{cases} \lambda_2^{1/2}\tan(\lambda_2^{1/2}u + a_1) & \text{for } \lambda_2 > 0, \\ -\dfrac{1}{u + a_1} & \text{for } \lambda_2 = 0, \\ (-\lambda_2)^{1/2}\tanh[(-\lambda_2)^{1/2}u + a_1] & \text{for } \lambda_2 < 0, \end{cases}$$

where a_1 is a constant. The solution of $f^2+f'=-\lambda_1$ can be directly read from the above-given relation after the replacement $(g,u,\lambda_2)\to(f,-\theta,\lambda_1)$.

An important point is that, by the usual linearization of the Riccati equation, if we substitute

$$f(\theta)=\frac{\psi'(\theta)}{\psi(\theta)}, \quad g(u)=-\frac{\Psi'(u)}{\Psi(u)}, \tag{31}$$

into (29) we arrive at two 1D Schrödinger equations,

$$-\psi''(\theta)=\lambda_1\psi(\theta), \quad -\Psi''(u)=\lambda_2\Psi(u). \tag{32}$$

While the second one can be considered as a free motion, this is not the case for the first since $0\leqslant\theta<2\pi$. An appealing case is to consider one or both of them as infinite square-well problem. Normalized eigenfunctions subjected to boundary conditions, say, $\psi(0)=0=\psi(2\pi)$ and corresponding eigenvalues are

$$\psi_k(\theta)=\pi^{-1/2}\sin\left(\frac{1}{2}k\theta\right), \quad \lambda_{1,k}=\frac{k^2}{4}, \quad k=1,2,\ldots. \tag{33}$$

Hence $f_k=(k/2)\cot(k\theta/2)$ and by virtue of Eqs. (22) and (24) we have

$$V_0^{(k)}=\frac{k^2}{2r^2\sin^2\frac{1}{2}k\theta}+a, \quad \mathcal{L}_{10}^{(k)}=\frac{k}{2}\cot\left(\frac{1}{2}k\theta\right)+\partial_\theta. \tag{34}$$

To distinguish the resulting potentials, corresponding intertwining operators and the parameter λ_1 we have labeled them by the quantum number k. The u-problem can be treated in a similar way. In any case, the potentials and transformations among them are generated by solutions of these two auxiliary 1D problems. The existence of $V_1=a$ explicitly shows that the member potentials are isospectral to a 2D free motion. As a result we have found a five-parameter $(a,a_1,\lambda_1,\lambda_2,\phi)$ family of 2D potentials that are generated, in a nontrivial way, by two 1D problems.

We specify a second subfamily of potentials by taking, in (23)–(24) and (27),

$$h=\frac{\lambda_1}{r^2}+\frac{1}{2}\alpha r^2+a, \tag{35}$$

and $V_+=-\lambda_1$. These lead us to the same equation as in (29) for f and to the Riccati's equation

$$g^2-g'-\tfrac{1}{2}\alpha u^2+\lambda_2=0 \tag{36}$$

for g. By Eqs. (23)–(24) and (26) the member potentials are found to be

$$V_0=\frac{1}{2}\alpha r^2+\frac{2(f^2+\lambda_1)}{r^2}+a,$$

$$V_1=\tfrac{1}{2}\alpha r^2+a, \tag{37}$$

$$V_2=\tfrac{1}{2}\alpha r^2\cos 2(\theta+\phi)+2g^2(u)+(a+2\lambda_2),$$

where g is any solution of (36) and f is any solution of $f^2+f'=-\lambda_1$.

Now the ansatz (31) for g transforms (36) into

$$-\Psi''(u)+\tfrac{1}{2}\alpha u^2\Psi(u)=\lambda_2\Psi(u), \tag{38}$$

which is the well-known Schrödinger equation for the 1D harmonic oscillator. In that case the entire family will have 2D isotropic harmonic oscillator spectrum given by the eigenvalues

$$E_{\ell}^{(1)}=\hbar\omega(\ell+1), \quad \ell=0,1,2,\ldots, \tag{39}$$

which are $\ell+1$ times degenerate for a given ℓ. For concrete examples we recall the normalized eigenfunctions and corresponding eigenvalues of the 1D harmonic oscillator:

$$\Psi_n(u)=N_n e^{-\beta^2u^2/2}H_n(\beta u), \quad E_n=\frac{\hbar^2}{2m}\lambda_{2,n}=\hbar\omega\left(n+\frac{1}{2}\right), \quad n=0,1,2,\ldots, \tag{40}$$

where N_n is the normalization constant, H_n denote the Hermite polynomials, and

$$\beta=\left(\frac{m\omega}{\hbar}\right)^{1/2}=\left(\frac{\alpha}{2}\right)^{1/4}, \quad N_n=\left(\frac{\beta}{\pi^{1/2}2^n n!}\right)^{1/2}. \tag{41}$$

In writing Eqs. (39)–(41) we have restored $2m/\hbar^2$ in our notation in which the dimension of β is $(\text{length})^{-1}$. Like λ_2, also $V_2, \mathcal{L}_{21}$ and the function g must be labeled by the quantum number n:

$$g_n(u)=-\frac{\Psi_n'(u)}{\Psi_n(u)}=\beta^2u-\partial_u\ln[H_n(\beta u)],$$

$$V_2^{(n)}=\beta^4r^2\cos 2(\theta+\phi)+2g_n^2(u)+a+4\beta^2(n+\tfrac{1}{2}), \tag{42}$$

$$\mathcal{L}_{21}^{(n)}=g_n(u)+\sin(\theta+\phi)\partial_r+\frac{1}{r}\cos(\theta+\phi)\partial_\theta.$$

For the first three Hermite polynomials $H_0(x)=1, H_1(x)=2x, H_2(x)=4x^2-2$, we have

$$g_0=\beta^2u, \quad g_1=\beta^2u-\frac{1}{u}, \quad g_2=\beta^2\frac{2\beta^2u^2-5}{2\beta^2u^2-1}u.$$

Considering the f-problem as noted previously, $\mathcal{L}_{10}^{(k)}$ is given by (34) and V_0 is

$$V_0^{(k)}=\frac{1}{2}\alpha r^2+\frac{k^2}{2r^2\sin^2(\frac{1}{2}k\theta)}+a. \tag{43}$$

VII. GENERAL FORM OF THE POTENTIALS

Returning the general discussion of Sec. V, the most general potentials are obtained by choosing, in Eq. (27), h as in (35) and by postulating the equation

$$\cos(\theta+\phi)V_+'(\theta)-2\sin(\theta+\phi)V_+(\theta)=2\lambda_1\sin(\theta+\phi)-\frac{2c}{\sin^3(\theta+\phi)} \tag{44}$$

for V_+. It is not hard to check that (35) and (44) are the most general relations which make the right-hand side of Eq. (27) only a function of the u variable. The general solution of Eq. (44) is

$$V_+=f^2(\theta)+f'(\theta)=\frac{b}{\cos^2(\theta+\phi)}+\frac{c}{\sin^2(\theta+\phi)}-\lambda_1, \tag{45}$$

where λ_1, b, and c are some constants. When (35) and (44) are inserted into (27) we obtain a new Riccati's equation for $g(u)$,

$$g^2-g'=\frac{1}{2}\alpha u^2+\frac{c}{u^2}-\lambda_2. \tag{46}$$

By virtue of (23), (28), (35), (45), and (46) the corresponding potentials can be written as

$$V_0=\frac{1}{2}\alpha r^2-\frac{1}{r^2}\left[\frac{b}{\cos^2(\theta+\phi)}+\frac{c}{\sin^2(\theta+\phi)}\right]+\frac{2(f^2+\lambda_1)}{r^2}+a,$$

$$V_1=\frac{1}{2}\alpha r^2+\frac{1}{r^2}\left[\frac{b}{\cos^2(\theta+\phi)}+\frac{c}{\sin^2(\theta+\phi)}\right]+a, \tag{47}$$

$$V_2=\frac{1}{2}\alpha r^2\cos 2(\theta+\phi)+\frac{1}{r^2}\left[\frac{b}{\cos^2(\theta+\phi)}-\frac{c}{\sin^2(\theta+\phi)}\right]+2\left(g^2+\lambda_2+\frac{a}{2}\right).$$

V_1 is immediately recognized as one of 2D Smorodinsky–Winternitz potentials which accepts separation of variables in the Cartesian, polar, and elliptic coordinates. Being fixed in the whole family it determines the structure of spectrum of all potentials. While V_0 is separable in the plane polar coordinates V_2 is separable only in the Cartesian coordinates. V_0 and V_2 represent two families of the superintegrable and isospectral potentials generated by the functions f and g which are subjected to Eqs. (45) and (46). The normalized eigenfunctions, corresponding eigenvalues, and the symmetry generators will be the subject of Secs. VII, IX, and X.

Having specified the most general forms of the potentials we now show how to develop a hierarchy of the potentials.

On substituting (31) into (45) and (46) we arrive at the following two 1D problems:

$$H_{\mathrm{PT}}\psi_k(\theta)=\lambda_{1,k}\psi_k(\theta),\quad H_{\mathrm{SO}}\Psi_n(u)=\lambda_{2,n}\Psi_n(u), \tag{48}$$

where k and n are possible quantum numbers and

$$H_{\mathrm{PT}}=-\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}+V_{\mathrm{PT}},\quad V_{\mathrm{PT}}=\frac{b}{\cos^2(\theta+\phi)}+\frac{c}{\sin^2(\theta+\phi)}, \tag{49}$$

$$H_{\mathrm{SO}}=-\frac{\mathrm{d}^2}{\mathrm{d}u^2}+V_{\mathrm{SO}},\quad V_{\mathrm{SO}}=\frac{1}{2}\alpha u^2+\frac{c}{u^2}. \tag{50}$$

These are the well-known generalized Pöschl–Teller (PT) and singular oscillator (hence the subscript SO), or the radial oscillator potentials. By virtue of (28) and (31) the potentials can be rewritten as

$$V_0^{(k)}=V_1-\frac{2}{r^2}\partial_\theta^2\ln\psi_k(\theta),\quad V_2^{(n)}=V_1-2\partial_u^2\ln\Psi_n(u). \tag{51}$$

Here and in the following we label the potentials by the quantum numbers of the associated 1D problems that generate them. Equation (51) explicitly shows that $V_0^{(k)}$ and $V_2^{(n)}$ are generated from V_1 by the Darboux-type transformations. The functions that generate these transformations are the eigenfunctions of the associated 1D problems. This constitutes an extension of Darboux transformations for 2D problems. Another point worth emphasizing is that any solution of these 1D problems can be used in generating the potentials. But, as easily accessible results from the literature, only normalizable solutions of these problems will be presented in the following. From now on we take $\phi=0$ and in Secs. VIII and X we include $2m/\hbar^2$ into our notation.

VIII. BOUND STATES OF THE ASSOCIATED PROBLEMS AND V_1

Provided that $c \geqslant -1/4$, the bound states of H_{SO} belonging to the Hilbert space $L^2(0,\infty)$ are given as follows:[3,25–27]

$$\Psi_n^{\varepsilon}(u) = N_n^{\mathrm{SO}} u^{1/2+\varepsilon\nu} e^{-\beta^2 u^2/2} L_n^{\varepsilon\nu}(\beta^2 u^2),$$

$$E_n^{\varepsilon} = \frac{\hbar^2}{2m}\lambda_{2,n}^{\varepsilon} = \hbar\omega(2n+\varepsilon\nu+1), \quad n=0,1,2,\ldots, \tag{52}$$

$$N_n^{\mathrm{SO}} = \left[\frac{n!\,2\beta^{2(1+\varepsilon\nu)}}{\Gamma(n+\varepsilon\nu+1)}\right]^{1/2}, \quad \nu = \frac{1}{2}(1+4c)^{1/2},$$

where N_n^{SO} is the normalization constant, $L_n^{\varepsilon\nu}(z)$ are the generalized Laguerre polynomials, β is defined by Eq. (41), Γ stands for the gamma function, and $\varepsilon = \pm$. $\Psi_n^{\varepsilon}(u)$'s satisfy the orthogonality relation[28]

$$\int_0^{\infty} \Psi_n^{\varepsilon}(u)\Psi_{n'}^{\varepsilon}(u)\,\mathrm{d}u = \delta_{nn'}, \tag{53}$$

which is valid for $\varepsilon\nu > -1$. This implies that for $c \in I = [-1/4, 3/4)$ (that is for $-1/4 \leqslant c < 3/4$) both values of $\varepsilon = \pm$, and for $c \geqslant 3/4$ only $\varepsilon = +$ can be used for each n. Although the generated potentials do not depend on the normalization constants of the associated 1D problems we write them for completeness.

From the most general point of view and in accordance with the fact that H_{SO} is parity invariant, defined parity states of H_{SO} belonging to the Hilbert space $L^2(-\infty,\infty)$ can be given as follows:[26]

$$\Psi_n^{\varepsilon}(u) = \frac{1}{2^{1/2}} N_n^{\mathrm{SO}} \begin{cases} |u|^{1/2+\varepsilon\nu} e^{-\beta^2 u^2/2} L_n^{\varepsilon\nu}(\beta^2 u^2) & \text{for } u \geqslant 0, \\ -\varepsilon |u|^{1/2+\varepsilon\nu} e^{-\beta^2 u^2/2} L_n^{\varepsilon\nu}(\beta^2 u^2) & \text{for } u < 0. \end{cases} \tag{54}$$

These obey the following orthogonality relation:

$$\int_{-\infty}^{\infty} \Psi_n^{\varepsilon}(u)\Psi_{n'}^{\bar{\varepsilon}}(u)\,\mathrm{d}u = \delta_{nn'}\delta_{\varepsilon\bar{\varepsilon}}, \tag{55}$$

where $\varepsilon, \bar{\varepsilon}$ may equal $\pm$. For $\varepsilon = \bar{\varepsilon}$ (55) follows from the orthogonality of the generalized Laguerre polynomials[28] and for $\varepsilon \neq \bar{\varepsilon}$ from the parity reasons as can be verified directly from (54). The corresponding energy eigenvalues are given by (52). For $c < -1/4$ the energy spectrum is not bounded from below which implies "falling of the particle to the center" and physical interpretation is lost.[26,27] As $c \to 0$, $\nu \to 1/2$, and $\Psi_n^{\varepsilon}(u)$'s go over, for $\varepsilon = +$ to odd parity and for $\varepsilon = -$ to even parity harmonic oscillator wave functions. This follows from the relations between the Hermite and Laguerre polynomials.[26,28] The corresponding limits of the energy eigenvalues are obvious from (52).

The normalized eigenfunctions and corresponding eigenvalues of V_1 can now be written as

$$\Psi_{\ell}^{(1)\bar{\varepsilon}\varepsilon}(x,y) = \Psi_{n_1}^{\bar{\varepsilon}}(x)\Psi_{n_2}^{\varepsilon}(y),$$

$$E_{\ell}^{\bar{\varepsilon}\varepsilon} = E_{n_1}^{\bar{\varepsilon}} + E_{n_2}^{\varepsilon} = \hbar\omega(2\ell + \overline{\varepsilon\nu} + \varepsilon\nu + 1), \tag{56}$$

$$\ell = n_1 + n_2, \quad \ell, n_1, n_2 = 0,1,2,\ldots,$$

where $\overline{\nu}=(1+4b)^{1/2}/2$. $\Psi^{\overline{\varepsilon}}_{n_1}(x)$, $\Psi^{\varepsilon}_{n_2}(y)$, and $E^{\overline{\varepsilon}}_{n_1}$, $E^{\varepsilon}_{n_2}$ are given by (52) [or (54)] with suitable replacements of the parameters and variables. It follows that bound states of V_1 exist for $b,c \geqslant -1/4$. For $b,c\in I$ there are four different states for each value of ℓ. In the case of $b\in I, c \geqslant 3/4$, or $c\in I, b\geqslant 3/4$ there are two different states for each value of ℓ, and one state in the case of $b,c\geqslant 3/4$. In each case, for a given value of ℓ the state with energy $E^{\overline{\varepsilon}\varepsilon}_{\ell}$ is $(\ell+1)$-fold degenerate. We should also note that if we require the wave functions to be separately continuous at the origin the interval $I=[-1/4,3/4)$ and the conditions $b,c\geqslant 3/4$ must be replaced as $I=[-1/4,0]$ and as $b,c\geqslant 0$.

The singular oscillator problem has the spectrum generating algebra $su(1,1)=\{J_0,J_\pm:[J_0,J_\pm]=\pm J_\pm,[J_+,J_-]=-2J_0\}$ realized as[25,29]

$$J_0=\frac{H_{\mathrm{SO}}}{4\beta^2},\quad J_\pm=-\frac{1}{4}\left[\beta^2(u\mp\beta^{-2}\partial_u)^2-\frac{c}{\beta^2u^2}\right], \tag{57}$$

with the Casimir invariant $C^2=-J_+J_-+J_0^2-J_0=(4c-3)/16$. Therefore, as will be shown in Sec IX, the symmetry algebra of the H_1-problem is closely connected with this kind two commuting copies of $su(1,1)$ algebra.

For later use it will be convenient to consider the H_{PT}-problem in relation with the solution of the H_1-problem in the polar coordinates. In this case the eigenvalue equation of H_1 separates, by taking $\Psi^{(1)}(r,\theta)=R_{k_1}(r)\psi_k(\theta)$, into the Pöschl–Teller problem given by (48) and into the radial equation

$$\left[-\left(\frac{\mathrm{d}^2}{\mathrm{d}\rho^2}+\frac{1}{\rho}\frac{\mathrm{d}}{\mathrm{d}\rho}\right)+\rho^2+\frac{\lambda_{1,k}}{\rho^2}\right]R_{k_1}(\rho)=\lambda R_{k_1}(\rho), \tag{58}$$

where $\rho=\beta r$ and $\lambda=E/\beta^2$. In terms of $v=\sin^2\theta$, and $\psi_k(\theta)=v^{(1/2)(1/2+\varepsilon\nu)}(1-v)^{(1/2)(1/2+\varepsilon\overline{\nu})}F(v)$, the eigenvalue equation of H_{PT} leads us to the hypergeometric equation for $F(v)$:

$$v(1-v)\frac{\mathrm{d}^2F}{\mathrm{d}v^2}+[\zeta-v(\gamma+\eta+1)]\frac{\mathrm{d}F}{\mathrm{d}v}-\gamma\eta F=0.$$

The general solution of this equation is

$$F(v)=A\,{}_2F_1(\gamma,\eta;\zeta;v)+Bv^{1-\zeta}\,{}_2F_1(\gamma-\zeta+1,\eta-\zeta+1;2-\zeta;v),$$

where A and B are arbitrary constants, ${}_2F_1$ denotes the hypergeometric function and

$$\gamma=\tfrac{1}{2}(1+\varepsilon\nu+\overline{\varepsilon\nu}+\sqrt{\lambda_{1,k}}),\quad \eta=\tfrac{1}{2}(1+\varepsilon\nu+\overline{\varepsilon\nu}-\sqrt{\lambda_{1,k}}),\quad \zeta=1+\varepsilon\nu.$$

For normalizable solutions B must be zero and γ (or η) must be a negative integer, say, $-k$. In that case the hypergeometric function goes over to Jacobi polynomials $P_k^{(\varepsilon\nu,\overline{\varepsilon\nu})}(1-2v)$ and the resulting eigenfunctions and eigenvalues can be written as follows:[7,30]

$$\psi_k(\theta)=N_k^{PT}\sin^{1/2+\varepsilon\nu}\theta\cos^{1/2+\overline{\varepsilon\nu}}\theta P_k^{(\varepsilon\nu,\overline{\varepsilon\nu})}(\cos 2\theta),$$

$$E_k=\frac{\hbar^2}{2m}\lambda_{1,k}=\frac{\hbar^2}{2m}(2k+\varepsilon\nu+\overline{\varepsilon\nu}+1)^2,\quad k=0,1,2,\ldots, \tag{59}$$

$$N_k^{\mathrm{PT}}=\left[\frac{2(2k+\varepsilon\nu+\overline{\varepsilon\nu}+1)\Gamma(k+1)\Gamma(k+\varepsilon\nu+\overline{\varepsilon\nu}+1)}{\Gamma(k+\varepsilon\nu+1)\Gamma(k+\overline{\varepsilon\nu}+1)}\right]^{1/2}.$$

Substituting $\lambda_{1,k}=(2k+\varepsilon\nu+\overline{\varepsilon\nu}+1)^2$ into Eq. (58) and trying the solution $R_{k_1}(\rho)=\rho^{\mu}e^{-\rho^2/2}G_{k_1}(\rho)$ we end up, for $\mu=\sqrt{\lambda_{1,k}}=(2k+\varepsilon\nu+\overline{\varepsilon\nu}+1)$, with

$$z\frac{d^2G_{k_1}}{dz^2}+(\mu+1-z)\frac{dG_{k_1}}{dz}-\frac{1}{4}[2(\mu+1)-\lambda]G_{k_1}=0, \tag{60}$$

where $z=\rho^2$. Provided that $-[2(\mu+1)-\lambda]/4$ is an integer, say $k_1=0,1,2,\ldots$, the solutions of (60) are the generalized Laguerre polynomials. Hence, the radial solutions are

$$R_{k_1}(\rho)=N_{k_1}\rho^{\mu}e^{-\rho^2/2}L_{k_1}^{\mu}(\rho^2),\quad N_{k_1}=\left[\frac{2\Gamma(k_1+1)}{\Gamma(k_1+\mu+1)}\right]^{1/2}. \tag{61}$$

One can easily verify that $\psi_k(\theta)$'s and $R_{k_1}(\rho)$'s obey the following orthogonality relations:

$$\int_0^{\infty}R_{k_1}(\rho)R_{k_1'}(\rho)r\,dr=\delta_{k_1k_1'},\quad \int_0^{\pi/2}\psi_k(\theta)\psi_{k'}(\theta)d\theta=\delta_{kk'}. \tag{62}$$

As a result the eigenfunctions of H_1 can be written in polar coordinates as follows:

$$\Psi_{\ell}^{(1)\overline{\varepsilon\varepsilon}}(r,\theta)=N_{k_1}N_{k_2}^{\mathrm{PT}}(\beta r)^{\mu}e^{-\beta^2r^2/2}\sin^{1/2+\varepsilon\nu}\theta\cos^{1/2+\overline{\varepsilon\nu}}\theta L_{k_1}^{\mu}(\beta^2r^2)P_{k_2}^{(\varepsilon\nu,\overline{\varepsilon\nu})}(\cos 2\theta), \tag{63}$$

with $\ell=k_1+k_2;\ell,k_1,k_2=0,1,2,\ldots$, and $\mu=(2k_2+\varepsilon\nu+\overline{\varepsilon\nu}+1)$. Since $\psi_k(\theta)$ given by (59) will be used in generating $V_0^{(k)}$ potentials, in writing (63) we have changed the quantum number k as k_2. Observe that a similar change $(n\to n_2)$ has been made in writing (56). Note also that the condition $-[2(\mu+1)-\lambda]/4=k_1$ gives the eigenvalue (56) for the V_1-problem, with $\ell=k_1+k_2$. We should also note that, as has been done in Eq. (54), the solutions (63) may be extended to all xy plane such that they have definite parity under 2D parity transformation: $(r,\theta)\to(r,\theta+\pi)$.

Inserting ψ_k and Ψ_n into (51) explicit expressions of the potentials labeled by the quantum numbers k and n become available. Besides that presented in Sec. VI several more special subfamilies can be identified. In doing that one should take care of the range of the parameters and the domain of definition for potentials. The bound states of $V_0^{(k)}$ and $V_2^{(n)}$ will be taken up in Sec. X after considering the symmetry generators in Sec. IX.

IX. SYMMETRY GENERATORS AND THEIR ALGEBRAS

As is apparent from Secs. VII and VIII, the intertwining operators, symmetry generators, and the Hamiltonians H_0, H_2 must be labeled by the quantum numbers (k,n) of the associated potentials. In terms of $e(2)$ generators the labeled intertwining operators are

$$\begin{aligned}\mathcal{L}_{10}^{(k)}&=f_k(\theta)+J,\quad \mathcal{L}_{10}^{(k)\dagger}=f_k(\theta)-J,\\ \mathcal{L}_{21}^{(n)}&=g_n(u)+T_2,\quad \mathcal{L}_{21}^{(n)\dagger}=g_n(u)-T_2.\end{aligned} \tag{64}$$

It is easy to verify that they obey the following commutators:

$$\begin{aligned}&[\mathcal{L}_{10}^{(k)},\mathcal{L}_{10}^{(k)\dagger}]=2f_k'(\theta),\quad [\mathcal{L}_{21}^{(n)},\mathcal{L}_{21}^{(n)\dagger}]=2g_n'(u),\\ &[\mathcal{L}_{10}^{(k)},\mathcal{L}_{21}^{(n)}]=K_{-}^{(k,n)}+T_1,\quad [\mathcal{L}_{10}^{(k)\dagger},\mathcal{L}_{21}^{(n)\dagger}]=-K_{-}^{(k,n)}+T_1,\\ &[\mathcal{L}_{10}^{(k)},\mathcal{L}_{21}^{(n)\dagger}]=K_{+}^{(k,n)}-T_1,\quad [\mathcal{L}_{10}^{(k)\dagger},\mathcal{L}_{21}^{(n)}]=-K_{+}^{(k,n)}-T_1,\end{aligned} \tag{65}$$

where

$$K_{\pm}^{(k,n)}=r\cos\theta\left[g_n'(u)\pm\frac{1}{r^2}f_k'(\theta)\right].$$

By virtue of (28) we have

$$K_{+}^{(k,n)}=\tfrac{1}{2}r\cos\theta[H_2^{(k)}-H_0^{(n)}],\quad K_{-}^{(k,n)}=\tfrac{1}{2}r\cos\theta[H_0^{(k)}+H_2^{(n)}-2H_1]. \tag{66}$$

It will be convenient to start with the symmetry generators of H_1,

$$X_1^{(k)}=\mathcal{L}_{10}^{(k)}\mathcal{L}_{10}^{(k)\dagger}=H_{\mathrm{PT}}-\lambda_{1,k}, \tag{67}$$

$$Y_1^{(n)}=\mathcal{L}_{21}^{(n)\dagger}\mathcal{L}_{21}^{(n)}=H_{\mathrm{SO}}-\lambda_{2,n}, \tag{68}$$

where we have made use of $T_2 g_n(u)=g_n'(u)$. H_{PT} and H_{SO} are defined by (49) and (50). Second-order symmetry generators of $H_0^{(k)}$ and $H_2^{(n)}$ can also be written as follows:

$$X_0^{(k)}=\mathcal{L}_{10}^{(k)\dagger}\mathcal{L}_{10}^{(k)}=V_{-}^{(k)}-J^2=\overline{H}_{\mathrm{PT}}^{(k)}-\lambda_{1,k}, \tag{69}$$

$$X_2^{(n)}=\mathcal{L}_{21}^{(n)}\mathcal{L}_{21}^{(n)\dagger}=g_n^2+g_n'-T_2^2=\overline{H}_{\mathrm{SO}}^{(n)}-\lambda_{2,n}, \tag{70}$$

where

$$\overline{H}_{\mathrm{PT}}^{(k)}=-\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}+V_{\mathrm{PT}}-2\partial_\theta^2\ln\psi_k(\theta), \tag{71}$$

$$\overline{H}_{\mathrm{SO}}^{(n)}=-\frac{\mathrm{d}^2}{\mathrm{d}u^2}+V_{\mathrm{SO}}-2\partial_u^2\ln\Psi_n(u). \tag{72}$$

These are the so-called super partners of H_{PT} and H_{SO}. As a result, the Hamiltonians of 1D auxiliary problems are, up to some constants, the second-order symmetry generators of H_1 and their super partners are the second-order symmetry generators of $H_0^{(k)}$ and $H_2^{(n)}$.

The simplest forms of remaining fourth-order generators seem to be their factorized forms given by (5). Making use of (65) and (67)–(70) these can be expressed in a variety of ways, some of which are as follows:

$$\begin{aligned}Y_0^{(k,n)}&=\mathcal{L}_{10}^{(k)\dagger}Y_1^{(n)}\mathcal{L}_{10}^{(k)}=\mathcal{L}_{10}^{(k)\dagger}H_{\mathrm{SO}}\mathcal{L}_{10}^{(k)}-\lambda_{2,n}X_0^{(k)}\\&=Y_1^{(n)}X_0^{(k)}-[(K_{-}^{(k,n)}-T_1)\mathcal{L}_{21}^{(n)}+\mathcal{L}_{21}^{(n)\dagger}(K_{+}^{(k,n)}+T_1)]\mathcal{L}_{10}^{(k)}\\&=X_0^{(k)}Y_1^{(n)}-\mathcal{L}_{10}^{(k)\dagger}[(K_{+}^{(k,n)}-T_1)\mathcal{L}_{21}^{(n)}+\mathcal{L}_{21}^{(n)\dagger}(K_{-}^{(k,n)}+T_1)],\end{aligned} \tag{73}$$

$$\begin{aligned}Y_2^{(k,n)}&=\mathcal{L}_{21}^{(n)}X_1^{(k)}\mathcal{L}_{21}^{(n)\dagger}=\mathcal{L}_{21}^{(n)}H_{PT}\mathcal{L}_{21}^{(n)\dagger}-\lambda_{1,k}X_2^{(n)}\\&=X_1^{(k)}X_2^{(n)}-[(K_{-}^{(k,n)}+T_1)\mathcal{L}_{10}^{(k)\dagger}-\mathcal{L}_{10}^{(k)}(K_{+}^{(k,n)}+T_1)]\mathcal{L}_{21}^{(n)\dagger}\\&=X_2^{(n)}X_1^{(k)}-\mathcal{L}_{21}^{(n)}[\mathcal{L}_{10}^{(k)}(K_{-}^{(k,n)}-T_1)-(K_{+}^{(k,n)}-T_1)\mathcal{L}_{10}^{(k)\dagger}].\end{aligned} \tag{74}$$

At this point we have to emphasize the following. The existence of $\lambda_{1,k}$ and $\lambda_{2,n}$ as additive constants in $X_1^{(k)}$, $Y_1^{(n)}$ and $X_0^{(k)}$, $X_2^{(n)}$ seems to be redundant in regard of superintegrability of H_1. In particular, our labeling of the fourth-order generators with two indices may seem as if we have more symmetries than is needed for superintegrability. But an inspection of the first lines of Eqs. (73) and (74) immediately shows that, for a given, say, k and all n the set $\{Y_0^{(k,n)},X_0^{(k)}\}$ spans only a 2D vector space. As fourth-order symmetries labeled with one index one may take

$$\overline{Y}_0^{(k)}\equiv Y_0^{(k,n)}+\lambda_{2,n}X_0^{(k)}=\mathcal{L}_{10}^{(k)\dagger}H_{\mathrm{SO}}\mathcal{L}_{10}^{(k)},$$

$$\overline{Y_2^{(n)}} \equiv Y_2^{(k,n)} + \lambda_{1,k} X_2^{(n)} = \mathcal{L}_{21}^{(n)} H_{\rm PT} \mathcal{L}_{21}^{(n)\dagger} - \lambda_{1,k} X_2^{(n)}.$$

However, for overall consistency of the hierarchy such as intertwining of H_1 with $H_0^{(k)}$, $H_2^{(n)}$ and, as we will show in Sec. V, in determining the spectra of $H_0^{(k)}$ and $H_2^{(n)}$ these seemingly redundant constants and labels play an essential role.

One of the virtues of our approach is that the commutativity of the symmetry generators with the corresponding Hamiltonian is guaranteed by construction from the outset. For justification we first note that the relations

$$[H_1, X_1^{(k)}] = 0 = [H_1, Y_1^{(k)}], \quad k = 0,1,\ldots, \tag{75}$$

immediately follow from the fact that $X_1^{(k)}$ and $Y_1^{(k)}$ emerge from the separation of H_1 in different coordinate systems. Second at a glimpse of Eqs. (67)–(72) we observe that

$$X_0^{(k)} = X_1^{(k)} - 2\partial_\theta^2 \ln \psi_k(\theta), \quad X_2^{(n)} = Y_1^{(n)} - 2\partial_u^2 \ln \Psi_n(u).$$

That is, the second-order symmetry generators of $H_0^{(k)}$ and $H_2^{(n)}$ are Darboux transforms of symmetry generators of H_1 as are, apart from the factor r^{-2}, $H_0^{(k)}$ and $H_2^{(n)}$ Darboux transforms of H_1 along different legs of diagram (3). In view of this fact the relations

$$[H_0^{(k)}, X_0^{(k)}] = 0 = [H_2^{(n)}, X_2^{(n)}], \quad n,k = 0,1,\ldots, \tag{76}$$

follow from, or, in a sense, are Darboux transforms of (75). Only the explicit check of

$$[H_0^{(k)}, Y_0^{(k,n)}] = 0 = [H_2^{(n)}, Y_2^{(k,n)}], \quad n,k = 0,1,\ldots, \tag{77}$$

tediously takes a lot of time. This shows an advantage of our method compared with the conventional approach in which much effort is devoted to verify the commutativity for specified forms of generators. There it is known that for symmetries higher than second order, equations resulting from commutativity are almost intractable.

It is not so hard to check that $[X_j^{(\,)}, Y_j^{(\,)}] \neq 0$, $j = 0,1,2$, since the highest order derivatives with constant coefficients will appear on the right-hand side. For example,

$$[X_0^{(k)}, Y_0^{(k,n)}]_{\rm hot} = [J^2, JT_2^2 J] = 4T_1T_2J^3 + 2(2T_1^2 - 2T_2^2 + T_1T_2)J^2 - 8T_1T_2J,$$

$$[X_2^{(n)}, Y_2^{(k,n)}]_{\rm hot} = [T_2^2, T_2J^2T_2] = 2T_2^4 - 6T_1^2T_2^2 - 4T_1T_2^3J,$$

where $[X_0^{(k,n)}, Y_0^{(k,n)}]_{\rm hot}$ represents only the highest order terms resulting from $[X_0^{(k)}, Y_0^{(k,n)}]$. Therefore, the symmetry generators of each potential do not close in a finite dimensional Lie algebra structure. Note that by the Jacobi identity $Z_j = [X_j, Y_j]$, $j = 0,1,2$, is also a symmetry generator, but it is algebraically dependent to X_j and Y_j.

There is an elegant way of expressing the symmetry algebra of H_1. For this purpose we introduce the generators

$$X_\pm = \frac{1}{4\beta^2}\left(-\partial_x^2 \pm \frac{1}{2}\alpha x^2 + \frac{b}{x^2}\right), \quad D_1 = \frac{1}{4}(1 + 2x\partial_x), \tag{78}$$

$$Y_\pm = \frac{1}{4\beta^2}\left(-\partial_y^2 \pm \frac{1}{2}\alpha y^2 + \frac{c}{y^2}\right), \quad D_2 = \frac{1}{4}(1 + 2y\partial_y), \tag{79}$$

which obey the Lie algebras

$$[X_\pm, D_1] = X_\mp, \quad [X_+, X_-] = D_1, \tag{80}$$

$$[Y_\pm, D_2] = Y_\mp, \quad [Y_+, Y_-] = D_2, \tag{81}$$

with the Casimir invariants

$$X_+^2 - X_-^2 + D_1^2 = \frac{4b-3}{16}, \quad Y_+^2 - Y_-^2 + D_2^2 = \frac{4c-3}{16}. \tag{82}$$

It is straightforward to show that in terms of (78) and (79) we have

$$\begin{aligned} H_1 &= 4\beta^2(X_+ + Y_+), \\ X_1^{(k)} &= 8(X_+Y_+ - X_-Y_- + D_1D_2) + K, \\ Y_1^{(n)} &= 4\beta^2 Y_+ - \lambda_{2,n}, \end{aligned} \tag{83}$$

where $K = b + c - \lambda_{1,k} - (1/2)$. Equations (80)–(82) are defining relations of two commuting copies of a $su(1,1)$ algebra which can be written as a direct sum $su(1,1) \oplus su(1,1)$. The basis given by (78) and (79) is connected with that mentioned in Sec. VIII by linear transformations, for instance, by comparing (57) and (79) we have $Y_+ = J_0$, $Y_- \pm D_2 = J_\pm$. Equation (83) shows that the symmetries of H_1 are quadratic in the generators of centrally extended (because of the constant K) $su(1,1) \oplus su(1,1)$ algebra.

By defining

$$W^{(k,n)} \equiv \tfrac{1}{8}[X_1^{(k)}, Y_1^{(n)}] = 4\beta^2(X_-D_2 - Y_-D_1), \tag{84}$$

one can easily show that

$$\begin{aligned} [X_1^{(k)}, W^{(k,n)}] = \{X_1^{(k)}, Y_1^{(n)}\} + X_1^{(k)}(2\lambda_{2,n} - H_1) + (2Y_1^{(n)} \\ + 2\lambda_{2,n} - H_1)(\lambda_{1,k} - 1) + H_1(b-c), \end{aligned} \tag{85}$$

$$[Y_1^{(n)}, W^{(k,n)}] = (Y_1^{(n)} + \lambda_{2,n})(H_1 - Y_1^{(n)} - \lambda_{2,n}) - 2\beta^4(X_1^{(k)} - K), \tag{86}$$

where $\{,\}$ represents the anticommutator. These explicitly show that the extended symmetry algebra of H_1 spanned by $\{H_1, X_1^{(k)}, Y_1^{(n)}, W^{(k,n)}\}$, with the inclusion of $W^{(k,n)}$, closes in a quadratic associative algebra for all values of k,n. We also observe that this algebra is a cubic associative algebra in the enveloping algebra of the centrally extended $su(1,1) \oplus su(1,1)$. Recently such finitely generated associative algebras have attracted a great deal of interest. The structure we have obtained coincides, up to some additive constants, with that presented in Ref. 31 for the Winternitz potential V_1. In Ref. 29 this structure is constructed as a cubic associative algebra in which counterparts of X_1, Y_1 are taken to be purely quadratic in the generators of $su(1,1) \oplus su(1,1)$. We end this section by emphasizing that exploring similar algebraic structures for $H_0^{(k)}$ and $H_2^{(n)}$ and connection between them seems to be an important problem which deserves to be taken up in another study.

X. BOUND STATES OF $H_0^{(k)}$, $H_2^{(n)}$ AND THEIR DEGENERACIES

Representing $\Psi_{n_1}^{\bar{\varepsilon}}$, $\Psi_{n_2}^{\varepsilon}$, and $\Psi_{\ell}^{(1)\bar{\varepsilon}\varepsilon}$ given by (52) and (56), in the Dirac notation, respectively, by the kets $|n_1\bar{\varepsilon}\rangle$, $|n_2\varepsilon\rangle$, and $|1;\ell\bar{\varepsilon}\varepsilon\rangle$, we write (56) as follows:

$$|1;\ell\bar{\varepsilon}\varepsilon\rangle = |n_1\bar{\varepsilon}\rangle|n_2\varepsilon\rangle, \quad \ell = n_1 + n_2. \tag{87}$$

In this notation, the corresponding isospectral states of $H_2^{(n)}$ are

$$|2n;\ell\bar{\varepsilon}\varepsilon\rangle = \mathcal{L}_{21}^{(n)}|1;\ell\bar{\varepsilon}\varepsilon\rangle. \tag{88}$$

From (53) [or, (55)], (56), (68), and (87) one can easily show that

$$\langle 2n;\ell\overline{\varepsilon\varepsilon}|2n;\ell\overline{\varepsilon\varepsilon}\rangle=\langle 1;\ell\overline{\varepsilon\varepsilon}|Y_1^{(n)}|1;\ell\overline{\varepsilon\varepsilon}\rangle=\langle n_2\varepsilon|H_{\rm SO}|n_2\varepsilon\rangle-\lambda_{2,n}=2\hbar\omega(n_2-n), \quad (89)$$

where $\langle\cdot|\cdot\rangle$ represents the usual inner product of $\mathcal{H}=L^2(R^2)$ and in the third line we have included $2m/\hbar^2$ into the notation. Since $\ell=n_1+n_2$, this implies that as physically acceptable states only those with $\ell>n$ will survive in the spectrum of $H_2^{(n)}$. Moreover, the degeneracies of the survived states will be shifted to $\ell-n$ since the states corresponding to $n_2\leqslant n$ cannot be normalized. As a result, the normalized states of $H_2^{(n)}$ are as follows:

$$|2n;\ell\overline{\varepsilon\varepsilon}\rangle=[2\hbar\omega(n_2-n)]^{-1/2}\mathcal{L}_{21}^{(n)}|1;\ell\overline{\varepsilon\varepsilon}\rangle, \quad (90)$$

provided that $\ell=n_1+n_2$ and $n_2>n$.

In a similar way, if we represent ψ_{k_2} and R_{k_1}'s given by (59) and (61), respectively, by the kets $|k_2\overline{\varepsilon\varepsilon}\rangle$ and $|k_1\overline{\varepsilon\varepsilon}\rangle$, the states given by (63) can be expressed as

$$|1;\ell\overline{\varepsilon\varepsilon}\rangle=|k_1\overline{\varepsilon\varepsilon}\rangle|k_2\overline{\varepsilon\varepsilon}\rangle, \quad \ell=k_1+k_2. \quad (91)$$

In that case the corresponding isospectral states of $H_0^{(k)}$ are $|0k;\ell\overline{\varepsilon\varepsilon}\rangle=\mathcal{L}_{10}^{(k)\dagger}|1;\ell\overline{\varepsilon\varepsilon}\rangle$ and by virtue of (62), (67), and (91) we have

$$\langle 0k;\ell\overline{\varepsilon\varepsilon}|0k;\ell\overline{\varepsilon\varepsilon}\rangle=\langle 1;\ell\overline{\varepsilon\varepsilon}|X_1^{(k)}|1;\ell\overline{\varepsilon\varepsilon}\rangle=\langle k_2\overline{\varepsilon\varepsilon}|H_{\rm PT}|k_2\overline{\varepsilon\varepsilon}\rangle-\lambda_{1,k}$$
$$=\frac{2\hbar^2}{m}(k_2-k)(k+k_2+\overline{\varepsilon\nu}+\varepsilon\nu+1). \quad (92)$$

Hence, the normalized states of $H_0^{(k)}$ are

$$|0k;\ell\overline{\varepsilon\varepsilon}\rangle=\left[\frac{2\hbar^2}{m}(k_2-k)(k+k_2+\overline{\varepsilon\nu}+\varepsilon\nu+1)\right]^{-1/2}\mathcal{L}_{10}^{(k)\dagger}|1;\ell\overline{\varepsilon\varepsilon}\rangle, \quad (93)$$

provided that $\ell=k_1+k_2$ and $k_2>k$. In this case the degeneracy of the state $|0k;\ell\overline{\varepsilon\varepsilon}\rangle$ is $\ell-k$. Explicit functional realizations of the states (91) and (93) can easily be obtained by applying $\mathcal{L}_{21}^{(n)}$, $\mathcal{L}_{10}^{(k)\dagger}$ to the wave functions given by (56) and (63).

XI. CONCLUDING REMARKS

The method of intertwining is a unified approach widely used in various fields of physics and mathematics such as in investigating particle propagation on a curved space,[16,24,32] in constructing matrix-Hamiltonian to realize higher dimensional superalgebras,[17,33] in solving both ordinary and partial differential equations,[16] in generating exact solutions of nonstationary Schrödinger equation,[17,34] and in constructing isospectral potentials in an arbitrary space dimension.[35] The method we have introduced increases the power and enlarges the range of applicability of the intertwining operator idea. It allows us to perform Darboux transformations in higher dimensions in such a manner that, in addition to their isospectral deformation property, they acquire integrability and superintegrability preserving property. In particular, as we have shown the realization of this method for 2D systems generates two infinite families of isospectral and superintegrable quantum systems intertwined to a 2D Winternitz system. Work on 3D realization of the method is in progress.

The space of purely second-order operators quadratic in the generators of $e(2)$ has, under the adjoint action of $E(2)$, only four orbits whose representatives can be taken to be; T_1^2, J^2, $J^2+a_0T_1^2$ and T_1J+JT_1, where a_0 is a constant. Existence of only four types Winternitz potentials is closely connected with this orbit structure since each corresponds to a different 2D orthogonal coordinate system.[3,24] T_1^2, J^2 constitute the differential parts of the symmetry generators of V_1 and account for its separation in the Cartesian and polar (hence in elliptic) coordinates. Therefore, the appearance of the Winternitz potential V_1 as the common member of two families is of no surprise; it is a direct result of our orbit prescription in constructing the intertwinings in Sec. V. We

also observe that since only T_1^2 and J^2 can be factorized as $\mathcal{L}\mathcal{L}^\dagger$ (or, as $\mathcal{L}^\dagger\mathcal{L}$) the other three Winternitz potentials cannot be utilized as V_1 in the context of this paper. In this regard, a combination of our method and the conventional approach may be used for similar purposes. Finally we point out that what made it possible to implement Darboux transformations in our approach is that when the eigenvalue equation of V_1 is separated in the Cartesian and polar coordinates, at least one of the separated equation is of the Schrödinger type.

(Received 8 November 2001; accepted for publication 4 February 2002)

The most general admissible boundary conditions are derived for an idealized Aharonov–Bohm flux intersecting the plane at the origin on the background of a homogeneous magnetic field. A standard technique based on self-adjoint extensions yields a four-parameter family of boundary conditions; the other two parameters of the model are the Aharonov–Bohm flux and the homogeneous magnetic field. The generalized boundary conditions may be regarded as a combination of the Aharonov–Bohm effect with a point interaction. Spectral properties of the derived Hamtonians are studied in detail. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1463712]

I. INTRODUCTION

The purpose of this paper is to determine the most general admissible boundary conditions for the Aharonov–Bohm (AB) effect in the plane on the background of a homogeneous magnetic field, and also to investigate the basic properties of Hamiltonians obtained this way. The history of the effect goes four decades back and starts from the observation of Aharonov and Bohm[1] that the behavior of a charged quantum particle is influenced by a magnetic flux even if the field is zero in the region where the particle is localized. A particularly elegant treatment is possible in case of an idealized setup in which the AB flux is concentrated along a line perpendicularly intersecting the plane, conventionally at the origin.[2]

The boundary conditions of the previously mentioned paper are not the most general ones; the full family of such conditions giving the AB effect in the plane was derived in Ref. 3, and simultaneously also in Ref. 4. These generalized boundary conditions may be interpreted as a combination of the AB effect with a point interaction supported, too, at the origin, although this is just one possible point of view. In any case they can be described and investigated by the technique of self-adjoint extensions, which is in principle the same one as that used in Ref. 5 in which two-dimensional point interactions were introduced.

A natural question is what happens if such a system is placed into a background homogeneous magnetic field. This problem attracted some attention recently, even with a controversy: Refs. 6–8 consider the ''pure'' AB effect in this setting for the Pauli operator, i.e., a spin 1/2 particle. The last named property leads to specific behavior related to the Aharonov–Casher effect, which we will not discuss here.

Our aim here is different: we are going to consider a spinless particle with a point flux and a homogeneous background, and ask about the most general class of boundary conditions analogous to those of Refs. 3 and 4. The basic difference between the situations without and with a homogeneous magnetic field is that in the former case the spectrum is absolutely continuous and equal

[a]Electronic mail: stovicek@kmlinux.fjfi.cvut.cz

to the positive half-line possibly augmented with at most two negative eigenvalues (depending on the choice of boundary conditions), while in the latter case the spectrum is pure point and the point flux and interaction gives rise to eigenvalues in each gap between neighboring Landau levels. Our goal is to discuss these spectral properties in detail.

II. FORMULATION OF THE PROBLEM: PRELIMINARIES

We consider the symmetric operator

$$L=-(\nabla-A(\nabla))^2, \quad \mathrm{Dom}(L)=C_0^\infty(\mathbb{R}^2\backslash\{0\}),$$

where the vector potential A is a sum of two parts, $A=A_{\mathrm{hmf}}+A_{\mathrm{AB}}$, with the part A_{hmf} corresponding to the homogeneous magnetic field in the circular gauge,

$$A_{\mathrm{hmf}}=-\frac{\iota B}{2}(-x_2\,\mathrm{d}x_1+x_1\,\mathrm{d}x_2),$$

and with the part A_{AB} corresponding to the idealized AB effect,

$$A_{\mathrm{AB}}=\frac{\iota\Phi}{2\pi r^2}(-x_2\,\mathrm{d}x_1+x_1\,\mathrm{d}x_2), \quad r^2=x_1^2+x_2^2.$$

Without loss of generality we may assume that $B>0$. Further, we rescale the Aharonov–Bohm flux,

$$\alpha=-\frac{\Phi}{2\pi},$$

to have a variable which expresses the number of flux quanta and, as usual, we make use of the gauge symmetry allowing us to assume that $\alpha\in]0,1[$. Hence the case $\Phi\in 2\pi\mathbb{Z}$ is excluded since it is gauge equivalent to the vanishing AB flux. Our goal is to describe all the self-adjoint extensions of L as well as to investigate their basic properties.

It is straightforward to determine the adjoint operator L^*,

$$\psi\in\mathrm{Dom}(L^*)\Leftrightarrow\psi\in L^2(\mathbb{R}^2,\mathrm{d}^2x)\cap H^{2,2}_{\mathrm{loc}}(\mathbb{R}^2\backslash\{0\}) \ \text{ and } \ (\nabla-A(\nabla))^2\psi\in L^2(\mathbb{R}^2,\mathrm{d}^2x).$$

Next we can employ the rotational symmetry when using the polar coordinates (r,θ) and decomposing the Hilbert space into the orthogonal sum of the eigenspaces of the angular momentum,

$$L^2(\mathbb{R}^2,\mathrm{d}^2x)=\sum_{m\in\mathbb{Z}}^{\oplus}L^2(\mathbb{R}_+,r\,\mathrm{d}r)\otimes\mathbb{C}e^{\iota m\theta}. \tag{1}$$

In the polar coordinates the operator L (and correspondingly L^*) takes the form

$$L=-\frac{1}{r}\partial_r r\partial_r+\frac{1}{r^2}\left(-\iota\partial_\theta+\alpha+\frac{Br^2}{2}\right)^2.$$

The operator L^* commutes on $\mathrm{Dom}(L^*)$ with the projectors P_m onto the eigenspaces of the angular momentum,

$$P_m\psi(r,\theta)=\frac{1}{2\pi}\int_0^{2\pi}\psi(r,\theta')e^{\iota m(\theta-\theta')}\,\mathrm{d}\theta',$$

and therefore L^* decomposes in correspondence with the orthogonal sum (1),

$$L^* = \sum_{m \in \mathbb{Z}}^{\oplus} (L^*)_m . \tag{2}$$

Thus we can reduce the problem and work in the sectors $\mathrm{Ran}\, P_m$, $m \in \mathbb{Z}$. For a given spectral parameter $\lambda \in \mathbb{C}$ we choose two independent solutions (except of particular values of λ) of the differential equation

$$\left(-\frac{1}{r}\partial_r r \partial_r + \frac{1}{r^2}\left(m + \alpha + \frac{Br^2}{2} \right)^2 \right) g(r) = \lambda\, g(r), \tag{3}$$

namely

$$\begin{aligned} g_m^1(\lambda; r) &= r^{|m+\alpha|} F\left(\beta(m,\lambda), \gamma(m), \frac{Br^2}{2} \right) \exp\left(-\frac{Br^2}{4} \right), \\ g_m^2(\lambda; r) &= r^{|m+\alpha|} G\left(\beta(m,\lambda), \gamma(m), \frac{Br^2}{2} \right) \exp\left(-\frac{Br^2}{4} \right), \end{aligned} \tag{4}$$

where

$$\begin{aligned} \beta(m,\lambda) &= \frac{1}{2}\left(1 + m + \alpha + |m+\alpha| - \frac{\lambda}{B} \right), \\ \gamma(m) &= 1 + |m+\alpha|. \end{aligned} \tag{5}$$

Here F and G are confluent hypergeometric functions (Ref. 9, Chap. 13),

$$F(\beta,\gamma,z) = \sum_{n=0}^{\infty} \frac{(\beta)_n z^n}{(\gamma)_n n!},$$

and

$$G(\beta,\gamma,z) = \frac{\Gamma(1-\gamma)}{\Gamma(\beta-\gamma+1)} F(\beta,\gamma,z) + \frac{\Gamma(\gamma-1)}{\Gamma(\beta)} z^{1-\gamma} F(\beta-\gamma+1, 2-\gamma, z). \tag{6}$$

Notice that $F(\beta,\gamma,z)$ and $G(\beta,\gamma,z)$ are linearly dependent if and only if $\beta \in -\mathbb{Z}_+$. Moreover, $F(\beta,\gamma,z)$ is an entire function, particularly, it is regular at the origin while $G(\beta,\gamma,z)$ has a singularity there provided $\gamma > 1$ and $\beta \notin -\mathbb{Z}_+$, and in that case it holds true that

$$\lim_{z \to 0_+} z^{\gamma-1} G(\beta,\gamma,z) = \frac{\Gamma(\gamma-1)}{\Gamma(\beta)}.$$

Thus in the case when $1 < \gamma < 2$ we have the asymptotic behavior, as $z \to 0_+$,

$$G(\beta,\gamma,z) = \frac{\Gamma(\gamma-1)}{\Gamma(\beta)} z^{1-\gamma} + \frac{\Gamma(1-\gamma)}{\Gamma(\beta-\gamma+1)} + O(z^{2-\gamma}). \tag{7}$$

We shall also need some information about the asymptotic behavior at infinity. If $\beta \in -\mathbb{Z}_+$ then $F(\beta,\gamma,z)$ is a polynomial with the leading term $(\Gamma(\gamma)/\Gamma(\gamma-\beta))(-z)^{-\beta}$, and if $\beta \notin -\mathbb{Z}_+$ then it holds true that

$$F(\beta,\gamma,z) = \frac{\Gamma(\gamma)}{\Gamma(\beta)} e^z z^{\beta-\gamma} (1 + O(z^{-1})) \quad \text{for } z \to +\infty. \tag{8}$$

Further,

$$G(\beta,\gamma,z)=z^{-\beta}(1+O(z^{-1})) \quad \text{for } z\to+\infty.$$

III. THE STANDARD AHARONOV–BOHM HAMILTONIAN

With the above-mentioned preliminaries it is straightforward to solve the spectral problem for the standard AB Hamiltonian as we mentioned in Sec. I. This means to solve the eigenvalue problem

$$L^*\psi=\lambda\psi$$

with the boundary condition

$$\lim_{r\to 0_+}\psi(r,\theta)=0. \tag{9}$$

By virtue of the decomposition (2) the problem is reduced to the countable set of equations

$$(L^*)_m f=\lambda f, \quad m\in\mathbb{Z},$$

and hence to the differential equations (3).

The solution $g_m^2(\lambda;r)$ of (3) is ruled out because it contradicts the condition (9) and the solution $g_m^1(\lambda;r)$ belongs to $L^2(\mathbb{R}_+,r\,\mathrm{d}r)$ if and only if $\beta(m,\lambda)=-n$, with $n\in\mathbb{Z}_+$. Since it holds

$$F(-n,1+\sigma,z)=\frac{n!\,\Gamma(\sigma+1)}{\Gamma(n+\sigma+1)}L_n^\sigma(z), \quad n\in\mathbb{Z}_+,$$

we get a countable set of eigenvalues,

$$\lambda_{m,n}=B\,(m+\alpha+|m+\alpha|+2n+1), \quad m\in\mathbb{Z},n\in\mathbb{Z}_+,$$

with the corresponding eigenfunctions

$$f_{m,n}(r,\theta)=C_{m,n}\,r^{|m+\alpha|}\,L_n^{|m+\alpha|}\left(\frac{Br^2}{2}\right)\exp\left(-\frac{Br^2}{4}\right)e^{\imath m\theta},$$

where $L_n^\sigma(z)$ is a Laguerre polynomial and

$$C_{m,n}=\left(\frac{B}{2}\right)^{(1/2)(|m+\alpha|+1)}\left(\frac{n!}{\pi\,\Gamma(n+|m+\alpha|+1)}\right)^{1/2}$$

are the normalization constants.

As it is well known if we fix $m\in\mathbb{Z}$ then the functions $\{f_{m,n}(r,\theta)\}_{n=0}^\infty$ form an orthonormal basis in $L^2(\mathbb{R}_+,r\,\mathrm{d}r)\otimes\mathbb{C}\,e^{\imath m\theta}$ and so the complete set of eigenfunctions $\{f_{m,n}(r,\theta)\}_{m\in\mathbb{Z},n\in\mathbb{Z}_+}$ is an orthonormal basis in $L^2(\mathbb{R}_+,r\,\mathrm{d}r)\otimes L^2([0,2\pi],\mathrm{d}\,\theta)$. Since all the eigenvalues $\lambda_{m,n}$ are real we get in this way a well-defined self-adjoint operator which is an extension of L. We conventionally call it the standard AB Hamiltonian and denote it by H^{AB}. Thus the spectrum of H^{AB} is pure point and can be written as a union of two parts,

$$\sigma(H^{\mathrm{AB}})=\sigma_{pp}(H^{\mathrm{AB}})=\{B(2k+1);k\in\mathbb{Z}_+\}\cup\{B(2\alpha+2k+1);k\in\mathbb{Z}_+\}.$$

Notice that the eigenvalues belonging to the first part are nothing but the Landau levels. All the eigenvalues $B(2k+1)$ have infinite multiplicities while the multiplicity of the eigenvalue $B(2\alpha+2k+1)$ is finite and equals $k+1$.

A final short remark concerning the Hamiltonian H^{AB} is devoted to the Green function. Naturally, the Green function is expressible as an infinite series

$$G^{\mathrm{AB}}(z;r_1,\theta_1,r_2,\theta_2)=\frac{1}{2\pi}\sum_{m=-\infty}^{\infty} G_m^{\mathrm{AB}}(z;r_1,r_2)\,e^{\imath m(\theta_1-\theta_2)},$$

where

$$G_m^{\mathrm{AB}}(z;r_1,r_2)=2\left(\frac{B}{2}\right)^{|m+\alpha|+1}(r_1r_2)^{|m+\alpha|}\exp\left(-\frac{1}{4}B({r_1}^2+{r_2}^2)\right)\times\sum_{n=0}^{\infty}\frac{n!}{\Gamma(n+|m+\alpha|+1)}$$
$$\times\frac{L_n^{|m+\alpha|}(\frac{1}{2}B{r_1}^2)\,L_n^{|m+\alpha|}(\frac{1}{2}B{r_2}^2)}{B(m+\alpha+|m+\alpha|+2n+1)-z}.$$

The radial parts can be rewritten with the aid of the standard construction of the Green function for ordinary differential operators of second order,

$$G_m^{\mathrm{AB}}(z;r_1,r_2)=\left(\frac{B}{2}\right)^{|m+\alpha|+1}(r_1r_2)^{|m+\alpha|}\exp\left(-\frac{1}{4}B({r_1}^2+{r_2}^2)\right)\frac{\Gamma(-w(m,z))}{\Gamma(|m+\alpha|+1)}F(-w(m,z),|m$$
$$+\alpha|+1,r_<)\times G(-w(m,z),|m+\alpha|+1,r_>),$$

where

$$w(m,z)=\frac{z}{2B}-\frac{1}{2}(m+\alpha+|m+\alpha|+1)$$

and $r_<=\min(r_1,r_2)$, $r_>=\max(r_1,r_2)$. This amounts to the identity

$$\sum_{n=0}^{\infty}\frac{n!}{\Gamma(n+\sigma+1)}\frac{L_n^{\sigma}(y_1)\,L_n^{\sigma}(y_2)}{n-w}=\frac{\Gamma(-w)}{\Gamma(\sigma+1)}F(-w,\sigma+1,y_<)G(-w,\sigma+1,y_>).$$

We do not expect that a simpler form for the Green function could be derived since the Hamiltonian H^{AB} enjoys only the rotational symmetry.

IV. SELF-ADJOINT EXTENSIONS OF *L*

Recalling what has been summarized in Sec. II. it is easy to determine the deficiency indices. The solution $g_m^1(\pm\imath;r)$ diverges exponentially at infinity [cf. (8)] while $g_m^2(\pm\imath;r)$ behaves well at infinity but has a singularity at the origin of the order $r^{-|m+\alpha|}$. Thus $g_m^2(\pm\imath;r)\in L^2(\mathbb{R}_+,r\,\mathrm{d}r)$ if and only if $m=-1$ or $m=0$. This means that the deficiency indices are (2,2). For a basis in the deficiency subspaces $\mathcal{N}_{\pm\imath}$ we can choose

$$\left\{f_{m,\pm}(r,\theta)=\frac{1}{\sqrt{2\pi}}N_m\,g_m^2(\pm\imath;r)\,e^{\imath m\theta};m=-1,0\right\}.$$

Thus

$$f_{-1,\pm}(r,\theta)=\frac{1}{\sqrt{2\pi}}N_{-1}\,r^{1-\alpha}\,G\left(\frac{1}{2}\mp\frac{\imath}{2B},2-\alpha,\frac{Br^2}{2}\right)\exp\left(-\frac{Br^2}{4}\right)e^{-\imath\theta},$$

$$f_{0,\pm}(r,\theta)=\frac{1}{\sqrt{2\pi}}N_0\,r^{\alpha}\,G\left(\frac{1}{2}+\alpha\mp\frac{\imath}{2B},1+\alpha,\frac{Br^2}{2}\right)\exp\left(-\frac{Br^2}{4}\right),$$

where N_{-1} and N_0 are normalization constants making the basis orthonormal.

We shall need the explicit values of N_{-1} and N_0. Using the relation

$$W_{v,\tau}(z)=z^{\tau+1/2}e^{-z/2}\,G(\tfrac{1}{2}-v+\tau,2\tau+1,z),$$

where W is the Whittaker function we get

$$N_m^{-2}=\int_0^\infty |g_m^2(\pm\iota;r)|^2\,r\,\mathrm{d}r=\frac{1}{2}\left(\frac{2}{B}\right)^{|m+\alpha|+1}\int_0^\infty x^{-1}W_{\varrho,\sigma}(x)\,W_{\bar{\varrho},\sigma}(x)\mathrm{d}x,$$

where

$$\varrho=\frac{1}{2}\left(-m-\alpha+\frac{\iota}{B}\right),\quad \sigma=\frac{1}{2}|m+\alpha|.$$

Combining the identities (Ref. 10, 2.19.24.6)

$$\int_0^\infty x^{-1}W_{\varrho,\sigma}(x)\,W_{\mu,\sigma}(x)\mathrm{d}x=\frac{\pi}{\sin(2\pi\sigma)}\times\left(-\frac{1}{\Gamma(\frac{1}{2}-\sigma-\mu)\Gamma(\frac{3}{2}+\sigma-\varrho)}\right.$$
$$\left.{}_2F_1\left(\frac{1}{2}+\sigma-\mu,1;\frac{3}{2}+\sigma-\varrho;1\right)+\frac{1}{\Gamma(\frac{1}{2}+\sigma-\mu)\,\Gamma(\frac{3}{2}-\sigma-\varrho)}\right.$$
$$\left.{}_2F_1\left(\frac{1}{2}-\sigma-\mu,1;\frac{3}{2}-\sigma-\varrho;1\right)\right)$$

and

$${}_2F_1(a,b;c;z)=\frac{\Gamma(c)\,\Gamma(c-a-b)}{\Gamma(c-a)\,\Gamma(c-b)}\,{}_2F_1(a,b;a+b-c+1;1-z)$$
$$+\frac{\Gamma(c)\,\Gamma(a+b-c)}{\Gamma(a)\,\Gamma(b)}(1-z)^{c-a-b}\,{}_2F_1(c-a,c-b;c-a-b+1;1-z)$$

we arrive at the relation

$$\int_0^\infty x^{-1}W_{\varrho,\sigma}(x)\,W_{\mu,\sigma}(x)\mathrm{d}x=\frac{\pi}{\sin(2\pi\sigma)(\mu-\varrho)}$$
$$\times\left(-\frac{1}{\Gamma(\frac{1}{2}-\mu-\sigma)\Gamma(\frac{1}{2}-\varrho+\sigma)}+\frac{1}{\Gamma(\frac{1}{2}-\mu+\sigma)\,\Gamma(\frac{1}{2}-\varrho-\sigma)}\right).$$

Finally we get

$$N_{-1}=\left(\frac{B}{2}\right)^{(1/2)(1-\alpha)}\sqrt{\frac{\sin(\pi\alpha)}{2\pi}}\left(\mathrm{Im}\,\frac{1}{\Gamma\left(-\frac{1}{2}+\alpha+\frac{\iota}{2B}\right)\Gamma\left(\frac{1}{2}-\frac{\iota}{2B}\right)}\right)^{-1/2},$$

$$N_0=\left(\frac{B}{2}\right)^{(1/2)\,\alpha}\sqrt{\frac{\sin(\pi\alpha)}{2\pi}}\left(\mathrm{Im}\,\frac{1}{\Gamma\left(\frac{1}{2}+\frac{\iota}{2B}\right)\Gamma\left(\frac{1}{2}+\alpha-\frac{\iota}{2B}\right)}\right)^{-1/2}.$$

Let us have a look at the asymptotic behavior at the origin of the basis functions in the deficiency subspaces $\mathcal{N}_{\pm\iota}$. By (4) and (7) we have

$$\begin{aligned} g^2_{-1}(\pm\iota;r) &= a_{-1,\pm}\, r^{-1+\alpha} + b_{-1,\pm}\, r^{1-\alpha} + O(r^{1+\alpha}), \\ g^2_0(\pm\iota;r) &= a_{0,\pm}\, r^{-\alpha} + b_{0,\pm}\, r^{\alpha} + O(r^{2-\alpha}), \end{aligned} \tag{10}$$

where

$$a_{-1,\pm} = \frac{\Gamma(1-\alpha)}{\Gamma\left(\frac{1}{2} \mp \frac{\iota}{2B}\right)} \left(\frac{B}{2}\right)^{-1+\alpha}, \quad b_{-1,\pm} = \frac{\Gamma(-1+\alpha)}{\Gamma\left(-\frac{1}{2} + \alpha \mp \frac{\iota}{2B}\right)},$$

$$a_{0,\pm} = \frac{\Gamma(\alpha)}{\Gamma\left(\frac{1}{2} + \alpha \mp \frac{\iota}{2B}\right)} \left(\frac{B}{2}\right)^{-\alpha}, \quad b_{0,\pm} = \frac{\Gamma(-\alpha)}{\Gamma\left(\frac{1}{2} \mp \frac{\iota}{2B}\right)}.$$

The coefficients $a_{m,\pm}$, $b_{m,\pm}$ are related to the normalization constants N_m for it holds true that

$$\det M_{-1} = -\frac{\iota}{1-\alpha}(N_{-1})^{-2}, \quad \det M_0 = -\frac{\iota}{\alpha}(N_0)^{-2}. \tag{11}$$

where

$$M_m = \begin{pmatrix} a_{m,+} & b_{m,+} \\ a_{m,-} & b_{m,-} \end{pmatrix}.$$

Particularly, we shall need the fact that the matrices M_{-1} and M_0 are regular.

Let us now describe the closure of the operator L. In virtue of the decomposition (2) we have

$$\overline{L} = \sum_{m\in\mathbb{Z}}^{\oplus} \overline{L_m},$$

where $\overline{L_m} = (L^*)^*_m$. As is well known, $\psi \in \mathrm{Dom}(L^*)$ belongs to $\mathrm{Dom}(\overline{L})$ if and only if $\langle \psi, L^*\varphi\rangle = \langle L^*\psi, \varphi\rangle$ for all $\varphi \in \mathcal{N}_\iota + \mathcal{N}_{-\iota}$. Thus $(L^*)_m = \overline{L_m}$ for $m \notin \{-1,0\}$, and if $m \notin \{-1,0\}$ then $\varphi(r)\, e^{\iota m\theta} \in \mathrm{Dom}((L^*)_m)$ belongs to $\mathrm{Dom}(\overline{L_m})$ if and only if

$$\lim_{r\to 0_+} r\, W(\overline{\varphi(r)}, g^2_m(\pm\iota, r)) = 0,$$

where $W(f,g) = (\partial_r f)g - f\,\partial_r g$ is the Wronskian. Using the asymptotic behavior (10) and the regularity of the matrix M_m we arrive at two conditions

$$\lim_{r\to 0_+} \left(-|m+\alpha|\, r^{-|m+\alpha|}\varphi(r) - r^{-|m+\alpha|+1}\partial_r\varphi(r)\right) = 0,$$

$$\lim_{r\to 0_+} \left(|m+\alpha|\, r^{|m+\alpha|}\varphi(r) - r^{|m+\alpha|+1}\partial_r\varphi(r)\right) = 0,$$

which can be rewritten in the equivalent form,

$$\lim_{r\to 0_+} r^{-2|m+\alpha|+1}\partial_r(r^{|m+\alpha|}\varphi(r)) = 0, \quad \lim_{r\to 0_+} r^{|m+\alpha|}\varphi(r) = 0.$$

But since

$$r^{-|m+\alpha|}|\varphi(r)| \leqslant \frac{1}{2|m+\alpha|} \sup_{x\in\,]0,r[} |x^{-2|m+\alpha|+1}\partial_x(x^{|m+\alpha|}\varphi(x))|$$

we finally get a sufficient and necessary condition for $\varphi(r)e^{\imath m\theta}\in \mathrm{Dom}((L^*)_m)$ to belong to $\mathrm{Dom}(\overline{L})$, namely

$$\begin{aligned} &\lim_{r\to 0_+} r^{-1+\alpha}\varphi(r)=0 \ \text{ and } \lim_{r\to 0_+} r^{\alpha}\varphi'(r)=0 \quad \text{if } \ m=-1, \\ &\lim_{r\to 0_+} r^{-\alpha}\varphi(r)=0 \ \text{ and } \lim_{r\to 0_+} r^{-\alpha+1}\varphi'(r)=0 \ \text{ if } \ m=0. \end{aligned} \tag{12}$$

This shows that if $\psi\in \mathrm{Dom}(L^*)=\mathrm{Dom}(\overline{L})+\mathcal{N}_\imath+\mathcal{N}_{-\imath}$ then

$$\psi(r,\theta)=(\Phi_1^1(\psi)r^{-1+\alpha}+\Phi_2^1(\psi)r^{1-\alpha})e^{-\imath\theta}+\Phi_1^2(\psi)r^{-\alpha}+\Phi_2^2(\psi)r^{\alpha}+\text{a regular part.}$$

Let us formally introduce the functionals Φ_j^k on $\mathrm{Dom}(L^*)$,

$$\Phi_1^{-1}(\psi)=\lim_{r\to 0_+} r^{1-\alpha}\frac{1}{2\pi}\int_0^{2\pi}\psi(r,\theta)\,e^{\imath\theta}\,\mathrm{d}\theta,$$

$$\Phi_2^{-1}(\psi)=\lim_{r\to 0_+} r^{-1+\alpha}\left(\frac{1}{2\pi}\int_0^{2\pi}\psi(r,\theta)\,e^{\imath\theta}\,\mathrm{d}\theta-\Phi_1^1(\psi)\,r^{-1+\alpha}\right),$$

$$\Phi_1^0(\psi)=\lim_{r\to 0_+} r^{\alpha}\frac{1}{2\pi}\int_0^{2\pi}\psi(r,\theta)\mathrm{d}\theta,$$

$$\Phi_2^0(\psi)=\lim_{r\to 0_+} r^{-\alpha}\left(\frac{1}{2\pi}\int_0^{2\pi}\psi(r,\theta)\mathrm{d}\theta-\Phi_1^2(\psi)\,r^{-\alpha}\right).$$

Notice that the upper index refers to the sector of angular momentum while the lower index refers to the order of the singularity. If $\psi\in\mathrm{Dom}(\overline{L})$ then according to (12) it actually holds $\Phi_j^k(\psi)=0$ for $j=1,2$, $k=-1,0$. On the other hand, if $\psi\in\mathcal{N}_\imath+\mathcal{N}_{-\imath}$ and $\Phi_j^k(\psi)=0$ for all indices $j=1,2$, $k=-1,0$, then $\psi=0$ (this is again guaranteed by the regularity of the matrices M_{-1} and M_0).

Let us introduce some more notation. It is convenient to arrange the functionals Φ_j^k into column vectors as follows:

$$\Phi_j(\psi)=\begin{pmatrix}\Phi_j^{-1}(\psi)\\ \Phi_j^0(\psi)\end{pmatrix},\quad j=1,2.$$

Further, applying the functionals to the basis functions in $\mathcal{N}_\imath+\mathcal{N}_{-\imath}$ we obtain four 2×2 diagonal matrices. More precisely, set

$$(\Phi_{j,\pm})_{k\ell}=\sqrt{2\pi}\,\Phi_j^{k-2}(f_{\ell-2,\pm}),\quad j,k,\ell=1,2.$$

Then

$$\Phi_{1,\pm}=\begin{pmatrix}N_{-1}a_{-1,\pm} & 0\\ 0 & N_0\,a_{0,\pm}\end{pmatrix},\quad \Phi_{2,\pm}=\begin{pmatrix}N_{-1}b_{-1,\pm} & 0\\ 0 & N_0\,b_{0,\pm}\end{pmatrix}.$$

Now it is straightforward to give a formal definition of a self-adjoint extension H^U of the symmetric operator L determined by a unitary operator $U:\mathcal{N}_\imath\to\mathcal{N}_{-\imath}$. We identify U with a

unitary 2×2 matrix via the choice of the orthonormal bases $\{f_{-1,\pm}, f_{0,\pm}\}$ in $\mathcal{N}_{\pm\imath}$. The self-adjoint operator H^U is unambiguously defined by the condition: $H^U \subset L^*$ and $\psi \in \mathrm{Dom}(L^*)$ belongs to $\mathrm{Dom}(H^U)$ if and only if

$$\begin{pmatrix} \Phi_1(\psi) \\ \Phi_2(\psi) \end{pmatrix} \in \mathrm{Ran}\begin{pmatrix} \Phi_{1,+} + \Phi_{1,-}U \\ \Phi_{2,+} + \Phi_{2,-}U \end{pmatrix}. \tag{13}$$

However condition (13) is rather inconvenient and we shall replace it in Sec. V by another one which is more suitable for practical purposes.

V. BOUNDARY CONDITIONS

To turn (13) into a convenient requirement which would involve boundary conditions we shall need the following proposition. Set

$$D = \begin{pmatrix} 1-\alpha & 0 \\ 0 & \alpha \end{pmatrix}.$$

There is a one-to-one correspondence between unitary matrices $U \in U(2)$ and couples of matrices $X_1, X_2 \in \mathrm{Mat}(2,\mathbb{C})$ obeying

$$\mathrm{rank}\begin{pmatrix} X_1 \\ X_2 \end{pmatrix} = 2 \tag{14}$$

and

$$X_1^* D X_2 = X_2^* D X_1 \tag{15}$$

modulo the right action of the group of regular matrices $GL(2,\mathbb{C})$. The one-to-one correspondence is given by the equality

$$\mathrm{Ran}\begin{pmatrix} X_1 \\ X_2 \end{pmatrix} = \mathrm{Ran}\begin{pmatrix} \Phi_{1,+} + \Phi_{1,-}U \\ \Phi_{2,+} + \Phi_{2,-}U \end{pmatrix}.$$

Let us note that the equivalence class of a couple (X_1, X_2) modulo $GL(2,\mathbb{C})$ corresponds to a two-dimensional subspace in $\mathbb{C}^4$ and hence to a point in the Grassmann manifold $\mathbb{G}_2(\mathbb{C}^4)$. The complex dimension of $\mathbb{G}_2(\mathbb{C}^4)$ equals 4, i.e., $\dim_{\mathbb{R}} \mathbb{G}_2(\mathbb{C}^4) = 8$. The points of $\mathbb{G}_2(\mathbb{C}^4)$ obeying the (''real'') condition (15) form a real four-dimensional submanifold which is diffeomorphic, according to the proposition, to the unitary group $\mathrm{U}(2)$.

To verify the proposition we first show that to any couple (X_1, X_2) with the properties (14), (15) there are related unique $Y \in GL(2,\mathbb{C})$ and $U \in \mathrm{U}(2)$ such that

$$\begin{pmatrix} X_1 \\ X_2 \end{pmatrix} Y = \mathbf{J}\begin{pmatrix} I \\ U \end{pmatrix}, \tag{16}$$

where we have set

$$\mathbf{J} = \begin{pmatrix} \Phi_{1,+} & \Phi_{1,-} \\ \Phi_{2,+} & \Phi_{2,-} \end{pmatrix} = \begin{pmatrix} N_{-1}a_{-1,+} & 0 & N_{-1}a_{-1,-} & 0 \\ 0 & N_0 a_{0,+} & 0 & N_0 a_{0,-} \\ N_{-1}b_{-1,+} & 0 & N_{-1}b_{-1,-} & 0 \\ 0 & N_0 b_{0,+} & 0 & N_0 b_{0,-} \end{pmatrix}.$$

Using (11) one easily finds that $\mathbf{J}$ is regular and

$$\mathbf{J}^{-1}=\iota\begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix}\begin{pmatrix} \Phi_{2,-} & -\Phi_{1,-} \\ -\Phi_{2,+} & \Phi_{1,+} \end{pmatrix}.$$

Let us introduce another couple of matrices, $V_+, V_- \in \mathrm{Mat}(2,\mathbb{C})$, by the relation

$$\begin{pmatrix} V_- \\ V_+ \end{pmatrix}=\mathbf{J}^{-1}\begin{pmatrix} X_1 \\ X_2 \end{pmatrix},$$

thus $V_\pm = \mp\,\iota D(\Phi_{2,\pm}X_1-\Phi_{1,\pm}X_2)$. It follows that

$$V_\pm^* V_\pm=(X_1^* X_2^*)\begin{pmatrix} \Phi_{2,\pm}^* D^2\Phi_{2,\pm} & -\Phi_{2,\pm}^* D^2\Phi_{1,\pm} \\ -\Phi_{1,\pm}^* D^2\Phi_{2,\pm} & \Phi_{1,\pm}^* D^2\Phi_{1,\pm} \end{pmatrix}\begin{pmatrix} X_1 \\ X_2 \end{pmatrix}$$

and, consequently,

$$V_-^* V_- - V_+^* V_+=(X_1^* X_2^*)\begin{pmatrix} 0 & -\iota D \\ \iota D & 0 \end{pmatrix}\begin{pmatrix} X_1 \\ X_2 \end{pmatrix}=\iota(X_2^* D X_1 - X_1^* D X_2)$$

for $\Phi_{j,\pm}$ and D commute (all of them are diagonal), $\Phi_{j,\pm}^*=\Phi_{j,\mp}$ and

$$-\Phi_{1,+}\Phi_{2,-}+\Phi_{1,-}\Phi_{2,+}=\iota D^{-1}$$

[cf. (11)]. Owing to the property (15) we have

$$V_-^* V_- = V_+^* V_+, \tag{17}$$

which jointly with the property (14) implies that

$$\mathrm{Ker}\, V_- = \mathrm{Ker}\, V_+ = \mathrm{Ker}\begin{pmatrix} V_- \\ V_+ \end{pmatrix}=\mathrm{Ker}\begin{pmatrix} X_1 \\ X_2 \end{pmatrix}=0.$$

The only possible choice of the matrices Y and U satisfying (16) is

$$Y=V_-^{-1}, \quad U=V_+ V_-^{-1}.$$

The matrix U is actually unitary because of (17).

Conversely, we have to show that any couple of matrices X_1, X_2 related to a unitary matrix U according to the rule

$$\begin{pmatrix} X_1 \\ X_2 \end{pmatrix}=\mathbf{J}\begin{pmatrix} I \\ U \end{pmatrix}$$

obeys (14) and (15). Condition (14) is obvious since $\mathbf{J}$ is regular and condition (15) is again a matter of a direct computation. In more detail, since it holds

$$X_1^* D X_2 - X_2^* D X_1=(IU^*)\mathbf{J}^*\begin{pmatrix} 0 & D \\ -D & 0 \end{pmatrix}\mathbf{J}\begin{pmatrix} I \\ U \end{pmatrix}$$

it suffices to verify that

$$\mathbf{J}^*\begin{pmatrix} 0 & D \\ -D & 0 \end{pmatrix}\mathbf{J}=\iota\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}.$$

This concludes the proof of the above proposition.

Using this correspondence one can relate to a couple X_1, $X_2 \in \mathrm{Mat}(2,\mathbb{C})$ obeying (14) and (15) a self-adjoint extension H determined by the condition

$$\psi \in \mathrm{Dom}(H) \Leftrightarrow \begin{pmatrix} \Phi_1(\psi) \\ \Phi_2(\psi) \end{pmatrix} \in \mathrm{Ran} \begin{pmatrix} X_1 \\ X_2 \end{pmatrix}. \tag{18}$$

Two couples (X_1, X_2) and (X_1', X_2') determine the same self-adjoint extension if and only if there exists a regular matrix Y such that $(X_1', X_2') = (X_1 Y, X_2 Y)$. Moreover, all the self-adjoint extensions can be obtained in this way.

We shall restrict ourselves to an open dense subset in the space of all self-adjoint extensions by requiring the matrix X_2 to be regular. In that case we can set directly $X_2 = I$ and rename $X_1 = \Lambda$. Thus Λ is a 2×2 complex matrix satisfying

$$D\Lambda = \Lambda^* D. \tag{19}$$

The corresponding self-adjoint extension will be denoted H^Λ. The condition (18) simplifies in an obvious way. We conclude that $H^\Lambda \subset L^*$ and $\psi \in \mathrm{Dom}(L^*)$ belongs to $\mathrm{Dom}(H^\Lambda)$ if and only if

$$\Phi_1(\psi) = \Lambda \Phi_2(\psi), \tag{20}$$

and this is in fact the sought boundary condition.

Matrices Λ obeying (19) can be parametrized by four real parameters (or two real and one complex). We choose the parametrization

$$\Lambda = \begin{pmatrix} u & \alpha \overline{w} \\ (1-\alpha) w & v \end{pmatrix}, \quad u, v \in \mathbb{R}, w \in \mathbb{C}.$$

The relation between Λ and U reads

$$\Lambda = (\Phi_{1,+} + \Phi_{1,-} U)(\Phi_{2,+} + \Phi_{2,-} U)^{-1} \tag{21}$$

(provided the right-hand side makes sense).

The "most regular" among the boundary conditions is $\Phi_1(\psi) = 0$, i.e., the one determined by $\Lambda = 0$, and the corresponding self-adjoint extension is nothing but the standard Aharonov–Bohm Hamiltonian H^{AB} discussed in Sec. III. According to (21) H^{AB} corresponds to the unitary matrix

$$U = -\Phi_{1,-}^{-1} \Phi_{1,+} = \mathrm{diag} \left\{ -\frac{\Gamma\left(\frac{1}{2} + \frac{\iota}{2B}\right)}{\Gamma\left(\frac{1}{2} - \frac{\iota}{2B}\right)}, -\frac{\Gamma\left(\frac{1}{2} + \alpha + \frac{\iota}{2B}\right)}{\Gamma\left(\frac{1}{2} + \alpha - \frac{\iota}{2B}\right)} \right\}.$$

VI. THE SPECTRUM

Let us now proceed to the discussion of spectral properties of the described self-adjoint extensions. It is clear from what has been explained up to now that everything interesting is happening in the two critical sectors of the angular momentum labeled by $m = -1$ and $m = 0$. To state it more formally we decompose the Hilbert space into an orthogonal sum of the "stable" and "critical" parts,

$$\mathcal{H} = \mathcal{H}_s \oplus \mathcal{H}_c,$$

where

$$\mathcal{H}_s = \sum_{m \in \mathbb{Z} \setminus \{-1,0\}}^{\oplus} L^2(\mathbb{R}_+, r\,\mathrm{d}r) \otimes \mathbb{C} e^{\iota m \theta}, \quad \mathcal{H}_c = L^2(\mathbb{R}_+, r\,\mathrm{d}r) \otimes (\mathbb{C} e^{-\iota\theta} \oplus \mathbb{C}1).$$

A self-adjoint extension H^Λ decomposes correspondingly,

$$H^\Lambda = H^\Lambda|_{\mathcal{H}_s} \oplus H^\Lambda|_{\mathcal{H}_c},$$

and we know that on $\mathcal{H}_s$ the operator H^Λ coincides with the standard AB Hamiltonian,

$$H^\Lambda|_{\mathcal{H}_s} = H^{\mathrm{AB}}|_{\mathcal{H}_s}.$$

Thus

$$\sigma(H^\Lambda) = \sigma(H^{\mathrm{AB}}|_{\mathcal{H}_s}) \cup \sigma(H^\Lambda|_{\mathcal{H}_c})$$

and, as explained in Sec. III,

$$\sigma(H^{\mathrm{AB}}|_{\mathcal{H}_s}) = \{B(2k+1); k \in \mathbb{Z}_+\} \cup \{B(2k+2\alpha+1); k \in \mathbb{N}\},$$

where the multiplicity of the eigenvalue $B(2k+1)$ is infinite while the multiplicity of the eigenvalue $B(2k+2\alpha+1)$ equals k. On the other hand,

$$\sigma(H^{\mathrm{AB}}|_{\mathcal{H}_c}) = \{B(2k+1); k \in \mathbb{Z}_+\} \cup \{B(2k+2\alpha+1); k \in \mathbb{Z}_+\},$$

where all the eigenvalues are simple (the first set is a contribution of the sector $m=-1$ while the second one comes from the sector $m=0$). Since the deficiency indices are finite the Krein's formula[11] jointly with Weyl's theorem (Ref. 12, Theorem XIII.14) tells us that the essential spectrum $\sigma_{\mathrm{ess}}(H^\Lambda|_{\mathcal{H}_c})$ is empty for any Λ. Thus the spectrum of $H^\Lambda|_{\mathcal{H}_c}$ is formed by eigenvalues which are at most finitely degenerated and have no finite accumulation points.

Let us derive the equation on eigenvalues for the restriction $H^\Lambda|_{\mathcal{H}_c}$. Let $\lambda \in \mathbb{R}$. In each of the sectors $m=-1,0$ there exists exactly one (up to a multiplicative constant) solution of the equation $(L^*)_m f = \lambda f$ which is L^2-integrable at infinity (with respect to the measure $r\,\mathrm{d}r$) and we may take for it the function $g^2_m(\lambda;r)\,e^{\imath m\theta}$ [cf. (4)]. For a second linearly independent solution one may take $g^1_m(\lambda;r)\,e^{\imath m\theta}$ provided $\beta(m,\lambda) \notin -\mathbb{Z}_+$ [cf. (5)]. If $\beta(m,\lambda) \in -\mathbb{Z}_+$ then a possible choice of a second linearly independent solution is

$$r^{|m+\alpha|}\, H\left(\beta(m,\lambda), \gamma(m), \frac{Br^2}{2}\right) \exp\left(-\frac{Br^2}{4}\right),$$

where

$$H(\beta,\gamma,z) = z^{1-\gamma} F(\beta-\gamma+1, 2-\gamma, z)$$

[cf. (6)].

Thus λ is an eigenvalue of $H^\Lambda|_{\mathcal{H}_c}$ if and only if there exists a vector $(\mu,\nu) \in \mathbb{C}^2 \setminus \{0\}$ such that the function

$$\psi_\lambda(r,\theta) = \mu\, g^2_{-1}(\lambda;r)\, e^{-\imath\theta} + \nu\, g^2_0(\lambda;r)$$

satisfies the boundary condition (20). Using again (4) and (7) one finds that

$$\Phi_1(\psi_\lambda) = \begin{pmatrix} a_{-1} & 0 \\ 0 & a_0 \end{pmatrix} \begin{pmatrix} \mu \\ \nu \end{pmatrix}, \quad \Phi_2(\psi_\lambda) = \begin{pmatrix} b_{-1} & 0 \\ 0 & b_0 \end{pmatrix} \begin{pmatrix} \mu \\ \nu \end{pmatrix},$$

where

$$a_{-1}=\frac{\Gamma(1-\alpha)}{\Gamma\left(\frac{1}{2}-\frac{\lambda}{2B}\right)}\left(\frac{B}{2}\right)^{-1+\alpha},\quad b_{-1}=\frac{\Gamma(-1+\alpha)}{\Gamma\left(-\frac{1}{2}+\alpha-\frac{\lambda}{2B}\right)},$$

$$a_0=\frac{\Gamma(\alpha)}{\Gamma\left(\frac{1}{2}+\alpha-\frac{\lambda}{2B}\right)}\left(\frac{B}{2}\right)^{-\alpha},\quad b_0=\frac{\Gamma(-\alpha)}{\Gamma\left(\frac{1}{2}-\frac{\lambda}{2B}\right)}.$$

This immediately leads to the desired equation on eigenvalues which takes the form $\det\mathbf{A}=0$ where

$$\mathbf{A}=\begin{pmatrix} a_{-1} & 0 \\ 0 & a_0 \end{pmatrix}-\Lambda\begin{pmatrix} b_{-1} & 0 \\ 0 & b_0 \end{pmatrix}.$$

After the substitution

$$z=\frac{1}{2}-\frac{\lambda}{2B},$$

$$\text{i.e.,}\quad \lambda=B(1-2z),$$

we get

$$\frac{\Gamma(1-\alpha)\Gamma(\alpha)}{\Gamma(z)\Gamma(z+\alpha)}\frac{2}{B}-\frac{\Gamma(\alpha)\Gamma(\alpha-1)}{\Gamma(z+\alpha-1)\Gamma(z+\alpha)}\left(\frac{2}{B}\right)^{\alpha}u-\frac{\Gamma(1-\alpha)\Gamma(-\alpha)}{\Gamma(z)^2}\left(\frac{2}{B}\right)^{1-\alpha}v$$
$$+\frac{\Gamma(\alpha-1)\Gamma(-\alpha)}{\Gamma(z)\Gamma(z+\alpha-1)}(uv-\alpha(1-\alpha)|w|^2)=0.$$

To simplify somewhat the form of the equation it is convenient to rescale the parameters as follows:

$$\xi=\left(\frac{B}{2}\right)^{1-\alpha}\frac{\Gamma(\alpha)}{\Gamma(2-\alpha)}u,\quad \eta=\left(\frac{B}{2}\right)^{\alpha}\frac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)}v,\quad \zeta=\sqrt{\frac{B}{2}}|w|. \tag{22}$$

Finally we arrive at an equation depending on three real parameters ξ,η,ζ, namely

$$\frac{1}{\Gamma(z)\,\Gamma(z+\alpha)}+\frac{\xi}{\Gamma(z+\alpha-1)\,\Gamma(z+\alpha)}+\frac{\eta}{\Gamma(z)^2}+\frac{\xi\,\eta-\zeta^2}{\Gamma(z)\,\Gamma(z+\alpha-1)}=0. \tag{23}$$

There is no chance to solve Eq. (23) explicitly apart from some particular cases. One of them, of course, corresponds to the standard AB Hamiltonian. This case is determined by the values of parameters $\xi=\eta=\zeta=0$ and the roots of (23) form the set $-\mathbb{Z}_+\cup(-\alpha-\mathbb{Z}_+)$. Consider also the case when $\xi=\eta=0$ and $\zeta\neq0$ with the set of roots equal to $-\mathbb{Z}_+\cup(-\alpha-\mathbb{Z}_+)\cup\{1-\alpha+\zeta^{-2}\}$. Comparing the latter case to the former one we see that there is one additional root, namely $1-\alpha+\zeta^{-2}$, which escapes to infinity when $\zeta\to0$.

In the last particular case one can also consider the limit $\zeta\to\infty$. More generally, suppose that $\det\Lambda\neq0$, i.e., $\xi\eta-\zeta^2\neq0$, replace Λ with $t\,\Lambda$ in (20) and take the limit $t\to\infty$. The limiting boundary condition reads

$$\Phi_2(\psi)=0$$

and the corresponding self-adjoint extension which we shall call H^∞ is one of those omitted when we restricted ourselves to an open dense subset in the space of all self-adjoint extensions (regarded as a a four-dimensional real manifold). Equation (23) reduces in this limit to

$$\frac{1}{\Gamma(z)\,\Gamma(z+\alpha-1)}=0 \tag{24}$$

with the set of roots $-\mathbb{Z}_+\cup(1-\alpha-\mathbb{Z}_+)$.

Another case when Eq. (23) simplifies though it is not solvable explicitly is $\zeta=0$. This is easy to understand since if $\zeta=0$ then the matrix Λ is diagonal and the two critical sectors of angular momentum do not interfere. This is reflected in the fact that Eq. (23) splits into two independent equations,

$$\frac{1}{\Gamma(z)}+\frac{\xi}{\Gamma(z+\alpha-1)}=0, \quad \frac{1}{\Gamma(z+\alpha)}+\frac{\eta}{\Gamma(z)}=0.$$

Let us briefly discuss the dependence of roots of Eq. (23) on the parameters ξ,η,ζ. Since the derivative of the left-hand side of (23) with respect to z and with the values of parameters $(\xi,\eta,\zeta)=(0,0,0)$ equals

$$\frac{(-1)^m m!}{\Gamma(-m+\alpha)}\neq 0 \quad \text{for } z=-m, \quad \text{and} \frac{(-1)^m m!}{\Gamma(-m-\alpha)}\neq 0 \quad \text{for } z=-m-\alpha,$$

where $m\in\mathbb{Z}_+$, the standard implicit function theorem (analytic case) is sufficient to conclude that the roots are analytic functions in ξ,η,ζ at least in some neighborhood of the origin (depending in general on the root). Let us denote by $z_{1,m}(\xi,\eta,\zeta)$ and $z_{2,m}(\xi,\eta,\zeta)$ the roots of (23) regarded as analytic functions in ξ,η,ζ and such that $z_{1,m}(0,0,0)=-m$ and $z_{2,m}(0,0,0)=-\alpha-m$, with $m\in\mathbb{Z}_+$. A straightforward computation results in the following power series truncated at degree 4.

Set

$$h^0_m(z)=\sum_{j=1}^{m}\frac{1}{j}-\gamma-\psi(z),$$

$$h^1_m(z)=\frac{\pi^2}{6}+\sum_{j=1}^{m}\frac{1}{j^2}-\psi'(z),$$

$$h^2_m(z)=-2\,\boldsymbol{\zeta}(3)+2\sum_{j=1}^{m}\frac{1}{j^3}-\psi''(z),$$

where γ is the Euler constant, $\psi(z)=\Gamma'(z)/\Gamma(z)$ is the digamma function, and $\boldsymbol{\zeta}$ is the zeta function. Then

$$\begin{aligned} z_{1,m}(\xi,\eta,\zeta)=&-m+\frac{(-1)^{m+1}}{m!\,\Gamma(-1-m+\alpha)}\xi+\frac{h^0_m(-1-m+\alpha)}{(m!)^2\,\Gamma(-1-m+\alpha)^2}\xi^2\\ &+\frac{(-1)^{m+1}(3\,h^0_m(-1-m+\alpha)^2+h^1_m(-1-m+\alpha))}{2\,(m!)^3\,\Gamma(-1-m+\alpha)^3}\xi^3+\frac{(-1)^m(1+m-\alpha)}{m!\,\Gamma(-1-m+\alpha)}\xi\,\zeta^2\\ &+\frac{1}{6\,(m!)^4\,\Gamma(-1-m+\alpha)^4}(4\,h^0_m(-1-m+\alpha)(4\,h^0_m(-1-m+\alpha)^2+3\,h^2_m(-1 \end{aligned}$$

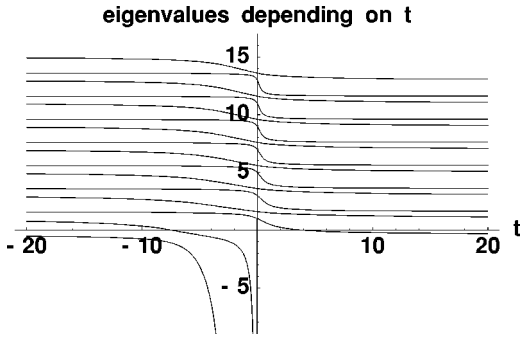

FIG. 1. The Hamiltonian is determined by the boundary conditions corresponding to the parameters $(\xi,\eta,\zeta)=(0.95\,t,0.25\,t,0.25\,t)$, $\alpha=0.3$, $B=1$.

$$-m+\alpha))+h_m^2(-1-m+\alpha))\,\xi^4+\frac{3-2\,(1+m-\alpha)\,h_m^0(-m+\alpha)}{(m!)^2\,\Gamma(-1-m+\alpha)^2}\,\xi^2\zeta^2+\cdots, \tag{25}$$

$$\begin{aligned} z_{2,m}(\xi,\eta,\zeta)=&-\alpha-m+\frac{(-1)^{m+1}}{m!\,\Gamma(-m-\alpha)}\,\eta+\frac{h_m^0(-m-\alpha)}{(m!)^2\,\Gamma(-m-\alpha)^2}\,\eta^2\\ &+\frac{(-1)^{m+1}(3\,h_m^0(-m-\alpha)^2+h_m^1(-m-\alpha))}{2\,(m!)^3\,\Gamma(-m-\alpha)^3}\,\eta^3+\frac{(-1)^m\,(m+1)}{m!\,\Gamma(-m-\alpha)}\,\eta\,\zeta^2\\ &+\frac{1}{6\,(m!)^4\,\Gamma(-m-\alpha)^4}(4\,h_m^0(-m-\alpha)(4\,h_m^0(-m-\alpha)^2+3\,h_m^2(-m-\alpha))\\ &+h_m^2(-m-\alpha))\,\eta^4+\frac{1-2\,(m+1)\,h_m^0(-m-\alpha)}{(m!)^2\,\Gamma(-m-\alpha)^2}\,\eta^2\zeta^2+\cdots. \end{aligned} \tag{26}$$

A similar analysis can be carried out to get the asymptotic behavior of roots for ξ,η,ζ large. To this end assume that $\xi\eta-\zeta^2\neq 0$ and set

$$\xi'=\frac{\xi}{\xi\eta-\zeta^2},\quad \eta'=\frac{\eta}{\xi\eta-\zeta^2},\quad \zeta'=\frac{\zeta}{\xi\eta-\zeta^2}.$$

Notice that $\xi'\,\eta'-\zeta'^2=(\xi\eta-\zeta^2)^{-1}$. Equation (23) becomes

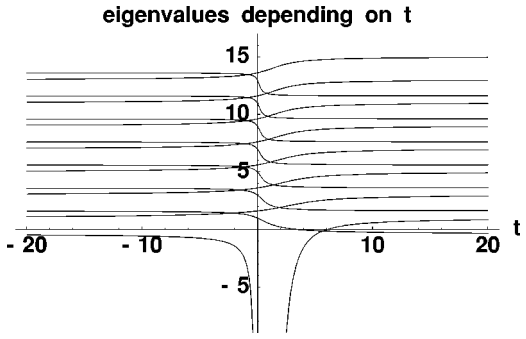

FIG. 2. The Hamiltonian is determined by the boundary conditions corresponding to the parameters $(\xi,\eta,\zeta)=(0.95\,t,-0.25\,t,0)$, $\alpha=0.3$, $B=1$.

TABLE I. Roots in the interval $]1-\alpha,+\infty[$.

Interval $]1-\alpha,+\infty[$			
Conditions			Number of roots
$\xi\geqslant 0$	$\eta\geqslant 0$	$\zeta^2>\xi\eta$	1
$\xi\geqslant 0$	$\eta\geqslant 0$	$\zeta^2\leqslant\xi\eta$	0
$\xi\geqslant 0$	$-\Gamma(1-\alpha)<\eta<0$	no condition	1
$\xi\geqslant 0$	$\eta\leqslant-\Gamma(1-\alpha)$	no condition	0
$\xi<0$	$\eta\geqslant 0$	no condition	1
$\xi<0$	$-\Gamma(1-\alpha)<\eta<0$	$\zeta^2\geqslant\xi\eta$	1
$\xi<0$	$-\Gamma(1-\alpha)<\eta<0$	$\zeta^2<\xi\eta$	2
$\xi<0$	$\eta\leqslant-\Gamma(1-\alpha)$	$\zeta^2\geqslant\xi\eta$	0
$\xi<0$	$\eta\leqslant-\Gamma(1-\alpha)$	$\zeta^2<\xi\eta$	1

$$\frac{\xi'\eta'-\zeta'^2}{\Gamma(z)\,\Gamma(z+\alpha)}+\frac{\xi'}{\Gamma(z+\alpha-1)\,\Gamma(z+\alpha)}+\frac{\eta'}{\Gamma(z)^2}+\frac{1}{\Gamma(z)\,\Gamma(z+\alpha-1)}=0. \tag{27}$$

Roots of (27) are analytic functions in ξ',η',ζ' at least in some neighborhood of the origin. Again, it would be possible to compute the beginning of the corresponding power series and to derive formulas similar to those of (25) and (26) but we avoid doing it here explicitly.

Instead we prefer to plot two graphs (Figs. 1 and 2) in order to give the reader some impression about how the eigenvalues may depend on the parameters, i.e., on the boundary conditions. In each graph we choose a line in the parameter space, $\{(\xi t,\eta t,\zeta t)\in\mathbb{R}^3; t\in\mathbb{R}\}$, and we depict the dependence on t of several first eigenvalues for the corresponding self-adjoint extension restricted to $\mathcal{H}_c$ [see (22) for the substitution]. In both graphs we have set $\alpha=0.3$ and $B=1$.

Probably the most complete general information which is available about solutions of Eq. (23) might be a localization of roots of this equation with respect to a suitable splitting of the real line into intervals. Let us choose the splitting into intervals with boundary points coinciding with the roots of Eq. (24). To get the localization let us rewrite Eq. (23), equivalently provided $z\neq -\mathbb{Z}_+\cup(1-\alpha-\mathbb{Z}_+)$, as follows:

$$\left(\frac{\Gamma(z-1+\alpha)}{\Gamma(z)}+\xi\right)\left(\frac{\Gamma(z)}{\Gamma(z+\alpha)}+\eta\right)=\zeta^2. \tag{28}$$

Put

$$F_\alpha(z)=\frac{\Gamma(z-1+\alpha)}{\Gamma(z)}$$

so that Eq. (28) can be rewritten as

$$(F_\alpha(z)+\xi)(F_{1-\alpha}(z+\alpha)+\eta)=\zeta^2. \tag{29}$$

It is easy to carry out some basic analysis of the function $F_\alpha(z)$. We have $F_\alpha'(z)=F_\alpha(z)\,(\psi(z-1+\alpha)-\psi(z))$. One observes that $F_\alpha(z)>0$ for $z\in\,]1-\alpha,+\infty[\,\cup(\cup_{m\in\mathbb{Z}_+}]-\alpha$

TABLE II. Roots in the interval $]0,1-\alpha[$.

Interval $]0,1-\alpha[$		
Conditions		Number of roots
$\xi\leqslant 0$	$\eta\geqslant-\Gamma(1-\alpha)$	0
$\xi\leqslant 0$	$\eta<-\Gamma(1-\alpha)$	1
$\xi>0$	$\eta\geqslant-\Gamma(1-\alpha)$	1
$\xi>0$	$\eta<-\Gamma(1-\alpha)$	2

TABLE III. Roots in the intervals $]-\alpha-m,-m[, m\in\mathbb{Z}_+$.

Conditions		Intervals $]-\alpha-m,-m[, m\in\mathbb{Z}_+$ Number of roots
$\xi\geqslant 0$	$\eta\leqslant 0$	0
$\xi\geqslant 0$	$\eta>0$	1
$\xi<0$	$\eta\leqslant 0$	1
$\xi<0$	$\eta>0$	2

$-m,-m[)$, and $F_\alpha(z)<0$ for $z\in\cup_{m\in\mathbb{Z}_+}]-m,1-\alpha-m[$, and in any case $F_\alpha{}'(z)<0$. In the former case this follows from the fact that $\psi(z)$ is strictly increasing on each of the intervals $]0,+\infty[$ and $]-m-1,-m[$, with $m\in\mathbb{Z}_+$. In the latter case this is a consequence of the identity

$$\psi(z-1+\alpha)-\psi(z)=\frac{\pi\sin(\pi\alpha)}{\sin(\pi z)\sin(\pi(z+\alpha))}+\int_0^\infty \frac{e^{-(1-z)t}(1-e^{-(1-\alpha)t})}{1-e^{-t}}\,\mathrm{d}t.$$

Moreover,

$$\lim_{z\to+\infty} F_\alpha(z)=0,\qquad \lim_{z\to(1-\alpha-m)\pm} F_\alpha(z)=\pm\infty,\quad F_\alpha(-m)=0\quad \text{for } m\in\mathbb{Z}_+.$$

This also implies that $F_{1-\alpha}(z+\alpha)>0$ for $z\in]0,+\infty[\cup(\cup_{m\in\mathbb{Z}_+}]-1-m,-\alpha-m[)$ and $F_{1-\alpha}(z)<0$ for $z\in\cup_{m\in\mathbb{Z}_+}]-\alpha-m,-m[$, in any case $F_{1-\alpha}{}'(z+\alpha)<0$, and

$$\lim_{z\to+\infty} F_{1-\alpha}(z+\alpha)=0,\qquad \lim_{z\to-m\pm} F_{1-\alpha}(z+\alpha)=\pm\infty,$$

$$\text{and } F_{1-\alpha}(-\alpha-m)=0 \text{ for } m\in\mathbb{Z}_+.$$

With the knowledge of these basic properties of the function $F_\alpha(z)$ it is a matter of an elementary analysis to determine the number of roots of Eq. (29) in each of the intervals $]1-\alpha,+\infty[$, $]-m,1-\alpha-m[$ and $]-\alpha-m,-m[$, with $m\in\mathbb{Z}_+$. The result is summarized in Tables I–IV.

This is to be completed with the simple observation that $1-\alpha$ is a root of (23) if and only if $\eta=-\Gamma(1-\alpha)$, and $-m$, with $m\in\mathbb{Z}_+$, is a root if and only if $\xi=0$, and finally $-\alpha-m$, with $m\in\mathbb{Z}_+$, is a root if and only if $\eta=0$.

Let us note that this localization is in agreement with a general result according to which if A and B are two self-adjoint extensions of the same symmetric operator with finite deficiency indices (d,d) then any interval $J\subset\mathbb{R}$ not intersecting the spectrum of A contains at most d eigenvalues of the operator B (including multiplicities) and no other part of the spectrum of B (Ref. 13, Sec. 8.3). Thus in our example if J is an open interval whose boundary points are either two subsequent eigenvalues of H^∞ or the lowest eigenvalue of H^∞ and $-\infty$ then any self-adjoint extension H^Λ has at most two eigenvalues in J.

TABLE IV. Roots in the intervals $]-1-m,-\alpha-m[, m\in\mathbb{Z}_+$.

Conditions		Intervals $]-1-m,-\alpha-m[, m\in\mathbb{Z}_+$ Number of roots
$\xi\leqslant 0$	$\eta\geqslant 0$	0
$\xi\leqslant 0$	$\eta<0$	1
$\xi>0$	$\eta\geqslant 0$	1
$\xi>0$	$\eta<0$	2

VII. CONCLUDING REMARKS

The above-presented discussion does not exhaust all questions related to the system under consideration. One may ask, for instance, how the state of such a particle evolves under an adiabatic change of parameters. In particular, since the model exhibits eigenvalue crossings, one may expect that there are parameter loops exhibiting a nontrivial Berry phase. Another question concerns the physical meaning of our idealized model. More specifically, one is interested in which sense the model Hamiltonian can be approximated by those with smeared flux and a regular interaction. We leave these problems to a future publication.

Phase-amplitude method for numerically exact solution of the differential equations of the two-center Coulomb problem

Per Olof Fröman and Kilian Larsson
Department of Theoretical Physics, University of Uppsala, Box 803, S-751 08 Uppsala, Sweden

(Received 25 July 2001; accepted for publication 22 January 2002)

A numerically exact phase-amplitude method that has been presented earlier by P. O. Fröman, Larsson, and Hökback [J. Math. Phys. **40**, 1764–1779 (1999)] is particularized and modified in order to make it adapted to the solution of the differential equations of the two-center Coulomb problem. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1465098]

I. INTRODUCTION

We start by quoting some well-known results.

The time-independent Schrödinger equation for the motion of an electron of mass μ and charge $-e(e>0)$ in the field of two fixed Coulomb centers with charges Z_1e and Z_2e takes the following form:

$$\left(-\frac{\hbar^2}{2\mu}\Delta_{\mathbf{r}}-\frac{Z_1e}{r_1}-\frac{Z_2e}{r_2}\right)\psi(\mathbf{r})=E\psi(\mathbf{r}), \tag{1.1}$$

where r_1 and r_2 are the distances of the electron from the two centers, $\mathbf{r}$ is the position vector of the electron, and E is the electronic energy. To obtain the total energy one must add the potential energy of the two fixed charges, getting

$$E_{\text{total}}=Z_1Z_2e^2/r_{12}+E, \tag{1.2}$$

where r_{12} is the distance between the two centers. The differential equation (1.1) is separable in elliptic coordinates. If one introduces the variables

$$\xi=\frac{r_1+r_2}{r_{12}}, \quad 1\leqslant\xi<+\infty, \tag{1.3a}$$

$$\eta=\frac{r_1-r_2}{r_{12}}, \quad -1\leqslant\eta\leqslant+1, \tag{1.3b}$$

and puts

$$\psi(\mathbf{r})=X(\xi)Y(\eta)e^{im\varphi}, \tag{1.4}$$

where m is the magnetic quantum number (integer or zero), and φ is the corresponding angle, the separation yields, in *atomic units* ($\hbar=e=\mu=1$), the two differential equations

$$\frac{\mathrm{d}}{\mathrm{d}\xi}\left((\xi^2-1)\frac{\mathrm{d}X}{\mathrm{d}\xi}\right)+\left(-p^2\xi^2+b'\xi+A-\frac{m^2}{\xi^2-1}\right)X=0, \tag{1.5a}$$

$$\frac{\mathrm{d}}{\mathrm{d}\eta}\left((1-\eta^2)\frac{\mathrm{d}Y}{\mathrm{d}\eta}\right)+\left(p^2\eta^2+b\eta-A-\frac{m^2}{1-\eta^2}\right)Y=0, \tag{1.5b}$$

where A is the separation constant and

$$p^2=-\tfrac{1}{2}r_{12}^2E, \tag{1.6a}$$

$$b'=r_{12}(Z_2+Z_1), \tag{1.6b}$$

$$b=r_{12}(Z_2-Z_1). \tag{1.6c}$$

The differential equations (1.5a) and (1.5b) are to be solved under the boundary conditions that the functions $X(\xi)$ and $Y(\eta)$ are regular, and hence finite, for $\xi=+1$, $\xi=+\infty$ and $\eta=-1$, $\eta=+1$.

The differential equations (1.5a) and (1.5b) or the corresponding differential equations in Rydberg units have been solved in various ways by several authors. In Rydberg units, results have been given by Bates, Ledsham, and Stewart,[1] Bates and Carson,[2] Bates and Reid,[3] Rosenthal and Wilson,[4] and Murai and Takatsu.[5] In atomic units, results have been given by Wallis and Hulburt,[6] Wind,[7] Peek,[8,9] Ponomarev and Puzynina,[10] Rothstein,[11] Murai,[12] Murai and Takatsu,[13] and Bhattacharje *et al.*[14] Due to the difficulty of the numerical problem these results are not in complete agreement with each other. In the present paper we shall treat the two-center Coulomb problem in a new way by means of a numerically exact method that has been fruitful in connection with other problems.

Putting

$$X(\xi)=\frac{f(\xi)}{(\xi^2-1)^{1/2}}, \tag{1.7a}$$

$$Y(\eta)=\frac{g(\eta)}{(1-\eta^2)^{1/2}}, \tag{1.7b}$$

we can transform the differential equations (1.5a) and (1.5b) into

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}\xi^2}+\tilde{R}(\xi)\right)f(\xi)=0, \tag{1.8a}$$

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}\eta^2}+R(\eta)\right)g(\eta)=0, \tag{1.8b}$$

where

$$\tilde{R}(\xi)=-p^2+\frac{b'\xi+A'}{\xi^2-1}-\frac{m^2-1}{(\xi^2-1)^2}, \tag{1.9a}$$

$$R(\eta)=-p^2+\frac{b\eta-A'}{1-\eta^2}-\frac{m^2-1}{(1-\eta^2)^2}, \tag{1.9b}$$

with

$$A'=A-p^2. \tag{1.10}$$

The differential equations (1.8a) and (1.8b) are to be solved under the boundary conditions that the functions $f(\xi)$ and $g(\eta)$ are regular and equal to zero for $\xi=+1$, $\xi=+\infty$ and $\eta=-1$, $\eta=+1$. The effective potential corresponding to the function $-\tilde{R}(\xi)$ always has the form of a single-well

potential on the interval $1 \leqslant \xi < +\infty$, while the effective potential corresponding to the function $-R(\eta)$ has the character of either a single-well potential or a double-well potential on the interval $-1 \leqslant \eta \leqslant +1$. To solve the differential equations (1.8a) and (1.8b) we shall particularize and modify the numerically exact phase-amplitude method described in Appendix B of P. O. Fröman, Larsson, and Hökback.[15] For the general background and for the notations we refer to the brief summary of that appendix that is presented in our appendix. To start the integrations of the q-equations corresponding to the differential equations (1.8a) and (1.8b) we approximate $\hat{\tilde{q}}(\xi)$ and $\hat{q}(\eta)$ in the middle of the classically allowed regions by the base functions (see Chap. 1 in Fröman and Fröman[16])

$$\tilde{Q}(\xi) = \left(-p^2 + \frac{b'\xi + A' - \tilde{C}}{\xi^2 - 1} - \frac{m^2}{(\xi^2-1)^2} \right)^{1/2}, \tag{1.11a}$$

$$Q(\eta) = \left(-p^2 + \frac{b\eta - A' + C}{1-\eta^2} - \frac{m^2}{(1-\eta^2)^2} \right)^{1/2}, \tag{1.11b}$$

where $\tilde{C}$ and C are so far unspecified constants, which are to be chosen conveniently. By solving the q-equations simultaneously one can obtain the energy eigenvalue E and the redefined separation constant A' as functions of the distance r_{12} and the quantum numbers.

II. TREATMENT OF THE ξ-EQUATION

For the differential equation (1.8a) we have $N=1$ in our appendix, and the q-equation is

$$\frac{\mathrm{d}^2}{\mathrm{d}\xi^2}\hat{\tilde{q}}_1^{-1/2} + \tilde{R}(\xi)\hat{\tilde{q}}_1^{-1/2} = \hat{\tilde{q}}_1^{3/2}, \quad 1 \leqslant \xi < +\infty. \tag{2.1}$$

We satisfy the boundary condition at $\xi = +1$ by writing

$$f(\xi) = \tilde{F}_1 \hat{\tilde{q}}_1^{-1/2}(\xi) \sin\left(\int_1^{\xi} \hat{\tilde{q}}_1(\xi)\mathrm{d}\xi \right), \quad 1 \leqslant \xi < +\infty, \tag{2.2}$$

and then we satisfy the boundary condition at $\xi = +\infty$ by requiring that

$$\int_1^{+\infty} \hat{\tilde{q}}_1(\xi)\mathrm{d}\xi = (\hat{\tilde{s}}+1)\pi, \quad \hat{\tilde{s}} = 0,1,2,\ldots . \tag{2.3}$$

The numerical calculation of the integral in (2.3) is rather easily performed except when $m=0$, in which case $\hat{\tilde{q}}_1(\xi)$ approaches zero so slowly as $\xi \to +1$ that the integral in (2.3) cannot be calculated numerically with sufficient accuracy by conventional methods. P. O. Fröman, Hökback, and N. Fröman[17] have overcome this difficulty with the use of the comparison equation technique. Recalling their approximate formula (8.3.16′), we can replace (2.3) by

$$\arctan \frac{2(\xi-1)\hat{\tilde{q}}_1(\xi)}{1 + \dfrac{\xi-1}{\hat{\tilde{q}}_1(\xi)} \dfrac{\mathrm{d}\hat{\tilde{q}}_1(\xi)}{\mathrm{d}\xi}} + \int_{\xi}^{+\infty} \hat{\tilde{q}}_1(\xi)\mathrm{d}\xi = (\hat{\tilde{s}}+1)\pi, \quad \hat{\tilde{s}} = 0,1,2,\ldots, \tag{2.3′}$$

where we choose ξ to lie so close to $+1$ that the expression on the left-hand side of (2.3′) remains constant (within the prescribed degree of numerical accuracy) when ξ decreases further toward $+1$. One thus evaluates the expression on the left-hand side of (2.3′) for various values of ξ that decrease toward $+1$, and one continues until the expression in question remains constant within the prescribed degree of numerical accuracy.

III. TREATMENT OF THE η-EQUATION

The η-equation has the character of a Schrödinger equation associated with either a single-well potential or a double-well potential. For our purpose it is natural to consider the case of a single-well potential for superbarrier energies and the case of a double-well potential for subbarrier energies.

A. The case of a single-well potential

For the differential equation (1.8b) we have in this case $N=1$ in our appendix, and the q-equation is

$$\frac{\mathrm{d}^2}{\mathrm{d}\eta^2}\hat{q}_1^{-1/2}+R(\eta)\hat{q}_1^{-1/2}=\hat{q}_1^{3/2}\ , \quad -1\leqslant\eta\leqslant+1. \tag{3.1}$$

We satisfy the boundary condition at $\eta=-1$ by writing

$$g(\eta)=F_1\hat{q}_1^{-1/2}(\eta)\sin\left(\int_{-1}^{\eta}\hat{q}_1(\eta)\mathrm{d}\eta\right), \quad -1\leqslant\eta\leqslant+1, \tag{3.2}$$

and then we satisfy the boundary condition at $\eta=+1$ by requiring that

$$\int_{-1}^{+1}\hat{q}_1(\eta)\mathrm{d}\eta=(\hat{s}+1)\pi, \quad \hat{s}=0,1,2,\ldots. \tag{3.3}$$

When $m=0$ one encounters the same difficulty with (3.3) as with (2.3), and thus one replaces (3.3) by

$$\arctan\frac{2(1+\eta')\hat{q}_1(\eta')}{1+\dfrac{1+\eta'}{\hat{q}_1(\eta')}\dfrac{\mathrm{d}\hat{q}_1(\eta')}{\mathrm{d}\eta'}}+\int_{\eta'}^{\eta''}\hat{q}_1(\eta)\mathrm{d}\eta+\arctan\frac{2(1-\eta'')\hat{q}_1(\eta'')}{1-\dfrac{1-\eta''}{\hat{q}_1(\eta'')}\dfrac{\mathrm{d}\hat{q}_1(\eta'')}{\mathrm{d}\eta''}}=(\hat{s}+1)\pi,$$

$$\hat{s}=0,1,2,\ldots, \tag{3.3$'$}$$

where one chooses η' and η'' $(>\eta')$ to lie so close to -1 and $+1$, respectively, that the expression on the left-hand side of (3.3$'$) remains constant (within the prescribed degree of numerical accuracy) when η' and η'' further approach -1 and $+1$, respectively. One thus evaluates the expression on the left-hand side of (3.3$'$) for various values of η' that decrease toward -1 and various values of η'' that increase toward $+1$, and one continues until the expression in question remains constant within the prescribed degree of numerical accuracy.

The case when the single-well potential is symmetric $(b=0)$. In this case the wave function $g(\eta)$ is either symmetric or antisymmetric. When it is symmetric, it has an even number of nodes, and the quantum number $\hat{s}$ is an even number which we write as $\hat{s}=2\hat{s}'$. When it is antisymmetric, it has an odd number of nodes, and the quantum number $\hat{s}$ is an odd number which we write as $\hat{s}=2\hat{s}'+1$. One starts the integration of (3.1) at $\eta=0$ by approximating there $\hat{q}_1(\eta)$ by the symmetric (with respect to the origin) base function $Q(\eta)$, i.e., with initial conditions such that $\hat{q}_1(\eta)$ becomes symmetric with respect to the origin. From (3.3) one then obtains

$$\int_{-1}^{0}\hat{q}_1(\eta)\mathrm{d}\eta=(\hat{s}'+\Delta)\pi, \quad \hat{s}'=0,1,2,\ldots, \tag{3.3$''$}$$

with $\Delta=1/2$ for the symmetric wave functions $g(\eta)$ and $\Delta=1$ for the antisymmetric wave functions $g(\eta)$. When $m=0$ the function $\hat{q}_1(\eta)$ approaches zero so slowly as $\eta\to-1$ that there appear difficulties in the accurate numerical calculation of the integral in (3.3$''$), and one therefore replaces this equation by

$$\arctan\frac{2(1+\eta')\hat{q}_1(\eta')}{1+\dfrac{1+\eta'}{\hat{q}_1(\eta')}\dfrac{\mathrm{d}\hat{q}_1(\eta')}{\mathrm{d}\eta'}}+\int_{\eta'}^{0}\hat{q}_1(\eta)\,\mathrm{d}\eta=(\hat{s}'+\Delta)\pi,\quad \hat{s}'=0,1,2,\ldots, \tag{3.3'''}$$

and proceeds similarly as described below (2.3′).

B. The case of a double-well potential

For the differential equation (1.8b) we have in this case $N=2$ in our appendix, and the q-equations are

$$\frac{\mathrm{d}^2}{\mathrm{d}\eta^2}\hat{q}_n^{-1/2}+R(\eta)\hat{q}_n^{-1/2}=\hat{q}_n^{3/2},\quad n=1,2, \tag{3.4}$$

where $-1\leqslant\eta\leqslant\eta_1$ for $n=1$ and $\eta_1\leqslant\eta\leqslant+1$ for $n=2$, η_1 being a point in the potential barrier. We satisfy the boundary condition at $\eta=-1$ by writing

$$g(\eta)=F_1\hat{q}_1^{-1/2}(\eta)\sin\left(\int_{-1}^{\eta}\hat{q}_1(\eta)\,\mathrm{d}\eta\right),\quad -1\leqslant\eta\leqslant\eta_1. \tag{3.5}$$

Writing

$$g(\eta)=F_2\hat{q}_2^{-1/2}(\eta)\sin\left(\int_{\eta_1}^{\eta}\hat{q}_2(\eta)\,\mathrm{d}\eta\right)+G_2\hat{q}_2^{-1/2}(\eta)\cos\left(\int_{\eta_1}^{\eta}\hat{q}_2(\eta)\,\mathrm{d}\eta\right),\quad \eta_1\leqslant\eta\leqslant+1, \tag{3.6}$$

and matching the two expressions (3.5) and (3.6) for $g(\eta)$ at $\eta=\eta_1$, we obtain from (A5a) and (A5b) with $N=2$, $n=1$, and $G_1=0$,

$$\frac{F_2}{F_1}=\hat{q}_1^{-1/2}(\eta_1)\hat{q}_2^{-1/2}(\eta_1)\left(\frac{\hat{q}_2'(\eta_1)}{2\hat{q}_2(\eta_1)}-\frac{\hat{q}_1'(\eta_1)}{2\hat{q}_1(\eta_1)}\right)\sin\left(\int_{-1}^{\eta_1}\hat{q}_1(\eta)\,\mathrm{d}\eta\right)+\frac{\hat{q}_1^{1/2}(\eta_1)}{\hat{q}_2^{1/2}(\eta_1)}\cos\left(\int_{-1}^{\eta_1}\hat{q}_1(\eta)\,\mathrm{d}\eta\right), \tag{3.7a}$$

$$\frac{G_2}{F_1}=\frac{\hat{q}_2^{1/2}(\eta_1)}{\hat{q}_1^{1/2}(\eta_1)}\sin\left(\int_{-1}^{\eta_1}\hat{q}_1(\eta)\,\mathrm{d}\eta\right). \tag{3.7b}$$

According to (3.6) the boundary condition at $\eta=+1$ gives

$$F_2\sin\left(\int_{\eta_1}^{+1}\hat{q}_2(\eta)\,\mathrm{d}\eta\right)+G_2\cos\left(\int_{\eta_1}^{+1}\hat{q}_2(\eta)\,\mathrm{d}\eta\right)=0. \tag{3.8}$$

Inserting (3.7a) and (3.7b) into (3.8), we obtain

$$\frac{\hat{q}_2'(\eta_1)/\hat{q}_2(\eta_1)-\hat{q}_1'(\eta_1)/\hat{q}_1(\eta_1)}{2\hat{q}_1(\eta_1)\hat{q}_2(\eta_1)}\tan\left(\int_{-1}^{\eta_1}\hat{q}_1(\eta)\,\mathrm{d}\eta\right)\tan\left(\int_{\eta_1}^{+1}\hat{q}_2(\eta)\,\mathrm{d}\eta\right)+\frac{1}{\hat{q}_1(\eta_1)}\tan\left(\int_{-1}^{\eta_1}\hat{q}_1(\eta)\,\mathrm{d}\eta\right)+\frac{1}{\hat{q}_2(\eta_1)}\tan\left(\int_{\eta_1}^{+1}\hat{q}_2(\eta)\,\mathrm{d}\eta\right)=0. \tag{3.9}$$

When $m=0$ one encounters the same difficulty with (3.9) as with (3.3), and one masters this difficulty analogously as described below (3.3), i.e., by replacing in (3.9)

$$\int_{-1}^{\eta_1}\hat{q}_1(\eta)\mathrm{d}\eta$$

by

$$\arctan\frac{2(1+\eta')\hat{q}_1(\eta')}{1+\dfrac{1+\eta'}{\hat{q}_1(\eta')}\dfrac{\mathrm{d}\hat{q}_1(\eta')}{\mathrm{d}\eta'}}+\int_{\eta'}^{\eta_1}\hat{q}_1(\eta)\mathrm{d}\eta$$

and

$$\int_{\eta_1}^{+1}\hat{q}_2(\eta)\mathrm{d}\eta$$

by

$$\int_{\eta_1}^{\eta''}\hat{q}_2(\eta)\mathrm{d}\eta+\arctan\frac{2(1-\eta'')\hat{q}_2(\eta'')}{1-\dfrac{1-\eta''}{\hat{q}_2(\eta'')}\dfrac{\mathrm{d}\hat{q}_2(\eta'')}{\mathrm{d}\eta''}}.$$

After having modified (3.9) as described previously, one thus evaluates the expression on the left-hand side for various values of η' that decrease toward -1 and various values of η'' that increase toward $+1$, and one continues until the expression in question remains constant within the prescribed degree of numerical accuracy.

The case when the double-well potential is symmetric ($b=0$). When the double-well potential is symmetric, η_1 is chosen to be equal to zero and hence to lie at the symmetry point of the potential. To determine $\hat{q}_1(\eta)$ and $\hat{q}_2(\eta)$ we start the integrations of (3.4) by approximating $\hat{q}_1(\eta)$ and $\hat{q}_2(\eta)$ in the middle of the classically allowed regions by the symmetric (with respect to the origin) base function $Q(\eta)$, i.e., with such initial conditions that $\hat{q}_1(\eta)$ and $\hat{q}_2(\eta)$ become mirror symmetric with respect to the origin. Then we have

$$\hat{q}_1(0)=\hat{q}_2(0)>0, \tag{3.10a}$$

$$\hat{q}_1'(0)=-\hat{q}_2'(0)<0, \tag{3.10b}$$

$$\hat{q}_1(-\eta)=\hat{q}_2(\eta), \tag{3.10c}$$

$$\int_{-1}^{0}\hat{q}_1(\eta)\mathrm{d}\eta=\int_{0}^{+1}\hat{q}_2(\eta)\mathrm{d}\eta>0. \tag{3.10d}$$

Using (3.10a), (3.10b), and (3.10d), we can write (3.7a), (3.7b), and (3.9) with $\eta_1=0$ as

$$\frac{F_2}{F_1}=\frac{\hat{q}_2'(0)}{\hat{q}_2^2(0)}\sin\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right)+\cos\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right), \tag{3.11a}$$

$$\frac{G_2}{F_1}=\sin\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right), \tag{3.11b}$$

and

$$\tan\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right)\left[\tan\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right)+\frac{2\hat{q}_2^2(0)}{\hat{q}_2'(0)}\right]=0. \tag{3.12}$$

From (3.12) we obtain the two quantization conditions

$$\int_0^{+1} \hat{q}_2(\eta)\mathrm{d}\eta=(\hat{s}+1)\pi, \tag{3.13a}$$

$$\int_0^{+1} \hat{q}_2(\eta)\mathrm{d}\eta=(\hat{s}+1)\pi-\arctan\frac{2\hat{q}_2^2(0)}{\hat{q}_2'(0)}, \tag{3.13b}$$

where $\hat{s}$ is an integer. When $m=0$ one encounters the same difficulty with (3.13a) and (3.13b) as with (3.9), and one masters this difficulty in a similar way as is described below (3.3).

In the following we shall show that (3.13a) and (3.13b) are the quantization conditions for the states with antisymmetric and symmetric wave functions $g(\eta)$, respectively.

The *antisymmetric* wave function $g(\eta)$ must be equal to zero for $\eta=0$, and therefore we obtain from (3.5) with $\eta_1=0$ and (3.10d) the quantization condition

$$\int_0^{+1} \hat{q}_2(\eta)\mathrm{d}\eta=(\hat{s}+1)\pi, \quad \hat{s}=0,1,2,\ldots, \tag{3.14}$$

which is in agreement with (3.13a). Recalling (3.5) with $\eta_1=0$ and (3.10c), we realize that for $0\leqslant\eta\leqslant+1$ the antisymmetric wave function is

$$\begin{aligned} g(\eta)&=F_1\hat{q}_2^{-1/2}(\eta)\sin\left(\int_{+1}^{\eta}\hat{q}_2(\eta)\mathrm{d}\eta\right)\\ &=F_1\hat{q}_2^{-1/2}(\eta)\sin\left(\int_0^{\eta}\hat{q}_2(\eta)\mathrm{d}\eta-\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right)\\ &=F_1\cos\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right)\hat{q}_2^{-1/2}(\eta)\sin\left(\int_0^{\eta}\hat{q}_2(\eta)\mathrm{d}\eta\right)\\ &\quad -F_1\sin\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right)\hat{q}_2^{-1/2}(\eta)\cos\left(\int_0^{\eta}\hat{q}_2(\eta)\mathrm{d}\eta\right), \quad 0\leqslant\eta\leqslant+1. \end{aligned} \tag{3.15}$$

Comparing (3.6) for $\eta_1=0$ with (3.15), we see that

$$F_2=F_1\cos\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right), \tag{3.16a}$$

$$G_2=-F_1\sin\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right). \tag{3.16b}$$

With the use of (3.14) one can obtain (3.16a) and (3.16b) from (3.11a) and (3.11b) Recalling (3.14), we obtain from (3.16a) and (3.16b)

$$F_2=(-1)^{\hat{s}+1}F_1, \tag{3.17a}$$

$$G_2=0. \tag{3.17b}$$

The *symmetric* wave function $g(\eta)$ fulfills the condition $g'(0)=0$ which, with the aid of (3.5) with $\eta_1=0$, (3.10a), (3.10b), and (3.10d), can be written as

$$\tan\left(\int_0^{+1}\hat{q}_2(\eta)\mathrm{d}\eta\right)=-\frac{2\hat{q}_2^2(0)}{\hat{q}_2'(0)}. \tag{3.18}$$

It is seen that this quantization condition is in agreement with (3.13b). Recalling (3.5) with $\eta_1 = 0$ and (3.10c), we realize that for $0 \leqslant \eta \leqslant +1$ the symmetric wave function is

$$\begin{aligned} g(\eta) &= -F_1 \hat{q}_2^{-1/2}(\eta) \sin\left(\int_{+1}^{\eta} \hat{q}_2(\eta) \mathrm{d}\eta \right) \\ &= -F_1 \hat{q}_2^{-1/2}(\eta) \sin\left(\int_0^{\eta} \hat{q}_2(\eta) \mathrm{d}\eta - \int_0^{+1} \hat{q}_2(\eta) \mathrm{d}\eta \right) \\ &= -F_1 \cos\left(\int_0^{+1} \hat{q}_2(\eta) \mathrm{d}\eta \right) \hat{q}_2^{-1/2}(\eta) \sin\left(\int_0^{\eta} \hat{q}_2(\eta) \mathrm{d}\eta \right) \\ &\quad + F_1 \sin\left(\int_0^{+1} \hat{q}_2(\eta) \mathrm{d}\eta \right) \hat{q}_2^{-1/2}(\eta) \cos\left(\int_0^{\eta} \hat{q}_2(\eta) \mathrm{d}\eta \right), \quad 0 \leqslant \eta \leqslant +1. \end{aligned} \tag{3.19}$$

Comparing (3.6) for $\eta_1 = 0$ with (3.19), we see that

$$F_2 = -F_1 \cos\left(\int_0^{+1} \hat{q}_2(\eta) \mathrm{d}\eta \right), \tag{3.20a}$$

$$G_2 = F_1 \sin\left(\int_0^{+1} \hat{q}_2(\eta) \mathrm{d}\eta \right). \tag{3.20b}$$

It is seen that (3.20b) agrees with (3.11b), and with the aid of (3.18) we can obtain (3.20a) from (3.11a).

IV. NUMERICAL RESULTS

Before presenting our numerical results, we shall give a brief description of the formulas that are to be used in calculations of the energy levels and the separation constants of the two-center Coulomb system.

When $-Q^2(\eta)$ has the character of a single-well potential, which is the case when r_{12} is sufficiently small, the functions $\hat{\tilde{q}}_1(\xi)$ and $\hat{q}_1(\eta)$ are obtained by means of the differential equations (2.1) and (3.1). For given values of the quantum numbers, the quantities p^2 and A', which according to (1.6a) and (1.10) are closely related to the energy E and the separation constant A, are obtained from the appropriate ones of the quantization conditions (2.3), (2.3′), (3.3), (3.3′), (3.3″), and (3.3‴).

When $-Q^2(\eta)$ has the character of a double-well potential, which is the case when r_{12} is sufficiently large, the functions $\hat{\tilde{q}}_1(\xi)$ and $\hat{q}_1(\eta)$, $\hat{q}_2(\eta)$ are obtained by means of the differential equations (2.1) and (3.4). For given values of the quantum numbers, the quantities p^2 and A', which according to (1.6a) and (1.10) are closely related to the energy E and the separation constant A, are obtained from the appropriate ones of the quantization conditions (2.3), (2.3′), (3.9), (3.13a), and (3.13b), of which (3.9), (3.13a), and (3.13b) are to be modified when $m = 0$ as described below (3.9).

We have calculated the energy eigenvalues and the separation constants for some states of the hydrogen molecule ion with different values of the internuclear distance. We shall explain how we have performed these calculations by describing briefly our calculations for the state $1s\sigma$ with the internuclear distance equal to 10 a.u. To start the integration of the q-equations one must in some way or another have obtained fairly accurate approximate initial values of p^2 and A'. We used the initial values $p^2 = 30$ and $A' = -10$, which we obtained by approximating the numerically exact values obtained by Murai and Takatsu[13] and quoted later in this section. Using the approximate initial values $p^2 = 30$ and $A' = -10$, we thus started the numerical integration of the q-equations by approximating $\hat{\tilde{q}}(\xi)$ and $\hat{q}_1(\eta)$, $\hat{q}_2(\eta)$ by the base functions $\tilde{Q}(\xi)$ and $Q(\eta)$, respectively, in

TABLE I. The numerically exact values quoted have been obtained by Murai and Takatsu (Ref. 13). The number of digits in our results is chosen such that the error is at most five units in the last decimal.

the middle of the classically allowed regions for the ξ- and η-equations. A computer iteration program yielded the values $p^2=30.028\,936\,2$ and $A'=-9.895\,643\,5$, but could not produce more accurate values. With these values of p^2 and A' as initial values we used the computer iteration program again and obtained the values $p^2=30.028\,936\,3$ and $A'=-9.895\,643\,7$. When we again used the program with these values of p^2 and A' as initial values, the program was not able to improve the accuracy, and this was the case also for the other states for which we performed calculations. The numerically exact values for the state $1s\sigma$ with $r_{12}=10$ are $p^2=30.028\,936\,446\,8$ and $A'=-9.895\,643\,268\,8$. Our results for some states and different internuclear distances r_{12} of the hydrogen molecule ion, obtained as described previously, are presented in Table I together with numerically exact results obtained by Murai and Takatsu.[13]

APPENDIX: EXTENSION OF THE PHASE-AMPLITUDE METHOD FOR ACCURATE NUMERICAL SOLUTION OF THE ONE-DIMENSIONAL SCHRÖDINGER EQUATION

The phase-amplitude method developed by Milne,[18] Wilson,[19] Young,[20,21] and Wheeler[22] is an efficient method for numerically exact solution of the one-dimensional Schrödinger equation that describes the motion of a quantal particle in a single-well potential. It has been extended by P. O. Fröman, Larsson, and Hökback[15] to apply to the Schrödinger equation describing a quantal particle confined in a potential with N wells separated by $N-1$ superdense barriers. This extension is, like the original phase-amplitude method, in principle numerically exact but may meet with numerical difficulties that limit the accuracy obtainable. It will be described briefly in this appendix.

Consider the differential equation

$$\frac{\mathrm{d}^2\psi}{\mathrm{dz}^2}+R(z)\psi=0, \tag{A1}$$

where, for real z-values, $R(z)$ is positive in N regions that are separated by $N-1$ regions in which $R(z)$ is negative. The boundary conditions are imposed at the points z_0 and $z_N(>z_0)$ which lie in regions where $R(z)$ is negative and are separated by N regions where $R(z)$ is positive and $N-1$ regions where $R(z)$ is negative. We introduce in the $N-1$ regions where $R(z)$ is negative further points $z_1,\ldots,z_{N-1}$ such that $z_0<z_1<\cdots<z_{N-1}<z_N$.

To solve the differential equation (A1) numerically we put

$$\psi = F_n \hat{q}_n^{-1/2}(z)\sin\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)\,dz\right) + G_n \hat{q}_n^{-1/2}(z)\cos\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)\,dz\right),$$
$$z_{n-1} \leqslant z \leqslant z_n, \quad n = 1,...,N, \tag{A2}$$

where F_n and G_n are constants, and $\hat{q}_n(z)$ is to be determined numerically as a nonoscillating solution of the q-equation

$$\frac{d^2}{dz^2}\hat{q}_n^{-1/2} + R(z)\hat{q}_n^{-1/2} = \hat{q}_n^{+3/2}, \tag{A3}$$

which one obtains by inserting (A2) into (A1) and requiring that the resulting equation be satisfied for arbitrary constant values of F_n and G_n. In passing we remark that the q-equation appears not only in the phase-amplitude method[15,18–22] but also in connection with the Ermakov–Lewis invariant,[23,24] which is discussed in Chap. 1 of Ref. 16; see also Ref. 25. This invariant is, however, not needed in the present paper. To determine the functions $\hat{q}_n(z)$ one starts the integration of the differential equation (A3) in the middle of the actual potential well by using for $\hat{q}_n(z)$ a phase-integral expression of convenient order. The boundary condition imposed at z_0 determines the ratio G_1/F_1. If $N=1$ the boundary condition imposed at z_1 gives rise to a quantization condition. If $N>1$ the continuity of $\psi(z)$ and $\psi'(z)$ at $z=z_n$, where $1\leqslant n\leqslant N-1$, implies the conditions

$$F_n\left[\hat{q}_n^{-1/2}(z)\sin\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)\,dz\right)\right]_{z=z_n} + G_n\left[\hat{q}_n^{-1/2}(z)\cos\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)\,dz\right)\right]_{z=z_n}$$
$$= F_{n+1}\left[\hat{q}_{n+1}^{-1/2}(z)\sin\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)\,dz\right)\right]_{z=z_n} + G_{n+1}\left[\hat{q}_{n+1}^{-1/2}(z)\cos\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)\,dz\right)\right]_{z=z_n} \tag{A4a}$$

and

$$F_n\left\{\frac{d}{dz}\left[\hat{q}_n^{-1/2}(z)\sin\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)\,dz\right)\right]\right\}_{z=z_n} + G_n\left\{\frac{d}{dz}\left[\hat{q}_n^{-1/2}(z)\cos\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)\,dz\right)\right]\right\}_{z=z_n}$$
$$= F_{n+1}\left\{\frac{d}{dz}\left[\hat{q}_{n+1}^{-1/2}(z)\sin\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)\,dz\right)\right]\right\}_{z=z_n}$$
$$+ G_{n+1}\left\{\frac{d}{dz}\left[\hat{q}_{n+1}^{-1/2}(z)\cos\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)\,dz\right)\right]\right\}_{z=z_n}, \tag{A4b}$$

from which we obtain

$$F_{n+1} = \frac{\hat{q}'_{n+1}(z_n)/\hat{q}_{n+1}(z_n) - \hat{q}'_n(z_n)/\hat{q}_n(z_n)}{2\hat{q}_{n+1}^{1/2}(z_n)\hat{q}_n^{1/2}(z_n)}\left[F_n\sin\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)\,dz\right) + G_n\cos\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)\,dz\right)\right]$$
$$+ \frac{\hat{q}_n^{1/2}(z_n)}{\hat{q}_{n+1}^{1/2}(z_n)}\left[F_n\cos\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)\,dz\right) - G_n\sin\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)\,dz\right)\right], \quad n = 1,...,\ N-1, \tag{A5a}$$

and

$$G_{n+1}=\frac{\hat{q}_{n+1}^{1/2}(z_n)}{\hat{q}_n^{1/2}(z_n)}\left[F_n\sin\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)\mathrm{d}z\right)+G_n\cos\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)\mathrm{d}z\right)\right],\quad n=1,...,\ N-1. \tag{A5b}$$

Formula (A5a) is a corrected version of Eq. (B6a) in Ref. 15. The numerator of the factor in front of the first bracket on the right-hand side of Eq. (B6a) in Ref. 15 is in fact to be replaced by $\hat{q}'_{n+1}(z_n)/\hat{q}_{n+1}(z_n)-\hat{q}'_n(z_n)/\hat{q}_n(z_n)$. The error appeared in a rather late version of the manuscript of Ref. 15. All calculations of the results presented there had then been performed with the use of the correct formula. Starting from the value of G_1/F_1 one can with the aid of (A5a) and (A5b) succesively obtain the values of G_n/F_n up to $n=N$. With the use of the last one of these values and the boundary condition imposed at z_N one obtains a quantization condition.

(Received 1 January 2002; accepted for publication 22 January 2002)

We introduce a new, more general type of nonlinear gauge transformation in nonrelativistic quantum mechanics that involves derivatives of the wave function and belongs to the class of Bäcklund transformations. These transformations satisfy certain reasonable, previously proposed requirements for gauge transformations. Their application to the Schrödinger equation results in higher order partial differential equations. As an example, we derive a general family of sixth-order nonlinear Schrödinger equations, closed under our nonlinear gauge group. We also introduce a new gauge invariant current $\sigma=\rho\nabla\Delta\ln\rho$, where $\rho=\bar{\psi}\psi$. We derive gauge invariant quantities, and characterize the subclass of the sixth-order equations that is gauge equivalent to the free Schrödinger equation. We relate our development to nonlinear equations studied by Doebner and Goldin, and by Puszkarz. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1465514]

I. INTRODUCTION

The notion of nonlinear gauge transformation, introduced in quantum mechanics by Doebner and Goldin, extends the usual group of unitary gauge transformations.[1–3] The resulting nonlinear transformations act on a parametrized family of nonlinear Schrödinger equations (NLSEs) that includes the linear Schrödinger equation as a special case. They are called gauge transformations because they leave invariant the outcomes of all physical measurements. In this paper we extend the notion of gauge transformation further to include transformations that depend explicitly on derivatives of the wave function. The result is a group of transformations of Bäcklund type.[4]

As described in earlier work,[3] a (nonlinear) gauge transformation is implemented by a transformation $\psi'=\mathcal{N}[\psi]$, assumed to satisfy the following conditions.

(1) The *principle of gauge-independence of positional measurements:* Invariance is required of all quantities describing outcomes of positional measurements, including *sequences* of measurements performed successively at different times. In particular, $\rho(\mathbf{x},t)=|\psi(\mathbf{x},t)|^2$ should be invariant under $\mathcal{N}$ for the single-particle wave function ψ.

(2) *Strict locality:* If ψ is a single-particle function, the value of ψ' at $(\mathbf{x},t)$ is assumed to depend only on the value of $\mathbf{x}$, the value of t, and the value of ψ at $(\mathbf{x},t)$.

(3) A *separation condition:* If $\psi^{(N)}$ is a wave function describing a set of N noninteracting particles (i.e., a product state), then $\psi^{(N)'}$ is well defined as the product of gauge transformed single-particle wave functions. This condition ensures that gauge transformations extend to the whole N-particle hierarchy of wave functions in a way that subsystems that are uncorrelated remain so in the gauge-transformed theory.

Here we modify the condition of strict locality, allowing $\psi'(\mathbf{x},t)$ to depend not only on the

a)Electronic mail: gagoldin@dimacs.rutgers.edu
b)Electronic mail: shtelen@math.rutgers.edu

values of $\psi(\mathbf{x},t)$, $\mathbf{x}$, and t, but also on finitely many spatial derivatives of ψ evaluated at $(\mathbf{x},t)$. Thus our transformations are local, in that $\psi'(\mathbf{x},t)$ does not depend on space-time points any distance from $(\mathbf{x},t)$, but they are no longer "strictly" local, since derivative terms are allowed. We shall call this property *weak locality*. One motivation for introducing this generalization is to explore the relation between the resulting nonlinear gauge generalization of the Schrödinger equation and the equations proposed by Puszkarz.[5]

The condition that our set of transformations forms a group (i.e., that it is closed under composition and includes all inverse transformations) while the number of derivatives of ψ remains bounded, imposes an additional restriction. This *group property* is automatically satisfied in the strictly local theory, but here it requires explicit discussion. Thus, we shall add it to the conditions already mentioned. We then call the transformations that obey the following four conditions *weakly local gauge transformations:* (1) the principle of gauge-independence of positional measurements; $(2')$ weak locality; (3) the separation condition; and (4) the group property.

In Sec. II of this paper, we first consider a general class of nonlinear, single-particle Schrödinger equations that are equivalent to the free Schrödinger equation under the assumption that condition (1) is satisfied. Using the other three conditions, we obtain a particularly simple form for weakly local gauge transformations. Following the method of "gauge generalization," [3] we then derive a general family of sixth-order nonlinear Schrödinger equations, closed under our nonlinear gauge group, which are not all equivalent to the free second-order Schrödinger equation. In Sec. III we construct a complete set of gauge invariant quantities. As particular cases, we use these to characterize the subclass of the sixth-order equations that are gauge equivalent to the Schrödinger equation, and those equivalent to the wider class of nonlinear equations studied by Doebner and Goldin. We further relate our development to the nonlinear equations proposed by Puszkarz based on additional quantum currents that involve higher derivatives of ψ.

II. GAUGE TRANSFORMATIONS AND NLSEs

Consider the transformation

$$\psi'(\mathbf{x},t)=e^{i\varphi}\psi(\mathbf{x},t), \tag{2.1}$$

where φ is a real-valued functional that depends on $\psi,\mathbf{x}$, and t. By this we mean that φ can depend explicitly on ψ, $\overline{\psi}$, derivatives of ψ and $\overline{\psi}$ of arbitrary order, integrals or integral transforms of ψ and $\overline{\psi}$, etc., as well as directly on $\mathbf{x}$ and t. Equation (2.1) preserves the probability density $\rho(\mathbf{x},t)=\overline{\psi}(\mathbf{x},t)\psi(\mathbf{x},t)$, as required by the first condition in Sec. I, but if nonlocal it does not generally respect sequences of positional measurements. The following then describes the general class of NLSEs that are equivalent via (2.1) to the free Schrödinger equation: if ψ' satisfies

$$i\frac{\partial\psi'}{\partial t}+\frac{\hbar}{2m}\Delta\psi'=i\frac{\partial\psi'}{\partial t}-\nu_1'\Delta\psi'=0, \tag{2.2}$$

then ψ satisfies the NLSE

$$i\frac{\partial\psi}{\partial t}-\nu_1'\Delta\psi+iI[\psi,\mathbf{x},t]\psi+R[\psi,\mathbf{x},t]\psi=0, \tag{2.3}$$

where

$$R[\psi,\mathbf{x},t]=\frac{\partial\varphi}{\partial t}-2\nu_1'\left(\frac{\nabla\varphi\cdot\hat{\mathbf{j}}}{\rho}+\frac{1}{2}(\nabla\varphi)^2\right) \tag{2.4}$$

and

$$I[\psi,\mathbf{x},t]=\nu_1'\left(\Delta\varphi+\frac{\nabla\varphi\cdot\nabla\rho}{\rho}\right)=\nu_1'\left[\frac{1}{\rho}\nabla\cdot(\rho\nabla\varphi)\right], \tag{2.5}$$

with

$$\hat{\mathbf{j}}=\frac{m}{\hbar}\mathbf{j}=\frac{1}{2i}[\bar{\psi}\nabla\psi-(\nabla\bar{\psi})\psi]. \tag{2.6}$$

The verification is by direct substitution of (2.1) into (2.2).

As was shown by Doebner and Goldin,[1] a general form for strictly local gauge transformations (that satisfy all the initial requirements discussed in Sec. I) corresponds to the choice

$$\varphi=\tfrac{1}{2}\gamma(t)\ln\rho+[\Lambda(t)-1]S+\theta(\mathbf{x},t),\quad \Lambda\neq 0, \tag{2.7}$$

where $\psi=\sqrt{\rho}\,e^{iS}$. For simplicity, we consider γ and Λ independent of t, and $\theta(\mathbf{x},t)\equiv 0$. The family of NLSEs with arbitrary coefficients that directly generalizes (2.3) and is invariant (as a family) under gauge transformations (2.1) with φ as in (2.7), then has the form[1]

$$i\frac{\partial\psi}{\partial t}=\left\{i\sum_{j=1}^{2}\nu_jR_j+\sum_{j=1}^{5}\mu_jR_j\right\}\psi, \tag{2.8}$$

where, the ν_j and μ_j are real, and

$$R_1=\frac{\nabla\cdot\hat{\mathbf{j}}}{\rho},\quad R_2=\frac{\Delta\rho}{\rho},\quad R_3=\frac{\hat{\mathbf{j}}^2}{\rho^2},\quad R_4=\frac{\hat{\mathbf{j}}\cdot\nabla\rho}{\rho^2},\quad R_5=\frac{(\nabla\rho)^2}{\rho^2}. \tag{2.9}$$

In obtaining (2.8), one uses the identity $\Delta\psi/\psi=iR_1+\frac{1}{2}R_2-R_3-\frac{1}{4}R_5$. Invariance of the family (2.8) under (2.1) and (2.7) means that if ψ satisfies an equation in this family with coefficients ν_j and μ_j, then ψ' satisfies another equation in the family with coefficients ν_j' and μ_j'; thus our choice of the primed coefficient ν_1' in writing Eq. (2.2).

Now the class of nonlinear gauge transformations in quantum mechanics can be essentially extended if we replace strict locality by weak locality, thus allowing the gauge functional φ to depend on derivatives of ψ. Under this assumption the gauge transformation is no longer simply a point transformation; it is a *Bäcklund transformation*.[4] Here we consider gauge transformations of Bäcklund type that form a group, satisfying the physically motivated requirements discussed in Sec. I, with strict locality replaced by weak locality.

We observe that if φ is permitted to depend on derivatives of S as well as derivatives of ρ, then the set of gauge transformations in general does not respect the group property. However, if the derivatives of S are excluded from φ, then the transformations do respect this property. One way to see this is to write nonlinear gauge transformations as they act on logarithmic coordinates T and S, with $\ln\psi=T+iS$ (so that $T=\frac{1}{2}\ln\rho$), omitting for simplicity the explicit $\mathbf{x}$ and t dependence:

$$\begin{pmatrix}S'\\T'\end{pmatrix}=\begin{pmatrix}L & G\\0 & 1\end{pmatrix}\begin{pmatrix}S\\T\end{pmatrix}, \tag{2.10}$$

where L is a linear or nonlinear functional of S and its derivatives, and G is a linear or nonlinear functional of T and its derivatives. In the strictly local case, we have $L[S]=\Lambda S$ and $G[T]=\gamma T$. If we perform two transformations (2.10) successively, $T''=T'=T$ and $S''=L_2[L_1[S]+G_1[T]\,]+G_2[T]$. Then derivatives present in the form of G never act successively, so that their order does not increase; but derivatives in the form of L do act successively. Thus the group property, with the condition that the number of derivatives of ψ remains bounded, rules out derivative terms in L—but not in G.

Now a simple gauge transformation that is no longer strictly local, but satisfies the four requirements discussed in Sec. I, has the form (2.1) with

$$\varphi=\tfrac{1}{2}\gamma\ln\rho+(\Lambda-1)S+\eta\Delta\ln\rho=\tfrac{1}{2}\gamma\ln\rho+(\Lambda-1)S+\eta(R_2-R_5), \tag{2.11}$$

where η is a real parameter that, like γ and Λ, can in principle depend on t. This corresponds to the choice $G[T]=\gamma T+\eta\Delta T$ in (2.10). Thus we have a group of nonlinear gauge transformations modeled on three (in general time-dependent) parameters, obeying the group law

$$\mathcal{N}_{(\gamma_2,\Lambda_2,\eta_2)}\circ\mathcal{N}_{(\gamma_1,\Lambda_1,\eta_1)}=\mathcal{N}_{(\gamma_2+\Lambda_2\gamma_1,\Lambda_2\Lambda_1,\eta_2+\Lambda_2\eta_1)}. \tag{2.12}$$

But we note further that $G[T]$ need not be linear in T. Indeed, while the linear term $\Delta\ln\rho=R_2-R_5$ satisfies the separation condition, its nonlinear parts R_2 and R_5 do so separately! Considering a two-particle product wave function $\psi^{(2)}(\mathbf{x}_1,\mathbf{x}_2,t)=\psi_1(\mathbf{x}_1,t)\psi_2(\mathbf{x}_2,t)$, and defining $\rho^{(2)}=\overline{\psi^{(2)}}\psi^{(2)}$, $\rho_1=\overline{\psi}_1\psi_1$, and $\rho_2=\overline{\psi}_2\psi_2$, we have

$$R_2^{(2)}[\psi^{(2)}]=\frac{\Delta^{(2)}\rho^{(2)}}{\rho^{(2)}}=\frac{\Delta^{(2)}(\rho_1\rho_2)}{\rho_1\rho_2}=\frac{\Delta_1\rho_1}{\rho_1}+\frac{\Delta_2\rho_2}{\rho_2}=R_2[\psi_1]+R_2[\psi_2],$$

where $\Delta^{(2)}=\Delta_1+\Delta_2$. Similarly for R_5:

$$R_5^{(2)}[\psi^{(2)}]=\frac{[\nabla^{(2)}\rho^{(2)}]^2}{(\rho^{(2)})^2}=\frac{[(\nabla_1,\nabla_2)\rho_1\rho_2]^2}{(\rho_1\rho_2)^2}=R_5[\psi_1]+R_5[\psi_2].$$

Thus a further generalization of (2.11) that gives weakly local nonlinear gauge transformations is to allow the derivative terms to enter with different coefficients:

$$\varphi=\tfrac{1}{2}\gamma\ln\rho+(\Lambda-1)S+\eta_1R_2+\eta_2R_5. \tag{2.13}$$

Let us next write the gauge generalized family of NLSEs derived from (2.11). Beginning with the standard, free Schrödinger equation in the form

$$i\frac{\partial\psi'}{\partial t}=-\frac{\hbar}{2m}\left[iR_1'+\left(\frac{1}{2}R_2'-R_3'-\frac{1}{4}R_5'\right)\right]\psi', \tag{2.14}$$

where R_j' means $R_j[\psi']$, we transform by (2.1) with φ as in (2.11), and from (2.3) to (2.5) we find the form of the resulting NLSEs for ψ. We generalize, following Ref. 3, by allowing arbitrary coefficients for the nonlinear functionals, maintaining the invariance of the family of NLSEs under the nonlinear gauge group. In this fashion, we obtain

$$i\frac{\partial\psi}{\partial t}=\left\{i\sum_{j=1,2,6}\nu_jR_j+\sum_{j=1}^{12}\mu_jR_j\right\}\psi=\{i\hat{I}+\hat{R}\}\psi, \tag{2.15}$$

where $R_1,\ldots,R_5$ are as in (2.9), and where the new functionals $R_6,\ldots,R_{12}$ are given by

$$R_6=\frac{\nabla\cdot\sigma}{\rho},\quad R_7=\frac{\hat{\mathbf{j}}\cdot\sigma}{\rho^2},\quad R_8=\frac{\sigma\cdot\nabla\rho}{\rho^2}, \tag{2.16}$$

$$R_9=\frac{\sigma^2}{\rho^2},\quad R_{10}=\Delta R_1,\quad R_{11}=\Delta R_2,\quad R_{12}=\Delta R_6,$$

with

$$\sigma=\rho\nabla\Delta\ln\rho=\rho\nabla(R_2-R_5). \tag{2.17}$$

Note that the functionals $R_6,\ldots,R_{11}$ involve no higher than fourth derivatives of ψ, but the presence of the term R_{12} in (2.15) makes it in general of sixth order. If we use (2.13) in place of (2.11), we shall need separately the new currents $\rho\nabla R_2$ and $\rho\nabla R_5$. These give rise to additional nonlinear functionals in ψ.

Equation (2.15) still conserves the quantum probability $\bar{\psi}\psi$. It gives rise to the gauge invariant current

$$\mathbf{J}^{\mathrm{gi}}=-2(\nu_1\hat{\mathbf{J}}+\nu_2\nabla\rho+\nu_6\sigma) \tag{2.18}$$

that enters the continuity equation

$$\frac{\partial\rho}{\partial t}=-\nabla\cdot\mathbf{J}^{\mathrm{gi}}=2\hat{I}\rho. \tag{2.19}$$

III. GAUGE TRANSFORMATIONS AND INVARIANTS FOR THE FAMILY OF SIXTH-ORDER NLSEs

Under the gauge transformations (2.1), with φ given by (2.11), the coefficients ν_j, μ_j of (2.15) transform as follows:

$$\nu_1'=\frac{\nu_1}{\Lambda},\quad \nu_2'=\nu_2-\frac{1}{2}\gamma\frac{\nu_1}{\Lambda},\quad \nu_6'=\nu_6-\frac{\eta\nu_1}{\Lambda}, \tag{3.1}$$

$$\mu_1'=\mu_1-\frac{\gamma\nu_1}{\Lambda},\quad \mu_2'=\Lambda\mu_2-\frac{1}{2}\gamma\mu_1+\frac{\gamma^2}{2\Lambda}\nu_1-\gamma\nu_2,\quad \mu_3'=\frac{\mu_3}{\Lambda},$$

$$\mu_4'=\mu_4-\frac{\gamma\mu_3}{\Lambda},\quad \mu_5'=\Lambda\mu_5-\frac{1}{2}\gamma\mu_4+\frac{\gamma^2}{4\Lambda}\mu_3,$$

$$\mu_6'=\Lambda\mu_6-\gamma\nu_6-\eta\mu_1+\frac{\eta\gamma}{\Lambda}\nu_1,\quad \mu_7'=\mu_7-\frac{2\eta\mu_3}{\Lambda}, \tag{3.2}$$

$$\mu_8'=\Lambda\mu_8-\eta\mu_4-\frac{1}{2}\gamma\mu_7+\frac{\gamma\eta\mu_3}{\Lambda},\quad \mu_9'=\Lambda\mu_9-\eta\mu_7+\frac{\eta^2\mu_3}{\Lambda},\quad \mu_{10}'=\mu_{10}-\frac{2\eta\nu_1}{\Lambda},$$

$$\mu_{11}'=\Lambda\mu_{11}-2\eta\nu_2-\frac{1}{2}\gamma\mu_{10}+\frac{\gamma\eta\nu_1}{\Lambda},\quad \mu_{12}'=\Lambda\mu_{12}-2\eta\nu_6-\eta\mu_{10}+\frac{2\eta^2\nu_1}{\Lambda}.$$

Note that as expected, η does not enter the transformation laws for ν_1, ν_2, or $\mu_1,\ldots,\mu_5$, which are the same as in Refs. 1–3. Note also that if we begin with $\mu_{12}=0$, then $\eta\neq0$ leads to $\mu_{12}'\neq0$; thus we cannot have an invariant family of fourth-order partial differential equations for these transformations.

We now write functionally independent gauge invariants $\tau_j(j=1,2,\ldots,12)$ as follows:

$$\tau_1=\nu_2-\frac{\mu_1}{2},\quad \tau_2=\nu_1\mu_2-\mu_1\nu_2,\quad \tau_3=\frac{\mu_3}{\nu_1},\quad \tau_4=\mu_4-\mu_1\frac{\mu_3}{\nu_1},\quad \hat{\tau}_5=\mu_5\mu_3-(1/4)\mu_4^2,$$

$$\tau_6=\mu_6\nu_1-\mu_1\nu_6,\quad \tau_7=\mu_7-2\nu_6\frac{\mu_3}{\nu_1},\quad \tau_8=\mu_8\nu_1-\mu_4\nu_6+\mu_6\mu_3-(1/2)\mu_7\mu_1, \tag{3.3}$$

$$\tau_9=\mu_9\mu_3-(1/4)\mu_7^2,\quad \tau_{10}=\mu_{10}-2\nu_6,\quad \tau_{11}=\mu_{11}\nu_1-\mu_{10}\nu_2,\quad \tau_{12}=\mu_{12}\nu_1-\nu_6^2-(1/4)\mu_{10}^2.$$

In this list of gauge invariants, we have included a new quantity $\hat{\tau}_5$ instead of the original $\tau_5=\nu_1\mu_5-\nu_2\mu_4+\nu_2^2(\mu_3/\nu_1)$ that was used in Refs. 1–3, since the expression for $\hat{\tau}_5$ is simpler. The relation between these two gauge invariants is, of course, wholly gauge invariant: $\hat{\tau}_5=\tau_3\tau_5+\tau_1\tau_3(\tau_4-\tau_1\tau_3)-(1/4)\tau_4^2=\tau_3\tau_5-(\tau_1\tau_3-\frac{1}{2}\tau_4)^2$.

It should be noted that (2.15) is invariant under Galilean transformations

$$\tilde{\mathbf{x}}=\mathbf{x}-\mathbf{v}t,\quad \tilde{t}=t,\quad \tilde{\psi}(\tilde{\mathbf{x}},\tilde{t})=\psi(\mathbf{x},t)\exp\left(\frac{i}{2\nu_1}\left(\mathbf{x}\cdot\mathbf{v}+\frac{1}{2}v^2t\right)\right) \tag{3.4}$$

when

$$\frac{\mu_3}{\nu_1}=-1,\quad \mu_1+\mu_4=0,\quad \mu_7+\mu_{10}=0, \tag{3.5}$$

and consequently, the gauge invariants $\tau_1,\ldots,\tau_{12}$ must satisfy the conditions

$$\tau_3=-1,\quad \tau_4=0,\quad \tau_7+\tau_{10}=0. \tag{3.6}$$

Under time reversal, all the coefficients ν_j, μ_j change sign. Thus time reversal invariance requires

$$\tau_1=0,\quad \tau_4=0,\quad \tau_7=0,\quad \tau_{10}=0. \tag{3.7}$$

In particular, when (2.15) is the Schrödinger equation, we have

$$\nu_1=-\frac{\hbar}{2m},\quad \mu_2=-\frac{\hbar}{4m},\quad \mu_3=\frac{\hbar}{2m},\quad \mu_5=\frac{\hbar}{8m}, \tag{3.8}$$

and all other coefficients are zero. Equations (3.7) then give

$$\tau_2=\frac{\hbar^2}{8m^2},\quad \tau_3=-1,\quad \tau_5=\frac{\hbar^2}{16m^2}, \tag{3.9}$$

with all other τ's equal to zero. For the equations studied by Doebner and Goldin, $\tau_1,\ldots,\tau_5$ are arbitrary, but $\tau_6,\ldots,\tau_{12}$ are zero.

Some of the equations discussed by Puszkarz,[5] belong to the class (2.15), when $\mu_{12}=0$. Puszkarz's modification of the Schrödinger equation is the formal extension of the equations of Doebner and Goldin obtained by modifying the current (2.6), adding to it any or all of the following terms with higher derivatives:

$$\rho\Delta\left(\frac{\mathbf{j}}{\rho}\right),\quad \rho\nabla\left(\frac{\mathbf{j}\cdot\nabla\rho}{\rho^2}\right),\quad \rho\nabla\left(\frac{\mathbf{j}^2}{\rho^2}\right),\quad \rho\nabla R_2,\quad \rho\nabla R_5.$$

Since Puszkarz's modification directly affects only the imaginary part of the nonlinear functional for $i(\partial\psi/\partial t)/\psi$, namely $(-1/2\rho)\nabla\cdot\mathbf{J}$ where $\mathbf{J}$ is the current that appears in the equation of continuity, and does not change the real part, the resulting equation is fouth-order. Our equations are in general sixth-order because of the term with R_{12}, which is needed in order to maintain invariance under the nonlinear gauge group. The equations of Puszkarz with the first three currents do not belong to any family that is closed under a group of weakly local nonlinear gauge transformations, since the transformations giving rise to those currents involve derivatives of the phase S. His equations with the latter two currents belong to the family obtained from (2.15) through gauge generalization.

In short, we have obtained a natural family of sixth-order partial differential equations invariant (as a family) under nonlinear gauge transformations of Bäcklund type, that includes a subclass gauge equivalent to the linear Schrödinger equation, a wider subclass gauge equivalent to the equations that Doebner and Goldin studied, and another subclass that intersects the family of

equations proposed by Puszkarz. Given a particular equation in our family, we can calculate the 12 gauge-invariant parameters, and from these immediately determine whether the equation is physically equivalent to the free Schrödinger equation or an equation of Doebner–Goldin type, and whether it is Galilean and/or time-reversal invariant.

We investigate relations between Uhlmann's parallelism, monotone Riemannian metrics and dual affine connections on the space of density matrices. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467966]

I. INTRODUCTION

On the space of density operators, several differential geometrical structures were defined. In finite dimensional case, the class of monotone Riemannian metrics was specified by Petz in Ref. 1, using the set of real symmetric operator monotone functions. These metrics are the quantum generalizations of the classical Fisher metric, which is, together with the class of dual α-connections, the basic structure of the classical information geometry.

The quantum counterpart of the classical exponential and mixture connections was defined by Nagaoka in Ref. 2 and this definition was generalized to α-connections for $\alpha \in [-3,3]$ in Ref. 3.

In Ref. 4, the geometric phase of curves of pure states was extended to mixed states, using purifying lifts of curves of density matrices. Among such lifts, the one with the least Hilbert space length is used to define the phase. As it turns out, this defines a connection form a^{geo} in the space $\mathcal{W}$ of Hilbert–Schmidt operators, which is the $U(n)$–principal bundle over the space of non-normalized density operators $\mathcal{M}$, here n is the dimension of the underlying Hilbert space $\mathcal{H}$. Later, in Ref. 5 a class of such connection forms was introduced, containing the above form a^{geo}.

It is natural to ask what the relations between the above structures are. In Ref. 6 it was shown that the connection forms are naturally linked with some Riemannian or Hermitian metrics on the purifying space $\mathcal{W}$. Such metrics can be projected onto $\mathcal{M}$ and all the monotone metrics are obtained in this way. Further, in Ref. 7, a parallel transport, respecting the connection form a^{geo} was defined on $\mathcal{W}$, such that, if projected onto $\mathcal{M}$, it coincides with Nagaoka's (e)-connection. The aim of the present paper is to obtain all the affine α-connections and their duals in a similar way. For the sake of simplicity, we will assume that the underlying Hilbert space is finite dimensional and the density operators are invertible.

Section II below gives a brief description of purification and some formulas to be used later. In Sec. III, we define the class of connection forms and Riemannian metrics on $\mathcal{W}$ and relate them to the class of monotone metrics on $\mathcal{M}$ as in Ref. 6. In Secs. IV and V, we use the duality of two real subspaces in the tangent space to $\mathcal{W}$ to define two dual parallel transports, induced from the trivial affine connection on $\mathcal{B}=\mathcal{B}(\mathcal{H})$. We show that the projections of such parallel transports onto $\mathcal{M}$ coincide with the α-connection and its dual. Finally, we define a natural notion of duality of Riemannian metrics on $\mathcal{M}$.

II. THE PURIFICATION PROCEDURE

Let $\mathcal{H}$ be Hilbert space (not necessarily of finite dimension) and let $\mathcal{B}=\mathcal{B}(\mathcal{H})$ be the algebra of bounded operators acting on $\mathcal{H}$. Let $\mathcal{K}$ be another Hilbert space, with $\dim(\mathcal{H}) \leqslant \dim(\mathcal{K})$ and let

$$\mathcal{A}=\mathcal{B}(\mathcal{H}\otimes\mathcal{K}).$$

a)Electronic mail: jenca@mat.savba.sk

Let us consider the *-representation $\phi:\mathcal{B}\to\mathcal{A}$, given by $b\mapsto b\otimes 1_{\mathcal{K}}$. Let ρ be a positive linear functional on $\mathcal{B}$. The vector $\xi\in\mathcal{H}\otimes\mathcal{K}$ is said to be a purification of ρ if for each $b\in\mathcal{B}$

$$\rho(b)=\mathrm{Tr}\rho b=\langle\xi,\phi(b)\xi\rangle=\mathrm{Tr}b\otimes 1P_{\xi},$$

here the density operator was also denoted by ρ and P_{ξ} is the orthogonal projector onto the subspace spanned by ξ. It is clear that ξ is a purification of ρ if

$$\rho=\mathrm{Tr}_2P_{\xi},$$

where Tr_2 is the partial trace over $\mathcal{K}$.

In the sequel, we will use the choice $\mathcal{K}=\mathcal{H}^*$. The Hilbert space $\mathcal{H}\otimes\mathcal{H}^*$ can be identified with the space of Hilbert–Schmidt operators over $\mathcal{H}$, with the Hilbert–Schmidt inner product

$$\langle w_1,w_2\rangle=\mathrm{Tr}w_1^*w_2.$$

This identification is easily seen if we use Dirac's notations, then the product vectors are identified with

$$\varphi\otimes\psi^*\mapsto|\varphi\rangle\langle\psi|,$$

where $\psi^*(\varphi)=\langle\psi,\varphi\rangle$. The operation $w\mapsto w^*$ on $\mathcal{W}$ corresponds to the anti-unitary operator J on $\mathcal{H}\otimes\mathcal{H}^*$, given by

$$J(\varphi\otimes\psi^*)=\psi\otimes\varphi^*.$$

The representation ϕ is equivalent to $b\mapsto L_b$, where $L_b(w)=bw$ is the left multiplication operator on $\mathcal{W}$. Then $w\in\mathcal{W}$ is a purification of ρ if

$$\rho(b)=\mathrm{Tr}b\rho=\langle w,L_bw\rangle=\mathrm{Tr}w^*bw=\mathrm{Tr}b\,\pi(w),$$

for each $b\in\mathcal{B}$, where $\pi(w)=ww^*$.

In a similar way, we may represent the algebra $\mathcal{B}^*=\mathcal{B}(\mathcal{H}^*)$ in $\mathcal{A}$ by

$$\phi':b\mapsto 1\otimes b\mapsto R_{b^*}.$$

Here, $b\in\mathcal{B}^*$ is the linear operator given by $b\varphi^*=(b\varphi)^*$ and $R_b(w)=wb$ is the right multiplication operator on $\mathcal{W}$. Then $\phi'(\mathcal{B}^*)$ is the commutant of $\phi(\mathcal{B})$. If σ is a positive linear functional on $\mathcal{B}^*$, the vector ξ purifies σ if

$$\sigma=\mathrm{Tr}_1P_{\xi}=\mathrm{Tr}_2P_{J\xi},$$

where Tr_1 is the partial trace over $\mathcal{H}$. This is equivalent to

$$\sigma=\pi'(w),\quad \pi'(w)=w^*w$$

where w is the Hilbert–Schmidt operator corresponding to the vector ξ.

Let $w\in\mathcal{W}$ be invertible, $\pi(w)=\rho$, $\pi'(w)=\sigma$ and let $w=\rho^{1/2}u=u\sigma^{1/2}$ be the polar decomposition of w. Then

$$\rho=\sum_i\lambda_i|\varphi_i\rangle\langle\varphi_i|,\quad \sigma=\sum_i\lambda_i|\psi_i\rangle\langle\psi_i|,$$

$\lambda_i>0$ for all i are the spectral decompositions of ρ and σ and $w=\Sigma_i\lambda_i^{1/2}|\varphi_i\rangle\langle\psi_i|$, where $u\psi_i=\varphi_i$.

Following Ref. 6, we will use a certain class of operators from $\mathcal{B}(\mathcal{W})$ to introduce a Riemannian structure in $\mathcal{W}$. Let us denote $L=L_\rho$, $R=R_\rho$, $\tilde{L}=L_\sigma$ and $\tilde{R}=R_\sigma$ and let Δ be the modular operator $\Delta=L\tilde{R}^{-1}$. Then the spectral decomposition of Δ is

$$\Delta=\sum_i \frac{\lambda_i}{\lambda_j}(P_{\varphi_i}\otimes P_{\psi_j^*}),$$

so that if f is a smooth function and $x\in\mathcal{W}$, we have

$$f(\Delta)(x)=\sum_i f\left(\frac{\lambda_i}{\lambda_j}\right)|\varphi_i\rangle\langle\varphi_i|x\psi_j\rangle\langle\psi_j|.$$

Similar expressions are obtained for $f(LR^{-1})$, $f(\tilde{L}\tilde{R}^{-1})$, etc.

III. CONNECTION FORMS AND MONOTONE METRICS

Let $\dim(\mathcal{H})=n$. Let $\mathcal{W}_0\subset\mathcal{W}$ be the open subset of invertible operators, then it can be viewed as a real $2n^2$-dimensional differentiable manifold. Let T_w denote the tangent space at w, then T_w can be identified with $\mathcal{W}$ with the structure of a real linear space. Throughout the text, the capital letters X, Y, etc. denote the elements of T_w as differential operators, whereas small letters refer to their representations $x=X(w)$.

Let $\mathcal{M}\subset\mathcal{W}_0$ be the submanifold of (non-normalized) density matrices, i.e., the positive complex matrices. Then $\mathcal{W}_0$ can be realized as the principal bundle with base space $\mathcal{M}$ and structure group $U(n)$. The projection $\pi:\mathcal{W}_0\to\mathcal{M},\pi(w)=ww^*$ is the canonical projection. Let $T_\rho(\mathcal{M})$ be the tangent space of $\mathcal{M}$ at ρ. The canonical projection induces a linear map $T_w\to T_{\pi(w)}(\mathcal{M})$ (also denoted by π)

$$\pi(x)=xw^*+wx^*.$$

The vertical subspace $V_w\subset T_w$ is given by the condition

$$x\in V_w\Leftrightarrow\pi(x)=0.$$

It is easy to see that

$$V_w=\{wa:a+a^*=0\}.$$

We will describe the class of connections defined in Refs. 5 and 6. If a connection is defined in $\mathcal{W}_0$, the tangent space T_w is decomposed as the direct sum of V_w and a horizontal subspace H_w. For each vector $x\in T_w$ there is a unique decomposition $x=x^h+x^v$ into its horizontal and vertical part. We introduce a Riemannian structure in $\mathcal{W}_0$ as follows. Let $(\cdot,\cdot)$ denote the real part of the Hilbert–Schmidt inner product, i.e.,

$$(x,y)=\Re\langle x,y\rangle=\tfrac{1}{2}\mathrm{Tr}(x^*y+y^*x).$$

Let $k:\mathbb{R}^+\to\mathbb{R}^+$ be a smooth function such that $k(1)=1$ and let Δ be the modular operator. Let us define

$$(x,y)_w=(x,k(\Delta)^{-1}(y)),\quad x,y\in T_w.$$

The horizontal subspace H_w is defined as the orthogonal complement of V_w with respect to $(\cdot,\cdot)_w$. A tangent vector x is then horizontal iff it has the form

$$x=k(\Delta)(gw)=k(L/R)(g)w,\quad g=g^*.$$

The corresponding connection form is given by

$$\omega = r(\tilde{L}/\tilde{R})(w^{-1}dw) - r(\tilde{R}/\tilde{L})(w^{-1}dw)^* \tag{1}$$

$$= w^{-1}dw - (w^{-1}dw)^* + w^{-1}(F(L/R)d\rho)(w^{-1})^*, \tag{2}$$

where r is a smooth positive function with $r(t)+r(t^{-1})=1$ and $F(t)=r(t)-r(t^{-1})$. The functions r and k are connected by

$$r(t) = \frac{tk(t^{-1})}{k(t)+tk(t^{-1})}.$$

The above Riemannian structure can be projected onto the base space $\mathcal{M}$ via the projection π: Let $\pi(w)=\rho$ and let $h \in T_\rho(\mathcal{M})$. Then there exists a unique vector $\hat{h} \in T_w$ such that $\hat{h}$ is horizontal and $\pi(\hat{h})=h$, it is called the horizontal lift of h to w. We have

$$\hat{h} = \tfrac{1}{2}R^{-1}(1-F(L/R))(h)w = r(R/L)(h)(w^*)^{-1}.$$

Let us define

$$\langle h,k\rangle_\rho = 4(\hat{h},\hat{k})_w \quad h,k \in T_\rho(\mathcal{M}). \tag{3}$$

It is easy to see that the right-hand side depends only on $ww^*=\rho$, so that this defines a Riemannian structure on $\mathcal{M}$. We are particularly interested in Riemannian metrics that are monotone with respect to completely positive, trace preserving maps. It was proved by Petz in Ref. 1, that such metrics are of the form

$$\langle h,k\rangle_\rho = \mathrm{Tr} h J_\rho(k) \quad J_\rho = R^{-1}f(L/R)^{-1}, \tag{4}$$

where f is an operator monotone function which is symmetric, i.e., it satisfies $f(t)=tf(t^{-1})$. If we require that this metric coincides with the Fisher information metric on commutative submanifolds, we need an additional condition $f(1)=1$. The last requirement also gives rise to the multiplication factor 4 in (3).

If the induced Riemannian metric on $\mathcal{M}$ is of the form (4) for some smooth positive function f, then we have

$$k(t) = f(t)(1-F(t)), \quad f(t) = \tfrac{1}{2}(k(t)+tk(t^{-1})). \tag{5}$$

It is easy to see that given a monotone Riemannian metric, the connection that induces it is not unique. On the other hand, as the connection depends only from $k(t)/k(t^{-1})$, the induced Riemannian metric is again not unique. To get uniqueness, one more condition is needed. A natural requirement is that the inner product $(\cdot,\cdot)_w$ in T_w coincides with the real part of the Hilbert–Schmidt inner product, if restricted to horizontal vectors. It was proved in Ref. 6 that for each operator monotone function f there is a unique positive function k such that the above condition is satisfied. Let us put

$$p(t) = \frac{k(t)}{k(t^{-1})},$$

then $k(t)=\sqrt{p(t)}q(t)$, where the function $q(t)=q(t^{-1})$ is uniquely given by the condition $(x,k(\Delta)^{-1}y)=(x,y)$ for $x,y \in H_w$. Thus we have

Theorem 3.1: *For each monotone metric $\langle\cdot,\cdot\rangle_\rho$ on $\mathcal{M}$, there exists a unique smooth function $p:\mathbb{R}^+\to\mathbb{R}^+$ satisfying $p(t^{-1})=(p(t))^{-1}$, such that*

(i) *if*

$$r(t)=\frac{t}{p(t)+t},$$

then the corresponding connection form induces the given monotone metric;

(ii) *if*

$$k(t)=p(t)\frac{p(t)+t}{p(t)^2+t}, \tag{6}$$

then $p(t)=k(t)/k(t^{-1})$ *and the corresponding connection is the same as in* (i). *Moreover,* $(x,y)_w=(x,y)$ *for all horizontal vectors* x, y;

(iii) *the corresponding operator monotone function is of the form*

$$2f(t)=\frac{(p(t)+t)^2}{p(t)^2+t}.$$

In the sequel, we will always suppose that k and p are smooth functions related by Eq. (6).

Example 3.1: Let $p(t)=1$. Then $f(t)=(1+t)/2$ is the largest symmetric operator monotone function. It is related to the Bures metric, J_ρ is the symmetric logarithmic derivative (SLD). Here, $k(t)=1$ and $r(t)=t/(1+t)$. The horizontal subspace H_w consists of vectors of form $x=gw$, $g=g^*$. See Refs. 8 and 9.

Example 3.2: For the smallest symmetric operator monotone function $f(t)=2t/(1+t)$, we have $p(t)=t$, $k(t)=2t/(1+t)$ and $r(t)=\frac{1}{2}$. The vector $x\in H_w$ if and only if $x=2L/(L+R)(g)w$ for $g=g^*$. This is equivalent to $x=wh$ for some $h=h^*$. In this case, $J_\rho(h)=\frac{1}{2}(h\rho^{-1}+\rho^{-1}h)$ and the monotone metric is called the metric of the right logarithmic derivative (RLD). The connection form given by r is the canonical connection form on the bundle $GL(n)/U(n)$.[10]

Example 3.3: For $p(t)=\sqrt{t}$, we obtain the operator monotone function $f(t)=(1+\sqrt{t})^2/4$. The corresponding monotone metric is the smallest in a special class of monotone metrics, defined in Refs. 11 and 12. This class is important in the context of quantum information geometry, see Ref. 13. It contains also the monotone metric from the previous example. Here, $k(t)=(1+\sqrt{t})/2$ and $r(t)=\sqrt{t}/(1+\sqrt{t})$. The horizontal vectors for $w=\sqrt{ww^*}u$ are of the form $x=gu$, $g=g^*$.

IV. DUAL AFFINE CONNECTIONS

For the Riemannian manifold $\mathcal{M}$ with a monotone metric, Nagaoka in Ref. 2 defined the quantum version of the exponential and mixture connections of the classical information geometry. There, the mixture connection ((m)-connection) coincides with the trivial affine structure on $\mathcal{M}$ and the exponential (e)-connection is its dual with respect to the given Riemannian structure. The corresponding parallel transports of a vector $h\in T_{\rho_0}(\mathcal{M})$ along a curve $\rho\in\mathcal{M}$, with $\rho(0)=\rho_0$, $\rho(1)=\rho_1$, are given by

$$\Pi_\rho^{(m)}(h)=h,$$

$$J_{\rho_1}(\Pi_\rho^{(e)}(h))=J_{\rho_0}(h).$$

The aim of this section is to show that this structure on $\mathcal{M}$ appears naturally in the context of Sec. III.

Let us fix a monotone metric on $\mathcal{M}$ and let k be as in theorem 3.1. To define the two dual connections, it is convenient to use a different characterization of the horizontal subspace, given in Ref. 6. Let us consider the space

$$T_w=\{gw\ :\ g\in\mathcal{B}\}=\{wg\ :\ g\in\mathcal{B}\},$$

with the complex Hilbert space structure, $\langle x,y\rangle_w=\langle x,k(\Delta)^{-1}(y)\rangle$, ($\langle\cdot,\cdot\rangle$ is the Hilbert–Schmidt inner product.) Let S and F be the conjugate linear operators of the Tomita–Takesaki theory, given by $S(gw)=g^*w$, $F(wg)=wg^*$, $S=J\Delta^{1/2}=\Delta^{-1/2}J$ and $F=\Delta^{1/2}J=J\Delta^{-1/2}$, where J is the modular conjugation. Let S^k be the modification of S given by

$$S^k(k(\Delta)(gw))=k(\Delta)(g^*w).$$

Then H_w is the fix point set of S^k.

Lemma 4.1:

(i) $S^k=Sp(\Delta)^{-1}=p(\Delta)S$;
(ii) *The adjoint of* S^k *with respect to* $\langle\cdot,\cdot\rangle_w$ *is* F;
(iii) *The polar decomposition of* S^k *is* $S^k=J^k(\Delta^k)^{1/2}$, *where*

$$J^k=Jp(\Delta)^{-1/2}=p(\Delta)^{1/2}J \quad \Delta^k=p(\Delta)^{-1}\Delta,$$

(iv) *let* H_w^* *be the fix point set of the operator* F. *Then for* $x\in H_w$, $y\in H_w^*$ *we have* $\langle x,y\rangle_w\in\mathbb{R}$.

Proof: (i) Observe first, that $k(\Delta)(gw)=\sqrt{p(\Delta)}(q(L/R)(g)w)$ with $q(t)=q(t^{-1})$, so that $S^k=S^{\sqrt{p}}$. Obviously

$$S^{\sqrt{p}}=p(\Delta)^{1/2}Sp(\Delta)^{-1/2}=p(\Delta)S=Sp(\Delta)^{-1}.$$

The statements (ii) and (iii) are easy to prove. To prove (iv), let $x\in H_w$ and $y\in H_w^*$. Then

$$\begin{aligned}\langle x,y\rangle_w&=\langle S^k(x),y\rangle_w\\&=\langle F(y),x\rangle_w=\langle y,x\rangle_w=\langle x,y\rangle_w^-\in\mathbb{R}.\end{aligned}$$

□

Let us introduce a linear operator $\mathcal{J}:H_w\to H_w^*$, such that for $x\in\mathcal{H}_w$, $\pi(x)=\pi(\mathcal{J}(x))$. Then $\mathcal{J}$ is well defined and invertible. Indeed, note that the real vector subspace $H_w^*=\{wg,g=g^*\}$ coincides with the horizontal subspace H_w from Example 3.2, so that both $\pi|_{H_w}$ and $\pi|_{H_w^*}$ are isomorphisms.

Further, let $\mathcal{L}_w^k$, $\mathcal{K}_w$ be two linear maps $T_w\to\mathcal{B}$, given by

$$\mathcal{L}_w^k(x)w=k(\Delta)^{-1}(x),\quad \mathcal{K}_w(x)=xw^*.$$

The operators $\mathcal{L}_w^k$ and $\mathcal{K}_w$ are invertible and $\mathcal{L}_w^k(H_w)=\mathcal{B}_h$, $\mathcal{K}_w(H_w^*)=\mathcal{B}_h$, where $\mathcal{B}_h$ is the subset of hermitian operators in $\mathcal{B}$. For $x,y\in T_w$, we have

$$\langle x,y\rangle_w=\langle\mathcal{L}_w^k(x),\mathcal{K}_w(y)\rangle. \tag{7}$$

Let $h\in T_\rho(\mathcal{M})$. The horizontal lift of h to w satisfies

$$\mathcal{L}_w^k(\hat{h})=\tfrac{1}{2}J_\rho(h), \tag{8}$$

$$y=\mathcal{J}(\hat{h})\Leftrightarrow\mathcal{K}_w(y)=\tfrac{1}{2}h. \tag{9}$$

Proposition 4.1: Let us define the bilinear form $(\cdot,\cdot)_w^\sim$ *on* H_w *by*

$$(x,y)_w^\sim=\langle x,\mathcal{J}(y)\rangle_w,$$

then we have $(x,y)_w^\sim=(x,y)_w$. *Moreover, the operator* $\mathcal{J}$ *coincides with the restriction of*

$$\tfrac{1}{2}(1+\Delta^k)=\tfrac{1}{2}(1+p(\Delta)^{-1}\Delta),$$

to H_w.

Proof: Let $x,y \in H_w$ and let $\pi(x)=h,\ \pi(y)=k$. Then $\mathcal{K}_w(\mathcal{J}(y))=\frac{1}{2}k$ and $\mathcal{L}_w^k(x)=\frac{1}{2}J_\rho(h)$. It follows from (7) that

$$(x,y)_w^{\sim}=\langle x,\mathcal{J}(y)\rangle_w=\tfrac{1}{4}\langle J_\rho(h),k\rangle$$
$$=\tfrac{1}{4}\langle h,k\rangle_\rho=(x,y)_w.$$

Let now $x \in H_w$, then

$$F(1+\Delta^k)(x)=F(1+F)(x)=(1+\Delta^k)(x),$$

so that $\frac{1}{2}(1+\Delta^k)(x) \in H_w^*$. From

$$\langle x,\Delta^k(y)\rangle_w=\langle x,FS^k(y)\rangle_w=\langle S^k(y),S^k(x)\rangle_w=\langle y,x\rangle_w$$

we have that

$$\langle x,\tfrac{1}{2}(1+\Delta^k)(y)\rangle_w=(x,y)_w=(x,y)_w^{\sim}.$$

□

From the above Proposition, we see that we may extend $\mathcal{J}$ to a positive operator on T_w. The inner product $(\cdot,\cdot)_w^{\sim}$ on T_w, given by

$$(x,y)_w^{\sim}=\langle x,\mathcal{J}(y)\rangle_w,$$

corresponds to the complexification of the real Hilbert space H_w with the inner product $(\cdot,\cdot)_w$.

Example 4.1: Let $k=1$. Let $\rho(\theta),\ \theta \in \Theta \subseteq \mathbb{R}^N$ be a smooth parametrization of the manifold $\mathcal{M}$. Let us denote

$$h_i(\theta)=\frac{\partial}{\partial\theta_i}\rho(\theta).$$

For simplicity, we will omit the indication of the point θ in the sequel.

In Ref. 14, Holevo introduced the symmetric logarithmic derivative L_i^S by

$$h_i=\tfrac{1}{2}(L_i^S\rho+\rho L_i^S),$$

and the right and left logarithmic derivatives

$$h_i=\rho L_i^R,\quad L_i^L=(L_i^R)^*.$$

It is easy to see that in our setting, the horizontal subspace H_w is spanned by the vectors

$$l_i^S=L_i^S w=2\hat{h}_i,\quad i=1,\ldots,N$$

and

$$\mathcal{J}(l_i^S)=l_i^L=L_i^L w,$$

so that H_w^* is the real linear span of $\{l_i^L,\ i=1,\ldots,N\}$, note that this is true for all k. We also have

$$l_i^R=L_i^R w=\Delta^{-1}(l_i^L).$$

Further, Holevo defined the sesquilinear forms in $a,b \in \mathcal{B}$

$$\langle a,b\rangle_\rho=\tfrac{1}{2}\mathrm{Tr}\,(a^*\rho b+a^*b\rho)=(aw,bw)^{\sim},$$

$$\langle a,b\rangle_\rho^+ = \mathrm{Tr}\, a^*b\rho = \langle aw, bw\rangle,$$

$$[a,b]_\rho = i\mathrm{Tr}\,(\rho a^*b - \rho ba^*) = \langle aw, i(1-\Delta)(bw)\rangle.$$

Another important notion is the commutation operator $\mathcal{D}_\rho$, given by

$$\langle a, \mathcal{D}_\rho(b)\rangle_\rho = [a,b]_\rho.$$

It is easy to see that the operator $aw \mapsto \mathcal{D}_\rho(a)w$ is equal to

$$i\mathcal{J}^{-1}(1-\Delta) = 2i\frac{1-\Delta}{1+\Delta} = -2iF(\Delta).$$

Example 4.2: Let $k(t) = 2t/(1+t)$, then $p(t) = t$, so that $\Delta^k = 1$. The horizontal subspace H_w coincides with H_w^* and the operator $\mathcal{J}$ is the identity. Clearly, $\hat{h}_i = \frac{1}{2}l_i^L$, $i = 1,\ldots,N$. Let us denote by $\mathcal{J}^S$ the operator $\frac{1}{2}(1+\Delta)$ from the previous example, then $k(\Delta) = (\mathcal{J}^S)^{-1}\Delta$ and we get

$$(l_i^L, l_j^L)_w = \langle l_i^L, l_j^L\rangle_w = \langle l_i^L, \mathcal{J}^S(l_j^R)\rangle = (l_i^L, l_j^R)^\sim,$$

where $(x,y)^\sim = \langle x, \mathcal{J}^S(y)\rangle$.

We can also describe the horizontal and vertical part of a vector in T_w, using the operators F, S^k, and $\mathcal{J}$ as follows. Let P be the orthogonal projector from T_w onto H_w with respect to $(\cdot,\cdot)_w$, then

$$P = \tfrac{1}{2}\mathcal{J}^{-1}(1+F).$$

Indeed, for each $x \in T_w$, we have $\frac{1}{2}(1+F)(x) \in H_w^*$ and $\pi(\frac{1}{2}(1+F)(x)) = \pi(x) = \pi(x^h)$. It follows that:

$$\tfrac{1}{2}\mathcal{J}^{-1}(1+F)(x) = x^h = Px.$$

From this, we have

$$x^v = x - x^h = \tfrac{1}{2}\mathcal{J}^{-1}(\Delta^k - F)(x) = \tfrac{1}{2}\mathcal{J}^{-1}F(S^k - 1)(x).$$

We will now define dual affine connections in $\mathcal{W}_0$. The space $\mathcal{B}$ is a differentiable manifold and $\mathcal{W}_0$ is an open submanifold in $\mathcal{B}$. Let us consider the trivial affine connection in $\mathcal{B}$. The maps $\mathcal{L}_w^k : T_w \to T_w(\mathcal{B})$ and $\mathcal{K}_w : T_w \to T_w(\mathcal{B})$ induce affine connections in $\mathcal{W}_0$. Let Π^* and Π be the corresponding parallel transports and let γ be a smooth curve in $\mathcal{W}_0$, $\gamma(0) = w_0$, $\gamma(1) = w_1$. Then for $X \in T_w$,

$$\mathcal{K}_{w_1}(\Pi_\gamma(X)) = \mathcal{K}_{w_0}(X),$$

$$\mathcal{L}_{w_1}^k(\Pi_\gamma^*(X)) = \mathcal{L}_{w_0}^k(X).$$

The corresponding covariant derivatives ∇ and ∇^* are given by

$$\mathcal{K}_w(\nabla_X Y) = X\mathcal{K}_w(Y) = \mathcal{K}_w(XY) + yx^*,$$

$$\mathcal{L}_w^k(\nabla_X^* Y) = X\mathcal{L}_w^k(Y),$$

where X, Y are smooth vector fields on $\mathcal{W}_0$.

It is clear from (7) that $\langle X, Y\rangle_{w_0} = \langle \Pi_\gamma(X), \Pi_\gamma^*(Y)\rangle_{w_1}$ so that the connections ∇ and ∇^* are dual with respect to $\langle\cdot,\cdot\rangle_w$.

As we are interested in the projections onto $\mathcal{M}$, we restrict the parallel transports to horizontal vectors. From $\mathcal{L}_w^k(H_w)=\mathcal{B}_h$, we see that the restriction of Π^* to the bundle $\cup\{(w,H_w),\ w\in\mathcal{W}_0\}$ is induced from the trivial parallel transport restricted to $\cup\{(b,\mathcal{B}_h),\ b\in\mathcal{B}\}$. It means that the parallel transport of a horizontal vector stays horizontal. This is not necessarily true for Π. On the other hand, the above restriction of the trivial connection on $\mathcal{B}$ induces the restriction of Π to the bundle $\cup\{(w,H_w^*),\ w\in\mathcal{W}_0\}$. We may therefore define the parallel transport Π^h for $x\in H_w$ by

$$\Pi^h(x)=\mathcal{J}^{-1}(\Pi(\mathcal{J}(x))).$$

Then the parallel transports Π^* and Π^h are dual with respect to $(\cdot,\cdot)_w$. Indeed, if $x,y\in H_w$,

$$\begin{aligned}(\Pi_\gamma^*(x),\Pi_\gamma^h(y))_{w_1}&=\langle\Pi_\gamma^*(x),\Pi_\gamma(\mathcal{J}(y))\rangle_{w_1}\\&=\langle x,\mathcal{J}(y)\rangle_{w_0}=(x,y)_{w_0}.\end{aligned}$$

Note also that Π^h coincides with the horizontal part of Π.

Proposition 4.2: Let γ be a smooth curve in $\mathcal{W}_0$, $\gamma(0)=w_0$, $\gamma(1)=w_1$, where w_0 and w_1 are any elements of $\mathcal{W}_0$, satisfying $\pi(w_0)=\rho_0$ and $\pi(w_1)=\rho_1$. Let $h\in T_{\rho_0}(\mathcal{M})$ and let $\hat{h}$ be the horizontal lift to w_0. Then

$$\Pi_{\pi(\gamma)}^{(m)}(h)=\pi(\Pi_\gamma(\hat{h}))=\pi(\Pi_\gamma^h(\hat{h})),$$

$$\Pi_{\pi(\gamma)}^{(e)}(h)=\pi(\Pi_\gamma^*(\hat{h})).$$

Proof: Follows easily from (8) and (9). □

Let H,K be vector fields on $\mathcal{M}$ and let $\hat{H},\hat{K}$ be horizontal lifts. From the above Proposition, it also follows that $\pi(\nabla_{\hat{H}}^*\hat{K})=\nabla_H^{(e)}K$, so that $\nabla_{\hat{H}}^*\hat{K}$ is a horizontal lift of $\nabla_H^{(e)}K$. Similarly, $\nabla_{\hat{H}}^h\hat{K}$ is the horizontal lift of $\nabla_H^{(m)}K$.

V. THE α-CONNECTIONS

In Ref. 3, the α-connections on $\mathcal{M}$ were defined as generalizations of the (e) and (m)-connections for $\alpha\in[-3,3]$. There, the α-connection was given by the trivial affine structure on $g_\alpha(\mathcal{M})$, where

$$g_\alpha(t)=\begin{cases}\dfrac{2}{1-\alpha}t^{(1-\alpha)/2} & \alpha\neq 1\\ \log t & \alpha=1\end{cases}.$$

The connection was determined using the differentiation operators $L_\alpha[\rho]:T_\rho(\mathcal{M})\to T_{g_\alpha(\rho)}(\mathcal{M})$, given by

$$L_\alpha[\rho](H)=\frac{d}{dt}g_\alpha(\rho+tH)|_{t=0}.$$

The corresponding α-parallel transport from ρ_0 to ρ_1 along a curve ρ is

$$L_\alpha[\rho_1](\Pi_\rho^{(\alpha)}(X))=L_\alpha[\rho_0](X),\quad X\in T_{\rho_0}(\mathcal{M}).$$

The parallel transport $\Pi_\rho^{(\alpha)*}$, dual with respect to the given monotone metric is given by

$$L_\alpha^{-1}[\rho_1]J_{\rho_1}(\Pi_\rho^{(\alpha)*}(X))=L_\alpha^{-1}[\rho_0]J_{\rho_0}(X).$$

Again, we will show that the above affine connections are closely related to the class of connection forms from Sec. III. To this end, we define the projection π^α from $\mathcal{W}_0$ to $\mathcal{M}$ by

$$\pi^\alpha(w)=g_\alpha(ww^*).$$

Let $\rho=ww^*$. The induced linear map $\pi^\alpha: T_w\to T_{\pi^\alpha(w)}(\mathcal{M})$ is

$$\pi^\alpha(x)=L_\alpha[\rho](xw^*+wx^*).$$

The operator $L_\alpha[\rho]$ is invertible, therefore,

$$\pi^\alpha(x)=0\Leftrightarrow\pi(x)=0,$$

so that we have the same vertical subspace V_w. Hence we have the horizontal subspace H_w and the dual space H_w^* as in the previous section. Let $k\in T_{g_\alpha(\rho)}(\mathcal{M})$ and let us denote $\hat{k}^\alpha$ the horizontal lift of k with respect to π^α, i.e. a horizontal vector such that $\pi^\alpha(\hat{k}^\alpha)=k$. Let $h\in T_\rho(\mathcal{M})$. The horizontal lifts with respect to π and π^α are connected by

$$\hat{h}=\hat{k}^\alpha\Leftrightarrow k=L_\alpha[\rho](h). \tag{10}$$

In the sequel, we extend the differential operator $L_\alpha[\rho]$ to all of $\mathcal{B}$. We define the two maps $\mathcal{L}_w^\alpha,\mathcal{K}_w^\alpha: T_w\to\mathcal{B}$ by

$$\mathcal{L}_w^\alpha(X)=L_\alpha^{-1}[\rho](\mathcal{L}_w(X)),$$

$$\mathcal{K}_w^\alpha(X)=L_\alpha[\rho](\mathcal{K}_w(X)).$$

The operators $\mathcal{K}_w^\alpha$ and $\mathcal{L}_w^\alpha$ have similar properties as $\mathcal{K}_w$ and $\mathcal{L}_w$. We also have

$$\langle x,y\rangle_w=\langle\mathcal{L}_w(X),\mathcal{K}_w(Y)\rangle=\langle\mathcal{L}_w^\alpha(X),\mathcal{K}_w^\alpha(Y)\rangle. \tag{11}$$

The horizontal lift $\hat{h}^\alpha$ of a vector $h\in T_{\pi^\alpha(w)}(\mathcal{M})$ satisfies the conditions

$$\mathcal{L}_w^\alpha(\hat{h}^\alpha)=\tfrac{1}{2}L_\alpha^{-1}[\rho]J_\rho L_\alpha^{-1}[\rho](h)=:\tfrac{1}{2}K_\alpha(h), \tag{12}$$

$$y=\mathcal{J}(\hat{h}^\alpha)\Leftrightarrow\mathcal{K}_w^\alpha(y)=\tfrac{1}{2}h. \tag{13}$$

The induced inner product in $T_{\pi^\alpha(w)}(\mathcal{M})$ is then

$$\begin{aligned}4(\hat{h}^\alpha,\hat{k}^\alpha)_w&=4\langle\hat{h}^\alpha,\mathcal{J}(\hat{k}^\alpha)\rangle_w\\&=4\langle\mathcal{L}_w^\alpha(\hat{h}^\alpha),\mathcal{K}_w^\alpha(\mathcal{J}(\hat{k}^\alpha))\rangle=\langle K_\alpha(h),k\rangle.\end{aligned}$$

This coincides with the inner product, induced from $\langle\cdot,\cdot\rangle_\rho$ in the α-representation of the cotangent space, see Ref. 3.

As in the previous section, we use the trivial affine connection on $\mathcal{B}$ and the maps $\mathcal{K}_w^\alpha$ and $\mathcal{L}_w^\alpha$ to obtain the parallel transports Π^α and $\Pi^{\alpha*}$ on $\mathcal{W}_0$. From Eq. (11) it follows that the parallel transports are dual. The parallel transports Π^α and $\Pi^{\alpha*}$ can again be restricted to the bundles $\cup\{(w,H_w^*),\ w\in\mathcal{W}_0\}$ and $\cup\{(w,H_w),\ w\in\mathcal{W}_0\}$, respectively. We put

$$\Pi^{\alpha h}(x)=\mathcal{J}^{-1}\Pi^\alpha(\mathcal{J}(x)),$$

for $x\in H_w$. As before, this corresponds to the horizontal part of Π^α and the parallel transports $\Pi^{\alpha*}$ and $\Pi^{\alpha h}$ are dual with respect to $(\cdot,\cdot)_w$.

In the next Proposition, we show how these connections are projected onto $\mathcal{M}$.

Proposition 5.1: Let γ be a smooth curve in $\mathcal{W}_0$, $\gamma(0)=w_0$, $\gamma(1)=w_1$, where w_0 and w_1 are any elements of $\mathcal{W}_0$, satisfying $\pi(w_0)=\rho_0$ and $\pi(w_1)=\rho_1$. Let $h\in T_{\rho_0}(\mathcal{M})$. Then

$$\Pi^{(\alpha)}_{\pi(\gamma)}(h)=\pi(\Pi^{\alpha}_{\gamma}(\hat{h}))=\pi(\Pi^{\alpha h}_{\gamma}(\hat{h})),$$

$$\Pi^{(\alpha*)}_{\pi(\gamma)}(h)=\pi(\Pi^{\alpha*}_{\gamma}(\hat{h})).$$

Proof: The proof follows from (10), (12), (13) and the definition of the (α)- and (α^*)-parallel transports. □

From the above Proposition, it also follows that $\nabla^{\alpha h}_{\hat{H}}\hat{K}$ and $\nabla^{\alpha*}_{\hat{H}}\hat{K}$ are the π-horizontal lifts of $\nabla^{(\alpha)}_{H}K$ and $\nabla^{(\alpha*)}_{H}K$, respectively.

Let us now compute the Riemannian curvature of the α-connections.

Proposition 5.2: Let R^{α} and $R^{\alpha}*$ be the Riemannian curvature tensor of ∇^{α} and $\nabla^{\alpha}*$. Then

$$R^{\alpha}=R^{\alpha}*=0.$$

Proof: We have for smooth vector fields X,Y,Z on $\mathcal{W}$

$$\begin{aligned}\mathcal{L}^{\alpha}(R^{\alpha}*(X,Y)Z)&=\mathcal{L}^{\alpha}(\nabla^{\alpha}_{X}\nabla^{\alpha}_{Y}Z-\nabla^{\alpha}_{Y}\nabla^{\alpha}_{X}Z-\nabla^{\alpha}_{[X,Y]}Z)\\&=X\mathcal{L}^{\alpha}(\nabla^{\alpha}_{Y}Z)-Y\mathcal{L}^{\alpha}(\nabla^{\alpha}_{X}Z)-[X,Y]\mathcal{L}^{\alpha}(Z)\\&=(XY-YX-[X,Y])\mathcal{L}^{\alpha}(Z)=0.\end{aligned}$$

The statement for R^{α} can be proved similarly. It follows also from duality of the corresponding parallel transports.

□

VI. THE CURVATURE FORM

In this section, we compute the curvature form of the connection ω and show the relation between the curvature form and the torsion of the α-connections.

Let us choose a connection form ω from Sec. III 1. We will compute its curvature form. From the structure equation

$$d\omega=-\tfrac{1}{2}[\omega,\omega]+\Omega,$$

it follows that:

$$\omega[X,Y]=-2\Omega(X,Y), \tag{14}$$

for horizontal vector fields X,Y, see Ref. 10, pp. 81.

Let $w\in\mathcal{W}_0$ and let $\pi(w)=\rho$. Let us define the operator $C_{\rho}:\mathcal{B}\to\mathcal{B}$, given by

$$C_{\rho}(a)=R^{-1}r(R/L)(a)$$

Proposition 6.1: Let H,K be smooth vector fields on $\mathcal{M}$, such that $[H,K]=0$. Then

$$\begin{aligned}\Omega_{w}(\hat{H},\hat{K})=-\tfrac{1}{2}w^{-1}(&HC_{\rho}(k)\\&-KC_{\rho}(h)-[C_{\rho}(h),C_{\rho}(k)]_{\mathcal{B}})w,\end{aligned}$$

where $[a,b]_{\mathcal{B}}=ab-ba$ is the usual commutator on matrices.

Proof: From $\pi([\hat{H},\hat{K}])=[H,K]=0$ and Eq. (14), it follows that:

$$[\hat{H},\hat{K}]=[\hat{H},\hat{K}]^{v}=w\omega([\hat{H},\hat{K}])=-2w\Omega(\hat{H},\hat{K}).$$

Further, the horizontal lift of H is given by the condition

$$\hat{H}(w)=r(R/L)(H(\rho))(w^*)^{-1}=C_\rho(H(\rho))w,$$

so that

$$\hat{H}\hat{K}(w)=\hat{H}[C_\rho(k)]w+C_\rho(k)\hat{H}(w)=(HC_\rho(k)+C_\rho(k)C_\rho(h))w$$

It is now easy to finish the proof.

□

Example 6.1: Let $k=1$. Then $r(t)=t/(1+t)$ and $C_\rho=\frac{1}{2}J_\rho$. Let H,K be vector fields on $\mathcal{M}$, such that $[H,K]=0$. Let us denote $L_H^S=J_\rho(h)$. Then

$$-2w\Omega(\hat{H},\hat{K})w^{-1}=\tfrac{1}{2}(HL_K^S-KL_H^S)-\tfrac{1}{4}[L_H^S,L_K^S]_{\mathcal{B}}.$$

Let T^* be the torsion of the (e)-connection on $\mathcal{M}$, then

$$T^*(H,K)=J_\rho^{-1}(HL_K^S-KL_H^S)=\tfrac{1}{4}[[L_H^S,L_K^S]_{\mathcal{B}},\rho]_{\mathcal{B}},$$

see Refs. 2 and 6. We compute

$$\Omega(\hat{H},\hat{K})=\tfrac{1}{8}w^*J_\rho([L_H^S,L_K^S]_{\mathcal{B}})w.$$

We see that the curvature form $\Omega(H,K)=0$ if and only if the symmetric logarithmic derivatives commute. In this case also the torsion $T^*(H,K)$ vanishes.

Example 6.2: Let $\omega=\omega^{\mathrm{can}}$ be the connection form of the canonical connection (Example 3.2). Then $r=\frac{1}{2}$ and $C_\rho=\frac{1}{2}R^{-1}$. Let us denote $L_H^L=h\rho^{-1}=2C_\rho$. The curvature form is

$$\begin{aligned}\Omega^{\mathrm{can}}(H,K)&=\tfrac{1}{8}w^{-1}[L_K^L,L_H^L]_{\mathcal{B}}w\\&=\tfrac{1}{8}[w^{-1}k(w^*)^{-1},w^{-1}h(w^*)^{-1}]_{\mathcal{B}}.\end{aligned}$$

Again, the curvature form is zero iff the left (or, equivalently, the right) logarithmic derivatives commute. We have $T^*(H,K)=\Re[L_H^L,L_K^L]_{\mathcal{B}}$, so that the torsion also vanishes.

We see that in both examples, there is a close relation between the curvature form of ω and the exponential connection on $\mathcal{M}$: Vanishing of the curvature form implies vanishing of the torsion of the (e)-connection. As we shall see next, this is not always true.

Example 6.3: Let ω be the connection form from Example 3.3. Let $u\in U(n)$ and let us define $\sigma:\mathcal{M}\to\mathcal{W}_0$ by $\sigma(\rho)=\rho^{\frac{1}{2}}u$. Then σ is a global horizontal section. It follows that the curvature form of Ω vanishes. On the other hand, the torsion of the (e)-connection is not always zero, see Ref. 13.

Let now T^α and $T^{\alpha*}$ be the torsion of the connection $\nabla^{\alpha h}$ and $\nabla^{\alpha *}$ on $\mathcal{W}_0$.

Proposition 6.2: Let H,K be vector fields on $\mathcal{M}$ and let $T^{(\alpha*)}$ be the torsion of the connection $\nabla^{(\alpha*)}$ on $\mathcal{M}$. Then the horizontal part of $T^{\alpha*}(\hat{H},\hat{K})$ is the horizontal lift of $T^{(\alpha*)}(H,K)$ and

$$\omega(T^{\alpha*}(\hat{H},\hat{K}))=2\Omega(\hat{H},\hat{K}),$$

where Ω is the curvature form of ω.

Proof: The vector fields $\nabla_{\hat{H}}^{\alpha*}\hat{K}$ and $\nabla_{\hat{K}}^{\alpha*}\hat{H}$ are horizontal lifts of $\nabla_H^{(\alpha*)}K$ and $\nabla_K^{(\alpha*)}H$, so that

$$(T^{\alpha*}(\hat{H},\hat{K}))^h=\nabla_{\hat{H}}^{\alpha*}\hat{K}-\nabla_{\hat{H}}^{\alpha*}\hat{K}-[\hat{H},\hat{K}]^h.$$

But $[\hat{H},\hat{K}]^h$ is the horizontal lift of $[H,K]$, so that

$$\pi(T^{\alpha *}(\hat{H},\hat{K}))=T^{(\alpha *)}(H,K).$$

It also follows that

$$\omega(T^{\alpha *}(\hat{H},\hat{K}))=-\omega([\hat{H},\hat{K}])=2\Omega(\hat{H},\hat{K}).$$

□

Proposition 6.3: Let H, K be as above and let $T^{(\alpha)}$ be the torsion of the connection $\nabla^{(\alpha)}$ on $\mathcal{M}$. Then $T^{\alpha}(\hat{H},\hat{K})$ is vertical, with

$$\omega(T^{\alpha}(\hat{H},\hat{K}))=2\Omega(\hat{H},\hat{K}).$$

Proof: The proof is analogical to the previous proof, using the fact that the connection $\nabla^{(\alpha)}$ on $\mathcal{M}$ is torsion-free.

□

Proposition 6.4: *Let $x,y\in H_w^*$ and let $\overline{T^{\alpha}}$ be the torsion of the connection ∇^{α}. Then $\overline{T^{\alpha}}(X,Y)$ is vertical and*

$$\overline{T^{\alpha}}(X,Y)=2w\Omega^{\mathrm{can}}(X,Y)$$

Proof: Let the horizontal subspace be given by the cannonical connection, then $H_w=H_w^*$ and $\mathcal{J}$ is the identity map. It follows that $\nabla^{\alpha}=\nabla^{\alpha h}$. The vectors $X,Y\in H_w^*$ can be extended to vector fields on $\mathcal{W}_0$, such that $\pi(X)$ and $\pi(Y)$ are smooth vector fields on $\mathcal{M}$. The statement now follows from the previous Proposition.

□

Remark 6.1: If $\alpha=-1$, i.e., $\nabla^{\alpha}=\nabla$, it is easy to compute that

$$\mathcal{K}_w(\overline{T}(X,Y))=yx^*-xy^*,$$

and $\overline{T}(X,Y)$ is, therefore, vertical for all smooth vector fields X,Y.

VII. DUAL RIEMANNIAN METRICS

It follows from symmetry of the representation $\mathcal{B}\otimes 1$ and its commutant $1\otimes\mathcal{B}$ that we may equally well use the projection $\pi':\mathcal{W}_0\to\mathcal{M}$,

$$\pi':w\mapsto w^*w,$$

instead of π. In this case, the induced linear map $T_w\to T_{w^*w}(\mathcal{M})$ is

$$\pi'(x)=x^*w+w^*x.$$

It is easy to show that $\pi'(x)=0$ if xw^{-1} is anti-Hermitian, so that the vertical subspace is given by

$$V'_w=\{aw:a+a^*=0\}.$$

Let the horizontal subspace H'_w be the orthogonal complement of V'_w with respect to

$$(x,y)'_w=(x,k(\Delta^{-1})^{-1}(y)),$$

for a positive function k. It is quite clear that given a function k, we obtain the same Riemannian structure on $\mathcal{M}$ from $(\cdot,\cdot)'_w$ and π' as from $(\cdot,\cdot)_w$ and π. Moreover, $(\cdot,\cdot)_w$ coincides with $(\cdot,\cdot)$ on H_w if and only if the same is true for $(\cdot,\cdot)'_w$ and H'_w.

Let F^k be the modification of the Tomita–Takesaki operator F, given by

$$F^k(k(\Delta^{-1})(wg))=k(\Delta^{-1})(wg^*).$$

Lemma 7.1:

(i) $F^k=Fp(\Delta)=p(\Delta)^{-1}F$;
(ii) *The horizontal subspace* H'_w *is the fix point space of* F^k;
(iii) F^k *is the adjoint operator of* S^k *with respect to* $\langle\cdot,\cdot\rangle$;
(iv) *The polar decomposition of* S^k *with respect to* $\langle\cdot,\cdot\rangle$ *is* $S^k=J\Delta^{\sim k1/2}$, *where*

$$\Delta^{\sim k}=\Delta p(\Delta)^{-2}=\frac{\tilde{p}(\Delta)}{p(\Delta)}=\tilde{p}(\Delta)p(\Delta^{-1}),$$

(v) $F^{\sqrt{p}}=S^{\sqrt{\tilde{p}}}$, *where* $\tilde{p}=tp(t^{-1})=t/p(t)$

Proof: (i) is proved similarly as Lemma 4.1 (i), the statements (ii)–(iv) are easy to prove. To get (v), write

$$F^{\sqrt{p}}=Fp(\Delta)=J\Delta^{-1/2}p(\Delta)=J\Delta^{1/2}\tilde{p}(\Delta)^{-1}=S^{\sqrt{\tilde{p}}}.$$

□

Let the functions f and $\tilde{f}$ be obtained from p and $\tilde{p}$ as in Theorem 3.1 (iii). Then we will say that the corresponding Riemannian metrics on $\mathcal{M}$ are dual.

From the above Lemma, we see that the horizontal subspace H'_w, given by the function p, coincides with the subspace H_w, obtained from $\tilde{p}$. It means that a pair of dual Riemannian structures on $\mathcal{M}$ is obtained from the real part of Hilbert–Schmidt inner product on a horizontal subspace (H_w or H'_w), using the projections π and π'. Another way to do it is to use the same projection (π or π') on two dual subspaces H_w and H'_w.

Example 7.1: It is easy to see that if $k=1$, the dual subspace H'_w coincides with H^*_w from Sec. IV. Moreover, H_w and H^*_w are the SLD and RLD subspaces from Examples 3.1 and 3.2. It follows that SLD and RLD are dual Riemannian metrics. The metric from Example 3.3 is the unique self-dual Riemannian metric.

Let H_w and H'_w be two dual horizontal subspaces given by the function k, i.e., H_w and H'_w are the fix point space of S^k and F^k, respectively. Let $\mathcal{J}^k$ be the operator $H_w\to H'_w$, satisfying

$$\langle x,\mathcal{J}^k(y)\rangle=(x,y)_w,\quad x,y\in H_w.$$

Then

$$\mathcal{J}^k=\tfrac{1}{2}(1+\Delta^{\sim k})|_{H_w}.$$

Indeed, let $x,y\in H_w$, then

$$(1+\Delta^{\sim k})(x)=x+F^k(x)\in H'_w$$

and

$$\tfrac{1}{2}\langle x,(1+\Delta^{\sim k})(y)\rangle=\tfrac{1}{2}(\langle x,y\rangle+\langle x,F^kS^k(y)\rangle)=(x,y)=(x,y)_w.$$

Let now $h_1,h_2\in T_\rho(\mathcal{M})$ and let $\langle\cdot,\cdot\rangle_\rho$ be the inner product, given by the function $f=\frac{1}{2}(k(t)+tk(t^{-1}))$. Then it can be realized on H^*_w as

$$\begin{aligned}\langle h_1,h_2\rangle_\rho&=\langle l_1^L,\mathcal{J}^{-1}\mathcal{J}^k\mathcal{J}^{-1}(l_2^L)\rangle\\&=\langle l_1^L,2(1+\tilde{p}(\Delta))^{-1}[1+\tilde{p}(\Delta)p(\Delta^{-1})]\\&\quad\times(1+\tilde{p}(\Delta))^{-1}(L_2^L)\rangle,\end{aligned}$$

where $l_i^L = h_i(w^*)^{-1}$, $i=1,2$. Note that this corresponds to the decomposition of the function f

$$f(t) = \frac{1}{2}\frac{(1+\tilde{p}(t))^2}{1+\tilde{p}(t)p(t^{-1})},$$

from Theorem 3.1 (iii).

We conclude with two natural questions:

(1) From Theorem 3.1, we see that there is a one-to-one correspondence between the set of all operator monotone functions and a subset of
$$\{p:\mathbb{R}^+\to\mathbb{R}^+,\ p \text{ is smooth},\ p(t^{-1})=p(t)^{-1}\}.$$
How is this subset characterized?

(2) Let the Riemannian metric $\langle\cdot,\cdot\rangle_\rho$ be monotone. Does it follow that the dual Riemannian metric is monotone?

Exact evolution equations for SU(2) quasidistribution functions

A. B. Klimov[a)]
Departamento de Física, Universidad de Guadalajara, Revolución 1500, 44410, Guadalajara, Jal., Mexico

(Received 31 October 2001; accepted for publication 4 February 2002)

We derive an exact (differential) evolution equation for a class of SU(2) quasiprobability distribution functions. Linear and quadratic cases are considered as well as the quasiclassical limit of the large dimension of representation, $S \gg 1$. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1463711]

I. INTRODUCTION

Phase-space representation provides a very useful insight into nonrelativistic quantum mechanics and allows us to treat it as a statistical theory in a classical phase space. Since the famous paper of Wigner[1] the phase-space methods have been successfully applied in different branches of quantum mechanics (see, e.g., Ref. 2). Special attention has been paid to Heisenberg–Weyl quasidistribution functions[3] describing a quantum system dynamics in the flat q-p $(\alpha-\alpha^*)$ space. The dynamics of quasiprobability distributions in phase space is governed by quantum Liouville-like equations, which in the limit $\hbar \to 0$ turn to the classical Liouville equation,[4–6] providing the most suitable approach to the quasiclassical limit in quantum mechanics.

The phase-space description of spin systems was initiated by Stratonovich,[7] Beresin,[8] and Agarwal[9] (see also Refs. 10–15), where different types of the quasiprobability distribution function on the sphere $(\theta,\phi) \in \mathcal{S}_2$ have been introduced. These functions, naturally related to the SU(2) dynamical group, are useful to visualize nonclassical properties of a collection of two-level atoms.[16,17] In the present article we find the exact differential form of the evolution equations for some special types of SU(2) quasidistribution functions and discuss quasiclassical limit of the large dimension of representation. In particular we will be interested in P- and Q-Beresin symbols and the Stratonovich–Weyl function W (see Ref. 12 for review). These SU(2) quasidistribution functions can be unified introducing an s-parametrized family of phase-space functions[15,18] defined as follows:

$$W_\rho^{(s)}(\theta,\phi) = \mathrm{Tr}(\rho \hat{w}_s(\theta,\phi)), \tag{1}$$

where ρ is the system density matrix and $\hat{w}_s(\theta,\phi)$ is the operator

$$\hat{w}_s(\theta,\phi) = \frac{2\sqrt{\pi}}{\sqrt{2S+1}} \sum_{L=0}^{2S} \sum_{M=-L}^{L} (C_{SS,L0}^{SS})^{-s} Y_{LM}^*(\theta,\phi) \hat{T}_{LM}^{(S)}, \tag{2}$$

where $Y_{LM}(\theta,\phi)$ are the spherical harmonics, $\hat{T}_{LM}^{(S)}$ are the irreducible tensor operators[19] which form an orthogonal operator basis in the space of $(2S+1)\times(2S+1)$ matrices and are defined as

$$\hat{T}_{LM}^{(S)} = \sqrt{\frac{2L+1}{2S+1}} \sum_{m,m'=-S}^{S} C_{Sm,LM}^{Sm'} |S,m'\rangle \langle S,m|. \tag{3}$$

a)Electronic mail: klimov@cencar.udg.mx

Here $C^{Sm'}_{Sm,LM}$ are the Clebsch–Gordan coefficients which couple two representations of spin S and L $(0\leqslant L\leqslant 2S)$ to a total spin S. The value $s=0$ corresponds to the Stratonovich–Weyl function, meanwhile $s=\pm 1$ leads to contravariant P-symbol and covariant Q-symbol correspondingly. Both self-dual $\hat{w}_{s=0}(\theta,\phi)$ and dual $\hat{w}_{s=\pm 1}(\theta,\phi)$ kernels are normalized according to

$$\mathrm{Tr}\,\hat{w}_s(\theta,\phi)=1, \quad \frac{2S+1}{4\pi}\int_{\mathcal{S}_2} \mathrm{d}\Omega\, \hat{w}_s(\theta,\phi)=I. \tag{4}$$

The quasidistribution functions $W^{(s)}_\rho(\theta,\phi)$ are covariant under rotations and provide the overlap relation

$$\frac{2S+1}{4\pi}\int_{\mathcal{S}_2} \mathrm{d}\Omega\, W^{(s)}_\rho(\theta,\phi) W^{(-s)}_A(\theta,\phi)=\mathrm{Tr}(\rho A), \tag{5}$$

where $\mathrm{d}\Omega=\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi$ is the invariant measure on the sphere and $W^{(s)}_A(\theta,\phi)$ is the (s-ordered) Weyl symbol of the operator $\hat{A}$,

$$W^{(s)}_A(\theta,\phi)=\mathrm{Tr}(\hat{A}\hat{w}_s(\theta,\phi)). \tag{6}$$

The density matrix can be reconstructed from any quasidistribution function (1) through the following relation:

$$\rho=\frac{2S+1}{4\pi}\int_{\mathcal{S}_2} \mathrm{d}\Omega\, \hat{w}_{-s}(\theta,\phi) W^{(s)}_\rho(\theta,\phi). \tag{7}$$

In what follows we will consider only *integer* spin S, which corresponds to the SO(3) rather than the SU(2) group.

II. EVOLUTION EQUATIONS

A. General systems

Let us consider the dynamics of quasidistribution functions $W^{(s)}_\rho(\theta,\phi)$ under the action of a Hamiltonian from $2S+1$ dimensional representation of the universal enveloping algebra of $su(2)$. We represent the Hamiltonian as a series on the irreducible tensor operators $\hat{T}^{(S)}_{lk}$ (3),

$$H=\sum_{l=0}^{2S}\sum_{k=-l}^{l}\alpha_{lk}\hat{T}^{(S)}_{lk}. \tag{8}$$

The degree of nonlinearity [on the generators of the $su(2)$ algebra] of the Hamiltonian (8), $\deg H$, is defined by the maximum value of l, such that $\alpha_{lk}\neq 0$. Substituting the density matrix in terms of the quasidistribution function $W^{(s)}_\rho(\theta,\phi)$ (7) to the equation of motion,

$$i\partial_t\rho=[H,\rho], \tag{9}$$

we obtain

$$i\int_{\mathcal{S}_2}\mathrm{d}\Omega\,\hat{w}_{-s}(\theta,\phi)\partial_t W^{(s)}_\rho(\theta,\phi)=\int_{\mathcal{S}_2}\mathrm{d}\Omega[H,\hat{w}_{-s}(\theta,\phi)]W^{(s)}_\rho(\theta,\phi). \tag{10}$$

The commutator of two irreducible tensor operators can be represented as a linear form on irreducible tensor operators,[19]

$$[\hat{T}^{(S)}_{lk},\hat{T}^{(S)}_{LM}]=\sqrt{(2l+1)(2L+1)}\sum_{L',M'}[(-1)^{L'}-(-1)^{L+l}]C^{L'M'}_{lk,LM}\begin{Bmatrix} l & L & L' \\ S & S & S \end{Bmatrix}\hat{T}^{(S)}_{L'M'}, \quad (11)$$

where $\{\begin{smallmatrix} l & L & L' \\ S & S & S \end{smallmatrix}\}$ are $6j$-symbols. We will use the following representation [which can be obtained by comparing Eqs. 9.2.1 (5) and 8.2.1 (4) from Ref. 19] of $6j$-symbols in terms of expansion on the Clebsch–Gordan coefficients,

$$\begin{Bmatrix} l & L & L' \\ S & S & S \end{Bmatrix}=\frac{(-1)^l}{\sqrt{(2l+1)}}\left(\frac{F(L)F(l)}{F(L')}\right)^{1/2}\sum_j a_j b^L_{jl}C^{lj}_{Lj,L'0}, \quad (12)$$

where

$$a_j=\frac{(-1)^j}{j!(2S+j+1)!}, \quad b^L_{jl}=\left[\frac{(L+j)!(l+j)!}{(L-j)!(l-j)!}\right]^{1/2}, \quad (13)$$

and

$$F(L)=\sqrt{(2S+L+1)!(2S-L)!}. \quad (14)$$

Making use of (11) and (12) we get

$$[H,\hat{w}_{-s}(\theta,\phi)]=\frac{2\sqrt{\pi}}{\sqrt{2S+1}}\sum_{l,k}\alpha_{lk}\sum_{L,M}(C^{SS}_{SS,L0})^s Y^*_{LM}(\theta,\phi)$$
$$\times\sum_{L',M'}[1-(-1)^{L+l+L'}]\hat{T}^{(S)}_{L'M'}C^{LM}_{L'M',l-k}g(L,L',l), \quad (15)$$

$$g(L,L',l)=\sqrt{\frac{(2L'+1)(2l+1)}{2L+1}}\,\frac{F(L)F(l)}{F(L')}\sum_j a_j b^L_{jl}C^{Lj}_{L'0,lj}, \quad (16)$$

where we have used the following transformation properties of the Clebsch-Gordan coefficients:

$$C^{L'M'}_{lk,LM}=(-1)^{l-k}\sqrt{\frac{2L'+1}{2L+1}}C^{LM}_{L'M',l-k}, \quad C^{lj}_{Lj,L'0}=(-1)^{L'}\sqrt{\frac{2l+1}{2L+1}}C^{Lj}_{L'0,lj}. \quad (17)$$

Using the integral representation[19] for a product of two Clebsch–Gordan coefficients in terms of the Wigner D-function,

$$C^{Lj}_{L'0,lj}C^{LM}_{L'M',l-k}=\frac{2L+1}{8\pi^2}\int \mathrm{d}V D^{L'}_{M'0}(\phi,\theta,\psi)D^{l}_{-kj}(\phi,\theta,\psi)D^{L*}_{Mj}(\phi,\theta,\psi), \quad (18)$$

where $\mathrm{d}V=\mathrm{d}\phi\,\mathrm{d}\Omega$, and relations

$$D^{L'}_{M'0}(\phi,\theta,\psi)=\sqrt{\frac{4\pi}{2L'+1}}Y^*_{L'M'}(\theta,\phi),$$

$$D^{l}_{-kj}(\phi,\theta,\psi)=(-1)^k\sqrt{\frac{4\pi}{2l+1}}\sqrt{\frac{(l-j)!}{(l+j)!}}S^{+j}Y_{lk}(\theta,\phi), \quad (19)$$

$$D^{L*}_{Mj}(\phi,\theta,\psi)=\sqrt{\frac{4\pi}{2L+1}}\sqrt{\frac{(L-j)!}{(L+j)!}}S^{-j}Y_{LM}(\theta,\phi),$$

where

$$S^{\pm}=ie^{\mp i\psi}\left(\pm\cot\theta\frac{\partial}{\partial\psi}+i\frac{\partial}{\partial\theta}\mp\frac{1}{\sin\theta}\frac{\partial}{\partial\phi}\right), \tag{20}$$

$$S^{\pm}D^{L}_{mm'}(\phi,\theta,\psi)=-\sqrt{L(L+1)}C^{Lm'\pm1}_{Lm,1\pm1}D^{L}_{mm'\pm1}(\phi,\theta,\psi) \tag{21}$$

are contravariant components of angular momentum operator in the rotating frame,[19] we obtain from (15)

$$[H,\hat{w}_{-s}(\theta,\phi)]=\frac{2}{\sqrt{2S+1}}\sum_{l,k}\alpha_{lk}\sum_{L,M}(C^{SS}_{SS,L0})^{s}Y^{*}_{LM}(\theta,\phi)\sum_{L',M'}\hat{T}^{(S)}_{L'M'}\sum_{j}a_j f_j(L,L',l), \tag{22}$$

$$f_j(L,L',l)=\frac{F(L)F(l)}{F(L')}\int dV Y^{*}_{L'M'}(\theta,\phi)[S^{+j}Y_{lk}(\theta,\phi)S^{-j}Y_{LM}(\theta,\phi) -S^{-j}Y_{lk}(\theta,\phi)S^{+j}Y_{LM}(\theta,\phi)]. \tag{23}$$

Now we note that the function $F(L)$ (14) depends on the combination $L(L+1)$ rather than on L itself and, thus, we can write

$$F(L)Y_{LM}(\theta,\phi)=\tilde{F}(\mathcal{L}^2)Y_{LM}(\theta,\phi), \tag{24}$$

where $\tilde{F}(\mathcal{L}^2)$ is some function (whose explicit form is not needed for concrete calculations) of the Casimir operator on the sphere $\mathcal{L}^2$,

$$\mathcal{L}^2=-\left[\frac{\partial^2}{\partial\theta^2}+\cot\theta\frac{\partial}{\partial\theta}+\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}\right], \tag{25}$$

such that $\mathcal{L}^2Y_{L,M}(\theta,\phi)=L(L+1)Y_{L,M}(\theta,\phi)$. Taking into account that

$$C^{SS}_{SS,L0}=\frac{\sqrt{(2S+1)!(2S)!}}{F(L)}, \tag{26}$$

we obtain after integrating by parts Eq. (23)

$$(C^{SS}_{SS,L0})^{s}f_j(L,L',l)=(-1)^{j}\int \mathrm{d}V\, Y_{LM}(\theta,\phi)\tilde{F}^{1-s}(\mathcal{L}^2) \times[S^{-j}(\tilde{F}^{-1}(\mathcal{L}^2)Y^{*}_{L'M'}(\theta,\phi)S^{+j}\tilde{F}(\mathcal{L}^2)Y_{lk}(\theta,\phi)) -S^{+j}(\tilde{F}^{-1}(\mathcal{L}^2)Y^{*}_{L'M'}(\theta,\phi)S^{-j}\tilde{F}(\mathcal{L}^2)Y_{lk}(\theta,\phi))][(2S+1)!(2S)!]^{s/2}. \tag{27}$$

Due to the sum

$$\sum_{L,M}Y^{*}_{LM}(\theta,\phi)Y_{LM}(\theta',\phi')=K(\Omega,\Omega') \tag{28}$$

is a reproductive kernel on the sphere,[12] i.e.,

$$\int \mathrm{d}\Omega\, Z(\Omega)K(\Omega,\Omega')=Z(\Omega') \tag{29}$$

for any function $Z(\Omega)$ defined on the sphere. We get from (22) and (27)

$$[H,\hat{w}_{-s}(\theta,\phi)]=\frac{\sqrt{2S+1}}{2\pi}\sum_j (-1)^j a_j \int \mathrm{d}\psi\, \tilde{F}^{1-s}(\mathcal{L}^2)$$
$$\times[S^{-j}(\tilde{F}^{s-1}(\mathcal{L}^2)\hat{w}_{-s}(\theta,\phi)S^{+j}\tilde{F}(\mathcal{L}^2)W_H^{(0)}(\theta,\phi))$$
$$-S^{+j}(\tilde{F}^{s-1}(\mathcal{L}^2)\hat{w}_{-s}(\theta,\phi)S^{-j}\tilde{F}(\mathcal{L}^2)W_H^{(0)}(\theta,\phi))], \tag{30}$$

where

$$W_H^{(0)}(\theta,\phi)=\frac{2\sqrt{\pi}}{\sqrt{2S+1}}\sum_{l,k}\ \alpha_{lk}Y_{lk}(\theta,\phi) \tag{31}$$

is a symmetrized, $s=0$ (Stratonovich–Weyl) symbol of the Hamiltonian (8). Substituting (30) into (10) and integrating by parts we obtain (after integrating over the angle ψ)

$$i\partial_t W_\rho^{(s)}(\theta,\phi)=\sqrt{2S+1}\tilde{F}^{s-1}(\mathcal{L}^2)\sum_j\ a_j[S^{-(j)}(\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi))S^{+(j)}(\tilde{F}(\mathcal{L}^2)W_H^{(0)}(\theta,\phi))$$
$$-S^{+(j)}(\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi))S^{-(j)}(\tilde{F}(\mathcal{L}^2)W_H^{(0)}(\theta,\phi))], \tag{32}$$

where symbolic power $S^{\pm(j)}$ has been introduced according to

$$S^{\pm j}=e^{\mp ij\psi}S^{\pm(j)}, \tag{33}$$

such that

$$S^{\pm(j)}=\Pi_{k=0}^{j-1}\left(k\cot\theta-\frac{\partial}{\partial\theta}\mp\frac{i}{\sin\theta}\frac{\partial}{\partial\phi}\right). \tag{34}$$

It follows from (21) and (33) that

$$S^{\pm(j)}W_H^{(0)}(\theta,\phi)=0,\quad j>\deg H. \tag{35}$$

Equation (32) can be rewritten in the following suitable form:

$$i\partial_t W_\rho^{(s)}(\theta,\phi)=(\hat{\mu}-\hat{\mu}^*)(W_\rho^{(s)}(\theta,\phi)W_H^{(0)}(\theta,\phi)), \tag{36}$$

where

$$\hat{\mu}=\sqrt{2S+1}\tilde{F}^{s-1}(\mathcal{L}^2)\sum_j\ a_j(S^{-(j)}\tilde{F}^{1-s}(\mathcal{L}^2))_\rho\otimes(S^{+(j)}\tilde{F}(\mathcal{L}^2))_H, \tag{37}$$

$$\hat{\mu}^*=\sqrt{2S+1}\tilde{F}^{s-1}(\mathcal{L}^2)\sum_j\ a_j(S^{+(j)}\tilde{F}^{1-s}(\mathcal{L}^2))_\rho\otimes(S^{-(j)}\tilde{F}(\mathcal{L}^2))_H, \tag{38}$$

and the operator with subindex "ρ" acts on $W_\rho^{(s)}(\theta,\phi)$, the operator with subindex "H" acts on $W_H^{(s)}(\theta,\phi)$, whereas the external operator $\tilde{F}^{s-1}(\mathcal{L}^2)$ acts on both terms. The number of terms in the sums (37) and (38) is defined by the degree of nonlinearity of the Hamiltonian (8), i.e., $j=0,1,\ldots,j_{\max}$, $j_{\max}=\deg H$, although formally, because of (35), these sums can be extended to infinity. Equations (36)–(38) is the main result of this paper. It is worth noting that although the operator function $\tilde{F}(\mathcal{L}^2)$ has explicitly entered into (37) and (38), the property (24) is sufficient to obtain the evolution equation for any particular Hamiltonian of the form (8).

Note that as a consequence of (33) the symbolic powers $S^{\pm(j)}$in Eqs. (37) and (38) can be substituted by normal powers of the operators (20). This allows us formally to rewrite (37) and (38) in the following form:

$$\hat{\mu}=\sqrt{2S+1}\tilde{F}^{s-1}(\mathcal{L}^2)\sigma(S_\rho^-\otimes S_H^+)\tilde{F}^{1-s}(\mathcal{L}^2)_\rho\otimes\tilde{F}(\mathcal{L}^2)_H,$$
$$\hat{\mu}^*=\sqrt{2S+1}\tilde{F}^{s-1}(\mathcal{L}^2)\sigma(S_\rho^+\otimes S_H^-)\tilde{F}^{1-s}(\mathcal{L}^2)_\rho\otimes\tilde{F}(\mathcal{L}^2)_H, \tag{39}$$

where the function $\sigma(z)$ is defined as

$$\sigma(z)=\sum_j \frac{(-1)^j}{j!(2S+j+1)!}z^j=\frac{1}{z^{S+1/2}}J_{2S+1}(2\sqrt{z}), \tag{40}$$

and $J_n(x)$ is the Bessel function.

Let us consider the first nontrivial term $(j=1)$ in (37) and (38) in $\hat{\mu}-\hat{\mu}^*$,

$$\frac{\sqrt{2S+1}}{(2S+2)!}\tilde{F}^{s-1}(\mathcal{L}^2)[(S^{+(1)})_\rho\otimes(S^{-(1)})_H-(S^{-(1)})_\rho\otimes(S^{+(1)})_H]\tilde{F}^{1-s}(\mathcal{L}^2)_\rho\otimes\tilde{F}(\mathcal{L}^2)_H. \tag{41}$$

One can observe that

$$(S^{+(1)})_\rho\otimes(S^{-(1)})_H-(S^{-(1)})_\rho\otimes(S^{+(1)})_H=\frac{2i}{\sin\theta}\left(\frac{\partial}{\partial\phi_\rho}\otimes\frac{\partial}{\partial\theta_H}-\frac{\partial}{\partial\theta_\rho}\otimes\frac{\partial}{\partial\phi_H}\right)=2i\{,\}_P, \tag{42}$$

where $\{,\}_P$ means the Poisson brackets on the sphere. Thus, the first term on the right-hand side of (36) acquires the form of the Poisson brackets:

$$2i\frac{\sqrt{2S+1}}{(2S+2)!}\tilde{F}^{s-1}(\mathcal{L}^2)\{\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi),\tilde{F}(\mathcal{L}^2)W_H^{(0)}(\theta,\phi)\}_P. \tag{43}$$

B. Linear Hamiltonians

In the particular case of linear Hamiltonians, $l=1$ in (8) [when only the term with $j=1$ contributes to (37) and (38)],

$$H=\omega_0 S_z+gS_++g^*S_-, \tag{44}$$

the Weyl symbol of the Hamiltonian takes the form

$$W_H^{(0)}(\theta,\phi)=\frac{2\sqrt{\pi}}{\sqrt{2S+1}}\sum_{k=-1}^{1}\alpha_{1k}Y_{1k}(\theta,\phi),$$
$$\alpha_{10}=\sqrt{2}A_S\omega_0,\quad \alpha_{11}=-2A_Sg,\quad \alpha_{1-1}=2A_Sg^*, \tag{45}$$
$$A_S=\sqrt{\frac{S(S+1)(2S+1)}{6}}.$$

The above expressions can be represented in a more familiar form[12]

$$W_H^{(0)}(\theta,\phi)=\omega_0W_{S_z}^{(0)}(\theta,\phi)+gW_{S_+}^{(0)}(\theta,\phi)+g^*W_{S_-}^{(0)}(\theta,\phi), \tag{46}$$

where

$$W_{S_z}^{(0)}(\theta,\phi)=\sqrt{S(S+1)}\cos\theta,\quad W_{S_\pm}^{(0)}(\theta,\phi)=\sqrt{S(S+1)}\sin\theta e^{\pm i\phi}. \tag{47}$$

In this case due to

$$\{Y^*_{LM}(\theta,\phi),Y_{1k}(\theta,\phi)\}_P \sim Y^*_{LM-k}(\theta,\phi), \quad k=0,\pm 1, \tag{48}$$

we obtain

$$(\hat{\mu}-\hat{\mu}^*)(W^{(s)}_\rho(\theta,\phi)W^{(0)}_H(\theta,\phi))=\frac{2i\sqrt{2S+1}F(1)}{(2S+2)!}\{W^{(s)}_\rho(\theta,\phi),W^{(0)}_H(\theta,\phi)\}_P,$$
$$F(1)=\sqrt{(2S+2)!(2S-1)!}, \tag{49}$$

which leads to the following evolution equation

$$\partial_t W^{(s)}_\rho(\theta,\phi)=\frac{1}{\sqrt{S(S+1)}}\{W^{(s)}_\rho(\theta,\phi),W^{(0)}_H(\theta,\phi)\}_P. \tag{50}$$

Thus, in the case of the linear Hamiltonian the evolution equation for s-ordered quasidistribution functions (1) coincides with the classical Liouville equation.[12]

C. Quadratic Hamiltonians

In the nonlinear case quantum corrections to classical evolution equation come from two different sides. First of all, more terms in the sums (37) and (38) appear. On the other hand, the relation (48) is not true for higher spherical harmonics (with $L\geqslant 2$), which means that expression (43) is not reduced to simple Poisson brackets of $W^{(s)}_\rho(\theta,\phi)$ and $W^{(0)}_H(\theta,\phi)$. Let us write the evolution equation (36) for the case of quadratic Hamiltonians, $\deg H=2$. We have

$$\begin{aligned} i\partial_t W^{(s)}_\rho(\theta,\phi)&=2i\frac{\sqrt{2S+1}}{(2S+2)!}\tilde{F}^{s-1}(\mathcal{L}^2)\{\tilde{F}^{1-s}(\mathcal{L}^2)W^{(s)}_\rho(\theta,\phi),\tilde{F}(\mathcal{L}^2)W^{(0)}_H(\theta,\phi)\}_P \\ &+\frac{\sqrt{2S+1}}{2(2S+3)!}\tilde{F}^{s-1}(\mathcal{L}^2)((S^{-(2)})_\rho\otimes(S^{+(2)})_H-(S^{+(2)})_\rho\otimes(S^{-(2)})_H) \\ &\times(\tilde{F}^{1-s}(\mathcal{L}^2)W^{(s)}_\rho(\theta,\phi)\tilde{F}(\mathcal{L}^2)W^{(0)}_H(\theta,\phi)). \end{aligned} \tag{51}$$

We note that the second term in the above equation is not equal to zero only for the part of the symbol $W^{(0)}_H(\theta,\phi)$ which corresponds to quadratic [on the $su(2)$ algebra generators] terms of the Hamiltonian (8) (the linear part of $W^{(0)}_H(\theta,\phi)$ disappears under the action of the operators $S^{\pm(2)}$). After some algebra the second term on the right-hand side of (51) can be rewritten in the following form

$$-\frac{i}{\sqrt{(2S+3)(S+1)S(2S-1)}}\tilde{F}^{s-1}(\mathcal{L}^2)(\hat{Q}_\rho\otimes\hat{P}_H-\hat{P}_\rho\otimes\hat{Q}_H)(\tilde{F}^{1-s}(\mathcal{L}^2)W^{(s)}_\rho(\theta,\phi)W^{(0)}_H(\theta,\phi)), \tag{52}$$

where we have introduced

$$\hat{Q}=\frac{1}{\sin\theta}\frac{\partial}{\partial\phi}\left(\frac{\partial}{\partial\theta}-\cot\theta\right),$$
$$\hat{P}=\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}-\left(\frac{\partial}{\partial\theta}-\cot\theta\right)\frac{\partial}{\partial\theta}. \tag{53}$$

Here we took into account that $\tilde{F}(\mathcal{L}^2)Y_{2k}(\theta,\phi)=F(2)Y_{2k}(\theta,\phi)$ and, from (14), $F(2)=\sqrt{(2S-2)!(2S+3)!}$. Finally, the evolution equation acquires the form

$$\partial_t W_\rho^{(s)}(\theta,\phi)=2\frac{\sqrt{2S+1}}{(2S+2)!}\tilde{F}^{s-1}(\mathcal{L}^2)\{\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi),\tilde{F}(\mathcal{L}^2)W_H^{(0)}(\theta,\phi)\}_P$$

$$+\frac{1}{2\alpha}\tilde{F}^{s-1}(\mathcal{L}^2)\{\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_{P_1}. \tag{54}$$

where

$$\alpha=1/2\sqrt{(2S+3)(2S-1)S(S+1)} \tag{55}$$

and we defined

$$\{,\}_{P_1}=\hat{P}_\rho\otimes\hat{Q}_H-\hat{Q}_\rho\otimes\hat{P}_H. \tag{56}$$

Obviously, the brackets $\{,\}_{P_1}$ conserve the area on the sphere, i.e.,

$$\int d\Omega\{f,g\}_{P_1}=0, \tag{57}$$

for any two functions defined on the sphere. Separating the Hamiltonian into linear H_1, and quadratic H_2 parts, $H=H_1+H_2$, we get

$$W_H^{(0)}(\theta,\phi)=W_{H_1}^{(0)}(\theta,\phi)+W_{H_2}^{(0)}(\theta,\phi), \tag{58}$$

and Eq. (54) takes the form

$$\partial_t W_\rho^{(s)}(\theta,\phi)=\frac{1}{\sqrt{S(S+1)}}\{W_\rho^{(s)}(\theta,\phi),W_{H_1}^{(0)}(\theta,\phi)\}_P+\frac{1}{2\alpha}\tilde{F}^{s-1}(\mathcal{L}^2)[(2S+3)$$

$$\times\{\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi),W_{H_2}^{(0)}(\theta,\phi)\}_P+\{\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi),W_{H_2}^{(0)}(\theta,\phi)\}_{P_1}]. \tag{59}$$

D. Example

Let us consider, for example, the simplest nonlinear Hamiltonian (for physical applications see, e.g., Refs. 20–22)

$$H=\chi S_z^2. \tag{60}$$

The corresponding $W_H^{(0)}(\theta,\phi)$ symbol has the form

$$W_H^{(0)}(\theta,\phi)=\alpha\frac{4}{3}\sqrt{\frac{\pi}{5}}Y_{20}(\theta,\phi)+\frac{S(S+1)}{3}=\alpha\left(\cos^2\theta-\frac{1}{3}\right)+\frac{S(S+1)}{3}, \tag{61}$$

where α is defined in (55). Taking into account that

$$\{W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P=-2\alpha\cos\theta\partial_\phi W_\rho^{(s)}(\theta,\phi),$$

$$\{\tilde{F}^{1-s}(\mathcal{L}^2)W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P=-2\alpha\cos\theta\tilde{F}^{1-s}(\mathcal{L}^2)\partial_\phi W_\rho^{(s)}(\theta,\phi), \tag{62}$$

and

$$\hat{Q}W_H^{(0)}(\theta,\phi)=0, \quad \hat{P}W_H^{(0)}(\theta,\phi)=2\alpha\sin^2\theta, \tag{63}$$

we obtain from (54)

$$\partial_t W_\rho^{(s)}(\theta,\phi)=-\chi[2(S+1)\tilde{F}^{s-1}(\mathcal{L}^2)\cos\theta\tilde{F}^{1-s}(\mathcal{L}^2) + \tilde{F}^{s-1}(\mathcal{L}^2)\sin\theta\partial_\theta\tilde{F}^{1-s}(\mathcal{L}^2)]\partial_\phi W_\rho^{(s)}(\theta,\phi). \tag{64}$$

One can show (see the Appendix) that Eq. (64) acquires the following forms according to the value of the parameter s:

$$\partial_t W_\rho^{(1)}(\theta,\phi)=-\chi[2(S+1)\cos\theta+\sin\theta\partial_\theta]\partial_\phi W_\rho^{(1)}(\theta,\phi), \tag{65}$$

$$\partial_t W_\rho^{(0)}(\theta,\phi)=-\chi\left[\left(S+\frac{1}{2}\right)\Phi(\mathcal{L}^2)\cos\theta+\varepsilon\Phi^{-1}(\mathcal{L}^2)\left(\frac{3}{2}\cos\theta+\sin\theta\partial_\theta\right)\right]\partial_\phi W_\rho^{(0)}(\theta,\phi), \tag{66}$$

$$\partial_t W_\rho^{(-1)}(\theta,\phi)=-\chi[2S\cos\theta-\sin\theta\partial_\theta]\partial_\phi W_\rho^{(-1)}(\theta,\phi), \tag{67}$$

where the function $\Phi(\mathcal{L}^2)$ is defined as

$$\Phi(\mathcal{L}^2)=[2-\varepsilon^2(2\mathcal{L}^2+1)+2\sqrt{1-\varepsilon^2(2\mathcal{L}^2+1)+\varepsilon^4\mathcal{L}^4}]^{1/2}, \tag{68}$$

and

$$\varepsilon=\frac{1}{2S+1}. \tag{69}$$

One can observe that Eq. (65) is just an equation for the P-function [which can be easily obtained by using the $su(2)$ coherent states method].

E. Large dimensions of representation

Now let us consider the limit of the large dimension of representation, $S\gg 1$ (in this case $\varepsilon \ll 1$). In this limit it is useful to represent the function $\tilde{F}(\mathcal{L}^2)$ in the following form

$$\tilde{F}(\mathcal{L}^2)=\frac{(2S+1)!}{\sqrt{2S+1}}\left(1+\frac{\varepsilon}{2}\mathcal{L}^2+O(\varepsilon^2)\right). \tag{70}$$

Taking into account that

$$\sum_{j=0}^{\infty}\frac{(-x)^j}{j!(2S+j+1)!}=f\left(x\frac{\partial}{\partial x}\right)\exp(-\varepsilon x), \tag{71}$$

where the function $f(z)$ in the above equation is a series on ε,

$$f(z)=1-\frac{\varepsilon}{2}(z^2+z)+O(\varepsilon^2), \tag{72}$$

we can approximate the evolution equation (36) as follows:

$$\partial_t W_\rho^{(s)}(\theta,\phi)\approx 2\varepsilon\{W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P+2\varepsilon^2\Bigg[\frac{1-s}{2}\{\mathcal{L}^2W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P$$
$$+\frac{1}{2}\{W_\rho^{(s)}(\theta,\phi),\mathcal{L}^2W_H^{(0)}(\theta,\phi)\}_P+\left(\frac{s-1}{2}\mathcal{L}^2-1\right)\{W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P$$
$$+\{W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_{P_1}\Bigg]. \tag{73}$$

Taking into account the following relation between $\{,\}_P$ and $\{,\}_{P_1}$:

$$\{f,g\}_{P_1}=(\tfrac{1}{2}\mathcal{L}^2+1)\{f,g\}_P-\tfrac{1}{2}\{\mathcal{L}^2f,g\}_P-\tfrac{1}{2}\{f,\mathcal{L}^2g\}_P, \tag{74}$$

where $f(\theta,\phi)$ and $g(\theta,\phi)$ are functions on the sphere, Equation (73) is rewritten in the form

$$\partial_t W_\rho^{(s)}(\theta,\phi)=2\varepsilon\{W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P+\varepsilon^2 s[\mathcal{L}^2\{W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P$$
$$-\{\mathcal{L}^2W_\rho^{(s)}(\theta,\phi),W_H^{(0)}(\theta,\phi)\}_P]+O(\varepsilon^3). \tag{75}$$

The first term on the right-hand side of Eq. (75) is, as expected, a classical evolution equation [Poisson brackets of the s-ordered quasidistribution function $W_\rho^{(s)}(\theta,\phi)$ and symmetrized Stratonovich–Weyl symbol of the system Hamiltonian]. The second term represents a first correction to the classical evolution equation. One can observe that this correction vanishes when $s=0$, i.e., the first correction to the classical evolution of motion is absent for the Stratonovich–Weyl quasidistribution function.

For example, in the case of the Hamiltonian (60) we get for the symmetrized Stratonovich–Weyl symbol the following approximate equation of motion [corresponding to expansion of the function $\Phi(\mathcal{L}^2)$ in (66) in series on ε]

$$\partial_t W_\rho^{(0)}(\theta,\phi)=-\chi[(2S+1)\cos\theta\partial_\phi+\varepsilon\,\hat{\Xi}]W_\rho^{(0)}(\theta,\phi), \tag{76}$$

where $\hat{\Xi}$ is a diffusion-like operator

$$\hat{\Xi}=-\tfrac{1}{2}[(\cos\theta+1)\mathcal{L}^2+\sin\theta\partial_\theta]\partial_\phi, \tag{77}$$

which describes quantum corrections to the quasiclassical motion in analogy to the quasiclassical expansion in the Moyal equation for the Heisenberg–Weyl group. It is worth noting that in general only the evolution equation for the Stratonovich–Weyl quasidistribution function $W_\rho^{(0)}(\theta,\phi)$ (not for Q- or for P-Beresin symbols) reduces to the classical equation of motion in the limit $\varepsilon\to 0$ [compare, for example, (62) with (65) and (67)].

III. CONCLUSIONS

In summary, we have found exact evolution equations for the s-parametrized family SU(2) quasiprobability distribution functions on the sphere. It was shown that for polynomial [on the generators of the $su(2)$ algebra] Hamiltonians the equation of motion contains a finite number of terms, defined by the degree of nonlinearity of the Hamiltonian. For linear systems the evolution equation reduces to the Liouville equation. We also have given an explicit form of the equation of motion for quadratic systems, which are the most usual in quantum-optical applications (see, e.g., Ref. 23 and references therein). In the limit of the large value of spin ($S\gg 1$) the first term of the quasiclassical expansion is just the Poisson brackets (on the sphere) of the s-ordered quasidistribution function with the symmetrized (Stratonovich–Weyl) symbol of the Hamiltonian.

Connection with the star-product of generalized Weyl symbols on the SU(2) group[11] and its contraction to the Heisenberg-Weyl group will be considered elsewhere.

APPENDIX: DERIVATION OF EQS. (65)–(67)

In this Appendix we obtain Eqs. (65)–(67) starting from Eq. (64).

To transform Eq. (64) to a more simple form we use the following algebraic relations

$$\tilde{F}^{s-1}(\mathcal{L}^2)\cos\theta\tilde{F}^{1-s}(\mathcal{L}^2)Y_{LM}(\theta,\phi)=[\tfrac{1}{2}(f_L+3g_L)\cos\theta+g_L\sin\theta\partial_\theta]Y_{LM}(\theta,\phi), \tag{A1}$$

$$\begin{aligned}&\tilde{F}^{s-1}(\mathcal{L}^2)\sin\theta\partial_\theta\tilde{F}^{1-s}(\mathcal{L}^2)Y_{LM}(\theta,\phi)\\&\quad=[(L+2)(L-1)g_L\cos\theta+\tfrac{1}{2}(f_L-3g_L)\sin\theta\partial_\theta]Y_{LM}(\theta,\phi),\end{aligned} \tag{A2}$$

where

$$f_L=a_L+a_{L+1}^{-1},\quad g_L=\frac{a_L-a_{L+1}^{-1}}{2L+1}, \tag{A3}$$

$$a_L=F^{s-1}(L)F^{1-s}(L-1)=\left(\frac{2S+1-L}{2S+1+L}\right)^{\frac{1-s}{2}}, \tag{A4}$$

and the relation between $F(L)$ and $\tilde{F}(\mathcal{L}^2)$ is given by (24).

One can observe that Eqs. (65) and (67) are obtained directly by substituting (A3) and (A4) and (A1) and (A2) into (64) for values $s=\pm1$. In the following we deduce Eq. (66), when the parameter takes value $s=0$. To this end we rewrite Eq. (A4) as follows:

$$a_L=\frac{\varphi_L}{1+\varepsilon L},\quad a_{L+1}^{-1}=\frac{\varphi_{L+1}}{1-\varepsilon(L+1)}, \tag{A5}$$

where

$$\varphi_L=\sqrt{1+\varepsilon^2L^2}. \tag{A6}$$

Then we obtain from (A1) and (A2)

$$\begin{aligned}&\tilde{F}^{s-1}(\mathcal{L}^2)[2(S+1)\cos\theta+\sin\theta\partial_\theta]\tilde{F}^{1-s}(\mathcal{L}^2)Y_{LM}(\theta,\phi)\\&\quad=\frac{1}{\varepsilon}\left[\frac{\varphi_L+\varphi_{L+1}}{2}\cos\theta+\frac{\varphi_L-\varphi_{L+1}}{2L+1}\left(\frac{3}{2}\cos\theta+\sin\theta\partial_\theta\right)\right]Y_{LM}(\theta,\phi).\end{aligned} \tag{A7}$$

Now we take into account

$$\frac{\varphi_L-\varphi_{L+1}}{2L+1}=\frac{\varepsilon^2}{\varphi_L+\varphi_{L+1}}, \tag{A8}$$

and observe that

$$(\varphi_L+\varphi_{L+1})Y_{LM}(\theta,\phi)=\Phi(\mathcal{L}^2)Y_{LM}(\theta,\phi), \tag{A9}$$

where the operator function $\Phi(\mathcal{L}^2)$ is defined in (68). Equations (A7) and (A9) immediately lead to (66).

An attempt is made to clarify the ballistic nonlinear sigma model formalism recently proposed for quantum chaotic systems, by looking at the spectral determinant $Z(s)=\mathrm{Det}(1-sU)$ for quantized maps $U\in \mathrm{U}(N)$, and studying the correlator $\omega_U(s)=\int d\theta |Z(e^{i\theta}s)|^2$. By identifying $\mathrm{U}(N)$ as one member of a dual pair acting in the spinor representation of $\mathrm{Spin}(4N)$, the expansion of $\omega_U(s)$ in powers of s^2 is shown to be a decomposition into irreducible characters of $\mathrm{U}(N)$. In close analogy with the ballistic nonlinear sigma model, a coherent-state integral representation of $\omega_U(s)$ is developed. For generic U this integral has $\binom{2N}{N}$ saddle points and the leading-order saddle-point approximation turns out to reproduce $\omega_U(s)$ *exactly*, up to a constant factor. This miracle is explained by interpreting $\omega_U(s)$ as a character of $\mathrm{U}(2N)$, and arguing that the leading-order saddle-point result corresponds to the *Weyl character formula*. Unfortunately, the Weyl decomposition behaves nonsmoothly in the semiclassical limit $N\to\infty$, and to make further progress some additional averaging needs to be introduced. Several schemes are investigated, including averaging over basis states and an ''isotropic'' average. The saddle-point approximation applied in conjunction with these schemes is demonstrated to give incorrect results in general, one notable exception being a semiclassical averaging scheme, for which all loop corrections vanish identically. As a side product of the dual pair decomposition with isotropic averaging, the crossover between the Poisson and CUE limits is obtained. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1462417]

I. INTRODUCTION

One of the striking characteristics of a quantized chaotic Hamiltonian system is found in the correlations inherent in its spectrum at small energy differences. Extensive numerical work has shown that various quantities (such as the nearest-neighbor spacing distribution and the two-level correlation function) of a quantum chaotic system are *universal*: their behavior coincides with that of a Wigner–Dyson random matrix ensemble of the appropriate symmetry class.[1] This property, first noticed in billiards, was found to apply to many chaotic systems, including symplectic *maps*. In contrast, if the dynamics is integrable (in the sense that the $2f$-dimensional phase space foliates into f-dimensional submanifolds invariant under the Hamiltonian flow), the generic behavior of the eigenvalues is expected[2] to be that of independent random variables, so that their correlations are in the Poisson universality class.

The present article will be concerned with quantum maps, i.e., with quantizations of some canonical transformation $\phi: M\to M$ of a compact symplectic manifold M. We assume that the problem of quantization itself has been tackled, so the phase space has been prequantized into a Hilbert space $\mathcal{H}_N$ of dimension $N\sim\hbar^{-1}$, and the quantum map acts on it as a unitary operator.[3,4] With respect to a basis of $\mathcal{H}_N$ this operator is represented by an $N\times N$ unitary matrix $U_{\phi,N}$. The latter has a semiclassical limit, in the sense that traces of its powers can be estimated in terms of

classical periodic points.[4] For a system with one degree of freedom, the Gutzwiller-Tabor trace formula reads

$$\mathrm{Tr}(U_{\phi,N}^n) \overset{N\to\infty}{\sim} \sum_{p\subset \mathrm{Fix}(\phi^n)} N^{\dim(p)/2} A_p \mathrm{e}^{\mathrm{i}N\Phi p}, \tag{1}$$

where p is one component of the set of n-periodic points; for an Anosov system, it is an isolated point $[\dim(p)=0]$, whereas if the dynamics conserves energy, p is one-dimensional. Φ_p and A_p are purely classical quantities related to the dynamics around the set p.

The quantum spectrum consists of the N eigenvalues (pseudo-energies) $\{\mathrm{e}^{\mathrm{i}\theta_j}\}_{j=1,\ldots,N}$ of $U_{\phi,N}$. The first analytical estimates of the two-level correlation function [which is the Fourier transform of the *form factor* $F(n)=|\mathrm{Tr}(U_{\phi,N}^n)|^2$] for such spectra were based on the above trace formula, combined with some known ergodic properties of long periodic orbits.[5] In the present article we focus attention on another statistic, namely the autocorrelation function of the spectral determinant:

$$\Omega_U(\gamma) \overset{\mathrm{def}}{=} \gamma^{-N/2} \int_0^{2\pi} \frac{d\phi}{2\pi} \mathrm{Det}(1-\gamma \mathrm{e}^{\mathrm{i}\phi} U)\mathrm{Det}(1-\mathrm{e}^{-\mathrm{i}\phi} U^\dagger). \tag{2}$$

(The parameter γ will be a complex number close to unity, with the scaling $|\gamma-1|\sim 1/N$.) This correlation function has already been considered[6,7] for chaotic versus integrable quantum maps, and the same universality was observed as for the form factor or the nearest-neighbor distribution. A semiclassical analysis of this correlation function was performed using the Gutzwiller trace formula in Ref. 7.

The computation of correlation functions from the trace formula (1) always requires some sort of averaging. In the semiclassical theory of the form factor $F(n)$ one wants to use the so-called diagonal approximation, neglecting the off-diagonal terms in the double-sum over periodic orbits.[5] To justify this step one must average over energy or some family of systems: one needs slight variations in the classical actions Φ_p to make the phase interferences $\sim \mathrm{e}^{\mathrm{i}N(\Phi_p-\Phi_{p'})}$ average to zero. The need for averaging was emphasized in Refs. 6 and 8, where it was pointed out that the spectrum of an individual quantum system is too noisy to allow universality to be seen in its bare form factor. In addition to the noise problem, there exist some quantum chaotic systems with arithmetic symmetries, which lead to periodic orbit degeneracies and nonuniversal spectral correlations.[9,10] (Such systems are nongeneric, however, in any decent space of smooth maps.)

Thus universal behavior is expected only in the generic case, and to make a correct mathematical statement about universality of the spectral correlations of a general system one ought to define the precise meaning of the word "generic." (In the case of integrable systems, the spectral correlations could sometimes be studied directly, by utilizing the explicit expressions for the eigenvalues; two-point correlations were shown to be Poisson for a rather subtle set of parameters.)[11] We can avoid the issue of genericity by averaging the correlation function over some set of quantum maps. That is, we specify a measure $\mathrm{d}\mathcal{P}_N(U)$ on the unitary group $\mathrm{U}(N)$, and the function to be studied then reads

$$\langle \Omega_U(\gamma)\rangle = \int_{\mathrm{U}(N)} \mathrm{d}\mathcal{P}_N(U)\Omega_U(\gamma).$$

We want this measure to be very concentrated (or "local") around the quantum map $U_{\phi,N}$ (see Secs. IV C and VI). In the course of this article, we will also consider cases for which this measure has a broader support (Sec. V), including the case where the measure is the Haar measure on $\mathrm{U}(N)$. We are then dealing with the circular unitary ensemble (CUE), for which the determinant correlation function has been thoroughly investigated.[6,12]

The Gutzwiller trace formula has the attractive feature of relating quantum to classical properties, but its use for estimating the spectral correlation functions still raises questions. The prob-

lem is that the formula is rigorous in general only for times shorter than the Ehrenfest time: $n \leqslant \log N$ (and $N \to \infty$). Yet, long-time traces ($n \sim N$) are needed to obtain spectral correlation functions at the scale of the mean level spacing where universality emerges. The diagonal approximation, which assumes statistical independence of the different periodic orbits, is unsatisfactory at large times where the exponential proliferation of periodic orbits clashes with the finite (N) number of eigenvalues: the classical information is then overcomplete, which implies some sort of hidden correlation between the contributions from classical orbits. A recipe to overcome this difficulty has been devised by Bogomolny and Keating,[13] but so far lacks rigorous justification.

To bypass these problems, a second approach to estimate spectral correlations has recently emerged, inspired by the study of disordered metals. It consists in expressing the correlation function as a quantum field theory (or functional integral) of the type of a nonlinear sigma model (NLσM). One then tries to analyze the functional integral by standard field-theoretic methods such as perturbation expansion, saddle-point analysis and the renormalization group. This approach was first applied successfully to systems with disorder, where the dynamics is governed by a diffusion operator.[14] The formalism was later extended to the ''ballistic case,'' [15,16] and quantum correlation functions were put in relation with the spectrum of the Frobenius–Perron operator (i.e., the evolution operator for classical densities). Although quite elegant, this approach suffered from several drawbacks. Among these are the appearance of unwanted zero modes around the main saddle point, and the problem of ''mode locking.'' [17] Besides, the results do not exactly agree with the correlations calculated numerically for the Riemann zeta function (the prototype of a quantum chaotic spectral determinant);[13] nor do they explain the nongeneric spectral correlations featured by systems with arithmetic symmetries. More recent treatments of the ballistic NLσM have also stressed the need for averaging over a smooth disorder if one wants to avoid the above problems.[18,19]

In an attempt to resolve these uncertainties, we have adapted the latter approach, which had originally been conceived for Hamiltonian systems, to the case of quantum maps $U_{\phi,N}$. Our objective was to prove the universality of the determinant correlation function $\Omega_U(\gamma)$ (Sec. II B) upon averaging wrt a suitable measure on U(N). This correlation function is easier to treat than the two-level correlation function, as it does not require the use of a supersymmetric representation[15,16] but can be expressed as an ordinary c-number integral over a finite-dimensional manifold $\mathcal{M}_N$ (Sec. II D). We write this integral in the form

$$\Omega_U(\gamma) = \int_{\mathcal{M}_N} dQ \mathrm{e}^{-S(\gamma,U,Q)}, \tag{3}$$

where $S(\gamma,U,\cdot)$ is called the *effective action*.

For the reasons stated, we will consider averages of Ω_U with respect to certain probability measures $\mathrm{d}\mathcal{P}_N(U)$. The averaged correlation function, denoted by $\langle \Omega_U(\gamma) \rangle$, can still be obtained by integrating the Boltzmann weight given by an effective action:

$$\langle \Omega_U(\gamma) \rangle = \int_{\mathcal{M}_N} dQ \mathrm{e}^{-S_{\mathrm{av}}(\gamma,Q)}.$$

To estimate these integrals, we apply the same technique that was used in Ref. 15: we expand $S_{\mathrm{av}}(\gamma,Q)$ up to quadratic order around its saddle-points Q_{crit}, and perform the Gaussian integrals. The result obtained in this way,

$$\langle \Omega_U(\gamma) \rangle_{|\text{s.p. exp.}} = \sum_{Q_{\mathrm{crit}}} \{\mathrm{Det}\delta^2 S_{\mathrm{av}}(\gamma,Q_{\mathrm{crit}})\}^{-1/2} \mathrm{e}^{-S_{\mathrm{av}}(\gamma,Q_{\mathrm{crit}})}, \tag{4}$$

is called the leading-order saddle-point expansion of the integral.

Owing to the absence of a large parameter in front of the action S_{av}, the expansion is *a priori* not justified mathematically. A more careful treatment should in principle include perturbative corrections around each critical point (we actually compute the expansion up to two loops in a particular case, see Sec. IV D).

We have succeeded in computing the leading-order term for a few averaging schemes. For an individual matrix U_N we can actually reproduce the exact value of the correlation function (3) in this way (Sec. III). In Sec. IV C we define a ''semiclassical'' averaging scheme, which we think is a good candidate to obtain universality of correlations;[20] unfortunately, in that case we can only compute the contributions from the two standard saddle points.

In order to test the leading-order saddle-point approximation, we selected a sequence of statistical ensembles [i.e., a sequence of measures $\mathrm{d}\mathcal{P}_N(U)$] for which the averaged correlation function can be computed exactly, and compared the exact result with the saddle-point approximation for the corresponding effective action. All these ensembles are U(N)-rotation invariant, that is, we first average over all bases of $\mathcal{H}_N$ (Sec. V), then possibly over the spectrum of U_N (Secs. V C and VI A). In most cases, the saddle-point expansion of these ensembles yields erroneous results. We still hope that the expansion is better behaved in the case of local averages, like the semiclassical one.

These disappointing results seem to challenge the use of NLσM methods for the study of quantum ballistic systems, unless our understanding and control of these methods significantly improves. In Sec. VI, we introduce a U(N)-isotropic local averaging scheme which we treat by an alternative method; unfortunately, this scheme does not discriminate between the different universal behaviors that are expected for chaotic versus integrable maps. Nevertheless, we use it in Sec. VI A to compute the correlations along a crossover between the Poisson and CUE universality classes.

II. ALGEBRAIC MANIPULATION OF Ω_U

A. Fourier decomposition of Ω_U

We first remind the reader of some known results concerning the correlation function Ω_U.[6,7] The spectral determinant of $U \in \mathrm{U}(N)$ may be expanded as

$$\mathrm{Det}(1-sU)=\sum_{k=0}^{N} s^k a_k(U). \tag{5}$$

The unitarity of U implies a ''self-inversive'' property for the secular coefficients:[21]

$$a_{N-k}(U)=\mathrm{Det}(-U)a_k(\overline{U}).$$

Each coefficient a_k may be obtained from the traces $\{t_l=\mathrm{Tr}U^l\}$ by

$$a_k=-\frac{1}{k}\left(t_k+\sum_{l=1}^{k-1} a_l t_{k-l}\right)=\frac{(-1)^k}{k!}\begin{vmatrix} t_1 & t_2 & t_3 & \dots & t_k \\ 1 & t_1 & t_2 & \dots & t_{k-1} \\ 0 & 2 & t_1 & \ddots & t_{k-2} \\ 0 & 0 & 3 & & \vdots \\ \vdots & \ddots & & & \vdots \\ 0 & \dots & \dots & k-1 & t_1 \end{vmatrix}.$$

Because this dependence is highly nonlinear, the secular coefficients inherit non-Gaussian distributions in the RMT ensembles.[6] However, to compute the ensemble averages of $\Omega_U(\gamma)$ one only needs to know their variances, since

$$\Omega_U(\gamma)=\sum_{k=0}^{N}\ \gamma^{k-N/2}\ |a_k|^2=\sum_{k=0}^{N/2}\ (\gamma^{k-N/2}+\gamma^{N/2-k})|a_k|^2. \tag{6}$$

For the Poisson and the CUE ensemble of random matrices, these variances were computed in Ref. 6, and have the following large-N asymptotics:

$$\langle|a_k|^2\rangle_{\text{Poisson}}=\binom{N}{k},\quad \langle|a_k|^2\rangle_{\text{CUE}}=1, \tag{7}$$

$$\langle\Omega_U(e^{ix/N})\rangle_{\text{Poisson}}\sim 2^N,\quad \langle\Omega_U(e^{ix/N})\rangle_{\text{CUE}}\sim N\frac{\sin(x/2)}{x/2}. \tag{8}$$

In Ref. 7, a semiclassical estimation of the $|a_k|^2$ was given for integrable and chaotic quantum maps. The authors used the explicit expression in terms of the traces t_l, and estimated the latter by the Gutzwiller trace formula (1). They made a generalized diagonal approximation treating the traces t_l as statistically independent variables. To obtain the correlation function, one has to estimate the $|a_k|^2$ (and hence the t_k) up to times $k\lesssim N/2$, where the Gutzwiller formula is nonrigorous.

B. Representation-theoretic content of Ω_U

We now introduce a more group-theoretic expression for the correlation function. Instead of performing the expansion (5), we will express $\Omega_U(\gamma)$ as a *character* in a certain irreducible representation of U($2N$), which is best described using the physical language of fermions.

Let $\mathcal{F}_N$ be the Fock space for N types of fermions f_i, $f_i^\dagger$. In mathematics $\mathcal{F}_N$ is known as the spinor representation space of the group Spin($2N$). Then, for any $N\times N$ unitary matrix U,

$$\mathrm{Det}(1-U)=\mathrm{Tr}_{\mathcal{F}_N}(-1)^{\sum_i f_i^\dagger f_i}\exp\sum_{i,j=1}^{N} f_i^\dagger(\log U)_{ij}f_j.$$

The exponential on the right-hand side can be shown to be well defined in spite of the multivaluedness of $\log U$. To account for both determinants, we use $2N$ fermions, whose creation operators are denoted by $f_{+j}^\dagger$ and $f_{-j}^\dagger$, $j=1,\ldots,N$. The integration over ϕ in the integral (2) projects on the subspace $\mathcal{F}\underset{\text{def}}{=}\mathrm{Ker}(F_+-F_-)$, where $F_\pm=\Sigma_i f_{\pm i}^\dagger f_{\pm i}$ are the number operators for the two types of fermions. The correlation function reads

$$\Omega_U(\gamma)=\mathrm{Tr}_{\mathcal{F}}\gamma^{(F_++F_--N)/2}\exp\sum_{i,j=1}^{N}(\log U)_{ij}(f_{+i}^\dagger f_{+j}-f_{-j}^\dagger f_{-i}). \tag{9}$$

The operator under the trace belongs to an irreducible representation R of the group U($2N$), realized on the space $\mathcal{F}$, which has dimension $\binom{2N}{N}$. This representation may be defined through its Lie algebra version: any skew-Hermitian $2N\times 2N$ matrix $\mathbf{X}=\left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right)$ is represented by the operator

$$R(\mathbf{X})=\sum_{i,j=1}^{N} a_{ij}f_{+i}^\dagger f_{+j}+b_{ij}f_{+i}^\dagger f_{-j}^\dagger+c_{ij}f_{-i}f_{+j}+d_{ij}f_{-i}f_{-j}^\dagger. \tag{10}$$

By exponentiating, $R(\exp\mathbf{X})=\exp R(\mathbf{X})$, we obtain a U($2N$)-representation, which we still denote by R. The correlation function $\Omega_U(\gamma)$ for any $N\times N$ unitary matrix U may be recast as a character in this representation:

$$\Omega_U(\gamma)=\gamma^{-N/2}\mathrm{Det}(U)^{-1}\ \mathrm{Tr}\,R(\Gamma\mathbf{U}) \tag{11}$$

where

$$\mathbf{U} \overset{\text{def}}{=} \begin{pmatrix} U & 0 \\ 0 & U \end{pmatrix}, \quad \Gamma \overset{\text{def}}{=} \begin{pmatrix} \gamma & 0 \\ 0 & 1 \end{pmatrix} \in \mathrm{U}(2N).$$

As it stands, the construction assumes $\gamma = e^{i\theta} \in \mathrm{U}(1)$. It can also be used for other values of γ, since R naturally extends to a representation of $\mathrm{GL}(2N, \mathbb{C})$. In the following, matrices in bold print will always be of size $2N \times 2N$.

The assignment $U \mapsto \mathbf{U}$ embeds $\mathrm{U}(N)$ into $\mathrm{U}(2N)$. By this embedding, R restricts to a *reducible* representation of $\mathrm{U}(N)$ on $\mathcal{F}$, which we simply denote by $R(U)$. To express the correlation function, we may also consider the $\mathrm{U}(N)$-representation $R_{-1}(U) \overset{\text{def}}{=} \det(U)^{-1} R(U)$.

In the next section, we decompose $R(U)$ [or equivalently $R_{-1}(U)$] into irreducible representations (irreps) of $\mathrm{U}(N)$, thus expressing the correlation function $\Omega_U(\gamma)$ as a sum of $\mathrm{U}(N)$-characters.

C. Ω_U as a sum of U(N)-characters

The crucial mathematical tool to use is the *dual pair* structure.[22] The subalgebra $\{X_N \otimes \mathbb{I}_2 \,|\, X_N \in \mathfrak{u}(N)\}$ of $\mathfrak{u}(2N)$ commutes with the subalgebra $\{\mathbb{I}_N \otimes x_2 \,|\, x_2 \in \mathfrak{u}(2)\}$, and each is the commutant of the other inside $\mathfrak{u}(2N)$: they are said to form a dual pair. This means that for all $U \in \mathrm{U}(N)$, the operator $R(U)$ commutes with the set

$$J_\uparrow = \sum_i f_{+i}^\dagger f_{-i}^\dagger,$$

$$J_\downarrow = \sum_i f_{-i} f_{+i},$$

$$J_0 = F_+ + F_- - N.$$

The operators J_0, $J^\uparrow$ and $J^\downarrow$ generate an $\mathfrak{su}(2)$ algebra. The equation $J_0 R(U) = R(U) J_0$ implies that $R(U)$ conserves the total number of particles and hence acts inside the subspaces $\mathcal{F}^p = \mathcal{F} \cap \mathrm{Ker}(F_+ + F_- - 2p)$.

The dual pair structure provides us with a prescription[22] to decompose $R(U)$. Inside the reduced Fock space $\mathcal{F}$, we consider the subspace of lowest SU(2) weights, ${}^0\mathcal{F} = \mathcal{F} \cap \mathrm{Ker} J_\downarrow$, and expand it according to its particle content: ${}^0\mathcal{F}^p \overset{\text{def}}{=} {}^0\mathcal{F} \cap \mathcal{F}^p$. Classical results of invariant theory, due mostly to H. Weyl[23] and succinctly summarized by R. Howe,[22] amount to the following statements:

(i) The operator $R(U)$ acts inside each space ${}^0\mathcal{F}^p$, through a certain irrep $\tilde{\rho}_p(U)$ of $\mathrm{U}(N)$. Equivalently, $R_{-1}(U)$ acts on this space through $\rho_p(U) = \mathrm{Det}(U)^{-1} \tilde{\rho}_p(U)$. Furthermore, two irreps ρ_p and $\rho_{p'}$ are inequivalent if $p \neq p'$.

(ii) The image of ${}^0\mathcal{F}^p$ under $(J_\uparrow)^k$ is the space ${}^k\mathcal{F}^{p+k} \subset \mathcal{F}^{p+k}$ which is either trivial (if $k > N - 2p$) or carries the irrep ρ_p (if $k \leqslant N - 2p$). The operators $J_\uparrow$, $J_\downarrow$, J_0 act on this tower of spaces according to the $\mathfrak{su}(2)$-irrep of dimension $N - 2p + 1$.

(iii) The direct sum of these towers exhausts $\mathcal{F}$.

We summarize these statements in the following diagram. All entries in a given row are subspaces containing the same number of fermions; all entries in a given column (or tower) carry the same $\mathrm{U}(N)$-irrep. We only show the case where N is an even integer (the odd-N case being very similar):

$$
\begin{array}{lcccccccc}
\mathcal{F}^N & = & {}^N\mathcal{F}^N & & & & & & \\
 & & \uparrow J_\uparrow & & & & & & \\
\mathcal{F}^{N-1} & = & {}^{N-1}\mathcal{F}^{N-1} & \oplus & {}^{N-2}\mathcal{F}^{N-1} & & & & \\
\vdots & & \uparrow J_\uparrow & & \uparrow J_\uparrow & & \ddots & & \\
\vdots & & \vdots & & \vdots & & & & {}^0\mathcal{F}^{N/2} \\
\vdots & & \uparrow J_\uparrow & & \uparrow J_\uparrow & & \uparrow J_\uparrow & & \\
\mathcal{F}^2 & = & {}^2\mathcal{F}^2 & \oplus & {}^1\mathcal{F}^2 & \oplus & {}^0\mathcal{F}^2 & & \\
 & & \uparrow J_\uparrow & & \uparrow J_\uparrow & & & & \\
\mathcal{F}^1 & = & {}^1\mathcal{F}^1 & \oplus & {}^0\mathcal{F}^1 & & & & \\
 & & \uparrow J_\uparrow & & & & & & \\
\mathcal{F}^0 & = & {}^0\mathcal{F}^0 & & & & & & \\
U(N)-\text{irreps:} & & \rho_0 & & \rho_1 & & \rho_2 & \cdots & \rho_{N/2}
\end{array}
\tag{12}
$$

The leftmost tower on the right-hand side carries the trivial $\mathfrak{u}(N)$-irrep, so all spaces ${}^p\mathcal{F}^p = (J_\uparrow)^p\,{}^0\mathcal{F}^0$ are one-dimensional.

Each irrep ρ_p (or $\tilde{\rho}_p$) may be described by a Young diagram. ρ_p mixes the action of U on p fermions f_+ with the action of $\overline{U}$ on p fermions f_-. Owing to antisymmetrization, it corresponds to the diagram with p rows of length 2 followed by $N-2p$ rows of length one:

$$\tilde{\rho}_p(U_N) = \mathrm{Det}(U_N)\rho_p(U_N) = U_N^{[2^p\,1^{N-2p}]}.$$

In view of the above diagram, the dimensions of the representation spaces ${}^k\mathcal{F}^{k+p}$ follow immediately from those of the spaces $\mathcal{F}^p$:

$$\dim({}^k\mathcal{F}^{k+p}) = \dim(\mathcal{F}^p) - \dim(\mathcal{F}^{p-1}) = \binom{N}{p}^2 - \binom{N}{p-1}^2. \tag{13}$$

By doing the sum over each $\mathfrak{su}(2)$-multiplet we can now express the correlation function (11) in terms of the irreps ρ_p:

$$\Omega_U(\gamma) = \sum_{p=0}^{N/2} \mathrm{Tr}\rho_p(U)\,\frac{\gamma^{p-N/2} - \gamma^{N/2+1-p}}{1-\gamma}, \tag{14}$$

or, making the substitution $\gamma = \mathrm{e}^{\mathrm{i}x/N}$,

$$\Omega_U(\mathrm{e}^{\mathrm{i}x/N}) = \sum_{p=0}^{N/2} \mathrm{Tr}\rho_p(U)\,\frac{\sin\{(x/2)\,[1-(2p-1)/N]\}}{\sin(x/2N)}.$$

For large values of N we may replace the denominator $\sin(x/2N)$ by $x/2N$. A quick comparison shows that this decomposition is actually equivalent to the pedestrian expansion (6) written down in Sec. II A. The squared coefficients $|a_k|^2$ now acquire a representation-theoretic meaning:

$$\forall p \leqslant N/2: \quad |a_p(U)|^2 = \mathrm{Tr}_{\mathcal{F}^p} R_{-1}(U) = \sum_{k=0}^{p} \mathrm{Tr}\rho_k(U), \tag{15}$$

or, equivalently,

$$\mathrm{Tr}\rho_p(U) = |a_p(U)|^2 - |a_{p-1}(U)|^2.$$

As it stands, the decomposition into irreducibles (14) is not very informative if one takes for U the matrix of a quantum map. We have no way *a priori* to estimate the character $\mathrm{Tr}\rho_p(U_N)$ from semiclassical information, except by using the relationship, via the $|a_k|^2$, to the original traces $\mathrm{Tr}(U_N^k)$, as was done in Ref. 7. This decomposition will, however, allow us to obtain rigorous results when adopting a $\mathrm{U}(N)$-isotropic averaging centered around U_N (see Sec. VI).

D. Ω_U as a coherent-state integral

Instead of decomposing the character $\mathrm{Tr}R_{-1}(U)$ into irreducibles, we can rewrite it as an integral over the symmetric space $\mathcal{M}_N=\mathrm{U}(2N)/\mathrm{U}(N)\times\mathrm{U}(N)$. This integral can be interpreted as a variant of the nonlinear sigma model used in Ref. 15 to study the spectral statistics of quantum chaotic Hamiltonians on infinite-dimensional Hilbert spaces. In our case the integral representation is exact, and is well defined mathematically.

To write the character $\Omega_U(\gamma)$ as an integral, one uses the coherent states $R(\mathbf{g})|0\rangle$, where $|0\rangle$ is the vacuum of $\mathcal{F}$ and $\mathbf{g}$ is any matrix in $\mathrm{U}(2N)$.[24] These coherent states provide a resolution of unity on $\mathcal{F}$, i.e., they can be combined to build the orthogonal projector on $\mathcal{F}$, as

$$P_{\mathcal{F}}\overset{\text{def}}{=}\int_{\mathrm{U}(2N)} d\mathbf{g}\quad R(\mathbf{g})|0\rangle\langle 0|R(\mathbf{g})^{-1},$$

where the Haar measure $d\mathbf{g}$ has to be suitably normalized. Let H_N be the block-diagonal subgroup $\mathrm{U}(N)\times\mathrm{U}(N)$ of $\mathrm{U}(2N)$. Then for all $\mathbf{h}\in H_N$, the states $R(\mathbf{g})|0\rangle$ and $R(\mathbf{gh})|0\rangle$ only differ by a phase factor. Therefore, it suffices to integrate over the equivalence classes in $\mathrm{U}(2N)$ modulo H_N:

$$P_{\mathcal{F}}=\int_{\mathrm{U}(2N)/H_N} d[\mathbf{g}]_H R(\mathbf{g})|0\rangle\langle 0|R(\mathbf{g})^{-1}.$$

It is convenient to represent the H_N-equivalence classes (i.e., the points on $\mathcal{M}_N$) by $2N\times 2N$ matrices. To each $\mathbf{g}\in\mathrm{U}(2N)$ one associates $Q_{\mathbf{g}}=\mathbf{g}\Sigma_3\mathbf{g}^{-1}$, where $\Sigma_3=\mathbb{I}_N\otimes\sigma_3$. The set of all these matrices Q is isomorphic to $\mathcal{M}_N$. It is the set of all Hermitian matrices with two eigenvalues, $+1$ and -1, each with multiplicity N. This nonlinear set of matrices is naturally equipped with $\mathrm{U}(2N)$-invariant symplectic structure and metric (and therefore an invariant measure dQ).

The matrix elements Q_{ij} are not all independent, and for practical calculations we need to introduce a bona fide coordinate system on $\mathcal{M}_N$. If we denote by $Q_{\mathbf{12}}$, $Q_{\mathbf{22}}$ the two $N\times N$ blocks in the right half of the matrix Q, the entries of the complex matrix $Z=Q_{\mathbf{12}}(Q_{\mathbf{22}}-1)^{-1}$ are good coordinates on the open subset of $\mathcal{M}_N$ where $(Q_{\mathbf{22}}-1)$ is invertible. Geometrically, these $N\times N$ complex coordinates represent a certain stereographic mapping of $\mathcal{M}_N$ onto $\mathbb{C}^{N\times N}$. The matrix Z corresponding to a point $Q_{\mathbf{g}}$ can be extracted from the Gaussian decomposition of $\mathbf{g}$:

$$\mathbf{g}=\begin{pmatrix}1 & Z\\ 0 & 1\end{pmatrix}\begin{pmatrix}A & 0\\ C & D\end{pmatrix}. \tag{16}$$

These complex coordinates also provide a simple definition of the coherent states. Indeed, $R(\mathbf{g})|0\rangle$ is co-linear with

$$|Z\rangle\overset{\text{def}}{=}\exp\left\{\sum_{i,j=1}^{N} f_{+i}^{\dagger}Z_{ij}f_{-j}^{\dagger}\right\}|0\rangle=\exp\left\{R\begin{pmatrix}0 & Z\\ 0 & 0\end{pmatrix}\right\}|0\rangle=R\begin{pmatrix}1 & Z\\ 0 & 1\end{pmatrix}|0\rangle. \tag{17}$$

As it stands, $|Z\rangle$ is not normalized, but has the following properties:

(i) The overlap between two coherent states reads $\langle Z|Z'\rangle=\mathrm{Det}(1+Z^{\dagger}Z')$. In particular, the norm of $|Z\rangle$ is $\mathrm{Det}(1+Z^{\dagger}Z)^{1/2}$.

(ii) The resolution of unity takes the form

$$P_{\mathcal{F}}=\int_{\mathbb{C}^{N\times N}} d\mu_N(Z,Z^\dagger)\frac{|Z\rangle\langle Z|}{\mathrm{Det}(1+Z^\dagger Z)}, \tag{18}$$

where the measure $d\mu_N(Z,Z^\dagger)=C_N\times\mathrm{Det}(1+Z^\dagger Z)^{-2N}\Pi_{i,j=1}^N d^2Z_{ij}/\pi$ is the expression for dQ in the coordinates Z_{ij}. The value of the normalization factor C_N is given at the end of Appendix B.

(iii) The group $\mathrm{U}(2N)$ acts on these coherent states as follows:

$$R\begin{pmatrix} A & B \\ C & D \end{pmatrix}|Z\rangle=\mathrm{Det}(CZ+D)\,|(AZ+B)(CZ+D)^{-1}\rangle. \tag{19}$$

The resolution of unity allows us to write the character (11) as

$$\begin{aligned}\Omega_U(\gamma)&=\gamma^{-N/2}\mathrm{Det}(U)^{-1}\int_{\mathcal{M}_N} d[\mathbf{g}]_H\ \langle 0|R(\mathbf{g})^{-1}R\begin{pmatrix}\gamma U & 0\\ 0 & U\end{pmatrix}R(\mathbf{g})|0\rangle\\ &=\gamma^{-N/2}\int_{\mathbb{C}^{N\times N}} d\mu_N(Z,Z^\dagger)\ \frac{\mathrm{Det}(1+\gamma Z^\dagger UZU^{-1})}{\mathrm{Det}(1+Z^\dagger Z)}\\ &=\int_{\mathcal{M}_N} dQ\ \ \mathrm{e}^{-S(\gamma,U,Q)}.\end{aligned} \tag{20}$$

This expression is the central result of the current section. It is an exact formula, which parallels the ''ballistic'' nonlinear sigma model derived in Ref. 15 for Hamiltonian systems with an infinite-dimensional Hilbert space. In our finite-dimensional framework, the non local field $Q(q',q)$ of 4×4 supermatrices on configuration space is replaced by a ''lattice field'' $Q_{i\alpha,j\beta}$ of 2×2 matrices (with elements indexed by α,β) depending on two discrete positions i,j. The ''effective action'' of the present model,

$$S(\gamma,U,Q)=-\mathrm{Tr}\{\log(1+\gamma Z^\dagger UZU^{-1})-\log(1+ZZ^\dagger)\}+\frac{N}{2}\log\gamma, \tag{21}$$

can be presented[17] in the form

$$S(\mathrm{e}^{\mathrm{i}x/N},U,Q)=-\mathrm{Tr}\log[\cosh(H_{x,U})-\sinh(H_{x,U})Q],$$

with

$$H_{x,U}\overset{\mathrm{def}}{=}\frac{\mathrm{i}x}{4N}\Sigma_3+\frac{1}{2}\log\mathbf{U}.$$

In Ref. 17, this action was further transformed, using the Wigner representation of wave functions, to obtain the same ballistic non-linear sigma model as in Ref. 15. We will not perform these steps, which require some further approximations, but rather try to estimate the integral with the above (purely quantum) effective action.

III. SADDLE-POINT ANALYSIS OF THE ACTION $S(\gamma,U,Q)$

To estimate the field integral of their nonlinear sigma model, the authors in Ref. 15 expand the effective action around two critical points (usually referred to as saddle points in this context). Since there is no large parameter in front of this action, a leading-order saddle-point expansion—see Eq. (4)—is not justified mathematically *a priori*. In the present section we explicitly compute this expansion for the action (21) and compare it to the results of Ref. 15 and the exact correlation function.

The saddle points are determined by requiring the variation of the action to be zero. In the absence of a large parameter, one first needs to understand exactly which action to vary. This point is not entirely obvious: one might be tempted to lift (part of) the denominator $\mathrm{Det}(1+ZZ^\dagger)^{-2N}$ of the measure $d\mu_N(Z,Z^\dagger)$ into the exponent; this modification of the effective action would yield a different saddle-point expansion. However, the requirement of coordinate invariance tells us to keep the U($2N$)-invariant measure dQ as it is, forbidding such manipulations. With this convention the saddle-point expansion of $S(\gamma,U,Q)$ will turn out to yield *the exact* γ*-dependence* for $\Omega_U(\gamma)$. In particular, the problem of "unphysical zero modes" occurring in Refs. 15 and 17 is resolved.

We now describe the saddle-point analysis of $S(\gamma,U,Q)$ in some detail. We first use the fact that the action is invariant under simultaneous rotations of both U and Q:

$$S(\gamma,U,Q)=S(\gamma,VUV^{-1},\mathbf{V}Q\mathbf{V^{-1}}), \tag{22}$$

where we used the shorthand notation $\mathbf{V}=V\otimes\mathbb{I}_2$, for $V\in\mathrm{U}(N)$. Such a V-rotation of Q is an isometry of the Riemannian manifold $\mathcal{M}_N$ and leaves the measure dQ invariant. It therefore suffices to study the simpler situation where U is *diagonal*: $U\equiv D=\mathrm{diag}(e^{i\theta_j})$.

One sees from formula (21) that the point $Z=0$ (or equivalently, $Q=\Sigma_3$) is a saddle point, and the quadratic approximation to S for small Z reads

$$S(\gamma,D,Z)\approx\frac{1}{2}N\log\gamma-\mathrm{Tr}(\gamma Z^\dagger DZD^{-1}-Z^\dagger Z)\approx\frac{1}{2}N\log\gamma+\sum_{i,j=1}^{N}|Z_{ij}|^2(1-\gamma e^{i(\theta_i-\theta_j)}).$$

This saddle point is the only one on $\mathcal{M}_N$ which is located at a finite Z. It is sometimes called the "perturbative" saddle point in the physics literature. For a generic matrix U, there are N directions Z_{jj} that have a coefficient $(1-\gamma)\sim-ix/N$; these directions are called "zero modes,"[15] because their coefficient vanishes as $x\to0$. Doing the integral in this quadratic approximation around $Z=0$ yields

$$\Omega_U(\gamma)_{|\Sigma_3}=C_N\frac{\gamma^{-N/2}}{(1-\gamma)^N\Pi_{i\neq j}(1-\gamma e^{i(\theta_i-\theta_j)})}. \tag{23}$$

We chose to separate the zero mode contributions from the others.

The existence of a second saddle point was pointed out (in the context of the diffusive nonlinear sigma model) in Ref. 25. It may be exhibited through the change of variable $Z'=1/Z$, which amounts to switching to the stereographic projection of $\mathcal{M}_N$ from the antipodal point. In terms of the new variable Z', the integrand reads

$$\gamma^{N/2}\frac{\mathrm{Det}(1+\gamma^{-1}Z'^\dagger UZ'U^{-1})}{\mathrm{Det}(1+Z'^\dagger Z')},$$

so it has the same structure as the original integrand, but for the replacement $\gamma\to\gamma^{-1}$. Quadratic expansion around $Z'=0$ (or, equivalently, around $Q=-\Sigma_3$) yields

$$\Omega_U(\gamma)_{|-\Sigma_3}=C_N\frac{\gamma^{N/2}}{(1-\gamma^{-1})^N\Pi_{i\neq j}(1-\gamma^{-1}e^{i(\theta_i-\theta_j)})}. \tag{24}$$

These two saddle points $Q=\pm\Sigma_3$ (we call them "standard") are the only ones taken into account in the treatment of the ballistic nonlinear sigma model in Refs. 15 and 17. The problem with this approximation is that, in the limit $\gamma\to1$, the sum of the two contributions Eq. (23) and (24) diverges at least as strongly as $1/(1-\gamma)^{N-1}$, whereas the exact correlation function is bounded. This phenomenon was attributed to the $N-1$ "unphysical" zero modes appearing at each saddle

point (as opposed to the single ''ergodic'' zero mode $\Sigma_j Z_{jj}$). More generally, these contributions become singular each time U and γU happen to have common eigenvalues.

We will argue below that this problem with zero modes is actually resolved by taking into account *further* saddle points of the effective action.

A. Weyl character formula

To identify all saddle points, we return to the expression (20) of the integrand. We still study the case where $U=D$ is diagonal, and we write $\Gamma\mathbf{D}\equiv\mathrm{diag}(\gamma D,D)$.

Let ζ be a complex $N\times N$ matrix. The point $Q_{\mathbf{g}}$ of $\mathcal{M}_N$ is a saddle point of the integrand iff the Taylor expansion of $\langle\zeta|R(\mathbf{g}^{-1}\Gamma\mathbf{D}\mathbf{g})|\zeta\rangle$ around $\zeta=0$ contains no term linear in ζ and $\zeta^\dagger$. (Note that this statement is independent of the choice of representative $\mathbf{g}$ for $Q_{\mathbf{g}}$.) Moreover, we do not want the integrand to vanish at $\zeta=0$. If we decompose the unitary matrix as $\mathbf{g}^{-1}\Gamma\mathbf{D}\mathbf{g}=\left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right)$, these conditions read

$$b=c=0, \quad \mathrm{Det}(d)\neq 0. \tag{25}$$

This means that the matrix $\mathbf{g}^{-1}\Gamma\mathbf{D}\mathbf{g}$ [for $\gamma=\mathrm{e}^{\mathrm{i}x/N}\in\mathrm{U}(1)$] belongs to the subgroup H_N of $\mathrm{U}(2N)$, which in turn allows $\mathbf{g}$ to be written as the product of a *permutation matrix* $\mathbf{g}_\sigma$ with some element $\mathbf{h}\in H_N$. By $\mathbf{g}_\sigma$ we mean the unitary matrix $(\mathbf{g}_\sigma)_{ij}=\delta_{i,\sigma(j)}$, where σ is a permutation of $\{1,\ldots,2N\}$. To each permutation σ there corresponds a single point $Q_\sigma=\mathbf{g}_\sigma\Sigma_3\mathbf{g}_\sigma{}^{-1}$. Moreover, two permutations σ, σ' lead to the same point if $\sigma=\sigma'\tau$ where τ permutes indices separately inside $\{1,\ldots,N\}$ and $\{N+1,...,2N\}$; this property defines a partition of the symmetric group $\mathfrak{S}_{2N}$ into $\binom{2N}{N}$ equivalence classes, each one corresponding to a saddle point of the integrand.

These classes are in one-to-one correspondence with the sets $S=\sigma(\{1,\ldots,N\})$, so we can write $Q_\sigma=Q_S$. Q_S is then the diagonal matrix with entries $+1$ at the positions $j\in S$, and -1 at the positions $j\in\overline{S}$ (the complement of S in $\{1,\ldots,2N\}$). We partition the set S into $S_1=S\cap\{1,\ldots,N\}$ and $\widetilde{S}_2=S\cap\{N+1,\ldots,2N\}$. In the following we will also use the set $S_2=\{j-N|j\in\widetilde{S}_2\}$, and the sets $\overline{S_1}$ and $\overline{S_2}$ which are the complements in $\{1,\ldots,N\}$ of S_1, resp. S_2. The point Q_S corresponds to the following (coherent) state in $\mathcal{F}$:

$$|S\rangle\overset{\mathrm{def}}{=}R(\mathbf{g}_\sigma)|0\rangle=\pm\prod_{i\in\overline{S_1}} f^\dagger_{+i}\prod_{j\in S_2} f^\dagger_{-j}|0\rangle. \tag{26}$$

The matrix $\mathbf{g}_\sigma$ admits a Gaussian decomposition (16) iff σ is in the trivial class, i.e., $S=\{1,\ldots,N\}$, which explains why only the perturbative saddle point $Q=\Sigma_3$ could be exhibited from the Z-coordinates.

We now compute the leading-order contribution from each saddle point Q_S. In the vicinity of Q_S the integrand in (20) takes the values

$$\langle\zeta|R(\mathbf{g}_\sigma^{-1}\Gamma\mathbf{D}\mathbf{g}_\sigma)|\zeta\rangle/\langle\zeta|\zeta\rangle,$$

where the entries of the matrix ζ are ''small'' (ζ defines a local coordinate system near Q_S). We partition the diagonal matrix $\mathbf{g}_\sigma^{-1}\Gamma\mathbf{D}\mathbf{g}_\sigma$ into two halves: $\mathbf{g}_\sigma^{-1}\Gamma\mathbf{D}\mathbf{g}_\sigma=\mathrm{diag}(\Delta_1,\Delta_2)$. The above integrand then reads

$$\mathrm{Det}(D)\times\frac{\mathrm{Det}(1+\zeta^\dagger\Delta_1\zeta\Delta_2^{-1})}{\mathrm{Det}(1+\zeta^\dagger\zeta)}.$$

Expanding to quadratic order and integrating over $\zeta,\zeta^\dagger$, we obtain from the saddle point Q_S a contribution similar to (23):

$$\Omega_D(\gamma)_{|Q_S}=C_N\gamma^{-N/2}\prod_{\substack{i\in S_1\\ j\in S_2}}\gamma e^{i(\theta_i-\theta_j)}\prod_{\substack{i\in S_1\\ j\in \overline{S_2}}}(1-\gamma e^{i(\theta_i-\theta_j)})^{-1}\prod_{\substack{i\in S_1\\ j\in S_2}}(1-\gamma^{-1}e^{-i(\theta_i-\theta_j)})^{-1}$$

$$\times\prod_{\substack{i\in \overline{S_1}\\ j\in S_1}}(1-e^{i(\theta_i-\theta_j)})^{-1}\prod_{\substack{i\in S_2\\ j\in S_2}}(1-e^{-i(\theta_i-\theta_j)})^{-1}. \tag{27}$$

Note that the product contains a factor, $(1-\gamma)^{-N+2r}$, with $r=\sharp(S_1\cap S_2)$. The most singular case $r=0$ arises for $S_2=\overline{S_1}$, i.e., saddle points of the type $\Pi_{i\in\overline{S_1}}f^\dagger_{+i}f^\dagger_{-i}|0\rangle$.

In the general case $U=VDV^{-1}$, the saddle points are the points $Q_{V,S}=\mathbf{V}Q_S\mathbf{V^{-1}}$, and they lead to the same contributions (cf. the covariance of the action and the measure dQ). The two standard saddle points $Q=\pm\Sigma_3$ are the only ones unaffected by these V-rotations.

It is illuminating to present the result of the approximation (27) in an alternative fashion. For that purpose, we denote the nonzero elements of the diagonal matrix $\Gamma\mathbf{D}$ by $e^{i\phi_\nu}$ ($\nu=1,\ldots,2N$). The sum of contributions (27) can then be rewritten in the form

$$\Omega_D(\gamma)=C_N\gamma^{-N/2}\sum_S\frac{\Pi_{\mu\in\overline{S}_1}\Pi_{\nu\in\tilde{S}_2}e^{i(\phi_\mu-\phi_\nu)}}{\Pi_{\mu\in S}\Pi_{\nu\in\overline{S}}(1-e^{i(\phi_\mu-\phi_\nu)})}. \tag{28}$$

Save for the prefactor C_N, the expression (28) agrees with the result that follows from the *Weyl character formula*[26] for the trace of $R(\Gamma\mathbf{D})$ over $\mathcal{F}$. In general, this formula expresses the character of an element of U($2N$) [more generally, GL($2N,\mathbb{C}$)] in some representation R as a sum over all permutations $\sigma\in\mathfrak{S}_{2N}$ [this being the so-called Weyl group of U($2N$)]. In our case, the terms from the $(2N)!$ elements of $\mathfrak{S}_{2N}$ may be grouped into $\binom{2N}{N}$ classes, according to the equivalence relation described above. Since Weyl's formula is an exact result, the expression (28) remains finite in the limit $\gamma\to1$, which means that the singularities $1/(1-\gamma)^{N-2r}$ of the various terms cancel each other. The complete sum over saddle-point contributions thus solves the problem of "unphysical zero modes," i.e., the divergence problem of the two standard saddle points.

The mathematical reason behind the "almost exactness" of the leading-order saddle-point expansion is as follows. The action of $R(\mathbf{g})$ on coherent states $|Z\rangle$ may be interpreted as the equivariant action of $\mathbf{g}$ on the space of holomorphic sections of a certain complex line bundle $\mathcal{L}_R$ over $\mathcal{M}_N$.[27] This equivariant action can be extended to the (infinite-dimensional) space of square-integrable differential forms of degree $(0,p)$ on the bundle. On the enlarged space, the character becomes a (super)trace, which can still be written as an integral over $\mathcal{M}_N$. Owing to an $N=2$ supersymmetry, the integrand may be continuously deformed without changing the value of the integral. In one limit of the deformation, one gets $\mathrm{Tr}R(\mathbf{g})$; in the other, the integrand *localizes* at the fixed points of $\mathbf{g}$ on $\mathcal{M}_N$, yielding Gaussian integrals around these points.

It turns out that these fixed points coincide with our $Q_{V,S}$, and their (Gaussian) contributions are equal to (27), save for the prefactor C_N. As a result, the leading-order saddle-point approximation (for our nonlocalized integrand) delivers the correct answer (omitting the prefactor). In Sec. IV D, we investigate the higher-order terms of the expansion at $Q=\Sigma_3$ up to two loops: we find that these terms only renormalize the prefactor C_N, without affecting the U- or γ-dependence. We speculate that the (adequately resummed) full series yields the exact answer, including the correct normalization.

To achieve agreement with the Weyl character formula, it was crucial to regard the denominator $\mathrm{Det}(1+Z^\dagger Z)^{-2N}$ as part of the measure (as opposed to lifting it into the action). Indeed, in order for the mechanism of equivariant localization to take effect, the integration measure must be U($2N$)-invariant—a property not enjoyed by the flat measure $\Pi_{i,j}d^2Z_{ij}$ without the factor $\mathrm{Det}(1+Z^\dagger Z)^{-2N}$.

IV. WHY DO WE NEED AVERAGING?

While the Weyl character formula for $\Omega_U(\gamma)$ constitutes an exact result, it is of no use—at least not as it stands—towards our goal of proving universality of the correlation function. This formula relies on the knowledge of the eigenphases $e^{i\theta_i}$ of U, which are not given *a priori*. It does not exhibit the semiclassical features of the quantum map at all. On the contrary, it is a "purely quantum" decomposition of the correlation function, a complicated reordering of the Fourier decomposition (6).

As was explained in the Introduction, it is not conceivable in general that a universal result for Ω_U can be obtained without doing some kind of averaging over the matrix U. Given the results of the previous section, one might try to perform the averaging term by term in the Weyl decomposition, hoping that most of the terms might average to zero. Such a hope is quickly discouraged by a look at the expression (23): aside from having an Nth-order singularity at $\gamma=1$, whose degree increases each time some $\gamma e^{i(\theta_i-\theta_j)}$ crosses unity, this contribution to $\Omega_U(\gamma)$ is *strictly positive* for real $\gamma<1$. We know that the singularities are artifacts of the Weyl decomposition, as the correlation function $\Omega_U(\gamma)$ itself is uniformly bounded wrt U and γ. Unfortunately, because of the positivity of (23) the singularities can only be removed by reorganizing the entire sum of contributions, not by averaging individual terms.

For this reason, we will adopt a different strategy: we first perform the $d\mathcal{P}_N(U)$ average on the *integrand* of the coherent-state integral, obtaining a new effective action

$$e^{-S_{\rm av}(\gamma,Q)} \overset{\rm def}{=} \langle e^{-S(\gamma,U,Q)} \rangle_{\mathcal{P}_N}. \tag{29}$$

We then estimate the resulting Q-integral by performing a saddle-point approximation on the action $S_{\rm av}(Q)$.[20]

A priori, this approximation is no more justified than the one in the previous section, as $S_{\rm av}$ is preceded by no large parameter either. The absence of a large parameter also implies that averaging and making the saddle-point approximation are noncommuting operations. Therefore, the saddle-point expansion of $S_{\rm av}$ will yield qualitatively different results from the direct expansion for $S(\gamma,U,Q)$. We explained above that averaging the Weyl character formula is hopeless for our aims. The other way around (i.e., performing the expansion after averaging the action) will prove more interesting.

A. Where are the critical points of $S_{\rm av}$?

For any averaging measure $d\mathcal{P}_N$, the two points $Q=\pm\Sigma_3$ remain saddle points of $S_{\rm av}(\gamma,Q)$. In the vicinity of Σ_3, the integrand expands as

$$\left\langle \frac{\mathrm{Det}(1+\gamma Z^\dagger U Z U^{-1})}{\mathrm{Det}(1+Z^\dagger Z)} \right\rangle \approx \exp \mathrm{Tr}(\langle \gamma Z^\dagger \mathrm{Ad}U\cdot Z\rangle - Z^\dagger Z) = e^{-\mathrm{Tr}\, Z^\dagger(\mathbb{I}-\gamma\langle \mathrm{Ad}U\rangle)Z},$$

where $\mathrm{Ad}U\cdot Z \overset{\rm def}{=} UZU^{-1}$ is the adjoint action of U on Z. The approximation is valid for Z small. For larger values of Z, one should add higher cumulants to the right-hand side. However, for the time being we stick to the purely quadratic approximation, and carry out the Gaussian integral to obtain

$$\langle \Omega_U(\gamma)\rangle_{|\Sigma_3} = C_N \gamma^{-N/2} \mathrm{Det}(\mathbb{I}-\gamma\langle \mathrm{Ad}U\rangle)^{-1}. \tag{30}$$

When the averaging is absent (that is, $d\mathcal{P}_N$ is a Dirac δ-measure at U), we recover the contribution (23). The saddle point $Q=-\Sigma_3$ yields the same result, with $\gamma\to\gamma^{-1}$. On setting $\gamma=e^{ix/N}$, the sum of contributions becomes

$$\langle \Omega_U(e^{ix/N})\rangle_{|\Sigma_3\cup-\Sigma_3} = 2C_N \Re\left(\frac{e^{-ix/2}}{\mathrm{Det}(\mathbb{I}-e^{ix/N}\langle \mathrm{Ad}U\rangle)} \right). \tag{31}$$

In the next section, we examine the possible occurrence of further saddle points of $S_{\rm av}$.

1. Searching for other saddle points

In Sec. III A we located the saddle points of the function $Q \mapsto \langle Z(Q)|R(\Gamma\mathbf{U})|Z(Q)\rangle$, using the action of the group $\mathrm{U}(2N)$ on the coherent states $|Z\rangle$. This function may be interpreted as the *Husimi function* (or Q-symbol) of the operator $R(\Gamma\mathbf{U})$ acting on $\mathcal{F}$, and we denote it by $H_{R(\Gamma\mathbf{U})}(Q)$. By the same procedure we can obtain the saddle points of $H_{R(\mathbf{g})}(Q)$ for any nondegenerate matrix $\mathbf{g}\in\mathrm{U}(2N)$; in that case, the saddle points $Q_{\rm crit}$ are given in general by finite matrices $Z_{\rm crit}$ and $Z_{\rm crit}^\dagger$, which are solutions of the saddle-point equations

$$\frac{\partial}{\partial Z_{ij}} H_{R(\mathbf{g})}(Z,Z^\dagger)=0=\frac{\partial}{\partial \overline{Z}_{ij}} H_{R(\mathbf{g})}(Z,Z^\dagger) \qquad (i,j=1,\ldots,N). \tag{32}$$

It is useful to extend $H_{R(\mathbf{g})}$ to a function of two independent complex matrices Z,Z^* (that makes $2N^2$ complex variables). The saddle-point equations pose $2N^2$ constraints on the degrees of freedom Z and Z^*, which yields isolated solutions (Z_i,Z_i^*), provided that the constraints are independent of each other.

The *reality* of these solutions (i.e., $Z_i^*=(Z_i)^\dagger$) is due to a symmetry of the operator $R(\mathbf{g})$, which is not conserved if we replace $R(\mathbf{g})$ by any operator $\mathcal{R}$ on $\mathcal{F}$. For instance, if the representation R is extended to matrices $\mathbf{G}\in\mathrm{GL}(2N,\mathbb{C})$, one can show that the saddle points of $H_{R(\mathbf{G})}(Z,Z^*)$ are real iff $\mathbf{G}$ is a normal matrix (i.e., $\mathbf{G}\mathbf{G}^\dagger=\mathbf{G}^\dagger\mathbf{G}$). We are presently unable to determine the conditions for the saddle points to be real for the most general $\mathcal{R}$. In any case, the saddle points will be real if $\mathcal{R}$ is a Hermitian operator. The Husimi function is then real, and Morse theory applies to it. By Morse's theorem,[28] the number of saddle points (which we assume to be isolated) is at least the sum of all Betti numbers of $\mathcal{M}_N$, which is $\binom{2N}{N}$.[29] This is exactly the number of saddle points we found for $H_{R(\mathbf{X})}(Q)$ when $\mathbf{X}$ is a $2N\times 2N$ Hermitian matrix, so this function is called a *perfect Morse function* for $\mathcal{M}_N$. $\mathbf{X}$ can be joined to $\mathbf{g}\in\mathrm{U}(2N)$ by a continuous path inside the set of nondegenerate normal matrices: this explains why $H_{R(\Gamma\mathbf{U})}$, although a complex function, still has $\binom{2N}{N}$ real saddle points.

Unlike reality, the property that the solutions of (32) are isolated points is robust; (Z_i,Z_i^*) are the common zeros of $2N^2$ polynomials in Z and Z^*, so they are *stable* wrt perturbations of the coefficients, as long as the equations do not become degenerate. In Sec. III A the saddle points of $H_{R(\Gamma\mathbf{U})}(Q)$ were called $Q_{V,S}$. We now switch to such complex coordinates ζ that a saddle point $Q_{V,S}$ is situated at $\zeta=0=\zeta^\dagger$, and perturb $R(\Gamma\mathbf{U})$ in $\mathrm{GL}(\mathcal{F})$ to $\mathcal{R}=R(\Gamma\mathbf{U})+\epsilon\,\delta\mathcal{R}$. Then for ϵ small, $H_{\mathcal{R}}(\zeta,\zeta^\dagger)$ will have an isolated saddle point at $(\zeta_\epsilon,\zeta_\epsilon^*)$, where both ζ_ϵ and ζ_ϵ^* are of order ϵ. Even if it is not real, this saddle point will contribute to the integral over $\mathcal{M}_N$: starting from real coordinates $\Re\zeta_{ij},\Im\zeta_{ij}$, we can locally deform the contour so as to reach the point

$$(\Re\zeta_{ij})^{\rm crit}=(\zeta_{\epsilon,ij}+\zeta_{\epsilon,ji}^*)/2, \qquad (\Im\zeta_{ij})^{\rm crit}=(\zeta_{\epsilon,ij}-\zeta_{\epsilon,ji}^*)/2\mathrm{i},$$

and we can compute the saddle-point expansion of $\int H_{\mathcal{R}}(\Re\zeta,\Im\zeta)$ around it.

The averaged integrands we want to consider are all of the type $H_{\mathcal{R}}(Q)$, where

$$\mathcal{R}=\int_{\mathrm{U}(N)} \mathrm{d}\mathcal{P}_N(V)\ \frac{1}{\mathrm{Det}V} R(\Gamma\mathbf{V}),$$

and $\mathrm{d}\mathcal{P}_N(V)$ is a normalized measure on $\mathrm{U}(N)$. If this measure is very strongly peaked near a matrix U_N, the resulting operator will be a perturbation of $R(\Gamma\mathbf{U}_N)/\mathrm{Det}U_N$, so the above stability arguments apply: the saddle points are then isolated points near the unperturbed ones, and they are "almost real" and hence will lie on the integration contour after a slight contour deformation.

For less concentrated measures $\mathrm{d}\mathcal{P}_N(V)$, the structure of the saddle points can change. In Sec. V we exhibit an averaging scheme for which the saddle points are real but not isolated: they form submanifolds of $\mathcal{M}_N$; this is also the case for $H_{R(\mathbf{g})}$ if $\mathbf{g}$ is degenerate. We do not have a good

estimate of the typical ''width'' of the measure $d\mathcal{P}_N(V)$ above which saddle points can coalesce, spread over higher-dimensional sets, or cease to contribute to the integral (for instance, when they depart too far away from reality).

In general, we are unable to explicitly locate these extra saddle points, even for the relatively narrow averages described in Secs. IV C and IV F; consequently, we cannot do better than stick to the approximation (31) to describe the correlation function. The remaining task then is to investigate the spectrum of the operator $\langle \mathrm{Ad}U\rangle$, which depends on U and on $d\mathcal{P}_N$.

B. Common spectral features of $\langle \mathrm{Ad}U\rangle$

The spectrum of $\langle \mathrm{Ad}U\rangle$ has a few features that are independent of the averaging scheme. Before averaging, the eigenvalue unity occurs in $\mathrm{Ad}U$ with multiplicity N, corresponding to the N-dimensional space spanned by the U-eigenstate projectors $|\psi_j\rangle\langle\psi_j|$ $(j=1,\ldots,N)$, and the remaining N^2-N eigenvalues lie on the unit circle. After averaging, only the uniform mode $\mathbb{I}_N = \Sigma_j |\psi_j\rangle\langle\psi_j|$ is left with eigenvalue at unity, while all other eigenvalues have moved inside the unit disk. As a result, the sum of the contributions (31) stays finite in the limit $\gamma\to 1$. Averaging thus removes the ''unphysical zero mode'' problem associated with the two standard saddle points in Sec. III.

More precisely, the large-N behavior of $\langle \Omega_U(e^{ix/N})\rangle_{|\pm\Sigma_3}$ for finite x mostly depends on the positions of the eigenvalues of $\langle \mathrm{Ad}U\rangle$ *closest to unity*. Within the approximation (31), these eigenvalues are *the relevant dynamical data* of the correlation function.

C. Semiclassical averaging

In Ref. 20, a semiclassical averaging scheme around a quantized map $U_{\phi,N}$ was proposed as a promising candidate to obtain universal spectral statistics, differentiating between integrability versus chaotic behavior of the classical map ϕ. One chooses a finite set of Hamiltonian functions H_j, corresponding to Hamiltonian vector fields Ξ_{H_j} $(j=1,\ldots,r)$, on the classical phase space. These Hamiltonians are quantized on each of the quantum Hilbert spaces $\mathcal{H}_N$, yielding operators $\{\hat{H}_j\}$, which are represented by Hermitian $N\times N$ matrices wrt an orthonormal basis of $\mathcal{H}_N$. An ensemble average is then introduced by

(1) composing $U_{\phi,N}$ with the operator $\exp(-i\Sigma_j t_j \hat{H}_j/\hbar)$, where the ''times'' t_j are real numbers;
(2) averaging over the parameters t_j in a window around the origin of width ϵ using, for instance, the Gaussian weight $(\epsilon^2\pi)^{-r/2} e^{-\Sigma_j t_j^2/\epsilon^2}$.

The width ϵ is taken to be $\hbar$-dependent: $\epsilon\sim\hbar^\alpha\sim N^{-\alpha}$ for some $1>\alpha>0$, so that the probability measure for the classical maps $\exp(\Sigma_j t_j \Xi_{H_j})\circ\phi$ shrinks to a single point, ϕ, in the classical limit $N\to\infty$. The set of Hamiltonians $\{H_j\}$ is chosen once and for all, and is independent of N and the map ϕ. The only constraint on this set is that the second-order differential operator $-\Delta = \Sigma_j \Xi_{H_j}^2$ must be *elliptic*.[20]

As explained in the Introduction, this averaging procedure is introduced in order to suppress the nongeneric spectral statistics of quantum chaotic systems with arithmetic symmetries. In this respect we must mention the results obtained in Ref. 10, where the authors show how nonlinear perturbations of quantum cat maps exhibit generic spectral statistics, as long as one perturbs in both directions of the two-dimensional phase space; in contradistinction, perturbation in a single direction may leave one arithmetic symmetry intact, leading to nongeneric quantum spectral statistics. This need for ''phase-space-isotropy'' of the perturbations is very similar to our ellipticity requirement: Δ is elliptic only if the vector fields Ξ_{H_j} span the whole tangent space at every point of phase space.

Some recent articles[30,31] have dealt with the spectral analysis of the operator $\langle \mathrm{Ad}U\rangle_{\mathrm{semiclas}}$, and obtained interesting results concerning its largest eigenvalues. For a classically chaotic map, these were shown to converge (as $N\to\infty$) to the *Ruelle–Pollicott resonances* of the corresponding

Frobenius-Perron operator.[32] These resonances are inside the unit circle, which means that $\langle \mathrm{Ad}U_N\rangle_{\mathrm{semiclas}}$ has a *finite gap* between unity and the rest of the spectrum, for $N\to\infty$. The huge majority of eigenvalues tend to accumulate on the origin (see the discussion at the end of Sec. V A).

These properties allow us to estimate the contribution from the two standard saddle points for the case of a quantum chaotic map. To lowest order in $1/N$,

$$\langle \Omega_{U_N}(\gamma=\mathrm{e}^{\mathrm{i}x/N})\rangle_{\mathrm{semiclas}|\pm\Sigma_3} \overset{N\to\infty}{\approx} \frac{NC_N}{\mathrm{Det}_\perp(\mathbb{I}-\langle \mathrm{Ad}U\rangle_{\mathrm{semiclas}})}\,\frac{\sin(x/2)}{x/2}, \tag{33}$$

where $\mathrm{Det}_\perp$ means that the determinant is computed after restriction to the traceless matrices, i.e., to the subspace orthogonal to the uniform mode $\mathbb{I}_N$. Apart from the non-universal prefactor, the x-dependence agrees with the CUE result (8) in the limit of large matrices.

In the case of an integrable map, the eigenvalues of $\langle \mathrm{Ad}U_N\rangle_{\mathrm{semiclas}}$ behave differently: some of them populate more and more densely a few curves which connect the origin to some point on the unit circle (including unity). For this reason, one cannot separate unity in $\mathrm{Det}(\mathbb{I}-\mathrm{e}^{\mathrm{i}x/N}\langle \mathrm{Ad}U\rangle_{\mathrm{semiclas}})$ from the rest of the spectrum. All we can say is that the approximation (31) does not yield the CUE formula in that case (in general it does not yield the Poisson answer either).

1. Warning

One might be tempted to present formula (33) as a ''physicist's proof'' of a weak universality conjecture for quantum chaotic maps. The reason why it is not a proof is clear:

(i) As was explained in Sec. IV A 1, there certainly exist other saddle points of (29). The calculation of their contributions is a difficult task, which we have not yet performed. It is far from obvious why these saddle points should be less important than $Q=\pm\Sigma_3$ in the semiclassical averaging scheme.

(ii) As was emphasized before, there is no large parameter in front of the effective action. Without such a parameter, the correction terms of the asymptotic expansion around each saddle point are not small, and their neglect in the formula (33) seems to be unjustified.

The second worry is addressed in the next subsection.

D. Loop expansion

We are now going to investigate those corrections to the formula (33) that result from systematically expanding around the saddle point $Q=\Sigma_3$. The computations will be done up to what is called two-loop order in field-theoretic language.

As a first step, we approximate the integrand by taking the ensemble average inside the determinant:

$$\langle \mathrm{Det}(1+\gamma Z^\dagger \mathrm{Ad}U\cdot Z)\rangle_{\mathrm{semiclas}} \approx \mathrm{Det}(1+\gamma Z^\dagger \langle \mathrm{Ad}U\rangle_{\mathrm{semiclas}}\cdot Z). \tag{34}$$

Although ϵ, the ''width'' of the perturbation, decreases like $\hbar^\alpha$, its effect is strong enough to completely modify the spectrum of $\mathrm{Ad}U$, even in the semiclassical limit. This shows that the above approximation is not necessarily valid if we just suppose that the matrices Z are bounded (uniformly wrt N) in the operator norm on $\mathcal{H}_N$. Using the expansion

$$\mathrm{Det}(1+A)=1+\mathrm{Tr}A+\sum_{j=2}^{N}\mathrm{Tr}(\wedge^j A),$$

Eq. (34) will hold as long as the terms for $j \geqslant 2$ are small compared to $\mathrm{Tr}A$. A sufficient condition for that is $\mathrm{Tr}(|A|) \ll 1$, where $|A| \stackrel{\text{def}}{=} \sqrt{A^\dagger A}$. Upon the replacement $A = \gamma Z^\dagger \mathrm{Ad}U \cdot Z$, this condition will be met if

$$\mathrm{Tr}(Z^\dagger Z) = \sum_{i,j=1}^{N} |Z_{ij}|^2 \ll 1, \tag{35}$$

uniformly wrt N. It would be desirable to better control the error in (34) for the larger set of matrices Z satisfying (N-uniformly) $\|Z\|_{\mathcal{L}(\mathcal{H}_N)} \leqslant \mathrm{const}$.

Taking (34) for granted, we proceed to the computation of higher loops. To simplify the notation we abbreviate $T \stackrel{\text{def}}{=} \gamma \langle \mathrm{Ad}U \rangle_{\mathrm{semiclas}}$. Next we formally introduce a parameter M (which will be reset to unity at the end of the calculation) by making in the integrand the replacement

$$\frac{\mathrm{Det}(1+Z^\dagger T Z)}{\mathrm{Det}(1+Z^\dagger Z)} \to \left(\frac{\mathrm{Det}(1+Z^\dagger T Z)}{\mathrm{Det}(1+Z^\dagger Z)} \right)^M .$$

A contribution to the perturbative saddle-point expansion is said to be of n-loop order if it varies as M^{-n} relative to the leading-order term. On rescaling the integration variables to $\zeta = Z\sqrt{M}$ and $\zeta^\dagger = Z^\dagger \sqrt{M}$, the $1/M$ expansion of the integrand looks as follows:

$$d\mu_N(Z,Z^\dagger) \frac{\mathrm{Det}^M(1+Z^\dagger T Z)}{\mathrm{Det}^M(1+Z^\dagger Z)} = C_N \prod_{i,j=1}^{N} \frac{d^2\zeta_{ij}}{\pi M} \mathrm{e}^{-\mathrm{Tr}\zeta^\dagger(1-T)\zeta} (1 + M^{-1} f_1 + M^{-2} f_2 + \cdots)$$

where f_1 and f_2 are the one- and two-loop terms, respectively, and are given by

$$f_1 = \frac{1}{2}\mathrm{Tr}(\zeta^\dagger\zeta)^2 - \frac{1}{2}\mathrm{Tr}(\zeta^\dagger T \zeta)^2 - 2N\mathrm{Tr}\zeta^\dagger\zeta,$$

$$\begin{aligned} f_2 = &-\frac{1}{3}\mathrm{Tr}(\zeta^\dagger\zeta)^3 + \frac{1}{3}\mathrm{Tr}(\zeta^\dagger T\zeta)^3 + \frac{1}{8}[\mathrm{Tr}(\zeta^\dagger\zeta)^2 - \mathrm{Tr}(\zeta^\dagger T\zeta)^2]^2 \\ &+ 2N^2(\mathrm{Tr}\zeta^\dagger\zeta)^2 + N\mathrm{Tr}(\zeta^\dagger\zeta)^2 - N\mathrm{Tr}(\zeta^\dagger\zeta)(\mathrm{Tr}(\zeta^\dagger\zeta)^2 - \mathrm{Tr}(\zeta^\dagger T\zeta)^2). \end{aligned}$$

The Gaussian integral at leading order just yields the result (30). Using standard diagrammatic techniques to do the one-loop integral we find the following expression:

$$\begin{aligned} \frac{1}{2} C_N M^{-N\times N} \mathrm{Det}(1-T)^{-1} \Bigg\{ &-4N \sum_{ij} \left(\frac{1}{1-T} \right)_{ij,ij} + \sum_{ijkl} \left(\frac{1}{1-T} \right)_{ij,kj} \left(\frac{1}{1-T} \right)_{kl,il} \\ &- \sum_{ijkl} \left(\frac{T}{1-T} \right)_{ij,kj} \left(\frac{T}{1-T} \right)_{kl,il} + \sum_{ijkl} \left(\frac{1}{1-T} \right)_{ij,il} \left(\frac{1}{1-T} \right)_{kl,kj} - \sum_{ijkl} \left(\frac{T}{1-T} \right)_{ij,il} \left(\frac{T}{1-T} \right)_{kl,kj} \Bigg\}. \end{aligned}$$

By the relation $(1-T)^{-1} = 1 + T(1-T)^{-1}$ these terms combine to yield the simple answer

$$C_N \int_{\mathbb{C}^{N\times N}} \prod_{i,j=1}^{N} \frac{d^2\zeta_{ij}}{\pi M} \mathrm{e}^{-\mathrm{Tr}\zeta^\dagger(1-T)\zeta} f_1(\zeta,\zeta^\dagger) = C_N M^{-N\times N} \mathrm{Det}(1-T)^{-1}(-N^3).$$

We see that the dependence of the one-loop contribution on T cancels completely, leaving only a constant, $-N^3$. This cancellation is not accidental but continues to higher loop order. By a lengthy but straightforward calculation, the complete perturbative result up to two-loop order can be shown to be

$$\int_{\mathbb{C}^{N\times N}} d\mu_N(Z,Z^\dagger)\,\frac{\mathrm{Det}^M(1+Z^\dagger TZ)}{\mathrm{Det}^M(1+Z^\dagger Z)}$$
$$= C_N M^{-N\times N}\mathrm{Det}(1-T)^{-1}\left(1-M^{-1}N^3+M^{-2}\left(\frac{1}{2}N^6+\frac{7}{12}N^4-\frac{1}{12}N^2\right)+\mathcal{O}(M^{-3})\right).$$

Again, all the T-dependence has disappeared from the loop correction terms. This is true for all M including the case of interest, $M=1$.

The cancellation does not come as a total surprise. The above perturbation expansion, whose low-order terms we have computed, is formally identical to the same expansion *before* averaging. The latter is obtained from the former by simply substituting $\gamma\mathrm{Ad}U$ for $T=\gamma\langle\mathrm{Ad}U\rangle_{\mathrm{semiclas}}$. In the case before averaging we know from Ref. 27 that an index-theoretic mechanism (sometime called *localization*) causes the perturbation expansion to be deformable (by an underlying $N=2$ supersymmetry) to a harmonic oscillator problem (or, equivalently, a Gaussian integral) at $Z=0$. The process of deformation to the Gaussian limit explains why the dependence on $\gamma\mathrm{Ad}U$ is exhausted by the leading-order term. It leads to the Weyl character formula, which implies that the contribution to the character from $Z=0$ (or $Q=\Sigma_3$) is *exactly* given by

$$\int_{\mathbb{C}^{N\times N}} d\mu_N(Z,Z^\dagger)\,\frac{\mathrm{Det}(1+Z^\dagger\gamma\mathrm{Ad}U\cdot Z)}{\mathrm{Det}(1+Z^\dagger Z)}\Big|_{Z=0,\text{all orders}}=\mathrm{Det}(\mathbb{I}-\gamma\mathrm{Ad}U)^{-1},$$

where the normalization constant C_N has now been replaced by unity. The last fact provides the raison d'ĉtre for the N-dependent terms produced by the loop expansion: their role is to cancel, after proper resummation, the prefactor C_N. This property does not depend on the unitarity of $\gamma\mathrm{Ad}U$, so it holds as well after replacing it by its average. Thus, after summing all orders of the perturbation expansion, we expect that the saddle point $Z=0$ contributes to the correlation function as

$$\langle\Omega_U(\gamma)\rangle_{|\Sigma_3,\text{all orders}}=\gamma^{-N/2}\,\mathrm{Det}(\mathbb{I}-\gamma\langle\mathrm{Ad}U\rangle)^{-1}.$$

This perturbative result should be used with some care. Although the function $f(Z,Z^\dagger;T)=\mathrm{Det}(1+Z^\dagger TZ)/\mathrm{Det}(1+Z^\dagger Z)$ is locally well defined, it does not extend to a global smooth function on the manifold $\mathcal{M}_N$ (in particular, this function is NOT the Husimi function of an operator on $\mathcal{F}$). Indeed, setting $Z=zG$ with any invertible matrix G and sending $z\to\infty$ always leads to the same point $Q=-\Sigma_3$ on $\mathcal{M}_N$, regardless of which matrix G we choose, whereas the limit of $f(zG,\overline{z}\overline{G}^\dagger;T)$ as $z\to\infty$ does depend on the choice of G. Thus, the function $f(Z,Z^\dagger;T)$ is not smooth at $Q=-\Sigma_3$.

This singularity reflects the fact that the cumulants neglected by our basic approximation (34) are small (compared to the terms kept) only for small matrices Z [cf. the discussion following Eq. (34)]. If $Z,Z^\dagger$ (or some matrix elements thereof) are allowed to go to infinity, the approximation clearly loses its validity. To control the error incurred near the saddle point $Q=-\Sigma_3$, one needs to switch to another scheme, by first changing coordinates $Z\to 1/Z$ and $Z^\dagger\to 1/Z^\dagger$ and only afterwards repeating the above steps. The contribution from $Q=-\Sigma_3$ can then be calculated in the same way as the one for $Q=\Sigma_3$. The treatment of further saddle points remains an open problem.

What makes this procedure unsatisfactory is that we are simultaneously working with several approximation schemes, each of which is only locally controlled. To localize the integral at the saddle points in a mathematically rigorous manner, we would need an approximation that is *globally well defined* and well controlled. It is not clear whether such an approximation exists, given the stringent requirement that the integrand should also have the index-theoretic features that allow localization techniques to be used.

V. AVERAGING *U* OVER EIGENBASES

By its definition (2) as a correlation function of spectral determinants, $\Omega_U(\gamma)$ is invariant under any change of basis $U \mapsto VUV^{-1}$, with V an arbitary unitary matrix. In the Q-matrix formulation, this invariance is reflected by the relation $S(\gamma,U,Q)=S(\gamma,VUV^{-1},\mathbf{V}Q\mathbf{V}^{-1})$. Since the transformation $Q \mapsto \mathbf{V}Q\mathbf{V}^{-1}$ has unit Jacobian, we may absorb $\mathbf{V}$ into the integration variable Q and compute $\Omega_U(\gamma)$ by first averaging $\mathrm{e}^{-S(\gamma,U,Q)}$ over all rotations $U \mapsto VUV^{-1}$:

$$\mathrm{e}^{-S_{V\mathrm{av}}(\gamma,U,Q)} \overset{\text{def}}{=} \frac{1}{\mathrm{Vol\ U}(N)} \int_{\mathrm{U}(N)} dV \exp\{-S(\gamma,VUV^{-1},Q)\}, \tag{36}$$

and then integrating $\mathrm{e}^{-S_{V\mathrm{av}}}$ over Q. We saw in Sec. III A that if the matrix $D=V^{-1}UV$ is diagonal, then the saddle points of $S(\gamma,U,Q)$ are situated on the points $Q_{V,S}=\mathbf{V}Q_S\mathbf{V}^{-1}$. Because the locations of these points explicitly *depend* on V, we expect that a smoothing mechanism takes place and the divergences of the individual terms in the Weyl character formula disappear on averaging over V. In fact, as we will see, the expansion obtained by saddle-point analysis of the effective action $S_{V\mathrm{av}}(\gamma,U,Q)$ is qualitatively quite different from Weyl's formula.

A. Analysis around $\pm\Sigma_3$

We first describe $S_{V\mathrm{av}}(\gamma,U,Q)$ near the two saddle points $Q=\pm\Sigma_3$ (cf. Sec. IV A). The V-averaged adjoint operator $\langle \mathrm{Ad}\rangle_V$ has a rather simple spectrum: unity is a simple eigenvalue (associated with $\mathbb{I}_N$), and on the remaining (N^2-1)-dimensional space the operator is proportional to the identity:

$$\langle \mathrm{Ad}U\rangle_V = P_{\mathbb{I}} + (1-P_{\mathbb{I}})\frac{|\mathrm{Tr}U|^2-1}{N^2-1}. \tag{37}$$

($P_{\mathbb{I}}$ is the orthogonal projector on $\mathbb{I}_N$.) We see that $\langle \mathrm{Ad}U\rangle_V$ has a large gap between unity and the second eigenvalue, and this gap has the maximal degeneracy. Assuming that this degenerate eigenvalue is small ($|\mathrm{Tr}U| \ll N$), we get the following leading-order contribution:

$$\langle \Omega_U(\mathrm{e}^{\mathrm{i}x/N})\rangle_{V|\Sigma_3 \cup -\Sigma_3} \sim \frac{2NC_N}{(1-\alpha/N)^{N^2}} \frac{\sin\{x(1/2-\alpha)\}}{x}, \tag{38}$$

$$\text{with} \qquad \alpha \overset{\text{def}}{=} (|\mathrm{Tr}U|^2-1)/N. \tag{39}$$

Within this approximation, the correlation function depends on $U=U_{\phi,N}$ only through the simple quantity $|\mathrm{Tr}U|^2$, which can be estimated semiclassically by the Gutzwiller–Tabor trace formula (1): typically, α is of order $\mathcal{O}(1/N)$ for a chaotic map, and of order $\mathcal{O}(1)$ for an integrable one.

Notice that, due to the high degeneracy of the second eigenvalue, we do not get in general the CUE result (8), although this eigenvalue is far inside the unit circle. This shows that, to obtain the CUE result (33), we not only need a finite gap in the spectrum of $\langle \mathrm{Ad}U\rangle$, but also a fast accumulation of the eigenvalues to the origin. The precise condition on the eigenvalues is $\Sigma_{j=2}^{N^2}[\lambda_j/(1-\lambda_j)] \ll N$. In the present averaging scheme, this means $\alpha \ll 1$.

B. Critical submanifolds

We need to investigate the possible influence of other saddle points of $S_{V\mathrm{av}}(\gamma,U,Q)$; for the present averaging scheme, we will explicitly describe a critical set, which we believe to be exhaustive. The effective action possesses the symmetry $S_{V\mathrm{av}}(Q)=S_{V\mathrm{av}}(\mathbf{W}Q\mathbf{W}^{-1})$ for all $W \in \mathrm{U}(N)$. Therefore, the saddle points are grouped into stationary *submanifolds*, each of them invariant under $\mathrm{U}(N)$.

1. Description of the manifolds

In Appendix A we prove the following statement: for any initial matrix U and any γ, the action (36) is stationary at the points $Q=\mathbf{W}Q_\sigma\mathbf{W}^{-1}$, for all rotations $W\in \mathrm{U}(N)$ and any permutation σ (see Sec. III A for the notations σ, $S=S_1\cup S_2$, etc). Since $\mathrm{U}(N)$ is connected, the points $\mathcal{M}_S \overset{\text{def}}{=} \{\mathbf{W}Q_S\mathbf{W}^{-1} \,|\, W\in \mathrm{U}(N)\}$ form a connected submanifold of $\mathcal{M}_N$.

Let τ be any permutation among N indices. The set $S'=(\tau(S_1),\tau(S_2))$ is in general different from S, and we have $Q_S\neq Q_{S'}$; however, $Q_{S'}\in\mathcal{M}_S$, or equivalently $\mathcal{M}_S=\mathcal{M}_{S'}$. Putting $p=\sharp S_2$ and $r=\sharp(S_1\cap S_2)$, we find that $\mathcal{M}_S$ contains $\binom{N}{p}\binom{p}{r}\binom{N-p}{r}$ different points $Q_{S'}$. The manifolds $\mathcal{M}_S$ are in one-to-one correspondence with the integers (p,r), and their total number is $(N/2+1)^2$ for N even, and $(N+1)(N+3)/4$ for N odd (including the isolated points $\pm\Sigma_3$ in the count).

For generic U and $\gamma\neq 1$ [genericity means here that the matrix $\mathrm{diag}(\gamma U,U)$ is not degenerate], we conjecture that the submanifolds $\mathcal{M}_{(p,r)}$ exhaust all the critical points of the action $S_{V\mathrm{av}}(\gamma,U,Q)$.

2. Contributions of the manifolds

The leading-order contribution of each submanifold $\mathcal{M}_S$ to the Q-integral is calculated by separating the tangent space at Q_S into two parts, one parallel and one transverse to $\mathcal{M}_S$. The integrand in the vicinity of Q_S then reads (to quadratic order)

$$\mathrm{e}^{-S_{V\mathrm{av}}(Q_S)}\mathrm{e}^{-\mathrm{Hess}_T(X_T)+\mathcal{O}(|X_T|^3)},$$

where Hess_T is the Hessian of $S_{V\mathrm{av}}$ around $\mathcal{M}_S$, viewed as a nondegenerate quadratic form on the transverse part of tangent space (coordinatized by X_T). The exact integral over $\mathcal{M}_S$ and the Gaussian integral over the transverse directions yield the contribution

$$\langle\Omega_U(\gamma)\rangle_{|\mathcal{M}_S}=C_N\gamma^{-N/2+p}\frac{\mathrm{Vol}\mathcal{M}_S}{\sqrt{\mathrm{Det}(\mathrm{Hess}_T)}}\mathrm{e}^{-S_{V\mathrm{av}}(\gamma,Q_S)}. \tag{40}$$

In Appendix B, we explicitly compute the volumes of the submanifolds $\mathcal{M}_S=\mathcal{M}_{(p,r)}$:

$$\mathrm{Vol}\mathcal{M}_{(p,r)}=\frac{(\Gamma(1)\cdots\Gamma(r))^2\Gamma(1)\cdots\Gamma(p-r)\Gamma(1)\cdots\Gamma(N-p-r)}{\Gamma(1)\cdots\Gamma(N)}.$$

For all submanifolds $\mathcal{M}_S\neq\{\pm\Sigma_3\}$ (i.e., $0<p<N$), these volumes are N-exponentially small. The quantities Hess_T and $S_{V\mathrm{av}}(Q_S)$ depend on U and γ; we are unable to compute them in general. What we know for sure is that $|\mathrm{e}^{-S_{V\mathrm{av}}}|\leqslant 1$, since $\mathrm{e}^{-S(\gamma,U,Q)}$ has this property.

For a nondegenerate U and $\gamma=\mathrm{e}^{\mathrm{i}x/N}$, the Hessian around $\mathcal{M}_S$ will possess a single eigenvalue that vanishes with x, while all other eigenvalues stay at least of order $\mathcal{O}(1)$. This means that the contribution from $\mathcal{M}_S$ goes like $1/x$ as $x\to 0$. However, the "particle-hole duality" between the submanifolds $\mathcal{M}_{(p,r)}$ and $\mathcal{M}_{(N-p,r)}$ cancels this divergence in the sum of their two contributions (as it does for $\pm\Sigma_3$).

As a result, we conjecture that each contribution $\langle\Omega_U(\gamma)\rangle_{|\mathcal{M}_S\cup\mathcal{M}_S^-}$ is x-uniformly, N-exponentially small compared to that from $\pm\Sigma_3$ for large N, owing to the small volumes of $\mathcal{M}_{(p,r)}$. Since the number of critical submanifolds grows like N^2, we deduce that the leading-order saddle-point expansion for the action $S_{V\mathrm{av}}(U,\gamma,Q)$ can be truncated to (38) for large N.

C. Averaging over random matrix ensembles

We may go further and average e^{-S} not only over the conjugates of a fixed matrix U, but also over the spectrum $\{\mathrm{e}^{\mathrm{i}\theta_j}\}$. For instance, we can average U over all matrices in $\mathrm{U}(N)$, with a weight corresponding to one of the standard random matrix ensembles (Poisson, CUE). The averaged

action will be U(N)-rotation invariant, and its saddle points will still lie on the submanifolds $\mathcal{M}_S$. As a result, the leading-order saddle-point (l.o.s.p.) expansion for such ensemble-averaged actions can again be truncated to the contribution (38), upon replacing the coefficient α by its average $\langle\alpha\rangle_{\text{ensemble}}$ over the ensemble considered.

D. Conclusion: No l.o.s.p. expansion for the *V*-averaged actions

The contribution (38) depends in a very simple manner on the matrix U, namely only on its first trace. This is in contradiction with the fact that *a priori*, all traces up to $\mathrm{Tr}(U^{N/2})$ enter into $\Omega_U(\gamma)$ [cf. Eq. (14)]. By selecting some particular cases, it becomes obvious that the l.o.s.p. expansion (38) deviates strongly from the exact correlation function. The most immediate counterexample is the Poisson ensemble, whose correlation function is given in Eq. (8). For this ensemble, $\langle\alpha\rangle_{\text{Poisson}}=1$, which yields the CUE result (!) when inserted into the formula (38). We are hence forced to abandon the l.o.s.p. expansion for the V-averaged actions.

Nevertheless, we hope that this expansion is still meaningful when the averaging over U is *local* in U(N), which is the case for the semiclassical average in Sec. IV C (but not for the V-average). Hopefully, a local average will still conserve some memory of the "localization" property, which entailed the "almost exactness" of the l.o.s.p. expansion for $S(\gamma,U,Q)$.

In the next section, we will consider a local averaging scheme different from the semiclassical one. It possesses group-theoretic properties, which will allow us to analyze it from the character decomposition (14) instead of the coherent-state integral.

VI. ISOTROPIC AVERAGING

Starting from a fixed matrix U, one may define an *isotropic* averaging around U, by composing U with the $N\times N$ unitary matrices $\mathrm{e}^{-\mathrm{i}H}$, weighted by $\exp(-\mathrm{Tr}H^2/4\epsilon)dH$ with small ϵ (so that the weight is concentrated at the identity). Isotropy here means that the measure dH is U(N)-invariant. Note that this in sharp contrast with the semiclassical averaging of Sec. IV C, where H was a linear combination of r matrices $\hat{H}_j$, with r independent of N. In the semiclassical case, the perturbation spanned only a r-dimensional submanifold, whereas in the present case the perturbation completely fills the N^2-dimensional ϵ-ball centered at $H=0$.

One can replace the Gaussian weight by any positive normalized U(N)-invariant function of H. For our purposes, it is convenient to use the *heat kernel* on U(N), i.e., the kernel of the regularizing operator $\exp(-\epsilon\Delta)$, where Δ is the (positive) Laplace–Beltrami operator on U(N). The heat kernel centered on U is defined as follows:

$$\forall\,\epsilon>0:\ -\Delta_V K_\epsilon(V,U)=\frac{\partial}{\partial\epsilon}K_\epsilon(V,U)$$

$$\lim_{\epsilon\to+0} K_\epsilon(V,U)=\delta_U(V).$$

Owing to the compactness of U(N), the density $K_\epsilon(\cdot,U)$ for any matrix U converges to the uniform density on U(N) as $\epsilon\to\infty$. Switching ϵ from 0 to ∞ therefore realizes a crossover from the Dirac delta measure $\delta_U(\cdot)$ to the Haar (or CUE) measure. For small values of ϵ, the kernel $K_\epsilon(V,U)=k_\epsilon(VU^{-1})$ is concentrated around $\mathrm{e}^{-\mathrm{i}H}=VU^{-1}\approx 1$ and is approximately given by the Gaussian weight introduced above: $k_\epsilon(\mathrm{e}^{-\mathrm{i}H})\sim\exp(-\mathrm{Tr}H^2/4\epsilon)$.

Schur's lemma ensures that Δ is proportional to the identity on each U(N)-irreducible subspace of $L^2(\mathrm{U}(N))$. As a consequence, its action on each representation matrix $\rho_p(U)$ of Eq. (14) is simply a multiplication by a positive factor, called the quadratic Casimir invariant, which we denote by $\rho_p(\Delta)$. In formulas,

$$\int_{\mathrm{U}(N)} dV\rho_p(V)K_\epsilon(V,U)\overset{\text{def}}{=}\mathrm{e}^{-\epsilon\Delta_U}\rho_p(U)=\mathrm{e}^{-\epsilon\rho_p(\Delta)}\rho_p(U).$$

The factor $\rho_p(\Delta)$ may be computed from the Young diagram of ρ_p; a more direct way is to express Δ in terms of fermionic operators acting on the Fock space $\mathcal{F}$:

$$\Delta|_{\mathcal{F}}=\sum_{i,j=1}^{N}(f_{+i}^{\dagger}f_{+j}-f_{-j}^{\dagger}f_{-i})(f_{+j}^{\dagger}f_{+i}-f_{-i}^{\dagger}f_{-j})=(N+1)(F_{+}+F_{-})-(F_{+}^{2}+F_{-}^{2})-2J_{\uparrow}J_{\downarrow}.$$

Applying this to any element of the subspace ${}^{0}\mathcal{F}^{p}$ (which carries ρ_p) we find

$$\rho_p(\Delta)=2p(N+1-p). \tag{41}$$

On employing the decomposition (14), the heat-kernel averaged correlation function for $\gamma=e^{ix/N}$ takes the form

$$\langle\Omega_U(\gamma)\rangle_{\epsilon}\overset{\text{def}}{=}e^{-\epsilon\Delta_U}\Omega_U(\gamma)=\sum_{p=0}^{N/2}e^{-2\epsilon p(N+1-p)}\mathrm{Tr}\rho_p(U)\,\frac{\sin[x/2\,(1-(2p-1)/N)]}{\sin(x/2N)}. \tag{42}$$

The effect of the averaging procedure is to damp the large-p traces, which are difficult to estimate from the Gutzwiller trace formula. In the above equation the $\epsilon\to\infty$ behavior is obvious: all traces except the trivial one $\mathrm{Tr}\rho_0(U)=1$ are killed by the exponential, no matter what the matrix U is. It is actually not necessary to set ϵ to ∞ to get the CUE correlation. Since the irreps ρ_p are unitary, their traces are bounded by

$$|\mathrm{Tr}\rho_p(U)|\leqslant\dim\rho_p=\mathrm{Tr}\rho_p(\mathbb{I}).$$

The dimensions of the ρ_p's are given in Eq. (13); for finite p, they are bounded by $\dim\rho_p\leqslant N^{2p}$. In the limit $N,p\to\infty$ with $y=p/N$ fixed, Stirling's formula yields

$$\dim(\rho_{p=Ny})\sim(\pi N)^{-1}\frac{f'(y)}{y(1-y)}e^{2Nf(y)},$$

where the function $f(y)=-y\log y-(1-y)\log(1-y)$ increases monotonically from $f(0)=0$ to $f(1/2)=\log 2$.

For any sequence $\{U_N\}_{N\in\mathbb{N}}$, if we tune ϵ (possibly varying with N) such that

$$\varepsilon\overset{\text{def}}{=}N\epsilon\gg 1,$$

all the terms making a significant contribution to (42) satisfy $p\ll N$. The x-dependence of all these terms is the same [being given by the CUE correlation $x^{-1}\sin(x/2)$], so the averaged correlation will also have this dependence. Only the prefactor will depend on the matrices U_N explicitly. If ϵ is increased further to $\varepsilon\gg\log N$, the prefactor itself becomes universal.

These statements hold even in the most general case, when the sequence $\{U_N\}$ is completely arbitrary. Therefore, to be able to differentiate between integrable and chaotic quantum maps, one must tune the "disorder strength" ε to smaller values, so that contributions from the "high" traces $\mathrm{Tr}\rho_p(U_N)$ start to contribute. To recover the Poisson behavior for integrable maps, one actually needs contributions to (42) coming from the whole region $p\lesssim N/2$.

This puts us in a no-win situation. On the one hand, we should tune ε to small enough values so that the high traces $p\sim Ny$ $(y>0)$ survive and Poisson behavior stands a chance to emerge. On the other hand, for a chaotic map we have no control over these high traces (we don't for an integrable map either).

For our purposes, the present averaging scheme is probably "too algebraic," as opposed to the semiclassical average presented in Sec. IV C. To motivate this statement in the spirit of Sec. IV C, let us compare the spectra of the operators $\langle\mathrm{Ad}U\rangle$ for the two schemes:

(i) The spectrum of $\langle \mathrm{Ad}U\rangle_{\mathrm{semiclas}}$ *qualitatively* depends on the nature of the classical dynamics (see Sec. IV C). It has a finite gap for a chaotic map, whereas eigenvalues accumulate near the unit circle for an integrable one.

(ii) In the isotropic scheme, $\langle \mathrm{Ad}U\rangle_{\epsilon}$ is decomposed into the irreps $\rho_0(U)\oplus\rho_1(U)$. Therefore, apart from the single eigenvalue unity, $\langle \mathrm{Ad}U\rangle_{\varepsilon}$ has the eigenvalues $\{e^{-2\varepsilon}e^{i(\theta_i-\theta_j)}\}$, where $\{e^{i\theta_j}\}$ are the eigenvalues of U; the eigenvalue $e^{-2\varepsilon}$ is $(N-1)$-fold degenerate. This spectrum is qualitatively the same for chaotic versus integrable systems.

A. Crossover Poisson-CUE

We now present an application of the above scheme in the area of random matrices. More precisely, we use the isotropic averaging to build a crossover between the Poisson and CUE ensembles, and we derive the transitional determinant correlation function that interpolates between the formulas (8). This crossover, as well as the method used to compute $\langle\Omega_U\rangle$, can be compared to the GOE→GUE crossover studied in Ref. 7.

Our crossover is defined as follows. We start from the Poisson ensemble, then convolute it with the isotropic (heat kernel) measure of width ϵ:

$$\langle\Omega_U(\gamma)\rangle_{\mathrm{Poisson},\epsilon}\overset{\mathrm{def}}{=}\int_{\mathrm{U}(N)}\mathrm{d}\mathcal{P}_{\mathrm{Poisson}}(U)\int_{\mathrm{U}(N)}dV\,K_{\epsilon}(V,U)\Omega_V(\gamma).$$

For $\epsilon=0$, this is the Poisson ensemble. In the large-ϵ limit, the second integral converges U-uniformly to the CUE correlation function, so the output $\langle\Omega_U(\gamma)\rangle_{\mathrm{Poisson},\epsilon}$ does, too.

To calculate the correlation function along the crossover, we will use the decomposition (42) as in the previous section: averaging being a linear operation, we only need to replace the characters $\mathrm{Tr}\rho_p(U)$ by their Poisson averages [see Eqs. (7) and (15)]:

$$\langle\mathrm{Tr}\rho_p(U)\rangle_{\mathrm{Poisson}}=\binom{N}{p}-\binom{N}{p-1}.$$

The asymptotics of these traces in the regime $p,N\to\infty$ with $y=p/N$ fixed, again follows easily from Stirling's formula:

$$\langle\mathrm{Tr}\rho_p(U)\rangle_{\mathrm{Poisson}}\sim(2\pi N)^{-1/2}\frac{f'(y)}{\sqrt{y(1-y)}}e^{Nf(y)}. \tag{43}$$

The sum over characters therefore approaches the following integral (as $N\to\infty$):

$$\langle\Omega_U(e^{ix/N})\rangle_{\mathrm{Poisson},\epsilon}\sim\frac{2N^2}{\sqrt{2\pi N}}\int_0^{1/2}dy\,\frac{f'(y)}{\sqrt{y(1-y)}}\frac{\sin(\frac{1}{2}x-yx)}{x}e^{N(f(y)-2\varepsilon y(1-y))}. \tag{44}$$

In the limit $N\to\infty$, this integral is determined by the saddle points (rather, the maximum) of $f_{\varepsilon}(y)\overset{\mathrm{def}}{=}f(y)-2\varepsilon y(1-y)$ on $[0,\frac{1}{2}]$. Three cases have to be distinguished:

(i)If $\varepsilon<1$, the boundary point $y=\frac{1}{2}$ is a maximum of f_{ε} and is the only critical point on $[0,\frac{1}{2}]$. Because of the vanishing of the integrand at $y=\frac{1}{2}$, the saddle-point analysis requires some care. For x of order $\mathcal{O}(N^0)$ the result turns out to be independent of x:

$$\langle\Omega_U(e^{ix/N})\rangle_{\mathrm{Poisson},\varepsilon}\sim 2^N e^{-N\varepsilon/2}(1-\varepsilon)^{-3/2},$$

which shows that the Poisson result 2^N is retrieved in the limit $\varepsilon\to0$. The correlation functions starts depending on x on scales of order $x\sim\mathcal{O}(N^{1/2})$.

(ii) If $\varepsilon>1$, the maximum of f_ε is situated at the point $y_\varepsilon \in (0,\frac{1}{2})$ which solves the transcendental equation $f'_\varepsilon(y)=0$. The correlation function depends on $x\sim\mathcal{O}(N^0)$ as

$$\langle \Omega_U(\mathrm{e}^{\mathrm{i}x/N})\rangle_{\mathrm{Poisson},\varepsilon} \propto \frac{\sin[x(\frac{1}{2}-y_\varepsilon)]}{x}. \tag{45}$$

The flat correlation function has been replaced by an oscillatory function, with the period of oscillation being controlled by the ''frequency shift'' y_ε. When ε becomes large, the shift vanishes as $y_\varepsilon\sim \mathrm{e}^{-2\varepsilon}$, so the CUE correlation function is retrieved.

(iii) If $\varepsilon=1$, the correlation function is ''critical'' (in the sense of a phase transition), as the two points $y=\frac{1}{2}$ and y_ε coalesce for $\varepsilon\to 1$ to form a degenerate critical point. In this case the correlation function varies on scales $x\sim\mathcal{O}(N^{1/4})$.

VII. CONCLUSIONS

In this article we have adapted the NLσM approach introduced in Refs. 15 and 16 to the framework of quantized maps on a Hilbert space of dimension $N\sim\hbar^{-1}$. We focused on the spectral determinant correlation function $\Omega_U(\gamma)$ instead of the pair correlation function, thereby obviating the need to introduce supersymmetry; we obtained an *exact* expression for the correlation function as an ordinary integral over a N^2-dimensional complex manifold. Because the manifold is compact and the integrand uniformly bounded, no regularization needs to be introduced (unlike in Ref. 15).

To estimate this integral we expand the integrand around its saddle points, first restricting ourselves to the leading-order perturbative expansion around each point. Owing to the absence of a large parameter in front of the effective action, this approximation is uncontrolled, and the connection between its output and the exact value of the integral seems fortuitous at best.

Yet, for any matrix $U\in \mathrm{U}(N)$, we find that the result from lowest-order saddle-point expansion of the effective action $S(\gamma,U,Q)$ coincides with the exact correlation function, up to a global prefactor:

$$\Omega_U(\gamma)_{|\mathrm{l.o.s.p.\ exp.}} = C_N\ \ \Omega_U(\gamma)_{\mathrm{exact}}. \tag{46}$$

This remarkable coincidence is linked to a cancellation property of the higher-order terms of the perturbation expansion, which modify only the prefactor, and is explained by the group-theoretic structure of the integrand and the Weyl character formula. Unfortunately, the expansion is of no use for estimating the correlation function of quantized maps in the semiclassical limit.

We argue that a decent semiclassical estimate of the correlation function $\Omega_U(\gamma)$ can only be reached if one takes an average over a set of unitary matrices in the vicinity of U. To estimate this averaged correlation, we first average the integrand $\mathrm{e}^{-S(\gamma,U,Q)}$ over U, and then perform the saddle-point expansion of the output. Because averaging and saddle-point expansion are operations that do not commute, this procedure yields an expansion different from that of the ''individual'' action. At the same time, averaging *a priori* breaks the group-theoretic structure, and with it the exactness (modulo prefactor) of the leading-order saddle-point expansion. Moreover, the explicit computation of saddle points and their contributions is, in general, a nontrivial task for a general averaging scheme.

We have been able to locate the complete set of critical points only for a certain type of average, namely averaging over all bases of Hilbert space. This produces a U(N)-invariant effective action, the critical points of which are grouped into submanifolds, and are independent of the matrix U we started from (as long as its spectrum is nondegenerate). Two of these submanifolds are isolated points; we conjectured that the contributions from these two ''standard'' saddle points, which can be computed explicitly, always dominate the leading-order saddle-point expansion.

The contributions from these two points are unfortunately ''too simple'' to constitute a good approximation of the correlation function, except in some exceptional cases, which we do not truly

understand. If we average over $U \in \mathrm{U}(N)$ with the Poisson measure, the saddle-point result strongly differs from the exact one. We are thus led to conclude that the leading-order saddle-point expansion of rotation-averaged effective actions does not yield a good estimate of the full integral.

What happens in the case of a *local* average, i.e., when the weight of the probability measure is concentrated near the quantized map U_N, is unclear. For one thing, we are only able to exhibit the two standard saddle points of the averaged action, but there surely exist many more.

In the case of the ''semiclassical'' averaging scheme, expansion around these saddle points yields results similar to those obtained in Ref. 15, except that the ''resonances'' we identify are eigenvalues of a quantum operator. Yet, these resonances for large N seem related to the (classical) Ruelle–Pollicott resonances,[30,31] in particular they indicate whether the classical dynamics is chaotic or integrable.

To connect these resonances with the determinant correlation function on a rigorous footing, we need two nontrivial assumptions to be fulfilled. First, we must assume that the leading-order saddle-point expansion of the (local average) $S_{\mathrm{semiclas}}(\gamma, U_N, Q)$ makes sense, i.e., gives a good approximation of the exact result; the two-loop calculation around $\pm\Sigma_3$ in Sec. IV D seems to support this assumption. Second, hindered by our inability to compute the contributions from further saddle points, we are forced to assume that the full expansion can be truncated to the two standard saddle points, or at least that this truncation provides a reasonable approximation. We presently see no way to prove these assumptions.

APPENDIX A: PROOF OF CRITICALITY OF THE SUBMANIFOLDS $\mathcal{M}_S$

To prove that the V-averaged integrand $\mathrm{e}^{-S_{V\mathrm{av}}(\gamma,U,Q)}$ is stationary on the submanifolds $\mathcal{M}_S \subset \mathcal{M}_N$, we employ the coherent-state formulation of the Q-integral. The point Q_S corresponds to the state $|S\rangle = R(\mathbf{g}_\sigma)|0\rangle$, and the points in a neighborhood of Q_S may be parametrized as $R(\mathbf{g}_\sigma)|\zeta\rangle$, where ζ runs through the $N\times N$ matrices (with small coefficients) and $|\zeta\rangle$ is the corresponding coherent state. The permutation $\sigma \in \mathfrak{S}_{2N}$ is chosen in such a way as to interchange the sets $\overline{S_1}$ and $\widetilde{S}_2 = S_2 + N$, and to keep S_1 and $\widetilde{\overline{S_2}} = \overline{S_2} + N$ fixed.

We write the $2N\times 2N$ matrix $\mathbf{g}_\sigma^{-1}\mathbf{\Gamma}\mathbf{U}\mathbf{g}_\sigma$ in the block form $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$, and first compute the value of the integrand in the vicinity of Q_S *before averaging*:

$$\frac{\langle\zeta|R(\mathbf{g}_\sigma^{-1}\mathbf{\Gamma}\mathbf{U}\mathbf{g}_\sigma)|\zeta\rangle}{\langle\zeta|\zeta\rangle} = \mathrm{Det}(D)\left(1+\mathrm{Tr}(D^{-1}C\zeta + BD^{-1}\zeta^\dagger) + \mathcal{O}(|\zeta|^2)\right).$$

Then we perform the V-average on U (recall that $V \in \mathrm{U}(N)$ acts on $U \in \mathrm{U}(N)$ by conjugation: $U \mapsto VUV^{-1}$), and study its output on the right-hand side of the above equation. To first order in ζ and $\zeta^\dagger$, we need the averages $\langle \mathrm{Det}(D)\rangle_V$, $\langle D^{-1}C\ \mathrm{Det}(D)\rangle_V$ and $\langle BD^{-1}\mathrm{Det}(D)\rangle_V$. By decomposing the sets $\{1,\ldots,N\} = S_1 \cup \overline{S_1}$ and $\{N+1,\ldots,2N\} = \widetilde{S}_2 \cup \widetilde{\overline{S_2}}$, the $N\times N$ matrices B,C,D may be written in block form:

$$B = \begin{pmatrix} \gamma U_{S_1\overline{S_1}} & 0 \\ 0 & U_{S_2\overline{S_2}} \end{pmatrix}, \quad C = \begin{pmatrix} \gamma U_{\overline{S_1}S_1} & 0 \\ 0 & U_{\overline{S_2}S_2} \end{pmatrix}, \quad D = \begin{pmatrix} \gamma U_{\overline{S_1}\overline{S_1}} & 0 \\ 0 & U_{\overline{S_2}\overline{S_2}} \end{pmatrix},$$

where each entry $U_{ss'}$ is a matrix of size $\sharp s \times \sharp s'$, whose indices take values in the sets s, s'. Thus the V-averaged coefficients of the term linear in ζ are the following matrix elements:

$$\langle \mathrm{Det}(U_{\overline{S_1}\overline{S_1}})\mathrm{Det}(U_{\overline{S_2}\overline{S_2}})(U^{-1}_{\overline{S_1}\overline{S_1}}U_{\overline{S_1}S_1})_{ik}\rangle_V, \quad \langle \mathrm{Det}(U_{\overline{S_1}\overline{S_1}})\mathrm{Det}(U_{\overline{S_2}\overline{S_2}})(U^{-1}_{\overline{S_2}\overline{S_2}}U_{\overline{S_2}S_2})_{lm}\rangle_V,$$

where we have displayed only the dependence on U (and omitted the γ-dependence). We now use the invariance of the Haar measure dV under (left) multiplication by any unitary matrix and any diagonal unitary matrix $\delta = \mathrm{diag}(\delta_1,\ldots,\delta_N)$ in particular. Under such a left translation, the above matrix elements acquire extra factors δ_i/δ_k (resp. δ_l/δ_m). Hence

$$\langle \mathrm{Det}(D)(D^{-1}C)_{ik}\rangle_V = \langle \mathrm{Det}(D)(D^{-1}C)_{ik}\rangle_V \delta_i/\delta_k \quad \text{for any} \quad \delta_i, \delta_k .$$

Since $i \in \overline{S_1}$ and $k \in S_1$ (resp. $l \in \overline{S_2}$ and $m \in S_2$) are never equal and the ratio δ_i/δ_k may take any value in U(1), we conclude

$$\langle \mathrm{Det}(D)(D^{-1}C)_{ik}\rangle_V = 0.$$

By the same reasoning, the terms linear in $\zeta^\dagger$ vanish after V-averaging.

We have thus shown that the point Q_S on $\mathcal{M}_N$ is a critical point of the V-averaged action $S_{V\mathrm{av}}$, Eq. (36). By the U(N)-invariance of $S_{V\mathrm{av}}$, it follows that the whole submanifold $\mathcal{M}_S$ is critical for the V-averaged action, no matter what U is.

APPENDIX B: VOLUMES OF THE CRITICAL SUBMANIFOLDS

We treat the general case with $\sharp S_1 = \sharp \overline{S_2} = N-p$, $\sharp \overline{S_1} = \sharp S_2 = p$, $\sharp(S_1 \cap S_2) = \sharp(\overline{S_1} \cap \overline{S_2}) = r$, and to build Q_S we use the same permutation σ as in the previous appendix.

The manifold $\mathcal{M}_S$ is given by the set of states $\{R(\mathbf{V}\mathbf{g}_\sigma)|0\rangle | V \in \mathrm{U}(N)\}$. These states may be written (up to normalization) in the form $R(\mathbf{g}_\sigma)|\zeta_V\rangle$ where the coherent state $|\zeta_V\rangle$ is determined by the matrix

$$\zeta_V = \begin{pmatrix} V_{S_1\overline{S_1}} V_{\overline{S_1}\overline{S_1}}^{-1} & 0 \\ 0 & V_{S_2\overline{S_2}} V_{\overline{S_2}\overline{S_2}}^{-1} \end{pmatrix} \overset{\mathrm{def}}{=} \begin{pmatrix} \zeta^{(1)} & 0 \\ 0 & \zeta^{(2)} \end{pmatrix} \tag{B1}$$

according to Eqs. (16) and (17). The block structure of this matrix derives from the sets (S_1, S_2) vertically, and $(\overline{S_1}, \overline{S_2})$ horizontally.

When V runs through U(N), the upper-left matrix $\zeta^{(1)}$ takes all possible values in $\mathbb{C}^{(N-p)\times p}$. The matrix $\zeta^{(2)}$ is not independent of $\zeta^{(1)}$. For a fixed $\zeta^{(1)}$, we need to identify the remaining degrees of freedom in $\zeta^{(2)}$, which is quite easy to do if $\zeta^{(1)}=0$, i.e., if V has the structure $V = \mathrm{diag}(V_{S_1S_1}, V_{\overline{S_1}\overline{S_1}})$. The matrices $V_{S_2\overline{S_2}}$ and $V_{\overline{S_2}\overline{S_2}}$ in this case block decompose as

$$V_{S_2\overline{S_2}} = \begin{pmatrix} V_{12,\overline{12}} & 0 \\ 0 & V_{\overline{12},\overline{12}} \end{pmatrix}, \quad V_{\overline{S_2}\overline{S_2}} = \begin{pmatrix} V_{\overline{12},\overline{12}} & 0 \\ 0 & V_{\overline{12},12} \end{pmatrix}$$

where the index 12 refers to the set $S_1 \cap S_2$, etc. The degrees of freedom of the lower-right part of ζ_V are thus two matrices, $\zeta^{(11)} \overset{\mathrm{def}}{=} V_{12,\overline{12}} V_{\overline{12},\overline{12}}^{-1} \in \mathbb{C}^{r\times(N-p-r)}$, and $\zeta^{(\overline{11})} \overset{\mathrm{def}}{=} V_{\overline{12},12} V_{\overline{12},\overline{12}}^{-1} \in \mathbb{C}^{(p-r)\times r}$. They are independent of each other, and take all possible values in their respective vector spaces. Since the subgroup U($N-p$)$\times$U(p) of U(N) acts transitively on the submanifold $\zeta^{(1)}=0$ of $\mathcal{M}_S$, there exists a natural choice of invariant measure on that submanifold. It has the factorized form

$$\mathrm{Det}(1+\zeta^{(11)\dagger}\zeta^{(11)})^{N-p} \prod_{i,j} d^2\zeta_{ij}^{(11)}/\pi \times \mathrm{Det}(1+\zeta^{(\overline{11})\dagger}\zeta^{(\overline{11})})^{p} \prod_{i,j} d^2\zeta_{ij}^{(\overline{11})}/\pi .$$

The matrix $\zeta^{(1)}$ parametrizes a coset space U(N)/U($N-p$)$\times$U(p), with the corresponding invariant measure being $\mathrm{Det}(1+\zeta^{(1)\dagger}\zeta^{(1)})^N \Pi_{i,j} d^2\zeta_{ij}^{(1)}/\pi$. By group invariance arguments, the volume element of $\mathcal{M}_S$ (normalized so that it agrees with the Riemannian measure inherited from the Riemannian manifold $\mathcal{M}_N$) is the product of the measures for $\zeta^{(1)}$, $\zeta^{(11)}$, and $\zeta^{(\overline{11})}$ above. Using this fact and the result[33]

$$I(m,n) \overset{\mathrm{def}}{=} \int_{\mathbb{C}^{m\times n}} \prod_{i=1}^{m} \prod_{j=1}^{n} \frac{d^2Z_{ij}}{\pi} \mathrm{Det}(1+Z^\dagger Z)^{-n-m} = \frac{\Gamma(1)\cdots\Gamma(n)\ \ \Gamma(1)\cdots\Gamma(m)}{\Gamma(1)\cdots\Gamma(n+m)},$$

we obtain the volume of $\mathcal{M}_S$:

$$\mathrm{Vol}\mathcal{M}_S = I(p,N-p)I(r,p-r)I(r,N-p-r).$$

A similar integral yields the normalization factor C_N of the measure $d\mu_N(Z,Z^\dagger)$ on the full manifold $\mathcal{M}_N$:

$$\frac{1}{C_N} = \int_{\mathbb{C}^{N\times N}} \prod_{i,j=1}^{N} \frac{d^2 Z_{ij}}{\pi} \mathrm{Det}(1+Z^\dagger Z)^{-2N-1} = \frac{\Gamma(2)\cdots\Gamma(N+1)}{\Gamma(N+2)\cdots\Gamma(2N+1)}.$$

(Received 24 June 2001; accepted for publication 7 February 2002)

We construct a kind of annihilation–creation operators related to the affine coherent states. Next, we re-interpret them as annihilation–creation operators associated with the irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$, by adding another generator to the two generators of the unitary representation of the one-dimensional affine group. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1470707]

I. INTRODUCTION

In quantum mechanical systems, the canonical commutation relation

$$[X,Y]=-iI \tag{1}$$

is important, and the annihilation and creation operators, coherent states, number states, and the number operator are derived from this commutation relation. Here, we will treat the commutation relation

$$[X,Y]=-iX \tag{2}$$

similar to (1). The Lie group associated with this algebra is called the (one-dimensional) affine group ($ax+b$ group), and it is well known that it has only two irreducible unitary representations in the sense of unitary equivalence (see Gel'fand and Naimark,[1] or Aslaksen and Klauder[2]). For the commutation relation (2), in a similar manner to the case of the canonical commutation relation (1), the corresponding coherent states (affine coherent states) have been known.[3,4] The affine coherent states are the minimum uncertainty states between an operator and the inverse of the other operator of the canonical commutation pair. In signal processing, the wave packets corresponding to the affine coherent states are called Cauchy wavelets and they are important in the theory of the continuous wavelet transformation.[5]

In this paper, in this context, we will derive not only the coherent states but also the analogs of the annihilation and creation operators, the number operator, and the number states which are associated to the commutation relation (2). Moreover, we will interpret them more naturally by starting from the irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$, because the irreducible unitary representation of the affine group is closely related to the irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$ associated with the Lie group SU(1,1).

II. ANNIHILATION–CREATION RELATION RELATED TO IRREDUCIBLE UNITARY REPRESENTATION OF AFFINE GROUP: A HEURISTIC APPROACH

It has been known[2] that the irreducible unitary representation of the affine group can be reduced to

$$Y=\frac{PQ+QP}{2}, \quad X=Q \ \text{ on } \ L^2(\mathbb{R}^+),$$

$$Y=\frac{PQ+QP}{2}, \quad X=Q \ \text{ on } \ L^2(\mathbb{R}^-),$$

where Q denotes the position coordinate operator and P denotes the momentum operator. In the following discussions, we will treat only the former representation, because the latter representation can be discussed in almost the same way only with minor changes of the signs.

It has been known that the wave function of the coherent state $|\eta\rangle^k$ associated with the affine group is

$${}_Q\langle x|\eta\rangle^k := \sqrt{\frac{(2\ \mathrm{Im}\ \eta)^{2k+1}}{\Gamma(2k+1)}}\, x^k \ \ e^{i\eta x}, \quad \eta\in H,$$

where H denotes the upper half plane and k is a real parameter ($k>-\frac{1}{2}$). In particular, in the cases of the representations with $k>0$, the system of the coherent states constitutes the resolution of identity

$$\frac{1}{2k}\int_H |\eta\rangle^k \ \ {}^k\langle\eta| \frac{d^2\eta}{4\pi(\mathrm{Im}\ \eta)^2}=I,$$

while this does not exist in the cases of the representations with $-1/2<k<0$ because of the divergence of the integration.

Next, we will introduce the operator which has $|\eta\rangle^k$ as its eigenvector associated with the eigenvalue η for $\forall\,\eta\in H$. Define

$$A_k := P+ikQ^{-1},$$

formally. Since this operator is unbounded, precisely, we should give its precise definition taking its domain into consideration. The precise definition and its justification will be done from a viewpoint of group representation in Sec. IV. For this operator defined formally and the above-mentioned coherent states, it is easily shown that

$$A_k|\eta\rangle^k=\eta|\eta\rangle^k, \quad \forall\,\eta\in H.$$

The operator A_k has a similar property to the boson annihilation operator in the sense that it has the coherent states as its eigenvectors. However, the operator A_k does not have the property of the annihilation operator which decreases the number of states.

We can find heuristically an operator having both of the above-mentioned properties, as a function of A_k, as follows. Define

$$a_k := (A_k-iI)(A_k+iI)^{-1}. \tag{3}$$

Then

$$a_k|\eta\rangle^k=\frac{\eta-i}{\eta+i}|\eta\rangle^k, \quad \forall\,\eta\in H.$$

By letting $\zeta := (\eta - i)/(\eta + i)$ and $|\zeta\rangle_a^k := |\eta\rangle^k$, we have

$$a_k|\zeta\rangle_a^k = \zeta|\zeta\rangle_a^k, \quad \forall \zeta \in D,$$

where D denotes the inside of the unit disk. Moreover, by regarding $|0\rangle_a^k$ as the vacuum, define

$$|n\rangle_N^k := \frac{1}{||(a_k^*)^n|0\rangle_a^k||}(a_k^*)^n|0\rangle_a^k.$$

Then we have a kind of annihilation–creation relations

$$a_k|n\rangle_N^k = \sqrt{\frac{n}{n+2k}}\,|n-1\rangle_N^k,$$

$$a_k^*|n\rangle_N^k = \sqrt{\frac{n+1}{n+2k+1}}\,|n+1\rangle_N^k.$$

Moreover, by defining

$$N_k := \tfrac{1}{2}(PQP + k^2Q^{-1} + Q - (2k+1)I),$$

we have

$$N_k|n\rangle_N^k = n|n\rangle_N^k,$$

where N_k can be regarded as the number operator. The wave function of the number state is

$${}_Q\langle x|n\rangle_N^k = \sqrt{\frac{2^{2k+1}n!}{\Gamma(n+2k+1)}}\,e^{-x}x^k S_n^{2k}(2x),$$

where $S_n^l(x)$ is the Sonine polynomial (or the associated Laguerre polynomial) defined by

$$S_n^l(x) := \sum_{m=0}^{n} \frac{(-1)^m}{(n-m)!}\frac{\Gamma(n+l+1)x^m}{\Gamma(m+l+1)m!}.$$

(Sometimes another definition with $n+l$ instead of l is used.)

Among the operators a_k, a_k^*, and N_k, the following relations hold;

$$a_k^* a_k = (N_k + 2kI)^{-1}N_k,$$

$$a_k a_k^* = (N_k + (2k+1)I)^{-1}(N_k + I),$$

$$[a_k, a_k^*] = 2k(N_k + 2kI)^{-1}(N_k + (2k+1)I)^{-1},$$

$$[a_k, N_k] = a_k, \tag{4}$$

$$[N_k, a_k^*] = a_k^*, \tag{5}$$

where relations (4) and (5) have the same forms as usual boson cases.

III. INTERPRETATION OF ANNIHILATION–CREATION RELATIONS RELATED TO AFFINE GROUP IN TERMS OF ALGEBRA $\mathfrak{su}(1,1)$

The linear fractional transform (Möbius transform) used in (3) was found only heuristically. However, in this section, we will give a natural derivation of this structure from the context of the

irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$ which satisfies some conditions. In this context, we will re-interpret the annihilation–creation relations introduced in Sec. II more clearly in this section and Sec. IV.

The irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$ is given by the triple of skew-adjoint operators (E_0,E_+,E_-) satisfying the commutation relations

$$[E_0,E_\pm]=\pm 2E_\pm, \quad [E_+,E_-]=E_0. \tag{6}$$

(Note that the unitary representation of the affine group is given here if we pay attention only to $-iE_0$ and $-iE_+$.) Here, be careful about the fact that the representation of the Lie group SU(1,1) cannot always be constructed from the representation of the algebra $\mathfrak{su}(1,1)$, because SU(1,1) is not a universal covering group. Since the operators E_0, E_+, and E_- have continuous spectra usually under each unitary representation, it is difficult to analyze the forms of the representation. In order to avoid this difficulty, instead of the triple (E_0,E_+,E_-), we will use the triple (L_0,L_+,L_-) defined by

$$L_0 := i(E_- - E_+),$$

$$L_\pm := (E_0 \pm i(E_+ + E_-))/2,$$

where the triple (L_0,L_+,L_-) satisfies the same commutation relations

$$[L_0,L_\pm]=\pm 2L_\pm, \quad [L_+,L_-]=L_0. \tag{7}$$

The operators L_0, L_+, and L_- are not skew-adjoint, but they satisfy

$$L_0^*=L_0, \quad L_+^*=L_-. \tag{8}$$

It has been known that giving the triple of skew-adjoint operators which satisfy (6) is equivalent to giving the triple which satisfies (7) and (8).[6] The commutation relation $[L_0,L_\pm]=\pm 2L_\pm$ shows that the operator $L_\pm$ is a kind of up/down-ladder of the eigenvector system of L_0. From this fact, and from the irreducibility and the unitarity, it is shown that only the following three cases are possible;

$$\text{Case 1:} \quad \dim \mathrm{Ker}\, L_+ = 0, \quad \dim \mathrm{Ker}\, L_- = 1,$$

$$\text{Case 2:} \quad \dim \mathrm{Ker}\, L_+ = 1, \quad \dim \mathrm{Ker}\, L_- = 0,$$

$$\text{Case 3:} \quad \dim \mathrm{Ker}\, L_+ = 0, \quad \dim \mathrm{Ker}\, L_- = 0.$$

Case 2 can be reduced to case 1 by some changes of the signs. In this paper, we will not treat case 3, and we will discuss only case 1 in the following. In this case, the minimum eigenvalue of L_0 exists.

Let λ be the minimum eigenvalue of L_0. From the unitarity of the representation, λ should be positive.[6] Let v_0 be the eigenvector of L_0 associated with the eigenvalue λ. Then, we have

$$L_0 v_n=(\lambda+2n)v_n (n\geqslant 0), \quad L_+ v_n = v_{n+1} (n\geqslant 0),$$

$$L_- v_n = -n(\lambda+n-1)v_{n-1} (n\geqslant 1), \quad L_- v_0 = 0$$

for

$$v_n := (L_+)^n v_0.$$

Here, from the irreducibility of the representation, we can show that $\{v_n | n=0,1,2,3,\ldots\}$ constitutes a CONS.

These facts show that the minimum eigenvalue λ of L_0 specifies the irreducible unitary representation uniquely in case 1. Especially, in case 1, the irreducible unitary representation of the Lie group SU(1,1), which is not a universal covering group, can be constructed if and only if λ is a positive integer.

For the normalization of v_n, we define

$$|n\rangle_N := \sqrt{\frac{\Gamma(\lambda)}{n!\Gamma(\lambda+n)}}v_n, \quad N := \frac{1}{2}(L_0-\lambda).$$

Then we have

$$N|n\rangle_N = n|n\rangle_N,$$

hence N and $|n\rangle_N$ are regarded as the number operator and the number state, respectively.

Next, we define $a := L_+^{-1}N = \frac{1}{2}L_+^{-1}(L_0-\lambda)$, where the well-definedness is guaranteed because $\mathrm{Ran}\,L_+$ is included in $\mathrm{Ran}\,N$. Then, we have

$$a|n\rangle_N = \sqrt{\frac{n}{n+\lambda-1}}|n-1\rangle_N,$$

and similarly we have

$$a^*|n\rangle_N = \sqrt{\frac{n+1}{n+\lambda}}|n+1\rangle_N.$$

Moreover, we have the following relations;

$$a^*a = (N+(\lambda-1)I)^{-1}N,$$

$$aa^* = (N+\lambda I)^{-1}(N+I),$$

$$[a,a^*] = (\lambda-1)(N+(\lambda-1)I)^{-1}(N+\lambda I)^{-1},$$

$$[a,N] = a,$$

$$[N,a^*] = a^*.$$

Thus, with the correspondence $\lambda = 2k+1$, we have made a systematic derivation of the same type of the relations as the relations introduced at the end of Sec. II, in terms of the irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$.

Next we will introduce the coherent states. According to Perelomov,[7] define the coherent state associated with SU(1,1) by

$$\begin{aligned}|\zeta\rangle_a &:= U\left(\frac{1}{2}e^{i\arg\zeta}\ln\frac{1+|\zeta|}{1-|\zeta|}\right)|0\rangle_N \\ &= \exp(\zeta L_+)\exp\left(\frac{1}{2}\ln(1-|\zeta|^2)L_0\right)\exp(\zeta^* L_-)|0\rangle_N \\ &= (1-|\zeta|^2)^{\lambda/2}\exp(\zeta L_+)|0\rangle_N\end{aligned}$$

with

$$U(\xi) := \exp(\xi L_+ - \xi^* L_+^*).$$

Then, from the commutation relation $[a,\exp(\zeta L_+)]=\zeta\exp(\zeta L_+)$ which is derived from $[a,L_+]=I$, and by using the relation $\exp(\frac{1}{2}\ln(1-|\zeta|^2)L_0)\exp(\zeta^* L_-)|0\rangle_N=(1-|\zeta|^2)^{\lambda/2}|0\rangle_N$, we have

$$a|\zeta\rangle_a=\exp(\zeta L_+)a|0\rangle_N+\zeta\exp(\zeta L_+)|0\rangle_N=\zeta|\zeta\rangle_a.$$

This shows that the operator a has the other property of the annihilation operator—the property that it has the coherent states as its eigenvectors.

Thus, the annihilation–creation relations and their relation to the coherent states have been defined naturally from the context of the irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$. In our framework, we have not used L_- as the annihilation operator but we have used $a=L_+^{-1}N$, because L_- does not have the coherent states as the eigenvectors.

Note that the above-mentioned operator a approaches the boson annihilation operator as λ tends to infinity, in the following sense. Let $U_\lambda:\mathcal{H}\to L^2(\mathbb{R})$ be the unitary map such that $U_\lambda(|n\rangle_N)=|n\rangle_{\text{boson}}$. Then, we can show that $U_\lambda a U_\lambda^*$ converges to the boson annihilation operator in the sense of the weak convergence as λ tends to infinity.

IV. CONCRETE REPRESENTATION OF $\mathfrak{su}(1,1)$ CORRESPONDING TO DISCUSSIONS FOR AFFINE GROUP GIVEN IN SEC. II

In this section, we will discuss what concrete representation explains the correspondence between the framework given in Sec. III in terms of the irreducible unitary representation and the heuristic discussions for the affine group given in Sec. III.

On $L^2(\mathbb{R}^+)$, we choose two generators of $\mathfrak{su}(1,1)$ from two generators of affine group as:

$$E_0=i(PQ+QP),\quad E_+=iQ.$$

Adding the other generator,

$$E_-:=-i(PQP+k^2Q^{-1})$$

formally, we construct a representation of $\mathfrak{su}(1,1)$ from a representation of affine group. [Conversely, choosing two generators E_0 and E_+, we can construct a representation of affine group from a representation of $\mathfrak{su}(1,1)$.]

In the following, the discussion for the affine group given in Sec. II is directly derived from the general framework given in Sec. III. However, especially in the cases where $-1/2<k<1/2$, we should be careful about the domain of the operator E_-, as will be shown.

First, define the operator

$$\tilde{E}_{-,k}:=-i(PQP+k^2Q^{-1})\quad(k>-1/2)$$

on the dense subspace $\mathcal{D}_0(\tilde{E}_{-,k})$ of $L^2(\mathbb{R}^+)$ defined by

$$\mathcal{D}_0(\tilde{E}_{-,k}):=\left\{\begin{array}{c|c} f(x)=x^k f_0(x) & (2k+1)x^k f_0'(x)+x^{k+1}f_0''(x)\in L^2(\mathbb{R}^+), \\ \in L^2(\mathbb{R}^+)\cap C^1(\mathbb{R}^+) & \limsup_{s\to 0} f_0(s)<\infty, \\ & x^k f_0(x)\to 0 \ \text{ as } \ x\to\infty \end{array}\right\}.$$

Then, it is confirmed that the operator $i\tilde{E}_{-,k}=PQP+k^2Q^{-1}$ is a symmetric operator on $\mathcal{D}_0(\tilde{E}_{-,k})$ from the fact that the difference

$$\int_s^t ((PQP+k^2Q^{-1})f)^*(x)g(x)\,dx-\int_s^t (f(x))^*((PQP+k^2Q^{-1})g)(x)\,dx$$
$$=[x(f'(x))^*g(x)-xg'(x)(f(x))^*]_s^t$$
$$=t(f'(t))^*g(t)-tg'(t)(f(t))^*-\left(sg(s)\left((f'(s))^*-\frac{k}{s}(f(s))^*\right)\right.$$
$$\left.-s(f(s))^*\left(g'(s)-\frac{k}{s}g(s)\right)\right)$$
$$=t(f'(t))^*g(t)-tg'(t)(f(t))^*-(sg(s)s^k(f_0'(s))^*-s(f(s))^*s^kg_0'(s))$$

tends to zero as $s\to 0, t\to\infty$. Moreover, we can show that $\mathcal{D}_0(\tilde{E}_{-,k}^*)\cap C^2(\mathbb{R}^+)=\mathcal{D}_0(\tilde{E}_{-,k})$. Therefore, $\tilde{E}_{-,k}$ is a closable operator and $iE_{-,k}:=i\overline{\tilde{E}_{-,k}}$ is a self-adjoint operator. Hence, we can show that $\tilde{E}_{-,k}$ is a closable operator and the operator $iE_{-,k}:=i\overline{\tilde{E}_{-,k}}$ is a self-adjoint operator. Note that the operator $E_{-,k}$ is quite different from $E_{-,-k}$.

By letting $L_{+,k}, L_{-,k}, L_{0,k}, \tilde{A}_k, N_k$ be $L_+, L_-, L_0, \tilde{A}, N$, $|n\rangle_N$, respectively, with $\tilde{A}:=-i(a+I)(a-I)^{-1}$ defined on the vector space whose elements are finite linear sums of $\{|n\rangle_N\}_{n=0}^{\infty}$, we have

$$L_{+,k}=\tfrac{1}{2}(i(PQ+QP)-Q+PQP+k^2Q^{-1}),$$
$$L_{-,k}=\tfrac{1}{2}(i(PQ+QP)+Q-PQP-k^2Q^{-1}),$$
$$L_{0,k}=(PQP+k^2Q^{-1}+Q),\quad A_k=P+ikQ^{-1},$$
$$N_k=\tfrac{1}{2}(PQP+k^2Q^{-1}+Q-1-2k).$$

In this representation, the minimum eigenvalue of $L_{0,k}$ is $\lambda=2k+1$. Moreover, the number state $|n\rangle_N^k$ is shown to be the $\mathfrak{su}(1,1)$-number state $|n\rangle_N$.

The domain of the adjoint operator $\tilde{A}_k$ is given by

$$\mathcal{D}_0(\tilde{A}_k^*)\cap C^1(\mathbb{R}^+)=\left\{x^{-k}f(x)\in L^2(\mathbb{R}^+)\cap C^1(\mathbb{R}^+)\,\middle|\,\begin{matrix}x^{-k}f'(x)\in L^2(\mathbb{R}^+)\\ f(s)\to 0\ \text{ as }\ s\to 0,\end{matrix}\right\},\tag{9}$$

which implies that $\mathcal{D}_0(\tilde{A}_k^*)$ is dense in $L^2(\mathbb{R}^+)$. Thus $\tilde{A}_k$ is shown to be a closable operator. Since $A_k=\overline{\tilde{A}_k}$, the relation

$$\mathcal{D}_0(A_k)\cap C^1(\mathbb{R}^+)=\left\{x^kf(x)\in L^2(\mathbb{R}^+)\cap C^1(\mathbb{R}^+)\,\middle|\,\begin{matrix}x^kf'(x)\in L^2(\mathbb{R}^+),\\ \limsup_{s\to 0} f(s)<\infty\end{matrix}\right\}.\tag{10}$$

is confirmed. Note that $\overline{X}=X^{**}$ and $X^*=\overline{X}^*$ hold for a densely defined linear operator X, and that $\limsup_{x\to\infty} f_0(x)=0$ for $k>-\frac{1}{2}$ when $x^kf_0(x)\in L^2(\mathbb{R}^+)$. From (10), we can show that $|\zeta\rangle^k$ belongs to $\mathcal{D}_0(A_k)$ and coincides with the $\mathfrak{su}(1,1)$-coherent state $|-i(\zeta+1)/(\zeta-1)\rangle_a$. Thus, the whole discussion given in Sec. II has been justified and reinterpreted in terms of the irreducible unitary representations of the algebra $\mathfrak{su}(1,1)$.

In the following, we discuss the properties of A_k and A_k^*, more deeply. The subspaces $\mathcal{D}_0(A_k^*)\cap C^1(\mathbb{R}^+)$ and $\mathcal{D}_0(A_k)\cap C^1(\mathbb{R}^+)$ are the cores of A_k^* and A_k.[8] When $-\frac{1}{2}<k<\frac{1}{2}$, the domain of A_k is larger than the domain of A_{-k}^*, though A_k and A_{-k}^* are the same formally, i.e., $A_{-k}^*\subset_{\neq}A_k$. In the special case where $\lambda=1$ (i.e., where $k=0$), A_0^* is symmetric. Since $A_0=A_0^{**}$ has no spectrum in the lower half plane, A_0^*'s deficiency indices are (1,0). (For the definition of deficiency indices, see p. 138 of Reed and Simon[9] or p. 360 of Rudin.[10]) Therefore,

the operator A_0^* is a maximal symmetric operator. These relations $\mathcal{D}_0(A_k^*)\subset\mathcal{D}_0(A_k)$ and $\mathcal{D}_0(A_k^*)\subset\mathcal{D}_0(E_+^{-1})$ are shown in the cases where $\lambda<1(k>0)$, only the relation $\mathcal{D}_0(A_k^*)\subset\mathcal{D}_0(A_k)$ is shown when $\lambda=1(k=0)$, and these relations $\mathcal{D}_0(A_k)\subset\mathcal{D}_0(A_k^*)$ and $\mathcal{D}_0(A_k)\subset\mathcal{D}_0(E_+^{-1})$ are shown when $0<\lambda<1(-\frac{1}{2}<k<0)$.

As another representation of $\mathfrak{su}(1,1)$ on $L^2(\mathbb{R})$, the Holstein–Primakoff representation is known as[11,12]

$$L_0 := Q^2+P^2+2k-2,$$

$$L_+ := \frac{1}{\sqrt{2}}(Q-iP)\sqrt{\frac{1}{2}(Q^2+P^2)+2k-\frac{3}{2}},$$

$$L_+ := \frac{1}{\sqrt{2}}\sqrt{\frac{1}{2}(Q^2+P^2)+2k-\frac{3}{2}}(Q+iP).$$

This representation is algebraicly equivalent with our representation. However, it has a completely different form from our representation.

V. CONCLUSION

We have derived a kind of annihilation/creation relation similar to the boson annihilation/creation relation, from the irreducible unitary representation of the algebra $\mathfrak{su}(1,1)$. The proposed framework contains an annihilation/creation relation related to the affine coherent states as a special case. In signal processing, in a similar manner to the boson-annihilation/creation relation which is applied to the operator method in Wiener–Hermite expansion of Gaussian stochastic processes, our results may be applied to an analogous operator method for the stochastic processes related to the χ^2-distribution and the wavelets, because the affine coherent states are closely related to them. This discussion can be treated from another viewpoint[13,14]

This paper concerns a relationship between the kernel of the Bargmann transform and the corresponding canonical transformation. We study this fact for a Bargmann transform introduced by Thomas and Wassell [J. Math. Phys. **36**, 5480–5505 (1995)]—when the configuration space is the two-sphere S^2 and for a Bargmann transform that we introduce for the three-sphere S^3. It is shown that the kernel of the Bargmann transform is a power series in a function which is a generating function of the corresponding canonical transformation (a classical analog of the Bargmann transform). We show in each case that our canonical transformation is a composition of two other canonical transformations involving the complex null quadric in $\mathbf{C}^3$ or $\mathbf{C}^4$. We also describe quantizations of those two other canonical transformations by dealing with spaces of holomorphic functions on the aforementioned null quadrics. Some of these quantizations have been studied by Bargmann and Todorov [J. Math. Phys. **18**, 1141–1148 (1977)] and the other quantizations are related to the work of Guillemin [Integ. Eq. Operator Theory **7**, 145–205 (1984)]. Since suitable infinite linear combinations of powers of the generating functions are coherent states for $L^2(S^2)$ or $L^2(S^3)$, we show finally that the studied Bargmann transforms are actually coherent states transforms. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1468254]

I. INTRODUCTION

Bargmann[1] introduced the so-called Bargmann transform as a unitary transformation from $L^2(\mathbf{R}^n)$ onto a space $\mathcal{B}_n$ of analytic functions (of n complex variables) which are square integrable with respect to a Gaussian measure. The Bargmann transform is defined as the integral operator

$$\mathbf{B}_{\mathbf{R}^n}\Psi(\mathbf{z}) \equiv \frac{1}{\pi^{n/4}} \int_{\mathbf{R}^n} \exp\left(-\frac{1}{2}(\mathbf{z}^2+\mathbf{x}^2) + \sqrt{2}\mathbf{z}\cdot\mathbf{x} \right) \Psi(\mathbf{x}) d\mathbf{x} \tag{1.1}$$

(see Sec. I for notation). The Bargmann transform is also called the ''Segal–Bargmann transform.'' (See Ref. 2 for a historical remark about Bargmann and Segal's work on this transform. Segal[3] studied the infinite dimensional case $n=\infty$.)

The Bargmann space $\mathcal{B}_n$ provides a very adequate framework to represent and study the n-dimensional quantum harmonic oscillator (i.e., the addition of n one-dimensional harmonic oscillators with the same frequency). It is known[4] that the Hamiltonian of such an oscillator can be written as

$$\hat{H} = \sum_{j=1}^{n} a_j^\dagger a_j, \tag{1.2}$$

where $a_j^\dagger$ and a_j, $j=1,2,\ldots,n$ are creation and annihilation operators given by

[b)]Electronic mail: villegas@matcuer.unam.mx

$$a_j^\dagger = \frac{1}{\sqrt{2}}(\hat{q}_j - \imath\hat{p}_j) = \frac{1}{\sqrt{2}}\left(q_j - \frac{\partial}{\partial q_j}\right),$$
$$a_j = \frac{1}{\sqrt{2}}(\hat{q}_j + \imath\hat{p}_j) = \frac{1}{\sqrt{2}}\left(q_j + \frac{\partial}{\partial q_j}\right), \tag{1.3}$$

with $\widehat{q_j}$ the operator of multiplication by the coordinate q_j and $\hat{p}_j = -\imath(\partial/\partial q_j)$.

The operators corresponding to $a_j^\dagger$, a_j, and $\hat{H}$ in the Bargmann space $\mathcal{B}_n$ are multiplication by the complex variable z_j, partial derivative with respect to z_j and $\Sigma_{j=1}^n z_j(\partial/\partial z_j)$, respectively. In particular, the spectrum of the n-dimensional quantum harmonic oscillator is easy to compute because in the Bargmann representation the monomials $z_1^{a_1}z_2^{a_2}\cdots z_n^{a_n}$ (with a_j, $j=1,2,\ldots,n$, nonnegative integers) are the eigenfunctions of the operator $\Sigma_{j=1}^n z_j\,\partial/\partial z_j)$.

From the viewpoint of classical mechanics, the problem of an n-dimensional harmonic oscillator can be studied in the phase space $\mathbf{R}^{2n}=\{(\mathbf{q},\mathbf{p})|\mathbf{q},\mathbf{p}\in\mathbf{R}^n\}$ with symplectic form $\omega_n = \Sigma_{j=1}^n \mathrm{d}q_j\wedge\mathrm{d}p_j$ and Hamiltonian

$$H = \frac{1}{2}\sum_{j=1}^n p_j^2 + q_j^2. \tag{1.4}$$

It is known[4] that this problem can also be described by introducing complex variables $z_j = (1/\sqrt{2})(q_j - \imath p_j)$, $j=1,2,\ldots,n$. In these complex variables, the Hamiltonian H is given by $\Sigma_{j=1}^n z_j\overline{z_j}$. This is the classical analog of Eq. (1.2).

A remarkable and fundamental idea for this paper is the following: as in Ref. 5, let us consider the exponent of the kernel of the Bargmann transform in Eq. (1.1),

$$\Phi_n(\mathbf{q},\mathbf{z}) \equiv -\imath(-\tfrac{1}{2}(\mathbf{z}^2+\mathbf{q}^2) + \sqrt{2}\mathbf{z}\cdot\mathbf{q}). \tag{1.5}$$

It turns out that the function $\Phi_n(\mathbf{q},\mathbf{z})$ *is a generating function of a canonical transformation (symplectomorphism) from the phase space* $(\mathbf{R}^{2n},\omega_n)$ *onto the phase space* $(\mathbf{C}^n,\mu_n)$, *where* μ_n *is the symplectic form* $\mu_n = -\imath\Sigma_{j=1}^n \mathrm{d}z_j\wedge\mathrm{d}\overline{z_j}$ (see Sec. III for details). Thus we shall say that $\mathcal{C}_n$ is the classical analog of the Bargmann transform (or that $\mathbf{B}_{\mathbf{R}^n}$ is the quantization of $\mathcal{C}_n$) in the sense that $\mathbf{B}_{\mathbf{R}^n}$ is a unitary transformation between the Hilbert spaces $L^2(\mathbf{R}^n)$ and $\mathcal{B}_n$, and $\mathcal{C}_n$ is a diffeomorphism between the phase spaces $(\mathbf{R}^{2n},\omega_n)$ and $(\mathbf{C}^n,\mu_n)$.

This paper concerns the same relationship between the Bargmann transform and a corresponding canonical transformation when the configuration space $\mathbf{R}^n$ is replaced by the two-sphere S^2 or the three sphere S^3 (here we mean by S^n the set of unit vectors in $\mathbf{R}^{n+1}$). For the S^2 case, Thomas and Wassell[6] introduced a Bargmann transform from $L^2(S^2)$ onto a proper subspace of $\mathcal{B}_2$. For the S^3 case, a Bargmann transform was introduced by Villegas-Blas.[7] This last transform goes from $L^2(S^3)$ onto a proper subspace of $\mathcal{B}_4$ determined by the kernel of an operator which carries the restriction in quantum mechanics of the classical fact that the angular momentum and Runge–Lenz vectors should be orthogonal for the Kepler problem. We show in both cases—S^2 and S^3—that the kernel of the Bargmann transform is a power series in a function which plays the role of a generating function of a canonical transformation which in turn is the classical analog of the Bargmann transform.

In Sec. II, we describe the Bargmann transform for the three cases $\mathbf{R}^n$, S^2, and S^3. The mentioned relationship between the Bargmann transform and corresponding canonical transformations is established in Sec. III. For the S^2 and S^3 cases we do this by using spherical coordinates (a local chart). In order to define and extend our canonical transformations to the whole spaces $T^*S^2-\{0\}$ and $T^*S^3-\{0\}$ (we need to remove the zero section in both cases to avoid singularities) we use a key property of the generating functions, namely that these functions can be written as the inner product of the position vector $\mathbf{x}$ (in S^2 or S^3) and a complex vector in the null quadric

$\mathbf{Q}^2$ (for the S^2 case) and $\mathbf{Q}^3$ (for the S^3 case). Here, for n a positive integer, the null quadric $\mathbf{Q}^n$ is the set of vectors in $\mathbf{C}^{n+1}$ such that the addition of the square of their components is zero. Note that a vector in $\mathbf{C}^{n+1}$ belongs to $\mathbf{Q}^n$ if and only if the norm of its real and imaginary parts is the same and these two vectors are orthogonal to one another. Thus $\mathbf{Q}^2-\{0\}$ and $\mathbf{Q}^3-\{0\}$ can be identified with $T^*S^2-\{0\}$ and $T^*S^3-\{0\}$, respectively.

Thus we are able to extend our canonical transformation as the inverse of a composition of two maps. For the S^2 case, one map $\rho_2(\mathbf{z})$ goes from $\tilde{\mathbf{C}}^2-\{0\}$ [that is $\mathbf{C}^2$ minus the origin and (z_1,z_2) identified with $(-z_1,-z_2)$] onto $\mathbf{Q}^2-\{0\}$ and the other one, σ_2, goes from $\mathbf{Q}^2-\{0\}$ onto $T^*S^2-\{0\}$. These maps are symplectomorphisms with T^*S^2 endowed with the restriction of the canonical symplectic form of the ambient $T^*\mathbf{R}^3$, and $\mathbf{Q}^2-\{0\}$ endowed with the symplectic form given by the pull-back of the symplectic form on T^*S^2 under the map σ_2. We remark here that the symplectic form on $\mathbf{Q}^2-\{0\}$ is not the restriction of the canonical symplectic form for the ambient $\mathbf{C}^3$. For the S^3 case, we have a similar extension, but instead of $\tilde{\mathbf{C}}^2-\{0\}$, we have a six real-dimensional phase space $\tilde{\mathbf{C}}^4-\{0\}$ which is a quotient of a submanifold of $\mathbf{C}^4$ and determined by reduction. Thus in this second case we extend our canonical transformation by considering the inverse of the composition of two maps ρ_3 (from $\tilde{\mathbf{C}}^4-\{0\}$ onto $\mathbf{Q}^3-\{0\}$) and σ_3 (from $\mathbf{Q}^3-\{0\}$ onto $T^*S^3-\{0\}$).

Once we have, for each case S^2 or S^3, the symplectomorphisms between the three phase spaces, a natural question is to ask for a description of their corresponding quantizations. This is the goal of Section IV. Bargmann and Todorov[8] have already considered the quantizations of ρ_2 and ρ_3 by introducing Hilbert spaces of holomorphic functions on the null quadrics $\mathbf{Q}^2$ and $\mathbf{Q}^3$, respectively. However, we include a brief description of such quantizations for completeness and to introduce some notation. Our procedure differs from the one followed by Bargmann and Todorov in the way the measure on the null quadric is introduced. We also include in Sec. IV a discussion on the relation between our quantizations of σ_2 and σ_3 and work of Guillemin.[9]

The fact that our generating functions for the S^2 and S^3 cases are inner products of position vectors and vectors in the null quadric has another important implication. The Bargmann transforms described in Sec. II for S^2 and S^3 are *coherent states transforms*. That is, they can be written as inner products with coherent states. This is in analogy with the Bargmann transform $\mathbf{B}_{\mathbf{R}^n}$, which acting on a function is the inner product of the function and a coherent state of the n-dimensional harmonic oscillator. The coherent states appearing here are infinite linear combinations of integer powers of our generating functions. The latter functions are known in the literature (see Ref. 10) and sometimes they are called coherent states as well. We prefer to call them great-circle states because they concentrate on great circles of S^2 or S^3 in the semiclassical regime. The great-circle states give a resolution of the identity for each eigenspace of the spherical Laplacian on S^2 or S^3, respectively [these eigenspaces are irreducible representations of the groups SO(3) or SO(4)]. As a consequence, we also obtain a resolution of the identity for $L^2(S^2)$ and $L^2(S^3)$ through our coherent states.

Section V is devoted to the describing the Bargmann transforms as coherent states transforms. In this Section we also show how the great-circle states help us to obtain reproducing kernels for the range of our Bargmann transforms for both the $\mathcal{S}^2$ and $\mathcal{S}^3$ cases. We also show reproducing kernels for spaces of holomorphic functions on the null quadrics $\mathbf{Q}^2$ and $\mathbf{Q}^3$ related with the range and domain of the quantizations described in Sec. IV.

There are other Bargmann-type transforms introduced by Rawnsley[11] (for the n-sphere), Ii[12] and Wada[13] (for the n-sphere), Hall[2,14,15] (for compact Lie groups), Stenzel[16] (for symmetric spaces of compact type), Kowalski and Rembieliński[17,18] (for the two-sphere), and Hall and Mitchell[19] (for the n-sphere); but they are different from the transformations introduced in this paper. We devote Sec. VI to briefly describe these Bargmann-type transformations.

We also include two appendices to prove that the kernel of the Bargmann transforms for both spheres $\mathcal{S}^2$ and $\mathcal{S}^3$ is a power series in a certain function.

We finally remark that the case of the three-sphere is physically relevant in both quantum and classical mechanics. The symmetries of the bound states of the hydrogen atom are given by the

Lie algebra of the group SO(4) (see Refs. 7 and 20). In this way we can explain the degeneracy of the negative energies for the hydrogen atom. In classical mechanics, Moser[21] showed that the Hamiltonian flow for the Kepler problem (with negative energy) is equivalent, after a time reparametrization, to the geodesic flow on S^3. In this way, Moser is able to regularize the motion of the Kepler problem.

II. BARGMANN TRANSFORM FOR $L^2(S^2)$ AND $L^2(S^3)$

The purpose of this section is to describe both the Bargmann transform for $L^2(S^2)$ (introduced by Thomas and Wassell[6]) and $L^2(S^3)$ (introduced by Villegas-Blas[7]). In both cases we need the usual Bargmann spaces introduced by Bargmann[1] in his transform for $L^2(\mathbf{R}^n)$. To that end, and as a reference for the following sections, we begin by reviewing these spaces and their Bargmann transforms.

A. Bargmann transform for $L^2(\mathbf{R}^n)$

In this section we review important properties of the Bargmann transform that are needed for later sections of this paper. For a detailed explanation and proofs see Refs. 1 and 2.

The Bargmann space $\mathcal{B}_n$ is the space of analytic functions of n complex variables $\mathbf{z}=(z_1,z_2,\ldots,z_n)$ which are square integrable with respect to the Gaussian measure

$$d\nu_n(\mathbf{z})=\frac{1}{\pi^n}\exp(-|\mathbf{z}|^2)\prod_{j=1}^{n} dx_j\,dy_j, \tag{2.1}$$

where $|\mathbf{z}|^2=|z_1|^2+|z_2|^2+\cdots+|z_n|^2$ and $z_j=x_j+\imath y_j$, x_j, $y_j\in\mathbf{R}$, with $j=1,2,\ldots,n$.

The space $\mathcal{B}_n$ is a Hilbert space with inner product

$$\langle F,G\rangle_{\mathcal{B}_n}=\int_{\mathbf{C}^n} F(\mathbf{z})\overline{G}(\mathbf{z})d\nu_n(\mathbf{z}). \tag{2.2}$$

The set of all monomials $(z_1^{a_1}z_2^{a_2}\cdots z_n^{a_n})/(\sqrt{a_1!a_2!\cdots a_n!})$, with $a_1,a_2,\ldots,a_n$ non-negative integers, is an orthonormal basis of $\mathcal{B}_n$.

The coherent states in $\mathcal{B}_n$,

$$\Psi_{\mathbf{a}}(\mathbf{z})=\exp(\overline{\mathbf{a}}\mathbf{z}) \quad \text{with} \quad \mathbf{a}\in\mathbf{C}^n, \tag{2.3}$$

provide a reproducing kernel for the space $\mathcal{B}_n$. That is, for $\Phi\in\mathcal{B}_n$,

$$\Phi(\mathbf{z})=\langle\Phi,\Psi_{\mathbf{z}}\rangle_{\mathcal{B}_n}=\int_{\mathbf{C}^n}\exp(\mathbf{z}\overline{\mathbf{w}})\Phi(\mathbf{w})d\nu_n(\mathbf{w}). \tag{2.4}$$

The Bargmann transform for $L^2(\mathbf{R}^n)$ is defined as the operator $\mathbf{B}_{\mathbf{R}^n}:L^2(\mathbf{R}^n)\mapsto\mathcal{B}_n$ given by

$$\mathbf{B}_{\mathbf{R}^n}\Psi(\mathbf{z})=\frac{1}{\pi^{n/4}}\int_{\mathbf{R}^n}A(\mathbf{x},\mathbf{z})\Psi(\mathbf{x})d\mathbf{x}, \quad \Psi\in L^2(\mathbf{R}^n), \tag{2.5}$$

where $d\mathbf{x}$ is the usual Lebesgue measure on $\mathbf{R}^n$ and

$$A(\mathbf{x},\mathbf{z})=\exp(-\tfrac{1}{2}(\mathbf{z}^2+\mathbf{x}^2)+\sqrt{2}\mathbf{z}\cdot\mathbf{x}), \tag{2.6}$$

with $\mathbf{z}^2=z_1^2+z_2^2+\cdots+z_n^2$, $\mathbf{x}=(x_1,x_2,\ldots,x_n)$, $\mathbf{x}^2=x_1^2+x_2^2+\cdots+x_n^2$, and $\mathbf{z}\cdot\mathbf{x}=z_1x_1+z_2x_2+\cdots+z_nx_n$. The Bargmann transform $\mathbf{B}_{\mathbf{R}^n}$ is a unitary operator [with $L^2(\mathbf{R}^n)$ endowed with the usual inner product].

The inverse $\mathbf{B}_{\mathbf{R}^n}^{-1}$ is given by

$$\mathbf{B}_{\mathbf{R}^n}^{-1} f(\mathbf{x}) = \lim_{M \mapsto \infty} \int_{|\mathbf{z}| \leqslant M} \overline{A(\mathbf{x},\mathbf{z})} f(\mathbf{z}) \mathrm{d}\nu_n(\mathbf{z}). \tag{2.7}$$

Here we need to take the limit because the integral over all the space $\mathbf{C}^n$ might not exist [note that, for fixed $\mathbf{x}$, $A(\mathbf{x},\mathbf{z}) \notin \mathcal{B}_n$].

B. Bargmann transform for $L^2(S^2)$

Let us first define the space $L^2(S^n)$ for a given integer n. Let $\mathrm{d}\sigma_n$ be the usual normalized Lebesgue surface measure on S^n. Let us define $L^2(S^n)$ as the space of Lebesgue measurable functions on S^n which are square integrable with respect to the measure $\mathrm{d}\sigma_n$.

The space $L^2(S^n)$ is a Hilbert space with inner product

$$\langle F,G \rangle_{S^n} = \int_{S^n} F(\mathbf{x}) \overline{G}(\mathbf{x}) \mathrm{d}\sigma_n(\mathbf{x}). \tag{2.8}$$

In order to define the Bargmann transform for $L^2(S^2)$, we first remind the reader of some well-known facts about two different representations of the SO(3) group of rotations of the space $\mathbf{R}^3$.

Let us consider the Laplacian operator on the two-sphere S^2 denoted by Δ_{S^2}. We will actually consider the normalized Laplacian operator with spectrum the set $\{(\ell+1/2)^2 | \ell = 0,1,2...\}$.

Let $0 < \theta < \pi$, $0 \leqslant \phi \leqslant 2\pi$ be spherical coordinates on S^2:

$$x_1 = \sin(\theta)\cos(\phi), \quad x_2 = \sin(\theta)\sin(\phi), \quad x_3 = \cos(\theta). \tag{2.9}$$

The expression for the Laplacian on S^2 in spherical coordinates is

$$\Delta_{S^2} = -\frac{1}{\sin(\theta)} \frac{\partial}{\partial\theta} \sin(\theta) \frac{\partial}{\partial\theta} - \frac{1}{\sin^2(\theta)} \frac{\partial^2}{\partial\phi^2} + \frac{1}{4}. \tag{2.10}$$

The Laplacian Δ_{S^2} is in turn related to the addition of the square of the generators L_j of rotations in $\mathbf{R}^3$ around the plane perpendicular to the axis x_j for $j = 1,2,3$:

$$\Delta_{S^2} = L_1^2 + L_2^2 + L_3^2 + 1/4, \tag{2.11}$$

where

$$L_1 = \iota \sin(\phi) \frac{\partial}{\partial\theta} + \iota \cot(\theta)\cos(\phi) \frac{\partial}{\partial\phi},$$

$$L_2 = -\iota \cos(\phi) \frac{\partial}{\partial\theta} + \iota \cot(\theta)\sin(\phi) \frac{\partial}{\partial\phi}, \tag{2.12}$$

$$L_3 = -\iota \frac{\partial}{\partial\phi}.$$

The operators L_j act on a dense subspace of $L^2(S^2)$ and provide a representation for the Lie algebra $so(3)$ of SO(3). They also satisfy the commutation relations

$$[L_i, L_j] = \iota \epsilon_{ijk} L_k, \quad i,j,k = 1,2,3, \tag{2.13}$$

where $\{i,j,k\}$ is a permutation of $\{1,2,3\}$. If this permutation is even (odd) then $\epsilon_{ijk} = 1$ ($\epsilon_{ijk} = -1$).

It is known that the eigenfunctions of the Laplacian Δ_{S^2} provide a basis for $L^2(S^2)$. Moreover, $L^2(S^2)$ is the direct sum of the eigenspaces of the Laplacian. For each $\ell=0,1,2...$, we shall denote by V_ℓ the eigenspace of the Laplacian Δ_{S^2} associated with the eigenvalue $(\ell+1/2)^2$.

The group SO(3) acts on $L^2(S^2)$ as follows. Given $R\in \mathrm{SO}(3)$, we define $T_R: L^2(S^2)\mapsto L^2(S^2)$ by

$$T_R\Psi(\mathbf{x})=\Psi(R^{-1}\mathbf{x}), \quad \mathbf{x}\in S^2. \tag{2.14}$$

A particular and important basis of $L^2(S^2)$ is obtained by taking common normalized eigenfunctions of both operators Δ_{S^2} and L_3 (these two operators commute). These functions are known as ''spherical harmonics'' and we shall denote them by

$$Y_{\ell m} \quad \text{with } \ell=0,1,2... \text{ and } m=-\ell,-\ell+1,\ldots,\ell. \tag{2.15}$$

Moreover, if, for each $\ell=0,1,2,\ldots$, we let the group $\{T_R|R\in \mathrm{SO}(3)\}$ act on the space

$$V_\ell=\mathrm{span}\{Y_{\ell m}|m=-\ell,-\ell+1,\ldots,\ell\}, \tag{2.16}$$

then we obtain all the irreducible representations of SO(3).

On the other hand, we can obtain irreducible representations for SO(3) on the basis of the knowledge of irreducible representations of SU(2) (the group of two by two unitary matrices with complex entries and determinant one). An important representation of the SU(2) group is obtained by letting this group act on the Bargmann space $\mathcal{B}_2$ of analytic functions in two complex variables $\mathbf{z}=(z_1,z_2)$ in a similar way as we made the SO(3) group act on $L^2(S^2)$.

Let us denote by $\mathbf{S}$ the set of all numbers of the form $p/2$ with p a non-negative integer. For $s\in\mathbf{S}$, let us also denote by $\mathcal{W}_s$ the subspace of $\mathcal{B}_2$ of homogeneous polynomials in two complex variables (z_1,z_2) of degree $2s$. An orthonormal basis for $\mathcal{W}_s$ is given by the monomials

$$y_{sm}=\frac{z_1^{s+m}z_2^{s-m}}{\sqrt{(s+m)!(s-m)!}} \tag{2.17}$$

with $m=-s,-s+1,\ldots,s-1,s$.

When we restrict the action of SU(2) to the spaces $\mathcal{W}_s$, we get all of the irreducible representations of SU(2). In particular, when we take $s=\ell$ a non-negative integer, we obtain all of the irreducible representations of SO(3).

In order to define a Bargmann transform for $L^2(S^2)$, the above-given description of two types of irreducible representations of SO(3) suggests defining the following assignment:

$$Y_{\ell m}\mapsto y_{\ell m} \quad \text{for all } \ell=0,1,2,\ldots \text{ and } m=-\ell,-\ell+1,\ldots,\ell. \tag{2.18}$$

Thus we define the Bargmann transform $\mathbf{B}_{S^2}$ for $L^2(S^2)$ as the linear extension of this assignment. Notice that $\mathbf{B}_{S^2}$ is a unitary operator from $L^2(S^2)$ onto the closed subspace $\mathcal{B}_{S^2}$ of $\mathcal{B}_2$ generated by the monomials with even degree, that is $\mathcal{B}_{S^2}=\oplus\mathcal{W}_\ell$ (where the direct sum is taken over all non-negative integers).

The Bargmann transform $\mathbf{B}_{S^2}$ can be written as an integral operator

$$\mathbf{B}_{S^2}\Psi(\mathbf{z})=\int_{\mathbf{x}\in S^2}K_{S^2}(\mathbf{x},\mathbf{z})\Psi(\mathbf{x})\mathrm{d}\sigma_2(\mathbf{x}), \tag{2.19}$$

with kernel

$$K_{S^2}(\mathbf{x},\mathbf{z})=\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{m=\ell}\overline{Y}_{\ell m}(\mathbf{x})y_{\ell m}(\mathbf{z}). \tag{2.20}$$

This kernel has the property of being a power series in the function

$$\Phi_{S^2}(\mathbf{x},\mathbf{z})=\sum_{m=-1}^{m=1}\overline{Y}_{1m}(\mathbf{x})y_{1m}(\mathbf{z}) \tag{2.21}$$

in the following way:

$$K_{S^2}(\mathbf{x},\mathbf{z})=\sum_{\ell=0}^{\infty}\frac{\sqrt{2\ell+1}}{\ell!}\left(\frac{1}{\sqrt{3}}\right)^{\ell}(\Phi_{S^2}(\mathbf{x},\mathbf{z}))^{\ell}, \tag{2.22}$$

with the following explicit expression for $\Phi_{S^2}(\mathbf{x},\mathbf{z})$:

$$\Phi_{S^2}(\mathbf{x},\mathbf{z})=(\sqrt{3}/2)\,(-\sin(\theta)\exp(-\imath\phi)z_1^2+2\cos(\theta)z_1z_2+\sin(\theta)\exp(\imath\phi)z_2^2). \tag{2.23}$$

We give a proof of this fact in Appendix A.

The Bargmann transform $\mathbf{B}_{S^2}$ intertwines L_1,L_2,L_3,Δ_S^2 with the following operators:

$$\begin{aligned}
L_1'&=\frac{1}{2}\left(z_1\frac{\partial}{\partial z_2}+z_2\frac{\partial}{\partial z_1}\right),\\
L_2'&=\frac{1}{2\imath}\left(z_1\frac{\partial}{\partial z_2}-z_2\frac{\partial}{\partial z_1}\right),\\
L_3'&=\frac{1}{2}\left(z_1\frac{\partial}{\partial z_1}-z_2\frac{\partial}{\partial z_2}\right),\\
\Delta_{S^2}'&=\left(\frac{1}{2}\left(z_1\frac{\partial}{\partial z_1}+z_2\frac{\partial}{\partial z_2}\right)+\frac{1}{2}\right)^2,
\end{aligned} \tag{2.24}$$

respectively.

Notice that the operator $L_0=z_1(\partial/\partial z_1)+z_2(\partial/\partial z_2)$ is the sum of Hamiltonians of two independent harmonic oscillators $z_j(\partial/\partial z_j)$, $j=1,2$, with the same frequency.

C. Bargmann transform for $L^2(S^3)$

In analogy with the case $L^2(S^2)$, let us consider the spherical normalized Laplacian on S^3. In spherical coordinates:

$$\begin{aligned}
x_1&=\sin(\lambda)\sin(\theta)\cos(\phi),\quad x_2=\sin(\lambda)\sin(\theta)\sin(\phi),\\
x_3&=\sin(\lambda)\cos(\theta),\quad x_4=\cos(\lambda),
\end{aligned} \tag{2.25}$$

where $0<\theta,\lambda<\pi$ and $0\leqslant\phi\leqslant 2\pi$.

The expression for Δ_{S^3} is

$$\Delta_{S^3}=-\frac{\partial^2}{\partial\lambda^2}-2\cot(\lambda)\frac{\partial}{\partial\lambda}+\frac{\Delta_2}{\sin^2(\lambda)}+1, \tag{2.26}$$

where

$$\Delta_2=\frac{-1}{\sin(\theta)}\frac{\partial}{\partial\theta}\sin(\theta)\frac{\partial}{\partial\theta}+\frac{-1}{\sin^2(\theta)}\frac{\partial^2}{\partial\phi^2}. \tag{2.27}$$

Note that we are taking Δ_{S^3} such that its spectrum is the set $\{n^2|n$ is a positive integer$\}$.

Let us also consider generators for rotations on the (μ,ν) plane with $\mu,\nu=1,2,3,4$, given by restrictions to S^3 of the following operators:

$$E_{\mu\nu}=\frac{1}{\iota}\left(x_\mu\frac{\partial}{\partial x_\nu}-x_\nu\frac{\partial}{\partial x_\mu}\right),\quad \mu,\nu=1,2,3,4. \tag{2.28}$$

There are six linearly independent operators among the operators $E_{\mu\nu}$. These operators provide a representation of the Lie algebra $so(4)$. It is well known that this Lie algebra describes the symmetries of the hydrogen atom problem[7,20] for a fixed negative energy. This can be shown by considering restrictions of the angular momentum operator $\mathbf{L}=(L_1,L_2,L_3)$ and the Runge–Lenz $\mathbf{A}=(A_1,A_2,A_3)$ operator to eigenspaces of the Hamiltonian of the hydrogen atom problem. In order to keep track of this fact, we rename the operators $L_1=E_{23}$, $L_2=E_{31}$, $L_3=E_{12}$, $A_j=E_{4j}$ $j=1,2,3$.

The expressions for the operators $\mathbf{L}$ and $\mathbf{A}$ in spherical coordinates are

$$\begin{aligned}
L_1&=\iota\left(\sin(\phi)\frac{\partial}{\partial\theta}+\cot(\theta)\cos(\phi)\frac{\partial}{\partial\phi}\right),\\
L_2&=-\iota\left(\cos(\phi)\frac{\partial}{\partial\theta}-\cot(\theta)\sin(\phi)\frac{\partial}{\partial\phi}\right),\\
L_3&=-\iota\frac{\partial}{\partial\phi},\\
A_1&=-\iota\cot(\lambda)\left(\cos(\theta)\cos(\phi)\frac{\partial}{\partial\theta}-\frac{\sin(\phi)}{\sin(\theta)}\frac{\partial}{\partial\phi}\right)-\iota\sin(\theta)\cos(\phi)\frac{\partial}{\partial\lambda},\\
A_2&=-\iota\cot(\lambda)\left(\cos(\theta)\sin(\phi)\frac{\partial}{\partial\theta}+\frac{\cos(\phi)}{\sin(\theta)}\frac{\partial}{\partial\phi}\right)-\iota\sin(\theta)\sin(\phi)\frac{\partial}{\partial\lambda},\\
A_3&=-\iota\left(\cos(\theta)\frac{\partial}{\partial\lambda}-\sin(\theta)\cot(\lambda)\frac{\partial}{\partial\theta}\right).
\end{aligned} \tag{2.29}$$

Note that if we denote $L^2=L_1^2+L_2^2+L_3^2$ and $A^2=A_1^2+A_2^2+A_3^2$, then we have

$$\Delta_{S^3}=L^2+A^2+1. \tag{2.30}$$

Since Δ_{S^3}, L^2, and L_3 commute, we can find common normalized eigenfunctions of these operators. We shall call these functions hyperspherical harmonics[22] and denote them by $Y_{n\ell m}$ with $n=1,2,3...$, $\ell=0,1,\ldots,n-1$, $m=-\ell,-\ell+1,\ldots,\ell$. For each n, we have n^2 linearly independent hyperspherical harmonics, which is exactly the multiplicity of the corresponding eigenvalues of Δ_{S^3} and the Hamiltonian of the hydrogen atom[7,20]. The n^2-dimensional vector spaces generated by $Y_{n\ell m}$ (one space for each n) provide irreducible representations of the group SO(4).

In order to find a Hilbert space of analytic functions related to $L^2(S^3)$, we notice that the commutation relations satisfied by $\mathbf{L}$ and $\mathbf{A}$ are

$$\begin{aligned}
[L_i,L_j]&=\iota\epsilon_{ijk}L_k,\\
[L_i,A_j]&=\iota\epsilon_{ijk}A_k,\\
[A_i,A_j]&=\iota\epsilon_{ijk}L_k.
\end{aligned} \tag{2.31}$$

Now let us define the operators

$$\mathbf{C}=\frac{\mathbf{L}+\mathbf{A}}{2},\quad \mathbf{D}=\frac{\mathbf{L}-\mathbf{A}}{2}. \tag{2.32}$$

The commutation relation for these operators are

$$[C_i,C_j]=\imath\epsilon_{ijk}C_k,$$
$$[D_i,D_j]=\imath\epsilon_{ijk}D_k, \tag{2.33}$$
$$[C_i,D_j]=0.$$

Thus we obtain $so(4)=su(2)\times su(2)$.

Notice that the operators **L** and **A** satisfy the relation

$$\mathbf{L}\cdot\mathbf{A}\Psi=(L_1A_1+L_2A_2+L_3A_3)\Psi=0. \tag{2.34}$$

This relation implies

$$C^2\Psi=D^2\Psi=\left(\frac{L^2+A^2}{4}\right)\Psi. \tag{2.35}$$

Since the eigenvalues of the operators C^2 and D^2 are of the form $u(u+1)$ and $v(v+1)$ (with $u,v\in\mathbf{S}$), respectively, then we must have $u(u+1)=v(v+1)$. This equation implies $u=v$.

Since $\Delta_{S^3}=L^2+A^2+1$ and the eigenvalues of Δ_{S^3} are n^2, then we have $n^2=4u(u+1)+1$, which in turn implies $u=v=(n-1)/2$. Since n is a positive integer, **S** is the set of permitted values of u and v (including $\frac{1}{2}$, $\frac{3}{2}$, ...).

From the previous discussion, we want to consider two copies of the representation of su(2) on the Bargmann space $\mathcal{B}_2$ of analytical functions of two complex variables described previously.

Let us consider the Bargmann space $\mathcal{B}_4=\mathcal{B}_2\otimes\mathcal{B}_2$ of analytical functions of four complex variables (z_1,z_2,z_3,z_4). For each positive integer n, let us also consider the n^2-dimensional subspaces $\mathcal{M}_n$ of $\mathcal{B}_4$ given by

$$\mathcal{M}_n=\mathcal{W}_{(n-1)/2}\otimes\mathcal{W}_{(n-1)/2}, \tag{2.36}$$

with $\mathcal{W}_{(n-1)/2}$ the vector space of homogeneous polynomials of degree $n-1$ in two complex variables.

The functions

$$y_{nm_1m_2}=\frac{z_1^{(n-1)/2+m_1}z_2^{(n-1)/2-m_1}z_3^{(n-1)/2+m_2}z_4^{(n-1)/2-m_2}}{\sqrt{\left(\frac{n-1}{2}+m_1\right)!\left(\frac{n-1}{2}-m_1\right)!\left(\frac{n-1}{2}+m_2\right)!\left(\frac{n-1}{2}-m_2\right)!}}, \tag{2.37}$$

with $-(n-1)/2\leqslant m_1,m_2\leqslant(n-1)/2$ provide a basis for the space $\mathcal{M}_n$.

Since we want to assign an analytic function (of four complex variables) to the hyperspherical harmonics $Y_{n\ell m}$ and these functions are in turn common eigenfunctions of Δ_{S^3}, L^2, and L_3, we must assign to each $Y_{n\ell m}$ a function which is an eigenfunction of the representations of the operators Δ_{S^3}, L^2, and L_3 in the Bargmann space $\mathcal{B}_4$. Since $\mathbf{L}=\mathbf{C}+\mathbf{D}$ and by the theory of addition of angular momenta,[23] the function to be assigned to each $Y_{n\ell m}$ is

$$y_{n\ell m}(z_1,z_2,z_3,z_4)=\sum_{m_1+m_2=m}C\left(\frac{n-1}{2},m_1,\frac{n-1}{2},m_2;\ell,m\right)y_{nm_1m_2}, \tag{2.38}$$

where $C((n-1)/2,m_1,(n-1)/2,m_2;\ell,m)$ are Clebsh–Gordon coefficients.[23]

Let us define the Bargmann transform for $L^2(S^3)$ as the linear extension of the previous assignment. Thus

$$\mathbf{B}_{S^3}:L^2(S^3)\mapsto\mathcal{F}_4, \tag{2.39}$$

where $\mathcal{F}_4$ is the closed subspace of $\mathcal{B}_4$ generated by the spaces $\mathcal{M}_n$: that is $\mathcal{F}_4=\oplus_{n=1}^{\infty}\mathcal{M}_n$.

The Bargmann transform $\mathbf{B}_{S^3}$ is a unitary operator and intertwines the operators L_1, L_2, L_3, A_1, A_2, A_3 with the following operators:

$$\begin{aligned}
L_1'&=\frac{1}{2}\left(z_1\frac{\partial}{\partial z_2}+z_3\frac{\partial}{\partial z_4}+z_2\frac{\partial}{\partial z_1}+z_4\frac{\partial}{\partial z_3}\right),\\
L_2'&=\frac{1}{2\iota}\left(z_1\frac{\partial}{\partial z_2}+z_3\frac{\partial}{\partial z_4}-z_2\frac{\partial}{\partial z_1}-z_4\frac{\partial}{\partial z_3}\right),\\
L_3'&=\frac{1}{2}\left(z_1\frac{\partial}{\partial z_1}+z_3\frac{\partial}{\partial z_3}-z_2\frac{\partial}{\partial z_2}-z_4\frac{\partial}{\partial z_4}\right),\\
A_1'&=\frac{1}{2}\left(z_1\frac{\partial}{\partial z_2}+z_2\frac{\partial}{\partial z_1}-z_3\frac{\partial}{\partial z_4}-z_4\frac{\partial}{\partial z_3}\right),\\
A_2'&=\frac{1}{2\iota}\left(z_1\frac{\partial}{\partial z_2}+z_4\frac{\partial}{\partial z_3}-z_2\frac{\partial}{\partial z_1}-z_3\frac{\partial}{\partial z_4}\right),\\
A_3'&=\frac{1}{2}\left(z_1\frac{\partial}{\partial z_1}+z_4\frac{\partial}{\partial z_4}-z_2\frac{\partial}{\partial z_2}-z_3\frac{\partial}{\partial z_3}\right),
\end{aligned}\tag{2.40}$$

respectively.

The Laplacian on S^3 is intertwined with the operator

$$\Delta_{S^3}'=\left(\frac{1}{2}\left(z_1\frac{\partial}{\partial z_1}+z_2\frac{\partial}{\partial z_2}+z_3\frac{\partial}{\partial z_3}+z_4\frac{\partial}{\partial z_4}\right)+1\right)^2.\tag{2.41}$$

Thus the Laplacian Δ_{S^3}' is essentially the square of the sum of four harmonic oscillators having the same frequency.

The expression for $\mathbf{L}\cdot\mathbf{A}$ in the space $\mathcal{F}_4$ is given by the following operator:

$$\mathcal{L}\equiv z_1\frac{\partial}{\partial z_1}+z_2\frac{\partial}{\partial z_2}-z_3\frac{\partial}{\partial z_3}-z_4\frac{\partial}{\partial z_4}.\tag{2.42}$$

The restriction $(\mathbf{L}\cdot\mathbf{A})\Psi=0$ is already included in the space $\mathcal{F}_4$, as the following proposition establishes it:

Proposition 2.1: The range of the Bargmann transform $\mathbf{B}_{S^3}$ is equal to the kernel of the operator $\mathcal{L}$, that is

$$\mathcal{F}_4=\{f\in\mathcal{B}_4\,|\,\mathcal{L}f=0\}\equiv\mathrm{Ker}\,\mathcal{L}.\tag{2.43}$$

Proof: Let f in $\mathcal{F}_4$. Then

$$f=\sum_{n=0}^{\infty}\sum_{m_1,m_2}A_{nm_1m_2}\frac{z_1^{(n-1)/2+m_1}z_2^{(n-1)/2-m_1}z_3^{(n-1)/2+m_2}z_4^{(n-1)/2-m_2}}{\sqrt{\left(\frac{n-1}{2}+m_1\right)!\left(\frac{n-1}{2}-m_1\right)!\left(\frac{n-1}{2}+m_2\right)!\left(\frac{n-1}{2}-m_2\right)!}}\tag{2.44}$$

where the convergence is with respect to the norm of $\mathcal{B}_4$.

Since norm-convergence in $\mathcal{B}_4$ implies pointwise convergence (this is because $\mathcal{B}_4$ has a reproducing kernel and the Schwartz inequality) then f is an analytic function which can be differentiated termwise.

Since

$$\mathcal{L}(z_1^{(n-1)/2+m_1}z_2^{(n-1)/2-m_1}z_3^{(n-1)/2+m_2}z_4^{(n-1)/2-m_2})=0$$

for all permitted values of n,m_1,m_2, we conclude $f\in\mathrm{Ker}\,\mathcal{L}$.

Conversely, suppose $f\in\mathrm{Ker}\,\mathcal{L}$. Since

$$\left\{\left.\frac{z_1^{a_1}z_2^{a_2}z_3^{a_3}z_4^{a_4}}{\sqrt{a_1!a_2!a_3!a_4!}}\right| a_j \text{ is a non-negative integer } j=1,2,3,4\right\}$$

is an orthonormal basis of $\mathcal{B}_4$, f can be written as

$$f=\sum_{\mathbf{a}} A_{\mathbf{a}}\frac{z_1^{a_1}z_2^{a_2}z_3^{a_3}z_4^{a_4}}{\sqrt{a_1!a_2!a_3!a_4!}} \tag{2.45}$$

with $\mathbf{a}=(a_1,a_2,a_3,a_4)$. Thus we have

$$0=\mathcal{L}f=\sum_{\mathbf{a}} A_{\mathbf{a}}(a_1+a_2-a_3-a_4)\frac{z_1^{a_1}z_2^{a_2}z_3^{a_3}z_4^{a_4}}{\sqrt{a_1!a_2!a_3!a_4!}}. \tag{2.46}$$

Now consider the case when $\mathbf{b}=(b_1,b_2,b_3,b_4)$ is such that $b_1+b_2-b_3-b_4\neq 0$. By taking the inner product of $\mathcal{L}f$ with $z_1^{b_1}z_2^{b_2}z_3^{b_3}z_4^{b_4}$ we obtain $A_{\mathbf{b}}=0$. Thus f must be a linear combination of monomials $z_1^{b_1}z_2^{b_2}z_3^{b_3}z_4^{b_4}$ where $b_1+b_2-b_3-b_4=0$. But each one of these monomials belongs to some space $\mathcal{M}_n$, therefore $f\in\mathcal{F}_4$. □

The Bargmann transform $\mathbf{B}_{S^3}$ is an integral operator

$$\mathbf{B}_{S^3}\Psi(\mathbf{z})=\int_{x\in S^3}K_{S^3}(\mathbf{x},\mathbf{z})\Psi(\mathbf{x})\mathrm{d}\sigma_3(\mathbf{x}) \tag{2.47}$$

with kernel

$$K_{S^3}(\mathbf{x},\mathbf{z})=\sum_{n=1}^{\infty}\sum_{\ell=0}^{n-1}\sum_{m=-\ell}^{\ell}\overline{Y}_{n\ell m}(\mathbf{x})y_{n\ell m}(\mathbf{z}). \tag{2.48}$$

As in the case of the two-sphere, K_{S^3} can be written as a power series in the function

$$\Phi_{S^3}=\sum_{\ell=0}^{1}\sum_{m=-\ell}^{m=\ell}\overline{Y}_{2\ell m}(\mathbf{x})y_{2\ell m}(\mathbf{z}) \tag{2.49}$$

in the following way:

$$K_{S^3}=\sum_{n=1}^{\infty}\frac{\sqrt{2n}}{(n-1)!}\frac{1}{2^{n/2}}(\Phi_{S^3})^{n-1} \tag{2.50}$$

with the following explicit expression for $\Phi_{S^3}(\mathbf{x},\mathbf{z})$:

$$\begin{aligned}\Phi_{S^3}(\mathbf{x},\mathbf{z})=\sqrt{2}[&z_1z_4(\cos(\lambda)-\iota\cos(\theta)\sin(\lambda))-z_2z_3(\cos(\lambda)+\iota\cos(\theta)\sin(\lambda))\\&+\iota z_1z_3\sin(\theta)\sin(\lambda)\exp(-\iota\phi)-\iota z_2z_4\sin(\theta)\sin(\lambda)\exp(\iota\phi)].\end{aligned} \tag{2.51}$$

The proof of this last fact is given in Appendix B.

III. THE KERNEL OF THE BARGMANN TRANSFORM AND CANONICAL TRANSFORMATIONS

In this section we describe a beautiful relationship between the Bargmann transform and a corresponding canonical transformation which plays the role of its classical analog. This fact occurs in the three cases described in Sec. II. Namely, we have shown that the kernel of the Bargmann transform is a power series in a certain function. This function is in turn a generating function of the above mentioned canonical transformation. This will give us symplectomorphisms mapping the phase space of a particle moving in $\mathbf{R}^n$, S^2, or S^3 onto a phase space described by complex variables.

We start by describing this relationship in the case of the Bargmann transform for $L^2(\mathbf{R}^n)$ and then for the cases $L^2(S^2)$ and $L^2(S^3)$.

A. Canonical transformation for a particle moving in $\mathbf{R}^n$

In this case the relationship between the kernel of the Bargmann transform and a corresponding canonical transformation is well known (see Refs. 5 and 24).

Following Graffi and Parmeggiani,[5] let us consider the function

$$\Phi_n(\mathbf{q},\mathbf{z}) = -\iota(-\tfrac{1}{2}(\mathbf{z}^2+\mathbf{q}^2)+\sqrt{2}\mathbf{z}\cdot\mathbf{q}), \tag{3.1}$$

which appears in the argument of the exponential function giving the kernel $A(\mathbf{q},\mathbf{z})$ of $\mathbf{B}_{\mathbf{R}^n}$.

Let us consider now a particle moving in $\mathbf{R}^n$. The phase space in this case is $T^*\mathbf{R}^n$ with coordinates $(\mathbf{q},\mathbf{p})$ and symplectic form $\omega_n = \sum_{j=1}^n \mathrm{d}q_j \wedge \mathrm{d}p_j$.

Now consider the function Φ_n as a generating function of a canonical transformation mapping the variables $(\mathbf{q},\mathbf{p})$ to the variables $(\mathbf{z},\mathbf{w}) \in T^*(\mathbf{C}^n)$ via the following:

$$\begin{aligned} p_j &= -\frac{\partial \Phi_n}{\partial q_j}, \quad j=1,2,\ldots,n, \\ w_j &= \iota \frac{\partial \Phi_n}{\partial z_j}, \quad j=1,2,\ldots,n. \end{aligned} \tag{3.2}$$

Note that by considering these equations we guarantee that

$$\sum_{j=1}^n \mathrm{d}q_j \wedge \mathrm{d}p_j = -\iota \sum_{j=1}^n \mathrm{d}z_j \wedge \mathrm{d}w_j. \tag{3.3}$$

The expressions for $(\mathbf{z},\mathbf{w})$ in terms of $(\mathbf{q},\mathbf{p})$ are

$$\begin{aligned} z_j &= \frac{1}{\sqrt{2}}(q_j - \iota p_j), \\ w_j &= \frac{1}{\sqrt{2}}(q_j + \iota p_j). \end{aligned} \tag{3.4}$$

In this way we see that w_j must be the complex conjugate of z_j. This fact suggests that we define the following submanifold of $T^*(\mathbf{C}^n)$:

$$\mathcal{D}_n = \{(\mathbf{z},\mathbf{w}) \in \mathbf{C}^{2n} \mid w = \overline{\mathbf{z}}\}. \tag{3.5}$$

Since the space $T^*(\mathbf{C}^n)$ is a symplectic manifold with symplectic form $\kappa_n = -\iota \sum_{j=1}^n \mathrm{d}z_j \wedge \mathrm{d}w_j$, we may consider $\mathcal{D}_n$ as a symplectic manifold with symplectic form τ_n given by the restriction of

κ_n to $\mathcal{D}_n$. Notice that we may regard the symplectic manifold $(\mathcal{D}_n,\tau_n)$ as the symplectic manifold $(\mathbf{C}_n,\mu_n)$, where $\mu_n=-\iota\Sigma_{j=1}^n dz_j\wedge d\overline{z_j}$ and $(\mathbf{z},\overline{\mathbf{z}})\mapsto(\mathbf{z})$ being the symplectomorphism between $(\mathcal{D}_n,\tau_n)$ and $(\mathbf{C}_n,\mu_n)$.

Thus we obtain the following

Theorem 3.1: *The function Φ_n is a generating function of a linear canonical transformation, which is a symplectomorphism $\mathcal{C}_n$ from $(T^*\mathbf{R}^n,\omega_n)$ onto $(\mathbf{C}_n,\mu_n)$ given by the equations $z_j=(1/\sqrt{2})(q_j-\iota p_j)$, $j=1,2,\ldots,n$. The transformation $\mathcal{C}_n$ maps the Hamiltonian $H=\frac{1}{2}\Sigma_{j=1}^n q_j^2+p_j^2$ to the Hamiltonian $H'=\Sigma_{j=1}^n z_j\overline{z_j}$.*

This theorem gives the classical analog of the Bargmann transform $\mathbf{B}_{\mathbf{R}^n}$ in the sense that $\mathbf{B}_{\mathbf{R}^n}$ is a unitary operator from $L^2(\mathbf{R}^n)$ onto the Bargmann space $\mathcal{B}_n$ and intertwines the quantum Hamiltonian of the harmonic oscillator $\hat{H}=\frac{1}{2}\Sigma_{j=1}^n(-\partial^2/\partial q_j^2+q_j^2)-n/2$ with the operator $\hat{H}'=\Sigma_{j=1}^n z_j(\partial/\partial z_j)$.

B. Canonical transformation for a particle moving on S^2

The above-noted description for a particle moving in $\mathbf{R}^n$ suggests considering the function $(-\iota/\sqrt{3})\Phi_{S^2}(\mathbf{x},\mathbf{z})$ (the factor $1/\sqrt{3}$ is just to scale variables in a convenient way) as a generating function of a canonical transformation $\mathcal{C}_{S^2}$ which maps the phase space $T^*S^2-\{0\}$ (i.e., T^*S^2 minus the zero section) onto a submanifold of $T^*\mathbf{C}^2$.

Thus let us consider

$$p_\theta=-\frac{\partial}{\partial\theta}\frac{-\iota}{\sqrt{3}}\Phi_{S^2},\quad p_\phi=-\frac{\partial}{\partial\phi}\frac{-\iota}{\sqrt{3}}\Phi_{S^2}$$

$$w_j=\iota\frac{\partial}{\partial z_j}\frac{-\iota}{\sqrt{3}}\Phi_{S^2},\quad j=1,2. \tag{3.6}$$

From Eq. (2.23), the equations above take the following explicit form:

$$\begin{aligned}
p_\theta&=-\frac{\iota}{2}(\cos(\theta)\exp(-\iota\phi)z_1^2+2\sin(\theta)z_1z_2-\cos(\theta)\exp(\iota\phi)z_2^2),\\
p_\phi&=\frac{-1}{2}(\sin(\theta)\exp(-\iota\phi)z_1^2+\sin(\theta)\exp(\iota\phi)z_2^2),\\
w_1&=-\sin(\theta)\exp(-\iota\phi)z_1+\cos(\theta)z_2,\\
w_2&=\cos(\theta)z_1+\sin(\theta)\exp(\iota\phi)z_2.
\end{aligned} \tag{3.7}$$

Note that by working with spherical coordinates for S^2, we are dealing with a specific local chart of S^2 and hence with a local chart for $T^*S^2-\{0\}$. Later on we shall define the canonical transformation $\mathcal{C}_{S^2}$ by extending the relationship between $(\theta,\phi,p_\theta,p_\phi)$ and (z_1,z_2,w_1,w_2) [determined by Eq. (3.7)] to the whole space $T^*S^2-\{0\}$.

In order to identify the submanifold of $T^*\mathbf{C}^2$ which is the image of $T^*S^2-\{0\}$, we need to find how the variables (w_1,w_2) are related to (z_1,z_2). To do this, we shall make use of the fact that the variables $\theta,\phi,p_\theta,p_\phi$ are real variables. Thus from the first two equations of (3.7) and the reality condition $\theta=\overline{\theta}$, $\phi=\overline{\phi}$, $p_\theta=\overline{p_\theta}$, $p_\phi=\overline{p_\phi}$, we obtain

$$\sin(\theta)=\frac{|\overline{z_1}z_2-z_2^2|}{|z_1|^2+|z_2|^2},$$

$$\cos(\theta)=\pm\frac{\overline{z_1}\overline{z_2}+z_1z_2}{|z_1|^2+|z_2|^2},$$
$$\exp(\iota\phi)=\pm\frac{\overline{z}_2^2-z_1^2}{|\overline{z}_2^2-z_1^2|}. \tag{3.8}$$

If we substitute Eq. (3.8) into the last two equations of (3.7), we obtain

$$w_1=\pm\overline{z_1},\quad w_2=\pm\overline{z_2}. \tag{3.9}$$

We shall restrict ourselves to considering the plus sign in Eqs. (3.8) and (3.9) in such a way that $(w_1,w_2)=(\overline{z_1},\overline{z_2})$. It can be shown, by expressing (z_1,z_2) in terms of $(\theta,\phi,p_\theta,p_\phi)$, that given $(\theta,\phi,p_\theta,p_\phi)$, there are four solutions for (z_1,z_2) [note that, if (z_1,z_2) is a solution then $(-z_1,-z_2)$, $(\overline{z_2},-\overline{z_1})$ and $(-\overline{z_2},\overline{z_1})$ are solutions too]. Two of these solutions correspond to considering the plus sign in Eqs. (3.8) and (3.9) and the other two correspond to the minus sign. The two solutions corresponding to the plus sign are related to each other by a minus sign [i.e., if (z_1,z_2) is a solution of Eq. (3.7), with $(\theta,\phi,p_\theta,p_\phi)$ given, then $(-z_1,-z_2)$ is a solution too]. Thus we need to identify (z_1,z_2) with $-(z_1,z_2)$ in order to make our canonical transformation $\mathcal{C}_{S^2}$ a function. In this way, we see that $\mathcal{C}_{S^2}$ takes values in the following submanifold of $T^*\mathbf{C}^2$:

$$\mathcal{D}_2=\{(z_1,z_2,w_1,w_2)\in\mathbf{C}^4|w_1=\overline{z_1},\ \ w_2=\overline{z_2}\}/\{1,-1\}. \tag{3.10}$$

Note that the symplectic manifold $(\mathcal{D}_2,\tau_2)$ can be regarded as $\mathbf{C}^2/\{1,-1\}$ with symplectic form $\mu_2=-\iota(dz_1\wedge d\overline{z_1}+dz_2\wedge d\overline{z_2})$.

Once we have chosen the plus sign in Eqs. (3.8) and (3.9), we find the following expressions for p_θ,p_ϕ in terms of $(z_1,z_2,\overline{z_1},\overline{z_2})$:

$$p_\theta=\left(\frac{z_1z_2-\overline{z_1}\overline{z_2}}{2\iota}\right)\left(\frac{|z_1|^2+|z_2|^2}{z_1^2-\overline{z}_2^2}\right),\quad p_\phi=\frac{1}{2}(|z_1|^2-|z_2|^2),$$
$$H=p_\theta^2+\frac{1}{\sin^2(\theta)}p_\phi^2=\left(\frac{|z_1|^2+|z_2|^2}{2}\right)^2. \tag{3.11}$$

Note that we have a singularity in Eq. (3.8) when the energy H is zero. Thus we need to remove the zero section of T^*S^2 (which we shall denote by $\{0\}$) and the origin of the manifold $\mathbf{C}_2/\{1,-1\}$. (denoted by $\{0\}$, too). The other singularity in the expression for p_θ corresponds to the point $z_1^2=\overline{z}_2^2$, which in turn is equivalent to the equation $\sin(\theta)=0$ (north and south poles). We actually do not have such a singularity since we are taking $0<\theta<\pi$, and (as we shall see later on) it will not appear in the extension of our canonical transformation.

Canonical transformation for S^2 and the null quadric $\mathbf{Q}^2$. In the following we identify the equations giving $(\theta,\phi,p_\theta,p_\phi)$ as functions of $(z_1,z_2,\overline{z_1},\overline{z_2})$ with the composition of two maps involving the null quadric in $\mathbf{C}^3$, defined by

$$\mathbf{Q}^2\equiv\{(\alpha_1,\alpha_2,\alpha_3)\in\mathbf{C}^3/\alpha_1^2+\alpha_2^2+\alpha_3^2=0\}. \tag{3.12}$$

One of the maps takes $\mathbf{C}^2/\{1,-1\}-\{0\}$ onto $\mathbf{Q}^2-\{0\}$ and the other one takes $\mathbf{Q}^2-\{0\}$ onto $T^*S^2-\{0\}$. In this manner, we shall extend our canonical transformation $\mathcal{C}_{S^2}$ to be the inverse of such a composition. The map that goes from $\mathbf{C}^2/\{1,-1\}-\{0\}$ onto $\mathbf{Q}^2-\{0\}$ has also been considered by Bargmann and Todorov.[8] We will refer to their work in Sec. IV when we describe the quantization of the above mentioned maps.

The generating function $(-\iota/\sqrt{3})\,\Phi_{S^2}$ of our canonical transformation $\mathcal{C}_{S^2}$ can be written as an inner product:

$$\frac{-\iota}{\sqrt{3}}\Phi_{S^2}=-\iota(\alpha(\mathbf{z})\cdot\mathbf{x}), \tag{3.13}$$

where

$$\begin{gathered}\mathbf{x}=(\sin(\theta)\cos(\phi),\sin(\theta)\sin(\phi),\cos(\theta)),\\ \alpha(\mathbf{z})=\tfrac{1}{2}(-z_1^2+z_2^2,\iota z_1^2+\iota z_2^2,2z_1z_2).\end{gathered} \tag{3.14}$$

Here we are taking the usual inner product of two vectors $\alpha=(\alpha_1,\alpha_2,\alpha_3)$ and $\beta=(\beta_1,\beta_2,\beta_3)$ in $\mathbf{C}^3$:

$$\alpha\cdot\beta\equiv\alpha_1\overline{\beta_1}+\alpha_2\overline{\beta_2}+\alpha_3\overline{\beta_3}. \tag{3.15}$$

Notice the relevant fact that $\alpha(\mathbf{z})$ is in the null quadric $\mathbf{Q}^2$. This suggests that $\mathbf{Q}^2$ might have an important role to play related to our canonical transformation $\mathcal{C}_{S^2}$. Thus let us define the following map:

$$\begin{gathered}\rho_2:\tilde{\mathbf{C}}^2\mapsto\mathbf{Q}^2,\\ \rho_2(z_1,z_2)=\tfrac{1}{2}(-z_1^2+z_2^2,\iota z_1^2+\iota z_2^2,2z_1z_2),\end{gathered} \tag{3.16}$$

where we define $\tilde{\mathbf{C}}^2$ as the set of equivalence classes of $\mathbf{C}^2$ identifying (z_1,z_2) with $(-z_1,-z_2)$.

Now being in the null quadric $\mathbf{Q}^2-\{0\}$, we can go to $T^*S^2-\{0\}$ through the following map:

$$\begin{gathered}\sigma_2:\mathbf{Q}^2-\{0\}\mapsto T^*S^2-\{0\},\\ \sigma_2(\alpha_1,\alpha_2,\alpha_3)=\left(\frac{\Re(\alpha)}{|\Re(\alpha)|},-\Im(\alpha)\right).\end{gathered} \tag{3.17}$$

Here $\Re(\alpha)$ and $\Im(\alpha)$ are the real and imaginary parts of $\alpha=(\alpha_1,\alpha_2,\alpha_3)$, respectively.

Thus the composition map is

$$\begin{aligned}&\sigma_2\circ\rho_2:\tilde{\mathbf{C}}^2-\{0\}\mapsto T^*S^2-\{0\},\\ &\sigma_2\circ\rho_2(z_1,z_2)=\left(\frac{\Re(-z_1^2+z_2^2)}{|z_1|^2+|z_2|^2},\frac{\Re(\iota z_1^2+\iota z_2^2)}{|z_1|^2+|z_2|^2},\frac{\Re(2z_1z_2)}{|z_1|^2+|z_2|^2},\right.\\ &\qquad\left.-\frac{1}{2}\Im(z_2^2-z_1^2),-\frac{1}{2}\Im(\iota z_1^2+\iota z_2^2),-\frac{1}{2}\Im(2z_1z_2)\right).\end{aligned} \tag{3.18}$$

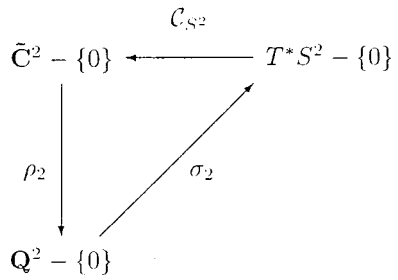
On the other hand, since a point in T^*S^2 can be described in spherical coordinates by

$$\begin{aligned}&\left(\sin(\theta)\cos(\phi),\sin(\theta)\sin(\phi),\cos(\theta),\cos(\theta)\cos(\phi)p_\theta-\frac{\sin(\phi)}{\sin(\theta)}p_\phi,\cos(\theta)\sin(\phi)p_\theta\right.\\ &\qquad\left.+\frac{\cos(\phi)}{\sin(\theta)}p_\phi,-\sin(\theta)p_\theta\right)\end{aligned} \tag{3.19}$$

then, we find after some computation [by using Eqs. (3.7) and (3.8)] that this point in T^*S^2 expressed in terms of $(z_1,z_2,\overline{z_1},\overline{z_2})$ is exactly the same point that the composition $\sigma_2\circ\rho_2$ assigns

to $(z_1,\ z_2,\ \overline{z_1},\ \overline{z_2})$. This conclusion allows us to extend our canonical transformation $\mathcal{C}_{S^2}$ (without referring to spherical coordinates) as the map $(\sigma_2\circ\rho_2)^{-1}$. Let us state our conclusions in the following theorem:

Theorem 3.2: *The function* $(-\iota/\sqrt{3})\,\Phi_{S^2}$ *is a generating function of a transformation that can be extended as a canonical transformation* $\mathcal{C}_{S^2}$ *which makes the following triangle of canonical transformations commute:*



where (a) the symplectic form ν_2 *on* T^*S^2 *is given by the restriction to* T^*S^2 *of the canonical symplectic form* ω_3 *on* $T^*\mathbf{R}^3$,
(b) the symplectic form μ_2 *on* $\tilde{\mathbf{C}}^2-\{0\}$ *is given by*

$$\mu_2=-\iota(\mathrm{d}z_1\wedge\mathrm{d}\overline{z_1}+\mathrm{d}z_2\wedge\mathrm{d}\overline{z_2}), \tag{3.20}$$

(c) the symplectic form q_3 *on* $\mathbf{Q}^2-\{0\}$ *is given by*

$$q_3=\frac{1}{2\iota|\Re\alpha|}\sum_{j=1}^{3}\mathrm{d}\alpha_j\wedge d\overline{\alpha}_j-\frac{1}{8\iota|\Re\alpha|^3}\sum_{j,k=1}^{3}(\alpha_j+\overline{\alpha}_j)(\alpha_k+\overline{\alpha}_k)\mathrm{d}\alpha_j\wedge\mathrm{d}\overline{\alpha}_k, \tag{3.21}$$

which is not the restriction to $\mathbf{Q}^2-\{0\}$ *of the symplectic form* $\Sigma_{j=1}^{3}\mathrm{d}\alpha_j\wedge\mathrm{d}\overline{\alpha}_j$ *defined on the ambient* $\mathbf{C}^3$.

The transformation $\mathcal{C}_{S^2}$ *maps the components* (L_1,L_2,L_3) *of the angular momentum and the energy* H *as follows:*

$$\begin{aligned}
L_1&=-\sin(\phi)p_\theta-\frac{\cos(\theta)\cos(\phi)}{\sin(\theta)}p_\phi=\frac{1}{2}(z_1\overline{z_2}+\overline{z_1}z_2),\\
L_2&=\cos(\phi)p_\theta-\frac{\cos(\theta)\sin(\phi)}{\sin(\theta)}p_\phi=\frac{-\iota}{2}(z_1\overline{z_2}-\overline{z_1}z_2),\\
L_3&=p_\phi=\tfrac{1}{2}(|z_1|^2-|z_2|^2),\\
H&=\frac{1}{2}\left(p_\theta^2+\frac{1}{\sin^2(\theta)}p_\phi^2\right)=\frac{1}{2}\left(\frac{|z_1|^2+|z_2|^2}{2}\right)^2,
\end{aligned} \tag{3.22}$$

which is the classical analog of what the Bargmann transform $\mathbf{B}_{S^2}$ *does in quantum mechanics [see eq. (2.24)].*

C. Canonical transformation for a particle moving on S^3

In analogy with the cases where the configuration space is $\mathbf{R}^n$ or S^2, we want to consider the function $(-\iota/\sqrt{2})\,\Phi_{S^3}$ as a generating function of a canonical transformation $\mathcal{C}_{S^3}$ which maps $T^*S^3-\{0\}$ onto a space involving four complex variables and their conjugates [we used four complex variables when we defined the Bargmann transform for $L^2(S^3)$]. Notice that $T^*S^3-\{0\}$ is a six (real) dimensional manifold, whereas to determine four complex variables we need

eight real parameters. Thus we expect to have some restrictions among the four complex variables. The first restriction we expect is the following [in analogy with Eq. (2.34) in quantum mechanics]:

$$|z_1|^2+|z_2|^2=|z_3|^2+|z_4|^2. \tag{3.23}$$

This equation is actually contained in the equations determined by the generating function $(-\iota/\sqrt{2})\,\Phi_{S^3}$ as we show it in the following. The second restriction comes from an S^1 invariance of those equations.

Thus let us consider the canonical transformation generated by $(-\iota/\sqrt{2})\,\Phi_{S^3}$ through the following equations:

$$\begin{gathered} p_\theta=-\frac{\partial}{\partial\theta}\frac{-\iota}{\sqrt{2}}\Phi_{S^3},\quad p_\phi=-\frac{\partial}{\partial\phi}\frac{-\iota}{\sqrt{2}}\Phi_{S^3},\quad p_\lambda=-\frac{\partial}{\partial\lambda}\frac{-\iota}{\sqrt{2}}\Phi_{S^3},\\ w_j=\iota\frac{\partial}{\partial z_j}\frac{-\iota}{\sqrt{2}}\Phi_{S^3},\quad j=1,2,3,4. \end{gathered} \tag{3.24}$$

From Eq. (2.51) we obtain

$$\begin{aligned} p_\theta&=-z_1z_4\sin(\theta)\sin(\lambda)-z_2z_3\sin(\theta)\sin(\lambda)-z_1z_3\cos(\theta)\sin(\lambda)\exp(-\iota\phi)\\ &\quad+z_2z_4\cos(\theta)\sin(\lambda)\exp(\iota\phi),\\ p_\phi&=\iota\sin(\theta)\sin(\lambda)[z_1z_3\exp(-\iota\phi)+z_2z_4\exp(\iota\phi)],\\ p_\lambda&=-\iota z_1z_4(\sin(\lambda)+\iota\cos(\theta)\cos(\lambda))-\iota z_2z_3(-\sin(\lambda)+\iota\cos(\theta)\cos(\lambda))\\ &\quad-z_1z_3\sin(\theta)\cos(\lambda)\exp(-\iota\phi)+z_2z_4\sin(\theta)\cos(\lambda)\exp(\iota\phi),\\ w_1&=z_4(\cos(\lambda)-\iota\cos(\theta)\sin(\lambda))+\iota z_3\sin(\theta)\sin(\lambda)\exp(-\iota\phi),\\ w_2&=-z_3(\cos(\lambda)+\iota\cos(\theta)\sin(\lambda))-\iota z_4\sin(\theta)\sin(\lambda)\exp(\iota\phi),\\ w_3&=-z_2(\cos(\lambda)+\iota\cos(\theta)\sin(\lambda))+\iota z_1\sin(\theta)\sin(\lambda)\exp(-\iota\phi),\\ w_4&=z_1(\cos(\lambda)-\iota\cos(\theta)\sin(\lambda))-\iota z_2\sin(\theta)\sin(\lambda)\exp(\iota\phi). \end{aligned} \tag{3.25}$$

As in the case for S^2, let us state the reality condition:

$$\begin{gathered} \theta=\overline{\theta},\quad \phi=\overline{\phi},\quad \lambda=\overline{\lambda},\\ p_\theta=\overline{p_\theta},\quad p_\phi=\overline{p_\phi},\quad p_\lambda=\overline{p_\lambda}. \end{gathered} \tag{3.26}$$

This condition implies

$$\sin(\theta)=\frac{|z_1z_3+\overline{z_2}\,\overline{z_4}|}{\sqrt{(|z_1|^2+|z_2|^2)(|z_3|^2+|z_4|^2)-(\Re(z_1z_4-z_2z_3))^2}},$$

$$\cos(\theta)=\frac{\pm\Im(z_1z_4+z_3z_2)}{\sqrt{(|z_1|^2+|z_2|^2)(|z_3|^2+|z_4|^2)-(\Re(z_1z_4-z_2z_3))^2}},$$

$$\exp(\iota\phi)=\pm\frac{\iota|z_2z_4+\overline{z_1}\,\overline{z_3}|}{z_2z_4+\overline{z_1}\,\overline{z_3}},$$

$$\sin(\lambda)=\frac{\sqrt{(|z_1|^2+|z_2|^2)(|z_3|^2+|z_4|^2)-(\Re(z_1z_4-z_2z_3))^2}}{\sqrt{(|z_1|^2+|z_2|^2)(|z_3|^2+|z_4|^2)}},\tag{3.27}$$

$$\cos(\lambda)=\pm\frac{\Re(z_1z_4-z_2z_3)}{\sqrt{(|z_1|^2+|z_2|^2)(|z_3|^2+|z_4|^2)}}.$$

These equations in turn imply

$$(w_1,w_2,w_3,w_4)=\pm(\overline{z_1},\overline{z_2},\overline{z_3},\overline{z_4}).\tag{3.28}$$

We shall choose the plus sign wherever we have a choice of either a plus or minus sign in the above-given equations. Thus we have the relation $(w_1,w_2,w_3,w_4)=(\overline{z_1},\overline{z_2},\overline{z_3},\overline{z_4})$. Using this relation in the last four equations we obtain the expected restriction

$$|z_1|^2+|z_2|^2=|z_3|^2+|z_4|^2.\tag{3.29}$$

This restriction will appear as part of the definition of the manifold where our canonical transformation $\mathcal{C}_{S^3}$ should take values in.

On the other hand, the expressions for p_θ, p_ϕ, p_λ in terms of (z_1,z_2,z_3,z_4) are

$$p_\theta=-\frac{\Re(z_1z_4)(|z_3|^2+|z_2|^2)+\Re(z_2z_3)(|z_1|^2+|z_4|^2)}{|z_1z_3+\overline{z_2}\overline{z_4}|},$$

$$p_\phi=\tfrac{1}{2}(|z_1|^2-|z_2|^2+|z_3|^2-|z_4|^2),\tag{3.30}$$

$$p_\lambda=\frac{(|z_3|^2+|z_4|^2)\Im(z_1z_4+\overline{z_2}\overline{z_3})}{\sqrt{(|z_3|^2+|z_4|^2)^2-(\Re(z_1z_4-z_2z_3))^2}}.$$

Now notice the following relevant property of Eq. (3.25): Suppose $(\theta,\phi,\lambda,p_\theta,p_\phi,p_\lambda)$ is given. If (z_1,z_2,z_3,z_4) is a solution of Eq. (3.25), then, for any real number ψ, $(z_1\exp(\imath\psi),z_2\exp(\imath\psi),z_3\exp(-\imath\psi),z_4\exp(-\imath\psi))$ is a solution, as well. Thus we define the following equivalence relation $\sim$ in $\mathbf{C}^4$ in order to consider the invariance of Eq. (3.25):

$$(z_1,z_2,z_3,z_4)\sim(z_1',z_2',z_3',z_4') \text{ iff } \exists\psi\in\mathbf{R} \text{ such that}$$

$$(z_1',z_2',z_3',z_4')=(z_1\exp(\imath\psi),z_2\exp(\imath\psi),z_3\exp(-\imath\psi),z_4\exp(-\imath\psi)).\tag{3.31}$$

We shall denote by $[(z_1,z_2,z_3,z_4)]$ the equivalence class of (z_1,z_2,z_3,z_4).

Thus our canonical transformation $\mathcal{C}_{S^3}$ should take values in the following six (real) dimensional set:

$$\tilde{\mathbf{C}}^4\equiv\{(z_1,z_2,z_3,z_4)\in\mathbf{C}^4\,|\,|z_1|^2+|z_2|^2=|z_3|^2+|z_4|^2\}/\sim.\tag{3.32}$$

We shall regard the manifold $\tilde{\mathbf{C}}^4-\{0\}$ as a symplectic manifold endowed with the following symplectic form:

$$\mu_3=-\imath(dz_1\wedge d\overline{z_1}+dz_2\wedge d\overline{z_2}+dz_3\wedge d\overline{z_3}+dz_4\wedge d\overline{z_4}).\tag{3.33}$$

Canonical transformation for S^3 and the null quadric $\mathbf{Q}^3$. Now we want to extend the assignment $(\theta,\phi,\lambda,p_\theta,p_\phi)\mapsto[(z_1,z_2,z_3,z_4)]$ given by Eq. (3.25) to the whole space $T^*S^3-\{0\}$ in a similar way as we did for the case of S^2. Here again the null quadric

$$\mathbf{Q}^3=\{(\alpha_1,\alpha_2,\alpha_3,\alpha_4)\in\mathbf{C}^4/\alpha_1^2+\alpha_2^2+\alpha_3^2+\alpha_4^2=0\}\tag{3.34}$$

will play an important role and we will extend the mentioned assignment as the inverse of a composition of two maps, one going from $\tilde{\mathbf{C}}^4-\{0\}$ onto $\mathbf{Q}^3-\{0\}$ and the other one from $\mathbf{Q}^3-\{0\}$ onto $T^*S^3-\{0\}$. A similar map to the first one appears in the work of Bargmann and Todorov,[8] we will be back to this point in Sec. IV.

Let us write the generating function $(-\iota/\sqrt{2})\Phi_{S^3}$ as an inner product:

$$\frac{-\iota}{\sqrt{2}}\Phi_{S^3}=-\iota(\alpha(\mathbf{z})\cdot\mathbf{x}), \tag{3.35}$$

where

$$\begin{gathered}\alpha(\mathbf{z})=(\iota z_1z_3-\iota z_2z_4,z_1z_3+z_2z_4,-\iota z_1z_4-\iota z_2z_3,z_1z_4-z_2z_3),\\ \mathbf{x}=(\sin(\lambda)\sin(\theta)\cos(\phi),\sin(\lambda)\sin(\theta)\sin(\phi),\sin(\lambda)\cos(\theta),\cos(\lambda)).\end{gathered} \tag{3.36}$$

Now notice that for all $(z_1,z_2,z_3,z_4)\in\mathbf{C}^4$, the vector $\alpha(\mathbf{z})$ belongs to the null quadric $\mathbf{Q}^3$. This suggests defining the following map:

$$\begin{gathered}\rho_3:\tilde{\mathbf{C}}^4\mapsto\mathbf{Q}^3,\\ \rho_3([\mathbf{z}])=(\iota z_1z_3-\iota z_2z_4,z_1z_3+z_2z_4,-\iota z_1z_4-\iota z_2z_3,z_1z_4-z_2z_3)\end{gathered} \tag{3.37}$$

with (z_1,z_2,z_3,z_4) a representative of the equivalent class $[z_1,z_2,z_3,z_4]$. From now on we shall denote $\rho_3([z_1,z_2,z_3,z_4])$ just by $\rho_3(z_1,z_2,z_3,z_4)$.

Let us also define the map

$$\begin{gathered}\sigma_3:\mathbf{Q}^3-\{0\}\mapsto T^*S^3-\{0\},\\ \sigma_3(\alpha)=\left(\frac{\Re\alpha}{|\Re\alpha|},-\Im\alpha\right).\end{gathered} \tag{3.38}$$

As in the case for S^2, we shall extend our assignment $(\theta,\phi,\lambda,p_\theta,p_\phi)\mapsto[(z_1,z_2,z_3,z_4)]$ determined by Eq. (3.25) to the whole space $T^*S^3-\{0\}$. For this purpose, we first check that if we consider a point in $T^*S^3-\{0\}$ given in spherical coordinates by

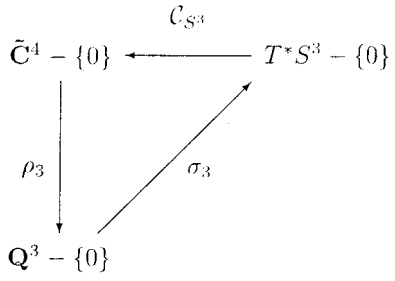
$$\begin{gathered}(\sin(\lambda)\sin(\theta)\cos(\phi),\sin(\lambda)\sin(\theta)\sin(\phi),\sin(\lambda)\cos(\theta),\cos(\lambda),\\ \cos(\lambda)\sin(\theta)\cos(\phi)p_\lambda+\cos(\theta)\cos(\phi)p_\theta/\sin(\lambda)-\frac{\sin(\phi)p_\phi}{\sin(\lambda)\sin(\theta)},\\ \cos(\lambda)\sin(\theta)\sin(\phi)p_\lambda+\cos(\theta)\sin(\phi)p_\theta/\sin(\lambda)-\frac{\cos(\phi)p_\phi}{\sin(\lambda)\sin(\theta)},\\ \cos(\lambda)\cos(\theta)p_\lambda-\sin(\theta)p_\theta/\sin(\lambda),-\sin(\lambda)p_\lambda)\end{gathered} \tag{3.39}$$

and we use Eq. (3.27), then we obtain a map which assigns to the point (z_1,z_2,z_3,z_4) the same element in T^*S^3 as the evaluation of the function $\sigma_3\circ\rho_3$ in (z_1,z_2,z_3,z_4). This allows us to extend our canonical transformation $\mathcal{C}_{S^3}$ as the map $(\sigma_3\circ\rho_3)^{-1}$.

Let us state our conclusions in the following

Theorem 3.3: *The function* $(-\iota/\sqrt{2})\Phi_{S^3}$ *generates a transformation which can be extended as a canonical transformation* $\mathcal{C}_{S^3}$ *that makes the following triangle of canonical transformations*

commute:



where (a) the symplectic form ν_3 on T^*S^3 is given by the restriction to T^*S^3 of the canonical symplectic form ω_4 on $T^*\mathbf{R}^4$,

(b) the symplectic form μ_3 on $\tilde{\mathbf{C}}^4-\{0\}$ is given by

$$\mu_3=-\iota(\mathrm{d}z_1\wedge\mathrm{d}\overline{z_1}+\mathrm{d}z_2\wedge\mathrm{d}\overline{z_2}+\mathrm{d}z_3\wedge\mathrm{d}\overline{z_3}+\mathrm{d}z_4\wedge\mathrm{d}\overline{z_4}), \tag{3.40}$$

(c) the symplectic form q_4 on $\mathbf{Q}^3-\{0\}$ is given by

$$q_4=\frac{1}{2\iota|\Re\alpha|}\sum_{j=1}^{4}\mathrm{d}\alpha_j\wedge\mathrm{d}\overline{\alpha}_j-\frac{1}{8\iota|\Re\alpha|^3}\sum_{j,k=1}^{4}(\alpha_j+\overline{\alpha}_j)(\alpha_k+\overline{\alpha}_k)\mathrm{d}\alpha_j\wedge\mathrm{d}\overline{\alpha}_k, \tag{3.41}$$

which is not the restriction to $\mathbf{Q}^3-\{0\}$ of the symplectic form $\Sigma_{j=1}^4\,\mathrm{d}\alpha_j\wedge\mathrm{d}\overline{\alpha}_j$ defined on the ambient $\mathbf{C}^4$. The components of the angular momentum and Runge–Lenz vectors are

$$\begin{aligned}
L_1&=\tfrac{1}{2}(z_1\overline{z_2}+z_3\overline{z_4}+z_2\overline{z_1}+z_4\overline{z_3}),\\
L_2&=\frac{1}{2\iota}(z_1\overline{z_2}+z_3\overline{z_4}-z_2\overline{z_1}-z_4\overline{z_3}),\\
L_3&=\tfrac{1}{2}(z_1\overline{z_1}+z_3\overline{z_3}-z_2\overline{z_2}-z_4\overline{z_4}),\\
A_1&=\tfrac{1}{2}(z_1\overline{z_2}+z_2\overline{z_1}-z_3\overline{z_4}-z_4\overline{z_3}),\\
A_2&=\frac{1}{2\iota}(z_1\overline{z_2}+z_4\overline{z_3}-z_2\overline{z_1}+z_3\overline{z_4}),\\
A_3&=\tfrac{1}{2}(z_1\overline{z_1}+z_4\overline{z_4}-z_2\overline{z_2}+z_3\overline{z_3}).
\end{aligned} \tag{3.42}$$

The expressions for $L^2=L_1^2+L_2^2+L_3^2$, $A^2=A_1^2+A_2^2+A_3^2$ and the energy H are

$$\begin{aligned}
L^2&=\tfrac{1}{4}(z_1\overline{z_1}+z_2\overline{z_2})^2+\tfrac{1}{4}(z_3\overline{z_3}+z_4\overline{z_4})^2+\tfrac{1}{2}(4\Re(z_1z_4\overline{z_2}\overline{z_3})+(|z_2|^2-|z_1|^2)(|z_4|^2-|z_3|^2)),\\
A^2&=\tfrac{1}{4}(z_1\overline{z_1}+z_2\overline{z_2})^2+\tfrac{1}{4}(z_3\overline{z_3}+z_4\overline{z_4})^2-\tfrac{1}{2}(4\Re(z_1z_4\overline{z_2}\overline{z_3})+(|z_2|^2-|z_1|^2)(|z_4|^2-|z_3|^2)),
\end{aligned} \tag{3.43}$$

$$H=\frac{1}{2}\left(p_\lambda^2+\frac{p_0^2}{\sin^2(\lambda)}+\frac{p_\phi^2}{\sin^2(\lambda)\sin^2(\theta)}\right)=\frac{1}{2}\left(\frac{\Sigma_{j=1}^4 z_j\overline{z_j}}{2}\right)^2.$$

IV. QUANTIZATIONS OF THE MAPS ρ_2,σ_2 AND ρ_3,σ_3

Once we have the commuting triangles of canonical transformations of Theorems (3.2) and (3.3), and the analogy between $\mathbf{B}_{S^2}$, $\mathbf{B}_{S^3}$ and their corresponding canonical transformations $\mathcal{C}_{S^2}$, $\mathcal{C}_{S^3}$, a natural question to ask is about the description of unitary transformations which play the

role of quantizations of the maps ρ_2, σ_2 and ρ_3, σ_3 (for the case of S^2 and S^3, respectively). Such a description is the goal of this section. The unitary transformations corresponding to σ_2, and σ_3 are related to work of Guillemin.[9] The unitary transformations corresponding to ρ_2, and ρ_3 have been studied by Bargmann and Todorov.[8] For completeness of this paper, we will describe these last unitary transformations, too.

A. Quantizations of ρ_2 and σ_2

Let $d\mu_2(\alpha)$ be the measure on $\mathbf{Q}^2$ obtained from the Gaussian measure

$$d\nu_2(\mathbf{z}) = \frac{1}{\pi^2} \exp(-|\mathbf{z}|^2) \prod_{j=1}^{2} dx_j\, dy_j \tag{4.1}$$

through the map ρ_2 (here we are actually regarding the map ρ_2 as a function from $\mathbf{C}^2$ onto $\mathbf{Q}^2$).

Given $\ell \geqslant 0$ an integer, let $\mathcal{X}_\ell$ be the complex vector space of homogeneous polynomials of order ℓ in three complex variables $(\alpha_1, \alpha_2, \alpha_3)$ with the restriction $\alpha_1^2 + \alpha_2^2 + \alpha_3^2 = 0$. The space $\mathcal{X}_\ell$ has dimension $2\ell + 1$ and a particular basis for it can be obtained by considering the monomials

$$y_{\ell m} = \frac{z_1^{\ell+m} z_2^{\ell-m}}{\sqrt{(\ell+m)!(\ell-m)!}}$$

and the map ρ_2^{-1}. That is, we shall consider the following functions as a basis for $\mathcal{X}_\ell$:

$$\Upsilon_{\ell m}(\alpha) = y_{\ell m}(\mathbf{z}(\alpha)), \quad m = -\ell, -\ell+1 \ldots \ell, \quad \alpha = (\alpha_1, \alpha_2, \alpha_3), \tag{4.2}$$

with $\mathbf{z}(\alpha)$ determined by

$$z_1^2 = -\alpha_1 - \iota\alpha_2, \quad z_2^2 = \alpha_1 - \iota\alpha_2, \quad z_1 z_2 = \alpha_3. \tag{4.3}$$

Note that the functions $y_{\ell m}$ depend on $\mathbf{z} = (z_1, z_2)$ through integer powers of z_1^2, z_2^2 and $z_1 z_2$, so Eq. (4.3) is enough in order to express $y_{\ell m}$ in terms of α_1, α_2, and α_3.

Let $\mathcal{E}_2$ be the Hilbert space generated by all of the spaces $\mathcal{X}_\ell$ endowed with the inner product:

$$\langle F, G \rangle = \int_{\alpha \in \mathbf{Q}^2} F(\alpha) \overline{G(\alpha)}\, d\mu_2(\alpha). \tag{4.4}$$

Thus the quantization of the map ρ_2 is the unitary transformation $\mathbf{U}_{\rho_2}: \mathcal{B}_{S^2} \mapsto \mathcal{E}_2$ given by

$$\mathbf{U}_{\rho_2} \Psi(\alpha) = \Psi(\mathbf{z}(\alpha)), \quad \Psi \in \mathcal{B}_{S^2}. \tag{4.5}$$

where $\mathbf{z}(\alpha)$ is determined by Eq. (4.3).

Bargmann and Todorov[8] have considered the space $\mathcal{E}_2$ [with the same inner product and a measure very similar to $d\mu_2(\alpha)$] and actually the inverse of $\mathbf{U}_{\rho_2}$. They introduce the measure $d\mu_2(\alpha)$ in a different way than we do. They require that the adjoint of the multiplication operators by coordinates in the null quadric $\mathbf{Q}^2 - \{0\}$ must have a given expression. Their expression for the map ρ_2 is very similar to ours. In terms of the Pauli matrices

$$\beta_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \beta_2 = \begin{pmatrix} 0 & -\iota \\ \iota & 0 \end{pmatrix}, \quad \beta_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{4.6}$$

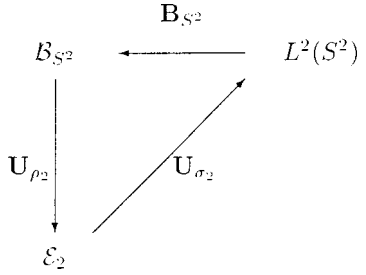
the expression they consider for the map $\rho_2(z_1, z_2)$ is $(1/2\sqrt{2})\,(z_1, z_2)\epsilon\beta_j(z_1, z_2)^t$ where j $= 1,2,3$; $(z_1, z_2)^t$ is the transpose of the vector (z_1, z_2) and the matrix $\epsilon = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. Our expression for $\rho_2(z_1, z_2)$ in the same notation is $\frac{1}{2}(-1)^j (z_1, z_2)\epsilon\beta_j(z_1, z_2)^t$.

The quantization of σ_2, $\mathbf{U}_{\sigma_2}:\mathcal{E}_2\mapsto L^2(S^2)$, can be found by considering the orthonormal basis $\{Y_{\ell m}\}$ and $\{Y_{\ell m}\}$ of the Hilbert spaces $\mathcal{E}_3$ and $L^2(S^2)$, respectively:

$$\mathbf{U}_{\sigma_2}\Psi(\mathbf{x})=\lim_{M\mapsto\infty}\left(\int_{|\alpha|\leq M}\sum_{\ell=0}^{\infty}\frac{\sqrt{2\ell+1}}{\ell!}(\mathbf{x}\cdot\alpha)^{\ell}\right)\Psi(\alpha)\mathrm{d}\mu_2(\alpha),\quad \Psi\in\mathcal{E}_2. \tag{4.7}$$

Let us summarize the conclusions of this section in the following

Theorem 4.1: *The following triangle of unitary transformations commutes*:



This triangle is the quantum version of the commuting triangle of canonical transformations in Theorem (3.2).

Remark 1: Guillemin[9] has introduced a transformation p_* which is related to our unitary transformation $\mathbf{U}_{\sigma_2}:\mathcal{E}_2\mapsto L^2(S^2)$. The transformation p_* can be described in our terms as follows. The unit cotangent bundle $S^*(S^2)$ of S^2 can be identified with the following subset of the null quadric $\mathbf{Q}^2$:

$$X\equiv\{\mathbf{x}+\imath\mathbf{y}|\|\mathbf{x}\|=\|\mathbf{y}\|=1,\ \mathbf{x}\cdot\mathbf{y}=0\}. \tag{4.8}$$

Let V_ℓ be the subspace of $L^2(S^2)$ generated by the spherical harmonics of order ℓ as previously. Let $f\in V_\ell$. Let us denote by $F_\ell(x_1,x_2,x_3)$ the unique polynomial in three real variables $(x_1,x_2,x_3)\in\mathbf{R}^3$ which is homogeneous of degree ℓ, harmonic ($\Delta_{\mathbf{R}^3}F_\ell\equiv\Sigma_{k=1}^3(\partial^2/\partial x_k^2)F_\ell=0$) and whose restriction to S^2 is equal to f. Let $\tilde{F}_\ell(w_1,w_2,w_3)$ be the polynomial in three complex variables $(w_1,w_2,w_3)\in\mathbf{C}^3$ obtained from F_ℓ by replacing (x_1,x_2,x_3) by (w_1,w_2,w_3). Let us denote by $\mathbf{S}_1$ the assignment $f\mapsto\tilde{F}_\ell$. Now let $\mathbf{S}_2$ be the operator which assigns to $\tilde{F}_\ell$ its restriction $\tilde{F}_\ell|_X$ to the space X. Then finally let us introduce the transformation p_* which applied to $\tilde{F}_\ell|_X$ gives us a function in the space V_ℓ:

$$p_*\tilde{F}_\ell|_X(\mathbf{x})\equiv\int_{\mathbf{y}\in\mathcal{C}_\mathbf{x}}\tilde{F}_\ell|_X(\mathbf{x},\mathbf{y})\mathrm{d}\mu(\mathbf{y}), \tag{4.9}$$

where, for fixed $\mathbf{x}$, the integration is on the unit circle $\mathcal{C}_\mathbf{x}$ in the cotangent space of $\mathbf{x}\in S^2$ and $\mathrm{d}\mu$ is the usual normalized measure on that circle.

It can be shown that the operator $p_*\mathbf{S}_2\mathbf{S}_1$ commutes with all the rotation operators in the representation of SO(3) acting on the space $L^2(S^2)$. Thus, by Schur's lemma, there exist a constant λ_ℓ such that

$$p_*\mathbf{S}_2\mathbf{S}_1f=\lambda_\ell f,\quad f\in V_\ell. \tag{4.10}$$

The constant λ_ℓ can be evaluated by considering the polynomial $(x_1+\imath x_2)^\ell$ and the point $\mathbf{x}=(1,0,0)$ (see Ref. 9). In this way we have $\lambda_\ell=(2\ell-1)!!/\ell!$.

Since the elements of $\mathcal{X}_\ell$ are homogeneous polynomials of degree ℓ in the null quadric $\mathbf{Q}^2$, the exposition above for the operator $p_*\mathbf{S}_2\mathbf{S}_1$ suggests considering the following operator.

Let $f \in V_\ell$ and consider the function $\mathbf{U}_{\sigma_2}^{-1} f$ defined on $\mathbf{Q}^2$. Let G_ℓ be the unique homogeneous polynomial of order ℓ in three complex variables (z_1, z_2, z_3) which is harmonic ($\Delta_{\mathbf{C}^3} F_\ell \equiv \Sigma_{k=1}^{3} (\partial^2/\partial z_k^2) F_\ell = 0$) and whose restriction to $\mathbf{Q}^2$ is equal to $\mathbf{U}_{\sigma_2}^{-1} f$ (denote the assignment $\mathbf{U}_{\sigma_2}^{-1} f \mapsto G_\ell$ by $\mathbf{T}$). Let us now consider the operator $p_* \mathbf{S}_2 \mathbf{T} \mathbf{U}_{\sigma_2}^{-1}$. It can be shown that the operator $p_* \mathbf{S}_2 \mathbf{T} \mathbf{U}_{\sigma_2}^{-1}$ also commutes with all the rotation operators in the representation of SO(3) acting on $L^2(S^2)$. Thus, by Schur's lemma, there exist a constant μ_ℓ such that

$$p_* \mathbf{S}_2 \mathbf{T} \mathbf{U}_{\sigma_2}^{-1} f = \mu_\ell f, \quad f \in V_\ell. \tag{4.11}$$

To evaluate the constant μ_ℓ, we also consider the polynomial $(x_1 + \iota x_2)^\ell$ in V_ℓ and the point $\mathbf{x} = (1,0,0)$, to obtain $\mu_\ell = 1/\ell! \sqrt{2\ell + 1}$.

Thus we finally have, for $F \in \mathcal{X}_\ell$:

$$p_* \mathbf{S}_2 \mathbf{T} F = \frac{1}{\ell! \sqrt{2\ell + 1}} \mathbf{U}_{\sigma_2} F. \tag{4.12}$$

Therefore, we can think of the operator $\mathbf{U}_{\sigma_2}$ as the unitarization of the operator $p_* \mathbf{S}_2 \mathbf{T}$.

B. Quantizations of ρ_3 and σ_3

As in Sec. IV A, let $d\mu_3(\alpha)$ be the measure on $\mathbf{Q}^3$ obtained from the measure $d\nu_4(\mathbf{z}) = (1/\pi^4) \exp(-|\mathbf{z}|^2) \Pi_{j=1}^{4} dx_j\, dy_j$ by push forward along the map ρ_3 (again, here we are regarding the map ρ_3 as a function from $\mathbf{C}^4$ onto $\mathbf{Q}^3$).

Now, given $n \geqslant 1$, let $\mathcal{Z}_n$ be the space of homogeneous polynomials of degree $n-1$ in four complex variables $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ with the restriction $\alpha_1^2 + \alpha_2^2 + \alpha_3^2 + \alpha_4^2 = 0$. We shall consider the following inner product in $\mathcal{Z}_n$,

$$\langle F, G \rangle = \int_{\alpha \in \mathbf{Q}^3} F(\alpha) \overline{G(\alpha)} d\mu_3(\alpha). \tag{4.13}$$

The space $\mathcal{Z}_n$ has dimension n^2 and the following particular orthonormal basis:

$$\Upsilon_{n\ell m} = y_{n\ell m}(\mathbf{z}(\alpha)), \tag{4.14}$$

where since $y_{n\ell m}$ depend on $\mathbf{z}$ through the variables $z_1 z_3$, $z_1 z_4$, $z_2 z_3$, $z_2 z_4$, we mean by $\mathbf{z}(\alpha)$,

$$z_1 z_3 = \frac{-\iota \alpha_1 + \alpha_2}{2}, \quad z_1 z_4 = \frac{\iota \alpha_3 + \alpha_4}{2}, \quad z_2 z_3 = \frac{\iota \alpha_3 - \alpha_4}{2}, \quad z_2 z_4 = \frac{\iota \alpha_1 + \alpha_2}{2}. \tag{4.15}$$

Let $\mathcal{E}_3$ be the Hilbert space generated by the spaces $\mathcal{Z}_n$ with the inner product (4.13).

The quantization of ρ_3 is the unitary operator $\mathbf{U}_{\rho_3} : \mathcal{F}_4 \mapsto \mathcal{E}_3$ given by

$$\mathbf{U}_{\rho_3} \Psi((\alpha)) = \Psi(\mathbf{z}(\alpha)). \tag{4.16}$$

Bargmann and Todorov[8] have studied the inverse of $\mathbf{U}_{\rho_3}$ and considered the space $\mathcal{E}_3$ of holomorphic functions on the null quadric $\mathbf{Q}^3$. As in Sec. IV A, they find the measure $d\mu_3(\alpha)$ by requiring that certain given operators are adjoints of the multiplicative operators by the coordinates in $\mathbf{Q}^3$. The expression they consider for the map ρ_3 has components $(1/\sqrt{2})(\overline{w}_1, \overline{w}_2) q_j(z_1, z_2)^t$ where $j = 1,2,3,4$, $(\overline{w}_1, \overline{w}_2) \in \mathbf{C}^2$ and the 2×2 matrices $q_j = \iota \beta_j$ for $j = 1,2,3$ and q_4 is the 2×2 identity matrix. The expression that we consider in the above-given notation is $(-1)^{j+1}(z_3, z_4) \epsilon q_j (z_1, z_2)^t$.

From Bargmann and Todorov's work we have that the space $\mathcal{F}_4$ is the same subspace of $\mathcal{B}_4$ given by $\{f \in \mathcal{B}_4 | Mf = f\}$, where Mf is the mean value of f:

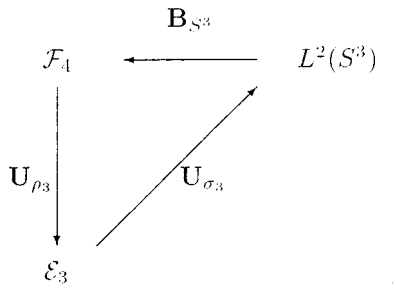
$$Mf(\mathbf{z}) \equiv \int_0^{\pi} f(z_1 \exp(\imath\psi), z_2 \exp(\imath\psi), z_3 \exp(-\imath\psi), z_4 \exp(-\imath\psi)) \frac{d\psi}{2\pi}. \tag{4.17}$$

One can prove this fact by following the proof of proposition (2.1).

The quantization of σ_3 is the unitary map $\mathbf{U}_{\sigma_3}: \mathcal{E}_3 \mapsto L^2(S^3)$ given by the linear extension of the assignment $\Upsilon_{n\ell m} \mapsto Y_{n\ell m}$:

$$\mathbf{U}_{\sigma_3}\Psi(\mathbf{x}) = \lim_{M\mapsto\infty} \int_{|\alpha|\leq M} \left(\sum_{n=1}^{\infty} \frac{\sqrt{n}}{(n-1)!} (\mathbf{x}\cdot\alpha)^{n-1} \right) \Psi(\alpha) d\mu_3(\alpha), \quad \Psi \in \mathcal{E}_3. \tag{4.18}$$

Theorem 4.2: *The following triangle of unitary transformations commutes:*



This triangle is the quantum version of the commuting triangle of canonical transformations in Theorem (3.3).

Remark 2: We can also relate our transformation $\mathbf{U}_{\sigma_3}: \mathcal{E}_4 \mapsto L^{(2)}(S^3)$ with the transformation p_* of Guillemin:[9] For $F \in \mathcal{Z}_n$,

$$p_* \mathbf{S}_2 \mathbf{T} F = \frac{1}{n!\sqrt{n}} \mathbf{U}_{\sigma_3} F, \tag{4.19}$$

where the operators $\mathbf{S}_2$ and $\mathbf{T}$ are defined in a similar way as previously. The proof of this last equation follows the same steps as the one to prove Eq. (4.12). Thus we can think of the operator $\mathbf{U}_{\sigma_3}$ as the unitarization of $p_* \mathbf{S}_2 \mathbf{T}$.

V. THE BARGMANN TRANSFORM AS A COHERENT STATE TRANSFORM

It is known that the Bargmann transform $\mathbf{B}_{\mathbf{R}^n}$ can be identified as a coherent state transform. That is, for any $F \in L^2(\mathbf{R}^n)$, the function $\mathbf{B}_{\mathbf{R}^n} F(\mathbf{z})$ can be expressed as the inner product of F with a canonical coherent state, labeled by $\mathbf{z} \in \mathbf{C}^n$, of the n-dimensional harmonic oscillator.

In this section we show that both Bargmann transforms $\mathbf{B}_{S^2}$ and $\mathbf{B}_{S^3}$ can also be written as coherent states transforms. Here sets of coherent states in $L^2(S^2)$ $[L^2(S^3)]$ appear as linear combinations of states (which we will call great-circle states) for each irreducible representation of SO(3) [SO(4)] that we considered when we defined the Bargmann transform $\mathbf{B}_{S^2}$ $[\mathbf{B}_{S^3}]$.

A. $\mathbf{B}_{\mathbf{R}^n}$ as a coherent state transform

Let us note that the kernel of $\mathbf{B}_{\mathbf{R}^n}$ can be expressed in the following way: let us take $\mathbf{z} = (\mathbf{q} - \imath\mathbf{p})/\sqrt{2}$ with $\mathbf{q}, \mathbf{p} \in \mathbf{R}^n$, then

$$A(\mathbf{x}, \mathbf{z}) = \exp\left(-\frac{(\mathbf{x}-\mathbf{q})^2}{2} + \frac{\imath\mathbf{p}\cdot\mathbf{q}}{2} - \imath\mathbf{p}\cdot\mathbf{x} + \frac{\mathbf{q}^2+\mathbf{p}^2}{4} \right). \tag{5.1}$$

Now let us denote

$$\Phi^{(\mathbf{z})}(\mathbf{x}) = \frac{1}{\pi^{n/4}} \overline{A(\mathbf{x},\mathbf{z})}. \tag{5.2}$$

The functions $\Phi^{(\mathbf{z})} \in L^2(\mathbf{R}^n)$, labeled by $\mathbf{z} \in \mathbf{C}^n$, are the canonical coherent states of the n-dimensional harmonic oscillator.

Since

$$\frac{1}{\pi^{n/2}} \int_{\mathbf{x}\in\mathbf{R}^n} A(\mathbf{x},\mathbf{w})\overline{A(\mathbf{x},\mathbf{z})}\,\mathrm{d}\mathbf{x} = \exp(\overline{\mathbf{z}}\mathbf{w}), \quad \mathbf{z},\mathbf{w} \in \mathbf{C}^n, \tag{5.3}$$

then we have that the Bargmann transform sends the coherent states of the n-dimensional harmonic oscillator into the coherent states defined in Sec. II:

$$\mathbf{B}_{\mathbf{R}^n}\Phi^{(\mathbf{z})}(\mathbf{w}) = \Psi_{\mathbf{z}}(\mathbf{w}), \tag{5.4}$$

thus the Bargmann transform $\mathbf{B}_{\mathbf{R}^n}$ acting on a function $F \in L^2(\mathbf{R}^n)$ can be expressed as a coherent state transform:

$$\mathbf{B}_{\mathbf{R}^n}F(\mathbf{z}) = \langle F, \Phi^{(\mathbf{z})}\rangle = \int_{\mathbf{x}\in\mathbf{R}^n} F(\mathbf{x})\overline{\Phi^{(\mathbf{z})}(\mathbf{x})}\,\mathrm{d}\mathbf{x}. \tag{5.5}$$

It is also known that the set of coherent states $\Phi^{(\mathbf{z})}$ gives a resolution of the identity in the sense that every function $F \in L^2(\mathbf{R}^n)$ can be written as

$$F(\mathbf{x}) = \lim_{M\mapsto\infty} \int_{|\mathbf{z}|\le M} \langle F, \Phi^{(\mathbf{z})}\rangle_{\mathbf{R}^n}\Phi^{(\mathbf{z})}(\mathbf{x})\,\mathrm{d}\nu_n(\mathbf{z}), \tag{5.6}$$

where $\mathrm{d}\nu_n(\mathbf{z})$ is the measure given in Eq. (2.1).

B. $\mathbf{B}_{S^2}$ as a coherent state transform

In Sec. III we showed that the generating function Φ_{S^2} can be written as the inner product of the vectors $\rho_2(\mathbf{z}) \in \mathbf{Q}^2$ and $\mathbf{x} \in S^2$ [see Eq. (3.13)]. Thus we are able to establish the following

Theorem 5.1: *The Bargmann transform* $\mathbf{B}_{S^2}$ *is a coherent state transform in the sense that* $\mathbf{B}_{S^2}$ *acting on a function* $\Psi \in L^2(S^2)$ *can be written in the following way:*

$$\mathbf{B}_{S^2}\Psi(\mathbf{z}) = \langle \Psi, \Phi_{\rho_2(\mathbf{z})}\rangle_{S^2} \tag{5.7}$$

where, for each $\alpha \in \mathbf{Q}^2$, *we define the coherent states*

$$\Phi_\alpha(\mathbf{x}) = \sum_{\ell=0}^{\infty} \frac{\sqrt{2\ell+1}}{\ell!}\Phi_{\alpha,\ell}(\mathbf{x}) \tag{5.8}$$

with the states $\Phi_{\alpha,\ell}$ *given by*

$$\Phi_{\alpha,\ell}(\mathbf{x}) = (\mathbf{x}\cdot\alpha)^{\ell}. \tag{5.9}$$

The states $\Phi_{\alpha,\ell}$ have the following properties.

(a) For each integer $\ell \ge 1$, the states $\Phi_{\alpha,\ell}$, belong to the eigenspace V_ℓ of the Laplacian Δ_{S^2} (see Ref. 10).

(b) For large ℓ, and $\alpha \neq 0$, the state $\Phi_{\alpha,\ell}$ is concentrated around the great circle in S^2 (classical orbit) generated by the vectors $\Re(\alpha)/\|\Re(\alpha)\|$ in S^2 and $-\Im(\alpha)$ in T^*S^2 at the point $\Re(\alpha)/\|\Re(\alpha)\|$. The concentration is in the sense that most of the $L^2(S^2)$-norm of $\Phi_{\alpha,\ell}$ comes from a small neighborhood of the great circle (see Ref. 7). This is the reason why we call the states $\{\Phi_{\alpha,\ell}\}$ great-circle states.

(c) The states $\{\Phi_{\alpha,\ell}\}$ give a resolution of the identity in the space V_ℓ. Namely, for each function $\Psi \in V_\ell$, the following equation holds

$$\Psi(\mathbf{x}) = r(\ell)\int_{\mathbf{Q}^2}\langle \Psi, \Phi_{\alpha,\ell}\rangle_{S^2}\Phi_{\alpha,\ell}(\mathbf{x})\,\mathrm{d}\mu_2(\alpha) \tag{5.10}$$

for some constant $r(\ell)$ which will be evaluated in the following.

This equation is a consequence of the following three facts: (i) the operator on the right-hand side of Eq. (5.10) commutes with all the rotations in SO(3) acting as operators on V_ℓ, (ii) the irreducibility of the representation of SO(3) acting on V_ℓ, and (iii) the invariance of the measure $\mathrm{d}\mu_2(\alpha)$ under rotations in SO(3), which we state as follows:

Proposition 5.2: Let $R \in \mathrm{SO}(3)$, then for any $\mathrm{d}\mu_2$-integrable function $f(\alpha)$ we have

$$\int_{\mathbf{Q}^2} f(R\alpha)\,\mathrm{d}\mu_2(\alpha) = \int_{\mathbf{Q}^2} f(\alpha)\,\mathrm{d}\mu_2(\alpha). \tag{5.11}$$

Here, $R\alpha$ means $R\Re(\alpha) + \imath R\Im(\alpha)$.

We are calling the states Φ_α coherent states because, for $\alpha \neq 0$, they are labeled by elements of $T^*(S^2) - \{0\}$ (through the map σ_2) and they give a resolution of the identity for the space $L^2(S^2)$:

$$\Psi(\mathbf{x}) = \int_{\mathbf{Q}^2}\langle \Psi, \Phi_\alpha\rangle_{S^2}\Phi_\alpha(\mathbf{x})\,\mathrm{d}\mu_2(\alpha), \qquad \Psi \in L^2(S^2). \tag{5.12}$$

This last equation is a consequence of Eq. (5.10) and the fact that homogeneous polynomials in $\mathcal{E}_2$ of different order are orthogonal.

For each ℓ, the images of the great-circle states $\Phi_{\alpha,\ell}$ under the transformation $\mathbf{U}_{\sigma_2}^{-1} = \mathbf{B}_{S^2} \circ \mathbf{U}_{\rho_2}$ provides a reproducing kernel for the space $\mathcal{X}_\ell$. The proof of this fact is based on the following two propositions:

Proposition 5.3: The inner product of two great-circle states $\Phi_{\beta,\ell}$ and $\Phi_{\alpha,k}$ in $L^2(S^2)$ $(\alpha, \beta \in \mathbf{Q}^2)$ is

$$\langle \Phi_{\beta,\ell}, \Phi_{\alpha,k}\rangle_{S^2} = \frac{\gamma_\ell}{2^{\ell+1}}(\alpha\cdot\beta)^\ell \delta_{\ell,k}, \tag{5.13}$$

with $\gamma_\ell \equiv \int_0^\pi \sin^{2\ell+1}(\theta)\,\mathrm{d}\theta = 2[(2\ell)!!/(2\ell+1)!!]$ [here the notation $(2\ell)!!$ means the product of all positive even integers less than or equal to 2ℓ, the notation for $(2\ell+1)!!$ is similar].

Proof: Given $\beta \in \mathbf{Q}^2 - 0$, there exists $\lambda > 0$ and a rotation $R \in \mathrm{SO}(3)$ such that $\beta = \lambda R(\mathbf{e}_1 - \imath\mathbf{e}_2)$ (with $\{\mathbf{e}_j, j = 1,2,3\}$ the canonical orthonormal basis of $\mathbf{R}^3$). Thus

$$\langle \Phi_{\beta,\ell}, \Phi_{\alpha,\ell}\rangle_{S^2} = \lambda^\ell \int_{\mathbf{x}\in S^2} (\mathbf{x}\cdot R(\mathbf{e}_1 - \imath\mathbf{e}_2))^\ell \overline{(\mathbf{x}\cdot\alpha)^\ell}\,\mathrm{d}\sigma_2(\mathbf{x}). \tag{5.14}$$

By making the change of variable $\mathbf{y} = R^{-1}\mathbf{x}$, using spherical coordinates for the variable $\mathbf{y}$ and the orthogonality of the matrix R, the result follows by a straightforward computation. □

Proposition 5.4: The Bargmann transform $\mathbf{B}_{S^2}$ of the great-circle state $\Phi_{\beta,\ell}$ $(\beta \in \mathbf{Q}^2)$ is

$$\mathbf{B}_{S^2}\Phi_{\beta,\ell}(\mathbf{z}) = \frac{\sqrt{2\ell+1}}{\ell!}\,\frac{\gamma_\ell}{2^{\ell+1}}(\rho_2(\mathbf{z})\cdot\beta)^\ell. \tag{5.15}$$

Thus the image of the coherent state $\Phi_{\beta,\ell}$ under the transformation $\mathbf{U}_{\sigma_2}^{-1}$ is

$$\mathbf{U}_{\sigma_2}^{-1}\Phi_{\beta,\ell}(\alpha) = \frac{\sqrt{2\ell+1}}{\ell!}\,\frac{\gamma_\ell}{2^{\ell+1}}(\alpha\cdot\beta)^\ell. \tag{5.16}$$

The factor $(\alpha\cdot\beta)^{\ell}$ appearing in Eq. (5.16) provides us with a reproducing kernel for the space $\mathcal{X}_{\ell}$, as the following theorem establishes it:

Theorem 5.5: *For each integer* $\ell \geqslant 1$, *the function* $K_{\mathbf{Q}^2,\ell}:\mathbf{Q}^2\times\mathbf{Q}^2\mapsto\mathbf{C}$ *given by*

$$K_{\mathbf{Q}^2,\ell}(\alpha,\beta)=\frac{2^{\ell}}{(2\ell)!}(\beta\cdot\alpha)^{\ell} \tag{5.17}$$

is a reproducing kernel for the space $\mathcal{X}_{\ell}$, *that is,*

$$\int_{\mathbf{Q}^2} f(\alpha)K_{\mathbf{Q}^2,\ell}(\alpha,\beta)\mathrm{d}\mu_2(\alpha)=f(\beta), \qquad f\in\mathcal{X}_{\ell}. \tag{5.18}$$

Proof: It is enough to prove Eq. (5.18) when $f=\Upsilon_{\ell,m}$. From the definition of $\mathrm{d}\mu_2$ we have

$$\int_{\mathbf{Q}^2}\Upsilon_{\ell,m}(\alpha)K(\alpha,\beta)\mathrm{d}\mu_2(\alpha)=\int_{\mathbf{z}\in\mathbf{C}^2} y_{\ell,m}(\mathbf{z})\frac{2^{\ell}}{(2\ell)!}\overline{(\rho_2(\mathbf{z})\cdot\boldsymbol{\beta})^{\ell}}\mathrm{d}\nu_2(\mathbf{z}). \tag{5.19}$$

Now let us define the function

$$\Phi_{\rho_2}(\mathbf{z},\alpha)\equiv\overline{y_{1,1}(\mathbf{z})}\Upsilon_{1,1}(\alpha)+\overline{y_{1,0}(\mathbf{z})}\Upsilon_{1,0}(\alpha)+\overline{y_{1,-1}(\mathbf{z})}\Upsilon_{1,-1}(\alpha)=\alpha\cdot\rho_2(\mathbf{z}). \tag{5.20}$$

Since

$$(\Phi_{\rho_2}(\mathbf{z},\beta))^{\ell}=\frac{(2\ell)!}{2^{\ell}}\sum_{m=-\ell}^{\ell}\overline{y_{\ell,m}}(\mathbf{z})\Upsilon_{\ell,m}(\beta), \tag{5.21}$$

the result follows. □

We can use this theorem, in particular, to evaluate the constant $r(\ell)$ appearing in Eq. (5.10) in the following manner: Let us apply Eq. (5.10) to the state $\Phi_{\beta,\ell}$:

$$\begin{aligned}\Phi_{\beta,\ell}(\mathbf{x})&=r(\ell)\int_{\alpha\in\mathbf{Q}^2}\langle\Phi_{\beta,\ell}\Phi_{\alpha,\ell}\rangle_{S^2}\Phi_{\alpha,\ell}(\mathbf{x})\mathrm{d}\mu_2(\alpha)\\&=r(\ell)\frac{\gamma_{\ell}}{2^{\ell+1}}\int_{\alpha\in\mathbf{Q}^2}(\alpha\cdot\beta)^{\ell}\Phi_{\alpha,\ell}(\mathbf{x})d\mu_2(\alpha)\\&=r(\ell)\frac{\gamma_{\ell}(2\ell)!}{2^{2\ell+1}}\overline{\int_{\alpha\in\mathbf{Q}^2}(\alpha\cdot\mathbf{x})^{\ell}K_{\mathbf{Q}^2,\ell}(\alpha,\beta)\mathrm{d}\mu_2(\alpha)}.\end{aligned} \tag{5.22}$$

Thus from Eq. (5.18) we must have

$$r(\ell)=\frac{2^{2\ell+1}}{\gamma_{\ell}(2\ell)!}. \tag{5.23}$$

From Theorem (5.5) we also obtain a reproducing kernel for the space $\mathcal{E}_3$:

Theorem 5.6: *The function*

$$K_{\mathbf{Q}^2}(\alpha,\beta)\equiv\sum_{\ell=0}^{\infty}\frac{2^{\ell}}{(2\ell)!}(\beta\cdot\alpha)^{\ell}=\frac{1}{2}(\exp(\sqrt{2\beta\cdot\alpha})+\exp(-\sqrt{2\beta\cdot\alpha})) \tag{5.24}$$

is an analytic function in the space $\mathcal{E}_3$ *(for* α *fixed) and provides a reproducing kernel for this space:*

$$\int_{\mathbf{Q}^2} f(\alpha) K_{\mathbf{Q}^2}(\alpha,\beta)\mathrm{d}\mu_2(\alpha) = f(\beta), \qquad f \in \mathcal{E}_3. \tag{5.25}$$

Note that Eq. (5.24) is independent of the branch of the square root function we have chosen.

Proof: The series $\Sigma_{\ell=0}^{\infty}[2^{\ell}/(2\ell)!]z^{\ell}$ is absolutely convergent for all values of $z \in \mathbf{C}$, so $K_{\mathbf{Q}^2}(\alpha,\beta)$ is an analytic function in the variable β (α fixed).

Moreover, each function $2^{\ell}(\beta\cdot\alpha)^{\ell}/(2\ell)!$ belongs to the space $\mathcal{X}_{\ell}$ and its norm $a_{\ell}^2 \equiv \|2^{\ell}(\beta\cdot\alpha)^{\ell}/(2\ell)!\|^2$ is equal to $2^{3\ell+1}/(2\ell+1)\gamma_{\ell}(\ell!/(2\ell)!)^2|\alpha|^{2\ell}$. Since $\Sigma_{\ell=0}^{\infty} a_{\ell}^2$ is finite, we conclude that the kernel $K_{\mathbf{Q}^2}$ is in $\mathcal{E}_3$ (α fixed). The equality in Eq. (5.24) can be checked directly by using the Taylor series of the exponential function. □

The kernel $K_{\mathbf{Q}^2}$ and the function ρ_2 give an expected reproducing kernel for the space $\mathcal{B}_{S^2}$:

Theorem 5.7: *The following function* $\frac{1}{2}(\exp(\mathbf{z}\cdot\mathbf{w}) + \exp(-\mathbf{z}\cdot\mathbf{w}))$ *is a reproducing kernel of the space* $\mathcal{B}_{S^2}$. *This function is in the space* $\mathcal{B}_{S^2}$ *for* $\mathbf{w}$ *fixed.*

C. B_{S^3} as a coherent state transform

This section is the analog of Sec. IV B concerning the Bargmann Transform $\mathbf{B}_{S^3}$. Namely, we will show that this transform can also be written as a coherent state transform (with the coherent states defined in a similar way as before), and we also have a reproducing kernel for the spaces $\mathcal{Z}_n$, $\mathcal{E}_4$, and $\mathcal{F}_4$.

From the definition of $\mathbf{B}_{S^3}$, Eq. (2.47), we obtain:

Theorem 5.8:

$$\mathbf{B}_{S^3}\Psi(\mathbf{z}) = \langle \Psi, \Phi_{\rho_3(\mathbf{z})}\rangle_{S^3}, \quad \Psi \in L^2(S^3), \tag{5.26}$$

where the coherent states in $L^2(S^3)$ *are defined by*

$$\Phi_{\alpha}(\mathbf{x}) = \sum_{n=1}^{\infty} \frac{\sqrt{n}}{(n-1)!}\Phi_{\alpha,n-1}(x), \qquad \alpha \in \mathbf{Q}^3 \tag{5.27}$$

and the great-circle states $\Phi_{\alpha,n-1}$ *are defined by*

$$\Phi_{\alpha,n-1}(\mathbf{x}) = (\mathbf{x}\cdot\alpha)^{n-1}, \qquad \alpha \in \mathbf{Q}^3, \qquad n \geqslant 1. \tag{5.28}$$

The great-circle states $\Phi_{\alpha,n-1}$ have properties analogous to those of the states defined in Sec. IV B and in particular they provide a resolution of the identity:

For $\Psi \in \mathcal{M}_n$, the following equation holds:

$$\Psi(\mathbf{x}) = \frac{n}{((n-1)!)^2}\int_{\mathbf{Q}^3-\{0\}} \langle \Psi, \Phi_{\alpha,n-1}\rangle_{S^3}\Phi_{\alpha,n-1}(\mathbf{x})\mathrm{d}\mu_4(\alpha), \tag{5.29}$$

and therefore the coherent states Φ_{α}, $\alpha \in \mathbf{Q}^3$, give a resolution of the identity for $L^2(S^3)$:

$$\Psi(\mathbf{x}) = \int_{\mathbf{Q}^3-\{0\}} \langle \Psi, \Phi_{\alpha}\rangle_{S^3}\Phi_{\alpha}(\mathbf{x})\mathrm{d}\mu_4(\alpha), \qquad \Psi \in L^2(S^3). \tag{5.30}$$

Note that the coherent states Φ_{α} are labeled by elements of $T^*S^3 - \{0\}$ through the map σ_3.

Equation (5.29) is a consequence of the following four facts:

Proposition 5.9: The inner product of two coherent states in $L^2(S^3)$ *is*

$$\langle \Phi_{\beta,k}, \Phi_{\alpha,\ell}\rangle_{S^3} = \frac{1}{(k+1)2^k}(\alpha\cdot\beta)^k\delta_{\ell,k}, \qquad k \geqslant 0. \tag{5.31}$$

The invariance of the measure $\mathrm{d}\mu_4$ under rotations $R \in \mathrm{SO}(4)$:

Proposition 5.10: Let $R \in \mathrm{SO}(4)$. *for any* $\mathrm{d}\mu_4$*-integrable function* $f(\alpha)$ *the following equation holds:*

$$\int_{\mathbf{Q}^3} f(R\alpha)\mathrm{d}\mu_4(\alpha) = \int_{\mathbf{Q}^3} f(\alpha)\mathrm{d}\mu_4(\alpha). \tag{5.32}$$

Proposition 5.11: The Bargmann transform $\mathbf{B}_{S^3}$ *maps the great-circle states* $\Phi_{\beta,k}$ *as follows:*

$$\mathbf{B}_{S^3}\Phi_{\beta,k}(\mathbf{z}) = \frac{\sqrt{k+1}}{(k+1)!\,2^k}(\rho_3(\mathbf{z})\cdot\beta)^k, \qquad k \geqslant 0 \tag{5.33}$$

and then the image of the coherent states $\Phi_{\beta,k}$ *under the unitary transformation* $\mathbf{U}_{\sigma_3}^{-1}$ *is*

$$\mathbf{U}_{\sigma_3}^{-1}\Phi_{\beta,k}(\alpha) = \frac{\sqrt{k+1}}{(k+1)!\,2^k}(\alpha\cdot\beta)^k, \qquad k \geqslant 0. \tag{5.34}$$

Theorem 5.12: *For each integer* $n \geqslant 1$, *the function* $K_{\mathbf{Q}^3,n}: \mathbf{Q}^3 \times \mathbf{Q}^3 \mapsto \mathbf{C}$ *given by*

$$K_{\mathbf{Q}^3,n-1}(\alpha,\beta) \equiv \frac{1}{((n-1)!)^2 2^{n-1}}(\beta\cdot\alpha)^{n-1} \tag{5.35}$$

is a reproducing kernel for the space $\mathcal{Z}_n$.

The proofs of these facts are similar to those given in Sec. IV B.

Theorem 5.12 provides us with a reproducing kernel for the space $\mathcal{E}_4$:

Theorem 5.12: *The function*

$$K_{\mathbf{Q}^3}(\alpha,\beta) \equiv \sum_{n=1}^{\infty} \frac{1}{((n-1)!)^2 2^{n-1}}(\beta\cdot\alpha)^{n-1} \tag{5.36}$$

belongs to the space $\mathcal{E}_4$ *(for* α *fixed) and it is a reproducing kernel of this space.*

From this last theorem and the map ρ_3 we obtain the following

Theorem 5.13: *The function*

$$\tilde{K}_{\mathbf{Q}^3}(\mathbf{z},\mathbf{w}) \equiv \sum_{n=1}^{\infty} \frac{1}{((n-1)!)^2}((\overline{w}_1 z_1 + \overline{w}_2 z_2)(\overline{w}_3 z_3 + \overline{w}_4 z_4))^{n-1} \tag{5.37}$$

belongs to the space $\mathcal{F}_4$ *(for* $\mathbf{w}$ *fixed) and it is a reproducing kernel of this space.*

As noted by Bargmann and Todorov,[8] the function $\tilde{K}_{\mathbf{Q}^3}$ can be expressed in terms of the modified Bessel function of the first kind $I_0(z) \equiv \Sigma_{m=0}^{\infty}[1/(m!)^2](z/2)^{2m}$:

$$\tilde{K}_{\mathbf{Q}^3}(\mathbf{z},\mathbf{w}) = I_0(2\sqrt{(\overline{w}_1 z_1 + \overline{w}_2 z_2)(\overline{w}_3 z_3 + \overline{w}_4 z_4)}). \tag{5.38}$$

VI. DISCUSSION

The transformations $\mathbf{U}_{\sigma_2}$ and $\mathbf{U}_{\sigma_3}$ can be generalized to a unitary transformation $\mathbf{U}_{\sigma_n}$ for the case of the n-sphere S^n (with $n \geqslant 2$) on the basis of the work of Bargmann and Todorov.[8] Namely, these two authors describe a Hilbert space $\mathcal{E}_n$ of holomorphic functions on the null quadric $\mathbf{Q}^n$ endowed with an inner product which in turn is determined by an $\mathrm{SO}(n+1)$ invariant measure on $\mathbf{Q}^n$. Thus, by taking the hyperspherical harmonics as a basis of $L^2(S^n)$ and assigning to them corresponding elements of a basis of $\mathcal{E}_n$, we can define $\mathbf{U}_{\sigma_n}$ as the linear extension of such assignment. The detailed description of this transform will appear in a further work.

There are other Bargmann-type transforms like $\mathbf{U}_{\sigma_2}$, $\mathbf{U}_{\sigma_3}$, and $\mathbf{U}_{\sigma_n}$ that have been introduced by several authors. They all are different from our transforms. Here we briefly discuss these transforms and compare them with ours.

Rawnsley,[11] in analogy with the case of the Bargmann transform for $L^2(\mathbf{R}^n)$, considered real and complex polarizations of the phase space $T^*S^n-\{0\}$ and the half-form pairing between them (which turns out to be nonunitary).

Ii[12] considered an integral operator between $L^2(S^n)$, with $n\geqslant 2$ even, and a Hilbert space of holomorphic functions on the null quadric $\mathbf{Q}^n$. This operator is defined through an integral kernel given by the exponential of $\alpha\cdot\mathbf{x}$ ($\alpha\in\mathbf{Q}^n$, and $\mathbf{x}\in S^n$), whereas we consider a different power series in this function. Ii makes his integral operator unitary by endowing $\mathbf{Q}^n$ with a different measure than the one considered by ourselves and Bargmann and Todorov. Note that our transform $\mathbf{U}_{\sigma_n}$ is defined first by setting the measure on $\mathbf{Q}^n$ and then by adjusting the coefficients of the power series in $\alpha\cdot\mathbf{x}$ in order to make $\mathbf{U}_{\sigma_n}$ unitary. Wada[13] was able to remove the condition that n must be even and then she obtained a unitary transformation for all $n\geqslant 2$ that coincides with the transformation of Ii for n even.

Hall[14,15] and Stenzel[16] have considered a Bargmann-type transform when the configuration space is either a compact Lie group or a symmetric space of compact type. They base their approach on the heat kernel for the corresponding manifold. Thus they define their Bargmann transform and coherent states. One of the main differences with our approach is that they consider the quadric $\{\alpha\in\mathbf{C}^{(n+1)}|\,\alpha_1^2+\cdots\alpha_{n+1}^2=1\}$ whereas we consider the null quadric $\mathbf{Q}^n$.

Kowalski and Rembieliński[17] have considered coherent states for the two-sphere as eigenvectors of suitable operators. On the basis of a suggestion by Hall, the states of Kowalski and Rembieliński can be related with the coherent states appearing in the work of Hall[14,15] and Stenzel.[16] This suggestion allowed Kowalski and Rembieliński[18] to solve an equation through a heat kernel and then to be able to set up a Bargmann-type transform for $L^2(S^2)$. They also deal with the quadric $\{\alpha\in\mathbf{C}^{(n+1)}|\,\alpha_1^2+\cdots\alpha_{n+1}^2=1\}$.

Inspired in part by the work of Kowalski and Rembieliński,[18] Hall and Mitchell[19] have written a recent paper describing in detail coherent states and a Bargmann-type transform for $L^2(S^n)$ related to the work of Hall[14,15] and Stenzel.[16]

ACKNOWLEDGMENTS

Part of this work appeared in the Ph.D. thesis of the author, who deeply thanks the thesis adviser Lawrence E. Thomas. The author thanks A. Uribe-Ahumada for suggesting that the canonical transformations could be written as the compositions of two maps involving the null quadrics and Brian C. Hall for his permanent interest and important suggestions to improve the research and presentation of this paper. The following people are thanked for very illuminating discussions and suggestions: Stephan De Bievre, Amine El Gradechi, Stephen B. Sontz, and Alberto Verjovsky-Sola. Timothy Gendron is acknowledged for his help in the preparation of the manuscript. This paper was partially supported by the following grants: PAPIIT UNAM No. IN102998 and CONACYT No. 32146-E.

APPENDIX A: THE KERNEL OF THE BARGMANN TRANSFORM FOR S^2

The purpose of this appendix is to prove Eqs. (2.22) and (2.23). We want to do this by showing that the following equation holds for all $k\geqslant 0$:

$$\mathcal{K}_k(\mathbf{x},\mathbf{z})=\frac{\sqrt{2k+1}}{k!}\left(\frac{1}{\sqrt{3}}\right)^k(\Phi_{S^2})^k(\mathbf{x},\mathbf{z}),$$

with $\mathcal{K}_k(\mathbf{x},\mathbf{z})=\Sigma_{m=-k}^{k}Y_{km}^*(\mathbf{x})y_{km}(\mathbf{z})$.

The main idea of the proof is based on the fact that the following function $G_k(\mathbf{x},\mathbf{z})\equiv\mathcal{K}_k(\mathbf{x},\mathbf{z})/c(k)(\Phi_{S^2}(\mathbf{x},\mathbf{z}))^k$ [with $c(k)$ some constant] satisfies an homogeneous system of first-

order differential equations with initial condition $G_k(\mathbf{x}_0,\mathbf{z}_0)=1$. Then we show that the gradient of G_k must be zero, which implies that the solution of the system must be $G_k(\mathbf{x},\mathbf{z})\equiv 1$, i.e., $\mathcal{K}_k(\mathbf{x},\mathbf{z})=c(k)(\Phi_{S^2}(\mathbf{x},\mathbf{z}))^k$. Next, we evaluate the constant $c(k)$.

We know that the Bargmann transform $\mathbf{B}_{S^2}$ intertwines the operators L_i and L_i', $i=1,2,3$. Thus for any smooth function $\Psi(\mathbf{x})$,

$$L_i'\mathbf{B}_{S^2}\Psi=\mathbf{B}_{S^2}L_i\Psi.$$

Now we want to show that for any $k\geqslant 0$,

$$(L_i+L_i')\mathcal{K}_k(\mathbf{x},\mathbf{z})=0, \qquad i=1,2,3.$$

Let P_k be the projector on the span of $\{y_{km}(\mathbf{z})/m=-k,\ldots,k\}$. P_k acts on the Bargmann space $\mathcal{B}_2$. Thus we have for any smooth function $\Psi(\mathbf{x})$,

$$P_k\mathbf{B}_{S^2}\Psi(\mathbf{z})=\int_{\mathbf{x}\in S^2}\mathcal{K}_k(\mathbf{x},\mathbf{z})\Psi(\mathbf{x})\mathrm{d}\Omega(\mathbf{x}),$$

which implies

$$P_k\mathbf{B}_{S^2}L_i\Psi(\mathbf{z})=-\int_{\mathbf{x}\in S^2}(L_i\mathcal{K}_k(\mathbf{x},\mathbf{z}))\Psi(\mathbf{x})\mathrm{d}\Omega(\mathbf{x}),$$

where we have used the self-adjointness of L_i.

On the other hand, if we apply P_k to both sides of the equation $L_i'\mathbf{B}_{S^2}\Psi=\mathbf{B}_{S^2}L_i\Psi$ and use the fact that P_k commutes with L_i', $i=1,2,3$, we get

$$P_k\mathbf{B}_{S^2}L_i\Psi(\mathbf{z})=\int_{\mathbf{x}\in S^2}L_i'\mathcal{K}_k(\mathbf{x},\mathbf{z})\Psi(\mathbf{x})\mathrm{d}\Omega(\mathbf{x}).$$

Since the last two equations hold for a dense set in $L^2(S^2)$, we conclude that $(L_i+L_i')\mathcal{K}_k(\mathbf{x},\mathbf{z})=0$, $i=1,2,3$.

The function $\mathcal{K}_k$ satisfies another differential equation which is a consequence that $\mathcal{K}_k$ is an homogeneous polynomial of degree $2k$ in the variables (z_1,z_2). Thus we must have for all $k\geqslant 0$:

$$(H_0-2k)\mathcal{K}_k=0 \quad \text{with} \quad H_0=z_1\partial_1+z_2\partial_2.$$

The above-given analysis must hold, in particular, for $k=1$. Thus we have

$$(L_i+L_i')\Phi_{S^2}(\mathbf{x},\mathbf{z})=0, \quad i=1,2,3 \quad \text{and} \quad (H_0-2)\Phi_{S^2}=0.$$

Since L_i, L_i', and H_0 are first-order linear differential operators, we have for all $k\geqslant 0$,

$$(L_i'+L_i)\Phi_{S^2}^k=0, \quad (H_0-2k)\Phi_{S^2}^k=0.$$

Now consider a particular point $(\mathbf{x}_0,\mathbf{z}_0)$ where $\Phi_{S^2}(\mathbf{x}_0,\mathbf{z}_0)\neq 0$. Let

$$c(k)=\mathcal{K}_k(\mathbf{x}_0,\mathbf{z}_0)/\Phi_{S^2}^k(\mathbf{x}_0,\mathbf{z}_0).$$

Define the function

$$G_k(\mathbf{x},\mathbf{z})=\frac{\mathcal{K}_k(\mathbf{x},\mathbf{z})}{c(k)\Phi_{S^2}^k(\mathbf{x},\mathbf{z})}.$$

This function satisfies the following system of homogeneous first-order differential equations:

$$(L_i' + L_i)G_k(\mathbf{x},\mathbf{z}) = 0, \quad i = 1,2,3 \quad \text{and} \quad H_0 G_k(\mathbf{x},\mathbf{z}) = 0$$

with initial condition $G_k(\mathbf{x}_0,\mathbf{z}_0) = 1$.

The system of equations can also be written as

$$\mathbf{M}\nabla G_k = 0$$

with $\nabla = (\partial/\partial\theta, \partial/\partial\phi, \partial/\partial z_1, \partial/\partial z_2)$ and $\mathbf{M}$ a 4×4 matrix given by

$$\mathbf{M} = \begin{bmatrix} \imath \sin(\phi) & \imath \cot(\theta)\cos(\phi) & \frac{1}{2}z_2 & \frac{1}{2}z_1 \\ -\imath \cos(\phi) & \imath \cot(\theta)\sin(\phi) & -\frac{1}{2\imath}z_2 & \frac{1}{2\imath}z_1 \\ 0 & -\imath & \frac{1}{2}z_1 & \frac{-1}{2}z_2 \\ 0 & 0 & z_1 & z_2 \end{bmatrix}.$$

The determinant of the matrix $\mathbf{M}$ is

$$\det \mathbf{M} = \frac{-1}{\sqrt{3}\sin(\theta)}\Phi_{S^2}(\mathbf{x},\mathbf{z}).$$

Since $\Phi_{S^2}(\mathbf{x}_0,\mathbf{z}_0) \neq 0$, $\mathbf{M}$ is then invertible on a neighborhood $\mathcal{V}$ of the point $(\mathbf{x}_0,\mathbf{z}_0)$. Therefore, we must have

$$G_k(\mathbf{x},\mathbf{z}) = 1 \quad \text{for all} \quad (\mathbf{x},\mathbf{z}) \in \mathcal{V}$$

and then

$$\mathcal{K}_k = c(k)\Phi_{S^2}^k(\mathbf{x},\mathbf{z}) \quad \text{for all} \quad (\mathbf{x},\mathbf{z}) \in \mathcal{V}.$$

Since $\mathcal{K}_k$ and $\Phi_{S^2}^k$ are analytic functions of $(\mathbf{x}, \mathbf{z})$, the last equation must actually hold for all $(\mathbf{x}, \mathbf{z})$.

Finally, we want to evaluate the constant $c(k)$ appearing in the last equation. By using

$$Y_{11}(\mathbf{x}) = -\sqrt{\frac{3}{2}}\sin(\theta)\exp(\imath\phi), \quad Y_{1-1}(\mathbf{x}) = \sqrt{\frac{3}{2}}\sin(\theta)\exp(-\imath\phi),$$

$$Y_{10}(\mathbf{x}) = \sqrt{3}\cos(\theta), \quad y_{11}(\mathbf{z}) = \frac{z_1^2}{\sqrt{2}}, \quad y_{10}(\mathbf{z}) = z_1 z_2, \quad y_{1-1}(\mathbf{z}) = \frac{z_2^2}{\sqrt{2}},$$

we obtain Eq. (2.23).

Now consider the relation

$$Y_{km}(\mathbf{x}) = \sqrt{\frac{(2k+1)(k-m)!}{(k+m)!}}P_k^m(\cos(\theta))\exp(\imath m\phi),$$

with P_k^m the associated Legendre polynomials. By taking $\theta = 0$ and since $P_k^m(1) = 1\,\delta_{m0}$,

$$\sqrt{(2k+1)}\frac{z_1^k z_2^k}{k!}=c(k)(\sqrt{3}z_1z_2)^k,$$

which in turn implies $c(k)=[\sqrt{2k+1}/k!](1/\sqrt{3})^k$, and then Eq. (2.22).

APPENDIX B: THE KERNEL OF THE BARGMANN TRANSFORM FOR S^3

The purpose of this appendix is to demonstrate Eqs. (2.50) and (2.51).

We want to do it by showing that for all $n\geqslant 1$:

$$\tilde{\mathcal{K}}_n(\mathbf{x},\mathbf{z})=\frac{\sqrt{2n}}{(n-1)!}\frac{1}{2^{n/2}}(\Phi_{S^3})^{n-1}(\mathbf{x},\mathbf{z})$$

with

$$\tilde{\mathcal{K}}_n(\mathbf{x},\mathbf{z})=\sum_{\ell=0}^{n-1}\sum_{m=-\ell}^{m=\ell}Y^*_{n\ell m}(\mathbf{x})y_{n\ell m}(\mathbf{z}).$$

The idea of the proof is exactly the same as the one we used in Appendix A. Thus for each $n\geqslant 1$, let us define the function

$$F_n(\mathbf{x},\mathbf{z})=\tilde{\mathcal{K}}_n(\mathbf{x},\mathbf{z})/(c(n)(\Phi_{S^3})^{n-1}(\mathbf{x},\mathbf{z}))$$

[in a neighborhood $\mathcal{V}$ of a point $(\mathbf{x}_0,\mathbf{z}_0)$ where $(\Phi_{S^3})(\mathbf{x}_0,\mathbf{z}_0)\neq 0$] such that F_n is a solution of the system of differential equations:

$$\mathbf{M}\nabla F_n=0$$

with $\nabla=(\partial/\partial\theta,\partial/\partial\phi,\partial/\partial\lambda,\partial/\partial z_1,\partial/\partial z_2,\partial/\partial z_3,\partial/\partial z_4)$ and $\mathbf{M}$ the 7×7 matrix

$$\begin{bmatrix}
\imath\sin(\phi) & \imath\cot(\theta)\cos(\phi) & 0 & \frac{z_2}{2} & \frac{z_1}{2} & \frac{z_4}{2} & \frac{z_3}{2}\\
-\imath\cos(\phi) & \imath\cot(\theta)\sin(\phi) & 0 & -\frac{z_2}{2\imath} & \frac{z_1}{2\imath} & -\frac{z_4}{2\imath} & \frac{z_3}{2\imath}\\
0 & -\imath & 0 & \frac{z_1}{2} & -\frac{z_2}{2} & \frac{z_3}{2} & -\frac{z_4}{2}\\
f(\phi,\lambda) & \frac{-\cot(\lambda)\sin(\phi)}{\imath\sin(\theta)} & -\imath\sin(\theta)\cos(\phi) & \frac{z_2}{2} & \frac{z_1}{2} & -\frac{z_4}{2} & -\frac{z_3}{2}\\
g(\phi,\lambda) & \frac{\cot(\lambda)\cos(\phi)}{\imath\sin(\theta)} & -\imath\sin(\theta)\sin(\phi) & -\frac{z_2}{2\imath} & \frac{z_1}{2\imath} & \frac{z_4}{2\imath} & -\frac{z_3}{2\imath}\\
\frac{\sin(\theta)\cot(\lambda)}{-\imath} & 0 & -\imath\cos(\theta) & \frac{z_1}{2} & -\frac{z_2}{2} & -\frac{z_3}{2} & \frac{z_4}{2}\\
0 & 0 & 0 & z_1 & z_2 & z_3 & z_4
\end{bmatrix}$$

with $f(\phi,\lambda)=-\imath\cot(\lambda)\cos(\theta)\cos(\phi)$ and $g(\phi,\lambda)=-\imath\cot(\lambda)\cos(\theta)\sin(\phi)$. The function F_n also satisfies the initial condition $F_n(\mathbf{x}_0,\mathbf{z}_0)=1$.

The determinant of $\mathbf{M}$ is

$$\det\mathbf{M}=\frac{-1}{4\sin^2(\lambda)\sin(\theta)}(\Phi_{S^3}(\mathbf{x},\mathbf{z}))^2.$$

Since $\Phi_{S^3}(\mathbf{x}_0,\mathbf{z}_0)\neq 0$, we proceed as in Appendix A to conclude that

$$\tilde{\mathcal{K}}_n(\mathbf{x},\mathbf{z})=c(n)(\Phi_{S^3})^{n-1}(\mathbf{x},\mathbf{z}).$$

It is just left to evaluate the constant $c(n)$. Since,

$$Y_{100}=1,\quad Y_{200}=2\cos(\lambda),\quad Y_{211}=-\imath\sqrt{2}\sin(\theta)\sin(\lambda)e^{\imath\phi},$$

$$Y_{210}=2\imath\cos(\theta)\sin(\lambda),\quad Y_{21-1}=\imath\sqrt{2}\sin(\theta)\sin(\lambda)e^{-\imath\phi},$$

$$y_{100}=1,\quad y_{200}=\frac{1}{\sqrt{2}}[z_1z_4-z_2z_3],\quad y_{211}=z_1z_3,$$

$$y_{210}=\frac{1}{\sqrt{2}}[z_1z_4+z_2z_3],\quad y_{21-1}=z_2z_4$$

we obtain Eq. (2.51)

Now consider $\lambda=0$. Since $Y_{n\diagup m}(\theta,\phi,\lambda=0)=n\delta_{\diagup 0}$ we get

$$ny_{n00}(\mathbf{z})=c(n)(\sqrt{2}(z_1z_4-z_2z_3))^{n-1}.$$

By taking the norm in both sides of the last equation, we have

$$n=c(n)2^{(n-1)/2}\sqrt{n}(n-1)!,$$

where we used $\|(z_1z_4-z_2z_3)^{n-1}\|=\sqrt{n}(n-1)!$.

Thus we conclude $c(n)=[\sqrt{2n}/(n-1)!](1/2^{n/2})$ and prove Eq. (2.50).

(Received 10 July 2001; accepted for publication 28 January 2002)

We demonstrate how one can describe explicitly the present arbitrariness in solutions of relativistic wave equations in external electromagnetic fields of special form. This arbitrariness is connected to the existence of a transformation, which effectively reduces the number of variables in the initial equations. Then we use the corresponding representations to construct new sets of exact solutions, which may have a physical interest. Namely, we present new sets of stationary and nonstationary solutions in magnetic field and in some superpositions of electric and magnetic fields. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1461428]

I. INTRODUCTION

Relativistic wave equations (Dirac and Klein–Gordon) provide a basis for relativistic quantum mechanics and quantum electrodynamics of spinor and scalar particles.[1] In relativistic quantum mechanics, solutions of relativistic wave equations are referred to as one-particle wave functions of fermions and bosons in external electromagnetic fields. In quantum electrodynamics, such solutions allow the development of the perturbation expansion known as the Furry picture, which incorporates the interaction with the external field exactly, while treating the interaction with the quantized electromagnetic field perturbatively.[2] The physically most important exact solutions of the Klein–Gordon and the Dirac equations are: an electron in a Coulomb field, a uniform magnetic field, the field of a plane wave, the field of a magnetic monopole, the field of a plane wave combined with a uniform magnetic and electric fields parallel to the direction of wave propagation, crossed fields, and some simple one-dimensional electric fields (for a complete review of solutions of relativistic wave equations see Ref. 3).

Considering, for example, stationary solutions of relativistic wave equations, we can see that in the general case, there exist different sets of stationary solutions for one and the same Hamiltonian. The possibility to get different sets of stationary states reflects the existence of an arbitrariness in the solutions of the eigenvalue problem for a Hamiltonian. Considering nonstationary solutions, we also encounter the possibility of constructing different complete sets of such solutions. There is no regular method of describing such an arbitrariness explicitly. Especially in the presence of an external field the problem appears to be nontrivial.

In the present article we demonstrate how one can describe explicitly the present arbitrariness in solutions of the relativistic wave equations for some types of external electromagnetic fields, namely, for uniform magnetic fields and combination of these fields with some electric fields. This arbitrariness is connected to the existence of a transformation, which effectively reduces the number of variables in the initial equations. Then we use the corresponding representations to construct new sets of exact solutions, which may have a physical interest. In Sec. II we consider relativistic wave equations in pure uniform magnetic fields. Here we derive a representation for the exact solutions, in which the above-mentioned arbitrariness is described explicitly by an

arbitrary function. From a suitable choice of this function, we get both the well-known set of solutions and new ones. Section II contains the most complete (at present) description of the problem of a uniform magnetic field in relativistic quantum mechanics. Among new sets of solutions there are both stationary, generalized coherent solutions and nonstationary solutions. Then, in Sec. III, we consider more complicated configurations of external electromagnetic fields, namely, longitudinal electromagnetic fields. Here we describe all the arbitrariness in the solutions, and on this basis present various sets of new exact solutions. In Sec. IV we interpret the above-mentioned results from the point of view of the general theory of differential equations.

II. UNIFORM MAGNETIC FIELD

A. Arbitrariness in solutions of relativistic wave equations

Consider a uniform magnetic field $\mathbf{H}=(0,0,H)$ directed along the x^3 axis $(H>0)$. The electromagnetic potentials are chosen in the symmetric gauge

$$A_0=A_3=0,\ A_1=\tfrac{1}{2}Hx^2,\quad A_2=-\tfrac{1}{2}Hx^1. \tag{2.1}$$

We write the Klein–Gordon and the Dirac equations in the form

$$\begin{gathered}\mathcal{K}\Psi=0,\quad \hbar^2\mathcal{K}=\mathcal{P}^2-m_0^2c^2,\quad \mathcal{P}_\mu=i\hbar\partial_\mu-\frac{e}{c}A_\mu,\\ \mathcal{D}\Theta=0,\quad \hbar\mathcal{D}=\gamma^\mu\mathcal{P}_\mu-m_0c.\end{gathered} \tag{2.2}$$

Here $e=-|e|$ and γ-matrices are chosen in the standard representation.[3]

In the field under consideration, the operators $\mathcal{P}_0$ and $\mathcal{P}_3$ are mutually commuting integrals of motion, $[\mathcal{K},\mathcal{P}_0]=[\mathcal{K},\mathcal{P}_3]=[\mathcal{D},\mathcal{P}_0]=[\mathcal{D},\mathcal{P}_3]=[\mathcal{P}_0,\mathcal{P}_3]=0$.

In the case of the Klein–Gordon equation, the operator L_z,

$$L_z=i\hbar(x^2\partial_1-x^1\partial_2),\quad [L_z,\mathcal{P}_0]=[L_z,\mathcal{P}_3]=[\mathcal{K},L_z]=0, \tag{2.3}$$

can be included (together with $\mathcal{P}_0$ and $\mathcal{P}_3$) in the complete set of integrals of motion, whereas for the Dirac equation case, the operator J_z,

$$J_z=L_z+\frac{\hbar}{2}\Sigma_3,\quad [J_z,\mathcal{P}_0]=[J_z,\mathcal{P}_3]=[\mathcal{D},J_z]=0, \tag{2.4}$$

can be included (together with $\mathcal{P}_0$ and $\mathcal{P}_3$) in the complete set of integrals of motion. Here $\Sigma_3=\mathrm{diag}(\sigma_3,\sigma_3)$.

We are going to use dimensionless coordinates $-\infty<x<\infty$, $-\infty<y<\infty$ or $0\leqslant\rho<\infty$, $0\leqslant\varphi<2\pi$ defined by

$$\begin{gathered}\sqrt{\frac{\gamma}{2}}x^1=x=\sqrt{\rho}\cos\varphi,\quad \sqrt{\frac{\gamma}{2}}x^2=y=\sqrt{\rho}\sin\varphi,\quad \gamma=\frac{|e|H}{c\hbar}>0,\\ \mathrm{d}x^1\,\mathrm{d}x^2=\frac{2}{\gamma}\mathrm{d}x\,\mathrm{d}y=\frac{1}{\gamma}\mathrm{d}\rho\,\mathrm{d}\varphi,\quad x+iy=\sqrt{\rho}\exp i\varphi.\end{gathered} \tag{2.5}$$

It is useful to introduce the operators a_1, a_2, $a_1^\dagger$, $a_2^\dagger$,

$$a_2=\frac{1}{\sqrt{2\gamma\hbar}}[\mathcal{P}_2-i\mathcal{P}_1+\hbar\gamma(x^1+ix^2)]=\frac{1}{2}(x+iy+\partial_x+i\partial_y)=\frac{e^{i\varphi}}{2\sqrt{\rho}}(\rho+i\partial_\varphi+2\rho\partial_\rho),$$

$$a_2^\dagger=\frac{1}{\sqrt{2\gamma\hbar}}[\mathcal{P}_2+i\mathcal{P}_1+\hbar\gamma(x^1-ix^2)]=\frac{1}{2}(x-iy-\partial_x+i\partial_y)=\frac{e^{-i\varphi}}{2\sqrt{\rho}}(\rho+i\partial_\varphi-2\rho\partial_\rho).$$

$$a_1=-\frac{1}{\sqrt{2\gamma\hbar}}(i\mathcal{P}_1+\mathcal{P}_2)=\frac{1}{2}(x-iy+\partial_x-i\partial_y)=\frac{e^{-i\varphi}}{2\sqrt{\rho}}(\rho-i\partial_\varphi+2\rho\partial_\rho), \tag{2.6}$$

$$a_1^\dagger=\frac{1}{\sqrt{2\gamma\hbar}}(i\mathcal{P}_1-\mathcal{P}_2)=\frac{1}{2}(x+iy-\partial_x-i\partial_y)=\frac{e^{i\varphi}}{2\sqrt{\rho}}(\rho-i\partial_\varphi-2\rho\partial_\rho).$$

They obey the commutation relations

$$[a_k,a_s^\dagger]=\delta_{k,s},\quad [a_k,a_s]=[a_k^\dagger,a_s^\dagger]=0,\quad k,s=1,2. \tag{2.7}$$

Thus, we can interpret these operators as creation and annihilation ones. One can also find the following relations:

$$\mathcal{P}_1^2+\mathcal{P}_2^2=\hbar^2\gamma(a_1a_1^\dagger+a_1^\dagger a_1)=2\hbar^2\gamma\mathcal{N}+\hbar^2\gamma,$$
$$L_z=\hbar(\mathcal{N}-a_2^\dagger a_2),\quad \mathcal{N}=a_1^\dagger a_1. \tag{2.8}$$

Then the Klein–Gordon and the Dirac operators can be written as

$$\mathcal{K}=\hbar^{-2}(\mathcal{P}_0^2-\mathcal{P}_3^2)-2\gamma\mathcal{N}-\gamma-m^2,\quad m=\frac{m_0c}{\hbar},$$
$$\mathcal{D}=\hbar^{-1}(\gamma^0\mathcal{P}_0+\gamma^3\mathcal{P}_3)-\sqrt{\frac{\gamma}{2}}[(\gamma^2-i\gamma^1)a_1+(\gamma^2+i\gamma^1)a_1^\dagger]-m. \tag{2.9}$$

The operator $\mathcal{N}$ commutes with $\mathcal{P}_0,\mathcal{P}_3,\ L_z$, plus it is an integral of motion in the case of the Klein–Gordon equation. Its generalization for the Dirac equation has the form $\mathcal{N}_D=\mathcal{N}+\frac{1}{2}\Sigma_3$.

One ought to remark that the operators $\mathcal{K}$ and $\mathcal{D}$ do not contain the operators $a_2^\dagger$, a_2. Thus, the latter operators are integrals of motion, which commute with $\mathcal{N}$, $\mathcal{N}_D$, $\mathcal{P}_0$, $\mathcal{P}_3$, but do not commute with L_z and J_z.

The operators of creation and annihilation with different numbers commute. One can find a representation in which these operators are acting on different variables. To this end, we present the wave functions from (2.2) in the following form (we make a Fourier transform in the variable y only, and call such a representation the semi-momentum representation):

$$\Psi(x,y)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{iky}\tilde{\Psi}(x,k)\mathrm{d}k. \tag{2.10}$$

Of course the functions Ψ and $\tilde{\Psi}$ depend on the variables x^2 and x^3 as well, but we do not indicate this dependence explicitly. In terms of $\tilde{\Psi}$ the multiplication and differentiation have the form $y\to i\partial_k,\quad i\partial_y\to -k$. Then, the expressions for the creation and annihilation operators in the semi-momentum representation take the form

$$2a_1 = x + k + \partial_x + \partial_k, \quad 2a_1^\dagger = x + k - \partial_x - \partial_k,$$
$$2a_2 = x - k + \partial_x - \partial_k, \quad 2a_2^\dagger = x - k - \partial_x + \partial_k. \tag{2.11}$$

Now we pass from x, k to new variables ξ, η,

$$\sqrt{2}\xi = x + k, \quad \sqrt{2}\eta = x - k, \quad \sqrt{2}x = \xi + \eta, \quad \sqrt{2}k = \xi - \eta. \tag{2.12}$$

Then the creation and annihilation operators can be written as

$$\sqrt{2}a_1 = \xi + \partial_\xi, \quad \sqrt{2}a_1^\dagger = \xi - \partial_\xi, \quad \sqrt{2}a_2 = \eta + \partial_\eta, \quad \sqrt{2}a_2^\dagger = \eta - \partial_\eta. \tag{2.13}$$

In the new variables,

$$2\mathcal{N} = \xi^2 - \partial_\xi^2 - 1, \tag{2.14}$$

and the Klein–Gordon and the Dirac operators read

$$\mathcal{K} = \hbar^{-2}(\mathcal{P}_0^2 - \mathcal{P}_3^2) + \gamma(\partial_\xi^2 - \xi^2) - m^2,$$
$$\mathcal{D} = \hbar^{-1}(\gamma^0\mathcal{P}_0 + \gamma^3\mathcal{P}_3) - \sqrt{\gamma}(\gamma^2\xi - i\gamma^1\partial_\xi) - m. \tag{2.15}$$

One can see that the latter operators do not contain the variable η. Notice that both operators L_z and J_z contain variables ξ, η. For example,

$$2L_z = \xi^2 - \partial_\xi^2 - \eta^2 + \partial_\eta^2. \tag{2.16}$$

The integration over k in (2.10) can be replaced by an integration over η,

$$\Psi(x,y) = \frac{e^{ixy}}{\sqrt{\pi}} \int_{-\infty}^{\infty} e^{-i\sqrt{2}y\eta}\tilde{\Psi}(\xi,\eta)\mathrm{d}\eta, \quad \xi = \sqrt{2}x - \eta. \tag{2.17}$$

Besides, one can write

$$(\Psi,\Phi) = \int_{-\infty}^{\infty}\mathrm{d}x \quad \int_{-\infty}^{\infty}\mathrm{d}y\ \Psi^*(x,y)\Phi(x,y) = (\tilde{\Psi},\tilde{\Phi}) = \int_{-\infty}^{\infty}\mathrm{d}\xi\int_{-\infty}^{\infty}\mathrm{d}\eta\ \tilde{\Psi}^*(\xi,\eta)\tilde{\Phi}(\xi,\eta). \tag{2.18}$$

The independence of the operators (2.15) on the variable η will allow us to separate explicitly the functional arbitrariness in the solutions (2.17), as will be seen in the following.

B. Stationary states

1. Arbitrariness in stationary states

Known sets of stationary solutions in a uniform magnetic field (that were found in the first works[4–8]) are eigenfunctions of the operators $\mathcal{P}_0, \mathcal{P}_3, \mathcal{N}$ in the scalar case and of the operators $\mathcal{P}_0$, $\mathcal{P}_3$, $\mathcal{N}_D$ in the spinor case. Thus for scalar wave functions Ψ we have the conditions

$$\mathcal{P}_0\Psi = \hbar k_0\Psi, \quad \mathcal{P}_3\Psi = \hbar k_3\Psi, \quad \mathcal{N}\Psi = n\Psi, \quad n = 0,1,2,\ldots, \tag{2.19}$$

and for Dirac wave functions $\mathbf{\Theta}$ the conditions

$$\mathcal{P}_0\mathbf{\Theta} = \hbar k_0\mathbf{\Theta}, \quad \mathcal{P}_3\mathbf{\Theta} = \hbar k_3\mathbf{\Theta}, \quad \mathcal{N}_D\mathbf{\Theta} = (n - \tfrac{1}{2})\mathbf{\Theta}, \quad n = 0,1,2,\ldots. \tag{2.20}$$

Consider first the scalar case. It follows from (2.15) that

$$k_0^2=m^2+\gamma+k_3^2+2\gamma n=m^{*2}+k_3^2+2\gamma n, \quad m^{*2}=m^2+\gamma, \tag{2.21}$$

and

$$\Psi_{n,k_3}(x^\mu)=N\exp(-ik_0x^0-ik_3x^3)\Psi_n(x,y). \tag{2.22}$$

Here N is a normalization factor. In the semi-momentum representation (2.10) the function $\Psi_n(x,y)$ has the following image:

$$\tilde{\Psi}_n(\xi,\eta)=U_n(\xi)\Phi(\eta), \quad \xi=\sqrt{2}x-\eta. \tag{2.23}$$

Here Eqs. (2.19) and (2.14) were used. $U_n(\xi)$ are Hermite functions; they are related to the corresponding polynomials $H_n(\xi)$ as $U_n(x)=(2^n n!\sqrt{\pi})^{-\frac{1}{2}}\exp(-x^2/2)H_n(x)$.[9] The function $\Phi(\eta)$ is arbitrary. The functions $\Psi_n(x,y)$ from (2.22) obey the relations

$$a_1\Psi_n=\sqrt{n}\Psi_{n-1}, \quad a_1^\dagger\Psi_n=\sqrt{n+1}\Psi_{n+1}, \quad \Psi_n(x,y)=\frac{(a_1^\dagger)^n}{\sqrt{\Gamma(n+1)}}\Psi_0(x,y), \tag{2.24}$$

$$\Psi_0(x,y)=\pi^{-3/4}\exp(-x^2+ixy)\int_{-\infty}^{\infty}d\eta\exp\left[-\frac{\eta^2}{2}+\sqrt{2}\eta(x-iy)\right]\Phi(\eta). \tag{2.25}$$

Dirac wave functions are of the form $\mathbf{\Theta}_{n,k_3}(x^\mu)=N\exp(-ik_0x^0-ik_3x^3)\mathbf{\Theta}_{k_3,n}(x,y)$ with bispinors $\mathbf{\Theta}_{k_3,n}(x,y)$ having the structure

$$\mathbf{\Theta}^T_{n,k_3}(x,y)=(c_1\Psi_{n-1}(x,y), \quad ic_2\Psi_n(x,y), \quad c_3\Psi_{n-1}(x,y), \quad ic_4\Psi_n(x,y)). \tag{2.26}$$

The functions $\Psi_n(x,y)$ are defined by relations (2.17), (2.23), whereas the constant bispinor C (with the elements c_k) obeys an algebraic system of equations

$$AC=0, \quad A=\gamma^0k_0+\gamma^3k_3-\sqrt{2\gamma n}\gamma^1-m. \tag{2.27}$$

The condition $\det A=(k_0^2-k_3^2-2\gamma n-m^2)^2=0$ results in an equation which is an analog of (2.21),

$$k_0^2=k_3^2+2\gamma n+m^2. \tag{2.28}$$

Since the rank of the matrix A is equal to 2, a general solution of (2.27) has the form

$$C=\begin{pmatrix}(k_0+m)v\\(\sqrt{2\gamma n}\sigma_1-k_3\sigma_3)v\end{pmatrix}, \quad C^+C=2k_0(k_0+m)v^+v, \tag{2.29}$$

where v is an arbitrary constant bispinor and σ are Pauli matrices. We can specify v selecting a spin integral of motion (see Ref. 3). The state $n=0$ is a special case. Here we must set $c_1=c_3=0$, which corresponds to the choice $v^T=(0, \quad c_2)$, $c_2\neq 0$. The latter means that $\Sigma_3\Theta_D=-\Theta_D$. Thus, for $n=0$, the electron spin can only point to the direction opposite to the magnetic field.

Expressions for $\Psi_n(x,y)$ in the semi-momentum representation explicitly contain a functional arbitrariness, which means that every energy level is infinitely degenerated. Let us demand that the scalar and spinor wave functions be eigenvectors of the operators L_z and J_z, respectively. According to (2.4) and (2.8) that means that the functions $\Psi_n(x,y)$ have to obey an additional condition

$$a_2^\dagger a_2 \Psi_n(x,y) = s\Psi_n(x,y), \quad s=0,1,2,\ldots,$$
$$L_z = \hbar(n-s) = \hbar l, \quad l = n-s, \quad n \geqslant l > -\infty, \quad J_z = \hbar(l-\tfrac{1}{2}). \tag{2.30}$$

This condition defines the function $\Phi(\eta)$ according to (2.13), $a_2^\dagger a_2 \Phi_s(\eta) = s\Phi_s(\eta)$, therefore $\Phi_s(\eta) = U_s(\eta)$. Substituting this result into (2.23) and into (2.17), and doing the integral over η, we find in the coordinate representation,

$$\Psi_{n,s}(x,y) = \frac{(-1)^n}{\sqrt{2\pi}} e^{il\varphi} I_{s,n}(\rho) = \frac{(-1)^n}{\sqrt{2\pi}} \left(\frac{x+iy}{x-iy}\right)^{(n-s)/2} I_{s,n}(x^2+y^2). \tag{2.31}$$

Here $I_{m,n}(x)$ are Laguerre functions, which are connected to the corresponding polynomials $L_n^\alpha(x)$ by the relations (see Ref. 9) $I_{m,n}(x) = (\Gamma(n+1)/\Gamma(m+1))^{1/2} e^{-x/2} x^{\alpha/2} L_n^\alpha(x)$, $\alpha = m-n$. The states (2.31) were first obtained in Refs. 4–8. Besides (2.24) and (2.25), the functions (2.31) obey the following relations as well:

$$a_2 \Psi_{n,s} = \sqrt{s}\,\Psi_{n,s-1}, \quad a_2^\dagger \Psi_{n,s} = \sqrt{s+1}\,\Psi_{n,s+1},$$
$$\Psi_{n,s} = \frac{(a_1^\dagger)^n (a_2^\dagger)^s}{\sqrt{\Gamma(n+1)\Gamma(s+1)}} \Psi_{0,0}, \quad \Psi_{0,0}(x,y) = \frac{1}{\sqrt{\pi}} \exp\left[-\frac{1}{2}(x^2+y^2)\right] = \frac{e^{-\rho/2}}{\sqrt{\pi}}. \tag{2.32}$$

In the following we are going to find new sets of solutions imposing complementary conditions different from (2.30). This results in a different form for the function $\Phi(\eta)$.

2. Generalized squeezed coherent states

Taking into account that the operators $a_2^\dagger$, a_2 are integrals of motion, we may construct stationary states, which are eigenvectors of a linear combination $A_2^{\alpha,\beta}$ of these operators,

$$A_2^{\alpha,\beta} = \alpha a_2 + \beta a_2^\dagger. \tag{2.33}$$

Here α, β are arbitrary complex numbers. Here one has to distinguish three nonequivalent cases.

(1) If $|\alpha|^2 < |\beta|^2$, then there do not exist any normalizable eigenvectors of the operator (2.33). We are not going to consider such case.

(2) If $|\alpha|^2 = |\beta|^2$, then $A_2^{\alpha,\beta}$ is, in fact, reduced to a Hermitian operator

$$A_2^\mu = \mu a_2 + \mu^* a_2^\dagger, \quad A_2^{+\mu} = A_2^\mu, \quad \mu \neq 0, \tag{2.34}$$

where μ is an arbitrary complex number.

(3) If $|\alpha|^2 > |\beta|^2$, then without loss of generality we can assume that operators $A_2^{\alpha,\beta}$ have the form

$$A_2^{\alpha,\beta} = \alpha a_2 + \beta a_2^\dagger, \quad |\alpha|^2 - |\beta|^2 = 1, \quad [A_2^{\alpha,\beta}, A_2^{+\alpha,\beta}] = 1. \tag{2.35}$$

Then $A_2^{+\alpha,\beta}$, $A_2^{\alpha,\beta}$ are creation and annihilation operators, which are related to $a_2^\dagger$, a_2 by a canonical transformation,

$$a_2 = \alpha^* A_2^{\alpha,\beta} - \beta A_2^{+\alpha,\beta}, \quad a_2^\dagger = \alpha A_2^{+\alpha,\beta} - \beta^* A_2^{\alpha,\beta}. \tag{2.36}$$

Consider eigenvectors of the operator (2.34), i.e., $A_2^\mu \Psi_{n,z}^\mu(x,y) = z\Psi_{n,z}^\mu(x,y)$, $z = z^*$. This equation results in the equation $A_2^\mu \Phi_z^\mu(\eta) = z\Phi_z^\mu(\eta)$ for the function $\Phi(\eta)$. Taking into account (2.13), one can find that solutions of the latter equation are

$$\Phi_z^{\mu}(\eta)=\left[\frac{\mu}{\sqrt{2}\pi|\mu|(\mu-\mu^*)}\right]^{1/2}\exp Q_1,$$

$$4(\mu-\mu^*)Q_1=-2(\mu+\mu^*)\eta^2+4\sqrt{2}z\eta-z^2(\mu+\mu^*)|\mu|^{-2}. \tag{2.37}$$

These solutions obey the orthonormality and completeness relations,

$$\int_{-\infty}^{\infty}\Phi_{z'}^{*\,\mu}(\eta)\Phi_z^{\mu}(\eta)\mathrm{d}\eta=\delta(z-z'),\quad \int_{-\infty}^{\infty}\Phi_z^{*\,\mu}(\eta')\Phi_z^{\mu}(\eta)\mathrm{d}z=\delta(\eta-\eta'). \tag{2.38}$$

Their overlapping has the form

$$R^{\mu',\mu}(z',z)=\int_{-\infty}^{\infty}\Phi_{z'}^{*\,\mu'}(\eta)\Phi_z^{*\,\mu}(\eta)\mathrm{d}\eta=N_1\exp\left[\frac{Q_2}{4(\mu'\mu^*-\mu\mu'^*)}\right],$$

$$N_1^2=\frac{\mu'^*\mu}{2\pi^2|\mu'||\mu|(\mu\mu'^*-\mu'\mu^*)}, \tag{2.39}$$

$$Q_2=\left(z\sqrt{\frac{\mu'}{\mu}}-z'\sqrt{\frac{\mu}{\mu'}}\right)^2+\left(z\sqrt{\frac{\mu'^*}{\mu^*}}-z'\sqrt{\frac{\mu^*}{\mu'^*}}\right)^2.$$

It defines the mutual decomposition

$$\Phi_z^{\mu}(\eta)=\int_{-\infty}^{\infty}\Phi_{z'}^{\mu'}(\eta)R^{\mu',\mu}(z',z)\mathrm{d}z'. \tag{2.40}$$

The coordinate representation (2.17) for the solutions under consideration has the form

$$\Psi_{n,z}^{\mu}(x,y)=(\sqrt{2}\pi|\mu|)^{-1/2}\left(\frac{\mu^*}{\mu}\right)^{n/2}U_n(p_1)\exp iQ_3,$$

$$4|\mu|^2Q_3=[i(\mu^*-\mu)x+(\mu+\mu^*)y][(\mu+\mu^*)x+i(\mu-\mu^*)y-2z], \tag{2.41}$$

$$\sqrt{2}|\mu|p_1=(\mu+\mu^*)x+i(\mu-\mu^*)y-z.$$

Their scalar product (2.18) reads $(\Psi_{n',z'}^{\mu},\Psi_{n,z}^{\mu})=\delta_{n,n'}\delta(z-z')$. Relation (2.40) results in the following decomposition in the coordinate representation:

$$\Psi_{n,z}^{\mu}(x,y)=\int_{-\infty}^{\infty}\Psi_{n,z'}^{\mu'}(x,y)R^{\mu',\mu}(z',z)\mathrm{d}z'. \tag{2.42}$$

In particular, in the cases of real or pure imaginary μ, such wave functions were known before.[3]

Consider eigenvectors of the operator (2.35), i.e., $A_2^{\alpha,\beta}\Psi_{n,z}^{\alpha,\beta}(x,y)=z\Psi_{n,z}^{\alpha,\beta}(x,y)$, where z is a complex number. In fact, we get coherent (squeezed) stationary states. They are labeled by z and by two complex parameters α, β, which are related by the condition (2.35). In the semi-momentum representation the above-given equation is reduced to

$$A_2^{\alpha,\beta}\Phi_z^{\alpha,\beta}(\eta)=z\Phi_z^{\alpha,\beta}(\eta). \tag{2.43}$$

It is well known that such solutions form a complete (overcomplete) set at any fixed α, β. Solutions within each set are not orthogonal. One can use these functions to construct an orthogonal set of solutions.

Since the operators $A_2^{+\alpha,\beta}$, $A_2^{\alpha,\beta}$ are integrals of motion (both for the Klein–Gordon equation and for the Dirac equation), they are symmetry operators for the equations. The action of these operators on a solution again provides a solution. For example, applying the operators $(\Gamma(1+s))^{-1/2}(A_2^{+\alpha,\beta}-z^*)^s$, $s=0,1,2,\ldots$ to normalized solutions of Eq. (2.43), we get normalized solutions labeled by the index s. These new solutions are orthogonal with respect to s,

$$\Phi_{s,z}^{\alpha,\beta}(\eta)=\frac{(A_2^{+\alpha,\beta}-z^*)^s}{\sqrt{\Gamma(1+s)}}\Phi_z^{\alpha,\beta}(\eta),\quad \Phi_{0,z}^{\alpha,\beta}(\eta)=\Phi_z^{\alpha,\beta}(\eta),$$
$$\int_{-\infty}^{\infty}\Phi_{s',z}^{*\,\alpha,\beta}(\eta)\Phi_{s,z}^{\alpha,\beta}(\eta)d\eta=\delta_{s,s'}\int_{-\infty}^{\infty}|\Phi_z^{\alpha,\beta}(\eta)|^2\,\mathrm{d}\eta. \tag{2.44}$$

We call such states generalized squeezed coherent states. It is possible to get an explicit form for these states,

$$\begin{aligned}\Phi_{s,z}^{\alpha,\beta}(\eta)&=\left[\frac{\alpha}{|\alpha|(\alpha-\beta)}\right]^{1/2}\left(\frac{\alpha^*-\beta^*}{\alpha-\beta}\right)^{s/2}e^{Q_4}U_s(p_2),4|\alpha-\beta|^2Q_4\\&=2(\alpha\beta^*-\alpha^*\beta)\eta^2+2\sqrt{2}\,\eta[z(\alpha^*-\beta^*)-z^*(\alpha-\beta)]+z^{*2}(\alpha-\beta)^2\\&\quad-z^2(\alpha^*-\beta^*)^2,2|\alpha-\beta|p_2=2\eta-\sqrt{2}z(\alpha^*-\beta^*)-\sqrt{2}z^*(\alpha-\beta).\end{aligned} \tag{2.45}$$

The functions (2.45) form a complete set for each fixed z,

$$\sum_{s=0}^{\infty}\Phi_{s,z}^{*\,\alpha,\beta}(\eta')\Phi_{s,z}^{\alpha,\beta}(\eta)=\delta(\eta'-\eta), \tag{2.46}$$

and for each fixed s,

$$\int\frac{\mathrm{d}^2z}{\pi}\Phi_{s,z}^{*\,\alpha,\beta}(\eta')\Phi_{s,z}^{\alpha,\beta}(\eta)=\delta(\eta-\eta'),\quad \mathrm{d}^2z=\mathrm{d}\,\mathrm{Re}\,z\,\mathrm{d}\,\mathrm{Im}\,z. \tag{2.47}$$

The overlapping

$$R_{s',s}^{\alpha',\beta';\alpha,\beta}(z',z)=\int_{-\infty}^{\infty}\Phi_{s',z'}^{*\,\alpha',\beta'}(\eta)\Phi_{s,z}^{\alpha,\beta}(\eta)\mathrm{d}\eta, \tag{2.48}$$

allows us to find mutual decompositions

$$\Phi_{s,z}^{\alpha,\beta}(\eta)=\sum_{s'=0}^{\infty}R_{s',s}^{\alpha',\beta';\alpha,\beta}(z',z)\Phi_{s',z'}^{\alpha',\beta'}(\eta),\quad \Phi_{s,z}^{\alpha,\beta}(\eta)=\int\mathrm{d}^2z'R_{s',s}^{\alpha',\beta';\alpha,\beta}(z',z)\Phi_{s',z'}^{\alpha',\beta'}(\eta). \tag{2.49}$$

Unfortunately, the overlapping (2.48) has a complicated form via a finite sum of Hermite functions. In some particular cases this sum can be simplified. For example, if $\alpha'=\alpha$, $\beta'=\beta$, then the overlapping does not depend on α,β and has the form

$$R_{s',s}^{\alpha,\beta;\alpha,\beta}(z',z)=R_{s',s}(z',z)=\left(\frac{z-z'}{z^*-z'^*}\right)^{(s'-s)/2}\exp\left[\frac{1}{2}(zz'^*-z^*z')\right]I_{s',s}(|z-z'|^2). \tag{2.50}$$

For $s=s'=0$ we get

$$R_{0,0}^{\alpha',\beta';\alpha,\beta}(z',z)=\sqrt{\frac{\alpha\alpha'^*}{|\alpha\alpha'|}}(\alpha\alpha'^*-\beta\beta'^*)^{-1/2}\exp Q_5,$$
$$2Q_5=\frac{z^2(\alpha'^*\beta^*-\alpha^*\beta'^*)+(z'^*)^2(\alpha\beta'-\alpha'\beta)+2zz'^*}{\alpha\alpha'^*-\beta\beta'^*}-z'z^*-zz'^*-|z-z'^*|^2. \tag{2.51}$$

The wave function $\Psi_{n,s,z}^{\alpha,\beta}(x,y)$ also has a very complicated form in the general case. However, in some particular cases it can be simplified. For example,

$$\Psi_{n,s,z}^{1,0}(x,y)=\frac{(-1)^n}{\sqrt{\pi}}\left(\frac{x+iy-z}{x-iy-z^*}\right)^{(n-s)/2}e^M I_{s,n}(|x+iy-z|^2),$$
$$M=z(x-iy)-z^*(x+iy). \tag{2.52}$$

For $z=0$ we arrive at the set (2.31).

For $s=0$ we get a compact form for a set of stationary squeezed coherent states,

$$\Psi_{n,0,z}^{\alpha,\beta}(x,y)=\Psi_{n,z}^{\alpha,\beta}(x,y)=(-1)^n\frac{\pi^{1/4}}{\sqrt{|\alpha|}}\left(\frac{\beta}{\alpha}\right)^{n/2}U_n\left(\frac{p_3}{\sqrt{2\alpha\beta}}\right)\exp Q_6,$$
$$p_3=z-\alpha(x+iy)-\beta(x-iy), \tag{2.53}$$
$$4\alpha\beta Q_6=(1+2|\beta|^2)z^2-2\alpha\beta|z|^2+(z+p_3)[\beta(x-iy)-\alpha(x+iy)].$$

Additional simplifications are available for $\alpha=1,\beta=0$,

$$\Psi_{n,z}^{1,0}(x,y)=\Psi_{n,z}(x,y)=\varphi_{n,z}(x,y)\exp(-\tfrac{1}{2}|z|^2),$$
$$\varphi_{n,z}(x,y)=\frac{(x+iy-z)^n}{\sqrt{\pi\Gamma(n+1)}}\exp\left[z(x-iy)-\frac{1}{2}(x^2+y^2)\right]. \tag{2.54}$$

Namely, these states were found in Ref. 10. However, the meaning of the parameter z was not clarified.

For arbitrary α, β, the functions $\Psi_{n,s,z}^{\alpha,\beta}(x,y)$ obey, besides (2.24), the following:

$$A_2^{\alpha,\beta}\Psi_{n,s,z}^{\alpha,\beta}=z\Psi_{n,s,z}^{\alpha,\beta}+\sqrt{s}\Psi_{n,s-1,z}^{\alpha,\beta},\quad A_2^{+\alpha,\beta}\Psi_{n,s,z}^{\alpha,\beta}=z^*\Psi_{n,s,z}^{\alpha,\beta}+\sqrt{s+1}\Psi_{n,s+1,z}^{\alpha,\beta}. \tag{2.55}$$

Taking into account that $a_2^\dagger\varphi_{n,z}=\partial\varphi_{n,z}/\partial z$, we can construct a new set of stationary states by successive differentiations,

$$\overline{\Psi}_{n,s,z}(x,y)=\frac{(-1)^nN}{\sqrt{\pi}}\exp\left[i(n-s)\varphi+\frac{\rho-q}{2}\right]\left(\frac{q}{\rho}\right)^{(n-s)/2}I_{s,n}(q)$$
$$=\frac{(-1)^nN}{\sqrt{\pi}}\exp\left[\frac{z}{2}(x+iy)\right]\left(\frac{x+iy-z}{x-iy}\right)^{(n-s)/2}I_{s,n}(q),$$
$$q=\rho-z\sqrt{\rho}e^{-i\varphi}=(x-iy)(x+iy-z). \tag{2.56}$$

For $N=1$ the above-mentioned set obeys [besides (2.24)]

$$a_2\overline{\Psi}_{n,s,z}=z\overline{\Psi}_{n,s,z}+\sqrt{s}\overline{\Psi}_{n,s-1,z},\quad a_2^\dagger\overline{\Psi}_{n,s,z}=\frac{\partial}{\partial z}\overline{\Psi}_{n,s,z}=\sqrt{s+1}\overline{\Psi}_{n,s+1,z}. \tag{2.57}$$

The set (2.31) is a particular case of (2.56), it corresponds to $z=0$. The set (2.56) is not orthogonal,

$$(\overline{\Psi}_{n',s',z'},\overline{\Psi}_{n,s,z})=N'^{*}N\delta_{n,n'}\mathcal{J}_{s,s'}(z,z'),$$

$$\mathcal{J}_{s,s'}(z,z')=\sqrt{\frac{\Gamma(s+1)}{\Gamma(s'+1)}}z^{s'-s}e^{zz'^{*}}L_{s}^{s'-s}(-zz'^{*}),\quad s\leqslant s', \tag{2.58}$$

$$\mathcal{J}_{s,s'}(z,z')=\sqrt{\frac{\Gamma(s'+1)}{\Gamma(s+1)}}(z'^{*})^{s-s'}e^{zz'^{*}}L_{s'}^{s-s'}(-zz'^{*}),\quad s'\leqslant s.$$

The functions from the set (2.56) are normalized to unity for $N=N_s(z)=\exp(-|z|^2/2)[L_s(-|z|^2)]^{-1/2}$. For $N=1$, the following mutual decompositions take place:

$$\overline{\Psi}_{n,s+k,z'}(x,y)=\sqrt{\frac{\Gamma(k+1)}{\Gamma(s+k+1)}}\int\frac{\mathrm{d}^2z}{\pi}z^{*\,s}e^{(z'z^{*}-|z|^2)}\overline{\Psi}_{n,k,z}(x,y),$$

$$\overline{\Psi}_{n,s,z'}(x,y)=\sum_{k=0}^{\infty}\sqrt{\frac{\Gamma(k+s+1)}{\Gamma(s+1)}}\frac{(z'-z)^k}{k!}\overline{\Psi}_{n,s+k,z}(x,y). \tag{2.59}$$

That means, in particular, that (2.56) is a complete set since the set (2.31) is complete.

Selecting different forms for the function $\Phi(\eta)$, we can get other sets of stationary states for a charge in a uniform magnetic field.

C. Nonstationary states

1. Generalized coherent states

The most interesting nonstationary solutions of relativistic wave equations for a charge in a uniform magnetic field are coherent states; such solutions were presented for the first time in Refs. 11–14, see also Ref. 3. In the following we present a new family of nonstationary solutions, which includes the above-mentioned coherent states as a particular case.

Here we are going to use light-cone variables $u^0=x^0-x^3$, $u^3=x^0+x^3$, and the corresponding momentum operators

$$\widetilde{\mathcal{P}}_0=i\hbar\widetilde{\partial}_0=\tfrac{1}{2}(\mathcal{P}_0-\mathcal{P}_3),\quad \widetilde{\mathcal{P}}_3=i\hbar\widetilde{\partial}_3=\tfrac{1}{2}(\mathcal{P}_0+\mathcal{P}_3), \tag{2.60}$$

where $\widetilde{\partial}_0=\partial/\partial u^0$, $\widetilde{\partial}_3=\partial/\partial u^3$. Then the Klein–Gordon operator can be presented in the form

$$\mathcal{K}=4\hbar^{-2}\widetilde{\mathcal{P}}_3\widetilde{\mathcal{P}}_0-2\gamma\mathcal{N}-m^{*2}, \tag{2.61}$$

whereas the Dirac equation reads ($\boldsymbol{\Theta}$ is a Dirac bispinor)

$$4\hbar^{-2}\widetilde{\mathcal{P}}_3\widetilde{\mathcal{P}}_0\Theta_{(-)}=(2\gamma\mathcal{N}_D+m^{*2})\Theta_{(-)},\quad 2\widetilde{\mathcal{P}}_3\Theta_{(+)}=[(\alpha\mathcal{P}_\perp)+\hbar\rho_3 m]\Theta_{(-)},$$
$$\mathcal{P}_\perp=-(\mathcal{P}_1,\mathcal{P}_2,0),\quad \boldsymbol{\Theta}=\Theta_{(+)}+\Theta_{(-)},\quad \Theta_{(\pm)}=p_\pm\boldsymbol{\Theta},\quad 2p_\pm=1\pm\alpha_3. \tag{2.62}$$

Here α and ρ_3 are Dirac matrices,[3] and $p_\pm$ projection operators.

In the case of the uniform magnetic field under consideration, the operators $\widetilde{\mathcal{P}}_3$, $\widetilde{\mathcal{P}}_0$ are integrals of motion. Thus, we will consider solutions that are eigenvectors of $\widetilde{\mathcal{P}}_3$,

$$\widetilde{\mathcal{P}}_3\Psi=\hbar\frac{\lambda}{2}\Psi. \tag{2.63}$$

The scalar wave function obeys (2.63) and can be written as

$$\Psi(x^\mu)=N\exp\left(-i\frac{\lambda}{2}u^3-i\frac{m^{*2}}{2\lambda}u^0\right)\psi(u^0,x,y). \tag{2.64}$$

It is easy to see that $\psi(u^0,x,y)$ obeys a first-order equation, which can be treated as a Schrödinger equation,

$$i\partial_0\psi(u^0,x,y)=\omega a_1^\dagger a_1\psi(u^0,x,y),\quad \omega=\frac{\gamma}{\lambda}. \tag{2.65}$$

Suppose Eq. (2.63) holds, then $\Theta_{(-)}$ can be presented in the form:

$$\Theta_{(-)}(x^\mu)=N\exp\left(-i\frac{\lambda}{2}u^3-i\frac{m^{*2}}{2\lambda}u^0\right)W(1-\alpha_3)C\psi(u^0,x,y). \tag{2.66}$$

Here C is an arbitrary constant bispinor, and W is a unitary matrix (φ_0 is a constant phase),

$$W=\cos\kappa-i\Sigma_3\sin\kappa,\quad 2\kappa=\omega u^0+\varphi_0,\quad W^+W=I, \tag{2.67}$$

and $\psi(u^0,x,y)$ is a scalar function. The latter function obeys Eq. (2.65). Then, the $\Theta_{(+)}$ projection can be found from (2.62), $\Theta_{(+)}=(\hbar\lambda)^{-1}[(\alpha\mathcal{P}_\perp)+\hbar m\rho_3]\Theta_{(-)}$.

Thus, both in the scalar and spinor cases we have to solve the same Eq. (2.65).

In the semi-momentum representation, the corresponding function $\tilde{\psi}(u^0,\xi,\eta)$ obeys the same Eq. (2.65), where, however, one has to use expression (2.14) for the operator $\mathcal{N}=a_1^\dagger a_1$. The relation between the functions $\tilde{\psi}(u^0,\xi,\eta)$ and $\psi(u^0,x,y)$ still has the form (2.17).

Let us introduce the operators

$$A_1^{f,g}=fa_1+ga_1^\dagger,\quad A_1^{+f,g}=f^*a_1^\dagger+g^*a_1, \tag{2.68}$$

where the complex quantities f and g can depend on u^0. These operators are integrals of motion whenever f, g obey (derivatives with respect to u^0 are denoted by dots)

$$i\dot{f}+\omega f=0,\quad i\dot{g}-\omega g=0. \tag{2.69}$$

It is easy to find

$$f=f_0\exp(i\omega u^0),\quad g=g_0\exp(-i\omega u^0), \tag{2.70}$$

where f_0, g_0 are some complex constants. Bearing in mind considerations related to operators (2.33), we are going to consider two nonequivalent cases only. The first one corresponds to $|f|^2=|g|^2$ or equivalently to $|f_0|^2=|g_0|^2$. In this case we can, in fact, only consider the Hermitian operator

$$A_1^\nu=\nu a_1+\nu^*a_1^\dagger,\quad \nu=\nu_0e^{i\omega u^0},\quad \nu_0=\text{const}. \tag{2.71}$$

The second case corresponds to $|f|^2>|g|^2$, and here we can suppose that

$$|f|^2-|g|^2=|f_0|^2-|g_0|^2=1, \tag{2.72}$$

without the loss of generality. In both cases the operators (2.68) are, within constant complex factors, creation and annihilation operators.

Let us include operators (2.71) and (2.34) (they are integrals of motion) into the complete set of operators. Then

$$A_1^{\nu}\psi^{\nu,\mu}_{z_1,z_2}=z_1\psi^{\nu,\mu}_{z_1,z_2},\quad A_2^{\mu}\psi^{\nu,\mu}_{z_1,z_2}=z_2\psi^{\nu,\mu}_{z_1,z_2},\quad z_k^*=z_k,\quad k=1,2. \tag{2.73}$$

In the semi-momentum representation we find

$$\tilde{\psi}(u^0,\xi,\eta)=\Phi^{\nu}_{z_1}(\xi)\Phi^{\mu}_{z_2}(\eta), \tag{2.74}$$

where functions $\Phi^{\nu}_{z_1}$ are defined in (2.37). The corresponding coordinate representation reads

$$\begin{aligned}\psi^{\nu,\mu}_{z_1,z_2}(u^0,x,y)&=\left[\frac{\mu\nu}{2\pi^2|\mu||\nu|(\mu\nu-\mu^*\nu^*)}\right]^{1/2}\exp\left[\frac{Q_6}{4(\mu^*\nu^*-\mu\nu)}\right],\\ Q_6&=2(\mu+\mu^*)(\nu+\nu^*)x^2+2(\mu-\mu^*)(\nu-\nu^*)y^2+4i(\mu\nu^*-\mu^*\nu)xy\\ &\quad-4x[z_1(\mu+\mu^*)+z_2(\nu+\nu^*)]-4iy[z_1(\mu-\mu^*)-z_2(\nu-\nu^*)]\\ &\quad+\left(z_1\sqrt{\frac{\mu^*}{\nu}}+z_2\sqrt{\frac{\nu}{\mu^*}}\right)^2+\left(z_1\sqrt{\frac{\mu}{\nu^*}}+z_2\sqrt{\frac{\nu^*}{\mu}}\right)^2.\end{aligned} \tag{2.75}$$

These solutions are orthogonal at any fixed u^0, $(\psi^{\nu,\mu}_{z_1',z_2'},\psi^{\nu,\mu}_{z_1,z_2})=\delta(z_1-z_1')\,\delta(z_2-z_2')$, and obey the completeness relation

$$\int_{-\infty}^{\infty}dz_1\int_{-\infty}^{\infty}\mathrm{d}z_2\,\psi^{*\nu,\mu}_{z_1,z_2}(u^0,x',y')\,\psi^{\nu,\mu}_{z_1,z_2}(u^0,x,y)=\delta(x-x')\,\delta(y-y'). \tag{2.76}$$

Consider now generalized squeezed coherent states, which can be constructed by analogy with (2.44) in the semi-momentum representation. Here we use the operators (2.68) supposing that relations (2.69), (2.70), (2.72), and (2.35) hold,

$$\tilde{\psi}^{f,g;\alpha,\beta}_{n,s;z_1,z_2}(u^0,\xi,\eta)=\Phi^{f,g}_{n,z_1}(\xi)\Phi^{\alpha,\beta}_{s,z_2}(\eta). \tag{2.77}$$

The functions $\Phi^{a,b}_{n,z}(x)$ are defined in (2.45). Thus,

$$\psi^{f,g;\alpha,\beta}_{n,s;z_1,z_2}(u^0,x,y)=\frac{(A_1^{+f,g}-z_1^*)^n(A_2^{+\alpha,\beta}-z_2^*)^s}{\sqrt{\Gamma(n+1)\Gamma(s+1)}}\psi^{f,g;\alpha,\beta}_{z_1,z_2}(u^0,x,y),\psi^{f,g;\alpha,\beta}_{z_1,z_2}=\psi^{f,g;\alpha,\beta}_{0,0;z_1,z_2}. \tag{2.78}$$

The solutions (2.78) obey the relations

$$\begin{aligned}&(A_1^{f,g}-z_1)\,\psi^{f,g;\alpha,\beta}_{n,s;z_1,z_2}=\sqrt{n}\,\psi^{f,g;\alpha,\beta}_{n-1,s;z_1,z_2},(A_1^{+f,g}-z_1^*)\,\psi^{f,g;\alpha,\beta}_{n,s;z_1,z_2}=\sqrt{n+1}\,\psi^{f,g;\alpha,\beta}_{n+1,s;z_1,z_2},\\ &(A_2^{\alpha,\beta}-z_2)\,\psi^{f,g;\alpha,\beta}_{n,s;z_1,z_2}=\sqrt{s}\,\psi^{f,g;\alpha,\beta}_{n,s-1;z_1,z_2},(A_2^{+\alpha,\beta}-z_2^*)\,\psi^{f,g;\alpha,\beta}_{n,s;z_1,z_2}=\sqrt{s+1}\,\psi^{f,g;\alpha,\beta}_{n,s+1;z_1,z_2}.\end{aligned} \tag{2.79}$$

Equation (2.78) describes the most general form of relativistic wave equation solutions in a constant uniform magnetic field. All the formerly known solutions can be obtained from this equation by a particular choice of parameters. For instance, by selecting $f_0=\alpha=1$, $g=\beta=0$, $z_1=0$, $z_2=z$ with $z=0$ we get the states (2.31), on the other hand, if one puts $s=0$, $z\neq 0$, then one gets the states (2.54). For $n=s=0$, $f_0=\alpha=1$, $g=\beta=0$, we get coherent states.[11–14]

In the general case, an explicit coordinate representation for solutions (2.78) looks complicated enough. However, some particular cases admit essential simplifications. For example, suppose $f_0=\alpha=1$, $g=\beta=0$, then

$$\Psi^{1,0;1,0}_{n,s;z_1,z_2}(u^0,x,y)=\frac{(-1)^n}{\sqrt{\pi}}\left(\frac{x+iy-\overline{z_1}^*-z_2}{x-iy-\overline{z_1}-z_2^*}\right)^{(n-s)/2}e^{M_1}I_{s,n}(p_4),$$

$$2M_1=(\overline{z_1}-z_2^*)(x+iy)-(\overline{z_1}^*-z_2)(x-iy)+\overline{z_1}^*z_2-\overline{z_1}z_2^*-2in\omega u^0, \tag{2.80}$$

$$p_4=|x+iy-\overline{z_1}^*-z_2|^2,\quad \overline{z_1}=z_1\exp(-i\omega u^0).$$

For $n=s=0$, we get the coordinate representation for the squeezed coherent states in the form

$$\Psi^{f;g;\alpha,\beta}_{z_1,z_2}(u^0,x,y)=\left[\frac{\alpha f}{(\alpha f-\beta g)\pi|\alpha||f|}\right]^{1/2}\exp Q_7,$$

$$Q_7=-\frac{1}{2}(|z_1|^2+|z_2|^2)+\frac{q}{2(\alpha f-\beta g)}, \tag{2.81}$$

$$q=-(\alpha+\beta)(f+g)x^2-(\alpha-\beta)(f-g)y^2+2i(\beta f-\alpha g)xy+2x[(\alpha+\beta)z_1+(f+g)z_2]$$
$$+2iy[(\alpha-\beta)z_1-(f-g)z_2]+(\alpha g^*-\beta f^*)z_1^2+(\beta^* f-\alpha^* g)z_2^2-2z_1z_2.$$

Solutions from Refs. 11 to 14 are particular cases of (2.81) for $f_0=\alpha=1$, $g=\beta=0$.

Calculating mean values in the states (2.78), we get (one can obtain the same results using spinor wave functions for the calculations)

$$\overline{\mathcal{P}_1}=i\hbar\sqrt{\frac{\gamma}{2}}[(f^*+g^*)z_1-(f+g)z_1^*],\quad \overline{\mathcal{P}_2}=-\hbar\sqrt{\frac{\gamma}{2}}[(f^*-g^*)z_1+(f-g)z_1^*]. \tag{2.82}$$

Here we have taken into account the relations (2.6), (2.36), (2.79), and the orthogonality of the states with respect to the indices n,s. Remember now that in classical theory the corresponding momenta $\mathcal{P}_1^{\rm cl}$, $\mathcal{P}_2^{\rm cl}$ have the following parametric representation [with u^0 being the evolution parameter, R radius of the classical orbit, and κ is given by (2.67)]:

$$\mathcal{P}_1^{\rm cl}=\hbar\gamma R\sin 2\kappa,\quad \mathcal{P}_2^{\rm cl}=-\hbar\gamma R\cos 2\kappa. \tag{2.83}$$

It is easy to see that (2.82) coincides with (2.83) for $z_1=(\gamma/2)^{1/2}R(f_0e^{-i\varphi_0}+g_0e^{i\varphi_0})$. Calculating mean values of the coordinates $\overline{x^1}$, $\overline{x^2}$, we find that they evolve as the corresponding classical quantities $x^{1\rm cl}$, $x^{2\rm cl}$ ($x^1_{(0)}$, $x^2_{(0)}$ are coordinates of the orbit center),

$$x^{1\rm cl}=R\cos\kappa+x^1_{(0)},\quad x^{2\rm cl}=R\sin\kappa+x^2_{(0)}, \tag{2.84}$$

for $z_2=(\gamma/2)^{1/2}[(\alpha+\beta)x^1_{(0)}+i(\alpha-\beta)x^2_{(0)}]$.

Thus, mean-value trajectories in the plane x^1, x^2 do not depend on quantum numbers n,s. These trajectories have classical forms under a proper choice of z_1, z_2.

Calculating quadratic fluctuations in the states (2.78), we get

$$2\overline{(\Delta\mathcal{P}_1)^2}=\hbar^2\gamma|f+g|^2(2n+1),\quad 2\overline{(\Delta\mathcal{P}_2)^2}=\hbar^2\gamma|f-g|^2(2n+1),$$

$$2\gamma\overline{(\Delta x^1)^2}=|f-g|^2(2n+1)+|\alpha-\beta|^2(2s+1),$$

$$2\gamma\overline{(\Delta x^2)^2}=|f+g|^2(2n+1)+|\alpha+\beta|^2(2s+1), \tag{2.85}$$

$$\sigma_1=-\sigma_2=i(fg^*-gf^*)(2n+1),$$

$$\sigma_k=\overline{(\Delta x^k)(\Delta P_k)+(\Delta P_k)(\Delta x^k)},\quad k=1,2.$$

They do not depend on z_1, z_2, but do depend on quantum numbers n,s and on parameters f_0, g_0, α, β. The relations (2.85) imply the generalized Heisenberg inequalities

$$4\mathcal{J}_1=\hbar^2(2n+1)[(2n+1)+(2s+1)|(\alpha-\beta)(f+g)|^2]\geqslant\hbar^2,$$

$$4\mathcal{J}_2=\hbar^2(2n+1)[(2n+1)+(2s+1)|(\alpha+\beta)(f-g)|^2]\geqslant\hbar^2, \tag{2.86}$$

$$\mathcal{J}_k=\overline{(\Delta x^k)^2(\Delta\mathcal{P}_k)^2}-\frac{1}{4}\sigma_k^2, \quad k=1,2.$$

One can fix any given $\overline{(\Delta x^k)^2}$ or $\overline{(\Delta\mathcal{P}_k)^2}$ in a given "instant" u^0 by means of a choice of parameters f_0, g_0, α, β. Then they evolve with "time" u^0 according Eq. (2.85).

2. Eigenfunctions of the L_z operator

In the following we present another type of nonstationary states, which are quite different from the above-mentioned generalized coherent states. Recall that the problem was reduced to solving Eq. (2.65) under the condition (2.63). All the integrals of motion for such an equation can be constructed as functional combination of the operators

$$fa_1, \quad ga_1^\dagger, \quad a_2, \quad a_2^\dagger, \tag{2.87}$$

whenever f, g obey relations (2.69) and (2.70). Constructing integrals of motion that are linear combinations of these operators, we get coherent states. Any linear combinations of the operators (2.87) do not commute with the operator L_z (2.8) or J_z (2.4). Thus, coherent states with definite values of these quantities cannot be constructed. The generalized squeezed coherent states (2.44) and (2.77) are eigenvectors of the operators $\mathcal{N}_1$, $\mathcal{N}_2$ [that follows from (2.79)]. The latter operators are integrals of motion and are quadratic in creation and annihilation operators,

$$\mathcal{N}_1=(A_1^{+f,g}-z_1^*)(A_1^{f,g}-z_1), \quad \mathcal{N}_2=(A_2^{+\alpha,\beta}-z_2^*)(A_2^{\alpha,\beta}-z_2). \tag{2.88}$$

The operators $A_1^{f,g}$ are defined in (2.68), and $A_2^{\alpha,\beta}$ are defined in (2.35). The operators (2.88) do not commute with L_z, J_z as well.

One can see that besides the operators a_1a_2, $a_1^\dagger a_2^\dagger$, the only one quadratic combination that commutes with L_z, J_z is

$$\overline{A}=fa_1a_2+ga_1^\dagger a_2^\dagger. \tag{2.89}$$

It is known[15] that eigenvectors for such an operator can be normalized only for $|f|>|g|$, or for $|f|=|g|$. In the first case the eigenvectors have a finite norm, and in the second case they can be normalized to a δ function. Let us consider the case $|f|\geqslant|g|$ only. Here the operator (2.89) differs from

$$A^p=e^{i\kappa}(a_1a_2-\overline{p}^2a_1^\dagger a_2^\dagger), \quad \overline{p}=pe^{-i\kappa}, \quad -1\leqslant p\leqslant 1, \quad \kappa=\omega u^0+\kappa_0, \quad \kappa_0=\text{const} \tag{2.90}$$

by a complex factor only. Thus, it is enough to consider the latter operator only. Let us demand that functions $\psi(u^0,\rho,\varphi)$ be solutions of Eq. (2.65), and, at the same time, eigenvectors of the operators A^p, L_z,

$$A^p\psi_{q,l}^p=-q\psi_{q,l}^p, \quad L_z\psi_{q,l}^p=\hbar l\psi_{q,l}^p, \quad l=0,\pm1,\pm2,\ldots. \tag{2.91}$$

Such solutions can be constructed in terms of the Laguerre functions $I_{n,m}(x)$ with noninteger indices,

$$\psi^p_{q,l}(u^0,\rho,\varphi)=N\exp(il\varphi-\Gamma)(1+\overline{p})^{-\alpha}(1-\overline{p})^{-\beta}I_{|l|+s,s}(x),$$

$$\Gamma=i\frac{l\omega u^0}{2}+\frac{1+\overline{p^2}}{2(1-\overline{p^2})}\rho,\quad \alpha=\frac{p-q}{2p},\quad \beta=\frac{p+q}{2p},\tag{2.92}$$

$$s=\frac{q}{2p}-\frac{|l|+1}{2},\quad x=\frac{2\overline{p}\rho}{1-\overline{p^2}},$$

$$I_{n,m}(x)=\sqrt{\frac{\Gamma(1+n)}{\Gamma(1+m)}}\frac{\exp\left(-\frac{x}{2}\right)}{\Gamma(1+n-m)}x^{(n-m)/2}\Phi(-m,n-m+1;x).$$

Here $\Phi(\alpha,\beta;x)$ is the degenerate hypergeometric function (see Ref. 9, 9.210). For $p^2=1$, the operator (2.90) is anti-Hermitian and q is imaginary, $\mathrm{Re}\,q=0$. For $p=0$, solutions have a very simple form

$$\psi^0_{q,l}(u^0,\rho,\varphi)=N_0\exp(il\varphi+\overline{q}-\Gamma_0)J_{|l|}(2\sqrt{\overline{q}\rho}),\quad \Gamma_0=\frac{i}{2}l\omega u^0+\frac{\rho}{2},\quad \overline{q}e^{-ik},\tag{2.93}$$

where $J_\nu(x)$ is the Bessel function (see Ref. 9, 8.402). The functions (2.93) can be obtained from (2.92) as a limit $p\to 0$, as can be seen with the help of the property

$$\lim_{r\to\infty} I_{r+\alpha,r+\beta}\left(\frac{x^2}{4r}\right)=J_{\alpha-\beta}(x).\tag{2.94}$$

The functions (2.92) and (2.93) are orthogonal only with respect to quantum numbers l,

$$(\psi^p_{q',l'},\psi^p_{q,l})=\delta_{l,l'}QF(-s,-s'^*;1+|l|;y),\quad y=\left(\frac{2p}{1+p^2}\right)^2,$$

$$Q=\left[\frac{\Gamma(1+|l|+s)\Gamma(1+|l|+s'^*)}{p^2\Gamma(1+s)\Gamma(1+s'^*)}\right]^{1/2}\frac{\pi NN'^*}{\Gamma(1+|l|)}y^{(1+|l|)/2}(1-y)^{-(q+q^*)/4p},$$

$$(\psi^0_{q',l'},\psi^0_{q,l})=\delta_{l,l'}2\pi N_0N_0'^*I_{|l|}(2\sqrt{qq'^*}).\tag{2.95}$$

Here $F(\alpha,\beta;\gamma;x)$ is the hypergeometric function (see Ref. 9, 9.100), and $I_\alpha(x)$ is the Bessel function of imaginary argument (see Ref. 9, 8.404). Calculating (2.95), we have used the integral table (see Ref. 9, 6.633.2; 7.622.1).

The states (2.92) are not coherent states, however, they are, in a sense, close to such states. Indeed, let us consider the equations (2.6) on classical trajectories. Then we get a classical relation

$$\rho=\rho(u^0)=\sqrt{L_z^2\hbar^{-2}+4|a_1a_2|^2}-a_1a_2-a_1^\dagger a_2^\dagger.\tag{2.96}$$

For $p=0$, it follows from (2.91) that $a_1a_2=-\overline{q}$, $L_z=\hbar l$. Thus, we can rewrite (2.96) in the form

$$\rho(u^0)=\rho_0^{\mathrm{cl}}+\overline{q}+\overline{q}^*,\quad \rho_0^{\mathrm{cl}}=\sqrt{l^2+4|q|^2}.\tag{2.97}$$

Calculating the mean value $\overline{\rho}$ by means of the functions (2.93), we find

$$\overline{\rho}=\rho_0+\overline{q}+\overline{q}^*,\quad \rho_0=|l|-1-2|q|\frac{I_{|l|-1}(2|q|)}{I_{|l|}(2|q|)}.\tag{2.98}$$

Thus, the time dependence of $\overline{\rho}$ is classical. The only constant which can differ from its classical value is ρ_0.

III. EXACT SOLUTIONS OF RELATIVISTIC WAVE EQUATIONS IN LONGITUDINAL FIELDS

A. Definition of fields

Consider here longitudinal electromagnetic fields, which have the form

$$\mathbf{E}=\mathbf{n}E, \quad \mathbf{H}=\mathbf{n}H. \tag{3.1}$$

Here $\mathbf{n}$ is a unit vector, $\mathbf{n}^2=1$. Suppose $\mathbf{n}$ is directed along x^3 axis. Then, the fields (3.1) obey the free Maxwell equations whenever

$$E=E(x^0,x^3), \quad H=H(x^1,x^2),$$

where $E(x^0,x^3)$, $H(x^1,x^2)$ are arbitrary functions of the indicated arguments. Thus, the fields under consideration can be represented by potentials of the form

$$\begin{gathered} A_0=A_0(x^0,x^3), \quad A_1=A_1(x^1,x^2), \quad A_3=A_3(x^0,x^3), \quad A_2=A_2(x^1,x^2), \\ E=\partial_0 A_3-\partial_3 A_0, \quad H=\partial_2 A_1-\partial_1 A_2. \end{gathered} \tag{3.2}$$

Thus, the operators (2.6) do not depend on the electric field (on A_0, A_3). Therefore, imposing restrictions only on the magnetic field, we can maintain relations (2.6)–(2.11). For a uniform magnetic field (2.1), the commutation relations (2.7) are still valid and we use the semi-momentum representation, where these operators act on different variables [see (2.10)–(2.12), (2.17)].

Lorentz equations have the following form

$$\begin{gathered} m\ddot{x}^0+E\dot{x}^3=0, \quad m\ddot{x}^3+E\dot{x}^0=0, \\ m\ddot{x}^1+H\dot{x}^2=0, \quad m\ddot{x}^2+H\dot{x}^1=0, \quad \dot{x}^\mu\dot{x}_\mu=1, \end{gathered} \tag{3.3}$$

which implies the following first integrals of motion:

$$m^2((\dot{x}_1)^2+(\dot{x}_2)^2)=k_1^2, \quad m^2((\dot{x}_0)^2-(\dot{x}_3)^2)=m^2+(k_1)^2, \tag{3.4}$$

where k_1 is an integration constant.

B. Klein–Gordon equation

Consider the Klein–Gordon equation in the fields under consideration. Representing the wave function as

$$\Psi=\varphi(x^0,x^3)\,\psi(x^1,x^2), \tag{3.5}$$

we find

$$(\mathcal{P}_1^2+\mathcal{P}_2^2-k_1^2)\,\psi(x^1,x^2)=0, \quad (\mathcal{P}_0^2-\mathcal{P}_3^2-m^2-k_1^2)\,\varphi(x^0,x^3)=0. \tag{3.6}$$

Using the variables x, y, η, ξ defined in (2.5) and (2.12), we can rewrite the equation for $\psi(x^1,x^2)$ in the following form:

$$(\xi^2-\partial_\xi^2-k_1'^2)\,\psi(x^1,x^2)=0, \quad k_1'^2=\frac{k_1^2}{\hbar^2\gamma}. \tag{3.7}$$

The operator $(\xi^2-\partial_\xi^2-k_1'^2)$ does not depend on η. Thus, it is convenient to go over to the semi-momentum representation,

$$\psi(x,y)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{iky}\tilde{\psi}(x,k)\mathrm{d}k.$$

Substituting the integration over k by an integration over η, we obtain

$$\psi(x,y)=\frac{e^{ixy}}{\sqrt{\pi}}\int_{-\infty}^{\infty}e^{-i\sqrt{2y}\,\eta}\tilde{\psi}(\xi,\eta)\mathrm{d}\eta,\quad \xi=\sqrt{2}x-\eta. \tag{3.8}$$

The function ψ is an eigenvector of the operator $\mathcal{N}$ (2.14). The latter operator commutes with the operators from Eq. (3.6). In the semi-momentum representation we can write

$$\mathcal{N}\tilde{\psi}_n=n\tilde{\psi}_n\Rightarrow\tilde{\psi}_n(\xi,\eta)=U_n(\xi)\Phi(\eta), \tag{3.9}$$

where $\Phi(\eta)$ is an arbitrary function of η. It follows from (2.8) and the first equation in (3.6) that

$$\mathcal{P}_1^2+\mathcal{P}_2^2=2\hbar^2\gamma\mathcal{N}+\hbar^2\gamma,\quad k_1^2=2\hbar^2\gamma n+\hbar^2\gamma.$$

Solution of the last equation in (3.6) can be found for fields that admit separation of the variables x^0, x^3. For example, let us choose the potentials in the form: $|e|A_0=A(x^3)$, $A_3=0$, $|e|E=-\partial_3 A$. In this case, stationary solutions of Eq. (3.6) read

$$\varphi(x^0,x^3)=e^{-ik_0x^0}\chi(x^3),\quad \chi''+R\chi=0,\quad R(x^3)=(k_0+A)^2-m^2-k_1^2. \tag{3.10}$$

Thus, the functions (3.5) being written in the semi-momentum representation take the form

$$\Psi_n=e^{-ik_0x^0}\chi(x^3)U_n(\xi)\Phi(\eta). \tag{3.11}$$

Equation (3.10) for χ can be solved exactly for the following choices of the function $A(x^3)$:

$$A(x^3)=\alpha x,\quad A(x^3)=\alpha\exp(\beta x^3),\quad A(x^3)=\frac{\alpha}{x^3},$$

$$A(x^3)=\alpha\tanh(\beta x^3),\quad A(x^3)=\alpha\tan(\beta x^3),\quad A(x^3)=\beta\coth(\beta x^3).$$

The corresponding exact solutions are presented in Ref. 3. Demanding that the Klein–Gordon function be an eigenvector of the operator L_z (2.16), we get an equation for the function $\Phi(\eta)$ from (3.11),

$$a_2^\dagger a_2\Phi(\eta)=s\Phi(\eta). \tag{3.12}$$

Thus, $\Phi(\eta)=U_s(\eta)$, and $L_Z\Psi_{ns}=\hbar(n-s)\Psi_{ns}$. Keeping this in mind and doing the integral (3.8), we obtain

$$\Psi_{n,s}=e^{-ik_0x^0}\chi(x^3)\frac{(-1)^n}{\sqrt{2\pi}}\left(\frac{x+iy}{x-iy}\right)^{(n-s)/2}I_{n,s}(x^2+y^2),$$

where $I_{n,s}$ are the Laguerre functions. Solutions of Eq. (3.12) have been analyzed above.

C. Dirac equation

Let us present the Dirac wave function in the form

$$\mathbf{\Theta}=\mathbf{M}\begin{pmatrix}\psi_1\\ \psi_{-1}\end{pmatrix}\varphi(x^0,x^3)v,$$

$$\mathbf{M}=\begin{pmatrix}k_1(m+\mathcal{P}_0+\mathcal{P}_3-ik_1\sigma_2) & (\mathcal{P}_1-i\mathcal{P}_2)(m+\mathcal{P}_0+\mathcal{P}_3-ik_1\sigma_2)\\ (\mathcal{P}_1+i\mathcal{P}_2)[(m-\mathcal{P}_0-\mathcal{P}_3)\sigma_3-k_1\sigma_1] & k_1[(m-\mathcal{P}_0-\mathcal{P}_3)\sigma_3-k_1\sigma_1]\end{pmatrix},$$

where ν is an arbitrary spinor, which can be fixed by supplementary conditions. Then the following equations take place:

$$(\mathcal{P}_0^2-\mathcal{P}_3^2-m^2-k')\varphi(x^0,x^3)=0,\quad k'=k_1^2+ieE, \tag{3.13}$$

$$(\mathcal{P}_1+i\mathcal{P}_2)\psi_1(x^1,x^2)=\hbar k_1\psi_{-1}(x^1,x^2), \tag{3.14}$$

$$(\mathcal{P}_1-i\mathcal{P}_2)\psi_{-1}(x^1,x^2)=\hbar k_1\psi_1(x^1,x^2). \tag{3.15}$$

As a consequence of Eqs. (3.14) and (3.15), we get

$$a_1\psi_{-1}=-i\sqrt{n}\psi_1,\quad a_1^\dagger\psi_1=i\sqrt{n}\psi_{-1},\quad k_1^2=2\gamma n.$$

Thus, we see that $\psi_1=\psi_{n-1}$, $\psi_{-1}=-i\psi_n$, and the problem is reduced to solving Eq. (3.13). The latter coincides with the second equation in (3.6).

Considering, for example, the constant and uniform magnetic field (2.1) together with the electric field described by potentials $|e|A_0=A(x^3)$, $A_3=0\Rightarrow|e|E=-\partial_3 A$, we get

$$\varphi(x^0,x^3)=\exp(-ik_0x^0)\chi(x^3),\quad \chi''+(i\partial_3+k_0+A)\chi=0.$$

All possible solutions of the latter equation for the function χ are presented in Ref. 3.

IV. PECULIARITIES OF INTEGRATION OF LINEAR DIFFERENTIAL EQUATIONS WITH NONCOMMUTATIVE SYMMETRIES

Here we are going to return to the above-mentioned results from a point of view of general theory of differential equation. Recall that we succeeded to explicitly find the transformation (2.10)–(2.13) which has effectively reduced the number of the variables in the initial equations. In fact, that was the main starting point for all further constructions. However, one can see that this ''reduction'' of variables is a particular example of a general situation, which is described briefly in the following.

Consider first the case of an integrable classical $2N$-dimensional Hamiltonian system with the Hamiltonian H. Suppose this system has N independent integrals of motion that are in involution. It is well known that in such a case the variables of the type action-angle $(J,\ \varphi)$ are available, and the Hamiltonian depends on the action variables only, $H=H(J)$. Let us suppose that for such a system exists one more independent integral of motion Y. Since Y is independent, it cannot commute with the former integrals, and, therefore, Y must depend on the angle variables. One can demonstrate that in such a case the Hamiltonian system is degenerate, $\det\|\partial H(J)/\partial J_i\partial J_j\|=0$, and, therefore, the Hamiltonian does not depend on some combinations of the action variables. For example, suppose the integral Y does not commute with the integral J_N only. Then the Hamiltonian can depend on the variables $J_1,\ldots,J_{N-1}$ only, otherwise H cannot commute with Y. Thus, we see that the noncommutative algebra of integrals of motion allows one to find canonical variables such that part of the corresponding action variables disappears from the Hamiltonian. This phenomenon is closely related to the topological properties of orbits for the Hamiltonian system. Namely, trajectories of the integrable Hamiltonian system with N-dimensional commuta-

tive set of integrals of motion form (in the compact case) a winding of N-torus in $2N$-dimensional phase space. If the set of the integrals is noncommutative then the dimension of the corresponding torus is $r<N$ (see Ref. 16).

The phenomenon of variable ''reduction'' takes place in the quantum integrable Hamiltonian system as well. As will be demonstrated in the following, by constructing a special isomorphism of linear functional spaces, we can transform the initial differential operator of an equation into another one with a reduced number of variables. The method which we are going to use for such a demonstration, is, in fact, the harmonic analysis on the noncommutative functional algebras.

Consider a differential equation

$$H(x,\partial_x)\psi(x)=0, \tag{4.1}$$

for functions $\psi(x)\in\mathcal{L}$ of N independent variables $x\in R^N$. The space $\mathcal{L}\subset C^\infty(R^N)$ and depends on the problem under consideration. Some suppositions about $\mathcal{L}$ will be introduced below. Suppose that Eq. (4.1) admits a noncommutative algebra of functionally independent symmetry operators $\mathcal{F}=\{X_a(x,\partial_x)\}$. The corresponding commutation relations are in the general case nonlinear,

$$\frac{i}{\hbar}[X_a,X_b]=\Omega_{ab}(X), \quad a,b=1,\ldots,n\equiv\dim\mathcal{F}. \tag{4.2}$$

Here $\Omega_{ab}(X)$ are symmetric operator functions. The linear case, when $\Omega_{ab}(X)=C_{ab}^cX_c$, corresponds to a Lie algebra, the quadratic symmetric functions $\Omega_{ab}(X)$ correspond to a quadratic algebra, and so on. The algebra $\mathcal{F}$ corresponds to the algebra $\mathcal{F}'=\{Y_\alpha(x,\partial_x)\}$ of the invariant operators on $\mathcal{L}$:

$$[X_a,Y_\alpha]=0, \quad \frac{i}{\hbar}[Y_\alpha,Y_\beta]=\omega_{\alpha\beta}(Y), \quad \alpha,\beta=1,\ldots,n'\equiv\dim\mathcal{F}'. \tag{4.3}$$

We denote via $E(\mathcal{F})$ and $E(\mathcal{F}')$ enveloping fields for the algebras $\mathcal{F}$ and $\mathcal{F}'$, respectively. Elements of $E(\mathcal{F})$ and $E(\mathcal{F}')$ are symmetrized operator functions of the generating operators X_a Y_α. It is clear that the centers of the enveloping fields coincide, i.e., $Z(E(\mathcal{F}))=Z(E(\mathcal{F}'))$. The elements of the center $Z=Z(E(\mathcal{F}))$ are called Casimir operators. The number of the independent Casimir operators, which generate the center Z, is called the index of the algebra $\mathcal{F}$: $r\equiv\operatorname{ind}\mathcal{F}$ $=\operatorname{ind}\mathcal{F}'$. If we replace the operators X and Y in the operator functions $\omega_{\alpha\beta}(Y)$ and $\Omega_{ab}(X)$ by arbitrary complex numbers ξ and f, then the index of the algebras $\mathcal{F}$ and $\mathcal{F}'$ can be calculated according to

$$r=\sup_{\xi\in C}\operatorname{corank}\,\Omega_{ab}(\xi)=\sup_{f\in C}\operatorname{corank}\,\omega_{\alpha\beta}(f). \tag{4.4}$$

One can show that the following relation takes place:

$$n+n'=2N. \tag{4.5}$$

Let us introduce the notion of the λ-representation of the algebra $\mathcal{F}$.[17] In fact, the λ-representation is the result of the quantization of the classical Poisson bracket and can be understood as a realization of the algebra $\mathcal{F}$ by an irreducible set of differential operators $\tilde{X}$ $=\tilde{X}(q,\partial_q,j)$, dependent on r parameters $j=(j_1,\ldots,j_r)$, and acting in a space of functions of $[q]=(n-r)/2$ independent variables (via $[q]$ we denote the number of the variables q, similar notations are used in the following) $q\in Q$,

$$\frac{i}{\hbar}[\tilde{X}_a,\tilde{X}_b]=-\Omega_{ab}(\tilde{X}), \quad K_\mu(\tilde{X}(q,\partial_q,j))=\kappa_\mu(j), \quad \det\left\|\frac{\partial\kappa_\mu(j)}{\partial j_\nu}\right\|\neq 0. \tag{4.6}$$

Here K_μ are all the independent Casimir operators of $\mathcal{F}$. In a similar manner, we construct the λ-representation $\{\tilde{Y}\}$ of $\mathcal{F}'$ in a space of functions of $[q']=(n'-r)/2$ independent variables q' $\in Q'$,

$$\frac{i}{\hbar}[\tilde{Y}_\alpha,\tilde{Y}_\beta]=\omega_{\alpha\beta}(\tilde{Y}),\quad K'_\mu(\tilde{Y}(q',\partial_{q'},j))=K_\mu(\tilde{X}(q,\partial_q,j))=\kappa_\mu(j). \tag{4.7}$$

Suppose that in the spaces of functions of x, of q, and of q' are defined scalar products

$$(\varphi,\psi)=\int_{R^N}\overline{\varphi(x)}\psi(x)\mathrm{d}\mu(x),\quad (\tilde{\varphi},\tilde{\psi})=\int_Q\overline{\tilde{\varphi}(q)}\tilde{\psi}(q)\mathrm{d}\mu(q),$$
$$(\tilde{\varphi},\tilde{\psi})'=\int_{Q'}\overline{\tilde{\varphi}(q')}\tilde{\psi}(q')\mathrm{d}\mu(q'), \tag{4.8}$$

where $\mathrm{d}\mu(x)$, $\mathrm{d}\mu(q)$, and $\mathrm{d}\mu(q')$ are some measures on R^N, Q, and Q', respectively. And suppose that the operators $X_a(x,\partial_x)$, $Y_\alpha(x,\partial_x)$ and the operators $\tilde{X}_a(q,\partial_q,j),\tilde{Y}(q',\partial_{q'},j)$ are self-conjugate with respect to the corresponding scalar products (this supposition is not necessary and is introduced to simplify the consideration). Now we define the set of distributions $D^j_{qq'}(x)$ as a solution of the overdetermined system of the equations:

$$[X_a(x,\partial_x)-\tilde{X}_a(q,\partial_q,j)]D^j_{qq'}(x)=0;\quad [Y_\alpha(x,\partial_x)-\tilde{Y}_a(q',\partial_{q'},j)]D^j_{qq'}(x)=0. \tag{4.9}$$

The distributions $D^j_{qq'}(x)$ obey the completeness and orthogonality relations:

$$\int\overline{D^j_{qq'}(x)}D^{\tilde{j}}_{\tilde{q}\tilde{q}'}(x)\,\mathrm{d}\mu(x)=\delta(j,\tilde{j})\,\delta(q,\tilde{q})\,\delta(q',\tilde{q}'), \tag{4.10}$$

$$\int\overline{D^j_{qq'}(x)}D^j_{qq'}(\tilde{x})\mathrm{d}\mu(j)\mathrm{d}\mu(q)\mathrm{d}\mu(q')=\delta(x,\tilde{x}). \tag{4.11}$$

Here $\mathrm{d}\mu(j)$ is the spectral measure of the Casimir operators $K(X)(=K'(Y))$. Due to Eqs. (4.6), (4.7) and (4.9) the distributions $D^j_{qq'}(x)$ are eigenfunctions of all the Casimir operators,

$$K_\mu(X(x,\partial_x))D^j_{qq'}(x)=\kappa_\mu(j)D^j_{qq'}(x),\quad \mu=1,\ldots,r. \tag{4.12}$$

Usually one can find $D^j_{qq'}(x)$ by an integration, at least in the case when $\mathcal{F}$ is a Lie algebra. As a consequence of (4.11) and (4.10) we can define the direct and the inverse Fourier transforms:

$$\tilde{\psi}(q,q',j)=\int D^j_{qq'}(x)\overline{\psi(x)}\,\mathrm{d}\mu(x), \tag{4.13}$$

$$\psi(x)=\int D^j_{qq'}(x)\overline{\tilde{\psi}(q,q',j)}\mathrm{d}\mu(j)\mathrm{d}\mu(q)\mathrm{d}\mu(q'). \tag{4.14}$$

Equations (4.13) and (4.14) establish an isomorphism of the spaces $\mathcal{L}$ and $\tilde{\mathcal{L}}=\{\tilde{\psi}\}$. It is important to stress that under such an isomorphism the operators X, Y are transformed into the differential operators $\tilde{X},\tilde{Y}$ that act in the spaces of functions, which depend on a smaller number of variables,

$$X(x,\partial_x)\psi(x)\leftrightarrow\tilde{X}(q,\partial_q,j)\tilde{\psi}(q,q',j),\quad Y(x,\partial_x)\psi(x)\leftrightarrow\tilde{Y}(q',\partial_{q'},j)\tilde{\psi}(q,q',j). \tag{4.15}$$

Let us return to Eq. (4.1). Here we can conclude that $H\in E(\mathcal{F}')$ since the operator H commutes with all the operators of the algebra $\mathcal{F}=\{X_a\}$. In turn, that means that there exists an operator function $H(Y)$ such that $H(x,\partial_x)=H(Y(x,\partial_x))$. Let us look for solutions of Eq. (4.1) in the form (4.14). Using the isomorphism (4.15), we get

$$H(\tilde{Y}(q',\partial_{q'},j))\tilde{\psi}(q,q',j)=0. \tag{4.16}$$

Thus, departing from Eq. (4.1) without loss of any information, we have arrived at a differential equation with $\tilde{N}=[q']=(n'-r)/2$ independent variables. Taking into account (4.5), one can obtain

$$\tilde{N}=N-\tfrac{1}{2}(\dim\mathcal{F}+\operatorname{ind}\mathcal{F}). \tag{4.17}$$

Thus, the existence of a noncommutative symmetry algebra results in the phenomenon of variable reduction. Indeed, we started with $N=[q']+[q]+r$ variables. $[q]$ variables have disappeared completely, and $r=[j]$ variables remain in the equations as some parameters. The solution of Eq. (4.16) contains as a factor an arbitrary function of the variables q,j. The number of variables q is equal to $[q]=(n-r)/2=(\dim\mathcal{F}-\operatorname{ind}\mathcal{F})/2$. In the commutative case: $\operatorname{ind}\mathcal{F}=\dim\mathcal{F}$, and $[q]=0$. In the noncommutative case: $\dim\mathcal{F}>\operatorname{ind}\mathcal{F}$, and $[q]>0$. Thus, the reduction of variables always takes place when there exists a noncommutative algebra of the integrals of motion.

Let us apply the above-mentioned consideration to the Klein–Gordon equation (2.2) in a uniform magnetic field. In this case we have four ($N=4$) variables and five ($n=5$) independent symmetry operators: $\mathcal{F}=\{P_0,P_3,a_2,a_2^\dagger,L_z=\hbar L\}$,

$$P_0=i\hbar\partial_0,\quad P_3=i\hbar\partial_3,\quad L=u\partial_u-\bar{u}\partial_{\bar{u}},\quad a_2=\partial_{\bar{u}}+u/2,\quad a_2^\dagger=-\partial_u+\bar{u}/2,\quad u\equiv x+iy.$$

The nonzero commutation relations are $[a_2,a_2^\dagger]=1$, $[L,a_2]=a_2$, $[L,a_2^\dagger]=-a_2^\dagger$. It follows from (4.4) that $r=\operatorname{ind}\mathcal{F}=3$. $\tilde{N}=[q']=0$ $\mathcal{K}\in Z$ according to (4.17). Thus, Eq. (4.16) presents algebraic relations on the parameters j (and on the parameters of the equation itself). Besides, $\dim\mathcal{F}'=3=r$, due to (4.5). Thus, the algebra of the invariant operators is placed completely in the center. Or more simply, there are no operators $Y,\tilde{Y}$ and variables q' in the case under consideration. The center Z is generated by three Casimir operators, those are $K_1=P_0$, $K_2=P_3$, $K_3=\mathcal{N}=L+a_2^\dagger a_2=L+\frac{1}{2}(a_2^\dagger a_2+a_2a_2^\dagger-1)$.

Let us construct the λ-representation of the algebra $\mathcal{F}$:

$$\tilde{P}_0=j_1=\hbar k_0,\quad \tilde{P}_3=j_2=\hbar k_3,\quad \tilde{a}_2=q,\quad \tilde{a}_2^+=\partial_q,\quad \tilde{L}=-q\partial_q+n,\quad n=j_3=0,1,\ldots.$$

The operators $\tilde{a}_2$ and $\tilde{a}_2^+$ are mutually conjugate with respect to the scalar product (4.8) with the measure $\mathrm{d}\mu(q)=\exp(-q\bar{q})\mathrm{d}^2q/\pi,(\mathrm{d}^2q\equiv\mathrm{d}q_1\mathrm{d}q_2,\quad q=q_1+iq_2)$. The operator $\tilde{L}$ is self-conjugate, and the space $\tilde{\mathcal{L}}$ is built up from analytic functions dependent on the variable q and on the parameters $j=(k_0,k_3,n)$. Here the Casimir operator $\tilde{\mathcal{N}}$ has the following form $\tilde{\mathcal{N}}=\tilde{L}+\frac{1}{2}(\tilde{a}_2^+\tilde{a}_2+\tilde{a}_2\tilde{a}_2^+-1)=n$.

From Eq. (4.9) we can find the set $D_q^j(x)$ that obeys the completeness and orthogonality relations. Such a set has the form

$$D_q^j(x)=e^{i(k_0x^0+k_3x^3)}e^{q\bar{u}-u\bar{u}/2}(u-q)^n/(2\pi\sqrt{\pi n!}), \tag{4.18}$$

$$\int\overline{D_q^j(x)}\tilde{D_{\tilde{q}}^j}(x)\mathrm{d}x=\delta(k_0-\tilde{k}_0)\,\delta(k_3-\tilde{k}_3)\,\delta(\tilde{q},q)\,\delta_{n\tilde{n}}, \tag{4.19}$$

$$\sum_{n=0}^{\infty}\int\overline{D_q^j(x)}D_q^j(\tilde{x})\,\mathrm{d}k_0\mathrm{d}k_3\mathrm{d}\mu(q)=\delta(x^0-\tilde{x}^0)\,\delta(x^3-\tilde{x}^3)\,\delta(x-\tilde{x})\,\delta(y-\tilde{y}). \tag{4.20}$$

In Eq. (4.19) $\delta(\tilde{q},q)=\exp(\bar{q}\tilde{q})$ is a δ-function with respect to the measure $\mathrm{d}\mu(q)$. To justify the validity of (4.19) and (4.20) one can use the following relations.[18]

$$\int\overline{v_n(q)}v_m(q)\,d\mu(q)=\delta_{nm},\quad \sum_{n=0}^{\infty}\overline{v_n(q)}v_n(\tilde{q})=\delta(\tilde{q},q)=\exp(\bar{q}\tilde{q}),\quad v_n(q)\equiv q^n/\sqrt{n!}.$$

As was previously mentioned, the Klein–Gordon operator $\mathcal{K}$ belongs to the center Z, and, therefore, can be presented in a polynomial form of the Casimir operators $P_0, P_3, \mathcal{N}$, which generate this center. Such a representation is given by Eq. (2.9). The Klein–Gordon equation in the space $\tilde{\mathcal{L}}$, i.e., Eq. (4.16), is, in fact, relation (2.21) for the parameters $j=(k_0, k_3, n)$. Thus, the functions (4.18) form a basis of the Klein–Gordon equation (2.2) [with allowance made for (2.21)].

We discuss in this article the canonical structure of classical field theory in finite dimensions within the *pataplectic* Hamiltonian formulation, where we put forward the role of Legendre correspondence. We define the generalized Poisson $\mathfrak{p}$-brackets which are the analogs of the Poisson bracket on forms. We formulate the equations of motion of forms in terms of $\mathfrak{p}$-brackets. As illustration of our formalism we present three examples: the interacting scalar fields, conformal string theory and the electromagnetic field. © *2002 American Institute of Physics.*

I. INTRODUCTION

In the standard Hamiltonian formulation of classical point particle mechanics, the phase space of a system with N degrees of freedom is a $2N$ dimensional manifold, which represents the space of possible positions and momenta of the system. In field theories the dynamical objects typically have an infinite number of degrees of freedom. Thus we need to employ infinite dimensional manifolds to model their evolution. This requires a generalization of the familiar theory of finite dimensional manifolds, and so we are motivated to stipulate that an infinite dimensional manifold is a manifold modeled for example on an infinite dimensional Banach space.

Infinite dimensional manifolds do, of course, differ in many significant ways from their finite dimensional counterparts. No infinite dimensional manifold is locally compact, for instance, although every finite dimensional one is. Furthermore, the fact that the tangent spaces are infinite dimensional leads to some complications which are not present in the finite dimensional case. Two are worth mentioning here:

(1) In the finite dimensional case, a linear map $T:V\to V$ is one to one iff it is onto; in the infinite dimensional case a linear operator on V can be one to one but not onto.
(2) Similarly, in the finite dimensional case, all linear operators are continuous maps from V to V; in the infinite dimensional case, the continuous linear operators, i.e., the bounded operators, often have as their domain of definition a dense (proper) subset of V.

A crucial step in the formulation of Hamiltonian mechanics is the construction of the Poisson bracket of a pair of physical observables. This is obtained from the natural symplectic structure on $T^\star M$ (where M is the configuration space of the physical system). In this phase space approach to classical mechanics, the dynamical evolution from an initial point $x_O \in T^\star M$ is the solution to Hamilton's first order differential equations. Geometrically, dynamical trajectories in phase space can be identified with the flow lines of a special vector field ξ_H on $T^\star M$ associated with the Hamiltonian function H. Those dynamical equations imply the time rate of change of any physical observable $f \in C^\infty(T^\star M, \mathbb{R})$, precisely through the Poisson bracket of f with H which is defined

a)Electronic mail: helein@cmla.ens-cachan.fr
b)Electronic mail: kouneiher@paris7.jussieu.fr

thanks to Hamiltonian vector fields ξ_f on $T^\star M$ associated to each f. There are a couple of potential difficulties here. If $T^\star M$ is infinite dimensional, then some perfectly good functions may not have a Hamiltonian vector field (this problem does not arise in the finite dimensional case). Even when ξ_f exists, its integral curves may be incomplete (i.e., the vector field is only locally defined).

Further, in this viewpoint space and time are treated asymmetrically, therefore we do not have a covariant scheme.

In order to avoid these difficulties, an alternative approach is to construct covariant canonical formulations of (finite dimensional) field theories which treat the space and time on equal footing (symmetrically). Remark that there is a whole variety of such theories and interestingly enough they offer a generalization of the Hamilton canonical equations of motion to field theory (see, for instance Refs. 1–4, 11, 12, and 24). Further details can be found in Refs. 5–15, 19, 22, and 23. One point there is that the observable quantities are not represented by (generalized) functions on a phase space, but rather by $(n-1)$-forms, whose integrals on Cauchy hypersurfaces give back the usual observables. But many of those approaches share a characteristic, which is an obstacle to the development of a field quantization: the lack of an appropriate generalization of the Poisson bracket. And even if a Poisson bracket was proposed, the related construction was too restrictive and not appropriate for representing the generalized Hamiltonian field equations in Poisson bracket formulation.

More recently, a definition of the Poisson brackets on a subclass of forms and the equations of motion of forms from De Donder–Weyl point of view was given (see Refs. 16, 17, 20, and 21). [In this approach we associate to the generalized coordinates (the field variables) u^i a set of n momentumlike variables (which are defined from the Lagrangian as the conjugate momenta associated with each space–time—here $\alpha=1,\ldots,n$ is the space–time index—derivative of the field), $p_i^\alpha := \partial L/\partial(\partial_\alpha u^i)$, and we have the Legendre transform: $\partial_\alpha u^i \to p_i^\alpha$, $L(u^i,\partial_\alpha u^i,x^\alpha) \to H(u^i,p_i^\alpha,x^\alpha) := p_i^\alpha \partial_\alpha u^i - L$. So, the phase space is replaced by a finite dimensional space.] The main point is to derive the Hamiltonian fields equations from the Poincaré–Cartan n-form and its differential, called there *polysymplectic form* using ''vertical multivector fields'' (which generalize the Hamiltonian vector fields in mechanics). Constructions of brackets can be done using also the polysymplectic form, but a correct expression of the dynamics of these forms requires a decomposition of forms and multivectors along ''vertical'' and ''horizontal'' components. This decomposition, however, essentially implies a triviality of the ''extended polymomentum phase space'' as a bundle over the space–time manifold. Moreover, we notice that in those works although a natural link between Poisson brackets and dynamics exists for $n-1$-forms, in the case of forms of arbitrary degrees the link is not clear. [This generalization of the Poisson bracket formulation of the equations of motion to forms of arbitrary degree requires a certain extension, namely by adding horizontal forms of degree n and the vertical-vector valued horizontal one-forms (objects of formal degree zero) associated with n-forms. This extension calls for a generalization of Lie, Schouten–Nijenhuis and Frölicher–Nijenhuis brackets.] This affect the possibility of a precise formulation, for example (of the dynamics), of Maxwell's electrodynamics. In addition, we do not have a representation of the energy-momentum tensor.

In this article we exhibit a general construction of a *universal* Hamiltonian formalism (which contains all previously known formalisms, which explains the appelation *universal*) and define the generalized Poisson $\mathfrak{p}$-brackets, the analogs of the Poisson bracket on forms, as defined in Refs. 16 and 17. We formulate the equations of motion of forms in terms of those $\mathfrak{p}$-brackets. The main focus in this construction is on the role of Legendre correspondence and the hypothesis concerning the generalized Legendre condition. We want to emphasize here that in our formalism there is no need of the decomposition into ''vertical'' and ''horizontal'' parts thanks to the use of Eq. (17), which is much more enlightened than Eq. (15). This implies Theorems 2 and 3. On the other hand, the energy-momentum tensor is clearly represented and the Hamiltonian formulation of Maxwell's electrodynamics, for instance, is properly given.

In Sec. II we establish the Hamiltonian formalism: the Euler–Lagrange equations, Legendre's correspondence (and the generalized Legendre condition) and Hamilton's equations. In fact, we

recover the Hamilton's equations using three different approaches: (a) as necessary and sufficient conditions for the existence of a critical point $u:\mathcal{X}\to\mathcal{Y}$, (b) by contracting the *pataplectic* form Ω with any n-vector $X\in\Lambda^n T_{(q,p)}\mathcal{M}$ where $\mathcal{M}=\Lambda^n T^\star(\mathcal{X}\times\mathcal{Y})$ and for any $(q,p)\in\mathcal{M}$ and, finally, (c) by variational formulation, i.e., as the Euler–Lagrange equations of some simple functional. In Sec. III we review the usual approach to quantum field theory from the standard canonical viewpoint and *pataplectic* geometry point of view where we express the various brackets using an analog of the Poisson brackets, the Poisson $\mathfrak{p}$-brackets, defined on $(n-1)$-forms. In Sec. III D we give a dynamical formulation for the $(n-1)$-forms in terms of $\mathfrak{p}$-brackets with the n-form $\mathcal{H}\omega$.

In Sec. IV, and after introducing the internal and external $\mathfrak{p}$-brackets, we generalize the definition of $\mathfrak{p}$-bracket on $(n-1)$-forms to a class of forms of an arbitrary degrees $0\leqslant p\leqslant n$ using anticommuting (Grassmann) variables $\tau_1,\ldots,\tau_n$, which behave under change of coordinates like $\partial/\partial x^1,\ldots,\partial/\partial x^n$. Notice also that the generalized Poisson bracket obtained here differs from the one proposed in Refs. 16 and 17 for forms of degree lower than $n-1$. In particular, one of our results is that these p-forms are composed basically of "position" observables unless we have some gauge symmetry and constraints. Then we can represent some "momentum" observable by a p-form with $p\leqslant n$ (in Sec. V C we study the electromagnetic field which is an instance of such a situation). Finally, in Sec. V we present three examples: the interacting scalar fields, conformal string theory and the electromagnetic field.

II. CONSTRUCTION OF THE HAMILTONIAN FORMALISM

In this section we show how to build a universal Hamiltonian formalism for variational problems involving a Lagrangian functional depending on first derivatives, and that for the case of maps between two manifolds. We derive it through a universal Legendre correspondence.

A. Notations

Let $\mathcal{X}$ and $\mathcal{Y}$ be two differentiable manifolds. $\mathcal{X}$ plays the role of the space–time manifold and $\mathcal{Y}$ is the target manifold. We fix some volume form ω on $\mathcal{X}$. This volume form may be chosen according to the variational problem that we want to study (for instance, if we look at the Klein–Gordon functional on some pseudo-Riemannian manifold, we choose ω to be the Riemannian volume), but in more general situation with less symmetries we just choose some arbitrary volume form. We set $n=\dim\mathcal{X}$ and $k=\dim\mathcal{Y}$. We denote $\{x^1,\ldots,x^n\}$ local coordinates on $\mathcal{X}$ and $\{y^1,\ldots,y^k\}$ local coordinates on $\mathcal{Y}$. For simplicity we shall assume that the coordinates x^α are always chosen such that $dx^1\wedge\cdots\wedge dx^n=\omega$, though it is not essential. Then on the product $\mathcal{X}\times\mathcal{Y}$ we denote $\{q^1,\ldots,q^{n+k}\}$ local coordinates in such a way that

$$q^\mu=x^\alpha \quad \text{if } 1\leqslant\mu=\alpha\leqslant n,$$

$$q^\mu=y^i \quad \text{if } n+1\leqslant\mu\leqslant n+k \text{ and } i=\mu-n.$$

Generally we shall denote the indices running from 1 to n by $\alpha,\beta,\ldots$, the indices between 1 and k by $i,j,\ldots$, and the indices between 1 and $n+k$ by $\mu,\nu,\ldots$. To any map $u:\mathcal{X}\to\mathcal{Y}$ we may associate the map

$$U:\mathcal{X}\to\mathcal{X}\times\mathcal{Y},$$

$$x\mapsto(x,u(x)),$$

whose image is the graph of u, $\{(x,u(x))/x\in\mathcal{X}\}$. We also associate to u the bundle $u^\star T\mathcal{Y}\otimes_{\mathcal{X}}T^\star\mathcal{X}$ over $\mathcal{X}$. This bundle is naturally equipped with the coordinates $(x^\alpha)_{1\leqslant\alpha\leqslant n}$ (for $\mathcal{X}$) and $(v^i_\alpha)_{1\leqslant i\leqslant k;1\leqslant\alpha\leqslant n}$, such that a point $(x,v)\in u^\star T\mathcal{Y}\otimes_{\mathcal{X}}T^\star\mathcal{X}$ is represented by

$$v=\sum_{\alpha=1}^{n}\sum_{i=1}^{k}v^i_\alpha\frac{\partial}{\partial y^i}\otimes dx^\alpha.$$

We can think $u^\star T\mathcal{Y}\otimes_{\mathcal{X}} T^\star\mathcal{X}$ as a subset of $T\mathcal{Y}\otimes_{\mathcal{X}\times\mathcal{Y}} T^\star\mathcal{X}:=\{(x,y,v)/(x,y)\in\mathcal{X}\times\mathcal{Y}, v\in T_y\mathcal{Y}\otimes T_x^\star\mathcal{X}\}$ by the inclusion map $(x,v)\mapsto(x,u(x),v)$.

The differential of u, du is a section of the bundle $u^\star T\mathcal{Y}\otimes_{\mathcal{X}} T^\star\mathcal{X}$ over $\mathcal{X}$. Hence the coordinates for du are simply $v_\alpha^i=\partial u^i/\partial x^\alpha$. Notice that $u^\star T\mathcal{Y}\otimes_{\mathcal{X}} T^\star\mathcal{X}$ is an analog of the tangent bundle $T\mathcal{Y}$ to a configuration space $\mathcal{Y}$ in classical particle mechanics.

It turns out to be more convenient to consider $\Lambda^n T(\mathcal{X}\times\mathcal{Y})$ the analog of $T(\mathbb{R}\times\mathcal{Y})$, the tangent bundle to a space–time, or rather $S\Lambda^n T(\mathcal{X}\times\mathcal{Y})$, the submanifold of $\Lambda^n T(\mathcal{X}\times\mathcal{Y})$, as the analog of the subset $ST(\mathbb{R}\times\mathcal{Y}):=\{(t,x;\xi^0,\vec{\xi})\in T(\mathbb{R}\times\mathcal{Y})/dt(\xi^0,\vec{\xi})=1\}$, which is diffeomorphic to $\mathbb{R}\times T\mathcal{Y}$ by the map $(t,x,\xi)\mapsto(t,x,\vec{\xi})$, and where

$$S\Lambda^n T(\mathcal{X}\times\mathcal{Y}):=\{(q,z)\in\Lambda^n T(\mathcal{X}\times\mathcal{Y})/z=z_1\wedge\cdots\wedge z_n, z_1,\ldots,z_n\in T_q(\mathcal{X}\times\mathcal{Y}), \omega(z_1,\ldots,z_n)=1\}.$$

For any $(x,y)\in\mathcal{X}\times\mathcal{Y}$, the fiber $S\Lambda^n T_{(x,y)}(\mathcal{X}\times\mathcal{Y})$ can be identified with $T_y\mathcal{Y}\otimes T_x^\star\mathcal{X}$ by the diffeomorphism

$$\begin{aligned} &T_y\mathcal{Y}\otimes T_x^\star\mathcal{X}\to S\Lambda^n T_{(x,y)}(\mathcal{X}\times\mathcal{Y}),\\ &v=\sum_{\alpha=1}^{n}\sum_{i=1}^{k} v_\alpha^i\frac{\partial}{\partial y^i}\otimes dx^\alpha\mapsto z=z_1\wedge\cdots\wedge z_n, \end{aligned} \tag{1}$$

where for all $1\leqslant\beta\leqslant n$, $z_\beta=\partial/\partial x^\alpha+\Sigma_{i=1}^k v_\alpha^i\,\partial/\partial y^i$. We denote by $(z_\alpha^\mu)_{1\leqslant\mu\leqslant n+k;1\leqslant\alpha\leqslant n}$ the coordinates of z_α, so that $z_\beta=\Sigma_{\mu=1}^{n+k} z_\alpha^\mu\,\partial/\partial q^\mu$ (or $z_\alpha^\beta=\delta_\alpha^\beta$ for $1\leqslant\beta\leqslant n$ and $z_\alpha^{n+i}=v_\alpha^i$ for $1\leqslant i\leqslant k$). This induces an identification $T\mathcal{Y}\otimes_{\mathcal{X}\times\mathcal{Y}} T^\star\mathcal{X}\simeq S\Lambda^n T(\mathcal{X}\times\mathcal{Y})$.

Thus coordinates $(x^\alpha,y^i,v_\alpha^i)$ [or equivalentely $(x^\alpha,y^i,z_\alpha^\mu)$] can be thought as coordinate on $T\mathcal{Y}\otimes_{\mathcal{X}\times\mathcal{Y}} T^\star\mathcal{X}$ or $S\Lambda^n T(\mathcal{X}\times\mathcal{Y})$.

Given a Lagrangian function $L: T\mathcal{Y}\otimes_{\mathcal{X}\times\mathcal{Y}} T^\star\mathcal{X}\mapsto\mathbb{R}$, we define the functional

$$\mathcal{L}[u]:=\int_{\mathcal{X}} L(x,u(x),du(x))dx.$$

B. The Euler–Lagrange equations

The critical points of the action are the maps $u:\mathcal{X}\to\mathcal{Y}$ which are solutions of the system of Euler–Lagrange equations

$$\frac{\partial}{\partial x^\alpha}\left(\frac{\partial L}{\partial v_\alpha^i}(x,u(x),du(x))\right)=\frac{\partial L}{\partial y^i}(x,u(x),du(x)). \tag{2}$$

This equation implies also other equations involving the *stress-energy* tensor associated to $u:\mathcal{X}\to\mathcal{Y}$:

$$S_\beta^\alpha(x):=\delta_\beta^\alpha L(x,u(x),du(x))-\frac{\partial L}{\partial v_\alpha^i}(x,u(x),du(x))\,\frac{\partial u^i}{\partial x^\beta}(x).$$

Indeed, for any u,

$$\frac{\partial S^\alpha_\beta}{\partial x^\alpha}(x)=\delta^\alpha_\beta\left(\frac{\partial L}{\partial x^\alpha}(x,u,du)+\frac{\partial L}{\partial y^i}(x,u,du)\,\frac{\partial u^i}{\partial x^\alpha}(x)+\frac{\partial L}{\partial v^i_\gamma}(x,u,du)\,\frac{\partial^2 u^i}{\partial x^\alpha\partial x^\gamma}(x)\right)$$
$$-\frac{\partial}{\partial x^\alpha}\left(\frac{\partial L}{\partial v^i_\alpha}(x,u,du)\right)\frac{\partial u^i}{\partial x^\beta}(x)-\frac{\partial L}{\partial v^i_\alpha}(x,u,du)\,\frac{\partial^2 u^i}{\partial x^\alpha\partial x^\beta}(x)$$
$$=\frac{\partial L}{\partial x^\beta}(x,u,du)-\left[\frac{\partial}{\partial x^\alpha}\left(\frac{\partial L}{\partial v^i_\alpha}(x,u(x),du(x))\right)-\frac{\partial L}{\partial y^i}(x,u(x),du(x))\right]\frac{\partial u^i}{\partial x^\beta}(x).$$

Thus we conclude that if u is a solution of (2), then

$$\frac{\partial S^\alpha_\beta}{\partial x^\alpha}(x)=\frac{\partial L}{\partial x^\beta}(x,u,du). \tag{3}$$

It follows that if L does not depend on x, then S^α_β is divergence-free for all solutions of (2), a property which can be predicted by Noether's theorem.

C. The Legendre correspondence

Let $\mathcal{M}:=\Lambda^n T^\star(\mathcal{X}\times\mathcal{Y})$. Every point $(q,p)\in\mathcal{M}$ has coordinates q^μ and $p_{\mu_1\dots\mu_n}$ such that $p_{\mu_1\dots\mu_n}$ is completely antisymmetric in $(\mu_1,\dots,\mu_n)$ and

$$p=\sum_{\mu_1<\dots<\mu_n} p_{\mu_1\dots\mu_n}dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_n}.$$

We shall define a Legendre correspondence

$$S\Lambda^n T(\mathcal{X}\times\mathcal{Y})\times\mathbb{R}\leftrightarrow\mathcal{M}=\Lambda^n T^\star(\mathcal{X}\times\mathcal{Y}),$$

$$(q,v,w)\leftrightarrow(q,p),$$

where $w\in\mathbb{R}$ is some extra parameter (its significance is not clear for the moment, w is related to the possibility of fixing arbitrarily the value of some Hamiltonian). Notice that we do not name it a transform, like in the classical theory, but a correspondence, since generally there will be many possible values of (q,p) corresponding to a single value of (q,v,w). But we expect that, in generic situations, there corresponds a unique (q,v,w) to some (q,p). This correspondence is generated by the function

$$W:S\Lambda^n T(\mathcal{X}\times\mathcal{Y})\times\mathcal{M}\to\mathbb{R},\quad (q,v,p)\mapsto\langle p,v\rangle-L(q,v),$$

where

$$\langle p,v\rangle\simeq\langle p,z\rangle:=\langle p,z_1\wedge\cdots\wedge z_n\rangle=\sum_{\mu_1,\dots,\mu_n} p_{\mu_1\dots\mu_n}z_1^{\mu_1}\cdots z_n^{\mu_n}.$$

Definition 1: We *write that* $(q,v,w)\leftrightarrow(q,p)$ *if and only if*

$$L(q,v)+w=\langle p,v\rangle\quad\text{or}\quad W(q,v,p)=w \tag{4}$$

and

$$\frac{\partial L}{\partial v^i_\alpha}(q,v)=\frac{\partial\langle p,v\rangle}{\partial v^i_\alpha}=\left\langle p,z_1\wedge\cdots\wedge z_{\alpha-1}\wedge\frac{\partial}{\partial y^i}\wedge z_{\alpha+1}\wedge\cdots\wedge z_n\right\rangle\quad\text{or}\frac{\partial W}{\partial v^i_\alpha}(q,v,p)=0. \tag{5}$$

Notice that for any $(q,v,w)\in S\Lambda^n T(\mathcal{X}\times\mathcal{Y})\times\mathbb{R}$ there exist $(q,p)\in\mathcal{M}$ such that $(q,v,w)\leftrightarrow(q,p)$. This will be proven in Sec. II F. But (q,p) is not unique in general. In the following we shall need to suppose that the inverse correspondence is well-defined.

Hypothesis: Generalized Legendre condition: *There exists an open subset $\mathcal{O}\subset\mathcal{M}$ which is nonempty such that for any $(q,p)\in\mathcal{O}$ there exists a unique $v\in T_x\mathcal{Y}\otimes T_y^\star\mathcal{X}$ [or equivalentely a unique $z\in S\Lambda^n T_q(\mathcal{X}\times\mathcal{Y})$] which is a critical point of $v\mapsto W(q,v,p)$. We denote $v=\mathcal{V}(q,p)$ this unique solution (or $z=\mathcal{Z}(q,p)$). We assume further that $\mathcal{V}$ is a smooth function on $\mathcal{O}$ (or the same for $\mathcal{Z}$).*

We now suppose that this hypothesis is true. Then we can define on $\mathcal{O}$ the following Hamiltonian function:

$$\mathcal{H}:\mathcal{O}\to\mathbb{R},$$

$$(q,p)\mapsto\langle p,\mathcal{V}(q,p)\rangle-L(q,\mathcal{V}(q,p))=W(q,\mathcal{V}(q,p),p).$$

We then remark that (4) is equivalent to $w=\mathcal{H}(q,p)$.

We now compute the differential of $\mathcal{H}$. The main point is to exploit the condition

$$\frac{\partial W}{\partial v_\alpha^i}(q,\mathcal{V}(q,p),p)=0 \tag{6}$$

(which defines $\mathcal{V}$):

$$\begin{aligned}d\mathcal{H}=&\sum_\mu\frac{\partial W}{\partial q^\mu}(q,\mathcal{V}(q,p),p)dq^\mu+\sum_{\mu,\nu}\sum_\alpha\frac{\partial W}{\partial v_\alpha^\nu}(q,\mathcal{V}(q,p),p)\frac{\partial\mathcal{V}_\alpha^\nu}{\partial q^\mu}dq^\mu\\&+\sum_{\nu,\alpha}\sum_{\mu_1<\cdots<\mu_n}\frac{\partial W}{\partial v_\alpha^\nu}(q,\mathcal{V}(q,p),p)\frac{\partial\mathcal{V}_\alpha^\nu}{\partial p_{\mu_1\cdots\mu_n}}dp_{\mu_1\cdots\mu_n}\\&+\sum_{\mu_1<\cdots<\mu_n}\frac{\partial W}{\partial p_{\mu_1\cdots\mu_n}}(q,\mathcal{V}(q,p),p)dp_{\mu_1\cdots\mu_n}\\=&\sum_\mu\frac{\partial W}{\partial q^\mu}(q,\mathcal{V}(q,p),p)dq^\mu+\sum_{\mu_1<\cdots<\mu_n}\frac{\partial W}{\partial p_{\mu_1\cdots\mu_n}}(q,\mathcal{V}(q,p),p)dp_{\mu_1\cdots\mu_n}.\end{aligned}$$

Now since

$$\frac{\partial W}{\partial q^\mu}(q,v,p)=-\frac{\partial L}{\partial q^\mu}(q,v)$$

and

$$\frac{\partial W}{\partial p_{\mu_1\cdots\mu_n}}(q,v,p)=\begin{vmatrix}z_1^{\mu_1}&\cdots&z_n^{\mu_1}\\\vdots&&\vdots\\z_1^{\mu_n}&\cdots&z_n^{\mu_n}\end{vmatrix},$$

we get

$$d\mathcal{H}=-\sum_\mu\frac{\partial L}{\partial q^\mu}(q,\mathcal{V}(q,p))dq^\mu+\sum_{\mu_1<\cdots<\mu_n}\mathcal{Z}_{1\cdots n}^{\mu_1\cdots\mu_n}(q,p)dp_{\mu_1\cdots\mu_n}, \tag{7}$$

where

$$\mathcal{Z}_{1\ldots n}^{\mu_1\cdots\mu_n}(q,p) := \begin{vmatrix} \mathcal{Z}_1^{\mu_1}(q,p) & \ldots & \mathcal{Z}_n^{\mu_1}(q,p) \\ \vdots & & \vdots \\ \mathcal{Z}_1^{\mu_n}(q,p) & \ldots & \mathcal{Z}_n^{\mu_n}(q,p) \end{vmatrix}$$

are the components of the n-vector

$$\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p) = \sum_{\mu_1<\cdots<\mu_n} \mathcal{Z}_{1\ldots n}^{\mu_1\cdots\mu_n}(q,p)\,\frac{\partial}{\partial q^{\mu_1}}\wedge\cdots\wedge\frac{\partial}{\partial q^{\mu_n}}.$$

To conclude let us see how the stress-energy tensor appears in this Hamiltonian setting. We define the Hamiltonian tensor on $\mathcal{C}$ to be $H(q,p)=\Sigma_{\alpha,\beta}H_\beta^\alpha(q,p)\,\partial/\partial x^\alpha\otimes dx^\beta$, with

$$H_\beta^\alpha(q,p) := \frac{\partial L}{\partial v_\alpha^i}(q,\mathcal{V}(q,p))\mathcal{V}_\beta^i(q,p) - \delta_\beta^\alpha L(q,\mathcal{V}(q,p)).$$

It is clear that if $(x,u(x),du(x),w)\leftrightarrow(q,p)$, then

$$H_\beta^\alpha(q,p) = -S_\beta^\alpha(x).$$

Let us now compute $H_\beta^\alpha(q,p)$. We first use (5):

$$\begin{aligned}
&\sum_i \frac{\partial L}{\partial v_\alpha^i}(q,\mathcal{V}(q,p))\mathcal{V}_\beta^i(q,p) \\
&\quad= \sum_i \frac{\partial\langle p,v\rangle}{\partial v_\alpha^i}_{|v=\mathcal{V}(q,p)}\mathcal{V}_\beta^i(q,p) \\
&\quad= \sum_i \left\langle p,\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_{\alpha-1}(q,p)\wedge\frac{\partial}{\partial y^i}\wedge\mathcal{Z}_{\alpha+1}(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p)\right\rangle\mathcal{V}_\beta^i(q,p) \\
&\quad= \sum_\mu \left\langle p,\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_{\alpha-1}(q,p)\wedge\frac{\partial}{\partial q^\mu}\wedge\mathcal{Z}_{\alpha+1}(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p)\right\rangle\mathcal{Z}_\beta^\mu(q,p) \\
&\qquad- \left\langle p,\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_{\alpha-1}(q,p)\wedge\frac{\partial}{\partial x^\beta}\wedge\mathcal{Z}_{\alpha+1}(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p)\right\rangle \\
&\quad= \langle p,\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_{\alpha-1}(q,p)\wedge\mathcal{Z}_\beta(q,p)\wedge\mathcal{Z}_{\alpha+1}(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p)\rangle \\
&\qquad- \left\langle p,\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_{\alpha-1}(q,p)\wedge\frac{\partial}{\partial x^\beta}\wedge\mathcal{Z}_{\alpha+1}(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p)\right\rangle \\
&\quad= \delta_\beta^\alpha\langle p,\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p)\rangle \\
&\qquad\times\left\langle p,\mathcal{Z}_1(q,p)\wedge\cdots\wedge\mathcal{Z}_{\alpha-1}(q,p)\wedge\frac{\partial}{\partial x^\beta}\wedge\mathcal{Z}_{\alpha+1}(q,p)\wedge\cdots\wedge\mathcal{Z}_n(q,p)\right\rangle.
\end{aligned}$$

Hence since

$$\langle p, \mathcal{Z}_1(q,p) \wedge \ldots \wedge \mathcal{Z}_n(q,p) \rangle = \mathcal{H}(q,p) + L(q, \mathcal{V}(q,p)),$$

$$H^\alpha_\beta(q,p) = \delta^\alpha_\beta \mathcal{H}(q,p) - \left\langle p, \mathcal{Z}_1(q,p) \wedge \cdots \ \mathcal{Z}_{\alpha-1}(q,p) \wedge \frac{\partial}{\partial x^\beta} \wedge \mathcal{Z}_{\alpha+1}(q,p) \cdots \ \wedge \mathcal{Z}_n(q,p) \right\rangle$$

$$= \delta^\alpha_\beta \mathcal{H}(q,p) - \frac{\partial \langle p,z \rangle}{\partial z^\beta_\alpha}_{|z=\mathcal{Z}(q,p)}. \tag{8}$$

D. Hamilton equations

Let $x \mapsto (q(x),p(x))$ be some map from $\mathcal{X}$ to $\mathcal{O}$. To insure that this map is related to a critical point $u: \mathcal{X} \to \mathcal{Y}$, we find that the necessary and sufficient conditions split in two parts:

(1) *What are the conditions on* $x \mapsto (q(x),p(x))$ *for the existence of a map* $x \mapsto u(x)$ *such that* $(x,u(x),du(x)) \leftrightarrow (q(x),p(x))$?

The first obvious condition is $q(x) = (x,u(x)) = U(x)$. The second condition is that in $T\mathcal{Y} \otimes T^\star\mathcal{X}$, $(x,y,v^i_\alpha) = (x,y,\partial u^i/\partial x^\alpha)$ coincides with $(q(x), \mathcal{V}^i_\alpha(q(x),p(x)))$. If we translate that using (1), we obtain that in $S\Lambda^n T(\mathcal{X} \times \mathcal{Y})$,

$$\frac{\partial q}{\partial x^1} \wedge \ \cdots \wedge \frac{\partial q}{\partial x^n} = \frac{\partial U}{\partial x^1} \wedge \ \cdots \wedge \frac{\partial U}{\partial x^n} = \mathcal{Z}_1(q(x),p(x)) \wedge \ \cdots \wedge \mathcal{Z}_n(q(x),p(x)).$$

But we found in (7) that the components in the basis $(\partial/\partial q^{\mu_1} \wedge \cdots \wedge \partial/\partial q^{\mu_n})$ of the right-hand side are $\mathcal{Z}^{\mu_1 \ldots \mu_n}_{1 \ldots n}(q(x),p(x)) = \partial \mathcal{H}/\partial p_{\mu_1 \ldots \mu_n}(q(x),p(x))$. Hence denoting

$$\frac{\partial(q^{\mu_1}, \ldots, q^{\mu_n})}{\partial(x^1, \ldots, x^n)} := \begin{vmatrix} \dfrac{\partial q^{\mu_1}}{\partial x^1} & \cdots & \dfrac{\partial q^{\mu_1}}{\partial x^n} \\ \vdots & & \vdots \\ \dfrac{\partial q^{\mu_n}}{\partial x^1} & \cdots & \dfrac{\partial q^{\mu_n}}{\partial x^n} \end{vmatrix},$$

so that

$$\frac{\partial q}{\partial x^1} \wedge \cdots \wedge \frac{\partial q}{\partial x^n} = \sum_{\mu_1 < \ldots < \mu_n} \frac{\partial(q^{\mu_1}, \ldots, q^{\mu_n})}{\partial(x^1, \ldots, x^n)} \frac{\partial}{\partial q^{\mu_1}} \wedge \cdots \wedge \frac{\partial}{\partial q^{\mu_n}},$$

we obtain the condition

$$\frac{\partial(q^{\mu_1}, \ldots, q^{\mu_n})}{\partial(x^1, \ldots, x^n)}(x) = \frac{\partial \mathcal{H}}{\partial p_{\mu_1 \ldots \mu_n}}(q(x),p(x)). \tag{9}$$

(2) *Now what are the conditions on* $x \mapsto (q(x),p(x))$ *for* u *to be a solution of the Euler–Lagrange equations*?

It amounts to eliminating u in (2) in function of (q,p). For that purpose we use (5) to derive

$$\begin{aligned}
&\sum_\alpha \frac{\partial}{\partial x^\alpha}\left\langle \frac{\partial L}{\partial v^i_\alpha}(x,u(x),du(x))\right\rangle\\
&\quad=\sum_\alpha \frac{\partial}{\partial x^\alpha}\left\langle p,\frac{\partial U}{\partial x^1}\wedge\cdots\wedge\frac{\partial U}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial y^i}\wedge\frac{\partial U}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial U}{\partial x^n}\right\rangle\\
&\quad=\sum_\alpha \left\langle \frac{\partial p}{\partial x^\alpha},\frac{\partial U}{\partial x^1}\wedge\cdots\wedge\frac{\partial U}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial y^i}\wedge\frac{\partial U}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial U}{\partial x^n}\right\rangle\\
&\qquad+\sum_{\alpha\neq\beta}\left\langle p,\frac{\partial U}{\partial x^1}\wedge\cdots\wedge\frac{\partial^2 U}{\partial x^\alpha\partial x^\beta}\wedge\cdots\wedge\frac{\partial U}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial y^i}\wedge\frac{\partial U}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial U}{\partial x^n}\right\rangle\\
&\quad=\sum_\alpha \left\langle \frac{\partial p}{\partial x^\alpha},\frac{\partial U}{\partial x^1}\wedge\cdots\wedge\frac{\partial U}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial y^i}\wedge\frac{\partial U}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial U}{\partial x^n}\right\rangle.
\end{aligned}$$

On the other hand, we know from (7) that $(\partial\mathcal{H}/\partial q^i)(q,p)=-(\partial L/\partial q^i)(q,\mathcal{V}(q,p))$. Thus we obtain

$$\sum_\alpha \left\langle \frac{\partial p}{\partial x^\alpha},\frac{\partial q}{\partial x^1}\wedge\cdots\wedge\frac{\partial q}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial y^i}\wedge\frac{\partial q}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial q}{\partial x^n}\right\rangle=-\frac{\partial\mathcal{H}}{\partial q^i}(q(x),p(x)). \tag{10}$$

The latter equation may be transformed using the relation

$$\begin{aligned}
&\sum_\alpha \left\langle \frac{\partial p}{\partial x^\alpha},\frac{\partial q}{\partial x^1}\wedge\cdots\wedge\frac{\partial q}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial y^i}\wedge\frac{\partial q}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial q}{\partial x^n}\right\rangle\\
&\quad=\sum_\alpha \sum_{\substack{\mu_1<\cdots<\mu_n\\ \mu_\alpha=n+i}}\begin{vmatrix}
\frac{\partial q^{\mu_1}}{\partial x^1} & \cdots & \frac{\partial q^{\mu_1}}{\partial x^n}\\
\vdots & & \vdots\\
\frac{\partial q^{\mu_{\alpha-1}}}{\partial x^1} & \cdots & \frac{\partial q^{\mu_{\alpha-1}}}{\partial x^n}\\
\frac{\partial p_{\mu_1\cdots\mu_n}}{\partial x^1} & \cdots & \frac{\partial p_{\mu_1\cdots\mu_n}}{\partial x^n}\\
\frac{\partial q^{\mu_{\alpha+1}}}{\partial x^1} & \cdots & \frac{\partial q^{\mu_{\alpha+1}}}{\partial x^n}\\
\vdots & & \vdots\\
\frac{\partial q^{\mu_n}}{\partial x^1} & \cdots & \frac{\partial q^{\mu_n}}{\partial x^n}
\end{vmatrix}\\
&\quad=\sum_\alpha \sum_{\substack{\mu_1<\cdots<\mu_n\\ \mu_\alpha=n+i}}\frac{\partial(q^{\mu_1},\ldots,q^{\mu_{\alpha-1}},p_{\mu_1\cdots\mu_n},q^{\mu_{\alpha+1}},\ldots,q^{\mu_n})}{\partial(x^1,\ldots,x^n)}.
\end{aligned}$$

We summarize: the necessary and sufficient conditions we were looking for are

$$\frac{\partial(q^{\mu_1},\ldots,q^{\mu_n})}{\partial(x^1,\ldots,x^n)}=\frac{\partial\mathcal{H}}{\partial p_{\mu_1\ldots\mu_n}}(q,p),$$
$$\sum_\alpha \sum_{\substack{\mu_1<\cdots<\mu_n\\ \mu_\alpha=n+i}} \frac{\partial(q^{\mu_1},\ldots,q^{\mu_{\alpha-1}},p_{\mu_1\ldots\mu_n},q^{\mu_{\alpha+1}},\ldots,q^{\mu_n})}{\partial(x^1,\ldots,x^n)}=-\frac{\partial\mathcal{H}}{\partial y^i}(q,p). \tag{11}$$

Some further relations: Besides these equations, we have to remark also that Eq. (3) on the stress-energy tensor has a counterpart in this formalism. For that purpose we use Eq. (8). Assuming that $(x,u(x),du(x))\leftrightarrow(q(x),p(x))$, we have

$$\begin{aligned}-\frac{\partial S^\alpha_\beta}{\partial x^\alpha}(x)&=\frac{\partial H^\alpha_\beta(q(x),p(x))}{\partial x^\alpha}\\ &=\frac{\partial\mathcal{H}(q(x),p(x))}{\partial x^\beta}-\frac{\partial}{\partial x^\alpha}\left\langle p(x),\frac{\partial q(x)}{\partial x^1}\wedge\cdots\wedge\frac{\partial q(x)}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial x^\beta}\wedge\frac{\partial q(x)}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial q(x)}{\partial x^n}\right\rangle\\ &=\frac{\partial\mathcal{H}(q(x),p(x))}{\partial x^\beta}-\left\langle\frac{\partial p(x)}{\partial x^\alpha},\frac{\partial q(x)}{\partial x^1}\wedge\cdots\wedge\frac{\partial q(x)}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial x^\beta}\wedge\frac{\partial q(x)}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial q(x)}{\partial x^n}\right\rangle.\end{aligned}$$

Now assume that u is a critical point. Then, because of (3) and (7),

$$\frac{\partial S^\alpha_\beta}{\partial x^\alpha}(x)=\frac{\partial L}{\partial x^\beta}(x,u(x),du(x))=-\frac{\partial\mathcal{H}}{\partial x^\beta}(q(x),p(x)),$$

and we obtain

$$\left\langle\frac{\partial p}{\partial x^\alpha},\frac{\partial q}{\partial x^1}\wedge\cdots\wedge\frac{\partial q}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial x^\beta}\wedge\frac{\partial q}{\partial x^{\alpha+1}}\wedge\cdots\wedge\frac{\partial q}{\partial x^n}\right\rangle-\frac{\partial}{\partial x^\beta}(\mathcal{H}(q,p))=-\frac{\partial\mathcal{H}}{\partial x^\beta}(q,p)$$

or equivalently

$$\sum_\alpha\sum_{\substack{\mu_1<\ldots<\mu_n\\ \mu_\alpha=\beta}}\frac{\partial(q^{\mu_1},\ldots,q^{\mu_{\alpha-1}},p_{\mu_1\ldots\mu_n},q^{\mu_{\alpha+1}},\ldots,q^{\mu_n})}{\partial(x^1,\ldots,x^n)}-\frac{\partial}{\partial x^\beta}(\mathcal{H}(q,p))=-\frac{\partial\mathcal{H}}{\partial x^\beta}(q,p). \tag{12}$$

Conclusion: The Hamilton equations (11) can be completed by adding (12) [which are actually a consequence of (11)]. We thus obtain

$$\frac{\partial(q^{\mu_1},\ldots,q^{\mu_n})}{\partial(x^1,\ldots,x^n)}=\frac{\partial\mathcal{H}}{\partial p_{\mu_1\ldots\mu_n}}(q,p),$$
$$\sum_\alpha\sum_{\substack{\mu_1<\cdots<\mu_n\\ \mu_\alpha=\nu}}\frac{\partial(q^{\mu_1},\ldots,q^{\mu_{\alpha-1}},p_{\mu_1\ldots\mu_n},q^{\mu_{\alpha+1}},\ldots,q^{\mu_n})}{\partial(x^1,\ldots,x^n)}-\sum_\alpha\delta^\alpha_\nu\frac{\partial}{\partial x^\alpha}(\mathcal{H}(q,p))$$
$$=-\frac{\partial\mathcal{H}}{\partial q^\nu}(q,p). \tag{13}$$

E. The Cartan–Poincaré and pataplectic forms on $\mathcal{M}=\Lambda^nT^*(\mathcal{X}\times\mathcal{Y})$

Motivated by the previous contruction, we define the Cartan–Poincaré form on $\Lambda^nT^*(\mathcal{X}\times\mathcal{Y})$ to be

$$\theta := \sum_{\mu_1 < \ldots < \mu_n} p_{\mu_1 \ldots \mu_n} dq^{\mu_1} \wedge \ldots \wedge dq^{\mu_n}.$$

Its differential is

$$\Omega := \sum_{\mu_1 < \ldots < \mu_n} dp_{\mu_1 \ldots \mu_n} \wedge dq^{\mu_1} \wedge \ldots \wedge dq^{\mu_n},$$

which we will call the *pataplectic form*, a straightforward generalization of the symplectic form.

A first property is that we can express the system of Hamilton's equations (13) in an elegant way using Ω. For any $(q,p) \in \mathcal{M}$ and any n-vector $X \in \Lambda^n T_{(q,p)}\mathcal{M}$ we define $X \rfloor \Omega \in T^\star_{(q,p)}\mathcal{M}$ as follows. If X is decomposable, i.e., if there exist n vectors $X_1, \ldots, X_n \in T_{(q,p)}\mathcal{M}$ such that $X = X_1 \wedge \ldots \wedge X_n$, we let

$$X \rfloor \Omega(V) := \Omega(X_1, \ldots, X_n, V), \quad \forall V \in T_{(q,p)}\mathcal{M}.$$

We extend this definition to non-decomposable X by linearity. Let us analyze $X \rfloor \Omega$ using coordinates. Writing X as

$$\sum_{\mu_1 < \ldots < \mu_n} X^{\mu_1 \ldots \mu_n} \partial_{\mu_1} \wedge \ldots \wedge \partial_{\mu_n}$$

$$+ \sum_{\substack{\mu_1 < \ldots < \mu_{\alpha-1} < \mu_{\alpha+1} < \ldots < \mu_n \\ \nu_1 < \ldots < \nu_n}} X^{\mu_1 \ldots \mu_{\alpha-1} \{\nu_1 \ldots \nu_n\} \mu_{\alpha+1} \ldots \mu_n} \partial_{\mu_1}$$

$$\wedge \cdots \wedge \partial_{\mu_{\alpha-1}} \wedge \partial^{\nu_1 \ldots \nu_n} \wedge \partial_{\mu_{\alpha+1}} \wedge \cdots \wedge \partial_{\mu_n} + \quad \text{etc.},$$

with the notations $\partial_\mu := \partial/\partial q^\mu$, $\partial^{\nu_1 \ldots \nu_n} := \partial/\partial p_{\nu_1 \ldots \nu_n}$, we have

$$X \rfloor \Omega = (-1)^n \left[\sum_{\mu_1 < \ldots < \mu_n} X^{\mu_1 \ldots \mu_n} dp_{\mu_1 \ldots \mu_n} \right.$$

$$\left. - \sum_\nu \sum_\alpha \sum_{\substack{\mu_1 < \ldots < \mu_n \\ \mu_\alpha = \nu}} X^{\mu_1 \ldots \mu_{\alpha-1} \{\mu_1 \ldots \mu_n\} \mu_{\alpha+1} \ldots \mu_n} dq^\nu \right].$$

Algebraic similarities with (13) are evident if we replace X by $\partial(q,p)/\partial(x^1, \ldots, x^n) := \partial(q,p)/\partial x^1 \wedge \cdots \wedge \partial(q,p)/\partial x^n$. In particular we can see easily that the coefficients of dy^i and $dp_{\mu_1 \ldots \mu_n}$ in $(-1)^n \partial(q,p)/\partial(x^1, \ldots, x^n) \rfloor \Omega$ and $d\mathcal{H}$ coincide if and only if the Hamilton system (11) holds. Thus we are led to define $\mathcal{I}$ to be the algebraic ideal in $\Lambda^\star \mathcal{M}$ spanned by $\{dx^1, \ldots, dx^n\}$ and hence (11) is equivalent to

$$(-1)^n \frac{\partial(q,p)}{\partial(x^1, \ldots, x^n)} \rfloor \Omega = d\mathcal{H} \mod \mathcal{I}. \tag{14}$$

Definition 2: An n-vector $X \in \Lambda^n T_{(q,p)}\mathcal{M}$ is $\mathcal{H}$-Hamiltonian if and only if

$$(-1)^n X \rfloor \Omega = d\mathcal{H} \mod \mathcal{I}. \tag{15}$$

For such an X, it is possible to precise the relation between the left- and right-hand sides of (15) in the case where X is decomposable, i.e., $X = X_1 \wedge \cdots \wedge X_n$. Notice that (15) implies in

particular $X^{1\cdots n}=\partial\mathcal{H}/\partial\epsilon=1$ [where $\epsilon:=p_{1\cdots n}$, see (13)], which is equivalent to $\omega(X_1,\ldots,X_n)=1$. Hence we may always assume without loss of generality that the X_α are chosen so that $dx^\beta(X_\alpha)=\delta^\beta_\alpha$. Such vectors are unique.

Lemma 1: Let $X=X_1\wedge\cdots\wedge X_n\in\Lambda^n T_{(q,p)}\mathcal{M}$ *such that* $dx^\beta(X_\alpha)=\delta^\beta_\alpha$. *Then* X *is* $\mathcal{H}$*-Hamiltonian if and only if one of the two following relations is satisfied:*

$$(-1)^n X\rfloor\Omega=d\mathcal{H}-\sum_\alpha d\mathcal{H}(X_\alpha)dx^\alpha \tag{16}$$

or

$$X\rfloor(\Omega-d(\mathcal{H}\omega))=0. \tag{17}$$

Proof: Let us prove first that (15) implies (16). Since for any α, β, $dx^\beta(X_\alpha-\partial/\partial x^\alpha)=0$, Eq. (15) implies that for all α,

$$\begin{aligned}(-1)^n X\rfloor\Omega\left(X_\alpha-\frac{\partial}{\partial x^\alpha}\right)=d\mathcal{H}\left(X_\alpha-\frac{\partial}{\partial x^\alpha}\right)&\Leftrightarrow(-1)^n\Omega\left(X_1,\ldots,X_n,X_\alpha-\frac{\partial}{\partial x^\alpha}\right)\\&=d\mathcal{H}(X_\alpha)-\frac{\partial\mathcal{H}}{\partial x^\alpha}\Leftrightarrow(-1)^n X\rfloor\Omega\left(\frac{\partial}{\partial x^\alpha}\right)=\frac{\partial\mathcal{H}}{\partial x^\alpha}-d\mathcal{H}(X_\alpha).\end{aligned}$$

This implies

$$(-1)^n\sum_\alpha X\rfloor\Omega\left(\frac{\partial}{\partial x^\alpha}\right)dx^\alpha=\sum_\alpha\frac{\partial\mathcal{H}}{\partial x^\alpha}dx^\alpha-\sum_\alpha d\mathcal{H}(X_\alpha)dx^\alpha. \tag{18}$$

Now if we rewrite (15) as

$$\begin{aligned}&(-1)^n\left(\sum_i X\rfloor\Omega\left(\frac{\partial}{\partial y^i}\right)dy^i+\sum_{\mu_1<\cdots<\mu_n}X\rfloor\Omega\left(\frac{\partial}{\partial p_{\mu_1\cdots\mu_n}}\right)dp_{\mu_1\cdots\mu_n}\right)\\&=\sum_i\frac{\partial\mathcal{H}}{\partial y^i}dy^i+\sum_{\mu_1<\cdots<\mu_n}\frac{\partial\mathcal{H}}{\partial p_{\mu_1\cdots\mu_n}}dp_{\mu_1\cdots\mu_n},\end{aligned}$$

and sum with (18), we obtain exactly (16).

Now relation (17) is equivalent to (16) because of the following calculation. For all vector V and for any decomposable n-vector $X=X_1\wedge\cdots\wedge X_n\in\Lambda^n T_{(q,p)}\mathcal{M}$ such that $dx^\beta(X_\alpha)=\delta^\beta_\alpha$ (not necessarily $\mathcal{H}$-Hamiltonian), we have

$$\begin{aligned}X\rfloor d(\mathcal{H}\omega)(V)&=d\mathcal{H}\wedge\omega(X_1,\ldots,X_n,V)\\&=\sum_\alpha(-1)^{\alpha-1}d\mathcal{H}(X_\alpha)\omega(X_1,\ldots,X_{\alpha-1},X_{\alpha+1},\ldots,X_n,V)\\&\quad+(-1)^n d\mathcal{H}(V)\omega(X_1,\ldots,X_n,V)\\&=\sum_\alpha(-1)^{n-1}d\mathcal{H}(X_\alpha)dx^\alpha(V)+(-1)^n d\mathcal{H}(V),\end{aligned}$$

thus

$$X\rfloor d(\mathcal{H}\omega)=(-1)^n\left(d\mathcal{H}-\sum_\alpha d\mathcal{H}(X_\alpha)dx^\alpha\right)$$

and (16) $\Leftrightarrow$ (17). Conversely, it is obvious that (16) and (17) implies (15). ■

As a Corollary of this result we deduce that a reformulation of (14) is

$$\frac{\partial(q,p)}{\partial(x^1,\ldots,x^n)}\rfloor\Omega=\frac{\partial(q,p)}{\partial(x^1,\ldots,x^n)}\rfloor(d\mathcal{H}\wedge\omega). \tag{19}$$

It is an exercise to check that actually this relation is a direct translation of (13).

F. A variational formulation of (13)

We shall now prove that Eqs. (13) are the Euler–Lagrange equations of some simple functional. For that purpose, let Γ be an oriented submanifold of dimension n in $\Lambda^n T^\star(\mathcal{X}\times\mathcal{Y})$ such that $\omega_{|\Gamma}>0$ everywhere. Then we define the functional

$$\mathcal{A}[\Gamma]:=\int_\Gamma \theta-\lambda\mathcal{H}(q,p)\omega.$$

Here λ is a (real) scalar function defined over Γ which plays the role of a Lagrange multiplier. We now characterize submanifolds Γ which are critical points of $\mathcal{A}$.

1. Variations with respect to p

Let δp be some infinitesimal variation of Γ with compact support. We compute

$$\delta\mathcal{A}_\Gamma(\delta p)=\int_\Gamma \delta p_{\mu_1\ldots\mu_n}\left(dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_n}-\lambda\frac{\partial\mathcal{H}}{\partial p_{\mu_1\ldots\mu_n}}\omega\right).$$

Assuming that this vanishes for all δp, we obtain

$$(dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_n})_{|\Gamma}=\lambda\frac{\partial\mathcal{H}}{\partial p_{\mu_1\ldots\mu_n}}\omega_{|\Gamma}.$$

This relation means that for any orientation preserving parametrization $(t^1,\ldots,t^n)\mapsto(q,p)\times(t^1,\ldots,t^n)$ of Γ,

$$\frac{\partial(q^{\mu_1},\ldots,q^{\mu_n})}{\partial(t^1,\ldots,t^n)}=\lambda\frac{\partial\mathcal{H}}{\partial p_{\mu_1\ldots\mu_n}}\omega\left(\frac{\partial q^{\mu_1}}{\partial t^1},\ldots,\frac{\partial q^{\mu_n}}{\partial t^n}\right).$$

But we remark that because $\partial\mathcal{H}/\partial p_{1\ldots n}=1$, the above relation for $(\mu_1,\ldots,\mu_n)=(1,\ldots,n)$ forces $\lambda=1$. Hence

$$\mathcal{A}[\Gamma]=\int_\Gamma \theta-\mathcal{H}(q,p)\omega.$$

Moreover, the equation obtained here can be written using the natural parametrization $(x^1,\ldots,x^n)\mapsto(x,u(x),p(x))$ [for which $\omega(\partial/\partial x^1,\ldots,\partial/\partial x^n)=1$] and then we obtain

$$\frac{\partial q}{\partial x^1}\wedge\cdots\wedge\frac{\partial q}{\partial x^n}=\frac{\partial\mathcal{H}}{\partial p}(q,p),$$

i.e., exactly Eq. (9). [Note that this relation actually implies $\mathcal{A}[\Gamma]=\int_\mathcal{X} L(x,q,dq)\omega$. Hence, as in the one-dimensional Hamilton formalism, $\theta-\mathcal{H}\omega$ plays the role of the Lagrangian density.]

2. Variations with respect to q

Now δq is some infinitesimal variation of Γ with compact support. And we have

$$\delta\mathcal{A}_\Gamma(\delta q)=\int_\Gamma \sum_{\mu_1<\ldots<\mu_n}\sum_\alpha p_{\mu_1\ldots\mu_n} dq^{\mu_1}\wedge\cdots\wedge d(\delta q^{\mu_\alpha})\wedge\cdots\wedge dq^{\mu_n} - \sum_\mu \frac{\partial\mathcal{H}}{\partial q^\mu}\delta q^\mu\omega-\mathcal{H}(q,p)\,\delta\omega.$$

We pay special attention to $\delta\omega$:

$$\delta\omega=d(\delta x^1)\wedge\cdots\wedge dx^n+\cdots+dx^1\wedge\cdots\wedge d(\delta x^n).$$

Hence

$$\int_\Gamma \mathcal{H}(q,p)\,\delta\omega=-\int_\Gamma \delta x^1(d(\mathcal{H}(q,p))\wedge\cdots\wedge dx^n)+\cdots+\delta x^n(dx^1\wedge\cdots\wedge d(\mathcal{H}(q,p)))$$

$$=-\sum_\alpha \delta x^\alpha\frac{\partial}{\partial x^\alpha}(\mathcal{H}(q,p))\omega.$$

Thus after integrations by parts, we obtain

$$\delta\mathcal{A}_\Gamma(\delta q)=\int_\Gamma -\sum_{\mu_1<\ldots<\mu_n}\sum_\alpha \delta q^{\mu_\alpha} dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_{\alpha-1}}\wedge dp_{\mu_1\ldots\mu_n}\wedge dq^{\mu_{\alpha+1}}\wedge\cdots\wedge dq^{\mu_n} - \sum_\mu\frac{\partial\mathcal{H}}{\partial q^\mu}\delta q^\mu\omega+\sum_\alpha \delta x^\alpha\frac{\partial}{\partial x^\alpha}(\mathcal{H}(q,p))\omega.$$

And this vanishes if and only if

$$\sum_\alpha \sum_{\substack{\mu_1<\cdots<\mu_n\\ \mu_\alpha=\nu}} dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_{\alpha-1}}\wedge dp_{\mu_1\ldots\mu_n}\wedge dq^{\mu_{\alpha+1}}\wedge\cdots\wedge dq^{\mu_n}-\sum_\alpha \delta^\alpha_\nu\frac{\partial}{\partial x^\alpha}(\mathcal{H}(q,p))\omega$$

$$=-\frac{\partial\mathcal{H}}{\partial q^\nu}\omega.$$

Again by choosing the parametrization $(x^1,\ldots,x^n)\mapsto(x,u(x),p(x))$, this relation is easily seen to be equivalent to (10) and (12).

By the same token we have proven that if we look to critical points of the functional $\int_\Gamma\theta$ with the constraint $\mathcal{H}(q,p)=h$, for some constant h, then the Lagrange multiplier is 1 and they satisfy the same equations.

Theorem 1: *Let Γ be an oriented submanifold of dimension n in $\Lambda^n T^\star(\mathcal{X}\times\mathcal{Y})$ such that $\Omega_{|\Gamma}>0$ everywhere. Then the three following assertions are equivalent*

(i) Γ *is the graph of a solution of the generalized Hamilton equations (13).*
(ii) Γ *is a critical point of the functional* $\int_\Gamma\theta-\mathcal{H}(q,p)\omega$.
(iii) Γ *is a critical point of the functional* $\int_\Gamma\theta$ *under the constraint that* $\mathcal{H}(q,p)$ *is constant.*

G. Some particular cases

By restricting the variables (q,p) to lie in some submanifold of $\mathcal{M}=\Lambda^n T^\star(\mathcal{X}\times\mathcal{Y})$, the Legendre correspondence becomes in some situations a true map.

(a) We assume that all components $p_{\mu_1,\ldots\mu_n}$ vanished except for

$$p_{1\ldots n}=:\epsilon \quad \text{and} \quad p_{1\ldots(\alpha-1)(n+i)(\alpha+1)\ldots n}=:p_i^\alpha$$

and all obvious permutations in the indices. This defines a submanifold $\mathcal{M}_{\text{Weyl}}$ of $\mathcal{M}$. It means that

$$\theta_{|\mathcal{M}_{\text{Weyl}}}=\epsilon dx^1\wedge\cdots\wedge dx^n+\sum_\alpha\sum_i p_i^\alpha dx^1\wedge\cdots\wedge dx^{\alpha-1}\wedge dy^i\wedge dx^{\alpha+1}\wedge\cdots\wedge dx^n.$$

Then for any $(q,p)\in\mathcal{M}_{\text{Weyl}}$, $\langle p,z_1\wedge\cdots\wedge z_n\rangle=\epsilon+\Sigma_\alpha\Sigma_i p_i^\alpha v^i_\alpha$, $W(q,v,p)=\epsilon+\Sigma_\alpha\Sigma_i p_i^\alpha v^i_\alpha - L(q,v)$. Hence the relation (5) $(\partial W/\partial v^i_\alpha)(q,v)=0$ is equivalent to

$$p_i^\alpha=\frac{\partial L}{\partial v^i_\alpha}(q,v)\Leftrightarrow v^i_\alpha=\mathcal{V}^i_\alpha(q,p).$$

The relation (4) $W(q,v,p)=w$ gives

$$\epsilon=w+L(q,v)-\sum_\alpha\sum_i\frac{\partial L}{\partial v^i_\alpha}(q,v)v^i_\alpha.$$

Last we have that $\mathcal{H}(q,p)=\epsilon+\Sigma_\alpha\Sigma_i p_i^\alpha\mathcal{V}^i_\alpha(q,p)-L(q,\mathcal{V}(q,p))$.

This example shows that for any $(q,v,w)\in S\Lambda^nT(\mathcal{X}\times\mathcal{Y})\times\mathbb{R}$, there exist $(q,p)\in\mathcal{M}$ such that $(q,v,w)\leftrightarrow(q,p)$ and this (q,p) is unique if it is chosen in $\mathcal{M}_{\text{Weyl}}$.

To summarize, we recover the Weyl theory (see Refs. 4 and 10). As an exercise, the reader can check that in this situation, Eqs. (11) are equivalent to

$$\frac{\partial y^i}{\partial x^\alpha}=\frac{\partial\mathcal{H}}{\partial p_i^\alpha},\quad \sum_\alpha\frac{\partial p_i^\alpha}{\partial x^\alpha}=-\frac{\partial\mathcal{H}}{\partial y^i}. \tag{20}$$

(b) We assume that (q,p) are such that there exist coefficients $(\pi^\alpha_\mu)_{\alpha,\mu}$ with

$$p_{\mu_1\ldots\mu_n}=\begin{vmatrix}\pi^1_{\mu_1} & \cdots & \pi^1_{\mu_n}\\ \vdots & & \vdots\\ \pi^n_{\mu_1} & \cdots & \pi^n_{\mu_n}\end{vmatrix}.$$

This constraint defines a submanifold $\mathcal{M}_{\text{Carathéodory}}$ of $\mathcal{M}$. Then

$$\theta_{|\mathcal{M}_{\text{Carathéodory}}}=\left(\sum_{\mu_1}\pi^1_{\mu_1}dq^{\mu_1}\right)\wedge\cdots\wedge\left(\sum_{\mu_n}\pi^1_{\mu_n}dq^{\mu_n}\right).$$

Then it is an exercise to see that, by choosing $w=0$, it leads to the formalism developed in Refs. 4 and 10 associated to the Carathéodory theory of equivalent integrals. However, it is not clear in general whether it is possible to perform the Legendre transform in this setting by being able to fix arbitrarily the value of w. It is so if we do not impose a condition on w (see Ref. 10).

III. COMPARISON WITH THE USUAL HAMILTONIAN FORMALISM FOR QUANTUM FIELDS THEORY

A. Reminder of the usual approach to quantum field theory

Here we compare the preceeding construction with the classical approach to quantum field theory by so-called canonical quantization. We shall first explore it in the case where $\mathcal{X}$ is the Minkowski space $\mathbb{R}\times\mathbb{R}^{n-1}$ and $y=\phi$ is a real scalar field. Hence $\mathcal{Y}=\mathbb{R}$. Our functional is

$$\mathcal{L}[\phi]:=\int_{\mathbb{R}\times\mathbb{R}^{n-1}}L(x,\phi,d\phi)dx.$$

For simplicity, we may keep in mind the following example of a Lagrangian:

$$\int_{\mathbb{R}\times\mathbb{R}^{n-1}} L(x,\phi,d\phi)dx = \int_{\mathbb{R}\times\mathbb{R}^{n-1}} \left(\frac{1}{2}\left(\frac{\partial\phi}{\partial x^0}\right)^2 - \frac{1}{2}\sum_{\alpha=1}^{n-1}\left(\frac{\partial\phi}{\partial x^\alpha}\right)^2 - V(\phi)\right) dx^0 d\vec{x},$$

where we denote $\vec{x}=(x^\alpha)_{1\leqslant\alpha\leqslant n-1}$. We shall also denote $t=x^0$.

The usual approach consists in selecting a global time coordinate t as we already implicitly assumed here. Then for each time the instantaneous state of the field is seen as a point in the infinite dimensional "manifold" $\mathfrak{F}:=\{\Phi:\mathbb{R}^{n-1}\to\mathbb{R}\}$. Hence we view the field ϕ rather as a path:

$$\mathbb{R}\to\mathfrak{F},$$

$$t\mapsto[\vec{x}\mapsto\phi(t,\vec{x})=\Phi^{\vec{x}}(t)].$$

We thus recover the problem of studying the dynamics of a point moving in a configuration space $\mathfrak{F}$. The prices to pay are (1) $\mathfrak{F}$ is infinite dimensional and (2) we lose relativistic invariance.

In this viewpoint, $\mathcal{L}[\phi]=\int_{\mathbb{R}}\mathfrak{L}[t,\Phi(t),(d\Phi/dt)(t)]dt$, where $\Phi(t)=[\vec{x}\mapsto\phi(t,\vec{x})]\in\mathfrak{F}$, $(d\Phi/dt)(t)=[\vec{x}\mapsto\partial\phi/\partial t(t,\vec{x})]\in T_{\Phi(t)}\mathfrak{F}$ and $\mathfrak{L}[t,\Phi(t),(d\Phi/dt)(t)]=\int_{\mathbb{R}^{n-1}}L(x,\phi(x),d\phi(x))d\vec{x}$.

Then we consider the "symplectic" manifold which is formally $T^\star\mathfrak{F}$, i.e., we introduce the dual variable

$$\Pi:=\frac{\partial\mathfrak{L}}{\partial(d\Phi/dt)},$$

or equivalently $\Pi(t)=[\vec{x}\mapsto\pi(t,\vec{x})=\Pi_{\vec{x}}(t)]$ with

$$\Pi_{\vec{x}}(t)=\frac{\partial\mathfrak{L}}{\partial d\Phi^{\vec{x}}/dt}[t,\Phi(t),(d\Phi/dt)(t)]\Leftrightarrow\pi(t,\vec{x})$$

$$=\frac{\delta\mathfrak{L}}{\delta(\partial\phi(t,\vec{x})/\partial t)}[t,\Phi(t),(d\Phi/dt)(t)]=\frac{\partial L}{\partial v_0}(x,\phi(x),d\phi(x)).$$

Here $\delta/\delta\phi(\vec{x})$ is the Fréchet derivative. In our example

$$\Pi_{\vec{x}}(t)=\frac{\partial\phi}{\partial t}(t,\vec{x}).$$

We define the Hamiltonian functional to be

$$\mathfrak{H}[\Phi,\Pi]:=\int_{\mathbb{R}^{n-1}}\Pi_{\vec{x}}\dot{\Phi}^{\vec{x}}d\vec{x}-\mathfrak{L}[t,\Phi,(d\Phi/dt)]=\int_{\mathbb{R}^{n-1}}\left(\frac{1}{2}\pi(\vec{x})^2+\frac{1}{2}|\nabla\phi(\vec{x})|^2+V(\phi(\vec{x}))\right)d\vec{x}.$$

Now we can write the equations of motion as

$$\frac{\partial\pi}{\partial t}(t,\vec{x})=\frac{d\Pi_{\vec{x}}}{dt}=-\frac{\partial\mathfrak{H}}{\partial\Phi^{\vec{x}}}(\Phi,\Pi)=\Delta\phi-V'(\phi),$$

$$\frac{\partial\phi}{\partial t}(t,\vec{x})=\frac{d\Phi^{\vec{x}}}{dt}=\frac{\partial\mathfrak{H}}{\partial\Pi^{\vec{x}}}(\Phi,\Pi)=\pi(t,\vec{x}).$$

A Poisson bracket can be defined on the set of functionals $\{A:T^\star\mathfrak{F}\mapsto\mathbb{R}\}$ by

$$\{A,B\}:=\int_{\mathbb{R}^{n-1}}\left(\frac{\delta A}{\delta\pi(\vec{x})}\frac{\delta B}{\delta\phi(\vec{x})}-\frac{\delta A}{\delta\phi(\vec{x})}\frac{\delta B}{\delta\pi(\vec{x})}\right)d\vec{x},$$

where $\delta A/\delta\phi(\vec{x})$ is the Fréchet derivative with respect to $\phi(\vec{x})$, i.e., the distribution such that for any smooth compactly supported deformation $\delta\phi$ of ϕ,

$$dA_\phi[\,\delta\phi]=\int_{\mathbb{R}^{n-1}}\delta\phi(\vec{x})\frac{\delta A}{\delta\phi(\vec{x})}d\vec{x}.$$

And we may formulate the dynamical equations using the Poisson bracket as

$$\frac{d\Pi_{\vec{x}}}{dt}=\{\mathfrak{H},\Pi_{\vec{x}}\},$$

$$\frac{d\Phi^{\vec{x}}}{dt}=\{\mathfrak{H},\Phi^{\vec{x}}\},$$

with

$$\{\Phi^{\vec{x}},\Phi^{\vec{x}'}\}=\{\Pi_{\vec{x}},\Pi_{\vec{x}'}\}=0,\quad\{\Pi_{\vec{x}},\Phi^{\vec{x}'}\}=\delta_{\vec{x}}^{\vec{x}'}=\delta^{n-1}(\vec{x}-\vec{x}').$$

This singular Poisson bracket means that for any test functions $f,\ g\in\mathcal{C}_c^\infty(\mathbb{R}^{n-1},\mathbb{R})$,

$$\left\{\int_{\mathbb{R}^{n-1}}g(\vec{x})\Pi_{\vec{x}}d\vec{x},\int_{\mathbb{R}^{n-1}}f(\vec{x}')\Phi^{\vec{x}'}d\vec{x}'\right\}=\int_{\mathbb{R}^{n-1}}f(\vec{x})g(\vec{x})d\vec{x}.$$

This implies in particular

$$\left\{\int_{\mathbb{R}^{n-1}}g(\vec{x})\Pi_{\vec{x}}d\vec{x},\int_{\mathbb{R}^{n-1}}f(\vec{x}')V(\Phi^{\vec{x}'})d\vec{x}'\right\}=\int_{\mathbb{R}^{n-1}}V'(\Phi^{\vec{x}})f(\vec{x})g(\vec{x})d\vec{x},$$

because of the derivation property of the Poisson bracket.

B. Translation in pataplectic geometry

We first adapt and modify our notations: the coordinates on $\mathcal{M}=\Lambda^nT^\star(\mathbb{R}\times\mathbb{R}^{n-1}\times\mathbb{R})$ are now written $(q^\mu,p_{\mu_1\ldots\mu_n})=(x^\alpha,y,\epsilon,p^\alpha)$ where $0\leqslant\alpha\leqslant n-1$, $q^0=x^0=t$, $(x^\alpha)_{1\leqslant\alpha\leqslant n-1}=\vec{x}$, $q^n=y$ and

$$\epsilon:=p_{0\ldots(n-1)},\quad p^\alpha:=p_{0\ldots(\alpha-1)n(\alpha+1)\ldots(n-1)}.$$

Hence

$$\theta=\epsilon dx^0\wedge\cdots\wedge dx^{n-1}+\sum_{\alpha=0}^{n-1}p^\alpha dx^0\wedge\cdots\wedge dx^{\alpha-1}\wedge dy\wedge dx^{\alpha+1}\wedge\cdots\wedge dx^{n-1},$$

or letting $\omega:=dx^0\wedge\cdots\wedge dx^{n-1}$ and $\omega_\alpha:=(-1)^\alpha dx^0\wedge\cdots\wedge dx^{\alpha-1}\wedge dx^{\alpha+1}\wedge\cdots\wedge dx^{n-1}=\frac{\partial}{\partial x^\alpha}\rfloor\omega$,

$$\theta=\epsilon\omega+\sum_{\alpha=0}^{n-1}p^\alpha dy\wedge\omega_\alpha\quad\text{and}\quad\Omega=d\epsilon\wedge\omega+\sum_{\alpha=0}^{n-1}dp^\alpha\wedge dy\wedge\omega_\alpha.$$

Thus we see that in the present case the pataplectic formalism reduces essentially to the Weyl formalism, because the fields are one dimensional.

Let us consider some field ϕ and a map $x \mapsto p(x)$ such that $(x,\phi(x),d\phi(x)) \leftrightarrow (x,\phi(x),p(x))$ [meaning that for some w: $\mathbb{R}\times\mathbb{R}^{n-1}\to\mathbb{R}$, we have $(x,\phi(x),d\phi(x),w(x)) \leftrightarrow (x,\phi(x),p(x))$]. This implies the following relations:

$$p^\alpha = \frac{\partial L}{\partial v_\alpha}(x,\phi(x),d\phi(x)) \quad \text{and} \quad \epsilon = w + L(x,\phi(x),d\phi(x)) - \sum_{\alpha=0}^{n-1} p^\alpha \frac{\partial \phi}{\partial x^\alpha}(x).$$

We let $\Gamma := \{(x,\phi(x),p(x))/x \in \mathbb{R}\times\mathbb{R}^{n-1}\} \subset \mathcal{M}$ and we consider the instantaneous slices $S_t := \Gamma \cap \{x^0 = t\}$. These slices are oriented by the condition $\partial/\partial t \rfloor \omega_{|S_t} > 0$. Then we can express the observables

$$\Phi^f(t) := \int_{\mathbb{R}^{n-1}} f(\vec{x})\Phi^{\vec{x}}(t)d\vec{x}, \quad \Pi_g(t) := \int_{\mathbb{R}^{n-1}} g(\vec{x})\Pi_{\vec{x}}(t)d\vec{x}$$

and

$$\mathfrak{H}[\Phi(t),\Pi(t)] = \int_{\mathbb{R}^{n-1}} \left(\pi(t,\vec{x})\frac{\partial \phi}{\partial t}(t,\vec{x}) - L(t,\vec{x},\phi(x),d\phi(x)) \right) d\vec{x} = \int_{\mathbb{R}^{n-1}} H_0^0(t,\vec{x},\phi)\,\omega_0$$

as integrals of $(n-1)$-forms on S_t. First

$$\Phi^f(t) = \int_{S_t} f(\vec{x})\phi(t,\vec{x})dx^1\wedge\cdots\wedge dx^{n-1} = \int_{S_t} Q^f, \quad \text{with } Q^f := f(\vec{x})y\,\omega_0,$$

$$\Pi_g(t) = \int_{S_t} g(\vec{x})\pi(t,\vec{x})dx^1\wedge\cdots\wedge dx^{n-1} = \int_{S_t} P_g, \quad \text{with } P_g := g(\vec{x})\sum_{\alpha=0}^{n-1} p^\alpha \omega_\alpha,$$

because $\pi(t,\vec{x}) = \partial L/\partial v_0(x,\phi(x),d\phi(x)) = p^0$ and $\omega_{\alpha|S_t} = 0$ if $\alpha \geqslant 1$.

And, finally,

$$\mathfrak{H}[\Phi(t),\Pi(t)] = \int_{\mathbb{R}^{n-1}} \mathcal{H}(q,p)\,\omega_0 - \int_{\mathbb{R}^{n-1}} \epsilon\omega_0 + \sum_{\alpha=1}^{n-1} p^\alpha dy \wedge \left(\frac{\partial}{\partial x^\alpha} \rfloor \omega_0 \right) = \int_{S_t} \eta_0,$$

where

$$\eta_0 := \mathcal{H}(q,p)\,\omega_0 - \left(\epsilon\omega_0 + \sum_{\alpha=1}^{n-1} p^\alpha dx^1\wedge\cdots\wedge dx^{\alpha-1}\wedge dy\wedge dx^{\alpha+1}\wedge\cdots\wedge dx^{n-1} \right),$$

because $H_0^0(x,\phi) = \mathcal{H}(q,p) - \langle p, \partial/\partial t \wedge z_1 \wedge\cdots\wedge z_{n-1}\rangle = \mathcal{H}(q,p) - (\epsilon + \Sigma_{\alpha=1}^{n-1} p^\alpha \partial\phi/\partial x^\alpha)$.

We remark that

$$\eta_0 = -\frac{\partial}{\partial t} \rfloor (\theta - \mathcal{H}(q,p)\omega).$$

[We observe also that $P_g = g(\vec{x})\partial/\partial y \rfloor \theta = g(\vec{x})\partial/\partial y \rfloor (\theta - \mathcal{H}(q,p)\omega)$.]

C. Recovering the usual Poisson brackets as a local expression

Our aim is now to express the various Poisson brackets involving the quantities $\Phi^f(t)$ and $\Pi_g(t)$ along Γ using some analog of the Poisson bracket defined on $(n-1)$-forms. We generalize slightly the definition of Q^f to be

$$Q^f = \sum_{\alpha=0}^{n-1} f^\alpha(x) y \omega_\alpha, \tag{21}$$

where $f := \Sigma_{\alpha=0}^{n-1} f^\alpha(x)\, \partial/\partial x^\alpha$ is some vector field. Hence our observables become

$$\Phi^f(t) = \int_{S_t} Q^f \quad \text{and} \quad \Pi_g(t) = \int_{S_t} P_g, \tag{22}$$

where $P_g := g(x) \Sigma_{\alpha=0}^{n-1} p^\alpha \omega_\alpha$ as before. [Notice that actually $\int_{S_t} Q^f = \int_{S_t} f^0(x) y \omega_0$.] We shall see here that we can define a bracket operation $\{.,.\}$ between Q^f, P_g and η_0 such that the usual Poisson bracket of fields actually derives from $\{.,.\}$ by

$$\int_{S_t} \{P_g, Q^f\} = \left\{ \int_{S_t} P_g, \int_{S_t} Q^f \right\}, \text{ etc.} \tag{23}$$

First we remark that

$$dQ^f = \sum_{\alpha=0}^{n-1} f^\alpha dy \wedge \omega_\alpha + \sum_{\alpha=0}^{n-1} y \frac{\partial f^\alpha}{\partial x^\alpha} \omega = \sum_{\alpha=0}^{n-1} f^\alpha \frac{\partial}{\partial p^\alpha} \rfloor \Omega + \sum_{\alpha=0}^{n-1} y \frac{\partial f^\alpha}{\partial x^\alpha} \frac{\partial}{\partial \epsilon} \rfloor \Omega = -\xi_{Qf} \rfloor \Omega$$

and

$$dP_g = \sum_{\alpha=0}^{n-1} p^\alpha \frac{\partial g}{\partial x^\alpha} \omega + \sum_{\alpha=0}^{n-1} g\, dp^\alpha \wedge \omega_\alpha = \sum_{\alpha=0}^{n-1} p^\alpha \frac{\partial g}{\partial x^\alpha} \frac{\partial}{\partial \epsilon} \rfloor \Omega - g \frac{\partial}{\partial y} \rfloor \Omega = -\xi_{P_g} \rfloor \Omega,$$

where

$$\xi_{Qf} := -\sum_{\alpha=0}^{n-1} f^\alpha \frac{\partial}{\partial p^\alpha} - y \sum_{\alpha=0}^{n-1} \frac{\partial f^\alpha}{\partial x^\alpha} \frac{\partial}{\partial \epsilon} \tag{24}$$

and

$$\xi_{P_g} := g \frac{\partial}{\partial y} - \sum_{\alpha=0}^{n-1} p^\alpha \frac{\partial g}{\partial x^\alpha} \frac{\partial}{\partial \epsilon}. \tag{25}$$

Also notice that

$$d\eta_0 = (d\mathcal{H} - d\epsilon) \wedge \omega_0 - \sum_{\alpha=1}^{n-1} dp^\alpha \wedge dy \wedge \left(\frac{\partial}{\partial x^\alpha} \rfloor \omega_0 \right).$$

Definition 3: We define the Poisson $\mathfrak{p}$*-brackets of these* $(n-1)$*-forms to be*

$$\{\eta_0, Q^f\} := -\xi_{Qf} \rfloor d\eta_0, \quad \{\eta_0, P_g\} := -\xi_{P_g} \rfloor d\eta_0,$$

$$\{P_g, Q^f\} := -\xi_{Qf} \rfloor dP_g = \xi_{P_g} \rfloor dQ^f = \xi_{Qf} \rfloor (\xi_{P_g} \rfloor \Omega),$$

and

$$\{Q^f, Q^{f'}\} := \xi_{Qf'} \rfloor (\xi_{Qf} \rfloor \Omega), \quad \{P_g, P_{g'}\} := \xi_{P_{g'}} \rfloor (\xi_{P_g} \rfloor \Omega).$$

Let us now compute these $\mathfrak{p}$-brackets. We use in particular the fact that $\partial\mathcal{H}/\partial\epsilon = 1$:

$$\{\eta_0,Q^f\}=\left(\sum_{\alpha=0}^{n-1} f^\alpha\frac{\partial}{\partial p^\alpha}+y\sum_{\alpha=0}^{n-1}\frac{\partial f^\alpha}{\partial x^\alpha}\frac{\partial}{\partial\epsilon}\right)\rfloor\left((d\mathcal{H}-d\epsilon)\wedge\omega_0-\sum_{\alpha=1}^{n-1} dp^\alpha\wedge dy\wedge\left(\frac{\partial}{\partial x^\alpha}\rfloor\omega_0\right)\right)$$
$$=\sum_{\alpha=0}^{n-1} f^\alpha\frac{\partial\mathcal{H}}{\partial p^\alpha}\omega_0-\sum_{\alpha=1}^{n-1} f^\alpha dy\wedge\left(\frac{\partial}{\partial x^\alpha}\rfloor\omega_0\right),$$

$$\{\eta_0,P_g\}=\left(\sum_{\alpha=0}^{n-1} p^\alpha\frac{\partial g}{\partial x^\alpha}\frac{\partial}{\partial\epsilon}-g\frac{\partial}{\partial y}\right)\rfloor\left((d\mathcal{H}-d\epsilon)\wedge\omega_0-\sum_{\alpha=1}^{n-1} dp^\alpha\wedge dy\wedge\left(\frac{\partial}{\partial x^\alpha}\rfloor\omega_0\right)\right)$$
$$=-g\frac{\partial\mathcal{H}}{\partial y}\omega_0-g\sum_{\alpha=1}^{n-1} dp^\alpha\wedge\left(\frac{\partial}{\partial x^\alpha}\rfloor\omega_0\right),$$

$$\{P_g,Q^f\}=\left(\sum_{\alpha=0}^{n-1} f^\alpha\frac{\partial}{\partial p_\alpha}+y\sum_{\alpha=0}^{n-1}\frac{\partial f^\alpha}{\partial x^\alpha}\frac{\partial}{\partial\epsilon}\right)\rfloor\left(\sum_{\alpha=0}^{n-1} p^\alpha\frac{\partial g}{\partial x^\alpha}\omega-g\frac{\partial}{\partial y}\rfloor\Omega\right)=g\sum_{\alpha=0}^{n-1} f^\alpha\omega_\alpha,$$

and $\{Q^f,Q^{f'}\}=\{P_g,P_{g'}\}=0$. We now integrate the $\mathfrak{p}$-brackets on a constant time slice $S_t\subset\Gamma$. We immediately see that

$$\int_{S_t}\{P_g,Q^f\}=\int_{S_t} g\,f^0\omega_0=\{\pi_g(t),\Phi^f(t)\}=\left\{\int_{S_t}P_g,\int_{S_t}Q^f\right\}$$

and we recover (23). Second,

$$\int_{S_t}\{\eta_0,Q^f\}=\int_{S_t}\sum_{\alpha=0}^{n-1} f^\alpha\frac{\partial\mathcal{H}}{\partial p^\alpha}\omega_0-\sum_{\alpha=1}^{n-1} f^\alpha\frac{\partial\phi}{\partial x^\alpha}\omega_0.$$

Third,

$$\int_{S_t}\{\eta_0,P_g\}=\int_{S_t}-g\frac{\partial\mathcal{H}}{\partial y}\omega_0-\sum_{\alpha=1}^{n-1} g\frac{\partial p^\alpha}{\partial x^\alpha}\omega_0.$$

Now let us assume that Γ is the graph of a solution of the Hamilton equations (11) or (20). Since then $\partial\phi/\partial x^\alpha=\partial\mathcal{H}/\partial p^\alpha$ along Γ,

$$\int_{S_t}\{\eta_0,Q^f\}=\int_{S_t} f^0\frac{\partial\phi}{\partial t}\omega_0,$$

and because of $-\partial\mathcal{H}/\partial y-\Sigma_{\alpha=1}^{n-1}\partial p^\alpha/\partial x^\alpha=\partial p^0/\partial t$,

$$\int_{S_t}\{\eta_0,P_g\}=\int_{S_t} g\frac{\partial p^0}{\partial t}\omega_0.$$

We conclude that

$$\frac{d}{dt}\int_{S_t}Q^f=\frac{d}{dt}\Phi^f(t)=\int_{S_t} f^0\frac{\partial\phi}{\partial t}\omega_0+\frac{\partial f^0}{\partial t}\phi\omega_0=\int_{S_t}\{\eta_0,Q^f\}+\Phi^{\partial f/\partial t}(t)$$

and

$$\frac{d}{dt}\int_{S_t}P_g=\frac{d}{dt}\Pi_g(t)=\int_{S_t} g\frac{\partial p^0}{\partial t}\omega_0+\frac{\partial g}{\partial t}p^0\omega_0=\int_{S_t}\{\eta_0,P_g\}+\Pi_{\partial g/\partial t}(t).$$

This has to be compared with the usual canonical equations for fields:

$$\frac{d}{dt}\int_{S_t} Q^f = \left\{ \int_{S_t} \eta_0, \int_{S_t} Q^f \right\} + \Phi^{\partial f/\partial t}(t) \qquad \text{and} \qquad \frac{d}{dt}\int_{S_t} P_g = \left\{ \int_{S_t} \eta_0, \int_{S_t} P_g \right\} + \Pi_{\partial g/\partial t}(t).$$

D. An alternative dynamical formulation using $\mathfrak{p}$-brackets

We can also define the $\mathfrak{p}$-bracket of an n-form with forms Q^f or P_g as given by (21) and (22). If ψ is such an n-form,

$$\{\psi, Q^f\} := -\xi_{Qf} \rfloor d\psi \qquad \text{and} \qquad \{\psi, P_g\} := -\xi_{P_g} \rfloor d\psi,$$

where (24) and (25) have been used. An important instance is for $\psi = \mathcal{H}\omega$:

$$\{\mathcal{H}\omega, Q^f\} = \sum_{\alpha=0}^{n-1} f^\alpha \frac{\partial \mathcal{H}}{\partial p^\alpha}\omega + \sum_{\alpha=0}^{n-1} y \frac{\partial f^\alpha}{\partial x^\alpha}\omega.$$

We shall integrate this $\mathfrak{p}$-bracket on $\Gamma_{t_1}^{t_2} := \{(q,p) \in \Gamma / t_1 < t < t_2\}$, where we still assume that Γ is the graph of a solution of the Hamilton equations (19). An integration by parts gives

$$\int_{\Gamma_{t_1}^{t_2}} \{\mathcal{H}\omega, Q^f\} = \int_{\partial\Gamma_{t_1}^{t_2}} \phi \sum_{\alpha=0}^{n-1} f^\alpha \omega_\alpha + \int_{\Gamma_{t_1}^{t_2}} \sum_{\alpha=0}^{n-1} f^\alpha \left(\frac{\partial \mathcal{H}}{\partial p^\alpha} - \frac{\partial \phi}{\partial x^\alpha} \right) \omega = \int_{\partial\Gamma_{t_1}^{t_2}} Q^f = \int_{S_{t_2}} Q^f - \int_{S_{t_1}} Q^f.$$

Similarly we find that

$$\{\mathcal{H}\omega, P_g\} = \sum_{\alpha=0}^{n-1} p^\alpha \frac{\partial g}{\partial x^\alpha}\omega - g\frac{\partial \mathcal{H}}{\partial y}\omega,$$

and thus

$$\int_{\Gamma_{t_1}^{t_2}} \{\mathcal{H}\omega, P_g\} = \int_{\partial\Gamma_{t_1}^{t_2}} \sum_{\alpha=0}^{n-1} g p^\alpha \omega_\alpha - \int_{\Gamma_{t_1}^{t_2}} g \left(\frac{\partial \mathcal{H}}{\partial y} + \sum_{\alpha=0}^{n-1} \frac{\partial p^\alpha}{\partial x^\alpha} \right) \omega = \int_{\partial\Gamma_{t_1}^{t_2}} P_g = \int_{S_{t_2}} P_g - \int_{S_{t_1}} P_g.$$

We are tempted to conclude that

$$\mathbf{d}Q^f = \{\mathcal{H}\omega, Q^f\} \quad \text{and} \quad \mathbf{d}P_g = \{\mathcal{H}\omega, P\},$$

where $\mathbf{d}$ is the differential along a graph Γ of a solution of the Hamilton equations (11). This is precisely what will be proven in the next section.

IV. POISSON $\mathfrak{p}$-BRACKETS FOR $(p-1)$-FORMS ON $\mathcal{M}$

We have seen on some examples that the Poisson bracket algebra of the classical field theory can actually be derived from brackets on $(n-1)$-forms which are integrated on constant time slices. Actually these constructions can be generalized in several ways.

A. $\mathfrak{p}$-brackets on $(n-1)$-forms

We turn back to $\mathcal{M} = \Lambda^n T^\star(\mathcal{X}\times\mathcal{Y})$ and to the notation of the previous section. Let $\Gamma(\mathcal{M}, \Lambda^{n-1}T^\star\mathcal{M})$ be the set of smooth $(n-1)$-forms on $\mathcal{M}$. We consider the subset $\mathfrak{P}^{n-1}\mathcal{M}$ of $\Gamma(\mathcal{M}, \Lambda^{n-1}T^\star\mathcal{M})$ of forms a such that there exists a vector field $\xi_a = \Xi(a)$ which satisfies the property

$$da = -\xi_a \rfloor \Omega.$$

Obviously $\Xi(a)$ depends only on a modulo exact forms and the map $a\mapsto\Xi(a)$ from $\mathfrak{P}^{n-1}\mathcal{M}$ to the set of vector fields induces a map on the quotient $\mathfrak{P}^{n-1}\mathcal{M}/C^{n-1}(\mathcal{M})$, where $C^{n-1}(\mathcal{M})$ is the set of closed $(n-1)$-forms. A property of vector fields $\Xi(a)$ is that there are infinitesimal symmetries of Ω, for

$$\mathcal{L}_{\Xi(a)}\Omega = d(\Xi(a)\rfloor\Omega) + \Xi(a)\rfloor d\Omega = -d\circ da = 0.$$

We shall denote $\mathfrak{pp}\mathcal{M}$ the set of pataplectic vector fields, i.e., vector fields X such that $X\rfloor\Omega$ is exact. Clearly $\Xi:\mathfrak{P}^{n-1}\mathcal{M}/C^{n-1}(\mathcal{M})\to\mathfrak{pp}\mathcal{M}$ is a vector space isomorphism.

Then we define the *internal* $\mathfrak{p}$-*bracket* on $\mathfrak{P}^{n-1}\mathcal{M}$ by

$$\{a,b\} := \Xi(b)\rfloor\Xi(a)\rfloor\Omega.$$

Lemma 2: For any $a,b\in\mathfrak{P}^{n-1}\mathcal{M}$,

$$d\{a,b\} = -[\Xi(a),\Xi(b)]\rfloor\Omega. \tag{26}$$

Proof: Let $\xi_a=\Xi(a)$ and $\xi_b=\Xi(b)$. Then denoting $\mathcal{L}_{\xi_a}$ the Lie derivative with respect to ξ_a,

$$\begin{aligned}[\xi_a,\xi_b]\rfloor\Omega &= \mathcal{L}_{\xi_a}(\xi_b)\rfloor\Omega = \mathcal{L}_{\xi_a}(\xi_b\rfloor\Omega) - \xi_b\rfloor\mathcal{L}_{\xi_a}(\Omega)\\ &= d(\xi_a\rfloor\xi_b\rfloor\Omega) + \xi_a\rfloor d(\xi_b\rfloor\Omega) - \xi_b\rfloor(d(\xi_a\rfloor\Omega) + \xi_a\rfloor d\Omega).\end{aligned}$$

But since $d\Omega = d(\xi_a\rfloor\Omega) = d(\xi_b\rfloor\Omega) = 0$, we find that $[\xi_a,\xi_b]\rfloor\Omega = d(\xi_a\rfloor\xi_b\rfloor\Omega) = -d\{a,b\}$. ■

Lemma 3: $\Xi:\mathfrak{P}^{n-1}\mathcal{M}/C^{n-1}(\mathcal{M})\to\mathfrak{pp}\mathcal{M}$ *is a Lie algebra isomorphism. More precisely we have*

$$\Xi(\{a,b\}) = [\Xi(a),\Xi(b)]. \tag{27}$$

This implies the Jacobi identity modulo exact terms in $\mathfrak{P}^{n-1}\mathcal{M}$*:*

$$\{\{a,b\},c\} + \{\{b,c\},a\} + \{\{c,a\},b\} = d(\xi_c\rfloor\xi_b\rfloor\xi_a\rfloor\Omega). \tag{28}$$

Proof: Relation (27) is a direct consequence of (26) in Lemma 2. The Jacobi identity follows from

$$\begin{aligned}\{\{a,b\},c\} = \xi_c\rfloor[\xi_a,\xi_b]\rfloor\Omega &= \xi_c\rfloor d(\xi_a\rfloor\xi_b\rfloor\Omega)\\ &= \mathcal{L}_{\xi_c}(\xi_a\rfloor\xi_b\rfloor\Omega) - d(\xi_c\rfloor\xi_a\rfloor\xi_b\rfloor\Omega)\\ &= [\xi_c,\xi_a]\rfloor\xi_b\rfloor\Omega + \xi_a\rfloor[\xi_c,\xi_b]\rfloor\Omega + \xi_a\rfloor\xi_b\rfloor\mathcal{L}_{\xi_c}(\Omega) + d(\xi_c\rfloor\xi_b\rfloor\xi_a\rfloor\Omega)\\ &= -\{\{c,a\},b\} - \{\{b,c\},a\} + d(\xi_c\rfloor\xi_b\rfloor\xi_a\rfloor\Omega),\end{aligned}$$

where we have used (27). ■

We can extend the definition of the $\mathfrak{p}$-bracket: for any $0\leqslant p\leqslant n$ the *external* $\mathfrak{p}$-bracket of a p-form $a\in\Gamma(\mathcal{M},\Lambda^pT^\star\mathcal{M})$ with a form $b\in\mathfrak{P}^{n-1}\mathcal{M}$ is

$$\{a,b\} = -\{b,a\} := -\Xi(b)\rfloor da.$$

Of course this definition coincides with the previous one when $a\in\mathfrak{P}^{n-1}\mathcal{M}$.

1. Examples of external $\mathfrak{p}$-brackets

For any $a\in\mathfrak{P}^{n-1}\mathcal{M}$,

$$\{\theta,a\} = -\Xi(a)\rfloor d\theta = -\Xi(a)\rfloor\Omega = da.$$

We can add that it is worthwhile to write in the external $\mathfrak{p}$-brackets of observable forms like q^μ, $q^\mu dq^\nu$, etc.:

$$\{P_{i,g},q^\mu\}=\Xi(P_{i,g})\rfloor dq^\mu=g\,\delta_i^\mu,$$

$$\{Q^{i,f},q^\mu\}=\Xi(Q^{i,f})\rfloor dq^\mu=0,$$

$$\{P_{i,g},q^\mu dq^\nu\}=\Xi(P_{i,g})\rfloor dq^\mu\wedge dq^\nu=g(\delta_i^\mu dq^\nu-\delta_i^\nu dq^\mu).$$

Theorem 2: *Let* Γ *be the graph in* $\mathcal{M}$ *of a solution of the Hamilton equations (11) and write* $\mathcal{U}:x\mapsto\mathcal{U}(x)=(x,u(x),p(x))$ *the natural parametrization of* Γ. *Then for any form* $a\in\mathfrak{P}^{n-1}\mathcal{M}$,

$$\mathbf{d}a=\{\mathcal{H}\omega,a\},$$

where **d** *is the differential along* Γ (*meaning that* $da_{|\Gamma}=\{\mathcal{H}\omega,a\}_{|\Gamma}$).

Proof: We choose an arbitrary open subset $D\subset\Gamma$ and, denoting $\xi_a=\Xi(a)$, we compute

$$\begin{aligned}\int_D\{\mathcal{H}\omega,a\}&=-\int_D\xi_a\rfloor(d\mathcal{H}\wedge\omega)\\&=-\int_{\mathcal{U}^{-1}(D)}d\mathcal{H}\wedge\omega\left(\xi_a,\frac{\partial\mathcal{U}}{\partial x^1},\ldots,\frac{\partial\mathcal{U}}{\partial x^n}\right)\omega\\&=-\int_{\mathcal{U}^{-1}(D)}(-1)^n\frac{\partial\mathcal{U}}{\partial x^1\ldots\partial x^n}\rfloor(d\mathcal{H}\wedge\omega)(\xi_a)\omega.\end{aligned}$$

We use Eq. (19) and obtain

$$\begin{aligned}\int_D\{\mathcal{H}\omega,a\}&=-\int_{\mathcal{U}^{-1}(D)}(-1)^n\frac{\partial\mathcal{U}}{\partial x^1\ldots\partial x^n}\rfloor\Omega(\xi_a)\omega\\&=-\int_{\mathcal{U}^{-1}(D)}\Omega\left(\xi_a,\frac{\partial\mathcal{U}}{\partial x^1},\ldots,\frac{\partial\mathcal{U}}{\partial x^n}\right)\omega\\&=-\int_D\xi_a\rfloor\Omega=\int_D da.\end{aligned}$$

And Theorem 2 follows. ■

Another way to state this result is that

$$\int_D\{\mathcal{H}\omega,a\}=\int_{\partial D}a \tag{29}$$

along any solution of (11).

B. Expression of the standard observable $(n-1)$-forms

These quantities are integrals of $(n-1)$-forms on hypersurfaces which are thought of as "constant time slices," the transversal dimension being then considered as a local time. The target coordinates observables are weighted integrals of the value of the field and are induced by the "*position*" $\mathfrak{p}$-*forms*

$$Q^{i,f}:=y^i\sum_\alpha f^\alpha(x)\omega_\alpha=y^i f\rfloor\omega,$$

where $f=\Sigma_\alpha f^\alpha(x)\,\partial/\partial x^\alpha$ is a tangent vector field on $\mathcal{X}$ and $\omega_\alpha=\partial/\partial x^\alpha\rfloor\omega$. (Comparing with the one-dimensional Hamiltonian formalism, we can see these target coordinates as generalizations of the position observables.) The ''momentum'' and ''energy'' observables are obtained from the *momentum form*

$$P^\star_{\mu,g}:=g(x)\frac{\partial}{\partial q^\mu}\rfloor(\theta-\mathcal{H}(q,p)\omega),$$

where g is a smooth function on $\mathcal{X}$. Alternatively we may sometimes prefer to use the $\mathfrak{p}$-forms

$$P_{\mu,g}:=g(x)\frac{\partial}{\partial q^\mu}\rfloor\theta.$$

For $1\leqslant\mu=\alpha\leqslant n$, $P^\star_{\mu,g}=:H_{\alpha,g}$ generates the components of the Hamiltonian tensor but $P_{\alpha,g}$ (which is different from $P^\star_{\alpha,g}$) does not in general. However, the restrictions of $P^\star_{\mu,g}$ and $P_{\mu,g}$ on the hypersurface $\mathcal{H}=0$ coincide so that if we work on this hypersurface both forms can be used. For $n+1\leqslant\mu=n+i\leqslant n+k$, $P^\star_{\mu,g}=P_{\mu,g}=:P_{i,g}$ generates the momentum components. (The advantage of $P_{\mu,g}$ with respect to $P^\star_{\mu,g}$ is that $P_{\mu,g}$ belongs to $\mathfrak{P}^{n-1}\mathcal{M}$ for all values of μ.)

To check that, we consider a parametrization $\mathcal{U}:x\mapsto(x,u(x),p(x))$ of some graph Γ and look at the pull-back of these forms by $\mathcal{U}$. We write $\mathcal{U}^\star P^\star_{\mu,g}=\Sigma_\beta s^\beta\omega_\beta$, which implies $s^\beta\omega=dx^\beta\wedge\mathcal{U}^\star P^\star_{\mu,g}$ and we compute

$$\begin{aligned}s^\beta&=g(x)\left\langle p,\frac{\partial q}{\partial x^1}\wedge\cdots\wedge\frac{\partial q}{\partial x^{\beta-1}}\wedge\frac{\partial}{\partial q^\mu}\wedge\frac{\partial q}{\partial x^{\beta+1}}\wedge\cdots\wedge\frac{\partial q}{\partial x^n}\right\rangle_{|z=\partial U/\partial x}-g(x)\,\delta^\beta_\mu\mathcal{H}\\&=g(x)\frac{\partial\langle p,z\rangle}{\partial z^\mu_\beta}{}_{|z=\partial U/\partial x}-g(x)\,\delta^\beta_\mu\mathcal{H}.\end{aligned}$$

Hence we find that

$$\mathcal{U}^\star H_{\alpha,g}=-g(x)\sum_\beta H^\beta_\alpha(q(x),p(x))\omega_\beta=g(x)\sum_\beta S^\beta_\alpha(x,u(x),du(x))\omega_\beta,$$

$$\mathcal{U}^\star P_{i,g}=g(x)\sum_\beta\frac{\partial\langle p,z\rangle}{\partial z^i_\beta}{}_{|z=\partial U/\partial x}\omega_\beta=g(x)\sum_\beta\frac{\partial L}{\partial v^i_\beta}(x,u(x),du(x))\omega_\beta.$$

We shall prove below that $P_{\mu,g}$ (and hence $P_{i,g}$) and $Q^{i,f}$ belong to $\mathfrak{P}^{n-1}\mathcal{M}$.

1. Larger classes of observables

These forms, which are enough to translate most of the observables studied in the usual field theory, are embedded in two more general classes of observables, the definition of which follows.

(a) Generalized positions. They are forms Q^ζ in $\Lambda^{n-1}T^\star(\mathcal{X}\times\mathcal{Y})$, i.e.,

$$Q^\zeta:=\sum_{\mu_1<\ldots<\mu_{n-1}}\zeta_{\mu_1\ldots\mu_{n-1}}(q)dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_{n-1}}.$$

An example is $Q^{i,f}=y^i f(x)\partial_\alpha\rfloor\omega$. We denote $\mathfrak{P}^{n-1}_Q\mathcal{M}=\Lambda^{n-1}T^\star(\mathcal{X}\times\mathcal{Y})$.

(b) Generalized momenta. For each section of $T(\mathcal{X}\times\mathcal{Y})$, i.e., a vector field

$$\xi:=\sum_\mu\xi^\mu(q)\frac{\partial}{\partial q^\mu},$$

we define the $(n-1)$-form

$$P_\xi := \xi \rfloor \theta = \sum_\mu \xi^\mu \frac{\partial}{\partial q^\mu} \rfloor \theta.$$

An example is that for $\xi = g(x)\,\partial/\partial q^\mu$, then we obtain $P_{g(x)\,\partial/\partial q^\mu} = P_{\mu,g}$. We denote $\mathfrak{P}_P^{n-1}\mathcal{M}$ the set of such $(n-1)$-forms.

Lemma 4: $\mathfrak{P}_Q^{n-1}\mathcal{M}$ *ans* $\mathfrak{P}_P^{n-1}\mathcal{M}$ *are subsets of* $\mathfrak{P}^{n-1}\mathcal{M}$, *precisely*

$$\Xi(Q^\zeta) = \sum_{\mu_1 < \ldots < \mu_n} \sum_\alpha (-1)^\alpha \frac{\partial \zeta_{\mu_1 \ldots \mu_{\alpha-1}\mu_{\alpha+1} \ldots \mu_n}}{\partial q^{\mu_\alpha}} \frac{\partial}{\partial p_{\mu_1 \ldots \mu_n}},$$

$$\Xi(P_\xi) = \xi - \sum_\mu \sum_\nu \frac{\partial \xi^\mu}{\partial q^\nu} \Pi_\mu^\nu,$$

where

$$\Pi_\mu^\nu := \sum_{\mu_1 < \ldots < \mu_n} \sum_\alpha p_{\mu_1 \ldots \mu_{\alpha-1}\mu\mu_{\alpha+1} \ldots \mu_n} \delta^\nu_{\mu_\alpha} \frac{\partial}{\partial p_{\mu_1 \ldots \mu_n}}$$

so that

$$dq^\nu \wedge \frac{\partial}{\partial q^\mu} \rfloor \theta = \Pi_\mu^\nu \rfloor \Omega.$$

Proof: We have

$$\begin{aligned} dQ^\zeta &= \sum_\nu \sum_{\mu_1 < \ldots < \mu_{n-1}} \frac{\partial \zeta_{\mu_1 \ldots \mu_{n-1}}}{\partial q^\nu} dq^\nu \wedge dq^{\mu_1} \wedge \cdots \wedge dq^{\mu_{n-1}} \\ &= \sum_\alpha \sum_{\mu_1 < \ldots < \mu_n} \frac{\partial \zeta_{\mu_1 \ldots \mu_{\alpha-1}\mu_{\alpha+1} \ldots \mu_n}}{\partial q^{\mu_\alpha}} dq^{\mu_\alpha} \wedge dq^{\mu_1} \wedge \cdots \wedge dq^{\mu_{\alpha-1}} \wedge dq^{\mu_{\alpha+1}} \wedge \cdots \wedge dq^{\mu_n} \\ &= \sum_\alpha (-1)^{\alpha-1} \sum_{\mu_1 < \ldots < \mu_n} \frac{\partial \zeta_{\mu_1 \ldots \mu_{\alpha-1}\mu_{\alpha+1} \ldots \mu_n}}{\partial q^{\mu_\alpha}} \frac{\partial}{\partial p_{\mu_1 \ldots \mu_n}} \rfloor \Omega. \end{aligned}$$

And the expression for $\Xi(Q^\zeta)$ follows.

Next we write

$$dP_\xi = \sum_\mu \sum_\nu \frac{\partial \xi^\mu}{\partial q^\nu} dq^\nu \wedge \frac{\partial}{\partial q^\mu} \rfloor \theta - \sum_\mu \xi^\mu \frac{\partial}{\partial q^\mu} \rfloor \Omega$$

and we conclude by computing $dq^\nu \wedge \partial/\partial q^\mu \rfloor \theta$, indeed

$$\begin{aligned} dq^\nu \wedge \frac{\partial}{\partial q^\mu} \rfloor \theta &= \sum_{\mu_1 < \ldots < \mu_n} \sum_\alpha p_{\mu_1 \ldots \mu_n} \delta^{\mu_\alpha}_\mu dq^{\mu_1} \wedge \cdots \wedge dq^{\mu_{\alpha-1}} \wedge dq^\nu \wedge dq^{\mu_{\alpha+1}} \wedge \cdots \wedge dq^{\mu_n} \\ &= \sum_{\mu_1 < \ldots < \mu_n} \sum_\alpha p_{\mu_1 \ldots \mu_{\alpha-1}\mu\mu_{\alpha+1} \ldots \mu_n} \delta^\nu_{\mu_\alpha} dq^{\mu_1} \wedge \cdots \wedge dq^{\mu_n} \\ &= \sum_{\mu_1 < \ldots < \mu_n} \sum_\alpha p_{\mu_1 \ldots \mu_{\alpha-1}\mu\mu_{\alpha+1} \ldots \mu_n} \delta^\nu_{\mu_\alpha} \frac{\partial}{\partial p_{\mu_1 \ldots \mu_n}} \rfloor \Omega. \end{aligned}$$

Hence we deduce the result on P_ξ. ■

(c) Poisson $\mathfrak{p}$*-brackets*. We are now in position to compute the $\mathfrak{p}$-brackets of these forms. The results are summarized in the following proposition.

Proposition 1: The $\mathfrak{p}$*-brackets of forms in* $\mathfrak{P}_Q^{n-1}\mathcal{M}$ *and* $\mathfrak{P}_P^{n-1}\mathcal{M}$ *are the following*:

$$\{Q^\zeta, Q^{\tilde{\zeta}}\}=0,$$

$$\{P_\xi, P_{\tilde{\xi}}\}=P_{[\xi,\tilde{\xi}]}+d(\tilde{\xi}\rfloor\xi\rfloor\theta),$$

$$\{P_\xi, Q^\zeta\}=\sum_{\mu_1<\cdots<\mu_n}\sum_\alpha\sum_\mu(-1)^{\alpha+1}\xi^\mu\frac{\partial\zeta_{\mu_1\cdots\mu_{\alpha-1}\mu_{\alpha-1}\cdots\mu_n}}{\partial q^{\mu_\alpha}}\frac{\partial}{\partial q^\mu}\rfloor dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_n}.$$

Proof: These results are all straighforward except for $\{P_\xi, P_{\tilde{\xi}}\}$. We remark that $\Xi(P_\xi)\rfloor\theta=\xi\rfloor\theta=P_\xi$ and

$$\mathcal{L}_{\Xi(P_\xi)}(\theta)=\Xi(P_\xi)\rfloor d\theta+d(\Xi(P_\xi)\rfloor\theta)=\Xi(P_\xi)\rfloor\Omega+dP_\xi=0, \tag{30}$$

so that $\Xi(P_\xi)$ may be viewed as the extension of ξ to a vector field leaving θ invariant. Now we deduce that

$$\begin{aligned}[\xi,\tilde{\xi}]\rfloor\theta&=[\Xi(P_\xi),\Xi(P_{\tilde{\xi}})]\rfloor\theta=\mathcal{L}_{\Xi(P_\xi)}(\Xi(P_{\tilde{\xi}}))\rfloor\theta=\mathcal{L}_{\Xi(P_\xi)}(\Xi(P_{\tilde{\xi}})\rfloor\theta)-\Xi(P_{\tilde{\xi}})\rfloor\mathcal{L}_{\Xi(P_\xi)}\theta\\&=\Xi(P_\xi)\rfloor d(\Xi(P_{\tilde{\xi}})\rfloor\theta)+d(\Xi(P_\xi)\rfloor\Xi(P_{\tilde{\xi}})\rfloor\theta)-\Xi(P_{\tilde{\xi}})\rfloor 0=\Xi(P_\xi)\rfloor dP_{\tilde{\xi}}+d(\xi\rfloor\tilde{\xi}\rfloor\theta)\\&=-\Xi(P_\xi)\rfloor\Xi(P_{\tilde{\xi}})\rfloor\Omega+d(\xi\rfloor\tilde{\xi}\rfloor\theta)=\{P_\xi,P_{\tilde{\xi}}\}-d(\tilde{\xi}\rfloor\xi\rfloor\theta),\end{aligned}$$

and the result follows. ■

2. Back to the standard observables

As an application of the previous results we can express the pataplectic vector fields associated to $Q^{i,f}$ and $P_{\mu,g}$ and their $\mathfrak{p}$-brackets. For that purpose, it is useful to introduce other notations:

$$\epsilon:=p_{1\ldots n},$$

$$p_i^\alpha:=p_{1\ldots(\alpha-1)(n+i)(\alpha+1)\ldots n},$$

$$p_{i_1i_2}^{\alpha_1\alpha_2}:=p_{1\ldots(\alpha_1-1)(n+i_1)(\alpha_1+1)\ldots(\alpha_2-1)(n+i_2)(\alpha_2+1)\ldots n},\ \text{etc.},$$

and

$$\omega_\alpha^i:=dy^i\wedge\left(\frac{\partial}{\partial x^\alpha}\rfloor\omega\right)=:(dy^i\wedge\partial_\alpha)\rfloor\omega,$$

$$\omega_{\alpha_1\alpha_2}^{i_1i_2}:=(dy^{i_1}\wedge\partial_{\alpha_1})\rfloor(dy^{i_2}\wedge\partial_{\alpha_2})\rfloor\omega,\ \text{etc.},$$

in such a way that

$$\theta=\epsilon\omega+\sum_{p=1}^n\frac{1}{p^{!2}}\sum_{i_1,\ldots,i_p;\alpha_1,\ldots,\alpha_p}p_{i_1\ldots i_p}^{\alpha_1\ldots\alpha_p}\omega_{\alpha_1\ldots\alpha_p}^{i_1\ldots i_p}.$$

(Notice that the Weyl theory corresponds to the assumption that $p^{\alpha_1 \cdots \alpha_p}_{i_1 \cdots 1_p}=0$, $\forall p \geqslant 2$.) We have

$$dQ^{i,f}=\sum_\alpha f^\alpha \frac{\partial}{\partial p^\alpha_i}\rfloor\Omega + y^i \sum_\alpha \frac{\partial f^\alpha}{\partial x^\alpha}\frac{\partial}{\partial \epsilon}\rfloor\Omega,$$

$$dP_{\mu,g}=\sum_\alpha \frac{\partial g}{\partial x^\alpha}\Pi^\alpha_\mu\rfloor\Omega - g\frac{\partial}{\partial q^\mu}\rfloor\Omega,$$

where

$$\Pi^\alpha_\beta=\delta^\alpha_\beta \epsilon \frac{\partial}{\partial \epsilon}+\sum_{p=1}^n \frac{1}{p!^2}\sum_{i_1,\ldots,i_p;\alpha_1,\ldots,\alpha_p}\left(p^{\alpha_1\cdots\alpha_p}_{i_1\cdots i_p}\delta^\alpha_\beta - \sum_{j=1}^p p^{\alpha_1\cdots\alpha_{j-1}\,\alpha\alpha_{j+1}\cdots\alpha_n}_{i_1\cdots i_{j-1}\,i_j i_{j+1}\cdots i_n}\delta^{\alpha_j}_\beta\right)\frac{\partial}{\partial p^{\alpha_1\cdots\alpha_p}_{i_1\cdots i_p}},$$

$$\Pi^\alpha_{n+i}=\sum_{p=0}^{n-1}\frac{1}{p!^2}\sum_{i_1,\ldots,i_p;\alpha_1,\ldots,\alpha_p} p^{\alpha\alpha_1\cdots\alpha_p}_{i i_1\cdots i_p}\frac{\partial}{\partial p^{\alpha_1\cdots\alpha_p}_{i_1\cdots i_p}}.$$

The pataplectic vector fields are

$$\Xi(Q^{i,f})=-\sum_\alpha f^\alpha\frac{\partial}{\partial p^\alpha_i}-y^i\sum_\alpha\frac{\partial f^\alpha}{\partial x^\alpha}\frac{\partial}{\partial\epsilon},$$

$$\Xi(P_{\mu,g})=g\frac{\partial}{\partial q^\mu}-\sum_\alpha\frac{\partial g}{\partial x^\alpha}\Pi^\alpha_\mu.$$

Finally, by using Proposition 1, the Poisson $\mathfrak{p}$-brackets will be

$$\{Q^{i,f},Q^{j,\tilde f}\}=0,$$

$$\{P_{i,g},P_{j,\tilde g}\}=d\left(g\tilde g\frac{\partial}{\partial y^j}\rfloor\frac{\partial}{\partial y^i}\rfloor\theta\right),$$

$$\{P_{i,g},Q^{j,f}\}=\delta^j_i\sum_\alpha f^\alpha g\omega_\alpha.$$

Hence if g and $\tilde g$ have compact support, we obtain that on any submanifold S of dimension $n-1$ without boundary,

$$\int_S\{Q^{i,f},Q^{j,\tilde f}\}=\int_S\{P_{i,g},P_{j,\tilde g}\}=0 \quad \text{and} \quad \int_S\{P_{i,g},Q^{j,f}\}=\delta^j_i\int_S\sum_\alpha f^\alpha g\omega_\alpha.$$

C. Extension of the $\mathfrak{p}$-bracket to forms of degree less than $n-1$

The $\mathfrak{p}$-brackets defined above allow us to express the dynamics of an observable which is in $\mathfrak{P}^{n-1}\mathcal{M}$. We shall extend this bracket to some forms in $\Gamma(\mathcal{M},\Lambda^p T^\star\mathcal{M})$, where $0\leqslant p\leqslant n-1$. Like in the case $p=n-1$, not every p-form is admissible and, as we shall see, the class of such p-forms is quite restricted and is basically composed of ''position'' observables. However, when the Hamiltonian system is degenerate, due to some gauge symmetry and constraints, some ''mo-

mentum'' observable can be represented by p-forms with $p<n-1$. An instance of such a situation is the electromagnetic field studied in Sec. V C. Our aim now is to find a generalization of Theorem 2, using the following construction:

For $1\leqslant p\leqslant n$, we define $\mathfrak{P}^{p-1}\mathcal{M}$ to be the set of sections a of $\Gamma(\mathcal{M},\Lambda^{p-1}T^\star\mathcal{M})$ such that, for all $1\leqslant\alpha_1<\cdots<\alpha_{n-p}\leqslant n$,

$$dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a\in\mathfrak{P}^{n-1}\mathcal{M}.$$

We introduce anticommuting (Grassmann) variables $\tau_1,\ldots,\tau_n$, which behave under a change of coordinates like $\partial/\partial x^1,\ldots,\partial/\partial x^n$. We shall consider functions and forms depending on the variables $(\tau_\alpha,x^\alpha,y^i,p_{\mu_1,\ldots,\mu_n})$. Alternatively they can be seen as functions on the bundle $\Pi T\mathcal{X}\otimes_{\mathcal{X}}\mathcal{M}$, where $\Pi T\mathcal{X}$ is a copy of $T\mathcal{X}$ in which the parity of vectors in the fibers $T_x\mathcal{X}$ has been reversed. We consider ${}^s\Gamma(\mathcal{M},\Lambda^{n-1}T^\star\mathcal{M})$ to be the set of $(n-1)$-forms on $\mathcal{M}$ whose coefficients are in the algebra $\mathbb{R}[\tau_1,\ldots,\tau_n]$. More intrinsically, ${}^s\Gamma(\mathcal{M},\Lambda^{n-1}T^\star\mathcal{M})$ can be identified with $\mathcal{C}^\infty(\Pi T\mathcal{X})\otimes_{\mathcal{C}^\infty(\mathcal{X})}\Gamma(\mathcal{M},\Lambda^{n-1}T^\star\mathcal{M})$, meaning that any form $A\in{}^s\Gamma(\mathcal{M},\Lambda^{n-1}T^\star\mathcal{M})$ is a finite sum of terms of the form $\phi(x,\tau)\theta$, where $\phi\in\mathcal{C}^\infty(\Pi T\mathcal{X})$ and $\theta\in\Gamma(\mathcal{M},\Lambda^{n-1}T^\star\mathcal{M})$. Through this identification we can define ${}^s\mathfrak{P}^{n-1}\mathcal{M}$ to be the subset of ${}^s\Gamma(\mathcal{M},\Lambda^{n-1}T^\star\mathcal{M})$ linearly spanned by $\phi(x,\tau)\theta$, where $\phi\in\mathcal{C}^\infty(\Pi T\mathcal{X})$ and $\theta\in\mathfrak{P}^{n-1}\mathcal{M}$.

Obviously for any $A\in{}^s\mathfrak{P}^{n-1}\mathcal{M}$, there exists some vector field $\Xi(A)$ on $\mathcal{M}$ with coefficients in $\mathbb{R}[\tau_1,\ldots,\tau_n]$ such that $dA=-\Xi(A)\rfloor\Omega$. A more geometrical description of $\Xi(A)$ is that it is a section of the bundle $\Pi T\mathcal{X}\otimes_{\mathcal{X}}T\mathcal{M}$ over $\mathcal{M}$.

We embed each $\mathfrak{P}^{p-1}\mathcal{M}$ in ${}^s\mathfrak{P}^{n-1}\mathcal{M}$ by

$$\mathfrak{P}^{p-1}\mathcal{M}\to{}^s\mathfrak{P}^{n-1}\mathcal{M},$$

$$a\mapsto{}^sa,$$

where the ''s-form'' ${}^sa$ is defined by

$${}^sa:=\sum_{\alpha_1<\ldots<\alpha_{n-p}}\tau_{\alpha_1}\cdots\tau_{\alpha_{n-p}}dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a.$$

Then

$$\Xi({}^sa)=\sum_{\alpha_1<\ldots<\alpha_{n-p}}\tau_{\alpha_1}\cdots\tau_{\alpha_{n-p}}\Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a).$$

We endow ${}^s\mathfrak{P}^{n-1}\mathcal{M}$ with the Poisson $\mathfrak{p}$-sbracket defined by

$$\{A,B\}_s:=(\Xi(A)\wedge\Xi(B))\rfloor\Omega,$$

where assuming that A and B are homogeneous in τ_α and are given by

$$A=\sum_{\alpha_1<\ldots<\alpha_{n-p}}\tau_{\alpha_1}\cdots\tau_{\alpha_{n-p}}A^{\alpha_1\cdots\alpha_{n-p}},$$

$$B=\sum_{\beta_1<\ldots<\beta_{n-q}}\tau_{\beta_1}\cdots\tau_{\beta_{n-q}}B^{\beta_1\cdots\beta_{n-q}},$$

$$\{A,B\}_s=\sum_{\alpha_1<\ldots<\alpha_{n-p}}\ \sum_{\beta_1<\ldots<\beta_{n-q}}\tau_{\alpha_1}\cdots\tau_{\alpha_{n-p}}\tau_{\beta_1}\cdots\tau_{\beta_{n-q}}\Xi(B^{\beta_1\cdots\beta_{n-q}})\rfloor\Xi(A^{\alpha_1\cdots\alpha_{n-p}})\rfloor\Omega.$$

Lemma 2 implies immediately that

$$d\{A,B\}_s = -[\xi_A,\xi_B]_s \rfloor \Omega,$$

where $\xi_A = \Xi(A)$, $\xi_B = \Xi(B)$ and the s-Lie bracket $[.,.]_s$ is defined for homogeneous forms A and B by $[\xi_A,\xi_B]_s f = \xi_A \rfloor d(\xi_B \rfloor df) + (-1)^{|A||B|+1}\xi_B \rfloor d(\xi_A \rfloor df)$ (here $|A|$ and $|B|$ are the homogeneity degrees in the variables τ_α). Furthermore, one can deduce easily from Lemma 3 the following relations for all homogeneous forms A, B and C in ${}^s\mathfrak{P}^{n-1}\mathcal{M}$:

$$\{A,B\}_s = (-1)^{|A||B|+1}\{B,A\}_s,$$

$$(-1)^{|A||C|}\{\{A,B\}_s,C\}_s + (-1)^{|B||A|}\{\{B,C\}_s,A\}_s + (-1)^{|C||B|}\{\{C,A\}_s,B\}_s$$
$$= (-1)^{|A||C|} d((\xi_A \wedge \xi_B \wedge \xi_C)\rfloor \Omega).$$

Hence ${}^s\mathfrak{P}^{n-1}\mathcal{M}$ has the structure of a graded Lie algebra modulo exact terms.

Now suppose that we can prove that for some forms $a \in \mathfrak{P}^{p-1}\mathcal{M}$ and $b \in \mathfrak{P}^{q-1}\mathcal{M}$, $\{{}^s a, {}^s b\}_s$ is equal to some ${}^s c$ where $c \in \mathfrak{P}^{p+q-n-1}\mathcal{M}$. Then we could define the *internal* $\mathfrak{p}$-bracket between a and b by $\{a,b\} := c$. This turns out actually to be true for a simple reason: all these brackets vanish by Proposition 2 which follows (except of course the case where $p=n$ or $q=n$). However, this fact is no longer true in general in the interesting case where we have constraints as shown in Sec. V C.

Lemma 5: For $1 \leqslant p < n$, $\mathfrak{P}^{p-1}\mathcal{M}$ *coincides with* $\Lambda^{p-1}T^\star(\mathcal{X}\times\mathcal{Y})$.

Proof: First step: let $1 \leqslant p < n$ and $a \in \mathfrak{P}^{p-1}\mathcal{M}$ and choose any $1 \leqslant \alpha_1 < \cdots < \alpha_{n-p} \leqslant n$, so that $dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a \in \mathfrak{P}^{n-1}\mathcal{M}$. Let us denote $\xi := \Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a)$. Decompose ξ:

$$\xi = \sum_\mu \xi^\mu \frac{\partial}{\partial q^\mu} + \sum_{\mu_1 < \ldots < \mu_n} \xi_{\mu_1 \ldots \mu_n} \frac{\partial}{\partial p_{\mu_1 \ldots \mu_n}}.$$

Then

$$-\xi\rfloor\Omega = -\sum_{\mu_1<\ldots<\mu_n} \xi_{\mu_1\ldots\mu_n} dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_n} - \sum_\nu \xi^\nu$$
$$\times \sum_{\alpha=1}^{n} (-1)^\alpha \sum_{\substack{\mu_1<\cdots<\mu_n \\ \mu_\alpha=\nu}} dp_{\mu_1\ldots\mu_n}\wedge dq^{\mu_1}\wedge\ldots\wedge dq^{\mu_{\alpha-1}}\wedge dq^{\mu_{\alpha+1}}\wedge\ldots\wedge dq^{\mu_n}.$$

This expression should be equal to $(-1)^{n-p-1}dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge da$. Note that for any $1 \leqslant \nu \leqslant n+k$, there exist n integers $\mu_1<\cdots<\mu_n$ such that $\nu \in \{\mu_1,\ldots,\mu_n\}$ but $\alpha_1 \notin \{\mu_1,\ldots,\mu_n\}$. This forces $\xi^\nu = 0$. Hence we are left with

$$(-1)^{n-p-1}dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge da = -\sum_{\mu_1<\ldots<\mu_n} \xi_{\mu_1\ldots\mu_n} dq^{\mu_1}\wedge\cdots\wedge dq^{\mu_n},$$

which implies that a does not depend on the variables $p_{\mu_1\ldots\mu_n}$. Hence $a \in \Lambda^{p-1}T^\star(\mathcal{X}\times\mathcal{Y})$.

Second step: Conversely let $a \in \Lambda^{p-1}T^\star(\mathcal{X}\times\mathcal{Y})$. Then, for each $1 \leqslant \alpha_1 < \cdots < \alpha_{n-p} \leqslant n$, $dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a$ belongs to $\Lambda^{n-1}T^\star(\mathcal{X}\times\mathcal{Y})$, which is a subset of $\in \mathfrak{P}^{n-1}\mathcal{M}$ by Lemma 4. So $a \in \mathfrak{P}^{p-1}\mathcal{M}$. ■

Proposition 2: (a) *For* $1 \leqslant p,q < n$, $a \in \mathfrak{P}^{p-1}\mathcal{M}$ *and* $b \in \mathfrak{P}^{q-1}\mathcal{M}$ *the* $\mathfrak{p}$*-s bracket of* ${}^s a$ *with* ${}^s b$ *vanishes:* $\{{}^s a, {}^s b\}_s = 0$ *and hence the internal* $\mathfrak{p}$*-bracket* $\{a,b\}$ *exists and is equal to 0.*

(b) *For* $1 \leqslant p < n$, $a \in \mathfrak{P}^{n-1}\mathcal{M}$ *and* $b \in \mathfrak{P}^{p-1}\mathcal{M}$,

$$\{{}^s a, {}^s b\}_s = -{}^s(db)\Xi(a)(\tau) + {}^s\{a,b\}, \tag{31}$$

where $\{a,b\} = \Xi(a)\rfloor db$ *is the external* $\mathfrak{p}$*-bracket and*

$$\Xi(a)(\tau) := \sum_{\alpha} dx^{\alpha}(\Xi(a))\tau_{\alpha}.$$

(*It is actually a superfunction on* $\Pi T\mathcal{X}$.) *As a consequence, if* $dx^{\alpha}(\Xi(a))=0$, $\forall\alpha$, *the internal* $\mathfrak{p}$*-bracket* $\{a,b\}$ *exists and coincides with the external* $\mathfrak{p}$*-bracket*.

Remark: We think that the first term on the right-hand side of (31) does not play an essential role in our construction, which may be the case in other contexts. We believe that in a much more elaborate construction this term will not appear.

Proof: Case (a): By Lemma 5 a and b are in $\Lambda^{p-1}T^{\star}(\mathcal{X}\times\mathcal{Y})$ and $\Lambda^{q-1}T^{\star}(\mathcal{X}\times\mathcal{Y})$, respectively, so ${}^{s}a$ and ${}^{s}b$ are in $\mathcal{C}^{\infty}(\Pi T\mathcal{X})\otimes_{\mathcal{C}^{\infty}(\mathcal{X})}\Lambda^{n-1}T^{\star}(\mathcal{X}\times\mathcal{Y})$. Hence their $\mathfrak{p}$-sbracket vanishes by Proposition 1.

Let us consider the case b. Let us denote $\xi_a=\Xi(a)$ and write

$$\xi_a=\sum_{\mu}\xi_a^{\mu}\frac{\partial}{\partial q^{\mu}}+\sum_{\mu_1<\ldots<\mu_n}\xi_{a,\mu_1\ldots\mu_n}\frac{\partial}{\partial p_{\mu_1\ldots\mu_n}},$$

then

$$\begin{aligned}
\{a,{}^{s}b\}_s &= \sum_{\alpha_1<\ldots<\alpha_{n-p}}(-1)^{n-p}\tau_{\alpha_1}\ldots\tau_{\alpha_{n-p}}\xi_a\rfloor(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge db)\\
&=(-1)^{n-p}\sum_{\alpha}\sum_{\alpha_1<\ldots<\alpha_{n-p}}\sum_{l=1}^{n-p}\delta_{\alpha}^{\alpha_l}\xi_a^{\alpha}\tau_{\alpha_l}\tau_{\alpha_1}\cdots\tau_{\alpha_{l-1}}\tau_{\alpha_{l+1}}\\
&\quad\cdots\tau_{\alpha_{n-p}}dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{l-1}}\wedge dx^{\alpha_{l+1}}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge db\\
&\quad+\sum_{\alpha_1<\ldots<\alpha_{n-p}}\tau_{\alpha_1}\cdots\tau_{\alpha_{n-p}}dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge(\xi_a\rfloor db)\\
&=(-1)^{n-p}\sum_{\alpha}\xi_a^{\alpha}\tau_{\alpha}\sum_{\alpha_1<\ldots<\alpha_{n-p-1}}\tau_{\alpha_1}\ldots\tau_{\alpha_{n-p-1}}dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p-1}}\wedge db+{}^{s}(\xi_a\rfloor db)\\
&=(-1)^{n-p}\sum_{\alpha}\xi_a^{\alpha}\tau_{\alpha}{}^{s}(db)+{}^{s}\{a,b\}.
\end{aligned}$$

And the claim is proved. ■

One simple example is the zero-form y^j. The associated s-form is

$${}^{s}y^j=\sum_{\alpha}y^j(-1)^{\alpha-1}\tau_1\cdots\tau_{\alpha-1}\tau_{\alpha+1}\cdots\tau_n\frac{\partial}{\partial x^{\alpha}}\rfloor\omega.$$

Since

$$d\,{}^{s}y^j=\sum_{\alpha}(-1)^{\alpha-1}\tau_1\cdots\tau_{\alpha-1}\tau_{\alpha+1}\cdots\tau_n\omega_{\alpha}^{j},$$

we have

$$\Xi({}^{s}y^j)=\sum_{\alpha}(-1)^{\alpha}\tau_1\cdots\tau_{\alpha-1}\tau_{\alpha+1}\cdots\tau_n\frac{\partial}{\partial p_j^{\alpha}}.$$

Let us compute the $\mathfrak{p}$-sbracket with $P_i=\partial/\partial y^i\rfloor\theta$:

$$\{P_i, {}^s y^j\}_s = \sum_\alpha (-1)^\alpha \tau_1 \cdots \tau_{\alpha-1}\tau_{\alpha+1}\cdots \tau_n \frac{\partial}{\partial p_j^\alpha} \rfloor \frac{\partial}{\partial y^i} \rfloor \Omega$$

$$= \sum_\alpha (-1)^{\alpha-1} \tau_1 \cdots \tau_{\alpha-1}\tau_{\alpha+1}\cdots \tau_n \delta_i^j \frac{\partial}{\partial x_\alpha} \rfloor \omega = {}^s\delta_i^j .$$

Thus

$$\{P_i, y^j\} = \delta_i^j .$$

D. Integral of an observable in $\mathfrak{P}^{p-1}\mathcal{M}$ and dynamical equations

Let Γ be a submanifold of dimension n on $\mathcal{M}$ and let D be be some oriented submanifold with boundary of dimension p $(1 \leqslant p \leqslant n)$ included in Γ. We consider D_Γ, the fiber bundle over D whose fiber at the point $m \in D$ is the oriented tangent space to Γ at m.

Definition 4: Let $a \in \mathfrak{P}^{p-1}\mathcal{M}$ and $\psi \in \Gamma(\mathcal{M}, \Lambda^n T^\star \mathcal{M})$. We define the $\mathfrak{p}$-bracket

$$\{\psi, {}^s a\}_s := -\Xi({}^s a) \rfloor d\psi = -\sum_{\alpha_1 < \cdots < \alpha_{n-p}} \tau_{\alpha_1} \cdots \tau_{\alpha_{n-p}} \Xi(dx^{\alpha_1} \wedge \ldots \wedge dx^{\alpha_{n-p}} \wedge a) \rfloor d\psi. \quad (32)$$

We define the integral of $\{\psi, {}^s a\}_s$ over D_Γ to be

$$\int_{D_\Gamma} \{\psi, {}^s a\}_s := -\int_D \sum_{\alpha_1 < \ldots < \alpha_{n-p}} (X_{\alpha_1} \wedge \cdots \wedge X_{\alpha_{n-p}} \wedge \Xi(dx^{\alpha_1} \wedge \cdots \wedge dx^{\alpha_{n-p}} \wedge a)) \rfloor d\psi, \quad (33)$$

where $X = X_1 \wedge \cdots \wedge X_n$ is the n-vector tangent to Γ at m such that $dx^\alpha(X_\beta) = \delta_\beta^\alpha$. Notice that this definition does not depend on the parametrization which is used.

Theorem 3: *Assume that Γ is the graph of some solution of the Hamilton equations (19). Then for any $a \in \mathfrak{P}^{p-1}\mathcal{M}$,*

$$\int_D da = \int_{D_\Gamma} \{\mathcal{H}\omega, {}^s a\}_s . \quad (34)$$

Proof: We can always assume that D is the image of some parametrization

$$\Delta \to D,$$

$$t \mapsto \mathcal{U}(x(t)) = (x(t), u(t), p(t)),$$

where Δ is an open subset of $\mathbb{R}^p$. Then

$$\int_{D\Gamma} \{\mathcal{H}\omega, {}^s a\}_s$$

$$= \int_\Delta - \sum_{\alpha_1 < \ldots < \alpha_{n-p}} (X_{\alpha_1} \wedge \cdots \wedge X_{\alpha_{n-p}} \wedge \Xi(dx^{\alpha_1} \wedge \cdots \wedge dx^{\alpha_{n-p}} \wedge a)) \rfloor d\mathcal{H}$$

$$\wedge \omega\left(\frac{\partial \mathcal{U} \circ x}{\partial t^1}, \ldots, \frac{\partial \mathcal{U} \circ x}{\partial t^p}\right) dt^1 \wedge \cdots \wedge dt^p$$

$$= \int_\Delta - \sum_{\alpha_1 < \ldots < \alpha_{n-p}} \sum_{\beta_1 < \ldots < \beta_p} d\mathcal{H} \wedge \omega(X_{\alpha_1}, \ldots, X_{\alpha_{n-p}}, \Xi(dx^{\alpha_1} \wedge \ldots \wedge dx^{\alpha_{n-p}} \wedge a),$$

$$\times X_{\beta_1}, \ldots, X_{\beta_p}) \det\left(\frac{\partial x^{\beta_1}}{\partial t^1}, \ldots, \frac{\partial x^{\beta_p}}{\partial t^p}\right) dt^1 \wedge \cdots \wedge dt^p .$$

Now by using (19),

$$\begin{aligned}
&\int_{D_\Gamma}\{\mathcal{H}\omega,{}^s a\}_s\\
&\quad=\int_\Delta(-1)^{n-p+1}\sum_{\alpha_1<\ldots<\alpha_{n-p}}\sum_{\beta_1<\ldots<\beta_p}\Omega(\Xi(dx^{\alpha_1}\\
&\qquad\wedge\ldots\wedge dx^{\alpha_{n-p}}\wedge a),X_{\alpha_1},\ldots,X_{\alpha_{n-p}},X_{\beta_1},\ldots,X_{\beta_p})\det\left(\frac{\partial x^{\beta_1}}{\partial t^1},\ldots,\frac{\partial x^{\beta_p}}{\partial t^p}\right)dt^1\wedge\cdots\wedge dt^p\\
&\quad=\int_\Delta\sum_{\alpha_1<\ldots<\alpha_{n-p}}\sum_{\beta_1<\ldots<\beta_p}dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge da(X_{\alpha_1},\ldots,X_{\alpha_{n-p}},X_{\beta_1},\ldots,X_{\beta_p})\\
&\qquad\times\det\left(\frac{\partial x^{\beta_1}}{\partial t^1},\ldots,\frac{\partial x^{\beta_p}}{\partial t^p}\right)dt^1\wedge\cdots\wedge dt^p\\
&\quad=\int_\Delta\sum_{\beta_1<\ldots<\beta_p}da(X_{\beta_1},\ldots,X_{\beta_p})\det\left(\frac{\partial x^{\beta_1}}{\partial t^1},\ldots,\frac{\partial x^{\beta_p}}{\partial t^p}\right)dt^1\wedge\cdots\wedge dt^p=\int_D da.
\end{aligned}$$

■

There exists, however, a much simpler concept of a bracket between $\mathcal{H}\omega$ and observables in $\mathfrak{P}^{p-1}\mathcal{M}$ which is also suitable for the dynamical equation in most cases. Namely we call a form a in $\mathfrak{P}^{p-1}\mathcal{M}$ an *admissible* form if $\forall\,\alpha_1<\cdots<\alpha_{n-p}$,

$$\begin{gathered}
dx^\alpha(\Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a))=0,\quad\forall\,\alpha\\
\text{or equivalently}\quad dx^\alpha(\Xi({}^s a))=0,\quad\forall\,\alpha.
\end{gathered}\tag{35}$$

The reader may wonder about the meaning of this definition since, in view of Lemma 5, all forms in $\mathfrak{P}^{p-1}\mathcal{M}$ are admissible for $p<n$. Again the point is that we may encounter variational problems with gauge symmetry and constraints for which nonadmissible forms exist in $\mathfrak{P}^{p-1}\mathcal{M}$.

Definition 5: Assume that $a\in\mathfrak{P}^{p-1}\mathcal{M}$ satisfies (35) and let $\psi\in\Gamma(\mathcal{M},\Lambda^n T^\star\mathcal{M})$. Then we define the $\mathfrak{p}$*-bracket*

$$\{\psi,a\}:=-\sum_{\alpha_1<\ldots<\alpha_{n-p}}\frac{\partial}{\partial x^{\alpha_1}}\wedge\cdots\wedge\frac{\partial}{\partial x^{\alpha_{n-p}}}\wedge\Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a)\rfloor d\psi.$$

Lemma 6: Let $a\in\mathfrak{P}^{p-1}\mathcal{M}$ be an admissible form [i.e., such that (35) holds] and let Γ be an n-dimensional submanifold of $\mathcal{M}$ which is a graph over $\mathcal{X}$. Then for any oriented submanifold D of dimension p included in Γ,

$$\int_{D_\Gamma}\{\mathcal{H}\omega,{}^s a\}_s=\int_D\{\mathcal{H}\omega,a\}.\tag{36}$$

Proof: We use the same notations as in the proof of Theorem 3. Because of the condition (35),

$$\sum_{\alpha_1<\ldots<\alpha_{n-p}} d\mathcal{H}\wedge\omega(X_{\alpha_1},\ldots,X_{\alpha_{n-p}},\Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a),X_{\beta_1},\ldots,X_{\beta_{n-p}})$$

$$=\sum_{\alpha_1<\ldots<\alpha_{n-p}} (-1)^{n-p} d\mathcal{H}(\Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a))\omega(X_{\alpha_1},\ldots,X_{\alpha_{n-p}},X_{\beta_1},\ldots,X_{\beta_{n-p}})$$

$$=\sum_{\alpha_1<\ldots<\alpha_{n-p}} (-1)^{n-p} d\mathcal{H}(\Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a))\omega$$

$$\times\left(\frac{\partial}{\partial x^{\alpha_1}},\ldots,\frac{\partial}{\partial x^{\alpha_{n-p}}},X_{\beta_1},\ldots,X_{\beta_{n-p}}\right)$$

$$=\sum_{\alpha_1<\ldots<\alpha_{n-p}} d\mathcal{H}\wedge\omega\left(\frac{\partial}{\partial x^{\alpha_1}},\ldots,\frac{\partial}{\partial x^{\alpha_{n-p}}},\Xi(dx^{\alpha_1}\wedge\cdots\wedge dx^{\alpha_{n-p}}\wedge a),X_{\beta_1},\ldots,X_{\beta_{n-p}}\right)$$

$$=-\sum_{\alpha_1<\ldots<\alpha_{n-p}} \{\mathcal{H}\omega,a\}(X_{\beta_1},\ldots,X_{\beta_{n-p}}).$$

This implies the result by summation over $\beta_1<\cdots<\beta_{n-p}$ and integration over D. ■

Corollary 1: Let $a\in\mathfrak{P}^{p-1}\mathcal{M}$ be an admissible form and let Γ be an n-dimensional submanifold of $\mathcal{M}$ which is a graph over $\mathcal{X}$ of a solution of the Hamilton equations (19). Then for any oriented submanifold D of dimension p included in Γ,

$$\int_D \{\mathcal{H}\omega,a\}=\int_D da. \tag{37}$$

Examples: The zero-form y^i and the one-form $y^i dy^j$ are admissible and

$$\{\mathcal{H}\omega,y^i\}=\sum_\alpha \frac{\partial\mathcal{H}}{\partial p_i^\alpha}\,dx^\alpha,$$

$$\{\mathcal{H}\omega,y^i dy^j\}=\sum_{\alpha<\beta} \frac{\partial\mathcal{H}}{\partial p_{ij}^{\alpha\beta}}\,dx^\alpha\wedge dx^\beta.$$

E. Noether theorem

It is natural to relate the Noether theorem to the pataplectic structure.

Let ξ be a tangent vector field on $\mathcal{X}\times\mathcal{Y}$. The ξ will be an infinitesimal symmetry of the variational problem if

$$\mathcal{L}_{\Xi(P_\xi)}(\theta-\mathcal{H}\omega)=0,$$

since then the integral $\int_\Gamma\theta-\mathcal{H}\omega$ is invariant under the action of the flow of ξ. Then for any solution $x\mapsto(U(x),p(x))$, of the Hamilton equations, the form $P_\xi^\star$ is closed along the graph of this solution. This means that if Γ is the graph of (U,p),

$$dP^\star_{\xi|\Gamma}=d(\xi](\theta-\mathcal{H}\omega))_{|\Gamma}=0.$$

This is a direct consequence of Theorem 2 and of the following calculation.

Lemma 7: For any section ξ of $\Gamma(\mathcal{X}\times\mathcal{Y},T(\mathcal{X}\times\mathcal{Y}))$, we have the relation

$$\{\mathcal{H}\omega,P_\xi\}=\mathcal{L}_{\Xi(P_\xi)}(\theta-\mathcal{H}\omega)+d(\xi]\mathcal{H}\omega). \tag{38}$$

Proof: Using the definition of $\{\mathcal{H}\omega,P_\xi\}$, we have

$$\mathcal{L}_{\Xi(P_\xi)}(\theta-\mathcal{H}\omega)=\Xi(P_\xi)\rfloor(d\theta-d\mathcal{H}\wedge\omega)+d(\Xi(P_\xi)\rfloor(\theta-\mathcal{H}\omega))=\Xi(P_\xi)\rfloor\Omega-\Xi(P_\xi)\rfloor d\mathcal{H}\wedge\omega$$
$$+d(\xi\rfloor\theta-\xi\rfloor\mathcal{H}\omega)=-dP_\xi+\{\mathcal{H}\omega,P_\xi\}+d(P_\xi-\xi\rfloor\mathcal{H}\omega),$$

and the result follows. ■

Remark 1: It appears that it will be interesting to study solutions of the Hamilton equations with the constraint $\mathcal{H}=0$. This is possible, because of the freedom left in the Legendre correspondence, thanks to the parameter ϵ. The advantage is that then the energy-momentum observables are described by $P_{a,g}$ which belongs to $\mathfrak{P}^{n-1}\mathcal{M}$.

Remark 2: As a consequence of these observations it is clear that on the submanifold $\mathcal{H}=0$, the set of Noether currents can be identified with $\mathfrak{P}_P^{n-1}\mathcal{M}$. So we can interpret the results of Proposition 1 concerning $\mathfrak{P}_P^{n-1}\mathcal{M}$ by saying that the set of Noether currents equipped with the $\mathfrak{p}$-bracket is a representation modulo exact terms of the Lie algebra of vector fields on $\mathcal{X}\times\mathcal{Y}$ with the Lie bracket. We recover thus various constructions of brackets on Noether currents (see for instance, Ref. 18).

V. EXAMPLES

We present here some examples from mathematical physics in order to illustrate our formalism. We shall see that, by allowing variants of the above theory, one can find formalisms which are more adapted to some special situations.

A. Interacting scalar fields

As the simplest example, consider a system of interacting scalar fields $\{\phi^1,\ldots,\phi^k\}$ on an oriented (pseudo-)Riemannian manifold $(\mathcal{X},g)$. One should keep in mind that $\mathcal{X}$ is a four-dimensional space–time and $g_{\alpha\beta}$ is a Minkowski metric. These fields can be seen as a map ϕ from $\mathcal{X}$ to $\mathbb{R}^k$ with its standard Euclidian structure. The metric g on $\mathcal{X}$ induces a volume form which reads in local coordinates

$$\omega:=g\,dx^1\wedge\cdots\wedge dx^n,\quad \text{where}\quad g:=\sqrt{|\det g_{\alpha\beta}(x)|}.$$

Let $V:\mathcal{X}\to\mathbb{R}^k$ be the interaction potential of the fields. Then the Lagrangian density is

$$L(x,\phi,d\phi):=\frac{1}{2}g^{\alpha\beta}(x)\frac{\partial\phi^i}{\partial x^\alpha}\frac{\partial\phi_i}{\partial x^\beta}-V(\phi(x)).$$

Here $\phi_i=\phi^i$ and we assume that we sum over all repeated indices. Alternatively one could work with the volume form being $dx^1\wedge\cdots\wedge dx^n$ and the Lagrangian density being gL, in order to apply directly the theory constructed in the previous sections. But we shall not choose this approach here and use a variant which makes clear the covariance of the problem.

We restrict ourselves to the Weyl theory, i.e., we work on the the submanifold $\mathcal{M}_{\text{Weyl}}$, as in Sec. II G. So we introduce the momentum variables ϵ and p_i^α and we start from the Cartan form,

$$\theta=\epsilon\omega+p_i^\alpha d\phi^i\wedge\omega_\alpha,$$

where $\omega_\alpha:=\partial_\alpha\rfloor\omega$. But here ω_α is not closed in general (because g is not constant), so

$$\Omega=d\theta=d\epsilon\wedge\omega+dp_i^\alpha\wedge d\phi^i\wedge\omega_\alpha-p_i^\alpha\frac{1}{g}\frac{\partial g}{\partial x^\alpha}d\phi^i\wedge\omega.$$

The Legendre transform is given by

$$p_i^\alpha=\frac{\partial L}{\partial(\partial_\alpha\phi^i)}=g^{\alpha\beta}\frac{\partial\phi^i}{\partial x^\beta}\Leftrightarrow\frac{\partial\phi^i}{\partial x^\alpha}=g_{\alpha\beta}p_i^\beta,$$

and the Hamiltonian is

$$\mathcal{H}(x,\phi,p)=\epsilon+\tfrac{1}{2}g_{\alpha\beta}p_i^\alpha p_i^\beta+V(\phi).$$

We use as conjugate variables the zero-forms ϕ^j and the $(n-1)$-forms

$$P_{i,f}:=f(x)p_i^\alpha\omega_\alpha=f(x)\frac{\partial}{\partial\phi^i}\rfloor\theta\in\mathfrak{P}^{n-1}\mathcal{M}_{\text{Weyl}}.$$

Taking account of the fact that ω_α is not closed, one finds

$$\Xi(P_{i,f})=f\frac{\partial}{\partial\phi^i}-\frac{\partial f}{\partial x^\alpha}p_i^\alpha\frac{\partial}{\partial\epsilon}$$

and

$$\{P_{i,f},\phi^j\}=\Xi(P_{i,f})\rfloor d\phi^j=f\delta_i^j.$$

Also the observables ϕ^j are admissible: $\Xi({}^s\phi^j)=\Sigma_\alpha(-1)^\alpha/g\ \tau_1\ldots\tau_{\alpha-1}\tau_{\alpha+1}\ldots\tau_n\,\partial/\partial p_j^\alpha$, and, according to Definition 5,

$$\{\mathcal{H}\omega,\phi^j\}=\frac{\partial\mathcal{H}}{\partial p_j^\alpha}dx^\alpha=g_{\alpha\beta}p_j^\beta dx^\alpha.$$

Moreover,

$$\{\mathcal{H}\omega,P_{i,f}\}=-\Xi(P_{i,f})\rfloor d(\mathcal{H}\omega)=\left(-f\frac{\partial V}{\partial\phi^i}+\frac{\partial f}{\partial x^\alpha}p_i^\alpha\right)\omega.$$

The dynamical equations are those along the graph of a solution,

$$\mathbf{d}\phi^i=\{\mathcal{H}\omega,\phi^i\}=g_{\alpha\beta}p_i^\beta dx^\alpha,$$

$$\mathbf{d}(fp_i^\alpha\omega_\alpha)=\{\mathcal{H}\omega,P_{i,f}\}=\left(-f\frac{\partial V}{\partial\phi^i}+\frac{\partial f}{\partial x^\alpha}p_i^\alpha\right)\omega.$$

The second equation gives

$$\frac{f}{g}\left(\frac{\partial g}{\partial x^\alpha}p_i^\alpha+g\frac{\partial p_i^\alpha}{\partial x^\alpha}+g\frac{\partial V}{\partial\phi^i}\right)=0, \tag{39}$$

while the first relation gives $\partial\phi^i/\partial x^\alpha=g_{\alpha\beta}p_i^\beta$. By substitution in (39) we find

$$\frac{1}{g}\frac{\partial}{\partial x^\alpha}\left(g\,g^{\alpha\beta}\frac{\partial\phi^i}{\partial x^\beta}\right)+\frac{\partial V}{\partial\phi^i}=0,$$

the Euler–Lagrange equations of the problem.

B. Conformal string theory

We consider maps u from a two-dimensional (pseudo-)Riemannian manifold $(\mathcal{X},g)$ with values in another (pseudo-)Riemannian manifold $(\mathcal{Y},h)$ of arbitrary dimension. The most general bosonic action for such maps is $\mathcal{L}[u]:=\int_{\mathcal{X}}L(x,u,du)\omega$ with $\omega:=g(x)dx^1\wedge dx^2$ and $g(x):=\sqrt{|\det g_{\alpha\beta}(x)|}$ as before, and

$$L(x,u,du) := \frac{1}{2}\left(h_{ij}(u(x))g^{\alpha\beta}(x) + b_{ij}(u(x))\frac{\epsilon^{\alpha\beta}}{g(x)}\right)\frac{\partial u^i}{\partial x^\alpha}\frac{\partial u^j}{\partial x^\beta},$$

where $b := \Sigma_{i<j} b_{ij}(y)dy^i \wedge dy^j$ is a given two-form on $\mathcal{Y}$ and $\epsilon^{12} = -\epsilon^{21} = 1$, $\epsilon^{11} = \epsilon^{22} = 0$. Hence

$$\mathcal{L}[u] = \int_{\mathcal{X}} \frac{1}{2} h_{ij}(u) g^{\alpha\beta}(x) \frac{\partial u^i}{\partial x^\alpha}\frac{\partial u^j}{\partial x^\beta}\omega + u^\star b.$$

Setting

$$G_{ij}^{\alpha\beta}(x,y) := h_{ij}(y)g^{\alpha\beta}(x) + b_{ij}(y)\frac{\epsilon^{\alpha\beta}}{g(x)} = G_{ji}^{\beta\alpha}(x,y),$$

we see that $L(x,u,du) = 1/2\, G_{ij}^{\alpha\beta}(x,u)(\partial u^i/\partial x^\alpha)(\partial u^j/\partial x^\beta)$ and the Euler–Lagrange equation for this functional is

$$\frac{1}{g}\frac{\partial}{\partial x^\alpha}\left(g\, G_{ij}^{\alpha\beta}(x,u(x))\frac{\partial u^j}{\partial x^\beta}\right) = \frac{\partial G_{jk}^{\beta\gamma}}{\partial y^i}\frac{\partial u^j}{\partial x^\beta}\frac{\partial u^k}{\partial x^\gamma}. \tag{40}$$

More covariant formulations exists for the case $b = 0$, which correspond to the harmonic map equation or when the metric on $\mathcal{X}$ is Riemannian using conformal coordinates and complex variables (see Ref. 10). The Cartan–Poincaré form on $\mathcal{M}$ is

$$\theta := \epsilon\omega + \sum_{\alpha,i} p_i^\alpha \omega_\alpha^i + \sum_{i<j} p_{ij}\omega_{12}^{ij}$$

(where $\omega_1^i = g\, dy^i \wedge dx^2$, $\omega_2^i = g\, dx^1 \wedge dy^i$ and $\omega_{12}^{ij} = g\, dy^i \wedge dy^j$). The pataplectic form is

$$\Omega = d\theta = d\epsilon\wedge\omega + \sum_{\alpha,i} dp_i^\alpha \wedge \omega_\alpha^i + \sum_{i<j} dp_{ij}\wedge\omega_{12}^{ij} - \sum_{\alpha,i}\frac{p_i^\alpha}{g}\frac{\partial g}{\partial x^\alpha}dy^i\wedge\omega$$
$$+ \sum_{i<j}\sum_\alpha p_{ij}\frac{\partial g}{\partial x^\alpha}dx^\alpha\wedge dy^i\wedge dy^j.$$

The Legendre correspondence is generated by the function

$$W(x,u,v,p) := \epsilon + p_i^\alpha v_\alpha^i + p_{ij}v_1^i v_2^j - L(x,u,v) = \epsilon + p_i^\alpha v_\alpha^i - \tfrac{1}{2}M_{ij}^{\alpha\beta}(x,y,p)v_\alpha^i v_\beta^j,$$

where we have denoted

$$M_{ij}^{\alpha\beta}(x,y,p) := h_{ij}(y)g^{\alpha\beta}(x) + \left(\frac{b_{ij}(y)}{g(x)} - p_{ij}\right)\epsilon^{\alpha\beta} = G_{ij}^{\alpha\beta}(x,y) - p_{ij}\epsilon^{\alpha\beta}.$$

This correspondence is given by the relation $\partial W/\partial v_\alpha^i = 0$ which gives

$$M_{ij}^{\alpha\beta}(x,y,p)v_\beta^j = p_i^\alpha. \tag{41}$$

Thus, given (x,y,p), finding (x,y,v,w) such that $(x,u,v,w)\leftrightarrow(x,y,p)$ amounts to solving first the linear system (41) for v and then w is just $W(x,y,v,p)$. This system has a solution in general in the open subset $\mathcal{O}$ of $\mathcal{M}$ on which the matrix

$$M=\begin{pmatrix} h_{ij}(y)g^{11}(x) & h_{ij}(y)g^{12}(x)+\dfrac{b_{ij}(y)}{g(x)}-p_{ij} \\ h_{ij}(y)g^{21}(x)-\dfrac{b_{ij}(y)}{g(x)}+p_{ij} & h_{ij}(y)g^{22}(x) \end{pmatrix}$$

is invertible. We remark that $\mathcal{O}$ contains actually the submanifold $\mathcal{R}:=\{(x,y,p)\in\mathcal{M}/g(x)p_{ij}=b_{ij}(y)\}$, so that the Legendre correspondence induces a diffeomorphism between $T\mathcal{Y}\otimes T^{\star}\mathcal{X}$ and $\mathcal{R}$.

We shall need to define on $\mathcal{O}$ the inverse of M, i.e., $K^{ij}_{\alpha\beta}(x,y,p)$ such that

$$K^{ij}_{\alpha\beta}(x,y,p)M^{\beta\gamma}_{jk}(x,y,p)=\delta^i_k\delta^\gamma_\alpha. \tag{42}$$

Now we can express the solution of (41) by

$$v^i_\alpha=K^{ij}_{\alpha\beta}(x,y,p)p^\beta_j, \tag{43}$$

and the Hamiltonian function is

$$\mathcal{H}(x,y,p):=\epsilon+\tfrac{1}{2}K^{ij}_{\alpha\beta}(x,y,p)p^\alpha_i p^\beta_j.$$

We use as conjugate variables the position functions y^i and the momentum one-forms

$$P_i:=\frac{\partial}{\partial y^i}\rfloor\theta=p^\alpha_i\omega_\alpha+gp_{ij}dy^j.$$

The Poisson brackets are obtained as follows. First, concerning $\{\mathcal{H}\omega,y^i\}$, we compute $\Xi({}^sy^i)=(1/g)(\tau_1\,\partial/\partial p^2_i-\tau_2\,\partial/\partial p^1_i)$. Since $dx^\alpha(\Xi({}^sy^i))=0$, $\forall\alpha$,

$$\{\mathcal{H}\omega,y^i\}=-\frac{1}{g}\left(\frac{\partial}{\partial x^1}\wedge\frac{\partial}{\partial p^2_i}-\frac{\partial}{\partial x^2}\wedge\frac{\partial}{\partial p^1_i}\right)\rfloor d\mathcal{H}\wedge\omega=\frac{\partial\mathcal{H}}{\partial p^\alpha_i}dx^\alpha=K^{ij}_{\alpha\beta}p^\beta_j dx^\alpha.$$

Next we compute dP_i:

$$dP_i=dp^\alpha_i\wedge\omega_\alpha+gdp_{ij}\wedge dy^j+p^\alpha_i\frac{\partial g}{\partial x^\alpha}\frac{\omega}{g}+p_{ij}\frac{\partial g}{\partial x^\alpha}dx^\alpha\wedge dy^j=-\frac{\partial}{\partial y^i}\rfloor\Omega.$$

Hence

$$\Xi(P_i)=\frac{\partial}{\partial y^i}.$$

Because of $dx^\alpha(\Xi(P_i))=0$, $\forall\alpha$, and of Proposition 2 we deduce that

$$\{P_i,y^j\}=\Xi(P_i)\rfloor dy^j=\delta^j_i,$$

$$\{\mathcal{H}\omega,P_i\}=-\Xi(P_i)\rfloor d(\mathcal{H}\omega)=-\frac{\partial K^{jk}_{\alpha\beta}}{\partial y^i}p^\alpha_j p^\beta_k\omega.$$

Notice that, because of (42),

$$\frac{\partial K^{jk}_{\alpha\beta}}{\partial y^i}=-K^{jl}_{\alpha\gamma}\frac{\partial M^{\gamma\delta}_{lm}}{\partial y^i}K^{mk}_{\delta\beta},$$

and thus

$$\{\mathcal{H}\omega, P_i\} = \frac{\partial M_{lm}^{\gamma\delta}}{\partial y^i} K_{\alpha\gamma}^{jl} K_{\delta\beta}^{mk} p_j^\alpha p_k^\beta \omega.$$

The equations of motion are

$$\begin{aligned} \mathbf{d}y^i &= \{\mathcal{H}\omega, y^i\} = K_{\alpha\beta}^{ij} p_j^\beta dx^\alpha, \\ \mathbf{d}P_i &= \{\mathcal{H}\omega, P_i\} = \frac{\partial M_{lm}^{\gamma\delta}}{\partial y^i} K_{\alpha\gamma}^{jl} K_{\delta\beta}^{mk} p_j^\alpha p_k^\beta \omega, \end{aligned} \tag{44}$$

along the graph Γ of any solution of the Hamilton equations. From the first equation we deduce that

$$\frac{\partial y^i}{\partial x^\alpha} = K_{\alpha\beta}^{ij} p_j^\beta \Leftrightarrow p_i^\alpha = M_{ij}^{\alpha\beta} \frac{\partial y^j}{\partial x^\beta}. \tag{45}$$

Now using (45) we see that along Γ,

$$\begin{aligned} P_{i|\Gamma} = (p_i^\alpha \omega_\alpha + g p_{ij} dy^j)_{|\Gamma} &= \left(M_{ij}^{\alpha\beta} \frac{\partial y^j}{\partial x^\beta} + p_{ij} \epsilon^{\alpha\beta} \frac{\partial y^j}{\partial x^\beta} \right) \omega_\alpha \\ &= G_{ij}^{\alpha\beta} \frac{\partial y^j}{\partial x^\beta} \omega_\alpha = \left(h_{ij} g^{\alpha\beta} + \frac{b_{ij}}{g} \epsilon^{\alpha\beta} \right) \frac{\partial y^j}{\partial x^\beta} \omega_\alpha, \end{aligned}$$

and so the left-hand side of the second equation of (44) is

$$dP_{i|\Gamma} = \frac{1}{g} \frac{\partial}{\partial x^\alpha} \left[g G_{ij}^{\alpha\beta} \frac{\partial y^j}{\partial x^\beta} \right] \omega.$$

And still using (45) the right-hand side of the second equation of (44) along Γ is

$$\frac{\partial M_{jk}^{\alpha\beta}}{\partial y^i} \frac{\partial y^j}{\partial x^\alpha} \frac{\partial y^k}{\partial x^\beta} \omega.$$

Hence we recover the Euler–Lagrange equation (40).

C. The electromagnetic field

Here the field is a one-form $A = A_\alpha dx^\alpha$ defined on the (pseudo-)Riemannian manifold $\mathcal{X}$ [which can also be thought of as a connection one-form on a U(1)-bundle]. Its differential $dA := F$ is the electromagnetic field. We still denote $g_{\alpha\beta}$ the metric on $\mathcal{X}$ and $\omega = g dx^1 \wedge \cdots \wedge dx^n$ the volume form. We are given some vector field $\vec{J} = j^\alpha \partial_\alpha$ on $\mathcal{X}$ (the electric current field) and we define the Lagrangian density by

$$L(x, A, dA) := -\tfrac{1}{4} F_{\alpha\beta} F^{\alpha\beta} - j^\alpha A_\alpha,$$

where $F_{\alpha\beta} := \partial_\alpha A_\beta - \partial_\beta A_\alpha$ and $F^{\alpha\beta} := g^{\alpha\gamma} g^{\beta\delta} F_{\gamma\delta}$.

The Euler–Lagrange equation could be written

$$\frac{1}{g} \frac{\partial}{\partial x^\alpha} (g F^{\alpha\beta}) \omega_\beta = j^\beta \omega_\beta, \tag{46}$$

or using the notations

$$\star F := \sum_{\alpha<\beta} F^{\alpha\beta} \frac{\partial}{\partial x^\alpha} \rfloor \frac{\partial}{\partial x^\beta} \rfloor \omega \quad \text{and} \quad j := j^\alpha \omega_\alpha ,$$
$$d(\star F) = j. \tag{47}$$

We remark that in order to have solutions it is necessary to suppose that $dj=0$, which is the electric charge conservation law. [Note also that by writing the electromagnetic functional $\int 1/2 F\wedge\star F - A\wedge j$, one sees immediately that the condition $dj=0$ ensures that this functional is invariant by gauge transformations $A\mapsto A+df$ up to the addition of $\int d(fj)$.]

In our framework the fact that the field is a one-form means that we replace the configuration space $\mathcal{X}\times\mathcal{Y}$ by $T^\star\mathcal{X}$. Thus the pataplectic manifold is $\mathcal{M} := \Lambda^n T^\star(T^\star\mathcal{X})$. We shall here restrict to the "Weyl" submanifold of $\mathcal{M}$ (see Sec. II G) which is described by

$$\mathcal{M}_{\text{Weyl}} := \{(x,A,p)/x\in\mathcal{X}, A\in T^\star_x\mathcal{X}, p\in\Lambda^n T^\star_{(x,A)}(T^\star\mathcal{X}), \partial_{A_\alpha}\wedge\partial_{A_\beta}\rfloor p=0, \forall\,\alpha,\beta\}.$$

The latter condition on p means that in local coordinates, $p=\epsilon\omega+\Sigma_{\alpha,\beta}p^{A_\alpha\beta}dA_\alpha\wedge\omega_\beta$. The Cartan form is

$$\theta := \epsilon\omega + \sum_{\alpha,\beta} p^{A_\alpha\beta} dA_\alpha\wedge\omega_\beta ,$$

with still $\omega_\beta := \partial_\beta\rfloor\omega$, and the pataplectic form is

$$\Omega := d\theta = d\epsilon\wedge\omega + \sum_{\alpha,\beta} dp^{A_\alpha\beta}\wedge dA_\alpha\wedge\omega_\beta - \sum_{\alpha,\beta} p^{A_\alpha\beta}\frac{1}{g}\frac{\partial g}{\partial x^\beta} dA_\alpha\wedge\omega.$$

Computing the Legendre transform in $\mathcal{M}_{\text{Weyl}}$, using $W(x,A,dA,p)=\epsilon+\Sigma_{\alpha,\beta}p^{A_\alpha\beta}\partial_\beta A_\alpha - L(x,A,dA)$, gives the momenta

$$p^{A_\alpha\beta} := \frac{\partial L}{\partial(\partial_\beta A_\alpha)} = F^{\alpha\beta}.$$

We see that the Legendre transform works only provided the compatibility condition

$$p^{A_\alpha\beta} + p^{A_\beta\alpha} = 0 \tag{48}$$

is satisfied. It is an example of a Dirac primary constraint. Henceforth we shall be restricted to the submanifold

$$\mathcal{M}_{\text{Maxwell}} := \{(x,A,p)\in\mathcal{M}_{\text{Weyl}}/p^{A_\alpha\beta}+p^{A_\beta\alpha}=0\},$$

along which we are able to obtain an expression for the Hamiltonian

$$\mathcal{H}(x,A,p) = \epsilon - \tfrac{1}{4} g_{\alpha\gamma} g_{\beta\delta} p^{A_\alpha\beta} p^{A_\gamma\delta} + j^\alpha A_\alpha .$$

A naive use of this Hamiltonian function leads to incorrect dynamical equations. Another possibility, which was already proposed in Ref. 16, is to use the one-form on $\mathcal{M}_{\text{Maxwell}}$ as dynamical variable

$$A := A_\alpha dx^\alpha .$$

Note that here A_α is not a local function of x but fiber coordinate. Then, as it will be proved below, the momentum variable canonically conjugate to A may be chosen to be the $(n-2)$-form

$$\pi := \frac{1}{2}\sum_{\alpha,\beta} p^{A_\alpha\beta}\frac{\partial}{\partial x^\alpha}\rfloor\frac{\partial}{\partial x^\beta}\rfloor\omega.$$

Its associated s-form is

$${}^s\pi = \frac{1}{2}\sum_{\alpha,\beta} p^{A_\alpha\beta}\left(\tau_\alpha\frac{\partial}{\partial x^\beta} - \tau_\beta\frac{\partial}{\partial x^\alpha}\right)\rfloor\omega = \sum_{\alpha,\beta} p^{A_\alpha\beta}\tau_\alpha\frac{\partial}{\partial x^\beta}\rfloor\omega.$$

Hence, using (48),

$$d\,{}^s\pi = \sum_{\alpha,\beta}\tau_\alpha dp^{A_\alpha\beta}\wedge\left(\frac{\partial}{\partial x^\beta}\rfloor\omega\right) + \sum_{\alpha,\beta}\frac{p^{A_\alpha\beta}}{g}\tau_\alpha\frac{\partial g}{\partial x^\beta}\omega = -\sum_\alpha \tau_\alpha\frac{\partial}{\partial A_\alpha}\rfloor\Omega$$

and

$$\Xi({}^s\pi) = \sum_\alpha \tau_\alpha\frac{\partial}{\partial A_\alpha}.$$

We also have (denoting $\omega_\beta := \partial/\partial x^\beta\rfloor\omega$ and $\tau_{1\ldots\ldots n}^{\ldots\alpha\ldots\beta\ldots} := \tau_1\cdots\tau_{\alpha-1}\tau_{\alpha+1}\cdots\tau_{\beta-1}\tau_{\beta+1}\cdots\tau_n$)

$${}^sA = \sum_{\alpha<\beta}(-1)^{n+\alpha+\beta}\frac{A_\alpha}{g}\tau_{1\ldots\ldots n}^{\ldots\alpha\ldots\beta\ldots}\omega_\beta - \sum_{\beta<\alpha}(-1)^{n+\alpha+\beta}\frac{A_\alpha}{g}\tau_{1\ldots\ldots n}^{\ldots\beta\ldots\alpha\ldots}\omega_\beta$$

and

$$\Xi({}^sA) = \sum_{\alpha<\beta}(-1)^{n+\alpha+\beta+1}\frac{A_\alpha}{g}\tau_{1\ldots\ldots n}^{\ldots\alpha\ldots\beta\ldots}\frac{\partial}{\partial p^{A_\alpha\beta}} - \sum_{\beta<\alpha}(-1)^{n+\alpha+\beta+1}\frac{A_\alpha}{g}\tau_{1\ldots\ldots n}^{\ldots\beta\ldots\alpha\ldots}\frac{\partial}{\partial p^{A_\alpha\beta}}.$$

A computation using (48) gives

$$\begin{aligned}\{{}^s\pi, {}^sA\}_s &= \sum_{\alpha,\beta,\gamma}(-1)^{n+\alpha+\beta+1}\tau_\gamma\left(\sum_{\alpha<\beta}\frac{A_\alpha}{g}\tau_{1\ldots\ldots n}^{\ldots\alpha\ldots\beta\ldots} - \sum_{\beta<\alpha}\frac{A_\alpha}{g}\tau_{1\ldots\ldots n}^{\ldots\beta\ldots\alpha\ldots}\right)\frac{\partial}{\partial p^{A_\alpha\beta}}\rfloor\frac{\partial}{\partial A_\gamma}\rfloor\Omega\\ &= 2(-1)^n(n-1)\sum_\alpha \tau_1\cdots\tau_{\alpha-1}\tau_{\alpha+1}\cdots\tau_n\frac{\partial}{\partial x^\alpha}\rfloor dx^1\wedge\cdots\wedge dx^n\\ &= {}^s(2(-1)^n(n-1)).\end{aligned}$$

Thus

$$\{\pi, A\} = 2(-1)^n(n-1).$$

As it may be anticipated by Corollary 1, the dynamical equations are described by the following identities to be true along the graph of a solution of the Hamilton equations:

$$\mathbf{d}A=\{\mathcal{H}\omega,A\}$$

$$=(-1)^{n+\alpha+\beta}\Bigg[\sum_{\alpha<\beta}\frac{1}{g}\frac{\partial}{\partial x^1}\wedge\cdots\frac{\partial}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial x^{\alpha+1}}\wedge\cdots\frac{\partial}{\partial x^{\beta-1}}\wedge\frac{\partial}{\partial x^{\beta+1}}\wedge\cdots\frac{\partial}{\partial x^n}\wedge\frac{\partial}{\partial p^{A_\alpha\beta}}$$

$$-\sum_{\beta<\alpha}\frac{1}{g}\frac{\partial}{\partial x^1}\wedge\cdots\frac{\partial}{\partial x^{\beta-1}}\wedge\frac{\partial}{\partial x^{\beta+1}}\wedge\cdots\frac{\partial}{\partial x^{\alpha-1}}\wedge\frac{\partial}{\partial x^{\alpha+1}}\wedge\cdots\frac{\partial}{\partial x^n}\wedge\frac{\partial}{\partial p^{A_\alpha\beta}}\Bigg]\rfloor d\mathcal{H}\wedge\omega$$

$$=\sum_{\alpha,\beta}\frac{\partial\mathcal{H}}{\partial p^{A_\alpha\beta}}dx^\beta\wedge dx^\alpha=\sum_{\alpha<\beta}g_{\alpha\gamma}g_{\beta\delta}p^{A_\gamma\delta}dx^\alpha\wedge dx^\beta,$$

$$\mathbf{d}\pi=\{\mathcal{H}\omega,\pi\}=-\sum_\alpha\frac{\partial}{\partial x^\alpha}\wedge\frac{\partial}{\partial A_\alpha}\rfloor d\mathcal{H}\wedge\omega=\frac{\partial\mathcal{H}}{\partial A_\alpha}\omega_\alpha=j^\alpha\omega_\alpha=j.$$

The first equation leads to $\partial A_\beta/\partial x^\alpha-\partial A_\alpha/\partial x^\beta=g_{\alpha\gamma}g_{\beta\delta}p^{A_\gamma\delta}$ which implies $F_{\alpha\beta}=g_{\alpha\gamma}g_{\beta\delta}p^{A_\gamma\delta}$ or equivalently $p^{A_\alpha\beta}=F^{\alpha\beta}$. This can be translated into the relation

$$\pi=\star F,\quad \text{along } \Gamma.$$

By substitution in the second equation, $\mathbf{d}\pi=j$, it gives immediately (47).

A last observation is that infinitesimal gauge transformations $\delta A=df$ [for $f\in\mathcal{C}^\infty(\mathcal{X})$] are generated by the Poisson bracket with $df\wedge\pi$. We have indeed

$$d(df\wedge\pi)=-df\wedge d\pi=-\sum_\alpha\frac{\partial f}{\partial x^\alpha}\frac{\partial}{\partial A_\alpha}\rfloor\Omega,$$

so that $df\wedge\pi\in\mathfrak{P}^{n-1}\mathcal{M}$ and $\Xi(df\wedge\pi)=\Sigma_\alpha\partial f/\partial x^\alpha\partial/\partial A_\alpha$. We deduce that

$$\{df\wedge\pi,\pi\}=\Xi(df\wedge\pi)\rfloor d\pi=0,$$

$$\{df\wedge\pi,A\}=\Xi(df\wedge\pi)\rfloor dA=df.$$

Notice that we could replace $df\wedge\pi$ by $-fd\pi$ or $f(j-d\pi)$ without changing the brackets with π and A.

VI. CONCLUSION

We obtained a Hamiltonian formulation for variational problems with an arbitrary number of variables. This could be the starting point for building a covariant quantum field theory without requiring the space–time to be Minkowskian. Notice also that we may enlarge the concept of pataplectic manifolds as manifolds equipped with a closed $(n+1)$-form, and extend to this context notions like the $\mathfrak{p}$-bracket. Some of these questions will be treated in a forthcoming paper.

Boltzmanngasse 5, A-1090 Vienna, Austria

(Received 25 September 2001; accepted for publication 29 January 2002)

We perform the Batalin–Vilkovisky quantization of Yang–Mills theory on a two-point space, discussing the formulation of Connes–Lott as well as Connes' real spectral triple approach. Despite the model's apparent simplicity the gauge structure reveals infinite reducibility and the gauge fixing is afflicted with the Gribov problem. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467096]

I. INTRODUCTION

Noncommutative geometry constitutes one of the fascinating new concepts in current theoretical physics research with many promising impacts and applications in a diverse set of fields.[1–5] Specifically we mention the construction of the classical action of the standard model,[6,7] unifying the Einstein–Hilbert action, the Yang–Mills action, the Dirac action, and the Klein–Gordon action with the Higgs potential and spontaneous symmetry breaking.

The basic idea of noncommutative geometry is to replace the notion of differential manifolds and functions by specific noncommutative algebras of functions; the geometric setting of gauge theories as fiber bundles finds a noncommutative generalization in terms of finitely generated projective modules over noncommutative algebras.

It seems, however, that within this noncommutative algebraic framework the concepts of *quantizing* gauge theories, specifically the issues of gauge fixing and the proper definition of a path integral measure for the standard model, are not yet fully understood.[8] Our intention for this paper is not to present new results in these rather fundamental issues. Instead we quantize one of the simplest toy models for noncommutative gauge theories, which is Yang–Mills theory on a two-point space, by applying the standard Batalin–Vilkovisky method.[9–12] Somewhat surprisingly we find that despite the model's original simplicity the gauge structure reveals infinite reducibility and the gauge fixing is afflicted with the Gribov[13] problem.

In Sec. II we work out the formulation of the model following the approach of Connes–Lott.[14] In Sec. III the infinite reducibility of the gauge symmetry is explained; the Batalin–Vilkovisky quantization of the model is performed in Sec. IV. We discuss the Gribov problem in Sec. V and finally, in Sec. VI, recast our results within Connes' real spectral triple approach.[6,15]

II. THE FORMULATION OF CONNES–LOTT

Following Ref. 14 we define the Yang–Mills Theory on a two-point space in terms of the algebra $\mathbf{A}=C\oplus C$, which is represented by diagonal complex valued 2×2 matrices; the Dirac operator D is given by $D=\left(\begin{smallmatrix}0 & \mu\\ \mu & 0\end{smallmatrix}\right)$, where $\mu\in\mathrm{R}$ is an arbitrary parameter. The differential p-forms ω_p are constant, diagonal or off-diagonal 2×2 matrices, depending on whether p is even or odd, respectively. One has a $\mathcal{Z}_2$ grading of matrices (to be diagonal or off-diagonal) and obtains a matrix derivative $\mathbf{d}$. Acting on 2×2 matrices it is a nilpotent graded derivation, $\mathbf{d}a=i\mu\left(\begin{smallmatrix}a_{21}+a_{12} & a_{22}-a_{11}\\ a_{11}-a_{22} & a_{21}+a_{12}\end{smallmatrix}\right)$ where $a=\left(\begin{smallmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{smallmatrix}\right)$, $a_{ij}\in\mathrm{C}$, with respect to the matrix product and the matrix $\mathcal{Z}_2$ grading.

Specifically the one-forms are given by $\omega_1=a\,\mathbf{d}b$, where $a,b\in\mathbf{A}$, which are odd (i.e., off-diagonal) matrices. The subset of anti-Hermitean one-forms $\mathcal{A}$ can be parametrized by

a)Electronic mail: helmuth.hueffel@univie.ac.at

$$\mathcal{A}=\begin{pmatrix} 0 & i\mu\phi \\ i\mu\overline{\phi} & 0 \end{pmatrix} \tag{2.1}$$

and constitute the gauge fields of the model; here $\phi\in\mathrm{C}$ denotes a (constant) scalar field. The (rigid) gauge transformations of $\mathcal{A}$ are defined by

$$\mathcal{A}^U=U^{-1}\mathcal{A}U+U^{-1}\mathbf{d}U \tag{2.2}$$

with U being a unitary element of the algebra **A**. It is a constant, even and unitary matrix which we define to have only Abelian entries; it can exponentially be parametrized by the even matrix ϵ,

$$U=\begin{pmatrix} e^{i\alpha} & 0 \\ 0 & e^{i\beta} \end{pmatrix}=e^{i\epsilon},\quad \epsilon=\begin{pmatrix} \alpha & 0 \\ 0 & \beta \end{pmatrix},\quad \alpha,\beta\in\mathrm{R}. \tag{2.3}$$

We point out that the Yang–Mills theory on the two-point space is an ideal play ground to study quantization techniques: Due to the non-Abelian form of the gauge transformations (2.2) the model shares many interesting features with the standard Yang–Mills theory, yet it has no physical space–time dependence and allows extremely simple calculations. We even restrict ourselves to just Abelian entries along the diagonal of U, thus studying a $U(1)\times U(1)$ gauge model with non-Abelian features.

We define a scalar product for 2×2 matrices a,b by $\langle a|b\rangle=\mathrm{tr}\, a^\dagger b$ where † denotes taking the Hermitian conjugate. The curvature $\mathcal{F}$ is defined as usual by $\mathcal{F}=\mathbf{d}\mathcal{A}+\mathcal{A}\mathcal{A}$ and transforms under gauge transformations as $\mathcal{F}^U=U^{-1}\mathcal{F}U$; for an action which is automatically invariant under the gauge transformations (2.2) one takes

$$S_{\mathrm{inv}}=\tfrac{1}{2}\langle\mathcal{F}|\mathcal{F}\rangle. \tag{2.4}$$

Written out in components the scalars' contribution is given by

$$S_{\mathrm{inv}}=\mu^4((\phi+\overline{\phi})+\phi\overline{\phi})^2. \tag{2.5}$$

It was pointed out in Refs. 16 and 17 that the most general form of the gauge invariant action also allows a term proportional to $\mathrm{tr}\,\mathcal{F}$,

$$\hat{S}_{\mathrm{inv}}=\tfrac{1}{2}(\langle\mathcal{F}|\mathcal{F}\rangle+\gamma\,\mathrm{tr}\,\mathcal{F}) \tag{2.6}$$

where $\gamma\in R$ is an arbitrary parameter. We note, however, that one requires the scalars ϕ to be vanishing at the minimum of the action so that in the case of (2.6) the scalars have to be shifted appropriately. Explicitly we have

$$\hat{S}_{\mathrm{inv}}=\mu^4(2u+u^2+v^2)\left(2u+u^2+v^2-\frac{\gamma}{\mu^2}\right), \tag{2.7}$$

where we introduced $\phi=u+iv$. Whereas the local maximum is at

$$u_{\max}=-1,\quad v_{\max}=0, \tag{2.8}$$

the circle of local minima is given by

$$(u+1)^2+v^2=1+\frac{\gamma}{2\mu^2},\quad \text{where}\quad \gamma\geqslant-2\mu^2. \tag{2.9}$$

We choose

$$u_{\min}=\sqrt{1+\frac{\gamma}{2\mu^2}}-1, \quad v_{\min}=0 \tag{2.10}$$

and define shifted scalars $\tilde{\phi}=\phi-u_{\min}$ which by construction are vanishing at the minimum of the action. From

$$\hat{S}_{\text{inv}}=\mu^4\left((\tilde{\phi}+\bar{\tilde{\phi}})\sqrt{1+\frac{\gamma}{2\mu^2}}+\tilde{\phi}\bar{\tilde{\phi}}\right)^2-\frac{\gamma^2}{2}. \tag{2.11}$$

we omit the irrelevant constant $-\gamma^2/2$, rescale $\tilde{\phi}=\hat{\phi}\sqrt{1+\gamma/2\mu^2}$ and $\mu\sqrt{1+\gamma/2\mu^2}=\hat{\mu}$ so that finally

$$\hat{S}_{\text{inv}}=\hat{\mu}^4((\hat{\phi}+\bar{\hat{\phi}})+\hat{\phi}\bar{\hat{\phi}})^2. \tag{2.12}$$

We see that the inclusion of the action term linear in $\mathcal{F}$ can be compensated by shifting and rescaling of the scalar field ϕ, as well as by rescaling of the parameter μ. As the scalar fields and the parameter are arbitrary from the outset the inclusion of the action term linear in $\mathcal{F}$ appears to be unnecessary. In the following we will set $\mu=1$ for simplicity and stick to the action term (2.4) quadratic in $\mathcal{F}$.

III. GAUGE TRANSFORMATIONS AND INFINITE REDUCIBILITY

The (zero-stage) gauge transformations (2.2) explicitly are given by

$$\mathcal{A}^U=\begin{pmatrix} 0 & ie^{i(\beta-\alpha)}(\phi+1)-i \\ ie^{-i(\beta-\alpha)}(\bar{\phi}+1)-i & 0 \end{pmatrix}, \tag{3.1}$$

so that the usual Abelian gauge transformations are implied for the Higgs fields $H=\phi+1$ and $\bar{H}=\bar{\phi}+1$. To discuss infinitesimal (zero-stage) gauge transformations we introduce an even, infinitesimal (zero-stage) gauge parameter matrix $\boldsymbol{\epsilon}_e^0$ in terms of which $U\simeq\mathbf{1}+\boldsymbol{\epsilon}_e^0$. The infinitesimal (zero-stage) gauge variation of $\mathcal{A}$ derives as

$$\delta_{\boldsymbol{\epsilon}_e^0}\mathcal{A}=i\mathbf{R}^0\,\boldsymbol{\epsilon}_e^0,$$

$$\text{where} \quad \mathbf{R}^0=\mathbf{D}. \tag{3.2}$$

Here the (zero-stage) gauge generator $\mathbf{R}^0$ is defined in terms of the covariant matrix derivative $\mathbf{D}$, which acting on $\boldsymbol{\epsilon}_e^0$ is given by $\mathbf{D}\boldsymbol{\epsilon}_e^0=\mathbf{d}\boldsymbol{\epsilon}_e^0+[\mathcal{A},\boldsymbol{\epsilon}_e^0]$.

A gauge symmetry is called irreducible if the (zero-stage) gauge generator $\mathbf{R}^0$ does not possess any zero mode.[9–12]

It is amusing to note that the Yang–Mills theory on the two-point space reveals an infinitely reducible gauge symmetry: We observe that $\mathbf{D}\,\mathbf{d}$ is vanishing on arbitrary odd matrices. Thus there exists a zero mode $\boldsymbol{\epsilon}_e^1$ for the (zero-stage) gauge generator $\mathbf{R}^0$, such that

$$\mathbf{R}^0\boldsymbol{\epsilon}_e^1=0$$

$$\text{where} \quad \boldsymbol{\epsilon}_e^1=\mathbf{R}^1\boldsymbol{\epsilon}_o^1 \quad \text{with} \quad \mathbf{R}^1=\mathbf{d}. \tag{3.3}$$

Here $\boldsymbol{\epsilon}_o^1$ denotes an odd, infinitesimal (first-stage) gauge parameter matrix and $\mathbf{R}^1$ the corresponding (first-stage) gauge generator. As a matter of fact an infinite tower of (higher-stage) gauge generators $\mathbf{R}^s$, $s=1,2,3,\ldots$ with never ending gauge invariances for gauge invariances is arising: We define $\mathbf{R}^s=\mathbf{d}$ for $s=1,2,3,\ldots$ so that for each gauge generator there exists an additional zero mode

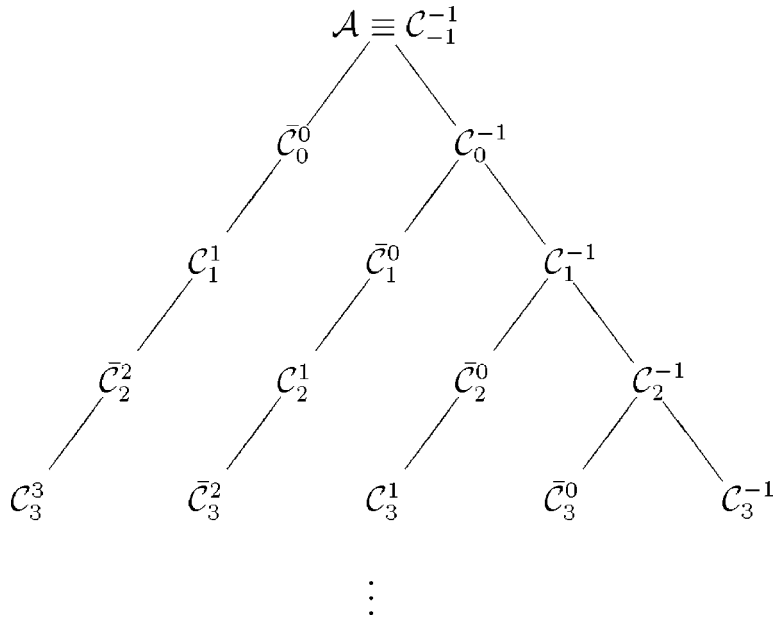

FIG. 1. The infinite tower of ghost fields

$$\begin{aligned} &\mathbf{R}^1\epsilon_o^2=0 \quad (\epsilon_o^2=\mathbf{R}^2\epsilon_e^2),\\ &\mathbf{R}^2\epsilon_e^3=0 \quad (\epsilon_e^3=\mathbf{R}^3\epsilon_o^3),\\ &\cdots \quad \cdots \end{aligned} \tag{3.4}$$

due to the nilpotency $\mathbf{d}^2=0$.

IV. GAUGE FIXING AND *BV*-QUANTIZATION

In this section we straightforwardly apply the usual field theory *BV*-path integral quantization scheme[10–12] to the Connes–Lott two-point model: In addition to the original gauge field $\mathcal{A}$, which for notational convenience we temporarily denote by $\mathcal{A}\equiv\mathcal{C}_{-1}^{-1}$, we introduce ghost fields $\mathcal{C}_s^k$, $\infty\geqslant s\geqslant -1$, $s\geqslant k\geqslant -1$ with k odd, as well as auxiliary ghost fields $\bar{\mathcal{C}}_s^k$, $\infty\geqslant s\geqslant 0$, $s\geqslant k\geqslant 0$ with k even (see Fig. 1).

Furthermore we add Lagrange multiplier fields π_s^k, $\infty\geqslant s\geqslant 1, s\geqslant k\geqslant 1$ with k odd and $\bar{\pi}_s^k$, $\infty\geqslant s\geqslant 0$, $s\geqslant k\geqslant 0$ with k even. Finally we introduce antifields $\mathcal{C}_s^k{}^*$, $\bar{\mathcal{C}}_s^k{}^*$. All the ghosts $\mathcal{C}_s^k$, $\bar{\mathcal{C}}_s^k$, multiplier fields π_s^k, $\bar{\pi}_s^k$, and antifields $\mathcal{C}_s^k{}^*$, $\bar{\mathcal{C}}_s^k{}^*$ are matrices which are even for s even and odd for s odd, respectively. We define all the ghost fields $\mathcal{C}_s^k$, $\bar{\mathcal{C}}_s^k$ to be anti-Hermitean, all the multiplier fields π_s^k, $\bar{\pi}_s^k$ to be Hermitean. When s is taken to be odd the ghosts are bosonic whereas the multiplier fields are fermionic; for s even the ghosts are fermionic and the multiplier fields are bosonic, respectively.

An important quantity for the construction of the *BV*-action is the commutator of (zero-stage) infinitesimal gauge transformations $[\delta_{\epsilon_1},\delta_{\epsilon_2}]\mathcal{A}$, where $\delta_{\epsilon_k}\mathcal{A}=i\mathbf{R}^0\epsilon_k$ with even matrices ϵ_k, $k=1,2$. It is easy to see that this commutator is vanishing. The *BV*-action therefore obtains as

$$S_{BV}=S_{\text{inv}}+S_{\text{aux}}-\langle\mathcal{C}_{-1}^{-1}{}^*|\mathbf{D}\,\mathcal{C}_0^{-1}\rangle-\sum_{s=1,3,5,\ldots}^{\infty}\langle\mathcal{C}_s^{-1}{}^*|\mathbf{d}\,\mathcal{C}_{s+1}^{-1}\rangle-i\sum_{s=0,2,4,\ldots}^{\infty}\langle\mathcal{C}_s^{-1}{}^*|\mathbf{d}\,\mathcal{C}_{s+1}^{-1}\rangle, \tag{4.1}$$

where we denote by S_{aux} the auxiliary field action

$$S_{\text{aux}}=\sum_{k=0,2,4,\ldots}^{\infty}\sum_{s=k}^{\infty}\langle\overline{\pi}_s^k|\overline{\mathcal{C}}_s^k *\rangle+\sum_{k=1,3,5,\ldots}^{\infty}\sum_{s=k}^{\infty}\langle\mathcal{C}_s^k *|\pi_s^k\rangle. \tag{4.2}$$

By $\boldsymbol{\delta}$ we denote a nilpotent matrix coderivative operator, $\boldsymbol{\delta}a=i\left(\begin{smallmatrix}a_{12}-a_{21} & -a_{11}-a_{22}\\ -a_{11}-a_{22} & -a_{12}+a_{21}\end{smallmatrix}\right)$ where $a=\left(\begin{smallmatrix}a_{11}\,a_{12}\\ a_{21}\,a_{22}\end{smallmatrix}\right)$, $a_{ij}\in\mathrm{C}$, which is defined by $\langle\boldsymbol{\delta}a_o|b_e\rangle=\langle a_o|\mathbf{d}b_e\rangle$ and $\langle\boldsymbol{\delta}a_e|b_o\rangle=\langle a_e|\mathbf{d}b_o\rangle$. It allows one to define gauge fixing conditions

$$\begin{aligned}&\boldsymbol{\delta}\mathcal{C}_s^k=0,\quad \infty\geqslant s\geqslant -1,\quad s\geqslant k\geqslant -1\quad \text{with } k \text{ odd},\\ &\boldsymbol{\delta}\overline{\mathcal{C}}_s^k=0,\quad \infty\geqslant s\geqslant 0,\quad s\geqslant k\geqslant 0\quad \text{with } k \text{ even},\end{aligned} \tag{4.3}$$

which are similar to the Feynman gauge in standard Yang–Mills theory. In the BV-approach we implement these gauge fixing conditions by defining the gauge fixing fermion $\Psi=\Psi_\delta+\Psi_\pi$ by

$$\Psi_\delta=\sum_{s=0,2,4,\ldots}^{\infty}\sum_{k=0,2,4,\ldots k\leqslant s}(-\langle\overline{\mathcal{C}}_s^k|\,\boldsymbol{\delta}\mathcal{C}_{s-1}^{k-1}\rangle+\langle\boldsymbol{\delta}\overline{\mathcal{C}}_{s+1}^k|\,\mathcal{C}_{s+2}^{k+1}\rangle+i\langle\overline{\mathcal{C}}_{s+1}^k|\,\boldsymbol{\delta}\mathcal{C}_s^{k-1}\rangle+i\langle\boldsymbol{\delta}\overline{\mathcal{C}}_s^k|\,\mathcal{C}_{s+1}^{k+1}\rangle),$$

$$\begin{aligned}\Psi_\pi=\frac{1}{2}\sum_{s=0,2,4,\ldots}^{\infty}\sum_{k=0,2,4,\ldots k<s}&(\langle\overline{\mathcal{C}}_s^k|\,\pi_s^{k+1}\rangle+\langle\overline{\pi}_s^k|\,\mathcal{C}_s^{k+1}\rangle+i\langle\overline{\mathcal{C}}_{s+1}^k|\,\pi_{s+1}^{k+1}\rangle\\&+i\langle\overline{\pi}_{s+1}^k|\,\mathcal{C}_{s+1}^{k+1}\rangle)+\frac{1}{2}\sum_{k=0,2,4,\ldots}^{\infty}\langle\overline{\mathcal{C}}_k^k|\,\overline{\pi}_k^k\rangle.\end{aligned} \tag{4.4}$$

We eliminate the antifields by using the gauge fixing fermion Ψ via

$$\langle\mathcal{C}_s^k *|=\frac{\partial\Psi}{\partial|\mathcal{C}_s^k\rangle},\quad |\overline{\mathcal{C}}_s^k *\rangle=\frac{\partial\Psi}{\partial\langle\overline{\mathcal{C}}_s^k|}, \tag{4.5}$$

so that the gauge fixed action S_Ψ reads

$$\begin{aligned}S_\Psi=S_{\text{inv}}&-i\langle\overline{\mathcal{C}}_0^0|\,\boldsymbol{\delta}\mathbf{D}\,\mathcal{C}_0^{-1}\rangle-i\sum_{s=1,3,5,\ldots}^{\infty}\langle\overline{\mathcal{C}}_{s+1}^0|\,\boldsymbol{\delta}\mathbf{d}\,\mathcal{C}_{s+1}^{-1}\rangle+\sum_{s=0,2,4,\ldots}^{\infty}\langle\overline{\mathcal{C}}_{s+1}^0|\,\boldsymbol{\delta}\mathbf{d}\,\mathcal{C}_{s+1}^{-1}\rangle\\&+\sum_{k=0,2,4,\ldots}^{\infty}\sum_{s=k+1,\text{ odd}}^{\infty}(i\langle\overline{\pi}_s^k|\,\pi_s^{k+1}\rangle+\langle\overline{\pi}_s^k|\,(i\,\boldsymbol{\delta}\mathcal{C}_{s-1}^{k-1}+\mathbf{d}\mathcal{C}_{s+1}^{k+1})\rangle+\langle(i\,\boldsymbol{\delta}\overline{\mathcal{C}}_{s-1}^k-\mathbf{d}\overline{\mathcal{C}}_{s+1}^{k+2})|\,\pi_s^{k+1}\rangle)\\&+\sum_{k=0,2,4,\ldots}^{\infty}\sum_{s=k+2,\text{ even}}^{\infty}(\langle\overline{\pi}_s^k|\,\pi_s^{k+1}\rangle+\langle\overline{\pi}_s^k|\,(-\boldsymbol{\delta}\mathcal{C}_{s-1}^{k-1}+i\,\mathbf{d}\mathcal{C}_{s+1}^{k+1})\rangle+\langle(\boldsymbol{\delta}\overline{\mathcal{C}}_{s-1}^k\\&+i\,\mathbf{d}\overline{\mathcal{C}}_{s+1}^{k+2})|\,\pi_s^{k+1}\rangle)+\sum_{k=0,2,4,\ldots}^{\infty}\left\langle\overline{\pi}_k^k\middle|\left(-\boldsymbol{\delta}\mathcal{C}_{k-1}^{k-1}+i\,\mathbf{d}\mathcal{C}_{k+1}^{k+1}+\frac{1}{2}\overline{\pi}_k^k\right)\right\rangle.\end{aligned} \tag{4.6}$$

We can now eliminate the Lagrange multiplier fields π_s^k and $\overline{\pi}_s^k$ and arrive at

$$S_\Psi \to S_{\rm inv} + \tfrac{1}{2}\langle \mathcal{A} \,|\, \mathbf{d}\boldsymbol{\delta}\mathcal{A}\rangle - i\langle \overline{\mathcal{C}}_0^0 \,|\, (\boldsymbol{\delta}\mathbf{D} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_0^{-1}\rangle - i \sum_{s=1,3,5,\ldots}^{\infty} \langle \overline{\mathcal{C}}_{s+1}^0 \,|\, (\boldsymbol{\delta}\mathbf{d} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_{s+1}^{-1}\rangle$$
$$+ \sum_{s=0,2,4,\ldots}^{\infty} \langle \overline{\mathcal{C}}_{s+1}^0 \,|\, (\boldsymbol{\delta}\mathbf{d} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_{s+1}^{-1}\rangle - i \sum_{k=0,2,4,\ldots}^{\infty} \sum_{s=k+1,\ \text{odd}}^{\infty} \langle \overline{\mathcal{C}}_{s+1}^{k+2} \,|\, (\boldsymbol{\delta}\mathbf{d} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_{s+1}^{k+1}\rangle$$
$$+ \sum_{k=0,2,4,\ldots}^{\infty} \sum_{s=k+2,\ \text{even}}^{\infty} \langle \overline{\mathcal{C}}_{s+1}^{k+2} \,|\, (\boldsymbol{\delta}\mathbf{d} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_{s+1}^{k+1}\rangle + \frac{1}{2} \sum_{k=0,2,4,\ldots}^{\infty} \langle \mathcal{C}_{k+1}^{k+1} \,|\, (\boldsymbol{\delta}\mathbf{d} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_{k+1}^{k+1}\rangle. \tag{4.7}$$

All the higher-stage ghost contributions can be integrated away without any effect as $\boldsymbol{\delta}\mathbf{d} + \mathbf{d}\boldsymbol{\delta} = 4 \cdot \mathbf{1}$ and we simply obtain

$$S_\Psi \to S_{\rm inv} + \tfrac{1}{2}\langle \mathcal{A} \,|\, \mathbf{d}\boldsymbol{\delta}\mathcal{A}\rangle - i\langle \overline{\mathcal{C}}_0^0 \,|\, (\boldsymbol{\delta}\mathbf{D} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_0^{-1}\rangle \tag{4.8}$$

We see that the gauge fixed action contains the invertible quadratic part $2\langle \mathcal{A} \,|\, \mathcal{A}\rangle$ for the gauge field, as well as $-4i\langle \overline{\mathcal{C}}_0^0 \,|\, \mathcal{C}_0^{-1}\rangle$ for the $\overline{\mathcal{C}}_0^0$, $\mathcal{C}_0^{-1}$ ghost fields.

V. THE GRIBOV PROBLEM

The Yang–Mills theory on the two-point space suffers from a Gribov problem[13] even for the Abelian $U(1)\times U(1)$ case. This can be demonstrated easily by recasting the ghost part of the gauge fixed action (4.8) into the form

$$\langle \overline{\mathcal{C}}_0^0 \,|\, (\boldsymbol{\delta}\mathbf{D} + \mathbf{d}\boldsymbol{\delta})\, \mathcal{C}_0^{-1}\rangle = (\overline{c_1} \quad \overline{c_2}) \begin{pmatrix} 4 + \phi + \overline{\phi} & -\phi - \overline{\phi} \\ -\phi - \overline{\phi} & 4 + \phi + \overline{\phi} \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix}, \tag{5.1}$$

where we introduced the component ghosts fields $\overline{c_1}, \overline{c_2}$ and c_1, c_2 which are the diagonal elements of $\overline{\mathcal{C}}_0^0$ and $\mathcal{C}_0^{-1}$, respectively. The Faddeev–Popov matrix $M_{\rm FP}$

$$M_{\rm FP} = \begin{pmatrix} 4 + \phi + \overline{\phi} & -\phi - \overline{\phi} \\ -\phi - \overline{\phi} & 4 + \phi + \overline{\phi} \end{pmatrix} \tag{5.2}$$

has a vanishing determinant for $2 + \phi + \overline{\phi} = 0$ which forces $\phi = u + iv$ to lie on the line $u = -1$. We note the distinguished value $\phi = -1$, which we discussed previously by demanding the action to be maximal, see (2.8). Now this value arises by inserting the gauge fixing condition $\boldsymbol{\delta}\mathcal{A} = 0$ into the Faddeev–Popov determinant $\det M_{\rm FP}$.

We observe that the classical action $S_{\rm inv}$ not only has an invariance under the (rigid) gauge transformations (2.2), but also under the discrete charge conjugation operation (conveniently expressed in terms of the Higgs fields $H, \overline{H}$)

$$H \to -\overline{H}, \quad \overline{H} \to -H. \tag{5.3}$$

After the spontaneous symmetry breakdown this discrete symmetry guarantees that the minima of the action are degenerated. In the quantum case, however, due to the Gribov problem, these discrete jumps no longer are allowed and the quantum corrections to the action will lift the classical degeneracy of the minima.

VI. CONNES' REAL SPECTRAL TRIPLE FORMULATION

The formulation of the Yang–Mills theory model on the two-point space in terms of Connes's real spectral triple approach proceeds by specifying the spectral triple $(\mathbf{A}, \mathcal{H}, D)$ together with the

antilinear isometry $\mathcal{J}$, fulfilling a set of specific properties.[6,15] We represent the elements $a=(a_1,a_2,a_3)$ of the algebra $\mathbf{A}=C\oplus C\oplus C$, as well as D and $\mathcal{J}$, by specific 4×4 matrices; the Hilbert space $\mathcal{H}$ simply is C^4. Specifically we have

$$a=\begin{pmatrix} a_1 & 0 & 0 & 0 \\ 0 & a_2 & 0 & 0 \\ 0 & 0 & a_3 & 0 \\ 0 & 0 & 0 & a_3 \end{pmatrix}, \quad D=\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad \mathcal{J}=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}\circ \text{c.c.}, \tag{6.1}$$

where c.c. denotes complex conjugation. As an example one sees that for $a, b\in\mathbf{A}$ the differential one-form $\omega_1=a[iD,b]$ is given by

$$\omega_1=i\begin{pmatrix} 0 & a_1(b_2-b_1) & 0 & 0 \\ a_2(b_1-b_2) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{6.2}$$

We recognize that apart from irrelevant zeros in the upper right, lower left and lower right matrix corners of the differential forms our previous discussion of the gauge symmetries, the gauge fixing and the ghost structure proves right as well.

We conclude that the quantization of the Yang–Mills theory model on the two-point space within the Connes–Lott scheme and within Connes' real spectral triple approach are equivalent; the model reveals infinite reducibility and is afflicted with the Gribov problem.

Note added in proof: After finishing our paper a related article[18] appeared. One of its main purposes is to analyze in depth the counting argument of Feynman diagrams in the presence of spontaneous symmetry breaking. Concerning the gauge fixing procedure and the introduction of ghost fields, however, the investigation appears to be incomplete.

ACKNOWLEDGMENTS

The author thanks John Madore for suggesting the study of the Yang–Mills theory model on the two-point space. Harald Grosse and Raimar Wulkenhaar are acknowledged for innumerable helpful discussions.

We study self-dual multivortex solutions of Chern–Simons Higgs theory in a background curved space–time. The existence and decaying property of a solution are demonstrated. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1471365]

I. INTRODUCTION

Chern–Simons gauge theories have provided intriguing questions and answers to various subjects of both physics and mathematics. One of the interdisciplinary topics that has attracted attention is the so-called self-dual Chern–Simons solitons.[1–3] A natural extension is to include gravity which can be background[4,5] or dynamical.[6,7] Once the Bogomolnyi-type bound is obtained and detailed mathematical properties of those self-dual vortices are studied in the Chern–Simons Higgs model in the presence of background gravity, it would be helpful to address related physics-wise problems involving condensed matter systems, e.g., quantum Hall effects, supergravity, Lorentz-symmetry breaking due to parity-violating term, existence of time-like closed curve around gravitating spinning strings, cosmological implication of cosmic strings, and even cosmological constant problem.

Because it is applicable to diverse fields, mathematical study of self-dual Chern–Simons solitons is going on. The existence of a topological multivortex solution of relativistic Chern–Simons–Higgs theory in flat R^2 is shown by Wang.[8] In the same setting, rotationally symmetric nontopological solitons and vortices were proven to exist by Spruck and Yang.[9] Yang also proved the existence of a topological self-dual multivortex solution when the gauge symmetry is extended to non-Abelian.[10] When the topological vortices or nontopological solitons are generated in condensed matter systems or in the early universe, they are likely to form a lattice structure or a network. In such sense important works have been done on torus[11–14] or on standard sphere.[4,15] Condensed matter experiments are usually performed by turning on constant external electric or magnetic field. In relation to this, Chae *et al.* demonstrated the existence of soliton solutions of the self-dual Chern–Simons Higgs model coupled to an external background charge density.[16] Another study to have cosmological implications was done by Kurata and Choe with nontopological soliton solutions under decaying metric.[17,18]

Now let us take into account the curved space–time geometry of a straight string in the early universe. Then, an extremely small core region of the string is curved by matter fields, and the intermediate region is slightly curved or locally flat because of no graviton to the transverse directions. However, the asymptote of the global universe is known to be flat. All of such geometry should be dynamically determined by examining Einstein equations in the exact sense, but it is practically too difficult to do with mathematical rigor. A meaningful starting point is to assume a physically allowable set of background metrics and to study possible string configurations. In this paper, we study Chern–Simons Higgs theory on a uniformly Euclidean metric, which is not necessarily radial. A spatial metric $\gamma_{ij}=b(x,y)\delta_{ij}$ is called uniformly Euclidean metric if there

[a)]Electronic mail: stkim@skku.ac.kr
[b)]Electronic mail: yoonbai@skku.ac.kr

exist positive constants a_1 and a_2 with $a_1 \leqslant b(x,y) \leqslant a_2$. We show the existence of a self-dual topological multivortex solution and the fast decay property of a solution at infinity. The mathematical conditions we bring up are relevant to the physical situation discussed previously, e.g., the gravity is not far from that of the flat case at the end of universe.

A brief outline of the paper is in order. In Sec. II, under the most general static metric, we shall derive the Bogomolnyi-type bound of the Chern–Simons Higgs theory in background gravity. In Sec. III, we present the existence and asymptotic behavior of a solution of the self-dual Chern–Simons vortices. Conclusions with some discussions about our results are presented in Sec. IV.

II. BOGOMOLNYI BOUND OF CHERN–SIMONS HIGGS THEORY IN BACKGROUND GRAVITY

In this section we recapitulate derivation of the so-called Bogomolnyi bound of the Chern–Simons Higgs theory coupled to background gravity by assuming the general static metric

$$ds^2 = N^2(x^k)dt^2 - \gamma_{ij}(x^k)dx^i\,dx^j \quad (i,j,k,\ldots = 1,2), \tag{2.1}$$

where the metric of the two-dimensional spatial hypersurface can always be diagonalized by a conformal gauge $\gamma_{ij} = \delta_{ij} b(x^k)$. Later we shall show that the Bogomolnyi bound is attained only when the lapse function $N(x^i)$ is constant, i.e., $N(x^k) = 1$ after a rescaling of time coordinate t.

The Chern–Simons Higgs theory is described by the action

$$S = \int d^3x \sqrt{g} \left[\frac{\kappa}{2} \frac{\epsilon^{\mu\nu\rho}}{\sqrt{g}} A_\mu \partial_\nu A_\rho + \frac{1}{2} g^{\mu\nu} \overline{D_\mu \phi} D_\nu \phi - V(|\phi|) \right], \tag{2.2}$$

where $\phi = e^{i\Theta}|\phi|$ is a complex scalar field, A_μ a U(1) gauge field, and $D_\mu = \partial_\mu - ieA_\mu$ is gauge-covariant but not covariant under general coordinate transformation. Since the Bogomolnyi limit is our interest, the form of the scalar potential $V(|\phi|)$ is taken to be

$$V(|\phi|) = \frac{e^4}{8\kappa^2} |\phi|^2 (|\phi|^2 - v^2)^2. \tag{2.3}$$

From here on all the metric components and fields are assumed to be static because the self-dual solitons of our interest are static objects.

Symmetric energy–momentum tensor is

$$T_{\mu\nu} = \tfrac{1}{2}(\overline{D_\mu \phi} D_\nu \phi + \overline{D_\nu \phi} D_\mu \phi) - g_{\mu\nu}[\tfrac{1}{2} g^{\rho\sigma} \overline{D_\rho \phi} D_\sigma \phi - V(|\phi|)]. \tag{2.4}$$

A physically meaningful derivation of the Bogomolnyi bound is to investigate vanishing of stress components of the energy–momentum tensor. Since the lapse function $N(x^i)$ disappears in every stress component by the help of Gauss' law $\kappa NB = e^2 A_0 |\phi|^2$, an appropriate rearrangement of them gives

$$T^{ij} = \frac{1}{2}\gamma^{ij}\left[\frac{\kappa^2}{2e^2} \frac{B^2}{|\phi|^2} - V(|\phi|) \right] - \frac{1}{2}(\gamma^{ij}\gamma^{kl} - \gamma^{ik}\gamma^{jl} - \gamma^{il}\gamma^{jk}) \overline{D_k \phi} D_l \phi \tag{2.5}$$

$$
\begin{aligned}
&= \frac{\kappa^2}{2e^2}\frac{\gamma^{ij}}{|\phi|^2}\left[B-\frac{e^3}{2\kappa^2}\left|\phi\right|^2(|\phi|^2-v^2)\right]\left[B+\frac{e^3}{2\kappa^2}\left|\phi\right|^2(|\phi|^2-v^2)\right] \\
&\quad+\frac{1}{8}\left\{\left[\overline{\left(D^i\phi\mp i\frac{\epsilon^{ik}}{\sqrt{\gamma}}\gamma_{kl}D^l\phi\right)}\left(D^j\phi\pm i\frac{\epsilon^{jm}}{\sqrt{\gamma}}\gamma_{mn}D^n\phi\right)\right.\right. \\
&\quad\left.+\overline{\left(D^j\phi\pm i\frac{\epsilon^{jk}}{\sqrt{\gamma}}\gamma_{kl}D^l\phi\right)}\left(D^i\phi\mp i\frac{\epsilon^{im}}{\sqrt{\gamma}}\gamma_{mn}D^n\phi\right)\right] \\
&\quad+\left[\overline{\left(D^i\phi\pm i\frac{\epsilon^{ik}}{\sqrt{\gamma}}\gamma_{kl}D^l\phi\right)}\left(D^j\phi\mp i\frac{\epsilon^{jm}}{\sqrt{\gamma}}\gamma_{mn}D^n\phi\right)\right. \\
&\quad\left.\left.+\overline{\left(D^j\phi\mp i\frac{\epsilon^{jk}}{\sqrt{\gamma}}\gamma_{kl}D^l\phi\right)}\left(D^i\phi\pm i\frac{\epsilon^{im}}{\sqrt{\gamma}}\gamma_{mn}D^n\phi\right)\right]\right\},
\end{aligned}
\tag{2.6}
$$

where γ^{ij} is inverse of the γ_{ij}, $\sqrt{\gamma}=\sqrt{\det\gamma_{ij}}$, and the magnetic field is defined by $B=-(\epsilon^{ij}/\sqrt{\gamma})\,\partial_i A_j$.

We read the first-order Bogomolnyi equations from Eq. (2.6),

$$
B=\mp\frac{e^3}{2\kappa^2}|\phi|^2(|\phi|^2-v^2), \tag{2.7}
$$

$$
D_i\phi\mp i\sqrt{\gamma}\epsilon_{ij}\gamma^{jk}D_k\phi=0. \tag{2.8}
$$

The second equation (2.8) expresses the spatial components of the gauge field A_i in terms of the scalar field, i.e., $eA_i=\partial_i\Theta\mp\sqrt{\gamma}\epsilon_{ij}\gamma^{jk}\partial_k\ln|\phi|$. Substituting it into the first Bogomolnyi equation (2.7) together with the conformal gauge, we have

$$
\partial^2\ln|\phi|=\frac{e^4}{2\kappa^2}b|\phi|^2(|\phi|^2-v^2)\mp\epsilon^{ij}\partial_i\partial_j\Theta, \tag{2.9}
$$

where the Dirac-delta function like contribution of the scalar phase Θ comes from multivalued function such as $\Theta=\Sigma_{k=1}^{n}\tan^{-1}(x^2-x_k^2)/(x^1-x_k^1)$.

Let us check a consistency condition to determine whether or not the Bogomolnyi equations (2.7) and (2.8) reproduce second-order Euler–Lagrange equations. Since we used Gauss' law, let us consider the scalar field equation

$$
\frac{1}{\sqrt{g}}D_\mu(\sqrt{g}g^{\mu\nu}D_\nu\phi)=-\frac{\phi}{|\phi|}\frac{\mathrm{d}V}{\mathrm{d}|\phi|}. \tag{2.10}
$$

For a static configuration, insertion of the Bogomolnyi equations (2.7), (2.8), and (2.8) into the scalar equation (2.10) leads to

$$
\frac{1}{N}\gamma^{ij}\partial_i N\partial_j|\phi|=0. \tag{2.11}
$$

As is well known, for every configuration of the self-dual solitons, derivative of the scalar amplitude vanishes nowhere, and both derivatives, $\partial_i N$ and $\partial_j|\phi|$, are not perpendicular to each other. Then, the lapse function N should be a constant which we set to be one by a rescaling of time variable, i.e., $\mathrm{d}t\to\mathrm{d}t/N$. Note that the spatial components of the gauge-field equation are automatically reproduced for $N=1$ without giving any additional constraint.

Now that we have the condition $N=1$, the derivation of the Bogomolnyi bound reduces to the original one by Schiff.[4] The energy is exactly proportional to the magnetic flux $\Phi=\int d^2x\sqrt{\gamma}B$ as follows

$$E=\int \mathrm{d}^2x\sqrt{\gamma}\left[\frac{\kappa^2}{2e^2}\frac{B^2}{|\phi|^2}+\frac{1}{2}\gamma^{ij}\overline{D_i\phi}D_j\phi+V(|\phi|)\right]$$

$$=\int \mathrm{d}^2x\sqrt{\gamma}\Bigg\{\frac{\kappa^2}{2e^2}\frac{1}{|\phi|^2}\left[B\pm\frac{e^3}{2\kappa^2}|\phi|^2(|\phi|^2-v^2)\right]^2$$

$$+\frac{1}{4}\gamma^{ij}(\overline{D_i\phi\mp i\sqrt{\gamma}\epsilon_{ik}\gamma^{kl}D_l\phi})(D_j\phi\pm i\sqrt{\gamma}\epsilon_{jm}\gamma^{mn}D_n\phi)$$

$$\pm\frac{ev^2}{2}B\pm\frac{i}{4}\frac{1}{\sqrt{\gamma}}\partial_i[\epsilon^{ij}(\overline{\phi}D_j\phi-\overline{D_j\phi}\phi)]\Bigg\} \tag{2.12}$$

$$\geqslant\left|\frac{ev^2}{2}\Phi\right|. \tag{2.13}$$

The first and second lines of Eq. (2.12) vanish by substituting the Bogomolnyi equations (2.7) and (2.8), and the last total-divergence term in the third line of Eq. (2.12) does not contribute to the energy since U(1) current decays rapidly at spatial asymptote.

We read possible boundary conditions of the scalar amplitude at spatial infinity from the scalar potential (2.3), that is, $\lim_{|x|\to\infty}|\phi|\to 0$ or v. The former is a nontopological soliton or vortex, and the latter a topological vortex. All of them carry the magnetic flux Φ [or equivalently U(1) charge $Q=e\int \mathrm{d}^2x\sqrt{\gamma}A_0|\phi|^2$ related by the Gauss' law], and spin

$$J\equiv\int \mathrm{d}^2x\sqrt{\gamma}\sqrt{\gamma}\epsilon_{ij}x^iT_0^j \tag{2.14}$$

$$=\int \mathrm{d}^2x\sqrt{\gamma}\frac{1}{2}\sqrt{\gamma}\epsilon_{ij}x^i(\overline{D^j\phi}D_0\phi+\overline{D_0\phi}D^j\phi) \tag{2.15}$$

$$=\frac{e^2}{8\kappa}\int \mathrm{d}^2x\sqrt{\gamma}x^i\partial_i(|\phi|^2-v^2)^2, \tag{2.16}$$

which distinguishes the Chern–Simons solitons from the solitons in Abelian Higgs model.

III. EXISTENCE OF A SOLUTION

Throughout this section, we denote that (R^2,γ) is a two-dimensional complete Riemann surface which is diffeomorphic to R^2 with the metric $\gamma_{ij}=b(x,y)\delta_{ij}$. We assume that there exist positive constants a_1 and a_2 with $a_1\leqslant b(x,y)\leqslant a_2$ for all $z=(x,y)\in R^2$ ($x^1=x$ and $x^2=y$ from here on). Let $\Delta=[1/\sqrt{\det(\gamma_{ij})}](\partial^2/\partial x^2+\partial^2/\partial y^2)$ ($\Delta_0=\partial^2/\partial x^2+\partial^2/\partial y^2$), $|\nabla u|(|\nabla u|_E)$ and $\delta(\delta_E)$ is the Laplacian, the norm of the gradient and Dirac-delta function with respect to the metric γ_{ij} (Euclidean metric). We denote $\mathrm{d}z=\mathrm{d}x\,\mathrm{d}y$, $\mathrm{d}V_\gamma=b(x,y)\mathrm{d}z$ and H_1^2 is the Sobolev space, which is the completion of $C_c^\infty(R^2)$ with respect to the norm $||w||=(\int_{R^2}|\nabla w|^2+w^2\,dV_\gamma)^{1/2}$.

In this section, we show the following Theorem.

Theorem 1: There exists a solution for the following self-dual Chern–Simons vortex equation on (R^2,γ);

$$\Delta w=e^w(e^w-1)+4\pi\sum_{k=1}^{n}\delta(z-z_k) \tag{3.1}$$

with the boundary condition $\lim_{|z|\to\infty} w=0$. Moreover, w satisfies $-ae^{-b|x|}\leqslant w(x)<0$ at infinity for some positive constants a and b.

Equation (3.1) comes from Eq. (2.9) by rescaling the scalar field $|\phi|=ve^{w}$ and the spatial coordinates $x^i\to(\kappa/e^2v^2)x^i$.

When there is no vortex, there is no nontrivial H_1^2 solution for

$$\Delta w=e^{w}(e^{w}-1) \tag{3.2}$$

because

$$\int_{\Omega} e^{w}(e^{w}-1)w\,dV_{\gamma}=-\int_{\Omega}|\nabla w|^2\,dV_{\gamma}+\int_{\partial\Omega} w\frac{\partial w}{\partial\eta}dS \tag{3.3}$$

for a sufficiently large smooth bounded domain Ω (see Ref. 4). Note that the second term of (3.3) goes to zero for suitably large Ω because $w\in H_1^2$. Applying the maximum principle for H_1^2 solution (cf. Theorem 8.1 of Ref. 19), we see that any H_1^2 solution w of Eq. (3.1) satisfies $w\leqslant 0$. For this, take $\Omega'=\{p\in R^2|w(p)>0\}$. Note that $z_k\notin\Omega'$. If Ω' is bounded, $w(p)\leqslant 0$ by taking $\Omega=\Omega'$ in Eq. (3.3). When Ω' is not bounded, take a sequence of smooth bounded domains $K(r)$, and $\partial K(r)$, the boundary of $K(r)$, for $r=1,2\ldots$, satisfying $K(r)\subset K(r+1), R^2=\cup K(r)$, and $\int_{\partial K(r)} w(\partial w/\partial\eta)\,dS\to 0$, as $r\to\infty$. Then,

$$\int_{\Omega'\cap K(r)} e^{w}(e^{w}-1)w\,dV_{\gamma}=-\int_{\Omega'\cap K(r)}|\nabla w|^2\,dV_{\gamma}+\int_{\partial\Omega'} w\frac{\partial w}{\partial\eta}dS+\int_{\Omega'\cap\partial K(r)} w\frac{\partial w}{\partial\eta}dS, \tag{3.4}$$

where the second term vanishes and third term goes to zero as $r\to\infty$. Therefore Ω' is the empty set and $w\leqslant 0$ on R^2.

Proof of Theorem 1: To show the existence of a solution, we follow Ref. 8. Take u_0 to be

$$u_0=-\sum_{k=1}^{n}\ln(1+\mu|z-z_k|^{-2}), \tag{3.5}$$

then

$$\Delta_0 u_0=-4\sum_{k=1}^{n}\frac{\mu}{(\mu+|z-z_k|^2)^2}+4\pi\sum_{k=1}^{n}\delta_E(z-z_k). \tag{3.6}$$

Define h_0, h, and B as

$$h_0=4\sum_{k=1}^{n}\frac{\mu}{(\mu+|z-z_k|^2)^2},\quad h=h_0/b,$$

and

$$B=e^{u_0}=\prod_{k=1}^{n}\frac{|z-z_k|^2}{\mu+|z-z_k|^2}. \tag{3.7}$$

Take $w=u_0+u$, then Eq. (3.1) turns out to be

$$\Delta u=Be^{u}(Be^{u}-1)+h. \tag{3.8}$$

A critical point of functional E defined on H_1^2 is a solution of Eq. (3.8) where

$$E(u)=\int_{R^2}|\nabla u|^2+(Be^u-1)^2+2hu\,dV_\gamma. \tag{3.9}$$

By the basic inequality,

$$(e^u-1)^2\geqslant\frac{|u|^2}{(1+|u|)^2}, \tag{3.10}$$

and

$$\int_{R^2}2hu\,dV_\gamma=\int_{R^2}2h_0\,u\,dz\leqslant 2\left(\int_{R^2}h_0^2\,dz\right)^{1/2}\left(\int_{R^2}u^2\,dz\right)^{1/2}. \tag{3.11}$$

Note that there exist constants c_1 and c_2 such that

$$2\left(\int_{R^2}h_0^2\,dz\right)^{1/2}\leqslant\frac{c_1}{\sqrt{\mu}} \tag{3.12}$$

and

$$\int_{R^2}(B-1)^2\,dV_\gamma\leqslant c_2. \tag{3.13}$$

Note that Eq. (3.13) holds when $dV_\gamma<cr^{3-\epsilon}\,dr$ for any positive constant c and any positive small constant ϵ. The second term of Eq. (3.9) can be estimated as

$$\int_{R^2}(Be^u-1)^2\,dV_\gamma\geqslant\frac{1}{2}\int_{R^2}B^2(e^u-1)^2-(B-1)^2\,dV_\gamma. \tag{3.14}$$

Let us define $\Omega_1=\{x\in R^2|B^2(x)\leqslant 1/2\}$ and $|\Omega_1|$ be the area of Ω_1. The finiteness of $|\Omega_1|$ implies

$$\int_{\Omega_1}\left(B^2-\frac{1}{2}\right)\frac{|u|^2}{(1+|u|)^2}dV_\gamma\geqslant\int_{\Omega_1}-\frac{1}{2}\frac{|u|^2}{(1+|u|)^2}dV_\gamma\geqslant-\frac{1}{2}|\Omega_1|. \tag{3.15}$$

From Eqs. (3.10) and (3.15), there is a constant c_3 that

$$\begin{aligned}\int_{R^2}B^2(e^u-1)^2\,dV_\gamma&\geqslant\int_{R^2}\frac{B^2|u|^2}{(1+|u|)^2}dV_\gamma\\&=\int_{R^2-\Omega_1}\frac{B^2|u|^2}{(1+|u|)^2}dV_\gamma+\int_{\Omega_1}\frac{B^2|u|^2}{(1+|u|)^2}dV_\gamma\\&\geqslant\frac{1}{2}\int_{R^2}\frac{|u|^2}{(1+|u|)^2}dV_\gamma-c_3.\end{aligned} \tag{3.16}$$

For $f\in H_1^1(R^2)$, $\int_{R^2}f^2dz\leqslant 1/4(\int_{R^2}|\nabla f|dz)^2$. Set $f=u^2$ and we have

$$\int_{R^2}u^4\,dz\leqslant\left(\int_{R^2}|u\nabla u|\,dV_\gamma\right)^2\leqslant\int_{R^2}u^2\,dz\int_{R^2}|\nabla u|^2\,dz, \tag{3.17}$$

and

$$\left(\int_{R^2} u^2\,dz\right)^2 \leqslant \left[\int_{R^2}\left(\frac{|u|}{1+|u|}\right)(1+|u|)|u|\,dz\right]^2$$
$$\leqslant \int_{R^2}\left(\frac{|u|}{1+|u|}\right)^2 dz \int_{R^2} u^2(1+|u|)^2\,dz$$
$$\leqslant 2\int_{R^2}\left(\frac{|u|}{1+|u|}\right)^2 dz \int_{R^2} u^2+u^4\,dz. \tag{3.18}$$

Using Eqs. (3.17) and (3.18), we obtain

$$\int_{R^2} u^2\,dz \leqslant 2\int_{R^2}\left(\frac{|u|}{1+|u|}\right)^2 dz\left(1+\int_{R^2}|\nabla u|^2\,dz\right). \tag{3.19}$$

By the Hölder inequality and Eq. (3.19), $u\in H_1^2(R^2)$ satisfies

$$\left(\int_{R^2} u^2\,dz\right)^{1/2} \leqslant \int_{R^2}\frac{|u|^2}{(1+|u|)^2}\,dz+2\int_{R^2}|\nabla u|_E^2\,dz+2. \tag{3.20}$$

From the above, there exists a constant c_4 such that

$$E(u)\geqslant \int_{R^2}|\nabla u|^2\,dV_\gamma+\frac{1}{2}\int_{R^2}\frac{|u|^2}{(1+|u|)^2}\,dV_\gamma$$
$$-\frac{c_1}{\sqrt{\mu}}\left[\int_{R^2}\frac{|u|^2}{(1+|u|)^2}\,dz+2\int_{R^2}|\nabla u|_E^2\,dz+2\right]-c_3-c_2 \tag{3.21}$$
$$\geqslant\left(1-\frac{2c_1}{\sqrt{\mu}}\right)\int_{R^2}|\nabla u|^2\,dV_\gamma+\left(\frac{1}{2}-\frac{c_1}{a_1\sqrt{\mu}}\right)\int_{R^2}\frac{|u|^2}{(1+|u|)^2}\,dV_\gamma-c_4, \tag{3.22}$$

where we used $\int_{R^2}|\nabla u|^2\,dV_\gamma=\int_{R^2}|\nabla u|_E^2\,dz$. From Eq. (3.20) and by taking large μ, there exist constants c_5 and c_6 such that

$$E(u)\geqslant c_5\left(\int_{R^2}|\nabla u|^2+u^2\,dV_\gamma\right)^{1/2}-c_6. \tag{3.23}$$

Therefore $E(u)$ is coercive on H_1^2 and $\inf_{u\in H_1^2}E(u)$ is finite. Moreover, $E(u)$ is weakly lower semicontinuous functional on H_1^2. We take a minimizing sequence $\{u_n\}$ for $\inf_{u\in H_1^2}E(u)$. Then $\{u_n\}$ is bounded on H_1^2, which has a subsequence $\{u_{n_k}\}$ converging to $u\in H_1^2$, a minimizer for $\inf_{u\in H_1^2}E(u)$. By the elliptic regularity, u is smooth. Finally, u satisfies Eq. (3.8).

Next we study the behavior of solution of Eq. (3.1). From above u is smooth, therefore $w=u_0+u$ is smooth on $R^2-\{z_1,\ldots,z_n\}$. By the argument below Eq. (3.3), $w\leqslant 0$, which implies $\Delta w=e^w(e^w-1)\leqslant 0$ on $R^2-\{z_1,\ldots,z_n\}$. Following Ref. 8, take $\beta=1-e^w$. On $R^2-\{z_1,\ldots,z_n\}$, β is smooth and satisfies

$$\Delta\beta=-e^w(|\nabla w|^2+e^w(e^w-1))\leqslant(\beta-1)^2\beta. \tag{3.24}$$

Applying the strong maximum principle for β, we have $\beta>0$ on R^2. Therefore $w<0$ on R^2. Since w is superharmonic on the ball $B(x,1)$ whose radius is one and center x lies in the outside of a large compact set, we have $-c||w||_{L^2(B(x,1))}\leqslant w(x)<0$ for some positive constant c (see Ref. 19). Therefore w decays to zero uniformly at infinity because $w\in L_2(R^2)$. For a sufficiently small positive constant δ, $-\delta<w<0$ implies

$$w\Delta_0 w = be^w(e^w-1)w \geqslant \frac{w^2}{2}. \tag{3.25}$$

By Jaffe and Taubes[20] methods (p. 83), $-ae^{-b|x|} \leqslant w(x) < 0$ for some positive constants a and b at infinity.

Remarks: Since a_2 does not appear in Eq. (3.22), we can generalize Theorem 1 if the integral value of Eq. (3.13) is bounded. For example, Theorem 1 holds if $c'\,\mathrm{d}r \leqslant dV_\gamma = b(x,y)dz \leqslant cr^{3-\epsilon}\,\mathrm{d}r$ at infinity for any positive constants c', c and any small positive constant ϵ.

IV. CONCLUDING REMARKS

We extend the existence and decay property of topological multivortex solutions of Chern–Simons Higgs theory in a general background curved space–time, which have been studied on flat space or on special background metric. Finding the borderline of growth or decaying condition of the given metric, which gives Theorem 1, is an interesting question. Related issues, e.g., the existence of nontopological solitons and vortices, self-dual topological vortices in a suitably decaying metric and Chern–Simons solitons under a dynamical gravity, need further study.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 5 MAY 2002

Local existence proofs for the boundary value problem for static spherically symmetric Einstein–Yang–Mills fields with compact gauge groups

Todd A. Oliynyk[a] and H. P. Künzle[b]
Department of Mathematical Sciences, University of Alberta, Edmonton T6G 2G1, Canada

(Received 25 August 2000; accepted for publication 1 February 2002)

We prove local existence and uniqueness of static spherically symmetric solutions of the Einstein–Yang–Mills (EYM) equations for an arbitrary compact semisimple gauge group in the so-called regular case. By this we mean the equations obtained when the rotation group acts on the principal bundle on which the Yang–Mills connection takes its values in a particularly simple way (the only one ever considered in the literature). The boundary value problem that results for possible asymptotically flat soliton or black hole solutions is very singular and just establishing that local power series solutions exist at the center and asymptotic solutions at infinity amounts to a nontrivial algebraic problem. We discuss the possible field equations obtained for different group actions and solve the algebraic problem on how the local solutions depend on initial data at the center and at infinity. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1463216]

I. INTRODUCTION

Over the last dozen years much has been learned about the classical interaction of Yang–Mills fields with the gravitational field of Einstein's general relativity. Most investigations have concentrated on Yang–Mills fields with the gauge group SU(2) starting with Bartnik and Mckinnon's[1] discovery of globally regular and asymptotically flat numerical solutions. Their global existence was analytically proved[2,3] and many further properties like stability of these particlelike or soliton solutions and the corresponding black hole solutions were investigated numerically as well as analytically. Moreover, many different matter fields can be minimally coupled to the gravitational and Yang–Mills fields, and corresponding spherically symmetric solutions have been, mostly numerically, but sometimes also analytically studied. We refer for the (hundreds of) references to the review article.[4]

Some similar phenomena were found for special models with gauge groups SU(n) for $n>2$,[5–8] and the general static spherically symmetric equations for general compact gauge groups were derived already quite early.[9,10]

For larger gauge groups than SU(2) the notion of spherical symmetry is no longer straight forward enough for a simple ansatz to work. Instead one needs to consider the possible actions of the symmetry group SO(3) or SU(2) by automorphisms of principal bundles over space–times whose structure group G is the gauge group of the Yang–Mills field. A conjugacy class of such automorphisms is characterized by a generator Λ_0 which is an element of a Cartan subalgebra $\mathfrak{h}$ of the complexified Lie algebra $\mathfrak{g}$ of G.[9,10] Mostly one restricts consideration to fields which are regular at the center or, for black hole fields, to those for which the Yang–Mills-curvature falls off sufficiently fast at infinity. In Ref. 11 these are called regular models. They also correspond to the ''no magnetic charge'' case in Ref. 12. For these group actions the element Λ_0 of $\mathfrak{h}$ must be an A_1-*vector* or *defining vector* of an $\mathfrak{sl}(2)$-subalgebra of $\mathfrak{g}$. That there is a remarkable variety of possible actions was shown by Bartnik[11] for the case where G is any group with Lie algebra

[a]Electronic mail: toliynyk@ualberta.ca
[b]Electronic mail: hp.kunzle@ualberta.ca

$\mathfrak{su}(n)$. More generally, for arbitrary semisimple Lie algebras these A_1-vectors were classified by Mal'cev[13] and Dynkin[14] and can now also be obtained more conveniently from the theory of nilpotent orbits.[15]

One of these classes of actions of the symmetry group is somewhat distinguished. It corresponds to a principal A_1-vector in Dynkin's terminology and we will call it a *principal action*. To our knowledge almost all work for larger gauge groups has been done for this case.[8,16–18] For a slightly bigger class of actions, the ''generic'' class in Ref. 12 which we will call *regular*, the A_1-vector lies in the interior of a fundamental Weyl chamber. Brodbeck and Straumann[12,19] proved that all regular static asymptotically flat solutions are unstable against time dependent perturbations. They were able to do this without establishing existence or any properties of these solutions.

While it is easy to show that, at least for the regular case, some global solutions exist, namely those which arise by scaling from some imbedded SU(2) solutions, only isolated, mostly numerical, results have been obtained about more general global solutions for the principal SU(n) actions for $n=3, 4, 5$.[8,16–18,20]

The purpose of this paper is to discuss the classification of all the regular actions of SU(2) by automorphisms of G-principal bundles over spherically symmetric static space–times and to analyze the resulting Einstein–Yang–Mills field equations to the extent of establishing that the singular boundary value problem obtained for the globally regular and asymptotically flat solutions is well defined ''at both ends,'' namely at the center or the black hole horizon and at infinity. The local solutions that we obtain near these points are actually analytic. Consequently, there exists convergent powerseries representations for these solutions at least for small distances from the center, the black hole horizon and infinity. Essentially we generalize the results of Ref. 16 from the principal action on SU(n)-bundles to regular actions on bundles with (simply connected) semisimple compact structure groups. Although this represents only a first step in an analysis of possible (nonscaled) global solutions establishing these local existence theorems is already quite complicated. It is worthwhile to note, that if any of the local solutions can be extended to a global one, then the results of Brodbeck and Straumann[19] apply and show that the solution must be unstable.

For all these regular models it turns out that the Yang–Mills potential can be chosen (i.e., suitably gauged) to depend only on ℓ real-valued functions of a radial coordinate r where ℓ is the rank of the Lie algebra of the gauge group. In addition, the metric will be given by two more functions of r. These $(\ell+2)$ functions satisfy a nonlinear system of ordinary differential equations which has singularities at $r=0$, when $r\to\infty$, and at the horizon where $r=r_H$, say. We need to analyze these singularities to determine the ''initial conditions'' for these functions and the number of free parameters that can be chosen when solving the equations numerically, for example, by the method of shooting to a meeting point. In this paper we will only establish what these parameters are, we will not solve the equations numerically.

There are many models for which the A_1-vector Λ_0 is on the boundary of a Weyl chamber. To our knowledge almost no results have been obtained for them, but we have reason to believe that some of our methods may also be useful for these irregular models.

In Sec. II we review the description of the class of static spherically symmetric models and in Sec. III we show, starting from the field equations, that the special class of models we call regular can be reduced to the principal case for imbedded semisimple groups. We discuss the initial value problems somewhat informally in Sec. IV where we derive the relatively complicated way in which a solution depends on parameters chosen at the endpoints of the r-interval. In Sec. V we extend some elementary facts that are well known for SU(2)-solutions to general compact G. Finally, the major part of this paper consists of the proofs, divided into Sec. VI containing algebraic lemmas and the proof of the local existence theorems for the differential equation system in Sec. VII.

II. CLASSES OF SPHERICALLY SYMMETRIC YANG–MILLS CONNECTIONS

Since there is no natural action of the symmetry group on the principal bundle we need to consider all possibilities, i.e., all conjugacy classes of actions of SO(3), or for simplicity, SU(2) by

automorphisms on principal G-bundles P over space–time M which project onto isometries of M with orbits diffeomorphic to two-spheres. We assume throughout that G is a compact semisimple connected and simply connected Lie group.

Then these conjugacy classes are in one-to-one correspondence with integral elements Λ_0 of the closed fundamental Weyl chamber $\overline{W(S)}$ belonging to some basis S of the roots of $\mathfrak{g}$ for some chosen Cartan subalgebra $\mathfrak{h}$.[9–11] Here $\mathfrak{g}=(\mathfrak{g}_0)_{\mathbb{C}}$ stands for the complexification of the Lie algebra $\mathfrak{g}_0$ of the structure group G of P. If $\{\tau_i\}$ is a standard basis of the Lie algebra $\mathfrak{su}(2)$ such that $[\tau_i,\tau_j]=\epsilon_{ij}^k\tau_k$ then Λ_0 may be chosen such that

$$\Lambda_0=2i\lambda(\tau_3),$$

where λ is the (induced Lie algebra) homomorphism from the isotropy group I_{x_0} of the SU(2)-action on M at $x_0\in M$ determined by $k\cdot u_0=u_0\cdot\lambda(k)\forall k\in I_{x_0}$ if $u_0\in\pi^{-1}(x_0)$.

Wang's theorem[21,22] on connections that are invariant under actions transitive on the base manifold has been adapted to spherically symmetric space–time manifolds by Brodbeck and Straumann.[10] They show that in a Schwarzschild type coordinate system (t,r,θ,ϕ) and the metric

$$g=-NS^2dt^2+N^{-1}dr^2+r^2(d\theta^2+\sin^2\theta d\phi^2), \tag{2.1}$$

a gauge can always be chosen such that the Yang–Mills-connection form is locally given by

$$A=\tilde{A}+\hat{A},$$

where $\tilde{A}$ is a one-form on the quotient space parametrized by the r and t coordinates and

$$\hat{A}=\Lambda_1 d\theta+(\Lambda_2\sin\theta+\Lambda_3\cos\theta)d\phi, \tag{2.2}$$

where $\Lambda_3=-(i/2)\Lambda_0$ is the constant isotropy generator and Λ_1 and Λ_2 are functions of r and t that satisfy

$$[\Lambda_2,\Lambda_3]=\Lambda_1 \quad \text{and} \quad [\Lambda_3,\Lambda_1]=\Lambda_2. \tag{2.3}$$

Since we only consider static fields we can assume that Λ_1 and Λ_2 depend only on r. Moreover, we will also concentrate on the ''magnetic'' case and assume that the part $\tilde{A}$ of the gauge potential which contributes ''electric'' or ''Coulomb'' terms vanishes, i.e., we put

$$\tilde{A}=0.$$

This condition is not as restrictive as it seems. For, as proved in Ref. 12, it also follows in the regular case (defined below) if the field is smooth at the center $r=0$ and falls off sufficiently fast at infinity.

So far we still have infinitely many possible actions of SU(2) on the principal bundle, namely one for each element in the intersection $\overline{W(S)}\cap I$ of the fundamental Weyl chamber and the integral lattice $I:=\ker(\exp|_{\mathfrak{h}})$. However, since we want the Yang–Mills-connection to be regular also at a center ($r=0$, defined as a connected set of fixed points of the SU(2)-action on M) and/or the Yang–Mills-field to fall off in an asymptotic region (have no magnetic charge according to Ref. 12) we must have

$$[\Omega_1^0,\Omega_2^0]=\Lambda_3 \quad \text{and/or} \quad [\Omega_1^\infty,\Omega_2^\infty]=\Lambda_3, \tag{2.4}$$

where

$$\Omega_i^{0,\infty}:=\lim_{r\to 0,\infty}\Lambda_i(r), \quad (i=1,2).$$

In other words, in these limits there must exist a Lie algebra homomorphism of $\mathfrak{su}(2)$ into $\mathfrak{g}_0$. This is shown most easily by observing that the Einstein equations would otherwise lead to infinite pressure or density at a center.

Since Λ_3 is constant, however, Eqs. (2.4) represent not only conditions on $\Lambda_1(r)$ and $\Lambda_2(r)$, but also on Λ_3 and hence on Λ_0 which must now be the generating (or defining) vector of an $\mathfrak{sl}(2)$ (i.e., A_1) subalgebra of $\mathfrak{g}$. (If both limits exist it then also follows that there must be an automorphism of $\mathfrak{g}$ taking Ω_i^0 into Ω_i^∞.) The set of these so-called A_1-vectors, however, is finite [and in one-to-one correspondence with conjugacy classes of $\mathfrak{sl}(2)$ subalgebras]. It has been studied and tabulated by Mal'cev[13] and Dynkin[14] and is described by so-called weighted Dynkin diagrams (called *characteristics* in Ref. 14), where to each simple root in the diagram is associated a number from the set $\{0,1,2\}$. (See Ref. 15 for a more recent exposition). These numbers represent the values of the simple roots on the generating vector Λ_0 chosen such that it lies in $\overline{W(S)}$.

Thus these tables serve as a classification of all the spherically symmetric magnetic Einstein–Yang–Mills models which are regular at the center and/or obey the standard fall-off conditions at infinity for any given compact gauge group.

III. FIELD EQUATIONS AND REDUCTION OF THE REGULAR MODELS

The field equations are well known. We state them here in a form following Ref. 10 for the static regular case only, where Λ_0 is an A_1-vector. Let the space–time metric g be given by (2.1) and the Yang–Mills-potential $A=\hat{A}$ by (2.2). Define, in addition to Λ_0

$$\Lambda_\pm := \mp\Lambda_1 - i\Lambda_2,$$

so that the Wang Eqs. (2.3) become

$$[\Lambda_0,\Lambda_\pm] = \pm 2\Lambda_\pm. \tag{3.1}$$

Then $\Lambda_+(r)$ and $\Lambda_-(r)\}$ are $\mathfrak{g}$-valued functions, Λ_0 a (constant) vector in the fundamental Weyl chamber of $\mathfrak{h}$ and $\{\Lambda_0,\Lambda_+,\Lambda_-\}$ is a standard triple in the limit $r\to 0$ or $r\to\infty$ for the Lie algebra $\mathfrak{g}$. Now $\mathfrak{h}$ is the Cartan subalgebra of the complexified Lie algebra $\mathfrak{g}$, i.e., $\mathfrak{h}=\mathfrak{h}_0\oplus i\mathfrak{h}_0$, where $\mathfrak{h}_0$ is the real Cartan subalgebra of a compact real form $\mathfrak{g}_0$ of $\mathfrak{g}$, and we choose conventions such that the conjugation operator $c:\mathfrak{g}\to\mathfrak{g}$ satisfies $c(X+iY)=X-iY\,\forall X,Y\in\mathfrak{g}_0$. Then

$$\Lambda_- = -c(\Lambda_+), \tag{3.2}$$

so that the dependent variables consist only of N, S, and the components of Λ_+.
The field equations now reduce to

$$m' = (NG + r^{-2}P), \tag{3.3}$$

$$S^{-1}S' = 2r^{-1}G, \tag{3.4}$$

$$r^2N\Lambda_+'' + 2(m - r^{-1}P)\Lambda_+' + \mathcal{F} = 0, \tag{3.5}$$

$$[\Lambda_+,\Lambda_-'] - [\Lambda_+',\Lambda_-] = 0, \tag{3.6}$$

where $'=d/dr$ and

$$N =: 1 - \frac{2m}{r}, \quad G := \frac{1}{2}(\Lambda_+',\Lambda_-'), \quad P := -\frac{1}{2}(\hat{F},\hat{F}),$$

$$\hat{F} := \frac{i}{2}(\Lambda_0 - [\Lambda_+,\Lambda_-]), \tag{3.7}$$

$$\mathcal{F} := -i[\hat{F}, \Lambda_+]. \tag{3.8}$$

Here $(,)$ is an invariant inner product on $\mathfrak{g}$. It is determined up to a factor on each simple component of a semisimple $\mathfrak{g}$ and induces a norm $|\cdot|$ on (the Euclidean) $\mathfrak{h}$ and therefore its dual. We choose these factors so that $(,)$ is a positive multiple of the Killing form on each simple component. If they are chosen such that the length of the long simple roots are all 1 then the equations will agree with those in Ref. 16 for the principal SU(n) case.

Note that $G \geqslant 0$ and also $P \geqslant 0$. This follows from (3.2), $c(\hat{F}) = \hat{F}$, and the fact that $\langle X|Y\rangle := -[c(X), Y]$ is a Hermitian inner product on $\mathfrak{g}$ [cf. (6.1)]. Energy density, radial and tangential pressure are then given by

$$4\pi e = r^{-2}(NG + r^{-2}P), \quad 4\pi p_r = r^{-2}(NG - r^{-2}P),$$

$$4\pi p_\theta = r^{-4}P. \tag{3.9}$$

We now choose a Chevalley–Weyl basis of $\mathfrak{g}$ using mostly the notation of Ref. 23. Let R be the set of roots in $\mathfrak{h}^*$, $S = \{\alpha_1, \ldots, \alpha_\ell\}$ a base of R (ℓ being the rank of $\mathfrak{g}$), define

$$\langle \alpha, \beta \rangle := \frac{2(\alpha, \beta)}{|\beta|^2},$$

$$(\mathbf{t}_\alpha, X) := \alpha(X) \forall X \in \mathfrak{h},$$

and

$$\mathbf{h}_\alpha := \frac{2\mathbf{t}_\alpha}{|\alpha|^2}.$$

Then $\{\mathbf{h}_i := \mathbf{h}_{\alpha_i}, \mathbf{e}_\alpha, \mathbf{e}_{-\alpha} | i = 1, \ldots, \ell, \alpha \in R\}$ is a basis of $\mathfrak{g}$ corresponding to the decomposition

$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in R^+} (\mathfrak{g}_\alpha \oplus \mathfrak{g}_{-\alpha}),$$

(R^+ being the set of positive roots with respect to the base S) for which we choose the conventions

$$[\mathbf{e}_\alpha, \mathbf{e}_{-\alpha}] = \mathbf{h}_\alpha, \quad [\mathbf{e}_{-\alpha}, \mathbf{e}_{-\beta}] = -[\mathbf{e}_\alpha, \mathbf{e}_\beta],$$

$$(\mathbf{e}_\alpha, \mathbf{e}_{-\alpha}) = \frac{2}{|\alpha|^2}. \tag{3.10}$$

Now it follows directly[14] from the defining relations

$$[\mathbf{e}_0, \mathbf{e}_\pm] = \pm 2\mathbf{e}_\pm, \quad [\mathbf{e}_+, \mathbf{e}_-] = \mathbf{e}_0,$$

of an $\mathfrak{sl}(2)$-subalgebra span$\{\mathbf{e}_0, \mathbf{e}_\pm\}$ of $\mathfrak{g}$, with the help of

$$[\mathbf{h}, \mathbf{e}_\alpha] = \alpha(\mathbf{h})\mathbf{e}_\alpha,$$

that $\mathbf{e}_0$ can only be an A_1-vector provided

$$\alpha(\mathbf{e}_0) = 2 \quad \text{for some} \quad \alpha \in R.$$

Thus, if we let

$$\Lambda_0 = \sum_{i=1}^{\ell} \lambda_i \mathbf{h}_i \in \mathfrak{h}. \tag{3.11}$$

then Eqs. (3.1) imply that

$$\Lambda_+(r) = \sum_{\alpha \in S_\lambda} w_\alpha(r) \mathbf{e}_\alpha,$$

where

$$S_\lambda := \{\alpha \in R \mid \alpha(\Lambda_0) = 2\}, \tag{3.12}$$

is a set of roots depending only on the homomorphism λ or, equivalently, on the coefficients λ_i in (3.11).

Similarly we have

$$\Lambda_-(r) = \sum_{\alpha \in S_\lambda} v_\alpha(r) \mathbf{e}_{-\alpha}, \tag{3.13}$$

but by (3.2) and the fact that complex conjugation maps

$$c: \mathbf{h}_i \mapsto -\mathbf{h}_i, \quad \mathbf{e}_\alpha \mapsto -\mathbf{e}_{-\alpha},$$

it follows that

$$v_\alpha(r) = \overline{w}_\alpha(r).$$

Our system is thus determined once the two real functions $m(r)$ and $S(r)$ and the complex functions $w_\alpha(r)$ for all $\alpha \in S_\lambda$ are known.

If we now substitute (3.13) into Eqs. (3.3)–(3.8) we need to calculate the Lie brackets between the various $\mathbf{e}_\alpha$ for $\alpha \in S_\lambda$. In general, this may produce many more equations than dependent variables. On the other hand the Yang–Mills-potential $\hat{A}$ determined by Λ_+ still contains some gauge freedom. It is not known, at present, whether there is any systematic method to solve this system of equations.

However, as Brodbeck and Straumann[12] have observed, there are special symmetry actions for which this system of equations is much simpler, in fact, very similar to the principal SU(n) case. This happens when Λ_0 is a vector in the *open* fundamental Weyl chamber of $\mathfrak{h}$. They call these models generic, but since, as we will see, they are really a small minority of all possible ones we will call them *regular*.

In the following Λ_0 is not required to be an A_1-vector.

Theorem 1 (Brodbeck–Straumann[12]): *If Λ_0 is in the open Weyl chamber $W(S)$ then the set S_λ is a* Π*-system, i.e., satisfies*

(*i*) *if $\alpha, \beta \in S_\lambda$ then $\alpha - \beta \notin R$,*

(*ii*) *S_λ is linearly independent,*

and is therefore the base of a root system R_λ which generates a Lie subalgebra $\mathfrak{g}_\lambda$ of $\mathfrak{g}$ spanned by $\{\mathbf{h}_\alpha, \mathbf{e}_\alpha, \mathbf{e}_{-\alpha} | \alpha \in R_\lambda\}$.

Moreover, if $\mathfrak{h}_\lambda := \operatorname{span}\{\mathbf{h}_\alpha | \alpha \in S_\lambda\}$ and $\mathfrak{h}_\lambda^\perp := \cap_{\alpha \in S_\lambda} \ker \alpha$ then

$$\mathfrak{h} = \mathfrak{h}_\lambda'' \oplus \mathfrak{h}_\lambda^\perp \quad \textit{and} \quad \Lambda_0 = \Lambda_0'' + \Lambda_0^\perp \quad \textit{with} \quad \Lambda_0'' = \sum_{\alpha \in R_\lambda^+} \mathbf{h}_\alpha.$$

If Λ_0 is an A_1-vector then $\Lambda_0^\perp = 0$ (but $\mathfrak{h}_\lambda^\perp$ need not be trivial).

In particular, Λ_0'' is twice the lowest weight vector of $\mathfrak{h}_\lambda$ and we have by the definitions of S_λ and $\mathfrak{h}_\lambda^\perp$

$$\alpha(\Lambda_0'')=2 \quad \text{and} \quad \alpha(\Lambda_0^{\perp})=0 \quad \forall \quad \alpha\in S_\lambda\,.$$

We will from now on only consider the regular case.

First, Λ_+ can be treated as a $\mathfrak{g}_\lambda$-valued function

$$\Lambda_+(r)=\sum_{j=1}^{\ell_\lambda} w_j(r)\tilde{\mathbf{e}}_j\,,$$

where now $\{\tilde{\alpha}_1,\ldots,\tilde{\alpha}_{\ell_\lambda}\}$ is the base of S_λ and $\tilde{\mathbf{e}}_j:=\mathbf{e}_{\tilde{\alpha}_j}$. Moreover, $\Lambda_0''=\Sigma_j^{\ell_\lambda}\lambda_j''\tilde{\mathbf{h}}_j$ with $\tilde{\mathbf{h}}_j:=\mathbf{h}_{\tilde{\alpha}_j}$. Then, by (3.7) noting also that $\tilde{\alpha}_j(\Lambda_0^{\perp})=0$,

$$\begin{aligned}\hat{F}&=\frac{i}{2}\left(\sum_{j=1}^{\ell_\lambda}\lambda_j''\tilde{\mathbf{h}}_j+\Lambda_0^{\perp}-\left[\sum_{j=1}^{\ell_\lambda} w_j\tilde{\mathbf{e}}_j,\sum_{k=1}^{\ell_\lambda}\overline{w}_k\tilde{\mathbf{e}}_k\right]\right)\\&=\frac{i}{2}\left(\sum_{j=1}^{\ell_\lambda}(\lambda_j''-|w_j|^2)\tilde{\mathbf{h}}_j+\Lambda_0^{\perp}\right),\end{aligned}\tag{3.14}$$

where (3.10) was used and the fact that differences of two simple roots are not roots which implies that

$$[\mathbf{e}_\alpha,\mathbf{e}_{-\beta}]=0 \quad \forall \quad \alpha,\beta\in S_\lambda\,, \quad \alpha\neq\beta.\tag{3.15}$$

Substituting this expression into (3.8) gives

$$\begin{aligned}\mathcal{F}=&\frac{1}{2}\sum_{j,k=1}^{\ell_\lambda} w_j\langle\tilde{\alpha}_j,\tilde{\alpha}_k\rangle(\lambda_k''-|w_k|^2)\tilde{\mathbf{e}}_j\\&+\frac{1}{2}\sum_{j=1}^{\ell_\lambda} w_j[\Lambda_0^{\perp},\tilde{\mathbf{e}}_j].\end{aligned}\tag{3.16}$$

But since $[\Lambda_0^{\perp},\tilde{\mathbf{e}}_k]=\tilde{\alpha}_k(\Lambda_0^{\perp})\tilde{\mathbf{e}}_k=0$, in view of the definition of $S_\lambda^{\perp}$, the last term vanishes. Equation (3.5), therefore, becomes

$$r^2Nw_j''+2(m-r^{-1}P)w_j'+\frac{1}{2}\sum_{k=1}^{\ell_\lambda} w_jc_{jk}(\lambda_k''-|w_k|^2)=0,$$

where we have introduced

$$c_{jk}:=\langle\tilde{\alpha}_j,\tilde{\alpha}_k\rangle,$$

for the Cartan matrix of $\mathfrak{g}_\lambda$ and where now

$$P=\frac{1}{8}\sum_{j,k=1}^{\ell_\lambda}(\lambda_j''-|w_j|^2)h_{jk}(\lambda_k''-|w_k|^2)+|\Lambda_0^{\perp}|^2$$

$$\text{with} \quad h_{jk}:=\frac{2\langle\tilde{\alpha}_j,\tilde{\alpha}_k\rangle}{|\tilde{\alpha}_j|^2},\tag{3.17}$$

$$G=\sum_{j=1}^{\ell_\lambda}\frac{|w_j'|^2}{|\tilde{\alpha}_j|^2}.\tag{3.18}$$

Finally, (3.6) simply becomes in view of (3.10)

$$\sum_{j,k=1}^{\ell_\lambda} (w_j \overline{w}_k' - w_j' \overline{w}_k)[\mathbf{e}_{\tilde{\alpha}_j}, \mathbf{e}_{-\tilde{\alpha}_k}] = \sum_{j=1}^{\ell_\lambda} (w_j \overline{w}_j' - w_j' \overline{w}j)\tilde{\mathbf{h}}_j = 0, \tag{3.19}$$

so that the phase of w_j is constant and may be chosen to be zero by a gauge transformation. One can thus assume that the $w_j(r)$ are real-valued functions.

It remains to determine the subalgebra $\mathfrak{g}_\lambda$ for a given A_1-vector Λ_0 in the open fundamental Weyl chamber.

First, we note that for a semisimple group for which the Cartan subalgebra $\mathfrak{h}$ splits into an orthogonal sum $\mathfrak{h} = \oplus \mathfrak{h}_k$ the decomposition in Theorem 1 splits into corresponding decompositions of each of the $\mathfrak{h}_k$. So we need only investigate the regular actions of simple Lie groups.

Now the A_1-vector in the Cartan subalgebra $\mathfrak{h}$ of a semisimple Lie algebra $\mathfrak{g}$ is uniquely given by the numbers

$$\boldsymbol{\chi} = (\chi_1, \ldots, \chi_\ell) := (\alpha_1(\Lambda_0), \ldots, \alpha_\ell(\Lambda_0)), \tag{3.20}$$

called the *characteristic* in Ref. 14. It is known[14,15] that if Λ_0 is in the closed fundamental Weyl chamber then $\chi_k \in \{0,1,2\}$, and all possible such characteristic have been found and tabulated. It is clear from the definition of S_λ in (3.12) that $\chi_k = 2\ \forall\ k$ for $\mathfrak{h}_\lambda$. Such A_1-vectors define *principal* A_1-subalgebras and thus *principal actions* of SU(2) on the bundle. We now have

Theorem 2:

(*i*) *The possible regular A_1-subalgebras of simple Lie algebras consist of the principal subalgebras of all Lie algebras A_ℓ, B_ℓ, C_ℓ, D_ℓ, E_ℓ, F_4 and G_2 and of those subalgebras of $A_\ell = \mathfrak{sl}(\ell+1)$ with even ℓ corresponding to partitions $[\ell+1-k,k]$ for any integer $k = 1,\ldots,\ell/2$ or, equivalently, characteristic* (22..211..112..22) (2k '1's *in the middle,* '2's *in all other positions*);

(*ii*) *the Lie algebra $\mathfrak{g}_\lambda$ is equal to $\mathfrak{g}$ in the principal case, and for A_ℓ with even ℓ equal to $A_{\ell-1}$ for $k=1$ and to $A_{\ell-k} \oplus A_{k-1}$ for $k = 2,\ldots,\ell/2$;*

(*iii*) in the principal case $\mathfrak{h}_\lambda'' = \mathfrak{h}$. *For all A_1-subalgebras of A_ℓ with even ℓ the orthogonal space $\mathfrak{h}_\lambda^\perp$ is one-dimensional.*

Proof: Part (i) follows quite easily from the discussion and the tables in Ref. 15 (Secs. 5.3 and 4.4).

For part (ii) that $\mathfrak{h}_\lambda = \mathfrak{h}$ in the principal case is obvious. To compute S_λ for a given $\ell = 2m$ and given $k > 0$ note that all positive roots of A_ℓ are of the form $\Sigma_{p=j}^k \alpha_p$ for $1 \leqslant j \leqslant k \leqslant 2m$ so that using that $\alpha_i(\Lambda_0) = 2$ for $i = 1,\ldots,m-k$ and $i = m+k+1,\ldots,2m$ and $\alpha_i(\Lambda_0) = 1$ otherwise one sees that

$$S_\lambda = \bigcup_{i=1}^{m-k} \alpha_i \cup \bigcup_{j=1}^{2k-1} (\alpha_{m-k+j} + \alpha_{m-k+j+1}) \ \cup \bigcup_{i=m+k+1}^{2m} \alpha_i . \tag{3.21}$$

Recalling that for A_ℓ

$$\langle \alpha_i, \alpha_j \rangle = \begin{cases} 2 & \text{if } i = j \\ -1 & \text{if } |i-j| = 1, \\ 0 & \text{otherwise} \end{cases}$$

it is seen immediately that the Cartan matrix for S_λ is the one for $A_{\ell-1}$ if $k=1$ while it takes a simple reordering of the roots to verify the statement in (ii) for $k = 2,\ldots,\ell/2$.

(iii) That $\mathfrak{h}_\lambda'' = \mathfrak{h}$ in the principal case is obvious from the definition and that $\dim S_\lambda^\perp = 1$ follows from the observation that $\alpha(X) = 0\ \forall\ \alpha \in S_\lambda$ amounts to $2m-1$ linearly independent equations according to (3.21). □

In summary, we have shown that all regular models can be reduced to those with the principal action for semisimple gauge groups. Also the term $\Lambda_0^{\perp}$ occuring in (3.14), (3.16), and (3.17) can now be dropped.

IV. CONSTRUCTING LOCAL SOLUTIONS REGULAR AT THE CENTER, HORIZON OR AT INFINITY

So far we have shown that the static spherically symmetric and magnetic EYM equations for the regular action reduce to those for the principal action for semisimple gauge groups. (We now drop the index λ from $\mathfrak{g}$, $\mathfrak{h}$, etc.) They consist of (3.4), which can be integrated easily once the other equations are solved, and

$$m' = (NG + r^{-2}P), \tag{4.1}$$

$$r^2 N w_j'' + 2(m - r^{-1}P)w_j' + \frac{1}{2}\sum_{k=1}^{\ell} w_j c_{jk}(\lambda_k - w_k^2) = 0, \tag{4.2}$$

where the w_k are real-valued functions of r, $(c_{ij}) := (\langle \alpha_j, \alpha_k \rangle)$ is the Cartan matrix of the reduced structure group, and

$$P = \frac{1}{8}\sum_{j,k=1}^{\ell} (\lambda_j - w_j^2) h_{jk} (\lambda_k - w_k^2), \tag{4.3}$$

$$G = \sum_{j=1}^{\ell} \frac{w_j'^2}{|\alpha_j|^2}, \tag{4.4}$$

$$h_{jk} = \frac{2c_{jk}}{|\alpha_j|^2}, \tag{4.5}$$

$$\lambda_j = 2\sum_{k=1}^{\ell} (c^{-1})_{jk}. \tag{4.6}$$

The expressions for components λ_k of the A_1-vector Λ_0 follow from (3.20) and the fact that for the principal action $\chi_k = 2 \forall k$.

In this section we will discuss the general problem of finding solutions that are regular at the center or at the horizon and have an appropriate fall off as $r \to \infty$. Proofs will be given later in Secs. VI and VII.

Equations (4.1) and (4.2) are very similar to the corresponding ones in the principal SU(n) case analyzed in detail in Ref. 16. So we can expect most of those results to generalize. First of all, when the dependent variables m and w_k are expanded in power series in terms of r at $r = 0$, in terms of $r - r_H$ at $r = r_H$, and in terms of r^{-1} at infinity (under the assumption that all the quantities are finite in these limits) then (4.1) and (4.2) yield a system of algebraic equations. For example, at $r = 0$ with $f(r) = \Sigma_{k=0}^{\infty} f_k r^k$ we find

$$m_{k+1} = \frac{1}{k+1}\left(G_k + P_{k+2} - 2\sum_{h=2}^{k-2} m_{k-h} G_h \right), \tag{4.7}$$

$$\sum_{j=1}^{\ell} (A_{ij} - k(k+1)\delta_{ij}) w_{j,k+1} = b_{i,k}, \tag{4.8}$$

for $k = 0,1,2,\ldots$ where

TABLE I. The eigenvalues of the coefficient matrix $\mathbf{A}$ for the simple Lie algebras are given by the set $\mathrm{spec}(\mathbf{A})=\{k(k+1)|k\in\mathcal{E}\}$. For the classical Lie algebras the table entry gives k_j for $j=1,2,\ldots=\ell=\mathrm{rank}(\mathfrak{g})$. Note that $k=1$ belongs to $\mathcal{E}$ for all Lie algebras.

Lie algebra	$\mathcal{E}$
A_ℓ	j
B_ℓ	$2j-1$
C_ℓ	$2j-1$
D_ℓ	$\begin{cases} 2j-1 & \text{if } j<(\ell+2)/2 \\ \ell-1 & \text{if } j=(\ell+2)/2 \\ 2j-3 & \text{if } j>(\ell+2)/2 \end{cases}$
E_6	1,4,5,7,8,11
E_7	1,5,7,9,11,13,17
E_8	1,7,11,13,17,19,23,29
F_4	1,5,7,11
G_2	1,5

$$A_{ij}:=w_{i,0}c_{ij}w_{j,0}, \tag{4.9}$$

and the $b_{i,k}$ are complicated expressions involving lower order terms. For the lowest order terms we find

$$m_0=m_1=m_2=0, \quad w_{i,0}^2=\lambda_i, \quad w_{i,1}=0. \tag{4.10}$$

That $r=0$ is a singular point for the system (4.1),(4.2) manifests itself in the fact that the initial data at $r=0$ for regular solutions are not simply the values of the functions m, w_i, and w_i' but that some of these values are restricted like in (4.10) and some higher order coefficients in the power series for the w_i remain arbitrary, namely for those orders k for which the matrix $\mathbf{A}=(A_{ij})$ has eigenvalue $k(k+1)$. It now turns out that the eigenvalues of $\mathbf{A}$ are precisely of this form for certain integer values of k. In fact, for the simple Lie algebras we can calculate the spectrum directly from the Cartan matrix and find the values given in Table I. The proof for the classical Lie algebras of arbitrary rank follows from the properties of the root system and results at the end of Sec. 6.

The eigenspaces for the simple Lie algebras are all onedimensional except for D_ℓ where certain "middle" eigenvalues occur twice. For semisimple Lie algebras the matrix $\mathbf{A}$ will be a direct sum of those for the simple components and thus may have multiple eigenvalues.

It is now clear that a formal power series solution of Eqs. (4.1) and (4.2) is well defined and contains ℓ free parameters provided Eq. (4.8) can be solved, i.e., provided the vector $\mathbf{b}_k:=(b_{1,k},\ldots,b_{\ell,k})$ lies in the left kernel of $(\mathbf{A}-k(k+1)\mathbb{I})$. Since $\mathbf{b}_k$ is a very complicated expression this is cumbersome to prove in general. In Ref. 16 the proof for $G=\mathrm{SU}(n)$ was achieved using properties of a class of orthogonal polynomials, an approach that does not easily generalize to other groups. In Secs. VI and VII we present a proof that depends directly on the root structure of the Lie algebra $\mathfrak{g}$ treated as an $\mathfrak{sl}(2,\mathbb{C})$-module.

The structure of the recursion relations for the power series of regular solutions in r^{-1} at infinity is very similar to the one at $r=0$. At the remaining singular point of (4.2), namely at a regular horizon $(N(r_H)=0, N'(r_H)>0)$, however, the only conditions on initial values turn out to be some inequalities.

Calculating the formal power series is indeed necessary to start off numerical integration when searching for global regular solutions. For an existence and uniqueness proof, however, it is more convenient to recast the equations in a form to which the following (slight generalization of a) theorem by Breitenlohner, Forgács, and Maison[3] applies.

Theorem 3: *The system of differential equations*

$$t\frac{du_i}{dt}=t^{\mu_i}f_i(t,u,v),\quad i=1,\ldots,m, \tag{4.11}$$

$$t\frac{dv_j}{dt}=-h_j(u)v_j+t^{\nu_j}g_j(t,u,v),\quad j=1,\ldots,n, \tag{4.12}$$

where μ_i, ν_j *are integers greater than 1,* f_i *and* g_j *analytic functions in a neighborhood of* $(0,c_0,0)\in\mathbb{R}^{1+m+n}$, *and* $h_j:\mathbb{R}^m\to\mathbb{R}$ *functions, positive in a neighborhood of* $c_0\in\mathbb{R}^m$, *has a unique analytic solution* $t\mapsto(u_i(t),v_j(t))$ *such that*

$$u_i(t)=c_i+O(t^{\mu_i})\quad \textit{and}\quad v_j(t)=O(t^{\nu_j}), \tag{4.13}$$

for $|t|<R$ *for some* $R>0$ *if* $|c-c_0|$ *is small enough. Moreover, the solution depends analytically on the parameters* c_i.

Proof: By the standard method solving the differential equation with initial data is replaced by finding a fixed point for the map $T:(u,v)\mapsto(\tilde{u},\tilde{v})$ with

$$\tilde{u}_i(t)=c_i+\int_0^t \tau^{\mu_i-1}f_i[\tau,u(\tau),v(\tau)]\,d\tau, \tag{4.14}$$

$$\tilde{v}_j(t)=t^{-\kappa_j}\int_0^t \tau^{\kappa_j\nu_j-1}\hat{g}_i[\tau,u(\tau),v(\tau)]\,d\tau, \tag{4.15}$$

where $\kappa_j:=h_j(c)$ and $\hat{g}(j)(t,u,v):=g_j(t,u,v)-t^{-\nu_j}[h_j(u)-h_j(c)]v_j$. To show that T is a contracting map on a suitable Banach space one can use a method very similar to the one in Ref. 16.□

To bring systems (4.1) and (4.2) into a form that satisfies the hypotheses of theorem 3 it is necessary to make a suitable transformation of the variables m and w_j. The proofs that this can be done are basically equivalent to showing that the formal power series exist and are given in Sec. VII. We then have

Theorem 4: *Systems* (4.1) *and* (4.2) *has an analytic solution for small* r *of the form*

$$w_i(r)=w_{i,0}+\sum_{j=1}^{\ell} C_{ij}r^{k_j+1}u_j(r),\quad i=1,\ldots,\ell \tag{4.16}$$

where $C=(C_{ij})$ *is a nonsingular matrix whose* j*th column is an eigenvector to eigenvalue* $k_j(k_j+1)$ *of the matrix* **A**. *The solution is uniquely determined by the initial values* $u_j(0)=\beta_j$ *for arbitrary* β_j. *The function* $m(r)$ *is then determined and satisfies* $m(r)=O(r^3)$ *for small* r.

Note that the $w_{i,0}$ are determined up to the sign by (4.10). From (7.18), we see that solutions from theorem 4 satisfy $P=O(r^4)$ and $G=O(r^2)$. It follows that for these solutions all physical quantities such as the pressure and mass density are finite at $r=0$.

The situation is rather similar for solutions analytic in r^{-1} near infinity. We have, with the same matrix C.

Theorem 5: *The systems (4.1) and (4.2) has an analytic solution for small* $z=r^{-1}$ *of the form*

$$w_i(r)=w_{i,\infty}+\sum_{j=1}^{\ell} C_{ij}r^{-k_j}u_j(r^{-1}),\quad i=1,\ldots,\ell, \tag{4.17}$$

$$m(r)=m_\infty+O(r^{-1}). \tag{4.18}$$

The solution is uniquely determined by the initial values $u_j(0)=\alpha_j$ *and* m_∞ *for arbitrary* α_j *and* m_∞.

Again $w_{i,\infty}$ is determined up to the sign by $w_{i,\infty}^2=\lambda_i$. An overall sign in $w_i(r)$ does not affect the Yang–Mills field nor the geometry and physics. But $w_{i,0}$ and $w_{i,\infty}$ may have the same or different signs for global solutions.

Finally we have the corresponding theorem for local solutions near a regular horizon.

Theorem 6: *The systems (4.1) and (4.2) has a solution analytic in $t=r-r_H$ for small t at a regular horizon, i.e., where $N(r_H)=0$ and $N'(rH)>0$. The solution is uniquely determined by the values of $w_j(r_H)$ which must be chosen such that*

$$N'(r_H)=\frac{1}{r_H}-\frac{2}{r_H^3}P(r_H)>0, \tag{4.19}$$

or, equivalently,

$$2P(r_H)=\frac{1}{4}\sum_{i,j=1}^{\ell}(\lambda_i-w_i(r_H))h_{ij}(\lambda_j-w_j(r_H))<r_H^2. \tag{4.20}$$

V. ELEMENTARY PROPERTIES AND SCALED SOLUTIONS

The observation already made in Ref. 1 for SU(2) and generalized to SU(n) that global solutions, if they exist, must be bounded by their values at infinity (or zero) is easily extended to the regular case for arbitrary G.

Theorem 7: *If a solution $(m,w_1,\ldots,w_\ell)$ is defined and C^2 in the connected outer domain $D:=\{r|0\leqslant r_H\leqslant r<\infty\}$ (where $N(r)>0$) and if*

$$m(r)=m_\infty+O(1/r) \quad \text{and} \quad w_j(r)=w_{j,\infty}+O(1/r) \quad \text{as} \quad r\to\infty$$

then

$$w_j(r)^2\leqslant w_{j,\infty}^2=\lambda_j \quad \forall r\in\mathring{D}.$$

Moreover, if G is a simple group and $w_j(r_1)=w_{j,\infty}$ for some j and for some $r_1\in\mathring{D}$ then $w_j(r)=w_{j,\infty}\forall r\in D$, $m=$const, the Yang–Mills field vanishes, and the metric is the Schwarzschild one.

If G is semisimple and $w_j(r_1)=w_{j,\infty}$ for some j and for some $r_1\in\mathring{D}$ then the field equations reduce to those of the subgroup of G obtained by deleting from the Cartan subalgebra $\mathfrak{h}$ of $\mathfrak{g}$ the simple component in which $\mathbf{h}_j$ lies.

Proof: Let $v_j:=w_j^2$. Then $v_j(r)\geqslant 0\forall r$ and (4.2) gives

$$2r^2Nv_jv_j''-r^2Nv_j'^2+4(m-r^{-1}P)v_jv_j'+2v_j^2\sum_{k=1}^{\ell}c_{jk}(\lambda_k-v_k)=0. \tag{5.1}$$

Let $V_j:=\sup_{r\in D}v_j(r)$. Then $V_j>0$ because the asymptotic value of $v_j(r)$ is $\lambda_j>0$. Now assume that $v_j(r_j)=V_j$ for some $r_j\in\mathring{D}$. Then $v_j(r_j)$ is an absolute maximum so that $v_j'(r_j)=0$ and $v_j''(r_j)\leqslant 0$. It follows from (5.1) that $\Sigma_{j=1}^{\ell}c_{ij}(\lambda_j-v_j(r_j))\geqslant 0$ which in view of (4.6) is equivalent to

$$\sum_{j=1}^{\ell}c_{ij}v_j(r_j)\leqslant 2\forall i,$$

or

$$v_i(r_i)\leqslant 1+\frac{1}{2}\sum_{j\neq i}(-c_{ij})v_j(r_i)\leqslant 1+\frac{1}{2}\sum_{j\neq i}(-c_{ij})\sup_{r\in D}v_j(r),$$

whence $V_i \leqslant 1 + \frac{1}{2}\Sigma_{j\neq i}(-c_{ij})V_j$ or

$$\sum_{j=1}^{\ell} c_{ij}V_j \leqslant 2 \forall i.$$

(Note that for all Cartan matrices $c_{ii}=2$ and $c_{ij}\leqslant 0$ if $i\neq j$.)
This last set of inequalities, however, can be multiplied with the inverse Cartan matrix since the latter has only positive entries. Using (4.6) again then gives $0\leqslant V_j \leqslant \lambda_j \forall j$, thus $V_j=\lambda_j$ since λ_j is the asymptotic value.

Suppose now that $v_i(r_*)=\lambda_i$ for some i and some $r_* \in \mathring{D}$. Then we find from (5.1)

$$r_* N(r_*) v_i''(r_*) = \lambda_i \sum_{j\neq i} (-c_{ij})(\lambda_j - v_j(r_*)) \geqslant 0,$$

which contradicts that $v_i(r)$ has a maximum at r_* unless $v_j''(r_*)=0$ and, in the case of a simple Lie algebra, the neighboring v_j also assume their maximal values. (For a simple Lie algebra there is a $c_{ij}<0$ for some $j\neq i$ for any i.) It follows that all $v_j(r_*)=\lambda_j$ for all j for which the root α_j is in the same simple component of $\mathfrak{h}^*$.

However, if all $v_j(r_*)=\lambda_j$ and thus $v_j'(r_*)=0\ \forall j$ then the initial conditions for the differential equations (5.1) are all trivial and since r_* is not a singular point it follows by the uniqueness of the solution that it must by the one for which $v_j(r)\equiv\lambda_j$. It then also follows from (4.1) that $m=$const so that the Yang–Mills field vanishes and the geometry is the one of the Schwarzschild solution. □

Theorem 7 shows among other things that for a given semisimple gauge group G and a given group action (characterized by Λ_0) there may be special solutions that reduce the YM-connection to a subgroup of G that is a product of some of the simple factors of G. Somewhat similarly, since the group SU(2) can be isomorphically imbedded in every compact (simply connected) semisimple or simple Lie group the Bartnik–McKinnon solution[1] can be obtained as a special solution for all the models considered here. The following special BM-solution for arbitrary compact G was already obtained in Ref. 24.

Consider the gauge group G and the symmetry group action (characterized by Λ_0) fixed and such that Λ_0 is regular so that the field equations are given by (3.4), (4.1), and (4.2). Select any Ω_+ such that the set $\{\Lambda_0,\Omega_+,\Omega_-\}$ is a standard triple with $c(\Omega_+)=-\Omega_-$ and let $\Lambda_+(r)=u(r)\Omega_+$ or, equivalently, $w_i(r)=w_{i,\infty}u(r)$. Then the field equations become

$$m' = g_0(Nu'^2 + \tfrac{1}{2}r^{-2}(1-u^2)^2), \tag{5.2}$$

$$r^2 N u'' + (2m - g_0 r^{-1}(1-u^2)^2)u' + u(1-u^2) = 0, \tag{5.3}$$

$$S^{-1}S' = 2g_0 r^{-1} u'^2. \tag{5.4}$$

where $g_0=\frac{1}{4}\Sigma_{i,j}\lambda_i h_{ij}\lambda_j$. By introducing a new radial variable $x:=r g_0^{-1/2}$ one sees easily that (5.2)–(5.4) reduce to the well studied equations for the SU(2)-Einstein–Yang–Mills fields.

Since Λ_0 fixes the conjugacy class of the symmetry group action on the bundle different choices of Ω_+ will lead to isomorphic gauge connections, namely reductions of the G-connection to an SU(2)-connection on the principal bundle for the particular space–time. They are thus physically equivalent.

In view of the existence theorems for the $G=\mathrm{SU}(2)$ case[2,3,25] it now follows that the systems (4.1) and (4.2) always admits some global solutions

Theorem 8: *There exists a countably infinite family of globally regular solutions of the Einstein–Yang–Mills–equations for any simply connected compact semisimple gauge group G on*

a static spherically symmetric asymptotically flat space–time diffeomorphic to $\mathbb{R}^4$. *Similarly, for any* $r_H>0$ *there exists an infinite family of asymptotically flat black hole solutions with black hole radius* r_H.

VI. THE LIE ALGEBRA $\mathfrak{g}$ AS AN $\mathfrak{sl}(2,\mathbb{C})$ SUBMODULE

In this section we collect all of the algebraic results needed to prove theorems 4 and 5. Introduce a nondegenerate Hermitian inner product $\langle\,|\,\rangle:\mathfrak{g}\times\mathfrak{g}\to\mathbb{C}$ by

$$\langle X|Y\rangle := -(c(X),Y) \quad \forall X,Y\in\mathfrak{g}, \tag{6.1}$$

recalling that $c:\mathfrak{g}\to\mathfrak{g}$ is the conjugation operator determined by the compact real form $\mathfrak{g}_0$. Then $\langle\,|\,\rangle$ restricts to a real positive definite inner product on $\mathfrak{g}_0$. From the invariance properties of $(\ ,\ )$ it follows that $\langle\,|\,\rangle$ satisfies

$$\langle X|Y\rangle=\overline{\langle Y|X\rangle},$$

$$\langle c(X)|c(Y)\rangle=\overline{\langle X|Y\rangle},$$

$$\langle [X,c(Y)]|Z\rangle=\langle X|[Y,Z]\rangle$$

for all $X,Y,Z\in\mathfrak{g}$. Treating $\mathfrak{g}$ as a $\mathbb{R}$-linear space by restricting scalar multiplication to multiplication by reals, we can introduce a positive definite inner product $\langle\langle\,|\,\rangle\rangle:\ \mathfrak{g}\times\mathfrak{g}\to\mathbb{R}$ on $\mathfrak{g}$ defined by

$$\langle\langle X|Y\rangle\rangle := \mathrm{Re}\langle X|Y\rangle \quad \forall X,Y\in\mathfrak{g}.$$

Let $\|\ \|$ denote the norm induced on $\mathfrak{g}$ by $\langle\langle\,|\,\rangle\rangle$, i.e.,

$$\|X\|=\sqrt{\langle\langle X|X\rangle\rangle} \quad \forall\ \ X\in\mathfrak{g}. \tag{6.2}$$

From the above properties satisfied by $\langle\,|\,\rangle$, it straighforward to verify that $\langle\langle\,|\,\rangle\rangle$ satisfies

$$\langle\langle X|Y\rangle\rangle=\langle\langle Y|X\rangle\rangle,$$

$$\langle\langle c(X)|c(Y)\rangle\rangle=\langle\langle X|Y\rangle\rangle, \tag{6.3}$$

$$\langle\langle [X,c(Y)]|Z\rangle\rangle=\langle\langle X|[Y,Z]\rangle\rangle$$

for all $X,Y,Z\in\mathfrak{g}$.

Let $\Omega_+,\Omega_-\in\mathfrak{g}$ be two vectors such that

$$[\Lambda_0,\Omega_\pm]=\pm 2\Omega_\pm,\ \ [\Omega_+,\Omega_-]=\Lambda_0,\ \text{ and }\ c(\Omega_+)=-\Omega_-.$$

Then $\mathrm{span}_{\mathbb{C}}\{\Lambda_0,\Omega_+,\Omega_-\}\simeq\mathfrak{sl}(2,\mathbb{C})$. The dot notation will often be used to denote the adjoint action of $\mathrm{span}_{\mathbb{C}}\{\Lambda_0,\Omega_+,\Omega_-\}$ on $\mathfrak{g}$, i.e.,

$$X.Y := \mathrm{ad}(X)(Y) \quad \forall\ \ X\in\mathrm{span}_{\mathbb{C}}\{\Lambda_0,\Omega_+,\Omega_-\},\quad Y\in\mathfrak{g}.$$

Because Λ_0 is a semisimple element, $\mathrm{ad}(\Lambda_0)$ is diagonalizable and it follows from $\mathfrak{sl}(2)$-representation theory[23] that the eigenvalues are integers. Let V_n denote the eigenspaces of $\mathrm{ad}(\Lambda_0)$, i.e.,

$$V_n := \{X\in\mathfrak{g}\,|\,\Lambda_0.X=nX\},\quad n\in\mathbb{Z}.$$

It also follows from $\mathfrak{sl}(2,\mathbb{C})$-representation theory that if $X\in\mathfrak{g}$ is a highest weight vector of the adjoint representation of $\mathrm{span}_{\mathbb{C}}\{\Lambda_0,\Omega_+,\Omega_-\}$ with weight n, and we define $X_{-1}=0$, $X_0=X$ and $X_j=(1/j!)\Omega_-^j.X_0\ (j\geqslant 0)$, then

$$\Lambda_0 . X_j = (n-2j) X_j ,$$

$$\Omega_- . X_j = (j+1) X_{j+1} , \tag{6.4}$$

$$\Omega_+ . X_j = (n-j+1) X_{j-1} \quad (j \geqslant 0).$$

Proposition 1: There exists M highest weight vectors $\xi^1, \xi^2, \ldots, \xi^M$ *for the adjoint representation of* $\mathrm{span}_{\mathbb{C}}\{\Lambda_0, \Omega_+, \Omega_-\}$ *on* $\mathfrak{g}$ *that satisfy*

(*i*) *the* ξ^j *have weights* $2k_j$ *where* $j = 1,2,\ldots,M$ *and* $1 = k_1 \leqslant k_2 \leqslant \cdots \leqslant k_M$,

(*ii*) *if* $V(\xi^j)$ *denotes the irreducible submodule of* $\mathfrak{g}$ *generated by* ξ^j, *then the sum* $\Sigma_{j=1}^{M} V(\xi^j)$ *is direct,*

(*iii*) *if* $\xi_l^j = (1/l!)\Omega_-^l . \xi^j$ *then*

$$c(\xi_l^j) = (-1)^l \xi_{2k_j - l}^j , \tag{6.5}$$

(*iv*) $M = |S_\lambda|$ *and the set* $\{\xi_{k_j - 1}^j | j = 1,2,\ldots M\}$ *forms a basis for* V_2 *over* $\mathbb{C}$.

Proof: (*i*) and (*ii*): The conjugation operator c satisfies

$$c([X,Y]) = [c(X), c(Y)] \quad \forall X, Y \in \mathfrak{g}. \tag{6.6}$$

Because $\Lambda_0 \in i\mathfrak{h}_0$

$$c(\Lambda_0) = -\Lambda_0 . \tag{6.7}$$

Using (3.2), (6.6), and (6.7), it is easy to see that

$$c \circ \mathrm{ad}(\Omega_\pm)^n = (-1)^n \mathrm{ad}(\Omega_\pm)^n \circ c \quad \text{for every } n \in \mathbb{Z}_{\geqslant 0}$$

$$\text{and} \quad c \circ \mathrm{ad}(\Lambda_0) = -\mathrm{ad}(\Lambda_0) \circ c. \tag{6.8}$$

As usual, define the Casimir operator $\mathcal{C}$ by

$$\mathcal{C} = \tfrac{1}{2}\mathrm{ad}(\Lambda_0)^2 + \mathrm{ad}(\Omega_+)\mathrm{ad}(\Omega_-) + \mathrm{ad}(\Omega_-)\mathrm{ad}(\Omega_+).$$

Then $\mathfrak{g}$ can be decomposed as follows:[26]

$$\mathfrak{g} = \bigoplus_p V(s_p, v^p), \tag{6.9}$$

where $V(s_p, v^p)$ is a highest weight module generated by the highest weight vector v^p of weight s_p, and it has the property

$$\mathcal{C}|_{V(s_p, v^p)} = (\tfrac{1}{2}s_p^2 + s_p)\mathrm{id}_{V(s_p, v^p)} \quad \forall \ p. \tag{6.10}$$

From (6.8) it follows that $\mathcal{C} \circ c = c \circ \mathcal{C}$. Using this result and (6.10), we see that

$$c(V(s_p, v^p)) \subset V(s_p, v^p) \quad \forall p. \tag{6.11}$$

Let $\{s_{p_1}, s_{p_2}, \ldots, s_{p_M}\}$ be the set of weights from the decomposition (6.9) that are even and greater than zero. We will assume that they are ordered so that $s_{p_1} \leqslant s_{p_2} \leqslant \cdots \leqslant s_{p_M}$. Define $k_j = s_{p_j}/2$. Then the k_j are positive integers that satisfy $k_1 \leqslant k_2 \leqslant \cdots \leqslant k_M$. Note that $k_1 = 1$ because Ω_+ is a highest weight vector with weight 2. To simplify notation, set $v^j := v^{p_j}$. As before with highest weight vectors [see (6.4)], we let $v_l^j = (1/l!)\Omega_-^l . v^j$. Define

$$\xi^j=\begin{cases} iv^j+c(iv^j_{2k_j}) & \text{if } c(v^j_{2k_j})=-c(v^j) \\ v^j+c(v^j_{2k_j}) & \text{otherwise} \end{cases}, \tag{6.12}$$

for $j=1,2,\ldots M$. Then straightforward calculation using (6.8) and (6.4) shows that $\Lambda_0.\xi^j=2k_j\xi^j$ and $\Omega_+.\xi^j=0$ for $j=1,2,\ldots M$. This implies that the ξ^j are all highest weight vectors of weight $2k_j$. Let $V(\xi^j)$ denote the irreducible submodule generated by ξ^j. From (6.11) and (6.12) it is clear that $\xi^j\subset V(2k_j,v^j)$ and hence $V(\xi^j)=V(2k_j,v^j)$. Thus the decomposition (6.9) shows that the sum $\Sigma_{j=1}^M V(\xi^j)$ is direct.

(iii): The relationship (6.5) follows from (6.8), (6.12), and (6.4).

(iv): Because the numbers $2k_1,2k_2,\ldots,2k_M$ exhaust all the positive even weights and the sum $\Sigma_{j=1}^M V(\xi^j)$ is direct, it follows from $\mathfrak{sl}(2,\mathbb{C})$-representation theory that $\{\xi^j|j=1,2,\ldots M\}$ is a basis over $\mathbb{C}$ for V_2. But $\{\mathbf{e}_\alpha|\alpha\in S_\lambda\}$ is also a basis over $\mathbb{C}$ for V_2. Therefore we must have $M=|S_\lambda|$. □

Define an $\mathbb{R}$-linear operator $A:\mathfrak{g}\to\mathfrak{g}$ by

$$A=\tfrac{1}{2}\mathrm{ad}(\Omega_+)\circ(\mathrm{ad}(\Omega_-)+\mathrm{ad}(\Omega_+)\circ c). \tag{6.13}$$

Proposition 2: The $\mathbb{R}$-linear operator A is symmetric with respect to the inner product $\langle\langle\ |\ \rangle\rangle$, i.e., $\langle\langle A(X)|Y\rangle\rangle=\langle\langle X|A(Y)\rangle\rangle\forall\ \ X,Y\in\mathfrak{g}$.

Proof: From (3.2) and the properties (6.3) of the inner product $\langle\langle\ |\ \rangle\rangle$, it is not hard to show that $\langle\langle[\Omega_+,[\Omega_-,X]]|Y\rangle\rangle=\langle\langle X|[\Omega_+,[\Omega_-,Y]]\rangle\rangle$ and $\langle\langle[\Omega_+,[\Omega_+,c(X)]]|Y\rangle\rangle=\langle\langle X|[\Omega_+,[\Omega_+,c(Y)]]\rangle\rangle$ for every $X,Y\in\mathfrak{g}$. From the definition of A, it is then obvious that $\langle\langle A(X)|Y\rangle\rangle=\langle\langle X|A(Y)\rangle\rangle$ for every $X,Y\in\mathfrak{g}$. □

Lemma 1:

$$A(V_2)\subset V_2. \tag{6.14}$$

Proof: It follows from $\mathfrak{sl}(2,\mathbb{C})$-representation theory that $\Omega_\pm.V_n\subset V_{n\pm2}$. From (6.8) it is clear that $c(V_n)\subset V_n$. Thus $\Omega_+.\Omega_-.V_2\subset V_2$ and $\Omega_+.\Omega_+.c(V_2)\subset V_2$ which implies that $A(V_2)\subset V_2$. □

This proposition shows that A restricts to an operator on V_2. We denote this operator by

$$A_2:=A|_{V_2}. \tag{6.15}$$

Label the integers k_j from proposition 1 as follows

$$1=k_{J_1}=k_{J_1+1}=\cdots=k_{J_1+m_1-1}<k_{J_2}=k_{J_2+1}=\cdots=k_{J_2+m_2-1}$$
$$<\cdots<k_{J_I}=k_{J_I+1}=\cdots=k_{J_I+m_I-1},$$

where $J_1=1$, $J_l+m_l=J_{l+1}$ for $l=1,2,\ldots,I$ and $J_{I+1}=M-1$. Define

$$\mathsf{k}_l:=k_{J_l}\quad l=1,2,\ldots,I. \tag{6.16}$$

The set $\{\xi^j_{k_j-1}|j=1,2,\ldots M\}$ forms a basis over $\mathbb{C}$ of V_2 by proposition 1 (iv). Therefore, the set of vectors $\{X^l_s,Y^l_s|l=1,2,\ldots,I;s=0,1,\ldots,m_l-1\}$ where

$$X^l_s:=\begin{cases} \xi^{J_l+s}_{\mathsf{k}_l-1} & \text{if } \mathsf{k}_l \text{ is odd} \\ i\xi^{J_l+s}_{\mathsf{k}_l-1} & \text{if } \mathsf{k}_l \text{ is even} \end{cases} \text{ and } Y^l_s:=iX^l_s, \tag{6.17}$$

forms a basis of V_2 over $\mathbb{R}$. By proposition 2, we know that A is symmetric and therefore diagonalizable. This forces A_2 to also be diagonalizable. The next lemma shows that $\{X_s^l, Y_s^l | l = 1,2,\ldots, Is = 0,1,\ldots, m_l - 1\}$ is in fact an eigenbasis of A_2.

Lemma 2:

$$A_2(X_s^l) = \mathsf{k}_l(\mathsf{k}_l+1)X_s^l \quad \textit{and} \quad A_2(Y_s^l) = 0 \quad \textit{for} \quad l = 1,2,\ldots,I \tag{6.18}$$

and $s = 0,1,\ldots, m_l - 1$.

Proof: Using the formulas (6.4) and proposition 1 (*iii*) it is easy to show that $A(\xi^j_{k_j-1}) = \frac{1}{2}k_j(k_j+1)(1+(-1)^{k_j-1})\xi^j_{k_j-1}$ and $A(i\xi^j_{k_j-1}) = \frac{1}{2}k_j(k_j+1)(1+(-1)^{k_j})i\xi^j_{k_j-1}$ for $j = 1,2,\ldots M$. The proposition then follows from (6.16) and 6.17. □

An immediate consequence of this lemma is that $\text{spec}(A_2) = \{0\} \cup \{\mathsf{k}_j(\mathsf{k}_j+1) | j = 1,2,\ldots I\}$ and m_j is the dimension of the eigenspace corresponding to the eigenvalue $\mathsf{k}_j(\mathsf{k}_j+1)$. Note that I is the number of distinct positive eigenvalues of A_2.

Define

$$E_0^l = \text{span}_{\mathbb{R}}\{Y_s^l | s = 0,1,\ldots, m_l - 1\},$$

$$E_+^l = \text{span}_{\mathbb{R}}\{X_s^l | s = 0,1,\ldots, m_l - 1\} \tag{6.19}$$

and

$$E_0 = \bigoplus_{l=1}^{I} E_0^l, \quad E_+ = \bigoplus_{l=1}^{I} E_+^l. \tag{6.20}$$

Then $E_0 = \ker(A_2)$ and E_+^l is the eigenspace of A_2 corresponding to the eigenvalue $\mathsf{k}_l(\mathsf{k}_l+1)$. Moreover, using proposition 1 (*iv*), we see that

$$V_2 = E_0 \oplus E_+. \tag{6.21}$$

Lemma 3: Suppose $X \in V_2$. *Then* $X \in \oplus_{q=1}^{l} E_0^q \oplus E_+^q$ *if and only if* $\Omega_+^{\mathsf{k}_l}.X = 0$.

Proof: From the formulas (6.4), we get

$$\Omega_+^{q-1}.\xi^l_{k_l-1} = \begin{cases} 0 & \text{if } q > k_l \\ d(q,k_l)\xi^l_{k_l-q} & \text{if } q \leqslant k_l \end{cases},$$

where $d(q,r) = (q+r)!/(r+1)!$. This implies that

$$\Omega_+^{l-1}.X_p^q = \begin{cases} 0 & \text{if } l > \mathsf{k}_q \\ \beta_q d(l,\mathsf{k}_q)\xi^{J_q+p}_{\mathsf{k}_q-l} & \text{if } l \leqslant \mathsf{k}_q \end{cases} \tag{6.22}$$

and

$$\Omega_+^{l-1}.Y_p^q = \begin{cases} 0 & \text{if } l > \mathsf{k}_q \\ \overline{\beta}_q\, d(l,\mathsf{k}_q) i\xi^{J_q+p}_{\mathsf{k}_q-l} & \text{if } l \leqslant \mathsf{k}_q \end{cases}, \tag{6.23}$$

where

$$\beta_q = \begin{cases} 1 & \text{if } \mathsf{k}_q \text{ is odd} \\ i & \text{if } \mathsf{k}_q \text{ is even} \end{cases}.$$

Suppose $X \in V_2 = \oplus_{q=1}^{I} E_0^q \oplus E_+^q$. Then there exists real constants a_{qp} and b_{qp} such that

$$X=\sum_{q=1}^{I}\sum_{p=0}^{m_q-1}(a_{qp}\,Y_p^q+b_{qp}\,X_p^q). \tag{6.24}$$

Suppose $\Omega_+^{\mathsf{k}_l}.X=0$. Then (6.22)–(6.24) imply that

$$\sum_{q=l+1}^{I}\sum_{p=0}^{m_q-1}(a_{qp}\,\overline{\beta}_q\,d(\mathsf{k}_l+1,\mathsf{k}_q)i\,\xi^{J_q+p}_{\mathsf{k}_q-\mathsf{k}_l-1}+b_{qp}\,\beta_q\,d(\mathsf{k}_l+1,\mathsf{k}_q)\,\xi^{J_q+p}_{\mathsf{k}_q-\mathsf{k}_l-1})=0.$$

But the set of vectors

$$\{\overline{\beta}_q i\,\xi^{J_q+p}_{\mathsf{k}_q-\mathsf{k}_l-1},\beta_q\,\xi^{J_q+p}_{\mathsf{k}_q-\mathsf{k}_l-1}|q=l+1,l+2,\ldots I,p=0,1,\ldots,m_q-1\},$$

is linearly independent over $\mathbb{R}$. Therefore, $X=\Sigma_{q=1}^{l}\Sigma_{p=0}{}^{m_q+1}(a_{qp}Y_p^q+b_{qp}X_p^q)$ which implies that $X\in\oplus_{q=1}^{l}E_0^q\oplus E_+^q$.

Conversely, suppose $X\in\oplus_{q=1}^{l}E_0^q\oplus E_+^q$. The X can be written in the form (6.24) and it is easy using (6.22) and (6.23) to verify that $\Omega_+^{\mathsf{k}_l}.X=0$. □

Lemma 4: Suppose $X\in V_2$. Then $X\in\oplus_{q=1}^{l}E_0^q\oplus E_+^q$ if and only if $\Omega_+^{\mathsf{k}_l+2}.c(X)=0$.

Proof: Proved in a similar fashion as lemma 3. □

Lemma 5: Let $\widetilde{\ }:\mathbb{Z}_{\geqslant -1}\to\{1,2,\ldots,I\}$ be the map defined by

$$\widetilde{-1}=\widetilde{0}=1\quad and\quad \tilde{s}=\max\{l|\mathsf{k}_l\leqslant s\}\quad if\quad s>0.$$

Then

(*i*) $\mathsf{k}_{\tilde{s}}\leqslant s$ *for every* $s\in\mathbb{Z}_{\geqslant 0}$.

(*ii*) $\mathsf{k}_{\tilde{s}}\leqslant s<\mathsf{k}_{\tilde{s}+1}$ *for every* $s\in\{0,1,\ldots\mathsf{k}_I-1\}$.

Proof: (*i*) This is obvious from the definition of $\widetilde{\ }$.

(*ii*) From part (i), $\mathsf{k}_{\tilde{s}}\leqslant s$. So suppose $\mathsf{k}_{\tilde{s}+1}\leqslant s$. Then from the definition of $\widetilde{\ }$ it is clear $\mathsf{k}_{\tilde{s}+1}\leqslant\mathsf{k}_{\tilde{s}}$. But because $\mathsf{k}_1<\mathsf{k}_2<\cdots<\mathsf{k}_I$, it follows that $\tilde{s}+1\leqslant s$ which is a contradiction. Thus $\mathsf{k}_{\tilde{s}+1}>s$ and we are done. □

Lemma 6: If $X\in V_2$, $\mathsf{k}_{\tilde{p}}+s<\mathsf{k}_{\tilde{p}+1}$ $(s\geqslant 0)$, and $\Omega_+^{\mathsf{k}_{\tilde{p}}+s}.X=0$, then $\Omega_+^{\mathsf{k}_{\tilde{p}}}.X=0$.

Proof: Assume $s>0$, otherwise we are done. Because $X\in V_2$, we have $\Omega_+^{\mathsf{k}_{\tilde{p}}+s-1}.X\in V_{2(\mathsf{k}_{\tilde{p}}+s)}$. By assumption $\Omega_+^{\mathsf{k}_{\tilde{p}}+s}.X=0$, so

$$\Omega_+^{\mathsf{k}_{\tilde{p}}+s-1}.X\in V_{2(\mathsf{k}_{\tilde{p}}+s)}\cap\ker(\mathrm{ad}(\Omega_+)).$$

But, if $n\in\mathbb{Z}_{>0}$, then

$$V_{2n}\cap\ker(\mathrm{ad}(\Omega_+))\neq\{0\}\Leftrightarrow n\in\{\mathsf{k}_1,\mathsf{k}_2,\ldots,\mathsf{k}_I\},$$

because otherwise $\mathfrak{g}$ would contain an irreducible $\mathrm{span}_{\mathbb{C}}\{\Lambda_0,\Omega_+,\Omega_-\}$-submodule with weight $2n\in\mathbb{Z}_{>0}\backslash\{2\mathsf{k}_1,2\mathsf{k}_2,\ldots,2\mathsf{k}_I\}$. This is impossible as the set $\{2\mathsf{k}_1,2\mathsf{k}_2,\ldots,2\mathsf{k}_I\}$ exhausts all the positive even weights of the irreducible $\mathrm{span}_{\mathbb{C}}\{\Lambda_0,\Omega_+,\Omega_-\}$-submodules in $\mathfrak{g}$. Therefore $\Omega_+^{\mathsf{k}_{\tilde{p}}+s-1}.X=0$ as $\mathsf{k}_{\tilde{p}}<\mathsf{k}_{\tilde{p}}+s<\mathsf{k}_{\tilde{p}+1}$ implies that $(\mathsf{k}_{\tilde{p}}+s)$ is not in $\{\mathsf{k}_1,\mathsf{k}_2,\ldots,\mathsf{k}_I\}$. Repeat the above argument with $s'=s-1$ to arrive at $\Omega_+^{\mathsf{k}_{\tilde{p}}+s'-1}.X=\Omega_+^{\mathsf{k}_{\tilde{p}}+s-2}.X=0$. Continuing in this manner, we find $\Omega_+^{\mathsf{k}_{\tilde{p}}}.X=0$. □

The next theorem is the key result needed to prove that the EYM equations can be put into a form where theorem 3 applies in a neighborhood of the origin $r=0$.

Theorem 9: *Suppose $p\in\{1,2,\ldots,\mathsf{k}_I-1\}$ and $Z_0,Z_1,\ldots,Z_{p+1}\in V_2$ is a sequence of vectors that satisfy $Z_0\in E_0^1\oplus E_+^1$ and $Z_{n+1}\in\oplus_{q=1}^{\tilde{n}}E_0^q\oplus E_+^q$ for $n=0,1,\ldots p$. Then for every $j\in\{1,2,\ldots,p+1\}$, $s\in\{0,1,2,\ldots,j\}$*

(*i*) $[[c(Z_{j-s}),Z_s],Z_{p+2-j}]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$,

(ii) $[[c(Z_{p+2-j}),Z_{j-s}],Z_s]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$.

Proof: (i) Suppose $Z_0,Z_1,\ldots,Z_{p+1}\in V_2$ is a sequence satisfying $Z_0\in E_0^1\oplus E_+^1$ and $Z_{n+1}\in\oplus_{q=1}^{\tilde{n}}E_0^q\oplus E_+^q$ for $n=0,1,\ldots p$. Then

$$\Omega_+^{\mathsf{k}_{(n-1)^\sim}}.Z_n=\Omega_+^{\mathsf{k}_{(n-1)^\sim}+2}.c(Z_n)=0, \tag{6.25}$$

for $n=0,1,2,\ldots,p+1$ by lemmas 3 and 4. Now, if $j\in\{1,2,\ldots,p+1\}$ and $s\in\{0,1,\ldots,j\}$, then

$$\Omega_+^p.[[c(Z_{j-s}),Z_s],Z_{p+2-j}]=\sum_{l=0}^{p}\sum_{m=0}^{l}\binom{p}{l}\binom{l}{m}a_{psjlm},$$

where

$$a_{psjlm}=[[\Omega_+^m.c(Z_{j-s}),\Omega_+^{l-m}.Z_s],\Omega_+^{p-l}.Z_{p+2-j}].$$

Applying (6.25) yields $a_{psjlm}=0$ if $m-2\geqslant\mathsf{k}_{(j-s-1)^\sim}$ or $l-m\geqslant\mathsf{k}_{(s-1)^\sim}$ or $p-l\geqslant\mathsf{k}_{(p+1-j)^\sim}$. But because of lemma 5 (i), this implies that $a_{psjlm}=0$ if $m-2\geqslant j-s-1$ or $l-m\geqslant s-1$ or $p-l\geqslant p+1-j$. It follows that $a_{psjlm}=0$ unless l and m satisfy $j-1<l<m+s-1<j$ which is impossible. Therefore, $a_{psjlm}=0$ for all l and m. Thus $\Omega_+^p.[[c(Z_{j-s}),Z_s],Z_{p+2-j}]=0$. But then it follows from lemmas 5 (ii) and 6 that $\Omega_+^{\tilde{p}}.[[c(Z_{j-s}),Z_s],Z_{p+2-j}]=0$ and hence $[[c(Z_{j-s}),Z_s],Z_{p+2-j}]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$ by lemma 3.

(ii) It follows from similar arguments that $[[c(Z_{p+2-j}),Z_{j-s}],Z_s]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$. □

It is worthwhile to note that all the the above results did not depend on Λ_0 being regular. However, for what follows we will need Λ_0 to be regular.

Proposition 3: Suppose Λ_0 is regular. Then $span_{\mathbb{C}}\{\xi^1,\xi^2,\ldots,\xi^M\}$ is an Abelian subalgebra of $\mathfrak{g}_\lambda$ and hence also an Abelian subalgebra of $\mathfrak{g}$.

Proof: From the definition of $\mathfrak{g}_\lambda$, it follows that $\mathrm{span}_{\mathbb{C}}\{\Lambda_0,\Omega_+,\Omega_-\}\subset\mathfrak{g}_\lambda$ and $V_2\subset\mathfrak{g}_\lambda$. But by proposition 1 $V_2=\mathrm{span}_{\mathbb{C}}\{\xi^1_{k_1-1},\xi^2_{k_2-1},\xi^M_{k_M-1}\}$, and hence

$$\frac{(k_l+1)!}{(2k_l)!}\Omega_+^{k_l-1}.\xi^l_{k_l-1}=\xi^l\in\mathfrak{g}_\lambda,$$

for $i=1,2,\ldots,M$. Therefore $\mathrm{span}_{\mathbb{C}}\{\xi^1,\xi^2,\ldots,\xi^M\}\subset\mathfrak{g}_\lambda$. The ξ^j are highest weight vectors, consequently

$$\mathrm{span}_{\mathbb{C}}\{\xi^1,\xi^2,\ldots,\xi^M\}\subset\mathfrak{g}_\lambda^{\Omega_+} \tag{6.26}$$

where $\mathfrak{g}_\lambda^{\Omega_+}=\{X\in\mathfrak{g}_\lambda|[\Omega_+,X]=0\}$. Define $V_{\lambda,n}:=\{X\in\mathfrak{g}_\lambda|\Lambda_0.X=nX\}$. By theorem 1, S_λ is a base a system of roots of $\mathfrak{g}_\lambda$ and $\alpha(\Lambda_0)=2$ for every $\alpha\in S_\lambda$ and hence it follows that $V_{\lambda,2}=V_2$. Using $\mathfrak{sl}(2,\mathbb{C})$-representation theory, it is not hard to show that $\dim_{\mathbb{C}}\mathfrak{g}_\lambda^{\Omega_+}=\dim_{\mathbb{C}}V_{\lambda,2}$. But $\dim_{\mathbb{C}}V_2=|S_\lambda|$, and therefore $\dim_{\mathbb{C}}\mathfrak{g}_\lambda^{\Omega_+}=|S_\lambda|$. By proposition 1, $|S_\lambda|=M$ and hence we get from (6.26) that

$$\mathrm{span}_{\mathbb{C}}\{\xi^1,\xi^2,\ldots,\xi^M\}=\mathfrak{g}_\lambda^{\Omega_+}. \tag{6.27}$$

Theorem 1 proved that $|S_\lambda|=\dim_{\mathbb{C}}\mathfrak{h}_\lambda$ which in turn gives, via the above result, $\dim_{\mathbb{C}}\mathfrak{g}_\lambda^{\Omega_+}=\dim_{\mathbb{C}}\mathfrak{h}_\lambda$. Applying lemma 2.1.15 of Ref. 15 then shows that

$$\dim_{\mathbb{C}}\mathfrak{g}_\lambda^{\Omega_+}=\min\{\dim_{\mathbb{C}}\mathfrak{g}_\lambda^X|X\in\mathfrak{g}_\lambda\}. \tag{6.28}$$

We can identify $\mathfrak{g}_\lambda$ with the dual $\mathfrak{g}_\lambda^*$ using the form $(\ ,\ )$, i.e.,

$$\iota:\mathfrak{g}_{\lambda,0}\to\mathfrak{g}_{\lambda,0}^*;\quad \iota(X)(\cdot)=(X,\cdot).$$

So if $f\in\mathfrak{g}_\lambda^*$ and we define $\mathfrak{g}_\lambda^f=\{X\in\mathfrak{g}_\lambda|\mathrm{ad}_X^*(f)=0\}$, then it can be shown that

$$\mathfrak{g}_\lambda^{\iota(X)}=\mathfrak{g}_\lambda^X\quad\forall X\in\mathfrak{g}. \tag{6.29}$$

Let G_λ be a connected complex semisimple Lie group with Lie algebra $\mathfrak{g}_\lambda$. Then for $f\in\mathfrak{g}_\lambda^*$, $\mathfrak{g}_\lambda^f$ is the Lie algebra of coadjoint isotropy group $G_{\lambda,f}=\{a\in G_\lambda|\mathrm{Ad}_a^*(f)=f\}$. But then (6.27), (6.28), (6.29) and a straightforward generalization of theorem 9.3.10 in Ref. 27 to complex Lie groups imply that $\mathrm{span}_{\mathbb{C}}\{\xi^1,\xi^2,\ldots,\xi^M\}$ is an Abelian subalgebra. □

The next theorem is the key result needed to prove that the EYM equations can be put into a form where theorem 3 applies in a neighborhood $r=\infty$. Although this theorem looks very similar to theorem 9, it is more difficult to prove. Similar arguments as in theorem 9 are employed, but these only go part of the way. Proposition 3 is needed to complete the proof.

Theorem 10: *Assume that Λ_0 is regular. Suppose $p\in\{0,1,2,\ldots,\mathsf{k}_I\}$ and $Z_0,Z_1,\ldots,Z_p\in V_2$ is a sequence of vectors that satisfy $Z_n\in\oplus_{q=1}^{\tilde{n}}E_0^q\oplus E_+^q$ for $n=0,1,2...p$. Then for every $j\in\{1,2,\ldots,p\}$, $s\in\{0,1,\ldots,j\}$*

(i) $[[c(Z_{j-s}),Z_s],Z_{p+1-j}]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$,

(ii) $[[c(Z_{p+1-j}),Z_{j-s}],Z_s]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$.

Proof: *(i)* Suppose $Z_0,Z_1,\ldots,Z_p\in V_2$ is a sequence satisfying $Z_n\in\oplus_{q=1}^{\tilde{n}}E_0^q\oplus E_+^q$ for $n=0,1,\ldots p$. Then

$$\Omega_+^{\mathsf{k}_{\tilde{n}}}.Z_n=\Omega_+^{\mathsf{k}_{\tilde{n}}+2}.c(Z_n)=0, \tag{6.30}$$

for $n=0,1,2,\ldots,p$ by lemmas 3 and 4. Suppose $j\in\{1,2,\ldots,p\}$ and $s\in\{0,1,\ldots,j\}$. Then

$$\Omega_+^p.[[c(Z_{j-s}),Z_s],Z_{p+1-j}]=\sum_{l=0}^{p}\sum_{m=0}^{l}\binom{p}{l}\binom{l}{m}a_{psjlm}, \tag{6.31}$$

where

$$a_{psjlm}=[[\Omega_+^m.c(Z_{j-s}),\Omega_+^{l-m}.Z_s],\Omega_+^{p-l}.Z_{p+1-j}].$$

Applying (6.30) yields $a_{psjlm}=0$ if $m-2\geqslant\mathsf{k}_{(j-s)^\sim}$ or $l-m\geqslant\mathsf{k}_{\tilde{s}}$ or $p-l\geqslant\mathsf{k}_{(p+1-j)^\sim}$. But because of lemma 5 (i), this implies that $a_{psjlm}=0$ if $m-2\geqslant j-s$ or $l-m\geqslant s$ or $p-l\geqslant p+1-j$. It follows that $a_{psjlm}=0$ unless l and m satisfy $j-1<l<m+s<j+2$ which implies that $l=j$ and $m+s=j+1$. Thus the sum (6.31) reduces to

$$\Omega_+^p.[[c(Z_{j-s}),Z_s],Z_{p+1-j}]=\binom{p}{j}\binom{j}{j+1-s}[[X_1,X_2],X_3],$$

where $X_1=\Omega_+^{j-s+1}.c(Z_{j-s})$, $X_2=\Omega_+^{s-1}.Z_s$, and $X_3=\Omega_+^{p-j}.Z_{p+1-j}$. Applying (6.30) then shows that $\Omega_+.X_a=0$ for $a=1,2,3$. Because the X_a have even weights,

$$X_1,X_2,X_3\in\mathrm{span}_{\mathbb{C}}\{\xi^1,\xi^2,\ldots,\xi^M\}.$$

But $\mathrm{span}_{\mathbb{C}}\{\xi^1,\xi^2,\ldots,\xi^M\}$ is an Abelian subalgebra by proposition 3, so $[[X_1,X_2],X_3]=0$ which implies that $\Omega_+^p.[[c(Z_{j-s}),Z_s],Z_{p+1-j}]=0$. We then get via lemma 6 that $\Omega_+^{\mathsf{k}_{\tilde{p}}}.[[c(Z_{j-s}),Z_s],Z_{p+1-j}]=0$ and hence $[[c(Z_{j-s}),Z_s],Z_{p+1-j}]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$ by lemma 3.
(ii) The proof that $[[c(Z_{p+1-j}),Z_{j-s}],Z_s]\in\oplus_{q=1}^{\tilde{p}}E_0^q\oplus E_+^q$ is similar to part *(i)*. □

Proposition 4: If $\Omega_+\in\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha$ and Λ_0 is regular, then $E_+=\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha$.

Proof: Introduce a basis $\{Z_j|1\leqslant j\leqslant M\}$ over $\mathbb{R}$ for E_+ by defining

$$Z_j=\begin{cases}\xi^j_{k_j-1} & \text{if } k_j \text{ is odd}\\ i\,\xi^j_{k_j-1} & \text{if } k_j \text{ is even}\end{cases}\qquad 1\leqslant j\leqslant M.$$

Equations (6.4) and proposition 1 (iii) can be used to show that

$$\Omega_+ .c(Z_j)=\Omega_- .Z_j \quad 1\leqslant j\leqslant M. \tag{6.32}$$

By assumption $\Omega_+=\Sigma_{\alpha\in S_\lambda}w_\alpha\mathbf{e}_\alpha$ for some set of constants $w_\alpha\in\mathbb{R}$. Because $c(\Omega_+)=-\Omega_-$ and $c(\mathbf{e}_\alpha)=-\mathbf{e}_{-\alpha}$, $\Omega_-=\Sigma_{\alpha\in S_\lambda}w_\alpha\mathbf{e}_{-\alpha}$. Since $Z_j\in V_2$, $Z_j=\Sigma_{\alpha\in S_\lambda}a_{j\alpha}\mathbf{e}_\alpha$ for some set of constants $a_{j\alpha}\in\mathbb{C}$. So then $c(Z_j)=-\Sigma_{\alpha\in S_\lambda}\overline{a}_{j\alpha}\mathbf{e}_{-\alpha}$. Now, since Λ_0 is regular, Eq. (3.15) holds. Therefore,

$$\Omega_- .Z_j=\sum_{\alpha\in S_\lambda} w_\alpha a_{j\alpha}[\mathbf{e}_{-\alpha},\mathbf{e}_\alpha]=\sum_{\alpha\in S_\lambda} -w_\alpha a_{j\alpha}\mathbf{h}_\alpha, \tag{6.33}$$

while

$$\Omega_+ .c(Z_j)=\sum_{\alpha\in S_\lambda} -w_\alpha\overline{a}_{j\alpha}[\mathbf{e}_\alpha,\mathbf{e}_{-\alpha}]=\sum_{\alpha\in S_\lambda} -w_\alpha\overline{a}_{j\alpha}\mathbf{h}_\alpha. \tag{6.34}$$

The three results (6.32)–(6.34) then yield

$$\sum_{\alpha\in S_\lambda} w_\alpha(a_{j\alpha}-\overline{a}_{j\alpha})\mathbf{h}_\alpha=0.$$

Since Λ_0 is regular, it follows that $w_\alpha\neq 0$ for all $\alpha\in S_\lambda$ and the set $\{\mathbf{h}_\alpha|\alpha\in S_\lambda\}$ is linearly independent.[12] Thus $a_{j\alpha}-\overline{a}_{j\alpha}=0$ for all $\alpha\in S_\lambda$ and $j=1,2,\ldots,M$. So $Z_j\in\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha$ for $j=1,2,\ldots,M$ which implies that $E_+\subset\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha$. However, $\dim_{\mathbb{R}}E_+=\dim_{\mathbb{R}}(\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha)=|S_\lambda|$ and, therefore, $E_+=\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha$. □

Suppose Λ_0 is regular and $\Omega_+=\Sigma_{\alpha\in S_\lambda}w_\alpha\mathbf{e}_\alpha$ where $w_\alpha\in\mathbb{R}$ for every $\alpha\in S_\lambda$. Then using (3.10), (3.15), and the fact that $c(\mathbf{e}_\alpha)=-\mathbf{e}_{-\alpha}$, it is not difficult to show that

$$A_2(\mathbf{e}_\alpha)=\sum_{\beta\in S_\lambda} w_\beta\langle\beta,\alpha\rangle w_\alpha\mathbf{e}_\beta.$$

This result along with (6.21) and proposition 4 shows that $\{\mathbf{e}_\alpha|\alpha\in S_\lambda\}$ can be completed to a basis over $\mathbb{R}$ of V_2 so that the matrix of A_2 with respect to this basis takes the form

$$[A_2]=\begin{pmatrix}0 & 0\\ 0 & [A_{\alpha\beta}]\end{pmatrix}, \tag{6.35}$$

with

$$A_{\alpha\beta}=w_\alpha\langle\alpha,\beta\rangle w_\beta. \tag{6.36}$$

VII. LOCAL UNIQUENESS AND EXISTENCE PROOFS

In this section we present the proofs of theorems 4–6. The proof of theorem 6 is the easiest and does not depend on the results of the Sec. 6.
Define

$$\mathcal{E}:=\{\mathsf{k}_j|j=1,2,\ldots I\},$$

with the k_j defined in (6.16) and let

$$\mathrm{pr}_+^q : E_+ \to E_+^q \quad q = 1,2,\ldots I,$$

denote the projection operators between the spaces defined in (6.19) and (6.20). If $a \in \mathbb{R}$, we will use $I_\epsilon(a)$ to denote an interval of radius ϵ about a, i.e.,

$$I_\epsilon(a) = (a-\epsilon, a+\epsilon).$$

From proposition 4 and (3.19), we know that the the solution $\Lambda_+(r)$ to Eq. (3.6) is, up to a gauge transformation, completely characterized by the condition

$$\Lambda_+(r) \in E_+ \quad \forall r. \tag{7.1}$$

As discussed previously, if we can solve the two EYM equations (3.3) and (3.5) for the variables $\{\Lambda_+(r), m(r)\}$ the remaining equation (3.4) can be integrated to yield S. Consequently, we are only interested in Eqs. (3.3) and (3.5).

Proof of theorem 4: The proof of this theorem involves finding a change of variables to put the system of differential equations (3.3) and (3.5) into a form where theorem 3 applies in a neighborhood of $r=0$.

Since Λ_+ satisfies (7.1), we can introduce new variables $\{u_{s+1}(r) | s \in \mathcal{E}\}$ that satisfy

$$\Lambda_+(r) = \Omega_+ + \sum_{s \in \mathcal{E}} u_{s+1}(r) r^{s+1}, \tag{7.2}$$

where $\Omega_+ = \Lambda_+(0)$ and $u_{s+1}(r) \in E_+^{\tilde{s}}$ for all r and $s \in \mathcal{E}$. Because $E_+ = \oplus_{q=1}^I E_+^q$, it is obvious that this transformation is invertible. Define

$$\chi_{s+1} = \begin{cases} 1 & \text{if } s \in \mathcal{E} \\ 0 & \text{otherwise} \end{cases}.$$

Then we can write $\Lambda_+(r) = \Omega_+ + \Sigma_{k=0}^\infty \chi_k u_k(r) r^k$. Substituting this in (3.8) shows that there exists an integer N_1 such that

$$\mathcal{F} = -\sum_{k \in \mathcal{E}} A_2(u_{k+1}) r^{k+1} + \sum_{k=2}^{N_1} f_k r^k,$$

where

$$f_k = \frac{1}{2} \sum_{j=2}^{k-2} \Big\{ [[\Omega_+, c(\chi_j u_j)] + [\Omega_-, \chi_j u_j], \chi_{k-j} u_{k-j}] + [[\chi_j u_j, c(\chi_{k-j} u_{k-j})], \Omega_+] + \sum_{s=2}^{j-2} [[\chi_s u_s, c(\chi_{j-s} u_{j-s})], \chi_{k-j} u_{k-j}] \Big\}.$$

But $A_2(u_{k+1}) = k(k+1) u_{k+1}$ for every $k \in \mathcal{E}$ by lemma 2 and hence

$$\mathcal{F} = -\sum_{k \in \mathcal{E}} k(k+1) u_{k+1} r^{k+1} + \sum_{k=2}^{N_1} f_k r^k. \tag{7.3}$$

Define

$$v_{s+1} = u'_{s+1} \quad \forall s \in \mathcal{E}. \tag{7.4}$$

Using (7.2), (7.3) and (7.4), the EYM equation (3.5) can be written as

$$r\sum_{k\in\mathcal{E}} v'_{k+1}r^{k+1} = -2\sum_{k\in\mathcal{E}}(k+1)v_{k+1}r^{k+1} + \sum_{k\in\mathcal{E}}\frac{k(k+1)}{r}\left(\frac{1}{N}-1\right)u_{k+1}r^{k+1} - \frac{2}{rN}\left(m-\frac{1}{r}P\right)\sum_{k\in\mathcal{E}}(v_{k+1}r^{k+1}+(k+1)u_{k+1}r^k) - \frac{1}{N}\sum_{k=4}^{N_1} f_k r^{k-1}. \quad (7.5)$$

Applying the projections $\mathrm{pr}_+^{\tilde{k}}$ for every $k\in\mathcal{E}$ to Eq. (7.5) yields

$$\begin{aligned} rv'_{k+1} = &-2(k+1)v_{k+1} - \frac{2}{rN}\left(m-\frac{1}{r}P\right)v_{k+1} \\ &+ \frac{k(k+1)}{r}\left(\frac{1}{N}-1\right)u_{k+1} - \frac{2}{r^2N}\left(m-\frac{1}{r}P\right) \\ &\times(k+1)u_{k+1}r^k - \frac{1}{r^{k+1}N}\sum_{s=2}^{N_1-2}\mathrm{pr}_+^{\tilde{k}}(f_{s+2})r^{s+1} \quad \forall k\in\mathcal{E}. \end{aligned} \quad (7.6)$$

The last term in (7.6) is the main obstruction to putting the equation into a form where theorem 3 applies. It seems to contain terms of order $r^{-s}(s>0)$. However, as we shall now see, the results of Sec. VI can be used to show that

$$\frac{1}{r^{k+1}N}\sum_{s=0}^{N_1-2}\mathrm{pr}_+^{\tilde{k}}(f_{s+2})r^{s+1} = \frac{1}{N}\sum_{s=k}^{N_1-2}\mathrm{pr}_+^{\tilde{k}}(f_{s+2})r^{s-k}. \quad (7.7)$$

Namely, by using proposition 4, we can show that $f_k\in E_+$ for all k. From the definition of the u_{s+1} it is clear that $\chi_{s+1}u_{s+1}\in\oplus_{q=1}^{\tilde{s}}E_+^q$ for $0\leqslant s\leqslant \mathsf{k}_I$, and so it follows from theorem 9 by letting $Z_0=\Omega_+$ and $Z_{k+1}=\chi_{k+1}u_{k+1}$ for $k\geqslant 0$ that $f_{s+2}\in\oplus_{q=1}^{\tilde{s}}E_+^q$. Consequently, for every $k\in\mathcal{E}$

$$\mathrm{pr}_+^{\tilde{k}}(f_{s+2}) = 0 \quad \text{if } s<k,$$

because $k\in\mathcal{E}$ implies that $k=\mathsf{k}_{\tilde{k}}$ and hence it follows for $s<k=\mathsf{k}_{\tilde{k}}$ that $\tilde{s}<\tilde{k}$. This proves (7.7). Therefore, we can rewrite (7.6) as

$$\begin{aligned} rv'_{k+1} = &-2(k+1)v_{k+1} - \frac{2}{rN}\left(m-\frac{1}{r}P\right)v_{k+1} + \frac{k(k+1)}{r}\left(\frac{1}{N}-1\right)u_{k+1} - \frac{2}{r^2N}\left(m-\frac{1}{r}P\right) \\ &\times(k+1)u_{k+1} - \frac{r}{N}\sum_{s=k}^{N_1-1}\mathrm{pr}_+^{\tilde{k}}(f_{s+3})r^{s-k} + \left(1-\frac{1}{N}\right)\mathrm{pr}_+^{\tilde{k}}(f_{k+2}) - \mathrm{pr}_+^{\tilde{k}}(f_{k+2}) \quad \forall k\in\mathcal{E}. \end{aligned} \quad (7.8)$$

Using the properties (6.3) of $\langle\langle\ |\ \rangle\rangle$ and the fact that $A_2(u_2)=2u_2$, it can be shown that there exists analytic functions

$$\hat{P}:E_+\times\mathbb{R}\to\mathbb{R} \quad \text{and} \quad \hat{G}:E_+\times E_+\times\mathbb{R}\to\mathbb{R},$$

such that

$$P = r^4\|u_2\|^2 + r^5\hat{P}(u,r) \ \text{ and } \ G = r^2 2\|u_2\|^2 + r^3\hat{G}(u,v,r), \quad (7.9)$$

where $u=\Sigma_{s\in\mathcal{E}}u_{s+1}$, $v=\Sigma_{s\in\mathcal{E}}v_{s+1}$, and $\|\ \|$ is defined by (6.2). Introduce a new "mass" variable μ by

$$\mu = \frac{1}{r^3}(m - r^3\|u_2\|^2). \tag{7.10}$$

Recall that $\mathsf{k}_1 = 1$, so 1 is always in $\mathcal{E}$ and hence u_2 is always defined. We can then write the EYM equation (3.3) as

$$r\mu' = -3\mu + r\{\hat{P}(u,r) + \hat{G}(u,v,r) - 2\langle\langle\, u_2 | v_2 \,\rangle\rangle - 2r(\mu + \|u_2\|^2)(2\|u_2\|^2 + r\hat{G}(u,v,r))\}. \tag{7.11}$$

Introduce one last change of variables via

$$\hat{v}_{k+1} = v_{k+1} + \frac{1}{2(k+1)}\,\mathrm{pr}_+^{\tilde{k}}(f_{k+2}). \tag{7.12}$$

Fix $X \in E_+$ and define $\hat{v} = \Sigma_{s\in\mathcal{E}}\hat{v}_{s+1}$. Then using (7.8), (7.10), and (7.12), it can be shown that there exists a neighborhood of $\mathcal{N}_X$ of X in E_+, an $\epsilon > 0$, and a sequence of analytic maps

$$\mathcal{G}_k : \mathcal{N}_X \times E_+ \times I_\epsilon(0) \times I_\epsilon(0) \to E_0^{\tilde{k}} \forall k \in \mathcal{E},$$

such that

$$r\hat{v}'_{k+1} = -2(k+1)\hat{v}_{k+1} + r\mathcal{G}_k(u,\hat{v},\mu,r) \forall k \in \mathcal{E}. \tag{7.13}$$

Also from (7.4), (7.11), and (7.12), it is not difficult to show that there exists analytic maps

$$\mathcal{H}_k : E_+ \times E_+ \to E_+^{\tilde{k}} \forall k \in \mathcal{E} \text{ and } \mathcal{K} : E_+ \times E_+ \times \mathbb{R} \times \mathbb{R} \to \mathbb{R},$$

such that

$$ru'_{k+1} = r\mathcal{H}_k(u,\hat{v}) \quad \forall k \in \mathcal{E}, \tag{7.14}$$

$$r\mu' = -3\mu + r\mathcal{K}(u,\hat{v},\mu,r). \tag{7.15}$$

The system of differential equations (7.13)–(7.15) are in the form for which theorem 3 applies. Applying this theorem shows that for fixed $X \in E_+$ there exist a unique solution $\{u_{k+1}(r,Y), \hat{v}_{k+1}(r,Y), \mu(r,Y)\}$ to this system of differential equations that is analytic in a neighborhood of $(r,Y) = (0,X)$ and that satisfies

$$u_{s+1}(r,Y) = Y_s + O(r) \quad \forall s \in \mathcal{E}, \tag{7.16}$$

$$\hat{v}_{s+1}(r,Y) = O(r) \quad \forall s \in \mathcal{E}, \tag{7.17}$$

$$\mu(r,Y) = O(r),$$

where $Y_s = \mathrm{pr}_+^{\tilde{s}}(Y)$. From Eq. (7.10), it is then clear that mass m satisfies

$$m(r) = O(r^3).$$

Also from (7.9), (7.12), (7.16), and (7.17) it is not difficult to see that

$$P = O(r^4) \text{ and } G = O(r^2). \tag{7.18}$$

From the results of the previous section there exists an orthonormal basis $\{\mathbf{f}_j | j = 1,2,\ldots M\}$ for E_+ consisting of eigenvectors for A_2, i.e, $A_2(\mathbf{f}_j) = k_j(k_j+1)\mathbf{f}_j$. Thus we can introduce new variables $\{\hat{u}_j(r) | j = 1,2,\ldots M\}$ via

$$\sum_{s\in\mathcal{E}} u_{s+1}(r)r^{s+1}=\sum_{j=1}^{M}\hat{u}_j(r)r^{k_j+1}\mathbf{f}_j. \tag{7.19}$$

From proposition 1 we know that $M=|S_\lambda|$. So we can write $S_\lambda=\{\alpha_j|j=1,2,\ldots M\}$ and we get from proposition 4 that $\{\mathbf{e}_{\alpha_j}|j=1,2,\ldots M\}$ is also a basis for E_+. Therefore there exists a real nonsingular matrix C_{ij} such that

$$\mathbf{f}_j=\sum_{k=1}^{M} C_{kj}\mathbf{e}_{\alpha_k}. \tag{7.20}$$

Expand Ω_+ and Λ_+ in the basis $\{\mathbf{e}_{\alpha_j}|j=1,2,\ldots M\}$ as follows:

$$\Omega_+=\sum_{j=1}^{M} w_{j,0}\mathbf{e}_{\alpha_j} \quad \text{and} \quad \Lambda_+(r)=\sum_{j=1}^{M} w_j(r)\mathbf{e}_{\alpha_j}. \tag{7.21}$$

Then results (7.2), (7.19)–(7.21) imply that

$$w_i(r)=w_{i,0}+\sum_{j=1}^{M} C_{ij}\hat{u}_j(r)r^{k_j+1} \quad i=1,2,\ldots M,$$

while from (7.16) and (7.19) it is clear that

$$\hat{u}_j(r,Y)=\beta_j(Y)+O(r) \quad j=1,2\ldots,M,$$

where $\beta_j(Y)=\langle\langle\mathbf{f}_j|Y\rangle\rangle$. □

Proof of theorem 5: The proof of this theorem involves finding a change of variables to put the system of differential equations (3.3) and (3.5) into a form where theorem 3 applies in a neighborhood of $z=0$ where $z=1/r$. This proof is similar to the proof of theorem 4 with the exception that theorem 10 is needed instead of theorem 9.

Since Λ_+ satisfies (7.1), we can introduce new variables $\{u_s(z)|s\in\mathcal{E}\}$ that satisfy

$$\Lambda_+(z)=\Omega_++\sum_{s\in\mathcal{E}} u_s(z)z^s, \tag{7.22}$$

where $\Omega_+=\Lambda_+|_{z=0}$ and $u_s(z)\in\tilde{E_+^s}$ for all z and $s\in\mathcal{E}$. Because $E_+=\oplus_{q=1}^{I}E_+^q$, it is obvious that this transformation is invertible. Define

$$\chi_s=\begin{cases}1 & \text{if } s\in\mathcal{E}\\ 0 & \text{otherwise}\end{cases}.$$

Then we can write $\Lambda_+(z)=\Omega_++\Sigma_{k=0}^{\infty}\chi_k u_k(z)z^k$. Substituting this in (3.8) shows that there exists an integer N_1 such that

$$\mathcal{F}=-\sum_{k\in\mathcal{E}} A_2(u_k)z^k+\sum_{k=1}^{N_1} f_k z^k,$$

where

$$f_k=\frac{1}{2}\sum_{j=1}^{k-1}\Big\{[[\Omega_+,c(\chi_j u_j)]+[\Omega_-,\chi_j u_j],\chi_{k-j}u_{k-j}]+[[\chi_j u_j,c(\chi_{k-j}u_{k-j})],\Omega_+]$$
$$+\sum_{s=1}^{j-1}[[\chi_s u_s,c(\chi_{j-s}u_{j-s})],\chi_{k-j}u_{k-j}]\Big\}.$$

But $A_2(u_k)=k(k+1)u_k$ for every $k\in\mathcal{E}$ by lemma 2 and hence

$$\mathcal{F}=-\sum_{k\in\mathcal{E}}k(k+1)u_k z^k+\sum_{k=1}^{N_1}f_k z^k. \tag{7.23}$$

Define

$$v_s=\mathring{u}_s \quad \forall s\in\mathcal{E}. \tag{7.24}$$

where $\mathring{(\cdot)}=d/dz(\cdot)$. Using (7.22)–(7.24), the EYM equation (3.5) can be written as

$$\sum_{k\in\mathcal{E}}\mathring{v}_k z^{k+1}=\sum_{k\in\mathcal{E}}-2(k+1)v_k z^k+\sum_{k\in\mathcal{E}}\Big\{\frac{2}{z}\Big(1-\frac{1}{N}\Big)v_k+\frac{1}{z^2}\Big(\frac{1}{N}-1-2mz\Big)k(k-1)u_k$$
$$+\frac{4m}{z}\Big(\frac{1}{N}-1\Big)ku_k+\frac{2}{N}(2m-z^2P)v_k-\frac{zP}{N}ku_k\Big\}z^{k+1}$$
$$+\sum_{k\in\mathcal{E}}2mk(k+1)u_k z^k-\frac{1}{N}\sum_{k=1}^{N_1}f_k z^{k-1}. \tag{7.25}$$

Applying the projections $\mathrm{pr}_+^{\tilde{k}}$ for every $k\in\mathcal{E}$ to Eq. (7.25) yields

$$z\mathring{v}_k=-2(k+1)v_k+z\Big\{\frac{2}{z}\Big(1-\frac{1}{N}\Big)v_k+\frac{1}{z^2}\Big(\frac{1}{N}-1-2mz\Big)k(k-1)u_k$$
$$+\frac{4m}{z}\Big(\frac{1}{N}-1\Big)ku_k+\frac{2}{N}(2m-z^2P)v_k-\frac{zP}{N}ku_k\Big\}$$
$$+2mk(k+1)u_k-\frac{1}{z^kN}\sum_{s=0}^{N_1-1}\mathrm{pr}_+^{\tilde{k}}(f_{s+1})z^s \quad \forall k\in\mathcal{E}. \tag{7.26}$$

The last term in (7.26) is the main obstruction to putting this equation into a form where theorem 3 applies. It seems to contain terms of order $z^{-s}(s>0)$. But this is not the case as the results of Sec. VI can be used to show that

$$\frac{1}{z^kN}\sum_{s=0}^{N_1-1}\mathrm{pr}_+^{\tilde{k}}(f_{s+1})z^s=\frac{1}{N}\sum_{s=k}^{N_1-1}\mathrm{pr}_+^{\tilde{k}}(f_{s+1})z^{s-k}.$$

Namely, using proposition 4, it can be shown that $f_k\in E_+$ for all k. From the definition of the u_s it is obvious that $\chi_s u_s\in\oplus_{q=1}^{\tilde{s}}E_+^q$ for $1\leqslant s\leqslant \mathsf{k}_I$, and therefore, by letting $Z_0=\Omega_+$ and $Z_k=\chi_k u_k$ for $k\geqslant 1$ we get $f_{s+1}\in\oplus_{q=1}^{\tilde{s}}E_+^q$ via theorem 10. Consequently, for every $k\in\mathcal{E}$

$$\mathrm{pr}_+^{\tilde{k}}(f_{s+1})=0 \quad \text{if } s<k,$$

because $k\in\mathcal{E}$ implies that $k=\mathsf{k}_{\tilde{k}}$ and hence it follows for $s<k=\mathsf{k}_{\tilde{k}}$ that $\tilde{s}<\tilde{k}$. Therefore we can rewrite (7.26) as

$$z\mathring{v}_k=-2(k+1)v_k+z\Bigg\{\frac{2}{z}\left(1-\frac{1}{N}\right)v_k+\frac{1}{z^2}\left(\frac{1}{N}-1-3mz\right)k(k-1)u_k$$
$$+\frac{4m}{z}\left(\frac{1}{N}-1\right)ku_k+\frac{2}{N}(2m-z^2P)v_k-\frac{zP}{N}ku_k-\frac{z}{N}\sum_{s=k+1}^{N_1-1}\mathrm{pr}_+^{\tilde{k}}(f_{s+1})z^{s-k-1}$$
$$+\left(1-\frac{1}{N}\right)\mathrm{pr}_+^{\tilde{k}}(f_{k+1})\Bigg\}+2mk(k+1)u_k-\mathrm{pr}_+^{\tilde{k}}(f_{k+1})\quad\forall k\in\mathcal{E}. \tag{7.27}$$

It is clear that there exists analytic functions

$$\hat{P}:E_+\times\mathbb{R}\to\mathbb{R}\ \text{ and }\ \hat{G}:E_+\times E_+\times\mathbb{R}\to\mathbb{R},$$

such that

$$P=\hat{P}(u,z)\ \text{ and }\ G=z^4\hat{G}(u,v,z),$$

where $u=\Sigma_{s\in\mathcal{E}}u_s$ and $v=\Sigma_{s\in\mathcal{E}}v_s$. The EYM equation (3.3) can then be written as

$$z\mathring{m}=z[(2mz-1)z^2\hat{G}(u,v,z)-P(u,z)]. \tag{7.28}$$

Introduce one last change of variables via

$$\hat{v}_k=v_k+\frac{1}{2(k+1)}\mathrm{pr}_+^{\tilde{k}}(f_{k+1})-kmu_k. \tag{7.29}$$

Fix $a>0$ and define $\hat{v}=\Sigma_{s\in\mathcal{E}}\hat{v}_s$. Then using (7.27), and (7.29), it can be shown that there exists and $\epsilon>0$, and a sequence of analytic maps

$$\mathcal{G}_k:E_+\times E_+\times I_\epsilon(a)\times I_\epsilon(0)\to E_0^{\tilde{k}}\quad\forall k\in\mathcal{E},$$

such that

$$z\mathring{\hat{v}}_k=-2(k+1)\hat{v}_k+z\mathcal{G}_k(u,\hat{v},m,z)\quad\forall k\in\mathcal{E}. \tag{7.30}$$

Also from (7.24), (7.28), and (7.29), it is not hard to show that there exists analytic maps

$$\mathcal{H}_k:E_+\times E_+\times\mathbb{R}\to E_+^{\tilde{k}}\quad\forall k\in\mathcal{E}$$
$$\text{and}\quad\mathcal{K}:E_+\times E_+\times\mathbb{R}\times\mathbb{R}\to\mathbb{R}, \tag{7.31}$$

such that

$$z\mathring{u}_k=z\mathcal{H}_k(u,\hat{v},m)\quad\forall k\in\mathcal{E}, \tag{7.32}$$

$$z\mathring{m}=z\mathcal{K}(u,\hat{v},m,z). \tag{7.33}$$

The system of differential equations (7.30), (7.32), and (7.33) are in the form for which theorem 3 applies. Applying this theorem shows that for fixed $(X,a)\in E_+\times(0,\infty)$ there exist a unique solution $\{u_k(z,Y,m_\infty),\hat{v}_k(z,Y,m_\infty),m(z,Y,m_\infty)\}$ to this system of differential equations that is analytic in a neighborhood of $(z,Y,m_\infty)=(0,X,a)$ and satisfies

$$u_s(z,Y,m_\infty)=Y_s+O(z) \quad \forall s\in\mathcal{E},$$

$$\hat{v}_s(z,Y,m_\infty)=O(z) \quad \forall s\in\mathcal{E}, \tag{7.34}$$

$$m(z,Y,m_\infty)=m_\infty+O(z),$$

where $Y_s=\mathrm{pr}_+^{\tilde{s}}(Y)$. Let $\{\mathbf{f}_j|j=1,2,\ldots M\}$ and $\{\mathbf{e}_{\alpha_j}|j=1,2,\ldots M\}$ be the same basis for E_+ as introduced in the proof of theorem 4. Then we can introduce new variables $\{\hat{u}_j(z)|j=1,2,\ldots M\}$ via

$$\sum_{s\in\mathcal{E}} u_s(z)z^s=\sum_{j=1}^{M}\hat{u}_j(z)z^{k_j}\mathbf{f}_j. \tag{7.35}$$

Expand Ω_+ and Λ_+ in the basis $\{\mathbf{e}_{\alpha_j}|j=1,2,\ldots M\}$ as follows:

$$\Omega_+=\sum_{j=1}^{M} w_{j,\infty}\mathbf{e}_{\alpha_j} \quad \text{and} \quad \Lambda_+(z)=\sum_{j=1}^{M} w_j(z)\mathbf{e}_{\alpha_j}. \tag{7.36}$$

Results (7.22), (7.35), (7.20), and (7.36) then imply that

$$w_i(z)=w_{i,\infty}+\sum_{j=1}^{M} C_{ij}\hat{u}_j(z)z^{k_j} \quad i=1,2,\ldots M,$$

while from (7.34) and (7.35) it is clear that

$$\hat{u}_j(z,Y,m_\infty)=\alpha_j(Y)+O(z) \quad j=1,2\ldots,M,$$

where $\alpha_j(Y)=\langle\langle\mathbf{f}_j|Y\rangle\rangle$. □

Proof of theorem 6: The proof of this theorem involves finding a change of variables to put the system of differential equations (3.3) and (3.5) into a form where theorem 3 applies in a neighborhood of $r=r_H$.

Note that although we use the space E_+ which was defined in Sec. VI, this proof does not depend on the results of Sec. VI. Indeed, E_+ can be replaced by $\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha$ everywhere in the proof below and one does not have to know that $E_+=\Sigma_{\alpha\in S_\lambda}\mathbb{R}\mathbf{e}_\alpha$, which is the content of proposition 4. The notation E_+ is used for convenience.

Introduce new variables t, μ, and υ via

$$t=r-r_H, \quad N=t(\mu+\nu), \quad \upsilon=(\mu+\nu)\Lambda_+'. \tag{7.37}$$

where ν is a constant. Then

$$t\frac{d\Lambda_+}{dt}=t\left(\frac{\upsilon}{\mu+\nu}\right), \tag{7.38}$$

and it is clear that there exists analytic maps

$$\hat{\mathcal{F}}:E_+\to E_+ \quad \text{and} \quad \hat{P}:E_+\to\mathbb{R},$$

such that

$$\hat{\mathcal{F}}(\Lambda_+)=\mathcal{F} \quad \text{and} \quad \hat{P}(\Lambda_+)=P.$$

Assume $|\nu|>0$. Define a analytic map

$$\hat{G}: E_+ \times I_{|\nu|}(0) \to \mathbb{R},$$

by

$$\hat{G}(X,a) = \frac{1}{2(a+\nu)^2}\|X\|^2.$$

Then

$$G = \hat{G}(v,\mu).$$

Using these new variables, we can write the EYM equations (3.3) and (3.5) as

$$t\frac{d\mu}{dt} = -(\mu+\nu) + \frac{1}{r_H} - \frac{2}{r_H^3}\hat{P}(\Lambda_+) + t\left[\frac{1}{t}\left(\frac{1}{t+r_H} - \frac{1}{r_H}\right) - \frac{2}{t}\left(\frac{1}{(t+r_H)^3} - \frac{1}{r_H^3}\right)\hat{P}(\Lambda_+) + \left(\frac{\mu+\nu}{t+r_H}\right)(1+2\hat{G}(v,\mu))\right] \tag{7.39}$$

and

$$t\frac{dv}{dt} = -v - \frac{1}{(t+r_H)^2}\hat{\mathcal{F}}(\Lambda_+) - t\left(\frac{2\hat{G}(v,\mu)}{t+r_H}\right)v, \tag{7.40}$$

respectively. Introduce two new variables μ and $\hat{v}$ via

$$\hat{\mu} = \mu + \nu - \frac{1}{r_H} + \frac{2}{r_H^3}\hat{P}(\Lambda_+), \tag{7.41}$$

$$\hat{v} = v + \frac{1}{r_H^2}\hat{\mathcal{F}}(\Lambda_+). \tag{7.42}$$

Define an analytic map

$$\gamma: E_+ \times \mathbb{R} \to \mathbb{R},$$

by

$$\gamma(X,a) = a - \nu + \frac{1}{r_H} - \frac{2}{r_H^3}\hat{P}(X).$$

Fix a vector $Z \in E_+$ that satisfies $\| 1/r_H - 2/r_H^3\hat{P}(Z)\| > 0$. Then if we set

$$\nu = \frac{1}{r_H} - \frac{2}{r_H^3}\hat{P}(Z),$$

we get $\gamma(Y,0) = 0$. So we can define an open neighborhood D of $(Z,0) \in E_+ \times \mathbb{R}$ by

$$D = \{(X,a) | \| \gamma(X,a)\| < \|\nu\|\}.$$

Then from (7.38)–(7.42), it is not hard to show that there exists an $\epsilon > 0$ and analytic maps

$$\mathcal{G}: E_+ \times D \to \mathbb{R},$$

$$\mathcal{H}: E_+ \times D \times I_\epsilon(0) \to \mathbb{R},$$

$$\mathcal{K}: E_+ \times D \times I_\epsilon(0) \to \mathbb{R},$$

such that

$$t\frac{d\Lambda_+}{dt} = t\mathcal{G}(\hat{v}, \Lambda_+, \hat{\mu}), \tag{7.43}$$

$$t\frac{d\hat{v}}{dt} = -\hat{v} + t\mathcal{H}(\hat{v}, \Lambda_+, \hat{\mu}, t), \tag{7.44}$$

$$t\frac{d\hat{\mu}}{dt} = -\hat{\mu} + t\mathcal{K}(\hat{v}, \Lambda_+, \hat{\mu}, t\ddot{u}. \tag{7.45}$$

The system of differential equations (7.43)–(7.45) is in the form for which theorem 3 applies. Applying this theorem shows that exists a unique solution $\{\Lambda_+(t,Y), \hat{v}(t,Y), \hat{\mu}(t,Y)\}$ to this system of differential equations that is analytic in a neighborhood of $(t,Y) = (0,Z)$ and that satisfies

$$\Lambda_+(t,Y) = Z + O(t), \tag{7.46}$$

$$\hat{v}(t,Y) = O(t),$$

$$\hat{\mu}(t,Y) = O(t). \tag{7.47}$$

Expand Z and Λ_+ in the basis $\{\mathbf{e}_\alpha | \alpha \in S_\lambda\}$ as follows:

$$Z = \sum_{\alpha \in S_\lambda} w_{\alpha, r_H} \mathbf{e}_\alpha \quad \text{and} \quad \Lambda_+(t) = \sum_{\alpha \in S_\lambda} w_\alpha(t) \mathbf{e}_\alpha .$$

Then Eq. (7.46) shows that

$$w_\alpha(t,Z) = w_{\alpha, r_H} + O(t) \quad \forall \alpha \in S_\lambda .$$

It also not difficult to show that Eqs. (7.37), (7.41), and (7.47) imply that

$$N(t,Z) = \nu t + O(t^2).$$

From this it follows immediately that

$$N(r_H) = 0 \quad \text{and} \quad N'(r_H) = \nu.$$

(Received 13 August 2001; accepted for publication 28 January 2002)

The scattering theory of Lax and Phillips, originally developed for classical wave equations, has recently been extended to the description of the evolution of resonant states in the framework of quantum theory. The resulting evolution law of the unstable system is that of a semigroup, and the resonant state is a well-defined function in the Lax–Phillips Hilbert space. In this paper we apply this theory to a relativistically covariant quantum field theoretical form of the two (or more) channel relativistic quantum field theoretical form of the Lee model. We show that this theory provides a rigorous underlying basis for the Lee–Oehme–Yang–Wu construction. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1461426]

I. INTRODUCTION

The theory of Lax and Phillips (1967),[1] originally developed for the description of resonances in electromagnetic or acoustic scattering phenomena, has been used as a framework for the construction of a description of irreversible resonant phenomena in the quantum theory[2–5] (which we will refer to as the quantum Lax–Phillips theory). This leads to a time evolution of resonant states which is of semigroup type, i.e., essentially exponential decay. Semigroup evolution is necessarily a property of irreversible processes.[6] It appears experimentally that elementary particle decay, to a high degree of accuracy, follows a semigroup law, and hence such processes seem to be irreversible.

The theory of Weisskopf and Wigner,[7] which is based on the definition of the survival amplitude of the initial state ϕ (associated with the unstable system) as the scalar product of that state with the unitarily evolved state,

$$(\phi, e^{-iHt}\phi), \tag{1.1}$$

cannot have exact exponential behavior.[8] One can easily generalize this construction to the problem of more than one resonance.[9,10] If P is the projection operator into the subspace of initial states (N-dimensional for N resonances), the reduced evolution operator is given by

$$Pe^{-iHt}P. \tag{1.1$'$}$$

Since the Laplace transform of this operator has a cut and not just poles, this operator cannot be an element of an exact semigroup.[8]

Experiments on the decay of the neutral K-meson system[11] show clearly that the phenomenological description of Lee, Oehme, and Yang,[12] and Wu and Yang,[13] by means of a 2×2 effective Hamiltonian which corresponds to an exact semigroup evolution of the unstable system, provides a very accurate description of the data. It can be proved that the Wigner–Weisskopf theory cannot provide a semigroup evolution law[8] and, thus, the effective 2×2 Hamiltonian cannot emerge in the framework of this theory. Furthermore, it has been shown, using estimates based on the

a)Also at: Department of Physics, Bar Ilan University, Ramat Gan 52900, Israel; electronic mail: larry@ccsg.tau.ac.il

quantum mechanical Lee–Friedrichs model,[14] that the experimental results appear to rule out the application of the Wigner–Weisskopf theory to the decay of the neutral K-meson system. While the exponential decay law can be exhibited explicitly in terms of a Gel'fand triple[15] (rigged Hilbert space), the representation of the resonant state in this framework is in a space which does not coincide with the quantum mechanical Hilbert space, and does not have the properties of a Hilbert space, such as scalar products and the possibility of calculating physical properties associated with expectation values.

The seminal work of Lax and Phillips[1] has provided us with the basic ideas necessary for the construction of a fundamental theoretical description, in the framework of the quantum theory,[2–5] of a resonant system which has exact semigroup evolution, and represents the resonance as a *state in a Hilbert space*. In the following, we briefly describe the structure of this theory, a rather straightforward generalization of standard quantum scattering theory, and give some physical interpretation for the states of the Lax–Phillips Hilbert space.

The Lax–Phillips theory is defined in a Hilbert space $\overline{H}$ of states which contains two distinguished subspaces, $D_{\pm}$, called "outgoing" and "incoming." There is a unitary evolution law which we denote by $U(\tau)$, for which these subspaces are invariant in the following sense:

$$U(\tau)D_{+}\subset D_{+}, \quad \tau\geqslant 0,$$
$$U(\tau)D_{-}\subset D_{-}, \quad \tau\leqslant 0. \tag{1.2}$$

The translates of $D_{\pm}$ under $U(\tau)$ are dense, i.e.,

$$\overline{\bigcup_{\tau} U(\tau)D_{\pm}}=\overline{H} \tag{1.3}$$

and the asymptotic property

$$\bigcap_{\tau} U(\tau)D_{\pm}=\varnothing \tag{1.4}$$

is assumed. It follows from these properties that

$$Z(\tau)=P_{+}U(\tau)P_{-}, \tag{1.5}$$

where $P_{\pm}$ are projections into the subspaces orthogonal to $\mathcal{D}_{\pm}$, is a strongly contractive semigroup,[1] i.e.,

$$Z(\tau_1)Z(\tau_2)=Z(\tau_1+\tau_2) \tag{1.6}$$

for τ_1, τ_2 positive, and $\|Z(\tau)\|\to 0$ for $\tau\to 0$. It follows from (1.2) that $Z(\tau)$ takes the subspace $\mathcal{K}$, the orthogonal complement of $D_{\pm}$ in $\overline{H}$ (associated with the resonances in the Lax–Phillips theory), into itself,[1] i.e.,

$$Z(\tau)=P_{\mathcal{K}}U(\tau)P_{\mathcal{K}}. \tag{1.7}$$

The relation (1.7) is of the same structure as (1.1′); there is, as we shall see in the following, an essential difference in the way that the subspaces associated with resonances are defined. The argument that (1.1') cannot form a semigroup is not valid[3] for (1.7); the generator of $U(\tau)$ restricted to $\mathcal{K}$ is not self-adjoint.

A Hilbert space with the properties that there are distinguished subspaces satisfying, with a given law of evolution $U(\tau)$, the properties (1.2), (1.3), and (1.4) has a foliation[16] into a one-parameter (which we shall denote as s) family of isomorphic Hilbert spaces, which are called *auxiliary* Hilbert spaces, $\{H_s\}$, for which

$$\overline{H}=\int_{\oplus} H_s\,. \tag{1.8}$$

Representing these spaces in terms of square-integrable functions, we define the norm in the direct integral space as

$$\|f\|^2=\int_{-\infty}^{\infty} \mathrm{d}s\|f_s\|_H^2\,, \tag{1.9}$$

where $f\in\overline{H}$ represents a vector in the L^2 function space $\overline{H}=L^2(-\infty,\infty,H)$; f_s is an element of H, the L^2 function space (the *auxiliary space*) corresponding to H_s for any s (we shall not add in what follows a subscript to the norm or scalar product symbols for scalar products of elements of the auxiliary Hilbert space associated with a point s on the foliation axis since these spaces are all isomorphic).

There are representations for which the action of the full evolution group $U(\tau)$ on $L^2(-\infty,\infty;H)$ is translation by τ units. Given $D_{\pm}$ there is such a representation, called the *incoming representation*,[1] for which the set of all functions in D_- have support in $(-\infty,0)$ and constitute the subspace $L^2(-\infty,0;H)$ of $L^2(-\infty,\infty;H)$; there is another representation, called the *outgoing representation*, for which functions in D_+ have support in $(0,\infty)$ and constitute the subspace $L^2(0,\infty;H)$ of $L^2(-\infty,\infty;H)$. The fact that $Z(\tau)$ in Eq. (1.7) is a semigroup is a consequence of the definition of the subspaces $D_{\pm}$ in terms of support properties on intervals along the foliation axis in the *outgoing* and *incoming* translation representations, respectively. The non-self-adjoint character of the generator of the semigroup $Z(\tau)$ is a consequence of this structure.[3]

Lax and Phillips[1] show that there are unitary operators $W_{\pm}$, called wave operators, which map elements in $\overline{H}$ to these representations. They define an S matrix,

$$S=W_+W_-^{-1} \tag{1.10}$$

which connects the incoming to the outgoing representations; it is unitary, commutes with translations, and maps $L^2(-\infty,0;H)$ into itself. Since S commutes with translations, it is diagonal in Fourier (spectral) representation. As pointed out by Lax and Phillips,[1] according to a special case of a theorem of Fourès and Segal,[17] an operator with these properties can be represented as a multiplicative operator-valued function $S(\sigma)$ which maps H into itself, and satisfies the following conditions:

(a) $S(\sigma)$ *is the boundary value of an operator-valued function* $S(z)$ *analytic for* $\mathrm{Im}\,z>0$,
(b) $\|S(z)\|\leqslant 1$ *for all* z *with* $\mathrm{Im}\,z>0$,
(c) $S(\sigma)$ *is unitary for almost all real* σ.

An operator with these properties is known as an inner function;[18] such operators arise in the study of shift invariant subspaces, the essential mathematical content of the Lax–Phillips theory. The singularities of this S matrix, in what is called *spectral representation* (defined in terms of the Fourier transform on the foliation variable s), correspond to the spectrum of the generator of the semigroup characterizing the evolution of the unstable system.

In the framework of quantum theory, one may identify the Hilbert space H with a space of physical states, and the variable τ with the laboratory time (the semigroup evolution is observed in the laboratory according to this time). The representation of this space in terms of the foliated L^2 space $\overline{H}$ provides a natural probabilistic interpretation for the auxiliary spaces associated with each value of the foliation variable s, i.e., the quantity $\|f_s\|^2$ corresponds to the probability density for

the system to be found in the neighborhood of s. For example, consider an operator A defined on $\overline{H}$ which acts pointwise, i.e., contains no shift along the foliation. Such an operator can be represented as a direct integral

$$A=\int_{\oplus} A_s. \tag{1.11}$$

It produces a map of the auxiliary space H into H for each value of s, and thus, if it is self-adjoint, A_s may act as an observable in a quantum theory associated with the point s;[4] The expectation value of A_s in a state in this Hilbert space defined by the vector ψ_s, the component of $\psi\in\overline{H}$ in the auxiliary space at s, is

$$\langle A_s\rangle_s=\frac{(\psi_s,A_s\psi_s)}{\|\psi_s\|^2}. \tag{1.12}$$

Taking into account the *a priori* probability density $\|\psi_s\|^2$ that the system is found at this point on the foliation axis, we see that the expectation value of A in $\overline{H}$ is

$$\langle A\rangle=\int \mathrm{d}s\langle A_s\rangle_s\|\psi_s\|^2=\int \mathrm{d}s(\psi_s,A_s\psi_s), \tag{1.13}$$

the direct integral representation of $(\psi,A\psi)$.

As we have remarked previously, in the translation representations for $U(\tau)$ the foliation variable s is shifted (this shift, for sufficiently large $|\tau|$, induces the transition of the state into the subspaces $D_{\pm}$). It follows that s may be identified as an intrinsic time associated with the evolution of the state; since it is a variable of the measure space of the Hilbert space $\overline{H}$, this quantity itself has the meaning of a quantum variable.

We are presented here with the notion of a virtual history. To understand this idea, suppose that at a given time τ_0, the function which represents the state has some distribution $\|\psi_s^{\tau_0}\|^2$. This distribution provides an *a priori* probability that the system would be found at time s (greater or less than τ_0), if the experiment were to be performed at time s corresponding to $\tau=s$ on the laboratory clock. The state of the system therefore contains information on the structure of the *history* of the system as it is inferred at τ_0.

We shall assume the existence of a unitary evolution on the Hilbert space $\overline{H}$, and that for

$$U(\tau)=e^{-iK\tau}, \tag{1.14}$$

the generator K can be decomposed as

$$K=K_0+V \tag{1.15}$$

in terms of an unperturbed operator K_0 with spectrum $(-\infty,\infty)$ and a perturbation V, under which this spectrum is stable. We shall, furthermore, assume that wave operators exist, defined on some dense set, as

$$\Omega_{\pm}=\lim_{\tau\to\pm\infty} e^{iK\tau}e^{-iK_0\tau}. \tag{1.16}$$

In the soluble model that we shall treat as an example in this paper, the existence of the wave operators is assured.

With the help of the wave operators, we can define translation representations for $U(\tau)$. The translation representation for K_0 is defined by the property

$${}_0\langle s,\alpha|e^{-iK_0\tau}f)={}_0\langle s-\tau,\alpha|f), \tag{1.17}$$

where α corresponds to a label for the basis of the auxiliary space. Noting that

$$K\Omega_{\pm}=\Omega_{\pm}K_0 \tag{1.18}$$

we see that

$${}_{\text{in}}^{\text{out}}\langle s,\alpha|e^{-iK\tau}f\rangle={}_{\text{in}}^{\text{out}}\langle s-\tau,\alpha|f\rangle, \tag{1.19}$$

where

$${}_{\text{in}}^{\text{out}}\langle s,\alpha|f\rangle={}_0\langle s,\alpha|\Omega_{\pm}^{\dagger}f\rangle. \tag{1.20}$$

It will be convenient to work in terms of the Fourier transform of the in and out translation representations; we shall call these the in and out spectral representations, i.e.,

$${}_{\text{in}}^{\text{out}}\langle\sigma,\alpha|f\rangle=\int_{-\infty}^{\infty}e^{-i\sigma s}{}_{\text{in}}^{\text{out}}\langle s,\alpha|f\rangle. \tag{1.21}$$

In these representations, (1.20) is

$${}_{\text{in}}^{\text{out}}\langle\sigma,\alpha|f\rangle={}_0\langle\sigma,\alpha|\Omega_{\pm}^{\dagger}f\rangle \tag{1.22}$$

and (1.19) becomes

$${}_{\text{in}}^{\text{out}}\langle\sigma,\alpha|e^{-iK\tau}|f\rangle=e^{-i\sigma\tau}{}_{\text{in}}^{\text{out}}\langle\sigma,\alpha|f\rangle. \tag{1.23}$$

Equation (1.17) becomes, under Fourier transform,

$${}_0\langle\sigma,\alpha|e^{-iK_0\tau}f\rangle=e^{-i\sigma\tau}{}_0\langle\sigma,\alpha|f\rangle. \tag{1.24}$$

For f in the domain of K_0, (1.24) implies that

$${}_0\langle\sigma,\alpha|K_0f\rangle=\sigma\,{}_0\langle\sigma,\alpha|f\rangle. \tag{1.25}$$

With the solution of (1.25), and the wave operators, the in and out spectral representations of a vector f can be constructed from (1.24).

We are now in a position to construct the subspaces $D_{\pm}$, which are not given *a priori* (as they are in the classical theory[1]) in the Lax–Phillips quantum theory. We shall define D_+ as the set of functions with support in $(0,\infty)$ in the *outgoing* translation representation. Similarly, we shall define D_- as the set of functions with support in $(-\infty,0)$ in the *incoming* translation representation. The corresponding elements of $\overline{H}$ constitute the subspaces $D_{\pm}$. By construction, $D_{\pm}$ have the required invariance properties under the action of $U(\tau)$.

The *outgoing spectral representation* of a vector $g\in\mathcal{H}$ is

$$\begin{aligned}{}_{\text{out}}\langle\sigma\alpha|g\rangle={}_0\langle\sigma\alpha|\Omega_+^{-1}g\rangle&=\int\mathrm{d}\sigma'\sum_{\alpha'}\,{}_0\langle\sigma\alpha|\mathbf{S}|\sigma'\alpha'\rangle_0\,{}_0\langle\sigma'\alpha'|\Omega_-^{-1}g\rangle\\&=\int\mathrm{d}\sigma'\sum_{\alpha'}\,{}_0\langle\sigma\alpha|\mathbf{S}|\sigma'\alpha'\rangle_0\,{}_{\text{in}}\langle\sigma'\alpha'|g\rangle,\end{aligned} \tag{1.26}$$

where we call

$$\mathbf{S}=\Omega_+^{-1}\Omega_- \tag{1.27}$$

the quantum Lax–Phillips S operator. We see that the kernel ${}_0\langle\sigma\alpha|\mathbf{S}|\sigma'\alpha'\rangle_0$ maps the incoming to outgoing spectral representations. Since $\mathbf{S}$ commutes with K_0, it follows that

$$ {}_0\langle\sigma\alpha|\mathbf{S}|\sigma'\alpha'\rangle_0 = \delta(\sigma-\sigma')S^{\alpha\alpha'}\cdot(\sigma). \tag{1.28}$$

It follows from (1.16) and (1.22), in the standard way,[19] that

$$ {}_0\langle\sigma\alpha|\mathbf{S}|\sigma'\alpha'\rangle_0 = \lim_{\epsilon\to 0}\delta(\sigma-\sigma')\{\delta^{\alpha\alpha'}-2\pi i\,{}_0\langle\sigma\alpha|\mathbf{T}(\sigma+i\epsilon)|\sigma'\alpha'\rangle_0\}, \tag{1.29}$$

where

$$ \mathbf{T}(z)=V+VG(z)V=V+VG_0(z)\mathbf{T}(z). \tag{1.30}$$

We remark that, by this construction, $S^{\alpha\alpha'}(\sigma)$ is *analytic in the upper half plane* in σ. The Lax–Phillips S matrix[1] is given by the inverse Fourier transform,

$$ S=\{{}_0\langle s\alpha|\mathbf{S}|s'\alpha'\rangle_0\}; \tag{1.31}$$

this operator clearly commutes with translations.

From (1.29) it follows that the inner function property (a) of $S(\sigma)$ above is true. Property (c), unitarity for real σ, is equivalent to asymptotic completeness, a property which is stronger than the existence of wave operators. For the relativistic Lee model, which we shall treat in this paper, this condition is satisfied. In the model that we shall study here, we shall see that there is a wide class of potentials V for which the operator $S(\sigma)$ satisfies the property (b).

In Sec. II, we briefly review the structure of the relativistic Lee model,[19] and explicitly construct the Lax–Phillips spectral representations and S matrix. Introducing auxiliary space variables, we then characterize the properties of the finite rank Lee model potential which assure that the S matrix is an inner function, i.e., that property (b) listed above is satisfied.

II. THE MULTICHANNEL RELATIVISTIC LEE–FRIEDRICHS MODEL

The multichannel relativistic Lee–Friedrichs model is defined in terms of bosonic quantum fields on space–time. These fields, which emerge from the second quantization of the Stueckelberg covariant quantum theory,[20] evolve with an invariant evolution parameter[5] τ (which we identify here with the evolution parameter of the Lax–Phillips theory discussed previously); at equal τ, they satisfy the commutation relations (with $\psi_i^\dagger$ as the canonical conjugate field to ψ_i; the fields ψ_i, which satisfy first-order evolution equations as for nonrelativistic Schrödinger fields, are just annihilation operators)

$$ [\psi_{i\tau}(x),\psi_{j\tau}^\dagger(x')]=\delta^4(x-x')\,\delta_{ij}. \tag{2.1}$$

Transforming to momentum space, in which we have

$$ \psi_{i\tau}(p)=\frac{1}{(2\pi)^2}\int d^4x\, e^{-ip_\mu x^\mu}\psi_{i\tau}(x), \tag{2.2}$$

relation (2.1) becomes

$$ [\psi_{i\tau}(p),\psi_{j\tau}^\dagger(p')]=\delta^4(p-p')\,\delta_{ij}. \tag{2.3}$$

The manifestly covariant space–time structure of these fields is admissible when $E,\mathbf{p}$ are not *a priori* constrained by a sharp mass–shell relation. In the mass–shell limit (for which the variation in m^2 defined by $E^2-\mathbf{p}^2$ is small), multiplying both sides of (2.3) by $\Delta E=\Delta m^2/2E$, one obtains the usual commutation relations for on shell fields,

$$[\tilde{\psi}_{i\tau}(\mathbf{p}),\tilde{\psi}^{\dagger}_{j\tau}(\mathbf{p})]=2E\,\delta^3(\mathbf{p}-\mathbf{p}')\,\delta_{ij}\,, \tag{2.4}$$

where $\tilde{\psi}_{i\tau}(\mathbf{p})=\sqrt{\Delta m^2}\psi_{i\tau}(\mathbf{p})$. In this limit, t and τ coincide. The generator of evolution

$$K=K_0+V \tag{2.5}$$

for which the Heisenberg picture fields are

$$\psi_{i\tau}(p)=e^{iK\tau}\psi_{i0}(p)e^{-iK\tau} \tag{2.6}$$

is given, in this model, as (we write $p^2=p_\mu p^\mu, k^2=k_\mu k^\mu$ in the following)

$$K_0=\sum_{i=1,2}\left\{\int \mathrm{d}^4p\,\frac{p^2}{2M_{V_i}}b_i^{\dagger}(p)b_i(p)+\int \mathrm{d}^4p\,\frac{p^2}{2M_{N_i}}a_{N_i}^{\dagger}(p)a_{N_i}(p)\right\}$$
$$+\sum_{i=1,2}\int \mathrm{d}^4p\,\frac{p^2}{2M_{\theta_i}}a_{\theta_i}^{\dagger}(p)a_{\theta_i}(p) \tag{2.7}$$

and

$$V=\sum_{i,j=1,2}\int \mathrm{d}^4p\int \mathrm{d}^4k(f_{ij}(k)b_i^{\dagger}(p)a_{N_j}(p-k)a_{\theta_j}(k)+f_{ij}^{*}(k)b_i(p)a_{N_j}^{\dagger}(p-k)a_{\theta_j}^{\dagger}(k)). \tag{2.8}$$

(We remark that Antoniou *et al.*[21] have constructed a relativistic Lee model of a somewhat different type; their field equation is second order in derivative with respect to the variable conjugate to the mass.) This model describes the process $V_i\rightarrow N_j+\theta_j$. We assume that the fields associated with different particles commute. The fields $b_i(p)$, $a_{N_i}(p)$ and a_{θ_i} are annihilation operators for the V_i, N_i, and θ_i particles, respectively. We take M_{V_i}, M_{N_i}, and M_{θ_i} to be the mass parameters for the fields.[19,22] We restrict our development to the two channel case in the following. The generalization to any number of channels is straightforward.

The following operators are conserved:

$$Q_1=\sum_{i=1,2}\int \mathrm{d}^4p(b_i^{\dagger}(p)b_i(p)+a_{N_i}^{\dagger}(p)a_{N_i}(p)),$$

$$Q_2=\int \mathrm{d}^4p\ \ (a_{N_1}^{\dagger}(p)a_{N_1}(p)-a_{\theta_1}^{\dagger}(p)a_{\theta_1}(p)), \tag{2.9}$$

$$Q_3=\int \mathrm{d}^4p(a_{N_2}^{\dagger}(p)a_{N_2}(p)-a_{\theta_2}^{\dagger}(p)a_{\theta_2}(p)).$$

This fact enables us to decompose the Fock space to sectors. We study the sector with $Q_1=1, Q_2=0, Q_3=0$. This is identified as a sector containing either one V_i particle *or* one N_j together with one θ_j particle. It follows from the commutativity of the fields that the states $|V_1\rangle, |V_2\rangle$, as well as $|N_1\theta_1\rangle, |N_2,\theta_2\rangle$, which exist in this sector, are orthogonal. In this sector the generator of evolution K can be rewritten in the form

$$K=\int \mathrm{d}^4pK^p=\int \mathrm{d}^4p(K_0^p+V^p),$$

where

$$K_0^p=\sum_{i=1,2}\left\{\frac{p^2}{2M_{V_i}}b_i^\dagger(p)b_i(p)+\int \mathrm{d}^4k\left(\frac{(p-k)^2}{2M_{N_i}}+\frac{k^2}{2M_{\theta_i}}\right)a_{N_i}^\dagger(p-k)a_{\theta_i}^\dagger(k)a_{\theta_i}(k)a_{N_i}(p-k)\right\}$$

and

$$V^p=\sum_{i,j=1,2}^{n}\int \mathrm{d}^4k(f_{ij}(k)b_i^\dagger(p)a_{N_j}(p-k)a_{\theta_j}(k)+f_{ij}^*(k)b_i(p)a_{N_j}^\dagger(p-k)a_{\theta_j}^\dagger(k)).$$

In this form it is clear that both K and K_0 have a direct integral structure. This implies a similar structure for the wave operator $\Omega_\pm$ and the possibility of defining restricted wave operators $\Omega_\pm^p$ for each value of p. We see from the expression for K_0^p that $|V_i(p)\rangle=b_i^\dagger(p)|0\rangle$ can be regarded as a set of discrete eigenstates of K_0^p (for each p) which span a subspace which is, therefore, annihilated by the restricted wave operators $\Omega_\pm^p$. This implies immediately that $\Omega_\pm|V(p)\rangle=0$ for every p (an explicit demonstration of this fact is given in Appendix A).

In order to construct the Lax–Phillips incoming and outgoing spectral representations for the model presented here it is necessary, according to the discussion following Eq. (1.25), to obtain appropriate expressions for the wave operators $\Omega_\pm^\dagger$ and the spectral representation for the generator K_0 of free evolution, i.e, the solution of Eq. (1.25).

We begin our discussion with a derivation of the appropriate expressions, for the model considered here, of the wave operators $\Omega_\pm$. We first calculate the following matrix elements of Ω_+:

$$\langle V_m(q)|\Omega_+|N_n(p),\theta_n(k)\rangle,\quad \langle N_m(p'),\theta_m(k')|\Omega_+|N_n(p),\theta_n(k)\rangle.$$

Equation (1.16) can be rewritten, following the standard procedure,[23] in the integral form

$$\Omega_+=1+i\lim_{\epsilon\to 0}\int_0^{+\infty}U^\dagger(\tau)VU_0(\tau)e^{-\epsilon\tau}\mathrm{d}\tau, \tag{2.10}$$

where $U(\tau)=e^{-iK\tau}$, $U_0(\tau)=e^{-iK_0\tau}$. Using (2.7), we have

$$\begin{aligned}\Omega_+&|N_n(p_1),\theta_n(p_2)\rangle\\ &=|N_n(p_1),\theta_n(p_2)\rangle+i\lim_{\epsilon\to 0}\int_0^{+\infty}\mathrm{d}\tau\, e^{-\epsilon\tau}U^\dagger(\tau)VU_0(\tau)a_{N_n}^\dagger(p)a_{\theta_n}^\dagger(k)|0\rangle\\ &=|N_n(p_1),\theta_n(p_2)\rangle+i\lim_{\epsilon\to 0}\int_0^{+\infty}\mathrm{d}\tau\, e^{-i(\omega_{N_n}(p_1)+\omega_{\theta_n}(p_2)-i\epsilon)\tau}U^\dagger(\tau)Va_{N_n}^\dagger(p)a_{\theta_n}^\dagger(k)|0\rangle,\end{aligned} \tag{2.11}$$

where $\omega_{N_n}(p)=p^2/2M_{N_n}$, $\omega_{\theta_n}(p)=p^2/2M_{\theta_n}$. Using (2.8) we find

$$Va_{N_n}^\dagger(p_1)a_{\theta_n}^\dagger(p_2)|0\rangle=\sum_{k=1,2}f_{kn}(p_2)b_k^\dagger(p_1+p_2)|0\rangle. \tag{2.12}$$

Inserting (2.12) into (2.11) and changing the integration variable from τ to $-\tau$ it follows that

$$\begin{aligned}\Omega_+&|N_n(p_1),\theta_n(p_2)\rangle\\ &=|N_n(p_1),\theta_n(p_2)\rangle-i\lim_{\epsilon\to 0}\sum_{k=1,2}\int_0^{-\infty}\mathrm{d}\tau\, e^{i(\omega_{N_n}(p_1)+\omega_{\theta_n}(p_2)-i\epsilon)\tau}U(\tau)f_{kn}(p_2)b_k^\dagger(p_1+p_2)|0\rangle.\end{aligned} \tag{2.13}$$

In order to continue with the evaluation of the integral in (2.13) we find the time evolution of some arbitray state χ under the action of $U(\tau)$,

$$\psi(\tau)=U(\tau)\chi=e^{-iK\tau}\chi. \tag{2.14}$$

In the sector of the Fock space that we are considering, the state $\psi(\tau)$ at any time τ can be expanded as

$$\psi(\tau)=\sum_{i=1,2}\int \mathrm{d}^4q A_i(q,\tau)b_i^\dagger(q)|0\rangle+\sum_{i=1,2}\int \mathrm{d}^4p\int \mathrm{d}^4k B_i(p,k,\tau)a_{N_i}^\dagger(p)a_{\theta_i}^\dagger(k)|0\rangle. \tag{2.15}$$

In particular, we see that the initial conditions for the evolution in (2.13), where the state χ is taken to be $\psi_0=\Sigma_k f_{kn}(p_2)b_k^\dagger(p_1+p_2)|0\rangle$, are

$$A_i(q,0)=f_{in}(p_2)\,\delta^4(q-p_1-p_2),\quad B_i(p,k,0)=0. \tag{2.16}$$

The equations of evolution for the coefficients $A(q,\tau)$ and $B(p,k,\tau)$ are then obtained from (2.14) and (2.15), i.e.,

$$\begin{aligned} i\frac{\partial B_i(p-k,k,\tau)}{\partial\tau}&=B_i(p-k,k,\tau)\left(\frac{(p-k)^2}{2M_{N_i}}+\frac{k^2}{2M_{\theta_i}}\right)+\sum_{j=1,2}f_{ji}^*(k)A_j(p,\tau),\\ i\frac{\partial A_i(p,\tau)}{\partial\tau}&=\frac{p^2}{2M_{V_i}}A_i(p,\tau)+\sum_{j=1,2}\int \mathrm{d}^4k f_{ij}(k)B_j(p-k,k,\tau). \end{aligned} \tag{2.17}$$

These equations can be solved algebraically[10,19] by performing Laplace transforms and defining

$$\begin{aligned} \tilde{B}_i(p,k,z)&=\int_{-\infty}^0 \mathrm{d}\tau\, e^{iz\tau}B_i(p,k,\tau),\quad \mathrm{Im}\,z<0,\\ \tilde{A}_i(p,z)&=\int_{-\infty}^0 \mathrm{d}\tau\, e^{iz\tau}A_i(p,\tau),\quad \mathrm{Im}\,z<0. \end{aligned} \tag{2.18}$$

Equation (2.17) is transformed into

$$\begin{aligned} \tilde{B}_i(p-k,k,z)\left(z-\frac{(p-k)^2}{2M_{N_i}}-\frac{k^2}{2M_{\theta_i}}\right)&=iB_i(p-k,k,0)+\sum_{j=1,2}f_{ji}^*(k)\tilde{A}_j(p,z),\\ \tilde{A}_i(p,z)\left(z-\frac{p^2}{2M_{V_i}}\right)&=iA_i(p,0)+\sum_{j=1,2}\int \mathrm{d}^4k f_{ij}(k)\tilde{B}_j(p-k,k,z). \end{aligned} \tag{2.19}$$

Using the initial conditions (2.16) we obtain the following expressions for the Laplace transformed coefficients:

$$\begin{aligned} \tilde{A}_k(p,z)&=i\sum_{i=1}^n W_{ki}^{-1}(z,p)A_i(p,0),\\ \tilde{B}_j(p-k,k,z)&=i\left(\frac{z-(p-k)^2}{2M_{N_j}}-\frac{k^2}{2M_{\theta_j}}\right)^{-1}\left[\sum_{k,i=1,2}^n f_{kj}^*(k)W_{ki}^{-1}(z,p)A_i(p,0)\right], \end{aligned} \tag{2.20}$$

where

$$W_{ik}(z,p)=\delta_{ik}\left(z-\frac{p^2}{2M_{V_i}}\right)-\sum_{j=1,2}^{n}\int \mathrm{d}^4k\,\frac{f_{ij}(k)f_{kj}^*(k)}{z-\frac{(p-k)^2}{2M_{N_j}}-\frac{k^2}{2M_{\theta_j}}}. \tag{2.21}$$

The Laplace transform of $\psi(\tau)$ is then

$$\begin{aligned}\psi(z)=&i\sum_{i,k=1,2}\int \mathrm{d}^4q\,W_{ik}^{-1}(z,q)A_k(q,0)b_i^\dagger(q)|0\rangle\\&+i\sum_{i,j,k=1,2}\int \mathrm{d}^4p\int \mathrm{d}^4k\,\frac{f_{ki}^*(k)W_{kj}^{-1}(z,p+k)A_j(p+k,0)}{\left(z-\frac{p^2}{2M_{N_i}}-\frac{k^2}{2M_{\theta_i}}\right)}a_{N_i}^\dagger(p)a_{\theta_i}^\dagger(k)|0\rangle.\end{aligned} \tag{2.22}$$

From (2.13), (2.22) and the initial conditions—Eq. (2.16)—we get

$$\begin{aligned}&\Omega_+|N_n(p_1),\theta_n(p_2)\rangle\\&\quad=|N_n(p_1),\theta_n(p_2)\rangle+i\sum_{i,k=1,2}W_{ik}^{-1}(\omega_n-i\epsilon,p_1+p_2)f_{kn}(p_2)b_i^\dagger(p_1+p_2)|0\rangle\\&\qquad+i\sum_{i,j,k=1,2}\int \mathrm{d}^4k\,\frac{f_{ki}^*(k)W_{kj}^{-1}(\omega_n-i\epsilon,p_1+p_2)f_{jn}(p_2)}{\omega_n-i\epsilon-\frac{(p_1+p_2-k)^2}{2M_{N_i}}-\frac{k^2}{2M_{\theta_i}}}a_{N_i}^\dagger(p_1+p_2-k)a_{\theta_i}^\dagger(k)|0\rangle,\end{aligned} \tag{2.23}$$

where we denote $\omega_n\equiv\omega_{N_n}(p_1)+\omega_{\theta_n}(p_2)$. We can now evaluate the desired matrix elements of the wave operator Ω_+. From (2.23) one fimds

$$\langle V_m(p)|\Omega_+|N_n(p_1),\theta_n(p_2)\rangle=\sum_{k=1,2}W_{mk}^{-1}(\omega_n-i\epsilon,p_1+p_2)f_{kn}(p_2)\,\delta^4(p-p_1-p_2) \tag{2.24}$$

and

$$\begin{aligned}&\langle N_m(\tilde{p}_1),\theta_m(\tilde{p}_2)|\Omega_+|N_n(p_1),\theta_n(p_2)\rangle\\&\quad=\delta_{mn}\delta^4(\tilde{p}_1-p_1)\,\delta^4(\tilde{p}_2-p_2)\\&\qquad+\sum_{k,j=1,2}\frac{f_{km}^*(\tilde{p}_2)W_{kj}^{-1}(\omega_n-i\epsilon,p_1+p_2)f_{jn}(p_2)}{\omega_n-i\epsilon-\frac{\tilde{p}_1^2}{2M_{N_m}}-\frac{\tilde{p}_2^2}{2M_{\theta_m}}}\,\delta^4(p_1+p_2-\tilde{p}_1-\tilde{p}_2).\end{aligned} \tag{2.25}$$

In a similar fashion one can find the corresponding matrix elements of the wave operator Ω_-:

$$\langle V_m(p)|\Omega_-|N_n(p_1),\theta_n(p_2)\rangle=\sum_{k=1,2}W_{mk}^{-1}(\omega_n+i\epsilon,p_1+p_2)f_{kn}(p_2)\,\delta^4(p-p_1-p_2) \tag{2.26}$$

and

$$\langle N_m(\tilde{p}_1),\theta_m(\tilde{p}_2)|\Omega_-|N_n(p_1),\theta_n(p_2)\rangle$$
$$=\delta_{mn}\delta^4(\tilde{p}_1-p_1)\,\delta^4(\tilde{p}_2-p_2)$$
$$+\sum_{k,j=1,2}\frac{f^*_{km}(\tilde{p}_2)W^{-1}_{kj}(\omega_n+i\epsilon,p_1+p_2)f_{jn}(p_2)}{\omega_n+i\epsilon-\dfrac{\tilde{p}_1^2}{2M_{N_m}}-\dfrac{\tilde{p}_2^2}{2M_{\theta_m}}}\,\delta^4(p_1+p_2-\tilde{p}_1-\tilde{p}_2). \quad (2.27)$$

According to Eqs. (1.22) and (1.25) the complete transformation to the *incoming* or *outgoing* representations requires us to solve for the (improper) eigenvectors with spectrum $\{\sigma\}$ on $(-\infty, +\infty)$ of K_0. The complete set of these states is decomposed into two subsets corresponding to the quantum numbers for states containing N and θ particles and states containing a V particle. These quantum numbers are denoted σ, α (for the $N+\theta$ states)and σ, β (V states), respectively. For the projections into these two subspaces, we have

$$|\sigma,\alpha\rangle_0=\sum_{n=1,2}\int \mathrm{d}^4p\int \mathrm{d}^4k|N_l(p),\theta_l(k)\rangle\langle N_l(p),\theta_l(k)|\sigma,\alpha\rangle_0,$$
$$|\sigma,\beta\rangle_0=\sum_{m=1}\int \mathrm{d}^4p|V_m(p)\rangle\langle V_m(p)|\sigma,\beta\rangle_0. \quad (2.28)$$

It is convenient to define

$$O^{\sigma,\alpha}_{n,p,k}\equiv\langle N_n(p),\Theta_n(k)|\sigma,\alpha\rangle_0,$$
$$O^{\sigma,\beta}_{m,p}\equiv\langle V_m(p)|\sigma,\beta\rangle_0. \quad (2.29)$$

With the help of these definitions we can rewrite (2.28) as

$$|\sigma,\alpha\rangle_0=\sum_{n=1,2}\int \mathrm{d}^4p\int \mathrm{d}^4kO^{\sigma,\alpha}_{n,p,k}|N_l(p),\theta_l(k)\rangle,$$
$$|\sigma,\beta\rangle_0=\sum_{m=1,2}\int \mathrm{d}^4pO^{\sigma,\beta}_{m,p}|V_m(p)\rangle. \quad (2.30)$$

It follows from Eqs. (1.25) and (2.30) that

$$K_0|\sigma,\alpha\rangle_0=\sum_{n=1,2}\int \mathrm{d}^4p\int \mathrm{d}^4k(\omega_{N_n}(p)+\omega_{\theta_n}(k))O^{\sigma,\alpha}_{n,p,k}|N_n(p),\Theta_n(k)\rangle=\sigma|\sigma,\alpha\rangle_0,$$
$$K_0|\sigma,\beta\rangle_0=\sum_{m=1,2}\int \mathrm{d}^4p\,\omega_{V_m}(p)O^{\sigma,\beta}_{m,p}|V_m(p)\rangle=\sigma|\sigma,\beta\rangle_0. \quad (2.31)$$

From the orthogonality of the final state channels, it follows that we must have

$$O^{\sigma,\alpha}_{n,p,k}=\delta(\sigma-\omega_{N_n}(p)-\omega_{\theta_n}(k))\tilde{O}^{\sigma,\alpha}_{n,p,k},$$
$$O^{\sigma,\beta}_{m,p}=\delta(\sigma-\omega_{V_m}(p))\tilde{O}^{\sigma,\beta}_{m,p} \quad (2.32)$$

to satisfy the kinematic conditions imposed by Eq. (2.31). A more detailed analysis of the structure of the matrix elements (2.32) requires further knowledge regarding the nature of the variables α, β. We will postpone the discussion of this point to later and remark here only that orthogonality and completeness requires that

$$\sum_{\alpha} \int \mathrm{d}\sigma (O^{\sigma,\alpha}_{n,p,k})^* O^{\sigma,\alpha}_{n',p',k'} = \delta^4(p-p')\,\delta^4(k-k')\,\delta_{nn'},$$

$$\sum_{n=1,2} \int \mathrm{d}^4p \int \mathrm{d}^4k (O^{\sigma,\alpha}_{n,p,k})^* O^{\sigma',\alpha'}_{n,p,k} = \delta(\sigma-\sigma')\,\delta_{\alpha,\alpha'}, \tag{2.33}$$

$$\sum_{\beta} \int \mathrm{d}\sigma (O^{\sigma,\beta}_{m,p})^* O^{\sigma,\beta}_{m',p'} = \delta^4(p-p')\,\delta_{mm'},$$

$$\sum_{m=1,2} \int \mathrm{d}^4p (O^{\sigma,\beta}_{m,p})^* O^{\sigma',\beta'}_{m,p} = \delta(\sigma-\sigma')\,\delta_{\beta,\beta'}. \tag{2.34}$$

To complete the transformation to the *outgoing* spectral representation we have to calculate, according to Eq. (1.22), the following quantities:

$$\langle V_m(p)|\Omega_+|\sigma,\beta\rangle_0, \quad \langle N_n(p),\theta_n(k)|\Omega_+|\sigma,\beta\rangle_0$$

and

$$\langle V_m(p)|\Omega_+|\sigma,\alpha\rangle_0, \quad \langle N_n(p),\Theta_n(k)|\Omega_+|\sigma,\alpha\rangle_0.$$

From the second equation of (2.31), the discussion following Eq. (2.9) and the results of Appendix A, it is clear that the first two transformation matrix elements are identically zero (since $\Omega_+|V(p)P=0$). We obtain expressions for the second pair with the help of (2.24), (2.25), and (2.32). For the first matrix element in the second pair above we have

$$\begin{aligned}
&\langle V_m(p)|\Omega_+|\sigma,\alpha\rangle_0 \\
&\quad = \sum_{n=1,2} \int \mathrm{d}^4p_1 \int \mathrm{d}^4p_2 \langle V_m(p)|\Omega_+|N_n(p_1),\theta_n(p_2)\rangle \langle N_n(p_1),\theta_n(p_2)|\sigma,\alpha\rangle_0 \\
&\quad = \sum_{n=1,2} \int \mathrm{d}^4p_1 \int \mathrm{d}^4p_2 \sum_{k=1,2} W^{-1}_{mk}(\omega_n - i\epsilon, p_1+p_2) f_{kn}(p_2)\,\delta^4(p-p_1-p_2) O^{\sigma,\alpha}_{n,p_1,p_2} \\
&\quad = \sum_{k=1,2} W^{-1}_{mk}(\sigma - i\epsilon, p) \sum_{n=1,2} \int \mathrm{d}^4p_2 f_{kn}(p_2) O^{\sigma,\alpha}_{n,p-p_2,p_2} \\
&\quad = \sum_{k=1,2} W^{-1}_{mk}(\sigma - i\epsilon, p) F^{\alpha}_{k}(\sigma,p),
\end{aligned} \tag{2.35}$$

where we have used (2.30) and the defininition

$$F^{\alpha}_{k}(\sigma,p) \equiv \sum_{n=1,2} \int \mathrm{d}^4p' f_{kn}(p') O^{\sigma,\alpha}_{n,p-p',p'}. \tag{2.36}$$

For the second matrix element we get in a similar way

$$\langle N_m(p_1),\theta_m(p_2)|\Omega_+|\sigma,\alpha\rangle_0$$
$$=\sum_{n=1,2}\int d^4p_1'\int d^4p_2'\langle N_m(p_1),\theta_m(p_2)|\Omega_+|N_n(p_1'),\theta_n(p_2')\rangle\langle N_n(p_1'),\theta_n(p_2')|\sigma,\alpha\rangle_0$$
$$=O^{\sigma,\alpha}_{m,p_1,\tilde{p}_2}+\sum_{k,j=1,2}\frac{f^*_{km}(\tilde{p}_2)W^{-1}_{kj}(\sigma-i\epsilon,p_1+p_2)F^\alpha_j(\sigma,p_1+p_2)}{\sigma-i\epsilon-\frac{{p_1}^2}{2M_{N_m}}-\frac{{p_2}^2}{2M_{\theta_m}}}. \tag{2.37}$$

Following the same steps we obtain for the matrix elements of the wave operator Ω_-,

$$\langle V_m(p)|\Omega_-|\sigma,\alpha\rangle_0=\sum_{k=1,2}W^{-1}_{mk}(\sigma+i\epsilon,p)F^\alpha_k(\sigma,p) \tag{2.38}$$

and

$$\langle N_m(p_1),\theta_m(p_2)|\Omega_-|\sigma,\alpha\rangle_0=O^{\sigma,\alpha}_{m,p_1,p_2}+\left(\sigma+i\epsilon-\frac{{p_1}^2}{2M_{N_m}}-\frac{{p_2}^2}{2M_{\theta_m}}\right)^{-1}$$
$$\times\sum_{k,j=1,2}f^*_{km}(p_2)W^{-1}_{kj}(\sigma+i\epsilon,p_1+p_2)F^\alpha_j(\sigma,p_1+p_2). \tag{2.39}$$

This completes the calculation of the Lax–Phillips wave operators providing the transformation to the *incoming* and *outgoing* (spectral) representations. Given these transformations it is possible in principle to construct the subspaces $D_\pm$ according to the method described in Sec. I. We can now calculate the Lax–Phillips S matrix mapping the incoming representation into the outgoing representation. If this S matrix satisfies the conditions (a), (b), (c) given in Sec. I then there exist incoming and outgoing subspaces $D_\pm$ orthogonal to each other and the Lax–Phillips structure is complete.

From Eq. (1.26) we see that the Lax–Phillips S matrix is given by ${}_0\langle\sigma',\alpha'|S|\sigma,\alpha\rangle_0$. We can calculate explicitly the Lax–Phillips S matrix for the model presented here with the help of the following useful expression (valid in the sector of the Fock space in which we are working):

$${}_0\langle\sigma',\alpha'|S|\sigma,\alpha\rangle_0=\sum_{m=1,2}\int d^4p\ {}_0\langle\sigma',\alpha'|\Omega_+^\dagger|V_m(p)\rangle\langle V_m(p)|\Omega_-|\sigma,\alpha\rangle_0$$
$$+\sum_{m=1,2}\int d^4\tilde{p}_1\int d^4\tilde{p}_2\ {}_0\langle\sigma',\alpha'|\Omega_+^\dagger|N_m(\tilde{p}_1),\theta_m(\tilde{p}_2)\rangle$$
$$\times\langle N_m(\tilde{p}_1),\theta_m(\tilde{p}_2)|\Omega_-|\sigma,\alpha\rangle_0. \tag{2.40}$$

Using the expressions obtained for the wave operator equations (2.35), (2.37), (2.38), (2.39) and the definition (2.36) we get

$${}_0\langle\sigma',\alpha'|S|\sigma,\alpha\rangle_0=\sum_{m=1,2}\int d^4p\sum_{k,k'=1,2}W^{-1*}_{mk}(\sigma'+i\epsilon,p)F^{\alpha'*}_k(\sigma',p)W^{-1}_{mk'}(\sigma+i\epsilon,p)F^\alpha_{k'}(\sigma,p)$$
$$+\delta(\sigma'-\sigma)\delta_{\alpha\alpha'}+\frac{1}{\sigma-\sigma'+i\epsilon}$$
$$\times\int d^4p_1\sum_{k',j'}F^{\alpha'*}_{k'}(\sigma',p_1)W^{-1}_{k'j'}(\sigma+i\epsilon,p_1)F^\alpha_{j'}(\sigma,p_1)+\frac{1}{\sigma'-\sigma+i\epsilon}$$

$$\times \int \mathrm{d}^4 p_1 \sum_{k,j} F_k^{\alpha}(\sigma,p_1) W_{kj}^{-1\,*}(\sigma'+i\epsilon,p_1) F_j^{\alpha'\,*}(\sigma',p_1)$$

$$+ \sum_{m=1,2} \int \mathrm{d}^4 p_1 \int \mathrm{d}^4 p_2$$

$$\times \Bigg[\sum_{k,j,k',j'=1,2} \frac{f_{km}(p_2) W_{kj}^{-1\,*}(\sigma'+i\epsilon,p_1+p_2) F_j^{\alpha'\,*}(\sigma',p_1+p_2)}{\sigma'+i\epsilon-\frac{p_1^{\,2}}{2M_{N_m}}-\frac{p_2^{\,2}}{2M_{\theta_m}}}$$

$$\times \frac{f_{k'm}^{*}(p_2) W_{k'j'}^{-1}(\sigma+i\epsilon,p_1+p_2) F_{j'}^{\alpha}(\sigma,p_1+p_2)}{\sigma+i\epsilon-\frac{p_1^{\,2}}{2M_{N_m}}-\frac{p_2^{\,2}}{2M_{\theta_m}}} \Bigg]. \tag{2.41}$$

The last term in Eq. (2.41) can be put into a simpler form by the following manipulation:

$$\sum_{m=1,2} \int \mathrm{d}^4 p_1 \int \mathrm{d}^4 p_2 \Bigg[\sum_{k,j,k',j'=1,2} \frac{f_{km}(p_2) W_{kj}^{-1\,*}(\sigma'+i\epsilon,p_1+p_2) F_j^{\alpha'\,*}(\sigma',p_1+p_2)}{\sigma'+i\epsilon-\frac{p_1^{\,2}}{2M_{N_m}}-\frac{p_2^{\,2}}{2M_{\theta_m}}}$$

$$\times \frac{f_{k'm}^{*}(p_2) W_{k'j'}^{-1}(\sigma+i\epsilon,p_1+p_2) F_{j'}^{\alpha}(\sigma,p_1+p_2)}{\sigma+i\epsilon-\frac{p_1^{\,2}}{2M_{N_m}}-\frac{p_2^{\,2}}{2M_{\theta_m}}} \Bigg]$$

$$= \int \mathrm{d}^4 p_1 \sum_{k,j,k',j'=1,2} \frac{1}{\sigma-\sigma'} [\delta_{kk'}(\sigma'-\sigma) - W_{kk'}(\sigma'+i\epsilon,p_1) + W_{kk'}(\sigma+i\epsilon,p_1)]$$

$$\times W_{kj}^{-1\,*}(\sigma'+i\epsilon,p_1) F_j^{\alpha'\,*}(\sigma',p_1) W_{k'j'}^{-1}(\sigma+i\epsilon,p_1) F_{j'}^{\alpha}(\sigma,p_1)$$

$$= -\int \mathrm{d}^4 p_1 \sum_{k,j,j'=1,2} W_{kj}^{-1\,*}(\sigma'+i\epsilon,p_1) F_j^{\alpha'\,*}(\sigma',p_1) W_{kj'}^{-1}(\sigma+i\epsilon,p_1) F_{j'}^{\alpha}(\sigma,p_1)$$

$$+ P\frac{1}{\sigma-\sigma'} \int \mathrm{d}^4 p_1 \sum_{j,j'=1,2} F_{j'}^{\alpha}(\sigma,p_1) W_{j'j}^{-1\,*}(\sigma'+i\epsilon,p_1) F_j^{\alpha'\,*}(\sigma',p_1)$$

$$- P\frac{1}{\sigma-\sigma'} \int \mathrm{d}^4 p_1 \sum_{j,j'=1,2} F_j^{\alpha'\,*}(\sigma',p_1) W_{jj'}^{-1}(\sigma+i\epsilon,p_1) F_{j'}^{\alpha}(\sigma,p_1), \tag{2.42}$$

where P stands for the principle part and we have performed a partial fraction decomposition at the second step in (2.41) and used the definition Eq. (2.21) of $W_{ik}(z,p)$. Combining (2.42) and (2.41) we find for the Lax–Phillips S matrix

$$ {}_0\langle \sigma',\alpha'|S|\sigma,\alpha\rangle_0 = \delta(\sigma-\sigma') \Bigg[\delta_{\alpha\alpha'} - 2\pi i \int \mathrm{d}^4 p \sum_{k,j} F_k^{\alpha}(\sigma,p) W_{kj}^{-1\,*}(\sigma'+i\epsilon,p) F_j^{\alpha'\,*}(\sigma',p_1) \Bigg]$$

$$= \delta(\sigma-\sigma') \Bigg[\delta_{\alpha\alpha'} - 2\pi i \int \mathrm{d}^4 p \sum_{k,j} F_j^{\alpha'\,*}(\sigma,p) W_{jk}^{-1}(\sigma+i\epsilon,p) F_k^{\alpha}(\sigma,p) \Bigg]. \tag{2.43}$$

[In (2.42) we use a partial fraction decomposition of the denominators of the form $(\sigma+i\epsilon_1-A)^{-1}\times(\sigma'+i\epsilon_2-A)^{-1}=(\sigma-\sigma'+i(\epsilon_2-\epsilon_1))^{-1}\times((\sigma'+i\epsilon_1-A)^{-1}-(\sigma+i\epsilon_2-A)^{-1})$

$=(P(\sigma-\sigma')^{-1}\pm i\pi\delta(\sigma-\sigma'))\times((\sigma'+i\epsilon_1-A)^{-1}-(\sigma+i\epsilon_2-A)^{-1})=P(\sigma-\sigma')^{-1}\times((\sigma'+i\epsilon_1-A)^{-1}$
$-(\sigma+i\epsilon_2-A)^{-1})$.] We observe that in Eq. (2.43) the quantity $F_j^{\alpha *}(\sigma,p)$ can be considered, for each fixed value of $\tilde{p}_1'$, as a vector-valued function on the independent variable σ, taking its values in an auxiliary Hilbert space defined by the variables α. We write it as [see Eqs. (2.29) and (2.36)]

$$F_j^{\alpha *}(\sigma,p)\equiv(|n_j\rangle_{\sigma,p})^{\alpha}, \tag{2.44}$$

where (for a fixed value of p) $(|n_j\rangle_{\sigma,p})^{\alpha}$ is the α component of the vector valued function $|n_j\rangle_{\sigma,p}$. With this notation we have (we supress the auxiliary Hilbert space variables α)

$$S(\sigma)=1-2\pi i\int \mathrm{d}^4p\sum_{k,j}\ |n_j\rangle_{\sigma,p}W_{jk}^{-1}(\sigma+i\epsilon,p)_{\sigma,p}\langle n_k|. \tag{2.45}$$

Further simplification of the expression given here for the S matrix can be achieved by identifying the auxiliary Hilbert space variables α. This results in an observation of the direct integral structure of the S matrix on the center of momentum P and the definition of the reduced S matrix $S_P(\sigma)$ for each value of P. Another important result is the fact that the requirement that the Lax–Phillips S matrix is an inner function implies that an analysis of its action involves a consideration of only a two-dimensional subspace of the auxiliary Hilbert space. These simplifications in the structure of the Lax–Phillips S matrix is the subject of Sec III.

III. THE AUXILIARY HILBERT SPACE AND CHARACTERIZATION OF THE LAX–PHILLIPS *S* MATRIX

The auxiliary Hilbert space of the Lax–Phillips representation of the relativistic Lee–Friedrichs model acquires a complete characterization when an exact specification of the variables α in the transformation matrix $O_{n,p.k}^{\sigma,\alpha}$ of Eq. (2.29) is given. To achieve this goal we proceed in two steps. The first one is to define a new set of independent variables $\{n,p,k\}\rightarrow\{n,P,p_{\mathrm{rel}}\}$ by the following linear combination of p and k:

$$a.\quad P=p+k,\quad b.\quad p_{\mathrm{rel}}=\frac{M_{\theta_n}p-M_{N_n}k}{M_{\theta_n}+M_{N_n}}. \tag{3.1}$$

These momentum space variables correspond to the following configuration space variables:

$$a.\quad X_{\mathrm{c.m.}}=\frac{M_{N_n}x_1+M_{\theta_n}x_2}{M_{N_n}+M_{\theta_n}},\quad b.\quad x_{\mathrm{rel}}=x_1-x_2.$$

From Eq. (2.32) we know that

$$O_{n,p,k}^{\sigma,\alpha}=\delta(\sigma-\omega_{N_n}(p)-\omega_{\Theta_n}(k))\tilde{O}_{n,p,k}^{\sigma,\alpha}.$$

This implies that

$$\sigma=\frac{p^2}{2M_{N_n}}+\frac{k^2}{2M_{\theta_n}}=\frac{P^2}{2M_n}+\frac{p_{\mathrm{rel}}^2}{2\mu_n}, \tag{3.2}$$

where $M_n=M_{N_n}+M_{\theta_n}$ and $\mu=M_{N_n}M_{\theta_n}/(M_{N_n}+M_{\theta_n})$. We take σ and P to be independent variables. In this case p_{rel}^2 is a dependent variable with a value given by

$$p_{\mathrm{rel}}^2=2\mu_n\left(\sigma-\frac{P^2}{2M_n}\right).$$

To complete the set of independent quantum numbers we have to find a complete set of commuting operators that commute with $p_{\rm rel}^2$ and P. Since $p_{\rm rel}^2$ is a Casimir of the Poincaré group on the relative coordinates, we may take for the set of commuting operators on the *relative motion*, the second Casimir of the Lorentz group and L^2, L_3. We denote by γ the full set of quantum numbers corresponding to the latter three operators. We then have $\{\sigma,\alpha\}\equiv\{\sigma,n,P,\gamma\}$. It follows from Eqs. (2.32) and (3.1*a*.) that

$$O^{\sigma,\alpha}_{n,p,k}\equiv O^{\sigma,P,\gamma,i}_{n,p,k}=\delta(\sigma-p^2/2M_{N_n}-k^2/2M_{\theta_n})\,\delta_{ni}\,\delta^4(P-p-k)\,\hat{O}^{n,p_{\rm rel}^2,\gamma}_{n,p_{\rm rel}}\Big|_{\substack{p_{\rm rel}^2=2\mu_n(\sigma-P^2/2M_n)\\ p_{\rm rel}=(M_{\theta_n}p-M_{N_n}k)/M_n}} \tag{3.3}$$

Inserting this into the definition of $F_k^{\alpha}(\sigma,p)(\equiv F_k^{P,\gamma,i}(\sigma,p))$, Eq. (2.36) we get

$$\begin{aligned}
&F_k^{P,\gamma,i}(\sigma,p)\\
&\equiv\delta^4(P-p)\sum_{n=1,2}\int {\rm d}^4p'\,f_{kn}(p')\,\delta_{ni}\,\delta\left(\sigma-\frac{(p-p')^2}{2M_{N_n}}-\frac{p'^2}{2M_{\theta_n}}\right)\hat{O}^{n,p_{\rm rel}^2,\gamma}_{n,p_{\rm rel}}\Big|_{\substack{p_{\rm rel}^2=2\mu_n(\sigma-P^2/2M_n)\\ p_{\rm rel}=M_{\theta_n}P/M_n-p'}}\\
&=\delta^4(P-p)\sum_{n=1,2}\int {\rm d}^4p_{\rm rel}f_{kn}(M_{\theta_n}P/M_n-p_{\rm rel})\,\delta_{ni}\,\delta\left(\sigma-\frac{P^2}{2M_n}-\frac{p_{\rm rel}^2}{2\mu_n}\right)\hat{O}^{n,p_{\rm rel}^2,\gamma}_{n,p_{\rm rel}}.
\end{aligned}\tag{3.4}$$

We define the following P-dependent vector valued function:

$$(|n_k\rangle_{\sigma,P})^{\gamma,i}\equiv\sum_{n=1,2}\int {\rm d}^4p_{\rm rel}f^*_{kn}(M_{\theta_n}P/M_n-p_{\rm rel})\,\delta_{ni}\,\delta\left(\sigma-\frac{P^2}{2M_n}-\frac{p_{\rm rel}^2}{2\mu_n}\right)(\hat{O}^{n,p_{\rm rel}^2,\gamma}_{n,p_{\rm rel}})^* \tag{3.5}$$

so that $F_k^{P,\gamma,i}(p,\sigma)^*=\delta^4(P-p)(|n_k\rangle^{\gamma,i}_{\sigma,P}$. When this form of $F_k^{\alpha}(p,\sigma)$ is used in Eq. (2.43) we get

$${}_0\langle\sigma',\alpha'|S|\sigma,\alpha\rangle_0={}_0\langle\sigma',P',\gamma',i'|S|\sigma,P,\gamma,i\rangle_0=\delta(\sigma'-\sigma)\,\delta(P'-P)S_P^{\gamma',i',\gamma,i}(\sigma), \tag{3.6}$$

where we define the reduced S matrix, for a specified value of the center of momentum four-vector P, to be

$$S_P^{\gamma',i',\gamma,i}(\sigma)=\left[1-2\pi i\sum_{k,j=1,2}|n_j\rangle_{\sigma,P}W^{-1}_{jk}(\sigma+i\epsilon,P)_{\sigma,P}\langle n_k|\right]^{\gamma',i',\gamma,i}. \tag{3.7}$$

The form of $S_P(\sigma)$ allows for a further simplification. For each value of σ the two vectors $|n_k\rangle_{\sigma,P}$, $k=1,2$ span a two-dimensional subspace of the auxiliary Hilbert space. These vectors are, in general, not orthogonal. We find the orthogonal projection onto the two-dimensional subspace using these nonorthogonal vectors by finding linear combinations, denoted ${}_{\sigma,P}\langle F_i|$ such that

$${}_{\sigma,P}\langle F_i|n_j\rangle_{\sigma,P}=\delta_{ij}\,. \tag{3.8}$$

Denoting the projection operator on the subspace spanned by $|n_k\rangle_{\sigma,P}$, $k=1,2$ by $P_2(\sigma,P)$ we have

$$P_2(\sigma,P)=\sum_{i=1,2}|n_i\rangle_{\sigma,P}\ {}_{\sigma,P}\langle F_i|. \tag{3.9}$$

With this projection we construct the unit operator $1_{\sigma,P}$ on the auxiliary Hilbert space and write

$$1_{\sigma,P}=(1_{\sigma,P}-P_2(\sigma,P))+P_2(\sigma,P).$$

Multiplying $S_P(\sigma)$ of Eq. (3.7) by this unit operator from the right we obtain (here, and in the sequel, we suppress reference to the auxiliary Hilbert space variables γ', i, γ, i)

$$S_P(\sigma)=1-P_2(\sigma,P)$$
$$+\sum_i \left[|n_i\rangle_{\sigma,P}\ {}_{\sigma,P}\langle F_i| - 2\pi i \sum_{k,j} |n_j\rangle_{\sigma,P} W^{-1}_{jk}(\sigma+i\epsilon,P)_{\sigma,P}\langle n_k|n_i\rangle_{\sigma,P}\ {}_{\sigma,P}\langle F_i| \right]$$
$$=1-P_2(\sigma,P)+\sum_{i,j} |n_j\rangle_{\sigma,P}\left[\delta_{ji} - 2\pi i \sum_k W^{-1}_{jk}(\sigma+i\epsilon,P)_{\sigma,P}\langle n_k|n_i\rangle_{\sigma,P}\right]_{\sigma,P}\langle F_i|. \tag{3.10}$$

We now write the Kronecker delta δ_{ij} in the form $\delta_{ji}=\Sigma_k W^{-1}_{jk}(\sigma+i\epsilon,P)W_{ki}(\sigma+i\epsilon,P)$ and get

$$S_P(\sigma)=1-P_2(\sigma,P)+\sum_{i,j,k} |n_j\rangle_{\sigma,P} W^{-1}_{jk}(\sigma+i\epsilon,P)[W_{ki}(\sigma+i\epsilon,P)-2\pi i_{\sigma,p}\langle n_k|n_i\rangle_{\sigma,P}]_{\sigma,P}\langle F_i|. \tag{3.11}$$

In order to proceed at this point it is necessary to evaluate explicitly the expression ${}_{\sigma,P}\langle n_k|n_i\rangle_{\sigma,P}$. Using the definition (3.5) we obtain

$${}_{\sigma,P}\langle n_k|n_i\rangle_{\sigma,P}=\sum_j \int \mathrm{d}^4 p_{\mathrm{rel}} \int \mathrm{d}^4 p'_{\mathrm{rel}} f^*_{kj}(M_{\theta_j}P/M_j-p_{\mathrm{rel}}) f_{ij}(M_{\theta_j}P/M_j-p'_{\mathrm{rel}})$$
$$\times \delta\left(\sigma-\frac{P^2}{2M_j}-\frac{p^2_{\mathrm{rel}}}{2\mu_j}\right)\delta\left(\frac{p^2_{\mathrm{rel}}}{2\mu_j}-\frac{p'^2_{\mathrm{rel}}}{2\mu_j}\right)\sum_\gamma (\hat{O}^{j,p^2_{\mathrm{rel}},\gamma}_{j,p_{\mathrm{rel}}})^* \hat{O}^{j,p^2_{\mathrm{rel}},\gamma}_{j,p'_{\mathrm{rel}}}$$
$$=\sum_j \int \mathrm{d}^4 p_{\mathrm{rel}} \delta\left(\sigma-\frac{P^2}{2M_j}-\frac{p^2_{\mathrm{rel}}}{2\mu_j}\right) f^*_{kj}(M_{\theta_j}P/M_j-p_{\mathrm{rel}}) f_{ij}(M_{\theta_j}P/M_j-p_{\mathrm{rel}})$$
$$=\sum_j \int \mathrm{d}^4 k \,\delta\left(\sigma-\frac{(P-k)^2}{2M_{N_j}}-\frac{k^2}{2M_{\theta_j}}\right) f^*_{kj}(k) f_{ij}(k). \tag{3.12}$$

We compare this result with the jump across the cut on the real axis of the complex σ plane of $W_{ki}(\sigma,P)$. With the help of the definition (2.21) we find

$$W_{ki}(\sigma+i\epsilon,P)-W_{ki}(\sigma-i\epsilon,P)=2\pi i\sum_j \int \mathrm{d}^4 k\,\delta\left(\sigma-\frac{(P-k)^2}{2M_{N_j}}-\frac{k^2}{2M_{\theta_j}}\right) f^*_{kj}(k) f_{ij}(k). \tag{3.13}$$

Using Eqs. (3.12) and (3.13) we can write Eq. (3.11) as

$$S_P(\sigma)=1-P_2(\sigma,P)+\sum_{i,j,k} |n_j\rangle_{\sigma,P} W^{-1}_{jk}(\sigma+i\epsilon,P) W_{ki}(\sigma-i\epsilon,P)_{\sigma,P}\langle F_i|. \tag{3.14}$$

The operator valued function $P_2(\sigma,P)$ defined in Eq. (3.9) is a projection operator for each value of σ,

$$P_2(\sigma,P)P_2(\sigma,P)=P_2(\sigma,P).$$

It is, therefore, a bounded positive operator on the real σ axis. In order to characterize $P_2(\sigma,P)$ we need several definitions and results from operator theory on positive operator valued functions. We give these in the appendix, where we prove that $P_2(\sigma,P)$ is an *outer function*[18] and that it is actually independent of σ, that is

$$P_2(\sigma,P)=P_{2,P}, \tag{3.15}$$

where $P_{2,P}$ is a projection operator on some fixed two-dimensional subspace of the auxiliary space. This proof rests on the properties of $S_P(\sigma)$ as an *inner function*.[18] We shall assume that the functions $f_{ij}(k)$ are such that the operator valued function defined by Eq. (3.14) has the appropriate analytic properties in the upper half plane.

In Eqs. (3.8) and (3.9) the vectors $|n_i\rangle_{\sigma,P}$ and ${}_{\sigma,P}\langle F_i|$ may depend on σ, but this dependence is such that the projection operator $P_2(\sigma,P)$ projects on a fixed two-dimensional subspace of the auxiliary space for each and every value of σ. Equation (3.14) can then be written in the form

$$S_P(\sigma)=1-P_{2,P}+\sum_{i,j,k}|n_j\rangle_{\sigma,P}W^{-1}_{jk}(\sigma+i\epsilon,P)W_{ki}(\sigma-i\epsilon,P)\,{}_{\sigma,P}\langle F_i| \tag{3.16}$$

and we see that the S matrix $S_P(\sigma)$ acts in a non trivial way only on a two-dimensional subspace of the auxiliary space.

We now complete the characterization of the Lax–Phillips S matrix $S_P(\sigma)$. Equation (3.15) implies that the projection valued function $P_2(\sigma,P)$ projects the Hilbert space $L^2(-\infty,+\infty;H)$ on the subspace $L^2(-\infty,+\infty;H_2)$ of vector valued functions taking their values in some fixed two-dimensional subspace H_2 of the auxiliary Hilbert space. We again use the notation $P_{2,P}$ to denote the projection $P_2(\sigma,P)$ as an operator valued function projecting on $L^2(-\infty,+\infty;H_2)$, that is

$$P_{2,P}:L^2(-\infty,+\infty;H)\to L^2(-\infty,+\infty;H_2). \tag{3.17}$$

We denote by $P_{I-2,P}$ the operator projecting on the subspace of functions with a range in $H\ominus H_2$. We have

$$P_{I-2,P}:L^2(-\infty,+\infty;H)\to L^2(-\infty,+\infty;H\ominus H_2). \tag{3.18}$$

It is obvious from Eqs. (3.17) and (3.18) that

$$L^2(-\infty,+\infty;H)=P_{2,P}L^2(-\infty,+\infty;H)\oplus P_{I-2,P}L^2(-\infty,+\infty;H). \tag{3.19}$$

In particular, if $U(\tau)$ is the operator of right translation by τ units then any left translation invariant subspace $I^-_H\subset H^2_H(\Pi)$ can be written as

$$I^-_H=P_{2,P}I^-_H\oplus P_{I-2,P}I^-_H. \tag{3.20}$$

The translation $U(\tau)$ commutes with the projections $P_{2,P}$, $P_{I-2,P}$ and, since I^-_H is a left translation invariant subspace, we have $U(\tau)I^-_H\subset I^-_H$. Denoting $I^-_{H_2}=P_{2,P}I^-_H$ we find

$$U(\tau)I^-_{H_2}=U(\tau)P_{2,P}I^-_H=P_{2,P}U(\tau)I^-_H\subset P_{2,P}I^-_H=I^-_{H_2}. \tag{3.21}$$

We see that if I^-_H is a left translation invariant subspace then $I^-_{H_2}=P_{2,P}I^-_H$ is a two-dimensional invariant subspace under left translations.

In the Lax–Phillips theory the Lax–Phillips S matrix is an inner function that generates a left translation invariant subspace from the Hardy class $H^2_H(\Pi)$ (this corresponds to the stability property of $\mathcal{D}_-$). In this case we can write

$$I^-_H=S^{\mathrm{LP}}H^2_H(\Pi), \tag{3.22}$$

where S^{LP} is the Lax–Phillips S matrix. From Eq. (3.16) we see that in the case of the two channel relativistic Lee-model we have [$S_P(\sigma)$ is the realization of S^{LP} in terms of an operator valued function]

$$[S^{\mathrm{LP}},P_{2,P}]=0. \tag{3.23}$$

From Eqs. (3.22) and (3.23) and the definition of $I^-_{H_2}$ we find that

$$I^-_{H_2}=P_{2,P}I^-_H=P_{2,P}S^{\mathrm{LP}}H^2_H(\Pi)=S^{\mathrm{LP}}P_{2,P}H^2_H(\Pi)=S^{\mathrm{LP}}H^2_{H_2}(\Pi),$$

where $H^2_{H_2}(\Pi)\equiv P_{2,P}H^2_H(\Pi)$. We can write this result in the form

$$I^-_{H_2}=P_{2,P}S^{\mathrm{LP}}P_{2,P}H^2_{H_2}(\Pi). \tag{3.24}$$

From this we see that $P_{2,P}S^{\mathrm{LP}}P_{2,P}$, when it acts on the Hardy space $H^2_{H_2}(\Pi)$, generates a two-dimensional left translation invariant subspace. From Eq. (3.16) we get [if A is an operator on a Hardy class $H^2_H(\Pi)$ or $H^2_{H_2}(\Pi)$ then $T(A)$ is its realization in terms of an operator valued function]

$$T(P_{2,P}S^{\mathrm{LP}}P_{2,P})=\delta(\sigma-\sigma')\sum_{i,j,k}|n_j\rangle_{\sigma,P}W^{-1}_{jk}(\sigma+i\epsilon,P)W_{ki}(\sigma-i\epsilon,P)\,{}_{\sigma,P}\langle F_i|. \tag{3.25}$$

According to Eq. (3.24) this immediately implies that the right-hand side of Eq. (3.25) is an *inner function* acting on the Hardy space $H^2_{H_2}(\Pi)$ consisting of vector valued functions taking their values in some fixed two-dimensional subspace of the auxiliary Hilbert space. This observation allows for a complete characterization of the Lax–Phillips S matrix, Eq. (3.16). Such an inner function can be represented as a product of a *rational* inner function containing the poles and zeros of $S_P(\sigma)$ and a factor which is an inner function with nonvanishing determinant.[24] If the latter factor is bounded exponentially, it corresponds to a trivial inner factor[1] and does not change the spectrum of the semigroup. In the following, we consider the case of a purely rational S matrix.

IV. THE RESONANT STATES FOR A RATIONAL *S* MATRIX

In this section we shall identify the resonant states of the relativistic two channel Lee model in the Lax–Phillips *outgoing* translation representation for the case of a rational S matrix of the form

$$S(\sigma)=1+\left(\frac{\mathrm{Res}\,S(z_1)}{\sigma-z_1}+\frac{\mathrm{Res}\,S(z_2)}{\sigma-z_2}\right),\qquad \mathrm{Im}\,z_1,\mathrm{Im}\,z_2<0. \tag{4.1}$$

We also have

$$S^\dagger(\sigma)=1+\left(\frac{\mathrm{Res}\,S^\dagger(\overline{z_1})}{\sigma-\overline{z_1}}+\frac{\mathrm{Res}\,S^\dagger(\overline{z_2})}{\sigma-\overline{z_2}}\right),\qquad \mathrm{Im}\,\overline{z_1},\mathrm{Im}\,\overline{z_2}>0. \tag{4.2}$$

A rational S matrix of this form implies the property, as assumed in the remarks following Eq. (3.15), that $S(\sigma)$ is an inner factor. There are simple conditions, which we shall discuss elsewhere, for which the converse is true, i.e., that an inner function is rational.

In order to identify the resonant states we obtain, in the *outgoing* translation representation, an expression for the generator of the Lax–Phillips semigroup. We then find the eigenfunctions of this generator. Lax and Phillips then assert that these are the resonant states associated with the poles of the Lax–Phillips S matrix.

The Lax–Phillips semigroup is defined as $Z(\tau)=P_+U(\tau)P_-,\tau>0$. The generator of the semigroup is given by

$$B=i\lim_{\tau\to 0^+}\frac{Z(\tau)-Z(0)}{\tau}. \tag{4.3}$$

In the outgoing translation representation we have

$$
\begin{aligned}
{}_{\text{out}}\langle s,\beta|B|s',\beta'\rangle_{\text{out}} = i \lim_{\tau\to 0^+}\frac{1}{\tau}\sum_{\gamma,\gamma'}\int \mathrm{d}\eta\int \mathrm{d}\eta' \\
\times[{}_{\text{out}}\langle s,\beta|P_+|\eta,\gamma\rangle_{\text{out out}}\langle \eta,\gamma|U(\tau)|\eta',\gamma'\rangle_{\text{out out}}\langle \eta',\gamma'|P_-|s',\beta'\rangle_{\text{out}} \\
-{}_{\text{out}}\langle s,\beta|P_+|\eta,\gamma\rangle_{\text{out out}}\langle \eta,\gamma|U(0)|\eta',\gamma'\rangle_{\text{out out}}\langle \eta',\gamma'|P_-|s',\beta'\rangle_{\text{out}}].
\end{aligned}
\tag{4.4}
$$

In this representation the subspace D_+ is given by $L^2(-\infty,+\infty;H)$, i.e., it is defined in a simple way by its support properties. Therefore, the operator P_+, the projection into the subspace $K\oplus D_-$ is given simply by

$$
{}_{\text{out}}\langle s,\beta|P_+|\eta,\gamma\rangle_{\text{out}} = \Theta(-s)\,\delta(s-\eta)\,\delta_{\gamma,\gamma'}.
$$

Furthermore, in the outgoing translation representation the evolution is just translation

$$
{}_{\text{out}}\langle \eta,\gamma|U(\tau)|\eta',\gamma'\rangle_{\text{out}} = \delta(\eta-\tau-\eta')\,\delta_{\gamma,\gamma'}.
$$

Then (4.4) becomes

$$
{}_{\text{out}}\langle s,\beta|B|s',\beta'\rangle_{\text{out}} = i\lim_{\tau\to 0^+}\frac{1}{\tau}[\Theta(-s)\,{}_{\text{out}}\langle s-\tau,\beta|P_-|s',\beta'\rangle_{\text{out}} - \Theta(-s)\,{}_{\text{out}}\langle s,\beta|P_-|s',\beta'\rangle_{\text{out}}].
\tag{4.5}
$$

We use the fact that the subspace D_- is given in the incoming translation representation in terms of its support properties. This allows us to write

$$
P_- = \sum_\gamma \int \mathrm{d}\eta\,|\eta,\gamma\rangle_{\text{in}}\Theta(\eta)\langle\eta,\gamma|_{\text{in}} = \sum_\gamma \int \mathrm{d}\eta\,\Omega_-|\eta,\gamma\rangle_f\Theta(\eta)\langle\eta,\gamma|_f\Omega_-^\dagger.
\tag{4.6}
$$

In the outgoing translation representation we have

$$
\begin{aligned}
{}_{\text{out}}\langle s,\beta|P_-|s',\beta'\rangle_{\text{out}} &= \sum_\gamma \int \mathrm{d}\eta\,\text{out}\langle s,\beta|\Omega_-|\eta,\gamma\rangle_f\Theta(\eta)\langle\eta,\gamma|_f\Omega_-^\dagger|s',\beta'\rangle_{\text{out}} \\
&= \sum_\gamma \int \mathrm{d}\eta\, f\langle s,\beta|\Omega_+^\dagger\Omega_-|\eta,\gamma\rangle_f\Theta(\eta)\langle\eta,\gamma|_f\Omega_-^\dagger\Omega_+|s',\beta'\rangle_f \\
&= \sum_\gamma \int \mathrm{d}\eta\, f\langle s,\beta|S|\eta,\gamma\rangle_f\Theta(\eta)\langle\eta,\gamma|_f S^\dagger|s',\beta'\rangle_f.
\end{aligned}
$$

In this expression we would like to represent the scattering operator S and its adjoint $S^\dagger$ in the spectral representation. Performing the appropriate Fourier transforms we get

$$
\begin{aligned}
{}_{\text{out}}\langle s,\beta|P_-|s',\beta'\rangle_{\text{out}} &= \int \mathrm{d}\sigma\int \mathrm{d}\sigma'\sum_\alpha \int \mathrm{d}\eta\, e^{i\sigma s}S^{\beta,\alpha}(\sigma)e^{-i\eta\sigma}\Theta(\eta)e^{i\eta\sigma'}S^\dagger(\sigma')^{\alpha,\beta}e^{-i\sigma' s'} \\
&= \frac{-i}{4\pi^2}\int \mathrm{d}\sigma\int \mathrm{d}\sigma'\sum_\alpha e^{i\sigma s}\frac{S^{\beta,\alpha}(\sigma)S^\dagger(\sigma')^{\alpha,\beta'}}{\sigma-(\sigma'+i\epsilon)}e^{-i\sigma' s'}.
\end{aligned}
\tag{4.7}
$$

The operator valued function $S(\sigma)$ is analytic in the upper half of the complex σ plane. Its adjoint $S^\dagger(\sigma)$ is analytic in the lower half plane. We assume that $S(\sigma)$ has the form (4.1) and has two poles in the lower half plane, located at z_1 and z_2. The poles of $S^\dagger(\sigma)$ are thus at $\overline{z_1}$ and $\overline{z_2}$. The

form of $S(\sigma)$ and of $S^\dagger(\sigma)$ allows the integrals in (4.7) to performed by contour integration, according to the various possible signs of s and s'. The result is (through the rest of this section we suppress in our notation the auxiliary Hilbert space variables)

$$
\begin{aligned}
{}_{\text{out}}\langle s|P_-|s'\rangle_{\text{out}} &= \Theta(s)\,\delta(s-s') + \frac{1}{2\pi}\Theta(-s)\Bigg[e^{iz_1 s}\operatorname{Res} S(z_1)\int \mathrm{d}\sigma' \frac{S^\dagger(\sigma')}{z_1-(\sigma'+i\epsilon)} e^{-i\sigma' s'} \\
&\quad + e^{iz_2 s}\operatorname{Res} S(z_2)\int \mathrm{d}\sigma' \frac{S^\dagger(\sigma')}{z_2-(\sigma'+i\epsilon)} e^{-i\sigma' s'}\Bigg] \\
&= \Theta(s)\,\delta(s-s') - i\Theta(-s)\Theta(s')\big[e^{iz_1 s}\operatorname{Res} S(z_1) S^\dagger(z_1) e^{-iz_1 s'} \\
&\quad + e^{iz_2 s}\operatorname{Res} S(z_2) S^\dagger(z_2) e^{-iz_2 s'}\big] + i\Theta(-s)\Theta(-s') \\
&\quad \times\Bigg[e^{iz_1 s}\operatorname{Res} S(z_1)\left(\frac{\operatorname{Res} S^\dagger(\overline{z_1})}{z_1-\overline{z_1}} e^{-i\overline{z_1} s'} + \frac{\operatorname{Res} S^\dagger(\overline{z_2})}{z_1-\overline{z_2}} e^{-i\overline{z_2} s'}\right) \\
&\quad + e^{iz_2 s}\operatorname{Res} S(z_2)\left(\frac{\operatorname{Res} S^\dagger(\overline{z_1})}{z_2-\overline{z_1}} e^{-i\overline{z_1} s'} + \frac{\operatorname{Res} S^\dagger(\overline{z_2})}{z_2-\overline{z_2}} e^{-i\overline{z_2} s'}\right)\Bigg].
\end{aligned}
\tag{4.8}
$$

The Lax–Phillips S matrix is analytic in the upper half-plane. Its analytic continuation into the lower half-plane is given by $S(\sigma)\equiv(S^\dagger(\overline{\sigma}))^{-1}$, $\operatorname{Im}\sigma<0$. Similarily, $S^\dagger(\sigma)$ is analytic in the lower half-plane and its analytic continuation to the upper half-plane is given by $S^\dagger(\sigma)\equiv(S(\sigma))^{-1}$, $\operatorname{Im}\sigma>0$. At any point in the complex plane we have

$$
S(\sigma)S^\dagger(\sigma) = S^\dagger(\sigma)S(\sigma) = 1. \tag{4.9}
$$

This relation is obtained by analytic continuation and does not imply unitarity of the S matrix off the real axis. From (4.2) and (4.9) we have

$$
S(\sigma)\left[1+\left(\frac{\operatorname{Res} S^\dagger(\overline{z_1})}{\sigma-\overline{z_1}} + \frac{\operatorname{Res} S^\dagger(\overline{z_2})}{\sigma-\overline{z_2}}\right)\right] = 1.
$$

In the limit as σ goes to $\overline{z_1}$ or to $\overline{z_2}$ we then get

$$
\begin{aligned}
&S(\sigma)\operatorname{Res} S^\dagger(\overline{z_1}) \simeq A_1(\sigma-\overline{z_1}), \quad \sigma\to\overline{z_1}, \\
&S(\sigma)\operatorname{Res} S^\dagger(\overline{z_2}) \simeq A_2(\sigma-\overline{z_2}), \quad \sigma\to\overline{z_2}, \\
&\operatorname{Res} S^\dagger(\overline{z_1})S(\sigma) \simeq \hat{A}_1(\sigma-\overline{z_1}), \quad \sigma\to\overline{z_1}, \\
&\operatorname{Res} S^\dagger(\overline{z_2})S(\sigma) \simeq \hat{A}_2(\sigma-\overline{z_2}), \quad \sigma\to\overline{z_2}
\end{aligned}
\tag{4.10}
$$

for some fixed (i.e., independent of σ) operators A_1, A_2, $\hat{A}_1$, $\hat{A}_2$. From (4.1) and (4.9) we have

$$
S^\dagger(\sigma)\left[1-\left(\frac{\operatorname{Res} S(z_1)}{\sigma-z_1} + \frac{\operatorname{Res} S(z_2)}{\sigma-z_2}\right)\right] = 1
$$

and in the limit as σ approaches z_1 or z_2 we get

$$
\begin{aligned}
&S^\dagger(\sigma)\operatorname{Res} S(z_1) \simeq -B_1(\sigma-z_1), \quad \sigma\to z_1, \\
&S^\dagger(\sigma)\operatorname{Res} S(z_2) \simeq -B_2(\sigma-z_2), \quad \sigma\to z_2, \\
&\operatorname{Res} S(z_1)S^\dagger(\sigma) \simeq -\hat{B}_1(\sigma-z_1), \quad \sigma\to z_1,
\end{aligned}
\tag{4.11}
$$

$$\mathrm{Res}\, S(z_2)S^{\dagger}(\sigma)\simeq -\hat{B}_2(\sigma-z_2),\quad \sigma\to z_2.$$

With the help of Eq. (4.11) we find that the second term of Eq. (4.8) vanishes and the representation of P_- in the outgoing translation representation to be

$$\begin{aligned}
{}_{\mathrm{out}}\langle s,\beta|P_-|s',\beta'\rangle_{\mathrm{out}} &= \Theta(s)\,\delta(s-s')-\frac{1}{2\pi}\Theta(-s)\Bigg[e^{iz_1 s}\mathrm{Res}\, S(z_1)\int \mathrm{d}\sigma'\frac{S^{\dagger}(\sigma')}{z_1-(\sigma'+i\epsilon)}e^{-i\sigma' s'}\\
&\quad + e^{iz_2 s}\mathrm{Res}\, S(z_2)\int \mathrm{d}\sigma'\frac{S^{\dagger}(\sigma')}{z_2-(\sigma'+i\epsilon)}e^{-i\sigma' s'}\Bigg]\\
&= \Theta(s)\,\delta(s-s')+i\Theta(-s)\Theta(-s')\\
&\quad\times\Bigg[e^{iz_1 s}\mathrm{Res}\, S(z_1)\left(\frac{\mathrm{Res}\, S^{\dagger}(\overline{z_1})}{z_1-\overline{z_1}}e^{-i\overline{z_1}s'}+\frac{\mathrm{Res}\, S^{\dagger}(\overline{z_2})}{z_1-\overline{z_2}}e^{-i\overline{z_2}s'}\right)\\
&\quad + e^{iz_2 s}\mathrm{Res}\, S(z_2)\left(\frac{\mathrm{Res}\, S^{\dagger}(\overline{z_1})}{z_2-\overline{z_1}}e^{-i\overline{z_1}s'}+\frac{\mathrm{Res}\, S^{\dagger}(\overline{z_2})}{z_2-\overline{z_2}}e^{-i\overline{z_2}s'}\right)\Bigg].
\end{aligned}\tag{4.12}$$

Inserting (4.12) in (4.5) we get for the generator of the semigroup

$$\begin{aligned}
{}_{\mathrm{out}}\langle s,\beta|B|s',\beta'\rangle_{\mathrm{out}} &= i\lim_{\tau\to 0^+}\frac{1}{\tau}[\Theta(-s)_{\mathrm{out}}\langle s-\tau,\beta|P_-|s',\beta'\rangle_{\mathrm{out}}-\Theta(-s)_{\mathrm{out}}\langle s,\beta|P_-|s',\beta'\rangle_{\mathrm{out}}]\\
&= i\lim_{\tau\to 0^+}\frac{1}{\tau}\{\Theta(-s)(\Theta(s-\tau)\,\delta(s-\tau-s')+i\Theta(-s+\tau)\Theta(-s')\\
&\quad\times[e^{iz_1(s-\tau)}\mathrm{Res}\, S(z_1)K_1(s')+e^{iz_2(s-\tau)}\mathrm{Res}\, S(z_2)K_2(s')])-\Theta(-s)\\
&\quad\times(\Theta(s)\,\delta(s-s')+i\Theta(-s)\Theta(-s')[e^{iz_1 s}\mathrm{Res}\, S(z_1)K_1(s')\\
&\quad + e^{iz_2 s}\mathrm{Res}\, S(z_2)K_2(s')])\}\\
&= i\Theta(-s)\Theta(-s')\lim_{\tau\to 0^+}\frac{1}{\tau}[(e^{iz_1(s-\tau)}-e^{iz_1 s})\\
&\quad\times\mathrm{Res}\, S(z_1)K_1(s')+(e^{iz_2(s-\tau)}-e^{iz_2 s})\mathrm{Res}\, S(z_2)K_2(s')]\\
&= \Theta(-s)\Theta(-s')[z_1\,e^{iz_1 s}\mathrm{Res}\, S(z_1)K_1(s')+z_2\,e^{iz_2 s}\mathrm{Res}\, S(z_2)K_2(s')],
\end{aligned}\tag{4.13}$$

where we have denoted

$$\begin{aligned}
K_1(s') &= \frac{\mathrm{Res}\, S^{\dagger}(\overline{z_1})}{z_1-\overline{z_1}}e^{-i\overline{z_1}s'}+\frac{\mathrm{Res}\, S^{\dagger}(\overline{z_2})}{z_1-\overline{z_2}}e^{-i\overline{z_2}s'},\\
K_2(s') &= \frac{\mathrm{Res}\, S^{\dagger}(\overline{z_1})}{z_2-\overline{z_1}}e^{-i\overline{z_1}s'}+\frac{\mathrm{Res}\, S^{\dagger}(\overline{z_2})}{z_2-\overline{z_2}}e^{-i\overline{z_2}s'}.
\end{aligned}\tag{4.14}$$

We show that, in the outgoing translation representation, the eigenvectors of the generator B of the Lax–Phillips semigroup are

$$\psi_1(s)=\Theta(-s)\mathrm{Res}\, S(z_1)e^{iz_1 s},\quad \psi_2(s)=\Theta(-s)\mathrm{Res}\, S(z_2)e^{iz_2 s}\tag{4.15}$$

in the sense that a vector in $\overline{H}$ given by $\psi_\beta(s)=\Theta(-s)e^{iz_1 s}(\mathrm{Res}\,S(z_1))^{\beta\beta'}\phi^{\beta'}$ or by $\psi_\beta(s)=\Theta(-s)e^{iz_2 s}(\mathrm{Res}\,S(z_2))^{\beta\beta'}\phi^{\beta'}$ where $\phi\in H$, is an eigenvector of the generator of the semigroup. This is achieved by demostrating that these vectors satisfy the eigenvalue equation

$$\int \mathrm{d}s'\,{}_{\mathrm{out}}\langle s,\beta|B|s',\beta'\rangle_{\mathrm{out}}\psi_{1,2}^{\beta'}(s')=z_{1,2}\psi_{1,2}^{\beta}(s'). \tag{4.16}$$

We verify Eq. (4.16) for $\psi_1(s)$. Inserting (4.13) into (4.16) and performing the integration we find for the second term, containing the factor z_2,

$$\begin{aligned}
&\mathrm{Res}\,S(z_2)\int_{-\infty}^{0}\left(\frac{\mathrm{Res}\,S^\dagger(\overline{z_1})}{z_2-\overline{z_1}}e^{-i\overline{z_1}s'}+\frac{\mathrm{Res}\,S^\dagger(\overline{z_2})}{z_2-\overline{z_2}}e^{-i\overline{z_2}s'}\right)e^{iz_1s'}\mathrm{Res}\,S(z_1)\\
&\quad=\frac{i}{z_2-z_1}\mathrm{Res}\,S(z_2)\left(\frac{\mathrm{Res}\,S^\dagger(\overline{z_1})}{z_2-\overline{z_1}}+\frac{\mathrm{Res}\,S^\dagger(\overline{z_1})}{\overline{z_1}-z_1}+\frac{\mathrm{Res}\,S^\dagger(\overline{z_2})}{z_2-\overline{z_2}}+\frac{\mathrm{Res}\,S^\dagger(\overline{z_2})}{\overline{z_2}-z_1}\right)\mathrm{Res}\,S(z_1)\\
&\quad=\mathrm{Res}\,S(z_2)(S^\dagger(z_2)-S^\dagger(z_1))\mathrm{Res}\,S(z_1)=0
\end{aligned} \tag{4.17}$$

and for the first term containing the factor z_1,

$$\begin{aligned}
&\mathrm{Res}\,S(z_1)\int_{-\infty}^{0}\left(\frac{\mathrm{Res}\,S^\dagger(\overline{z_1})}{z_1-\overline{z_1}}e^{-i\overline{z_1}s'}+\frac{\mathrm{Res}\,S^\dagger(\overline{z_2})}{z_1-\overline{z_2}}e^{-i\overline{z_2}s'}\right)e^{iz_1s'}\mathrm{Res}\,S(z_1)\\
&\quad=-i\mathrm{Res}\,S(z_1)\left(\frac{\mathrm{Res}\,S^\dagger(\overline{z_1})}{(z_1-\overline{z_1})^2}+\frac{\mathrm{Res}\,S^\dagger(\overline{z_2})}{(z_1-\overline{z_2})^2}\right)\mathrm{Res}\,S(z_1)\\
&\quad=i\mathrm{Res}\,S(z_1)\frac{dS^\dagger(\sigma)}{d\sigma}\bigg|_{\sigma=z_1}\mathrm{Res}\,S(z_1).
\end{aligned} \tag{4.18}$$

In order to simplify this last expression we need two identities, the first of which is obtained by exploiting the unitarity of $S(\sigma)$ for real σ. Taking the derivative $\mathrm{d}/\mathrm{d}\sigma(S^\dagger(\sigma)S(\sigma))$ we can write

$$\frac{\mathrm{d}S^\dagger(\sigma)}{\mathrm{d}\sigma}=-S^\dagger(\sigma)\frac{\mathrm{d}S(\sigma)}{\mathrm{d}\sigma}S^\dagger(\sigma). \tag{4.19}$$

The second identity is obtained with the help of Eq. (4.1)

$$\mathrm{Res}\,S(z_1)=S(\sigma)S^\dagger(\sigma)\mathrm{Res}\,S(z_1)=\left(1-\frac{\mathrm{Res}\,S(z_1)}{\sigma-z_1}-\frac{\mathrm{Res}\,S(z_2)}{\sigma-z_2}\right)S^\dagger(\sigma)\mathrm{Res}\,S(z_1).$$

From this identity and Eq. (4.10) we get, for small values of $|\sigma-z_1|$,

$$\mathrm{Res}\,S(z_1)S^\dagger(\sigma)\mathrm{Res}\,S(z_1)\simeq-\mathrm{Res}\,S(z_1)(\sigma-z_1). \tag{4.20}$$

When Eqs. (4.19) and (4.20) are used in (4.18) we get

$$\begin{aligned}
&i\,\mathrm{Res}\,S(z_1)\frac{\mathrm{d}S^\dagger(\sigma)}{\mathrm{d}\sigma}\bigg|_{\sigma=z_1}\mathrm{Res}\,S(z_1)\\
&\quad=(-i)\lim_{\sigma\to z_1}\mathrm{Res}\,S(z_1)S^\dagger(\sigma)\frac{\mathrm{d}S(\sigma)}{\mathrm{d}\sigma}S^\dagger(\sigma)\mathrm{Res}\,S(z_1)\\
&\quad=-i\lim_{\sigma\to z_1}\mathrm{Res}\,S(z_1)S^\dagger(\sigma)\left(\frac{\mathrm{Res}\,S(z_1)}{(\sigma-z_1)^2}+\frac{\mathrm{Res}\,S(z_2)}{(\sigma-z_2)^2}\right)S^\dagger(\sigma)\mathrm{Res}\,S(z_1)
\end{aligned}$$

$$= -i \lim_{\sigma \to z_1} \frac{1}{(\sigma - z_1)^2} \operatorname{Res} S(z_1) S^\dagger(\sigma) \operatorname{Res} S(z_1) S^\dagger(\sigma) \operatorname{Res} S(z_1) = -i \operatorname{Res} S(z_1). \tag{4.21}$$

Making use of the results (4.21), (4.17) it is easy to verify Eq. (4.16) for $\psi_1(s)$. A similar calculation shows that $\psi_2(s)$ also satisfies Eq. (4.16).

A rational Lax–Phillips S matrix is a rational, operator valued inner function. Such an operator can be written as[25]

$$S(\sigma) = \frac{\sigma - \overline{z}_1 P_1}{\sigma - z_1 P_1} \frac{\sigma - \overline{z}_2 P_2}{\sigma - z_2 P_2}, \tag{4.22}$$

where $P_1 = |n_1\rangle\langle n_1|$ and $P_2 = |n_2\rangle\langle n_2|$ are projectors on one-dimensional subspaces of the auxiliary Hilbert space (we take $|n_1\rangle$ and $|n_2\rangle$ to be normalized and that, in general, $P_1 P_2 \neq 0$). This S matrix can be rewritten in a form corresponding to Eq. (4.1) as

$$S(\sigma) = 1 + \frac{1}{\sigma - z_1}\left[(z_1 - \overline{z}_1) P_1 \frac{z_1 - \overline{z}_2 P_2}{z_1 - z_2 P_2}\right] + \frac{1}{\sigma - z_2}\left[\frac{z_2 - \overline{z}_1 P_1}{z_2 - z_1 P_1}(z_2 - \overline{z}_2) P_2\right]. \tag{4.23}$$

From Eq. (4.23) we identify the two residues

$$\begin{aligned} \operatorname{Res} S(z_1) &= (z_1 - \overline{z}_1) P_1 \left(1 + \frac{z_2 - \overline{z}_2}{z_1 - z_2} P_2\right), \\ \operatorname{Res} S(z_2) &= \left(1 + \frac{z_1 - \overline{z}_1}{z_2 - z_1} P_1\right)(z_2 - \overline{z}_2) P_2. \end{aligned} \tag{4.24}$$

Inserting in (4.24) the expressions for P_1 and P_2 in terms of $|n_1\rangle$ and $|n_2\rangle$ we find

$$\begin{aligned} \operatorname{Res} S(z_1) &= (z_1 - \overline{z}_1)|n_1\rangle\left(\langle n_1| + \frac{z_2 - \overline{z}_2}{z_1 - z_2}\langle n_1|n_2\rangle\langle n_2|\right), \\ \operatorname{Res} S(z_2) &= \left(|n_2\rangle + \frac{z_1 - \overline{z}_1}{z_2 - z_1}|n_1\rangle\langle n_1|n_2\rangle\right)(z_2 - \overline{z}_2)\langle n_2|. \end{aligned} \tag{4.25}$$

The eigenvectors of the generator B of the semigroup, which we denote by $|\chi_1\rangle$ and $|\chi_2\rangle$, can now be immediately identified, in light of the remarks following Eq. (4.15), from Eq. (4.25),

$$\begin{aligned} |\chi_1\rangle &= \Theta(-s)(z_1 - \overline{z}_1)|n_1\rangle e^{iz_1 s}, \\ |\chi_2\rangle &= \Theta(-s)\left(|n_2\rangle + \frac{z_1 - \overline{z}_1}{z_2 - z_1}|n_1\rangle\langle n_1|n_2\rangle\right) e^{iz_2 s}. \end{aligned} \tag{4.26}$$

Once the residues of the S matrix and the eigenvectors $|\chi_1\rangle$, $|\chi_2\rangle$ are given explicitly in Eqs. (4.25) and (4.26) we can insert these expressions into Eq. (4.13) to achieve an explicit expression for the generator B of the semigroup. We find that

$$B = z_1 |\chi_1\rangle\langle\tilde{\chi}_1| + z_2 |\chi_2\rangle\langle\tilde{\chi}_2|, \tag{4.27}$$

where $\langle\chi_i|\chi_j\rangle = \delta_{ij}$ and

$$\langle\tilde{\chi}_1| = a_1\langle\chi_1| + b_1\langle\chi_2|,$$
$$\langle\tilde{\chi}_2| = a_2\langle\chi_1| + b_2\langle\chi_2| \tag{4.28}$$

with the coefficients a_1, b_1, a_2, b_2 given by

$$a_1 = |\langle n_1|n_2\rangle|^2 \frac{(z_1-\overline{z_2})(\overline{z_2}-z_2)}{z_1-z_2} + 1,$$
$$b_1 = \frac{\overline{z_2}-z_2}{z_1-z_2}\langle n_1|n_2\rangle,$$
$$a_2 = \frac{z_2-\overline{z_2}}{\overline{z_2}-\overline{z_1}}\langle n_2|n_1\rangle, \tag{4.29}$$
$$b_2 = \overline{z_2}-z_2.$$

Equation (4.27) has the diagonalized form of the Lee–Oehme–Yang–Wu phenomenological Hamiltonian in the subspace of the two resonance channel containing, in this case, the K^0 and $\overline{K^0}$ (or K_S, K_L) states. One sees from Eqs. (3.12) and (3.13) that the jump function containing the essential parameters of the S matrix in this subspace contain the matrix elements $\{f_{ij}\}$ of the perturbation. These transition matrix elements coincide in form with the quantities calculated in quantum field theoretical models for the vertex for neutral K meson decay. The theory that we have given here explains how the neutral K meson corresponds to a *state* in the quantum mechanical Hilbert space (even though it is relatively short-lived) with an exact semigroup decay law, as seen to high accuracy in experiment.[11]

V. DISCUSSION AND CONCLUSIONS

We have shown that the quantum mechanical formulation of Lax–Phillips theory for the description of resonances and decay[5] can be generalized to a system with a finite discrete set of resonances. If this set of resonances spans the unstable system subspace, the most general form of the S matrix is that of a rational inner function,[25] treated in detail in Sec. IV for the two-dimensional case.

The eigenstates corresponding to the poles of the S matrix are well-defined vectors in the full Hilbert space $\overline{H}$, and the left and right eigenvectors are orthogonal with respect to the scalar product of $\overline{H}$. They span a two-dimensional subspace of $\overline{H}$; the S matrix acts nontrivially on a two-dimensional subspace of the auxiliary space H for each value of the foliation parameter σ (independently of σ). This corresponds to an ideal form of ''resonance dominance.''

The relation between the eigenvectors of the generator of the semigroup in the space $\overline{H}$ and the vectors spanning the two-dimensional subspace of H is very simple [see Eq. (4.15)]. We are therefore able to construct a model completely within the two-dimensional subspace, containing an effective non-Hermitian generator of the semigroup, and a set of vectors in a two-dimensional space with scalar products taking the same value as the corresponding vectors in the full space. This two-dimensional (in general, N-dimensional) space and the generator of the semigroup acting on it coincides with the Lee–Oehme–Yang–Wu model. Moreover, as we have seen in the simple Lee model which we have studied here, the matrix elements of the model Hamiltonian are related to the perturbation formally in the same way as in the framework of the Wigner–Weisskopf model.

APPENDIX A

We show that $\Omega_\pm|V_i(\tilde{p})\rangle = 0$ applying the methods used in Sec. II. The procedure is explicitly performed for $\Omega_+|V_i(\tilde{p})\rangle = 0$. The result for $\Omega_-|V_i(\tilde{p})\rangle = 0$ is obtained in a similar way.

We start with the integral representation of the wave operator [see Eq. (2.10)]

$$\Omega_+ = 1 + i \lim_{\epsilon\to 0} \int_0^{+\infty} U^\dagger(\tau) V U_0(\tau) e^{-\epsilon\tau} \mathrm{d}\tau; \tag{A1}$$

applying this operator to $|V_i(\tilde{p})\rangle$ we get

$$\begin{aligned}\Omega_+ |V_i(\tilde{p})\rangle &= |V(\tilde{p})\rangle + i \lim_{\epsilon\to 0} \int_0^{+\infty} \mathrm{d}\tau\, U^\dagger(\tau) V U_0(\tau) e^{-\epsilon\tau} b_i^\dagger(\tilde{p})|0\rangle \\ &= |V_i(\tilde{p})\rangle - i \lim_{\epsilon\to 0} \int_0^{-\infty} \mathrm{d}\tau\, U(\tau) V e^{i(\omega_{V_i}(\tilde{p}) - i\epsilon)\tau} b_i^\dagger(\tilde{p})|0\rangle,\end{aligned} \tag{A2}$$

where $\omega_{V_i}(p) = p^2/2M_{V_i}$. As in Sec. II, we want to evaluate the time evolution in the integral and perform a Laplace transform. The result of the action of the potential operator, given in Eq. (2.8) to $|V_i(p)\rangle$, is

$$V|V_i(\tilde{p})\rangle = V b_i^\dagger(\tilde{p})|0\rangle = \sum_{j=1,2} \int \mathrm{d}^4k f_{ij}^*(k) a_{N_j}^\dagger(\tilde{p}-k) a_{\theta_j}^\dagger(k)|0\rangle. \tag{A3}$$

A general form of a state in the sector of the Fock space with $Q_1 = 1$, $Q_2 = 0$ is given in Eq. (2.20). From Eq. (A3) we find, at time $\tau = 0$,

$$A_j(q,0) = 0, \quad B_j(p,k,0) = f_{ij}^*(k)\,\delta^4(\tilde{p}-p-k). \tag{A4}$$

Defining the Laplace transformed coefficients $\tilde{A}_j(q,z)$ and $\tilde{B}_j(p,k,z)$ as in Eq. (2.18), we use Eq. (2.19) and the fact that in Eq. (A4) $A_j(q,0) = 0$ to obtain

$$\begin{aligned}\tilde{A}_l(p,z)\left(z - \frac{p^2}{2M_{V_l}}\right) &= \sum_{j=1,2} \int \mathrm{d}^4k f_{lj}(k) \tilde{B}_j(p-k,k,z), \\ \tilde{B}_l(p-k,k,z)\left(z - \frac{(p-k)^2}{2M_{N_l}} - \frac{k^2}{2M_{\theta_l}}\right) &= iB_l(p-k,k,0) + \sum_{j=1,2} f_{jl}^*(k)\tilde{A}_j(p,z).\end{aligned} \tag{A5}$$

Solving for $\tilde{A}_l(p,z)$ we get

$$\begin{aligned}\tilde{A}_l(p,z) &= i \sum_{i=1,2} W_{lk}^{-1}(z,p) \sum_{j=1,2} \int \mathrm{d}^4k \frac{f_{ij} B_j(p-k,k,0)}{z - \dfrac{(p-k)^2}{2M_{N_l}} - \dfrac{k^2}{2M_{\theta_l}}}, \\ \tilde{B}_l(p-k,k,z) &= \left(z - \frac{(p-k)^2}{2M_{N_l}} - \frac{k^2}{2M_{\theta_l}}\right)^{-1} \left[iB_l(p-k,k,0) + \sum_{j=1,2} f_{jl}^*(k)\tilde{A}_j(p,z)\right].\end{aligned} \tag{A6}$$

Inserting the initial condition for $B_l(p-k,k,0)$ from Eq. (A4) in Eq. (A6) we have

$$\begin{aligned}\tilde{A}_l(p,z) &= i\left[W_{li}^{-1}(p,z)\left(z - \frac{p^2}{2M_{V_i}}\right) - \delta_{li}\right]\delta^4(p-\tilde{p}), \\ \tilde{B}_l(p-k,k,z) &= \left(z - \frac{(p-k)^2}{2M_{N_l}} - \frac{k^2}{2M_{\theta_l}}\right)^{-1} \sum_{j=1,2} i f_{jl}^*(k) W_{ji}^{-1}(p,z)\left(z - \frac{p^2}{2M_{V_i}}\right)\delta^4(p-\tilde{p}).\end{aligned} \tag{A7}$$

Performing the Laplace transform of Eq. (2.15) implied by Eq. (A2), we use the coefficients from Eq. (A7) and evaluate the resulting expression at the point $z=\omega_{V_i}(\tilde{p})-i\epsilon=\tilde{p}^2/2M_{V_i}-i\epsilon$. This procedure gives the simple answer

$$\lim_{\epsilon\to 0}\int_0^{-\infty} d\tau\, U(\tau)Ve^{i(\omega_{V_i}(\tilde{p})-i\epsilon)}b_i^\dagger(\tilde{p})|0\rangle=-ib_i^\dagger(\tilde{p})|0\rangle=-i|V_i(\tilde{p})\rangle \tag{A8}$$

and this implies the desired result.

APPENDIX B

We prove here that the value taken by the projection valued function $P_{2,P}(\sigma)$ is actually a projection operator, for all values of σ, on a fixed two-dimensional subspace of the auxiliary Hilbert space of the Lax–Phillips representation of the relativistic Lee–Friedrichs model, this projection operator is denoted $P_{2,P}$, i.e., we prove that

$$P_{2,P}(\sigma)=P_{2,P}.$$

We start with the observation made at the begining of Sec. IV [see Eq. (4.1) and the discussion following it] that the operator valued function $P_{2,P}(\sigma)$, defined in Eq. (3.14) is a projection operator for each value of σ,

$$P_{n,P}(\sigma)P_{n,P}(\sigma)=P_{n,P}(\sigma). \tag{B1}$$

It is, therefore, a bounded positive operator on the real σ axis.

In order to proceed we need several definitions and results from the theory of operator valued functions. We denote the upper half plane of the complex σ plane by Π. If b is some separable Hilbert space, we denote by $\mathcal{B}(b)$ the set of bounded linear operators on b. We define the following sets of $\mathcal{B}(b)$ valued functions.[18]

Definition A:

(i) A holomorphic $\mathcal{B}(b)$ valued function $f(\sigma)$ on Π is of bounded type on Π if $\log^+|f(\sigma)|_{\mathcal{B}(b)}$ has a harmonic majorant on Π. The class of all such functions is denoted $N_{\mathcal{B}(b)}(\Pi)$.

(ii) If ϕ is any strongly convex function, then by $\mathcal{H}_{\phi,\mathcal{B}(b)}(\Pi)$ we mean the class of all holomorphic $\mathcal{B}(b)$ valued functions $f(\sigma)$ on Π such that $\phi(\log^+|f(z)|_{\mathcal{B}(b)})$ has a harmonic majorant on Π.

(iii) We define $N^+_{\mathcal{B}(b)}(\Pi)=\cup\mathcal{H}_{\phi,\mathcal{B}(b)}(\Pi)$, where the union is over all strongly convex functions ϕ.

(iv) By $H^\infty_{\mathcal{B}(b)}(\Pi)$ we mean the set of all bounded holomorphic $\mathcal{B}(b)$ valued functions on Π.

Here $\log^+ t=\max(\log t,0)$ for $t>0$ and $\log 0=-\infty$. The sets $N_{\mathcal{B}(b)}$ and $N^+_{\mathcal{B}(b)}$ are called Nevanlinna classes and $\mathcal{H}_{\phi,\mathcal{B}(b)}(\Pi)$ is a Hardy–Orlicz class.

We will need the following theorems and definitions:

Theorem A: The following

$$H^\infty_{\mathcal{B}(b)}(\Pi)\subseteq\mathcal{H}_{\phi,\mathcal{B}(b)}(\Pi)\subseteq N^+_{\mathcal{B}(b)}(\Pi)\subseteq N_{\mathcal{B}(b)(\Pi)}$$

is a valid sequence.

Definition B: Let u,v be nonzero scalar valued functions in $N^+(R)$ [$N^+(R)$ is the boundary function for a scalar Nevanlinna class function]. A $\mathcal{B}(b)$-valued function F on R is of class $\mathcal{M}(u_i,v_i)$ if $uF,vF^*\in N^+_{\mathcal{B}(b)}(R)$.

Definition C: If $A\in H^\infty_{\mathcal{B}(b)}(\Pi)$ then:

(i) A is an *inner function* if the operator

$$T(A):f\to Af,\quad f\in H^2_b(\Pi)$$

is a *partial isometry* on $H^2_b(\Pi)$;

(ii) A is an *outer function* if

$$\cup\{Af: f \in H_b^2(\Pi)\} = H_M^2(\Pi)$$

for some subspace M of b.

The main theorem which we will apply here is the following:

Theorem B: Let v be any nonzero scalar function in $N^+(R)$. If F is any nonnegative $\mathcal{B}(b)$-valued function of class $\mathcal{M}(v,v)$ on R then

$$F = G^* G$$

on R, where G is an outer function of class $\mathcal{M}(1,v)$ on R. The factorization of F is essentially unique.

As we have remarked previously, we have assumed that the functions $f_{ij}(k)$ of the Lee model are such that $S_P(\sigma)$ is an inner function. Since $P_{n,P}(\sigma)$ is a bounded operator then, from definition A(iv), the relation (3.14), and Theorem A, we see that

$$P_{n,P}(\sigma) \in N^+_{\mathcal{B}(H)}(\Pi),$$

where H is the auxiliary Hilbert space of the Lax–Phillips representation of the relativistic Lee–Friedrichs model, defined by the variables γ in Eq. (3.3) [or eqs. (3.5) and (3.6)]. Furthermore, the projection operator $P_{2,P}(\sigma)$ satisfies $(P_{2,P}(\sigma))^* = P_{2,P}(\sigma)$ and, from definition B we immediately have

$$P_{2,P}(\sigma) \in \mathcal{M}(1,1).$$

We can apply theorem B with the result that there is a unique decomposition of $P_{2,P}(\sigma)$,

$$P_{2,P}(\sigma) = G^* G = (P_{2,P}(\sigma))^* P_{2,P}(\sigma) = P_{2,P}(\sigma) P_{2,P}(\sigma)$$

and that $G = P_{2,P}(\sigma)$ is an *outer function*. We denote by P the operator on $H_H^2(\Pi)$ for which the realization is the operator valued function $P_{2,P}(\sigma)$. From definition C(ii) we therefore have

$$\{\cup Pf: f \in H_H^2(\Pi)\} = H_M^2(\Pi) \tag{B2}$$

where M is a subspace of the auxiliary Hilbert space H.

Now $P_{2,P}(\sigma)$ is a projection operator for each value of σ. We have that the range of $P_{2,P}(\sigma)$ is a two-dimensional subspace of the auxiliary Hilbert space H for each σ. We denote $M(\sigma) = \mathrm{Im}\, P_{2,P}(\sigma)$. Define

$$\hat{M} = \sum_{\sigma} M(\sigma).$$

For each vector valued function $f \in H_H^2(\Pi)$ we have

$$P_{2,P}(\sigma) f(\sigma) \in \hat{M}. \tag{B3}$$

Furthermore, there is no subspace of $\hat{M}$ that has the property (B3). Since $(Pf)(\sigma) = P_{2,P}(\sigma) f(\sigma) \in \hat{M}$ for $f \in H_H^2(\Pi)$ we must have

$$\{\cup Pf: f \in H_H^2(\Pi)\} = H_{\hat{M}}^2(\Pi). \tag{B4}$$

We conclude that $\hat{M}$ must be a two-dimensional subspace of the auxiliary Hilbert space H. If it has a higher dimension we consider two different values of σ, say $\sigma = \sigma_0$ and $\sigma = \sigma_1 \neq \sigma_0$, such that $P_{2,P}(\sigma_1) \neq P_{2,P}(\sigma_0)$. We then take a vector $v_0 \in P_{2,P}(\sigma_0)H, v_0 \in (P_{2,P}(\sigma_1)H)^\perp$, a scalar valued Hardy class function $g(\sigma) \in H^2(\Pi)$ and construct the vector valued function $j(\sigma)$

$=g(\sigma)v_0$. Clearly, $j \in H^2_{\hat{M}}(\Pi)$ [where we denote by j the vector valued function taking the value $j(\sigma)$ at the point σ] but $j \notin \{\cup Pf: f \in H^2_H(\Pi)\}$, since for any $f \in H^2_H(\Pi)$ we have $j(\sigma_1) = g(\sigma_1)v_0 \perp (Pf)(\sigma_1) = P_{2,P}(\sigma_1)f(\sigma_1)$. Therefore we have

$$\{Pf: f \in H^2_H(\Pi)\} \subset H^2_{\hat{M}}(\Pi) \tag{B5}$$

and we have a contradiction with Eq. (B3).

Since $\mathrm{Dim}\,\hat{M} = 2$ we must have $P_{2,P}(\sigma) = P_{2,P}(\sigma')$ for arbitrary σ and σ' and we may write

$$P_{2,P}(\sigma) = P_{2,P},$$

where $P_{2,P}$ is a projection operator on some fixed (independent of σ) two-dimensional subspace of H, which is the desired result.

(Received 2 October 2001; accepted for publication 30 January 2002)

Technical results are presented on motion in $N(>4)$D manifolds to clarify the physics of brane theory, Kaluza–Klein theory, induced-matter theory, and string theory. The so-called canonical or warp metric in five dimensions (5D) effectively converts the manifold from a coordinate space to a momentum space, resulting in a new force (per unit mass) parallel to the four-dimensional (4D) velocity. The form of this extra force is actually independent of the form of the metric, but for an unbound particle is tiny because it is set by the energy density of the vacuum or cosmological constant. It can be related to a small change in the rest mass of a particle, and can be evaluated in two convenient gauges relevant to gravitational and quantum systems. In the quantum gauge, the extra force leads to Heisenberg's relation between increments in the position and momenta. If the 4D action is quantized then so is the higher-dimensional part, implying that particle mass is quantized, though only at a level of 10^{-65} g or less, which is unobservably small. It is noted that massive particles which move on timeline paths in 4D can move on null paths in 5D. This agrees with the view from inflationary quantum field theory, that particles acquire mass dynamically in 4D but are intrinsically massless. A general prescription for dynamics is outlined, wherein particles move on null paths in an $N(>4)$D manifold which may be flat, but have masses set by an embedded 4D manifold which is curved. © *2002 American Institute of Physics.*

I. INTRODUCTION

The motion of a test particle in a higher-dimensional manifold is a prime way to investigate extensions of four-dimensional (4D) Einstein theory. In five-dimensional (5D) Kaluza-Klein theory, older studies concentrated on the case where the 4D space-time was independent of the extra coordinate.[1–6] This condition was relaxed in newer work on 5D induced-matter theory, where the 5D field equations for apparent vacuum are broken down into 4D ones with an energy–momentum tensor derived from the extra dimension.[7–15] Dynamical effects in 4D, when the metric is allowed to depend on one or more extra coordinates, have also become the subject of studies in string and membrane theory.[16–19] The main result is the appearance in 4D of extra forces.[16,20,21] These are expected to be small in gravitational problems, but could be significant in particle physics, where a unification of the interactions could be achieved via ten-dimensional superstrings or eleven-dimensional supergravity.[22,23] In view of current interest in the subject, some results will be given aimed at clarifying higher-dimensional dynamics.

II. GEODESICS IN *N* DIMENSIONS AND 4D

Consider an N-dimensional Riemannian manifold with a metric tensor g_{AB} that depends on coordinates x^C, with a line element $dS^2 = g_{AB}dx^A dx^B$, through which a particle moves along a path described by an affine parameter λ. It contains a 4D submanifold with line element $ds^2 = g_{\alpha\beta}dx^\alpha dx^\beta$. Here and in the following it is instructive to concentrate on the 5D case, when Latin indices run from 0 to 4 and Greek indices run from 0 to 3.

a)Electronic mail: wesson@astro.uwaterloo.ca

In general relativity, the particle moves along a geodesic which minimizes s via $\delta[\int \mathrm{d}s] = 0$. For a particle with mass m, $\lambda = s$ is normally chosen, the geodesic is non-null, and the four-momentum is defined by $p^\alpha \equiv m u^\alpha$, where the four-velocity is $u^\alpha \equiv \mathrm{d}x^\alpha/\mathrm{d}s$. For a massless particle (photon), λ is often unspecified because the geodesic is null and can be obtained directly from the metric. The four-velocities are conventionally normalized for non-null and null paths via $u^\alpha u_\alpha = 1, 0$, respectively. However, S contains s, and the former defines geodesics via $\delta[\int \mathrm{d}S] = 0$.

A question which arises in the literature is whether the particle should follow a geodesic in ND or in 4D (in brane theory, this is connected with whether the particle is constrained to move on the brane or can wander through the bulk). The answer is that it is most natural to assume that the motion is geodesic in S, provided that the extra terms which then appear in the geodesic in s are compatible with observation (see the following). In this regard, it should be recalled that even in 4D the acceleration of the particle $\mathrm{d}^2x^\alpha/\mathrm{d}s^2$ is *not* a covariantly defined vector. The appropriate quantity is the absolute or covariant derivative, which defines the path via $Du^\alpha/\mathrm{d}s \equiv \mathrm{d}u^\alpha/\mathrm{d}s + \Gamma^\alpha_{\beta\gamma} u^\beta u^\gamma = 0$, where $\Gamma^\alpha_{\beta\gamma}$ are the Christoffel symbols. It is the latter which yield the forces on the particle, which are thereby recognized as being inertial in origin, meaning that they arise from the motion of the reference frame. In ND, the same philosophy should hold. We can use $\delta[\int \mathrm{d}S] = 0$, and the absolute derivative or the Lagrange equations to obtain the dynamics, but the latter will in general contain terms which arise from the motion with respect to the larger reference frame.

The only comment which needs to be added to this concerns the case of null geodesics with $\mathrm{d}S = 0$. This has been considered by several workers.[1,14,24,25] It should be recalled that 4D causility is defined by $\mathrm{d}s^2 \geqslant 0$, and does not constrain $\mathrm{d}S^2$.[5] There is no impediment to assuming that particles with $m \neq 0$ move along paths with $\mathrm{d}S^2 = 0$, when their motions can be described consistently by choosing $\lambda = s$.

There is, however, another issue which relates to geodesics and requires notice. Geodesics in general relativity really describe accelerations, not forces or changes in momentum. The distinction is often unnecessary, because the mass is constant. But even in Newtonian mechanics, a rocket changes mass as its fuel burns, feeling a force along the direction of its motion. And in inflationary quantum field theory, particles are intrinsically massless, gaining mass by a dynamical mechanism involving the Higgs field.[26] As noted occasionally in the literature,[27] the correct dynamics in situations where the mass changes, follows not from $\delta[\int \mathrm{d}s] = 0$ but from $\delta[\int m\,\mathrm{d}s] = 0$. That is, dynamics is a theory not of four-velocities but of four-momenta. In this regard, it should be noted that there is no *contradiction* between the normalization condition used in relativity for the four-velocities $u^\alpha u_\alpha = 1$, and the condition used in particle physics for the four-momenta $p^\alpha p_\alpha = m^2$. (The latter is often written $E^2 - p^2 = m^2$ and effectively uses the energy and three-momentum to define the rest mass of a particle.) It is just that the conventional geodesic does not give any information about the origin or variability of mass, a problem which is of central importance in cosmology.

The subjects of the preceding paragraphs, while perhaps familiar, underlie much of the recent work which has been done on higher-dimensional dynamics.[1–27] While it is not exclusive, we wish to concentrate in the following on an approach which resolves most of the issues raised previously.[7–16] Specifically, we wish to present new results on metrics of the so-called canonical or warp type in 5D (the extension to $N > 5$ is straightforward). This has line element

$$\mathrm{d}S^2 = \frac{\ell^2}{L^2} g_{\alpha\beta}(x^\gamma, \ell)\,\mathrm{d}x^\alpha\,\mathrm{d}x^\beta - \mathrm{d}\ell^2, \tag{2.1}$$

where $x^4 = \ell$ is the extra coordinate and L is a constant length. Certain things are already known about this metric, and certain others may be deduced from the comments made previously. It is convenient to list these here. (a) Mathematically (2.1) is general, insofar as the five available coordinate degrees of freedom have been used to set $g_{4\alpha} = 0$, $g_{44} = -1$. Physically, this removes the potentials of electromagnetic type and flattens the potential of scalar type. (b) The metric (2.1)

has been extensively used in the field equations, which in terms of the Ricci tensor are $R_{AB}=0$, and many solutions are known.[14] These include solutions for the one-body problem[28] and cosmology[29] which have acceptable dynamics, and solutions with the opposite sign for g_{44} which describe waves.[30] (c) When $\partial g_{\alpha\beta}/\partial\ell=0$ in (2.1), the 15 field equations $R_{AB}=0$ contain as a subset the 10 field equations of general relativity, which in terms of the Einstein tensor are $G_{\alpha\beta}=3g_{\alpha\beta}/L^2$. The scale L is thereby identified, in cosmology, in terms of the cosmological constant via $\Lambda=3/L^2$ and in other situations as the characteristic size of the four-space.[12] (d) This kind of local embedding of a 4D Riemann space in a 5D Ricci-flat space can be applied to any N, and is guaranteed by Campbell's theorem.[31–35] (e) The factorization in (2.1) says in effect that the 4D part of the 5D interval is $(\ell/L)\mathrm{d}s$, which defines a *momentum* space rather than a *coordinate* space if ℓ is related to m.[8] This resolves the issue of forces versus accelerations noted previously. (f) Partial confirmation of this comes from a study of the 5D geodesic and a comparison of the constants of the motion in 5D and 4D.[14,36,37] In the Minkowski limit, the energy of a particle moving with velocity v is $E=\ell(1-v^2)^{-1/2}$ in 5D, which agrees with the expression in 4D if $\ell=m$. (g) The five components of the geodesic equation for (2.1) split naturally into four space–time components and an extra component. For $\partial g_{\alpha\beta}/\partial\ell\neq 0$, the former contain terms parallel to the four-velocity u^α as noted previously for the case of a rocket.[12,37] For $\partial g_{\alpha\beta}/\partial\ell=0$, the motion is not only geodesic in 5D but geodesic in 4D.

III. THE NATURE OF THE CANONICAL METRIC

The metric (2.1) is not mathematically unique but is physically rich, which prompts a deeper examination of its nature.

Consider a 4D space with $\mathrm{d}s^2=g_{\alpha\beta}\mathrm{d}x^\alpha\mathrm{d}x^\beta$ embedded in a 5D space with line element

$$\mathrm{d}S^2=\mathrm{d}s^2-\mathrm{d}\ell^2. \tag{3.1}$$

Then the transformation

$$\begin{aligned} s&\to\ell\sinh\ (s/L),\\ \ell&\to\ell\cosh\ (s/L), \end{aligned} \tag{3.2}$$

causes (2.1) to become

$$\mathrm{d}S^2=\frac{\ell^2}{L^2}\mathrm{d}s^2-\mathrm{d}\ell^2. \tag{3.3}$$

This is of the canonical form, which is therefore recognized to be a spherical form of a two-plane (the opposite sign for g_{44} may be obtained by replacing the hyperbolic functions by their trigonometric counterparts). Physically, there is an analogy with the angular momentum (per unit mass) of a particle rv moving with velocity v at distance r from the center of a circle. Recalling from the previous discussion that ℓ plays the role of m in the canonical metric, we see that mu^α is the product of the velocity in 4D with the distance in the orthogonal fifth direction. In other words, p^α is a true 5D moment.

The above suggests that physically significant 4D structure may even be present in a flat 5D manifold. The latter in spherical polars has line element

$$\mathrm{d}S^2=\mathrm{d}t^2-\mathrm{d}r^2-r^2\,\mathrm{d}\Omega^2-\mathrm{d}\ell^2, \tag{3.4}$$

where $\mathrm{d}\Omega^2\equiv(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\phi^2)$. Introducing a dimensionless parameter α, consider the transformation

$$t \to \left(\frac{\alpha}{2}\right) t^{1/\alpha} \ell^{1/(1-\alpha)} \left(1 + \frac{r^2}{\alpha^2}\right) - \frac{\alpha}{2(1-2\alpha)} [t^{-1} \ell^{\alpha/(1-\alpha)}]^{(1-2\alpha)/\alpha},$$

$$r \to r t^{1/\alpha} \ell^{1/(1-\alpha)}, \tag{3.5}$$

$$\ell \to \left(\frac{\alpha}{2}\right) t^{1/\alpha} \ell^{1/(1-\alpha)} \left(1 - \frac{r^2}{\alpha^2}\right) + \frac{\alpha}{2(1-2\alpha)} [t^{-1} \ell^{\alpha/(1-\alpha)}]^{(1-2\alpha)/\alpha}$$

with $\theta \to \theta$, $\phi \to \phi$. Then some algebra shows that (3.4) becomes

$$dS^2 = \ell^2 \, dt^2 - t^{2/\alpha} \ell^{2/(1-\alpha)} (dr^2 + r^2 \, d\Omega^2) - \alpha^2 (1-\alpha)^{-2} t^2 \, d\ell^2. \tag{3.6}$$

This is the metric of a class of cosmological models first found as solutions of the field equations $R_{AB} = 0$ by Ponce de Leon.[38] They are separable in ℓ, t and reduce to the 4D Friedmann–Robertson–Walker models with flat three-dimensional sections on the hypersurfaces ℓ = constant. (The dust or Einstein–de Sitter solution has $\alpha = 3/2$ while the radiation solution has $\alpha = 2$.) For this reason they are often regarded as the standard 5D cosmologies, but (3.5) shows that they are actually canonical forms of 5D Minkowski space.

The same cannot be said of the standard one-body solution of $R_{AB} = 0$.[28] This has the line element

$$dS^2 = \frac{\Lambda \ell^2}{3} \left\{ \left[1 - \frac{2M}{r} - \frac{\Lambda r^2}{3} \right] dt^2 - \left[1 - \frac{2M}{r} - \frac{\Lambda r^2}{3} \right]^{-1} dr^2 - r^2 \, d\Omega^2 \right\} - d\ell^2, \tag{3.7}$$

where M is a constant usually identified with the mass at the center of the three-geometry. Metric (3.7) is pure canonical in the sense that it has the form (2.1) with $\Lambda = 3/L^2$ and $\partial g_{\alpha\beta} / \partial \ell = 0$. However, it is not 5D flat like (3.6), as may be verified by computer. This agrees with the well-known fact that the 4D Schwarzschild–de Sitter solution [given by the part inside the large brackets in Eq. (3.7)] can only be embedded in a flat space with dimension $N \geqslant 6$. However, since any 4D solution can be embedded in $N \geqslant 10$, the use of the canonical form obviously has relevance to superstring theory.

The field equations $R_{AB} = 0$ mentioned previously clearly contain physical information which is relevant to why the canonical metric (2.1) is so effective. These fifteen relations can in general be broken down into one wave equation, four conservation equations, and ten Einstein equations $G_{\alpha\beta} = 8\pi T_{\alpha\beta}$ with an effective or induced energy–momentum tensor.[39] However, only the last quantity contains u^α, and via the 4D covariant derivative $T^{\alpha\beta}{}_{;\beta} = 0$ is usually interpreted as describing the dynamics of a fluid consisting of particles. We will return to the field equations later, but let us here take a look at particle dynamics.

This subject has been studied using both the geodesic equation[7,8] and the Lagrange equations.[12,15] These approaches are compatible, of course, but the latter is the more instructive for investigating the special status of (2.1). Thus consider a Lagrangian which generalizes (2.1) and has the form

$$\mathcal{L} = \left\{ \frac{\ell^2}{L^2} g_{\alpha\beta}(x^\gamma, \ell) \frac{dx^\alpha}{d\lambda} \frac{dx^\beta}{d\lambda} - \Phi^2(x^\gamma, \ell) \left(\frac{d\ell}{d\lambda}\right)^2 \right\}^{1/2}. \tag{3.8}$$

This is dimensionless, and contains a scalar field $g_{44} = -\Phi^2$ which is the classical analog of the Higgs potential that is responsible for particle masses in quantum field theory.[14,26] The Lagrangian (3.8) defines an action $I = \int \mathcal{L}(x^A, \dot{x}^A) \, d\lambda$, where λ is an affine parameter along the path of the particle and $\dot{x}^A \equiv dx^A/d\lambda$ is its five-velocity. The action is an extremum if

$$\frac{d}{d\lambda} \left(\frac{\partial \mathcal{L}}{\partial \dot{x}^A} \right) - \frac{\partial \mathcal{L}}{\partial x^A} = 0. \tag{3.9}$$

The space–time and extra components of this can be worked out explicitly once λ is chosen. A natural choice might appear to be $\lambda = S$,[8] in which case (3.9) is equivalent to

$$\frac{dU^A}{dS} + \Gamma^A_{BC} U^B U^C = 0, \tag{3.10}$$

the 5D geodesic equation in $U^A \equiv dx^A/dS$ with appropriately defined Christoffel symbols (see Sec. II). However, this is undefined for 5D null geodesics, and if another affine parameter λ is used instead then (3.10) acquires an extra term on the right-hand side equivalent to $U^A \mathcal{L}^{-1} d\mathcal{L}/d\lambda$.[40] Also, the object of the exercise is to understand 4D dynamics in $u^\alpha \equiv dx^\alpha/ds$ rather than 5D dynamics in $U^A \equiv dx^A/dS$. For these reasons, we choose $\lambda = s$.[7,12,15] We also choose $u_\alpha u^\alpha = 1$ for a massive particle following a timelike 4D path. Then the substitution of (3.8) into (3.9) results in two rather complicated expressions for the α, four components of the motion, of which the second is the more enlightening:

$$\frac{\ell}{\Phi^2}\left(\frac{\Phi^2 \dot{\ell}}{\ell}\right)^{\cdot} - \frac{L^2 \Phi \dot{\Phi} \dot{\ell}^3}{\ell^2} - \frac{1}{L\Phi}\left(1 - \frac{L^2 \Phi^2 \dot{\ell}^2}{\ell^2}\right)\left(1 + \frac{\ell u^\alpha u^\beta}{2}\frac{\partial g_{\alpha\beta}}{\partial \ell} - \frac{L^2 \Phi \dot{\Phi} \dot{\ell}^2}{\ell}\right) = 0. \tag{3.11}$$

Remarkably, this is satisfied with no constraint on the last parentheses by $(L\Phi\dot{\ell}/\ell)^2 = 1$, which by (3.8) implies $\mathcal{L} = 0$. That is, the particle is traveling along a timelike path in 4D but a null path in 5D.

We end this section by stating explicitly the equations of motion which follow from (3.9) or (3.10). The space–time components can be written as a part which is geodesic in s and an extra part:

$$\frac{du^\mu}{ds} + \Gamma^\mu_{\beta\gamma} u^\beta u^\gamma = F^\mu, \tag{3.12}$$

$$F^\mu \equiv \left(-g^{\mu\alpha} + \frac{u^\mu u^\alpha}{2}\right) u^\beta \frac{\partial g_{\alpha\beta}}{\partial \ell}\frac{d\ell}{ds}. \tag{3.13}$$

Here F^μ is a force per unit (inertial) mass, or acceleration. It can be written as a sum of components normal and parallel to u^μ, so $F^\mu = N^\mu + P^\mu$ where

$$N^\mu = (-g^{\mu\alpha} + u^\mu u^\alpha) u^\beta \frac{\partial g_{\alpha\beta}}{\partial \ell}\frac{d\ell}{ds}, \tag{3.14}$$

$$P^\mu = \frac{-u^\mu}{2}\left(u^\alpha u^\beta \frac{\partial g_{\alpha\beta}}{\partial \ell}\right)\frac{d\ell}{ds}. \tag{3.15}$$

The normal component obeys $N^\mu u_\mu = 0$ (by construction), which is the behavior typical of Einstein gravity and Maxwell electromagnetism.[12,14] The parallel component obeys

$$P^\mu u_\mu = \frac{-u^\alpha u^\beta}{2}\frac{\partial g_{\alpha\beta}}{\partial \ell}\frac{d\ell}{ds} \equiv \beta. \tag{3.16}$$

Here the four-velocities are still normalized via $u^\alpha u_\alpha = 1$ (see above and Sec. IV). But the scalar quantity β is finite if $\partial g_{\alpha\beta}/\partial \ell \neq 0$ in the canonical metric (2.1), and there is motion in the extra dimension as measured with the particle's proper 4D time s. The quantity β is a kind of power per unit (inertial) mass. *It has no analog in standard 4D field theory*. The magnitude of β depends on $d\ell/ds$, which is given by the extra component of the equation of motion:

$$\frac{d^2\ell}{ds^2}-\frac{2}{\ell}\left(\frac{d\ell}{ds}\right)^2+\frac{\ell}{L^2}=-\frac{1}{2}\left[\frac{\ell^2}{L^2}-\left(\frac{d\ell}{ds}\right)^2\right]u^\alpha u^\beta\frac{\partial g_{\alpha\beta}}{\partial\ell}. \tag{3.17}$$

This implies that there is no intrinsic state of rest for the particle in the extra dimension. [Formally, Eq. (3.17) is satisfied with $\ell=\ell_0$, $u^{123}=0$, $u^0=1$, and $g_{\alpha\beta}=L^2/\ell_0^2$, but then $d\ell=0$ and the metric reverts to a 4D one.] This is basically because the 4D proper time has been used as a parameter for the 5D motion. Thus in general, $d\ell/ds\neq 0$ in (3.17), $\partial g_{\alpha\beta}/\partial\ell\neq 0$ in (2.1), and $\beta\neq 0$ in (3.16). The existence of finite scalar quantities like β is expected to be typical of the dynamics of any $N(>4)$-dimensional theory.

IV. EXTRA FORCES IN $N(>4)$D THEORY

In Sec. II, it was noted that the word ''force'' has to be treated with some caution, because theories like general relativity describe accelerations while theories of particle physics describe momenta, and the two concepts can only be consistently joined via a suitable definition of mass. The canonical metric (2.1) opens a route to this, as well as providing a number of other interesting results. In Sec. III, it was seen that the effectiveness of the canonical metric can be traced partly to the fact that it is an algebraically convenient way to parametize a 5D manifold, but mainly to the fact that it is a natural basis for 5D dynamics. In the present section we wish to go beyond the canonical metric and note some general results on forces.

It is straightforward to see that any $N(>4)$D theory will yield extra accelerations as viewed in 4D, which modulo an appropriate definition of mass will be interpreted as extra forces.[16,20,21] Given an ND line element $dS^2=g_{AB}dx^Adx^B$, the N velocities $u^A\equiv dx^A/dS$ are normalized for a non-null path via $U^AU_A=1$, and the path is extremized in terms of an ND covariant derivative via $U^BU^A{}_{;B}=0$. This when contracted gives $U_AF^A=0$, where the F^A are forces per unit (inertial) mass. However, this implies $U_\alpha F^\alpha=-U_{(N-\alpha)}F^{(N-\alpha)}\neq 0$ when viewed from 4D.

To relate this to what was done in Sec. III, consider one extra coordinate and the normalization condition

$$g_{\alpha\beta}(x^\gamma,\ell)u^\alpha u^\beta=1. \tag{4.1}$$

Differentiating this with respect to an affine parameter λ gives

$$g_{\alpha\beta,\gamma}\ u^\gamma u^\alpha u^\beta+\frac{\partial g_{\alpha\beta}}{\partial\ell}\frac{d\ell}{d\lambda}u^\alpha u^\beta+2g_{\alpha\mu}\frac{du^\mu}{d\lambda}u^\alpha=0, \tag{4.2}$$

where $u^\alpha\equiv dx^\alpha/d\lambda$ and $g_{\alpha\beta,\gamma}\equiv\partial g_{\alpha\beta}/\partial\ell$. Introducing the Christoffel symbols and noting symmetries under the exchange of α and β, the first term on the left-hand side of (4.2) can be rewritten using

$$(g_{\alpha\beta,\gamma}+g_{\alpha\gamma,\beta}-g_{\beta\gamma,\alpha})u^\gamma u^\alpha u^\beta=2g_{\alpha\mu}\Gamma^\mu_{\beta\gamma}u^\gamma u^\alpha u^\beta. \tag{4.3}$$

Then (4.2) reads

$$2g_{\alpha\mu}u^\alpha\left(\frac{du^\mu}{d\lambda}+\Gamma^\mu_{\beta\gamma}\ u^\beta u^\gamma\right)+\frac{\partial g_{\alpha\beta}}{\partial\ell}\frac{d\ell}{d\lambda}u^\alpha u^\beta=0. \tag{4.4}$$

With $F^\mu\equiv(du^\mu/d\lambda+\Gamma^\mu_{\beta\gamma}u^\beta u^\gamma)$ as in (3.12) this says

$$u_\mu F^\mu=-\frac{u^\alpha u^\beta}{2}\frac{\partial g_{\alpha\beta}}{\partial\ell}\frac{d\ell}{d\lambda}. \tag{4.5}$$

There is clearly a force per unit (inertial) mass parallel to u^μ given by

$$P^\mu = -\frac{u^\mu}{2}\left(u^\alpha u^\beta \frac{\partial g_{\alpha\beta}}{\partial \ell}\right)\frac{d\ell}{d\lambda}. \tag{4.6}$$

When $\lambda = s$ this is identical to (3.15), which was derived starting from the canonical metric (2.1). But here, we started from the normalization condition (4.1) for a massive particle following a 4D timelike path. This means that the existence of (4.6) does not depend on the form of the metric. It is a consequence of defining and normalizing four-velocities in the conventional way when space–time is part of a bigger manifold.

Given the manner in which 4D dynamics is conventionally set up, it is difficult to conceive of any way in which a force parallel to the four-velocity could be interpreted other than by relating it to the mass of the particle which feels it. For a particle moving under the influence of standard gravity and the extra force, the equation of motion in space–time is

$$\frac{du^\mu}{ds} + \Gamma^\mu_{\alpha\beta}\ u^\alpha u^\beta = P^\mu \tag{4.7}$$

with P^μ given by (4.6) with $\lambda = s$. In the following, we will consider some significant applications of (4.7). Here, as an illustration, we can take a canonical metric with $g_{\alpha\beta} = (\ell^2/L^2)\,\eta_{\alpha\beta}$ where $\eta_{\alpha\beta}$ = diagonal $(1,-1,-1,-1)$. Then $\partial g_{\alpha\beta}/\partial\ell = (2/\ell) g_{\alpha\beta}$ and $u^\alpha u^\beta \partial g_{\alpha\beta}/\partial\ell = 2/\ell$ in (4.6). The equation of motion (4.7) reads

$$\frac{du^\mu}{ds} = -\frac{u^\mu}{\ell}\frac{d\ell}{ds}, \tag{4.8}$$

which yields $\ell u^\mu = \ell_0$ where ℓ_0 is a constant of the (4D) motion. The latter is clearly the momentum mu^μ, confirming that in canonical coordinates the extra coordinate plays the role of particle mass. [See Sec. II and Refs. 8, 12, 14 and 15. Equation (4.8) is the analog of what is sometimes called the rocket equation in Newtonian mechanics, which just says that $d(mv)/dt = 0$ or $dv/dt = -(v/m)dm/dt$.] However, while $p^\mu = mu^\mu$ is a constant of the 4D motion, it should be noted that $m = m(s)$ in general.

This cannot be fixed in the conventional approach to 4D dynamics, except by appeal to some external condition. But in 5D dynamics it can, notably by the extra component of the geodesic (3.17). This in general requires a solution of the field equations, but as noted in Sec. III a natural parametrization of 5D geodesics is via $dS = 0$. Then for the canonical metric (2.1) we have

$$dS^2 = 0 = \frac{\ell^2}{L^2}ds^2 - d\ell^2, \tag{4.9}$$

which yields

$$\ell = \ell_0 e^{\pm s/L}. \tag{4.10}$$

The rate of variation of ℓ depends on the characteristic dimension of the four-space L. As noted in Sec. II, for pure-canonical metrics with $\partial g_{\alpha\beta}/\partial\ell = 0$, $L = (3/\Lambda)^{1/2}$, where Λ is the cosmological constant.[12,14] Thus from (4.10), with the identification $\ell = m$, the rate of variation of the rest mass is given by

$$\frac{1}{m}\left|\frac{dm}{ds}\right| \simeq \frac{1}{m}\left|\frac{dm}{dt}\right| = \left(\frac{\Lambda}{3}\right)^{1/2}. \tag{4.11}$$

The value of Λ is severely constrained by astrophysical data.[41–43] These indicate $|\dot{m}|/m \lesssim 2 \times 10^{-18}\ \mathrm{s}^{-1}$ by (4.11), which is observationally acceptable. There are also other constraints on extra forces like (4.6), but these are relatively weak.[44] However, it should be noted that Λ mea-

sures the energy density of the vacuum in general relativity,[14] and this could be larger on small scales,[26] so in principle mass variation and extra forces could be measured.

To do this in practice, though, requires solutions of the field equations. These in turn require the specification of a system of coordinates or gauge. In this context, it should be noted that the extra force P^μ of (4.6) for the 5D case is a four-vector. As such, it is covariant under the usual group of 4D coordinate transformations $x^\mu \rightarrow x^\mu(x^\nu)$, but will in general change under the group of 5D coordinate transformations $x^A \rightarrow x^A(x^B)$. This is inevitable given that the field equations $R_{AB}=0$ are covariant in 5D, but may represent a problem regarding the interpretation of observations made in 4D. This problem will be greater in the (algebraically straightforward) extension of the results of this section to $N(>5)$D. There is a considerable relevant literature on gauges.[14,22,23,45,46] Fortunately, if attention is restricted to dynamics there are only two natural gauges, to which we now turn our attention.

V. THE EINSTEIN AND PLANCK GAUGES

It has been seen that the pure canonical gauge, namely (2.1) with a factor ℓ^2 attached to an ℓ-independent space–time, is remarkably successful as a basis for conventional 4D dynamics. This is because the use of $\ell=m$ effectively converts the 4D part of the 5D manifold from a coordinate space to a momentum space. However, that success concerns the classical concept of momentum as the product of mass and velocity. In modern quantum field theory the mass of a particle is not defined *a priori*,[26] and even in old quantum theory the momentum is described by a de Broglie wave and derived from a wave function. A superior formulation of dynamics ought to address both the classical and quantum nature of momentum. In this section, we will assume that the differences in description are due to differences in gauge choices for a higher-dimensional metric, and narrow the choices for the gauges using field equations.

The latter are still the subject of discussion in ND field theory, but in 5D there is a consensus that they are given by the Ricci tensor as

$$R_{AB}=0 \quad (A,B=0,1,2,3,4). \tag{5.1}$$

Let us consider these for a generalized form of the pure canonical metric (2.1) with line element

$$dS^2=\left(\frac{L}{\ell}\right)^{2a}\overline{g}_{\alpha\beta}(x^\gamma)dx^\alpha dx^\beta-\left(\frac{L}{\ell}\right)^{4b}d\ell^2. \tag{5.2}$$

Here a, b are constants which it is desired to constrain using (5.1). These fifteen, 5D relations can be decomposed into 4D ones under only the four coordinate conditions $g_{\alpha 4}=0$.[39] For (5.2) it is convenient to take the components in the order $AB=44$, 4α, $\alpha\beta$. The result is

$$a^2-2ab+a=0, \tag{5.3}$$

$$V^\beta_{\alpha;\beta}=0,$$
$$V^\beta_\alpha \equiv \frac{1}{2|g_{44}|^{1/2}}\left(g^{\beta\sigma}\frac{\partial g_{\sigma\alpha}}{\partial\ell}-\delta^\beta_\alpha g^{\mu\nu}\frac{\partial g_{\mu\nu}}{\partial\ell}\right)=\frac{3a\,\delta^\beta_\alpha}{\ell}\left(\frac{\ell}{L}\right)^{2b}, \tag{5.4}$$

$$G_{\alpha\beta}=\frac{(2a^2+2ab-a)}{\ell^2}\left(\frac{L}{\ell}\right)^{2a-4b}\overline{g}_{\alpha\beta}. \tag{5.5}$$

Here a semicolon denotes the usual 4D covariant derivative, $g_{\alpha\beta}=(L/\ell)^{2a}\overline{g}_{\alpha\beta}$, $g_{44}=-(L/\ell)^{4b}$ and indices have been raised and lowered using $g_{\alpha\beta}$ in order to get the 4D Einstein tensor. This in mixed form is $G^\beta_\alpha=(2a^2+2ab-a)\ell^{-2}(\ell/L)^{4b}\delta^\beta_\alpha$, and as usual $G^\beta_\alpha \equiv R^\beta_\alpha - R\delta^\beta_\alpha/2$ in terms of the 4D Ricci tensor and Ricci scalar. The latter may be found by direct calculation, and is

$$R=\frac{-12a^2}{\ell^2}\left(\frac{\ell}{L}\right)^{4b}. \tag{5.6}$$

This determines the curvature of the 4D part of the manifold, which by (5.5) has the form of a vacuum space with an effective cosmological constant $\Lambda=(2a^2+2ab-a)\ell^{-2}(L/\ell)^{2a-4b}$. This is zero for $a=b=0$, in which case (5.2) describes general relativity embedded in a flat and physically innocuous extra dimension. For $a=-1$, $b=0$ we have $\Lambda=3/L^2$, and (5.2) is the pure canonical metric already discussed. Interestingly, the same value of Λ results for $a=+1$, $b=+1$, which implies that (5.5) would give the same 4D physics even though the metric (5.2) does not have the canonical form. We will return to this later. Here we note that the 4D physics is contained in the ten Einstein equations (5.5), while the four conservation equations (5.4) are satisfied, and the one scalar relation (5.3) provides a constraint between the constants a, b. In this regard it should be noted that the relation $G=-R$ (which follows from the definition of the Einstein tensor), when combined with (5.6) reproduces (5.3), which is the only meaningful constraint.

The comments of the preceding paragraph imply that (5.2) as constrained by (5.3) contains interesting physics in (5.5). For example, the fact that the 4D cosmological constant depends in general on 5D parameters opens the way to a resolution of the conflict in its size as inferred from cosmology and particle physics.[47–49] However, it is apparent that for dynamics there are two natural gauges, namely those with $a=-1$, $b=0$ and $a=+1$, $b=+1$. For these (5.2) has the forms

$$dS^2=\frac{\ell^2}{L^2}\overline{g}_{\alpha\beta}(x^\gamma)dx^\alpha dx^\beta-d\ell^2, \tag{5.7}$$

$$dS^2=\frac{L^2}{\ell^2}\overline{g}_{\alpha\beta}(x^\gamma)dx^\alpha dx^\beta-\frac{L^4}{\ell^4}d\ell^2. \tag{5.8}$$

Mathematically, these are equivalent since (5.7)$\rightarrow$(5.8) under the simple coordinate transformation

$$\ell\rightarrow L^2/\ell. \tag{5.9}$$

Physically, this corresponds to changing the way the rest mass of a particle is described. We saw previously that for the pure canonical metric the dynamics implies the identification $\ell=m$. Let us restore physical units for the speed of light c, the gravitational constant G, and Planck's constant h. Then (5.7) corresponds to the shift from gravitational ''units,'' to quantum ''units,'' where the extra coordinate in (5.7), (5.8) is given, respectively, by

$$\ell=\frac{Gm}{c^2},\quad \ell=\frac{h}{mc}. \tag{5.10}$$

There is nothing really fundamental about the presence of the dimensional constants here. Dimensional analysis is an elementary group-theoretic technique based on the Pi theorem.[50–52] The purpose of c, G, and h in (5.10) is merely to transpose the dimensions of mass to length so that it can be geometrized. And since the dimensions of these quantities are LT^{-1}, $M^{-1}L^3T^{-2}$, and ML^2T^{-1} and are not degenerate,[51] they can all be set to unity as is the common practice. This said, it is convenient to rename the pure canonical metric (5.7) the Einstein gauge and its other form (5.8) the Planck gauge.

The dynamics in these gauges can be studied for (5.7) by using (3.12)–(3.17), and for both (5.7) and (5.8) by using (4.6) and (4.7). As an illustration, let us revisit the short calculation which

led to (4.8) but now in both gauges. That is, we take $g_{\alpha\beta}=(L/\ell)^{2a}\eta_{\alpha\beta}$ so $\partial g_{\alpha\beta}/\partial\ell=-(2a/\ell)g_{\alpha\beta}$ and $u^\alpha u^\beta\partial g_{\alpha\beta}/\partial\ell=-2a/\ell$, which causes the 4D equation of motion (4.7) with the parallel force (4.6) to read

$$\frac{du^\mu}{ds}=P^\mu=-\frac{u^\mu}{2}\left(u^\alpha u^\beta\frac{\partial g_{\alpha\beta}}{\partial\ell}\right)\frac{d\ell}{ds}=\frac{au^\mu}{\ell}\frac{d\ell}{ds}. \tag{5.11}$$

This yields $u^\mu=(\ell/\ell_0)^a$, where ℓ_0 is a constant of the 4D motion. Alternatively, Eq. (5.11) can be written as

$$d(\ell^{-a}u^\mu)=0. \tag{5.12}$$

This says that in the Einstein gauge ($a=-1$) ℓu^μ is conserved, while in the Planck gauge ($a=+1$) u^μ/ℓ is conserved. That is, by (5.10), the conserved quantities are the classical momentum $(G/c^2)mu^\mu$ and the quantum momentum or inverse de Broglie wavelength $(c/h)mu^\mu$. These are as expected, but as before in both quantities $m=m(s)$ in general. If as in (4.9) we take a null 5D geodesic, (5.2) gives

$$dS^2=0=\left(\frac{L}{\ell}\right)^{2a}ds^2-\left(\frac{L}{\ell}\right)^{4b}d\ell^2. \tag{5.13}$$

This yields for *both* gauges

$$\ell=\ell_0 e^{\pm s/L}=\ell_0\exp[\pm(\Lambda/3)^{1/2}s], \tag{5.14}$$

which is the same as (4.10) and has similar implications for mass variation.

This process is intrinsic to 5D dynamics and warrants a closer examination, because it opens the way to understanding the Heisenberg uncertainty relation. The latter is not a part of classical 4D dynamics, and neither is the parallel 4D acceleration P^μ derived previously. This was calculated from the canonical metric (2.1) in (3.15) and has an associated scalar power per unit (inertial) mass (3.16), but was also calculated from the normalization condition (4.1) in (4.6) where it was found to be of general form. This agrees with the Hamiltonian approach to Kaluza–Klein theory, where a $(4+1)$ split can always be performed in order to recover Einstein theory.[53–55] In the Einstein and Planck gauges, P^μ has the form (5.11), whose associated scalar is $P^\mu u_\mu=(a/\ell)d\ell/ds$ where $a=\pm1$. This quantity has no analog in conventional classical dynamics, whose forces as noted before obey $F^\mu u_\mu=0$. However, an observer could interpret P^μ as causing an anomalous change in momentum $d\overline{p}^\mu$, such that by (5.11)

$$\frac{1}{m}\frac{d\overline{p}^\mu}{ds}=P^\mu=\frac{au^\mu}{\ell}\frac{d\ell}{ds}. \tag{5.15}$$

This implies the associated scalar quantity

$$dx_\mu d\overline{p}^\mu=\frac{am}{\ell}d\ell\,ds. \tag{5.16}$$

For both the Einstein gauge and the Planck gauge, this reads

$$dx_\mu d\overline{p}^\mu=-dm\,ds. \tag{5.17}$$

That is, there is a Heinsenberg-type relation in 4D which depends on the mass change associated with 5D. The relation (5.17) is general, insofar as no use has been made of (5.14) for $m=m(s)$ which follows from (5.13) for a null 5D geodesic. The generality of (5.17) may also be appreciated by recalling from previous work that the momentum is really conserved along a 5D path, so

$d(mu^\mu)=0$ or $m\,du^\mu+u^\mu\,dm=0$, where the second term represents an anomalous change in momentum $d\bar{p}^\mu=-u^\mu\,dm$, so there is a scalar $dx_\mu d\bar{p}^\mu=-dx_\mu(dx^\mu/ds)dm=-dm\,ds$.

Let us now ask how a 5D null path with $dS^2=0$ relates to the motion of a particle of mass m moving along a 4D timelike path with $ds^2>0$. We work in the Planck gauge with conventional units. Then (5.14) gives $dm=\pm L^{-1}m\,ds$, and (5.17) may be written

$$dx_\mu d\bar{p}^\mu=\frac{(mc\,ds)^2}{h}\left(\frac{\ell}{L}\right). \tag{5.18}$$

The first term in parentheses here is the 4D action, which as usual is defined and quantized for integers n via

$$I\equiv\int mc\,ds,\quad dI=nh. \tag{5.19}$$

The second term in parentheses in (5.18) is the ratio of the Compton wavelength of the particle $l=h/mc$ and the characteristic dimension of the four-space it inhabits $L=(3/\Lambda)^{1/2}$. Now the 5D null condition (5.13) in the Planck gauge ($a=1$, $b=1$) shows that if the 4D action is quantized via (5.19) then so is the extra part of the 5D line element. We therefore put $L/\ell=n$, which says that the Compton wavelength is an excitation of the fundamental mode. The result is that (5.18) reads

$$dx_\mu d\bar{p}^\mu=nh, \tag{5.20}$$

which is Heisenberg's relation. The above-mentioned approach can clearly be generalized to other box sizes. But if free particles have masses set by the energy density of the vacuum,[26] constraints on the cosmological constant[41–43] show that mass is quantized in units of

$$m=\frac{h}{cL}=\frac{h}{c}\left(\frac{\Lambda}{3}\right)^{1/2}\lesssim 10^{-65}g. \tag{5.21}$$

This is too small to detect with current methods, and miniscule compared to the so-called Planck mass $(hc/G)^{1/2}\approx 10^{-5}$ g, which is seen to be an artifact produced by a mixture of the Einstein and Planck gauges discussed in this section.

VI. WAVES IN $N(>4)$D THEORY

Section V showed that Heisenberg's relation follows as a consequence of the extra force which results when a causal 4D manifold is extended to a null 5D one. It is therefore natural to ask if other aspects of particles, including their wave nature, can be understood as manifestations of an $N(>4)$-dimensional space. That quantum field theory and general relativity are in principle compatible has been shown by work on the Hartle-Hawking and Vilenkin wave functions.[56–58] And exact solutions of Einstein's equations are known which can describe nongravitational waves.[30,46,59–64] There is of course the potential problem that the metric may be complex,[65–70] but this can be avoided if the view is taken that only the physically relevant quantities calculated from it need to be real.[30,46,64] In this section we will therefore proceed to see if it is possible to set up a consistent framework for 4D wave mechanics in $N(>4)$D theory, concentrating as before on the 5D case.

The 4D Klein–Gordon equation for a relativistic particle with zero spin and finite mass should be derivable, based on what has been shown previously, from the 5D equation for a null geodesic. However, since the Klein–Gordon equation is a second-order relation in a complex wave function, we take the line element to have signature $(+----)$. Then

$$dS^2=0=\left(\frac{L}{\ell}\right)^{2a}ds^2+\left(\frac{L}{\ell}\right)^{4b}d\ell^2, \tag{6.1}$$

where $g_{\alpha\beta}=(L/\ell)^{2a}\overline{g}_{\alpha\beta}dx^\alpha dx^\beta$ and $a=(-1,+1)$ with $b=(0,+1)$ for the Einstein and Planck gauges as before. The last relation is satisfied by

$$\ell=\ell_0 e^{\pm is/L}, \tag{6.2}$$

which is the complex analog of (4.10). The mass (squared) involves $\ell\ell^*=\ell_0^2$ and is constant and real. Without loss of generality we can take the upper sign in (6.2) and define a dimensionless wave function

$$\psi=e^{is/L}. \tag{6.3}$$

This satisfies a hierachy of wave equations

$$\frac{d^n\psi}{ds^n}=\left(\frac{i}{L}\right)^n\psi, \tag{6.4}$$

where we are interested primarily in the cases $n=1, 2$. [The n in (6.4) should not be confused with that in (5.19).] The first-order equation of (6.4) implies $i\psi/L=dx/ds=(\partial\psi/\partial x^\alpha)(dx^\alpha/ds)=(\partial\psi/\partial x^\alpha)u^\alpha$ or $1=(L/i\psi)(\partial\psi/\partial x^\alpha)u^\alpha$. But $1=u^\alpha u_\alpha$, so

$$u_\alpha=\frac{L}{i\psi}\frac{\partial\psi}{\partial x^\alpha}. \tag{6.5}$$

This for the fundamental mode of the Planck gauge with $L=h/mc$ just says $p_\alpha=(h/ic\psi)\partial\psi/\partial x^\alpha$, which is the usual prescription for obtaining the momenta from the wave function. The second-order equation of (6.4) can be treated similarly, and with (6.5) yields

$$\frac{u^\alpha u^\beta}{\psi}\frac{\partial^2\psi}{\partial x^\alpha\partial x^\beta}+\frac{1}{L^2}+\frac{iu_\alpha}{L}\frac{du^\alpha}{ds}=0. \tag{6.6}$$

The imaginary part of this is $u_\alpha du^\alpha/ds=0$ or the usual orthogonality relation. The parallel acceleration (4.6) or (5.11) which follows from the metric in form (5.2) does not appear, which agrees with the fact that the effective mass is a constant for the metric in form (6.1). In this regard, it is instructive to consider the geodesic equation $dU^\mu/d\lambda+\Gamma^\mu_{\beta\gamma}U^\beta U^\gamma=0$ with $U^\alpha\equiv dx^\alpha/d\lambda$, $d\lambda=e^{\mp is/L}ds$ and $\Gamma^\mu_{\beta\gamma}$ constructed from $g_{\alpha\beta}=(L/\ell)^{\pm1}\overline{g}_{\alpha\beta}$, as implied by (6.1). This geodesic, it may be verified, splits naturally into real and imaginary parts:

$$\frac{du^\mu}{ds}+\overline{\Gamma}^\mu_{\beta\gamma}u^\beta u^\gamma=0, \tag{6.7}$$

$$u^\mu=\overline{g}^{\mu\alpha}\left(\overline{g}_{\alpha\gamma}\frac{\partial s}{\partial x^\beta}+\overline{g}_{\alpha\beta}\frac{\partial s}{\partial x^\gamma}-\overline{g}_{\gamma\beta}\frac{\partial s}{\partial x^\alpha}\right)u^\beta u^\gamma. \tag{6.8}$$

Here $u^\mu\equiv dx^\mu/ds$ and $\overline{\Gamma}^\mu_{\beta\gamma}$ is constructed from $\overline{g}_{\alpha\beta}$. We see from (6.7) that the motion is geodesic in the embedded four-space. And (6.8) is identically satisfied if $s=\int u_\alpha dx^\alpha$ so $\partial s/\partial x^\alpha=u_\alpha$ as usual for the four-interval. In other words, the 4D dynamics is standard. Returning now to (6.6), its real part may be rewritten by noting that $u^\alpha u^\beta\partial^2\psi/\partial x^\alpha\partial x^\beta=\overline{g}^{\alpha\beta}\partial^2\psi/\partial x^\alpha\partial x^\beta$, which can be shown using (6.5) and $u^\alpha u_\alpha=1$. Then for the fundamental mode of the Planck gauge, the real part of (6.6) reads

$$\overline{g}^{\alpha\beta}\frac{\partial^2\psi}{\partial x^\alpha \partial x^\beta}+\frac{m^2c^2\psi}{L^2}=0. \tag{6.9}$$

This is the standard 4D Klein–Gordon equation.

The preceding paragraph started with the complex metric (6.1) and ended with the relativistic wave equation (6.9). Both are statements about dynamics, and neither uses the field equations. Solutions of the latter of relevant type were mentioned previously.[30,46,59–64] It would be inappropriately long to discuss these here; but to show that there is a match between the dynamics and the field equations, let us take the metric (6.1) in the Planck gauge ($a=1$, $b=1$) and consider the 5D field equations $R_{AB}=0(A,B=0,1,2,3,4)$. The latter may be shown to be satisfied, either tardily using algebra[39] or quickly using a computer package,[71] by

$$dS^2=\left(\frac{L}{\ell}\right)^2(dt^2-e^{i(\omega t+k_x x)}dx^2-e^{i(\omega t+k_y y)}dy^2-e^{i(\omega t+k_z z)}dz^2)+\left(\frac{L}{\ell}\right)^4 d\ell^2. \tag{6.10}$$

Here k_{xyz} are arbitrary wave numbers along the Cartesian axes and ω is a frequency fixed by the field equations as $\omega=\pm 2/L$. This solution may be regarded as the canonical one in 5D, since not only does the Ricci tensor R_{AB} vanish but the Riemann tensor R_{ABCD} does also. That is, (6.10) describes a wave propogating in the 4D part of a *flat* 5D manifold. However, the 4D part of (6.10) is *curved*. In the induced-matter picture,[14] it is curved by a cosmological constant $\Lambda=-3\ell^2/L^4$. If the latter is modeled as in general relativity by a classical pressure and density, the wave in 4D is supported by a medium with the equation of state $8\pi p=-8\pi\rho=-\Lambda=3\ell^2/L^4$ typical of the classical vacuum. Another way of appreciating what is involved here is by considering the extra coordinate ℓ, or equivalently the inertial rest mass of the particle m. By (6.2), ℓ oscillates in and out of the 4D space–time hypersurface defined by s. The average value of ℓ is zero, agreeing with the fact that R_{ABCD} describes a flat 5D manifold; but the average value of its square is finite, agreeing with the fact that the 4D manifold is curved. By (6.10) directly, or by (5.6) modulo a sign due to the change in signature from (5.2) to (6.1), the 4D Ricci scalar is

$$R=\frac{12\ell^2}{L^4}=\frac{12m^2c^2}{h^2}. \tag{6.11}$$

Here we have put $\ell=L=h/mc$ for the fundamental mode in the Planck gauge. The last relation just says that the scalar curvature of the 4D space is set by the Compton wavelength or mass of the particle which inhabits it. This agrees with Mach's principle,[14] and with the idea from inflationary quantum field theory that particles are intrinsically massless.[26] There is no contradiction, as long as the view is taken that particles with finite rest mass are 4D objects in a 5D vacuum.

The generalization of the above is expected to be straightforward, both for spin-1/2 particles described by the Dirac equation in 5D[72,73] and spin-0 particles described by scalar wave equations in ND.[14,74] In the latter context, it is clear that the defining equation for classical dynamics in terms of the N velocities should be $U^A U_A=0$. The corresponding quantum wave function can be derived from the metric as fixed by solutions of $R_{AB}=0(A,B=0,1,2,3,\ldots,N)$. Probabilities should be defined from the metric using the element of proper volume $(|g|)^{1/2}dx^N$, so $|g|$ will be a nontrivial factor. [This is already evident in 5D from metrics like (6.10), where the 4D wave function may be augmented by g_{44} to yield a 5D one whose extra component will be related to the spectrum of particle masses.] It is expected that these issues will be reported on in the future.

VII. CONCLUSION

In Sec. II, we noted that the canonical 5D metric (2.1) justifies its name by providing a basis for $N(>4)$D geodesics and leading to many useful results. The utility of the canonical (or warp) metric can be understood as a result of embeddings, which on 4D hypersurfaces reduce to physically acceptable solutions for cosmology (3.6) and the one-body problem (3.7). However, as shown elsewhere in Sec. III, its efficacy is mainly due to the fact that it converts a *coordinate*

space to a *momentum* space, *with the extra coordinate playing the role of rest mass even for null 5D geodesics*. In general, the velocity in the extra dimension results in a new inertial force (per unit mass) given by (3.15). This and its associated power (per unit mass) given by (3.16) have no analog in conventional 4D dynamics. The same is true of any nontrivial ND manifold. In Sec. IV, it was seen that the normalization condition (4.1) results in an extra acceleration parallel to the four-velocity which has the form (4.6) independent of the coordinate system. This can most logically be handled by connecting it to the change in the (inertial) rest mass of the particle which feels it, which means that the 4D motion is technically nongeodesic in the four-velocity (4.7), even though it agrees with the conventional law for the conservation of the four-momentum as applied (say) to the motion of a rocket (4.8). However, the rate of variation of mass in the Minkowski limit is set by the cosmological constant as in (4.11) and is tiny, so for apparently free particles there is no conflict with observed dynamics. In Sec. V, the field equations (5.1) were used to constrain the form of a generalized canonical metric (5.2), leading to the recognition of two natural choices for the extra coordinate in (5.7) and (5.8). These are related by an elementary coordinate transformation (5.9), whose physical meaning is however significant: classical physics uses the gravitational constant of Newton or Einstein to geometrize the mass, while quantum physics uses Planck's constant to geometrize the mass, as in (5.10). That is, classical and quantum dynamics in 4D are descriptions of 5D dynamics in what can be termed the Einstein and Planck gauges. In both gauges, the extra or parallel force (per unit mass) of (5.15) leads to a relation between the increments in the coordinates and momenta (5.17) which is reminiscent of Heisenberg's relation. Further study confirms that the extra force—which is inertial is the Einstein sense of coming from the motion in the (extra part of the) coordinate frame—results in Heisenberg's uncertainty relation (5.20). A corollary of this is that the inertial rest mass of a particle is quantized, though the unit is set by the cosmological constant and is less than 10^{-65} g by (5.21) and so too small to be observed using current methods. These results prompted the brief study in Sec. VI of waves in $N(>4)$D. In 5D, what is in effect a Wick rotation of the extra part of the null metric (6.1) was found to lead to a wave function (6.3) which satisfies a hierachy of wave equations (6.4). The first of these, (6.5), is a restatement of the standard prescription for the derivation of four-momenta from a wave function. The second, (6.6), splits naturally into two parts, of which one is a restatement of the geodesic equation of classical theory (6.7), while the other is equivalent to the Klein–Gordon equation of relativistic quantum theory (6.9). It should be noted that the latter was derived without the use of operators, and of course contains the Schrödinger equation in the nonrelativistic limit. More importantly, it should be noted that solutions of the 5D field equations exist which have complex metrics but which result (because of the structure of the field equations) in measurable quantities which are real. An example is (6.10), which is the canonical solution for a wave in a 5D manifold. It describes an oscillation of the extra coordinate in and out of the hypersurface called space–time. The mass of the particle associated with the wave also oscillates, with a mean value which is zero, in accordance with inflationary quantum field theory and the flatness of the 5D manifold. However, the square of the mass is finite and in fact set by (6.11), which says that the square of the inverse Compton wavelength of the particle is proportional to the Ricci scalar of the embedded and curved 4D manifold. This last property is manifestly Machian, and is expected to be generic to $N(>4)$D manifolds which contain submanifolds that proscribe the 4D ''boxes'' which particles inhabit. The general prescription for dynamics in N-dimensional spaces would appear to be a null product of N-vectors (specifying the coordinate velocities in the classical case or the wave numbers in the quantum case). This means that particles are in causal contact in ND even though they appear to be out of contact in 4D, so there are obvious implications for the Aharanov–Bohm effect and the double-slit experiment. These phenomena, and other consequences for membranes and strings especially, will surely repay further investigation.

Global prescribed mean curvature foliations in cosmological space–times. I

Oliver Henkel[a)]
Max Planck Institute for Gravitational Physics, Am Mühlenberg 1, 14476 Golm, Germany

(Received 1 December 2001; accepted for publication 28 January 2002)

This work investigates some global questions about cosmological space–times with two-dimensional spherical, plane, and hyperbolic symmetry containing ''well-behaved'' matter. The result is that these space–times admit a global foliation by prescribed mean curvature surfaces, which extends at least toward a crushing singularity. The time function of the foliation is geometrically defined and unique up to the choice of an initial Cauchy surface. This work generalizes a similar analysis on constant mean curvature foliations and avoids the topological obstructions arising from the existence problem. © *2002 American Institute of Physics.*

I. INTRODUCTION

The flavor of General Relativity viewed as an initial value problem for the field equations is based on the geometrical nature of the equations, which implies the diffeomorphism invariance and the absence of a metric background structure. This has consequences for spacelike foliations, in that the time function of a foliation is not canonical, but arbitrary unless it is tied to some geometrical quantity. The latter would turn the analysis of the global structure of space–times into an investigation of the asymptotic behavior of such a foliation.

In space–times with certain symmetries some global foliations, defined by time coordinates tied to the symmetries, are known, e.g., Rein (1996), Andréasson (1999).

A geometrically defined foliation which does not depend on the symmetries are the well-known constant mean curvature (CMC) foliations, where the time coordinate is given by the mean curvature of the leaves, which varies continuously from leaf to leaf, see Rendall (1996) for a survey of this topic and Rendall (1995b), Rendall (1997c) for foliations of space–times with symmetries.

Unfortunately the CMC constructions suffer from the existence problem, which is unsolved in general. To overcome this difficulty, a foliation with leaves of prescribed mean curvature (PMC) has been constructed at least locally in time in (Henkel, 2001b) for cosmological space–times. The prescription is given implicitly, letting the mean curvature vary continuously along the normal vector field of the foliation relative to a given Cauchy surface. The time function of the foliation is geometrically defined and turns out to be intrinsic, in that coupled to Einstein's field equations adapted to the leaves, one obtains Cauchy data for space–times foliated by PMC leaves.

The aim of the present paper is to globalize this result for certain space–times. Motivated by the method in Rendall (1995a), where satisfying results about cosmic censorship have been obtained for spatially homogeneous models, I consider here cosmological space–times with two-dimensional spherical, plane, and hyperbolic symmetry. This choice is the first step of successively lowering the degree of symmetry to obtain more and more general results. I focus on the following questions: How large is the maximal interval for the time function and does this maximal foliation cover the whole space–time?

One guideline taken from Rendall (1995a) is that the foliation may be extendible as long as

[a)]Present address: Heinrich-Hertz-Institut für Nachrichtentechnik Berlin GmbH, Einsteinufer 37, 10587 Berlin, Germany; electronic mail: henkel@hhi.de

the mean curvature of the leaves remains finite. We will see that this principle stays true with some modifications.

Another important aspect for the construction of global foliations is the choice of an appropriate matter model. The key requirements for the matter fields are their regularity in a regular geometric background as well as some energy conditions. These requirements are not trivially satisfied, since the former rules out matter such as the perfect fluid, which is known to develop singularities (shocks) in a regular geometric background. For dust it has been shown in Rendall (1997b) and Isenberg (1998) that there is no way to construct a global CMC foliation which covers the whole dust-filled cosmological space–time. These counterexamples dramatically emphasize the importance of choosing appropriate matter models. Furthermore demanding energy conditions seems natural and obvious, but we will see, that the non-negative pressures condition plays a special role in the improvements in Sec. III E.

Section II fixes notation and states some basic definitions. We attack the main questions in Sec. III, following closely the treatment in Rendall (1995b). The results will be discussed in Sec. IV.

II. BASIC DEFINITIONS AND FORMULAS

A. Space–times and foliations

A space–time is a pair (M,g), where M denotes a four-dimensional smooth and orientable Lorentz manifold with metric g and signature $(-+++)$. The metric induces the Levi-Civita connection ${}^4\nabla$ on M. If $\{X_\alpha\}$ denotes a local basis of vector fields on M, we define the connection coefficients ${}^4C^\gamma_{\alpha\beta}$ relative to this basis by ${}^4\nabla_{X_\alpha}X_\beta={}^4C^\gamma_{\alpha\beta}X_\gamma$ and we get the Christoffel symbols ${}^4\Gamma$ and Ricci rotation coefficients ${}^4\gamma$ by specializing to a coordinate basis or an orthonormal frame, respectively. The sign convention for the curvature is fixed by the definition ${}^4R(X,Y)Z := {}^4\nabla_X{}^4\nabla_Y Z-{}^4\nabla_Y{}^4\nabla_X Z-{}^4\nabla_{[X,Y]}Z$, where X, Y Z are vector fields. The curvature tensor is then defined as ${}^4R(W,Z,X,Y):=g(W,{}^4R(X,Y)Z)$ with Ricci tensor ${}^4R_{\alpha\beta}={}^4R^\mu_{\alpha\mu\beta}$ and scalar curvature ${}^4R={}^4R^\mu_\mu$, written in abstract index notation of the Ricci calculus.

Then the Einstein tensor reads $G_{\alpha\beta}={}^4R_{\alpha\beta}-\frac{1}{2}{}^4Rg_{\alpha\beta}$ and the field equations are $G_{\alpha\beta}=8\pi T_{\alpha\beta}$ or equivalently ${}^4R_{\alpha\beta}=8\pi(T_{\alpha\beta}-\frac{1}{2}(\mathrm{tr}\,T)g_{\alpha\beta})$, where $T_{\alpha\beta}$ denotes the energy momentum tensor of the matter fields. The matter quantities are the energy density $\rho:=T_{\mu\nu}n^\mu n^\nu$, the momentum density $j_\beta:=-T_{\mu\nu}n^\mu h^\nu_\beta$ and the stress tensor $S_{\alpha\beta}:=T_{\mu\nu}h^\mu_\alpha h^\nu_\beta$ with respect to an observer, represented by a unit timelike vector n, where $h_{\alpha\beta}:=g_{\alpha\beta}+n_\alpha n_\beta$ denotes the orthogonal projector on $\{n\}^\perp$ in covariant notation.

Einstein's field equations in vacuum ($T_{\alpha\beta}=0$) have a well-posed Cauchy problem in harmonic coordinates, thus one obtains space–times as solutions of Einstein's field equations with matter, whenever the equations describing the matter fields and the energy momentum tensor couple to the field equations in harmonic coordinates, such that the Cauchy problem remains well posed. We will see examples in Sec. II B (compare Wald, 1984 and Friedrich and Rendall, 2000) for an introduction/analysis of the Cauchy problem for Einstein's equations.

In this work we confine ourselves to *cosmological* solutions (M,g) of Einstein's field equations. Due to Bartnik (1988) these are globally hyperbolic and spatially compact space–times, where the Ricci tensor contracted twice with any timelike vector is non-negative (timelike convergence condition). This last condition can be reexpressed in terms of the matter variables as $\rho+\mathrm{tr}\,S\geqslant 0$ for any observer, which is the strong energy condition.

Now let us pay attention to an additional structure. A foliation $\{S_t\}$, $t\in I\subset\mathbb{R}$ (I interval containing zero) of (a part of) (M,g) by spacelike hypersurfaces induces on each leaf the unit normal vector field n, the metric $h_{\alpha\beta}=g_{\alpha\beta}+n_\alpha n_\beta$, which also serves as orthogonal projection and the second fundamental form $k_{\alpha\beta}:=-h^\mu_\alpha h^\nu_\beta{}^4\nabla_\mu n_\nu$ (the definition of $k_{\alpha\beta}$ fixes the sign conventions used in this work). The second fundamental form is a symmetric tensor, intrinsic to the leaves of the foliation, and can also be written as the Lie derivative of the three-metric h with respect to the normal vector field, $k_{\alpha\beta}=-\frac{1}{2}\mathcal{L}_n h_{\alpha\beta}$. The three-metric determines further geometri-

cal objects on the leaves, such as the Levi-Civita connection ∇, the Christoffel symbols Γ, the Ricci rotation coefficients γ, and the curvature tensor $R(\cdot)$. Tensors intrinsic to the leaves of the foliation will carry Latin indices in the abstract index notation.

The parameter t of the foliation has timelike gradient and thus can be regarded as (coordinate) time. Given local coordinates (x^i) on S_0, we can Lie-transport them to neighboring leaves along an arbitrary family of transversal curves, parametrized by x. We will express equations containing coordinate components with respect to the adapted coordinates (t,x).

The lapse function N and the shift vector $\nu \perp n$ on the leaves are defined by $\partial_t = Nn + \nu$, thus $N = -g(\partial_t, n)$ and $\nu = \partial_t - Nn$. Then we have $1 = \mathrm{d}t(\partial_t) = N\,\mathrm{d}t(n)$. Further, $\mathrm{d}t$ is (co-)orthogonal to the leaves and if we denote the conormal of the leaves by σ we see that $\mathrm{d}t = -N^{-1}\sigma$ or $\sigma = -N\,\mathrm{d}t$, thus N^{-1} measures the length of $\mathrm{d}t$.

The most common example involving the lapse function is the event horizon in Schwarzschild space–time, where the coordinate time explodes along the worldline of infalling observers n, thus N^{-1} explodes or $N \to 0$. In this work we will be faced with a complementary scenario, where we have to ensure that the lapse function does not explode, corresponding to the phenomena of recollapse, where coordinate time freezes as $\mathrm{d}t \to 0$. If this occurs, one could try to reparametrize the foliation by setting $\tilde{t} = f(t)$ for some monotone function f and one gets $\mathrm{d}\tilde{t} = f'(t)\mathrm{d}t$,

$$\tilde{N} = \frac{1}{f'(t)} N = \frac{\mathrm{d}t}{\mathrm{d}\tilde{t}} N,$$

and the same relation holds for shift.

The $3+1$ split of the space–time geometry by means of lapse and shift ends up in the $3+1$ form of the field equations. The constraint equations are

$$R + H^2 - |K|^2 = 16\pi\rho \quad \text{(Hamiltonian constraint)}, \tag{1a}$$

$$\nabla^j k_{ij} - \nabla_i H = 8\pi j_i \quad \text{(momentum constraint)}, \tag{1b}$$

with $|k|^2 = k_{\alpha\beta}k^{\alpha\beta}$ and $H = \mathrm{tr}\,k$ denotes the mean curvature of the leaves. The Arnowitt–Deser–Misner (ADM) equations read

$$\partial_t h_{ij} = -2Nk_{ij} + \nabla_i \nu_j + \nabla_j \nu_i, \tag{2a}$$

$$\begin{aligned}\partial_t k_{ij} = &-\nabla_i\nabla_j N + N(R_{ij} + Hk_{ij} - 2k_i^r k_{rj} - 8\pi(S_{ij} + \tfrac{1}{2}(\rho - \mathrm{tr}\,S)h_{ij})) \\ &+ \nu^r \nabla_r k_{ij} + k_{rj}\nabla_i \nu^r + k_{ir}\nabla_j \nu^r.\end{aligned} \tag{2b}$$

Taking the trace of the second equation and eliminating the scalar curvature R by the Hamiltonian constraint we obtain the lapse equation

$$\Delta N + N(|k|^2 + 4\pi(\rho + \mathrm{tr}\,S)) = (\partial_t - \nu)H, \tag{3}$$

which serves as a constraint of the foliation. Note that in cosmological space–times the term in brackets is always non-negative. If it turns out to be nonvanishing, then the left-hand side of (3) can be shown to be an isomorphic mapping of N, considered as an element of some Sobolev space H^s into H^{s-2}. This observation motivates the following

Definition 2.1: A *prescribed mean curvature (PMC) foliation* is defined to be a foliation $\{S_t\}$ satisfying (3), with

$$(\partial_t - \nu)H = Nn(H) := 1, \tag{4}$$

thus the mean curvature of the leaves is forced to vary uniformly along the normals of the leaves. In Henkel (2001b) I proved the following local in time result:

Theorem 2.2: *Let (M,g) be a smooth, globally hyperbolic space–time, obeying the strong energy condition, with compact Cauchy surface* Σ *and*

$$\lambda = |k|^2 + 4\pi(\rho + \operatorname{tr} S) \tag{5}$$

does not vanish identically on Σ. *Then there exists a* $T>0$ *and a unique smooth PMC foliation* $\{S_t\}$, $t \in [-T,T]$ *in* (M,g), *with* $\Sigma = S_0$.

Note that the setting here is quite general, no symmetry assumptions have to be made, and essentially the strong energy condition turns out to be sufficient for the local in time existence of a unique PMC foliation up to the choice of an initial Cauchy surface.

The aim of the present paper is to globalize the result. Here are two problems involved: How large is the interval of values taken by the time coordinate and does the global foliation then cover the whole space–time? To answer these questions in general there seem to be no techniques available up to now. One strategy to obtain global results is to study first space–times with some spatial symmetry, taking advantage of the simplifications of the equations. Then the hope is that the techniques developed in these cases give insight into the nature of more general classes of space–times, by successively lowering the degree of symmetry. Here we will focus on space–times with two-dimensional spacelike orbits of symmetry and three (local) Killing vector fields. In the second part of this paper we will consider space–times with two commuting (local) Killing vector fields. These cases are indeed the first steps of this program, since the initial analysis for locally spatially homogeneous space–times has already been done and leads to very strong results (see Rendall, 1995a) for the exact analysis or Henkel (2001a) for an overview about the results in the present context.

B. Matter models

Before getting deeper into the analysis just motivated I introduce some matter models and their coupling to the Einstein equations, with special emphasis on the Cauchy problem. Since energy conditions will play an important role in the estimates we perform later on, I assemble the relevant ones for the present work first.

(1) The dominant energy condition. Its statement is that for all orthonormal frames $\{{}^4e_\alpha\}$ with ${}^4e_0$ timelike

$$T({}^4e_0, {}^4e_0) \geqslant |T({}^4e_\alpha, {}^4e_\beta)|.$$

Another formulation of this condition is, that for any observer, the local energy density ρ is non-negative and the momentum density j is nonspacelike, thus "matter cannot travel faster than light," a statement that can be proved rigorously (see, e.g., Sec. 4.3 of Hawking (1973)), leading to the result that if the energy momentum tensor obeys the dominant energy condition and vanishes on a set S, then it vanishes on the whole Cauchy development $D(S)$ of the set, thus $D(S)$ is a vacuum space–time.

(2) The strong energy condition states that for all timelike vectors v the inequality

$$T(v,v) \geqslant \tfrac{1}{2}(\operatorname{tr} T) g(v,v)$$

holds, or equivalently for any observer $\rho + \operatorname{tr} S \geqslant 0$, thus the stresses do not become too negative. Another formulation is ${}^4R(v,v) \geqslant 0$, also known as the timelike convergence condition, which contributes to the expansion of timelike geodesic congruences a negative term, thus shifting the balance toward contraction to a final singularity of the congruence. Hawking's famous singularity theorems then guarantee geodesic incompleteness in the past provided further the existence of a Cauchy surface with uniform negative mean curvature.

We already used the strong energy condition as an integral part in the definition of cosmological space–times and its meaning for foliations.

(3) The non-negative pressures condition demands the stress tensor S to be positive definite. This condition ensures in some sense that the pressures contribute more to attraction than to

repulsion, leading to a finite lifetime of the space–time under certain circumstances. This somewhat unexpected behavior is a true relativistic effect, which does not have a Newtonian counterpart.

1. The Maxwell equations

The Maxwell field is described by a two-form F, subject to the Maxwell equations

$$dF=0\Leftrightarrow {}^4\nabla_{[k}F_{\mu\nu]}=0, \tag{6a}$$

$$d\star F=4\pi\star J\Leftrightarrow {}^4\nabla_\mu F^{\alpha\mu}=4\pi J^\alpha, \tag{6b}$$

where J denotes the electromagnetic charge current density. Alternatively the covariant derivatives can be replaced by ordinary derivatives.

It is well known that the Maxwell equations admit (locally) a reformulation in terms of the vector potential A, a one-form with $\mathrm{d}A=F$. Then the remaining inhomogeneous equation reads ${}^4\nabla^\mu{}^4\nabla_\alpha A_\mu-{}^4\nabla^\mu{}^4\nabla_\mu A_\alpha=4\pi J_\alpha$. Fixing the gauge invariance of the equation by the Lorentz gauge, we obtain the system

$${}^4\nabla^\mu A_\mu=0 \quad \text{(Lorentz-gauge)}, \tag{7a}$$

$$\Box A_\alpha=4\pi J_\alpha-R_{\alpha\mu}A^\mu, \tag{7b}$$

with $\Box=-{}^4\nabla^\mu{}^4\nabla_\mu$ and the curvature term arises as a consequence of some commutations of derivative operators. In this formulation the second equation is a wave equation, and hence can be brought into first-order symmetric hyperbolic form, if the source term is appropriate. Thus we get local existence and uniqueness for this equation in a given space–time. One can further show then that the Lorentz gauge propagates and we indeed get a unique local solution of the Maxwell equations. Spatially global solution can be obtained by the usual patching argument, arising from localizing the equation with respect to an appropriate partition of unity of the initial data on some Cauchy surface.

Given an electromagnetic field F we can form the associated energy momentum tensor E, defined as

$$E_{\alpha\beta}=\frac{1}{4\pi}\left(F_{\alpha\mu}F_\beta{}^\mu-\tfrac{1}{4}|F|^2 g_{\alpha\beta}\right), \tag{8}$$

where $|F|^2=F^{\mu\nu}F_{\mu\nu}$.

E is trace-free, satisfies the relation ${}^4\nabla_\mu E^{\alpha\mu}=-F^\alpha{}_\mu J^\mu$ and the dominant and strong energy conditions hold.

Since the Maxwell equations turn out to be symmetric hyperbolic at least locally, we can couple them to the Einstein equation to get a symmetric hyperbolic system of equations in harmonic coordinates. Thus we end up with a well-posed Cauchy problem for the Einstein–Maxwell system, as long as the electromagnetic charge current density is in appropriate form.

2. The Vlasov equation

The Vlasov equation is a model for a collisionless gas. It describes the motion of a huge number of structureless particles in space–time. We need only the case where the particles have unit mass, where the equation is composed of a non-negative function f, defined on the mass shell of particles of mass one $P:=\{v\in TM\,|\,g(v,v)=-1,\ \text{future pointing}\}$, representing the particle distribution, and a geodesic spray X on P. The equation reads

$$X(f)=0 \tag{9a}$$

with

$$X = p^\mu \partial_\mu - {}^4\Gamma^k_{\mu\nu} p^\mu p^\nu \frac{\partial}{\partial p^k} = v^\alpha {}^4e_\alpha - {}^4\gamma^k_{\mu\nu} v^\mu v^\nu \frac{\partial}{\partial v^k}, \tag{9b}$$

where p^μ denotes the components of the momentum of the particles with respect to the given coordinates and v^α are the components of the momentum with respect to an orthonormal frame. They are related by $p^\mu = ({}^4e_\alpha)^\mu v^\alpha$ and on the mass shell p^0 is determined by the components p^i and $v^0 = \sqrt{1 + \delta_{ij} v^i v^j}$.

Inserting the definition ${}^4e_\alpha = ({}^4e_\alpha)^\mu \partial_\mu$ and doing a $3+1$ decomposition (with the exception that we do not write down the explicit expression for ${}^4\gamma^k_{0j}$) we can reformulate the Vlasov equation as

$$\begin{aligned} 0 = {} & \partial_t f + \left(N \frac{v^j}{v^0} (e_j)^i - \nu^i \right) \partial_i f \\ & - \left(e_i(N) v^0 + N(-k_{rs}(e_i)^r (e_j)^s + \delta_{ik} {}^4\gamma^k_{0j}) v^j + N \delta_{ik} \gamma^k_{rs} \frac{v^r v^s}{v^0} \right) \frac{\partial}{\partial v^i} f. \end{aligned} \tag{9'}$$

The Cauchy problem for the Vlasov equation in a given space–time is easy, since it is a linear, scalar equation with characteristic vector field (Y,Q) satisfying

$$\dot{Y}^\alpha = Q^\alpha,$$

$$\dot{Q}^\alpha = - {}^4\Gamma^\alpha_{\kappa\lambda} Q^\kappa Q^\lambda,$$

and since $X(f) = 0$, f is constant along the characteristics.

From the particle distribution f one can construct other physically meaningful quantities such as the energy–momentum tensor by integration over the tangent spaces. We denote the part of the mass shell in the fiber over $x \in M$ by $P_x := P \cap T_x M$. Then we define the energy–momentum tensor T by

$$T_{\alpha\beta}(x) := - \int_{P_x} f p_\alpha p_\beta \sqrt{|g|} / p_0 \mathrm{d}p^1 \mathrm{d}p^2 \mathrm{d}p^3. \tag{10}$$

T is divergence free and satisfies the dominant and strong energy condition and the non-negative pressures condition.

To obtain the matter quantities ρ, j, and S one has to calculate the components of the energy–momentum tensor with respect to an orthonormal frame. These components have the following representation:

$$T({}^4e_\alpha, {}^4e_\beta)(x) = \int_{P_x} f v_\alpha v_\beta / v^0 \mathrm{d}v^1 \mathrm{d}v^2 \mathrm{d}v^3. \tag{10'}$$

Now let us consider the Einstein–Vlasov system. The energy–momentum tensor automatically satisfies $\operatorname{div} T = 0$ as mentioned previously, thus there arise no additional equations from the Bianchi identities. But unfortunately the coupled system of equations is not symmetric hyperbolic in any sense, due to the fact that it is a system of integro-differential equations. Nevertheless, the local existence proof applies similar techniques as in the case of quasilinear symmetric hyperbolic systems where the peculiarity in the construction for the Einstein–Vlasov system consists in bounding the support of f in the tangent space: There is no *a priori* bound on the velocities of the particles, and no localization argument available as for the space–time coordinates. In order to estimate the matter quantities appearing in the coupled system, one has to control the maximal velocity uniformly during the construction. This has been done, for example, in Rendall (1997a), establishing a well-posed Cauchy problem for the Einstein–Vlasov system.

With this result at hand, it is easy to extend this result to the Einstein–Vlasov–Maxwell system, since the Einstein–Maxwell equations are symmetric hyperbolic and when coupling the Vlasov equation to them nothing new appears.

C. Further conventions

I adopt the convention of denoting any generic constant by C. For the convenience of the reader I cite the well-known Gronwall estimate, which is central to the analysis of partial differential equations and will be used here in this work.

Proposition 2.3 (Gronwall's inequality): Let $I\subset\mathbb{R}$ *be an interval,* $t_0\in I$ *and* α, β, $u\in C(I,\mathbb{R}_+)$, *with*

$$u(t)\leqslant\alpha(t)+\left|\int_{t_0}^{t}\beta(s)u(s)\mathrm{d}s\right|$$

for all $t\in I$.

Then

$$u(t)\leqslant\alpha(t)+\left|\int_{t_0}^{t}\alpha(s)\beta(s)\exp\int_{s}^{t}\beta(r)\mathrm{d}r|\mathrm{d}s|\right|$$

holds for all $t\in I$.

The proof of Gronwall's inequality in this particular form can be found in Amann (1995).

III. SPACE–TIMES WITH TWO-DIMENSIONAL SPHERICAL, PLANE, AND HYPERBOLIC SYMMETRY

A. The geometry of surface symmetric space–times

Let (M,g) be a smooth, globally hyperbolic space–time which is topologically of the form $\mathbb{R}\times S^1\times F$, with F a compact, orientable surface. The submanifolds $\{\tau\}\times S^1\times F$ are assumed to be Cauchy surfaces of M. The universal covering $\hat{F}$ of F induces a space–time $(\hat{M},\hat{g})$ by $\hat{M}=\mathbb{R}\times S^1\times\hat{F}$ and $\hat{g}=p^*g$, $p:\hat{M}\to M$ the canonical projection. Moreover, there is a group G of isometries acting on $(\hat{M},\hat{g})$.

Then (M,g)

(1) is called *spherically symmetric*, if $F=S^2$ and $G=\mathrm{SO}(3)$ acts isometrically and without fixed points on $S^1\times S^2$,
(2) is *plane symmetric*, if $F=T^2$ and $G=E_2$ (Euclidian group) acts isometrically on $\hat{F}=\mathbb{R}^2$,
(3) has *hyperbolic symmetry*, if F has genus greater than one and the connected component of the symmetry group G of the hyperbolic plane, H^2, acts isometrically on $\hat{F}=H^2$ (thus $F=H^2/\Gamma$, with Γ a discrete group of isometries of H^2)

and the matter quantities remain invariant under the isometries.

To collect these cases, each such space–time is called *surface symmetric*, the diffeomorphic images of F in the product decomposition of M *surfaces of symmetry* and each surface in M diffeomorphic to $S^1\times F$ will be called *symmetric*.

In expressions involving indices, lower case Greek indices range from 0 to 3, lower case Latin indices (preferably taken from the middle of the alphabet) range from 1 to 3, and upper case Latin indices (from the beginning of the alphabet) take the values 2 or 3.

The isometric action forces the curvature of the surfaces of symmetry up to rescaling to be $\epsilon=1,\ 0,\ -1$ in the spherical, plane, and hyperbolic cases, respectively. Therefore they admit coordinates (ϑ,φ) which cast the metric $\tilde{g}$ of the surfaces of symmetry (considered for a moment as abstract manifolds) into the form

$$\tilde{g}=\mathrm{d}\vartheta^2+\epsilon_\vartheta^2\mathrm{d}\varphi^2,\quad \epsilon_\vartheta:=\begin{cases}\sin\vartheta, & \epsilon=1\\ 1, & \epsilon=0\\ \sinh\vartheta, & \epsilon=-1.\end{cases} \tag{11}$$

Define the area radius function r on a surface of symmetry F (embedded in M) to be

$$r=\sqrt{\frac{1}{4\pi}\mathrm{Vol}(F)}, \tag{12}$$

then r is independent of (ϑ,φ) and the metric of F reads

$$\overline{g}=r^2\tilde{g}. \tag{13}$$

With respect to any symmetric Cauchy surface S we have the timelike unit normal vector n of S in M. Regarding n as a normal vector to F in M, we can define a second unit normal m of F by the conditions that m is tangent to S and the system $(n,m,\overline{e_2},\overline{e_3})$ is positively oriented, where we set $\overline{e_A}:=r^{-1}\tilde{e}_A$, $\tilde{e}_2:=\partial_2$, $\tilde{e}_3:=\epsilon_\vartheta^{-1}\partial_3$. We denote the associated second fundamental forms of $(F,\overline{g})$ in (M,g) by κ and λ, with

$$\lambda_{AB}=-\frac{1}{2}m(\overline{g}_{AB})=-\frac{1}{2}m(r^2)\tilde{g}_{AB}=\frac{1}{2}(\mathrm{tr}\,\lambda)\overline{g}_{AB},\quad \mathrm{tr}\,\lambda=-\frac{2}{r}m(r), \tag{14a}$$

$$\kappa_{AB}=-\frac{1}{2}n(\overline{g}_{AB})=-\frac{1}{2}n(r^2)\tilde{g}_{AB}=\frac{1}{2}(\mathrm{tr}\,\kappa)\overline{g}_{AB},\quad \mathrm{tr}\,\kappa=-\frac{2}{r}n(r). \tag{14b}$$

Consider now a Gaussian coordinate neighborhood (x',ϑ,φ) of a surface of symmetry F, covering (a part of) a symmetric Cauchy surface S. The metric h of S then takes the form $h=\mathrm{d}x'^2+\sqrt{|h|}\tilde{g}$. The projection of geodesics starting in $(\hat{M},\hat{g})$ orthogonal at F remain orthogonal to all surfaces of symmetry. Following them until their projection meets F again, the symmetry allows only two possibilities: The point of return is the same as the starting point or an antipodal point, in which case we force the geodesic to turn a second time around the circle. Let L denote the length of the geodesic. Setting $a=2\pi(\int_0^L|h(z)|^{-1/4}\mathrm{d}z)^{-1}$, we define a new coordinate $x(x')$ by $a\int_0^{x'}|h(z)|^{-1/4}\mathrm{d}z$. In the coordinates $(x^i)=(x,\vartheta,\varphi)$ the metric has the representation

$$h=A^2(dx^2+a^2\tilde{g})=A^2\mathrm{d}x^2+\overline{g} \tag{15}$$

with $A(x)=a^{-1}|h(x)|^{1/4}$ defined on S^1. Comparing this with Eq. (13) shows $r=Aa$. The corresponding Laplacian Δ acting on a function ψ on S can now be calculated to

$$\begin{aligned}\Delta\psi&=-h^{ij}\nabla_i\nabla_j\psi=-h^{11}\nabla_1\nabla_1\psi-h^{AB}\nabla_A\nabla_B\psi\\ &=-h^{11}\nabla_1\nabla_1\psi+h^{AB}\Gamma^1_{AB}\psi'+\overline{\Delta}\psi\\ &=-A^{-2}(\psi''+A^{-1}A'\psi')+\overline{\Delta}\psi,\end{aligned}$$

where $\overline{\Delta}$ denotes the Laplacian of $\overline{g}$, and the prime differentiation with respect to x, a convention, which we adopt for the rest of this work.

Furthermore, the symmetry and the given coordinate representations permit the second fundamental form k to have the form

$$k=A^2K\,\mathrm{d}x^2+\tfrac{1}{2}(\mathrm{tr}\,\kappa)\overline{g}, \tag{16}$$

where the coefficients are functions on S^1. Taking the trace yields the mean curvature $H=\mathrm{tr}\,k$ and we get the relation

$$H-K=\operatorname{tr}\kappa. \tag{17}$$

So far we know the intrinsic and extrinsic geometry for a symmetric Cauchy surface Σ in M. Let us turn now to the $3+1$-geometry. Theorem 2.2 states the conditions to guarantee local in time existence for a PMC foliation $\{S_t\}$ of a neighborhood of Σ. We need that λ defined by Eq. (5) is non-negative and does not vanish identically on Σ. Again n is the unit normal on Σ and T the energy–momentum tensor of the space–time. Therefore we get a sufficient condition by the assumption that M satisfies the strong energy condition [hence the matter term in (5) is non-negative] and that there exists at least one point in Σ, with $\lambda>0$. The strictness of the inequality is not a restriction, since one always can perform a slight deformation of Σ, such that the second fundamental form is not identically zero, which does the job. The same reasoning works, of course, if M satisfies the dominant energy condition and the non-negative-pressures condition [then both parts of the matter term in (5) are non-negative]. Thus, in surface symmetric space–times, some energy conditions are sufficient for the existence of a local in time PMC foliation.

Having constructed a local in time PMC foliation, one can ask if the leaves of the foliation are symmetric, when Σ has been chosen to be symmetric [note that due to symmetry $\lambda=\lambda(x)$ is a function on S^1 only]. As described in Henkel (2001b) the PMC foliation is given as a limit (w,N) of functions (w^j,N^j) on Σ in some Sobolev space. Here w^j describes a family of spacelike hypersurfaces in M and N^j converges toward the lapse function of w. (w^j,N^j) are defined as solutions of the sequence of symmetric-hyperbolic elliptic systems

$$\partial_t w^j+A^i(w^{j-1},N^{j-1})\partial_i w^j+B(w^{j-1},N^{j-1},DN^{j-1})=0,$$

$$\Delta(w^{j-1})N^j+\lambda(w^{j-1},Dw^{j-1})N^j=1$$

with w^0 representing Σ and $N^0=1$, hence respecting the symmetries. The underlying metric structure of the system is the sequence of first fundamental forms h_{j-1} of the surfaces w^{j-1}. If all the (w^j,N^j) respect the symmetries, then the PMC foliation also, hence it suffices to show that (w^j,N^j) respects the symmetries, if w^{j-1},N^{j-1} does so. This is clear for w^j, because the symmetric-hyperbolic equation can be localized, and the pullback to $\hat{M}$ is invariant under the action of the isometry group.

Suppressing the index $j-1$ from some quantities determined by the metric h_{j-1}, the Laplacian reads

$$\Delta(w^{j-1})N^j=-A^{-2}((N^j)''+A^{-1}A'(N^j)')+\overline{\Delta}(w^{j-1})N^j.$$

The elliptic equation then becomes

$$-A^{-2}((N^j)''+A^{-1}A(N^j)')+\lambda(w^{j-1},Dw^{j-1})N^j+\overline{\Delta}(w^{j-1})N^j=1.$$

If $\overline{\Omega}=\sqrt{|\overline{g}|}=r^2\epsilon_\vartheta$ denotes the volume form of the surfaces of symmetry F in M, one finds $\mathrm{Vol}(F)=\int_{[0,\pi]\times[0,2\pi]}\overline{\Omega}=4\pi r^2$, as desired. Setting

$$L:=-A^{-2}\left(\frac{\mathrm{d}^2}{\mathrm{d}x^2}+A^{-1}A'\frac{\mathrm{d}}{\mathrm{d}x}\right)\quad\text{and}\quad\widetilde{N}^j(x):=\frac{1}{\mathrm{Vol}(F)}\int_{[0,\pi]\times[0,2\pi]}N^j\overline{\Omega}=\frac{1}{4\pi}\int_{[0,\pi]\times[0,2\pi]}N^j\epsilon_\vartheta,$$

then integration of the elliptic equation, $\int_{[0,\pi]\times[0,2\pi]}\epsilon_\vartheta(L+\lambda+\overline{\Delta})N^j=\int_{[0,\pi]\times[0,2\pi]}\epsilon_\vartheta=4\pi$, yields

$$(L+\lambda+\overline{\Delta})\widetilde{N}^j=1,$$

since on the one hand $\int_{[0,\pi]\times[0,2\pi]}(L+\lambda)N^j\epsilon_\vartheta = 4\pi(L+\lambda)\tilde{N}^j$ and on the other hand $\int_{[0,\pi]\times[0,2\pi]}(\overline{\Delta}N^j)\epsilon_\vartheta = r^{-2}\int_{[0,\pi]\times[0,2\pi]}(\overline{\Delta}N^j)\overline{\Omega} = r^{-2}\int_F \overline{\Delta}N^j$ vanishes as well as $\overline{\Delta}\tilde{N}^j$. Thus $\tilde{N}^j$ is a solution of the elliptic equation. Uniqueness then gives us $N^j=\tilde{N}^j$, thus $N^j=N^j(x)$, which expresses the symmetry of N^j, as desired.

Thus we have shown, given a symmetric Cauchy surface Σ in M admitting a local in time PMC foliation, that all leaves of the foliation are symmetric, too, and coordinatizing them in the above-described way yields:

Proposition 3.1: Let (M, g) be a surface symmetric space–time obeying the strong energy condition. Then there are coordinates $(x^\mu)=(t,x,\vartheta,\varphi)$ *adapted to a local in time PMC foliation* $\{S_t\}$ *of a neighborhood* $U=]t_1,t_2[\times\Sigma$ *of* $\Sigma=S_0$ *in M, which cast the metric into the form*

$$g=-N^2\mathrm{d}t^2+A^2((\mathrm{d}x+\nu\,\mathrm{d}t)^2+a^2\tilde{g}). \tag{18}$$

All coefficients except a are functions on $]t_1,t_2[\times S^1$, *whereas a depends only on the time function t. A and a are everywhere positive, N denotes the lapse function of the foliation, and* ν *the nonvanishing component of the shift vector, uniquely fixed by the condition* $\nu(t,0)=0$.

Supplementary to the notation already introduced, let an overdot denote differentiation with respect to *t*, while keeping the prime as a marker for differentiation with respect to the coordinate *x*.

Finally we find for the orthonormal frame $\{{}^4e_\mu\}$ and its dual $\{{}^4\sigma^\mu\}$ canonically induced by the $3+1$-split:

$$
\begin{aligned}
{}^4e_0 &= n = N^{-1}(\partial_0-\nu\partial_1), \quad {}^4\sigma^0 = N\,\mathrm{d}t,\\
{}^4e_1 &= m = A^{-1}\partial_1, \quad {}^4\sigma^1 = A(\nu\,\mathrm{d}t+\mathrm{d}x^1),\\
{}^4e_2 &= (Aa)^{-1}\partial_2, \quad {}^4\sigma^2 = Aa\,\mathrm{d}x^2,\\
{}^4e_3 &= (Aa\epsilon_\vartheta)^{-1}\partial_3, \quad {}^4\sigma^3 = Aa\epsilon_\vartheta\,\mathrm{d}x^3.
\end{aligned}
$$

B. The field equations

1. 3+1 decomposition of the filled squared lines

Given the PMC foliation, we can write down the field equations in the $3+1$-representation. The symmetries suggest representing the matter quantities completely with respect to an orthonormal frame, thus we define $j:=-T(n,m)=A^{-1}j_1$ and $S_{ij}=T({}^4e_i,{}^4e_j)$.
Then one calculates the constraint equations (1) to be

$$(A^{1/2})''=\tfrac{1}{8}A^{5/2}(H^2-\tfrac{1}{2}(H-K)^2-K^2-16\pi\rho)+\tfrac{1}{4}A^{1/2}a^{-2}\epsilon, \tag{19}$$

$$K'=-3A^{-1}A'K+A^{-1}A'H+H'+8\pi Aj. \tag{20}$$

The foliation is fixed by the lapse equation (3) and the PMC condition (4)

$$N''=-A^{-1}A'N'+A^2N(\tfrac{1}{2}(H-K)^2+K^2+4\pi(\rho+\mathrm{tr}\,S))-A^2, \tag{21}$$

$$\dot{H}=1+\nu H', \tag{22}$$

and the evolution equations (2) read

$$\dot{A}=-NAK+A\nu'+A'\nu, \tag{23}$$

$$\dot{a}=-\tfrac{1}{2}Na(H-3K)-a\nu', \tag{24}$$

$$\dot{K}=\nu K'-A^{-2}(N''-A^{-1}A'N')+N(-4A^{-5/2}(A^{1/2})''+(A^{-2}A')^2 + HK-8\pi(A^{-2}S_{11}+\tfrac{1}{2}(\rho-\operatorname{tr}S))). \tag{25}$$

Integrating the equation for a over the circle yields $\dot{a}=\mu a$, with $\mu=-1/2\int_{S^1}N(H-3K)$, since $\int_{S^1}\nu'$ vanishes. Inserting this back gives an equation for shift:

$$\nu'=-\frac{1}{2}N(H-3K)+\frac{1}{2}\int_{S^1}N(H-3K). \tag{26}$$

Differentiation of the equation for H with respect to x yields an equation for H':

$$(\partial_t-\nu\partial_x)H'=\nu'H'. \tag{27}$$

In summary we have equations for space and time derivatives of the fundamental forms h and k. Moreover there are equations for the spacelike derivatives of lapse and shift, but unfortunately there is no information about their time derivatives.

So far we started with a given surface symmetric space–time, admitting a local in time PMC foliation, to which we adapted the field equations. This raises the opposite question: Given Eqs. (19)–(27) and appropriate data, does there exist a solution, and how unique is it? To answer this question we first need to state more precisely the term ''appropriate data:''

Definition 3.2: A *symmetric initial data set* is a smooth collection (Σ, h, k) consisting of a three-manifold Σ diffeomorphic to $S^1\times F$ with metric h and a symmetric tensor field k on Σ, where Σ admits coordinates, such that h and k could be written in the form shown in Sec. III A.

If there are matter fields present, then it is assumed that there is also smooth symmetric matter data and equations, leading to a well-posed Cauchy problem of the reduced field equations in harmonic coordinates.

The smoothness of the quantities appearing in the definition is required, since the transformation to harmonic coordinates involves derivatives.

Proposition 3.3: Let (Σ, h, k) *be a symmetric initial data set, with matter obeying the strong energy condition and [compare Eq. (5) for definition]* $\lambda>0$ *somewhere on* Σ. *Further, let* t_0 *denote an arbitrary real number*.

Then there exists a $\delta>0$ *and a PMC foliated surface symmetric space–time* $(\overline{M},\overline{g})$ *diffeomorphic to* $]t_0-\delta,t_0+\delta[\times\Sigma$ *with an embedding* $\iota:\Sigma\to\overline{M}$, *satisfying* $\iota(\Sigma)=S_{t_0}$ *and* ι_*h, ι_*k *are the first and second fundamental form of* S_{t_0} *in* $(\overline{M},\overline{g})$. $(\overline{M},\overline{g})$ *obeys the strong energy condition and* $\overline{g}$ *can be written in the form described in Proposition 3.1. This construction is unique up to the choice of* t_0 *and* δ.

Proof: On the induced manifold $\hat{\Sigma}$ diffeomorphic to $S^1\times\hat{F}$ the induced data are invariant under the group action, hence the Cauchy developments also and we get a surface symmetric Cauchy development of the data, admitting a symmetric local in time PMC foliation near Σ on some time interval $]t_0-\delta,t_0+\delta[$ and allowing a set of coordinates stated in Proposition 3.1. The uniqueness property stated previously follows from the geometric uniqueness of solutions of Einstein's equations associated with the uniqueness of the PMC foliation, once the remaining degree of freedom has been fixed by the requirement $\iota(\Sigma)=S_{t_0}$. Note that lapse is fixed by the ellipticity of the respective PMC equation and shift is fixed by Eq. (26) and the condition $\nu(t,0)=0$. ■

In surface symmetric space–times, there is another way to express the constraint equations (19) and (20) in terms of ''optical scalars,'' see Guven (1995) for an enlightening presentation.

The geodesic null congruences determined by $k_\pm=m\pm n$ give rise to the null expansions

$$\vartheta_\pm:=-(\operatorname{tr}\lambda\pm\operatorname{tr}\kappa)=\frac{2}{r}(m(r)\pm n(r))=\frac{2}{r}k_\pm(r)=2A^{-2}A'\mp(H-K), \tag{28}$$

where (14) with (17) has been used, together with the relation $r=Aa$ for the area radius defined in (12). The formula illustrates the definition of r as a volume measure, whose variation along $k_{\pm}$ is described by the (negative of the) trace of the second fundamental form associated with this direction.

Now we can write the constraint equations for an arbitrary symmetric Cauchy surface S symmetrically as

$$8\pi(\rho+j)=-m(\vartheta_-)-\tfrac{3}{4}\vartheta_-^2+\vartheta_-H+r^{-2}\epsilon,$$

$$8\pi(\rho-j)=-m(\vartheta_+)-\tfrac{3}{4}\vartheta_+^2-\vartheta_+H+r^{-2}\epsilon$$

and taking $\omega_{\pm}:=r\vartheta_{\pm}$ as the fundamental variable we get [compare Guven (1995)]

$$m(\omega_{\pm})=-8\pi r(\rho\mp j)\mp\omega_{\pm}H+\frac{1}{4r}(\omega_+\omega_--2\omega_{\pm}^2+4\epsilon). \tag{29}$$

Furthermore, the area radius serves as a warping function in the warped product $M=B\times_r F$ of the two-dimensional space–time $(B,\underline{g})$ with $(F,\overline{g})$, where $B=\mathbb{R}\times S^1$ is the quotient M/G and $\underline{g}=g_{|B}$. We adopt the convention that lower case Latin letters from the beginning of the alphabet range from 0 to 1, and objects intrinsic or orthogonally projected to $(B,\underline{g})$ will be marked by an underbar. Einsteins equations in this framework can be considered as equations in $(B,\underline{g})$ for the field $r:B\to\mathbb{R}$:

$$\underline{\nabla}_a\underline{\nabla}_b r=\frac{M}{r^2}\underline{g}_{ab}-4\pi r(\underline{T}_{ab}-\mathrm{tr}\ \underline{T}\underline{g}_{ab}), \tag{30}$$

where $\underline{T}$ denotes the projected energy–momentum tensor into the space–time $(B,\underline{g})$ and the mass function M is defined as

$$M:=\tfrac{1}{2}r(\epsilon-\underline{\nabla}^a r\underline{\nabla}_a r)=\tfrac{1}{2}r(\epsilon-{}^4\nabla^\alpha r\,{}^4\nabla_\alpha r)=\tfrac{1}{2}r(\epsilon-\tfrac{1}{4}r\vartheta_+r\vartheta_-), \tag{31}$$

since $\vartheta_+\vartheta_-=4/r^2{}^4\nabla^\alpha r\,{}^4\nabla_\alpha r$. M turns out to be the Hawking mass $m_H(F)$ (up to a factor $-\frac{1}{2}\chi$ for genus $(F)\geqslant 3$):

$$m_H(F):=\frac{\mathrm{Vol}(F)^{1/2}}{(4\pi)^{3/2}}\left(\pi\chi(F)-1/8\int_F\vartheta_+\vartheta_-\right) \tag{32}$$

and differentiation of (31) yields the mass flux equation

$$\underline{\nabla}_a M=4\pi r^2(\underline{T}_{ab}-\mathrm{tr}\,\underline{T}\underline{g}_{ab})\underline{\nabla}^b r. \tag{33}$$

2. Expanding and recollapsing models

Let us first consider the definition of mass in (31). In the spherically symmetric case we see, that grad r is spacelike as long as $2M<r$ holds, a condition we are familiar with in connection with the Schwarzschild space–time.

In the plane and hyperbolic case the picture is quite different, since grad r turns out to be timelike, as long as $2M/r>\epsilon$. In fact, Lemmas 2.3, 2.4, and 2.5 in Rendall (1995b) prove for space–times with hyperbolic symmetry and in nonflat plane symmetric space–times grad r is timelike, provided the dominant energy condition is fulfilled. Thus we cannot think about r as some radial, spacelike coordinate any longer and this fact will play a central role in our further analysis.

We can choose the time orientation in those space–times to find r past pointing, *throughout the whole space–time*. Then we define the time orientation on the cotangent bundle by metric transport from the tangent bundle, such that dr turns out to be future pointing. Therefore r increases with time, which means that the area of the surfaces of symmetry increases with time, and the space–time expands in this sense. Thus we will call these space–times expanding. We get

an equivalent characterization by the relation between grad r and the null expansions: ϑ_+ and ϑ_- have fixed and opposite signs (in particular $\vartheta_+>0$, $\vartheta_-<0$), since $\vartheta_\pm=(2/r)k_\pm(r)=(2/r)dr(k_\pm)$ is the contraction of a timelike with a null vector.

Therefore we can decide, given a symmetric initial data set (Σ,h,k) with nonflat plane or hyperbolic symmetry, with matter obeying the dominant energy condition, which direction is expanding or contracting. This is important, since we expect some singularity toward the contracting direction and therefore we will pay attention to the past development $D^-(\Sigma)$, which represents the contracting direction with respect to our conventions.

Note that we obtained this information without referring to the mean curvature $H=\operatorname{tr} k$. But it turns out that the mean curvature of an arbitrary Cauchy surface S in expanding space–times is also restricted in some way.

First, remember that $H=\operatorname{tr} k=-\operatorname{div} n$ measures the convergence of the geodesic congruence, future pointing and orthogonal to S. Thus, $H<0$ everywhere on S corresponds to the notion of expansion and Hawking's theorem proves the existence of a singularity in the past. In an expanding space–time in our sense, H is not necessarily confined to be negative everywhere. But we will see that it is impossible for H to become non-negative everywhere on S: The explicit formula (28) for $\vartheta_\pm$ shows, in connection with our sign conventions, that $H<K$. If H were non-negative, then $|H|<|K|$, thus $H^2-K^2<0$ and integration of the Hamiltonian constraint (19) over S^1 yields a contradiction.

With the dominant energy condition we can show more. Writing the Hamiltonian constraint as $R+H^2-|k|^2=16\pi\rho$ we get $R+H^2\geqslant 0$. Assuming $H\equiv 0$ on S, we would get $R\geqslant 0$. But symmetric surfaces S in space–times with plane and hyperbolic symmetry obey, respectively, the topological conditions (i) and (ii) of theorem 5.2 in Schoen and Yau (1979), which imply that S cannot have positive scalar curvature and must be flat in the case of non-negative scalar curvature. Thus S must be flat and the scalar curvature vanishes. This in turn forces $\rho=0$ and $k=0$ by the Hamiltonian constraint. In the plane symmetric case then the space–time is flat by $k=0$, $\rho=0$ and the dominant energy condition, contradiction. In the hyperbolic symmetric case integration of Eq. (19) yields a contradiction, too. Putting all this together we conclude without loss of generality, that surface symmetric space–times, obeying the dominant energy condition, which are plane symmetric and not flat or have hyperbolic symmetry, are everywhere expanding, with dr timelike future pointing, $\vartheta_+>0$, $\vartheta_-<0$, and any symmetric Cauchy surface S is not maximal with mean curvature not everywhere positive on S.

Of course, these arguments do not work in the spherically symmetric case, where grad r is spacelike in $\{2M<r\}$ and no fixed sign of the expansions $\vartheta_\pm$ can be expected, fitting into the general belief in the closed universe recollapse conjecture, which precludes expansion of the whole space–time. In particular we expect the existence of a maximal hypersurface in M.

C. *A priori* estimates for the field equations

Our aim now is to get sufficient estimates that allow the construction of a global PMC foliation. The ''size'' of the foliation is measured by the mean curvature H, thus *we are looking for* uniform *estimates of the geometric and matter quantities in terms of H*.

So let (M, g) be a surface symmetric space–time, satisfying the dominant and strong energy condition. Let us assume that there is a Cauchy surface Σ in M with mean curvature $H<0$. In particular we get a local in time PMC foliation $\{S_t\}$, $t\in]t_1,t_2[$ with $\Sigma=S_0$ by Theorem 2.2. If the space–time possesses plane or hyperbolic symmetry, we choose the time orientation in correspondence to the conventions introduced in Sec. III B, thus H decreases with decreasing PMC time. If (M, g) is spherically symmetric we choose the time orientation that H decreases with PMC time, too. Then in either case we expect to find a singularity at least in the past $D^-(\Sigma)$ of Σ.

In $D^-(\Sigma)$ the mean curvature is bounded from above by $H\leqslant\overline{H}<0$ and $H=\overline{H}$ only on Σ. Thus $|H|$ is bounded from below and we find the following estimates for the field equations in $D^-(\Sigma)$ as long as H remains finite:

(1) At first we consider the constraint equation (29) on a fixed leaf. At the critical points of $\omega_\pm$

we find together with the dominant energy condition the important inequality

$$|r\vartheta_{\pm}| \leqslant 2(|Hr| + \sqrt{(Hr)^2 + \epsilon}) \tag{34}$$

as shown in Rendall (1995b).

For plane and hyperbolic symmetry this inequality (34) can be strengthened to

$$|\vartheta_{\pm}| \leqslant 4|H| \leqslant C \Rightarrow |A^{-2}A'| \leqslant C \quad \text{and} \quad |K| \leqslant C$$

by the definition (28) of the null expansions.

In the spherically symmetric case the argument is more complicated: First, the work of Burnett (1991) shows that under the additional assumption of the non-negative-pressures condition we have $r \leqslant C$ and $0 < C \leqslant M$. Using the upper bound for r on the right-hand side of (34) we get with (31)

$$|r\vartheta_{\pm}| \leqslant C \Rightarrow \frac{M}{r} \leqslant C.$$

Thus we get $r^{-1} \leqslant C_{M^{-1}} \leqslant C$; hence r is bounded above and below away from zero. Inserting this in the estimate (34) leads to $|\vartheta_{\pm}| \leqslant Cr^{-1} \leqslant C$ and we are in the same situation as in the plane/hyperbolic case, hence $|A^{-2}A'| \leqslant C$ and $|K| \leqslant C$.

(2) Now consider the lapse equation (21) on a fixed leaf. At the point where N attains its maximum $\overline{N}$, we have

$$\overline{N} \leqslant (\tfrac{1}{2}(H-K)^2 + K^2 + 4\pi(\rho + \operatorname{tr} S))^{-1} \leqslant C/H^2 \leqslant C$$

due to the strong energy condition. Hence we have a bound for $|N|$.

(3) Next, there is a bound for shift. Examination of formula (26) shows that all quantities on the right-hand side are bounded, so we get $|\nu'| \leqslant C$, and therefore, using $\nu(t,0) = 0$: $|\nu(t,x| \leqslant |\nu(t,0)| + \int'_{S^1} |\nu'| \leqslant C$.

(4) By the way, Eq. (27) for H' provides a bound for $|H'|$, since the coefficient on the right-hand side is bounded and applying Gronwall gives the desired estimate.

(5) With the information about ν' examination of (24), $\dot{a} = a(-\frac{1}{2}N(H-3K) - \nu')$ shows that the factor in brackets is already bounded and we get an inequality of the form $|\partial_t \ln|a|| \leqslant C$, which leads to a bound for $|a|$ and $|a^{-1}|$.

(6) The same line of argumentation works for A. Equation (23) can be written as $\dot{A} - \nu A' = A(-NK + \nu')$, with the factor on the right-hand side bounded. So we get bounds for $|A|$ and $|A^{-1}|$, too.

Since we have already bounded the null expansions $\vartheta_{\pm} = 2A^{-2}A' \pm (H-K)$, one sees easily that even $|A'| \leqslant C$.

(7) Integration of Eq. (19) over the circle yields an inequality

$$\frac{1}{8}\int_{S^1} A^{5/2} 16\pi\rho = \frac{1}{8}\int_{S^1} A^{5/2}\left(H^2 - K^2 - \frac{1}{2}(H-K)^2\right) + \frac{1}{4}\int_{S^1} A^{1/2}a^{-2}\epsilon$$

$$\leqslant \frac{1}{8}\int_{S^1} A^{5/2}H^2 + \frac{1}{4}\int_{S^1} A^{1/2}a^{-2}.$$

From this one concludes the boundedness of $\int_{S^1}\rho$, and by the dominant energy condition the boundedness of $\int_{S^1}|j|$ and $\int_{S^1}|S|$. Now integrating Eq. (21) starting at a point where $N' = 0$, we get

$$N' = -\int A^{-1}A'N' + \int A^2 N\left(\frac{1}{2}(H-K)^2 + K^2 + 4\pi(\rho + \operatorname{tr} S)\right) - \int A^2,$$

$$|N'| \leqslant C + \int |A^{-1}A'N'|.$$

The bound for $|N'|$ then follows from Gronwall's inequality.

(8) Furthermore, the bounds for A, A^{-1} together with the basic estimate for ϑ_+ and the boundedness of $\int_{S^1}\rho$ are enough to apply the proof of the lemma in Rendall (1997b), which ends up with $|N^{-1}| \leqslant C$.

Collecting all these estimates we get the

Proposition 3.4: Let (M,g) *be a surface symmetric space–time, obeying the dominant and strong energy condition and in the spherically symmetric case the non-negative-pressures condition, too. Assume the existence of a symmetric Cauchy surface* Σ *with strictly negative mean curvature. In particular we get from Proposition 3.1 a PMC time coordinate* t, *ranging in* $]t_1,t_2[$ *with* $\Sigma=\{t=0\}$ *and* H *decreases with decreasing* t.

Then we have uniformly on $]t_1,0]$,

$$|A|,|A^{-1}|,|A'|,|a|,|a^{-1}|,|H|,|H'|,|K|,|N|,|N^{-1}|,|N'|,|\nu|,|\nu'| \leqslant C.$$

To put this result into some framework, we establish some formalism to have useful abbreviations at hand as well as to make clear the dependence between estimates of geometric quantities and matter variables.

Definition 3.5:

$$\mathcal{F} := (A,a,N,\nu,H,K)$$

collects the quantities describing the geometry of the foliation and

$$\Phi := (\rho,j,S)$$

abbreviates the matter quantities.

We have already estimated the quantities $\mathcal{F}$, A^{-1}, a^{-1}, N^{-1}, as well as A', N', ν', H' and $\dot{A}$, $\dot{a}$, $\dot{H}$ (by inspection of the field equations). The idea is now to bound all quantities $\mathcal{F}$, Φ together with all of their derivatives uniformly on the time interval $]t_1,0]$. Then there exists a smooth extension to the closure of the interval, which serves as a new symmetric initial data set for the field equations in the sense described in Definition 3.2. Note that the bounds for A^{-1}, a^{-1}, N, N^{-1} ensure that the geometry remains regular at the boundary of the time interval and the C^∞-bounds for lapse and shift turn out to be necessary to obtain C^∞-bounds for the fundamental forms.

Proposition 3.3 then sets us in the position to extend the foliation at least in the past direction, where $H<0$ holds: Construct the solution stated in Proposition 3.3 and embed M into the maximal Cauchy development of the data.

To carry out this program, we need some knowledge about the matter quantities. First, the matter has to obey the dominant and strong energy conditions. Second, assume that the regularity of the geometry guarantees the regularity of the matter in a certain way. For all non-negative integers m and n we have

$$\begin{aligned} |\partial_t^m \partial_x^n \mathcal{F}| \leqslant C &\Rightarrow |\partial_t^m \partial_x^n \Phi| \leqslant C \\ |\partial_t^m \partial_x^{n+1} \mathcal{F}| \leqslant C &\Rightarrow |\partial_t^{m+1} \partial_x^n \Phi| \leqslant C, \end{aligned} \tag{35}$$

then the following lemmas hold.

Lemma 3.6: Assume that the matter fulfills (35). Then for arbitrary non-negative integers m, n,

$$\left.\begin{array}{l}\forall_{k<m}\forall_l|\partial_t^k\partial_x^l\mathcal{F}|\leqslant C\\ \forall_{l<n}|\partial_t^m\partial_x^l\mathcal{F}|\leqslant C\end{array}\right\}\Rightarrow|\partial_t^m\partial_x^{n+1}\mathcal{F}|\leqslant C$$

holds.

Lemma 3.7: Assume that the matter fulfills (35). Then for arbitrary non-negative integers m, n,

$$\left.\begin{array}{l}\forall_{k<m}\forall_l|\partial_t^k\partial_x^l\mathcal{F}|\leqslant C\\ \forall_{l<n+1}|\partial_t^m\partial_x^l\mathcal{F}|\leqslant C\end{array}\right\}\Rightarrow|\partial_t^{m+1}\partial_x^n\mathcal{F}|\leqslant C$$

holds.

Together with Proposition 3.4 the lemmas accomplish the task of bounding all necessary derivatives of the geometric quantities, by first bounding all spatial derivatives $\partial_x^n\mathcal{F}$ (Proposition 3.4 and Lemma 3.6) and then successively all derivatives $\partial_t^k\partial_x^l\mathcal{F}$, with $k+l=n$ by alternative applications of the lemmas. Therefore, in view of Proposition 3.4 the validity of property (35) will be enough to extend the foliation. We will prove (35) for some matter models in the next section. But first, of course, we have to prove the lemmas.

Proof of Lemma 3.6:

A: Applying $\partial_t^m\partial_x^n$ on Eq. (19) and integrating along S^1 yields a bound for the difference $|(\partial_t^m\partial_x^nA^{1/2})'(y)-(\partial_t^m\partial_x^nA^{1/2})'(x)|$ and using $\int_{S^1}(\partial_t^m\partial_x^nA^{1/2})'=0$ (hence is bounded) gives a bound for $\partial_t^m\partial_x^{n+1}A^{1/2}$, hence for $\partial_t^m\partial_x^{n+1}A$.

a: Trivial.

ν: Apply $\partial_t^m\partial_x^n$ on (26), then the right-hand side of (26) is bounded by assumption, from which the claim follows immediately.

N: Again applying $\partial_t^m\partial_x^n$ on the lapse equation (21) yields an equation of the form (21) for $\partial_t^m\partial_x^nN''$ plus some already bounded term (by assumption and the already proven bound for $\partial_t^m\partial_x^nA'$). The boundedness of $\partial_t^m\partial_x^nN'$ follows then from Gronwall's estimate after integrating the equation for $\partial_t^m\partial_x^nN''$ along S^1 starting at a point with $\partial_t^m\partial_x^nN'=0$.

H: Differentiation of Eq. (27) gives an expression of the form $(\partial_t-\nu\partial_x)\partial_t^m\partial_x^nH'=B_1\partial_t^m\partial_x^nH'+B_2$, with B_1, B_2 bounded, where the assumptions and the already obtained bound for $\partial_t^m\partial_x^{n+1}\nu$ have been used. Thus applying Gronwall's inequality yields a bound for $\partial_t^k\partial_x^{n+1}H$.

K: Apply $\partial_t^m\partial_x^n$ on Eq. (20), then the right-hand side is bounded by the previous estimates, hence bounding $\partial_t^m\partial_x^{n+1}K$. ■

Proof of Lemma 3.7:

A: Applying $\partial_t^m\partial_x^n$ on (23) yields immediately a bound for $\partial_t^m\partial_x^n\dot{A}$, since the right-hand side is already bounded.

a: The same argument with ∂_t^m instead of $\partial_t^m\partial_x^n$ applied to Eq. (24) works in this case to bound $\partial_t^m\partial_x^n\dot{a}$.

H: And again, $\partial_t^m\partial_x^n$ on Eq. (22) yields an estimate for $\partial_t^m\partial_x^n\dot{H}$.

K: Apply $\partial_t^m\partial_x^n$ on Eq. (25), then the only terms on the right-hand side not already known to be bounded are $\partial_t^m\partial_x^nN''$ and $\partial_t^m\partial_x^nA''$. But inserting Eqs. (21) and (19) for N'' and A'', respectively, one sees easily that $\partial_t^m\partial_x^nN''$ and $\partial_t^m\partial_x^nA''$ indeed are bounded by the right-hand sides of their equations, hence $\partial_t^{m+1}\partial_x^nK$ is bounded.

N: Unfortunately there is no explicit equation for $\dot{N}$. So we have to apply the derivative operator $\partial_t^{m+1}\partial_x^n$ to Eq. (21), therefore producing already estimated terms involving $\partial_t^{m+1}\partial_x^n$ applied on the quantities treated previously, as well as on Φ [bounded by property (35)], but also a term involving $\partial_t^{m+1}\partial_x^{n+1}A$ on the right-hand side. If this term turns out to be bounded, then the equation for $\partial_t^{m+1}\partial_x^nN''$ has the form

$$\partial_t^{m+1}\partial_x^nN''=B-A^{-1}A'\partial_t^{m+1}\partial_x^nN'+A^2\partial_t^{m+1}\partial_x^nN((\tfrac{1}{2}H-K)^2+K^2+4\pi(\rho+\mathrm{tr}\,S))-A^2$$

with $|B|$ bounded. On S^1, $\partial_t^{m+1}\partial_x^nN$ attains its maximum, from which we can infer

$$\partial_t^{m+1}\partial_x^n N \leqslant \{(1-B/A^2)(\tfrac{1}{2}(H-K)^2+K^2+4\pi(\rho+\mathrm{tr}\,S))^{-1}\}_{\max}$$

hence it is bounded from above. Similarly for the minimum,

$$\partial_t^{m+1}\partial_x^n N \geqslant \{(1-B/A^2)(\tfrac{1}{2}(H-K)^2+K^2+4\pi(\rho+\mathrm{tr}\,S))^{-1}\}_{\min},$$

which is bounded from below and we get $|\partial_t^{m+1}\partial_x^n N| \leqslant C$.

It remains to show the boundedness of $\partial_t^{m+1}\partial_x^{n+1}A = \partial_t^m \partial_x^{n+1}\dot{A}$. Inserting Eq. (23) for $\dot{A}$, we see on the right-hand side beside a bounded term the quantities $\partial_t^m\partial_x^n A''$ and $\partial_t^m\partial_x^{n+1}\nu'$. Inserting Eq. (19) for A'' and Eq. (26) for ν', we finally obtain bounds for $\partial_t^m\partial_x^n A''$ and $\partial_t^m\partial_x^{n+1}\nu'$, and hence for $\partial_t^m\partial_x^{n+1}\dot{A}$, as desired.

ν: The final estimate is straightforward: Apply the operator $\partial_t^{m+1}\partial_x^{n-1}$ to Eq. (26), which immediately yields a bound for $\partial_t^{m+1}\partial_x^n\nu$ since the right-hand side of the equation is already bounded by the above-given arguments. ■

D. Higher order estimates

Here we prove the matter regularity condition (35) for Einstein–Vlasov, Einstein–Maxwell, and the Einstein–Vlasov–Maxwell systems, achieving the goal of this work.

1. Collisionless matter

The $3+1$-split of the Vlasov equation (9) with respect to the symmetries reads

$$0 = \partial_t f + \left(NA^{-1}\frac{v^1}{v^0} - \nu\right)\partial_x f + \left(-A^{-1}N'v^0 + NKv^1 + NA^{-2}A'\frac{(v^2)^2+(v^3)^3}{v^0}\right)\frac{\partial}{\partial v^1}f$$
$$-N\left(A^{-2}A'\frac{v^1}{v^0} - \frac{1}{2}(H-K)\right)v^B\frac{\partial}{\partial v^B}f, \tag{36}$$

where $v^0 := \sqrt{1+\delta_{ij}v^iv^j}$ and $0 = \partial_{x^2}f = \partial_{x^3}f = v^3(\partial/\partial v^2)f - v^2(\partial/\partial v^3)f$ (by symmetry) has been used.

The energy–momentum tensor (10) associated with the Vlasov equation leads to the matter quantities

$$\rho = \int f v^0 \,\mathrm{d}v,$$

$$j = \int f v^1 \,\mathrm{d}v,$$

$$S_{ab} = \int f v_a v_b / v^0 \,\mathrm{d}v.$$

Now we investigate the matter regularity property (35). Since f is constant along the characteristics of the Vlasov equation, given an initial particle distribution f_0 on the mass shell over Σ, we get the matter distribution for each time t as a function $f(t,y,w)$ on the mass shell over the leaf S_t by $f(t,y,w) = f_0(Y(t,y,w),V(t,y,w))$, where (Y,V) denotes the characteristic curve of the Vlasov equation through the point $(0,y,w) \in P_{(0,y)}$, $(0,y) \in \Sigma$.

Thus the matter quantities ρ,j,S are bounded, provided the support of f remains bounded. Define now

$$\overline{P}_f(t) := \{\sup|v| \,|\, v \in \mathrm{supp}\, f(t,y,w) \forall_{(0,y,w)\in P_{(0,y)}}\},$$

then the matter quantities are bounded by $C(1+\overline{P}_f(t))^4$, hence it is sufficient to control $\overline{P}_f(t)$ on $]t_1,0]$.

Since the characteristic curves (Y,V) are integral curves of X and all coefficients in the components of X are already bounded by Proposition 3.4, the characteristics themselves are bounded, $\overline{P}_f(t)\leqslant C$ as desired.

Now we need to iterate this procedure. Assume, that all $\partial_t^k\partial_x^l\mathcal{F}$ and $\partial_t^k\partial_x^l\Phi$ for $k+l=m+n$ are bounded. To bound the derivatives of the matter quantities of order $m+n+1$, differentiate the Vlasov equation $m+n+1$ times (with respect to t and x only). This yields linear equations for $\partial_t^{\overline{k}}\partial_x^{\overline{l}}f$, for all non-negative integers $\overline{k}+\overline{l}=m+n+1$ of the form

$$X(\partial_t^{\overline{k}}\partial_x^{\overline{l}}f)=B,$$

where B vanishes outside the support of f, which bounds the support of B. Moreover, B involves derivatives of order $m+n+1$ of the quantities $\mathcal{F}$ and A', N'. For derivatives of order at most m in t, we see the boundedness of $|B|$ by applying similar arguments as used in the proof of Lemma 3.6. Thus in this case $\partial_t^{\overline{k}}\partial_x^{\overline{l}}f$ is bounded and $\overline{P}_{\partial_t^{\overline{k}}\partial_x^{\overline{l}}f}$, since they have the same characteristics. Hence the derivatives of the matter quantities of order $m+n+1$, involving derivatives of order at most m in t, are bounded. Moreover, due to the simple dependence of the characteristics on the frame variables v, all derivatives of f with respect to v are bounded, too.

In view of this fact, we are able to bound all derivatives of order $m+n+1$ of the matter quantities by considering the Vlasov equation as an equation for $\partial_t^{m+1}\partial_x^{n+1}f$, for which the right-hand side is known to be bounded.

Therefore the first part of property (35) holds. For the second part we must show that the spacelike derivatives of $\mathcal{F}$ can be redistributed to timelike derivatives of Φ. But this has already been done in the proof of the first part of (35), and we get the

Theorem 3.8: *Let (M,g,f) be a surface symmetric solution of the Einstein–Vlasov system, which possesses a symmetric Cauchy surface Σ with strictly negative mean curvature $H\leqslant\overline{H}<0$ and $H=\overline{H}$ somewhere on Σ.*

Then all of the past of Σ admits a PMC foliation $\{S_t\}$, where t takes all values in the interval $]-\infty,0]$ and H takes all values in $]-\infty,\overline{H}]$.

2. Maxwell field

Let F denote the electromagnetic field. The symmetry simplifies F: Due to the symmetries F can be written relative to the orthonormal coframe $\{{}^4\sigma^\mu\}$ introduced in Sec. III A as

$$F=-\hat{e}(t,x)\,{}^4\sigma^0\wedge{}^4\sigma^1+\hat{b}(t,x)\,{}^4\sigma^2\wedge{}^4\sigma^3,$$

since all other components are forced to vanish and F and ${}^4\sigma^0\wedge{}^4\sigma^1$, ${}^4\sigma^2\wedge{}^4\sigma^3$ remain invariant under the action of the symmetry group.

To obtain an explicit form of the Maxwell equations, F and $*F$ are represented in the given coordinates by

$$F_{\alpha\beta}\sim\begin{pmatrix}0&-e&0&0\\ e&0&0&0\\ 0&0&0&b\\ 0&0&-b&0\end{pmatrix},\quad \begin{aligned}&e(t,x)=NA\hat{e},\\ &b(t,x,\vartheta)=(Aa)^2\epsilon_\vartheta\hat{b},\end{aligned}$$

$$*F_{\alpha\beta}\sim\begin{pmatrix} 0 & \kappa b & 0 & 0 \\ -\kappa b & 0 & 0 & 0 \\ 0 & 0 & 0 & \kappa^{-1}e \\ 0 & 0 & -\kappa^{-1}e & 0 \end{pmatrix}, \quad \sqrt{|g|}=NA^3a^2|\epsilon_\vartheta|, \quad \kappa:=NA^{-1}a^{-2}|\epsilon_\vartheta^{-1}|.$$

The Maxwell equations (6) in vacuum are given by setting $J^\alpha=0$. We get for the magnetic field

$$F'_{23}=0 \qquad b'=0$$
$$\Leftrightarrow$$
$$\dot{F}_{23}=0 \qquad \dot{b}=0\,.$$

Since ϵ_ϑ does not depend on (t,x), we find $\partial_\alpha((Aa)^2\hat{b})=0$ for $\alpha=0,1$, hence

$$\hat{b}=C(Aa)^{-2},$$

$$b=C\epsilon_\vartheta\,.$$

For the electric field we find

$$*F'_{23}=0 \qquad (\kappa^{-1}e)'=0$$
$$\Leftrightarrow$$
$$*\dot{F}_{23}=0 \qquad (\kappa^{-1}e)^{\cdot}=0\,.$$

(Note, that $*F_{01,2}$ vanishes, since κb contains no ϵ_ϑ.) Again, since ϵ_ϑ does not depend on (t,x), we get $\partial_\alpha((Aa)^2\hat{e})=0$, for $\alpha=0$, 1, hence

$$\hat{e}=C(Aa)^{-2},$$

$$e=CNA^{-1}a^{-2}.$$

Since N, A^{-1}, a^{-1} are already bounded, the same is true for the electromagnetic fields e and b.

The energy–momentum tensor (8) takes the simple form

$$E({}^4e_\alpha,{}^4e_\beta)=\frac{1}{8\pi}(\hat{e}^2+\hat{b}^2)\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

and we get the matter quantities as

$$\rho=E({}^4e_0,{}^4e_0)=-S_{11}=\operatorname{tr}S=\frac{1}{8\pi}(\hat{e}^2+\hat{b}^2)=\frac{1}{8\pi}(C(Aa)^{-4}+C(Aa)^{-4}),$$

$$j=0.$$

The property (35) posed in Sec. III C is obviously fulfilled, hence we get

Theorem 3.9: *Let (M,g,F) be a surface symmetric solution of the Einstein–Maxwell system with plane or hyperbolic symmetry, which possesses a symmetric Cauchy surface Σ with strictly negative mean curvature $H\leqslant\overline{H}<0$ and $H=\overline{H}$ somewhere on Σ. Then all of the past of Σ admits a PMC foliation $\{S_t\}$, where t takes all values in the interval $]-\infty,0]$ and H takes all values in $]-\infty,\overline{H}]$.*

Note that the restriction to plane and hyperbolic symmetry is necessary, since the electromagnetic energy–momentum tensor does not obey the non-negative pressures condition, and therefore fails to satisfy the assumptions of Proposition 3.4 in the case of spherical symmetry.

3. Charged particles

Now consider the Vlasov–Maxwell system in (M,g). We obtain the coupled equations by modifying the uncharged Vlasov equation (36) by adding the term

$$e\left(A^{-1}+A^{-2}A'-N^{-1}\nu(1+A^{-1}A')\frac{v^1}{v^0}\right)\frac{\partial f}{\partial v^1}$$

on the right-hand side. The matter current J according to the energy–momentum tensor

$$\Theta=T+E,\quad \begin{matrix}\rho=\Theta({}^4e_0,{}^4e_0)\\ j=-\Theta({}^4e_0,{}^4e_1),\end{matrix}$$

is of the form

$$J=\rho\,{}^4e_0+j\,{}^4e_1=N^{-1}\rho\partial_0+(A^{-1}j-N^{-1}\nu\rho)\partial_1.$$

The homogeneous Maxwell equations remain unchanged, which yields as before

$$\hat{b}=C(Aa)^{-2},$$

$$b=C\epsilon_\vartheta.$$

Since ${}^*J_{\alpha\beta\gamma}=\sqrt{|g|}\epsilon_{\mu\alpha\beta\gamma}J^\mu$, and again for $\alpha=0$, 1, $\partial_\alpha(\kappa^{-1}e)=|\epsilon_\vartheta|\partial_\alpha((Aa)^2\hat{e})$ the inhomogeneous equations read

$$(\kappa^{-1}e)'=4\pi\sqrt{|g|}J^0 \qquad \hat{e}'=-2A^{-1}A'\hat{e}+4\pi A\rho$$

$$\Leftrightarrow$$

$$(\kappa^{-1}e)^{\cdot}=-4\pi\sqrt{|g|}J^1 \qquad \dot{\hat{e}}=-2(Aa)^{-1}(Aa)^{\cdot}\hat{e}+4n(A\nu\rho\text{-}Nj).$$

To get a bound for $\hat{e}$, note that the inhomogeneous Maxwell equations are of the form

$$\partial_\alpha\hat{e}=\varphi_\alpha\hat{e}+\psi_\alpha\cdot\begin{pmatrix}\rho\\ j\end{pmatrix},\quad \alpha=0,1$$

with $\varphi_\alpha,\psi_\alpha$ bounded by Proposition 3.4. Integrating the second equation gives

$$\left|\int_{S^1}\dot{\hat{e}}\right|=\left|\int_{S^1}\varphi_0\hat{e}+\int_{S^1}\psi_0\cdot\begin{pmatrix}\rho\\ j\end{pmatrix}\right|\leqslant C\left|\int_{S^1}\hat{e}\right|+C,$$

since $\int_{S^1}\rho$, $\int_{S^1}|j|\leqslant C$ by integrating Eq. (19), as shown in the proof of Proposition 3.4. Then using the inequality

$$\left|\int_{S^1}\hat{e}\right|(t)\leqslant\left|\int_{S^1}\hat{e}\right|(0)+\int_0^t\left|\int_{S^1}\dot{\hat{e}}\right|$$

and applying Gronwall's inequality on $|\int_{S^1}\hat{e}|$ we obtain

$$\left|\int_{S^1}\hat{e}\right|\leqslant C.$$

Now using the first equation, we get analogously

$$|\hat{e}(t,y)-\hat{e}(t,x)|=\left|\int_x^y \hat{e}'\right|=\left|\int_{S^1}\varphi_1\hat{e}+\int_{S^1}\psi_1\cdot\begin{pmatrix}\rho\\ j\end{pmatrix}\right|\leqslant C\left|\int_{S^1}\hat{e}\right|+C\leqslant C,$$

where $\left|\int_{S^1}\hat{e}\right|\leqslant C$ has been used.
Thus we have

$$\left.\begin{aligned}&|\hat{e}(t,y)-\hat{e}(t,x)|\leqslant C\\ &\left|\int_{S^1}\hat{e}\right|\leqslant C\end{aligned}\right\}\Rightarrow\quad |\hat{e}|\leqslant C$$

as desired.

Now property (35) is obtained by bounding appropriate derivatives of $\hat{e}$: Application of $\partial_t^m\partial_x^{n-1}$ on the equation for $\hat{e}'$ shows the first part of property (35) and application of $\partial_t^m\partial_x^n$ on the equation for $\dot{\hat{e}}$ establishes the second part. This proves:

Theorem 3.10: *Let* (M,g,f,F) *be a surface symmetric solution of the Einstein–Vlasov–Maxwell system with plane or hyperbolic symmetry, which possesses a symmetric Cauchy surface* Σ *with strictly negative mean curvature* $H\leqslant\overline{H}<0$ *and* $H=\overline{H}$ *somewhere on* Σ. *Then all of the past of* Σ *admits a PMC foliation* $\{S_t\}$, *where t takes all values in the interval* $]-\infty,0]$ *and H takes all values in* $]-\infty,\overline{H}]$.

E. Improving the results

The purpose of this section is to get rid of the requirement of strictly negative mean curvature on the Cauchy surfaces, which seems to be a rather technical restriction. Let us instead assume Σ to be a symmetric Cauchy surface in the surface symmetric space–time (M,g) with matter obeying the dominant and strong energy condition as well as the non-negative pressures condition, such as the surface symmetric Einstein–Vlasov system (M,g,f). Note that we assume the non-negative pressures condition not only for the spherically symmetric case. Indeed we will see that this energy condition is necessary for the arguments given in this section, thus we cannot apply them to matter involving electromagnetic fields.

As pointed out in Sec. III B 2 there is an important difference between the possible types of surface symmetry and it turns out to be a good idea to analyze the spherically symmetric case separately.

1. Spherically symmetric space–times

There are some results already obtained elsewhere, so we can exclude some special cases from our analysis. Namely for the Einstein–Vlasov system (as well as for the massless scalar field) it has been proven in Rendall (1995b) and Burnett (1996) that given an arbitrary symmetric constant mean curvature Cauchy surface, there exists a global CMC foliation with the mean curvature taking all real values. So we may assume that the mean curvature H on Σ is not constant, and we immediately get from Theorem 2.2 the existence of a local in time PMC foliation $]t_1,t_2[\times\Sigma$ of a neighborhood of Σ in M.

There are some *a priori* estimates:

(1) It is shown in Burnett (1991) that r and M^{-1} are bounded. Theorem 2.1 in Burnett (1991) then shows that all timelike curves have finite length.

(2) Inserting the bound for r on the right-hand side of the estimate (34), we get from (31) bounds for r^{-1} and M on any finite time interval.

(3) Section III in Burnett (1996) shows that in light of the fact that all timelike curves have finite lengths, the volumes of two arbitrary Cauchy surfaces Σ_1 and Σ_2 are related by

$$\mathrm{Vol}(\Sigma_2) \leqslant \mathrm{Vol}(\Sigma_1)\left(1 + C \sup_{\Sigma_1} |H|\right)^3.$$

This implies that the volumes of all Cauchy surfaces S in M are bounded above by the volume of Σ and, since H is bounded on each finite time interval, interchanging the roles of Σ and S shows that the volumes are bounded from below, too, on each finite time interval.

If we denote the volume form of a PMC leaf S_t by Ω and the volume of S_t by $V(t)$ we have $\Omega = \sqrt{|h|}$ and $V(t) = \int \Omega \, \mathrm{d}x \mathrm{d}\vartheta \mathrm{d}\varphi = 4\pi a^{-1} \int_{S^1} r^3$.

With the bounds of V, V^{-1}, r, r^{-1} we now get a, $a^{-1} \leqslant C$, and again using the bounds for the radius function we get A, $A^{-1} \leqslant C$, thus the first fundamental form of the leaves is bounded from above and below on each finite time interval.

Moreover, as shown in Sec. III C, the estimate (34) bounds $|A^{-2}A'|$ and $|K|$, so that the second fundamental form is also bounded (from above) on each finite time interval as well as $|A'| = |A^2||A^{-2}A'|$.

Consider now the lapse equation (21), written in the form

$$(AN')' = A^3 N(\tfrac{1}{2}(H-K)^2 + K^2 + 4\pi(\rho + \mathrm{tr}\, S)) - A^3,$$

where the term in brackets is non-negative. Therefore, setting this term to zero, we get the estimate $(AN')' \geqslant -C$, hence, for arbitrary $p, q \in S_t$: $(AN')(p) - (AN')(q) \geqslant -C$. Now choosing q to be a critical point of N yields $N'(p) \geqslant -C$, and similarily choosing p as a critical point of N gives $N'(q) \leqslant C$. From this we see that $|N'|$ is bounded, since p, respectively, q is arbitrary on S_t.

The difference from the situation considered in Sec. III C is that we are no longer confined to a mean curvature, having everywhere fixed sign. The difficulty with the estimates done there is that they provide no information about the behavior of the lapse function, when H becomes zero. The estimates done here so far do not rely on this fact and the uniform bound of N' shows that either lapse remains finite or diverges uniformly to infinity.

In order to prove the global existence of a symmetric PMC foliation assume that $]t_1, t_2[$ is the maximal time interval of existence. Without loss of generality let us consider only a possible extension toward the past, where H decreases with decreasing t. Thus, we are looking for regular symmetric initial data for $t = t_1$ in the sense of Definition 3.2.

Then there are two cases: First, $H(t)$ is everywhere positive or everywhere negative near t_1, the arguments in Sec. III C apply (the fixed sign of H is enough to perform the estimates, whether H is positive or negative), extending the foliation and we get a contradiction to the maximality of the time interval, hence $t_1 = -\infty$.

Second, $\lim_{t \to t_1} H(t)$ possesses no unique sign near t_1. Then we have to prove Proposition 3.4 and the two subsequent Lemmas 3.6 and 3.7. The discussion at the beginning of this section has shown that some of these quantities are already bounded. The crucial step is to find a bound for lapse and its derivatives.

The idea is to reparametrize the foliation as has been done for a CMC foliation in Burnett (1996). The effect of the reparametrization on lapse and shift was outlined in Sec. II A. Let us introduce a function τ by

$$\tau := t + \int_{t_1}^{t} N(u, x_0)\, \mathrm{d}u,$$

where $\int_{t_1}^{t}$ means $\lim_{s \to t_1} \int_s^t$. It is well defined, since $\int N(\gamma(u))\mathrm{d}u$ along the integral curves of the normals of the leaves measures the length of γ, which we already know to be finite, and $|N'| \leqslant C$ ensures the integrability of $N(t, x_0) \leqslant N(\gamma(t)) + C$. This construction works in either case, whether N is bounded or diverges uniformly to infinity. The function $t \mapsto \tau(t)$ is monotone since $\mathrm{d}\tau/\mathrm{d}t = 1 + N(t, x_0)$ and turns out to be an orientation preserving diffeomorphism $]t_1, t_2[\to]\tau_1 = t_1, \tau_2[$, thus τ can be used as a new time function for the foliation, which squeezes the time

differences of neighboring leaves compared with the normal vector by adding to t the normal component of the length of the piece of the $x_0=\text{const}$ line connecting (t_1,x_0) with (t,x_0). This produces a new lapse function and a new shift vector:

$$\tilde{N}=\left(\frac{\mathrm{d}\tau}{\mathrm{d}t}\right)^{-1}N=\frac{N}{1+N(t,x_0)},$$

$$\tilde{\nu}=\left(\frac{\mathrm{d}\tau}{\mathrm{d}t}\right)^{-1}\nu=\frac{\nu}{1+N(t,x_0)}.$$

Conversely, t stretches time differences of adjacent leaves, such that we get the inverse transformation by $t=\tau-\int_{\tau_1}^{\tau}\tilde{N}(u,x_0)\mathrm{d}u$, which subtracts from τ the former added "length" of the $x_0=\text{const}$ line now expressed in terms of the new time coordinate. By the inverse transformation, we see that $\mathrm{d}t/\mathrm{d}\tau=1-\tilde{N}(\tau,x_0)$, and therefore get the relation $1-\tilde{N}(\tau,x_0)=(1+N(t,x_0))^{-1}$ in points with spatial coordinate x_0.

The benefit of this reparametrization is, that due to $|N'|\leqslant C$, $\tilde{N}$ and $|\tilde{N}'|$ remain bounded, and we could try to analyze the field equations according to the reparametrized foliation. Inspection of these equations shows that we get the field equations in the new coordinates from Eqs. (19) to (27) by replacing everywhere ∂_t by ∂_τ, N by $\tilde{N}$, ν by $\tilde{\nu}$ (since reformulating of the constraint and evolution equations preserves their form) while the lapse equation (21) and the PMC condition (22) depend on the parametrization, and hence have to be modified: The subtraction of A^2 on the right-hand side stems from the term $A^2Nn(H)$, where the PMC condition sets $Nn(H)$ equal to one. Replacing N by $\tilde{N}$ yields $(Nn(H))(1+N(t,x_0))^{-1}=(1+N(t,x_0))^{-1}=1-\tilde{N}(\tau,x_0)$. The PMC condition (22), which holds in the old parametrization, can be formulated in the new coordinates by expressing ν in terms of $\tilde{\nu}$, which produces an additional summand $1-\tilde{N}(\tau,x_0)$ on the right-hand side, besides the replacement of ν by $\tilde{\nu}$.

Now we start to analyze the new field equations, trying to retain the same line of thought of Sec. III C: The analysis already done here bounds A, A^{-1}, $|A'|$, a, a^{-1}, $|H|$, $|K|$ as well as, of course, $\tilde{N}$ and $|\tilde{N}'|$. The arguments carried out in Sec. III C now bound $|\tilde{\nu}|$, $|\tilde{\nu}'|$ and $|H'|$. Finally we need a bound for $\tilde{N}^{-1}$. Since it is not clear, in the case where N diverges near t_1, whether N grows monotonically or not, we divide the time interval $]t_1,t_2[$ into two subsets. First consider all points, where $N(t,x_0)\geqslant M$, with some suitable chosen real number M, which will be specified later. Then we get the estimate

$$|1-\tilde{N}(\tau,x)|=\left|1-\frac{N(t,x)}{1+N(t,x_0)}\right|=\left|\frac{1+N(t,x_0)-N(t,x)}{1+N(t,x_0)}\right|\leqslant\frac{1+C}{1+M},$$

where C is an upper bound for $|N(t,x_0)-N(t,x)|$, whose existence is guaranteed by the bounds for $|N'|$ and the volume of the leaves of the foliation. Choose now $M=2C$ and we get

$$|1-\tilde{N}|\leqslant\frac{1+C}{1+2C}<1,$$

thus $\tilde{N}$ is bounded away from zero for all points where $N(t,x_0)\geqslant M$. Consider now the points where $N(t,x_0)\leqslant M$. Then we have

$$|1-\tilde{N}(\tau,x_0)|=\left|1-\frac{N(t,x_0)}{1+N(t,x_0)}\right|=\left|\frac{1+N(t,x_0)-N(t,x_0)}{1+N(t,x_0)}\right|\geqslant\frac{1}{1+M}.$$

Now we can apply the arguments in Rendall (1997b) to the modified lapse equation, as has been done in Sec. III C [whereupon the factor $1-\tilde{N}(\tau,x_0)$ causes no trouble, since it is bounded from above and below] and we get a bound for $\tilde{N}^{-1}$ for all points, where $N(t,x_0)\leqslant M$, and we are done.

Therefore we have estimated all quantities appearing in Proposition 3.4. Lemma 3.6 is also true for the new field equations without the need to modify the proof, while the proof of Lemma 3.7 has to be modified, since the argument bounding $|\partial_t^{m+1}\partial_x^n\tilde{N}|$ does not carry over. The lapse equation and the equation for its time derivatives are

$$(A\tilde{N}')' = A^3\tilde{N}(\tfrac{1}{2}(H-K)^2+K^2+4\pi(\rho+\mathrm{tr}\,S))-A^3(1-\tilde{N}(\tau,x_0))$$

$$(A\partial_t^m\tilde{N}')' = A^3\partial_t^m\tilde{N}(\tfrac{1}{2}(H-K)^2+K^2+4\pi(\rho+\mathrm{tr}\,S))-A^3(1-\partial_t^m\tilde{N}(\tau,x_0))+B,$$

where B denotes an already bounded quantity at the corresponding stage in the inductive argument in Lemma 3.7. In this situation Lemma 1 in Burnett (1996) applies literally, bounding the time derivatives of the lapse function, therefore completing the proof of Lemma 3.7.

Putting all arguments together we are able to extend the foliation beyond t_1, contradicting the assumed maximality of the interval of existence, thus arriving at the following:

Theorem 3.11: *Let (M,g,f) be a surface symmetric solution of the Einstein–Vlasov system with spherical symmetry. Then we can foliate the whole space–time by a PMC foliation, where the time function takes on all real values and the mean curvature of the leaves tends uniformly to $\pm\infty$ for $t\to\pm\infty$, thus producing crushing singularities.*

This theorem provides barrier surfaces [see Gerhardt (1983)], establishing now the existence of CMC hypersurfaces for each value of the mean curvature, therefore proving the closed universe recollapse conjecture in this case:

Corollary 3.12: In the situation of Theorem 3.11, the space–time possesses a global CMC foliation and the mean curvature takes on all real values. In particular, the space–time admits a maximal Cauchy surface.

2. Space–times with plane and hyperbolic symmetry

We will see that most of the arguments performed in the spherically symmetric case carry over to the past domain of dependence $D^-(\Sigma)$ in the expanding models (compare Sec. III B 2 for a precise definition of this terminology). Due to this fact we perform the following analysis only on the half-open time interval $]t_1,0[$ and assume further, (M,g) to be nonflat in the plane symmetric case and the mass function (31) to be positive on Σ in the hyperbolic case.

Again we can exclude some cases already investigated (although this does not matter, since the arguments here apply to these cases). It has been proven in Rendall (1995b) and Burnett (1996) that given a symmetric Cauchy surface with negative constant mean curvature H_0 (remember the restrictions on the mean curvature in the expanding models, compare Sec. III B 2), there exists a global CMC foliation with the mean curvature taking all values in the interval $]-\infty,H_0[$. So we can assume without loss of generality that the mean curvature H on Σ is not constant and not everywhere positive. Again, this assumption ensures the existence of a local in time PMC foliation $]t_1,t_2[\times\Sigma$ of a neighborhood of Σ in M.

Now we find similar *a priori* bounds.

(1) In $D^-(\Sigma)$ r is bounded, since dr is future pointing timelike everywhere and Σ is compact. M^{-1} is bounded on Σ by assumption in the hyperbolic case and in the plane symmetric case this follows from Lemma 2.4 in Rendall (1995b). By the mass flux equation (33) together with the non-negative pressures condition, M grows along past pointing timelike curves, thus M^{-1} is bounded in all of $D^-(\Sigma)$. Theorem 2.1 in Burnett (1991) then shows that all timelike curves in $D^-(\Sigma)$ have finite length.

(2) Applying the arguments in the corresponding place of Sec. III E 1 we get bounds for r^{-1} and M for any finite time interval of the form $]t_1,0]$.

(3) Again, the corresponding argument performed in the spherically symmetric case holds, and we get upper and lower bounds for the volumes of arbitrary Cauchy surfaces in M.

Finally, the volume of the leaves S_t is given by $V(t)=Ca^{-1}\int_{S^1} r^3$, establishing bounds for the first fundamental form and its inverse (in $D^-(\Sigma)$) as has been shown in Sec. III E 1, therefore all of the remaining arguments performed there apply and we get the

Theorem 3.13: *Let (M,g,f) be a surface symmetric solution of the Einstein–Vlasov system with plane or hyperbolic symmetry and Σ a symmetric Cauchy surface in M. If (M,g) is nonflat in the plane symmetric case and the mass function is positive on Σ in the hyperbolic case, then we can foliate all of the past of Σ by PMC hypersurfaces, where the time function takes on all values in the interval $]-\infty,0]$ and the mean curvature of the leaves tends uniformly to $-\infty$ for $t\to-\infty$.*

Again using the PMC leaves as barrier surfaces we get the

Corollary 3.14: *In the situation of Theorem 3.13 $D^-(\Sigma)$ possesses a CMC Cauchy surface for each value of the mean curvature in $]-\infty,\min_\Sigma H[$.*

3. Comparing the results

To close Sec. III, there are some remarks concerning Theorems 3.11 and 3.13 and the relation to the work done in the preceding sections.

At first, it is obvious that Theorem 3.11 generalizes Theorem 3.8 in the spherically symmetric case. In the plane and hyperbolic case Theorem 3.13 does not generalize Theorems 3.8, 3.9, and 3.10. The latter ones only establish a global PMC foliation unless the mean curvature of the leaves becomes zero somewhere (and again the leaves provide barrier surfaces for CMC Cauchy surfaces, establishing Corollary 3.14 in the situation of those theorems). Theorem 3.13 is not restricted to this condition, but it needs the extra non-negative pressures condition, which excludes electromagnetic fields.

Apart from the non-negative pressures condition the assumption of positive mass on Σ is a nontrivial constraint in the hyperbolic case, while automatically fulfilled in the nonflat plane symmetric case by Lemma 2.4 in Rendall (1995b). As shown previously, the positivity of mass is needed to obtain a bound for the length of timelike curves in *M*, by applying the arguments in Burnett (1991), and thus necessary to the construction done here.

IV. CONCLUSION AND OUTLOOK

First I list the main results achieved in this work.

(1) For the space–times considered so far the existence of a global PMC foliation has been shown, where several matter models have been taken into account.

(2) For the model, which is not expanding or contracting everywhere, the closed universe recollapse conjecture has been proved. In particular the foliation covers the whole Cauchy development of the initial hypersurface, with a crushing singularity both in the distant past and future. Moreover the space–time possesses a maximal hypersurface.

(3) In the expanding models the foliation covers at least the whole past of the initial hypersurface toward a crushing singularity.

The choice of matter turned out to be important only insofar as some energy conditions are satisfied and the matter fields do not become singular in a regular geometric background.

The necessary energy conditions are the dominant and strong energy conditions. Furthermore to obtain stronger results, which do not rely on a fixed sign condition for the mean curvature, the non-negative pressures condition is required to ensure that the Hawking mass does not tend to zero, contributing enough attraction that the lifetime of timelike curves becomes finite.

The rather strong results about locally spatially homogeneous space–times in Rendall (1995a) likewise rely on this condition, which appears in the slightly relaxed form, that only the sum of the pressures has to be non-negative, due to the high degree of symmetry in those models. This relaxed condition even permits electromagnetic fields, a type of matter which does not satisfy the non-negative pressures condition, thus not leading to the stronger results in the context of space–times with less symmetry.

The close analogy of the proofs for the global existence of CMC and PMC foliations indicates that all results obtained for CMC foliations may also be proved for PMC foliations. If this

conjecture turns out to be true (the second part of this paper will give another positive example for this conjecture), then we are no longer concerned with the topological restrictions imposed on the existence of CMC hypersurfaces, having a much more flexible tool at hand. Moreover, the global results on PMC foliations can be used to provide barrier surfaces, which guarantee the existence of a CMC foliation, where the mean curvature ranges between these barriers (compare Corollaries 3.12 and 3.14).

The results demonstrate that in the cases considered in this work a satisfying answer has been given to the global existence problem for PMC foliations. Then the related question arises—whether the foliation covers the whole space–time. The present work gives only a partial answer to this question. Denoting the initial Cauchy surface by Σ, we saw that we have covered the whole past $D^-(\Sigma)$ in the expanding space–times and the whole Cauchy development $D(\Sigma)$ in the recollapsing models. These positive results have two limits.

(1) In the expanding models there remains an open question about the future of Σ in M. Either the mean curvature becomes zero somewhere or there is no control on the radius function toward the expanding direction. In each case the present techniques do not apply. In addition there are topological obstructions in the expanding direction, preventing the mean curvature from becoming positive, a foliation of the future of Σ must stop before this happens. But this does not imply that the whole of $D^+(\Sigma)$ can be covered by such a foliation, since the leaves of the foliation may become null or noncompact where the general notion of singularity avoidance comes up. Namely, compared with the strong results obtained in Rendall (1995a) in the locally spatially homogeneous models, we require more information about the asymptotic behavior of the foliation to obtain results on geodesic completeness.

(2) In the contracting direction and in the recollapsing models things look different. In the contracting direction the theorems ensure the existence of crushing singularities, and all of the Cauchy development of Σ is covered by the foliation. This is a consequence of Hawking's famous incompleteness theorem for globally hyperbolic space–times, satisfying the timelike convergence condition, where the maximal time of existence is estimated by $3/|H|$ and $H \to -\infty$. But there is no information about the boundary of $D(\Sigma)$, which might be either a curvature singularity or merely a Cauchy horizon.

The work in Rendall (1995a) indicates roughly what remains to be done. Relating the particle current density to the energy density and investigating the asymptotic behavior of the former may give rise to unbounded curvature and produce a curvature singularity.

For the space–times considered here, the work is Rein (1996) is important. He succeeded in finding satisfying answers to the above questions by using a time function intimately tied to the symmetry. Unfortunately it is not clear how to generalize his approach to other space–times. Although the estimates done here also exploit the high symmetry of the models, the construction itself does not depend on it, motivating this work. A generalization to space–times with two commuting local Killing vector fields will be the content of the second part.

Global prescribed mean curvature foliations in cosmological space–times. II

Oliver Henkel[a)]
Max Planck Institute for Gravitational Physics, Am Mühlenberg 1, 14476 Golm, Germany

(Received 1 December 2001; accepted for publication 28 January 2002)

This paper is devoted to the investigation of global properties of prescribed mean curvature (PMC) foliations in cosmological space–times with local $U(1)\times U(1)$ symmetry and matter described by the Vlasov equation. It turns out that these space–times admit a global foliation by PMC surfaces as well, but the techniques to achieve this goal are more complex than in the cases considered in Paper I [Henkel (2002)]. © *2002 American Institute of Physics.*

I. INTRODUCTION

For the main motivation see the introduction in Paper I [Henkel (2002)]. Only some remarks special to the present situation remain.

The structure of this paper (Paper II) is as close as possible to the structure of Paper I. Although the preliminary section (Sec. II) of Paper I has been omitted, the formulas here refer to it as well.

The space–times considered here are cosmological space–times with two commuting local Killing vector fields. This symmetry will be referred to as (local) $U(1)\times U(1)$ symmetry. In comparison with Paper I, there are now only two (local) Killing fields instead of three, generalizing the plane symmetric case of Paper I. The absence of a third Killing field requires a more detailed description of the geometry and a deeper analysis to control the momenta of the Vlasov particles. Thus the estimates in this work rely on the simple structure of the Vlasov equation. Despite this there seems to exist no crucial obstructions for other types of ''well-behaved'' matter.

II. SPACE–TIMES WITH LOCAL $U(1)\times U(1)$ SYMMETRY

A. The geometry of space–times with local $U(1)\times U(1)$ symmetry

Following the analysis in Rendall (1997), we consider now the globally hyperbolic space–time (M,g) with topology $\mathbb{R}\times\Sigma$, where Σ denotes a bundle with base S^1 and compact orientable fiber F. As usual it is assumed that the submanifolds $\{t\}\times\Sigma$ are Cauchy hypersurfaces in M. The coordinates of Σ are denoted by $(x,y^2,y^3)=(x,y^A)$, $A=2,3$, where (y^A) denote coordinates on F. As usual, Greek indices range in the interval 0,...,3, lower case Latin indices from the middle of the alphabet take values in 1,...,3, while those from the beginning of the alphabet take the values 0,1 and upper case ones are confined to the values 2, 3.

The covering map $\mathbb{R}\to S^1$ defines a pullback of the bundle Σ with base $\mathbb{R}$, hence we get a trivial bundle. If $\hat{F}$ denotes the universal covering space of F, we get a natural covering $\hat{\Sigma}=\mathbb{R}\times\hat{F}$ of Σ with canonical projection p. Now we can associate a space–time $(\hat{M},\hat{g})$, where $\hat{M}=\mathbb{R}\times\hat{\Sigma}$ and $\hat{g}$ is the pullback of g under the projection $\mathrm{id}\times p$.

The fibers $\hat{F}$ in the trivial bundle $\hat{M}$ are assumed to be the orbits of a two-dimensional translation group G of isometries of $\hat{g}$. Hence $\hat{F}$ is the Euclidean space form E_2 and $F=E_2/\Gamma$, for a discrete subgroup Γ of G. The compactness and orientability of F then implies $F=T^2$, so Γ can

a)Present address: Heinrich-Hertz-Institut für Nachrichtentechnik Berlin GmbH, Einsteinufer 37, 10587 Berlin, Germany; electronic mail: henkel@hhi.de

be represented by a two-parameter lattice, Σ turns out to be a torus bundle over the circle, and the induced action of G on (M,g) is given by the quotient action $G/\Gamma = U(1)\times U(1)$ with orbits F. As in Paper I we will call the orbits surfaces of symmetry, hypersurfaces in M diffeomorphic to $\{t\}\times\Sigma$, which consist of a union of surfaces of symmetry called symmetric surfaces and we call (M,g) a space–time with local $U(1)\times U(1)$ symmetry.

The induced action of $U(1)\times U(1)$ on (M,g) is local, if the bundle is nontrivial. In that case we have to deal with nontrivial transformations for the transition $x\mapsto x+2\pi$ in S^1 by lattice preserving translations and automorphisms $\mathrm{GL}(2,\mathbb{Z})$ of G. To represent the metric $\overline{g}$ of the orbits in M at first locally for $x\in[0,2\pi[$, define the area radius by $r:=\sqrt{(4\pi)^{-1}\,\mathrm{Vol}(F)}$, and write the metric as

$$\overline{g}=r^2\tilde{g}, \tag{1}$$

with a metric $\tilde{g}$ of unit determinant. Due to symmetry, both quantities (r and $\tilde{g}$) do not depend on the points of F, and one easily verifies that the curvature of $\overline{g}$ vanishes, as required. For $\tilde{g}$ there are two remaining degrees of freedom, V and W, and we can use them to parametrize the metric:

$$\tilde{g}=\begin{pmatrix} e^{W}\cos V & \sin V \\ \sinh V & e^{-W}\cosh V \end{pmatrix}. \tag{2}$$

If the bundle is trivial, then this representation of the metric is global, but if the bundle is not trivial, then the translation of 2π in S^1 induces a transformation of $\overline{g}$ by an element Z of $\mathrm{GL}(2,\mathbb{Z})$,

$$\overline{g}(x+2\pi)=Z^T\overline{g}(x)Z, \tag{3}$$

which fixes the geometry of the space–time.

Given a globally acting symmetry we can specialize to some well known geometries: If $V=W=0$ then we get the plane symmetric case $\epsilon=0$ of Paper I. Setting only $V=0$ we get a symmetry called polarized, corresponding to the reflection symmetries $y^2\mapsto -y^2$ or $y^3\mapsto -y^3$, respectively. If the composition of these reflections is an isometry (regardless whether the individual reflections act isometrically), we call this symmetry *Gowdy-type*, since the Gowdy space–times are defined by this symmetry and the additional requirement that the space–time is vacuum. Thus, in general $V\neq 0$ in a space–time with Gowdy-type symmetry, but if V vanishes also we call the Gowdy-type symmetry polarized.

We construct the coordinate system $\{x^\mu\}$ mentioned in the beginning of this section locally by the following procedure. Consider first an arbitrary symmetric Cauchy surface S in M. Then we extend the coordinates (y^A) of F to a Gaussian neighborhood of F in S. Later on we will do some rescaling along S^1, such that we choose the coordinates, such that the metric h of S takes the general form $h=A^2\,\mathrm{d}x+\overline{g}$. Now we embed this structure into the space–time. In general the time coordinate t defines lapse N and shift $\nu=\nu^i\partial_i$, thus the space–time metric g is not in block diagonal form. The components g_{0A} which prevent g being block diagonal can be represented by $\overline{\nu_A}:=\overline{g}_{AB}\nu^B$.

1. The 2+2-geometry

Now we want to investigate the geometry of $(F,\overline{g})$ in (M,g) more closely. As before let S denote a symmetric Cauchy surface in M, foliated by its symmetric surfaces. The unit normal of F in $S\subset M$ will be denoted by m and n is the unit normal of S in M, as usual. Then there are some canonical geometrical objects induced:

(a) the two second fundamental forms

$$\lambda(v,w)=g({}^4\nabla_v w,m), \tag{4a}$$

$$\kappa(v,w)=g({}^4\nabla_v w,n) \tag{4b}$$

for $v,w\in TF$ with arbitrary extensions to vector fields, in order to make the expressions well defined. In the sequel it turns out to be convenient to deal with the trace free parts $\tilde{\lambda}$ and $\tilde{\kappa}$ instead, defined by $\lambda=\tilde{\lambda}+\frac{1}{2}\mathrm{tr}\,\lambda\bar{g}$ and $\kappa=\tilde{\kappa}+\frac{1}{2}\mathrm{tr}\,\kappa\bar{g}$, respectively.

In the given coordinates we have explicit formulas:

$$\lambda_{AB}=-\tfrac{1}{2}m(\bar{g}_{AB})=-\tfrac{1}{2}A^{-1}(\bar{g}_{AB})',$$

$$\mathrm{tr}\,\lambda=-\tfrac{1}{2}\bar{g}^{AB}m(\bar{g}_{AB})=-\frac{1}{2}\frac{m(\det\bar{g})}{\det\bar{g}}=-\frac{2}{r}m(r)=-2A^{-2}A',$$

$$\kappa_{AB}=-\tfrac{1}{2}n(\bar{g}_{AB})=-\tfrac{1}{2}N^{-1}(\bar{g}_{AB})^{\cdot}-N^{-1}A\nu^{1}\lambda_{AB},$$

$$\mathrm{tr}\,\kappa=-\frac{2}{r}n(r),$$

reflecting the definition of the area radius r as a volume measure and the second fundamental forms as its rate of change. In the above-mentioned formulas $\bar{g}$ is considered as intrinsic to F (and we maintain this from now on) and $\bar{g}^{AB}=r^{-2}\tilde{g}^{AB}$ denotes the inverse of $\bar{g}_{AB}$. Differentiating $\tilde{g}$ directly one gets from its relation to $\bar{g}$ and the above-mentioned formulas the following representations of the trace free parts of the second fundamental forms:

$$\tilde{\lambda}_{AB}=-\tfrac{1}{2}r^{2}m(\tilde{g}_{AB}),\quad \tilde{\lambda}^{AB}=\tfrac{1}{2}r^{-2}m(\tilde{g}^{AB}),$$

$$\tilde{\kappa}_{AB}=-\tfrac{1}{2}r^{2}n(\tilde{g}_{AB}),\quad \tilde{\kappa}^{AB}=\tfrac{1}{2}r^{-2}n(\tilde{g}^{AB}).$$

(b) The connection in the normal bundle $T^{\perp}F$. This can be represented by a single one-form η, defined as

$$\begin{aligned}\eta(v)&=g({}^{4}\nabla_{v}n,m)=-g({}^{4}\nabla_{v}m,n)\\&=-\tfrac{1}{2}g([n,m],v),\quad v\in TF.\end{aligned}\tag{5}$$

From this formula one can see that $\eta=0$ is equivalent to $[n,m]\in T^{\perp}F$, thus $[T^{\perp}F,T^{\perp}F]\subset T^{\perp}F$ and the theorem of Frobenius tells us that $T^{\perp}F$ is an integrable distribution of two planes in TM. If $T^{\perp}F$ is integrable, then we can decompose the space–time into a direct sum $(M,g)=(F^{\perp},\underline{g})+(F,\bar{g})$, with $g=\underline{g}\oplus\bar{g}$. Sufficient for the existence of an integral manifold $F^{\perp}$ of the distribution $T^{\perp}F$ is the Gowdy-type symmetry $y^{A}\mapsto -y^{A}$, $A=2,3$, since then it follows $\eta=0$ immediately, because $v\mapsto\eta(v)$ is an antisymmetric map.

Whether or not $T^{\perp}F$ is integrable, we can orthogonally split the tensor bundle over M, following Kundu (1978). To perform this task we start with the two-dimensional Riemannian manifold $(F,\bar{g})$. With our choice of space–time coordinates we have Killing fields $Y_{A}=\partial_{A}$. Their space–time components define projection operators

$$p_{A}{}^{\mu}:=Y_{A}{}^{\mu},\quad p_{A}=\partial_{A},$$

$$p^{A}{}_{\mu}:=\bar{g}^{AB}g_{\mu\nu}p_{B}{}^{\nu},\quad p^{A}=\bar{\nu}^{A}\mathrm{d}t+\mathrm{d}y^{A},$$

where $\bar{\nu}^{A}:=\bar{g}^{AB}\bar{\nu}_{B}=\nu^{A}$, and the metric components g_{1B} are zero by our definition of the coordinates.

The projection operators into $T^{\perp}F$ can now be defined as follows: Let the unit normal vectors n and m serve as projection operators $q_{a}{}^{\mu}$ and define their duals by the relations $q_{a}{}^{\mu}q^{b}{}_{\mu}=\delta_{a}^{b}$ and $p_{A}{}^{\mu}q^{b}{}_{\mu}=0$. The result is

$$q_{0}=n=N^{-1}(\partial_{t}-\nu^{i}\partial_{i}),\quad q_{1}=m=A^{-1}\partial_{1},$$

$$q^0 = N\,\mathrm{d}t, \quad q^1 = A\,\nu^1 dt + A\,\mathrm{d}x.$$

Now we are ready to define the transversal metric $\underline{g}$ in $T^\perp F$ by

$$\underline{g}_{ab} = g_{\mu\nu} q_a{}^\mu q_b{}^\nu, \tag{6}$$

thus in the given frame $\underline{g}$ and its inverse are represented by the two-dimensional Minkowski metric and from now on we consider $\underline{g}$ as an intrinsic object in the tensor bundle over $T^\perp F$. In summary we have constructed a complete set of projection operators, projecting orthogonally tensors over (TM,g) into $(TF,\overline{g})$ and $(T^\perp F,\underline{g})$, characterized by the relations

$$p_A{}^\mu p^A{}_\nu + q_a{}^\mu q^a{}_\nu = \delta^\mu_\nu \quad \text{(completeness)},$$

$$p_A{}^\mu p^B{}_\mu = \delta^B_A, \quad p_A{}^\mu q^b{}_\mu = 0,$$

$$q_a{}^\mu p^B{}_\mu = 0, \quad q_a{}^\mu q^b{}_\mu = \delta^b_a \quad \text{(orthogonality)},$$

with $p_A = \partial_A$ and $q_0 \perp q_1$ (these two relations fix the component representations shown previously).

Now we define the convention already used in some expressions previously mentioned that wherever confusion might arise, we attach a bar to quantities, which will be considered as intrinsic to the associated bundle, and a tensor index furnished with such a bar denotes projected components, which also can be considered as intrinsic. For example $\underline{T}_{ab}$ denotes a tensor in the bundle $(T^\perp F,\underline{g})$, but $T_{\underline{ab}} = q_a{}^\mu q_b{}^\nu T_{\mu\nu}$, too, although T might be a space–time tensor. The philosophy lying beyond this $\underline{\ }$ notation is that quantities with a bar attached to them or to their indices can be manipulated by the associated metric, while indices without a bar always denote component indices corresponding to the bundle the tensor is intrinsic to. If we apply this notational convention to the metric itself we get the definitions for $\underline{g}$ and $\overline{g}$ back, e.g., we get the identities $g_{\underline{ab}} = q_a{}^\mu q_a{}^\nu g_{\mu\nu} = \underline{g}_{ab}$ and $g_{\overline{AB}} = p_A{}^\mu p_B{}^\nu g_{\mu\nu} = \overline{g}_{AB}$. In particular we have

$$\underline{\nabla}_a = q_a{}^\mu {}^4\nabla_\mu,$$

$$\overline{\nabla}_A = p_A{}^\mu {}^4\nabla_\mu,$$

defining the Levi-Civita connection in the projected bundles, and the algebraic identity

$$T^\mu_\nu = T^{\underline{a}}_{\underline{a}} + T^{\overline{A}}_{\overline{A}}.$$

For later use we need the projected components of the Ricci tensor. First note that the normal connection η on $(F,\overline{g})$ reads in our new notation

$$\overline{\eta}^A = -\tfrac{1}{2}[q_0,q_1]^{\overline{A}} = -\tfrac{1}{2} p^A{}_\mu [q_0,q_1]^\mu = \tfrac{1}{2} dp^A(q_0,q_1),$$

or equivalently $\epsilon_{ab}\overline{\eta}^A = 1/2\mathrm{d}p^A(q_a,q_b)$, making use of the relation $0 = \nabla(p^A{}_\mu q_a{}^\mu)$, which gives $\nabla q_a{}^\mu = -q_a{}^\nu p_B{}^\mu \nabla p^B{}_\nu$. The ϵ_{ab} here has its standard meaning as the totally antisymmetric symbol (independent of the frame used, so it is not necessary here to attach a bar to it). On $T^\perp F$ we find $\mathrm{d}p_A = \mathrm{d}(\overline{g}_{AB}p^B) = \overline{g}_{AB}\,\mathrm{d}p^B$, so that index manipulations with $\overline{g}$ can be applied, as desired.

After some calculations we arrive at formulas for the projected components of the Ricci tensor:

$${}^4R_{\underline{ab}} = \underline{R}_{ab} - 2r^{-1}\underline{\nabla}_a\underline{\nabla}_b r + 2r^{-2}(\underline{\nabla}_a r)(\underline{\nabla}_b r) + \tfrac{1}{4}(\underline{\nabla}_a \overline{g}_{AB})(\underline{\nabla}_b \overline{g}^{AB}) + 2\underline{g}_{ab}|\,\eta|^2, \tag{7a}$$

$${}^4R_{\overline{A}\underline{b}} = r^{-2}\epsilon^c{}_b \underline{\nabla}_c (r^2 \overline{\eta}_A), \tag{7b}$$

$$ {}^4\overline{R}_{AB} = -\tfrac{1}{2}\overline{g}_{AD}\underline{\nabla}^c(\overline{g}^{CD}\underline{\nabla}_c\overline{g}_{BC}) - r^{-1}(\underline{\nabla}^c r)(\underline{\nabla}_c\overline{g}_{AB}) - 2\,\overline{\eta}_A\overline{\eta}_B\,. \tag{7c} $$

Contraction of the last equation yields a formula for the Laplacian of r (note that the Laplacian is really a wave operator in the present situation):

$$ \underline{\Delta} r = \tfrac{1}{2}\,{}^4\overline{R}^{\overline{A}}_{\overline{A}} + r^{-1}(\underline{\nabla}_c r)(\underline{\nabla}^c r) + r\,|\overline{\eta}|^2, \tag{8} $$

Finally we consider other frames of reference and their relation to the frames already in use in the projected spaces. At first we concentrate on $(TF,\overline{g})$, which is canonically endowed with the coordinate vector fields ∂_A. Alternatively we can introduce the orthonormal frame $\{\overline{e}_A\}$, defined by $\overline{e}_A := r^{-1}\tilde{e}_A$, with

$$ \tilde{e}_2 = e^{-W/2}\cosh V/2\,\partial_2 - e^{W/2}\sinh V/2\,\partial_3, $$

$$ \tilde{e}_3 = -e^{-W/2}\sinh V/2\,\partial_2 + e^{W/2}\cosh V/2\,\partial_3\,. $$

The dual frame $\{\overline{\sigma}^A\}$ is defined by $\overline{\sigma}^A := r\tilde{\sigma}^A$, with $(\tilde{\sigma}^A)_\mu(\tilde{e}_B)^\mu = \delta^A_B$, thus

$$ \tilde{\sigma}^2 = e^{W/2}\cosh V/2\,dy^2 + e^{-W/2}\sinh V/2\,dy^3, $$

$$ \tilde{\sigma}^3 = e^{W/2}\sinh V/2\,dy^2 + e^{-W/2}\cosh V/2\,dy^3. $$

Finally we introduce the two-dimensional quotient manifold $B := M/(U(1)\times U(1))$. Then we have isomorphisms $TB \simeq TM/TF \simeq T^\perp F$ and we can consider the metric $\underline{g}$ as acting on TB, so having constructed the two-dimensional (quotient) space–time $(B,\underline{g})$. If we take (t,x) as coordinates of B, then the metric $\underline{g}$ has coordinate components $\underline{g}_{ab} = -(q^0)^2 + (q^1)^2 = (-N^2 + (A\nu^1)^2)\mathrm{d}t^2 + 2A^2\nu^1\mathrm{d}t\,\mathrm{d}x + A^2\mathrm{d}x^2$, giving an alternative way to describe tensor components in $(T^\perp F,\underline{g})$, even if this bundle is not integrable. The dual base $\{\underline{e}_a\}$ to $\{\underline{\sigma}^a = q^a\}$ in $(B,\underline{g})$ has the coordinate components $\underline{e}_0 = N^{-1}(\partial_t - \nu^1\partial_x)$, $\underline{e}_1 = A^{-1}\partial_x$. The component notation just introduced conflicts with the conventions described previously, and in the following sections we are forced to make clear which conventions we will follow.

2. The 3+1-geometry

To describe the three-geometry of an arbitrary symmetric Cauchy surface S, we construct the coordinate system (x',y^A) explicitly. On the surface of symmetry $F \subset S$ we already have coordinates, such that the scaled metric $\tilde{g}$ takes the form (2). In a Gaussian neighborhood of F the metric h of S then has the form $h = \mathrm{d}x'^2 + \sqrt{|h|}\tilde{g}(x')$. Now we introduce a scale factor $a = 2\pi(\int_0^L |h(z)|^{-1/4}\mathrm{d}z)^{-1}$, where L denotes the length of a (projected) geodesic along all of S^1 orthogonal to the orbits F. Define a new coordinate x by $x(x') = a\int_0^{x'}|h(z)|^{-1/4}\mathrm{d}z$, then we get a convenient representation of h as

$$ h(x) = A(x)^2(\mathrm{d}x^2 + a^2\tilde{g}(x)) \tag{9} $$

with $A(x) = a^{-1}|h(x)|^{1/4}$ defined on S^1, and $\tilde{g}$ transforms under some element of $\mathrm{GL}(2,\mathbb{Z})$ like $\overline{g}$ in (3). By the way, from this explicit formula and the definition of $\overline{g}$ in (1) it follows easily that the relation $r = Aa$ holds.

The Laplacian of S acting on functions ψ then has the form

$$ \Delta\psi = -h^{11}\nabla_1\nabla_1\psi + h^{AB}\Gamma^1_{AB}\psi' + \overline{\Delta}\psi $$

$$ = -A^{-2}(\psi'' + A^{-1}A'\psi') + \overline{\Delta}\psi $$

with $\overline{\Delta}\psi = -h^{AB}\partial_A\partial_B\psi$ since $\overline{\Gamma}^C_{AB} = 0$.

Finally we cast the second fundamental form k of S into a convenient form. Set $K := k(m,m) = A^{-2}k_{11}$ and observe $k_{1B} = -{}^4\nabla_B n_1 = -A\,\eta_B$ we get

$$k(x) = A^2 K\,\mathrm{d}x - 2A\,\eta_B\,\mathrm{d}x\,\mathrm{d}y^B + \kappa_{AB}\mathrm{d}y^A\,\mathrm{d}y^B, \tag{10}$$

where all quantities on the right-hand side depend on x. Taking the trace yields the relation

$$H - K = \mathrm{tr}\,\kappa.$$

3. The four-geometry

We will describe the four-geometry (locally) in terms of a PMC foliation by symmetric Cauchy surfaces (Σ, h). It turns out that there is not much left to do. Of course, we need the strong energy condition in M, and we can choose Σ without loss of generality to have nonvanishing second fundamental form. In view of Theorem 2.2 of Paper I this is enough to guarantee the existence of a local in time PMC foliation of a neighborhood of Σ in M. The remaining question is if the leaves of the foliation turn out to be symmetric. But the arguments given in the corresponding place in Paper I do apply to the present situation, since the Laplacian of Σ splits into the Laplacian of F and a part depending only on x, which coincides with the one in the plane symmetric case and we end up with

Proposition 2.1: Let (M,g) be a globally hyperbolic, spatially compact space–time with local $U(1)\times U(1)$ symmetry, obeying the strong energy condition.

Then there exists a local in time PMC foliation $\{S_t\}$ in M, covering a neighborhood $]t_1,t_2[\times\Sigma$ of $\Sigma = S_0$, in M. Moreover, if Σ is symmetric, then all the leaves of the foliation are symmetric, too, and there are coordinates $(x^\mu) = (t,x,y^2,y^3)$ adapted to the foliation, which cast the metric into the form

$$g = \begin{pmatrix} -N^2 + (A\nu^1)^2 + |\overline{\nu}|^2 & A^2\nu^1 & \overline{\nu_2} & \overline{\nu_3} \\ A^2\nu^1 & A^2 & 0 & 0 \\ \overline{\nu_2} & 0 & \overline{g_{22}} & \overline{g_{23}} \\ \overline{\nu_3} & 0 & \overline{g_{32}} & \overline{g_{33}} \end{pmatrix}, \tag{11}$$

where N,A, ν^1, $\nu^A = \overline{\nu^A}$, $\overline{\nu_A} = \overline{g_{AB}}\,\overline{\nu^B}$, $\overline{g} = r^2\tilde{g}$ are functions on $]t_1,t_2[\times S^1$, with $r = Aa$ and $a = a(t)$ only. The quantities with an overbar transform under some representation of $\mathrm{GL}(2,\mathbb{Z})$ after each transition $x \mapsto x + 2\pi$ in S^1. The shift functions are fixed by the conditions $\nu^1(t,0) = \nu^1(t,2\pi) = 0$ and $\nu^A(t,0) = 0$.

The orthonormal frames $\{{}^4e_\mu\}$ and $\{{}^4\sigma^\mu\}$ associated with the $3+1$-split read explicitly

$${}^4e_0 = n = N^{-1}(\partial_t - \nu^i\partial_i),$$

$${}^4e_1 = m = A^{-1}\partial_1,$$

$${}^4e_2 = e_2 = (Aa)^{-1}(+e^{-W/2}\cosh V/2\,\partial_2 - e^{W/2}\sinh V/2\,\partial_3),$$

$${}^4e_3 = e_3 = (Aa)^{-1}(-e^{-W/2}\sinh V/2\,\partial_2 + e^{W/2}\cosh V/2\,\partial_3),$$

$${}^4\sigma^0 = N\,\mathrm{d}t,$$

$${}^4\sigma^1 = A(\nu^1\mathrm{d}t + \mathrm{d}x),$$

$${}^4\sigma^2 = (Aa)(e^{W/2}\cosh V/2(\overline{\nu^2}\,\mathrm{d}t + \mathrm{d}y^2) + e^{-W/2}\sinh V/2(\overline{\nu^3}\mathrm{d}t + \mathrm{d}y^3)),$$

$${}^4\sigma^3 = (Aa)(e^{W/2}\sinh V/2(\overline{\nu^2}\mathrm{d}t + \mathrm{d}y^2) + e^{-W/2}\cosh V/2(\overline{\nu^3}\mathrm{d}t + \mathrm{d}y^3)).$$

Finally, the Ricci rotation coefficients will be calculated. Some expressions are not explicitly given, since they turn out to be too complicated. Instead, the dependence on the geometric quantities involved will be specified in square brackets:

$$
\begin{gathered}
{}^4\gamma^0_{01}={}^4\gamma^1_{00}=A^{-1}N^{-1}N',\\
{}^4\gamma^0_{0B}={}^4\gamma^B_{00}=0,\\
{}^4\gamma^0_{11}={}^4\gamma^1_{01}=-K,\\
{}^4\gamma^0_{1B}={}^4\gamma^B_{10}=(Aa)^{-1}\overline{e}_B{}^C\eta_C,\\
{}^4\gamma^0_{AB}={}^4\gamma^B_{A0}=-\overline{e}_A{}^C\overline{e}_B{}^D\kappa_{CD},\\
{}^4\gamma^1_{01}=0,\\
{}^4\gamma^1_{0B}={}^4\gamma^1_{0B}[N^{-1},\overline{\nu},\overline{\nu}',A,A^{-1},A',a,a^{-1},V,W,V',W',\dot{V},\dot{W}]=-{}^4\gamma^B_{01},\\
{}^4\gamma^C_{0B}={}^4\gamma^C_{0B}[N^{-1},\nu^1,A,A^{-1},A',a,a^{-1},V,W,V',W',\dot{V},\dot{W}],\\
{}^4\gamma^k_{ij}=\gamma^k_{ij}[A^{-1},A',V,W,V',W'].
\end{gathered}
$$

where the dependence on the derivatives of V and W is linear.

B. The field equations

Again we represent the matter quantities by $\rho=T(n,n)$, $j=-T(n,m)=A^{-1}j_1$ and $S_{ij}=T({}^4e_i,{}^4e_j)$.

1. 2+1-decomposition of the constraints

First consider the Hamiltonian constraint

$$R+H^2-|k|^2=16\pi\rho.$$

Decomposing R by the Gauss–Codazzi formula and k by (10) we get

$$m(\mathrm{tr}\lambda)=8\pi\rho-H\,\mathrm{tr}\,\kappa+|\eta|^2+\tfrac{1}{2}(\tfrac{3}{2}(\mathrm{tr}\,\lambda)^2+|\tilde{\lambda}|^2)+\tfrac{1}{2}(\tfrac{3}{2}(\mathrm{tr}\,\kappa)^2+|\tilde{\kappa}|^2). \tag{12}$$

The first component of the momentum constraint

$$\nabla^i k_{i1}-\nabla_1 H=8\pi j_1$$

can be decomposed into

$$m(\mathrm{tr}\,\kappa)=-8\pi j_1-H\,\mathrm{tr}\,\lambda+\tfrac{3}{2}\mathrm{tr}\,\kappa\,\mathrm{tr}\,\lambda+\tilde{\lambda}^{AB}\tilde{\kappa}_{AB} \tag{13}$$

(where the symmetry forced div $\eta=0$). The other components of the momentum constraints are calculated analogously to (again some terms cancel out due to symmetry)

$$m(\eta_B)=-8\pi j_B+(\mathrm{tr}\,\lambda)\,\eta_B. \tag{14}$$

As in Paper I a convenient form of the equation is achieved by introducing the null expansions

$$\vartheta_\pm:=-(\mathrm{tr}\,\lambda\pm\mathrm{tr}\,\kappa)=\frac{2}{r}k_\pm(r) \tag{15}$$

(compare the formulas for λ and κ in Sec. II A 1), which yields an easy formula for the Hawking mass

$$\mathrm{M} := m_H(F) = -\tfrac{1}{8} r(r\vartheta_+)(r\vartheta_-) = -\tfrac{1}{2} r({}^4\nabla^\alpha r)({}^4\nabla_\alpha r), \tag{16}$$

by $\vartheta_+\vartheta_- = 4/r^2({}^4\nabla^\alpha r)({}^4\nabla_\alpha r)$.

Adding and subtracting the constraint equations now yield

$$m(\vartheta_\pm) = -8\pi(\rho \mp j_1) - |\eta|^2 - \tfrac{1}{2}|\tilde{\lambda} \pm \tilde{\kappa}|^2 \mp H\vartheta_\pm - \tfrac{3}{4}\vartheta_\pm^2 \tag{17}$$

and the transition to the variables $\omega_\pm := r\vartheta_\pm$ casts this equation into

$$\begin{aligned} m(\omega_\pm) &= m(r)\vartheta_\pm + r m(\vartheta_\pm) \\ &= -8\pi r(\rho \mp j_1) - r|\eta|^2 - \frac{1}{2} r|\tilde{\lambda} \pm \tilde{\kappa}|^2 \mp H\omega_\pm + \frac{1}{4\pi}(\omega_+\omega_- - 2\omega_\pm^2), \end{aligned} \tag{18}$$

where the identity $m(r)\vartheta_\pm = (1/4\pi)((\omega_+ + \omega_-)\omega_\pm)$ has been used.

2. 2+2-decomposition of the field equations

With the $2+2$-geometry in mind, where we denote tensor components with respect to the frame of projection operators $\{q_a, p_A\}$, we write Eq. (7a) for ${}^4\underline{R}_{ab}$ in terms of $\tilde{g}$,

$${}^4\underline{R}_{ab} = \underline{R}_{ab} - 2r^{-1}\underline{\nabla}_a\underline{\nabla}_b r + \tfrac{1}{4}(\underline{\nabla}_a\tilde{g}_{AB})(\underline{\nabla}_b\tilde{g}^{AB}) + 2\underline{g}_{ab}|\eta|^2,$$

as a field equation in the quotient space–time $(B, \underline{g})$ for the radius function r. We still have to eliminate the unknown $\underline{R}_{ab} = -\underline{K}\underline{g}_{ab}$, where $\underline{K} := \underline{R}_{0101}$ denotes the Gaussian curvature of $(B, \underline{g})$ in (M, g). Contracting the equation for $\underline{R}_{ab}$ and replacing $\underline{\Delta} r$ by (8) yields an equation for $\underline{K}$:

$$\underline{K} = \tfrac{1}{2}(-{}^4\underline{R}^c_{\underline{c}} + {}^4\underline{R}^A_{\underline{A}}) + r^{-2}(\underline{\nabla}^c r)(\nabla_{\underline{c}} r) + \tfrac{1}{8}(\underline{\nabla}^c\tilde{g}_{AB})(\underline{\nabla}_c\tilde{g}^{AB}) + 3|\eta|^2.$$

Inserting this into the equation for ${}^4\underline{R}_{ab}$ results in

$$\begin{aligned} \underline{\nabla}_a\underline{\nabla}_b r = &-\tfrac{1}{2} r^{-1}(\underline{\nabla}^c r)(\underline{\nabla}_c r)\underline{g}_{ab} - \tfrac{1}{2} r({}^4\underline{R}_{ab} - \tfrac{1}{2}({}^4\underline{R}^c_{\underline{c}} - {}^4\underline{R}^{\overline{A}}_{\overline{A}})\underline{g}_{ab}) \\ &+ \tfrac{1}{8} r((\underline{\nabla}_a\tilde{g}_{AB})(\underline{\nabla}_b\tilde{g}^{AB}) - \tfrac{1}{2}(\underline{\nabla}^c\tilde{g}_{AB})(\underline{\nabla}_c\tilde{g}^{AB})\underline{g}_{ab}) - \tfrac{1}{2} r|\eta|^2\underline{g}_{ab}. \end{aligned}$$

Now we are going to interpret the first three terms appearing on the right-hand side of the field equation: Recalling the definition of the mass function M in (16) we can write the first term as $(M/r^2)\underline{g}_{ab}$. The curvature expression in the second term can be rewritten using Einstein's equations in terms of the projected energy momentum tensor $\underline{T}$ in the form $8\pi(\underline{T}_{ab} - \mathrm{tr}\underline{T}\,\underline{g}_{ab})$.

To simplify the third term, there is more structure involved than already presented. The space of two-dimensional metrics Bil(2, $\mathbb{R}$) is a three-dimensional real vector space, whose elements we denote by $\tilde{\phi} = \tilde{\phi}^i E_i$, where the basis $\{E_i\}$ has been chosen as $E_1 = \left(\begin{smallmatrix}1 & 0\\ 0 & 1\end{smallmatrix}\right)$, $E_2 = \left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$, $E_3 = \left(\begin{smallmatrix}0 & 1\\ 1 & 0\end{smallmatrix}\right)$. In this picture the determinant is a quadratic form on Bil(2, $\mathbb{R}$), and the matrix representation with respect to the given basis turns out to be $-\eta_{ij}$, where $\eta_{ij} = \mathrm{diag}(-++)$ denotes the standard Minkowski metric in three-dimensional Minkowski space. The restriction of this space to the hypersurface $\eta(\tilde{\phi}, \tilde{\phi}) = -1 \Leftrightarrow \det\tilde{\phi} = 1$ is the well-known hyperbolic plane H^2, and we have established a correspondence between the two-dimensional unit-determinant metrics $\tilde{g}$ and the elements of the hyperbolic plane. Considering $\tilde{\phi}$ as a function on the quotient manifold B, introduced in Sec. II A 1, we have a map $\tilde{\phi}: (B, \underline{g}) \to (H^2 \subset \mathbb{R}^{2,1}, \eta_{ij})$, $(t,x) \mapsto \tilde{\phi}^i(\tilde{g}(t,x))E_i$. Now let us interpret $\tilde{\phi}$ for a moment as a wave map from B to H^2, then the energy–momentum tensor ${}^\phi\underline{T}$ associated with $\tilde{\phi}$ reads

$$ {}^{\phi}\underline{T}_{ab} = \underline{\nabla}_a \tilde{\phi}^i \underline{\nabla}_b \tilde{\phi}_i - \tfrac{1}{2}(\underline{\nabla}^c \tilde{\phi}^i \underline{\nabla}_c \tilde{\phi}_i)\underline{g}_{ab} \tag{19} $$

and with the correspondences $\tilde{\phi}_i = \eta_{ij}\tilde{\phi}^j = -\tilde{g}^{AB}$ and $\tilde{\phi}_i\tilde{\phi}^i = -\frac{1}{2}\tilde{g}_{AB}\tilde{g}^{AB}$, we see that the third term in the field equation for r can be rewritten as $-\frac{1}{4}r\,{}^{\phi}\underline{T}_{ab}$.

Collecting all these things together we get the field equation for r in a convenient form:

$$ \underline{\nabla}_a\underline{\nabla}_b r = \frac{M}{r^2}\underline{g}_{ab} - 4\pi r(\underline{T}_{ab} - \operatorname{tr}\underline{T}\underline{g}_{ab}) - \frac{1}{4}r\,{}^{\phi}\underline{T}_{ab} - \frac{1}{2}r|\eta|^2\underline{g}_{ab}. \tag{20} $$

Differentiating the mass function we find for the mass flux equation the formula

$$ \underline{\nabla}_a M = (4\pi r^2(\underline{T}_{ab} - \operatorname{tr}\underline{T}\underline{g}_{ab}) + \tfrac{1}{4}r\,{}^{\phi}\underline{T}_{ab})(\underline{\nabla}^b r) + \tfrac{1}{2}r^2|\eta|^2\underline{\nabla}_a r. \tag{21} $$

The contribution of ${}^{\phi}\underline{T}$ to the right-hand sides of these equations is known insofar that ${}^{\phi}\underline{T}$ obeys the dominant and strong energy conditions. Furthermore, we can again rewrite its components using the formulas for the trace free parts of λ and κ in Sec. II A 1 (remember that ∇_0, ∇_1 act as n, respectively, m, on $\tilde{g}$, in the formula for ${}^{\phi}\underline{T}_{ab}$). The result is

$$ {}^{\phi}\rho = {}^{\phi}p = |\tilde{\lambda}|^2 + |\tilde{\kappa}|^2, \tag{22a} $$

$$ {}^{\phi}j_{\underline{1}} = -2\tilde{\lambda}_{AB}\tilde{\kappa}^{AB}. \tag{22b} $$

Now we want to analyze the underlying wave map. To make things more explicit, consider the parameters V, W of $\tilde{g}$ as coordinates of H^2 in view of the correspondence $\tilde{\phi}^i E_i$. The pullback under this parametrization yields a representation $\hat{h}$ of the metric $(\eta_{ij})_{|H^2}$, with the explicit form $\hat{h}_{IJ} = \mathrm{d}V^2 + (\cosh V)^2\mathrm{d}W^2$, leading to $\hat{\Gamma}^3_{23} = \tanh V$ and $\hat{\Gamma}^2_{33} = -\sinh V\cosh V$ as nonvanishing Christoffel symbols. The pullback of the map $\tilde{\phi}$ under this parametrization induces a map $\phi:(B,\underline{g})\to(H^2,\hat{h})$, $\phi(t,x) = (V(t,x),W(t,x))$. The wave map ϕ is then defined to obey

$$ \underline{\nabla}^c\underline{\nabla}_c\phi^K + \hat{\Gamma}^K_{IJ}\underline{\nabla}^c\phi^I\underline{\nabla}\phi^J = 0. \tag{23} $$

Let us turn back to the field equations. Writing Eq. (7c) in the form

$$ {}^4\overline{R_{AB}} + 2\,\overline{\eta}_A\,\overline{\eta}_B = -\tfrac{1}{2}r^{-2}\overline{g}_{AD}\underline{\nabla}^c(r^2\overline{g}^{CD}\underline{\nabla}_c\overline{g}_{BC}) = -\tfrac{1}{2}\tilde{g}_{AD}\underline{\nabla}^c(\tilde{g}^{CD}\underline{\nabla}_c r^2\tilde{g}_{BC}) $$

we arrive after some calculation at

$$ \underline{\nabla}^c(r^2\underline{\nabla}_c\tilde{g}_{AB}) = r^2\tilde{g}^{CD}(\underline{\nabla}^c\tilde{g}_{AD})(\underline{\nabla}_c\tilde{g}_{BC}) - 16\pi(\overline{T}_{AB} - \tfrac{1}{2}\operatorname{tr}\overline{T}\overline{g}_{AB}) - 4(\overline{\eta}_A\,\overline{\eta}_B - \tfrac{1}{2}|\eta|^2\overline{g}_{AB}), $$

where $\overline{T}$ denotes the orthogonal projection of the energy momentum tensor T into $(F,\overline{g})$. More explicitly we get

$$ \begin{aligned} \underline{\nabla}^c(r^2\underline{\nabla}_c V) = {} & r^2\sinh V\cosh V(\underline{\nabla}^c W)(\underline{\nabla}_c W) - 2r^2(\cosh V)^{-1}((T_{23} - \tfrac{1}{2}\tilde{g}^{AB}T_{AB}\tilde{g}_{23}) \\ & - \tfrac{1}{2}(\eta_2\eta_3 - \tfrac{1}{2}\tilde{g}^{AB}\eta_A\eta_B\tilde{g}_{23})), \end{aligned} \tag{24a} $$

$$ \begin{aligned} \underline{\nabla}^c(r^2\underline{\nabla}_c W) = {} & -r^2\tanh V(\underline{\nabla}^c W)(\underline{\nabla}_c V) - r^2(\cosh V)^{-1}((e^{-W}T_{22} - e^{W}T_{33}) \\ & - \tfrac{1}{2}(e^{-W}(\eta_2)^2 - e^{W}(\eta_3)^2)), \end{aligned} \tag{24b} $$

or

$$ \begin{aligned} \underline{\nabla}^c\underline{\nabla}_c V - \sinh V\cosh V(\underline{\nabla}^c W)(\underline{\nabla}_c W) = {} & -2/r(\underline{\nabla}^c r)(\underline{\nabla}_c V) - 2(\cosh V)^{-1}((T_{23} - \tfrac{1}{2}\tilde{g}^{AB}T_{AB}\tilde{g}_{23}) \\ & - \tfrac{1}{2}(\eta_2\eta_3 - \tfrac{1}{2}\tilde{g}^{AB}\eta_A\eta_B\tilde{g}_{23})), \end{aligned} \tag{25a} $$

$$\nabla^c\nabla_c W+\tanh V(\nabla^c W)(\nabla_c V)=-2/r(\nabla^c r)(\nabla_c W)-(\cosh V)^{-1}((e^{-W}T_{22}-e^{W}T_{33}) -\tfrac{1}{2}(e^{-W}(\eta_2)^2-e^{W}(\eta_3)^2)). \tag{25b}$$

The left-hand sides of Eq. (25) coincide with the left-hand side of (23) and we conclude that V and W solve an inhomogeneous wave map.

3. 3+1-decomposition of the field equations

Now we want to calculate the ADM equations and bring them into a form most similar to the equations in the plane symmetric case of Paper I. The formulas concerning the three-geometry in Sec. III A 2 are of particular importance for the calculations here, as well as the definitions of λ, κ, and η in Sec. II A 1. A straightforward calculation then yields the following set of equations.

The constraint equations,

$$(A^{1/2})''=\tfrac{1}{8}A^{5/2}(H^2-\tfrac{1}{2}(H-K)^2-K^2-|\tilde{\kappa}|^2-|\tilde{\lambda}|^2-2|\eta|^2-16\pi\rho), \tag{26}$$

$$K'=-3A^{-1}A'K+A^{-1}A'H+H'-A\tilde{\kappa}_{AB}\tilde{\lambda}^{AB}+8\pi Aj, \tag{27}$$

$$\eta_B'=-2A^{-1}A'\eta_B-8\pi Aj_B. \tag{28}$$

The equations fixing the foliation,

$$N''=-A^{-1}A'N'+A^2N(\tfrac{1}{2}(H-K)^2+K^2+|\tilde{\kappa}|^2+2|\eta|^2+4\pi(\rho+\mathrm{tr}\,S))-A^2, \tag{29}$$

$$\dot{H}=1+\nu^1H', \tag{30}$$

$$(\partial_t-\nu^1\partial_x)H'=\nu^{1'}H'. \tag{31}$$

The evolution equations,

$$\dot{A}=-NAK+A\nu^{1'}+A'\nu^1, \tag{32}$$

$$\dot{a}=-\tfrac{1}{2}Na(H-3K)-a\nu^{1'}, \tag{33}$$

$$\dot{K}=\nu^1K'-A^{-2}(N''-A^{-1}A'N')+N(-4A^{-5/2}(A^{1/2})''+(A^{-2}A')^2 +HK-|\tilde{\lambda}|^2+2|\eta|^2-8\pi(A^{-2}S_{11}+\tfrac{1}{2}(\rho-\mathrm{tr}\,S))), \tag{34}$$

$$\dot{\eta}_B=(\tfrac{1}{2}N(H+K)-2A^{-1}A'\nu^1)\eta_B-2N\tilde{\kappa}_{BC}\eta^C+\tfrac{1}{2}A^{-2}A'(H-K)\nu_B -(\tilde{\kappa}_B^D\tilde{\lambda}_{DC}+\tfrac{1}{2}(H-K)\tilde{\lambda}_{BC}-A^{-2}A'\tilde{\kappa}_{BC})\nu^C-8\pi A\nu^1j_B. \tag{35}$$

As in Paper I integration of (33) over the circle yields the analogous equation for the first component of the shift vector,

$$\nu^{1'}=-\frac{1}{2}N(H-3K)+\frac{1}{2}\int_{S^1}N(H-3K) \tag{36}$$

and the definition of the second fundamental form provides some additional equations, namely

$$\nu^{B'}=-2NA\eta^B \tag{37}$$

and the coordinate representations of λ and κ in Sec. II A 1. The remaining equations for V and W are still missing. To this end we supplement the system (26)–(37) by the field equations (24) or (25), and end up with the full system of equations.

As in the plane symmetric case, we can formulate an existence and uniqueness theorem for solutions of Eqs. (26)–(37), (25). First we define a *symmetric initial data set* for a space–time with local $U(1)\times U(1)$ symmetry by the smooth collection (Σ,h,k), where Σ denotes a (possibly nontrivial) torus bundle over the circle and the fundamental forms h and k are represented in a suitable coordinate system as (9) and (10), respectively. If there are matter fields, then we assume the matter data and equations to be smooth and symmetric, leading to a well-posed Cauchy problem coupled to the reduced field equations in harmonic coordinates.

On the universal cover $\hat{\Sigma}$ of Σ the induced data then is invariant under the action of G, hence G acts isometrically on the whole Cauchy development, which induces a local $U(1)\times U(1)$ symmetry on the Cauchy development of (Σ,h,k). Assuming $\lambda := |k|^2 + 4\pi(\rho + \operatorname{tr} S) > 0$ somewhere on Σ, we get for $t_0 \in \mathbb{R}$ a unique symmetric local in time PMC foliation, defined on some time interval containing t_0, with $\Sigma = S_{t_0}$, and coordinates described in Proposition 2.1 and we just have proved:

Proposition 2.2: Let (Σ,h,k) *be a symmetric initial data set for a space–time with local* $U(1)\times U(1)$ *symmetry, with matter obeying the strong energy condition and* $\lambda > 0$ *somewhere on* Σ. *Further, let* t_0 *denote an arbitrary real number.*

Then there exists a $\delta > 0$ *and a PMC foliated surface symmetric space–time* $(\overline{M},\tilde{g})$ *diffeomorphic to* $]t_0-\delta,t_0+\delta[\times\Sigma$ *with an embedding* $\iota:\Sigma\to\overline{M}$, *satisfying* $\iota(\Sigma) = S_{t_0}$ *and* $\iota_* h$, $\iota_* k$ *are the first and second fundamental form of* S_{t_0} *in* $(\overline{M},\overline{g})$. $(\overline{M},\overline{g})$ *obeys the strong energy condition and* $\overline{g}$ *can be written in the form described in Proposition 2.1. This construction is unique up to the choice of* t_0 *and* δ.

4. The expanding model

Now we can proceed in close analogy to the corresponding analysis in Paper I. Formula (16) for the Hawking mass shows that $\operatorname{grad} r$ is timelike as long as $m > 0$. Indeed, Proposition 3.1 in Rendall (1997) proves this, provided the space–time is not flat and the dominant energy condition holds.

Therefore, under these conditions $\operatorname{grad} r$ is timelike and ϑ_+, ϑ_- have fixed and opposite signs. Without loss of generality we choose the time orientation, such that r is past pointing and $\mathrm{d}r$ is future pointing (by the induced time orientation of the cotangent bundle). Then $\vartheta_+ > 0$ and $\vartheta_- < 0$ which classifies the space–time as expanding in the sense described in Paper I.

Again we expect the singularity in the distant past from our symmetric initial data Cauchy surface Σ and any symmetric Cauchy surface S in M is not maximal with mean curvature not everywhere positive on S.

C. *A priori* estimates for the field equations

Assume the dominant and strong energy condition to be fulfilled in (M,g). Let Σ be a symmetric Cauchy surface in M with strictly negative mean curvature H and denote by $\{S_t\}$, $t \in]t_1,t_2[$ the local in time PMC foliation with $\Sigma = S_0$ and the time orientation chosen in correspondence with Sec. II B D, such that H decreases with decreasing PMC time.

We consider the past $D^-(\Sigma)$ of Σ. In $D^-(\Sigma)$ the mean curvature is bounded from above by some $\overline{H} < 0$, and $H = \overline{H}$ only on Σ. Thus $|H|$ is bounded from below and as long as H remains finite, we find the following estimates.

Consider first the constraint equation in the form (18). The dominant energy condition gives the inequality

$$m(\omega_\pm) \leqslant \mp H\omega_\pm + \frac{1}{4\pi}(\omega_+\omega_- - 2\omega_\pm^2),$$

from which we infer the basic estimate

$$|\vartheta_{\pm}| \leqslant 4|H| \Rightarrow |A^{-2}A'| \leqslant C, \quad |K| \leqslant C. \tag{38}$$

Now we can perform nearly the same estimates, as we have done in the corresponding place in Paper I. The additional terms appearing here in the more general equations (26)–(27), (29)–(33), and (36) do not cause any problems. There is only one additional estimate, which will become important in our further analysis, resulting from the integration of Eq. (26) along S^1, bounding not only $\int_{S^1}\rho$, but also $\int_{S^1}(|\tilde{\lambda}|^2+|\tilde{\kappa}|^2+|\eta|^2)=\int_{S^1}({}^{\phi}\rho+|\eta|^2)$, and we can state the analogous

Proposition 2.3: Let (M,g) *be a globally hyperbolic, spatially compact space–time with local* $U(1)\times U(1)$ *symmetry, obeying the dominant and strong energy condition. Assume the existence of a symmetric Cauchy surface* Σ *with strictly negative mean curvature. In particular we get from proposition 2.1 a PMC time coordinate t, ranging in* $]t_1,t_2[$ *with* $\Sigma=\{t=0\}$ *and H decreases with decreasing t.*

Then we have uniformly on $]t_1,0]$

$$|A|,|A^{-1}|,|A'|,|a|,|a^{-1}|,|H|,|H'|,|K|,|N|,|N^{-1}|,|N'|,|\nu^1|,|\nu^{1\prime}| \leqslant C.$$

Until now the control over the coefficients of the fundamental forms h and k is not complete. We still need bounds for the metric coefficients V, W, the components η and κ of k and the remaining components ν^B of the shift vector. We will get bounds for most of these quantities here in this section, using the bound for $\int_{S^1}(\rho+{}^{\phi}\rho+|\eta|^2)$.

Proposition 2.4: Under the hypotheses of Proposition 2.3 we get uniform bounds for

$$|V|,|W|,|\eta_B|,|\nu^B|,|\nu^{B\prime}|$$

on $]t_1,0]$.

Proof: The bounds for η_B, ν^B and $\nu^{B\prime}$ are simple consequences of the bounds for V and W, since having bounded them, we can conclude as follows: The bounds for V and W allow coordinate components to be bounded in terms of components according to the orthonormal frame vectors $\overline{e_2}$, $\overline{e_3}$ in $(F,\overline{g})$ defined in Sec. II A 1. We adopt the convention, that a caret above indices denotes components with respect to an orthonormal frame. Having this in mind we see, that $\int_{S^1}\rho$ bounds $\int_{S^1}j_B \leqslant C\int_{S^1}j_B$ by the dominant energy condition, so integration of the constraint (28) yields a bound for the difference $A^2\eta_B|_{x_1}^{x_2}$, which is independent of t. Using $\eta_B \leqslant C\hat{\eta_B} \leqslant C(1+|\eta|^2)$ we can bound integral $\int_{S^1}|A^2\eta_B|$ by $C\int_{S^1}(1+|\eta|^2)$, which together with the estimated difference yields the desired estimate for η_B. Now we get immediately a bound for $\nu^{B\prime}$ by inspection of Eq. (37), and the condition $\nu^B(t,0)=0$ bounds ν^B.

Let us now investigate the field equations (24) for V and W, considered as equations on $(B,\underline{g})$ endowed with the coordinates (t,x), as described in the end of Sec. II A 1. Then we calculate explicitly in these coordinates

$$\begin{aligned}|\tilde{\lambda}|^2+|\tilde{\kappa}|^2 &= \tfrac{1}{4}(m(\tilde{g}_{AB})m(\tilde{g}^{AB})+n(\tilde{g}_{AB})n(\tilde{g}^{AB}))\\ &= \tfrac{1}{2}A^{-2}(V'^2+(\cosh V)^2W'^2)+\tfrac{1}{2}N^{-2}((\dot{V}-\nu^1V')^2\\ &\quad +(\cosh V)^2(\dot{W}-\nu^1W')^2),\end{aligned}$$

and we see that the first term on the right-hand side of Eq. (24) can be bounded in terms of this expression.

For the second term on the right-hand side of (24) we exploit the special structure appearing there. The first aim is to express the tensor components with respect to an orthonormal frame. Looking at the definitions of the coframe $\{\overline{\sigma}^B\}$ defined in Sec. II A 1 we recognize the relations

$$e^{W/2}\mathrm{d}y^2 = r^{-1}(+\cosh V/2\overline{\sigma}^2-\sinh V/2\overline{\sigma}^3),$$

$$e^{-W/2}\mathrm{d}y^3 = r^{-1}(-\sinh V/2\,\overline{\sigma}^2 + \cosh V/2\,\overline{\sigma}^3).$$

If we mark tensor components expressed in this basis by a tilde, we see that the terms in brackets in both equations (24) are easily rewritten with respect to this basis, by simply putting a tilde above each tensor component and deleting the factors $e^{\pm W/2}$. But we have schematically $\eta = \eta_B\,\mathrm{d}y^B = \widetilde{\eta}_B e^{\pm W/2}\,\mathrm{d}y^B = f_B(\cosh V/2)\,\widetilde{\eta}_B\,\overline{\sigma}^B$, with $f_B(\cosh V/2)\,\widetilde{\eta}_B = \eta_{\hat{B}}$ is the component according to the orthonormal frame. A similar relation holds for T_{AB}. Since we have $\eta_{\hat{B}} \leqslant 1 + |\eta|^2$ and $T_{\hat{A}\hat{B}} \leqslant \rho$ we conclude that the terms in brackets in (24) are bounded by $C\cosh V(1+\rho+|\eta|^2)$, which leads together with our result about the first term on the right-hand side of (24) to

$$|\underline{\nabla}^c(r^2\underline{\nabla}_c\phi)| \leqslant C(1+\rho+|\widetilde{\lambda}|^2+|\widetilde{\kappa}|^2+|\eta|^2),$$

and since the integration of the right-hand side along S^1 is already bounded we get

$$\int_{S'} |\underline{\nabla}^c(r^2\underline{\nabla}_c\phi)| \leqslant C$$

uniformly for each $t \in]t_1,0]$. Note that we use the wave map $\phi=(V,W)$ defined in Sec. II B 2 in order to abbreviate some formulas only.

On the other hand, we can interpret the integrated quantity as a divergence, a fact we will take advantage of to get rid of the integral sign. To this end consider a point (t,x) in the quotient manifold B, with $t \in]t_1,0[$. We need estimates uniformly in t for t approaching t_1. We define the (upside down) characteristics triangle T in B, by its counterclockwise oriented boundary $\partial T = \gamma_+ + \gamma_0 + \gamma_-$, where $\gamma_\pm$ denote the characteristic curves of (24), with $\dot{\gamma}_\pm = k_\pm = m \pm n$ connecting (t,x) with $(0,x_\pm)$ and γ_0 is the curve in the hypersurface $\{t=0\}$ from $(0,x_+)$, to $(0,x_-)$ with $\dot{\gamma}_0 = -m$. Define $v \in T^\perp F$ by $v^a = r^2\underline{\nabla}^a\phi$, then the corresponding one-form ω reads $\omega = \iota(v)\underline{\Omega}$, where $\underline{\Omega}$ denotes the volume form with respect to $\underline{g}$. Expressing tensor components with respect to the project orthonormal frame $\{\underline{e}_a = q_a\}$ (see Sec. II A 1) we have $v^a = r^2\binom{-\nabla_0\phi}{\nabla_1\phi}$, and $\omega = -r^2(m(\phi)\underline{e}^0 + n(\phi)\underline{e}^1)$. The pullback of ω along ∂T has the three parts $\gamma_\pm^*\omega = \mp r^2 k_\pm(\phi\circ\gamma_\pm(u))du$, $\gamma_0^*\omega = r^2 n(\phi(x))A\,\mathrm{d}x$. Thus, setting $\tau := \sqrt{2}t$,

$$\begin{aligned}
\int_{\partial T}\omega &= \int_\tau^0 -r^2 k_+(\phi(\gamma_+(u)))\mathrm{d}u + \int_{x_+}^{x_-} n(\phi(x))A\,\mathrm{d}x + \int_0^\tau + r^2 k_-(\phi(\gamma_-(u)))\mathrm{d}u \\
&= -\int_\tau^0 r^2 k_+(\phi(\gamma_+(u)))\mathrm{d}u - \int_\tau^0 r^2 k_-(\phi(\gamma_-(u)))\mathrm{d}u + \int_{x_+}^{x_-} n(\phi(x))A\,\mathrm{d}x \\
&= -r^2\phi|_{\gamma_+(r)}^{\gamma_+(0)} - r^2\phi|_{\gamma_-(r)}^{\gamma_-(0)} + \int_\tau^0 k_+(r^2)\phi + \int_\tau^0 k_-(r^2)\phi + \int_{x_+}^{x_-} n(\phi(x))A\,\mathrm{d}x,
\end{aligned}$$

where integration by parts has been carried out in the last step. Note, that the last term is bounded, since that integration takes place on the line $t=0$ in B, where ϕ is smooth. In addition $k_\pm(r^2)$ is bounded everywhere by Proposition 2.3. Further, the first terms can be evaluated to $-r^2\phi|_{\gamma_+(\tau)}^{\gamma_+(0)} - r^2\phi|_{\gamma_-(\tau)}^{\gamma_-(0)} = 2(r^2\phi)(t,x) - (r^2\phi)(0,x_+) - (r^2\phi)(0,x_-)$, where the last two terms live on the line $t=0$, and therefore are bounded.

Stokes' theorem now applies to the present situation, $\int_{\partial T}\omega = \int_T \mathrm{d}w = \int_T (\mathrm{div}\,v)\underline{\Omega}$. Putting all this together we get an estimate

$$\|r^2\phi(t)\|_{L^\infty} \leqslant C\left(1 + \int_t^0 \|r^2\phi(s)\|_{L^\infty}\,\mathrm{d}s + \int_t^0\int_{S'} |\underline{\nabla}^c(r^2\underline{\nabla}_c\phi)|\mathrm{d}s\right),$$

where the last term is already known to be bounded uniformly in t by our previous analysis. Hence we can apply Gronwall's inequality and the bounds for r, r^{-1} obtained in Proposition 2.3 complete our argument, arriving finally at $|V|$, $|W| \leq C$ uniformly on $]t_1,0[$. ■

Unfortunately, there is still a lack of control over the components κ of k [respectively, its traceless part, since $(\mathrm{tr}\,\kappa)\underline{g} = (H-K)\underline{g} \leq C$]. It turns out, that the necessary bounds for the first derivatives of ϕ depend on a bound for the matter quantities and vice versa. The analysis of this dependence will be performed in Sec. II D, where we have to take a specific matter model into account.

D. Higher order estimates

1. First-order estimates

We start with the derivation of first-order estimates for the metric coefficients $\phi = (V,W)$. To keep things simple, we consider collisionless matter, as described by the Einstein–Vlasov system.

The particle density f on the mass shell is governed by the geodesic spray X with $X = v^\alpha\, {}^4e_\alpha - {}^4\gamma^\kappa_{\mu\nu} v^\mu v^\nu (\partial/\partial v^\kappa)$, and the killing vector fields ∂_A define two conserved quantities $g(X,\partial_A)$, which bound v^A. To bound v^1 we consider the characteristics of the Vlasov equation (compare the explicit formulas in Paper I):

$$\frac{\mathrm{d}v^1}{\mathrm{d}s} = -(e_1(N)v^0 + N(-k_{rs}e_1{}^r e_j{}^s + {}^4\gamma^1_{0j})v^j + N\gamma^1_{jk}v^j v^k/v^0) \leq C(1 + Q_1(s) + v^1(s)),$$

where $Q_1 := \|\underline{D}\phi\|_{D^\infty}$, $\underline{D} := (\partial_t, \partial_x)$ and we used the fact, that in view of the boundedness of v^A, the vanishing of ${}^4\gamma^1_{01}$ and the special form of the nonvanishing rotation coefficients no term involving the product $Q_1 v^1$ occurs. Thus we find for the quantity $\overline{P_f}(s) = \{\sup|v| \,|\, v \in \mathrm{supp}\, f\}$ (which measures the matter quantities, compare Paper I the Gronwall-like estimate

$$1 + \overline{P_f}(t) \leq C\left(1 + \overline{P_f}(0) + \int_t^0 (\overline{P_f}(s) + Q_1(s))\mathrm{d}s\right).$$

This inequality shows that we indeed have to estimate the matter quantities together with the second fundamental form κ. The next step consists in finding a complementary inequality for Q_1, which yields in combination with the inequality just obtained a true Gronwall estimate for $1 + \overline{P_f} + Q_1$.

We again need the field equations for V and W, but now it is more convenient to analyze the equations in the "wave map form" (25). First consider the left-hand side of the field equation. We want to express this derivative operator in terms of the characteristic vector fields $k_\pm = m \pm n$ tangent to the characteristic curves $\gamma_\pm$ introduced in the previous section (in the proof of Proposition 2.4). In the quotient manifold $(B,\underline{g})$ one calculates the nonvanishing Ricci rotation coefficients to

$$\gamma^0_{01} = \gamma^1_{00} = (AN)^{-1}N',$$

$$\gamma^0_{11} = \gamma^1_{01} = (AN)^{-1}(\dot{A} - (A\nu^1)'),$$

thus $\underline{\nabla}_{\underline{e}_a}\underline{e}_b$ is bounded. The characteristics $k_\pm$ expressed in the coordinates of B are simple linear combinations of the $\underline{e}_a$, hence $\underline{\nabla}_{k_\pm}k_\pm$ is also bounded in B. We will use this fact to estimate commutators such as $[m,n]$ or $[k_+,k_-]$. Transforming from the orthonormal frame $\{\underline{e}_a\}$ in $(B,\underline{g})$ to the frame $\{k_\pm\}$, we can write the left-hand side of (25) as

$$\underline{\nabla}^c\underline{\nabla}_c\phi^K + \hat{\Gamma}^K_{IJ}\underline{\nabla}^c\phi^I\underline{\nabla}\phi^J = \underline{\nabla}_{k_+}(k_-(\phi^K)) + \hat{\Gamma}^K_{IJ}k_+(\phi^I)k_-(\phi^J) + [k_+,k_-](\phi^K)$$

and there is an analogous equation for k_+ and k_- interchanged.

Let us turn now to the right-hand side of (25). The terms not known to be bounded are of the form $k_{\pm}(\phi)$ and T_{AB}. Fortunately we have control over the matter term, since the bounds on V, W, and v^A justify the inequality $T_{AB} \leqslant C\overline{P}_f$ and we obtain

$$\nabla_{k_+}(k_-(\phi^K)) + \hat{\Gamma}^K_{IJ} k_+(\phi^I) k_-(\phi^J) \leqslant C(1 + k_{\pm}(\phi) + \overline{P}_f).$$

The left-hand side is still nonlinear in the first derivatives of ϕ, so this inequality is not in the appropriate form to apply some kind of Gronwall estimate. But we can overcome this difficulty by adapting an observation of Gu (1980), see also Rendall (1997) for explanation, who considered wave maps defined on two-dimensional Minkowski space. We already performed the first step, consisting of a transformation to characteristic coordinates. Now we define the vector field $\hat{k}_{\pm}$ over the map ϕ,

$$\hat{k}_{\pm} := \phi_*(k_{\pm}) = k_{\pm}(\phi) = k_{\pm}(\phi^K) \frac{\partial}{\partial \phi^K} = k_{\pm}(V) \frac{\partial}{\partial V} + k_{\pm}(W) \frac{\partial}{\partial W},$$

thus bounding the length of $\hat{k}_{\pm}$ accomplishes the estimate of Q_1. The vector field $\hat{k}_{\pm}$ over ϕ is a section in the bundle $\phi^*(TH^2)$ over B and the covariant derivative operator $\phi^*\hat{\nabla}$ over ϕ acts like

$$(\phi^*\hat{\nabla})_v \hat{X} = v(\hat{w}^K) \frac{\partial}{\partial \phi^K} + \hat{w}^K \hat{\nabla}_{\phi^* v} \frac{\partial}{\partial \phi^K}$$

for every vector $v \in TB$ and every $\hat{X} = \hat{w}^K(\partial/d\phi^K)$ with $w^K: B \to H^2$.

Evaluating this expression with $v = k_+$ and $\hat{X} = \hat{k}_-$ gives

$$(\phi^*\hat{\nabla})_{k_+} \hat{k}_- = k_+(k_-(\phi^K)) \frac{\partial}{\partial \phi^K} + \hat{\Gamma}^K_{IJ} k_+(\phi^I) k_-(\phi^J) \frac{\partial}{\partial \phi^K}$$

(and analogously for $k_{\pm}$ interchanged). The components in this equation are similar to the left-hand side of the inequality already obtained for the field equations. The remaining term involves $k_{\pm}(\phi)$ times the connection coefficients in B with respect to the frame $\{k_{\pm}\}$, which we know to be bounded. Thus we get for the field equations the inequality

$$|(\phi^*\hat{\nabla})_{k_+} \hat{k}_-| \leqslant C(1 + k_{\pm}(\phi) + \overline{P}_f),$$

expressing an estimate about the growth of $\hat{k}_{\pm}$ during the transport along the characteristic curve $\gamma_{\mp}$. This inequality is in the appropriate form for a Gronwall-like estimate: Taking the maximum for each fixed t allows us to combine the inequalities for $|\hat{k}_+|$ and $|\hat{k}_-|$, replaced collectively in terms of Q_1. Hence

$$Q_1(t) \leqslant C\left(1 + Q_1(0) + \int_t^0 (\overline{P}_f(s) + Q_1(s))\mathrm{d}s\right),$$

where $\gamma_{\pm}$ has been reparametrized in terms of t. Combining this with the inequality for $\overline{P}_f$ we arrive at

$$1 + \overline{P}_f(t) + Q_1(t) \leqslant C\left(1 + \overline{P}_f(0) + Q_1(0) + \int_t^0 (1 + \overline{P}_f(s) + Q_1(s))\mathrm{d}s\right).$$

Performing a Gronwall argument we have proven

Proposition 2.5: Let (M,g,f) be a globally hyperbolic, spatially compact solution of the Einstein–Vlasov system with local $U(1)\times U(1)$ symmetry, which possesses a symmetric Cauchy surface Σ with strictly negative mean curvature. The PMC time coordinate t ranges in $]t_1,t_2[$ with $\Sigma=\{t=0\}$ and H decreases with decreasing t.

Then we get uniform bounds for

$$|\dot{V}|,|\dot{W}|,|V'|,|W'|,\rho$$

on $]t_1,0]$.

2. Second-order estimates

We still have to do one further step before it will be possible to apply some iteration scheme. We need to establish bounds for the second derivatives of $\phi=(V,W)$ together with bounds for the first derivatives of the matter variables. Again it turns out that it is not possible to get separate estimates for these quantities.

First we differentiate the field equation (25) and obtain an equation of the form

$$k_{\pm}(k_{\mp}(\partial_x\phi^K))+2\hat{\Gamma}^K_{IJ}k_{\pm}(\phi^I)k_{\mp}(\partial_x\phi^J)=[\ldots]\partial_x T_{AB}+\text{lower order terms},$$

where [...] is an abbreviation for some term involving already bounded quantities, in particular we see by a quick look at the 3+1-field equations, whose right-hand sides are now bounded, that for the Ricci rotation coefficients $\partial_x\underline{\gamma}\leqslant C$ holds. Note that the differentiation kills the nonlinearity in the equation, but we have to deal with first-order derivatives of the matter variables instead. These quantities cause serious trouble, because if we differentiate the Vlasov equation, terms involving the second derivatives of ϕ times first derivatives of f come up, thus there is no direct Gronwall argument possible. To attack this difficulty we have to combine the equations, using an idea of Glassey (1990).

First we integrate the equation along the characteristics $\gamma_{\pm}$ to get an integral inequality. In order to apply a Gronwall argument all that remains to do is to bound the term $\int_{\gamma_{\pm}}\partial_x T_{AB}$. Then we express T_{AB} in terms of its components with respect to the orthonormal frame, merely producing some already bounded quantities and the frame components of the energy–momentum tensor for Vlasov-type matter look like $\int_{\gamma_{\pm}}(\int v_A v_B/v^0\partial_x f\,dv)$. Finally we represent ∂_x by a linear combination of $k_{\pm}$ and $\underline{X}:=\partial_t+(NA^{-1}v^1/v^0-\nu^1)\partial_x$, which is the part of the characteristic vector field for the Vlasov equation, lying in B. The transformation to this basis is obviously bounded and we can proceed as follows. The part involving $k_{\pm}$ permits a direct application of the integration by parts rule, which contributes something bounded by Proposition 2.5. The remaining part can be treated in a similar fashion, after inserting the Vlasov equation into $\underline{X}(f)$. This yields terms involving only first-order derivations of ϕ (arising from the ${}^4\gamma$'s) times $\partial f/\partial v$, and again we can perform an integration by parts with respect to the velocity integral. The result consists in terms already bounded and we are through. Now applying Gronwall's inequality we arrive at a bound for $\|\partial_x\underline{D}\phi\|_{L^\infty}$ and inserting this result into the field equation (25) we get $Q_2:=\|D^2\phi\|_{L^\infty}$ bounded.

An immediate consequence is that we also have established a bound for the first derivatives of f. Differentiating the Vlasov equation with respect to x or v yields an equation for $\partial_x f$ or $\partial_v f$, respectively, with bounded characteristics and an inhomogeneous term, consisting of $({}^4e_\mu)^\alpha$, ${}^4\gamma^\kappa_{\mu\nu}$ and their derivatives with respect to x. These terms are either bounded by what has been said previously or by inspection of the field equations (26)–(37). Having bounded the spatial and velocity derivatives of f, the structure of the Vlasov equation bounds immediately $\partial_t f$ and we have proven

Proposition 2.6: Under the hypotheses of Proposition 2.5 we get uniform bounds for

$$|\ddot{V}|,|\dot{V}'|,|V''|,|\ddot{W}|,|\dot{W}'|,|W''|\ \text{ and }\ |\dot{\rho}|,|\rho'|$$

on $]t_1,0]$.

3. The iteration scheme

Following the analysis of Paper I we need some additional framework.

Definition 2.7:

$$\mathcal{F} := (A, a, V, W, N, \nu^1, \nu^B, H, K, \eta_B),$$

$$\Phi := (\rho, {}^{\phi}\rho).$$

It turns out that what we have done in the previous subsections are the first steps toward the matter regularity property of Paper I. Here we will define this property adapted to the present situation with the notational conventions introduced as follows: α denotes a multi-index for derivatives in $(B, \underline{g})$ and $\underline{D} := (\partial_t, \partial_x)$. Then the matter regularity property reads

$$|\underline{D}^{\alpha}\mathcal{F}| \leqslant C \Rightarrow |\underline{D}^{\alpha}\Phi| \leqslant C \tag{39}$$

and we state

Proposition 2.8: Under the hypotheses of Proposition 2.5, (39) *holds for all α uniformly on* $]t_1, 0]$.

Proof: We prove the statement by induction with respect to $|\alpha|$. The induction hypotheses for $\alpha = 0$ are contained in the statements of Propositions 2.5 and 2.6. To proceed further let us assume $|\underline{D}^{\alpha}\mathcal{F}| \leqslant C$ for some α with $|\alpha| := p \geqslant 1$. Then we can assume $|\underline{D}^{p-1}\Phi| \leqslant C$ by induction. We have to show $|\underline{D}^{p}\Phi| \leqslant C$, or extending our previous notation, $P_p := \|\underline{D}^{p} f\|_{L^\infty} \leqslant C$ and $Q_{p+1} := \|\underline{D}^{p+1}\phi\|_{L^\infty} \leqslant C$.

Following the analysis of Sec. II D 2 we set $q := p - 1$ and differentiate the field equations (25) with $\partial_x \underline{D}^q$, which yields schematically

$$k_{\pm}(k_{\mp}(\partial_x \underline{D}^q \phi)) = [\partial_x \underline{D}^q \underline{\gamma}, \partial_x \underline{D}^p r, \partial_x \underline{D}^q \phi](k_{\mp}\partial_x \underline{D}^q \phi) + [\underline{D}^q \phi]\partial_x \underline{D}^q T_{AB}$$
$$+ [\partial_x \underline{D}^q \phi, \partial_x \underline{D}^q \eta, \underline{D}^q T_{AB}],$$

where quantities in square brackets abbreviate some expressions formed by them, whose detailed structure is not important for our analysis here. We want to perform the same kind of argument as we have done in the proof of the second-order estimates. In order to do this we must bound the quantities in the square brackets:

(1) The terms in the second and third set of square brackets are bounded by the induction hypotheses.

(2) For the first square bracket we can proceed as follows. $\partial_x \underline{D}^q \phi$ is already bounded. For $\partial_x \underline{D}^p r$ we have to estimate $\partial_x \underline{D}^p A = \partial_x^2 \underline{D}^q A$. This can be done by applying $\underline{D}^q$ to (26) in a strictly analogous manner as in the first item in the proof of Lemma 3.6 in Paper I, applied to Eq. (26). The definition of $\underline{\gamma}$ in Sec. II D 1 shows that the terms in $\partial_x \underline{D}^q \underline{\gamma}$ not already bounded are $\partial_x^2 \underline{D}^q \nu^1$, $\partial_x^2 \underline{D}^q N$, and $\partial_x \partial_t \underline{D}^q A$. Applying $\underline{D}^p$ to (36) gives a bound for the first quantity. Using $\underline{D}^q$ on (29), then the argument in the fourth step in the proof of Lemma 3.6 in Paper I, applied to (29) bounds the second quantity. Now all quantities appearing on the right-hand side of ($\partial_x \underline{D}^q$ applied to) (32) are bounded, and this bounds $\partial_t \partial_x \underline{D}^q A$.

Turning now to the Vlasov equation and applying $\partial_x \underline{D}^q$ yields an inhomogeneous equation for $\partial_x \underline{D}^q f$ with the same characteristics. Thus we can apply the same trick as in Sec. II D 2, substituting ∂_x by $k_{\pm}$ and $\underline{X}$. Then again we are concerned with integration by parts, which yields only bounded terms, and the inhomogeneous term of the differentiated Vlasov equation, which is also bounded by induction hypotheses. All together we can apply Gronwall's inequality to find $\|\partial_x \underline{D}^p \phi\|_{L^\infty} \leqslant C$, and immediately $Q_{p+1} \leqslant C$ by inserting the spatial bounds into the field equation. The Vlasov equation for $\partial_x \underline{D}^q f$ now bounds $\partial_x \underline{D}^q f$ and analogously for $\partial_v \underline{D}^q f$, which automatically bounds $\partial_t \underline{D}^q f$ by inserting the spatial and velocity bounds into the differentiated Vlasov equation. Thus we have also bounded P_p, which completes the proof of the proposition. ■

To extend the local in time PMC foliation, our aim is to find uniform C^∞ bounds of all geometric and matter quantities, when the PMC time t approaches t_1. Property (39) shows that it is enough to bound the geometric quantities $\underline{D}^\alpha \mathcal{F}$ for all α as long as t or, respectively, the mean curvature remains finite. Therefore all we need is the analog of Lemmas 3.6 and 3.7 in Paper I, starting with Propositions 2.3, 2.4, 2.5, and 2.6.

The first part is straightforward, given an arbitrary multi-index α and $|\underline{D}^\alpha \mathcal{F}| \leqslant C$ we find $|\partial_x \underline{D}^\alpha \mathcal{F}| \leqslant C$ by inspection of the relevant (differentiated) field equations (26)–(37) (compare the arguments given in the proof of Lemma 3.6 in Paper I where necessary), with the terms on the right-hand sides bounded by property (39). Moreover, Proposition 2.8 provides not only bounds for the spatial derivatives, but also for the time derivatives of ϕ by the definition of ${}^{\phi}\rho$. This allows us to proceed as follows: First we bound, starting from $\underline{D}^\alpha \mathcal{F}$ all spatial derivatives $\partial_x^k \underline{D}^\alpha \mathcal{F}$, $k=1,2,\ldots$. Then we bound, starting successively from $\partial_x^k \underline{D}^\alpha \mathcal{F}$, $k=1,2,\ldots$, the quantities $\underline{D}^\beta \mathcal{F}$ for all multi-indices β with $|\beta| = |\alpha| + k$, redistributing the spatial derivatives into time derivatives. This procedure will successively bound all derivatives of $\mathcal{F}$, taking advantage of the fact that in each step all lower order derivatives with the same order of time derivatives have been bounded as well as at least one more spatial order derivative in the step with one order less in time derivatives. In a more compact formulation, we have to show the boundedness of $\partial_t \underline{D}^\alpha \mathcal{F}$, having already bounds for $\partial_x \underline{D}^\alpha \mathcal{F}$ and $\underline{D}^\alpha \mathcal{F}$.

We accomplish this step for each member of $\mathcal{F}$, by again considering some of the (differentiated by $\underline{D}^\alpha$) $3+1$-field equations. We see immediately from (32) and (33) that we have bounds for $\partial_t \underline{D}^\alpha A$, $\partial_t \underline{D}^\alpha a$. The bounds for $\partial_t \underline{D}^\alpha$ applied on H, K, and η are straightforward, too. Of course, $\partial_t \underline{D}^\alpha \phi$ is already bounded by property (39). Moreover we can strengthen the regularity. Since we have already a bound for $\partial_x \underline{D}^\alpha \mathcal{F}$ Proposition 2.8 provides us with bounds for $\partial_x \underline{D}^\alpha$ applied to ρ and $\underline{D}\phi$. Applying $\partial_x \underline{D}^\alpha$ to the field equation (25) we first get a bound for $\partial_x \underline{D}^\alpha \phi$ and then for $\partial_t^2 \underline{D}^\alpha \phi$ by inserting the first result into the field equation. This in turn used together with the bounds for the differentiated matter variable in the differentiated Vlasov equation, bounds $\partial_t \underline{D}^\alpha \rho$.

Now we turn to the analysis of the differentiated lapse equation. First we see that the bound for $\partial_t \underline{D}^\alpha \nu$ follows from the bound of $\partial_t \underline{D}^\alpha N$. For the latter one, we follow the argument given in the corresponding place in the proof of Lemma 3.7 in Paper I, where all that is needed has already been bounded by the arguments just given here and we are done.

Therefore we end up with

Theorem 2.9: *Let (M,g,f) be a globally hyperbolic, spatially compact solution of the Einstein–Vlasov system with local $U(1)\times U(1)$ symmetry, which possesses a symmetric Cauchy surface Σ with strictly negative mean curvature $H \leqslant \overline{H} < 0$ and $H = \overline{H}$ somewhere on Σ. Then all of the past of Σ admits a PMC foliation $\{S_t\}$, where t takes all values in the interval $]-\infty, 0]$ and H takes all values in $]-\infty, \overline{H}]$.*

4. Improving the result

Here we will try to do the same construction as in the corresponding place in Paper I, to get rid of the restriction concerning the fixed sign of the mean curvature H on the Cauchy surfaces. So we assume M to be nonflat and denote by Σ an arbitrary symmetric Cauchy surface in M. In order to follow the steps performed in the plane symmetric case in Paper I, remember first from Sec. II B 4, that the space–time is expanding. Note further that the Einstein–Vlasov system fulfills the dominant and strong energy condition as well as the non-negative pressures condition.

Then we find for the past domain of dependence $D^-(\Sigma)$

(1) Since the space–time is expanding, dr is future pointing, thus r is bounded in $D^-(\Sigma)$. By assumption, μ^{-1} is bounded on the compact surface Σ. Unfortunately, unlike in the plane symmetric case we cannot conclude from the non-negative pressures condition and the fact that dr is future pointing, that dμ is past pointing, since in Eq. (21) for the mass flux the term involving η contributes with the wrong sign [luckily, the contribution of the energy momentum tensor ${}^{\phi}T$ (19)

for the wave map ϕ does not cause any trouble, due to the energy conditions automatically fulfilled by ${}^{\phi}T$].

To overcome this difficulty we impose the Gowdy-type symmetry condition, thus η vanishes identically in the space–time [and by the gauge condition $\nu^B(t,0)=0$ this is also true for $\overline{\nu}$ in view of (37)]. Then we conclude that M^{-1} is bounded in $D^-(\Sigma)$ as desired.

Now we want to apply theorem 2.1 in Burnett (1999) to establish a bound for the length of all timelike curves in $D^-(\Sigma)$. For this we have to adapt the proof a little bit. Inspection of the proof shows that the argument relies on the inequality $\ddot{r}\leqslant -\mathrm{M}/r^2$ satisfied by the area radius along timelike geodesics, where the dot denotes differentiation along the curve. But looking at the field equation (20) for the area radius easily establishes this relation (since η vanishes) and we are through.

(2) The basic estimate (38) together with (16) shows that r^{-1} and M are bounded.

(3) Lemma 2 in Burnett (1996) applies and we get bounds for the volume and its inverse for any Cauchy surface in $D^-(\Sigma)$.

The volume $V(t)$ for the leaf S_t of the PMC foliation is given by $V(t)=(4\pi)^2 a^{-1}\int_{S^1} r^3$ and a closer look at the estimates given in the corresponding place in Paper I shows that the arguments apply literally. This relies on the facts that on the one hand the additional equations (25) are unaffected by the reparametrization of the foliation, thus the estimates for ϕ and its derivatives done in the previous subsections hold. On the other hand the construction in Paper I is based mainly on the structures introduced by the matter regularity property and Lemmas 3.6 and 3.7, a program we adapted successfully to the more general situation here.

So we finally arrive at

Theorem 2.10: *Let (M,g,f) be a globally hyperbolic, spatially compact solution of the Einstein–Vlasov system with Gowdy-type local $U(1)\times U(1)$ symmetry and Σ be a symmetric Cauchy surface. If (M,g) is non-flat then we can foliate all of the past of Σ by PMC hypersurfaces, where the time function takes on all values in the interval $]-\infty, 0]$ and the mean curvature of the leaves tends uniformly to $-\infty$ for $t\to-\infty$.*

Using the PMC leaves as barrier surfaces we get the

Corollary 2.11: In the situation of Theorem 2.10 *$D^-(\Sigma)$ possesses a CMC Cauchy surface for each value of the mean curvature in $]-\infty, \min_\Sigma H[$.*

III. CONCLUSION AND OUTLOOK

We have seen in this paper that the program initiated in Paper I has been successfully extended to the more general case of local $U(1)\times U(1)$ symmetric space–times in close analogy to the plane symmetric space–times. Therefore all that has been mentioned in the corresponding place in Paper I applies.

A corresponding analysis for space–times with local $U(1)\times U(1)$ symmetry has been independently performed in Andréasson (1999). His construction leads to stronger results (as well as [Rein (1996)] in the surface symmetric case of Paper I), but the time functions used are defined in terms of the symmetry. Thus it is not clear how to generalize them. In view of Andréasson's work, the present analysis can be seen as a suggestion pointing in a slightly different direction.

In comparison with the space–times considered in Paper I the control of the momenta of the Vlasov particles turned out to be more complicated, in particular the coupling to gravitational waves required second-order estimates before the iteration procedure could be performed. In this process we took advantage from the wave-map structure of the dynamical part of the geometry driven by the simple form of the Vlasov equation. Nevertheless one can hope that the approach may be generalized to other matter models and geometries, since the obstructions seem to be of technical nature only.

ACKNOWLEDGMENT

I want to thank Alan Rendall, who guided me through those parts of my work, which depend heavily on his previous developments.

(Received 16 October 2001; accepted for publication 26 December 2001)

In this article we construct and analyze new classes of wormhole and flux tubelike solutions for the 5D vacuum Einstein equations. These 5D solutions possess generic local anisotropy which gives rise to a gravitational running or scaling of the Kaluza–Klein ''electric'' and ''magnetic'' charges of these solutions. It is also shown that it is possible to self-consistently construct these anisotropic solutions with various rotational 3D hypersurface geometries (i.e., ellipsoidal, cylindrical, bipolar and toroidal). The local anisotropy of these solutions is handled using the technique of anholonomic frames with their associated nonlinear connection structures [S. Vacaru, Ann. Phys. (N.Y.) **256**, 39 (1997); Nucl. Phys. B **434**, 590 (1997); J. Math. Phys. **37**, 508 (1996); J. High Energy Phys. **09**: 011 (1998); Phys. Lett. B **498**, 74 (2001)]. Through the use of the anholonomic frames the metrics are diagonalized, in contrast to holonomic coordinate frames where the metrics would have off-diagonal components. In the local isotropic limit these solutions are shown to be equivalent to spherically symmetric 5D wormhole and flux tube solutions. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467967]

I. INTRODUCTION

The first solutions describing black holes and wormholes in 4D and higher dimensional gravity were spherical symmetric solutions with diagonal metrics.[1] Later Salam, Strathee and Perracci[2] showed that including off-diagonal components in higher dimensional metrics is equivalent to including gauge fields. They concluded that geometrical gauge fields could act as sources of exotic matter necessary for the construction of a wormhole. References 3 and 4 examined locally isotropic solutions with off-diagonal metric components for 5D vacuum Einstein equations. These solutions were similar to spherically symmetric 4D wormhole or flux tube metrics with ''electric'' and/or ''magnetic'' fields running along the throat of the wormhole. These ''electromagnetic'' fields arose as a consequence of the off-diagonal elements of the metric. By varying certain free parameters of the off-diagonal elements of the 5D metrics it was possible to change the relative strengths of the fields in the wormhole's throat, and to change the longitudinal and transverse size of the wormhole's throat. In Ref. 5 we constructed *anisotropic* wormhole and flux tube solutions, which reduced to the solutions of Refs. 3 and 4 in the isotropic limit. The anisotropy of these metrics was handled using the method of anholonomic frames with associated nonlinear connections, which has been developed by one of the authors (SV) in Refs. 6 and 7. It was shown that these anisotropic solutions exhibited a variation or running of the ''electromagnetic'' parameters as a result of the angular anisotropies and/or through variations of the extra spatial dimension.

In this article we extend the investigation of Ref. 5 by applying the anholonomic frames method to construct anisotropic wormhole and flux tube solutions to 5D Kaluza-Klein theory which possess a range of different symmetries (elliptic, cylindrical, bipolar, toroidal). We will discuss the physical consequences of these solutions, in particular the variation of the ''electro-

magnetic'' parameters (e.g., the ''electric'' and ''magnetic'' charges associated with the solutions). This variation of the ''electromagnetic'' charges, which here occurs in the context of a higher dimensional gravity theory, can be likened to the variation or running of electric charge that occurs when a real electric charge is placed into some dielectric medium or in a quantum vacuum where quantum fluctuations produce a scale dependent electric charge. We will sometimes loosely refer to this gravitational variation of the ''electromagnetic'' parameters of the solutions as the gravitational running, scaling or renormalization of the charges of the solutions.

II. ANHOLONOMIC FRAMES AND 5D VACUUM EINSTEIN EQUATIONS

In this section we outline the basic formulas for 5D Einstein gravity, and introduce the method of anholonomic frames. We construct locally anisotropic metrics which are generalizations of those considered in Ref. 5. These 5D metrics have a mixture of holonomic and anholonomic variables, and are most naturally dealt with using anholonomic frames. Finally we analyze the physical and mathematical properties of these 5D, locally anisotropic vacuum solutions.

A. Metric ansatz

Let us consider a 5D pseudo-Riemannian space–time of signature $(+,-,-,-,-)$ and denote the local coordinates $u^{\alpha}=(x^i,y^a)=(x^1,x^2,x^3,y^4=s,y^5=p)$, or more compactly $u=(x,y)$, where the Greek indices are split into two subsets x^i (holonomic coordinates) and y^a (anholonomic coordinates) labeled respectively by Latin indices $i,j,k,\ldots=1,2,3$ and $a,b,\ldots=4,5$. The local coordinate bases, $\partial_{\alpha}=(\partial_i,\partial_a)$, and their duals, $d^{\alpha}=(d^i,d^a)$, are written respectively as

$$\partial_{\alpha}\equiv\frac{\partial}{du^{\alpha}}=\left(\partial_i=\frac{\partial}{dx^i},\partial_a=\frac{\partial}{dy^a}\right) \tag{1}$$

and

$$d^{\alpha}\equiv du^{\alpha}=(d^i=dx^i,d^a=dy^a). \tag{2}$$

We can treat an arbitrary coordinate, x^i or y^a, as spacelike (x,y,z), timelike (t) or as the fifth spatial coordinate (χ). The aim is then to study anisotropies and anholonomic constraints for various coordinates.

With respect to the coordinate frame base (2) the 5D pseudo-Riemannian metric

$$dS^2=g_{\alpha\beta}du^{\alpha}du^{\beta} \tag{3}$$

with its metric coefficients $g_{\alpha\beta}$ parametrized as

$$\begin{bmatrix} g_1+w_1^2h_4+n_1^2h_5 & w_1w_2h_4+n_1n_2h_5 & w_1w_3h_4+n_1n_3h_5 & w_1h_4 & n_1h_5 \\ w_1w_2h_4+n_1n_2h_5 & g_2+w_2^2h_4+n_2^2h_5 & w_2w_3h_4+n_2n_3h_5 & w_2h_4 & n_2h_5 \\ w_1w_3h_4+n_1n_3h_5 & w_3w_2h_4+n_2n_3h_5 & g_3+w_3^2h_4+n_3^2h_5 & w_3h_4 & n_3h_5 \\ w_1h_4 & w_2h_4 & w_3h_4 & h_4 & 0 \\ n_1h_5 & n_2h_5 & n_3h_5 & 0 & h_5 \end{bmatrix}. \tag{4}$$

The ansatz functions of this metric are smooth function of the form

$$g_1=1,\quad g_{2,3}=g_{2,3}(x^2,x^3)=\epsilon_{2,3}\exp[2b_{2,3}(x^2,x^3)], \tag{5}$$

$$h_{4,5}=h_{4,5}(x^2,x^3,s)=\exp[2f_{4,5}(x^2,x^3,s)], \tag{6}$$

$$w_1=w_1(x^2),\quad w_{2,3}=w_{2,3}(x^2,x^3,s),$$

$$n_1=n_1(x^2),\quad n_{2,3}=n_{2,3}(x^2,x^3,s);$$

The ansatz functions of the metric are taken to depend on two isotropic variables (x^2,x^3) and on one anisotropic variable, $y^4=s$.

Metric (3) can be greatly simplified into the form

$$\delta S^2=g_{ij}(x)dx^i dx^i+h_{ab}(x,s)\,\delta y^a\,\delta y^b, \tag{7}$$

with diagonal coefficients

$$g_{ij}=\begin{bmatrix}1 & 0 & 0\\ 0 & g_2 & 0\\ 0 & 0 & g_3\end{bmatrix} \quad \text{and} \quad h_{ab}=\begin{bmatrix}h_4 & 0\\ 0 & h_5\end{bmatrix} \tag{8}$$

if instead of coordinate bases (1) and (2) one used anholonomic frames (anisotropic bases)

$$\delta_\alpha\equiv\frac{\delta}{du^\alpha}=\left(\delta_i=\partial_i-N_i^b(u)\partial_b\,,\partial_a=\frac{\partial}{dy^a}\right) \tag{9}$$

and

$$\delta^\alpha\equiv\delta u^\alpha=(\delta^i=dx^i,\delta^a=dy^a+N_k^a(u)dx^k), \tag{10}$$

where the N-coefficients are parametrized as

$$N_1^4=w_1\,,\quad N_{2,3}^4=w_{2,3} \text{ and } N_1^5=n_1\,,\quad N_{2,3}^5=n_{2,3}.$$

They define an associated nonlinear connection (N-connection) structure (see Refs. 6 and 7). Here, we shall not emphasize the N-connection formalism. The anisotropic frames (9) and (10) are anholonomic because, in general, they satisfy some anholonomic relations,

$$\delta_\alpha\delta_\beta-\delta_\beta\delta_\alpha=W_{\alpha\beta}^\gamma\delta_\gamma,$$

with nontrivial anholonomy coefficients

$$\begin{gathered}W_{ij}^k=0,\quad W_{ai}^k=0,\quad W_{ab}^k=W_{ab}^c=0,\\ W_{ij}^a=-\Omega_{ij}^a\,,\quad W_{bj}^a=-\partial_b N_j^a\,,\quad W_{ia}^b=\partial_a N_j^b\,,\end{gathered} \tag{11}$$

where

$$\Omega_{ij}^a=\delta_j N_i^a-\delta_i N_j^a\,.$$

Conventionally, the N-coefficients decompose space–time objects (e.g., tensors, spinors and connections) into objects with mixed holonomic-anholonomic characteristics. The holonomic parts of an object are indicated with indices of type $i,j,k,\ldots$, while the anholonomic parts have indices of type $a,b,c,\ldots$. Tensors, metrics and linear connections with coefficients defined with respect to anholonomic frames (9) and (10) are distinguished (d) by N-coefficients into holonomic and anholonomic subsets and are called d-tensors, d-metrics and d-connections.

B. Einstein equations in holonomic-anholonomic variables

The main ''trick'' of the anholonomic frames method for integrating Einstein's equations in general relativity and various (super)string and higher/lower dimension gravitational theories is to find the coefficients N_j^a such that the block matrices g_{ij} and h_{ab} are diagonalized.[6,7] This greatly simplifies computations. With respect to such anholonomic frames the partial derivatives are N-elongated (locally anisotropic).

Metric (3) with coefficients (4) [or equivalently, the d-metric (7) with coefficients (8)] is assumed to solve the 5D Einstein equations

$$R_{\alpha\beta}-\tfrac{1}{2}g_{\alpha\beta}R=\kappa\Upsilon_{\alpha\beta}, \tag{12}$$

where κ and $\Upsilon_{\alpha\beta}$ are respectively the coupling constant and the energy-momentum tensor. For most of the article we will consider vacuum solutions, $\Upsilon_{\alpha\beta}=0$. The nontrivial components of the Ricci tensor (details of the computations are given in Refs. 5 and 7), for the ansatz, are

$$R_2^2=R_3^3=-\frac{1}{2g_2g_3}\left[\ddot{g_3}-\frac{\dot{g_2}\dot{g_3}}{2g_2}-\frac{(\dot{g_3})^2}{2g_3}+g_2''-\frac{g_2'g_3'}{2g_3}-\frac{(g_2')^2}{2g_2}\right], \tag{13}$$

$$R_4^4=R_5^5=-\frac{\beta}{2h_4h_5}, \tag{14}$$

$$R_{42}=-w_2\frac{\beta}{2h_5}-\frac{\alpha_2}{2h_5},\qquad R_{43}=-w_3\frac{\beta}{2h_5}-\frac{\alpha_3}{2h_5}, \tag{15}$$

$$R_{52}=-\frac{h_5}{2h_4}[n_2^{**}+\gamma n_2^*],\qquad R_{53}=-\frac{h_5}{2h_4}[n_3^{**}+\gamma n_3^*], \tag{16}$$

where

$$\alpha_2=h_5^{*\bullet}-\frac{h_5^*}{2}\left(\frac{\dot{h_4}}{h_4}+\frac{\dot{h_5}}{h_5}\right)=h_5^*(\ln|f_5^*|+f_5-f_4)^{\bullet},\quad h_5^*\neq 0; \tag{17}$$

$$\alpha_3=h_5^{*\prime}-\frac{h_5^*}{2}\left(\frac{h_4'}{h_4}+\frac{h_5'}{h_5}\right)=h_5^*(\ln|f_5^*|+f_5-f_4)',\quad h_5^*\neq 0; \tag{18}$$

$$\beta=h_5^{**}-\frac{h_5^*}{2}\left(\frac{h_5^*}{h_5}+\frac{h_4^*}{h_4}\right)=h_5^*(\ln|f_5^*|+f_5-f_4)^*,\quad h_5^*\neq 0; \tag{19}$$

$$\gamma=\frac{3}{2}\frac{h_5^*}{h_5}-\frac{h_4^*}{h_4}=[3f_5-2f_4]^*. \tag{20}$$

The partial derivatives are denoted as $h^{\bullet}=\partial h/\partial x^2, f'=\partial f/\partial x^3$ and $f^*=\partial f/\partial s$. We have given the formulas both in terms of $h_{4,5}$ and $f_{4,5}$ since we will need this later.

Formulas (13)–(16) were obtained with respect to anholonomic frames for a fixed linear connection adapted to the N-connection structure, called the canonical distinguished connection.[8] [Miron and Anastasiei introduced this connection on vector bundles, but it can be used in a similar fashion on (pseudo) Riemannian spaces if the N-connection is considered.] The coefficients of a distinguished connection $\Gamma^{\alpha}_{\beta\gamma}=(L^i_{jk},L^a_{bk},C^i_{jc},C^a_{bc})$ are computed from the formulas

$$L^i_{jk}=\tfrac{1}{2}g^{in}(\delta_k g_{nj}+\delta_j g_{nk}-\delta_n g_{jk}),$$

$$L^a_{bk}=\partial_b N^a_k+\tfrac{1}{2}h^{ac}(\delta_k h_{bc}-h_{dc}\partial_b N^d_k-h_{db}\partial_c N^d_k), \tag{21}$$

$$C^i_{jc}=\tfrac{1}{2}g^{ik}\partial_c g_{jk},\quad C^a_{bc}=\tfrac{1}{2}h^{ad}(\partial_c h_{db}+\partial_b h_{dc}-\partial_d h_{bc}).$$

The coefficients in (21) reduce to the Christoffel symbols if the metric components g_{ij} depend only on x-variables, the h_{ab} depend only on y-variables, and the N-connection vanishes. We emphasize that if the anholonomic frames are introduced into consideration, there is a certain class

of linear connections which satisfy the metricity condition for a given metric, or inversely, there is a certain class of metrics which satisfy the metricity conditions for a given linear connection. (This result was originally obtained by A. Kawaguchi[9] in 1937. Details can be found in Ref. 8; see Theorems 5.4 and 5.5 in Chapter. III.) So, we need to state explicitly what type of linear connection is used for the definition of the curvature and Ricci tensor if the space-time is provided with an anholonomic frame structure. In this work and in Refs. 5 and 7 the linear connection is considered to be of the form (21). The off-diagonal metrics studied in this article will be compatible with the canonical linear connection, but may not have a trivial limit to a diagonal holonomic metric.

The scalar curvature is

$$R=2(R_2^2+R_4^4).$$

Using this along with the components of the Ricci tensor in Eqs. (13)–(16) one can show that for the metric ansatz (4) the coefficients of the energy-momentum d-tensor satisfy

$$\Upsilon_1^1=\Upsilon_2^2+\Upsilon_4^4, \quad \Upsilon_2^2=\Upsilon_3^3=\Upsilon_2, \quad \Upsilon_4^4=\Upsilon_5^5=\Upsilon_4,$$

with respect to anholonomic bases (9) and (10). Thus the Einstein equations can be written as

$$R_2^2=-\kappa\Upsilon_4, \quad R_4^4=-\kappa\Upsilon_2, \quad R_{4\hat{i}}=\kappa\Upsilon_{4\hat{i}}, \quad R_{5\hat{i}}=\kappa\Upsilon_{5\hat{i}}, \tag{22}$$

where $\hat{i}=2,3$.

With this setup it is possible to construct very general classes of solutions to these equations[5,7] which describe locally anisotropic solitons, black holes, black tori and wormhole solutions.

C. General properties of the anisotropic vacuum solutions

In the vacuum case Eqs. (22) reduce to

$$g_3^{\cdot\cdot}-\frac{g_2^{\cdot}g_3^{\cdot}}{2g_2}-\frac{(g_3^{\cdot})^2}{2g_3}+g_2''-\frac{g_2'g_3'}{2g_3}-\frac{(g_2')^2}{2g_2}=0, \tag{23}$$

$$h_5^{**}-\frac{h_5^*}{2}\left(\frac{h_5^*}{h_5}+\frac{h_4^*}{h_4}\right)=0, \tag{24}$$

$$\beta w_{2,3}+\alpha_{2,3}=0, \tag{25}$$

$$n_{2,3}^{**}+\gamma n_{2,3}^*=0. \tag{26}$$

We now discuss general features for the d-metric coefficients, $(g_2,g_3),(h_4,h_5)$, and the N-connection coefficients $w_{2,3}$ and $n_{2,3}$ which solve this system of equations:

(1) Equation (23) relates two functions $g_2(x^2,x^3)$ and $g_3(x^2,x^3)$ and their partial derivatives in the isotropic coordinates x^2 and x^3. If one of the functions is fixed, by some symmetry and boundary conditions the second function is found by solving a second order partial differential equation. For example, by redefinition of the coordinates or a conformal transformation one can transform g_3, (or conversely, g_2) into a constant. Using this technique one of the authors (SV) was able to construct various 2D soliton-dilaton and black-hole-like configurations[7]

(2) Equation (24) contains partial derivatives of only the anisotropic coordinate s, and relates the two functions $h_4(x^2,x^3,s)$ and $h_5(x^2,x^3,s)$. By fixing one of these functions the second one is found by solving a second or first order differential equation in s (the x-variables being treated as parameters). These equations reduce to the Bernoulli equations,[10] and are satisfied by two arbitrary functions $h_{4,5}(x^2,x^3)$ for which $h_{4,5}^*=0$. Thus there are three classes of solutions:

(a) class A, for which $h_4^*=0,\ h_5^*\neq 0$;
(b) class B, for which $h_5^*=0,\ h_4^*\neq 0$; and

(c) class C, both $h^*_{4,5}\neq 0$.

If the condition $h^*_5\neq 0$ is satisfied, we can write (24), in f-variables [see (19)], as

$$(\ln|f^*_5|+f_5-f_4)^*=0,$$

which is solved by arbitrary functions $f_5(x^2,x^3,s)$ and

$$f_4(x^1,x^2,s)=f_{4[0]}(x^1,x^2)+\ln|f^*_5|+f_5. \tag{27}$$

Bracketed subscripts indicate ''constants'' of integration with respect to the s variable. The general solution of (24) expressing h_5 via h_4 is

$$\begin{aligned} h_5(x^2,x^3,s)&=\left[h_{5[1]}(x^2,x^3)+h_{5[2]}(x^2,x^3)\int\sqrt{h_4(x^2,x^3,s)}ds,\right]^2\\ &=h_{5[0]}(x^2,x^3)[1+\varpi(x^2,x^3)s]^2,\quad h^*_4=0. \end{aligned} \tag{28}$$

The integration ''constants,'' $f_{5[0,1,2]}(x^2,x^3)$ and $\varpi(x^2,x^3)$, are determined by boundary conditions and locally anisotropic limits as well as from the requirement that Eqs. (25) and (26) are compatible. Conversely, for a given h_5, the general solution of (24) is (27) which can be rewritten with respect to variables $h_{4,5}$, as

$$h_4(x^2,x^3,s)=h_{4[0]}(x^2,x^3)[(\sqrt{|h_5(x^2,x^3,s)|})^*]^2. \tag{29}$$

(3) If the functions $h_4(x^2,x^3,s)$ and $h_5(x^2,x^3,s)$ are known, then Eqs. (25) become linearly independent algebraic equations for $w_{2,3}$:

$$w_{2,3}\beta+\alpha_{2,3}=0.$$

If in the case of vacuum Einstein equations $h^*_5=0$; we have $\alpha_{\hat{i}}=\beta=0$ and, as a consequence, Eq. (25) becomes trivial, allowing arbitrary values of the functions $w_{2,3}(x^2,x^3,s)$. For $h^*_5\neq 0$ we must impose the condition $\alpha_{2,3}=0$, or identify these values with the corresponding nondiagonal components of the energy-momentum tensor. We also note that ansatz (4) admits an arbitrary function $w_1(x^2)$ which is not contained in the vacuum Einstein equations. This function can be fixed by requiring that it be compatible with some locally isotropic solutions.

(4) Equations (26) can be solved in general form if the functions $h_4(x^2,x^3,s)$ and $h_5(x^2,x^3,s)$ [and therefore the coefficient γ from (20)] are known:

$$\begin{aligned} n_{2,3}(x^2,x^3,s)&=n_{2,3[0]}(x^2,x^3)+n_{2,3[1]}(x^2,x^3)\int\frac{h_4(x^2,x^3,s)}{h_5^{3/2}(x^2,x^3,s)}ds,\quad \gamma\neq 0;\\ n_{2,3}(x^2,x^3,s)&=n_{2,3[0]}(x^2,x^3)+n_{2,3[1]}(x^2,x^3)s,\quad \gamma=0, \end{aligned} \tag{30}$$

where the functions $n_{2,3[0]}(x^2,x^3)$ and $n_{2,3[1]}(x^2,x^3)$ are defined from some boundary conditions. Again the ansatz (4) admits another arbitrary function $n_1(x^2)$ which is not contained in the vacuum Einstein equations. This function can be fixed by requiring compatibility with some locally isotropic solutions.

If the metric coefficients h_4 and h_5 are solutions to Eq. (24), then one can define two new $[\hat{h}_4=\eta_4 h_4,\ \hat{h}_5=\eta_5 h_5]$ solutions. We call the functions $\eta_{4,5}=\eta_{4,5}(x^2,x^3,s)$ gravitational polarizations since they modify the behavior of the metric coefficients h_4 and h_5 in a manner similar to how a material modifies the behavior of electric and magnetic fields in media.

The ''renormalization'' of $h_{4,5}$ into $\hat{h}_{4,5}$ results in the ''renormalization'' of $n_{2,3}: n_{2,3}\to\hat{n}_{2,3}$ from formula (30) with $h_{4,5}\to\hat{h}_{4,5}$ and $\gamma\to\hat{\gamma}$.

III. LOCALLY ISOTROPIC WORMHOLES, FLUX TUBES, AND ANISOTROPIC RUNNING OF CONSTANTS

We give a brief review of the locally isotropic wormhole and flux tube solutions (DS-solutions) constructed in Refs. 4 and 11, and their anisotropic generalization proposed in Ref. 5. The isotropic DS-solutions represent 5D gravitational field configurations which carry ''electric'' and/or ''magnetic'' charges. Various authors have studied related 5D solutions: Liu and Wesson investigated 5D solitonic solutions;[12] they also considered 5D charged black holes;[13] 5D wormhole configurations with electromagnetic charges were studied in Ref. 14; Ref. 15 looks at 5D solutions with magnetic charge; and a general reference for 5D Kaluza-Klein theory and solutions is Ref. 16. The anisotropic constructions considered in this article are slightly different from Ref. 5. Here we use a fixed conformal factor, in order to construct anisotropic solutions with background geometries more general than spherical. The study of these more general background geometries will be carried out in Sec. V.

A. 5D locally isotropic wormholes and flux tubes

Reference 11 considered the following spherically symmetric 5D metric, with off-diagonal terms

$$ds^2_{(DS)}=e^{2\nu(r)}dt^2-dr^2-a(r)(d\theta^2+\sin^2\theta d\varphi^2) - r_0^2 e^{2\psi(r)-2\nu(r)}[d\chi_{(DS)}+\omega(r)dt+n\cos\theta d\varphi]^2, \tag{31}$$

where $\chi_{(DS)}$ is the fifth coordinate; r, θ,φ are $3D$ spherical coordinates; n is an integer; $r\in\{-R_0,+R_0\}$ ($R_0\leqslant\infty$) and r_0 is a constant. All functions $\nu(r),\psi(r)$ and $a(r)$ were considered to be even functions of r satisfying $\nu'(0)=\psi'(0)=a'(0)=0$. Here we shall study a particular class of this metric, with $\nu(r)=0$. We also introduce a new fifth coordinate

$$\chi=\chi_{(DS)}-\mu(\theta,\varphi)^{-1}\int d\xi(\theta,\varphi)$$

for which

$$d\chi_{(DS)}+n\cos\theta d\varphi=d\chi+n\cos\theta d\theta$$

and

$$\frac{\partial\xi}{\partial\varphi}=\mu n\cos\theta,\quad \frac{\partial\xi}{\partial\theta}=-\mu n\cos\theta,$$

if the factor $\mu(\theta,\varphi)$ is taken, for instance,

$$\mu(\theta,\varphi)=\exp(\theta-\varphi)|\cos\theta|^{-1}.$$

This redefinition of the fifth coordinate $\chi_{(DS)}\to\chi$, with $d\chi$ elongated by N-coefficients proportional to t,r,θ (isotropic coordinates), allows us to consider anisotropies on coordinates (φ,χ). The metric (31), in coordinates $(t,r,\theta,\varphi,\chi)$ and for $\nu(r)=0$, is equivalently rewritten as

$$ds^2_{(DS)}=dt^2-dr^2-a(r)(d\theta^2+\sin^2\theta d\varphi^2)-r_0^2e^{2\psi(r)}[d\chi+\omega(r)dt+n\cos\theta d\theta]^2. \tag{32}$$

This form of the metric will be used to find new, anisotropic solutions of Einstein's equations. The coefficient $\omega(r)$ in (32) is treated as the t-component of the electromagnetic potential and $n\cos\theta$ as the θ-component. These electromagnetic potentials lead to the metric having radial Kaluza–Klein ''electrical'' and ''magnetic'' fields. The 5D Kaluza–Klein ''electric'' field is

$$E_{KK}=r_0\omega' e^{3\psi}=q_0/a(r). \tag{33}$$

The "electric" charge $q_0=r_0\omega'(0)$ can be parametrized as

$$q_0=2\sqrt{a(0)}\sin\alpha_0.$$

The corresponding dual, "magnetic" field is

$$H_{KK}=Q_0/a(r) \tag{34}$$

with "magnetic" charge $Q_0=nr_0$ parametrized as

$$Q_0=2\sqrt{a(0)}\cos\alpha_0.$$

The following "circle" relation,

$$\frac{(q_0^2+Q_0^2)}{4a(0)}=1, \tag{35}$$

relates the "electric" and "magnetic" charges. As the free parameters of the metric are varied there are five classes of solutions with the properties:

(1) $Q_0=0$ or $H_{KK}=0$, a wormholelike "electric" object;
(2) $q_0=0$ or $E_{KK}=0$, a finite "magnetic" flux tube;
(3) $q_0=Q_0$ or $H_{KK}=E_{KK}$, an infinite "electromagnetic" flux tube;
(4) $Q_0<q_0$ or $H_{KK}<E_{KK}$, a wormholelike "electromagnetic" object; and
(5) $Q_0>q_0$ or $H_{KK}>E_{KK}$, a finite, "magnetic-electric" flux tube.

Metric (32) is a particular example of a d-metric of type (7), with the ansatz functions given by (4), or equivalently (8). For the coordinates $x^1=t,x^2=r,x^3=\theta,y^4=s=\chi,y^5=p=\varphi$ the set of ansatz functions

$$\begin{gathered} g_1=1,\quad g_2=-1,\quad g_3=-a(r),\\ h_4=-a(r)\sin^2\theta,\quad h_5=-r_0^2e^{2\psi(r)},\\ w_i=0,\quad n_1=\omega(r),\quad n_2=0,\quad n_3=n\cos\theta \end{gathered} \tag{36}$$

define a trivial, locally isotropic solution of the vacuum Einstein equations (23)–(26) which satisfies the conditions $h^*_{4,5}=0$. We next deal with anisotropic deformations of this solution.

B. Anisotropic generalizations of DS-solution

The simplest way to obtain anisotropic wormhole/flux tube solutions[5] is to take r_0^2 from (32) or (36)) not as a constant, but as "renormalized" via $r_0^2\to\hat{r}_0^2=\hat{r}_0^2(r,\theta,s)$.

1. DS-solutions with anisotropy via $s=\chi$

From the isotropic solution (36) we generate an anisotropic solution of class A by taking

$$\hat{h}_4(r,\theta)=h_4(r,\theta)=-a(r)\sin^2\theta,$$

with $\eta_4=1$ so that $\hat{h}^*_4=h^*_4=0$, but $\hat{h}^*_5=\eta^*_5(r,\theta,\chi)h_5(r)\neq 0$. Using Eq. (28) we parametrize

$$\hat{r}_0^2(\chi)\simeq r^2_{0(0)}[1+\varpi(r,\theta)\chi]^2 \tag{37}$$

so that

$$h_5(r,\theta,\chi)=\eta_5(r,\theta,\chi)h_5(r),$$

$$h_{5[0]}(r,\theta)=h_5(r)=-r_0^2e^{2\psi(r)},\quad \eta_5(r,\theta,\chi)=[1+\varpi(r,\theta)\chi]^2.$$

Under the conditions in this subsection β and $\alpha_{2,3}$ from Eqs. (17)–(19) (and therefore $w_{2,3}$) can be arbitrary functions. Here we will require $w_{2,3}\to 0$ in the locally isotropic limit, $\varpi\chi\to 0$. From Eq. (30) $n_{2,3}$ depends on the anisotropic variable $s=\chi$ in the following way:

$$n_3(r,\theta,\chi)=n_{3[0]}(r,\theta)+n_{3[1]}(r,\theta)[1+\varpi_0\chi]^{-2}$$

with $\varpi(r,\theta)=\varpi_0=\text{const}$. We obtain the locally isotropic limit of (36), for $\varpi\chi\to 0$, if we fix the boundary conditions with $n_{2[0,1]}=0, n_{3[0]}=0$, $n_{3[1]}(r,\theta)=n\cos\theta$ and $n_1=\omega(r)$.

The 5D gravitational vacuum polarization induced by variation of "constant" $\hat{r}_0(\chi)$ renormalizes the electromagnetic charge as $q(\chi)=\hat{r}_0(\chi)\omega'(r=0)$. In terms of the angular parametrization the "electric" charge becomes

$$q(\chi)=2\sqrt{a(0)}\sin\alpha(\chi).$$

The "electric" field from (33) becomes

$$E_{KK}=\frac{q(\chi)}{a(r)}.$$

The renormalization of the magnetic charge, $Q_0\to Q(\chi)$, can be obtained using the renormalized "electric" charge in relationship (35) and solving for $Q(\chi)$. The form of (35) implies that the running of $Q(\chi)$ will be the opposite that of $q(\chi)$. For example, if $q(\chi)$ increases with χ, then $Q(\chi)$ will decrease. The locally anisotropic polarizations $\alpha(\chi)$ are either defined from experimental data or computed from a quantum model of 5D gravity. With the coordinates taken as $x^1=t, x^2=r, x^3=\theta, y^4=s=\chi, y^5=p=\varphi$, one can construct a locally anisotropic solution of the vacuum Einstein equations (23)-(26) by making the following identifications for the ansatz functions from (32):

$$\begin{gathered}g_1=1,\quad g_2=-1,\quad g_3=-a(r),\\ \hat{h}_4=h_4=-a(r)\sin^2\theta,\quad \eta_4=1,\\ \hat{h}_5=\eta_5h_5,\quad h_5(r)=-r_0^2e^{2\psi(r)},\quad \eta_5=[1+\varpi_0\chi]^2,\\ w_i=0,\quad n_1=\omega(r),\quad n_2=0,\quad n_3=n\cos\theta[1+\varpi_0\chi]^{-2}.\end{gathered}\tag{38}$$

This generalizes the DS-solution (32) by allowing the Kaluza-Klein electric and magnetic charges to be dependent on (i.e., scale with) the fifth coordinate $s=\chi$. We will call these the χ-solutions).

2. DS-solutions with anisotropy via φ

In a similar fashion we can consider anisotropic dependencies with respect to $s=\varphi$. These will be called φ-solutions. The simplest option is to take $h_5^*=0$ but $h_4^*\neq 0$, i.e., to define a solution with

$$\hat{h}_4(r,\theta,\varphi)=\eta_4h_4(r),\quad h_4(r)=-r_0^2e^{2\psi(r)},$$

$$\hat{h}_5(r,\theta)=h_5(r,\theta)=-a(r)\sin^2\theta,$$

$$\eta_4=\exp[\varpi(r,\theta,\varphi)],\quad \eta_5=1.$$

This allows $w_{2,3}$ to take arbitrary values since β and $\alpha_{2,3}$ from Eqs. (25) vanish. For small polarizations we can approximate

$$\hat{h}_4(r,\theta,\varphi)=h_{4[0]}(r,\theta)[1+\varpi\varphi].$$

The general solution of (26) for $\hat{\gamma}=-(\ln|\hat{h}_4|)^*$ is

$$n_{2,3}(r,\theta,\varphi)=n_{2,3[0]}(r,\theta)+n_{2,3[1]}(r,\theta)\int \exp\,\varpi(r,\theta,\varphi)d\varphi;$$

we take $w_1=\omega(r), w_2=0, w_3=n\cos\theta$, $n_{2[0]}(r,\theta)=0$ and $n_{3[0]}(r,\theta)=n\cos\theta$, $n_{,3[1]}(r,\theta)=1$ which are compatible with the local isotropic limit [i.e. $\varpi(r,\theta,\varphi)\to 0$ and $\int\varpi(r,\theta,\varphi)d\varphi\to 0$]. Taking the coordinates as $x^1=t, x^2=r, x^3=\theta, y^4=s=\varphi, y^5=p=\chi$ the following form for the ansatz functions,

$$\begin{gathered}
g_1=1,\quad g_2=-1,\quad g_3=-a(r),\\
\hat{h}_4=\eta_4 h_4,\quad h_4=-r_0^2e^{2\psi(r)},\quad \eta_4=\exp[\varpi(r,\theta,\varphi)],\\
\hat{h}_5=h_5,\quad h_5=-a(r)\sin^2\theta,\quad \eta_5=1,\\
w_1=\omega(r),\quad w_2=0,\quad w_3=n\cos\theta,\\
n_1=0,\quad n_{2,3}=n_{2,3[1]}(r,\theta)\int \exp\varpi(r,\theta,\varphi)d\varphi,
\end{gathered}\tag{39}$$

gives a locally anisotropic generalization of the DS-metric (32) for anisotropic dependencies on the angle φ.

We have constructed two classes of locally anisotropic generalizations of the DS-solution: $s=\varphi$ (i.e., anisotropic angular polarizations) or $s=\chi$ (i.e., dependence of the Kaluza-Klein charges on the fifth coordinate). If the metric (32), describing these two classes of solutions, were given with respect to a coordinate frame (1) nondiagonal terms would occur, and the study of these solutions would be more difficult.

IV. GRAVITATIONAL θ-POLARIZATION OF KALUZA–KLEIN CHARGES

We can further generalize the forms (38) and (39) to generate new solutions of the 5D vacuum Einstein equations with deformations of the constants r_0^2 and n with respect to the θ variable. These θ deformations take the form of the equation for an ellipsoid in polar coordinates. This again leads to varying electric, q, and magnetic, Q, charges.

A. Gravitational renormalization of Kaluza–Klein charges via variable r_0

In this subsection we give a solution for which the Kaluza–Klein charges are gravitationally renormalized by the radius becoming dependent on θ [i.e., in Eq. (35) $a(0)\to a(\theta)$].

1. θ-renormalization of charges for χ-solutions

The easiest way to obtain such θ-polarizations for the χ-solutions of (28) and (37) is to consider the coordinates as $x^1=t, x^2=r, x^3=\theta, y^4=s=\chi, y^5=p=\varphi$, and let the ansatz functions take the form

$$\begin{gathered}
g_1=1,\quad g_2=-1,\quad g_3=-a(r),\\
\hat{h}_4=h_4=-a(r)\sin^2\theta,\quad \eta_4=1,\\
\hat{h}_5=\eta_5 h_5(r),\quad h_5(r)=-r_0^2e^{2\psi(r)},\quad \eta_5=[1+\varepsilon_r\cos\theta]^{-2}[1+\varpi_0\chi]^2,\\
w_i=0,\quad n_1=\omega(r),\quad n_2=0,\quad n_3=n\cos\theta[1+\varpi_0\chi]^{-2},
\end{gathered}\tag{40}$$

where η_5 is the polarizaton and

$$\hat{r}_0^2(r,\theta,\chi)\simeq r_{0(0)}^2[1+\varepsilon_r\cos\theta]^{-2}[1+\varpi_0\chi]^2,$$

where ε_r is the eccentricity. The "constant," $\hat{r}_0$, has both an elliptic variation in θ (i.e., $r_{0(0)}[1+\varepsilon_r\cos\theta]^{-1}$) and a linear variation on the fifth coordinate (i.e., $[1+\varpi(r,\theta)\chi]$).

For these χ-solutions with elliptic variations as given above the 5D Kaluza–Klein charges get renormalized through the elliptic variation of $\hat{r}_0(r,\theta,\varepsilon_r,\chi)$. This renormalizes the "electric" charge as

$$q(\theta,\chi)=r_0\sqrt{\eta_5(\theta,\varepsilon_r,\chi)}\omega'(0)=\sqrt{\eta_5(\theta,\varepsilon_r,\chi)}q_0$$

or in terms of the angular parametrization

$$q(\theta,\chi)=2\sqrt{a(0)}\sqrt{\eta_5(\theta,\varepsilon_r,\chi)}\sin\alpha_0.$$

The "electric" field (33) transforms into

$$E_{KK}=\frac{q(\theta,\chi)}{a(r)}=\frac{q_0}{(\sqrt{\eta_5})^{-1}a(r)}.$$

Here $(\sqrt{\eta_5})^{-1}$ can be treated as an anisotropic, gravitationally induced permittivity. The renormalization of the magnetic charge, $Q_0\to Q(\theta,\chi)$, can be obtained from Eq. (35) using $q(\theta,\chi)$ from above. In this case the corresponding dual "magnetic" field is $H_{KK}=Q(\theta,\chi)/a(r)$ with the "magnetic" charge $Q_0=nr_0$ given by

$$Q=2\sqrt{a(0)}\sqrt{\eta_5(\theta,\varepsilon_r,\chi)}\cos\alpha_0.$$

These gravitationally polarized charges satisfy the circumference equation (35) with variable radius $2\sqrt{a(0)}\sqrt{\eta_5(\theta,\varepsilon_r,\chi)}$:

$$\frac{(q_0^2+Q_0^2)}{4a(0)\,\eta_5(\theta,\varepsilon_r,\chi)}=1. \tag{41}$$

2. Elliptic renormalization of charges for φ-solutions

The φ-solutions can also be modified to have an elliptic variation with respect to θ. As in the case of the χ-solutions this gives an effective gravitational renormalization of the charges. With the coordinates defined as $x^1=t,x^2=r,x^3=\theta,y^4=s=\varphi,y^5=p=\chi$ the form of this variation of the φ-solutions is

$$g_1=1,\quad g_2=-1,\quad g_3=-a(r),$$

$$\hat{h}_4=\eta_4 h_4,\quad h_4=-r_0^2e^{2\psi(r)},\quad \eta_4=[1+\varepsilon_r\cos\theta]^{-2}\exp[\varpi(r,\theta,\varphi)],$$

$$\hat{h}_5=h_5=-a(r)\sin^2\theta,\quad \eta_5=1,\quad \hat{h}_5^*=h_5^*=0, \tag{42}$$

$$w_1=\omega(r),\quad w_2=0,\quad w_3=n\cos\theta,$$

$$n_1=0,\quad n_{2,3}=n_{2,3[1]}(r,\theta)\int\exp\varpi(r,\theta,\varphi)d\varphi.$$

The renormalized charges arise as in the previous example via $r_0^2\to\hat{r}_0^2(r,\theta,\varphi)$. The "electric" charge becomes

$$q(\theta,\varphi)=r_0\sqrt{\eta_4(\theta,\varepsilon_r,\varphi)}\,\omega'(0)=\sqrt{\eta_4(\theta,\varepsilon_r,\varphi)}\,q_0.$$

In terms of the angular parametrization this becomes

$$q(\theta,\varphi)=2\sqrt{a(0)}\sqrt{\eta_4(\theta,\varepsilon_r,\varphi)}\sin\alpha.$$

The "electric" field (33) transforms into

$$E_{KK}=\frac{q(\theta,\varphi)}{a(r)}=\frac{q_0}{(\sqrt{\eta_4})^{-1}a(r)}.$$

Here $(\sqrt{\eta_4})^{-1}$ can be treated as an anisotropic gravitationally induced permittivity depending on the angular variables. The renormalized magnetic charge, $Q_0\to Q(\theta,\varphi)$, can be determined using Eq. (35) and $q(\theta,\varphi)$ giving

$$Q(\theta,\varphi)=2\sqrt{a(0)}\sqrt{\eta_4(\theta,\varepsilon_r,\varphi)}\cos\alpha_0.$$

The "magnetic" field is then $H_{KK}=Q(\theta,\varphi)/a(r)$. The gravitationally polarized charges satisfies Eq. (35) with a variable radius of $2\sqrt{a(0)}\sqrt{\eta_4(\theta,\varepsilon_r,4)}$:

$$\frac{(q_0^2+Q_0^2)}{4a(0)\,\eta_4(\theta,\varepsilon_r,\varphi)}=1. \tag{43}$$

There is again an elliptical variation in θ, and also an anisotropic dependence in φ.

Comparing formulas (41) and (43) we find that there are two types of anisotropic gravitational polarizations of the charges: in the first case the running with respect to the fifth coordinate is emphasized; in the second case the anisotropy comes just from the angular variables. In both cases there is an elliptical dependence on θ.

B. Gravitational renormalization of Kaluza–Klein charges via r_0 and n

A different class of solutions from those given in Eqs. (38), (39), (40), and (42) can be constructed if, in addition to r_0, we allow the n in the $n\cos\theta$ term in Eq. (32) to vary. For the χ-solutions this variable n will affect n_3, while for the φ-solutions it will affect w_3. The variability of r_0 and n is parametrized using the gravitational vacuum polarizations $\kappa_r(r,\theta,s)$ and $\kappa_n(r,\theta,s)$ as

$$r_0\to\hat{r}_0=r_0/\kappa_r(r,\theta,s)\qquad\text{and}\qquad n\to\hat{n}=n/\kappa_n(r,\theta,s),$$

where $\kappa_r(r,\theta,s)=[\sqrt{\eta_4(r,\theta,s)}]^{-1}$ or $=[\sqrt{\eta_5(r,\theta,s)}]^{-1}$. The polarized charges are

$$q=q_0/\kappa_r=2\sqrt{a(0)}\sin\alpha_0/\kappa_r$$

and

$$Q=Q_0/\kappa_n=2\sqrt{a(0)}\,\cos\alpha_0/\kappa_n.$$

Using these charges in Eq. (35) gives the formula for an ellipse in the charge space coordinates (q_0,Q_0),

$$\frac{q_0^2}{4a(0)\kappa_r^2}+\frac{Q_0^2}{4a(0)\kappa_n^2}=1, \tag{44}$$

where the axes of the ellipse are $2\sqrt{a(0)}\kappa_r$ and $2\sqrt{a(0)}\kappa_n$. Formula (44) contains formulas (41) and (43) as special cases.

The form of the χ- and φ-solutions from the previous two subsections gets modified by this "elliptic" renormalization of the Kaluza–Klein charges.

(a) With the coordinates defined as $x^1=t,x^2=r,x^3=\theta,y^4=s=\chi,y^5=p=\varphi$ the χ-solutions with $\kappa_r=[\sqrt{\eta_5(r,\theta,\chi)}]^{-1}$ take the form

$$\begin{gathered} g_1=1, \quad g_2=-1, \quad g_3=-a(r), \\ \hat{h}_4=h_4=-a(r)\sin^2\theta, \quad \hat{h}_4^*=0, \quad h_4^*=0, \quad \eta_4=1, \\ \hat{h}_5=\eta_5 h_5, \quad h_5=-r_0^2 e^{2\psi(r)}, \quad \eta_5=1/\kappa_r^2(r,\theta,\chi), \\ w_i=0, \quad n_1=\omega(r), \quad n_2=0, \quad n_3=n\cos\theta/\kappa_n(r,\theta,\chi). \end{gathered} \tag{45}$$

(b) With the coordinates defined as $x^1=t,x^2=r,x^3=\theta,y^4=s=\varphi,y^5=p=\chi$ the φ-solutions with $\kappa_r=[\sqrt{\eta_4(r,\theta,\chi)}]^{-1}$ take the form

$$\begin{gathered} g_1=1, \quad g_2=-1, \quad g_3=-a(r), \\ \hat{h}_4=\eta_4 h_4, \quad h_4=-r_0^2 e^{2\psi(r)}, \quad \eta_4=1/\kappa_r^2(r,\theta,\varphi), \\ \hat{h}_5=h_5=-a(r)\sin^2\theta, \quad \eta_5=1, \quad h_5^*=0, \\ w_1=\omega(r), \quad w_2=0, \quad w_3=n\cos\theta/\kappa_n(r,\theta,\varphi), \\ n_1=0, \quad n_{2,3}=n_{2,3[1]}(r,\theta)\int \ln|\kappa_r(r,\theta,\varphi)|d\varphi. \end{gathered} \tag{46}$$

V. WORMHOLES IN ELLIPSOIDAL, CYLINDRICAL, BIPOLAR AND TOROIDAL BACKGROUNDS

The locally anisotropic wormhole/flux tube solutions presented in the previous sections are anisotropic deformations from a spherical 3D hypersurface background. These solutions can be generalized to other rotational hypersurface geometry backgrounds. In this section we will give the explicit forms for these generalized solutions and analyze their basic properties. The notations and metric relations for the 3D Euclidean rotational hypersurfaces that we use will be those of Ref. 17.

A. Elongated rotation ellipsoid hypersurfaces

An elongated rotation ellipsoid hypersurface (a 3D e-ellipsoid) is given by the formula

$$\frac{x^2+y^2}{\sigma^2-1}+\frac{z^2}{\sigma^2}=\tilde{a}^2(r), \tag{47}$$

where $\sigma\geqslant 1$, and x,y,z here are the usual Cartesian coordinates. $\tilde{a}(r)$ is similar to the radius in the spherical symmetric case. The 3D, ellipsoidal coordinate system is defined

$$x=\tilde{a}\sinh u\sin v\cos s, \quad y=\tilde{a}\sinh u\sin v\sin s, \quad z=\tilde{a}\cosh u\cos v, \tag{48}$$

where $\sigma=\cosh u$ and $0\leqslant u<\infty$, $0\leqslant v\leqslant\pi$, $0\leqslant s<2\pi$. The hypersurface metric is

$$g_{uu}=g_{vv}=\tilde{a}^2(\sinh^2 u+\sin^2 v), \quad g_{ss}=\tilde{a}^2\sinh^2 u\sin^2 v. \tag{49}$$

It will be more useful to consider a conformally transformed metric, where the components in Eq. (49) are multiplied by the conformal factor $\tilde{a}^{-2}(\sinh^2 u+\sin^2 v)^{-1}$, giving

$$ds^2_{(3e)} = du^2 + dv^2 + g_{ss}(u,v)ds^2,$$
$$g_{ss}(u,v) = \sinh^2 u \sin^2 v/(\sinh^2 u + \sin^2 v). \tag{50}$$

B. Flattened rotation ellipsoid hypersurfaces

In a similar fashion we consider the hypersurface equation for a flattened rotation ellipsoid (a 3D f-ellipsoid),

$$\frac{x^2+y^2}{1+\sigma^2} + \frac{z^2}{\sigma^2} = \tilde{a}^2(r), \tag{51}$$

Here $\sigma \geqslant 0$ and $\sigma = \sinh u$. In this case the 3D coordinate system is defined as

$$x = \tilde{a}\cosh u \sin v \cos s, \quad y = \tilde{a}\cosh u \sin v \sin s, \quad z = \tilde{a}\sinh u \cos v, \tag{52}$$

where $0 \leqslant u < \infty$, $0 \leqslant v \leqslant \pi$, $0 \leqslant s < 2\pi$. The hypersurface metric is

$$g_{uu} = g_{vv} = \tilde{a}^2(\sinh^2 u + \cos^2 v), \quad g_{\varphi\varphi} = \tilde{a}^2 \sinh^2 u \cos^2 v. \tag{53}$$

Again for later convenience we consider a conformally transformed version of this metric:

$$ds^3_{(3f)} = du^2 + dv^2 + g_{ss}(u,v)ds^2,$$
$$g_{ss}(u,v) = \sinh^2 u \cos^2 v/(\sinh^2 u + \cos^2 v). \tag{54}$$

C. Ellipsoidal cylindrical hypersurfaces

The formula for an ellipsoidal cylindrical hypersurface is

$$\frac{x^2}{\sigma^2} + \frac{y^2}{\sigma^2 - 1} = \rho^2, \quad z = s, \tag{55}$$

where $\sigma \geqslant 1$. The 3D radial coordinate is given as $\tilde{a}^2 = \rho^2 + s^2$. The 3D coordinate system is defined

$$x = \rho \cosh u \cos v, \quad y = \rho \sinh u \sin v, \quad z = s,$$

where $\sigma = \cosh u$ and $0 \leqslant u < \infty$, $0 \leqslant v \leqslant \pi$. Using the expressions for x,y and Eq. (55) we can make the change $\rho(x,y) \to \rho(u,v)$. The hypersurface metric is

$$g_{uu} = g_{vv} = \rho^2(u,v)(\sinh^2 u + \sin^2 v), \quad g_{ss} = 1;$$

we will again consider a conformally transformed version of this metric:

$$ds^2_{(3c)} = du^2 + dv^2 + g_{ss}(u,v,\rho(u,v))ds^2,$$
$$g_{ss}(u,v) = 1/\rho^2(u,v)(\sinh^2 u + \sin^2 v). \tag{56}$$

D. Bipolar coordinates

Now we consider a bipolar hypersurface given by the formula

$$\left(\sqrt{x^2+y^2} - \frac{\tilde{a}(r)}{\tan\xi}\right)^2 + z^2 = \frac{\tilde{a}^2(r)}{\sin^2\xi}, \tag{57}$$

which describes a hypersurface obtained by rotating the circles

$$\left(y-\frac{\tilde{a}(r)}{\tan\xi}\right)^2+z^2=\frac{\tilde{a}^2(r)}{\sin^2\xi}$$

around the z axis; because $|\tan\xi|^{-1}<|\sin\xi|^{-1}$, the circles intersect the z axis. The relationship between the Cartesian coordinates and the bipolar coordinates is

$$x=\frac{\tilde{a}(r)\sin\xi\cos s}{\cosh\tau-\cos\xi},\quad y=\frac{\tilde{a}(r)\sin\xi\sin s}{\cosh\tau-\cos\xi},\quad z=\frac{\tilde{a}(r)\sinh\tau}{\cosh\tau-\cos\xi},$$

where $-\infty<\tau<\infty,0\leqslant\xi<\pi,0\leqslant s<2\pi$. The hypersurface metric is

$$g_{\tau\tau}=g_{\xi\xi}=\frac{\tilde{a}^2(r)}{(\cosh\tau-\cos\xi)^2},\quad g_{ss}=\frac{\tilde{a}^2(r)\sin^2\xi}{(\cosh\tau-\cos\xi)^2},$$

which, after multiplication by the conformal factor $(\cosh\tau-\cos\sigma)^2/\rho^2$, becomes

$$ds^2_{(3b)}=d\tau^2+d\xi^2+g_{ss}(\xi)ds^2,\quad g_{ss}(\xi)=\sin^2\xi. \tag{58}$$

E. Toroidal coordinates

Now we consider a toroidal hypersurface with nontrivial topology given by the formula

$$(\sqrt{x^2+y^2}-\tilde{a}(r)(\coth\xi))^2+z^2=\frac{\tilde{a}^2(r)}{\sinh^2\xi}. \tag{59}$$

The relationship to the Cartesian coordinates is given by

$$x=\frac{\tilde{a}(r)\sinh\tau\cos s}{\cosh\tau-\cos\xi},\quad y=\frac{\tilde{a}(r)\sin\xi\sin s}{\cosh\tau-\cos\xi},\quad z=\frac{\tilde{a}(r)\sinh\xi}{\cosh\tau-\cos\xi},$$

where $-\pi<\xi<\pi,0\leqslant\tau<\infty,0\leqslant s<2\pi$. The hypersurface metric is

$$g_{\sigma\sigma}=g_{\tau\tau}=\frac{\tilde{a}^2(r)}{(\cosh\tau-\cos\xi)^2},\quad g_{ss}=\frac{\tilde{a}^2(r)\sin^2\xi}{(\cosh\tau-\cos\xi)^2}.$$

After multiplication by the conformal factor $(\cosh\tau-\cos\sigma)^2/\tilde{a}^2(r)$ this takes the same form as (58)

$$ds^3_{(3t)}=d\tau^2+d\xi^2+g_{ss}(\xi)ds^2,\quad g_{ss}(\xi)=\sin^2\xi. \tag{60}$$

Although this looks identical to the metric in (58), the coordinates (τ,ξ,s) have different meanings in each case. This can be seen by the different ranges for the two cases.

F. Anisotropic wormholes in rotation deformed hypersurface backgrounds

In order to construct wormholes which exhibit the various 3D geometries cataloged above, we will associate one of the ansatz functions of the wormhole solutions with $g_{ss}(x^2,x^3)$. For the χ-solutions this is accomplished by letting $h_4=g_{ss}(x^2,x^3)$; for the φ-solutions this is accomplished letting by $h_5=g_{ss}(x^2,x^3)$.

The construction of such solutions is based on the assumption that $g_{ss}(x^2,x^3)$ for the five nonspherical geometries listed above is to be taken as $h_4=g_{ss}(x^2,x^3)$ (for χ-solutions), or as $h_5=g_{ss}(x^2,x^3)$ [for $\varphi(z)$-solutions]. In each case $h_{4,5}$ is multiplied by corresponding gravitational polarizations, $\eta_{4,5}$, so as to give wormhole/flux tube configurations of the form (38), (40), and (45) (for χ-solutions) or configurations of the form (39), (42), and (46) [for $\varphi(z)$-solutions].

1. The χ-solutions

For the five 3D geometries given above, the d-metrics (8) for the χ-solutions from Eqs. (38), (40), and (45) have the coordinates defined as

$$x^k=\begin{cases}(t,u,v),0\leqslant u<\infty,0\leqslant v\leqslant\pi,\cosh u\geqslant 1,\ \text{ellipsoid}\ (47);\\ (t,u,v),0\leqslant u<\infty,0\leqslant v\leqslant\pi,\sinh u\geqslant 0,\ \text{ellipsoid}\ (51);\\ (t,u,v),0\leqslant u<\infty,0\leqslant v\leqslant\pi,\cosh u\geqslant 1,\ \text{cylinder}\ (55);\\ (t,\tau,\xi),-\infty<\tau<\infty,0\leqslant\xi<\pi,\ \text{bipolar}\ (57);\\ (t,\tau,\xi),0\leqslant\tau<\infty,-\pi<\xi<\pi,\ \text{torus}\ (59);\end{cases}$$

$$y^4=s=\chi,\quad y^5=p=\begin{cases}\varphi\in[0,2\pi),\ \text{ellipsoids; bipolar; torus;}\\ z\in(-\infty,\infty),\ \text{cylinder;}\end{cases}$$

and the ansatz functions given as

$$g_1=1,\quad g_2=-1,\quad g_3=-1, \tag{61}$$

$$\hat{h}_4=\eta_4 h_4,\quad h_4=g_{ss}(x^2,x^3)=\begin{cases}\dfrac{\sinh^2 u\sin^2 v}{\sinh^2 u+\sin^2 v},\ \text{ellipsoid}\ (50);\\ \dfrac{\sinh^2 u\cos^2 v}{\sinh^2 u+\cos^2 v},\ \text{ellipsoid}\ (54);\\ \dfrac{\rho^{-2}(u,v)}{\sinh^2 u+\sin^2 v},\ \text{cylinder}\ (55);\\ \sin^2\xi,\ \text{bipolar}\ (57);\ \text{torus}\ (59);\end{cases}$$

$$\eta_4=[(\sqrt{\hat{h}_5(x^2,x^3,\chi)})^*]^2,\ \text{see}\ (27); \tag{62}$$

$$\eta_5=\begin{cases}[1+\varpi_0\chi]^2,\ \text{see}\ (38);\\ [1+\varepsilon_r\cos x^3]^{-2}[1+\varpi_0\chi]^2,\ \text{see}\ (40);\\ 1/\kappa_r^2(x^2,x^3,\chi),\ \text{see}\ (45);\end{cases}$$

$$\hat{h}_5=\eta_5 h_5,\quad h_5(x^2,x^3,\chi)=-r_0^2\exp\{2\psi[r(x^2,x^3,\chi)]\};\quad w_i=0;$$

$$r=\tilde{a}^{(\text{invers})}(x^2,x^3,\chi)\ \ \text{from}\ (47),(51),(55),(57),(59);$$

$$n_1=\omega(x^2),\quad n_2=0,\quad n_3=n\cos x^2\times\begin{cases}[1+\varpi_0\chi]^{-2},\ \text{see}\ (38);\\ [1+\varpi_0\chi]^{-2},\ \text{see}\ (40);\\ 1/\kappa_n(x^2,x^3,\chi),\ \text{see}\ (45)\ .\end{cases}$$

The formulas (61) describe wormhole/flux tube configurations which are defined self-consistently in the various rotational hypersurface backgrounds listed above. As in the case of the spherical background, these solutions have an anisotropic deformation with respect to the given hypersurface backgrounds.

2. The φ-solutions

Now we give the form of the d-metric (8) for the φ-solutions embedded in the five 3D rotational hypersurfaces. The coordinates are taken as

$$x^k=\begin{cases}(t,u,v),0\leqslant u<\infty,\ 0\leqslant v\leqslant\pi,\cosh u\geqslant 1,\ \text{ellipsoid (47)};\\ (t,u,v),0\leqslant u<\infty,\ 0\leqslant v\leqslant\pi,\sinh u\geqslant 0,\ \text{ellipsoid (51)};\\ (t,u,v),0\leqslant u<\infty,\ 0\leqslant v\leqslant\pi,\cosh u\geqslant 1,\ \text{cylinder (55)};\\ (t,\tau,\xi),-\infty<\tau<\infty,\ 0\leqslant\xi<\pi,\ \text{bipolar (57)};\\ (t,\tau,\xi),0\leqslant\tau<\infty,-\pi<\xi<\pi,\ \text{torus (59)};\end{cases}$$

$$y^4=s=\begin{cases}\varphi\in[0,2\pi),\ \text{ellipsoid; bipolar; torus;}\\ z\in(-\infty,\infty),\ \text{cylinder;}\end{cases}\qquad y^5=p=\chi,$$

and the ansatz functions given as

$$g_1=1,\quad g_2=-1,\quad g_3=-1, \tag{63}$$

$$\hat{h}_4=\eta_4 h_4,\quad h_4=g_{ss}(x^2,x^3)=\begin{cases}\dfrac{\sinh^2 u\sin^2 v}{\sinh^2 u+\sin^2 v},\ \text{ellipsoid (50)};\\ \dfrac{\sinh^2 u\cos^2 v}{\sinh^2 u+\cos^2 v},\ \text{ellipsoid (54)};\\ \dfrac{\rho^{-2}(u,v)}{\sinh^2 u+\sin^2 v},\ \text{cylinder (55)};\\ \sin^2\xi,\ \text{bipolar (57); torus (59)};\end{cases}$$

$$\eta_4=\begin{cases}\exp[\varpi(x^2,x^3,s],\ \text{see (39)};\\ [1+\varepsilon_r\cos x^3]^{-2}\exp[\varpi(x^2,x^3,s)],\ \text{see (42)};\\ 1/\kappa_r^2(x^2,x^3,s),\ \text{see (46)};\end{cases} \tag{64}$$

$$\eta_5=\begin{cases}\eta_{5[0]}(x^2,x^3)+\eta_{5[1]}(x^2,x^3)\displaystyle\int\eta_4(x^2,x^3,s)ds,\ \text{for } \hat{h}_4^*\neq 0,\\ \eta_{5[0]}(x^2,x^3)+\eta_{5[1]}(x^2,x^3)s;\ \text{for } \hat{h}_4^*=0;\end{cases}$$

$$\hat{h}_5=\eta_5 h_5,\quad h_5(x^2,x^3,s)=-r_0^2\exp\{2\psi[r(x^2,x^3,s)]\};$$

$$r=\tilde{a}^{(invers)}(x^2,x^3,s)\ \text{ from (47),(51),(55),(57),(59);}$$

$$w_1=\omega(x^2),\quad w_2=0,\quad w_3=n\cos x^2\times\begin{cases}1,\ \text{see (39)};\\ 1,\ \text{see (42)};\\ 1/\kappa_n(x^2,x^3,s),\ \text{see (46)};\end{cases}$$

$$n_1=0,\quad n_{2,3}=n_{2,3[0]}(x^2,x^3)\times\begin{cases}\displaystyle\int\exp\varpi_0(x^2,x^3,s)ds,\ \text{see (39)};\\ \displaystyle\int\exp\varpi_0(x^2,x^3,s)ds,\ \text{see (42)};\\ \displaystyle\int|\ln\kappa_n(x^2,x^3,s)|ds,\ \text{see (46)}.\end{cases}$$

Formulas (63) describe a large class of wormhole/flux tube configurations which are defined self-consistently in the various 3D rotation hypersurface backgrounds. The deformations in this case come from the angular coordinate $s=\varphi$ (for the ellipsoid, bipolar and toroidal cases) or from the axial coordinate $s=z$ (for the cylindrical case). These ''deformation'' or anisotropic coordinates, φ or z, are also third coordinates about which the rotation of the hypersurfaces occurs.

VI. CONCLUSIONS

The construction of wormhole and/or flux tube solutions in modern string theory, extra dimensional gravity and quantum chromodynamics is of fundamental importance in understanding these theories (especially their nonperturbative aspects). Such solutions are difficult to find, and the solutions which are known usually have a high degree of symmetry. In this article we have applied the method of anholonomic frames to construct the general form of wormholes and flux tubes in 5D Kaluza–Klein theory. These solutions have local anisotropy which would make their study using holonomic frames difficult. This helps to demonstrate the usefulness of the anholonomic frames method in studying anisotropic solutions. Most physical situations do not possess a high degree of symmetry, and so the anholonomic frame method provides a useful mathematical framework for studying these less symmetric configurations.

The key result of this article is the demonstration that off-diagonal metrics in 5D Kaluza–Klein theory can be parametrized into forms that define new, interesting classes of solutions of Einstein's vacuum equations. These solutions represent wormhole and flux tube configurations which are locally anisotropic. These anisotropic solutions reduce to previously known spherically symmetric wormhole metrics[3,4,11] in the local isotropic limit. These anisotropic solutions also extend the idea of Salam, Strathee and Perracci[3] that including off-diagonal components in higher dimensional metrics gives rise to gauge fields and charges. Not only do we find ''electric'' and ''magnetic'' charges for our solutions, but the anisotropies in the fifth coordinate (χ) and/or in the angular coordinate (φ) give a gravitational scaling or running of these Kaluza-Klein charges. Such a gravitational scaling of charges could provide an experimental signature for the presence of extra dimensions (i.e., if some charge were observed to exhibit a running which was not in agreement with that given by 4D quantum field theory, this could be evidence for a gravitational running of the charge).

In the first part of this article these anisotropic solutions were constructed as deformations from a spherical background. In the final section of this article we showed that it is possible to construct a large variety of such anisotropic solutions as deformations from various background geometries: elliptic (elongated and flattened), cylindrical, toroidal and bipolar.

A general notion of bi-quasi-Hamiltonian systems is introduced and is related to previous work on various special cases of such systems. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1462856]

I. INTRODUCTION

In a previous paper [Crampin and Sarlet (2001)], we have generalized work by Lundmark (2001a,b) on a class of integrable systems, from Euclidean spaces to (pseudo) Riemannian manifolds. In doing so, we came across an interesting class of conformal Killing tensors, called ''special conformal Killing tensors,'' and the integrable systems of interest live on spaces whose metric allows the coexistence of two such tensors. Physically speaking, the integrable systems in question represent Lagrangian systems with nonconservative forces, but whose force form has a kind of double ''generalized potential'' representation. Whereas most classical (finite dimensional) integrable systems are known to have a bi-Hamiltonian formulation, the ones referred to here have a double quasi-Hamiltonian representation and thus could be called bi-quasi-Hamiltonian systems. But they do lead to a bi-Hamiltonian system on an extended space.

In the present paper, we will introduce a general concept of bi-quasi-Hamiltonian systems and explore under what circumstances they can have the property of complete integrability. Bi-quasi-Hamiltonian systems should not be confused with quasi-bi-Hamiltonian systems, as introduced by Brouzet *et al.* (1996) and developed by Morosi and Tondo (1997, 1998). The similarity of the two terms is unfortunate, but the name ''bi-quasi-Hamiltonian system'' describes what we have in mind so well that after some reflection we decided to use it even so. The two concepts are in fact related, but the relation is not entirely straightforward: we discuss it in Sec. VII.

Following the description of the general concept in Secs. II and III, we specialize in Sec. IV to the case where the two Poisson structures involved in the bi-quasi-Hamiltonian representation each come from a Poisson–Nijenhuis structure. Most of the discussion in such a case is transferred from the Poisson structures involved to the type (1,1) tensor fields which generate them. We then make a further specialization, to the case where the manifold is a cotangent bundle and the (1,1) tensors are the complete lifts of tensor fields on the base manifold. This brings us back to the kind of system studied in Crampin and Sarlet (2001), and we take this opportunity to complement our previous work with some results about the possible generation of families of such bi-quasi-Hamiltonian systems. The final section contains an explicit example which illustrates the theory.

We carry out coordinate calculations at various points in the paper; where we do so, we use the Einstein summation convention.

II. QUASI-HAMILTONIAN SYSTEMS

We begin by recalling some generalities about Poisson structures.

A Poisson structure on a manifold M is a bivector field Π which satisfies $[\Pi,\Pi]=0$, where $[\cdot,\cdot]$ is the Schouten bracket. The associated Poisson bracket of functions f, g is given by $\{f,g\}=\Pi(df,dg)$; the vanishing of the Schouten bracket entails the Jacobi identity for the Poisson bracket. Also associated with such a bivector field is a map P of one-forms to vector fields on M, given by $\langle P(\alpha),\beta\rangle=\Pi(\alpha,\beta)$ for any pair of one-forms α, β. The Poisson bracket can be extended to one-forms with the aid of P, as follows (Magri, 1985): for any one-forms α, β,

$$\{\alpha,\beta\}=\mathcal{L}_{P(\alpha)}\beta-\mathcal{L}_{P(\beta)}\alpha-d(\Pi(\alpha,\beta));$$

then $\{df,dg\}=d\{f,g\}$. The Schouten bracket condition on Π can be stated equivalently in terms of the Poisson map and the bracket of one-forms:

$$[P(\alpha),P(\beta)]=P(\{\alpha,\beta\}).$$

The Poisson structure is nonsingular if its Poisson map is.

The vector field $P(dH)$ is the Hamiltonian vector field corresponding to the Hamiltonian function H. If Z is a Hamiltonian vector field then $\mathcal{L}_Z\Pi=0$, or equivalently $\mathcal{L}_ZP=0$. Conversely, when Π is nonsingular, if $\mathcal{L}_Z\Pi=0$ then Z is locally Hamiltonian, in the sense that in a neighborhood of any point one can find a function H such that $Z=P(dH)$ on that neighborhood. In fact the condition $\mathcal{L}_Z\Pi=0$ states that Z is a cocycle in the Lichnerowicz–Poisson complex corresponding to Π, and Z is Hamiltonian if and only if it is a coboundary. The Poisson map P, when it is nonsingular, induces an isomorphism of the Lichnerowicz–Poisson and the de Rham cohomology groups [Vaisman (1994)], and so the vanishing of the first de Rham cohomology group of M is a sufficient condition for a vector field which satisfies $\mathcal{L}_Z\Pi=0$ to be Hamiltonian. We shall deal mostly with nonsingular Poisson structures, and we shall generally assume that $\mathcal{L}_Z\Pi=0$ is sufficient as well as necessary for Z to be Hamiltonian.

A vector field Z on a Poisson manifold is said to be quasi-Hamiltonian if there is a nowhere-vanishing function F such that FZ is Hamiltonian. Thus $FZ=P(dH)$ for some function H. Note that if M is connected F must be everywhere positive or everywhere negative; we can assume the former without loss of generality by absorbing a negative sign in H if necessary. We assume henceforth that M is connected and F is positive. Now let $V=F^{-1}P(dF)=P(d\log F)$; then $\mathcal{L}_Z\Pi=Z\wedge V$, and of course $\mathcal{L}_V\Pi=0$. Conversely, if $\mathcal{L}_Z\Pi=Z\wedge V$ and $V=P(d\Phi)$ say then

$$\mathcal{L}_{e^{\Phi}Z}\Pi=e^{\Phi}\mathcal{L}_Z\Pi-Z\wedge P(d(e^{\Phi}))=0.$$

Thus if $\mathcal{L}_Z\Pi=Z\wedge V$ where $\mathcal{L}_V\Pi=0$, and Π is nonsingular, then Z is quasi-Hamiltonian, at least locally.

The function H is a first integral of Z.

Let Z be a vector field on a manifold M which is quasi-Hamiltonian with respect to a Poisson bivector Π, so that $FZ=P(dH)$. Then, as shown in Crampin and Sarlet (2001), the bivector $\hat{\Pi}$ on $M\times\mathbb{R}$ given by

$$\hat{\Pi}=\Pi+(Z+zV)\wedge\frac{\partial}{\partial z},$$

where z is the coordinate on $\mathbb{R}$ and $V=F^{-1}P(dF)$, is a Poisson bivector which projects onto Π. Here Π is extended to $M\times\mathbb{R}$ simply by ignoring z. The Hamiltonian vector field with respect to $\hat{\Pi}$ corresponding to $-z$ is $Z+zV$; its restriction to the zero section is Z. Furthermore, $H+zF$ is a Casimir of $\hat{\Pi}$. In fact the conditions for $\hat{\Pi}$ to be Poisson are again

$$\mathcal{L}_Z\Pi=Z\wedge V,\quad \mathcal{L}_V\Pi=0,$$

given that Π is Poisson.

III. BI-QUASI-HAMILTONIAN SYSTEMS

We now set up a general framework for the study of systems with a dual quasi-Hamiltonian representation, within which a notion of complete integrability occurs naturally, and which covers as a special case the class of cofactor pair systems studied in Lundmark (2001a, b) and Crampin and Sarlet (2001).

Definition: A vector field Z on M is said to be bi-quasi- Hamiltonian if

(i) M is equipped with two compatible Poisson structures Π_a, $a=1,2$;
(ii) Z is quasi-Hamiltonian with respect to both Poisson structures, i.e., $F_a Z = P_a(dH_a)$ for some functions H_a and (nowhere vanishing) F_a;
(iii) $\mathcal{L}_{V_1}\Pi_2 + \mathcal{L}_{V_2}\Pi_1 = 0$, where $V_a = (F_a)^{-1} P_a(dF_a)$.

Condition (iii), which is a form of compatibility condition (and will be referred to as such in the following), can be motivated as follows.

Suppose that Z is quasi-Hamiltonian with respect to two Poisson structures Π_1 and Π_2, with $F_a Z = P_a(dH_a)$, $a=1,2$. Then we can form the two extended Poisson structures

$$\hat{\Pi}_a = \Pi_a + (Z + zV_a) \wedge \frac{\partial}{\partial z}.$$

We now ask for the conditions for these Poisson structures to be compatible, that is, for $[\hat{\Pi}_1, \hat{\Pi}_2] = 0$. Now

$$\begin{aligned}
&\left[\Pi_1 + (Z+zV_1)\wedge\frac{\partial}{\partial z}, \Pi_2 + (Z+zV_2)\wedge\frac{\partial}{\partial z}\right] \\
&\quad = [\Pi_1,\Pi_2] + (\mathcal{L}_Z\Pi_1 + z\mathcal{L}_{V_2}\Pi_1)\wedge\frac{\partial}{\partial z} + (\mathcal{L}_Z\Pi_2 + z\mathcal{L}_{V_1}\Pi_2)\wedge\frac{\partial}{\partial z} + (V_1+V_2)\wedge Z\wedge\frac{\partial}{\partial z} \\
&\quad = [\Pi_1,\Pi_2] + z(\mathcal{L}_{V_1}\Pi_2 + \mathcal{L}_{V_2}\Pi_1)\wedge\frac{\partial}{\partial z}
\end{aligned}$$

since $\mathcal{L}_Z\Pi_a = Z\wedge V_a$ by assumption. Thus $\mathcal{L}_{V_1}\Pi_2 + \mathcal{L}_{V_2}\Pi_1 = 0$ is the necessary and sufficient condition for the Poisson structures $\hat{\Pi}_1$ and $\hat{\Pi}_2$ to be compatible, assuming that Π_1 and Π_2 are compatible.

We now establish the existence of involutive first integrals of a bi-quasi-Hamiltonian system.

It follows from the compatibility condition $\mathcal{L}_{V_1}\Pi_2 + \mathcal{L}_{V_2}\Pi_1 = 0$, together with the conditions $\mathcal{L}_{V_a}\Pi_a = 0$, that $\mathcal{L}_{V_1 - tV_2}(\Pi_1 - t\Pi_2) = 0$ for all t. Now if Π_1 is nonsingular so is $\Pi_1 - t\Pi_2$ for t sufficiently close to zero. Thus there is some function $\Phi(t)$ such that $V_1 - tV_2 = (P_1 - tP_2)(d\Phi(t))$. Since further $\mathcal{L}_Z(\Pi_1 - t\Pi_2) = Z\wedge(V_1 - tV_2)$, there is some function $H(t)$ such that $F(t)Z = (P_1 - tP_2)(dH(t))$, where $F(t) = e^{\Phi(t)}$; moreover $H(t)$ is a first integral of Z for all t. On setting $t=0$ we see that $F(0)Z = P_1(dH(0))$.

Now for $k = 0,1,2,\ldots$ set

$$H_{(k)} = \frac{1}{k!}\frac{\partial^k H}{\partial t^k}\Big|_{t=0},$$

and define $F_{(k)}$ similarly. Then each $H_{(k)}$ is a first integral of Z, and

$$F_{(k+1)}Z = P_1(dH_{(k+1)}) - P_2(dH_{(k)}).$$

It follows that for every $j = 0,1,2,\ldots$,

$$\{H_{(j)},H_{(k+1)}\}_1=\{H_{(j)},H_{(k)}\}_2,$$

where $\{\cdot,\cdot\}_a$ is the Poisson bracket of functions defined by Π_a. Thus

$$\{H_{(j)},H_{(k+1)}\}_1=\{H_{(j+1)},H_{(k)}\}_1.$$

It follows that if l and m differ by an even integer then $\{H_{(l)},H_{(m)}\}_1=0$, since

$$\{H_{(l)},H_{(l+2n)}\}_1=\{H_{(l+n)},H_{(l+n)}\}_1.$$

If l and m differ by an odd integer, on the other hand,

$$\{H_{(l)},H_{(m)}\}_1=\{H_{(l)},H_{(m-1)}\}_2;$$

since l and $m-1$ differ by an even integer, $\{H_{(l)},H_{(m-1)}\}_2=0$ by the same argument. Thus $\{H_{(l)},H_{(m)}\}_1=0$ for all l, m, and $\{H_{(l)},H_{(m)}\}_2=0$ likewise. We summarize the results in the following statement.

Theorem: Let Z be bi-quasi-Hamiltonian. Then there exist functions $H_{(k)}$ $(k=0,1,2,\ldots)$, such that

$$F_{(0)}Z=P_1(dH_{(0)}),$$

$$F_{(k+1)}Z=P_1(dH_{(k+1)})-P_2(dH_{(k)}),\quad k=0,1,2,\ldots$$

for some functions $F_{(k)}$. The $H_{(k)}$ are in involution with respect to both Poisson brackets. In particular, if the manifold M is $2n$-dimensional and the functions $H_{(k)}$, $k=0,1,\ldots,n-1$, are functionally independent then Z is completely integrable in the sense of Liouville.

IV. POISSON-NIJENHUIS PENCILS

We now specialize the results of Sec. III to the case where each of the two Poisson structures giving rise to a bi-quasi-Hamiltonian system actually comes from a Poisson–Nijenhuis structure.

A Poisson–Nijenhuis structure (Π,J) on a manifold M consists of a Poisson structure Π and a type (1,1) tensor field J such that $PJ^*=JP$, the Magri–Morosi concomitant $\mu_{P,J}$ of P and J is zero, and the torsion, or Nijenhuis tensor, N_J of J is zero. (Here J^* denotes the adjoint of J.)

The Magri–Morosi concomitant is defined as follows [Magri and Movosi (1984); Nunes da Costa and Marle (1996)]: for any one-form α and vector field X on M,

$$\mu_{P,J}(\alpha,X)=(\mathcal{L}_{P(\alpha)}J)(X)-P(\mathcal{L}_X(J^*\alpha))+P(\mathcal{L}_{J(X)}\alpha).$$

When $PJ^*=JP$, $\mu_{J,P}$ is a type (1,2) tensor field on M.

These conditions are sufficient for JP to define a second Poisson structure on M [Magri and co-workers (1984, 1985); Kosmann–Schwarzbach and Magri (1990)]. We denote the Poisson bivector by Π_J and the associated Poisson map by $P_J=JP=PJ^*$.

Note that when $N_J=0$ we have available the differential d_J of Frölicher–Nijenhuis theory [Frölicher and Nijenhuis (1956)], which satisfies $dd_J+d_Jd=0$, ${d_J}^2=0$; it is determined essentially by these properties and by its action on functions, which is given by $d_Jf=J^*(df)$.

We shall be interested in vector fields Z that are quasi-Hamiltonian with respect to Π_J, with $FZ=P_J(dH)$. Of particular interest are those for which $d_Jd\Phi=0$, where $F=e^{\Phi}$. Alternatively, we then have $dd_J\Phi=0$, so $d_J\Phi=d\phi$ for some function ϕ (at least locally), whence $d_JF=Fd\phi$. One important case covered by this occurs when $\Phi=\log\det J$, so that $F=\det J$ (assuming, without essential loss of generality, that $\det J>0$).

Proposition: For any J such that $N_J=0$, we have $d_J(\det J)=(\det J)d(\operatorname{tr}J)$.

Proof: This follows from the formula

$$d(\det J)=J^i_{j|k}C^j_i dx^k,$$

where C is the cofactor tensor of J, and the calculation is carried out using any symmetric connection (or indeed partial differentiation). Thus

$$\begin{aligned} d_J(\det J) &= J^i_{j|k} J^k_l C^j_i dx^l \\ &= (J^i_{l|k} J^k_j + J^k_{j|l} J^i_k - J^k_{l|j} J^i_k) C^j_i dx^l \\ &= (J^i_{l|k} \delta^k_i + J^k_{j|l} \delta^j_k - J^k_{l|j} \delta^j_k)(\det J) dx^l \\ &= J^k_{k|l} (\det J) dx^l \end{aligned}$$

as asserted. □

It follows that $d_J\Phi = d(\operatorname{tr} J)$, and so $d_J d\Phi = 0$. Slightly more generally, if $F = (\det J)^r$ for some power r then $d_J\Phi = d(r \operatorname{tr} J)$ and $d_J d\Phi = 0$ also.

Definition: A quasi-Hamiltonian vector field Z such that $(\det J)^r Z = P_J(dH)$ will be called a Pfaffian quasi-Hamiltonian vector field.

This is a slight extension of the terminology used in Morosi and Tondo (1997). All of our examples of bi-quasi-Hamiltonian systems, later in the paper, will actually be of the Pfaffian type.

Now suppose that we have two Poisson–Nijenhuis structures with the same initial Poisson bivector Π, and type (1,1) tensors J and K, which both commute with P, have zero Magri–Morosi concomitants with respect to P, and satisfy $N_J = N_K = 0$. Let the corresponding bivectors be Π_J, Π_K.

Definition: The Poisson–Nijenhuis structures (Π, J) and (Π, K) are said to be compatible if the Poisson bivectors Π_J and Π_K are compatible with each other (each is compatible with Π by construction).

Proposition: For Π_J and Π_K to be compatible, it is sufficient that the Nijenhuis bracket $[J,K] = 0$. If P, J, and K are invertible, the condition is also necessary.

Proof: When $[J,K] = 0$, we have $N_{(J+K)} = 0$. Obviously, $J+K$ commutes with P and $\mu_{P,J+K} = \mu_{P,J} + \mu_{P,K} = 0$. Hence,

$$[\Pi_{(J+K)}, \Pi_{(J+K)}] = [\Pi_J + \Pi_K, \Pi_J + \Pi_K] = 2[\Pi_J, \Pi_K] = 0.$$

Conversely, if P, J, and K are invertible, the compatibility of Π_J and Π_K implies that $[J,K] = 0$. Indeed, the condition for the compatibility of two Poisson structures, expressed in terms of their Poisson maps Q, R, say, is

$$[Q(\alpha), R(\beta)] + [R(\alpha), Q(\beta)] = Q(\{\alpha,\beta\}_R) + R(\{\alpha,\beta\}_Q).$$

If we take $Q = P_J$, $R = P_K$, and set $\alpha = P^{-1}(X)$, $\beta = P^{-1}(Y)$ for vector fields X, Y, we obtain

$$[J(X), K(Y)] + [K(X), J(Y)] = JK^{-1}([K(X), K(Y)]) + KJ^{-1}([J(X), J(Y)]).$$

When the facts that $N_J = N_K = 0$ are used to substitute for the terms on the right-hand side, this becomes $[J,K](X,Y) = 0$. □

We consider, therefore, two Poisson–Nijenhuis structures (Π, J), (Π, K) such that $[J,K] = 0$. Then $(\Pi, J - tK)$ is a Poisson–Nijenhuis structure for every constant t. We then have a pencil of Poisson bivectors $\Pi_{J-tK} = \Pi_J - t\Pi_K$, so we call $(\Pi, J - tK)$ a Poisson–Nijenhuis pencil. We shall be mostly interested in the case in which P, J, and K are all invertible.

We next discuss the compatibility condition for a system to be bi-quasi-Hamiltonian with respect to a Poisson–Nijenhuis pencil.

Suppose given a Poisson–Nijenhuis pencil, and a vector field Z such that

$$\mathcal{L}_Z \Pi_J = Z \wedge V, \quad \mathcal{L}_V \Pi_J = 0,$$

$$\mathcal{L}_Z \Pi_K = Z \wedge W, \quad \mathcal{L}_W \Pi_K = 0;$$

thus (still assuming that Π_J and Π_K are nonsingular) Z is quasi-Hamiltonian with respect to both Π_J and Π_K and we can put $V=P_J(d\Phi)=P(d_J\Phi)$, $W=P_K(d\Psi)=P(d_K\Psi)$ for some Φ,Ψ. In order for Z to be bi-quasi-Hamiltonian the compatibility condition

$$\mathcal{L}_W\Pi_J+\mathcal{L}_V\Pi_K=0,$$

or equivalently

$$\mathcal{L}_WP_J+\mathcal{L}_VP_K=0,$$

must hold. When we express P_J and P_K in terms of P we find that

$$\mathcal{L}_WP_J+\mathcal{L}_VP_K=(\mathcal{L}_WJ+\mathcal{L}_VK)P+J\mathcal{L}_WP+K\mathcal{L}_VP.$$

So a particular case of interest occurs when $\mathcal{L}_WP=\mathcal{L}_VP=0$, that is, when V and W are Hamiltonian with respect to the standard Poisson structure P as well as the derived ones P_J, P_K. In such a case there will be functions ϕ, ψ such that

$$V=P(d\phi)\quad\Rightarrow\quad d\phi=d_J\Phi\quad\Rightarrow\quad dd_J\phi=-d_Jd\phi=0;$$

$$W=P(d\psi)\quad\Rightarrow\quad d\psi=d_K\Psi\quad\Rightarrow\quad dd_K\psi=-d_Kd\psi=0.$$

Note that these conditions hold in the Pfaffian case, with $\phi=r\,\mathrm{tr}\,J$, $\Phi=r\log\det J$, etc.

Under these assumptions, the compatibility condition reduces to

$$\mathcal{L}_WJ+\mathcal{L}_VK=0.$$

Now from the vanishing of the Magri–Morosi concomitant,

$$(\mathcal{L}_WJ)(X)=(\mathcal{L}_{P(d\psi)}J)(X)=P(\mathcal{L}_X(d_J\psi)-\mathcal{L}_{JX}d\psi)$$

for all X, whence the compatibility condition becomes

$$\mathcal{L}_X(d_J\psi+d_K\phi)-\mathcal{L}_{JX}d\psi-\mathcal{L}_{KX}d\phi=0.$$

When the homotopy formula is used to express the Lie derivatives, this reduces simply to

$$X]\,(dd_J\psi+dd_K\phi)=0.$$

Thus the compatibility condition can be written

$$d_J\beta+d_K\alpha=0,\quad \alpha=d\phi,\quad \beta=d\psi,$$

where $d_J\alpha=d_Jd\phi=0$, $d_K\beta=d_Kd\psi=0$.

In particular, it follows easily from the coordinate representation of the Nijenhuis bracket that if $[J,K]=0$ then $d_J(\mathrm{tr}\,K)+d_K(\mathrm{tr}\,J)=d(\mathrm{tr}\,JK)$; so the requisite conditions are satisfied in the Pfaffian case, and we have the following result.

Proposition: Suppose that Z is Pfaffian quasi-Hamiltonian with respect to both Π_J and Π_K, so that $(\det J)^rZ=P_J(dG)$ and $(\det K)^rZ=P_K(dH)$ (same power): then the necessary and sufficient condition for Z to be bi-quasi-Hamiltonian is that $[J,K]=0$.

When this condition holds, or more generally for any system that is bi-quasi-Hamiltonian with respect to a Poisson–Nijenhuis pencil, the results of Sec. III concerning the existence of first integrals in involution apply.

V. BI-DIFFERENTIAL CALCULI

We now investigate the conditions for a bi-quasi-Hamiltonian system whose Poisson structures form a Poisson–Nijenhuis pencil, to give rise to a scalar gauged bi-differential calculus, according to the definition given by Dimakis and Müller-Hoissen (2000a), and discussed further in Crampin *et al.* (2000).

We consider two Poisson–Nijenhuis structures (Π,J), (Π,K) such that $[J,K]=0$. Then the operators d_J, d_K satisfy

$$d_J{}^2=d_K{}^2=d_Jd_K+d_Kd_J=0,$$

and therefore form a simple bi-differential calculus [Dimakis and Müller-Hoissen (2000a)] or bicomplex [Dimakis and Müller-Hoissen (2000b)].

Let α be a one-form, and denote by D_J the operator on forms given by

$$D_J\theta=d_J\theta+\alpha\wedge\theta,$$

or $D_J=d_J+\alpha$ for short. Two such operators $D_J=d_J+\alpha$, $D_K=d_K+\beta$ form a scalar gauged bi-differential calculus if

$$D_J{}^2=D_K{}^2=D_JD_K+D_KD_J=0;$$

these conditions hold if and only if

$$d_J\alpha=d_K\beta=d_J\beta+d_K\alpha=0.$$

But as we showed in Sec. IV, the compatibility condition for a system which is quasi-Hamiltonian with respect to a Poisson–Nijenhuis pencil and is such that $\mathcal{L}_VP=\mathcal{L}_WP=0$ is that $d_J\beta+d_K\alpha=0$, where the one-forms α and β satisfy $d_J\alpha=d_K\beta=0$. Thus any bi-quasi-Hamiltonian system of this type, and in particular any Pfaffian bi-quasi-Hamiltonian system, has associated with it a scalar gauged bi-differential calculus.

Furthermore, there are functions ϕ and Φ such that $\alpha=d\phi=d_J\Phi$, and functions ψ and Ψ such that $\beta=d\psi=d_K\Psi$. We can express D_J in the form

$$D_J\theta=d_J\theta+d\phi\wedge\theta=e^{-\Phi}d_J(e^{\Phi}\theta),$$

and similarly for D_K.

Now consider the dynamics Z. We can write

$$\begin{aligned}Z&=e^{-\Phi}P_J(dG)=P(e^{-\Phi}d_JG)=P(D_J(e^{-\Phi}G))\\&=e^{-\Psi}P_K(dH)=P(e^{-\Psi}d_KH)=P(D_K(e^{-\Psi}H))\end{aligned}$$

for Hamiltonian functions G, H. These Hamiltonians are related by $D_J(e^{-\Phi}G)=D_K(e^{-\Psi}H)$; thus the functions $U=e^{-\Phi}G$ and $U=e^{-\Psi}H$ both satisfy the equation $D_JD_KU=0$, a generalization of what was called the fundamental equation in Rauch-Wojciechowski *et al.* (1999) and Lundmark (2001b). If we take the view that the vector fields V and W, or the functions Φ and Ψ, are the givens, then this equation provides a way of generating dynamical vector fields Z which fit the corresponding bi-quasi-Hamiltonian structure; in particular, we can take the Pfaffian set-up with $\Phi=r\log\det J$, $\Psi=r\log\det K$.

In the Poisson–Nijenhuis case the recurrence relation

$$P_J(dH_{(k+1)})-P_K(dH_{(k)})=F_{(k+1)}Z=\frac{F_{(k+1)}}{F_{(0)}}P_J(dH_{(0)})$$

can be expressed in terms of differential operators as follows:

$$d_J H_{(k+1)} = d_K H_{(k)} + \frac{F_{(k+1)}}{F_{(0)}} d_J H_{(0)}.$$

Furthermore, the general formula $V_1 - tV_2 = (P_1 - tP_2)(d\Phi(t))$ from Sec. III here becomes $V - tW = P_{J-tK}(d\Phi(t))$, from which it follows that $d_J\Phi - td_K\Psi = d_{J-tK}\Phi(t)$. For $F(t) = e^{\Phi(t)}$, there results: $d_{J-tK}F(t) = F(t)(d_J\Phi - td_K\Psi) = F(t)(d\phi - td\psi)$. Hence, the $F_{(k)}$ satisfy the recurrence relation

$$d_J F_{(k+1)} - d_K F_{(k)} = F_{(k+1)} d\phi - F_{(k)} d\psi.$$

That is to say, we have

$$d_J F_{(k+1)} - (d\phi) F_{(k+1)} = d_K F_{(k)} - (d\psi) F_{(k)},$$

$$d_J H_{(k+1)} - \vartheta F_{(k+1)} = d_K H_{(k)},$$

where

$$\vartheta = \frac{1}{F_{(0)}} d_J H_{(0)}.$$

Note that $P(\vartheta) = Z$, whence $\vartheta = e^{-\Phi} d_J G = e^{-\Psi} d_K H$; it follows that $d_J\vartheta = \vartheta \wedge d\phi$ and $d_K\vartheta = \vartheta \wedge d\psi$.

Define the 2×2 matrix differential operators

$$\Delta_J = d_J + \begin{bmatrix} -d\phi & 0 \\ -\vartheta & 0 \end{bmatrix}, \quad \Delta_K = d_K + \begin{bmatrix} -d\psi & 0 \\ 0 & 0 \end{bmatrix}.$$

It follows from the formulas for $d_J\vartheta$ and $d_K\vartheta$ just obtained that $\Delta_J{}^2 = \Delta_K{}^2 = 0$ and $\Delta_J\Delta_K + \Delta_K\Delta_J = 0$. Thus Δ_J and Δ_K are the differential operators of a gauged bi-differential calculus operating on two-component column vectors, and

$$\Delta_J \begin{bmatrix} F_{(k+1)} \\ H_{(k+1)} \end{bmatrix} = \Delta_K \begin{bmatrix} F_{(k)} \\ H_{(k)} \end{bmatrix}.$$

A special case of this construction was discussed in Crampin *et al.* (2000).

VI. COFACTOR AND COFACTOR PAIR SYSTEMS

In Secs. IV and V, the discussion centered on a general Poisson manifold (M,P), with additional structure coming from some type (1,1) tensor fields on M. An interesting particular case occurs when M is a cotangent bundle T^*Q say, equipped with its standard Poisson structure Π, and the type (1,1) tensors on M are complete lifts of torsionless tensors L on the base manifold Q. For the complete lift $\tilde{L}$ of L, we have $\det\tilde{L} = (\det L)^2$. Moreover, for any two such tensors L_1, L_2,

$$[\tilde{L}_1, \tilde{L}_2] = \widetilde{[L_1, L_2]};$$

so a vector field Z on T^*Q which is Pfaffian quasi-Hamiltonian with respect to $\tilde{L}_1$ and $\tilde{L}_2$ will be bi-quasi-Hamiltonian if and only if $[L_1, L_2] = 0$. This result, which we have deduced from the more general analysis of Sec. IV, can also be proved easily by an explicit computation.

The following class of quasi-Hamiltonian systems has been studied in Marciniak and Rauch-Wojciechowski (1998), Rauch-Wojciechowski *et al.* (1999), Lundmark (2001a, b), and Crampin and Sarlet (2001). Let g be a (pseudo) Riemannian metric on Q and L a symmetric type (0,2) tensor field such that

$$(\nabla_X L)(Y,Z)=\tfrac{1}{2}(g(X,Y)\langle Z,\alpha\rangle+g(X,Z)\langle Y,\alpha\rangle).$$

Such a tensor is a conformal Killing tensor of g, and the type (1,1) tensor obtained by raising an index on L with g automatically has vanishing torsion. The one-form α is given by $d(\operatorname{tr} L)$. Such a tensor L is called a special conformal Killing tensor. We shall generally be concerned with special conformal Killing tensors which are nonsingular. We shall denote such a tensor by the same letter whatever the position of its indices. Let A be the cofactor tensor of a special conformal Killing tensor, so that $AL=(\det L)I$, and let μ be a one-form on Q which satisfies $D_L\mu=d_L\mu+d(\operatorname{tr} L)\wedge\mu=0$. Let H be the function on T^*Q given by

$$H(q^i,p_i)=\tfrac{1}{2}A^{ij}p_ip_j+V(q),$$

where V is a function such that $D_L((\det L)^{-1}V)=\mu$. Then the quasi-Hamiltonian vector field Z where $(\det L)Z=P_{\tilde{L}}(dH)$ is called a cofactor system. Since $\det\tilde{L}=(\det L)^2$ it is Pfaffian, with $r=\frac{1}{2}$. The vector field Γ on TQ obtained via the diffeomorphism $(q^i,p_i)\mapsto(q^i,g^{ij}p_j)$ takes the form

$$\Gamma=\Gamma_0-M^V,$$

where Γ_0 is the geodesic field of the metric and M is the vector field obtained by raising the index on μ. It is an example of a nonconservative Lagrangian system, and μ represents a generalized force.

If L_1 and L_2 are two special conformal Killing tensors then clearly L_1+L_2 is also a special conformal Killing tensor. The torsion of L_1+L_2 therefore vanishes; it follows that $[L_1,L_2]=0$, and so the corresponding Poisson–Nijenhuis structures are compatible. If Z is a cofactor system with respect to both special conformal Killing tensors then it is Pfaffian quasi-Hamiltonian with respect to each Poisson–Nijenhuis structure and is therefore bi-quasi-Hamiltonian. The force form μ must satisfy $D_{L_1}\mu=D_{L_2}\mu=0$.

The functions $H(t)$ and $F(t)$ in this case are polynomials in t, and the system is completely integrable; $H(t)$ takes the form

$$H(t)=\tfrac{1}{2}A(t)^{ij}p_ip_j+V(t),$$

where $A(t)$ is the cofactor tensor of L_1-tL_2, and $V(t)$ is a polynomial of degree $n-1$ such that

$$D_{(L_1-tL_2)}(\det(L_1-tL_2)^{-1}V(t))=\mu.$$

For given g, μ there are functions V_1, V_2 such that

$$D_{L_1}((\det L_1)^{-1}V_1)=D_{L_2}((\det L_2)^{-1}V_2)=\mu;$$

these are the ''generalized potentials'' of μ with respect to L_1 and L_2 referred to in Sec. I.

Now consider $\nu=D_{L_2}((\det L_1)^{-1}V_1)$. We have

$$D_{L_1}\nu=-D_{L_2}D_{L_1}((\det L_1)^{-1}V_1)=-D_{L_2}\mu=0,$$

and of course $D_{L_2}\nu=0$: so ν defines a new bi-cofactor system, with the same metric but a different force form. The quadratic part of the new first integral function is unchanged; the ''potential'' part $W(t)$ satisfies

$$D_{(L_1-tL_2)}(\det(L_1-tL_2)^{-1}W(t))=\nu.$$

In fact $W(t)$ is given in terms of $V(t)$ by

$$tW(t)=V(t)-\frac{\det(L_1-tL_2)}{\det L_1}V(0).$$

Note that $V(0)=V_1$. The right-hand side is a polynomial of degree n in t, which takes the value 0 when $t=0$; so $W(t)$ is a polynomial of degree $n-1$. Moreover

$$D_{(L_1-tL_2)}\left(\det(L_1-tL_2)^{-1}\left(V(t)-\frac{\det(L_1-tL_2)}{\det L_1}V(0)\right)\right)$$
$$=\mu-D_{L_1}(\det(L_1)^{-1}V_1)+tD_{L_2}((\det L_1)^{-1}V_1)=t\nu$$

as required. With these considerations, we have supplemented the analysis in Crampin and Sarlet (2001) with the appropriate generalization of Lundmark's construction (Lundmark, 2001b) of a hierarchy of cofactor pair systems.

VII. QUASI-BI-HAMILTONIAN SYSTEMS

The theory we have described previously covers, of course, the special case in which the vector field Z is Hamiltonian, not just quasi-Hamiltonian, with respect to one of the two Poisson structures, so that (say) $F_1=1$ in the notation of Sec. III. This case corresponds roughly to that of a quasi-bi-Hamiltonian system as defined and discussed in Brouzet *et al.* (1996), Morosi and Tondo (1997, 1998); however, the compatibility condition for a bi-quasi-Hamiltonian system, which reduces to $\mathcal{L}_{V_2}\Pi_1=0$, is not required to hold in the definition of a quasi-bi-Hamiltonian system given in those papers. But to the best of our knowledge, all of the examples of quasi-bi-Hamiltonian systems in the literature do fall within our framework: in fact they all appear to be cases of cofactor systems, for which the compatibility condition holds automatically anyway. We therefore feel justified in discussing briefly some of the results in the literature on quasi-bi-Hamiltonian systems in the light of our approach.

We wish first to compare our main integrability result with the following proposition, due to Tondo [Tondo (1995); Morosi and Tondo (1997)]. (The statement of the proposition has been edited to fit in with the notation and terminology of the present paper.)

Proposition: Let M be a $2n$-dimensional manifold equipped with an invertible Poisson tensor P_1, and let Z be a Hamiltonian vector field with Hamiltonian H: $Z=P_1(dH)$. Let a tensor $J:TM\to TM$ exist such that the tensor $P_2:T^*M\to TM$ defined by $P_2=JP_1$ is skew-symmetric. Denote by $\alpha_{(k)}=(J^*)^k dH$ $(k=0,1,2,\dots)$ the one-forms obtained by the iterated action of J^*. If there exist $n-1$ independent functions $H_{(l)}$ $(l=1,2,\dots,n)$ and $\frac{1}{2}n(n+1)$ functions $\rho_{(kl)}$ $(k=0,1,\dots,n-1;\ 0\leqslant l\leqslant k)$ with $\rho_{(00)}=1$ and $\rho_{(kk)}\neq 0$ $(k\neq 0)$, such that the one-forms $\alpha_{(k)}$ can be written as $\alpha_{(k)}=\sum_{l=0}^{k}\rho_{(kl)}dH_{(l)}$ $(k=0,1,\dots,n-1)$, then the functions $H_{(k)}$ are in involution with respect to the Poisson bracket defined by P_1 and are first integrals of Z. The Hamiltonian system is Liouville integrable. Moreover, if P_2 is a Poisson tensor then the functions $H_{(k)}$ are in involution also with respect to the Poisson bracket defined by P_2.

In our analysis, we have assumed the existence of two nonsingular Poisson tensors from the first; we may define J as $P_2P_1^{-1}$. On the other hand, we assume only that Z is quasi-Hamiltonian. To relate our results to Tondo's proposition we must show that the functions $H_{(k)}$ defined in Sec. III are related to the one-forms $\alpha_{(k)}=(J^*)^k dH_{(0)}$ in the manner specified in the proposition. Now we can write

$$F_{(k+1)}Z=P_1(dH_{(k+1)})-P_1(J^*dH_{(k)}),$$

and $F_{(0)}Z=P_1(dH_{(0)})$. Thus

$$dH_{(k+1)}=J^*dH_{(k)}+\hat{F}_{(k+1)}dH_{(0)},$$

where $\hat{F}_{(k)}=F_{(k)}/F_{(0)}$, from which it follows that

$$dH_{(k)}=\sum_{l=0}^{k}\hat{F}_{(k-l)}\alpha_{(l)}.$$

Note that the matrix of coefficients on the right-hand side is lower triangular with 1*s* on the diagonal. When this system of equations is solved for the $\alpha_{(k)}$ we obtain a relation of the required form. In fact we have $\rho_{(kk)}=1$ for all k, not just for $k=0$; and moreover $\rho_{(kl)}=\rho_{(ij)}$ when $k-l=i-j$. In Morosi and Tondo (1997), Tondo's proposition is applied to a couple of examples of quasi-bi-Hamiltonian systems. It is a feature of these examples, not remarked on let alone explained in this paper, that the $\rho_{(ij)}$ follow the pattern identified previously. While Tondo's proposition is rather more general than our result, so far as we know it has been applied only to quasi-bi-Hamiltonian systems, and indeed only to systems of cofactor type (as we have already remarked); so this greater generality is in practice somewhat illusory.

When one considers the examples in Morosi and Tondo (1997) more carefully, one realizes that it is not at all clear what role the fact that the systems in question are quasi-bi-Hamiltonian plays, since the expressions for the $H_{(k)}$ and $\rho_{(kl)}$ are merely quoted and no indication is given as to how they were derived. To clarify what is going on, we shall consider one of these examples, and analyze it using our techniques. We have chosen the first example from the paper for this purpose. It is the Hamiltonian system $Z=P_0(dH)$ where P_0 is the standard Poisson structure on $T^*\mathbb{R}^3$ and

$$H=\tfrac{1}{2}(2p_1p_2+p_3^2)-\tfrac{5}{8}q_1^4+\tfrac{5}{2}q_1^2q_2+\tfrac{1}{2}q_1q_3^2-\tfrac{1}{2}q_2^2.$$

It is stated that Z is also quasi-Hamiltonian with respect to the Poisson tensor P_1 given by

$$P_1=\begin{bmatrix}0 & A\\ -A^T & B\end{bmatrix},\quad \text{where } A=-\begin{bmatrix}q_1 & -1 & 0\\ 2q_2 & q_1 & q_3\\ q_3 & 0 & 0\end{bmatrix},\quad B=-\begin{bmatrix}0 & -p_2 & -p_3\\ p_2 & p_3 & 0\\ 0 & 0 & 0\end{bmatrix};$$

in fact $q_3^2Z=P_1(dH_{(2)})$ where

$$H_{(2)}=\tfrac{1}{2}q_3^2p_2^2+(\tfrac{1}{2}q_1^2+q_2)p_3^2-q_3p_1p_3-q_1q_3p_2p_3+\tfrac{1}{2}q_1^3q_3^2-q_1q_2q_3^2-\tfrac{1}{8}q_3^4.$$

Note first that the terms quadratic in momenta in H are derived from the flat metric whose matrix representation is

$$\begin{bmatrix}0 & 1 & 0\\ 1 & 0 & 0\\ 0 & 0 & 1\end{bmatrix},$$

which is of normal hyperbolic type. When this metric is used to lower an index on A we obtain the symmetric matrix

$$-\begin{bmatrix}-1 & q_1 & 0\\ q_1 & 2q_2 & q_3\\ 0 & q_3 & 0\end{bmatrix},$$

which is easily seen to be a special conformal Killing tensor. The tensor P_1 is, apart from sign, the Poisson–Nijenhuis tensor associated with the complete lift of the type (1,1) tensor A. The determinant of A is $-q_3^2$, and its cofactor tensor, in type (2,0) form, is

$$-\begin{bmatrix} 0 & 0 & -q_3 \\ 0 & q_3^2 & -q_1q_3 \\ -q_3 & -q_1q_3 & q_1^2+2q_2 \end{bmatrix};$$

it is clear that this determines the terms in $H_{(2)}$ quadratic in momenta. Moreover, it is easy to check that if V represents the potential of $H=H_{(0)}$ and W the potential of $H_{(2)}$ then $d_AW=(\det A)dV$. This is therefore an example of a cofactor system, and the preceding theory applies, explaining for example why the relevant functions $\rho_{(ij)}$ satisfy $\rho_{(11)}=\rho_{(22)}=1$, $\rho_{(21)}=\rho_{(32)}$.

VIII. AN EXAMPLE

We finish with an example of a true bi-quasi-Hamiltonian system. It is a cofactor pair system on the sphere and as such illustrates our generalization [Crampin and Sarlet (2001)] of the work on Euclidean spaces of Lundmark [Lundmark (2001a, b)]. Starting from a known example of a kinetic energy Lagrangian with two further quadratic integrals, we will use a constructive approach to find all force forms which determine a nonconservative system of cofactor pair type.

Take the kinetic energy to be

$$T=\tfrac{1}{2}g_{ij}(q)\dot{q}_i\dot{q}_j=\tfrac{1}{2}(\dot{q}_1^2+\sin^2 q_1\dot{q}_2^2).$$

It is straightforward to verify that the symmetric type (0,2) tensors with matrix representation

$$L_1=\begin{bmatrix} \sin 2q_1\cos q_2 & -\sin^2 q_1\sin q_2 \\ -\sin^2 q_1\sin q_2 & 0 \end{bmatrix},\quad L_2=\begin{bmatrix} \sin 2q_1\sin q_2 & \sin^2 q_1\cos q_2 \\ \sin^2 q_1\cos q_2 & 0 \end{bmatrix},$$

are special conformal Killing tensors with respect to the given metric. The corresponding type (1,1) tensors which one needs to set up the differential operators $D_{L_a}=d_{L_a}+\alpha_a$ read

$$L_1=\sin 2q_1\cos q_2\frac{\partial}{\partial q_1}\otimes dq_1-\sin q_2\left(\frac{\partial}{\partial q_1}\otimes dq_2+\sin^2 q_1\frac{\partial}{\partial q_2}\otimes dq_1\right),$$

$$L_2=\sin 2q_1\sin q_2\frac{\partial}{\partial q_1}\otimes dq_1+\cos q_2\left(\frac{\partial}{\partial q_1}\otimes dq_2+\sin^2 q_1\frac{\partial}{\partial q_2}\otimes dq_1\right).$$

We further have $\alpha_a=d(\operatorname{tr}L_a)$, where $\operatorname{tr}L_1=\sin 2q_1\cos q_2$, $\operatorname{tr}L_2=\sin 2q_1\sin q_2$. All we need now to identify a dynamical system which has a bi-quasi-Hamiltonian representation with respect to the two compatible Poisson–Nijenhuis structures $P_{\tilde{L}_a}$, obtained from the standard Poisson structure P on the cotangent bundle of the sphere, is an admissible force form $\mu=M_1dq_1+M_2dq_2$, that is to say, a solution of the simultaneous equations $D_{L_a}\mu=0$. In coordinates, each of these conditions gives rise to a single, linear first-order partial differential equation for the M_a. Taking suitable linear combinations with $\sin q_2$ and $\cos q_2$, the set of conditions is equivalent to

$$\frac{\partial M_1}{\partial q_1}=\sin^2 q_1\frac{\partial M_2}{\partial q_2},$$

$$\frac{\partial M_2}{\partial q_1}=\left(\frac{3}{2}\tan q_1-\cot q_1\right)M_2.$$

These equations are readily solved and give

$$\mu=\frac{2\rho'(q_2)}{\cos^{1/2}q_1}dq_1+\frac{\rho(q_2)}{\cos^{3/2}q_1\sin q_1}dq_2,$$

where ρ is an arbitrary function of q_2. The ''potentials'' V_a for which $\mu = D_{L_a}((\det L_a)^{-1} V_a)$ are most easily obtained by computing $dV_a = A_a \mu$, where A_a is the cofactor matrix of L_a. We find

$$V_1 = \frac{2\rho(q_2)\sin q_2}{\cos^{1/2} q_1}, V_2 = -\frac{2\rho(q_2)\cos q_2}{\cos^{1/2} q_1}.$$

Since we have actually obtained the most general form of μ, we should not expect here to find new cofactor pair systems by applying the procedure explained in Sec. VI. In fact, we have

$$\nu = D_{L_2}((\det L_1)^{-1} V_1) = (\det L_2)^{-1} d_{L_2}\left(\frac{\det L_2}{\det L_1} V_1\right),$$

and since the ratio of the two determinants depends on q_2 only, it can be absorbed into the arbitrary function ρ; thus ν is indistinguishable from μ.

(Received 20 September 2001; accepted for publication 22 January 2002)

Let $S:[0,1]\to[0,1]$ be a nonsingular chaotic map that preserves an integrable density f^* that describes the statistics of the orbits. In this article we use the maximum entropy approach to approximate the density f^* and the corresponding Lyapunov exponent. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1465100]

I. INTRODUCTION

In physical sciences, such as statistical physics, mathematical biology, and fluid dynamics, exploration of statistical properties of an underlying dynamical system S defined on $[0,1]$ is the only effective and practical means for understanding the asymptotic behavior of the orbits in phase space.[1] Such an investigation often leads to a study of the existence and computation of the integrable fixed density of the dynamics.[2] Since such fixed densities describe the chaotic dynamics for almost all initial points, they are usually referred to as physical measures. For the determination of these physical measures, one must calculate a fixed density, f^*, of the so-called Frobenius–Perron operator associated with S. In addition, the Lyapunov exponent λ, closely related to the sensitivity of the orbits on the initial conditions, can also be determined in terms of the fixed density as[1]

$$\lambda = \int_0^1 f^*(x)\ln|S'(x)|dx. \tag{1}$$

The exponent describes the average expansion rate: a positive Lyapunov exponent means that small uncertainties in the initial conditions expand on average, while a negative Lyapunov exponent means that the interval of uncertainty shrinks on average. The important issues, therefore, in physical applications of chaotic dynamics are how to numerically determine the density of a physical measure and the associated Lyapunov exponent.

To numerically predict the densities and the associated exponents, we will use the maximum entropy method (maxent). Maxent is widely used in the context of the moment problem which appears naturally in many branches of physics and engineering; it is used to numerically recover the density with ''least bias'' from finitely many known moments.[3] High precision numerical integration techniques permit the sought after density to be determined with up to 20 moments as input. Averages over the approximate distribution are known to be rapidly convergent in many cases of interest.[4,5] The idea of solving operator equations using maxent was first proposed by Mead[6] and has been used by Ding in forming a new numerical method for solving the fixed density problem for the Frobenius–Perron operator.[7] Even with only $N=4$ moments the maxent algorithm performs better than the usual Ulam method.[8,9] In this article, we will sufficiently extend

[a)]Author to whom correspondence should be addressed. Electronic mail: lawrence.mead@usm.edu

the numerical accuracy of the algorithm used by Ding to allow the numerical maxent prediction of the Lyapunov exponent associated with the distribution (physical measure).

The article continues as follows. In the next section, we present some background mathematical preliminaries on which the work is based. In Sec. III, we present the results of numerical calculations for the fixed densities and the exponents. We conclude briefly in Sec. IV.

II. PRELIMINARIES

Let $S:[0,1]\to[0,1]$ be a nonlinear map such that the Lebesgue measure $m(A)=0$ implies $m(S^{-1}(A))=0$ for every measurable set $A\subset[0,1]$. The operator $P:L^1(0,1)\to L^1(0,1)$ defined by

$$Pf(x)=\frac{d}{dx}\int_{S^{-1}([0,x])}f(t)dt \tag{2}$$

is called the *Frobenius–Perron operator* associated with S.

A *density* f is any function $f\geqslant 0$ such that its L^1-norm $\int_0^1 f(t)\,dt=1$. It is obvious that the Frobenius–Perron operator P is a Markov operator which by definition is any linear operator that maps densities to densities. For any density f, the absolutely continuous probability measure

$$\mu(A)=\int_A f dm \quad \forall \text{ measurable sets } A\subset[0,1]$$

is invariant under S: that is, $\mu(S^{-1}(A))=\mu(A)$ for all measurable sets $A\subset[0,1]$, if and only if f is a fixed point of P.

A basis of the maximum entropy method for computing a fixed density of the Frobenius–Perron operator $P:L^1(0,1)\to L^1(0,1)$ associated with $S:[0,1]\to[0,1]$ is the following result which has been proved in Ref. 7. Let D be the set of all densities.

Proposition 2.1: $f^*\in D$ is a fixed point of P if and only if

$$\int_0^1 [x^n-S(x)^n]f^*(x)\,dx=0, \quad =1,2,\ldots. \tag{3}$$

The Boltzmann (information) entropy of $f\in L^1(0,1)$ is defined as

$$H(f)=-\int_0^1 f(x)\log f(x)dx. \tag{4}$$

Then the maximum entropy method for solving the homogeneous system (3) with infinitely many equations is the following:

Algorithm: Choose N and solve the maximum entropy problem

$$\max\left\{H(f):f\in D,\ \int_0^1 [x^n-S(x)^n]f(x)\,dx=0,\ i=1,\ldots,N\right\} \tag{5}$$

to obtain an approximate solution f_N of the operator equation $Pf=f$.

It was shown in Ref. 7 that the above algorithm is well-posed under the mild assumption that the set of N functions

$$x-S(x),\ x^2-S(x)^2,\ldots,x^N-S(x)^N$$

are linearly independent. The optimization problem (5) will then have a unique solution f_N given by

$$f_N(x)=\frac{\exp\Sigma_{n=1}^{N}a_n[x^n-S(x)^n]}{\int_0^1\exp\Sigma_{n=1}^{N}a_n[x^n-S(x)^n]dx}, \tag{6}$$

where $a_1,\ldots,a_N$ satisfy the N constraints

$$\int_0^1[x^i-S(x)^i]\exp\sum_{n=1}^{N}a_n[x^n-S(x)^n]\,dx=0,\quad i=1,\ldots,N. \tag{7}$$

Lastly, the Lyapunov exponent associated with the map can be calculated approximately from Eq. (1) where f^* is replaced by the maxent approximation f_N.

III. NUMERICAL EXPERIMENTS

In this section we present some numerical results from our maximum entropy algorithm using a high precision Gaussian quadrature. The test maps are

$$S_1(x)=\begin{cases}\dfrac{2x}{1-x^2}, & 0\leqslant x\leqslant\sqrt{2}-1\\[2ex] \dfrac{1-x^2}{2x}, & \sqrt{2}-1\leqslant x\leqslant 1\end{cases},$$

$$S_2(x)=\begin{cases}\dfrac{2x}{1-x}, & 0\leqslant x\leqslant\dfrac{1}{3},\\[2ex] \dfrac{1-x}{2x}, & \dfrac{1}{3}\leqslant x\leqslant 1\end{cases},$$

$$S_3(x)=4x(1-x)\quad(\text{logistic map}),$$

$$S_4(x)=\sqrt{2}x-\operatorname{sgn}(x)\quad(\text{sigma-delta modulator}).$$

In the last entry, sgn(x) denotes the sign of x. The third of these maps, $S_3(x)$, is the well-known logistic map. This map played a historical role in the development of the theory of chaos,[1] and appears in ecological population dynamics. The last example, $S_4(x)$, describes chaos in various electronic signal analyzers,[10] and is a direct example taken from practical physics.

The unique fixed densities of S_i are known exactly:

$$f_1^*(x)=\frac{4}{\pi(1+x^2)},$$

$$f_2^*(x)=\frac{2}{(1+x)^2},$$

$$f_3^*(x)=\frac{1}{\pi\sqrt{x(1-x)}},$$

$$f_4^*(x)=\begin{cases}\dfrac{1+\sqrt{2}}{2\sqrt{2}}, & \sqrt{2}-1<|2x-1|<1,\\[2ex] 0, & |2x-1|=\sqrt{2}-1,\\[2ex] \dfrac{1+\sqrt{2}}{2}, & |2x-1|<\sqrt{2}-1.\end{cases}$$

TABLE I. Averages of the computed fixed densities.

N	S_1	S_2	S_3
2	0.314 926	0.298 290	0.358 972
3	0.314 709	0.296 827	0.358 821
4	0.314 178	0.295 487	0.353 476
5	0.314 022	0.294 904	0.353 752
6	0.314 016	0.293 889	0.353 705
7	0.314 018	0.293 881	0.353 391
8	0.314 018	0.293 999	0.348 839
9	0.313 765		0.348 915
10	0.311 964		0.348 916
α^*	0.310 349	0.285 398	0.318 310

The numerical computations were performed on the Cray C90 supercomputer at the Mississippi Center for Super-computing Research. Double precision was used throughout all calculations. In the maxent algorithm, Newton's method is used to solve the nonlinear system of equations (7) to a high precision (up to 15 significant digits). To evaluate the derivative matrix required in the algorithm, we used the 50-node Gaussian quadrature for the numerical integrations. For the first three of these, we compared the quantity

$$\alpha_N \equiv \int_0^1 f_N(x) \frac{\sqrt{x}}{2} dx$$

with the exact average

$$\alpha^* \equiv \int_0^1 f^*(x) \frac{\sqrt{x}}{2} dx$$

to estimate the error. In problems not involving chaos, averages such as α_N are known to be rapidly convergent as the number of input moments increases.[3]

In Table I, we list the quantities α_N versus N for the first three examples with the exact averages α^* for f_1^*, f_2^*, f_3^* listed in the last row. For each of these maps, we have computed the Lyapunov exponent according to Eq. (1). The results are shown in Table II.

IV. CONCLUSIONS

In this article, we are able to compute fixed densities of the Frobenius–Perron operator equation for various chaotic maps with the help of the maximum entropy approach. In addition, we calculated the associated Lyapunov exponents. The exponent was calculated from Eq. (1) which is an average over the fixed density. Normally, one expects such averages to converge rapidly with increasing numbers of input moments; for example, achieving several decimal places of accuracy with from 5 to 10 moments, even if the point-wise convergence of the distribution is poor. Looking at Table I for the three test averages, α, we see that for even as many as ten

TABLE II. Computed Lyapunov exponents and exact values.

Map	N	λ_{exact}	λ_{maxent}
S_1	10	0.664 24	0.692 90
S_2	8	$\ln 2 = 0.693\,147\,0$	0.689 70
S_3	10	$\ln 2 = 0.693\,147\,0$	0.684 25
S_4	12	$\frac{1}{2}\ln 2 = 0.346\,573$	0.346 573

moments of input we obtain averages only at the few percent level, that for S_1 being the most accurate at only about 0.3%. This level of accuracy is also reflected in Table II for the corresponding exponents where the level of accuracy is likewise just a few percent. However, for the modulator map, S_4, the exponent turned out to be accurate to a remarkable nine digits of accuracy (only six are given in the table) with 12 moments of input.

In some cases, therefore, our method may be able to generate Lyapunov exponents of chaotic maps to good accuracy. In others, accuracy may be achieved only at the 1% level with the same number of input moments. Clearly, the moment problem Eqs. (3)–(5) for chaotic maps is an especially challenging numerical problem.[11] In general, it is unclear how much the accuracy of λ may be improved with higher numbers of input moments.

(Received 28 May 2001; accepted for publication 17 January 2002)

We present the sequence of parametrically driven discrete nonlinear Schrödinger systems with the progressively extending range of intersite couplings. In the case of time-independent coupling parameters the sequence is reduced to the Ablowitz–Ladik hierarchy, which is known to be integrable by the inverse scattering transform. However the models with the time-dependent intersite interactions are shown to be integrable too irrespective of a particular form of time dependencies of coupling parameters. Any of such parametrically driven systems might exhibit rather complex soliton dynamics and is described by the unconserved Hamiltonian function. We reveal an important subclass of parametrically driven systems demonstrating the parametrical localization of soliton dynamics on a confined domain of space. Meanwhile an appropriate choice of time dependencies in intersite interactions allow us to transform the original parametrically driven system into another one but subjected to the linear external potential. As a result the latter system can be readily integrated as well. In particular the peculiarities of Bloch oscillations in the systems with time-independent long range intersite interactions and linear external potential of constant strength are analyzed. In general, regulating the range of intersite couplings, the strengths and time dependencies of coupling parameters, we are able to model a number of physically important quasi-one-dimensional systems. We develop an alternative approach to solve the Marchenko equations permitting one to obtain the multisoliton solutions in the most simple and natural way. Finally, we point out how to reformulate any model in row in terms of corrected amplitudes with the standard Poisson brackets. © *2002 American Institute of Physics.*

I. INTRODUCTION

Inspecting recent publications dealing with the integrable nonlinear evolution models on one-dimensional or quasi-one-dimensional lattices, one could readily see that, apart from a few exceptions,[1,2] they treat the couplings between the molecules in longitudinal direction to be of nearest-neighboring type.[3–10] Meanwhile the intermolecular interactions in real physical systems are either the long-range[11,12] or at least moderate-range[13] ones. For example, in unharmonic chains the impact of long-range intermolecular interactions was shown to be so crucial that it is able to affect the whole structure of soliton-like modes.[11,12] In this respect developing physically motivated integrable nonlinear models with moderate-range and long-range intermolecular couplings appear to be reasonable.

In the present paper we will try to fill this gap by extending the range of intersite couplings in discrete nonlinear Schrödinger systems and to inspire, at least indirectly, interest in the effects of moderate-range and long-range couplings feasible, e.g., in arrays of tunnel-coupled nonlinear

a)Electronic mail: vakhnenko@bitp.kiev.ua

optical fibers[14] or nonlinear transmission lines[15] as well as in discrete geophysical media.[16]

Starting from the Ablowitz–Ladik auxiliary spectral problem[17–19] but relaxing the basic constraint on the form of the auxiliary evolution operator, it is possible both to extend the range of intersite interactions and to postulate an arbitrary time dependence of coupling parameters. The latter fact generates a substantially richer class of dynamical systems as compared with that adopted by the usual definition of integrable hierarchy where the coupling parameters are supposed to be time independent.[20,21] Here we may observe a direct analogy with the dynamics of parametrically driven oscillators (e.g., the Mathieu oscillator[22] or Kapytsya pendulum,[23,24]) which are now developed into a special theory.[25,26]

II. THE SEQUENCE OF INTEGRABLE MODELS

One way to obtain an integrable nonlinear model on the one-dimensional[3–5,17–19] or quasi-one-dimensional[7,10] lattice consists in starting with the set of auxiliary linear problems

$$\mathbf{u}(n+1|z)=L(n|z)\mathbf{u}(n|z), \tag{1}$$

$$\dot{\mathbf{u}}(n|z)=A(n|z)\mathbf{u}(n|z), \tag{2}$$

restricted by the compatibility condition (Lax equation)

$$\dot{L}(n|z)=A(n+1|z)L(n|z)-L(n|z)A(n|z). \tag{3}$$

Here $L(n|z)$ and $A(n|z)$ are the spectral and evolution matrix operators, respectively, while the overdot stands for the derivative with respect to dimensionless time τ. The numerical longitudinal coordinate n is supposed to run from minus to plus infinity whereas the spectral parameter z is supposed to be time independent. According to the general rule[17–19] the Lax equation (3) is nothing but a direct consequence of the so-called cross-differentiation condition

$$[\mathrm{d}\mathbf{u}(m|z)/\mathrm{d}\tau]_{m=n+1}=\mathrm{d}\mathbf{u}(n+1|z)/\mathrm{d}\tau \tag{4}$$

imposed on the column vector $\mathbf{u}(n|z)$ as the most natural demand.

The next step is to postulate the form of the spectral operator and to specify the general form of evolution operator by some reasonable constraint. Then with good luck the Lax equation (3) becomes sufficient both to restore the explicit form of evolution operator and to isolate some nontrivial integrable nonlinear evolution equation by collecting the terms proportional to the same powers in z. The phrase ''good luck'' implies that in practice it is more common to gain either the mathematical contradiction or rather trivial result of minor physical interest.

Nevertheless, there always exists a safe opportunity to use the well-recommended spectral operator but in combination with the evolution operator specified by a new constraint. We will follow this opportunity and take $L(n|z)$ in the form[17–19]

$$L(n|z)=\begin{pmatrix} z & iq(n) \\ ir(n) & 1/z \end{pmatrix}, \tag{5}$$

where the quantities $q(n)$ and $r(n)$ are pretending to become the on-site amplitudes of any model under future consideration.

In this paper we will be interested in the sequence of integrable models built-up under the constraint that the evolution operator of the Mth model in order must contain the spectral parameter z in the same powers as the multiplicative operator $L^{2M}(n|z)$, with $L(n|z)$ given by expression (5). Here M is an arbitrary positive integer.

Relying upon the above-described guiding scheme it may be concluded that any Mth model in row can be written as

$$+i\dot{q}(n)=[1+q(n)r(n)]\partial H/\partial r(n), \tag{6}$$

$$-i\dot{r}(n)=[1+q(n)r(n)]\partial H/\partial q(n) \tag{7}$$

with H given by

$$H=-2\omega_0 I_0-\sum_{\alpha=1}^{M}[\bar{\omega}_\alpha \bar{I}_\alpha+\overset{+}{\omega}_\alpha \overset{+}{I}_\alpha]. \tag{8}$$

Here $\bar{I}_\alpha$, $\overset{+}{I}_\alpha$, and I_0 are, respectively, $-\alpha$th, $+\alpha$th, and zeroth conserved quantities generated by the spectral operator (5), while $\bar{\omega}_\alpha$, $\overset{+}{\omega}_\alpha$ and ω_0 are arbitrary coordinate independent parameters. The first seven conserved quantities are

$$\begin{aligned}\bar{I}_3=&\sum_{m=-\infty}^{\infty} q(m)r(m-3)[1+q(m-2)r(m-2)][1+q(m-1)r(m-1)]\\&+\sum_{m=-\infty}^{\infty} q(m)q(m-1)r^2(m-2)[1+q(m-1)r(m-1)]\\&+\sum_{m=-\infty}^{\infty} q^2(m)r(m-1)r(m-2)[1+q(m-1)r(m-1)]\\&+\sum_{m=-\infty}^{\infty}\frac{1}{3}q^3(m)r^3(m-1),\end{aligned} \tag{9}$$

$$\bar{I}_2=\sum_{m=-\infty}^{\infty} q(m)r(m-2)[1+q(m-1)r(m-1)]+\sum_{m=-\infty}^{\infty}\frac{1}{2}q^2(m)r^2(m-1), \tag{10}$$

$$\bar{I}_1=\sum_{m=-\infty}^{\infty} q(m)r(m-1), \tag{11}$$

$$I_0=\sum_{m=-\infty}^{\infty}\ln[1+q(m)r(m)], \tag{12}$$

$$\overset{+}{I}_1=\sum_{m=-\infty}^{\infty} q(m)r(m+1), \tag{13}$$

$$\overset{+}{I}_2=\sum_{m=-\infty}^{\infty} q(m)r(m+2)[1+q(m+1)r(m+1)]+\sum_{m=-\infty}^{\infty}\frac{1}{2}q^2(m)r^2(m+1), \tag{14}$$

$$\begin{aligned}\overset{+}{I}_3=&\sum_{m=-\infty}^{\infty} q(m)r(m+3)[1+q(m+2)r(m+2)][1+q(m+1)r(m+1)]\\&+\sum_{m=-\infty}^{\infty} q(m)q(m+1)r^2(m+2)[1+q(m+1)r(m+1)]\\&+\sum_{m=-\infty}^{\infty} q^2(m)r(m+1)r(m+2)[1+q(m+1)r(m+1)]\end{aligned}$$

$$+\sum_{m=-\infty}^{\infty}\frac{1}{3}q^3(m)r^3(m+1). \tag{15}$$

The higher ones are obtainable within the framework of the recurrence method proposed by Wadati's team.[3]

In general the parameters $\overset{-}{\omega}_\alpha$, $\overset{+}{\omega}_\alpha$, and ω_0 are proved to be arbitrary functions of time, which is usually either overlooked or deliberately neglected in standard theories of integrable hierarchies.[20,21] As a consequence the Hamiltonian function H (8) is not bound to be conserved and can describe some parametrically driven system with sophisticated dynamics.

For physical applications and in particular for the understanding of low amplitude spectrum it is convenient to write down the linear part of the nonlinear model (6)–(8) explicitly. To do so we observe that up to the bilinear terms the recurrence technique[3] yields

$$\overset{-}{I}_\alpha \sim \sum_{m=-\infty}^{\infty} q(m)r(m-\alpha), \tag{16}$$

$$\overset{+}{I}_\alpha \sim \sum_{m=-\infty}^{\infty} q(m)r(m+\alpha). \tag{17}$$

Hence for the linear part of the Mth model (6)–(8) we obtain

$$+i\dot{q}(n) \sim -2\omega_0 q(n) - \sum_{\alpha=1}^{M} [\overset{-}{\omega}_\alpha q(n+\alpha) + \overset{+}{\omega}_\alpha q(n-\alpha)], \tag{18}$$

$$-i\dot{r}(n) \sim -2\omega_0 r(n) - \sum_{\alpha=1}^{M} [\overset{+}{\omega}_\alpha r(n+\alpha) + \overset{-}{\omega}_\alpha r(n-\alpha)]. \tag{19}$$

Thus the parameters $\overset{-}{\omega}_\alpha$ and $\overset{+}{\omega}_\alpha$ are seen to characterize the coupling strength between two αth-neighboring sites. The terms proportional to ω_0 correspond to the regular energy shift and can be easily eliminated by the standard gauge transformation.

Regulating the strength of coupling parameters $\overset{-}{\omega}_\alpha$ and $\overset{+}{\omega}_\alpha$ and the range of intersite interaction M we gain a remarkable opportunity to model a variety of different physical situations. For example, assuming all $\overset{-}{\omega}_\alpha$ and $\overset{+}{\omega}_\alpha$ except $\overset{-}{\omega}_1$, $\overset{-}{\omega}_M$ and $\overset{+}{\omega}_1$, $\overset{+}{\omega}_M$ are equal to zero, we are in a position to describe the dynamics of some nonlinear intramolecular excitations on a spiral-like chain with M molecules per one wind. Moreover, provided the excitations are charged, it is possible to take into account in this case even an impact of longitudinal spatially homogeneous magnetic field via the complex phases of coupling parameters $\overset{-}{\omega}_1$ and $\overset{+}{\omega}_1$ in a way similar to that used in Ref. 10. At last, the freedom in choosing particular time modulations of coupling parameters $\overset{-}{\omega}_\alpha$, $\overset{+}{\omega}_\alpha$ appears to provide a practically inexhaustible source of parametrically driven physical systems integrable by the inverse scattering transform.

We complete this section by presenting the asymptotic part

$$A(z) \equiv \lim_{|n|\to\infty} A(n|z) \tag{20}$$

of the evolution operator $A(n|z)$ in assumption of rapidly decreasing boundary conditions $q(n)\to 0$ and $r(n)\to 0$ as $|n|\to\infty$, since its full expression already for the third model in row ($M=3$) occupies a lot of place. Specifically for the matrix elements $A_{jk}(z)$ of $A(z)$ we have

$$A_{11}(z) = +i\omega_0 + i\sum_{\alpha=1}^{M} \bar{\omega}_\alpha z^{2\alpha}, \tag{21}$$

$$A_{12}(z) = A_{21}(z) = 0, \tag{22}$$

$$A_{22}(z) = -i\omega_0 - i\sum_{\alpha=1}^{M} \overset{+}{\omega}_\alpha z^{-2\alpha}. \tag{23}$$

Fortunately it is precisely the operator $A(z)$ which is of true practical value.

III. SCATTERING PROBLEM AND MARCHENKO EQUATIONS

Although the basic results on the scattering problem and Marchenko equations related to the spectral operator (5) are already well known,[17–19] here we give a brief sketch of them in terminology more convenient for the compact analytical presentation of any multisoliton solution of the nonlinear model under study (6)–(8).

Thus, restricting ourselves to the case of amplitudes $q(n)$ and $r(n)$ rapidly decreasing at both infinities we define the left $\{\boldsymbol{\varphi}_j(n|z)\}$ and the right $\{\boldsymbol{\psi}_j(n|z)\}$ Jost bases ($j=1,2$) as the two component vector sets satisfying the auxiliary spectral problem (1), (5) and fixed by the asymptotic conditions

$$\boldsymbol{\varphi}_j(n|z) \sim \mathbf{J}_1 \delta_{1j} z^n + \mathbf{J}_2 \delta_{2j} z^{-n} \quad \text{as} \quad n \to -\infty \tag{24}$$

and

$$\boldsymbol{\psi}_j(n|z) \sim \mathbf{J}_1 \delta_{1j} z^n + \mathbf{J}_2 \delta_{2j} z^{-n} \quad \text{as} \quad n \to +\infty, \tag{25}$$

respectively. Here $\mathbf{J}_k$ is the two-component column vector with the ith component J_{ik} equal to δ_{ik}.

The transition matrix $a(z) \equiv [a_{jk}(z)]$ is that transforming one Jost basis into another,

$$\boldsymbol{\varphi}_k(n|z) = \sum_{j=1}^{2} \boldsymbol{\psi}_j(n|z) a_{jk}(z) \quad (k=1,2). \tag{26}$$

Formally resolving this equation with respect to matrix elements $a_{ij}(z)$ we have

$$a_{ij}(z) = \frac{\overset{2}{W}_{k=1}\{(1-\delta_{ik})\boldsymbol{\psi}_k(n|z) + \delta_{ik}\boldsymbol{\varphi}_j(n|z)\}}{\overset{2}{W}_{k=1}\{\boldsymbol{\psi}_k(n|z)\}}. \tag{27}$$

Here

$$\overset{2}{W}_{k=1}\{\mathbf{v}_k(n|z)\} \equiv \det[v_{ik}(n|z)] \tag{28}$$

stands for the Wronskian of any two solutions $\mathbf{v}_1(n|z)$ and $\mathbf{v}_2(n|z)$ of the spectral problem (1), (5) with $v_{ik}(n|z)$ denoting the ith component of vector $\mathbf{v}_k(n|z)$. Further, taking the Wronskian from both parts of (26) we come to the normalizing condition

$$\det[a_{ij}(z)] = \frac{\overset{2}{W}_{k=1}\{\boldsymbol{\varphi}_k(n|z)\}}{\overset{2}{W}_{k=1}\{\boldsymbol{\psi}_k(n|z)\}} = \prod_{m=-\infty}^{\infty} [1+q(m)r(m)], \tag{29}$$

where the following readily checked relations,

$$\overset{2}{W}_{k=1}\{\varphi_k(n|z)\}=\prod_{m=-\infty}^{n-1}[1+q(m)r(m)], \tag{30}$$

$$\overset{2}{W}_{k=1}\{\psi_k(n|z)\}=\prod_{m=n}^{\infty}[1+q(m)r(m)]^{-1}, \tag{31}$$

have been used.

Another important statement says that two sets of vectors $\{\varphi_1(n|z)z^{-n},\psi_2(n|z)z^n\}$ and $\{\psi_1(n|z)z^{-n},\varphi_2(n|z)z^n\}$ must be analytic outside $|z|>1$ and inside $|z|<1$ the unit circle, respectively. On the one hand, it enables us to conclude that the diagonal elements $a_{11}(z)$ and $a_{22}(z)$ of the transition matrix are analytic outside $|z|>1$ and inside $|z|<1$ the unit circle, respectively [see (27)]. On the other hand, we might seek the vectors of right Jost basis in the form

$$\psi_j(n|z)=\sum_{l=n}^{\infty}\mathbf{K}_j(n|l)[\delta_{j1}z^l+\delta_{j2}z^{-l}] \quad (j=1,2). \tag{32}$$

Direct substitution of these expansions into the spectral equation (1) with $L(n|z)$ given by (5) yields

$$q(n)=iK_{12}(n|n+1)/K_{22}(n|n), \tag{33}$$

$$r(n)=iK_{21}(n|n+1)/K_{11}(n|n), \tag{34}$$

where $K_{ij}(n|m)$ is the ith component of $\mathbf{K}_j(n|m)$. These relations resolve the nonlinear problem (6)–(8) provided the quantities $K_{12}(n|n+1)$, $K_{22}(n|n)$ and $K_{21}(n|n+1)$, $K_{11}(n|n)$ are found.

In contrast to the original nonlinear evolution model (6)–(8) the vectors $\mathbf{K}_j(n|m)$ obey the linear summation equations (Marchenko equations) with the time τ inserted parametrically through the evolution of scattering data. To derive the Marchenko equations one must rely only on the auxiliary spectral problem (1), (5) (more precisely, on the analytical properties of transition matrix $[a_{jk}(z)]$ and Jost bases $\{\varphi_j(n|z)\}$, $\{\psi_j(n|z)\}$). In so doing we may follow the main arguments of Ablowitz and Ladik[17–19] or simply adapt formulas derived for the multicomponent auxiliary linear problem[10] for the needs of the two-component one—(1), (5). The result is

$$\mathbf{K}_k(n|m)+\sum_{l=n}^{\infty}\sum_{j=1}^{2}\mathbf{K}_j(n|l)F_{jk}(l+m)=\mathbf{J}_k\delta_{nm} \quad (m\geqslant n; \quad k=1,2). \tag{35}$$

Here the matrix elements $F_{jk}(n)$ of the kernel operator are given by

$$F_{11}(n)=F_{22}(n)=0, \tag{36}$$

$$F_{21}(n)=\frac{1}{2\pi i}\oint_{|z|=1}\mathrm{d}z\,z^{-n-1}\frac{a_{21}(z)}{a_{11}(z)}+\sum_{r=1}^{N_{\mathrm{ext}}}[z_{11}(r)]^{-n-1}\frac{a_{21}(z_{11}(r))}{a'_{11}(z_{11}(r))}, \tag{37}$$

$$F_{12}(n)=\frac{1}{2\pi i}\oint_{|z|=1}\mathrm{d}z\,z^{n-1}\frac{a_{12}(z)}{a_{22}(z)}-\sum_{r=1}^{N_{\mathrm{int}}}[z_{22}(r)]^{n-1}\frac{a_{12}(z_{22}(r))}{a'_{22}(z_{22}(r))}, \tag{38}$$

where $z_{kk}(r)$ stands for the rth root of equation $a_{kk}(z)=0$, $a'_{kk}(z_{kk}(r))$ refers to the derivative $[\mathrm{d}a_{kk}(z)/\mathrm{d}z]_{z=z_{kk}(r)}$, while N_{ext} and N_{int} mark the total number of roots of equations $a_{11}(z)=0$ and $a_{22}(z)=0$, respectively. The equalities (37) and (38) have been found with the understanding of simple roots $z_{kk}(r)$. The case of multiple roots can be covered by obtaining limiting expressions in the final results.

IV. TIME EVOLUTION OF SCATTERING DATA

According to expressions (36)–(38) the time evolution of a kernel operator is determined by that of scattering data $a_{21}(z)/a_{11}(z)$, $z_{11}(r)$, $a_{21}(z_{11}(r))/a'_{11}(z_{11}(r))$ and $a_{12}(z)/a_{22}(z)$, $z_{22}(r)$, $a_{12}(z_{22}(r))/a'_{22}(z_{22}(r))$. The time evolution of scattering data in turn follows from

$$\dot{a}_{jk}(z)=\sum_{i=1}^{2}\,[A_{ji}(z)a_{ik}(z)-a_{ji}(z)A_{ik}(z)]\quad (j=1,2;\quad k=1,2). \tag{39}$$

These equations can be derived thanks to the standard observation[20] that at every $j=1,2$ the combination $\dot{\boldsymbol{\varphi}}_j(n|z)-A(n|z)\boldsymbol{\varphi}_j(n|z)$ satisfies the spectral problem (1), (5) and consequently is presentable by some linear superposition of the left Jost vectors $\Sigma_{i=1}^{2}\,\boldsymbol{\varphi}_i(n|z)d_{ij}(z)$. The key steps of such derivation are based upon the direct use of limiting expressions $\lim_{n\to-\infty}\dot{\boldsymbol{\varphi}}_j(n|z)=\mathrm{col}(0,0)$ and $\lim_{n\to+\infty}\dot{\boldsymbol{\psi}}_j(n|z)=\mathrm{col}(0,0)$ evident from the asymptotic conditions (24) and (25), respectively.

Substituting formulas (21)–(23) for $A_{jk}(z)$ into the evolution equation (39) and using (where necessary) the time independence of roots $\dot{z}_{kk}(r)=0$ [the latter statement is nothing but a direct consequence of $a_{kk}(z_{kk}(r))\equiv 0$, $a'_{kk}(z_{kk}(r))\neq 0$ and $\dot{a}_{kk}(z)=0$] we formally integrate to obtain

$$a_{21}(z|\tau)=a_{21}(z|0)\exp\left\{-2i\,\eta_0(\tau)-i\sum_{\alpha=1}^{M}\,[\overset{-}{\eta}_{\alpha}(\tau)z^{2\alpha}+\overset{+}{\eta}_{\alpha}(\tau)z^{-2\alpha}]\right\}, \tag{40}$$

$$a_{12}(z|\tau)=a_{12}(z|0)\exp\left\{+2i\,\eta_0(\tau)+i\sum_{\alpha=1}^{M}\,[\overset{-}{\eta}_{\alpha}(\tau)z^{2\alpha}+\overset{+}{\eta}_{\alpha}(\tau)z^{-2\alpha}]\right\}, \tag{41}$$

$$a_{kk}(z|\tau)=a_{kk}(z|0)\quad (k=1,2), \tag{42}$$

$$a_{jk}(z_{kk}(r)|\tau)=[a_{jk}(z|\tau)]_{z=z_{kk}(r)}\quad (j\neq k), \tag{43}$$

$$a'_{kk}(z_{kk}(r)|\tau)=a'_{kk}(z_{kk}(r)|0)\quad (k=1,2). \tag{44}$$

Here

$$\eta_0(\tau)=\int_0^{\tau}\mathrm{d}t\;\omega_0(t), \tag{45}$$

$$\overset{-}{\eta}_{\alpha}(\tau)=\int_0^{\tau}\mathrm{d}t\;\overset{-}{\omega}_{\alpha}(t), \tag{46}$$

$$\overset{+}{\eta}_{\alpha}(\tau)=\int_0^{\tau}\mathrm{d}t\;\overset{+}{\omega}_{\alpha}(t), \tag{47}$$

and an explicit indication on time variable τ has been restored: $a_{jk}(z)\equiv a_{jk}(z|\tau)$, $a_{jk}(z_{kk}(r))\equiv a_{jk}(z_{kk}(r)|\tau)$, $\omega_0\equiv\omega_0(\tau)$, $\overset{-}{\omega}_{\alpha}\equiv\overset{-}{\omega}_{\alpha}(\tau)$, $\overset{+}{\omega}_{\alpha}\equiv\overset{+}{\omega}_{\alpha}(\tau)$.

Only in the simplest case, when the coupling parameters ω_0, $\overset{-}{\omega}_{\alpha}$, $\overset{+}{\omega}_{\alpha}$ are assumed to be time independent, does the scattering data come to evolve in a way typical for systems from the standard Ablowitz–Ladik hierarchy.

V. MULTISOLITON SOLUTIONS: AN ALTERNATIVE APPROACH

We begin this section with the standard reshaping of the Marchenko equations (35) into the form where the equations for $\mathbf{K}_1(n|m)$ and $\mathbf{K}_2(n|m)$ are completely splitted

$$\mathbf{K}_1(n|m)-\sum_{l=n}^{\infty}\sum_{p=n}^{\infty}\mathbf{K}_1(n|l)F_{12}(l+p)F_{21}(p+m)=\mathbf{J}_1\delta_{nm}-\mathbf{J}_2F_{21}(n+m)\quad(m\geqslant n),\tag{48}$$

$$\mathbf{K}_2(n|m)-\sum_{l=n}^{\infty}\sum_{p=n}^{\infty}\mathbf{K}_2(n|l)F_{21}(l+p)F_{12}(p+m)=\mathbf{J}_2\delta_{nm}-\mathbf{J}_1F_{12}(n+m)\quad(m\geqslant n).\tag{49}$$

However unlike in the usually adopted scheme,[4,17–19] we will treat Eqs. (48) and (49) in an absolutely different way, omitting the parts for the components $K_{21}(n|m)$ and $K_{12}(n|m)$ as quite unnecessary. Instead we will consider the equations for the components $K_{11}(n|m)$ and $K_{22}(n|m)$,

$$K_{11}(n|m)-\sum_{l=n}^{\infty}\sum_{p=n}^{\infty}K_{11}(n|l)F_{12}(l+p)F_{21}(p+m)=\delta_{nm}\quad(m\geqslant n),\tag{50}$$

$$K_{22}(n|m)-\sum_{l=n}^{\infty}\sum_{p=n}^{\infty}K_{22}(n|l)F_{21}(l+p)F_{12}(p+m)=\delta_{nm}\quad(m\geqslant n),\tag{51}$$

to be the basic ones.

Indeed, knowing the solutions $K_{11}(n|m)$ and $K_{22}(n|m)$ reduces two of the four components of the original Marchenko equations (35) taken at $m=n+1$ to the sheer definitions of $K_{21}(n|n+1)$ and $K_{12}(n|n+1)$. Namely, we have

$$K_{21}(n|n+1)=-\sum_{l=n}^{\infty}K_{22}(n|l)F_{21}(l+n+1),\tag{52}$$

$$K_{12}(n|n+1)=-\sum_{l=n}^{\infty}K_{11}(n|l)F_{12}(l+n+1),\tag{53}$$

which in combination with $K_{11}(n|m)$, $K_{22}(n|m)$ and (33), and (34) formally resolves the nonlinear problem of interest—(6)–(8).

Now let us analyze Eqs. (50) and (51) and expressions (52) and (53) using the parity properties of transition matrix $[a_{jk}(z)]$. These properties are as follows: $a_{11}(-z)=a_{11}(z)$, $a_{22}(-z)=a_{22}(z)$, $a_{12}(-z)=-a_{12}(z)$, $a_{21}(-z)=-a_{12}(z)$, and can easily be proved for rapidly abating amplitudes $q(n)$ and $r(n)$ close to those on the compact support. When applied to the matrix elements (37) and (38) of the kernel operator they allow us to conclude that $F_{21}(n)$ and $F_{12}(n)$ must be equal to zero identically at every even n. As a result the equations for $K_{11}(n|n+2m)$ become separated from those for $K_{11}(n|n+2m+1)$ while the equations for $K_{22}(n|n+2m)$ become separated from those for $K_{22}(n|n+2m+1)$ [see (50) and (51)]. Moreover the right-hand sides of expressions (52) and (53) must contain only the terms with $K_{22}(n|n+2m)$ and $K_{11}(n|n+2m)$, respectively.

Hence all information of interest can be obtained from

$$K_{11}(n|n+2m)-\sum_{l=0}^{\infty}\sum_{p=0}^{\infty}K_{11}(n|n+2l)F_{12}(2l+2n+1+2p)F_{21}(2p+1+2n+2m)$$
$$=\delta_{0m}\quad(m\geqslant 0),\tag{54}$$

$$K_{22}(n|n+2m)-\sum_{l=0}^{\infty}\sum_{p=0}^{\infty}K_{22}(n|n+2l)F_{21}(2l+2n+1+2p)F_{12}(2p+1+2n+2m)$$
$$=\delta_{0m}\quad(m\geqslant 0),\tag{55}$$

supplemented by the relations

$$K_{21}(n|n+1)=-\sum_{m=0}^{\infty} K_{22}(n|n+2m)F_{21}(2m+1+2n), \tag{56}$$

$$K_{12}(n|n+1)=-\sum_{m=0}^{\infty} K_{11}(n|n+2m)F_{12}(2m+1+2n). \tag{57}$$

In order to proceed with the multisolitonic solutions we must equalize the scattering data of continuous spectrum $a_{21}(z)/a_{11}(z)$ and $a_{12}(z)/a_{22}(z)$ to zero at $|z|=1$. Then, on the one hand, the matrix elements of the kernel operator appeared in Eqs. (54) and (55) become degenerate [see (37) and (38)] and, on the other, the form of the diagonal matrix elements $a_{kk}(z)$ can be reconstructed explicitly

$$a_{11}(z)=\prod_{s=1}^{N}\frac{z^2-\exp[\mu_{11}(s)+ik_{11}(s)]}{z^2-\exp[-\mu_{22}(s)+ik_{22}(s)]} \quad (|z|\geqslant 1), \tag{58}$$

$$a_{22}(z)=\prod_{s=1}^{N}\frac{z^{-2}-\exp[\mu_{22}(s)-ik_{22}(s)]}{z^{-2}-\exp[-\mu_{11}(s)-ik_{11}(s)]} \quad (|z|\leqslant 1). \tag{59}$$

Here $k_{11}(s)$ and $k_{22}(s)$ are real constants, whereas $\mu_{11}(s)$ and $\mu_{22}(s)$ are positive real constants. Except for the restrictions imposed by the assumed simplicity of roots $z_{kk}(r)$, the constants $\mu_{11}(s)$, $k_{11}(s)$ and $\mu_{22}(s)$, $k_{22}(s)$ are supposed to be arbitrary in all other respects. Finally, N represents an arbitrary but fixed positive integer, being the number of solitons in a particular multisoliton solution. Evidently $N_{\text{ext}}=N_{\text{int}}=2N$.

Despite being valid only for the reflectionless case, expressions (58) and (59) are consistent with the analyticity conditions [$a_{11}(z)$ is analytical at $|z|>1$ and $a_{22}(z)$ is analytical at $|z|<1$] and parity conditions $a_{kk}(-z)=a_{kk}(z)$ as well as with the normalizing condition (29) and limiting conditions $\lim_{|z|\to\infty} a_{11}(z)=1$ and $\lim_{|z|\to 0} a_{22}(z)=1$. Although not mentioned earlier, the limiting conditions for $a_{kk}(z)$ are a direct consequence of those for the scattering vectors $\mathbf{S}_{kk}(n|z)$, defined by $\mathbf{S}_{kk}(n|z)a_{kk}(z)\equiv\varphi_k(n|z)$.

Adopting the roots $z_{kk}(r)$ in (37) and (38) to be enumerated in accordance with

$$z_{kk}(2s)=-z_{kk}(2s-1) \quad (s=1,2,3,\ldots,N) \tag{60}$$

and using (58) and (59) to find them, we can write $F_{21}(2n+1)$ and $F_{12}(2n+1)$ for the reflectionless case as follows:

$$F_{21}(2n+1)=\sum_{s=1}^{N} b_{21}(s)\exp[-\sigma_{11}(s)n], \tag{61}$$

$$F_{12}(2n+1)=\sum_{s=1}^{N} b_{12}(s)\exp[-\sigma_{22}(s)n]. \tag{62}$$

Here

$$b_{21}(s)\equiv\frac{2a_{21}(z_{11}(2s))}{[z_{11}(2s)]^2 a'_{11}(z_{11}(2s))}, \tag{63}$$

$$b_{12}(s)\equiv-\frac{2a_{12}(z_{22}(2s))}{a'_{22}(z_{22}(2s))}, \tag{64}$$

$$\sigma_{11}(s)\equiv\mu_{11}(s)+ik_{11}(s), \tag{65}$$

$$\sigma_{22}(s) \equiv \mu_{22}(s) - ik_{22}(s). \tag{66}$$

Combining the reduced Marchenko equations (54) and (55) with the explicit expressions for matrix elements of kernel operator (61) and (62) we introduce two auxiliary functions,

$$X_{11}(n|s) \equiv \sum_{m=0}^{\infty} K_{11}(n|n+2m)\exp[-\sigma_{22}(s)m], \tag{67}$$

$$X_{22}(n|s) \equiv \sum_{m=0}^{\infty} K_{22}(n|n+2m)\exp[-\sigma_{11}(s)m], \tag{68}$$

which are proved to be governed by two sets of linear algebraic equations,

$$X_{11}(n|s) - \sum_{s'=1}^{N} X_{11}(n|s')\langle s'|\hat{B}_{12}(n)\hat{B}_{21}(n)|s\rangle = 1 \quad (s=1,2,3,\ldots,N), \tag{69}$$

$$X_{22}(n|s) - \sum_{s'=1}^{N} X_{22}(n|s')\langle s'|\hat{B}_{21}(n)\hat{B}_{12}(n)|s\rangle = 1 \quad (s=1,2,3,\ldots,N). \tag{70}$$

Here

$$\langle s'|\hat{B}_{12}(n)\hat{B}_{21}(n)|s\rangle \equiv \sum_{s''=1}^{N} \langle s'|\hat{B}_{12}(n)|s''\rangle\langle s''|\hat{B}_{21}(n)|s\rangle, \tag{71}$$

$$\langle s'|\hat{B}_{21}(n)\hat{B}_{12}(n)|s\rangle \equiv \sum_{s''=1}^{N} \langle s'|\hat{B}_{21}(n)|s''\rangle\langle s''|\hat{B}_{12}(n)|s\rangle \tag{72}$$

with $\langle s'|\hat{B}_{12}(n)|s''\rangle$ and $\langle s''|\hat{B}_{21}(n)|s'\rangle$ defined by

$$\langle s'|\hat{B}_{12}(n)|s''\rangle = \frac{b_{12}(s')\exp[-\sigma_{22}(s')n]}{1-\exp[-\sigma_{22}(s')-\sigma_{11}(s'')]}, \tag{73}$$

$$\langle s''|\hat{B}_{21}(n)|s'\rangle = \frac{b_{21}(s'')\exp[-\sigma_{11}(s'')n]}{1-\exp[-\sigma_{11}(s'')-\sigma_{22}(s')]}. \tag{74}$$

Then all quantities of interest are seen to be presented in terms of $X_{11}(n|s)$ and $X_{22}(n|s)$ exclusively. Indeed, the direct use of definitions (67) and (68) in formulas (54)–(57) gives rise to

$$K_{11}(n|n) = 1 + \sum_{s'=1}^{N}\sum_{s''=1}^{N} X_{11}(n|s')\langle s'|\hat{B}_{12}(n)|s''\rangle b_{21}(s'')\exp[-\sigma_{11}(s'')n], \tag{75}$$

$$K_{22}(n|n) = 1 + \sum_{s'=1}^{N}\sum_{s''=1}^{N} X_{22}(n|s')\langle s'|\hat{B}_{21}(n)|s''\rangle b_{12}(s'')\exp[-\sigma_{22}(s'')n], \tag{76}$$

$$K_{21}(n|n+1) = -\sum_{s=1}^{N} X_{22}(n|s)b_{21}(s)\exp[-\sigma_{11}(s)n], \tag{77}$$

$$K_{12}(n|n+1) = -\sum_{s=1}^{N} X_{11}(n|s)b_{12}(s)\exp[-\sigma_{22}(s)n]. \tag{78}$$

Thus the only question yet to be handled is to write down the solutions of (69) and (70) explicitly. To do so we define $N\times N$ matrixes $\hat{C}_{11}(n)\equiv[\langle s'|\hat{C}_{11}(n)|s''\rangle]$ and $\hat{C}_{22}(n)\equiv[\langle s'|\hat{C}_{22}(n)|s''\rangle]$ by their matrix elements

$$\langle s'|\hat{C}_{11}(n)|s''\rangle=\delta_{s's''}-\langle s'|\hat{B}_{12}(n)\hat{B}_{21}(n)|s''\rangle \tag{79}$$

and

$$\langle s'|\hat{C}_{22}(n)|s''\rangle=\delta_{s's''}-\langle s'|\hat{B}_{21}(n)\hat{B}_{12}(n)|s''\rangle, \tag{80}$$

respectively, and obtain

$$X_{11}(n|s)=\sum_{s'=1}^{N}\frac{\partial \ln\det \hat{C}_{11}(n)}{\partial\langle s|\hat{C}_{11}(n)|s'\rangle}, \tag{81}$$

$$X_{22}(n|s)=\sum_{s'=1}^{N}\frac{\partial \ln\det \hat{C}_{22}(n)}{\partial\langle s|\hat{C}_{22}(n)|s'\rangle}. \tag{82}$$

Hence according to formulas (33), (34) and (75)–(78) any multisoliton solution of the nonlinear problem (6)–(8) looks as follows:

$$\begin{aligned} q(n)&=iK_{12}(n|n+1)/K_{22}(n|n)\\ &=\frac{-i\sum_{s=1}^{N}X_{11}(n|s)b_{12}(s)\exp[-\sigma_{22}(s)n]}{1+\sum_{s'=1}^{N}\sum_{s''=1}^{N}X_{22}(n|s')\langle s'|\hat{B}_{21}(n)|s''\rangle b_{12}(s'')\exp[-\sigma_{22}(s'')n]}, \end{aligned} \tag{83}$$

$$\begin{aligned} r(n)&=iK_{21}(n|n+1)/K_{11}(n|n)\\ &=\frac{-i\sum_{s=1}^{N}X_{22}(n|s)b_{21}(s)\exp[-\sigma_{11}(s)n]}{1+\sum_{s'=1}^{N}\sum_{s''=1}^{N}X_{11}(n|s')\langle s'|\hat{B}_{12}(n)|s''\rangle b_{21}(s'')\exp[-\sigma_{11}(s'')n]}, \end{aligned} \tag{84}$$

where $X_{11}(n|s)$ and $X_{22}(n|s)$ are given by (81) and (82), respectively. Here, of course, we should understand the scattering data $b_{12}(s)$ and $b_{21}(s)$ to be the time dependent ones:

$$\begin{aligned} b_{12}(s)&\equiv b_{12}(s|\tau)\\ &=b_{12}(s|0)\exp\left\{+2i\eta_0(\tau)+i\sum_{\alpha=1}^{M}[\overset{-}{\eta}_{\alpha}(\tau)\exp(-\alpha\sigma_{22}(s))+\overset{+}{\eta}_{\alpha}(\tau)\exp(+\alpha\sigma_{22}(s))]\right\} \end{aligned} \tag{85}$$

$$\begin{aligned} b_{21}(s)&\equiv b_{21}(s|\tau)\\ &=b_{21}(s|0)\exp\left\{-2i\eta_0(\tau)-i\sum_{\alpha=1}^{M}[\overset{-}{\eta}_{\alpha}(\tau)\exp(+\alpha\sigma_{11}(s))+\overset{+}{\eta}_{\alpha}(\tau)\exp(-\alpha\sigma_{11}(s))]\right\}. \end{aligned} \tag{86}$$

We complete this section by adapting the obtained time dependencies (85) and (86) for the needs of reduction $r(n)=q^*(n)$.

Then the dynamical equations (6) and (7) will be mutually consistent under the constraint $H^*=H$. As a consequence the parameter ω_0 must be purely real, while $\overset{-}{\omega}_\alpha$ and $\overset{+}{\omega}_\alpha$ can be parametrized by two real parameters, ω_α and φ_α. In particular,

$$\overset{-}{\omega}_\alpha=\omega_\alpha\exp(-i\varphi_\alpha), \tag{87}$$

$$\overset{+}{\omega}_\alpha=\omega_\alpha\exp(+i\varphi_\alpha), \tag{88}$$

where in general $\omega_\alpha\equiv\omega_\alpha(\tau)$ and $\varphi_\alpha\equiv\varphi_\alpha(\tau)$ are supposed to be time dependent.

Moreover, calculating the matrix elements of $a^+(1/z^*)a(z)$ and combining them with the normalizing condition (29) we can obtain

$$a_{11}^*(1/z^*)=a_{22}(z), \tag{89}$$

$$a_{21}^*(1/z^*)=-a_{12}(z). \tag{90}$$

These relations yield

$$z_{11}(r)=1/z_{22}^*(r), \tag{91}$$

$$\left[\frac{a_{12}(z_{22}(r))}{a_{22}'(z_{22}(r))}\right]^*=\frac{a_{21}(z_{11}(r))}{[z_{11}(r)]^2a_{11}'(z_{11}(r))}. \tag{92}$$

Hence seeking the multisoliton solutions we have to set

$$\mu_{11}(s)=\mu_{22}(s)\equiv\mu(s), \tag{93}$$

$$k_{11}(s)=k_{22}(s)\equiv k(s), \tag{94}$$

$$b_{12}^*(s)=-b_{21}(s). \tag{95}$$

As a result the expressions (85) and (86) for $b_{12}(s|\tau)$ and $b_{21}(s|\tau)$ can be reduced to

$$b_{12}(s|\tau)=2i\,\mathrm{sh}\mu(s)\exp[\mu(s)x(s)+i\theta(s)]\cdot\exp\left\{+2i\int_0^\tau \mathrm{d}t\;\omega_0(t)+2i\sum_{\alpha=1}^{M}\int_0^\tau \mathrm{d}t\;\omega_\alpha(t)\,\mathrm{ch}[\alpha\mu(s)-i\alpha k(s)+i\varphi_\alpha(t)]\right\}, \tag{96}$$

$$b_{21}(s|\tau)=2i\,\mathrm{sh}\mu(s)\exp[\mu(s)x(s)-i\theta(s)]\cdot\exp\left\{-2i\int_0^\tau \mathrm{d}t\;\omega_0(t)-2i\sum_{\alpha=1}^{M}\int_0^\tau \mathrm{d}t\;\omega_\alpha(t)\,\mathrm{ch}[\alpha\mu(s)+i\alpha k(s)-i\varphi_\alpha(t)]\right\}, \tag{97}$$

where the parametrization

$$b_{12}(s|0)=2i\,\mathrm{sh}\mu(s)\exp[\mu(s)x(s)+i\theta(s)], \tag{98}$$

$$b_{21}(s|0)=2i\,\mathrm{sh}\mu(s)\exp[\mu(s)x(s)-i\theta(s)] \tag{99}$$

has been adopted.

Depending on a particularly chosen swing in amplitudes $\omega_\alpha(\tau)$ and phases $\varphi_\alpha(\tau)$ of coupling parameters the nonlinear dynamical system (6)–(8) might exhibit a variety of absolutely different

regimes of soliton dynamics from the uniform infinite motion to the dynamical localization. We will consider some such regimes in Sec. VII although, in principle, their number appears to be inexhaustible. Of course a variety of effects in soliton dynamics may be caused also by the interplay between the different coupling parameters, which as we know couple the molecules on different spatial distances.

VI. TRANSFORMATION TO THE PHYSICALLY CORRECTED AMPLITUDES

Although the Poisson brackets related to models (6)–(8) are proved to be nonstandard they are unable to cause any discrepancy in physical applications. Indeed, introducing the corrected amplitudes[27]

$$Q(n)=\sqrt{[q(n)/r(n)]\ln[1+q(n)r(n)]}, \tag{100}$$

$$R(n)=\sqrt{[r(n)/q(n)]\ln[1+q(n)r(n)]}, \tag{101}$$

we might always transform any original model (6)–(8) into the standard form

$$+i\dot{Q}(n)=\partial H/\partial R(n)\equiv+i\{H,Q(n)\}, \tag{102}$$

$$-i\dot{R}(n)=\partial H/\partial Q(n)\equiv-i\{H,R(n)\} \tag{103}$$

with the Poisson brackets given by

$$\{Q(n),R(m)\}=+i\delta_{nm}, \quad \{R(n),Q(m)\}=-i\delta_{nm}, \tag{104}$$

$$\{Q(n),Q(m)\}=0, \quad \{R(n),R(m)\}=0. \tag{105}$$

Here, in order to write H in terms of $Q(n)$ and $R(n)$ we simply must substitute

$$q(n)=\sqrt{[\exp(Q(n)R(n))-1]Q(n)/R(n)}, \tag{106}$$

$$r(n)=\sqrt{[\exp(Q(n)R(n))-1]R(n)/Q(n)} \tag{107}$$

into formula (8).

Remarkably, the corrected model (102), (103) possesses the same linear part (18) and (19) as the original one (6)–(8) and hence exhibits the same low amplitude spectrum.

The precise meaning of amplitudes $Q(n)$ and $R(n)$ depends on a particular adopted reduction. For example, in the case when $r(n)=q^*(n)$ [and hence $R(n)=Q^*(n)$] the amplitudes $Q(n)$ and $R(n)$ are nothing but the probability amplitudes since according to expression (12) the total number of excitations,

$$I_0=\sum_{m=-\infty}^{\infty} Q(m)R(m), \tag{108}$$

has to be conserved.

The use of probability amplitudes allows us to calculate the mean value $\langle\Phi(n)\rangle$ of any physical quantity $\Phi(n)$ in the most natural way

$$\langle\Phi(n)\rangle=\frac{\Sigma_{m=-\infty}^{\infty}\Phi(m)Q(m)R(m)}{\Sigma_{m=-\infty}^{\infty}Q(m)R(m)}. \tag{109}$$

In Sec. VII we apply this definition to the analysis of one soliton dynamics.

VII. ONE SOLITON DYNAMICS: PARAMETRICAL LOCALIZATION

Assuming the reduction $r(n)=q^*(n)$ let us discuss the dynamics of the model (6)–(8) in one soliton case $N=1$.

According to general expressions (83), (84) and (96), (97) the one soliton solution itself looks as follows:

$$q(n|\tau)=\frac{\mathrm{sh}\mu\,\exp[+ikn+i\theta-i\int_0^\tau \mathrm{d}t\,\Omega(k|t|\mu)]}{\mathrm{ch}\{\mu[n-x-\int_0^\tau \mathrm{d}t\,v(k|t|\mu)]\}}, \tag{110}$$

$$r(n|\tau)=\frac{\mathrm{sh}\mu\,\exp[-ikn-i\theta+i\int_0^\tau \mathrm{d}t\,\Omega(k|t|\mu)]}{\mathrm{ch}\{\mu[n-x-\int_0^\tau \mathrm{d}t\,v(k|t|\mu)]\}}, \tag{111}$$

where

$$\Omega(k|\tau|\mu)=-2\omega_0(\tau)-2\sum_{\alpha=1}^{M}\omega_\alpha(\tau)\mathrm{ch}(\alpha\mu)\cos[\alpha k-\varphi_\alpha(\tau)], \tag{112}$$

$$v(k|\tau|\mu)=\frac{2}{\mu}\sum_{\alpha=1}^{M}\omega_\alpha(\tau)\mathrm{sh}(\alpha\mu)\sin[\alpha k-\varphi_\alpha(\tau)] \tag{113}$$

and we have denoted $\mu(1)\equiv\mu$, $k(1)\equiv k$, $x(1)\equiv x$, $\theta(1)\equiv\theta$.

To analyze this solution we rely on the explicit formula for the coordinate of soliton center

$$x(k|\tau|\mu)\equiv\langle n\rangle_s=x+\int_0^\tau \mathrm{d}t\,v(k|t|\mu)\,. \tag{114}$$

We also estimate the typical soliton width $d(\langle n\rangle_s)$ defined by

$$d(\langle n\rangle_s)=2\sqrt{\langle(n-\langle n\rangle_s)^2\rangle_s}. \tag{115}$$

Here the brackets $\langle\ \rangle_s$ stand for the average operation (109) taken on the corrected [according to (100) and (101)] one-soliton amplitudes (110) and (111). The result written on the right-hand side of expression (114) is an exact one and has been calculated via the well-known Poisson summation formula [see, e.g., formula (A2) in the Appendix].

From expression (114) we clearly see that x marks the coordinate of soliton center in an initial moment $\tau=0$ whereas $v(k|\tau|\mu)$ describe the velocity of the soliton center in an arbitrary moment. According to formula (113) this velocity consists of superposition of partial velocities emanated from the different coupling parameters. The αth partial velocity is determined by the amplitude $\omega_\alpha(\tau)$ and phase $\varphi_\alpha(\tau)$ modulations of the αth coupling parameter as well as by the product αk. The amplitude of the αth partial velocity in turn is enhanced by the factor $(2/\mu)\mathrm{sh}(\alpha\mu)$.

In a particular case of uniform motion, when the nonlinear system (6)–(8) is parametrically undriven $\omega_\alpha(\tau)\equiv\omega_\alpha(0)$ and $\varphi_\alpha(\tau)\equiv\varphi_\alpha(0)$, the parameter k may be identified with the momentum of a soliton as a whole. However in general this meaning may be completely devaluated.

Indeed assuming that $\omega_\alpha(\tau)\equiv\omega_\alpha(0)$ and $\varphi_\alpha(\tau)\equiv\varphi_\alpha(0)-\mathcal{E}_\alpha(0)\tau$ we come to the case of parametrically localized soliton dynamics with the coordinate of soliton center oscillating by the law

$$x(k|\tau|\mu)=x-\frac{2}{\mu}\sum_{\alpha=1}^{M}\frac{\omega_\alpha(0)}{\mathcal{E}_\alpha(0)}\mathrm{sh}(\alpha\mu)\{\cos[\mathcal{E}_\alpha(0)\tau+\alpha k-\varphi_\alpha(0)]-\cos[\alpha k-\varphi_\alpha(0)]\} \tag{116}$$

on a confined domain of space. Thus we have obtained the superposition of incommensurate oscillations where the product αk simply merges with the initial phase $\varphi_\alpha(0)$ of the respective coupling parameter. When the partial frequencies $|\mathcal{E}_\alpha(0)|/2\pi$ are decreased the amplitudes of oscillations are increased so that in the limit of zero frequencies $|\mathcal{E}_\alpha(0)|/2\pi \to 0$ we come back to the case of uniform soliton motion on an unconfined spatial domain,

$$x(k|\tau|\mu) = x + \frac{2\tau}{\mu} \sum_{\alpha=1}^{M} \omega_\alpha(0)\,\mathrm{sh}(\alpha\mu)\sin[\alpha k - \varphi_\alpha(0)]. \tag{117}$$

Of course in the general case of an arbitrary parametrical swing the soliton center might exhibit rather complex dynamics, e.g., the regular drift and oscillations combined.

Calculating the soliton width $d(\langle n\rangle_s)$ (see the Appendix for some details) we have observed that it has to breathe between its two extreme values $d_{\min} \equiv d(0)$ and $d_{\max} \equiv d(\pm 1/2)$, although the peculiarities of such oscillations should undoubtedly be governed by a particular dynamics of soliton center. At $\mu \ll 1$ the amplitude of this breathing mode is exponentially suppressed and both extreme soliton widths $d(0)$ and $d(\pm 1/2)$ become practically indistinguishible: $d(0) \simeq d(\pm 1/2) \simeq \pi/\mu\sqrt{3}$. However at $\mu > 1$ the breathing effect is strictly pronounced and the soliton width is determined not only by the parameter $1/\mu$ but also by the position of soliton center-of-mass $\langle n\rangle_s$ with the easily checked properties $d(y) = d(y - [y])$ and $d(-y) = d(y)$ bearing in mind. Specifically for $d(0)$ and $d(\pm 1/2)$ at large μ (i.e., at $\mu \gg 1$) we have $d(0) \simeq \sqrt{(4/\mu)\ln 2}$ and $d(\pm 1/2) \simeq 1$. These results have nothing to do with those for continuous integrable models where the soliton width d could not breathe and is determined by the single parameter $1/\mu$ via unique formula $d = \pi/\mu\sqrt{3}$ at all positive μ.

It is interesting to note that the one soliton solution (110), (111) is also characterized by the time-dependent cyclic frequency $\Omega(k|\tau|\mu)$ (112) which is formally analogous to the energy spectrum of the low amplitude mode with k playing the role of wave number. This analogy becomes especially clear in the limit of wide solitons $\mu \to 0$ when the identity

$$v(k|\tau|0) = \partial\Omega(k|\tau|0)/\partial k, \tag{118}$$

similar to the definition of group velocity of planar wave holds. The frequency $\Omega(k|\tau|\mu)$ (112) consists of partial frequencies and might exhibit the nonmonotonic dependence on parameter k. The latter facts extend the general rule established for the low amplitude excitations in spatially regular structures with the long-range interaction[28] to the case of soliton-like excitations.

VIII. DISCRETE NONLINEAR SCHRÖDINGER SYSTEMS IN LINEAR POTENTIAL: BLOCH OSCILLATIONS

Let us consider the dynamical system

$$+i\dot{q}(n) = [1 + q(n)r(n)]\partial\mathcal{H}/\partial r(n), \tag{119}$$

$$-i\dot{r}(n) = [1 + q(n)r(n)]\partial\mathcal{H}/\partial q(n) \tag{120}$$

with the Hamiltonian

$$\mathcal{H} = -2\omega_0 I_0 - \sum_{m=-\infty}^{\infty} \mathcal{E}m \ln[1 + q(m)r(m)] - \sum_{\alpha=1}^{M} \omega_\alpha[\exp(-i\psi_\alpha)\bar{I}_\alpha + \exp(+i\psi_\alpha)\overset{+}{I}_\alpha], \tag{121}$$

where $\omega_0 \equiv \omega_0(\tau)$, $\omega_\alpha \equiv \omega_\alpha(\tau)$, $\psi_\alpha \equiv \psi_\alpha(\tau)$, and $\mathcal{E} \equiv \mathcal{E}(\tau)$ are supposed to be time-dependent real parameters, whereas $r(n) \equiv q^*(n)$. At $\mathcal{E} = 0$ and $\psi_\alpha = \varphi_\alpha$ this system coincides literally with that given by (6)–(8) provided the reduction $r(n) = q^*(n)$ is adopted and the parametrization (87) and (88) is used. At $\mathcal{E} \neq 0$ the system (119)–(121) can be treated as the parametrically driven system of

nonlinear Schrödinger type subjected to linear potential with strength $\mathcal{E}$. The latter statement becomes especially clear when we reformulate the model (119)–(121) in terms of corrected amplitudes (100) and (101).

The question arises whether it is possible to convert the system (119)–(121) into the form

$$+i\dot{q}(n)=[1+q(n)r(n)]\partial H/\partial r(n), \tag{122}$$

$$-i\dot{r}(n)=[1+q(n)r(n)]\partial H/\partial q(n), \tag{123}$$

$$H=-2\omega_0 I_0-\sum_{\alpha=1}^{M}\omega_\alpha[\exp(-i\varphi_\alpha)\bar{I}_\alpha+\exp(+i\varphi_\alpha)\overset{+}{I}_\alpha], \tag{124}$$

and hence to integrate it by the inverse scattering transform.

In a particular case of nearest-neighboring coupling $M=1$ with $\omega_1(\tau)=1$ and $\psi_1(\tau)=0$ the answer is known to be positive,[29] which actually had been preordained earlier in Refs. 30 and 31.

In the general case of a parametrically driven system with the exploding range of intersite couplings in the presence of linear potential (119)–(121), the reply happens to be positive too. Indeed, replacing $q(n)$ and $r(n)$ in (119)–(121) by the rule

$$q(n)\to q(n)\exp\left[+in\int_0^\tau \mathrm{d}t\,\mathcal{E}(t)\right], \tag{125}$$

$$r(n)\to r(n)\exp\left[-in\int_0^\tau \mathrm{d}t\,\mathcal{E}(t)\right], \tag{126}$$

we readily come to the system (122)–(124) with $\varphi_\alpha(\tau)$ given by

$$\varphi_\alpha(\tau)=\psi_\alpha(\tau)-\alpha\int_0^\tau \mathrm{d}t\,\mathcal{E}(t). \tag{127}$$

Thus in order to obtain the solutions $q(n)$ and $r(n)$ of the system in linear potential (119)–(121) we have to multiply the solutions of the system without linear potential (122)–(124) on $\exp[+in\int_0^\tau \mathrm{d}t\,\mathcal{E}(t)]$ and $\exp[-in\int_0^\tau \mathrm{d}t\,\mathcal{E}(t)]$, respectively, substituting simultaneously expression (127) for $\varphi_\alpha(\tau)$.

We demonstrate this recipe for system (119)–(121) with the constant parameters $\omega_0\equiv\omega_0(0)$, $\omega_\alpha=\omega_\alpha(0)$, $\psi_\alpha\equiv\psi_\alpha(0)$, and $\mathcal{E}\equiv\mathcal{E}(0)$ on an example of one soliton solution and obtain

$$q(n|\tau)=\frac{\mathrm{sh}\mu\,\exp[+i(k+\mathcal{E}(0)\tau)n+i\theta-i\int_0^\tau \mathrm{d}t\,\Omega(k|t|\mu)]}{\mathrm{ch}\{\mu[n-x(k|\tau|\mu)]\}}, \tag{128}$$

$$r(n|\tau)=\frac{\mathrm{sh}\mu\,\exp[-i(k+\mathcal{E}(0)\tau)n-i\theta+i\int_0^\tau \mathrm{d}t\,\Omega(k|t|\mu)]}{\mathrm{ch}\{\mu[n-x(k|\tau|\mu)]\}}. \tag{129}$$

Here

$$\int_0^\tau \mathrm{d}t\,\Omega(k|t|\mu)=-2\omega_0(0)\tau - 2\sum_{\alpha=1}^{M}\frac{\omega_\alpha(0)}{\alpha\mathcal{E}(0)}\mathrm{ch}(\alpha\mu)\{\sin[\alpha\mathcal{E}(0)\tau+\alpha k-\psi_\alpha(0)]-\sin[\alpha k-\psi_\alpha(0)]\}, \tag{130}$$

$$x(k|\tau|\mu)=x-\frac{2}{\mu}\sum_{\alpha=1}^{M}\frac{\omega_\alpha(0)}{\alpha\mathcal{E}(0)}\mathrm{sh}(\alpha\mu)\{\cos[\alpha\mathcal{E}(0)\tau+\alpha k-\psi_\alpha(0)]-\cos[\alpha k-\psi_\alpha(0)]\}. \tag{131}$$

Thus the linear potential of constant strength $\mathcal{E}(0)$ gives rise to the dynamically localized soliton motion in a parametrically undriven system resembling the parametrically localized soliton dynamics described in Sec. VII. However here the frequencies of oscillations $\alpha|\mathcal{E}(0)|/2\pi$ are bound to be commensurate and are determined by the single parameter $\mathcal{E}(0)$, i.e., by the strength of external field.

In condensed matter physics the oscillations caused by the interplay between the linear potential and the spatial discreteness of the lattice are known as the Bloch oscillations.[32,33] Such effects are experimentally observable only in spatially discrete systems (e.g., on semiconductor superlattices[34]) and are principally forbidden in continuous ones. When related to the bent arrays of optical waveguides, the effects, generally analogous to those of Bloch oscillations and dynamical localization, have also recently been described.[35]

IX. CONCLUSION

Summarizing, we have shown how to extend step by step the range of intersite interactions in discrete nonlinear Schrödinger systems generated by the Ablowitz–Ladik auxiliary spectral problem. As a result it is possible to obtain the sequence of nonlinear models with the Hamiltonians given by some special type of linear superpositions of conserved quantities. However unlike in the standard Ablowitz–Ladik hierarchy, where the superposing coefficients are assumed to be constant, we have observed that they may be either constants or arbitrary functions of time. These superposing coefficients play the role of intersite coupling parameters and hence in general can beget the parametrically driven systems with rather rich soliton dynamics. The Hamiltonian of any such parametrically driven system is not bound to be conserved, however the system itself still remains to be integrable by the inverse scattering transform.

We have revealed an important subclass of parametrically driven systems demonstrating the effects of parametric localization of solitons on a confined domain of space and have analyzed the corresponding one soliton dynamics.

In some particular cases it is possible to establish the formal equivalence between the original parametrically driven system and another parametrically driven system but subjected to the additional linear potential. When the strength of the potential field is constant the total Hamiltonian of the new dynamical system becomes conserved, provided its coupling parameters are time independent. Nevertheless the infinite soliton trajectories in the latter system are forbidden due to the so-called dynamical localization accompanied by the Bloch–Zener oscillations of soliton center of mass.

We point out once again that the alternative method of solving the Marchenko equations developed here appears to be more straightforward than the early known ones.[4,17–19] The final formulas for the multisoliton solutions (83) and (84) are also the original ones. Moreover, unlike in the usual approaches, they were derived for the most general case relinquishing any particular reduction for the amplitudes $q(n)$ and $r(n)$. The detailed analysis of such unreduced solutions goes beyond the scope of present report, however, the interested reader could look through their one soliton prototype recently obtained for the undriven nonlinear Schrödinger system on a ladder lattice with nearest-neighboring intermolecular couplings [see formulas (86) and (87) in Ref. 7].

Finally we have reformulated the models of interest in terms of corrected amplitudes with the standard Poisson brackets, which sometimes seems to be a necessary step useful for physical applications. So we have presented the explicit formulas of respective transformations.

We believe that the wide possibilities in extending the range of intersite interactions as well as in appropriate choice of coupling parameters (i.e., their strengths and time dependencies) could stimulate the described class of parametrically driven integrable models to be applied to the needs of different physically motivated discrete quasi-one-dimensional systems.[14–16,34,35]

APPENDIX: CALCULATIONS OF SQUARED SOLITON WIDTH

According to definition (115) the squared typical soliton width $d^2(y)$ as a function of mean coordinate of soliton pattern $x(k|\tau|\mu)\equiv y$ can be presented in the form

$$d^2(y)=\frac{4\Sigma_{m=-\infty}^{\infty}(m-y)^2\ln[1+\mathrm{sh}^2\mu\,\mathrm{sech}^2\,\mu(m-y)]}{\Sigma_{m=-\infty}^{\infty}\ln[1+\mathrm{sh}^2\mu\,\mathrm{sech}^2\mu(m-y)]}. \tag{A1}$$

Applying the Poisson summation formula[36]

$$\sum_{m=-\infty}^{\infty}V(m)=\sum_{f=-\infty}^{\infty}\int_{-\infty}^{\infty}\mathrm{d}\eta\exp(2\pi i f\eta)V(\eta) \tag{A2}$$

to the denominator of (A1) we obtain

$$\sum_{m=-\infty}^{\infty}\ln[1+\mathrm{sh}^2\mu\,\mathrm{sech}^2\,\mu(m-y)]=2\mu \tag{A3}$$

and hence

$$d^2(y)=\frac{2}{\mu}\sum_{m=-\infty}^{\infty}(m-y)^2\ln[1+\mathrm{sh}^2\mu\,\mathrm{sech}^2\,\mu(m-y)]. \tag{A4}$$

From this expression we see clearly that both $d^2(-y)$ and $d^2(y\pm1)$ coincide with $d^2(y)$, i.e., $d^2(y)$ is an even periodic function of its argument with the period equal to unity or the same to the lattice constant. Another confirmation of this statement follows from an alternative expression

$$d^2(y)=\frac{2}{3}\left[1+\frac{1}{2}(\pi/\mu)^2\right]-\frac{4}{\mu}\sum_{f=1}^{\infty}\frac{\cos(2\pi fy)}{f\,\mathrm{sh}(\pi^2 f/\mu)} \tag{A5}$$

obtainable within the framework of Poisson summation formula (A2).

Formula (A5) allows us to detect at least two sets of extremums, namely at $y=\ldots,-2,-1,0,+1,+2,\ldots$ and at $y=\ldots,-3/2,-1/2,+1/2,+3/2,\ldots$ corresponding to the location of the soliton center on a lattice site and precisely between two neighboring lattice sites, respectively. All of the extremums in a particular set are physically equivalent due to periodicity of $d^2(y)$. Hence we can restrict ourselves to the interval $-1/2\leqslant y\leqslant+1/2$. Evidently $d^2(0)<d^2(\pm1/2)$ and moreover $d^2(0)$ is seen to be the smallest possible value of $d^2(y)$. As to the value $d^2(\pm1/2)$ we claim it to be an absolute maximum of $d^2(y)$ relying on the direct computer simulations with the formula (A4) as well as on the analytical estimations by formula (A4) at $\mu\gg1$ and by formula (A5) at $\mu\ll1$.

For the sake of convenience we will write down here one more result of summation

$$\sum_{m=-\infty}^{\infty}m\ln[1+\mathrm{sh}^2\mu\,\mathrm{sech}^2\,\mu(m-y)]=2\mu y, \tag{A6}$$

which along with formula (A3) becomes useful in calculating the mean coordinate of soliton pattern (114).

Piezoelectricity and Piezomagnetism: Duality in two-dimensional checkerboards

Leonid G. Fel[a)]
School of Physics and Astronomy, Raymond and Beverly Sackler Faculty of Exact Sciences, Tel Aviv University, Tel Aviv 69978, Israel

(Received 1 March 2001; accepted for publication 30 January 2002)

The duality approach in two-dimensional two-component regular checkerboards is extended to piezoelectricity and piezomagnetism. The relation between the effective piezoelectric and piezomagnetic moduli is found for a checkerboard with the $p6'mm'$-plane symmetry group (*dichromatic triangle*). © *2002 American Institute of Physics.* [DOI: 10.1063/1.1466881]

I. INTRODUCTION

A duality transformation for two-dimensional (2D) heterogeneous composites was discovered by Keller[1] and Dykhne.[2] It is based upon the simple observation that any 2D divergence-free vector field, when rotated locally at each point by 90° becomes curl free and vice versa. This leads to duality relations for the effective physical properties of 2D two-component composites, like electrical conductivity $\hat{\sigma}_{\mathsf{ef}}$, thermal conductivity $\hat{\kappa}_{\mathsf{ef}}$, and other second rank symmetric tensors $\hat{\upsilon}_{\mathsf{ef}}$. All these physical problems can be described by the same set of equations

$$\mathbf{Y}=\hat{\upsilon}\cdot\mathbf{X}, \quad \nabla\cdot\mathbf{Y}=\nabla\times\mathbf{X}=0, \quad \hat{\upsilon}_{ij}=\hat{\upsilon}_{ji}. \tag{1}$$

The duality relations are universal[3] and do not depend on composite's microstructure. For nonisotropic structures they become[2,4]

$$\det\hat{\upsilon}_{\mathsf{ef}}=\sqrt{\det\hat{\upsilon}_{\mathsf{a}}\cdot\det\hat{\upsilon}_{\mathsf{b}}}, \tag{2}$$

where subscripts ''a'' and ''b'' correspond to the a and b components of composite, respectively, while ''ef'' denotes an effective medium.

The further attempts[5] to extend the dual symmetry onto 2D elasticity

$$\mathbf{u}^{ij}=\hat{\mathcal{K}}^{ij}_{kl}\cdot\tau_{kl}, \quad \sum_j \partial_j\tau_{ij}=0, \tag{3}$$

$$\partial^2_{yy}u^{xx}+\partial^2_{xx}u^{yy}=2\ \partial^2_{xy}u^{xy} \tag{4}$$

had shown no duality transformation for the strain $\mathbf{u}^{ij}$ and the stress $\hat{\tau}_{kl}$ tensor fields. Therefore, one cannot write a duality relation for the fourth rank compliance tensor $\hat{\mathcal{K}}^{ij}_{kl}$.

In this paper we consider physical phenomena which one can describe using the third rank tensors when a high symmetry of 2D two-component checkerboard makes it possible to exploit the duality transformation. The best known phenomena are the piezoelectricity and the piezomagnetism.

II. DUALITY RELATIONS

Let us consider a homogeneous 2D medium under mechanical stress $\hat{\tau}$, which produces a dielectric displacement **D** and a magnetic induction **B**,

$$D^i=\hat{e}^i_{jk}\cdot\tau_{jk},\quad B^i=\hat{m}^i_{jk}\cdot\tau_{jk},\quad \tau_{jk}=\tau_{kj},$$
$$\nabla\cdot\mathbf{D}=\nabla\cdot\mathbf{B}=0,\quad \sum_j \partial_j\tau_{ij}=0. \tag{5}$$

The piezoelectric $\hat{e}^i_{jk}$ and the piezomagnetic $\hat{m}^i_{jk}$ coefficients are polar and axial tensors of the rank three, respectively,

$$\hat{e}^i_{jk}=\hat{e}^i_{kj},\quad \hat{m}^i_{jk}=\hat{m}^i_{kj}.$$

In order to represent this problem in a form similar to (1) we define the following vectors:

$$\mathbf{t}_1=(\tau_{xx},\tau_{xy}),\quad \mathbf{t}_2=(\tau_{yx},\tau_{yy}),\quad \nabla\cdot\mathbf{t}_k=0, \tag{6}$$

that simplifies (5)

$$\mathbf{D}=\hat{g}_{11}\cdot\mathbf{t}_1+\hat{g}_{12}\cdot\mathbf{t}_2,\quad \mathbf{B}=\hat{g}_{21}\cdot\mathbf{t}_1+\hat{g}_{22}\cdot\mathbf{t}_2. \tag{7}$$

It is convenient to represent each of the tensors $\hat{e}^i_{jk}$, $\hat{m}^i_{jk}$ by two nonsymmetric tensors of the second rank

$$\hat{g}_{11}=\begin{pmatrix} e^x_{xx} & e^x_{xy}\\ e^y_{xx} & e^y_{xy}\end{pmatrix},\quad \hat{g}_{12}=\begin{pmatrix} e^x_{yx} & e^x_{yy}\\ e^y_{yx} & e^y_{yy}\end{pmatrix},$$
$$\hat{g}_{21}=\begin{pmatrix} m^x_{xx} & m^x_{xy}\\ m^y_{xx} & m^y_{xy}\end{pmatrix},\quad \hat{g}_{22}=\begin{pmatrix} m^x_{xy} & m^x_{yy}\\ m^y_{xy} & m^y_{yy}\end{pmatrix}. \tag{8}$$

The general case of the inner symmetry allows only six independent piezomoduli of each tensor $\hat{e}^i_{jk}$ and $\hat{m}^i_{jk}$.

Our approach is based on the validity of the matrix identities for a special kind of inner symmetry group G of the transport tensors $\hat{g}_{kl}(G)$:

$$\hat{g}_{11}(G)=\hat{M}\cdot\hat{g}_{21}(G),\quad \hat{g}_{12}(G)=\hat{M}\cdot\hat{g}_{22}(G), \tag{9}$$

where $\hat{M}$ is a nondegenerated 2×2 transform matrix. This point symmetry group G will be specified later.

The relation

$$\mathbf{D}=\hat{M}\cdot\hat{g}_{21}(G)\cdot\mathbf{t}_1+\hat{M}\cdot\hat{g}_{22}(G)\cdot\mathbf{t}_2=\hat{M}\cdot\mathbf{B} \tag{10}$$

makes our problem similar to (1) if we link a divergence-free field **D** and a curl-free field $\hat{\mathcal{R}}\mathbf{B}$,

$$\mathbf{D}=\hat{L}\cdot\hat{\mathcal{R}}\mathbf{B},\quad \hat{L}=\hat{M}\cdot\hat{\mathcal{R}}^{-1},$$
$$\nabla\cdot\mathbf{D}=\nabla\times\hat{\mathcal{R}}\mathbf{B}=0,\quad \hat{\mathcal{R}}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}. \tag{11}$$

Here $\hat{\mathcal{R}}$ is a 90° rotation operator. Applying the duality transformation to (11) and making use of the relation (2) results in

$$\det \hat{M}_{\mathrm{ef}} = \sqrt{\det \hat{M}_{\mathrm{a}} \cdot \det \hat{M}_{\mathrm{b}}}. \tag{12}$$

III. SYMMETRY CONSIDERATIONS

Let us look for such symmetry group G that makes valid two relations (9), which can be reduced

$$\hat{g}_{11} = \hat{g}_{12} \cdot \hat{g}_{22}^{-1} \cdot \hat{g}_{21}. \tag{13}$$

This should be satisfied not accidentally.

Following Ref. 6 we recall some basic facts about a coexistence of piezoelectric and piezomagnetic properties in anisotropic media. In three-dimensional media there exist 45 Shubnikov point groups permitting both piezoelectricity and piezomagnetism. In general case the forms of $\hat{e}^i_{jk}$ and $\hat{m}^i_{jk}$ coincide[6] only in 20 point groups (9 ferromagnetic and 11 antiferromagnetic). In 2D media these numbers diminish: there are only 4 ferromagnetic point groups 1, m', 3, $3m'$. Let us consider the point group $G=3$ which leaves only two independent piezomoduli of each tensor $\hat{e}^i_{jk}$ and $\hat{m}^i_{jk}$,[7]

$$\begin{aligned} \hat{g}_{11}(3) &= \begin{pmatrix} e_1 & e_2 \\ e_2 & -e_1 \end{pmatrix}, \quad \hat{g}_{12}(3) = \begin{pmatrix} e_2 & -e_1 \\ -e_1 & -e_2 \end{pmatrix}, \\ \hat{g}_{21}(3) &= \begin{pmatrix} m_1 & m_2 \\ m_2 & -m_1 \end{pmatrix}, \quad \hat{g}_{22}(3) = \begin{pmatrix} m_2 & -m_1 \\ -m_1 & -m_2 \end{pmatrix}, \end{aligned} \tag{14}$$

where e_k, m_k are real numbers. It is easy to see that matrices (14) satisfy the requirement (13) and $\hat{M}$ is an antisymmetric positive definite matrix

$$\hat{M} = \frac{1}{m_1^2 + m_2^2} \begin{pmatrix} m_1 e_1 + m_2 e_2 & m_2 e_1 - m_1 e_2 \\ m_1 e_2 - m_2 e_1 & m_1 e_1 + m_2 e_2 \end{pmatrix}. \tag{15}$$

Up to this moment we have not specified a crystallographic type of two-component tessellation of the plane since according to Ref. 3 a duality relation is universal there. Due to Curie principle[8] the point symmetry group G_{ef} of a physical phenomenon in composed medium is a maximal common subgroup of the microstructure group G_{st} and inner symmetry groups G_{a}, G_{b} of this phenomenon in both components "a," "b"

$$G_{\mathrm{ef}} = G_{\mathrm{st}} \cap G_{\mathrm{a}} \cap G_{\mathrm{b}}. \tag{16}$$

We will look for 2D checkerboards with regular *dichromatic* tessellation by polygons that are compatible with point symmetry group $G=3$. From 46 *dichromatic plane mosaics*[9] the only compatible is *dichromatic triangle* which possesses a $p6'mm'$-plane group (Fig. 1). The choice of the three-symmetry is not accidental but is concerned with the special properties of the transport tensors $\hat{g}_{kl}$ in (14), namely,

$$3 = 6'mm' \cap 3 \cap 3.$$

Making use of (12) and (15) after simple algebra we obtain finally

$$\frac{e_{1\mathrm{ef}}^2 + e_{2\mathrm{ef}}^2}{m_{1\mathrm{ef}}^2 + m_{2\mathrm{e}}^2} = \sqrt{\frac{e_{1\mathrm{a}}^2 + e_{2\mathrm{a}}^2}{m_{1\mathrm{a}}^2 + m_{2\mathrm{a}}^2} \cdot \frac{e_{1\mathrm{b}}^2 + e_{2\mathrm{b}}^2}{m_{1\mathrm{b}}^2 + m_{2\mathrm{b}}^2}}. \tag{17}$$

If the inner symmetry G_{a}, G_{b} will be upgraded up to $G=3m'$ we have in (14): $e_2 = m_2 = 0$, and the duality relation (17) looks more simple

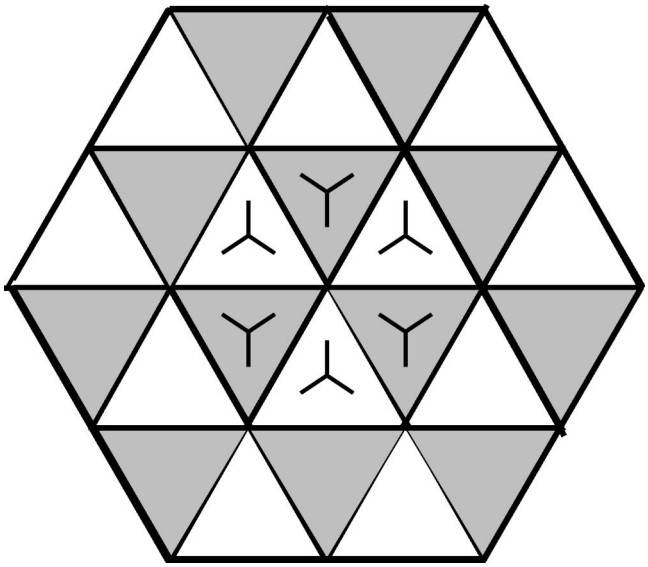

FIG. 1. Dichromatic plane mosaic $G_{\mathrm{st}}p6'mm'$. The principal axes of inner medium symmetry $G_{\mathrm{a}}=G_{\mathrm{b}}=3$ are pointed out within the triangles.

$$\frac{e_{1\mathrm{ef}}^2}{m_{1\mathrm{ef}}^2}=\left|\frac{e_{1\mathrm{a}}}{m_{1\mathrm{a}}}\cdot\frac{e_{1\mathrm{b}}}{m_{1\mathrm{b}}}\right|. \tag{18}$$

Note that Eq. (7) does not permit one to write the duality relations for the piezoelectric $\hat{e}_{jk}^{i}$ and piezomagnetic $\hat{m}_{jk}^{i}$ tensors separately.

IV. CONCLUSION

In the present paper we have considered the coexistence of the piezoelectric and the piezomagnetic phenomena in 2D two-component composites with triangular tessellation of the plane ($p6'mm'$-plane symmetry group). The duality approach for 2D two-component regular composites was extended onto physical problem dealt with third rank tensors.

In the conclusion we will mention some compounds which have a trigonal symmetry and the piezoelectricity and the piezomagnetism coexist.[10] These are the rare-earth maganites having the overall formula $RMnO_3$, where R=Y, Ho, Er, Tm, Yb, Lu, or Sc. The Mn atoms lie inside the bipyramidial bonds, while the rare-earth atoms lie inside the bipyramids.

A new approach to static force-free electromagnetic fields

Barton L. Willis[a)]

(Received 29 May 2001; accepted for publication 18 January 2002)

In the early 1950s, Lundquist showed the significance of electromagnetic fields with a vanishing Lorentz force density to magnetohydrostatic fluids. Today, these fields are known as force-free electromagnetic fields. Later that decade, Lüst and Schlüter demonstrated that cosmic magnetic fields are force-free and Chandrasekhar and Kendall then constructed a large class of force-free fields whose electric charge density field is also vanishing. In this article, we constructed force-free fields without assuming that the electric charge density vanishes, and in some cases we established a connection between force-free fields and nonlinear Schrödinger equations. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1465099]

I. INTRODUCTION

In his study of magnetohydrostatic fluids in the early 1950s, Lundquist[1] showed the significance of electromagnetic fields with a vanishing Lorentz force density. Such fields are now known as force-free fields. Later, in the mid-1950s Lüst and Schlüter[2] noted that cosmic magnetic fields are force-free. A few years later, Chandrasekhar and Kendall,[3,4] working from the assumption that the electric charge density vanishes, characterized a large class of force-free fields by resolving the magnetic field into its poloidal and toroidal components, and they called these fields *force-free magnetic* fields. In this case, the electric and magnetic terms in the force density are separately equal to zero. For recent work on such fields, the reader should consult Marsh,[5,6] Neukirch and Rastätter,[7] Démoulin, Cuperman, and Semel,[8] and Cuperman, Li, and Semel.[9] Additionally, recent work by MacLeod[10] has characterized force-free magnetic fields by making use of the work of Moses[11] on the eigenfunctions of the curl.

Force-free magnetic fields have many applications to cosmic magnetic fields, magnetic clouds, and magnetohydrodynamics in general.[12–14] Two recent review articles[15,16] discuss the astrophysical significance of force-free magnetic fields; additionally, there is an older review article by Michel.[17] In comparison to force-free magnetic fields, the more general concept of a force-free field has received less attention. Some work on general force-free fields has been done by Chu and Ohkawa,[18,19] who have investigated fields with **E** and **B** parallel. The investigations most closely related to this article are the articles by Osherovich[20,21] and Osherovich and Gliner.[22] The first two of these articles investigates oscillations of cylindrically symmetric force-free fields; the third presents an example of a force-free electromagnetic wave in one space and one time dimension. Central to these three papers is the use of the Poisson bracket to demonstrate a functional dependence. We make extensive use of functional dependency between fields and potentials as well.

The theory of force-free magnetic fields is well developed, but a theory of more general force-free fields is lacking. In this article, we partially fill this gap by introducing techniques for constructing force-free fields with nonvanishing electric charge density and with planar and rotational symmetry. Assuming Gaussian units, the static Maxwell equations are

$$\nabla\cdot\mathbf{B}=0, \quad \nabla\cdot\mathbf{E}=4\pi\rho,$$

a)Electronic mail: willisb@unk.edu

$$\nabla\times\mathbf{B}=\frac{4\pi}{c}\mathbf{J},\quad \nabla\times\mathbf{E}=\mathbf{0}.$$

Specifically, we construct fields for which

$$0=\mathbf{J}\cdot\mathbf{E},\quad \mathbf{0}=\rho\mathbf{E}+\frac{1}{c}\mathbf{J}\times\mathbf{B}.$$

We begin with the observations that when the charge density ρ is nonzero, the second condition implies the first, and further, again when ρ is nonzero, these conditions also imply that $\mathbf{E}$ and $\mathbf{B}$ are perpendicular.

We cover planar symmetry in Sec. II and rotational symmetry in Sec. III. Finally, in Sec. IV, a general result on force-free null fields is given.

II. PLANAR SYMMETRY

In this section, we construct two types of force-free fields with planar symmetry. For the first field, we assume that the magnetic field is parallel to the z axis, and for the second we assume that the electric and magnetic fields are coplanar.

For the first case, we set $\mathbf{E}=-\nabla\Phi$ and $\mathbf{B}=g\mathbf{k}$, where the functions Φ and g are z independent and $\mathbf{k}$ is the standard Cartesian unit vector. The Maxwell equations $\operatorname{div}\mathbf{B}=0$ and $\operatorname{curl}\mathbf{E}=\mathbf{0}$ are satisfied while $\mathbf{J}\cdot\mathbf{E}=0$ implies

$$0=g_y\Phi_x-g_x\Phi_y,$$

where the subscripts indicate partial derivatives. From this we conclude that $\nabla\Phi$ and ∇g are parallel; therefore, Φ and g are functionally dependent. Thus we introduce a function $U:\mathbf{R}^1\rightarrow\mathbf{R}^1$ for which $g=U(\Phi)$. [Here, and throughout this paper, by $U(\Phi)$ we mean the composition of U with Φ.] Using this relation to eliminate g in the expression for the Lorentz force density, we obtain a nonlinear Schrödinger equation for the potential

$$-\Delta\Phi+(UU')(\Phi)=0. \tag{1}$$

The function U is arbitrary; however, if $U(x)=k\sqrt{x^2+c^2}$, where k and c are real constants, Eq. (1) reduces to a Helmholtz equation. In this case, the charge density is proportional to the electric potential.

Assuming Φ is a function of the cylindrical coordinate r only, the solutions to Eq. (1) have a simple representation. Provided $\mathbf{E}$ vanishes toward infinity, the fields are given by

$$\mathbf{E}(r)=\pm\left(g^2(r)+(2/r^2)\int_r^\infty sg^2(s)\mathrm{d}s\right)^{1/2}\mathbf{e}_r,$$

$$\mathbf{B}(r)=g(r)\mathbf{e}_z,$$

where g is any integrable function that vanishes sufficiently rapidly toward infinity and $\mathbf{e}_r$ and $\mathbf{e}_z$ are the usual cylindrical coordinate unit vectors. The electric field diverges like $1/r$ toward the origin. As an example, let

$$g(r)=-\frac{\sigma\exp(-r/\mu)}{\sqrt{2}\pi\mu},$$

where μ and σ are real positive constants. Then

$$\mathbf{E}(r)=\pm\frac{\sigma\sqrt{2\,r^2+2\,\mu r+\mu^2}\,\exp(-r/\mu)}{2\,\pi\mu r}\mathbf{e}_r,$$

$$\mathbf{B}(r)=-\frac{\sigma\exp(-r/\mu)}{\sqrt{2}\,\pi\mu}\mathbf{e}_z.$$

The charge per unit length is $\mp\sigma$.

For the second case, we assume that **E** and **B** are coplanar. To proceed, we introduce an analytic function $u+iv$ and we set **E** and **B** equal to

$$\mathbf{E}=\nabla H(u)=H'(u)\nabla u,\quad \mathbf{B}=g(u,v)\nabla v,$$

where $H:\mathbf{R}^1\to\mathbf{R}^1$. Since $u+iv$ is analytic, $\nabla u\cdot\nabla v=0$; consequently, $\mathbf{E}\cdot\mathbf{B}=0$. Using the fact that the Laplacian of v vanishes, the Maxwell equation $\operatorname{div}\mathbf{B}=0$ implies that the function g depends on u only. Substituting $g(u,v)=U(u)$, where U is an arbitrary function, in the force-free condition yields

$$\rho H'(u)\nabla u+U(u)U'(u)(\nabla u\times\nabla v)\times\nabla v=0. \tag{2}$$

After expanding the vector products and verifying that $\rho=H''(u)\|\nabla u\|^2$, we find that Eq. (2) reduces to a scalar differential equation

$$H'H''-UU'=0.$$

Thus U and H are related by $U^2=H'^2+k$, where k is an integration constant. To generate radially symmetric fields, let $u+iv=\log(x+iy)$. Then

$$\mathbf{E}(r)=h(r)\mathbf{e}_r,\quad \mathbf{B}(r)=\pm\sqrt{h^2(r)+k/r^2}\,\mathbf{e}_\theta,$$

where h is an arbitrary smooth function and k is a constant. Finally, if $k=0$ and assuming integrability, the field satisfies $\mathbf{E}\cdot\mathbf{B}=0$ and $E^2=B^2$; in the terminology of Barut,[23] such a field is known as a null field or a pure radiation field. For additional background on the significance of null fields, the reader may also consult Parrott.[24]

Section III examines rotational symmetry.

III. ROTATIONAL SYMMETRY

We now construct two types of force-free fields that have rotational symmetry. First, we assume the magnetic field is purely azimuthal; and second, we assume that the azimuthal components of the electric and magnetic fields vanish.

For the first case we use circular cylindrical coordinates and we set

$$\mathbf{E}=-\nabla\Phi=-\Phi_r\mathbf{e}_r-\Phi_z\mathbf{e}_z,\quad \mathbf{B}=g\mathbf{e}_\theta,$$

where Φ and g are θ independent. The Maxwell equations $\operatorname{curl}\mathbf{E}=\mathbf{0}$ and $\operatorname{div}\mathbf{B}=0$ are satisfied while the Lorentz force density is zero provided that

$$\Phi_r((r\Phi_r)_r+r\Phi_{zz})=g(rg)_r, \tag{3}$$

$$\Phi_z((r\Phi_r)_r+r\Phi_{zz})=g(rg)_z. \tag{4}$$

Eliminating Φ_{zz} from these equations, we find that

$$(rg)_z\Phi_r=(rg)_r\Phi_z.$$

Thus there is a function $U:\mathbf{R}^1\to\mathbf{R}^1$ for which $rg=U(\Phi)$. Eliminating g from (3) and (4), we derive a single equation for the potential

$$-\Delta\Phi+(U'U)(\Phi)/r^2=0. \tag{5}$$

In general, this is a nonlinear Schrödinger equation with potential $1/r^2$; however, assuming that $U(x)=kx$, where k is a real constant, Eq. (5) reduces to the linear equation

$$\Phi_{rr}+\Phi_r/r+\Phi_{zz}=k^2\Phi/r^2.$$

A general solution of this equation is

$$\Phi(r,z)=r^k\int_{-1}^{1}(1-s^2)^{k-1/2}(A(iz+rs)+B(-iz+rs))\mathrm{d}s,$$

where A and B are arbitrary functions and i is the imaginary unit. Choosing $k=1/2$, $A(x)=i/x^3$, and $B(x)=0$, we find

$$\Phi(r,z)=-\frac{2\sqrt{r}z}{(z^2+r^2)^2}.$$

For the second case, we assume that the azimuthal components of the electric and magnetic fields vanish. In spherical coordinates the fields are given by

$$\mathbf{E}=-\nabla\Phi=-\Phi_r\mathbf{e}_r-\Phi_\theta\mathbf{e}_\theta/r,$$

$$\mathbf{B}=g(\Phi_\theta\mathbf{e}_r/r-\Phi_r\mathbf{e}_\theta)/r\sin\theta,$$

where Φ and g depend only on r and θ and are independent of the azimuthal variable φ. The Maxwell equation $\nabla\cdot\mathbf{B}=0$ implies Φ and g are functionally dependent; thus we define g by $g=U(\Phi)$. We can show that the field is force-free provided that

$$0=\nabla\cdot\left(\frac{U^2-r^2\sin^2\theta}{r^2\sin^2\theta}\nabla\Phi\right)-UU'\|\nabla\Phi\|^2/2\,r^2\sin^2\theta. \tag{6}$$

Given the singularities in Eq. (6), it is not clear that there are solutions that have a well-behaved charge density. Using numerical integration, we will give evidence that suggests that such solutions do exist. A Lagrangian density $\mathcal{L}$ for this equation is

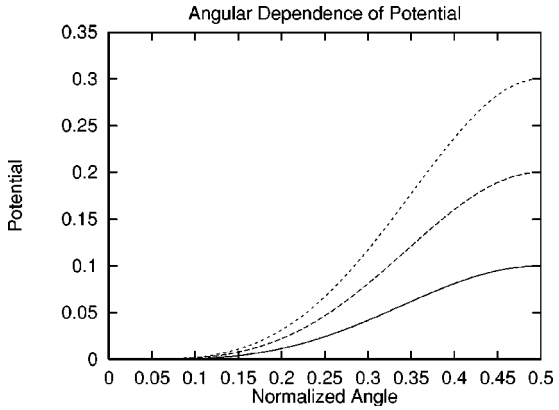

FIG. 1. Angular dependence of the potential ($n=2$) as a function of normalized angle (θ/π) for three initial values of $Q(\pi/2)$.

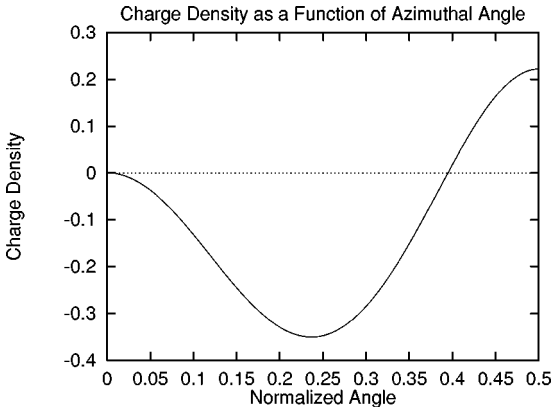

FIG. 2. Charge density ($n=2$) as a function of normalized angle (θ/π) for $Q(\pi/2)=0.1$.

$$\mathcal{L}(\Phi,\nabla\Phi,r)=(U^2-r^2\sin^2\theta)\|\nabla\Phi\|^2/2\,r^2\sin^2\theta.$$

If U is a power function $U(x)=\alpha x^{-1/n}$, where n and α are nonzero real constants, then Eq. (6) has separated variable solutions of the form $\Phi(r,\theta)=Q(\theta)/r^n$. For $n=1$, a solution is

$$\Phi=\sqrt{2}\,\alpha/r\sin\theta.$$

For $n=2$, a series expansion reveals there is a solution that behaves like

$$Q=\theta^4\,(q_0-2q_0\theta^2/3+q_0\,\theta^4/5+\cdots),\quad \theta\to 0,$$

where $q_0\in\mathbf{R}$ is arbitrary. Using numerical integration and initial conditions $Q(\pi/2)=0.1, 0.2$, and 0.3 and $Q'(0)=0$, we get the results shown in Fig. 1. As the series solution suggests, each solution approaches zero toward the poles sufficiently rapidly to make the charge density well behaved there. A graph of the charge density for the case $Q(0)=0.1$ is shown in Fig. 2.

IV. NULL FIELDS

In this section, we give a rule for transforming one force-free null field into another field with the same properties.

Let $\mathbf{E}=-\nabla\Phi$ and $\mathbf{B}$ be force-free and null. Thus $\mathbf{E}\cdot\mathbf{B}=0$ and $\|\mathbf{E}\|=\|\mathbf{B}\|$. Define a new field (the field with a caret) by $\widehat{\mathbf{E}}=\sigma(\Phi)\mathbf{E}$ and $\widehat{\mathbf{B}}=\mu(\Phi)\mathbf{B}$. The field with a caret satisfies $\operatorname{curl}\mathbf{E}=\mathbf{0}$ and $\operatorname{div}\mathbf{B}=0$; further, its Lorentz force density is

$$\hat{\rho}\,\widehat{\mathbf{E}}+\widehat{\mathbf{J}}\times\widehat{\mathbf{B}}=((\mu^2-\sigma^2)\nabla\cdot\mathbf{E}+(\mu\mu'-\sigma\sigma')\|\mathbf{E}\|^2)\mathbf{E}.$$

If $\mu=\pm\sigma$, the field with a caret is force-free and null.

V. CONCLUSION

We have introduced techniques for constructing force-free electromagnetic fields. In a few cases, we established a relation between force-free fields and nonlinear Schrödinger equations.

Enstrophy is an averaged measure of fluid vorticity. This quantity is particularly important in *rotating* geophysical flows. We investigate the dynamical evolution of enstrophy for large-scale quasi-geostrophic flows under random wind forcing. We obtain upper bounds on the enstrophy, as well as results establishing its Hölder continuity and describing the small-time asymptotics. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1459755]

I. INTRODUCTION

Randomness is ubiquitous in fluid systems. Macroscopic partial differential equation models for fluid flows contain such randomness as stochastic forcing, uncertain parameters, random sources, and random boundary conditions.

There has been active recent research on stochastic approaches to geophysical flows[1–5] and numerical simulations of stochastically forced geophysical flows.[6–10] It is generally understood that random fluctuations can have delicate impact on geophysical fluid dynamics.[1,3,6,7,11]

A class of large-scale geophysical flows under random forcing are modeled by the quasi-geostrophic equation:[1]

$$\Delta\psi_t + J(\psi,\Delta\psi) + \beta\psi_x = \nu\Delta^2\psi - r\Delta\psi + \dot{W}, \tag{1}$$

where $\psi(x,y,t)$ is the stream function ($\psi_x := \partial_x\psi$), $\beta \geqslant 0$ is the meridional gradient of the Coriolis parameter, $\nu > 0$ is the viscous dissipation constant, $r > 0$ is the Ekman dissipation constant, and $W(x,y,t)$ is a space–time Wiener process to be defined below on a probability space $(\Omega,\mathcal{A},\mathbb{P})$. Moreover, $J(f,g) = f_x g_y - f_y g_x$ denotes the Jacobian operator. The generalized time derivative $\dot{W}$ models the noisy wind forcing.

Introducing $\omega(x,y,t) = \Delta\psi(x,y,t)$, Eq. (1) can be rewritten in the form

$$\omega_t + J(\psi,\omega) + \beta\psi_x = \nu\Delta\omega - r\omega + \dot{W}, \tag{2}$$

where $(x,y) \in D$ and $D \subset \mathbb{R}^2$ denotes a bounded domain with sufficiently smooth boundary. The boundary conditions are no normal flow ($\psi = 0$ on ∂D) and free-slip ($\omega = 0$ on ∂D) as in Pedlosky (Ref. 12, p. 34) or in Dymnikov and Kazantsev:[13]

$$\psi = \omega = 0 \text{ on } \partial D. \tag{3}$$

An appropriate initial condition $\omega(0)$ is also imposed.

The mean enstrophy for a fluid flow is half the squared mean-square norm of the vorticity,[14,15] i.e., we have

---

[a)]Present address: Institut für Mathematik, RWTH Aachen, D-52056 Aachen, Germany.

$$\mathrm{Ens}(t)=\frac{1}{2}\cdot\mathbb{E}\int_D|\omega(x,y,t)|^2d(x,y).$$

The enstrophy $\mathrm{Ens}(t)$ is an averaged measure of fluid vorticity $\omega(t)$. In this article, we discuss the time evolution of the enstrophy. We present results which establish upper bounds on the enstrophy, as well as results on Hölder continuity and small-time asymptotics for $\mathrm{Ens}(t)$. These results are contained in Secs. III, IV, and V, respectively. The mathematical framework for our discussion is described in Sec. II.

II. MATHEMATICAL FRAMEWORK

As it stands, the stochastic quasi-geostrophic equation (2) still has to be given a mathematically precise meaning. This can be accomplished using the framework of stochastic partial differential equations, as described, for example, in Ref. 16. In our situation, we formally rewrite (2) in the Ito formulation

$$d\omega=(\nu\Delta\omega-r\omega-\beta\psi_x-J(\psi,\omega))dt+dW. \tag{4}$$

In the following we use the abbreviations $L^2=L^2(D)$, $L^\infty=L^\infty(D)$, $H_0^k=H_0^k(D)$, $H^k=H^k(D)$, $0<k<\infty$, for the standard Sobolev spaces. Let $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ denote the standard scalar product and norm in L^2, respectively. Moreover, the norms for H_0^k and L^∞ are denoted by $\|\cdot\|_{H^k}$ and $\|\cdot\|_\infty$, respectively. Due to the Poincaré inequality (Ref. 17 p. 164), the expression $\|\Delta\cdot\|$ is an equivalent norm for H_0^2. It is well-known that the operator $A=\nu\Delta:L^2\to L^2$ with domain $D(A)=H^2\cap H_0^1$ is self-adjoint. Note that A generates an analytic semigroup $S(t)$ on L^2.[18] The spectrum of A consists of eigenvalues $0>\lambda_1>\lambda_2\geqslant\lambda_3\geqslant\cdots$ with corresponding normalized eigenfunctions φ_1, $\varphi_2,\ldots$. The set of these eigenfunctions is complete in L^2. For example, for the square domain $D=(0,1)\times(0,1)$ the eigenvalues are given by $-\nu(m^2+n^2)\pi^2$ for $m,n\in\mathbb{N}$, and the associated eigenfunctions are suitable multiples of $\sin(m\pi x)\sin(n\pi y)$.

Now we can define an appropriate class of Wiener processes W. Let β_k, $k\in\mathbb{N}$, denote a family of independent real-valued standard Brownian motions. Furthermore, choose positive constants μ_k, $k\in\mathbb{N}$, such that

$$\sum_{k=1}^{\infty}\frac{\mu_k^2}{|\lambda_k|^{1-\theta}}<\infty \tag{5}$$

for some $0<\theta<1$. Then we consider the Wiener process W defined by

$$W(t):=\sum_{k=1}^{\infty}\mu_k\cdot\beta_k(t)\cdot\varphi_k,\quad t\geqslant 0. \tag{6}$$

Note that we explicitly allow Wiener processes W whose covariance operator is not of trace class, i.e., for which $\Sigma_{k=1}^{\infty}\mu_k^2=\infty$.

For the domain D we basically assume that the eigenfunctions φ_k of A satisfy

$$\begin{gathered}\varphi_k\in C_0(\overline{D}),\quad |\varphi_k(x,y)|\leqslant C,\\ |\nabla\varphi_k(x,y)|\leqslant C\sqrt{|\lambda_k|},\end{gathered} \tag{7}$$

for all $(x,y)\in D$ and $k\in\mathbb{N}$, where $C>0$ denotes a constant which depends only on D. Domains D which satisfy these conditions include rectangular domains, as well as equilateral triangles. Unfortunately, there are many domains for which they are violated. See, for example, Ref. 19. However, in this paper it is conjectured that in (7) one generally should expect an upper bound which is logarithmic in $|\lambda_k|$. Even though our results remain valid in this situation, we will assume the above stronger condition.

Under the above assumptions, Theorem 5.2.9 in Ref. 20 guarantees that the stochastic convolution

$$W_A(t)=\int_0^t S(t-s)dW(s), \quad t>0, \tag{8}$$

has a continuous version with values in $C_0(D)$, the Banach space of continuous functions satisfying zero Dirichlet boundary conditions on D. To be more precise, W_A has a version which is even Hölder continuous with some small exponent, which depends on the asymptotic behavior of the coefficients μ_k.

If we define the nonlinear operator F by $F(\omega)=-r\omega-\beta\psi_x-J(\psi,\omega)$, then (4) can be rewritten as the abstract evolution equation together with initial condition

$$\begin{aligned} d\omega&=(A\omega+F(\omega))dt+dW,\\ \omega(0)&=\omega_0. \end{aligned} \tag{9}$$

For technical reasons we translate the operator A by a suitable multiple of the identity. Consider a constant $\alpha\geqslant 0$ which will be chosen later on, usually sufficiently large. Defining $A_\alpha := A-\alpha I$, we get the initial value problem

$$\begin{aligned} d\omega&=(A_\alpha\omega+F(\omega)+\alpha\omega)dt+dW,\\ \omega(0)&=\omega_0 \end{aligned}$$

or in mild (integral) form

$$\omega(t)=S_\alpha(t)\omega_0+\int_0^t S_\alpha(t-s)(F(\omega(s))+\alpha\omega(s))ds+W_{A_\alpha}(t), \tag{10}$$

where the analytic semigroup S_α is given by $S_\alpha(t)=e^{-t\alpha}\cdot S(t)$ for $t>0$ and the stochastic convolution $W_{A_\alpha}(t)$ is defined as in (8) with the semigroup S replaced by S_α. Finally, let $U:=\omega-W_{A_\alpha}$. Then U is the weak solution of

$$\begin{aligned} \partial_t U&=AU+F(U+V)+\alpha V,\\ U(0)&=\omega_0, \end{aligned}$$

where we use the abbreviation $V:=W_{A_\alpha}$. Notice that both U and V depend on α.

III. ENSTROPHY ESTIMATE: UPPER BOUNDS

We begin by establishing upper bounds on the time evolution of the enstrophy $\mathrm{Ens}(t)=\mathbb{E}\|\omega(t)\|^2/2$. Improving the *a priori* estimate of Ref. 5 Sec. 3, we obtain

$$\begin{aligned} \frac{1}{2}\cdot\frac{d}{dt}\|U(t)\|^2 \leqslant{}& \|\nabla U(t)\|^2\cdot(\varepsilon-\nu)\\ &+\|U(t)\|^2\cdot((\varepsilon-r+c_1\beta)+C\cdot\|V\|_\infty\cdot(1+C_\varepsilon\cdot\|V\|_\infty))\\ &+C_\varepsilon\cdot(r+\beta+\alpha^2)\cdot\|V\|_\infty^2+C\cdot\|V\|_\infty^3+C_\varepsilon\cdot\|V\|_\infty^4, \end{aligned} \tag{11}$$

where C denotes a generic constant which depends only on D, and whose specific value may change from line to line. Similarly, C_ε denotes a generic constant which depends only on D and

ε, where $\varepsilon>0$ is some arbitrarily small number. The constant c_1 denotes the optimal constant in the Poincare inequality $\|U\|\leqslant c_1\|\nabla U\|$ for mean zero functions U. For $\varepsilon<\nu$ the improved *a priori* estimate immediately yields the following lemma.

Lemma 1: For any $\gamma>-\nu\cdot c_1^{-2}-r+c_1\cdot\beta$ there exist constants depending only on γ, D, β, and r which are all denoted by C such that

$$\frac{d}{dt}\|U(t)\|^2\leqslant A(t)\|U(t)\|^2+B(t),\quad t\geqslant 0, \tag{12}$$

with

$$\begin{aligned} A(t)&=2\gamma+C\cdot(\|V\|_\infty+\|V\|_\infty^2),\\ B(t)&=C\cdot((1+\alpha^2)\cdot\|V\|_\infty^2+\|V\|_\infty^4)>0. \end{aligned} \tag{13}$$

Together with Theorem I.6.1 in Ref. 21 this yields

$$\|U(t)\|^2\leqslant\|\omega_0\|^2\cdot e^{\int_0^t A(s)ds}+\int_0^t B(s)e^{\int_s^t A(\tau)d\tau}ds,\quad t\geqslant 0. \tag{14}$$

Suppose for simplicity that ω_0 and W are stochastically independent. It is possible to drop this assumption in this section, but in this case we additionally need $\mathbb{E}\|\omega_0\|^{2+\delta}<\infty$ for some small $\delta>0$.

The critical term for taking the expectation in (14) is the squared L^∞-norm of $V=W_{A_\alpha}$ in the exponent, which is in general not finite. To complicate matters further, the L^∞-norm in the exponent cannot easily be dealt with, since we do not have a Hilbert space structure.

For our situation we will improve on some ideas of Ref. 22. Using Fernique's Theorem (Ref. 16, Theorem 2.6) we get that $\mathbb{P}(t\|V(\tau)\|_\infty^2>r^2)\leqslant 1/(1+e^{1+32\lambda r^2})$ implies $\mathbb{E}(e^{\lambda t\|V(\tau)\|_\infty^2})\leqslant e^{16\lambda r^2}+e^2/(e^2-1)$ for any $t,\tau,r,\lambda>0$. Hence, by Jensen's inequality

$$\mathbb{E}(e^{\lambda\int_0^t\|V(\tau)\|_\infty^2 d\tau})\leqslant\frac{1}{t}\cdot\int_0^t\mathbb{E}(e^{\lambda t\|V(\tau)\|_\infty^2})d\tau\leqslant C_\lambda,$$

provided $\mathbb{P}(t\|V(\tau)\|_\infty^2>1)\leqslant 1/(1+e^{1+32\lambda})$ for any $\tau\leqslant t$. The latter inequality follows immediately from Chebychev's inequality, provided we have

$$t\cdot\mathbb{E}\|V(\tau)\|_\infty^2\leqslant\frac{1}{1+e^{1+32\lambda}} \tag{15}$$

for any $\tau\leqslant t$. The following lemma is proven similarly as Ref. 16, Theorem 5.20.

Lemma 2: For any $p\geqslant 1$ and any sufficiently small $\theta>0$ there exists a constant C which depends only on p, θ, and D such that for any $\tau\geqslant 0$

$$\mathbb{E}\|V(\tau)\|_\infty^{2p}\leqslant C\cdot\underbrace{\left(\sum_{k=1}^\infty\frac{\mu_k^2}{\alpha-\lambda_k}\cdot|\lambda_k|^\theta\right)^p}_{=:\varphi(\alpha)^p}. \tag{16}$$

We remark that the assumption (7) on the eigenfunctions is essential for the proof of this lemma. Notice also that the series in (16) is finite according to (5). Lemma 2 implies that (15) is satisfied for any $t\leqslant C/\varphi(\alpha)$. It is now straightforward to verify that

$$\mathbb{E}e^{m\int_s^t A(\tau)d\tau}\leqslant C\cdot e^{m(t-s)2\gamma}$$

for any $s \leqslant t \leqslant C/\varphi(\alpha)$ and $m=1,2$, where γ and $A(t)$ were defined in Lemma 1. Moreover, Lemma 2 implies for $B(t)$ in (13)

$$(\mathbb{E}B(t)^2)^{1/2} \leqslant C \cdot ((1+\alpha^2)\cdot\varphi(\alpha)+\varphi(\alpha)^2)$$

for any $t>0$. We finally obtain from (14) that

$$\begin{aligned}\mathbb{E}\|U(t)\|^2 &\leqslant \mathbb{E}\left(\|\omega_0\|^2 \cdot e^{\int_0^t A(s)ds} + \int_0^t B(s) e^{\int_s^t A(\tau)d\tau} ds \right) \\ &\leqslant \mathbb{E}\|\omega_0\|^2 \cdot \mathbb{E}e^{\int_0^t A(s)ds} + \int_0^t (\mathbb{E}B(s)^2)^{1/2} (\mathbb{E}e^{2\int_s^t A(\tau)d\tau})^{1/2} ds \\ &\leqslant C \cdot \mathbb{E}\|\omega_0\|^2 \cdot e^{2\gamma t} + C\cdot((1+\alpha^2)\cdot\varphi(\alpha)+\varphi(\alpha)^2)\cdot \int_0^t e^{2\gamma\tau} d\tau \end{aligned} \tag{17}$$

for any $t \leqslant C/\varphi(\alpha)$. Using $\mathbb{E}\|\omega\|^2 \leqslant 2\mathbb{E}\|U\|^2 + 2\mathbb{E}\|V\|^2$, this immediately implies the following theorem on upper bounds for the enstrophy.

Theorem 1 (upper bound): *Suppose that ω_0 and W are stochastically independent and that $\mathbb{E}\|\omega_0\|^2 < \infty$. Moreover, let $\gamma > -\nu \cdot c_1^{-2} - r + c_1 \cdot \beta$. Then* $\mathrm{Ens} \in L^\infty([0,T])$ *for any $T>0$. More precisely,*

$$\begin{aligned}\mathrm{Ens}(t) &\leqslant C \cdot \mathbb{E}\|\omega_0\|^2 \cdot e^{2\gamma t} + C\cdot\varphi(\alpha) \\ &\quad + C\cdot((1+\alpha^2)\cdot\varphi(\alpha)+\varphi(\alpha)^2)\cdot\int_0^t e^{2\gamma\tau} d\tau\end{aligned}$$

for any $t \leqslant C/\varphi(\alpha)$, with constants C independent of t, α, and ω_0.

Remark 1: It can be shown that for any choice of $p \geqslant 1$ similar bounds hold for $\mathbb{E}\sup_{\tau\in[0,t]}\|U(\tau)\|^{2p}$, provided both $\mathbb{E}\|\omega_0\|^{2p} < \infty$ and $t \leqslant C/\varphi(\alpha)$.

Moreover, all bounds on $\mathbb{E}\|U(t)\|^{2p}$ or $\mathbb{E}\sup_{\tau\in[0,t]}\|U(\tau)\|^{2p}$ immediately imply analogous bounds on $\mathrm{Ens}(t)$ *or $\mathbb{E}\sup_{\tau\in[0,t]}\|\omega(\tau)\|^{2p}$. For this one has to employ estimates for $\mathbb{E}\sup_{\tau\in[0,t]}\|W_{A_\alpha}(\tau)\|^{2p}$ which can be obtained for example as in Ref. 23, Corollary 2.3.*

In order to obtain a bound for $t\to\infty$, we note that for $\alpha\to\infty$ one obviously has $\varphi(\alpha)\to 0$. However, the rate of convergence is essential. To this end, we distinguish two cases. If we suppose that $\Sigma_{k=1}^\infty \mu_k^2 \cdot |\lambda_k|^\theta < \infty$ for some $\theta > 0$, then the estimate $\varphi(\alpha) \leqslant \Sigma_{k=1}^\infty \mu_k^2 \cdot |\lambda_k|^\theta/\alpha$ is immediate—and choosing α proportional to t in Theorem 1 furnishes

$$\mathrm{Ens}\,(t) \leqslant C\cdot\left(\mathbb{E}\|\omega_0\|^2 \cdot e^{2\gamma t} + t\cdot\int_0^t e^{2\gamma\tau} d\tau + 1 \right) \quad \text{for all } \ t \geqslant 0.$$

If, on the other hand, $\Sigma_{k=1}^\infty \mu_k^2 \cdot |\lambda_k|^\theta = \infty$, we additionally assume $\mu_k^2 \leqslant C k^{-\mu}$ for some $\mu \in (\theta, 1]$, with arbitrarily small θ defined in Lemma 2. (For $\mu > 1$ we can always find some small θ such that the first case applies.) Using the fact that $|\lambda_k| \sim Ck$ for $k\to\infty$ (cf. Ref. 24) we obtain

$$\begin{aligned}\varphi(\alpha) &\leqslant C\cdot\sum_{k=1}^\infty \frac{k^{-\mu}}{ck+\alpha}\cdot k^\theta \leqslant C\cdot\int_0^\infty \frac{k^{\theta-\mu}}{ck+\alpha} dk \\ &= C\cdot\alpha^{\theta-\mu}\cdot\int_0^\infty \frac{\tau^{\theta-\mu}}{c\tau+1} d\tau.\end{aligned}$$

Choosing $\alpha^{\mu-\theta}$ proportional to t in Theorem 1, we derive

$$\mathrm{Ens}(t) \leqslant C\cdot\left(\mathbb{E}\|\omega_0\|^2 \cdot e^{2\gamma t} + t^{2/(\mu-\theta)-1}\cdot\int_0^t e^{2\gamma\tau} d\tau + 1 \right) \quad \text{for all} \quad t \geqslant 0.$$

Notice that $2/(\mu-\theta)-1>1$. We have proved the following result.

Theorem 2 (global upper bound): *Assume again that ω_0 and W are stochastically independent, that $\mathbb{E}\|\omega_0\|^2<\infty$, and let $\gamma>-\nu\cdot c_1^{-2}-r+c_1\cdot\beta$. Then the following holds.*

(a) If $\mu_k^2\leqslant Ck^{-\mu}$ for some $\mu\in(0,1]$, we can find a $\tilde{\mu}\in(0,\mu)$ such that

$$\mathrm{Ens}(t)\leqslant C\cdot\left(\mathbb{E}\|\omega_0\|^2\cdot e^{2\gamma t}+t^{(2-\tilde{\mu})/\tilde{\mu}}\cdot\int_0^t e^{2\gamma\tau}d\tau+1\right)\quad \text{for all } t\geqslant 0.$$

(b) If $\Sigma_{k=1}^{\infty}\mu_k^2\cdot|\lambda_k|^{\theta}<\infty$ for some $\theta>0$, then

$$\mathrm{Ens}(t)\leqslant C\cdot\left(\mathbb{E}\|\omega_0\|^2\cdot e^{2\gamma t}+t\cdot\int_0^t e^{2\gamma\tau}d\tau+1\right)\quad \text{for all } t\geqslant 0.$$

The constants C are independent of t and ω_0, but they can depend on θ, γ, μ, $\tilde{\mu}$, the domain D, or the coefficients in (1).

Remark 2: If $-\nu\cdot c_1^{-2}-r+c_1\cdot\beta\geqslant 0$, then necessarily $\gamma>0$. In this case we obtain an exponentially growing upper bound for $\mathrm{Ens}(t)$ *with growth rate slightly larger than $-\nu\cdot c_1^{-2}-r+c_1\cdot\beta$.*

If, on the other hand, $-\nu\cdot c_1^{-2}-r+c_1\cdot\beta<0$, then we can choose $\gamma<0$. This furnishes a polynomial upper bound which grows at least linearly in time. The precise growth exponent is determined by the regularity of the noise.

Remark 3: As we already stated in the beginning of this section, one can remove the condition of stochastic independence of ω_0 and W in the previous theorem, if one additionally assumes $\mathbb{E}\|\omega_0\|^{2+\delta}<\infty$ for some small δ.

Our above results hold for a large class of noise processes, in particular also for more irregular Wiener processes W whose covariance operator is not of trace class. If, however, one assumes that the Wiener process is of trace class, i.e., if $\mathrm{Tr}(Q)=\Sigma_{k=1}^{\infty}\mu_k^2<\infty$, then the results can be improved significantly by employing Ito's formula. One advantage of this approach is that it avoids the conditions on the eigenfunction in (7). Therefore, we will briefly outline the main ideas.

By applying Ito's formula (Ref. 16, Sec. 4.5) to the squared L^2-norm of the vorticity $\omega(t)$, it can easily be verified that

$$\mathbb{E}\|\omega(t)\|^2=2\,\mathbb{E}\int_0^t\langle A\omega(\tau)+F(\omega(\tau)),\omega(\tau)\rangle d\tau+\mathrm{Tr}(Q)\cdot t,$$

where $\mathrm{Tr}(Q)=\Sigma_{k=1}^{\infty}\mu_k^2$ denotes the trace of the covariance operator Q of W. Using calculations analogous to the ones leading to the *a priori* estimate in Lemma 1, we formally obtain

$$\begin{aligned}\partial_t\mathbb{E}\|\omega(t)\|^2&=2\,\mathbb{E}\langle A\omega(\tau)+F(\omega(\tau)),\omega(\tau)\rangle+\mathrm{Tr}(Q)\\&\leqslant 2\gamma\cdot\mathbb{E}\|\omega(t)\|^2+\mathrm{Tr}(Q),\end{aligned}$$

where $\gamma>-\nu\cdot c_1^{-2}-r+c_1\cdot\beta$ as in Lemma 1. Hence, for any $t\geqslant 0$ we have

$$\mathrm{Ens}(t)\leqslant\mathrm{Ens}(0)\cdot e^{2\gamma\cdot t}+\mathrm{Tr}(Q)\cdot\frac{e^{2\gamma\cdot t}-1}{4\gamma}.\tag{18}$$

Especially if one can choose a growth exponent $\gamma<0$, this significantly improves the estimates of Theorem 2, since in this case the right-hand side of (18) approaches $-\mathrm{Tr}(Q)/(4\gamma)$ for $t\to\infty$.

IV. ENSTROPHY ESTIMATE: HÖLDER CONTINUITY

In this section we establish regularity properties of the enstrophy as a function of time. More precisely, we will prove that $\mathrm{Ens}(t)=\mathbb{E}\|\omega(t)\|^2/2$ is Hölder continuous. To this end, we need the following lemma from Ref. 5

Lemma 3: Define a nonlinear mapping $\mathcal{F}: C([0,T];H_0^1) \to C([0,T];L^2)$ *by*

$$(\mathcal{F}(\omega))(t) := \int_0^t S(t-s)F(\omega(s))ds, \quad \text{for} \quad t \in [0,T],$$

where $\omega \in C([0,T];H_0^1)$, *and* A *and* F *are as in* (9). *Then* $\mathcal{F}$ *is continuous, and it can be extended to a continuous mapping from the space* $C([0,T];L^2)$ *to* $C([0,T];L^2)$. *Furthermore, the image of the extended mapping* $\mathcal{F}$ *is contained in* $C([0,T],H^a(D))$ *for* $0 \leqslant a < \frac{1}{2}$.

In fact, it is shown in Ref. 5 that for arbitrary positive constants $a \in [0,\frac{1}{4})$ and $\rho \in (0,\frac{1}{4})$ satisfying $0 < \rho + a < \frac{1}{4}$ the estimate

$$\begin{aligned}\left\| (-A)^a \int_0^t S(t-s)F(\omega(s))ds \right\| &\leqslant \frac{rc+\beta c}{1-a} \cdot t^{1-a} \cdot \sup_{0\leqslant s\leqslant t} \|\omega(s)\| \\ &\quad + \left(\frac{8c}{1-4\rho-4a} \cdot t^{1/4-\rho-a} + \frac{4c}{1-2\rho-2a} \cdot t^{1/2-\rho-a} \right) \cdot \sup_{0\leqslant s\leqslant t} \|\omega(s)\|^2\end{aligned}$$

holds. Especially for $a = 0$ we obtain

$$\begin{aligned}\|\mathcal{F}(\omega)(t)\| = \left\| \int_0^t S(t-s)F(\omega(s))ds \right\| &\leqslant (rc+\beta c) \cdot t \cdot \sup_{0\leqslant s\leqslant t} \|\omega(s)\| \\ &\quad + \left(\frac{8c}{1-4\rho} \cdot t^{1/4-\rho} + \frac{4c}{1-2\rho} \cdot t^{1/2-\rho} \right) \cdot \sup_{0\leqslant s\leqslant t} \|\omega(s)\|^2,\end{aligned}$$

for every $0 < \rho < \frac{1}{4}$. Together with Theorem 1 and Remark 1 these bounds immediately furnish the following result.

Lemma 4: Suppose that ω_0 *and* W *are stochastically independent and that for some* $p \geqslant 1$ *we have* $\mathbb{E}\|\omega_0\|^{2p} < \infty$. *Moreover, let* $T > 0$ *be arbitrary, and let* $a \in [0,\frac{1}{4})$ *and* $\rho \in (0,\frac{1}{4})$ *be such that* $0 < \rho + a < \frac{1}{4}$. *Then there exists a constant* C *such that*

$$\mathbb{E}\|(-A)^a \mathcal{F}(\omega)(t)\|^p \leqslant C \cdot t^{p\cdot(1/4-\rho-a)} \quad \textit{for all} \quad t \in [0,T].$$

The following theorem states our main result on the regularity of the enstrophy. It will be proved in the remainder of this section.

Theorem 3 (Hölder continuity): *Suppose that* ω_0 *and* W *are stochastically independent and that* $\mathbb{E}\|\omega_0\|^4 < \infty$. *Then the enstrophy* $\mathrm{Ens}(\cdot)$ *defined by* $\mathrm{Ens}(t) = \mathbb{E}\|\omega(t)\|^2/2$ *is Hölder continuous with arbitrary exponent less than* $\frac{1}{4}$ *on every compact interval in* $(0,\infty)$.

Remark 4: Note that in general we cannot expect the solution ω *to be Hölder continuous with arbitrary exponent less than* $\frac{1}{4}$, *since* W_A *is in general less regular. As one can see from (10) with* $\alpha = 0$, *one cannot expect* ω *to be more regular than* W_A.

To prove the above theorem establishing the Hölder continuity of the enstrophy, we first define

$$\mathcal{G}(\omega)(t) := S(t)\omega_0 + \mathcal{F}(\omega)(t). \tag{19}$$

According to (10) for $\alpha = 0$, we therefore have $\omega(t) = \mathcal{G}(\omega)(t) + W_A(t)$. Consider a fixed interval $J = [\varepsilon, T] \subset (0,\infty)$. For $t \in J$ and h with $t + h \in J$ the identity (10) then implies

$$\begin{aligned}\mathbb{E}\|\omega(t+h)\|^2-\mathbb{E}\|\omega(t)\|^2&=\mathbb{E}\|\mathcal{G}(\omega)(t+h)+W_A(t+h)\|^2-\mathbb{E}\|\mathcal{G}(\omega)(t)+W_A(t)\|^2\\&=\mathbb{E}\|\mathcal{G}(\omega)(t+h)\|^2-\mathbb{E}\|\mathcal{G}(\omega)(t)\|^2+2\mathbb{E}\langle\mathcal{G}(\omega)(t+h),W_A(t+h)\rangle\\&\quad-2\mathbb{E}\langle\mathcal{G}(\omega)(t),W_A(t)\rangle+\mathbb{E}\|W_A(t+h)\|^2-\mathbb{E}\|W_A(t)\|^2\\&=:D_1+2D_2+D_3.\end{aligned}$$

For simplicity we assume $h>0$ in the following. The case $h<0$ can be treated analogously.

We begin by estimating D_3. Due to Ref. 25 one has $\mathbb{E}\|W_A(\cdot)\|^2\in C^\infty(0,\infty)$. Hence, $|D_3|\leqslant C\cdot h$ for some constant $C>0$.

In order to estimate D_2, we define the shift-operator τ_t by $\tau_t\omega=\omega(t+\cdot)$ for $t>0$. Then the definitions of $\mathcal{G}$ and $\mathcal{F}$ in (19) and Lemma 3, respectively, furnish

$$\mathcal{G}(\omega)(t+h)=S(h)\mathcal{G}(\omega)(t)+\mathcal{F}(\tau_t\omega)(h). \tag{20}$$

Since $\{\omega(s)\}_{s\in[0,t]}$ is stochastically independent of $\{W(s)\}_{s\in[t,t+h]}$ we get

$$\begin{aligned}\mathbb{E}\langle\mathcal{G}(\omega)(t+h),W_A(t+h)\rangle&=\mathbb{E}\left\langle S(h)\mathcal{G}(\omega)(t),\int_0^t S(t+h-s)dW(s)\right\rangle+\mathbb{E}\langle\mathcal{F}(\tau_t\omega)(h),W_A(t+h)\rangle\\&=\mathbb{E}\langle S(h)\mathcal{G}(\omega)(t),S(h)W_A(t)\rangle+\mathbb{E}\langle\mathcal{F}(\tau_t\omega)(h),W_A(t+h)\rangle\end{aligned}$$

and together with the self-adjointness of $S(h)$ we finally arrive at

$$D_2=\mathbb{E}\langle(S(2h)-I)\mathcal{G}(\omega)(t),W_A(t)\rangle+\mathbb{E}\langle\mathcal{F}(\tau_t\omega)(h),W_A(t+h)\rangle. \tag{21}$$

The boundedness of $\mathbb{E}\|W_A(t)\|^2$ on J and Lemma 4 now yield

$$|\mathbb{E}\langle\mathcal{F}(\tau_t\omega)(h),W_A(t+h)\rangle|\leqslant(\mathbb{E}\|\mathcal{F}(\tau_t\omega)(h)\|^2)^{1/2}\cdot(\mathbb{E}\|W_A(t+h)\|^2)^{1/2}\leqslant C\cdot h^{1/4-\rho}.$$

As for the first term in (21), notice that

$$\|(S(h)-I)v\|\leqslant\int_0^h\|(-A)S(s)v\|ds\leqslant C\cdot h^a\cdot\|(-A)^a v\| \tag{22}$$

for any $v\in D((-A)^a)$, with a constant C which depends on $a\in[0,1)$. Thus,

$$\begin{aligned}&|\mathbb{E}\langle(S(2h)-I)\mathcal{G}(\omega)(t),W_A(t)\rangle|\\&\quad\leqslant C\cdot h^{1/4-\rho}\cdot(\mathbb{E}\|(-A)^{1/4-\rho}\mathcal{F}(\omega)(t)\|^2+\mathbb{E}\|(-A)^{1/4-\rho}S(t)\omega_0\|^2)^{1/2}\end{aligned}$$

for any $\rho\in(0,\frac{1}{4})$. Together with $\|(-A)^{1/4-\rho}S(t)\omega_0\|\leqslant C\cdot\varepsilon^{\rho-1/4}\cdot\|\omega_0\|$ and Lemma 4 we eventually obtain

$$|D_2|\leqslant C\cdot h^{1/4-\rho}. \tag{23}$$

Finally we turn our attention to D_1. Its definition and (20) imply

$$\begin{aligned}D_1&=\mathbb{E}\|\mathcal{G}(\omega)(t+h)\|^2-\mathbb{E}\|\mathcal{G}(\omega)(t)\|^2\\&=\mathbb{E}\langle\mathcal{G}(\omega)(t+h)-\mathcal{G}(\omega)(t),\underbrace{\mathcal{G}(\omega)(t+h)+\mathcal{G}(\omega)(t)}_{=:D_{\mathcal{G}}}\rangle\\&=\mathbb{E}\langle(S(h)-I)\mathcal{G}(\omega)(t),D_{\mathcal{G}}\rangle+\mathbb{E}\langle\mathcal{F}(\tau_t\omega)(h),D_{\mathcal{G}}\rangle.\end{aligned}$$

As in the discussion leading to (23), we obtain for any $\tilde{a}\in[0,\frac{1}{4})$

$$|\mathbb{E}\langle (S(h)-I)\mathcal{G}(\omega)(t), D_{\mathcal{G}}\rangle| \leq C\cdot h^{2\tilde{a}}\cdot \mathbb{E}(\|(-A)^{\tilde{a}}\mathcal{G}(\omega)(t)\|\cdot\|(-A)^{\tilde{a}}D_{\mathcal{G}}\|) \leq C\cdot h^{2\tilde{a}}. \tag{24}$$

Using again Lemma 4 we further derive

$$|\mathbb{E}\langle \mathcal{F}(\tau_t\omega)(h), D_{\mathcal{G}}\rangle| \leq C\cdot(\mathbb{E}\|\mathcal{F}(\tau_t\omega)(h)\|^2)^{1/2}\cdot(\mathbb{E}\|\|D_{\mathcal{G}}\|^2)^{1/2} \leq C\cdot h^{1/4-\rho}. \tag{25}$$

Combining (24) for fixed $\tilde{a}$ near $\frac{1}{4}$ with (25) furnishes $|D_1| \leq C\cdot h^{1/4-\rho}$, and we finally obtain

$$|\mathrm{Ens}(t+h)-\mathrm{Ens}(t)| \leq C\cdot h^{1/4-\rho}$$

for arbitrary $\rho\in(0,\frac{1}{4})$. This completes the proof of Theorem 3.

V. ENSTROPHY ESTIMATE: ASYMPTOTICS

In Sec. III we established upper bounds on the growth of the enstrophy $\mathrm{Ens}(t) = \mathbb{E}\|\omega(t)\|^2/2$. Unfortunately, these bounds fail to accurately describe the dynamics of $\mathrm{Ens}(t)$ as $t\to 0$. For example, the bound derived in Theorem 1 will generally not even converge to $\mathrm{Ens}(0)$ as $t\to 0$. Therefore, this section is devoted to investigating the small-time asymptotics of the enstrophy. Similar to Ref. 25 and 26 this will be accomplished by relating $\mathrm{Ens}(t)$ to the stochastic convolution.

In order to bound the growth of $\mathbb{E}\|W_A(t)\|^2$, we assume that the coefficients μ_k in (6) are bounded by $\mu_k^2 \leq c_\mu\cdot k^{-\delta}$ for some $\delta\in(0,1)$ and some positive constant $c_\mu>0$. In this situation we obtain similar to Ref. 25, Theorem 5.4, the estimate

$$\mathbb{E}\|W_A(t)\|^2 \leq C_0\cdot t^{\delta} \tag{26}$$

for arbitrary $t\in[0,T]$, where C_0 denotes a positive constant which depends on T. Using the mild integral form (10) we further get

$$\|\omega(t)-\omega_0-W_A(t)\| \leq \|(S(t)-I)\omega_0\| + \|\mathcal{F}(\omega)(t)\|.$$

If we now assume that $\mathbb{E}\|\omega_0\|^4<\infty$, then an application of Lemma 4 furnishes

$$\begin{aligned}\mathbb{E}\|\omega(t)-\omega_0-W_A(t)\|^2 &\leq 2\mathbb{E}\|(S(t)-I)\omega_0\|^2 + 2\mathbb{E}\|\mathcal{F}(\omega)(t)\|^2\\ &\leq 2\mathbb{E}\|(S(t)-I)\omega_0\|^2 + C\cdot t^{1/2-2\rho}\\ &\leq C\cdot t^{2\gamma}\cdot\mathbb{E}\|(-A)^{\gamma}\omega_0\|^2 + C\cdot t^{1/2-2\rho}\end{aligned} \tag{27}$$

for fixed $\rho\in(0,\frac{1}{4})$ and $\gamma\in[0,1)$. Thus, the additional assumption $\mathbb{E}\|(-A)^{\gamma}\omega_0\|^2<\infty$ for some small $\gamma\in[0,1)$ implies

$$\mathbb{E}\|\omega(t)-\omega_0-W_A(t)\|^2 \leq C\cdot t^{2\gamma}.$$

Hence,

$$\begin{aligned}(\mathbb{E}\|\omega(t)\|^2)^{1/2} &\leq (\mathbb{E}\|\omega_0\|^2)^{1/2} + (\mathbb{E}\|W_A(t)\|^2)^{1/2} + (\mathbb{E}\|\omega(t)-\omega_0-W_A(t)\|^2)^{1/2}\\ &= (\mathbb{E}\|\omega_0\|^2)^{1/2} + \mathcal{O}(t^{\gamma}+t^{\delta/2}).\end{aligned}$$

Similarly one obtains

$$\begin{aligned}(\mathbb{E}\|\omega(t)\|^2)^{1/2} &\geq (\mathbb{E}\|\omega_0\|^2)^{1/2} - (\mathbb{E}\|W_A(t)\|^2)^{1/2} - (\mathbb{E}\|\omega(t)-\omega_0-W_A(t)\|^2)^{1/2}\\ &= (\mathbb{E}\|\omega_0\|^2)^{1/2} + \mathcal{O}(t^{\gamma}+t^{\delta/2}),\end{aligned}$$

and together these estimates show that $\mathbb{E}\|\omega(t)\|^2 = \mathbb{E}\|\omega_0\|^2 + \mathcal{O}(t^{\gamma}+t^{\delta/2})$. If, on the other hand, we have $\omega_0=0$, then (27) implies

$$\mathbb{E}\|\omega(t)-W_A(t)\|^2 \leqslant t^{1/2-2\rho},$$

which analogously results in $\mathbb{E}\|\omega(t)\|^2=\mathbb{E}\|W_A(t)\|^2+\mathcal{O}(t^{\frac{1}{4}-\rho+\delta/2})$. Using the definition of Ens, this furnishes the following result on the small-time asymptotics of the enstrophy.

Theorem 4(asymptotics): *Assume that* $\mathbb{E}\|(-A)^{\gamma}\omega_0\|^2<\infty$ *for some small constant* $\gamma>0$ *and that* $\mathbb{E}\|\omega_0\|^4<\infty$. *Furthermore, suppose that (26) holds for some small* $\delta>0$. *Then*

$$\mathrm{Ens}(t)=\tfrac{1}{2}\cdot\mathbb{E}\|\omega_0\|^2+\mathcal{O}(t^{\gamma}+t^{\delta/2}).$$

If in addition we have $\omega_0=0$ *and let* $\rho\in(0,\frac{1}{4})$ *be arbitrary, then*

$$\mathrm{Ens}(t)=\tfrac{1}{2}\cdot\mathbb{E}\|W_A(t)\|^2+\mathcal{O}(t^{(1+2\delta)/4-\rho}).$$

Notice that in the case $\omega_0=0$ the second term on the right-hand side is of higher order than $\mathbb{E}\|W_A(t)\|^2/2$ only under additional assumptions. For this we need $\delta<\frac{1}{2}-2\rho$, as well as a suitable lower bound on the growth of the first term $\mathbb{E}\|W_A(t)\|^2/2$ for small values of t. The latter can be achieved by imposing a lower bound on the growth of the coefficients μ_k. For details we refer the reader to Refs. 25 and 27.

VI. SUMMARY

The enstrophy $\mathrm{Ens}(t)=\mathbb{E}\|\omega(t)\|^2/2$ is an averaged measure of fluid vorticity $\omega(t)$. We have investigated the enstrophy evolution of large-scale quasi-geostrophic flows under random wind forcing. Thereby we have obtained results on upper bounds (Theorems 1 and 2), Hölder continuity (Theorem 3), as well as small-time asymptotics (Theorem 4) for the enstrophy.

Annihilation-diffusion processes: An exactly solvable model

Farinaz Roshani[a] and Mohammad Khorrami[b]
Institute for Advanced Studies in Basic Sciences, P.O. Box 159, Zanjan 45195, Iran

(Received 21 October 2001; accepted for publication 3 January 2002)

A family of diffusion-annihilation processes is introduced, which is exactly solvable. This family contains parameters that control the diffusion and annihilation rates. The solution is based on the Bethe ansatz and using special boundary conditions to represent the reaction. The processes are investigated, both on the lattice and on the continuum. Special cases of this family of processes are the simple exclusion process and the drop-push model. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1466532]

I. INTRODUCTION

In recent years, the asymmetric exclusion process and the problems related to it, including, for example, the biopolymerization,[1] dynamical models of interface growth,[2] traffic models,[3] the noisy Burgers equation,[4] and the study of shocks,[5,6] have been extensively studied. The dynamical properties of this model have been studied in Refs. 6–8. As the results obtained by approaches like mean field are not reliable in one dimension, it is useful to introduce solvable models and analytic methods to extract exact physical results. Among these methods is the coordinate Bethe ansatz, which was used in Ref. 9 to solve the asymmetric simple exclusion process on a one-dimensional lattice. In Ref. 10, a similar technique was used to solve the drop-push model,[11] and a generalized one-parameter model interpolating between the asymmetric simple exclusion model and the drop-push model. In Ref. 12, this family was further generalized to a family of processes with arbitrary left- and right-diffusion rates. All of these models were lattice models. Finally, the behavior of the latter model on continuum was investigated in Ref. 13. The continuum models of this kind are also investigated in Refs. 14 and 15.

In the generalized model interpolating between the asymmetric simple exclusion model and the drop-push model,[10,12,13] there are two parameters λ and μ, which control the pushing rate. Normalizing the diffusion rate to one, it is seen that the sum of these two parameters should be one to ensure the conservation of probability. These two parameters appear in the boundary condition used instead of the reaction. The question arises of what happens if this conservation of probability is violated. This is what is investigated in the present paper. The main point of the paper is that the Bethe-ansatz approach, which is normally used for exactly solvable systems with constant number of particles, can also be used for some exactly solvable systems in them the number of particles decreases.

The scheme of the paper is the following. In Sec. II, the allowed boundary conditions are investigated. It is shown that if $\lambda+\mu<1$, then the number of the particles will be decreasing, that is, there is an annihilation process as well. It is shown that one can in fact write a two-particle to one-particle annihilation process which results in such a boundary condition.

In Sec. III, the Bethe-ansatz solution for the N-particle probability of this process is obtained, and its large-time behavior is investigated. This is done for the process on the lattice as well as on the continuum. Finally, in Sec. IV the special case of the two-particle initial condition is fully

[a]Electronic mail: roshani@iasbs.ac.ir
[b]Electronic mail: mamwad@iasbs.ac.ir

investigated, and it is explicitly shown that at large times, there remains only one particle. For a special value of the annihilation rate, an explicit form for the one-particle density is also obtained.

II. BOUNDARY CONDITIONS

Consider the following master equation for an asymmetric exclusion process:

$$\frac{\partial}{\partial t}P(x_1,x_2,\ldots,x_N;t)=P(x_1-1,x_2,\ldots,x_N;t)+P(x_1,x_2-1,\ldots,x_N;t)+\cdots$$
$$+P(x_1,x_2,\ldots,x_N-1;t)-NP(x_1,x_2,\ldots,x_N;t). \tag{1}$$

This equation describes a collection of N particles drifting to the right with unit rate. If the particles are to exclude each other, that is if no two particles are to occupy the same site, then (1) is valid only for

$$x_i<x_{i+1}-1. \tag{2}$$

One can, however, assume that (1) is correct for all of the physical region $x_i<x_{i+1}$, and impose certain boundary conditions for $x_i=x_{i+1}$. Note that if $x_i=x_{i+1}-1$ for some i, then on the right-hand side of (1) there will be terms with $x_i=x_{i+1}$, which is out of the physical region. The boundary condition determines the nature of the interaction between particles. But what are the allowed boundary conditions? Let us rewrite (1) for the case of two particles and use the conservation of probability. We arrive at

$$\frac{\partial}{\partial t}\sum_{x_2}\sum_{x_1<x_2}P(x_1,x_2;t)=\sum_{x_2}\sum_{x_1<x_2}P(x_1,x_2;t)-\sum_{x}P(x,x+1;t)$$
$$+\sum_{x_2}\sum_{x_1<x_2}P(x_1,x_2;t)+\sum_{x}P(x,x;t)-2\sum_{x_2}\sum_{x_1<x_2}P(x_1,x_2;t),$$
$$=-\sum_{x}P(x,x+1;t)+\sum_{x}P(x,x;t). \tag{3}$$

If the right-hand side of (3) is to be identical to zero, then $P(x,x)$ should be a linear combination of $P(x-1+i,x+i)$'s. This may work for the two-particle process, but in many-particle processes it may introduce terms with $x_i>x_{i+1}$, which need additional boundary conditions. The only exception is when $P(x,x)$ is a linear combination of only $P(x,x+1)$ and $P(x-1,x)$. So one can write

$$P(x,x)=\lambda P(x,x+1)+\mu P(x-1,x). \tag{4}$$

Inserting this in (3), one arrives at

$$\frac{\partial}{\partial t}\sum_{x_2}\sum_{x_1<x_2}P(x_1,x_2;t)=(\lambda+\mu-1)\sum_{x}P(x,x+1;t). \tag{5}$$

In order that the right-hand side of (5) be zero, one must impose

$$\lambda+\mu=1. \tag{6}$$

This is the boundary condition used in Refs. 10, 12, and 13.

This kind of boundary condition ensures the conservation of particle number. But in a process where annihilation exists as well, the number of the particles is not conserved; it is decreasing. It is seen that if

$$\lambda+\mu<1, \tag{7}$$

then the probability of finding two particles is decreasing. Suppose one begins with two particles. They drift to right with unit rate. If they meet each other, either the left particle is stopped, or one of them is annihilated. That is, we have the following processes:

$$\begin{aligned} &A\varnothing\rightarrow\varnothing A, \quad \text{with rate } 1,\\ &AA\rightarrow\varnothing A, \quad \text{with rate } \alpha,\\ &AA\rightarrow A\varnothing, \quad \text{with rate } \beta. \end{aligned} \tag{8}$$

In this case, still the more-than-two particle densities are zero, since no particles are generated during the process. But the two-particle density does not determine the one-particle density. And the summation of the former need not be a constant (one). It is seen that the master equation for the two-particle probability is

$$\frac{\partial}{\partial t}P(x_1,x_2;t)=P(x_1-1,x_2;t)+P(x_1,x_2-1;t)-2P(x_1,x_2;t), \quad x_1<x_2-1, \tag{9}$$

and

$$\frac{\partial}{\partial t}P(x,x+1;t)=P(x-1,x+1;t)-(1+\alpha+\beta)P(x,x+1;t). \tag{10}$$

But (10) is the same as (9), provided one uses the boundary condition

$$P(x,x)=\lambda P(x,x+1), \tag{11}$$

with

$$\lambda=1-(\alpha+\beta). \tag{12}$$

So the difference $1-\lambda$ is in fact related to the annihilation rate, as expected. There is one other thing to be noted. As the number of particles is not conserved, one cannot calculate the one-particle probability by a simple summation of the two-particle probability. That is,

$$P(x)\neq\sum_{y>x}P(x,y)+\sum_{y<x}P(y,x). \tag{13}$$

In fact, for the process described, the particles interact and annihilate each other, until there remains only one particle. This means that at $t\rightarrow\infty$, there will be only one particle. So the more-than-one-particle probabilities will tend to zero, whereas the summation of the one-particle probability tends to one. However, if the initial condition is that there are N particles, one can write differential equations for n-particle probabilities in which n-particle probabilities and $n+1$-particle probabilities occur (if $n<N$). For $n>N$, the n-particle probability is identically zero, and the equation for the N-particle probability is closed. So, in principle, one can find the N-particle probability first and use this to find less-than-N-particle probabilities. To be specific, the evolution equation for the one-particle probability is

$$\begin{aligned} \frac{\partial}{\partial t}P(x;t)=&[P(x-1;t)-P(x-1,x;t)]-[P(x;t)-P(x,x+1;t)]\\ &-\alpha P(x,x+1;t)-\beta P(x-1,x;t). \end{aligned} \tag{14}$$

III. BETHE-ANSATZ SOLUTION FOR THE *N*-PARTICLE PROBABILITY

Consider the master equation (1), with the boundary condition

$$P(\ldots,x,x,\ldots)=\lambda P(\ldots,x,x+1,\ldots), \tag{15}$$

where $\lambda<1$. Following Refs. 9, 10, 12, and 13, one can obtain the conditional probability using the Bethe ansatz. Writing

$$P(\mathbf{x};t)=e^{Et}\Psi(\mathbf{x}), \tag{16}$$

and

$$\Psi(\mathbf{x})=\sum_{\sigma} A_{\sigma}e^{i\sigma(\mathbf{p})\cdot\mathbf{x}}, \tag{17}$$

where the summation runs over the elements of the permutation group, one arrives at

$$E=-N+\sum_{j} e^{-ip_j}, \tag{18}$$

and

$$A_{\sigma\sigma_i}=S[\sigma(p_i),\sigma(p_{i+1})]A_{\sigma}, \tag{19}$$

where σ is that permutation which only interchanges p_i and p_{i+1}. One also finds that

$$S_{jk}:=S(p_j,p_k)=-\frac{1-\lambda e^{ip_k}}{1-\lambda e^{ip_j}}. \tag{20}$$

This is the same as what found in Refs. 10 and 12 with $\mu=0$, and if one puts $\lambda=1$, the result of Ref. 9 is obtained. The conditional probability is thus written as

$$P(\mathbf{x};t|\mathbf{y};0)=\int \frac{\mathrm{d}^N p}{(2\pi)^N}\Psi_{\mathbf{p}}(\mathbf{x})e^{E(\mathbf{p})t-i\mathbf{p}\cdot\mathbf{y}}, \tag{21}$$

where Ψ is defined as (17) with $A_{\text{identity}}=1$. This looks like similar to what obtained in Refs. 9, 10, and 12. There is, however, a difference. As $\lambda<1$, there is no pole in S, and hence in A. So for large times, when the probability distribution becomes smooth and its Fourier transform for large frequencies tends to vanish, one can put $p_j=0$ in S as an approximation to arrive at

$$S\approx -1, \tag{22}$$

and

$$A_{\sigma}\approx(-1)^{\sigma}. \tag{23}$$

One can also approximate $E(\mathbf{p})$ as

$$E(\mathbf{p})\approx\sum_{j}\left(-ip_j-\frac{p_j^2}{2}\right). \tag{24}$$

So, for large times,

$$P(\mathbf{x};t|\mathbf{y};0)\approx\frac{1}{(2\pi t)^{N/2}}\sum_{\sigma}(-1)^{\sigma}\exp\left(-\sum_{j}[x_j-\sigma(y_j)-t]^2/(2t)\right). \tag{25}$$

It is clearly seen that the integral of this distribution over the physical region tends to zero as $t\to\infty$. This should be the case, since the number of the particles does not remain constant and decreases.

Using the boundary condition (4) with (7), does not change the results drastically. In fact, E does not change at all, while S is changed to

$$S_{jk}=-\frac{1-\lambda e^{ip_k}-\mu e^{-ip_j}}{1-\lambda e^{ip_j}-\mu e^{-ip_k}}. \tag{26}$$

The approximate result for large times does not depend on λ or μ, so long as their sum is less than 1.

One can also investigate the continuous-space form of the evolution. Following Ref. 13, the master equation is changed to

$$\frac{\partial}{\partial t}P(\mathbf{x};t)=-\sum_j \partial_j P(\mathbf{x};t)+\frac{1}{2}\sum_j \partial_j^2 P(\mathbf{x};t), \tag{27}$$

and the boundary condition to

$$(1-\lambda-\mu-\lambda\partial_{j+1}+\mu\partial_j)P|_{x_{j+1}=x_j}=0. \tag{28}$$

Using the Galilean transformation $x_i\to x_i+vt$ and $t\to t$, the master equation (27) is simplified to

$$\frac{\partial}{\partial t}P(\mathbf{x};t)=\frac{1}{2}\nabla^2 P(\mathbf{x};t). \tag{29}$$

Using a Bethe-ansatz solution like (16) and (17), one arrives at

$$E=-\frac{1}{2}\sum_j p_j^2, \tag{30}$$

and

$$S_{jk}=-\frac{1-\lambda-\mu-i\lambda p_k+i\mu p_j}{1-\lambda-\mu-i\lambda p_j+i\mu p_k}. \tag{31}$$

For large times, one can approximate S to -1, and arrive at a result similar to (25). The difference is that in the exponent the term $x_j-t-\sigma(y_j)$ is replaced by $x_j-\sigma(y_j)$, as the Galilean transformation used has canceled the drift from the master equation.

IV. TWO-PARTICLE SYSTEMS AND THE EXACT SOLUTION

As was seen in Sec. III, the conditional probability for the two-particle system described by (9) and (11) is

$$P(\mathbf{x};t|\mathbf{y};0)=\int \frac{\mathrm{d}^2p}{4\pi^2}e^{Et-i\mathbf{p}\cdot\mathbf{y}}\times\left[e^{i(p_1x_1+p_2x_2)}-\frac{1-\lambda e^{ip_2}}{1-\lambda e^{ip_1}}e^{i(p_1x_2+p_2x_1)}\right], \tag{32}$$

where E is obtained from (18). This integration is easily done and the result is

$$P(\mathbf{x};t|\mathbf{y};0)=e^{-2t}\frac{t^{x_1-y_1}}{(x_1-y_1)!}\frac{t^{x_2-y_2}}{(x_2-y_2)!}$$
$$+e^{-2t}\sum_{l=0}^{\infty}\frac{t^{l+x_2-y_1}}{(l+x_2-y_1)!}\frac{t^{x_1-y_2}}{(x_1-y_2)!}\lambda^l\left(-1+\frac{\lambda t}{x_1-y_2+1}\right). \tag{33}$$

Another interesting quantity is the average number of the particles. This is equal to the summation of the one-particle probability:

$$N(t):=\sum_x P(x;t). \tag{34}$$

Using (14), one arrives at

$$\dot{N}=-(\alpha+\beta)\sum_x P(x-1,x;t)$$
$$=-\frac{1-\lambda}{\lambda}\sum_x P(x,x;t). \tag{35}$$

The right-hand side can be calculated using the Bethe-ansatz solution directly. Using (32), one has

$$\sum_x P(x,x;t)=\int\frac{\mathrm{d}^2p}{2\pi}\delta(p_1+p_2)[1+S(p_1,p_2)]e^{Et-i(p_1y_1+p_2y_2)}$$
$$=\lambda\int\frac{\mathrm{d}p}{2\pi}e^{2t(\cos p-1)+ip(y_2-y_1)}\frac{e^{-ip}-e^{ip}}{1-\lambda e^{ip}}$$
$$=\lambda\int\frac{\mathrm{d}p}{2\pi}e^{2t(\cos p-1)+ip(y_2-y_1)}\times\sum_{m=0}^{\infty}\lambda^m[e^{i(m-1)p}-e^{i(m+1)p}]$$
$$=\lambda\sum_{m=0}^{\infty}e^{-2t}\lambda^m[\mathrm{I}_{y_2-y_1+m-1}(2t)-\mathrm{I}_{y_2-y_1+m+1}(2t)]$$
$$=\lambda\sum_{m=0}^{\infty}e^{-2t}\lambda^m\frac{y_2-y_1+m}{t}\mathrm{I}_{y_2-y_1+m}(2t), \tag{36}$$

where I denotes the modified Bessel function. This can be inserted in (35) to obtain

$$N(t)=N(0)-\frac{1-\lambda}{\lambda}\int_0^t\mathrm{d}t'\sum_x P(x,x;t')$$
$$=N(0)-(1-\lambda)\sum_{m=0}^{\infty}\int_0^t\mathrm{d}t'\ e^{-2t'}\lambda^m\frac{y_2-y_1+m}{t'}\mathrm{I}_{y_2-y_1+m}(2t'). \tag{37}$$

This is simplified for $t\to\infty$. Using

$$\int_0^\infty\mathrm{d}s\frac{e^{-s}}{s}\mathrm{I}_n(s)=\frac{1}{n}, \tag{38}$$

one arrives at

$$N(\infty)=N(0)-(1-\lambda)\sum_{m=0}^{\infty}\lambda^m=N(0)-1. \tag{39}$$

But note that

$$N(0)=2, \tag{40}$$

since at the beginning there were two particles at y_1 and y_2. That is,

$$P(x;0)=\delta(x-y_1)+\delta(x-y_2). \tag{41}$$

So, at $t\to\infty$, there remains only one particle, as one of the two particles has been annihilated.

The continuous-space analog of this model can also be solved easily. Using (29) as the master equation, and (30) and (31) (with $\mu=0$), one is led to

$$P(\mathbf{x};t|\mathbf{y};0)=\int \frac{\mathrm{d}^2p}{4\pi^2}e^{Et-i\mathbf{p}\cdot\mathbf{y}} \times\left[e^{i(p_1x_1+p_2x_2)}-\frac{1-\lambda-i\lambda p_2}{1-\lambda-i\lambda p_1}e^{i(p_1x_2+p_2x_1)}\right]. \tag{42}$$

Using the change of variable $p:=p_1+i(1-\lambda)/\lambda$ in the second integral, (42) is written as

$$P(\mathbf{x};t|\mathbf{y};0)=\frac{1}{2\pi t}e^{-[(x_1-y_1)^2+(x_2-y_2)^2]/(2t)}+\frac{1}{\sqrt{8\pi t}} \times\left[A+\frac{x_1-y_2}{t}\right]e^{-(x_1-y_2)^2/(2t)}e^{[2A(x_2-y_1)+tA^2]/2}\times\left\{-1+\mathrm{erf}\left[\frac{1}{\sqrt{2t}}(x_2-y_1+tA)\right]\right\}, \tag{43}$$

where

$$A:=\frac{1-\lambda}{\lambda}. \tag{44}$$

One notes that at $t\to\infty$, the conditional probability is simplified. We have

$$1-\mathrm{erf}(x)\approx\frac{e^{-x^2}}{x\sqrt{\pi}}, \quad \text{for large } x. \tag{45}$$

From this, it is seen that at $t\to\infty$,

$$P(\mathbf{x};t|\mathbf{y};0)\approx\frac{1}{2\pi t}\{e^{-[(x_1-y_1)^2+(x_2-y_2)^2]/(2t)}-e^{-[(x_1-y_2)^2+(x_2-y_1)^2]/(2t)}\}. \tag{46}$$

This is a special case of what was obtained in Sec. III.

Another quantity to be considered is the one-point probability. In the continuum limit, and after performing the Galilean transformation, (14) becomes

$$\frac{\partial}{\partial t}P(x;t)=\frac{1}{2}\frac{\partial^2}{\partial x^2}P(x;t)+(\partial_1+\partial_2)P(x,x;t)-[\alpha(1+\partial_2)+\beta(1-\partial_1)]P(x,x;t). \tag{47}$$

From this, using the boundary condition (28), with $\mu=0$, one arrives at

$$\dot{N}(t)=-\frac{1-\lambda}{\lambda}\int \mathrm{d}x\ P(x,x;t), \tag{48}$$

where

$$N(t)\coloneqq\int \mathrm{d}x\ P(x;t). \tag{49}$$

Using (42), the integral at the right-hand side is calculated to be

$$\int \mathrm{d}x\ P(x,x;t)=\int \frac{\mathrm{d}p}{2\pi}\frac{-2i\lambda p}{1-\lambda-i\lambda p}e^{-tp^2+ip(y_2-y_1)}. \tag{50}$$

To obtain $N(\infty)$, one integrates (50) from 0 to ∞. This results in

$$\int_0^\infty \mathrm{d}t\int \mathrm{d}x\ P(x,x;t)=\frac{\lambda}{\pi}\,\mathrm{P}\int \frac{\mathrm{d}p}{ip}\frac{e^{ip(y_2-y_1)}}{1-\lambda-i\lambda p}=\frac{\lambda}{1-\lambda}. \tag{51}$$

The symbol P denotes the Cauchy's principle value, and use has been made of the fact that $y_2>y_1$. From this, it is found that

$$N(\infty)=N(0)-1=1. \tag{52}$$

This is the same result obtained for the lattice, as expected.

The special case $\lambda=0$. $\lambda=0$, or $\alpha+\beta=1$, means that the diffusion rate is equal to the annihilation rate. This criterion simplifies the boundary condition to

$$P(x,x;t)=0. \tag{53}$$

Using this, it is easily seen that the two-point function on the continuum is

$$P(\mathbf{x};t|\mathbf{y};0)=\frac{1}{2\pi t}\{e^{-[(x_1-y_1)^2+(x_2-y_2)^2]/(2t)}-e^{-[(x_1-y_2)^2+(x_2-y_1)^2]/(2t)}\}. \tag{54}$$

One notes that this means that the approximate result (46) for large times is here an exact result for all times.

For the one-point function on the continuum, using (47) and (53), one arrives at

$$\dot{P}(x;t)=\frac{1}{2}\frac{\partial^2}{\partial x^2}P(x;t)-\partial_2 P(x,x;t). \tag{55}$$

This is a diffusion equation with a sink term. The solution to it is

$$\begin{aligned}P(x;t)=&\frac{1}{\sqrt{2\pi t}}\int \mathrm{d}x'\ e^{-(x-x')^2/(2t)}P(x';0)\\&+\int_0^t \mathrm{d}t'\int \mathrm{d}x'\ \frac{1}{\sqrt{2\pi(t-t')}}e^{-(x-x')^2/[2(t-t')]}\times[-\partial_2 P(x',x';t')],\end{aligned} \tag{56}$$

which can be simplified as

$$P(x;t)=\frac{1}{\sqrt{2\pi t}}[e^{-(x-y_1)^2/(2t)}+e^{-(x-y_2)^2/(2t)}]$$

$$-\int_0^t dt'\ \frac{y_2-y_1}{\sqrt{4\pi^2 t'^3(2t-t')}}e^{-(y_2-y_1)^2/(4t')}e^{-(x-Y)^2/(2t-t')}, \tag{57}$$

where use has been made of the initial condition

$$P(x;0)=\delta(x-y_1)+\delta(x-y_2), \tag{58}$$

with $y_2>y_1$, and we have defined

$$Y:=\frac{y_1+y_2}{2}. \tag{59}$$

From (57), one can also obtain the explicit time dependence of N, the particle number. This is the integral of the one-point function, and we have

$$N(t)=2-\int_0^t dt'\ \frac{y_2-y_1}{2\sqrt{\pi t'^3}}\,e^{-(y_2-y_1)/(4t')}, \tag{60}$$

which can be simplified as

$$N(t)=1+\mathrm{erf}\left(\frac{y_2-y_1}{2\sqrt{t}}\right). \tag{61}$$

It is clearly seen that this quantity tends to 1 as $t\to\infty$, as is expected. One also notes that the time scale for annihilation is the square of the initial distance between the particles. This is also expected, as after a time of this order the particles reach each other.

(Received 17 October 2001; accepted for publication 23 January 2002)

The exact perturbation approach is used to derive the (seven) elementary correlation lengths and related mass gaps of the two-dimensional dilute A_4 lattice model in regime 2^- from the Bethe Ansatz solution. This model provides a realization of the integrable $\phi_{(1,2)}$ perturbation of the $c=\frac{7}{10}$ conformal field theory, which is known to describe the off-critical thermal behavior of the tricritical Ising model. The E_7 masses predicted from purely elastic scattering theory follow in the approach to criticality. Universal amplitudes for the tricritical Ising model are calculated. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1465515]

I. INTRODUCTION

The deep relationship between conformal field theory and criticality has provided a wealth of detailed information on phase transitions and critical phenomena. Moreover, *perturbed* conformal field theory provides a description of the *approach* to criticality in certain models.[1] One of the most striking examples is the $\phi_{(1,2)}$ perturbation of the minimal unitary conformal field theory $\mathcal{M}_{3,4}$ which is known to describe the scaling limit of the two-dimensional Ising model at $T=T_c$ in a magnetic field. In particular, Zamolodchikov's construction of nontrivial local integrals of motion and thus an integrable quantum field theory led to the remarkable prediction of eight fundamental mass ratios for the magnetic Ising model.[2] The masses coincide with the components of the Perron–Frobenius vector of the Cartan matrix of the Lie algebra E_8.

In another development, the exactly solvable dilute A_3 lattice model was discovered[3] and (in regime 2 of its four regimes) seen to be in the same universality class as the magnetic Ising model. Most importantly the dilute A_L model[3,4] admits an off-critical extension in which the Boltzmann weights are parametrized in terms of elliptic theta functions.[3] In the dilute A_3 model the elliptic nome plays the role of magnetic field. Its hidden E_8 structure has been revealed by a number of studies.[5–13] The masses, obtained from the eigenspectrum, may be summarized by the formula[11,13]

$$m_j \sim \sum_a \sin\left(\frac{a\pi}{g}\right), \tag{1}$$

where index j labels the eight particles, $g=30$ is the Coxeter number for E_8 and the set of allowed a values is given in Table I.

In addition to the correspondence between the dilute A_3 model and E_8, there are similar correspondences between the dilute A_4 model and E_7, and the dilute A_6 model and E_6. In regime 2 these models are lattice realizations of the $\phi_{(1,2)}$ perturbation of the $\mathcal{M}_{4,5}$ and $\mathcal{M}_{6,7}$ minimal

unitary conformal field theories, respectively, known to have connection to the other exceptional Lie algebras.[14] Some E-type structures have been observed for these dilute A models.[15,16]

Based on the results for the eigenspectrum of the dilute A_3 model[13] and general inversion relations, we proposed[17,18] that, in the thermodynamic limit and in the appropriate regime, the row transfer matrix eigenvalue excitations

$$r_j(w)=\lim_{N\to\infty}\frac{\Lambda_j(w)}{\Lambda_0(w)} \tag{2}$$

of the dilute A_3, A_4 and A_6 models are given by the following general expression.

Proposition: The excitation spectrum of the dilute A_3, A_4 and A_6 models in regime 2 is given by

$$r_j(w)=\prod_a w\,\frac{E(-x^{6sa/g}/w,x^{12s})E(-x^{6s(g-a)/g}/w,x^{12s})}{E(-x^{6sa/g}w,x^{12s})E(-x^{6s(g-a)/g}w,x^{12s})}. \tag{3}$$

Here the elliptic nome is $p=e^{-\epsilon}$, $w=e^{-2\pi u/\epsilon}$, and $x=e^{-\pi^2/r\epsilon}$. Regime 2 is specified by the range of the spectral parameter: $0<u<3\lambda$, and the value of the crossing parameter: $\lambda=\pi s/r$ where $s=L+2$ and $r=4(L+1)$. For the dilute A_4 model the E_7 Coxeter number is $g=18$, while for the A_6 model the E_6 Coxeter number is $g=12$. The standard (conjugate modulus) elliptic function is defined by

$$E(z,q)=\prod_{n=1}^{\infty}(1-q^{n-1}z)(1-q^n/z)(1-q^n).$$

The numbers a appearing in (3) are given in Tables I–III. The integers in these tables have appeared in other contexts in relation to the E-algebras.[19,20]

In this article we explicitly derive the elementary excitation spectrum of the dilute A_4 model, thereby confirming our Proposition in this case. The result (3) leads to the inverse correlation lengths and mass gaps. Our input to these calculations are the string solutions to the Bethe equations found by Grimm and Nienhuis.[9,10,21] As discussed later in Sec. IV, our results are

applicable to the tricritical Ising model which is in the same universality class. In particular, the elliptic nome appearing in the dilute A_4 weights in regime 2 corresponds to the leading thermal off-critical perturbation in the tricritical Ising model. This perturbation is identified with $\phi_{(1,2)}$[22] and has been shown to exhibit E_7 structures.[14,23] We are able to obtain exact results for some universal amplitudes of the tricritical Ising model. These results are in agreement with those found recently by other means.[24,25]

The outline of the article is as follows. The dilute A_L lattice model is defined along with the corresponding Bethe equations in Sec. II. The bulk free energy and the eigenvalue expressions in regime 2 for $L=4$ associated with the seven E_7 masses are derived via the exact perturbation approach in Sec. III (continued in the Appendix). The article concludes in Sec. IV with a discussion of the results and their relevance to universal behavior in the tricritical Ising model.

II. THE DILUTE A_4 MODEL

We here give a short summary of facts about the dilute A_L models[26,13] which are pertinent to our calculations.

The dilute A_L model is an exactly solvable, L-state restricted solid-on-solid model defined on the square lattice. Its adjacency diagram is the Dynkin diagram of A_L with the additional possibility that a state may be adjacent to itself on the lattice. The model is solvable in four off-critical regimes, with the elliptic nome p of its Boltzmann weights taking the model off-critical. At criticality, the dilute A_L model can be constructed[3,4] from the dilute O(n) loop model.[27,28] In regime 2 of the model the central charge is

$$c=1-\frac{6}{L(L+1)}.$$

In the majority of exactly solved models the elliptic nome plays the role of temperature.[29] In the dilute A_L model the interpretation of the elliptic nome differs according to whether L is even or odd. For L odd the elliptic nome plays the role of a magnetic field,[3] and $p>0$ and $p<0$ are related by simple label reversal of the heights. For L even the nome plays a thermal role, and the behavior of the model depends on whether $p>0$ (regime 2^+) or $p<0$ (regime 2^-). More specifically, it was shown[26] that in regime 2 the nome corresponds to perturbation of the $\mathcal{M}_{L,L+1}$ minimal unitary conformal field theories by the operator $\phi_{(1,2)}$.

Using the conjugate variables introduced after (3), and setting $w_j=e^{-2\pi u_j/\epsilon}$, the eigenvalues of the row transfer matrix of the dilute A models (for a periodic strip of width N where for convenience N has been taken as even) can be written[5]

$$\begin{aligned}\Lambda(w)=\omega&\left[\frac{E(x^{4s}/w,x^{2r})E(x^{6s}/w,x^{2r})}{E(x^{4s},x^{2r})E(x^{6s},x^{2r})}\right]^N\prod_{j=1}^{N} w_j^{1-2s/r}\frac{E(x^{2s}w/w_j,x^{2r})}{E(x^{2s}w_j/w,x^{2r})}\\
&+\left[\frac{x^{2s}}{w}\frac{E(w,x^{2r})E(x^{6s}/w,x^{2r})}{E(x^{4s},x^{2r})E(x^{6s},x^{2r})}\right]^N\prod_{j=1}^{N} w_j\frac{E(w/w_j,x^{2r})E(x^{6s}w_j/w,x^{2r})}{E(x^{2s}w_j/w,x^{2r})E(x^{4s}w_j/w,x^{2r})}\\
&+\omega^{-1}\left[x^{2s}\frac{E(w,x^{2r})E(x^{2s}/w,x^{2r})}{E(x^{4s},x^{2r})E(x^{6s},x^{2r})}\right]^N\prod_{j=1}^{N} w_j^{2s/r}\frac{E(x^{8s}w_j/w,x^{2r})}{E(x^{4s}w_j/w,x^{2r})},\end{aligned}\tag{4}$$

TABLE IV. String positions u_j and corresponding eigenvalue bands for the seven elementary mass excitations m_i of the dilute A_4 model in regime 2^-.[21] The strings are in units of $\pi/20$.

i	String positions	Band
1	$\pm 2,10$	w
2	± 7	w^2
3	$\pm 6,10$	w^2
4	$\pm 3,\pm 9$	w^2
5	$\pm 6,\pm 8$	w^3
6	$\pm 4,\pm 8,10$	w^3
7	$\pm 5,\pm 7,\pm 9$	w^4

where $\omega=\exp(i\pi\ell/(L+1))$ for $\ell=1,\ldots,L$, and $s=L+2$ and $r=4(L+1)$ in regime 2. The Bethe equations which give the N roots u_j have the form

$$\omega\left[w_j\frac{E(x^{2s}/w_j,x^{2r})}{E(x^{2s}w_j,x^{2r})}\right]^N=-\prod_{k=1}^{N} w_k^{2s/r}\frac{E(x^{2s}w_j/w_k,x^{2r})E(x^{4s}w_k/w_j,x^{2r})}{E(x^{2s}w_k/w_j,x^{2r})E(x^{4s}w_j/w_k,x^{2r})}. \tag{5}$$

In the limit $|p|\to 1$ with u/ϵ fixed, or equivalently $x\to 0$, the excitations in the eigenspectrum $r_j(w)$, defined in (2), break up into a number of distinct bands labeled by integer powers of w. Numerical investigations of the eigenspectrum[5,9,10,21,17] have revealed eight and seven thermodynamically significant excitations for $L=3$ and $L=4$, respectively, and provided the data in Table IV.

We previously[12,13] applied the exact perturbation approach initiated by Baxter[30] to calculate the excitations in the eigenspectrum for $L=3$. This involved perturbing away from the strong magnetic field limit at $p\to 1$; for $L=4$ this limit corresponds to moving far away from the critical temperature. The calculations follow.

III. MASS SPECTRUM

A. Preliminaries

To apply the perturbation technique[30] to find the form of the excitations (4), the string structure of the Bethe ansatz roots (5) is required input. The groundstate roots all have u_j pure imaginary, so that $w_j=e^{-2\pi u_j/\epsilon}=a_j$ for $j=1,\ldots,N$ with $|a_j|=1$; in this sense they all live on a unit circle. For each excitation i, certain roots acquire a real part $m\pi/20$, as shown in Table IV. (If there are n_i such roots, one says there is an n_i-string associated with the excitation.) For these roots $w_j=b_jx^{2m}$, so that the string entries can be thought of as living on circles of radius x^{2m} with phase b_j, while the other $N-n_i$ roots again lie on the unit circle.

The process of finding the excitations involves using the Bethe equations (5) to set up recurrence relations for auxiliary functions of the unknown roots a_j. As the roots only enter the eigenvalue expression (4) through the auxiliary functions, it just remains to solve the recurrence relations by iteration and to simplify the resulting expressions. The largest eigenvalue Λ_0, relative to which excitations are measured, was calculated previously in this way[13] for all L.

The relationship between the excitations (2), the correlation lengths ξ_j and the mass spectrum m_j of the associated field theory is

$$\xi_j^{-1}=-\log r_j=m_j, \tag{6}$$

where we take the isotropic value $u=3\lambda/2$.

It is convenient to use the notation for products:

$$(z;p_1,\ldots,p_k)_\infty=\prod_{n_1,\ldots n_k=0}^{\infty}(1-p_1^{n_1}\cdots p_k^{n_k}z),$$

$$(z_1,\ldots z_m;p_1,\ldots,p_k)_\infty=\prod_{j=1}^{m}(z_j;p_1,\ldots,p_k)_\infty,$$

which satisfy many identities, the ones used repeatedly in what follows being

$$\frac{(z;p)_\infty}{(zp;p)_\infty}=(1-z),$$

$$\frac{(z;p,q)_\infty}{(zp;p,q)_\infty}=(z;q)_\infty,$$

$$\frac{(zq/p;p,q)_\infty}{(z;p,q)_\infty}=\frac{(zq/p;q)_\infty}{(z;p)_\infty}.$$

The standard elliptic function is thus rewritten as

$$E(z,q)=\prod_{n=1}^{\infty}(1-q^{n-1}z)(1-q^n/z)(1-q^n)=(z,q/z,q;q)_\infty. \tag{7}$$

It also proves convenient to use the shorthand notation $\Pi_{j=1}^{m}a_j=A_m$.

For each m_i, if the associated string of excited roots has length n_i, we define the required auxiliary functions of the as-yet-unknown roots to be

$$F_i(w)=\prod_{j=1}^{N-n_i}(w/a_j;x^{2r})_\infty,$$

$$G_i(1/w)=\prod_{j=1}^{N-n_i}(x^{2r}a_j/w;x^{2r})_\infty. \tag{8}$$

In fact, we actually solve for combinations of these:

$$\mathcal{F}_i(w)=F_i(w)/F_i(x^{16}w)=F_i(w)/F_i(x^{2r-4s}w),$$

$$\mathcal{G}_i(1/w)=G_i(1/w)/G_i(1/x^{16}w)=G_i(1/w)/G_i(1/x^{2r-4s}w), \tag{9}$$

for $i=2,4,5,6,7$ (but for $i=1,3$ slightly different definitions are convenient and are given as required).

So far as possible, we write factors and powers which are common to all eigenvalues (or indeed to all the eigenvalues for other A_L models) in terms of the generic r and s to distinguish them from the particular integers which arise from the input strings. Of course, $r=20$ and $s=6$ throughout. Once the particular string form for the roots has been applied, the calculations are straightforward for all masses except m_1 and m_3. For this reason, we sketch below the details for the first three masses. The other cases follow similar paths to m_2 or indeed to most of the masses for the dilute A_3 model,[13] so we relegate them to the appendix. We make some comments concerning m_1, m_3 and m_6 later on.

B. Mass m_1

We begin the perturbation argument with the structure $w_j=a_j$ for $j=1,\ldots,N-3$ with $w_{N-1}=b_1x^{-4}$, $w_{N-2}=b_2x^4$ and $w_N=b_3x^{20}$, so that the string length is $n_1=3$. From the Bethe equations (5) for $j=N-2$, $j=N-1$ and $j=N$ in the limit $x\to 0$ we can show that $b_1=b_2=b_3=b$. The Bethe equation for the other roots $a_k=a$ is then

$$-\omega\left[a\frac{E(x^{2s}/a)}{E(x^{2s}a)}\right]^N=(A_{N-3}b^3)^{3/5}\frac{a^2}{b^2}\times\frac{E(x^4b/a)E(x^{24}b/a)E(x^{28}b/a)}{E(x^4a/b)E(x^{24}a/b)E(x^{28}a/b)}\prod_{j=1}^{N-3}\frac{E(x^{2s}a/a_j)E(x^{4s}a_j/a)}{E(x^{2s}a_j/a)E(x^{4s}a/a_j)}. \quad (10)$$

In the $x\to 0$ limit this gives the equation

$$a^{N-2}+\frac{1}{\omega}(A_{N-3}b^3)^{3/5}/b^2=0, \quad (11)$$

which is an equation of order $(N-2)$, so that there is a missing root on the unit circle, a ''hole'' which we call a_{N-2}. Since this is an equation for the roots, its left hand side must be equivalent to $\Pi_{j=1}^{N-2}(a-a_j)$, and equating the constant terms from these two expressions we obtain

$$\frac{1}{\omega}(A_{N-3}b^3)^{3/5}=A_{N-2}b^2=A_{N-3}a_{N-2}b^2 \quad (12)$$

(which we later apply to prefactors in Λ_1). The Bethe equations for b, taken together in this limit and combined with (12), give

$$\left[\frac{1}{\omega}(A_{N-3}b^3)^{3/5}\right]^3=-b^6(A_{N-3})^2\Rightarrow A_{N-3}(a_{N-2})^3=-1.$$

We use this, together with the fact that each root a_j, including the hole, must satisfy (11), to show

$$(a_{N-2})^{N-2}=-A_{N-3}a_{N-2}\Rightarrow(a_{N-2})^N=1. \quad (13)$$

We define the following auxiliary functions of the roots [see (8)]:

$$\mathcal{F}_1(w)=\frac{F_1(w)}{F_1(x^{16}w)}\frac{(x^4w/b;x^{2r})_\infty}{(x^{12}w/b;x^{2r})_\infty},$$

$$\mathcal{G}_1(1/w)=\frac{G_1(1/w)}{G_1(1/x^{16}w)}\frac{(x^{36}b/w;x^{2r})_\infty}{(x^{24}b/w;x^{2r})_\infty}.$$

They must satisfy recurrence relations arising from (10):

$$\mathcal{F}_1(a)=\left[\frac{(x^{2s}a;x^{2r})_\infty}{(x^{2r-2s}a;x^{2r})_\infty}\right]^N\frac{(x^{24}a/a_{N-2},x^{28}a/a_{N-2};x^{2r})_\infty}{(x^{12}a/a_{N-2},x^{16}a/a_{N-2};x^{2r})_\infty}\frac{\mathcal{F}_1(x^{2s}a)}{\mathcal{F}_1(x^{4s}a)},$$

$$\mathcal{G}_1(1/a)=\left[\frac{(x^{2r+2s}/a;x^{2r})_\infty}{(x^{6s}/a;x^{2r})_\infty}\right]^N\frac{(x^{36}a_{N-2}/a,x^{40}a_{N-2}/a;x^{2r})_\infty}{(x^{48}a_{N-2}/a,x^{52}a_{N-2}/a;x^{2r})_\infty}\frac{\mathcal{G}_1(x^{2s}/a)}{\mathcal{G}_1(x^{4s}/a)}. \quad (14)$$

Solving these we obtain

$$\mathcal{F}_1(a)=\mathcal{F}_0(a)\,\frac{(x^{40}a/a_{N-2};x^{2r})_\infty}{(x^{16}a/a_{N-2};x^{2r})_\infty}\,\frac{(x^{36}a/a_{N-2},x^{48}a/a_{N-2};x^{12s})_\infty}{(x^{12}a/a_{N-2},x^{72}a/a_{N-2};x^{12s})_\infty},$$
$$\mathcal{G}_1(1/a)=\mathcal{G}_0(1/a)\,\frac{(x^{40}a_{N-2}/a;x^{2r})_\infty}{(x^{64}a_{N-2}/a;x^{2r})_\infty}\,\frac{(x^{36}a_{N-2}/a,x^{96}a_{N-2}/a;x^{12s})_\infty}{(x^{60}a_{N-2}/a,x^{72}a_{N-2}/a;x^{12s})_\infty}. \tag{15}$$

Here $\mathcal{F}_0$ and $\mathcal{G}_0$ arise from the square bracketed factors in (14) and give rise to the square bracketed factor in (16). They are related to the groundstate eigenvalue Λ_0, they are common to the calculation of each mass and we will suppress these factors for $m_2,\ldots,m_7$. We now write the eigenvalue expression in terms of the auxiliary functions, the first term being

$$\frac{\Lambda_1}{3}=-\frac{w}{a_{N-2}}\left[\frac{(x^{2r-6s}w,x^{2r-4s}w,x^{4s}/w,x^{6s}/w;x^{2r})_\infty}{(x^{2r-6s},x^{2r-4s},x^{4s},x^{6s};x^{2r})_\infty}\right]^N$$
$$\times\frac{(x^{28}w/a_{N-2},x^{12}a_{N-2}/w;x^{2r})_\infty}{(x^{12}w/a_{N-2},x^{28}a_{N-2}/w;x^{2r})_\infty}\mathcal{F}_1(x^{2s}w)\mathcal{G}_1(1/x^{2s}w). \tag{16}$$

Substituting the solutions (15) gives an expression for the excitation $r_1(w)$ which may be written in elliptic functions (7) as

$$\frac{\Lambda_1}{\Lambda_0}=w\,\frac{E(-x^{12}/w,x^{12s})E(-x^{48}w,x^{12s})}{E(-x^{12}w,x^{12s})E(-x^{48}/w,x^{12s})}, \tag{17}$$

where we have set $a_{N-2}=-1$. (The other two terms in the eigenvalue always give identical elliptic function expressions to the first, upon simplification.)

The Bethe equations involving b and the ''hole'' equation, which is (10) with $a=a_{N-2}$, can also be expressed in terms of the auxiliary functions. Application of identities and simplification gives

$$E(x^{12}b/a_{N-2},x^{2r-4s})=E(x^{12}a_{N-2}/b,x^{2r-4s}),$$
$$\left[\frac{E(x^{12}a_{N-2},x^{12s})E(x^{48}/a_{N-2},x^{12s})}{E(x^{12}/a_{N-2},x^{12s})E(x^{48}a_{N-2},x^{12s})}\right]^N=(a_{N-2})^N.$$

Clearly $a_{N-2}=b=-1$ (identified initially from numerical studies) satisfy these conditions; the second reduces to (13) in the $x\to 0$ limit, and note the similarities with (17).

C. Mass m_2

We begin the perturbation argument with the structure $w_j=a_j$ for $j=1,\ldots,N-2$ with $w_{N-1}=b_1x^{-14}$ and $w_N=b_2x^{14}$, so that $n_2=2$. From the Bethe equations for $j=N-1$ and $j=N$ we can show that $b_1=b_2=b$. The Bethe equation for the other roots $a_k=a$ is then

$$-\omega\left[a\,\frac{E(x^{2s}/a)}{E(x^{2s}a)}\right]^N=(A_{N-2}b^2)^{3/5}\frac{a^2}{b^2}\,\frac{E(x^{10}b/a)E(x^{14}b/a)}{E(x^{10}a/b)E(x^{14}a/b)}\prod_{j=1}^{N-2}\frac{E(x^{2s}a/a_j)E(x^{4s}a_j/a)}{E(x^{2s}a_j/a)E(x^{4s}a/a_j)}. \tag{18}$$

In the $x\to 0$ limit this gives the equation

$$a^{N-2}+\frac{1}{\omega}(A_{N-2}b^2)^{3/5}/b^2=0,$$

which has the same order as the number of unknown roots $(N-2)$ so that there is no hole. Equating this with $\Pi_{j=1}^{N-2}(a-a_j)$ we obtain

$$\frac{1}{\omega}(A_{N-2}b^2)^{3/5}=A_{N-2}b^2$$

(which we later apply to prefactors in Λ_2). From the other Bethe equations in this limit,

$$\left[\frac{1}{\omega}(A_{N-2}b^2)^{3/5}\right]^2=\frac{(A_{N-2}b^2)^2}{b^{2N}}\Rightarrow b^{2N}=1. \tag{19}$$

Treating the Bethe equation (18) as before gives, in terms of the functions defined in (8) and (9), the recurrences

$$\mathcal{F}_2(a)=\frac{(x^{26}a/b,x^{30}a/b;x^{2r})_\infty}{(x^{10}a/b,x^{14}a/b;x^{2r})_\infty}\frac{\mathcal{F}_2(x^{2s}a)}{\mathcal{F}_2(x^{4s}a)},$$

$$\mathcal{G}_2(1/a)=\frac{(x^{38}b/a,x^{34}b/a;x^{2r})_\infty}{(x^{50}b/a,x^{54}b/a;x^{2r})_\infty}\frac{\mathcal{G}_2(x^{2s}/a)}{\mathcal{G}_2(x^{4s}/a)}.$$

Solving these we obtain

$$\mathcal{F}_2(a)=\frac{(x^{30}a/b,x^{42}a/b;x^{2r})_\infty}{(x^{14}a/b,x^{26}a/b;x^{2r})_\infty}\frac{(x^{26}a/b,x^{38}a/b,x^{46}a/b,x^{58}a/b;x^{12s})_\infty}{(x^{10}a/b,x^{22}a/b,x^{62}a/b,x^{74}a/b;x^{12s})_\infty},$$

$$\mathcal{G}_2(1/a)=\frac{(x^{38}b/a,x^{50}b/a;x^{2r})_\infty}{(x^{54}b/a,x^{66}b/a;x^{2r})_\infty}\frac{(x^{34}b/a,x^{46}b/a,x^{86}b/a,x^{98}b/a;x^{12s})_\infty}{(x^{50}b/a,x^{62}b/a,x^{70}b/a,x^{82}b/a;x^{12s})_\infty}.$$

We now substitute these into the eigenvalue expression, the first term of which is

$$\frac{\Lambda_2}{3}=\frac{w^2}{b^2}\frac{(x^{26}w/b,x^{38}w/b,x^2b/w,x^{14}b/w;x^{2r})_\infty}{(x^2w/b,x^{14}w/b,x^{26}b/w,x^{38}b/w;x^{2r})_\infty}\mathcal{F}_2(x^{2s}w)\mathcal{G}_2(1/x^{2s}w).$$

This gives an expression for the excitation in elliptic functions (setting $b=-1$):

$$\frac{\Lambda_2}{\Lambda_0}=w^2\frac{E(-x^2/w,x^{12s})E(-x^{14}/w,x^{12s})E(-x^{38}w,x^{12s})E(-x^{50}w,x^{12s})}{E(-x^2w,x^{12s})E(-x^{14}w,x^{12s})E(-x^{38}/w,x^{12s})E(-x^{50}/w,x^{12s})}. \tag{20}$$

If the product of the six Bethe equations involving b is expressed in terms of the auxiliary functions, the equation for b [generalizing $b^{2N}=1$ seen in the $x\to 0$ limit in (19)] is clearly satisfied by $b=-1$:

$$\left[\frac{E(x^2b,x^{12s})E(x^{14}b,x^{12s})E(x^{38}/b,x^{12s})E(x^{50}/b,x^{12s})}{E(x^2/b,x^{12s})E(x^{14}/b,x^{12s})E(x^{38}b,x^{12s})E(x^{50}b,x^{12s})}\right]^N=b^{2N}.$$

Compare the pattern of powers of x in this equation with those in (20); this equation has a precise analog for each mass $m_4,\ldots,m_7$, which will not be given.

D. Mass m_3

We begin the perturbation argument with the string structure $w_j=a_j$ for $j=1,\ldots,N-3$ with $w_{N-2}=b_1x^{-12}$, $w_{N-1}=b_2x^{12}$ and $w_N=b_3x^{20}$. From the Bethe equations for $j=N-2$ and $j=N-1$ we can show that $b_1=b_2=\alpha$, but the Bethe equation for $j=N$ does not link $b_3=b$ to α in the $x\to 0$ limit. (This feature was observed also in the $L=3$ case, for a string of odd length.[13]) The Bethe equation for the other roots $a_k=a$ is then

$$-\omega\left[a\frac{E(x^{2s}/a)}{E(x^{2s}a)}\right]^N=(A_{N-3}\alpha^2 b)^{3/5}\frac{a^3}{\alpha b^2}\frac{E(x^4b/a)E(x^8b/a)}{E(x^4a/b)E(x^8a/b)}$$
$$\times\frac{E(x^{12}\alpha/a)E(x^{16}\alpha/a)E(x^{36}\alpha/a)}{E(x^{12}a/\alpha)E(x^{16}a/\alpha)E(x^{36}a/\alpha)}\prod_{j=1}^{N-3}\frac{E(x^{2s}a/a_j)E(x^{4s}a_j/a)}{E(x^{2s}a_j/a)E(x^{4s}a/a_j)}. \quad (21)$$

In the $x\to 0$ limit this gives the equation

$$a^{N-3}-\frac{1}{\omega}(A_{N-3}\alpha^2 b)^{3/5}/\alpha b^2=0.$$

Equating this as usual with $\Pi_{j=1}^{N-3}(a-a_j)$, we obtain

$$\frac{1}{\omega}(A_{N-3}\alpha^2 b)^{3/5}=A_{N-3}\alpha b^2$$

(which we later apply to prefactors in Λ_3). From the other Bethe equations in this limit,

$$\left[\frac{1}{\omega}(A_{N-3}\alpha^2 b)^{3/5}\right]^3=\frac{(A_{N-3}\alpha b^2)^3}{b^{2N}}\Rightarrow b^{2N}=1.$$

In this case it is convenient to define

$$\mathcal{F}_3(w)=\frac{F_3(w)}{F_3(x^{16}w)}\frac{(x^{12}w/\alpha;x^{2r})}{(x^4w/\alpha;x^{2r})},$$
$$\mathcal{G}_3(1/w)=\frac{G_3(1/w)}{G_3(1/x^{16}w)}\frac{(x^{28}\alpha/w;x^{2r})}{(x^{36}\alpha/w;x^{2r})}, \quad (22)$$

because this choice will make it clear that α is a spectator in the solution to the recurrence relation; it does not appear in the eigenvalue expression.

Treating the Bethe equation (21) as before gives the recurrences

$$\mathcal{F}_3(a)=\frac{(x^{32}a/b,x^{36}a/b;x^{2r})_\infty}{(x^4a/b,x^8a/b;x^{2r})_\infty}\frac{\mathcal{F}_3(x^{2s}a)}{\mathcal{F}_3(x^{4s}a)},$$
$$\mathcal{G}_3(1/a)=\frac{(x^{56}b/a,x^{60}b/a;x^{2r})_\infty}{(x^{28}b/a,x^{32}b/a;x^{2r})_\infty}\frac{\mathcal{G}_3(x^{2s}/a)}{\mathcal{G}_3(x^{4s}/a)}.$$

Solving these we obtain

$$\mathcal{F}_3(a)=\frac{(x^{36}a/b;x^{2r})_\infty}{(x^{20}a/b;x^{2r})_\infty}\frac{(x^{32}a/b,x^{40}a/b,x^{44}a/b,x^{52}a/b;x^{12s})_\infty}{(x^4a/b,x^8a/b,x^{16}a/b,x^{68}a/b;x^{12s})_\infty},$$
$$\mathcal{G}_3(1/a)=\frac{(x^{44}b/a;x^{2r})_\infty}{(x^{60}b/a;x^{2r})_\infty}\frac{(x^{28}b/a,x^{32}b/a,x^{40}b/a,x^{92}b/a;x^{12s})_\infty}{(x^{56}b/a,x^{64}b/a,x^{68}b/a,x^{76}b/a;x^{12s})_\infty}.$$

We now substitute these into the eigenvalue expression, the first term of which is, in terms of the functions (22),

$$\frac{\Lambda_3}{3}=\frac{w^2}{b^2}\frac{(x^{32}w/b,x^8b/w;x^{2r})_\infty}{(x^8w/b,x^{32}b/w;x^{2r})_\infty}\mathcal{F}_3(x^{2s}w)\mathcal{G}_3(1/x^{2s}w).$$

With $b=-1$ this gives the expression in elliptic functions

$$\frac{\Lambda_3}{\Lambda_0}=w^2\frac{E(-x^8/w,x^{12s})E(-x^{16}/w,x^{12s})E(-x^{44}w,x^{12s})E(-x^{52},w,x^{12s})}{E(-x^8w,x^{12s})E(-x^{16}w,x^{12s})E(-x^{44}/w,x^{12s})E(-x^{52}/w,x^{12s})}. \tag{23}$$

The Bethe equations involving α and b, also expressed in terms of the auxiliary functions, give

$$E(x^{12}b/\alpha,x^{2r-4s})=E(x^{12}\alpha/b,x^{2r-4s}),$$

$$\left[\frac{E(x^8b,x^{12s})E(x^{16}b,x^{12s})E(x^{44}/b,x^{12s})E(x^{52}/b,x^{12s})}{E(x^8/b,x^{12s})E(x^{16}/b,x^{12s})E(x^{44}b,x^{12s})E(x^{52}b,x^{12s})}\right]^N=b^{2N}.$$

Notice that $b=-1$ satisfies this second equation, and the (so far missing) link between α and b is provided by the first.

E. Comments on the "odd" strings

To close this rather technical section of the article, we wish to briefly comment on the strings of odd length (see Table IV).

For this model strings of odd length appear for the first, third and sixth masses. In the first case, the odd string of excited roots is accompanied by a "hole" among the roots on the unit circle; it is only this hole a_{N-2} which appears in the eigenvalue expression. In the case of the third mass, the phase b of the string entry $m=10$ appears alone in the eigenvalue expression, and the other entries of the string seem to have a spectator role. (For the sixth mass, there was nothing special about the calculation.) In the calculations for dilute A_3 (Ref. 13) odd strings were involved for masses 4 and 6, where again the calculation of the associated excitation was less straightforward than for even strings. In one case, both the coefficient of the "odd" entry *and* a hole appeared in the eigenvalue, while the other calculation resembles that of m_3 in this article. In general the string entries come in pairs $\pm m$, except for $m=r/2$, which stands alone if it occurs, due to the period of the original elliptic functions in u_j. This is the only source of strings of odd length; we can only conclude that when such an entry occurs, it in some sense dominates calculations following the exact perturbation technique. For strings of even length, all the excited roots seem to contribute in a more equal fashion to the calculation and to the resulting eigenvalue expression.

IV. DISCUSSION

In this article we have made use of the Bethe Ansatz string solutions found by Grimm and Nienhuis to derive the excitation spectrum of the dilute A_4 model via the exact perturbation approach. Our expressions for the seven thermodynamically significant excitations for the dilute A_4 eigenspectrum in regime 2^- are given in (17), (20), (23), (A2), (A4), (A6) and (A7). In this way we have verified for a second case the Proposition given by (3).

It is perhaps unsatisfying that an elegant closed form expression such as (3) has been confirmed in the A_4 case by relying on numerical data for the strings (Table IV). Indeed, as described for the A_3 case in Ref. 13, and in the detailed study of Ref. 10, tracing the strings from $p=0$ (criticality) to the position they take in the scaling (massive) limit reveals complicated structure (reported with one difference by two groups of authors[5,10]). Fortunately, (3) was conjectured[17,18] on the basis of general properties of the dilute A models and of the E-type algebras, known to be linked by their common connection to the $\phi_{(1,2)}$ perturbation of the minimal unitary series; the (scaling limit) string data used here has not contradicted it, and (admittedly limited) numerical studies agreed with the lower eigenvalues.[17] A forthcoming paper[31] should shed some new light, from the perspective of Coxeter geometry, on the excitations (3) and, hence, among other things, on the string conjectures to which they are related as demonstrated here in the $L=4$ case.

Recall that the central charge for dilute A_4 in regime 2 is $c=\frac{7}{10}$. There are several other known manifestations of the $c=\frac{7}{10}$ theory. The Blume–Capel model[32] is related to the Blume–Emery–Griffiths model,[33] a classical spin-1 Ising model with lattice Hamiltonian

TABLE V. The four perturbations of the tricritical Ising model, and the objects from statistical mechanics to which they are related in the scaling limit.

Perturbation	Field	Weight	IRF model	$\mathcal{H}_{\mathrm{BEG}}$
Leading magnetic	$\phi_{(2,2)}$	$\frac{3}{80}$	Not integrable	H
Leading thermal	$\phi_{(1,2)}$	$\frac{1}{10}$	Dilute A_4, regime 2	$1/J$
Subleading magnetic	$\phi_{(2,1)}$	$\frac{7}{16}$	Dilute A_3, regime 1	H_3
Subleading thermal	$\phi_{(1,3)}$	$\frac{3}{5}$	ABF A_4, regime III	D

$$\mathcal{H}_{\mathrm{BEG}}=-J\sum_{\langle i,j\rangle} S_iS_j-D\sum_i (1-S_i^2)-H\sum_i S_i-H_3\sum_{\langle i,j\rangle} S_iS_j(S_i+S_j), \tag{24}$$

where J is the nearest-neighbor interaction, D is a crystal field, H a magnetic field term, and H_3 is a staggered magnetic field. The phase diagrams of these models exhibit a tricritical point, as had been observed in physical systems.[34] The critical exponents, known from renormalization group studies, are related to the Kac table of the $c=\frac{7}{10}$ conformal field theory.[1]

After the Ising critical point, the universality class of the tricritical Ising model corresponds to the second simplest unitary conformal field theory in two dimensions. It is also the first of the super-conformal minimal models. It can be perturbed by its four relevant scaling fields, shown in Table V ordered according to the associated conformal weight. The leading magnetic perturbation is believed to be nonintegrable,[22] and each of the other three perturbations give integrable quantum field theories. In the scaling limit these can each be associated with a solvable interaction round a face (IRF) model [or to the terms in (24)]. The ABF A_4 model in regime III[35,36] realizes the subleading thermal perturbation. A lattice realization of the subleading magnetic perturbation is given by the dilute A_3 model in regime 1,[37] and the scaling limit of the leading thermal perturbation corresponds to the dilute A_4 model as considered in this article.

The leading thermal perturbation is known to be integrable and massive, the masses being described by E_7 Toda field theory.[14,23] Numerical results from a finite-size analysis in the spin-chain formulation,[38] and from field theory via the truncated conformal space approach[22] demonstrated the first few masses.

These are

$$\begin{aligned}
m_1&=1 && \text{odd},\\
m_2&=2\cos\frac{5\pi}{18}=1.285\,575\ldots && \text{even},\\
m_3&=2\cos\frac{\pi}{9}=1.879\,385\ldots && \text{odd},\\
m_4&=2\cos\frac{\pi}{18}=1.969\,615\ldots && \text{even},\\
m_5&=4\cos\frac{\pi}{18}\cos\frac{5\pi}{18}=2.532\,088\ldots && \text{even},\\
m_6&=4\cos\frac{\pi}{9}\cos\frac{2\pi}{9}=2.879\,385\ldots && \text{odd},\\
m_7&=4\cos\frac{\pi}{18}\cos\frac{\pi}{9}=3.701\,666\ldots && \text{even}.
\end{aligned} \tag{25}$$

The mass spectrum can be classified[22] into even and odd states [as indicated in (25)] corresponding to the $\mathbb{Z}_2$ symmetry of the affine E_7 Dynkin diagram. Each of the above seven masses appears in the high-temperature phase of the tricritical Ising model. However, only the even subset appears in the low-temperature phase. This is consistent with the numerical observations on the eigenspectrum of the dilute A_4 model.[21,17] For regime 2^+, in a study of the low-lying excitations, the first and third were absent. As we have demonstrated, all seven excitations are present in regime 2^- which (through a quirk in labelling) corresponds to $T>T_c$.

Our expression (3) gives the correlation lengths and related masses (6), expressed in terms of standard elliptic functions and the original nome p, as

$$m_j=\xi_j^{-1}=2\sum_a \log\frac{\vartheta_4(a\pi/36+\pi/4,p^{5/9})}{\vartheta_4(a\pi/36-\pi/4,p^{5/9})}. \tag{26}$$

In the critical limit $p\to 0$ the leading order behavior is

$$m_j\sim 8p^{5/9}\sum_a \sin\frac{a\pi}{18}. \tag{27}$$

Substituting the integers of Table II, applying trigonometric identities and taking mass ratios it was demonstrated[17] that the E_7 mass spectrum (25) is recovered.

The ground states of the tricritical Ising model (in zero magnetic field) have been identified.[32,22] For $T<T_c$, the system is in a two-phase region of spontaneously broken spin reversal symmetry, with two degenerate ground states in the thermodynamic limit. For $T>T_c$ there is one ground state. This ground state picture is also consistent with that of the dilute A_4 model[39] as $|p|\to 1$. In regime 2^+ there are two possible ferromagnetic ground states, while in regime 2^- there is a single disordered ground state. (It is the presence of such disordered states for L even which complicates the calculation of order parameters for this half of the dilute A_L hierarchy.)

Very recently, an array of universal ratios for the critical amplitudes of the tricritical Ising model have been calculated[24,25] by field theoretic methods. Not all of these quantities appear to be accessible via the dilute A_4 model. However, one such ratio involves the correlation length prefactors $\xi_0^{\pm}$, above and below the critical temperature. Our results and observations on the eigenspectrum of dilute A_4 give this same value:

$$\frac{\xi_0^+}{\xi_0^-}=\frac{\xi_1}{\xi_2}=2\cos\frac{5\pi}{18}.$$

We previously[17] derived the amplitude

$$f_s\xi_1^2=\frac{1}{8\sqrt{3}\cos(2\pi/9)}=0.094\,20\ldots, \tag{28}$$

where f_s is the singular part of the free energy. This agrees with the determination of this quantity for the $\phi_{(1,2)}$ perturbation of the $c=\frac{7}{10}$ field theory.[40] A related universal quantity is the amplitude ratio associated with the correlation length[41]

$$R_\xi^{\pm}=A^{1/2}\xi_0^{\pm},$$

where A/α is the amplitude of the specific heat and α is the related critical exponent. Our expressions for these quantities are

$$R_\xi^+=\left[\frac{10}{9^3\sqrt{3}\cos(2\pi/9)}\right]^{1/2}=0.101\,678\ldots,$$

$$R_\xi^- = \left[\frac{5}{2^3 9^2 \sqrt{3} \cos(5\pi/18)\sin(5\pi/9)} \right]^{1/2} = 0.083\,889\ldots,$$

which agree with the numerical values of Ref. 25 (allowing for a difference in definition by a factor $\alpha^{1/2}$). As remarked,[24,25] such values may be observed in experimental systems within the tricritical Ising universality class.

ACKNOWLEDGMENTS

The authors thank Bernard Nienhuis and Uwe Grimm for making available their unpublished results. The authors also acknowledge interaction on this topic with Vladimir Bazhanov, and thank Giuseppe Mussardo for his interest in our work. This article was completed while K.A.S. enjoyed the hospitality of the University of Melbourne and SUNY Stony Brook. This work has been supported by the Australian Research Council.

APPENDIX: FURTHER MASS CALCULATIONS

1. Mass m_4

We begin the perturbation argument with the structure $w_j = a_j$ for $j = 1,\ldots,N-4$ with $w_{N-3} = b_1 x^{-18}$, $w_{N-2} = b_2 x^{18}$, $w_{N-1} = b_3 x^{-6}$ and $w_N = b_4 x^6$. From the Bethe equations for $j = N-3,\ldots,N$ we can show that $b_1 = b_2 = b_3 = b_4 = b$. The Bethe equation for the other roots is

$$-\omega \left[a \frac{E(x^{2s}/a)}{E(x^{2s}a)} \right]^N = (A_{N-4} b^4)^{3/5} \frac{a^4}{b^4} \frac{E(x^2 b/a)E(x^6 b/a)}{E(x^2 a/b)E(x^6 a/b)} \prod_{j=1}^{N-4} \frac{E(x^{2s}a/a_j)E(x^{4s}a_j/a)}{E(x^{2s}a_j/a)E(x^{4s}a/a_j)}. \tag{A1}$$

In the $x \to 0$ limit this gives the equation

$$a^{N-4} + \frac{1}{\omega}(A_{N-4} b^4)^{3/5}/b^4 = 0,$$

so that as usual we find an expression involving the prefactors

$$\frac{1}{\omega}(A_{N-4} b^4)^{3/5} = A_{N-4} b^4.$$

Using this with the other Bethe equations in the $x \to 0$ limit we obtain

$$\left[\frac{1}{\omega}(A_{N-4} b^4)^{3/5} \right]^4 = \frac{(A_{N-4} b^4)^4}{b^{4N}} \Rightarrow b^{4N} = 1.$$

From (A1) come the recurrences

$$\mathcal{F}_4(a) = \frac{(x^{34}a/b, x^{38}a/b; x^{2r})_\infty}{(x^2 a/b, x^6 a/b; x^{2r})_\infty} \frac{\mathcal{F}_4(x^{2s}a)}{\mathcal{F}_4(x^{4s}a)},$$

$$\mathcal{G}_4(1/a) = \frac{(x^{30}b/a, x^{26}b/a; x^{2r})_\infty}{(x^{58}b/a, x^{62}b/a; x^{2r})_\infty} \frac{\mathcal{G}_4(x^{2s}/a)}{\mathcal{G}_4(x^{4s}/a)}.$$

The solutions are

$$\mathcal{F}_4(a) = \frac{(x^{38}a/b, x^{42}a/b, x^{50}a/b, x^{54}a/b; x^{2r})_\infty}{(x^2 a/b, x^6 a/b, x^{14}a/b, x^{18}a/b; x^{2r})_\infty} \frac{(x^{34}a/b, x^{38}a/b, x^{46}a/b, x^{50}a/b; x^{12s})_\infty}{(x^{70}a/b, x^{74}a/b, x^{82}a/b, x^{86}a/b; x^{12s})_\infty},$$

$$\mathcal{G}_4(1/a)=\frac{(x^{26}b/a,x^{30}b/a,x^{38}b/a,x^{42}b/a;x^{2r})_\infty}{(x^{62}b/a,x^{66}b/a,x^{74}b/a,x^{78}b/a;x^{2r})_\infty}\frac{(x^{94}b/a,x^{98}b/a,x^{106}b/a,x^{110}b/a;x^{12s})_\infty}{(x^{58}b/a,x^{62}b/a,x^{70}b/a,x^{74}b/a;x^{12s})_\infty}.$$

In terms of these functions the eigenvalue may be represented as

$$\frac{\Lambda_4}{3}=\frac{w^2}{b^2}\frac{(x^{18}w/b,x^{30}w/b,x^{10}b/w,x^{22}b/w;x^{2r})_\infty}{(x^{10}w/b,x^{22}w/b,x^{30}b/w,x^{18}b/w;x^{2r})_\infty}\mathcal{F}_4(x^{2s}w)\mathcal{G}_4(1/x^{2s}w).$$

Thus, application of the perturbation argument yields the excitation to be

$$\frac{\Lambda_4}{\Lambda_0}=w^2\frac{E(-x^{10}/w,x^{12s})E(-x^{14}/w,x^{12s})E(-x^{46}w,x^{12s})E(-x^{50}w,x^{12s})}{E(-x^{10}w,x^{12s})E(-x^{14}w,x^{12s})E(-x^{46}/w,x^{12s})E(-x^{50}/w,x^{12s})},\tag{A2}$$

where we have put $b=-1$.

2. Mass m_5

We begin the perturbation argument with $w_j=a_j$ for $j=1,\ldots,N-4$ and $w_{N-3}=b_1x^{-16}$, $w_{N-2}=b_2x^{16}$, $w_{N-1}=b_3x^{-12}$, $w_N=b_4x^{12}$. We can show that the b_i are equal, and we call them b. The Bethe equation for the other roots is

$$-\omega\left[a\frac{E(x^{2s}/a)}{E(x^{2s}a)}\right]^N=(A_{N-4}b^4)^{3/5}\frac{a^4}{b^4}\frac{E(x^8b/a)E^2(x^{12}b/a)}{E(x^8a/b)E^2(x^{12}a/b)}\times\frac{E(x^{16}b/a)}{E(x^{16}a/b)}\prod_{j=1}^{N-4}\frac{E(x^{2s}a/a_j)E(x^{4s}a_j/a)}{E(x^{2s}a_j/a)E(x^{4s}a/a_j)}.\tag{A3}$$

In the $x\to 0$ limit this gives the equation

$$a^{N-4}+\frac{1}{\omega}(A_{N-4}b^4)^{3/5}/b^4=0,$$

which leads in the usual way to a prefactor expression

$$\frac{1}{\omega}(A_{N-4}b^4)^{3/5}=A_{N-4}b^4.$$

From this and the other Bethe equations

$$\left[\frac{1}{\omega}(A_{N-4}b^4)^{3/5}\right]^4=\frac{(A_{N-4}b^4)^4}{b^{5N}}\Rightarrow b^{5N}=1.$$

Rearranging (A3), the auxiliary functions obey the recurrences

$$\mathcal{F}_5(a)=\frac{(x^{24}a/b,x^{28}a/b,x^{28}a/b,x^{32}a/b;x^{2r})_\infty}{(x^8a/b,x^{12}a/b,x^{12}a/b,x^{16}a/b;x^{2r})_\infty}\frac{\mathcal{F}_5(x^{2s}a)}{\mathcal{F}_5(x^{4s}a)},$$

$$\mathcal{G}_5(1/a)=\frac{(x^{32}b/a,x^{36}b/a,x^{36}b/a,x^{40}b/a;x^{2r})_\infty}{(x^{48}b/a,x^{52}b/a,x^{52}b/a,x^{56}b/a;x^{2r})_\infty}\frac{\mathcal{G}_5(x^{2s}/a)}{\mathcal{G}_5(x^{4s}/a)}.$$

The solutions are

$$\mathcal{F}_5(a)=\frac{(x^{32}a/b,x^{40}a/b,x^{44}a/b;x^{2r})_\infty}{(x^{12}a/b,x^{16}a/b,x^{24}a/b;x^{2r})_\infty}\frac{(x^{28}a/b,x^{36}a/b,x^{40}a/b,x^{44}a/b,x^{48}a/b,x^{56}a/b;x^{12s})_\infty}{(x^8a/b,x^{12}a/b,x^{20}a/b,x^{64}a/b,x^{72}a/b,x^{76}a/b;x^{12s})_\infty},$$

$$\mathcal{G}_5(1/a)=\frac{(x^{40}b/a,x^{36}b/a,x^{48}b/a;x^{2r})_\infty}{(x^{56}b/a,x^{64}b/a,x^{68}b/a;x^{2r})_\infty}\frac{(x^{32}b/a,x^{36}b/a,x^{44}b/a,x^{88}b/a,x^{96}b/a,x^{100}b/a;x^{12s})_\infty}{(x^{52}b/a,x^{60}b/a,x^{64}b/a,x^{68}b/a,x^{72}b/a,x^{80}b/a;x^{12s})_\infty},$$

which we next substitute into the eigenvalue expression

$$\frac{\Lambda_5}{3}=-\frac{w^3}{b^3}\frac{(x^{24}w/b,x^{28}w/b,x^{36}w/b,x^4b/w,x^{12}b/w,x^{16}b/w;x^{2r})_\infty}{(x^4w/b,x^{12}w/b,x^{16}w/b,x^{24}b/w,x^{28}b/w,x^{36}b/w;x^{2r})_\infty}\mathcal{F}_5(x^{2s}w)\mathcal{G}_5(1/x^{2s}w),$$

to obtain (with $b=-1$) an expression in elliptic functions of nome x^{12s},

$$\frac{\Lambda_5}{\Lambda_0}=w^3\frac{E(-x^4/w)E(-x^{12}/w)E(-x^{16}/w)E(-x^{40}w)E(-x^{48}w)E(-x^{52}w)}{E(-x^4w)E(-x^{12}w)E(-x^{16}w)E(-x^{40}/w)E(-x^{48}/w)E(-x^{52}/w)}. \tag{A4}$$

3. Mass m_6

We begin the perturbation argument with $w_j=a_j$ for $j=1,\ldots,N-5$ and $w_{N-4}=b_1x^{20}$, $w_{N-3}=b_2x^{-16}$, $w_{N-2}=b_3x^{16}$, $w_{N-1}=b_4x^{-8}$, $w_N=b_5x^8$. We can show that the b_i are equal, and we call them b. The Bethe equation for the other roots is

$$\omega\left[a\frac{E(x^{2s}/a)}{E(x^{2s}a)}\right]^N=(A_{N-5}b^5)^{3/5}\frac{a^5}{b^5}\frac{E(x^4b/a)E(x^8b/a)}{E(x^4a/b)E^2(x^8a/b)}\times\frac{E(x^{12}b/a)E(x^{16}b/a)}{E(x^{12}a/b)E(x^{16}a/b)}\prod_{j=1}^{N-5}\frac{E(x^{2s}a/a_j)E(x^{4s}a_j/a)}{E(x^{2s}a_j/a)E(x^{4s}a/a_j)}. \tag{A5}$$

In the $x\to 0$ limit this gives the equation

$$a^{N-5}-\frac{1}{\omega}(A_{N-5}b^5)^{3/5}/b^5=0,$$

which leads in the usual way to the expression

$$\frac{1}{\omega}(A_{N-5}b^5)^{3/5}=A_{N-5}b^5.$$

From this and the other Bethe equations

$$\left[\frac{1}{\omega}(A_{N-5}b^5)^{3/5}\right]^5=\frac{(A_{N-5}b^5)^5}{b^{5N}}\Rightarrow b^{5N}=1.$$

After rearranging (A5), the auxiliary functions obey the recurrences

$$\mathcal{F}_6(a)=\frac{(x^{24}a/b,x^{28}a/b,x^{32}a/b,x^{36}a/b;x^{2r})_\infty}{(x^4a/b,x^8a/b,x^{12}a/b,x^{16}a/b;x^{2r})_\infty}\frac{\mathcal{F}_6(x^{2s}a)}{\mathcal{F}_6(x^{4s}a)},$$

$$\mathcal{G}_6(1/a)=\frac{(x^{28}b/a,x^{32}b/a,x^{36}b/a,x^{40}b/a;x^{2r})_\infty}{(x^{48}b/a,x^{52}b/a,x^{56}b/a,x^{60}b/a;x^{2r})_\infty}\frac{\mathcal{G}_6(x^{2s}/a)}{\mathcal{G}_6(x^{4s}/a)}.$$

The solutions are

$$\mathcal{F}_6(a)=\frac{(x^{36}a/b,x^{40}a/b;x^{2r})_\infty}{(x^{16}a/b,x^{20}a/b;x^{2r})_\infty}\frac{(x^{32}a/b,x^{36}a/b,x^{40}a/b,x^{44}a/b,x^{48}a/b,x^{52}a/b;x^{12s})_\infty}{(x^4a/b,x^8a/b,x^{12}a/b,x^{16}a/b,x^{68}a/b,x^{72}b/a;x^{12s})_\infty},$$

$$\mathcal{G}_6(1/a)=\frac{(x^{40}b/a,x^{44}b/a;x^{2r})_\infty}{(x^{60}b/a,x^{64}b/a;x^{2r})_\infty}\frac{(x^{28}b/a,x^{32}b/a,x^{36}b/a,x^{40}b/a,x^{92}b/a,x^{96}b/a;x^{12s})_\infty}{(x^{56}b/a,x^{60}b/a,x^{64}b/a,x^{68}b/a,x^{72}b/a,x^{76}b/a;x^{12s})_\infty},$$

which we next substitute into the eigenvalue expression

$$\frac{\Lambda_6}{3}=-\frac{w^3}{b^3}\frac{(x^{28}w/b,x^{32}w/b,x^8b/w,x^{12}b/w;x^{2r})_\infty}{(x^8w/b,x^{12}w/b,x^{28}b/w,x^{32}b/w;x^{2r})_\infty}\mathcal{F}_6(x^{2s}w)\mathcal{G}_6(1/x^{2s}w),$$

to obtain (with $b=-1$) an expression in elliptic functions of nome x^{12s},

$$\frac{\Lambda_6}{\Lambda_0}=w^3\frac{E(-x^8/w)E(-x^{12}/w)E(-x^{16}/w)E(-x^{44}w)E(-x^{48}w)E(-x^{52}w)}{E(-x^8w)E(-x^{12}w)E(-x^{16}w)E(-x^{44}/w)E(-x^{48}/w)E(-x^{52}/w)}. \tag{A6}$$

4. Mass m_7

We begin with $w_j=a_j$ for $j=1,\ldots,N-6$ and $w_{N-5}=b_1x^{-18}$, $w_{N-4}=b_2x^{18}$, $w_{N-3}=b_3x^{-14}$, $w_{N-2}=b_4x^{14}$, $w_{N-1}=b_5x^{-10}$, $w_N=b_6x^{10}$. Once again the $b_i(=b)$ are all equal. The Bethe equation for the other roots is

$$-\omega\left[a\frac{E(x^{2s}/a)}{E(x^{2s}a)}\right]^N=(A_{N-6}b^6)^{3/5}\frac{a^6}{b^6}\frac{E(x^6b/a)E^2(x^{10}b/a)}{E(x^6a/b)E^2(x^{10}a/b)}$$
$$\times\frac{E^2(x^{14}b/a)E(x^{18}b/a)}{E^2(x^{14}a/b)E(x^{18}a/b)}\prod_{j=1}^{N-6}\frac{E(x^{2s}a/a_j)E(x^{4s}a_j/a)}{E(x^{2s}a_j/a)E(x^{4s}a/a_j)}.$$

In the $x\to 0$ limit this gives

$$a^{N-6}+\frac{1}{\omega}(A_{N-6}b^6)^{3/5}/b^6=0,$$

which leads to the expression in the various coefficients

$$\frac{1}{\omega}(A_{N-6}b^6)^{3/5}=A_{N-6}b^6,$$

and from the six Bethe equations involving b,

$$\left[\frac{1}{\omega}(A_{N-6}b^6)^{3/5}\right]^6=\frac{(A_{N-6}b^6)^6}{b^{4N}}\Rightarrow b^{4N}=1.$$

The recurrences to be solved for the auxiliary functions are

$$\mathcal{F}_7(a)=\frac{(x^{22}a/b,x^{26}a/b,x^{26}a/b,x^{30}a/b,x^{30}a/b,x^{34}a/b;x^{2r})_\infty}{(x^6a/b,x^{10}a/b,x^{10}a/b,x^{14}a/b,x^{14}a/b,x^{18}a/b;x^{2r})_\infty}\frac{\mathcal{F}_7(x^{2s}a)}{\mathcal{F}_7(x^{4s}a)},$$

$$\mathcal{G}_7(1/a)=\frac{(x^{30}b/a,x^{34}b/a,x^{34}b/a,x^{38}b/a,x^{38}b/a,x^{42}b/a;x^{2r})_\infty}{(x^{46}b/a,x^{50}b/a,x^{50}b/a,x^{54}b/a,x^{54}b/a,x^{58}b/a;x^{2r})_\infty}\frac{\mathcal{G}_7(x^{2s}/a)}{\mathcal{G}_7(x^{4s}/a)},$$

which have solution

$$\mathcal{F}_7(a)=\frac{(x^{34}a/b\,,x^{38}a/b\,,x^{42}a/b\,,x^{46}a/b\,;x^{2r})_\infty}{(x^{10}a/b\,,x^{14}a/b\,,x^{18}a/b\,,x^{22}a/b\,;x^{2r})_\infty}$$
$$\times\frac{(x^{30}a/b\,,x^{34}a/b\,,x^{38}a/b\,,x^{42}a/b\,,x^{42}a/b\,,x^{46}a/b\,,x^{50}a/b\,,x^{54}a/b\,;x^{12s})_\infty}{(x^{6}a/b\,,x^{10}a/b\,,x^{14}a/b\,,x^{18}a/b\,,x^{66}a/b\,,x^{70}a/b\,,x^{74}a/b\,,x^{78}a/b\,;x^{12s})_\infty},$$

$$\mathcal{G}_7(1/a)=\frac{(x^{34}b/a\,,x^{38}b/a\,,x^{42}b/a\,,x^{46}b/a\,;x^{2r})_\infty}{(x^{58}b/a\,,x^{62}b/a\,,x^{66}b/a\,,x^{70}b/a\,;x^{2r})_\infty}$$
$$\times\frac{(x^{30}b/a\,,x^{34}b/a\,,x^{38}b/a\,,x^{42}b/a\,,x^{90}b/a\,,x^{94}b/a\,,x^{98}b/a\,,x^{102}b/a\,;x^{12s})_\infty}{(x^{54}b/a\,,x^{58}b/a\,,x^{62}b/a\,,x^{66}b/a\,,x^{66}b/a\,,x^{70}b/a\,,x^{74}b/a\,,x^{78}b/a\,;x^{12s})_\infty}.$$

Substitution into

$$\frac{\Lambda_7}{3}=\frac{w^4}{b^4}\,\frac{(x^{22}w/b,x^{26}w/b,x^{30}w/b,x^{34}w/b,x^{6}b/w,x^{10}b/w,x^{14}b/w,x^{18}b/w;x^{2r})_\infty}{(x^{6}w/b,x^{10}w/b,x^{14}w/b,x^{18}w/b,x^{22}b/w,x^{26}b/w,x^{30}b/w,x^{34}b/w;x^{2r})_\infty}$$
$$\times\mathcal{F}_7(x^{2s}w)\mathcal{G}_7(1/x^{2s}w)$$

yields the result (with $b=-1$ and elliptic nome x^{12s})

$$\frac{\Lambda_7}{\Lambda_0}=w^4\frac{E(-x^6/w)E(-x^{10}/w)E(-x^{14}/w)E(-x^{18}/w)}{E(-x^6w)E(-x^{10}w)E(-x^{14}w)E(-x^{18}w)}$$
$$\times\frac{E(-x^{42}w)E(-x^{46}w)E(-x^{50}w)E(-x^{54}w)}{E(-x^{42}/w)E(-x^{46}/w)E(-x^{50}/w)E(-x^{54}/w)}. \tag{A7}$$

Nonlinear Fokker–Planck equation exhibiting bifurcation phenomena and generalized thermostatistics

Masatoshi Shiino[a)]

(Received 9 August 2001; accepted for publication 30 January 2002)

A nonlinear Fokker–Planck equation exhibiting bifurcation phenomena is proposed within the framework of generalized thermostatistics. The nonlinearity responsible for the occurrence of bifurcation of solutions is assumed to be of the form appearing in the standard mean field model. A Liapunov function is defined that takes the form of free energy involving generalized entropies of Tsallis and an H-theorem is proved to show that the free energy, which is bounded below, continues to decrease until the system approaches one of the equilibrium distributions. The H-theorem ensures, instead of uniqueness of the equilibrium distribution, global stability of the system in that either one of multisolutions must be approached for large times. Local stability analysis is conducted and the second-order variation of the Liapunov function is computed to find its relevant part whose sign governs stability of the equilibrium distribution of the system. The case with a bistable potential is investigated, as an example of confirming the theory, to give the bifurcation diagram displaying the order parameter as a function of the coefficient of the nonlinear diffusion term. © *2002 American Institute of Physics.*

I. INTRODUCTION

Tsallis developed generalized thermostatistics[1–3] using generalized nonextensive entropies[4–10] which are obtained by extending the well-known Boltzmann entropy. Equilibrium properties of the novel thermostatistics have extensively been studied by a number of researchers to understand similarity as well as dissimilarity between the standard Boltzmann statistics and the generalized one.[11] A characteristic feature of the generalized thermostatistics is a power-law type equilibrium probability distribution that is derived from the maximum entropy principle with a certain constraint of internal energy.[1–3]

One may, however, expect that an equilibrium distribution should be derived, as a fixed point type solution, from a certain dynamical evolution equation of a time-dependent probability distribution such as a master equation of a Markovian dynamics. Several authors have studied nonlinear Fokker–Planck equations that are related to generalized thermostatistics.[12–20] Plastino and Plastino[12] proposed a nonlinear Fokker–Planck equation with a nonlinear diffusion term characterized by a real parameter q,

$$\frac{\partial p}{\partial t} = -\frac{\partial}{\partial x}\left(-\frac{\partial \phi}{\partial x}p\right) + D\frac{\partial^2}{\partial x^2}p^q \tag{1}$$

and showed that it exhibits an equilibrium solution taking the form of Tsallis equilibrium distribution of the so-called first choice[1]

$$P_{\mathrm{eq}}(x) = [(Dq\beta)^{-1}(1-\beta(q-1)\phi(x))]^{1/(q-1)}, \tag{2}$$

a)Electronic mail: mshiino@ap.titech.ac.jp

where β is determined by the normalization condition. In the absence of the drift term in Eq. (1) with $\phi(x)=\text{const}$ there exists no equilibrium distribution and one has nonlinear diffusion, which was studied by several authors in connection with diffusion in porous media.[21–25]

In the case where the potential $\phi(x)$ is quadratic, the nonlinear Fokker–Planck equation (NFPE) was shown to be solved for its temporal solution in a rigorous way.[12,15,16] A phenomenological derivation of the NFPE itself was given in Refs. 13 and 14, where the author considered a stochastic differential equation with a self-reference type feedback representing the nonlinear diffusion term.

While the Tsallis equilibrium distribution was shown to satisfy the NFPE, its stability and uniqueness has been another problem. The relationship between the NFPE and the generalized entropy is also of interest and worth studying.

In the case of linear Fokker–Planck equations, which appear as master equations for stochastic systems with Markovian dynamics, stability and uniqueness of their equilibrium solutions is known to be ensured by the so-called H-theorems.[26–30] Liapunov functions as the H-functions can be chosen as closely related to the free energy of a system[31] and also to the conventional Kullback–Leibler divergence[26–30,32] or generalized Kullback–Leibler divergences.[31,33–39]

Recently I have tackled the above-mentioned kind of problems with the NFPE to provide a dynamics-level linkage of the generalized entropy to the NFPE together with knowledge of the asymptotic approach of temporal solutions of the NFPE to its equilibrium solution.[18] Constructing a Lyapunov functional that takes the form of a free energy based on the generalized entropy,[18]

$$F=\int_{-\infty}^{\infty}\phi p\,\mathrm{d}x-\frac{D}{q-1}\left[1-\int_{-\infty}^{\infty}p^{q}\,\mathrm{d}x\right], \tag{3}$$

I showed that an H-theorem holds for the NFPE (1):[18]

$$\frac{\mathrm{d}F}{\mathrm{d}t}\leqslant 0, \tag{4}$$

which ensures stability and uniqueness of its equilibrium solution. Such convergence property with an H-theorem is not specific to the system described by the above-mentioned NFPE (1). A NFPE with a nonlocal time-dependent nonlinear diffusion coefficient,[18]

$$\frac{\partial p}{\partial t}=-\frac{\partial}{\partial x}(A(x)p)+\frac{1}{\beta}\left(\int_{-\infty}^{\infty}p^{Q}\,\mathrm{d}x\right)^{-(Q+1)/Q}\frac{\partial^{2}}{\partial x^{2}}p^{Q}, \tag{5}$$

which allows for an equilibrium solution corresponding to another type of equilibrium distribution of Tsallis thermostatistics (the escort probability distribution of the so-called third version[3]),

$$P_{\mathrm{eq}}(x)=\tilde{C}_{0}(Q)^{-Q/(Q-1)}\left[1-\frac{\beta(Q-1)}{\tilde{C}_{0}(Q)Q}(\phi(x)-\langle\phi\rangle)\right]^{1/(Q-1)}, \tag{6}$$

also exhibits similar convergence properties based on an H-theorem, when the modified generalized entropy

$$\tilde{S}\equiv\frac{1}{\frac{1}{Q}-1}\left[1-\left(\int_{-\infty}^{\infty}p^{Q}\,\mathrm{d}x\right)^{-1/Q}\right] \tag{7}$$

is considered.[18] The above-mentioned entropy is a special case of the Sharma and Mittal entropy.[6] H-theorems for a little more general types of NFPEs related to generalized thermostatistics including Eq. (1) have recently been studied by Frank and Daffertshofer.[19]

The above-mentioned results indicate that although the time evolution equations (1) and (5) are nonlinear, there occurs no bifurcation of solutions with change in parameters characterizing the system. This situation is in sharp contrast to the case of NFPE for a mean field model, where one deals with another type of NFPE that is derived, in the thermodynamic limit, for a coupled Langevin equation system.[40–42] The simplest NFPE exhibiting bifurcation phenomena reads[40–42]

$$\frac{\partial p}{\partial t} = -\frac{\partial}{\partial x}\left[\left(x - x^3 + \varepsilon \int_{-\infty}^{\infty} xp\, \mathrm{d}x\right)p\right] + D\frac{\partial^2}{\partial x^2}p \tag{8}$$

Such mean field type of NFPE has attracted much attention from researchers in a number of areas of physical science, since it is quite convenient to observe the effect of noise on a variety of cooperative phenomena of coupled systems and to systematically study equilibrium as well as nonequilibrium phase transitions. The NFPE (8) with a double well potential $\phi(x) = -(x^2/2) + (x^4/4)$ can describe ferro–para magnetic phase transitions of mean field type.[40–43] NFPEs corresponding to mean field coupled limit cycle[44] or phase oscillator systems[45–48] have been studied by several authors from the viewpoint of synchronization–desynchronization transitions due to noise and of neural network theory. An NFPE for chaotic systems has been recently studied in the light of control of chaos with noise.[49]

The problem of phase transitions within the framework of Tsallis thermostatistics will be of interest, but it has been far less studied.[50]

The purpose of this paper is to study the occurrence of bifurcations for NFPEs that are related to Tsallis thermostatistics. To this end I propose a double nonlinear Fokker–Planck equation that is obtained by introducing such a mean field type nonlinear term as considered in Eq. (8) into the NFPE (1) and investigate the issue of convergence to equilibrium solutions together with their global and local stability.

After describing the model in Sec. II, I show in Sec. III that a Liapunov function for our double NFPE can be defined so that it takes the form of free energy involving generalized entropies of Tsallis. I prove an H-theorem to show that the free energy, which is bounded below, continues to decrease until the system approaches one of the equilibrium distributions. The H-theorem ensures, instead of uniqueness of the equilibrium distribution, global stability of the system in that either one of multisolutions must be approached for large times. In Sec. IV local stability analysis is conducted and the second-order variation of the Liapunov function is computed to find its relevant part whose sign governs stability of the equilibrium distribution of the system. As an example of confirming the theory, I investigate the case with a bistable potential to give the bifurcation diagram displaying the order parameter as a function of the coefficient of the nonlinear diffusion term. In Sec. V I present a summary and discussion.

II. MODEL

We consider a double nonlinear Fokker–Planck equation of the following form:

$$\frac{\partial p}{\partial t} = -\frac{\partial}{\partial x}\left[\left(A(x) + \varepsilon \int_I xp\, \mathrm{d}x\right)p\right] + D\frac{\partial^2}{\partial x^2}p^q, \tag{9}$$

which is obtained by introducing, into the drift coefficient of the NFPE (1), a term representing nonlocal feedback from the entire system in terms of the average of the state variable x. Here ε (a real number) controls the magnitude of the feedback, and q is a real number, D a positive constant, and $A(x)$ in the drift coefficient an arbitrary function with potential $\phi(x)$:

$$\phi(x) = -\int^x A(x)\mathrm{d}x. \tag{10}$$

The symbol I in the integral denotes the region where non-negative valued $p(t,x)$ is defined. Since the equation with $\varepsilon=0$ itself is already a nonlinear one, we will refer to the above-mentioned nonlinear Fokker Planck equation as double nonlinear Fokker–Planck equation (DNFPE).

Since introducing the probability current j,

$$j=\left(A(x)+\varepsilon\int_I xp\,\mathrm{d}x\right)p-D\frac{\partial}{\partial x}p^q, \tag{11}$$

one can rewrite our DNFPE in the form of the continuity equation. The conservation law of probability holds:

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_I p\,\mathrm{d}x=0$$

under the boundary condition that the probability current j vanishes at the boundary of I. For the sake of simplicity, in this article we consider the case of $I=R^1\equiv(-\infty,\infty)$ to choose the natural boundary condition:

$$p(t,\pm\infty)=0,\quad \frac{\partial p^q}{\partial x}(t,\pm\infty)=0. \tag{12}$$

Since $\partial p/\partial t=0$ implies $j=0$, one has

$$P_{\mathrm{eq}}^{q-1}=\frac{-(q-1)\tilde{\phi}(x)}{Dq}+(Dq\beta)^{-1}, \tag{13}$$

where

$$\tilde{\phi}(x)=\phi(x)-\varepsilon x\int_I xP_{\mathrm{eq}}\,\mathrm{d}x$$

and the integration constant is set to be $(Dq\beta)^{-1}$.

Accordingly, the equilibrium distribution for the DNFPE (9) can be formally obtained as

$$P_{\mathrm{eq}}(x)=[(Dq\beta)^{-1}(1-\beta(q-1)\tilde{\phi}(x))]^{1/(q-1)}, \tag{14}$$

where β will be determined by normalization of $P_{\mathrm{eq}}(x)$.

For the purpose of studying phenomena of spontaneous symmetry breaking, it will suffice to suppose the potential ϕ to take the form of double well type such as $\phi=ax^2+bx^4$ $(a<0,b>0)$. When $\phi(x)\to\infty$ as $|x|\to\infty$, Eq. (14) implies $0<q<1$ and hence $P_{\mathrm{eq}}\to 0(|x|\to\infty)$. Assuming that $0<q<1$ and $\phi(x)\approx|x|^m$ with $m>0$ $(|x|\to\infty)$, one also has

$$\frac{\partial {P_{\mathrm{eq}}}^q}{\partial x}\approx|x|^{mq/(q-1)-1}\to 0(|x|\to\infty).$$

In what follows we deal with the case with $0<q<1$, where the natural boundary condition (12) makes sense, and assume the existence of the integrals $\int\phi p\,\mathrm{d}x$ and $\int p^q\,\mathrm{d}x$, where the integrals are meant to be performed over the real line $I=R^1\equiv(-\infty,\infty)$ and hereafter the I will be omitted. For $p=P_{\mathrm{eq}}$ and $\phi(x)\approx|x|^m$ (for large $|x|$), the condition of such integrability becomes $1/(m+1)<q<1$.

Since the expression for the equilibrium distribution P_{eq} contains P_{eq} itself, the problem of approach to the equilibrium distribution is not trivial. This issue can be more clearly seen in the study of nonlinear stability analysis of the solutions.

III. H-THEOREM

We define a Liapunov functional taking the form of a free energy based on Tsallis entropy as

$$F(p(\cdot))=\int\left(\phi-\varepsilon x\int_R xp\,\mathrm{d}x\right)p\,\mathrm{d}x+\frac{\varepsilon}{2}\left(\int_R xp\,\mathrm{d}x\right)^2-\frac{D}{q-1}\left[1-\int p^q\,\mathrm{d}x\right]=U-DS, \quad (15)$$

where the energy U represents the first two terms on the right-hand side of the first line:

$$U=\int\left(\phi-\varepsilon x\int_R xp\,\mathrm{d}x\right)p\,\mathrm{d}x+\frac{\varepsilon}{2}\left(\int_R xp\,\mathrm{d}x\right)^2=\int\phi p\,\mathrm{d}x-\frac{\varepsilon}{2}\left(\int_R xp\,\mathrm{d}x\right)^2 \quad (16)$$

and the entropy S is the nonextensive one given within Tsallis thermostatistics:[1–3]

$$S\equiv\frac{1}{q-1}\left[1-\int p^q\,\mathrm{d}x\right]. \quad (17)$$

With this Liapunov functional taken as the H-functional we can show an H-theorem for the DNFPE (9).

H-theorem: Let $0<q<1$. Let $p(t,x)$ satisfy the DNFPE (9). Then we have
(1) the free energy $F(p(t,\cdot))$ is bounded from below:

$$F(p(t,\cdot))>C_F(\text{const}); \quad (18)$$

(2) $F(p(t,\cdot))$ is decreasing with time:

$$\frac{\mathrm{d}F(p(t,\cdot))}{\mathrm{d}t}\leqslant 0. \quad (19)$$

Proof of (1): In the case with $\varepsilon\leqslant 0$, it immediately follows from Eqs. (15) and (16) that

$$F(p(\cdot))\geqslant\int\phi p\,\mathrm{d}x-\frac{D}{q-1}\left(1-\int p^q\,\mathrm{d}x\right)\equiv F^{(\varepsilon=0)}(p(\cdot)). \quad (20)$$

Note that as was studied in Ref. 18 the free energy $F^{(\varepsilon=0)}(p(\cdot))$ with $0<q<1$ is bounded from below:

$$F^{(\varepsilon=0)}(p(\cdot))\geqslant F^{(\varepsilon=0)}(P_{\mathrm{eq}}(\cdot;\varepsilon=0))=-D\int {P_{\mathrm{eq}}}^q(\cdot;\varepsilon=0)\mathrm{d}x+\frac{1}{q-1}\left(\frac{1}{\beta}-D\right), \quad (21)$$

where $P_{\mathrm{eq}}(\cdot;\varepsilon=0)$ is given by the equilibrium distribution (2).
Accordingly one has

$$F(p(\cdot))\geqslant F^{(\varepsilon=0)}(P_{\mathrm{eq}}(\cdot;\varepsilon=0)) \quad (22)$$

to confirm Eq. (18).

To deal with the case with $\varepsilon>0$ putting

$$\langle x\rangle_p\equiv\int_R xp\,\mathrm{d}x \quad (23)$$

we first note that one can define the normalized positive-valued function $R_p(t,x)$ as

$$\phi-\varepsilon x\langle x\rangle_p=\frac{Dq\beta_0{R_p}^{q-1}-1}{(1-q)\beta_0}, \quad (24)$$

$$\int R_p(t,x)\mathrm{d}x=1$$

with β_0 denoting a constant determined uniquely as a function of D and $\varepsilon\langle x\rangle_p$. The existence of such β_0 can easily be confirmed by noting that the integral of the solution R_p to the first equation of Eq. (24) as a function of β_0 would monotonically increase from 0 to ∞ as β_0 varies from

$$\beta_0=+0 \quad \text{to} \quad \beta_0=\frac{-1}{(1-q)\mathrm{Min}_{-\infty<x<\infty}(\phi(x)-\varepsilon x\langle x\rangle_p)}>0$$

where we have assumed, for simplicity, that the minimum of $\phi(x)$ is negative to make β_0 of the latter positive. Note that in general β_0 in Eq. (24) may be determined to take a negative value.

The R_p turns out to satisfy

$$-\frac{\partial}{\partial x}\{(-\phi_x(x)+\varepsilon\langle x\rangle_p)R_p\}+D\frac{\partial^2}{\partial x^2}R_p^q=0. \tag{25}$$

To prove inequality (18) with $\varepsilon>0$, using (24) we rewrite $F(p(t,\cdot))$ as

$$F(p(\cdot))=\frac{D}{q-1}\int (p^q-qpR_p^{q-1}+(q-1)R_p^q)\mathrm{d}x+\frac{1}{q-1}\left(\frac{1}{\beta_0}-D\right)+\frac{\varepsilon}{2}[\langle x\rangle_p]^2-D\int R_p^q\,\mathrm{d}x. \tag{26}$$

Since for $0<q<1$,

$$p^q-qpR_p^{q-1}+(q-1)R_p^q=R_p^q(y^q-qy+q-1)\leqslant 0 \tag{27}$$

with $y\equiv p/R_p$ and equality being given only by $y=1$, we have

$$\frac{D}{q-1}\int (p^q-qpR_p^{q-1}+(q-1)R_p^q)\mathrm{d}x\geqslant 0 \tag{28}$$

and hence

$$F(p(\cdot))\geqslant L(\varepsilon\langle x\rangle_p), \tag{29}$$

where we have defined L as a function of $\varepsilon\langle x\rangle_p$ as

$$L(\varepsilon\langle x\rangle_p)=\frac{1}{2\varepsilon}(\varepsilon\langle x\rangle_p)^2+\frac{1}{q-1}\left(\frac{1}{\beta_0}-D\right)-D\int R_p^q\,\mathrm{d}x. \tag{30}$$

We will show that L is bounded from below. To this end, we differentiate L with respect to $\varepsilon\langle x\rangle_p$:

$$\frac{\mathrm{d}L(h)}{\mathrm{d}h}=\frac{h}{\varepsilon}+\frac{\partial\tilde{F}(D,h)}{\partial h}, \tag{31}$$

where we have defined

$$\tilde{F}(D,h)=\frac{1}{q-1}\left(\frac{1}{\beta_0}-D\right)-D\int R_p^q\,\mathrm{d}x \tag{32}$$

with $h=\varepsilon\langle x\rangle_p$.

Here we note that the above-defined $\tilde{F}(D,h)$ turns out to be the free energy function[18] corresponding to the equilibrium distribution (2) with $\phi(x)$ being replaced by $\phi(x)-hx$ and $\beta=\beta_0$, which the R_p (24) with $h=\varepsilon\langle x\rangle_p$ coincides with.

Then it follows that

$$\frac{\partial\tilde{F}(D,h)}{\partial h}=-\langle x\rangle_{R_{D,h}}\equiv-\int xR_{D,h}(x)\mathrm{d}x \tag{33}$$

together with

$$\frac{\partial\tilde{F}(D,h)}{\partial D}=-S, \tag{34}$$

which exhibit the Legendre transform structure of the Tsallis thermostatistics of the first choice, and can be confirmed by straightforward calculations. In Eq. (33) we have written $R_{D,h}$ instead of R_p to emphasize the h-dependence of R in Eq. (24) with $h=\varepsilon\langle x\rangle_p$.

Furthermore, $\partial\tilde{F}/\partial h$ has the following properties:

(A)

$$-\frac{\partial^2\tilde{F}}{\partial h^2}>0. \tag{35}$$

(B) If $\phi(x)$ increases faster than $\phi(x)\propto x^2$ when $|x|\to\infty$, then

$$-\frac{1}{h}\frac{\partial\tilde{F}}{\partial h}\to 0 \quad (h\to\pm\infty). \tag{36}$$

The proof is given in the appendices.

Applying Eq. (36) to Eq. (31) one has $\mathrm{d}L(h)/\mathrm{d}h>0$ (for large h) and $\mathrm{d}L(h)/\mathrm{d}h<0$ (for large $-h$) when $\varepsilon>0$.

This implies that $L(h)$ can exhibit its minimum at a certain $\bar{h}$ satisfying $\mathrm{d}L(\bar{h})/\mathrm{d}h=0$ to have a lower bound: $L(h)\geqslant L(\bar{h})$, which together with Eq. (29) shows that $F(p(\cdot))$ is bounded from below.

Proof of (2): To prove the second inequality (19) we differentiate $F(p(t,\cdot))$ with respect to t. Using Eq. (9) one obtains

$$\begin{aligned}\frac{\mathrm{d}F(p(t,\cdot))}{\mathrm{d}t}&=\int(\phi-\varepsilon x\langle x\rangle_p)\frac{\partial p}{\partial t}\mathrm{d}x-\frac{\mathrm{d}}{\mathrm{d}t}\frac{D}{q-1}\left[1-\int p^q\,\mathrm{d}x\right]\\&=\int\left(\phi-\varepsilon x\langle x\rangle_p+\frac{Dq}{q-1}p^{q-1}\right)\left[-\frac{\partial}{\partial x}\{(-\phi_x(x)+\varepsilon\langle x\rangle_p)p\}+D\frac{\partial^2}{\partial x^2}p^q\right]\mathrm{d}x\\&=\int\left[\frac{\partial}{\partial x}\left(\phi-\varepsilon x\langle x\rangle_p+\frac{Dq}{q-1}p^{q-1}\right)\right]\left[(-\phi_x(x)+\varepsilon\langle x\rangle_p)p-D\frac{\partial}{\partial x}p^q\right]\mathrm{d}x,\end{aligned} \tag{37}$$

where integration by parts has been used in the last line.

Substituting (24) into (37), we further rewrite $\mathrm{d}F/\mathrm{d}t$ as

$$\frac{\mathrm{d}F(p(t,\cdot))}{\mathrm{d}t}=\int\left[B_1\left(\frac{\partial p}{\partial x}\right)^2+B_2\frac{\partial p}{\partial x}\frac{\partial R_p}{\partial x}+B_3\left(\frac{\partial R_p}{\partial x}\right)^2\right]\mathrm{d}x, \tag{38}$$

where

$$B_1 = -D^2 q^2 p^{2q-3},$$
$$B_2 = 2D^2 q^2 p^{q-1} {R_p}^{q-2}, \tag{39}$$
$$B_3 = -D^2 q^2 p {R_p}^{2q-4}$$

and we have assumed

$$\int p^{2q-3} \left(\frac{\partial p}{\partial x} \right)^2 \mathrm{d}x < \infty,$$
$$\int p {R_p}^{2q-4} \left(\frac{\partial R_p}{\partial x} \right)^2 \mathrm{d}x < \infty.$$

Then it follows that

$$\begin{aligned} \frac{\mathrm{d}F(p(t,\cdot))}{\mathrm{d}t} &= -D^2 q^2 \int p \left(p^{q-2} \frac{\partial p}{\partial x} - {R_p}^{q-2} \frac{\partial R_p}{\partial x} \right)^2 \mathrm{d}x \\ &= -\frac{D^2 q^2}{(q-1)^2} \int p \left[\frac{\partial}{\partial x} (p^{q-1} - {R_p}^{q-1}) \right]^2 \mathrm{d}x \\ &\leqslant 0. \end{aligned} \tag{40}$$

This concludes the proof.

We see that equality is implied by

$$p^{q-1} - {R_p}^{q-1} = c(\text{const}). \tag{41}$$

Since $F(p(t,\cdot))$ is decreasing with time and is bounded from below, $\mathrm{d}F/\mathrm{d}t = 0$ is attained when $t \to \infty$, and then p must satisfy Eq. (41):

$$p = R_p, \tag{42}$$

where we have set $c = 0$, because the R_p is already normalized [see Eq. (24)].

This means that the distribution p_∞ that is approached for large times takes the form of the equilibrium distribution (14) of the DNFPE (9):

$$p_\infty = [(Dq\beta)^{-1}(1 - \beta(q-1)(\phi - \varepsilon x \langle x \rangle_{p_\infty}))]^{1/(q-1)}, \tag{43}$$

where the value of β and the order parameter $\langle x \rangle_{p_\infty}$ should be determined simultaneously by the normalization condition and the self-consistent equation

$$\langle x \rangle_{p_\infty} = \int x p_\infty \mathrm{d}x. \tag{44}$$

We note that since conservation of probability holds for the DNFPE (9), the $p_\infty(x)$ in (43) should be normalizable. Although our system allows for the H-theorem, unlike the case with $\varepsilon = 0$ we can no longer expect uniqueness of the equilibrium distribution $p_\infty(x)$ in the case with $\varepsilon > 0$, where the self-consistent equations, in general, admit multisolutions (m,β) with $m = \langle x \rangle_{p_\infty}$. This arises from the fact that $R_p(x)$ appearing in Eq. (40) is not a fixed function such as an equilibrium distribution, but does depend on the time-dependent probability distribution $p(t,x)$ [see Eq. (24)]. Which of those multisolutions are relevant has to be determined by the stability condition. In other words, there may occur bifurcation phenomena involving stability switches, as the control parameter D varies. This situation is reminiscent of the mean field model of phase

transitions that is described by the NFPE (8).[40–42] It is noted that owing to the expression of the free energy (15) together with the thermodynamic relation (34) the parameter D can be viewed as playing the role of temperature of Boltzmann–Gibbs statistics.

IV. LOCAL STABILITY ANALYSIS

To conduct local stability analysis we follow the procedure developed previously by the author[40] for the NFPE (8) of mean field models and calculate the second-order variation of the Liapunov functional (15). Differentiating F with respect to p one obtains

$$\delta F=\delta U-\delta DS=\int\left(\phi-\varepsilon x\int xp\,\mathrm{d}x\right)\delta p\,\mathrm{d}x+\frac{D}{q-1}\int qp^{q-1}\delta p\,\mathrm{d}x. \tag{45}$$

Substituting Eq. (24) and noting

$$\int\delta p\,\mathrm{d}x=0, \tag{46}$$

one obtains

$$\delta F=\frac{Dq}{q-1}\int(p^{q-1}-{R_p}^{q-1})\,\delta p\,\mathrm{d}x. \tag{47}$$

Let P_{eq} be one of the probability distributions satisfying Eq. (43) for p_∞. The first-order variation $\delta F^{(1)}|_{\mathrm{eq}}$ evaluated at $p=P_{\mathrm{eq}}$ turns out to vanish because of Eqs. (42) and (46). Differentiating δF again with respect to p one has

$$2\,\delta F^{(2)}=Dq\int[p^{q-2}(\delta p)^2-{R_p}^{q-2}\delta p\,\delta R_p]\mathrm{d}x. \tag{48}$$

Using

$$\varepsilon x\int x\delta p\,\mathrm{d}x=Dq{R_p}^{q-2}\delta R_p+\frac{1}{1-q}\frac{\partial\left(\frac{1}{\beta_0}\right)}{\partial\varepsilon\langle x\rangle_p}\varepsilon\int x\delta p\,\mathrm{d}x, \tag{49}$$

which follows from Eq. (24), one obtains

$$2\,\delta F^{(2)}=Dq\int p^{q-2}(\delta p)^2\mathrm{d}x-\varepsilon\left(\int x\delta p\,\mathrm{d}x\right)^2. \tag{50}$$

Putting $p=P_{\mathrm{eq}}$ leads to the second-order variation $\delta F^{(2)}|_{\mathrm{eq}}$ evaluated at the equilibrium point:

$$2\,\delta F^{(2)}|_{\mathrm{eq}}=Dq\int {P_{\mathrm{eq}}}^{q-2}(\delta p)^2\mathrm{d}x-\varepsilon\left(\int x\delta p\,\mathrm{d}x\right)^2, \tag{51}$$

which will be used to determine stability of the equilibrium point.

Assuming $\varphi(x)\in L^2$ (class of square integrable functions) we put

$$\delta p={P_{\mathrm{eq}}}^{(2-q)/2}\varphi(x). \tag{52}$$

We further assume that

$$\int x^2{P_{\mathrm{eq}}}^{2-q}\,\mathrm{d}x<\infty. \tag{53}$$

Decomposing $\varphi(x)$ as

$$\varphi(x)=\alpha P_{\mathrm{eq}}^{(2-q)/2}+\gamma x P_{\mathrm{eq}}^{(2-q)/2}+\varphi_{\perp}, \tag{54}$$

where $\varphi_{\perp}$ is the subspace of L^2 perpendicular to the subspace spanned by

$$P_{\mathrm{eq}}^{(2-q)/2} \text{ and } xP_{\mathrm{eq}}^{(2-q)/2},$$

we compute the second-order variation $\delta F^{(2)}|_{\mathrm{eq}}$.

Substituting Eq. (52) into Eq. (51) yields

$$2\,\delta F^{(2)}|_{\mathrm{eq}}=Dq\int[(\alpha P_{\mathrm{eq}}^{(2-q)/2}+\gamma x P_{\mathrm{eq}}^{(2-q)/2})^2+\varphi_{\perp}{}^2]\mathrm{d}x$$
$$-\varepsilon\left[\int xP_{\mathrm{eq}}^{(2-q)/2}(\alpha P_{\mathrm{eq}}^{(2-q)/2}+\gamma x P_{\mathrm{eq}}^{(2-q)/2}+\varphi_{\perp})\mathrm{d}x\right]^2. \tag{55}$$

Put

$$I_0=\int P_{\mathrm{eq}}{}^{2-q}\,\mathrm{d}x,\quad I_1=\int xP_{\mathrm{eq}}{}^{2-q}\,\mathrm{d}x,\quad I_2=\int x^2P_{\mathrm{eq}}{}^{2-q}\,\mathrm{d}x. \tag{56}$$

Noting that Eq. (46) gives

$$0=\int \delta p\,\mathrm{d}x=\alpha I_0+\gamma I_1, \tag{57}$$

one has from Eq. (55)

$$2\,\delta F^{(2)}|_{\mathrm{eq}}=Dq\left[\int \varphi_{\perp}{}^2\,\mathrm{d}x+\alpha^2I_0+\gamma^2I_2+2\alpha\gamma I_1-\frac{\varepsilon}{Dq}(\alpha I_1+\gamma I_2)^2\right]$$
$$=Dq\int \varphi_{\perp}{}^2\,\mathrm{d}x+Dq\,\gamma^2\left(I_2-\frac{I_1{}^2}{I_0}\right)\left[1-\frac{\varepsilon}{Dq}\left(I_2-\frac{I_1{}^2}{I_0}\right)\right]. \tag{58}$$

It follows from Schwartz's inequality that

$$I_2-\frac{I_1{}^2}{I_0}\geqslant 0. \tag{59}$$

Accordingly the stability condition $\delta F^{(2)}|_{\mathrm{eq}}>0$ can be reduced to

$$1-\frac{\varepsilon}{Dq}\left(I_2-\frac{I_1{}^2}{I_0}\right)>0 \tag{60}$$

and the stability switch occurs at a certain critical value D_c satisfying

$$1-\frac{\varepsilon}{D_cq}\left(I_2-\frac{I_1{}^2}{I_0}\right)=0. \tag{61}$$

This condition can also be derived from another kind of analysis based on the graphical representation[40] of the equation determining the order parameter of the system [see Eq. (44)]:

$$m=\int x[(Dq\beta)^{-1}(1-\beta(q-1)(\phi-\varepsilon x m))]^{1/(q-1)}\mathrm{d}x, \tag{62}$$

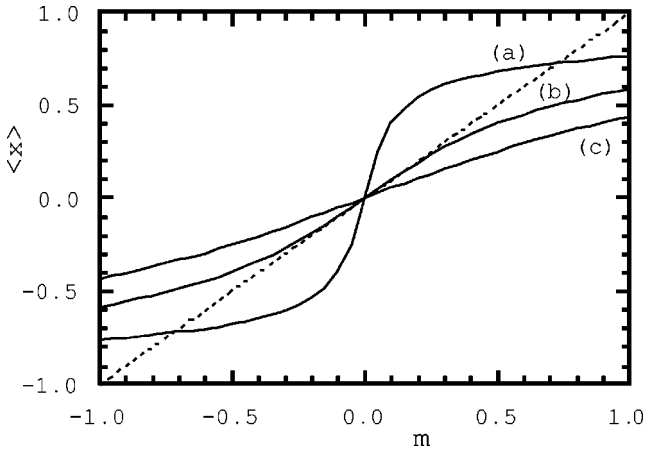

FIG. 1. Graphical representation of solving Eqs. (62) and (63) for determining the order parameter of a bistable system with $\phi(x)=-x^2+x^4$. $q=0.4$ and $\varepsilon=0.5$ are assumed. Plots as a function of m are shown of the order parameter $\langle x\rangle_{p_\infty}$ given by the right-hand side of Eq. (62) with $\beta=\beta(m)$ from Eq. (63) being substituted, for three typical values of D: (a) $D<D_c$ ($D=0.1$), (b) $D=D_c$ ($\approx 0.346\,54$), and (c) $D>D_c$ ($D=0.6$). At the bifurcation point $D=D_c$ the $\langle x\rangle_{p_\infty}$ curve (b) touches the straight line (dashed) representing the left-hand side of Eq. (62) at $m=0$.

$$1=\int [(Dq\beta)^{-1}(1-\beta(q-1)(\phi-\varepsilon xm))]^{1/(q-1)}\mathrm{d}x, \tag{63}$$

where we put $m\equiv\langle x\rangle_{p_\infty}$.

If the potential $\phi(x)$ is symmetric, i.e., $\phi(x)=\phi(-x)$, $m=0$ turns out to be a solution of the above-mentioned equations. The onset of instability of the $m=0$ solution is given by the tangency condition at $m=0$ for the curve representing the right-hand side of Eq. (62) as a function of m. In general, the tangency condition at arbitrary m reads

$$1=\frac{\mathrm{d}}{\mathrm{d}m}\int x[(Dq\beta(m))^{-1}(1-\beta(m)(q-1)(\phi-\varepsilon xm))]^{1/(q-1)}\mathrm{d}x, \tag{64}$$

which is obtained by differentiating Eq. (62) with respect to m.
Differentiating Eq. (63) with respect to m yields

$$\frac{\mathrm{d}\beta}{\mathrm{d}m}=\frac{\varepsilon(q-1)\beta^2\int x p_{\infty\,m}^{2-q}\mathrm{d}x}{\int p_{\infty\,m}^{2-q}\mathrm{d}x}, \tag{65}$$

where the m dependence of p_∞ is expressed as $p_{\infty\,m}$. Substituting this into Eq. (64) one immediately obtains

$$1=\frac{\varepsilon}{Dq}\left[\int x^2 p_{\infty\,m}^{2-q}\mathrm{d}x-\frac{(\int x p_{\infty\,m}^{2-q}\mathrm{d}x)^2}{\int p_{\infty\,m}^{2-q}\mathrm{d}x}\right]. \tag{66}$$

This is exactly the same as Eq. (61) with $P_{\mathrm{eq}}=p_{\infty\,m}$ and $D=D_c$.

We show an example of the occurrence of bifurcations for a bistable system having the potential $\phi(x)=-x^2+x^4$. Figure 1 displays the behavior of the right-hand side of Eq. (62) with $\beta=\beta(m)$, that is, the order parameter $\langle x\rangle_{p_\infty}$, plotted as a function of m for three typical values of D and how those $\langle x\rangle_{p_\infty}$ curves intersect the straight line representing the left-hand side of Eq. (62). Since the potential has symmetry, one always has the intersection at the origin that gives rise to the

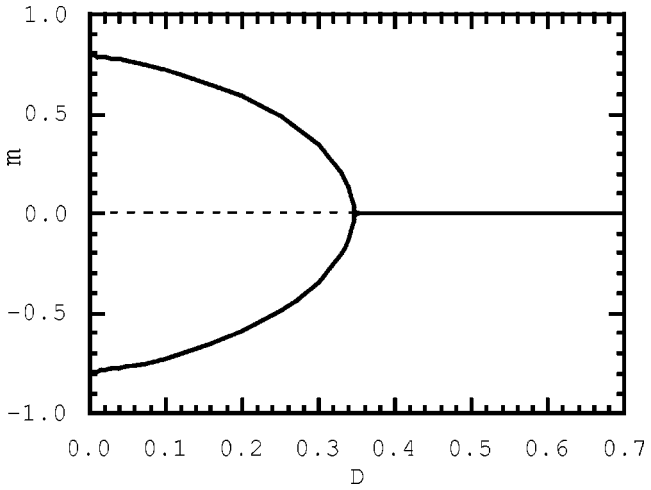

FIG. 2. Bifurcation diagram of pitch-fork type for the bistable system of Fig. 1 showing the dependence of the order parameter of the stable branch on the control parameter D together with stability switches at $D=D_c$ between stable (solid line) and unstable (dashed line) branches.

trivial solution $m=0$. We see the $\langle x\rangle_{p_\infty}$ curve for the critical value D_c touches the straight line at the origin to satisfy the criticality condition given by Eq. (66). While for $D>D_c$ the symmetric probability distribution with the order parameter $m=0$ is stable with

$$1>\frac{\mathrm{d}}{\mathrm{d}m}\int x[(Dq\beta(m))^{-1}(1-\beta(m)(q-1)(\phi-\varepsilon xm))]^{1/(q-1)}\mathrm{d}x, \tag{67}$$

it becomes unstable for $D<D_c$ and two symmetrically generated intersection points having $m\neq 0$ gain stability, because the stability condition (60) is broken. Note that in this example the symmetric probability distribution with $m=0$ for $D=D_c$ is stable because of the global stability of the system implied by the H-theorem [Eqs. (18) and (19)].

We depict in Fig. 2 the bifurcation diagram showing the dependence of the order parameter of the stable branch on the control parameter D together with stability switches between stable and unstable branches. We see as D is decreased from high values passing through the critical value D_c a symmetry breaking phenomenon occurs. When the diffusion constant D is viewed as temperature, such behavior is reminiscent of the ferromagnetic phase transition.

V. SUMMARY AND DISCUSSION

We have proposed a double nonlinear Fokker–Planck equation (DNFPE) (9) exhibiting bifurcation phenomena within the framework of generalized thermostatistics based on nonextensive-type generalized entropies. The nonlinearity responsible for the occurrence of bifurcations, which is added to the drift term of the previously known nonlinear Fokker–Planck equation of Plastino type, takes the form appearing in the standard mean field model. Our DNFPE exhibits, in general, multisolutions unlike the original NFPE (1) and then criteria for choosing relevant solutions are required.

To tackle this problem we have proven an H-theorem by constructing a Liapunov function that takes the form of free energy involving generalized entropies of Tsallis. Our H-theorem shows that the free energy, which is bounded below, continues to decrease until the system approaches one of the equilibrium distributions. More precisely, it ensures, instead of uniqueness of the equilibrium distribution, global stability of the system in that either one of the multisolutions must be approached for large times.

Stability of each ergodic component is determined by the local stability analysis in which the second-order variation of the Liapunov function takes positive values. We have computed the

second-order variation of the Liapunov function to find its relevant part whose sign governs stability of the equilibrium distribution of the system, and found that the latter can be amenable to graphical analysis used in graphically solving the order parameters.

We have given an example of the systems exhibiting bifurcation phenomena to confirm our theory. We have dealt with the case with a bistable potential and shown the bifurcation diagram displaying the order parameter as a function of the coefficient of the nonlinear diffusion term. The resultant bifurcation is similar to the behavior of the standard mean field model of ferromagnetic phase transitions.

As far as the thermodynamic equilibrium is concerned, the problem of phase transitions for infinite-range Ising ferromagnet was studied in Ref. 50 within generalized thermostatistics. Their treatment allows for energy-constant-dependent physical quantities in the thermodynamic limit, which may come from the use of the so-called second choice[2,3] of Tsallis thermostatistics, where average of unity is not unity. In our approach the constant term in the potential energy $\phi(x)$ does not matter in the equilibrium distribution (35) [see Eq. (33)] to give a standard result.

In this paper we have studied the DNFPE obtained based on the NFPE (1) exhibiting the equilibrium distribution of the first choice rather than on the NFPE of Eq. (5) that was recently proposed for the dynamics associated with the third choice of Tsallis thermostatistics. Since both choices of thermostatistics are quite similar to each other if viewed from the NFPEs,[18] we consider that it will suffice to deal with the simplest case as given by the present model to explore the crux of bifurcation phenomena exhibited by the DNFPEs within the framework of generalized thermostatistics.

Although our DNFPE is, to date, not known to have appropriate corresponding N-body Langevin equations or equivalently N-body linear Fokker–Planck equation as considered in the case of the NFPE (8), this work might help search for possible candidates for models explaining dynamic aspects of mean-field type phase transitions within the framework of Tsallis or generalized thermostatistics.

APPENDIX A

Proof of Eq. (35): $-(\partial^2\tilde{F}/\partial h^2)>0$.

Noting

$$\phi - hx = \frac{DqR_{D,h}^{q-1}}{1-q} - \frac{1}{(1-q)\beta_0}, \tag{A1}$$

we differentiate it with respect to h to have

$$-x = -DqR_{D,h}^{q-2}\frac{\partial R_{D,h}}{\partial h} - \frac{1}{1-q}\frac{\partial}{\partial h}\left(\frac{1}{\beta_0}\right). \tag{A2}$$

Then using Eq. (33) one has

$$\begin{aligned} -\frac{\partial^2\tilde{F}}{\partial h^2} = \frac{\partial}{\partial h}\int xR_{D,h}\mathrm{d}x &= \int x\frac{\partial}{\partial h}R_{D,h}\mathrm{d}x \\ &= Dq\int {R_{D,h}}^{q-2}\left(\frac{\partial R_{D,h}}{\partial h}\right)^2\mathrm{d}x + \frac{1}{1-q}\frac{\partial}{\partial h}\left(\frac{1}{\beta_0}\right)\frac{\partial}{\partial h}\int R_{D,h}\mathrm{d}x \\ &= Dq\int {R_{D,h}}^{q-2}\left(\frac{\partial R_{D,h}}{\partial h}\right)^2\mathrm{d}x > 0. \end{aligned} \tag{A3}$$

APPENDIX B

Proof of Eq. (36): $-(1/h)(\partial\tilde{F}/\partial h)\to 0$ $(h\to\pm\infty)$.

Taking the probability distribution $R_{D,h}(x)$ in the form

$$R_{D,h}(x)=[(Dq\beta_0)^{-1}\{1-\beta_0(q-1)(\phi(x)-hx)\}]^{1/(q-1)} \quad (0<q<1) \tag{B1}$$

with

$$\phi(x)=\sum_{k=0}^{n-1} a_k x^{n-k} \quad (a_0>0,\ n(:\text{even})\geqslant 4) \tag{B2}$$

and noting Eq. (33), we will show that

$$\lim_{h\to\infty} h^{-1/(n-1)}\int xR_{D,h}\mathrm{d}x=\omega \ \ (\text{const}). \tag{B3}$$

Note that when D is a given constant, β_0 is determined as a function of D and h and that the partition function Z defined below remains constant as h is varied:

$$Z=\int\left[\frac{1}{q\beta_0(D,h)}+\frac{(1-q)}{q}(\phi(x)-hx)\right]^{-1/(1-q)}\mathrm{d}x=D^{1/(q-1)}. \tag{B4}$$

Introducing a change of variable as

$$x=h^{1/(n-1)}y \tag{B5}$$

one has

$$\langle x\rangle=\int xR_{D,h}\mathrm{d}x=h^{1/(n-1)}\int y\tilde{R}(y,h)\mathrm{d}y, \tag{B6}$$

where

$$\tilde{R}(y,h)=\frac{1}{Z}h^{\alpha}g(y,h)^{-1/(1-q)} \tag{B7}$$

with

$$g(y,h)=\frac{1-q}{q}\psi(y,h)+\frac{1}{q\beta_0}h^{-n/(n-1)}>0 \quad (\forall y,h),$$

$$\psi(y,h)=a_0y^n-y+\sum_{k=1}^{n-1} a_k h^{-k/(n-1)}y^{n-k}$$

$$\alpha=\frac{n+q-1}{(n-1)(q-1)}<0. \tag{B8}$$

We note that

$$\lim_{h\to\infty}\mathrm{Min}_{-\infty<y<\infty}\psi(y,h)=\mathrm{Min}_{-\infty<y<\infty}(a_0y^n-y)=\frac{1-n}{n}\left(\frac{1}{na_0}\right)^{1/(n-1)}\equiv\omega<0 \tag{B9}$$

and the minimum of the right-hand side of Eq. (B9) is attained at

$$y=y^*=\left(\frac{1}{na_0}\right)^{1/(n-1)}. \tag{B10}$$

Since $\int \tilde{R}(y,h)\mathrm{d}y=1$, $\alpha<0$, and Z remains constant, it follows

$$\int g(y,h)^{-1/(1-q)}\mathrm{d}y\to\infty \quad (h\to\infty), \tag{B11}$$

and hence the minimum of $g(y,h)$ over $-\infty<y<\infty$, $\Omega(h)$,

$$\Omega(h)\equiv\frac{1-q}{q}\mathrm{Min}_{-\infty<y<\infty}\psi(y,h)+\frac{1}{q\beta_0}h^{-n/(n-1)}, \tag{B12}$$

which must be positive, tends to 0 as $h\to\infty$. Accordingly one has

$$\lim_{h\to\infty}\frac{1}{q\beta_0}h^{-n/(n-1)}=\frac{-(1-q)\omega}{q}>0. \tag{B13}$$

Letting $\varepsilon>0$ be an arbitrary number, we evaluate the integral

$$\begin{aligned} I(h)\equiv\int y\tilde{R}(y,h)\mathrm{d}y-y^*&=\int (y-y^*)\tilde{R}(y,h)\mathrm{d}y \\ &=\int_{|y-y^*|<\varepsilon}(y-y^*)\tilde{R}(y,h)\mathrm{d}y+\int_{|y-y^*|\geqslant\varepsilon}(y-y^*)\tilde{R}(y,h)\mathrm{d}y. \end{aligned} \tag{B14}$$

One then has

$$\left|\int_{|y-y^*|<\varepsilon}(y-y^*)\tilde{R}(y,h)\mathrm{d}y\right|\leqslant\varepsilon. \tag{B15}$$

Since, using the dominated convergence theorem, one has

$$\begin{aligned} &\lim_{h\to\infty}\int_{|y-y^*|\geqslant\varepsilon}|y-y^*|g(y,h)^{-1/(1-q)}\mathrm{d}y \\ &\quad=\int_{|y-y^*|\geqslant\varepsilon}|y-y^*|\left[\frac{(1-q)}{q}(-\omega+a_0y^n-y)\right]^{-1/(1-q)}\mathrm{d}y, \end{aligned} \tag{B16}$$

it follows that for sufficiently large h,

$$\frac{h^\alpha}{Z}\int_{|y-y^*|\geqslant\varepsilon}|y-y^*|g(y,h)^{-1(1-q)}\mathrm{d}y<\varepsilon. \tag{B17}$$

Accordingly, from Eqs. (B14), (B15), and (B17) we obtain

$$\lim_{h\to\infty}I(h)=0 \tag{B18}$$

to have

$$\lim_{h\to\infty}\int y\tilde{R}(y,h)\mathrm{d}y=y^*, \tag{B19}$$

which together with Eq. (B6) yields Eq. (B3) with $\omega=y^*$.

Since the case with $h\to-\infty$ can be dealt with in the same way, we have Eq. (36) to conclude the proof.

Lévy flights: Exact results and asymptotics beyond all orders

T. M. Garoni and N. E. Frankel[a)]
School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia

(Received 3 April 2001; accepted for publication 15 January 2002)

A comprehensive study of the symmetric Lévy stable probability density function is presented. This is performed for orders both less than 2, and greater than 2. The latter class of functions are traditionally neglected because of a failure to satisfy non-negativity. The complete asymptotic expansions of the symmetric Lévy stable densities of order greater than 2 are constructed, and shown to exhibit intricate series of transcendentally small terms—asymptotics beyond all orders. It is demonstrated that the symmetric Lévy stable densities of any arbitrary rational order can be written in terms of generalized hypergeometric functions, and a number of new special cases are given representations in terms of *special functions*. A link is shown between the symmetric Lévy stable density of order 4, and Pearcey's integral, which is used widely in problems of optical diffraction and wave propagation. This suggests the existence of applications for the symmetric Lévy stable densities of order greater than 2, despite their failure to define a probability density function. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467095]

I. INTRODUCTION

It is widely recognized that the Lévy stable densities have enormously varied applicability to stochastic phenomena in the physical sciences. The characteristic feature of these densities is the divergence of their low order moments. Random walks in which the steps are of random length and distributed according to a Lévy stable density are referred to as Lévy flights,[1] and are much discussed in the literature.[2] Continuous time random walks (CTRWs) in which the pausing time distributions follow a Lévy stable law are also widely studied.[2–4]

The Gaussian density is an important case of the Lévy stable densities, as is the Cauchy density which is known to physicists in the context of atomic line shapes. Another early physical application of the Lévy stable densities is the Holtsmark distribution of the random fluctuations of the gravitational field of stars.[5] Apart from these cases however, physical applications of the Lévy stable densities were scarce prior to the ''fractal revolution,'' and their chief applications were traditionally to probability theory itself; notably to limit theorems, and random processes such as branching processes and random determinants.[6] A flood of physical applications of Lévy flights have arisen in recent years, notable amongst these are models of turbulence, polymer transport, and Hamiltonian chaos. A remarkable feature of turbulent flows is enhanced diffusion which requires a probability distribution with infinite moments, and recently work has been done in applying Lévy flights and their generalizations to this phenomenon.[7,8] A review of the application of Lévy stable densities to anomalous diffusion can be found in Ref. 9. CTRWs distributed according to Lévy stable laws prove important in studies of charge transport in amorphous materials.[3,4] Articles discussing these and many more topics appear in Ref. 2.

Biological applications of Lévy stable densities have become plentiful, and Lévy flights have been harnessed in modeling wide ranging phenomena, from the structure of DNA[2] to the flight paths of the wandering albatross.[10] Such is the great utility of the stable densities, they even pervade less piquant disciplines such as economics. Lévy stable densities are asymptotically of the form $1/x^{\alpha+1}$.[11] The economic sociologist Pareto[12] first noted that empirical data of the income

a)Electronic mail: frankel@physics.unimelb.edu.au

distributions for various countries followed an inverse power law distribution, and it is now believed[13] that many economic quantities display this behavior. In the economics literature densities with such asymptotic behavior are referred to as Pareto densities. Mandelbrot[13,14] has attempted to explain this asymptotic behavior by arguing that quantities such as price change are ruled by Lévy stable distributions. For a more recent discussion on the use of stochastic processes in finance see Ref. 15.

The Lévy stable densities are stable in the sense that if independent random variables X and Y are distributed according to the same type of Lévy stable density, then $X+Y$ will again be distributed according to this density. More precisely, let X_1 and X_2 be independent random variables with the same probability density function (pdf) $p_\alpha(x)$. $p_\alpha(x)$ is defined to be Lévy stable if it is a solution to the following,[4,16–19] for all positive c_1 and c_2,

$$c_1X_1+c_2X_2=cX, \tag{1.1}$$

where X has the same pdf as X_1 and X_2.

The constant c is determined via

$$c_1^\alpha+c_2^\alpha=c^\alpha. \tag{1.2}$$

We refer to α as the order of the stable density.

The question, ''when is the sum of independent and identically distributed random variables again distributed in the same way,'' expressed in modern terminology translates into that paradigm of fractals, self-similarity: ''when does the whole look like its parts?'' It is known that the trajectory of a Lévy flight is self-similar and that the order of the corresponding stable density, α, is equal to the Hausdorff–Besicovitch dimension of this trajectory.[4,13] This self-similarity manifests itself as a hierarchy of clusters in the trajectory of a Lévy flight, see, e.g., Refs. 3 and 13. The origin of this self-similar scaling behavior lies in the divergence of the moments of the Lévy stable density. This divergence of the moments of Lévy stable pdfs can be understood quite simply from their $1/x^{\alpha+1}$ leading order asymptotic behavior, which implies that all moments $\langle x^m\rangle$ for $m\geqslant\alpha$ diverge.[20]

The divergence of the moments is also obvious from the structure of the Fourier transform, $\tilde{p}_\alpha(k)$, of the symmetric Lévy stable density

$$\tilde{p}_\alpha(k)=\exp(-|k|^\alpha), \tag{1.3}$$

which clearly displays leading order nonanalytic behavior. It is well known (e.g., Ref. 16) that the moments of a pdf, if they exist, are proportional to the coefficients of the power series expansion of the corresponding characteristic function. Thus we see that the moments of the symmetric Lévy stable pdfs will not exist in general, and hence there exists no characteristic scale. It is this divergence of moments and the consequent nonexistence of characteristic scales that endows the Lévy stable densities with their great utility, and intrinsic interest.

Taking the inverse Fourier transform of (1.3), it follows that the symmetric Lévy stable density, $p_\alpha(x)$, has the following form:

$$p_\alpha(x)=\frac{1}{\pi}\int_0^\infty \cos(kx)\exp(-k^\alpha)\mathrm{d}k. \tag{1.4}$$

We note here that the most general form of $\tilde{p}_\alpha(k)$ is actually $\tilde{p}_\alpha(k)=\exp(-a|k|^\alpha)$ for some non-negative a, where a has the dimension of (length)$^\alpha$. However we can clearly scale a out of the integral defining $p_\alpha(x)$ with no loss of generality, and thus we neglect a in all future discussions. This implies that x is being scaled by $a^{1/\alpha}$ and is therefore dimensionless.

It will be the analytic and asymptotic behavior of the integral (1.4) that will be the focus of this work. Equation (1.4) only defines a pdf when $0<\alpha\leqslant 2$, because for $\alpha>2$ it fails the nonnegativity requirement,[21,22] although it is interesting to note that it is still both stable and normal-

izable. We shall not be dissuaded from investigating the interesting properties of (1.4) for $\alpha>2$ however, and in fact this is one of the principle aims of this work. We shall refer to the integral in (1.4) as $p_\alpha(x)$, even when it does not define a pdf. We show that the asymptotic forms of $p_\alpha(x)$ for $\alpha>2$ possess highly intricate transcendentally small terms lying beyond all orders of the asymptotic power series. We study these structures in detail and discuss why these results will likely find interesting physical applications despite the inability of using $p_\alpha(x)$ as a pdf in this region. This work further demonstrates our continuing interest in the newly emerging field of asymptotics beyond all orders.[23–25]

It is easily shown that $p_4(x)$ is related to a special case of Pearcey's integral, $P(y,z)$,[26,27]

$$P(y,z)=2e^{i(\pi/8)}\int_0^\infty \mathrm{d}k\,\exp(-k^4-yk^2)\cos(zk) \tag{1.5}$$

via

$$P(0,z)=2\pi e^{(i\pi/8)}p_4(z). \tag{1.6}$$

The dominant exponential asymptotics displayed by $P(0,z)$, discussed in Ref. 26, is a perfect example of the behavior displayed by $p_\alpha(x)$ when α is an even integer. As we shall show, in these cases the asymptotic power series generated by the standard Mellin transform technique vanishes. Pearcey's integral is important in the theoretical treatment of short wavelength problems, e.g., wave propagation and optical diffraction.[26] It is the oscillatory nature of the exponential asymptotics that endows $p_4(x)$ with its utility in such problems, and it is behavior that is displayed by all other $p_\alpha(x)$ when $\alpha>2$. We thus feel it perfectly natural to anticipate that similar applications will exist for $p_\alpha(x)$ for other values of α.

There exists a wealth of knowledge of the analytic properties of the function $p_\alpha(x)$, e.g., Refs. 3 and 6. However, finding an expression for $p_\alpha(x)$ for general α in terms of known functions is traditionally considered impossible, e.g., Ref. 17. We demonstrate that for all rational α, $p_\alpha(x)$ can in fact be expressed as a finite sum of generalized hypergeometric functions, ${}_pF_q$.[28] It is also known,[29] albeit perhaps not widely, that the Lévy stable pdfs can be expressed in terms of the Fox H-function.[30] The Fox H-function is a generalization of the Meijer G-function, which in turn is a generalization of the less complicated generalized hypergeometric functions ${}_pF_q$.[31] The hypergeometric representation of $p_\alpha(x)$ is more practical since the analytic and asymptotic properties of the ${}_pF_q$, which we employ extensively, have been well studied.[31,32]

Zolotarev[33] provides a small list of values of α for which $p_\alpha(x)$ can be expressed in terms of *special functions*, and one of these results is recovered in Ref. 29. We not only recover Zolotarev's results but add a number of new cases, and display for the first time a detailed exposition of the compelling asymptotics beyond all orders for $\alpha>2$.

II. SERIES REPRESENTATIONS FOR $p_\alpha(x)$

Here we demonstrate a convenient method of deriving the known[2–4,16,17] convergent series, and asymptotic power series representations of $p_\alpha(x)$, since we shall have need to employ these expansions in later discussions. One can easily construct the Mellin–Barnes integral representation of $p_\alpha(x)$ by simply calculating its Mellin transform and then using the inverse Mellin transform formula.

$$p_\alpha(x)=\frac{1}{\pi}\frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty}\mathrm{d}s\,\frac{\cos\left(\frac{\pi s}{2}\right)\Gamma(s)\Gamma\left(\frac{1-s}{\alpha}\right)}{\alpha}x^{-s},\quad 0<\sigma<1. \tag{2.1}$$

Obtaining series expansions of $p_\alpha(x)$ is then merely a case of closing the contour to either the left or the right and calculating the residues. If we close to the left we obtain the small x expansion,

$$p_\alpha(x)=\frac{1}{\alpha\pi x}\sum_{m=0}^{\infty}(-1)^m x^{2m+1}\frac{\Gamma\left[\dfrac{2m+1}{\alpha}\right]}{\Gamma[2m+1]},\quad \forall\, x,\quad \alpha>1,$$
$$p_\alpha(x)\sim\frac{1}{\alpha\pi x}\sum_{m=0}^{\infty}(-1)^m x^{2m+1}\frac{\Gamma\left[\dfrac{2m+1}{\alpha}\right]}{\Gamma[2m+1]},x\to 0,\quad \alpha<1. \tag{2.2}$$

Via application of the ratio test we determine that (2.2) provides a convergent series representation of $p_\alpha(x)$ for all real x when $\alpha>1$, and an asymptotic expansion as $x\to 0$ for $\alpha<1$.

Closing the contour to the right we obtain the large x expansion of $p_\alpha(x)$,

$$p_\alpha(x)=\frac{\alpha}{\pi x}\sum_{m=0}^{\infty}\sin\left[\frac{(m+1)\pi\alpha}{2}\right](-1)^m(x^{-\alpha})^{m+1}\frac{\Gamma[(m+1)\alpha]}{\Gamma[m+1]},\quad x>0,\quad 0<\alpha<1,$$
$$p_\alpha(x)\sim\frac{\alpha}{\pi x}\sum_{m=0}^{\infty}\sin\left[\frac{(m+1)\pi\alpha}{2}\right](-1)^m(x^{-\alpha})^{m+1}\frac{\Gamma[(m+1)\alpha]}{\Gamma[m+1]},\quad x\to\infty,\quad \alpha>1. \tag{2.3}$$

Thus we have a convergent large x expansion of $p_\alpha(x)$ when $\alpha<1$. When $\alpha>1$ (2.3) provides an asymptotic expansion, but as we shall discuss later there are certain interesting cases in which this expansion is not *complete*.[34,35] In particular when α is integral and greater than 2, we find that (2.3) provides only the asymptotic power series component of the complete asymptotic expansion, i.e., there are a series of exponentially small terms that (2.3) neglects. If α is an even integer (2.3) vanishes identically, which for $\alpha=2$ expresses the fact that in the limit of large argument the Gaussian is smaller than any power. For even integral α, with $\alpha>2$, we see that the exponentially small terms lying beyond all orders of (2.3) become dominant, and the complete asymptotic expansion of $p_\alpha(x)$ consists solely of these transcendentally small series. We shall return to the delicate problem of calculating the terms that lie beyond all orders of (2.3) when $\alpha>2$. We devote an extensive section to the detailed construction of the exponential asymptotics for $p_\alpha(x)$ for the cases $\alpha=3,4,5,6,7$, which will demonstrate the increasing intricacy of the exponentially small asymptotic series as α increases.

III. $p_{p/q}(x)$ EXPRESSED IN TERMS OF HYPERGEOMETRIC FUNCTIONS

If we let $\alpha=p/q$, i.e., let α be rational, then $p_{p/q}(x)$ can be expressed as a finite sum of generalized hypergeometric functions. The serendipitous process by which we discovered this fact originated in the investigation of the exponential asymptotics of a number theoretic series which we refer to as the generalized Euler–Jacobi series, and denote by $S_{p/q}(a)$.[24] After a suitable transformation of the summand of $S_{p/q}(a)$, it becomes apparent that this summand is very simply related to $p_{p/q}(x)$. Thus the detailed asymptotic and analytic of investigation $S_{p/q}(a)$ that was undertaken in Ref. 24 can be applied to the investigation of $p_{p/q}(x)$. It is for this reason that we now discuss the relationship between $S_{p/q}(a)$ and $p_{p/q}(x)$.

We define the generalized Euler–Jacobi series as

$$S_{p/q}(a)\equiv\sum_{m=0}^{\infty}e^{-am^{p/q}} \tag{3.1}$$

and upon application of the Euler–Maclaurin summation formula this becomes

$$S_{p/q}(a)=\frac{q\Gamma\left(\dfrac{q}{p}\right)}{pa^{q/p}}+\frac{1}{2}+\sum_{n=1}^{\infty}\frac{a}{n\pi}\int_0^{\infty}\mathrm{d}t\,\sin(2n\pi t^{q/p})\exp(-at). \tag{3.2}$$

We refer to (3.2) as the inversion formula for $S_{p/q}(a)$. In order to simplify (3.2) a systematic study of integrals of the form

$$I_{p/q}(a,\beta)=\int_0^\infty \mathrm{d}t\,\exp(-at)\sin(\beta t^{q/p}) \tag{3.3}$$

was carried out in Ref. 24.

To see the relationship between $p_{p/q}(x)$ and $I_{p/q}(\alpha,\beta)$ we take $p_{p/q}(x)$ and integrate by parts

$$\begin{aligned} p_{p/q}(x)&=\frac{1}{\pi}\int_0^\infty \mathrm{d}k\,\cos(kx)\exp(-k^{p/q}),\\ p_{p/q}(x)&=\frac{1}{\pi x}\int_0^\infty \mathrm{d}(k^{p/q})\,\exp(-k^{p/q})\sin(kx), \end{aligned} \tag{3.4}$$

$$p_{p/q}(x)=\frac{1}{\pi x^{p/q+1}}\int_0^\infty \mathrm{d}t\,\exp\left(\frac{-t}{x^{p/q}}\right)\sin(t^{q/p}), \tag{3.5}$$

$$p_{p/q}(x)=\frac{1}{\pi x^{p/q+1}}I_{p/q}(x^{-p/q},1). \tag{3.6}$$

Hence we identify the summand in the generalized Euler–Jacobi inversion formula with $p_{p/q}(x)$. Specifically we see that

$$S_{p/q}(a)=\frac{q\Gamma\left(\frac{q}{p}\right)}{pa^{q/p}}+\frac{1}{2}+\frac{2\pi}{a^{q/p}}\sum_{n=1}^{\infty} p_{p/q}\left(\frac{2n\pi}{a^{q/p}}\right). \tag{3.7}$$

Thus the number theoretic series $S_{p/q}(a)$ can be interpreted as a sum over Lévy flights of different arguments.

All analytic and asymptotic results in Ref. 24 for $I_{p/q}(\alpha,\beta)$ or $S_{p/q}(a)$ can now be translated into results for $p_{p/q}(x)$ by application of this simple algorithm. We shall utilize this fact in the following sections to list a number of significant examples of the analytic behavior of $p_{p/q}(x)$ for various values of p/q, and also to discuss the delicate exponential asymptotic behavior of $p_{p/q}(x)$ for $p/q>2$.

One fundamental result of the analysis of $I_{p/q}(\alpha,\beta)$ in Ref. 24 is the representation of $I_{p/q}(\alpha,\beta)$ in terms of a sum of hypergeometric functions, which forms the foundation of the asymptotic results discussed therein. The method of construction of such a representation for $I_{p/q}(\alpha,\beta)$ suggests an obvious method for constructing a corresponding representation of $p_\alpha(x)$ in terms of hypergeometric functions, which we shall now delineate.

We begin our analysis with (2.2), letting $\alpha=p/q$. This series could also be obtained by simply expanding $\sin(t^{q/p})$ in (3.5) into its Maclaurin series and integrating term by term. As noted in Sec. II, (2.2) is convergent $\forall x$ when $p/q>1$, but is divergent when $p/q<1$. Despite this we will still identify (2.2) with $p_{p/q}(x)$ even for $p/q<1$, and when necessary the technique of Borel summation[36] can be utilized to recast the original series, for specific p/q, into convergent integrals which can then be evaluated. This process is discussed in detail in Ref. 24 in the treatment of $I_{p/q}(a,\beta)$.

The series representation for the generalized hypergeometric equation is

$${}_jF_k\left(\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_j\\ \beta_1,\beta_2,\ldots,\beta_k\end{matrix}\middle| z\right)=\sum_{m=0}^{\infty}\frac{z^m\,\Pi_{h=1}^{j}(\alpha_h)_m}{m!\,\Pi_{h=1}^{k}(\beta_h)_m}, \tag{3.8}$$

where $(a)_m$ is Pochhammer's symbol

$$(a)_m=\frac{\Gamma(a+m)}{\Gamma(a)}. \tag{3.9}$$

We can see from (3.8) and (3.9) that (2.2) clearly displays hypergeometric behavior, in that its coefficients are a ratio of gamma functions. To make this identification manifest we need to massage the gamma functions into the form $\Gamma(m+\text{stuff})$. We begin by using the change of index $m=np+l$,

$$p_{p/q}(x)=\frac{q}{\pi px}\sum_{n=0}^{\infty}\sum_{l=0}^{p-1}e^{i\pi(np+l)}x^{2np+2l+1}\frac{\Gamma\left[2nq+\dfrac{(2l+1)q}{p}\right]}{\Gamma(2np+2l+1)} \tag{3.10}$$

then we follow this with $s=2n$,

$$p_{p/q}(x)=\frac{q}{\pi px}\sum_{s=0}^{\infty}\left[\frac{1+(-1)^s}{2}\right]\sum_{l=0}^{p-1}e^{i\pi(sp/2+l)}x^{sp+2l+1}\frac{\Gamma\left[sq+\dfrac{(2l+1)q}{p}\right]}{\Gamma(sp+2l+1)}. \tag{3.11}$$

Finally we can now transform the ratio of gamma functions into the required form by utilizing Gauss' multiplication formula[31] and (3.9), which results in

$$\begin{aligned}&\frac{\Gamma\left[sq+\dfrac{(2l+1)q}{p}\right]}{\Gamma(sp+2l+1)}\\&\quad=\frac{(2\pi)^{(p-q)/2}q^{sq+(2l+1)q/p-1/2}}{p^{sp+2l+1/2}}\frac{\displaystyle\prod_{h=1}^{(q-1)}\Gamma\left[\frac{(2l+1)}{p}+\frac{h}{q}\right]}{\displaystyle\prod_{h=1}^{(p-1)}\Gamma\left[\frac{(2l+1)}{p}+\frac{h}{p}\right]}\frac{\left(\dfrac{2l+1}{p}+\dfrac{h}{q}\right)_s}{\left(\dfrac{2l+1}{p}+\dfrac{h}{p}\right)_s}.\end{aligned} \tag{3.12}$$

Inserting (3.12) into (3.11)

$$\begin{aligned}p_{p/q}(x)=&\frac{q^{q/p+1/2}}{p^{3/2}}(2\pi)^{(p-q-2)/2}\sum_{l=0}^{p-1}(-1)^l\left(\frac{q^qx^p}{p^p}\right)^{2l/p}\frac{\displaystyle\prod_{h=1}^{(q-1)}\Gamma\left[\frac{(2l+1)}{p}+\frac{h}{q}\right]}{\displaystyle\prod_{h=1}^{(p-1)}\Gamma\left[\frac{(2l+1)}{p}+\frac{h}{p}\right]}\\&\times\sum_{t=0}^{1}\sum_{s=0}^{\infty}\left((-1)^te^{p\pi i/2}\frac{q^qx^p}{p^p}\right)^s\frac{1}{s!}\frac{(1)_s\displaystyle\prod_{h=1}^{(q-1)}\left(\dfrac{2l+1}{p}+\dfrac{h}{q}\right)_s}{\displaystyle\prod_{h=2}^{p}\left(\dfrac{2l+h}{p}\right)_s}.\end{aligned} \tag{3.13}$$

The following useful notation, $f(\pm z)^{\pm}\equiv f(z)\pm f(-z)$ for some function f, will be used throughout this work. Using (3.13) and (3.8) then, we finally obtain

$$p_{p/q}(x)=\frac{q^{q/p+1/2}}{p^{3/2}}(2\pi)^{(p-q-2)/2}\sum_{l=0}^{p-1}(-1)^l\left(\frac{q^q x^p}{p^p}\right)^{2l/p}\times\frac{\prod_{h=1}^{(q-1)}\Gamma\left[\frac{(2l+1)}{p}+\frac{h}{q}\right]}{\prod_{h=1}^{(p-1)}\Gamma\left[\frac{(2l+1)}{p}+\frac{h}{p}\right]}\times{}_qF_{p-1}\left(\left.\begin{matrix}1,\frac{2l+1}{p}+\frac{1}{q},\frac{2l+1}{p}+\frac{2}{q},\ldots,\frac{2l+1}{p}+\frac{q-1}{q}\\ \frac{2l+2}{p},\frac{2l+3}{p},\ldots,\frac{2l+p}{p}\end{matrix}\right|\pm i^p\frac{q^q x^p}{p^p}\right)^+. \quad (3.14)$$

In order to simply the appearance of this further, we can use the known relationship between the Meijer G-function and the generalized hypergeometric function[31] to obtain

$$p_{p/q}(x)=\frac{q^{q/p+1/2}}{p^{3/2}}(2\pi)^{(p-q-2)/2}\sum_{l=0}^{p-1}(-1)^l\left(\frac{q^q x^p}{p^p}\right)^{2l/p}\times G_{q,p}^{1,q}\left(\left.\pm i^p\frac{q^q x^p}{p^p}\right|\begin{matrix}0,\frac{1}{q}-\frac{2l+1}{p},\frac{2}{q}-\frac{2l+1}{p},\ldots,\frac{q-1}{q}-\frac{2l+1}{p}\\ 0,\frac{-2l}{p},\frac{1}{p}-\frac{2l}{p},\ldots,\frac{p-2l-2}{p}\end{matrix}\right)^+. \quad (3.15)$$

IV. SPECIAL FUNCTION REPRESENTATIONS OF $p_{p/q}(x)$

In this section we list a number of new cases of special function representations of $p_{p/q}(x)$, in which (3.15) decomposes into simpler forms. We also recover, and in one instance correct, some results obtained by Zolotarev. We begin by deriving the familiar forms of the the Cauchy and Gaussian densities from (3.15) in order to illustrate how the general expression simplifies in these more transparent cases. We show that the Holtsmark density can be expressed as a sum of Bessel functions. For details of the derivation of these results the reader should consult Ref. 24, applying (3.7).

A. The Cauchy and Gaussian densities

It is easily shown that for $\alpha=1$, (3.14) decomposes as follows:

$$p_1(x)=\frac{1}{2\pi}{}_1F_0(1;\pm ix)^+,$$
$$p_1(x)=\frac{1}{\pi(1+x^2)}. \quad (4.1)$$

This second expression will be recognized as the well-known Cauchy pdf.

Recovering the Gaussian pdf from (3.14) when $\alpha=2$ is equally straightforward,

$$p_2(x)=\frac{1}{2\sqrt{4\pi}}\sum_{l=0}^{1}(-1)^l\left(\frac{x^2}{4}\right)^l {}_1F_1\left(1;l+1;\pm\frac{x^2}{4}\right)^+,$$
$$p_2(x)=\frac{e^{-x^2/4}}{\sqrt{4\pi}}. \tag{4.2}$$

Thus our general result (3.14) easily reproduces the standard forms of these two principal special cases of $p_{p/q}(x)$.

B. $\alpha=3/2$: The Holtsmark density

With the exception of the Gaussian and Cauchy densities, the Holtsmark density was the first recognized application of the Lévy stable densities to the physical sciences. Chandrasekhar[5] gives an elegant derivation of the pdf for the force per unit mass acting on a given star due to the gravitational attraction of the neighboring stars, which shows this pdf to be $p_{3/2}(x)$. He did not give the closed form expression for the pdf however, but instead tabulated various numerically obtained values for it. We now present the special functions representation for the Holtsmark density, in which $J_\mu(x)$ is the Bessel function of the first kind of order μ,

$$p_{3/2}(x)=\frac{2^{2/3}}{3^{3/2}\sqrt{\pi}}\sum_{l=0}^{2}\left(\frac{4x^3}{27}\right)^{2l/3}(-1)^l G_{2,3}^{1,2}\left(\pm i\frac{4x^3}{27}\,\middle|\,\begin{matrix}0,\frac{1}{2}-\frac{2l+1}{3}\\ 0,\frac{-2l}{3},\frac{1}{3}-\frac{2l}{3}\end{matrix}\right)^+, \tag{4.3}$$

$$p_{3/2}(x)=\frac{4x^2}{27\sqrt{3}}\cos\left(\frac{2x^3}{27}\right)J_{-2/3}\left(\frac{2x^3}{27}\right)-\frac{4x^2}{27\sqrt{3}}\cos\left(\frac{2x^3}{27}\right)J_{2/3}\left(\frac{2x^3}{27}\right)-\frac{4x^2}{27\sqrt{3}}\sin\left(\frac{2x^3}{27}\right)J_{-1/3}\left(\frac{2x^3}{27}\right)$$
$$-\frac{4x^2}{27\sqrt{3}}\sin\left(\frac{2x^3}{27}\right)J_{1/3}\left(\frac{2x^3}{27}\right)+\frac{x^2}{6\pi}{}_2F_2\left(1,\frac{3}{2};\frac{4}{3},\frac{5}{3};\pm\frac{i4x^3}{27}\right)^+.$$

C. Zolotarev's results: Correcting $p_{2/3}(x)$ and recovering $p_{1/2}(x)$

Zolotarev[33] states a representation of $p_{2/3}(x)$ in terms of a Whittaker function, but this result, which is much quoted, e.g. Ref. 3, is incorrect. That the result in Ref. 33 cannot be correct can be simply deduced by observing its large x behavior and comparing it to (2.3). We now list the correct result in terms of a Tricomi confluent hypergeometric function $\Psi(\beta,\gamma,z)$. We also state the result less elegantly in terms of a Whittaker function, $W_{a,b}(z)$, which is similar in form to the incorrect result stated in Ref. 33,

$$p_{2/3}(x)=\frac{3}{4\sqrt{\pi}}{}_2F_0\left(\frac{5}{6},\frac{7}{6};-\frac{27x^2}{4}\right),$$
$$p_{2/3}(x)=\frac{x^{-5/3}}{2^{1/3}3^{3/2}\sqrt{\pi}}\Psi\left(\frac{5}{6},\frac{2}{3};\frac{4}{27x^2}\right), \tag{4.4}$$
$$p_{2/3}(x)=\frac{1}{6x}\sqrt{\frac{3}{\pi}}\exp\left(\frac{2}{27x^2}\right)W_{-1/2,1/6}\left(\frac{4}{27x^2}\right).$$

In Ref. 33 Zolotarev derives $p_{1/2}(x)$ by a rather complicated procedure. By massaging (3.14) appropriately we obtain

$$p_{1/2}(x)=\frac{1}{\pi}{}_2F_0\left(1,\frac{3}{2};\pm i4x\right)^+,$$

$$p_{1/2}(x)=\frac{1}{8x^2}\left[J_{1/2}\left(\frac{1}{4x}\right)+J_{-1/2}\left(\frac{1}{4x}\right)\right]-\frac{1}{2\pi\sqrt{2}x^2}\left[\mathbf{J}_{1/2}\left(\frac{1}{4x}\right)+\mathbf{E}_{1/2}\left(\frac{1}{4x}\right)\right], \tag{4.5}$$

$$p_{1/2}(x)=\frac{1}{\sqrt{2\pi}x^{3/2}}\left[\frac{1}{2}-C\left(\frac{1}{\sqrt{2\pi x}}\right)\right]\cos\left(\frac{1}{4x}\right)+\frac{1}{\sqrt{2\pi}x^{3/2}}\left[\frac{1}{2}-S\left(\frac{1}{\sqrt{2\pi x}}\right)\right]\sin\left(\frac{1}{4x}\right),$$

where $\mathbf{J}_\nu(\mathbf{z})$ and $\mathbf{E}_\nu(\mathbf{z})$ are the Anger and Weber functions, respectively, and $C(z)$, $S(z)$ are the Fresnel integrals. The last form listed in (4.5) in terms of the Fresnel integrals is in agreement with that stated by Zolotarev.

D. A miscellany of other new results: $\alpha=1/3,3,4/3$

By an examination of the integral[24] corresponding to $p_{1/3}(x)$, it was found that the case of $p_{1/3}(x)$ has an especially simple representation in terms of a complex conjugate pair of Lommel functions. This is a new and rather attractive result,

$$\begin{aligned}p_{1/3}(x)&=\frac{27\sqrt{3}}{(2\pi)^2}\Gamma\left(\frac{4}{3}\right)\Gamma\left(\frac{5}{3}\right){}_3F_0\left(1,\frac{4}{3},\frac{5}{3};\pm i27x\right)^+,\\ p_{1/3}(x)&=\frac{1}{3\sqrt{3}\pi x^{3/2}}e^{-i\pi/4}S_{0,1/3}\left(\frac{2e^{i\pi/4}}{3\sqrt{3x}}\right)+\frac{1}{3\sqrt{3}\pi x^{3/2}}e^{i\pi/4}S_{0,1/3}\left(\frac{2e^{-i\pi/4}}{3\sqrt{3x}}\right).\end{aligned} \tag{4.6}$$

The case of $\alpha=3$ is especially interesting and we discuss in detail its asymptotic properties in Sec. V. Here we observe that the integral for $p_3(x)$ is exactly solvable and is again given by a complex conjugate pair of Lommel functions,

$$\begin{aligned}p_3(x)&=\frac{1}{3\sqrt{3}}\sum_{l=0}^{2}(-1)^l\left(\frac{x^2}{9}\right)^l G^{1,1}_{1,3}\left(\pm i\frac{x^3}{27}\middle|{}^{0}_{0,-2l/3,(1-2l)/3}\right)^+,\\ p_3(x)&=\frac{1}{3\pi}\sqrt{\frac{x}{3}}e^{i\pi/4}S_{0,1/3}\left[2e^{3i\pi/4}\left(\frac{x}{3}\right)^{3/2}\right]+\frac{1}{3\pi}\sqrt{\frac{x}{3}}e^{-i\pi/4}S_{0,1/3}\left[2e^{-3i\pi/4}\left(\frac{x}{3}\right)^{3/2}\right].\end{aligned} \tag{4.7}$$

Due to the appearance of the Cauchy density, $\alpha=1$, Gaussian density, $\alpha=2$, and Pearcey integral, $\alpha=4$, in physical applications, and also the elegance of the closed form representation of $p_3(x)$, it seems unlikely that nature would choose not to also utilize $p_3(x)$ in her description.

It will be noticed that the Lommel function representation of $p_3(x)$, (4.7), is very similar in form to that of the Lommel function representation of $p_{1/3}(x)$ (4.6). There is no direct relationship between $p_3(x)$ and $p_{1/3}(x)$ in the sense of a duality transform[17,33,6] however, since such a transform sends symmetric Lévy stable densities to asymmetric Lévy stable densities in general, and both our $p_3(x)$ and $p_{1/3}(x)$ are symmetric. To see the reason for the similarity in structure and also to illuminate the absence of a direct map between $p_3(x)$ and $p_{1/3}(x)$, we compare the series representations discussed in Sec. II for the case of $\alpha>1$ and $1/\alpha$. Using the simple identity

$$\sum_{n=0}^{\infty}(-1)^n a_n=\sum_{m=0}^{\infty}(-1)^m\sin\left[\frac{(m+1)\pi}{2}\right]a_{m/2} \tag{4.8}$$

we can transform (2.2) into a form very similar to (2.3). Using (2.3) with order $1/\alpha$ we arrive at

$$p_\alpha(x)=\frac{1}{\alpha\pi x}\sum_{m=0}^{\infty}\sin\left[\frac{(m+1)\pi}{2}\right](-1)^m x^{m+1}\frac{\Gamma\left(\frac{m+1}{\alpha}\right)}{\Gamma(m+1)}, \tag{4.9}$$

$$p_{1/\alpha}(x)=\frac{1}{\alpha\pi x}\sum_{m=0}^{\infty}\sin\left[\frac{(m+1)\pi}{2\alpha}\right](-1)^m (x^{-1/\alpha})^{m+1}\frac{\Gamma\left(\frac{m+1}{\alpha}\right)}{\Gamma(m+1)}. \tag{4.10}$$

The only difference in the structure of (4.9) versus (4.10), apart from $x\to x^{-1/\alpha}$, is the factor of $1/\alpha$ in the argument of the sine. This difference however prohibits us from producing $p_\alpha(x)$ via any transform of the argument of $p_{1/\alpha}(x)$, since it is impossible to express

$$\sin\left[\frac{(m+1)\pi}{2}\right]$$

as a multiple of

$$\sin\left[\frac{(m+1)\pi}{2\alpha}\right].$$

Thus we see that there is good reason for the similar structure of (4.7) and (4.6), but there exists no rule whereby we can construct one by knowing the other.

We list for completeness another useful form of $p_3(x)$ in terms of Anger functions, and the Kelvin functions $ber_\nu(z)$ and $bei_\nu(z)$,

$$\begin{aligned}p_3(x)=&\frac{\sqrt{2x}}{9}[ber_{-1/3}(2\sqrt{x^3/27})-bei_{-1/3}(2\sqrt{x^3/27})]+\frac{\sqrt{2x}}{9}[bei_{1/3}(2\sqrt{x^3/27})\\&-ber_{1/3}(2\sqrt{x^3/27})]-\frac{\sqrt{ix}}{9}[\mathbf{J}_{1/3}(2e^{-i\pi/4}\sqrt{x^3/27})-\mathbf{J}_{-1/3}(2e^{-i\pi/4}\sqrt{x^3/27})]\\&-\frac{1}{9}\sqrt{\frac{x}{i}}\,[\mathbf{J}_{1/3}(2e^{i\pi/4}\sqrt{x^3/27})-\mathbf{J}_{-1/3}(2e^{i\pi/4}\sqrt{x^3/27})].\end{aligned} \tag{4.11}$$

We finally list the case of $p/q=4/3$, in which the sum over the eight G functions decomposes into two ${}_2F_2$ functions. It would be expected that similar simplifications should exist for other cases such as $p/q=5/3$ should they be sought,

$$p_{4/3}(x)=\frac{3^{5/4}}{8\sqrt{2\pi}}\sum_{l=0}^{3}(-1)^l\left(\frac{3^{3/2}x^2}{16}\right)^l G^{1,3}_{3,4}\left(\pm\frac{3^3x^4}{4^4}\,\middle|\,\begin{matrix}0,\frac{1}{3}-\frac{2l+1}{4},\frac{2}{3}-\frac{2l+1}{4}\\0,\frac{-l}{2},\frac{1-2l}{4},\frac{1-l}{2}\end{matrix}\right)^+, \tag{4.12}$$

$$\begin{aligned}p_{4/3}(x)=&\frac{3^{5/4}}{4\sqrt{2\pi}}\frac{\Gamma(\frac{7}{12})\Gamma(\frac{11}{12})}{\Gamma(\frac{1}{2})\Gamma(\frac{3}{4})}{}_2F_2\left(\frac{7}{12},\frac{11}{12};\frac{1}{2},\frac{3}{4};\frac{3^3x^4}{4^4}\right)\\&-\frac{3^{11/4}x^2}{4^3\sqrt{2\pi}}\frac{\Gamma(\frac{13}{12})\Gamma(\frac{17}{12})}{\Gamma(\frac{3}{2})\Gamma(\frac{5}{4})}{}_2F_2\left(\frac{13}{12},\frac{17}{12};\frac{3}{2},\frac{5}{4};\frac{3^3x^4}{4^4}\right).\end{aligned}$$

V. COMPLETE ASYMPTOTIC EXPANSIONS AS $x\to\infty$

It has been shown previously that $p_{p/q}(x)$ can be represented as a sum of hypergeometric functions, which is convergent when $p/q>1$. Hence, when $p/q>1$, the complete asymptotic expansions of $p_{p/q}(x)$ for large x can be deduced in a straightforward way by making use of the known complete asymptotic expansions of the hypergeometric function ${}_qF_{p-1}$.

For the cases of $p/q<1$ no such asymptotic large x expansion is required since the convergent expansion, (2.3), is already a large x expansion. Consequently, since all $p_{p/q}(x)$ with $p/q<1$ possess a convergent large x power series, their asymptotic behavior in this limit must be purely algebraic. This fact manifests itself in the special functions representations discussed in Sec. IV since $p_{1/2}(x)$, $p_{2/3}(x)$ and $p_{1/3}(x)$ all have special functions representations in which the arguments of these special functions contain negative powers of x. Thus the convergent, small argument series expansions of these special functions provide the large x behavior of these $p_{p/q}(x)$. This observation explains why the large x asymptotic expansion of $p_{1/3}(x)$ is totally algebraic whereas that of $p_3(x)$ contains both algebraic and transcendental terms, as we shall show, despite the fact that these two functions have very similar representations in terms of the same Lommel function, $S_{0,1/3}$. That is, because $p_3(x)$ is expressed in terms of Lommel functions whose argument contains positive powers of x, whereas $p_{1/3}(x)$ is expressed in terms of Lommel functions whose arguments contain negative powers.

Luke (Ref. 31, Chap. 5), gives a detailed discussion of the complete asymptotic expansions of the Meijer G function and the generalized hypergeometric function, and the particular nuances of the complete expansions of ${}_jF_{k-1}$ are discussed fully in Ref. 24. The complete asymptotic expansion of ${}_jF_{k-1}$, for $j\leqslant k-2$, is given by

$$\begin{aligned}&\frac{\Pi_{h=1}^{j}\Gamma(\alpha_h)}{\Pi_{h=1}^{k-1}\Gamma(\rho_h)}{}_jF_{k-1}\left(\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_j\\ \rho_1,\rho_2,\ldots,\rho_{k-1}\end{matrix}\middle|-z\right)\\ &\quad\sim\sum_{m=0}^{r-1}\Gamma_k^{1,j}(m)K_{j,k-1}(ze^{-i\pi(2m+1)})\\ &\qquad+\sum_{m=0}^{k-j-r-1}\overline{\Gamma}_k^{1,j}(m)K_{j,k-1}(ze^{i\pi(2m+1)})+L_{j,k-1}(z),\end{aligned}\tag{5.1}$$

$$K_{j,k-1}(z)=\frac{(2\pi)^{(j+1-k)/2}}{(k-j)^{1/2}}e^{(k-j)z^{1/(k-j)}}z^{\gamma}\sum_{m=0}^{\infty}N_m z^{-m/(k-j)},\tag{5.2}$$

$$L_{j,k-1}=\sum_{t=1}^{j}z^{-\alpha_t}\frac{\Pi_{t=1}^{j}\Gamma(\alpha_t)\Gamma(\alpha_j-\alpha_t)^*}{\Pi_{t=1}^{k-1}\Gamma(\rho_{k-1}-\alpha_t)}{}_kF_{j-1}\left(\begin{matrix}\alpha_t,1+\alpha_t-\rho_{j-1}\\ 1+\alpha_t-\alpha_j^*\end{matrix}\middle|\frac{(-)^{k-j-1}}{z}\right),\tag{5.3}$$

where the asterisk signifies that $\Gamma(\alpha_j-\alpha_j)$ is excluded, and r is an arbitrary integer such that $0\leqslant r\leqslant k-j$. The values of the $\Gamma_k^{1,j}(m)$ and $\overline{\Gamma}_k^{1,j}(m)$ are given in Ref. 31. The argument of z is subject to the two constraints $|\arg(z)|\leqslant 2\pi-\delta$ with $\delta<0$, and $\delta_1+(4r-3k+3j-2)\pi/2\leqslant\arg(z)\leqslant\delta_2+(4r-k+j+2)\pi/2$ where δ_1 and δ_2 are arbitrarily small. The N_m are found recursively, and the details of the recursion relation in the general case, as well as the specific recursion relations for the cases $\alpha=3,4,5,6,7$ and there construction, can be found in Ref. 24. We shall not discuss the construction of the N_m here, since the procedure is straightforward but unenlightening. We note, however, that the N_m are dependent on the parameters of the given hypergeometric function.

We refer in this work, following the above-given notation used in the complete asymptotic expansions of the generalized hypergeometric functions, to the component asymptotic power series of a given hypergeometric function or $p_\alpha(x)$ as the L asymptotics of that function, and to the series of exponentially small terms as the K asymptotics of that function.

The L asymptotics of the sum of hypergeometric functions composing a given $p_{p/q}(x)$ must conspire to reproduce (2.3), since the K asymptotics contain no algebraic terms. This is verified to occur for the asymptotic expansions of the equivalent $I_{p/q}(\alpha,\beta)$ in Ref. 24, for all the special cases of $p_{p/q}(x)$ considered in Sec. IV. There is also a formal demonstration in Ref. 24 of how the L asymptotics of the $I_{2n+1}(\alpha,\beta)$ corresponding to $p_{2n+1}(x)$ coalesce into (2.3). When p/q is an even integer the L asymptotics of the complete asymptotic expansion of $p_{p/q}(x)$ vanish, as discussed previously. The L asymptotics for $p/q=3,4,5,6,7$ are thus easily found and require little discussion. We list the nonvanishing series here for completeness,

$$p_3(x)\sim\frac{3}{\pi x}\sum_{m=0}^{\infty}\frac{(-1)^{m+1}}{(2m)!}\frac{\Gamma(6m+3)}{(x^3)^{2m+1}}, \tag{5.4}$$

$$p_5(x)\sim\frac{5}{\pi x}\sum_{m=0}^{\infty}\frac{(-1)^{m}}{(2m)!}\frac{\Gamma(10m+5)}{(x^5)^{2m+1}}, \tag{5.5}$$

$$p_7(x)\sim\frac{7}{\pi x}\sum_{m=0}^{\infty}\frac{(-1)^{m+1}}{(2m)!}\frac{\Gamma(14m+7)}{(x^7)^{2m+1}}. \tag{5.6}$$

Upon investigation of the special cases $p_{4/3}(x)$ and $p_{3/2}(x)$ discussed in Sec. IV, it is found that the K asymptotic series exactly cancel in both of these cases, thus producing purely algebraic complete asymptotic expansions. The derivations of these results can be deduced from Ref. 24.

It is found however that the asymptotics of the $p_n(x)$ for integral n possess intricate series of exponentially small terms when $n>2$, i.e., nonvanishing K asymptotics. In order to determine the contribution of the K asymptotics to the complete asymptotic expansion of $p_n(x)$, which we denote by $p_n^K(x)$, we simply use our expression for $p_n(x)$ in terms of hypergeometric functions and then substitute the K asymptotic series from (5.2). We sketch the procedure for the case of $p_3(x)$, and then simply state the results for the other cases. Details of the construction of all the cases listed may be deduced from Ref. 24 using (3.7).

For convenience we introduce the notation $z=q^q x^p/p^p$ so that (4.7) reduce to

$$3\sqrt{3}p_3(x)=G_{1,3}^{1,1}(\pm iz|_{0,0,1/3}^{0})^{+}-z^{2/3}G_{1,3}^{1,1}(\pm iz|_{0,-2/3,-1/3}^{0})^{+}+z^{4/3}G_{1,3}^{1,1}(\pm iz|_{0,-4/3,-1}^{0})^{+}. \tag{5.7}$$

By massaging this expression we find that the G functions reduce to

$$G_{1,3}^{1,1}(\pm iz|_{0,0,1/3}^{0})^{+}=\Gamma\left(\frac{2}{3}\right)^{-1}{}_0F_1\left(\frac{2}{3};\pm iz\right)^{+}, \tag{5.8}$$

$$G_{1,3}^{1,1}(\pm iz|_{0,-2/3,-1/3}^{0})^{+}=\left[\Gamma\left(\frac{4}{3}\right)\Gamma\left(\frac{5}{3}\right)\right]^{-1}{}_1F_2\left(1;4/3,\frac{5}{3};\pm iz\right)^{+}, \tag{5.9}$$

$$G_{1,3}^{1,1}(\pm iz|_{0,-4/3,-1}^{0})^{+}=\frac{1}{iz}\Gamma\left(\frac{4}{3}\right)^{-1}{}_0F_1\left(4/3;\pm iz\right)^{-}. \tag{5.10}$$

We note that the asymptotic expansions of (5.8) and (5.10) contain only K asymptotic expansions since the sum in (5.3) is void in these cases. Thus (5.4) is constructed purely from the L asymptotics of (5.9).

The complete asymptotic expansion of (5.8) is constructed using (5.1) and (5.2). We obtain

$$\Gamma(\tfrac{2}{3})^{-1}{}_0F_1(\tfrac{2}{3};\pm iz)^{+}\sim K_{0,1}(e^{\pm\pi i/2}z)^{+}+K_{0,1}(e^{\pm 3\pi i/2}z)^{+}, \tag{5.11}$$

where

$$K_{0,1}(e^{\pm\pi i/2}z)^+ = \frac{z^{-1/12}}{\sqrt{\pi}} e^{\sqrt{2z}} \sum_{m=0}^{\infty} N_m z^{-m/2} \cos\left(\sqrt{2z} - \frac{\pi}{24} - \frac{m\pi}{4} \right), \tag{5.12}$$

$$K_{0,1}(e^{\pm 3\pi i/2}z)^+ = \frac{z^{-1/12}}{\sqrt{\pi}} e^{-\sqrt{2z}} \sum_{m=0}^{\infty} N_m z^{-m/2} \cos\left(\sqrt{2z} - \frac{3\pi}{24} - \frac{3m\pi}{4} \right). \tag{5.13}$$

The K asymptotics of (5.9) and (5.10) are found in a similar way and yield

$$\begin{aligned} \frac{{}_1F_2(1;\frac{4}{3},\frac{5}{3};\pm iz)^+}{[\Gamma(\frac{4}{3})\Gamma(\frac{5}{3})]} \sim{}& \frac{z^{-3/4}}{\sqrt{\pi}} e^{\sqrt{2z}} \sum_{m=0}^{\infty} N_m z^{-m/2} \cos\left(\sqrt{2z} - \frac{3\pi}{8} - \frac{m\pi}{4} \right) \\ &+ \frac{z^{-3/4}}{\sqrt{\pi}} e^{-\sqrt{2z}} \sum_{m=0}^{\infty} N_m z^{-m/2} \cos\left(\sqrt{2z} - \frac{9\pi}{8} - \frac{3m\pi}{4} \right) + L \text{ asymptotics}, \end{aligned} \tag{5.14}$$

$$\begin{aligned} \Gamma\left(\frac{4}{3}\right)^{-1} {}_0F_1\left(\frac{4}{3};\pm iz\right)^- \sim{}& \frac{z^{-5/12}}{\sqrt{\pi}} e^{\sqrt{2z}} \sum_{m=0}^{\infty} N_m z^{-m/2} \sin\left(\sqrt{2z} - \frac{5\pi}{24} - \frac{m\pi}{4} \right) \\ &- \frac{z^{-5/12}}{\sqrt{\pi}} e^{-\sqrt{2z}} \sum_{m=0}^{\infty} N_m z^{-m/2} \sin\left(\sqrt{2z} - \frac{5\pi}{8} - \frac{3m\pi}{4} \right). \end{aligned} \tag{5.15}$$

An interesting thing to note is the presence in the K asymptotics of all three hypergeometric contributions, of terms which grow exponentially with z. Since the integral representation of $p_\alpha(x)$ does not display such drastic behavior, it must be the case that the N_m are the same for all three contributions so that the exponentially growing terms can cancel. When the recurrence relation for the N_m, which is dependent on the parameters in the given G function, is calculated[24] it is in fact found to be the same in all three cases. This coincidence of the N_m and consequent cancellation of exponentially growing terms is in fact a general trend in the K asymptotics of $p_n(x)$, and occurs for all of the cases we display in the following.

Investigation of the recurrence relation for the N_m of $p_3(x)$ results in[24]

$$N_m = \frac{\Gamma(m+1/6)\Gamma(m+5/6)}{2^{2m} m! \Gamma(1/6)\Gamma(5/6)}. \tag{5.16}$$

Adding the three separate contributions (5.11), (5.14), and (5.15) we obtain the K asymptotic contribution to the asymptotic expansion of $p_3(x)$. We note that the exponentially growing terms do in fact cancel as expected. The complete asymptotic expansion is obtained by adding (5.4),

$$p_3^K(x) \sim \frac{1}{\sqrt{\pi}(3x)^{1/4}} \exp\left(-\sqrt{\frac{2x^3}{27}} \right) \sum_{m=0}^{\infty} N_m \left(\sqrt{\frac{27}{x^3}} \right)^m \cos\left(\sqrt{\frac{2x^3}{27}} - \frac{\pi}{8} - \frac{3m\pi}{4} \right). \tag{5.17}$$

Since $p_3(x)$ has such an elegant representation in terms of Lommel functions, (4.7), one might be tempted to construct the asymptotic expansion of $p_3(x)$ from the tabulated asymptotic expansions of the Lommel functions. We note however that the asymptotic expansions for the Lommel functions that are listed in books, e.g., Refs. 31 and 37, contain only a power series, whereas we find using the general theory of the asymptotics of G functions that $p_3(x)$ contains both a power series and series of exponentially small terms that lie beyond all orders of this power series. Hence the commonly quoted asymptotic expansions of the Lommel functions must be incomplete, and it

seems that the complete asymptotic expansions of the Lommel functions are unknown. The complete asymptotic expansions of the Lommel functions will form the subject of a future publication.

The complete asymptotic expansions of $p_n(x)$ for larger values of n can be found from the asymptotic expansions of the hypergeometric function in a similar manner to that used for $p_3(x)$. We list below the expansion for $n=4,5,6,7$. The details of the derivations can be deciphered from the discussion in Ref. 24. We see that as n increases the complexity of the K asymptotic expansions increases. We list here the first four N_m for each case, but avoid details of the recursion relation, the details of which can be found in Ref. 24,

$$p_4^K(x)\sim \frac{2^{1/6}}{\sqrt{3\pi}x^{1/3}}\exp\left(\frac{-3x^{4/3}}{2^{11/3}}\right)\sum_{m=0}^{\infty} N_m\left(\frac{4}{x}\right)^{4m/3}\cos\left(\frac{3\sqrt{3}}{2^{11/3}}x^{4/3}-\frac{\pi}{6}-\frac{2m\pi}{3}\right). \tag{5.18}$$

Due to the intimate relationship between $p_4(x)$ and Pearcey's integral we include the values of N_m for $0\leqslant m\leqslant 20$ in Table I. The N_m for $m>20$ may be obtained from the following recursion relation, with $N_m=3^{-m}c_m$:

$$c_m=(7/48m-1+m)c_{m-1}+(7/48m-13/16+m-m^2/3)c_{m-2}, \tag{5.19}$$

$$p_5^K(x)\sim \frac{1}{\sqrt{2\pi}5^{1/8}x^{3/8}}\sum_{m=0}^{\infty} N_m\left(\frac{5}{x}\right)^{5m/4}\exp\left[4\cos\left(\frac{5\pi}{8}\right)\left(\frac{x}{5}\right)^{5/4}\right]\cos\left[4\sin\left(\frac{5\pi}{8}\right)\left(\frac{x}{5}\right)^{5/4}-\frac{3\pi}{16}-\frac{5m\pi}{8}\right], \tag{5.20}$$

where $N_0=1$, $N_1=\frac{9}{160}$, $N_2=\frac{441}{51\,200}$, $N_3=\frac{202\,509}{81\,920\,000}$,

$$p_6^K(x)\sim \frac{1}{2\sqrt{15\pi}}\sum_{m=0}^{\infty} N_m\left(\frac{6}{x}\right)^{(6/5)(m+1/3)}(-1)^m\exp\left[-5\left(\frac{x}{6}\right)^{6/5}\right]+\frac{1}{\sqrt{15\pi}}\sum_{m=0}^{\infty} N_m\left(\frac{6}{x}\right)^{(6/5)(m+1/3)}$$
$$\times\exp\left[5\cos\left(\frac{3\pi}{5}\right)\left(\frac{x}{6}\right)^{6/5}\right]\cos\left[5\sin\left(\frac{3\pi}{5}\right)\left(\frac{x}{6}\right)^{6/5}-\frac{\pi}{5}-\frac{3m\pi}{5}\right], \tag{5.21}$$

where $N_0=1$, $N_1=\frac{11}{180}$, $N_2=\frac{517}{64\,800}$, $N_3=\frac{-22\,253}{174\,960\,000}$,

$$p_7^K(x)\sim \frac{1}{7^{1/12}\sqrt{3\pi}x^{5/12}}\sum_{m=0}^{\infty} N_m\left(\frac{7}{x}\right)^{(7/6)m}\exp\left[6\cos\left(\frac{7\pi}{12}\right)\left(\frac{x}{7}\right)^{7/6}\right]\cos\left[6\sin\left(\frac{7\pi}{12}\right)\left(\frac{x}{7}\right)^{7/6}-\frac{5\pi}{24}\right.$$
$$\left.-\frac{7m\pi}{12}\right]+\frac{1}{7^{1/12}\sqrt{3\pi}x^{5/12}}\sum_{m=0}^{\infty} N_m\left(\frac{7}{x}\right)^{(7/6)m}\exp\left[6\cos\left(\frac{11\pi}{12}\right)\left(\frac{x}{7}\right)^{7/6}\right]$$
$$\times\cos\left[6\sin\left(\frac{11\pi}{12}\right)\left(\frac{x}{7}\right)^{7/6}-\frac{\pi}{24}-\frac{11m\pi}{12}\right], \tag{5.22}$$

where $N_0=1$, $N_1=\frac{65}{1008}$, $N_2=\frac{219\,307}{33\,592\,320}$, $N_3=\frac{8\,304\,286\,951}{995\,515\,121\,664}$.

Note that for $p_6(x)$ and $p_7(x)$ there are two exponentially small series not just one. We should therefore expect that the K asymptotic expansions of $p_n(x)$ will contain ever more decaying exponentials as n increases.

VI. MOMENTS

The divergence of the moments of $p_\alpha(x)$ was explained in Sec. I to be a consequence of the $1/x^{\alpha+1}$ asymptotic power law behavior. We have shown in Sec. V however that the large x asymptotic behavior of $p_{2n}(x)$ is purely exponential and contains no algebraic terms, which leads one to expect that their moments might exist. One also reaches this conclusion by observing that

in general the nonanalytic behavior of the Fourier transform, $\tilde{p}_\alpha(k)=\exp(-|k|^\alpha)$, is intimately involved in the divergence of sufficiently late moments of $p_\alpha(x)$, because if $\tilde{p}_\alpha(k)$ were analytic it would possess an expansion of the following form:

$$\tilde{p}_\alpha(k)=\sum_{m=0}^{\infty}\frac{(ik)^m}{m!}\langle x^m\rangle, \tag{6.1}$$

where we define $\langle x^m \rangle$ in the usual way as

$$\langle x^m \rangle = \int_{-\infty}^{\infty} \mathrm{d}x\, x^m p_\alpha(x). \tag{6.2}$$

When $0<\alpha<2$, so that $p_\alpha(x)$ defines a pdf, $\langle x^m \rangle$ is therefore the mth moment. Regardless of whether $p_\alpha(x)$ defines a pdf or not (6.2) is still perfectly well defined, we therefore shall refer to $\langle x^m \rangle$ as the mth moment in both cases.

When $\alpha=2n$, $\tilde{p}_\alpha(k)$ is analytic and hence according to (6.1) the moments of $p_{2n}(x)$ must exist. This implies that $p_{2n}(x)$ will not display the self-similar Lévy behavior discussed in Sec. I, but is a rather different type of mathematical animal.

Since $p_\alpha(x)$ is an even function the $(2m+1)$th moment vanishes by symmetry for all $m \geqslant 0$, regardless of the value of α. The calculation of the $2m$th moment is somewhat subtle and is facilitated by considering not (6.2), but instead the following integral, $\langle x^{2m} \rangle_\lambda$, which is tempered by the factor $e^{-\lambda x}$.

$$\langle x^{2m} \rangle_\lambda = \frac{2}{\pi} \int_0^\infty \int_0^\infty \mathrm{d}k\, \mathrm{d}x\, e^{-\lambda x} x^{2m} \cos(kx) \exp(-k^\alpha). \tag{6.3}$$

By observing the small λ behavior of this well-behaved integral we can determine whether the $2m$th moment diverges for a given α, and if this moment is finite we can calculate its numerical value by taking $\lambda \to 0$. To ascertain the small λ behavior of $\langle x^{2m} \rangle_\lambda$ we wish to construct a Mellin–Barnes contour integral representation of $\langle x^{2m} \rangle_\lambda$ from which we shall be able to derive a small λ expansion by simply closing the contour. To this end we insert into (6.3) the contour integral representation of e^{-k^α} obtained by expressing it as the inverse Mellin transform of its Mellin transform.

$$\langle x^{2m} \rangle_\lambda = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \mathrm{d}s \left(\frac{2}{\pi\alpha} \right) \Gamma\left(\frac{s}{\alpha} \right) \int_0^\infty \mathrm{d}x\, x^{2m} e^{-\lambda x} \int_0^\infty \mathrm{d}k\, k^{-s} \cos(xk), \quad c>0. \tag{6.4}$$

The integral over k is well known and can be identified with $x^{s-1}\Gamma(1-s)\sin(s\pi/2)$. The integral over x is then simply a gamma function,

$$\begin{aligned} \langle x^{2m} \rangle_\lambda &= \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \mathrm{d}s \left(\frac{2}{\pi\alpha} \right) \Gamma(1-s) \lambda^{-s-2m} \Gamma\left(\frac{s}{\alpha} \right) \Gamma(2m+s) \sin\left(\frac{s\pi}{2} \right), \quad 0<c<1, \\ \langle x^{2m} \rangle_\lambda &= \frac{1}{2\pi i} \int_{\sigma-i\infty}^{\sigma+i\infty} \mathrm{d}s \left(\frac{-2}{\pi\alpha} \right) \Gamma(1+s) \lambda^{s-2m} \Gamma\left(\frac{-s}{\alpha} \right) \Gamma(2m-s) \sin\left(\frac{s\pi}{2} \right), \quad -1<\sigma<0. \end{aligned} \tag{6.5}$$

In the last step we have chosen to let $s \to -s$ so that all the relevant poles needed to construct the expansion in ascending powers of λ by closing the contour will lie on the positive real axis.

To obtain the small λ expansion of $\langle x^{2m} \rangle_\lambda$ from (6.5) we close the contour to the right. If we denote the integrand by $R(s)$, the terms of this small λ expansion then arise from the residues of $R(s)$ at the poles of $\Gamma(-s/\alpha)\Gamma(2m-s)\sin(s\pi/2)$. We denote the set of all poles of $R(s)$ for $\Re(s)>-1$ by $\mathcal{P}$. When this series in ascending powers of λ is constructed for a given choice of α and $2m$ the leading term will behave like $\lambda^{\Delta-2m}$ where $\Delta=\min(\mathcal{P})$, i.e., Δ is the pole closest to the origin on the positive real line. Hence we see that it is Δ alone that determines the existence or nonexistence of the $2m$th moment of $p_\alpha(x)$. If $\Delta<2m$ the limit as $\lambda \to 0$ will not exist and the corresponding moment diverges. The sign of the residue at this pole determines if the divergence is to positive or negative infinity. For a class of values of $\alpha>2$ the moments in fact diverge to $-\infty$ as we will show, which is a consequence of the fact that $p_\alpha(x)$ is then not a pdf. If $\Delta>2m$ the limit as $\lambda \to 0$ vanishes, and the corresponding moment exists but is zero. The interesting case is when $\Delta=2m$ in which case the limit $\lambda \to 0$ exists and is nonzero.

The set $\mathcal{P}$ is the difference of the set of zeros of the sine function, with the union of the poles of the gamma functions.

$$\begin{aligned}\mathcal{P}&=\{\alpha,2\alpha,3\alpha,\dots\}\cup\{2m,2m+1,2m+2,\dots\}\backslash\{2,4,6,\dots\},\\ \mathcal{P}&=\{2m+1,2m+3,2m+5,\dots\}\cup\{\alpha,2\alpha,3\alpha,\dots\}\backslash\{2,4,6,\dots,2(m-1)\}.\end{aligned}\tag{6.6}$$

Note that the even poles of $\Gamma(2m-s)$ have all been cancelled by the zeros of $\sin(s\pi/2)$. The pole of $\Gamma(-s/\alpha)$ and the zero of $\sin(s\pi/2)$ at the origin have been neglected since they cancel and there is then no pole at the origin provided $m>0$, which we shall assume. The case $m=0$ merely corresponds to the normalization requirement for $p_\alpha(x)$, which is easily shown to result in $\langle x^0\rangle=1$.

If α is not an even integer there can be no further cancellation of poles with zeros and $\mathcal{P}=\{2m+1,2m+3,2m+5,\dots\}\cup\{\alpha,2\alpha,3\alpha,\dots\}\Rightarrow\Delta=\min\{2m+1,\alpha\}$. We thus deduce for non-even integral α that if $\alpha>2m$ then $\langle x^{2m}\rangle$ will exist and vanish, and that if $\alpha<2m$ then $\langle x^{2m}\rangle$ will diverge. Thus if α is not an even integer we can never obtain a finite nonzero moment of any order for $p_\alpha(x)$. To ascertain whether $\langle x_{2m}\rangle$ diverges to positive or negative infinity when $\Delta=\alpha<2m$ and α is not an even integer we calculate the residue at $s=\alpha$, which we denote by $\mathrm{Res}(R(s)|s=\alpha)$. This is straightforward and yields

$$\mathrm{Res}(R(s)|s=\alpha)=-\left[\frac{2}{\pi}\Gamma(1+\alpha)\Gamma(2m-\alpha)\right]\sin\left(\frac{\alpha\pi}{2}\right)\frac{1}{\lambda^{2m-\alpha}}.\tag{6.7}$$

Closing the contour to the right results in an additional minus sign and hence $\langle x^{2m}\rangle_\lambda$ behaves like

$$\langle x^{2m}\rangle_\lambda=\left[\frac{2}{\pi}\Gamma(1+\alpha)\Gamma(2m-\alpha)\right]\sin\left(\frac{\alpha\pi}{2}\right)\frac{1}{\lambda^{2m-\alpha}}+o(\lambda^{\alpha-2m}),\quad \lambda\to 0.\tag{6.8}$$

When $\alpha<2m$ we note that $[(2/\pi)\,\Gamma(1+\alpha)\Gamma(2m-\alpha)]>0$ and thus the sign of the divergence of $\langle x^{2m}\rangle$ depends only on the sign of $\sin(\alpha\pi/2)$. We conclude then that for $\alpha\notin\{2,4,6,\dots\}$ and $\alpha<2m$,

$$\langle x^{2m}\rangle\to+\infty,\quad \alpha\in\cup_{k=0}^{\infty}(4k,4k+2),\tag{6.9}$$

$$\langle x^{2m}\rangle\to-\infty,\quad \alpha\in\cup_{k=0}^{\infty}(4k+2,4k+4).\tag{6.10}$$

Note that $\langle x^{2m}\rangle\to+\infty$ when $0<\alpha<2$ and $\alpha<2m$ as one would expect since in this region $p_\alpha(x)$ is the symmetric Lévy stable pdf.

If α is an even integer we definitely cannot obtain a diverging moment since in order to do this we would require $\Delta=2k\in\{\alpha,2\alpha,3\alpha,\dots\}$ and $2k<2m$, but $2k<2m\Rightarrow 2k\leqslant 2(m-1)\Rightarrow 2k\in\{2,4,6,\dots 2(m-1)\}$ in which case this pole at $s=2k$ would cancel with the zero at $s=2k$, which contradicts the assumption that $\Delta=2k$. Thus all moments are finite when α is an even integer. When $2m=\min(\mathcal{P})$ the $2m$th moment will be nonzero, which implies that we obtain nonzero moments only when $2m=j\alpha$ and $m/j\in\{1,2,3,..\}$, where $j\in\{1,2,3,\dots\}$. In other words, for a given even integral value of α only the moments $\langle x^{j\alpha}\rangle$, $\forall j\in\{1,2,3,\dots\}$, will be nonzero. We now calculate these nonzero moments for $m\in\{1,2,3,\dots\}$ and $\alpha\in\{2,4,6,\dots\}$.

$\Gamma(2m-s)\sin(s\pi/2)$ is analytic around $s=2m$ since the simple zero cancels the simple pole. Hence the pole of $R(s)$ at $s=2m$ is due to $\Gamma(-s/\alpha)$. Multiplying the Laurent expansion of $\Gamma(2m-s)$ with the Taylor expansion of $\sin(s\pi/2)$ around $s=2m$ we obtain

$$\Gamma(2m-s)\sin\left(\frac{s\pi}{2}\right)=\frac{(-1)^{m+1}\pi}{2}+O(s-2m).\tag{6.11}$$

The residue of $R(s)$ at the pole $s=2m$ is then given by

$$\mathrm{Res}(R(s)|s=2m)=\frac{(-1)^m}{\alpha}(2m)!\lim_{s\to 2m}(s-2m)\Gamma\left(\frac{-s}{\alpha}\right),$$
$$\mathrm{Res}(R(s)|s=2m)=\frac{(-1)^{m+1+j}}{j!}(2m)!. \tag{6.12}$$

Since we closed the contour to the right $\langle x^{j\alpha}\rangle=-\mathrm{Res}(R(s)|s=2m)$. All the other terms in the small λ expansion vanish upon taking $\lambda\to 0$ because $\Delta=2m$ by assumption. Thus the only finite nonzero moments of $p_\alpha(x)$ are

$$\langle x^{j\alpha}\rangle=\frac{(-1)^{j\alpha+j}(j\alpha)!}{j!},\quad \forall j\in\{1,2,3,\ldots\}, \tag{6.13}$$

where $\alpha\in\{2,4,6,\ldots\}$.

It is easily seen that by inserting this result into (6.1) that the correct analytic power series expansion of $\tilde{p}_{2n}(k)$ is recovered.

We can summarize the moments of $p_\alpha(x)$ quite simply then as

$$\langle x^{2m}\rangle=\begin{cases}\dfrac{(-1)^{m+j}(2m)!}{j!}, & \alpha=2\dfrac{m}{j}\in\{2,4,6,\ldots\}\\ +\infty, & \alpha<2m \text{ and } \alpha\in\cup_{k=0}^{\infty}(4k,4k+2)\\ -\infty, & \alpha<2m \text{ and } \alpha\in\cup_{k=0}^{\infty}(4k+2,4k+4)\\ 0, & \text{otherwise}\end{cases}. \tag{6.14}$$

VII. DISCUSSION

Various properties of $p_\alpha(x)$ have been expounded in the preceding sections, and in this section we seek to briefly discuss their utility. The utility of the representations of $p_\alpha(x)$ in terms of hypergeometric functions and special functions when $0<\alpha<2$ is obvious, so we shall constrain the discussion to the cases of $\alpha>2$.

The intricate exponential asymptotic behavior of $p_\alpha(x)$ as $x\to\infty$ when $\alpha>2$ provides another powerful case study into the exciting new field of asymptotics beyond all orders, and is a principal reason why we carried out this study. The increasing complexity of the K-asymptotics of $p_n(x)$ as n increases is an example of the level of information that can be contained in these components of a complete asymptotic expansion which traditionally have been neglected.

The discussion of the moments has demonstrated to us that $\{p_\alpha(x):0<\alpha<\infty\}$ is composed of two classes of functions whose behavior is in one sense quite different. The functions $p_{2n}(x)$ have finite moments of all orders and hence do not display the type of scale invariant behavior that makes the Lévy stable pdfs so ubiquitous in applications. This is a direct consequence of the fact that the complete asymptotic expansion of $p_{2n}(x)$ contains no algebraic terms and is purely exponential. Despite, or perhaps because of this fact, we know already that the two lowest order members of this class, $p_2(x)$ and $p_4(x)$, have important applications in the physical sciences, even though $p_4(x)$ does not define a pdf. It is quite reasonable to expect then that other members of this class, e.g., $p_6(x),p_8(x),\ldots,$ should also find similar applications. Looking at things in the opposite light however, the functions in the complement of this class, i.e., all the $p_\alpha(x)$ with α not an even integer, do display the self-similar behavior that makes the Lévy stable pdfs so utile and thus for this reason we might expect that they also will find applications in the fullness of time. With such a diversity of interesting and useful properties it would seem quite uncharacteristic of nature not to harness some of the functions in $\{p_\alpha(x):2<\alpha<\infty\}$.

Standing firmly on the platform of concrete mathematical results that we have delineated herein, we would now like to ascend into a Lévy flight of fancy. The situation with $p_\alpha(x)$ for $\alpha>2$ is reminiscent of the role played by the Wigner function in quantum theory. The Wigner

function is in some sense a measure of probability and is highly useful in applications, but does not satisfy the non-negativity axiom required to define a pdf. In the same way we find applications of $p_4(x)$ to wave phenomena appearing, despite the fact that it does not define a pdf. Perhaps though it may be fruitful to extend the notion of probability to include negative numbers, and hence to consider $p_\alpha(x)$ as a pdf for all $\alpha>0$. There has been a steady flow of articles on *negative probabilities* ever since the advent of quantum mechanics, including notable articles by Feynman.[38,39] For a reasonably up-to-date review article with a large list of references we direct the reader to Ref. 40. In the literature negative probabilities are investigated in order to solve a plethora of problems from the inherent divergences in quantum field theories to issues of interpretation in quantum theory itself such as the Einstein–Podolsky–Rosen paradox. One interesting idea that we would like to mention is the possible connection between classical mechanics and a theory of quantum mechanics with negative probabilities discussed by Feynman.[38] To quote Feynman,

"...a closer study of the relation of classical and quantum theory might involve us in negative probabilities." We find it interesting to table the idea that since the Lévy stable densities are so fundamentally useful in classical stochastic processes, that perhaps $\{p_\alpha(x):\alpha>2\}$ might play a similar role in a stochastic formulation of quantum theory in which negative probabilities are allowed. In general, if it should emerge that extended theories of probability do bear fruit, then $\{p_\alpha(x):\alpha>2\}$ must surely play as fundamental a role in it as the Lévy stable densities play in classical probability theory.

ACKNOWLEDGMENTS

We would like to thank Barry Hughes for a number of helpful discussions, and Peter Forrester for bringing our attention to the link between $p_4(x)$ and Pearcey's integral. We are also grateful to the Australian Research Council for funding this work.

APPENDIX A: ERRATA GENERALIZED EULER–JACOBI INVERSION FORMULA AND ASYMPTOTICS BEYOND ALL ORDERS

We present here a list of typographical errors that appear in Ref. 24, and which were detected during the preparation of this work. The errors and their corrections are emphasized via boldface.

In (5.13), $\Sigma_{n=1}^{\infty}\mathbf{4}/z^{3/2}$ should read $\Sigma_{n=1}^{\infty}\mathbf{8}/z^{3/2}$.

In (6.29), $\cos((\sqrt{3}/2)y-k\pi/3-\pi/6)$ should read $\cos((\sqrt{3}/2)y-\mathbf{2}(k\pi/3)-\pi/6)$.

In (6.52), the correct argument of the Lommel functions is $(\mathbf{2}/\sqrt{a})(2n\pi/3)^{3/2}e^{\pm 3\pi i/4}$ not $\sqrt{\mathbf{2}/\mathbf{a}}(2n\pi/3)^{3/2}e^{\pm 3\pi i/4}$ as stated.

In (6.58), ${}_0F_1(4/3;\pm iz)^{+}$ should read ${}_0F_1(4/3;\pm iz)^{-}$.

(Received 26 March 2001; accepted for publication 30 January 2002)

We consider real-valued functions $\alpha(s)$ and wavelets $\psi \in L^2(\mathbb{R})$ such that $e^{i\alpha(s)}|\hat{\psi}(s)|$ is the Fourier transform of a wavelet. Such a function $\alpha(s)$ is called an attainable phase for the wavelet ψ. It is known that for all multiresolution analysis (MRA) wavelets, the phase function $\alpha(s)=\frac{1}{2}s$ is attainable, and any real function $\alpha(s)$ is attainable by any minimally-supported-frequency (MSF) wavelet. Besides this, very little is known in the literature about attainable phases for wavelets. We study the problem of determining functions which are attainable phases for some (non-MSF) wavelets. We prove that there exists a non-MSF wavelet for which there is no attainable ''set-wise'' linear phase. This answers a basic question about wavelet phases. Although we do not know whether for any irrational number a, as is attainable by some non-MSF wavelets, we show that there exist certain rational numbers a such that as is not attainable by any non-MSF wavelet. We also prove that there exists a large class of rational numbers a such that as is attainable by some non-MSF wavelets. We examine the relationship between different classes of wavelets admitting linear phases. In particular we present an example of a non-MSF wavelet which is not an MRA wavelet but admits linear phase $\frac{1}{2}s$. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1462416]

I. INTRODUCTION

Wavelet analysis arises from many branches of science and provides means of representing functions in a way similar to Fourier series. Recall that a *dyadic orthonormal (or orthogonal) wavelet* is a function $\psi \in \mathcal{L}^2(\mathbb{R})$ (the Hilbert space of square-integrable functions on $\mathbb{R}$) with the property that the set

$$\{2^{n/2}\psi(2^n t-l): n,l \in \mathbb{Z}\}$$

is an orthonormal basis for $\mathcal{L}^2(\mathbb{R})$, where $\mathbb{Z}$ is the set of all the integers. Let $\mathcal{F}$ be the Fourier–Plancherel transformation on $\mathcal{L}^2(\mathbb{R})$, normalized so that it is unitary. Thus for $f,g \in \mathcal{L}^1(\mathbb{R}) \cap \mathcal{L}^2(\mathbb{R})$,

$$\mathcal{F}(f)(s) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-ist} f(t)\,dt$$

and

[a)]Electronic mail: guqing22181@sina.com
[b)]Electronic mail: dhan@pegasus.cc.ucf.edu

$$\mathcal{F}^{-1}(f)(s) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{ist} f(t)\, dt.$$

We will write $\mathcal{F}(h)$ as $\hat{h}$ throughout this article. Recall from Ref. 1 that a wavelet ψ is called an *MSF (minimally-supported-frequency) wavelet* if $\operatorname{supp}\hat{\psi}$ has measure 2π. It is also called an *s-elementary wavelets* in Refs. 2 and 3. A wavelet which is not an MSF wavelet will be referred to as a *non-MSF wavelet*. It is well known that a wavelet ψ is an MSF wavelet if and only if for almost any $s \in \mathbb{R}$ with $\hat{\psi}(s) \neq 0$, we have $\hat{\psi}(s + 2l\pi) = 0$ whenever $l \in \mathbb{Z}\setminus\{0\}$. In this article, we will use this fact to determine whether any given wavelet ψ is an MSF wavelet. More importantly, the following characterization of wavelets quoted from Ref. 1 will play a central role in this article. If $\psi \in \mathcal{L}^2(\mathbb{R})$, then ψ is a wavelet iff the norm of ψ is 1 and

$$\sum_{\ell \in \mathbb{Z}} |\hat{\psi}(2^{\ell} s)|^2 = \frac{1}{2\pi}, \quad \text{a.e. } s \in \mathbb{R}, \tag{1.1}$$

$$\sum_{\ell=0}^{\infty} \hat{\psi}(2^{\ell} s)\, \overline{\hat{\psi}(2^{\ell}(s + 2k\pi))} = 0. \quad \text{a.e. } s \in \mathbb{R}, \quad \text{for each } k \in 2\mathbb{Z}+1. \tag{1.2}$$

In wavelet analysis, one of the most important concepts is *multiresolution analysis*, which was introduced and developed by Mallat[4] and Meyer[5] as an important tool in constructing orthogonal wavelets. Wavelets obtained through multiresolution analysis are called *MRA wavelets*. We refer to standard books (cf. Refs. 1 and 5–7) for the definition of multiresolution (MRA) wavelets. For the purpose of this article, we will use the fact (Ref. 1) that a wavelet ψ is an MRA wavelet if and only if its *dimension function* $D_{\psi}(s) = (2\pi)\Sigma_{n=1}^{\infty}\Sigma_{k\in\mathbb{Z}} |\hat{\psi}(2^n(s + 2k\pi))|^2 = 1$, a.e. $s \in \mathbb{R}$.

For any function $h \in \mathcal{L}^2(\mathbb{R})$, the *phase* of h is the real-valued function $\alpha(s)$ defined on the support of $\hat{h}$ determined uniquely a.e. modulo 2π by the equation $\hat{h}(s) = e^{i\alpha(s)}|\hat{h}(s)|$. Phases carry useful information contained in signals. For instance, an electrocardiogram or a video image can be represented in terms of magnitude and phase information. Since wavelets provide building blocks in reconstructing signals, we are interested in knowing more about phases of wavelets.

The phase of a given wavelet could be quite complicated, even when the wavelet is an MRA wavelet. However, it was established in Refs. 8 and 9 that for any MRA wavelet ψ, $e^{i(1/2)s}|\hat{\psi}(s)|$ is always the Fourier transform of some MRA wavelet. This fact was used to study wavelet multipliers and the connectivity properties of MRA wavelet (cf. Refs. 8 and 9). Naturally, it leads one to the consideration of the case when ψ is a wavelet in general. We say that a function $\alpha(s)$ is an *attainable* phase (or simply attainable) for wavelet ψ, or that wavelet ψ admits phase function $\alpha(s)$, if $e^{i\alpha(s)}|\hat{\psi}(s)|$ is the Fourier transform of a wavelet. Using this terminology, the above mentioned result says that function $\frac{1}{2}s$ is attainable for any MRA wavelet.

When ψ is an MSF wavelet, we see that for almost any $s \in \mathbb{R}$, each $k \in 2\mathbb{Z}+1$, and $\ell \in \mathbb{N}\cup\{0\}$, the term $\hat{\psi}(2^{\ell} s)\,\overline{\hat{\psi}(2^{\ell}(s + 2k\pi))}$ to the left of equation (1.2) in the characterization of wavelets is 0, therefore $e^{i\alpha(s)}|\hat{\psi}|$ also satisfies all the equations in the characterization of wavelets for any real function $\alpha(s)$. Hence any real function is an attainable phase for any fixed MSF wavelet. Therefore, when we talk about attainable phases, we are only interested in those that are attainable by non-MSF wavelets.

It is known (cf. Ref. 6) that admitting linear phase $\alpha(s) = as + b$ can be a useful property for a wavelet to have, and it was expected that all the wavelets admit the phase $\frac{1}{2}s$. Therefore, one would expect that at least every wavelet admits a linear phase. Unfortunately this is not true, as a counterexample constructed in Ref. 8 shows. However, the wavelet in that example admits a piece-wise linear phase. Therefore, it is natural to ask the following question.

Question 1: Does every wavelet admit at least a piece-wise linear phase?

The answer to this question is also negative. In Sec. IV, we construct an example of a wavelet such that it even does not admit any ''set-wise'' linear phase function (Example 4.2). The main

part of this article is devoted to linear phase functions. First, let us note that the following can be easily checked by using the two equations in the characterization of wavelets.

Lemma 1.1: If function $\alpha(s)$ is attainable for a wavelet ψ, then $-\alpha(s)$ and $\alpha(s)+ks+r$ are also attainable for the same wavelet ψ where k is any integer and r is any real number.

Because of the above lemma, we only need to consider linear phase functions of the form $\alpha(s)=as$ for $a\in[0,\frac{1}{2}]$. Hence we are interested in the following question:

Question 2: For which $a\in[0,\frac{1}{2}]$ is there a non-MSF wavelet that admits the phase function $\alpha(s)=as$?

Although we are not able to completely answer this question, we obtain the following theorems.

Theorem 1.2: *Let a be a real number such that either*

(i) $a=m/2^j n$ *with* $m, n\in 2\mathbb{Z}+1$ *and* $j\in\mathbb{N}$, *or*

(ii) $a=m/9n$ *with* $n\in 2\mathbb{Z}+1$ *and* $m\in\mathbb{Z}\backslash\{0\}$ *such that* m *is not divisible by* 3. *Then there exists a non-MSF wavelet ψ which admits the phase function $\alpha(s)=as$.*

We also prove (Proposition 2.1) that 0, $\frac{1}{3}s$, $\frac{1}{7}s$, $\frac{2}{7}s$, $\frac{3}{7}s$ are not attainable for any non-MSF wavelets. We do not know whether there exists an irrational a such that as is a phase for a non-MSF wavelet. This illustrates the complexity of the problem.

In Sec. III, we will concentrate on the class of wavelets which admits linear phase $\frac{1}{2}s$. If we denote by $\mathcal{W}_a$ the set of all the wavelets that admit phase function as, then, as we mentioned in the abstract, $\mathcal{W}_{1/2}$ contains all the MRA wavelets. Example 4.1 in this article shows that there exists a non-MSF wavelet which is not an MRA wavelet and admits phase $\frac{1}{2}s$. In other words, $\mathcal{W}_{1/2}$ is larger than the set of all MRA wavelets (modulo the MSF wavelets). We also study the relationship between $\mathcal{W}_{1/2}$ and $\mathcal{W}_a$ with various $a\in[0,\frac{1}{2}]$. In particular, we give characterizations for wavelets in $\mathcal{W}_{1/2}$ and $\mathcal{W}_{1/4}$, and prove the following:

Theorem 1.3: *Let a be a real number. Then there exists a non-MSF wavelet admitting both phases as and $\frac{1}{2}s$ if and only if $a=m/2n$ for some $m, n\in 2\mathbb{Z}+1$. In particular, $\mathcal{W}_{1/2}\cap\mathcal{W}_a$ does not contain any non-MSF wavelets if a is irrational.*

II. LINEAR PHASES OF WAVELETS

Before giving proof of Theorem 1.2, we first prove that there exist rational numbers $a\in[0,1/2]$ such that $\alpha(s)=as$ is not attainable by any non-MSF wavelet. Note that to determine whether or not any choice of $a\in[0,1/2]$ yields an attainable phase $\alpha(s)=as$ for a wavelet ψ, we only need to look at Eq. (1.2) in the characterization of wavelets, since the choices of function $\alpha(s)$ do not affect any other conditions.

Proposition 2.1: If $a\in\{m/3,m/7:m\in\mathbb{Z}\}$, then phase function $\alpha(s)=as$ is attainable only by MSF wavelets.

Proof: Let m be an arbitrary fixed number in $\mathbb{Z}$. First we consider the case when $\alpha(s)=(m/3)s$ is attainable for a wavelet ψ. Applying Eq. (1.2) to the wavelet whose Fourier transform is $e^{i\alpha(s)}|\hat{\psi}(s)|$, after taking complex conjugates to both sides of the resulting equation, we have that

$$\sum_{j=0}^{\infty} e^{i(2^j 2km\pi/3)}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0 \tag{2.1}$$

holds for a.e. $s\in\mathbb{R}$ and for each $k\in 2\mathbb{Z}+1$.

Equation (2.1) implies that

$$\sum_{j=0}^{\infty} |\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0 \tag{2.2}$$

holds for a.e. $s\in\mathbb{R}$ and for each $k\in 2\mathbb{Z}+1$ with $km\in 3\mathbb{Z}$.

Note that for each $j=2\ell\in 2(\mathbb{N}\cup\{0\})$, we can write $2^{j+1}=2^{2\ell+1}=2(4^{\ell}-1)+2$. Likewise, for each $j=2\ell+1\in 2(\mathbb{N}\cup\{0\})+1$, we can write $2^{j+1}=2^{2\ell+2}=4(4^{\ell}-1)+4$. Hence Eq. (2.1) also implies that

$$\sum_{j\in 2(\mathbb{N}\cup\{0\})} e^{i2\pi/3}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|+\sum_{j\in 2(\mathbb{N}\cup\{0\})+1} e^{i4\pi/3}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0 \tag{2.3}$$

holds for a.e. $s\in\mathbb{R}$ and for each $k\in 2\mathbb{Z}+1$ with $mk\in 3\mathbb{Z}+1$.

Similarly, Eq. (2.1) implies that

$$\sum_{j\in 2(\mathbb{N}\cup\{0\})} e^{i4\pi/3}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|+\sum_{j\in 2(\mathbb{N}\cup\{0\})+1} e^{i2\pi/3}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0 \tag{2.4}$$

holds for a.e. $s\in\mathbb{R}$ and for each $k\in 2\mathbb{Z}+1$ with $mk\in 3\mathbb{Z}+2$.

Note that for non-negative real numbers a and b, $ae^{i2\pi/3}+be^{i4\pi/3}=0$ implies $a=0$ and $b=0$. It follows then from Eqs. (2.2)–(2.4) that for almost all $s\in\mathbb{R}$, and each $k\in 2\mathbb{Z}+1$ and each $j\in\mathbb{N}\cup\{0\}$, $|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0$.

When $j=0$, the above says that for any $s\in\mathbb{R}$ such that $|\hat{\psi}(s)|\neq 0$, we have $|\hat{\psi}(s+2k\pi)|=0$ for each $k\in 2\mathbb{Z}+1$. When $j\in\mathbb{N}$, by using a substitution, we see from above that for any $s\in\mathbb{R}$ such that $|\hat{\psi}(s)|\neq 0$, we must have $|\hat{\psi}(s+2^j 2k\pi)|=0$ for each $k\in 2\mathbb{Z}+1$. Thus we conclude that for any $s\in\mathbb{R}$ such that $|\hat{\psi}(s)|\neq 0$, we must have $|\hat{\psi}(s+2\ell\pi)|=0$ for each $l\ell\in\mathbb{Z}$. This implies that ψ is an MSF wavelet.

Next, we consider the case when $\alpha(s)=(m/7)s$ is attainable for a wavelet ψ. Similarly, from Eq. (1.2) we have that

$$\sum_{j=0}^{\infty} e^{i(2^j 2km\pi/7)}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0 \tag{2.5}$$

holds for a.e. $s\in\mathbb{R}$ and for each $k\in 2\mathbb{Z}+1$.

Just as before, we discuss how Eq. (2.5) turns out for different $k\in 2\mathbb{Z}+1$. To avoid repetition, we point out first that Eq. (2.5) implies that for almost all $s\in\mathbb{R}$ and each $k\in 2\mathbb{Z}+1$ with $mk\in 7\mathbb{Z}+1$,

$$\sum_{j\in 3(\mathbb{N}\cup\{0\})} e^{i2\pi/7}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|+\sum_{j\in 3(\mathbb{N}\cup\{0\})+1} e^{i4\pi/7}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|$$
$$+\sum_{j\in 3(\mathbb{N}\cup\{0\})+2} e^{i8\pi/7}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0.$$

Other cases (seven cases altogether) turn out to be similar. Equation (2.5) implies that for almost all $s\in\mathbb{R}$ and each $k\in 2\mathbb{Z}+1$ with $mk\in 7\mathbb{Z}+2$ (respectively, $mk\in 7\mathbb{Z}+3$, or $mk\in 7\mathbb{Z}+4$, or $mk\in 7\mathbb{Z}+5$, or $mk\in 7\mathbb{Z}+6$), an equation similar to the above holds with only the numbers $2\pi/7$, $4\pi/7$, $8\pi/7$ replaced by $4\pi/7$, $8\pi/7$, $2\pi/7$ (respectively, $6\pi/7$, $12\pi/7$, $10\pi/7$, or $8\pi/7$, $2\pi/7$, $4\pi/7$, or $10\pi/7$, $6\pi/7$, $12\pi/7$, or $12\pi/7$, $10\pi/7$, $6\pi/7$) in that order.

Lastly, Eq. (2.5) implies that for almost all $s\in\mathbb{R}$ and each $k\in 2\mathbb{Z}+1$ with $mk\in 7\mathbb{Z}$, $\Sigma_{j=0}^{\infty}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0$.

Note that for non-negative real numbers a, b and c, $ae^{i2\pi/7}+be^{i4\pi/7}+ce^{i8\pi/7}=0$ implies that a, b and c are necessarily 0. Likewise, $ae^{i6\pi/7}+be^{i10\pi/7}+ce^{i12\pi/7}=0$ also implies that a, b and c are necessarily 0. Thus we conclude that for almost all $s\in\mathbb{R}$, for each $k\in 2\mathbb{Z}+1$, and each j

$\in \mathbb{N}\cup\{0\}$, $|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|=0$. Applying the same argument as in the case when $\alpha(s)=m/3s$ is attainable, we conclude also that ψ is an MSF wavelet. □

From the above proposition we have that for $a\in\{0,1/3,1/7,2/7,3/7\}\subset[0,1/2]$, phase function $\alpha(s)=as$ is attainable only by MSF wavelets. However, Theorem 1.2 tells us that there exist "many" rationals a such that as is attainable by non-MSF wavelets.

To prove Theorem 1.2, we need a result of Speegle in Ref. 10 concerning path-connectedness of the s-elementary wavelets. Let $\tilde{\tau}:\mathbb{R}\to[-2\pi,-\pi)\cup[\pi,2\pi)$ and $\tilde{d}:\mathbb{R}_0=(\mathbb{R}\backslash\{0\})\to[-2\pi,-\pi)\cup[\pi,2\pi)$ be the measurable maps defined by $\tilde{\tau}(x)=x+2\pi m(x)$, $\tilde{d}(x)=2^{n(x)}x$, where m and n are the unique integers which map x into $[-2\pi,-\pi)\cup[\pi,2\pi)$ under translation by $2\pi m$ and dilation by 2^n, respectively. Then a measurable subset W of $\mathbb{R}$ is called a *subwavelet set* if both $\tilde{d}|_W$ and $\tilde{\tau}|_W$ are injections modulo null sets. Moreover, W is a *wavelet set* if and only if $\tilde{d}|_W$ and $\tilde{\tau}|_W$ are bijections (modulo null sets). Equivalently, W is a wavelet set if and only if both $\{W+2km\pi:m\in\mathbb{Z}\}$ and $\{2^nW:n\in\mathbb{Z}\}$ are partitions (modulo null sets) for $\mathbb{R}$. We point out in passing that wavelet sets are exactly the support set of MSF wavelets. For a subwavelet set A we define two subsets of $[-2\pi,-\pi)\cup[\pi,2\pi)$ by $A^d=\tilde{d}(A)$ and $A^\tau=\tilde{\tau}(A)$.

Lemma 2.2:[10] *Let A be a subwavelet set. Suppose*

(1) there is an $\epsilon>0$ such that $A^\tau\subset[-2\pi+\epsilon,-\pi)\cup[\pi,2\pi-\epsilon)$ and

(2) $S:=([-2\pi,-\pi)\cup[\pi,2\pi))\backslash A^d$ has a nonempty interior.

Then there is a wavelet set $W\supset A$.

Proof of Theorem 1.2:

Case (i): $a=m/2^jn$, $m,n\in 2\mathbb{Z}+1$, $j\in\mathbb{N}$:

Without loss of generality, we may only consider the case when $n\in 2(\mathbb{N}\cup\{0\})+1$. For fixed $n\in 2(\mathbb{N}\cup\{0\})+1$ and $j\in\mathbb{N}$, let $A_1=[-\pi,-\pi/2)$ and $A_2=2^jn\pi+[-\pi/2,-\pi/4)$. Let us first show that $A=A_1\cup A_2$ is a subwavelet set, namely that both $\tilde{\tau}|_A$ and $\tilde{d}|_A$ are injective.

To this end, it suffices to show that for some k_1, $k_2\in\mathbb{Z}$, $A_1+2k_1\pi$ and $A_2+2k_2\pi$ are disjoint subsets of $[-2\pi,-\pi)\cup[\pi,2\pi)$, and also that for some j_1, $j_2\in\mathbb{Z}$, $2^{j_1}A_1$ and $2^{j_2}A_2$ are disjoint subsets of $[-2\pi,-\pi)\cup[\pi,2\pi)$.

Indeed, $A_1+2\pi=[\pi,\frac{3}{2}\pi)$, $A_2-2^jn\pi+2\pi=[\frac{3}{2}\pi,\frac{7}{4}\pi)$.

Observe that when $n=1$, $A_2=2^j\pi+[-\pi/2,-\pi/4)=2^{j-1}[2\pi-(\pi/2^j),2\pi-(\pi/2^{j+1}))$. Clearly $[2\pi-(\pi/2^j),2\pi-(\pi/2^{j+1}))\subset[\pi,2\pi)$. When $n\in 2\mathbb{N}+1$, there exists $k\in\mathbb{N}$ such that $2^k<n<2^{k+1}$. Thus $2^k<(n-(1/2^{j+1}))$. Since $A_2=2^jn\pi+[-\pi/2,-\pi/4)=2^{j+k}[(n/2^k)\pi-(\pi/2^{j+k+1}),(n/2^k)\pi-(\pi/2^{j+k+2}))$. It follows that A_2 is contained in $2^{j+k}[\pi,2\pi)$. On the other hand, we always have $2A_1=[-2\pi,-\pi)$. Thus both $\tilde{\tau}|_A$ and $\tilde{d}|_A$ are injective, so A is a subwavelet set.

Now let us check that conditions in Lemma 2.2 are satisfied. From the last paragraph, we see that the ϵ in the first condition can be taken as large as $\pi/4$ and that the interior of set S in the second condition contains the open interval $(2\pi-(\pi/2^{j+1}),2\pi)$ when $n=1$ and the open interval $((n/2^k)\pi-(\pi/2^{j+k+2}),2\pi)$ when $n\in 2\mathbb{N}+1$ (where $k\in\mathbb{N}$ and $2^k<n<2^{k+1}$). According to Lemma 2.2, there is a wavelet set $W\supset A$.

Now let $B_1=[-\pi/2,-\pi/4)$ and $B_2=2^{j+1}n\pi+[-\pi,-\pi/2)$. We see that $2B_1=A_1$, $2A_2=B_2$. Also $A_1+2^{j+1}n\pi=B_2$ and $B_1+2^jn\pi=A_2$. Thus $B=B_1\cup B_2$ is also a subwavelet set. Note that sets A and B are disjoint from each other. Also, because the disjoint union of sets $W\backslash A$ and A is a wavelet set, so for any $j\in\mathbb{Z}$, $2^j(W\backslash A)$ is disjoint from A; for any $k\in\mathbb{Z}$, $W\backslash A+2k\pi$ is also disjoint from A. Thus from the relations between A_1, A_2 and B_1, B_2, we see that $W\backslash A$ is disjoint from B and the disjoint union of $W\backslash A$ and B also forms a wavelet set. Now we can construct a non-MSF wavelet which admits phase $(m/2^jn)s$.

We first define a measurable function g on $A\cup B$ in the following way: Let g be any measurable function on A_1. By using the relations between sets A_1, A_2 and B_1, B_2, we define g so that $g(s)=g(s-2^{j+1}n\pi)$ when $s\in B_2$, $g(s)=g(2s-2^{j+1}n\pi)$ when $s\in A_2$ and $g(s)=g(2s)$ when $s\in B_1$. Let

$$|f(s)|=\begin{cases}\dfrac{|\sin(g(s))|}{\sqrt{2\pi}}, & s\in A,\\ \dfrac{|\cos(g(s))|}{\sqrt{2\pi}}, & s\in B,\\ \dfrac{1}{\sqrt{2\pi}}, & s\in W\backslash A,\\ 0, & \text{otherwise.}\end{cases}$$

First we compute the norm of $|f|$. By definition of g and relations between sets A and B, through change of variables in integration, we see that $\int_A|\cos(g(s))|^2\,ds=\int_B|\cos(g(s))|^2\,ds$. Also note that since W is a wavelet set, we have $\mu(W)=2\pi$, where μ is the Lebesgue measure on $\mathbb{R}$. Thus

$$\|f\|^2=\int_{\mathbb{R}}|f(s)|^2ds=\frac{1}{2\pi}\left(\int_A|\sin(g(s))|^2ds+\int_B|\cos(g(s))|^2ds+\mu(W\backslash A)\right)$$
$$=\frac{1}{2\pi}(\mu(A)+\mu(W\backslash A))=\frac{\mu(W)}{2\pi}=1.$$

Second, we check whether Eq. (1.1) is satisfied by the function whose Fourier transform has modulus $|f|$. Since W is a wavelet set, it follows that $\{2^\ell W:\ell\in\mathbb{Z}\}$ forms a partition of $\mathbb{R}$ (modulo a measure zero set). So it suffices to check (1.1) for $s\in W$. If $s\in A_1$, then $2^{-1}s\in B_1$ and $g(2^{-1}s)=g(s)$ by definition of g. Also, for any $\ell\neq 0,\ -1$, since $2^\ell s\in\mathbb{R}\backslash(W\cup B)$, we have $f(2^\ell)=0$. Thus,

$$\sum_{\ell\in\mathbb{Z}}|f(2^\ell s)|^2=|f(s)|^2+|f(2^{-1}s)|^2$$
$$=\frac{1}{2\pi}(|\sin g(s)|^2+|\cos g(2^{-1}s)|^2)$$
$$=\frac{1}{2\pi}(|\sin g(s)|^2+|\cos g(s)|^2)=\frac{1}{2\pi}.$$

Hence (1.1) holds when $s\in A_1$. Similarly, it holds when $s\in A_2$. When $s\in W\backslash A$, all the terms in (1.1) are zero except for $|f(s)|^2$ which is $1/2\pi$. Therefore we conclude that (1.1) holds for all $s\in W$.

For any fixed $m\in 2\mathbb{Z}+1$, we claim that $\hat{\psi}(s)=e^{ims/n2^j}|f(s)|$ is Fourier transform of a wavelet, and hence ψ is a wavelet admitting the phase $(m/2^jn)s$. (Obviously we can choose g such that ψ is not an MSF wavelet.) Taking all the properties enjoyed by $|f|$ into consideration, we see that we only need to check that $\hat{\psi}$ satisfies Eq. (1.2). By definition of g and relations between sets A_1, A_2, and B_1, B_2, we see that every term to the left of Eq. (1.2) is 0 unless when $s\in 2^{-j+1}B_1$, $k=n$ or when $s\in 2^{-j+1}A_2$, $k=-n$. In the first case, we have $2^{j-1}s\in B_1$, $2^{j-1}(s+2n\pi\in A_2)$, $2^js\in A_1$ and $2^j(s+2n\pi)\in B_2$. Thus

$$\sum_{\ell=0}^{\infty} \hat{\psi}(2^{\ell}s)\overline{\hat{\psi}(2^{\ell}(s+2n\pi))} = \hat{\psi}(2^{j-1}s)\overline{\hat{\psi}(2^{j-1}(s+2n\pi))} + \hat{\psi}(2^{j}s)\overline{\hat{\psi}(2^{j}(s+2n\pi))}$$

$$= \frac{1}{2\pi}(-|\cos g(2^{j-1}s)\|\sin g(2^{j-1}s+2^{j}n\pi)|$$

$$+|\sin g(2^{j}s)\|\cos g(2^{j}s+2^{j+1}n\pi)|)$$

$$= \frac{1}{2\pi}(-|\cos g(2^{j-1}s)\|\sin g(2^{j-1}s)|$$

$$+|\sin g(2^{j-1}s)\|\cos g(2^{j-1}s)|) = 0.$$

We use both translation and dilation periodicity properties of g on $A\cup B$ in the above calculation. The second case can be treated similarly.

Case (ii): $a=m/9n$, $n\in 2\mathbb{Z}+1$, $m\in\mathbb{Z}\backslash\{0\}$, $m\notin 3\mathbb{Z}$:

The proof of case (*ii*) is similar to that of case (*i*). So we will be brief at certain places. Again, as in case (*i*), it suffices to consider the case when n is a positive odd integer. Fix an $n\in 2(\mathbb{N}\cup\{0\})+1$, let $A_1=[-\pi,-\pi/2)$, $A_2=8n\pi+[-\pi/4,-\pi/8)$ and $A_3=4n\pi+[-\pi/16,-\pi/32)$. We first show that the set $A=A_1\cup A_2\cup A_3$ is a subwavelet set.

First note that $A_1+2\pi=[\pi,\frac{3}{2}\pi)$, $A_2-8n\pi+2\pi=[2\pi-(\pi/4),2\pi-(\pi/8))$, $A_3-4n\pi+2\pi=[2\pi-(\pi/16),2\pi-(\pi/32))$. Therefore $\tilde{\tau}|_A$ is injective.

Observe also that when $n=1$, $A_2=8\pi+[-\pi/4,-\pi/8)=4[\frac{31}{16}\pi,\frac{63}{32}\pi)$, and $A_3=4\pi+[-\pi/16,-\pi/32)=2[\frac{63}{32}\pi,\frac{127}{64}\pi)$. When $n\in 2\mathbb{N}+1$, there exists $k\in\mathbb{N}$ such that $2^k<n<2^{k+1}$, thus $2^k<(n-\frac{1}{32})$. Note that $2A_3$ and A_2 are disjoint and $2A_3\cup A_2=8n\pi+[-\pi/4,-\pi/16)=2^{k+3}[(n/2^k)\pi-(1/2^{k+5})\pi,(n/2^k)\pi-(1/2^{k+7})\pi)$. Hence, $2A_3\cup A_2$ is contained in $2^{k+3}[\pi,2\pi)$. On the other hand, $2A_1=[-2\pi,-\pi)$. Thus $\tilde{d}|_A$ is injective. So A is a subwavelet set.

To check that the conditions in Lemma 2.2 are satisfied, we observe that from the last paragraph the ϵ in the first condition can be taken as large as $\pi/32$ and that the interior of set S in the second condition contains the open interval $(\frac{127}{64}\pi,2\pi)$ in the case $n=1$ and the open interval $((n/2^k)\pi-(1/2^{k+7})\pi,2\pi)$ in the case $n\in 2\mathbb{N}+1$ (where $k\in\mathbb{N}$ such that $2^k<n<2^{k+1}$). According to Lemma 2.2, there is a wavelet set $W\supset A$.

Now let $B_1=[-\pi/4,-\pi/8)$, $B_2=2n\pi+[-\pi/16,-\pi/32)$ and $B_3=64n\pi+[-\pi,-\pi/2)$. Also let $C_1=[-\pi/16,-\pi/32)$, $C_2=32n\pi+[-\pi,-\pi/2)$ and $C_3=16n\pi+[-\pi/4,-\pi/8)$. Note that $A_1=4B_1=16C_1$, $C_2=4A_2=16B_2$, and $B_3=4C_3=16A_3$. Also $A_1=C_2-32n\pi=B_3-64n\pi$, $B_1=A_2-8n\pi=C_3-16n\pi$, and $C_1=B_2-2n\pi=A_3-4n\pi$. Thus $B=B_1\cup B_2\cup B_3$, $C=C_1\cup C_2\cup C_3$ are also subwavelet sets. Observe that sets A, B and C are mutually disjoint from each other. Moreover, $W\backslash A$ is disjoint from B and C, and the union of $W\backslash A$ and B also forms a wavelet set. So does the disjoint union of $W\backslash A$ and C.

Let us define function f so that

$$|f(s)| = \begin{cases} \dfrac{1}{\sqrt{6\pi}}, & s\in A\cup B\cup C, \\ \dfrac{1}{\sqrt{2\pi}}, & s\in W\backslash A, \\ 0, & \text{otherwise.} \end{cases}$$

As in case (*i*), one can easily check that $\|f\|=1$ and Eq. (1.1) is satisfied by $|f|$. To see that for each $m\in\mathbb{Z}\backslash\{0\}$ such that m is not divisible by 3, $e^{i(m/9n)s}|f|$ is a Fourier transform of a wavelet, it is left to check whether Eq. (1.2) is satisfied by the function whose Fourier transform is $e^{i(m/9n)s}|f|$. By definition of f and relations between sets A_1,A_2,A_3, B_1,B_2,B_3 and C_1,C_2,C_3,

we see that each term to the left of Eq. (1.2) is 0 unless one of the following is true: (1) $s \in C_1$, $k=n$; (2) $s \in \frac{1}{2}C_1$, $k=n$; (3) $s \in B_2$, $k=n$; (4) $s \in B_2$, $k=-n$; (5) $s \in A_3$, $k=-n$; and (6) $s \in \frac{1}{2}A_3$, $k=-n$. In case (1), when $s \in C_1$, we have that $4s \in B_1$, $16s \in A_1$ and that $s+2n\pi \in B_2$, $4(s+2n\pi) \in A_2$, $16(s+2n\pi) \in C_2$. Thus when $m=9m_1+1$ with some $m_1 \in \mathbb{Z}$, we have

$$\sum_{\ell=0}^{\infty} \hat{\psi}(2^{\ell}s)\overline{\hat{\psi}(2^{\ell}(s+2n\pi))} = \hat{\psi}(s)\overline{\hat{\psi}(s+2n\pi)} + \hat{\psi}(4s)\overline{\hat{\psi}(4(s+2n\pi))} + \hat{\psi}(16s)\overline{\hat{\psi}(16(s+2n\pi))}$$
$$= \frac{1}{6\pi}(e^{-i(2/9)\pi} + e^{-i(8/9)\pi} + e^{-i(32/9)\pi}) = 0,$$

Similarly, when $m=9m_1+2$ (resp. $m=9m_1+4$) with some $m_1 \in \mathbb{Z}$, we see that $\Sigma_{\ell=0}^{\infty}\hat{\psi}(2^{\ell}s)\overline{\hat{\psi}(2^{\ell}(s+2n\pi))}$ is $(1/6\pi)(e^{-i(4/9)\pi}+e^{-i(16/9)\pi}+e^{-i(64/9)\pi})=0$ [resp. $(1/6\pi)\times(e^{-i(8/9)\pi}+e^{-i(32/9)\pi}+e^{-i(128/9)\pi})=0$]. Finally, when $m=9m_1-1$ (resp. $m=9m_1-2$, or $m=9m_1-4$) with some $m_1 \in \mathbb{Z}$, the left-hand side of Eq. (2.1) becomes the complex conjugate of what one gets when $m=9m_1+1$ (resp. $m=9m_1+2$, or $m=9m_1+4$). Thus we are done for $s \in C_1$, $k=n$.

The other five cases are treated similarly. Therefore $\hat{\psi}=e^{i(m/9n)s}|f(s)|$ defines a non-MSF wavelet ψ which admits the phase function $\alpha(s)=(m/9n)s$. □

We end this section with the following comments:

Proposition 2.1 is based on a simple fact that vectors with certain specific angles between them never add up to zero unless each vector is zero in the first place. We can generalize Proposition 2.1 to all applicable linear phase functions and get the following Proposition 2.3.

First, for any real number a, let us define $res(a)$ such that $a-res(a) \in \mathbb{Z}$ and $0 \leqslant res(a) < 1$.

Proposition 2.3: Let a be any real number. The phase function as is not attainable for any non-MSF wavelet, if for any $k \in 2\mathbb{Z}+1$, the difference between the supremum and infimum the set $\{res(2^j ka): j \in \mathbb{N}\cup\{0\}\}$ is less than $\frac{1}{2}$.

The proof of Proposition 2.3 is essentially the same as that of Proposition 2.1 and so we omit it. Theorem 1.2 suggests the following conjecture.

Conjecture 1: Let $a=p/qr$ be a rational number where $p, q \in \mathbb{Z}\setminus\{0\}$, $r \in 2\mathbb{Z}+1$ and p, q are relatively prime. If there is a non-MSF wavelet which admits phase function $(1/q)s$, then there is a (possibly different) non-MSF wavelet which admits phase function $\alpha(s)=as$.

III. WAVELETS WHICH ADMIT PHASE FUNCTION $\frac{1}{2}s$

In this section we study the class of wavelets which admit phase function $\frac{1}{2}s$. We know that all MRA wavelets admit phase function $\frac{1}{2}s$. In a sense, this class holds more attraction than other classes of wavelets. First of all, let us introduce some notation.

For any $a \in [0,1/2]$, we denote by $\mathcal{W}_a$ the set of all wavelets which admit phase function as. As pointed out earlier, such $\mathcal{W}_a$ is never empty since it contains the set of all MSF wavelets. Note that from the proof of Theorem 1.2 above, we see that $\mathcal{W}_a \cap \mathcal{W}_b$ contains also non-MSF wavelets for certain a, b. In fact, for fixed $n \in 2(\mathbb{N}\cup\{0\})+1$ and $j \in \mathbb{N}$, in the proof of Theorem 1.2 we constructed a wavelet which admits phase function $(m/2^j n)s$ for any $m \in 2\mathbb{Z}+1$. In general, the relationship between different $\mathcal{W}_a$ can be very complicated. Here we concentrate on $\mathcal{W}_{1/2}$, to explore its relationship with various $\mathcal{W}_a$. As a byproduct, we also obtain similar results concerning $\mathcal{W}_{1/4}$.

First we give a characterization of wavelets in $\mathcal{W}_{1/2}$.

Proposition 3.1: If $a=1/2$, then phase function $\alpha(s)=as$ is attainable for a wavelet ψ if and only if the wavelet ψ satisfies the condition that for almost all $s \in \mathbb{R}$ and each $k \in 2\mathbb{Z}+1$,

$$|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)| = \sum_{j=1}^{\infty} |\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|. \tag{3.1}$$

Proof: Assume that ψ is a wavelet. Observe that $e^{i(1/2)s}|\hat{\psi}(s)|$ is a Fourier transform of a wavelet if and only if for almost all $s \in \mathbb{R}$ and for each $k \in 2\mathbb{Z}+1$,

$$\sum_{j=0}^{\infty} e^{i2^j k\pi}|\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))| = 0,$$

due to the fact that for each fixed $k \in 2\mathbb{Z}+1$, $e^{i2^j k\pi} = 1$ for any $j \in \mathbb{N}$ and $e^{i2^0 k\pi} = -1$. The condition above is equivalent to the condition that for almost all $s \in \mathbb{R}$ and each $k \in 2\mathbb{Z}+1$,

$$|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)| = \sum_{j=1}^{\infty} |\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|.$$

□

Observe that with the same argument employed in the proof of Proposition 2.1, we see that if phase function $\frac{1}{2}s$ is attainable for a wavelet ψ, and if for almost all $s \in \mathbb{R}$ and each $k \in 2\mathbb{Z}+1$, $|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)| = 0$, then it follows that ψ is an MSF wavelet. So, in particular, Proposition 3.1 says that if a non-MSF wavelet ψ admits phase $\frac{1}{2}s$, then there exists a set A of positive measure and some $k \in 2\mathbb{Z}+1$ such that $|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)| \neq 0$ for all $s \in A$.

Proposition 3.2: Let a be any real number. If both phase functions $s/2$ and $\alpha(s) = as$ are attainable for a non-MSF wavelet ψ, then a must be of the form $m/2n$ for some m, $n \in 2\mathbb{Z}+1$.

Proof: Since ψ is a non-MSF wavelet and admits phase function $\frac{1}{2}s$, according to Proposition 3.1 and the comments after its proof, there exists a set A of positive measure and some $k \in 2\mathbb{Z}+1$ such that $|\hat{\psi}(s)||\hat{\psi}(s+2k\pi)| \neq 0$ for all $s \in A$ and

$$|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)| = \sum_{j=1}^{\infty} |\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|$$

holds in particular for the same $k \in 2\mathbb{Z}+1$ and all $s \in A$.

Thus for each fixed $s \in A$, there must be at least one nonzero term to the right of the above equation. By passing to a subset of A, we can assume that the Jth term is nonzero for all $s \in A$ and some $J \in \mathbb{N}$. Since ψ also admits phase function $\alpha(s) = as$, Eq. (1.2) implies in particular that for that same $k \in 2\mathbb{Z}+1$ and all $s \in A$,

$$|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)| = (-1)\sum_{j=1}^{\infty} e^{i2k(1-2^j)a\pi}|\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|.$$

This implies that $(-1)e^{i2k(1-2^J)a\pi} = 1$. Therefore, $2k(1-2^J)a\pi = (2\ell+1)\pi$ for some $\ell \in \mathbb{Z}$. Hence a must be of the form $m/2n$ for some m, $n \in 2\mathbb{Z}+1$. □

Proof of Theorem 1.3: One direction is precisely Proposition 3.2. For the other direction, note that we only need to consider the case when $n \in 2(\mathbb{N}\cup\{0\})+1$ and $m \in \mathbb{Z}+1$. Recall that in the proof of Theorem 1.2, for each fixed $n \in 2(\mathbb{N}\cup\{0\})+1$, we actually constructed a non-MSF wavelet which is contained in $\mathcal{W}_{m/2n}$ for any $m \in \mathbb{Z}+1$. In particular, this wavelet is in $\mathcal{W}_{1/2}$. Hence $\mathcal{W}_{1/2} \cap \mathcal{W}_{m/2n}$ contains a non-MSF wavelet for any $n \in 2(\mathbb{N}\cup\{0\})+1$ and $m \in \mathbb{Z}+1$. □

For the rest of this section, we consider possibly containment between $\mathcal{W}_{1/2}$ and various $\mathcal{W}_a$. The main result is the following Theorem, which shows the complexity of the situation.

Theorem 3.3:

(i) $\mathcal{W}_{1/2}$ *is not contained in any* $\mathcal{W}_a$ *with* $a \in [0,\frac{1}{2})$.
(ii) $\mathcal{W}_{1/6}$ *is contained in* $\mathcal{W}_{1/2}$.
(iii) $\mathcal{W}_{1/10}$ *is not contained in* $\mathcal{W}_{1/2}$.

Proof: (i) The Fourier transform of a wavelet which is in $\mathcal{W}_{1/2}$ but not in $\mathcal{W}_a$ for any $a \in [0,1/2)$ is found by letting $n=1$ and $j=1$ in the construction presented in the proof of Theorem 1.2. Indeed, for $n=j=1$, the wavelet ψ constructed in the proof of Theorem 1.2 is in $\mathcal{W}_{m/2}$ for any $m \in 2\mathbb{Z}+1$. According to Lemma 1.1, $\mathcal{W}_{m/2}=\mathcal{W}_{1/2}$ for each $m \in 2\mathbb{Z}+1$.

Now we prove that the above mentioned wavelet ψ is not in $\mathcal{W}_a$ for $a \in [0,1/2)$. In fact, assume that ψ admits $\alpha(s)=as$ as a phase function. Equation (1.2), when applied to the wavelet whose Fourier transform is $\epsilon^{i\alpha(s)}|\hat{\psi}|$, says that, in particular, for $s \in B_1$ and $k=1$, we have

$$\sum_{\ell \in \mathbb{Z}} \hat{\psi}(2^{\ell}s)\overline{\hat{\psi}(2^{\ell}(s+2k\pi))} = \frac{1}{2\pi}(e^{-i2a\pi}|\cos g(s)||\sin g(s)| + e^{-i4a\pi}|\cos g(s)||\sin g(s)|) = 0.$$

It follows that $2a$ must be $2\ell+1$ for some $\ell \in \mathbb{Z}$. Thus $a=(2l+1)/2$, which is impossible since a is assumed to be in $[0, 1/2)$. Hence $\psi \notin \mathcal{W}_a$ for $a \in [0,\frac{1}{2})$.

(ii) Let ψ be a wavelet admitting phase function $\frac{1}{6}s$. We need to show that $\hat{\psi}$ satisfies the condition (3.1) in Proposition 3.1. According to Eq. (1.2), for almost all $s \in \mathbb{R}$ and for each $k \in 2\mathbb{Z}+1$, we must have

$$\sum_{j=0}^{\infty} e^{i(2^j 2k\pi/6)}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))| = 0. \tag{3.2}$$

When $k \in 6\mathbb{Z}+3$, from (3.2) we have that for almost all $s \in \mathbb{R}$,

$$|\hat{\psi}(s)||\hat{\psi}(s+2k\pi)| = \sum_{j=1}^{\infty} |\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|.$$

When $k \in 6\mathbb{Z}+1$, from (3.2), we have that for almost all $s \in \mathbb{R}$,

$$e^{i(1/3)\pi}|\hat{\psi}(s)||\hat{\psi}(s+2k\pi)| + e^{i(2/3)\pi} \sum_{j \in 2(\mathbb{N}\cup\{0\})+1} |\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))|$$

$$+ e^{i(4/3)\pi} \sum_{j \in 2\mathbb{N}} |\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))| = 0.$$

It then follows that the second term to the left side of the above equality must be zero, i.e.,

$$\sum_{n \in 2(\mathbb{N}\cup\{0\})+1} |\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))| = 0.$$

Consequently, for almost all $s \in \mathbb{R}$,

$$e^{i(1/3)\pi}|\hat{\psi}(s)||\hat{\psi}(s+2k\pi)| + \sum_{j \in 2\mathbb{N}} e^{i(4/3)\pi}|\hat{\psi}(2^j s)||\hat{\psi}(2^j(s+2k\pi))| = 0.$$

Hence,

$$
\begin{aligned}
|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)| &= \sum_{j\in 2\mathbb{N}} |\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))| \\
&= \sum_{j\in 2\mathbb{N}} |\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))| + \sum_{j\in 2(\mathbb{N}\cup\{0\})+1} |\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))| \\
&= \sum_{j=1}^{\infty} |\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|,
\end{aligned}
$$

i.e., (3.1) holds when $k\in 6\mathbb{Z}+1$.

Similar discussion yields that (3.1) holds when $k\in 6\mathbb{Z}+5$. Hence, by Proposition 3.1, $\psi \in \mathcal{W}_{1/2}$ as claimed.

(iii) We construct a non-MSF wavelet $\psi\in\mathcal{W}_{1/10}$ such that ψ does not admit phase $\frac{1}{2}s$.

We use similar sets as defined in the proof of Theorem 1.2 (*ii*). Let $A_1=[-\pi,-\pi/2)$, $A_2=8\pi+[-\pi/2,-\pi/4)$ and $A_3=4\pi+[-\pi/8,-\pi/16)$. Let us first show that $A=A_1\cup A_2\cup A_3$ is a subwavelet set. In fact, since $A_1+2\pi=[\pi,\frac{3}{2}\pi)$, $A_2-8\pi+2\pi=[2\pi-\pi/2,2\pi-\pi/4)$, and $A_3-4\pi+2\pi=[2\pi-\pi/8,2\pi-\pi/16)$, it follows that $\tilde{\tau}|_A$ is injective. Similarly, since $2A_1=[-2\pi,-\pi)$, $A_2=4[\frac{15}{8}\pi,\frac{31}{16}\pi)$, and $A_3=2[\frac{31}{16}\pi,\frac{63}{32}\pi)$, we have that $\tilde{d}|_A$ is injective. Therefore A is a subwavelet set.

Now to see that conditions in Lemma 2.2 are satisfied, we observe that the ϵ in the first condition can be taken as large as $\pi/16$ and that the interior of set S in the second condition contains the open interval $(\frac{63}{32}\pi,2\pi)$. According to Lemma 2.2, there is a wavelet set $W\supset A$.

Now let $B_1=[-\pi/2,-\pi/4)$, $B_2=2\pi+[-\pi/8,-\pi/16)$ and $B_3=32\pi+[-\pi,-\pi/2)$. Also let $C_1=[-\pi/8,-\pi/16)$, $C_2=16\pi+[-\pi,-\pi/2)$ and $C_3=16\pi+[-\pi/2,-\pi/4)$. Note that $A_1=2B_1=8C_1$, $C_2=2A_2=8B_2$, and $B_3=2C_3=8A_3$. Also $A_1=C_2-16\pi=B_3-32\pi$, $B_1=A_2-8\pi=C_3-16\pi$, and $C_1=B_2-2\pi=A_3-4\pi$. Thus $B=B_1\cup B_2\cup B_3$ and $C=C_1\cup C_2\cup C_3$ are also subwavelet sets. It can be checked that sets A_1, A_2, A_3, B_1, B_2, B_3 and C_1, C_2, C_3 are mutually disjoint from each other. Moreover, $W\backslash A$ is disjoint from B and C, and the union of sets $W\backslash A$ and B also forms a wavelet set. So does the union of $W\backslash A$ and C.

We define a function f in such a way that:

$$
|f(s)| = \begin{cases}
\dfrac{1}{\sqrt{2\pi}}, & s\in W\backslash A, \\
\dfrac{1}{\sqrt{2+2\cos(\pi/5)}\sqrt{2\pi}}, & s\in A_1\cup B_1\cup B_3\cup C_3, \\
\dfrac{\sqrt{2\cos(\pi/5)}}{\sqrt{2+2\cos(\pi/5)}\sqrt{2\pi}}, & s\in A_2\cup A_3\cup C_1\cup C_2, \\
\dfrac{1}{2\cos(\pi/5)\sqrt{2+2\cos(\pi/5)}\sqrt{2\pi}}, & s\in B_2, \\
0, \quad \text{otherwise.}
\end{cases}
$$

First we check that $\|f\|^2=1$. By definition of $|f|$ and relations between sets A_i, B_i, C_i for $i\in\{1,2,3\}$, through a change of variables in integration, we see that

$$
\int_{A_1}|f(s)|^2ds+\int_{C_2}|f(s)|^2ds+\int_{B_3}|f(s)|^2ds=\frac{1}{2\pi}\int_{A_1}\frac{1+2\cos(\pi/5)+1}{2+2\cos(\pi/5)}ds=\frac{1}{2\pi}\int_{A_1}ds.
$$

Likewise, we have

$$\int_{B_1}|f(s)|^2ds+\int_{A_2}|f(s)|^2ds+\int_{C_3}|f(s)|^2ds=\frac{1}{2\pi}\int_{A_2}\frac{1+2\cos(\pi/5)+1}{2+2\cos(\pi/5)}ds=\int_{A_2}ds$$

and

$$\int_{C_1}|f(s)|^2ds+\int_{B_2}|f(s)|^2ds+\int_{A_3}|f(s)|^2ds$$
$$=\frac{1}{2\pi}\int_{A_3}\frac{2\cos(\pi/5)+\{1/[4\cos^2(\pi/5)]\}+2\cos(\pi/5)}{2+2\cos(\pi/5)}ds=\int_{A_3}ds.$$

The last equality follows from the identity $8\cos^3(\pi/5)+1=8\cos^2\pi/5$.

Hence,

$$\|f\|^2=\int_{\mathbb{R}}|f(s)|^2ds=\frac{1}{2\pi}\left(\int_A|f(s)|^2ds+\int_B|f(s)|^2ds+\int_C|f(s)|^2ds+\mu(W\backslash A)\right)$$
$$=\frac{1}{2\pi}(\mu(A)+\mu(W\backslash A))=\frac{\mu(W)}{2\pi}=1.$$

Next we check that Eq. (1.1) holds by the function whose Fourier transform has modulus $|f|$. As we reasoned before, it suffices to check (1.1) for $s\in W$. If $s\in A_1$, then $2^{-1}s\in B_1$ and $2^{-3}s\in C_1$. For any $\ell\neq 0,-1,-3$, since $2^{\ell}s\in\mathbb{R}\backslash(W\cup B\cup C)$, we have $|f(2^{\ell}s)|=0$.

Thus

$$\sum_{\ell\in\mathbb{Z}}|f(2^{\ell}s)|^2=|f(s)|^2+|f(2^{-1}s)|^2+|f(2^{-3}s)|^2=\frac{1}{2\pi}\left(\frac{1+2\cos(\pi/5)+1}{2+2\cos(\pi/5)}\right)=\frac{1}{2\pi}.$$

Hence (1.1) holds when $s\in A_1$. Similarly, we can check that (1.1) holds when $s\in A_3$. We point out that to verify that (1.1) holds for $s\in A_2$, the identity $8\cos^3(\pi/5)+1=8\cos^2(\pi/5)$ may be useful.

Now let $\hat{\psi}(s)=e^{i(1/10)s}|f(s)|$. To prove that ψ is a wavelet, the only thing left is to check that Eq. (1.2) is satisfied by ψ. By definition of $|f|$ and relations between sets A_i, B_i, C_i for $i\in\{1,2,3\}$, every term to the left of Eq. (1.2) is 0 unless one of the following is true: (1) $s\in C_1$, $k=1$, (2) $s\in\frac{1}{2}C_1$, $k=1$, (3) $s\in B_2$, $k=1$, (4) $s\in B_2$, $k=-1$, (5) $s\in A_3$, $k=-1$, or (6) $s\in\frac{1}{2}A_3$, $k=-1$.

In case (1), when $s\in C_1$, we have that $4s\in B_1$ and $8s\in A_1$ and that $s+2\pi\in B_2$, $4(s+2\pi)\in A_2$, and $8(s+2\pi)\in C_2$. Thus we have

$$\sum_{\ell=0}^{\infty}\hat{\psi}(2^{\ell}s)\overline{\hat{\psi}(2^{\ell}(s+2\pi))}=\hat{\psi}(s)\overline{\hat{\psi}(s+2\pi)}+\hat{\psi}(4s)\overline{\hat{\psi}(4(s+2\pi))}+\hat{\psi}(8s)\overline{\hat{\psi}(8(s+2\pi))}$$
$$=\frac{1}{2\pi}\frac{1}{2+2\cos\pi/5}\left(e^{-i(2/10)\pi}\frac{1}{\sqrt{2\cos\pi/5}}+e^{-i(8/10)\pi}\sqrt{2\cos\frac{\pi}{5}}\right.$$
$$\left.+e^{-i(16/10)\pi}\sqrt{2\cos\frac{\pi}{5}}\right)=0.$$

The last equality can be verified in many different ways. (The quickest way probably is to view it as a representation of three vectors which sum to zero and use geometry.) We omit the details.

Thus we checked the first case. The cases (3)–(5) turn out to be similar. In cases (2) and (4), the final equality looks quite different. For instance, in case (2), we are required to verify the following equality:

$$\frac{1}{2\pi}\frac{1}{2+2\cos(\pi/5)}\left(e^{-i(4/10)\pi}2\cos\frac{\pi}{5}+e^{-i(16/10)\pi}+e^{-i(32/10)\pi}\right)=0.$$

We omit the calculation.

To show that $\psi\notin\mathcal{W}_{1/2}$, we use characterization of $\mathcal{W}_{1/2}$ in Proposition 3.1. Again, take $s\in C_1$ and $k=1$. Through similar computation we see that for the function whose Fourier transform is $e^{i(1/2)s}|f|$, satisfying Eq. (3.1) would imply $1=4\cos(\pi/5)$, which is untrue. (In fact, $1=4\cos(\pi/5)\cos(2\pi/5)$.) The proof is completed. □

As a byproduct of the proof of (*ii*), we obtain a characterization of $\mathcal{W}_{1/6}$.

Proposition 3.4: Wavelet ψ is in $\mathcal{W}_{1/6}$ if and only if for almost all $s\in\mathbb{R}$ and each $k\in 6\mathbb{Z}+3$,

$$|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)|=\sum_{j=1}^{\infty}|\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|;$$

and for almost all $s\in\mathbb{R}$, each $k\in 6\mathbb{Z}+1$ or $k\in 6\mathbb{Z}+5$, each $j\in 2(\mathbb{N}\cup\{0\})+1$, $|\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|=0$ and

$$|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)|=\sum_{j\in 2\mathbb{N}}|\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+2k\pi))|=0.$$

We point out that parallel investigation of $\mathcal{W}_{1/4}$ yields some results similar to that of $\mathcal{W}_{1/2}$. We only list results with a few comments. The proofs are omitted since technically they are quite the same as their counterpart.

Lemma 3.5: If $a=1/4$, then phase function $\alpha(s)=as$ is attainable for a wavelet ψ if and only if ψ satisfies the condition that for almost all $s\in\mathbb{R}$ and for each $k\in 2\mathbb{Z}+1$, $|\hat{\psi}(s)\|\hat{\psi}(s+2k\pi)|=0$ and

$$|\hat{\psi}(s)\|\hat{\psi}(s+4k\pi)|=\sum_{j=1}^{\infty}|\hat{\psi}(2^j s)\|\hat{\psi}(2^j(s+4k\pi))|.$$

The only thing new in the proof of Lemma 3.5 is the observation that for real numbers $\{a_k\}$ with $k\in N$ such that $a_1 e^{i(1/2)\pi}+\Sigma_{k=2}^{\infty}a_k=0$, a_1 must be 0.

We point out some consequences of Lemma 3.5. First, we note that by the same argument employed in the proof of Proposition 2.3, it follows from Lemma 3.5 that if phase function $\frac{1}{4}s$ is attainable for a wavelet ψ, and if for almost all $s\in\mathbb{R}$ and each $k\in 2\mathbb{Z}+1$, $|\hat{\psi}(s)\|\hat{\psi}(s+4k\pi)|=0$, then ψ is a MSF wavelet. In other words, if a non-MSF wavelet ψ admits phase $\frac{1}{4}s$, then there exists a set A of positive measure and some $k\in 2\mathbb{Z}+1$ such that $|\hat{\psi}(s)\|\hat{\psi}(s+4k\pi)|\neq 0$ for all $s\in A$.

Second, by using Eq. (1.2), it follows from Lemma 3.5 that for any wavelet ψ admitting phase $(\frac{1}{4})s$, for almost every $s\in\mathbb{R}$ and each $k\in 2\mathbb{Z}+1$, we have

$$\sum_{\ell=0}^{\infty}\hat{\psi}(2^{\ell}s)\overline{\hat{\psi}(2^{\ell}(s+4k\pi))}=0.$$

Using these consequences of Lemma 3.5, we obtain a proof of Proposition 3.6 similar to the proof of Proposition 3.2. Now a proof of Theorem 3.7 is not much different from that of Theorem 1.3.

Proposition 3.6: Let a be any real number. If both phase functions $s/4$ and $\alpha(s)=as$ are attainable for a non-MSF wavelet ψ, then a must be of the form $m/4n$ for some m, $n\in 2\mathbb{Z}+1$.

Theorem 3.7: *Let a be a real number. Then there exists a non-MSF wavelet admitting both phases as and $\frac{1}{4}s$ if and only if $a=m/4n$ for some m, $n\in 2\mathbb{Z}+1$. In particular, $\mathcal{W}_{1/4}\cap\mathcal{W}_a$ does not contain any non-MSF wavelets if a is irrational.*

Fourier transform of a wavelet in $\mathcal{W}_{1/4}$ is found by letting $n=1$ and $j=2$ in the construction presented in the proof of Theorem 1.2 (*i*). The assumption that such a wavelet admits also $\alpha(s)=as$ as a phase function leads to the conclusion that $4a$ must be $2\ell+1$ for some $\ell\in\mathbb{Z}$. Thus the wavelet is only in $\mathcal{W}_{(2\ell+1)/4}$ which, according to Lemma 1.1, is exactly the same as $\mathcal{W}_{1/4}$. Therefore we have the following.

Proposition 3.8: $\mathcal{W}_{1/4}$ is not contained in $\mathcal{W}_a$ for any $a\in[0,1/2]\backslash\{\frac{1}{4}\}$.

To finish this section, we point out that a similar method does not produce a characterization of wavelets in $\mathcal{W}_{m/8}$ for $m\in\{1,3\}$, nor some counterpart to (*ii*) and (*iii*) in Theorem 3.3. Things apparently get harder as one progresses from $\mathcal{W}_{1/2}$ to other $\mathcal{W}_a$'s.

IV. TWO EXAMPLES

In this section we provide the two important examples mentioned in the Introduction. The first one shows that $\mathcal{W}_{1/2}$ is larger (modulo the MSF wavelets) than the set of all MRA wavelets. We refer to standard books (cf. Refs. 1, 6, and 7) for the definition of multiresolution (MRA) wavelets. We will use the fact (cf. Ref. 1) that a wavelet ψ is an MRA wavelet if and only if its *dimension function* $D_\psi(s)=(2\pi)\Sigma_{n=1}^{\infty}\Sigma_{k\in\mathbb{Z}}|\hat{\psi}(2^n(s+2k\pi))|^2=1$, a.e. $s\in\mathbb{R}$.

The second example shows that there exists a non-MSF wavelet which does not even admit any piece-wise linear phase function. A function $\alpha(s)$ on $(-\infty,\infty)$ is called *set-wise linear* if $(-\infty,\infty)$ can be decomposed into countable disjoint (modulo null sets) union of measurable subsets such that $\alpha(s)$ is linear on each subset.

Example 4.1: There exists a non-MSF wavelet ψ such that ψ is not an MRA wavelet and ψ admits phase $\frac{1}{2}s$.

Proof: Let $A_1=[-\frac{8}{15}\pi,-\frac{2}{5}\pi)$ and $A_2=[\frac{176}{15}\pi,\frac{64}{5}\pi)$. Then $A_1\cup A_2$ is a subwavelet set contained in wavelet set $A_1\cup A_2\cup C$ where $C=[-\frac{2}{5}\pi,-\frac{4}{15}\pi)\cup[\frac{4}{5}\pi,\frac{22}{15}\pi)$. Also define $B_1=[\frac{22}{15}\pi,\frac{8}{5}\pi)=A_1+2\pi=1/8A_2$ and $B_2=[-\frac{64}{15}\pi,-\frac{16}{5}\pi)=A_2-16\pi=8A_1$.

Let us define function f to be such that

$$|f(s)|=\begin{cases}\dfrac{1}{\sqrt{2\pi}}, & s\in C,\\[2ex] \dfrac{1}{2\sqrt{\pi}}, & s\in A_1\cup A_1\cup B_1\cup B_2,\\[2ex] 0, & \text{otherwise.}\end{cases}$$

Then $\|f\|^2=(1/2\pi)\mu(C)+(1/4\pi)\mu(A_1\cup A_1\cup B_1\cup B_2)=\frac{6}{15}+\frac{9}{15}=1$. To check that Eq. (1.1) is satisfied by any function whose Fourier transform has modulus $|f|$, we note that it suffices to check (1.1) for s in the wavelet set $A_1\cup A_2\cup C$. When $s\in C$, $|f(s)|$ is the only nonzero term to the left of Eq. (1.1). So $\Sigma_{\ell\in\mathbb{Z}}|f(2^\ell s)|^2=|f(s)|^2=1/2\pi$. If $s\in A_1$, then $\Sigma_{\ell\in\mathbb{Z}}|f(2^\ell s)|^2=|f(s)|^2+|f(2^3s)|^2=1/2\pi$. Similarly, when $s\in A_2$, we have $\Sigma_{\ell\in\mathbb{Z}}|f(2^\ell s)|^2=|f(s)|^2+|f(2^{-3}s)|^2=1/2\pi$.

To prove that $\hat{\psi}(s)=e^{i(1/2)s}|f(s)|$ is Fourier transform of a wavelet, it is left to check that Eq. (1.2) is satisfied by ψ. We see that each term to the left of Eq. (1.2) is 0 unless when $s\in A_1$, $k=1$, or when $s\in B_1$, $k=-1$. In the first case, the only nonzero terms in (1.2) involve $s\in A_1$, $s+2\pi\in B_1$, $2^3s\in A_2$ and $2^3(s+2\pi)\in B_2$. Hence

$$\sum_{\ell=0}^{\infty} \overline{\hat{\psi}}(2^{\ell}s)\overline{\hat{\psi}(2^{\ell}(s+2\pi))} = \hat{\psi}(s)\overline{\hat{\psi}((s+2\pi))} + \hat{\psi}(2^3 s)\overline{\hat{\psi}(2^3(s+2\pi))} = \frac{1}{4\pi}(e^{-\pi i}+e^{-8\pi i}) = 0.$$

The second case is similar.

Finally we show that ψ is not an MRA wavelet. For this, we need to note that $\frac{1}{4}A_1+6\pi = [-\frac{2}{15}\pi,-\frac{1}{10}\pi)+6\pi = [\frac{88}{15}\pi,\frac{59}{10}\pi)\subset[\frac{88}{15}\pi,\frac{32}{5}\pi) = \frac{1}{2}A_2$, and $\frac{1}{4}A_1-2\pi\subset\frac{1}{2}B_2$. Let $s\in\frac{1}{4}A_1 = [-\frac{2}{15}\pi,-\frac{1}{10}\pi)$. Direct calculation shows then that $2^2 s\in A_1$, $2^5 s\in B_2$, $2(s+6\pi)\in A_2$ and $2(s-2\pi)\in B_2$. Thus

$$D_{\psi}(s)\geqslant(2\pi)(|\hat{\psi}(2^2 s)|^2+|\hat{\psi}(2^5 s)|^2+|\hat{\psi}(2(s+6\pi))|^2+|\hat{\psi}(2(s-2\pi))|^2) = 2.$$

Therefore ψ is not an MRA wavelet. □

Example 4.2: There exists a non-MSF wavelet ψ such that ψ does not admit any set-wise linear phase $\alpha(s)=as$.

Proof: Let A_1, A_2, A_3, B_1, B_2, B_3, C_1, C_2, C_3 and A, B, C be defined as in the proof of Theorem 3.3 (*iii*), and W be the wavelet set containing A. Also recall that $A_1=[-\pi,-\pi/2)$ and all these subsets satisfy the following conditions: $A_1=2B_1=8C_1$, $C_2=2A_2=8B_2$, $B_3=2C_3=8A_3$, $A_1=C_2-16\pi=B_3-32\pi$, $B_1=A_2-8\pi=C_3-16\pi$ and $C_2=B_2-2\pi=A_3-4\pi$.

Let $g(x)$ be defined on $C_1=[-\pi/8,-\pi/16)$ such that $g(-\pi/8)=0$, $g(-\pi/16)=1/\sqrt{3}$ and that $g(x)$ is linear. Then we extend the definition of $g(x)$ to the union of $A\cup B\cup C$ in such a way that $g(s)=g(s+2\pi)$ and $g(s)=g(2s)$ holds whenever s, $s+2\pi$ or s, $2s$ are in the union of $A\cup B\cup C$. Using the relations among sets A_i, B_i, C_i with $i\in\{1,2,3\}$, we can verify that g is well defined.

Now we define function f as follows:

$$f(s)=\begin{cases} \dfrac{1}{\sqrt{2\pi}}, & s\in W\backslash A,\\[2ex] \dfrac{1}{\sqrt{2\pi}}g(s), & s\in B\cup C,\\[2ex] \dfrac{1}{\sqrt{2\pi}}\sqrt{1-2g^2(s)}, & s\in A,\\[2ex] 0, & \text{otherwise.}\end{cases}$$

Note that f is well defined and $f\geqslant 0$ since $g^2(s)\leqslant\frac{1}{3}$. Similar to all the other examples, it can be checked that $\|f\|^2=1$ and $\Sigma_{\ell\in\mathbb{Z}}|f(2^{\ell}s)|^2=1/2\pi$, a. e. $s\in\mathbb{R}$.

Let $\alpha(s)$ be zero on $B\cup C$ and $\frac{1}{2}\pi+\arcsin g(s)/2\sqrt{1-2g^2(s)}$ on A and 0 everywhere else. We claim that $\hat{\psi}(s)=e^{i\alpha(s)}f(s)$ is the Fourier transform of a wavelet. By the above paragraph we only need to check Eq. (1.2). Similarly, we only need to check the following six cases: (1) $s\in C_1$, $k=1$; (2) $s\in\frac{1}{2}C_1$, $k=1$; (3) $s\in B_2$, $k=1$; (4) $s\in B_2$, $k=-1$; (5) $s\in A_3$, $k=-1$; and (6) $s\in\frac{1}{2}A_3$, $k=-1$. We treat only the first case, and the other five cases can be dealt similarly. In case (1), we have $s\in C_1$, $2^2 s\in B_1$, $2^3 s\in A_1$, $s+2\pi\in B_2$, $2^2(s+2\pi)\in A_2$, and $2^3(s+2\pi)\in C_2$. Thus

$$\sum_{j=0}^{\infty} |\hat{\psi}(2^j s)\overline{\hat{\psi}(2^j(s+2\pi))} = \hat{\psi}(s)\overline{\hat{\psi}(s+2\pi)} + \hat{\psi}(2^2 s)\overline{\hat{\psi}(2^2(s+2\pi))} + \hat{\psi}(2^3 s)\overline{\hat{\psi}(2^3(s+2\pi))}$$

$$= \frac{1}{2\pi} g^2(s) + \frac{1}{2\pi} g(s)\sqrt{1-2g^2(s)}\left[\exp\left(-\frac{\pi}{2} - \arcsin\frac{g(s)}{2\sqrt{1-2g^2(s)}}\right)\right.$$

$$\left. + \exp\left(\frac{\pi}{2} + \arcsin\frac{g(s)}{2\sqrt{1-2g^2(s)}}\right)\right]$$

$$= \frac{1}{2\pi} g^2(s) - \frac{1}{2\pi} g(s)\sqrt{1-2g^2(s)}\frac{g(s)}{\sqrt{1-2g^2(s)}} = 0.$$

Now, suppose that the wavelet also admits set-wise linear phase $\beta(s)$. It follows that there exists subset E of C_1 such that E has positive measure and $\beta(s)$ is linear on E. By passing to a subset of E, we can also assume that $\beta(s)$ is linear on each set 2^2E, 2^3E, $E+2\pi$, $2^2(E+2\pi)$, $2^3(E+2\pi)$. Considering (1.2), we see that when $s \in E$ there are only three nonzero terms which involve the above six sets. Hence, by the definition of f, it follows from Eq. (1.2) that

$$e^{i(a_1 s+b_1)} g(s) + (e^{i(a_2 s+b_2)} + e^{i(a_3 s+b_3)})\sqrt{1-2g^2(s)} = 0$$

holds for all $s \in E$, where a_1, a_2, a_3, b_1, b_2, b_3 are real constants. After multiplying $e^{-i(a_1 s+b_1)}$ on both sides, we see that

$$g(s) + (e^{i(as+b)} + e^{i(cs+d)})\sqrt{1-2g^2(s)} = 0$$

holds for all $s \in E$, where a, b, c, d are real constants. By considering the real and imaginary parts, we obtain

$$(\sin(as+b) + \sin(cs+d))\sqrt{1-2g^2(s)} = 0 \tag{4.1}$$

and

$$g(s) + (\cos(as+b) + \cos(cs+d))\sqrt{1-2g^2(s)} = 0 \tag{4.2}$$

for $s \in E$. Since $0 < g(s) < 1\sqrt{3}$ on E, it follows from (4.1) and (4.2) that $\sin(as+b)+\sin(cs+d) = 0$ and $\cos(as+b)+\cos(cs+d) \neq 0$ for $s \in E$, which implies from (4.2) that

$$\cos(as+b) = -\frac{g(s)}{2\sqrt{1-2g^2(s)}}$$

and hence

$$\cos^2(as+b) = \frac{g^2(s)}{4(1-2g^2(s))} \tag{4.3}$$

holds for $s \in E$.

Note that $g(s) = (16/\pi\sqrt{3})s + (2/\sqrt{3})$ on E and hence

$$h(z) := \frac{((16/\pi\sqrt{3})z + 2/\sqrt{3})^2}{4(1-2((16/\pi\sqrt{3})z + 2/\sqrt{3})^2)}$$

is a nonconstant rational function. By (4.3) and a standard complex analysis argument we will have $\cos(az+b)=h(z)$ for all $z\in\mathbb{C}$ such that $1-2((16/\pi\sqrt{3})z+2/\sqrt{3})^2\neq 0$, which is obviously impossible. Therefore ψ does not admit any set-wise linear phase. □

(Received 19 October 2001; accepted for publication 4 February 2002)

A class of spherical functions is studied which can be viewed as the matrix generalization of Bessel functions. We derive a recursive structure for these functions. We show that they are only special cases of more general radial functions which also have a properly generalized, recursive structure. Some explicit results are worked out. For the first time, we identify a subclass of such radial functions which consist of a finite number of terms only. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1463709]

I. INTRODUCTION

In 1957, Harish-Chandra[1] derived a famous formula for a certain class of group integrals. Let $\mathcal{G}$ be a compact semisimple Lie group and let a and b be elements of its Cartan subalgebra $\mathcal{H}$, then

$$\int_{U\in\mathcal{G}} \mathrm{d}\mu(U)\exp(\mathrm{tr}\,U^{-1}aUb)=\frac{1}{|\mathcal{W}|}\sum_{w\in\mathcal{W}}\frac{\exp(\mathrm{tr}\,w(a)b)}{\Pi(a)\Pi(w(b))}. \tag{1.1}$$

Here, $\mathrm{d}\mu(U)$ is the invariant measure, $\Pi(a)$ is the product of all positive roots of $\mathcal{H}$, and $\mathcal{W}$ is the Weyl reflection group of $\mathcal{G}$ with $|\mathcal{W}|$ elements w.

This result depends crucially on the condition that a and b are in the Cartan subalgebra $\mathcal{H}$. In other words, $U^{-1}aUb$ has to be in the algebra of the group. If one replaces a and b in the integral on the left-hand side with more general matrices x and k which are not in $\mathcal{H}$, formula (1.1) is *not valid anymore*. The *spherical functions* introduced by Gelfand[2,3] form an important class of such integrals which are, in general, not covered by Harish-Chandra's result (1.1). In another work, Harish-Chandra[4] studies in great detail the harmonic analysis involving these spherical functions. In a more physics oriented contribution, Olshanetsky and Perelomov[5] discussed them in the framework of quantum integrable systems.

Here, we wish to address spherical functions of the following kind: we take x and k as diagonal matrices containing the eigenvalues of a Hamiltonian in a matrix representation. The Hamiltonian is diagonalized by the integration matrix U. In particular, we assume that the Hamiltonian $U^{-1}xU$ or, equivalently, UkU^{-1} is real-symmetric, Hermitian, or Hermitian self-dual. Thus, $\mathcal{G}$ is the orthogonal, the unitary or the unitary-symplectic group. We will refer to these spherical functions as *matrix Bessel functions*. We notice that the unitary case is special: since it so happens that the eigenvalues x and k do lie in the Cartan subalgebra $\mathcal{H}$, the result (1.1) applies and coincides with the Itzykson–Zuber formula.[6] In the orthogonal and the unitary-symplectic cases, however, formula (1.1) is not valid.

[b)]Electronic mail: heiner.kohler@uam.es

We choose the term matrix Bessel function for the spherical functions to be discussed here, because they can be viewed as a natural extension of the ordinary vector Bessel functions. However, due to the rich features of the spherical functions, other extensions relating to ordinary Bessel functions are equally natural. Related functions have been discussed and terms similar to matrix Bessel functions have already been used by Hertz,[7] by Gross and Kunze,[8,9] by Holman,[10] and by Okounkov and Olshanski.[11] Kontsevich[12] introduced the matrix Airy functions.

Duistermaat and Heckman[13] developed a stationary phase approach involving localization for a class of spherical functions, see also the treatise by Szabo.[14]

Remarkably, our matrix Bessel functions are only special cases of more general objects which we call *radial functions*. Moreover, there is an important connection to the Calogero–Sutherland models which we will discuss separately, see the following.

The matrix Bessel functions are of considerable interest for applications in physics. They appear in random matrix theory,[15–17] which models spectral fluctuations of complex systems, such as quantum chaotic ones. In particular, they are the kernels of Dyson's Brownian motion[18,19] describing crossover transitions between different symmetry or invariance classes. Unfortunately, only the case of broken time-reversal invariance can be treated explicitly with the help of the Itzykson–Zuber formula. In the physically important cases of conserved time-reversal invariance, the kernels are not known analytically, as argued previously. Muirhead[20] discusses spherical functions in the framework of multivariate statistical theory. In his book, an expansion in terms of Jack polynomials for the orthogonal case can be found. Such an expansion for arbitrary Dyson index was recently worked out by Okounkov and Olshanski.[11]

The goal of the present paper is to explore the structure of the radial functions which contain the matrix Bessel functions as special cases. In particular, we show how explicit results can be obtained. The paper is organized as follows. In Sec. II, we briefly review some properties of the vector Bessel functions. In doing so we wish to help the reader in developing an intuition for the matrix Bessel functions which we introduce in Sec. III. In Sec. IV, we state and derive a fundamental recursive structure for matrix Bessel functions. We show in Sec. V that this recursion is an iterative solution of general radial functions which contain group integrals defining the matrix Bessel functions as special case. Sections IV and V are our main results. In Sec. VI we illustrate how the recursion can lead to closed and explicit formulas. Because of its special importance, we discuss the connection to Calogero–Sutherland models separately in Sec. VII. In Sec. VIII, we summarize and conclude. Various aspects and calculations are collected in the appendices.

II. VECTOR BESSEL FUNCTIONS REVISITED

Before turning to the matrix case, we compile, for the convenience of the reader, some well-known results for the vector case.

In a real, d dimensional space with $d=2,3,4,\ldots$, we consider a position vector $\vec{r}=(x_1,\ldots,x_d)$ and a wave vector $\vec{k}=(k_1,\ldots,k_d)$. The plane wave $\exp(i\vec{k}\cdot\vec{r})$ satisfies the wave equation

$$\Delta \exp(i\vec{k}\cdot\vec{r}) = -\vec{k}^2 \exp(i\vec{k}\cdot\vec{r}), \tag{2.1}$$

where we define the Laplacian as in the physics literature,

$$\Delta = \frac{\partial^2}{\partial \vec{r}^2} = \sum_{i=1}^{d} \frac{\partial^2}{\partial x_i^2}. \tag{2.2}$$

The zeroth-order Bessel function in this space is the angular average of the plane wave,

$$\chi^{(d)}(kr) = \int \mathrm{d}\Omega \exp(i\vec{k}\cdot\vec{r}), \tag{2.3}$$

over the solid angle Ω, defining the orientation of either $\vec{r}$ or $\vec{k}$. In our context, it is advantageous to take Ω as the solid angle of $\vec{k}$. Obviously, only the relative angle between $\vec{r}$ and $\vec{k}$ matters and $\chi^{(d)}(kr)$ can only depend on the product of the lengths $r=|\vec{r}|$ and $k=|\vec{k}|$ of the two vectors. We normalize the measure $d\Omega$ with the volume $2\pi^{d/2}/\Gamma(d/2)$ of the unit sphere, i.e., we have

$$\int d\Omega = 1. \tag{2.4}$$

Thus, by construction, we also have

$$\chi^{(d)}(0) = 1. \tag{2.5}$$

It is convenient to view $\vec{r}$ as the azimuthal direction of the coordinate system in which we measure Ω. Thus, in these spherical coordinates, one finds $\vec{k}\cdot\vec{r} = kr\cos\vartheta$ where ϑ is the azimuthal angle. The measure $d\Omega$ contains $\sin^{d-2}\vartheta$ and one has

$$\chi^{(d)}(kr) = \frac{\Gamma(d/2)}{\sqrt{\pi}\Gamma((d-1)/2)} \int_0^\pi \exp(ikr\cos\vartheta)\sin^{d-2}\vartheta\, d\vartheta = 2^{(d-2)/2}\Gamma(d/2)\,\frac{J_{(d-2)/2}(kr)}{(kr)^{(d-2)/2}}, \tag{2.6}$$

where $J_\nu(z)$ is the standard Bessel function[21] of order ν. The functions (2.6) are often referred to as zonal functions.

There is a remarkable difference for the functions $\chi^{(d)}(kr)$ if one compares even and odd dimensions. For example, one has in $d=2$ dimensions $\chi^{(2)}(kr) = J_0(kr)$ and in $d=3$ dimensions $\chi^{(3)}(kr) = (\pi/2)^{1/2}J_{1/2}(kr)/(kr)^{1/2} = j_0(kr)$ with the spherical Bessel function $j_0(z)$ of zeroth order.[21] In $d=2$ dimensions, $J_0(z)$ is a complicated infinite series in the argument z, in $d=3$ dimensions, however, $j_0(z)$ is the simple ratio $j_0(z) = \sin z/z$. One easily sees how this generalizes. Upon introducing $\xi = \cos\vartheta$ as integration variable in Eq. (2.6), one finds the representation

$$\chi^{(d)}(kr) = \frac{\Gamma(d/2)}{\sqrt{\pi}\Gamma((d-1)/2)} \int_{-1}^{+1} \exp(ikr\xi)(1-\xi^2)^{(d-3)/2}\, d\xi. \tag{2.7}$$

In dimensions $d \geqslant 3$, this can be cast into the form

$$\chi^{(d)}(kr) = \frac{2\Gamma(d/2)}{\sqrt{\pi}\Gamma((d-1)/2)} \sum_{\mu=0}^{\infty} \binom{(d-3)/2}{\mu} \frac{\partial^{2\mu}}{\partial(kr)^{2\mu}} \frac{\sin kr}{kr}. \tag{2.8}$$

For even d, the exponent $(d-3)/2$ is a fraction $-1/2, +1/2, +3/2, \ldots$, and the function $(1-\xi^2)^{(d-3)/2}$ in the integrand in Eq. (2.7) is an *infinite* power series. This yields, for $d=4,6,8,\ldots$, the complicated power series (2.8) involving an infinite number of inverse powers of kr. However, if d is odd, the exponent $(d-3)/2$ is an integer $0,1,2,\ldots$, and the function $(1-\xi^2)^{(d-3)/2}$ is a *finite* polynomial of order $(d-3)/2$ in ξ^2. Thus, $\chi^{(d)}(kr)$ acquires a comparatively simple structure, because it only contains a finite number of inverse powers of kr. Formally, this means that for odd d all binomial coefficients for $\mu > (d-3)/2$ are zero.

The differential equation for the functions $\chi^{(d)}(kr)$ is easily obtained by averaging Eq. (2.1) over the solid angle Ω of $\vec{k}$, i.e., by integrating both sides,

$$\Delta \int d\Omega \exp(i\vec{k}\cdot\vec{r}) = -\vec{k}^2 \int d\Omega \exp(i\vec{k}\cdot\vec{r}). \tag{2.9}$$

We notice that the Laplacian Δ commutes with the integral, because the former is in the space of the position vector, the latter in the space of the wave vector. Moreover, the integral trivially commutes with $\vec{k}^2 = k^2$. Hence, one arrives at

$$\Delta_r \chi^{(d)}(kr) = -k^2 \chi^{(d)}(kr). \tag{2.10}$$

Since $\chi^{(d)}(kr)$ depends exclusively on radial variables, we replaced the full Laplacian Δ with its radial part

$$\Delta_r = \frac{1}{r^{d-1}} \frac{\partial}{\partial r} r^{d-1} \frac{\partial}{\partial r} = \frac{\partial^2}{\partial r^2} + \frac{d-1}{r} \frac{\partial}{\partial r}. \tag{2.11}$$

In general, there are two fundamental solutions $\chi_+^{(d)}(kr)$ and $\chi_-^{(d)}(kr)$ of the differential equation (2.10) which behave as $\exp(\pm ikr)/(kr)^{(d-1)/2}$ for large arguments kr. Thus, to obtain the full solutions, one can make the Hankel ansatz

$$\chi_\pm^{(d)}(kr) = \frac{\exp(\pm ikr)}{(kr)^{(d-1)/2}} w_\pm^{(d)}(kr). \tag{2.12}$$

Here, $w_\pm^{(d)}(kr)$ is a function with the property $w_\pm^{(d)}(kr) \to 1$ for $kr \to \infty$. The differential equation follows easily from Eq. (2.11) and is given by

$$\left(\frac{\partial^2}{\partial r^2} \pm i2k \frac{\partial}{\partial r} - \frac{d-1}{2} \left(\frac{d-1}{2} - 1 \right) \frac{1}{r^2} \right) w_\pm^{(d)}(kr) = 0. \tag{2.13}$$

For $d \geqslant 3$, one uses the ansatz as an asymptotic power series

$$w_\pm^{(d)}(kr) = \sum_{\mu=0}^{\infty} \frac{a_\mu}{(\pm kr)^\mu}, \tag{2.14}$$

which yields a recursion for the coefficients

$$a_{\mu+1} = \frac{1}{i2(\mu+1)} \left(\mu(\mu+1) - \frac{d-1}{2} \left(\frac{d-1}{2} - 1 \right) \right) a_\mu, \tag{2.15}$$

with the starting value $a_0 = 1$. A special situation occurs when the integer running index μ reaches the critical value $\mu_c = (d-3)/2$. If d is odd, μ_c is integer and the recursion terminates at $\mu = \mu_c$, i.e., one has $a_\mu = 0$, $\mu > \mu_c$. Thus, the asymptotic series becomes a *finite* polynomial in inverse powers of kr. However, if d is even, μ_c is half-odd integer and the series cannot terminate, it is always *infinite*. This explains the different structure of the Bessel functions in even and odd dimensional spaces from the viewpoint of the differential equation.

In Appendix A we discuss an alternative integral representation which has an interesting analog in the matrix space.

III. MATRIX BESSEL FUNCTIONS

We compile the basics features of the matrix spaces we want to work with in Sec. III A before we define the matrix Bessel functions as group integrals in Sec. III B.

Two general aspects are shifted into the appendices. First, we present an interesting alternative integral representation in Appendix B. Second, the matrix Bessel functions play a crucial role in harmonic analysis or, equivalently, in Fourier–Bessel analysis in matrix spaces. For the general theory, we refer the reader to Harish-Chandra's treatise in Ref. 4 and to Helgason's book.[3] However, to achieve our goal of being explicit, we collect, for the convenience of the reader, some results for the Fourier–Bessel analysis of invariant functions in matrix spaces in Appendix C.

A. Basics and notation

We introduce $N \times N$ matrices H whose elements H_{nm}, $n,m = 1,\ldots,N$ are real, complex, or quaternion variables. In other words, each element H_{nm} has β real components $H_{nm}^{(\alpha)}$, $\alpha = 0,\ldots,(\beta-1)$ with $\beta = 1,2,4$, respectively,

$$H_{nm}=\sum_{\alpha=0}^{\beta-1} H_{nm}^{(\alpha)}\tau^{(\alpha)}. \tag{3.1}$$

Here, we use the basis $\tau^{(\alpha)}$, $\alpha=0,\ldots,(\beta-1)$. We have $\tau^{(0)}=1$ for the real case with $\beta=1$. For the complex case with $\beta=2$, we have $\tau^{(0)}=1$ and $\tau^{(1)}=i$. Finally, we have

$$\tau^{(0)}=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix},\quad \tau^{(1)}=\begin{bmatrix}0 & +1\\ -1 & 0\end{bmatrix},$$
$$\tau^{(2)}=\begin{bmatrix}0 & -i\\ -i & 0\end{bmatrix},\quad \tau^{(3)}=\begin{bmatrix}+i & 0\\ 0 & -i\end{bmatrix} \tag{3.2}$$

in the quaternion case for $\beta=4$ where the $\tau^{(\alpha)}$, $\alpha=1,2,3$ are the Pauli matrices. We notice that the total H is a $2N\times 2N$ matrix for $\beta=4$. However, here and in the following, the dimensions that we use always refer to the number of matrix elements such as H_{nm}. These are scalar for $\beta=1,2$ and quaternion for $\beta=4$. The label β is often referred to as Dyson index.

We assume that the matrix H is real symmetric, Hermitian, or Hermitian self-dual in the three cases $\beta=1,2,4$. We always write $H^{\dagger}=H$ to indicate this symmetry. There are N independent real variables $H_{nn}=H_{nn}^{(0)}$, $n=1,\ldots,N$ on the diagonal and $\beta N(N-1)/2$ independent real variables $H_{nm}^{(\alpha)}$, $\alpha=0,\ldots,(\beta-1),1\leqslant n<m\leqslant N$ outside the diagonal. We write the volume element of H in the form

$$\mathrm{d}[H]=\prod_{n=1}^{N}\mathrm{d}H_{nn}^{(0)}\prod_{n<m}\prod_{\alpha=0}^{\beta-1}\mathrm{d}H_{nm}^{(\alpha)}. \tag{3.3}$$

The matrix H is diagonalized by the matrix U, with columns U_n, $n=1,\ldots,N$. Depending on the value of β, the matrix U is either orthogonal, unitary, or unitary-symplectic. Following Gilmore's notation,[22] we write $U\in \mathrm{U}(N;\beta)$ with $\mathrm{U}(N;1)=\mathrm{SO}(N)$, $\mathrm{U}(N;2)=\mathrm{U}(N)$ and $\mathrm{U}(N;4)=\mathrm{USp}(2N)$. The volume of these groups is given by

$$\mathrm{vol}\,\mathrm{U}(N;\beta)=\prod_{n=1}^{N}\frac{2\pi^{\beta n/2}}{\Gamma(\beta n/2)}=\frac{2^N\pi^{\beta N(N+1)/4}}{\Pi_{n=1}^{N}\Gamma(\beta n/2)}. \tag{3.4}$$

We use it to normalize the invariant measure $\mathrm{d}\mu(U)$ of $U\in\mathrm{U}(N;\beta)$ to unity,

$$\int \mathrm{d}\mu(U)=1. \tag{3.5}$$

The N real eigenvalues x_n, $n=1,\ldots,N$ of H are ordered in the diagonal matrix x. We have $x=\mathrm{diag}(x_1,\ldots,x_N)$ for $\beta=1$ and $\beta=2$. For $\beta=4$, the eigenvalues are doubly degenerate and we have $x=\mathrm{diag}(x_1,x_1,\ldots,x_N,x_N)$. Physically, this doubling of the eigenvalues is due to Kramer's degeneracies. Thus, the diagonalization reads

$$H=U^{\dagger}xU,\quad \text{with}\quad H_{nm}=U_n^{\dagger}xU_m. \tag{3.6}$$

The diagonalizing matrix U has the property $U^{-1}=U^{\dagger}$. The volume element in eigenvalue–angle coordinates is given by[15,23]

$$\mathrm{d}[H]=C_N^{(\beta)}|\Delta_N(x)|^{\beta}\mathrm{d}[x]\mathrm{d}\mu(U) \tag{3.7}$$

where $\mathrm{d}[x]$ denotes the product of all differentials dx_n. We have introduced the Vandermonde determinant

$$\Delta_N(x) = \prod_{n<m} (x_n - x_m). \tag{3.8}$$

The normalization constant

$$C_N^{(\beta)} = \frac{\pi^{\beta N(N-1)/4}}{N!} \frac{\Gamma^N(\beta/2)}{\Pi_{n=1}^N \Gamma(\beta n/2)} \tag{3.9}$$

obtains from the constants given in Mehta's book[15] and from Eq. (3.4).

To avoid inconveniences and to ensure a compact notation, we define the trace Tr and the determinant Det with Tr=tr and Det=det for $\beta=1,2$ and with

$$\mathrm{Tr}\, K = \tfrac{1}{2}\mathrm{tr} K, \quad \mathrm{Det}\, K = \sqrt{\det K} \tag{3.10}$$

in the case $\beta=4$ for a matrix K with quaternion entries. If k denotes the diagonal matrix of the eigenvalues of a real-symmetric, Hermitian or Hermitean self-dual matrix, it is also useful to define the associate matrix $\hat{k}$. In all three cases β, it is the $N\times N$ matrix $\hat{k} = \mathrm{diag}(k_1, k_2, ..., k_N)$, i.e., we have $\hat{k}=k$ for $\beta=1,2$ and no degeneracies for $\beta=4$.

B. Integral definition and differential equation

As in the case of vector Bessel functions, we start in the matrix case with the plane wave. For two matrices H and K with the same symmetries $H^\dagger = H$ and $K^\dagger = K$, we introduce the matrix plane wave as $\exp(i\,\mathrm{Tr}\, HK)$ where the trace is the proper scalar product in the matrix space. The matrix plane wave has the property

$$\frac{1}{(2\pi)^N \pi^{\beta N(N-1)/2}} \int \mathrm{d}[H] \exp(i\mathrm{Tr}\, HK) = \delta(K), \tag{3.11}$$

where $\delta(K)$ is the product of the δ distributions of all independent variables. We define the matrix gradient $\partial/\partial H$ and the Laplacian operator

$$\Delta = \mathrm{Tr} \frac{\partial^2}{\partial H^2} = \sum_{n=1}^{N} \frac{\partial^2}{\partial H_{nn}^{(0)2}} + \frac{1}{2} \sum_{n<m} \sum_{\alpha=0}^{\beta-1} \frac{\partial^2}{\partial H_{nm}^{(\alpha)2}}, \tag{3.12}$$

which acts on the matrix plane wave as

$$\Delta \exp(i\,\mathrm{Tr}\, HK) = -\,\mathrm{Tr}\, K^2 \exp(i\mathrm{Tr}\, HK). \tag{3.13}$$

We notice that, for $\beta=4$, inconvenient factors of 2 would occur if we used tr instead of Tr.

Analogously to vector Bessel functions, we define the matrix Bessel functions as the angular average

$$\Phi_N^{(\beta)}(x,k) = \int \mathrm{d}\mu(U) \exp(i\,\mathrm{Tr}\, HK). \tag{3.14}$$

The diagonal matrix k contains the eigenvalues of K, which is diagonalized by a matrix V such that $K = V^\dagger k V$. Due to the invariance of the measure $\mathrm{d}\mu(U)$, the matrix V is absorbed and the functions $\Phi_N^{(\beta)}(x,k)$ depend on the eigenvalues x and k only,

$$\Phi_N^{(\beta)}(x,k) = \int \mathrm{d}\mu(U) \exp(i\,\mathrm{Tr}\, U^\dagger x U k). \tag{3.15}$$

Thus, in the scalar product $\mathrm{Tr}\, HK$, solely the relative angles between H and K matter. The matrix Bessel functions are symmetric in the arguments,

$$\Phi_N^{(\beta)}(x,k)=\Phi_N^{(\beta)}(k,x) \tag{3.16}$$

and normalized to unity,

$$\Phi_N^{(\beta)}(x,0)=1, \quad \Phi_N^{(\beta)}(0,k)=1 \tag{3.17}$$

due to Eq. (3.5). These are spherical functions in the sense of Ref. 2.

As in the vector case, the differential equation is obtained by averaging Eq. (3.13) over the relative angles,

$$\Delta \int \mathrm{d}\mu(V)\exp(i\,\mathrm{Tr}\,HK)=-\mathrm{Tr}\,K^2 \int \mathrm{d}\mu(V)\exp(i\,\mathrm{Tr}\,HK). \tag{3.18}$$

Again, the Laplacian Δ commutes with the integral, because the former is in the space of the matrix H, the latter over the diagonalizing matrix V of K. The integral also commutes with $\mathrm{Tr}\,K^2=\mathrm{Tr}\,k^2$. Due to the symmetry between H and K, the integral is obviously identical to the definition (3.15) and we find

$$\Delta_x \Phi_N^{(\beta)}(x,k)=-\mathrm{Tr}\,k^2\,\Phi_N^{(\beta)}(x,k). \tag{3.19}$$

Since the matrix Bessel function $\Phi_N^{(\beta)}(x,k)$ depends only on the radial variables, i.e., on the eigenvalues, we replaced the full Laplacian with its radial part Δ_x. Because of the transformation rule (3.7), it reads

$$\begin{aligned}\Delta_x &= \sum_{n=1}^{N} \frac{1}{|\Delta_N(x)|^\beta}\frac{\partial}{\partial x_n}|\Delta_N(x)|^\beta \frac{\partial}{\partial x_n} \\ &= \sum_{n=1}^{N}\frac{\partial^2}{\partial x_n^2}+\sum_{n<m}\frac{\beta}{x_n-x_m}\left(\frac{\partial}{\partial x_n}-\frac{\partial}{\partial x_m}\right).\end{aligned} \tag{3.20}$$

We notice that these steps are fully parallel to the corresponding discussion in Sec. II. Importantly, due to the symmetry (3.16), the functions $\Phi_N^{(\beta)}(x,k)$ must also solve the differential equation in the k_n, $n=1,\ldots,N$, which results from Eq. (3.19) by exchanging x and k. Obviously, this a very restrictive requirement.

Comparing the radial operator (2.10) in the vector case and the radial operator (3.20), we see that it is the β that corresponds to the *spatial* dimension d or, more precisely, to $d-1$. The role played by the *matrix* dimension N is a different one. To illustrate this, we study the two simplest cases. First, we can formally set $N=1$ and find from the definition (3.14) that $\Phi_1^{(\beta)}(x,k)=\exp(ix_1k_1)$, where $H_{11}=x_1$ and $K_{11}=k_1$. In this case, the matrix U has dropped out trivially. This reflects simply that the scalar product $\vec{k}\cdot\vec{r}$ is linear in the relative solid angle Ω between the vectors whereas the scalar product $\mathrm{Tr}\,HK$ is quadratic in the relative diagonalizing matrix U. The corresponding radial Laplacian Δ_x for $N=1$ is identical to the Cartesian Δ. Therefore, the case $N=1$ is too trivial to give any further insight. Second, we set $N=2$ and find straightforwardly from the differential equation (3.19)

$$\Phi_2^{(\beta)}(x,k)=\exp\left(i\frac{(x_1+x_2)(k_1+k_2)}{2}\right)\chi^{(\beta+1)}\left(\frac{(x_1-x_2)(k_1-k_2)}{2}\right), \tag{3.21}$$

where $\chi^{(d)}$ is the vector Bessel function in d dimensions as defined in Eq. (2.3). This functions appears in the solution, because the differences x_1-x_2 and k_1-k_2 directly correspond to the lengths $|\vec{r}|$ and $|\vec{k}|$. In higher matrix dimensions N, this simple correspondence is lost. However, we will see in great detail that the features of the functions $\Phi_N^{(\beta)}(x,k)$, in particular whether or not explicit solutions can be constructed, are more strongly influenced by β than by N.

Another point in this context deserves to be underlined. In the vector case, the differential equation (2.10) and the solution (2.6) were constructed for integer dimensions d. However, both equations are also well defined for any real and positive d. Similarly, we observe in the matrix case that the differential equation (3.19) was derived for the cases $\beta=1,2,4$. However, neither itself nor its solution (3.21) for $N=2$ are confined to these cases $\beta=1,2,4$, they are valid for any real and positive β. Thus, the cases $\beta=1,2,4$ which correspond to a matrix model, i.e., to the defining integral (3.14) of the matrix Bessel functions, are only special cases of a much more general problem, namely finding the solutions of the differential equation (3.19) for every integer N and for *arbitrary* real values of β. We will return to this in Sec. V.

IV. RECURSION FORMULA

The matrix Bessel functions show a recursive structure which we construct by introducing radial Gelfand–Tzetlin coordinates. The result is stated in Sec. IV A and derived in Sec. IV B. The corresponding invariant measure is calculated in Sec. IV C.

A. Statement of the result

The matrix Bessel functions, defined in Eq. (3.15),

$$\Phi_N^{(\beta)}(x,k)=\int \mathrm{d}\mu(U)\exp(i\,\mathrm{Tr}\,U^{\dagger}xUk) \tag{4.1}$$

depend on the radial space of the eigenvalues x and k. As before, we write $x=\mathrm{diag}(x_1,...,x_N)$ and $k=\mathrm{diag}(k_1,...,k_N)$ for $\beta=1,2$ and, for $\beta=4$, we write $x=\mathrm{diag}(x_1,x_1,...,x_N,x_N)$ and $k=\mathrm{diag}(k_1,k_1,...,k_N,k_N)$. We emphasize that the radial spaces do not lie in the manifolds covered by the groups $\mathrm{U}(N;\beta)$. However, we will show that the group integral (4.1) can be exactly mapped onto a recursive structure which acts exclusively in the radial space. This remarkable feature is the main result of this section.

Under rather general circumstances, the matrix Bessel functions $\Phi_N^{(\beta)}(x,k)$ can be calculated iteratively by the explicit *recursion formula*

$$\Phi_N^{(\beta)}(x,k)=\int \mathrm{d}\mu(x',x)\exp(i\,(\mathrm{Tr}\,x-\mathrm{Tr}\,x')k_N)\Phi_{N-1}^{(\beta)}(x',\tilde{k}), \tag{4.2}$$

where $\Phi_{N-1}^{(\beta)}(x',\tilde{k})$ is the group integral (4.1) over $\mathrm{U}(N-1;\beta)$. We have introduced the diagonal matrix $\tilde{k}=\mathrm{diag}(k_1,...,k_{N-1})$ for $\beta=1,2$ and $\tilde{k}=\mathrm{diag}(k_1,k_1,...,k_{N-1},k_{N-1})$ for $\beta=4$ such that $k=\mathrm{diag}(\tilde{k},k_N)$ for $\beta=1,2$ and $k=\mathrm{diag}(\tilde{k},k_N,k_N)$ for $\beta=4$. Importantly, the $N-1$ integration variables x_n', $n=1,\ldots,N-1$, ordered in the diagonal matrix $x'=\mathrm{diag}(x_1',...,x_{N-1}')$ for $\beta=1,2$ and $x'=\mathrm{diag}(x_1',x_1',...,x_{N-1}',x_{N-1}')$ for $\beta=4$ are arguments of $\Phi_{N-1}^{(\beta)}(x',\tilde{k})$. Moreover, we notice that their further appearance in the exponential is a simple one due to the trace.

The coordinates x' are constructed in the spirit of, but they are different from, the Gelfand–Tzetlin coordinates of Refs. 24 and 25. To clearly distinguish these two sets of coordinates from each other, we refer to the latter as *angular* Gelfand–Tzetlin coordinates and to the variables x' as *radial* Gelfand–Tzetlin coordinates. The difference is at first sight minor, but of crucial importance. In the angular case, x is in the Cartan subalgebra belonging to $\mathrm{U}(N;\beta)$. In the radial case, however, x is in the *radial* space of the eigenvalues of the real-symmetric, Hermitian, or Hermitian self-dual matrix H, which are the arguments of the functions (4.1). While the angular Gelfand–Tzetlin coordinates never leave the group space, the radial ones establish an exact and unique relation between the group and the radial space. The radial Gelfand–Tzetlin coordinates reparametrize the sphere that is described by the Nth column U_N of the matrix $U\in\mathrm{U}(N;\beta)$. The recursion formula (4.2) can only be constructed in the radial coordinates x', but not in the angular ones. The radial and the angular Gelfand–Tzetlin coordinates are, in general, different. They happen to coincide for $\beta=2$, i.e., for the unitary group $\mathrm{U}(N)$. This illustrates, in the framework of our recursion formula, the special role played by the unitary group.

The invariant measure $d\mu(x',x)$ is, apart from phase angles, the invariant measure $d\mu(U_N)$ on the sphere in question, expressed in the radial coordinates x'. It only contains algebraic functions and reads explicitly

$$d\mu(x',x)=\frac{2^{N-1}\Gamma(N\beta/2)}{\pi^{N(\beta-2)(\beta-4)/6}}\frac{\Delta_{N-1}(x')}{\Delta_N^{\beta-1}(x)}\left(-\prod_{n,m}(x_n-x'_m)\right)^{(\beta-2)/2}d[x']. \tag{4.3}$$

The normalization constant obtains from results in Gilmore's book.[22] It ensures normalization to unity according to Eq. (3.5). The domain of integration is compact and given by

$$x_n\leqslant x'_n\leqslant x_{n+1},\quad n=1,\ldots,(N-1), \tag{4.4}$$

reflecting a ''betweenness condition'' for the radial Gelfand–Tzetlin coordinates. This is why no absolute value signs appear in the measure (4.3).

The general recursion formula (4.2) states an iterative way for constructing the matrix Bessel function $\Phi_N^{(\beta)}(x,k)$ for arbitrary N from the matrix Bessel function $\Phi_2^{(\beta)}(x,k)$ for $N=2$ which can usually be obtained trivially. We remark that the recursion formula allows one to express the matrix Bessel functions in the form

$$\begin{aligned}\Phi_N^{(\beta)}(x,k)=&\int\prod_{n=1}^{N-1}d\mu(x^{(n)},x^{(n-1)})\\&\times\exp(i(\mathrm{Tr}\,x^{(n-1)}-\mathrm{Tr}\,x^{(n)})k_{N-n+1})\exp(ix_1^{(N-1)}k_1),\end{aligned} \tag{4.5}$$

where we have introduced the radial Gelfand–Tzetlin coordinates $x_m^{(n)}$, $m=1,\ldots,N-n$ on $N-1$ levels $n=1,\ldots,(N-1)$. We define $x^{(0)}=x$ and $x^{(1)}=x'$.

B. Derivation

We introduce a matrix $V=\mathrm{diag}(\tilde{V},V_0)$ with $\tilde{V}\in\mathrm{U}(N-1;\beta)$ and $V_0\in\mathrm{U}(1;\beta)$ such that $V\in\mathrm{U}(N-1;\beta)\otimes\mathrm{U}(1;\beta)\subset\mathrm{U}(N;\beta)$ and multiply the right-hand side of the definition (4.1) with

$$1=\int d\mu(V)=\int d\mu(V_0)\int d\mu(\tilde{V}). \tag{4.6}$$

The invariance of the Haar measure $d\mu(U)$ allows us to replace U with $UV^\dagger$ and to write

$$\Phi_N^{(\beta)}(x,k)=\int d\mu(V_0)\int d\mu(\tilde{V})\int d\mu(U)\exp(i\,\mathrm{Tr}\,U^\dagger xUV^\dagger kV). \tag{4.7}$$

We collect the first $N-1$ columns U_n of U in the $N\times(N-1)$ rectangular matrix B such that $B=[U_1\,U_2\cdots U_{N-1}]$ and $U=[B\,U_N]$. We notice that

$$\begin{aligned}B^\dagger B&=1_{N-1},\\BB^\dagger&=\sum_{n=1}^{N-1}U_nU_n^\dagger=1_N-U_NU_N^\dagger.\end{aligned} \tag{4.8}$$

As already stated in Sec. III A, the elements of a vector or a matrix are scalar for $\beta=1,2$ and quaternion for $\beta=4$. In this sense, we also write 1_N as the unit matrix for $\beta=4$ because its elements are $\tau^{(0)}$. By defining the $(N-1)\times(N-1)$ square matrices $\tilde{H}=B^\dagger xB$ and $\tilde{K}=\tilde{V}^\dagger\tilde{k}\tilde{V}$ we may rewrite the trace in Eq. (4.7) as

$$\mathrm{Tr}\,U^\dagger xUV^\dagger kV=\mathrm{Tr}\,\tilde{H}\tilde{K}+H_{NN}k_N \tag{4.9}$$

with $H_{NN}=U_N^\dagger x U_N$ according to Eq. (3.6). We notice that V_0 has dropped out. Since the first term of the right-hand side of Eq. (4.9) depends only on the first $N-1$ columns U_n collected in B and the second term depends only on U_N, we use the decomposition

$$\mathrm{d}\mu(U)=\mathrm{d}\mu(B)\mathrm{d}\mu(U_N) \tag{4.10}$$

of the measure to cast Eq. (4.7) into the form

$$\Phi_N^{(\beta)}(x,k)=\int \mathrm{d}\mu(U_N)\exp(iH_{NN}k_N)\int \mathrm{d}\mu(\tilde{V})\int \mathrm{d}\mu(B)\exp(i\,\mathrm{Tr}\,\tilde{H}\tilde{K}), \tag{4.11}$$

where we have already done the trivial integration over V_0.

The difficulty to overcome lies in the decomposition (4.10). While $\mathrm{d}\mu(U_N)$ is simply the invariant measure on the sphere described by U_N, the measure $\mathrm{d}\mu(B)$ is rather complicated. Pictorially speaking, the degrees of freedom in $\mathrm{d}\mu(B)$ have always to know that they are locally orthogonal to U_N. Thus, $\mathrm{d}\mu(B)$ depends on U_N. Luckily, there is one distinct set of coordinates that is perfectly suited to this situation. It is the system of the radial Gelfand–Tzetlin coordinates. We construct it by transferring the methods of Ref. 26 for the angular case to the radial case.

The $N\times N$ matrix $(1_N-U_NU_N^\dagger)$ is a projector onto the $(N-1)\times(N-1)$ space obtained from the original $N\times N$ space by slicing off the vector U_N. We project the radial coordinates x onto this space and study its spectrum. The defining equation reads

$$(1_N-U_NU_N^\dagger)\,x\,(1_N-U_NU_N^\dagger)\,E_n'=x_n'\,E_n',\quad n=1,\ldots,N-1. \tag{4.12}$$

Equation (4.12) determines the $N-1$ radial Gelfand–Tzetlin coordinates x_n' and the corresponding vectors E_n' as eigenvalues and eigenvectors of the matrix $(1_N-U_NU_N^\dagger)\,x\,(1_N-U_NU_N^\dagger)$ which has the rank $N-1$. Since we have by construction $U_N^\dagger E_n'=0$, we may as well write

$$(1_N-U_NU_N^\dagger)\,x\,E_n'=x_n'\,E_n',\quad n=1,\ldots,N-1. \tag{4.13}$$

The eigenvalues $x_n', n=1,\ldots,N$ are obtained from the characteristic equation

$$\begin{aligned}0&=\mathrm{Det}((1_N-U_NU_N^\dagger)x-x_n')\\&=\mathrm{Det}(x-x_n')\det(1_N-(x-x_n')^{-1}U_NU_N^\dagger x)\\&=\mathrm{Det}(x-x_n')\left(1-U_N^\dagger\frac{x}{x-x_n'}U_N\right)\\&=-x_n'\,\mathrm{Det}(x-x_n')\,\mathrm{Tr}U_N^\dagger\frac{1_N}{x-x_n'}U_N.\end{aligned} \tag{4.14}$$

Together with the normalization $\mathrm{Tr}\,U_N^\dagger U_N=1$, this yields the N equations

$$\begin{aligned}1&=\mathrm{Tr}\,U_N^\dagger U_N=\sum_{n=1}^{N}\sum_{\alpha=0}^{\beta-1}U_{nN}^{(\alpha)2},\\0&=\mathrm{Tr}\,U_N^\dagger\frac{1_N}{x-x_n'}U_N=\sum_{m=1}^{N}\sum_{\alpha=0}^{\beta-1}\frac{U_{mN}^{(\alpha)2}}{x_m-x_n'},\quad n=1,\ldots,N-1.\end{aligned} \tag{4.15}$$

In these formulas, the trace Tr is only needed in the symplectic case. We notice that the equations for the variables x' depend on the variables x as parameters. We emphasize once more that x in these equations is in the radial space and, in general, not in the Cartan subalgebra of $\mathrm{U}(N;\beta)$.

At this point, it is not clear yet why the introduction of the radial Gelfand–Tzetlin coordinates is at all helpful. The great advantage will reveal itself when we express the matrix $\tilde{H}$ and the matrix element H_{NN} in the trace (4.11) in these coordinates. To this end, we first multiply Eq. (4.12) from the right with $E_n'^{\dagger}$ and sum over n,

$$(1_N - U_N U_N^{\dagger})\, x\, (1_N - U_N U_N^{\dagger}) = \sum_{n=1}^{N-1} x_n' E_n' E_n'^{\dagger}, \tag{4.16}$$

where we used the completeness relation

$$\sum_{n=1}^{N-1} E_n' E_n'^{\dagger} + U_N U_N^{\dagger} = 1_N. \tag{4.17}$$

Taking the trace of the spectral expansion (4.16) we find immediately

$$\mathrm{Tr}\, x - \mathrm{Tr}\, x' = \mathrm{Tr}\, U_N^{\dagger} x U_N = H_{NN}. \tag{4.18}$$

This is a remarkably simple result. An analogous expression exists for the NN matrix element of the unitary group in the theory of angular Gelfand–Tzetlin coordinates for the unitary group.[24,25] Here we have shown that Eq. (4.18) is a general feature in every radial space.

We now turn to the $(N-1)\times(N-1)$ matrix $\tilde{H}$. Its $N-1$ eigenvalues y_n, $n=1,\ldots,N-1$ are determined by the characteristic equation

$$\begin{aligned} 0 &= \mathrm{Det}(\tilde{H} - y_n) = \mathrm{Det}(B^{\dagger} x B - y_n) \\ &= -\frac{1}{y_n} \mathrm{Det}(B B^{\dagger} x - y_n) \\ &= -\frac{1}{y_n} \mathrm{Det}((1_N - U_N U_N^{\dagger}) x - y_n), \end{aligned} \tag{4.19}$$

where we used Eq. (4.8) and reexpressed an $(N-1)\times(N-1)$ determinant as an $N\times N$ determinant. The comparison of Eq. (4.19) with Eq. (4.14) shows that, most advantageously, we have $y_n \equiv x_n'$, $n=1,\ldots,N-1$. Thus we may write

$$\tilde{H} = B^{\dagger} x B = \tilde{U}^{\dagger} x' \tilde{U} \tag{4.20}$$

by introducing the $(N-1)\times(N-1)$ *square* matrix $\tilde{U}$ which diagonalizes $\tilde{H}$. Obviously, $\tilde{U}$ must be a complicated function of the $N\times(N-1)$ *rectangular* matrix B, i.e., of the columns U_n, $n=1,\ldots,N-1$. However, all we need to know is that $\tilde{U}$ must be in the group $\mathrm{U}(N-1;\beta)$ because, by construction, $\tilde{H}$ has the symmetry $\tilde{H}^{\dagger} = \tilde{H}$.

Collecting everything, we cast Eq. (4.11) into the form

$$\begin{aligned} \Phi_N^{(\beta)}(x,k) = &\int \mathrm{d}\mu(x',x) \exp(i(\mathrm{Tr}\, x - \mathrm{Tr} x')k_N) \\ &\times \int \mathrm{d}\mu(\tilde{V}) \int \mathrm{d}\mu(B) \exp(i\, \mathrm{Tr}\, \tilde{U}^{\dagger} x' \tilde{U} \tilde{V}^{\dagger} \tilde{k} \tilde{V}). \end{aligned} \tag{4.21}$$

We may now use the invariance of the Haar measure $\mathrm{d}\mu(\tilde{V})$ to absorb $\tilde{U}$ such that

$$\Phi_N^{(\beta)}(x,k)=\int \mathrm{d}\mu(x',x)\exp(i(\mathrm{Tr}\,x-\mathrm{Tr}\,x')k_N)$$
$$\times\int \mathrm{d}\mu(\widetilde{V})\exp(i\,\mathrm{Tr}\,x'\widetilde{V}^{\dagger}\widetilde{k}\widetilde{V})\int \mathrm{d}\mu(B). \tag{4.22}$$

Thus, the integration over B is trivial and yields unity due to our normalization. The remaining integration over $\widetilde{V}$ gives precisely the matrix Bessel function $\Phi_{N-1}^{(\beta)}(x',\widetilde{k})$. This completes the derivation of the recursion formula in Sec. IV A. The reader experienced with group integration has realized that the introduction of the matrix $V=\mathrm{diag}(\widetilde{V},V_0)$ was not strictly necessary. Alternatively, one could have shown that the measure $\mathrm{d}\mu(B)$ can be identified with $\mathrm{d}\mu(\widetilde{U})$ and have done the corresponding integral. However, we believe that the introduction of V makes this part of the derivation more transparent.

C. Invariant measure

The invariant measure $\mathrm{d}\mu(U_N)$ has to be expressed in terms of the radial coordinates x'. To this end, we first have to solve Eq. (4.15) for the moduli squared of the vector U_N as a function of the new coordinates x'. Since Eq. (4.15) for the total moduli square for all β coincides with the equation for the *angular* Gelfand–Tzetlin coordinates of the unitary group, we can use the results as derived in Refs. 24 and 25. We have in the three cases

$$|U_{nN}|^2=\sum_{\alpha=0}^{\beta-1}(U_{nN}^{(\alpha)})^2=\frac{\Pi_{m=1}^{N-1}(x_n-x'_m)}{\Pi_{m\neq n}(x_n-x_m)}. \tag{4.23}$$

The betweenness condition (4.4) follows from the positive definiteness of this expression. We parametrize the remaining degrees of freedom of U_{nN} in the cases $\beta=2,4$. We set $U_{nN}^{(0)}=\cos\gamma_n^{(1)}$ and $U_{nN}^{(1)}=\sin\gamma_n^{(1)}$ in the case $\beta=2$ and

$$U_{nN}=\begin{bmatrix}\cos\psi_n\exp(i\gamma_n^{(1)}) & \sin\psi_n\exp(i\gamma_n^{(2)})\\ -\sin\psi_n\exp(-i\gamma_n^{(2)}) & \cos\psi_n\exp(-i\gamma_n^{(1)})\end{bmatrix} \tag{4.24}$$

for $\beta=4$ in the basis (3.2). The invariant length element reads

$$\mathrm{Tr}\,\mathrm{d}U_N^{\dagger}\,\mathrm{d}U_N=\sum_{n=1}^{N}\sum_{\alpha=0}^{\beta-1}(\mathrm{d}U_{nN}^{(\alpha)})^2$$
$$=\sum_{n=1}^{N}\left(\frac{1}{4|U_{nN}|^2}(\mathrm{d}|U_{nN}|^2)^2\right.$$
$$\left.+\sum_{i=1}^{\beta/2}|U_{nN}|^2(\mathrm{d}\gamma_n^{(i)})^2+\delta_{\beta 4}|U_{nN}|^2(\mathrm{d}\cos\psi_n)^2\right). \tag{4.25}$$

To express the differential $\mathrm{d}|U_{nN}|^2$ in terms of the $\mathrm{d}x'_n$, we again take advantage of the results in Refs. 24 and 25,

$$\sum_{n=1}^{N}\frac{1}{4|U_{nN}|^2}(\mathrm{d}|U_{nN}|^2)^2=\sum_{n=1}^{N-1}\frac{\Pi_{m=1}^{N-1}(x'_m-x'_n)}{4\Pi_{m=1}^{N}(x_m-x'_n)}(\mathrm{d}x'_n)^2. \tag{4.26}$$

From these equations, we can read off the metric g in the basis of the coordinates x'_n, $\gamma_n^{(i)}$ and ψ_n. Conveniently, it is diagonal. The determinant of g is given by

$$\det g = \frac{\Delta_{N-1}^2(x')}{\Delta_N^{2\beta-2}(x)} \prod_{n,m} (x_n - x'_m)^{(\beta-2)}, \tag{4.27}$$

which yields the invariant measure $d\mu(U_N)$ in terms of the x'_n and of the additional coordinates $\gamma_n^{(j)}$ and ψ_n. These angles can be integrated out trivially. This yields Eq. (4.3).

V. RADIAL FUNCTIONS FOR ARBITRARY β

Remarkably, the recursion introduced in Sec. IV, is the iterative solution of the radial equation for arbitrary values of β. Thus, the matrix Bessel functions are special cases of more general functions which we want to refer to as radial functions. We give the precise formulation of the problem in Sec. V A and show in Sec. V B that the recursion is the general iterative solution. In Sec. V C, we discuss a Hankel ansatz for the radial functions.

A. Definition by the differential equation

In Sec. III B, we defined the matrix Bessel function through the group integral (3.14) or, equivalently, the group integral (3.15). This definition confines the dimension β to the values $\beta = 1,2,4$, corresponding to the groups $U(N;\beta)$. However, discussing the simplest case $N=2$, we already saw in Sec. III B that $\Phi_2^{(\beta)}$ is well defined for *arbitrary* values of β. This was a simple consequence of the explicit form (3.21) which expresses $\Phi_2^{(\beta)}$ in terms of the Bessel function $\chi^{(\beta+1)}$. The latter is known to be well defined for arbitrary β. Hence, we conclude that the cases $\beta=1,2,4$ which relate to matrices and groups are embedded into a space of far more general functions.

It seems natural that this phenomenon also extends to $N>2$. The problem has to be posed as follows: We seek the solutions $\Phi_N^{(\beta)}$ of the differential equation

$$\Delta_x \Phi_N^{(\beta)}(x,k) = -\sum_{n=1}^{N} k_n^2 \Phi_N^{(\beta)}(x,k), \tag{5.1}$$

where the operator is given by

$$\Delta_x = \sum_{n=1}^{N} \frac{\partial^2}{\partial x_n^2} + \sum_{n<m} \frac{\beta}{x_n - x_m} \left(\frac{\partial}{\partial x_n} - \frac{\partial}{\partial x_m} \right). \tag{5.2}$$

Here, β is arbitrary. For technical reasons, however, we restrict ourselves for the time being to real and positive values of β. We make no reference whatsoever to matrices, eigenvalues, and groups. To emphasize this, we view x and k as sets of N variables x_n, $n=1,\ldots,N$ and k_n, $n=1,\ldots,N$ for every positive β. We do not use traces.

We require that the solutions are symmetric in the argument

$$\Phi_N^{(\beta)}(x,k) = \Phi_N^{(\beta)}(k,x) \tag{5.3}$$

and normalized

$$\Phi_N^{(\beta)}(0,k) = 1 \quad \text{or} \quad \Phi_N^{(\beta)}(x,0) = 1 \tag{5.4}$$

at the origin $x=0$ and $k=0$. Due to the symmetry, one of the two normalization conditions suffices.

In the sequel, we want to refer to the functions $\Phi_N^{(\beta)}(x,k)$ for arbitrary β as *radial functions* while we reserve the term *matrix Bessel functions* to the cases $\beta=1,2,4$ where the direct connection to matrices and Lie groups exists.

B. Recursive solution

We claim that the solutions are, for arbitrary β, given as an iteration in N by the recursion formula

$$\Phi_N^{(\beta)}(x,k)=\int \mathrm{d}\mu(x',x)\exp\left(i\left(\sum_{n=1}^{N} x-\sum_{n=1}^{N-1} x' \right) k_N \right) \Phi_{N-1}^{(\beta)}(x',\tilde{k}), \tag{5.5}$$

where $\Phi_{N-1}^{(\beta)}(x',\tilde{k})$ is the solution of the differential equation (5.2) for $N-1$. Here, $\tilde{k}$ denotes the set of variables k_n, $n=1,\ldots,(N-1)$ and x' the set of integration variables x_n', $n=1,\ldots,(N-1)$. The integration measure

$$\mathrm{d}\mu(x',x)=G_N^{(\beta)}\frac{\Delta_{N-1}(x')}{\Delta_N^{\beta-1}(x)}\left(-\prod_{n,m}(x_n-x_m') \right)^{(\beta-2)/2} \mathrm{d}[x'] \tag{5.6}$$

is the continuation of Eq. (4.3) to arbitrary positive β. The normalization constant

$$G_N^{(\beta)}=2^{N-1}\frac{\Gamma(N\beta/2)}{\Gamma^N(\beta/2)} \tag{5.7}$$

is also the continuation of the constant in Eq. (4.3). We calculate it in Appendix F. As in the cases $\beta=1,2,4$, the inequalities

$$x_n\leqslant x_n'\leqslant x_{n+1}, \quad n=1,\ldots,(N-1) \tag{5.8}$$

define the domain of integration.

We stress that we derived the recursion formula (5.5) in Sec. IV for the cases $\beta=1,2,4$. To prove that it is the iterative solution for arbitrary positive β, we show that it solves the differential equation (5.1). The keystone for the proof is the identity

$$\Delta_x\Phi_N^{(\beta)}(x,k)=-k_N^2\Phi_N^{(\beta)}(x,k)+\int \mathrm{d}\mu(x',x)\exp\left(i\left(\sum_{n=1}^{N} x_n-\sum_{n=1}^{N-1} x_n' \right) k_N \right) \Delta_{x'}\Phi_{N-1}^{(\beta)}(x',\tilde{k}), \tag{5.9}$$

which is derived in Appendix D. Equation (5.9) establishes a not immediately obvious, but nevertheless natural connection between, on the one hand, the action of the Laplacian Δ_x in the N variables x_n on the radial function in N dimensions, i.e., on the recursion integral (5.5), and, on the other hand, the recursion integral over the Laplacian $\Delta_{x'}$ in the $N-1$ variables x_n' acting on the radial function in $N-1$ dimensions. There is a compensation term which is just $-k_N^2\Phi_N^{(\beta)}(x,k)$. Thus, we can prove the eigenvalue equation (5.1) by induction: assuming that it is correct for $N-1$, identity (5.9) implies Eq. (5.1) for N. The induction starts with $N=2$ where the eigenvalue equation (5.1) is clearly valid for arbitrary β as shown in Sec. III B by deriving the explicit solution (3.21).

The symmetry relation (5.3) is nontrivial. In the matrix cases $\beta=1,2,4$, it is obvious from the integral definitions (3.14) and (3.15). For arbitrary β, we cannot use this argument, we only have the recursion (5.5). In Appendix E, we prove the symmetry relation (5.3) by an explicit change of variables.

The normalization $\Phi_N^{(\beta)}(x,0)=1$ in Eq. (5.4) follows directly from the normalization of the measure (5.6). The symmetry relation (5.3) then also yields $\Phi_N^{(\beta)}(0,k)=1$.

Regarding the domain of β, a comment is in order. We have seen in Sec. III B that for $N=2$ the matrix Bessel function is well defined for arbitrary complex β. This should also be true for our recursion formula (5.5). However, for $\beta\leqslant 0$ nonintegrable singularities arise at the boundaries in the integral in Eq. (5.5). At the same time the normalization constant becomes zero for $\beta=0$,

$-2,-4,\ldots$, compensating the singularities of the integral. This makes the recursion formula for $\beta \leqslant 0$ not ill-defined but it gets more difficult to treat. Therefore, we have restricted ourselves to positive values of β.

In the work of Okounkov and Olshanski[11] an expansion of the radial functions for arbitrary β in Jack polynomials is derived. The series run over sets of partitions $\{\lambda\}$. These authors also derive a recursion formula for the Jack polynomials depending on one set of continuous variables x, say, and belonging to such partitions $\{\lambda\}$. It is related to, but different from ours, which involves two sets of continuous varables x and k. The crucial difference rests in the exponential function which is present in our formula (5.5), but not in the formula of Ref. 11. Importantly, it is this exponential term which makes sure that the symmetry condition (5.3) is fulfilled on all levels of the recursion. Since the Jack polynomials themselves do not obey such a symmetry condition, there is no exponential term in the recursion formula of Ref. 11. However, it must be possible to derive the recursion formula for the radial functions from the one for the Jack polynomials. An interesting, although probably not very elegant approach would be the following: If one inserted the recursion formula for the Jack polynomials into the expansion[11] of the radial functions in terms of these Jack polynomials, one ought to see that the series over the partitions can, at least partly, be *resummed* to yield the exponential function present in the recursion formula (5.5). This is remarkable and could be very helpful for the application of Jack polynomials, because, in general, resummations over partitions are known to be difficult and involved. For the connection to Calogero–Sutherland models, we refer the reader to Sec. VII.

C. Hankel ansatz

In the spirit of Eq. (2.12) for the vector case, we make a Hankel ansatz for our radial functions for arbitrary positive β. We also do this in view of the applications in Sec. VI. Since the sum over the k_n^2 on the right-hand side of the eigenvalue equation (5.1) is invariant under all permutations of the k_n or, equivalently, their indices n, we can label a set of solutions $\Phi^{(\beta)}_{N,\omega}(x,k)$ by an element ω of the permutation group S_N of N objects. For these solutions, we make the ansatz

$$\Phi^{(\beta)}_{N,\omega}(x,k)=\frac{\exp(i\Sigma_{n=1}^{N}x_n k_{\omega(n)})}{|\Delta_N(x)\Delta_N(k)|^{\beta/2}}\,W^{(\beta)}_{N,\omega}(x,k), \tag{5.10}$$

where $\omega(k)$ is the diagonal matrix constructed from k by permuting the k_n, or the indices n. The full solution $\Phi^{(\beta)}_N(x,k)$, satisfying the constraints (5.3) and (5.4), is then, apart from possible normalization constants, given as the linear combination

$$\Phi^{(\beta)}_N(x,k)=\frac{1}{N!}\sum_{\omega\in S_N}(-1)^{\pi(\omega)}\Phi^{(\beta)}_{N,\omega}(x,k) \tag{5.11}$$

of the functions (5.10). Here, $\pi(\omega)$ is the parity of the permutation.

We find for the function $W^{(\beta)}_{N,\omega}(x,k)$ the differential equation

$$L_{x,\omega(k)}\,W^{(\beta)}_{N,\omega}(x,k)=0, \tag{5.12}$$

where the operator is given by

$$L_{x,\omega(k)}=\sum_{n=1}^{N}\frac{\partial^2}{\partial x_n^2}+i2\sum_{n=1}^{N}k_{\omega(n)}\frac{\partial}{\partial x_n}-\beta\left(\frac{\beta}{2}-1\right)\sum_{n<m}\frac{1}{(x_n-x_m)^2}. \tag{5.13}$$

This differential equation generalizes Eq. (2.13) to the matrix case for $\beta=1,2,4$ and, furthermore, the latter to general radial functions for arbitrary β. Due to the symmetry (5.3), the differential equation (5.12) must also hold if x and $\omega(k)$ are interchanged.

The functions $W^{(\beta)}_{N,\omega}(x,k)$ are translation invariant, i.e., they depend only on the differences (x_n-x_m). We show this in Appendix G. Again, because of the symmetry, this argument carries

over to k, and $W_{N,\omega}^{(\beta)}(x,k)$ depends only on the differences (k_n-k_m) as well. Moreover, the symmetry implies that it depends only on the products $(k_{\omega(n)}-k_{\omega(m)})(x_n-x_m)$.

It is the last term of the operator $L_{x,\omega(k)}$ that makes the differential equation (5.12) so difficult. In the sequel, we are only interested in solutions $W_{N,\omega}^{(\beta)}(x,k)$ which are translation invariant. Moreover, in the case $\beta=2$, when the last term of the operator $L_{x,\omega(k)}$ vanishes, oscillatory solutions can be possible. We exclude them because, first, they are, in general, not translation invariant and, second, they can be absorbed in the oscillatory part of the ansatz (5.10). Thus, we simply have $W_{N,\omega}^{(2)}(x,k)=1$. This is the Itzykson–Zuber case[6] corresponding to unitary matrices $U\in \mathrm{U}(N)$. For arbitrary β, it is obvious from the differential operator that $W_{N,\omega}^{(\beta)}(x,k)\to 1$ if $|x_n-x_m|\to\infty$ for all pairs $n<m$. Once more, this must also be true if $|k_n-k_m|\to\infty$. Thus, we expect that $W_{N,\omega}^{(\beta)}(x,k)$ is some kind of asymptotic series, generalizing Eq. (2.14) in the vector case.

Hence, we rederive a known result by concluding that the leading contribution in an asymptotic expansion of the functions (5.10) is given by

$$\Phi_{N,\omega}^{(\beta)}(x,k)\sim \frac{\exp(i\Sigma_{n=1}^{N}x_nk_{\omega(n)})}{|\Delta_N(x)\Delta_N(k)|^{\beta/2}}. \tag{5.14}$$

According to Eq. (5.11), this means that

$$\Phi_{N}^{(\beta)}(x,k)\sim \frac{\det[\exp(ix_nk_m)]_{n,m=1,\ldots,N}}{|\Delta_N(x)\Delta_N(k)|^{\beta/2}} \tag{5.15}$$

is the asymptotic behavior of the radial functions $\Phi_N^{(\beta)}(x,k)$ if the differences $|x_n-x_m|$ and $|k_n-k_m|$ are large for all pairs $n<m$.

Collecting all pieces of information, we make the ansatz

$$W_{N,\omega}^{(\beta)}(x,k)=\sum_{\{\mu\}}\frac{a_{\mu_{12}\mu_{13}\cdots\mu_{(N-1)N}}}{\Pi_{n<m}((k_{\omega(n)}-k_{\omega(m)})(x_n-x_m))^{\mu_{nm}}} \tag{5.16}$$

with coefficients $a_{\mu_{12}\mu_{13}\cdots\mu_{(N-1)N}}$ that depend on $N(N-1)/2$ integer indices μ_{nm}, as many as there are differences. The summation is over the set of these indices. The presence of the k_n makes it very difficult to solve Eq. (5.12) with the ansatz (5.16). In the vector case, one easily sees that the differential equation (2.13) in r can be transformed into an equation in the dimensionless variables kr such that k does not appear anymore. This leads to the simple recursion (2.15) for the coefficients. Here, in the matrix case, the k_n cannot easily be absorbed and the recursion formulas for the coefficients will depend on the k_n in a nontrivial way. However, in some simple cases, it is possible to solve them. These difficulties were an important motivation for us to develop the methods which we introduced in Sec. IV.

VI. APPLICATIONS

Can we obtain an explicit formula for the radial functions by using the recursion formula (5.5)?—At least in some cases, this ought to be possible. Here, we present some results.

For the sake of completeness, we comment once more on the special case $\beta=2$, i.e., the unitary case. Obviously, the measure (5.6) simplifies enormously. This is so because the radial Gelfand–Tzetlin coordinates coincide with the angular ones. Thus, the case $\beta=2$ is identical to the rederivation of the Itzykson–Zuber integral by Shatashvili.[25]

We now consider the orthogonal case $\beta=1$. The recursion formula reads

$$\Phi_N^{(1)}(x,k)=G_N^{(1)}\int\frac{\Delta_{N-1}(x')}{\sqrt{-\Pi_{n,m}(x_n-x'_m)}}\exp\left(i\left(\sum_{n=1}^{N}x_n-\sum_{n=1}^{N-1}x'\right)k_N\right)\Phi_{N-1}^{(1)}(x',\tilde{k})\mathrm{d}[x']. \tag{6.1}$$

The square roots appearing in the measure make a further evaluation very difficult. As is obvious from the trivial case $N=2$, given in Eq. (3.21), the function $\Phi_N^{(1)}(x,k)$ will be an *infinite* series for all values of N. However, we expect that, due to the different construction, this series is different from the expansion in *zonal functions* which was obtained by Muirhead.[20]

Obviously, there is a pattern emerging. The integration measure (5.6) is purely *rational* for all even and positive values of β. This is reminiscent of the situation for vector Bessel functions in *odd* dimensions d, which consist of a *finite* number of terms, as discussed in Sec. II. Hence, we conjecture that the radial functions $\Phi_N^{(\beta)}(x,k)$ can also be written as a *finite* sum, exclusively containing exponential and rational functions.

For all other values of β, the measure (5.6) is algebraic, but not rational, and the radial functions $\Phi_N^{(\beta)}(x,k)$ must be *infinite* series. Nevertheless, these infinite series contain exponential and rational functions. Thus, they are different from expansions in terms of zonal polynomials.

To furnish our conjecture about the form of the radial functions for even and positive values of β with an illustrative example, we turn to the unitary-symplectic case $\beta=4$. The results given here in the sequel were first derived by the present authors in Ref. 27. Later, they were also given by Brézin and Hikami in Ref. 28.

To simplify the notation we avoid the imaginary unit by writing

$$\Phi_N^{(4)}(-ix,k)=\int_{U\in \mathrm{USp}(2N)} \exp(\mathrm{Tr}\, u^{-1}xuk)\mathrm{d}\mu(U), \tag{6.2}$$

where $x=\mathrm{diag}(x_1,x_1,\ldots,x_N,x_N)$ and $k=\mathrm{diag}(k_1,k_1,\ldots,k_N,k_N)$ are diagonal matrices with Kramers degeneracies. The starting point of the recursion is the smallest nontrivial case $N=2$, i.e., the group USp(4). We obtain after an elementary calculation

$$\Phi_2^{(4)}(-ix,k)=G_2^{(4)}\sum_{\omega\in S_2}\left(\frac{1}{\Delta_2^2(x)\Delta_2^2(\omega(k))}-\frac{2}{\Delta_2^3(x)\Delta_2^3(\omega(k))}\right)\exp(\mathrm{Tr}\, x\omega(k)). \tag{6.3}$$

The sum runs over the elements of the permutation group S_N for $N=2$. Inserting Eq. (6.3) into the recursion formula, we find for USp(6), the next step in the recursion,

$$\Phi_3^{(4)}(-ix,k)=G_3^{(4)}G_2^{(4)}\sum_{\omega\in S_2}\int_{x_1}^{x_2}\mathrm{d}x_1'\int_{x_2}^{x_3}\mathrm{d}x_2'\frac{\Pi_{i=1}^3\Pi_{j=1}^2(x_i-x_j')}{\Delta_3^3(x)\Delta_2^2(\omega(\tilde{k}))}\exp((\mathrm{Tr}\, x-\mathrm{Tr}\, x')k_3+\mathrm{Tr}\, x\omega(\tilde{k}))$$
$$\times\left(\frac{1}{\Delta_2(x')}-\frac{2}{\Delta_2^2(x')\Delta_2(\omega(\tilde{k}))}\right). \tag{6.4}$$

Although the integrand is finite everywhere, in particular at $x_1'=x_2'=x_2$, the denominators $\Delta_2(x')$ and $\Delta_2^2(x')$ raise a technical difficulty. The key to remove them is to use the identity

$$\frac{2}{\Delta_2^2(x')}=-\left(\frac{\partial}{\partial x_1'}-\frac{\partial}{\partial x_2'}\right)\frac{1}{\Delta_2(x')} \tag{6.5}$$

and to observe that the product $\Pi_{i=1}^3\Pi_{j=1}^2(x_i-x_j')$ annihilates all boundary terms. Hence, we can integrate by parts and arrive at

$$\Phi_3^{(4)}(-ix,k)=G_3^{(4)}G_2^{(4)}\sum_{\omega\in S_2}\frac{1}{\Delta_3^3(x)\Delta_2^3(\omega(\tilde{k}))}\int_{x_1}^{x_2}\mathrm{d}x_1'\int_{x_2}^{x_3}\mathrm{d}x_2'\sum_{i=1}^3\prod_{\substack{j=1\\ j\neq i}}^3(x_j-x_1')(x_j-x_2')$$
$$\times\exp((\mathrm{Tr}\, x-\mathrm{Tr}\, x')k_3+\mathrm{Tr}\, x\omega(\tilde{k})), \tag{6.6}$$

where no denominator is left. Due to the permutation symmetry of the original integral, we can restrict ourselves to the unity element e of the permutation group in the further evaluation of Eq. (6.6). Thus we need only to consider the limits $x_i' \to x_i$, $i=1,2$ while integrating by parts. After collecting orders in k we find

$$\Phi_{3,e}^{(4)}(-ix,k) = G_3^{(4)} G_2^{(4)} \frac{1}{\Delta_3^3(x)\Delta_3^3(k)} \left(-\Delta_3(x)\Delta_3(k) + 2\sum_{i<j}^{3} \left(\frac{\Delta_3(x)\Delta_3(k)}{(x_i-x_j)(k_i-k_j)} \right) \right.$$
$$\left. -4\sum_{i<j}^{3} (x_i-x_j)(k_i-k_j) + 12 \right) \exp(\mathrm{Tr}\, xk). \tag{6.7}$$

By introducing the composite variables

$$z_{\omega(ij)} = (x_i - x_j)(k_{\omega(i)} - k_{\omega(j)}), \quad i,j = 1,\ldots,3, \quad \omega \in S_3, \tag{6.8}$$

we can express $\Phi_3^{(4)}(-ix,k)$ in a compact form as

$$\Phi_3^{(4)}(-ix,k) = G_3^{(4)} G_2^{(4)} \sum_{\omega \in S_3} \frac{1}{\Delta_3^3(x)\Delta_3^3(\omega(k))} \left(4 + \prod_{i<j}^{3} (2 - z_{\omega(ij)}) \right) \exp(\mathrm{Tr}\, x\omega(k)). \tag{6.9}$$

So far, we have not been able to extend this procedure to all values of N.

However, we succeeded in calculating $\Phi_4^{(4)}(-ix,k)$, i.e., the case of the group USp(8), by an hybrid method which combines information obtained from the recursion with a Hankel ansatz as described previously. We extend the right hand side of Eq. (6.9) for $N=3$ to $N=4$ and use this expression as an ansatz for the function $W_{N,\omega}^{(4)}(x,k)$. As it turns out, a correction term is needed and, furthermore a correction to the correction. Fortunately, there is a structure to this. We give the details in Appendix H. We emphasize that the knowledge of $\Phi_3^{(4)}(-ix,k)$ is essential for this hybrid procedure, in particular the fact that $\Phi_3^{(4)}(-ix,k)$ contains only linear terms in every composite variable $z_{\omega(ij)}$. Up to a normalization, $\Phi_4^{(4)}(-ix,k)$ is given by

$$\Phi_4^{(4)}(-ix,k) = \sum_{\omega \in S_4} \frac{1}{\Delta_4^3(x)\Delta_4^3(\omega(k))} \left(\prod_{i<j} (2 - z_{\omega(ij)}) + 2^2 \sum_{l<m<n} \prod_{\substack{i<j \\ \neq lm \\ \neq ln \\ \neq mn}} (2 - z_{\omega(ij)}) \right.$$
$$\left. + 2^3 \sum_{\substack{l<m \\ k<n}} \prod_{\substack{i<j, \neq lk, \neq ln \\ \neq mk, \neq mn, \neq kn}} (2 - z_{\omega(ij)}) \right) \exp(\mathrm{Tr}\, x\omega(k)). \tag{6.10}$$

Comparing this result with Eq. (6.9) we notice that, once more, the composite variables $z_{\omega(ij)}$ enter only linearly in the polynomial part of $\Phi_4^{(4)}(-ix,k)$. Similarly, the spherical Bessel function $j_1(z)$, which is the counterpart of $\Phi_N^{(4)}(x,k)$ in the vector case given in Eqs. (2.6) and (3.21), has a polynomial part linear in z. We expect that such analogies are also present for higher values of β and the dimension d.

Formula (6.10) indicates a general structure for $\Phi_N^{(4)}(x,k)$. The leading term is always the generating function of the elementary symmetric functions in z. To this term combinations of other symmetric functions are added, where certain combinations of indices are cut out. In the supersymmetric case, we could apply the present method in even more complicated cases and also find explicit results.[40]

VII. CONNECTION TO CALOGERO–SUTHERLAND MODELS

The radial functions are related to, but different from, the eigenfunctions which are usually employed in models of the Calogero–Sutherland type. Since this issue is so important for applications and so often raised in discussions, we briefly collect the main points.

The radial Laplace operator defined in Eq. (5.2) is closely related to the Calogero–Sutherland Hamiltonians. In general one can always cast a Fokker–Planck operator in a Hamilton operator by adjunction[29] with the square root of the stationary probability distribution defined through $\Delta_x P_{\mathrm{eq}}(x)=0$. Choosing $P_{\mathrm{eq}}(x)=|\Delta_N(x)|^{-\beta/2}$, the operator (5.2) can be associated with the Hamiltonian

$$H_D=-\sum_{n=1}^{N}\frac{\partial^2}{\partial x_n^2}+\frac{\beta(\beta-2)}{2}\sum_{n<m}^{N}\frac{1}{(x_n-x_m)^2}. \tag{7.1}$$

It describes a scattering system with a continuous spectrum, the large time behavior is determined by the states near the ground state. Apart from a sign, this operator H_D coincides with the operator $L_{x,0}$ in Eq. (5.13) for $k=0$. We also notice that the interaction vanishes for $\beta=2$.

To have a well-defined thermodynamic limit one often confines the motion of the particles to a circle. This yields the Calogero–Sutherland Hamiltonian

$$H_{\mathrm{CS}}=-\sum_{n=1}^{N}\frac{\partial^2}{\partial x_n^2}+\frac{\beta(\beta-2)}{2}\sum_{n<m}^{N}\frac{(\pi/N)^2}{\sin^2(\pi(x_n-x_m)/N)}, \tag{7.2}$$

which can also be derived directly from Dyson's circular ensembles.[15] Another way of confining the particles is by a harmonic potential. This leads to the Calogero Hamiltonian[30]

$$H_C=-\sum_{n=1}^{N}\frac{\partial^2}{\partial x_n^2}+\frac{\beta(\beta-2)}{2}\sum_{n<m}^{N}\frac{1}{(x_m-x_m)^2}+\frac{1}{16}\sum_{n=1}^{N}x_n^2. \tag{7.3}$$

In the thermodynamic limit the particle density $R_1(x)$ of the ground state is described by Wigner's semicircle law. The mean particle level spacing $D=1/R_1(0)$ scales as $D\propto 1/\sqrt{N}$. Therefore in the thermodynamic limit the harmonic confining term in Eq. (7.3) vanishes on the scale of the mean level spacing. On this *unfolded scale* the correlation functions become independent of the confinement mechanism. The three Hamiltonians H_C, H_D, and H_{CS} are known to be integrable systems for arbitrary β.[31] However, the three values $\beta=1,2,4$ are distinguished, since they establish a connection to the random matrix ensembles. Indeed, for these values of β they belong to a much wider class of integrable systems, which can be constructed by means of the root space of a simple Lie algebra or—still more generally—of a Kac–Moody algebra.[5] This class comprises Hamiltonians which can be derived by an adjunction procedure from a Laplace–Beltrami operator of a group acting in a symmetric space. This space has positive curvature for H_{CS} and zero curvature for H_D, H_C. In Refs. 32 and 33 it was pointed out that the Dorokhov–Mello–Pereyra–Kumar equation for scattering matrices with broken time reversal symmetry corresponds to a Laplace–Beltrami operator in a symmetric space of negative curvature.
