$$H_c(\mathbf{h}, \epsilon^2, \lambda\epsilon) \leqslant a(\mathbf{h})\epsilon + O(\epsilon^3). \tag{4.28}$$

From (4.6) and (4.28) we get conclusion (i). □

We next consider the case where κ is fixed. To describe the minimal solutions we need the vector field $\mathbf{F}_\mathbf{h}$ [see (1.6)], the function $w_\mathbf{h}$ [see (2.3)], and the function $\psi_\mathbf{h}$ which is the unique solution of the following equation:

$$\begin{aligned}
&-\Delta \psi = 2\mathbf{F}_\mathbf{h} \cdot \nabla w_\mathbf{h} - |\mathbf{F}_\mathbf{h}|^2 + \omega(\mathbf{h}) \quad \text{in } \Omega, \\
&\frac{\partial \psi}{\partial \nu} = -w_\mathbf{h} \mathbf{F}_\mathbf{h} \cdot \nu \quad \text{on } \partial\Omega, \quad \int_\Omega \psi \, dx = 0.
\end{aligned} \tag{4.29}$$

Note that $\psi_\mathbf{h}$ can be represented by

$$\psi_\mathbf{h} = \frac{w_\mathbf{h}^2}{2} + \frac{1}{2} \fint_\Omega w_\mathbf{h}^2 \, dx + \phi_\mathbf{h},$$

where $\phi_\mathbf{h}$ satisfies

$$\begin{aligned}
&-\Delta \phi_\mathbf{h} = \omega(\mathbf{h}) - |\mathbf{F}_\mathbf{h} - \nabla w_\mathbf{h}|^2 \quad \text{in } \Omega, \\
&\frac{\partial \phi_\mathbf{h}}{\partial \nu} = 0 \quad \text{on } \partial\Omega, \quad \int_\Omega \phi_\mathbf{h} \, dx = 0.
\end{aligned} \tag{4.30}$$

Theorem 4.2: *Let* $\mathbf{h}$ *be a unit vector and* $\kappa>0$ *be fixed.*

(i) As $\mu\to 0$,

$$H_c(\mathbf{h},\mu,\kappa)=a(\mathbf{h})\sqrt{\mu}+O(\mu^{3/2}). \tag{4.31}$$

(ii) Assume $\sigma=a\sqrt{\mu}$, *where* a *is fixed and* $0<a<a(\mathbf{h})$. *Let* $(\psi_\mu,\mathbf{A}_\mu)$ *be a minimal solution of (1.5). Then we have, as* $\mu\to 0$,

$$\begin{gathered}\psi_\mu=c_\mu[1+ia\sqrt{\mu}w_{\mathbf{h}}+a^2\mu\psi_{\mathbf{h}}+O(\mu^{3/2})],\\ \mathbf{A}_\mu=\mathbf{F}_{\mathbf{h}}+\frac{\mu|c_\mu|^2}{\kappa^2}\mathbf{U}_{\mathbf{h}}+O(\mu^{3/2}),\\ |c_\mu|=\sqrt{1-\left(\frac{a}{a(\mathbf{h})}\right)^2}+O(\sqrt{\mu}).\end{gathered} \tag{4.32}$$

(iii) Assume $\sigma=a_\mu\sqrt{\mu}<H_c(\mathbf{h},\mu,\kappa)$, *where* $a_\mu\to a(\mathbf{h})$ *as* $\mu\to 0$. *The minimizer* $(\psi_\mu,\mathbf{A}_\mu)$ *has the expansions*

$$\begin{gathered}\psi_\mu=l_\mu(1+ia_\mu\sqrt{\mu}w_{\mathbf{h}}+\mu v_\mu),\\ \mathbf{A}_\mu=\mathbf{F}_{\mathbf{h}}+\frac{\mu|l_\mu|^2}{\kappa^2}\mathbf{U}_{\mathbf{h}}+O(\mu^{3/2}|l_\mu|^2),\\ |l_\mu|^2+\mu\int_\Omega|\nabla v_\mu|^2\,dx\leqslant C\mu+2\left[1-\left(\frac{a_\mu}{a(\mathbf{h})}\right)^2\right].\end{gathered} \tag{4.33}$$

Proof: Write $\epsilon=\sqrt{\mu}$ and $\sigma=a\sqrt{\mu}=a\epsilon$. Then

$$\mathcal{G}[\psi,\mathbf{A}]=\int_\Omega\left\{|\nabla_{a\epsilon\mathbf{A}}\psi|^2+\frac{\epsilon^2}{2}(1-|\psi|^2)^2\right\}dx+a^2\kappa^2\int_{\mathbb{R}^3}|\operatorname{curl}\mathbf{A}-\mathbf{h}|^2\,dx,$$

and (1.5) is written as

$$\begin{gathered}-\nabla^2_{a\epsilon\mathbf{A}}\psi=\epsilon^2(1-|\psi|^2)\psi\quad\text{in }\Omega,\\ \operatorname{curl}^2\mathbf{A}=\frac{\epsilon}{a\kappa^2}\Im\{\overline{\psi}\nabla_{a\epsilon\mathbf{A}}\psi\}\chi_\Omega\quad\text{in }\mathbb{R}^3,\\ (\nabla_{a\epsilon\mathbf{A}}\psi)\cdot\nu=0,\quad[\nu\cdot\mathbf{A}]=0,\quad[\nu\times\operatorname{curl}\mathbf{A}]=0\quad\text{on }\partial\Omega,\\ \operatorname{curl}\mathbf{A}\to\mathbf{h}\quad\text{as }|x|\to\infty.\end{gathered} \tag{4.34}$$

Step 1. We show that there exists $L>0$ independent of $\mathbf{h}$ such that

$$H_c(\mathbf{h},\epsilon^2,\kappa)\geqslant a(\mathbf{h})\epsilon-L\epsilon^2. \tag{4.35}$$

Let $a_\epsilon=a(\mathbf{h})-L\epsilon^2$, and choose a test field $(\phi^\epsilon,\mathbf{A}^\epsilon)$ by

$$\begin{gathered}\phi^\epsilon=c(\epsilon)(1+ia_\epsilon\epsilon w_{\mathbf{h}}+a_\epsilon^2\epsilon^2\psi_{\mathbf{h}}),\\ \mathbf{A}^\epsilon=\mathbf{F}_{\mathbf{h}}+\frac{\epsilon^2|c(\epsilon)|^2}{\kappa^2}\mathbf{U}_{\mathbf{h}},\\ |c(\epsilon)|=\sqrt{1-a_\epsilon^2\omega(\mathbf{h})}.\end{gathered}$$

Computations show that

$$\mathcal{G}[\phi^\epsilon,\mathbf{A}^\epsilon]=\epsilon^2|\Omega|\left[\frac{1}{2}(1-|c(\epsilon)|^2)^2+a_\epsilon^2\omega(\mathbf{h})|c(\epsilon)|^2\right]+O(\epsilon^4)$$
$$=\frac{\epsilon^2|\Omega|}{2}[1-(1-a_\epsilon^2\omega(\mathbf{h}))^2]+O(\epsilon^4).$$

Choose L sufficiently large and we find $C(\mathbf{h},\epsilon^2,\kappa,a_\epsilon\epsilon)\leqslant G[\phi^\epsilon,\mathbf{A}^\epsilon]<|\Omega|\epsilon^2/2$ for small ϵ. So the minimizers are nontrivial. Therefore (4.35) holds.

Step 2. Proof of conclusion (ii): Fix a such that

$$0<a<a(\mathbf{h}). \tag{4.36}$$

Let $\sigma=a\epsilon$. From step 1 we know that (4.34) has a nontrivial minimal solution $(\psi_\epsilon,\mathbf{A}_\epsilon)$ satisfying $\operatorname{div}\mathbf{A}_\epsilon=0$ in $\mathbb{R}^3$, $\int_\Omega\mathbf{A}_\epsilon\,dx=\mathbf{0}$, and for small $\epsilon>0$ we have

$$\mathcal{G}[\psi_\epsilon,\mathbf{A}_\epsilon]=C(\mathbf{h},\epsilon^2,\kappa,a\epsilon)\leqslant\frac{\epsilon^2|\Omega|}{2}[1-(1-a^2\omega(\mathbf{h}))^2]+O(\epsilon^4). \tag{4.37}$$

We shall show that ψ_ϵ and $\mathbf{A}_\epsilon$ have expansions as described in (4.32).

Step 2.1. Proof of the leading terms: The energy estimate (4.37) yields

$$\mathbf{A}_\epsilon\to\mathbf{F}_\mathbf{h}\ \text{ strongly in }\ \mathbf{D}^{1,2}(\mathbb{R}^3)\quad\text{and}\quad\nabla\psi_\epsilon\to0\ \text{ in }\ L^2(\Omega)\quad\text{as}\quad\epsilon\to0.$$

Recall that $|\psi_\epsilon|\leqslant1$. Replacing ψ_ϵ be $\psi_\epsilon e^{ic(\epsilon)}$ if necessary, we may assume that, for some constant c_0, $\psi_\epsilon\to c_0$ in $W^{1,2}(\Omega)$ as $\epsilon\to0$.

Set $\mathbf{A}_{1,\epsilon}=(1/\epsilon)(\mathbf{A}_\epsilon-\mathbf{F}_\mathbf{h})$. We claim that

$$\mathbf{A}_{1,\epsilon}\to\mathbf{0}\quad\text{in}\ \ C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)\quad\text{and weakly in}\ \ \mathbf{D}^{1,2}(\mathbb{R}^3)\quad\text{as}\quad\epsilon\to0. \tag{4.38}$$

To prove (4.38), note that $\mathbf{A}_{1,\epsilon}$ is a weak solution of

$$\operatorname{curl}^2\mathbf{A}_{1,\epsilon}=\mathbf{f}_{0,\epsilon}\quad\text{and}\ \ \operatorname{div}\mathbf{A}_{1,\epsilon}=0\quad\text{in}\ \ \mathbb{R}^3,$$

where $\mathbf{f}_{0,\epsilon}=(1/a\kappa^2)\Im\{\overline{\psi_\epsilon}\nabla_{a\epsilon\mathbf{A}_\epsilon}\psi_\epsilon\}\chi_\Omega$. Since $\|\mathbf{f}_{0,\epsilon}\|_{L^2(\mathbb{R}^3)}\to0$ as $\epsilon\to0$ and $\{\mathbf{A}_{1,\epsilon}\}$ is bounded in $\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div})$, as in the proof of Lemma 3.3 we can show that, $\{\mathbf{A}_{1,\epsilon}\}$ is bounded in $C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$. Passing to a subsequence we have $\mathbf{A}_{1,\epsilon}\to\mathbf{A}_1$ in $C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$ and weakly in $\mathbf{D}^{1,2}(\mathbb{R}^3)$ as $\epsilon\to0$, and $\mathbf{A}_1$ satisfies

$$\Delta\mathbf{A}_1=\mathbf{0},\quad\mathbf{A}_1\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div}),\quad\int_\Omega\mathbf{A}_1\,dx=\mathbf{0}.$$

Since the only harmonic functions on $\mathbb{R}^3$ with their gradients in $L^2(\mathbb{R}^3)$ are constant, we must have $\mathbf{A}_1=\mathbf{0}$. Thus (4.38) is true.

Now we use (4.38) to compute the energy $\mathcal{G}[\psi_\epsilon,\mathbf{A}_\epsilon]$, and compare it with the energy upper bound (4.37) to conclude that $c_0\neq0$. Let $c_\epsilon=\int_\Omega\psi_\epsilon\,dx$. $c_\epsilon\to c_0$ as $\epsilon\to0$, and thus $c_\epsilon\neq0$ for all small ϵ. So we can write

$$\psi_\epsilon=c_\epsilon(1+a\epsilon\psi_{1,\epsilon}),\quad\text{where}\ \int_\Omega\psi_{1,\epsilon}\,dx=0.$$

From the first equation in (4.34) we find an equation for $\psi_{1,\epsilon}$,

$$-\Delta\psi_{1,\epsilon}+2ia\epsilon\mathbf{A}_\epsilon\cdot\nabla\psi_{1,\epsilon}+a\epsilon|\mathbf{A}_\epsilon|^2(1+a\epsilon\psi_{1,\epsilon})=\epsilon(1-|c_\epsilon|^2|1+a\epsilon\psi_{1,\epsilon}|^2)(1+a\epsilon\psi_{1,\epsilon}) \quad \text{in } \Omega,$$
$$\frac{\partial\psi_{1,\epsilon}}{\partial\nu}=i(1+a\epsilon\psi_{1,\epsilon})\mathbf{A}_\epsilon\cdot\nu \quad \text{on } \partial\Omega. \tag{4.39}$$

Applying the elliptic estimate to (4.39), we can pass to a subsequence and find $\psi_{1,\epsilon}\to\psi_1$ in $C^{2+\alpha}(\bar{\Omega})$ as $\epsilon\to0$, where ψ_1 satisfies

$$\Delta\psi_1=0 \quad \text{in } \Omega, \quad \frac{\partial\psi_1}{\partial\nu}=i\mathbf{F}_\mathbf{h}\cdot\nu \quad \text{on } \partial\Omega, \quad \int_\Omega\psi_1\,dx=0.$$

Thus $\psi_1=iw_\mathbf{h}$. So $\psi_{1,\epsilon}\to iw_\mathbf{h}$ in $C^{2+\alpha}(\bar{\Omega})$ as $\epsilon\to0$.

Step 2.2. Proof of the correction terms: Write $\psi_{1,\epsilon}=iw_\mathbf{h}+\epsilon\psi_{2,\epsilon}$, $\mathbf{A}_{1,\epsilon}=(\epsilon/\kappa^2)|c_\epsilon|^2\mathbf{A}_{2,\epsilon}$. Then

$$\psi_\epsilon=c_\epsilon(1+ia\epsilon w_\mathbf{h}+a\epsilon^2\psi_{2,\epsilon}), \quad \mathbf{A}_\epsilon=\mathbf{F}_\mathbf{h}+\frac{\epsilon^2}{\kappa^2}|c_\epsilon|^2\mathbf{A}_{2,\epsilon}. \tag{4.40}$$

We can show

$$\|\mathbf{A}_{2,\epsilon}-\mathbf{U}_\mathbf{h}\|_{L^\infty(\mathbb{R}^3)}\leqslant C\epsilon,$$
$$\|\psi_{2,\epsilon}-a\psi_\mathbf{h}\|_{C^{2+\alpha}(\bar{\Omega})}\leqslant C\epsilon, \tag{4.41}$$
$$|c_\epsilon|^2=1-a^2\omega(\mathbf{h})+O(\epsilon).$$

Then (4.32) follows. The proof of (4.41) is lengthy and is in the same sprint as in step 2.2 of the proof of Theorem 4.1, and hence will be given in Appendix C. From (4.41) we get conclusion (ii).

Step 3. Proof of conclusions (i) and (iii): We first show that

$$H_c(\mathbf{h},\epsilon^2,\kappa)\leqslant a(\mathbf{h})\epsilon+o(\epsilon). \tag{4.42}$$

Let us choose a sequence $\{a_\epsilon\}$ such that $\sigma=\epsilon a_\epsilon<H_c(\mathbf{h},\epsilon^2,\kappa)$ and $a_\epsilon\to a$ as $\epsilon\to0$, where $a\geqslant a(\mathbf{h})$. So the functional $\mathcal{G}$ has a nontrivial minimizer $(\phi_\epsilon,\mathbf{A}_\epsilon)$. We shall show that $a=a(\mathbf{h})$. The proof is similar to step 3 in the proof of Theorem 4.1.

First we show that $\phi_\epsilon\to0$ in $C^{2+\alpha}(\bar{\Omega})$ and $\mathbf{A}_\epsilon\to\mathbf{F}_\mathbf{h}$ in $C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3)$ as $\epsilon\to0$. Write

$$\phi_\epsilon=l^\epsilon+\epsilon m^\epsilon\phi_{1,\epsilon}, \quad \mathbf{A}_\epsilon=\mathbf{F}_\mathbf{h}+\epsilon\mathbf{A}_{1,\epsilon},$$

where l^ϵ and m^ϵ are constants,

$$l^\epsilon\to0 \quad \text{as } \epsilon\to0, \quad m^\epsilon>0, \quad \int_\Omega\phi_{1,\epsilon}\,dx=0, \quad \|\phi_{1,\epsilon}\|_{L^\infty(\Omega)}=1. \tag{4.43}$$

As in step 2 we can show that $\mathbf{A}_{1,\epsilon}\to\mathbf{0}$ in $C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3)$ as $\epsilon\to0$.

We claim that

$$\left|\frac{l^\epsilon}{m^\epsilon}\right|\leqslant C. \tag{4.44}$$

The proof of (4.44) will be given in Appendix C. From (4.44) and passing to a subsequence if necessary, we may assume $\lim_{\epsilon\to0}(l^\epsilon/m^\epsilon)=b$. From (4.34) we get an equation of $\phi_{1,\epsilon}$,

$$
\begin{aligned}
&-\Delta\phi_{1,\epsilon}+2i\epsilon a_\epsilon(\mathbf{F_h}+\epsilon\mathbf{A}_{1,\epsilon})\cdot\nabla\phi_{1,\epsilon}+a_\epsilon^2\epsilon|\mathbf{F_h}+\epsilon\mathbf{A}_{1,\epsilon}|^2\left(\frac{l^\epsilon}{m^\epsilon}+\epsilon\phi_{1,\epsilon}\right)\\
&\quad=\epsilon(1-|l^\epsilon+\epsilon m^\epsilon\phi_{1,\epsilon}|^2)\left(\frac{l^\epsilon}{m^\epsilon}+\epsilon\phi_{1,\epsilon}\right)\quad\text{in }\ \Omega,\\
&\frac{\partial\phi_{1,\epsilon}}{\partial\nu}=ia_\epsilon\left(\frac{l^\epsilon}{m^\epsilon}+\epsilon\phi_{1,\epsilon}\right)(\mathbf{F_h}+\epsilon\mathbf{A}_{1,\epsilon})\cdot\nu\quad\text{on }\ \partial\Omega.
\end{aligned}
\tag{4.45}
$$

Using (4.44) and applying the elliptic estimate to (4.55) we know that $\{\phi_{1,\epsilon}\}$ is uniformly bounded in $C^{2+\alpha}(\bar{\Omega})$. Passing to a subsequence again we may assume that $\phi_{1,\epsilon}\to\phi_1$ in $C^{2+\alpha}(\bar{\Omega})$ as $\epsilon\to0$, $\|\phi_1\|_{L^\infty(\Omega)}=1$, $\int_\Omega\phi_1\,dx=0$, and ϕ_1 satisfies

$$
\Delta\phi=0\quad\text{in }\ \Omega,\quad\frac{\partial\phi}{\partial\nu}=iab\mathbf{F_h}\cdot\nu\quad\text{on }\ \partial\Omega.
$$

Therefore $\phi_1=iabw_\mathbf{h}$, which implies $b\neq0$ since $\phi_1\not\equiv0$. So we have

$$
m^\epsilon=\frac{l^\epsilon}{b}+o(l^\epsilon)\quad\text{and }\ \phi_{1,\epsilon}-ia_\epsilon bw_\mathbf{h}\to0\quad\text{in }\ C^{2+\alpha}(\bar{\Omega})\quad\text{as }\ \epsilon\to0.
$$

Thus we can write

$$
\phi_\epsilon=l^\epsilon(1+i\epsilon a_\epsilon w_\mathbf{h}+\epsilon^2v_\epsilon),\quad\mathbf{A}_\epsilon=\mathbf{F_h}+\epsilon^2\mathbf{B}_\epsilon,
\tag{4.46}
$$

where v_ϵ satisfies $\int_\Omega v_\epsilon\,dx=0$ and $\epsilon\|v_\epsilon\|_{C^{2+\alpha}(\bar{\Omega})}=o(1)$. We can apply the elliptic estimate to the equation of $\mathbf{B}_\epsilon$ to show that $\{\mathbf{B}_\epsilon\}$ is bounded in $C^{1+\alpha}(\bar{\Omega})$. Using this and (4.46) we compute

$$
\begin{aligned}
\int_\Omega|\nabla_{\epsilon a_\epsilon\mathbf{A}_\epsilon}\phi_\epsilon|^2\,dx=a_\epsilon^2\epsilon^2|l^\epsilon|^2\Bigg\{&\int_\Omega\left[|\nabla w_\mathbf{h}-\mathbf{F_h}|^2+a_\epsilon^2\epsilon^2|w_\mathbf{h}\mathbf{F_h}|^2+\frac{\epsilon^2}{a_\epsilon^2}|\nabla v_\epsilon+O(1)|^2\right]dx\\
&+\frac{2\epsilon}{a_\epsilon}\Im\int_\Omega(\nabla w_\mathbf{h}-\mathbf{F_h}+i\epsilon a_\epsilon w_\mathbf{h}\mathbf{F_h})\cdot\nabla v_\epsilon\,dx+O(\epsilon^2)\Bigg\}.
\end{aligned}
$$

Note that $\int_\Omega(\nabla w_\mathbf{h}-\mathbf{F_h})\cdot\nabla v_\epsilon\,dx=0$. We use Cauchy inequality to control the last term on the right-hand side (see step C2 in Appendix C for a similar computation) and get

$$
\int_\Omega|\nabla_{\epsilon a_\epsilon\mathbf{A}_\epsilon}\phi_\epsilon|^2\,dx\geqslant a_\epsilon^2\epsilon^2|l^\epsilon|^2\int_\Omega\left\{\left|\nabla w_\mathbf{h}-\mathbf{F_h}\right|^2+\frac{\epsilon^2}{2a_\epsilon^2}\left|\nabla v_\epsilon\right|^2\right\}dx-C\epsilon^4|l^\epsilon|^2.
$$

On the other hand, since

$$
(|\phi_\epsilon|^2-1)^2=(1-|l^\epsilon|^2)^2-4\epsilon^3|l^\epsilon|^2(1-|l^\epsilon|^2)\Re(v_\epsilon)+O(\epsilon^2|l^\epsilon|^2)
$$

and $\int_\Omega v_\epsilon\,dx=0$, we find

$$
\int_\Omega(|\phi_\epsilon|^2-1)^2\,dx=(1-|l^\epsilon|^2)^2|\Omega|+O(\epsilon^2|l^\epsilon|^2).
$$

Thus

$$\frac{\epsilon^2}{2}|\Omega| \geqslant \mathcal{G}[\phi_\epsilon, \mathbf{A}_\epsilon]$$

$$\geqslant \int_\Omega \left\{ \left| \nabla_{\epsilon a_\epsilon \mathbf{A}_\epsilon} \phi_\epsilon \right|^2 + \frac{\epsilon^2}{2}(|\phi_\epsilon|^2 - 1)^2 \right\} dx$$

$$\geqslant a_\epsilon^2 \epsilon^2 |l^\epsilon|^2 \int_\Omega \left\{ |\nabla w_{\mathbf{h}} - \mathbf{F}_{\mathbf{h}}|^2 + \frac{\epsilon^2}{2a_\epsilon^2} |\nabla v_\epsilon|^2 \right\} dx + \frac{\epsilon^2}{2}(1 - |l^\epsilon|^2)^2 |\Omega| - C\epsilon^4 |l^\epsilon|^2.$$

From these inequalities we find

$$a_\epsilon^2 \omega(\mathbf{h}) - 1 + \frac{|l^\epsilon|^2}{2} + \frac{\epsilon^2}{2} \fint_\Omega |\nabla v_\epsilon|^2 \, dx \leqslant C\epsilon^2.$$

Comparing this with the condition $a \geqslant a(\mathbf{h})$ we find $a = a(\mathbf{h})$. So (4.42) is proved.

Moreover, from the above inequality we get

$$\fint_\Omega |\nabla v_\epsilon|^2 + \frac{|l^\epsilon|^2}{\epsilon^2} \leqslant 2C + 2\omega(\mathbf{h}) \frac{a^2 - a_\epsilon^2}{\epsilon^2}. \tag{4.47}$$

On the other hand, we can show that

$$\mathbf{A}_\epsilon = \mathbf{F}_{\mathbf{h}} + \frac{\epsilon^2}{\kappa^2} |l^\epsilon|^2 \mathbf{U}_{\mathbf{h}} + O(\epsilon^3 |l^\epsilon|^2), \tag{4.48}$$

see step C2 in Appendix C for more details of the argument. From (4.46), (4.47), and (4.48) we get (4.33). Conclusion (iii) is proved.

Plugging $a = a(\mathbf{h})$ into (4.47) we also get $a_\epsilon \leqslant a(\mathbf{h})\sqrt{1 + C\epsilon^2}$, which implies that, the functional $\mathcal{G}$ has nontrivial minimizers only if

$$|\sigma| \leqslant a(\mathbf{h})\epsilon + M\epsilon^3.$$

We can show that M can be chosen independent of $\mathbf{h}$. Thus we find

$$H_c(\mathbf{h}, \epsilon^2, \kappa) \leqslant a(\mathbf{h})\epsilon + M\epsilon^3.$$

This and (4.35) together give (4.31). Conclusion (i) is proved. □

Proof of Theorems 1 and 2: Theorem 2 is a direct consequence of Theorems 4.1 and 4.2. To obtain Theorem 1 we need to show that the estimate (1.8) holds uniformly for all $\kappa \geqslant \lambda(\mathbf{h})\sqrt{\mu}$. Note that Theorem 3.2 gives a lower bound for $H_c(\mathbf{h}, \mu, \kappa)$ uniformly for all $\kappa > 0$. Also note that the functional $\mathcal{G}$ is increasing in κ and hence $H_c(\mathbf{h}, \mu, \kappa)$ is decreasing in κ. Thus the first conclusion of Theorem 4.1 gives a uniform upper bound of $H_c(\mathbf{h}, \mu, \kappa)$ for all $\kappa \geqslant \lambda(\mathbf{h})\sqrt{\mu}$. □

Note added in proof: During proofreading we learned from Professor B. Helffer that, the result of Lemma 2.1 can also be proved and improved by using the Kato's perturbation theory, see: T. Kato, *Perturbation Theory of Linear Operators* (Springer-Verlag, New York, 1966). For superconductivity in one dimensional slabs, various limiting cases $\kappa \to 0$ or size to the film tending to zero have been analyzed by C. Bolley and B. Helffer in their papers: Rigorous results on Ginzburg-Landau models in a film submitted to an exterior parallel magnetic field, I, II, Nonlinear Stud. **3**, 1–29, 121–152 (1996). We would like to thank Professor Helffer for giving the information.

APPENDIX A: PROOF OF LEMMA 2.1

Without loss of generality we may assume that $\mathbf{h}=(0,0,1)$ and choose $\mathbf{F_h}=(0,x_3,0)$. For convenience, we write $\mu(\epsilon)=\mu(\epsilon\mathbf{F_h})$. From the variational characteristic of the lowest eigenvalue,

$$\mu(\epsilon)=\inf_{\phi\in W^{1,2}(\Omega)}\frac{\int_\Omega|\nabla_{\epsilon\mathbf{F_h}}\phi|^2\,dx}{\int_\Omega|\phi|^2\,dx}.$$

Taking a test function $\phi=1+i\epsilon w_{\mathbf{h}}$, where $w_{\mathbf{h}}$ is the solution of (2.3), we have

$$\mu(\epsilon)\leqslant\frac{\int_\Omega|\nabla_{\epsilon\mathbf{F_h}}\phi|^2\,dx}{\int_\Omega|\phi|^2\,dx}=\epsilon^2\frac{\int_\Omega(|\nabla w_{\mathbf{h}}-\mathbf{F_h}|^2+\epsilon^2|w_{\mathbf{h}}\mathbf{F_h}|^2)dx}{\int_\Omega(1+\epsilon^2|w_{\mathbf{h}}|^2)dx}=\omega(\mathbf{h})\epsilon^2+O(\epsilon^4).$$

So we can write $\mu(\epsilon)=\epsilon^2\lambda_\epsilon$, where $\{\lambda_\epsilon\}$ is bounded. Passing to a subsequence if necessary, we may assume that $\lim_{\epsilon-0}\lambda_\epsilon=\lambda_0$. We shall prove that $\lambda_0=\omega(\mathbf{h})$.

Let ϕ_ϵ be a normalized eigenfunction of (2.1), $\|\phi_\epsilon\|_{L^\infty(\Omega)}=1$. From the elliptic estimate we have $\|\phi_\epsilon\|_{C^{2+\alpha}(\Omega)}\leqslant C(\alpha)$ for all small ϵ. After passing to a subsequence we have $\phi_\epsilon\to\phi_0$ in $C^{2+\alpha}(\Omega)$ as $\epsilon\to0$, $\|\phi_0\|_{L^\infty(\Omega)}=1$, $\Delta\phi_0=0$ in Ω and $\partial\phi_0/\partial\nu=0$ on $\partial\Omega$. Thus $\phi_0\equiv$constant. We may assume $\phi_0=1$. So $\phi_\epsilon\to1$ in $C^{2+\alpha}(\Omega)$ as $\epsilon\to0$.

Let us write

$$\alpha_\epsilon=\fint_\Omega\phi_\epsilon\,dx,\quad \psi_\epsilon=\phi_\epsilon-\alpha_\epsilon.$$

Using (2.1) we find

$$\Delta\psi_\epsilon-2i\epsilon x_3\partial_{x_2}\psi_\epsilon-\epsilon^2x_3^2\psi_\epsilon+\epsilon^2\lambda_\epsilon\psi_\epsilon=\epsilon^2\alpha_\epsilon(x_3^2-\lambda_\epsilon)\quad\text{in }\Omega,$$

$$\frac{\partial\psi_\epsilon}{\partial\nu}-i\epsilon\mathbf{F_h}\cdot\nu\psi_\epsilon=i\epsilon\alpha_\epsilon\mathbf{F_h}\cdot\nu\quad\text{on }\partial\Omega.$$

Recall that $\|\nabla_{\epsilon\mathbf{F_h}}\phi_\epsilon\|^2_{L^2(\Omega)}=\epsilon^2\lambda_\epsilon\|\phi_\epsilon\|^2_{L^2(\Omega)}$. We have

$$\begin{aligned}\|\psi_\epsilon\|_{L^2(\Omega)}&=\|\phi_\epsilon-\alpha_\epsilon\|_{L^2(\Omega)}\\&\leqslant C\|\nabla\phi_\epsilon\|_{L^2(\Omega)}\\&=C\|\nabla_{\epsilon\mathbf{F_h}}\phi_\epsilon+i\epsilon\mathbf{F_h}\phi_\epsilon\|_{L^2(\Omega)}\\&\leqslant C\|\nabla_{\epsilon\mathbf{F_h}}\phi_\epsilon\|_{L^2(\Omega)}+C\epsilon\|\mathbf{F_h}\phi_\epsilon\|_{L^2(\Omega)}\\&\leqslant C\epsilon.\end{aligned}$$

We apply the elliptic estimate to get $\|\psi_\epsilon\|_{W^{k.2}(\Omega)}\leqslant C(k)\epsilon$, and then use the Sobolev imbedding theorem to find $\|\psi_\epsilon\|_{L^\infty(\Omega)}\leqslant C\epsilon$. Let

$$\phi_1^\epsilon=\frac{\psi_\epsilon}{\epsilon}=\frac{\phi_\epsilon-\alpha_\epsilon}{\epsilon}.$$

We have $\|\phi_1^\epsilon\|_{L^\infty(\Omega)}\leqslant C$, $\int_\Omega\phi_1^\epsilon\,dx=0$, and

$$\begin{aligned}&\Delta\phi_1^\epsilon-2i\epsilon x_3\partial_{x_2}\phi_1^\epsilon-\epsilon^2x_3^2\phi_1^\epsilon+\epsilon^2\lambda_\epsilon\phi_1^\epsilon=\epsilon\alpha_\epsilon(x_3^2-\lambda_\epsilon)\quad\text{in }\Omega,\\&\frac{\partial\phi_1^\epsilon}{\partial\nu}-i\epsilon\mathbf{F_h}\cdot\nu\phi_1^\epsilon=i\alpha_\epsilon\mathbf{F_h}\cdot\nu\quad\text{on }\partial\Omega.\end{aligned}\tag{A1}$$

Applying the elliptic estimate we find $\|\phi_1^\epsilon\|_{C^{2+\alpha}(\Omega)} \leqslant C(\alpha)$. After passing to a subsequence we have $\phi_1^\epsilon \to \phi_1$ in $C^{2+\alpha}(\Omega)$ as $\epsilon \to 0$. $\int_\Omega \phi_1 \, dx = 0$, $\Delta \phi_1 = 0$ in Ω and $\partial \phi_1 / \partial \nu = i \mathbf{F_h} \cdot \nu$ on $\partial\Omega$. Let $\phi_1 = iw$, then w solves (2.3). Thus $\phi_1 = i w_{\mathbf{h}}$.

Let us write

$$\phi_1^\epsilon = i \beta_\epsilon w_{\mathbf{h}} + \epsilon \phi_2^\epsilon, \quad \beta_\epsilon = -i \frac{\int_\Omega w_{\mathbf{h}} \phi_1^\epsilon \, dx}{\int_\Omega |w_{\mathbf{h}}|^2 \, dx}.$$

Note that $\int_\Omega w_{\mathbf{h}} \phi_2^\epsilon \, dx = 0$. Since $\int_\Omega \phi_1^\epsilon \, dx = 0$ and $\int_\Omega w_{\mathbf{h}} \, dx = 0$, we have $\int_\Omega \phi_2^\epsilon \, dx = 0$. From (A1) we find

$$\begin{aligned} &\Delta \phi_2^\epsilon - 2i\epsilon x_3 \partial_{x_2} \phi_2^\epsilon - \epsilon^2 x_3^2 \phi_2^\epsilon + \epsilon^2 \lambda_\epsilon \phi_2^\epsilon = f_\epsilon \quad \text{in } \Omega, \\ &\frac{\partial \phi_2^\epsilon}{\partial \nu} - i\epsilon \mathbf{F_h} \cdot \nu \phi_2^\epsilon = (i\delta_\epsilon - \beta_\epsilon w_{\mathbf{h}}) \mathbf{F_h} \cdot \nu \quad \text{on } \partial\Omega, \end{aligned} \tag{A2}$$

where

$$f_\epsilon = -2\beta_\epsilon x_3 \partial_{x_2} w_{\mathbf{h}} + i\epsilon \beta_\epsilon w_{\mathbf{h}} (x_3^2 - \lambda_\epsilon) + \alpha_\epsilon (x_3^2 - \lambda_\epsilon), \quad \delta_\epsilon = \frac{\alpha_\epsilon - \beta_\epsilon}{\epsilon}.$$

Since $\phi_1^\epsilon \to i w_{\mathbf{h}}$ in $C^{2+\alpha}(\Omega)$, we have $\beta_\epsilon \to 1$ as $\epsilon \to 0$. Recall that we have chosen a subsequence such that $\lambda_\epsilon \to \lambda_0$. Thus $f_\epsilon \to -2x_3 \partial_{x_2} w_{\mathbf{h}} + x_3^2 - \lambda_0$ uniformly as $\epsilon \to 0$.

Now we show that

$$|\delta_\epsilon| \leqslant C \quad \text{for all small } \epsilon. \tag{A3}$$

Suppose (A3) were not true. Passing to a subsequence we may assume that $\delta_\epsilon \to \infty$. Let $\xi_\epsilon = \phi_2^\epsilon / \delta_\epsilon$. Then we have

$$\int_\Omega \xi_\epsilon \, dx = 0, \quad \int_\Omega w_{\mathbf{h}} \xi_\epsilon \, dx = 0. \tag{A4}$$

From (A2) we have

$$-\nabla^2_{\epsilon \mathbf{F_h}} \xi_\epsilon - \epsilon^2 \lambda_\epsilon \xi_\epsilon = -\frac{f_\epsilon}{\delta_\epsilon} \quad \text{in } \Omega,$$

$$\nabla_{\epsilon \mathbf{F_h}} \xi_\epsilon \cdot \nu = \left(i - \frac{\beta_\epsilon}{\delta_\epsilon} w_{\mathbf{h}} \right) \mathbf{F_h} \cdot \nu \quad \text{on } \partial\Omega.$$

Case 1: $\|\xi_\epsilon\|_{L^2(\Omega)} \leqslant C$ for all small ϵ. Applying the elliptic estimate we find that $\|\xi_\epsilon\|_{W^{k.2}(\Omega)} \leqslant C(\kappa)$ and $\|\xi_\epsilon\|_{C^{2+\alpha}(\Omega)} \leqslant C(\alpha)$. So we can find a subsequence, still denoted by ξ_ϵ, such that $\xi_\epsilon \to \xi_0$ in $C^{2+\alpha}(\Omega)$ as $\epsilon \to 0$. $\int_\Omega \xi_0 \, dx = 0$, $\Delta \xi_0 = 0$ in Ω and $\partial \xi_0 / \partial \nu = i \mathbf{F_h} \cdot \nu$ on $\partial\Omega$. Hence $\xi_0 = i w_{\mathbf{h}}$. But this is impossible since, from the second equality of (A4), we have $\int_\Omega w_{\mathbf{h}} \xi_0 \, dx = 0$. So case 1 cannot happen.

Case 2: $\|\xi_\epsilon\|_{L^2(\Omega)}$ is not bounded. Passing to a subsequence we may assume that $c_\epsilon = \|\xi_\epsilon\|_{L^2(\Omega)} \to \infty$. Let $\tilde{\xi}_\epsilon = \xi_\epsilon / c_\epsilon$. Then $\tilde{\xi}_\epsilon$ satisfies the following equation:

$$-\nabla^2_{\epsilon \mathbf{F_h}} \tilde{\xi}_\epsilon - \epsilon^2 \lambda_\epsilon \tilde{\xi}_\epsilon = -\frac{f_\epsilon}{c_\epsilon \delta_\epsilon} \quad \text{in } \Omega,$$

$$\nabla_{\epsilon \mathbf{F_h}} \tilde{\xi}_\epsilon \cdot \nu = \left(\frac{i}{c_\epsilon} - \frac{\beta_\epsilon}{c_\epsilon \delta_\epsilon} w_{\mathbf{h}} \right) \mathbf{F_h} \cdot \nu \quad \text{on } \partial\Omega.$$

Again we can find a subsequence, still denoted by $\tilde{\xi}_\epsilon$, such that $\tilde{\xi}_\epsilon \to \tilde{\xi}_0$ in $C^{2+\alpha}(\Omega)$, $\|\tilde{\xi}_0\|_{L^2(\Omega)} = 1$, $\int_\Omega \tilde{\xi}_0 \, dx = 0$, $\Delta \tilde{\xi}_0 = 0$ in Ω and $\partial \tilde{\xi}_0 / \partial \nu = 0$ on $\partial\Omega$. Thus $\tilde{\xi}_0 = 0$. This contradicts the condition $\|\tilde{\xi}_0\|_{L^2(\Omega)} = 1$. Case 2 cannot happen.

We have proved that (A3) is true. We may assume that $\lim_{\epsilon \to 0} \delta_\epsilon = \delta_0$. Now we return to (A2). Repeating the argument used in case 2, we can show that $\|\phi_2^\epsilon\|_{L^2(\Omega)} \leqslant C$. Then we apply the elliptic estimate to show that $\|\phi_2^\epsilon\|_{C^{2+\alpha}(\Omega)}$ is bounded. Thus we can find a subsequence, still denoted by ϕ_2^ϵ, such that $\phi_2^\epsilon \to \phi_2$ in $C^{2+\alpha}(\Omega)$ as $\epsilon \to 0$. ϕ_2 satisfies

$$\begin{aligned} -\Delta \phi_2 &= 2x_3 \partial_{x_2} w_{\mathbf{h}} - x_3^2 + \lambda_0 \quad \text{in } \Omega, \\ \frac{\partial \phi_2}{\partial \nu} &= (i\delta_0 - w_{\mathbf{h}}) \mathbf{F_h} \cdot \nu \quad \text{on } \partial\Omega. \end{aligned} \tag{A5}$$

Integrating the equation we find

$$\begin{aligned} \lambda_0 |\Omega| &= \int_\Omega \{x_3^2 - 2x_3 \partial_{x_2} w_{\mathbf{h}} - \Delta \phi_2\} dx \\ &= \int_\Omega x_3^2 \, dx - \int_{\partial\Omega} \left\{ 2x_3 w_{\mathbf{h}} \mathbf{e}_2 \cdot \nu + \frac{\partial \phi_2}{\partial \nu} \right\} dS \\ &= \int_\Omega |\mathbf{F_h}|^2 \, dx - \int_{\partial\Omega} (w_{\mathbf{h}} + i\delta_0) \mathbf{F_h} \cdot \nu \, ds \\ &= \int_\Omega |\mathbf{F_h}|^2 \, dx - \int_{\partial\Omega} w_{\mathbf{h}} \mathbf{F_h} \cdot \nu \, dS \\ &= \int_\Omega (|\mathbf{F_h}|^2 - |\nabla w_{\mathbf{h}}|^2) dx \\ &= \omega(\mathbf{h}) |\Omega|. \end{aligned}$$

Thus $\lambda_0 = \omega(\mathbf{h})$, namely, $\lambda_\epsilon \to \omega(\mathbf{h})$ as $\epsilon \to 0$.

Furthermore, following the same spirit we can examine the higher order terms and show that $\lambda_\epsilon - \omega(\mathbf{h}) = O(\epsilon)$. Thus we have proved that, as $\epsilon \to 0$,

$$\mu(\epsilon) = \omega(\mathbf{h}) \epsilon^2 + O(\epsilon^3), \quad \phi_\epsilon = \alpha_\epsilon + i\epsilon \beta_\epsilon w_{\mathbf{h}} + \epsilon^2 \phi_2 + o(\epsilon^2), \tag{A6}$$

where $\alpha_\epsilon \to 1$, $\beta_\epsilon \to 1$, $w_{\mathbf{h}}$ is the unique real solution of (2.3), and ϕ_2 is a solution of (A5). Thus (2.5) and (2.6) are proved. □

APPENDIX B: PROOF OF CLAIMS 1 AND 2

In this section we keep the notations in the proof of Theorem 4.1.

Proof of claim 1: Step B1. We first show the following

Subclaim 1: If the condition $\lim_{\epsilon - 0} |b_\epsilon| = +\infty$ holds, then there exists a constant C independent of ϵ such that, for all small ϵ,

$$\|\psi_{2,\epsilon}\|_{L^\infty(\Omega)} \leqslant C |b_\epsilon|. \tag{B1}$$

Suppose (B1) were not true. We pass to a subsequence if necessary and assume that

$$d_\epsilon=\frac{\|\psi_{2,\epsilon}\|_{L^\infty(\Omega)}}{|b_\epsilon|}\to\infty \quad \text{as} \quad \epsilon\to 0.$$

Set

$$\phi_\epsilon=\frac{\psi_\epsilon}{b_\epsilon d_\epsilon}, \quad \mathbf{D}_\epsilon=\frac{\mathbf{A}_{1,\epsilon}}{b_\epsilon d_\epsilon}.$$

$(\phi_\epsilon,\mathbf{D}_\epsilon)$ satisfies

$$\Delta\phi_\epsilon=O\left(\frac{1}{b_\epsilon d_\epsilon}\right) \quad \text{in} \quad \Omega,$$

$$\lambda^2\,\mathrm{curl}^2\,\mathbf{D}_\epsilon=\left\{\frac{1}{d_\epsilon}(\nabla w_a-\mathbf{A}_a)+|c_\epsilon|^2\Im\left(\nabla\phi_\epsilon-i\mathbf{D}_\epsilon+\frac{\mathbf{q}_\epsilon}{b_\epsilon d_\epsilon}\right)\right\}\chi_\Omega \quad \text{in} \quad \mathbb{R}^3,$$

$$\frac{\partial\phi_\epsilon}{\partial\nu}=i\mathbf{D}_{1,\epsilon}\cdot\nu-\frac{1}{b_\epsilon d_\epsilon}w_a\mathbf{A}_a\cdot\nu+O\left(\frac{r_\epsilon}{b_\epsilon d_\epsilon}\right) \quad \text{on} \quad \partial\Omega.$$

Recall that $\int_\Omega\phi_\epsilon\,dx=0$, $\int_\Omega\mathbf{D}_\epsilon\,dx=\mathbf{0}$, and $\mathbf{D}_\epsilon\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div})$. From the second equation we get

$$\lambda^2\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbf{D}_\epsilon|^2\,dx+|c_\epsilon|^2\int_\Omega|\nabla\phi_\epsilon-i\mathbf{D}_\epsilon|^2\,dx=\int_\Omega\left\{\frac{1}{d_\epsilon}(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{D}_\epsilon+\frac{|c_\epsilon|^2}{b_\epsilon d_\epsilon}\mathbf{q}_\epsilon\cdot\mathbf{D}_\epsilon\right\}dx.$$

Thus we can pass to a subsequence again and assume that $\phi_\epsilon\to\phi$ in $C^{2+\alpha}(\overline{\Omega})$ and $\mathbf{D}_\epsilon\to\mathbf{D}$ in $C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$ as $\epsilon\to 0$, $\mathbf{D}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div})$, $\int_\Omega\phi\,dx=0$, $\|\phi\|_{L^\infty(\Omega)}=1$, and $(\phi,\mathbf{D})$ satisfies

$$\Delta\phi=0 \quad \text{in} \quad \Omega,$$

$$\lambda^2\,\mathrm{curl}^2\,\mathbf{D}=c_\alpha^2\Im\{\nabla\phi-i\mathbf{D}\}\chi_\Omega \quad \text{in} \quad \mathbb{R}^3, \tag{B2}$$

$$\frac{\partial\phi}{\partial\nu}=i\mathbf{D}\cdot\nu \quad \text{on} \quad \partial\Omega.$$

From the proof of Lemma 3.4 we know that the only finite energy solution of (B2) is $\phi=$constant and $\mathbf{D}=$constant vector. The condition $\int_\Omega\phi\,dx=0$ implies that $\phi=0$, which contradicts the condition $\|\phi\|_{L^\infty(\Omega)}=1$. Hence (B1) is true.

Step B2. Now we show that $\{b_\epsilon\}$ is bounded. Suppose not. We may assume that $\lim_{\epsilon\to 0}|b_\epsilon|=\infty$. Let

$$\varphi_\epsilon=\frac{\psi_{1,\epsilon}}{b_\epsilon}, \quad \mathbf{B}_\epsilon=\frac{\mathbf{A}_{1,\epsilon}}{b_\epsilon}.$$

Then $(\varphi_\epsilon,\mathbf{B}_\epsilon)$ satisfies

$$\Delta\varphi_\epsilon=O\left(\frac{1}{b_\epsilon}\right) \quad \text{in} \quad \Omega,$$

$$\lambda^2\,\mathrm{curl}^2\,\mathbf{B}_\epsilon=\left\{(\nabla w_a-\mathbf{A}_a)+|c_\epsilon|^2\Im\left(\nabla\varphi_\epsilon-i\mathbf{B}_\epsilon+\frac{\mathbf{q}_\epsilon}{b_\epsilon}\right)\right\}\chi_\Omega \quad \text{in} \quad \mathbb{R}^3,$$

$$\frac{\partial\varphi_\epsilon}{\partial\nu}=i\mathbf{B}_{1,\epsilon}\cdot\nu-\frac{1}{b_\epsilon}w_a\mathbf{A}_a\cdot\nu+O\left(\frac{r_\epsilon}{b_\epsilon}\right) \quad \text{on} \quad \partial\Omega.$$

Using subclaim 1, we can pass to a subsequence and assume that $\varphi_\epsilon \to \varphi$ in $C^{2+\alpha}(\overline{\Omega})$ and $\mathbf{B}_\epsilon \to \mathbf{B}$ in $C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$ as $\epsilon \to 0$, $\mathbf{B} \in \mathbf{D}^{1,2}(\mathbb{R}^3, \mathrm{div})$, $\int_\Omega \varphi \, dx = 0$, and $(\varphi, \mathbf{B})$ satisfies

$$\Delta \varphi = 0 \quad \text{in } \Omega,$$

$$\lambda^2 \operatorname{curl}^2 \mathbf{B} = \{\nabla w_a - \mathbf{A}_a + c_a^2 \Im(\nabla \varphi - i\mathbf{B})\}\chi_\Omega \quad \text{in } \mathbb{R}^3,$$

$$\frac{\partial \varphi}{\partial \nu} = i\mathbf{B} \cdot \nu - w_a \mathbf{A}_a \cdot \nu \quad \text{on } \partial\Omega.$$

Comparing this with (3.22) and (4.1) we find that

$$\varphi = u_a + i v_a, \quad \mathbf{B} = \mathbf{B}_a.$$

Next, to derive a contradiction we compute the energy $\mathcal{G}[\psi_\epsilon, \mathbf{A}_\epsilon]$. Write

$$\psi_\epsilon = c_\epsilon(1 + ia\epsilon w_a + a^2 \epsilon^2 b_\epsilon \varphi_\epsilon), \quad \mathbf{A}_\epsilon = \mathbf{A}_a + a\epsilon b_\epsilon \mathbf{B}_\epsilon.$$

Under the condition $\lim_{\epsilon \to 0} |b_\epsilon| = \infty$ we have,

$$\mathcal{G}[\psi_\epsilon, \mathbf{A}_\epsilon] = (I_{1,\epsilon} + I_{2,\epsilon} + I_{3,\epsilon})\epsilon^2,$$

where

$$I_{1,\epsilon} = a^2 |c_\epsilon|^2 \|\nabla w_a - \mathbf{A}_a\|^2_{L^2(\Omega)} + a^2 \lambda^2 \|\operatorname{curl} \mathbf{A}_a - \mathbf{h}\|^2_{L^2(\mathbb{R}^3)} + \frac{|\Omega|}{2}(1 - |c_\epsilon|^2)^2,$$

$$I_{2,\epsilon} = 2a^2 \epsilon b_\epsilon \left\{ \lambda^2 \int_{\mathbb{R}^3} (\operatorname{curl} \mathbf{A}_a - \mathbf{h}) \cdot \operatorname{curl} \mathbf{B}_\epsilon \, dx - |c_\epsilon|^2 \int_\Omega (\nabla w_a - \mathbf{A}_a) \cdot \mathbf{B}_\epsilon \, dx \right\},$$

$$I_{3,\epsilon} = a^4 \epsilon^2 b_\epsilon^2 \{ |c_\epsilon|^2 \|\nabla \varphi_\epsilon - i\mathbf{B}_\epsilon\|^2_{L^2(\Omega)} + \lambda^2 \|\operatorname{curl} \mathbf{B}_\epsilon\|^2_{L^2(\mathbb{R}^3)} \}$$
$$- a^2 \epsilon^2 |c_\epsilon|^2 (1 - |c_\epsilon|^2) \|w_a\|^2_{L^2(\Omega)} + O(\epsilon^2 b_\epsilon).$$

Using the last equality in (3.21) we find

$$I_{1,\epsilon} = I_a + \frac{|\Omega|}{2}(|c_\epsilon|^2 - c_a^2)^2,$$

where I_a was given in step 1.1 of the proof of Theorem 4.1. Using (3.22) we find

$$I_{2,\epsilon} = 2a^3 \epsilon b_\epsilon (c_a^2 - |c_\epsilon|^2) \int_\Omega (\nabla w_a - \mathbf{A}_a) \cdot \mathbf{B}_\epsilon \, dx$$

$$= -2a^2 (|c_\epsilon|^2 - c_a^2)^2 \left\{ \int_\Omega (\nabla w_a - \mathbf{A}_a) \cdot \mathbf{B}_a \, dx + o(1) \right\}.$$

We have assumed $|b_\epsilon| \to \infty$, hence $(|c_\epsilon|^2 - c_a^2)^2 \gg \epsilon^2$. Using (3.22) we have

$$I_{3,\epsilon} = a^2 (|c_\epsilon|^2 - c_a^2)^2 \{ \lambda^2 \|\operatorname{curl} \mathbf{B}_a\|^2_{L^2(\mathbb{R}^3)} + c_a^2 \|\nabla v_a - \mathbf{B}_a\|^2_{L^2(\Omega)} + o(1) \}$$

$$= a^2 (|c_\epsilon|^2 - c_a^2)^2 \left\{ \int_\Omega (\nabla w_a - \mathbf{A}_a) \cdot \mathbf{B}_a \, dx + o(1) \right\}.$$

From these and (3.23), we can find a positive constant C such that

$$\frac{\mathcal{G}[\psi_\epsilon,\mathbf{A}_\epsilon]}{\epsilon^2}-I_a=a^2(|c_\epsilon|^2-c_a^2)^2\left\{\frac{|\Omega|}{2a^2}-\int_\Omega(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{B}_a\,dx+o(1)\right\}>C(|c_\epsilon|^2-c_a^2)^2\gg\epsilon^2,$$

which contradicts (4.9). Thus $\{b_\epsilon\}$ is bounded. □

Proof of claim 2: Suppose $\{l_\epsilon/m_\epsilon\}$ were not bounded. Passing to a subsequence we may assume $m_\epsilon\ll|l_\epsilon|$. Then we use (4.18) to get

$$\mathcal{G}[\phi_\epsilon,\mathbf{A}_\epsilon]=\epsilon^2\left\{a_\epsilon^2|l_\epsilon|^2\|\mathbf{A}_\epsilon-\nabla\zeta_\epsilon\|^2_{L^2(\Omega)}+a_\epsilon^2\lambda^2\|\mathrm{curl}\,\mathbf{A}_\epsilon-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}+\frac{|\Omega|}{2}(1-|l_\epsilon|^2)^2+o(\epsilon|l_\epsilon|^2)\right\},\tag{B3}$$

where $\zeta_\epsilon=-(im_\epsilon/l_\epsilon)\phi_{1,\epsilon}$.

Case 1: $l_0\neq0$. Since $a_\epsilon\to a$ as $\epsilon\to0$, from (B3) we have

$$\mathcal{G}[\phi_\epsilon,\mathbf{A}_\epsilon]=\epsilon^2\left\{a^2l_0^2\|\mathbf{A}_\epsilon-\nabla\zeta_\epsilon\|^2_{L^2(\Omega)}+a^2\lambda^2\|\mathrm{curl}\,\mathbf{A}_\epsilon-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}+\frac{|\Omega|}{2}(1-l_0^2)^2+o(1)\right\}.$$

On the other hand, if we let $\rho=l_0^2$ and choose a test field $(\psi,\mathbf{A})$, where $\psi=l_0(1+\epsilon a_\epsilon w^\rho)$ and $\mathbf{A}=\mathbf{A}^\rho$, we find an energy upper bound

$$\mathcal{G}[\psi,\mathbf{A}]=\epsilon^2\left\{a^2l_0^2\|\mathbf{A}^\rho-\nabla w^\rho\|^2_{L^2(\Omega)}+a^2\lambda^2\|\mathrm{curl}\,\mathbf{A}^\rho-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}+\frac{|\Omega|}{2}(1-l_0^2)^2+o(1)\right\}.$$

Since $(\phi_\epsilon,\mathbf{A}_\epsilon)$ is a minimizer, we have $\mathcal{G}[\phi_\epsilon,\mathbf{A}_\epsilon]\leqslant\mathcal{G}[\psi,\mathbf{A}]$, from which we derive

$$\begin{aligned}\mathcal{J}_\rho[\zeta_\epsilon,\mathbf{A}_\epsilon]&=l_0^2\|\mathbf{A}_\epsilon-\nabla\zeta_\epsilon\|^2_{L^2(\Omega)}+\lambda^2\|\mathrm{curl}\,\mathbf{A}_\epsilon-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}\\&\leqslant l_0^2\|\mathbf{A}^\rho-\nabla w^\rho\|^2_{L^2(\Omega)}+\lambda^2\|\mathrm{curl}\,\mathbf{A}^\rho-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}+o(1)\\&=\mathcal{J}_\rho[w^\rho,\mathbf{A}^\rho]+o(1).\end{aligned}$$

Thus $\{(\zeta_\epsilon,\mathbf{A}_\epsilon)\}$ is a minimizing sequence of the functional $\mathcal{J}_\rho$, hence contains a subsequence which converges to the minimizer $(w^\rho,\mathbf{A}^\rho)$. However, $|\zeta_\epsilon|=|(m_\epsilon/l_\epsilon)\phi_{1,\epsilon}|\to0$ as $\epsilon\to0$. This contradiction shows that case 1 cannot happen.

Case 2: $l_0=0$. Then $l_\epsilon\to0$ and $\|\zeta_\epsilon\|_{L^\infty(\Omega)}\to0$ as $\epsilon\to0$. Since $\mathcal{G}[\phi_\epsilon,\mathbf{A}_\epsilon]\leqslant|\Omega|\epsilon^2/2$, we have

$$a_\epsilon^2|l_\epsilon|^2\|\mathbf{A}_\epsilon-\nabla\zeta_\epsilon\|^2_{L^2(\Omega)}+a_\epsilon^2\lambda^2\|\mathrm{curl}\,\mathbf{A}_\epsilon-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}+\frac{|\Omega|}{2}(1-|l_\epsilon|^2)^2+o(\epsilon|l_\epsilon|^2)\leqslant\frac{|\Omega|}{2},$$

so

$$a_\epsilon^2\|\mathbf{A}_\epsilon-\nabla\zeta_\epsilon\|^2_{L^2(\Omega)}+\frac{a_\epsilon^2\lambda^2}{|l_\epsilon|^2}\|\mathrm{curl}\,\mathbf{A}_\epsilon-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}\leqslant|\Omega|-\frac{|\Omega|}{2}|l_\epsilon|^2+o(\epsilon).\tag{B4}$$

Especially we have $\|\mathrm{curl}\,\mathbf{A}_\epsilon-\mathbf{h}\|^2_{L^2(\mathbb{R}^3)}\leqslant C|l_\epsilon|^2\to0$. Thus $\mathbf{A}_\epsilon\to\mathbf{F}_\mathbf{h}$ in $L^2(\Omega)$ as $\epsilon\to0$. Plugging it back to (B4) and using the minimality of $w_\mathbf{h}$, we have

$$a^2\|\mathbf{F}_\mathbf{h}-\nabla w_\mathbf{h}\|^2_{L^2(\Omega)}\leqslant a^2\|\mathbf{F}_\mathbf{h}-\nabla\zeta_\epsilon\|_{L^2(\Omega)}\leqslant|\Omega|+o(1).$$

Hence $a^2\|\mathbf{F}_\mathbf{h}-\nabla w_\mathbf{h}\|^2_{L^2(\Omega)}\leqslant|\Omega|$. From this and (4.17) we conclude that $a=a(\mathbf{h})$, and $\nabla\zeta_\epsilon\to\nabla w_\mathbf{h}$ as $\epsilon\to0$. Then we apply the elliptic estimate to the equation of ζ_ϵ [which can be derived from (4.19)], and use the condition $\int_\Omega\zeta_\epsilon\,dx=0$ to conclude that $\zeta_\epsilon\to w_\mathbf{h}$ as $\epsilon\to0$, which contradicts the fact $\|\zeta_\epsilon\|_{L^\infty(\Omega)}\to0$ as $\epsilon\to0$. Case 2 cannot happen. Now claim 2 is proved. □

APPENDIX C: PROOF OF (4.41) AND (4.44)

In this section we keep the notations in the proof of Theorem 4.2.

Proof of (4.41): Step C1. Using (4.40) we compute

$$\nabla_{a\epsilon\mathbf{A}_\epsilon}\psi_\epsilon = a\epsilon c_\epsilon\Bigg[i(\nabla w_{\mathbf{h}} - \mathbf{F}_{\mathbf{h}}) + \epsilon(\nabla\psi_{2,\epsilon} + a w_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}) - i\epsilon^2\left(a\psi_{2,\epsilon}\mathbf{F}_{\mathbf{h}} + \frac{|c_\epsilon|^2}{\kappa^2}\mathbf{A}_{2,\epsilon}\right) + a\epsilon^3\frac{|c_\epsilon|^2}{\kappa^2}\mathbf{A}_{2,\epsilon}(i w_{\mathbf{h}} - \epsilon\psi_{2,\epsilon})\Bigg]. \tag{C1}$$

From step 2.1 of the proof of Theorem 4.2 we have $\epsilon\psi_{2,\epsilon}\to 0$ in $C^{2+\alpha}(\overline{\Omega})$ and $\epsilon\mathbf{A}_{2,\epsilon}\to\mathbf{0}$ in $C^{1+\alpha}(\overline{\Omega})$ as $\epsilon\to 0$. So we can write

$$\mathfrak{I}\{\overline{\psi_\epsilon}\nabla_{a\epsilon\mathbf{A}_\epsilon}\psi_\epsilon\} = a\epsilon|c_\epsilon|^2(\nabla w_{\mathbf{h}} - \mathbf{F}_{\mathbf{h}} + \epsilon\mathfrak{I}\{\nabla\psi_{2,\epsilon}\} + \epsilon\hat{\mathbf{q}}_\epsilon),$$

where $\|\hat{\mathbf{q}}_\epsilon\|_{C^{1+\alpha}(\overline{\Omega})}\leq C$ for some C independent of ϵ. $\mathbf{A}_{2,\epsilon}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div})$ and satisfies the equation

$$\mathrm{curl}^2\,\mathbf{A}_{2,\epsilon} = (\nabla w_{\mathbf{h}} - \mathbf{F}_{\mathbf{h}} + \epsilon\mathfrak{I}\{\nabla\psi_{2,\epsilon}\} + \epsilon\hat{\mathbf{q}}_\epsilon)\chi_\Omega \quad \text{in } \mathbb{R}^3,$$

and $\int_\Omega \mathbf{A}_{2,\epsilon}\,dx = \mathbf{0}$. Let

$$\mathbf{B}_\epsilon = \mathbf{A}_{2,\epsilon} - \mathbf{U}_{\mathbf{h}}, \quad \mathbf{f}_{1,\epsilon} = \epsilon(\mathfrak{I}\{\nabla\psi_{2,\epsilon}\} + \hat{\mathbf{q}}_\epsilon)\chi_\Omega\,.$$

Then $\int_\Omega \mathbf{B}_\epsilon\,dx = \mathbf{0}$, and

$$\mathrm{curl}^2\,\mathbf{B}_\epsilon = \mathbf{f}_{1,\epsilon} \quad \text{in } \mathbb{R}^3. \tag{C2}$$

As $\epsilon\to 0$ we have $\epsilon\psi_{2,\epsilon}\to 0$ in $C^{2+\alpha}(\overline{\Omega})$ and hence $\|\mathbf{f}_{1,\epsilon}\|_{C^{1+\alpha}(\overline{\Omega})}\to 0$. Although $\mathbf{f}_{1,\epsilon}$ depends on $\mathbf{A}_{2,\epsilon}$ and hence depends on $\mathbf{B}_\epsilon$, we treat it as a given vector field, and treat $\mathbf{B}_\epsilon$ as a solution of a linear system. Recall that $\mathbf{B}_\epsilon\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div})$, and hence $\mathbf{B}_\epsilon$ is a finite energy solution of (C2). Write (C2) as

$$-\Delta\mathbf{B}_\epsilon = \mathbf{f}_{1,\epsilon} \quad \text{in } \mathbb{R}^3. \tag{C3}$$

Using Newton potential we can show that (C3) has a finite energy solution $\mathbf{u}_\epsilon$ which decays to $\mathbf{0}$ as $|x|\to\infty$, and

$$\|\mathbf{u}_\epsilon\|_{L^\infty(\mathbb{R}^3)}\leq C'\|\mathbf{f}_\epsilon\|_{L^\infty(\mathbb{R}^3)} = C'\epsilon\|\mathfrak{I}\{\nabla\psi_{2,\epsilon}\} + \hat{\mathbf{q}}_\epsilon\|_{L^\infty(\Omega)},$$

where C' is independent of ϵ. On the other hand, as in the proof of Lemma 3.4 we can show that, up to an additive constant vector, $\mathbf{B}_\epsilon$ is the only solution of (C3) in $\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div})$. Therefore $\mathbf{B}_\epsilon = \mathbf{u}_\epsilon - \mathbf{c}_\epsilon$, where $\mathbf{c}_\epsilon = \fint_\Omega \mathbf{u}_\epsilon\,dx$. Hence we conclude that

$$\mathbf{A}_{2,\epsilon} = \mathbf{U}_{\mathbf{h}} + \mathbf{B}_\epsilon, \quad \|\mathbf{B}_\epsilon\|_{L^\infty(\mathbb{R}^3)}\leq C\epsilon\|\mathfrak{I}\{\nabla\psi_{2,\epsilon}\} + \hat{\mathbf{q}}_\epsilon\|_{L^\infty(\Omega)}, \tag{C4}$$

where C is independent of ϵ.

Step C2. Now we use the energy estimate to show that

$$|c_\epsilon|^2 = 1 - a^2\omega(\mathbf{h}) + O(\epsilon), \quad \int_\Omega |\nabla\psi_{2,\epsilon}|^2\,dx\leq C. \tag{C5}$$

Note that at moment we do not know yet whether $\psi_{2,\epsilon}$ is bounded in $W^{1,2}(\Omega)$, but we know that $\epsilon\psi_{2,\epsilon}\to 0$ in $C^{2+\alpha}(\overline{\Omega})$ as $\epsilon\to 0$. Using (C1) and (C4) we find

$$\int_\Omega |\nabla_{a\epsilon\mathbf{A}_\epsilon}\psi_\epsilon|^2\,dx = a^2\epsilon^2|c_\epsilon|^2\int_\Omega \{|\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}}|^2+\epsilon^2|\nabla\psi_{2,\epsilon}+aw_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}-ia\epsilon\psi_{2,\epsilon}\mathbf{F}_{\mathbf{h}}+O(\epsilon)|^2$$
$$+2\epsilon(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\Im[\nabla\psi_{2,\epsilon}+aw_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}-ia\epsilon\psi_{2,\epsilon}\mathbf{F}_{\mathbf{h}}+O(\epsilon)]\}dx.$$

Recall that

$$\int_\Omega (\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\nabla\psi_{2,\epsilon}\,dx=0.$$

Note that we always have

$$\int_\Omega \{|\nabla\psi_{2,\epsilon}+aw_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}-ia\epsilon\psi_{2,\epsilon}\mathbf{F}_{\mathbf{h}}+O(\epsilon)|^2+2a(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\Im[-i\psi_{2,\epsilon}\mathbf{F}_{\mathbf{h}}+O(1)]\}dx$$
$$\geqslant\frac{1}{2}\int_\Omega|\nabla\psi_{2,\epsilon}|^2\,dx-C, \tag{C6}$$

where C is independent of ϵ. In fact, since $\int_\Omega\psi_{1,\epsilon}\,dx=0$, (C6) is obviously true when $\|\psi_{2,\epsilon}\|_{L^2(\Omega)}$ is uniformly bounded. If $\|\psi_{2,\epsilon}\|_{L^2(\Omega)}\to\infty$, we have

$$\int_\Omega|\nabla\psi_{2,\epsilon}+aw_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}-ia\epsilon\psi_{2,\epsilon}\mathbf{F}_{\mathbf{h}}+O(\epsilon)|^2\,dx=(1+o(1))\int_\Omega|\nabla\psi_{2,\epsilon}|^2\,dx\geqslant C\int_\Omega|\psi_{2,\epsilon}|^2\,dx$$
$$\geqslant 4a\int_\Omega|(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\Im[i\psi_{2,\epsilon}\mathbf{F}_{\mathbf{h}}+O(1)]|dx.$$

So (C6) is true. Using (C6) we find

$$\int_\Omega|\nabla_{a\epsilon\mathbf{A}_\epsilon}\psi_\epsilon|^2\,dx\geqslant a^2\epsilon^2|c_\epsilon|^2\left\{\omega(\mathbf{h})|\Omega|+\frac{\epsilon^2}{2}\int_\Omega|\nabla\psi_{2,\epsilon}|^2\,dx-C\epsilon^2\right\}. \tag{C7}$$

From (4.40) we have

$$|\psi_\epsilon|^2=|c_\epsilon|^2(1+a^2\epsilon^2g_\epsilon),$$

where

$$g_\epsilon=w_{\mathbf{h}}^2+\frac{2}{a}\Re(\psi_{2,\epsilon})+2\epsilon w_{\mathbf{h}}\Im(\psi_{2,\epsilon})+\epsilon^2|\psi_{2,\epsilon}|^2.$$

So

$$\int_\Omega(|\psi_\epsilon|^2-1)^2\,dx=(|c_\epsilon|^2-1)^2|\Omega|+2a^2\epsilon^2|c_\epsilon|^2(|c_\epsilon|^2-1)\int_\Omega g_\epsilon\,dx+a^4\epsilon^4|c_\epsilon|^4\int_\Omega g_\epsilon^2\,dx.$$

$\int_\Omega g_\epsilon\,dx=O(1)$ since $\int_\Omega\psi_{2,\epsilon}\,dx=0$, and $\epsilon^2g_\epsilon^2=o(1)$ since $\epsilon\psi_{2,\epsilon}=o(1)$. So

$$\int_\Omega(|\psi_\epsilon|^2-1)^2\,dx=(|c_\epsilon|^2-1)^2|\Omega|+O(\epsilon^2). \tag{C8}$$

From (C7) and (C8) we get

$$\int_\Omega \left\{ |\nabla_{a\epsilon \mathbf{A}_\epsilon} \psi_\epsilon|^2 + \frac{\epsilon^2}{2}(|\psi_\epsilon|^2-1)^2 \right\} dx$$
$$\geqslant \frac{\epsilon^2|\Omega|}{2}\left\{ 2a^2|c_\epsilon|^2\omega(\mathbf{h}) + \epsilon^2 \fint_\Omega |\nabla \psi_{2,\epsilon}|^2\, dx + (|c_\epsilon|^2-1)^2 - C\epsilon^2 \right\}.$$

Comparing this with (4.37) we find

$$a^2|c_\epsilon|^2\omega(\mathbf{h}) + \frac{1}{2}(|c_\epsilon|^2-1)^2 + \frac{\epsilon^2}{2}\fint_\Omega |\nabla \psi_{2,\epsilon}|^2\, dx \leqslant a^2\omega(\mathbf{h}) - \frac{1}{2}a^4\omega(\mathbf{h})^2 + C\epsilon^2.$$

Thus

$$[|c_\epsilon|^2 - 1 + a^2\omega(\mathbf{h})]^2 + \epsilon^2 \fint_\Omega |\nabla \psi_{2,\epsilon}|^2\, dx \leqslant C\epsilon^2.$$

(C5) is proved.

Step C3. Plugging $\psi_{1,\epsilon} = i w_{\mathbf{h}} + \epsilon \psi_{2,\epsilon}$ into (4.39) we find

$$\begin{aligned} &-\Delta \psi_{2,\epsilon} + 2ia(\mathbf{F_h} + \epsilon \mathbf{A}_{1,\epsilon})\cdot(i\nabla w_{\mathbf{h}} + \epsilon \nabla \psi_{2,\epsilon}) + a|\mathbf{F_h} + \epsilon \mathbf{A}_{1,\epsilon}|^2(1 + ia\epsilon w_{\mathbf{h}} + a\epsilon^2 \psi_{2,\epsilon}) \\ &\quad = (1-|c_\epsilon^2||1 + a\epsilon(i w_{\mathbf{h}} + \epsilon \psi_{2,\epsilon})|^2)\left(\frac{1}{a} + i\epsilon w_{\mathbf{h}} + \epsilon^2 \psi_{2,\epsilon}\right) \quad \text{in } \Omega, \\ &\frac{\partial \psi_{2,\epsilon}}{\partial \nu} = -a w_{\mathbf{h}} \mathbf{F_h}\cdot \nu + i\epsilon[a\psi_{2,\epsilon}\mathbf{F_h}\cdot\nu + (1 + a\epsilon(i w_{\mathbf{h}} + \epsilon \psi_{2,\epsilon}))\mathbf{A}_{1,\epsilon}\cdot \nu] \quad \text{on } \partial\Omega. \end{aligned} \tag{C9}$$

Recall that $\|\mathbf{A}_{1,\epsilon}\|_{C^{1+\alpha}(\Omega)} = O(\epsilon)$ and $\int_\Omega \psi_{2,\epsilon}\, dx = \underline{0}$. Using (C5) and applying the elliptic estimate to (C9) we see that $\{\psi_{2,\epsilon}\}$ is bounded in $C^{2+\alpha}(\overline{\Omega})$. Passing to a subsequence we find that $\psi_{2,\epsilon} \to \psi_2$ in $C^{2+\alpha}(\overline{\Omega})$ as $\epsilon \to 0$, and ψ_2 satisfies

$$-\Delta \psi_2 - 2a\mathbf{F_h}\cdot\nabla w_{\mathbf{h}} + a|\mathbf{F_h}|^2 = a\omega(\mathbf{h}) \quad \text{in } \Omega,$$

$$\frac{\partial \psi_2}{\partial \nu} = -a w_{\mathbf{h}} \mathbf{F_h}\cdot\nu \quad \text{on } \partial\Omega.$$

Moreover $\int_\Omega \psi_2\, dx = 0$. Comparing this equation with (4.29) we find that $\psi_2 = a\psi_{\mathbf{h}}$. Since the limit is independent of the choice of subsequences, we must have $\psi_{2,\epsilon} \to a\psi_{\mathbf{h}}$ in $C^{2+\alpha}(\Omega)$ as $\epsilon \to 0$. From this and (C4) we find $\|\mathbf{B}_\epsilon\|_{L^\infty(\mathbb{R}^3)} \leqslant C\epsilon$. This verifies the first inequality in (4.41). Using this, and applying the elliptic estimate to the equation of $\psi_{2,\epsilon} - a\psi_{\mathbf{h}}$ derived from (C9), we get the second inequality in (4.41). The third inequality in (4.41) has been proved in (C5). □

Proof of (4.44): Suppose (4.44) were not true. Passing to a subsequence we assume $m^\epsilon \ll |l^\epsilon|$. Let

$$\zeta^\epsilon = -\frac{i m^\epsilon}{a_\epsilon l^\epsilon}\phi_{1,\epsilon}.$$

Since $|\mathbf{A}_{1,\epsilon}| = o(\epsilon)$ and $m^\epsilon/l^\epsilon = o(1)$, we have

$$\frac{\epsilon^2}{2}|\Omega| \geqslant \mathcal{G}[\phi_\epsilon, \mathbf{A}_\epsilon] \geqslant \int_\Omega \left\{ |\nabla_{\epsilon a_\epsilon \mathbf{A}_\epsilon} \phi_\epsilon|^2 + \frac{\epsilon^2}{2}(1-|\phi_\epsilon|^2)^2 \right\} \mathrm{d}x$$
$$= \epsilon^2 \left\{ a_\epsilon^2 |l^\epsilon|^2 \int_\Omega |\mathbf{F_h} - \nabla \zeta^\epsilon|^2 \, \mathrm{d}x + \frac{1}{2}(1-|l^\epsilon|^2)^2 |\Omega| + o(\epsilon |l^\epsilon|^2) \right\}$$
$$= \epsilon^2 |\Omega| \left\{ \frac{1}{2} + a_\epsilon^2 |l^\epsilon|^2 \fint_\Omega |\mathbf{F_h} - \nabla \zeta^\epsilon|^2 \, \mathrm{d}x - |l^\epsilon|^2 + \frac{1}{2}|l^\epsilon|^4 + o(\epsilon |l^\epsilon|^2) \right\}.$$

Therefore

$$a_\epsilon^2 \fint_\Omega |\mathbf{F_h} - \nabla \zeta^\epsilon|^2 \, \mathrm{d}x \leqslant 1 + o(\epsilon).$$

From (4.17), $a_\epsilon \geqslant a(\mathbf{h}) + o(1)$. So we find

$$\fint_\Omega |\mathbf{F_h} - \nabla \zeta^\epsilon|^2 \, \mathrm{d}x \leqslant \omega(\mathbf{h}) + o(1).$$

It implies that $\{\zeta^\epsilon\}$ is a minimizing sequence of $\omega(\mathbf{h})$. Note that $\int_\Omega \zeta^\epsilon \, \mathrm{d}x = 0$. We can pass to a subsequence and assume that $\zeta^\epsilon \to w_\mathbf{h}$ weakly in $W^{1,2}(\Omega)$ and strongly in $L^2(\Omega)$ as $\epsilon \to 0$. However, using (4.43) we find

$$\|\zeta^\epsilon\|_{L^2(\Omega)} = \left\| \frac{m_\epsilon}{a_\epsilon l^\epsilon} \phi_{1,\epsilon} \right\|_{L^2(\Omega)} \to 0 \quad \text{as} \quad \epsilon \to 0.$$

This contradiction shows that (4.44) is true. □

Tensor operators and constructing indecomposable representations of semidirect product groups

Chris Conidis and Joe Repka
Department of Mathematics, University of Toronto, Toronto, Ontario M5S 3G3, Canada

(Received 28 November 2002; accepted 5 March 2003)

Consider a semidirect product group $G=H\ltimes V$, where H is reductive and V is a vector group. Two irreps π_1 and π_2 of H can be ''assembled'' into a representation of G if it is possible to construct an indecomposable representation Π of G whose restriction to H is $\pi_1\oplus\pi_2$. It is shown that this is equivalent to the existence of a tensor operator from π_2 to π_1 carrying a representation of H which is equivalent to a nontrivial quotient of the representation which defines the semidirect product. This provides a systematic method for deciding whether two irreps can be assembled, and, if so, in how many inequivalent ways. The method is applied in many of the standard examples that arise in physical questions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1571659]

I. INTRODUCTION

Cantoni[1] considered semidirect product groups $G=H\ltimes V$, where H is reductive and V is Abelian. Suppose π_1 and π_2 are finite-dimensional irreps of H. He asked whether it is possible to ''assemble'' them into an indecomposable representation of G, that is, to construct an indecomposable representation Π of G whose restriction to H is $\pi_1\oplus\pi_2$. By explicit calculation, he answered this question in a number of cases.

In the present work, we consider the special case in which V is a vector group, a case which includes many groups that are important in physics. From Proposition 3.1 below, it follows that any finite-dimensional irreducible representation of G is obtained by taking an irrep of H and extending it to G by letting V act trivially. The interest in indecomposable representations of the sort described above is that they show how the action of the Abelian subgroup V can couple different irreps of the reductive subgroup H.

After some preliminaries about the structure of an ''assembled'' representation, we show that the construction of such a representation Π amounts to specifying a ''tensor operator'' in the sense of Rowe and Repka.[3] This leads to a systematic approach which makes it possible to describe not only when such a construction is possible, but also to describe the number of mutually inequivalent constructions there are. For a given group G, the theory provides a straightforward method for deciding whether particular irreps π^λ and π^μ of H can be assembled into an indecomposable representation of G. For many of the groups of interest in physics, the representation of H which defines the semidirect product is sufficiently simple that it is possible to give an explicit description of all pairs π^λ and π^μ which can be assembled into indecomposable representations of G.

A number of examples are given, including the semidirect product of each of the groups $\mathrm{SU}(n)$, $\mathrm{Sp}(n)$, and $\mathrm{SO}(n)$ with its standard representation. In particular, we recover and extend most of the examples of Cantoni, with additional information about multiplicities.

II. PRELIMINARIES AND NOTATION

Let H be a reductive group, and π_0 a representation of H on a finite dimensional vector space V. Construct a semidirect product group, $G=H\ltimes V$, with the following multiplication: $\forall\ (g_1,v_1),\ (g_2,v_2)\in G,(g_1,v_1)(g_2,v_2)=(g_1g_2,\pi_0(g_2^{-1})v_1+v_2)$. We will consider the problem of constructing representations of G given representations of H.

For convenience, we will assume H is connected, as it usually is in the examples of interest. Also assume that π_0 does not contain the trivial representation of H. If V is a complex vector space, we will nonetheless consider it as a real vector space (i.e., by restricting to real scalars). We write π_0^c for the complexification of π_0.

We write $\{\alpha\}$ for the positive roots of H, $\{\beta_i\}$ for the simple roots, and $\{\beta_i^*\}$ for the corresponding fundamental weights. Though we will define the $\{\beta_i\}$ and $\{\beta_i^*\}$ as elements of the dual and co-dual spaces of the root space (respectively), we will also treat them as elements of the root space under the standard identification. As usual, $\delta=\frac{1}{2}\Sigma_{\alpha>0}\alpha$. If λ is a dominant integral weight and π^λ is a representation of G on a finite dimensional vector space with highest weight λ, then the dimension of π^λ is given by the Weyl dimension formula (cf., Humphreys[2]),

$$\dim(\pi^\lambda)=\frac{\Pi_{\alpha>0}(\lambda+\delta,\alpha)}{\Pi_{\alpha>0}(\delta,\alpha)}. \tag{1}$$

III. INDECOMPOSABLE REPRESENTATIONS

A. Structure of indecomposable representations

Proposition 3.1: Suppose Π *is a representation of* G *on a finite-dimensional (complex) Hilbert space* $\mathbb{H}$. *Then* $\mathbb{H}$ *contains a nonzero* G*-invariant subspace* $\mathbb{H}'$ *on which* V *acts trivially*.

Proof: Since V is Abelian, it is in particular solvable, so Lie's Theorem says that there exists a nonzero $\varphi\in\mathbb{H}$ which is a simultaneous eigenvector for the restriction of Π to V, i.e., for every $v\in V$, $\Pi(v)\varphi=\alpha_\varphi(v)\varphi$, for some $\alpha_\varphi(v)\in\mathbb{C}$.

Now, for any $v\in V$, $h\in H$, we have

$$\Pi(v)\Pi(h)\varphi=\Pi(h)\Pi(h^{-1}vh)\varphi=\Pi(h)\Pi(v^{h^{-1}})\varphi=\Pi(h)\alpha_\varphi(v^{h^{-1}})\varphi=\alpha_\varphi(v^{h^{-1}})\Pi(h)\varphi,$$

showing that not only φ, but also $\Pi(h)\varphi$, for any $h\in H$, is an eigenvector for $\Pi(v)$.

Let $\mathbb{H}'$ be the H-invariant subspace generated by φ. Since it is spanned by eigenvectors for V, it is in fact G-invariant. For fixed $v\in V$, note that the eigenvalue $\alpha_\varphi(v^{h^{-1}})$ is a continuous function of $h\in H$. Since there can be only finitely many distinct eigenvalues in a finite-dimensional space, the connectedness of H implies that it must be a constant function. In other words, for each $v\in V$, $\Pi(v)$ acts on $\mathbb{H}'$ as a scalar $\alpha(v)\cdot I$. In particular, on $\mathbb{H}'$, $\Pi(v)$ commutes with $\Pi(h)$, for all $v\in V$, $h\in H$.

The character α of V can be written as $\alpha(v)=e^{A(v)}$, for some $A\in V^*\otimes\mathbb{C}$, where V^* means the real dual of V, with V regarded as a real vector space. The action of $h\in H$ is given by $\alpha(v^h)=e^{A(v^h)}=e^{A(\pi_0(h)(v))}=e^{(\overline{\pi_0}(h^{-1})(A))(v)}$, where $\overline{\pi_0}$ is the contragredient to π_0, acting on $V^*\otimes\mathbb{C}$. But since $\alpha(v^h)=\alpha(v)$, for all $v\in V$, $h\in H$, we see that A is fixed by $\overline{\pi_0}$. Since π_0 is assumed not to contain the trivial representation of H, this is possible only if $A=0$. This shows that V acts trivially on $\mathbb{H}'$, completing the proof. ●

Theorem 3.2: *Suppose* Π *is an indecomposable representation of* G *on a finite-dimensional Hilbert space* $\mathbb{H}$, *which, when restricted to* H, *is the direct sum of two irreps. Then it is possible to find an* H*-decomposition* $\mathbb{H}=\mathbb{H}_1\oplus\mathbb{H}_2$, *such that* $\mathbb{H}_1$ *and* $\mathbb{H}_2$ *carry irreps of* H *and* $\mathbb{H}_1$ *is* G*-invariant. Moreover, the action of* V *is trivial on* $\mathbb{H}_1$ *and on* $\mathbb{H}/\mathbb{H}_1$.

Proof: Let $\mathbb{H}_1$ be the subspace $\mathbb{H}'$ defined in proposition 3.1. Applying the proposition again to $\mathbb{H}/\mathbb{H}_1$ shows that V acts trivially there (in this case, $\mathbb{H}'$ is the whole space). Define $\mathbb{H}_2$ as an H-complementary subspace to $\mathbb{H}_1$. ●

B. Assembling irreps

Suppose Π is an indecomposable representation of G and define $\mathbb{H}_i$, $i=1,2$, as in theorem 3.2. Let π_i be the representation of H on $\mathbb{H}_i$, $i=1,2$. In this situation, we will say that "π_1 and π_2 are assembled into the representation Π of G." Note that the first irrep mentioned, π_1, occurs as a G-subrepresentation of Π.

If a basis is chosen for $\mathbb{H}$ which consists of a basis for $\mathbb{H}_1$ followed by a basis for $\mathbb{H}_2$, then for any $h \in H$, $v \in V$, the corresponding operators have block upper triangular matrices of the following forms:

$$\Pi(h) = \begin{pmatrix} \pi_1(h) & 0 \\ 0 & \pi_2(h) \end{pmatrix}, \quad \Pi(v) = \begin{pmatrix} I & T(v) \\ 0 & I \end{pmatrix}. \tag{2}$$

The indecomposability of Π implies that $T(v)$ is not identically zero.

IV. TENSOR OPERATORS

Suppose Π is an indecomposable representation of G on a finite-dimensional Hilbert space $\mathbb{H}$, which, when restricted to H, is the direct sum of two irreps. Define subspaces $\mathbb{H}_1$ and $\mathbb{H}_2$ as in theorem 3.2 and, for each $v \in V$, define $T(v) \in \hom(\mathbb{H}_2, \mathbb{H}_1)$ as in (2). Then $\{T(v): v \in V\}$ is a tensor operator in the sense of Rowe and Repka.[3] It can be written as a sum of tensor operators, each of which has rank equal to the rank of one of the irreducible constituents of π_0^c. Specifically, for $v \in V$, $h \in H$, $\psi \in \mathbb{H}_2$, $\pi_1(h)T(v)\psi = \pi_1(h)T(v)\pi_2(h^{-1})\pi_2(h)\psi = T^h(v)\pi_2(h)\psi$, where

$$T^h(v) = T(v^h); \tag{3}$$

i.e., under the action $h: T \mapsto T^h = \pi_1(h)T\pi_2(h^{-1})$, the matrices $\{T(v): v \in V\}$ carry a representation of H which is isomorphic to a nontrivial quotient of π_0^c.

Conversely, suppose we are given such a tensor operator, i.e., a (nonzero) collection of linear maps $T(v) \in \hom(\mathbb{H}_2, \mathbb{H}_1)$ which satisfy (3) and which carry a representation of H which is isomorphic to a nontrivial quotient of π_0^c. Then Eq. (2) gives an indecomposable representation Π of G whose restriction to H is $\pi_1 \oplus \pi_2$, with π_1 acting on a G-invariant subspace.

Let us consider possible equivalences between such representations. Any operator which commutes with the action of G must be block upper triangular because of the invariance of $\mathbb{H}_1$. Because of the irreducibility of both π_1 and π_2, the diagonal blocks must be scalars. If π_1 and π_2 are inequivalent representations of H, then the top right block must be zero. If π_1 and π_2 are equivalent, then, choosing compatible bases for $\mathbb{H}_1$ and $\mathbb{H}_2$, we find that the top right block must be a scalar. In either case, the only representations equivalent to the representation Π constructed above are those constructed in the same way using scalar multiples of the tensor operator T.

We have proven the following:

Theorem 4.1: *Let π_1 and π_2 be irreducible finite-dimensional representations of H. Then, in the language of Cantoni,[1] π_1 and π_2 can be "assembled" into an indecomposable representation of G if and only if there is a tensor operator T from π_2 into π_1, with T carrying a representation of H which is isomorphic to some nontrivial quotient of π_0^c.*

Moreover, if, up to scalar multiples, there is only one such tensor operator T from π_2 into π_1, then there is only one such assemblage, up to equivalence. If there are more than one such tensor operator, then there are infinitely many inequivalent assemblages, indexed by tensor operators modulo nonzero scalar multiples.

One of the main results of Rowe and Repka[3] is that the existence of a tensor operator from π_2 into π_1 having the same rank as an irrep π is equivalent to the occurrence of π_1 in the tensor product $\pi_2 \otimes \pi$. Combining this result with theorem 4.1, we obtain the following theorem:

Theorem 4.2: *With π_1 and π_2 as above, π_1 and π_2 can be "assembled" into an indecomposable representation of G if and only if the tensor product $\pi_0^c \otimes \pi_2$ contains π_1. Moreover, the number of inequivalent such assemblages is determined by the multiplicity with which π_1 occurs in $\pi_0^c \otimes \pi_2$: if it occurs only once, then there is only one assemblage, up to equivalence. Otherwise, there are infinitely many inequivalent assemblages.*

V. EXAMPLE: THE EUCLIDEAN GROUP E(2)

The two-dimensional Euclidean group E(2) is the semidirect product of SO(2) and $\mathbb{R}^2$, the groups of rotations and translations of the plane, respectively. We write χ_n for the character of SO(2) given by

$$\chi_n\left(\begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix}\right) = e^{in\theta}.$$

It is also possible to express E(2) as the semidirect product of the unit circle $S^1=\{e^{i\theta}\}$ and $\mathbb{C}$, using the matrix realization,

$$\mathrm{E}(2)=\left\{\begin{pmatrix} e^{i\theta} & z \\ 0 & 1 \end{pmatrix} : \theta\in\mathbb{R},\ \ z\in\mathbb{C}\right\}. \tag{4}$$

Here we could think of $V=\mathbb{C}$ as a one-dimensional complex vector space carrying the irrep χ_1 of $S^1\cong\mathrm{SO}(2)$, but as described above, it is necessary for present purposes to regard it as a two-dimensional real vector space on which $S^1\cong\mathrm{SO}(2)$ acts by rotations. In particular, the complexification $\mathbb{C}\otimes V$ is the direct sum $\chi_1\oplus\chi_{-1}$.

In this context, theorem 4.2 says that an irrep χ_n of $H=\mathrm{SO}(2)$ can be assembled into an indecomposable representation of G with either χ_{n+1} or χ_{n-1}, reproducing the result of Cantoni.[1] Explicitly, these representations are given as follows:

$$\begin{pmatrix} e^{i\theta} & z \\ 0 & 1 \end{pmatrix}\mapsto\begin{pmatrix} e^{in\,\theta} & e^{i(n+1)\theta}\overline{z} \\ 0 & e^{i(n+1)\theta} \end{pmatrix},\quad \begin{pmatrix} e^{i\theta} & z \\ 0 & 1 \end{pmatrix}\mapsto\begin{pmatrix} e^{in\theta} & e^{i(n-1)\theta}z \\ 0 & e^{i(n-1)\theta} \end{pmatrix}.$$

If we had worked with V as a complex vector space, we would have missed the first possibility.

VI. EXAMPLE: SU($N+1$)

Let $H=\mathrm{SU}(n+1)$; then the simple roots of H are $\beta_1,\ldots,\beta_n$, given by $\beta_i(u_0,\ldots,u_n)=u_{i-1}-u_i$. The fundamental weights are $\beta_1^*,\ldots,\beta_n^*$, given by $\beta_i^*(u_0,\ldots,u_n)=\Sigma_{j=0}^{i-1}u_j$. It follows that $\delta=\frac{1}{2}\Sigma_{\alpha>0}\alpha=\Sigma_{k=1}^n\beta_k^*$. Let $e_0=\beta_1^*, e_i=\beta_i^*-\beta_{i-1}^*$ $(2\leqslant i\leqslant n-1)$, and $e_n=-\beta_n^*$.

We shall consider the case where π_0 is the "standard" $(n+1)$-dimensional (complex) representation of SU$(n+1)$; its highest weight is e_0, and its weights e_i all have multiplicity one. The complexification of this $2(n+1)$-dimensional real vector space carries two irreps, π_0^1, which is the irrep just mentioned, with highest weight e_0, and its contragredient π_0^2, which has weights $-e_i$, $i=0,\ldots,n$, and highest weight $-e_n$.

We note that for $n=1$, i.e., for $H=\mathrm{SU}(2)$, these irreps π_0^1 and π_0^2 are equivalent, but for $n>1$, they are inequivalent, and the difference between their highest weights is e_0+e_n, which is not in the root lattice.

For any dominant integral weight λ, we write π^λ for the irrep with highest weight λ.

Proposition 6.1: For any dominant integral weight λ,

$$\sum_{\ell=0}^{n}\prod_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)=(n+1)\prod_{\alpha>0}(\delta+\lambda,\alpha).\ (*)$$

Proof: Write $\lambda=\Sigma_{k=1}^n c_k\beta_k^*$; then $\lambda+\delta=\Sigma_{k=1}^n(c_k+1)\beta_k^*=\Sigma_{k=1}^n x_k\beta_k^*$, where $x_k=c_k+1$.

Fix i and j with $1\leqslant i\leqslant j\leqslant n$; note that the right side of $(*)$ is a product of factors of the form $X_{ij}=\Sigma_{k=i}^j x_k$. Assume that $X_{ij}=0$; it follows that all products in $(*)$ are zero except for $\Pi_{\alpha>0}(e_{i-1}+\delta+\lambda,\alpha)$ and $\Pi_{\alpha>0}(e_j+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^j\beta_k=Y_{ij}$ is zero. Now, we shall show that $\Pi_{\alpha>0}(e_{i-1}+\delta+\lambda,\alpha)$

$=-\Pi_{\alpha>0}(e_j+\delta+\lambda,\alpha)$. To do this, still under the assumption that $X_{ij}=0$, we shall consider both of the remaining products as polynomials in $x_1,\ldots,x_n$, show that they have the same roots, and finally conclude that they differ by a sign.

Define a real-valued function m on the root space as follows: if $\alpha=\Sigma_{k=1}^n p_k\beta_k$, let $m(\alpha)=p_{j+1}-p_j-p_i+p_{i-1}$. Let $\gamma=\Sigma_{k=1}^n a_k\beta_k$ be a fixed positive root of H, and for convenience, let $a_0=a_{n+1}=0$ and $m=m(\gamma)$. Now, $(e_{i-1}+\delta+\lambda,\gamma)=(\delta+\lambda,\gamma)+a_i-a_{i-1}=(\delta+\lambda,\gamma)+a_i-a_{i-1}+mX_{ij}=(\delta+\lambda,\gamma)+a_{j+1}-a_j-m+mX_{ij}=(\delta+\lambda,\gamma)+(e_j,\gamma)+(e_j+\delta+\lambda,mY_{ij})=(e_j+\delta+\lambda,\gamma+mY_{ij})$. The map $T:\alpha\to\alpha+m(\alpha)Y_{ij}$ is the reflection in the hyperplane perpendicular to Y_{ij}, and thus $\gamma+mY_{ij}$ is a root of H. So, if $(e_{i-1}+\delta+\lambda,\gamma)=0$, then $(e_j+\delta+\lambda,\pm(\gamma+mY_{ij}))=0$, and since T is one-to-one, the two polynomials have exactly the same roots. Furthermore, as an element of the Weyl group, T has an odd length, so T maps an odd number of positive roots to negative roots. Hence the products differ by a minus sign.

Since each factor of $\Pi_{\alpha>0}(\delta+\lambda,\alpha)$ is equal to X_{ij} for some i and j, we have shown that the roots of the right side of $(*)$ are contained within the roots of the left side of $(*)$. Since the right side of $(*)$ is a product of distinct linear factors (in the x_i), then the left side of $(*)$ is divisible by each of these factors. But both sides of $(*)$ are of the same degree, hence it follows that they differ by a multiplicative constant. Substituting $\lambda=0$ shows that the constant must be $n+1$. ●

Proposition 6.2: Fix $j\in\{1,\ldots,n\}$ and consider a dominant integral weight $\lambda=\Sigma_{k=1}^n c_k\beta_k^*$ with $c_j=0$; then

$$\prod_{\alpha>0}(e_j+\delta+\lambda,\alpha)=0.$$

Proof: Let $\alpha=\beta_j>0$. Then, if $j\neq n$, $(e_j+\delta+\lambda,\alpha)=(\beta_{j+1}^*-\beta_j^*+\Sigma_{k=1}^n\beta_k^*+\Sigma_{k=1}^n c_k\beta_k^*,\beta_j)=-1+1+c_j=0$, so the product is zero. The proof is similar for $j=n$. ●

In the tensor product $\pi^\lambda\otimes\pi_0^1$, any irreducible representation that occurs must have highest weight $\lambda+e_i$, for some $i\in\{0,\ldots,n\}$, and cannot occur more than once. By the Weyl dimension formula (1), the sum of the dimensions of the irreducible representations with highest weights $\lambda+e_i$ is $\Sigma_{\ell=0}^n\Pi_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)$, and $\dim(\pi^\lambda\otimes\pi_0^1)=\dim(\pi_0^1)\dim(\pi^\lambda)=(n+1)\times[\Pi_{\alpha>0}(\delta+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)]$. Now, we would like to show that the sum of the dimensions of the $\pi^{\lambda+e_i}$ $(i=0,\ldots,n)$ is equal to the dimension of the tensor product $\pi^\lambda\otimes\pi_0^1$; this follows immediately from proposition 6.1 if all the $\lambda+e_i$ are dominant integral weights.

Now $\mu=\Sigma_{i=1}^n z_i\beta_i^*$ is not a dominant integral weight if and only if $z_i<0$, for some $i\in\{1,\ldots,n\}$. Since $\lambda=\Sigma_{k=1}^n c_i\beta_i$ is the highest weight of π^λ, the one and only way that $\lambda+e_i$ would not be a dominant integral weight is if $c_i=0$. Thus, proposition 6.2 implies that if $\lambda+e_i$ is not a dominant integral weight, then the dimension formula gives a value of zero. Taken together, propositions 6.1 and 6.2 imply that the irreducible representations that occur in the tensor product $\pi^\lambda\otimes\pi_0^1$ are exactly the $\pi^{\lambda+e_i}$ for which $\lambda+e_i$ is a dominant integral weight. Taking contragredients, we also see that the irreducible representations that occur in the tensor product $\pi^\lambda\otimes\pi_0^2$ are exactly the $\pi^{\lambda-e_i}$ for which $\lambda-e_i$ is a dominant integral weight. Noting that $\lambda+e_i$ is never equal to $\lambda-e_j$, we have proved the following.

Theorem 6.3: *The irreducible representations π^λ and π^μ of $H=\mathrm{SU}(n+1)$ can be assembled into an indecomposable representation of $G=\mathrm{SU}(n+1)\ltimes\mathbb{C}^{n+1}$ if and only if $\mu=\lambda\pm e_i$, for some $i\in\{0,\ldots,n\}$.*

For $n=1$, i.e., for $H=\mathrm{SU}(2)$, each such assemblage can be constructed in infinitely many inequivalent ways. If $n>1$, for each of the possible pairs of representations, the assemblage is unique.

VII. EXAMPLE: SU(3)$\ltimes\mathbb{R}^8$

Let $H=\mathrm{SU}(3)$ and let π_0 be the eight-dimensional real (adjoint) representation of H; it has weights: $e_1=\beta_1^*+\beta_2^*$, $e_2=2\beta_1^*-\beta_2^*$, $e_3=2\beta_2^*-\beta_1^*$, $e_4=-\beta_1^*-\beta_2^*$, $e_5=-2\beta_1^*-\beta_2^*$, e_6

$=-2\beta_2^*-\beta_1^*$, $e_7=0$, and $e_8=0$. Now we will consider the case where $G=\mathrm{SU}(3)\ltimes\mathbb{R}^8$. If the highest weight of a representation π^λ of H is $\lambda=c_1\beta_1^*+c_2\beta_2^*$, then the dimension of π^λ is given by (1); it is $\dim(\pi^\lambda)=(c_1+1)(c_2+1)(c_1+c_2+2)/2$.

Lemma 7.1: $\Sigma_{k=1}^8\dim(\pi^{\lambda+e_k})=8\dim(\pi^\lambda)$.

Proof: A direct calculation gives the result. ●

In the tensor product $\pi^\lambda\otimes\pi_0$, any irreducible representation that occurs must have highest weight $\lambda+e_i$, for some $i\in\{1,\ldots,8\}$ and cannot occur more than once unless it has highest weight λ, in which case it cannot occur more than twice. We would like to show that the irreducible representation with highest weight $\lambda+e_i, i\in\{1,\ldots,6\}$ occurs exactly once in the tensor product, provided that $\lambda+e_i$ is a dominant integral weight, and that there are two copies of the irreducible representation with highest weight λ in the tensor product. This is easy to show if neither c_1 nor c_2 is equal to zero; the proof is as follows.

If $\lambda=c_1\beta_1^*+c_2\beta_2^*$ is the highest weight of an irreducible representation π^λ of H, and c_1 and c_2 are both not zero, then the weight $\lambda+e_1$ occurs in the tensor product $\pi^\lambda\otimes\pi_0$ with multiplicity one; $\lambda+e_2$ occurs with multiplicity two, as does $\lambda+e_3$; and λ occurs with multiplicity six. This implies that the irreducible representations with highest weights $\lambda+e_1,\lambda+e_2$, and $\lambda+e_3$ occur in the tensor product with multiplicity one, and the irreducible representation with highest weight λ occurs with multiplicity 2. This result, along with lemma 7.1 and the fact that if $\lambda+e_i$ is not a dominant integral weight and is substituted into (1), a value of zero is obtained (this can be verified by direct computation), shows that the irreducible representations with highest weights $\lambda+e_i$ for some $i\in\{1,\ldots,6\}$ appear exactly once in the tensor product, and the irreducible representation with highest weight λ occurs twice.

Now, suppose that $\lambda=c_1\beta_1^*+c_2\beta_2^*$ is the highest weight of an irreducible representation π^λ of H, with $c_1>1$ and $c_2=0$. Then the only possible irreducible representations that may occur in the tensor product are those with highest weight $\lambda+e_1$, $\lambda+e_3$, $\lambda+e_5$, or λ, since these are the only $\lambda+e_i$ that are dominant integral weights. In the tensor product $\pi^\lambda\otimes\pi_0$, the weight $\lambda+e_1$ occurs with multiplicity one; $\lambda+e_3$ occurs with multiplicity two; $\lambda+e_5$ occurs with multiplicity six; and λ occurs with multiplicity four. This implies that the irreducible representations that occur in the tensor product occur only once and are those with highest weights $\lambda+e_1$, $\lambda+e_3$, $\lambda+e_5$, and λ. If $c_1=1$ and $c_2=0$ then one can check that the irreducible representations that occur in the tensor product $\pi^\lambda\otimes\pi_0$ all have multiplicity one and are those with highest weights $\lambda+e_1$, $\lambda+e_3$, and λ. Similarly, one can show that if $c_1=0$ and $c_2>1$, then the irreducible representations that occur in the tensor product all have multiplicity one and are those with highest weights $\lambda+e_1$, $\lambda+e_2$, $\lambda+e_6$, and λ. Also, if $c_1=0$ and $c_2=1$ then the irreducible representations that occur in the tensor product all have multiplicity one and are those with highest weights $\lambda+e_1$, $\lambda+e_2$, and λ. If $c_1=c_2=0$ then all that appears in the tensor product is the adjoint representation, which has highest weight $\lambda+e_1=0+e_1=e_1$.

Thus, we have proven the following theorem:

Theorem 7.2: *The representations of $H=\mathrm{SU}(3)$ that may be assembled with π^λ into a representation of $G=\mathrm{SU}(3)\ltimes\mathbb{R}^8$ are those that have highest weight $\lambda+e_i$, for some $i\in\{1,\ldots,8\}$. Furthermore, if $\lambda=c_1\beta_1^*+c_2\beta_2^*$ and neither c_1 nor c_2 are zero, then there are infinitely many inequivalent ways of assembling π^λ with itself and exactly one way of assembling π^λ and $\pi^{\lambda+e_i}$, $i\in\{1,\ldots,6\}$. If either $c_1=0$ or $c_2=0$ and $\lambda+e_i$ is a dominant integral weight, then there is exactly one way of assembling π^λ and $\pi^{\lambda+e_i}$.*

VIII. EXAMPLE: Sp(*N*)

Let $H=\mathrm{Sp}(n)$; then the simple roots of H are $\beta_1,\ldots,\beta_n$, given by $\beta_i(u_1,\ldots,u_n)=u_i-u_{i+1}$ for $i=1,\ldots,n-1$, and $\beta_n(u_1,\ldots,u_n)=2u_n$. The fundamental weights are $\beta_i^*,\ldots,\beta_n^*$ given by $\beta_i^*(u_1,\ldots,u_n)=\Sigma_{k=1}^i u_k$. It follows that $\delta=\frac{1}{2}\Sigma_{\alpha>0}\alpha=\Sigma_{k=1}^n\beta_k^*$. Let $e_1=\beta_1^*$, $e_i=\beta_i^*-\beta_{i-1}^*(2\leqslant i\leqslant n)$, and $e_{n+j}=-e_j$ for $j=1,\ldots,n$. We shall consider the case where π_0 is the "standard" $2n$-dimensional (real) representation of $\mathrm{Sp}(n)$; its highest weight is e_1, and all its weights have multiplicity one.

Proposition 8.1: For any dominant integral weight λ,

$$\sum_{\ell=1}^{2n} \prod_{\alpha>0} (e_\ell+\delta+\lambda,\alpha)=2n\prod_{\alpha>0}(\delta+\lambda,\alpha). \quad (*)$$

Proof: Let $\lambda=\Sigma_{k=1}^{n} c_k\beta_k^*$; then $\lambda+\delta=\Sigma_{k=1}^{n}(c_k+1)\beta_k^*=\Sigma_{k=1}^{n}x_k\beta_k^*$, where $x_k=c_k+1$.

Fix i and j with $1\leqslant i\leqslant j\leqslant n$.

Case A: Suppose that $X_{ij}=\Sigma_{k=i}^{j}x_k=0$. It follows that all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{j}\beta_k=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$ is the same as that given for SU$(n+1)$ if one changes e_{i-1} to e_i and e_j to e_{j+1}. The proof that $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$ can be obtained by making the following changes: e_{i-1} to e_{n+i}, e_j to e_{n+j+1}, and a_k to $-a_k$, for $k=i-1,i,j,j+1$.

Case B: Suppose that $X_{ij}=(\Sigma_{k=i}^{j}x_k)+(\Sigma_{k=j+1}^{n-1}2x_k)+x_n=0$. It follows that all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=(\Sigma_{k=i}^{j}\beta_k)+(\Sigma_{k=j+1}^{n-1}2\beta_k)+\beta_n=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$ is similar to the one given for SU$(n+1)$; it may be obtained by making the following changes: e_{i-1} to e_i, e_j to e_{n+j+1}, a_{j+1} to $-a_{j+1}$, and a_j to $-a_j$. The proof that $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$ can be obtained from the proof for SU$(n+1)$ by making the following changes: e_{i-1} to e_{n+i}, e_j to e_{j+1}, a_{i-1} to $-a_{i-1}$, a_i to $-a_i$.

Case C: Suppose that $X_{ij}=(2\Sigma_{k=i}^{n-1}x_k)+x_n=0$, $(i<n)$. Then all products in $(*)$ are zero except for $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=2\Sigma_{k=i}^{n-1}\beta_k+\beta_n=Y_{ij}$ is zero. Now, we will show that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$ by considering the two products as polynomials in $x_1,\ldots,x_n$, showing that they have the same roots, and then concluding that they must differ by a factor of -1.

Let γ be as in the proof for SU$(n+1)$, and let $m=m(\gamma)=a_i-a_{i-1}$. Now, $(e_i+\delta+\lambda,\gamma)=(\delta+\lambda,\gamma)+a_i-a_{i-1}=(\delta+\lambda,\gamma)+a_i-a_{i-1}+mX_{ij}=(\delta+\lambda,\gamma)+a_{i-1}-a_i-2m+mX_{ij}=(\delta+\lambda,\gamma)+(e_{n+i},\gamma)+(e_{n+i}+\delta+\lambda,mY_{ij})=(e_{n+i}+\delta+\lambda,\gamma+mY_{ij})$. Hence, by the same line of reasoning as in the proof for SU$(n+1)$, the products must differ by a sign.

Since each factor of $\Pi_{\alpha>0}(\delta+\lambda,\alpha)$ is covered by one of the above cases for some i and j, we have shown that the roots of the right side of $(*)$ are contained within the roots of the left side of $(*)$. By comparing degrees and substituting $\lambda=0$, we obtain the result. ●

Proposition 8.2: Fix $j\in\{1,\ldots,n\}$ *and consider a dominant integral weight* $\lambda=\Sigma_{k=1}^{n}c_k\beta_k^*$ *with* $c_j=0$; *then*

$$\prod_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)=0, \quad \text{if } j\neq n,$$

and

$$\prod_{\alpha>0}(e_{n+j}+\delta+\lambda,\alpha)=0.$$

Proof: If $j\in\{1,\ldots,n-1\}$, then $(e_{j+1}+\delta+\lambda,\beta_j)=-1+1+c_j=0$ and $(e_{n+j}+\delta+\lambda,\beta_j)=-1+1+c_j=0$. If $j=n$, then $(e_{2n}+\delta+\lambda,\beta_j)=-2+2+c_j=0$. Thus, the proposition has been proven. ●

In the tensor product $\pi^\lambda\otimes\pi_0$, any irreducible representation that occurs must have highest weight $\lambda+e_i$, for some $i\in\{1,\ldots,2n\}$, and cannot occur more than once. By (1), the sum of the dimensions of the irreducible representations with highest weights $\lambda+e_i$ $(i=1,\ldots,2n)$ is $\Sigma_{\ell=1}^{2n}\Pi_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)$, and $\dim(\pi^\lambda\otimes\pi_0)=\dim(\pi_0)\dim(\pi^\lambda)=(2n)[\Pi_{\alpha>0}(\delta$

$+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)]$. We would like to show that the sum of the dimensions of the $\pi^{\lambda+e_i}$ $(i=1,\ldots,2n)$ is equal to the dimension of the tensor product $\pi^{\lambda}\otimes\pi_0$; we can infer this from proposition 8.1 if we know that all the $\lambda+e_i$ are dominant integral weights.

Now $\mu=\Sigma_{i=1}^{n}z_i\beta_i^*$ is not a dominant integral weight if and only if $z_i<0$, for some $i\in\{1,\ldots,n\}$. Since $\lambda=\Sigma_{k=1}^{n}c_i\beta_i$ is the highest weight of π^{λ}, the one and only way that $\lambda+e_i$ $i\in\{1,\ldots,n\}$ would not be a dominant integral weight is if $i\neq 1$ and $c_{i-1}=0$. The only way that $\lambda+e_{n+j}, j\in\{1,\ldots,n\}$, would not be a dominant integral weight is if $c_j=0$. So, proposition 8.2 implies that if $\lambda+e_i$ is not a possible highest weight vector, then the dimension formula gives a value of zero. Taken together, propositions 8.1 and 8.2 imply that the irreducible representations that occur in the tensor product $\pi^{\lambda}\otimes\pi_0$ are exactly those $\pi^{\lambda+e_i}$ for which $\lambda+e_i$ is a dominant integral weight. Therefore, we have proven the following.

Theorem 8.3: *The representations of $H=Sp(n)=Sp(n,\mathbb{R})$ that may be assembled with π^{λ} into a representation of $G=Sp(n)\ltimes\mathbb{R}^{2n}$ are those that have highest weight $\lambda+e_i$, for some $i\in\{1,\ldots,2n\}$. For all of the possible representations this assemblage is unique.*

IX. EXAMPLE: SO(2*N*)

Let $H=\mathrm{SO}(2n)$; then the simple roots of H are $\beta_1,\ldots,\beta_n$, given by $\beta_i(u_1,\ldots,u_n)=u_i-u_{i+1}$ for $i=1,\ldots,n-1$, and $\beta_n(u_1,\ldots,u_n)=u_{n-1}+u_n$. The fundamental weights are $\beta_i^*,\ldots,\beta_n^*$ given by $\beta_i^*(u_1,\ldots,u_n)=\Sigma_{k=1}^{i}u_k$ for $i\in\{1,\ldots,n-2\}$, $\beta_{n-1}^*(u_1,\ldots,u_n)=\frac{1}{2}(\Sigma_{k=1}^{n-1}u_k-u_n)$, and $\beta_n^*(u_1,\ldots,u_n)=\frac{1}{2}\Sigma_{k=1}^{n}u_k$. It follows that $\delta=\frac{1}{2}\Sigma_{\alpha>0}\alpha=\Sigma_{k=1}^{n}\beta_k^*$. Let $e_1=\beta_1^*$, $e_i=\beta_i^*-\beta_{i-1}^*(2\leqslant i\leqslant n-2)$, $e_{n-1}=\beta_n^*+\beta_{n-1}^*-\beta_{n-2}^*$, $e_n=\beta_n^*-\beta_{n-1}^*$, and $e_{n+j}=-e_j$ for $j=1,\ldots,n$. As in the previous examples, we shall consider the case where π_0 is the "standard" $2n$-dimensional (real) representation of $\mathrm{SO}(2n)$; its highest weight is e_1, and all its weights have multiplicity one.

Proposition 9.1: For any dominant integral weight λ,

$$\sum_{\ell=1}^{2n}\prod_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)=2n\prod_{\alpha>0}(\delta+\lambda,\alpha).\quad(*)$$

Proof: Let $\lambda=\Sigma_{k=1}^{n}c_k\beta_k^*$; then $\lambda+\delta=\Sigma_{k=1}^{n}(c_k+1)\beta_k^*=\Sigma_{k=1}^{n}x_k\beta_k^*$, where $x_k=c_k+1$.

Case A: Fix i and j with $1\leqslant i\leqslant j<n-2$.

Subcase A1: Suppose that $X_{ij}=\Sigma_{k=i}^{j}x_k=0$. It follows that all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{j}\beta_k=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$ is the same as that given for $\mathrm{SU}(n+1)$. The proof that $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$ can be obtained by making the following changes: e_{i-1} to e_{n+i}, e_j to e_{n+j+1}, and a_k to $-a_k$, for $k=i-1,i,j,j+1$.

Subcase A2: Suppose that $X_{ij}=(\Sigma_{k=i}^{j}x_k)+(\Sigma_{k=j+1}^{n-2}2x_k)+x_{n-1}+x_n=0$. It follows that all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=(\Sigma_{k=i}^{j}\beta_k)+(\Sigma_{k=j+1}^{n-2}2\beta_k)+\beta_{n-1}+\beta_n=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$ is similar to the one given for $\mathrm{SU}(n+1)$; it may be obtained by making the following changes: e_{i-1} to e_i, e_j to e_{n+j+1}, a_{j+1} to $-a_{j+1}$, and a_j to $-a_j$. The proof that $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$ can be obtained from the proof for $\mathrm{SU}(n+1)$ by making the following changes: e_{i-1} to e_{n+i}, e_j to e_{j+1}, a_{i-1} to $-a_{i-1}$, a_i to $-a_i$.

Case B: Fix i and j with $1\leqslant i\leqslant j=n-2$ and suppose that $X_{ij}=\Sigma_{k=i}^{j}x_k=0$. Then all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n-1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{n-1}\beta_k=Y_{ij}$ is zero. Now, we shall show that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n-1}+\delta$

$+\lambda,\alpha)$. To do this, still under the assumption that $X_{ij}=0$, we shall consider both products as polynomials in $x_1,\ldots,x_n$, show that they have the same roots, and finally conclude that they differ by a sign.

Let $\gamma=\Sigma_{k=1}^{n}a_k\beta_k$ be a fixed positive root of H. Let $m=m(\gamma)=a_n+a_{n-1}-a_{n-2}-a_i+a_{i-1}$. Now, $(e_{i-1}+\delta+\lambda,\gamma)=(\delta+\lambda,\gamma)+a_i-a_{i-1}=(\delta+\lambda,\gamma)+a_i-a_{i-1}+mX_{ij}=(\delta+\lambda,\gamma)+a_n+a_{n-1}-a_{n-2}-m+mX_{ij}=(\delta+\lambda,\gamma)+(e_{n-1},\gamma)+(e_{n-1}+\delta+\lambda,mY_{ij})=(e_{n-1}+\delta+\lambda,\gamma+mY_{ij})$. Hence, by the same line of reasoning as in the proof for SU$(n+1)$, the products differ by a minus sign. The proof that $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)$ can be obtained by making the following changes: e_i to e_{n+i}, e_{n-1} to e_{2n-1}, and a_k to $-a_k$, for $k=i-1,i,n-2,n-1,n$.

Case C: Fix i and j with $1\leqslant i\leqslant j=n-1$.

Subcase C1: Suppose that $X_{ij}=\Sigma_{k=i}^{n-1}x_k=0,(i<n-1)$. Then all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{n-1}\beta_k=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$ is similar to that given for SU$(n+1)$; it may be obtained by making the following changes: e_{i-1} to e_i, e_j to e_n, a_{j+1} to a_n, and a_j to a_{n-1}. The proof that $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$ can be obtained from the proof for SU$(n+1)$ by making the following changes: e_{i-1} to e_{n+i}, e_j to e_{2n}, a_{i-1} to $-a_{i-1}$, a_i to $-a_i$, a_j to $-a_{n-1}$, and a_{j+1} to $-a_n$.

Subcase C2: Suppose that $X_{ij}=x_{n-1}=0$. Then all products in $(*)$ are zero except for $\Pi_{\alpha>0}(e_{n-1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\beta_{n-1}=Y_{ij}$ is zero. Now, we will show that $\Pi_{\alpha>0}(e_{n-1}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$ by considering the two products as polynomials in $x_1,\ldots,x_n$, showing that they have the same roots, and then concluding that they must differ by a factor of -1.

Let γ be as for SU$(n+1)$, and let $m=m(\gamma)=a_{n-2}-2a_{n-1}$. Then, $(e_{n-1}+\delta+\lambda,\gamma)=(\delta+\lambda,\gamma)+a_n+a_{n-1}-a_{n-2}=(\delta+\lambda,\gamma)+a_n+a_{n-1}-a_{n-2}+mX_{ij}=(\delta+\lambda,\gamma)+a_n-a_{n-1}-m+mX_{ij}=(\delta+\lambda,\gamma)+(e_n,\gamma)+(e_n+\delta+\lambda,mY_{ij})=(e_n+\delta+\lambda,\gamma+mY_{ij})$. Hence, by the same line of reasoning as in the proof for SU$(n+1)$, the products differ by a sign. The proof that $\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$ is similar; it may be obtained by making the following changes: e_{n-1} to e_{2n-1}, e_n to e_{2n}, a_{n-2} to $-a_{n-2}$, a_{n-1} to $-a_{n-1}$, and a_n to $-a_n$.

Case D: Fix i and j with $1\leqslant i\leqslant j=n$.

Subcase D1: Suppose that $X_{ij}=\Sigma_{k=i}^{n}x_k=0(i<n)$. Then all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n-1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{n-1}\beta_k=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)$ is similar to that given in case B; it can be obtained by making the following changes: e_n to e_{2n-1}, a_{n-2} to $-a_{n-2}$, and a_{n-1} to $-a_{n-1}$. The proof that $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$ can be obtained from the one given in case B, if one makes the following changes: e_i to e_{n+i}, and a_k to $-a_k$, $k=i-1,i,n$.

Subcase D2: Suppose that $X_{ij}=\Sigma_{k=i}^{n-2}x_k+x_n=0$ $(i\leqslant n-2)$. Then all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{n-2}\beta_k+\beta_n=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$ is similar to the one given for SU$(n+1)$; it may be obtained by making the following changes: e_{i-1} to e_i, e_j to e_{2n}, a_{j+1} to $-a_n$, and a_j to $-a_{n-1}$. The proof that $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$ can be obtained from the proof for SU$(n+1)$ by making the following changes: e_{i-1} to e_{n+i}, e_j to e_n, a_j to a_n, a_j to a_{n-1}, a_i to $-a_i$, and a_{i-1} to $-a_{i-1}$.

Subcase D3: Suppose that $X_{ij}=x_n=0$. Then all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_{n-1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\beta_n=Y_{ij}$ is zero. We will now prove that $\Pi_{\alpha>0}(e_{n-1}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)$ by considering both products as poly-

nomials in $x_1,\ldots,x_n$, showing that they have the same roots, and finally concluding that they must differ by a sign.

Let γ and $\{a_i\}$ be as for SU$(n+1)$, and let $m=m(\gamma)=a_{n-2}-2a_n$. Then, $(e_{n-1}+\delta+\lambda,\gamma)=(\delta+\lambda,\gamma)+a_n+a_{n-1}-a_{n-2}=(\delta+\lambda,\gamma)+a_n+a_{n-1}-a_{n-2}+mX_{ij}=(\delta+\lambda,\gamma)+a_{n-1}-a_n-m+mX_{ij}=(\delta+\lambda,\gamma)+(e_{2n},\gamma)+(e_{2n}+\delta+\lambda,mY_{ij})=(e_{2n}+\delta+\lambda,\gamma+mY_{ij})$. Hence, by the same line of reasoning as in the proof for SU$(n+1)$, the products must differ by a sign. The proof that $\Pi_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_n+\delta+\lambda,\alpha)$ is similar; it may be obtained by making the following changes: e_{n-1} to e_{2n-1}, e_{2n} to e_n, a_{n-2} to $-a_{n-2}$, a_{n-1} to $-a_{n-1}$, and a_n to $-a_n$.

Since each factor of $\Pi_{\alpha>0}(\delta+\lambda,\alpha)$ is equal to X_{ij} for some i, j, and some case or subcase above, we have shown that the roots of the right-hand side of $(*)$ are contained within the roots of the left-hand side of $(*)$. By comparing degrees and substituting $\lambda=0$, we obtain the result. ●

Proposition 9.2: Fix $j\in\{1,\ldots,n\}$ and consider a dominant integral weight $\lambda=\Sigma_{k=1}^{n}c_k\beta_k^*$ with $c_j=0$; then, if $j\neq n$,

$$\prod_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)=0,$$

and

$$\prod_{\alpha>0}(e_{n+j}+\delta+\lambda,\alpha)=0.$$

If $j=n$, then

$$\prod_{\alpha>0}(e_{2n-1}+\delta+\lambda,\alpha)=0,$$

and

$$\prod_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)=0.$$

Proof: If $j\in\{1,\ldots,n-1\}$, then $(e_{j+1}+\delta+\lambda,\beta_j)=-1+1+c_j=0$, and $(e_{n+j}+\delta+\lambda,\beta_j)=-1+1+c_j=0$. If $j=n$, then $(e_{2n-1}+\delta+\lambda,\beta_j)=-1+1+c_j=0$, and $(e_{2n}+\delta+\lambda,\beta_j)=-1+1+c_j=0$. ●

In the tensor product $\pi^\lambda\otimes\pi_0$, any irreducible representation that occurs must have highest weight $\lambda+e_i$, for some $i\in\{1,\ldots,2n\}$, and cannot occur more than once. By (1), the sum of the dimensions of the irreducible representations with highest weights $\lambda+e_i$ $(i=1,\ldots,2n)$ is $\Sigma_{\ell=1}^{2n}\Pi_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)$, and $\dim(\pi^\lambda\otimes\pi_0)=\dim(\pi_0)\dim(\pi^\lambda)=(2n)[\Pi_{\alpha>0}(\delta+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)]$. We would like to show that the sum of the dimensions of the $\pi^{\lambda+e_i}$ $(i=1,\ldots,2n)$ is equal to the dimension of the tensor product $\pi^\lambda\otimes\pi_0$; this follows from proposition 9.1 if all the $\lambda+e_i$ are dominant integral weights.

Now $\mu=\Sigma_{i=1}^{n}z_i\beta_i^*$ is not a dominant integral weight if and only if $z_i<0$, for some $i\in\{1,\ldots,n\}$. Since $\lambda=\Sigma_{k=1}^{n}c_i\beta_i$ is the highest weight of π^λ, the one and only way that $\lambda+e_i$ $i\in\{1,\ldots,n\}$ would not be a possible highest weight is if $i\neq 1$ and $c_{i-1}=0$. The only way that $\lambda+e_{n+j}, j\in\{1,\ldots,n\}$, would not be a dominant integral weight is if $c_j=0$, or if $j=n-1$ and $c_n=0$. So, proposition 9.2 implies that if $\lambda+e_i$ is not a possible highest weight, then the dimension formula gives a value of zero. Thus, propositions 9.1 and 9.2 imply that the irreducible representations that occur in the tensor product $\pi^\lambda\otimes\pi_0$ are exactly those $\pi^{\lambda+e_i}$ for which $\lambda+e_i$ is a dominant integral weight. Therefore, we have proven the following:

Theorem 9.3: *The representations of $H=\mathrm{SO}(2n)$ that may be assembled with π^λ into a representation of $G=\mathrm{SO}(2n)\times\mathbb{R}^{2n}$ are those that have highest weight $\lambda+e_i$, for some $i\in\{1,\ldots,2n\}$. For each of the possible representations this assemblage is unique.*

X. EXAMPLE: SO($2n+1$)

Let $H=\mathrm{SO}(2n+1)$; then the simple roots of H are $\beta_1,\ldots,\beta_n$, given by $\beta_i(u_1,\ldots,u_n)=u_i-u_{i+1}$ for $i=1,\ldots,n-1$, and $\beta_n(u_1,\ldots,u_n)=u_n$. The fundamental weights are $\beta_1^*,\ldots,\beta_n^*$ given by $\beta_i^*(u_1,\ldots,u_n)=\Sigma_{k=1}^{i}u_k$ for $i=1,\ldots,n-1$ and $\beta_n^*(u_1,\ldots,u_n)=\frac{1}{2}\Sigma_{k=1}^{n}u_k$. It follows that $\delta=\frac{1}{2}\Sigma_{\alpha>0}\alpha=\Sigma_{k=1}^{n}\beta_k^*$. Let $e_1=\beta_1^*$, $e_i=\beta_i^*-\beta_{i-1}^*(2\leqslant i\leqslant n-1)$, $e_n=2\beta_n^*-\beta_{n-1}^*$, $e_{n+j}=-e_j$ for $j=1,\ldots,n$, and $e_0=0$. As in the previous examples, we shall consider the case where π_0 is the "standard" $(2n+1)$-dimensional (real) representation of $\mathrm{SO}(2n+1)$; its highest weight is e_1, and all its weights e_i have multiplicity one.

Proposition 10.1: For any dominant integral weight λ,

$$\sum_{\ell=0}^{2n}\prod_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)=(2n+1)\prod_{\alpha>0}(\delta+\lambda,\alpha).$$

This is equivalent to

$$\sum_{\ell=1}^{2n}\prod_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)=(2n)\prod_{\alpha>0}(\delta+\lambda,\alpha). \quad (*)$$

Proof: Write $\lambda=\Sigma_{k=1}^{n}c_k\beta_k^*$; then $\lambda+\delta=\Sigma_{k=1}^{n}(c_k+1)\beta_k^*=\Sigma_{k=1}^{n}x_k\beta_k^*$, where $x_k=c_k+1$.

Fix i and j with $1\leqslant i\leqslant j\leqslant n$.

Case A: Suppose that $X_{ij}=\Sigma_{k=i}^{j}x_k=0$. It follows that all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{j}\beta_k=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$ is the same as that given for $\mathrm{SU}(n+1)$. The proof that $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$ can be obtained by making the following changes: e_{i-1} to e_{n+i}, e_j to e_{n+j+1}, and a_k to $-a_k$, for $k=i-1,i,j,j+1$.

Case B: Suppose that $X_{ij}=(\Sigma_{k=i}^{j}x_k)+(\Sigma_{k=j+1}^{n-2}2x_k)+x_{n-1}+x_n=0$. It follows that all products in $(*)$ are zero except for: $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)$, $\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$, and $\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$, since, for each of the other products, the factor corresponding to $\alpha=\Sigma_{k=i}^{j}\beta_k+\Sigma_{k=j+1}^{n-2}2\beta_k+\beta_{n-1}+\beta_n=Y_{ij}$ is zero. The proof that $\Pi_{\alpha>0}(e_i+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+j+1}+\delta+\lambda,\alpha)$ is similar to the one given for $\mathrm{SU}(n+1)$; it may be obtained by making the following changes: e_{i-1} to e_i, e_j to e_{n+j+1}, a_{j+1} to $-a_{j+1}$, and a_j to $-a_j$. The proof that $\Pi_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(e_{n+i}+\delta+\lambda,\alpha)$ can be obtained from the proof for $\mathrm{SU}(n+1)$ by making the following changes: e_{i-1} to e_{n+i}, e_j to e_{j+1}, a_{i-1} to $-a_{i-1}$, a_i to $-a_i$.

Since each factor of $\Pi_{\alpha>0}(\delta+\lambda,\alpha)$ is equal to X_{ij} for some i, j, and some case above, we have shown that the roots of the right-hand side of $(*)$ are contained within the roots of the left-hand side of $(*)$. By comparing degrees and substituting $\lambda=0$, we obtain the result. ●

Proposition 10.2: Fix $j\in\{1,\ldots,n-1\}$ *and consider a dominant integral weight* $\lambda=\Sigma_{k=1}^{n}c_k\beta_k^*$ *with* $c_j=0$; *then,*

$$\prod_{\alpha>0}(e_{j+1}+\delta+\lambda,\alpha)=0,$$

and

$$\prod_{\alpha>0}(e_{n+j}+\delta+\lambda,\alpha)=0.$$

Proof: $(e_{j+1}+\delta+\lambda,\beta_j)=-1+1+c_j=0$ and $(e_{n+j}+\delta+\lambda,\beta_j)=-1+1+c_j=0$. ●

Proposition 10.3: If $\lambda=\Sigma_{i=1}^{n-1}c_i\beta_i^*$, *then* $\Pi_{\alpha>0}(e_{2n}+\delta+\lambda,\alpha)=-\Pi_{\alpha>0}(\delta+\lambda,\alpha)$.

Proof: As in proposition 10.1, consider both products as polynomials in $x_1,\ldots,x_n$ and fix $\gamma = \Sigma_{k=1}^{n} a_k\beta_k > 0$. Now, $(e_{2n}+\delta+\lambda,\gamma) = (\delta+\lambda,\gamma) + a_{n-1} - a_n = (\delta+\lambda,\gamma+2(a_{n-1}-a_n)\beta_n)$. Therefore, by the same line of reasoning as in the proof for SU$(n+1)$, the products differ by a sign. ●

Proposition 10.4: If the highest weight of π^λ is $\lambda = \Sigma_{k=i}^{n-1} c_i\beta_i^*$, with $i<n$ and $c_i>0$, then π^λ is not contained in $\pi^\lambda\otimes\pi_0$.

Proof: If $\lambda = \Sigma_{k=i}^{n-1} c_k\beta_k^*$ with $i<n$ and $c_i>0$, then $(\lambda, \Sigma_{k=i}^{n}\beta_k)>0$, so $\lambda - \Sigma_{k=i}^{n}\beta_k = \lambda - e_i$ is a weight of the irreducible representation with highest weight λ; $\lambda - e_n$ is not a weight, since, if it was, the highest weight would be $\lambda + e_n$ and not λ. For the same reason none of the $\lambda - e_{n+i}$ are weights. Since λ has multiplicity one in the weight diagram of π^λ, then it follows that λ has multiplicity n in the weight diagram of the tensor product $\pi^\lambda\otimes\pi_0$, one for each of the irreps with highest weights $e_0,\ldots,e_{n-1}$ and no more. If $j,k\in\{1,\ldots,n\}$, $j\neq k$, then the weight $\lambda+e_k$ is not contained in the irreducible representation with highest weight $\lambda+e_j$, since λ is a weight of the irreducible representation with highest weight $\lambda+e_j$ and $(\lambda,e_k)>0$; so the irreducible representations with highest weights $\lambda+e_j$, $j=1,\ldots,n$ must all occur in the tensor product $\pi^\lambda\otimes\pi_0$. Now, since λ is a weight (of multiplicity one) of the irreducible representations with highest weight $\lambda + e_j$, $j=1,\ldots,n$, and these representations must all occur in $\pi^\lambda\otimes\pi_0$, then it follows that π^λ does not occur in $\pi^\lambda\otimes\pi_0$. ●

In the tensor product $\pi^\lambda\otimes\pi_0$, any irreducible representation that occurs must have highest weight $\lambda+e_i$, for some $i\in\{0,\ldots,2n\}$, and cannot occur more than once. By (1), the sum of the dimensions of the irreducible representations with highest weights $\lambda+e_i$ $(i=0,\ldots,2n)$ is $\Sigma_{\ell=0}^{2n}\Pi_{\alpha>0}(e_\ell+\delta+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)$, and $\dim(\pi^\lambda\otimes\pi_0) = \dim(\pi_0)\dim(\pi^\lambda) = (2n+1)[\Pi_{\alpha>0}(\delta+\lambda,\alpha)/\Pi_{\alpha>0}(\delta,\alpha)]$. We would like to show that the sum of the dimensions of the $\pi^{\lambda+e_i}$ $(i=0,\ldots,2n)$ is equal to the dimension of the tensor product $\pi^\lambda\otimes\pi_0$; this follows from proposition 10.1 if all the $\lambda+e_i$ are dominant integral weights.

Now $\mu = \Sigma_{i=1}^{n} z_i\beta_i^*$ is not a dominant integral weight if and only if $z_i<0$, for some $i\in\{1,\ldots,n\}$. Since $\lambda = \Sigma_{k=1}^{n} c_i\beta_i$ is the highest weight of π^λ, the one and only way that $\lambda+e_i$ $i\in\{1,\ldots,n\}$ would not be a dominant integral weight is if $i\neq 1$ and $c_{i-1}=0$. The only way that $\lambda+e_{n+j}, j\in\{1,\ldots,n\}$, would not be a dominant integral weight is if $c_j=0$. So, proposition 10.2 implies that if $\lambda+e_i$ $(i\neq 2n)$ is not a possible highest weight vector, then the dimension formula gives a value of zero. Together, propositions 10.3 and 10.4 show that if $c_n=0$, then π^λ is not contained in $\pi^\lambda\otimes\pi_0$, and if d_λ and $d_{\lambda+e_{2n}}$ are the values obtained by substituting λ and $\lambda+e_{2n}$ into (1), then $d_\lambda + d_{\lambda+e_{2n}} = 0$. This expresses the fact that neither π^λ nor $\pi^{\lambda+e_{2n}}$ occurs in the tensor product. Taken together, propositions 10.1, 10.2, 10.3, and 10.4 imply that the irreducible representations that occur in the tensor product $\pi^\lambda\otimes\pi_0$ are exactly those $\pi^{\lambda+e_i}$ for which $\lambda+e_i$ is a dominant integral weight, except in the case where $c_n=0$, in which case π^λ does not occur. Therefore, we have proven the following.

Theorem 10.5: *If $\lambda = \Sigma_{k=1}^{n} c_k\beta_k^*$ with $c_i\geqslant 0$ and $c_n>0$, the representations of $H=\mathrm{SO}(2n+1)$ that may be assembled with π^λ into a representation of $G=\mathrm{SO}(2n+1)\ltimes\mathbb{R}^{2n+1}$ are those that have highest weight $\lambda+e_i$, for some $i\in\{0,\ldots,2n\}$. If $c_n=0$, the representations of H that may be assembled with π^λ into a representation of G are those that have highest weight $\lambda+e_i$, for some $i\in\{1,\ldots,2n-1\}$. For all of the possible representations this assemblage is unique.*

XI. EXAMPLE: SO(3)⋉$\mathbb{R}^5$

Let $H=\mathrm{SO}(3)$ and let π_0 be the five-dimensional representation of H; it has weights $e_1 = 2\beta_1$, $e_2=\beta_1$, $e_3=0$, $e_4=-\beta_1$, and $e_5=-2\beta_1$ (all weights have multiplicity one). Now we will consider the case where $G=\mathrm{SO}(3)\ltimes\mathbb{R}^5$. For this group H, we have that $\beta_1^*(u_1) = \frac{1}{2}u_1$. If the highest weight of a representation π^λ of H is $\lambda = c_1\beta_1^*$, then the dimension of π^λ is given by (1); it is c_1+1.

Lemma 11.1: $\Sigma_{k=1}^{5}(c_1+2k-5) = 5(c_1+1)$.

Proof: A direct calculation gives the result. ●

In the tensor product $\pi^\lambda \otimes \pi_0$, any irreducible representation that occurs must have highest weight $\lambda + e_i$, for some $i \in \{1,\ldots,5\}$, and cannot occur more than once. By the dimension formula, the sum of the dimensions of the irreducible representations with highest weights $\lambda + e_i$ $(i = 1,\ldots,5)$ is $\Sigma_{k=1}^{5}(2(c_1+k)-5)$, and $\dim(\pi^\lambda \otimes \pi_0) = \dim(\pi_0)\dim(\pi^\lambda) = 5(2c_1+1)$. We would like to show that the sum of the dimensions of the $\pi^{\lambda+e_i}(i=1,\ldots,5)$ is equal to the dimension of the tensor product $\pi^\lambda \otimes \pi_0$; we can infer this from lemma 11.1 if all the $\lambda + e_i$ are dominant integral weights, that is, if $c_1 \notin \{0,1,2,3\}$; if this is the case, then it follows that the irreducible representations that occur in the tensor product $\pi^\lambda \otimes \pi_0$ are exactly those $\pi^{\lambda+e_i}$ for which $\lambda + e_i$ is a dominant integral weight. By explicit calculation, the same result can be shown when $c_1 \in \{0,1,2,3\}$. Therefore, we have proven the following:

Theorem 11.2: *The representations of* $H = \mathrm{SO}(3)$ *that may be assembled with* π^λ *into a representation of* $G = \mathrm{SO}(3) \ltimes \mathbb{R}^5$ *are those that have highest weight* $\lambda + e_i$, *for some* $i \in \{1,\ldots,5\}$. *For each of the possible representations this assemblage is unique*.

XII. CONCLUSIONS

The possibility of assembling two irreps of H into an indecomposable representation of the semidirect product $G = H \ltimes V$ is shown to be equivalent to the existence of a certain type of tensor operator between the two irreps. This in turn is shown to be equivalent to the occurrence of one irrep in the tensor product of the other with V.

This theory yields a systematic method for evaluating which irreps can be assembled into indecomposable representations. It is applied to various examples, and the results extend those of Cantoni,[1] also giving information about the number of inequivalent indecomposable representations built from any pair of irreps.

Given a specific semidirect product group $G = H \ltimes V$ and a particular irrep π^λ of H, it is straightforward to use the theory developed here to identify all irreps π^μ for which is it possible to assemble π^λ and π^μ into an indecomposable representation of G. In the examples given above, for various groups G of interest in physics, a description is given of all pairs π^λ and π^μ which can be assembled into an indecomposable representation.

Although it is not pursued here, this type of analysis could also be modified for application to infinite-dimensional representations.

Solutions of nonlinear multi-component Euler–Monge partial differential equations are constructed in n spatial dimensions by *dimension-doubling*, a method that completely linearizes the problem. Nonlocal structures are an essential feature of the method. The Euler–Monge equations may be interpreted as a boundary theory arising from a linearized bulk system such that all boundary solutions follow from simple limits of those for the bulk. © *2003 American Institute of Physics.*

I. INTRODUCTION

For any theory[22] with an infinite number of conservation laws, we may always assemble the conserved currents into a generating function involving a spectral parameter a. If that spectral parameter is independent of any other space–time dimensions in the theory, as is possible in the simplest cases, then effectively the theory possesses an *extra dimension*.[23] Moreover, it is always possible to openly include this extra dimension in some of the dynamical equations, and not just leave it as a *dimension sub rosa*.

For example, suppose a theory is originally expressed in terms of coordinates (x,t) with an infinite number of conserved currents: $\partial_t \rho^{(n)}(x,t)=\partial_x J^{(n)}(x,t)$, $n\in\mathbb{N}$. Then by defining $\rho(x,t,a)\equiv\Sigma_n(n+1)a^n\rho^{(n)}(x,t)$, as opposed to $\Sigma_n a^n\rho^{(n)}(x,t)$, and $J(x,t,a)\equiv\Sigma_n a^{n+1}J^{(n)}(x,t)$, as opposed to $\Sigma_n a^n J^{(n)}(x,t)$, we have rendered all the conservation laws as a single second-order higher-dimensional partial differential equation (PDE): $\partial_t\rho(x,t,a)=\partial_x\partial_a J(x,t,a)$, as opposed to the first-order $\partial_t\rho(x,t,a)=\partial_x J(x,t,a)$. Hence our choice for the current generating functions has fully exposed an extra dimension in the PDEs satisfied by those generating functions. The extra dimension here does not just ride along as a suppressible label for the currents but it appears explicitly, perhaps even unavoidably, in the dynamical equations. Of course this immediately raises issues about whether the theory requires a to appear explicitly for *all* dynamical equations to be cogently expressed in terms of the original plus extra dimensions, and about covariance properties for the theory in the complete set of dimensions.

In this article we address these issues for a simple but very generally applicable class of nonlinear PDE's:[10,17] The first order Euler–Monge (E-M) equations $\partial_t\mathbf{u}=(\mathbf{u}\cdot\nabla)\mathbf{u}$. We find the full dynamics of these *nonlinear* theories are elegantly encoded into a higher dimensional set of *linear* ''heat'' equations obtained through dimension doubling $(\mathbf{x})\to(\mathbf{x},\mathbf{a})$, where for each spatial coordinate x_i there is an *associated coordinate* given by spectral parameter a_i. The original dynamical variables are obtained as spectral parameter boundary limits, $\lim_{\mathbf{a}\to 0}U_i(\mathbf{x},t,\mathbf{a})=u_i(\mathbf{x},t,\mathbf{a})$. The fact that the higher dimensional theory is linearized strongly argues that this is the right approach to take. In the linearized theory, the pairs (x_i,a_i) act like ''light-cone'' variables in the enlarged set of dimensions such that the heat equations for all the dynamical variables are of the form $(\partial/\partial t-\Sigma_{j=1}^{n}\partial^2/\partial a_j\partial x_j)U_i(\mathbf{x},t,\mathbf{a})=0$. Thus the extra dimensions appear explicitly and, indeed, unavoidably in these linearized dynamical equations.

[b)]Electronic mail: david.fairlie@durham.ac.uk

We also find Nambu brackets[18] of the fields, of all orders up to the full Jacobian, as a remarkable feature of the linearizing maps. We know of only one other field theoretic example[3] where these brackets appear so naturally. Moreover, the linearizing maps are *nonlocal* in all but the simplest, one component case. The nonlocal structures appropriate for E-M equations with two components in two spatial dimensions are evocative of phase factors in Wilson loops (cf. strings), and when the E-M equations describe n component fields in the original n spatial dimensions these structures extend to higher dimensional constructions involving integrals over $n-1$ dimensional submanifolds [cf. $(n-1)$-branes]. In the one dimensional, one component case, the E-M solution is obtained algebraically from the dimensionally-doubled "bulk" solution for all values of the single spectral parameter. In higher dimensional or multi-component cases the dependence of the solutions on the spectral parameters is more involved. Nevertheless, in all cases the solutions of the E-M equations may be obtained from simple limits of those for the bulk.

II. HISTORICAL OVERVIEW AND OBJECTIVES

The Euler–Monge equations first appeared in 18th and 19th century studies of fluid dynamics[10] and analytic geometry.[17] Riemann took up a study of the equations in the context of gas dynamics, discussing the equations as a theory of invariants[20] (for a modern textbook treatment, see Ref. 8). His approach is widely applicable to almost all nonlinear flow problems, although it does not triumph over turbulence. A systematic modern discussion of the E-M equations that synthesizes ideas from both geometry and invariance theory can be found in the review by Dubrovin and Novikov.[9] Most contemporary texts and reviews stress the universal role played by these nonlinear transport equations in accordance with Whitham's theory.[21] Essentially all nonlinear waves, even those in dispersive and dissipative media, involve E-M equations, or simple variants of them, if the nonlinear wavetrains are slowly varying. This makes the equations particularly useful for analyzing the asymptotic behavior of nonlinear solutions. The E-M equations and their conservation laws also serve as a useful starting point in Polyakov's study of turbulence[19] but without yet leading to a general solution of the Navier–Stokes equations.

The first order E-M equation $\partial u/\partial t = u\,\partial u/\partial x$ also gives rise to the Bateman equation[4] upon substituting $u=(\partial\phi/\partial t)/(\partial\phi/\partial x)$. The resulting second order nonlinear PDE is $0=\phi_x^2\phi_{tt}-2\phi_x\phi_t\phi_{tx}+\phi_t^2\phi_{xx}$, and is well known to possess a general implicit solution given by solving $tS_0(\phi)+xS_1(\phi)=\text{const}$, where S_0 and S_1 are arbitrary differentiable functions of $\phi(x,t)$. The structure of this solution incorporates the covariance properties of the PDE: If ϕ is a solution, so is any function of ϕ. In fact, curiously, the generalization of this solution to $n+1$ functions $S_0(\phi), S_i(\phi)$ of $\phi(\mathbf{x},t)$, $\mathbf{x}=(x_1,\ldots,x_n)$, subject to a single constraint $tS_0(\phi)+\Sigma x_i\,S_i(\phi)=0$, is a "universal solution" [14] to *any* equation derived from a Lagrangian which is homogeneous of weight one in the first derivatives of ϕ.

Thus the Euler–Monge equations appear widespread across a very broad landscape of physics and applied mathematics problems, and therefore it is important to understand their solutions at as many levels as possible. To that end we shall map all solutions of the E-M equations in arbitrary dimensions into solutions of second-order linear equations. This type of map is reminiscent of the Cole–Hopf[6,15] transformation (thoroughly reviewed in Ref. 16) used to linearize the Burgers[5,15] nonlinear diffusion equation, but there are important differences here. The Cole–Hopf transformation only works for curl-free $\mathbf{u}$, does not use extra dimensions, and fails for $0=\kappa$ (the diffusivity). The map to follow works for all $\mathbf{u}$, curl-free or otherwise, does use extra dimensions, but works only for $\kappa=0$. (We hope to extend the method to $\kappa\neq 0$ and to include the effects of pressure in subsequent studies.)

III. METHOD AND ELEMENTARY RESULTS

We believe it is best to present our results summarily for the simplest examples of fields with one, two, and three components, and then to extend these results to the general case of n compo-

nents. We leave out most details but we do sketch the salient features of the derivations. In the following, $\mathcal{M}_n$ is the n dimensional nonlinear Euler–Monge operator and $\mathcal{H}_n$ is an associated hyperbolic heat operator (introduced in Ref. 19),

$$\mathcal{M}_n \equiv \frac{\partial}{\partial t} - \sum_{j=1}^{n} u_j \frac{\partial}{\partial x_j}$$
$$\mathcal{H}_n \equiv \frac{\partial}{\partial t} - \sum_{j=1}^{n} \frac{\partial^2}{\partial x_j \partial a_j}. \tag{1}$$

To begin, however, we will generalize these two definitions to allow for an arbitrary function F in the most *elementary* results in one spatial dimension. We find that

$$\frac{\partial}{\partial t} U(x,t,a) = F\left(\frac{\partial}{\partial a}\right) \frac{\partial}{\partial x} U(x,t,a) \tag{2}$$

if and only if

$$\frac{\partial}{\partial t} u(x,t) = F(u(x,t)) \frac{\partial}{\partial x} u(x,t) \tag{3}$$

where

$$U(x,t,a) \equiv \frac{e^{au(x,t)} - 1}{a}$$
$$u(x,t) = \frac{1}{a} \ln(1 + a U(x,t,a)) \tag{4}$$

and F is any function with a formal power series. This simple result follows by direct calculation

$$\left(\frac{\partial}{\partial t} - F\left(\frac{\partial}{\partial a}\right) \frac{\partial}{\partial x}\right) \frac{e^{au(x,t)} - 1}{a} = e^{au(x,t)} \left(\frac{\partial}{\partial t} u(x,t) - F(u(x,t)) \frac{\partial}{\partial x} u(x,t)\right). \tag{5}$$

The formal solution for $U(x,t,a)$ in terms of $U(x,t=0,a)$ is now obviously given by

$$(e^{au(x,t)} - 1)/a = e^{t\, F(\partial/\partial a)\, \partial/\partial x} ((e^{au(x)} - 1)/a) \tag{6}$$

with $u(x,t=0) = u(x)$.

The bulk solution $U(x,t,a)$ may also be viewed as a simple one-parameter deformation of the boundary data $u(x,t)$, with the extra dimension serving as the deformation parameter. In this exceptional one-component case, we may easily extract $u(x,t)$ from $U(x,t,a)$ for any value of the extra dimension a as given by the logarithmic expression above. But, in particular, we may extract $u(x,t)$ as a limit of the bulk solution $u(x,t) = \lim_{a \to 0} U(x,t,a)$. This immediately yields the time series solution[12] to the previous E-M equation as a limit:

$$u(x,t) = \lim_{a \to 0} e^{t\, F(\partial/\partial a)\, \partial/\partial x} \left(\frac{e^{au(x)} - 1}{a}\right) = F^{-1}\left[\sum_{j=0}^{\infty} \frac{t^j}{(1+j)!} \frac{d^j}{dx^j} (F[u(x)])^{1+j}\right], \tag{7}$$

where we assume F (locally) invertible in the last step.[24] While this time series is an immediate consequence of the previous results, we believe it is neither trivial nor obvious. Similar time series solutions are immediate consequences of all our results. For example, one independent field u in spatial dimensions $(x, y_1, \ldots, y_n)$ with dependent "velocity fields" $(u, v_1(u), \ldots, v_n(u))$ leads to

$$\frac{\partial}{\partial t}u(x,\mathbf{y},t)=u(x,\mathbf{y},t)\frac{\partial}{\partial x}u(x,\mathbf{y},t)+\sum_{i=1}^{n}v_i(u(x,\mathbf{y},t))\frac{\partial}{\partial y_i}u(x,\mathbf{y},t) \tag{8}$$

if and only if

$$\int_0^{u(x,\mathbf{y},t)}\mathrm{d}u\,\exp\left(au+\sum_{i=1}^{n}b_iv_i(u)\right)=e^{t(\partial^2/\partial x\partial a+\Sigma_{i=1}^{n}\partial^2/\partial y_i\partial b_i)}\int_0^{u(x,\mathbf{y})}\mathrm{d}u\,\exp\left(au+\sum_{i=1}^{n}b_iv_i(u)\right). \tag{9}$$

Again, this follows by direct calculation, with

$$U(x,\mathbf{y},t,a,\mathbf{b})\equiv\int_0^{u(x,\mathbf{y},t)}\mathrm{d}u\,\exp\left(au+\sum_{i=1}^{n}b_iv_i(u)\right) \tag{10}$$

since

$$\begin{aligned}\left(\frac{\partial}{\partial t}-\frac{\partial^2}{\partial x\partial a}-\sum_{i=1}^{n}\frac{\partial^2}{\partial y_i\partial b_i}\right)&U(x,\mathbf{y},t,a,\mathbf{b})\\&=\left(\frac{\partial}{\partial t}u(x,\mathbf{y},t)-u(x,\mathbf{y},t)\frac{\partial}{\partial x}u(x,\mathbf{y},t)-\sum_{i=1}^{n}v_i(u(x,\mathbf{y},t))\frac{\partial}{\partial y_i}u(x,\mathbf{y},t)\right)\\&\quad\times\exp\left(au(x,\mathbf{y},t)+\sum_{i=1}^{n}b_iv_i(u(x,\mathbf{y},t))\right).\end{aligned} \tag{11}$$

So, as given, the higher dimensional heat equation is satisfied by the integral form $U(x,\mathbf{y},t,a,\mathbf{b})$ if and only if the given one-component generalization of the E-M equations holds. The rhs of Eq. (10) is then just the formal solution of the heat equation.[25]

The last result does not allow for a simple extraction of $u(x,\mathbf{y},t)$ from the integral form of $U(x,\mathbf{y},t,a,\mathbf{b})$ for nonvanishing $a,\mathbf{b}$. However, it does have the simple limit $\lim_{a,\mathbf{b}\to 0}U(x,\mathbf{y},t,a,\mathbf{b})=u(x,\mathbf{y},t)$, so extraction is trivial on the boundary $a,\mathbf{b}\to 0$. This is true of all the other heat equation solutions to follow. Also note, $U(x,\mathbf{y},t,a,\mathbf{b})$ in this one-component case is an integral over the field value. Nevertheless U is still local in all the dimensions, no matter how many.

IV. MULTIPLE COMPONENTS AND NONLOCALITY

Locality in the original spatial dimensions will *not* hold, however, for maps of multi-component fields in higher dimensions. This is first illustrated by the next result,

$$\mathcal{H}_2U=\mathcal{H}_2V=0, \tag{12}$$

if and only if

$$\mathcal{M}_2u=\mathcal{M}_2v=0, \tag{13}$$

where $[\varepsilon(s)\equiv\pm\frac{1}{2}$ for $s\gtrless 0]$

$$U(x,y,t,a,b)\equiv\int_{-\infty}^{\infty}\mathrm{d}r\,\varepsilon(y-r)e^{au(x,r,t)+bv(x,r,t)}\ \frac{\partial u(x,r,t)}{\partial r}$$

$$V(x,y,t,a,b)\equiv\int_{-\infty}^{\infty}\mathrm{d}q\,\varepsilon(x-q)e^{au(q,y,t)+bv(q,y,t)}\ \frac{\partial v(q,y,t)}{\partial q}. \tag{14}$$

Once again this is established by direct calculation, assuming u, v, and their derivatives vanish asymptotically in x,y,

$$\mathcal{H}_2 U(x,y,t,a,b) = e^{au(x,y,t)+bv(x,y,t)}\mathcal{M}_2 u(x,y,t) + b\int_{-\infty}^{\infty} dr\ \varepsilon(y-r) \times e^{au(x,r,t)+bv(x,r,t)}\left(\frac{\partial u(x,r,t)}{\partial r}\mathcal{M}_2 v(x,r,t) - \frac{\partial v(x,r,t)}{\partial r}\mathcal{M}_2 u(x,r,t)\right) \tag{15}$$

$$\mathcal{H}_2 V(x,y,t,a,b) = e^{au(x,y,t)+bv(x,y,t)}\mathcal{M}_2 v(x,y,t) + a\int_{-\infty}^{\infty} dq\ \varepsilon(x-q) \times e^{au(q,y,t)+bv(q,y,t)}\left(\frac{\partial v(q,y,t)}{\partial q}\mathcal{M}_2 u(q,y,t) - \frac{\partial u(q,y,t)}{\partial q}\mathcal{M}_2 v(q,y,t)\right). \tag{16}$$

The converse result then follows by also using the obvious pair of limits $\lim_{a,b\to 0}\mathcal{H}_2 U(x,y,t,a,b) = \mathcal{M}_2 u(x,y,t)$ and $\lim_{a,b\to 0}\mathcal{H}_2 V(x,y,t,a,b) = \mathcal{M}_2 v(x,y,t)$.

As advertised, the two-component map in two spatial dimensions involves a nonlocal transformation between E-M and heat equation solutions: It features line integrals over the original spatial variables. The map is still local in the extra dimensions, however. This nonlocality in the original dimensions persists and is even extended when more components and more spatial dimensions are considered. As a further illustration before giving the generalization to an arbitrary number of dimensions, we have

$$\mathcal{H}_3 U = \mathcal{H}_3 V = \mathcal{H}_3 W = 0, \tag{17}$$

if and only if

$$\mathcal{M}_3 u = \mathcal{M}_3 v = \mathcal{M}_3 w = 0, \tag{18}$$

where

$$\begin{aligned} U(x,y,z,t,a,b,c) &\equiv \int dr\ \varepsilon(y-r)\, e^{au+bv+cw}\ \frac{\partial u(x,r,z,t)}{\partial r} \\ &\quad - c\int\int drds\ \varepsilon(y-r)\ \varepsilon(z-s)\, e^{au+bv+cw}\{u,w\}_{rs}(x,r,s,t), \\ V(x,y,z,t,a,b,c) &\equiv \int ds\ \varepsilon(z-s)\, e^{au+bv+cw}\ \frac{\partial v(x,y,s,t)}{\partial s} \\ &\quad - a\int\int dqds\ \varepsilon(x-q)\ \varepsilon(z-s)\, e^{au+bv+cw}\{v,u\}_{sq}(q,y,s,t), \\ W(x,y,z,t,a,b,c) &\equiv \int \mathrm{d}q\ \varepsilon(x-q)\, e^{au+bv+cw}\ \frac{\partial w(q,y,z,t)}{\partial q} \\ &\quad - b\int\int dqdr\ \varepsilon(x-q)\ \varepsilon(y-r)\, e^{au+bv+cw}\{w,v\}_{qr}(q,r,z,t). \end{aligned} \tag{19}$$

There are a few essential new ingredients needed to complete the argument by direct calculation in this case. Define Poisson brackets as usual by

$$\{u,v\}_{rs}=\frac{\partial u}{\partial r}\frac{\partial v}{\partial s}-\frac{\partial u}{\partial s}\frac{\partial v}{\partial r}, \tag{20}$$

where u and v are any two functions of the independent variables r and s. Then it is straightforward to show

$$\begin{aligned}&\frac{\partial}{\partial t}\{u,v\}_{zy}-\frac{\partial}{\partial x}(u\{u,v\}_{zy})-\frac{\partial}{\partial y}(v\{u,v\}_{zy})-\frac{\partial}{\partial z}(w\{u,v\}_{zy})=\{\mathcal{M}_3u,v\}_{zy}+\{u,\mathcal{M}_3v\}_{zy},\\ &\frac{\partial}{\partial t}\{u,v\}_{xy}-\frac{\partial}{\partial x}(u\{u,v\}_{xy})-\frac{\partial}{\partial y}(v\{u,v\}_{xy})-\frac{\partial}{\partial z}(w\{u,v\}_{xy})\\ &\quad=\{\mathcal{M}_3u,v\}_{xy}+\{u,\mathcal{M}_3v\}_{xy}-\{u,v,w\}_{xyz},\end{aligned} \tag{21}$$

as well as similar relations obtained by permutation of dependent and independent variables. In the last relation we have introduced the totally antisymmetric Nambu triple bracket (i.e., Jacobian, in this three-dimensional case)

$$\{u,v,w\}_{xyz}=\frac{\partial u}{\partial x}\{v,w\}_{yz}+\frac{\partial u}{\partial y}\{v,w\}_{zx}+\frac{\partial u}{\partial z}\{v,w\}_{xy}=\frac{\partial u}{\partial x}\{v,w\}_{yz}+\frac{\partial v}{\partial x}\{w,u\}_{yz}+\frac{\partial w}{\partial x}\{u,v\}_{yz}. \tag{22}$$

Once equipped with such relations, the complete derivation of the heat equation and E-M equivalence is tedious, perhaps, but not subtle. (See the generalization to follow for additional details.)

The nonlocality appearing in our map for three components in three spatial dimensions is two-dimensional: It features surface integrals over pairs of the original spatial dimensions, perhaps evocative of membrane-based phase factors. Nonetheless, the map is still local in the extra dimensions and the E-M solutions are again trivially given by boundary limits of the bulk constructions.

V. GENERAL RESULTS

The nonlocality is extended to $(n-1)$-dimensional integrals when n-component linearizing maps are constructed in n spatial dimensions. This is explicit in the following equations.

$$\mathcal{H}_nU_k(\mathbf{x},t,\mathbf{a})=0 \tag{23}$$

if and only if

$$\mathcal{M}_nu_i(\mathbf{x},t)=0 \tag{24}$$

for $i,k\in\{1,\ldots,n\}$ where

$$\begin{aligned}U_k(\mathbf{x},t,\mathbf{a})\equiv&\int\cdots\int \mathrm{d}q_1\cdots\mathrm{d}q_n\,\delta(q_k-x_k)\left(\frac{e^{a_ku_k}-1}{a_k}\right)\\ &\times\det\begin{pmatrix}\frac{\partial}{\partial q_1}(\varepsilon(q_1-x_1)e^{a_1u_1}) & \cdots & \frac{\partial}{\partial q_n}(\varepsilon(q_1-x_1)e^{a_1u_1})\\ \vdots & \ddots & \vdots\\ \frac{\partial}{\partial q_1}(\varepsilon(q_n-x_n)e^{a_nu_n}) & \cdots & \frac{\partial}{\partial q_n}(\varepsilon(q_n-x_n)e^{a_nu_n})\end{pmatrix}_{\substack{\text{exclude } k\text{th row}\\ \text{and } k\text{th column}}}.\end{aligned} \tag{25}$$

The equivalence is shown as follows. Consider only the first component (*et sic de similibus*).

$$U_1(\mathbf{x},t,\mathbf{a}) = \int\cdots\int \mathrm{d}q_1\cdots\mathrm{d}q_n\,\delta(q_1-x_1)\left(\frac{e^{a_1u_1}-1}{a_1}\right)$$

$$\times\det\begin{pmatrix} \frac{\partial}{\partial q_2}(\varepsilon(q_2-x_2)e^{a_2u_2}) & \cdots & \frac{\partial}{\partial q_n}(\varepsilon(q_2-x_2)e^{a_2u_2}) \\ \vdots & \ddots & \vdots \\ \frac{\partial}{\partial q_2}(\varepsilon(q_n-x_n)e^{a_nu_n}) & \cdots & \frac{\partial}{\partial q_n}(\varepsilon(q_n-x_n)e^{a_nu_n}) \end{pmatrix}$$

$$= \int\cdots\int \mathrm{d}q_2\cdots\mathrm{d}q_n\left(\frac{e^{a_1u_1}-1}{a_1}\right)$$

$$\times\det\begin{pmatrix} \frac{\partial}{\partial q_2}(\varepsilon(q_2-x_2)e^{a_2u_2}) & \cdots & \frac{\partial}{\partial q_n}(\varepsilon(q_2-x_2)e^{a_2u_2}) \\ \vdots & \ddots & \vdots \\ \frac{\partial}{\partial q_2}(\varepsilon(q_n-x_n)e^{a_nu_n}) & \cdots & \frac{\partial}{\partial q_n}(\varepsilon(q_n-x_n)e^{a_nu_n}) \end{pmatrix}(x_1,q_2,\cdots,q_n,t)$$

$$= \int\cdots\int \mathrm{d}q_2\cdots\mathrm{d}q_n\left(\frac{e^{a_1u_1}-1}{a_1}\right)$$

$$\times\varepsilon_{i_2\cdots i_n}\frac{\partial}{\partial q_{i_2}}(\varepsilon(q_2-x_2)e^{a_2u_2})\frac{\partial}{\partial q_{i_3}}(\varepsilon(q_3-x_3)e^{a_3u_3})\cdots\frac{\partial}{\partial q_{i_n}}(\varepsilon(q_n-x_n)e^{a_nu_n}),$$

where in the last expression the i_k dummy indices, $k\in\{2,\ldots,n\}$, are summed from 2 to n, i.e., 1 is excluded. Now we integrate by parts assuming all fields and their derivatives vanish as $x\to\infty$. To do this, there are clearly $n-1$ equivalent choices. We elect to integrate $\partial/\partial q_{i_2}$ by parts to obtain

$$U_1(\mathbf{x},t,\mathbf{a}) = -\varepsilon_{i_2\cdots i_n}\int\cdots\int \mathrm{d}q_2\cdots\mathrm{d}q_n\,\varepsilon(q_2-x_2)e^{a_2u_2}\frac{\partial}{\partial q_{i_2}}\left(\frac{e^{a_1u_1}-1}{a_1}\right)$$

$$\times\frac{\partial}{\partial q_{i_3}}(\varepsilon(q_3-x_3)e^{a_3u_3})\cdots\frac{\partial}{\partial q_{i_n}}(\varepsilon(q_n-x_n)e^{a_nu_n})$$

$$= -\varepsilon_{i_2\cdots i_n}\int\cdots\int \mathrm{d}q_2\cdots\mathrm{d}q_n\,\varepsilon(q_2-x_2)\frac{\partial u_1}{\partial q_{i_2}}$$

$$\times\left(\delta_{i_33}\delta(q_3-x_3)+a_3\varepsilon(q_3-x_3)\frac{\partial u_3}{\partial q_{i_3}}\right)\cdots\left(\delta_{i_nn}\delta(q_n-x_n)+a_n\varepsilon(q_n-x_n)\frac{\partial u_n}{\partial q_{i_n}}\right)e^{\mathbf{a}\cdot\mathbf{u}}.$$

Expanding out the products of the various paired terms in parentheses in the last line gives

$$
\begin{aligned}
U_1(\mathbf{x},t,\mathbf{a}) = &-\varepsilon_{i_2\cdots i_n} a_3\cdots a_n \int\cdots\int \mathrm{d}q_2\mathrm{d}q_3\cdots\mathrm{d}q_n\, \varepsilon(q_2-x_2)\\
&\times\varepsilon(q_3-x_3)\cdots\varepsilon(q_n-x_n)\,\frac{\partial u_1}{\partial q_{i_2}}\,\frac{\partial u_3}{\partial q_{i_3}}\cdots\frac{\partial u_n}{\partial q_{i_n}}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\varepsilon_{i_2\cdots i_n}\sum_{j=3}^{n}\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\,\delta_{ji_j}\\
&\times\left(\prod_{\substack{k=3\\k\neq j}}^{n}\left(a_k\int \mathrm{d}q_k\,\varepsilon(q_k-x_k)\,\frac{\partial u_k}{\partial q_{i_k}}\right)\right)\frac{\partial u_1}{\partial q_{i_2}}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\varepsilon_{i_2\cdots i_n}\sum_{j=3}^{n}\sum_{\substack{k=4\\k>j}}^{n}\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\,\delta_{ji_j}\,\delta_{ki_k}\\
&\times\left(\prod_{\substack{m=3\\m\neq j,k}}^{n}\left(a_m\int \mathrm{d}q_m\,\varepsilon(q_m-x_m)\,\frac{\partial u_m}{\partial q_{i_m}}\right)\right)\frac{\partial u_1}{\partial q_{i_2}}\,e^{\mathbf{a}\cdot\mathbf{u}}-\cdots\\
&-\sum_{j=3}^{n} a_j\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\int \mathrm{d}q_j\,\varepsilon(q_j-x_j)\left(\frac{\partial u_1}{\partial q_2}\,\frac{\partial u_j}{\partial q_j}-\frac{\partial u_1}{\partial q_j}\,\frac{\partial u_j}{\partial q_2}\right)e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\,\frac{\partial u_1}{\partial q_2}\,e^{\mathbf{a}\cdot\mathbf{u}}.
\end{aligned}
$$

That is to say, the result is given in terms of Nambu brackets[18] of all ranks from $n-1$ down to 2 (i.e., Poisson), as well as a final single derivative term. Thus

$$
\begin{aligned}
U_1(\mathbf{x},t,\mathbf{a}) = &-a_3\cdots a_n\int\cdots\int \mathrm{d}q_2\mathrm{d}q_3\cdots\mathrm{d}q_n\,\varepsilon(q_2-x_2)\,\varepsilon(q_3-x_3)\cdots\varepsilon(q_n-x_n)\\
&\times\{u_1,u_3,\ldots,u_n\}_{23\cdots n}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\sum_{j=3}^{n}\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\left(\prod_{\substack{k=3\\k\neq j}}^{n}\left(a_k\int \mathrm{d}q_k\,\varepsilon(q_k-x_k)\right)\right)\\
&\times\{u_1,u_3,\ldots,u_{j-1},u_{j+1},\ldots,u_n\}_{23\cdots j-1j+1\cdots n}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\cdots-\sum_{j=3}^{n}\sum_{\substack{k=4\\k>j}}^{n} a_j a_k\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\int \mathrm{d}q_j\,\varepsilon(q_j-x_j)\int \mathrm{d}q_k\,\varepsilon(q_k-x_k)\\
&\times\{u_1,u_j,u_k\}_{2jk}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\sum_{j=3}^{n} a_j\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\int \mathrm{d}q_j\,\varepsilon(q_j-x_j)\,\{u_1,u_j\}_{2j}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\,\frac{\partial u_1}{\partial q_2}\,e^{\mathbf{a}\cdot\mathbf{u}}.
\end{aligned}
$$

In the preceding equation, it is to be understood that the sum $\Sigma_{j=3}^{n}$ in the second term begins at its lower limit with

$$
-a_4\cdots a_n\int\cdots\int \mathrm{d}q_2\mathrm{d}q_4\cdots\mathrm{d}q_n\,\varepsilon(q_2-x_2)\,\varepsilon(q_4-x_4)\cdots\varepsilon(q_n-x_n)\,\{u_1,u_4,\ldots,u_n\}_{24\cdots n}\,e^{\mathbf{a}\cdot\mathbf{u}}
$$

and terminates at its upper limit with

$$-a_3\cdots a_{n-1}\int\cdots\int \mathrm{d}q_2\mathrm{d}q_3\cdots\mathrm{d}q_{n-1}\,\varepsilon(q_2-x_2)\,\varepsilon(q_3-x_3)\cdots\varepsilon(q_{n-1}-x_{n-1})$$
$$\times\{u_1,u_3,\cdots,u_{n-1}\}_{23\cdots n-1}\,e^{\mathbf{a}\cdot\mathbf{u}}.$$

Next we act with the heat operator on $U_1(\mathbf{x},t,\mathbf{a})$. The ε's permit the appropriate ''outside'' (i.e., x) partials to be converted, through integration by parts, into ''inside'' (i.e., q) partials. Also, factors of a_i outside the exponentials produce some extra terms from the cross-partials $\partial^2/\partial x_i\partial a_i$ in $\mathcal{H}_n$. We obtain

$$\begin{aligned}
\mathcal{H}_nU_1(\mathbf{x},t,\mathbf{a}) = &-a_3\cdots a_n\int\cdots\int \mathrm{d}q_2\mathrm{d}q_3\cdots\mathrm{d}q_n\,\varepsilon(q_2-x_2)\,\varepsilon(q_3-x_3)\cdots\varepsilon(q_n-x_n)\\
&\times\mathcal{H}_n(\{u_1,u_3,\ldots,u_n\}_{23\cdots n}\,e^{\mathbf{a}\cdot\mathbf{u}})\\
&+\sum_{i=3}^{n}\frac{\partial}{\partial a_i}(a_3\cdots a_n)\int\cdots\int \mathrm{d}q_2\mathrm{d}q_3\cdots\mathrm{d}q_n\frac{\partial}{\partial x_i}[\varepsilon(q_2-x_2)\,\varepsilon(q_3-x_3)\cdots\varepsilon(q_n-x_n)]\\
&\times\{u_1,u_3,\ldots,u_n\}_{23\cdots n}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\sum_{j=3}^{n}\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\left(\prod_{\substack{k=3\\k\neq j}}^{n}\left(a_k\int \mathrm{d}q_k\,\varepsilon(q_k-x_k)\right)\right)\\
&\times\mathcal{H}_n(\{u_1,u_3,\ldots,u_{j-1},u_{j+1},\ldots,u_n\}_{23\cdots j-1j+1\cdots n}\,e^{\mathbf{a}\cdot\mathbf{u}})\\
&+\sum_{j=3}^{n}\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\sum_{i=3}^{n}\frac{\partial}{\partial a_i}\frac{\partial}{\partial x_i}\left(\prod_{\substack{k=3\\k\neq j}}^{n}\left(a_k\int \mathrm{d}q_k\,\varepsilon(q_k-x_k)\right)\right)\\
&\times\{u_1,u_3,\ldots,u_{j-1},u_{j+1},\ldots,u_n\}_{23\cdots j-1j+1\cdots n}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-+\cdots-\sum_{j=3}^{n}a_j\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\int \mathrm{d}q_j\,\varepsilon(q_j-x_j)\,\mathcal{H}_n(\{u_1,u_j\}_{2j}\,e^{\mathbf{a}\cdot\mathbf{u}})\\
&+\sum_{i=3}^{n}\frac{\partial}{\partial a_i}\frac{\partial}{\partial x_i}\left(\sum_{j=3}^{n}a_j\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\int \mathrm{d}q_j\,\varepsilon(q_j-x_j)\right)\{u_1,u_j\}_{2j}\,e^{\mathbf{a}\cdot\mathbf{u}}\\
&-\int \mathrm{d}q_2\,\varepsilon(q_2-x_2)\,\mathcal{H}_n\left(\frac{\partial u_1}{\partial q_2}e^{\mathbf{a}\cdot\mathbf{u}}\right).
\end{aligned}$$

The first term (first two lines) on the rhs of $\mathcal{H}_nU_1$ reduces to terms linear in the E-M equations for the u's. The second term (third and fourth lines) and third term (fifth and sixth lines) on the rhs combine to give similar terms linear in the E-M equations. And so it goes with subsequent pairs of terms on the rhs of $\mathcal{H}_nU_1$, until finally the last two terms (last two lines) on the rhs combine to give terms linear in the E-M equations.

To establish these statements, one needs to use several identities involving the action of the heat operator on exponentially weighted derivatives of the component fields, in particular on so-weighted Nambu brackets. For example, these identities range from the simplest for the full Jacobian

$$\begin{aligned}
\mathcal{H}_n(e^{\mathbf{a}\cdot\mathbf{u}}\{u_1,u_2,\ldots,u_n\}_{12\cdots n}) = &\,e^{\mathbf{a}\cdot\mathbf{u}}(\mathbf{a}\cdot\mathcal{M}_n\mathbf{u})\{u_1,u_2,\ldots,u_n\}_{12\cdots n}+e^{\mathbf{a}\cdot\mathbf{u}}(\{\mathcal{M}_nu_1,u_2,\ldots,u_n\}_{12\cdots n}\\
&+\{u_1,\mathcal{M}_nu_2,\ldots,u_n\}_{12\cdots n}+\cdots+\{u_1,u_2,\cdots,\mathcal{M}_nu_n\}_{12\cdots n})
\end{aligned}$$

to those involving lower rank Nambu brackets such as

$$\mathcal{H}_n(e^{\mathbf{a}\cdot\mathbf{u}}\{u_2,u_3,\ldots,u_n\}_{23\cdots n}) = e^{\mathbf{a}\cdot\mathbf{u}}(-\{u_1,u_2,u_3,\ldots,u_n\}_{123\cdots n}+(\mathbf{a}\cdot\mathcal{M}_n\mathbf{u})\{u_2,u_3,\ldots,u_n\}_{23\cdots n}) + e^{\mathbf{a}\cdot\mathbf{u}}(\{\mathcal{M}_n u_2,u_3,\ldots,u_n\}_{23\cdots n}+\{u_2,\mathcal{M}_n u_3,\ldots,u_n\}_{23\cdots n}+\cdots + \{u_2,u_3,\ldots,\mathcal{M}_n u_n\}_{23\cdots n})$$

including that needed to deal with the first rhs line of $\mathcal{H}_n U_1$

$$\mathcal{H}_n(e^{\mathbf{a}\cdot\mathbf{u}}\{u_1,u_3,\ldots,u_n\}_{23\cdots n}) = e^{\mathbf{a}\cdot\mathbf{u}}(\mathbf{a}\cdot\mathcal{M}_n\mathbf{u})\{u_1,u_3,\ldots,u_n\}_{23\cdots n}+e^{\mathbf{a}\cdot\mathbf{u}}(\{\mathcal{M}_n u_1,u_3,\ldots,u_n\}_{23\cdots n} + \{u_1,\mathcal{M}_n u_3,\ldots,u_n\}_{23\cdots n}+\cdots+\{u_1,u_3,\ldots,\mathcal{M}_n u_n\}_{23\cdots n})$$

as well as other relations obtained by permutations of the indices of these, etc., all the way down to the final

$$\mathcal{H}_n(e^{\mathbf{a}\cdot\mathbf{u}}\partial_j u_k(\mathbf{x},t)) = e^{\mathbf{a}\cdot\mathbf{u}}\left(\partial_j(\mathcal{M}_n u_k)+(\mathbf{a}\cdot\mathcal{M}_n\mathbf{u})\partial_j u_k-\sum_i \{u_k,u_i\}_{ji}\right)$$

as needed to deal with the last two rhs lines in $\mathcal{H}_n U_1$. All such identities are straightforward to substantiate by direct calculation.

Thus, given the E-M equations for the u's, the heat equation for U_1 follows. Moreover, the only terms on the rhs of $\mathcal{H}_n U_1$ which survive in the limit of vanishing spectral parameters are the last two lines, which give

$$\lim_{\mathbf{a}\to\mathbf{0}}\mathcal{H}_n U_1(\mathbf{x},t,\mathbf{a}) = \mathcal{M}_n u_1(\mathbf{x},t). \tag{26}$$

Thus, given the heat equation for U_1, the E-M equation for u_1 follows. Similar results obtain for all the other components, so that $\mathcal{H}_n U_k = 0$ iff $\mathcal{M}_n u_j = 0$.

Formally, time evolution in the bulk is once more given by a simple exponentiation

$$\mathbf{U}(\mathbf{x},t,\mathbf{a}) = e^{t\sum_{j=1}^n \partial^2/\partial x_j\partial a_j}\mathbf{U}(\mathbf{x},t=0,\mathbf{a}). \tag{27}$$

This gives a time-series solution on the boundary upon taking the limit $\mathbf{a}\to\mathbf{0}$.

$$\mathbf{u}(\mathbf{x},t) = \lim_{\mathbf{a}\to\mathbf{0}} e^{t\sum_{j=1}^n \partial^2/\partial x_j\partial a_j}\mathbf{U}(\mathbf{x},t=0,\mathbf{a}) \tag{28}$$

with initial boundary data $\mathbf{u}(\mathbf{x}) = \lim_{\mathbf{a}\to\mathbf{0}}\mathbf{U}(\mathbf{x},t=0,\mathbf{a})$. Moreover, the n-fold infinite sequences of conservation laws for the E-M equations in n spatial dimensions are directly encoded into the bulk solutions.

$$\frac{\partial}{\partial t}U_k(\mathbf{x},t,\mathbf{a}) = \nabla\cdot\mathbf{J}_k(\mathbf{x},t,\mathbf{a}), \quad \mathbf{J}_k(\mathbf{x},t,\mathbf{a}) = \nabla_{\mathbf{a}}U_k(\mathbf{x},t,\mathbf{a}), \quad k\in\{1,2,\ldots,n\}. \tag{29}$$

Explicit sequences of charge and current densities on the boundary follow immediately from power series expansions in the a_j. These conservation laws are elementary consequences of the heat equation obeyed by $\mathbf{U}$.

VI. CONCLUSION

This is as far as we have completed the application of the extra dimensional approach to classical nonlinear PDEs. It remains to apply this approach to other types of nonlinear PDEs, in particular to those higher-order extensions of the E-M equations involving dispersion, such as the Korteweg–deVries equation, and to those involving diffusion, such as the Burgers and Navier–Stokes equations. Another immediately obvious challenge is to carry the method over to quantum field theories (QFTs). This will not be done here. However, we suspect that the implementation of

these ideas in QFT will involve the use of quantum Nambu brackets (QNBs), given that the classical versions of these appear above. QNBs have a long-standing notoriety, but recently[7] it has been shown that theirs is an undeserved bad reputation. QNBs can be defined in terms of operators (or in terms of noncommutative geometry) so as to fulfill their expected roles in the quantum evolution of dynamical systems. Perhaps these developments will be useful to meet the challenge of quantizing the E-M equations as well as their higher-order generalizations.

As emphasized previously, the Euler-Monge equations appear widespread throughout physics and the mathematics of nonlinear partial differential equations. Based on the maps we have presented to linearize these equations, we have come to the conclusion that extra dimensions and nonlocal structures are ubiquitous features to be found upon analyzing solutions of such nonlinear partial differential equations, and are quite natural constructs in many physical theories.

[22] We dedicate this paper to Peter Freund on the occasion of his becoming Professor Emeritus at the University of Chicago, and thereby begin with general remarks about the origin of extra dimensions, allowing for the possibility that these are similar to but not necessarily on the exact same footing as the original dimensions. For related points of view within the Kaluza–Klein physics framework,[1] see Ref. 2.
[23] More precisely, an extra *bosonic* dimension. A *finite* number of conservation laws evokes extra *fermionic* or *anyonic dimensions*, θ, involving kth order superspace or Grassman variables. This and other noncommutative geometries will not be discussed further here.
[24] Given the close relation of the Monge and Bateman equations, it might be expected that the latter also admits a power series solution of simple form. Indeed this is so. Treating the equation as hyperbolic with initial conditions $\phi(x,0)$

$=f(x)$, $\partial\phi(x,0)/\partial t=g(x)$, the time series solution of the Bateman equation is $\phi(x,t)=f(x)+tg(x)+\Sigma_{j=1}^{\infty}t^{1+j}/(1+j)!d^j/dx^j\ (g(x)^{1+j}/(df(x)/dx)^j)$.

[25] As is true for the Bateman equation and the one-component Monge equation in one spatial dimension, there is a corresponding second order equation for the case of one component in $n+1$ spatial dimensions which our solution satisfies. It is the so-called ''Universal Field Equation'' which may be obtained by elimination of u from the first order equations.[11,12]

Weak transversality and partially invariant solutions

I. INTRODUCTION

Lie group theory provides very general and efficient methods for obtaining exact analytic solutions of systems of partial differential equations, specially nonlinear ones.[1–9] The different methods have in common that they provide a reduction of the original system. This reduction usually means the reduction of the number of independent variables occurring, possibly a reduction of the number of dependent ones too.

The ''standard,'' or ''classical'' reduction method goes back to the original work of Sophus Lie and is explained in many modern texts.[1–9] Essentially, it amounts to requiring that a solution of the equation should be invariant under some subgroup $G_0 \subseteq G$, where G is the symmetry group of the considered system of equations. The subgroup G_0 must satisfy certain criteria, in order to provide such group invariant solutions (see below).

The purpose of this article is to further develop, compare and apply alternative reduction methods. They have in common the fact that they provide solutions not obtainable by a standard application of Lie's classical method. We shall survey the ''tool kit'' available for obtaining particular solutions of systems of partial differential equations, and further refine some of the tools. In the process we shall obtain new solutions of some physically important equations such as the Navier–Stokes equations, the Euler equations, the equations describing an isentropic compressible fluid model and the vector nonlinear Schrödinger equation.

We shall consider a system of m partial differential equations of order n, involving p independent variables $(x_1, x_2, \ldots, x_p)$ and q dependent variables $(u_1, u_2, \ldots, u_q)$,

$$\Delta_\nu(x, u^{(n)}) = 0, \quad \nu = 1, \ldots, m, \tag{1}$$

where $u^{(n)}$ denotes all partial derivatives of u_α, up to order n.

Lie's classical method of symmetry reduction consists of several steps.

(1) Find the local Lie group G of local point transformations taking solutions into solutions. Realize its Lie algebra $\mathfrak{g}$ in terms of vector fields and identify it as an abstract Lie algebra. The basis vector fields will have the form

$$\mathbf{v}_a = \sum_{i=1}^{p} \xi_a^i(x,u) \frac{\partial}{\partial x^i} + \sum_{\alpha=1}^{q} \varphi_a^\alpha(x,u) \frac{\partial}{\partial u^\alpha}, \quad a = 1,\ldots,r = \dim G. \tag{2}$$

[a]Electronic mail: grundlan@CRM.UMontreal.ca
[b]Electronic mail: tempesta@CRM.UMontreal.ca
[c]Electronic mail: wintern@CRM.UMontreal.ca

(2) Classify the subalgebras $\mathfrak{g}_i \subset \mathfrak{g}$ into conjugacy classes under the action of the largest group $\tilde{G}$ leaving the system of equations invariant (we have $G \subseteq \tilde{G}$). Choose a representative of each class.

(3) For each representative subalgebra $\mathfrak{g}_i$ find the invariants $I_\gamma(x_1,\ldots,x_p,u_1,\ldots,u_q)$ of the action of the group $G_i = \langle \exp \mathfrak{g}_i \rangle$ in the space $M \sim X \times U$ of independent and dependent variables. Let us assume that $p+q-s$ functionally independent invariants I_γ exist, at least locally (s is the dimension of the generic orbits of G_i).

(4) Divide (if possible) the invariants I_γ into two sets: $\{F_1,\ldots,F_q\}$ and $\{\xi_1,\ldots,\xi_k\}$, $k = p-s$ in such a manner that the Jacobian relating F_μ and u_α $(\alpha,\mu=1,\ldots,q)$ has maximal rank

$$J = \frac{\partial(F_1,\ldots,F_q)}{\partial(u_1,\ldots,u_q)}, \quad \operatorname{rank} J = q. \tag{3}$$

Then consider F_μ to be functions of the other invariants $\{\xi_i\}$ which serve as the new independent variables and use condition (3) to express the dependent variables u_α in terms of the invariants.

(5) Substitute the obtained expressions for u_α into the original system and obtain the reduced system, involving only invariants. The reduced system will involve only $k = p-s$, $s \geqslant 1$ independent variables.

(6) Solve the reduced system. If the variables ξ^i depend on $x_1,\ldots,x_p$ only, this will yield explicit solutions of system (1). Otherwise, if ξ_i depend also on the original dependent variables u_α, we obtain implicit solutions.

(7) Apply a general symmetry group transformation to these solutions.

This procedure provides a family of particular solutions that can be used to satisfy particular boundary or initial conditions. The classification of subgroups G_i can be viewed as a classification of conditions that can be imposed on the obtained solutions.

We mention that the dimension $r = \dim G$ of the symmetry group may be infinite. However, we shall always consider reductions by finite-dimensional subgroups of G.

Steps 3, 4, and 5 of Lie's method can be reformulated as follows. Take the vector fields $\{\mathbf{v}_a\}$ forming a basis of the considered Lie subalgebra $\mathfrak{g}_i \subset \mathfrak{g}$ and set their characteristics equal to zero

$$Q_a^\alpha = \varphi_a^\alpha(x,u) - \sum_{i=1}^{p} \xi_a^i(x,u)\, u_{x_i}^\alpha = 0, \quad \alpha = 1,\ldots,q, \quad a = 1,\ldots,r_i = \dim \mathfrak{g}_i. \tag{4}$$

Solve the systems (1) and (4) simultaneously.

Several alternative reduction procedures have been proposed, going beyond Lie's classical method and providing further solutions. They all have in common that they add some system of equations to the original system (1) and that the extended system is solved simultaneously. These additional equations replace the characteristic system (4).

In its generality, this was proposed as the method of "differential constraints," [10] and independently as the method of "side conditions." [11,12] Different methods differ by the choice of this system of side conditions.

Basically two different approaches exist in the literature. The first makes further use of the symmetry group G of system (1), the second approach goes beyond this group of point transformations, or even gives up group theory altogether. Let us briefly discuss some of these methods.

(1) "Group invariant solutions without transversality." This method was proposed by Anderson *et al.*[13] quite recently and deals with the situation when the rank condition (3) is not satisfied. It was shown[13] that under certain conditions on the subgroup $G_i \subset G$ one can still obtain G_i invariant solutions. We recall that a group invariant solution, with or without transversality, is transformed into itself by the subgroup $G_i \subset G$.

(2) The method of partially invariant solutions. A solution $u(x)$ is "partially invariant," [3,14,15] under a subgroup $G_i \subset G$ of the invariance group, if G_i, when acting on $u(x)$ sweeps out a manifold of a dimension that is larger than that of the graph of the solution, but less than the dimension of the entire space M. A group G_i may provide both invariant and partially invariant

solutions (see below in Sec. IV). However, if the rank condition (3) for the Jacobian is not satisfied, at least on a set of solutions, then G_i will not provide invariant solutions, but may provide partially invariant ones. If the rank of the Jacobian J is q', with $q'<q$, then we can express $u_1,\ldots,u_{q'}$ in terms of invariants and let $u_{q'+1},\ldots,u_q$ depend on all of the original variables $x_1,\ldots,x_p$. We then substitute the dependent variables back into the original system and obtain a ''partial reduction.'' Solving this system, we obtain the partially invariant solutions. Irreducible partially invariant solutions are partially invariant solutions that are not invariant under the subgroup G_i, nor under any other subgroup G_i' of the symmetry group of the considered equations. Such solutions were constructed for certain nonlinear Klein–Gordon and Schrödinger equations, in Refs. 16 and 17, and for some equations of hydrodynamics in Refs. 18–20.

The theory of partially invariant solutions was further developed by Ondich[21,22] who formulated irreducibility criteria for certain classes of equations. For other applications, see Refs. 23–26.

In terms of Eqs. (4), the method described above boils down to taking only $q'<q$ of Eqs. (4). As we shall show, it is possible to obtain further partially invariant solutions by different methods.

Among methods that go beyond the use of the symmetry group G we mention the following.

(3) The Clarkson–Kruskal direct reduction method[27,28] does not make explicit use of group theory. It is postulated that the dependent variables should be expressed in terms of new dependent variables that depend on fewer independent ones. The corresponding Ansatz is substituted into the original equation, which must then be solved. It has been shown that the direct method is intimately related to the method of conditional symmetries,[29–31] to the ''nonclassical method'' proposed by Bluman and Cole,[32,33] and to potential symmetries.[34] This method can also be interpreted in terms of side conditions.[11,12] The differential constraints added to system (1) in this case have the form of first order quasilinear partial differential equations of the form (4). However the coefficients φ_a^α and ξ_α^i are not related to a Lie point symmetry of Eq. (1).

(4) The group foliation method. The method goes back to Lie, is described by Ovsiannikov[3] and has recently been applied to obtain solutions of self-dual Einstein equations.[35,36] In terms of differential constraints this method amounts to embedding the system (1) into a larger system, consisting of all equations up to some definite order, invariant under the same Lie point symmetry group as (1) (and involving the same variables).

(5) The method of ''partial Lie-point symmetries,'' proposed by Cicogna and Gaeta.[37] This is a modification of the method of conditional symmetries. The method is in some cases easier to use and may provide solutions in cases when the equations of the conditional symmetry method prove to be untractable.

(6) For integrable equations[38] generalized symmetries can be used to generate side conditions. These will be higher order equations, rather than first order ones.

(7) The method of nonlocal symmetries. This consists in extending the space of dependent variables by adding some auxiliary variables, which can be potentials or pseudopotentials associated to the system of equations under analysis.[8,39–41] A nonlocal symmetry will be then a symmetry of the original system augmented with the equations defining the new nonlocal variables.

This article is organized as follows. In Sec. II we introduce the concept of ''weak transversality'' allowing us to formulate the method of ''group invariant solutions without transversality'' [13] in terms of local coordinates (the dependent and independent variables in the equation). We then relate the rank of the matrix of invariants (3) to that of the coefficients of vector fields. This makes the application of the method quite simple, as we shall show in Sec. III. Moreover, the requirement that the transformations be projectable is not needed. The method of weak transversality is applied in Sec. III to obtain new invariant solutions of the Navier–Stokes equations and of the isentropic compressible fluid model. In Sec. IV we establish a relation between partially invariant solutions and the transversality condition. This is then applied to obtain new irreducible partially invariant solutions of the vector nonlinear Schrödinger equation, of the Euler equations, of the Navier–Stokes equations and of the isentropic compressible fluid model in $(3+1)$ dimensions. The concept of the irreducibility of partially invariant solutions is discussed. Some conclusions are presented in the final Sec. V.

II. GROUP INVARIANT SOLUTIONS, STRONG AND WEAK TRANSVERSALITY

Lie's classical method of symmetry reduction was outlined in the Introduction. The first two steps are entirely algorithmic and we shall assume that they have already been performed. Thus, we are given a system of equations (1) and have found its Lie point symmetry group G, the Lie algebra of which is the symmetry algebra $\mathfrak{g}$. The symmetry algebra has dimension r and has a basis realized by vector fields of the form (2). Each vector field has the property that its nth prolongation annihilates the system (1) on its solution set

$$\mathrm{pr}^{(n)}\,\mathbf{v}\,\Delta_\nu\big|_{\Delta_\mu=0}=0,\quad \nu,\,\mu=1,\ldots,m. \tag{5}$$

The functions $\xi_a^i(x,u)$ and $\varphi_a^i(x,u)$ are thus explicitly known.

Let us now consider a subgroup $G_0\subset G$ and its Lie algebra $\mathfrak{g}_0$. A solution $u=f(x)$ of the system (1) is G_0 invariant if its graph $\Gamma_f\sim\{x,f(x)\}$ is a G_0 invariant set

$$g\cdot\Gamma_f=\Gamma_f,\quad g\in G_0. \tag{6}$$

The basis vector fields (2) can be written in evolutionary form[1] as

$$\mathbf{v}_{E,a}=\sum_{\alpha=1}^{q}\left(\varphi_a^\alpha(x,u)-\sum_{i=1}^{p}\xi_a^i(x,u)u_{x_i}^\alpha\right)\partial_{u_\alpha},\quad a=1,\ldots,r. \tag{7}$$

A G_0-invariant solution will satisfy the $q\times r_0$ characteristic equations (4) associated with the basis elements of the Lie algebra $\mathfrak{g}_0$ ($\dim\mathfrak{g}_0=r_0$).

The following matrices play an essential role in symmetry reduction using the symmetry group of the considered system of equations.

(1) The matrices Ξ_1 and Ξ_2 of the coefficients of the vector fields $\mathbf{v}_a$ spanning the algebra $\mathfrak{g}$, or its subalgebra $\mathfrak{g}_0$, and defined as follows:

$$\begin{gathered}\Xi_1=\{\xi_a^i(x,u)\},\quad \Xi_1\in\mathbb{R}^{r\times p},\\ \Xi_2=\{\xi_a^i(x,u),\varphi_a^\alpha(x,u)\},\quad \Xi_2\in\mathbb{R}^{r\times(p+q)},\end{gathered} \tag{8}$$

where $a=1,\ldots,r$ labels the rows, i and α label the columns.

(2) The matrix of characteristics of the vector fields (2) [or (7)] spanning the considered algebra $\mathfrak{g}$ (or its subalgebra $\mathfrak{g}_0$),

$$Q_a^\alpha=\{\mathbf{v}_a^E u_\alpha\},\quad a=1,\ldots,r,\quad \alpha=1,\ldots,q. \tag{9}$$

(3) The Jacobian matrix J of the transformation relating the dependent variables u_α and the invariants of the action of G_0 on the space $M\sim X\times U$ of independent and dependent variables.

Let us now consider a specific subalgebra $\mathfrak{g}_0\subset\mathfrak{g}$ and use it to obtain group invariant solutions via symmetry reduction. If the group G_0 acts regularly and transversally on $M\sim X\times U$ then

$$\mathrm{rank}\{\xi_a^i(x,u)\}=\mathrm{rank}\{\xi_a^i(x,u),\varphi_a^\alpha(x,u)\}. \tag{10}$$

This rank is equal to the dimension of the generic orbits of G_0 on M. If the transversality condition (10) is satisfied, at least locally, for all $\{x,u\}\in M$, then Lie's classical reduction method is directly applicable. Indeed, if (10) is satisfied then the rank of the matrix J of Eq. (3) is maximal, $\mathrm{rank}\,J=q$ (for a proof, see, e.g., Ref. 1, Chap. 3.5). It follows that all dependent variables can be expressed in terms of invariants and a reduction is immediate (to a system with q dependent variables and $p-s$ independent ones, where s is the dimension of the orbit of a generic point under the action of G_0.

If the action of G_0 on M is fiber preserving (i.e., the new independent variables only depend on the old independent ones), Lie's method provides explicit solutions. This happens because the new invariant independent variables z_i can be chosen to depend only on the original independent variables

$$z_i = z_i(x_1, \ldots, x_p), \quad i = 1, \ldots, p-s. \tag{11}$$

More generally, if we have $z_i = z_i(x,u)$, we obtain implicit solutions.

We shall call the rank condition (10) "strong transversality." Quite recently[13] a method was proposed for obtaining group invariant solutions when equation (10) is not satisfied. The method of Ref. 13 can actually be modified and made easier to apply by introducing the concept of "weak transversality."

The local transversality condition will be said to be satisfied in the weak sense if it holds only on a subset $\tilde{M} \subset M$, rather than on the entire space M:

$$\operatorname{rank}\{\xi_a^i(x,u)\}\big|_{\tilde{M}} = \operatorname{rank}\{\xi_a^i(x,u), \varphi_a^\alpha(x,u)\}\big|_{\tilde{M}}. \tag{12}$$

In other words, even if the transversality condition is not in general satisfied, there may exist a class S of functions $u = f(x)$ such that for them the condition (12) holds.

The "weak transversality" method is quite simple, when applicable. It consists of several steps.

(1) Determine the conditions on the functions $u = f(x)$ under which Eq. (12) is satisfied. Solve these conditions to obtain the general form of these functions.

(2) Substitute the obtained expressions into the matrix of characteristics (9) and require that the condition $\operatorname{rank} Q = 0$ be satisfied. This further constrains the functions $f(x)$.

(3) Substitute the obtained expressions into the system (1). By construction, the solutions, if they exist, will be G_0 invariant.

This method can only be applied if the matrix elements in the matrix Ξ_2 depend explicitly on the variables u_α. This poses strong restrictions on the considered algebra $\mathfrak{g}_0$. Step 1 of this method amounts to restricting to a domain where the original Lie method can be applied. Steps 2 and 3 are as in Lie's method. The "weak transversality method" is from this point of view a direct extension of Lie's classical method. Note that this method can be applied both to ordinary and partially differential equations. We shall give some examples of the method in Sec. III.

III. EXAMPLES OF INVARIANT SOLUTIONS OBTAINED BY THE WEAK TRANSVERSALITY METHOD

A. The Navier–Stokes equations

The Navier–Stokes equations in $(3+1)$ dimensions describing the flow of an incompressible viscuous fluid are

$$\vec{u}_t + \vec{u} \cdot \nabla \vec{u} + \nabla p - \nu \nabla^2 \vec{u} = 0, \tag{13}$$

$$\nabla \cdot \vec{u} = 0, \tag{14}$$

where $\vec{u} = (u_1(x,y,z,t), u_2(x,y,z,t), u_3(x,y,z,t))$ is the velocity field, $p = p(x,y,z,t)$ the fluid pressure and ν the viscosity coefficient.

The symmetry properties of these equations have been intensively investigated by many authors from different points of view (see, for instance, Ref. 42 and references therein). It is well known[43] that Eqs. (13) and (14) are invariant under the flow generated by the following vector fields:

$$B_1 = \alpha\, \partial_x + \dot{\alpha} \partial_{u_1} - \ddot{\alpha} x\, \partial_p, \tag{15}$$

$$B_2=\beta\,\partial_y+\dot{\beta}\partial_{u_2}-\ddot{\beta}y\,\partial_p\,, \tag{16}$$

$$B_3=\gamma\,\partial_z+\dot{\gamma}\partial_{u_3}-\ddot{\gamma}z\,\partial_p\,, \tag{17}$$

$$T=\partial_t\,, \tag{18}$$

$$Q=\partial_p\,, \tag{19}$$

$$D=x\partial_x+y\partial_y+z\partial_z+2t\partial_t-u_1\partial_{u_1}-u_2\partial_{u_2}-u_3\partial_{u_3}-2p\partial_p\,, \tag{20}$$

$$L_1=z\partial_y-y\partial_z+u_3\partial_{u_2}-u_2\partial_{u_3,} \tag{21}$$

$$L_2=x\partial_z-z\partial_x+u_1\partial_{u_3}-u_3\partial_{u_1}, \tag{22}$$

$$L_3=y\partial_x-x\partial_y+u_2\partial_{u_1}-u_1\partial_{u_2}, \tag{23}$$

where α,β,γ, and δ are arbitrary functions of time. The operators B_j generate symmetry transformations that can be interpreted as boosts to frames moving with arbitrary velocities $\vec{v(t)}=\lambda(\dot{\alpha},\dot{\beta},\dot{\gamma})$, where λ is a constant. Space translations and Galilei boosts are obtained if α,β, and γ are linear in t. The operators T and Q express the invariance of the Eqs. (13) and (14) under translations of time and pressure, D generates scaling transformations, and L_1,L_2, and L_3 are the generators of the group of the rotations of the Euclidean space.

Example 1: Let us consider the subalgebra generated by L_1, L_2, and L_3. Here we apply the ideas discussed in Sec. II to determine rotationally invariant solutions for the Navier–Stokes equations.

The matrices of the coefficients $\Xi_1=(\xi_a^i(x,u))$ and $\Xi_2=(\xi_a^i(x,u),\phi_a^\alpha(x,u))$ are represented by

$$\Xi_1=\begin{pmatrix} 0 & z & -y \\ -z & 0 & x \\ y & -x & 0 \end{pmatrix}, \quad \Xi_2=\begin{pmatrix} 0 & z & -y & 0 & u_3 & -u_2 \\ -z & 0 & x & -u_3 & 0 & u_1 \\ y & -x & 0 & u_2 & -u_1 & 0 \end{pmatrix}. \tag{24}$$

We observe that the matrix Ξ_1 has rank 2, whereas the matrix Ξ_2 has rank 3. In this situation, the transversality condition is violated in the strong sense. In other words, it is not true that for *every* function $\vec{u}=(u_1,u_2,u_3)$ the ranks of the matrices Ξ_1 and Ξ_2 coincide. In general, the system of characteristics is not compatible, the Jacobian matrix J will not have maximal rank, and it is *not* possible to use the classical symmetry reduction approach. To overcome these difficulties, let us force the matrix Ξ_2 to be of rank 2. This requirement is equivalent to a system of algebraic equations for $\vec{u}$, obtained imposing that the determinants of all 3×3 matrices constructed using the rows and the columns of Ξ_2 be equal to zero. Once this algebraic system is solved, we get the class S of functions $\vec{u}=(u_1,u_2,u_3)$ on which transversality is weakly restored. The class S in this case is characterized by the conditions:

$$u_1=f(x,y,z,t)x, \quad u_2=f(x,y,z,t)y, \quad u_3=f(x,y,z,t)z, \quad p=p(x,y,z,t). \tag{25}$$

The second step consists in solving the characteristic system $Q_k^\alpha(x,u^{(1)})=0$ for the class S of Eqs. (25). This forces the functions f and p to have the form

$$f=f(r,t), \quad p=p(r,t), \tag{26}$$

where $r=\sqrt{x^2+y^2+z^2}$. Relations (26) represent the most general form for the function $\vec{u}$ and p to be rotationally invariant in the Euclidean space. Substituting these expressions for $\vec{u}$ and p into Eqs. (13) and (14), we find the solution

$$\vec{u}=\frac{a(t)}{r^3}\vec{x}, \quad p=\frac{\dot{a}}{r}-\frac{a^2}{2r^4}+b. \tag{27}$$

The same vector fields L_1, L_2, and L_3 provide also a subalgebra of the symmetry algebra of the Euler equations. Anderson *et al.*[13] obtained a class of rotationally invariant solutions of the Euler equations by means of their technique of reduction diagrams. In Ref. 18 partially invariant solutions related to the subalgebra $\{L_1, L_2, L_3\}$ for the equations describing a nonstationary and isentropic flow for an ideal and compressible fluid in $(3+1)$ dimensions have been constructed using the transformation (25). A similar situation is also observed in magnetohydrodynamics.[19] Our solutions of the Navier–Stokes equations coincide with the solutions of the Euler equations found in Ref. 13. Physically that means that the solutions (27) describe a laminar flow for which viscosity plays no role. This phenomenon occurs because the components of the vector $\vec{u}$ in Eq. (27) are all harmonic functions, i.e., they satisfy the Laplace equation, in addition to the Navier–Stokes equations.

Example 2: Now, let us analyze the subalgebra defined by the operators

$$\begin{aligned} D&=x\partial_x+y\partial_y+z\partial_z+2t\partial_t-u_1\partial_{u_1}-u_2\partial_{u_2}-u_3\partial_{u_3}-2p\partial_p,\\ L_3&=y\partial_x-x\partial_y+u_2\partial_{u_1}-u_1\partial_{u_2},\\ X&=t^k\partial_x+k\,t^{k-1}\partial_{u_1}-k\,(k-1)\,t^{k-2}x\,\partial_p,\\ Y&=t^k\partial_y+k\,t^{k-1}\partial_{u_2}-k\,(k-1)\,t^{k-2}y\,\partial_p, \end{aligned} \tag{28}$$

which is a subalgebra of the Galilei–similitude algebra for a given $k\in\mathbb{R}$. It is immediate to check that the local transversality is violated for this subalgebra in the strong sense. The matrix Ξ_2 is now represented by

$$\begin{pmatrix} x & y & z & 2t & -u_1 & -u_2 & -u_3 & -2p \\ y & -x & 0 & 0 & u_2 & -u_1 & 0 & 0 \\ t^k & 0 & 0 & 0 & k\,t^{k-1} & 0 & 0 & -k\,(k-1)\,t^{k-2}x \\ 0 & t^k & 0 & 0 & 0 & k\,t^{k-1} & 0 & -k\,(k-1)\,t^{k-2}y \end{pmatrix}.$$

If we impose that the matrix Ξ_2 should have rank 3 (that is weak transversality), we get

$$u_1=k\frac{x}{t}, \quad u_2=k\frac{y}{t},$$

$$u_3=u_3(x,y,z,t), \quad p=p(x,y,z,t).$$

As a second step, let us solve the characteristic system $Q_a^{\alpha}(x,u^{(1)})=0$, which consists of 16 linear differential equations of first order in the derivatives of the velocity components u_j and the pressure p. The most general function living in the space of the dependent variables and invariant under the flow associated to the generators (28) is

$$u_1=k\frac{x}{t}, \quad u_2=k\frac{y}{t}, \quad u_3=\frac{\alpha\left(\dfrac{t}{z^2}\right)}{z^2}, \tag{29}$$

$$p=-\frac{k(k-1)(x^2+y^2)}{2t^2}+\frac{\beta\left(\frac{t}{z^2}\right)}{z^2}, \tag{30}$$

with α and β arbitrary functions of $t\ z^{-2}$. Substituting into the Navier–Stokes equations (13) and (14), we obtain the following three parameter set of solutions:

$$u_1=k\frac{x}{t},\quad u_2=k\frac{y}{t},\quad u_3=\frac{c_1}{\sqrt{t}}-2\frac{kz}{t}, \tag{31}$$

$$p=\frac{1}{2t^2}\{c_1\sqrt{t}z+k(x^2+y^2+4c_1\sqrt{t}z-2z^2)-k^2(x^2+y^2+4z^2)+2c_2t\}, \tag{32}$$

with $c_1,c_2,k\in\mathbb{R}$. This solution is invariant under the group generated by the algebra (28) and satisfies weak (but not strong) transversality.

B. The isentropic compressible fluid model

The equations describing the nonstationary isentropic flow of a compressible ideal fluid are[44]

$$\vec{u_t}+\vec{u}\cdot\nabla\vec{u}+k\,a\,\nabla a=0, \tag{33}$$

$$a_t+\vec{u}\cdot\nabla a+k^{-1}a\,\nabla\cdot\vec{u}=0, \tag{34}$$

where $\vec{u}=u_1(x,y,z,t)$, $u_2(x,y,z,t)$, $u_3(x,y,z,t)$ is the velocity field, $a=a(x,y,z,t)$ is the velocity of sound, related to the pressure p and the density ρ by the formula $a=(\gamma p/\rho)^{1/2}$, γ is the adiabatic exponent and $k=2/(\gamma-1)$. The symmetry group G of Eqs. (33) and (34) was derived in Ref. 20. For $k\neq 3$, G it is generated by the following vector fields:

$$P_0=\partial_t,\quad P_1=\partial_x,\quad P_2=\partial_y,\quad P_3=\partial_z, \tag{35}$$

$$K_1=t\partial_x+\partial_{u_1},\quad K_2=t\partial_y+\partial_{u_2},\quad K_3=t\partial_z+\partial_{u_3}, \tag{36}$$

$$L_1=z\partial_y-y\partial_z+u_3\partial_{u_2}-u_2\partial_{u_3,}, \tag{37}$$

$$L_2=x\partial_z-z\partial_x+u_1\partial_{u_3}-u_3\partial_{u_1}, \tag{38}$$

$$L_3=y\partial_x-x\partial_y+u_2\partial_{u_1}-u_1\partial_{u_2}, \tag{39}$$

$$F=x\partial_x+y\partial_y+z\partial_z+t\partial_t,\quad G=-t\partial_t+u_1\partial_{u_1}+u_2\partial_{u_2}+u_3\partial_{u_3}+a\,\partial_a. \tag{40}$$

We mention that for $k=3$ the symmetry algebra contains an additional element generating projective transformations. The operators P_i,K_i, and L_i are the infinitesimal generators of space translations, Galilei boosts and rotations, respectively. The operators F and G generate scaling transformations.

Example 3: Let us consider the subalgebra $\{L_3,F+G,K_1,K_2\}$. The matrix Ξ_2 is given by

$$\begin{pmatrix} y & -x & 0 & 0 & u_2 & -u_1 & 0 & 0\\ x & y & z & 0 & u_1 & u_2 & u_3 & a\\ t & 0 & 0 & 0 & 1 & 0 & 0 & 0\\ 0 & t & 0 & 0 & 0 & 1 & 0 & 0 \end{pmatrix} \tag{41}$$

and the transversality is again violated in the strong sense, because rank $\Xi_1=3$ and rank $\Xi_2=4$. If we force the matrix Ξ_2 to be of rank 3, then we get the following constraints:

$$u_1=\frac{x}{t}, \quad u_2=\frac{y}{t}, \quad u_3=u_3(x,y,z,t), \quad a=a(x,y,z,t). \tag{42}$$

From the characteristic system $Q_a^{\alpha}(x,u^{(1)})=0$ we deduce

$$u_3=z\,W(t), \quad a=z\,A(t), \tag{43}$$

where W and A are arbitrary functions of time. Now, substituting relations (42) and (43) into the system (33) and (34) we obtain the relation

$$A(t)=\sqrt{-\frac{1}{k}(W^2+W')} \tag{44}$$

and a second order ODE for W

$$W''+2\left(2+\frac{1}{k}\right)WW'+2\left(1+\frac{1}{k}\right)W^3+\frac{4}{k\,t}(W'+W^2)=0. \tag{45}$$

In general, Eq. (45) does not have the Painlevé property. For special values of the parameter k, namely $k=-1$ and $k=-2$, it does. In these cases it can be reduced to a canonical form (see Ref. 45, p.334) via a linear transformation of the type

$$W=\alpha(t)\,U(z(t))+\beta(t). \tag{46}$$

(1) For $k=-1$ we have

$$W''=-2WW'+p(t)\,(W'+W^2), \tag{47}$$

where $p(t)=4/t$. This equation can be integrated and its solution, which is regular, is

$$W=\frac{c_1t^2\left(I_{-5/6}\left(\frac{c_1t^3}{3}\right)+c_2I_{5/6}\left(\frac{c_1t^3}{3}\right)\right)}{I_{1/6}\left(\frac{c_1t^3}{3}\right)+c_2I_{-1/6}\left(\frac{c_1t^3}{3}\right)}, \tag{48}$$

where c_1 and c_2 are constants and $I_n(x)$ is the modified Bessel function of the first kind. Correspondingly we find

$$A=c_1t^2 \tag{49}$$

in Eq. (44).

(2) For $k=-2$ we have

$$W''=-3WW'-W^3+q(t)(W'+W^2), \tag{50}$$

where $q(t)=2/t$. In this case, we can integrate and the general solution is

$$W=\frac{4\,t^3+c_1}{t^4+c_1\,t+c_2}. \tag{51}$$

The solution of Eq. (44) is

$$A=2\sqrt{3}\sqrt{\frac{t^2}{t^4+c_1t+c_2}}, \tag{52}$$

where c_1, and c_2 are constants. The solutions for $k=-1$ and $k=-2$ represent nonscattering waves.

IV. PARTIALLY INVARIANT SOLUTIONS OF SYSTEMS OF DIFFERENTIAL EQUATIONS AND THE TRANSVERSALITY CONDITION

A useful tool applicable to the study of systems of differential equations, and intimately related to the standard Lie approach, is the theory of partially invariant solutions. The relevant notion in this context is the defect δ of a k-dimensional manifold M with respect to a Lie group G. When the group acts on a p-dimensional submanifold $\Gamma\subseteq M$, it sweeps out an orbit $G(\Gamma)$. The manifold Γ will be identified with the graph Γ_f of a function $u=f(x)$, so its dimension will coincide with the number of independent variables (also denoted p). As we already said, the case $G(\Gamma_f)=\Gamma_f$ corresponds to the G-invariance of the manifold. Otherwise, $G(\Gamma_f)$ will be a more generic subset of M. There is no guarantee that this subset will be a submanifold. However, if the intersection between an orbit O of G and Γ_f has a dimension which is constant in a neighborhood N of a point of Γ_f, then there exists a neighborhood $\tilde{G}$ of the identity of G such that the subset $\tilde{G}$ $(N\cap\Gamma_f)$ is a submanifold.[21] In the subsequent considerations, $G(\Gamma_f)$ will be considered as a submanifold.

Let G be a group, acting regularly with s-dimensional orbits. We call the number

$$\delta=\dim G(\Gamma_f)-\dim\Gamma_f \tag{53}$$

the defect δ of the function f with respect to G. The usual G-invariant functions correspond to the case $\delta=0$. A function will be said to be it *generic* if $\delta=m_0=\min\{s,k-p\}$. The more interesting situation is when $0<\delta<m_0$, which is the case we will dealing with. In this case, the function f will be said to be partially invariant.[3]

Let us consider the system (1) of partial differential equations, whose symmetry group G acts on the $p+q$-dimensional space $M=X\times U$. Let $\mathfrak{g}$ be a subalgebra of the symmetry algebra of Δ, and Q the characteristic matrix associated to the set of its generators. Then $u=f(x)$ is a partially invariant solution of Δ with defect δ with respect to $\mathfrak{g}$ if and only if[3,21,46]

$$\operatorname{rank}(Q(x,u^{(1)}))=\delta. \tag{54}$$

The condition (54) provides a system of differential equations involving the dependent variables $u=(u_1,\ldots,u_q)$. In order to determine partially invariant solutions, we can extend the original system Δ by adding the set of differential constraints given by the condition (54). We must then solve the extended system consisting of Eqs. (1) and (54). The equations given by the prescription (54) are less constraining than those required to obtain G-invariance, as in formulas (4). Indeed, condition (4) requires that the rank of Q be zero [compatible with (54) but stronger].

In this section we will study the role of the local transversality condition (and in particular of the notion of weak transversality) in the theory of partially invariant solutions and propose a strategy to find them.

Let us start by noticing that a partially invariant solution of a system of differential equations can be naturally related to the violation of the transversality condition. Indeed, let $\Delta(x,u^{(n)})=0$ be a system of differential equations defined over $M\subset X\times U$ and $u_0=u_0(x_0)$ be a solution of Δ. Let G be an r-dimensional subgroup of the symmetry group of Δ, acting regularly on M, whose generators are given by (2). If the condition

$$\operatorname{rank}(\xi_a^i(x_0,u_0))<\operatorname{rank}(\xi_a^i(x_0,u_0),\phi_a^\alpha(x_0,u_0)) \tag{55}$$

is satisfied, then $u_0=f(x_0)$ is a partially invariant solution of Δ (or possibly a generic one).

Example 4: The vector nonlinear Schrödinger equation

$$i\psi_t+\Delta\psi=(\overline{\psi}\psi)\psi, \tag{56}$$

where $\psi\in\mathbb{C}^N$ and Δ is the Laplace operator in n dimensions, plays an important role in many areas of physics. For instance, in nonlinear optics it describes the interaction of electromagnetic waves propagating with different polarizations in nonlinear media.[47,48] In hydrodynamics, it furnishes a model for the description of the interactions of N water waves in a deep fluid.[49–51] For these and other applications of the vector nonlinear Schrödinger equation, see also Ref. 52.

Let us consider the case of three components ($N=3$) and two spatial dimensions ($n=2$). The symmetry algebra has been computed in Ref. 53. In terms of amplitude and phase, the components of the wave function will be written as $\psi_\mu=\rho_\mu e^{i\omega_\mu}$. The symmetry algebra of Eq. (56) for $N=3$ and $n=2$ has the form

$$\mathfrak{g}=\mathrm{sch}(2)\oplus\mathrm{su}(3). \tag{57}$$

The Schrödinger algebra sch(2) has a basis realized by the vector fields

$$P_1=\partial_x,\quad P_2=\partial_y,\quad K_1=t\partial_x+\frac{1}{2}x\sum_\mu\partial\omega_\mu, \tag{58}$$

$$K_2=t\partial_y+\frac{1}{2}y\sum_\mu\partial\omega_\mu, \tag{59}$$

$$L_{12}=y\partial_x-x\partial_y,\quad M=\sum_\mu\partial\omega_\mu, \tag{60}$$

$$D=2t\partial_t+x\partial_x+y\partial_y-(x^2+y^2)\sum_\mu\partial\omega_\mu, \tag{61}$$

$$C=t^2\partial_t+t\left[x\partial_x+y\partial_y-\sum_\mu\rho_\mu\partial\rho_\mu\right]+\frac{1}{4}(x^2+y^2)\sum_\mu\partial\omega_\mu. \tag{62}$$

We shall not need the algebra su(3) (given in Ref. 53), only its Cartan subalgebra

$$T_1=\partial\omega_1-\partial\omega_2,\quad T_2=\partial\omega_2-\partial\omega_3. \tag{63}$$

Let us consider the subalgebra

$$\{\partial_x,\partial_y,y\,\partial_x-x\,\partial_y+a_1\partial\omega_1+a_2\partial\omega_2+a_3\partial\omega_3\}, \tag{64}$$

generated by the two translations in the plane and a rotation combined with a transformation of the phases. The matrix of the coefficients Ξ_2, given by

$$\begin{pmatrix}1&0&0&0&0&0&0&0\\0&1&0&0&0&0&0&0\\y&-x&a_1&a_2&a_3&0&0&0\end{pmatrix}$$

has rank 3, unless $(a_1,a_2,a_3)=(0,0,0)$. Let us consider the case $a_2=a_3=0$, $a_1\neq0$. We obtain $\rho_i=\rho_i(t)$ $(i=1,2,3)$, $\omega_1=\omega_1(t)$, $\omega_2=\omega_2(t)$, but ω_3 is not an invariant, so we keep $\omega_3=\omega_3(x,y,z,t)$. Substituting into Eq. (56), we obtain

$$\rho_1=\frac{\gamma_1}{\sqrt{t(t-t_0)}},\quad \rho_2=\gamma_2,\quad \rho_3=\gamma_3, \tag{65}$$

$$\omega_1=\frac{x^2}{4(t-t_0)}+\frac{y^2}{4\,t}+\frac{\gamma_1^2}{t_0}\ln\frac{t}{t-t_0}-(\gamma_2^2+\gamma_3^2)\,t, \tag{66}$$

$$\omega_2=\omega_3=\frac{\gamma_1^2}{t_0}\ln\frac{t}{t-t_0}-(\gamma_2^2+\gamma_3^2)\,t. \tag{67}$$

This solution is partially invariant with respect to the subgroup corresponding to the subalgebra (64) with $a_1\neq 0$, $a_2=a_3=0$. Using the expressions (58)–(62) we can check that this solution is in general not invariant under any subgroup of the Schrödinger group Sch(2). The one exception is the limit $t_0\to 0$ when the solution is invariant under rotations generated by L_{12}. Thus this partially invariant solution is in general irreducible and becomes reducible for $t_0\to 0$.

Example 5: Let us consider again the isentropic compressible model [formulas (33) and (34)]. For the subalgebra $\mathfrak{g}=\{K_1,K_2,K_3,P_3\}$ the matrix Ξ_2 is given by

$$\begin{pmatrix} t & 0 & 0 & 0 & 1 & 0 & 0 & 0\\ 0 & t & 0 & 0 & 0 & 1 & 0 & 0\\ 0 & 0 & t & 0 & 0 & 0 & 1 & 0\\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Here transversality is violated also in the weak sense. The invariants of the corresponding Lie group are $F=u_1t-x, G=u_2\,t-y$, a and t. The matrix J of (3) is not invertible, but we can write

$$u_1=\frac{F(t)+x}{t},\quad u_2=\frac{G(t)+y}{t},\quad a=A(t), \tag{68}$$

but leave u_3 general, i.e., $u_3=u_3(x,y,z,t)$. Substituting Eqs. (68) into (33), (34) we obtain the solution[18]

$$u_1=\frac{x}{t},\quad u_2=\frac{y}{t},\quad u_3=\frac{z+\lambda(\xi_1,\xi_2)}{t+t_0},\quad a=c\left(\frac{1}{t^2(t+t_0)}\right)^{1/k}, \tag{69}$$

where $\xi_1=x/t$, $\xi_2=y/t$, λ is an arbitrary function of ξ_1 and ξ_2, c and t_0 are constants. The rank of the matrix Q_a^α of the characteristics associated to (69) is equal to 1, and therefore this solution is partially invariant with respect to the subalgebra $\mathfrak{g}$, with $\delta=1$. Now let us check if it is reducible under any other subalgebra of the full symmetry algebra (35)–(40). To do this, it is useful to study the kernel K of the characteristic matrix Q for the full symmetry algebra (35)–(40) associated to the solution (69) and to determine its generators $\{\mathbf{k}_1,\ldots,\mathbf{k}_l\}$. It is clear that if at least a subspace of K can be generated by constant vectors, then the solution will be reducible with respect to the subalgebra identified by these vectors.

In the case of the solution (69), the kernel is generated by eight vectors, each having 12 components. It is possible to show that there exists only one constant generator, namely

$$\mathbf{k}=(0,0,0,t_0,0,0,0,0,0,1,0,0).$$

This implies that the solution (69) is reducible with respect to the one-dimensional subalgebra $\{K_3+t_0P_3\}$.

The concept of ''irreducibility'' of a partially invariant solutions needs further clarification. Once a solution $u=f(x)$, partially invariant under G_i is found, it is of course possible to verify whether it is invariant under some other subgroup $G_i'\subset G$. Let this be the case, let G_i' satisfy the

strong transversality condition, and have generic orbits of dimension r_i'. The standard Lie method using the subgroup G_i' would then reduce system (1) to a system with $q-r_i'$ variables. In general, specially for $q-r_i'>1$, we may not be able to solve this system and the methods of partial invariance for the original subgroup G_i may be more tractable. We have already seen an example of this situation, namely, Example 4 above. Solution (65)–(67) is invariant under rotations in the limit $t_0\to 0$. If we look for such an invariant solution directly, we must set $\rho_i=\rho_i(r,t)$, $\omega_i=\omega_i(r,t)$ with $r=\sqrt{x^2+y^2}$. This reduces Eq. (56) to a system of PDE's in two variables. This system is very hard to solve and solution (65)–(67) would be very hard to obtain (without knowing it in advance). If the invariance subgroup G_i' does not satisfy the weak transversality condition, it may not help us at all.

We observe that the violation of the transversality condition is *not* a necessary condition for the existence of partially invariant solutions of a system $\Delta(x,u^{(n)})=0$. In fact, there could be solutions of Δ which are not solutions of the characteristic system, even if it is compatible as an algebraic system.

Example 6: As a matter of fact, a counterexample was provided by Ondich,[21] namely the two variable Laplace equation, expressed in the following form:

$$v=u_x,\quad v_y=w_x,\quad w=u_y,\quad v_x=-w_y. \tag{70}$$

This system is clearly invariant with respect to the translations in the plane, generated by the vector fields $\{\partial_x,\partial_y\}$. The characteristic matrix Q has the form

$$\begin{pmatrix} -u_x & -v_x & -w_x \\ -u_y & -v_y & -w_y \end{pmatrix}. \tag{71}$$

Invariant solutions are obtained if and only if the rank of this matrix is equal to zero. This implies that u, v, and w are constants:

$$u=k,\quad v=\lambda,\quad w=\mu,\quad k,\lambda,\mu\in\mathbb{R}.$$

Let us impose that the rank of Q is equal to 1. This means that the two rows in Eq. (71) are proportional. Then solving the corresponding equations and replacing the result into Eqs. (70), we get the following solution:

$$(u,v,w)=(a\,x+b\,y+c,\,a,\,b),\quad a,\,b\in\mathbb{R}. \tag{72}$$

By construction, this solution is partially invariant with respect to the group of translations in the plane, with defect $\delta=1$. Nevertheless, the transversality condition is satisfied. More generally, the transversality condition is always satisfied if we have $\operatorname{rank}(\xi_a^i(x,u))=\dim\mathfrak{g}$.

We mention that the previous solution (72) can be also obtained starting from the symmetry subalgebra $\{\partial_x,\partial_y,\partial_u\}$ for which both the weak and strong transversality conditions are violated. In this case, the invariants are $I_1=v=a$, $I_2=w=b$, where a and b are arbitrary constants. The function u remains arbitrary. Putting these constraints into Eqs. (70), we recover immediately the solution (72). However, it should be noticed that the analysis of the rank of the characteristic matrix furnishes a complete characterization of the invariant and partially invariant solutions of a system of differential equations, and provides a more general procedure than the use of the invariants. For instance, this second approach does not allow to recognize the solution (72) as a partially invariant one with respect to the subalgebra $\{\partial_x,\partial_y\}$.

Example 7: To show that a symmetry group satisfying the strong transversality can produce both invariant and partially invariant solutions, let us consider the Euler equations for an incompressible nonviscuous fluid in $(3+1)$ dimensions:

$$\vec{u_t}+\vec{u}\cdot\nabla\vec{u}+\nabla p=0, \tag{73}$$

$$\nabla\cdot\vec{u}=0, \tag{74}$$

The symmetry group of the Euler equations is well known.[1,5] It coincides with the symmetry group of the Navier–Stokes equations, except that it contains an additional dilation. Thus, D of Eq. (20) is replaced by

$$D_1=x\partial_x+y\partial_y+z\partial_z+t\partial_t, \tag{75}$$

$$D_2=t\,\partial_t-u_1\partial_{u_1}-u_2\partial_{u_2}-u_3\partial_{u_3}-2p\,\partial_p. \tag{76}$$

We consider here the subgroup of Galilei transformations. Its Lie algebra is given by

$$K_1=t\partial_x+\partial_{u_1},\quad K_2=t\partial_y+\partial_{u_2},\quad K_3=t\partial_z+\partial_{u_3}. \tag{77}$$

Here the transversality holds in the strong sense and indeed an invariant solution will have the form

$$u_1=\frac{x}{t}+F_1(t),\quad u_2=\frac{y}{t}+F_2(t),\quad u_3=\frac{z}{t}+F_3(t),\quad p=P(t). \tag{78}$$

Let us now look for partially invariant solutions of the system (73) and (74) with respect to the same subgroup and impose that the defect be $\delta=2$. Writing down the characteristic system associated to (77) and imposing that rank $Q=2$, we get the following constraints on u_1 and u_2:

$$u_1=\frac{x}{t}-\mu\,\lambda\frac{z}{t}+\mu\,\lambda u_3+h_1(t), \tag{79}$$

$$u_2=\mu\,u_3+\frac{y}{t}-\mu\frac{z}{t}+h_2(t) \tag{80}$$

but $u_3=u_3(x,y,z,t)$ and $p=p(x,y,z,t)$ remain arbitrary.

Substituting the relations (79) and (80) into the Euler equations, and choosing for simplicity $h_1=h_2=0$, we obtain the solution

$$u_1=\frac{1}{t[\mu^2(1+\lambda^2)+1]}\{x[\mu^2(1-2\lambda^2)+1]-3\lambda\mu(\mu y+z)\}+\lambda\,\mu\,t^2F\left(\frac{\lambda y-x}{t},\frac{\lambda\,\mu\,z-x}{t}\right), \tag{81}$$

$$u_2=\frac{1}{t[\mu^2(1+\lambda^2)+1]}\{y[\mu^2(\lambda^2-2)+1]-3\mu(\lambda\mu x+z)\}+\mu\,t^2F\left(\frac{\lambda y-x}{t},\frac{\lambda\,\mu\,z-x}{t}\right), \tag{82}$$

$$u_3=\frac{1}{t[\mu^2(1+\lambda^2)+1]}\{z[\mu^2(1+\lambda^2)-2]-3(\lambda x+y)\}+t^2F\left(\frac{\lambda y-x}{t},\frac{\lambda\,\mu\,z-x}{t}\right), \tag{83}$$

$$p=-\frac{3\mu^2}{t^2(\lambda^2\mu^2+\mu^2+1)}\left(\lambda x+y+\frac{z}{\mu}\right)^2+p(t), \tag{84}$$

where λ, μ are constants, F is an arbitrary function of its arguments and p is an arbitrary function of t. We have checked explicitly that, if F is kept arbitrary, this solution is not invariant under any

subgroup of the symmetry group. Thus, it represents an irreducible partially invariant solution of the Euler equations of defect $\delta=2$, with respect to a subgroup satisfying the strong transversality condition. If

$$F=\left(\frac{\lambda y-x}{t}\right)^{(3a+2b)/a}\Phi\left(\frac{\lambda y-x}{\lambda\,\mu\, z-x}\right),\quad a,b\in\mathbb{R},$$

where Φ is an arbitrary function of its argument, then the solution (81)–(84) is invariant under the subgroup generated by aD_1+bD_2, where D_1 and D_2 are defined in Eqs. (75) and (76).

However, this subgroup provides a reduced system with three independent variables that would be very difficult to solve.

Particularly interesting is the case when partially invariant solutions can be found that satisfy weak but not strong transversality. Indeed, imposing weak transversality basically means that a class of functions $u=f(x)$ is chosen in such a way that the characteristic system is algebraically compatible. This condition is of course not sufficient to guarantee the invariance of these functions under the action of the considered group G. Indeed, if we compute the rank of the matrix Q_a^α on this class of functions, in general it will be not equal to zero. Then, once weak transversality is satisfied, we can choose either to have group invariant solutions, using the method outlined in Sec. III, or to use the class of functions $u=f(x)$ to get partially invariant solutions.

In the next two examples, we will see how this approach can be used to obtain in a simple and straightforward way new classes of solutions of hydrodynamic systems.

Example 8: In Example 2 we studied the algebra (28) which is a subalgebra of the symmetry algebra of both the Euler and the Navier–Stokes equations. We showed that the requirement of weak transversality implies

$$u_1=k\frac{x}{t},\quad u_2=k\frac{y}{t},\tag{85}$$

$$u_3=u_3(x,y,z,t),\quad p=p(x,y,z,t).\tag{86}$$

These formulas define a class of functions which is partially invariant with defect $\delta=2$ with respect to the subalgebra (28). At this stage, we can choose either to have group invariant solutions or partially invariant ones. Indeed, in Example 2 we forced the class of functions (85) and (86) to be a solution of the characteristic system, and then substituting the obtained expressions (29) and (30) into the system (13) and (14) we constructed the group invariant solutions (31) and (32).

Another possibility is to substitute formulas (85) and (86) directly into the Euler equations (73) and (74) or the Navier–Stokes equations (13) and (14) without requiring further invariance properties. For the case of the Euler equations we get the constraints

$$t^2p_x+k\,(k-1)\,x=0,\tag{87}$$

$$t^2p_y+k\,(k-1)\,y=0,\tag{88}$$

$$u_{3z}+\frac{2k}{t}=0,\tag{89}$$

$$u_{3t}+u_3u_{3z}+\frac{k}{t}(x\,u_{3x}+y\,u_{3y})+p_z=0.\tag{90}$$

We solve this system and obtain the following partially invariant solution of the Euler equations:

$$u_1 = k\frac{x}{t}, \quad u_2 = k\frac{y}{t}, \tag{91}$$

$$u_3 = -\frac{2kz}{t} + x^2 F\left(tx^{-1/k}, \frac{y}{x}\right), \tag{92}$$

$$p = -\frac{k(k-1)(x^2+y^2)}{2t^2} - \frac{k(2k+1)z^2}{t^2} + f(t), \tag{93}$$

where $\xi = tx^{-1/k}$, $\eta = y/x$ and $f(t)$ and $F(\xi,\eta)$ are arbitrary functions of their arguments. As always, the question of the irreducibility of this solution arises. To answer it we must invoke the entire symmetry algebra $\mathfrak{g}$ of the Euler equations, namely the algebra (15) and (23) with the dilation D replaced by the two dilations (75) and (76). The result is that solution (91)–(93) is not invariant under any subgroup of the symmetry group, unless the function $F(\xi,\eta)$ satisfies the following linear PDE:

$$\left[\left(c_1\frac{k-1}{k} + c_2\right)\xi - c_3\frac{\xi\eta}{k} - \frac{c_4}{k}\xi^{k+1} + c_5\xi^k\right]F_\xi + [-c_3(\eta^2+1) - c_4\xi^k\eta + c_5\xi^k]F_\eta$$
$$+ (2c_1 + c_2 + 2c_3\eta)F - c_6(4k+1)\xi^{2k} = 0. \tag{94}$$

If this equation is satisfied, the solution is invariant under the subgroup generated by

$$X = c_1D_1 + c_2D_2 + c_3L_3 + c_4B_1 + c_5B_2 + c_3B_3, \tag{95}$$

where $c_1,\ldots,c_6$ are real constants, D_1 and D_2 are the dilations given by Eqs. (75) and (76), L_3 is the generator (23), and the functions appearing in the boosts (15)–(17) are now monomials in t, namely

$$\alpha = t^k, \quad \beta = t^k, \quad \gamma = t^{2k+1}. \tag{96}$$

For any other function $F(\xi,\eta)$ the solution is irreducible. The same procedure can be applied to the Navier–Stokes equations. Repeating the previous steps, we obtain the following solution:

$$u_1 = k\frac{x}{t}, \quad u_2 = k\frac{y}{t}, \tag{97}$$

$$u_3 = -\frac{2kz}{t} + \alpha(x,y,t), \tag{98}$$

$$p = -\frac{k(k-1)(x^2+y^2)}{2t^2} - \frac{k(2k+1)z^2}{t^2} + f(t), \tag{99}$$

where $\alpha(x,y,t)$ satisfies the following equation:

$$\alpha_t + \frac{k}{t}(x\alpha_x + y\alpha_y - 2\alpha) - \nu(\alpha_{xx} + \alpha_{yy}) = 0. \tag{100}$$

We thus obtain a large class of partially invariant solutions of the Navier–Stokes equations parametrized by the solutions of the *linear* partial differential equation (100).

Example 9: Partially invariant solutions with weak transversality can be also found for the case of the compressible fluid model (33) and (34). Let us again consider the subalgebra $\{L_3, F+G, K_1, K_2\}$ and the corresponding weak transversality condition (42). Substituting into Eqs. (33) and (34) we obtain a coupled system of quasilinear first order PDE's, namely,

$$a_x=0, \quad a_y=0,$$

$$u_{3t}+u_3\,u_{3z}+\frac{x}{t}u_{3x}+\frac{y}{t}u_{3y}+k\,a\,a_z=0, \tag{101}$$

$$a_t+u_3\,a_z+\frac{a}{k}\left(\frac{2}{t}+u_{3z}\right)=0.$$

In particular, if we assume $a_z=0$, we reobtain the solution (69). However, the system (101) allows much more general solutions.

V. CONCLUSIONS

A brief comparison of the results of this article and Ref. 13 is in order. In Sec. III we address the same question, as Anderson *et al.* in Ref. 13 do, namely how to obtain ''Group Invariant Solutions Without Transversality'' (their title). The main difference between us is one of outlook. They prove rigorous theorems under well-defined assumptions, in particular that the local group action is projectable. They make efficient use of the geometric theory of differential equations and further develop this theory by introducing the concept of the ''kinematic bundle'' and using kinematic and dynamic reduction diagrams. They use this concept to impose transversality at point of the original fiber bundle.

Our approach is a pragmatic one, aimed at producing new solutions. We use simple and well-known mathematical concepts (though we do not sacrifice mathematical rigour). From the results of Ref. 13 we know that transversality is not always a necessary requirement. We wish to obtain particular solutions when transversality (which we call ''strong transversality'') is not satisfied. From the geometric point of view we restrict to local coordinates (x,u). From the point of view of differential equations these coordinates are the original independent and dependent variables (x,u). The kinematic bundle concepts are then replaced by an equivalent requirement, namely weak transversality. This is formulated in a ''user friendly'' way as the requirement (12) that two matrices should have the same rank. The subtleties of Ref. 13 are then avoided in applications. In particular, we do not require that the group action be projectable (fiber preserving). As an example, consider a system of two first order PDE's with two dependent and two independent variables $\{u_1,u_2,x_1,x_2\}$,

$$x_1u_{1x_1}+x_2u_{1x_2}-u_1=x_2u_{1x_1}F_1(x_2,u_1), \tag{102}$$

$$u_{1x_2}u_{2x_1}-u_{1x_1}u_{2x_2}+u_{1x_1}=u_{2x_1}F_2(x_2,u_1), \tag{103}$$

where F_1 and F_2 are arbitrary. This system is invariant under a group generated by

$$\mathbf{v}_1=u_1\partial_{x_1}, \quad \mathbf{v}_2=x_2\partial_{x_1}+(u_2-x_2)\partial_{u_2}. \tag{104}$$

Clearly the action is neither transversal, nor projectable. Weak transversality is imposed by putting $u_2=x_2$. An invariant solution will have the form $u_2=x_2$, $u_1=\phi(x_2)$. Substituting into (102) and (103) we obtain the group invariant solution

$$u_2=x_2, \quad u_1=cx_2. \tag{105}$$

Notice that the system (102) and (103) is linear if F_1 and F_2 depend on x_2 alone. To see that ''weak transversality without projectability'' is not limited to first order equations, consider the system of two second order PDE's,

$$u_{1x_1}u_{2x_1x_1}-u_{2x_1}u_{1x_1x_1}=(u_{1x_1})^2u_{2x_1x_2}-u_{1x_1}u_{2x_1}u_{1x_1x_2}+u_{2x_1}u_{1x_2}u_{1x_1x_1}-u_{1x_1}u_{1x_2}u_{2x_1x_1}, \tag{106}$$

$$u_{1x_1x_1}=u_{1x_1}u_{1x_1x_2}-u_{1x_2}u_{1x_1x_1}. \tag{107}$$

This system is invariant under the group generated by the algebra (104). The invariant solution with weak transversality is

$$u_2=x_2, \quad u_1=\phi(x_2), \tag{108}$$

where $\phi(x_2)$ is an arbitrary function. The solutions (105) and (108) are not ''irreducible'' and (104) is only a subalgebra of the symmetry algebra of these equations. The point we are making is that the ''weak transversality'' method works for this algebra, even though the corresponding group action (for $\mathbf{v}_1$) is not projectable.

The main conclusion of this article is that one can do considerably more with the symmetry group G of a system of partial differential equations than apply the standard method for finding group invariant solutions.

Indeed, let us assume that the largest group G (of local Lie point transformations) leaving the system (1) invariant has been found and its subgroups classified. For each subgroup G_0, or its Lie algebra $\mathfrak{g}_0$ we should proceed as follows.

(1) Obtain invariant solutions. First check whether the transversality condition (10) is satisfied (in the strong sense). If it is, we apply Lie's classical method. This is always possible since transversality assures that the rank condition (3) is satisfied. If the (strong) transversality condition is not satisfied, we may still be able to obtain solutions invariant under G_0,[13] by imposing ''weak transversality'' on solutions, as described in Sec. II above. This is illustrated in Sec. III by Examples 1, 2, and 3.

(2) Obtain partially invariant solutions. These can be obtained by (at least) three complementary methods. If the transversality condition (10) is not satisfied and weak transversality cannot be imposed, then the characteristic system (4) is not consistent and the rank condition (3) for the invariants is not satisfied. We then choose a subset of $q'<q$ invariants such that we can express q' dependent variables in terms of invariants. The remaining $q-q'$ variables u_α are considered as functions of all the original variables $x_1,\ldots,x_p$. Examples 4 and 5 of Sec. IV are of this type, as are those of Refs. 16 and 17.

If the transversality condition is satisfied for G_0 we may still be able to obtain partially invariant solutions, in addition to the invariant ones. Instead of imposing that the matrix of characteristics (4) have rank zero [i.e., that all Eqs. (4) be satisfied] we require that on solutions we have $\operatorname{rank} Q=\delta$, with $\delta=1,2,\ldots$, as the case may be. This rank condition must be solved explicitly for u_α and the result substituted into Eq. (1) (see Examples 6 and 7). The third possibility is to impose weak transversality (if possible), but still to impose $\operatorname{rank} Q=\delta\geqslant 1$ (see Examples 8 and 9).

(3) Go beyond invariant and partially invariant solutions, either by the method of group foliation,[3,35,36] or by other methods not using the symmetry group G.[27–34]

We emphasize that the weak transversality method is algorithmic and can be implemented as a computer package. It provides both invariant and partially invariant solutions and is widely applicable. Missing at this stage are clear criteria that tell us which approach will be fruitful. Furthermore, the same solution may be obtained by different methods and it is not clear which of these methods will lead to the least amount of calculations. For instance, solutions partially invariant under some subgroup $G_1\subset G$ have been called ''reducible,''[16–22] if they are actually invariant under some other subgroup $G_2\subset G$. However, it may be more difficult to use G_2, than G_1, specially if the dimension of G_2 is small with respect to the number of independent variables.

Eq. (3.7) of the paper defines the function $P(m)$ so that the formulas for $\{s,\overline{h}(s)\}$ yield $e(m)$ exactly, via Eq. (3.5). However, with the scaling parameters $\{\beta,\gamma,\lambda\}$ included, the "running" P which guarantees that Eq. (3.11) of the paper is exact is *not* simply $P(m)$, as claimed, but rather

$$P=P(\mu), \quad \text{where} \quad \mu=m\left(\frac{\beta}{\gamma\lambda}\right)^{1/3}.$$

With this correction, the expression for P is now consistent with the energy scaling formula given in Eq. (3.12) of the paper. In the application to the N-body problem, the expression $P(m)$ in Eq. (1.4) of Theorem 1 must be replaced by

$$P(\mu), \quad \text{where} \quad \mu=m(N/(\gamma(N-1)^2))^{1/3}.$$

The result is then consistent with the explicit N-body lower bound formula given in Eq. (5.7) of the paper. Figures 2 and 3 in the paper should be replaced by the revised Fig. 2 and 3 shown here. The upper and new lower bounds in Fig. 3 converge to the exact N-body energies in the Schrödinger limit $m\to\infty$.

We address the classical and quantum marginal problems, namely the question of simultaneous realizability through a common probability density in phase space of a given set of compatible probability distributions. We consider only distributions authorized by quantum mechanics, i.e., those corresponding to complete commuting sets of observables. For four-dimensional phase space with position variables $\vec{q}$ and momentum variables $\vec{p}$, we establish the two following points: (i) given *four* compatible probabilities for (q_1,q_2), (q_1,p_2), (p_1,q_2), and (p_1,p_2), there does not always exist a positive phase space density $\rho(\vec{q},\vec{p})$ reproducing them as marginals; this settles a long standing conjecture; it is achieved by first deriving Bell-type inequalities in phase space which have their own theoretical and experimental interest. (ii) Given instead at most *three* compatible probabilities, there always exist an associated phase space density $\rho(\vec{q},\vec{p})$; the solution is not unique and its general form is worked out. These two points constitute our ''three marginal theorem.'' © *2003 American Institute of Physics.* [DOI: 10.1063/1.1578532]

I. INTRODUCTION

In classical mechanics, position and momentum can be simultaneously specified. Hence phase space density has a well-defined meaning in classical statistical mechanics. In quantum theory the probability density for observing eigenvalues of a complete commuting set (CCS) of observables is specific to the experimental context for measuring that CCS. Joint probabilities for different CCS which contain mutually noncommuting operators are not defined. For example, for a two-dimensional configuration space, with $\vec{q},\vec{p}$ denoting position and momentum, probability densities of anyone of the four CCS (q_1,q_2), (q_1,p_2), (p_1,q_2) or (p_1,p_2) are defined, but not their joint probabilities. The question one may raise is can one define such joint probabilities, e.g., a phase space probability density $\rho(\vec{q},\vec{p})$ such that all its marginals (in agreement with common terminology, by ''marginal'' of a distribution over several variables, we denote integrals of the distribution over a subset of its variables) coincide with the quantum mechanical probabilities for the different individual CCS? This general question was first raised by Martin and Roy.[1]

The Martin–Roy contextuality theorem demonstrates the impossibility of realizing quantum probability densities of all possible choices of the CCS of observables as marginals of one positive definite phase space density. For example, consider a two-dimensional configuration space. Let

coordinates $q_{1\alpha}$, $q_{2\alpha}$ be obtained from q_1, q_2 by a rotation of arbitrary angle α, and momenta $p_{1\alpha}$, $p_{2\alpha}$ be related similarly to p_1, p_2

$$\begin{pmatrix} q_{1\alpha} \\ q_{2\alpha} \end{pmatrix} = V \begin{pmatrix} q_1 \\ q_2 \end{pmatrix}, \quad \begin{pmatrix} p_{1\alpha} \\ p_{2\alpha} \end{pmatrix} = V \begin{pmatrix} p_1 \\ p_2 \end{pmatrix}, \tag{1.1}$$

where

$$V = \begin{pmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{pmatrix}. \tag{1.2}$$

Does there exist for every quantum state (with density operator $\hat{\rho}$) a positive definite phase space density $\rho(\vec{q},\vec{p})$ such that its marginals agree with the corresponding quantum probabilities, i.e.,

$$\int \mathrm{d}p_{1\alpha}\,\mathrm{d}q_{2\alpha}\ \ \rho(\vec{q},\vec{p}) = \langle q_{1\alpha}, p_{2\alpha} |\, \hat{\rho}\, | q_{1\alpha}, p_{2\alpha} \rangle \tag{1.3}$$

for all α ranging from 0 to 2π? They answered this question in the negative by finding a state $\hat{\rho}$ for which Eq. (1.3) for all α are inconsistent with positivity of ρ. Since different α correspond to different experimental contexts, the Martin–Roy theorem is a new Gleason–Kochen–Specker-type contextuality theorem.[2] The positivity of the phase space density $\rho(\vec{q},\vec{p})$ is absolutely crucial for this theorem; otherwise the Wigner distribution function[3] would be a solution of (1.3).

Equations (1.3) constitute conditions on an infinite set of marginals of $\rho(\vec{q},\vec{p})$ (corresponding to the continuously infinite choices for α) to agree with corresponding quantum probability densities. Their inconsistency still leaves open the question of consistency of a finite number of such marginal conditions.

Indeed, the consistency of two marginal conditions where the marginals involve only nonintersecting sets of variables has been known for some time. Cohen and Zaparovanny[4] constructed the most general positive $\rho(\vec{q},\vec{p})$ obeying

$$\int \mathrm{d}\vec{p}\ \rho(\vec{q},\vec{p}) = \langle \vec{q} | \hat{\rho} | \vec{q} \rangle, \quad \int \mathrm{d}\vec{q}\ \rho(\vec{q},\vec{p}) = \langle \vec{p} | \hat{\rho} | \vec{p} \rangle.$$

Their solutions generalize the obvious simple uncorrelated solution for pure states ψ,

$$\rho(\vec{q},\vec{p}) = |\psi(\vec{q})|^2\ |\tilde{\psi}(\vec{p})|^2,$$

where tilde denotes Fourier transform. Based on generalized phase space densities exhibiting position momentum correlations, Roy and Singh[5] constructed a causal quantum mechanics reproducing quantum position and momentum probability densities, thus improving on De Broglie–Bohm mechanics[6] which only reproduced the quantum position probability densities. Later, going much further than the nonintersecting marginals of Cohen *et al.*,[4] Roy and Singh[7] constructed a causal quantum mechanics based on a positive $\rho(\vec{q},\vec{p})$ whose marginals reproduce the quantum probability densities of a chain of $N+1$ different CCS, e.g.,

$$(Q_1, Q_2, \ldots, Q_N),\ (P_1, Q_2, \ldots, Q_N),\ (P_1, P_2, Q_3, \ldots, Q_N), \ldots (P_1, P_2, \ldots, P_N).$$

Here N is the dimension of the configuration space, and each CCS in the chain is obtained from the preceding one by replacing one of the position operators Q_i by the conjugate momentum operator P_i.

Roy and Singh proposed the following definition: a **maximally realistic causal quantum mechanics** is a causal mechanics which simultaneously reproduces the quantum probability densities of the maximum number of different (mutually noncommuting) CCS of observables as marginals of the same positive definite phase space density. They also conjectured that for N-dimensional configuration space this maximum number is $N+1$.

A proof of this long standing conjecture is important for quantum mechanics where it quantifies the extent of simultaneous realizability of noncommuting CCS.

In this paper, we restrict ourselves to the case of $N=2$ degrees of freedom. The general case ($N>2$) will be dealt with in a forthcoming paper. In Sec. II below, we first state the classical and quantum marginal problems and second, show that, given four classical compatible two-variable probability distributions, there does not always exist a positive phase space distribution reproducing them as marginals. In Sec. III, we develop a new tool, "the phase space Bell inequalities," which are the phase space analogues of the standard Bell inequalities[8] for a system of two spin-half particles. We use them in Sec. IV to prove the conjecture for four-dimensional phase space ($N=2$), namely the impossibility of simultaneous realization of quantum probabilities of more than three CCS as marginals. In Sec. V, we explicitly construct the most general phase space distribution which reproduces probabilities of three CCS as marginals. These results, the three marginal theorem, are relevant for the construction of maximally realistic quantum mechanics.

As our results are essentially new theorems for multidimensional Fourier transforms, they are also expected to be useful for classical signal and image processing.[9] The theorems of the present paper and their generalizations to arbitrary N (Ref. 10) considerably advance previous results in the field, which have only dealt with nonintersecting sets of marginals (e.g., time and frequency). A summary of the results of this paper without detailed proofs is being reported separately.[11]

II. FOUR MARGINAL PROBLEM

Let us consider a physical system with two-dimensional configuration space. Let (q_1,p_1) and (q_2,p_2) be a set of canonical variables in the corresponding phase space. We look for a (normalized) probability distribution $\rho(q_1,q_2,p_1,p_2)$ such that

$$\rho(q_1,q_2,p_1,p_2)\geqslant 0\,, \tag{2.1}$$

$$\int \mathrm{d}p_1\,\mathrm{d}p_2\,\rho(q_1,q_2,p_1,p_2)=R(q_1,q_2)\,, \tag{2.2}$$

$$\int \mathrm{d}p_1\,\mathrm{d}q_2\,\rho(q_1,q_2,p_1,p_2)=S(q_1,p_2)\,, \tag{2.3}$$

$$\int \mathrm{d}q_1\,\mathrm{d}p_2\,\rho(q_1,q_2,p_1,p_2)=T(p_1,q_2)\,, \tag{2.4}$$

$$\int \mathrm{d}q_1\,\mathrm{d}q_2\,\rho(q_1,q_2,p_1,p_2)=U(p_1,p_2)\,, \tag{2.5}$$

where the four marginals $R(q_1,q_2)$, $S(q_1,p_2)$, $T(p_1,q_2)$, and $U(p_1,p_2)$, the respective joint probabilities, are given. For consistency we must have

$$R,S,T,U\geqslant 0, \tag{2.6}$$

and

$$\begin{aligned}
\int \mathrm{d}q_2\, R(q_1,q_2) &= \int \mathrm{d}p_2\, S(q_1,p_2)\,,\\
\int \mathrm{d}q_1\, R(q_1,q_2) &= \int \mathrm{d}p_1\, T(p_1,q_2)\,,\\
\int \mathrm{d}q_1\, S(q_1,p_2) &= \int \mathrm{d}p_1\, U(p_1,p_2)\,,\\
\int \mathrm{d}q_2\, T(p_1,q_2) &= \int \mathrm{d}p_2\, U(p_1,p_2)\,.
\end{aligned} \tag{2.7}$$

We shall refer to the following problem as the Classical four marginal problem: *Given four distributions R, S, T, and U, satisfying the consistency conditions, does there always exist a positive $\rho(q_1,q_2,p_1,p_2)$ with these distributions as marginals*?

When the system is quantum mechanical and is described by a state vector $|\Psi\rangle$, each of the four marginals involves a pair of compatible observables and we have

$$\begin{aligned}
R(q_1,q_2) &= |\langle q_1,q_2|\hat{\rho}|q_1,q_2\rangle|^2\,,\\
S(q_1,p_2) &= |\langle q_1,p_2|\hat{\rho}|q_1,p_2\rangle|^2\,,\\
T(p_1,q_2) &= |\langle p_1,q_2|\hat{\rho}|p_1,q_2\rangle|^2\,,\\
U(p_1,p_2) &= |\langle p_1,p_2|\hat{\rho}|p_1,p_2\rangle|^2\,.
\end{aligned} \tag{2.8}$$

In this case, the above consistency conditions are automatically satisfied. We then refer to the problem as the *quantum four marginal problem*. A positive answer to it for all states $\hat{\rho}$ would mean that a realistic interpretation of the quantum results is possible (to the extent that only measurements connected to the four marginals are involved).

We shall see that the answer to both problems is negative.

Let us first show that the classical four marginal problem does not always admit a solution. To this end, consider the following set of marginals:

$$R(q_1,q_2) = \tfrac{1}{2}[\,\delta(q_1-a_1)\,\delta(q_2-a_2)+\delta(q_1-a_1')\,\delta(q_2-a_2')\,]\,, \tag{2.9}$$

$$S(q_1,p_2) = \tfrac{1}{2}[\,\delta(q_1-a_1)\,\delta(p_2-b_2)+\delta(q_1-a_1')\,\delta(p_2-b_2')\,]\,, \tag{2.10}$$

$$T(p_1,q_2) = \tfrac{1}{2}[\,\delta(p_1-b_1)\,\delta(q_2-a_2)+\delta(p_1-b_1')\,\delta(q_2-a_2')\,]\,, \tag{2.11}$$

$$U(p_1,p_2) = \tfrac{1}{2}[\,\delta(p_1-b_1)\,\delta(p_2-b_2')+\delta(p_1-b_1')\,\delta(p_2-b_2)\,]\,, \tag{2.12}$$

which obviously satisfy the consistency conditions (2.6) and (2.7). They possess two essential features. First, their nonfactorized form. Second, in view of the expressions of R, S, and T, the positions of the factors $\delta(p_2-b_2)$ and $\delta(p_2-b_2')$ in the expression of U are not the "natural ones."

Equation (2.9) means that the support of the distribution R in the plane (q_1,q_2) consists in the two points (a_1,a_2) and (a_1',a_2'). As a consequence, any positive ρ satisfying (2.2) should have support from the projection of which on the plane (q_1,q_2) would also consist in those two points. That is

$$\rho = \delta(q_1-a_1)\,\delta(q_2-a_2)\,\alpha(p_1,p_2)+\delta(q_1-a_1')\,\delta(q_2-a_2')\,\alpha'(p_1,p_2)\,, \tag{2.13}$$

where α and α' are some positive distributions. Similarly, from Eqs. (2.3) to (2.5)

$$\rho=\delta(q_1-a_1)\,\delta(p_2-b_2)\beta(p_1,q_2)+\delta(q_1-a_1')\,\delta(p_2-b_2')\beta'(p_1,q_2) \tag{2.14}$$

$$=\delta(p_1-b_1)\,\delta(q_2-a_2)\,\gamma(q_1,p_2)+\delta(p_1-b_1')\,\delta(q_2-a_2')\,\gamma'(q_1,p_2) \tag{2.15}$$

$$=\delta(p_1-b_1)\,\delta(p_2-b_2')\,\eta(q_1,q_2)+\delta(p_1-b_1')\,\delta(p_2-b_2)\,\eta'(q_1,q_2)\,. \tag{2.16}$$

According to Eqs. (2.13)–(2.15)

$$\rho=v\;\delta(q_1-a_1)\,\delta(q_2-a_2)\,\delta(p_1-b_1)\,\delta(p_2-b_2)+v'\,\delta(q_1-a_1')\,\delta(q_2-a_2')\,\delta(p_1-b_1')\,\delta(p_2-b_2')\,, \tag{2.17}$$

with $v\geqslant 0$, $v'\geqslant 0$, $(v+v'=1)$. Clearly, Eqs. (2.16) and (2.17) are incompatible, which establishes the nonexistence of ρ, and settles the classical four marginal problem.

This however does not settle the quantum problem. Actually, the above example obviously cannot be strictly realized through a wave function in accordance with Eqs. (2.8). More than that, this example is so "twisted" that, even after smoothing out the δ measures in Eqs. (2.9)–(2.12), approaching it close enough through a wave function appears as very difficult (if not impossible). Instead, we develop a new mathematical tool.

III. PHASE SPACE BELL INEQUALITIES

Consider any choice of functions $r(q_1,q_2)$, $s(q_1,p_2)$, $t(p_1,q_2)$, and $u(p_1,p_2)$, obeying

$$A\leqslant r(q_1,q_2)+s(q_1,p_2)+t(p_1,q_2)+u(p_1,p_2)\leqslant B\quad(\forall q_1,q_2,p_1,p_2). \tag{3.1}$$

Multiply by $\rho(\vec{q},\vec{p})$, integrate over phase space and use positivity and normalization of $\rho(\vec{q},\vec{p})$. We deduce that the (classical as well as quantum) four marginal problem cannot have a solution unless

$$A\leqslant \int \mathrm{d}q_1\,\mathrm{d}q_2\,r(q_1,q_2)R(q_1,q_2)+\int \mathrm{d}q_1\,\mathrm{d}p_2\,s(q_1,p_2)S(q_1,p_2)$$
$$+\int \mathrm{d}p_1\,\mathrm{d}q_2\,t(p_1,q_2)T(p_1,q_2)+\int \mathrm{d}p_1\,\mathrm{d}p_2\,u(p_1,p_2)U(p_1,p_2)\leqslant B\,. \tag{3.2}$$

Here R, S, T, and U are defined by Eqs. (2.8) in the quantum case. It turns out that a particularly interesting choice is

$$\begin{aligned} r(q_1,q_2)&=\operatorname{sgn}F_1(q_1)\operatorname{sgn}F_2(q_2)\,,\\ s(q_1,p_2)&=\operatorname{sgn}F_1(q_1)\operatorname{sgn}G_2(p_2)\,,\\ t(p_1,q_2)&=\operatorname{sgn}G_1(p_1)\operatorname{sgn}F_2(q_2)\,,\\ u(p_1,p_2)&=-\operatorname{sgn}G_1(p_1)\operatorname{sgn}G_2(p_2)\,, \end{aligned} \tag{3.3}$$

with $A=-2$, $B=+2$ and with F_1, F_2, G_1, and G_2 arbitrary nonvanishing functions. (Note that, with this choice, the sum $r+s+t+u$ assumes only its two extremal values $A=-2$ and $B=+2$, which makes it in a sense optimal.) Then the inequalities (3.2) become a phase space analogue of the Bell inequalities for spin variables.

The necessary conditions (3.2) provide us with an alternative proof that the classical problem does not always admit a solution. Indeed, it is readily seen that they are violated for the marginals (2.9)–(2.12) and functions F's and G's such that

$$F_1(a_1),F_2(a_2),G_1(b_1),G_2(b_2)>0\,,$$

$$F_1(a_1'),F_2(a_2'),G_1(b_1'),G_2(b_2')<0\,.$$

We shall see in the next section that the necessary conditions (3.2) can be violated also in the quantum case. There, the analogy between our correlation inequalities (3.2) [with the choice (3.3)] and Bell inequalities will become more apparent, especially as regards to their implications.

IV. SOLVING THE FOUR MARGINAL QUANTUM PROBLEM

This section is divided into four parts. In the first one, we prove the existence of wave functions which violate the correlation inequalities (3.2). Strictly speaking, this already settles the problem. However, the explicit construction of such wave functions, which we present in Secs. IV B and IV C, is worthwhile in that it exhibits the physical implications of our inequalities. In Sec. IV D, we elaborate on the formal analogy with Bell inequalities.

A. Nonconstructive proof

One first notices that $\chi_1(q_1)\equiv\frac{1}{2}[1+\operatorname{sgn}F_1(q_1)]$ is the characteristic function of some set $S_1\subset\mathbb{R}$, and similarly for F_2, G_1, and G_2, so that Eqs. (3.3) read

$$\begin{aligned} r(q_1,q_2)&=(2\chi_1-1)(2\chi_2-1)\,,\\ s(q_1,p_2)&=(2\chi_1-1)(2\chi_2'-1)\,,\\ t(p_1,q_2)&=(2\chi_1'-1)(2\chi_2-1)\,,\\ u(p_1,p_2)&=-(2\chi_1'-1)(2\chi_2'-1)\,, \end{aligned} \tag{4.1}$$

where χ_i stands for $\chi_i(q_i)$ and χ_i' for $\chi_i'(p_i)$, $(i=1,2)$. Inequalities (3.1) then become

$$0\leqslant\mathcal{P}\leqslant 1\,, \tag{4.2}$$

and in fact $\mathcal{P}(1-\mathcal{P})=0$, where $\mathcal{P}(q_1,q_2,p_1,p_2)$ is given by

$$\mathcal{P}=\chi_1+\chi_2+\chi_1'\chi_2'-\chi_1\chi_2-\chi_1\chi_2'-\chi_1'\chi_2\,. \tag{4.3}$$

Let us define a corresponding quantum operator $\hat{\mathcal{P}}$ by

$$\hat{\mathcal{P}}=\hat\chi_1+\hat\chi_2+\hat\chi_1'\hat\chi_2'-\hat\chi_1\hat\chi_2-\hat\chi_1\hat\chi_2'-\hat\chi_1'\hat\chi_2\,, \tag{4.4}$$

where

$$\begin{aligned} \hat\chi_1&=\int_{S_1}\mathrm{d}q_1\,|q_1\rangle\langle q_1|\otimes\mathbf{1}_2\,,\\ \hat\chi_2&=\mathbf{1}_1\otimes\int_{S_2}\mathrm{d}q_2\,|q_2\rangle\langle q_2|\,,\\ \hat\chi_1'&=\int_{S_1'}\mathrm{d}p_1\,|p_1\rangle\langle p_1|\otimes\mathbf{1}_2\,,\\ \hat\chi_2'&=\mathbf{1}_1\otimes\int_{S_2'}\mathrm{d}p_2\,|p_2\rangle\langle p_2|\,. \end{aligned} \tag{4.5}$$

The $\hat{\chi}$'s are orthogonal projectors ($\hat{\chi}\dagger=\hat{\chi}$, $\hat{\chi}^2=\hat{\chi}$) acting on $\mathcal{H}\equiv L^2(\mathbb{R},\mathrm{d}q_1)\otimes L^2(\mathbb{R},\mathrm{d}q_2)$. [In Eqs. (4.5), S_1, S_2, S_1', S_2' are the supports of $\hat{\chi}_1$, $\hat{\chi}_2$, $\hat{\chi}_1'$, $\hat{\chi}_2'$, respectively. Also, $\int_{S_1} dq_1\,|q_1\rangle\langle q_1|$ is, in standard Dirac notation, the orthogonal projection $\psi(q_1)\to\chi_1(q_1)\psi(q_1)$, whereas $\int_{S_1'}\mathrm{d}p_1\,|p_1\rangle\langle p_1|$ is the orthogonal projection $\tilde{\psi}(p_1)\to\chi_1'(p_1)\tilde{\psi}(p_1)$, $\tilde{\psi}(p_1)$ being the Fourier transform of $\psi(q_1)$, and so on.] The product of two of them involving different indices commutes, so that $\hat{\mathcal{P}}$ is a (bounded) self-adjoint operator.

The inequalities (3.2) to be tested in the quantum context then become, for pure states $\hat{\rho}=|\Psi\rangle\langle\Psi|$,

$$0\leqslant\langle\Psi|\hat{\mathcal{P}}|\Psi\rangle\leqslant 1 \quad \forall\ |\Psi\rangle\in\mathcal{H} \ \text{ with } \ \langle\Psi|\Psi\rangle=1\,, \tag{4.6}$$

or, equivalently,

$$\hat{\mathcal{P}}\geqslant 0 \quad \text{and} \quad \mathbf{1}-\hat{\mathcal{P}}\geqslant 0 \quad \text{in the operator sense.} \tag{4.7}$$

Because $\hat{\chi}_j$ fails to commute with $\hat{\chi}_j'$ ($j=1,2$), $\hat{\mathcal{P}}$ is *not* an orthogonal projector (see below), in contrast to the classical equality $\mathcal{P}^2=\mathcal{P}$. Exploiting this fact leads to the following.

Proposition 1: The operators $\hat{\mathcal{P}}$ and $(\mathbf{1}-\hat{\mathcal{P}})$ cannot be both positive. As a consequence, there is at least one $|\Psi\rangle\neq 0$ such that the inequalities $\langle\Psi|\hat{\mathcal{P}}|\Psi\rangle\geqslant 0$ and $\langle\Psi|(\mathbf{1}-\hat{\mathcal{P}})|\Psi\rangle\geqslant 0$ cannot be simultaneously true. This just means that one of the two inequalities (4.6) is violated for that $|\Psi\rangle$, which settles the question.

Proof of proposition 1: Assume that $\hat{\mathcal{P}}$ and $(\mathbf{1}-\hat{\mathcal{P}})$ are both positive. This would imply

$$\hat{\mathcal{P}}(\mathbf{1}-\hat{\mathcal{P}})\geqslant 0 \tag{4.8}$$

(remember that the product of two positive *commuting* operators is positive).

Now, a straightforward calculation of $\hat{\mathcal{P}}^2$ from Eq. (4.4) yields

$$\hat{\mathcal{P}}^2=\hat{\mathcal{P}}-[\hat{\chi}_1,\hat{\chi}_1'][\hat{\chi}_2,\hat{\chi}_2']\,, \tag{4.9}$$

and Eq. (4.8) would mean that $[\hat{\chi}_1,\hat{\chi}_1'][\hat{\chi}_2,\hat{\chi}_2']$ is a positive operator. That this is wrong is not surprising. Let us show it. Take a factorized $|\Psi\rangle$, namely $|\Psi\rangle=|\Phi_1\rangle\otimes|\Phi_2\rangle$, so that

$$\langle\Psi|\hat{\mathcal{P}}(\mathbf{1}-\hat{\mathcal{P}})|\Psi\rangle=-\langle\Phi_1|i[\hat{\chi}_1,\hat{\chi}_1']|\Phi_1\rangle\langle\Phi_2|i[\hat{\chi}_2,\hat{\chi}_2']|\Phi_2\rangle\,.$$

It is enough to show that, for a given choice of the characteristic functions χ and χ', the real number

$$R[\Phi]\equiv\langle\Phi|i[\hat{\chi},\hat{\chi}']|\Phi\rangle \tag{4.10}$$

can assume both signs when $|\Phi\rangle$ is varied.

Let us define

$$|\Phi^+\rangle=\hat{\chi}\,|\Phi\rangle\,,\quad |\Phi^-\rangle=(\mathbf{1}-\hat{\chi})|\Phi\rangle\,.$$

Using the identity

$$[\hat{\chi},\hat{\chi}']=\hat{\chi}\hat{\chi}'(\mathbf{1}-\hat{\chi})-(\mathbf{1}-\hat{\chi})\hat{\chi}'\hat{\chi}$$

gives $R[\Phi]$ the form

$$R[\Phi]=i\langle\Phi^+|\hat{\chi}'|\Phi^-\rangle-i\langle\Phi^-|\hat{\chi}'|\Phi^+\rangle\,.$$

Obviously, for $|\tilde{\Phi}\rangle=|\Phi^+\rangle-|\Phi^-\rangle$, one has $R[\tilde{\Phi}]=-R[\Phi]$.

This concludes the proof.

Remarks: (1) When the wave function $|\Psi\rangle$ factorizes, i.e., $\Psi(q_1,q_2)=\Phi_1(q_1)\Phi_2(q_2)$, a corresponding probability distribution ρ always exists, namely

$$\rho(q_1,q_2,p_1,p_2)=|\Phi_1(q_1)|^2\,|\Phi_2(q_2)|^2\,|\tilde{\Phi}_1(p_1)|^2\,|\tilde{\Phi}_2(p_2)|^2\,, \tag{4.11}$$

where the $\tilde{\Phi}_i$'s are the Fourier transforms

$$\tilde{\Phi}_i(p_i)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}\mathrm{d}q_i\,e^{-ip_iq_i}\,\Phi_i(q_i)\,,\quad (i=1,2). \tag{4.12}$$

Of course, this implies that Eqs. (4.6) are automatically satisfied for such factorized $|\Psi\rangle$'s [which can also be checked from Eq. (4.4)].

(2) The fact (used in the proof) that $\langle\Psi|\hat{\mathcal{P}}(\mathbf{1}-\hat{\mathcal{P}})|\Psi\rangle<0$ for some factorized $|\Psi\rangle$'s is *not* inconsistent with the inequalities $0\leqslant\langle\Psi|\hat{\mathcal{P}}|\Psi\rangle\leqslant 1$ which are satisfied for those $|\Psi\rangle$'s.

B. Construction

We want to find wave functions $|\Psi\rangle$ violating the inequalities (4.6). According to the first of the above remarks, one has to depart from the class of factorized $|\Psi\rangle$'s. The simplest way to do it is to take just a sum of two such products.

Choose first

$$S_1=S_2\equiv S\quad\text{and}\quad S_1'=S_2'\equiv S'\,,$$

so that

$$\hat{\mathcal{P}}=\hat{\chi}\otimes\mathbf{1}_2+\mathbf{1}_1\otimes\hat{\chi}+\hat{\chi}'\otimes\hat{\chi}'-\hat{\chi}\otimes\hat{\chi}-\hat{\chi}\otimes\hat{\chi}'-\hat{\chi}'\otimes\hat{\chi}\,. \tag{4.13}$$

Take next

$$\begin{gathered}|\Psi\rangle=\frac{1}{\sqrt{1+|\lambda|^2}}(|\phi\rangle+\lambda|\varphi\rangle)\quad(\lambda\in\mathbb{C})\,,\\ \text{with}\quad\begin{cases}|\phi\rangle=|\phi_1\rangle\otimes|\phi_2\rangle\,,\quad|\varphi\rangle=|\varphi_1\rangle\otimes|\varphi_2\rangle\,,\\ \langle\phi_1|\phi_1\rangle=\langle\phi_2|\phi_2\rangle=\langle\varphi_1|\varphi_1\rangle=\langle\varphi_2|\varphi_2\rangle=1,\ \langle\phi_1|\varphi_1\rangle=0\,,\end{cases}\end{gathered} \tag{4.14}$$

so that $|\Psi\rangle$ is properly normalized.

For the moment, choose also

$$\phi_1=\phi_2\equiv f\quad\text{and}\quad\varphi_1=\varphi_2\equiv g\,, \tag{4.15}$$

with

$$\langle f|f\rangle=\langle g|g\rangle=1\,,\quad\langle f|g\rangle=0\,. \tag{4.16}$$

Then

$$\langle\Psi|\hat{\mathcal{P}}|\Psi\rangle=\frac{1}{1+|\lambda|^2}[\langle\phi|\hat{\mathcal{P}}|\phi\rangle+(\lambda\langle\phi|\hat{\mathcal{P}}|\varphi\rangle+\text{c.c.})+|\lambda|^2\langle\varphi|\hat{\mathcal{P}}|\varphi\rangle]\,, \tag{4.17}$$

with

$$\langle\phi|\hat{\mathcal{P}}|\phi\rangle = 2\langle f|\hat{\chi}|f\rangle + \langle f|\hat{\chi}'|f\rangle^2 - \langle f|\hat{\chi}|f\rangle^2 - 2\langle f|\hat{\chi}|f\rangle\langle f|\hat{\chi}'|f\rangle\,,$$

$$\langle\varphi|\hat{\mathcal{P}}|\varphi\rangle = 2\langle g|\hat{\chi}|g\rangle + \langle g|\hat{\chi}'|g\rangle^2 - \langle g|\hat{\chi}|g\rangle^2 - 2\langle g|\hat{\chi}|g\rangle\langle g|\hat{\chi}'|g\rangle\,, \tag{4.18}$$

$$\langle\phi|\hat{\mathcal{P}}|\varphi\rangle = \langle f|\hat{\chi}'|g\rangle^2 - \langle f|\hat{\chi}|g\rangle^2 - 2\langle f|\hat{\chi}|g\rangle\langle f|\hat{\chi}'|g\rangle\,.$$

We already know that $0\leqslant\langle\phi|\hat{\mathcal{P}}|\phi\rangle\leqslant 1$ and $0\leqslant\langle\varphi|\hat{\mathcal{P}}|\varphi\rangle\leqslant 1$. Clearly, in view of (4.17), our goal will be reached (namely $\langle\Psi|\hat{\mathcal{P}}|\Psi\rangle<0$ or $\langle\Psi|\hat{\mathcal{P}}|\Psi\rangle>1$) if one can find f and g such that

$$|\langle\phi|\hat{\mathcal{P}}|\varphi\rangle|^2 > \langle\phi|\hat{\mathcal{P}}|\phi\rangle\langle\varphi|\hat{\mathcal{P}}|\varphi\rangle\,. \tag{4.19}$$

We claim that this can be achieved with $S=S'=(0,\infty)$, $f(q)\equiv\langle q|f\rangle$ an even, normalized function in $L^2(-\infty,\infty)$, and

$$g(q)\equiv\langle q|g\rangle = \mathrm{sgn}(q)\, f(q)\,. \tag{4.20}$$

With this choice, Eqs. (4.16) are automatically satisfied and

$$\langle f|\hat{\chi}|f\rangle = \langle g|\hat{\chi}|g\rangle = \langle f|\hat{\chi}|g\rangle = \tfrac{1}{2}\,. \tag{4.21}$$

Also, since the Fourier transforms $\tilde{f}(p)$ and $\tilde{g}(p)$ are, respectively, even and odd functions

$$\langle f|\hat{\chi}'|f\rangle = \langle g|\hat{\chi}'|g\rangle = \tfrac{1}{2}\,. \tag{4.22}$$

As for the nontrivial interference term $\langle f|\hat{\chi}'|g\rangle$, it is given by (see Appendix A)

$$\langle f|\hat{\chi}'|g\rangle = -\frac{i}{\pi}\int_0^\infty \mathrm{d}q \int_0^\infty \mathrm{d}q'\, f^*(q) f(q')\left(\frac{1}{q+q'} - \frac{P}{q-q'}\right). \tag{4.23}$$

At this stage, it is advantageous to take f as a *real* function, so that by symmetry

$$\langle f|\hat{\chi}'|g\rangle = -\frac{i}{\pi}\int_0^\infty \mathrm{d}q \int_0^\infty \mathrm{d}q' \frac{f(q)f(q')}{q+q'}\,.$$

Let us set

$$h(q) = \sqrt{2}\, f(q)\,, \tag{4.24}$$

$$K(q,q') = \frac{1}{\pi}\frac{1}{q+q'}\,. \tag{4.25}$$

Then

$$\langle f|\hat{\chi}'|g\rangle = -\frac{i}{2}\gamma\,, \quad (\gamma\in\mathbb{R}) \tag{4.26}$$

with

$$\gamma = \int_0^\infty \mathrm{d}q \int_0^\infty \mathrm{d}q'\, h(q)\, K(q,q')\, h(q')\,, \tag{4.27}$$

and

$$\|h\|_{L^2(0,\infty)} = 1\,. \tag{4.28}$$

The insertion of Eqs. (4.21), (4.22), and (4.26) in (4.18) gives

$$\langle \phi|\hat{\mathcal{P}}|\phi\rangle = \langle \varphi|\hat{\mathcal{P}}|\varphi\rangle = \tfrac{1}{2},$$

$$\langle \phi|\hat{\mathcal{P}}|\varphi\rangle = -\frac{1}{4}(1+\gamma^2) + \frac{i}{2}\gamma,$$

so that Eq. (4.19) reads

$$(\gamma^2+1)^2 + 4\gamma^2 > 4,$$

which is satisfied provided that

$$|\gamma| > \sqrt{2\sqrt{3}-3} \cong 0.6813. \tag{4.29}$$

Moreover, with $\lambda = \rho e^{i\theta}$, Eq. (4.17) becomes

$$\langle \Psi|\hat{\mathcal{P}}|\Psi\rangle = \frac{1}{2} - \frac{\rho}{2(1+\rho^2)}[(1+\gamma^2)\cos\theta + 2\gamma\sin\theta]. \tag{4.30}$$

We already know that $|\gamma|$ cannot exceed 1, because $|\langle f|\hat{\chi}'|g\rangle|^2 \leqslant \langle f|\hat{\chi}'|f\rangle\langle g|\hat{\chi}'|g\rangle = \frac{1}{4}$. Are there however some h's [subjected to (4.28)] such that γ [given by Eq. (4.27)] fulfils (4.29)? If this occurs we have reached our goal and it only remains to maximize $|\gamma|$ in order to obtain the extremal values of $\langle \Psi|\hat{\mathcal{P}}|\Psi\rangle$ (within the present scheme) through Eq. (4.30). In other words, one has to solve the problem

$$\gamma_0 \equiv \sup_{\substack{\|h\|_{L^2(0,\infty)}=1 \\ h=h^*}} |\langle h|K|h\rangle| = \ ?$$

In Appendix B, it is shown that the (bounded) integral operator K with kernel (4.25) on $L^2(0,\infty)$ is positive and has the purely continuous spectrum $[0,1]$. This immediately entails $\gamma_0 = 1$, and we get

$$\langle \Psi|\hat{\mathcal{P}}|\Psi\rangle|_{\gamma=1} = \frac{1}{2} - \frac{\rho}{1+\rho^2}(\cos\theta + \sin\theta),$$

$$\begin{aligned} \inf_{\lambda} \langle \Psi|\hat{\mathcal{P}}|\Psi\rangle|_{\gamma=1} &= \langle \Psi|\hat{\mathcal{P}}|\Psi\rangle|_{\gamma=\rho=1,\,\theta=\pi/4} = \frac{1-\sqrt{2}}{2} \cong -0.2071, \\ \sup_{\lambda} \langle \Psi|\hat{\mathcal{P}}|\Psi\rangle|_{\gamma=1} &= \langle \Psi|\hat{\mathcal{P}}|\Psi\rangle|_{\gamma=\rho=1,\,\theta=-3\pi/4} = \frac{1+\sqrt{2}}{2} \cong 1.2071. \end{aligned} \tag{4.31}$$

Actually, as discussed in Appendix B, due to the continuous spectrum of K, these extremal values cannot be strictly reached, but only approached arbitrarily close via a family of normalized functions h, e.g.,

$$h_L(q) = \frac{\theta(L-q)}{\sqrt{\ln(L+1)}} \frac{1}{\sqrt{q+1}}, \quad L \to \infty$$

or smoothed forms of this. Of course, other functions h will also do the job (although less perfectly), that is meet the crucial requirement (4.29). Taking, for example, $h(q) = 1/(q+1)$ [which is normalized in $L^2(0,\infty)$], one gets

$$\gamma = \frac{\pi}{4} \cong 0.7854.$$

Finally, collecting the equations (4.14), (4.15), (4.20), and (4.24), together with $\lambda = \pi/4$, $-3\pi/4$, one obtains the wave functions leading to the maximal violations (4.31),

$$\Psi_{\pm}(q_1,q_2) = \frac{1}{2\sqrt{2}}[1 \pm e^{i(\pi/4)}\,\mathrm{sgn}(q_1)\mathrm{sgn}(q_2)]h(|q_1|)h(|q_2|)\,, \tag{4.32}$$

where $h(q)$ stands for some regularized form of $1/\sqrt{q}$, with $\int_0^\infty dq\, h(q)^2 = 1$.

C. Introducing Einstein locality and relative motion

Let us now interpret q_1 and q_2 as the coordinates of two particles (rather than the x and y coordinates of the same particle). Then the wave functions (4.32) describe states of two particles not spatially separated and with zero relative momentum. These two restrictions can be easily disposed of.

First, it can be checked that nothing is essentially changed in the previous derivation if one keeps

$$S_1 = S_1' = (0,\infty)\,, \quad \phi_1(q_1) = f(q_1)\,, \quad \varphi_1(q_1) = \mathrm{sgn}(q_1) f(q_1)\,, \tag{4.33}$$

but replaces

$$S_2 = S_2' = (0,\infty)\,, \quad \phi_2(q_2) = f(q_2)\,, \quad \varphi_2(q_2) = \mathrm{sgn}(q_2) f(q_2)\,, \tag{4.34}$$

by

$$S_2 = (a,\infty)\,, \quad S_2' = (0,\infty)\,, \quad \phi_2(q_2) = f(q_2 - a)\,, \quad \varphi_2(q_2) = \mathrm{sgn}(q_2 - a) f(q_2 - a)\,.$$

Then Eq. (4.32) becomes

$$\Psi_{\pm}(q_1,q_2) = \frac{1}{2\sqrt{2}}[1 \pm e^{i(\pi/4)}\,\mathrm{sgn}(q_1)\mathrm{sgn}(q_2 - a)]h(|q_1|)h(|q_2 - a|)\,,$$

with a arbitrary.

This allows us to let Einstein locality enter the game.

Similarly, nothing is essentially changed if one keeps Eqs. (4.33) but replaces Eqs. (4.34) by

$$S_2 = (0,\infty)\,, \quad S_2' = (P,\infty)\,, \quad \phi_2(q_2) = e^{iPq_2} f(q_2)\,, \quad \varphi_2(q_2) = e^{iPq_2}\,\mathrm{sgn}(q_2) f(q_2)\,.$$

Then Eq. (4.32) becomes

$$\Psi_{\pm}(q_1,q_2) = \frac{1}{2\sqrt{2}}[1 \pm e^{i(\pi/4)}\,\mathrm{sgn}(q_1)\mathrm{sgn}(q_2)]e^{iPq_2}h(|q_1|)h(|q_2|)\,,$$

with P arbitrary.

This allows us to put the two particles in relative motion.

D. Analogy with Bell spin-$\frac{1}{2}$ correlation inequalities

Let us denote by $|+\rangle$ a normalized function f close to the (symmetrized) eigenfunction of the operator K with "eigenvalue" $\lambda_0 = 1$ [i.e., $\gamma \cong 1$ in Eq. (4.26)], and by $|-\rangle$ the orthogonal func-

tion g [as given by Eq. (4.20)]. Consider the subspace $V=\mathrm{span}(|+\rangle,|-\rangle)$ of the full one-particle Hilbert space, together with the orthogonal projector Π onto V. Call Γ (respectively, Γ') the restriction of $\hat{\chi}$ (respectively, $\hat{\chi}'$) to the two-dimensional space V

$$\Gamma=\Pi\,\hat{\chi}\,\Pi\,,\quad \Gamma'=\Pi\,\hat{\chi}'\,\Pi\,.$$

Then Eqs. (4.21), (4.22), and (4.26) tell us that Γ and Γ' are represented in the orthonormal basis $\{|+\rangle,|-\rangle\}$ by the matrices

$$\Gamma=\begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}=\frac{1}{2}(1+\sigma_x)\,,$$

$$\Gamma'=\begin{pmatrix} \frac{1}{2} & \frac{i}{2}\gamma \\ -\frac{i}{2}\gamma & \frac{1}{2} \end{pmatrix}=\frac{1}{2}(1-\gamma\sigma_y)\,.$$

In the idealized limit $\gamma\to 1$ (and only in this limit), one observes that Γ and Γ' are themselves orthogonal projections $V\to V$

$$\Gamma=\Gamma^\dagger,\quad \Gamma^2=\Gamma\,,$$

$$\Gamma'=\Gamma'^\dagger,\quad \Gamma'^2=\Gamma'\,.$$

This implies that both operators $\hat{\chi}$ and $\hat{\chi}'$ leave the subspace V invariant

$$[\Pi,\hat{\chi}]=[\Pi,\hat{\chi}']=0\,.$$

Indeed, a straightforward calculation shows that

$$[(\mathbf{1}-\Pi)\hat{\chi}\Pi]^\dagger[(\mathbf{1}-\Pi)\hat{\chi}\Pi]=0\,,$$

which entails $(\mathbf{1}-\Pi)\hat{\chi}\Pi=0$ and $\hat{\chi}\Pi=\Pi\hat{\chi}$. The same for $\hat{\chi}'$.

Hence, in the two-particle Hilbert space, the operator (4.13) also leaves invariant $V\otimes V$, and $\overline{\mathcal{P}}:=\hat{\mathcal{P}}\Pi$ assumes the simple form

$$\overline{\mathcal{P}}=\tfrac{1}{2}+\tfrac{1}{4}(\sigma_y^{(1)}\sigma_y^{(2)}-\sigma_x^{(1)}\sigma_x^{(2)}+\sigma_x^{(1)}\sigma_y^{(2)}+\sigma_y^{(1)}\sigma_x^{(2)})\,, \tag{4.35}$$

whereas the maximally violating wave functions (4.32) read

$$|\Psi_\pm\rangle=\frac{1}{\sqrt{2}}(|+\rangle^{(1)}|+\rangle^{(2)}\pm e^{i\pi/4}|-\rangle^{(1)}|-\rangle^{(2)})\,. \tag{4.36}$$

From Eq. (4.35) one can check that

$$\overline{\mathcal{P}}(\mathbf{1}-\overline{\mathcal{P}})=-\tfrac{1}{4}\sigma_z^{(1)}\sigma_z^{(2)}\,, \tag{4.37}$$

which is just the projected form of $\hat{\mathcal{P}}(\mathbf{1}-\hat{\mathcal{P}})=[\hat{\chi}_1,\hat{\chi}_1'][\hat{\chi}_2,\hat{\chi}_2']$, and the expectation value of the operator (4.37) is

$$\langle\Psi_\pm|\overline{\mathcal{P}}(\mathbf{1}-\overline{\mathcal{P}})|\Psi_\pm\rangle=-\tfrac{1}{4}$$

for the wave functions (4.36).

The result (4.31) is also directly recovered from Eqs. (4.35) and (4.36),

$$\langle \Psi_{\pm} | \overline{\mathcal{P}} | \Psi_{\pm} \rangle = \frac{1 \mp \sqrt{2}}{2}.$$

Then one sees that, in the idealized limit $\gamma \to 1$, the original phase space setting up of the problem is formally equivalent to the standard EPR setting up for a two spin-$\frac{1}{2}$ system, together with its classical Bell inequalities.

V. GENERAL SOLUTION OF THE THREE MARGINAL PROBLEM

We have proved here the impossibility of reproducing quantum probabilities of four CCS as marginals. Roy and Singh[7] have given examples to show that reproducing three CCS is possible. In this section, we construct the most general non-negative phase space density which reproduces three different (noncommuting) CCS as marginals. Our results encapsulate the extent to which noncommuting CCS can be simultaneously realized in quantum mechanics.

Among the four marginals R,S,T,U obeying the compatibility conditions (2.7) which are at our disposal, the particular choice of three of them is completely irrelevant. For definiteness, we choose R, T, and U, which we rename $\sigma_0(q_1,q_2)$, $\sigma_1(p_1,q_2)$, and $\sigma_2(p_1,p_2)$.

We assume that these marginals are probability densities in the full mathematical sense, that is they are true (integrable and non-negative) *functions*. This means that we restrict our marginal probability distributions to *absolutely continuous* measures (with respect to Lebesgue measure) in $\mathbb{R}^2$. Notice that such a restriction is automatic in the quantum case, due to Eqs. (2.8).

Likewise, we look for the general solution of the three marginal problem in the class of absolutely continuous measures in the phase space $\mathbb{R}^4$. This means that we want to describe all the solutions ρ of the equations

$$\begin{aligned}
\sigma_0(q_1,q_2) &= \int \mathrm{d}p_1\, \mathrm{d}p_2\, \rho(\vec{q},\vec{p})\,, \\
\sigma_1(p_1,q_2) &= \int \mathrm{d}q_1\, \mathrm{d}p_2\, \rho(\vec{q},\vec{p})\,, \\
\sigma_2(p_1,p_2) &= \int \mathrm{d}q_1\, \mathrm{d}q_2\, \rho(\vec{q},\vec{p})\,,
\end{aligned} \tag{5.1}$$

which belong to $L^1(\mathbb{R}^4, \mathrm{d}^2q\, \mathrm{d}^2p)$.

Notice that this is a restricted problem even in the quantum case, since nothing prevents a probability measure containing a singular part to project on marginals which are L^1 functions. To some extent, the above restrictions can be removed, allowing us to include, e.g., probability measures partly concentrated on submanifolds of the phase space. However, dealing with such extensions at some degree of generality requires painful manipulations, and we shall ignore them here. (Special cases are treated in Refs. 5 and 7). As for the full inclusion of singular measures, it appears as both delicate and of little practical interest.

Let us introduce the one variable marginals

$$\begin{aligned}
\sigma_{01}(q_2) &= \int \mathrm{d}q_1\, \sigma_0(q_1,q_2)\,, \\
\sigma_{12}(p_1) &= \int \mathrm{d}q_2\, \sigma_1(p_1,q_2)\,.
\end{aligned} \tag{5.2}$$

Owing to the compatibility conditions (2.7), these definitions are equivalent to

$$\sigma_{01}(q_2)=\int \mathrm{d}p_1\,\sigma_1(p_1,q_2)\,,$$
$$\sigma_{12}(p_1)=\int \mathrm{d}p_2\,\sigma_2(p_1,p_2)\,. \tag{5.3}$$

As the support properties of the functions σ_j (which are allowed to vanish on some parts of $\mathbb{R}^2$) are not innocent in the forthcoming construction, we need to pay attention to them. Let $\Sigma_j\subset\mathbb{R}^2$ $(j=0,1,2)$ be the essential support of σ_j. The above compatibility conditions, together with the positivity conditions $\sigma_j\geqslant 0$, clearly yield two constraints on the supports Σ_j, namely,

$$\{q_2\in\mathbb{R}\mid \exists\ q_1\in\mathbb{R}\ \text{such that}\ (q_1,q_2)\in\Sigma_0\}=\{q_2\in\mathbb{R}\mid \exists\ p_1\in\mathbb{R}\ \text{such that}\ (p_1,q_2)\in\Sigma_1\}\,,$$
$$\{p_1\in\mathbb{R}\mid \exists\ q_2\in\mathbb{R}\ \text{such that}\ (p_1,q_2)\in\Sigma_1\}=\{p_1\in\mathbb{R}\mid \exists\ p_2\in\mathbb{R}\ \text{such that}\ (p_1,p_2)\in\Sigma_2\}\,. \tag{5.4}$$

To the Σ_j's we associate the subsets E_j's of the phase space defined by

$$E_0=\{\vec{q},\vec{p}\mid (q_1,q_2)\in\Sigma_0,(p_1,p_2)\in\mathbb{R}^2\}\,,$$
$$E_1=\{\vec{q},\vec{p}\mid (p_1,q_2)\in\Sigma_1,(q_1,p_2)\in\mathbb{R}^2\}\,, \tag{5.5}$$
$$E_2=\{\vec{q},\vec{p}\mid (p_1,p_2)\in\Sigma_2,(q_1,q_2)\in\mathbb{R}^2\}\,.$$

Finally, we denote by E the intersection of the E_j's,

$$E=E_0\cap E_1\cap E_2\,. \tag{5.6}$$

Again, due to positivity, any solution ρ of Eqs. (5.1) must have its essential support contained in E.

The three marginal problem in the precise form stated above is then completely solved by the following.

Theorem 1: *(1) The Lebesgue measure of E is not zero and the function ρ_0 defined (a.e.) by*

$$\rho_0(\vec{q},\vec{p})=\begin{cases}\sigma_0(q_1,q_2)\dfrac{1}{\sigma_{01}(q_2)}\sigma_1(p_1,q_2)\dfrac{1}{\sigma_{12}(p_1)}\sigma_2(p_1,p_2) & \text{if } (\vec{q},\vec{p})\in E\,,\\ 0 \quad \text{otherwise,}\end{cases} \tag{5.7}$$

is a non-negative solution of the problem (5.1) in $L^1(\mathbb{R}^4,\mathrm{d}^2q\,\mathrm{d}^2p)$.

(2) The general solution ρ of (5.1) in $L^1(\mathbb{R}^4,\mathrm{d}^2q\,\mathrm{d}^2p)$ is given by

$$\rho(\vec{q},\vec{p})=\rho_0(\vec{q},\vec{p})+\lambda\,\Delta(\vec{q},\vec{p})\,, \tag{5.8}$$

where

$$\lambda\in\left[-\frac{1}{m_+},\frac{1}{m_-}\right] \tag{5.9}$$

and

$$\Delta(\vec{q},\vec{p})=F(\vec{q},\vec{p})-\rho_0(\vec{q},\vec{p})\Bigg[\frac{1}{\sigma_0(q_1,q_2)}\int \mathrm{d}p_1'\,\mathrm{d}p_2'\,F(q_1,q_2,p_1',p_2')$$
$$+\frac{1}{\sigma_1(p_1,q_2)}\int \mathrm{d}q_1'\,\mathrm{d}p_2'\,F(q_1',q_2,p_1,p_2')+\frac{1}{\sigma_2(p_1,p_2)}\int \mathrm{d}q_1'\,\mathrm{d}q_2'\,F(q_1',q_2',p_1,p_2)$$
$$-\frac{1}{\sigma_{01}(q_2)}\int \mathrm{d}q_1'\,\mathrm{d}p_1'\,\mathrm{d}p_2'\,F(q_1',q_2,p_1',p_2')$$
$$-\frac{1}{\sigma_{12}(p_1)}\int \mathrm{d}q_1'\,\mathrm{d}q_2'\,\mathrm{d}p_2'\,F(q_1',q_2',p_1,p_2')\Bigg], \tag{5.10}$$

F being an arbitrary $L^1(\mathbb{R}^4,\mathrm{d}^2q\,\mathrm{d}^2p)$ function with essential support contained in E. The (F-dependent) constants $m_\pm$ in (5.9) are defined as

$$m_+=\operatorname*{ess\,sup}_{(\vec{q},\vec{p})\in E}\frac{\Delta(\vec{q},\vec{p})}{\rho_0(\vec{q},\vec{p})},\quad m_-=-\operatorname*{ess\,inf}_{(\vec{q},\vec{p})\in E}\frac{\Delta(\vec{q},\vec{p})}{\rho_0(\vec{q},\vec{p})}, \tag{5.11}$$

and are both positive if $\Delta\neq 0$ ($m_+=\infty$ or/and $m_-=\infty$ are not excluded).

Proof: (1) To begin with, ρ_0 given by (5.7) is well defined and non-negative. Indeed, due to (5.2) [or (5.3)] and the positivity of the σ_j's, $\sigma_{01}(q_2)$, and $\sigma_{12}(p_1)$ are a.e. nonzero for $(\vec{q},\vec{p})\in E_0$ and E_1 (or E_1 and E_2), so that the denominators in Eq. (5.7) do not vanish on E (except maybe on sets of Lebesgue measure 0).

Next, in order to check that ρ_0 obeys the first equation (5.1), we consider the integral

$$\int \mathrm{d}p_1\int \mathrm{d}p_2\,\rho_0(\vec{q},\vec{p}) \tag{5.12}$$

with this specific order of the p integrations. According to the relations (5.4) and the definition of E, one observes first that the projection of E on the (p_1,p_2) plane is the set Σ_2, so that the integration over p_2 removes the factor σ_2/σ_{12} in ρ_0; and second, that the projections of Σ_1 and Σ_2 on p_1 coincide, so that the integration over p_1 removes the factor σ_1/σ_{01} in ρ_0, and one is left with the expected result $\sigma_0(q_1,q_2)$. We can now write

$$\int \mathrm{d}p_1\,\mathrm{d}p_2\,\rho_0(\vec{q},\vec{p})=\sigma_0(q_1,q_2), \tag{5.13}$$

where thanks to Fubini theorem, the integration order is completely irrelevant. The other two equations (5.1) are derived in a similar way.

This calculation shows at once that the Lebesgue measure of E is not zero and that $\rho_0\in L^1(\mathbb{R}^4,\mathrm{d}^2q\,\mathrm{d}^2p)$.

(2) That any non-negative solution ρ of Eqs. (5.1) admits the representation (5.8)–(5.10) is easy to establish. Indeed, since the essential support of ρ is necessarily contained in E, we are allowed to take $F=\rho$ in Eq. (5.10), which gives [using (5.1)]

$$\Delta(\vec{q},\vec{p})=\rho(\vec{q},\vec{p})-\rho_0(\vec{q},\vec{p})\,. \tag{5.14}$$

Then, from (5.11)

$$m_-=-\operatorname*{ess\,inf}_{(\vec{q},\vec{p})\in E}\left(\frac{\rho}{\rho_0}-1\right)\leqslant 1\,.$$

As $1/m_-\geqslant 1$ in (5.9), we can choose $\lambda=1$, which makes Eq. (5.14) equivalent to the representation (5.8).

It remains to show that any function ρ defined by (5.8)–(5.11) (and thus with essential support E) is a non-negative solution of Eqs. (5.1) in $L^1(\mathbb{R}^4, d^2q\, d^2p)$. In order to prove that ρ satisfies the first equation (5.1), we rearrange pairwise the right-hand side of (5.10) as follows:

$$\Delta = \left[F - \frac{\rho_0}{\sigma_0} \int dp_1' \, dp_2' \, F \right] - \left[\frac{\rho_0}{\sigma_1} \int dq_1' \, dp_2' \, F - \frac{\rho_0}{\sigma_{01}} \int dq_1' \, dp_1' \, dp_2' \, F \right]$$
$$- \left[\frac{\rho_0}{\sigma_2} \int dq_1' \, dq_2' \, F - \frac{\rho_0}{\sigma_{12}} \int dq_1' \, dq_2' \, dp_2' \, F \right]. \tag{5.15}$$

Then, integrating the right-hand side over p_1 and p_2, one finds, by an extensive use of Eqs. (5.2) to (5.4) as in part (1), that the two terms coming from each square bracket cancel each other, leading to

$$\int dp_1 \, dp_2 \, \Delta(\vec{q}, \vec{p}) = 0 \, .$$

This, with (5.8) and (5.13), implies that ρ satisfies the first equation (5.1). That it satisfies the other two equations (5.1) is proved in a similar way.

This calculation also shows that $\rho \in L^1(\mathbb{R}^4, d^2q\, d^2p)$.

Finally

$$\int_E d^2q \, d^2p \, \Delta(\vec{q}, \vec{p}) = 0 \, ,$$

which implies that $m_\pm$ in Eqs. (5.11) are both strictly positive if Δ does not vanish, a.e. on $\mathbb{R}^4$. The positivity of ρ is then a trivial consequence of Eqs. (5.8), (5.9), and (5.11).

The proof is complete.

Remark: Theorem 1, as it is stated above, deals with L^1 functions, and thus excludes the occurrence of Dirac measures. We insist on the fact that this is unnecessarily restrictive. Indeed Dirac measures can be easily accommodated and the theorem suitably rephrased, to the price however of cumbersome mathematical intricacies which we do not want to enter into.

An immediate corollary of Proposition 1 and Theorem 1 is the following.

Theorem 2 (Three marginal theorem): *Let R, S, T, and U be probability distributions for (q_1,q_2), (q_1,p_2), (p_1,q_2), and (p_1,p_2) obeying the consistency conditions (2.7). Given n arbitrary distributions among $\{R,S,T,U\}$, a necessary and sufficient condition for them to be marginals of a probability density in the four-dimensional phase space is $n \leqslant 3$.*

VI. CONCLUSIONS

We have solved the four marginal problem in four-dimensional phase space thus proving a long standing conjecture[7] and vastly improving the first results of Martin and Roy[1] which dealt with infinite number of marginals. To achieve this, we first derived ''phase space Bell inequalities'' which have their own interest. Actually they allow, at least in principle, direct ''experimental'' tests of the orthodox-versus-hidden variable interpretations of quantum mechanics within the position-momentum sector, analogous to those performed within the spin sector.

The technique of phase space Bell inequalities established here has applications to quantum information processing. Generalizing the example (4.11), one can show that for any separable density operator $\hat{\rho}$ one can construct a phase space density obeying the four marginal conditions. Hence, the Bell inequalities (3.2), with R, S, T, and U given by (2.8) must hold for every separable quantum state, irrespective of any physical interpretation of the associated phase space density. Their violation by a quantum state is a signature and even a quantitative measure of entanglement of this state.

We have also constructed the most general positive definite phase space density which has the maximum number of marginals (three) coinciding with corresponding quantum probabilities of three different (noncommuting) CCS. These results should be useful in the construction of maximally realistic quantum theories.

ACKNOWLEDGMENTS

We thank André Martin for collaboration in the initial stages of this work. One of the authors (S.M.R.) thanks A. Fine and A. Garg for some remarks on the three marginal problem many years ago. APPENDIX A: PROOF OF EQ. (4.23)

Since $S'=(0,\infty)$, one has

$$\hat{\chi}'(p)\tilde{g}(p)=\theta(p)\tilde{g}(p)\,.$$

Assuming first that g belongs to $\mathcal{S}$ (the Schwartz space of infinitely differentiable functions on $\mathbb{R}$ with fast decrease at infinity), one can write

$$(\hat{\chi}'g)(q)=\int_{-\infty}^{\infty}\mathrm{d}q'\,\tilde{\theta}(q-q')g(q')\,,$$

where $\tilde{\theta}$ is the Fourier transform of θ in the distribution-theoretic sense

$$\tilde{\theta}(q)\equiv\frac{1}{2\pi}\int_{-\infty}^{\infty}\mathrm{d}p\,e^{ipq}\,\theta(p)=\frac{i}{2\pi}\,\frac{P}{q}+\frac{1}{2}\,\delta(q)\,.$$

Then, if f also belongs to $\mathcal{S}$

$$\langle f|\hat{\chi}'|g\rangle=\frac{i}{2\pi}\int_{-\infty}^{\infty}\mathrm{d}q\,f^*(q)\int_{-\infty}^{\infty}\mathrm{d}q'\frac{P}{q-q'}g(q')+\frac{1}{2}\langle f|g\rangle\,.$$

In particular, for even f and odd g, $\langle f|g\rangle$ vanishes, and

$$\langle f|\hat{\chi}'|g\rangle=-\frac{i}{\pi}\int_{0}^{\infty}\mathrm{d}q\,f^*(q)\int_{0}^{\infty}\mathrm{d}q'\left(\frac{1}{q+q'}-\frac{P}{q-q'}\right)g(q')\,,$$

which gives Eq. (4.23) if g coincides with f on $(0,\infty)$. The continuation from $\mathcal{S}$ to $L^2(-\infty,\infty)$ is performed as usual by continuity, using the fact that $\mathcal{S}$ is a dense subspace in $L^2(-\infty,\infty)$.

APPENDIX B: STUDY OF THE OPERATOR *K*

From the very definition of K through the integral kernel (4.25), one has

$$(Kh)(q)=\frac{1}{\pi}\int_{0}^{\infty}\mathrm{d}q'\frac{h(q')}{q+q'}\,.$$

Let us set

$$\overline{h}(u)=e^{u/2}h(e^u)\,.$$

Since $\int_{-\infty}^{\infty}\mathrm{d}u\,|\overline{h}(u)|^2=\int_{0}^{\infty}\mathrm{d}q\,|h(q)|^2$, the correspondence $h\mapsto\overline{h}$ defines a unitary mapping $L^2(0,\infty)\to L^2(-\infty,\infty)$ and

$$\overline{Kh}\,(u)=\int_{-\infty}^{\infty}\mathrm{d}v\;\overline{K}(u-v)\overline{h}(v)\,, \tag{B1}$$

where

$$\overline{K}(u)=\frac{1}{2\pi\cosh\dfrac{u}{2}}\,.$$

Then, another unitary mapping $L^2(-\infty,\infty)\to L^2(-\infty,\infty)$, namely the Fourier transform

$$\tilde{\overline{h}}(k)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\mathrm{d}u\;e^{iku}\,\overline{h}(u)\,,$$

reduces the convolution product in (B1) to an ordinary product

$$\tilde{\overline{Kh}}(k)=\tilde{\overline{K}}(k)\,\tilde{\overline{h}}(k)\,,$$

where

$$\tilde{\overline{K}}(k)\equiv\int_{-\infty}^{\infty}\mathrm{d}u\;e^{iku}\,\overline{K}(u)=\frac{1}{\cosh\pi k}\,. \tag{B2}$$

Therefore, the operator K on $L^2(0,\infty)$ is unitarily equivalent to the multiplicative operator (B2) on $L^2(-\infty,\infty)$. The latter is evidently a positive operator with purely continuous spectrum $[0,\,1]$. Its generalized (non-normalizable) ''eigenfunctions'' are

$$\tilde{\overline{h}}_s(k)=\delta(k-s)\quad(s\in\mathbb{R})\,,$$

with ''eigenvalues'' $\lambda_s=1/\cosh\pi s$, and their preimage in $L^2(0,\infty)$ are

$$h_s(q)=\frac{1}{\sqrt{2\pi q}}\,e^{-is\ln q}\,.$$

Of particular interest for us is the extremal one, with ''eigenvalue'' $\lambda_0=1$,

$$h_0(q)=\frac{1}{\sqrt{2\pi q}}\,.$$

Of course, the corresponding maximal value $\gamma_0=1$ of $\gamma=\langle h|K|h\rangle$ cannot be attained, but only approached arbitrarily close through a family of normalizable functions mimicking $1/\sqrt{q}$. For instance, introducing two cutoffs, ε at small q and L at large q, and setting

$$h_{\varepsilon,L}(q)=\frac{1}{\sqrt{\ln\dfrac{L}{\varepsilon}}}\,\chi_{(\varepsilon,L)}(q)\,\frac{1}{\sqrt{q}}\quad(\|h_{\varepsilon,L}\|=1)\,,$$

one gets

$$\langle h_{\varepsilon,L}|K|h_{\varepsilon,L}\rangle=1-\frac{4}{\pi\ln\dfrac{L}{\varepsilon}}\int_{\sqrt{\varepsilon/L}}^{1}\mathrm{d}x\,\frac{\arctan x}{x}=1-O\left(\frac{1}{\ln\dfrac{L}{\varepsilon}}\right)\,,$$

so that

$$\lim_{\substack{\varepsilon\to 0\\ L\to\infty}} \langle h_{\varepsilon,L}|K|h_{\varepsilon,L}\rangle = 1\ .$$

Notice that one can keep ε fixed (e.g., $\varepsilon=1$) and let L alone go to ∞ without changing anything (this is in fact a consequence of the scale invariance of the operator K), or even choose a family of less singular functions h, like

$$h_L(q) = \frac{1}{\sqrt{\ln(L+1)}}\,\theta(L-q)\,\frac{1}{\sqrt{q+1}}\,.$$

(Received 23 January 2003; accepted 4 April 2003)

We deal with trace formulas for half-line Schrödinger operators with long-range potentials. We generalize the Buslaev–Faddeev trace formulas to the case of square integrable potentials. The exact relation between the number of the trace formulas and the number of integrable derivatives of the potential is also given. The main results are optimal. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1579549]

I. INTRODUCTION

The present paper continues to study trace formulas for half-line Schrödinger operators with long-range potentials started previously by one of the authors in Ref. 20. The type of formulas we are concerned with was discovered 50 years ago by Gel'fand–Levitan in their remarkable note,[5] where it was shown that for the eigenvalues $\{\lambda_n\}$ of the regular Sturm–Liouville problem ($0 \leqslant x \leqslant \pi$),

$$\begin{cases} -u''+q(x)u=\lambda u, \\ u(0)=0=u(\pi), \end{cases}$$

the following holds:

$$\sum_{n\geqslant 1}\left\{\lambda_n - n^2 - \frac{1}{2\pi}\int_0^\pi q(x)dx\right\} = -\frac{q(0)+q(\pi)}{4} + \frac{1}{2\pi}\int_0^\pi q(x)dx. \tag{1.1}$$

Relation (1.1), commonly referred to as a trace formula, links a properly regularized trace of the Sturm–Liouville operator with some information on the potential q. Back in 1953 it was a completely new type of formula and its explicit nature originated an intensive search for similar relations eventually in all areas of mathematics dealing with operators. The literature with the key word *trace formula(s)* is enormous and we will not even make an attempt to review it here. We restrict ourselves to just mentioning some of the important stages of its development pertinent to our work.

The original Gel'fand–Levitan trace formula (1.1) belongs to the setting of operators with discrete spectrum (see also Dikii[3] and Podol'skii–Sadovnichii[16] for a recent account). In 1960 Buslaev–Faddeev[2] extended (1.1) to the case of a singular Sturm–Liouville problem,

$$\begin{cases} -u''+q(x)u=\lambda u, x\geqslant 0, \\ u(0)=0, \end{cases} \tag{1.2}$$

[a]Electronic mail: ftsmb@uaf.edu
[b]Electronic mail: ffavr@uaf.edu

with a short-range real potential q [i.e., integrable on $(0,\infty)$ with the first moment]. In this case, the Schrödinger operator H associated with (1.2) has an absolutely continuous spectrum filling $(0,\infty)$ and only a finite number of eigenvalues $\{\lambda_n\}$ which are all negative. The direct analog of (1.1) reads

$$-\sum_{n\geqslant 1}\lambda_n+\frac{2}{\pi}\int_0^\infty t\left(\theta(t)-\frac{1}{2t}\int_0^\infty q(x)dx\right)dt=-\frac{1}{4}q(0). \tag{1.3}$$

The function θ in (1.3), called the limiting phase, characterizes the absolutely continuous spectrum of H and has a scattering theoretical nature.

In 1971 Faddeev–Zakharov[4] discovered an amazing connection between trace formulas and the conservation laws for the Korteweg–de Vries equation (see also Ref. 8 for a more recent account). The natural Schrödinger operator in this setting is $H=-d^2/dx^2+q(x)$, defined on the whole line with a smooth, fast decaying potential q. The spectral situation here is similar to that of the half-line case and the first Faddeev–Zakharov trace formula reads

$$\sum_{n\geqslant 1}(-\lambda_n)^{1/2}+\frac{1}{2\pi}\int_0^\infty \ln|T(t)|dt=-\frac{1}{4}\int_{-\infty}^\infty q(x)dx, \tag{1.4}$$

where T is the transmission coefficient.

In 1993 Gesztesy–Holden–Simon–Zhao[6] put forward and consistently studied (see, e.g., Ref. 7) local versions of trace formulas which are valid eventually for any real potential. Their first trace relation is

$$E+\lim_{\varepsilon\to 0}\int_E^\infty e^{-\varepsilon t}\{1-2\xi(x,t)\}dt=q(x), \tag{1.5}$$

where E is the low bound of the spectrum of $H=-d^2/dx^2+q(x)$ and $\xi(x,t)$ is the so-called xi-function (see Ref. 7 for details). In the literature, formulas of type (1.5) are related to the trace approach to the inverse scattering problem (see, e.g., Ref. 21, and the literature cited therein).

There is also quite extensive literature on trace formulas in the three-space. We refer to the recent paper[13] by Korotyaev–Pushnitski and further literature cited there.

The list of trace formulas given above is not nearly complete. We mention only one recent development which can be regarded as a breakthrough. In Ref. 10, Killip–Simon introduced a new type of trace formula for Jacobi matrices that yields an exhaustive description of the spectrum of all Hilbert–Schmidt perturbations of the free discrete Schrödinger operator, which answered some open problems on orthogonal polynomials (see, also Ref. 22).

Note that the very term *trace formulas* is due to the fact that they are all related to computing regularized spectral traces of some operators. Moreover, each of (1.1), (1.3)–(1.5) actually represents the first formula in some infinite chain of higher order trace relations representing regularized moments of certain spectral characteristics. The full chain of trace formulas corresponding to (1.3) will be given below [formulas (4.6) and (4.7)].

The present paper deals with trace formulas for long-range potentials [i.e., nonintegrable on $(0,\infty)$]. In the context of the Coulomb potential, such formulas were studied in 1972 by Yafaev[23] and by Kvitsinsky in 1987.[14] For three-dimensional Schrödinger operators, a variant of trace formulas serving long-range potentials was put forward in 1991 by Melin[15] and recently by Bouclet.[1] Our goal is to derive a series of relations which are direct analogs to the Buslaev–Faddeev trace formulas [with the first formula (1.3)]. In 1999 one of the authors[20] proved that

$$-\sum_{n\geqslant 1}\lambda_n^2+2\int_0^\infty\left(\eta(t)+\frac{1}{4\pi\sqrt{t}}\int_0^\infty q^2(x)dx\right)dt=\frac{1}{4}q^2(0), \tag{1.6}$$

where η is the so-called modified spectral shift function that appears in the Koplienko trace formula[11] ($\mathrm{Im}\,\lambda \neq 0$),

$$\mathrm{tr}\{(H-\lambda)^{-1}-(H_0-\lambda)^{-1}-(H_0-\lambda)^{-1}V(H_0-\lambda)^{-1}\} = -\int_{-\infty}^{\infty}\left\{\frac{d^2}{dt^2}(t-\lambda)^{-1}\right\}\eta(t)\,dt, \tag{1.7}$$

where H_0, $H=H_0+V$ are self-adjoint operators such that $V|H_0-i|^{-1/2}$ is Hilbert–Schmidt. In the current paper we use a simpler approach which does not rely on (1.7). We obtain our trace formulas directly from Buslaev–Faddeev's ones using a certain limiting procedure. This way, we also improve on Ref. 20 by imposing in (1.6) weaker conditions on q.

Notation: We will adhere standard notation: $\mathbb{N}=\{1,2,3,\ldots\}$, $\mathbb{R}_+=(0,\infty)$, $\mathbb{C}_+=\{z\in\mathbb{C}:\mathrm{Im}\,z>0\}$, and $\overline{\mathbb{C}_+}=\mathbb{C}_+\cup\mathbb{R}$. All functions are assumed to be measurable and we will use the following Lebesgue classes:

$$L_p := \left\{ f : \|f\|_p^p \equiv \int_{\mathbb{R}_+} |f(x)|^p dx < \infty \right\}, \quad 1 \leqslant p < \infty,$$

$$L_\infty := \left\{ f : \|f\|_\infty \equiv ess \sup_{x\in\mathbb{R}_+} |f(x)| < \infty \right\},$$

and Sobolev classes,

$$W_1^n := \left\{ f : \sum_{m=0}^{n} \int_{\mathbb{R}_+} |f^{(m)}(x)|\,dx < \infty \right\}, \quad f^{(m)}(x) := (d^m/dx^m) f(x).$$

Furthermore, for a linear operator A we denote $\sigma(A)$ the spectrum of A, $\{\lambda_n(A)\}$ are its eigenvalues. By $\mathfrak{S}_p$, $p \geqslant 1$, as usual, we denote the ideal of compact operators A, for which

$$\|A\|_p^p := \sum_n \lambda_n^p(|A|) < \infty, \quad |A| := \sqrt{A^*A}.$$

The most important particular cases: $\mathfrak{S}_1$ is the space of trace class operators, and $\mathfrak{S}_2$ is the Hilbert–Schmidt class.

II. SOME KEY ASYMPTOTICS

In this section we obtain a suitable representation of the solution to the Schrödinger equation satisfying the WKB-type asymptotics at infinity. Such representations are well-known but we need a relation between the number of exact terms and the smoothness of the potential q. The proposition below is a long-range generalization of an analogous statement for L_1-potentials.[19]

Proposition 1: If $q \in L_2, q' \in W_1^{N-1}(\mathbb{R}_+)$ with some $N \in \mathbb{N}$, then the problem

$$\begin{cases} -u'' + q(x)u = k^2 u, \\ \lim\limits_{x\to\infty} u(x,k)\exp\left(-ikx - \dfrac{1}{2ik}\displaystyle\int_0^x q(s)\,ds \right) = 1 \end{cases} \tag{2.1}$$

has a unique bounded solution $u(x,k)$ for all $k \in \mathbb{R}, k \neq 0$. Moreover, for $M(k) := u(0,k)$ the representation

$$M(k)= 1+\sum_{j=2}^{N+1}\frac{m_j}{(-2ik)^j}+\frac{1}{(-2ik)^{N+1}} \times\int_0^\infty \exp\left(2ikx+\frac{1}{ik}\int_0^x q(s)ds\right)q^{(N)}(x)dx+O\left(\frac{1}{k^{N+2}}\right),\quad k\to\infty, \tag{2.2}$$

holds with some coefficients $\{m_j\}$ *depending only on* q.

Proof: It is enough to consider only the case $k\in\mathbb{R}_+$. Set

$$\Theta(x,k):=\exp\left(ikx+\frac{1}{2ik}\int_0^x q(s)ds\right)$$

and observe that $\Theta(x,k)$ satisfies the equation

$$-\Theta''+\{q(x)-q_1(x,k)-k^2\}\Theta=0, \tag{2.3}$$

where

$$q_1(x,k)=\frac{q'(x)}{-2ik}+\frac{q^2(x)}{4k^2}. \tag{2.4}$$

Rewrite (2.1) in the form

$$-u''+\{q(x)-q_1(x,k)-k^2\}u=-q_1(x,k)u \tag{2.5}$$

and note that (2.3) is the homogeneous equation for (2.5). Taking $\Theta(x,k)$ and $\Theta(x,k)\int_0^x\Theta^{-2}(s,k)ds$ as fundamental solutions to (2.3), by variation of parameters, Eq. (2.1) can be represented as

$$u(x,k)=\Theta(x,k)\left\{1+\int_x^\infty q_1(s,k)\Theta(s,k)\left(\int_x^s\Theta^{-2}(t,k)dt\right)u(s,k)ds\right\}. \tag{2.6}$$

Setting $y=\Theta^{-1}u$ and introducing the kernel

$$K(x,s,k)=q_1(s,k)\cdot\Theta^2(s,k)\int_x^s\Theta^{-2}(t,k)dt, \tag{2.7}$$

Eq. (2.6) reads

$$y(x,k)=1+\int_x^\infty K(x,s,k)y(s,k)ds=1+(\mathbb{K}y)(x,k), \tag{2.8}$$

where $\mathbb{K}$ stands for the Volterra integral operator with the kernel $K(x,s)$ (2.7). We show that $\mathbb{K}$ maps L_∞ to L_∞ and then (2.8) can be solved by iteration. Let us estimate

$$\int_x^s\Theta^{-2}(t,k)dt=\int_x^s e^{-2ikt}\cdot\exp\left(-\frac{1}{ik}\int_0^t q(z)dz\right)dt. \tag{2.9}$$

Integrating by parts twice in (2.9) yields

$$\int_x^s\Theta^{-2}(t,k)dt=\left\{\frac{\Theta^{-2}(t,k)}{-2ik}+\frac{q(t)\Theta^{-2}(t,k)}{-4ik^3}\right\}\Bigg|_{t=x}^{t=s}+\frac{1}{4ik^3}\int_x^s\Theta^{-2}(t,k)\left(q'(t)-\frac{q^2(t)}{ik}\right)dt. \tag{2.10}$$

Since $q' \in L_1$ implies $q \in L_\infty$, it follows from (2.10) that

$$\left| \int_x^s \Theta^{-2}(t,k)dt \right| \leqslant \frac{1}{k} + \frac{2\|q\|_\infty + \|q'\|_1}{4k^3} + \frac{\|q\|_2}{4k^4}. \tag{2.11}$$

Due to (2.11) and our conditions on q,

$$\begin{aligned} \int_x^\infty |K(x,s,k)|ds &\leqslant \int_x^\infty |q_1(s,k)| \left| \int_x^s \Theta^{-2}(t,k)dt \right| ds \\ &\leqslant \frac{1}{k^2}\left(1 + \frac{2\|q\|_\infty + \|q'\|_1}{4k^2} + \frac{\|q\|_2}{4k^3}\right)\left(\frac{1}{2}\int_x^\infty |q'(s)|ds + \frac{1}{4k}\int_x^\infty |q(s)|^2 ds\right) \end{aligned} \tag{2.12}$$

and we have

$$\|\mathbb{K}\| = \sup_{\|f\|_\infty = 1} \|\mathbb{K}f\|_\infty \leqslant \left\| \int_x^\infty |K(x,s,k)|ds \right\|_\infty \leqslant \frac{1}{k^2}\left(\frac{\|q'\|_1}{2} + \frac{\|q\|_2}{4k}\right)\left(1 + \frac{2\|q\|_\infty + \|q'\|_1}{4k^2} + \frac{\|q\|_2}{4k^3}\right). \tag{2.13}$$

Estimating (2.13) implies that for some positive constant r_q dependent only on q,

$$\|\mathbb{K}\| \leqslant 1/2 \quad \text{for} \quad k \geqslant r_q, \tag{2.14}$$

Eq. (2.8) can then be solved by iteration,

$$y(x,k) = 1 + \sum_{n=1}^{\infty} \Omega_j(x,k), \quad k \geqslant r_q, \tag{2.15}$$

where $\Omega_j(x,k) = (\mathbb{K}^j 1)(x,k)$, and

$$\|y\|_\infty \leqslant 2 \quad \text{for} \quad k \geqslant r_q. \tag{2.16}$$

This proves the existence.

Now we establish (2.2). To this end, introduce the differential operation

$$D := \frac{d}{dx} + \frac{q(x)}{ik}.$$

It is clear that if $q \in L_2$, $q' \in W_1^{m-1}(\mathbb{R}_+)$ and $f \in W_1^m(\mathbb{R}_+)$, for some $m \geqslant 1$, then

$$D^j f \in L_1, \ \forall \ 1 \leqslant j \leqslant m. \tag{2.17}$$

Denote

$$G(x,s,k) = \Theta^2(s,k)\int_x^s \Theta^{-2}(t,k)dt.$$

Integrating by part, one can easily verify that

$$\int_x^\infty G(x,s,k)f(s)ds = -\frac{1}{2ik}\int_x^\infty f(s)ds - \frac{1}{2ik}\int_x^\infty G(x,s,k)Df(s)ds. \tag{2.18}$$

Equation (2.18) is an integration by parts type formula. Since $q_1 \in W_1^{N-1}$, by (2.17), all $Dq_1, D^2q_1, \ldots, D^{N-1}q_1$ are from L_1, (2.18) can be applied $N-1$ times and the remaining integral will still be absolutely convergent. Setting in (2.15) $x=0$ we have

$$M(k) = 1 + \sum_{j=1}^{\infty} \Omega_j(k), \tag{2.19}$$

where $\Omega_j(k) = \Omega_j(0,k) = (\mathbb{K}^j 1)(0,k)$. Let us now evaluate each term in (2.19). Consider Ω_1 first. Apply (2.18) $N-1$ times to

$$\begin{aligned}
\Omega_1(x,k) &= \int_x^{\infty} G(x,s,k) q_1(s,k) ds \\
&= -\sum_{j=1}^{N-1} \frac{1}{(-2ik)^j} \int_x^{\infty} D^j q_1(s,k) ds + \frac{1}{(-2ik)^{N-1}} \int_x^{\infty} G(x,s,k) D^{N-1} q_1(s,k) ds \\
&= \sum_{j=2}^{N} \frac{\omega_j^{(1)}(x)}{(-2ik)^j} + \frac{1}{(-2ik)^{N-1}} \int_x^{\infty} G(x,s,k) D^{N-1} q_1(s,k) ds + O\left(\frac{1}{k^{N+2}}\right),
\end{aligned} \tag{2.20}$$

where $\omega_j^{(1)}(x)$ are some continuous functions whose expressions are inessential. By (2.10) one has that

$$G(x,s,k) = \frac{1 - \Theta^2(s,k)\Theta^{-2}(x,k)}{-2ik} + O\left(\frac{1}{k^2}\right)$$

and (2.20) reads

$$\begin{aligned}
\Omega_1(x,k) &= \sum_{j=2}^{N+1} \frac{\omega_j^{(1)}(x)}{(-2ik)^j} + \frac{\Theta^{-2}(x,k)}{(-2ik)^{N+1}} \int_x^{\infty} q^{(N)}(s) ds + \frac{\Theta^{-2}(x,k)}{(-2ik)^{N+1}} \int_x^{\infty} \Theta^2(s,k) q^{(N)}(s) ds \\
&\quad + O\left(\frac{1}{k^{N+2}}\right) \\
&= \sum_{j=2}^{N+1} \frac{\omega_j^{(1)}(x)}{(-2ik)^j} - \frac{q^{(N-1)}(x)\Theta^{-2}(x,k)}{(-2ik)^{N+1}} + \frac{\Theta^{-2}(x,k)}{(-2ik)^{N+1}} \int_x^{\infty} \Theta^2(s,k) q^{(N)}(s) ds + O\left(\frac{1}{k^{N+2}}\right).
\end{aligned} \tag{2.21}$$

Setting in (2.21) $x=0$ we finally have

$$\Omega_1(k) = \sum_{j=2}^{N+1} \frac{\omega_j^{(1)}}{(-2ik)^j} + \frac{1}{(-2ik)^{N+1}} \int_0^{\infty} \Theta^2(s,k) q^{(N)}(s) ds + O\left(\frac{1}{k^{N+2}}\right). \tag{2.22}$$

Similarly,

$$\Omega_2(k) = \sum_{j=4}^{N+1} \frac{\omega_j^{(2)}}{(-2ik)^j} + O\left(\frac{1}{k^{N+2}}\right), \quad k \to \infty. \tag{2.23}$$

For the general $1 \leqslant n \leqslant [(N+1)/2]$, where $[x]$ is the greatest integer $n \leqslant x$, we get

$$\Omega_n(k) = \sum_{j=2n}^{N+1} \frac{\omega_j^{(n)}}{(-2ik)^j} + O\left(\frac{1}{k^{N+2}}\right), \quad k \to \infty \tag{2.24}$$

and

$$\Omega_{[(N+1/2)]+1}(k)=O\left(\frac{1}{k^{N+2}}\right),\quad k\to\infty.$$

Since in Ω_j, $j>1$, all terms containing $\int_x^\infty \Theta^2(s,k)q^{(N)}(s)ds$ are included in the error term $o(1/k^{N+1})$, we can get the $N+2$ term if and only if $\int_0^\infty \Theta^2(x,k)q^{(N)}(x)dx=O(1/k)$, $k\to\infty$. From (2.13) and (2.14) is easy to see that

$$\left|\sum_{n\geqslant[(N+1)/2]+1}\Omega_n(k)\right|\leqslant\sum_{n\geqslant[(N+1)/2]+1}\|\mathbb{K}\|^n\leqslant 2\|\mathbb{K}\|^{[(N+1)/2]+1}\leqslant\frac{C_q}{k^{N+2}},$$

where C_q is a constant dependant only on q. Thus,

$$\sum_{n\geqslant[(N+1)/2]+1}\Omega_n(k)=O\left(\frac{1}{k^{N+2}}\right),\quad k\to\infty, \tag{2.25}$$

and combining (2.22)–(2.25) we arrive at

$$\begin{aligned}M(k)&=1+\sum_{n\geqslant 1}\Omega_n(k)\\&=1+\sum_{j=2}^{N+1}\frac{m_j}{(-2ik)^j}+\frac{1}{(-2ik)^{N+1}}\int_0^\infty\Theta^2(s,k)q^{(N)}(s)ds+O\left(\frac{1}{k^{N+2}}\right),\ k\to\infty,\end{aligned}$$

that completes the proof. □

Remark 1: Since, by condition, $q^{(N)}\in L_1$ we conclude that

$$\int_0^\infty\exp\left(2ikx+\frac{1}{ik}\int_0^x q(s)ds\right)q^{(N)}(x)dx=o(1),\quad k\to\infty$$

(*the proof is parallel to that of the Riemann–Lebesgue lemma) and hence the integral term in (2.2) is $o(k^{-N-1})$. The fact that we were able to extract an explicit "intermediate" term between the exact terms $\Sigma_{j=2}^{N+1}(-2ik)^{-j}m_j$ and $O(k^{-N-2})$ will be important in Sec. IV. Proposition 1 actually relates the number of exact terms in (2.2) with the smoothness of q but does not provide a recipe to evaluate coefficients $\{m_j\}$. Explicit formulas for $\{m_j\}$ can be derived, e.g., from Ref. 2.*

III. THE MODIFIED JOST FUNCTION

Introduce the half-line Schrödinger operator $H=-d^2/dx^2+q(x)$ with a Dirichlet boundary condition $u(0)=0$. It is well-known that if $q\in L_1$ then for any $k>0$ the equation $-u''+q(x)u=k^2u$ has the so-called Jost solution $u_0(x,k)$, i.e., a solution subject to the condition that $\lim_{x\to\infty}e^{-ikx}u_0(x,k)=1$. The function $M_0(k):=u_0(0,k)$ is commonly referred to as the Jost function. It is continuous on $\mathbb{R}\setminus\{0\}$ and analytic in $\mathbb{C}_+$ except for isolated poles at $i\sqrt{-\lambda_n}$, where $\{\lambda_n\}$ are (necessarily negative) eigenvalues of H accumulating only at 0. The function $M(k)$, defined in Proposition 1, can then be called *the modified Jost function*. Note that if $q\in L_1$; then

$$M(k)=M_0(k)\exp\left\{\frac{1}{2ik}\int_0^\infty q(x)dx\right\}. \tag{3.1}$$

Given potential q, let $\tilde{q}$ be its smooth cut-off approximation defined by

$$\tilde{q}(x,a)=q(x)\chi_a(x), \tag{3.2}$$

where χ_a is smooth such that $\chi_a(x)=1,0\leqslant x\leqslant a$, and $\chi_a(x)=0,x>a+1$.

It is clear that

$$\tilde{q}(x,a)\to q(x),\quad a\to\infty,$$

which we agree to write just as $\tilde{q}\to q$. In the sequel, we will drop a in $\tilde{q}(x,a)$ and put ~ on top of every object related to $\tilde{q}$.

The following lemma will be a key ingredient in our consideration:

Lemma 1: Let q be real and $q\in L_2$, $q'\in L_1$ and $\tilde{q}$ be defined by (3.2), then

(i) for every $k\in\overline{\mathbb{C}}_+$, $|k|>r_q$, with some $r_q>0$ dependent only on q,

$$\tilde{M}(k)\to M(k),\quad \tilde{q}\to q;$$

(ii) for any $p\geqslant 3/2$;

$$\sum_n |\tilde{\lambda}_n|^p\to\sum_n |\lambda_n|^p,\quad \tilde{q}\to q.$$

Proof: (i) Assume for the time being that $k>0$. In the notation of Proposition 1, by representation (2.15) we have: for any natural number N,

$$\begin{aligned}|M(k)-\tilde{M}(k)|&=|u(0,k)-\tilde{u}(0,k)|\\&=|y(0,k)-\tilde{y}(0,k)|\\&\leqslant\sum_{n=1}^{N}|(\mathbb{K}^n1)(0,k)-(\tilde{\mathbb{K}}^n1)(0,k)|+|(\mathbb{K}^{N+1}y)(0,k)-(\tilde{\mathbb{K}}^{N+1}\tilde{y})(0,k)|\\&\leqslant\sum_{j=1}^{N}\|\mathbb{K}^n-\tilde{\mathbb{K}}^n\|+\|\mathbb{K}^{N+1}-\tilde{\mathbb{K}}^{N+1}\|\|y\|+\|\mathbb{K}^{N+1}(y-\tilde{y})\|.\end{aligned}\tag{3.3}$$

Observing that for any $n\in\mathbb{N}$;

$$\mathbb{K}^n-\tilde{\mathbb{K}}^n=\sum_{m=0}^{n-1}\tilde{\mathbb{K}}^m(\mathbb{K}-\tilde{\mathbb{K}})\mathbb{K}^{n-m-1},$$

and by (2.16), estimate (3.3) for $k\geqslant r_q$ can be continued,

$$\begin{aligned}|M(k)-\tilde{M}(k)|\leqslant\sum_{n=1}^{N}\sum_{m=0}^{n-1}\|\tilde{\mathbb{K}}\|^m\|\mathbb{K}-\tilde{\mathbb{K}}\|\|\mathbb{K}\|^{n-m-1}+\|y\|\sum_{n=0}^{N}\|\tilde{\mathbb{K}}\|^n\|\mathbb{K}-\tilde{\mathbb{K}}\|\|\mathbb{K}\|^{N-n}\\+\|\mathbb{K}\|^{N+1}(\|y\|+\|\tilde{y}\|).\end{aligned}\tag{3.4}$$

But for $k>\max\{r_q,r_{\tilde{q}}\}=r_q$, by (2.14) and (2.16), $\|\tilde{\mathbb{K}}\|,\|\mathbb{K}\|\leqslant 1/2$ and $\|y\|,\|\tilde{y}\|\leqslant 2$ and (3.4) finally yields

$$\begin{aligned}|M(k)-\tilde{M}(k)|&\leqslant\sum_{n=1}^{N-1}n2^{-n}\cdot\|\mathbb{K}-\tilde{\mathbb{K}}\|+N2^{-N+1}\cdot\|\mathbb{K}-\tilde{\mathbb{K}}\|+2^{-N+1}\\&\leqslant 2(1+N2^{-N+1})\|\mathbb{K}-\tilde{\mathbb{K}}\|+2^{-N+1}.\end{aligned}\tag{3.5}$$

Letting in (3.5) $N\to\infty$, we have

$$|M(k)-\tilde{M}(k)|\leqslant 2\|\mathbb{K}-\tilde{\mathbb{K}}\|.\tag{3.6}$$

Show now that $\|\mathbb{K}-\tilde{\mathbb{K}}\|\to 0$ as $a\to\infty$. It follows from (2.4) and (2.7) that

$$\tilde{K}(x,s,k)=K(x,s,k)\quad\text{for}\quad x\leqslant s\leqslant a$$

and hence by (2.12) one obtains

$$\|\mathbb{K}-\widetilde{\mathbb{K}}\|\leqslant\sup_{x\geqslant a}\int_x^\infty|K(x,s,k)-\widetilde{K}(x,s,k)|ds\leqslant\sup_{x\geqslant a}\int_x^\infty\{|K(x,s,k)|+|\widetilde{K}(x,s,k)|\}ds\to 0,\ a\to\infty. \tag{3.7}$$

Combining (3.6) and (3.7) we prove (i) with real k and then using Phragmén–Lindelöf-type arguments we arrive at (i).

(ii) Let $H_0=-d^2/dx^2$ with $u(0)=0$. For the Green's function $G(x,s,\lambda)$ of H_0 one has

$$G(x,y,\lambda)=\frac{1}{i\sqrt{\lambda}}(e^{i\sqrt{\lambda}(x+y)}-e^{i\sqrt{\lambda}|x-y|}),$$

and hence for $\operatorname{Im}\lambda\neq 0$;

$$\|(q-\tilde{q})(H_0-\lambda I)^{-1}\|_2^2=\frac{1}{|\lambda|}\int_0^\infty\int_0^\infty|q(x)-\tilde{q}(x)|^2|e^{i\sqrt{\lambda}(x+y)}-e^{i\sqrt{\lambda}|x-y|}|^2dxdy$$

$$\leqslant\frac{5}{|\lambda|\operatorname{Im}\sqrt{\lambda}}\|q-\tilde{q}\|_2^2\to 0,\ \tilde{q}\to q. \tag{3.8}$$

Due to

$$(H_0-\lambda)^{-1}=(\widetilde{H}-\lambda)^{-1}(I+\tilde{q}(H_0-\lambda)^{-1}),$$

we have

$$\begin{aligned}\|(H-\lambda)^{-1}-(\widetilde{H}-\lambda)^{-1}\|_2&=\|(H-\lambda)^{-1}(\widetilde{H}-H)(\widetilde{H}-\lambda)^{-1}\|_2\\&\leqslant\|(H-\lambda)^{-1}\|\cdot\|(q-\tilde{q})(\widetilde{H}-\lambda)^{-1}\|_2\\&=\|(H-\lambda)^{-1}\|\cdot\|(q-\tilde{q})(H_0-\lambda)^{-1}(I+\tilde{q}(H_0-\lambda)^{-1})^{-1}\|_2\\&\leqslant\|(H-\lambda)^{-1}\|\|(I+\tilde{q}(H_0-\lambda)^{-1})^{-1}\|\cdot\|(q-\tilde{q})(H_0-\lambda)^{-1}\|_2.\end{aligned} \tag{3.9}$$

Since for $\operatorname{Im}\lambda\neq 0$ the first two norms on the right-hand side of (3.9) are finite and, by (3.8), the third one goes to zero and we conclude that

$$\|(H-\lambda)^{-1}-(\widetilde{H}-\lambda)^{-1}\|\leqslant\|(H-\lambda)^{-1}-(\widetilde{H}-\lambda)^{-1}\|_2\to 0,\ \tilde{q}\to q. \tag{3.10}$$

One can now employ some arguments from Ref. 8. Let $\Delta=[a,b]\subset(-\infty,0)$: $a<\inf\{\sigma(H),\sigma(\widetilde{H})\}$, $-1<b\neq\sigma(H),\sigma(\widetilde{H})$, and E_Δ be the spectral projection corresponding to Δ. It follows from (3.10) that[17] in the weak sense,

$$\widetilde{E}_\Delta\to E_\Delta,$$

which implies that

$$\sum_{\tilde{\lambda}_n\in\Delta}|\tilde{\lambda}_n|^p\to\sum_{\lambda_n\in\Delta}|\lambda_n|^p,\ p>0. \tag{3.11}$$

Consider ($p\geqslant 3/2$),

$$\left|\sum_n (|\tilde{\lambda}_n|^p - |\lambda_n|^p)\right| \leqslant \left|\sum_{\tilde{\lambda}_n, \lambda_n < b} (|\tilde{\lambda}_n|^p - |\lambda_n|^p)\right| + \sum_{\tilde{\lambda}_n > b} |\tilde{\lambda}_n|^p + \sum_{\lambda_n > b} |\lambda_n|^p. \tag{3.12}$$

Denote by $q_- = \frac{1}{2}(q - |q|)$ the negative part of q. Since $q_-(x) \leqslant \tilde{q}(x)$ we have $H_- = -d^2/dx^2 + q_-(x) \subseteq \tilde{H}$. Hence, by the standard fact of perturbation theory, $\lambda_n(H_-) \leqslant \tilde{\lambda}_n$ and (all eigenvalues are negative)

$$\sum_n |\tilde{\lambda}_n|^p \leqslant \sum_n |\lambda_n(H_-)|^p. \tag{3.13}$$

From the Lieb–Thirring bounds (see, e.g., Ref. 9),

$$\sum_n |\lambda_n(H_-)|^{3/2}, \ \sum_n |\lambda_n(H)|^{3/2} \leqslant \tfrac{3}{16}\|q_-\|_2^2 \leqslant \tfrac{3}{16}\|q\|_2^2, \tag{3.14}$$

and hence for $p \geqslant 3/2$ by (3.13) and taking into account that $|b| < 1$, we get

$$\sum_{\tilde{\lambda}_n > b} |\tilde{\lambda}_n|^p \leqslant \sum_{\tilde{\lambda}_n > b} |\tilde{\lambda}_n|^{3/2} \leqslant \sum_n |\tilde{\lambda}_n|^{3/2} \leqslant \sum_n |\lambda_n(H_-)|^{3/2} \leqslant \tfrac{3}{16}\|q\|_2^2 < \infty. \tag{3.15}$$

Due to (3.11), (3.14), and (3.15), by the standard $\varepsilon/3$ argument (3.12) yields (ii) and the lemma is proved. □

Remark 2: Since $M(k)$ is analytic in $\mathbb{C}_+$, (i) of Lemma 1 actually holds in $\overline{\mathbb{C}}_+ \backslash \{0\}$.

Remark 3: Lemma 1 improves on one result by Koplienko.[11] *Namely, if (H, H_0): $H_0 = -d^2/dx^2$ with $u(0) = 0$ and $H = H_0 + q$ with $q \in L_2, q' \in L_1$, then the modified spectral shift function $\eta(t)$ for (H, H_0) appearing in (1.7) is differentiable and*

$$\eta'(t) = \pi^{-1} \operatorname{Im} \ln M(\sqrt{t}), \ \ t > 0. \tag{3.16}$$

In Ref. 11, relation (3.16) was proven under stronger conditions involving q''.

IV. TRACE FORMULAS

This section contains the main results of the paper, the Buslaev–Faddeev trace formulas for certain long-range potentials. Relation (3.1), Proposition 1, Lemma 1, and some limiting arguments will let us not only adjust the original Buslaev–Faddeev trace formulas[2] to the long-range setting but also provide sharp conditions on potentials.

Set in (3.1) $M_0 = A_0 e^{i\theta_0}$, where $A_0 = |M_0|$ is the scattering amplitude and θ_0 is the scattering phase. Similarly, $M = Ae^{i\theta}$, where $A = |M|$ can be called *the modified scattering amplitude* and θ_0 *the modified scattering phase*. Relation (3.1) then implies that for $q \in L_1$ and $k > 0$,

$$\theta(k) = \theta_0(k) - \frac{1}{2k}\int_0^\infty q(t)\,dt, \ \ A(k) = A_0(k). \tag{4.1}$$

Following Ref. 2, introduce the sequence $\{Q_n\}_{n \geqslant 1}$:

$$Q_n = \lim_{x \to \infty}\left(V_{n-1}(x) + \sum_{j=1}^{n-2} \frac{j}{n} V_{n-j-1}(x) Q_j \right), \tag{4.2}$$

where

$$V_n(x) = q^{(n-1)}(0) + \sum_{m=1}^{n-1} \binom{l-1}{m} \int_0^x V_m(s) q^{(n-m-1)}(s)\,ds, V_0(x) = 0. \tag{4.3}$$

The following statement is our main result.

Theorem 1: *Suppose that for $q \in L_2(0,\infty)$ and $q' \in W_1^{N-1}(0,\infty), N \in \mathbb{N}$. Then for the modified scattering phase $\theta(k)$ and modified scattering amplitude $A(k)$ the following trace formulas are valid:*

$$(-1)^n \sum_{l=1}^{\infty} (-\lambda_l)^n + \frac{2n}{\pi} \int_0^{\infty} k^{2n-1} \left\{ \theta(k) - \sum_{l=1}^{n-1} \frac{(-1)^{l+1}}{(2k)^{2l+1}} Q_{2l+1} \right\} dk = (-1)^n \frac{n}{2^{2n}} Q_{2n},$$

$$2 \leqslant n \leqslant \frac{N}{2}; \tag{4.4}$$

$$(-1)^n \sum_{l=1}^{\infty} (-\lambda_l)^{n+1/2} - \frac{2n+1}{\pi} \int_0^{\infty} k^{2n} \left\{ \ln A(k) - \sum_{l=1}^{n} \frac{(-1)^{l+1}}{(2k)^{2l}} Q_{2l} \right\} dk$$
$$= (-1)^n \frac{2n+1}{2^{2n+1}} Q_{2n+1}, \quad 1 \leqslant n \leqslant \frac{N-1}{2}; \tag{4.5}$$

where coefficients $\{Q_n\}$ are computed by (4.2) and all integrals are absolutely convergent. In order to extract one additional formula in (4.4)–(4.5) with the absolutely convergent integral it is necessary and sufficient that

$$\frac{1}{k} \int_0^{\infty} \sin\left(2kx - \frac{1}{k} \int_0^x q(s)\,ds \right) q^{(N)}(x)\,dx \in L_1(r,\infty),$$

for some $r > 0$.

Proof: Introduce $\tilde{q}(x)$ by (3.2). Since $\tilde{q} \in L_1((1+x)dx, \mathbb{R}_+)$, then Faddeev–Buslaev trace formulas[2] for $\tilde{\theta}_0(k)$ and $\tilde{A}_0(k)$ apply

$$(-1)^n \sum_{l=1}^{\infty} (-\tilde{\lambda}_l)^n + \frac{2n}{\pi} \int_0^{\infty} k^{2n-1} \left[\tilde{\theta}_0(k) - \sum_{l=0}^{n-1} \frac{(-1)^{l+1}}{(2k)^{2l+1}} \tilde{Q}_{2l+1} \right] dk = (-1)^n \frac{n}{2^{2n}} \tilde{Q}_{2n},$$

$$1 \leqslant n \leqslant \frac{N}{2}; \tag{4.6}$$

$$(-1)^n \sum_{l=1}^{\infty} (-\tilde{\lambda}_l)^{n+1/2} - \frac{2n+1}{\pi} \int_0^{\infty} k^{2n} \left[\ln \tilde{A}_0(k) - \sum_{l=1}^{n} \frac{(-1)^{l+1}}{(2k)^{2l}} \tilde{Q}_{2l} \right] dk$$
$$= (-1)^n \frac{2n+1}{2^{2n+1}} \tilde{Q}_{2n+1}, \quad 1 \leqslant n \leqslant \frac{N-1}{2}. \tag{4.7}$$

In view of (4.1), relations (4.6) and (4.7) transform into

$$(-1)^n \sum_{l=1}^{\infty} (-\tilde{\lambda}_l)^n + \frac{2n}{\pi} \int_0^{\infty} k^{2n-1} \left[\tilde{\theta}(k) - \sum_{l=1}^{n-1} \frac{(-1)^{l+1}}{(2k)^{2l+1}} \tilde{Q}_{2l+1} \right] dk = (-1)^n \frac{n}{2^{2n}} \tilde{Q}_{2n},$$

$$2 \leqslant n \leqslant \frac{N}{2}; \tag{4.8}$$

$$(-1)^n\sum_{l=1}^{\infty}(-\tilde{\lambda}_l)^{n+1/2}-\frac{2n+1}{\pi}\int_0^{\infty}k^{2n}\left[\ln\tilde{A}(k)-\sum_{l=1}^{n}\frac{(-1)^{l+1}}{(2k)^{2l}}\tilde{Q}_{2l}\right]dk$$

$$=(-1)^n\frac{2n+1}{2^{2n+1}}\tilde{Q}_{2n+1},\qquad 1\leqslant n\leqslant\frac{N-1}{2}. \tag{4.9}$$

Since (4.8) and (4.9) are similar we treat only (4.8). Let now in (4.8) $\tilde{q}\to q$. Due to (4.2) and (4.3) one easily has that $\tilde{Q}_j\to Q_j, j\leqslant N$. It follows from Lemma 1 that $\Sigma_l(-\tilde{\lambda}_l)^n\to\Sigma_l(-\lambda_l)^n$ and (4.8) becomes

$$(-1)^n\sum_{l=1}^{\infty}(-\lambda_l)^n+\frac{2n}{\pi}\lim_{\tilde{q}\to q}\int_0^{\infty}k^{2n-1}\left[\tilde{\theta}(k)-\sum_{l=1}^{n-1}\frac{(-1)^{l+1}}{(2k)^{2l+1}}\tilde{Q}_{2l+1}\right]dk=(-1)^n\frac{n}{2^{2n}}Q_{2n},$$

$$2\leqslant n\leqslant\frac{N}{2}. \tag{4.10}$$

It is only left to pass to the limit under the integral sign in (4.10). To this end, represent this integral as the sum of the integrals over $(0,r)$ and (r,∞) with any $r\geqslant r_q$, where r_q is as in Lemma 1. It can be derived from Ref. 12 that $\int_0^k\tilde{\theta}(t)dt\to\int_0^k\theta(t)dt$ in $L_1(0,r)$ and hence $k\tilde{\theta}(k)\to k\theta(k)$ in $L_1(0,r)$-sense. Thus,

$$\lim_{\tilde{q}\to q}\int_0^r k^{2n-1}\left\{\tilde{\theta}(k)-\sum_{l=1}^{n-1}\frac{(-1)^{l+1}}{(2k)^{2l+1}}\tilde{Q}_{2l+1}\right\}dk=\int_0^r k^{2n-1}\left\{\theta(k)-\sum_{l=1}^{n-1}\frac{(-1)^{l+1}}{(2k)^{2l+1}}Q_{2l+1}\right\}dk, \tag{4.11}$$

since $k=0$ is not a singularity of the integrands in (4.11). Consider now the integral over (r,∞). Using the elementary fact

$$f(x)=\sum_{m\geqslant 1}a_m x^m\Rightarrow\ln\{1+f(x)\}=\sum_{m\geqslant 1}b_m x^m,$$

$$b_1=a_1, b_m=a_m-\sum_{j=1}^{m-1}\frac{j}{m}a_{m-j}b_j, m\geqslant 2,$$

it follows form Proposition 1 that for $k\geqslant r_q$ the function

$$\tilde{g}(k):=k^{2n-1}\left\{\tilde{\theta}(k)-\sum_{l=1}^{n-1}\frac{(-1)^{l+1}}{(2k)^{2l+1}}\tilde{Q}_{2l+1}\right\}-\frac{(-1)^n}{2^{2n}}\cdot\frac{1}{k}\int_0^{\infty}\sin\left(2kx-\frac{1}{k}\int_0^x\tilde{q}(s)ds\right)\tilde{q}^{(N)}(x)dx$$

has a majorant from $L_1(r,\infty)$ and by the dominated convergence theorem

$$g(k)=\lim_{\tilde{q}\to q}\tilde{g}(k)=k^{2n-1}\left\{\theta(k)-\sum_{l=1}^{n-1}\frac{(-1)^{l+1}}{(2k)^{2l+1}}Q_{2l+1}\right\}$$

$$-\frac{(-1)^n}{2^{2n}}\cdot\frac{1}{k}\int_0^{\infty}\sin\left(2kx-\frac{1}{k}\int_0^x q(s)ds\right)q^{(N)}(x)dx$$

$$\in L_1(r,\infty).$$

The latter means that

$$\lim_{\tilde{q}\to q}\int_r^\infty k^{2n-1}\left\{\tilde{\theta}(k)-\sum_{l=1}^{n-1}\frac{(-1)^{l+1}}{(2k)^{2l+1}}\tilde{Q}_{2l+1}\right\}dk=\int_r^\infty k^{2n-1}\left\{\theta(k)-\sum_{l=1}^{n-1}\frac{(-1)^{l+1}}{(2k)^{2l+1}}Q_{2l+1}\right\}dk, \tag{4.12}$$

and the integral on the right-hand side of (4.12) converges absolutely if and only if

$$\frac{1}{k}\int_0^\infty \sin\left(2kx-\frac{1}{k}\int_0^x q(s)ds\right)q^{(N)}(x)dx\in L_1(r,\infty)$$

with some positive r. Plug (4.11) and (4.12) into (4.10) and the theorem is proved. □

Corollary 1: If $q\in L_2(0,\infty)$, $q',q''\in L_1(0,\infty)$, *and*

$$\frac{1}{k}\int_0^\infty \sin\left(2kx-\frac{1}{k}\int_0^x q(s)ds\right)q''(x)dx\in L_1(r,\infty),\quad r>0, \tag{4.13}$$

then

$$\sum_{l\geqslant 1}(-\lambda_l)^{3/2}+\frac{3}{\pi}\int_0^\infty\left\{k^2\ln A(k)-\frac{1}{4}q(0)\right\}dk=\frac{3}{8}q'(0)+\frac{3}{8}\int_0^\infty q^2(x)dx. \tag{4.14}$$

If also $q'''\in L_1(0,\infty)$ *and*

$$\frac{1}{k}\int_0^\infty \sin\left(2kx-\frac{1}{k}\int_0^x q(s)ds\right)q'''(x)dx\in L_1(r,\infty),\quad r>0, \tag{4.15}$$

then

$$\sum_{l=1}^{\infty}\lambda_l^2+\frac{4}{\pi}\int_0^\infty\left\{k^3\theta(k)-\frac{1}{8}\left(q'(0)+\int_0^\infty q^2(x)dx\right)\right\}dk=\frac{1}{8}q''(0)-\frac{1}{4}q^2(0). \tag{4.16}$$

Conditions (4.13) and (4.15) are necessary for absolute convergence of the integrals in (4.14) and (4.16), respectively.

Remark 4: It is easy to verify that the function η *defined by*

$$\eta(t)=\frac{1}{\pi}\int_0^t\left(\theta(k)+\frac{1}{2k}\int_0^\infty q(x)\cos 2kx\,dx\right)dk$$

is actually the modified spectral shift function [see (1.6) and Remark 3] and formula (4.16) transforms into (1.6). Relation (1.6) was previously proven in Ref. 20 by different methods under slightly stronger conditions on q. *Note that Corollary 1 gives optimal conditions on* q *for (1.6) to hold with the absolutely convergent integral. In the short-range setting necessary and sufficient conditions for absolute summability of trace relations are recently given in Ref. 18.*

Remark 5: When it comes to long-range potentials there is a certain flexibility in choosing the limiting phase θ. *With a proper choice of* θ *some of the formulas (4.4) may actually simplify.*

The scattering matrix for the Schrödinger operator with a long-range electromagnetic potential

Ph. Roux[a] and D. Yafaev[b]
Department of Mathematics, University of Rennes, Campus Beaulieu, 35042, Rennes, France

(Received 11 November 2002; accepted 17 March 2003)

We consider the Schrödinger operator $H=(i\nabla+A)^2+V$ in the space $L_2(\mathbb{R}^d)$ with long-range electrostatic $V(x)$ and magnetic $A(x)$ potentials. Using the scheme of smooth perturbations, we give an elementary proof of the existence and completeness of modified wave operators for the pair $H_0=-\Delta$, H. Our main goal is to study spectral properties of the corresponding scattering matrix $S(\lambda)$. We obtain its stationary representation and show that its singular part (up to compact terms) is a pseudodifferential operator with an oscillating amplitude which is an explicit function of V and A. Finally, we deduce from this result that, in general, for each $\lambda>0$ the spectrum of $S(\lambda)$ covers the whole unit circle. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1576494]

I. INTRODUCTION

Let the Schrödinger operator H be defined by differential expression

$$H=H(V,A)=(i\nabla+A(x))^2+V(x), \tag{1.1}$$

where the scalar function $V(x)$ and the vector-valued function $A(x)=(A_1(x),\ldots,A_d(x))$ are real valued and called the electrostatic and magnetic potentials, respectively. We assume that the potentials are C^∞-functions satisfying the assumption

$$|\partial_x^\alpha A(x)|+|\partial_x^\alpha V(x)|\leqslant C_\alpha(1+|x|)^{-\rho-|\alpha|},\quad \rho>0, \tag{1.2}$$

for all multi-indices α. Then H is a self-adjoint operator in the space $\mathcal{H}=L_2(\mathbb{R}^d)$ on domain $\mathcal{D}(H)=\mathcal{D}(H_0)$ of the "free" operator $H_0=-\Delta$. Our approach to the scattering theory for the pair H_0, H relies on wave operators with non-trivial identifications $J_\pm$ (depending on the sign of t)

$$W_\pm=W_\pm(H,H_0;J_\pm)=s-\lim_{t\to\pm\infty} e^{iHt}J_\pm e^{-iH_0t}. \tag{1.3}$$

We construct $J_\pm$ as pseudodifferential operators (PDO). Such wave operators were first introduced by Isozaki and Kitada in Ref. 3, where the Enss method was used for the proof of their existence and completeness (the method of Ref. 3 was extended to long-range magnetic potentials in Ref. 13). We show that the long-range scattering fits into the theory of smooth perturbations (in the sense of Kato). This yields, in particular, the stationary (in terms of the resolvent) representation for the corresponding scattering matrix $S(\lambda)$ which allows us to study its structure and spectral properties. Actually, we follow closely Ref. 20, where the case $\rho>1/2$ (and $A=0$) was considered. However consideration of the general case $\rho>0$ is technically much more involved.

The operators $J_\pm$ emerge naturally as PDO with symbols constructed in terms of approximate eigenfunctions $\Psi_\pm(x,\xi)=e^{i\varphi_\pm(x,\xi)}$ of the operator H. Substituting $\Psi=e^{i\varphi}$ in the Schrödinger equation $H\Psi=|\xi|^2\Psi$ and neglecting imaginary terms, we obtain the eikonal equation

[a]Electronic mail: rouxph@maths.univ-rennes1.fr
[b]Electronic mail: yafaev@univ-rennes1.fr

$$|\nabla\varphi|^2-2\langle A,\nabla\varphi\rangle+V(x)+|A(x)|^2-|\xi|^2=0,\quad \nabla=\nabla_x, \tag{1.4}$$

for the phase function $\varphi=\varphi_\pm$. We seek approximate solutions of this equation in the form

$$\varphi_\pm(x,\xi)=\langle\xi,x\rangle+\Phi_\pm(x,\xi) \tag{1.5}$$

where $\Phi_\pm(x,\xi)=o(|x|)$ as $|x|\to\infty$. Such solutions can be constructed by an explicit procedure described in Sec. IV. Then the Schrödinger equation for $\Psi_\pm=e^{i\varphi_\pm}$ is satisfied up to short-range terms (that is, satisfying an estimate of the type (1.2) with $\rho>1$) off any neighborhood of the direction $\hat{x}=\mp\hat{\xi}$. To get rid of the "bad" direction $\hat{x}=\mp\hat{\xi}$, we introduce in the symbol $j_\pm(x,\xi)$ suitable cutoff functions $\zeta_\pm(x,\xi)$, such that $\zeta_\pm$ are asymptotically homogeneous in x of degree 0, $\zeta_\pm(x,\xi)=0$ in a conical neighborhood (in $\mathbb{R}^{2d}$) of the set $\hat{x}=\mp\hat{\xi}$ and $\zeta_\pm(x,\xi)=1$ off somewhat larger neighborhood of this set. At the same time we localize our considerations on a compact energy subinterval of $\mathbb{R}_+=(0,\infty)$. The symbol of the PDO $J_\pm$ can be defined by the equality

$$j_\pm(x,\xi)=e^{i\Phi_\pm(x,\xi)}\zeta_\pm(x,\xi). \tag{1.6}$$

As in Ref. 20, from analytical point of view our approach relies on the limiting absorption principle and the radiation estimates. The first of these results means that the operator $\langle x\rangle^{-p}$, $p>1/2$, is locally H-smooth on any bounded interval disjoint from zero (see Definition 3.1). The second, pertaining to the critical case $p=1/2$, ensures local H-smoothness of the operators $G_j=\langle x\rangle^{-1/2}\nabla_j^\perp$, $j=1,\ldots,d$, where

$$\nabla_j^\perp u=\partial_j u-|x|^{-2}\langle\nabla u,x\rangle x_j,\quad j=1,\ldots,d. \tag{1.7}$$

Let $T_\pm=HJ_\pm-J_\pm H_0$ be the "effective perturbation." It follows from definition (1.6) that both operators $T=T_\pm$ factorize into a sum of products of locally H_0- and H-smooth operators

$$T=\langle x\rangle^{-p}B^{(r)}\langle x\rangle^{-p}+\sum_{j=1}^{d}G_j^*B^{(s)}G_j,\quad p>1/2, \tag{1.8}$$

where the operators $B^{(r)}=B_\pm^{(r)}$, $B^{(s)}=B_\pm^{(s)}$ are bounded. This implies the existence of all wave operators $W_\pm(H,H_0,J_\gamma)$, $W_\pm(H_0,H,J_\gamma^*)$, both for $\gamma=$"$+$" and $\gamma=$"$-$." The operators $W_\pm(H,H_0,J_\pm)$ are isometric since $J_\pm^*J_\pm e^{-iH_0t}f\sim e^{-iH_0t}f$ as $t\to\pm\infty$. For the proof of completeness of $W_\pm(H,H_0,J_\pm)$, we use that, for a suitable choice of the cut-off functions ζ_+ and ζ_-, the operator $J_+J_+^*+J_-J_-^*-I$ is essentially compact. Finally, we check that wave operators (1.3) coincide with wave operators obtained by a time-dependent modification of the free dynamics in the coordinate representation (see Ref. 22). In the special case where $V=0$ and A satisfies assumption (1.2) with $\rho>1/2$ and the additional condition of transversal gauge

$$\langle A(x),x\rangle=0 \tag{1.9}$$

(for $x\in\mathbb{R}^d$ large enough), the identifications $J_\pm$ can be replaced in (1.3) by the identity operator, that is the usual wave operators $W_\pm(H,H_0)$ exist. Thus, we recover the well known result[9] of Loss and Thaller about long-range magnetic scattering.

Since the scattering operator $\mathbf{S}=W_+^*W_-$ commutes with H_0, it reduces in the spectral representation of H_0 to the multiplication by the operator-function $S(\lambda)$, $\lambda>0$, acting in the space $\mathfrak{N}=L_2(\mathbb{S}^{d-1})$ and known as the scattering matrix (SM). Our study of $S(\lambda)$ relies on its stationary representation in terms of the resolvent $R(z)=(H-z)^{-1}$ of the operator H. To describe it, we need to introduce the auxiliary wave operator $W_+(H_0,H_0;J_+^*J_-)$. It commutes with H_0 and hence acts in the spectral representation of H_0 as multiplication by the operator-function $\mathcal{W}(\lambda):\mathfrak{N}\to\mathfrak{N}$. Then (see Refs. 4, 20, 22)

$$S(\lambda)=\mathcal{W}(\lambda)-2\pi i\Gamma_0(\lambda)(J_+^*T_--T_+^*R(\lambda+i0)T_-)\Gamma_0^*(\lambda), \tag{1.10}$$

where

$$(\Gamma_0(\lambda)f)(\omega)=2^{-1/2}k^{(d-2)/2}\hat{f}(k\omega),\quad k=\lambda^{1/2}>0,\ \ \omega\in\mathbb{S}^{d-1},\tag{1.11}$$

is, up to the numerical factor, the restriction of the Fourier transform $\hat{f}=\mathcal{F}f$ to the sphere of radius k. Formula (1.10) is actually of abstract nature and, roughly speaking, is valid always when its right-hand side is well defined.

In our particular case $\mathcal{W}(\lambda)=0$ for all $\lambda>0$. Then, using the resolvent estimates called usually propagation estimates (see Refs. 6, 7, 11), we show that the part of $S(\lambda)$ containing in (1.10) the resolvent of H is a compact operator. Thus, the essential spectrum of $S(\lambda)$ is determined by the explicit operator $-2\pi i\Gamma_0(\lambda)J_+^*T_-\Gamma_0^*(\lambda)$ which we consider as a PDO on the unit sphere. In the general case $\rho>0$ this PDO is determined by its amplitude $a(y,\omega,\omega';\lambda)$ where $\omega,\omega'\in\mathbb{S}^{d-1}$ are close to some point ω_0 and y belongs to the hyperplane orthogonal to ω_0. It turns out that, essentially, $a(y,\omega,\omega';\lambda)=\exp(i\theta(y,\omega,\omega';\lambda))$ where $\theta(y,\omega,\omega;\lambda)\to\infty$ as $|y|\to\infty$. Actually, the asymptotics of $\theta(y,\omega,\omega;\lambda)$ as $|y|\to\infty$ is determined by the asymptotics of $V(x)$ and $A(x)$ as $|x|\to\infty$. For homogeneous potentials of degree $-\rho$, $\rho\in(0,1)$, the function θ is asymptotically homogeneous of degree $1-\rho$ and it has, generically, a logarithmic growth if $\rho=1$. In particular, this implies[21] that the spectrum of the SM covers the whole unit circle $\mathbb{T}$. This situation is completely different from the short-range case where the principal symbol of PDO $S(\lambda)$ equals 1 which corresponds to the Dirac function in its kernel. In this case the spectrum of $S(\lambda)$ consists of eigenvalues accumulating at the point 1 only. Thus, in the long- and short-range cases the singularities and the spectral structure of $S(\lambda)$ are of qualitatively different nature.

A detailed analysis of singularities (as well as asymptotic expansion as $\lambda\to\infty$) of the SM $S(\lambda)$ can be found in Ref. 23 where a method, somewhat different from this paper, was used.

Technically, our paper relies on the PDO calculus. Thus, we treat the operators $J_\pm$ and $T_\pm$ as PDO. For any $\rho\in(0,1)$, they belong to the Hörmander classes $\mathcal{S}^0_{\rho,1-\rho}$ and $\mathcal{S}^{-1}_{\rho,1-\rho}$, respectively. In these classes a convenient PDO calculus can be developed for $\rho>1/2$ only. This creates new difficulties for potentials satisfying (1.2) for $\rho\in(0,1/2]$. Fortunately, the operators $J_\pm$ and $T_\pm$ fit into the framework of PDO with oscillating symbols developed in Ref. 21. Auxiliary results concerning PDO calculus are discussed in Sec. II.

II. PSEUDODIFFERENTIAL OPERATORS

2.1. We need some elementary facts about PDO defined by the equality

$$(Af)(x)=(2\pi)^{-d/2}\int_{\mathbb{R}^d}e^{i\langle\xi,x\rangle}a(x,\xi)\hat{f}(\xi)d\xi,\tag{2.1}$$

where

$$\hat{f}(\xi)=(\mathcal{F}f)(\xi)=(2\pi)^{-d/2}\int_{\mathbb{R}^d}e^{-i\langle\xi,x\rangle}f(x)dx$$

is the Fourier transform of f from the Schwartz class $\mathcal{S}=\mathcal{S}(\mathbb{R}^d)$. We denote by $\mathcal{S}^m_{\rho,\delta}$ the class of symbols $a\in C^\infty(\mathbb{R}^d\times\mathbb{R}^d)$ satisfying, for all multi-indices α and β, the estimates

$$|\partial_x^\alpha\partial_\xi^\beta a(x,\xi)|\leqslant C_{\alpha,\beta}(1+|x|)^{m-\rho|\alpha|+\delta|\beta|}.\tag{2.2}$$

Here and below C,c are different positive constants, whose precise values are of no importance. Moreover, we assume that $a(x,\xi)=0$ for sufficiently large $|\xi|$. We always suppose that $\rho>0$, $\delta<1$ and set $\mathcal{S}^m=\mathcal{S}^m_{1,0}$. The operators A and A^* are well defined as mappings of the Schwartz class $\mathcal{S}$ into itself. The calculus of PDO can be conveniently developed (see, e.g., Ref. 2 or Ref. 17) in the classes $\mathcal{S}^m_{\rho,\delta}$ if $\rho>1/2>\delta$, but it fails in the general case.

To treat the case $\rho\leqslant 1/2$, we need a more special class of PDO with oscillating symbols introduced in Ref. 21. Let us denote by $\mathcal{C}^m(\Phi)$ the class of symbols admitting the representation

$$a(x,\xi)=e^{i\Phi(x,\xi)}b(x,\xi),\quad \Phi\in\mathcal{S}^r,\quad b\in\mathcal{S}^m,\quad r\in[0,1). \tag{2.3}$$

Since $\mathcal{C}^m(\Phi)\subset\mathcal{S}^m_{1-r,r}$, only the case $r\geqslant 1/2$ requires a special study. Occasionally we use the notation $\mathcal{S}^m_{\rho,\delta}$ and $\mathcal{C}^m(\Phi)$ for PDO (2.1) with symbols from these classes. The operator of multiplication by $(1+|x|^2)^{1/2}$ is denoted by $\langle x\rangle$.

Let us collect a necessary information on the calculus of PDO. Note that compared to the standard definition of PDO the roles of the variables x and ξ in (2.1) are interchanged. However, the operator $\mathcal{F}A^*\mathcal{F}^*$ satisfies the usual assumptions. This allows us to recover all results of PDO theory for operators (2.1). We start with an elementary assertion, which can be proven by the standard technique (see, e.g., Ref. 2 or Ref. 17).

Proposition 2.1: Suppose that $a_1\in\mathcal{C}^{m_1}(\Phi)$ *for some* $\Phi\in\mathcal{S}^r$, $r\in[0,1)$, $a_2\in\mathcal{S}^{m_2}$ *and* $a_0(x,\xi)=a_1(x,\xi)a_2(x,\xi)$. *Let* A_j *be the PDO with symbol* a_j, $j=0,1,2$. *Then* A_1A_2 *and* A_2A_1 *are PDO from the class* $\mathcal{C}^m(\Phi)$ *where* $m=m_1+m_2$ *and the PDO* $A_1A_2-A_0$ *and* $A_2A_1-A_0$ *belong to the class* $\mathcal{C}^{m+r-1}(\Phi)$.

The following two assertions are borrowed directly from Ref. 21.

Proposition 2.2: Let $A\in\mathcal{C}^m(\Phi)$. *Then the operator* A *is bounded in the space* $L_2(\mathbb{R}^d)$ *if* $m=0$, *and it is compact if* $m<0$.

Proposition 2.3: Let A_j, $j=1,2$, *be PDO with symbols* $a_j\in\mathcal{C}^0(\Phi)$ *and let* A *be the PDO with symbol* $a_1(x,\xi)a_2(x,\xi)$. *Then both operators* $A-A_1A_2^*$ *and* $A-A_2^*A_1$ *are compact in the space* $L_2(\mathbb{R}^d)$.

To formulate further results on PDO, we need the following technical lemma.

Lemma 2.4: Let $\Omega_0\in C_0^\infty(\mathbb{R}^d)$, $\Omega_0(\xi)=1$ *for* $|\xi|\leqslant R_0-1$ *and* $\Omega_0(\xi)=0$ *for* $|\xi|\geqslant R_0$ *(for some* $R_0>1$*). Let* $\Omega_1\in C^\infty(\mathbb{R}^d)$, $\Omega_1(\xi)=0$ *for* $|\xi|\leqslant R_1$ *and* $\Omega_1(\xi)=1$ *for* $|\xi|\geqslant R_1+1$. *Assume that* $R_1>R_0$. *We denote by* Ω_j, $j=0,1$, *the multiplication operators (in the momentum representation) by the functions* $\Omega_j(\xi)$. *Let* g *be the multiplication operator by a function* $g\in C^\infty(\mathbb{R}^d)$ *such that* $\partial^\alpha g(x)=O(|x|^{n-|\alpha|})$ *as* $|x|\to\infty$ *for some* n *and all* α. *Then the operator* $\Omega_0g\Omega_1=\Omega_0g_0\Omega_1$ *where* $g_0\in\mathcal{S}$.

Proof: In the momentum representation g acts as the convolution with the function $\hat g(\xi)$ where $\hat g\in C^\infty$ except the point zero and decays at infinity, together with all its derivatives, faster that any power of $|\xi|^{-1}$. Therefore $\Omega_0g\Omega_1$ is the integral operator with kernel

$$(2\pi)^{-d/2}\Omega_0(\xi)\hat g(\xi-\xi')\Omega_1(\xi'), \tag{2.4}$$

which equals 0 if $|\xi-\xi'|\leqslant R_1-R_0$. Let $\omega\in C^\infty(\mathbb{R}^d)$, $\omega(\xi)=0$ for $|\xi|\leqslant(R_1-R_0)/2$ and $\omega(\xi)=1$ for $|\xi|\geqslant R_1-R_0$. Then kernel (2.4) is not changed if we replace $\hat g(\xi-\xi')$ by $\hat g_0(\xi-\xi')$ where $\hat g_0(\xi)=\hat g(\xi)\omega(\xi)$ belongs to $\mathcal{S}$. □

Lemma 2.5: Let A *be a PDO with symbol* a *from the class* $\mathcal{S}^m_{\rho,\delta}$ *where* $\rho>0$, $\delta<1$ *and* m *are arbitrary and* $a(x,\xi)=0$ *if* $|\xi|\geqslant R$. *Let* g *and* Ω_1 *be the same as in Lemma 2.4 and* $R_1>R$. *Then for any* p *the operator* $Ag\Omega_1\langle x\rangle^p$ *is bounded in* $L_2(\mathbb{R}^d)$.

Proof: Assuming that p is an even integer and commuting the operators Ω_1 and $\langle x\rangle^p$, we reduce the problem to the case $p=0$. Let Ω_0 be the same as in Lemma 2.4 with $R_0\in(R,R_1)$. Then $Ag\Omega_1=A\Omega_0g\Omega_1$, so that, by Lemma 2.4, we may suppose that $g\in\mathcal{S}$. In the coordinate representation, the operator Ag has kernel

$$(2\pi)^{-d}\int_{\mathbb{R}^d}e^{i\langle\xi,x-x'\rangle}a(x,\xi)d\xi\,g(x'). \tag{2.5}$$

Using the formula $\langle x\rangle^{-k}\langle D_\xi\rangle^k e^{i\langle\xi,x\rangle}=e^{i\langle\xi,x\rangle}$ and integrating by parts, we estimate the kernel (2.5) by $\langle x\rangle^{m-(1-\delta)k}\langle x'\rangle^k|g(x')|$. For sufficiently large k, both functions of x and x' belong to $L_2(\mathbb{R}^d)$, and hence the operator Ag belongs to the Hilbert–Schmidt class. □

Now it easy to check the following two assertions.

Proposition 2.6: Let $A\in\mathcal{C}^m(\Phi)$ for some m. Then the operator $A\langle x\rangle^{-m}$ is bounded in the space $L_2(\mathbb{R}^d)$.

Proof: Assume that $a(x,\xi)=0$ for $|\xi|\geqslant R$. Let Ω_1 be the same operator as in Lemma 2.4 with $R_1>R$ and $\Omega_2=I-\Omega_1$. Clearly, $\langle x\rangle^{-m}\Omega_2$ is a PDO from the class $\mathcal{S}^{-m}$. Therefore, by Proposition 2.1, the PDO $A(\langle x\rangle^{-m}\Omega_2)$ belongs to the class $\mathcal{C}^0(\Phi)$ and hence, by Proposition 2.2, it is bounded. The operator $A\langle x\rangle^{-m}\Omega_1$ is bounded according to Lemma 2.5. □

Proposition 2.7: Suppose that A is a PDO with symbol $a\in\mathcal{C}^m(\Phi)$, for some $\Phi\in\mathcal{S}^r$ with $r\in[0,1)$, and G is a PDO (actually, a differential operator) with symbol $g(x,\xi)=\Sigma_{|s|\leqslant s_0}g_s(x)\xi^s$, where $g_s\in C^\infty(\mathbb{R}^d)$ and $\partial^\alpha g_s(x)=O(|x|^{n-|\alpha|})$ as $|x|\to\infty$ for some n and all α. Let T be the PDO with symbol $t(x,\xi)=|g(x,\xi)|^2a(x,\xi)$. Then the operator $\langle x\rangle^p(G^*AG-T)\times\langle x\rangle^p$ is bounded if $2p=-m-2n+1-r$.

Proof: Let $a_1(x,\xi)$ be the symbol of the PDO $A_1=G^*A$. By direct calculation we show that

$$a_1(x,\xi)-\overline{g(x,\xi)}a(x,\xi)\in C^{m+n+r-1}(\Phi).$$

Assuming that $a(x,\xi)=0$ for $|\xi|\geqslant R$, we introduce the same operators Ω_1,Ω_2 as in Proposition 2.6. Proposition 2.1 implies that, up to terms from the class $C^{m+2n+r-1}(\Phi)$, the operator $A_1G\Omega_2$ has symbol $t(x,\xi)$. Therefore the operator $\langle x\rangle^p(G^*AG\Omega_2-T)\langle x\rangle^p$ is bounded by Proposition 2.6. It remains to take into account that the operator $\langle x\rangle^pA_1G\Omega_1\langle x\rangle^p$ is bounded for any p according to Lemma 2.5. □

For the study of the SM we need to consider PDO defined by their amplitudes. We define such operators in terms of the corresponding sesquilinear forms on $\mathcal{S}\times\mathcal{S}$,

$$(\mathbf{A}f_1,f_2)=(2\pi)^{-d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}e^{i\langle\xi'-\xi,x\rangle}\mathbf{a}(x,\xi,\xi')\hat{f}_1(\xi')\overline{\hat{f}_2(\xi)}\,dx\,d\xi d\xi'. \tag{2.6}$$

We suppose that the amplitude $\mathbf{a}(x,\xi,\xi')$ belongs to the class $\mathcal{S}^m_{\rho,\delta,\delta}$ defined quite similarly to $\mathcal{S}^m_{\rho,\delta}$ with ξ replaced by (ξ,ξ') in (2.2) and that $\mathbf{a}(x,\xi,\xi')$ is compactly supported in ξ and ξ'. Again we denote $\mathcal{S}^m=\mathcal{S}^m_{1,0,0}$.

Let us consider [cf. (2.3)] a special class $\mathcal{C}^m(\Theta)$ of amplitudes admitting the representation

$$\mathbf{a}(x,\xi,\xi')=e^{i\Theta(x,\xi,\xi')}\mathbf{b}(x,\xi,\xi'),\quad \Theta\in\mathcal{S}^r,\quad r\in[0,1),\quad \mathbf{b}\in\mathcal{S}^m. \tag{2.7}$$

Such operators reduce to PDO with oscillating symbols.

Proposition 2.8: Let $\mathbf{A}$ be defined by (2.6) with amplitude (2.7). Then $\mathbf{A}=A$ where A is a PDO (2.1) with symbol (2.3) and

$$\Phi(x,\xi)=\Theta(x,\xi,\xi)+\Theta_1(x,\xi),\quad \Theta_1\in\mathcal{S}^{2r-1},$$

$$b(x,\xi)=\mathbf{b}(x,\xi,\xi)+b_1(x,\xi),\quad b_1\in\mathcal{S}^{m+r-1}.$$

In particular, if $\mathbf{b}(x,\xi,\xi)=0$, then A belongs to the class $\mathcal{C}^{m+r-1}(\Phi)$.

This result (its proof can be found in Ref. 21) allows us to extend Propositions 2.2 and 2.6 to operators $\mathbf{A}$ defined by (2.6).

Proposition 2.9: Let $\mathbf{A}\in\mathcal{C}^m(\Theta)$. Then the operator $\mathbf{A}$ is bounded in the space $L_2(\mathbb{R}^d)$ if $m=0$, and it is compact if $m<0$. Moreover, the operator $\mathbf{A}\langle x\rangle^{-m}$ is also bounded.

2.2. The spectral representation of $H_0=-\Delta$ can be constructed in terms of the operator $\Gamma_0(\lambda)$ defined by (1.11). Let $\mathfrak{N}=L_2(\mathbb{S}^{d-1})$ and $(\mathcal{U}f)(\lambda)=\Gamma_0(\lambda)f$, $f\in\mathcal{S}(\mathbb{R}^d)$, $\lambda>0$. Then the operator $\mathcal{U}$ extends by continuity to a unitary operator $\mathcal{U}:L_2(\mathbb{R}^d)\to L_2(\mathbb{R}_+;\mathfrak{N})$, and the operator H_0 is diagonalized by $\mathcal{U}$, that is $(\mathcal{U}H_0f)(\lambda)=\lambda(\mathcal{U}f)(\lambda)$ for $f\in\mathcal{D}(H_0)$.

The operator $\Gamma_0(\lambda)$ is directly related to the spectral family $E_0(\lambda)$ of the operator H_0 and to its resolvent $R_0(z)=(H_0-z)^{-1}$. Set

$$\delta_\varepsilon(H_0-\lambda)=(2\pi i)^{-1}(R_0(\lambda+i\varepsilon)-R_0(\lambda-i\varepsilon)).$$

For any $f_1, f_2 \in \mathcal{S}$ the limit and the derivative below exist and satisfy (see, e.g., Ref. 19)

$$\lim_{\varepsilon \to 0} (\delta_\varepsilon(H_0 - \lambda) f_1, f_2) = \mathrm{d}(E_0(\lambda) f_1, f_2)/\mathrm{d}\lambda = (\Gamma_0(\lambda) f_1, \Gamma_0(\lambda) f_2)_{\mathfrak{N}}.$$

We recall the Sobolev trace theorem.

Proposition 2.10: For $p > 1/2$ the operator-function $\Gamma_0(\lambda)\langle x\rangle^{-p} : \mathcal{H} \to \mathfrak{N}$ is compact and Hölder continuous in norm with respect to the parameter $\lambda > 0$.

For construction of the SM, we have to give a precise definition of the operator $\mathbf{A}^\flat(\lambda) := \Gamma_0(\lambda)\mathbf{A}\Gamma_0^*(\lambda)$ appearing in (1.10) which imposes rather stringent conditions on $\mathbf{A}$. Practically we consider only PDO $\mathbf{A}$ defined by (2.6), although the definition below is of abstract nature. Note that, for a PDO $\mathbf{A}$, the operator $\mathbf{A}^\flat(\lambda)$ is also defined as a PDO on the unit sphere $\mathbb{S}^{\mathrm{d}-1}$. It is convenient to define the operator $\mathbf{A}^\flat(\lambda)$ in terms of its sesquilinear form $(\mathbf{A}^\flat(\lambda) g_1, g_2)$.

Definition 2.11: Let $g_1, g_2 \in C^\infty(\mathbb{S}^{\mathrm{d}-1})$, and let $\psi_1, \psi_2 \in C_0^\infty(\mathbb{R}_+)$ be such that $\psi_1(k) = \psi_2(k) = 1$. Set $\hat{f}_j(\xi) = g_j(\hat{\xi})\psi_j(|\xi|)$, $j = 1,2$. Then

$$(\mathbf{A}^\flat(\lambda) g_1, g_2)_{\mathfrak{N}} := 2k^{2-d} \lim_{\varepsilon \to 0} (\mathbf{A}\delta_\varepsilon(H_0 - \lambda) f_1, \delta_\varepsilon(H_0 - \lambda) f_2), \tag{2.8}$$

provided this limit exists for all $g_1, g_2 \in C^\infty(\mathbb{S}^{d-1})$.

By definition (1.11), if $g \in C^\infty(\mathbb{S}^{d-1})$, $\psi \in C_0^\infty(\mathbb{R}_+)$ and $\hat{f}(\xi) = g(\hat{\xi})\psi(|\xi|)$, then

$$(\Gamma_0(\lambda) f)(\omega) = 2^{-1/2} k^{(d-2)/2} \psi(k) g(\omega), \quad k = \lambda^{1/2}.$$

The operator $\Gamma_0^*(\lambda)$ formally adjoint to $\Gamma_0(\lambda)$ is defined, e.g., for $g \in C^\infty(\mathbb{S}^{d-1})$ by the equality

$$(\Gamma_0^*(\lambda) g)(x) = 2^{-1/2} k^{(\mathrm{d}-2)/2} (2\pi)^{-\mathrm{d}/2} \int_{\mathbb{S}^{\mathrm{d}-1}} e^{ik\langle \omega, x\rangle} g(\omega)\, \mathrm{d}\omega, \quad k = \lambda^{1/2} > 0. \tag{2.9}$$

Therefore Definition 2.11 gives an exact meaning to the formal expression $\Gamma_0(\lambda)\mathbf{A}\Gamma_0^*(\lambda)$.

If $B = \mathcal{F}\mathbf{A}\mathcal{F}^*$ is an integral operator with kernel $B(\xi, \xi')$ which is continuous near the surface $|\xi| = |\xi'| = k$, then, by (1.11) and (2.9), $\mathbf{A}^\flat(\lambda)$ is also an integral operator with kernel

$$b(\omega, \omega'; \lambda) = 2^{-1} k^{\mathrm{d}-2} B(k\omega, k\omega').$$

If $\mathbf{A}$ is a PDO (2.6) with amplitude $\mathbf{a} \in \mathcal{S}^m_{\rho,\delta,\delta}$, then the kernel

$$B(\xi, \xi') = (2\pi)^{-\mathrm{d}} \int_{\mathbb{R}^{\mathrm{d}}} e^{i\langle \xi' - \xi, x\rangle} \mathbf{a}(x, \xi, \xi')\, \mathrm{d}x$$

(understood as an oscillatory integral) of the operator $B = \mathcal{F}\mathbf{A}\mathcal{F}^*$ is well defined and infinitely differentiable off the diagonal $\xi = \xi'$.

Thus, we have the following obvious assertion.

Proposition 2.12: Let $\mathbf{a} \in \mathcal{S}^m_{\rho,\delta,\delta}$ for some $\rho > 0$, $\delta < 1$, and let χ_1 and χ_2 be multiplication operators by $C^\infty(\mathbb{S}^{\mathrm{d}-1})$-functions with disjoint supports. Then $(\chi_1 \mathbf{A} \chi_2)^\flat(\lambda)$ is an integral operator with C^∞-kernel of variables ω, ω' (and $\lambda > 0$).

However due to a possible strong singularity of the function $B(\xi, \xi')$ at $\xi = \xi'$, the operator $\mathbf{A}^\flat(\lambda)$ exists only under special assumptions on $\mathbf{a}(x, \xi, \xi')$. In the case $\mathbf{a} \in \mathcal{C}^m(\Theta)$, $m < -1$, the diagonal singularity of $B(\xi, \xi')$ is weak, so no additional restrictions are required.

Proposition 2.13: Let $\mathbf{A}$ belong to the class $\mathcal{C}^m(\Theta)$ where $m < -1$. Then $\mathbf{A}^\flat(\lambda)$ is well defined for all $\lambda > 0$ and is a compact operator in $\mathfrak{N}$. Moreover, $\mathbf{A}^\flat(\lambda)$ depends norm continuously on λ.

Proof: Indeed,

$$\mathbf{A}^\flat(\lambda) = (\Gamma_0(\lambda)\langle x\rangle^{-p})(\langle x\rangle^p \mathbf{A} \langle x\rangle^p)(\langle x\rangle^{-p} \Gamma_0^*(\lambda)), \quad p = m/2.$$

Since $p>1/2$, Proposition 2.10 applies to the first and third factors. The second factor is bounded in $\mathcal{H}$ by Proposition 2.9. □

Let us now consider the general case $\mathbf{a}\in\mathcal{S}^m_{\rho,\delta,\delta}$ where m is arbitrary. It turns out (see Refs. 8 and 21) that for $m\geqslant -1$ the operator $\mathbf{A}^\flat(\lambda)$ exists if $\mathbf{a}(x,\xi,\xi')=0$ for (x,ξ) belonging to a neighborhood of the conormal bundle of the sphere $|\xi|=k$ and ξ' close to ξ. In view of Proposition 2.12, we may suppose that ξ and ξ' are close to each other or, to put it differently, we can take in Definition 2.11 functions g_1 and g_2 supported in a neighborhood of the same point $\omega_0\in\mathbb{S}^{d-1}$. Let Π_{ω_0} be the hyperplane orthogonal to ω_0, and let $\Omega=\Omega(\omega_0,\gamma)\subset\mathbb{S}^{d-1}$ be determined by the condition $\langle\omega,\omega_0\rangle>\gamma>0$. The number γ can be chosen arbitrary close to 1. We denote by $\zeta=\varkappa(\omega)$ the orthogonal projection of ω on Π_{ω_0}; in particular, we assume that $\varkappa(\omega_0)=0$. We denote by Σ the orthogonal projection of Ω on the hyperplane Π_{ω_0} and identify points $\omega\in\Omega$ and $\zeta=\varkappa(\omega)$. The hyperplane Π_{ω_0} can be identified with $\mathbb{R}^{d-1}$. Let us also consider the unitary mapping $Z=Z_\varkappa: L_2(\Omega)\to L_2(\Sigma)$ defined by

$$(Zu)(\zeta)=(1-|\zeta|^2)^{-1/4}u(\omega),\quad \zeta=\varkappa(\omega). \tag{2.10}$$

The next result (borrowed from Ref. 21) gives conditions of the existence of the operator $\mathbf{A}^\flat(\lambda)$.

Proposition 2.14: Let $\mathbf{a}\in\mathcal{S}^m_{\rho,\delta,\delta}$ *for some* $\rho>0$, $\delta<1$ *with* $\rho+\delta\leqslant 1$. *Suppose that there exists* $\varepsilon>0$ *such that* $\mathbf{a}(x,\xi,\xi')=0$ *if the following two estimates*

$$|\xi-\xi'|<\varepsilon,\quad |\langle\hat{x},\hat{\xi}\rangle|>1-\varepsilon \tag{2.11}$$

are satisfied. Then the operator $\mathbf{A}^\flat(\lambda)$ *is well-defined in the sense of Definition 2.11 for all* $\lambda>0$. *Moreover, the operator* $\mathbf{A}^\flat_\varkappa(\lambda)=Z_\varkappa\mathbf{A}^\flat(\lambda)Z_\varkappa^*$ *is the PDO with sesquilinear form*

$$(\mathbf{A}^\flat_\varkappa(\lambda)u_1,u_2)=(2\pi)^{-d+1}\int_{\mathbb{R}^{d-1}}\int_\Sigma\int_\Sigma e^{i\langle\zeta-\zeta',y\rangle}\mathbf{a}^\flat_\varkappa(y,\zeta,\zeta';\lambda)u_1(\zeta')\overline{u_2(\zeta)}\,d\zeta\,d\zeta'\,dy \tag{2.12}$$

for all $u_1,u_2\in\mathcal{C}_0^\infty(\Sigma)$. *The amplitude* $\mathbf{a}^\flat_\varkappa\in\mathcal{S}^{m+1}_{\rho,\delta,\delta}(\mathbb{R}^{d-1}\times\Sigma\times\Sigma)$ *is given by the formula*

$$\mathbf{a}^\flat_\varkappa(y,\zeta,\zeta';\lambda)=(2\pi k)^{-1}\alpha(\zeta,\zeta')\int_{-\infty}^{\infty}\mathbf{a}((\omega+\omega')z-y/k,k\omega,k\omega')\,dz \tag{2.13}$$

[this integral is taken over a finite interval due to condition (2.11)], where $k=\lambda^{1/2}$, $\zeta=\varkappa(\omega)$, $\zeta'=\varkappa(\omega')$, *and*

$$\alpha(\zeta,\zeta')=2^{-1}\left(\left(\frac{1-|\zeta|^2}{1-|\zeta'|^2}\right)^{1/4}+\left(\frac{1-|\zeta'|^2}{1-|\zeta|^2}\right)^{1/4}\right). \tag{2.14}$$

Consequently, (2.12) is a smooth function of $\lambda>0$ *for all* $u_1,u_2\in\mathcal{C}_0^\infty(\Sigma)$.

Definition 2.15: The function $\mathbf{a}^\flat_\varkappa(y,\zeta,\zeta';\lambda)$ *is called the amplitude of the operator* $\mathbf{A}^\flat(\lambda)$ *in the chart coordinates* $(\omega_0,\varkappa)$.

We emphasize that, from the point of view of PDO theory, in the formula (2.12) ζ plays the role of the space variable and y is the dual one.

A spectral information on PDO with oscillating amplitudes is given in the following assertion (see Ref. 21).

Proposition 2.16: Let $\mathbf{A}: C_0^\infty(\Sigma)\to C^\infty(\Sigma)$, $\Sigma\subset\mathbb{R}^{d-1}$, *be a PDO with amplitude*

$$\mathbf{a}(y,\zeta,\zeta')=e^{i\Theta(y,\zeta,\zeta')}\mathbf{b}(y,\zeta,\zeta'), \tag{2.15}$$

where $\Theta\in\mathcal{S}^r$, $r\in(0,1)$, $\mathbf{b}\in\mathcal{S}^0$. *Suppose that for some points* $y_0\neq 0,\zeta_0\in\Sigma$,

$$|\Theta(\tau y_0,\zeta_0,\zeta_0)|\geqslant c\tau^r, \quad |\nabla_y\Theta(\tau y_0,\zeta_0,\zeta_0)|\geqslant c\tau^{r-1}, \quad c>0, \tag{2.16}$$

for sufficiently large $\tau>0$ *and that*

$$\lim_{\tau\to\infty}\mathbf{b}(\tau y_0,\zeta_0,\zeta_0)=1. \tag{2.17}$$

Then for each $\mu\in\mathbb{T}$ *and arbitrary small neighborhood* Σ_0 *of* ζ_0 *there exists a (Weyl) sequence of functions* $u_n\in C_0^\infty(\Sigma_0)$ *such that*

$$\|u_n\|=1, \quad w-\lim_{n\to\infty}u_n=0, \quad \lim_{n\to\infty}\|\mathbf{A}u_n-\mu u_n\|=0.$$

In particular, the essential spectrum of the operator $\mathbf{A}$ *in the space* $L_2(\Sigma)$ *covers the unit circle* $\mathbb{T}$.

Remark 2.17: A simple version of Proposition 2.16 was proven and used in Ref. 20. Namely, let $\mathbf{a}\in\mathcal{S}^0_{\rho,\delta,\delta}$ with $\rho>1/2>\delta$, and let representation (2.15) hold. Then the conclusion of Proposition 2.16 remains true if, for some $y_0\neq 0,\zeta_0\in\Sigma$, the condition (2.17) is satisfied and

$$\limsup_{\tau\to\infty}\Theta(\tau y_0,\zeta_0,\zeta_0)=\infty \quad \text{or} \quad \liminf_{\tau\to\infty}\Theta(\tau y_0,\zeta_0,\zeta_0)=-\infty. \tag{2.18}$$

III. LIMITING ABSORPTION PRINCIPLE AND RADIATIONS ESTIMATES

3.1. Let us recall some basic notions of the theory of smooth perturbations (see, e.g., Refs. 15 and 19).

Definition 3.1: Let H *be a self-adjoint operator in a Hilbert space* $\mathcal{H}$, $R(z)=(H-z)^{-1}$ *be the resolvent of* H *and* K *be an* H*-bounded operator. The operator* K *is called* H*-smooth (in the sense of Kato) if one of the two equivalent conditions is satisfied*

$$\sup_{f\in\mathcal{D}(\mathcal{H}),\|f\|=1}\int_{-\infty}^{\infty}\|Ke^{-itH}f\|^2\,dt<\infty, \tag{3.1}$$

$$\sup_{\lambda\in\mathbb{R},\varepsilon>0}\|K(R(\lambda+i\varepsilon)-R(\lambda-i\varepsilon))K^*\|<\infty. \tag{3.2}$$

The following definition is essentially more flexible.

Definition 3.2: Let $E(\cdot)$ *be the spectral measure of* H. *Suppose that, for an* H*-bounded operator* K, *and intervals* Λ_n *such that* $\mathbb{R}\setminus\cup_{n=1}^\infty\Lambda_n$ *has the Lebesgue measure zero, the operators* $KE(\Lambda_n)$ *are* H*-smooth. Then we say that* K *is locally* H*-smooth*.

Note that condition (3.2), satisfied for $\lambda\in\Lambda$ only, implies that the operator $KE(\Lambda)$ is H-smooth.

The theory of H-smooth perturbations gives a sufficient condition for the existence of wave operators [which can easily be obtained from (3.1)].

Proposition 3.3: Let H_0, H *be a couple of self-adjoint operators, and let* J *be a bounded operator. Suppose that* $T=HJ-JH_0$ *admits the factorization*

$$T=\sum_{j=1}^{N}K_j^*K_{0,j},$$

where all operators $K_{0,j}$ *are locally* H_0*-smooth and* K_j *are locally* H*-smooth. Denote by* P_0 *and* P *the orthogonal projections on the absolutely continuous subspaces of the operators* H_0 *and* H, *respectively. Then the wave operators*

$$W_\pm(H,H_0;J)=s-\lim_{t\to\pm\infty}e^{itH}J^*e^{-itH_0}P_0$$

and

$$W_{\pm}(H_0,H;J^*)=s-\lim_{t\to\pm\infty} e^{iH_0t}J^*e^{-iHt}P$$

exist.

Note, finally, that for an arbitrary self-adjoint operator H and a compact operator K,

$$s-\lim_{|t|\to\infty} Ke^{-iHt}P=0. \tag{3.3}$$

3.2. Let us return to the Schrödinger operator (1.1). Recall first of all that, although it is really unimportant for our results, under assumption (1.2) the operator H does not have positive eigenvalues (see Refs. 5 and 18 where the proof of Ref. 15 was extended to magnetic potentials). The following well-known result (the limiting absorption principle; see Refs. 1, 10, and 14) can be easily obtained by the Mourre method.

Proposition 3.4: Let assumption (1.2) hold, and let $p>1/2$. *Then the operator function* $\langle x\rangle^{-p}R(z)\langle x\rangle^{-p}$ *is continuous in norm with respect to the parameter* z *in the closed complex plane cut along* $[0,\infty)$ *with exception of the point 0. In particular, the operator* $\langle x\rangle^{-p}E(\Lambda)$ *is* H*-smooth for any compact interval* $\Lambda\subset(0,\infty)$. *The positive spectrum of* H *is absolutely continuous*.

The following resolvent estimates borrowed from Ref. 22 are called radiation estimates.

Proposition 3.5: Let assumption (1.2) hold, and let the operators $\nabla_j^{\perp}$ *be defined by (1.7). Set* $G_j=\langle x\rangle^{-1/2}\nabla_j^{\perp}$. *Then for all* $j=1,\ldots,\mathrm{d}$ *the operators* $G_jE(\Lambda)$ *are* H*-smooth for any compact interval* $\Lambda\subset(0,\infty)$.

Propositions 3.4 and 3.5 are sufficient for the proof of existence and completeness of wave operators. However, our study of the SM requires additional resolvent estimates called usually propagation estimates.

Proposition 3.6: Let assumption (1.2) be fulfilled. Let $Q_{\pm}$ *be the PDO with symbol* $q_{\pm}(x,\xi)\in\mathcal{C}^m(\Phi_{\pm})$ *for some* $\Phi_{\pm}\in\mathcal{S}^r$ *with* $r\in[0,1)$. *Suppose that* $q_{\pm}(x,\xi)=0$ *for* $|\xi|\leqslant\varepsilon$, $|x|\leqslant\varepsilon$ *and that the support of* $q_{\pm}(x,\xi)$ *is contained in the cone*

$$\mp\langle\hat{\xi},\hat{x}\rangle\geqslant\varepsilon,\quad \hat{\xi}=\xi/|\xi|,\quad \hat{x}=x/|x|,$$

for some $\varepsilon\in(0,1)$. *Then the operator-functions*

$$\langle x\rangle^{p-\sigma}Q_+^*R(z)\langle x\rangle^{-p},\quad \langle x\rangle^{-p}R(z)Q_-\langle x\rangle^{p-\sigma},\quad p>1/2,\quad \sigma>m+1,$$

are bounded and continuous in norm with respect to the parameter z *in the region* $\mathrm{Re}\,z\in(\lambda_0,\infty)$, $\lambda_0>0$, $\mathrm{Im}\,z\geqslant0$.

Proposition 3.7: Under the assumptions of Proposition 3.6 the operator function

$$\langle x\rangle^{l}Q_+^*R(z)Q_-\langle x\rangle^{l},\quad \forall l,$$

is bounded and continuous in norm with respect to the parameter z *in the region* $\mathrm{Re}\,z\in(\lambda_0,\infty)$, $\lambda_0>0$, $\mathrm{Im}\,z\geqslant0$.

These two assertions were proven in Refs. 6, 7, and 11 for PDO $Q_{\pm}\in\mathcal{S}^m$. In the case $Q_{\pm}\in\mathcal{C}^m(\Phi_{\pm})$ the proofs are quite similar. In particular, they rely on the Mourre estimate.[10]

IV. THE EIKONAL EQUATION

In this section our goal is to construct approximate eigenfunctions of the Schrödinger operator with long-range electric and magnetic potentials. It is natural to seek these eigenfunctions in the form $\Psi=e^{i\varphi}$ with a real function φ. A simple calculation shows that

$$((i\nabla+A)^2+V-|\xi|^2)\Psi=e^{i\varphi}(|\nabla\varphi|^2-2\langle A,\nabla\varphi\rangle-i\Delta\varphi+V+|A|^2+i\,\mathrm{div}\,A-|\xi|^2), \quad (4.1)$$

where $\nabla=\nabla_x$. Neglecting here the imaginary terms, which turn out to be short-range, we see that the Schrödinger equation reduces to the eikonal equation (1.4) for $\varphi=\varphi_\pm$. Considering this equation, we always remove a conical neighborhood of the direction $\hat{x}=\mp\hat{\xi}$ and require that its right-hand side be short-range (not necessarily zero). We assume that $\varphi_\pm$ has the form (1.5) where $\Phi_\pm=o(|x|)$ as $|x|\to\infty$. Then Eq. (1.4) for $\varphi_\pm$ yields the equation

$$2\langle\xi,\nabla\Phi_\pm(x,\xi)\rangle+|\nabla\Phi_\pm(x,\xi)|^2-2\langle A(x),\xi+\nabla\Phi_\pm(x,\xi)\rangle+V(x)+|A(x)|^2=q_\pm(x,\xi) \quad (4.2)$$

for $\Phi_\pm$ with a short-range term $q_\pm$. Thus, according to (4.1),

$$((i\nabla+A)^2+V-|\xi|^2)(e^{i\varphi_\pm})=e^{i\varphi_\pm}\mathrm{q}_\pm, \quad (4.3)$$

where

$$\mathrm{q}_\pm=q_\pm+i\,\mathrm{div}\,A-i\Delta\Phi_\pm \quad (4.4)$$

is again a short-range term.

Equation (4.2) can be easily solved by iterations. Let us first consider an auxiliary linear equation

$$\langle\xi,\nabla\phi(x,\xi)\rangle+F(x,\xi)=0. \quad (4.5)$$

All estimates below are uniform in ξ if $\lambda_0\leqslant|\xi|\leqslant\lambda_1$ for some $0<\lambda_0<\lambda_1<\infty$.

Lemma 4.1: Suppose that $F=F_\pm$ satisfies for all multi-indices α,β the estimates

$$|\partial_x^\alpha\partial_\xi^\beta F_\pm(x,\xi)|\leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{-\rho-|\alpha|}, \quad \pm\langle\hat{x},\hat{\xi}\rangle\geqslant\kappa,$$

for some $\rho\in(0,1)$ and any $\kappa>-1$. Then the function

$$\phi_\pm(x,\xi)=\pm\int_0^\infty(F_\pm(x\pm t\xi,\xi)-F_\pm(\pm t\xi,\xi))\,\mathrm{d}t \quad (4.6)$$

is a solution of equation (4.5) which satisfies for all α,β and $\kappa>-1$ the estimates

$$|\partial_x^\alpha\partial_\xi^\beta\phi_\pm(x,\xi)|\leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{1-\rho-|\alpha|}, \quad \pm\langle\hat{x},\hat{\xi}\rangle\geqslant\kappa.$$

The proof can be obtained by a direct differentiation of (4.6), see Ref. 20 for details.

Let us seek $\Phi_\pm=\Phi_\pm^{(N)}$ in the form

$$\Phi_\pm(x,\xi)=\sum_{n=1}^{N}\phi_\pm^{(n)}(x,\xi), \quad (4.7)$$

where the functions $\phi_\pm^{(n)}$ are solutions of equations

$$2\langle\xi,\nabla\phi_\pm^{(1)}\rangle+V-2\langle A,\xi\rangle=0, \quad (4.8)$$

$$2\langle\xi,\nabla\phi_\pm^{(2)}\rangle+|\nabla\phi_\pm^{(1)}|^2-2\langle A,\nabla\phi_\pm^{(1)}\rangle+|A|^2=0, \quad (4.9)$$

$$2\langle\xi,\nabla\phi_\pm^{(n)}\rangle+\sum_{m+p=n}\langle\nabla\phi_\pm^{(m)},\nabla\phi_\pm^{(p)}\rangle-2\langle A,\nabla\phi_\pm^{(n-1)}\rangle=0, \quad n\geqslant3. \quad (4.10)$$

Then the remainder $q_\pm(x,\xi)=q_\pm^{(N)}(x,\xi)$ defined by (4.2) satisfies the equations

$$q_\pm^{(1)}=|\nabla\phi_\pm^{(1)}|^2-2\langle A,\nabla\phi_\pm^{(1)}\rangle+|A|^2,$$
$$q_\pm^{(N)}=\sum_{m+p\geqslant N+1}\langle\nabla\phi_\pm^{(m)},\nabla\phi_\pm^{(p)}\rangle-2\langle A,\nabla\phi_\pm^{(N)}\rangle,\quad N\geqslant 2. \tag{4.11}$$

Using Lemma 4.1, we derive inductively estimates for functions $\phi_\pm^{(n)}$, which gives also estimates for $\Phi_\pm$ and $q_\pm$.

Proposition 4.2: Let assumption (1.2) hold for some $\rho\in(0,1)$ such that ρ^{-1} is not integer and set $N=[\rho^{-1}]$. Then for all multi-indices α,β we have in the region $\pm\langle\hat{x},\hat{\xi}\rangle\geqslant\kappa$ (for any $\kappa>-1$),

$$|\partial_x^\alpha\partial_\xi^\beta\phi_\pm^{(n)}(x,\xi)|\leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{1-n\rho-|\alpha|}, \tag{4.12}$$

$$|\partial_x^\alpha\partial_\xi^\beta\Phi_\pm(x,\xi)|\leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{1-\rho-|\alpha|}, \tag{4.13}$$

$$|\partial_x^\alpha\partial_\xi^\beta q_\pm(x,\xi)|\leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{-1-\epsilon-|\alpha|},\quad \epsilon>0. \tag{4.14}$$

Equality (4.4) and estimates (4.13) imply that the function $q_\pm$ on the right-hand side of (4.3) obeys the same bound (4.14) as $q_\pm$.

We note that all assertions of Proposition 4.2 remain true for $\rho=1$, except that in this case the function $\Phi_\pm(x,\xi)=\phi_\pm^{(1)}(x,\xi)$ may have a logarithmic growth as $|x|\to\infty$. Similarly, if ρ^{-1} is integer, then $N=\rho^{-1}$ and the function $\phi_\pm^{(N)}(x,\xi)$ has a logarithmic growth. The assumption that ρ^{-1} is not integer does not of course reduce the generality.

Let us finally give an explicit expression for $\Phi_\pm=\phi_\pm^{(1)}$ in the case $\rho>1/2$,

$$\Phi_\pm(x,\xi)=\pm 2^{-1}\int_0^\infty(V(x\pm t\xi)-V(\pm t\xi)-2\langle A(x\pm t\xi)-A(\pm t\xi),\xi\rangle)\mathrm{d}t. \tag{4.15}$$

V. WAVE OPERATORS

5.1. Here we consider wave operators for the pair of Hamiltonians $H_0=-\Delta$, $H=(i\nabla+A)^2+V$, acting in the space $\mathcal{H}=L_2(\mathbb{R}^d)$. We always assume condition (1.2) on A and V. Below we fix a spectral interval $\Lambda=[\lambda_0,\lambda_1]\subset\mathbb{R}_+=(0,\infty)$. Let $\Phi_\pm$ be the function constructed in Proposition 4.2. We define the identification $J_\pm$ by the formula

$$(J_\pm f)(x)=(2\pi)^{-d/2}\int_{\mathbb{R}^d}e^{i\langle x,\xi\rangle+i\Phi_\pm(x,\xi)}\zeta_\pm(x,\xi)\hat{f}(\xi)\mathrm{d}\xi, \tag{5.1}$$

where the cutoff function

$$\zeta_\pm(x,\xi)=\sigma_\pm(\langle\hat{\xi},\hat{x}\rangle)\,\eta(x)\psi(|\xi|^2),\quad \hat{\xi}=\xi/|\xi|,\quad \hat{x}=x/|x|. \tag{5.2}$$

Here $\sigma_\pm\in C^\infty$ is such that $\sigma_\pm(\tau)=1$ near ± 1 and $\sigma_\pm(\tau)=0$ near ∓ 1, so that it "kills" a conical neighborhood of the bad direction $\hat{x}=\mp\hat{\xi}$ where estimates (4.13) are violated. The function $\eta\in C^\infty(\mathbb{R}^d)$, such that $\eta(x)=0$ near zero and $\eta(x)=1$ for large $|x|$, is introduced only to get rid of the singularity of the function $\hat{x}$ at the point $x=0$. Finally, $\psi\in C_0^\infty(\mathbb{R}_+)$ and $\psi(\lambda)=1$ for $\lambda\in\Lambda$. Thus, our considerations are localized on a bounded disjoint from zero energy interval. Since the function $\Phi_\pm$ satisfies estimates (4.13) on the support of $\zeta_\pm$, the operator $J_\pm$ fits into the framework of PDO with oscillating symbols (see 2.1 in Sec. II). In particular, by Proposition 2.2, $J_\pm$ is a bounded operator on $\mathcal{H}$. Abusing somewhat notation, we write $J_\pm\in\mathcal{C}^0(\Phi_\pm)$.

Our first goal in this section is to show that the pair H_0, H, with identifications J_+ and J_-, fits into the framework of the theory of smooth perturbations, so the wave operators $W_\pm(H,H_0;J_\gamma)$ and $W_\pm(H_0,H;J_\gamma^*)$ exist both for $\gamma=``+"$ and $\gamma=``-"$. The structure of the operators $T_\pm = HJ_\pm - J_\pm H_0$ is described in the following.

Lemma 5.1: The operator $T_\pm$ admits the decomposition $T_\pm = T_\pm^{(s)} + T_\pm^{(r)}$ where $T_\pm^{(s)}, T_\pm^{(r)}$ are, respectively, PDO with symbols

$$t_\pm^{(s)}(x,\xi) = -2i\,\eta(x)e^{i\Phi_\pm(x,\xi)}\langle \xi, \nabla\sigma_\pm(\langle\hat{\xi},\hat{x}\rangle)\rangle\psi(|\xi|^2)$$

$$= -2i\,\eta(x)|x|^{-1}e^{i\Phi_\pm(x,\xi)}(1-\langle\hat{\xi},\hat{x}\rangle^2)\sigma_\pm'(\langle\hat{\xi},\hat{x}\rangle)|\xi|\psi(|\xi|^2) \in \mathcal{C}^{-1}(\Phi_\pm) \qquad (5.3)$$

and $t_\pm^{(r)} \in \mathcal{C}^{-1-\epsilon}(\Phi_\pm)$ for some $\epsilon>0$.

Proof: According to (4.3) and (5.1), we have that

$$(T_\pm f)(x) = (2\pi)^{-d/2}\int_{\mathbb{R}^d} e^{i\langle x,\xi\rangle + i\Phi_\pm(x,\xi)}\tau_\pm(x,\xi)\hat{f}(\xi)d\xi,$$

where

$$\tau_\pm(x,\xi) = q_\pm(x,\xi)\zeta_\pm(x,\xi) - 2i\langle \xi + \nabla\Phi_\pm(x,\xi) - A(x), \nabla\zeta_\pm(x,\xi)\rangle - \Delta\zeta_\pm(x,\xi). \qquad (5.4)$$

We single out here the term

$$\tau_\pm^{(s)}(x,\xi) = -2i\,\eta(x)\langle \xi, \nabla\sigma_\pm(\langle\hat{\xi},\hat{x}\rangle)\rangle\psi(|\xi|^2)$$

decaying as $|x|^{-1}$. According to (1.2), (4.13), and (4.14) all other terms belong to the class $\mathcal{S}^{-1-\epsilon}$. Thus, we define $t_\pm^{(s)}$ and $t_\pm^{(r)}$ by the equalities

$$t_\pm^{(s)}(x,\xi) = e^{i\Phi_\pm(x,\xi)}\tau_\pm^{(s)}(x,\xi), \quad \tau_\pm^{(r)}(x,\xi) = \tau_\pm(x,\xi) - \tau_\pm^{(s)}(x,\xi), \quad t_\pm^{(r)}(x,\xi) = e^{i\Phi_\pm(x,\xi)}\tau_\pm^{(r)}(x,\xi).$$

Then $t_\pm = t_\pm^{(s)} + t_\pm^{(r)}$. □

Our study of the singular part $T_\pm^{(s)}$ relies on

Lemma 5.2: Let T be a PDO with symbol

$$t(x,\xi) = g(x,\xi)w(\langle\hat{x},\hat{\xi}\rangle)\,\eta(x)\psi(|\xi|^2),$$

where $g \in \mathcal{C}^{-1}(\Phi), \Phi \in \mathcal{S}^{1-\rho}$, $\rho>0$, $w \in C^\infty$ and $w(\pm 1)=0$. Let $G_j, j=1,\dots,d$, be the operators defined in Proposition 3.5. Then T admits the representation (1.8), where $p=(1+\rho)/2$ and the operators $B^{(s)}, B^{(r)}$ are bounded.

Proof: Let $B^{(s)}$ and T_j, $j=1,\dots,d$, be the PDO with symbols

$$b^{(s)}(x,\xi) = \langle x\rangle\,|\xi|^{-2}(1-\langle\hat{\xi},\hat{x}\rangle^2)^{-1}t(x,\xi),$$

$$t_j(x,\xi) = \langle x\rangle^{-1}(\xi_j - |x|^{-2}x_j\langle\xi,x\rangle)^2 b^{(s)}(x,\xi).$$

The function $(1-\tau^2)^{-1}w(\tau)$ is C^∞, so that $b^{(s)} \in \mathcal{C}^0(\Phi)$ and hence, by Proposition 2.2, the operator $B^{(s)}$ is bounded. Since G_j is the PDO with symbol

$$g_j(x,\xi) = i\langle x\rangle^{-1/2}(\xi_j - |x|^{-2}x_j\langle\xi,x\rangle)$$

and $t_j = |g_j|^2 b^{(s)}$, we get, by Proposition 2.7 where $m=0$, $n=-1/2$, $r=1-\rho$, that the operator

$$B^{(r)} = \sum_{j=1}^d \langle x\rangle^p (G_j^* B^{(s)} G_j - T_j)\langle x\rangle^p$$

is bounded for $2p=\rho+1$. It remains to remark that $t=\Sigma_{j=1}^{d}t_j$. □

Now it is easy to obtain representation (1.8).

Proposition 5.3: The operators $T_\pm$ admit representation (1.8) for $p>1/2$ and some bounded operators $B_\pm^{(r)}, B_\pm^{(s)}$.

Proof: Let us proceed from Lemma 5.1. Since $t_\pm^{(s)}\in\mathcal{C}^{-1}(\Phi_\pm)$ and $\sigma'_\pm(\tau)=0$ in neighborhoods of the points -1 and 1, Lemma 5.2 can be directly applied to the operators $T_\pm^{(s)}$ for $p_s=(1+\rho)/2$. Since $t_\pm^{(r)}\in\mathcal{C}^{-1-\epsilon}(\Phi_\pm)$, the operator $\langle x\rangle^p T_\pm^{(r)}\langle x\rangle^p$ is bounded for $p_r=(1+\epsilon)/2$ by Proposition 2.6. This leads to (1.8) with $p=\min\{p_s,p_r\}>1/2$. □

It follows from Propositions 3.4 and 3.5 that the triples $\{H_0,H,J_+\}$ and $\{H_0,H,J_-\}$ satisfy the assumptions of Proposition 3.3. This yields

Theorem 5.4: *Suppose that A and V satisfy (1.2). Let $J_\pm=J_\pm(\zeta_\pm)$ be defined by (5.1). Then all wave operators*

$$W_\pm(H,H_0;J_\pm),\quad W_\pm(H_0,H;J_\pm^*) \tag{5.5}$$

and

$$W_\pm(H,H_0;J_\mp),\quad W_\pm(H_0,H;J_\mp^*) \tag{5.6}$$

exist. Operators (5.5) as well as (5.6) are adjoint to each other.

Corollary 5.5: The wave operators satisfy the intertwining property, that is

$$W_\pm(H,H_0;J_\gamma)E_0(X)=E(X)W_\pm(H,H_0;J_\gamma)$$

for all Borel sets $X\subset\mathbb{R}$ and both signs of γ. In particular,

$$\mathrm{Ran}(W_\pm(H,H_0;J_\gamma)E_0(X))\subset E(X)\mathcal{H}. \tag{5.7}$$

5.2. Now we are able to prove the isometricity and completeness of the wave operators $W_\pm(H,H_0;J_\pm)$.

Lemma 5.6: Let A be a PDO with symbol $a\in\mathcal{S}^0$ such that $a(x,\xi)=0$ in some conical neighborhood of the direction $\hat{x}=\pm\hat{\xi}$ at least for sufficiently large $|x|$. Then

$$s-\lim_{t\to\pm\infty}Ae^{-iH_0t}=0.$$

Proof: The stationary point $\xi=x/(2t)$ of the integral

$$(Ae^{-iH_0t}f)(x)=(2\pi)^{-d/2}\int_{\mathbb{R}^d}e^{i\langle\xi,x\rangle-i|\xi|^2t}a(x,\xi)\psi^2(|\xi|^2))\hat{f}(\xi)d\xi \tag{5.8}$$

does not belong to the support of the function $a(x,\xi)$ if $t\to\pm\infty$. Here we have taken into account that according to (3.3) values of $a(x,\xi)$ for bounded x can be neglected. Therefore supposing that $\hat{f}\in C_0^\infty(\mathbb{R}^d)$ and integrating by parts, we estimate integral (5.8) by $C_N(1+|x|+|t|)^{-N}$ for arbitrary N. □

Lemma 5.7: The following relations hold:

$$s-\lim_{t\to\pm\infty}(J_\pm^*J_\pm-\psi^2(H_0))e^{-iH_0t}=0, \tag{5.9}$$

$$s-\lim_{t\to\pm\infty}J_\mp^*J_\mp e^{-iH_0t}=0. \tag{5.10}$$

Proof: By Proposition 2.3, up to compact terms [which are negligible according to (3.3)], $A_1=J_\pm^*J_\pm-\psi^2(H_0)$ and $A_2=J_\mp^*J_\mp$ are PDO with symbols $\zeta_\pm^2(x,\xi)-\psi^2(|\xi|^2)$ and $\zeta_\mp^2(x,\xi)$, respectively. Therefore Lemma 5.6 can be applied to both operators A_1 and A_2. □

Proposition 5.8: Under the assumptions of Theorem 5.4, the operators $W_\pm(H,H_0;J_\pm)$ *are isometric on the subspace* $E_0(\Lambda)\mathcal{H}$ *and*

$$W_\pm(H,H_0;J_\mp)=0, \quad W_\pm(H_0,H;J_\mp^*)=0. \tag{5.11}$$

Proof: The results on the operators $W_\pm(H,H_0;J_\pm)$ and $W_\pm(H,H_0;J_\mp)$ are immediate consequences of (5.9) and (5.10), respectively. The second equality (5.11) is a consequence of the first because $W_\pm(H_0,H;J_\mp^*)=W_\pm^*(H,H_0;J_\mp)$. □

Proposition 5.9: The operators $W_\pm(H,H_0;J_\pm(\zeta_\pm))$ *do not depend on the choice of functions* $\sigma_\pm$ *and* η *in the definition (5.2) provided they satisfy the assumptions formulated at the beginning of this section.*

Proof: Let $\sigma_\pm$, η and $\tilde\sigma_\pm$, $\tilde\eta$ be a couple of such functions, and let $\zeta_\pm$, $\tilde\zeta$ be defined by (5.2). Set $L_\pm=J_\pm(\zeta_\pm)-J_\pm(\tilde\zeta_\pm)$. It suffices to check that $L_\pm e^{-H_0t}\to 0$ strongly as $t\to\pm\infty$ or that

$$s-\lim_{t\to\pm\infty} L_\pm^* L_\pm e^{-iH_0t}=0.$$

By Proposition 2.3, up to a compact term, $A_\pm=L_\pm^*L_\pm$ is the PDO with symbol $(\zeta_\pm(x,\xi)-\tilde\zeta_\pm(x,\xi))^2$, and hence Lemma 5.6 can be applied to both operators $A_\pm$. □

Our main result in this section is the following.

Theorem 5.10: *Under the assumptions of Theorem 5.4, the asymptotic completeness holds,*

$$\mathrm{Ran}(W_\pm(H,H_0;J_\pm)E_0(\Lambda))=E(\Lambda)\mathcal{H}.$$

Proof: By virtue of (5.7) for $X=\Lambda$, it suffices to check that for any $f\in E(\Lambda)\mathcal{H}$ there exists $f_0^{(\pm)}\in E_0(\Lambda)\mathcal{H}$ such that $f=W_\pm(H,H_0;J_\pm)f_0^{(\pm)}$ or, to put it differently, that

$$\lim_{t\to\pm\infty}\|e^{-iHt}f-J_\pm e^{-iH_0t}f_0^{(\pm)}\|=0. \tag{5.12}$$

Let us set $f_0^{(\pm)}=W_\pm(H_0,H;J_\pm^*)f$. Then, by the definition of this wave operator,

$$\lim_{t\to\pm\infty}\|J_\pm^* e^{-iHt}f-e^{-iH_0t}f_0^{(\pm)}\|=0,$$

and hence

$$\lim_{t\to\pm\infty}\|J_\pm J_\pm^* e^{-iHt}f-J_\pm e^{-iH_0t}f_0^{(\pm)}\|=0. \tag{5.13}$$

The second equality (5.11) implies that $\lim_{t\to\pm\infty}\|J_\mp^* e^{-iHt}f\|=0$ and, consequently,

$$\lim_{t\to\pm\infty}\|J_\mp J_\mp^* e^{-iHt}f\|=0. \tag{5.14}$$

By Proposition 2.3, up to a compact term, $J_\pm J_\pm^*+J_\mp J_\mp^*$ is the PDO with symbol $\zeta_\pm^2(x,\xi)+\zeta_\mp^2(x,\xi)$. According to Proposition 5.9, we may assume that the functions $\sigma_\pm$ in (5.2) satisfy the condition $\sigma_+^2(\tau)+\sigma_-^2(\tau)=1$. Then it follows from (5.13) and (5.14) that

$$\lim_{t\to\pm\infty}\|\psi^2(H_0)e^{-iHt}f-J_\pm e^{-iH_0t}f_0^{(\pm)}\|=0.$$

Since the operator $\psi^2(H)-\psi^2(H_0)$ is compact and $\psi^2(H)f=f$, this yields (5.12). □

5.3. Here we find the asymptotics of the function

$$(J_\pm e^{-iH_0t}f)(x)=(2\pi)^{-d/2}\int_{\mathbb{R}^d} e^{i\langle x,\xi\rangle+i\Phi_\pm(x,\xi)-i|\xi|^2t}\zeta_\pm(x,\xi)\hat{f}(\xi)d\xi,\quad f\in\mathcal{S}(\mathbb{R}^d),\quad (5.15)$$

as $t\to\pm\infty$. This will allow us to show that $W_\pm(H,H_0;J_\pm)$ coincide with wave operators defined (see Ref. 22) in terms of a time-dependent modification of the free dynamics e^{-iH_0t}.

Stationary points $\omega(x,t)$ of the phase function in (5.15) are determined by the equation

$$x+(\nabla_\xi\Phi_\pm)(x,\omega(x,t))-2\omega(x,t)t=0,\quad \pm t>0. \quad (5.16)$$

Due to the function $\zeta_\pm(x,\xi)$ we are interested only in points $\omega=\omega(x,t)$ such that $|\omega|^2\in\operatorname{supp}\psi$ and $\pm\langle\hat{\omega},\hat{x}\rangle\geqslant\kappa$ for some $\kappa>-1$. Using estimate (4.13) on $\nabla_\xi\Phi_\pm$, we see that for large $|t|$ equation (5.16) has a unique solution $\omega(x,t)$ and

$$\omega(x,t)=(2t)^{-1}x+O(|t|^{-\rho}) \quad (5.17)$$

uniformly in x such that

$$c_1|t|\leqslant|x|\leqslant c_2|t|,\quad 0<c_1<c_2<\infty. \quad (5.18)$$

Let us set

$$\Xi(x,t)=\langle\omega(x,t),x\rangle+\Phi_\pm(x,\omega(x,t))-|\omega(x,t)|^2t,\quad \pm t>0. \quad (5.19)$$

Applying the stationary phase method to integral (5.15) and taking into account the equality $\sigma_\pm(\langle\hat{\omega}(x,t),\hat{x}\rangle)=1$ for sufficiently large $\pm t$, we find that

$$(J_\pm e^{-iH_0t}f)(x)=e^{\mp\pi id/4}e^{i\Xi(x,t)}(2|t|)^{-d/2}\psi(|\omega(x,t)|^2)\hat{f}(\omega(x,t))+r_\pm(x,t), \quad (5.20)$$

where $r_\pm(x,t)$ tends to zero in $L_2(\mathbb{R}^d)$ as $t\to\pm\infty$. Using Eq. (5.16), we can rewrite expression (5.19) as

$$\Xi(x,t)=|x|^2/(4t)+\Omega(x,t), \quad (5.21)$$

where

$$\Omega(x,t)=\Phi_\pm(x,\omega(x,t))-(4t)^{-1}|(\nabla_\xi\Phi_\pm)(x,\omega(x,t))|^2,\quad \pm t>0. \quad (5.22)$$

It follows from (5.17) that in Eq. (5.20) $\omega(x,t)$ can be replaced by $x/(2t)$. This gives us the following lemma.

Lemma 5.11: Suppose that $|t|$ is sufficiently large. Let $\omega(x,t)$ satisfy equation (5.16), and let $\Xi(x,t)$ be defined by formulas (5.21), (5.22). Define a family of unitary operators by the equality

$$(U_0(t)f)(x)=e^{\mp\pi di/4}e^{i\Xi(x,t)}(2|t|)^{-d/2}\hat{f}((2t)^{-1}x),\quad \pm t>0. \quad (5.23)$$

Then for any function $\zeta_\pm$ defined by (5.2)

$$\lim_{t\to\pm\infty}\|J_\pm(\zeta_\pm)e^{-iH_0t}f-U_0(t)\psi(H_0)f\|.=0,\quad \forall f\in L_2(\mathbb{R}^d).$$

Lemma 5.11 allows us to reformulate the results of Theorems 5.4 and 5.10 as follows.

Proposition 5.12: Suppose that A and V satisfy (1.2). Define $U_0(t)$ by equality (5.23) for sufficiently large $|t|$. Then the wave operators

$$\mathbf{W}_\pm=s-\lim_{t\to\pm\infty}e^{iHt}U_0(t) \quad (5.24)$$

exist, are isometric and $\mathrm{Ran}\,\mathbf{W}_\pm = P\mathcal{H}$. *Furthermore, for any function (5.2) satisfying the assumptions formulated at the beginning of this section*

$$\mathbf{W}_\pm \psi(H_0) = W_\pm(H,H_0;J_\pm(\zeta_\pm)).$$

Proposition 5.12 shows again that the operators $W_\pm(H,H_0;J_\pm(\zeta_\pm))$ do not depend on the choice of functions $\sigma_\pm$ and η in the definition (5.2).

Remark 5.13: If $\Xi(x,t) = |x|^2/(4t)$ in (5.23), then

$$\lim_{t\to\pm\infty} \|e^{-iH_0t}f - U_0(t)f\| = 0, \quad \forall f \in L_2(\mathbb{R}^d),$$

and hence the wave operators (5.24) coincide with

$$W_\pm(H,H_0) = s - \lim_{t\to\pm\infty} e^{iHt}e^{-iH_0t}.$$

If $\rho > 1/2$ then the function (5.22) can be replaced by a simpler expression. Recall first of all that in this case $\Phi_\pm$ is defined by formula (4.15). It follows from (4.13) and (5.17) that in the region (5.18) the functions

$$(4t)^{-1}|\nabla_\xi \Phi_\pm(x,\omega(x,t))|^2 = O(|t|^{1-2\rho}), \quad \Phi_\pm(x,\omega(x,t)) - \Phi_\pm(x,x/(2t)) = O(|t|^{1-2\rho})$$

tend to zero as $|t|\to\infty$. Thus, in place of (5.22) we can set $\Omega(x,t) = \Phi_\pm(x,x/(2t))$ which, according to (4.15), yields the expression

$$\Omega(x,t) = -t\int_0^1 V(sx)\mathrm{d}s + \int_0^1 \langle A(sx),x\rangle \mathrm{d}s.$$

This allows us to simplify considerably the expression for the operators $J_\pm$ in the case $V=0$.

Proposition 5.14: Suppose that $V=0$ *and A satisfies assumption* (1.2) *with* $\rho > 1/2$. *Set*

$$(Jf)(x) = \exp\left(i\int_0^1 \langle A(sx),x\rangle \mathrm{d}s \right) f(x).$$

Then the wave operators $W_\pm(H,H_0;J)$ *exist and coincide [up to the factor* $\psi(H_0)$*] with operators (1.3). If additionally the transversal gauge condition (1.9) is satisfied, then* $J=I$, *so that the same conclusions hold for the usual wave operators* $W_\pm(H,H_0)$.

Remark 5.15: All the results of this section remain true if $V = V_0 + V_1$ and $A = A_0 + A_1$ where V_0 and A_0 satisfy assumption (1.2) and

$$\begin{aligned} |V_1(x)| &\leqslant C(1+|x|)^{-\rho_1}, \\ |A_1(x)| + |\mathrm{div}\, A_1(x)| &\leqslant C(1+|x|)^{-\rho_1} \end{aligned} \tag{5.25}$$

for some $\rho_1 > 1$. In this case the identifications $J_\pm$ can be constructed in terms of the functions V_0 and A_0 only.

Indeed, by multiplication theorem for wave operators, it suffices to check that the usual wave operators for the pair $H(V_0,A_0)$, $H(V,A)$ exist and are complete. Under condition (5.25) this follows from the limiting absorption principle (Proposition 3.4) satisfied by both operators $H(V_0,A_0)$ and $H(V,A)$.

5.4. The direct definition of wave operators (5.24) in Ref. 22 used the function (5.21) with $\Omega(x,t)$ such that

$$\Omega_t(x,t)+t^{-1}\langle x,(\nabla\Omega)(x,t)\rangle+|(\nabla\Omega)(x,t)|^2-\langle A(x),x/t+2\nabla\Omega(x,t)\rangle+V(x)+|A(x)|^2$$
$$=O(|t|^{-1-\varepsilon}),\quad \varepsilon>0, \tag{5.26}$$

and

$$\partial_x^\alpha\Omega(x,t)=O(|t|^{1-\varepsilon-|\alpha|}),\quad |\alpha|=1,2, \tag{5.27}$$

in the region (5.18). These conditions allow to verify with the help of the Cook method the existence of wave operators (5.24). Of course, it is natural to expect that the functions $\Omega(x,t)$ defined in the previous subsection and in Ref. 22 coincide. Let us check it by a direct calculation.

Proposition 5.16: Let $\omega(x,t)$ satisfy equation (5.16) and let $\Omega(x,t)$ be defined by formula (5.22). Then $\Omega(x,t)$ satisfies the conditions (5.26) and (5.27).

Proof: To simplify notation, we omit variables (x,t) and indices "$\pm$." Differentiating (5.22), we find that

$$\Omega_t=(2t)^{-2}|\nabla_\xi\Phi|^2+\sum_j \Phi_{\xi_j}\Big(\partial\omega_j/\partial t-(2t)^{-1}\sum_k \Phi_{\xi_j\xi_k}\partial\omega_k/\partial t\Big), \tag{5.28}$$

$$\Omega_{x_i}=\Phi_{x_i}+\sum_j \Phi_{\xi_j}\Big(\partial\omega_j/\partial x_i-(2t)^{-1}\Big(\Phi_{\xi_jx_i}+\sum_k \Phi_{\xi_j\xi_k}\partial\omega_k/\partial x_i\Big)\Big). \tag{5.29}$$

Differentiating Eq. (5.16), we see that

$$\partial\omega_j/\partial t-(2t)^{-1}\sum_k \Phi_{\xi_j\xi_k}\partial\omega_k/\partial t=-2^{-1}t^{-2}x_j-2^{-1}t^{-2}\Phi_{\xi_j} \tag{5.30}$$

and

$$\partial\omega_j/\partial x_i-(2t)^{-1}\Big(\Phi_{\xi_jx_i}+\sum_k \Phi_{\xi_j\xi_k}\partial\omega_k/\partial x_i\Big)=(2t)^{-1}\delta_{ij}, \tag{5.31}$$

where $\delta_{ii}=1$ and $\delta_{ij}=0$ if $i\neq j$. Comparing (5.28) and (5.30) we obtain that

$$\Omega_t=-2^{-1}t^{-2}\langle x,\nabla_\xi\Phi\rangle-(2t)^{-2}|\nabla_\xi\Phi|^2.$$

Similarly, comparing (5.29) and (5.31), we obtain that

$$\nabla_x\Omega=\nabla_x\Phi+(2t)^{-1}\nabla_\xi\Phi. \tag{5.32}$$

These equalities imply that

$$\Omega_t+t^{-1}\langle x,\nabla_x\Omega\rangle+|\nabla_x\Omega|^2=t^{-1}\langle x+\nabla_\xi\Phi,\nabla_x\Phi\rangle+|\nabla_x\Phi|^2=2\langle\omega,\nabla_x\Phi\rangle+|\nabla_x\Phi|^2,$$

where at the last step we have again used Eq. (5.16). Comparing (5.16) and (5.32), we see also that

$$(2t)^{-1}x+\nabla_x\Omega=\omega+\nabla_x\Phi.$$

Thus, the sum (5.26) can be written as

$$2\langle\omega,\nabla_x\Phi\rangle+|\nabla_x\Phi|^2-2\langle A,\omega+\nabla_x\Phi\rangle+V+|A|^2.$$

It follows from Eq. (4.2) that this expression equals $q(x,\omega(x,t))$ which, by estimate (4.14), is of order $|t|^{-1-\epsilon}$ in the region considered. The condition (5.27) is a consequence of estimates (4.13) and (5.17). □

VI. THE SCATTERING MATRIX

6.1. It follows from Theorems 5.4, 5.10 and Proposition 5.8 that the scattering operator

$$\mathbf{S}=W_+^*(H,H_0;J_+)W_-(H,H_0;J_-)$$

commutes with H_0 and is unitary on the subspace $E_0(\Lambda)\mathcal{H}$. Thus, in the diagonal representation of H_0 (discussed in 2.2 of Sec. II) **S** reduces to the operator of multiplication by the operator function $S(\lambda):\mathfrak{N}\to\mathfrak{N}$ called the SM. It is defined for almost all $\lambda\in(0,\infty)$ and is unitary for almost all $\lambda\in\Lambda$. We suppose that $\lambda\in\Lambda$.

We need a stationary formula for the SM in the case when identifications J_+ and J_- for $t\to+\infty$ and $t\to-\infty$ are different. Below we always assume that the functions $\sigma_\pm$ in definition (5.1) of the operators $J_\pm$ obey the conditions

$$\sigma_+(\tau)=1 \quad \text{for} \quad \tau\in[-\varepsilon,1], \quad \sigma_+(\tau)=0 \quad \text{for} \quad \tau\in[-1,-2\varepsilon] \quad \text{and} \quad \sigma_-(\tau)=\sigma_+(-\tau) \tag{6.1}$$

for some $\varepsilon\in(0,1/2)$. Formally, the SM admits (see, e.g., Ref. 22) the representation (1.10) with $T_\pm=HJ_\pm-J_\pm H_0$. According to Lemma 5.1, $T_\pm=T_\pm^{(s)}+T_\pm^{(r)}$, where $T_\pm^{(s)}$ has symbol $t_\pm^{(s)}$ defined by (5.3) and $T_\pm^{(r)}\in\mathcal{C}^{-1-\epsilon}(\Phi_\pm)$, $\epsilon>0$. It follows from (5.10) that in our case $W_+(H_0,H_0;J_+^*J_-)=0$ and hence $\mathcal{W}(\lambda)=0$. We shall show that other terms in (1.10) satisfy Definition 2.11. Let us set

$$\begin{aligned} S_0(\lambda)&=-2\pi i\Gamma_0(\lambda)J_+^*T_-^{(s)}\Gamma_0^*(\lambda),\\ S_1(\lambda)&=-2\pi i\Gamma_0(\lambda)J_+^*T_-^{(r)}\Gamma_0^*(\lambda),\\ S_2(\lambda)&=2\pi i\Gamma_0(\lambda)T_+^*R(\lambda+i0)T_-\Gamma_0^*(\lambda). \end{aligned} \tag{6.2}$$

Then $S(\lambda)=S_0(\lambda)+S_1(\lambda)+S_2(\lambda)$. We emphasize that these operators depend on the choice of the cutoff functions $\sigma_\pm$ and η in the definition of $J_\pm$, but their sum does not depend on it (see Proposition 5.9).

For the study of the operator $S_2(\lambda)$, we have to consider previously the operator function

$$B(z)=\langle x\rangle^l T_+^*R(z)T_-\langle x\rangle^l, \quad l<(1+\epsilon)/2.$$

Lemma 6.1: The operator function $B(z):\mathcal{H}\to\mathcal{H}$ is bounded and continuous in norm with respect to z in the region $\operatorname{Re}z\in(\lambda_0,\infty),\lambda_0>0$, $\operatorname{Im}z\geqslant 0$.

Proof: Set $p=1+\epsilon-l$. Then $p>l$ and $p>1/2$. Clearly, $B=B_1+B_2+B_3$, where

$$\begin{aligned} B_1(z)&=(\langle x\rangle^p T_+^{(r)}\langle x\rangle^l)^*(\langle x\rangle^{-p}R(z)\langle x\rangle^{-p})(\langle x\rangle^p T_-^{(r)}\langle x\rangle^l),\\ B_2(z)&=(\langle x\rangle^p T_+^{(r)}\langle x\rangle^l)^*(\langle x\rangle^{-p}R(z)T_-^{(s)}\langle x\rangle^l)+(\langle x\rangle^l T_+^{(s)*}R(z)\langle x\rangle^{-p})(\langle x\rangle^p T_-^{(r)}\langle x\rangle^l),\\ B_3(z)&=\langle x\rangle^l T_+^{(s)*}R(z)T_-^{(s)}\langle x\rangle^l. \end{aligned} \tag{6.3}$$

Since $T_\pm^{(r)}\in\mathcal{C}^{-1-\epsilon}(\Phi_\pm)$, it follows from Proposition 2.6 that the operators $\langle x\rangle^p T_\pm^{(r)}\langle x\rangle^l$ are bounded. The second factor in (6.3) satisfies the assumptions of Proposition 3.4. According to (5.3) and (6.1), the operator $T_\pm^{(s)}\in\mathcal{C}^{-1}(\Phi_\pm)$ and its symbol is contained in the cone $\mp\langle\hat{x},\hat{\xi}\rangle\geqslant\varepsilon>0$. Therefore we can apply Proposition 3.6 to the operators

$$\langle x\rangle^{-p}R(z)T_-^{(s)}\langle x\rangle^l, \quad \langle x\rangle^l T_+^{(s)*}R(z)\langle x\rangle^{-p}$$

and Proposition 3.7 to the operator $B_3(z)$. □

Now it is easy to check the following.

Proposition 6.2: The operators $S_1(\lambda)$ *and* $S_2(\lambda)$ *are compact and norm continuous in* $\lambda > 0$.

Proof: Let $l \in (1/2,(1+\epsilon)/2)$. The operator $S_1(\lambda)$ factorizes as

$$S_1(\lambda) = 2\pi i(\Gamma_0(\lambda)\langle x\rangle^{-l})(\langle x\rangle^{-l} J_+ \langle x\rangle^{l})^*(\langle x\rangle^{l} T_-^{(r)} \langle x\rangle^{l})(\Gamma_0(\lambda)\langle x\rangle^{-l})^*,$$

where the operators $\langle x\rangle^{-l} J_+ \langle x\rangle^{l}$ and $\langle x\rangle^{l} T_-^{(r)} \langle x\rangle^{l}$ are bounded according to Proposition 2.6 and the operators $\Gamma_0(\lambda)\langle x\rangle^{-l}$ are compact and norm continuous according to Proposition 2.10. The operator

$$S_2(\lambda) = 2\pi i(\Gamma_0(\lambda)\langle x\rangle^{-l}) B(\lambda + i0)(\Gamma_0(\lambda)\langle x\rangle^{-l})^*$$

is well defined, compact and norm continuous according to Proposition 2.10 and Lemma 6.1. □

6.2. Let us now consider the singular term (6.2). The PDO $\mathbf{A}_0 = -2\pi i J_+^* T_-^{(s)}$ is defined by formula (2.6) with amplitude

$$\mathbf{a}_0(x,\xi,\xi') = -2\pi i \overline{j_+(x,\xi)} t_-^{(s)}(x,\xi').$$

Therefore, by Eqs. (5.1)–(5.3),

$$\mathbf{a}_0(x,\xi,\xi') = -4\pi e^{i\Theta(x,\xi,\xi')} \sigma_+(\langle \hat{x},\hat{\xi}\rangle)\langle \xi', \nabla\sigma_-(\langle \hat{x},\hat{\xi}'\rangle)\rangle \eta^2(x)\psi(|\xi|^2)\psi(|\xi'|^2), \tag{6.4}$$

where

$$\Theta(x,\xi,\xi') = \Phi_-(x,\xi') - \Phi_+(x,\xi) \tag{6.5}$$

and the functions $\Phi_\pm$ are defined in Proposition 4.2. Estimates (4.13) imply the following.

Lemma 6.3: The function $\Theta(x,\xi,\xi')$ *satisfies the estimates*

$$|\partial_x^\alpha \partial_{\xi,\xi'}^\beta \Theta(x,\xi,\xi')| \leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{1-\rho-|\alpha|} \tag{6.6}$$

in the region $\langle \hat{x},\hat{\xi}\rangle \geqslant \kappa$, $-\langle \hat{x},\hat{\xi}'\rangle \geqslant \kappa$ *for any* $\kappa > -1$ *and all* α,β.

Since Θ satisfies the estimates of the class $\mathcal{S}^{1-\rho}$ on the support of $\mathbf{a}_0$, (6.4) has the form (2.7) and hence the operator $\mathbf{A}_0$ fits into the framework of PDO with oscillating amplitudes (see 2.1 in Sec. II). Abusing somewhat notation, we say that $\mathbf{A}_0$ belongs to the class $\mathcal{C}^{-1}(\Theta)$. Moreover, due to the function $\nabla\sigma_-(\langle \hat{x},\hat{\xi}'\rangle)$, the operator $\mathbf{A}_0$ satisfies the assumptions of Proposition 2.14. Below we use the notation and the chart coordinates $(\omega_0,\varkappa)$ introduced in 2.2 in Sec. II. Thus, we have the following.

Proposition 6.4: The operator $S_0(\lambda) = \mathbf{A}_0^\flat(\lambda)$ *is well defined in the sense of Definition 2.11 for all* $\lambda > 0$. *Moreover, in the chart coordinates* $(\omega_0,\varkappa)$, $\mathbf{A}_0^\flat(\lambda)$ *is the PDO with amplitude*

$$\mathbf{a}_0^\flat(y,\zeta,\zeta';\lambda) = (2\pi k)^{-1}\alpha(\zeta,\zeta')\int_{-\infty}^{\infty} \mathbf{a}_0(x,k\omega,k\omega')\,dz,$$

where α *is the function (2.14),* $\zeta = \varkappa(\omega), \zeta' = \varkappa(\omega')$ *and*

$$x = (\omega+\omega')z - y/k, \quad \langle y,\omega_0\rangle = 0. \tag{6.7}$$

It follows from Propositions 2.12 and 2.14 that $(S_0(\lambda)g_1,g_2)$ is a smooth function of λ for $g_j \in C^\infty(\mathbb{S}^{d-1})$. Below we shall see that the operator $S_0(\lambda)$ is bounded in the space $\mathfrak{N}$.

Our next goal is to find a simple expression for a genuinely noncompact part of the operator $S_0(\lambda)$. First, we transform expression (6.4) for $\mathbf{a}_0$ to a more convenient form.

Proposition 6.5: Let $\mathbf{A}_1$ *be the PDO with amplitude*

$$\mathbf{a}_1(x,\xi,\xi')=-2\pi e^{i\Theta(x,\xi,\xi')}\sigma_+(\langle\hat{x},\hat{\xi}\rangle)\langle\xi+\xi',\nabla\sigma_-(\langle\hat{x},\hat{\xi}'\rangle)\rangle\,\eta^2(x)\,\psi(|\xi|^2)\psi(|\xi'|^2), \quad (6.8)$$

where Θ is given by (6.5). Then the operator $\mathbf{A}_1^\flat(\lambda)$ exists and the operator $S_0(\lambda)-\mathbf{A}_1^\flat(\lambda)$ is compact on $\mathfrak{N}$. Moreover, in the chart coordinates $(\omega_0,\varkappa)$, $\mathbf{A}_1^\flat(\lambda)$ is the PDO with amplitude

$$\mathbf{a}_1^\flat(y,\zeta,\zeta';\lambda)=-\alpha(\zeta,\zeta')\int_0^\infty e^{i\Theta(x,k\omega,k\omega')}\langle\omega+\omega',\nabla\sigma_-(\langle\hat{x},\omega'\rangle)\rangle\,\eta^2(x)\mathrm{d}z, \quad (6.9)$$

where x and y,z are related by formula (6.7).

Proof: Comparing (6.4) and (6.8), we see that the difference $\mathbf{B}=\mathbf{A}_0-\mathbf{A}_1$ is a PDO with amplitude

$$\mathbf{b}(x,\xi,\xi')=-2\pi e^{i\Theta(x,\xi,\xi')}\sigma_+(\langle\hat{x},\hat{\xi}\rangle)\langle\xi'-\xi,\nabla\sigma_-(\langle\hat{x},\hat{\xi}'\rangle)\rangle\,\eta^2(x)\,\psi(|\xi|^2)\psi(|\xi'|^2).$$

Since $\mathbf{b}(x,\xi,\xi)=0$, it follows from Proposition 2.8 that the operator $\mathbf{B}$ belongs to the class $\mathcal{C}^{-1-\rho}(\tilde{\Theta})$ for some $\tilde{\Theta}\in\mathcal{S}^{1-\rho}$. Thus, by Proposition 2.13, $\mathbf{B}^\flat(\lambda)$ is a compact operator on $\mathfrak{N}$.

It follows from conditions (6.1) that for ω' sufficiently close to ω the function $\sigma_+(\langle\hat{x},\omega\rangle)=1$ on the support of $\nabla\sigma_-(\langle\hat{x},\omega'\rangle)$. Hence σ_+ may be omitted in (6.8). We also take into account that, due to $\nabla\sigma_-(\langle\hat{x},\omega'\rangle)$, the function $\mathbf{a}_1((\omega+\omega')z-y/k,k\omega,k\omega')$ is supported in the region $z\geqslant 0$ and $\psi(\lambda)=1$ for $\lambda\in\Lambda$. Thus, applying Proposition 2.14 to the PDO $\mathbf{A}_1$, we obtain formula (6.9). □

An obvious drawback of this assertion is that the amplitude $\mathbf{a}_1^\flat$ contains the cutoff function σ_- although the SM does not depend on it.

6.3. Let us show that, up to a compact term, the operator $\mathbf{A}_1^\flat(\lambda)$ does not actually depend on σ_-. Below we always work in fixed chart coordinates $(\omega_0,\varkappa)$ and denote by χ a function from the class $C_0(\Omega)$. Recall, that for fixed $\omega,\omega'\in\Omega(\omega_0,\gamma)$, we always use in $\mathbb{R}^d$ the coordinates $(y,z)\in\mathbb{R}^{d-1}\times\mathbb{R}$ defined by (6.7). Then

$$k\langle\omega'-\omega,x\rangle=\langle\omega-\omega',y\rangle=\langle\zeta-\zeta',y\rangle, \quad (6.10)$$

$$\mathrm{d}x=k^{-d+1}\langle\omega+\omega',\omega_0\rangle\mathrm{d}z\,\mathrm{d}y \quad (6.11)$$

and

$$\langle\omega+\omega',\nabla f(x)\rangle=\partial_z f(x)$$

for any differentiable function f.

Integrating by parts in (6.9) and taking into account that $\sigma_-(\langle\hat{x},\omega'\rangle)$ varies from 1 to 0 as z varies from 0 to ∞, we get that

$$\mathbf{a}_1^\flat(y,\zeta,\zeta';\lambda)=\alpha(\zeta,\zeta')e^{i\Theta(-y/k,k\omega,k\omega')}\eta^2(-y/k)+\mathbf{b}(y,\zeta,\zeta';\lambda), \quad (6.12)$$

where

$$\mathbf{b}(y,\zeta,\zeta';\lambda)=\alpha(\zeta,\zeta')\int_0^\infty e^{i\Theta(x,k\omega,k\omega')}(i\partial_z\Theta(x,k\omega,k\omega')\,\eta^2(x)+\partial_z\eta^2(x))\sigma_-(\langle\hat{x},\omega'\rangle)\mathrm{d}z. \quad (6.13)$$

By Lemma 6.3 and Proposition 2.9, the first term in the right-hand side of (6.12) is the amplitude of a bounded operator in $L_2(\mathbb{S}^{d-1})$. We shall show that $\mathbf{b}$ is the amplitude of a compact operator $\mathbf{B}$. This is obvious for the part of $\mathbf{b}$ which contains $\partial_z\eta^2$ since it is compactly supported in y. To consider the part of $\mathbf{b}$ which contains $\partial_z\Theta$, we use the following.

Lemma 6.6: The function (6.5) satisfies the equality

$$\langle\xi+\xi',\nabla\Theta(x,\xi,\xi')\rangle=\langle\nabla G(x,\xi,\xi'),F(x,\xi,\xi')\rangle+q_0(x,\xi,\xi'), \quad (6.14)$$

where the functions G,F and q_0 are defined by

$$G(x,\xi,\xi')=\langle \xi'-\xi,x\rangle+\Theta(x,\xi,\xi'),$$

$$F(x,\xi,\xi')=2A(x)-\nabla(\Phi_-(x,\xi')+\Phi_+(x,\xi)), \tag{6.15}$$

$$q_0(x,\xi,\xi')=q_-(x,\xi')-q_+(x,\xi)$$

and $q_\pm$ are functions (4.2). The functions F and q_0 satisfy in the region $\langle \hat{x},\hat{\xi}\rangle \geqslant \kappa$, $-\langle \hat{x},\hat{\xi}'\rangle \geqslant \kappa$, for any $\kappa>-1$ and all α,β, the estimates

$$|\partial_x^\alpha \partial_{\xi,\xi'}^\beta F(x,\xi,\xi')|\leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{-\rho-|\alpha|}, \tag{6.16}$$

$$|\partial_x^\alpha \partial_{\xi,\xi'}^\beta q_0(x,\xi,\xi')|\leqslant C_{\alpha,\beta}(\kappa)(1+|x|)^{-1-\epsilon-|\alpha|}, \quad \epsilon>0. \tag{6.17}$$

Proof: One proceeds from eikonal equation (4.2) for $\Phi_+(x,\xi)$ and $\Phi_-(x,\xi')$ and takes their difference. This yields the equality (6.14). Estimates (6.16) and (6.17) are direct consequences of (4.13) and (4.14), respectively. □

Let us set expression (6.14) into (6.13) and consider the amplitude

$$\mathbf{b}_0(y,\zeta,\zeta';\lambda)=i\alpha(\zeta,\zeta')k^{-1}\int_0^\infty e^{i\Theta(x,k\omega,k\omega')}\langle \nabla G(x,k\omega,k\omega'),F(x,k\omega,k\omega')\rangle\,\eta^2(x)\mathrm{d}z \tag{6.18}$$

corresponding to the first term on the right-hand side of (6.14).

Lemma 6.7: The PDO $\mathbf{B}_0$ with amplitude (6.18) admits the representation $\mathbf{B}_0=\mathbf{B}_1+\mathbf{B}_2$ where $\mathbf{B}_1$, $\mathbf{B}_2$ are PDO with amplitudes

$$\mathbf{b}_1(y,\zeta,\zeta';\lambda)=-k^{-1}\alpha_1(\zeta,\zeta')e^{i\Theta(-y/k,k\omega,k\omega')}\langle \omega_0,F(-y/k,k\omega,k\omega')\rangle\,\eta^2(-y/k), \tag{6.19}$$

$$\mathbf{b}_2(y,\zeta,\zeta';\lambda)=\alpha(\zeta,\zeta')\int_0^\infty e^{i\Theta(x,k\omega,k\omega')}q(x,k\omega,k\omega')\mathrm{d}z. \tag{6.20}$$

Here

$$\alpha_1(\zeta,\zeta')=\langle \omega+\omega',\omega_0\rangle^{-1}\alpha(\zeta,\zeta')$$

and

$$q(x,\xi,\xi')=-k^{-1}\,\mathrm{div}_x(F(x,\xi,\xi')\sigma_-(\langle \hat{x},\hat{\xi}'\rangle)\,\eta^2(x)). \tag{6.21}$$

Proof: According to (6.10), (6.11), the PDO $\mathbf{B}_0$ has integral kernel

$$\begin{aligned}p_0(\zeta,\zeta';\lambda)&=(2\pi)^{-\mathrm{d}+1}\int_{\mathbb{R}^{\mathrm{d}-1}}e^{i\langle \zeta-\zeta',y\rangle}\mathbf{b}_0(y,\zeta,\zeta';\lambda)\mathrm{d}y\\&=i(2\pi)^{-\mathrm{d}+1}k^{\mathrm{d}-2}\alpha_1(\zeta,\zeta')\int_{\langle x,\omega_0\rangle\geqslant 0}\exp(iG(x,k\omega,k\omega'))\\&\quad\times\langle \nabla G(x,k\omega,k\omega'),F(x,k\omega,k\omega')\rangle\sigma_-(\langle \hat{x},\omega'\rangle)\,\eta^2(x)\mathrm{d}x.\end{aligned}$$

Integrating here by parts, we find that $p_0=p_1+p_2$ where

$$p_1(\zeta,\zeta';\lambda)=-\alpha_1(\zeta,\zeta')(2\pi)^{-d+1}k^{-1}\int_{\mathbb{R}^{d-1}}e^{iG(-y/k,k\omega,k\omega')}$$
$$\times\langle\omega_0,F(-y/k,k\omega,k\omega')\rangle\eta^2(-y/k)dy,$$

$$p_2(\zeta,\zeta';\lambda)=\alpha_1(\zeta,\zeta')(2\pi)^{-d+1}k^{d-1}\int_{\langle x,\omega_0\rangle\geqslant 0}e^{iG(x,k\omega,k\omega')}q(x,k\omega,k\omega')dx.$$

The amplitudes of PDO with kernels p_1,p_2 equal $\mathbf{b}_1,\mathbf{b}_2$, respectively. □

Let us consider the operators $\mathbf{B}_1$ and $\mathbf{B}_2$ separately.

Lemma 6.8: The PDO $\mathbf{B}_1$ *with amplitude (6.19) belongs to the class* $\mathcal{C}^{-\rho}(\Theta_0)$, *where*

$$\Theta_0(y,\zeta,\zeta';\lambda)=\Theta_0(-k^{-1}y,k\varkappa(\zeta),k\varkappa(\zeta'))$$

is given by (6.5). In particular, $\chi\mathbf{B}_1\chi$ *is a compact operator in* $L_2(\Sigma)$.

Proof: Since $\langle y,\omega_0\rangle=0$, we have that $|\langle\hat{y},\omega\rangle|\leqslant\varepsilon<1$ and $|\langle\hat{y},\omega'\rangle|\leqslant\varepsilon<1$ for $\omega,\omega'\in\Omega$. According to (6.6), (6.16) this implies that functions Θ and F in (6.19) belong to the classes $\mathcal{S}^{1-\rho}(\mathbb{R}^{d-1})$ and $\mathcal{S}^{-\rho}(\mathbb{R}^{d-1})$, respectively. Thus, $\mathbf{b}_1$ belongs to the class $\mathcal{C}^{-\rho}(\Theta_0)$, and hence $\mathbf{B}_1$ is a compact operator by Proposition 2.9. □

Lemma 6.9: Suppose that a function $q(x,\xi,\xi')$ *equals zero in a conical neighborhood of the set* $\hat{x}=\hat{\xi}'$ *and* $q(x,\xi,\xi')$ *satisfies the estimates (6.17) for* $\langle\hat{x},\hat{\xi}\rangle\geqslant\kappa>-1$ *and all* α,β. *Let* $\mathbf{B}_2$ *be PDO with amplitude (6.20). Then the operator* $\chi\mathbf{B}_2\chi$ *is compact in* $L_2(\Sigma)$.

Proof: Let $\vartheta_0\in C^\infty(\mathbb{R})$ be such that $\vartheta_0(z)=0$ for $z\leqslant 1/2$ and $\vartheta_0(z)=1$ for $z\geqslant 1$ and $\vartheta_1=1-\vartheta_0$. We first consider the operator $\mathbf{B}_{2,0}$ with amplitude

$$\mathbf{b}_{2,0}(y,\zeta,\zeta';\lambda)=\alpha(\zeta,\zeta')\int_{-\infty}^{\infty}e^{i\Theta(x,k\omega,k\omega')}q(x,k\omega,k\omega')\vartheta_0(\langle\omega+\omega',\omega_0\rangle z)dz. \qquad (6.22)$$

Let $f\in C^\infty(\mathbb{R}^d)$, $f(\xi)=1$ for $\xi\in\Omega$ and $f(\xi)=0$ off a small neighborhood of Ω. We introduce an auxiliary PDO $\mathbf{G}$ with amplitude

$$\mathbf{g}(x,\xi,\xi')=f(\xi)f(\xi')\exp(i\Theta(x,\xi,\xi'))q(x,\xi,\xi')\vartheta_0(\langle x,\omega_0\rangle).$$

The function $q\vartheta_0$ equals zero in conical neighborhoods of the sets $\hat{x}=\hat{\xi}'$ and $\hat{x}=-\hat{\xi}$, so that, by Lemma 6.3, Θ satisfies estimates (6.6) on the support of $q\vartheta_0$. Thus, $\mathbf{g}\in C^{-1-\epsilon}(\Theta)$. Comparing (2.13) and (6.22), we see that $\mathbf{B}_{2,0}(\lambda)=2\pi k\mathbf{G}^\flat(\lambda)$. Therefore the operator $\mathbf{B}_{2,0}$ is compact by Proposition 2.13.

Next we consider the PDO $\mathbf{B}_{2,1}$ with amplitude

$$\mathbf{b}_{2,1}(y,\zeta,\zeta';\lambda)=\alpha(\zeta,\zeta')e^{i\Theta(-y/k,k\omega,k\omega')}\int_0^{\infty}e^{i(\Theta(x,k\omega,k\omega')-\Theta(-y/k,k\omega,k\omega'))}q(x,k\omega,k\omega')$$
$$\times\vartheta_1(\langle\omega+\omega',\omega_0\rangle z)dz,$$

where, due to the function ϑ_1, the integral is actually taken over a finite interval. Therefore it follows from Lemma 6.3 that for $\omega,\omega'\in\Omega$ and sufficiently large $|y|$,

$$|\partial_y^\alpha\partial_{\zeta,\zeta'}^\beta e^{i(\Theta(x,k\omega,k\omega')-\Theta(-y/k,k\omega,k\omega'))}|=O(\langle y\rangle^{-\rho-|\alpha|}).$$

Taking also into account that $q\vartheta_1$ satisfies estimates (6.17), we obtain that $\mathbf{b}_{2,1}\in\mathcal{C}^{-1-\rho-\epsilon}(\Theta_0)$. Hence the operator $\chi\mathbf{B}_{2,1}\chi$ is also compact. □

Since the function (6.21) satisfies the assumptions of this lemma, it applies directly to the operator with amplitude (6.20). Moreover, the same conclusion is true if the role of $q(x,\xi,\xi')$ is played by the function $q_0(x,\xi,\xi')\sigma_-(\langle\hat{x},\omega'\rangle)$, where q_0 is defined by (6.15). This yields

Proposition 6.10: The PDO **B** *with amplitude (6.13) is compact in* $L_2(\Sigma)$.

Thus, we have verified that all terms in the right-hand side of (1.10) are well defined as bounded operators in the space $\mathfrak{N}$. As shown in Ref. 22, this justifies the representation (1.10) for the SM $S(\lambda)$. Since $(S(\lambda)g_1,g_2)$ is a smooth function of λ for $g_j\in C^\infty(\mathbb{S}^{d-1})$, it follows from unitarity of $S(\lambda)$ that actually $S(\lambda)$ is a strongly continuous operator-function of $\lambda>0$. Moreover, comparing Propositions 6.5 and 6.10, we see that, modulo compact operators, the SM $S(\lambda)$ can be considered as a PDO with amplitude given by the first term on the right-hand side of (6.12). Finally, neglecting again compact operators, we can omit in this term $\alpha(\zeta,\zeta')$ because $\alpha(\zeta,\zeta)=1$ and $\eta^2(-y/k)$ because it is 1 for sufficiently large $|y|$.

Let us summarize the results obtained in the following theorem.

Theorem 6.11: *Let condition (1.2) hold and let* $J_\pm$ *be defined by (5.1) where the function (5.2) satisfies the assumption (6.1). Then the SM* $S(\lambda)$ *for the pair* H_0, H *with identifications* $J_\pm$ *admits representation (1.10) where* $\mathcal{W}(\lambda)=0$. *The function* $S(\lambda):\mathfrak{N}\to\mathfrak{N}$ *is strongly continuous in* $\lambda>0$. *If* χ_1 *and* χ_2 *are multiplications by* $C^\infty(\mathbb{S}^{d-1})$ *functions with disjoint supports, then the operator* $\chi_1 S(\lambda)\chi_2$ *is compact. Finally, up to a compact term,* $S(\lambda)$ *is the PDO on* $\mathbb{S}^{d-1}$ *with amplitude given in arbitrary chart coordinates* $(\omega_0,\varkappa)$ *by the formula*

$$\mathbf{s}(y,\zeta,\zeta';\lambda)=\exp(i\Theta(-\lambda^{-1/2}y,\lambda^{1/2}\omega,\lambda^{1/2}\omega')). \tag{6.23}$$

6.4. Using Theorem 6.11, we can now describe the spectrum of the SM. Recall that the function $\Theta(x,\xi,\xi')$ is defined by formula (6.5) where $\Phi_\pm$ are constructed in Proposition 4.2. Let us consider the first approximation $\mathbf{V}(x,\xi)=\phi_-^{(1)}(x,\xi)-\phi_+^{(1)}(x,\xi)$ to the function $\Theta(x,\xi,\xi)$. According to (4.15)

$$\mathbf{V}(x,\xi)=2^{-1}\int_{-\infty}^{\infty}(V(t\xi)-V(x+t\xi)+2\langle A(x+t\xi)-A(t\xi),\xi\rangle)\mathrm{d}t. \tag{6.24}$$

Note that the function $\mathbf{V}$ does not depend on the projection of x on the direction of ξ. Typically, for asymptotically homogeneous functions $V(x)$ and $A(x)$ of order $-\rho$, the function $\mathbf{V}(x,\xi)$ is asymptotically homogeneous function of x as $|x|\to\infty$ of order $1-\rho$ if $\rho\in(0,1)$ and it has a logarithmic growth if $\rho=1$.

Theorem 6.12: *Let condition (1.2) hold and suppose that for some* $x_0\neq 0$, $\omega_0\in\mathbb{S}^{d-1}$, $\langle x_0,\omega_0\rangle=0$, *and* $k>0$ *the function (6.24) satisfies the conditions*

$$\limsup_{\tau\to\infty}\mathbf{V}(\tau x_0,k\omega_0)=\infty \quad\text{or}\quad \liminf_{\tau\to\infty}\mathbf{V}(\tau x_0,k\omega_0)=-\infty \tag{6.25}$$

if $\rho>1/2$ *or*

$$|\mathbf{V}(\tau x_0,k\omega_0))|\geqslant c\tau^{1-\rho},\quad |\nabla\mathbf{V}(\tau x_0,k\omega_0))|\geqslant c\tau^{-\rho},\quad c>0, \tag{6.26}$$

for sufficiently large $\tau>0$ *if* $\rho\in(0,1/2]$. *Then the spectrum of the SM* $S(\lambda)$ *coincides for* $\lambda=k^2$ *with the unit circle* $\mathbb{T}$.

Proof: It follows from definition (4.7) and estimates (4.12) for $n\geqslant 2$ that

$$|\partial_x^\alpha(\Theta(x,\xi,\xi)-\mathbf{V}(x,\xi))|\leqslant C_\alpha(1+|x|)^{1-2\rho-|\alpha|},\quad \langle x,\xi\rangle=0,\quad |\alpha|=0,1.$$

Thus, the function $\Theta(\tau x_0,k\omega_0,k\omega_0)$ where $\langle x_0,\omega_0\rangle=0$ also satisfies conditions (6.25) or (6.26). Let us consider the chart diffeomormism $(\omega_0,\varkappa)$ and the PDO $S_0^\varkappa(\lambda)$ with amplitude (6.23). We apply Proposition 2.16 to the operator $\chi_0^\varkappa S_0^\varkappa(\lambda)\chi_0^\varkappa$ where $\chi_0^\varkappa\in C_0^\infty(\Sigma)$ and $\chi_0^\varkappa(\zeta)=1$ in a neighborhood of the point $\zeta_0=0$. Conditions (2.16) [or (2.18)] for $\zeta_0=0$ and $y_0=-x_0$ are satisfied according to (6.26) [or (6.25)]. Therefore for each $\mu\in\mathbb{T}$ there exists a Weyl sequence u_n such that $\|u_n\|=1$, $u_n\to 0$ weakly and

$$\chi_0^\varkappa S_0^\varkappa(\lambda)\chi_0^\varkappa u_n-\mu u_n\to 0$$

~strongly as $n\to\infty$. Moreover, we may assume that supports of u_n are contained in an arbitrary neighborhood of the point $0\in\Pi_{\omega_0}$. Let the operator Z be defined by formula (2.10) and $\chi_0(\omega)=\chi_0^{\varkappa}(\zeta)$. It follows from Theorem 6.11 that $f_n=Z^*u_n$ is a Weyl sequence for the operator $\chi_0 S(\lambda)\chi_0$. Let $\chi_1\in C^\infty(\mathbb{S}^{d-1})$ be supported on the set where $\chi_0(\omega)=1$. Then supp $(1-\chi_0)\cap\operatorname{supp}\chi_1=\varnothing$ and hence, by Theorem 6.11, the operator $(1-\chi_0)S(\lambda)\chi_1$ is compact. Without losing generality, we assume that $\chi_0 f_n=\chi_1 f_n=f_n$. Since both terms on the right-hand side of the estimate

$$\|S(\lambda)f_n-\mu f_n\|\leqslant\|\chi_0 S(\lambda)\chi_0 f_n-\mu f_n\|+\|(1-\chi_0)S(\lambda)\chi_1 f_n\|$$

tend to zero as $n\to\infty$, the spectrum of the SM $S(\lambda)$ covers the unit circle. Finally, we take into account that $S(\lambda)$ is unitary, so that its spectrum actually coincides with $\mathbb{T}$. □

We emphasize that, at least in the cases $V=0$ or $A=0$, the conditions (6.25) and (6.26) are fulfilled for all points k at the same time.

According to Proposition 5.14 and Theorem 6.12, the following result is true for the SM defined in terms of the usual wave operators.

Proposition 6.13: Let $V=0$ and let A satisfy estimates (1.2) for $\rho\in(1/2,1)$ and the transversal condition (1.9) (at least for large $|x|$). Suppose that the corresponding function

$$\mathbf{V}(x,\xi)=\int_{-\infty}^{\infty}\langle A(x+t\xi),\xi\rangle\,dt$$

satisfies condition (6.25) for some point (x_0,ω_0), $\omega_0\in\mathbb{S}^{d-1}$, $\langle x_0,\omega_0\rangle=0$. Then the spectrum of the SM $S(\lambda)$ covers the unit circle $\mathbb{T}$ for all $\lambda>0$.

As an example of a potential satisfying the assumptions of Proposition 6.13 we note (for $d=2$) the potential $A(x)=\gamma|x|^{-1-\rho}(-x_2,x_1)$, $|x|\geqslant R$, $\rho\in(1/2,1)$, $\gamma\neq 0$. In this case for any $(x,\xi)\in\mathbb{R}^{2d}$, $\langle x,\xi\rangle=0$, $|x|\geqslant R$,

$$\mathbf{V}(x,\xi)=\pm\gamma v_0|x|^{1-\rho},\quad v_0=\int_{-\infty}^{\infty}\langle u\rangle^{-1-\rho}du>0,$$

if $\hat{\xi}$ is obtained from $\hat{x}$ by rotation at the angle $\pm\pi/2$. Thus, condition (6.25) is satisfied.

Of course, Proposition 6.13 remains true for all $\rho>0$, but, if $\rho\leqslant 1/2$, then the SM is defined in terms of modified wave operators and condition (6.25) should be replaced by (6.26). On the contrary, if $\rho=1$, then under transversal condition (1.9) $\mathbf{V}(x,\xi)$ has typically the finite limits as $|x|\to\infty$, so that the essential spectrum of $S(\lambda)$ might be a subset of $\mathbb{T}$. This is the case for the Aharonov–Bohm potential $A(x)=\gamma|x|^{-2}(-x_2,x_1)$; for more general potentials of this type, see Ref. 16.

Proposition 6.13 contradicts a preceding result of Nicoleau. It is claimed in Ref. 12 that under the assumptions of Proposition 6.13 the operator $S(\lambda)-I$ is compact. This is incompatible with the assertion that the essential spectrum of $S(\lambda)$ covers the unit circle.

(Received 24 February 2002; accepted 23 March 2003)

Based upon the general supercharges which involve not only generators C_j of the Clifford algebra C(4,0) with positive metric, but also operators of third order, $C_jC_kC_l$, the general form of $N=4$ supersymmetric quantum mechanics (SSQM), which brings out the richer structures, is realized. Then from them, a one-dimensional physical realization and a new multidimensional physical realization of $N=4$ SSQM are respectively obtained by solving the constraint conditions. As applications, $N=4$ dynamical superconformal symmetries, which possess both the $N=4$ supersymmetries and the usual dynamical conformal symmetries, are studied in detail by considering two simple superpotentials k/x and ωx, and their corresponding superalgebraic structures, which are spanned by eight fermionic generators and six bosonic generators, are established as well. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1578531]

I. INTRODUCTION

Since the idea of supersymmetry was applied to quantum mechanical systems[1,2] to discover dynamical supersymmetry in ordinary quantum mechanics in order to explain the degeneracies of energy spectra extensively studies have been undertaken over the last twenty years in many aspects such as atomic physics,[3–5] nuclear physics,[6] many-body systems,[7,8] and so on. According to Witten,[2] a supersymmetric quantum mechanical system is characterized by the existence of N Hermitian supercharges Q^α which, together with the supersymmetric Hamiltonian H of this system, satisfy the following superalgebraic structure:

$$\begin{aligned} &\{Q^\alpha,\ Q^\beta\}=2\,\delta_{\alpha\beta}H, \quad \alpha,\beta=1,2,\ldots,N,\\ &(Q^\alpha)^\dagger=Q^\alpha, \quad [H,\ Q^\alpha]=0, \end{aligned} \tag{1}$$

where $\{,\}$ and $[,]$ denote an anticommutator and a commutator, respectively. We call Eq. (1) a supersymmetric quantum mechanical algebra, denoted by SS(N). When $N=2$, the simplest nontrivial realization of SS(2) was first given by Witten,[2]

$$\begin{aligned} Q^1&=\tfrac{1}{2}\{p\sigma_1+U(x)\sigma_2\},\\ Q^2&=\tfrac{1}{2}\{p\sigma_2-U(x)\sigma_1\}, \end{aligned} \tag{2}$$

a)Electronic mail: dongruan@tsinghua.edu.cn

$$H^W=\tfrac{1}{2}\{p^2+[U(x)]^2+U'(x)\sigma_3\},$$

where $p=-i\,(\mathrm{d}/\mathrm{d}x)$, $U'(x)\equiv(\mathrm{d}/\mathrm{d}x)\,U(x)$, $U(x)$ is generally called a superpotential, and σ_i $(i=1,\ 2,\ 3)$ are the usual Pauli matrices.[9] This supersymmetric Hamiltonian H^W describes a quantum mechanical system of a spin-$\frac{1}{2}$ particle moving on a line (x axis).

While $N=2$ supersymmetric quantum mechanics (SSQM) has drawn much attention[10,11] due to its simpler mathematical structure, however, there were only a few attempts at studying $N=4$ SSQM,[12–20] which possesses the higher degeneracies than the $N=2$ SSQM. For example, in one dimension, fourfold degeneracies of energy spectrum may typically occur in the $N=4$ SSQM, whereas double degeneracies in the $N=2$ SSQM. All the supercharges considered in many papers have the following form:

$$Q^\alpha=\frac{1}{\sqrt{2}}\sum_{j=1}^{r}A_j^\alpha C_j,\quad \alpha=1,2,\ldots,N=4, \tag{3}$$

where A_j^α are first-order differential operators with respect to, bosonic degrees of freedoms, the Cartesian coordinates $\{x_n|n=1,\ 2,\ldots,\ d\}$ and the corresponding momentum operators $\{p_n=-i\,(\partial/\partial x_n)\equiv -i\,\partial_n|n=1,\ 2,\ldots,\ d\}$ in d-dimensional space, and C_j, fermionic degrees of freedoms, are generators of the Clifford algebra C(r,0) with positive metric in r-dimensional flat carrier space.[21,22] They satisfy

$$[x_n,\ p_m]=i\,\delta_{nm},\quad n,m=1,2,\ldots,d,$$

$$\{C_j,\ C_l\}=2\,\delta_{jl},\quad C_j^\dagger=C_j,\quad j,l=1,2,\ldots,r, \tag{4}$$

$$[x_n,\ C_j]=[p_n,\ C_j]=0.$$

Obviously, for arbitrary N, the supercharges (3), being linear combinations of the fermionic operators C_j multiplied by the bosonic operators A_j^α, are natural generalizations of the supercharges in Witten's realization (2) of $N=2$ SSQM.

In fact, when $r\geqslant 4$, the Clifford algebra C(r,0), after a graded structure introduced, may yield a superalgebra.[23,24] The generators C_j of C(r,0), together with operators of odd orders in C_j, span the odd space of this superalgebra, in which anticommuting operations among all these odd elements are allowed. For example, the odd space of the superalgebra associated with C(4,0) is spanned by the odd elements C_j $(j=1,\ 2,\ 3,\ 4)$ and $C_jC_kC_l$ $(1\leqslant j<k<l\leqslant 4)$. The purpose of this paper is to realize the general form of $N=4$ SSQM in arbitrary dimension starting from the general supercharges in which the fermionic degrees of freedoms include all the odd elements of the superalgebra associated with C(4,0). As we shall see below, this realization brings out the richer structures.

This paper is arranged as follows. In Sec. II, the general form of $N=4$ SSQM is studied in detail by means of the Clifford algebras C(4,0) and C(0,3). In Sec. III, a one-dimensional physical realization and a new multidimensional physical realization for the $N=4$ SSQM are, respectively, obtained by solving the constraint conditions. In Sec. IV, as applications, $N=4$ superconformal quantum mechanics in one dimension, which is expanded from the one-dimensional realization of $N=4$ SSQM obtained in Sec. III, is discussed in detail by considering two simple superpotentials k/x and ωx, and their corresponding superalgebraic structures are established. A simple summary is given in the final section.

Throughout this paper we shall adopt units wherein $\hbar=m=1$, the symbol $[x]$ means taking an integer part of the real number x, and T in the expression A^T is referred to as transpose of the matrix A.

II. GENERAL FORM OF $N=4$ SSQM

For $N=4$, the four supercharges take the following general form:

$$Q^{\alpha}=\frac{1}{\sqrt{2}}\left(\sum_{j} A_j^{\alpha}C_j+\frac{i}{3!}\sum_{jklm}\epsilon_{jklm}D_j^{\alpha}C_kC_lC_m\right), \qquad \alpha, j, k, l, m=1,2,3,4, \tag{5}$$

where ϵ_{jklm} is a four-dimensional Levi-Civita symbol, C_j are the generators of the Clifford algebra C(4,0), A_j^{α} and D_j^{α} are the Hermitian first-order differential operators of the d-dimensional coordinates $\{x_n\}$ and momentum operators $\{p_n\}$. Clearly, the supercharges (3) are the special cases of those given by Eq. (5) with setting $D_j^{\alpha}=0$.

Substituting Eq. (5) into the first equation of Eq. (1), we may obtain the corresponding supersymmetric Hamiltonian

$$H=\frac{1}{2}(U+VC_1C_2C_3C_4)+\frac{1}{2}\sum_{l}^{q}\sum_{j\,k}\wp_{jk}^{l}B_l\Gamma_{jk}, \tag{6}$$

where

$$(1)\quad U=\sum_{j}[(A_j^{\alpha})^2+(D_j^{\alpha})^2], \quad \text{for any } \alpha;$$

$$(2)\quad V=i\sum_{j}[A_j^{\alpha}, D_j^{\alpha}], \quad \text{for any } \alpha;$$

$$(3)\quad i[A_j^{\alpha}, A_k^{\alpha}]+i[D_j^{\alpha}, D_k^{\alpha}]+\frac{1}{2}\sum_{mn}\epsilon_{jkmn}(\{A_m^{\alpha}, D_n^{\alpha}\}-\{A_n^{\alpha}, D_m^{\alpha}\})$$

$$=-\sum_{l=1}^{q}\wp_{jk}^{l}B_l, \quad \text{for any } \alpha;$$

$$(4)\quad \sum_{j}(\{A_j^{\alpha}, A_j^{\beta}\}+\{D_j^{\alpha}, D_j^{\beta}\})=0, \quad \alpha\neq\beta; \tag{7}$$

$$(5)\quad [A_j^{\alpha}, A_k^{\beta}]-[A_k^{\alpha}, A_j^{\beta}]+[D_j^{\alpha}, D_k^{\beta}]-[D_k^{\alpha}, D_j^{\beta}]=-i\sum_{mn}\epsilon_{jkmn}(\{A_n^{\alpha}, D_m^{\beta}\}+\{A_n^{\beta}, D_m^{\alpha}\}),$$

$$\alpha\neq\beta;$$

$$(6)\quad \sum_{j}([A_j^{\alpha}, D_j^{\beta}]+[A_j^{\beta}, D_j^{\alpha}])=0, \ \alpha\neq\beta;$$

$$(7)\quad \Gamma_{jk}\equiv\frac{i}{4}[C_j, C_k].$$

In Eq. (6), q antisymmetric matrices $\wp^{l}$ ($\wp_{jk}^{l}=-\wp_{kj}^{l}$) and Hermitian operators B_l have to be determined by the third equation in Eq. (7).

Now introduce the following linear transformations:

$$A_i^{\bar{\alpha}}=\Xi_{ij}^{\bar{\alpha}}A_j^4, \quad A_j^4\equiv A_j, \quad \bar{\alpha}=1,2,3,$$

$$D_i^{\bar{\alpha}}=\Xi_{ij}^{\bar{\alpha}}D_j^4, \quad D_j^4\equiv D_j. \tag{8}$$

In order to satisfy the first, second, fourth, and sixth equations in Eq. (7), $\Xi^{\bar{\alpha}}$ should be real antisymmetric,

$$(\Xi^{\bar{\alpha}})^T=(\Xi^{\bar{\alpha}})^{-1}=-\Xi^{\bar{\alpha}}, \tag{9}$$

and satisfy

$$\{\Xi^{\bar{\alpha}}, \ \Xi^{\bar{\beta}}\}=-2\delta_{\bar{\alpha}\bar{\beta}}, \tag{10}$$

that is, $\Xi^{\bar{\alpha}}$ constitute the Clifford algebra C(0,3) with negative metric. The third and fifth equations in Eq. (7) require further that $\Xi^{\bar{\alpha}}$ and $\wp^l$ satisfy

$$\Xi_{jk}^{\bar{\alpha}}\epsilon_{jkmn}=-2\Xi_{mn}^{\bar{\alpha}}, \tag{11}$$

$$[\Xi^{\bar{\alpha}}, \ \wp^l]=0. \tag{12}$$

Equation (12) shows that the number of antisymmetric matrices $\wp^l$ is three, i.e., $l=1, 2, 3$. It follows that matrix representations of $\Xi^{\bar{\alpha}}$ and $\wp^l$ that satisfy Eqs. (9), (10), and (12) may be taken as[12,22]

$$\Xi^1=\begin{pmatrix} i\sigma_2 & 0 \\ 0 & i\sigma_2 \end{pmatrix}, \quad \Xi^2=\begin{pmatrix} 0 & \sigma_3 \\ -\sigma_3 & 0 \end{pmatrix}, \quad \Xi^3=\begin{pmatrix} 0 & \sigma_1 \\ -\sigma_1 & 0 \end{pmatrix}, \tag{13}$$

$$\wp^1=\begin{pmatrix} 0 & i\sigma_2 \\ i\sigma_2 & 0 \end{pmatrix}, \quad \wp^2=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad \wp^3=\begin{pmatrix} -i\sigma_2 & 0 \\ 0 & i\sigma_2 \end{pmatrix}. \tag{14}$$

With the help of Eqs. (8) and (13), the four supercharges (5), in which the differential operators A_j and D_j now are independent of the index α, read

$$\begin{aligned}
Q^1&=\frac{1}{\sqrt{2}}[A_2C_1-A_1C_2+A_4C_3-A_3C_4 \\
&\quad +i(D_2C_2C_3C_4+D_1C_3C_4C_1+D_4C_1C_2C_4+D_3C_1C_2C_3)], \\
Q^2&=\frac{1}{\sqrt{2}}[A_3C_1-A_4C_2-A_1C_3+A_2C_4 \\
&\quad +i(D_3C_2C_3C_4+D_4C_3C_4C_1-D_1C_1C_2C_4-D_2C_1C_2C_3)], \\
Q^3&=\frac{1}{\sqrt{2}}[A_4C_1+A_3C_2-A_2C_3-A_1C_4 \\
&\quad +i(D_4C_2C_3C_4-D_3C_3C_4C_1-D_2C_1C_2C_4+D_1C_1C_2C_3)], \\
Q^4&=\frac{1}{\sqrt{2}}[A_1C_1+A_2C_2+A_3C_3+A_4C_4 \\
&\quad +i(D_1C_2C_3C_4-D_2C_3C_4C_1+D_3C_1C_2C_4-D_4C_1C_2C_3)].
\end{aligned} \tag{15}$$

By making use of Eqs. (8), (13), and (14), we can obtain from the third equation in Eq. (7) constraint conditions that A_j and D_j need satisfying

$$\begin{aligned}
B_1 &= -i[A_1, A_4] - i[D_1, D_4] - \{A_2, D_3\} + \{A_3, D_2\} \\
&= +i[A_2, A_3] + i[D_2, D_3] + \{A_1, D_4\} - \{A_4, D_1\}, \\
B_2 &= -i[A_2, A_4] - i[D_2, D_4] + \{A_1, D_3\} - \{A_3, D_1\} \\
&= -i[A_1, A_3] - i[D_1, D_3] + \{A_2, D_4\} - \{A_4, D_2\}, \\
B_3 &= -i[A_3, A_4] - i[D_3, D_4] - \{A_1, D_2\} + \{A_2, D_1\} \\
&= +i[A_1, A_2] + i[D_1, D_2] + \{A_3, D_4\} - \{A_4, D_3\}.
\end{aligned} \tag{16}$$

Correspondingly, the supersymmetric Hamiltonian (6) becomes

$$\begin{aligned}
H = \frac{1}{2}\sum_{j=1}^{4} [A_j^2 + D_j^2] + [B_1(\Gamma_{14} + \Gamma_{32}) + B_2(\Gamma_{24} + \Gamma_{13}) + B_3(\Gamma_{34} + \Gamma_{21})] \\
+ \frac{i}{2}\sum_{j=1}^{4} [A_j, D_j] C_1 C_2 C_3 C_4.
\end{aligned} \tag{17}$$

Similar to $N=2$ SSQM,[10] we may further rewrite the four supercharges (15) in the raising/lowering form, which are closely related to the factorization method,[25]

$$Q_1^{\pm} = \frac{1}{\sqrt{2}}(Q_4 \mp iQ_1), \quad Q_2^{\pm} = \frac{1}{\sqrt{2}}(Q_2 \mp iQ_3), \tag{18}$$

and satisfy $Q_\mu^{\mp} = (Q_\mu^{\pm})^{\dagger}$ $(\mu = 1, 2)$, after redefining the four generators C_j $(j = 1, 2, 3, 4)$ of C(4,0) as

$$C_1^{\pm} = \tfrac{1}{2}(C_1 \pm iC_2), \quad C_2^{\pm} = \tfrac{1}{2}(C_3 \pm iC_4). \tag{19}$$

Thus, the four supercharges (15) and the supersymmetric Hamiltonian (17) can be written, respectively, in the forms

$$\begin{aligned}
Q_1^+ &= (A_1 - iA_2)C_1^+ + (A_3 - iA_4)C_2^+ - i(D_1 - iD_2)[C_2^+, C_2^-]C_1^+ + i(D_3 - iD_4)[C_1^+, C_1^-]C_2^+, \\
Q_1^- &= (A_1 + iA_2)C_1^- + (A_3 + iA_4)C_2^- + i(D_1 + iD_2)[C_2^+, C_2^-]C_1^- - i(D_3 + iD_4)[C_1^+, C_1^-]C_2^-, \\
Q_2^+ &= (A_3 - iA_4)C_1^- - (A_1 - iA_2)C_2^- - i(D_3 - iD_4)[C_2^+, C_2^-]C_1^- + i(D_1 - iD_2)[C_1^+, C_1^-]C_2^-, \\
Q_2^- &= (A_3 + iA_4)C_1^+ - (A_1 + iA_2)C_2^+ + i(D_3 + iD_4)[C_2^+, C_2^-]C_1^+ - i(D_1 + iD_2)[C_1^+, C_1^-]C_2^+,
\end{aligned} \tag{20}$$

and

$$\begin{aligned}
H = \frac{1}{2}\sum_{j=1}^{4} [A_j^2 + D_j^2] + \Big\{ -B_1(C_1^+C_2^- - C_1^-C_2^+) + iB_2(C_1^+C_2^- + C_1^-C_2^+) + \frac{1}{2}B_3([C_1^+, C_1^-] \\
- [C_2^+, C_2^-]) \Big\} - \frac{i}{2}\sum_{j=1}^{4} [A_j, D_j][C_1^+, C_1^-][C_2^+, C_2^-].
\end{aligned} \tag{21}$$

It is easy to check that Eqs. (20) and (21) satisfy SS(4) [see Eq. (1)], which now becomes

$$\{Q_\mu^+, Q_\nu^-\}=2\delta_{\mu\nu}H, \quad \mu,\nu=1,2,$$

$$\{Q_\mu^\pm, Q_\nu^\pm\}=0, \quad [H, Q_\mu^\pm]=0. \tag{22}$$

III. PHYSICAL REALIZATIONS OF $N=4$ SSQM

By virtue of the results obtained in Sec. II, we shall discuss in this section two physical realizations of $N=4$ SSQM through choosing the concrete forms for A_j and D_j in Eqs. (20) and (21) to ensure the kinetic energy and potential energy terms appear in the corresponding $N=4$ supersymmetric Hamiltonian.

A. One-dimensional realization

Take

$$A_4=p=-i\frac{d}{dx}, \quad D_{\bar{n}}=0, \quad \bar{n}=1,2,3, \tag{23}$$

and the other components $A_{\bar{n}}$ and D_4 are real functions of x. Substituting them into the constraint conditions (16) gives rise to

$$D_4=\frac{A_1'}{2A_1}=\frac{A_2'}{2A_2}=\frac{A_3'}{2A_3}, \tag{24}$$

where the prime means derivation with respect to x. In order to satisfy Eq. (24), we may choose for simplicity

$$A_{\bar{n}}=k_{\bar{n}}W, \tag{25}$$

where $k_{\bar{n}}$ are constants, and W, here referred to as a superpotential, is an arbitrary real function of x. Accordingly, we have

$$D_4=\frac{W'}{2W}. \tag{26}$$

It follows by inserting Eqs. (25) and (26) into Eqs. (20) and (21) that the four supercharges and $N=4$ supersymmetric Hamiltonian in one dimension have, respectively, the following forms:

$$\begin{aligned}
Q_1^+&=(-ip+k_3W)C_2^+ +k^-WC_1^+ +\frac{W'}{2W}[C_1^+, C_1^-]C_2^+,\\
Q_1^-&=(+ip+k_3W)C_2^- +k^+WC_1^- +\frac{W'}{2W}[C_1^+, C_1^-]C_2^-,\\
Q_2^+&=(-ip+k_3W)C_1^- -k^-WC_2^- -\frac{W'}{2W}[C_2^+, C_2^-]C_1^-,\\
Q_2^-&=(+ip+k_3W)C_1^+ -k^+WC_2^+ -\frac{W'}{2W}[C_2^+, C_2^-]C_1^+,
\end{aligned} \tag{27}$$

where $k^\pm\equiv k_1\pm ik_2$, and

$$H=\frac{1}{2}p^2+\frac{1}{2}k^2W^2+\frac{1}{2}\left(\frac{W'}{2W}\right)^2+\left\{-k_1W'(C_1^+C_2^--C_1^-C_2^+)+ik_2W'(C_1^+C_2^-+C_1^-C_2^+)\right.$$
$$\left.+\frac{1}{2}k_3W'([C_1^+,C_1^-]-[C_2^+,C_2^-])\right\}-\frac{1}{2}[C_1^+,C_1^-][C_2^+,C_2^-]\left(\frac{W'}{2W}\right)'\equiv\frac{1}{2}p^2+V(x;C_j), \tag{28}$$

with $k^2=k_1^2+k_2^2+k_3^2$. Obviously, the Hamiltonian (28) possesses a usual kinetic energy term $\frac{1}{2}p^2$ and a potential function $V(x;C_j)$, so this resulting realization, Eqs. (27) and (28), may be applied to the real quantum mechanical systems provided that W and C_j are appropriately taken.

For the sake of convenient applications, let us further discuss the explicit matrix form for the one-dimensional $N=4$ SSQM given by Eqs. (27) and (28). In fact the Clifford algebra C(4,0) is isomorphic to the well-known Dirac algebra in the relativistic quantum mechanics,[26] here we may take the following matrix representation for C_j:

$$C_{\bar{m}}=\begin{pmatrix}0 & i\sigma_{\bar{m}}\\ -i\sigma_{\bar{m}} & 0\end{pmatrix},\quad \bar{m}=1,2,3,\quad C_4=\begin{pmatrix}0 & I_{2\times2}\\ I_{2\times2} & 0\end{pmatrix}, \tag{29}$$

where $I_{2\times2}$ is a 2×2 unit matrix, then the four supercharges (27) and the supersymmetric Hamiltonian (28) read, respectively,

$$Q_1^+=\begin{pmatrix}0 & 0 & \eta^+ & \varepsilon^-\\ 0 & 0 & 0 & 0\\ 0 & -\varepsilon^- & 0 & 0\\ 0 & \zeta^+ & 0 & 0\end{pmatrix},\quad Q_2^+=\begin{pmatrix}0 & 0 & 0 & 0\\ 0 & 0 & \eta^+ & \varepsilon^-\\ \varepsilon^- & 0 & 0 & 0\\ -\zeta^+ & 0 & 0 & 0\end{pmatrix}, \tag{30}$$

where $\eta^{\pm}\equiv p\pm i[k_3W+(W'/2W)]$, $\zeta^{\pm}\equiv p\pm i[k_3W-(W'/2W)]$, $\varepsilon^{\pm}\equiv\mp ik^{\pm}W$, and

$$H=\frac{1}{2}p^2+\frac{1}{2}k^2W^2+\frac{1}{2}\left(\frac{W'}{2W}\right)^2$$
$$+\frac{1}{2}\begin{pmatrix}-\left(\frac{W'}{2W}\right)' & & & \\ & -\left(\frac{W'}{2W}\right)' & & \\ & & \left(\frac{W'}{2W}\right)'+2k_3W' & 2k^-W'\\ & & 2k^+W' & \left(\frac{W'}{2W}\right)'-2k_3W'\end{pmatrix}. \tag{31}$$

A comparison between Eq. (31) and the third equation in Eq. (2) shows that in one dimension the matrix form of $N=4$ supersymmetric Hamiltonian is quasidiagonal, whereas the one of $N=2$ supersymmetric Hamiltonian is completely diagonal. (The quasidiagonal form of $N=2$ supersymmetric Hamiltonian appear in multidimension only, for example, see Ref. 27.)

Especially, when $k^{\pm}=0$, it follows from Eq. (31) that we may obtain a completely diagonal $N=4$ supersymmetric Hamiltonian

$$\ddot{H}=\frac{1}{2}p^2+\frac{1}{2}k_3^2W^2+\frac{1}{2}\left(\frac{W'}{2W}\right)^2+\frac{1}{2}\begin{pmatrix}-\left(\frac{W'}{2W}\right)' & & & \\ & -\left(\frac{W'}{2W}\right)' & & \\ & & \left(\frac{W'}{2W}\right)'+2k_3W' & \\ & & & \left(\frac{W'}{2W}\right)'-2k_3W'\end{pmatrix}$$
$$\equiv \mathrm{diag}[\ddot{H}_1,\ \ddot{H}_2,\ \ddot{H}_3,\ \ddot{H}_4]. \tag{32}$$

Note that in Eq. (32) the first and second diagonal component Hamiltonians $\ddot{H}_1$ and $\ddot{H}_2$ are identical, but neither of them can be abandoned because of requirement of SS(4). The corresponding supercharges $\ddot{Q}_\mu^\pm$ $(\mu=1,2)$ may be directly obtained by setting $k^\pm=0$ in Eq. (30). Since $\ddot{H}$ commutes with $\ddot{Q}_\mu^\pm$, the energy spectra of $\ddot{H}_i$ $(i=1,2,3,4)$ are identical except for the ground state, which is also an elementary property of SSQM. Consequently, $\ddot{H}_i$ are called superpartner Hamiltonians.

Let four-component spinor eigenfunction of $\ddot{H}$ be $\ddot{\psi}=[\ddot{\psi}_1,\ \ddot{\psi}_2,\ \ddot{\psi}_3,\ \ddot{\psi}_4]^T$, in which $\ddot{\psi}_i$ $(i=1,2,3,4)$ are, respectively, eigenfunctions of $\ddot{H}_i$ belonging to energy eigenvalues $\ddot{E}_i$. In terms of the third equation in Eq. (22), the four eigenfunctions $\ddot{\psi}_1,\ \ddot{\psi}_2,\ \ddot{\psi}_3,\ \ddot{\psi}_4$ may be related by the four supercharges $\ddot{Q}_\mu^\pm$, or, more concretely, by the four first-order differential operators $\eta^\pm$ and $\zeta^\pm$ given in Eq. (30)

$$\ddot{\psi}_3 \overset{\eta^+}{\rightarrow} \ddot{\psi}_1=\ddot{\psi}_2 \overset{\zeta^+}{\rightarrow} \ddot{\psi}_4 \quad \text{and} \quad \ddot{\psi}_3 \overset{\eta^-}{\leftarrow} \ddot{\psi}_1=\ddot{\psi}_2 \overset{\zeta^-}{\leftarrow} \ddot{\psi}_4. \tag{33}$$

Similar to $N=2$ case,[10] the $N=4$ supersymmtery of some $N=4$ supersymmetric quantum mechanical system is broken if this system has no zero-energy ground state, and is unbroken if this system has a zero-energy ground state. A typical structure of the fourfold degenerate energy spectrum of $\ddot{H}$ is illustratively depicted in Fig. 1, which $N=4$ supersymmetry is broken.

Furthermore, introduce

$$X_3=\frac{1}{2}\sum_\mu\ [C_\mu^+,\ C_\mu^-], \quad X^\pm=\mp C_1^\pm C_2^\pm, \tag{34}$$

which satisfy

$$[X_3,\ X^\pm]=\pm 2X^\pm, \quad [X^+,\ X^-]=X_3, \tag{35}$$

that is, X_3 and $X^\pm$ span an internal SO(3) algebra. Due to the fact $[\ddot{H},\ X_3]=0$, we may use the values of X_3 to label the energy spectra of $\ddot{H}_i$ $(i=1,2,3,4)$. With the help of Eq. (29), the matrix representation of X_3 is

$$X_3=\begin{pmatrix}1 & & & \\ & -1 & & \\ & & 0 & \\ & & & 0\end{pmatrix}. \tag{36}$$

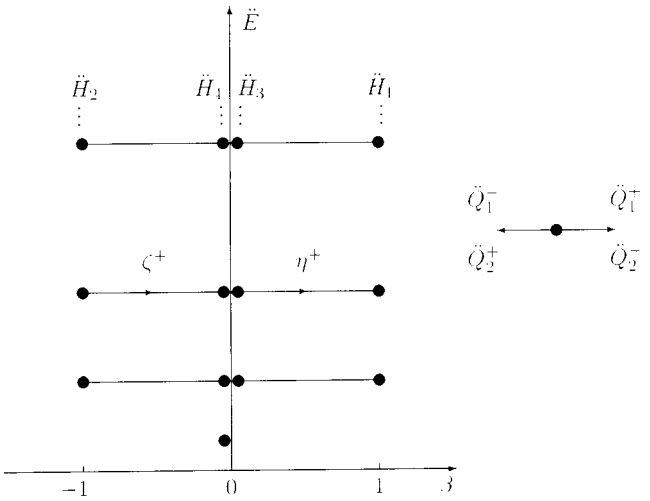

FIG. 1. Typical structure of the fourfold degenerate energy spectrum of $\ddot{H}$ given by Eq. (32). The energy spectra of H_1, H_2, H_3, H_4 correspond to the $\beta=1, -1, 0, 0$ sectors, respectively. The eigenstate belonging to some energy level (dot) may be connected with its left or right eigenstate by the supercharges $\ddot{Q}_\mu^\pm$ $(\mu=1,2)$, or, concretely, by the first-order differential operators $\eta^\pm$ and $\zeta^\pm$ along the horizontal line.

Denoting the values of X_3 by $\beta=1, -1, 0$ and 0, then the energy spectrum of $\ddot{H}_1$ belongs to the $\beta=1$ sector, that of $\ddot{H}_2$ to the $\beta=-1$ sector and so on. Hence, though the first and second superpartner Hamiltonians $\ddot{H}_1$ and $\ddot{H}_2$ are identical, their energy spectra belong to the different sectors, respectively; though the third and fourth superpartner Hamiltonians $\ddot{H}_3$ and $\ddot{H}_4$ are different, their energy spectra belong to the same $\beta=0$ sector.

B. New multidimensional realization

The $N=4$ SSQM obtained in Sec. II itself is valid for the arbitrary dimensions. In this section we shall put forward a new multidimensional physical realization of $N=4$ SSQM by taking the following matrix forms for the Hermitian operators A_4 and D_4 in Eq. (20):

$$A_4=\sum_{j=1}^{d}(p_j+L_j)\tau_j, \quad D_4=\sum_{j=1}^{d}F_j\tau_j, \tag{37}$$

and the other components, $D_{\bar{n}}=0$ $(\bar{n}=1,2,3)$, $A_{\bar{n}}$, together with L_j and F_j in Eq. (37), are the real functions of the coordinates $\{x_n\}$ in d-dimensional space. Here, τ_j are a set of Hermitian matrices which we assume to commute with p_j, L_j, F_j, and C_j. The fact that τ_j commute with C_j implies that they should be, respectively, considered as

$$\tau_j\sim I_{4\times4}\otimes\tau_j, \quad C_j\sim C_j\otimes I_{t\times t}, \tag{38}$$

where the subscript 4 is the dimension of the matrix representation of C(4,0), and the subscript t stands for the order of the matrices τ_j. Note that in the present realization the number of matrices τ_j is equal to the dimensions of space. In order to produce the usual kinetic energy term, we may, after substituting Eq. (37) into Eq. (21), take τ_j $(j=1,2,\ldots,d)$ so that

$$\{\tau_j, \ \tau_l\}=2\delta_{jl}, \tag{39}$$

that is, τ_j constitute the Clifford algebra C(d,0) as well.

The constraint conditions (16) require that

$$2A_{\bar{n}}F_j=\partial_j A_{\bar{n}},\quad \bar{n}=1,2,3,\quad j=1,2,\ldots,d. \tag{40}$$

Similar to the one-dimensional case [see Eq. (25)], a simple choice for Eq. (40) is

$$A_{\bar{n}}=k_{\bar{n}}W, \tag{41}$$

where $k_{\bar{n}}$ are constants, the superpotential W is a real function of $\{x_n\}$. In consequence, we have

$$F_j=\frac{\partial_j W}{2W}. \tag{42}$$

It follows by substituting Eqs. (37), (41), and (42) into Eq. (21) that we have the $N=4$ supersymmetric Hamiltonian in d-dimensional space,

$$\begin{aligned}H=&\frac{1}{2}\sum_j^d(-i\partial_j+L_j)^2+\frac{1}{2}k^2W^2+\frac{1}{2}\sum_j^d\left(\frac{\partial_j W}{2W}\right)^2-\frac{1}{2}\sum_{k<l}^d\mathcal{F}_{kl}\tau_{kl}+\sum_j^d\tau_j(\partial_j W)\\&\times\left\{-k_1(C_1^+C_2^--C_1^-C_2^+)+ik_2(C_1^+C_2^-+C_1^-C_2^+)+\frac{1}{2}k_3([C_1^+,C_1^-]-[C_2^+,C_2^-])\right\}\\&-\frac{1}{2}[C_1^+,C_1^-][C_2^+,C_2^-]\left\{\sum_j^d\left(\partial_j\frac{\partial_j W}{2W}\right)+\sum_{k<l}^d\left(\left\{-i\partial_k,\frac{\partial_l W}{2W}\right\}+2L_k\frac{\partial_l W}{2W}\right)\tau_{kl}\right\},\end{aligned} \tag{43}$$

where $\tau_{kl}\equiv(i/2)[\tau_k,\tau_l]$, and $\mathcal{F}_{kl}\equiv\partial_k L_l-\partial_l L_k$. The vector potential L_i naturally generates a gauge field interaction structure in d-dimensional space so that $\mathcal{F}_{kl}$ may be seen as the strength of vector field. The terms $\mathcal{F}_{kl}\tau_{kl}$ and $\{-i\partial_k,\partial_l W/2W\}\tau_{kl}$ generalize the Pauli coupling and the orbit-spin coupling interactions, respectively. For the simple three-dimensional case, these interpretations are more distinct. We take conveniently τ_j as the Pauli matrices

$$\tau_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \tau_2=\begin{pmatrix}0&i\\-i&0\end{pmatrix},\quad \tau_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}, \tag{44}$$

then the supersymmetric Hamiltonian (43) becomes

$$\begin{aligned}H=&\frac{1}{2}(\vec{p}+\vec{L})^2+\frac{1}{2}k^2W^2+\frac{1}{2}\left(\frac{\nabla W}{2W}\right)^2+\frac{1}{2}\nabla\cdot\left(\frac{\nabla W}{2W}\right)\begin{pmatrix}-I_{4\times4}&0\\0&I_{4\times4}\end{pmatrix}\\&+\frac{1}{2}\vec{B}\cdot\vec{\tau}-\frac{1}{2}\left(\frac{\nabla W}{2W}\right)\times(-i\nabla+\vec{L})\cdot\vec{\tau},\end{aligned} \tag{45}$$

where ∇ is a three-dimensional gradient operator, $\vec{B}\cdot\vec{\tau}\equiv\nabla\times\vec{L}\cdot\vec{\tau}$ and $(\nabla W/2W)\times(-i\nabla)\cdot\vec{\tau}$ are the usual Pauli coupling term and the orbit-spin coupling interaction, respectively.[9] It can be seen that in three dimension the new realized $N=4$ supersymmetric Hamiltonian (45) is an 8×8 matrix, whereas the original one (17) or (21), in which A_j and D_j are taken as some appropriate first-order differential operator functions of the three-dimensional coordinates and momentum operators, is a 4×4 matrix.

Of course, in Eq. (37), we may also take $A_4=\Sigma_j(ip_j+\tilde{L}_j)\tilde{\tau}_j$, $D_4=\Sigma_j\tilde{F}_j\tilde{\tau}_j$, and $A_{\bar{n}}$, $\tilde{L}_j$ and $\tilde{F}_j$ are the functions of $\{x_n\}$ as well. Thus, the Hermiticities of the supercharges $Q_\alpha^\pm$ require that $\tilde{L}_j$ and $\tilde{F}_j$ should be pure imaginary, and $\tilde{\tau}_i$ should be anti-Hermitian. The convenient choices $\tilde{L}_i=iL_j$, $\tilde{F}_j=iF_j$, and $\tilde{\tau}_j=i\tau_j$ [i.e., $\tilde{\tau}_j$ constitute the Clifford algebra C(0,d) with negative metric] will lead to the same results as Eq. (43).

IV. APPLICATIONS

In this section, using the diagonal matrix realization (32) of $N=4$ SSQM in one dimension, we shall study in detail $N=4$ SCQM, which, discussed first by Fubini *et al.*,[28] is a generalization of $N=4$ SSQM, by considering two simple superpotentials k/x and ωx. Here the main task is to find a set of special exactly solvable potentials which can be brought into the framework of $N=4$ SCQM and the corresponding superalgebraic structures.

(1) The first example is a one-dimensional superpotential

$$W(x)=\frac{k}{x}, \tag{46}$$

where k is a real constant, and $x\in(-\infty,\ \infty)$. Substituting Eq. (46) into Eq. (30) combined with $k^{\pm}=0$ and $k_3=1$ and Eq. (32), we may obtain, respectively, the supercharges

$$\overline{Q}_1^{+}=\begin{pmatrix}0&0&\overline{\eta}^{+}&0\\0&0&0&0\\0&0&0&0\\0&\overline{\zeta}^{+}&0&0\end{pmatrix},\quad \overline{Q}_2^{+}=\begin{pmatrix}0&0&0&0\\0&0&\overline{\eta}^{+}&0\\0&0&0&0\\-\overline{\zeta}^{+}&0&0&0\end{pmatrix}, \tag{47}$$

where $\overline{\eta}^{\pm}=p\pm i(k-\frac{1}{2})(1/x)$, $\overline{\zeta}^{\pm}=p\pm i(k+\frac{1}{2})(1/x)$, and the supersymmetric Hamiltonian

$$H^{\mathrm{sc}}=\frac{1}{2}p^2+\frac{1}{2x^2}\begin{pmatrix}k^2-\frac{1}{4}&&&\\&k^2-\frac{1}{4}&&\\&&k^2-2k+\frac{3}{4}&\\&&&k^2+2k+\frac{3}{4}\end{pmatrix}\equiv\mathrm{diag}[H_1^{\mathrm{c}},\ H_2^{\mathrm{c}},\ H_3^{\mathrm{c}},\ H_4^{\mathrm{c}}]. \tag{48}$$

It may be further verified that H^{sc}, together with the dilatation generator D and the conformal generator K, which are given explicitly by

$$D=-\tfrac{1}{4}\{p,x\},\quad K=\tfrac{1}{2}x^2 \tag{49}$$

fulfills the same commutation relations of the conformal algebra SO(2,1)[29–31]

$$[D,H^{\mathrm{sc}}]=-iH^{\mathrm{sc}},\quad [D,K]=iK,\quad [H^{\mathrm{sc}},K]=2iD, \tag{50}$$

as its four superpartner Hamiltonians H_i^{c} ($i=1,2,3,4$). Hence, H^{sc} given by Eq. (48) is the so-called superconformal Hamiltonian,[28] which possesses not only the $N=4$ supersymmetry but also the dynamical conformal symmetry. Different from the results of Fubini *et al.*,[28] here we realize successfully a $N=4$ superconformal quantum mechanics (SCQM) in one dimension.[33–35] However, the realization of $N=4$ SCQM obtained in Ref. 28, holding uniquely in two dimension, can not be reduced to the one-dimensional or extended to more than two-dimensional cases. Furthermore, in the quartet structure of H^{sc}, three superpartner Hamiltonians $H_1^{\mathrm{c}}(=H_2^{\mathrm{c}})$, H_3^{c}, H_4^{c} are different, whereas in the quartet structure in Ref. 28 only two different superpartner Hamiltonians, $H_1^{\mathrm{c}}(=H_2^{\mathrm{c}})$ and $H_3^{\mathrm{c}}(=H_4^{\mathrm{c}})$, appear.

Let the four-component spinor eigenfunction of H^{sc} be $\psi^{\mathrm{sc}}=[\psi_1^{\mathrm{c}},\ \psi_2^{\mathrm{c}},\ \psi_3^{\mathrm{c}},\ \psi_4^{\mathrm{c}}]^T$, where ψ_i^{c} ($i=1,2,3,4$) are, respectively, the eigenfunctions of H_i^{c} belonging to the energy eigenvalues E_i^{c}. According to the transformation property (33), ψ_i^{c} are related by $\overline{\eta}^{\pm}$ and $\overline{\zeta}^{\pm}$ given in Eq. (47). In order to look for the eigenfunctions and energy eigenvalues of H^{sc}, we check first whether or not a zero-energy ground state exists by solving the following four first-order differential equations

$$\overline{Q}_{\mu}^{\pm}\,\psi_0^{\mathrm{sc}}=0,\quad \mu=1,2, \tag{51}$$

where $\psi_0^{\mathrm{sc}}\equiv[\psi_{0,1}^{\mathrm{c}},\ \psi_{0,2}^{\mathrm{c}},\ \psi_{0,3}^{\mathrm{c}},\ \psi_{0,4}^{\mathrm{c}}]^T$ stands for a zero-energy eigenfunction. It is clear that neither of the four solutions to Eq. (51),

$$\begin{aligned}
&\psi_{0,1}^{\mathrm{c}}\sim x^{-(2k-1)/2},\\
&\psi_{0,2}^{\mathrm{c}}\sim x^{+(2k+1)/2},\\
&\psi_{0,3}^{\mathrm{c}}\sim x^{+(2k-1)/2},\\
&\psi_{0,4}^{\mathrm{c}}\sim x^{-(2k+1)/2}
\end{aligned} \tag{52}$$

is normalizable on $(-\infty,\infty)$ so that neither of H_i^{c} has zero-energy level. Hence, the supersymmetry of the $N=4$ superconformal quantum mechanical system described by H^{sc} is broken. From the SSQM point of view, we know that either of H_i^{c} $(i=1,2,3,4)$ has the same energy spectrum as the other three superpartner Hamiltonians, with E_i^{c} being larger than zero. Consider the special case of $k=1/2$, it follows immediately from Eq. (48) that the conformal Hamiltonian $\breve{H}_4^{\mathrm{c}}=\frac{1}{2}p^2+(1/x^2)$ is the superpartner of the Hamiltonian $\breve{H}_1=\frac{1}{2}p^2$ $(=\breve{H}_2=\breve{H}_3)$ of a free particle. Therefore, the normalizable eigenfunctions of H_i^{c} in Eq. (48) corresponding to some positive definite energy $E_i^{\mathrm{c}}>0$ are the normalizable wave plane eigenfunctions,[37] i.e., the Bessel functions, $\psi_i^{\mathrm{c}}=\sqrt{x}J_{\lambda_i}(x\sqrt{2E_i})$ $(i=1,2,3,4)$, with $\lambda_i=k+(-)^i[i/3]$.

Now let us establish a superalgebra that governs the above $N=4$ superconformal quantum mechanical system described by H^{sc}, in which both SS(4) and SO(2,1) should be contained. Direct calculations show that the five generators of SS(4) and three generators of SO(2,1) are not closed under the anticommutation and commutation relations, for example, commuting the generators $\overline{Q}_{\mu}^{\pm}$ of SS(4) and the generator K of SO(2,1) yields new operators

$$S_{\mu}^{\pm}=xC_{\mu}^{\pm},\quad \mu=1,2. \tag{53}$$

Thus, we obtain the following closed (anti)commutation relations:

$$\begin{aligned}
&(1)\ \{\overline{Q}_{\mu}^{+},\ \overline{Q}_{\nu}^{-}\}=2\delta_{\mu\nu}H^{\mathrm{sc}},\quad \{\overline{Q}_{\mu}^{\pm},\ \overline{Q}_{\nu}^{\pm}\}=0,\quad \mu,\ \nu=1,2;\\
&(2)\ \{S_{\mu}^{+},\ S_{\nu}^{-}\}=2\delta_{\mu\nu}K,\quad \{S_{\mu}^{\pm},\ S_{\nu}^{\pm}\}=0;\\
&(3)\ \{\overline{Q}_{\mu}^{\pm},\ S_{\nu}^{\mp}\}=\delta_{\mu\nu}(k+(-)^{\mu}X_3\pm 2iD)+2(\delta_{\mu\nu}-1)(\delta_{\mu 1}X^{\pm}+\delta_{\mu 2}X^{\mp}),\\
&\qquad \{\overline{Q}_{\mu}^{\pm},\ S_{\nu}^{\pm}\}=0;\\
&(4)\ [D,\ H^{\mathrm{sc}}]=-iH^{\mathrm{sc}},\quad [D,\ K]=iK,\quad [H^{\mathrm{sc}},\ K]=2iD;\\
&(5)\ [X_3,\ X^{\pm}]=\pm 2X^{\pm},\quad [X^{+},\ X^{-}]=X_3;\\
&(6)\ [H^{\mathrm{sc}},\ \overline{Q}_{\mu}^{\pm}]=0,\quad [D,\ \overline{Q}_{\mu}^{\pm}]=-\tfrac{1}{2}i\overline{Q}_{\mu}^{\pm},\quad [K,\ \overline{Q}_{\mu}^{\pm}]=\pm 2S_{\mu}^{\pm};\\
&\qquad [H^{\mathrm{sc}},\ S_{\mu}^{\pm}]=\pm 2\overline{Q}_{\mu}^{\pm},\quad [D,\ S_{\mu}^{\pm}]=\tfrac{1}{2}iS_{\mu}^{\pm},\quad [K,\ S_{\mu}^{\pm}]=0;\\
&(7)\ [H^{\mathrm{sc}},\ X_3]=0,\quad [D,\ X_3]=0,\quad [K,\ X_3]=0;\\
&\qquad [H^{\mathrm{sc}},\ X^{\pm}]=0,\quad [D,\ X^{\pm}]=0,\quad [K,\ X^{\pm}]=0;
\end{aligned} \tag{54}$$

$$(8)\quad [X_3,\ \overline{Q}_\mu^{\pm}]=\pm(-)^{\mu+1}\overline{Q}_\mu^{\pm},\quad [X^{\pm},\ \overline{Q}_\mu^{\pm}]=\pm(1-\delta_{\mu 1})\overline{Q}_1^{\pm},$$

$$[X^{\pm},\ \overline{Q}_\mu^{\mp}]=\mp(1-\delta_{\mu 2})\overline{Q}_2^{\mp},\quad [X_3,\ S_\mu^{\pm}]=\pm(-)^{\mu+1}S_\mu^{\pm},$$

$$[X^{\pm},\ S_\mu^{\pm}]=\pm(1-\delta_{\mu 1})\overline{S}_1^{\pm},\quad [X^{\pm},\ S_\mu^{\mp}]=\mp(1-\delta_{\mu 2})\overline{S}_2^{\mp}.$$

In practice the eight fermionic generators $S_\mu^{\pm}$, $\overline{Q}_\mu^{\pm}$ ($\mu=1, 2$) and six bosonic generators $H^{\rm sc}$, D, K, X_3, and $X^{\pm}$ span a superalgebra SU(1,1|2).[34,35] The first equation in the second set of equations in Eq. (54) indicates that the fermionic generators $S_\mu^{\pm}$ may be seen as square roots of the conformal generator K, which is similar as the supercharges are the square roots of the supersymmetric Hamiltonian. Similar to SO(2,1), the superconformal symmetry described by SU(1,1|2) is dynamical since $H^{\rm sc}$ does not commute with $S_\mu^{\pm}$, D and K. It is obvious that besides SS(4), SO(2,1), and SO(3) [see the fifth set of equations in Eq. (54)], SU(1,1|2) contains a Lie superalgebra OSp(2,1) as its subalgebra,[23] which, spanned by either $\{S_1^{\pm}, \overline{Q}_1^{\pm}, H^{\rm sc}, D, K, X_3\}$ or $\{S_2^{\pm}, \overline{Q}_2^{\pm}, H^{\rm sc}, D, K, X_3\}$, has been used to study $N=2$ SCQM.[28,32] Since the generators of SO(2,1) commute with those of SO(3) [see the seventh set of equations in Eq. (54)], SU(1,1|2) contains a maximum Lie subalgebra $\mathrm{SO}(3)\times\mathrm{SO}(2,1)$. Consequently, we have the following two group chains:

$$\mathrm{SU}(1,1|2)\supset\left\{\begin{matrix}\mathrm{OSp}(2,1)\supset\mathrm{SO}(2)\times\mathrm{SO}(2,1)\\ \mathrm{SO}(3)\times\mathrm{SO}(2,1)\end{matrix}\right\}\supset\underset{X_3}{\mathrm{SO}(2)}\times\underset{H^{\rm sc}}{\mathrm{SO}(2)}. \tag{55}$$

(2) The second example is a linear superpotential on the half-line,

$$W(x)=\omega x, \tag{56}$$

where ω is a real constant, and $x\in(0,\ \infty)$. Substitution into Eq. (30) combined with $k^{\pm}=0$ and $k_3=1$ and Eq. (32) gives, respectively, the supercharges

$$\tilde{Q}_1^{+}=\begin{pmatrix}0&0&\tilde{\eta}^{+}&0\\0&0&0&0\\0&0&0&0\\0&\tilde{\zeta}^{+}&0&0\end{pmatrix},\quad \tilde{Q}_2^{+}=\begin{pmatrix}0&0&0&0\\0&0&\tilde{\eta}^{+}&0\\0&0&0&0\\-\tilde{\zeta}^{+}&0&0&0\end{pmatrix}, \tag{57}$$

where $\tilde{\eta}^{\pm}\equiv p\pm i[\omega x+(1/2x)]$, $\tilde{\zeta}^{\pm}\equiv p\pm i[\omega x-(1/2x)]$, and the corresponding supersymmetric Hamiltonian

$$\tilde{H}=\frac{1}{2}p^2+\frac{1}{2}\omega^2x^2+\begin{pmatrix}\frac{3}{8x^2}&&&\\&\frac{3}{8x^2}&&\\&&-\frac{1}{8x^2}+\omega&\\&&&-\frac{1}{8x^2}-\omega\end{pmatrix}\equiv\mathrm{diag}[\tilde{H}_1,\ \tilde{H}_2,\ \tilde{H}_3,\ \tilde{H}_4]. \tag{58}$$

Note that the set of potential functions $\tilde{V}_i$ ($i=1, 2, 3, 4$) corresponding to the four superpartner Hamiltonians $\tilde{H}_i$ is different from the well-known radial harmonic oscillator potential $V_{\rm ho}(l)=\frac{1}{2}\omega^2x^2+[l(l+1)/2x^2]$,[9] in which the angular momentum quantum number l must be positive integer, though, from the point of view of mathematics, $\tilde{V}_i$ in Eq. (58) are the special cases of

$V_{\rm ho}(l)$ for l taking some special values: $\tilde{V}_1=\tilde{V}_2=V_{\rm ho}(l=\frac{1}{2})$, $\tilde{V}_3=V_{\rm ho}(l=-\frac{1}{2})+\omega$, and $\tilde{V}_4=V_{\rm ho}(l=-\frac{1}{2})-\omega$. It may be easily inferred by using Theorem X.7 in Ref. 36 that all $\tilde{H}_i$ are Hermitian on the half-line $(0,\infty)$ since either of $\tilde{V}_i$ is in the limit point case in both zero and infinity. Let the four-component spinor eigenfunction of $\tilde{H}$ be $\tilde{\psi}=[\tilde{\psi}_1,\tilde{\psi}_2,\tilde{\psi}_3,\tilde{\psi}_4]^T$, where $\tilde{\psi}_i$ $(i=1,2,3,4)$ are, respectively, the eigenfunctions of $\tilde{H}_i$ belonging to the energy eigenvalues $\tilde{E}_i$, and are related by the four first-order differential operators $\tilde{\eta}^{\pm}$ and $\tilde{\zeta}^{\pm}$ given in Eq. (57),

$$\tilde{\psi}_3 \overset{\tilde{\eta}^+}{\rightarrow} \tilde{\psi}_1=\tilde{\psi}_2 \overset{\tilde{\zeta}^+}{\rightarrow} \tilde{\psi}_4 \quad \text{and} \quad \tilde{\psi}_3 \overset{\tilde{\eta}^-}{\leftarrow} \tilde{\psi}_1=\tilde{\psi}_2 \overset{\tilde{\zeta}^-}{\leftarrow} \tilde{\psi}_4. \tag{59}$$

We notice that the quantum mechanical system described by $\tilde{H}$ has no additional symmetry that can be, together with the $N=4$ supersymmetry, embedded in a larger supersymmetry (for example, the superconformal symmetry). If we rewrite $\tilde{H}$ as

$$\tilde{H}=\dot{H}_0^{\rm sc}+\omega^2 K+\omega Y_3, \tag{60}$$

where $\dot{H}_0^{\rm sc}$ is the supersymmetric Hamiltonian given by Eq. (31) combined with $k_3=k^{\pm}=0$ and $W(x)=\omega x$, and Y_3 is a constant matrix,

$$\dot{H}_0^{\rm sc}=\frac{1}{2}p^2+\begin{pmatrix} \frac{3}{8x^2} & & & \\ & \frac{3}{8x^2} & & \\ & & -\frac{1}{8x^2} & \\ & & & -\frac{1}{8x^2} \end{pmatrix}, \quad Y_3=\begin{pmatrix} 0 & & & \\ & 0 & & \\ & & 1 & \\ & & & -1 \end{pmatrix}, \tag{61}$$

then using the same analysis employed in the last example, it is easy to find that $\dot{H}_0^{\rm sc}$ is a superconformal Hamiltonian since it satisfies not only SO(2,1), with the dilatation generator $D=-\frac{1}{4}\{p,x\}$ and the conformal generator $K=\frac{1}{2}x^2$, but also SS(4), with the four supercharges $\dot{Q}_{\mu}^{\pm}$ $(\mu=1,2)$

$$\dot{Q}_1^+=\begin{pmatrix} 0 & 0 & p+\frac{i}{2x} & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & p-\frac{i}{2x} & 0 & 0 \end{pmatrix}, \quad \dot{Q}_2^+=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & p+\frac{i}{2x} & 0 \\ 0 & 0 & 0 & 0 \\ -p+\frac{i}{2x} & 0 & 0 & 0 \end{pmatrix}. \tag{62}$$

Introducing extra three operators

$$Y_3=\frac{1}{2}\sum_{\mu}(-1)^{\mu+1}[C_{\mu}^+, C_{\mu}^-], \quad Y^{\pm}=\pm C_2^{\mp}C_1^{\pm}, \tag{63}$$

which constitute SO(3) as well [see the fifth set of equations in Eq. (64)], it follows that $\dot{Q}_{\mu}^{\pm}$, $S_{\mu}^{\pm}$, $\dot{H}_0^{\rm sc}$, D, K, Y_3, and $Y^{\pm}$ satisfy the following closed superalgebraic structure:

$$
\begin{aligned}
&(1)\ \{\dot{Q}_\mu^+,\dot{Q}_\nu^-\}=2\delta_{\mu\nu}\dot{H}_0^{\mathrm{sc}},\quad \{\dot{Q}_\mu^\pm,\dot{Q}_\nu^\pm\}=0,\quad \mu,\nu=1,2;\\
&(2)\ \{S_\mu^+,S_\nu^-\}=2\delta_{\mu\nu}K,\quad \{S_\mu^\pm,S_\nu^\pm\}=0;\\
&(3)\ \{\dot{Q}_\mu^\pm,S_\nu^\mp\}=\delta_{\mu\nu}(\pm 2iD+Y_3),\quad \{\dot{Q}_\mu^\pm,S_\nu^\pm\}=(-)^\mu(1-\delta_{\mu\nu})2Y^\mp;\\
&(4)\ [D,\dot{H}_0^{\mathrm{sc}}]=-i\dot{H}_0^{\mathrm{sc}},\quad [D,K]=iK,\quad [\dot{H}_0^{\mathrm{sc}},K]=2iD;\\
&(5)\ [Y_3,Y^\pm]=\pm 2Y^\pm,\quad [Y^+,Y^-]=Y_3;\\
&(6)\ [\dot{H}_0^{\mathrm{sc}},\dot{Q}_\mu^\pm]=0,\quad [D,\dot{Q}_\mu^\pm]=-\tfrac{1}{2}i\dot{Q}_\mu^\pm,\quad [K,\dot{Q}_\mu^\pm]=\pm S_\mu^\pm;\\
&\qquad [\dot{H}_0^{\mathrm{sc}},S_\mu^\pm]=\pm\dot{Q}_\mu^\pm,\quad [D,S_\mu^\pm]=\tfrac{1}{2}iS_\mu^\pm,\quad [K,S_\mu^\pm]=0;\\
&(7)\ [\dot{H}_0^{\mathrm{sc}},Y_3]=0,\quad [D,Y_3]=0,\quad [K,Y_3]=0;\\
&\qquad [\dot{H}_0^{\mathrm{sc}},Y^\pm]=0,\quad [D,Y^\pm]=0,\quad [K,Y^\pm]=0;\\
&(8)\ [Y_3,\dot{Q}_\mu^\pm]=\mp\dot{Q}_\mu^\pm,\quad [Y^\pm,\dot{Q}_\mu^\pm]=\pm(-)^{\mu+1}\dot{Q}_\nu^\mp,\quad [Y^\pm,\dot{Q}_\mu^\mp]=0;\\
&\qquad [Y_3,S_\mu^\pm]=\mp S_\mu^\pm,\quad [Y^\pm,S_\mu^\pm]=\pm(-)^\mu S_\nu^\mp,\quad [Y^\pm,S_\mu^\mp]=0;
\end{aligned}
\tag{64}
$$

where $S_\mu^\pm$ has been given by Eq. (53). We denote the above superalgebra by SC(4), which, different from SU(1,1|2) defined by Eq. (54), has the same subgroup structure as SU(1,1|2), i.e.,

$$
\mathrm{SC}(4)\supset\begin{Bmatrix}\mathrm{OSp}(2,1)\supset\mathrm{SO}(2)\times\mathrm{SO}(2,1)\\ \mathrm{SO}(3)\times\mathrm{SO}(2,1)\end{Bmatrix}\supset\underset{Y_3}{\mathrm{SO}(2)}\times\underset{\dot{H}_0^{\mathrm{sc}}}{\mathrm{SO}(2)}.
\tag{65}
$$

To determine the eigenfunctions and energy eigenvalues of $\tilde{H}$ by algebraic method, it is convenient to regroup the previous operators $\dot{H}_0^{\mathrm{sc}}$, D, K, $\dot{Q}_\mu^\pm$, and $S_\mu^\pm$ as

$$
\begin{aligned}
&T_3=\frac{1}{2\omega}\dot{H}_0^{\mathrm{sc}}+\frac{\omega}{2}K,\quad T^\pm=\frac{1}{2\omega}\dot{H}_0^{\mathrm{sc}}-\frac{\omega}{2}K\mp iD,\\
&L_\mu^\pm=\frac{1}{2\sqrt{\omega}}\dot{Q}_\mu^\pm-\frac{\sqrt{\omega}}{2}S_\mu^\pm,\quad R_\mu^\pm=\frac{1}{2\sqrt{\omega}}\dot{Q}_\mu^\pm+\frac{\sqrt{\omega}}{2}S_\mu^\pm.
\end{aligned}
\tag{66}
$$

Note that $R_\mu^\pm$ ($\mu=1,2$) are up to normalization constants the supercharges $\tilde{Q}_\mu^\pm$ associated with $\tilde{H}$, i.e., $R_\mu^\pm=(1/2\sqrt{\omega})\tilde{Q}_\mu^\pm$. Owing to the fact $\tilde{H}=2\omega(T_3+\frac{1}{2}Y_3)$, there exists a simple relation between the energy eigenvalues $\tilde{E}_i$ ($i=1,2,3,4$) of $\tilde{H}_i$ and the energy eigenvalues e_i ($i=1,2,3,4$) of $T_{i,3}$, the ith diagonal component of T_3,

$$
\tilde{E}_i=e_i+\Delta_i,\quad \Delta_i=(-)^{i+1}\frac{1}{2}\left[\frac{i}{3}\right],
\tag{67}
$$

and their corresponding eigenfunctions are identical. Therefore, the eigenfunctions and energy eigenvalues of $\tilde{H}$ may be directly obtained provided that those of T_3 are known. With the help of Eq. (64), the closed anticommutation and commutation relations satisfied by the six bosonic operators T_3, $T^\pm$, Y_3, $Y^\pm$ and eight fermionic operators $L_\mu^\pm$, $R_\mu^\pm$, read

$$
\begin{aligned}
&(1)\ [T_3,\ T^{\pm}]=\pm T^{\pm},\quad [T^{+},\ T^{-}]=-2T_3;\\
&(2)\ [Y_3,\ Y^{\pm}]=\pm 2Y^{\pm},\quad [Y^{+},\ Y^{-}]=Y_3;\\
&(3)\ \{L_{\mu}^{+},\ L_{\mu}^{-}\}=T_3-\tfrac{1}{2}Y_3,\quad \{L_{\mu}^{\pm},\ L_{\nu}^{\pm}\}=\{L_{\mu}^{\pm},\ L_{\nu}^{\mp}\}=0;\\
&(4)\ \{R_{\mu}^{+},\ R_{\mu}^{-}\}=T_3+\tfrac{1}{2}Y_3,\quad \{R_{\mu}^{\pm},\ R_{\nu}^{\pm}\}=\{R_{\mu}^{\pm},\ R_{\nu}^{\mp}\}=0;\\
&(5)\ \{L_{\mu}^{\pm},\ R_{\nu}^{\mp}\}=\delta_{\mu\nu}T^{\mp},\quad \{L_{\mu}^{\pm},\ R_{\nu}^{\pm}\}=(-1)^{\nu}(1-\delta_{\mu\nu})Y^{\mp};\\
&(6)\ [T_3,\ Y^{\pm}]=0,\quad [T_3,\ Y_3]=0,\quad [T^{\pm},\ Y^{\pm}]=0,\\
&\qquad [T^{\pm},\ Y_3]=0,\quad [T^{\pm},\ Y^{\mp}]=0;\\
&(7)\ [T_3,\ L_{\mu}^{\pm}]=\pm\tfrac{1}{2}L_{\mu}^{\pm},\quad [T^{\pm},\ L_{\mu}^{\mp}]=0,\quad [T^{\pm},\ L_{\mu}^{\pm}]=\pm L_{\mu}^{\mp};\\
&\qquad [T_3,\ R_{\mu}^{\pm}]=\pm\tfrac{1}{2}R_{\mu}^{\pm},\quad [T^{\pm},\ R_{\mu}^{\pm}]=0,\quad [T^{\pm},\ R_{\mu}^{\mp}]=\mp L_{\mu}^{\mp};\\
&(8)\ [Y_3,\ L_{\mu}^{\pm}]=\mp L_{\mu}^{\pm},\quad [Y^{\pm},\ L_{\mu}^{\mp}]=0,\quad [Y^{\pm},\ L_{\mu}^{\pm}]=\pm(-1)^{\mu+1}L_{\nu}^{\mp};\\
&\qquad [Y_3,\ R_{\mu}^{\pm}]=\mp R_{\mu}^{\pm},\quad [Y^{\pm},\ R_{\mu}^{\mp}]=0,\quad [Y^{\pm},\ R_{\mu}^{\pm}]=\pm(-1)^{\mu+1}L_{\nu}^{\mp},
\end{aligned}
\tag{68}
$$

where $\mu,\ \nu=1,\ 2$. We observe from Eq. (68) that (1) the first set of equations indicates that T_3, $T^{\pm}$ constitute SO(2,1) also, where T_3 is a compact operator with a discrete spectrum, and T^{+} (T^{-}) raises (lowers) the energy eigenvalues of T_3 by 1 unit. (2) Similar to SU(1,1|2), the superalgebra determined by Eq. (68) contains $\mathrm{SO}(2,1)\times\mathrm{SO}(3)$ as its maximum Lie subalgebra as well, moreover, the values of Y_3 [see Eq. (61)] may be used to label the energy eigenvalues e of T_3 or $\tilde{E}$ of $\tilde{H}$. (3) T_3 and $R_{\mu}^{\pm}$ (or T_3 and $L_{\mu}^{\pm}$, $\mu=1,\ 2$) do not form SS(4), therefore, the energy spectrum of T_3 is not fourfold degenerate. (4) The first column of equations in the seventh and eighth sets of equations show that R_{μ}^{+} and L_{μ}^{+} raise the energy eigenvalues of T_3 by $\frac{1}{2}$ unit meanwhile lower the values of Y_3 by 1 unit, whereas R_{μ}^{-} and L_{μ}^{-} lower the energy eigenvalues of T_3 by $\frac{1}{2}$ unit meanwhile raise the values of Y_3 by 1 unit.

Now turn to the eigenfunctions and energy eigenvalues of $\tilde{H}$ by means of the similar approach as used in the last example. Solving the following four equations:

$$
\tilde{Q}_{\mu}^{\pm}\,\tilde{\psi}_0=0,\quad \mu=1,2,
\tag{69}
$$

where $\tilde{\psi}_0\equiv[\tilde{\psi}_{0,1},\ \tilde{\psi}_{0,2},\ \tilde{\psi}_{0,3},\ \tilde{\psi}_{0,4}]^{T}$ stands for the zero-energy eigenfunction, gives rise to

$$
\begin{aligned}
&\tilde{\psi}_{0,1}\sim\frac{1}{\sqrt{x}}\exp(-\omega x^2/2),\\
&\tilde{\psi}_{0,2}\sim\frac{1}{\sqrt{x}}\exp(+\omega x^2/2),\\
&\tilde{\psi}_{0,3}\sim\sqrt{x}\exp(+\omega x^2/2),\\
&\tilde{\psi}_{0,4}\sim\sqrt{x}\exp(-\omega x^2/2).
\end{aligned}
\tag{70}
$$

It is not difficult to find by simple calculations that of the four eigenfunctions $\tilde{\psi}_{0,i}$ ($i=1,\ 2,\ 3,\ 4$), only $\tilde{\psi}_{0,4}$ is square-integrable on the interval $(0,\ \infty)$, whose normalized form is

$$\tilde{\psi}_{0,4}=\sqrt{\omega x}\exp(-\omega x^2/2), \tag{71}$$

that is, only $\tilde{H}_4$ has a normalizable zero-energy ground state, whereas the other three superpartner Hamiltonians $\tilde{H}_1$, $\tilde{H}_2$, $\tilde{H}_3$ do not have. Of course, $\tilde{\psi}_{0,4}$ is also the normalizable ground state eigenfunction of the fourth diagonal component $T_{4,3}$ of T_3, with its corresponding energy being larger than zero. With the help of the superalgebraic relations (68), the eigenfunctions $\tilde{\psi}_{n',i}$ ($n'=1, 2, \ldots$; $i=1, 2, 3, 4$) for arbitrary excited states may be obtained from $\tilde{\psi}_{0,4}$ through two steps: first applying n times the raising operator T^+ to $\tilde{\psi}_{0,4}$ produces all the excited states $\tilde{\psi}_{n',4}$ ($n'=1, 2, \ldots$) of $T_{4,3}$, and then acting, respectively, once and twice on $\tilde{\psi}_{n',4}$ with $\tilde{Q}^-_\mu$ or R^-_μ or L^-_μ gives the other excited states $\tilde{\psi}_{n,i'}$ ($n=0, 1, \ldots$; $i'=1, 2, 3$), i.e., all the eigenfunctions of $\tilde{H}_{i'}$ or $T_{i',3}$. With the help of Rodrigus' formula for the generalized Laguerre polynomial $L^a_n(x)$ of positive integer n and real parameter a in argument x, we can finally obtain by induction

$$\begin{aligned}
\tilde{\psi}_{n,1}&=\sqrt{2\omega x}\exp(-\omega x^2/2)L^0_n(\omega x^2),\\
\tilde{\psi}_{n,2}&=\sqrt{2\omega x}\exp(-\omega x^2/2)L^0_n(\omega x^2),\\
\tilde{\psi}_{n,3}&=\sqrt{\frac{2x}{n+1}}(\omega x)\exp(-\omega x^2/2)L^1_n(\omega x^2),\\
\tilde{\psi}_{n,4}&=\sqrt{\frac{2x}{n+1}}(\omega x)\exp(-\omega x^2/2)L^1_n(\omega x^2),\\
n&=0,\ 1,\ 2,\ldots .
\end{aligned} \tag{72}$$

Thus, the energy eigenvalues, $\tilde{E}_i$ and e_i ($i=1, 2, 3, 4$) related by Eq. (67), that correspond to the same normalized eigenfunctions (72), of $\tilde{H}_i$ and $T_{i,3}$ are, respectively,

$$\begin{aligned}
\tilde{E}_1&=2\omega(e_1+\Delta_1)=2\omega(n+1), \quad e_1=n+1,\\
\tilde{E}_2&=2\omega(e_2+\Delta_2)=2\omega(n+1), \quad e_2=n+1,\\
\tilde{E}_3&=2\omega(e_3+\Delta_3)=2\omega(n+1), \quad e_3=n+1/2,\\
\tilde{E}_4&=2\omega(e_4+\Delta_4)=2\omega n, \quad e_4=n+1/2,\\
n&=0,\ 1,\ 2,\ldots .
\end{aligned} \tag{73}$$

Equation (73) shows clearly that the $N=4$ supersymmetry of the quantum mechanical system described by $\tilde{H}$ is unbroken since its ground state energy is zero, and the fourfold degeneracies may be observed above the second level. However, the quartet energy spectrum structure of T_3, which is not fourfold degenerate, involves two sets of double degenerate spectra, moreover, the corresponding supersymmetry is broken since its ground state energy is $\frac{1}{2}$. The energy spectrum structures of $\tilde{H}$ and T_3 are depicted in Fig. 2 and Fig. 3, respectively. The solutions to the Schrödinger equations with the potentials $ax^2+(b/x^2)$ for different a's and b's may be obtained by different approaches, see Refs. 28, 29, 37–39.

V. SUMMARY

In this paper, we obtained the general form of $N=4$ SSQM in arbitrary dimension, starting from the general form of four supercharges, in which the fermionic degrees of freedoms include

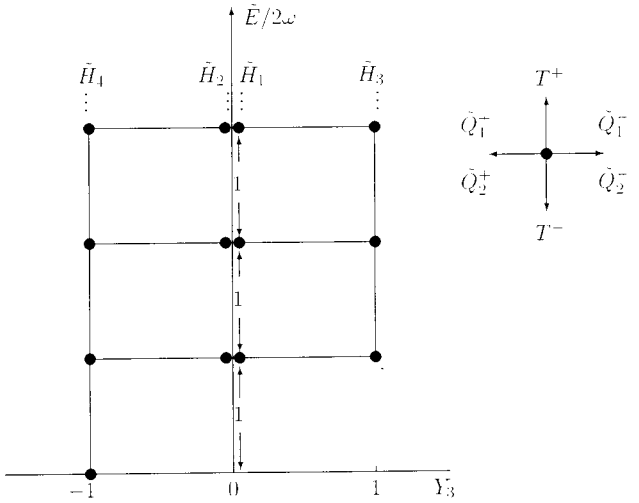

FIG. 2. Fourfold degenerate energy spectrum of $\tilde{H}$ given by Eq. (73), which $N=4$ supersymmetry is unbroken since its ground state energy is zero. Each eigenstate (dot) is connected with its surrounding eigenstates (dots) by the supercharges $\tilde{Q}_\mu^\pm$ $(\mu=1,2)$ along the horizontal line, and by the raising/lowering operators $T^\pm$ along the vertical line.

all the odd elements, C_j and $C_jC_kC_l$, of the superalgebra associated with the Clifford algebra C(4,0). Then, from them, we gave the one-dimensional physical realization and the new multidimensional physical realization for the $N=4$ SSQM by solving their respective constraint conditions. As applications, we studied in detail, on the base of the one-dimensional realization, two superconformal quantum mechanical systems with their superpotentials being k/x and ωx, which possess both the $N=4$ supersymmetries and the dynamical conformal symmetries, and established their corresponding superalgebraic structures, which are spanned by the eight fermionic generators and six bosonic generators. Our next work is to apply the general realizations of $N=4$ SSQM obtained in this paper to the other possible (quasi-) exactly solvable potentials, for example, listed in Refs. 10 and 40, and to discussing the nonlinear $N=4$ SSQM based on the deformations of Eq.

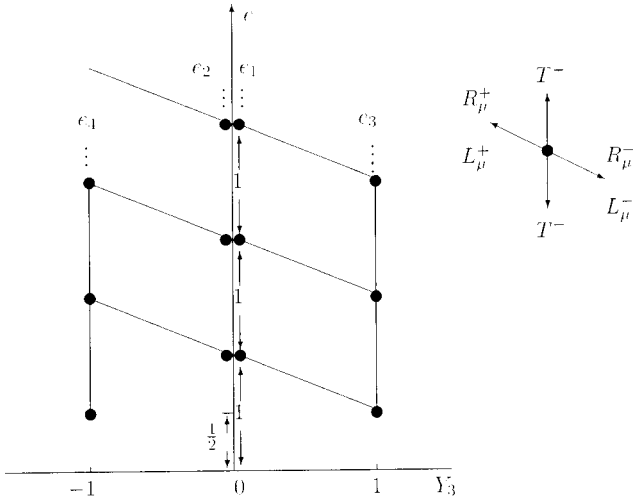

FIG. 3. Quartet structure of the energy spectrum of T_3 related tightly to $\tilde{H}$ [see Eq. (73)]. Different from that of $\tilde{H}$ exhibited in Fig. 2, T_3 possesses two sets of double degenerate spectra with the corresponding supersymmetry being broken. Each eigenstate (dot) is connected with its surrounding eigenstates (dots) by the fermionic operators $R_\mu^\pm$, $L_\mu^\pm$ $(\mu=1,2)$ along the slanting line, and by the raising/lowering operators $T^\pm$ along the vertical line.

(22),[41] which is similar to the deformations of angular momentum algebra.[42,43] From the point of view of mathematics, it is also of interest to investigate the representations of SU(1,1|2) and SC(4) and their relations to the classical Lie superalgebras.[23,44,45]

(Received 16 February 2002; accepted 24 March 2003)

We study the behavior of truncated Rayleigh–Schrödinger series for low-lying eigenvalues of the time-independent Schrödinger equation, in the semiclassical limit $\hbar \searrow 0$. In particular we prove that if the potential energy satisfies certain conditions, there is an optimal truncation of the series for the eigenvalues, in the sense that this truncation is exponentially close to the exact eigenvalue. These results were already discussed for the one-dimensional case in a previous article. This time we consider the multi-dimensional problem, where degeneracy plays a central role. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1581353]

I. INTRODUCTION

Perhaps one of the most elementary facts in quantum physics is that, for a sufficiently deep potential well, the eigenvalue problem defined by the time-independent Schrödinger equation admits normalizable solutions. Equivalently, if one considers Planck's constant as a parameter, the equation

$$H(\hbar)\tilde{\Psi}(\hbar;x) := \left[-\frac{\hbar^2}{2}\Delta_x + V(x) \right] \tilde{\Psi}(x) = E(\hbar)\tilde{\Psi}(\hbar;x) \tag{1}$$

is expected to have eigenvalues near the bottom of the potential well, in the semiclassical limit $\hbar \searrow 0$.

Along with the problem of existence of low-lying eigenvalues, one is also interested in the behavior of the corresponding perturbation series in powers of $\hbar$, the so-called Rayleigh–Schrödinger (R-S) series. It is well known that, in general, the R-S series are not convergent but only asymptotic to the solutions of Eq. (1). However, one often wants to consider truncations of these series as good approximations to the actual eigenvalues/eigenvectors. This raises the natural question of whether or not one can find an optimal truncation that minimizes the difference between the exact eigenvalues/eigenvectors and the corresponding truncated R-S series.

In this article we aim to find exponentially accurate asymptotics to the solutions of (1). We shall assume that the potential energy $V(x)$ satisfies the following conditions:

H1 $V(x)$ is a C^∞ real function on $\mathbb{R}^d$ such that $\liminf_{|x|\to\infty} V(x) =: V_\infty > 0$.

H2 $V(x)$ has a unique global minimum $V(0) = 0$ at $x = 0$.

H3 The global minimum of $V(x)$ is nondegenerate in the sense that

$$\mathrm{Hess}_V(0) = \mathrm{diag}[\omega_1^2, \ldots, \omega_d^2]$$

has only strictly positive eigenfrequencies $\omega_1, \ldots, \omega_d$.

H4 $V(x)$ has an analytic extension to a neighborhood of the region $S_\delta = \{z : |\mathrm{Im}\, z_i| \leqslant \delta + \epsilon\}$ for some

$\delta>0$ and $\epsilon>0$ arbitrarily small. Without loss we may assume that $\delta\leqslant 1$.

H5 $V(z)$ satisfies $|V(z)|\leqslant M\exp(\tau|z|^2)$ uniformly in S_δ, for some positive constants $M>0$ and $\omega_0/4\geqslant\tau>0$ where ω_0 denotes the lowest eigenfrequency of $\mathrm{Hess}_V(0)$.

We shall prove that one can truncate the R-S series so that the difference between the truncated series and the actual eigenvalue/eigenvector can be made smaller than $\Lambda\exp(-\Gamma/\hbar)$ where the positive constants Λ and Γ are explicitly calculated. Our construction is based entirely on a straighforward application of the formal R-S perturbation theory. These results extend those in Ref. 19, where we discussed optimal truncation for the one-dimensional problem. We follow the method explained in that article, which indeed is related with one developed by Hagedorn and Joye to study approximate solutions to the time-dependent Schrödinger equation.[4] Roughly speaking, we calculate upper bounds for each term in the R-S series for both eigenvalues and eigenfuctions. Then we combine these to obtain a recursion relation that yields an estimate for the growth of these terms. From that we compute an estimate of the difference of the two sides of (1) after truncation at order N; this estimate behaves like $ab^N\hbar^{N/2}(N!)^{1/2}$. For each $\hbar$ we choose N to minimize this quantity. This and some standard results of functional analysis yield our results. The main change with respect to Ref. 19 comes from the fact that, in several dimensions, we need to consider degenerate perturbation theory. There are also several technical nuissances which require special treatment.

The study of this problem is not new, of course. The first proof of existence of low-lying eigenvalues and asymptotic R-S series was presented by Combes *et al.* in 1983. Their proof, which involves Dirichlet–Newmann bracketing techniques, only considers the one-dimensional problem. Shortly after, Simon gave another proof, based on geometric arguments, that is valid in several dimensions.[16] This problem was also studied by Helffer and Sjöstrand in the broader framework of microlocal analysis of self-adjoint pseudodifferential operators.[6] From these works, it is known that eigenvalues/eigenfunctions near the bottom of the potential well admit asymptotic expansions in half-powers of $\hbar$, where the leading orders are given by the corresponding eigenvalues/eigenfunctions of the harmonic oscillator aproximation. These results require only to assume that the potential energy satisfies H1–H3, although further information has been obtained in Ref. 6 for potentials with analytic continuation in a neighborhood of the minimum. In particular, it is proved in Theorem 4.6 of Ref. 6 that the low-lying eigenvalues/eigenfunctions can be exponentially approximated by truncated series.

The last result mentioned above is based on the rather involved theory of analytic pseudodifferential operators.[18] On the other hand, the work by Hagedorn and Joye[4] suggests that a much simpler method, involving only formal R-S series, may be used to contruct exponentially accurate aproximations to the eigenvalues/eigenfunctions of (1). Indeed, the constructive method developed in this work relies upon only some elementary notions on complex and functional analysis. Moreover, we obtain explicit upper bounds to the growth of the R-S coefficients. Our construction might be used for numerical computation, although the many constants that we define along the way have not been optimized for that purpose. However, there is a tradeoff in our approach which consists on the need of somewhat stronger assumptions about the potential energy, namely, hypothesis H5. We finally would like to point out that our technique could be used to study the time-independent Born–Oppenheimer approximation.

Results analogous to those discussed in this work have also been obtained for a class of C^∞ potentials. Bambusi *et al.*[1] have studied exponentially accurate quasimodes up to an error of order $\exp(-\mathrm{const}/\hbar^{1/\rho})$ with $\rho>1$, when the potential energy is Gevrey of order $\mu>1$. Furthermore, their estimate on the error is uniform in $\hbar$ for all eigenvalues in $[0,\hbar^\delta]$ with $0<\delta<1$. The construction of those quasimodes is based upon quantization of the Birkhorff normal forms for the classical Hamiltonian associated to (1). Since their proof relies on the KAM theorem,[3] the authors assume that the eigenfrequencies $\omega_1,\ldots,\omega_d$ satisfy the nonresonant condition $|\Sigma_i\omega_i k_i|^{-1}\leqslant C(\Sigma_i|k_i|)^\alpha$, for $C>0$, $\alpha>0$, and for every nontrivial set of integers $(k_1,\ldots,k_d)$. Under similar assumptions, Popov[12,13] has proved more general results by quantization of the KAM theory.

This article is organized as follows. In Sec. II we make a transformation of Eq. (1), and some technical results are proven. In Sec. III we construct some operators through recursion relations,

which allow us to calculate the several correction terms involved in the formal series for eigenvalues and eigenvectors. In particular, this construction allows us to consider the cases where degeneracy occurs. Because of the tranformation done in Sec. II, we obtain a manageable recursion relation for the nth term of the R-S series. Then we state and prove an estimate of the growth of these terms. In Sec. IV we define a residual error function for Eq. (1) and prove an estimate for it. The main results are stated precisely in Sec. V. The Appendix is devoted to a computation needed in Sec. IV.

II. PRELIMINARIES

In this work we shall use the standard multi-index notation: for $\alpha=(\alpha_1,\ldots,\alpha_d)\in\mathbb{Z}_+^d$ and $x=(x_1,\ldots,x_d)\in\mathbb{R}^d$, we denote $|\alpha|:=\alpha_1+\cdots+\alpha_d$, $\alpha!:=\alpha_1!\cdot\cdots\cdot\alpha_d!$, $x^\alpha:=x_1^{\alpha_1}\cdot\cdots\cdot x_d^{\alpha_d}$, $D^\alpha:=\partial_{x_1}^{\alpha_1}\cdot\cdots\cdot\partial_{x_d}^{\alpha_d}$, and $x^2:=x_1^2+\cdots+x_d^2$. For $z=(z_1,\ldots,z_d)\in\mathbb{C}^d$, we denote $|z|^2:=z_1z_1^*+\cdots+z_dz_d^*$.

We first transform (1) by scaling $x\to\hbar^{1/2}x$ and then dividing the whole equation by $\hbar$. This unitary transformation scales the eigenvalues and eigenfunctions as $E\to\hbar^{-1}E$ and $\tilde{\Psi}(x)\to\tilde{\Psi}(\sqrt{\hbar}x)$, respectively. The transformed equation may be written as

$$[-\tfrac{1}{2}\Delta_x+V(\hbar;x)]\tilde{\Psi}(\hbar;x)=E(\hbar)\tilde{\Psi}(\hbar;x). \tag{2}$$

Because of hypothesis H3, $V(x)$ admits a Taylor expansion up to any order n. Thus we can write

$$V(\hbar;x)=\frac{1}{2}\sum_{i,j=1}^{d}A_{ij}x_ix_j+W(\hbar;x),$$

where the function $W(\hbar;x)$ can be asymptotically approximated by

$$W(\hbar;x)=\sum_{l=3}^{n}\hbar^{(l-2)/2}\sum_{|\alpha|=l}\frac{D^\alpha V(0)}{\alpha!}x^\alpha+O(\hbar^{(n-1)/2}x^{|\alpha|=n+1}). \tag{3}$$

Hypothesis H4 implies furthermore that the Taylor series (3) is convergent inside the open polydisc $\{z\in\mathbb{C}^d:|z_i|\leqslant\delta\}$. Upper bounds on the derivatives of $V(x)$ can be easily obtained by using the Cauchy integral formula. They are stated and proved below in Lemma 2.

Now we can rewrite (2) as

$$[H_0+W(\hbar;x)]\tilde{\Psi}(\hbar;x)=E(\hbar)\tilde{\Psi}(\hbar;x), \tag{4}$$

where, in suitable Cartesian coordinates,

$$H_0=-\frac{1}{2}\Delta_x+\frac{1}{2}\sum_{i=1}^{d}\omega_i^2x_i^2$$

is a harmonic oscillator Hamiltonian with eigenfrequencies $\omega_1,\ldots,\omega_d$. The eigenfunctions of H_0 are therefore

$$\Phi_\alpha(x)=\left(\pi^{-d}\prod_{i=1}^{d}\omega_i\right)^{1/4}(2^{|\alpha|}\alpha!)^{-1/2}\exp\left(-\frac{1}{2}\sum_{i=1}^{d}\omega_ix_i^2\right)\prod_{i=1}^{d}h_{\alpha_i}(\sqrt{\omega_i}x_i), \tag{5}$$

where $h_j(y)$ denotes the Hermite polynomial of degree j. The corresponding eigenvalues are $e_\alpha=\Sigma_{i=1}^{d}\omega_i\alpha_i+d/2$.

In the semiclassical limit we want to consider $W(\hbar,x)$ as a perturbation of H_0. Then we can propose formal Rayleigh–Schrödinger series for both $E(\hbar)$ and $\tilde{\Psi}(\hbar;x)$:

$$\tilde{\Psi}(x)\sim\tilde{\psi}_0(x)+\hbar^{1/2}\tilde{\psi}_1(x)+\hbar^{2/2}\tilde{\psi}_2(x)+\hbar^{3/2}\tilde{\psi}_3(x)+\hbar^{4/2}\tilde{\psi}_4(x)+\cdots, \tag{6}$$

$$E(\hbar)\sim\mathcal{E}_0+\hbar^{1/2}\mathcal{E}_1+\hbar^{2/2}\mathcal{E}_2+\hbar^{3/2}\mathcal{E}_3+\hbar^{4/2}\mathcal{E}_4+\cdots. \tag{7}$$

In this work we essentially follow the standard, formal method to compute the R-S coefficients (see, e.g., Ref. 11, Chap. XVI), although alternatively we could use the technique developed by Kato (Ref. 10 Chaps. VII and VIII). However, this last approach seems rather difficult to implement here, in particular when degeneracy occurs. Concerning asymptotics in degenerate perturbation theory, we must mention the approach developed by Hunziker–Pillet.[8,9]

We now insert (6) and (7) into (2) and equate powers of $\hbar^{1/2}$. The zeroth-order equation yields $H_0\psi_0=\mathcal{E}_0\psi_0$. Then $\mathcal{E}_0=e$ and $\psi_0\in G$, where e is some eigenvalue of H_0 with multiplicity g and associated eigenspace G. For $n=1,2,\ldots$, we have

$$(H_0-e)\tilde{\psi}_n+\sum_{l=1}^{n}\tilde{T}^{(l+2)}\tilde{\psi}_{n-l}=\sum_{l=1}^{n}\mathcal{E}_l\tilde{\psi}_{n-l}, \tag{8}$$

where we define

$$\tilde{T}^{(l)}:=\sum_{|\alpha|=l}\frac{1}{\alpha!}D^{\alpha}V(0)x^{\alpha}.$$

Existence of solutions to the set of equations (8) can be shown by explicit construction, as the one we shall develop in Sec. III. Also, the correction terms $\tilde{\psi}_n$ satisfies the following property:

Lemma 1: Let $P_{|\alpha|\leqslant l}$ be the projection onto the subspace spanned by $\{\Phi_\alpha:|\alpha|\leqslant l\}$ and $a=a_e$ be the smallest non-negative integer such that $G\subseteq\mathrm{Ran}(P_{|\alpha|\leqslant a})$. Then, for each $n\geqslant 1$, $\tilde{\psi}_n\in\mathrm{Ran}(P_{|\alpha|\leqslant a+3n})$

Proof: First, decompose $\tilde{\psi}_n=P_{|\alpha|\leqslant a}\tilde{\psi}_n+(1-P_{|\alpha|\leqslant a})\tilde{\psi}_n=:\tilde{\psi}_n^{(1)}+\tilde{\psi}_n^{(2)}$. We have to prove the assertion only for $\tilde{\psi}_n^{(2)}$. Equation (8) yields

$$\tilde{\psi}_n^{(2)}=(H_0-e)_r^{-1}(1-P_{|\alpha|\leqslant a})\left[\sum_{l=1}^{n}\mathcal{E}_l\tilde{\psi}_{n-l}-\sum_{l=1}^{n}\tilde{T}^{(l+2)}\tilde{\psi}_{n-l}\right],$$

where $(H_0-e)_r^{-1}$ is the inverse of the restriction of H_0-e onto $\mathrm{Ran}(1-P_{|\alpha|\leqslant a})$. Since

$$\mathrm{Ran}((H_0-e)_r^{-1}(1-P_{|\alpha|\leqslant a})P_{|\alpha|\leqslant a+3n})\subset\mathrm{Ran}(P_{|\alpha|\leqslant a+3n}),$$

it is sufficient to show that

$$\left(\sum_{l=1}^{n}\mathcal{E}_l\tilde{\psi}_{n-l}-\sum_{l=1}^{n}\tilde{T}^{(l+2)}\tilde{\psi}_{n-l}\right)\in P_{|\alpha|\leqslant a+3n}. \tag{9}$$

Now use mathematical induction. For $n=1$, the assertion $\tilde{T}^{(3)}\tilde{\psi}_0\in P_{|\alpha|\leqslant a+3}$ follows from the fact that $\tilde{T}^{(3)}$ contains terms that are at most proportional to the third power of creation operators, and that $\tilde{\psi}_0\in G\subset P_{|\alpha|\leqslant a}$. Assuming that statement is true for $s=1,\ldots,n-1$, then it is trivially true for the first term in (9). Also, a simple calculation with ladder operators shows that $x^{\alpha}\varphi\in\mathrm{Ran}(P_{|\beta|\leqslant a+3(n-l)+|\alpha|})$ whenever $\varphi\in\mathrm{Ran}(P_{|\beta|\leqslant a+3(n-l)})$. Finally, we have $3(n-l)+2+l=3n+2(1-l)\leqslant 3n$ for $l=1,\ldots,n$. □

The set of recursive equations (8) is not suitable for the purpose of finding the sharp upper bounds for the R-S coefficients that we shall need later. It turns out to be convenient to transform the problem in the following way: Let $\{\Phi_\alpha(x)\}$ be a basis of eigenvectors of H_0. For a given eigenvalue e of H_0, let us define a new operator A_e by

$$A_e\Phi_\alpha(x) = \begin{cases} \Phi_\alpha(x), & \text{if } \Phi_\alpha(x)\in G, \\ |e-e_\alpha|^{-1/2}\Phi_\alpha(x), & \text{otherwise,} \end{cases}$$

where e_α is the eigenvalue associated to $\Phi_\alpha(x)$. Then extend A_e to the whole Hilbert space $\mathcal{H}$ by linearity. So defined, A_e is a bounded operator with unit norm but unbounded inverse. However, $\mathrm{Ran}(P_{|\alpha|\leqslant a+3n})$ is clearly in the domain of A_e^{-1} for each $n\in\mathbb{N}$. This fact allows us to consider the equivalent set of equations

$$H_e\psi_n+\sum_{l=1}^{n} T^{(l+2)}\psi_{n-l}=\sum_{l=1}^{n}\mathcal{E}_l A_e^2\psi_{n-l}, \tag{10}$$

where $H_e:=A_e(H_0-e)A_e$, $T^{(m)}:=A_e\tilde{T}^{(m)}A_e$, and $\psi_m=A_e^{-1}\tilde{\psi}_m$. The operator H_e satisfies

$$H_e\Phi_\alpha(x) = \begin{cases} 0, & \text{if } \Phi_\alpha(x)\in G, \\ \dfrac{e-e_\alpha}{|e-e_\alpha|}\Phi_\alpha(x), & \text{otherwise.} \end{cases}$$

Therefore the norm of H_e is equal to 1. In Sec. III we shall prove that both $|\mathcal{E}_n|$ and $\|\psi_n\|$ essentially grow as $b^n\sqrt{n!}$ for large n.

We conclude this section with an assortment of technical lemmas. Lemma 2 states certain estimates on the derivatives of the potential energy. In Lemma 3 we show a key upper bound to the norm of the operators $T^{(l)}P_{|\alpha|\leqslant n}$. Finally, in Lemma 4 we state results about certain expressions involving factorials that we shall use extensively in the sequel.

Lemma 2: Assume $V(x)$ satisfies H4. Then there are constants C_1 and C_2 such that, for $l\geqslant 1$,

$$\sum_{|\alpha|=l}\frac{|D^\alpha V(0)|}{\alpha!}\delta^{|\alpha|}\leqslant C_1C_2^l.$$

If $V(x)$ also satisfies H5, then there exists a constant C_0 such that

$$\frac{\delta^{|\alpha|}}{\alpha!}|D^\alpha V(x)|\leqslant C_0\exp(2\tau x^2). \tag{11}$$

Proof: Let Γ_i be a circle of radius δ in the complex plane, centered at x_i. Then the Cauchy integral formula applied to $V(x)$, which makes sense because of hypothesis H4, states that for each multi-index $\alpha=(\alpha_1,\ldots,\alpha_d)$

$$D^\alpha V(x)=\frac{\alpha!}{(2\pi i)^d}\int_{\Gamma_1}dz_1\cdots\int_{\Gamma_d}dz_d\frac{V(z)}{\Pi_{i=1}^d(z_i-x_i)^{\alpha_i+1}},$$

which implies

$$|D^\alpha V(x)|\leqslant\frac{\alpha!}{\delta^{|\alpha|}}\max_{z_i\in\Gamma_i}|V(z)|. \tag{12}$$

Let us prove (11) first. Because of H5,

$$\max_{z_i\in\Gamma_i}|V(z)|\leqslant M\prod_{i=1}^{d}\max_{z_i\in\Gamma_i}\exp(\tau|z_i|^2)\leqslant M\prod_{i=1}^{d}\exp(\tau|x_i+\delta|^2)\leqslant M\exp(2d\tau\delta^2)\exp(2\tau x^2),$$

so (12) implies (11), after defining $C_0=M\exp(2d\tau\delta^2)$. If now the Γ_i's are circles centered at zero, we have (without assuming H5)

$$\frac{|D^\alpha V(0)|}{\alpha!}\delta^{|\alpha|}\leqslant\max_{z_i\in\Gamma_i}|V(z)|=:c<\infty.$$

Then

$$\sum_{|\alpha|=l}\frac{|D^\alpha V(0)|}{\alpha!}\delta^{|\alpha|}\leqslant c\sum_{|\alpha|=l}1$$

for all l. The last summation is the number of different ways to sum d non-negative integers such as the result is equal to l. That is,

$$\sum_{|\alpha|=l}1=\frac{(l+d-1)!}{l!(d-1)!}\leqslant\frac{1}{(d-1)!}(l+d-1)^{d-1}.$$

Therefore, we have

$$\sum_{|\alpha|=l}\frac{|D^\alpha V(0)|}{\alpha!}\delta^{|\alpha|}\leqslant\frac{c}{(d-1)!}(l+d-1)^{d-1}\leqslant C_1C_2^l$$

with obvious definition of C_1, and C_2 being either equal to $(d-1)\max_{l\geqslant1}\log(l+d-1)/l$ (when $d>1$) or equal to 1 (when $d=1$). □

Lemma 3: For $|\alpha|\geqslant2$, $n\geqslant0$ *and some constant* $\gamma>0$,

$$\|A_e x^\alpha A_e P_{|\beta|\leqslant n}\|\leqslant\gamma^2\left(\frac{2}{\omega_0}\right)^{(|\alpha|-2)/2}\left[\frac{(n+|\alpha|-1)!}{(n+1)!}\right]^{1/2}.$$

As a consequence,

$$\|T^{(l)}P_{|\beta|\leqslant n}\|\leqslant C_3\kappa^{(l-2)/2}\left[\frac{(n+l-1)!}{(n+1)!}\right]^{1/2}$$

for some $C_3>0$ *and* $\kappa\geqslant2$.

Proof: For a single coordinate x_i, we have

$$x_i=\frac{1}{\sqrt{2\omega_i}}(a_i+a_i^*)\tag{13}$$

where a_i and a_i^* are the associated ladder operators. Consider any $\varphi=\Sigma_\beta d_\beta\Phi_\beta\in\mathcal{H}$. Define $J_G:=\{\text{multi-indices }\beta:\Phi_\beta\in G\}$. Then

$$\begin{aligned}a_i^*A_e\varphi&=\sum_{\beta\in J_G}d_\beta a_i^*\Phi_\beta+\sum_{\beta\notin J_G}d_\beta|e-e_\beta|^{-1/2}a_i^*\Phi_\beta\\&=\sum_{\beta\in J_G}d_\beta\sqrt{\beta_i+1}\,\Phi_{\beta+1_i}+\sum_{\beta\notin J_G}d_\beta|e-e_\beta|^{-1/2}\sqrt{\beta_i+1}\,\Phi_{\beta+1_i}\end{aligned}$$

where $\beta+1_i:=(\beta_1,\ldots,\beta_i+1,\ldots,\beta_d)$. Thus,

$$\|a_i^* A_e \varphi\|^2 = \sum_{\beta \in J_G} |d_\beta|^2 (\beta_i + 1) + \sum_{\beta \notin J_G} |d_\beta|^2 |e - e_\beta|^{-1} (\beta_i + 1)$$

$$\leqslant (1+a) \sum_{\beta \in J_G} |d_\beta|^2 + \sum_{\beta \notin J_G} |d_\beta|^2 |e - e_\beta|^{-1} (\beta_i + 1)$$

because $\beta \in J_G$ implies $\beta_i \leqslant |\beta| \leqslant a$. Moreover,

$$\frac{\beta_i + 1}{|e - e_\beta|} = \frac{1}{\omega_i} \frac{\omega_i (\beta_i + \frac{1}{2})}{|e - e_\beta|} + \frac{\frac{1}{2}}{|e - e_\beta|} \leqslant \frac{1}{\omega_i} \frac{e_\beta}{|e - e_\beta|} + \frac{\frac{1}{2}}{|e - e_\beta|}.$$

Since $\sigma(H_0)$ has no accumulation points and $e_\beta \neq e$ for all $\beta \notin J_G$, $\inf_{\beta \notin J_G} |e - e_\beta| > 0$. Furthermore, since $\lim_{|\beta| \to \infty} e_\beta |e - e_\beta|^{-1} = 1$, $\sup_{\beta \notin J_G} e_\beta |e - e_\beta|^{-1} < \infty$. Thus,

$$|e - e_\beta|^{-1} (\beta_i + 1) \leqslant \frac{1}{\omega_i} \sup_{\beta \notin J_G} e_\beta |e - e_\beta|^{-1} + \frac{1}{2} \sup_{\beta \notin J_G} |e - e_\beta|^{-1} =: K_1 < \infty,$$

which implies

$$\|a_i^* A_e\|^2 \leqslant \max\{(1+a), K_1\} \leqslant \max_{\{\omega_i\}} \max\{(1+a), K_1\}. \tag{14}$$

A similar calculation yields

$$\|a_i A_e\|^2 \leqslant \max\{|1-a|, K_2\} \leqslant \max_{\{\omega_i\}} \max\{|1-a|, K_2\} \tag{15}$$

for some $K_2 < \infty$. Therefore,

$$\|x_i A_e\| \leqslant \frac{1}{\sqrt{2\omega_i}} \|a_i A_e\| + \frac{1}{\sqrt{2\omega_i}} \|a_i^* A_e\| \leqslant \frac{1}{\sqrt{2\omega_0}} (\|a_i A_e\| + \|a_i^* A_e\|) \leqslant \gamma,$$

where ω_0 is the lowest eigenfrequency of H_0, and we use the sum of the right-hand sides of (14) and (15) to define γ. Taking the adjoint yields

$$\|A_e x_i\| \leqslant \gamma.$$

Since $|\alpha| \geqslant 2$, we can write $x^\alpha = x_i x^{\alpha'} x_j$ for some x_i, x_j, with $|\alpha'| = |\alpha| - 2$. Then

$$\begin{aligned} \|A_e x^\alpha A_e P_{|\beta| \leqslant n}\| &\leqslant \|A_e x_i x^{\alpha'} P_{|\beta| \leqslant n+1} x_j A_e P_{|\beta| \leqslant n}\| \\ &\leqslant \|A_e x_i\| \|x_j A_e\| \|x^{\alpha'} P_{|\beta| \leqslant n+1}\| \\ &\leqslant \gamma^2 \left(\frac{2}{\omega_0}\right)^{|\alpha'|/2} \left[\frac{(n + |\alpha'| + 1)!}{(n+1)!}\right]^{1/2} \\ &= \gamma^2 \left(\frac{2}{\omega_0}\right)^{(|\alpha| - 2)/2} \left[\frac{(n + |\alpha| - 1)!}{(n+1)!}\right]^{1/2}, \end{aligned} \tag{16}$$

where we use Lemma 5.1 of Ref. 4 to bound $\|x^{\alpha'} P_{|\beta| \leqslant n+1}\|$. The last statement follows from the definition of $T^{(l)}$ and the first part of Lemma 2, along with the definitions $C_3 = C_1 \gamma^2 \delta^{-2} C_2^2$ and $\kappa = \max\{2, 2\omega_0^{-1} \delta^{-2} C_2^2\}$. □

Lemma 4: Let $\kappa \geqslant 2$ be the number defined in Lemma 3. Then we have the following.

(1) For each integer $a \geqslant 0$ there is a constant $C_4 = C_4(a)$ so that, for all $m \geqslant 0$,

$$\sum_{l=0}^{m}\left[\frac{(1+a+m-l)!(1+a+l)!}{(1+a+m)!}\right]^{1/2}\leqslant C_4.$$

(2) For all $a\geqslant -1$ *there is a constant* C_5 *so that, for all* $m\geqslant 0$,

$$\sum_{l=0}^{m}\kappa^{-5l/2}\left[\frac{(1+a+3m-2l)!(1+a+m-l)!}{(1+a+3m-3l)!(1+a+m)!}\right]^{1/2}\leqslant C_5.$$

(3) For each $a\geqslant 0$ *there is a constant* $C_6=C_6(a)$ *so that, for all* $m\geqslant 0$,

$$\sum_{l=1}^{m}\kappa^{-5l/2}\left[\frac{(1+a+m-l)!(1+a+l)!}{(1+a)!(a+m)!}\right]^{1/2}\leqslant C_6.$$

Proof: Statements (1) and (2) are shown in Lemma 2 of Ref. 19. To prove (3), notice that for $1\leqslant l\leqslant m-1$ we have

$$\frac{(1+a+l)!(1+a+m-l)!}{(a+m)!(1+a)!}=(1+a+l)\frac{\prod_{s=1}^{m-l}(1+a+s)}{\prod_{s=l}^{m-1}(1+a+s)}=(1+a+l)\prod_{s=1}^{m-l}\frac{1+a+s}{l+a+s}\leqslant 1+a+l.$$

Therefore

$$\sum_{l=1}^{m}\kappa^{-5l/2}\left[\frac{(1+a+l)!(1+a+m-l)!}{(a+m)!(1+a)!}\right]^{1/2}\leqslant\sum_{l=1}^{m}\kappa^{-5l/2}(1+a+l)^{1/2},$$

where the right-hand side converges to some constant $C_6(a)<\infty$. □

III. COMPUTATION OF THE R-S COEFFICIENTS

Let us assume that the zeroth-order eigenvalue e is g-fold degenerate, with associated eigenspace G. We allow g to be equal to 1. Let P be the projector onto G and $Q:=1-P$. Up to zeroth-order, ψ_0 can be any vector in G, which we may require to be normalized, $\|\psi_0\|=1$. Two cases may arise from solving (10) at higher order. Either the zeroth-order degeneracy is preserved at all orders, or it is removed to some extent at higher order. Let us start by discussing the former case, which trivially includes the nondegenerate one.

A. Degeneracy is preserved

Fix $\psi_0\in G$, with $\|\psi_0\|=1$. The first-order equation is

$$H_e\psi_1+T^{(3)}\psi_0=\mathcal{E}_1A_e^2\psi_0. \tag{17}$$

Let us multiply by P. Noting that $PH_e=0$ and $PA_e^2\psi_0=\psi_0$, we obtain

$$PT^{(3)}P\psi_0=\mathcal{E}_1\psi_0.$$

This is the secular equation for the finite-dimensional, self-adjoint operator $\Lambda^{(1)}:=PT^{(3)}P$. Since we assume that the zeroth-order degeneracy is not broken at any order, $\Lambda^{(1)}$ must have only one eigenvalue. Let us call it λ_1. Then $\mathcal{E}_1=\lambda_1$. Now multiply (17) by Q. We obtain

$$H_eQ\psi_1=-QT^{(3)}\psi_0.$$

Let us introduce more notation. For any vector $\psi\in\mathcal{H}$, define $\psi^{\parallel}:=P\psi$ and $\psi^{\perp}:=Q\psi$. Also, let $(H_e)_{\perp}$ be the restriction of H_e to $\mathrm{Ran}(Q)$. So defined, $(H_e)_{\perp}$ is invertible. Then we have

$$\psi_1^{\perp}=\Xi^{(1,\perp)}\psi_0,$$

where $\Xi^{(1,\perp)}:=(H_e)_\perp^{-1}(-QT^{(3)})$. So far $\psi_1^\parallel$ remains undefined.

The second-order equation is

$$H_e\psi_2+T^{(3)}\psi_1+T^{(4)}\psi_0=\mathcal{E}_2A_e^2\psi_0+\lambda_1A_e^2\psi_1. \tag{18}$$

Multiply (18) by P. After some algebra involving the definitions of $\Lambda^{(1)}$ and $\Xi^{(1,\perp)}$, we obtain

$$(PT^{(3)}\Xi^{(1,\perp)}P+PT^{(4)}P)\psi_0=\mathcal{E}_2\psi_0.$$

Then $\mathcal{E}_2$ has to be equal to the unique eigenvalue of

$$\Lambda^{(2)}:=P(T^{(3)}\Xi^{(1,\perp)}+T^{(4)})P.$$

That is, $\mathcal{E}_2=\lambda_2$. Now multiply (18) by Q to obtain

$$H_e\psi_2^\perp+QT^{(3)}(\psi_1^\parallel+\psi_1^\perp)+QT^{(4)}\psi_0=\lambda_1A_e^2\psi_1^\perp,$$

which yields

$$\psi_2^\perp=\Xi^{(2,\perp)}\psi_0+\Xi^{(1,\perp)}\psi_1^\parallel,$$

where we define

$$\Xi^{(2,\perp)}:=(H_e)_\perp^{-1}[(\lambda_1A_e^2-QT^{(3)})\Xi^{(1,\perp)}+QT^{(4)}]$$

and no requirement is imposed on either $\psi_2^\parallel$ or $\psi_1^\parallel$.

The third-order equation is

$$H_e\psi_3+T^{(3)}\psi_2+T^{(4)}\psi_1+T^{(5)}\psi_0=\mathcal{E}_3A_e^2\psi_0+\lambda_2A_e^2\psi_1+\lambda_1A_e^2\psi_2.$$

Following the procedure already described, we obtain

$$\Lambda^{(3)}\psi_0=\mathcal{E}_3\psi_0,$$

where

$$\Lambda^{(3)}:=P(T^{(3)}\Xi^{(2\perp)}+T^{(4)}\Xi^{(1,\perp)}+T^{(5)})P$$

has only one eigenvalue λ_3. Thus $\mathcal{E}_3=\lambda_3$. Also

$$\psi_3^\perp=\Xi^{(3,\perp)}\psi_0+\Xi^{(2,\perp)}\psi_1^\parallel+\Xi^{(1,\perp)}\psi_2^\parallel,$$

where

$$\Xi^{(3,\perp)}:=(H_e)_\perp^{-1}[(\lambda_1A_e^2-QT^{(3)})\Xi^{(2,\perp)}+(\lambda_2A_e^2-QT^{(4)})\Xi^{(1,\perp)}-QT^{(5)}]$$

and nothing is said about $\psi_3^\parallel$, $\psi_2^\parallel$ or $\psi_1^\parallel$.

As one can see, $\mathcal{E}_n$ and $\psi_n^\perp$ can be calculated through recursive definition of certain operators. The form of these operators is now easy to guess:

Proposition 1: For $n=1,2,\ldots$, *recursively define*

$$\Xi^{(1,\perp)}:=-(H_e)_\perp^{-1}QT^{(3)},$$

$$\Xi^{(n,\perp)}:=(H_e)_\perp^{-1}\left[-QT^{(n+2)}+\sum_{p=1}^{n-1}(\lambda_{n-p}A_e^2-QT^{(n+2-p)})\Xi^{(p,\perp)}\right],$$

where λ_l *is, by assumption, the unique eigenvalue of*

$$\Lambda^{(l)} := PT^{(l+2)}P + \sum_{p=1}^{n-1} PT^{(l+2-p)}\Xi^{(p,\perp)}P.$$

Then, given $\psi_0 \in G$, $\mathcal{E}_n = \lambda_n$ *and*

$$\psi_n = \Xi^{(n,\perp)}\psi_0 + \sum_{p=1}^{n-1} \Xi^{(n-p,\perp)}\psi_p^{\parallel} + \psi_n^{\parallel},$$

where $\psi_1^{\parallel}, \ldots, \psi_n^{\parallel}$ *are vectors arbitrarily chosen from* G.

This construction will be generalized in Proposition 2, from which the proof of Proposition 1 can be easily read out. To rule out arbitrariness, we set $\psi_n^{\parallel} = 0$ for all $n \geqslant 1$, which is equivalent to absorbing those vectors into ψ_0 and renormalizing.

The recursive expressions for the operators $\Lambda^{(n)}$ and $\Xi^{(n,\perp)}$ can be translated into recursive expressions for $\mathcal{E}_n$ and ψ_n. The result is

$$\mathcal{E}_n = \sum_{p=0}^{n-1} \langle T^{(n+2-p)} P_{|\alpha| \leqslant a} \psi_0, \psi_p \rangle,$$

$$\psi_n = (H_e)_{\perp}^{-1} \left[-QT^{(n+2)}\psi_0 + \sum_{p=1}^{n-1} (\mathcal{E}_{n-p}A_e^2 - QT^{(n+2-p)})\psi_p \right].$$

Furthermore, we can easily obtain the following inequalities:

$$|\mathcal{E}_n| \leqslant \sum_{l=1}^{n} \|T^{(l+2)} P_{|j| \leqslant a}\| \|\psi_{n-l}\|,$$

$$\|\psi_n\| \leqslant \sum_{l=1}^{n-1} |\mathcal{E}_l| \|\psi_{n-l}\| + \sum_{l=1}^{n} \|T^{(l+2)} P_{|j| \leqslant a+3(n-l)}\| \|\psi_{n-l}\|.$$

By resorting to Lemma 3, we finally obtain

$$|\mathcal{E}_n| \leqslant C_3 \sum_{l=1}^{n} \kappa^{l/2} \left[\frac{(1+a+l)!}{(1+a)!} \right]^{1/2} \|\psi_{n-l}\|,$$

$$\|\psi_n\| \leqslant \sum_{l=1}^{n-1} |\mathcal{E}_l| \|\psi_{n-l}\| + C_3 \sum_{l=1}^{n} \kappa^{l/2} \left[\frac{(1+a+3n-2l)!}{(1+a+3n-3l)!} \right]^{1/2} \|\psi_{n-l}\|.$$

As an immediate consequence, we have the following.

Theorem 1: *For each* $a \geqslant 0$, *there is* $b > 0$ *so that*

$$|\mathcal{E}_n| \leqslant \kappa^{3n} b^n [(1+a+n)!]^{1/2},$$

$$\|\psi_n\| \leqslant \kappa^{3n} b^n [(1+a+n)!]^{1/2},$$

for all $n \geqslant 1$.

A proof of this theorem is in Ref. 19, where the somewhat simpler one-dimensional problem is discussed. Alternatively, one can modify the proof of Theorem 3.2 below to get somewhat tighter bounds.

B. Degeneracy is removed

Let us examine the case where the zeroth-order degeneracy is partially removed only at first order.

First-order: Now the operator $\Lambda^{(1)}=PT^{(3)}P$ has $k\geqslant 2$ distinct eigenvalues $\lambda_{1,1},\ldots,\lambda_{1,k}$. Let $G_1,\ldots,G_k$ be the corresponding eigenspaces, and let $P^{(1)},\ldots,P^{(k)}$ be their orthogonal projections. Set $\mathcal{E}_1=\lambda_{1,i}$. Then ψ_0 must lie in G_i. As before, $\psi_1^{\perp}=\Xi^{(1,\perp)}\psi_0$ with $\Xi(1,\perp) \coloneqq(He)\perp-1(-QT(3))$.

Second-order: Because of the choice for $\mathcal{E}_1$ we have

$$H_e\psi_2+T^{(3)}\psi_1+T^{(4)}\psi_0=\mathcal{E}_2A_e^2\psi_0+\lambda_{1,i}A_e^2\psi_1. \tag{19}$$

Multiply (19) by $P^{(j)}$

$$P^{(j)}T^{(3)}\psi_1+P^{(j)}T^{(4)}\psi_0=\mathcal{E}_2P^{(j)}\psi_0+\lambda_{1,i}P^{(j)}\psi_1. \tag{20}$$

Note that $P=\Sigma_{j=1}^{k}P^{(j)}$. Then, for any vector ψ, we have $\psi^{\|}=\Sigma_{j=1}^{k}\psi^{(j)}$. On the other hand,

$$P^{(j)}T^{(3)}\psi^{\|}=\sum_{l=1}^{k}P^{(j)}PT^{(3)}PP^{(l)}\psi^{\|}=\sum_{l=1}^{k}P^{(j)}\Lambda^{(1)}P^{(l)}\psi^{\|}=\sum_{l=1}^{k}\lambda_{1,l}P^{(j)}P^{(l)}\psi^{\|}=\lambda_{1,j}\psi^{(j)}. \tag{21}$$

Therefore, $\Sigma_{l\neq i}P^{(i)}T^{(3)}\psi_n^{(l)}=0$. The identity (21) yields

$$P^{(j)}T^{(3)}\psi_1=P^{(j)}T^{(3)}\psi_1^{\|}+P^{(j)}T^{(3)}\psi_1^{\perp}=\lambda_{1,j}\psi_1^{(j)}+P^{(j)}T^{(3)}\psi_1^{\perp}. \tag{22}$$

Now insert (22) into (20). For $j=i$ we have

$$P^{(i)}T^{(4)}\psi_0+P^{(i)}T^{(3)}\psi_1^{\perp}=\mathcal{E}_2\psi_0.$$

Define

$$\Lambda^{(2,i)}\coloneqq P^{(i)}(T^{(4)}+T^{(3)}\Xi^{(1,\perp)})P^{(i)}.$$

Then we obtain $\Lambda^{(2,i)}\psi_0=\mathcal{E}_2\psi_0$. By assumption $\Lambda^{(2,i)}$ has only one eigenvalue $\lambda_{2,i}$. Therefore $\mathcal{E}_2=\lambda_{2,i}$.

For $j\neq i$ we have

$$P^{(j)}T^{(4)}\psi_0+P^{(j)}T^{(3)}\psi_1^{\perp}+\lambda_{1,j}\psi_1^{(j)}=\lambda_{1,i}P^{(j)}\psi_1$$

because $P^{(j)}\psi_0=0$ whenever $j\neq i$. Rearranging terms we finally obtain $\psi_1^{(j)}=\Xi^{(1,j)}\psi_0$, where we define

$$\Xi^{(1,j)}\coloneqq(\lambda_{1,i}-\lambda_{1,j})^{-1}P^{(j)}(T^{(4)}+T^{(3)}\Xi^{(1,\perp)})P^{(i)}. \tag{23}$$

So far no requirement is imposed to $\psi_1^{(i)}$.

Now multiply (19) by Q,

$$H_e\psi_2^{\perp}+QT^{(4)}\psi_0+QT^{(3)}\psi_1=\lambda_{1,i}A_e^2\psi_1^{\perp}. \tag{24}$$

Since

$$QT^{(3)}\psi_1=QT^{(3)}\psi_1^{\perp}+\sum_{l\neq i}QT^{(3)}\psi_1^{(l)}+QT^{(3)}\psi_1^{(i)}$$

$$=QT^{(3)}\Xi^{(1,\perp)}\psi_0+\sum_{l\neq i}QT^{(3)}\Xi^{(1,l)}\psi_0+QT^{(3)}\psi_1^{(i)},$$

(24) yields

$$H_e\psi_2^{\perp} = -QT^{(4)}\psi_0 + \lambda_{1,i}A_e^2\Xi^{(1,\perp)}\psi_0 - QT^{(3)}\Xi^{(1,\perp)}\psi_0 - \sum_{l\neq i} QT^{(3)}\Xi^{(1,l)}\psi_0 - QT^{(3)}\psi_1^{(i)}.$$

From there we obtain

$$\psi_2^{\perp} = \Xi^{(2,\perp)}\psi_0 + \Xi^{(1,\perp)}\psi_1^{(i)},$$

where

$$\Xi^{(2,\perp)} := (H_e)_{\perp}^{-1}\left[\lambda_{1,i}\Xi^{(1,\perp)}A_e^2 - QT^{(3)}\left(\Xi^{(1,\perp)} + \sum_{l\neq i}\Xi^{(1,l)}\right) - QT^{(4)}\right].$$

Third-order:

$$H_e\psi_3 + T^{(3)}\psi_2 + T^{(4)}\psi_1 + T^{(5)}\psi_0 = \mathcal{E}_3A_e^2\psi_0 + \lambda_{2,i}A_e^2\psi_1 + \lambda_{1,i}A_e^2\psi_2. \tag{25}$$

Multiply by $P^{(j)}$, rearrange terms, and use (21) to obtain

$$\begin{aligned}
\mathcal{E}_3P^{(j)}\psi_0 &= P^{(j)}T^{(3)}\psi_2 + P^{(j)}T^{(4)}\psi_1 + P^{(j)}T^{(5)}\psi_0 - \lambda_{2,i}\psi_1^{(j)} - \lambda_{1,i}\psi_2^{(j)} \\
&= P^{(j)}T^{(3)}(\psi_2^{\perp} + \psi_2^{\parallel}) + P^{(j)}T^{(4)}\left(\psi_1^{\perp} + \sum_{l\neq i}\psi_1^{(l)} + \psi_1^{(i)}\right) \\
&\quad + P^{(j)}T^{(5)}\psi_0 - \lambda_{2,i}\psi_1^{(j)} - \lambda_{1,i}\psi_2^{(j)} \\
&= P^{(j)}T^{(3)}\psi_2^{\perp} + P^{(j)}T^{(4)}\left(\psi_1^{\perp} + \sum_{l\neq i}\psi_1^{(i)} + \psi_1^{(i)}\right) \\
&\quad + P^{(j)}T^{(5)}\psi_0 - (\lambda_{1,i} - \lambda_{1,j})\psi_2^{(j)} - \lambda_{2,i}\psi_1^{(j)}.
\end{aligned} \tag{26}$$

For $j = i$ we have

$$\begin{aligned}
\mathcal{E}_3\psi_0 &= P^{(i)}T^{(3)}\Xi^{(2,\perp)}\psi_0 + P^{(i)}T^{(4)}\left(\Xi^{(1,\perp)} + \sum_{l\neq i}\Xi^{(1,l)}\right)\psi_0 \\
&\quad + P^{(i)}T^{(5)}\psi_0 + P^{(i)}T^{(3)}\Xi^{(1,\perp)}\psi_1^{(i)} + P^{(i)}T^{(4)}\psi_1^{(i)} - \lambda_{2,i}\psi_1^{(i)}.
\end{aligned}$$

Let us note that

$$P^{(i)}T^{(4)}\psi^{(i)} + P^{(i)}T^{(3)}\Xi^{(1,\perp)}\psi^{(i)} = \Lambda^{(2,i)}\psi^{(i)} = \lambda_{2,i}\psi^{(i)}.$$

Thus we obtain $\mathcal{E}_3\psi_0 = \Lambda^{(3,i)}\psi_0$, where

$$\Lambda^{(3,i)} := P^{(i)}\left[T^{(5)} + T^{(4)}\left(\Xi^{(1,\perp)} + \sum_{l\neq i}\Xi^{(1,l)}\right) + T^{(3)}\Xi^{(2,\perp)}\right]P^{(i)}.$$

By assumption $\Lambda^{(3,i)}$ has only one eigenvalue $\lambda_{3,i}$ so $\mathcal{E}_3 = \lambda_{3,i}$.

Now for $j \neq i$ we can rewrite (26) as

$$\begin{aligned}
(\lambda_{1,i} - \lambda_{1,j})\psi_2^{(j)} &= P^{(j)}T^{(5)}\psi_0 + P^{(j)}T^{(4)}\left(\Xi^{(1,\perp)} + \sum_{l\neq i}\Xi^{(1,l)}\right)\psi_0 + P^{(j)}T^{(3)}\Xi^{(2,\perp)}\psi_0 - \lambda_{2,i}\Xi^{(1,j)}\psi_0 \\
&\quad + P^{(j)}T^{(3)}\Xi^{(1,\perp)}\psi_1^{(i)} + P^{(j)}T^{(4)}\psi_1^{(i)}.
\end{aligned}$$

Now use (23) and define

$$\Xi^{(2,j)}:=(\lambda_{1,i}-\lambda_{1,j})^{-1}P^{(j)}\left[T^{(5)}+T^{(4)}\left(\Xi^{(1,\perp)}+\sum_{l\neq i}\Xi^{(1,l)}\right)+T^{(3)}\Xi^{(2,\perp)}-\lambda_{2,i}\Xi^{(1,j)}\right]P^{(i)}$$

to obtain

$$\psi_2^{(j)}=\Xi^{(2,j)}\psi_0+\Xi^{(1,j)}\psi_1^{(i)}.$$

The last step is to multiply (25) by Q,

$$H_e\psi_3^{\perp}=Q(\lambda_{1,i}A_e^2-T^{(3)})\psi_2+Q(\lambda_{2,i}A_e^2-T^{(4)})\psi_1-QT^{(5)}\psi_0. \tag{27}$$

We have

$$\begin{aligned}Q(\lambda_{1,i}A_e^2-T^{(3)})\psi_2&=Q(\lambda_{1,i}A_e^2-T^{(3)})\psi_2^{\perp}+\lambda_{1,i}A_e^2Q\psi_2^{\parallel}-QT^{(3)}\sum_{l\neq i}\psi_2^{(l)}-QT^{(3)}\psi_2^{(i)}\\&=Q(\lambda_{1,i}A_e^2-T^{(3)})\Xi^{(2,\perp)}\psi_0+Q(\lambda_{1,i}A_e^2-T^{(3)})\Xi^{(1,i)}\psi_1^{(i)}\\&\quad-QT^{(3)}\sum_{l\neq i}\Xi^{(2,l)}\psi_0-QT^{(3)}\sum_{l\neq i}\Xi^{(1,l)}\psi_1^{(i)}-QT^{(3)}\psi_2^{(i)}\\&=-QT^{(3)}\psi_2^{(i)}+Q\left[(\lambda_{1,i}A_e^2-T^{(3)})\Xi^{(1,\perp)}-\sum_{l\neq i}T^{(3)}\Xi^{(1,l)}\right]\psi_1^{(1)}\\&\quad+Q\left[(\lambda_{1,i}A_e^2-T^{(3)})\Xi^{(2,\perp)}-\sum_{l\neq i}T^{(3)}\Xi^{(2,l)}\right]\psi_0,\end{aligned} \tag{28}$$

and similarly

$$Q(\lambda_{2,i}A_e^2-T^{(4)})\psi_1=Q\left[(\lambda_{2,i}A_e^2-T^{(4)})\Xi^{(1,\perp)}-\sum_{l\neq i}T^{(4)}\Xi^{(1,l)}\right]\psi_0-QT^{(4)}\psi_1^{(i)}. \tag{29}$$

Insert (28) and (29) in (27) and multiply the whole equation by $(H_e)_{\perp}^{-1}$ to obtain

$$\psi_3^{\perp}=\Xi^{(3,\perp)}\psi_0+\Xi^{(2,\perp)}\psi_1^{(i)}+\Xi^{(1,\perp)}\psi_2^{(i)}$$

with

$$\begin{aligned}\Xi^{(3,\perp)}:=(H_e)_{\perp}^{-1}\Bigg[&(\lambda_{1,i}\Xi^{(2,\perp)}+\lambda_{2,i}\Xi^{(1,\perp)})A_e^2-QT^{(5)}-QT^{(4)}\left(\Xi^{(1,\perp)}+\sum_{l\neq i}\Xi^{(1,l)}\right)\\&-QT^{(5)}\left(\Xi^{(2,\perp)}+\sum_{l\neq i}\Xi^{(2,l)}\right)\Bigg].\end{aligned}$$

As before, one can guess the solution for arbitrary n. Let us summarize hypotheses and results:

Proposition 2: Define

$$\Lambda^{(1)}:=PT^{(3)}P,$$

$$\Xi^{(1,\perp)}:=-(H_e)_{\perp}^{-1}QT^{(3)}.$$

Suppose that $\Lambda^{(1)}$ *has* k *distinct eigenvalues* $\lambda_{1,1},\ldots,\lambda_{1,k}$ *with eigenspaces* $G_1,\ldots,G_k$. *Let* $P^{(1)},\ldots,P^{(k)}$ *be the associated projection operators. Given* $1\leqslant i\leqslant k$ *and* $j\neq i$, *set*

$$\Lambda^{(2,i)}:=P^{(i)}(T^{(4)}+T^{(3)}\Xi^{(1,\perp)})P^{(i)},$$

$$\Xi^{(1,j)}:=(\lambda_{1,i}-\lambda_{1,j})^{-1}P^{(j)}(T^{(4)}+T^{(3)}\Xi^{(1,\perp)})P^{(i)},$$

$$\Xi^{(2,\perp)}:=(H_e)_{\perp}^{-1}\left[\lambda_{1,i}\Xi^{(1,\perp)}A_e^2-QT^{(4)}-QT^{(3)}\left(\Xi^{(1,\perp)}+\sum_{l\neq i}\Xi^{(1,l)}\right)\right].$$

And then recursively define

$$\Lambda^{(n,i)}:=P^{(i)}\left(T^{(n+2)}+\sum_{s=1}^{n-1}T^{(n+2-s)}\Xi^{(s,\perp)}+\sum_{s=1}^{n-2}\sum_{l\neq i}T^{(n+2-s)}\Xi^{(s,l)}\right)P^{(i)},$$

$$\Xi^{(n-1,j)}:=(\lambda_{1,i}-\lambda_{1,j})^{-1}P^{(j)}\left(T^{(n+2)}+\sum_{s=1}^{n-1}T^{(n+2-s)}\Xi^{(s,\perp)}+\sum_{s=1}^{n-2}\sum_{l\neq i}T^{(n+2-s)}\Xi^{(s,l)}-\sum_{s=2}^{n-1}\lambda_{s,i}\Xi^{(n-s,j)}\right)P^{(i)},$$

$$\Xi^{(n,\perp)}:=(H_e)_{\perp}^{-1}\left[\sum_{s=1}^{n-1}\lambda_{s,i}\Xi^{(n-s,\perp)}A_e^2-QT^{(n+2)}-\sum_{s=1}^{n-1}QT^{(s+2)}\left(\Xi^{(n-s,\perp)}+\sum_{l\neq i}\Xi^{(n-s,l)}\right)\right],$$

where $\lambda_{s,i}$ *is, by assumption, the unique eigenvalue of* $\Lambda^{(s,i)}$ *when* $s\geqslant 2$.

Let $\mathcal{E}_n,\psi_n$ *be the R-S coefficients. Then* $\mathcal{E}_1$ *has to be equal to one of the eigenvalues of* $\Lambda^{(1)}$, *let us say* $\mathcal{E}_1=\lambda_{1,i}$. *Consequently,* $\psi_0\in G_i$ *and*

$$\mathcal{E}_n=\lambda_{n,i}, \tag{30}$$

$$\psi_{n-1}^{(j)}=\Xi^{(n-1,j)}\psi_0+\sum_{s=1}^{n-1}\Xi^{(n-s-1,j)}\psi_s^{(i)}, \tag{31}$$

$$\psi_n^{\perp}=\Xi^{(n,\perp)}\psi_0+\sum_{s=1}^{n-1}\Xi^{(n-s,\perp)}\psi_s^{(i)}, \tag{32}$$

$$\psi_n=\psi_n^{\perp}+\sum_{j\neq i}\psi_n^{(j)}+\psi_n^{(i)}.$$

The vectors $\psi_1^{(i)},\ldots,\psi_n^{(i)}$ *are arbitrarily chosen from* G_i.

Proof: Use mathematical induction. Because of the discussion above, we only have to prove the inductive step. Thus, let us assume that $\mathcal{E}_m$, $\psi_{m-1}^{(j)}$ and $\psi_m^{\perp}$ are given by (30)–(32), for $m=2,\ldots,n$. Let us compute $\mathcal{E}_{n+1}$, $\psi_n^{(j)}$ and $\psi_{n+1}^{\perp}$. The $(n+1)$-st-order equation is

$$H_e\psi_{n+1}+\sum_{p=0}^{n}T^{(n+3-p)}\psi_p=\sum_{s=0}^{n}\mathcal{E}_{n+1-s}A_e^2\psi_s. \tag{33}$$

We have

$$\sum_{p=0}^{n} T^{(n+3-p)}\psi_p = T^{(n+3)}\psi_0 + \sum_{p=1}^{n} T^{(n+3-p)}\psi_p^{\perp} + \sum_{p=1}^{n} T^{(n+3-p)}\sum_{l\neq i}\psi_p^{(l)} + \sum_{p=1}^{n} T^{(n+3-p)}\psi_p^{(i)}$$

$$= T^{(n+3)}\psi_0 + T^{(n+2)}\Xi^{(1,\perp)}\psi_0 + \sum_{p=2}^{n} T^{(n+3-p)}\left(\Xi^{(p,\perp)}\psi_0 + \sum_{s=1}^{p-1}\Xi^{(p-s,\perp)}\psi_s^{(i)}\right)$$

$$+ d\sum_{l\neq i} T^{(n+2)}\Xi^{(1,l)}\psi_0 + \sum_{p=2}^{n-1}\sum_{l\neq i} T^{(n+3-p)}\left(\Xi^{(p,l)}\psi_0 + \sum_{s=1}^{p-1}\Xi^{(p-s,l)}\psi_s^{(i)}\right)$$

$$+ \sum_{l\neq i} T^{(3)}\psi_n^{(l)} + \sum_{p=1}^{n} T^{(n+3-p)}\psi_p^{(i)}$$

$$= \left(T^{(n+3)} + \sum_{p=1}^{n} T^{(n+3-p)}\Xi^{(p,\perp)} + \sum_{p=1}^{n-1}\sum_{l\neq i} T^{(n+3-p)}\Xi^{(p,l)}\right)\psi_0$$

$$+ \sum_{s=1}^{n-1}\sum_{p=s+1}^{n} T^{(n+3-p)}\Xi^{(p-s,\perp)}\psi_s^{(i)}$$

$$+ \sum_{s=1}^{n-2}\sum_{p=s+1}^{n-1}\sum_{l\neq i} T^{(n+3-p)}\Xi^{(p-s,l)}\psi_s^{(i)} + \sum_{l\neq i} T^{(3)}\psi_n^{(l)} + \sum_{s=1}^{n} T^{(n+3-s)}\psi_s^{(i)}$$

$$= \left(T^{(n+3)} + \sum_{p=1}^{n} T^{(n+3-p)}\Xi^{(p,\perp)} + \sum_{p=1}^{n-1}\sum_{l\neq i} T^{(n+3-p)}\Xi^{(p,l)}\right)\psi_0$$

$$+ \sum_{s=1}^{n-1}\sum_{m=1}^{n-s} T^{(n+3-s-m)}\Xi^{(m,\perp)}\psi_s^{(i)} + \sum_{s=1}^{n-2}\sum_{m=1}^{n-1-s}\sum_{l\neq i} T^{(n+3-s-m)}\Xi^{(m,l)}\psi_s^{(i)}$$

$$+ \sum_{l\neq i} T^{(3)}\psi_n^{(l)} + \sum_{s=1}^{n} T^{(n+3-s)}\psi_s^{(i)}$$

where we use that $\Sigma_{p=1}^{r}\Sigma_{s=1}^{p-1}F_{sp} = \Sigma_{s=1}^{r-1}\Sigma_{p=s+1}^{r}F_{sp}$ and then we change index $p\to m = p-s$. Let us multiply (33) by $P^{(i)}$. Since $P^{(i)}H_e = 0$ and $P^{(i)}A_e^2 = A_e^2P^{(i)} = P^{(i)}$, we obtain

$$\sum_{p=0}^{n} P^{(i)}T^{(n+3-p)}\psi_p = \mathcal{E}_{n+1}\psi_0 + \sum_{s=1}^{n}\lambda_{n+1-s,i}\psi_s^{(i)}. \tag{34}$$

The left-hand side can be written as

$$\sum_{p=0}^{n} P^{(i)}T^{(n+3-p)}\psi_p = P^{(i)}\left(T^{(n+3)} + \sum_{p=1}^{n} T^{(n+3-p)}\Xi^{(p,\perp)} + \sum_{p=1}^{n-1}\sum_{l\neq i} T^{(n+3-p)}\Xi^{(p,l)}\right)\psi_0$$

$$+ \sum_{s=1}^{n-2} P^{(i)}\left(T^{(n+3-s)} + \sum_{m=1}^{n-s} T^{(n+3-s-m)}\Xi^{(m,\perp)}\right.$$

$$\left. + \sum_{m=1}^{n-1-s}\sum_{l\neq i} T^{(n+3-s-m)}\Xi^{(m,l)}\right)\psi_s^{(i)} + P^{(i)}\left(T^{(3)}\Xi^{(1,\perp)} + T^{(4)}\right)\psi_{n-1}^{(i)}$$

$$+ \sum_{l\neq i} P^{(i)}T^{(3)}\psi_n^{(l)} + P^{(i)}T^{(3)}\psi_n^{(i)}.$$

By the argument that leads to (21), we know that $\Sigma_{l\neq i}P^{(i)}T^{(3)}\psi_n^{(l)} = 0$. Also $\psi_s^{(i)} = P^{(i)}\psi_s^{(i)}$. Then

$$\sum_{p=0}^{n} P^{(i)}T^{(n+3-p)}\psi_p=\Lambda^{(n+1,i)}\psi_0+\sum_{s=1}^{n}\Lambda^{(n+1-s,i)}\psi_s^{(i)}. \tag{35}$$

Inserting (35) into (34) we conclude

$$\Lambda^{(n+1,i)}\psi_0=\mathcal{E}_{n+1}\psi_0.$$

Now let us multiply (33) by $P^{(j)}$ for $j\neq i$. Since $P^{(j)}\psi_0=0$, we have

$$\lambda_{1,i}\psi_n^{(j)}=\sum_{p=0}^{n} P^{(j)}T^{(n+3-p)}\psi_p-\sum_{s=1}^{n-1}\lambda_{n+1-s,i}\psi_s^{(j)}. \tag{36}$$

The right-hand side can be manipulated in the same way as before. The result is

$$\sum_{p=0}^{n} P^{(i)}T^{(n+3-p)}\psi_p-\sum_{s=1}^{n-1}\lambda_{n+1-s,i}\psi_s^{(j)}=(\lambda_{1,i}-\lambda_{1,j})\Xi^{(n,j)}\psi_0+\sum_{s=1}^{n-1}(\lambda_{1,i}-\lambda_{1,j})\Xi^{(n-s,j)}\psi_s^{(i)}$$
$$+\sum_{l=1}^{k} P^{(j)}T^{(3)}\psi_n^{(l)}.$$

As proven in (21), the last term above is equal to $\lambda_{1,j}\psi_n^{(j)}$. Thus (36) leads to

$$\psi_n^{(j)}=\Xi^{(n,j)}\psi_0+\sum_{s=1}^{n-1}\Xi^{(n-s,j)}\psi_s^{(i)}.$$

Finally, multiply (33) by Q,

$$H_e\psi_{n+1}^{\perp}=\sum_{p=1}^{n}\lambda_{n+1-p,i}A_e^2\psi_p^{\perp}-\sum_{p=0}^{n}QT^{(n+3-p)}\psi_p. \tag{37}$$

For the first term we have

$$\sum_{p=1}^{n}\lambda_{n+1-p,i}A_e^2\psi_p^{\perp}=\sum_{s=1}^{n}\lambda_{n+1-s,i}A_e^2\Xi^{(s,\perp)}\psi_0+\sum_{p=2}^{n}\sum_{s=1}^{p-1}\lambda_{n+1-p,i}A_e^2\Xi^{(p-s,\perp)}\psi_s^{(i)}$$
$$=\sum_{s=1}^{n}\lambda_{n+1-s,i}A_e^2\Xi^{(s,\perp)}\psi_0+\sum_{s=1}^{n-1}\sum_{m=1}^{n-s}\lambda_{n+1-s-m,i}A_e^2\Xi^{(m,\perp)}\psi_s^{(i)},$$

and for the second one

$$\sum_{p=0}^{n}QT^{(n+3-p)}\psi_p=Q\left(T^{(n+3)}+\sum_{p=1}^{n}T^{(n+3-p)}\Xi^{(p,\perp)}+\sum_{p=1}^{n-1}\sum_{l\neq i}T^{(n+3-p)}\Xi^{(p,l)}\right)\psi_0$$
$$+\sum_{s=1}^{n-2}Q\left(T^{(n+3-s)}+\sum_{m=1}^{n-s}T^{(n+3-s-m)}\Xi^{(m,\perp)}\right.$$
$$\left.+\sum_{m=1}^{n-1-s}\sum_{l\neq i}T^{(n+3-s-m)}\Xi^{(m,l)}\right)\psi_s^{(i)}+\quad Q(T^{(3)}\Xi^{(1,\perp)}+T^{(4)})\psi_{n-1}^{(i)}$$
$$+\sum_{l\neq i}QT^{(3)}\psi_n^{(l)}+QT^{(3)}\psi_n^{(i)}.$$

Then insert these expressions into (37). After multiplying the whole equation by $(H_e)_\perp^{-1}$ we obtain the desired result. □

As before, we set $\psi_n^{(i)}=0$ for all $n=1,2,\ldots$. Consequently, ψ_n will be orthogonal to ψ_0 and

$$\psi_n=\left(\Xi^{(n,\perp)}+\sum_{l\neq i}\Xi^{(n,l)}\right)\psi_0.$$

The following expressions will be useful later:

$$\Lambda^{(n,i)}\psi_0=P^{(i)}T^{(n+2)}\psi_0+\sum_{s=1}^{n-2}P^{(i)}T^{(n+2-s)}\psi_s+P^{(i)}T^{(3)}\psi_{n-1}^{\perp}, \tag{38}$$

$$\psi_n^{\perp}=(H_e)_\perp^{-1}\left[\sum_{s=1}^{n-1}\mathcal{E}_sA_e^2\psi_{n-s}^{\perp}-QT^{(n+2)}\psi_0-\sum_{s=1}^{n-1}QT^{(s+2)}\psi_{n-s}\right], \tag{39}$$

$$\psi_{n-1}^{(j)}=(\lambda_{1,i}-\lambda_{1,j})^{-1}\left(P^{(j)}T^{(n+2)}\psi_0+\sum_{s=1}^{n-2}P^{(j)}T^{(n+2-s)}\psi_s+P^{(j)}T^{(3)}P_{|j|\leqslant a+3(n-1)}\psi_{n-1}^{\perp}-\sum_{s=2}^{n-1}\mathcal{E}_s\psi_{n-s}^{(j)}\right). \tag{40}$$

Next, let us estimate the growth of these coefficients. Since $\mathcal{E}_n\psi_0=\Lambda^{(n,i)}\psi_0$,

$$\begin{aligned}|\mathcal{E}_n|&=|\langle\psi_0,\Lambda^{(n,i)}\psi_0\rangle|\\&\leqslant|\langle\psi_0,P^{(i)}T^{(n+2)}\psi_0\rangle|+\sum_{s=1}^{n-2}|\langle\psi_0,P^{(i)}T^{(n+2-s)}\psi_s\rangle|+|\langle\psi_0,P^{(i)}T^{(3)}\psi_{n-1}^{\perp}\rangle|\\&\leqslant\|T^{(n+2)}P_{|\alpha|\leqslant a}\|+\sum_{s=1}^{n-2}|\langle T^{(n+2-s)}\psi_0,\psi_s\rangle|+|\langle T^{(3)}\psi_0,\psi_{n-1}^{\perp}\rangle|\\&\leqslant\|T^{(n+2)}P_{|\alpha|\leqslant a}\|+\sum_{s=1}^{n-2}\|T^{(n+2-s)}P_{|\alpha|\leqslant a}\|\|\psi_s\|+\|T^{(3)}P_{|\alpha|\leqslant a}\|\|\psi_{n-1}^{\perp}\|\\&=\sum_{s=2}^{n}\|T^{(s+2)}P_{|\alpha|\leqslant a}\|\|\psi_{n-s}\|+\|T^{(3)}P_{|\alpha|\leqslant a}\|\|\psi_{n-1}^{\perp}\|.\end{aligned} \tag{41}$$

This calculation follows from (38), the self-adjointness of $T^{(l)}$, and Lemma 1.

From the definition of H_e, it is straightforward to see that $\|(H_e)_\perp^{-1}\|=1$. Also, $\|A_e\|=1$. Thus, from (39) we have

$$\begin{aligned}\|\psi_n^{\perp}\|&\leqslant\sum_{s=1}^{n-1}|\mathcal{E}_s|\|\psi_{n-s}^{\perp}\|+\|T^{(n+2)}P_{|\alpha|\leqslant a}\|\|\psi_0\|+\sum_{s=1}^{n-1}\|T^{(s+2)}P_{|\alpha|\leqslant a+3(n-s)}\|\|\psi_{n-s}\|\\&=\sum_{s=1}^{n-1}|\mathcal{E}_s|\|\psi_{n-s}^{\perp}\|+\sum_{s=1}^{n}\|T^{(s+2)}P_{|\alpha|\leqslant a+3(n-s)}\|\|\psi_{n-s}\|.\end{aligned} \tag{42}$$

Finally let us consider (40):

$$\|\psi_{n-1}^{(j)}\| \leqslant |\lambda_{1,i}-\lambda_{1,j}|^{-1}\left(\|T^{(n+2)}P_{|\alpha|\leqslant a}\|\|\psi_0\| + \sum_{s=1}^{n-2} \|P^{(j)}T^{(n+2-s)}\|\|\psi_s\| + \|P^{(j)}T^{(3)}\|\|\psi_{n-1}^{\perp}\| + \sum_{s=2}^{n-1} |\mathcal{E}_s|\|\psi_{n-s}^{(j)}\| \right).$$

Set $C_7 := \min_{j\neq i}|\lambda_{1,i}-\lambda_{1,j}|^{-1}$. Also, let us notice that $\|P^{(j)}T^{(n+2-s)}\| = \|T^{(n+2-s)}P^{(j)}\| = \|T^{(n+2-s)}P_{|\alpha|\leqslant a}P^{(j)}\| \leqslant \|T^{(n+2-s)}P_{|\alpha|\leqslant a}\|$. Thus,

$$\|\psi_{n-1}^{(j)}\| \leqslant C_7 \sum_{s=2}^{n-1} |\mathcal{E}_s|\|\psi_{n-s}^{(j)}\| + C_7 \sum_{s=2}^{n} \|T^{(s+2)}P_{|\alpha|\leqslant a}\|\|\psi_{n-s}\| + C_7\|T^{(3)}P_{|\alpha|\leqslant a}\|\|\psi_{n-1}^{\perp}\|. \quad (43)$$

These inequalities will allow us to obtain upper bounds for the growth of R-S coefficients. In the following theorem we make use of Lemmas 3 and 4.

Theorem 2: *Let k be the number of subspaces as defined in Proposition 3.2. Define $b_1 := C_3[kC_6+(2+a)^{1/2}]$, $b_2 := 8C_7[b_1C_4+C_3(2+a)^{1/2}+kC_3C_6]$ and $b_3 := b_1C_4+C_3C_5[1+b_2(k-1)]$. Then for any $b \geqslant \max\{b_1,b_2,b_3,1\}$ and for $n=1,2,\ldots$,*

$$|\mathcal{E}_n| \leqslant b_1\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}, \quad (44)$$

$$\|\psi_{n-1}^{(l)}\| \leqslant b_2\kappa^{3(n-1)}b^{n-2}[(a+n)!]^{1/2}, \quad (45)$$

$$\|\psi_n^{\perp}\| \leqslant b_3\kappa^{3n}b^{n-2}[(1+a+n)!]^{1/2}. \quad (46)$$

Proof: Assume the estimates are true for $s=1,\ldots,n-1$. This implies that

$$\|\psi_s\| \leqslant [b_3+b_2(k-1)]\kappa^{3s}b^{s-1}[(1+a+s)!]^{1/2} \leqslant \kappa^{3s}kb^s[(1+a+s)!]^{1/2} \quad (47)$$

for $s \leqslant n-2$. We shall use the second inequality in (47) to prove (44) and (45), and the first one to prove (46).

Let us start showing (44). Applying Lemmas 3 and 4, statement 2, we obtain

$$\begin{aligned}\sum_{s=2}^{n} \|T^{(s+2)}P_{|\alpha|\leqslant a}\|\|\psi_{n-s}\| &\leqslant C_3k\sum_{s=2}^{n} \kappa^{s/2}\left[\frac{(1+a+s)!}{(1+a)!}\right]^{1/2}\kappa^{3(n-s)}b^{n-s}[(1+a+n-s)!]^{1/2} \\ &\leqslant C_3k\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}\sum_{s=2}^{n} \kappa^{-5s/2}\left[\frac{(1+a+s)!(1+a+n-s)!}{(1+a)!(a+n)!}\right]^{1/2} \\ &\leqslant kC_3C_6\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}.\end{aligned}$$

Thus, (41) yields

$$\begin{aligned}|\mathcal{E}_n| &\leqslant kC_3C_6\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}+C_3\kappa^{3(n-1)}b_3b^{n-3}\kappa^{1/2}(2+a)^{1/2}[(a+n)!]^{1/2} \\ &\leqslant kC_3C_6\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}+C_3(2+a)^{1/2}\kappa^{3n}b^{n-2}[(a+n)!]^{1/2} \\ &\leqslant b_1\kappa^{3n}b^{n-2}[(a+n)!]^{1/2},\end{aligned}$$

which completes the proof of (44).

To prove (45) we start from (43) and proceed in the same fashion:

$$\|\psi_{n-1}^{(j)}\| \leqslant C_7\kappa^{3n}b_1b_2b^{n-3}\sum_{s=2}^{n-1}[(a+s)!(1+a+n-s)!]^{1/2}+C_3C_7\kappa^{3n}b_3b^{n-3}(2+a)^{1/2}$$

$$\times[(a+n)!]^{1/2}+C_3C_7k\kappa^{3n}b^{n-2}\sum_{s=2}^{n}\kappa^{-5s/2}\left[\frac{(1+a+s)!(1+a+n-s)!}{(1+a)!}\right]^{1/2}$$

$$\leqslant C_7b_1\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}\sum_{m=1}^{n-2}\left[\frac{(1+a+m)!(a+n-m)!}{(a+n)!}\right]^{1/2}$$

$$+C_3C_7(2+a)^{1/2}\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}$$

$$+C_3C_7k\kappa^{3n}b^{n-2}[(a+n)!]^{1/2}\sum_{s=2}^{n}\kappa^{-5s/2}\left[\frac{(1+a+s)!(1+a+n-s)!}{(1+a)!(a+n)!}\right]^{1/2},$$

where we have changed index $s\to m=s-1$ in the first term. From this and statements 1 and 3 of Lemma 4, we obtain

$$\|\psi_{n-1}^{(j)}\| \leqslant 8C_7[b_1C_4+C_3(2+a)^{1/2}+kC_3C_6]\kappa^{3(n-1)}b^{n-2}[(a+n)!]^{1/2}$$

$$=b_2\kappa^{3(n-1)}b^{n-2}[(a+n)!]^{1/2},$$

so (45) is done. Consequently, (47) must be valid for $s=n-1$.

Finally, let us show (46). Note that the first term of (42) is bounded like the first term of (43). Applying statement 2 of Lemma 4, it follows that

$$\|\psi_n^{\perp}\| \leqslant b_1b_3\kappa^{3n}b^{n-3}C_6[(a+n)!]^{1/2}+C_3[1+b_2(k-1)]\kappa^{3n}b^{n-2}[(1+a$$

$$+n)!]^{1/2}\sum_{s=1}^{n}\kappa^{-5s/2}\left[\frac{(1+a+3n-2s)!(1+a+n-s)!}{(1+a+3n-3s)!(1+a+n)!}\right]^{1/2}$$

$$\leqslant b_1C_6\kappa^{3n}b^{n-2}[(1+a+n)!]^{1/2}+C_3[1+b_2(k-1)]C_5\kappa^{3n}b^{n-2}[(1+a+n)!]^{1/2}$$

$$=b_3\kappa^{3n}b^{n-2}[(1+a+n)!]^{1/2} \quad .$$

□

Corollary 1:

$$|\mathcal{E}_n| \leqslant \kappa^{3n}b^{n-1}[(a+n)!]^{1/2},$$

$$\|\psi_n\| \leqslant \kappa^{3n}kb^n[(1+a+n)!]^{1/2}.$$

For the case where degeneracy is partly broken only up to second order, one needs to define certain operators $\Lambda^{(n,i_1,i_2)}$, $\Xi^{(n-2,i_1,i_2)}$, $\Xi^{(n,\perp)}$ for $n\geqslant 3$, in addition to those already defined in the last subsection. Now ψ_0 would be required to lie in a certain subspace $G_{i_1,1_2}\subset G_{i_1}\subset G$, and one would be able to determine ψ_n module an arbitrary component in $G_{i_1,1_2}$. This scheme may be extended to the general case. But the complexity of the set of equations that recursively defines those operators rapidly becomes wild. For that reason, we do not go further. We assume instead that, in general,

$$|\mathcal{E}_n| \leqslant \kappa^{3n}b^{n+w}[(1+a+n)!]^{1/2},$$

$$\|\psi_n\| \leqslant \kappa^{3n}b^{n+w}[(1+a+n)!]^{1/2},$$

for some positive integer w, which may depend on where degeneracy splits.

IV. THE TWO-SIDE ERROR FUNCTION

The upper bounds for $|\mathcal{E}_n|$ and $\|\psi_n\|$ will allow us to estimate the error made in the Schrödinger equation when truncated series are inserted on it. Here we basically follow the technique developed by Hagedorn and Joye in Ref. 4. Concretely, for $N\geqslant 1$ define

$$E_N := e+\sum_{n=1}^{N-1}\hbar^{n/2}\mathcal{E}_n, \quad \Psi_N(x) := \psi_0(x)+\sum_{n=1}^{N-1}\hbar^{n/2}\psi_n(x).$$

These are the truncations at order N of the R-S series. We define

$$\xi_N(x) := A_e[H_0+W(\hbar;x)-E_N]A_e\Psi_N(x)=\left[H_e+A_eW(\hbar;x)A_e-\sum_{j=1}^{N-1}\hbar^{j/2}\mathcal{E}_jA_e^2\right]\sum_{m=0}^{N-1}\hbar^{m/2}\psi_m(x). \tag{48}$$

We call $\xi_N(x)$ the two-side error function since it is the difference between both sides of the Schrödinger equation when exact eigenvalues and eigenfunctions are replaced by truncated series. It can be portrayed in a more suitable way through a number of cancellations. The calculation is outlined in the Appendix. The result is

$$\xi_N(x)=\sum_{n=0}^{N-1}\hbar^{n/2}A_eW^{[N-n+1]}(\hbar;x)A_e\psi_n(x)-\sum_{n=N}^{2N-2}\hbar^{n/2}\sum_{j=n-N+1}^{N-1}\mathcal{E}_jA_e^2\psi_{m-j}(x).$$

Here $W^{[j]}(\hbar;x)$ is the tail of the Taylor series of $V(\hbar;x)$:

$$W^{[j]}(\hbar;x)=V(\hbar;x)-\sum_{l=2}^{j}\hbar^{(l-2)/2}\sum_{|\alpha|=l}\frac{D^\alpha V(0)}{\alpha!}x^\alpha=\hbar^{(j-1)/2}\sum_{|\alpha|=j+1}\frac{D^\alpha V(\zeta_j)}{\alpha!}x^\alpha,$$

where $\zeta_j=\zeta_j(x)=\Theta_j x$ with $\Theta_j\in(0,1)$, as the Taylor theorem states. So we have

$$\xi_N(x)=\hbar^{N/2}\sum_{n=0}^{N-1}\sum_{|\alpha|=N-n+2}\frac{D^\alpha V(\zeta_n)}{\alpha!}A_ex^\alpha A_e\psi_n(x)-\sum_{n=N}^{2N-2}\hbar^{n/2}\sum_{l=n-N+1}^{N-1}\mathcal{E}_lA_e^2\psi_{n-l}(x). \tag{49}$$

Our main result in the next section relies on an upper bound of the L^2-norm of $(H-E_N)A_e\psi_N=A_e^{-1}\xi_N$. Note that, for each $N\geqslant 2$, ξ_N is in the domain of the unbounded operator A_e^{-1}. This estimate on the two-side error function is stated as follows:

Theorem 3: *There are positive constants A, B and N_0 so that*

$$\|A_e^{-1}\xi_N(x)\|\leqslant\sum_{n=N}^{2N}AB^N\hbar^{N/2}[(2+a+n)!]^{1/2}$$

whenever $N_0\leqslant N$ and $\hbar\leqslant 1$.

To estimate the norm of $A_e^{-1}\xi_N$, we first set a suitable closed region around the bottom of the potential well. Then we compute that norm inside and outside of that region. Most of the work is involved in the outside estimate, which requires control on the growth of derivatives of $V(x)$ far away from the minimum of $V(x)$. For that reason we shall summarize it as a separate lemma. Here the hypothesis H5 becomes crucial.

For $R>0$, let us define

$$\chi_R(x)=\begin{cases}1 & \text{if } \sum_i^d \omega_i x_i^2\leqslant R^2,\\ 0 & \text{otherwise.}\end{cases}$$

Lemma 5: Set $R=\sqrt{6N+2a+d-4}$. *Given a multi-index* α, *with* $|\alpha|\geqslant 2$, *and* $n=0,\ldots,N-1$, *there exists certain constants* C_8 *and* C_9 *such that*

$$\left\|\frac{\delta^{|\alpha|}}{\alpha!}D^{\alpha}V(\zeta_n)x^{\alpha'}(1-\chi_R)P_{|\beta|\leqslant a+3n+1}\right\| \leqslant C_8 C_9^{(3n+2+a)/2}\frac{(3n+a+d)^{(d-1)/2}}{\left(1-\frac{\tau}{\omega_0}\right)^{|\alpha|/2}}\left[\frac{(3n+|\alpha|+[\![d/2]\!]+a)!}{(3n+a)!}\right]^{1/2},$$

where $|\alpha'|=|\alpha|-1$, $\omega_0=\min\{\omega_1,\ldots,\omega_d\}$, *and* $[\![J]\!]$ *stands for the largest integer less than or equal to* J.

Proof: Since $|\zeta_n|\leqslant|x|$, the first part of Lemma 3 implies

$$\frac{\delta^{|\alpha|}}{\alpha!}|D^{\alpha}V(\zeta_n)|\leqslant C_0\exp(2\tau x^2). \tag{50}$$

Let us consider an eigenfunction $\Phi_\beta(x)$ of H_0. We have

$$\left\|\frac{\delta^{|\alpha|}}{\alpha!}D^{\alpha}V(\zeta)x^{\alpha'}(1-\chi_R)\Phi_\beta(x)\right\|^2=\int_{\mathbb{R}^d}\left|\frac{\delta^{|\alpha|}}{\alpha!}D^{\alpha}V(\zeta)\right|^2 x^{2\alpha'}|\Phi_\beta(x)|^2[1-\chi_R(x)]d^dx$$
$$\leqslant C_0^2\int_{\mathbb{R}^d}e^{4\tau x^2}x^{2\alpha'}|\Phi_\beta(x)|^2[1-\chi_R(x)]d^dx,$$

where we have dropped the index n in ζ_n. Now change variables $x_i\to y_i=\sqrt{\omega_i}x_i$ to get

$$\left\|\frac{\delta^{|\alpha|}}{\alpha!}D^{\alpha}V(\zeta)x^{\alpha'}(1-\chi_R)\Phi_\beta(x)\right\|^2$$
$$\leqslant C_0^2\left(\prod_{i=1}^{d}\omega_i^{-\alpha_i'-1/2}\right)\int_{\mathbb{R}^d}e^{\Sigma_i 4(\tau/\omega_i)y_i^2}y^{2\alpha'}|\Phi_\beta(y)|^2[1-\chi_R(y)]d^dy$$
$$\leqslant C_0^2\left(\prod_{i=1}^{d}\omega_i^{-\alpha_i'-1/2}\right)\int_{\mathbb{R}^d}e^{4(\tau/\omega_0)y^2}y^{2\alpha'}|\Phi_\beta(y)|^2[1-\chi_R(y)]d^dy$$
$$=D_1^2\left\|e^{2(\tau/\omega_0)y^2}y^{\alpha'}(1-\chi_R)\Phi_\beta(y)\right\|^2, \tag{51}$$

where D_1 is defined in the obvious way. In the new variables

$$\chi_R(y)=\begin{cases}1 & \text{if } y^2\leqslant R^2,\\ 0 & \text{otherwise.}\end{cases}$$

Using the new variables in (5), we see that $\Phi_\beta(y)$ is an eigenfunction of the normalized harmonic oscillator operator

$$H_0'=-\tfrac{1}{2}\Delta_y+\tfrac{1}{2}y^2$$

with energy $e_\beta=|\beta|+d/2$. For $d\geqslant 2$ this operator is equal to

$$H_0'=\frac{1}{2}\left(-\frac{\partial^2}{\partial r^2}-\frac{d-1}{r}\frac{\partial}{\partial r}+\frac{\mathcal{L}^2}{r^2}+r^2\right)$$

in spherical coordinates, where $\mathcal{L}^2$ is the angular momentum operator defined on S^{d-1}. The eigenvalues now read $e=2n+q+d/2$ and the eigenfunctions are

$$\Psi_{k,q,\nu}(r,\omega)=\left[\frac{2k!}{\Gamma(k+q+d/2)}\right]^{1/2} r^q L_k^{q+d/2-1}(r^2)\exp\left(-\frac{r^2}{2}\right)Y_{q,\nu}(\omega).$$

Here $Y_{q,\nu}(\omega)$ are the normalized eigenfunctions of $\mathcal{L}^2$, with quantum numbers q,ν. For each $q=0,1,\ldots$ there are ν_q values of ν. Although the explicit formula for ν_q is rather clumsy, there is a simple bound for it, namely $\nu_q \leqslant C_d e^{\mu_d q}$. This bound suffices for the purpose of our proof. $L_k^j(x)$ denotes the Laguerre polynomial. By Lemma 6.2 of Ref. 4, this polynomial satisfies $|L_k^{q+d/2-1}(x)|\leqslant x^k/k!$ for all $x>4k+2q+d$. Finally, by equating the expressions for the energy, we obtain $|\beta|=2k+q$.

Now $\Phi_\beta(y)$ is certain linear combination of $\Psi_{k,q,\nu}(r,\omega)$,

$$\Phi_\beta(y)=\sum_{\substack{k,q,\nu:\\ 2k+q=|\beta|}} c_{k,q,\nu}\Psi_{k,q,\nu}(r,\omega)$$

with $\Sigma|c_{k,q,\nu}|^2=1$. From (51), it follows that

$$\begin{aligned}\left\|\frac{\delta^{|\alpha|}}{\alpha!}D^\alpha V(\zeta)x^{\alpha'}(1-\chi_R)\Phi_\beta(x)\right\|^2 &\leqslant D_1^2\sum_{\substack{k,q,\nu:\\ 2k+q=|\beta|}}\left\|e^{2(\tau/\omega_0)y^2}y^{\alpha'}(1-\chi_R)\Psi_{k,q,\nu}(y)\right\|^2\\ &\leqslant D_1^2\sum_{\substack{k,q,\nu:\\ 2k+q=|\beta|}}\frac{2k!A_{d-1}}{\Gamma(k+q+d/2)}\int_R^\infty e^{-(1-4\tau/\omega_0)r^2}r^{2(|\alpha|-1+q)}\\ &\quad\times|L_k^{q+d/2-1}(r^2)|^2 r^{d-1}dr,\end{aligned}$$

where A_{d-1} is the area of the $(d-1)$ dimensional unit sphere. We also have used that $y^{2|\alpha'|}\leqslant r^{2|\alpha'|}=r^{2(|\alpha|-1)}$. Since $R\geqslant\sqrt{2|\alpha|+d}$, Lemma 6.2 of Ref. 4 applies so

$$\begin{aligned}&\left\|\frac{\delta^{|\alpha|}}{\alpha!}D^\alpha V(\zeta)x^{\alpha'}(1-\chi_R)\Phi_\beta(x)\right\|^2\\ &\leqslant D_1^2\sum_{\substack{k,q,\nu:\\ 2k+q=|\beta|}}\frac{2A_{d-1}}{k!\Gamma(k+q+d/2)}\int_R^\infty e^{-(1-4\tau/\omega_0)r^2}r^{2|\alpha|+2q+4k+d-3}dr\\ &= D_1^2\sum_{\substack{k,q,\nu:\\ 2k+q=|\beta|}}\frac{2A_{d-1}}{k!\Gamma(k+q+d/2)}\frac{\Gamma(|\alpha|+q+2k+d/2-1)}{2(1-4\tau/\omega_0)^{|\alpha|+q+2k+d/2-1}}\\ &= D_1^2A_{d-1}\frac{\Gamma(|\alpha|+|\beta|+d/2-1)}{(1-4\tau/\omega_0)^{|\alpha|+|\beta|+d/2-1}}\sum_{\substack{k,q:\\ 2k+q=|\beta|}}\frac{\nu_q}{k!\Gamma(k+q+d/2)}\\ &= D_1^2A_{d-1}\frac{\Gamma(|\alpha|+|\beta|+d/2-1)}{(1-4\tau/\omega_0)^{|\alpha|+|\beta|+d/2-1}}\sum_{k=0}^{[\![|\beta|/2]\!]}\frac{\nu_{|\beta|-2k}}{k!\Gamma(|\beta|-k+d/2)}\\ &\leqslant D_1^2A_{d-1}C_d e^{\mu_d|\beta|}\frac{\Gamma(|\alpha|+|\beta|+d/2-1)}{(1-4\tau/\omega_0)^{|\alpha|+|\beta|+d/2-1}}\sum_{k=0}^{[\![|\beta|/2]\!]}\frac{e^{-2\mu_d k}}{k!\Gamma(|\beta|-k+d/2)}.\end{aligned}\tag{52}$$

For $|\beta|\geqslant 1$, $|\beta|-k+d/2\geqslant 1+d/2\geqslant 2$ for all $0\leqslant k\leqslant[\![|\beta|/2]\!]$. Since $\Gamma(x)$ is an increasing function for $x\geqslant 2$, we have

$$\sum_{k=0}^{[\![|\beta|/2]\!]} \frac{e^{-2\mu_d k}}{k!\Gamma(|\beta|-k-d/2)} \leqslant \sum_{k=0}^{[\![|\beta|/2]\!]} \frac{1}{k!(|\beta|-k)!} \leqslant \frac{1}{|\beta|!} \sum_{k=0}^{|\beta|} \binom{|\beta|}{k} = \frac{1}{|\beta|!} 2^{|\beta|}.$$

For $|\beta|=0$, the sum above is smaller than $2/\sqrt{\pi}$. Therefore

$$\sum_{k=0}^{[\![|\beta|/2]\!]} \frac{e^{-2\mu_d k}}{k!\Gamma(|\beta|-k-d/2)} \leqslant \frac{2}{\sqrt{\pi}|\beta|!} 2^{|\beta|}$$

for all $|\beta| \geqslant 0$. Thus (52) becomes

$$\left\| \frac{\delta^{|\alpha|}}{\alpha!} D^\alpha V(\zeta) x^{\alpha'} (1-\chi_R) \Phi_\beta(x) \right\|^2 \leqslant D_2^2 2^{|\beta|} e^{\mu_d |\beta|} \frac{\Gamma(|\alpha|+|\beta|+d/2-1)}{|\beta|!(1-4\tau/\omega_0)^{|\alpha|+|\beta|+d/2-1}}$$

with $D_2^2 := 2D_1^2 A_{d-1} C_d \pi^{-1/2}$.

Now consider any $\varphi \in \mathrm{Ran}(P_{|\beta| \leqslant 3n+a+1})$ so $\varphi = \Sigma_{|\beta| \leqslant 3n+a+1} c_\beta \Phi_\beta(x)$. Then the Hölder inequality implies that

$$\left\| \frac{\delta^{|\alpha|}}{\alpha!} D^\alpha V(\zeta) x^{\alpha'} (1-\chi_R) P_{|\beta| \leqslant a+3n+1} \varphi \right\|^2 \leqslant \|\varphi\|^2 \sum_{|\beta| \leqslant 3n+a+1} \left\| \frac{\delta^{|\alpha|}}{\alpha!} D^\alpha V(\zeta) x^{\alpha'} (1-\chi_R) \Phi_\beta(x) \right\|^2.$$

Therefore

$$\begin{aligned}
&\left\| \frac{\delta^{|\alpha|}}{\alpha!} D^\alpha V(\zeta) x^{\alpha'} (1-\chi_R) P_{|\beta| \leqslant a+3n+1} \right\|^2 \\
&\quad \leqslant D_2^2 \frac{2^{3n+a+1} e^{\mu_d (3n+a+1)}}{\left(1-\dfrac{4\tau}{\omega_0}\right)^{3n+|\alpha|+a+d/2}} \sum_{|\beta| \leqslant 3n+a+1} \frac{\Gamma(|\alpha|+|\beta|+d/2-1)}{|\beta|!} \\
&\quad \leqslant D_2^2 \frac{2^{3n+a+1} e^{\mu_d (3n+a+1)}}{(1-4\tau/\omega_0)^{3n+|\alpha|+a+d/2}} \sum_{|\beta| \leqslant 3n+a+1} \frac{(|\alpha|+|\beta|+[\![d/2]\!]-1)!}{|\beta|!}
\end{aligned}$$

where we use that $0<(1-4\tau/\omega_0)<1$. The terms under the summation sign are increasing in $|\beta|$. Also,

$$\begin{aligned}
\sum_{|\beta| \leqslant 3n+a+1} 1 &= \sum_{s=0}^{3n+a+1} \#\{\beta : |\beta| = s\} \\
&= \sum_{s=0}^{3n+a+1} \frac{(s+d-1)!}{s!(d-1)!} \\
&\leqslant \sum_{s=0}^{3n+a+1} \frac{(s+d-1)^{d-1}}{(d-1)!} \\
&\leqslant \frac{(3n+a+d)^{d-1}}{(d-1)!} (3n+a+2),
\end{aligned}$$

and, moreover, $(3n+2+a)/(3n+1+a) \leqslant 2$. Thus,

$$\begin{aligned}
&\left\| \frac{\delta^{|\alpha|}}{\alpha!} D^\alpha V(\zeta) x^{\alpha'} (1-\chi_R) P_{|\beta| \leqslant a+3n+1} \right\|^2 \\
&\quad \leqslant D_2^2 \frac{2^{3n+a+2} e^{\mu_d (3n+a+1)}}{(1-4\tau/\omega_0)^{3n+|\alpha|+a+d/2}} (3n+a+d)^{d-1} \frac{(3n+|\alpha|+[\![d/2]\!]+a)!}{(3n+a)!}.
\end{aligned}$$

Now define $C_8 := D_2 e^{-\mu_d/2} (1-4\tau/\omega_0)^{1-d/4}$ and $C_9 := [2e^{\mu_d}/(1-4\tau/\omega_0)]^{1/2}$. □

Proof of Theorem 3: Recall that we assume that $\delta \leqslant 1$. We already know, from Theorem 2, that $b \geqslant 1$. From the proof of Lemma 3, we also know that $\|x_i A_e\| \leqslant \gamma$. Now, from (49), it follows that

$$\begin{aligned}
\|A_e^{-1}\xi_N(x)\| \leqslant & \hbar^{N/2} \sum_{n=0}^{N-1} \sum_{|\alpha|=N-n+2} \left\| \frac{D^\alpha V(\zeta_n)}{\alpha!}(1-\chi_R(x))x^\alpha A_e \psi_n(x) \right\| \\
& + \hbar^{N/2} \sum_{n=0}^{N-1} \sum_{|\alpha|=N-n+2} \left\| \frac{D^\alpha V(\zeta_n)}{\alpha!}\chi_R(x)x^\alpha A_e \psi_n(x) \right\| \\
& + \sum_{n=N}^{2N-2} \hbar^{n/2} \sum_{l=n-N+1}^{N-1} \|\mathcal{E}_l A_e \psi_{n-l}(x)\| \\
\leqslant & \hbar^{N/2} \sum_{n=0}^{N-1} \sum_{|\alpha|=N-n+2} \left\| \frac{D^\alpha V(\zeta_n)}{\alpha!}(1-\chi_R(x))x^{\alpha'} P_{|\beta|\leqslant 3n+a+1} \right\| \|x_i A_e\| \|\psi_n(x)\| \\
& + \hbar^{N/2} \sum_{n=0}^{N-1} \sum_{|\alpha|=N-n+2} \left\| \frac{D^\alpha V(\zeta_n)}{\alpha!}\chi_R(x)x^{\alpha'} P_{|\beta|\leqslant 3n+a+1} \right\| \|x_i A_e\| \|\psi_n(x)\| \\
& + \sum_{n=N}^{2N-2} \hbar^{n/2} \sum_{l=n-N+1}^{N-1} |\mathcal{E}_l| \|\psi_{n-l}(x)\|, \qquad (53)
\end{aligned}$$

where we split x^α into $x^{\alpha'}x_i$, which is possible for some coordinate x_i because $|\alpha| \geqslant 2$. Then $|\alpha'| = |\alpha| - 1$. Let us estimate each term on the right hand side of (53) individually. Applying Lemma 5 and the estimates for $\|x_\alpha A_e\|$ and $\|\psi_n\|$, we obtain

$$\begin{aligned}
\text{first term} \leqslant & \hbar^{N/2} \sum_{n=0}^{N-1} \sum_{|\alpha|=N+2-n} \delta^{|\alpha|} C_8 C_9^{(3n+a+2)/2} \left(1-\frac{4\tau}{\omega_0}\right)^{-|\alpha|/2} (3n+a+d)^{(d-1)/2} \\
& \times \left[\frac{(3n+|\alpha|+[\![d/2]\!]+a)!}{(3n+a)!}\right]^{1/2} \gamma \kappa^{3n} b^{n+w} [(1+a+n)!]^{1/2} \\
\leqslant & C_8 \gamma \hbar^{N/2} b^{N+w} \delta^{-(N+2)} C_9^{(3N+a+d+1)/2} \left(1-\frac{4\tau}{\omega_0}\right)^{-(N+2)/2} (3N+a+d-3)^{(d-1)/2} \\
& \times \sum_{n=0}^{N-1} \kappa^{3n} \left[\frac{(2n+N+[\![d/2]\!]+a+2)!(n+a+1)!}{(3n+a)!}\right]^{1/2} \sum_{|\alpha|=N+2-n} 1.
\end{aligned}$$

From the proof of Lemma 2, we know that $\Sigma_{|\alpha|=N+2-n} 1 \leqslant [(d-1)!]^{-1}(N+d+1)^{d-1}$. Let us define $A_1 := \gamma \delta^{-2} b^w C_8 C_9^{(a+d+1)/2} [(d-1)!(1-4\tau/\omega_0)]^{-1}$ and $B_1 := \delta^{-1} C_9^{3/2} b (1-4\tau/\omega_0)^{-1}$. Then

$$\begin{aligned}
\text{first term} \leqslant & A_1 B_1^N \hbar^{N/2} (N+d+1)^{d-1} (3N+a+d-3)^{(d-1)/2} \\
& \times \sum_{n=0}^{N-1} \kappa^{3n} \left[\frac{(2n+N+[\![d/2]\!]+a+2)!(n+a+1)!}{(3n+a)!}\right]^{1/2}.
\end{aligned}$$

Note that $(2n+N+[\![d/2]\!]+a+2)! \leqslant (2n+N+a+2)!(2n+N+[\![d/2]\!]+a+2)^{[\![d/2]\!]}$. Then

$$\begin{aligned}\text{first term} &\leqslant A_1 B_1^N \hbar^{N/2}(3N+a+d-3)^{(d-1)/2}(N+d+1)^{d-1}(3N+a+[\![d/2]\!])^{[\![d/2]\!]/2}\\ &\times[(2+a+N)!]^{1/2}\sum_{n=0}^{N-1}\kappa^{3n}\left[\frac{(2+a+N+2n)!(1+a+n)!}{(a+3n)!(2+a+N)!}\right]^{1/2}\\ &\leqslant A_1 B_1^N \kappa^{3N}\hbar^{N/2}(3N+a+d-3)^{(d-1)/2}(N+d+1)^{d-1}(3N+a+[\![d/2]\!])^{[\![d/2]\!]/2}\\ &\times[(2+a+N)!]^{1/2}\max_{1\leqslant l\leqslant N}\left[\frac{(3N-3l+a+1)(3N-3l+a+2)}{(N-l+a+2)}\right]^{1/2}\\ &\times\sum_{l=1}^{N}\kappa^{-5l/2}\left[\frac{(2+a+3N+2l)!(2+a+N-l)!}{(2+a+3N-3l)!(2+a+N)!}\right]^{1/2}.\end{aligned}$$

The change of index $n\to l=N-n$ was performed in the last sumation above. Now we need to apply Lemma 4, statement 2, to obtain

$$\begin{aligned}\text{first term} &\leqslant C_5 A_1 B_1^N \kappa^{3N}\hbar^{N/2}(3N+a+d-3)^{(d-1)/2}(N+d+1)^{d-1}(3N+a+[\![d/2]\!])^{[\![d/2]\!]/2}\\ &\times[3(3N+a+2)]^{1/2}[(2+a+N)!]^{1/2}.\end{aligned}$$

Finally, define N_1 as the smallest integer such that the inequality

$$(3N+a+[\![d/2]\!])^{[\![d/2]\!]/2}(3N+a+d-3)^{(d-1)/2}(N+d+1)^{d-1}[3(3N+a+2)]^{1/2}\leqslant\kappa^N$$

holds for all $N\geqslant N_1$. Then, whenever $N\geqslant N_1$,

$$\text{first term}\leqslant C_5 A_1 B_1^N \kappa^{4N}\hbar^{N/2}[(2+a+N)!]^{1/2}.$$

Statement 2 of Lemma 2 yields

$$\frac{\delta^{|\alpha|}}{\alpha!}|D^\alpha V(\zeta(x))|\leqslant C_0\exp\left(\frac{2\tau d}{\omega_0^2}R^2\right)=C_0\exp\left[\frac{2\tau d}{\omega_0^2}(2a+d-4)\right]\exp\left(\frac{12\tau d}{\omega_0^2}N\right)$$

on the support of $\chi_R(x)$. Thus, the second term of (53) satisfies

$$\begin{aligned}\text{second term} &\leqslant \hbar^{N/2}\gamma\delta^{-(N+2)}C_0\exp\left[\frac{2\tau d}{\omega_0^2}(2a+d-4)\right]\exp\left(\frac{12\tau d}{\omega_0^2}N\right)\\ &\times\sum_{n=0}^{N-1}\sum_{|\alpha|=N-n+2}\|x^{\alpha'}P_{|\beta|\leqslant 3n+a+1}\|\|\psi_n(x)\|\\ &\leqslant \hbar^{N/2}\gamma\delta^{-(N+2)}C_0\exp\left[\frac{2\tau d}{\omega_0^2}(2a+d-4)\right]\exp\left(\frac{12\tau d}{\omega_0^2}N\right)\\ &\times\sum_{n=0}^{N-1}\sum_{|\alpha|=N-n+2}\kappa^{(|\alpha|-1)/2}\left[\frac{(a+|\alpha|+3n)!}{(1+a+3n)!}\right]^{1/2}\kappa^{3n}b^{n+w}[(1+a+n)!]^{1/2}\\ &\leqslant \hbar^{N/2}\gamma\delta^{-(N+2)}C_0\exp\left[\frac{2\tau d}{\omega_0^2}(2a+d-4)\right]\exp\left(\frac{12\tau d}{\omega_0^2}N\right)b^{N+w}\kappa^{(N+1)/2}\\ &\times\sum_{n=0}^{N-1}\kappa^{5n/2}\left[\frac{(2+a+N+2n)!(1+a+n)!}{(1+a+3n)!}\right]^{1/2}\sum_{|\alpha|=N-n+2}1.\end{aligned}$$

Define $A_2:=\gamma\delta^{-2}\kappa^{1/2}C_0 b^w\exp[2\pi d(2a+d-4)][(d-1)!]^{-1}$ and $B_2:=\delta^{-1}\kappa^{1/2}b\exp(12\tau d/\omega_0^2)$. Then, following the argument we have used to estimate the first term, we obtain

$$\text{second term} \leqslant A_2 B_2^N \hbar^{N/2} (N+d+1)^{d-1} \sum_{n=0}^{N-1} \kappa^{3n} \left[\frac{(2+a+N+2n)!(1+a+n)!}{(1+a+3n)!} \right]^{1/2}$$

$$\leqslant A_2 B_2^N \kappa^{3N} \hbar^{N/2} (N+d+1)^{d-1} [(2+a+N)!]^{1/2}$$

$$\times \max_{1 \leqslant l \leqslant N} \left[\frac{2+a+3N-3l}{2+a+N-l} \right]^{1/2} \sum_{l=1}^{N} \kappa^{-5l/2} \left[\frac{(2+a+3N+2l)!(2+a+N-l)!}{(2+a+3N-3l)!(2+a+N)!} \right]^{1/2}$$

$$\leqslant 3^{1/2} C_5 A_2 B_2^N \kappa^{3N} \hbar^{N/2} (N+d+1)^{d-1} [(2+a+N)!]^{1/2}.$$

Now define N_2 such that $(N+d+1)^{d-1} \leqslant \kappa^N$ for every $N \geqslant N_2$. Then

$$\text{second term} \leqslant 3^{1/2} C_5 A_2 B_2^N \kappa^{4N} \hbar^{N/2} [(2+a+N)!]^{1/2}.$$

For the third term of (53), we only need to use the first statement of Lemma 4. The result is

$$\text{third term} \leqslant \sum_{n=N}^{2N} C_4 \kappa^{3n} b^{n+2w} \hbar^{N/2} [(1+a+n)!]^{1/2}.$$

To complete the proof define $N_0 = \max\{N_1, N_2\}$, $A = \max\{C_5 A_1, 3^{1/2} C_5 A_2, C_4 b^{2w}\}$ and $B = \max\{\kappa^4 B_1, \kappa^3 B_2, \kappa^3 b\}$. □

V. OPTIMAL TRUNCATION

In this section we shall prove that exact eigenvalues and eigenfunctions of $H(\hbar) := -\frac{1}{2}\Delta_x + V(\hbar, x)$ can be approximated by truncated R-S series, up to an exponentially small error. To that end, we shall use our estimate of the norm $A_e^{-1} \xi_N(x)$. We shall also need a couple of results. The first is a lower bound for the distance between perturbed eigenvalues that degenerate at $\hbar = 0$. The second is a ''reverse'' definition of asymptoticness.

Let us consider two distinct eigenvalues of $H(\hbar)$, $E(\hbar)$ and $E'(\hbar)$, which converge to the same eigenvalue of H_0 as $\hbar$ goes to 0. Also, let us assume that their asymptotic series have only a finite number of common R-S coefficients. That is,

$$E(\hbar) \sim e + \mathcal{E}_1 \hbar^{1/2} + \ldots + \mathcal{E}_{M-1} \hbar^{(M-1)/2} + \mathcal{E}_M \hbar^{M/2} + \mathcal{E}_{M+1} \hbar^{(M+1)/2} + \ldots,$$

$$E'(\hbar) \sim e + \mathcal{E}_1 \hbar^{1/2} + \ldots + \mathcal{E}_{M-1} \hbar^{(M-1)/2} + \mathcal{E}'_M \hbar^{M/2} + \mathcal{E}'_{M+1} \hbar^{(M+1)/2} + \ldots,$$

with $\mathcal{E}_M \neq \mathcal{E}'_M$. Then,

$$E(\hbar) - E'(\hbar) \sim (\mathcal{E}_M - \mathcal{E}'_M) \hbar^{M/2} + (\mathcal{E}_{M+1} - \mathcal{E}'_{M+1}) \hbar^{(M+1)/2} + \ldots,$$

so we expect that the difference between these exact eigenvalues be bounded below by $O(\hbar^{M/2})$. Since the series above is asymptotic, there are $C_M > 0$ and $\hbar_a(M) > 0$ so that

$$|E(\hbar) - E'(\hbar) - (\mathcal{E}_M - \mathcal{E}'_M) \hbar^{M/2}| \leqslant C_M \hbar^{(M+1)/2},$$

whenever $\hbar \leqslant \hbar_a(M)$. Then

$$|E(\hbar) - E'(\hbar)| \geqslant |\mathcal{E}_M - \mathcal{E}'_M| \hbar^{M/2} - C_M \hbar^{(M+1)/2}.$$

Set $\hbar_b(M) = |\mathcal{E}_M - \mathcal{E}'_M| / 2C_M$. Then for $\hbar \leqslant \hbar_b(M)$,

$$C_M \hbar^{(M+1)/2} \leqslant \tfrac{1}{2} |\mathcal{E}_M - \mathcal{E}'_M| \hbar^{M/2}.$$

Thus for $\hbar \leqslant \hbar_1 := \min\{\hbar_a(M), \hbar_b(M)\}$ we have

$$|E(\hbar)-E'(\hbar)|\geqslant \tfrac{1}{2}|\mathcal{E}_M-\mathcal{E}'_M|\hbar^{M/2}.$$

Let us denote $\mathcal{E}_M-\mathcal{E}'_M$ as $\Delta\mathcal{E}_M$. Therefore, so far we know the following.

Lemma 6: Let $E(\hbar)$ and $E'(\hbar)$ be distinct eigenvalues of $H(\hbar)$, which degenerate at $\hbar=0$. Then either

(1) $|E(\hbar)-E'(\hbar)|\leqslant O(\hbar^{N/2})$ for all non-negative integers N, or

(2) there exists M and $\hbar_1=\hbar_1(M)$ such that

$$|E(\hbar)-E'(\hbar)|\geqslant \tfrac{1}{2}|\Delta\mathcal{E}_M|\hbar^{M/2}$$

whenever $\hbar\leqslant\hbar_1$.

Remark: It is clear that Lemma 6 is also valid when several eigenvalues of $H(\hbar)$ converge to the same eigenvalue of H_0. As a shorthand, we will say that $E(\hbar)$ is *quasi-degenerate* if the condition 1 in the lemma above occurs.

Lemma 7: Suppose $\Sigma_{n=0}f_n\beta^n$ is asymptotic to $f(\beta)$ in the sense that given $N\geqslant N_0\geqslant M$, there exists C_N and $\beta(N)$ such that for all $\beta\leqslant\beta(N)$

$$\left| f(\beta)-\sum_{n=0}^{N-1} f_n\beta^n \right| < C_N\beta^N.$$

Then given $\epsilon>0$, there exists $\beta(\epsilon)>0$, such that for each $\beta\leqslant\beta(\epsilon)$ there is an $N(\beta)\geqslant N_0$ (maybe equal to ∞), so that

$$\left| f(\beta)-\sum_{n=0}^{N-1} f_n\beta^n \right| \leqslant \epsilon\beta^M \tag{54}$$

whenever $N_0\leqslant N<N(\beta)$.

Proof: Fix $\epsilon>0$. Define $\beta_1(N_0)=(\epsilon C_{N_0}^{-1})^{1/(N_0-M)}$. Then for $N>N_0$, recursively choose positive numbers $\beta_1(N)$ that satisfy

$$\beta_1(N)<\min\{(\epsilon C_N^{-1})^{1/(N-M)},\beta_1(N-1)\}.$$

Then

$$\left| f(\beta)-\sum_{n=0}^{N-1} f_n\beta^n \right| \leqslant (C_N\beta^{N-M})\beta^M \leqslant (C_N\beta_1(N)^{N-M})\beta^M \leqslant \epsilon\beta^M$$

whenever $\beta<\beta_1(N)$.

Define $\beta(\epsilon)=\beta_1(N_0)$, and define

$$N(\beta)=\begin{cases} N+1 & \text{if} \quad \beta_1(N+1)<\beta\leqslant\beta_1(N), \\ \infty & \text{if} \quad \beta<\beta_1(N) \quad \text{for all } N. \end{cases}$$

Then (54) holds whenever $N_0\leqslant N\leqslant N(\beta)$. □

Let $\{e_I\}_{I=0}^{\infty}$ be an arrangement in increasing order of the eigenvalues of H_0, counting multiplicities. Theorem 1.1 of Ref. 16 states that given a non-negative integer J, we can choose $\hbar_0$ so that for each $\hbar\leqslant\hbar_0$ there are at least $J+K$ eigenvalues of $H(\hbar)$, counting multiplicities. Furthermore, each one of them converges to one of the first $J+K$ eigenvalues of H_0. In the following proposition, we study the behavior of truncations of the R-S series of $E^J(\hbar)$, the Jth eigenvalue of $H(\hbar)$. We set K so that $e_{J+K}>e_J$.

Proposition 3: Let $E(\hbar)=E^J(\hbar)$ be a non-quasi-degenerate eigenvalue of $H(\hbar)$, which converges to $e=e_J$. Let $E_N(\hbar)$ be the associated R-S series, truncated at order N. Let N_0 be as defined in Theorem 3. Then there exists $\hbar_e>0$ and, for each $\hbar\leqslant\hbar_e$ there is an $N_e(\hbar)\geqslant N_0$ such that

$$|E_N(\hbar)-E(\hbar)|\leqslant\sum_{n=N}^{2N} AB^n\hbar^{n/2}[(2+a+n)!]^{1/2}$$

for all $N_0\leqslant N\leqslant N_e(\hbar)$.

Proof: We shall consider the case where there exists another eigenvalue of $H(\hbar)$ that converges to e. The proof can be easily simplified to accomodate the opposite situation, which is studied in Proposition 3 of Ref. 19. So said, let $E'(\hbar)$ be another eigenvalue of $H(\hbar)$ converging to e as $\hbar\searrow 0$. By Lemma 6, there are M and $\hbar_1$ so that $|E(\hbar)-E'(\hbar)|\geqslant\frac{1}{2}|\Delta\mathcal{E}_M|\hbar^{M/2}$ for $\hbar\leqslant\hbar_1$. Without loss we may assume that $N_0\geqslant M$. To simplify the proof, we furthermore assume that no other eigenvalue of $H(\hbar)$ converges to e. Let G_e be the eigenspace associated to e.

Now set $N_1(\hbar)$ as the largest $N\geqslant N_0$ such that

$$\sum_{n=N_1(\hbar)}^{2N_1(\hbar)} AB^n\hbar^{(n-M)/2}[(2+a+n)!]^{1/2}\leqslant\frac{1}{4}|\Delta\mathcal{E}_M|.$$

Then, from Theorem 3 it follows that

$$\|[H(\hbar)-E_N(\hbar)]A_e\Psi_N(\hbar;x)\|\leqslant\sum_{n=N}^{2N} AB^n\hbar^{n/2}[(2+a+n)!]^{1/2}\leqslant\frac{1}{4}|\Delta\mathcal{E}_M|\hbar^{M/2}$$

whenever $\hbar\leqslant\hbar_0:=\min\{1,|\Delta\mathcal{E}_M|^{-2/M}\}$ and $N_0\leqslant N\leqslant N_1(\hbar)$. On the other hand, note that $\Psi_N=\psi_0+\varphi_N$, where φ_N is orthogonal to $\psi_0\in G_e$ because of the normalization we chose for the correction terms ψ_n. Since $A_e\psi_0=\psi_0$, we conclude that $\|A_k\Psi_N(\hbar;x)\|\geqslant 1$. So Theorem 3 implies that

$$\|[H(\hbar)-E_N(\hbar)]A_e\Psi_N(\hbar;x)\|\leqslant\sum_{n=N}^{2N} AB^n\hbar^{n/2}[(2+a+n)!]^{1/2}\|A_e\Psi_N(\hbar;x)\|. \tag{55}$$

We may assume that $E_N(\hbar)\notin\sigma(H(\hbar))$, so $[H(\hbar)-E_N(\hbar)]$ is invertible. It follows that

$$\left\{\sum_{n=N}^{2N} AB^n\hbar^{n/2}[(2+a+n)!]^{1/2}\right\}^{-1}\leqslant\|[H(\hbar)-E_N(\hbar)]^{-1}\|.$$

Because H is self-adjoint, $\|(H-E)^{-1}\|=\mathrm{dist}\{E,\sigma(H)\}^{-1}$ by the spectral theorem. Thus,

$$\mathrm{dist}\{E_N(\hbar),\sigma(H)\}\leqslant\sum_{n=N}^{2N} AB^n\hbar^{n/2}[(2+a+n)!]^{1/2}\leqslant\frac{1}{4}|\Delta\mathcal{E}_M|\hbar^{M/2} \tag{56}$$

for $\hbar\leqslant\hbar_0$ and $N_0\leqslant N\leqslant N_1(\hbar)$. Let Δ be the minimum nonzero distance between the first $J+K$ eigenvalues of H_0. Since $E_I(\hbar)\to e_I$, we can set $\hbar_\Delta>0$ so that for $0\leqslant I\leqslant J+K$, $|E_I(\hbar)-e_I|\leqslant\frac{1}{4}\Delta$ if $\hbar\leqslant\hbar_\Delta$. That implies that, for $\hbar\leqslant\hbar_\Delta$ and $E''(\hbar)\in\sigma(H(\hbar))\backslash\{E(\hbar),E'(\hbar)\}$,

$$|E^{\#}(\hbar)-E''(\hbar)|\geqslant\tfrac{1}{2}\Delta$$

where $E^{\#}$ denotes either E or E'. Now set $\hbar_2=(\Delta/|\Delta\mathcal{E}_M|)^{2/M}$. Then for $\hbar\leqslant\hbar_2$ we have $\frac{1}{2}\Delta\geqslant\frac{1}{2}|\Delta\mathcal{E}_M|\hbar^{M/2}$. As a consequence,

$$|E(\hbar)-E''(\hbar)|\geqslant\tfrac{1}{2}|\Delta\mathcal{E}_M|\hbar^{M/2},$$

$$|E(\hbar)-E'(\hbar)|\geqslant \tfrac{1}{2}|\Delta\mathcal{E}_M|\hbar^{M/2},$$

which ultimately implies that

$$\operatorname{dist}\{E(\hbar),\sigma(H)\backslash E(\hbar)\}\geqslant \tfrac{1}{2}|\Delta\mathcal{E}_M|\hbar^{M/2} \tag{57}$$

whenever $\hbar\leqslant\min\{\hbar_0,\hbar_1,\hbar_\Delta,\hbar_2\}$. Since $E_N(\hbar)$ is asymptotic to $E(\hbar)$, we may apply Lemma 7. Then there is $\hbar_3>0$ such that for each $\hbar\leqslant\hbar_3$ we can fix $N_2(\hbar)\geqslant N_0$ so that

$$|E(\hbar)-E_N(\hbar)|\leqslant \tfrac{1}{4}|\Delta\mathcal{E}_M|\hbar^{M/2} \tag{58}$$

for $N_0\leqslant N\leqslant N_2(\hbar)$.

Now (57), (58) and the second inequality of (56) imply that

$$\operatorname{dist}\{E_N(\hbar),\sigma(H)\}=|E(\hbar)-E_N(\hbar)|$$

whenever $\hbar\leqslant\min\{\hbar_0,\hbar_1,\hbar_2,\hbar_3,\hbar_\Delta\}=:\hbar_e$ and $N_0\leqslant N\leqslant\min\{N_1(\hbar),N_2(\hbar)\}=:N_e(\hbar)$. □

Remark: The number $N_e(\hbar)$ defined in the proof must indeed be equal to $N_1(\hbar)$. Assume that $N_e(\hbar)<N_1(\hbar)$, and consider $N_e(\hbar)\leqslant N\leqslant N_1(\hbar)$. Then $E_N(\hbar)$ has to be near some eigenvalue $E''(\hbar)$ different to $E(\hbar)$. By reducing $\hbar$, $E_N(\hbar)$ approaches to $E(\hbar)$ while keeping itself close to $E''(\hbar)$, which leads to a contradiction.

Remark: $N_e(\hbar)$ grows like $g/\hbar$, as one can see from the proof of Theorem 4 below.

The requirement of $E(\hbar)$ to be non-quasi-degenerate can be relaxed, and we formulate the following weaker version of Proposition 3. The proof is a straighforward variation of it.

Proposition 4: Let $E(\hbar)=E^J(\hbar)$ be an eigenvalue of $H(\hbar)$, which converges to $e=e_J$. Let $E_N(\hbar)$ be the associated R-S series, truncated at order N. Also let $E^{\#}(\hbar)$ be any eigenvalue of $H(\hbar)$ that satisfies the condition 1 of Lemma 6 [including $E(\hbar)$ itself.] Then there exists $\hbar_e>0$ so that for each $\hbar\leqslant\hbar_e$ there is an $N_e(\hbar)\geqslant N_0$ such that

$$|E_N(\hbar)-E^{\#}(\hbar)|\leqslant\sum_{n=N}^{2N}AB^n\hbar^{n/2}[(2+a+n)!]^{1/2}$$

for all $\hbar\leqslant\hbar_e$, $N_0\leqslant N\leqslant N_e(\hbar)$, and $E^{\#}(\hbar)$.

In the following theorem we assume the hypotheses of Proposition 3. An analogous result follows from the hypotheses of Proposition 4.

Theorem 4: *Assume the hypotheses of Proposition 3. Then for each $0<g<B^{-2}$, there is $\hbar_g>0$ such that for each $\hbar\leqslant\hbar_g$ there exists $N(\hbar)$ such that*

$$|E_{N(\hbar)}(\hbar)-E(\hbar)|\leqslant\Lambda\exp\left(-\frac{\Gamma}{\hbar}\right)$$

for some $\Lambda>0$ and $\Gamma>0$ independent of $\hbar$.

Proof: Fix $0<g<B^{-2}$. Then $0<B^2g<1$; consequently there is $\Omega>0$ such that $B^2g=\exp(-\Omega)$. Consider the function

$$f(\hbar):=Ag\exp\left(-\frac{\Omega(1+a)}{4}\right)\hbar^{-(4+a+M)/2}\exp\left(-\frac{\Omega g}{4\hbar}\right).$$

It is clear that $f(\hbar)>0$ on $(0,\infty)$ has a single maximum, and $f(\hbar)\to0$ as $\hbar\to0$ or $\hbar\to\infty$. Now set

$$\hbar_4=\sup\{\hbar:f(\hbar)\ \text{ is increasing and }\ f(\hbar)\leqslant\tfrac{1}{4}|\Delta\mathcal{E}_M|\}.$$

Then set

$$\hat{\hbar}_g = \sup\left\{\hbar : \hbar \leqslant \min\{\hbar_e, \hbar_4\} \text{ and } \left[\!\left[\frac{g}{\hbar}\right]\!\right] \geqslant 2 + a + 2N_0\right\}.$$

Now for $\hbar \leqslant \hat{\hbar}_g$ define $N(\hbar)$ by $2 + a + 2N(\hbar) = [\![g/\hbar]\!]$. So defined, $N(\hbar) \geqslant N_0$. On the other hand, since we can assume $B \geqslant 1$ and $2 + a + n \leqslant g/\hbar$ for $N(\hbar) \leqslant n \leqslant 2N(\hbar)$ we have

$$\begin{aligned}\sum_{n=N(\hbar)}^{2N(\hbar)} AB^n \hbar^{n/2}[(2+a+n)!]^{1/2} &\leqslant \sum_{n=N(\hbar)}^{2N(\hbar)} AB^n \hbar^{n/2}(2+a+n)^{(2+a+n)/2} \\ &\leqslant A\hbar^{-(2+a)/2} \sum_{n=N(\hbar)}^{2N(\hbar)} [B^2\hbar(2+a+n)]^{(2+a+n)/2} \\ &\leqslant A\hbar^{-(2+a)/2} \sum_{n=N(\hbar)}^{2N(\hbar)} (B^2 g)^{(2+a+n)/2}.\end{aligned}$$

Now use that $B^2 g = \exp(-\Omega) < 1$ and the fact that $x^n \geqslant x^{n+1}$ if $x \leqslant 1$ to obtain

$$\begin{aligned}\sum_{n=N(\hbar)}^{2N(\hbar)} AB^n \hbar^{n/2}[(2+a+n)!]^{1/2} &\leqslant A\hbar^{-(2+a)/2} \sum_{n=N(\hbar)}^{2N(\hbar)} \exp\left\{-\frac{\Omega}{2}[2+a+N(\hbar)]\right\} \\ &= A\hbar^{-(2+a)/2} e^{-(\Omega/4)(2+a)}[1+N(\hbar)]\exp\left\{-\frac{\Omega}{4}[2+a+2N(\hbar)]\right\} \\ &\leqslant A\hbar^{-(2+a)/2} e^{-(\Omega/4)(2+a)}[2+a+2N(\hbar)]\exp\left[-\frac{\Omega}{4}\left(\frac{g}{\hbar}-1\right)\right] \\ &\leqslant Age^{-(\Omega/4)(1+a)}\hbar^{-(4+a+M)/2}\exp\left(-\frac{\Omega g}{4\hbar}\right)\hbar^{M/2} \\ &\leqslant f(\hbar_4)\hbar^{M/2} \qquad (59) \\ &\leqslant \tfrac{1}{4}|\Delta\mathcal{E}_M|\hbar^{M/2}. \qquad (60)\end{aligned}$$

Thus, $N(\hbar) \leqslant N_e(\hbar)$. Therefore, Proposition 3 holds for $\hbar < \hat{\hbar}_g$, which along with (59) implies

$$|E_{N(\hbar)}(\hbar) - E(\hbar)| \leqslant Age^{-(\Omega/4)(1+a)}\hbar^{-(4+a)/2}\exp\left(-\frac{\Omega g}{4\hbar}\right),$$

for all $\hbar \leqslant \hat{\hbar}_g$. Finally, define

$$\hbar_g = \max\left\{\hbar \leqslant \hat{\hbar}_g : \hbar^{-(4+a)/2}\exp\left(-\frac{\omega g}{8\hbar}\right) \leqslant 1\right\}.$$

Then the assertion is true for all $\hbar \leqslant \hbar_g$ with $\Gamma := \Omega g/8$ and $\Lambda := Ag\exp(-\Omega(1+a)/4)$. □

*Proposition 5: Let $E(\hbar)$ be a non-quasi-degenerate eigenvalue of $H(\hbar)$, with eigenspace G_E. Let P_E be the (orthogonal) projector onto G_E. Let $\tilde{\Psi}_N(\hbar;x)$ be the N*th *truncation of the R-S series (6). Let $\hbar_e$ and $N_e(\hbar)$ be defined as in Proposition 3. Then for each $\hbar \leqslant \hbar_e$ and $N_0 \leqslant N \leqslant N_e(\hbar)$,*

$$\left\| \frac{\tilde{\Psi}_N(\hbar;x)}{\|\tilde{\Psi}_N(\hbar;x)\|} - \frac{P_E\tilde{\Psi}_N(\hbar;x)}{\|P_E\tilde{\Psi}_N(\hbar;x)\|} \right\| \leqslant 16|\Delta\mathcal{E}_M|^{-1}\sum_{n=N}^{2N} AB^n\hbar^{(n-M)/2}[(2+a+n)!]^{1/2}$$

for some $M \leqslant N_0$.

Proof: Notice that (55) means that

$$\|[H(\hbar)-E_N(\hbar)]\|\tilde{\Psi}_N(\hbar;x)\|^{-1}\tilde{\Psi}_N(\hbar;x)\| \leqslant \sum_{n=N}^{2N} AB^n\hbar^{n/2}[(2+a+n)!]^{1/2}.$$

On the other hand, we can write

$$\|\tilde{\Psi}_N(\hbar;x)\|^{-1}\tilde{\Psi}_N(\hbar;x) = w_N\|P_E\tilde{\Psi}_N(\hbar;x)\|^{-1}P_E\tilde{\Psi}_N(\hbar;x)+\Omega_N(\hbar;x),$$

where $\Omega_N(\hbar;x)$ is orthogonal to G_E, and $|w_N|^2+\|\Omega_N(\hbar;x)\|^2=1$. Since these functions are defined up to a global phase, we can assume that indeed $0<w_n\leqslant 1$. Then the normalization condition implies

$$\|\Omega_N(\hbar;x)\| \geqslant \|\Omega_N(\hbar;x)\|^2 = 1-|w_N|^2 = (1+w_N)(1-w_N) \geqslant 1-w_N.$$

So we have

$$\|\|\tilde{\Psi}_N(\hbar;x)\|^{-1}\tilde{\Psi}_N(\hbar;x)-\|P_E\tilde{\Psi}_N(\hbar;x)\|^{-1}P_E\tilde{\Psi}_N(\hbar;x)\| \leqslant 2\|\Omega_N(\hbar;x)\|. \tag{61}$$

Since

$$[H(\hbar)-E_N(\hbar)]\Omega_N(\hbar;x) = [H(\hbar)-E_N(\hbar)]\frac{\tilde{\Psi}_N(\hbar;x)}{\|\tilde{\Psi}_N(\hbar;x)\|} - w_N[E(\hbar)-E_N(\hbar)]\frac{P_E\tilde{\Psi}_N(\hbar;x)}{\|P_E\tilde{\Psi}_N(\hbar;x)\|},$$

it follows from Proposition 3 that

$$\|[H(\hbar)-E_N(\hbar)]\Omega_N(\hbar;x)\| \leqslant 2\sum_{n=N}^{2N} AB^n\hbar^{n/2}[(2+a+n)!]^{1/2} \tag{62}$$

for $\hbar\leqslant\hbar_e$ and $N_0\leqslant N\leqslant N_e(\hbar)$.

Recall that $E_N(\hbar)\notin\sigma(H(\hbar))$. From the fact that $[H(\hbar)-E_N(\hbar)]\Omega_N(\hbar;x)$ is orthogonal to G_E, it follows that

$$\|\Omega_N(\hbar;x)\| \leqslant \|[H(\hbar)-E_N(\hbar)]_\perp^{-1}\|\|[H(\hbar)-E_N(\hbar)]\Omega_N(\hbar;x)\|, \tag{63}$$

where $[H(\hbar)-E_N(\hbar)]_\perp$ is the restriction of $[H(\hbar)-E_N(\hbar)]$ to the subspace orthogonal to G_E. For simplicity, let us assume that there is only one distinct eigenvalue $E'(\hbar)$ that converges to the same eigenvalue of H_0 as $E(\hbar)$. Since

$$\mathrm{dist}\{E_N(\hbar),\sigma(H)\backslash E(\hbar)\} \geqslant \tfrac{1}{2}\mathrm{dist}\{E(\hbar),\sigma(H)\backslash E(\hbar)\},$$

the spectral theorem along with (57) implies that

$$\|[H(\hbar)-E_N(\hbar)]_\perp^{-1}\| \leqslant 4|\Delta\mathcal{E}_M|^{-1}\hbar^{-M/2}. \tag{64}$$

The assertion now follows from (61)–(64). □

Remark: The assumption of non-quasi-degeneracy of $E(\hbar)$ is critical, as one can see in the argument that leads to (64).

The last result of this section concerns the optimal truncation for the eigenfunctions of $H(\hbar)$. It follows from Proposition 5 in the same way as Theorem 4 does from Proposition 3:

Theorem 5: *Fix* $0\leqslant g\leqslant B^{-2}$. *Let* Λ *and* Γ *be defined as in Theorem 4. Then there exists* $\hbar'_g>0$ *such that for each* $\hbar\leqslant\hbar'_g$ *there is* $N(\hbar)$ *so that*

$$\left\| \frac{\tilde{\Psi}_{N(\hbar)}(\hbar;x)}{\|\tilde{\Psi}_{N(\hbar)}(\hbar;x)\|} - \frac{P_E\tilde{\Psi}_{N(\hbar)}(\hbar;x)}{\|P_E\tilde{\Psi}_{N(\hbar)}(\hbar;x)\|} \right\| \leqslant 16|\Delta\mathcal{E}_M|\Lambda \exp\left(-\frac{\Gamma}{\hbar}\right).$$

Proof: Define

$$f'(\hbar) := Ag \exp\left(-\frac{\Omega(1+a)}{4}\right)\hbar^{-(4+a+2M)/2}\exp\left(-\frac{\Omega g}{4\hbar}\right),$$

$$\hbar_4' := \sup\{\hbar : f'(\hbar) \text{ is increasing and } f(\hbar) \leqslant \tfrac{1}{4}|\Delta\mathcal{E}_M|\},$$

$$\hat{\hbar}_g' := \sup\left\{\hbar : \hbar \leqslant \min\{\hbar_e, \hbar_4'\} \text{ and } \left[\!\left[\frac{g}{\hbar}\right]\!\right] \geqslant 2+a+2N_0\right\}.$$

$$\hbar_g' := \max\left\{\hbar \leqslant \hat{\hbar}_g' : \hbar^{-(4+a+M)/2}\exp\left(-\frac{\omega g}{8\hbar}\right) \leqslant 1\right\}.$$

Now proceed as in the proof of Theorem 4. □

APPENDIX: COMPUTATION OF ξ_N

Here we simplify the formula (48) by using the identity (10). This calculation is formally identical the one done in Ref. 19, with some notational change. We reproduce it here for a sake of convenience:

$$\begin{aligned}\xi_N &= \left[H_e + A_eWA_e - \sum_{j=1}^{N-1}\hbar^{j/2}\mathcal{E}_jA_e^2\right]\sum_{m=0}^{N-1}\hbar^{m/2}\psi_m \\ &= \sum_{m=0}^{N-1}\hbar^{m/2}H_e\psi_m + \sum_{m=0}^{N-1}\hbar^{m/2}A_eWA_e\psi_m - \sum_{j=1}^{N-1}\sum_{m=0}^{N-1}\hbar^{(j+m)/2}\mathcal{E}_jA_e^2\psi_m.\end{aligned}$$

We use $A_eWA_e = \Sigma_{j=3}^{N+2}\hbar^{(j-2)/2}T^{(j)} + A_eW^{[N+2]}A_e$ and change the index by $j \to j-2$. Using $H_e\psi_0 = 0$, we then obtain

$$\begin{aligned}\xi_N &= \sum_{m=1}^{N-1}\hbar^{m/2}H_e\psi_m + \sum_{m=0}^{N-1}\sum_{j=1}^{N}\hbar^{(m+j)/2}T^{(j+2)}\psi_m + \sum_{m=0}^{N-1}\hbar^{m/2}A_eW^{[N+2]}A_e\psi_m \\ &\quad - \sum_{m=0}^{N-1}\sum_{j=1}^{N-1}\hbar^{(j+m)/2}\mathcal{E}_jA_e^2\psi_m = \sum_{n=1}^{N-1}\hbar^{n/2}H_e\psi_n + \sum_{n=1}^{N-1}\hbar^{n/2}\sum_{j=1}^{n}T^{(j+2)}\psi_{n-j} \\ &\quad + \sum_{n=N}^{2N-1}\hbar^{n/2}\sum_{j=n-N+1}^{N}T^{(j+2)}\psi_{n-j} + \sum_{m=0}^{N-1}\hbar^{m/2}A_eW^{[N+2]}A_e\psi_m - \sum_{n=1}^{N-1}\hbar^{n/2}\sum_{j=1}^{n}\mathcal{E}_jA_e^2\psi_{n-j} \\ &\quad - \sum_{n=N}^{2N-2}\hbar^{n/2}\sum_{j=n-N+1}^{N-1}\mathcal{E}_jA_e^2\psi_{n-j}.\end{aligned}$$

The first, second and fifth terms of last equation cancel because of (10). In the third term define $m = n-j$ and then $p = n-N$. This yields

$$
\begin{aligned}
\xi_N &= \sum_{n=N}^{2N-1} \hbar^{n/2} \sum_{m=n-N}^{N-1} T^{(n-m+2)}\psi_m + \sum_{m=0}^{N-1} \hbar^{m/2} A_e W^{[N+2]} A_e \psi_m - \sum_{n=N}^{2N-2} \hbar^{n/2} \sum_{j=n-N+1}^{N-1} \mathcal{E}_j A_e^2 \psi_{n-j} \\
&= \sum_{p=0}^{N-1} \sum_{m=p}^{N-1} \hbar^{(p+N)/2} T^{(p+N-m+2)}\psi_m + \sum_{m=0}^{N-1} \hbar^{m/2} A_e W^{[N+2]} A_e \psi_m \\
&\quad - \sum_{n=N}^{2N-2} \hbar^{n/2} \sum_{j=n-N+1}^{N-1} \mathcal{E}_j A_e^2 \psi_{n-j} \\
&= \sum_{m=0}^{N-1} \hbar^{m/2} \sum_{p=0}^{m} \hbar^{(p+N-m)/2} T^{(p+N-m+2)}\psi_m \\
&\quad + \sum_{m=0}^{N-1} \hbar^{m/2} A_e W^{[N+2]} A_e \psi_m - \sum_{n=N}^{2N-2} \hbar^{n/2} \sum_{j=n-N+1}^{N-1} \mathcal{E}_j A_e^2 \psi_{n-j} \\
&= \sum_{m=0}^{N-1} \hbar^{m/2} \left[\sum_{i=2}^{m+2} \hbar^{(i+N-m-2)/2} T^{(i+N-m)} + A_e W^{[N+2]} A_e \right] \psi_m - \sum_{n=N}^{2N-2} \hbar^{n/2} \sum_{j=n-N+1}^{N-1} \mathcal{E}_j A_e^2 \psi_{n-j}.
\end{aligned}
$$

Finally, note that $\hbar^{(j-2/2)} T^{(j)} + A_e W^{[j+1]} A_e = A_e W^{[j]} A_e$. Therefore, it follows that

$$
\xi_N = \sum_{m=0}^{N-1} \hbar^{m/2} A_e W^{[N-m+1]} A_e \psi_m - \sum_{n=N}^{2N-2} \hbar^{n/2} \sum_{j=n-N+1}^{N-1} \mathcal{E}_j A_e^2 \psi_{m-j}.

Dynamical symmetry breaking and the Nambu–Goldstone theorem in the Gaussian wave functional approximation

(Received 27 January 2003; accepted 17 March 2003)

We analyze the group-theoretical ramifications of the Nambu–Goldstone (NG) theorem in the self-consistent relativistic variational Gaussian wave functional approximation to spinless field theories. In an illustrative example we show how the Nambu–Goldstone theorem would work in the O(N) symmetric ϕ^4 scalar field theory, if the residual symmetry of the vacuum were lesser than O($N-1$), e.g., if the vacuum were O($N-2$), or O($N-3$), . . . symmetric. (This does not imply that any of the ''lesser'' vacua is actually the absolute energy minimum: stability analysis has not been done.) The requisite number of NG bosons would be ($2N-3$), or ($3N-6$), . . . , respectively, which may exceed N, the number of elementary fields in the Lagrangian. We show how the requisite new NG bosons would appear even in channels that do not carry the same quantum numbers as one of N ''elementary particles'' [scalar field quanta, or Castillejo–Dalitz–Dyson (CDD) poles] in the Lagrangian, i.e., in those ''flavor'' channels that have no CDD poles. The corresponding Nambu–Goldstone bosons are composites (bound states) of pairs of massive elementary (CDD) scalar fields excitations. As a nontrivial example of this method we apply it to the physically more interesting 't Hooft σ model (an extended $N_f=2$ bosonic linear σ model with four scalar and four pseudoscalar fields), with spontaneously and explicitly broken chiral $O(4)\times O(2)\simeq SU_R(2)\times SU_L(2)\times U_A(1)$ symmetry. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1576907]

I. INTRODUCTION

The proof of the Nambu–Goldstone (NG) theorem[1–5] in the Gaussian wave functional approximation[6–13] used to be an open problem for over 30 years, see Refs. 14–17. The first proof was given in the O(2) symmetric ϕ^4 theory,[17] and then straightforwardly extended to O(4) in Ref. 18; the crucial assumption was that the ground state be O($N-1$) symmetric, i.e., that only one (scalar) field develops a vacuum expectation value (VEV). [That assumption is justified when the remaining $N-1$ fields are pseudoscalars, as in the Gell-Mann–Levy model, otherwise CP symmetry is (spontaneously) broken.] By the standard NG boson counting methods,[3,4] for every spontaneously broken symmetry Lie group generator there is one NG boson. As the Lie algebra O(N) has $N(N-1)/2$ generators, for a ground state (vacuum) with an O($N-1$) residual symmetry the number of NG bosons ought to be $N(N-1)/2-(N-1)(N-2)/2=N-1$. That is exactly the number of available fields in the Lagrangian. What happens when the residual symmetry in the ground state is ''smaller'' than O($N-1$) and there should be more than $N-1$ NG bosons?

In this paper we shall extend our proof of the NG theorem in the Gaussian approximation[17,18] to the O(N) symmetric ϕ^4 theory when the symmetry of the ground state is dynamically broken to some (proper) subgroup of O($N-1$), in this specific case to one of the following symmetries: $O(N-2)\times O(2)$, $O(N-3)\times O(3)$, . . . , $O(N/2)\times O(N/2)$ for N even, or $O((N-1)/2)\times O((N$

[a)]Present address: Nomura Research Institute, Shoken System 7-bu, 3-4-12-202 Higashi-Oi, Sinagawa-ku, Tokyo 140-0011, Japan.

$+1)/2$) for N odd. As we shall show, the residual symmetry pattern is dictated by the absolute minimum of the O(N) ϕ^4 model's ground state energy, which in turn depends on the dynamics (gap equation) in the Gaussian approximation, as well as the free parameters. Absolute minimization of the vacuum energy will not been done in this paper, only a search for the extremal and/or saddle points. In a different model or approximation, or for different values of the free parameters the residual symmetry might be different. In any case, with such an asymmetric ground state the number of NG bosons must exceed $N-1$, the largest number of ''elementary'' scalar fields available in the Lagrangian (at least one field must develop the vacuum expectation value and thus cannot create or destroy single NG bosons). Nevertheless the canonical number of massless spinless excitations appears in the spectrum.[4] Our proof should leave no doubt as to the composite nature of the NG bosons in the Gaussian approximation.

This paper falls into five sections and two Appendixes. First, in Sec. II we define the O(N) ϕ^4 model and the Gaussian approximation. In Sec. III we show exactly how the requisite number of massless NG (bosonic bound) states appear and that all the ''broken symmetry'' Nöther currents remain conserved, as the symmetry of the vacuum is reduced. NG bosons invariably appear in the Gaussian approximation to the O(N) ϕ^4 model in those channels that also contain CDD poles, so in Sec. IV we extend our proof to the 't Hooft ϕ^4 model which does not have this property. There we show how various bound NG states appear, or disappear as the symmetries of the ground state and/or the Lagrangian change. Finally, in Sec. V we draw our conclusions and set them in a wider context. In the Appendixes we present some technical details omitted in the main part of the paper.

II. PRELIMINARIES

A. The O(N) symmetric scalar ϕ^4 model

At first we confine ourselves to the O(N) symmetric scalar ϕ^4 theory for the sake of simplicity. All scalar field theories with other spontaneously broken internal symmetries can be reduced to some subgroup of O(N). Of course, in such cases there will be interaction terms other than the simple ϕ^4 one shown below. The Lagrangian density of this theory is

$$\mathcal{L}=\tfrac{1}{2}(\partial_\mu \boldsymbol{\phi})^2 - V(\boldsymbol{\phi}^2), \tag{1}$$

where

$$\boldsymbol{\phi}=(\phi_0,\phi_1,\phi_2,\ldots,\phi_{N-1})=(\sigma,\boldsymbol{\pi}),$$

is a column vector and

$$V(\boldsymbol{\phi}^2)=-\frac{1}{2}\mu_0^2\boldsymbol{\phi}^2+\frac{\lambda_0}{4}(\boldsymbol{\phi}^2)^2.$$

We assume here that λ_0 and μ_0^2 are not only positive, but such that spontaneous symmetry breakdown (SSB) occurs in the Gaussian approximation (GA) introduced below.

B. The Gaussian variational method

1. The Gaussian ground state ("vacuum")

The Rayleigh–Ritz variational approximation to quantum field theories is based on the (''elliptical'') Gaussian ground state (vacuum) functional Ansatz, Refs. 9–11, 13,

$$\Psi_0[\vec{\phi}]=\mathcal{N}\exp\left(-\frac{1}{4\hbar}\int d\mathbf{x}\int d\mathbf{y}[\phi_i(\mathbf{x})-\langle\phi_i(\mathbf{x})\rangle]G_{ij}^{-1}(\mathbf{x},\mathbf{y})[\phi_j(\mathbf{y})-\langle\phi_j(\mathbf{y})\rangle]\right), \tag{2}$$

where $\mathcal{N}$ is the normalization constant, and one sums all repeated (roman lettered) indices from 0 to $N-1$. $\langle\phi_i(\mathbf{x})\rangle$ is the vacuum expectation value (VEV) of the ith spinless field which henceforth we will assume to be translationally invariant $\langle\phi_i(\mathbf{x})\rangle=\langle\phi_i(0)\rangle\equiv\langle\phi_i\rangle$ and

$$G_{ij}(\mathbf{x},\mathbf{y})=\frac{1}{2}\delta_{ij}\int\frac{d\mathbf{k}}{(2\pi)^3}\frac{1}{\sqrt{\mathbf{k}^2+m_i^2}}e^{i\mathbf{k}\cdot(\mathbf{x}-\mathbf{y})}.$$

We have explicitly kept $\hbar$ (while setting the velocity of light $c=1$) to keep track of quantum corrections and count the number of ''loops'' in our calculation. Then the ''vacuum'' (ground state) energy density becomes

$$\begin{aligned}\mathcal{E}(m_i,\langle\phi_i\rangle)=&-\frac{1}{2}\mu_0^2\langle\boldsymbol{\phi}\rangle^2+\frac{\lambda_0}{4}[\langle\boldsymbol{\phi}\rangle^2]^2+\hbar\sum_{i=0}^{N-1}\left[I_1(m_i)-\frac{1}{2}(\mu_0^2+m_i^2)I_0(m_i)\right]\\&+\frac{\lambda_0}{4}\left\{6\hbar\sum_{i=0}^{N-1}\langle\phi_i\rangle^2I_0(m_i)+2\hbar\sum_{i\neq j=0}^{N-1}\langle\phi_i\rangle^2I_0(m_j)+\hbar^2\sum_{i=0}^{N-1}I_0^2(m_i)\right.\\&\left.+\hbar^2\sum_{i\neq j=0}^{N-1}I_0(m_i)I_0(m_j)\right\},\end{aligned}\tag{3}$$

where

$$I_0(m_i)=\frac{1}{2}\int\frac{d\mathbf{k}}{(2\pi)^3}\frac{1}{\sqrt{\mathbf{k}^2+m_i^2}}=i\int\frac{d^4k}{(2\pi)^4}\frac{1}{k^2-m_i^2+i\epsilon}=G_{ii}(\mathbf{x},\mathbf{x}),\tag{4}$$

$$I_1(m_i)=\frac{1}{2}\int\frac{d\mathbf{k}}{(2\pi)^3}\sqrt{\mathbf{k}^2+m_i^2}=-\frac{i}{2}\int\frac{d^4k}{(2\pi)^4}\log(k^2-m_i^2+i\epsilon)+\text{const.}\tag{5}$$

We may identify $\hbar I_1(m_i)$ with the familiar ''zero-point'' energy density of a free scalar field of mass m_i.

The divergent integrals $I_{0,1}(m_i)$ are understood to be regularized via an UV momentum cutoff Λ. Thus we have introduced a new free parameter into the calculation. This was bound to happen in one form or another, since even in the renormalized perturbation theory one must introduce a new dimensional quantity (the ''renormalization scale/point'') at the one loop level. We treat this model as an effective theory and thus keep the cutoff without renormalization. (There are several renormalization schemes for the Gaussian approximation, but they show signs of instability and ultimately seem to lead to ''triviality.'' [12])

2. The vacuum energy minimization equations

We vary the energy density with respect to the field vacuum expectation values $\langle\phi_i\rangle$ and the ''dressed'' masses m_i. The extremization condition with respect to the field vacuum expectation values reads

$$\left(\frac{\partial\mathcal{E}(m_i,\langle\phi_i\rangle)}{\partial\langle\phi_j\rangle}\right)_{\min}=0,\quad j\in 0,1,\ldots,N-1;\tag{6}$$

or explicitly

$$\langle\phi_j\rangle\left[-\mu_0^2+\lambda_0\left(\langle\boldsymbol{\phi}\rangle^2+3\hbar I_0(m_j)+\hbar\sum_{j\neq i=0}^{N-1}I_0(m_i)\right)\right]_{\min}=0.\tag{7}$$

The second set of energy extremization equations reads

$$\left(\frac{\partial\mathcal{E}(m_i,\langle\phi_i\rangle)}{\partial m_j}\right)_{\min}=0,\quad j\in 0,1,\ldots,N-1,\tag{8}$$

or

$$m_j^2+\mu_0^2=\lambda_0\left(3\langle\phi_j^2\rangle+\hbar\sum_{j\neq k=0}^{N-1}\langle\phi_k^2\rangle+3\hbar I_0(m_j)+\hbar\sum_{j\neq k=0}^{N-1}\hbar I_0(m_k)\right)_{\min}. \tag{9}$$

Equations (7) and (9) can be identified with the (truncated) Schwinger–Dyson (SD) equation[13,19] for the one- and two-point Green functions, see Refs. 17 and 18. The solutions to these equations plus the additional minimization requirements (positive-definite second derivatives matrix, i.e., the positive definiteness of its principal minors, which will not be discussed here) determine the symmetry of the ground state (vacuum).

3. The vacuum symmetry

Now one ordinarily assumes that only one of the scalar fields ϕ_i (by convention the $i=0$ one) develops a nonzero VEV, i.e., $\langle\phi_0\rangle\neq 0$ and then one proceeds with the proof of the NG theorem. [The validity of this assumption, of course, depends on the values of the bare parameters in the Lagrangian and the cutoff Λ, or the values of the renormalized parameters, if one insists on renormalization. One may also have an unbroken symmetry: with all the fields having a zero VEV, $\langle\phi_i\rangle=0,\ i\in 0,1,\ldots,N-1$, the gap equations (7) and (9) lead to all the masses m_i being equal. In other words the N fields form an O(N) multiplet, so we may say that the symmetry of the vacuum is O(N), i.e., not broken.]

In the conventional case the scalar field masses are $m_0=M; m_1=m_2=m_3=\cdots=\mu$, i.e., the $(N-1)$ fields $\phi_i;\ i\in 1,2,\ldots,N-1$, of mass $m_i=\mu$, form an $(N-1)$-plet and the residual symmetry of the vacuum is O$(N-1)$. That, however, is not the only logical possibility: one may assume that more than one field develops VEV. This, of course, means that the (residual) symmetry of the vacuum is ''lesser'' than the one in the (''canonical'') case with only one VEV. [In the Born approximation such a vacuum might be reducible to the ''one VEV'' vacuum by means of an O(N) transformation (if it lies in the same ''orbit'' of the symmetry group[20]), but in the Gaussian approximation dynamical symmetry breaking may lead to an irreducibly different ground state.]

The decision which of these possibilities actually takes place can be made on the basis of comparing their respective ground state energies. In the case with an O$(N-1)$ symmetric ground state, the vacuum energy, or effective potential is

$$\begin{aligned}&\mathcal{E}(M,\mu,\langle\phi_0\rangle)_{\min}\\&\quad=-\frac{1}{2}\mu_0^2\langle\phi_0\rangle^2+\frac{\lambda_0}{4}\langle\phi_0\rangle^4+\hbar\left[I_1(M)-\frac{1}{2}(\mu_0^2+M^2)I_0(M)\right]\\&\qquad+(N-1)\hbar\left[I_1(\mu)-\frac{1}{2}(\mu_0^2+\mu^2)I_0(\mu)\right]+\frac{\lambda_0}{4}\{2\hbar\langle\phi_0\rangle^2[3I_0(M)+(N-1)I_0(\mu)]\\&\qquad+3\hbar^2I_0^2(M)+(N-1)\hbar^2I_0(\mu)[2I_0(M)+(N+1)I_0(\mu)]\}.\end{aligned} \tag{10}$$

Similar expressions for ground states with lesser symmetries than O$(N-1)$ can be derived by applying the corresponding gap equations (7) and (9) to Eq. (3). The question of the *absolute* energy minimum will not be pursued in this paper, however. For the purpose of argument we shall assume that alternative ground states exist and are stable, i.e., energetically favorable to the standard one.

If two (or more) scalar fields' VEV are simultaneously nonzero, e.g., if $\langle\phi_0\rangle=v_1\neq 0$ and $\langle\phi_j\rangle=v_2\neq 0;\ j\in 1,2,\ldots,N-1\ \langle\phi_i\rangle=0;\ i\in 1,2,\ldots,j-1,j-2,\ldots,N-1$, we may change the scalar field labels such that the fields with nonzero VEVs are labeled successively $0,1,\ldots,k$ without loss of generality. In such a case the masses m_i may also take on different values.

For simplicity's sake we assume that only two fields have nonvanishing vacuum expectation values (extension to three, or more VEVs follows by straightforward analogy), $\phi_0,\phi_1\neq 0$ (we label their masses $m_0=M,\ m_1=\mu_1$). The remaining $(N-2)$ fields $\phi_i;\ i\in 2,\ldots,(N-1)$, with

mass $m_i=\mu_2$, form an $(N-2)$-plet. In that case, it is clear that the residual symmetry of the ground state is (at least) $O(N-2)$, i.e., that the $O(N)$ symmetry has been dynamically (spontaneously) broken to (at least) $O(N-2)$. We say "at least" because, when the masses $m_0=M=m_1=\mu_1$ are equal there is additional O(2) symmetry of the vacuum. Similar comments are valid in the case when more than two fields develop VEVs. Of course, the residual symmetry of the vacuum determines the number of the NG bosons. Next we turn to the case of two fields with VEV as worked out in Appendix A. We have shown in Appendix A that there are only two distinct mass solutions $M=\mu_1, \neq \mu_2$ to Eqs. (A12)–(A15). Thus the residual symmetry of the vacuum is $O(N-2)\times O(2)$, and the corresponding number of NG bosons must be $(2N-4)$. In the following we shall see how all these NG bosons come about.

III. THE NAMBU–GOLDSTONE THEOREM

A. The two-body equation

In Refs. 17 and 18 it was shown that in the Gaussian approximation to the O(2) and O(4) ϕ^4 model, the Nambu–Goldstone particles appear in the *two-particle spectra*, i.e., that they are massless bound states of two different massive elementary excitations with an admixture of the (massive elementary) one-body state with the same quantum numbers (the CDD pole). This admixture of the one-body state is crucial for the masslessness of the NG state (it also proved to be a source of confusion). As there are at most $(N-1)$ such elementary particles/CDD poles (one field adopts a VEV so it cannot create or destroy single NG bosons), it appears that there can be at most $(N-1)$ NG bosons in this theory. There are $N(N-1)/2$ (distinct) pairs of elementary particles in this model, however, and an equal number of distinct (potentially bound) two-body states. Thus there can be at most $N(N-1)/2$ NG bosons, precisely the maximum number allowed by the $O(N)$ Lie group generator counting. Next we must show that the number of "broken symmetry generators" corresponds precisely to the number of massless bound states and that the corresponding Nöther currents are conserved.

The two-body equation of motion in the Gaussian approximation is equivalent to the four-point Schwinger–Dyson (or Bethe–Salpeter) equation (for proof of this equivalence, see Refs. 9 and 21). All the NG channels obey a generic four-point SD equation that reads

$$D_{ij,ij}(s)=V_{ij,ij}(s)+V_{ij,kl}(s)\Pi_{kl,mn}(s)D_{mn,ij}(s), \tag{11}$$

where $D(s)$ is the four-point Green function $(N\times N)$ matrix (scattering amplitude), $\Pi(s)$ is the polarization function matrix and $V(s)$ is the potential matrix; ij denote the $O(N)$ indices of the two constituents, with the generic solution

$$\mathbf{D}(s)=\mathbf{V}(s)[1-\mathbf{V}(s)\mathbf{\Pi}(s)]^{-1}, \tag{12}$$

where $s=(p_1+p_2)^2\equiv P^2$ is the center-of-mass (CM) energy. These matrices may reduce to a direct sum of submatrices depending on the residual symmetry of the system. Such effective two-body propagators can also be written in the following form (see Ref. 22):

$$D_\alpha(s)\simeq\frac{g_\alpha^2}{s-m_\alpha^2}, \tag{13}$$

where m_α is the effective mass in channel α. The difference between various $O(N)$ "flavor" sectors appears in the polarization functions $\Pi(s)$ and potentials $V(s)$: more specifically in $(N-2)$ channels $[(i=0,\ j\subset 2,\ldots N-1)\equiv M\mu_2]$ the said matrices are diagonal and have the form

$$\Pi_{M\mu_2}(s)=I_{M\mu_2}(s)=i\hbar\int\frac{d^4k}{(2\pi)^4}\frac{1}{[k^2-M^2+i\epsilon][(k-P)^2-\mu_2^2+i\epsilon]}, \tag{14}$$

$$V_{M\mu_2}(s)=2\lambda_0\left[1+\left(\frac{2\lambda_0\langle\phi_0\rangle^2}{s-\mu_2^2}\right)\right]=2\lambda_0\left[1+\frac{M^2}{s-\mu_2^2}\right], \tag{15}$$

and another $(N-2)$ channels $[(i=1,\ j\subset 2,\ldots,N-1)\equiv\mu_1\mu_2$ have the form

$$\Pi_{\mu_1\mu_2}(s)=I_{\mu_1\mu_2}(s)=i\hbar\int\frac{d^4k}{(2\pi)^4}\frac{1}{[k^2-\mu_2^2+i\epsilon][(k-P)^2-\mu_1^2+i\epsilon]}, \tag{16}$$

$$V_{\mu_1\mu_2}(s)=2\lambda_0\left[1+\left(\frac{2\lambda_0\langle\phi_1\rangle^2}{s-\mu_2^2}\right)\right]=2\lambda_0\left[1+\frac{\mu_1^2}{s-\mu_2^2}\right]. \tag{17}$$

The poles $1/(s-\mu_{1,2}^2)$ in Eqs. (15) and (17) are called the Castillejo–Dalitz-Dyson (CDD) poles and correspond to one-particle states in the theory. Now due to Eqs. (A12)–(A15) these two channels happen to be equivalent in this case, but that degeneracy is accidental (for a different example see Sec. IV).

B. Massless (Nambu–Goldstone) two-body states

With an $O(N-2)\times O(2)$ residual symmetry there should be $(2N-4)=(N-2)+(N-2)$ NG bosons. This number of NG bosons quickly exceeds the number of available fields in the Lagrangian: $2(N-2)>(N-1)$ for $N>3$. Thus, there are not enough scalar fields to provide for all the NG bosons in case of nonstandard symmetry breaking. Does this mean that the NG theorem breaks down in such a case?

As in Ref. 17, we shall prove that at zero CM energy $P=0$, the matrix $[1-V_{M\mu_2}(0)\Pi_{M\mu_2}(0)]$ vanishes. We use Eq. (A6) to write

$$\begin{aligned}V_{M\mu_2}(0)&=2\lambda_0\left[1-\frac{M^2}{\mu_2^2}\right],\\ \Pi_{M\mu_2}(0)&=\hbar\left(\frac{I_0(M)-I_0(\mu_2)}{M^2-\mu_2^2}\right)\end{aligned} \tag{18}$$

then use Eq. (33) to obtain the final result

$$V_{M\mu_2}(0)\Pi_{M\mu_2}(0)=1. \tag{19}$$

Thus the inverse propagator Eq. (12) evaluated at zero momentum vanishes,

$$D^{-1}_{M\mu_2}(0)=[1-V_{M\mu_2}(0)\Pi_{M\mu_2}(0)]V_{M\mu_2}(0)^{-1}=0, \tag{20}$$

which is equivalent to the result $m^2_{M\mu_2}=0$. Similarly for the remaining $(N-2)$ $\mu_1\mu_2$ channels. Q.E.D.

Note that the proof in no way depended on the fact that $\mu_1=M$. In other words, if the gap Eqs. (A12)–(A15) allowed a solution such that $\mu_1\neq M$ and $\langle\phi_1\rangle=0$, the NG theorem would still hold. But, then the CDD poles would decouple in the latter $(N-2)$ channels, i.e., there would be no CDD poles in these channels. This shows that, at least in principle, $(N-2)$ NG bosons could be pure bound states with no single particle admixtures. In Sec. IV we shall give an example of a model with a gap equation that allows such solutions.

C. Conservation of Nöther currents

There are $N-2[a\subset 2,\ldots,N-1]$ dynamically broken $O(N)$ symmetry Nöther current matrix elements corresponding to

$$J^a_{\mu 5}(p',p)=\langle\phi^a(p')|J_\mu(0)|\phi_0(p)\rangle=(p'+p)_\mu+q_\mu\left(\frac{M^2}{q^2-\mu_2^2}\right)-\Gamma^{M\mu_2}_{\mu 5}(q)D_{M\mu_2}(q), \quad (21)$$

where $\Gamma^{M\mu_2}_{\mu 5}(q)$ is

$$\Gamma^{M\mu_2}_{\mu 5}(q)=i\int\frac{d^4k}{(2\pi)^4}\left[(2k+q)_\mu+q_\mu\left(\frac{M^2}{q^2-\mu_2^2}\right)\right]\frac{1}{[k^2-M^2][(k+q)^2-\mu_2^2]}$$
$$=\frac{q_\mu}{q^2}\left[\frac{\mu_2^2}{2\lambda_0}(V_{M\mu_2}(0)\Pi_{M\mu_2}(0)-V_{M\mu_2}(q^2)\Pi_{M\mu_2}(q^2))\right]. \quad (22)$$

Inserting the vertex $\Gamma^{M\mu_2}_{\mu 5}(q)$, Eq. (22) together with the two-body propagator $D_{M\mu_2}(q^2)$, Eq. (12) into Eq. (21) one finds

$$J^a_{\mu 5}(p',p)=(p'+p)_\mu+q_\mu\left(\frac{M^2}{q^2-\mu_2^2}\right)-\frac{q_\mu}{q^2}\left[\frac{\mu_2^2}{2\lambda_0}\right]V_{M\mu_2}(q^2)=(p'+p)_\mu+q_\mu\left(\frac{M^2-\mu_2^2}{q^2}\right), \quad (23)$$

where $q^\nu=(p'-p)^\nu$. This current is manifestly devoid of a pole at $q^2=\mu_2^2$. The composite state plays precisely the role of the Nambu–Goldstone boson in the conservation of the dynamically broken O(N) symmetry Nöther currents,[1] i.e., in the basic O(N) symmetry Ward–Takahashi identity, cf. Refs. 23 and 24,

$$q^\nu J^a_{\nu 5}(p',p)=(p'^2-\mu_2^2)-(p^2-M^2), \quad (24)$$

that follows directly from Eq. (23). Similarly for the remaining $N-2$ $[a\subset 2,\ldots,N-1]$ dynamically broken O(N) symmetry Nöther current matrix elements corresponding to

$$J^a_{\mu 5}(p',p)=\langle\phi^a(p')|J_\mu(0)|\phi_1(p)\rangle=(p'+p)_\mu+q_\mu\left(\frac{\mu_1^2}{q^2-\mu_2^2}\right)-\Gamma^{\mu_1\mu_2}_{\mu 5}(q)D_{\mu_1\mu_2}(q). \quad (25)$$

The identity of the two ''gap,'' or CDD masses $\mu_1=M$ and the concomitant ''excess'' O(2) vacuum symmetry are consequences of the simplicity of the vacuum equation (7) that only depends on one O(N) algebraic invariant.[4,20] That, in turn, is a consequence of the fact that we are dealing with fields in the fundamental irrep. of O(N) and the requirement that the Lagrangian (1) be renormalizable, i.e., at most of the fourth power in the fields. The assumption of a second VEV $\langle\phi_3\rangle=\langle\pi^0\rangle\neq 0$ is particularly unrealistic in the Gell-Mann–Levy model [O($N=4$) ϕ^4 model],[25] because of the negative parity of the π fields: their nonzero VEV would imply spontaneous breaking of P and CP ''parities.'' In Sec. IV we give an example of a ϕ^4 model with an internal symmetry that leads to a gap equation with distinct mass solutions and potentially exotic NG bound states.

IV. THE 't HOOFT MODEL

A. Definition of the model

't Hooft's[26] extension of the linear sigma model Lagrangian reads

$$\mathcal{L}_{\rm tH}=\mathrm{tr}[(\partial_\mu M\partial^\mu M^\dagger)+\mu^2 MM^\dagger]-\tfrac{1}{2}(\lambda_1-\lambda_2)[\mathrm{tr}(MM^\dagger)]^2$$
$$-\lambda_2\,\mathrm{tr}[(MM^\dagger)^2]+2\kappa[e^{i\theta}\det M+\text{c.c.}], \quad (26)$$

where

$$M=\frac{1}{\sqrt{2}}(\Sigma+i\Pi),$$

$$\Sigma=\frac{1}{\sqrt{2}}(\sigma+\boldsymbol{\alpha}\cdot\boldsymbol{\tau}), \tag{27}$$

$$\Pi=\frac{1}{\sqrt{2}}(\eta+\boldsymbol{\pi}\cdot\boldsymbol{\tau}).$$

Equation (26) is equivalent to the following:

$$\begin{aligned}\mathcal{L}_{\mathrm{tH}}=&\frac{1}{2}[(\partial_\mu\sigma)^2+(\partial_\mu\boldsymbol{\pi})^2+(\partial_\mu\eta)^2+(\partial_\mu\boldsymbol{\alpha})^2]+\frac{\mu^2}{2}[\sigma^2+\boldsymbol{\pi}^2+\eta^2+\boldsymbol{\alpha}^2]\\&+2\kappa\cos\theta[\sigma^2+\boldsymbol{\pi}^2-\eta^2-\boldsymbol{\alpha}^2]-4\kappa\sin\theta[\sigma\eta-\boldsymbol{\pi}\cdot\boldsymbol{\alpha}]-\frac{\lambda_1}{8}[\sigma^2+\boldsymbol{\pi}^2+\eta^2+\boldsymbol{\alpha}^2]^2\\&-\frac{\lambda_2}{2}[(\sigma\boldsymbol{\alpha}+\eta\boldsymbol{\pi})^2+(\boldsymbol{\pi}\times\boldsymbol{\alpha})^2]\end{aligned} \tag{28}$$

which describes the dynamics of the two chiral meson quartets, $(\sigma,\boldsymbol{\pi})$ and $(\boldsymbol{\alpha},\eta)$, in this model, and λ_1, λ_2, κ, θ are the bare coupling constants. Nonvanishing angle θ leads to the explicit (not spontaneous) CP violation in this model, so we set it equal to zero. Thus we see that the 't Hooft model consists of two coupled Gell-Mann–Lévy (GML) linear sigma models,[25] one with a light and the other with a heavy quartet of mesons.

Note that the symmetries of various parts of the interaction Lagrangian also vary, see Appendix B: (i)

$$\lambda_1\neq 0,\quad \lambda_2=\kappa=\theta=0 \tag{29}$$

implies O(8) symmetry. (ii)

$$\lambda_1\neq 0\neq\lambda_2,\quad \kappa=\theta=0 \tag{30}$$

implies $O(4)\times O(2)$ symmetry. (iii)

$$\lambda_1\neq 0\neq\lambda_2,\quad \kappa\neq 0=\theta \tag{31}$$

implies O(4) symmetry. And the number of NG bosons must change accordingly.

B. The gap equations

The first set of energy minimization equations (7) reads

$$0=-v(\mu_0^2+4\kappa)+\frac{\lambda_1}{2}v[v^2+3I_0(m_\sigma)+3I_0(m_\alpha)+3I_0(m_\pi)+I_0(m_\eta)]+3\lambda_2 vI_0(m_\alpha), \tag{32}$$

$$m_\sigma^2=-\mu_0^2-4\kappa+\frac{\lambda_1}{2}v[v^2+3I_0(m_\sigma)+3I_0(m_\alpha)+3I_0(m_\pi)+I_0(m_\eta)]+3\lambda_2 I_0(m_\alpha), \tag{33}$$

$$m_\alpha^2 = -\mu_0^2 - 4\kappa + \left(\frac{\lambda_1}{2} + \lambda_2\right)v^2 + \frac{\lambda_1}{2}[I_0(m_\sigma) + 5I_0(m_\alpha) + 3I_0(m_\pi) + I_0(m_\eta)] + \lambda_2[I_0(m_\sigma) + 2I_0(m_\pi)], \tag{34}$$

$$m_\pi^2 = -\mu_0^2 - 4\kappa + \frac{\lambda_1}{2}v^2 + \frac{\lambda_1}{2}[v^2 + I_0(m_\sigma) + 3I_0(m_\alpha) + 5I_0(m_\pi) + I_0(m_\eta)] + \lambda_2[I_0(m_\eta) + 2I_0(m_\alpha)], \tag{35}$$

$$m_\eta^2 = -\mu_0^2 - 4\kappa + \frac{\lambda_1}{2}v^2 + \frac{\lambda_1}{2}[v^2 + 3I_0(m_\sigma) + 3I_0(m_\alpha) + 3I_0(m_\pi) + I_0(m_\eta)] + 3\lambda_2 I_0(m_\pi), \tag{36}$$

where the divergent integral $I_0(m_i)$ is given by Eq. (4). For simplicity in the following we use the following short-hand notation $\alpha = m_\alpha^2; \eta = m_\eta^2; \sigma = m_\sigma^2; \pi = m_\pi^2$. Equations (32)–(36) can be solved for

$$\begin{aligned}
\Pi_{\alpha\eta}(0) &= \frac{I_0(\alpha) - I_0(\eta)}{\alpha - \eta} = \frac{1}{(\lambda_1^2 - \lambda_2^2)}\left(\lambda_1 + \lambda_2\left(\frac{\pi - \sigma}{\alpha - \eta}\right)\right), \\
\Pi_{\pi\sigma}(0) &= \frac{I_0(\alpha) - I_0(\eta)}{\alpha - \eta} = \frac{-1}{(\lambda_1^2 - \lambda_2^2)}\left(\lambda_1\frac{\pi}{\sigma - \pi} + \lambda_2\frac{\left(\alpha - \eta - \frac{\lambda_2}{\lambda_1}\sigma\right)}{\sigma - \pi}\right), \\
\Pi_{\pi\alpha}(0) &= \frac{I_0(\alpha) - I_0(\pi)}{\alpha - \pi} = \frac{1}{(\lambda_1^2 - 2\lambda_1\lambda_2 - 3\lambda_2^2)}\left(\lambda_1\left(1 - \frac{8\kappa}{\alpha - \pi}\right) + \lambda_2\frac{\eta - 8\kappa}{\alpha - \pi}\right), \\
\Pi_{\sigma\eta}(0) &= \frac{I_0(\sigma) - I_0(\eta)}{\sigma - \eta} \\
&= \frac{1}{(\lambda_1^2 - 2\lambda_1\lambda_2 - 3\lambda_2^2)}\left((\lambda_1 - 2\lambda_2)\left(\frac{8\kappa - \eta}{\sigma - \eta}\right) - 3\lambda_2\frac{\alpha - \pi - 8\kappa - \frac{\lambda_2}{\lambda_1}\sigma}{\sigma - \eta}\right),
\end{aligned} \tag{37}$$

whence follows

$$\Pi_{\pi\eta}(0) = \frac{I_0(\pi) - I_0(\eta)}{\pi - \eta} = \frac{1}{\lambda_1(\pi - \eta)}(8\kappa + \pi - \eta + \lambda_2(\alpha - \eta)\Pi_{\eta\alpha}(0) - 3\lambda_2(\alpha - \pi)\Pi_{\pi\alpha}(0)), \tag{38}$$

$$\begin{aligned}
\Pi_{\alpha\sigma}(0) &= \frac{I_0(\sigma) - I_0(\alpha)}{\sigma - \alpha} \\
&= \frac{1}{\lambda_1(\sigma - \alpha)}\left(8\kappa + \frac{\lambda_2}{\lambda_1}\sigma - \alpha + \lambda_2(\sigma - \pi)\Pi_{\pi\sigma}(0) - 3\lambda_2(\alpha - \pi)\Pi_{\pi\alpha}(0)\right).
\end{aligned}$$

C. The Nambu–Goldstone theorem in the isotensor pseudoscalar sector

Note that there are $8 \times 8 = 64$ possible initial or final two-body states here. Thus there are $64 \times 64 = 4096$ possible channels, but only $4 \times 7 = 28$ distinct pairs of particles, or equivalently at most 28 possible NG bosons. The last statement holds under the proviso of exact O(8) symmetry being broken to a discrete (non-Lie) symmetry, however. Otherwise there are fewer than 28 NG bosons, and when O(8) is explicitly broken down to $O(4) \times O(2)$, or O(4) by one of the terms in

the Lagrangian equation (26), there are even fewer than that. This fact tells us that many channels must be coupled and that the residual symmetry plays a crucial role in this coupling. We shall not look at every possible channel in this paper, but rather concentrate only on the exotic ones, in this case the isotensor, so as to show the existence of pure bound state NG bosons without CDD admixtures.

We may use the residual vacuum symmetry, e.g., the O(3) isospin invariance to split this 64×64 matrix equation into six invariant subspaces: three flavor channels [(a) isoscalar; (b) isovector; and (c) isotensor] of either parity. In the two-body, or Bethe–Salpeter (BS) equation for the four-point Green functions $D_{ij}(s)$, the indices i,j denote the isospin of the two-body initial and final states, respectively.

The negative parity (pseudoscalar) isotensor two-body equation is a single-channel one and straightforward to solve, see Eq. (12). We look at the zero CM energy $P=0$ function $V_{\pi\alpha}(0)\Pi_{\pi\alpha}(0)$; we use

$$V_{\pi\alpha}^{(I=2)}=\lambda_1+\lambda_2 \tag{39}$$

and Eq. (37) to obtain the final result

$$V_{\pi\alpha}^{(I=2)}(0)\Pi_{\pi\alpha}(0)=-\left(\frac{\lambda_1+\lambda_2}{\lambda_1^2-2\lambda_1\lambda_2-3\lambda_2^2}\right)\left(\lambda_1\left(1-\frac{8\kappa}{\alpha-\pi}\right)+\lambda_2\frac{\eta-8\kappa}{\alpha-\pi}\right) \quad . \tag{40}$$

Now set $\lambda_2=\kappa\to 0$ and find

$$\lim_{\lambda_2=\kappa\to 0} V_{\pi\alpha}^{(I=2)}(0)\Pi_{\pi\alpha}(0)=1. \tag{41}$$

The propagator Eq. (12) evaluated at zero momentum can be written as

$$D_{\pi\alpha}^{(I=2)}(0)=\frac{g_{\pi\alpha}^2}{-m_{\pi\alpha}^2}=\frac{V_{\pi\alpha}(0)}{1-V_{\pi\alpha}(0)\Pi_{\pi\alpha}(0)}, \tag{42}$$

whence it follows that

$$\begin{aligned} m_{\pi\alpha}^2&=\left[\frac{1}{\lambda_1+\lambda_2}-\left(\frac{1}{\lambda_1^2-2\lambda_1\lambda_2-3\lambda_2^2}\right)\left(\lambda_1\left(1-\frac{8\kappa}{\alpha-\pi}\right)+\lambda_2\frac{\eta-8\kappa}{\alpha-\pi}\right)\right]\left(\frac{\alpha-\pi}{v}\right)^2 \\ &=\mathcal{O}(\lambda_2)+\mathcal{O}(\kappa). \end{aligned} \tag{43}$$

Thus we see that the effective (pseudo) NG boson mass in this channel is proportional to λ_2, and/or κ, the two O(8) symmetry breaking parameters.

Q.E.D.

V. SUMMARY AND CONCLUSIONS

In summary, we have (1) proven the NG theorem in the variational Gaussian wave functional approximation to the O(N) symmetric ϕ^4 model when the symmetry of the ground state is a proper subgroup of O($N-1$); (2) proven conservation of Nöther currents corresponding to the dynamically broken symmetries; (3) proven the same NG theorem in the exotic isotensor channel of the 't Hooft model in the limit $\lambda_2=\kappa\to 0$. The NG bosons are massless bound states of two massive constituents. We emphasize that our proofs do not depend on the specific values of the bare parameters, or of the cutoff in the theory, so long as the system is in the spontaneously broken phase with appropriate symmetry.

We should like to put these results into their proper logical and chronological setting. The variational method in quantum field theory (QFT) is based on the Schrödinger representation and goes by the name of Gaussian approximation to the ground state wave functional. This method, in

its various guises, was pioneered by Schiff, Rosen, and Kuti[6–8] in the 1960s and 1970s, and later revived and elaborated in the 1980s by Barnes and Ghandour,[9,13] and by Symanzik[10] and by Consoli, Stevenson and collaborators.[11,12,16] Related formalisms based on effective potentials and other functional methods were discussed in Refs. 8, 16, 12 and references cited therein. Most of these studies addressed the ϕ^4 scalar field theory that is also the prime example of the Nambu–Goldstone (NG) theorem,[1–5] an exact result in the O(N) symmetric ϕ^4 scalar theory with spontaneous internal symmetry breaking.

The NG theorem was first shown *not* to be satisfied by the solutions to the mass, or ''gap'' equations in the Gaussian approximation by Kamefuchi and Umezawa in 1964,[14] practically simultaneously with the general proofs of the NG theorem.[3–5] This fact was subsequently rediscovered several times[15,16] and this unsatisfactory situation persisted until 1994.[17] Various conjectures as to the reasons for this failure and as to potential remedies were advanced during this period of time. It was first shown in Ref. 17 that this apparent breakdown of the NG theorem is not an intrinsic shortcoming of the Gaussian wave functional approximation, but rather a consequence of incomplete previous analyses. In other words, the NG theorem is satisfied, but the NG bosons are not excitations of the elementary scalar fields, as initially expected. Rather, they are massless bound states of two massive elementary scalar excitations, in close analogy with Nambu's[1] proof of the NG theorem in a self-interacting fermion theory. NG bosons are solutions to the two-body [or Bethe–Salpeter (BS)] equation in the Gaussian approximation. That equation was only rarely considered in the literature,[7,9] and never before Ref. 17 in the context of spontaneous symmetry breaking of purely bosonic models.

In this light the result is simple enough to understand, yet it drew strong, albeit unpublished criticism and affirmation.[27] Perhaps the underlying reason for the misunderstanding by some was the implication of the proof that the ϕ^4 scalar field theory could have bound states, which, as ''everybody knew,'' (Georgi in Ref. 27) disagrees with various ''rigorous no-go'' and ''triviality'' theorems in the same theory.[28] (For more recent results comparing constructive QFT to the Gaussian approximation in $1+1$ dimensional field theories, see Ref. 29.) The said theorems hold only in the limit of an infinite cutoff, however, in which the Gaussian approximation also becomes trivial.[11] For finite cutoffs, on the other hand, this is a nontrivial theory that may contain bound states.

Soon after the first proof in Ref. 17 it was also shown along the lines of Ref. 3 that the NG theorem also follows from the Gaussian effective potential, Ref. 30, but that proof did not shed much light on the mechanisms that made the NG bosons come about. Only later, in Refs. 31 and 32, it was explicitly shown how this formal proof relates to the Gaussian two-body equations of motion. Another source of confusion was the apparent doubling of degrees of freedom, at least in some ''flavor'' (internal symmetry) channels, *viz.* the existence of massive ''elementary'' and massless bound states in the same channel. This problem was resolved in Ref. 31, wherein the Källen–Lehmann spectral function was calculated in appropriate channels of the model. This spectral function clearly shows the presence of massless NG states and the absence of the massive single-particle excitations. That also constitutes a proof of the NG theorem along Gilbert's lines, Ref. 5, within the Gaussian wave functional approximation. Thus we have confirmed all the well-known proofs of the NG theorem in the Gaussian approximation.

The NG theorem is the simplest example of a Ward–Takahashi identity, which follows from the underlying internal symmetry of the ϕ^4 model. Ward–Takahashi identities typically relate $(n-1)$-point Green functions to n-point functions and/or matrix elements of Nöther currents. These identities were developed by Lee in the linear sigma model at the perturbative one loop level,[23] and by Symanzik for arbitrary orders of perturbation theory,[24] so we shall call them the Lee–Symanzik (LS) identities.

The *exact*, i.e., nonperturbative Green functions satisfy an infinite set of coupled integro-differential equations called the Schwinger–Dyson equations.[19] The iterative/perturbative solutions to the SD equations form (infinite/finite) sets of Feynman diagrams. If one decouples the SD equations for higher order Green functions from the lower order ones (in popular jargon, if one truncates the SD equations), one may obtain tractable equations and find their solutions that sum

infinite, albeit incomplete sets of Feynman diagrams. It has been known at least since 1980, Ref. 9, that the Gaussian approximation to the unbroken symmetry ϕ^4 theory corresponds to one such truncation of the SD equations. But, truncated SD equations need not obey the conservation laws of the original SD equations of motion, i.e., LS identities may be violated by the truncation. To our knowledge, no proof of LS identities had been given for truncated SD equations, i.e., for infinite classes of diagrams in the bosonic linear sigma model prior to Ref. 17, although a similar proof had been given by Nambu and Jona-Lasinio in their fermionic model some 30 years before.[1] Thus we have shown that the Gaussian functional approximation constitutes a closed, self-consistent symmetry-preserving approximation to the Schwinger–Dyson equations.

ACKNOWLEDGMENTS

One of the authors (V.D.) would like to acknowledge a center-of-excellence (COE) Professorship for the year 2000/2001 and the hospitality of RCNP. The same author also thanks Professor Paul Stevenson for valuable conversations and correspondence relating to the Gaussian functional approximation.

APPENDIX A: THE GAP EQUATIONS WITH TWO VEVs

The first set of energy minimization equations (7) read

$$\mu_0^2=\lambda_0[v^2+3\hbar I_0(M)+\hbar I_0(\mu_1)+(N-2)\hbar I_0(\mu_2)], \tag{A1}$$

$$\mu_0^2=\lambda_0[v^2+\hbar I_0(M)+3\hbar I_0(\mu_1)+(N-2)\hbar I_0(\mu_2)], \tag{A2}$$

$$v^2=\langle\phi_0\rangle^2+\langle\phi_1\rangle^2=\langle\boldsymbol{\phi}\rangle^2, \tag{A3}$$

$$\langle\phi_i\rangle=0 \qquad i=2,\ldots,N-1, \tag{A4}$$

where the divergent integral $I_0(m_i)$, Eq. (4) is understood to be regularized via an UV momentum cutoff Λ, either three-, or four dimensional. The second set of gap equations (7) read

$$M^2=-\mu_0^2+\lambda_0[2\langle\phi_0\rangle^2+\langle\boldsymbol{\phi}\rangle^2+3\hbar I_0(M)+\hbar I_0(\mu_1)+(N-2)\hbar I_0(\mu_2)], \tag{A5}$$

$$\mu_1^2=-\mu_0^2+\lambda_0[2\langle\phi_1\rangle^2+\langle\boldsymbol{\phi}\rangle^2+\hbar I_0(M)+3\hbar I_0(\mu_1)+(N-2)\hbar I_0(\mu_2)], \tag{A6}$$

$$\mu_2^2=-\mu_0^2+\lambda_0[\langle\boldsymbol{\phi}\rangle^2+\hbar I_0(M)+\hbar I_0(\mu_1)+N\hbar I_0(\mu_2)]. \tag{A7}$$

Upon inserting Eq. (A1) into Eq. (A5), the following coupled ''gap'' equations emerge:

$$M^2=2\lambda_0\langle\phi_0\rangle^2+2\lambda_0\hbar[I_0(M)-I_0(\mu_1)]=2\lambda_0\langle\phi_0\rangle^2, \tag{A8}$$

$$\mu_1^2=2\lambda_0\langle\phi_1\rangle^2-2\lambda_0\hbar[I_0(M)-I_0(\mu_1)]=2\lambda_0\langle\phi_1\rangle^2, \tag{A9}$$

$$M^2-\mu_1^2=2\lambda_0(\langle\phi_0\rangle^2-\langle\phi_1\rangle^2+2\lambda_0+\hbar[I_0(M)-I_0(\mu_1)]), \tag{A10}$$

$$\mu_2^2=2\lambda_0\hbar[I_0(\mu_2)-I_0(M)]=2\lambda_0\hbar[I_0(\mu_2)-I_0(\mu_1)]. \tag{A11}$$

Note that these equations lead to

$$I_0(M)-I_0(\mu_1)=0, \tag{A12}$$

$$M^2-\mu_1^2=2\lambda_0(\langle\phi_0\rangle^2-\langle\phi_1\rangle^2)=0, \tag{A13}$$

which, in turn have at least one solution, $\mu_1=M$ and $\langle\phi_0\rangle^2=\langle\phi_1\rangle^2$, that are solutions to a single nontrivial gap equation

$$M^2 = 2\lambda_0 \langle \phi_1 \rangle^2, \tag{A14}$$

$$\mu_2^2 = 2\lambda_0 \hbar [I_0(\mu_2) - I_0(M)], \tag{A15}$$

with two unknowns one of which is kept fixed, cf. Ref. 18. This gap equation has been solved numerically in Ref. 18: it admits only massive solutions $M > \mu > 0$, however, for real, positive values of λ_0, μ_0^2 and real ultraviolet cutoff Λ in the momentum integrals $I_0(m_i)$. In other words, the "would be NG boson fields" ($\phi_{1,2,\ldots,N-1}$) excitations are all massive ($\mu > 0$) in the MFA. This looks like a breakdown of the NG theorem in this approximation, but, as discussed in Refs. 17 and 18, there is a solution by way of the two-body (Bethe–Salpeter) equation.

APPENDIX B: SYMMETRIES OF THE 't HOOFT MODEL

The two field quartets, $(\sigma, \boldsymbol{\pi})$ and $(\boldsymbol{\alpha}, \eta)$, have different "chiral" $O(4) = O(3) \times O(3) \simeq SU_L(2) \times SU_R(2)$,

$$\delta_5 \sigma = \boldsymbol{\beta} \cdot \boldsymbol{\pi}, \tag{B1}$$

$$\delta_5 \eta = -\boldsymbol{\beta} \cdot \boldsymbol{\alpha}, \tag{B2}$$

$$\delta_5 \boldsymbol{\alpha} = \boldsymbol{\beta} \eta, \tag{B3}$$

$$\delta_5 \boldsymbol{\pi} = -\boldsymbol{\beta} \sigma, \tag{B4}$$

isospin

$$\delta \sigma = 0, \tag{B5}$$

$$\delta \eta = 0, \tag{B6}$$

$$\delta \boldsymbol{\alpha} = -\varepsilon \times \boldsymbol{\alpha}, \tag{B7}$$

$$\delta \boldsymbol{\pi} = -\varepsilon \times \boldsymbol{\pi}, \tag{B8}$$

and $U_A(1) \simeq O(2)$ transformation properties

$$\delta_5^0 \sigma = \beta \eta, \tag{B9}$$

$$\delta_5^0 \eta = -\beta \sigma, \tag{B10}$$

$$\delta_5^0 \boldsymbol{\alpha} = \beta \boldsymbol{\pi}, \tag{B11}$$

$$\delta_5^0 \boldsymbol{\pi} = -\beta \boldsymbol{\alpha}. \tag{B12}$$

The Lie algebra O(4) has two Casimir operators, but there is only one invariant in the $(\frac{1}{2}, \frac{1}{2})$ representation with one meson quartet, *viz.* (i) $[\sigma^2 + \boldsymbol{\pi}^2]$, whereas with two quartets one has three invariants: (i) above, (ii) $[\eta^2 + \boldsymbol{\alpha}^2]$, and (iii) $[\eta\sigma - \boldsymbol{\alpha} \cdot \boldsymbol{\pi}]$. Any odd power of the third invariant (iii) violates CP. Even without the third invariant the algebraic structure of the Lagrangian is rich enough to allow for multiple vacua [solutions to the energy minimization equations (6)] even in the (first) Born approximation. For example, Eq. (6) applied directly to the 't Hooft interaction (26) in the Born approximation allow two nonzero VEVs $[\langle \sigma \rangle_{0B} = v_{0B} \neq 0$ and $\langle \alpha_3 \rangle_{0B} = v_{1B} \neq 0]$,

$$-\mu_0^2 - 4\kappa + \frac{\lambda_1}{2}[v_{0B}^2 + v_{1B}^2] + \lambda_2 v_{1B}^2 = 0, \tag{B13}$$

$$-\mu_0^2+4\kappa+\frac{\lambda_1}{2}[v_{0\mathrm{B}}^2+v_{1\mathrm{B}}^2]+\lambda_2 v_{1\mathrm{B}}^2=0. \tag{B14}$$

Their solutions are

$$\langle\sigma\rangle_{0\mathrm{B}}=v_{0\mathrm{B}}=\frac{\mu_0^2}{\lambda_1+\lambda_2}-4\frac{\kappa}{\lambda_2}, \tag{B15}$$

$$\langle\alpha_3\rangle_{0\mathrm{B}}=v_{1\mathrm{B}}=\frac{\mu_0^2}{\lambda_1+\lambda_2}+4\frac{\kappa}{\lambda_2}, \tag{B16}$$

leading to a nontrivially broken ground state. Note, however, that (i) $\lambda_2\to 0$ is a singular limit point, i.e., these vacua are not continuously connected with the more conventional vacua at $\lambda_2=0$, and (ii) the two kinds of vacua/energy minima coincide whenever $\kappa=0$ and $\lambda_2\neq 0$. Hence it is possible for the system to be in an unconventional vacuum even with infinitesimally small λ_2 and κ when they vanish with a fixed nonzero ratio. This makes it plausible that unusual vacua may also appear in this model when the symmetry is broken dynamically, i.e., by ''loop'' effects. This doubling of vacua is a consequence of multiple (two) independent algebraic invariants in the Lagrangian (26) which in turn led to multiple (two) VEVs, in agreement with the general theory.[4,20]

(Received 24 September 2002; accepted 31 March 2003)

We develop a systematic method for classifying supersymmetric orbifold compactifications of *M*-theory. By restricting our attention to Abelian orbifolds with low order, in the special cases where elements do not include coordinate shifts, we construct a "periodic table" of such compactifications, organized according to the orbifolding group (order $\leqslant 12$) and dimension (up to 7). An intriguing connection between supersymmetric orbifolds and G_2 structures is explored. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1581972]

I. INTRODUCTION

Manifolds with SU(N) holonomy have been a source of significant interest for mathematicians and physicists alike. Indeed, the importance of $K3$ manifolds and Calabi–Yau threefolds in the arena of consistent superstring background geometries could hardly be overstated. Aside from their undisputed beauty, compactification on these spaces allows for important control of supersymmetry which, in turn, permits ready access to potentially testable phenomenological consequences of string theory itself. It is for such reasons that understanding the geometry of these objects, including the classification of associated gauge bundles,[1–3] has been such a relevant and fruitful endeavor. It is nowadays accepted, however, that there exists a more fundamental 11-dimensional underpinning, code-named *M*-theory, which appropriately describes nonperturbative aspects of fundamental physics. In contrast to the situation in perturbative string theory, within the context of *M*-theory the most important geometric compactification spaces have special holonomy.[4–6]

The connection between *M*-theory and four-dimensional $N=1$ supersymmetric models of particle physics is provided by 11-dimensional supergravity on compact seven manifolds with G_2 holonomy. Considerably less is known about these objects as compared to the case of Calabi–Yau manifolds. In light of the above discussion, however, it is important to develop a useful classification of the relevant supersymmetric *M*-theory models. The rudiments of a mathematical classification scheme for G_2 holonomy seven manifolds, each a resolution of an orbifold of a seven torus, has been provided by Joyce.[7] The purpose of this paper is to describe a complementary scheme, based on physics, of a class of seven-dimensional orbifold constructions which meet the criterion of $N=1$ supersymmetry preservation.

In previous papers[8–11] we described various technical aspects of the extraction of effective physics from *M*-theory. Generally, our techniques apply to global orbifold compactifications, and rely on significant constraints which follow from the requirement of chiral anomaly cancellation pointwise in 11 dimensions, most notably on distinguished even-dimensional submanifolds. Recently,[12] we have described how to obtain a pair of particular four-dimensional $N=1$ super Yang–Mills theories with chiral matter content from an *M*-theoretic intersecting brane-world scenario. In that paper we included a scan of multiplicities of supersymmetric *M*-theory orbifold

models of a particular class. In this paper we derive this scan, explaining in more detail the physical and mathematical criteria involved in finding such models.

Presupposing an ultimate connection between M-theory and standard model four-dimensional physics, a seven-dimensional compactification space must be Ricci-flat and admit singularities.[13] For these reasons, the class of toroidal orbifolds T^7/Γ, for a finite group Γ, holds special interest. The necessary geometrical singularities are of finite quotient type, and hence readily permit mathematical analysis. Each is modelled on $(M^1)^{7-n}\times\mathbb{R}^n/G$ for some subgroup $G\subset\Gamma$, where $M^1=S^1$ or the unit interval $I^1=S^1/\mathbb{Z}_2$. Moreover, as we shall see in this paper, under the right conditions one can explicitly describe a well-defined lift of the action of Γ to the 11-dimensional spinorial supercharge. This allows us to determine how much supersymmetry is preserved on the various fixed-point loci ("fixed-planes") of spacetime $T^7/\Gamma\times\mathbb{R}^{3,1}$.

The mathematical problem of identifying candidate compactification spaces with supersymmetric fixed-planes is quite elegant, and divides neatly into four parts. First of all, we must decide on a class of tori to orbifold. A torus T^7 is determined by a choice of a rank seven lattice $\Lambda\subset\mathbb{R}^7$. Throughout this paper we will assume that the lattice has the form $\Lambda:=A_1\oplus A_2^3$, i.e., the direct sum of three copies of the usual hexagonal lattice in the complex plane with one copy of $\mathbb{Z}$. More generally, our analysis applies to compactification on tori T^n modelled on lattices $A_1^a\oplus A_2^b$ with $a+2\,b=n$, $1\leqslant n\leqslant 7$. These are by no means the only lattices from which we could construct our tori. In fact, a particularly interesting case, especially as regards the discussion in Sec. V of this paper, is that of the irreducible lattice $A_7\subset\mathbb{R}^7$, whose automorphism group is one of the maximal finite subgroups of the group G_2. We choose to restrict attention to our particular class of decomposable lattices simply because it is both sufficiently general to subsume the orbifolds studied previously, and easy in this setting to describe the action on the 11-dimensional supercharge in the Clifford algebra.

The second step in identifying the desired supersymmetric orbifolds is to choose a particular class of groups Γ acting on T^7. An action on the torus is an action on $\mathbb{R}^7$ that preserves the lattice Λ. We will consider only group actions which respect the decomposition of Λ into direct summands. Thus, an element $g\in\Gamma$ acts as $\exp(2\pi i\vec{f})$, where $\vec{f}=(f_1,f_2,f_3,f_4)$, with $f_{1,2,3}\in\mathbb{Z}/6$ and $f_4\in\mathbb{Z}/2$. In this way we define a class of representations in which each element acts by rotations in two-dimensional subplanes plus the possibility of a parity reversal on one real coordinate. We call such actions "pseudoplanar representations," and groups which admit such representations "pseudoplanar groups." This eliminates, for the time being, orbifolds constructed from non-Abelian orbifolding groups, an omission we hope to rectify in future work.

Having restricted ourselves to pseudoplanar groups, next we need to enumerate all possible actions. For organizational purposes we wish to index the candidate orbifolds of T^n by their orbifolding groups Γ. For reasons of bounding complexity, in this paper we restrict attention to finite Abelian groups Γ of order $\leqslant 12$. The method we use, explained in detail in Sec. II, consists of classifying the Λ-compatible representations of Γ on $\mathbb{R}^7$, using the decomposition into irreducible characters to determine equivalence classes of group actions. Properly taking into account the automorphisms of the group Γ allows us to distinguish inequivalent group actions, and a matrix formalism makes quick work of computing the dimensions of the fixed-planes corresponding to each element of Γ, and provides for a concise accounting of various geometric data associated with each orbifold.

Finally, given this data, we must have a criterion for determining the exact amount of supersymmetry preserved on each fixed-plane. This fourth and final ingredient is provided by a systematic analysis of lifts of Γ to actions on 11-dimensional spinors. The necessary properties of Clifford algebra are reviewed in Sec. III A, and the criterion, our supersymmetric restriction theorem, is summarized in Table VI. We apply this criterion to the full class of groups Γ acting compatibly on our lattice Λ. In this way, we identify and classify the relatively small number of orbifolds T^n/Γ which maintain some supersymmetry at all points, constructions we refer to as *supersymmetric orbifolds*.

In the language of Ref. 12, the orbifolds considered here are all *hard* orbifolds, i.e., there are no fixed-point-free coordinate "shifts" in the Γ action, since we act directly through a represen-

TABLE I. The "periodic table" listing all supersymmetric, hard, pseudoplanar Abelian orbifolds T^n/Γ of M-theory, for cases $|\Gamma| \leqslant 12$. The labeling system is explained in Sec. II.

tation on the space $\mathbb{R}^7$ over $T^7=\mathbb{R}^7/\Lambda$. By contrast, Joyce's examples of orbifolds of T^7 admitting a resolution as a G_2 manifold[7] are all *soft* orbifolds. In Sec. V we use the first class of G_2 resolvable examples studied by Joyce[14,15] as a launching point for a discussion of the relationship between supersymmetric orbifolds of T^7 and the notion of a G_2-structure (a weaker, necessary condition for the orbifold to admit a G_2 holonomy resolution).

We have collected the results of our search, accounting for all pseudoplanar orbifold groups with low order, into a so-called periodic table of orbifolds, which we include in this introduction as Table I. In Table I we exhibit each supersymmetric orbifold T^n/Γ, with rows corresponding to distinct pseudoplanar groups Γ, listed by increasing group order, and columns corresponding to the representation dimensions $1\leqslant n\leqslant 7$. In each block of this table are listed the complete set of hard supersymmetric orbifolds corresponding to associated n-dimensional representations of Γ compatible with our lattices. Each orbifold is indicated by a particular *label*, which codifies the group action of Γ on T^n in a manner explained in detail in Sec. II. For a subset of the supersymmetric orbifolds, the corresponding orbifold label has an asterix appended. These models are those which split off a separate $S^1/\mathbb{Z}_2$ factor. Such models are the only ones which have 10-dimensional fixed-planes. Owing to this distinction, there is a more direct connection between this class of supersymmetric orbifolds and perturbative heterotic string models than is the case for the orbifolds listed without stars.

There are two natural extensions of our work in this paper which we plan to investigate in the near future. First, we would like to remove the pseudoplanar and abelian restrictions on the Γ action, allowing instead any $\Gamma\subset\mathrm{Aut}(\Lambda)$. In particular this will allow many non-Abelian group actions, which in turn will require a generalization of the supersymmetric restriction proof of Sec. III C. An important step towards such a formulation is described in Sec. IV. It would also be quite valuable to reformulate both the analysis herein and the anomaly cancellation compatibility checks in Refs. 11 and 12 using the theory of principal bundles on orbifolds. In this setting both the supersymmetric restriction criterion and anomaly cancellation mechanism should find expression in the language of characteristic classes of such bundles.

II. HARD ORBIFOLDS, SUPERSYMMETRY, AND CHARACTERS

Each distinct representation R, with real dimension $n\leqslant 7$, of any finite group $\Gamma\subset\mathrm{Aut}(T^n)$, can be used to define an orbifold T^n/Γ, and a corresponding compactification scheme in M-theory.

In this section we describe some useful tools for efficiently accounting for large numbers of such constructions, and explain how these feed naturally into an algorithm for selecting those which satisfy a particular criterion: that the 11-dimensional supercharge Q have nonvanishing components at all points in M^{11}. This is done in two steps. First we review some standard results pertaining to representations of finite groups. Then we explain some original technology which adapts these results to the special purpose of sifting through all possible representations and finding those which satisfy our criterion.

A. Representations of finite Abelian groups

Let Γ be an Abelian (commutative) group, and $\rho:\Gamma\to GL_n(\mathbb{C})$ an n-dimensional complex matrix representation of Γ, i.e., ρ is a homomophism of groups. Since Γ is Abelian, $g_1 g_2 = g_2 g_1$ for all $g_i \in \Gamma$, and each element $g \in \Gamma$ equals its own conjugacy class. A basic result in the theory of representations of finite groups states that for a group of order q, with s conjugacy classes, there are, up to equivalence, s distinct irreducible representations $R_1,\ldots,R_s$ over $\mathbb{C}$. Moreover, if R_i has dimension n_i, then

$$q := \sum_{i=1}^{s} (n_i)^2 \tag{2.1}$$

(Ref. 16, Theorem 2.3). When applied to an Abelian group Γ, this shows that each $n_i = 1$, i.e., that each of the irreducible representations of Γ is itself a *character* (one-dimensional representation) of the group.

In fact, it is a simple matter to describe all the characters of a finite Abelian group. Any finite Abelian group Γ can be written as a direct product of m cyclic groups of orders $q_1,\ldots,q_m$, respectively, so that

$$q = |\Gamma| = q_1 q_2 \cdots q_m . \tag{2.2}$$

A typical element of Γ can be represented by the m-tuple $\vec{a} := (a_1,a_2,\ldots,a_m)$, where $0 \leqslant a_i < q_i$, with composition of elements given by componentwise addition followed by reduction of the ith component to its least non-negative remainder modulo r_i, $i=1,\ldots,m$. Then corresponding to each m-tuple $\vec{c} := [c_1,c_2,\ldots,c_m]$, where $0 \leqslant c_i < r_i$, there exists a character

$$\Gamma_{\vec{c}}(\vec{a}) := \exp\left(2\pi\imath \sum_{i=1}^{m} \left(\frac{a_i c_i}{r_i} \right) \right) \tag{2.3}$$

of Γ, and all q characters arise in this way (Ref. 16, Theorem 2.4). The identity element of Γ corresponds to the trivial character.

The obvious correspondence between the characters $\vec{c}$ and elements $\vec{a}$ of Γ is not canonical. Even though they are each composed of m-tuples of integers modulo q_i, $i=1,\ldots,m$, the isomorphism between these is only well-defined up to an automorphism of the group Γ.

Any n dimensional representation of an Abelian group Γ can be written as a direct sum of n of its characters $\Gamma_{\vec{c}}$, i.e., by the data of an n-tuple $\{\vec{c}^1,\ldots,\vec{c}^n\}$ of m-tuples $\vec{c}^j := [c^j_1,\ldots,c^j_m]$, for $j=1,\ldots,n$. Two such representations are considered *equivalent* if these n-tuples agree as unordered lists.

B. Character tables and *C*-matrices

The set of hard orbifolds T^n/Γ is equivalent to the set of distinct n-dimensional representations of Γ consistent with the lattice that defines T^n. If Γ is a finite Abelian group, then these, in turn, are equivalent to the possible ways to order sets with elements chosen freely from among the characters of Γ, allowing for repetition. It is, therefore, a straightforward exercise, in principle, to construct comprehensive lists of hard orbifolds T^n/Γ. This is so because it is also straightforward

TABLE II. The "elemental" character tables for the groups $\mathbb{Z}_2$, $\mathbb{Z}_3$, and $\mathbb{Z}_4$.

$\mathbb{Z}_2$	Ω	Γ	$\mathbb{Z}_3$	Ω	Σ	$\overline{\Sigma}$	$\mathbb{Z}_4$	Ω	Ψ	Σ	$\overline{\Psi}$
1	+	+	**1**	+	+	+	**1**	+	+	+	+
α	+	−	β	+	1/3	−1/3	γ	+	1/4	1/2	−1/4
			β^2	+	−1/3	1/3	γ^2	+	1/2	+	1/2
							γ^3	+	−1/4	1/2	1/4

to determine the characters for any finite Abelian group, using the following simple algorithm. (As described above, we shall limit our discussion to the case of pseudoplanar groups.)

Each pseudoplanar group is given by the direct product of some number each of $\mathbb{Z}_2$, $\mathbb{Z}_3$, and $\mathbb{Z}_4$ factors. For each of these three "elemental" groups, the list of characters are contained in the character tables exhibited in Table II. In these tables, the elements of the group are enumerated rowwise, while each column corresponds to a distinct character. (Our convention differs from that used in the mathematical literature, wherein character tables typically list group elements as columns and characters as rows. Our choice of convention is more suited to the particular application to physics described in this paper.) For the case of $\mathbb{Z}_2$ the characters are real, i.e., each describes a group action on one real coordinate; in our case this corresponds to an action on an A_1 lattice; a plus sign in the table indicates a trivial action, while a minus sign indicates a sign change $x \to -x$ on the associated coordinate. For the groups $\mathbb{Z}_3$ and $\mathbb{Z}_4$ the nontrivial characters are complex; i.e., each describes a group action on a pair of real coordinates; in our case this corresponds to an action on an A_2 lattice; a plus sign indicates a trivial action, other rational numbers indicate the fraction of a complete counterclockwise rotation in the plane spanned by the relevant A_2 lattice. Such entries are defined modulo 1.

It is useful to assemble the entries of a given character table for a group Γ into a "character matrix" $\sigma(\Gamma)$. The data in Table II can be written as

$$\sigma(\mathbb{Z}_2)=\begin{pmatrix} 0 & 0 \\ 0 & 1/2 \end{pmatrix}, \quad \sigma(\mathbb{Z}_3)=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1/3 & -1/3 \\ 0 & -1/3 & 1/3 \end{pmatrix}, \quad \sigma(\mathbb{Z}_4)=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1/4 & 1/2 & -1/4 \\ 0 & 1/2 & 0 & 1/2 \\ 0 & -1/4 & 1/2 & 1/4 \end{pmatrix}.$$

We adopt the convention that trivial actions (plus signs in the character tables) are represented in the character matrix with zeros, and parity reversals (minus signs in the character tables) are represented with the fraction 1/2. The character matrix for a generic pseudoplanar group with m elemental factors $\Gamma = G_1 \times \cdots \times G_m$, is obtained by combining the character matrices $\sigma(G_i)$ as an outer sum. For instance, the character matrix $\sigma(\mathbb{Z}_2 \times \mathbb{Z}_3)$ can be written as a a two-by-two array of three-by-three block matrices, wherein the upper left block is computed by adding the upper left entry in $\sigma(\mathbb{Z}_2)$ to the entire matrix $\sigma(\mathbb{Z}_3)$, the second block in the first row of blocks in $\sigma(\mathbb{Z}_2 \times \mathbb{Z}_3)$ is given by adding the entry $\sigma(\mathbb{Z}_2)_{12}$ to the entire matrix $\sigma(\mathbb{Z}_3)$, and so forth. The matrix $\sigma(\mathbb{Z}_2 \times \mathbb{Z}_3)$ formed in this way can be usefully re-expressed in terms of a character table, with the result shown in Table III. In Table III, all rational entries are defined modulo 1. Furthermore, a trivial action, denoted by a zero in the corresponding character matrix, is represented in the character table by a plus sign. Finally, on complex characters an entry 1/2, describing a 180 degree rotation, is represented in the table by a minus sign. Upon reconstituting the character matrix $\sigma(\mathbb{Z}_2 \times \mathbb{Z}_3)$ into Table III we have inserted a useful naming convention for the group elements and characters; we have named the order-two generating element α and the order-three generating element β. Similarly, we have named the trivial character Ω, the order two character Λ, the order-three characters Σ and $\overline{\Sigma}$ and the order-six characters Ψ and $\overline{\Psi}$.

By repeating the operation of combining character matrices as outer sums, in the manner described above, the character matrix and, equivalently, the character table for any pseudoplanar

TABLE III. The character table for the group $\mathbb{Z}_2\times\mathbb{Z}_3$.

$\mathbb{Z}_2\times\mathbb{Z}_3$	Ω	Σ	$\overline{\Sigma}$	Λ	Ψ	$\overline{\Psi}$
1	+	+	+	+	+	+
β	+	1/3	−1/3	+	1/3	−1/3
β^2	+	−1/3	1/3	+	−1/3	1/3
α	+	+	+	−	−	−
$\alpha\beta$	+	1/3	−1/3	−	−1/6	1/6
$\alpha\beta^2$	+	−1/3	1/3	−	1/6	−1/6

group can be generated readily from the three elemental character matrices $\sigma(\mathbb{Z}_2)$, $\sigma(\mathbb{Z}_3)$, and $\sigma(\mathbb{Z}_4)$. For an illustration in the case $\Gamma=(\mathbb{Z}_2)^3$, see Table VII. Here $\Omega:=\Gamma_{[0,0,0]}$ is the trivial character, and the group elements down the left-hand side are indexed in the usual binary ordering:

$$1:=(0,0,0)\,,\quad \gamma:=(0,0,1)\,,\quad \beta:=(0,1,0)\,,\ldots,\alpha\beta\gamma:=(1,1,1).$$

In general, however, there is quite a lot of physically irrelevant redundancy in the full character table for a given orbifolding group Γ. For instance, in the case of $\Gamma=\mathbb{Z}_2\times\mathbb{Z}_3$, the characters which we have named Σ and Ψ describe group actions on a complex coordinate z. However, if we describe these same characters in terms of their actions on the complex conjugate $\overline{z}$, these same characters would appear to act precisely as do $\overline{\Sigma}$ and $\overline{\Psi}$ on the original coordinate z. Thus, complex characters are physically indistinguishable from their conjugates. Since conjugate pairs of characters can be can be mapped into each other by a merely semantical renaming of the coordinates, we can more efficiently describe the relevant representation theory of this group by considering a restricted set of essential nontrivial characters. For the case of $\Gamma=\mathbb{Z}_2\times\mathbb{Z}_3$, these would be Λ, Σ and Ψ. At the same time, elements with order greater than two have nontrivial inverses. These inverse elements have precisely the same locus of fixed-points in the physical space T^n/Γ as do the original elements. So we can characterize the geometry of a given orbifold in terms of a representative set of essential nontrivial elements, thereby removing this second, physical, redundancy.

The number of nontrivial representative elements of any finite Abelian group is equivalent to the number of essential nontrivial characters. This number provides a "physical rank" r of the group. By including only the essential nontrivial elements and characters, we can replace the full character table with an "abbreviated character table." For the case of $\Gamma=\mathbb{Z}_2\times\mathbb{Z}_3$, we would thereby replace Table III with the abbreviated character table shown in Table IV. Notice that we may choose at will the ordering of the elements (rows) and, independently, the ordering of the characters (columns) when we construct a character table; there is no *a priori* canonical ordering. Notice, as well, that no information is sacrificed by replacing a full character table with an abbreviated character table.

By multiplying the abbreviated character table by the order of the group we define an integer-valued, square $r\times r$ matrix, which we denote $C(\Gamma)$. For the case of $\Gamma=\mathbb{Z}_2\times\mathbb{Z}_3$, this is easily obtained from Table IV by multiplying the entries by 6, which is the order of $\mathbb{Z}_2\times\mathbb{Z}_3$. In this way we determine

TABLE IV. The abbreviated character table for the group $\mathbb{Z}_2\times\mathbb{Z}_3$.

$\mathbb{Z}_2\times\mathbb{Z}_3$	Γ	Σ	Ψ
α	1/2	0	1/2
β	0	1/3	1/3
$\alpha\beta$	1/2	1/3	−1/6

TABLE V. The representation $R=(322)$ of the group $\mathbb{Z}_2\times\mathbb{Z}_3$.

$\mathbb{Z}_2\times\mathbb{Z}_3$	x_1	x_2	x_3	z_1	z_2
α	$-$	$-$	$-$	$+$	$-$
β	$+$	$+$	$+$	1/3	1/3
$\alpha\beta$	$-$	$-$	$-$	1/3	$-1/6$

$$C(\mathbb{Z}_2\times\mathbb{Z}_3)=\begin{pmatrix} 3 & 0 & 3 \\ 0 & 2 & 2 \\ 3 & 2 & -1 \end{pmatrix}. \tag{2.4}$$

Of course, owing to the freedom to independently rearrange the rows and the columns of the abbreviated character matrix, the corresponding matrix $C(\Gamma)$ is defined only up to similar reorderings. However, such flexibility can always be used to render the C-matrix symmetrical. We deem this canonical. It is also possible, while keeping $C(\Gamma)$ symmetrical, to arrange the rows and columns so that the corresponding elements and characters have monotonically increasing order. This too, we deem canonical.

All the information described by Table III is also contained in the matrix $C(\mathbb{Z}_2\times\mathbb{Z}_3)$ shown in (2.4). It is interesting that quite a lot of information pertaining to properties of any finite Abelian group, including the complete representation theory can be codified in a symmetric matrix $C\in \mathrm{GL}(r,\mathbb{Z})$. As it turns out, the matrices $C(\Gamma)$ are valuable tools in the search for supersymmetric orbifolds. The matrices $C(\Gamma)$ for each of the pseudoplanar groups with group order $\leqslant 12$ are listed in the Appendix.

C. The enumeration of distinct orbifolds

A representation of Γ is designated by choosing a set of real and complex characters, including the possibility of degeneracy, from the list of essential nontrivial characters. Generally, order-two characters are real, while characters with higher order are complex. Therefore, if we select a order-two characters and b higher-order characters, the corresponding representation will act on $n=a+2b$ real dimensions, $2b$ of which are complexified. Since the set of essential nontrivial characters correlates with the columns of the matrix $C(\Gamma)$, we can unambiguously designate a representation by an ordered list of r multiplicities, each indicating the number of real coordinates transforming according to a corresponding character. The ordering of the multiplicities corresponds to the ordering of the characters described by the rows of the C matrix. Of course, the multiplicities corresponding to complex characters are necessarily even, while those corresponding to order-two characters may be even or odd.

As an example, in the case of the group $\Gamma=\mathbb{Z}_2\times\mathbb{Z}_3$, the physical rank is 3, and the corresponding C-matrix is given by (2.4). In this case, each representation is given by a 3-tuple, $R=(a_1,a_2,a_3)$, where a_1, a_2 and a_3 are the number of real coordinates transforming according to the characters Λ, Σ, and Ψ, respectively. In this case, $a_1\in\mathbb{N}$ since the character Γ is real, and $a_{2,3}\in 2\,\mathbb{N}$ since the characters Σ and Ψ are complex. To be quite specific, the representation of $\mathbb{Z}_2\times\mathbb{Z}_3$ described by the three-tuple $R=(3\,2\,2)$ is a representation which acts on $3+2+2=7$ real coordinates. In this case, however, four of the real coordinates are complexified as two complex coordinates. The first multiplicity (3) in the label (322) indicates that three real coordinates, say $x_{1,2,3}$ transform according to the character Λ, the second multiplicity (2) indicates that two real coordinates, combined into one complex coordinate, say z_1, transform according to the character Σ, and the third multiplicity (2) indicates that one more complex coordinate, say z_2, transforms according to the character Ψ. The corresponding group actions are shown in Table V.

The particular orbifold T^n/Γ which corresponds to a given representation R generically includes a locus of special points which remain invariant under elements of Γ. These generically constitute hyperplanes of various dimensionalities which intersect, forming an intricate network.

One of our primary concerns is to decide what sorts of physics, in the form of localized states, are described by these planes and their intersections. In the next section we will describe in detail how one studies the issue of how many supercharges are retained on these. A primary consideration in this regard is, of course, to describe the number of dimensions which are spanned by the fixed-planes associated with each group element.

There is a simple formula which allows one to compute the set of dimensions corresponding to the r representative nontrivial elements. This formula is most easily described in terms of another useful matrix, which we call $M(\Gamma)$, obtained from $C(\Gamma)$ by replacing all zero entries with ones, and all nonzero entries by zeros. By way of illustration, we focus again on the example $\Gamma = \mathbb{Z}_2 \times \mathbb{Z}_3$. In this case, this prescription, applied to $C(\mathbb{Z}_2 \times \mathbb{Z}_3)$, as given in (2.4), yields

$$M(\mathbb{Z}_2 \times \mathbb{Z}_3) = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} . \tag{2.5}$$

For a given orbifold, described by the representation R of a group Γ, the dimensionality of the fixed-planes of each representative element is described by another r-tuple, $d(R)$, given by

$$d(R) = (\,11 - n\,)\,\mathbf{1} + R\,M\,, \tag{2.6}$$

where $\mathbf{1}$ is the row vector with ones in each entry and $n = R \cdot \mathbf{1} = \Sigma_i a_i$. As an example, for the particular orbifold described by $R = (322)$, we compute $n = 7$ and

$$d(122) = (11-7)\,(1 \quad 1 \quad 1) + (3 \quad 2 \quad 2) \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} = (6 \quad 7 \quad 4)\,. \tag{2.7}$$

Thus, the respective fixed-planes associated with the elements α, β, and $\alpha\beta$ have dimensionality 6, 7, and 4. This result can be verified from the precise group actions in Table V.

Now we have all the information we need to form comprehensive lists of all pseudoplanar orbifolds, including all the data pertaining to the group actions. First we choose a group Γ. Then, we form lists of orbifolds T^n/Γ, for each value of $1 \leqslant n \leqslant 7$ by sequencing through the ordered partitions of n into r non-negative integers, in the manner described above. For the case of $T^7/(\mathbb{Z}_2 \times \mathbb{Z}_3)$ orbifolds, for example, we create the sequence of 3-tuples (a_1, a_2, a_3) which describe ordered partitions of $n = 7$ into sums of $r = 3$ nonnegative integers, subject to the constraints that $a_1 \in \mathbb{N}$ and $a_{2,3} \in 2\,\mathbb{N}$. The complete list of such 3-tuples is given in the usual ascending order in mod 7 arithmetic, as (106), (124), (142), (160), (304), (322), (340), (502), (520), (700). We describe these ordered sets of multiplicities as orbifold *labels*. In each case the corresponding group actions can be determined by dividing the C-matrix by the group order and then selecting rows from this divided C-matrix with the appropriate multiplicity indicated by the corresponding label. The group actions for the orbifold $T^7/(\mathbb{Z}_2 \times \mathbb{Z}_3)_{(322)}$, described above, were obtained in precisely this way, and stand as an example of this methodology.

D. The periodic table

We use the algorithm described in the previous paragraph to systematically cycle through each orbifold label of each pseudoplanar group, obtaining all of the relevant group actions in each case. In each instance, each element of Γ can be represented, by arranging the coordinates judiciously, by a set of three fractional rotations (f_1, f_2, f_3) describing counterclockwise rotations in respective planes spanned by three A_2 lattices, plus possibility of a parity reversal in one real coordinate, which we codify as the binary choice $P \in \{0,1\}$, describing the respective absence or presence of a parity reversal.

As it turns out, the values of $(f_1, f_2, f_3 \mid P)$ for each element of Γ corresponding to a given orbifold label provide all the data necessary to resolve the amount of supersymmetry on the corresponding orbifold plane. The precise corrrespondence is derived in the next section, where it is presented as a supersymmetric restriction theorem. This result says that an orbifold plane is supersymmetric if and only if there is at least one way to add or subtract the three corresponding fractions f_i to obtain, in the case $P=0$, an even integer, or, in the case $P=1$, any integer (even or odd).

For our restricted class of lattices, a given element is compatible only if the three f_i are each elements of the set $\{0, 1/2, \pm 1/3, \pm 1/4, \pm 1/6\}$ mod 1. (There are, therefore $7^3 \times 2 = 686$ possibilities for each element.) It is possible to have compatible elements which do not have compatible products. For example, in the case $\Gamma = \mathbb{Z}_3 \times \mathbb{Z}_4$, there are several models which pass the criteria of the supersymmetric restriction theorem, except that the representations in question involve order-twelve rotations in at least one plane. These would be acceptable as supersymmetric orbifolds of $\mathbb{R}^n$, but not of T^n, because there is no lattice in $\mathbb{C}$ compatible with such a rotation. The number of global orbifolds T^n/Γ is therefore much smaller than the number of orbifold singularities which can be modelled locally as $\mathbb{R}^n/\Gamma$.

The search for supersymmetric orbifolds consists of four steps. First, for a given choice of Γ and n, we generate the complete list of compatible orbifold labels. Second, for each orbifold label, we use the matrix $C(\Gamma)$ to determine the data $(f_1, f_2, f_3 \mid P)$ for each of the r representative elements. Third, we apply the supersymmetric restriction theorem to remove each orbifold which has any element whose data does not meet the restriction criterion. Fourth, we examine the list of orbifolds which satisfy these restrictions, and we remove cases which are redundant. We have created a number of Mathematica functions which fully automate this process, and have used this to generate Table I which appears in the introduction. In this way, we can easily generalize our periodic table to arbitrary group order.

Our periodic table includes all of the hard global *M*-theory orbifolds described previously by other authors as well as by ourselves. For instance the $S^1/\mathbb{Z}_2$ model corresponds to the original *M*-theory model described in Refs. 17 and 18. The four T^4/Γ models correspond to the four global orbifold limits of $K3$. The $T^5/\mathbb{Z}_2$ model was discussed in Refs. 19 and 20. (It was the study of that simple model which first implicated wandering five-branes as a means of unifying ostensibly unique vacua into classes linked by phase transitions.) The four starred models T^5/Γ correspond to the four global orbifold limits of $K3 \times S^1/\mathbb{Z}_2$ and were studied in Refs. 8–10 and 21. The $T^7/(\mathbb{Z}_2)^3$ model with label (2220001) was described in Ref. 11 and the $T^7/(\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_3)$ with label (0122022) was described in Ref. 12. Finally, resolutions of the softenings of the $T^7/(\mathbb{Z}_2)^3$ model with label (1111111) were presented by Joyce in Refs. 14, 15, and 7 as prototype G_2 manifolds, and studied by Acharya as candidate *M*-theory compactification spaces[22,23] (see also Sec. V).

III. A SUPERSYMMETRIC RESTRICTION THEOREM

In the bulk of M^{11} (i.e., at all points not within the locus of orbifold fixed-planes) the 11-dimensional supercharge is completely preserved. It is within the locus of fixed-planes, therefore, that the issue of supercharge preservation becomes important. Since the supercharge transforms nontrivially under elements of Γ, only those components of Q which remain invariant are not projected to zero on those spacetime points inert under those same elements. The invariant components of Q typically resolve as a d-dimensional spinor, where d is the total dimension of the invariant locus associated with that element near a given point. Precisely how many irreducible $\mathrm{SO}(d-1,1)$-spinors are included in this set determines the amount of local sypersymmetry preserved on that fixed plane. For the sorts of pseudoplanar orbifolds defined above, it is possible to delineate a concise criterion for selecting those which, in this way, retain supersymmetry. In this section, which is relatively technical, we derive this supersymmetric restriction theorem. We start by establishing notational conventions and stating the result, and then prove it by analyzing the question of how the spinorial supercharge is influenced by lifts of various elements of finite subgroups of SO(10,1).

A. Notations

We use space–time coordinates $x^I \equiv \{x^0, x^i\}$, where $i = 1, \ldots, 3, 5, \ldots 11$, and gamma matrices Γ_I, which satisfy the Clifford algebra $\{\Gamma_I, \Gamma_J\} = 2\,\eta_{IJ}$, where $\eta_{IJ} = \mathrm{diag}(-+\cdots+)$ is the flat metric. The gamma matrices are chosen such that Γ_0 is anti-Hermitian, $\Gamma_0^\dagger = -\Gamma_0$, and Γ_i are Hermitian, $\Gamma_i^\dagger = \Gamma_i$. It is sometimes useful to define $\Gamma_4 = i\,\Gamma_0$. Another useful identity is $\Gamma_{11} = i\,\Gamma_1 \cdots \Gamma_{10}$. The matrices $\Gamma_{IJ} = \frac{1}{2}[\,\Gamma_I, \Gamma_J\,]$ are the generators of spin (11). We define a complex structure by writing the six real coordinates $x_{5,\ldots,10}$ in terms of three complex coordinates, according to $z_{1,2,3} \equiv x_{5,7,9} + i\,x_{6,8,10}$.

Consider an element which acts as simultaneous rotations in three complex planes, with coordinates z_1, z_2, and z_3, and possibly a parity flip on one real coordinate x^{11},

$$\alpha : (\,z_1, z_2, z_3; x^{11}) \to (\,e^{i\,\theta_1} z_1, e^{i\,\theta_2} z_2, e^{i\,\theta_3} z_3; (-)^P x^{11}\,), \tag{3.1}$$

with $\theta_i = 2\,\pi\,f_i$. The three rational numbers f_i describe the fraction of a complete rotation imparted, respectively, on the three complex planes. The parameter $P \in \{0,1\}$ indicates whether or not the element includes a parity flip. The order of α is given by the least common positive integer multiple of the denominators of the reduced form of the three f_i's and also $(1/2)^P$.

For a given choice of $(\,f_1, f_2, f_3 \,|\, P\,)$, Eq. (3.1) describes a particular global SO(10,1) transformation plus the possibility of a parity transformation. On spinors this induces $\psi \to \Omega\,\psi$, where

$$\Omega = \exp(\,\tfrac{1}{4}\,\theta^{IJ}\,\Gamma_{IJ}\,)\,(\,\Gamma_{11}\,)^P \tag{3.2}$$

and where θ^{IJ} are the parameters of the SO(10,1) transformation. From (3.1) we read off the nonvanishing parameters as $\theta^{5,6} = -\theta^{6,5} \equiv \theta_1$, $\theta^{7,8} = -\theta^{8,7} \equiv \theta_2$, and $\theta^{9,10} = -\theta^{10,9} \equiv \theta_3$. Thus we can rewrite (3.2) as

$$\Omega = \exp(\,\tfrac{1}{2}\,\theta_1\,\Gamma_{5,6}\,)\,\exp(\,\tfrac{1}{2}\,\theta_2\,\Gamma_{7,8}\,)\,\exp(\,\tfrac{1}{2}\,\theta_3\,\Gamma_{9,10}\,)(\,\Gamma_{11}\,)^P\,. \tag{3.3}$$

The supercharge Q is an 11-dimensional Majorana spinor, which transforms precisely as $Q \to \Omega\,Q$. It is useful to append subscripts to spinors, and to spinorial operators, to indicate dimensionality. We thus write the 11-dimensional supercharge Q as $Q_{(11)}$ to indicate that this field takes its values in spin (11). Similarly, we write the operator Ω, defined in (3.3), as $\Omega_{(11)}$ to indicate that this object operates on 11-dimensional spinors.

If the fixed-point locus associated with an element (3.1) has dimensionality d, then, in the neighborhood of this locus, the structure group is broken from SO(10,1) down to $\mathrm{SO}(d-1,1) \times \mathrm{SO}(11-d)$. Accordingly, we write the supercharge as a tensor product of an $\mathrm{SO}(d-1,1)$ fixed-plane spinor and an $\mathrm{SO}(11-d)$ "normal" spinor, as $Q_{(11)} = Q_{(d)} \otimes Q_{(11-d)}$. Similarly, the operator Ω decomposes as $\Omega_{(11)} = \Omega_{(d)} \otimes \Omega_{(11-d)}$. In order to resolve the amount of unbroken fixed-plane supersymmetry, we solve the equation $Q_{(11)} = \Omega_{(11)}\,Q_{(11)}$, and then count the degrees of freedom which describe the most general solution.

The analysis described below is completely general, modulo irrelevant reordering of coordinates. Thus, in this section we consider the element $(\,0, 0, f \,|\, 0\,)$ equivalent to $(\,0, f, 0 \,|\, 0\,)$, for instance.

B. Statement of the theorem

The conclusions which we draw in each of the seven cases discussed in Sec. III C can be easily summarized as follows. The condition for supersymmetry on a fixed-plane associated with any element $\alpha \in \Gamma$, of the special sort characterized by (3.1), is

$$f_1 \pm f_2 \pm f_3 \in \begin{cases} 2\,\mathbb{Z}, & P = 0 \\ \mathbb{Z}, & P = 1 \end{cases} \tag{3.4}$$

TABLE VI. The seven sorts of elements, listed along with the associated fixed-plane dimensionality and the generic amount of supersymmetry retained when the conditions listed in (3.4) are satisfied. The $d=6$ and the $d=4$ cases have exceptions. In the $d=6$ case, if $f=1/2$ then the supersymmetry is merely halved, not quartered. In the $d=4$ case if $|f_1|$, $|f_2|$, and $|f_3|$ are drawn, one each, from either set (1/2, 1/3, 1/6) or (1/2, 1/4, 1/4) then supersymmetry is merely quartered, not eighthed.

$(f_1, f_2, f_3 \mid (-)^P)$	d_{fixed}	SUSY
$(0,0,0 \mid -)$	10	1/2
$(0,0,f \mid +)$	9	NONE
$(0,0,f \mid -)$	8	NONE
$(0,f,\pm f \mid +)$	7	1/2
$(0,f,\pm f \mid -)$	6	1/4*
$(f_1,f_2,f_3 \mid +)$	5	1/4
$(f_1,f_2,f_3 \mid -)$	4	1/8*

for any one of the four possible choices of unspecified signs. If condition (3.4) is satisfied, then supersymmetry is generically reduced to the minimal amount possible in the dimensionality of the fixed plane. Exceptions occur in cases where $P=1$, when one of the sums in (3.4) gives an even integer and another gives an odd integer. In such cases, the fixed-plane supersymmetry is twice the minimal amount. These results are reflected in Table VI.

Note that this result applies to orbifolds $\mathbb{R}^7/\Gamma$ as well as to orbifolds T^7/Γ. In the former case, there is no restriction on the choices of the f_i's other than that they should be rational. In the latter case, there are additional constraints which follow from the requirement that $\Gamma \subset \mathrm{Aut}(T^7)$. For the cases described in Sec. III C, this requirement amounts to the restriction that $f_{1,2,3}$ must be chosen from the set $\{0, 1/2, \pm 1/3, \pm 1/4, \pm 1/6\}$ mod 1.

C. Proof of the theorem

The result is established by explicitly analyzing how the spinorial supercharge is influenced by lifts of various elements of finite subgroups of SO(10,1).

Ten-dimensional fixed-planes: The only transformation (3.1) which has 10-dimensional fixed-planes is an order-two element acting as $(f_1,f_2,f_3 \mid P)=(0,0,0 \mid 1)$. In this case, the supercharge transforms as $Q_{(11)} \to \Gamma_{11} Q_{(11)}$. We decompose $Q_{(11)}$ according to $Q_{(11)}=Q_{(10)R} \oplus Q_{(10)L}$, where $Q_{(10)R,L}=\pm \Gamma_{11} Q_{(10)R,L}$ are 10-dimensional Majorana–Weyl projections of $Q_{(11)}$. The fixed-plane condition, $Q_{(11)}=\Omega_{(11)} Q_{(11)}$ can now be written

$$Q_{(10)\,R,L}=\pm Q_{(10)\,R,L}\,. \tag{3.5}$$

This equation is easy to solve. On the fixed-plane we have $Q_{(11)} \to Q_{(10)R}$. Thus, the bulk supersymmetry is *halved* on the fixed-planes.

Nine-dimensional fixed-planes: Nine-dimensional fixed-planes correspond to elements $(f_1,f_2,f_3 \mid P)=(0,0,f \mid 0)$, where $f \neq 0$ mod 1. In this case, the supercharge transforms as $Q_{(11)} \to \Omega_{(11)} Q_{(11)}$, where

$$\Omega_{(11)}=\exp(\pi f \Gamma_9 \Gamma_{10})\,. \tag{3.6}$$

We write $Q_{(11)}$ as a tensor product of a nine-dimensional fixed-plane spinor with an SO(2) "normal" spinor, according to $Q_{(11)}=Q_{(9)} \otimes Q_{(2)}$. Similarly, we use the following representation for the gamma matrices,

$$\Gamma_\mu = \hat{\Gamma}_\mu \otimes \mathbf{1}, \quad \mu = 1, \ldots, 8,$$
$$\Gamma_{8+i} = \hat{\Gamma}_9 \otimes \sigma_i, \quad i = 1,2, \tag{3.7}$$
$$\Gamma_{11} = \hat{\Gamma}_9 \otimes \sigma_3,$$

where $\{\hat{\Gamma}_\mu, \hat{\Gamma}_9\}$ are nine-dimensional gamma matrices and σ_i are the Pauli matrices. In addition, we decompose the normal spinors according to $Q_{(2)} = Q_{(2)R} + Q_{(2)L}$ where $Q_{(2)R,L} = \pm \sigma_3 Q_{(2)R,L}$. Using these conventions, and also the identity $\sigma_1 \sigma_2 = i \sigma_3$, we can write

$$Q_{(11)} = Q_{(9)} \otimes (Q_{(2)R} + Q_{(2)L}),$$
$$\Omega_{(11)} = \exp(i \pi f \mathbf{1} \otimes \sigma_3). \tag{3.8}$$

The fixed-plane condition $Q_{(11)} = \Omega_{(11)} Q_{(11)}$ can now be written as

$$Q_{(9)} \otimes Q_{(2)R,L} = e^{\pm i \pi f} Q_{(9)} \otimes Q_{(2)R,L}. \tag{3.9}$$

Because there are no nontrivial solutions to either of these equations, subject to the restriction that $f \neq 0 \bmod 1$, we conclude that, as we approach a fixed-nine-plane, $Q_{(11)} \to 0$. Thus supersymmetry is broken completely on any nine-dimensional fixed-plane associated with an element (3.1).

Eight-dimensional fixed-planes: Eight-dimensional fixed-planes correspond to elements $(f_1, f_2, f_3 \mid P) = (0, 0, f \mid 1)$, where $f \neq 0 \bmod 1$. In this case, the supercharge transforms as $Q_{(11)} \to \Omega_{(11)} Q_{(11)}$, where

$$\Omega_{(11)} = \exp(\pi f \Gamma_9 \Gamma_{10}) \Gamma_{11}. \tag{3.10}$$

We write $Q_{(11)}$ as a tensor product of an eight-dimensional fixed-plane spinor with an SO(3) "normal" spinor, according to $Q_{(11)} = Q_{(8)} \otimes Q_{(3)}$, and we represent the gamma matrices precisely as in (3.7). In addition we decompose the SO(7,1) spinors via $Q_{(8)} = Q_{(8)R} + Q_{(8)L}$ where $Q_{(8)R,L} = \pm \hat{\Gamma}_9 Q_{(8)R,L}$, and write the normal spinors as $Q_{(3)} = Q_{(2)R} + Q_{(2)L}$, where $Q_{(2)R,L} = \pm \sigma_3 Q_{(2)R,L}$. We introduce a useful shorthand notation whereby $L \equiv Q_{(2)L}$ and $R \equiv Q_{(2)R}$. Using these conventions, and also the identity $\sigma_1 \sigma_2 = i \sigma_3$, we can write

$$Q_{(11)} = (Q_{(8)R} + Q_{(8)L}) \otimes (R + L),$$
$$\Omega_{(11)} = \exp(i \pi f \mathbf{1} \otimes \sigma_3) \hat{\Gamma}_9 \otimes \sigma_3. \tag{3.11}$$

The fixed-plane condition $Q_{(11)} = \Omega_{(11)} Q_{(11)}$ can now be written

$$Q_{(8)R,L} \otimes R = \pm e^{i \pi f} Q_{(8)R,L} \otimes R,$$
$$Q_{(8)R,L} \otimes L = \mp e^{-i \pi f} Q_{(8)R,L} \otimes L. \tag{3.12}$$

Because there are no nontrivial solutions to any of these four equations, subject to the restriction that $f \neq 0 \bmod 1$, we conclude that, as we approach an eight-dimensional fixed-plane, $Q_{(11)} \to 0$. Thus, supersymmetry is broken completely on any eight-dimensional fixed-plane associated with an element (3.1).

Seven-dimensional fixed-planes: Seven-dimensional fixed-planes correspond to elements $(f_1, f_2, f_3 \mid P) = (0, f, f' \mid 0)$, where $f \neq 0 \bmod 1$ and $f' \neq 0 \bmod 1$. In this case, the supercharge transforms as $Q_{(11)} \to \Omega_{(11)} Q_{(11)}$, where

$$\Omega_{(11)} = \exp(\pi f \Gamma_7 \Gamma_8) \exp(\pi f' \Gamma_9 \Gamma_{10}). \tag{3.13}$$

We write $Q_{(11)}$ as a tensor product of a seven-dimensional fixed-plane spinor with an SO(4) ''normal'' spinor according to $Q_{(11)}=Q_{(7)}\otimes Q_{(4)}$. Similarly, we use the following representation for the gamma matrices,

$$\begin{aligned}\Gamma_{\mu}&=\hat{\Gamma}_{\mu}\otimes\mathbf{1}, \quad \mu=1,\ldots,6,\\ \Gamma_{6+i}&=\hat{\Gamma}_{7}\otimes\gamma_{i}, \quad i=1,\ldots,4,\\ \Gamma_{11}&=\hat{\Gamma}_{7}\otimes\gamma_{5},\end{aligned} \tag{3.14}$$

where $\{\hat{\Gamma}_{\mu},\hat{\Gamma}_{7}\}$ are the seven-dimensional Gamma matrices and γ_i are four-dimensional gamma matrices. In addition, we decompose the normal SO(4) SO(4)$\rightarrow$SO(2)$\times$SO(2), where SO(2)$\times$SO(2) is a convenient maximal subgroup of SO(4). Thus, we write the ''normal'' spinor as $Q_{(4)}=Q_{(2)}\otimes Q_{(2)}$, and the four-dimensional gamma matrices as $\gamma_{1,2}=\sigma_{1,2}\otimes\mathbf{1}$ and $\gamma_{3,4}=\sigma_3\otimes\sigma_{1,2}$, where σ_i are Pauli matrices. Also, using the identities $\gamma_5=\gamma_1\gamma_2\gamma_3\gamma_4$ and $\sigma_1\sigma_2=i\,\sigma_3$, we derive $\gamma_5=-\sigma_3\otimes\sigma_3$. This allows us to rewrite (3.14) as

$$\begin{aligned}\Gamma_{1,\ldots,6}&=\hat{\Gamma}_{1,\ldots,6}\otimes\mathbf{1}\otimes\mathbf{1},\\ \Gamma_{7,8}&=\hat{\Gamma}_{7}\otimes\sigma_{1,2}\otimes\mathbf{1},\\ \Gamma_{9,10}&=\hat{\Gamma}_{7}\otimes\sigma_{3}\otimes\sigma_{1,2},\\ \Gamma_{11}&=-\hat{\Gamma}_{7}\otimes\sigma_{3}\otimes\sigma_{3}.\end{aligned} \tag{3.15}$$

Note that the normal spinor can be decomposed as $Q_{(4)}=Q_{(4)\,R}+Q_{(4)\,L}$ where $Q_{(4)\,R,L}=\pm\gamma_5\,Q_{(4)\,R,L}$. In terms of SO(2)$\times$SO(2)$\subset$SO(4), however, these same objects can be written as

$$\begin{aligned}Q_{(4)R}&=Q_{(2)R}\otimes Q_{(2)L}+Q_{(2)L}\otimes Q_{(2)R},\\ Q_{(4)L}&=Q_{(2)R}\otimes Q_{(2)R}+Q_{(2)L}\otimes Q_{(2)L},\end{aligned} \tag{3.16}$$

where $Q_{(2)\,R,L}=\pm\sigma_3\,Q_{(2)\,R,L}$. Using these results we can decompose the 11-dimensional supercharge in two steps. First, we write $Q_{(11)}=Q_{(7)}\otimes(\,Q_{(4)\,R}+Q_{(4)\,L}\,)$ and then we rewrite the terms $Q_{(4)\,R,L}$ using (3.16). We now define $LL\equiv Q_{(2)L}\otimes Q_{(2)L}$, and similar expressions for LR, RL, and RR. Using these definitions, and also the conventions introduced above, we can write

$$\begin{aligned}Q_{(11)}&=Q_{(7)}\otimes(\,LL+LR+RL+RR\,),\\ \Omega_{(11)}&=\exp(\,i\,\pi\,f\,\mathbf{1}\otimes\sigma_3\otimes\mathbf{1}+i\,\pi\,f'\,\mathbf{1}\otimes\mathbf{1}\otimes\sigma_3\,).\end{aligned} \tag{3.17}$$

The fixed-plane condition $Q_{(11)}=\Omega_{(11)}\,Q_{(11)}$ can now be written as

$$\begin{aligned}Q_{(7)}\otimes LL&=e^{-i\,\pi\,(f+f')}\,Q_{(7)}\otimes LL,\\ Q_{(7)}\otimes LR&=e^{-i\,\pi\,(f-f')}\,Q_{(7)}\otimes LR,\\ Q_{(7)}\otimes RL&=e^{+i\,\pi\,(f-f')}\,Q_{(7)}\otimes RL,\\ Q_{(7)}\otimes RR&=e^{+i\,\pi\,(f+f')}\,Q_{(7)}\otimes RR.\end{aligned} \tag{3.18}$$

Therefore, as we approach a fixed-seven-plane, the bulk supercharge is projected according to

$$Q_{(11)}\rightarrow\begin{cases} Q_{(7)}\otimes(\,LL+RR\,), & f+f'\in 2\,\mathbb{Z},\\ Q_{(7)}\otimes(\,LR+RL\,), & f-f'\in 2\,\mathbb{Z},\end{cases} \tag{3.19}$$

and is projected to zero if neither of these conditions are met. Thus we retain some supersymmetry on a fixed-seven-plane if and only if one of the two sums $f\pm f'$ is an even integer. This is the case only if $f=\pm f'$ mod 1. In such cases, the bulk supersymmetry is *halved* on the fixed-plane in question.

Six-dimensional fixed-planes: Six-dimensional fixed-planes correspond to elements $(f_1,f_2,f_3\,|\,P)=(0,f,f'\,|\,1)$, where $f\neq 0$ mod 1 and $f'\neq 0$ mod 1. In this case the supercharge transforms as $Q_{(11)}\rightarrow\Omega_{(11)}\,Q_{(11)}$, where

$$\Omega_{(11)}=\exp(\,\pi f\,\Gamma_7\,\Gamma_8\,)\exp(\,\pi f'\,\Gamma_9\,\Gamma_{10}\,)\,\Gamma_{11}\,. \tag{3.20}$$

We write $Q_{(11)}$ as a tensor product of a six-dimensional fixed-plane spinor with an SO(5) ''normal'' spinor according to $Q_{(11)}=Q_{(6)}\otimes Q_{(5)}$, and we represent the Gamma matrices precisely as in (3.15). In addition, we decompose the SO(5,1) spinors via $Q_{(6)}=Q_{(6)\,R}+Q_{(6)\,L}$, where $=Q_{(6)\,R,L}=\pm\hat{\Gamma}_7\,Q_{(6)\,R,L}$, and write the normal SO(5) spinors as $Q_{(5)}=Q_{(4)\,R}\oplus Q_{(4)\,L}$, where $Q_{(4)\,R,L}$ are given by (3.16). Now, using the notation introduced above, we can write

$$\begin{aligned} Q_{(11)}&=(\,Q_{(6)R}+Q_{(6)L}\,)\otimes(\,LL+LR+RL+RR\,),\\ \Omega_{(11)}&=-\exp(\,i\,\pi f\,\mathbf{1}\otimes\sigma_3\otimes\mathbf{1}+i\,\pi f'\,\mathbf{1}\otimes\mathbf{1}\otimes\sigma_3\,)\,\hat{\Gamma}_7\otimes\sigma_3\otimes\sigma_3\,. \end{aligned} \tag{3.21}$$

The fixed-plane condition $Q_{(11)}=\Omega_{(11)}\,Q_{(11)}$ can now be written as

$$\begin{aligned} rQ_{(6)\,R,L}\otimes LL&=\mp e^{-i\,\pi(f+f')}\,Q_{(7)}\otimes LL,\\ Q_{(6)\,R,L}\otimes LR&=\pm e^{-i\,\pi(f-f')}\,Q_{(7)}\otimes LR,\\ Q_{(6)\,R,L}\otimes RL&=\pm e^{+i\,\pi(f-f')}\,Q_{(7)}\otimes RL,\\ Q_{(6)\,R,L}\otimes RR&=\mp e^{+i\,\pi(f+f')}\,Q_{(7)}\otimes RR\,. \end{aligned} \tag{3.22}$$

Therefore, as we approach a fixed-six-plane, the bulk supercharge is projected according to

$$Q_{(11)}\rightarrow\begin{cases} Q_{(6)L}\otimes(\,LL+RR\,), & f+f'\in 2\,\mathbb{Z},\\ Q_{(6)R}\otimes(\,LR+RL\,), & f-f'\in 2\,\mathbb{Z},\\ Q_{(6)R}\otimes(\,LL+RR\,), & f+f'\in 2\,\mathbb{Z}+1,\\ Q_{(6)L}\otimes(\,LR+RL\,), & f-f'\in 2\,\mathbb{Z}+1\,. \end{cases} \tag{3.23}$$

and is projected to zero if none of these conditions is met. Thus, we retain some supersymmetry on a fixed-six-plane if and only if one of the two sums $f\pm f'$ is integer (even or odd). In generic cases of this sort, the bulk supersymmetry is *quartered* on the fixed-plane in question. [A special case is when $(\,f\,,f'\,)=(\,1/2\,,1/2\,)$, in which case supersymmetry is merely *halved*. In that special case the difference $f-f'=0$ is an even integer, while the sum $f+f'=1$ is an odd integer; therefore, on the fixed-plane, $Q_{(11)}$ retains nonvanishing components of both the first and also the third case in (3.23).] Note that in the cases where the supersymmetry is quartered the element α necessarily has even order N. In those cases there is necessarily an order-two element in Γ, namely $\alpha^{N/2}$, for which $(f_1,f_2,f_3\,|\,P)=(0,0,0\,|\,1)$. The fixed-plane associated with $\alpha^{N/2}$ is 10-dimensional, while the six-plane associated with α is a submanifold of this ten-plane.

Five-dimensional fixed-planes: Five-dimensional fixed-planes correspond to elements $(f_1,f_2,f_3\,|\,P)=(f_1,f_2,f_3\,|\,0\,)$, where $f_{1,2,3}\neq 0$ mod 1. In this case, the supercharge transforms as $Q_{(11)}\rightarrow\Omega_{(11)}\,Q_{(11)}$, where

$$\Omega_{(11)}=\exp(\pi f_1\Gamma_5\Gamma_6)\exp(\pi f_2\Gamma_7\Gamma_8)\exp(\pi f_3\Gamma_9\Gamma_{10}). \tag{3.24}$$

We write $Q_{(11)}$ as a tensor product of a five-dimensional fixed-plane spinor with a normal spinor according to $Q_{(11)}=Q_{(5)}\otimes Q_{(6)}$. Similarly, we use the following representation for the gamma matrices,

$$\begin{aligned}\Gamma_\mu&=\gamma_\mu\otimes\mathbf{1},\quad \mu=1,\ldots,4,\\ \Gamma_{4+i}&=\gamma_5\otimes\hat{\Gamma}_i,\quad i=1,\ldots,6,\\ \Gamma_{11}&=\gamma_5\otimes\hat{\Gamma}_7.\end{aligned} \tag{3.25}$$

where $\{\gamma_\mu,\gamma_5\}$ are five-dimensional gamma matrices and $\hat{\Gamma}_i$ are six-dimensional gamma matrices. In addition, we decompose the normal SO(6) spinors using the decomposition $\mathrm{SO}(6)\rightarrow\mathrm{SO}(2)\times\mathrm{SO}(2)\times\mathrm{SO}(2)$, where $\mathrm{SO}(2)\times\mathrm{SO}(2)\times\mathrm{SO}(2)$ is a convenient maximal subgroup of SO(6). Thus, we write the normal spinor as $Q_{(6)}=Q_{(2)}\otimes Q_{(2)}\otimes Q_{(2)}$, and the six-dimensional gamma matrices as $\hat{\Gamma}_{1,2}=\sigma_{1,2}\otimes\mathbf{1}\otimes\mathbf{1}$ and $\hat{\Gamma}_{3,4}=\sigma_3\otimes\sigma_{1,2}\otimes\mathbf{1}$, and $\hat{\Gamma}_{5,6}=\sigma_3\otimes\sigma_3\otimes\sigma_{1,2}$, where $\sigma_{1,2,3}$ are Pauli matrices. Now, using the relation $\hat{\Gamma}_7=i\hat{\Gamma}_1\cdots\hat{\Gamma}_6$ we then derive $\hat{\Gamma}_7=\sigma_3\otimes\sigma_3\otimes\sigma_3$. Using these expressions, it is possible to rewrite (3.25) as

$$\begin{aligned}\Gamma_{1,\ldots,4}&=\gamma_{1,\ldots,4}\otimes\mathbf{1}\otimes\mathbf{1}\otimes\mathbf{1},\\ \Gamma_{5,6}&=\gamma_5\otimes\sigma_{1,2}\otimes\mathbf{1}\otimes\mathbf{1},\\ \Gamma_{7,8}&=\gamma_5\otimes\sigma_3\otimes\sigma_{1,2}\otimes\mathbf{1},\\ \Gamma_{9,10}&=\gamma_5\otimes\sigma_3\otimes\sigma_3\otimes\sigma_{1,2},\\ \Gamma_{11}&=\gamma_5\otimes\sigma_3\otimes\sigma_3\otimes\sigma_3.\end{aligned} \tag{3.26}$$

We now define $LLL\equiv Q_{(2)\,L}\otimes Q_{(2)\,L}\otimes Q_{(2)\,L}$, and similar expressions for LLR, LRL, LRR, RRR, RRL, RLR, and RLL, where $Q_{(2)\,R,L}=\pm\sigma_3\,Q_{(2)\,R,L}$. In terms of these definitions and conventions, we can write

$$\begin{aligned}Q_{(11)}&=Q_{(5)}\otimes(RRR+RLL+LRL+LLR+LLL+LRR+RLR+RRL),\\ \Omega_{(11)}&=\exp(i\pi f_1\,\mathbf{1}\otimes\sigma_3\otimes\mathbf{1}\otimes\mathbf{1}+i\pi f_2\,\mathbf{1}\otimes\mathbf{1}\otimes\sigma_3\otimes\mathbf{1}+i\pi f_3\,\mathbf{1}\otimes\mathbf{1}\otimes\mathbf{1}\otimes\sigma_3).\end{aligned} \tag{3.27}$$

The fixed-plane condition $Q_{(11)}=\Omega_{(11)}Q_{(11)}$ can now be written as

$$\begin{aligned}Q_{(5)}\otimes LLL&=e^{-i\pi(f_1+f_2+f_3)}LLL,\quad Q_{(5)}\otimes RRR=e^{+i\pi(f_1+f_2+f_3)}RRR\\ Q_{(5)}\otimes LLR&=e^{-i\pi(f_1+f_2-f_3)}LLR,\quad Q_{(5)}\otimes RRL=e^{+i\pi(f_1+f_2-f_3)}RRL\\ Q_{(5)}\otimes LRL&=e^{-i\pi(f_1-f_2+f_3)}LRL,\quad Q_{(5)}\otimes RLR=e^{+i\pi(f_1-f_2+f_3)}RLR\\ Q_{(5)}\otimes LRR&=e^{-i\pi(f_1-f_2-f_3)}RLL,\quad Q_{(5)}\otimes RLL=e^{+i\pi(f_1-f_2-f_3)}LRR.\end{aligned}$$

Therefore, as we approach a fixed-five-plane, the bulk supercharge is projected according to

$$Q_{(11)}\rightarrow\begin{cases}Q_{(5)}\otimes(RRR+LLL), & f_1+f_2+f_3\in 2\,\mathbb{Z},\\ Q_{(5)}\otimes(RLL+LRR), & f_1-f_2-f_3\in 2\,\mathbb{Z},\\ Q_{(5)}\otimes(LRL+RLR), & f_1-f_2+f_3\in 2\,\mathbb{Z},\\ Q_{(5)}\otimes(LLR+RRL), & f_1+f_2-f_3\in 2\,\mathbb{Z},\end{cases} \tag{3.28}$$

and is projected to zero if none of these conditions are met. Thus, we retain some supersymmetry on a fixed-five-plane if and only if at least one of the four sums $f_1 \pm f_2 \pm f_3$ is an even integer. In generic cases of this sort, the bulk supersymmetry is *quartered* on the fixed-plane in question.

Four-dimensional fixed-planes: Four-dimensional fixed-planes correspond to elements $(f_1, f_2, f_3 \,|\, P) = (f_1, f_2, f_3 \,|\, 1)$, where $f_{1,2,3} \neq 0 \bmod 1$. In this case the supercharge transforms as $Q_{(11)} \to \Omega_{(11)} Q_{(11)}$, where

$$\Omega_{(11)} = \exp(\pi f_1 \Gamma_5 \Gamma_6) \exp(\pi f_2 \Gamma_7 \Gamma_8) \exp(\pi f_3 \Gamma_9 \Gamma_{10}) \Gamma_{11}. \tag{3.29}$$

We write $Q_{(11)}$ as a tensor product of a four-dimensional fixed-plane spinor with a normal spinor according to $Q_{(11)} = Q_{(4)} \otimes Q_{(7)}$, and we represent the gamma matrices precisely as in (3.25). Furthermore, we decompose the four-dimensional spinors as $Q_{(4)} = Q_{(4)\,R} + Q_{(4)\,L}$ where $Q_{(4)\,R,L} = \pm \gamma_5 Q_{(4)\,R,L}$. We also write the SO(7) normal spinor as $Q_{(7)} = Q_{(6)R} \oplus Q_{(6)L}$. Finally, we can decompose the chiral six-dimensional spinors $Q_{(6)R,L}$ into two-dimensional chiral spinors as descried above. Using these conventions, we can write

$$\begin{aligned} Q_{(11)} &= (Q_{(4)\,R} + Q_{(4)\,L}) \otimes (RRR + RLL + LRL + LLR + LLL + LRR + RLR + RRL), \\ \Omega_{(11)} &= \exp(i\pi f_1 \, \mathbf{1} \otimes \sigma_3 \otimes \mathbf{1} \otimes \mathbf{1} + i\pi f_2 \, \mathbf{1} \otimes \mathbf{1} \otimes \sigma_3 \otimes \mathbf{1} + i\pi f_3 \, \mathbf{1} \otimes \mathbf{1} \otimes \mathbf{1} \otimes \sigma_3) \, \gamma_5 \\ &\quad \otimes \sigma_3 \otimes \sigma_3 \otimes \sigma_3. \end{aligned} \tag{3.30}$$

The fixed-plane condition $Q_{(11)} = \Omega_{(11)} Q_{(11)}$ can now be written as

$$\begin{aligned} &Q_{(4)\,R,L} \otimes LLL = \mp e^{-i\pi(f_1+f_2+f_3)} LLL, \quad Q_{(4)\,R,L} \otimes RRR = \pm e^{+i\pi(f_1+f_2+f_3)} RRR, \\ &Q_{(4)\,R,L} \otimes LLR = \pm e^{-i\pi(f_1+f_2-f_3)} LLR, \quad Q_{(4)\,R,L} \otimes RRL = \mp e^{+i\pi(f_1+f_2-f_3)} RRL, \\ &Q_{(4)\,R,L} \otimes LRL = \pm e^{-i\pi(f_1-f_2+f_3)} LRL, \quad Q_{(4)\,R,L} \otimes RLR = \mp e^{+i\pi(f_1-f_2+f_3)} RLR, \\ &Q_{(4)\,R,L} \otimes LRR = \mp e^{-i\pi(f_1-f_2-f_3)} RLL, \quad Q_{(4)\,R,L} \otimes RLL = \pm e^{+i\pi(f_1-f_2-f_3)} LRR. \end{aligned}$$

Therefore, as we approach a fixed-four-plane, the bulk supercharge is projected according to

$$Q_{(11)} \to \begin{cases} Q_{(4)L} \otimes LLL + Q_{(4)R} \otimes RRR, & f_1+f_2+f_3 \in 2\,\mathbb{Z}, \\ Q_{(4)R} \otimes LRL + Q_{(4)L} \otimes RLR, & f_1-f_2+f_3 \in 2\,\mathbb{Z}, \\ Q_{(4)R} \otimes RRL + Q_{(4)L} \otimes LLR, & f_1+f_2-f_3 \in 2\,\mathbb{Z}, \\ Q_{(4)L} \otimes RLL + Q_{(4)R} \otimes LRR, & f_1-f_2-f_3 \in 2\,\mathbb{Z}, \\ Q_{(4)R} \otimes LLL + Q_{(4)L} \otimes RRR, & f_1+f_2+f_3 \in 2\,\mathbb{Z}+1, \\ Q_{(4)L} \otimes LRL + Q_{(4)R} \otimes RLR, & f_1-f_2+f_3 \in 2\,\mathbb{Z}+1, \\ Q_{(4)L} \otimes RRL + Q_{(4)R} \otimes LLR, & f_1+f_2-f_3 \in 2\,\mathbb{Z}+1, \\ Q_{(4)R} \otimes RLL + Q_{(4)L} \otimes LRR, & f_1-f_2-f_3 \in 2\,\mathbb{Z}+1, \end{cases} \tag{3.31}$$

and is projected to zero if none of these conditions are met. Thus, we retain some supersymmetry on a fixed-four-plane if and only if any one of the four sums $f_1 \pm f_2 \pm f_3$ is an integer (even or odd). In generic cases of this sort, supersymmetry is *eighthed* on the fixed-plane in question.

There are special cases, however. For instance, for each of the two cases where (f_1, f_2, f_3) are given by $(1/2, 1/3, 1/6)$ and by $(1/2, 1/4, 1/4)$, one sum $f_1 - f_2 - f_3 = 0$ is an even integer, while another sum $f_1 + f_2 + f_3 = 1$ is an odd integer. Therefore, on the fixed-plane, $Q_{(11)}$ retains nonvanishing components of both the fourth and the also the fifth case in (3.31). Thus, supersymmetry is merely quartered to $D=4, N=2$, rather than eighthed to $D=4, N=1$, in these cases. (If the

fixed-four-plane in question is a submanifold of the fixed-plane of another element of Γ, one needs to account for the action of this other element as well before drawing conclusions as to the amount of fixed-plane supersymmetry.)

Note that the pairs of summands indicated in (3.31) have correlations owing to the Majorana constraint on $Q_{(11)}$. As a result, the two apparent summands in each of these expressions actually describe the same degrees of freedom. In terms of the choices we have made, this gives rise to a Majorana spinor supercharge in four dimensions. The pairs which appear in (3.31) represent left- and right-handed chiral projections of this four-dimensional Majorana supercharge. As is well known, in four dimensions spinor fields which are Majorana may be equally well represented in terms of either chiral projection.

IV. GENERALIZATION TO NON-ABELIAN ORBIFOLD GROUPS

One obvious extension of our criterion, still for orbifolds of tori of our class, is to consider *all* the automorphisms of the underlying lattices. In addition to the rotations and flips we have already considered, the only new type of ''generating'' automorphism to deal with is the permutations of the coordinates x^i. In fact, one can easily lift these permutation actions to spinors. Here are the details.

The lattices of our class are all of the form

$$\Lambda = (A_1)^a \oplus (A_2)^b \ , \tag{4.1}$$

with $a+2b=n$, the dimension of the orbifold. Such a lattice has an automorphism group of order $2^a \cdot a! \cdot b! \cdot 12^b$, a product of four factors. Let's check where these two pairs of factors come from.

The first pair, $2^a \cdot a!$, keeps track of the sign flips on each of a possible x^i (the 2^a), and permutations of the same a x^i's (the $a!$). We have already described a way to lift the flips to spinors, via Γ_i, so we only need to lift the permutations. The second pair, $b! \cdot 12^b$, keeps track of the permutations of the b different copies of A_2, i.e., of corresponding ordered pairs (x^i, x^{i+1}) (giving the $b!$), and automorphisms internal to each of the b A_2's (giving the 12^b, as the automorphism group of the A_2 lattice is the dihedral group D_6 of order 12). Consider a single A_2 lattice in the ''(x,y)-plane.'' The dihedral automorphism group D_6 consists entirely of the identity, rotations by $r^k := 2\pi k/6$, $k=1,2,3,4,5$, and flips $(s, sr, sr^2, sr^3, sr^4, sr^5)$ across lines through opposite vertices or opposite edge centers of the period hexagon (we can assume that s is the flip across the x-axis sending $y \mapsto -y$). In particular, D_6 is generated by a rotation r and a flip s, for each of which we have already described a lift to spinors. What remains is again to describe the effect of the permutation automorphisms on spinors.

Since every permutation of the x^i can be expressed as a product of simple transpositions $x^i \leftrightarrow x^j$, $i \neq j$, it suffices to write out the lift of such a transposition. Imagine the (x^i, x^j)-plane. Rotation counterclockwise by $\pi/2$ radians sends $x^i \mapsto x^j$ and $x^j \mapsto -x^i$. This is represented in the Clifford algebra by

$$\exp\left(\frac{\pi}{4} \Gamma_{ij} \right) = \cos(\pi/4) + \sin(\pi/4)\, \Gamma_i \Gamma_j = \left(\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2} \Gamma_i \Gamma_j \right) . \tag{4.2}$$

Now compose this with the flip sending $x^i \mapsto -x^i$ given by Γ_i, yielding

$$\Gamma_i \cdot \left(\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2} \Gamma_i \Gamma_j \right) = \frac{\sqrt{2}}{2} (\Gamma_i + \Gamma_j) . \tag{4.3}$$

We can build any permutation we like out of a product of these, and in particular all of the remaining automorphisms come from mixing these with the rotations and flips as above. By adding such permutations, we can obtain a complete supersymmetric restriction criterion for all orbifolds modelled on lattices of type (4.1). In particular, this allows one to check the supersym-

metry constraints for a large class of *non-Abelian* orbifold groups. The generalized supersymmetric restriction theorem, including the extension to non-Abelian orbifold groups, will be discussed in a forthcoming paper.

V. SOFT ORBIFOLDS AND G_2-STRUCTURES

Consider the supersymmetric orbifold of $\Gamma=(\mathbb{Z}_2)^3$ labeled (1111111) in Table I. The corresponding representation of Γ on $\mathbb{R}^7$ is given by the direct sum of the seven nontrivial characters $\Gamma_{[i,j,k]}$, each with multiplicity one. The character table for $\Gamma=\langle\alpha,\beta,\gamma\rangle$ is given in Table VII, and, by following the prescription given in Sec. II C, we see that the action of these generators on the coordinate 7-tuple $(x_1,\ldots,x_7)$ is given by

$$\alpha: \quad (x_1,x_2,x_3,-x_4,-x_5,-x_6,-x_7), \tag{5.1}$$

$$\beta: \quad (x_1,-x_2,-x_3,x_4,x_5,-x_6,-x_7), \tag{5.2}$$

$$\gamma: \quad (-x_1,x_2,-x_3,x_4,-x_5,x_6,-x_7). \tag{5.3}$$

Note that this Γ-action preserves the G_2-invariant differential 3-form φ_0 on $\mathbb{R}^7$,

$$\varphi_0 := dx_{123}+dx_{145}+dx_{167}+dx_{246}-dx_{257}-dx_{347}-dx_{356},$$

where $dx_{ijk}:=dx_i\wedge dx_j\wedge dx_k$. Such an action defines a G_2-*structure* on the orbifold T^7/Γ.

Our supersymmetric hard orbifold (1111111) is one of a family of orbifolds considered by Joyce. [In fact, in the notation of Ref. 15 Eqs. (23)–(25), ours corresponds to $b_1=b_2=c_1=c_3=c_5=0$. We will refer to notation and examples from Ref. 7 instead.] It was his goal to construct compact manifolds with holonomy group G_2. To this end he developed in Refs. 14, 15, and 7 a machinery which, starting with a sufficiently simple orbifold admitting a G_2-structure, establishes the existence of such a metric on a ''resolution'' of the orbifold. Joyce's method depends on the existence of certain *R-data* (''*R*'' for resolution) which, for a given orbifold with G_2-structure, may yield a large number of topologically distinct G_2 holonomy manifolds as resolutions.

In Ref. 7 Secs. 12.2, 3, and 5 three paricular softenings are considered. The actions of the generators of Γ take the form

$$\alpha: \quad (x_1,x_2,x_3,-x_4,-x_5,-x_6,-x_7), \tag{5.4}$$

$$\beta: \quad (x_1,-x_2,-x_3,x_4,x_5,b-x_6,-x_7), \tag{5.5}$$

$$\gamma: \quad (-x_1,x_2,-x_3,x_4,c-x_5,x_6,\tfrac{1}{2}-x_7)\ , \tag{5.6}$$

with $b,c\in\{0,\frac{1}{2}\}$. In fact, Joyce considers the three cases

$$(b,c)=(0,\tfrac{1}{2})\,,\quad (\tfrac{1}{2},0)\,,\quad \text{and } (\tfrac{1}{2},\tfrac{1}{2})\,,$$

and shows that each of these admits a set of R-data defining a G_2 holonomy resolution. In each case the generators α, β, and γ act with fixed-points as before, but some other elements, like

$$\beta\gamma:\quad (-x_1,-x_2,x_3,x_4,c-x_5,b+x_6,\tfrac{1}{2}+x_7)\ , \tag{5.7}$$

act freely. Thus softening an orbifold has the effect of simplifying the singularities. The singularities of the orbifold (1111111) are too complicated to visibly admit a compatible set of R-data, hence his interest in various softenings with simpler singularities. Furthermore, at least for these simplest examples, the set of fixed-plane dimensions associated to a hard orbifold contains as subsets those of all of its softenings. For this reason, one expects that much of the supersymmetric restriction analysis of Sec. III can be usefully adapted to the case of soft orbifolds.

It is clear that having a G_2-structure on a hard orbifold implies such a structure on all of its softenings. This raises the intriguing question of the relationship between our supersymmetry condition and such G_2-structures: Do all supersymmetric hard orbifolds (and hence all of their softenings) carry a G_2-structure? What about the converse: Do all orbifolds with a G_2-structure arise via softening from supersymmetric hard orbifolds? What about the more subtle issue of resolvability as a G_2-manifold (i.e., existence of compatible R-data)? These are all questions to be addressed in future work.

VI. CONCLUSIONS

We have described a systematic method for classifying supersymmetric orbifold compactifications of M-theory, specifically hard orbifolds defined by pseudo-planar representations of Abelian groups of order $\leqslant 12$. Although we stopped our ''periodic table'' (Table I) at order 12, the methods developed here apply to groups of arbitrary order, and the algorithmics are such that such an extension (using Mathematica) is computationally feasible.

It is physically relevant that we demand orbifold actions be compatible with particular lattices. By doing this we are able to keep control over two separate problems. On the one hand we are studying aspects of supersymmetric singularities. On the other hand, however, we are at the same time learning something about which sets of such singularities, and their neighborhoods, can be assembled together to create a global supersymmetric compactification space. Elucidating the relationship between our own supersymmetric configurations of singularities and those of intersecting branes as studied by other groups[24–35] seems an important direction for further investigation.

Furthermore, we touch upon the interesting mathematical problem of classifying G_2 manifolds. The vast majority of known compact G_2 holonomy manifolds arise by Joyce's resolution of singularities from orbifolds of T^7. Physically one expects that seven-dimensional supersymmetric compactification spaces of the sort we are studying should admit such G_2 resolutions. In order to compare in general Joyce's ''resolution data'' to the constraints arising from our global supersymmetric restriction, it seems necessary to formulate the restriction for the soft orbifolds of the introduction, as all of Joyce's examples are of this sort.

APPENDIX: THE *C*-MATRICES FOR SELECTED GROUPS

By applying the simple algorithm described in Sec. II B, we are able to derive the C-matrix for any pseudoplanar group $\Gamma = G_1 \times \cdots \times G_n$, where $G_i \in \{\mathbb{Z}_2, \mathbb{Z}_3, \mathbb{Z}_4\}$ for $1 \leqslant i \leqslant n$. In Tables VIII and IX we exhibit these for all cases for which $|\Gamma| \leqslant 12$.

TABLE VIII. The C-matrices for pseudoplanar Abelian groups of order $\leqslant 8$.

$$C(\mathbb{Z}_2) = 1$$

$$C(\mathbb{Z}_3) = 1$$

$$C(\mathbb{Z}_4) = \left(\begin{array}{c|c} 0 & 2 \\ \hline 2 & 1 \end{array}\right)$$

$$C(\mathbb{Z}_2\times\mathbb{Z}_2) = \begin{pmatrix} 0 & 2 & 2 \\ 2 & 0 & 2 \\ 2 & 2 & 0 \end{pmatrix}$$

$$C(\mathbb{Z}_2\times\mathbb{Z}_3) = \left(\begin{array}{c|c|c} 3 & 0 & 3 \\ \hline 0 & 2 & 2 \\ \hline 3 & 2 & -1 \end{array}\right)$$

$$C(\mathbb{Z}_2\times\mathbb{Z}_4) = \left(\begin{array}{ccc|cc} 0 & 0 & 0 & 4 & 4 \\ 0 & 4 & 4 & 0 & 4 \\ 0 & 4 & 4 & 4 & 0 \\ \hline 4 & 0 & 4 & 2 & 2 \\ 4 & 4 & 0 & 2 & -2 \end{array}\right)$$

$$C(\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2) = \begin{pmatrix} 4 & 0 & 4 & 0 & 4 & 0 & 4 \\ 0 & 4 & 4 & 0 & 0 & 4 & 4 \\ 4 & 4 & 0 & 0 & 4 & 4 & 0 \\ 0 & 0 & 0 & 4 & 4 & 4 & 4 \\ 4 & 0 & 4 & 4 & 0 & 4 & 0 \\ 0 & 4 & 4 & 4 & 4 & 0 & 0 \\ 4 & 4 & 0 & 4 & 0 & 0 & 4 \end{pmatrix}$$

TABLE IX. The C-matrices for pseudoplanar Abelian groups of orders 9 and 12.

$$C(\mathbb{Z}_3\times\mathbb{Z}_3) = \begin{pmatrix} 0 & 3 & 3 & -3 \\ 3 & 0 & 3 & 3 \\ 3 & 3 & -3 & 0 \\ -3 & 3 & 0 & 3 \end{pmatrix}$$

$$C(\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_3) = \left(\begin{array}{ccc|c|ccc} 0 & 6 & 6 & 0 & 0 & 6 & 6 \\ 6 & 0 & 6 & 0 & 6 & 0 & 6 \\ 6 & 6 & 0 & 0 & 6 & 6 & 0 \\ \hline 0 & 0 & 0 & 4 & 4 & 4 & 4 \\ \hline 0 & 6 & 6 & 4 & 4 & -2 & -2 \\ 6 & 0 & 6 & 4 & -2 & 4 & -2 \\ 6 & 6 & 0 & 4 & -2 & -2 & 4 \end{array}\right)$$

$$C(\mathbb{Z}_3\times\mathbb{Z}_4) = \left(\begin{array}{c|c|c|c|cc} 0 & 0 & 6 & 0 & 6 & 6 \\ \hline 0 & 4 & 0 & 4 & 4 & 4 \\ \hline 6 & 0 & 3 & 6 & 3 & -3 \\ \hline 0 & 4 & 6 & 4 & -2 & -2 \\ \hline 6 & 4 & 3 & -2 & -5 & 1 \\ 6 & 4 & -3 & -2 & 1 & -5 \end{array}\right)$$

(Received 4 March 2003; accepted 12 March 2003)

In this paper we present a method of constructing explicit classes of solutions of the Chaplygin and Born–Infeld systems of equations in $1+1$ dimensions. The approach adopted here is based on the symmetry reduction method for PDE's. A systematic use of the subgroup structure of the invariance group is made to generate symmetry variables. We concentrate only on the case when the symmetry variables are invariants of the subgroups having dimension one. The set of symmetry variables enables us to reduce, after some transformation, the original equations to many possible ODE's. We describe in detail how a composition of Lie subalgebras and singularity analysis applied to these systems provides us with classes of analytic solutions. Several new types of algebraic, rational and solitonlike solutions (among them kinks, bumps and multiple wave solutions) have been obtained in explicit form. We discuss also the existence of several classes of separable solutions admitted by the Chaplygin and Born–Infeld equations. Some physical interpretation of these results in the areas of fluid dynamics and field theory are given. [DOI: 10.1063/1.1576496]

I. INTRODUCTION

The motion of a d-brane in $(d+1)$ spatial dimensions moving in $(d+1,1)$-dimensional space–time is described by the Nambu–Goto (NG) action as given by Jackiw.[1] If $X^\mu=(X^0,X^1,\ldots,X^d,X^{d+1})$ describes the target space–time (in which the d-brane moves), and $\phi^\alpha=(\phi^0,\phi^1,\ldots,\phi^d)$ are world-volume variables which parametrize the d-dimensional extended object evolving in ϕ^0, then the Nambu–Goto action reads

$$I_{\mathrm{NG}}=\int d\phi^0\, d\phi^1\cdots d\phi^d\, \sqrt{(-1)^d \det\left(\frac{\partial X^\mu}{\partial\phi^\alpha}\frac{\partial X_\mu}{\partial\phi^\beta}\right)}. \tag{1}$$

This action is parametrization invariant, and in particular two different choices of the parametrization lead, respectively, to a nonrelativistic fluid dynamical model (the Chaplygin gas) and a relativistic fluid (the Born–Infeld model). In both cases, we choose $(X^1,X^2,\ldots,X^d)$ to coincide with $(\phi^1,\phi^2,\ldots,\phi^d)$ and rename them as the spatial vector $\mathbf{r}$ in d dimensions. The remaining variables X^0, X^{d+1}, and ϕ^0 are treated separately.

A. The Chaplygin gas

We now discuss the two distinct parametrizations, beginning with the nonrelativistic fluid. We define

[a)]Electronic mail: grundlan@crm.umontreal.ca
[b)]Electronic mail: hariton@dms.umontreal.ca
[c)]Electronic mail: hussin@dms.umontreal.ca

$$X^+ = \frac{1}{\sqrt{2}}(X^0 + X^{d+1}) = t, \quad X^- = \frac{1}{\sqrt{2}}(X^0 - X^{d+1}) = \theta(\mathbf{r},t) \tag{2}$$

and then identify t with $\sqrt{2\lambda}\,\phi^0$, where $\lambda \geqslant 0$ is a constant. This is called the light-cone parametrization. The Nambu–Goto action (1) then reduces to the Chaplygin action[1]

$$I_\lambda = -2\sqrt{\lambda}\int dt\, d\mathbf{r}\, \sqrt{\theta_t + \tfrac{1}{2}(\nabla\theta)^2}. \tag{3}$$

This action leads to the Euler–Lagrange equations of the form

$$\frac{\partial}{\partial t}\left(\frac{1}{\sqrt{\theta_t + \frac{1}{2}(\nabla\theta)^2}}\right) + \nabla\cdot\left(\frac{\nabla\theta}{\sqrt{\theta_t + \frac{1}{2}(\nabla\theta)^2}}\right) = 0, \tag{4}$$

which is known as the Chaplygin equation.[2] It should be noted that this equation is equivalent to the following system of differential equations for the density $\rho(\mathbf{r},t)$ and velocity potential $\theta(\mathbf{r},t)$ of a fluid in the interactive case ($\lambda \neq 0$)

$$\rho_t + (\nabla\rho)\cdot(\nabla\theta) + \rho\,(\nabla^2\theta) = 0, \tag{5}$$

$$\theta_t + \frac{1}{2}(\nabla\theta)^2 = \frac{\lambda}{\rho^2}. \tag{6}$$

These equations (5) and (6) correspond, respectively, to the equation of continuity and Euler's force equation for an ideal nonrelativistic fluid of zero vorticity, in which the pressure P is related to the density ρ by the equation[1]

$$P = \frac{-2\lambda}{\rho}. \tag{7}$$

The velocity $\mathbf{v}$ of the fluid is simply the gradient of the potential $\mathbf{v} = \nabla\theta$. It is possible to eliminate the variable ρ by using Eq. (6) to express it in terms of θ. In this way the system (5) and (6) reduces to Eq. (4).

In the free case ($\lambda = 0$) the variable ρ becomes completely independent, and the equations (5) and (6) are decoupled. Equation (6) can be solved for θ, and then equation (5) solved for ρ. A detailed discussion of the symmetry group in one spatial dimension can be found in Ref. 3. This case is not derived from the Nambu–Goto d-brane.

B. The Born–Infeld model

For the relativistic model, the variable X^0 is renamed ct, where c is the speed of light, and is also identified with $c\phi^0$. The remaining target space variable X^{d+1} is renamed $\theta(\mathbf{r},t)/c$, a function of $\mathbf{r}$ and t. This is called the Cartesian parametrization. The Nambu–Goto action (1) then reduces to the Born–Infeld action[1]

$$I_a = -a\int dt\, d\mathbf{r}\, \sqrt{c^2 - (\partial_\mu\theta)^2}. \tag{8}$$

The corresponding Euler–Lagrange equation is found to be

$$\partial^\nu\left(\frac{1}{\sqrt{c^2 - (\partial_\mu\theta)^2}}\,\partial_\nu\theta\right) = 0, \tag{9}$$

which in turn corresponds to the Born–Infeld equations

$$\rho_t + \nabla \cdot \left(\nabla\theta \sqrt{\frac{\rho^2 c^2 + a^2}{c^2 + (\nabla\theta)^2}} \right) = 0, \tag{10}$$

$$\theta_t + \rho c^2 \sqrt{\frac{c^2 + (\nabla\theta)^2}{\rho^2 c^2 + a^2}} = 0. \tag{11}$$

It should be noted that at the limit where $c \to \infty$ the relativistic Born–Infeld model reduces to the nonrelativistic Chaplygin model discussed previously, where λ is identified with $a^2/2$.[1] A solution $\theta_{NR}(\mathbf{r},t)$ of the Chaplygin equation (4) is thus related to its relativistic counterpart $\theta_R(\mathbf{r},t)$ for the Born–Infeld equations (9). This will be discussed in further detail in Sec. III C.

C. Objective and organization

The objective of this paper is to use the method of symmetry reduction (MSR) to determine group-invariant solutions of the Chaplygin and Born–Infeld equations. For simplicity, we shall restrict ourselves to the interactive one-dimensional case (that is in one spatial dimension x and time t). In future work, it will be our objective to extend this analysis to two-dimensional and supersymmetric generalizations[1,4,5] of this theory.

In Sec. II we begin by describing the structure of the six-dimensional Lie algebra which generates the symmetries of the system of Eqs. (5) and (6) of the Chaplygin gas. We also classify the associated one-parameter subalgebras in terms of conjugacy classes. Indeed, since the partial differential equations involved have only two independent variables, a one-dimensional subalgebra (which generates a one-dimensional orbit) will be sufficient to reduce the system to ordinary differential equations of the second order. In Sec. III we proceed to use MSR to determine solutions which are invariant under the various subalgebras, and compare the resulting solutions to those determined by Jackiw with the Legendre method of Riemann coordinates.[1] We use the link between the Chaplygin and Born–Infeld models to generate solutions of the Born–Infeld model. In Sec. IV we discuss the separation of variables admitted by the Chaplygin and Born–Infeld equations, which enables us to construct the families of solitonlike solutions. Finally, Sec. V summarizes the results and contains a future outlook concerning the possible extension of the classical Lie approach to partially invariant solutions (of defect $\delta=1$) for the Chaplygin and Born–Infeld equations.

II. THE SYMMETRY GROUP AND CLASSIFICATION OF SUBALGEBRAS

Let us now investigate the group of symmetries of the interactive Chaplygin gas in one spatial dimension. This fluid is now governed by the system of equations

$$\theta_t + \frac{1}{2}(\theta_x)^2 = \frac{\lambda}{\rho^2}, \quad \rho_t + \rho_x\theta_x + \rho\,\theta_{xx} = 0, \tag{12}$$

obtained from Eqs. (5) and (6) by taking $\mathbf{r}=x$. Following the standard method for determining the symmetry algebra of a system of differential equations,[6] we find that the symmetry algebra $\mathcal{G}$ of the system (12) is spanned by the six independent vector fields

$$\begin{gathered} P_1=\partial_x, \quad P_0=\partial_t, \quad B=t\partial_x+x\partial_\theta, \quad Z=\partial_\theta, \\ D_1=x\partial_x+2t\partial_t+\rho\partial_\rho, \quad D_2=x\partial_x+2\theta\partial_\theta-\rho\partial_\rho. \end{gathered} \tag{13}$$

The commutation relations of the Lie algebra $\mathcal{G}$ are given in Table I.

The vector fields P_1 and P_0 generate translations in space and time, respectively, while Z generates a translation in the dependent variable $\theta(\mathbf{r},t)$. The element B corresponds to a Galilean

TABLE I. Commutation table for the Lie algebra $\mathcal{G}$.

$X\backslash Y$	D_1	D_2	B	Z	P_1	P_0
D_1	0	0	B	0	$-P_1$	$-2P_0$
D_2	0	0	$-B$	$-2Z$	$-P_1$	0
B	$-B$	B	0	0	$-Z$	$-P_1$
Z	0	$2Z$	0	0	0	0
P_1	P_1	P_1	Z	0	0	0
P_0	$2P_0$	0	P_1	0	0	0

boost so that $\{P_0,P_1,B\}$ generate the Galilean algebra in one spatial dimension. The fields D_1 and D_2 correspond to two different types of dilatation. The group G of symmetries is obtained by integrating the vector fields in $\mathcal{G}$ and it acts on the independent and dependent variables as

$$\begin{aligned}\tilde{x} &= e^{d_1+d_2}((x-x_0)+b(t-t_0)),\\ \tilde{t} &= e^{2d_1}(t-t_0),\\ \tilde{\theta} &= e^{2d_2}(\theta+b(x-x_0)+\tfrac{1}{2}b^2(t-t_0)+z),\\ \tilde{\rho} &= e^{d_1-d_2}\rho,\end{aligned} \tag{14}$$

where $g=(d_1,d_2,b,x_0,t_0,z)$ is an arbitrary element of G, all the parameters being real numbers.

The Levi decomposition of the algebra $\mathcal{G}$ is given by

$$\mathcal{G}=\{D_1,D_2,B\}\ \textcircled{+}\ \{P_1,P_0,Z\}=\mathcal{L}\ \textcircled{+}\ \mathcal{N}, \tag{15}$$

where $\mathcal{L}=\{D_1,D_2,B\}$ and $\mathcal{N}=\{P_1,P_0,Z\}$ is an Abelian ideal, so that we can directly apply the method of subalgebra classification[7] to give the nonequivalent one-dimensional splitting and nonsplitting subalgebras of $\mathcal{G}$. The splitting subalgebras are given by

$$\mathcal{L}_1=\{D_1\},\quad \mathcal{L}_2=\{D_2\},\quad \mathcal{L}_3=\{B\},\quad \mathcal{L}_{4,a}=\{D_1+aD_2,\ a\in\Re/\{0\}\},$$

$$\mathcal{L}_{5,\varepsilon}=\{D_1+D_2+\varepsilon B,\ \ \varepsilon=\pm1\},$$

as subalgebras of $\mathcal{L}$, and by

$$\mathcal{N}_1=\{P_0\},\quad \mathcal{N}_2=\{P_1\},\quad \mathcal{N}_3=\{Z\},\quad \mathcal{N}_{4,\varepsilon}=\{Z+\varepsilon P_0,\varepsilon=\pm1\}, \tag{16}$$

as subalgebras of $\mathcal{N}$. The nonsplitting subalgebras in $\mathcal{G}$ are given by

$$\begin{aligned}&\mathcal{K}_{1,\varepsilon}=\{D_1+\varepsilon Z,\ \ \varepsilon=\pm1\},\quad \mathcal{K}_{2,\varepsilon}=\{D_1-D_2+\varepsilon P_1,\ \ \varepsilon=\pm1\},\\ &\mathcal{K}_{3,\varepsilon}=\{D_2+\varepsilon P_0,\ \ \varepsilon=\pm1\},\quad \mathcal{K}_{4,\varepsilon}=\{B+\varepsilon P_0,\ \ \varepsilon=\pm1\}.\end{aligned} \tag{17}$$

All of these subalgebras, except $\mathcal{N}_3$ which does not contain any derivative with respect to the independent variables x and t, will give rise to a reduction process and to invariant solutions.

III. SYMMETRY REDUCTION AND GROUP-INVARIANT SOLUTIONS

In this section, we use the method of characteristics to determine the invariants and reduced differential equations corresponding to each subalgebra listed in Sec. II. In particular for ODE's of second order it is possible to determine whether they are of Painlevé type (i.e., whether all their

TABLE II. Invariants of the subalgebras of the Lie algebra $\mathcal{G}$.

$\mathcal{K}_{2,\varepsilon}=\{D_1-D_2+\varepsilon P_1,\ \varepsilon=\pm1\}$	$\xi=x-\frac{1}{2}\varepsilon\ln t$	$\theta=\frac{1}{t}F(\xi)$	$\rho=tG(\xi)$
$\mathcal{K}_{3,\varepsilon}=\{D_2+\varepsilon P_0,\ \varepsilon=\pm1\}$	$\xi=xe^{-\varepsilon t}$	$\theta=x^2F(\xi)$	$\rho=\frac{1}{x}G(\xi)$
$\mathcal{K}_{4,\varepsilon}=\{B+\varepsilon P_0,\ \varepsilon=\pm1\}$	$\xi=\varepsilon x-\frac{1}{2}t^2$	$\theta=F(\xi)+\xi t+\frac{1}{6}t^3$	$\rho=G(\xi)$

critical points are independent of the initial data). When it is possible, we determine explicit solutions of the Chaplygin and Born–Infeld equations, and compare the former to the ones determined by Jackiw.[1]

A. Reduction of the system

Passing systematically through all subgroups of G with orbits of codimension one, we obtain all symmetry variables. Substituting each of these into the equations (12) we reduce them to a system of ODE's. The result of this analysis can be summarized as follows, where ξ is the symmetry variable, $F(\xi)$ and $G(\xi)$ are invariant functions related to θ and ρ, respectively, and have to be determined using the reduced differential equations. The different classes of symmetry reductions are summarized in Tables II and III. They lead us to 14 different types of solutions.

B. Group-invariant solutions of the Chaplygin model

Let us now discuss certain classes of solutions to the Chaplygin equations obtained from the solutions to the reduced equations determined in Sec. III A. We perform a singularity analysis to determine which of these reduced ODE's can be transformed to the standard Painlevé form.

For the case $\mathcal{L}_1$, we get

$$\theta(x,t)=\frac{1}{4\sqrt{a_0}}\ln\left(\frac{\sqrt{a_0}x^2+t}{\sqrt{a_0}x^2-t}\right)+c_0,\quad \rho(x,t)=\sqrt{\frac{2\lambda}{a_0}}\left(\frac{t^2-a_0x^4}{x^3}\right),\tag{18}$$

where a_0 and c_0 are real constants, and $a_0\neq0$. The velocity is given by

TABLE III. Reduced equations of the subalgebras of the Lie algebra $\mathcal{G}$.

$\mathcal{K}_{4,\varepsilon}$	$G=\sqrt{\lambda}(\xi+\frac{1}{2}(F_\xi)^2)^{-1/2}$	$\xi F_{\xi\xi}-\frac{1}{2}F_\xi=0$

$$v(x,t)=\frac{xt}{t^2-a_0x^4}. \tag{19}$$

This solution is defined for $\sqrt{a_0}x^2>|t|$. It is noticeable that at $t=0$ this solution reduces to $\theta=c_0$, $\rho=\sqrt{2\lambda a_0}x$. Thus, we have a zero velocity and linear density of the fluid.

In an analysis performed on the Chaplygin gas in one spatial dimension, Jackiw[1] considered the following method in order to determine solutions of the Chaplygin gas equations. A Legendre transform is used to exchange the independent variables (x,t) with the dependent ones (θ,ρ). In fact, the new independent variables used are

$$s=\sqrt{2\lambda}/\rho,\quad p=\frac{\partial\theta}{\partial x}=\theta_x, \tag{20}$$

where p is exactly the velocity $v(x,t)$. The following function of s and p is then defined:

$$\Psi(p,s)=\theta(x,t)-t\theta_t-x\theta_x. \tag{21}$$

From the equations (12) it is easily shown that

$$\Psi(p,s)=\theta(x,t)+\tfrac{1}{2}t(p^2-s^2)-xp \tag{22}$$

and so

$$\frac{\partial\Psi}{\partial p}=tp-x,\quad \frac{\partial\Psi}{\partial s}=-ts. \tag{23}$$

The equations (12) can then be rewritten as the linear equation

$$\frac{\partial^2\Psi}{\partial p^2}-\frac{\partial^2\Psi}{\partial s^2}+\frac{2}{s}\frac{\partial\Psi}{\partial s}=0. \tag{24}$$

The general solution of (24) is given in terms of two arbitrary functions $f=f(p+s)$ and $g=g(p-s)$ (where $p\pm s$ are called Riemann coordinates),

$$\Psi(p,s)=f(p+s)-sf'(p+s)+g(p-s)+sg'(p-s). \tag{25}$$

It is easy to show that the solution (18) corresponds to Jackiw's solution where

$$\Psi(p,s)=\frac{1}{4\sqrt{a_0}}\ln\left(\frac{s+p}{s-p}\right)+c_0+\frac{1}{2\sqrt{a_0}}\frac{sp}{(s-p)(s+p)}, \tag{26}$$

and

$$f(z)=\frac{1}{4\sqrt{a_0}}\ln z+\frac{1}{2}c_0,\quad g(-z)=-\frac{1}{4\sqrt{a_0}}\ln z+\frac{1}{2}c_0.$$

where, for each of the functions f and g, the variable z represents the corresponding argument as described in Eq. (25).

For $\mathcal{L}_2$, we have

$$\theta(x,t)=-a_0x^2\left(\frac{1+e^{4a_0(t-t_0)}}{1-e^{4a_0(t-t_0)}}\right),\quad \rho(x,t)=\sqrt{\frac{\lambda}{2a_0^2}}\,\frac{1}{x}, \tag{27}$$

$$v(x,t)=-2a_0x\left(\frac{1+e^{4a_0(t-t_0)}}{1-e^{4a_0(t-t_0)}}\right), \tag{28}$$

where a_0 and t_0 are real constants, and $a_0\neq 0$. This solution has a singularity at line $t=t_0$ which seems to indicate that it does not correspond to a physical theory at time t_0. As $t\to+\infty$, θ approaches the function $f_+(x)=ax^2$, and as $t\to-\infty$ it approaches $f_-(x)=-ax^2$. The density ρ has a pole at $x=0$ and is constant in time. This solution corresponds to the function (25) given explicitly by

$$\Psi(p,s)=-\frac{sp}{4a_0}+\frac{1}{8a_0}(p^2-s^2)\ln\left(\frac{p+s}{p-s}\right)+\frac{1}{2}t_0(p^2-s^2),$$

where

$$f(z)=\frac{t_0}{4}z^2+\frac{1}{8a_0}z^2\ln z,\quad g(z)=\frac{t_0}{4}z^2-\frac{1}{8a_0}z^2\ln z. \tag{29}$$

For $\mathcal{L}_3$, we have

$$\theta(x,t)=\frac{x^2}{2t}+\frac{\lambda t^3}{3a_0^2}+c_0,\quad \rho(x,t)=\frac{a_0}{t}, \tag{30}$$

so that the velocity is now

$$v(x,t)=\frac{x}{t}, \tag{31}$$

where a_0 and c_0 are real constants, and $a_0 \neq 0$. There is a pole singularity at $t=0$. As $t \to \infty$, the velocity potential θ becomes unbounded and the density ρ approaches zero. The velocity (31) is linear in x, but also approaches zero as $t \to \infty$. This solution corresponds to the case

$$\Psi(p,s) = c_0 - \frac{a_0 s^3}{3\sqrt{2\lambda}}, \tag{32}$$

where f and g in (25) are given by

$$f(z) = \frac{1}{2}\left(c_0 + \frac{1}{6\sqrt{2\lambda}} a_0 z^3 \right), \quad g(z) = \frac{1}{2}\left(c_0 - \frac{1}{6\sqrt{2\lambda}} a_0 z^3 \right).$$

It is interesting to note that the solution (32) of the equation (24) is invariant under translation by the variable p. This means that invariance under Galilean boost of the original set (12) implies a p-invariant solution for (24).

For $\mathcal{L}_{4,-1}$, we have

$$\theta(x,t) = \frac{2}{kt}\sinh^2\left(\frac{1}{2}\sqrt{k}(x+c_0) \right), \quad \rho(x,t) = \sqrt{\frac{k\lambda}{2}} \frac{t}{\sinh^2(\frac{1}{2}\sqrt{k}(x+c_0))}, \tag{33}$$

where k and c_0 are real constants. It is possible to rewrite this solution in a more familiar form. If we take $c_0 = i\pi/\sqrt{k}$ and define $a_0 = \frac{1}{2}\sqrt{k}$, we obtain the solution

$$\theta(x,t) = -\frac{1}{2a_0^2 t}\cosh^2(a_0 x), \quad \rho(x,t) = \sqrt{2\lambda}\frac{a_0 t}{\cosh^2(a_0 x)}, \tag{34}$$

$$v(x,t) = -\frac{1}{a_0 t}\cosh(a_0 x) \ \ \sinh(a_0 x), \tag{35}$$

which is exactly the soliton solution given by Jackiw.[1] This solution is not singular in x. The density ρ is zero at time $t=0$ and becomes unbounded as $t \to \infty$. This solution corresponds to the case

$$\Psi(p,s) = \frac{p}{2a_0}\ln\left(\frac{s+p}{s-p} \right) - \frac{s}{a_0}, \tag{36}$$

where $\Psi(p,s) =$ (25) with

$$f(z) = g(-z) = \frac{z}{2a_0}\ln z.$$

For $\mathcal{L}_{4,1}$, we get

$$\theta(x,t) = a_0 t - \frac{a_1}{2}x, \quad \rho(x,t) = \sqrt{\frac{\lambda}{\frac{1}{8}a_1^2 + a_0}}. \tag{37}$$

Here ρ and v are constant. In this case, the variables p and s defined in Eq. (20) are both constant, and so the change of variable $(x,t) \to (s,p)$ is noninvertible. This singular solution therefore cannot be found from the general solution proposed by Jackiw in the sense that we cannot find corresponding functions $\Psi(p,s)$, $f(z)$, and $g(z)$.

For the case $\mathcal{L}_{4,a}$ with $a \neq \pm 1,0$, we have to solve the equation for F listed in Table III. The analysis of this equation gives rise to a family of ODE's which do not enter the classification of Painlevé–Gambier[8,9] since they do not possess the Painlevé property.[10]

For $\mathcal{L}_{5,\varepsilon}$, the method of symmetry reduction on ODE's can be used to reduce the order of the equation for F listed in Table III. Using the infinitesimal symmetry generator $2\partial_x + x\partial_F$, we make the following change of variable:[6]

$$y = 4F - x^2, \quad w = \tfrac{1}{2}x, \tag{38}$$

which allows us to rewrite the equation as

$$2(y-1)w_{yy} + 16(1-y)(w_y)^3 + 4\varepsilon(w_y)^2 = 0. \tag{39}$$

Setting $z(y) = w_y$, we obtain the first-order ODE

$$2(y-1)z_y + 16(1-y)z^3 + 4\varepsilon z^2 = 0, \tag{40}$$

which is Abel's equation of the first kind, and therefore does not possess explicit analytical solutions.[11] In the literature[12] one can find existence theorems for solutions of (40) with property $z_y(0) = 0$ and $\lim_{u\to\infty} z(u) = 0$. For some solutions their Taylor expansions were found and others are given in the tables.[12]

For $\mathcal{N}_1$, $\theta = \theta(x)$ is an arbitrary function of x and we have

$$\rho = \frac{\sqrt{2\lambda}}{\theta_x}, \tag{41}$$

$$v(x,t) = \theta_x \neq 0. \tag{42}$$

Thus, any static velocity potential will satisfy the system of equations (12) provided that the density is also static and is related to θ through equation (41). Such a solution cannot be obtained from the general solution (25) since the change of variables $(x,t) \to (s,p)$ is again singular. Indeed, we have $s = p = \theta_x$.

For $\mathcal{N}_2$, we have

$$\theta(x,t) = \frac{\lambda}{a_0^2}t + c_0, \quad \rho(x,t) = a_0. \tag{43}$$

Here we obtain uniform (in x) solutions where the potential θ evolves in time in a linear manner. Thus, the velocity is zero and the density constant in both time and space.

For $\mathcal{N}_{4,\varepsilon}$, we have

$$\theta(x,t) = a_0 x + \varepsilon t + a_1, \quad \rho(x,t) = \sqrt{\frac{\lambda}{\frac{1}{2}a_0^2 + \varepsilon}}, \tag{44}$$

and

$$v(x,t) = a_0, \tag{45}$$

where a_0 and a_1 are constants. Again, we have a trivial constant solution.

For $\mathcal{K}_{1,\varepsilon}$, we get

$$\theta(x,t) = \tfrac{1}{2}\varepsilon \ln(x^2 - 2\varepsilon t) + c_0, \quad \rho(x,t) = \frac{\sqrt{2\lambda}(x^2 - 2\varepsilon t)}{\sqrt{4\varepsilon t - x^2}}, \tag{46}$$

$$v(x,t) = \frac{\varepsilon x}{x^2 - 2\varepsilon t}. \tag{47}$$

The two cases $\varepsilon = 1$ and $\varepsilon = -1$ are qualitatively different. When $\varepsilon = 1$ we require $2t < x^2 < 4t$ for the solution to be defined. When $\varepsilon = -1$ the condition becomes $-2t < x^2 < -4t$, which implies that the density ρ is real-valued only for negative values of t. Thus, it does not correspond to a physical density. The solution (46) corresponds to the case

$$\Psi(p,s) = \frac{1}{2}\varepsilon \frac{(s^2 - 3p^2)}{(p^2 - s^2)} - \frac{1}{2}\varepsilon \ln(p^2 - s^2) + \frac{1}{2}\varepsilon \ln 2 + c_0, \tag{48}$$

where $\Psi(p,s) =$ (25) with

$$f(z) = g(z) = \frac{1}{2}\varepsilon \ln\left(\frac{\sqrt{2}}{z}\right) - \frac{3}{4}\varepsilon + \frac{1}{2}c_0.$$

For $\mathcal{K}_{2,\varepsilon}$, we get

$$\theta(x,t) = te^{4\varepsilon(x_0 - x)}, \quad \rho(x,t) = \frac{\sqrt{\lambda}}{e^{2\varepsilon(x_0 - x)}\sqrt{1 + 8t^2 e^{4\varepsilon(x_0 - x)}}}, \tag{49}$$

$$v(x,t) = -4\varepsilon t e^{4\varepsilon(x_0 - x)}. \tag{50}$$

Thus ρ is always a finite, nonzero and positive function, while θ becomes infinite as $x \to -\infty$ or $|t| \to \infty$. This solution corresponds to the case

$$\Psi(p,s) = \tfrac{1}{4}\varepsilon p \ln(\tfrac{1}{2}(s^2 - p^2)) - x_0 p, \tag{51}$$

where $\Psi(p,s) =$ (25) with

$$f(z) = -g(-z) = \tfrac{1}{4}\varepsilon z \ln z - (\tfrac{1}{2}x_0 + \tfrac{1}{8}\varepsilon \ln 2)z.$$

For $\mathcal{K}_{3,\varepsilon}$, we have

$$\theta(x,t) = \tfrac{1}{2}(e^{a_0 + 2\varepsilon t} + \varepsilon x^2), \quad \rho(x,t) = \frac{\sqrt{\lambda}}{\sqrt{\varepsilon e^{a_0 + 2\varepsilon t} + \frac{1}{2}x^2}}, \tag{52}$$

$$v(x,t) = \varepsilon x. \tag{53}$$

Here θ and ρ are always nonzero, finite and positive. As $t \to \infty$ or $|x| \to \infty$, θ becomes unbounded and ρ approaches zero. This solution corresponds to the case

$$\Psi(p,s) = \tfrac{1}{4}\varepsilon(s^2 + p^2) - \tfrac{1}{4}\varepsilon(s^2 - p^2)\ln(\tfrac{1}{2}\varepsilon(s^2 - p^2)) + \tfrac{1}{4}\varepsilon(s^2 - p^2)a_0 - \varepsilon p^2, \tag{54}$$

where $\Psi(p,s) =$ (25) with

$$f(z) = g(-z) = -\tfrac{3}{8}\varepsilon z^2 - \tfrac{1}{8}\varepsilon a_0 z^2 + \tfrac{1}{8}\varepsilon z^2 \ln(z^2/2).$$

For $\mathcal{K}_{4,\varepsilon}$, we have

$$\theta(x,t) = \varepsilon x t - \frac{1}{3}t^3 + \frac{2}{3}a_0\varepsilon \frac{(\varepsilon x - \frac{1}{2}t^2)^{3/2}}{\sqrt{\lambda - a_0^2/2}} + c_0, \quad \rho(x,t) = \sqrt{\frac{\lambda - a_0^2/2}{\varepsilon x - \frac{1}{2}t^2}}, \tag{55}$$

$$v(x,t) = \varepsilon t + \frac{a_0}{\sqrt{\lambda - a_0^2/2}} \left(\varepsilon x - \frac{1}{2} t^2 \right)^{1/2}, \tag{56}$$

where $x > \frac{1}{2}t^2$ (in the case where $\varepsilon = 1$) or $x < -\frac{1}{2}t^2$ (in the case where $\varepsilon = -1$). This solution corresponds to the case

$$\Psi(p,s) = \frac{1}{6}\varepsilon p^3 + \frac{1}{3}\varepsilon \frac{a_0^3}{(2\lambda)^{3/2}} s^3 - \frac{1}{2}\varepsilon p s^2 + \frac{2}{3}\varepsilon \frac{a_0}{(2\lambda)^{3/2}} \sqrt{\lambda - a_0^2/2}\, s^3, \tag{57}$$

where $\Psi(p,s) =$ (25) with

$$f(z) = \frac{1}{12}\varepsilon z^3 - \frac{1}{12}\varepsilon \frac{a_0^3}{(2\lambda)^{3/2}} z^3 - \frac{1}{6}\varepsilon \frac{a_0}{(2\lambda)^{3/2}} \sqrt{\lambda - a_0^2/2}\, z^3,$$

$$g(z) = \frac{1}{12}\varepsilon z^3 + \frac{1}{12}\varepsilon \frac{a_0^3}{(2\lambda)^{3/2}} z^3 + \frac{1}{6}\varepsilon \frac{a_0}{(2\lambda)^{3/2}} \sqrt{\lambda - a_0^2/2}\, z^3.$$

It has therefore been demonstrated that for the subalgebras of types $\{\mathcal{L}_1, \mathcal{L}_2, \mathcal{L}_3, \mathcal{L}_{4,-1}\}$ and $\{\mathcal{K}_{1,\varepsilon}, \mathcal{K}_{2,\varepsilon}, \mathcal{K}_{3,\varepsilon}, \mathcal{K}_{4,\varepsilon}\}$, the invariant solutions fall into the general solution (25) given by Jackiw. However, for the subalgebras $\{\mathcal{L}_{4,1}, \mathcal{N}_1, \mathcal{N}_2, \mathcal{N}_{4,\varepsilon}\}$, the transformations $(x,t) \to (s,p)$ are noninvertible and so the invariant solutions are not included in the general solution (25).

C. Solutions of the Born–Infeld model

Each solution of the Chaplygin equations (12) can be used to obtain an equivalent solution of the relativistic Born–Infeld equations (10) and (11) in one spatial dimension. Since the Chaplygin and Born–Infeld models involve two distinct parametrizations of the Nambu–Goto target space variables X^0 and X^{d+1}, we equate these variables to both their relativistic and nonrelativistic representations:

$$X^0 = c t_R = \frac{1}{\sqrt{2}} (t_{NR} + \theta_{NR}(t_{NR}, \mathbf{r})), \tag{58}$$

$$X^{d+1} = \frac{1}{c}\theta(t_R, \mathbf{r}) = \frac{1}{\sqrt{2}} (t_{NR} - \theta_{NR}(t_{NR}, \mathbf{r})). \tag{59}$$

Renaming the time variables $T = (1/c)\, t_{NR}$ and $t = t_R$, we obtain the following method of solution transformation described by Jackiw.[1] If $\theta_{NR}(\mathbf{r},t)$ is a solution of the Chaplygin equation (4), then a solution $\theta_R(\mathbf{r},t)$ of the Born–Infeld equation can be determined as follows. First, determine the function $T(\mathbf{r},t)$ from the equation

$$T + \frac{1}{c^2}\theta_{NR}(\mathbf{r},T) = \sqrt{2}t, \tag{60}$$

then

$$\theta_R(\mathbf{r},T) = \frac{1}{\sqrt{2}} c^2 T - \frac{1}{\sqrt{2}}\theta_{NR}(\mathbf{r},T) = c^2(\sqrt{2}T - t) \tag{61}$$

is an associated Born–Infeld solution. Since the equation (60) cannot always be solved explicitly for $T(\mathbf{r},t)$ it follows that explicit Born–Infeld solutions cannot always be found in this manner. For instance, in the case of $\mathcal{L}_1$, the Born–Infeld solution is

$$\theta_R(x,t) = \frac{1}{\sqrt{2}}c^2T - \frac{1}{4\sqrt{2a_0}}\ln\left(\frac{\sqrt{a_0}x^2+T}{\sqrt{a_0}x^2-T}\right) - \frac{c^2}{\sqrt{2}}a_1, \tag{62}$$

where $T(x,t)$ satisfies the equation

$$T + \frac{1}{c^2}\left(\frac{1}{4\sqrt{a_0}}\ln\left(\frac{\sqrt{a_0}x^2+T}{\sqrt{a_0}x^2-T}\right)\right) + a_1 = \sqrt{2}t \tag{63}$$

and the density (for any general solution θ_R) is

$$\rho_R(x,t) = \frac{a(\theta_R)_t}{c^2\sqrt{c^2-\partial_\mu(\theta_R)\partial^\mu(\theta_R)}}. \tag{64}$$

However, for the subalgebras $\mathcal{L}_{4,1}$, $\mathcal{N}_1$, $\mathcal{N}_2$, $\mathcal{N}_{4,\varepsilon}$, and $\mathcal{K}_{2,\varepsilon}$, we do obtain explicit Born–Infeld solutions equivalent to the corresponding Chaplygin solutions.

For $\mathcal{L}_{4,1}$, we have

$$\begin{aligned}\theta_R(x,t) &= \frac{\frac{1}{\sqrt{2}}a_0x + \left(1-\frac{a_1}{c^2}\right)c^2t}{1+\frac{a_1}{c^2}}\ ,\\ \rho_R(x,t) &= \frac{a\left(1-\frac{a_1}{c^2}\right)}{\left(1+\frac{a_1}{c^2}\right)\sqrt{c^2+\frac{a_0^2}{2(1+a_1/c^2)^2}}}.\end{aligned} \tag{65}$$

This represents a travelling wave solution.

For $\mathcal{N}_1$, we have

$$\theta_R(x,t) = c^2t - \sqrt{2}f(x), \quad \rho_R(x,t) = -\frac{a}{\sqrt{2}\left(\frac{df}{dx}\right)}, \tag{66}$$

where $f=f(x)$ is an arbitrary function, and is in fact the nonrelativistic solution $\theta_{NR}=f(x)$. This is a generalized travelling wave (i.e., Riemann wave). The gradient catastrophe occurs where $df/dx=0$, which allows a shock wave.

For $\mathcal{N}_2$, we have

$$\theta_R(x,t) = a_0t + c_0, \quad \rho_R(x,t) = \frac{-aa_0}{c\sqrt{c^4-a_0^2}}, \tag{67}$$

where $|a_0|<c^2$. This is a trivial solution since using the invariance with respect to t leads us to a constant solution.

For $\mathcal{N}_{4,\varepsilon}$, we have

$$\theta_R(x,t) = \frac{1}{1+\frac{\varepsilon}{c^2}}((c^2-\varepsilon)t+a_0x+a_1), \quad \rho_R(x,t) = \frac{-a(c^2-\varepsilon)}{c^2\sqrt{4\varepsilon+a_0^2}}, \tag{68}$$

where if $\varepsilon=-1$ then $|a_0|>2$. This represents a travelling wave.

For $\mathcal{K}_{2,\varepsilon}$, we have

$$\theta_R(x,t)=\frac{c^2t(c^2-e^{4\varepsilon(x_0-x)})}{(c^2+e^{4\varepsilon(x_0-x)})},$$
$$\rho_R(x,t)=\frac{-a(c^4-e^{8\varepsilon(x_0-x)})}{\sqrt{4c^4e^{4\varepsilon(x_0-x)}(c^2+e^{4\varepsilon(x_0-x)})^2+64c^8t^2e^{4\varepsilon(x_0-x)}}}. \tag{69}$$

This is a kink-type solution.

IV. THE METHOD OF DIFFERENTIAL CONSTRAINTS

We determined in Sec. III that the group-invariant solutions of the Chaplygin system (12) were either singular or derivable from the general solution of the second-order partial differential equation (24). A further generalization of the classical symmetry reduction is the introduction of the general ''side conditions'' method.[13] This method includes all known methods for determining special classes of solutions of PDE's (among others group-invariant solutions, nonclassical and weak symmetries, partially invariant solutions, separation of variables, and many others). Differential constraints possess a group interpretation as ''conditional symmetries.''[14–16] It consists basically in modifying the original system by adding to it certain compatible differential constraints. The overdetermined system of equations obtained in this way admits, in some cases, a larger class of Lie point symmetry groups, and consequently can provide new classes of solutions of the original system. In this section our choice of differential constraints is motivated by our main aim which is the construction of multiplicative separation of dependent variables

$$u_i(x,t)=f_i(x)g_i(t),\quad i=1,2, \tag{70}$$

for some functions f_i and g_i of one variable. Here, u_1 and u_2 stand for ρ and θ, respectively. Ansatz (70) corresponds to the following second-order differential constraints:

$$\partial_x\partial_t \ln u_i=0,\quad i=1,2. \tag{71}$$

Note that the differential constraints (71) are no longer restricted to be first-order PDE's provided by the characteristics of symmetries generated by (13). Hence, according to Ref. 6 solutions of the overdetermined system composed of the Chaplygin equations (12) [or Born–Infeld equations (10), (11)] subjected to (71) are no longer group-invariant solutions.

We now show that these forms of constraints are compatible with the Chaplygin system (12) and enable us to construct several families of solitonlike solutions. Indeed, substituting (70) into (12) we obtain a system of differential equations

$$g_{2,t}f_2+\frac{1}{2}g_2^2(f_{2,x})^2=\frac{\lambda}{f_1^2g_1^2},$$
$$g_{1,t}f_1+g_1g_2f_{1,x}f_{2,x}+g_1g_2f_1f_{2,xx}=0. \tag{72}$$

Eliminating function f_1g_1 from (72) we obtain

$$-\tfrac{1}{2}g_{2,tt}f_2-g_2g_{2,t}(f_{2,x})^2+g_2g_{2,t}f_2f_{2,xx}=0. \tag{73}$$

Integrating with respect to t and relabeling the functions f_2 and g_2 as f and g, respectively, we obtain

$$-\tfrac{1}{2}g_tf-\tfrac{1}{2}g^2(f_x)^2+\tfrac{1}{2}g^2ff_{xx}=\gamma(x). \tag{74}$$

Let us consider separately three cases, namely (a) the case in which $\gamma(x)$ vanishes everywhere, (b) the case where $\gamma(x)=f$ and $ff_{xx}-(f_x)^2=f$, and (c) the case where $\gamma(x)=f$ and $ff_{xx}-(f_x)^2=-f$. It is easy to show that in case (a), when $\gamma(x)=0$ identically, the solution of the system (74) takes the form

$$\theta(x,t)=\frac{2K_2}{K_3(K_2t+K_1)}\sinh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right),$$
$$\rho(x,t)=\sqrt{\frac{K_3\lambda}{2}}\frac{K_2t+K_1}{K_2\sinh^2(\frac{1}{2}\sqrt{K_3}(x+x_0))}. \tag{75}$$

For $K_3\neq 0$ and $t\neq -K_1/K_2$, the expressions (75) represent a bump-type solution. Making use of the transformations (60) and (61), we get a solution of the Born–Infeld equation (9),

$$\theta_R(x,t)=-\frac{c^2K_1}{\sqrt{2}K_2}\pm\frac{c^2}{\sqrt{2}K_2}\sqrt{2K_2^2t^2+2\sqrt{2}K_1K_2t+K_1^2-\frac{8K_2^2}{c^2K_3}\sinh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)}. \tag{76}$$

This is a bump-type solution, called in literature a Gaussian solution.[17]

In the cases (b) and (c), the equation (74) can be integrated to give the solutions

$$\theta(x,t)=-\frac{2\sqrt{2}}{K_3}\sinh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)\left(\frac{1+e^{2\sqrt{2}(t+K_1)}}{1-e^{2\sqrt{2}(t+K_1)}}\right),$$
$$\rho(x,t)=\sqrt{\lambda}\left\{\frac{4}{K_3}\frac{\sinh^2(\frac{1}{2}\sqrt{K_3}(x+x_0))}{(1-e^{2\sqrt{2}(t+K_1)})^2}\left(-4e^{2\sqrt{2}(t+K_1)}+\cosh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)\right.\right.$$
$$\left.\left.\times(1+e^{2\sqrt{2}(t+K_1)})^2\right)\right\}^{-1/2} \tag{77}$$

and

$$\theta(x,t)=\frac{2\sqrt{2}}{K_3}\sinh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)\tan(\sqrt{2}(t_0-t)),$$
$$\rho(x,t)=\sqrt{\lambda}\left\{\frac{4}{K_3}\sinh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)\right.$$
$$\left.\times\left(\cosh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)\tan^2(\sqrt{2}(t_0-t))-\sec^2(\sqrt{2}(t_0-t))\right)\right\}^{-1/2}, \tag{78}$$

respectively. For $K_3\neq 0$ and $t\neq(\sqrt{2}/4)\ln 1-K_1$, the solution (77) represents a bump-type solution. With a specific choice of the constants K_1, K_3, and x_0 such that the density ρ is nonsingular at $x=0$, we get for the solution (77) the functions

$$\theta(x,t)=\frac{1}{\sqrt{2}}\cosh^2 x\left(\frac{1+e^{2\sqrt{2}t}}{1-e^{2\sqrt{2}t}}\right),$$
$$\rho(x,t)=\frac{\sqrt{\lambda}}{\cosh x}\left(\frac{(1-e^{2\sqrt{2}t})^2}{4e^{2\sqrt{2}t}+(1+e^{2\sqrt{2}t})^2\sinh^2 x}\right)^{1/2}. \tag{79}$$

These functions are represented in Figs. 1 and 2. For the solution (78), the same choice for the constants K_1, K_3, and x_0, along with $t_0=0$, lead to

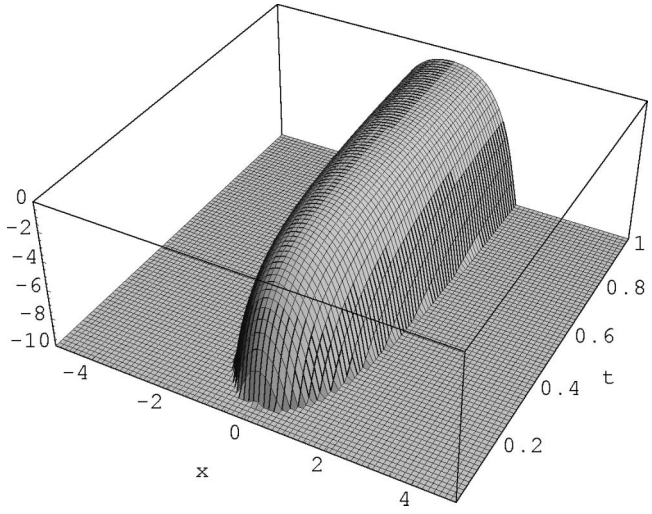

FIG. 1. The function $\theta(x,t)$ in Eq. (79).

$$\theta(x,t) = \frac{1}{\sqrt{2}}\cosh^2 x \tan(\sqrt{2}t),$$
$$\rho(x,t) = \frac{\sqrt{\lambda}}{\cosh x}\left(\frac{1}{\sec^2(\sqrt{2}t)+\sinh^2 x \tan^2(\sqrt{2}t)}\right)^{1/2}. \tag{80}$$

These functions are represented in Figs. 3 and 4. For this solution (78), the function $\theta(x,t)$ includes discontinuities at $t=t_0+n(\sqrt{2}\pi/4)$, where n is an integer. The density $\rho(x,t)$ is defined and continuous everywhere and is a multibump solution.

Once again, we obtain the Born–Infeld solutions,

$$\theta_R(x,t) = c^2(\sqrt{2}T-t), \tag{81}$$

where $T(x,t)$ satisfies the equations

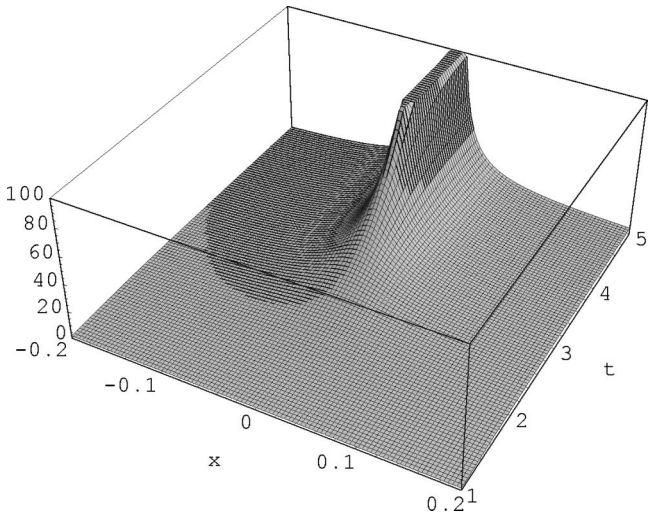

FIG. 2. The function $\rho(x,t)$ in Eq. (79).

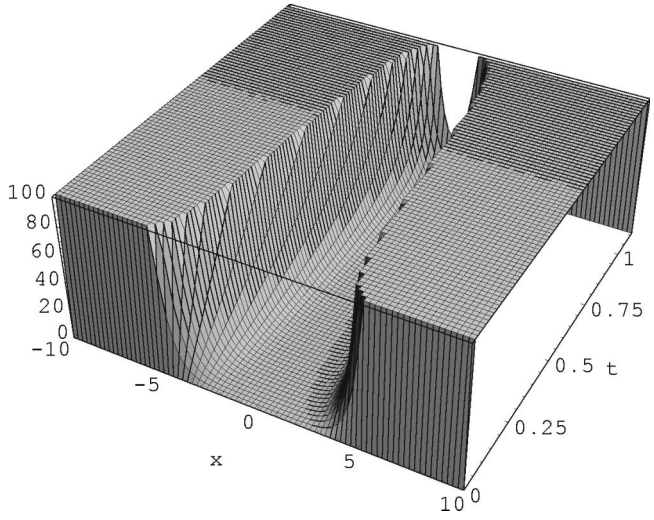

FIG. 3. The function $\theta(x,t)$ in Eq. (80).

$$T+\frac{1}{c^2}\left(-\frac{2\sqrt{2}}{K_3}\sinh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)\left(\frac{1+e^{2\sqrt{2}(T+K_1)}}{1-e^{2\sqrt{2}(T+K_1)}}\right)\right)=\sqrt{2}t \tag{82}$$

and

$$T+\frac{1}{c^2}\left(\frac{2\sqrt{2}}{K_3}\sinh^2\left(\frac{1}{2}\sqrt{K_3}(x+x_0)\right)\tan(\sqrt{2}(t_0-T))\right)=\sqrt{2}t, \tag{83}$$

respectively.

It is manifest that the solution (75), corresponding to case (a) is simply a generalization of the solution (33), found in Sec. III for the case $\mathcal{L}_{4,-1}$. In fact, solution (33) is the special case where $K_2=1$, $K_1=0$. By the simple change of variable $t\rightarrow(1/K_2)(t-K_1)$, (33) can be transformed to its generalized counterpart (75). For each of the solutions (77) and (78), corresponding to cases (b) and (c), respectively, the Jacobian of the transformation

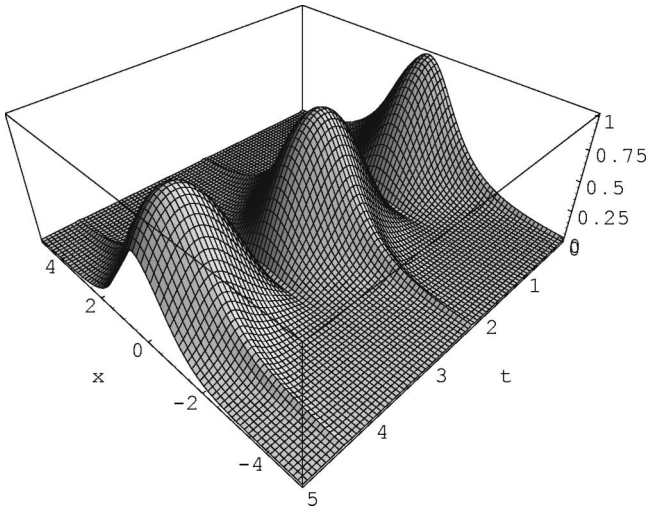

FIG. 4. The function $\rho(x,t)$ in Eq. (80).

$$J = \frac{\partial(p,s)}{\partial(x,t)} \tag{84}$$

is nonzero. This would indicate that the change of variables is invertible. However, attempts to invert the transformation lead to transcendental trigonometric equations for the variables x and t in both cases, so it is not possible to determine equivalent functions $\Psi(p,s)$. Therefore, we cannot determine whether or not the solutions (77) and (78) correspond to the general solution of Jackiw.[1]

V. CONCLUDING REMARKS

Group-invariant solutions of the Chaplygin gas equations have been determined for the one-dimensional subalgebras of the general Chaplygin Lie algebra. In addition, based on these solutions, a number of explicit solutions of the Born–Infeld relativistic model have been determined. The nonsingular solutions [where the transformation $(x,t)\rightarrow(s,p)$ is invertible] were found to be linked to special cases of the general solution described by Jackiw's approach.[1] Certain classes of solutions were found in which the density ρ of the fluid is constant in both time and space. These solutions were found not to be included in the classification presented in Ref. 1. In some cases, the reduced equations for the subalgebras $\mathcal{L}_2$, $\mathcal{N}_2$, and $\mathcal{N}_{4,\varepsilon}$ satisfy the first and fifth Painlevé equations.[10] In summary, we can state that the symmetry reduction method in the version presented here proved to be a useful tool in the sense that in the cases of Chaplygin and Born–Infeld it led to many new interesting solutions, among them kinks, bumps, and multiwave solutions.

A question arises as to whether our approach can be extended to obtain partially invariant solutions[18] with defect structure $\delta=1$. Further, can it provide new classes of solutions which will describe more diverse types of solutions than those found in group-invariant cases. This will be discussed in more detail in a future work.

Exact duality transformations for sigma models and gauge theories

Hendryk Pfeiffer[a)]

(Received 6 September 2002; accepted 26 March 2003)

We present an exact duality transformation in the framework of statistical mechanics for various lattice models with non-Abelian global or local symmetries. The transformation applies to sigma models with variables in a compact Lie group G with global $G\times G$-symmetry (the chiral model) and with variables in coset spaces G/H and a global G-symmetry [for example, the nonlinear O(N) or $\mathbb{RP}^N$ models] in any dimension $d\geqslant 1$. It is also available for lattice gauge theories with local gauge symmetry in dimensions $d\geqslant 2$ and for the models obtained from minimally coupling a sigma model of the type mentioned above to a gauge theory. The duality transformation maps the strong coupling regime of the original model to the weak coupling regime of the dual model. Transformations are available for the partition function, for expectation values of fundamental variables (correlators and generalized Wilson loops) and for expectation values in the dual model which correspond in the original formulation to certain ratios of partition functions (free energies of dislocations, vortices or monopoles). Whereas the original models are formulated in terms of compact Lie groups G and H, coset spaces G/H and integrals over them, the configurations of the dual model are given in terms of representations and intertwiners of G and H. They are spin networks and spin foams. The partition function of the dual model describes the group theoretic aspects of the strong coupling expansion in a closed form.
[DOI: 10.1063/1.1580071]

I. INTRODUCTION

The most prominent example of an exact duality transformation in statistical mechanics is the transformation for the two-dimensional Ising model.[1] It is an exact transformation which changes the variables of the full partition function of the model and maps the high temperature regime of the original model to the low temperature regime of the dual model and conversely (for the Ising model, the original and the dual model coincide).

In the following, we make use of the correspondence of quantum field theory in the Euclidean (imaginary time) formulation in d space dimensions plus time with equilibrium statistical mechanics in $d+1$ dimensions and often use the words *path integral*, *action*, and *coupling* for *partition function*, *energy*, and *temperature*, respectively.

The duality transformation of the Ising model was subsequently generalized to more general lattice systems with $\mathbb{Z}_2$ symmetries,[2] namely systems in d-dimensions whose variables are $\mathbb{Z}_2$-valued k-forms, $0\leqslant k\leqslant d$, i.e., spin models with global $\mathbb{Z}_2$ symmetry, pure lattice gauge theories with local $\mathbb{Z}_2$ gauge symmetry, theories for $\mathbb{Z}_2$-valued antisymmetric tensor fields, and so on, and to their counterparts with U(1)-symmetries,[3] in particular to the XY-model and pure U(1) gauge theory on the lattice.[3,4] For lattice models with Abelian symmetries, there exists an essentially complete picture,[5] and the systems to which the duality transformation applies include even

a)Electronic mail: H.Pfeiffer@damtp.cam.ac.uk

some Higgs models,[6] namely U(1)-lattice gauge theory minimally coupled to a U(1)-valued scalar field, i.e., a Higgs field with frozen radial component.

All these examples of the Abelian duality transformation have some features in common. They map the strong coupling regime of the original model to the weak coupling regime of the dual model. This is a consequence of the change of variables employed in the transformation which essentially involves the Fourier decomposition of the interaction terms e^{-S} for some action S. For example, this replaces U(1)-variables by integers $\mathbb{Z}$ and maps Boltzmann weights with narrow peaks to weights with wide peaks and conversely. The structure of the dual model can be sketched as follows. If, say in a sigma model, the variables are originally associated with the points of the lattice and the interaction terms with the bonds, then the variables of the dual model which are introduced by the Fourier expansion are located at the bonds. In a second step one removes the old variables by performing the relevant sums or integrals which yields additional Boltzmann weights, often constraints, for each point.

As a consequence of the strong–weak nature of the duality transformation, the dual partition function contains essential information on the strong coupling expansion of the original model. In fact, if one understands how the Fourier coefficients of the Boltzmann weight depend on the coupling, the summands of the dual partition function are precisely the terms of the strong coupling expansion and can be sorted by the magnitude of their contribution at strong coupling.

A systematic generalization of these transformations to systems with non-Abelian symmetries proved to be difficult. The calculation of strong coupling expansions of pure non-Abelian lattice gauge theory (see, for example Ref. 7) already exhibits some features of the dual model which one wishes to construct. Fourier expansion is generalized to character decomposition, and the dual variables are irreducible representations of the symmetry group, generalizing the wave numbers of the Fourier series. The main technical difficulties are first to solve the integrals over the variables of the original model in a systematic way, and second to disentangle the lattice combinatorics in order to make the structure of the dual model transparent. Both problems can be overcome if one deals with the non-Abelian group variables at a sufficiently abstract level and if one uses an efficient diagrammatic notation.

The first examples of non-Abelian generalizations were an explicit calculation for pure SU(2) lattice gauge theory in $d=3$ dimensions[8] and, much less obviously, the equivalence of lattice BF-theory (similar to pure lattice Yang–Mills theory, but with δ-functions as the Boltzmann weights) to certain topological state sum models.[9] This correspondence was developed in a nonperturbative approach to quantum gravity. For review articles, see, for example, Refs. 10 and 11. The approach to quantum gravity by quantizing a discrete version of the gauge theory formulation of general relativity has lead to the definition of spin foams.[12–14] A spin foam is an abstract two-complex, consisting of vertices, edges, and faces whose faces are labeled with irreducible representations of some symmetry group while the edges are labeled with compatible intertwiners. Spin foams can be understood as a higher dimensional analog of spin networks. A spin network is a graph whose edges are labeled with representations and whose vertices are labeled with compatible intertwiners (precise definitions of spin networks and spin foams are given below in Sec. III B).

Spin foams provide the appropriate language for a generalization of the exact duality transformation to pure non-Abelian lattice gauge theory in arbitrary dimension $d \geqslant 2$ whose gauge group is a generic compact Lie group G. See Refs. 15 and 16 for lattice gauge theory on hypercubic lattices and Refs. 17 and 18 for the generalization to more general lattices and quantum groups rather than Lie groups.

In this article, we extend the non-Abelian duality transformation to a large class of sigma models whose variables take values in G or G/H, G a compact Lie group and H a Lie subgroup, and which have certain global or local symmetries. (The author is grateful to Alan Sokal who suggested to study this generalization.) This includes, for example, the chiral, the O(N) and $\mathbb{RP}^N$ models, and the models that are obtained from minimally coupling such a sigma model to a non-Abelian lattice gauge theory, for example, some generalized Higgs models with frozen radial degree of freedom.

The duality transformation retains its key properties, namely that it provides a strong–weak relation, that it yields a closed form of the strong coupling expansion of the original model, and that it maps expectation values of the dual model to ratios of partition functions (free energies of dislocations, vortices, or monopoles) in the original formulation and conversely. It therefore relates the fundamental variables of one formulation with some topological defects (collective properties) in the other.

The transformation maps the original model which is formulated in terms of compact Lie groups G and H, functions on G and integrals over G or G/H, to the dual model which is given in terms of the irreducible representations and intertwiners of G and H. The transformation can be understood as a particular application of a Tannaka-Kreĭn-type duality relating groups to their representation categories. That these categories will appear in the dual formulation had already been proposed in Ref. 19. The dual model can be formulated using merely the language of category theory. In the simplest case, it uses the category of finite-dimensional representations of the symmetry group G. This can be extended to more general categories that do not arise as the representation categories of compact Lie groups. The generalization of lattice gauge theory to quantum groups[17,18] is one example. For more details on the relation of groups and quantum groups with certain tensor categories, see, for example, Ref. 20. In this article, we do not explicitly use the language of category theory, but rather present diagrams in addition to the explicit formulas so that one can easily infer the categorial formulation from these diagrams.

While the configurations of the model dual to lattice gauge theory are spin foams,[15] one obtains spin networks as the configurations of the model dual to a sigma model. We thus call the dual models *spin foam models* and *spin network models*, respectively. As the notions of spin networks and spin foams have been developed in an approach to quantum gravity, but might not be familiar to the reader working on statistical mechanics, we try to make this article self-contained and therefore review all relevant definitions and also some background material on the representation theory of compact Lie groups.

The present article is organized as follows. In Sec. II, we summarize some background material on the representation theory of compact Lie groups and introduce a convenient diagrammatical notation. In Sec. III, we present our notation for the lattices we use, namely graphs and abstract two-complexes, and we recall the definitions of spin networks and spin foams. In Sec. IV, we present the duality transformation for the lattice chiral model with symmetry group G. This is generalized in Sec. V to the nonlinear sigma model with variables in coset spaces G/H and in Sec. VI to the nonlinear sigma model for G/H coupled to a lattice gauge theory with gauge group G. We conclude in Sec. VII where we discuss applications, directions for future research, and open questions.

II. MATHEMATICAL BACKGROUND

In this section, we review some basic concepts and results from the representation theory of compact Lie groups. The material presented here is largely textbook knowledge, (see, for example, Refs. 21 and 22 where most of the proofs can be found). The purely algebraic evaluation of the group integrals was first given in Ref. 15; our diagrammatic language follows Refs. 17 and 18.

A. Representation functions

Let G be a compact Lie group. This notion includes in particular any finite group (with the discrete topology). We denote finite-dimensional complex vector spaces on which G is represented by V_ρ and by $\rho: G \to \mathrm{Aut}\, V_\rho$ the corresponding group homomorphisms. Since each finite-dimensional complex representation of G is equivalent to a unitary representation, we select a set $\tilde{\mathcal{R}}_G$ containing one unitary representation of G for each equivalence class of finite-dimensional representations. The tensor product, the direct sum, and taking the dual are supposed to be closed operations on this set. This amounts to a particular choice of representation isomorphisms $\rho_1 \otimes \rho_2 \leftrightarrow \rho_3$ etc., $\rho_j \in \tilde{\mathcal{R}}_G$, which is implicit in our formulas. We furthermore denote by $\mathcal{R}_G \subseteq \tilde{\mathcal{R}}_G$ the subset of irreducible representations.

For a representation $\rho \in \widetilde{\mathcal{R}}_G$, the dual representation is denoted by ρ^*, and the dual vector space of V_ρ by V_ρ^*. The dual representation is given by $\rho^*: G \mapsto \mathrm{Aut}\, V_\rho^*$, where

$$\rho^*(g): V_\rho^* \to V_\rho^*, \quad \eta \mapsto \eta \circ \rho(g^{-1}), \tag{2.1}$$

i.e., $(\rho^*(g)\,\eta)(v) = \eta(\rho(g^{-1})v)$ for all $v \in V_\rho$. There exists a one-dimensional "trivial" representation of G which is isomorphic to $\mathbb{C}$.

For the unitary representations V_ρ, $\rho \in \widetilde{\mathcal{R}}_G$, we have standard (sesquilinear) scalar products $\langle \cdot;\cdot \rangle$ and orthonormal bases $\{e_j\}_j$. Therefore, we can define a bijective antilinear map $*: V_\rho \to V_\rho^*$ induced by the scalar product,

$$*(v) := (w \mapsto \langle v; w \rangle), \quad v \in V_\rho, \tag{2.2}$$

and construct the dual bases $\{\eta^j\}_j$ by $\eta^j := *(e_j)$. Identifying $(V_\rho^*)^* = V_\rho$, this yields $\langle e_j; e_k \rangle = \eta^j(e_k) = \delta_{jk}$ and furthermore induces a scalar product on V_ρ^*, namely $\langle \eta^j; \eta^k \rangle = \eta^k(e_j)$, $1 \leqslant j,\ k \leqslant \dim V_\rho$.

The matrix elements of the representation matrices $\rho(g)$ define complex-valued functions,

$$t_{jk}^{(\rho)}: G \to \mathbb{C}, \quad g \mapsto t_{jk}^{(\rho)}(g) := \eta^j(\rho(g)e_k) = (\rho(g))_{jk}, \tag{2.3}$$

where $\rho \in \widetilde{\mathcal{R}}_G$, $1 \leqslant j,\ k \leqslant \dim V_\rho$. They are called *representation functions* of G and form a commutative and associative unital algebra over $\mathbb{C}$,

$$C_{\mathrm{alg}}(G) := \{t_{jk}^{(\rho)} :\ \rho \in \widetilde{\mathcal{R}}_G, 1 \leqslant j,k \leqslant \dim V_\rho\}, \tag{2.4}$$

whose product is given by the matrix elements of the tensor product of representations,

$$(t_{jk}^{(\rho)} \cdot t_{\ell m}^{(\sigma)})(g) := t_{j\ell,km}^{(\rho\otimes\sigma)}(g), \tag{2.5}$$

where $\rho, \sigma \in \widetilde{\mathcal{R}}_G$, $1 \leqslant j,\ k \leqslant \dim V_\rho$ and $1 \leqslant \ell,\ m \leqslant \dim V_\sigma$.

We find the following expressions involving the group unit $e \in G$,

$$t_{jk}^{(\rho)}(e) = \delta_{jk}, \tag{2.6}$$

products of group elements,

$$t_{jk}^{(\rho)}(g \cdot h) = \sum_{\ell=1}^{\dim V_\rho} t_{j\ell}^{(\rho)}(g) \cdot t_{\ell k}^{(\rho)}(h), \tag{2.7}$$

and inverse group elements,

$$t_{jk}^{(\rho)}(g^{-1}) = (\rho(g)^{-1})_{jk} = \overline{(\rho(g))_{kj}} = \overline{t_{kj}^{(\rho)}(g)}, \tag{2.8}$$

as well as

$$t_{jk}^{(\rho)}(g^{-1}) = \eta^j(\rho(g)^{-1}e_k) = (\rho^*(g)\,\eta^j)(e_k) = \langle \eta^k; \rho^*(g)\,\eta^j \rangle = t_{kj}^{(\rho^*)}(g), \tag{2.9}$$

so that for unitary representations, the dual representation is just the conjugate one. The bar denotes complex conjugation.

B. Peter–Weyl decomposition and theorem

The structure of the algebra $C_{\mathrm{alg}}(G)$ can be understood if $C_{\mathrm{alg}}(G)$ is considered as a representation of $G \times G$ by combined left and right translation of the function argument,

$$(G\times G)\times C_{\mathrm{alg}}(G)\to C_{\mathrm{alg}}(G),\quad ((g_1,g_2),f)\mapsto(h\mapsto f(g_1^{-1}hg_2)). \tag{2.10}$$

It can then be decomposed into its irreducible components as a representation of $G\times G$.

Theorem 2.1 (Peter–Weyl decomposition): Let G be a compact Lie group.

(1) There is an isomorphism

$$C_{\mathrm{alg}}(G)\cong\bigoplus_{\rho\in\mathcal{R}_G}(V_\rho\otimes V_\rho^*) \tag{2.11}$$

of representations of $G\times G$. Here the direct sum runs over the equivalence classes of finite-dimensional irreducible representations of G. The direct summands $V_\rho\otimes V_\rho^*$ are irreducible as representations of $G\times G$.

(2) The direct sum in (2.11) is orthogonal with respect to the L^2-scalar product on $C_{\mathrm{alg}}(G)$ which is formed using the Haar measure of G on the left-hand side, and using the standard scalar products on the right-hand side,

$$\langle t_{jk}^{(\rho)};t_{\ell m}^{(\sigma)}\rangle_{L^2}:=\int_G\overline{t_{jk}^{(\rho)}(g)}\cdot t_{\ell m}^{(\sigma)}(g)dg=\frac{1}{\dim V_\rho}\delta_{\rho\sigma}\delta_{j\ell}\delta_{km}, \tag{2.12}$$

where $\rho,\ \sigma\in\mathcal{R}_G$ are irreducible. The Haar measure is denoted by $\int_G$ and normalized so that $\int_G dg=1$.

If G is finite, the Haar measure coincides with the normalized summation over all group elements. The decomposition (2.11) directly corresponds to our notation of the representation functions $t_{jk}^{(\rho)}$ for irreducible $\rho\in\mathcal{R}_G$.

Corollary 2.2: Each representation function $f\in C_{\mathrm{alg}}(G)$ can be decomposed according to (2.11),

$$f(g)=\sum_{\rho\in\mathcal{R}_G}\sum_{j,k=1}^{\dim V_\rho}\hat{f}_{jk}^{(\rho)}t_{jk}^{(\rho)}(g),\quad\text{where}\ \ \hat{f}_{jk}^{(\rho)}=\dim V_\rho\int_G\overline{t_{jk}^{(\rho)}(g)}f(g)dg. \tag{2.13}$$

For any algebraic $f\in C_{\mathrm{alg}}(G)$, all except finitely many coefficients $f_{jk}^{(\rho)}$ are zero. The analytical aspects of $C_{\mathrm{alg}}(G)$ are given by the Peter–Weyl theorem.

Theorem 2.3 (Peter–Weyl theorem): Let G be a compact Lie group. Then $C_{\mathrm{alg}}(G)$ is dense in $L^2(G)$ with respect to the L^2-norm.

We use the Peter–Weyl theorem in order to complete $C_{\mathrm{alg}}(G)$ with respect to the L^2-norm to $L^2(G)$. Functions $f\in L^2(G)$ then correspond to square summable series in (2.13). These series are invariant under a reordering of summands, and their limits commute with group integrations. We make use of these invariances in the duality transformation. If G is a finite group, $C_{\mathrm{alg}}(G)$ is a finite-dimensional vector space so that the corresponding results hold trivially.

We can summarize these ideas and state that the algebraic structure of $C_{\mathrm{alg}}(G)$ is sufficient to determine the structure of the larger function space $L^2(G)$.

C. Character decomposition

The *characters* of G are the algebraic class functions, i.e., those functions $f\in C_{\mathrm{alg}}(G)$ that satisfy $f(hgh^{-1})=f(g)$ for all $g,\ h\in G$.

Proposition 2.4: For class functions $f\in C_{\mathrm{alg}}(G)$, the Peter–Weyl decomposition (2.13) specializes to the *character decomposition*

$$f(g)=\sum_{\rho\in\mathcal{R}_G}\hat{f}_\rho\chi^{(\rho)}(g),\quad\text{where}\ \ \hat{f}_\rho=\int_G\overline{\chi^{(\rho)}(g)}f(g)dg. \tag{2.14}$$

Here

$$\chi^{(\rho)} := \sum_{j=1}^{\dim V_\rho} t_{jj}^{(\rho)} \tag{2.15}$$

denotes the character of the representation $\rho \in \widetilde{\mathcal{R}}_G$. For irreducible ρ, $\sigma \in \mathcal{R}_G$, the orthogonality relation (2.12) implies

$$\langle \chi^{(\rho)}; \chi^{(\sigma)} \rangle_{L^2} = \int_G \overline{\chi^{(\rho)}(g)} \chi^{(\sigma)}(g) dg = \delta_{p\sigma}. \tag{2.16}$$

D. Algebraic evaluation of group integrals

For the duality transformation, it is important to understand the Haar measure of G in the picture of the Peter–Weyl decomposition (2.11). First we decompose a generic representation function into representation functions of irreducible representations.

Proposition 2.5: Let G be a compact Lie group and $\rho \in \widetilde{\mathcal{R}}_G$ be a finite-dimensional unitary representation of G with the complete decomposition

$$V_\rho \cong \bigoplus_{j=1}^{k} V_{\tau_j}, \quad \tau_j \in \mathcal{R}_G, k \in \mathbb{N}, \tag{2.17}$$

into irreducible components τ_j. Let $P^{(j)}: V_\rho \to V_{\tau_j} \subseteq V_\rho$ be the G-invariant orthogonal projectors associated with the above decomposition. Then

$$t_{mn}^{(\rho)}(g) = \sum_{j=1}^{k} \sum_{p,q=1}^{\dim V_{\tau_j}} \overline{P_{pm}^{(j)}} t_{pq}^{(\tau_j)}(g) P_{qn}^{(j)}, \tag{2.18}$$

where $P_{qn}^{(j)} = \langle w_q^{(j)}; v_n \rangle$. Here $\{v_i\}_i$ denotes an orthonormal basis of V_p and $\{w_i^{(j)}\}_i$ an orthonormal basis of $V_{\tau_j} \subseteq V_\rho$.

Proof: The representation function is Peter–Weyl decomposed by inserting $\mathbb{1} = \Sigma_{j=1}^{k} P^{(j)}$ twice into the right-hand side of $t_{mn}^{(\rho)}(g) = \langle v_m; \rho(g) v_n \rangle$. We use G-invariance $[P^{(j)}, \rho(g)] = 0$ and transversality $P^{(i)} P^{(j)} = \delta_{ij} P^{(j)}$ in order to obtain

$$t_{mn}^{(\rho)}(g) = \sum_{j=1}^{k} \langle v_m; P^{(j)} \rho(g) P^{(j)} v_n \rangle. \tag{2.19}$$

Here $\rho(g) P^{(j)} = \tau_j(g) P^{(j)}$ and

$$P^{(j)} = \sum_{p=1}^{\dim V_{\tau_j}} w_p^{(j)} \cdot \vartheta^{(j)p}, \tag{2.20}$$

where $\{\vartheta^{(j)i}\}_i$ denotes a basis dual to $\{w_i^{(j)}\}_i$. Inserting (2.20) into (2.19), we obtain (2.18). □

For representation functions of an irreducible representation $\rho \in \mathcal{R}_G$, the Haar measure is

$$\int_G t_{jk}^{(\rho)}(g) dg = \begin{cases} 1, & \text{if } \rho \text{ is trivial,} \\ 0, & \text{otherwise,} \end{cases} \tag{2.21}$$

as a consequence of its left–right translation invariance. This can be applied to (2.18) in order to derive an entirely algebraic expression for the Haar measure.

Corollary 2.6: Let G be a compact Lie group and $\rho \in \widetilde{\mathcal{R}}_G$ be a finite-dimensional unitary representation of G with the decomposition (2.17). Assume that precisely the first ℓ components $\tau_1,\ldots,\tau_\ell$, $0 \leqslant \ell \leqslant k$, are equivalent to the trivial representation. Then the Haar measure of a representation function $t^{(\rho)}_{mn}$, $1 \leqslant m,\ n \leqslant \dim V_\rho$, is given by

$$\int_G t^{(\rho)}_{mn}(g)dg = \sum_{j=1}^{\ell} \overline{P^{(j)}_m} P^{(j)}_n . \tag{2.22}$$

Here we have omitted the vector indices corresponding to the one-dimensional representations.

In our calculations, we will refer to Corollary 2.6 in a context in which the integrand is a product of representation functions of irreducible representations. This motivates the following definition.

Definition 2.7: Let G be a compact Lie group and $\rho_1,\ldots,\rho_r \in \mathcal{R}_G$, $r \in \mathbb{N}$, be finite-dimensional irreducible representations of G. The *Haar intertwiner*,

$$T: \bigotimes_{\ell=1}^{r} V_{\rho_\ell} \to \bigotimes_{\ell=1}^{r} V_{\rho_\ell}, \tag{2.23a}$$

is the linear map defined by its matrix elements

$$T_{m_1 m_2 \ldots m_r ; n_1 n_2 \ldots n_r} := \int_G t^{(\rho_1)}_{m_1 n_1}(g) t^{(\rho_2)}_{m_2 n_2}(g) \cdots t^{(\rho_r)}_{m_r n_r}(g) dg. \tag{2.23b}$$

Proposition 2.8: The Haar intertwiner T of (2.23) satisfies

$$T_{m_1 m_2 \ldots m_r ; n_1 n_2 \ldots n_r} = \sum_j \overline{P^{(j)}_{m_1 m_2 \ldots m_r}} P^{(j)}_{n_1 n_2 \ldots n_r}, \tag{2.24}$$

for the projectors

$$P^{(j)}_{n_1 n_2 \ldots n_r} := \langle w^{(j)}; e^{(\rho_1)}_{n_1} \otimes e^{(\rho_2)}_{n_2} \otimes \cdots \otimes e^{(\rho_r)}_{n_r} \rangle, \tag{2.25}$$

with the definitions of Proposition 2.5, as well as for all $h \in G$,

$$T = (\rho_1(h) \otimes \cdots \otimes \rho_r(h)) \circ T = T \circ (\rho_1(h) \otimes \cdots \otimes \rho_r(h)), \tag{2.26}$$

$$T \circ T = T. \tag{2.27}$$

The first equation (2.24) is a consequence of Corollary 2.6 while (2.26) and (2.27) follow from the translation invariance of the Haar measure. In particular, T forms a morphism of representations (*intertwiner*) of G. The map T has been studied in a more general context in Ref. 18.

In the subsequent sections, we will apply Corollary 2.6 in rather complicated calculations. It is therefore convenient to introduce diagrams which visualize the structure of the indices in these formulas (Fig. 1).

The diagrams are read from top to bottom. We draw directed lines which are labeled with representations $\rho \in \widetilde{\mathcal{R}}_G$ of G. If the arrow points down, the line denotes the identity map of V_p [Fig. 1(a)]. If the arrow points up, it refers to the identity map of the dual representation V^*_ρ. A representation function $t^{(\rho)}_{mn}$ is denoted by a box with an incoming and an outgoing line (b), and a product of representation functions by boxes placed next to each other (c). The Haar intertwiner is visualized by the box labeled T in (d), and the calculation of T given by (2.23b) is shown in diagram (e) where the full dots represent the projectors, and the dotted line indicates the simultaneous summation over them.

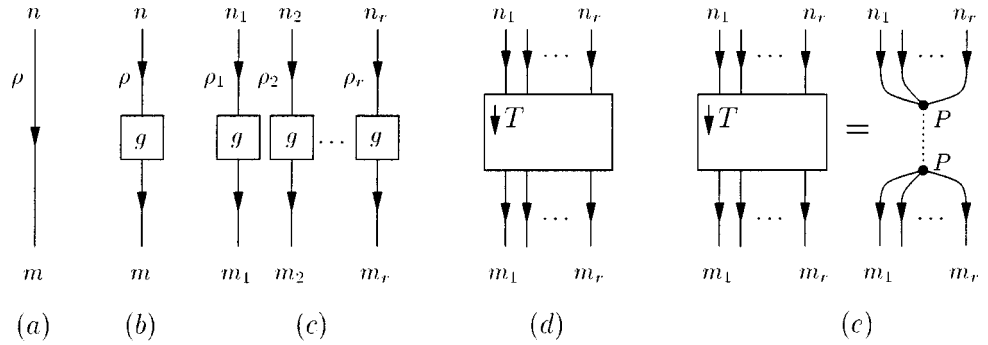

FIG. 1. Diagrams to visualize the index structure in the calculation of group integrals. (a) The identity map of V_ρ; (b) a representation function $t^{(\rho)}_{mn}$; (c) a product of representation functions $t^{(\rho_1)}_{m_1n_1}\cdots t^{(\rho_r)}_{m_rn_r}$; (d) the Haar intertwiner; and (e) the calculation of the Haar intertwiner (2.23b).

E. Coset spaces and spherical functions

In the study of coset spaces G/H, we allow H to be any Lie subgroup of G. First we recall some basic definitions.

Definition 2.9: Let G be a compact Lie group and $H\leqslant G$ be a Lie subgroup.

(1) A finite-dimensional irreducible representation V_ρ of G is said to be of *class-1 with respect to H* if V_ρ contains an H-invariant vector $0\neq v_0\in V_\rho$, i.e., $\rho(h)v_0=v_0$ for all $h\in H$. The subset $\mathcal{R}_H^G\subseteq\mathcal{R}_G$ denotes the set of class-1 representations of G with respect to H.

(2) H is called a *massive* subgroup of G if for each class-1 representation $\rho\in\mathcal{R}_H^G$, the subspace of H-invariant vectors,

$$\mathrm{Inv}_H^{(\rho)}=\{v\in V_\rho:\ \rho(h)v=v\quad\text{for all}\ \ h\in H\},\tag{2.28}$$

is one-dimensional.

Proposition 2.10: Let G be a compact Lie group, $H\leqslant G$ a Lie subgroup, and $\rho\in\mathcal{R}_G$ a finite-dimensional irreducible representation of G. The subspace of H-invariant vectors in V_ρ is spanned by the (not necessarily linearly independent) vectors

$$v^{(k)}:=\sum_{j=1}^{\dim V_\rho} v_j^{(k)}e_j:\quad\text{where}\ \ v_j^{(k)}:=\int_H t^{(\rho)}_{jk}(h)\,dh.\tag{2.29}$$

Here $\{e_j\}_j$ denotes the standard orthonormal basis of V_ρ, and $1\leqslant k\leqslant\dim V_\rho$.

The motivation for studying H-invariant vectors is given by the following result which allows us to construct functions on the space G/H of left cosets, i.e., functions on G that are constant on the cosets gH.

Proposition 2.11: Let $0\neq v^{(k)}\in V_\rho$ be an H-invariant vector. Then the *generalized spherical functions*

$$H^{(\rho)}_{jk}(g):=\sum_{\ell=1}^{\dim V_\rho} t^{(\rho)}_{j\ell}(g)v^{(k)}_\ell,\tag{2.30}$$

$1\leqslant j\leqslant\dim V_\rho$, are constant on the cosets $gH\in G/H$ and therefore induce functions $H^{(\rho)}_{jk}:G/H\to\mathbb{C}$, $x\mapsto H^{(\rho)}_{jk}(x):=H^{(\rho)}_{jk}(g_x)$, where $g_x\in G$ is a representative of the coset $x=g_xH\in G/H$.

Combining the Peter–Weyl decomposition (2.13) of $C_{\mathrm{alg}}(G)$ with the above ideas, we can construct the algebraic functions $C_{\mathrm{alg}}(G/H)$ on the coset space.

Corollary 2.12: Let G be a compact Lie group and $H\leqslant G$ be a Lie subgroup. Denote the dimensions of the H-invariant subspaces by $\kappa_\rho:=\dim\mathrm{Inv}_H^{(\rho)}$ and choose the orthonormal basis $\{e_j\}_j$ of each V_ρ so that precisely $e_1,\ldots,e_{\kappa_\rho}$ are H-invariant. Then the functions

$$H^{(\rho)}_{jk}: G/H \to \mathbb{C}, \quad x \mapsto H^{(\rho)}_{jk}(x) := t^{(\rho)}_{jk}(g_x), \tag{2.31}$$

$\rho \in \mathcal{R}^G_H$, $1 \leqslant j \leqslant \dim V_\rho$, $1 \leqslant k \leqslant \kappa_\rho$, form a basis of $C_{\text{alg}}(G/H)$. These functions satisfy the orthogonality relation,

$$\langle H^{(\rho)}_{jk}; H^{(\sigma)}_{\ell m} \rangle_{L^2} = \int_{G/H} \overline{H^{(\rho)}_{jk}(x)} H^{(\sigma)}_{\ell m}(x) dx = \frac{1}{\dim V_\rho} \delta_{\rho\sigma} \delta_{j\ell} \delta_{km}. \tag{2.32}$$

Remark 2.13: (1) Spherical functions exist only for class-1 representations as $\kappa_\rho \neq 0$ only there.

(2) In the case of a massive subgroup H, there is $\kappa_\rho = 1$ for all class-1 representations $\rho \in \mathcal{R}^G_H$. The second index of the spherical functions can thus be omitted, i.e.,

$$H^{(\rho)}_{j}: G/H \to \mathbb{C}, \quad x \mapsto H^{(\rho)}_{j}(x) := t^{(\rho)}_{j1}(g_x), \tag{2.33}$$

where $1 \leqslant j \leqslant \dim V_\rho$.

(3) If $H \trianglelefteq G$ is a normal subgroup, there is $\kappa_\rho = \dim V_\rho$ for all class-1 representations. In other words, for a given irreducible representation $\rho \in \mathcal{R}_G$ of G, either all representation functions $t^{(\rho)}_{jk}$, $1 \leqslant j, k \leqslant \dim V_\rho$, are spherical functions, or none of them is.

Example 2.14: (1) The spheres $S^N \cong \mathrm{SO}(N+1)/\mathrm{SO}(N)$ or $S^N \cong \mathrm{O}(N+1)/\mathrm{O}(N)$ are formed using massive subgroups.

(2) Odd spheres can alternatively be obtained from $S^{2N+1} \cong \mathrm{SU}(N+1)/\mathrm{SU}(N)$ or $S^{2N+1} \cong \mathrm{U}(N+1)/\mathrm{U}(N)$, in particular $S^3 \cong \mathrm{SU}(2)$. The spherical functions of S^3 can thus be constructed either as functions on SO(4)/SO(3) using the construction sketched above or from the identification $S^3 \cong \mathrm{SU}(2)$. For the latter approach, see the introductory part of Ref. 23.

(3) Other coset spaces which are of interest in the context of sigma models are $\mathbb{RP}^{N-1} \cong \mathrm{O}(N)/(\mathrm{O}(N-1) \times \mathrm{O}(1))$ as a special case of the Grassmanian $G^{\mathbb{R}}_{kN} \cong \mathrm{O}(N)/(\mathrm{O}(N-k) \times \mathrm{O}(k))$ and their complex counterparts $\mathbb{CP}^{N-1} \cong \mathrm{U}(N)/(\mathrm{U}(N-1) \times \mathrm{U}(1))$ and $G^{\mathbb{C}}_{kN} \cong \mathrm{U}(N)/(\mathrm{U}(N-k) \times \mathrm{U}(k))$.

Remark 2.15: Any function $f: G/H \to \mathbb{C}$ naturally extends to a function $\widetilde{f}: G \to \mathbb{C}$ which is constant on the cosets, i.e., $\widetilde{f}(gh) = \widetilde{f}(g)$ for all $g \in G$, $h \in H$. Obviously $f(x) = \widetilde{f}(g_x)$ for all $x \in G/H$ and an arbitrary representative $g_x \in G$ of x. Integrals over G/H can thus be evaluated using integrals over G,

$$\int_{G/H} f(x) dx = \int_G \widetilde{f}(g) dg. \tag{2.34}$$

As the context is usually clear, we omit the tilde ($\widetilde{\ }$) from now on.

The analog of the Haar intertwiner (2.23) for coset spaces can be defined as follows.

Definition 2.16: Let G be a compact Lie group, $H \leqslant G$ be a Lie subgroup, and $\rho_1, \ldots, \rho_r \in \mathcal{R}^G_H$, $r \in \mathbb{N}$, be of class-1 with respect to H. The *coset space Haar map*,

$$I: \bigotimes_{\ell=1}^{r} V_{\rho_\ell} \to \bigotimes_{\ell=1}^{r} V_{\rho_\ell}, \tag{2.35a}$$

is the linear map defined by its matrix elements

$$I_{m_1 m_2 \ldots m_r ; n_1 n_2 \ldots n_r} := \int_{G/H} H^{(\rho_1)}_{m_1 n_1}(x) H^{(\rho_2)}_{m_2 n_2}(x) \cdots H^{(\rho_r)}_{m_r n_r}(x) dx, \tag{2.35b}$$

where $1 \leqslant m_\ell \leqslant \dim V_{\rho_\ell}$ and $1 \leqslant n_\ell \leqslant \kappa_{\rho_\ell}$.

Proposition 2.17: The coset space Haar map (2.35) satisfies

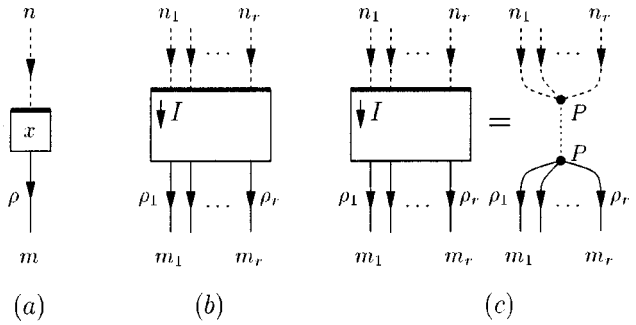

FIG. 2. (a) A spherical function $H^{(\rho)}_{mn}(x)$; (b) the coset space Haar map; and (c) its calculation in terms of G-invariant projectors (2.36), see Proposition 2.17.

$$I_{m_1 m_2 \ldots m_r ; n_1 n_2 \ldots n_r} = \sum_j \overline{P^{(j)}_{m_1 m_2 \ldots m_r}} P^{(j)}_{n_1 n_2 \ldots n_r}, \tag{2.36}$$

with the notation of Proposition 2.8, as well as for all $h \in G$,

$$I = (\rho_1(h) \otimes \cdots \otimes \rho_r(h)) \circ I, \tag{2.37}$$

which makes use of the left action of G on G/H. If in addition $H \trianglelefteq G$ is a normal subgroup, then I satisfies for all $y \in G/H$,

$$I = I \circ (\rho_1(y) \otimes \cdots \otimes \rho_r(y)), \tag{2.38}$$

using the notation $\rho_\ell(y) := \rho_\ell(g_y)$ for any representative g_y of y.

Proof: Equations (2.36) and (2.37) follow from Proposition 2.8 and Remark 2.15. The same is true for (2.38) if we write it for a representative of the coset $y \in G/H$. □

Observe that the coset space Haar map is in general not an intertwiner of G. However, for any fixed choice of indices $n_\ell \in \{1,\ldots,\kappa_{\rho_\ell}\}$, it defines a G-invariant vector $\tilde{I}_{n_1 n_2 \ldots n_r} \in \otimes_{\ell=1}^r V_{\rho_\ell}$.

We visualize spherical functions $H^{(\rho)}_{mn}(x)$ and the coset space Haar map as in Fig. 2. The contraction of indices whose range is restricted to $\{1,\ldots,\kappa_\rho\}$ is represented by dashed lines. They do not correspond to representations of G and are therefore not labeled with any symbol such as ρ. A thick line in the box for $H^{(\rho)}_{mn}$ and in the coset space Haar map I indicates that the indices on this side are special. Figure 2(c) shows the calculation (2.36).

If $H \trianglelefteq G$ is a normal subgroup, $\kappa_\rho = \dim V_\rho$ for all class-1 representations so that the dashed lines become solid again as they do correspond to representations of G. In particular Definition 2.16 and Proposition 2.17 restrict to Definition 2.7 and Proposition 2.8, respectively, if $H = \{e\}$ is the trivial group. The special case when H is a massive subgroup is also of interest.

Corollary 2.18: If $H \leqslant G$ is a massive subgroup, then $\kappa_\rho = 1$ for the class-1 representations. Therefore all indices n_ℓ can be omitted from the expressions so that the Haar map reduces to a map

$$I : \mathbb{C} \to \bigotimes_{\ell=1}^r V_{\rho_\ell}, \tag{2.39}$$

defined by its matrix elements

$$I_{m_1 m_2 \ldots m_r} := \int_{G/H} H^{(\rho_1)}_{m_1}(x) H^{(\rho_2)}_{m_2}(x) \cdots H^{(\rho_r)}_{m_r}(x) dx. \tag{2.40}$$

Equation (2.36) specializes to

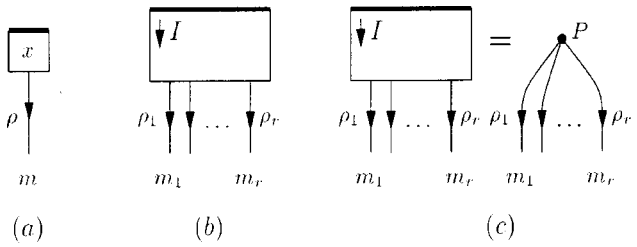

FIG. 3. The specialization of Fig. 2 to the case of a massive subgroup $H \leqslant G$, see Corollary 2.18.

$$I_{m_1 m_2 \ldots m_r} = \sum_j \overline{P^{(j)}_{m_1 m_2 \ldots m_r}}, \tag{2.41}$$

and (2.37) indicates that I defines a G-invariant vector $I \in \otimes_{\ell=1}^{r} V_{\rho_\ell}$.

The situation for massive subgroups is illustrated in Fig. 3. Further properties of the diagrams used in Fig. 3 can be deduced as in the introductory section of Ref. 23.

F. The center of the group

If representation functions are restricted to the center $Z(G)$, we obtain representation functions of the Abelian group $Z(G)$.

Lemma 2.19: Let G be a compact Lie group and $X \in Z(G)$. Then for any irreducible unitary representation ρ of G and $1 \leqslant i,\ j \leqslant \dim V_\rho$,

$$t^{(\rho)}_{ij}(X) = \delta_{ij} \cdot \tilde{t}^{(\rho)}(X), \tag{2.42}$$

where $\tilde{t}^{(\rho)}: Z(G) \to \mathbb{C}$ is a representation of the center $Z(G)$ which is induced by ρ.

Proof: By Schur's lemma, the center is mapped to multiples of the unit matrix. □

G. Special properties of some groups

For $G = U(1)$, all finite-dimensional irreducible representations are one-dimensional. They are denoted by $V_k \cong \mathbb{C}$ and characterized by integers $k \in \mathbb{Z}$ (wave numbers of the Fourier series). In the unitary case, their representation functions are given by $t^{(k)}(g) = g^k$, $g \in \mathrm{U}(1)$, and their duals by $t^{(k^*)}(g) = g^{-k}$. All representation functions are characters, $\chi^{(k)}(g) = t^{(k)}(g) = e^{ik\varphi}$, where we write $g = e^{i\varphi} \in \mathrm{U}(1)$.

From the representation functions and the definition (2.5), we can calculate the tensor product which is again one-dimensional,

$$V_{k_1} \otimes \cdots \otimes V_{k_n} \cong V_{\Sigma_{\ell=1}^n k_\ell}. \tag{2.43}$$

It is isomorphic to the trivial representation if and only if

$$\sum_{\ell=1}^{n} k_\ell = 0. \tag{2.44}$$

Since all irreducible representations are one-dimensional, the Haar intertwiner (2.23),

$$T: \bigotimes_{\ell=1}^{r} V_{k_\ell} \to \bigotimes_{\ell=1}^{r} V_{k_\ell}, \tag{2.45}$$

is just multiplication by a number. We have $T = 1$ if (2.44) holds and $T = 0$ otherwise. The sum over projectors (2.24) is either empty or contains a single unique term.

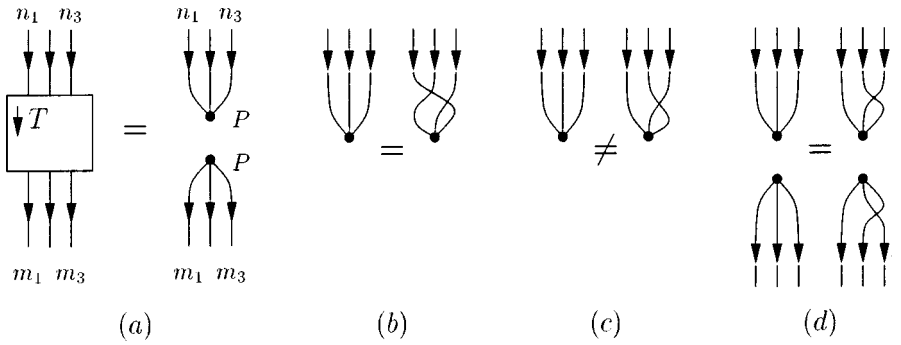

FIG. 4. (a) Simplification of (2.24) for $G=\mathrm{SU}(2)$ in the case of three tensor factors; (b)–(d) Even if we do not write the dotted line anymore, this does not mean that any conceivable symmetry holds.

We write the elements of the cyclic groups $G=\mathbb{Z}_N$ as roots of unity, $e^{2\pi i\ell/N}$, $\ell\in\{0,\ldots,N-1\}$, and parametrize their finite-dimensional irreducible unitary representations $V_k\cong\mathbb{C}$ by $k\in\{0,\ldots,N-1\}$. Representation functions and characters are $t^{(k)}(g)=g^k$, $t^{(k^*)}(g)=g^{-k}$, $\chi^{(k)}=t^{(k)}$, and (2.43) and (2.44) still hold if the sums are taken modulo N.

For $G=\mathrm{SU}(2)$, we characterize the finite-dimensional irreducible representations V_j, $\dim V_j=2j+1$, by non-negative half-integers $j\in 1/2\mathbb{N}_0$. Parametrizing elements of SU(2) by

$$g(\vartheta,\underline{n})=\mathbb{1}\cos\frac{\vartheta}{2}+i\underline{\sigma}\cdot\underline{n}\sin\frac{\vartheta}{2}, \tag{2.46}$$

where $\vartheta\in[0,4\pi)$, $\underline{n}\in S^2\subseteq\mathbb{R}^3$ and $\underline{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ are the Pauli matrices, the characters are given by

$$\chi^{(j)}(g)=\frac{\sin((2j+1)\vartheta/2)}{\sin\vartheta/2}, \tag{2.47}$$

in particular for the fundamental representation $\chi^{(1/2)}(g)=\cos\vartheta/2$.

Since for SU(2) there are no higher multiplicities in the decomposition of $V_{j_1}\otimes V_{j_2}$, the space of invariant projectors $V_{j_1}\otimes V_{j_2}\otimes V_{j_3}\to\mathbb{C}$ has a dimension of at most one. For three irreducible representations, we can therefore omit the summation over projectors from (2.24) as is illustrated in Fig. 4(a) and impose the conditions $|j_1-j_2|\leqslant j_3\leqslant j_1+j_2$, etc. instead. This provides a substantial simplification. However, the three-valent vertex that appears there has in general only a cyclic but not a full symmetry [Figs. 4(b)–4(d)] so that one still has to take the ordering of the tensor factors into account. Neglecting this subtlety is a common mistake.

H. Some character decompositions

For the duality transformation, we will apply the character decomposition to the Boltzmann weight $f(g)=\exp(-s(g))$ whose local action $s:G\to\mathbb{R}$ is an L^2-integrable class function that is bounded below. The most common example is the *Wilson action*,

$$s(g)=-\frac{\beta}{2\dim V_\rho}(\chi^{(\rho)}(g)+\overline{\chi^{(\rho)}(g)}), \tag{2.48}$$

where ρ denotes the fundamental representation of G and β is the inverse temperature or inverse coupling constant.

For $G=\mathrm{U}(1)$, the Wilson action reads $s(g)=-\beta\cos\varphi$, $g=e^{i\varphi}$. The character decomposition coincides with the Fourier series,

$$f(g)=\sum_{k=-\infty}^{\infty}\hat{f}_k e^{ik\varphi},\quad \hat{f}_k=\frac{1}{2\pi}\int_{\theta}^{2\pi}e^{-ik\varphi}\exp(-s(e^{i\varphi}))d\varphi=I_k(\beta),\tag{2.49}$$

where $I_k(\beta)$ denote modified Bessel functions.

For $G=\mathbb{Z}_N$, $g=e^{2\pi i\ell/N}$, we write this decomposition as

$$f(g)=\sum_{k=1}^{N-1}\hat{f}_k e^{2\pi ik\ell/N},\quad \hat{f}_k=\frac{1}{N}\sum_{\ell=0}^{N-1}e^{-2\pi ik\ell/N}\exp(-s(e^{2\pi i\ell/N})).\tag{2.50}$$

For $G=\mathrm{SU}(2)$, we have the Wilson action $s(g)=-\beta\cos\vartheta/2$, and the character expansion of $f(g)=\exp(-s(g))$ is given by

$$f(g)=\sum_{j\in(1/\nu)\mathbb{N}_0}\hat{f}_j\frac{\sin((2j+1)\vartheta/2)}{\sin\vartheta/2},\quad \hat{f}_j=\frac{2j+1}{\beta}I_{2j+1}(\beta).\tag{2.51}$$

Another common action is the *heat kernel* or *generalized Villain action* which is given for any compact Lie group in terms of the character decomposition of the corresponding Boltzmann weight,

$$f(g)=\sum_{\rho\in\mathcal{R}_G}\hat{f}_\rho\chi^{(\rho)}(g),\quad \hat{f}_\rho=\dim V_\rho\cdot\exp\left(-\frac{C_\rho}{2\beta}\right),\tag{2.52}$$

where C_ρ denotes the eigenvalue of a quadratic Casimir operator in the representation ρ. For example, we have for $G=\mathrm{U}(1)$,

$$\hat{f}_k=\exp\left(-\frac{k^2}{2\beta}\right),\tag{2.53}$$

and for $G=\mathrm{SU}(2)$,

$$\hat{f}_j=(2j+1)\exp\left(-\frac{j(j+1)}{2\beta}\right).\tag{2.54}$$

In all these cases, the Boltzmann weight $f(g)=\exp(-s(g))$ has a sharp peak at the group unit if β is large (weak coupling, low temperature) which facilitates a perturbative treatment whereas the peak is very wide for small β (strong coupling, high temperature). For small β, however, the dominant contribution to the character expansions listed above originates from the ''small'' representations of G. An expansion in terms of irreducible representations of G therefore provides us with a strong coupling expansion. This is most obvious for the heat kernel action where at small β the representations with small Casimir eigenvalue dominate.

More details on strong coupling expansion techniques can be found in Ref. 7. For spherical functions, see Ref. 22 and in particular for S^N also Ref. 24.

III. NOTATION AND DEFINITIONS

A. Graphs and abstract two-complexes

In order to formulate sigma models and gauge theories on very general lattices, it is sufficient to focus on the combinatorial structure of the lattices rather than on the details of their embedding into some space or space–time manifold. Therefore we employ the notions of graphs and abstract two-complexes. Sigma models are defined on graphs so that we obtain the same expressions for their partition function in any dimension $d\geqslant 1$. Similarly, gauge theories are defined on abstract two-complexes, and we obtain a uniform description of gauge theories valid in any dimension $d\geqslant 2$.

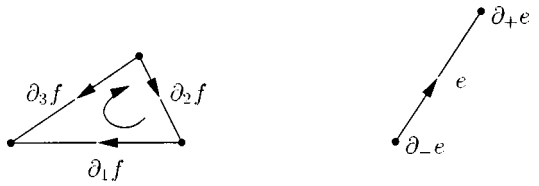

FIG. 5. The maps $\partial_\pm$, ∂_j and ϵ_j and the conditions (3.3). Here $N(f)=3$, $\epsilon_1 f=+1$, $\epsilon_2 f=+1$ and $\epsilon_3 f=(-1)$.

The following definitions differ slightly from what is standard, but will prove most convenient for the purpose of the duality transformation.

Definition 3.1: An *oriented* (or *directed*) *graph* (V,E) consists of finite sets V (vertices) and E (edges) together with maps

$$\partial_+ : E \to V \quad \text{(end point of an edge)}, \tag{3.1a}$$

$$\partial_- : E \to V \quad \text{(starting point of an edge)}. \tag{3.1b}$$

The notion of an abstract two-complex extends this definition and also includes faces whose boundary consists of a sequence of edges.

Definition 3.2: An *oriented two-complex* (V,E,F) is an oriented graph (V,E) together with a finite set F (*faces*) and maps

$$N : F \to \mathbb{N} \quad \text{(number of edges in the boundary of a face)}, \tag{3.2a}$$

$$\partial_j : F \to E \quad \text{(the } j\text{th edge in the boundary of a face)}, \tag{3.2b}$$

$$\epsilon_j : F \to \{-1,+1\} \quad \text{(its orientation)}, \tag{3.2c}$$

such that

$$\partial_{-\epsilon_j f} \partial_j f = \partial_{\epsilon_{j+1} f} \partial_{j+1} f, \quad 1 \leqslant j \leqslant N(f)-1, \tag{3.3a}$$

$$\partial_{-\epsilon_{N(f)} f} \partial_{N(f)} f = \partial_{\epsilon_1 f} \partial_1 f, \tag{3.3b}$$

for all $f \in F$.

The conditions (3.3) state that the edges in the boundary of a face $f \in F$ are in cyclic ordering from $\partial_{N(f)} f$ to $\partial_1 f$ where one encounters the edges with the orientation given by $\epsilon_j f$ (see Fig. 5). Observe that (3.3) contains combinatorial information similar to the condition $\partial \circ \partial = 0$ on the boundary operator ∂ in Abelian simplicial homology.

In the subsequent calculations, it is convenient to use the following abbreviations.

Definition 3.3: Let (V,E,F) denote an oriented two-complex. For a given edge $e \in E$, the sets

$$e_+ := \{f \in F:\ e = \partial_j f,\ \epsilon_j f = (+1) \quad \text{for some } j,\ 1 \leqslant j \leqslant N(f)\}, \tag{3.4a}$$

$$e_- := \{f \in F:\ e = \partial_j f,\ \epsilon_j f = (-1) \quad \text{for some } j,\ 1 \leqslant j \leqslant N(f)\}, \tag{3.4b}$$

contain all faces that have the edge e in their boundary with positive $(+)$ or negative $(-)$ orientation, and we write $\delta e := e_+ \cup e_-$ for the coboundary of an edge $e \in E$. For a given face $f \in F$, the set

$$f_0 := \{v \in V:\ v = \partial_- \partial_j f \quad \text{for some } j,\ 1 \leqslant j \leqslant N(f)\} \tag{3.5}$$

denotes all vertices that belong to the boundary of the face f. Finally, the sets

$$f_+ := \{e \in E:\ e = \partial_j f,\ \epsilon_j f = (+1) \quad \text{for some } j,\ 1 \leqslant j \leqslant N(f)\}, \tag{3.6a}$$

$$f_- := \{e \in E:\ e = \partial_j f,\ \epsilon_j f = (-1) \quad \text{for some } j,\ 1 \leqslant j \leqslant N(f)\}, \tag{3.6b}$$

contain all edges in the boundary of the face f that occur with positive $(+)$ or negative $(-)$ orientation, and $\partial f := f_+ \cup f_-$ denotes the full boundary of $f \in F$.

We have formulated our definitions of graphs and two-complexes so that they have only a finite number of vertices, edges, and faces. This condition ensures that our partition functions are well defined. The collections of points, links, and plaquettes of standard hyper-cubic lattices form a special case of oriented two-complexes in the obvious manner.

B. Spin networks and spin foams

Spin networks were introduced by Penrose[25] in the context of a quantization of space–time geometry. A spin network with symmetry group G is a graph together with a coloring of its edges with irreducible representations of G and a coloring of its vertices with compatible intertwiners (representation morphisms). For the subsequent calculations it is most convenient to separate the notions of graph and coloring and to speak of a *spin network* that *lives on a graph*.

Definition 3.4: Let G be a compact Lie group and (V,E) be an oriented graph. A *spin network* (τ,Q) with symmetry group G on (V,E) is a coloring of the edges with irreducible representations of G,

$$\tau: E \to \mathcal{R}_G, \quad e \mapsto \tau_e, \tag{3.7a}$$

together with a coloring of the vertices $v \in V$ with compatible intertwiners,

$$Q^{(v)} \in \mathrm{Hom}_G\left(\bigotimes_{\substack{e \in E:\\ v = \partial_+ e}} V_{\tau_e},\ \bigotimes_{\substack{e \in E:\\ v = \partial_- e}} V_{\tau_e} \right). \tag{3.7b}$$

The tensor product in the domain is over the ''incoming'' edges and that in the image over the ''outgoing'' edges.

Spin networks appeared first in the context of quantum gravity. There they define, for example, the physical states in the loop formulation of gauge theories and the kinematical states of loop quantum gravity.[26] The observables of non-Abelian lattice gange theory can also be constructed from spin networks.[15,16] They are given by the *spin network functions* (Definition 6.3 below).

The concept of a spin network can be generalized by introducing additional representations at the vertices, called *charges*, and by modifying the compatibility condition (3.7b) accordingly.

Definition 3.5: Let G be a compact Lie group, (V,E) an oriented graph, and $\rho: V \to \mathcal{R}_G$, $v \mapsto \rho_v$ assign an irreducible representation of G to each vertex. A *spin network* (τ,Q,ρ) *with charges* ρ is a coloring of the edges with irreducible representations,

$$\tau: E \to \mathcal{R}_G, \quad e \mapsto \tau_e, \tag{3.8a}$$

together with a coloring of the vertices $v \in V$ with compatible intertwiners,

$$Q^{(v)} \in \mathrm{Hom}_G\left(\left(\bigotimes_{\substack{e \in E:\\ v = \partial_+ e}} V_{\tau_e} \right) \otimes V_{\rho_v},\ \bigotimes_{\substack{e \in E:\\ v = \partial_- e}} V_{\tau_e} \right). \tag{3.8b}$$

We show in this article that spin networks with charges appear as the configurations in the dual expression for correlators in sigma models, and that they characterize the observables of generalized Higgs models.

A higher dimensional analog of spin networks is the concept of spin foams. Spin foams also appeared first in the context of quantum gravity.[12–14]

Definition 3.6: Let G be a compact Lie group and (V,E,F) be an oriented two-complex. A *spin foam* (ρ,P) with symmetry group G on (V,E,F) is a coloring of the faces with finite-dimensional irreducible representations of G,

$$\rho:F\to\mathcal{R}_G,\quad f\mapsto\rho_f, \tag{3.9a}$$

together with a coloring of the edges $e\in E$ with compatible intertwiners,

$$P^{(e)}\in\mathrm{Hom}_G\Big(\bigotimes_{f\in e_+}\rho_f,\ \bigotimes_{f\in e_-}\rho_f\Big). \tag{3.9b}$$

The tensor product in the domain is over the representations at the ''incoming'' faces, that in the image over the ''outgoing'' ones. Incoming and outgoing are here defined by the relative orientations of the edges and faces.

These spin foams are often called *closed spin foams* as opposed to *open spin foams* which are bounded by a spin network. Open spin foams can be understood as the higher dimensional analog of spin networks with charges and are defined as follows.

Definition 3.7: Let G be a compact Lie group, (V,E,F) define an oriented two-complex, and (τ,Q) be a spin network on (V,E). A *spin foam* (ρ,P,τ,Q) *bounded by* the spin network (τ,Q) is a coloring of the faces with finite-dimensional irreducible representations,

$$\rho:F\to\mathcal{R}_G,\quad f\mapsto\rho_f, \tag{3.10a}$$

together with a coloring of the edges $e\in E$ with compatible intertwiners,

$$P^{(e)}\in\mathrm{Hom}_G\Big(\Big(\bigotimes_{f\in e_+}V_{\rho_f}\Big)\otimes V_{\tau_e},\ \bigotimes_{f\in e_-}V_{\rho_f}\Big). \tag{3.10b}$$

IV. THE CHIRAL MODEL

In this section, we develop the duality transformation for the chiral model with a symmetry group G that is a compact Lie group. This model forms the basis for the generalizations to the nonlinear sigma model with variables in a coset space G/H and to the generalized Higgs models in which the chiral model or the nonlinear sigma model is coupled to a lattice gauge theory.

A. Partition function

Definition 4.1: Let G be a compact Lie group and (V,E) be an oriented graph. Let $s:G\to\mathbb{R}$ be an L^2-integrable and bounded class function that satisfies $s(g^{-1})=s(g)$. The *lattice chiral model* with action s is defined by the partition function

$$Z=\Big(\prod_{v\in V}\int_G dg_v\Big)\prod_{e\in E}w(g_{\partial_+e}\cdot g_{\partial_-e}^{-1}), \tag{4.1}$$

whose *Boltzmann weight* is given by $w(g)=\exp(-s(g))$.

Remark 4.2: (1) The set of configurations is the product $G^V:=G\times\cdots\times G$ of one copy of G per vertex $v\in V$. The partition sum is just the Haar measure of G^V. There is an interaction term for each edge $e\in E$ relating the variables at the two end points, g_{∂_+e} and g_{∂_-e}.

(2) It is possible to choose different actions $s_e:G\to\mathbb{R}$ for each edge $e\in E$ so that one obtains Boltzmann weights $w_e(g)=\exp(-s_e(g))$. This is useful, for example, if one wishes to study inhomogeneous or anisotropic systems or nonregular lattices for which one would introduce geometric factors in order to compensate for the different lengths of the various edges. All calculations presented below generalize to this case, too, but we try to keep the notation simple and do not write down the additional index e in the following sections.

Lemma 4.3: Orientation reversal of any edge $e \in E$ is a symmetry of the lattice chiral model. The model therefore depends only on the unoriented graph. Orientation reversal of an edge $e \in E$ maps $g_{\partial_- e} \mapsto g_{\partial_+ e}$ and conversely, which leaves the action invariant since $s(g^{-1}) = s(g)$.

Our subsequent calculations are most transparent for the generic case in which the partition function can depend on the orientations even though this generality is not required for the common examples.

Proposition 4.4: The lattice chiral model (4.1) has got a global left–right $G \times G$-symmetry. Let $h, \tilde{h} \in G$. Then the transformation

$$g_v \mapsto h \cdot g_v \cdot \tilde{h}^{-1}, \tag{4.2}$$

for all $v \in V$, is a symmetry of the action $s(g_{\partial_+ e} \cdot g_{\partial_- e}^{-1})$ for each edge $e \in E$ because s is a class function.

B. Expectation values

The observables of the lattice chiral model are all possible expectation values of functions $G^V \to \mathbb{C}$ that are compatible with the symmetries. With the help of the Peter–Weyl decomposition, it is possible to calculate the generic form of these observables. For the chiral model, one obtains the well-known n-point functions. We present the full calculation here because it illustrates the method and this method generalizes to the more complicated models for which we derive new results in the subsequent sections.

Theorem 4.5: Each algebraic function $f: G^V \to \mathbb{C}$ that is compatible with the global $G \times G$-symmetry (4.2) is a linear combination of functions (*observables*) of the following type,

$$f_{\rho,P,Q}(\{g_v\}_{v \in V}) = \left(\prod_{v \in V} \sum_{\ell_v, m_v = 1}^{\dim V_{\rho_v}} \right) P_{\underbrace{\ell_v \ldots}_{v \in V}} Q_{\underbrace{m_v \ldots}_{v \in V}} \prod_{v \in V} t^{(\rho_v)}_{\ell_v m_v}(g_v). \tag{4.3}$$

Here

$$\rho: V \to \mathcal{R}_G, \quad v \mapsto \rho_v \tag{4.4}$$

associates an irreducible representation of G with each vertex, and

$$P: \bigotimes_{v \in V} V_{\rho_v} \to \mathbb{C}, \quad Q: \bigotimes_{v \in V} V^*_{\rho_v} \to \mathbb{C}, \tag{4.5}$$

are intertwiners of G.

Remark 4.6: (1) By the notation

$$\prod_{v \in V} \sum_{\ell_v, m_v = 1}^{\dim V_{\rho_v}} = \underbrace{\sum_{\ell_v, m_v = 1}^{\dim V_{\rho_v}} \cdots \sum_{\ell_v, m_v = 1}^{\dim V_{\rho_v}}}_{v \in V} \tag{4.6}$$

we mean that there is one sum over ℓ_v and m_v for each vertex $v \in V$. Similarly,

$$P_{\underbrace{\ell_v \cdots}_{v \in V}} \tag{4.7}$$

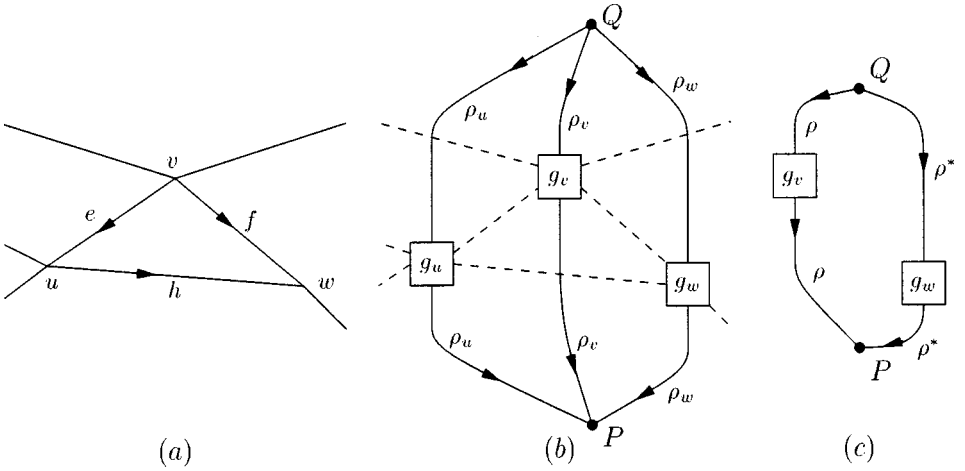

FIG. 6. (a) An oriented graph with vertices u, v, w and edges e, f, h. (b) The structure of the observable (4.3) of the lattice chiral model on that graph. (c) The two-point function (4.8).

indicates that the symbol P has got one index ℓ_v for each $v \in V$. It is also understood that the ordering of tensor factors in (4.5) corresponds to the ordering of indices of P and Q in (4.3). We use this notation frequently in the subsequent calculations.

(2) The structure of the observable (4.3) is illustrated in Fig. 6(b).

(3) The irreducible representations ρ_v describe the charges that are located at the vertices $v \in V$. If there are precisely k vertices whose ρ_v is nontrivial, the normalized expectation value of the observable is a k-point function. For each $v \in V$, there is a representation function $t^{(\rho_v)}_{\ell_v m_v}$ that describes the G-dependence of the observable, and the intertwiners P and Q involve its indices ℓ_v and m_v and are used in order to obtain a globally $G\times G$-invariant expression. The well-known two-point function for two vertices v, $w \in V$ is the normalized expectation value of

$$\chi^{(\rho)}(g_v \cdot g_w^{-1}) = \sum_{\ell_v, m_v = 1}^{\dim V_\rho} t^{(\rho)}_{\ell_v m_v}(g_v) \cdot t^{(\rho^*)}_{\ell_w m_w}(g_w) \cdot \delta_{\ell_v \ell_w} \delta_{m_v m_w} \tag{4.8}$$

[Fig. 6(c)]. It forms a special case of (4.3) in which the only nontrivial representations are a charge ρ at v and an anti-charge ρ^* at w, and the intertwiners are trivial, $P_{\ell_v \ell_w} = \delta_{\ell_v \ell_w}$, etc.

(4) As a consequence of the Peter–Weyl theorem, the L^2-integrable functions that are compatible with the global $G\times G$-symmetry are in the closure of the set of all algebraic $f_{\rho,P,Q}$, i.e., they can be obtained as limits of square summable series of functions $f_{\rho,P,Q}$.

Proof of Theorem 4.5: Algebraic functions $f: G^V \to \mathbb{C}$ are elements $f \in \otimes_{v \in V} C_{\mathrm{alg}}(G)$ and therefore have the Peter–Weyl decomposition

$$f(\{g_v\}_{v \in V}) = \left(\prod_{v \in V} \sum_{\rho_v \in \mathcal{R}_G} \right) \left(\prod_{v \in V} \sum_{j_v, k_v = 1}^{\dim V_{\rho_v}} \right) \hat{f}^{(\rho_v, \ldots)}_{j_v \ldots, k_v \ldots} \prod_{v \in V} t^{(\rho_v)}_{j_v k_v}(g_v). \tag{4.9}$$

If f satisfies the global $G\times G$-symmetry, we can apply (4.2) for each vertex, and as this holds for arbitrary h, $\tilde{h} \in G$, we can integrate the result over h and $\tilde{h}$,

$$\begin{aligned} f(\{g_v\}_{v \in V}) = \int_{G\times G} dh d\tilde{h} \left(\prod_{v \in V} \sum_{\rho_v \in \mathcal{R}_G} \right) \left(\prod_{v \in V} \sum_{j_v, k_v = 1}^{\dim V_{\rho_v}} \right) \hat{f}^{(\rho_v, \ldots)}_{j_v \ldots, k_v \ldots} \\ \times \prod_{v \in V} \sum_{\ell_v, m_v = 1}^{\dim V_{\rho_v}} t^{(\rho_v)}_{j_v \ell_v}(h) t^{(\rho_v)}_{\ell_v m_v}(g_v) t^{(\rho_v)}_{m_v k_v}(\tilde{h}^{-1}). \end{aligned} \tag{4.10}$$

We apply (2.9), writing $t^{(\rho_v)}_{m_v k_v}(\tilde{h}^{-1}) = t^{(\rho_v^*)}_{k_v m_v}(\tilde{h})$, and move all summations to the front of the expression. Then we sort the products by the arguments g_v, h, and $\tilde{h}$,

$$f(\{g_v\}_{v\in V}) = \left(\prod_{v\in V}\sum_{\rho_v\in\mathcal{R}_G}\right)\left(\prod_{v\in V}\sum_{j_v,k_v,\ell_v,m_v=1}^{\dim V_{\rho_v}}\right)\hat{f}^{(\rho_v,\ldots)}_{j_v\ldots,k_v\ldots}\left(\prod_{v\in V} t^{(\rho_v)}_{\ell_v m_v}(g_v)\right)$$
$$\times\left(\int_G\prod_{v\in V} t^{(\rho_v)}_{j_v\ell_v}(h)\,dh\right)\left(\int_G\prod_{v\in V} t^{(\rho_v^*)}_{k_v m_v}(\tilde{h})\,d\tilde{h}\right). \tag{4.11}$$

The integrals over G can be evaluated using (2.24) so that

$$f(\{g_v\}_{v\in V}) = \left(\prod_{v\in V}\sum_{\rho_v\in\mathcal{R}_G}\right)\sum_{P\in\mathcal{P}}\sum_{Q\in\mathcal{Q}}\left(\prod_{v\in V}\sum_{\ell_v,m_v=1}^{\dim V_{\rho_v}}\right)\tilde{f}^{(\rho_v,\ldots)}P_{\underbrace{\ell_v\ldots}_{v\in V}}Q_{\underbrace{m_v\ldots}_{v\in V}}\left(\prod_{v\in V} t^{(\rho_v)}_{\ell_v m_v}(g_v)\right), \tag{4.12}$$

where

$$\tilde{f}^{(\rho_v,\ldots)} = \left(\prod_{v\in V}\sum_{j_v,k_v=1}^{\dim V_{\rho_v}}\right)\hat{f}^{(\rho_v,\ldots)}_{j_v\ldots,k_v\ldots}\overline{P_{\underbrace{j_v\ldots}_{v\in V}}Q_{\underbrace{k_v\ldots}_{v\in V}}}. \tag{4.13}$$

Here $\mathcal{P}$ denotes a basis of the space of G-invariant projectors

$$\bigotimes_{v\in V} V_{\rho_v}\to\mathbb{C}, \tag{4.14}$$

whose elements $P\in\mathcal{P}$ are normalized so that $P^2=P$ where the trivial representation is embedded as $\mathbb{C}\subseteq\otimes_{v\in V}V_{\rho_v}$. Similarly, $\mathcal{Q}$ denotes a basis of G-invariant projectors

$$\bigotimes_{v\in V} V^*_{\rho_v}\to\mathbb{C}, \tag{4.15}$$

with the analogous normalization. The expression (4.12) is a linear combination of observables of the form (4.3). □

Remark 4.7: The global $G\times G$-symmetry can be realized as the translation symmetry of the multiple Haar measure because for each $v\in V$, h, $\tilde{h}\in G$ and any function $u\in C_{\text{alg}}(G)$,

$$\int_G u(g_v)\,dg_v = \int_G u(h\cdot g_v\cdot\tilde{h}^{-1})\,dg_v\,. \tag{4.16}$$

As the Boltzmann weight is invariant, the expectation value of any non-invariant function $f':G^V\to\mathbb{C}$ under the partition function vanishes. Note that this holds for any finite graph (V,E).

Similarly, the expectation value vanishes for any function that is not invariant under simultaneous orientation reversal of all edges which corresponds to taking the dual of all representations and which is realized by the inversion symmetry of the Haar measure,

$$\int_G u(g_v)\,dg_v = \int_G u(g_v^{-1})\,dg_v\,. \tag{4.17}$$

Therefore all interesting observables are functions $G^V\to\mathbb{R}$.

C. Duality transformation

The duality transformation consists of two steps. First, we character expand the Boltzmann weight of the original partition function (4.1) of the lattice chiral model. This introduces sums over all irreducible representations of G for each edge as the new dual variables. Furthermore, this step is responsible for the strong–weak or high temperature–low temperature relation of the duality transformation as we have explained in Sec. II H.

The second step is to employ the methods outlined in Sec. II D in order to solve all integrals over G and therefore to remove the old variables from the partition function.

We start with the partition function (4.1) and insert the character expansion (2.14) of the Boltzmann weight for each edge $e \in E$,

$$Z = \left(\prod_{v \in V} \int_G dg_v \right) \prod_{e \in E} \sum_{\tau_e \in \mathcal{R}_G} \hat{w}_{\tau_e} \chi^{(\tau_e)}(g_{\partial_+ e} \cdot g_{\partial_- e}^{-1}). \tag{4.18}$$

The character can be simplified using (2.7) and (2.9),

$$\chi^{(\tau_e)}(g_{\partial_+ e} \cdot g_{\partial_- e}^{-1}) = \sum_{p_e, q_e = 1}^{\dim V_{\tau_e}} t^{(\tau_e)}_{p_e q_e}(g_{\partial_+ e}) t^{(\tau_e^*)}_{p_e q_e}(g_{\partial_- e}). \tag{4.19}$$

The sums are moved to the front of the expression, and we sort the product of representation functions by the vertex $v \in V$ of their arguments g_v:

$$Z = \left(\prod_{e \in E} \sum_{\tau_e \in \mathcal{R}_G} \right) \left(\prod_{e \in E} \hat{w}_{\tau_e} \right) \left(\prod_{e \in E} \sum_{p_e, q_e = 1}^{\dim V_{\tau_e}} \right) \prod_{v \in V} \int_G dg_v \left(\prod_{\substack{e \in E: \\ v = \partial_+ e}} t^{(\tau_e)}_{p_e q_e}(g_v) \right) \left(\prod_{\substack{e \in E: \\ v = \partial_- e}} t^{(\tau_e^*)}_{p_e q_e}(g_v) \right). \tag{4.20}$$

Here the last two products are over all edges $e \in E$ that have $v = \partial_\pm e$. The integrals over G can be evaluated using (2.24),

$$Z = \left(\prod_{e \in E} \sum_{\tau_e \in \mathcal{R}_G} \right) \left(\prod_{e \in E} \hat{w}_{\tau_e} \right) \left(\prod_{e \in E} \sum_{p_e, q_e = 1}^{\dim V_{\tau_e}} \right) \prod_{v \in V} \sum_{S^{(v)} \in \mathcal{S}^{(v)}} \overline{S^{(v)}_{\underbrace{p_e \cdots}_{\substack{e \in E: \\ v = \partial_+ e}} \underbrace{p_e \cdots}_{\substack{e \in E: \\ v = \partial_- e}}}} S^{(v)}_{\underbrace{q_e \cdots}_{\substack{e \in E: \\ v = \partial_+ e}} \underbrace{q_e \cdots}_{\substack{e \in E: \\ v = \partial_- e}}}, \tag{4.21}$$

where $\mathcal{S}^{(v)}$, $v \in V$, denotes a basis of G-invariant projectors

$$\left(\bigotimes_{\substack{e \in E: \\ v = \partial_+ e}} V_{\tau_e} \right) \otimes \left(\bigotimes_{\substack{e \in E: \\ v = \partial_- e}} V^*_{\tau_e} \right) \to \mathbb{C}, \tag{4.22}$$

which are normalized so that $S^{(v)2} = S^{(v)}$ if the trivial representation $\mathbb{C}$ is embedded in the big tensor product. We obtain the following result.

Theorem 4.8 (Dual partition function): Let G be a compact Lie group and (V,E) denote an oriented graph. The partition function of the lattice chiral model (4.1) is equal to

$$Z = \left(\prod_{e \in E} \sum_{\tau_e \in \mathcal{R}_G} \right) \left(\prod_{v \in V} \sum_{S^{(v)} \in \mathcal{S}^{(v)}} \right) \left(\prod_{e \in E} \hat{w}_{\tau_e} \right) \left(\prod_{e \in E} \sum_{p_e, q_e = 1}^{\dim V_{\tau_e}} \right) \prod_{v \in V} \overline{S^{(v)}_{\underbrace{p_e \cdots}_{\substack{e \in E: \\ v = \partial_+ e}} \underbrace{p_e \cdots}_{\substack{e \in E: \\ v = \partial_- e}}}} S^{(v)}_{\underbrace{q_e \cdots}_{\substack{e \in E: \\ v = \partial_+ e}} \underbrace{q_e \cdots}_{\substack{e \in E: \\ v = \partial_- e}}}, \tag{4.23}$$

where $\mathcal{S}^{(v)}$ is a basis of G-invariant projectors (4.22).

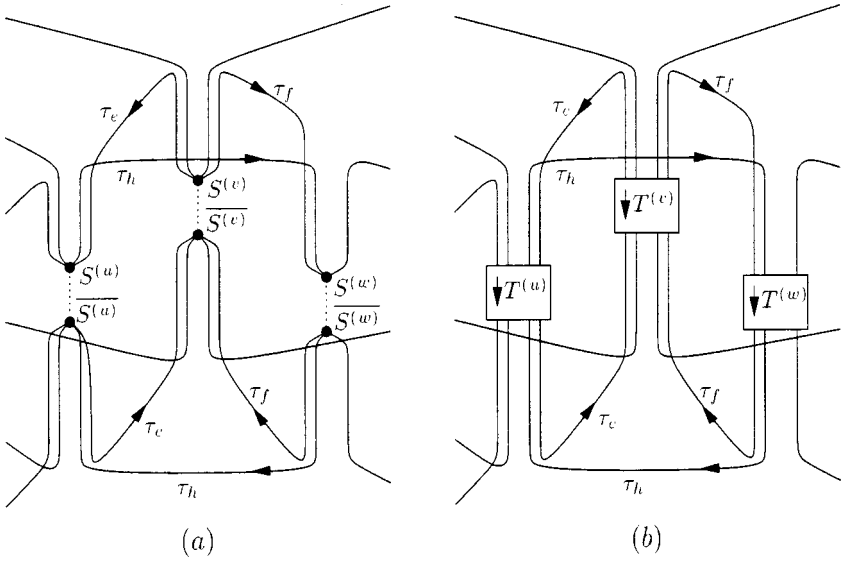

FIG. 7. (a) The spin network that appears in the dual partition function (4.23) of the lattice chiral model on the graph of Fig. 6(a). (b) The alternative expression (4.25) for the same graph.

Remark 4.9: (1) This dual partition function can be described in words as follows. The partition sum consists of a sum over all colorings of the edges $e \in E$ with irreducible representations τ_e of G and over all colorings of the vertices $v \in V$ with compatible intertwiners $S^{(v)}$. Compatible here means that each $S^{(v)}$ corresponds to a map from the tensor product of the representations at the incoming edges $e \in E: v = \partial_+ e$ to the tensor product of the outgoing edges $e \in E: v = \partial_- e$,

$$S^{(v)}: \left(\bigotimes_{\substack{e \in E: \\ v = \partial_+ e}} V_{\tau_e} \right) \to \left(\bigotimes_{\substack{e \in E: \\ v = \partial_- e}} V_{\tau_e} \right). \tag{4.24}$$

Indeed, such an $S^{(v)}$ is related to the one appearing in (4.22) by the canonical isomorphisms $\mathrm{Hom}_G(V \otimes W^*, \mathbb{C}) \cong \mathrm{Hom}_G(V, W)$. The Boltzmann weight of the dual partition function consists of the character expansion coefficients $\hat{w}_{\tau_e}$ for each edge $e \in E$ and of a spin network given by the $S^{(v)}$ whose indices are contracted by the summations over p_e and q_e. This is illustrated in Fig. 7(a).

(2) The dual partition function of the lattice chiral model is therefore given by a sum over spin networks. We call such a model *a spin network model* in analogy to the spin foam models which arise as the dual formulation of lattice gauge theory. The two layers of Fig. 7(a) reflect the chiral structure given by the twofold global G-symmetry. The fact that the spin networks extend over the entire graph is a consequence of the global nature of the symmetry.

(3) We comment on the Abelian special case below in Sec. IV D.

(4) There is an alternative form of the dual partition function which uses a diagrammatical formulation similar to that developed in Ref. 18 for lattice gauge theory. This result is given in the following corollary and illustrated in Fig. 7(b).

Corollary 4.10: From the intermediate step (4.20) of the proof, we obtain the following slightly different expression which involves the Haar intertwiner (2.23) instead of the sum over projectors $S^{(v)}$:

$$Z=\left(\prod_{e\in E}\sum_{\tau_e\in\mathcal{R}_G}\right)\left(\prod_{e\in E}\hat{w}_{\tau_e}\right)\left(\prod_{e\in E}\sum_{p_e,q_e=1}^{\dim V_{\tau_e}}\right)\prod_{v\in V}T^{(v)}_{\underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_-e}},\underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_-e}}},\tag{4.25}$$

where for each $v\in V$, the Haar intertwiner $T^{(v)}$ is a map

$$T^{(v)}:\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+e}}V_{\tau_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_-e}}V^*_{\tau_e}\right)\to\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+e}}V_{\tau_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_-e}}V^*_{\tau_e}\right).\tag{4.26}$$

The next step is the generalization of Theorem 4.8 to the expectation value of the observable (4.3),

$$\langle f_{\rho,P,Q}\rangle=\frac{1}{Z}\left(\prod_{v\in V}\int_G dg_v\right)\left(\prod_{e\in E}w(g_{\partial_+e}\cdot g_{\partial_-e}^{-1})\right)\left(\prod_{v\in V}\sum_{\ell_v,m_v=1}^{\dim V_{\rho_v}}\right)P_{\underbrace{\ell_v\ldots}_{v\in V}}Q_{\underbrace{m_v\ldots}_{v\in V}}\prod_{v\in V}t^{(\rho_v)}_{\ell_v m_v}(g_v).\tag{4.27}$$

Again, we character expand the Boltzmann weight, simplify the characters that occur in the expression and reorganize everything. The step that generalizes (4.20) then reads

$$\begin{aligned}\langle f_{\rho,P,Q}\rangle=&\frac{1}{Z}\left(\prod_{e\in E}\sum_{\tau_e\in\mathcal{R}_G}\right)\left(\prod_{e\in E}\hat{w}_{\tau_e}\right)\left(\prod_{e\in E}\sum_{p_e,q_e=1}^{\dim V_{\tau_e}}\right)\left(\prod_{v\in V}\sum_{\ell_v,m_v=1}^{\dim V_{\rho_v}}\right)P_{\underbrace{\ell_v\ldots}_{v\in V}}Q_{\underbrace{m_v\ldots}_{v\in V}}\\&\times\prod_{v\in V}\int_G dg_v\left(\prod_{\substack{e\in E:\\ v=\partial_+e}}t^{(\tau_e)}_{p_eq_e}(g_v)\right)\left(\prod_{\substack{e\in E:\\ v=\partial_-e}}t^{(\tau_e^*)}_{p_eq_e}(g_v)\right)t^{(\rho_v)}_{\ell_v m_v}(g_v).\end{aligned}\tag{4.28}$$

Compared with (4.20), there is an additional factor $t^{(\rho_v)}_{\ell_v m_v}$ for each $v\in V$ under the integral. Solving the integrals, we obtain the following result.

Theorem 4.11 (Dual observable): Let G be a compact Lie group, (V,E) be an oriented graph, and $f_{\rho,P,Q}$ denote an observable of the form (4.3). Then the expectation value (4.27) of $f_{\rho,P,Q}$ in the lattice chiral model is equal to

$$\begin{aligned}\langle f_{\rho,P,Q}\rangle=&\frac{1}{Z}\left(\prod_{v\in V}\sum_{\ell_v,m_v=1}^{\dim V_{\rho_v}}\right)P_{\underbrace{\ell_v\ldots}_{v\in V}}Q_{\underbrace{m_v\ldots}_{v\in V}}\left(\prod_{e\in E}\sum_{\tau_e\in\mathcal{R}_G}\right)\left(\prod_{v\in V}\sum_{S^{(v)}\in\tilde{\mathcal{S}}^{(v)}}\right)\left(\prod_{e\in E}\hat{w}_{\tau_e}\right)\\&\times\left(\prod_{e\in E}\sum_{p_e,q_e=1}^{\dim V_{\tau_e}}\right)\prod_{v\in V}\overline{S^{(v)}_{\underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_-e}}\ell_v}}S^{(v)}_{\underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_-e}}m_v}.\end{aligned}\tag{4.29}$$

For each vertex $v\in V$, $\tilde{\mathcal{S}}^{(v)}$ denotes a basis of G-invariant projectors

$$\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+e}}V_{\tau_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_-e}}V^*_{\tau_e}\right)\otimes V_{\rho_v}\to\mathbb{C}\tag{4.30}$$

with the usual normalization.

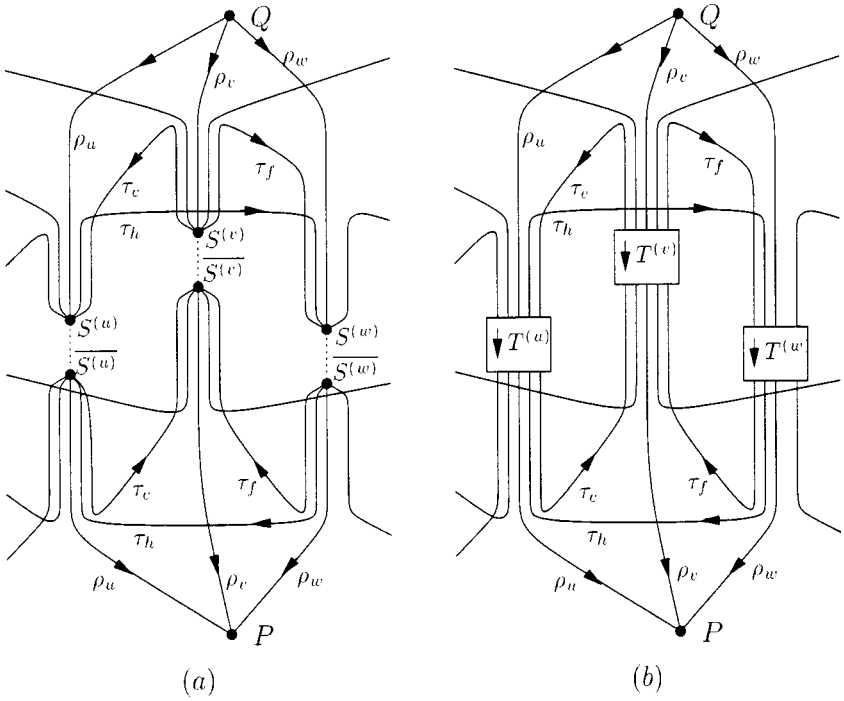

FIG. 8. (a) The dual expression (4.29) for the expectation value of the observable shown in Fig. 6(b), cf. the dual partition function in Fig. 7(a). (b) The alternative formulation (4.31).

Remark 4.12: (1) Compared with the dual partition function (4.23), the new features are the sums over the ℓ_v and m_v and the matrix elements of P and Q from the definition of the observable (4.3). The remainder of the expression has the same structure as the dual partition function except for the fact that the intertwiners $S^{(v)}$ have changed. They now include the charges ρ_v, $v \in V$, of the observable in the compatibility condition (4.30), and the spin networks of the dual partition function are coupled to these charges—the ℓ_v and m_v appear as additional indices of the $S^{(v)}$. The numerator of the dual expression is therefore given by a sum over spin networks with charges (Definition 3.5). This is illustrated in Fig. 8(a).

(2) Equation (4.29) shows that an expectation value of an observable is mapped to a ratio of partition functions in the dual picture, say $\langle f_{\rho,P,Q}\rangle = Z(\rho)/Z$. The numerator $Z(\rho)$ is similar to the partition function, but the spin networks appearing there are now coupled to the charges of the observable, i.e., the numerator corresponds to the partition function in the presence of ''background charges.''

(3) Again there exists an alternative formulation based on the intermediate step (4.28) and involving the Haar intertwiner. This is stated in the following corollary and shown in Fig. 8(b).

Corollary 4.13: From the intermediate step (4.28) of the proof, we obtain,

$$\langle f_{\rho,P,Q}\rangle = \frac{1}{Z}\left(\prod_{v\in V}\sum_{\ell_v,m_v=1}^{\dim V_{\rho_v}}\right) P_{\underbrace{\ell_v\ldots}_{v\in V}}{}^{\underbrace{m_v\ldots}_{v\in V}} \left(\prod_{e\in E}\sum_{\tau_e\in\mathcal{R}_G}\right)\left(\prod_{e\in E}\hat{w}_{\tau_e}\right)\left(\prod_{e\in E}\sum_{p_e,q_e=1}^{\dim V_{\tau_e}}\right) \times \prod_{v\in V} T^{(v)}{}^{\underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ \ell_v\,,\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ m_v}, \tag{4.31}$$

where the Haar intertwiner $T^{(v)}$ for any given $v \in V$ is a map

$$T^{(v)}:\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}} V_{\tau_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}} V^*_{\tau_e}\right)\otimes V_{\rho_v}\to\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}} V_{\tau_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}} V^*_{\tau_e}\right)\otimes V_{\rho_v}. \tag{4.32}$$

D. The Abelian special case

In this section, we illustrate the specialization to the Abelian case in detail.

For $G=\mathrm{U}(1)$, the partition function reads

$$Z=\left(\prod_{v\in V}\frac{1}{2\pi}\int_0^{2\pi}d\varphi_v\right)\prod_{e\in E}\exp(-s(e^{i(\varphi_{\partial_+ e}-\varphi_{\partial_- e})})) \tag{4.33}$$

for some action $s:U(1)\to\mathbb{R}$. For $G=\mathbb{Z}_N$ we have

$$Z=\left(\prod_{v\in V}\frac{1}{N}\sum_{\ell_v=0}^{N-1}\right)\prod_{e\in E}\exp(-s(e^{2\pi i(\ell_{\partial_+ e}-\ell_{v_- e})/N})), \tag{4.34}$$

i.e., the chiral model restricts to the XY-model if $G=\mathrm{U}(1)$, to the $\mathbb{Z}_N$-vector Potts model if $G=\mathbb{Z}_N$, and in particular to the Ising model if $G=\mathbb{Z}_2$. The dual partition function (4.23) contains a sum over irreducible representations for each edge which becomes in the Abelian case a sum over $\mathbb{Z}$ or $\mathbb{Z}_N$ (Sec. II G).

As all irreducible representations are one-dimensional, the indices of $S^{(v)}$ in (4.23) are absent, and the sum over projectors restricts to the constraint (2.44), therefore for $G=\mathrm{U}(1)$,

$$Z=\left(\prod_{e\in E}\sum_{k_e=-\infty}^{\infty}\right)\left(\prod_{v\in V}\delta\left(\sum_{\substack{e\in E:\\ v=\partial_+ e}}k_e-\sum_{\substack{e\in E:\\ v=\partial_- e}}k_e\right)\right)\left(\prod_{e\in E}\hat{w}_{k_e}\right), \tag{4.35}$$

where we write $\delta(x)$ for the constraint that $x=0$. For $G=\mathbb{Z}_N$, the sum over the k_e is over $\{0,\ldots,N-1\}$ and all arithmetic involving the k_e is modulo N. The coefficients $\hat{w}_k$ are the character expansion coefficients of the Boltzmann weight [see (2.49) and (2.50)].

Equation (4.35) is the well-known dual expression of the partition function at a stage before the constraints are solved (see, for example, Refs. 3 and 5). The solution of these constraints then depends on the dimension and on the topology of the lattice. For $G=\mathrm{U}(1)$ one obtains the solid-on-solid model in $d=2$ and $\mathbb{Z}$-lattice gauge theory in $d=3$ (Ref. 3) whereas for $G=\mathbb{Z}_N$, one finds again the $\mathbb{Z}_N$-vector Potts model in $d=2$ with the self-duality of the Ising model[1] as a special case for $N=2$, and a $\mathbb{Z}_N$-lattice gauge theory in $d=3$ whose $N=2$ case was studied in Ref. 2.

In the Abelian situation, the dual partition function (4.35) contains only a coloring at one level, namely the sum over all colorings of edges with irreducible representations (wave numbers). The generalization to non-Abelian symmetry groups introduces as a second level the sum over all colorings of the vertices with compatible intertwiners. This second coloring restricts to the familiar constraint of the form (2.44) if G is Abelian.

The symmetry compatible functions (4.3) read in the Abelian case $G=\mathrm{U}(1)$ [or $G=\mathbb{Z}_N$]

$$\underbrace{f_{\ell_v\ldots}}_{v\in V}(\{g_v\}_{v\in V})=\prod_{v\in V}g_v^{\ell_v}, \tag{4.36}$$

where the $\ell_v\in\mathbb{Z}$ [or $\ell_v\in\{0,\ldots,N-1\}$] specify the charges located at the vertices. The dual of the expectation value (4.29) is then given by

$$\langle \underbrace{f_{\ell_v \ldots}}_{v \in V} \rangle = \frac{1}{Z} \left(\prod_{e \in E} \sum_{k_e = -\infty}^{\infty} \right) \left(\prod_{v \in V} \delta \left(\sum_{\substack{e \in E: \\ v = \partial_+ e}} k_e - \sum_{\substack{e \in E: \\ v = \partial_- e}} k_e + \ell_v \right) \right) \left(\prod_{e \in E} \hat{w}_{k_e} \right) \tag{4.37}$$

for $G = \mathrm{U}(1)$ and the obvious aualog for $G = \mathbb{Z}_N$.

Already in the Abelian case, the duality transformation maps the expectation value to a ratio of partition functions whose numerator is a modification of the partition function in which the presence of background charges has modified the constraints or compatibility conditions.

E. Expectation values of the dual model

As Theorem 4.11 shows, the dual expression for the expectation value of an observable is given by a ratio of partition functions. In particular, this dual expression does not coincide with any expectation value under the dual partition function.

It is therefore an interesting problem to study the natural observables of the dual partition function and to transform these expressions back to the original formulation. From the Abelian special case it is familiar that the transformation maps expectation values to ratios of partition functions and therefore correlators constructed from fundamental variables to free energies of collective excitations and conversely (see, for example, Refs. 5 and 27).

For lattice gauge theory with gauge group $G = \mathrm{U}(1)$ in $d = 4$ dimensions, for example, there exist particular expectation values of the dual partition function which describe the correlators of world-lines of magnetic monopoles.[27] If one transforms these expressions back to the original picture, one obtains ratios of partition functions $Z(X)/Z$. The numerator can be understood as the partition function of the model in the presence of a background magnetic field probing monopoles, and the ratio $Z(X)/Z = e^{-F}$ is related to the free energy F of this monopole configuration. A first natural generalization to the non-Abelian case was given by the correlation functions of center monopoles in Ref. 16, expressions which have been studied in lattice gauge theory for some time, but which have not been seen in the context of the duality transformation.

In the Abelian sigma models, the analog of the magnetic monopoles is given by dislocations, vortices, or world lines of vortices, depending on the dimension and on the precise model. In the following, we present the analogous definition for the lattice chiral model with non-Abelian symmetry group G which we call *center dislocation* as it uses the center $Z(G)$ of the symmetry group G similarly to the center monopoles in order to parametrize the observables and because it specializes to the *dislocations* studied in Ref. 2 in the case $G = \mathbb{Z}_2$.

Definition 4.14: Let G be a compact Lie group, (V,E) be an oriented graph, and $X: E \to Z(G), e \mapsto X_e$ assign an element of the center $Z(G)$ to each edge $e \in E$. The *center dislocation* is the following function $\mathcal{O}_X: (\mathcal{R}_G)^V \to \mathbb{C}$ of the configurations of the dual partition function (4.23),

$$\mathcal{O}_X(\{\tau_e\}_{e \in E}) := \prod_{e \in E} \tilde{t}^{(\tau_e)}(X_e), \tag{4.38}$$

where $\tilde{t}^{(\tau_e)}$ denotes the representation functions of $Z(G)$ induced from the representation $\tau_e \in \mathcal{R}_G$ (Lemma 2.19).

We can now employ the techniques of Sec. IV C in order to transform the expectation value of the center dislocation back to the original picture.

Theorem 4.15: The normalized expectation value of the center dislocation (4.38) under the dual partition function (4.23) is equal to

$$\langle \mathcal{O}_X \rangle_{\mathrm{dual}} = \frac{1}{Z} \left(\prod_{v \in V} \int_G dg_v \right) \prod_{e \in E} w(g_{\partial_+ e} \cdot g_{\partial_- e}^{-1} \cdot X_e). \tag{4.39}$$

Proof: Start from (4.39), insert the expansion of $w(g)$ and apply Lemma 2.19. The proof is entirely analogous to that of Theorem 4.8 with one additional factor $\tilde{t}^{(\tau_e)}(X_e)$ for each edge $e \in E$ in the integrand. □

Remark 4.16: The expectation value of the dual observable takes the form of a ratio of partition functions in the original formulation. This is essentially the converse of Theorem 4.11. The numerator can again be viewed as the partition function in the presence of a background field X.

In the Abelian case, we have $Z(G)=G$. The possible choices for fields X depend on the particular group and on the dimension and topology of the lattice. They have been carefully studied for several models.

(1) If $G=\mathrm{U}(1)$ and (V,E) is a two-dimensional cubic lattice, then the disorder parameter of the XY-model, which is related to the free energy of a vortex–antivortex pair, is of the form (4.39). In higher dimensions, this generalizes to vortex strings, vortex sheets, etc.
(2) For $G=\mathbb{Z}_2$ we obtain the dislocations of Ref. 2 as the simplest dual observables. Their expectation value is again related to their free energies.

There are more general functions $(\mathcal{R}_G)^V \to \mathbb{C}$ whose expectation value under the dual partition function can be calculated. Let $e_0 \in E$ be an edge and $\sigma \in \mathcal{R}_G$ be an irreducible representation of G. Then we can study the indicator function,

$$\mathcal{O}_{e_0,\sigma}(\{\tau_e\}_{e\in E}) = \delta_{\tau_{e_0}\sigma}, \tag{4.40}$$

which probes whether the representation σ is assigned to the edge e_0. The center dislocations can be expressed as linear combinations of these indicator functions,

$$\mathcal{O}_X(\{\tau_e\}_{e\in E}) = \left(\prod_{e\in E}\sum_{\sigma_e\in\mathcal{R}_G}\right)\prod_{e\in E}\mathcal{O}_{e,\sigma_e}\tilde{t}^{(\sigma_e)}(X_e). \tag{4.41}$$

The expectation value of an indicator function (4.40) under the dual partition function (4.23) is then equal to

$$\langle \mathcal{O}_{e_0,\sigma}\rangle_{\mathrm{dual}} = \frac{1}{Z}\left(\prod_{v\in V}\int_G dg_v\right)\prod_{e\in E}\tilde{w}_e^{(e_0,\sigma)}(g_{\partial_+ e}\cdot g_{\partial_- e}^{-1}), \tag{4.42}$$

where the Boltzmann weight $w(g)$ is modified at the edge e_0,

$$\tilde{w}_e^{(e_0,\sigma)}(g) = \begin{cases} w(g), & \text{if } e\neq e_0, \\ \displaystyle\sum_{\rho\in\mathcal{R}_G}\delta_{\rho,\sigma}\hat{w}_\rho\chi^{(\rho)}(g), & \text{if } e=e_0, \end{cases} \tag{4.43}$$

In general, a function involving the indicator functions in the dual formulation leads to a convolution of the Boltzmann weight in the original picture.

Remark 4.17: (1) The definition of dual expectation values presented here is restricted to functions of the irreducible representations at the edges. It is also conceivable to make use of functions of the intertwiners at the vertices.

(2) Indicator functions similar to (4.40) have been used to construct geometrical observables in the spin foam model of three-dimensional quantum gravity.[28]

F. The strong–weak relation

The dual partition function (4.23) of the lattice chiral model is strong–weak dual to the original formulation (4.1). This follows from the properties of the character expansion of the Boltzmann weight and is most transparent for the heat kernel action (2.52). The only β-dependent term of the dual partition function is the product

$$\prod_{e\in E}\hat{w}_{\tau_e}=\exp\left(-\frac{1}{2\beta}\sum_{e\in E}C^{(2)}_{\tau_e}\right), \tag{4.44}$$

where the inverse temperature β appears in the denominator! The result for the Wilson action of $G=\mathrm{U}(1)$ or $G=\mathrm{SU}(2)$ looks more complicated and involves modified Bessel functions, but it is qualitatively quite similar. In all these cases, the term corresponding to (4.44) has a sharp peak as a function of the $C^{(2)}_{\tau}$ if β is small.

The β-dependence (4.44) of the dual partition function also encodes essential information on the strong coupling expansion of the lattice chiral model. For small β, the dominant contribution to (4.44) comes from spin networks (assignments of representations to the edges of the graph) whose sum of the quadratic Casimir eigenvalues over all edges is very small. It is now possible to sort them by the value of this sum so that the configurations of the dual partition function are precisely the terms of the strong coupling expansion!

V. THE NONLINEAR SIGMA MODEL

We construct the lattice nonlinear sigma model with variables in some coset space G/H, where $H\leqslant G$ is a Lie subgroup of G, starting from the chiral model. One half of the $G\times G$-symmetry of the chiral model is used to couple elements $h\in H$ to the action term. Integration over h then makes sure that the action is constant on the cosets gH and therefore defines a model with variables in G/H.

A. Partition function

Lemma 5.1: Let G be a compact Lie group and $H\leqslant G$ be a Lie subgroup. Let $f\in L^2(G)$ be a class function of G with character expansion

$$f(g)=\sum_{\rho\in\mathcal{R}_G}\hat{f}_\rho\chi^{(\rho)}(g). \tag{5.1}$$

(1) For any $g_1,\ g_2\in G$,

$$\int_H f(g_1\cdot h\cdot g_2^{-1})dh=\sum_{\rho\in\mathcal{R}_H^G}\hat{f}_\rho\sum_{j=1}^{\dim V_\rho}\sum_{k=1}^{\kappa_\rho}H^{(\rho)}_{jk}(g_1)H^{(\rho^*)}_{jk}(g_2), \tag{5.2}$$

using the conventions of Sec. II E.

(2) The function f defines a map $\tilde{f}:G/H\times G/H\to\mathbb{C}$,

$$\tilde{f}(x,y):=\int_H f(g_x\cdot h\cdot g_y^{-1})dh, \tag{5.3}$$

where $g_x,\ g_y\in G$ denote representatives of the cosets $x,\ y\in G/H$.

(3) The function $\tilde{f}(x,y)$ has a global left G-symmetry, i.e., for any $g\in G,\ x,\ y\in G/H$,

$$\tilde{f}(g\cdot x,g\cdot y)=\tilde{f}(x,y). \tag{5.4}$$

(4) If in addition $f(g^{-1})=f(g)$, then $\tilde{f}(x,y)=\tilde{f}(y,x)$.

Remark 5.2: If H is a massive subgroup of G, then $\kappa_\rho = 1$ for the class-1 representations. In this case, any L^2-function $G/H \times G/H \to \mathbb{C}$ with the symmetry (5.4) is of the form (5.2). This statement does, however, not extend to the case of generic Lie subgroups $H \leqslant G$. We define the lattice nonlinear sigma model for Boltzmann weights of the special form (5.2).

Definition 5.3: Let G be a compact Lie group, $H \leqslant G$ be a Lie subgroup, and (V,E) denote an oriented graph. Let $s: G \to \mathbb{R}$ be an L^2-integrable and bounded class function that satisfies $s(g^{-1}) = s(g)$. Construct $\tilde{w}: G/H \times G/H \to \mathbb{R}$ from $w(g) = \exp(-s(g))$ as in Lemma 5.1. The *lattice nonlinear sigma model* is defined by the partition function

$$Z = \left(\prod_{v \in V} \int_{G/H} dx_v \right) \prod_{e \in E} \tilde{w}(x_{\partial_+ e}, x_{\partial_- e}). \tag{5.5}$$

Proposition 5.4: The lattice nonlinear sigma model has got a global left-G symmetry. For any fixed $g \in G$, the transformation

$$x_v \mapsto g \cdot x_v, \tag{5.6}$$

for all $v \in V$, is a symmetry of the weight $\tilde{w}(x_{\partial_+ e}, x_{\partial_- e})$. In the special case in which $H \trianglelefteq G$ is a normal subgroup, there is also a global right-G/H symmetry. Let $y \in G/H$. Then the transformation

$$x_v \mapsto x_v \cdot y^{-1}, \tag{5.7}$$

for all $v \in V$, is also a symmetry of the weight.

Example 5.5: The Boltzmann weights $\tilde{w}(x,y) := \exp(-\tilde{s}(x,y))$ of the lattice N-vector model [the O(N) nonlinear sigma model] and of the $\mathbb{RP}^{N-1}$-model are of the type of Lemma 5.1. For the N-vector model, $G = \mathrm{O}(N)$, $H = \mathrm{O}(N-1)$, and

$$\tilde{s}(\underline{x},\underline{y}) = -\beta \underline{x} \cdot \underline{y}, \tag{5.8}$$

where $\underline{x}$, $\underline{y} \in S^{N-1} \subseteq \mathbb{R}^N$, and the dot denotes the standard scalar product. For the $\mathbb{RP}^{N-1}$-model, $G = \mathrm{O}(N)$, $H = \mathrm{O}(N-1) \times \mathbb{Z}_2$, and

$$\tilde{s}(\underline{x},\underline{y}) = -\frac{\beta}{2} (\underline{x} \cdot \underline{y})^2, \tag{5.9}$$

for representatives $\underline{x}$, $\underline{y}$ of classes in $\mathbb{RP}^{N-1} \cong S^{N-1}/\mathbb{Z}_2$. On cubic lattices, there exists in both cases a suitable naïve continuum (or weak field) limit in which the lattice constant tends to zero and the lattice action towards the action of the corresponding continuum model.

Remark 5.6: (1) The partition function again depends only on the unoriented graph.

(2) If $H = \{e\}$ is the trivial group, then any representation function is a generalized spherical function. The nonlinear sigma model for G/H coincides in this case with the chiral model for G, and the global $G \times G$-symmetry is restored.

B. Expectation values

The observables of the lattice nonlinear sigma model can be found by the same methods as for the chiral model (Sec. IV B). The calculation is very similar so that we just state the results.

Theorem 5.7: Each algebraic function $(G/H)^V \to \mathbb{C}$ that is compatible with the global left-G symmetry (5.6) is a linear combination of observables of the following type,

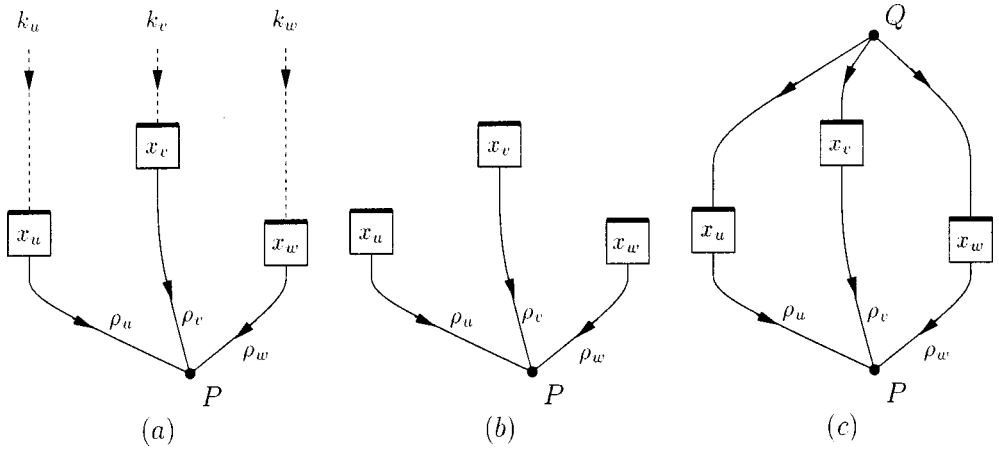

FIG. 9. (a) The observable (5.10) of the lattice nonlinear sigma model on the graph of Fig. 6. (b) The same function for the case of a massive subgroup $H \leqslant G$. (c) The observable (5.14) if $H \trianglelefteq G$ is a normal subgroup.

$$f_{\rho,P,k_v\ldots}(\{x_v\}_{v\in V}) = \left(\prod_{v\in V}\sum_{\ell_v=1}^{\dim V_{\rho_v}}\right) P_{\underbrace{\ell_v\ldots}_{v\in V}} \prod_{v\in V} H^{(\rho_v)}_{\ell_v,k_v}(x_v), \tag{5.10}$$

where

$$\rho: V \to \mathcal{R}_H^G, \quad v \mapsto \rho_v, \tag{5.11}$$

assigns a class-1 representation of G with respect to H to each vertex; $k_v \in \{1,\ldots,\kappa_{\rho_v}\}$ for all $v \in V$, and

$$P: \bigotimes_{v\in V} V_{\rho_v} \to \mathbb{C} \tag{5.12}$$

is an intertwiner of G.

Remark 5.8: (1) The structure of the function (5.10) is illustrated in Fig. 9(a).

(2) The well-known two-point function for a charge-anticharge pair ρ, ρ^* at $v, w \in V$ is a special case,

$$f_{k_v,k_v}(x_v,x_w) = \sum_{j_v=1}^{\dim V_\rho} H^{(\rho)}_{j_v k_v}(x_v) H^{(\rho^*)}_{j_w k_w}(x_w)\, \delta_{j_v j_w}, \tag{5.13}$$

for fixed k_v, $k_w \in \{1,\ldots,\kappa_\rho\}$.

(3) If H is a massive subgroup of G, we have $\kappa_\rho = 1$ for the class-1 representations so that the indices k_v can be omitted from all expressions [Fig. 9(b)].

Theorem 5.9: If in addition $H \trianglelefteq G$ is a normal subgroup, then the algebraic functions $(G/H)^V \to \mathbb{C}$ that are compatible with both the global left-G and the global right-G/H symmetry are linear combinations of observables of the following form,

$$f_{\rho,P,Q}(\{x_v\}_{v\in V}) = \left(\prod_{v\in V}\sum_{\ell_v=1}^{\dim V_{\rho_v}}\sum_{\ell_v=1}^{\kappa_{\rho_v}}\right) P_{\underbrace{\ell_v\ldots}_{v\in V}} Q_{\underbrace{k_v\ldots}_{v\in V}} \prod_{v\in V} H^{(\rho_v)}_{\ell_v k_v}(x_v). \tag{5.14}$$

Here

$$\rho: V \to \mathcal{R}_H^G, \quad v \mapsto \rho_v, \tag{5.15}$$

assigns a class-1 representation of G with respect to H to each vertex and

$$P: \bigotimes_{v \in V} V_{\rho_v} \to \mathbb{C}, \quad Q: \bigotimes_{v \in V} V_{\rho_v}^* \to \mathbb{C}, \tag{5.16}$$

are intertwiners of G.

Remark 5.10: (1) Figure 9(c) illustrates the structure of the observables (5.14) if $H \trianglelefteq G$ is a normal subgroup. Here the indices k_v of (5.10) are no longer independent, but rather exhibit a G/H-symmetry under which invariance is required. Therefore we need the second intertwiner Q. Furthermore, $\kappa_\rho = \dim V_\rho$ for all class-1 representations so that the dashed lines have become solid.

(2) In particular for $H = \{e\}$, we recover the observable (4.3) of the chiral model.

(3) In order to have nonvanishing expectation values, the observable not only has to be invariant under the symmetries (5.6) and (5.7) (if applicable), but also under orientation reversal (Remark 4.7).

C. Duality transformation

The duality transformation for the nonlinear sigma model is very similar to that of the chiral model. We summarize the main steps which differ from the calculation for the chiral model and focus directly on the most general case, the dual of an expectation value, from which the transformation of the partition function can be easily inferred.

We start with an observable $f_{\rho,P,Q}$ of the form (5.14). If $H \trianglelefteq G$ is a normal subgroup, then Q is an intertwiner of G. Otherwise, Q is arbitrary so that we obtain the function (5.10) for geueric $k_v \in \{1,\ldots,\kappa_{\rho_v}\}$, $v \in V$.

We start with the expectation value of the observable (5.14) under the partition function (5.5),

$$\begin{aligned}\langle f_{\rho,P,Q} \rangle = \frac{1}{Z} \left(\prod_{v \in V} \int_{G/H} dx_v \right) \left(\prod_{e \in E} \tilde{w}(x_{\partial_+ e}, x_{\partial_- e}) \right) \\ \times \left(\prod_{v \in V} \sum_{\ell_v=1}^{\dim V_{\rho_v}} \sum_{k_v=1}^{\kappa_{\rho_v}} \right) P_{\underbrace{\ell_v \ldots}_{v \in V}} \overline{Q_{\underbrace{k_v \ldots}_{v \in V}}} \prod_{v \in V} H^{(\rho_v)}_{\ell_v k_v}(x_v),\end{aligned} \tag{5.17}$$

and insert for each $e \in E$ the expansion of Lemma 5.1,

$$\tilde{w}(x_{\partial_+ e}, x_{\partial_- e}) = \sum_{\tau_e \in \mathcal{R}_H^G} \hat{w}_{\tau_e} \sum_{j_e=1}^{\dim V_{\tau_e}} \sum_{m_e=1}^{\kappa_{\tau_e}} H^{(\tau_e)}_{j_e m_e}(x_{\partial_+ e}) H^{(\tau_e^*)}_{j_e m_e}(x_{\partial_- e}), \tag{5.18}$$

where the $\hat{w}_\tau$ are the character expansion coefficients of the function $w(g) = \exp(-s(g))$ of Definition 5.3. The reorganized expression then reads

$$\begin{aligned}\langle f_{\rho,P,Q} \rangle = \frac{1}{Z} \left(\prod_{v \in V} \sum_{\ell_v=1}^{\dim V_{\rho_v}} \sum_{k_v=1}^{\kappa_{\rho_v}} \right) P_{\underbrace{\ell_v \ldots}_{v \in V}} \overline{Q_{\underbrace{k_v \ldots}_{v \in V}}} \left(\prod_{e \in E} \sum_{\tau_e \in \mathcal{R}_H^G} \right) \left(\prod_{e \in E} \hat{w}_{\tau_e} \right) \left(\prod_{e \in E} \sum_{j_e=1}^{\dim V_{\tau_e}} \sum_{m_e=1}^{\kappa_{\tau_e}} \right) \\ \times \prod_{v \in V} \int_{G/H} dx_v \left(\prod_{\substack{e \in E: \\ v = \partial_+ e}} H^{(\tau_e)}_{j_e m_e}(x_v) \right) \left(\prod_{\substack{e \in E: \\ v = \partial_- e}} H^{(\tau_e^*)}_{j_e m_e}(x_v) \right) H^{(\rho_v)}_{\ell_v k_v}(x_v),\end{aligned} \tag{5.19}$$

so that we can evaluate the integrals over G/H using (2.36),

$$\int_{G/H} dx_v(\cdots) = \sum_{S^{(v)} \in \tilde{\mathcal{S}}^{(v)}} \overline{S^{(v)}_{\underbrace{j_e \cdots}_{\substack{e\in E:\\ v=\partial_+ e}} \underbrace{j_e \cdots}_{\substack{e\in E:\\ v=\partial_- e}} \ell_v}} S^{(v)}_{\underbrace{m_e \cdots}_{\substack{e\in E:\\ v=\partial_+ e}} \underbrace{m_e \cdots}_{\substack{e\in E:\\ v=\partial_- e}} k_v}. \tag{5.20}$$

Here $\tilde{\mathcal{S}}^{(v)}$, $v \in V$, denotes a basis of G-invariant projectors

$$\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}} V_{\tau_e} \right) \otimes \left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}} V^*_{\tau_e} \right) \otimes V_{\rho_v} \to \mathbb{C} \tag{5.21}$$

with the usual normalization. We obtain the following result.

Theorem 5.11 (Dual observable): Let G be a compact Lie group, $H \leqslant G$ be a Lie subgroup, and (V,E) denote an oriented graph. The expectation value (5.17) of the observable of the lattice nonlinear sigma model is equal to the expressions

$$\begin{aligned}
\langle f_{\rho,P,Q} \rangle = & \frac{1}{Z} \left(\prod_{v\in V} \sum_{\ell_v=1}^{\dim V_{\rho_v}} \sum_{\kappa_v=1}^{\kappa_{\rho_v}} \right) P_{\underbrace{\ell_v \cdots}_{v\in V}} \overline{Q_{\underbrace{k_v \cdots}_{v\in V}}} \left(\prod_{e\in E} \sum_{\tau_e \in \mathcal{R}_H^G} \right) \left(\prod_{e\in E} \hat{w}_{\tau_e} \right) \\
& \times \left(\prod_{e\in E} \sum_{j_e=1}^{\dim V_{\tau_e}} \sum_{m_e=1}^{\kappa_{\tau_e}} \right) \prod_{v\in V} I^{(v)}_{\underbrace{j_e \cdots}_{\substack{e\in E:\\ v=\partial_+ e}} \underbrace{j_e \cdots}_{\substack{e\in E:\\ v=\partial_- e}} \ell_v ; \underbrace{m_e \cdots}_{\substack{e\in E:\\ v=\partial_+ e}} \underbrace{m_e \cdots}_{\substack{e\in E:\\ v=\partial_- e}} k_v}
\end{aligned} \tag{5.22}$$

$$\begin{aligned}
= & \frac{1}{Z} \left(\prod_{v\in V} \sum_{\ell_v=1}^{\dim V_{\rho_v}} \sum_{k_v=1}^{\kappa_{\rho_v}} \right) P_{\underbrace{\ell_v \cdots}_{v\in V}} \overline{Q_{\underbrace{k_v \cdots}_{v\in V}}} \times \left(\prod_{e\in E} \sum_{\tau_e \in \mathcal{R}_H^G} \right) \left(\prod_{v\in V} \sum_{S^{(v)} \in \tilde{\mathcal{S}}^{(v)}} \right) \left(\prod_{e\in E} \hat{w}_{\tau_e} \right) \\
& \times \left(\prod_{e\in E} \sum_{j_e=1}^{\dim V_{\tau_e}} \sum_{m_e=1}^{\kappa_{\tau_e}} \right) \prod_{v\in V} \overline{S^{(v)}_{\underbrace{j_e \cdots}_{\substack{e\in E:\\ v=\partial_+ e}} \underbrace{j_e \cdots}_{\substack{e\in E:\\ v=\partial_- e}} \ell_v}} S^{(v)}_{\underbrace{m_e \cdots}_{\substack{e\in E:\\ v=\partial_+ e}} \underbrace{m_e \cdots}_{\substack{e\in E:\\ v=\partial_- e}} k_v}.
\end{aligned} \tag{5.23}$$

Here $\tilde{\mathcal{S}}^{(v)}$, $v \in V$, denotes a basis of G-invariant projectors (5.21), and the $\hat{w}_\tau$ are the character expansion coefficients of the function $w(g) = \exp(-s(g))$ where $s(g)$ is the class function of Definition 5.3. The coset space Haar map $I^{(v)}$, $v \in V$, in (5.22) is a map

$$\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}} V_{\tau_e} \right) \otimes \left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}} V_{\tau_e} \right) \otimes V_{\rho_v} \to \left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}} V_{\tau_e} \right) \otimes \left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}} V_{\tau_e} \right) \otimes V_{\rho_v}. \tag{5.24}$$

Remark 5.12: (1) The dual expression (5.22) for the observable of the nonlinear sigma model is very similar to the dual observable of the chiral model in Theorem 4.11. The differences are the ranges of the indices which follow from the choice of the subgroup $H \leqslant G$. The structure of the dual observable is illustrated in Fig. 10(a) if $H \leqslant G$ is a generic, non-normal subgroup, in Fig. 10(b) if H is a massive subgroup, and in Fig. 10(c) for the case of a normal subgroup $H \trianglelefteq G$. Figures 10(a)–10(c) correspond to (5.22). The diagrams for the other formulation (5.23) are obtained by the replacements shown in Figs. 2(c) or 3(c).

(2) Again, the dual expression for the observable of the chiral model can be obtained from (5.23) for a trivial subgroup $H = \{e\}$.

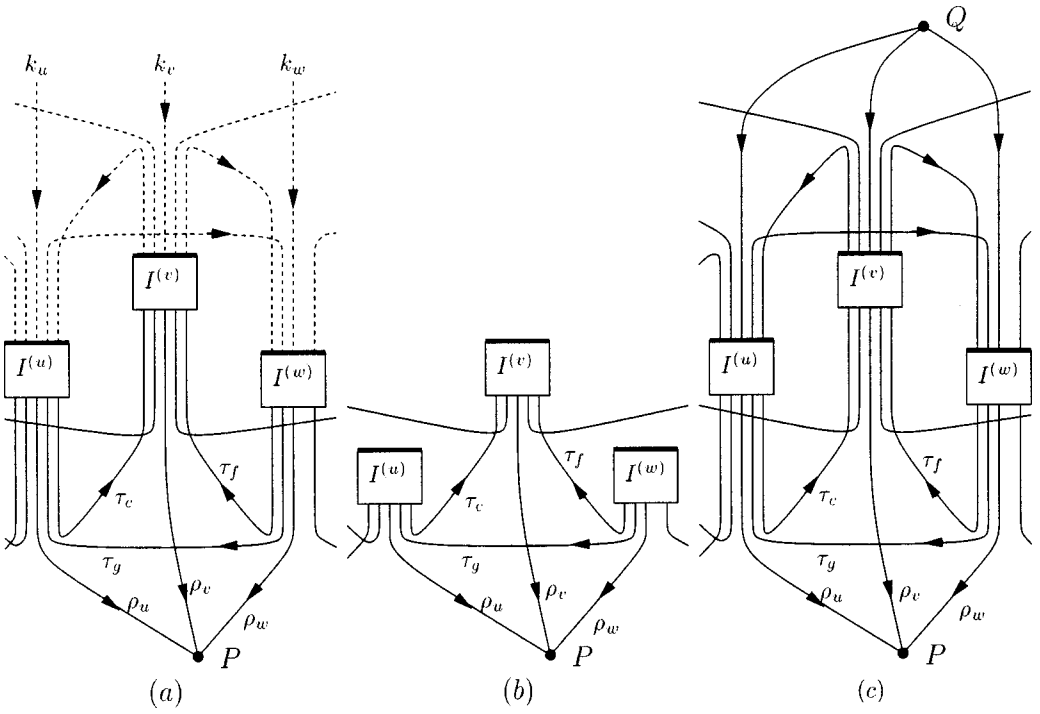

FIG. 10. (a) The structure of the dual form (5.22) for the expectation value of an observable of the lattice nonlinear sigma model on the graph of Fig. 6(a). (b) The special case of a massive subgroup $H \leqslant G$. (c) The situation for a normal subgroup $H \trianglelefteq G$.

(3) If one seeks a purely categorial picture of the dual nonlinear sigma model, one should generally view all representations as representations of H. Otherwise the integrals over H, which are still implicitly present in the spherical functions, would not be honest intertwiners. The dashed lines with open ends labeled k_v then enumerate different trivial representations of H. The special cases of massive and normal subgroups, however, are easier and can be handled already in the context of the representations of G.

The dual expression for the partition function can be calculated by specializing the numerator of (5.22) to the trivial observable. This result is given in the following corollary and visualized in Fig. 11.

Corollary 5.13 (Dual partition function): Let G be a compact Lie group with a Lie subgroup $H \leqslant G$ and (V,E) be an oriented graph. The partition function (5.5) of the lattice nonlinear sigma model is equal to

$$Z = \left(\prod_{e \in E} \sum_{\tau_e \in \mathcal{R}_H^G} \right) \left(\prod_{e \in E} \hat{w}_{\tau_e} \right) \left(\prod_{e \in E} \sum_{j_e=1}^{\dim V_{\tau_e}} \sum_{m_e=1}^{\kappa_{\tau_e}} \right) \prod_{v \in V} I^{(v)}_{\underbrace{j_e \ldots}_{\substack{e \in E: \\ v=\partial_+ e}} \underbrace{j_e \ldots}_{\substack{e \in E: \\ v=\partial_- e}} ; \underbrace{m_e \ldots}_{\substack{e \in E: \\ v=\partial_+ e}} \underbrace{m_e \ldots}_{\substack{e \in E: \\ v=\partial_- e}}} \tag{5.25}$$

$$= \left(\prod_{e \in E} \sum_{\tau_e \in \mathcal{R}_H^G} \right) \left(\prod_{v \in V} \sum_{S^{(v)} \in \mathcal{S}^{(v)}} \right) \left(\prod_{e \in E} \hat{w}_{\tau_e} \right)$$
$$\times \left(\prod_{e \in E} \sum_{j_e=1}^{\dim V_{\tau_e}} \sum_{m_e=1}^{\kappa_{\tau_e}} \right) \prod_{v \in V} \overline{S^{(v)}_{\underbrace{j_e \ldots}_{\substack{e \in E: \\ v=\partial_+ e}} \underbrace{j_e \ldots}_{\substack{e \in E: \\ v=\partial_- e}}}} S^{(v)}_{\underbrace{m_e \ldots}_{\substack{e \in E: \\ v=\partial_+ e}} \underbrace{m_e \ldots}_{\substack{e \in E: \\ v=\partial_- e}}} . \tag{5.26}$$

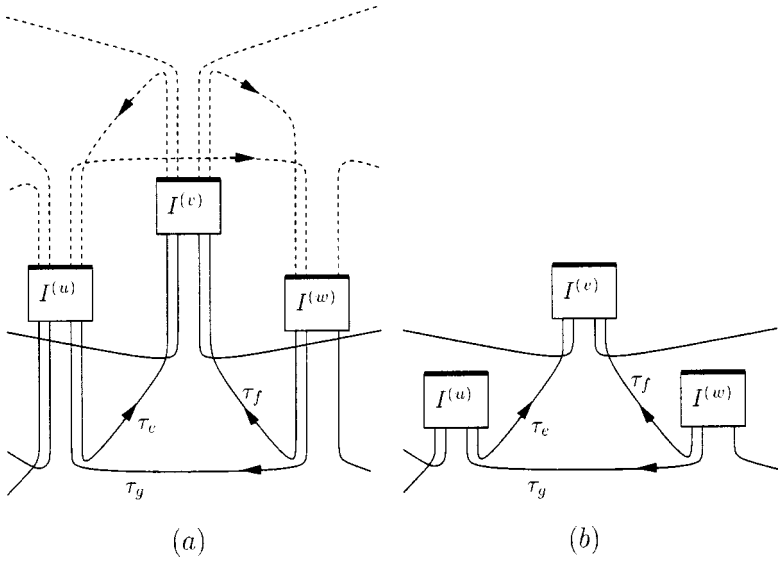

FIG. 11. (a) The structure of the dual partition function (5.25) of the lattice nonlinear sigma model on the graph of Fig. 6. (b) The special case of a massive subgroup $H \leqslant G$.

Here $\mathcal{S}^{(v)}$, $v \in V$, denotes a basis of G-invariant projectors

$$\left(\bigotimes_{\substack{e \in E: \\ v = \partial_+ e}} V_{\tau_e} \right) \otimes \left(\bigotimes_{\substack{e \in E: \\ v = \partial_- e}} V^*_{\tau_e} \right) \to \mathbb{C} \tag{5.27}$$

with the usual normalization, and the coset space Haar map $I^{(v)}$ is a linear map

$$\left(\bigotimes_{\substack{e \in E: \\ v = \partial_+ e}} V_{\tau_e} \right) \otimes \left(\bigotimes_{\substack{e \in E: \\ v = \partial_- e}} V_{\tau_e} \right) \to \left(\bigotimes_{\substack{e \in E: \\ v = \partial_+ e}} V_{\tau_e} \right) \otimes \left(\bigotimes_{\substack{e \in E: \\ v = \partial_- e}} V_{\tau_e} \right). \tag{5.28}$$

D. Expectation values of the dual model

If the natural observables of the dual partition function are again constructed from the labelling of the edges with representations, the result is the same as for the lattice chiral model in Sec. IV E, restricted to the class-1 representations. The analog of (4.39) is then

$$\langle \mathcal{O}_X \rangle_{\text{dual}} = \frac{1}{Z} \left(\prod_{v \in V} \int_{G/H} dx_v \right) \prod_{e \in E} \tilde{w}(X_e \cdot x_{\partial_+ e}; x_{\partial_- e}). \tag{5.29}$$

VI. THE GENERALIZED HIGGS MODELS

In this section, we couple the chiral model and the nonlinear sigma model to lattice gauge theory. In some particular cases, this yields certain Higgs models with frozen radial component which motivates the title of this section. Before we study the coupled models, it is useful to summarize the results of the duality transformation for lattice gauge theory[15–17] in the language of the present article.

A. Lattice gauge theory

Definition 6.1: Let G be a compact Lie group, (V,E,F) be an oriented two-complex, and $s: G \to \mathbb{R}$ be an L^2-integrable class function of G that is bounded below and satisfies $s(g^{-1}) = s(g)$ for all $g \in G$. The partition function of *lattice gauge theory* with gauge group G is defined by

$$Z=\left(\prod_{e\in E}\int_G dg_e\right)\prod_{f\in F}u(g_f),\quad g_f:=g_{\partial_1 f}^{\epsilon_1 f}\cdots g_{\partial_{N(f)}f}^{\epsilon_{N(f)}f},\tag{6.1}$$

where $u(g)=\exp(-s(g))$.

The set of configurations of lattice gauge theory is the product G^E of one copy of G for each edge $e\in E$. The ordered product of group elements attached to the edges in the boundary of the face $f\in F$ is denoted by g_f. The Boltzmann weight exhibits a local gauge symmetry.

Proposition 6.2: Let $h:V\to G$, $v\mapsto h_v$, associate a group element with each vertex. The Boltzmann weight $u(g_f)=\exp(-s(g_f))$ in (6.1) is invariant under the local gauge transformations

$$g_e\mapsto h_{\partial_+ e}\cdot g_e\cdot h_{\partial_- e}^{-1},\tag{6.2}$$

for all $e\in E$.

This definition of lattice gauge theory is motivated by the fact that on regular hypercubic lattices, the Wilson action tends towards the continuum Yang–Mills action in the weak field limit of vanishing lattice constant. The group elements g_e attached to the edges of the lattice correspond to the parallel transports of the gauge connection along these edges. For more details on lattice gauge theory, see, for example, Refs. 29 and 30.

The most general observable of lattice gauge theory whose expectation value under the partition function (6.1) can be calculated is constructed from spin networks. Each algebraic function $G^E\to\mathbb{C}$ that is invariant under the transformation (6.2) is a linear combination of *spin network functions*. They generalize the notion of Wilson loops and are defined as follows.

Definition 6.3: Let G be a compact Lie group, (V,E,F) be an oriented two-complex, and (σ,Q) be a spin network (Definition 3.4). The *spin network function* of (σ,Q) associates with each configuration a complex number,

$$W_{\sigma,Q}(\{g_e\}_{e\in E}):=\left(\prod_{e\in E}\sum_{k_e,\ell_e=1}^{\dim V_{\sigma_e}}\right)\left(\prod_{e\in E}t_{k_e\ell_e}^{(\sigma_e)}(g_e)\right)\left(\prod_{v\in V}Q^{(v)}_{\underbrace{\ell_e\cdots}_{\substack{e\in E:\\ v=\partial_- e}}\ \underbrace{k_e\cdots}_{\substack{e\in E:\\ v=\partial_+ e}}}\right).\tag{6.3}$$

Remark 6.4: (1) The above definition uses the spin network (σ,Q) to label edges with representations and vertices with intertwiners, and then employs a representation function for each edge in order to obtain a function $G^E\to\mathbb{C}$.

(2) All edges $e\in E$ for which $V_{\sigma_e}\cong\mathbb{C}$ is the trivial representation contribute only a factor 1 to the expression (6.3). For an ordinary Wilson loop, for example, all edges are labeled with the trivial representation except for those edges that are part of the loop. These are labeled with the fundamental representation of G. The intertwiners $Q^{(v)}$ (if nonvanishing) are in this case uniquely determined up to normalization.

(3) The spin network function (6.3) can be *evaluated* by putting $g_e=e$ (group unit) for all edges $e\in E$. The result is an invariant of G which is often called the *value* of the spin network (σ,Q).

(4) If G is Abelian, then the set $\mathcal{R}_G$ of irreducible representations forms an additive group, and all irreducible representations are one-dimensional. Thus $W_{\sigma,Q}$ can be decomposed into a sum of products of ordinary Wilson loops.

We have the following dual expressions for the partition function and the expectation value of a spin network function.[15,17]

Theorem 6.5 (Dual partition function): Let G be a compact Lie group. The partition function (6.1) of lattice gauge theory is equal to the expression

$$Z=\left(\prod_{f\in F}\sum_{\tau_f\in\mathcal{R}_G}\right)\left(\prod_{e\in E}\sum_{U^{(e)}\in\mathcal{U}(e)}\right)\left(\prod_{f\in F}\hat{u}_{\tau_f}\right)\left(\prod_{v\in V}C(v)\right).\tag{6.4}$$

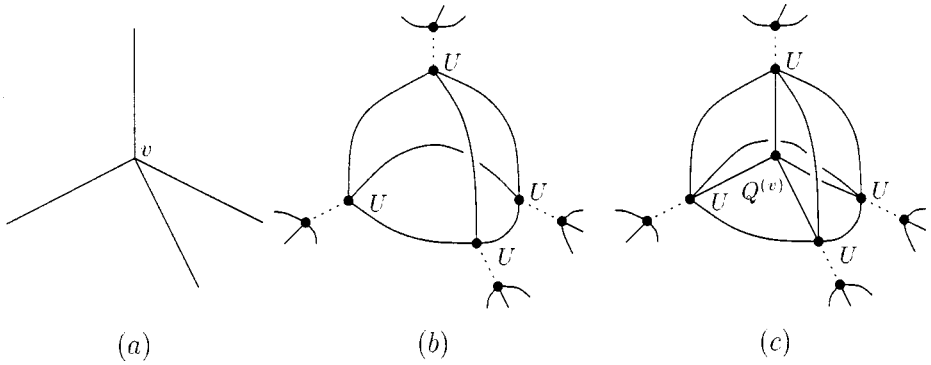

FIG. 12. (a) A two-complex with a vertex v attached to four edges. There are six faces, one between each pair of edges. (b) The spin network $C(v)$ of (6.6) that appears in the dual partition function of lattice gauge theory and (c) the spin network (6.14) from the dual of an expectation value.

Here $\mathcal{U}^{(e)}$, $e \in E$, denotes a basis of G-invariant projectors

$$\left(\bigotimes_{f \in e_+} V_{\tau_f} \right) \otimes \left(\bigotimes_{f \in e_-} V_{\tau_f}^* \right) \to \mathbb{C}. \tag{6.5}$$

The $\hat{u}_\tau$ are the coefficients of the character expansion of the Boltzmann weight $u(g)$. The weights per vertex $C(v)$ are given by a trace involving representations and projectors in the neighborhood of the vertex $v \in V$,

$$C(v) = \left(\prod_{\substack{f \in F: \\ v \in f_0}} \sum_{n_f=1}^{\dim V_{\tau_f}} \right) \left(\prod_{\substack{e \in E: \\ v = \partial + e}} \overline{U^{(e)}_{\underbrace{n_f n_f \ldots}_{f \in e_+} \underbrace{n_f n_f \ldots}_{f \in e_-}}} \right) \left(\prod_{\substack{e \in E: \\ v = \partial - e}} U^{(e)}_{\underbrace{n_f n_f \ldots}_{f \in e_+} \underbrace{n_f n_f \ldots}_{f \in e_-}} \right). \tag{6.6}$$

Here the range $f \in F: v \in f_0$ of the first product refers to all faces $f \in F$ that contain the vertex v in their boundary. The second product is over the range $e \in E: v = \partial_+ e$ of all edges that have v as their endpoint, etc. (see Sec. III A).

Remark 6.6: (1) For each edge $e \in E$, the projectors (6.5) are related by natural isomorphisms to intertwiners

$$\bigotimes_{f \in e_+} V_{\tau_f} \to \bigotimes_{f \in e_-} V_{\tau_f}, \tag{6.7}$$

from the tensor product of the representations at the ''incoming'' faces to the tensor product at the ''outgoing'' ones.

(2) The dual partition function (6.4) labels the faces with irreducible representations of G and the edges with compatible intertwiners in the sense of (6.7). The configurations of the dual partition function are therefore spin foams (Definition 3.6) so that the dual model is a spin foam model. Compared with the situation for the sigma models, all the labels appear one level ''higher,'' i.e., at the faces rather than at the edges, and at the edges rather than the vertices.

(3) The expression $C(v)$ for given projectors $U^{(e)}$ is itself a spin network. Figure 12(b) visualizes it for a vertex with four edges attached. In particular, for $G = \mathrm{SU}(2)$, the $C(v)$ are the $6j$-symbols of SU(2). The collection of all $C(v)$ in a two-complex is illustrated in Fig. 13(a).

(4) The spin networks of the dual partition function for lattice gauge theory decompose into one independent $C(v)$ for each vertex. This is a consequence of the local G-symmetry and is in contrast to the chiral model whose dual partition function involves two spin networks that extend over the entire graph, reflecting the two-fold global G-symmetry. For the nonlinear sigma model

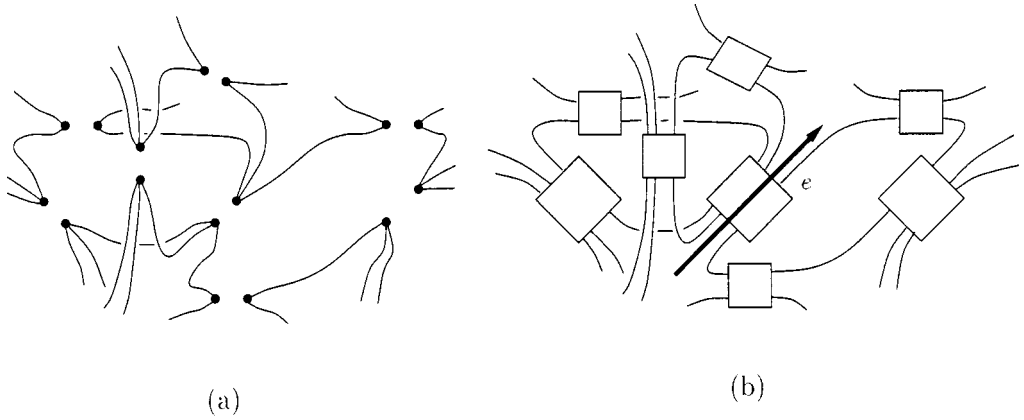

FIG. 13. An edge $e \in E$ in the boundary of three faces, two triangles and one quadrilateral. (a) The structure of the spin networks $C(v)$ in the dual partition function of lattice gauge theory (6.4). (b) The alternative formulation (6.8) using the Haar intertwiner. We have omitted labels and arrows in both diagrams.

with a massive subgroup $H \leqslant G$, the dual partition function still contains one spin network that extends over the entire graph which corresponds to a single global G-symmetry.

(5) Again there exists an alternative formulation using the Haar intertwiner rather than the sum over projectors which is stated in the following corollary. This result agrees with the purely diagrammatical picture of Ref. 18 and is illustrated in Fig. 13(b). Upon use of (2.24), we recover (6.4) and Fig. 13(a).

Corollary 6.7: Let G be a compact Lie group and (V,E,F) denote an oriented two-complex. The partition function of lattice gauge theory (6.4) is equal to

$$Z = \left(\prod_{f \in F} \sum_{\tau_f \in \mathcal{R}_G} \right) \left(\prod_{f \in F} \hat{u}_{\tau_f} \right) \left(\prod_{f \in F} \prod_{v \in f_0} \sum_{n(f,v)=1}^{\dim V_{\tau_f}} \right) \prod_{e \in E} T^{(e)}_{\underbrace{n(f,\partial_+ e)\ldots}_{f \in e_+} \underbrace{n(f,\partial_+ e)\ldots}_{f \in e_-} ; \underbrace{n(f,\partial_- e)\ldots}_{f \in e_+} \underbrace{n(f,\partial_- e)\ldots}_{f \in e_-}}, \tag{6.8}$$

where $T^{(e)}$, $e \in E$, denotes the Haar intertwiner (2.23) for the following representations:

$$T^{(e)} : \left(\bigotimes_{f \in e_+} V_{\tau_f} \right) \otimes \left(\bigotimes_{f \in e_-} V^*_{\tau_f} \right) \to \left(\bigotimes_{f \in e_+} V_{\tau_f} \right) \otimes \left(\bigotimes_{f \in e_-} V^*_{\tau_f} \right). \tag{6.9}$$

Finally, the analogous statements are available for expectation values of spin network functions.

Theorem 6.8 (Dual observable): Let G be a compact Lie group, (V,E,F) be an oriented two-complex, and Z denote the partition function (6.1) of lattice gauge theory. The expectation value of the spin network function (6.3),

$$\begin{aligned} \langle W_{\sigma,Q} \rangle = \frac{1}{Z} \left(\prod_{e \in E} \int_G dg_e \right) \prod_{f \in F} u(g_{\partial_1 f}^{\epsilon_1 f} \cdots g_{\partial_{N(f)} f}^{\epsilon_{N(f)} f}) \left(\prod_{e \in E} \sum_{k_e, \ell_e = 1}^{\dim V_{\sigma_e}} \right) \\ \times \left(\prod_{e \in E} t^{(\sigma_e)}_{k_e \ell_e}(g_e) \right) \left(\prod_{v \in V} Q^{(v)}_{\underbrace{\ell_e \ldots}_{\substack{e \in E: \\ v = \partial_- e}} \; \underbrace{k_e \ldots}_{\substack{e \in E: \\ v = \partial_+ e}}} \right), \end{aligned} \tag{6.10}$$

is equal to the following expressions:

$$\langle W_{\sigma,Q}\rangle = \frac{1}{Z}\left(\prod_{f\in F}\sum_{\tau_f\in\mathcal{R}_G}\right)\left(\prod_{f\in F}\hat{u}_{\tau_f}\right)\left(\prod_{f\in F}\prod_{v\in f_0}\sum_{n(f,v)=1}^{\dim V_{\tau_f}}\right)\left(\prod_{e\in E}\sum_{k_e,\ell_e=1}^{\dim V_{\sigma_e}}\right)$$
$$\times\left(\prod_{v\in V} Q^{(v)}_{\underbrace{\ell_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ \underbrace{k_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}}\right)\prod_{e\in E} T^{(e)}_{\underbrace{n(f,\partial_+e)\ldots n(f,\partial_+e)\ldots k_e}_{f\in e_+}\ \underbrace{n(f,\partial_+e)\ldots}_{f\in e_-}\ ;\underbrace{n(f,\partial_-e)\ldots}_{f\in e_+}\ \underbrace{n(f,\partial_-e)\ldots \ell_e}_{f\in e_-}} \tag{6.11}$$

$$= \frac{1}{Z}\left(\prod_{f\in F}\sum_{\tau_f\in\mathcal{R}_G}\right)\left(\prod_{e\in E}\sum_{U^{(e)}\in\tilde{\mathcal{U}}^{(e)}}\right)\left(\prod_{f\in F}\hat{u}_{\tau_f}\right)\left(\prod_{v\in V}\tilde{C}(v)\right). \tag{6.12}$$

Here $\tilde{\mathcal{U}}^{(e)}$, $e\in E$, denotes a basis of G-invariant projectors

$$\left(\bigotimes_{f\in e_+} V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-} V^*_{\tau_f}\right)\otimes V_{\sigma_e}\to\mathbb{C}. \tag{6.13}$$

The weights per vertex $\tilde{C}(v)$ are given by a trace involving representations and projectors in the neighborhood of the vertex $v\in V$,

$$\tilde{C}(v) = \left(\prod_{\substack{e\in E:\\ v=\partial_+ e}}\sum_{k_e=1}^{\dim V_{\sigma_e}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_- e}}\sum_{\ell_e=1}^{\dim V_{\sigma_e}}\right) Q^{(v)}_{\underbrace{\ell_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ \underbrace{k_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}}\left(\prod_{\substack{f\in F:\\ v\in f_0}}\sum_{n_f=1}^{\dim V_{\tau_f}}\right)$$
$$\times\left(\prod_{\substack{e\in E:\\ v=\partial_+ e}}\overline{U^{(e)}_{\underbrace{n_f n_f\ldots}_{f\in e_+}\ \underbrace{n_f\ldots k_e}_{f\in e_-}}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_- e}} U^{(e)}_{\underbrace{n_f n_f\ldots}_{f\in e_+}\ \underbrace{n_f\ldots \ell_e}_{f\in e_-}}\right). \tag{6.14}$$

The Haar intertwiner $T^{(e)}$, $e\in E$, in (6.11) is a map

$$T^{(e)}:\left(\bigotimes_{f\in e_+} V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-} V^*_{\tau_f}\right)\otimes V_{\sigma_e}\to\left(\bigotimes_{f\in e_+} V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-} V^*_{\tau_f}\right)\otimes V_{\sigma_e}. \tag{6.15}$$

Remark 6.9: (1) The general pattern is already familiar: The dual of the expectation value is given by a ratio of partition functions whose numerator is a modification of the partition function, here given by the background spin network (σ,Q) to which the spin foams couple. The structure remains unchanged, just the compatibility condition is modified so that the numerator of the dual expectation value is given by a sum over all spin foams bounded by the spin network (σ,Q) (Definition 3.7).

(2) The spin networks $\tilde{C}(v)$ of (6.14) are shown in Fig. 12(c). Compared with (b), there is in addition a piece of the spin network (σ,Q) in the middle of the diagram.

Similarly to the sigma models, we can again ask what are the natural functions whose expectation value under the dual partition function we can study. A construction using the center $Z(G)$, which is essentially analogous to Sec. IV E, was given in Ref. 16. In the language of the present article, it reads as follows.

Definition 6.10: Let G be a compact Lie group, (V,E,F) be an oriented two-complex, and $X:F\to Z(G)$, $f\mapsto X_f$ assign an element of the center to each face $f\in F$. The *center monopole correlator* is the following function $\mathcal{O}_X:(\mathcal{R}_G)^E\to\mathbb{C}$ of the configurations of the dual partition function (6.4),

$$\mathcal{O}_X(\{\tau_f\}_{f\in F}) := \prod_{f\in F}\tilde{t}^{(\tau_f)}(X_f), \tag{6.16}$$

where $\tilde{t}^{(\tau_f)}$ denotes the representation functions of $Z(G)$ of Lemma 2.19.

Theorem 6.11: The expectation value of the center monopole correlator under the dual partition function (6.4) reads in the original formulation

$$\langle \mathcal{O}_X \rangle_{\text{dual}} = \frac{1}{Z} \left(\prod_{e \in E} \int_G dg_e \right) \prod_{f \in F} u(gf \cdot X_f). \tag{6.17}$$

For a deliberate choice of X, this expression restricts to the monopole correlator[27] of U(1)-lattice gauge theory in $d=4$ and coincides with the $\mathbb{Z}_N$ center monopoles and vortices which are being studied in SU(N)-lattice gauge theory.

A construction using indicator functions in the dual formulation, which probe whether a particular face $f \in F$ is assigned a given representation $\tau_f \in \mathcal{R}_G$, results in a convolution of the Boltzmann weight in the original formulation. This construction proceeds in complete analogy to Sec. IV E.

B. The generalized Higgs model

In this section, we study the models that can be obtained by coupling a nonlinear sigma model with variables in G/H to a lattice gauge theory with gauge group G. When we study these models, we keep a particular Abelian special case in mind, namely the U(1)-Higgs model with frozen radial component for which Einhorn and Savit[6] have developed a duality transformation. In all the following steps, the lattice chiral model will be contained as a special case of the nonlinear sigma model for the choice $H=\{e\}$.

If we wish to couple a lattice gauge theory to the nonlinear sigma model, we have to make use of the left-action of G on G/H. A similar coupling has already been performed when we passed from the chiral model to the nonlinear sigma model. In Lemma 5.1, we have used the action of H by right-multiplication on G in order to couple one variable $h \in H$ for each edge to the variables of the chiral model. The collection of all the integrals over H for each edge just describes a lattice gauge theory with gauge group H and zero action for the gauge fields. Therefore we have coupled the chiral model with symmetry group G to a lattice gauge theory with gauge group H. The result of this ''nondynamical'' gauge field is merely to average over the cosets and therefore to give rise to a model with variables in G/H.

In this section, we couple a ''second'' gauge field with gauge group G to the chiral model which is dynamical and which realizes a lattice gauge theory as described in the previous section.

Definition 6.12: Let G be a compact Lie group, $H \leqslant G$ be a Lie subgroup, and (V,E,F) denote an oriented two-complex. Let $s_s, s_g : G \to \mathbb{R}$ be L^2-integrable class functions that are bounded below and satisfy $s_s(g^{-1}) = s_s(g)$, $s_g(g^{-1}) = s_g(g)$. The function s_g is called the *gauge action* and s_s is the *sigma model action.* Define furthermore the Boltzmann weight $u(g) = \exp(-s_g(g))$ and, using Lemma 5.1, a function $\tilde{w} : G/H \times G/H \to \mathbb{R}$ from $w(g) = \exp(-s_s(g))$. Then the generalized lattice Higgs model is given by the partition function

$$Z = \left(\prod_{e \in E} \int_G dg_e \right) \left(\prod_{v \in V} \int_{G/H} dx_v \right) \left(\prod_{f \in F} u(g_{\partial_1 f}^{\epsilon_1 f} \cdots g_{\partial_{N(f)} f}^{\epsilon_{N(f)} f}) \right) \left(\prod_{e \in E} \tilde{w}(g_e^{-1} \cdot x_{\partial_+ e}, x_{\partial_- e}) \right). \tag{6.18}$$

Remark 6.13: (1) This definition combines the partition sum of gauge theory, integration over G for each edge, with that of the nonlinear sigma model, integration over G/H for each vertex. The configurations of the partition function are elements of $G^E \times (G/H)^V$. The Boltzmann weight $u(g_f)$ of lattice gauge theory is unchanged whereas the Boltzmann weight of the nonlinear sigma model $\tilde{w}(x,y)$ is modified to $\tilde{w}(g^{-1} \cdot x, y)$ in order to implement the minimal coupling. We use g^{-1} rather than g here so that the subsequent results are consistent with the left-cosets which we have chosen for the nonlinear sigma model and with the notation established in the previous section for gauge theory.

(2) The expression does again not depend on the orientations as $\tilde{w}(g^{-1}\cdot x,y)=\tilde{w}(x,g\cdot y)$. Also we could choose different Boltzmann weights $u_f(g)$ for each face $f\in F$ and $\tilde{w}_e(x,y)$ for each edge $e\in E$.

(3) Many Higgs models with frozen radial modes appear as special cases of Definition 6.12 (see, for example, Ref. 7).

Proposition 6.14: The total Boltzmann weight of the generalized lattice Higgs model (6.18) has got a local left-G symmetry. For each function $h:V\to G$, $v\mapsto h_v$, which assigns a group element to each vertex, the Boltzmann weight is invariant under the transformations

$$\begin{aligned} x_v &\mapsto h_v\cdot x_v\,,\\ g_e &\mapsto h_{\partial_+ e}\cdot g_e\cdot h_{\partial_- e}^{-1}, \end{aligned} \tag{6.19}$$

for all $v\in V$ and $e\in E$. If in addition $H\trianglelefteq G$ is a normal subgroup, there is also a global right-G/H symmetry. Then the Boltzmann weight is invariant for each $y\in G/H$ under the transformation

$$x_v\mapsto x_v\cdot y^{-1}, \tag{6.20}$$

for all $v\in V$.

C. Expectation values

Using similar methods as in the previous sections, one can calculate all functions $G^E\times(G/H)^V\to\mathbb{C}$ that are compatible with these symmetries and therefore determine all observables whose expectation values under the partition function can be calculated.

Theorem 6.15: Any algebraic function $G^E\times(G/H)^V\to\mathbb{C}$ that is invariant under the transformations (6.19) is a linear combination of functions of the form

$$\begin{aligned} f_{\sigma,\rho,P,k_v\ldots}(\{g_e\}_{e\in E},\{x_v\}_{v\in V}) &= \left(\prod_{e\in E}\sum_{p_e,q_e=1}^{\dim V_{\sigma_e}}\right)\left(\prod_{v\in V}\sum_{j_v=1}^{\dim V_{\rho_v}}\right)\left(\prod_{v\in V} P^{(v)}_{\underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ j_v}\right)\\ &\quad\times\left(\prod_{e\in E} t^{(\sigma_e)}_{p_e q_e}(g_e)\right)\left(\prod_{v\in V} H^{(\rho_v)}_{j_v k_v}(x_v)\right). \end{aligned} \tag{6.21}$$

Here $\sigma:E\to\mathcal{R}_G$, $e\mapsto\sigma_e$ assigns an irreducible representation of G to each edge $e\in E$, and $\rho:V\to\mathcal{R}_H^G$, $v\mapsto\rho_v$ assigns a class-1 representation to each vertex $v\in V$. There are intertwiners of G,

$$P^{(v)}\in\mathrm{Hom}_G\left(\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}} V_{\sigma_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}} V^*_{\sigma_e}\right)\otimes V_{\rho_v},\mathbb{C}\right), \tag{6.22}$$

for each vertex, and the indices k_v are arbitrary, $k_v\in\{1,\ldots,\kappa_{\rho_v}\}$. If in addition $H\trianglelefteq G$ is a normal subgroup, then the invariant functions are of the form

$$\begin{aligned} f_{\sigma,\rho,P,Q}(\{g_e\}_{e\in E},\{x_v\}_{v\in V}) &= \left(\prod_{e\in E}\sum_{p_e,q_e=1}^{\dim V_{\sigma_e}}\right)\left(\prod_{v\in V}\sum_{j_v=1}^{\dim V_{\rho_v}}\sum_{k_v=1}^{\kappa_{\rho_v}}\right) Q_{\underbrace{k_v\ldots}_{v\in V}}\left(\prod_{v\in V} P^{(v)}_{\underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ j_v}\right)\\ &\quad\times\left(\prod_{e\in E} t^{(\sigma_e)}_{p_e q_e}(g_e)\right)\left(\prod_{v\in V} H^{(\rho_v)}_{j_v k_v}(x_v)\right), \end{aligned} \tag{6.23}$$

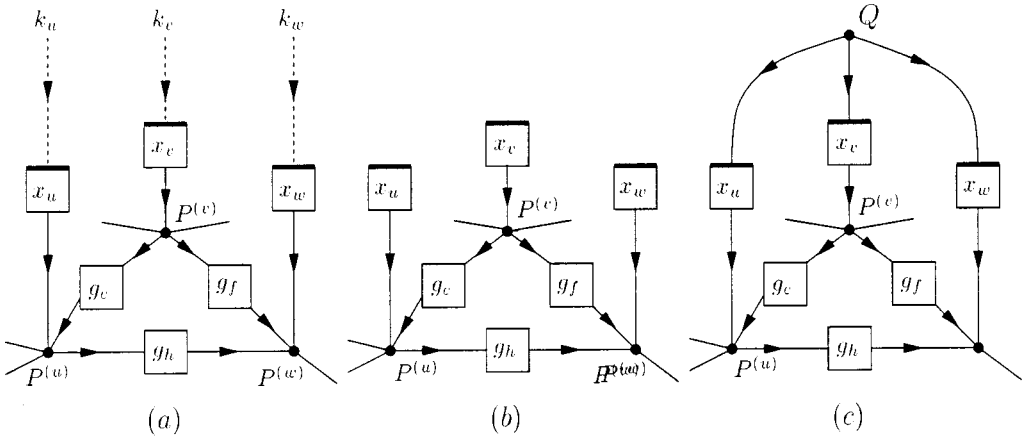

FIG. 14. The structure of the observables of the generalized Higgs model on the graph of Fig. 6(a). (a) The case (6.21) of a generic subgroup $H \leqslant G$. (b) The special case of a massive subgroup $H \leqslant G$ and (c) the situation (6.23) for a normal subgroup $H \trianglelefteq G$.

where σ, ρ, and P are as above, and Q is an intertwiner of G,

$$\bigotimes_{v \in V} V^*_{\rho_v} \to \mathbb{C}. \tag{6.24}$$

Remark 6.16: (1) These functions combine a spin network function of the type (6.3) given by the spin network (σ,P) with an observable of the type (5.10) specified by ρ and by the k_v or by ρ and Q, respectively. They are characterized by a spin network with charges (σ,P,ρ) (Definition 3.5). The fact that the local gauge transformation (6.19) also affects the variables x_v of the sigma model does not only fix the structure of the minimal coupling term, but also enforces the compatibility condition (6.22) between the spin network function and the sigma model observables. The structure of the functions (6.21) and (6.23) is illustrated in Figs. 14(a)–14(c) for the generic case, for a massive and for a normal subgroup.

(2) The chiral model coupled to a lattice gauge theory is contained as the special case for $H=\{e\}$. In this case, all dashed lines in Fig. 14(b) become solid.

D. Duality transformation

The duality transformation for the partition function (6.18) and for the expectation values of the functions (6.21) and (6.23) are straightforward using the methods established in the preceding sections. Since the expressions become very long, we only quote the results. As the very number of sum and product signs is probably deterring at first sight, we carefully comment on the meaning of the various terms and refer to the figures for illustration.

Theorem 6.17 (Dual partition function): Let G be a compact Lie group, $H \leqslant G$ be a Lie subgroup, and (V,E,F) denote an oriented two-complex. The partition function of the generalized lattice Higgs model (6.18) is equal to the following expressions,

$$Z=\left(\prod_{e\in E}\sum_{\eta_e\in\mathscr{R}_H^G}\right)\left(\prod_{f\in F}\sum_{\tau_f\in\mathscr{R}_G}\right)\left(\prod_{e\in E}\hat{w}_{\eta_e}\right)\left(\prod_{f\in F}\hat{u}_{\tau_f}\right)\left(\prod_{f\in F}\prod_{v\in f_0}\sum_{n(f,v)=1}^{\dim V_{\tau_f}}\right)\left(\prod_{e\in E}\sum_{i_e,\ell_e=1}^{\dim V_{\eta_e}}\sum_{m_e=1}^{\kappa_{\eta_e}}\right)$$
$$\times\left(\prod_{v\in V}I^{(v)}_{\underbrace{i_e\cdots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{\ell_e\cdots}_{\substack{e\in E:\\ v=\partial_-e}};\ \underbrace{m_e\cdots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{m_e\cdots}_{\substack{e\in E:\\ v=\partial_-e}}}\right)\left(\prod_{e\in E}T^{(e)}_{\underbrace{n(f,\partial_+e)\cdots}_{f\in e_+}\underbrace{n(f,\partial_+e)\cdots}_{f\in e_-}i_e;\underbrace{n(f,\partial_-e)\cdots}_{f\in e_+}\underbrace{n(f,\partial_-e)\cdots}_{f\in e_-}\ell_e}\right) \tag{6.25}$$

$$=\left(\prod_{e\in E}\sum_{\eta_e\in\mathscr{R}_H^G}\right)\left(\prod_{v\in V}\sum_{S^{(v)}\in\mathscr{S}^{(v)}}\right)\left(\prod_{f\in F}\sum_{\tau_f\in\mathscr{R}_G}\right)\left(\prod_{e\in E}\sum_{U^{(e)}\in\mathscr{U}^{(e)}}\right)\left(\prod_{e\in E}\hat{w}_{\eta_e}\right)\left(\prod_{f\in F}\hat{u}_{\tau_f}\right)$$
$$\times\left(\prod_{e\in E}\sum_{m_e=1}^{\kappa_{\eta_e}}\right)\left(\prod_{v\in V}S^{(v)}_{\underbrace{m_e\cdots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{m_e\cdots}_{\substack{e\in E:\\ v=\partial_-e}}}\right)\prod_{v\in V}D(v), \tag{6.26}$$

where for each $v\in V$,

$$D(v)=\left(\prod_{\substack{f\in F:\\ v\in f_0}}\sum_{n_f=1}^{\dim V_{\tau_f}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_-e}}\sum_{\ell_e=1}^{\dim V_{\eta_e}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_+e}}\sum_{i_e=1}^{\dim V_{\eta_e}}\right)\overline{S^{(v)}_{\underbrace{i_e\cdots}_{\substack{e\in E:\\ v=\partial_+e}}\ \underbrace{\ell_e\cdots}_{\substack{e\in E:\\ v=\partial_-e}}}}$$
$$\times\left(\prod_{\substack{e\in E\\ v=\partial_+e}}\overline{U^{(e)}_{\underbrace{n_f\cdots n_f\cdots i_e}_{f\in e_+f\in e_-}}}\right)\left(\prod_{\substack{e\in E\\ v=\partial_-e}}\overline{U^{(e)}_{\underbrace{n_f\cdots n_f\cdots\ell_e}_{f\in e_+f\in e_-}}}\right). \tag{6.27}$$

Here $\hat{u}_\tau$ and $\hat{w}_\eta$ denote the character expansion coefficients of the functions $u(g)$ and $w(g)$ of Definition 6.12. For each edge $e\in E$, $\mathcal{U}^{(e)}$ is a basis of G-invariant projectors

$$\left(\bigotimes_{f\in e_+}V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-}V^*_{\tau_f}\right)\otimes V^*_{\eta_e}\to\mathbb{C}, \tag{6.28}$$

and for each vertex $v\in V$, $\mathcal{S}^{(v)}$ denotes a basis of G-invariant projectors

$$\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+e}}V_{\eta_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_-e}}V^*_{\eta_e}\right)\to\mathbb{C}. \tag{6.29}$$

The coset space Haar map $I^{(v)}$, $v\in V$, in (6.25) is a map

$$\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+e}}V_{\eta_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_-e}}V^*_{\eta_e}\right)\to\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+e}}V_{\eta_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_-e}}V^*_{\eta_e}\right), \tag{6.30}$$

while the Haar intertwiner $T^{(e)}$, $e\in E$, maps

$$\left(\bigotimes_{f\in e_+}V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-}V^*_{\tau_f}\right)\otimes V^*_{\eta_e}\to\left(\bigotimes_{f\in e_+}V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-}V^*_{\tau_f}\right)\otimes V^*_{\eta_e}. \tag{6.31}$$

Remark 6.18: (1) We first comment on the dual partition function in the form (6.26). The dual partition sum comprises the partition sums of both the nonlinear sigma model and of lattice gauge

theory. For the nonlinear sigma model, we have a sum over all colorings of the edges with class-1 representations η_e and a sum over all colorings of the vertices with compatible intertwiners $S^{(v)}$ where the compatibility condition (6.29) is the same as for the nonlinear sigma model. For lattice gauge theory, there are additional sums over all colorings of the faces with irreducible representations τ_f and of the edges with compatible intertwiners $U^{(e)}$. This compatibility condition (6.28) is, however, not the same as in lattice gauge theory. The minimal coupling term has modified this condition so that each spin foam appearing in the dual of the gauge theory sector is bounded by the spin network that occurs in the dual of the nonlinear sigma model. In other words, the spin network diagrams of the high temperature expansion of the nonlinear sigma model appear as spin network functions whose expectation value is calculated under the partition function of gauge theory. The minimal coupling term of the generalized Higgs model could have been found from this entirely dual point of view.

(2) In addition to the character expansion coefficients, we find under the dual partition sum several spin networks. There is one would-be spin network from the nonlinear sigma model, given by the representations V_{η_c} and by the intertwiners $S^{(v)}$ which extends over the entire graph. It does not form a proper spin network because the summation over the indices m_e extends only over $1,...,\kappa_{\rho_e}$, i.e., over the H-invariant subspaces of the representations. This is the same type of network that is usually denoted by dashed lines and has already appeared in the dual partition function of the nonlinear sigma model [see the top layer of Fig. 11(a)].

(3) Under the partition sum, there are furthermore the spin networks denoted by $D(v)$ for each vertex. They are similar to the spin networks $C(v)$ from the dual partition function of lattice gauge theory (6.6), but include in addition a part of the spin network given by the representations V_{η_e} and the intertwiners $\overline{S^{(v)}}$. The difference between the $C(v)$ of lattice gauge theory and the $D(v)$ appearing here is essentially the same as that of the $C(v)$ and the $\widetilde{C}(v)$, cf. Figs. 12(b) and 12(c). The neighborhood of a vertex with the spin network $D(v)$ and the dashed lines of the would-be spin network is shown in Fig. 15(a).

(4) The structure of the dual partition function (6.26) of the generalized Higgs model can be explained in other words starting from the corresponding expression of the chiral model [Fig. 7(a)]. First, we are concerned with the nonlinear sigma model rather than with the chiral model. This was implemented by coupling elements $h \in H$ to one chiral half of the model which corresponds to the top layer in Fig. 7(a), and then by averaging over the subgroup in Lemma 5.1. This averaging is the reason why the top layer of Fig. 11(a) consists of dashed lines (''would-be spin network''). Then we have minimally coupled lattice gauge theory to the other chiral half which corresponds to the spin network in the bottom layer of Fig. 7(a). The effect of the minimal coupling term is that lattice gauge theory just considers this spin network as an observable to which it couples its spin foams. The bottom layer of Fig. 7(a) is therefore treated as the spin network function in the expectation value of lattice gauge theory, and becomes disconnected, leading to Fig. 12(c) for lattice gauge theory and to Fig. 15(a) for the generalized Higgs model.

(5) As usual, there is an alternative formulation of the dual partition function which uses the Haar intertwiners and Haar maps rather than sums over projectors. This version is given in the first equation (6.25).

(6) As G acts transitively on G/H, one can easily fix a ''unitary'' gauge by choosing $h_v := g_{x_v}^{-1}$ in (6.19) where g_{x_v} is a representative of x_v. This step is often convenient because it removes the scalar degrees of freedom from the model. For the duality transformation it is, however, pointless because the corresponding symmetry is already manifest in the dual picture.

Finally, the duality transformation is also available for the expectation value of the observable (6.23). The result is stated in the following theorem which contains the most complicated formulas we are going to present. We formulate the result for the correlator in the form (6.23). If $H \leqslant G$ is a non-normal subgroup, then the requirement that Q is G-invariant can be dropped so that one recovers the expression (6.21) for generic $k_v \in \{1,...,\kappa_{\rho_v}\}$.

Theorem 6.19 (Dual observable): Let G be a compact Lie group, $H \leqslant G$ be a Lie subgroup,

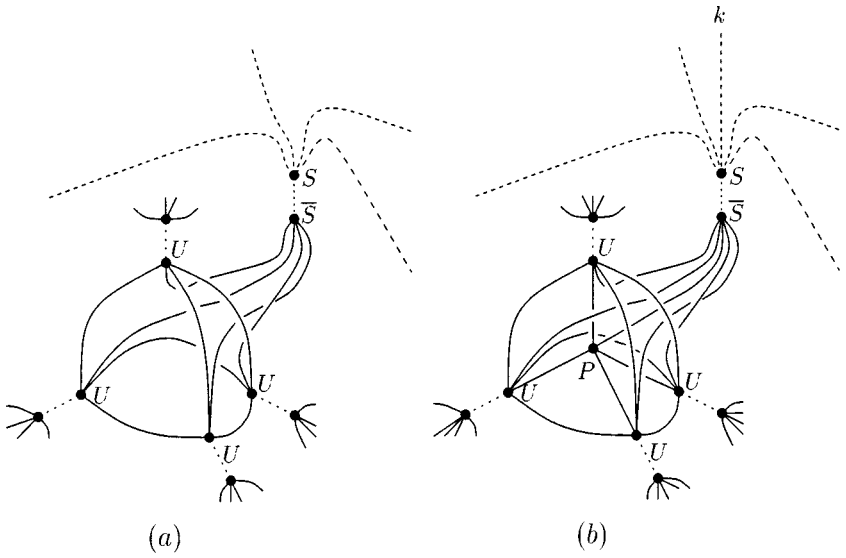

FIG. 15. (a) The dual partition function (6.26) of the generalized Higgs model in the neighborhood of a vertex with a spin network $D(v)$ of (6.27). (b) The analogous diagram for the dual expression (6.33) of the expectation value of an observable (6.21).

and (V,E,F) denote an oriented two-complex. The expectation value of the function (6.23) under the partition function of the generalized Higgs model is equal to

$$\begin{aligned}
\langle f_{\sigma,\rho,P,Q}\rangle = \frac{1}{Z}&\left(\prod_{e\in E}\sum_{p_e,q_e=1}^{\dim V_{\sigma_e}}\right)\left(\prod_{v\in V}\sum_{j_v=1}^{\dim V_{\rho_v}}\sum_{k_v=1}^{\kappa_{\rho_v}}\right)Q_{\underbrace{k_v\ldots}_{v\in V}}\left(\prod_{v\in V}P^{(v)}_{\underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ j_v}\right)\left(\prod_{e\in E}\sum_{\eta_e\in\mathcal{R}_H^G}\right)\\
&\times\left(\prod_{f\in F}\sum_{\tau_f\in\mathcal{R}_G}\right)\left(\prod_{e\in E}\hat{w}_{\eta_e}\right)\left(\prod_{f\in F}\hat{u}_{\tau_f}\right)\left(\prod_{f\in F}\prod_{v\in f_0}\sum_{n(f,v)=1}^{\dim V_{\tau_f}}\right)\left(\prod_{e\in E}\sum_{i_e,\ell_e=1}^{\dim V_{\eta_e}}\sum_{m_e=1}^{\kappa_{\eta_e}}\right)\\
&\times\left(\prod_{v\in V}I^{(v)}_{\underbrace{i_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{\ell_e\ldots}_{\substack{e\in E:\\ v-\partial_- e}}\ j_v\,;\,\underbrace{m_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{m_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ k_v}\right)\\
&\times\left(\prod_{e\in E}T^{(e)}_{\underbrace{n(f,\partial_+e)\ldots n(f,\partial_+e)\ldots i_e}_{f\in e_+}\ \underbrace{p_e}_{f\in e_-}\,;\,\underbrace{n(f,\partial_-e)\ldots n(f,\partial_-e)\ldots \ell_e}_{f\in e_+}\ \underbrace{q_e}_{f\in e_-}}\right)\qquad(6.32)\\
=\frac{1}{Z}&\left(\prod_{v\in V}\sum_{k_v=1}^{\kappa_{\rho_v}}\right)Q_{\underbrace{k_v\ldots}_{v\in V}}\left(\prod_{e\in E}\sum_{\eta_e\in\mathcal{R}_H^G}\right)\left(\prod_{v\in V}\sum_{S^{(v)}\in\tilde{\mathcal{S}}^{(v)}}\right)\left(\prod_{f\in F}\sum_{\tau_f\in\mathcal{R}_G}\right)\left(\prod_{e\in E}\sum_{U^{(e)}\in\tilde{\mathcal{U}}^{(e)}}\right)\\
&\times\left(\prod_{e\in E}\hat{w}_{\eta_e}\right)\left(\prod_{f\in F}\hat{u}_{\tau_f}\right)\left(\prod_{e\in E}\sum_{m_e=1}^{\kappa_{\eta_e}}\right)\left(\prod_{v\in V}S^{(v)}_{\underbrace{m_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{m_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}\ k_v}\right)\prod_{v\in V}\tilde{D}(v),
\end{aligned}$$

(6.33)

where

$$\tilde{D}(v)=\left(\prod_{\substack{f\in F:\\ v\in f_0}}\sum_{n_f=1}^{\dim V_{\tau_f}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_- e}}\sum_{\ell_e=1}^{\dim V_{\eta_e}}\sum_{q_e=1}^{\dim V_{\sigma_e}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_+ e}}\sum_{i_e=1}^{\dim V_{\eta_e}}\sum_{p_e=1}^{\dim V_{\sigma_e}}\right)$$
$$\times\sum_{j=1}^{\dim V_{\rho_v}}\times P^{(v)}_{\underbrace{p_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{q_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}}\ \overline{j S^{(v)}_{\underbrace{i_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{\ell_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}}\ j}\left(\prod_{\substack{e\in E\\ v=\partial_+ e}}\overline{U^{(e)}_{\underbrace{n_f\ldots}_{f\in e_+}\underbrace{n_f\ldots}_{f\in e_-}\ i_e p_e}}\right)$$
$$\times\left(\prod_{\substack{e\in E\\ v=\partial_- e}}U^{(e)}_{\underbrace{n_f\ldots n_f\ldots}_{f\in e_+ f\in e_-}\ \ell_e q_e}\right). \tag{6.34}$$

For each edge $e\in E$, $\tilde{\mathcal{U}}^{(e)}$ denotes a basis of G-invariant projectors

$$\left(\bigotimes_{f\in e_+}V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-}V^*_{\tau_f}\right)\otimes V^*_{\eta_e}\otimes V_{\sigma_e}\to\mathbb{C}, \tag{6.35}$$

and for each vertex $v\in V$, $\tilde{\mathcal{S}}^{(v)}$ is a basis of G-invariant projectors

$$\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}}V_{\eta_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}}V^*_{\eta_e}\right)\otimes V_{\rho_v}\to\mathbb{C}. \tag{6.36}$$

The coset space Haar map $I^{(v)}$, $v\in V$, in (6.32) is a map

$$\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}}V_{\eta_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}}V^*_{\eta_e}\right)\otimes V_{\rho_v}\to\left(\bigotimes_{\substack{e\in E:\\ v=\partial_+ e}}V_{\eta_e}\right)\otimes\left(\bigotimes_{\substack{e\in E:\\ v=\partial_- e}}V^*_{\eta_e}\right)\otimes V_{\rho_v}, \tag{6.37}$$

while the Haar intertwiner $T^{(e)}$, $e\in E$, maps

$$\left(\bigotimes_{f\in e_+}V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-}V^*_{\tau_f}\right)\otimes V^*_{\eta_e}\otimes V_{\sigma_c}\to\left(\bigotimes_{f\in e_+}V_{\tau_f}\right)\otimes\left(\bigotimes_{f\in e_-}V^*_{\tau_f}\right)\otimes V^*_{\eta_e}\otimes V_{\sigma e}. \tag{6.38}$$

Remark 6.20: (1) The features that are new in the dual expectation value (6.32) compared with the dual partition function (6.25) are first the sums and intertwiners from the definition (6.23). The presence of the spherical functions $H^{(\rho_v)}_{j_v k_v}$ for each vertex $v\in V$ has lead to an additional representation V_{ρ_v} in the coset space Haar map (6.37) and thus to a modification of the compatibility condition (6.36). The presence of the representation function $t^{(\sigma_e)}_{p_e q_c}$ has resulted in an additional representation V_{σ_e} of the Haar intertwiner (6.38) and thus in a modification of the compatibility condition (6.35). The correlator (6.23), which is given by a spin network with charges, has modified the numerator of (6.23) so that the configurations of the dual picture, spin foams bounded by spin networks, are now themselves bounded by the given spin network with charges. The structure of (6.33) is illustrated in Fig. 15(b) which shows the spin network $\tilde{D}(v)$ in the neighborhood of a vertex.

(2) For the special cases in which H is normal or massive, the situation is completely analogous to the nonlinear sigma model. The only changes in these cases apply to the open ends of the dashed lines labeled k_v.

E. Expectation values of the dual model

It is possible to construct natural observables for the dual partition function of the generalized Higgs model in the same way as for the nonlinear sigma model and for lattice gauge theory. If these observables only probe the representations η_e assigned to the edges and τ_f assigned to the faces, the result is the product of a dual observable of the nonlinear sigma model and one of lattice gauge theory, both independent of each other.

F. The Abelian special case

In analogy to Sec. IV D, we show the Abelian special case of the generalized Higgs model for $G=U(1)$, $H=\{e\}$, in greater detail.

We write $e^{i\varphi_e}\in U(1)$, $e\in E$, for the variables of lattice gauge theory and $e^{i\vartheta_v}$, $v\in V$, for the sigma model. The partition function (6.18) then reads

$$Z=\left(\prod_{v\in V}\frac{1}{2\pi}\int_0^{2\pi}d\vartheta_v\right)\left(\prod_{e\in E}\frac{1}{2\pi}\int_0^{2\pi}d\varphi_e\right)\left(\prod_{f\in F}\exp(-s_g(e^{i\Sigma_{j=1}^{N(f)}(\epsilon_j f)\cdot\varphi_{\partial_j f}}))\right)$$
$$\times\left(\prod_{e\in E}\exp(-s_s(e^{i(\vartheta_{\partial_+ e}-\vartheta_{\partial_- e}+\varphi_e)}))\right). \tag{6.39}$$

This is the U(1)-Higgs model studied by Einhorn and Savit.[6] The dual expression for the partition function, Eq. (6.26), specializes to

$$Z=\left(\prod_{e\in E}\sum_{\ell_e=-\infty}^{\infty}\right)\left(\prod_{f\in F}\sum_{k_f=-\infty}^{\infty}\right)\left(\prod_{e\in E}\hat{w}_{\ell_e}\right)\left(\prod_{f\in F}\hat{u}_{k_f}\right)$$
$$\times\left(\prod_{v\in V}\delta\left(\sum_{\substack{e\in E:\\ v=\partial_+ e}}\ell_e-\sum_{\substack{e\in E:\\ v=\partial_- e}}\ell_e\right)\right)\left(\prod_{e\in E}\delta\left(\sum_{f\in e_+}k_f-\sum_{f\in e_-}k_f+\ell_e\right)\right), \tag{6.40}$$

where $\hat{w}_\ell$ and $\hat{u}_k$ are the Fourier coefficients of $w(g)=\exp(-s_s(g))$ and $u(g)=\exp(-s_g(g))$, $g\in\mathrm{U}(1)$, respectively. This expression combines the dual partition function (4.35) of the XY-model with that of U(1)-lattice gauge theory and implements the minimal coupling by the compatibility condition encoded in the constraint. It agrees with the result of Ref. 6 before the constraint is integrated.

Since the labellings of the edges with integers ℓ_e and of the faces with integers k_f are Abelian, we can visualize (6.40) as a sum over all closed lines living on the edges together with a sum over all closed surfaces living on the faces where each surface is either closed or bounded by one of the lines.

If we use the Villain action for both the sigma model and gauge theory, i.e., $\hat{w}_\ell=e^{-\ell^2/2\beta_1}$ and $\hat{u}_k=e^{-k^2/2\beta_2}$, then the total exponent of the dual Boltzmann weight is the length of the lines weighted with $1/\beta_1$ plus the area of the surfaces weighted with $1/\beta_2$. This is the effective (open) string model for the strong coupling regime of the U(1)-Higgs model.

The observables (6.23) reduce to functions

$$f_{p_v\ldots,q_e\ldots}(\{\vartheta_v\}_{v\in V};\{\varphi_e\}_{e\in E}):=\left(\prod_{v\in V}e^{ip_v\vartheta_v}\right)\left(\prod_{e\in E}e^{iq_e\varphi_e}\right), \tag{6.41}$$

which describe charges $p_v\in\mathbb{Z}$ at the vertices $v\in V$ and Wilson loops $q_e\in\mathbb{Z}$ at the edges $e\in E$ provided that for each $v\in V$, the following compatibility condition holds:

$$\sum_{\substack{e\in E:\\ v=\partial_+ e}}q_e-\sum_{\substack{e\in E:\\ v=\partial_- e}}q_e+p_v=0. \tag{6.42}$$

The dual of the expectation value then reads

$$\langle f_{p_v \ldots, q_e \ldots} \rangle = \frac{1}{Z} \left(\prod_{e \in E} \sum_{\ell_e = -\infty}^{\infty} \right) \left(\prod_{f \in F} \sum_{k_f = -\infty}^{\infty} \right) \left(\prod_{e \in E} \hat{w}_{\ell_e} \right) \left(\prod_{f \in F} \hat{u}_{k_f} \right) \times \left(\prod_{v \in V} \delta \left(\sum_{\substack{e \in E: \\ v = \partial_+ e}} \ell_e - \sum_{\substack{e \in E: \\ v = \partial_- e}} \ell_e + p_v \right) \right) \left(\prod_{e \in E} \delta \left(\sum_{f \in e_+} k_f - \sum_{f \in e_-} k_f + \ell_e + q_e \right) \right), \tag{6.43}$$

i.e., the closed lines of (6.40) now couple to the charges p_v, $v \in V$, and can thus end at one of these charges while the surfaces are either closed or bounded by the lines or by the background Wilson loop q_e, $e \in E$.

This is the picture which is generalized to sums over spin networks and spin foams in the non-Abelian case.

VII. DISCUSSION

We have presented an exact duality transformation for the partition functions and expectation values of observables of the lattice chiral model, of the lattice nonlinear sigma model, and of a class of generalized Higgs models. We conclude with various miscellaneous comments on applications, limitations, and open questions.

Throughout the present article, we have chosen *ultra-local* actions, i.e., the action is a sum over all edges (or faces) and can be calculated independently for each edge (or face). A generalization to more complicated, less local, actions is straightforward. Observe that the character expansion of the Boltzmann weight is always a series of charges (or spin network functions) and that we can perform the duality transformation for generic expectation values of these charges (or spin network functions).

The dual form of the partition function can be used for numerical studies. From the Abelian special case it is familiar (see, for example, Ref. 31) that for some observables the original model is much easier to simulate whereas for others the simulations are much more efficient in the dual model. At present, algorithms are being developed for pure SU(2)-lattice gauge theory in three dimensions[32] and for a technically closely related model[33] in the context of quantum gravity.

If one wishes to implement Monte Carlo algorithms for the dual model, one has to make sure that the importance sampling is applied to a positive measure. While the character expansion coefficients of the common Boltzmann weights are positive, the situation is less clear for the spin networks [such as the $C(v)$ of (6.6)] which appear under the dual partition sum. At least for the O(4)-symmetric nonlinear sigma model and for the SU(2)-symmetric chiral model, these spin networks have non-negative real values.[34] Should there be alternating signs in other models, one has to associate the sign with the observable which is measured while the modulus can be dealt with by the importance sampling. This is familiar, for example, from the sign problems in the simulation of fermionic systems.

It might finally be more than a mere coincidence that the dual partition function resembles a cluster decomposition. The lack of efficient cluster algorithms for gauge theories may have a natural explanation in the dual picture where the weights $C(v)$ of lattice gauge theory are localized at the vertices as opposed to the spin network which appears in the dual sigma model and which extends over the entire lattice.

We emphasize that there are intermediate steps in the duality transformation, for example (4.20) and (5.19), in which both the old and the new variables are present and which resemble an extended ''phase space'' path integral whose weight, however, does not have any obvious positivity properties. Upon solving all sums, one recovers the original partition function with positive Boltzmann weights, while performing the integrals, one obtains the dual expression, again with positive weights (at least in some cases which we have listed above).

In the Abelian case, there are higher level generalizations of sigma models and gauge theories in which the fundamental variables are located not at vertices or edges, but rather at higher level, e.g., at cubes, hypercubes etc., and described by discretized k-forms.[2,3] This construction does not have any obvious generalization to the non-Abelian case. Any such model would make use of a suitable definition of non-Abelian cohomology.

We also stress that the non-Abelian generalization of the duality transformation parallels the Abelian special case only up to the point where one solves the constraints. In the non-Abelian situation, there are no longer just constraints, but rather sums over compatible intertwiners so that there exists no obvious step which generalizes the integration of the constraints. This restricts us to the original lattice as opposed to the Abelian case in which one usually passes to a suitable "dual" lattice. This can, however, also be seen as an advantage because our generalization is therefore independent of the topology of the lattice. The case of nontrivial topology in Abelian systems was studied in Ref. 35.

An interesting generalization of lattice gauge theory is available in $d \leqslant 4$ dimensions in the dual formulation where one can replace the gauge group by a quantum group.[17,18] This includes in particular supergroups as the gauge groups. Similar constructions in which the category of representations of a compact Lie group in the dual formulation is replaced by more general categories have already been known from the definition of topological invariants and from topological quantum field theory, (see, for example, Refs. 36 and 37). From the formulas stated in the present article, one obtains at least a formal topological invariant from the partition functions if the Boltzmann weights, say, $w(g)$, are replaced by δ-functions $w(g)=\delta(g)$ and similarly $\hat{w}_\rho = \dim V_\rho$ in the dual picture. Noncompact Lie groups have recently attracted attention in the context of quantum gravity, (see, for example, Ref. 38).

What has been missing so far is, first, a generalization which includes fermions (this is mainly due to the still rather limited understanding of fermions in a non perturbative formulation) and, second, an analog of the vortex–spin wave decomposition of Refs. 39 and 40.

The present article is entirely written in the Lagrangian language of path integrals and expectation values. All results are in one-to-one correspondence to the analogous statements in the Hamiltonian formulation which involves the quantum statistical operator e^{-H}. Matrix elements of this operator can be calculated in the dual picture from sums over spin networks and spin foams. (A detailed study is in preparation.)

As far as the strong–weak relation of the duality transformation is concerned, we stress that the dual partition function provides a closed form for the strong coupling expansion which makes it possible to separate the group combinatorics from the lattice combinatorics. This has been advocated in the context of high-order strong coupling expansions (see, for example, Refs. 7 and 41). The key to the duality transformation was to abstract from a particular group and to focus on the structures that are common to all compact Lie groups. It remains a considerable challenge to evaluate the dual expressions for particular groups, Boltzmann weights, and shapes of the lattice.

As far as the construction of strong coupling expansions in gauge theories is concerned, it is interesting to note that there exists an effective string model which describes the strong coupling regime of Abelian lattice gauge theories. In the non-Abelian case, however, mere strings are insufficient, and the world-sheets of the strings should rather be allowed to branch according to the combinatorics of the representation theory. A familiar example is the strong coupling calculation of the static three-quark potential in QCD. The lack of branchings of the world-sheets causes the string picture to break down when spin foams appear as the fundamental nonperturbative structure.

ACKNOWLEDGMENTS

(Received 15 January 2003; accepted 10 April 2003)

Consider the centered Gaussian field on $\mathbb{Z}^d$, $d \geqslant 2l+1$, with covariance matrix given by $(\Sigma_{j=l}^{K} q_j(-\Delta)^j)^{-1}$ where Δ is the discrete Laplacian on $\mathbb{Z}^d$, $1 \leqslant l \leqslant K$ and $q_j \in \mathbb{R}, l \leqslant j \leqslant K$ are constants satisfying $\Sigma_{j=l}^{K} q_j r^j > 0$ for $r \in (0,2]$ and a certain additional condition. We show the probability that all spins are positive in a box of volume N^d decays exponentially at a rate of order $N^{d-2l} \log N$ and under this hard-wall condition, the local sample mean of the field is repelled to a height of order $\sqrt{\log N}$. This extends the previously known result for the case that the covariance is given by the Green function of simple random walk on $\mathbb{Z}^d$ (i.e., $K=l=1, q_1=1$). © *2003 American Institute of Physics.* [DOI: 10.1063/1.1581354]

I. INTRODUCTION

We consider the continuous spin lattice models with massless interaction which can be thought of as an effective modelization of the random interface. The configuration $\phi = \{\phi_x\}_{x \in \mathbb{Z}^d} \in \mathbb{R}^{\mathbb{Z}^d}$ is interpreted as a (discretized) interface embedded in the $d+1$-dimensional space and the spin ϕ_x at the site $x \in \mathbb{Z}^d$ denotes the height of the interface. Formally speaking, for the Hamiltonian $H(\phi)$, the corresponding Gibbs measure is defined by

$$P(d\phi) = \frac{1}{Z} \exp\{-H(\phi)\} \prod_{x \in \mathbb{Z}^d} d\phi_x,$$

where $d\phi_x$ is Lebesgue measure on $\mathbb{R}$ and Z is a normalization factor. When the (formal) Hamiltonian is given by $H_0(\phi) = \Sigma_{\langle x,y \rangle} V(\phi_x - \phi_y)$ for appropriate potential V where the summation is taken over all nearest neighbor sites x and y, this model is called the massless fields model and recently the study of this model has been rapidly developing from both dynamical and statical aspects (cf. Ref. 14).

One of the problems related to the interfaces is the study of the effect of a hard wall. In this article we consider the problem of the entropic repulsion, that is, to examine the asymptotic behavior of the lattice massless fields under the condition that the height variables are all positive in a large finite box (cf. Ref. 20). To consider such asymptotics plays an important role in the construction of droplets on a hard wall (cf. Refs. 1 and 3) and also it is closely related to the problem of the wetting transition (cf. Refs. 6 and 8). For Gaussian case (harmonic crystal) it has been studied in Refs. 4, 5, 9, and 10 with several boundary conditions and a non-Gaussian case (anharmonic crystal) was studied in Ref. 11. But these results treated the Hamiltonian $H_0(\phi)$, the so-called $\nabla\phi$ models.

The purpose of this article is to investigate the entropic repulsion for a much more wide class of interactions determined by certain quadratic potentials. Namely, we consider the following (formal) Hamiltonian $H_1(\phi)$ instead of $H_0(\phi)$:

[a)]Electronic mail: sakagawa@math.keio.ac.jp

$$H_1(\phi)=\sum_{j=1}^{K} q_j \sum_{x\in\mathbb{Z}^d} V((-\Delta)^{j/2}\phi_x) \qquad \text{with } V(r)=r^2, \tag{1}$$

where $K\in\mathbb{N}$, $q=\{q_j\}_{1\leqslant j\leqslant K}\in\mathbb{R}^K$ and Δ is the discrete Laplacian on $\mathbb{Z}^d$. If j is odd, we consider $\Sigma_{x\in\mathbb{Z}^d}((-\Delta)^{j/2}\phi_x)^2$ as $\Sigma_{i=1}^{d}\Sigma_{x\in\mathbb{Z}^d}((-\Delta)^{[j/2]}\nabla_i\phi_x)^2$ where $[j/2]$ is an integral part of $j/2$ and ∇_i is the discrete gradient on $\mathbb{Z}^d$ for ith direction. Similarly to the $\nabla\phi$ case, this Hamiltonian has a continuum symmetry, i.e., changing the value of heights by adding a constant at each site does not change the Hamiltonian. When $d\geqslant 2l+1$ for $l=\min\{j;q_j\neq 0\}$, a corresponding infinite volume Gibbs measure actually exists and is characterized by DLR equations. It determines a Gaussian field on $\mathbb{Z}^d$; see Sec. II for more details.

The Hamiltonian $H_1(\phi)$ is related to several physical and mathematical models. For example, in the model of the membrane such as a lipid bilayer, the energy of the interface separating the water phase and the lipid phase is given by

$$H(\phi)=\sum_{x\in\mathbb{Z}^d}(\kappa_1(\nabla\phi_x)^2+\kappa_2(\Delta\phi_x)^2),$$

where κ_1 and κ_2 are called lateral tension and bending rigidity, respectively (cf. Refs. 23 and 26). And also when $d=1$, $K=2$ and $q_1=0, q_2>0$, this model corresponds to the integration of random walks which was studied in Ref. 25 (see Ref. 16 for the continuum version).

In Sec. II, we give a precise formulation of our model and state the results. The proof will be given in Secs. III and IV. Finally, in Sec. V we show the asymptotics of the Green function and the convergence of the capacity which are used in the proof. The strategy of the proof is similar to those for $\nabla\phi$ models. However, in our case, since we do not have the random walk representation of conditional expectation and covariance as $\nabla\phi$ models (cf. Refs. 2 and 5), we need to consider another conditioning argument which depends on the Markov property of the ϕ field and the range of the interaction.

II. MODEL AND RESULTS

Let $q(r)=\Sigma_{j=1}^{K}q_j r^j$, $q=\{q_j\}_{1\leqslant j\leqslant K}\in\mathbb{R}^K$, be a polynomial of degree $K\in\mathbb{N}$. Define $J_\varepsilon(x,y)=q(\varepsilon I-\Delta)(x,y)$ for $\varepsilon\geqslant 0$ and $x,y\in\mathbb{Z}^d$, where I is an identity matrix and Δ is the discrete Laplacian on $\mathbb{Z}^d$ determined by

$$(-\Delta)(x,y)=\begin{cases} -\dfrac{1}{2d} & \text{if } |x-y|=1,\\ 1 & \text{if } |x-y|=0,\\ 0 & \text{otherwise,}\end{cases}$$

and for $j\geqslant 2$

$$(-\Delta)^j(x,y)=\sum_{z_i\in\mathbb{Z}^d;\ i=1,2,\ldots,j-1}(-\Delta)(x,z_1)(-\Delta)(z_1,z_2)\cdots(-\Delta)(z_{j-1},y).$$

We will denote $J_0(x,y)$ by $J(x,y)$. At first we assume the following:

Assumption 1:

(i) $d\geqslant 2l+1$ where $l=\min\{j;q_j\neq 0\}$,
(ii) $\Sigma_{j=l}^{K}q_j r^j>0$ for every $0<r\leqslant 2$.

For any absolutely summable function $f:\mathbb{Z}^d\to\mathbb{R}$, we will denote its Fourier transform by $\hat{f}(\theta)=\Sigma_{x\in\mathbb{Z}^d}e^{i\theta\cdot x}f(x)$, $\theta\in[-\pi,\pi]^d$. It is easy to see that J_ε is translation invariant and $\hat{J}_\varepsilon(\theta)=\Sigma_{x\in\mathbb{Z}^d}e^{i\theta\cdot x}J_\varepsilon(0,x)=\Sigma_{j=l}^{K}q_j(\varepsilon+\mu(\theta))^j$ where $\mu(\theta)=(1/d)\Sigma_{i=1}^{d}(1-\cos\theta_i)$ is the Fourier

transform of $-\Delta$. From Assumption 1 and the fact that $\mu(\theta)=(1/2d)|\theta|^2+o(|\theta|^2)$ as $|\theta|\to 0$, $\hat{J}_\varepsilon(\theta)\geqslant 0$ and $\hat{J}_\varepsilon(\theta)^{-1}$ is integrable over $[-\pi,\pi]^d$ for any $\varepsilon\geqslant 0$ small enough. Hence, in this case, J_ε is positive definite, i.e., $\Sigma_{x,y\in\mathbb{Z}^d}J_\varepsilon(x,y)\xi_x\xi_y\geqslant 0$ for every $\xi=\{\xi_x\}_{x\in\mathbb{Z}^d}$ of finite range and the equality holds only when $\xi\equiv 0$. Therefore, J_ε^{-1} exists and it is also positive definite (cf. Chap. 13 of Ref. 13). Thus the centered Gaussian field on $\mathbb{Z}^d$ with covariance matrix $G=J^{-1}$ exists. We will denote its law on $\Omega\equiv\mathbb{R}^{\mathbb{Z}^d}$ by P. The infinite volume measure P is characterized by the following DLR equation as an infinite Gibbs distribution (cf. Ref. 13):

$$P(\cdot\,|\mathcal{F}_{\{x\}^c})=\mathcal{N}\left(-J(0,0)^{-1}\sum_{y\neq x}J(x,y)\phi_y,\,J(0,0)^{-1}\right)\qquad P\text{-a.s. }\phi,$$

where $\mathcal{F}_{\{x\}^c}=\sigma(\phi_y;y\neq x)$ is the σ-field generated by $\{\phi_y;y\neq x\}$ and $\mathcal{N}(m,\sigma^2)$ denotes the normal distribution with mean m and variance σ^2. Positivity of the variance $J(0,0)^{-1}$ follows from the positive definiteness of J.

Remark 2.1: Formally speaking, by summation by parts the measure P is represented as

$$P(d\phi)=\frac{1}{Z}\exp\left\{-\sum_{j=1}^{K}\left(\frac{1}{2d}\right)^{a_j}q_j\sum_{x\in\mathbb{Z}^d}((-\Delta)^{j/2}\phi_x)^2\right\}\prod_{x\in\mathbb{Z}^d}d\phi_x,$$

where $a_j=1$ if j is odd and $a_j=0$ if j is even. Hence P corresponds to the Gibbs measure with Hamiltonian $H_1(\phi)$ defined by (1).

Remark 2.2: By Lemma 5.1 below, we have

$$\mathrm{Cov}(\phi_x,\phi_y)\sim\frac{C}{|x-y|^{d-2l}}\quad\text{as }|x-y|\to\infty,$$

for some constant C when $d\geqslant 2l+1$. This implies that the field has a long range correlation similar to the $\nabla\phi$ interface model.

The following second assumption implies $G(x,y)=J^{-1}(x,y)\geqslant 0$ for all $x,y\in\mathbb{Z}^d$ which ensures that we can use a FKG inequality for the measure P (cf. Ref. 24).

Assumption 2: There exists a sequence of positive small numbers $\{\varepsilon_k\}_{k\geqslant 1}$ such that $\varepsilon_k\downarrow 0$ as $k\to\infty$ and $J_{\varepsilon_k}^{-1}(x,y)\geqslant 0$ for all $x,y\in\mathbb{Z}^d$ and $k\geqslant 1$.

We have the following example which satisfies our two assumptions.

Example: $q(r)=\alpha_0 r^l\Pi_{j=1}^{K-l}(\alpha_j r+\beta_j)$, where $\alpha_j,\beta_j>0$ for every $0\leqslant j\leqslant K-l$ and $1\leqslant l\leqslant K$.

Proof: Assumption 1 is obvious. We will check Assumption 2. For this $q(r)$, J_ε^{-1} is given by

$$\frac{1}{\alpha_0}((\varepsilon I-\Delta)^{-1})^l\prod_{j=1}^{K-l}(\alpha_j(\varepsilon I-\Delta)+\beta_j I)^{-1}.$$

However, $(-\Delta)^{-1}$ is the Green function of the d-dimensional simple random walk on $\mathbb{Z}^d$ and $(\alpha(\varepsilon I-\Delta)+\beta I)^{-1}$ is the Green function of the random walk with killing rate $(\varepsilon\alpha+\beta)/[\alpha(\varepsilon+1)+\beta]$ and killing starting at time 0 if $\alpha,\beta>0$ for any $\varepsilon\geqslant 0$. Thus all components of $(\varepsilon I-\Delta)^{-1},(\alpha_j(\varepsilon I-\Delta)+\beta_j I)^{-1}$ are positive and accordingly $J_\varepsilon^{-1}(x,y)>0$ for all $x,y\in\mathbb{Z}^d$ and $\varepsilon\geqslant 0$. □

Our attention will be focused on the following entropic repulsion event,

$$\Omega_N^+=\{\phi\in\Omega;\phi_x\geqslant 0\ \text{ for all }\ x\in V_N\},$$

where $V_N=NV\cap\mathbb{Z}^d, N\in\mathbb{N}$ and $V=[-1,1]^d$.

The first result is on the asymptotics of the probability of the event Ω_N^+. We always assume Assumptions 1 and 2.

Theorem 2.1: *There exist $C_1,C_2>0$ such that*

$$-C_1 \leqslant \liminf_{N\to\infty} \frac{1}{N^{d-2l}\log N} \log P(\Omega_N^+) \leqslant \limsup_{N\to\infty} \frac{1}{N^{d-2l}\log N} \log P(\Omega_N^+) \leqslant -C_2.$$

Remark 2.3: This theorem implies that in our model, the order of the decay of $P(\Omega_N^+)$ depends on the minimum degree l of the polynomial $q(r)$ and not on the maximum degree K of $q(r)$, namely the maximum range of the interaction of the (formal) Hamiltonian $H_1(\phi)$ defined by (1). This is because the asymptotics of the correlation of the field depends on l and not on K, and also formally speaking, if $\Sigma_{x\in\mathbb{Z}^d}((-\Delta)^{l/2}\phi_x)^2$ is small, then $\Sigma_{x\in\mathbb{Z}^d}((-\Delta)^{j/2}\phi_x)^2$ becomes small for every $l+1 \leqslant j \leqslant K$ and so the energy $H_1(\phi)$ becomes small.

By using these bounds, we obtain the asymptotics of the local sample mean of the height variables under the conditional probability $P(\cdot|\Omega_N^+)$ as $N\to\infty$. This implies that the field is repelled to the height of order $\sqrt{\log N}$ by a hard-wall at least under average.

Theorem 2.2: *Let $1-2l/d<\gamma\leqslant 1$ be fixed. Then for every $a<2G(0,0)\{(-1+\gamma)d+2l\}$, we have*

$$\lim_{N\to\infty} \sup_{\substack{z\in V_N, r>0 \\ V_{rN^\gamma}(z)\subset V_N}} P(\overline{\phi}_{z,rN^\gamma} \leqslant \sqrt{a\log N} | \Omega_N^+) = 0, \tag{2}$$

and there exists some $b>0$ such that

$$\lim_{N\to\infty} \sup_{\substack{z\in V_N, r>0 \\ V_{rN}(z)\subset V_N}} P(\overline{\phi}_{z,rN} \geqslant \sqrt{b\log N} | \Omega_N^+) = 0, \tag{3}$$

where $V_R(z)=z+V_R$ is a box with side-length $2R$ and centered at z and $\overline{\phi}_{z,R}=(1/|V_R(z)|)\Sigma_{x\in V_R(z)}\phi_x$ denotes the local sample mean of the height variables on $V_R(z)$.

Remark 2.4: The case that $K=l=1$ and $q_l=1$ was studied in Ref. 5. In this case, it is proved that the constants C_1 and C_2 in Theorem 2.1 coincide with each other. In our case, by the proof of Theorem 2.1 below, we can see that the constant C_1 of the lower bound is given by $C_1=2lq_lC_lG(0,0)$ where $C_l=Cap_l(V)\equiv\inf\{(1/2d)^l(\psi,(-\Delta_c)^l\psi)_{L^2(\mathbb{R}^d)}; \psi\in H_0^l(\mathbb{R}^d), \psi\geqslant 1_V\}$, Δ_c is the continuous Laplacian on $\mathbb{R}^d$, $(\cdot,\cdot)_{L^2(\mathbb{R}^d)}$ denotes $L^2(\mathbb{R}^d)$-scalar product and H_0^l denotes the usual Sobolev space with norm $(\psi,(-\Delta_c)^l\psi)_{L^2(\mathbb{R}^d)}^{1/2}$. If $K=l=1$ and $q_l=1$, this constant coincides with that in Ref. 5. To obtain the same constant (or good upper bound), the technique of subgrid conditioning argument was used in Ref 5. When considering such kind of conditioning argument, conditional expectation of height variable can be represented as the linear sum of the height variables of conditioned sites. In the $\nabla\phi$ case, each coefficient is given by the hitting probability of the simple random walk on $\mathbb{Z}^d$ and this is non-negative. But in our case, both positive coefficient and negative coefficient appear and we cannot obtain the estimate of the conditional expectations from below or above under the event Ω_N^+ at all. By this reason, we have not been able to prove the upper and lower bounds with the same constant.

Also in Ref. 5, Theorem 2.2 is proved for each height variable ϕ_x instead of the local sample mean of the height $\overline{\phi}_{z,rN^\gamma}$. In our model, since the well-known FKG criterion (cf. Corollary 1.7 of Ref. 15) does not hold, we cannot use FKG inequality for the conditioned measure $P(\cdot|\Omega_N^+)$. This causes the great difficulty to estimate the several expectations with respect to the measure $P(\cdot|\Omega_N^+)$. That is why we can prove Theorem 2.2 only for the local sample mean of the height variables.

Remark 2.5: We have restricted our discussion to the infinite volume Gaussian field P with $d\geqslant 2l+1$. It might be natural and interesting to consider the finite volume measure P_N with zero boundary condition outside V_N and investigate the behavior of $P_N(\Omega_{\delta N}^+)$ and $P_N(\cdot|\Omega_{\delta N}^+)$ for $0<\delta\leqslant 1$ in arbitrary dimensions. When $0<\delta<1$ and $d\geqslant 2l+1$, we can modify our proof and obtain similar results to Theorems 2.1 and 2.2. But when $0<\delta<1$ and $d\leqslant 2l$, since we do not have the estimate of the covariance given as in Proposition 1.6.7 of Ref. 19 for the $\nabla\phi$ case, we

have not obtained the corresponding results. Also, because of the same reason as Remark 2.4, it seems much more difficult to consider the boundary effect (i.e., the case where $\delta=1$*) even if* $d \geqslant 2l+1$.

III. PROOF OF THEOREM 2.1

A. Proof of the lower bound

We will use two-scale decomposition originally introduced in the proof of Proposition 4.1 of Ref. 10.

Step 1: Let $\phi^0=\{\phi_x^0\}_{x\in\mathbb{Z}^d}$ and $\phi^1=\{\phi_x^1\}_{x\in\mathbb{Z}^d}$ be two independent centered Gaussian fields with covariances

$$E[\phi_x^0\phi_y^0]=J^{-1}(x,y)-J_\varepsilon^{-1}(x,y)\equiv G_\varepsilon^{(0)}(x,y),$$

$$E[\phi_x^1\phi_y^1]=J_\varepsilon^{-1}(x,y)\equiv G_\varepsilon^{(1)}(x,y),$$

respectively. We will choose a parameter $\varepsilon>0$ along the sequence $\{\varepsilon_k\}_{k\geqslant 1}$ of Assumption 2 and for convenience omit the subscript k. Note that $\widehat{G_\varepsilon^{(0)}}(\theta)=(\Sigma_{j=l}^K q_j(\mu(\theta))^j)^{-1}-(\Sigma_{j=l}^K q_j(\varepsilon+\mu(\theta))^j)^{-1}$, $\widehat{G_\varepsilon^{(1)}}(\theta)=(\Sigma_{j=l}^K q_j(\varepsilon+\mu(\theta))^j)^{-1}$ and by Assumptions 1 and 2, the fields ϕ^0,ϕ^1 exist for any $\varepsilon>0$ small enough. The original field $\phi=\{\phi_x\}_{x\in\mathbb{Z}^d}$ is represented as the sum of these two fields: $\phi=\phi^0+\phi^1$. We will keep the notation P for the joint law of ϕ^0 and ϕ^1. By using the inversion formula and Lebesgue's dominated convergence theorem, it is easy to see that $\lim_{\varepsilon\to 0} G_\varepsilon^{(0)}(x,y)=0$ for every $x,y\in\mathbb{Z}^d$. We denote by $P_{\alpha,N}(\alpha>0)$ the law of the random field $\{\phi_x^0+\sqrt{\alpha\log N},\phi_x^1\}_{x\in\mathbb{Z}^d}$, which is still a Gaussian field with the same covariance as $\{\phi^0,\phi^1\}$ under P, but the mean of the ϕ^0-field is shifted.

For $\mathcal{F}^0=\sigma(\phi_x^0;x\in\mathbb{Z}^d)$, we have

$$P(\Omega_N^+)\geqslant E[P(\phi_x^0+\phi_x^1\geqslant 0 \text{ for all } x\in V_N|\mathcal{F}^0)I(\phi_x^0\geqslant\sqrt{\alpha\log N} \text{ for all } x\in V_N)].$$

Since ϕ^0 and ϕ^1 are independent, on $\{\phi_x^0\geqslant\sqrt{\alpha\log N}$ for all $x\in V_N\}$ we have

$$P(\phi_x^0+\phi_x^1\geqslant 0 \text{ for all } x\in V_N|\mathcal{F}^0)\geqslant P(\phi_x^1\geqslant-\sqrt{\alpha\log N} \text{ for all } x\in V_N).$$

Thus, we obtain $\log P(\Omega_N^+)\geqslant T_0+T_1$ where

$$T_0=\log P(\phi_x^0\geqslant\sqrt{\alpha\log N} \text{ for all } x\in V_N),$$

$$T_1=\log P(\phi_x^1\geqslant-\sqrt{\alpha\log N} \text{ for all } x\in V_N).$$

We will estimate T_0 in Steps 2 and 3 and T_1 in Step 4.

Step 2: Since $\lim_{\varepsilon\to 0} G_\varepsilon^{(0)}(0,0)=0$, in a completely analogous manner to the proof of (4.13) of Ref. 10 we can prove that for every $\alpha'>\alpha$ there exists $\varepsilon'>0$ such that for all $\varepsilon\leqslant\varepsilon'$

$$\lim_{N\to\infty} P_{\alpha',N}(\phi_x^0\geqslant\sqrt{\alpha\log N} \text{ for all } x\in V_N)=1. \tag{4}$$

Moreover, we have

$$\lim_{N\to\infty}\frac{1}{N^{d-2l}\log N}H_N(P_{\alpha',N}|P)=\frac{1}{2}\alpha' q_l\mathcal{C}_l, \tag{5}$$

where $H_N(P_{\alpha',N}|P)=E^{P_{\alpha',N}}[\log dP_{\alpha',N}/dP|_{\mathcal{F}_{V_N}}]$, $\mathcal{F}_{V_N}=\sigma(\phi_x;x\in V_N)$. We will prove this equality later. Combining (4) and (5) with entropy inequality (cf. Lemma 5.4.21 of Ref. 12), we obtain

$$\liminf_{N\to\infty}\frac{1}{N^{d-2l}\log N}T_0\geqslant-\frac{1}{2}\alpha q_l\mathcal{C}_l, \tag{6}$$

for every $\alpha>0$ and $\varepsilon>0$ small enough.

Step 3: It is easy to see that $H_N(P_{\alpha',N}|P)=\frac{1}{2}\alpha'\log N\langle 1_{V_N},(G^{(0)}_{\varepsilon,(N)})^{-1}1_{V_N}\rangle_{V_N}$ where $G^{(0)}_{\varepsilon,(N)}$ is a restriction of $G^{(0)}_\varepsilon$ to $V_N\times V_N$ and $\langle\cdot,\cdot\rangle_{V_N}$ denotes the $l^2(V_N)$-scalar product. So all we need to prove (5) is

$$\lim_{N\to\infty}\frac{1}{N^{d-2l}}\langle 1_{V_N},(G^{(0)}_{\varepsilon,(N)})^{-1}1_{V_N}\rangle_{V_N}=q_l\mathcal{C}_l, \tag{7}$$

for fixed $\varepsilon>0$ small enough. By the variational formula, we have for any $\psi\in L^2(V)$,

$$\langle\psi_N,(G^{(0)}_{\varepsilon,(N)})^{-1}\psi_N\rangle_{V_N}=\sup_{f\in L^2(V_N)}\{2\langle\psi_N,f\rangle_{V_N}-\langle f,G^{(0)}_{\varepsilon,(N)}f\rangle_{V_N}\}, \tag{8}$$

where $\psi_N(x)=\psi(x/N)$. By Assumption 2 and the definition of ϕ^0-field, we have $G^{(0)}_\varepsilon(x,y)\leqslant G(x,y)$ for every $x,y\in\mathbb{Z}^d$. The lower bound of (7) is an easy consequence of this fact, (8) and Lemma 5.2.

Next, we will prove the upper bound. By (8) we have

$$\langle 1_{V_N},(G^{(0)}_{\varepsilon,(N)})^{-1}1_{V_N}\rangle_{V_N}\leqslant\sup_{f\in L^2(\mathbb{Z}^d)}\{2\langle h_N,f\rangle_{V_N}-\langle f,G^{(0)}_\varepsilon f\rangle_{V_N}\}=\langle h_N,(G^{(0)}_\varepsilon)^{-1}h_N\rangle_{\mathbb{Z}^d},$$

where $h\in C_0^\infty(\mathbb{R}^d)$ with $h=1$ on V and $h_N(x)=h(x/N)$. It is easy to see that $\widehat{(G^{(0)}_\varepsilon)^{-1}}(\theta)-\widehat{G^{-1}}(\theta)\leqslant C(\Sigma_{j=l}^K q_j(\mu(\theta))^j)^2$ for some $C=C(\varepsilon)>0$ and every $\theta\in[-\pi,\pi]^d$. Hence by Parseval identity we know that

$$\langle h_N,((G^{(0)}_\varepsilon)^{-1}-G^{-1})h_N\rangle_{\mathbb{Z}^d}\leqslant\frac{C}{(2\pi)^d}\int_{[-\pi,\pi]^d}|\widehat{h_N}(\theta)|^2\left(\sum_{j=l}^K q_j(\mu(\theta))^j\right)^2 d\theta=C\langle h_N,J^2h_N\rangle_{\mathbb{Z}^d}.$$

Thus

$$\begin{aligned}\frac{1}{N^{d-2l}}\langle 1_{V_N},(G^{(0)}_{\varepsilon,(N)})^{-1}1_{V_N}\rangle_{V_N}&\leqslant\frac{1}{N^{d-2l}}(\langle h_N,Jh_N\rangle_{\mathbb{Z}^d}+C\langle h_N,J^2h_N\rangle_{\mathbb{Z}^d})\\&=\left(\frac{1}{2d}\right)^l q_l(h,(-\Delta_c)^lh)_{L^2(\mathbb{R}^d)}(1+o(1)),\end{aligned}$$

as $N\to\infty$, where the last equality follows from the fact that

$$\frac{1}{N^{d-2j}}\langle\psi_N,(-\Delta)^j\psi_N\rangle_{\mathbb{Z}^d}=\left(\frac{1}{2d}\right)^j(\psi,(-\Delta_c)^j\psi)_{L^2(\mathbb{R}^d)}(1+o(1)), \tag{9}$$

as $N\to\infty$, for every $\psi\in C_0^\infty(\mathbb{R}^d)$ and $j\geqslant 1$. Finally, taking $\liminf_{N\to\infty}$ and infimum over h we obtain the upper bound.

Step 4: By Assumption 2, we can use FKG inequality for ϕ^1-field (cf. Ref. 24). Therefore, elementary Gaussian estimate yields

$$\liminf_{N\to\infty}\frac{1}{N^{d-2l}\log N}T_1=0\quad\text{if}\quad\alpha\geqslant 4lG(0,0). \tag{10}$$

By (10) and (6), we can complete the proof. □

B. Proof of the upper bound

We consider the conditioning argument which corresponds to the even-odd procedure for $\nabla\phi$ case (cf. Ref. 11).

Step 1: Let $A_N=V_N\cap(K+1)\mathbb{Z}^d$, $\tilde{A}_N=\{x\in A_N;\mathrm{dist}(x,A_N^c)>K\}$ and $B_N=V_N-\tilde{A}_N$. Define $\mathcal{F}_{B_N}=\sigma(\phi_x;x\in B_N)$. Then by the Gibbsian description of P, $\{\phi_x\}_{x\in\tilde{A}_N}$ are independent Gaussian random variables with mean $m_x=-J(0,0)^{-1}\Sigma_{y\neq x}J(x,y)\phi_y$ and variance $\sigma^2=J(0,0)^{-1}$ under $P(\cdot\,|\mathcal{F}_{B_N})$. Define $C_N=\{x\in\tilde{A}_N;m_x\leqslant a_N\}$ for $a_N=\sqrt{\alpha\log N},\alpha>0$. Note that C_N is an $\mathcal{F}_{B_N}$-measurable random set and different from the $\nabla\phi$ case; m_x contains the sum for y with $J(x,y)<0$. For $0<\varepsilon<1$, we have

$$\begin{aligned}P(\Omega_N^+)&=E\left[\prod_{x\in\tilde{A}_N}P(\phi_x\geqslant 0|\mathcal{F}_{B_N})I(\Omega^+(B_N))\right]\\&\leqslant E\left[\prod_{x\in\tilde{A}_N}P(\phi_x\geqslant 0|\mathcal{F}_{B_N})I(|C_N|\geqslant\varepsilon|\tilde{A}_N|)\right]+P(\Omega^+(B_N)\cap\{|C_N|\leqslant\varepsilon|\tilde{A}_N|\})\\&\equiv T_0+T_1,\end{aligned}$$

where $\Omega^+(D)=\{\phi\in\Omega;\phi(x)\geqslant 0\text{ for all }x\in D\}$ for every $D\subset\mathbb{Z}^d$.

Step 2: Since $\{\phi_x-m_x\}_{x\in\tilde{A}_N}$ are centered Gaussian random variables under $P(\cdot\,|\mathcal{F}_{B_N})$, by following the argument of the proof of (2.16) of Ref. 11, we obtain

$$\limsup_{N\to\infty}\frac{1}{N^{d-2l}\log N}\log T_0=-\infty\quad\text{if}\quad\alpha<4l\sigma^2.$$

Step 3: Let $h(x,y)=-J(0,0)^{-1}J(x,y)$. Then m_x can be represented as

$$m_x=\sum_{\substack{y\neq x\\ h(x,y)>0}}h(x,y)\phi_y+\sum_{\substack{y\neq x\\ h(x,y)<0}}h(x,y)\phi_y\equiv m_x^+ + m_x^-.$$

Now on $\Omega^+(B_N)$, $m_x^+\geqslant 0$ and $m_x^-\leqslant 0$. Especially on $(C_N)^c$, $m_x^+\geqslant a_N$ since $m_x=m_x^++m_x^-\geqslant a_N$. Thus on $\Omega^+(B_N)\cap\{|C_N|\leqslant\varepsilon|\tilde{A}_N|\}$, we have

$$S_N^+\equiv\frac{1}{|\tilde{A}_N|}\sum_{x\in\tilde{A}_N}m_x^+\geqslant(1-\varepsilon)a_N.$$

Since S_N^+ is a linear sum of $\{\phi_x\}_{x\in B_N}$ this is a centered Gaussian, hence

$$T_1\leqslant P(S_N^+\geqslant(1-\varepsilon)a_N)\leqslant\exp\left\{-\frac{(1-\varepsilon)^2a_N^2}{2\mathrm{Var}(S_N^+)}\right\}.$$

By using the fact that $h(x,y)$ is independent of N and $G(x,y)\geqslant 0$ for all $x,y\in\mathbb{Z}^d$,

$$\begin{aligned}\mathrm{Var}(S_N^+)&=E\left[\left(\frac{1}{|\tilde{A}_N|}\sum_{x\in\tilde{A}_N}\sum_{\substack{y\neq x\\ h(x,y)>0}}h(x,y)\phi_y\right)^2\right]\\&\leqslant\frac{C}{|V_N|^2}E\left[\left(\sum_{x\in V_N}\phi_x\right)^2\right]\\&\leqslant\frac{C}{N^{2d}}\langle 1_{V_N},G_{(N)}1_{V_N}\rangle_{V_N}\\&=O(N^{-d+2l}),\end{aligned}$$

as $N\to\infty$, where $C>0$ is a constant independent of N and $G_{(N)}$ is a restriction of G to $V_N \times V_N$. The last equality follows from Lemma 5.2.

Finally, we obtain

$$\limsup_{N\to\infty} \frac{1}{N^{d-2l}\log N} \log T_1 \leqslant -C_2,$$

for some constant $C_2>0$ and complete the proof. □

IV. PROOF OF THEOREM 2.2

A. Proof of (2)

We will use the modified version of the conditioning argument which was used in Refs. 5 and 11. To obtain the independent field under conditioning, we consider thicker walls.

For fixed $L\in 2\mathbb{N}$ large enough, define $M_L=(L\mathbb{Z}\times\mathbb{Z}\times\cdots\times\mathbb{Z})\cup(\mathbb{Z}\times L\mathbb{Z}\times\mathbb{Z}\times\cdots\times\mathbb{Z})\cup\cdots\cup(\mathbb{Z}\times\cdots\times\mathbb{Z}\times L\mathbb{Z})$, $A_L=(\cup_{j=-[K/2]}^{[K/2]}(M_L+j\mathbf{1}))+(L/2)\,\mathbf{1}$, $A_L^c=\mathbb{Z}^d\backslash A_L$, $V_{rN\gamma}(z)=z+V_{rN\gamma}$, $\Lambda_N=V_N\cap L\mathbb{Z}^d$ and $\Lambda_{rN\gamma}(z)=V_{rN\gamma}(z)\cap L\mathbb{Z}^d$, where $z\in\mathbb{Z}^d$, $r>0$, $0<\gamma\leqslant 1$, $[a]$ denotes the integral part of a and $\mathbf{1}=(1,1,\ldots,1)$. A_L^c consists of separated d-dimensional cells with centered at $L\mathbb{Z}^d$ and side-length $L-2[K/2]-2$. We will denote a cell with centered at the origin and side-length $L-2[K/2]-2$ by B_L and the matrix inverse of $(J(x,y))_{x,y\in B_L}$ by $(G^L(x,y))_{x,y\in B_L}$. Next let $\mathcal{F}_{A_L}=\sigma(\phi_x;x\in A_L)$ and $\tilde{\phi}_x=E[\phi_x|\mathcal{F}_{A_L}]$. Under $P(\cdot|\mathcal{F}_{A_L})$, $\{\phi_x\}_{x\in\Lambda_N}$ are independent Gaussian random variables with mean $\{\tilde{\phi}_x\}_{x\in\Lambda_N}$ and by the Gibbsian description of P we have $\mathrm{Cov}(\phi_x,\phi_y|\mathcal{F}_{A_L})=\mathrm{Cov}(\phi_x,\phi_y|\mathcal{F}_{B_L^c})$ for $x,y\in B_L$, where $\mathcal{F}_{B_L^c}=\sigma(\phi_x;x\notin B_L)$. The following lemma follows from this fact and Theorems (1.5) and (1.6) of Ref. 18 (see also Sec. 4 of Ref. 17).

Lemma 4.1: (i) $\mathrm{Cov}(\phi_x,\phi_y|\mathcal{F}_{A_L})=G^L(x,y)$ *for every* $x,y\in B_L$.

(ii) For each fixed $x,y\in B_L$, $G^L(x,y)\to G(x,y)$ *as* $L\to\infty$.

By the translation invariance and the Gibbsian description of P, $\mathrm{Cov}(\phi_x,\phi_y|\mathcal{F}_{A_L})=G^L(x,y)$ if $x,y\notin A_L$ belong to the same cell of A_L^c and $\mathrm{Cov}(\phi_x,\phi_y|\mathcal{F}_{A_L})=0$ if $x,y\notin A_L$ belong to the different cells of A_L^c. Also, we have $G^L(0,0)>0$ for any $L\in 2\mathbb{N}$ large enough. The crucial step in the proof of (2) is the following:

Lemma 4.2: Let $1-2l/d<\gamma\leqslant 1$ *be fixed and take* $a<2G^L(0,0)\{(-1+\gamma)d+2l\}$. *Then for every* $\delta>0$

$$\lim_{N\to\infty} \sup_{\substack{z\in V_N, r>0\\ \Lambda_{rN^\gamma}(z)\subset V_N}} P(R_{\Lambda_{rN^\gamma}(z)}[0,\sqrt{a\log N}]\geqslant\delta|\Omega_N^+)=0,$$

where $R_D=(1/|D|)\,\Sigma_{x\in D}\delta_{\phi_x}$ *for each* $D\subset\mathbb{Z}^d$.

We will prove this lemma at the end. Once we have shown Lemma 4.2, in the similar way to the proof of (4.2) of Ref. 5 we can prove the following.

Lemma 4.3: Let $1-2l/d<\gamma\leqslant 1$ *be fixed and take* $a<2G(0,0)\{(-1+\gamma)d+2l\}$. *Then for every* $\delta>0$

$$\lim_{N\to\infty} \sup_{\substack{z\in V_N, r>0\\ V_{rN^\gamma}(z)\subset V_N}} P(R_{V_{rN^\gamma}(z)}[0,\sqrt{a\log N}]\geqslant\delta|\Omega_N^+)=0.$$

By using Lemma 4.3, we first prove (2).

Proof of (2): Let $a<2G(0,0)\{(-1+\gamma)d+2l\}$ be fixed. For every $a<a'<2G(0,0)\{(-1+\gamma)d+2l\}$, $\delta>0$ and $z\in V_N$, $r>0$ with $V_{rN^\gamma}(z)\subset V_N$, we have

$$P(\overline{\phi}_{z,rN^\gamma} \leqslant \sqrt{a \log N} | \Omega_N^+) = P(\{\overline{\phi}_{z,rN^\gamma} \leqslant \sqrt{a \log N}\} \cap \{R_{V_{rN^\gamma(z)}}[0, \sqrt{a' \log N}] \geqslant \delta\} | \Omega_N^+)$$
$$+ P(\{\overline{\phi}_{z,rN^\gamma} \leqslant \sqrt{a \log N}\} \cap \{R_{V_{rN^\gamma(z)}}[\sqrt{a' \log N}, \infty) \geqslant 1-\delta\} | \Omega_N^+).$$

By Lemma 4.3, the first term goes to 0 as $N \to \infty$. Next, on $\{R_{V_{rN^\gamma(z)}}[\sqrt{a' \log N}, \infty) \geqslant 1-\delta\} \cap \Omega_N^+$, we have $\overline{\phi}_{z,rN^\gamma} \geqslant (1-\delta)\sqrt{a' \log N}$. Hence the second term is less than $P((1-\delta)\sqrt{a' \log N} \leqslant \overline{\phi}_{z,rN^\gamma} \leqslant \sqrt{a \log N} | \Omega_N^+)$ which equals 0 for $\delta > 0$ small enough. □

Proof of Lemma 4.2:

Step 1: We will denote $\Lambda_{N^\gamma}(0)$ by Λ_N^γ. Set

$$I_N(a) = \{x \in \Lambda_N^\gamma ; \phi_x \leqslant \sqrt{a \log N}\},$$

$$\tilde{I}_N(a) = \{x \in \Lambda_N^\gamma ; \tilde{\phi}_x \leqslant \sqrt{a \log N}\}, \quad \tilde{I}_N(a)^c = \{x \in \Lambda_N^\gamma ; \tilde{\phi}_x > \sqrt{a \log N}\}.$$

As the proof of Lemma 4.4 of Ref. 5, on Ω_N^+ we have

$$\{R_{\Lambda_N^\gamma}[0, \sqrt{a \log N}] \geqslant \delta\} \subseteq \{|\tilde{I}_N(a')| \geqslant \delta' |\Lambda_N^\gamma|\} \cup \{|I_N(a) \cap \tilde{I}_N(a')^c| \geqslant (\delta - \delta')|\Lambda_N^\gamma|\} \equiv J_0 \cup J_1,$$

for each $0 < \delta' < \delta$ and $a' > a$.

Step 2: Since $\{\phi_x\}_{x \in \Lambda_N^\gamma}$ are independent Gaussian random variables under $P(\cdot | \mathcal{F}_{A_L})$, we have

$$P(J_0 \cap \Omega_N^+) \leqslant E_N\left[\prod_{x \in \Lambda_N^\gamma} P(\phi_x \geqslant 0 | \mathcal{F}_{A_L}) I(|\tilde{I}_N(a')| \geqslant \delta' |\Lambda_N^\gamma|)\right].$$

Note that $|\Lambda_N^\gamma| = CN^{\gamma d}$ for some $C > 0$ independent of N. Then in the same way as in Step 2 of the proof of Theorem 2.1 upper bound, we can obtain

$$P(J_0 \cap \Omega_N^+) \leqslant \exp\left\{-C \frac{\sqrt{G^L}}{\sqrt{\log N}} N^{\gamma d - a'/2G^L}\right\},$$

for some constant $C > 0$, where $G^L = G^L(0,0)$. Hence for every $a < a' < 2G^L\{(-1+\gamma)d + 2l\}$, we know that

$$P(J_0 \cap \Omega_N^+) \leqslant \exp\{-CN^{d-2l+\varepsilon}\}, \tag{11}$$

for some $C, \varepsilon > 0$. By this inequality and Theorem 2.1 lower bound, we obtain that $\lim_{N \to \infty} P(J_0 | \Omega_N^+) = 0$.

Step 3: Define

$$C_N = \{|\{x \in \Lambda_N^\gamma ; \phi_x - \tilde{\phi}_x \leqslant -(\sqrt{a'} - \sqrt{a})\sqrt{\log N}\}| \geqslant (\delta - \delta')|\Lambda_N^\gamma|\},$$

$$D_x = \{\phi_x - \tilde{\phi}_x \leqslant -(\sqrt{a'} - \sqrt{a})\sqrt{\log N}\}.$$

If $x \in I_N(a) \cap \tilde{I}_N(a')^c$, then the event D_x occurs, so we have $P(J_1 \cap \Omega_N^+) \leqslant P(C_N)$. For $x \in \Lambda_N^\gamma$,

$$P(D_x | \mathcal{F}_{A_L}) \leqslant \exp\left\{-\frac{(\sqrt{a'} - \sqrt{a})^2 \log N}{2G^L}\right\}. \tag{12}$$

Next, for every $\beta \in \mathbb{R}$,

$$
\begin{aligned}
T_1 &\equiv E\left[\exp\left\{N^\beta \frac{1}{|\Lambda_N^\gamma|}\sum_{x\in\Lambda_N^\gamma} I(\phi_x-\tilde{\phi}_x \leqslant -(\sqrt{a'}-\sqrt{a})\sqrt{\log N})\right\}\right] \\
&\geqslant E\left[\exp\left\{N^\beta \frac{1}{|\Lambda_N^\gamma|}\sum_{x\in\Lambda_N^\gamma} I(\phi_x-\tilde{\phi}_x \leqslant -(\sqrt{a'}-\sqrt{a})\sqrt{\log N})\right\} I(C_N)\right] \\
&\geqslant \exp\{(\delta-\delta')N^\beta\} P(C_N).
\end{aligned}
$$

Using the independence of $\{\phi_x-\tilde{\phi}_x\}_{x\in\Lambda_N^\gamma}$ under $P(\cdot|\mathcal{F}_{A_L})$ and (12),

$$
\begin{aligned}
T_1 &= E\left[\prod_{x\in\Lambda_N^\gamma} E\left[\exp\left\{N^\beta \frac{1}{|\Lambda_N^\gamma|} I(\phi_x-\tilde{\phi}_x \leqslant -(\sqrt{a'}-\sqrt{a})\sqrt{\log N})\right\}\middle| \mathcal{F}_{A_L}\right]\right] \\
&= E\left[\prod_{x\in\Lambda_N^\gamma}\left\{\left(\exp\left\{N^\beta\frac{1}{|\Lambda_N^\gamma|}\right\}-1\right)P(D_x|\mathcal{F}_{A_L})+1\right\}\right] \\
&\leqslant \left\{\left(\exp\left\{N^\beta\frac{1}{|\Lambda_N^\gamma|}\right\}-1\right)\exp\left\{-\frac{(\sqrt{a'}-\sqrt{a})^2\log N}{2G^L}\right\}+1\right\}^{|\Lambda_N^\gamma|} \\
&\leqslant \exp\left\{\left|\Lambda_N^\gamma\right|\left(\exp\left\{N^\beta\frac{1}{|\Lambda_N^\gamma|}\right\}-1\right)\exp\left\{-\frac{(\sqrt{a'}-\sqrt{a})^2\log N}{2G^L}\right\}\right\}.
\end{aligned}
$$

Hence we obtain

$$
P(J_1\cap\Omega_N^+) \leqslant \exp\{-(\delta-\delta')N^\beta\}\exp\{CN^{\gamma d-(\sqrt{a'}-\sqrt{a})^2/2G^L}(\exp\{CN^{\beta-\gamma d}\}-1)\},
$$

for some $C>0$. Now taking $\beta=\gamma d-(\sqrt{a'}-\sqrt{a})^2/2G^L$, we know that

$$
\limsup_{N\to\infty}\frac{1}{N^\beta}\log P(J_1\cap\Omega_N^+) \leqslant -(\delta-\delta'). \tag{13}
$$

Since $\beta>d-2l$ for $a<a'<2G^L\{(-1+\gamma)d+2l\}$, by (13) and Theorem 2.1 lower bound we obtain $\lim_{N\to\infty} P(J_1|\Omega_N^+)=0$.

Completely the same way, we can obtain the estimates (11) and (13) independent of $z\in V_N$, $r>0$ with $\Lambda_{rN^\gamma}(z)\subset V_N$ for $\Lambda_{rN^\gamma}(z)$ instead of Λ_N^γ and complete the proof. □

B. Proof of (3)

Take $z\in V_N$, $r>0$ so that $V_{rN}(z)\subset V_N$. By Chebyshev inequality and the Brascamp–Lieb inequality (cf. Ref. 7), which can be applied to the conditioned measure $P(\cdot|\Omega_N^+)$ (cf. Appendix of Ref. 11), we have

$$
P(\overline{\phi}_{z,rN}\geqslant\sqrt{b\log N}|\Omega_N^+) \leqslant \exp\left\{-\frac{|V_{rN}(z)|^2}{2\langle 1_{V_{rN}(z)}, G1_{V_{rN}(z)}\rangle_{V_N}}((\sqrt{b\log N}-E[\overline{\phi}_{z,rN}|\Omega_N^+])\vee 0)^2\right\}.
$$

Hence, by Lemma 5.2, we have only to prove that

$$
\limsup_{N\to\infty}\frac{1}{\sqrt{\log N}}E[\overline{\phi}_{z,rN}|\Omega_N^+] \leqslant C,
$$

for some constant $C>0$ and this estimate follows from the same argument as in the proof of Lemma 4.7 of Ref. 5. □

V. SOME TECHNICAL LEMMAS

In this section we show the asymptotics of the Green function and the convergence of the capacity which are used in Secs. III and IV.

Lemma 5.1: Let $d \geqslant 2l+1$. Then, it holds that

$$\lim_{|x|\to\infty} \frac{G(0,x)}{|x|^{-d+2l}} = \frac{1}{q_l}\gamma.$$

γ is given by

$$\gamma = \frac{1}{(2\pi)^d} \int_0^\infty \int_{\mathbb{R}^d} \exp\left\{ i\zeta\cdot\omega - \left(\frac{1}{2d}\right)^l |\omega|^{2l} t \right\} d\omega dt,$$

where $\zeta \in \mathbb{S}^{d-1}$ and the right hand side is independent of the choice of $\zeta \in \mathbb{S}^{d-1}$.

Proof: We follow the argument of Sec. 3 of Ref. 21 (see also Sec. 5 of Ref. 22). By the inversion formula we know that

$$G(0,x) = \frac{1}{(2\pi)^d} \int_{[-\pi,\pi]^d} \hat{G}(\theta) e^{ix\cdot\theta} d\theta.$$

Since we can write $q_l \hat{G}(\theta) = \int_0^\infty \exp\{-[1/q_l \hat{G}(\theta)]\, u\} du$, we have

$$\begin{aligned}(2\pi)^d q_l G(0,x) &= \int_0^\infty \int_{[-\pi,\pi]^d} \exp\left\{ ix\cdot\theta - \frac{1}{q_l}\hat{G}(\theta)^{-1} u \right\} d\theta du \\ &= |x|^{-d+2l} \int_0^\infty \int_{[-\pi|x|,\pi|x|]^d} \exp\left\{ i\frac{x}{|x|}\cdot\omega - \frac{1}{q_l}\hat{G}\left(\frac{\omega}{|x|}\right)^{-1} |x|^{2l} t \right\} d\omega dt,\end{aligned}$$

where the last equality follows from the change of variables $u = |x|^{2l} t$, $\theta = \omega/|x|$. Define

$$\Gamma(t,x) = \int_{[-\pi|x|,\pi|x|]^d} \exp\left\{ i\frac{x}{|x|}\cdot\omega - \frac{1}{q_l}\hat{G}\left(\frac{\omega}{|x|}\right)^{-1} |x|^{2l} t \right\} d\omega.$$

Since $\hat{G}(\theta)^{-1} = \hat{J}(\theta) = \Sigma_{j=l}^K q_j (\mu(\theta))^j$, $\mu(\theta) = (1/2d)\,|\theta|^2 (1+o(1))$ and $(\partial/\partial\theta_i)\,\mu(\theta) = (1/d)\,\theta_i (1+o(1))$ as $|\theta| \to 0$, in the similar way to the proof of Lemma 3.1 of Ref. 21, we can prove that $|\Gamma(t,x)| \leqslant C(t^{-1/2l} \wedge t^{-d/2l})$ for some $C>0$ independent of $x \in \mathbb{Z}^d \setminus \{0\}$ and the rhs is integrable with respect to $\int_0^\infty \cdot\, dt$ when $d \geqslant 2l+1$. Hence by Lebesgue's dominated convergence theorem, we have

$$\lim_{|x|\to\infty} \frac{(2\pi)^d q_l G(0,x)}{|x|^{-d+2l}} = \int_0^\infty \lim_{|x|\to\infty} \Gamma(t,x)\, dt.$$

Now by using the asymptotics of $\hat{G}(\theta)^{-1}$ as $|\theta| \to 0$ and Assumption 1, the absolute value of the integrand of $\Gamma(t,x)$ is bounded by $\exp\{-C|\omega|^{2l} t\}$ for some $C>0$ which is integrable with respect to $\int_{\mathbb{R}^d} \cdot\, d\omega$ and $1/q_l\, \hat{G}(\omega/|x|)^{-1} |x|^{2l} t$ converges to $(1/2d)^l |\omega|^{2l} t$ as $|x| \to \infty$. Hence by Lebesgue's dominated convergence theorem again, we obtain

$$\lim_{|x|\to\infty}\Gamma(t,x)=\int_{\mathbb{R}^d}\lim_{|x|\to\infty}\exp\left\{i\frac{x}{|x|}\cdot\omega-\frac{1}{q_l}\hat{G}\left(\frac{\omega}{|x|}\right)^{-1}|x|^{2l}t\right\}d\omega$$

$$=\int_{\mathbb{R}^d}\exp\left\{i\zeta\cdot\omega-\left(\frac{1}{2d}\right)^{l}|\omega|^{2l}t\right\}d\omega,$$

where $\zeta\in\mathbb{S}^{d-1}$ and the right hand side is independent of $\zeta\in\mathbb{S}^{d-1}$. □

Let $g_l(x)=\gamma|x|^{-d+2l}$ and define the integral operator K_V^l on $L^2(V)$ by

$$K_V^l f(x)=\int_V g_l(x-y)f(y)dy,\quad x\in V.$$

Using Lemma 5.1 and (9), in a way similar to Sec. 2 of Ref. 2 and the Appendix of Ref. 5, we can obtain the following lemma.

Lemma 5.2: Let $d\geqslant 2l+1$, $f\in C(V;\mathbb{R})$ *and* $(G_{(N)})^{-1}$ *be a matrix inverse of* $G_{(N)}$. *Set* $f_N(x)=f(x/N)$. *Then*

$$\lim_{N\to\infty}N^{-d-2l}\langle f_N,G_{(N)}f_N\rangle_{V_N}=\frac{1}{q_l}\langle f,K_V^l f\rangle_V,$$

$$\lim_{N\to\infty}N^{-d+2l}\langle 1_{V_N},(G_{(N)})^{-1}1_{V_N}\rangle_{V_N}=q_l Cap_l(V).$$

ACKNOWLEDGMENTS

I would like to express my sincere thanks to Professor T. Funaki for many helpful discussions and his encouragement. The problem was suggested by Professor H. Spohn.

Foldy–Wouthuysen transformation for relativistic particles in external fields

Alexander J. Silenko[a)]
Institute of Nuclear Problems, Belarusian State University, Bobruiskaya str., 11, 220080 Minsk, Belarus

(Received 16 November 2001; accepted 11 April 2003)

A method of Foldy–Wouthuysen transformation for relativistic spin-1/2 particles in external fields is proposed. It permits the determination of the Hamilton operator in the Foldy–Wouthuysen representation with any accuracy. Interactions between a particle having an anomalous magnetic moment and nonstationary electromagnetic and electroweak fields are investigated. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1579991]

I. INTRODUCTION

The Foldy–Wouthuysen (FW) representation[1] occupies a special place in the quantum theory. This is mainly due to the fact that the Hamiltonian and all operators in this representation are block-diagonal (diagonal in two spinors). For relativistic particles in external fields, operators have the same form as in the nonrelativistic quantum theory. Therefore, the FW representation in the relativistic quantum theory is similar to the nonrelativistic quantum theory. The basic advantages of the FW representation are described in Refs. 1 and 2 (see also below).

The transformation to the FW representation (FW transformation) holds only in the one-particle approximation where the radiative corrections are not calculated in a consistent way but are phenomenologically taken into account by including extra terms in the Dirac equation (see Ref. 3). The one-particle description is feasible even for ultrarelativistic particles if the external field is so weak that the probability of pair production or bremsstrahlung losses can be neglected for a given interaction energy of a particle. The range of applicability of this description is fairly wide and includes, in particular, the relativistic particle scattering and the interaction of relativistic particles with matter and external fields.

In the nonrelativistic case, there exist a lot of good methods of FW transformation with taking into account relativistic corrections.[1,4–6] However, they are not useful for relativistic particles. The known methods of solving this problem[9–12] either lead to cumbersome calculations or the field of their use is limited by the first approximation in field parameters. None of these methods permits an exact FW transformation for the particular cases described in Refs. 5, 7, and 8. Therefore, the FW representation does not take the right stand in the relativistic quantum theory. The Dirac and Melosh[13] representations are mostly used.

FW transformation can also be performed for particles with spin $s>1/2$.[7,14]

In the present work, a method of FW transformation for relativistic particles in external fields is proposed. This method permits obtaining a Hamiltonian of any accuracy by successive approximations, as a power series in the external field potentials and their derivatives. In some cases, this method permits performing an exact FW transformation.

The relativistic system of units $\hbar=c=1$ is used.

II. GENERAL PROPERTIES OF THE FOLDY–WOUTHUYSEN REPRESENTATION

The basic advantages of the FW representation are due to its specific properties.

a)Electronic mail: silenko@inp.minsk.by

The relations between the operators in the FW representation are similar to those between the respective classical quantities. In this representation, the operators have the same form as in the nonrelativistic quantum theory. Only the FW representation possesses these properties considerably simplifying the transition to the semiclassical description. The FW representation provides the best possibility of obtaining a meaningful classical limit of the relativistic quantum theory.

For example, the Hamiltonian for a free particle fully agrees with that of classical physics:

$$\mathcal{H}_{\mathrm{FW}}=\beta\sqrt{m^2+\mathbf{p}^2},\qquad \mathbf{p}=-i\boldsymbol{\nabla}, \tag{1}$$

in contrast with the Hamiltonian in the Dirac representation.[1,15] The position operator in the Dirac representation is the radius-vector, $\mathbf{r}$.[15] It corresponds to the mean position operator for the free particle in the FW representation,[1]

$$\mathbf{r}_{\mathrm{D}}=\mathbf{r}+\frac{i\beta\boldsymbol{\alpha}}{2\epsilon}-\frac{i\beta(\boldsymbol{\alpha}\cdot\mathbf{p})\mathbf{p}+[\boldsymbol{\Sigma}\times\mathbf{p}]p}{2\epsilon(\epsilon+m)p},\qquad p\equiv|\mathbf{p}|,\qquad \epsilon=\sqrt{m^2+p^2}.$$

Here and below the following designations for the matrices are used:

$$\boldsymbol{\gamma}=\begin{pmatrix}0 & \boldsymbol{\sigma}\\ -\boldsymbol{\sigma} & 0\end{pmatrix},\qquad \beta\equiv\gamma^0=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\qquad \boldsymbol{\alpha}=\beta\boldsymbol{\gamma}=\begin{pmatrix}0 & \boldsymbol{\sigma}\\ \boldsymbol{\sigma} & 0\end{pmatrix},$$

$$\boldsymbol{\Sigma}=\begin{pmatrix}\boldsymbol{\sigma} & 0\\ 0 & \boldsymbol{\sigma}\end{pmatrix},\qquad \boldsymbol{\Pi}=\beta\boldsymbol{\Sigma}=\begin{pmatrix}\boldsymbol{\sigma} & 0\\ 0 & -\boldsymbol{\sigma}\end{pmatrix},$$

where $0,1,-1$ mean the corresponding 2×2 matrices and $\boldsymbol{\sigma}$ is the Pauli matrix.

In the FW representation, the problem of "*zitterbewegung*" motion never arises.[2,15] The operators $\mathbf{l}=\mathbf{r}\times\mathbf{p}$ and $\boldsymbol{\Sigma}/2$ define the angular momentum and the spin for the free particle, respectively. In this representation, unlike the Dirac one, each of them is a constant of motion (see Ref. 1). The corresponding operators conserving in the Dirac representation are

$$\mathbf{l}_{\mathrm{D}}=\mathbf{r}_{\mathrm{D}}\times\mathbf{p},$$

$$\frac{\boldsymbol{\Sigma}_{\mathrm{D}}}{2}=\frac{\boldsymbol{\Sigma}}{2}-\frac{i\beta[\boldsymbol{\alpha}\times\mathbf{p}]}{2\epsilon}-\frac{[\mathbf{p}\times[\boldsymbol{\Sigma}\times\mathbf{p}]]}{2\epsilon(\epsilon+m)}.$$

The total angular momentum operator, $\mathbf{j}$, is a constant of motion in both representations, because

$$\mathbf{j}_{\mathrm{D}}=\mathbf{l}_{\mathrm{D}}+\frac{\boldsymbol{\Sigma}_{\mathrm{D}}}{2}=\mathbf{l}+\frac{\boldsymbol{\Sigma}}{2}=\mathbf{j}.$$

The FW representation is very convenient for describing the particle polarization. In this representation, polarization operators have simple forms. For example, the three-dimensional polarization operator equals the matrix $\boldsymbol{\Pi}$.[16,17] In the Dirac representation, this operator depends on the particle momentum:[16,17]

$$\mathbf{O}\equiv\boldsymbol{\Pi}_{\mathbf{D}}=\boldsymbol{\Pi}-\gamma^5\frac{\mathbf{p}}{\epsilon}-\frac{\mathbf{p}(\boldsymbol{\Pi}\cdot\mathbf{p})}{\epsilon(\epsilon+m)}.$$

For particles interacting with external fields, it also depends on the external field parameters.[17]

Thus, in the Dirac representation all operators corresponding to the basic classical quantities are defined by cumbersome expressions. These operators should also depend on the external field parameters for particles interacting with external fields.

The FW representation helps one to prove that the particle position can be measured up to its Compton wavelength.[1,15] However, this property is valid only for a particle not strongly interacting with external fields if the one-particle approximation is attainable. Otherwise, the effect of pair production prevents the use of both the Dirac equation (even with some corrections) and the ''traditional'' Hamilton approach. Obviously, in this case the FW transformation cannot be used either.

The FW transformation possesses another important property. The relativistic wave equations and all operators are block-diagonal (diagonal in two spinors). This property permits separating positive and negative energy states.[1] Of course, extraction of even parts of operators becomes unnecessary.

The detailed analysis performed in Ref. 18 shows that the wave functions in both the Dirac and FW representations are equal to each other only approximately, and they do not coincide. In these papers, the nonrelativistic case was considered and relativistic corrections were taken into account.

An analogous conclusion follows from the results obtained in Ref. 11. In this work, a more general situation has been investigated for the relativistic particle not strongly interacting with an electromagnetic field. It has been found that the upper spinors in the Dirac and FW representations are approximately proportional to each other, but this property is not exact.

Thus, the preferable employment of the FW representation is evident, although the relativistic wave equations are more complicated in this representation.

III. METHODS OF THE FOLDY–WOUTHUYSEN TRANSFORMATION

In the classical work by Foldy and Wouthuysen,[1] two different transformations, for free relativistic particles and for nonrelativistic particles in electromagnetic fields have been carried out. In the general case, transformation to a new representation described by the wave function Ψ' is performed with the unitary operator U:

$$\Psi' = U\Psi = e^{iS}\Psi,$$

where $\Psi = \binom{\phi}{\chi}$ is the wave function (bispinor) in the Dirac representation. As

$$\Psi = U^{-1}\Psi', \qquad i\frac{\partial}{\partial t}\Psi = \mathcal{H}\Psi, \qquad i\frac{\partial}{\partial t}\Psi' = \mathcal{H}'\Psi',$$

the following transformation can be carried out:

$$i\frac{\partial}{\partial t}\Psi = \mathcal{H}U^{-1}\Psi',$$

$$i\frac{\partial}{\partial t}\Psi = i\frac{\partial}{\partial t}(U^{-1}\Psi') = i\frac{\partial U^{-1}}{\partial t}\Psi' + iU^{-1}\frac{\partial \Psi'}{\partial t} = \left(i\frac{\partial U^{-1}}{\partial t} + U^{-1}\mathcal{H}'\right)\Psi',$$

$$U\mathcal{H}U^{-1}\Psi' = \left(iU\frac{\partial U^{-1}}{\partial t} + \mathcal{H}'\right)\Psi'.$$

Hence, the Hamilton operator in the new representation takes the form[1,19]

$$\mathcal{H}' = U\mathcal{H}U^{-1} - iU\frac{\partial U^{-1}}{\partial t}, \tag{2}$$

or

$$\mathcal{H}' = U\left(\mathcal{H} - i\frac{\partial}{\partial t}\right)U^{-1} + i\frac{\partial}{\partial t}.$$

There is an error in this transformation in Ref. 20.

The Hamiltonian can be split into operators commuting and noncommuting with the operator β:

$$\mathcal{H}=\beta m+\mathcal{E}+\mathcal{O}, \quad \beta\mathcal{E}=\mathcal{E}\beta, \quad \beta\mathcal{O}=-\mathcal{O}\beta. \tag{3}$$

The Hamiltonian $\mathcal{H}$ is Hermitian. We assume that both operators $\mathcal{E}$ and $\mathcal{O}$ are also Hermitian. For free Dirac particles $\mathcal{E}=0$, $\mathcal{O}=\boldsymbol{\alpha}\cdot\mathbf{p}$, and the operator S has the form

$$S=-i\beta\boldsymbol{\alpha}\cdot\mathbf{p}\theta(\mathbf{p}), \tag{4}$$

where θ is a function of the momentum operator. If we choose

$$\theta(\mathbf{p})=\frac{1}{2p}\arctan\left(\frac{p}{m}\right),$$

the transformed Hamiltonian $\mathcal{H}'$ contains no odd operators[1,20] and we obtain Eq. (1),

$$\mathcal{H}'=\beta\sqrt{m^2+\mathbf{p}^2}.$$

For nonrelativistic particles in an electromagnetic field, the FW transformation can be performed with the operator[1,20]

$$S=-\frac{i}{2m}\beta\mathcal{O}. \tag{5}$$

The transformed Hamiltonian can be written in the form

$$\mathcal{H}'=\mathcal{H}+i[S,\mathcal{H}]+\frac{i^2}{2!}[S,[S,\mathcal{H}]]+\frac{i^3}{3!}[S,[S,[S,\mathcal{H}]]]+\cdots-\dot{S}-\frac{i}{2!}[S,\dot{S}]-\frac{i^2}{3!}[S,[S,\dot{S}]]-\cdots, \tag{6}$$

where $[\cdots,\cdots]$ means a commutator. As a result of this transformation, we find

$$\mathcal{H}'=\beta\epsilon+\mathcal{E}'+\mathcal{O}', \qquad \beta\mathcal{E}'=\mathcal{E}'\beta, \qquad \beta\mathcal{O}'=-\mathcal{O}'\beta, \tag{7}$$

where the odd operator $\mathcal{O}'$ is now $O(1/m)$. This procedure can be repeated to obtain the required accuracy. Another form of the nonrelativistic FW transformation was given by Ericksen[5] (see also Ref. 21).

There are also other methods for obtaining the block-diagonal form of the Hamiltonian or the Lagrangian. The so-called elimination method of Pauli[22] permits us excluding the lower spinor from relativistic wave equations. As a result, the wave function of the final Pauli equation is the upper Dirac spinor, ϕ. This means that the upper Dirac spinor is also an eigenfunction of the transformed Hamiltonian. However, this property is not exact. The Pauli method was analyzed in detail in Refs. 18 and 21. It was shown that this method gives the right first approximation. Nevertheless, relativistic corrections of higher orders are incorrect. It is quite natural because a direct Pauli's reduction leads to a neglect of the contribution of the lower spinor.[18] The relation between the exact wave function in the FW representation and the upper Dirac spinor has been found in Ref. 11 in the relativistic case.

A more exact variant of the elimination method had been proposed earlier by Berestetskii and Landau[23] (see also Refs. 4 and 24). They showed that it was possible to find a nonunitary operator V for which

$$\psi=V\phi \tag{8}$$

is a two-component wave function with a correct norm. An appropriate form of the operator V can be obtained from the condition

$$\int \psi^\dagger \psi \, dV = \int (\phi^\dagger \phi + \chi^\dagger \chi) dV = 1.$$

The relation between the Dirac spinors can be expressed in the general form $\chi = Q\phi$. Therefore,

$$V^\dagger V = 1 + Q^\dagger Q.$$

If we additionally assume that the operator V is Hermitian, then both this operator and the Hamiltonian can be found by successive approximations.[4,23–25]

Of course, the elimination method is much simpler. However, it is mostly intuitive. Its validity is proved only by the coincidence of the results obtained by the FW and Akhiezer–Berestetskii–Landau methods.[21]

Another method of diagonalization of relativistic wave equations was proposed by Korner and Thompson.[6] In this work, the Lagrangian approach was used. The Korner–Thompson method is similar to the FW method. It also includes a successive decrease in the maximum order of odd terms. The results obtained by the FW and Korner–Thompson methods agree (see Ref. 12).

Thus, several nonrelativistic transformation methods give the same results. However, the FW transformation method has been justified in the best way.

In several cases, FW transformation can be performed exactly.[5,7,8] An exact FW transformation has also been performed for a wide class of external fields in Ref. 26. In this work, involutive symmetries of relativistic wave equations have been used. However, the transformed Hamiltonians contain ''nontraditional'' space reflection operators. The reduction of Hamiltonians to the ''traditional'' form is a difficult problem. It has not been investigated in Ref. 26. However, this reduction is necessary to do for solving many problems (e.g., finding particle and spin motion equations).

Generally, FW transformation for relativistic particles in external fields is complicated. The transformation methods explained in Refs. 9 and 10 require cumbersome calculations. A variant of the elimination method useful for relativistic particles has been developed in Ref. 11. On eliminating the lower spinor from the relativistic wave equations, the final equation for the upper spinor takes the form[11]

$$i\frac{\partial \phi}{\partial t} = F\left(\mathbf{r}, \mathbf{p}, i\frac{\partial}{\partial t}\right)\phi, \tag{9}$$

where F is the operator function. Further calculations are analogous to those in the Akhiezer–Berestetskii–Landau method. A new wave function with a correct norm, ψ, expressed by Eq. (8) is introduced. Substituting it for ϕ into Eq. (9), one can find the Hamilton operator for the relativistic particle.

The relativistic wave equation for an upper spinor similar to Eq. (9) is found by the Lagrangian approach.[12]

However, it is difficult to find a second approximation by using the relativistic variant of the elimination method proposed in Ref. 11. It is easier to determine relativistic corrections of higher orders.[12]

The right two-component wave function in the FW representation, ψ, does not coincide with the upper Dirac spinor, ϕ.[11] This conclusion is in agreement with the results obtained in Ref. 18.

There are other difficult problems. The diagonalization of relativistic wave equations needs carefulness, especially in the time-dependent case. As mentioned in Refs. 19 and 27, in the latter case $\mathcal{H}'$ is not equivalent to $\mathcal{H}$ since these operators have different matrix elements. Rather, $U\mathcal{H}U^{-1}$ is. There is a danger that one can arrive at a block-diagonal representation differing from the FW one even in the time-independent case. For example, the transformation performed in Ref. 8 (this is the Melosh transformation indeed[28]) leads to a block-diagonal Hamiltonian that differs from the Hamiltonian in the FW representation.[29] Therefore, the application of noncanonical

transformation methods is restricted by the necessity of verifying the results by comparing them with the corresponding results obtained by the canonical transformation method in some particular cases. Of course, other transformation methods may be simpler or less cumbersome. Nevertheless, the FW method is safer and substantiated very well.

In the present work, a relativistic extension to the FW method is proposed.

IV. EXACT FOLDY–WOUTHUYSEN TRANSFORMATION

Consider some cases of the exact FW transformation.

In Eq. (3), the operators β and $\mathcal{O}^2$ commute ($\beta\mathcal{O}^2=-\mathcal{O}\beta\mathcal{O}=\mathcal{O}^2\beta$). Therefore, the operator $\mathcal{O}^2$ is even.

The operator S can be defined by an expression similar to Eq. (4):

$$S=-i\frac{\beta\mathcal{O}}{C}\theta, \tag{10}$$

where C and θ are the functions of $\mathcal{O}^2$ and the operator C satisfies the following conditions:

$$C^2=\mathcal{O}^2, \qquad [\beta,C]=0. \tag{11}$$

It follows from conditions (11) that the operator C is also even.

It is possible to use the following formal definition of this operator:

$$C=\sqrt{\mathcal{O}^2}. \tag{12}$$

Relations (11) and (12) define the square root of matrix operators. To unambiguously define the square root, these relations should be complemented by the condition that the square root of the unit matrix $\mathcal{I}$ is equal to the unit matrix. This definition of the square root coincides with those of Refs. 1, 20, and 26. For example, for free particles,

$$\mathcal{O}=\boldsymbol{\alpha}\cdot\mathbf{p}, \qquad \mathcal{O}^2=\mathcal{I}\mathbf{p}^2, \qquad C=\mathcal{I}\sqrt{\mathbf{p}^2}\equiv\mathcal{I}|\mathbf{p}|.$$

Further, the symbol of the unit matrix $\mathcal{I}$ will be omitted.

Since

$$\mathcal{O}^2=-\beta\mathcal{O}\beta\mathcal{O}, \qquad C=\sqrt{-\beta\mathcal{O}\beta\mathcal{O}}, \qquad f(\mathcal{O}^2)=f(C^2),$$

the operators $\beta\mathcal{O},C,\mathcal{O}^2$, and θ commute with each other. The operator θ is the angle of rotation of the basic vector set in the spinor space.

The unitary transformation operator, U, can be written in the form

$$U=\cos\theta+\frac{\beta\mathcal{O}}{C}\sin\theta. \tag{13}$$

A FW transformation is exact if the external field is stationary and the operators $\mathcal{E}$ and $\mathcal{O}$ commute:

$$[\mathcal{E},\mathcal{O}]=0. \tag{14}$$

In this particular case,

$$[\mathcal{E},\beta\mathcal{O}]=\beta[\mathcal{E},\mathcal{O}]=0.$$

Condition (14) is a sufficient but not necessary condition of the exact transformation.

The Hamilton operator in the new representation takes the form

$$\mathcal{H}'=\left(\cos\theta+\frac{\beta\mathcal{O}}{C}\sin\theta\right)\mathcal{H}\left(\cos\theta-\frac{\beta\mathcal{O}}{C}\sin\theta\right)$$
$$=(\beta m+\mathcal{O})\left(\cos\theta-\frac{\beta\mathcal{O}}{C}\sin\theta\right)^2+\mathcal{E}$$
$$=(\beta m+\mathcal{O})\left(\cos 2\theta-\frac{\beta\mathcal{O}}{C}\sin 2\theta\right)+\mathcal{E}$$
$$=\beta(m\cos 2\theta+C\sin 2\theta)+\mathcal{O}\left(\cos 2\theta-\frac{m}{C}\sin 2\theta\right)+\mathcal{E}.$$

The Hamiltonian $\mathcal{H}'$ is even if the odd term (proportional to $\mathcal{O}$) vanishes. This takes place if

$$\tan 2\theta=\frac{C}{m}. \tag{15}$$

This equation has two solutions, θ_1 and θ_2, differing in $\pi/2$. Since

$$\tan 2\theta=\frac{2\tan\theta}{1-\tan^2\theta},\quad \tan\theta=\frac{\tan 2\theta}{1\pm\sqrt{1+\tan^2 2\theta}},$$

they are defined by the relations

$$\tan\theta_1=\frac{C}{\epsilon+m},\qquad \tan\theta_2=-\frac{C}{\epsilon-m},\qquad \epsilon=\sqrt{m^2+C^2}=\sqrt{m^2+\mathcal{O}^2}. \tag{16}$$

Thus, there are two unitary transformations of the operator $\mathcal{H}$ to an even form. They are characterized by the angles θ_1 and θ_2, where the angle θ_1 corresponds to the FW transformation.

As a result of both transformations, one of the spinors (lower for θ_1 and upper for θ_2) becomes zero as for free particles.

Note that the transformation under consideration is also similar to the Melosh transformation.[13]

If condition (14) is satisfied, then the Hamilton operator in the FW representation is defined exactly:

$$\mathcal{H}'=\beta\epsilon+\mathcal{E}. \tag{17}$$

Unlike Refs. 9, 10, and 11, Eq. (17) contains exact expressions for the Hamiltonian derived in Refs. 5, 7, and 8 as particular cases.

The transformation operator U can be written in nonexponential form. After the calculation of $\sin\theta_1$ and $\cos\theta_1$ with formulas (16),

$$\sin\theta_1=\frac{C}{\sqrt{2\epsilon(\epsilon+m)}},\qquad \cos\theta_1=\sqrt{\frac{\epsilon+m}{2\epsilon}},$$

we obtain the following expression:

$$U^{\pm}=\frac{\epsilon+m\pm\beta\mathcal{O}}{\sqrt{2\epsilon(\epsilon+m)}}, \tag{18}$$

where $U^+\equiv U$, $U^-\equiv U^{-1}$. This expression agrees with the well-known formula for free particles.[1] Since $(\beta\mathcal{O})^\dagger=\mathcal{O}\beta=-\beta\mathcal{O}$, the operator U is unitary. A simultaneous change of signs

of $\sin\theta_1$ and $\cos\theta_1$ does not affect the final result because the wave functions Ψ,Ψ' are determined up to a sign. The direct calculation of the Hamilton operator in the FW representation also leads to Eq. (17) in accordance with formulas (2), (3), (14), and (18).

Another class of Hamiltonians permitting exact FW transformation has been investigated in Ref. 26.

V. EXACT TRANSFORMATION FOR PARTICLES IN ELECTROWEAK FIELDS

Let us consider the interaction of a relativistic spin-1/2 particle, possessing an anomalous magnetic moment (AMM), with stationary electromagnetic and electroweak fields. The Hamiltonian of the electromagnetic interaction is defined by the Dirac–Pauli equation:[30]

$$\mathcal{H}_{\mathrm{DP}}=\boldsymbol{\alpha}\cdot\boldsymbol{\pi}+\beta m+e\Phi+\mu'(-\mathbf{\Pi}\cdot\mathbf{H}+i\boldsymbol{\gamma}\cdot\mathbf{E}),\qquad \boldsymbol{\pi}=\mathbf{p}-e\mathbf{A}, \tag{19}$$

where μ' is AMM, Φ, $\mathbf{A}$ and $\mathbf{E}$, $\mathbf{H}$ are the potentials and the strengths of an electromagnetic field. This equation is derived in the one-particle approximation and is useful when an electromagnetic field is not extremely strong (see Ref. 11).

The weak interaction Hamiltonian should be added to the Hamiltonian of Eq. (19). The weak interaction does not conserve the spatial parity. For the interaction transferred by neutral currents, the standard model gives the following expression for the parity-nonconserving weak interaction Hamiltonian in the approximation of a small transferred momentum:[31]

$$\mathcal{H}_{\mathrm{PNC}}=-\frac{G}{\sqrt{2}}(C_1\gamma^5+C_2\boldsymbol{\alpha}\cdot\boldsymbol{\sigma}')n(\mathbf{r}),\qquad \gamma^5=\begin{pmatrix}0 & -1\\ -1 & 0\end{pmatrix}, \tag{20}$$

where G is the Fermi constant, $\boldsymbol{\sigma}'$ is the Pauli matrix for matter particles, and $n(\mathbf{r})$ is the density of matter particles. For the interactions with nuclei, $n(\mathbf{r})$ characterizes the density of nucleons of a certain kind, and $\boldsymbol{\sigma}'$ should be replaced by the nucleus spin. Formulas (19) and (20) do not change if the external fields are nonstationary. The matter particles are considered to be at rest.

The coefficients C_1,C_2 are different for different pairs of interacting particles. The Hamiltonians corresponding to the interactions with different matter particles should be summed-up. The signs in formula (20) depend on the definition of the coefficients C_1,C_2 and matrix γ^5. The total Hamiltonian equals

$$\mathcal{H}=\mathcal{H}_{\mathrm{DP}}+\mathcal{H}_{\mathrm{PNC}}. \tag{21}$$

In this case, in formulas (3), (16)–(18) we have

$$\begin{aligned}\mathcal{E}&=e\Phi-\mu'\mathbf{\Pi}\cdot\mathbf{H},\\ \mathcal{O}&=\boldsymbol{\alpha}\cdot\boldsymbol{\pi}+i\mu'\boldsymbol{\gamma}\cdot\mathbf{E}-\frac{G}{\sqrt{2}}(C_1\gamma^5+C_2\boldsymbol{\alpha}\cdot\boldsymbol{\sigma}')n(\mathbf{r})\\ &=\beta\left[\boldsymbol{\gamma}\cdot\boldsymbol{\pi}+i\mu'\boldsymbol{\alpha}\cdot\mathbf{E}-\frac{G}{\sqrt{2}}(C_1\beta\gamma^5+C_2\boldsymbol{\gamma}\cdot\boldsymbol{\sigma}')n(\mathbf{r})\right].\end{aligned} \tag{22}$$

Let us consider some particular cases where Hamiltonian (21) satisfies condition (14). For these cases the FW transformation is exact. The general case will be analyzed in the next section.

The exact Hamiltonian in the FW representation is given by Eq. (17), where $\mathcal{E}$ is defined by Eq. (22), and

$$\epsilon=\left\{ m^2-\left[\boldsymbol{\gamma}\cdot\boldsymbol{\pi}+i\mu'\boldsymbol{\alpha}\cdot\mathbf{E}-\frac{G}{\sqrt{2}}(C_1\beta\gamma^5+C_2\boldsymbol{\gamma}\cdot\boldsymbol{\sigma}')n(\mathbf{r})\right]\right\}^{1/2}$$

$$=\Bigg\{ m^2+\boldsymbol{\pi}^2+\beta\mu'(\boldsymbol{\Sigma}\cdot[\boldsymbol{\pi}\times\mathbf{E}]-\boldsymbol{\Sigma}\cdot[\mathbf{E}\times\boldsymbol{\pi}]-\boldsymbol{\nabla}\cdot\mathbf{E})+\mu'^2\mathbf{E}^2-e\boldsymbol{\Sigma}\cdot\mathbf{H}$$

$$+\frac{G}{\sqrt{2}}(C_1\{\boldsymbol{\Sigma}\cdot\boldsymbol{\pi},n(\mathbf{r})\}_+-C_2\{\boldsymbol{\sigma}'\cdot\boldsymbol{\pi},n(\mathbf{r})\}_+ +C_2[\boldsymbol{\Sigma}\times\boldsymbol{\sigma}']\cdot\boldsymbol{\nabla}n(\mathbf{r})-2\beta\mu'C_2[\boldsymbol{\Sigma}\times\boldsymbol{\sigma}']\cdot\mathbf{E}n(\mathbf{r}))$$

$$+\frac{G^2}{2}n^2(\mathbf{r})[C_1^2+3C_2^2-2C_2(C_1+C_2)\boldsymbol{\Sigma}\cdot\boldsymbol{\sigma}']\Bigg\}^{1/2}. \tag{23}$$

Hence, the operator $U^{\pm}$ is expressed by formulas (18), (22), and (23). Although Eq. (23) is formally exact, the small terms proportional to C_1^2, C_1C_2, C_2^2 are wittingly negligible in the approximation of a small transferred momentum.

Formulas (17), (22), and (23) describe the exact Hamilton operator in the FW representation in the following particular cases:

(a) in the presence of only weak interaction ($\Phi=0,\mathbf{A}=0,\mathbf{E}=0,\mathbf{H}=0$);
(b) for Dirac particles ($\mu'=0$) in magnetic and weak fields ($\Phi=0,\mathbf{E}=0$);
(c) for uncharged particles with AMM in electric and weak fields ($e=0,\mathbf{A}=0,\mathbf{H}=0$);
(d) for particles with AMM moving in the plane orthogonal to a static uniform magnetic field ($\Phi=0,\mathbf{E}=0,P_z=0,C_1=C_2=0$);
(e) for uncharged particles with AMM moving in the plane orthogonal to a static uniform magnetic field. A static electric field (possibly nonuniform) is also orthogonal to the magnetic field ($e=0,\mathbf{E}\perp\mathbf{H},P_z=0,C_1=C_2=0$).

In two cases [(d) and (e)], $\mathbf{H}=H\mathbf{e}_z$, and in the case (e), the electric field strength does not depend on z. Otherwise, $\mathrm{rot}\,\mathbf{E}\neq 0$ and the magnetic field is not constant ($\partial\mathbf{H}/\partial t\neq 0$). Therefore, in these cases the operator $p_z=-i(\partial/\partial z)$ commutes with the Hamilton operator and has eigenvalues $P_z=\mathrm{const}$. Consequently, the consideration of the particular case $P_z=0$ is quite reasonable. All these cases satisfy condition (14).

Formulas (17), (22), and (23) agree with all exact expressions of the operator $\mathcal{H}'$ derived for uncharged particles with AMM in an electrostatic field, Dirac particles in a static magnetic field, and particles with AMM moving in the plane orthogonal to a static uniform magnetic field in Refs. 5, 7, 8. The weak interaction is not considered in these works.

VI. GENERAL CASE

In the general case, relativistic particles interact with external fields. We suggest performing the FW transformation in two stages. First, a transformation similar to the FW transformation for free particles is performed for particles in external fields. Second, a transformation similar to the FW transformation for nonrelativistic particles is carried out.

We assume that the external fields are not extremely strong and the transformed Hamiltonian can be expressed as a power series in the field potentials and their derivatives. The external fields can be nonstationary.

In the general case, formula (17) is not exact because $\mathcal{E}$ depends on the coordinates and contains Dirac matrices. We should calculate the commutator of the operators U and $\mathcal{E}-i(\partial/\partial t)$:

$$U\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)U^{-1}=\mathcal{E}-i\frac{\partial}{\partial t}+\left[U,\mathcal{E}-i\frac{\partial}{\partial t}\right]U^{-1}.$$

In this case, it is necessary to compute some commutators containing inverse operators and square roots of the operators. These commutators can be calculated using the following exact formulas which are valid for arbitrary operators A and B:[32]

$$[A^{-1},B]=A^{-1}[B,A]A^{-1}, \tag{24}$$

$$[A,B]=\tfrac{1}{4}\{A^{-1},[A^2,B]\}_+-\tfrac{1}{4}[[A,[A,B]],A^{-1}], \tag{25}$$

where $A^{-1}\equiv 1/A$ and $\{\ldots,\ldots\}_+$ stands for the anticommutator. If A is the square root of the operators and the commutator of the operators is small compared to their product, i.e.,

$$|[A,B]|\ll|AB|,$$

formulas (24) and (25) allow us to obtain the quantity $[A,B]$ with any accuracy by the method of successive approximations (see Ref. 32). As a rule, this condition is satisfied since it is equivalent to the inequality

$$\frac{\hbar c}{E}\ll l_c, \tag{26}$$

where E is the total energy including the rest energy and l_c is the characteristic size of the nonuniformity region of the external field. For the nonrelativistic particle, the quantity $\hbar c/E$ is equal to the Compton wavelength.

First, it is necessary to perform a unitary transformation with operator (18). After this operation, the Hamiltonian $\mathcal{H}'$ still contains odd terms proportional to the derivatives of the potentials. Let us write the operator $\mathcal{H}'$ as

$$\mathcal{H}'=\beta\epsilon+\mathcal{E}'+\mathcal{O}', \qquad \beta\mathcal{E}'=\mathcal{E}'\beta, \qquad \beta\mathcal{O}'=-\mathcal{O}'\beta, \tag{27}$$

where

$$\epsilon=\sqrt{m^2+\mathcal{O}^2},$$

$$\mathcal{E}'=i\frac{\partial}{\partial t}+\frac{\epsilon+m}{\sqrt{2\epsilon(\epsilon+m)}}\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\frac{\epsilon+m}{\sqrt{2\epsilon(\epsilon+m)}}-\frac{\beta\mathcal{O}}{\sqrt{2\epsilon(\epsilon+m)}}\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\frac{\beta\mathcal{O}}{\sqrt{2\epsilon(\epsilon+m)}}, \tag{28}$$

$$\mathcal{O}'=\frac{\beta\mathcal{O}}{\sqrt{2\epsilon(\epsilon+m)}}\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\frac{\epsilon+m}{\sqrt{2\epsilon(\epsilon+m)}}-\frac{\epsilon+m}{\sqrt{2\epsilon(\epsilon+m)}}\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\frac{\beta\mathcal{O}}{\sqrt{2\epsilon(\epsilon+m)}}.$$

Since

$$ABA=\tfrac{1}{2}(\{A^2,B\}_+-[A,[A,B]]),$$

relation (28) for the operator $\mathcal{E}'$ takes the form

$$\mathcal{E}'=\mathcal{E}-\frac{1}{4}\left[\frac{\epsilon+m}{\sqrt{\epsilon(\epsilon+m)}},\left[\frac{\epsilon+m}{\sqrt{\epsilon(\epsilon+m)}},\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\right]\right]+\frac{1}{4}\left[\frac{\beta\mathcal{O}}{\sqrt{\epsilon(\epsilon+m)}},\left[\frac{\beta\mathcal{O}}{\sqrt{\epsilon(\epsilon+m)}},\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\right]\right]. \tag{29}$$

The odd terms are small compared to both ϵ and the initial Hamiltonian $\mathcal{H}$. This circumstance allows us to apply the usual scheme of the nonrelativistic FW transformation.[1,20]

Second, the transformation should be performed with the following operator:

$$U'=\exp(iS'),\quad S'=-\frac{i}{4}\beta\left\{\mathcal{O}',\frac{1}{\epsilon}\right\}_+=-\frac{i}{4}\left[\frac{\beta}{\epsilon},\mathcal{O}'\right]. \tag{30}$$

The further calculations are similar to those given in Ref. 20. The particle mass should be replaced by the operator ϵ noncommuting with the operators $\mathcal{E}',\mathcal{O}'$. If only major corrections are taken into account, then the transformed Hamiltonian equals

$$\mathcal{H}''=\beta\epsilon+\mathcal{E}'+\frac{1}{4}\beta\left\{\mathcal{O}'^2,\frac{1}{\epsilon}\right\}_+. \tag{31}$$

This is the Hamiltonian in the FW representation.

To obtain the desired accuracy, the calculation procedure with the transformation operator (30) (S' is replaced by S'',S''', etc.) should be repeated multiply.

Let us calculate the Hamiltonian in the FW representation for the relativistic particle with AMM interacting with a nonstationary electroweak field. The Hamiltonian in the Dirac representation is defined by formulas (19)–(21). The transformed Hamiltonian is defined by Eq. (30), where the operator $\mathcal{O}'$ contains the field strengths and does not contain the field potentials. Let us deduce the Hamiltonian to within first-order terms in the field strengths and their first derivatives and second-order terms in the field potentials. The terms of the second order and higher in the field strengths and their derivatives and the first-order terms containing derivatives of the second order and higher of the field strengths will be omitted.

Since we neglect the second-order quantities in $\mathcal{O}'$, the operator $\mathcal{O}'$ does not make any contribution to the Hamiltonian $\mathcal{H}''$ at the second stage of transformation defined by formula (31). As a result, we obtain the following equation for the Hamiltonian in the FW representation:

$$\mathcal{H}''=\beta\epsilon+\mathcal{E}',$$

$$\begin{aligned}\mathcal{E}'=e\Phi&+\frac{e}{8}\left\{\frac{1}{\epsilon(\epsilon+m)},(\boldsymbol{\Sigma}\cdot[\boldsymbol{\pi}\times\mathbf{E}]-\boldsymbol{\Sigma}\cdot[\mathbf{E}\times\boldsymbol{\pi}]-\boldsymbol{\nabla}\cdot\mathbf{E})\right\}_+\\&+\frac{e}{32}\left\{\frac{2\epsilon^2+2\epsilon m+m^2}{\epsilon^4(\epsilon+m)^2},\boldsymbol{\pi}\cdot\boldsymbol{\nabla}(\boldsymbol{\pi}\cdot\mathbf{E}+\mathbf{E}\cdot\boldsymbol{\pi})\right\}_+\\&-\mu'\boldsymbol{\Pi}\cdot\mathbf{H}+\beta\frac{\mu'}{4}\left\{\frac{1}{\epsilon(\epsilon+m)},[(\mathbf{H}\cdot\boldsymbol{\pi})(\boldsymbol{\Sigma}\cdot\boldsymbol{\pi})+(\boldsymbol{\Sigma}\cdot\boldsymbol{\pi})(\boldsymbol{\pi}\cdot\mathbf{H})+2\pi(\boldsymbol{\pi}\cdot\mathbf{j}+\mathbf{j}\cdot\boldsymbol{\pi})]\right\}_+,\end{aligned} \tag{32}$$

where $\mathbf{j}=\boldsymbol{\nabla}\times\mathbf{H}-(1/4\pi)(\partial\mathbf{E}/\partial t)$ is the external current density, and ϵ is determined by formulas (23) and (27). It is important that the operators $\epsilon,\mathcal{E}'$ are found at the first stage, i.e., at the transformation with operator (18).

In the weak field approximation,

$$\epsilon=\epsilon'+\beta\frac{\mu'}{4}\left\{\frac{1}{\epsilon'},(\boldsymbol{\Sigma}\cdot[\boldsymbol{\pi}\times\mathbf{E}]-\boldsymbol{\Sigma}\cdot[\mathbf{E}\times\boldsymbol{\pi}]-\boldsymbol{\nabla}\cdot\mathbf{E})\right\}_+-\frac{e}{4}\left\{\frac{1}{\epsilon'},\boldsymbol{\Sigma}\cdot\mathbf{H}\right\}_++\frac{G}{4\sqrt{2}}\left\{\frac{1}{\epsilon'},W\right\}_+$$

and

$$\mathcal{H}''=\beta\epsilon'+e\Phi+\frac{1}{4}\left\{\left(\frac{\mu_0 m}{\epsilon'+m}+\mu'\right)\frac{1}{\epsilon'},(\mathbf{\Sigma}\cdot[\boldsymbol{\pi}\times\mathbf{E}]-\mathbf{\Sigma}\cdot[\mathbf{E}\times\boldsymbol{\pi}]-\boldsymbol{\nabla}\cdot\mathbf{E})\right\}_+$$
$$+\frac{\mu_0 m}{16}\left\{\frac{2\epsilon'^2+2\epsilon' m+m^2}{\epsilon'^4(\epsilon'+m)^2},\boldsymbol{\pi}\cdot\boldsymbol{\nabla}(\boldsymbol{\pi}\cdot\mathbf{E}+\mathbf{E}\cdot\boldsymbol{\pi})\right\}_+-\frac{1}{2}\left\{\left(\frac{\mu_0 m}{\epsilon'}+\mu'\right),\mathbf{\Pi}\cdot\mathbf{H}\right\}_+$$
$$+\frac{\mu'}{4}\left\{\frac{1}{\epsilon'(\epsilon'+m)},[(\mathbf{H}\cdot\boldsymbol{\pi})(\mathbf{\Pi}\cdot\boldsymbol{\pi})+(\mathbf{\Pi}\cdot\boldsymbol{\pi})(\boldsymbol{\pi}\cdot\mathbf{H})+2\pi(\boldsymbol{\pi}\cdot\mathbf{j}+\mathbf{j}\cdot\boldsymbol{\pi})]\right\}_+ +\frac{G}{4\sqrt{2}}\left\{\frac{1}{\epsilon'},W\right\}_+, \tag{33}$$

where

$$\epsilon'=\sqrt{m^2+\boldsymbol{\pi}^2},\qquad W=C_1\{\mathbf{\Sigma}\cdot\boldsymbol{\pi},n(\mathbf{r})\}_+-C_2\{\boldsymbol{\sigma}'\cdot\boldsymbol{\pi},n(\mathbf{r})\}_++C_2[\mathbf{\Sigma}\times\boldsymbol{\sigma}']\cdot\boldsymbol{\nabla}n(\mathbf{r}), \tag{34}$$

and $\mu_0=e/(2m)$ is the Dirac magnetic moment.

Unlike works,[9–11] formula (33) includes, as particular cases, the exact expressions for the Hamiltonian in the FW representation obtained in Refs. 5, 7, and 8. Formulas (32)–(34) also agree with the results obtained in Refs. 9, 10, 11, 33, and 34. A detailed analysis shows that the method of FW transformation used in Ref. 11 does not allow one to take into consideration the terms proportional to the double commutators of ϵ with $e\Phi$ and $\mu'\mathbf{\Pi}\cdot\mathbf{H}$ ($e[\epsilon,[\epsilon,\Phi]]$ and $\mu'[\epsilon,[\epsilon,\mathbf{\Pi}\cdot\mathbf{H}]]$). The terms proportional to $\mathbf{E}$ and $\mathbf{H}$ in the Hamiltonian obtained in Ref. 11 coincide with those in Refs. 9 and 10 and Eq. (33). However, only the Dirac particles were considered in Ref. 9, the derivatives of the field strengths were neglected in Ref. 10, and the nonrelativistic Hamiltonian with relativistic corrections was found in Ref. 33.

VII. PARTICLE AND SPIN MOTION EQUATIONS

Thus, the FW representation is very convenient for describing the particle and spin motion owing to the simple forms of operators. In order to derive corresponding quantum equations, it is necessary to compute the commutators of the Hamiltonian with the same operators as in the nonrelativistic theory. The kinetic momentum operator of particles in an electromagnetic field equals $\boldsymbol{\pi}=\mathbf{p}-e\mathbf{A}$.[35] The equation of particle motion in the electromagnetic field is defined in terms of the commutator of the Hamiltonian with this operator:

$$\frac{d\boldsymbol{\pi}}{dt}=i[\mathcal{H}'',\boldsymbol{\pi}]-e\frac{\partial\mathbf{A}}{dt}.$$

To determine the quantum equation of particle motion, we take into account Eq. (33) for the Hamiltonian,

$$\frac{d\boldsymbol{\pi}}{dt}=e\mathbf{E}+\beta\frac{e}{4}\left\{\frac{1}{\epsilon'},([\boldsymbol{\pi}\times\mathbf{H}]-[\mathbf{H}\times\boldsymbol{\pi}])\right\}_+$$
$$+\frac{1}{4}\left\{\left(\frac{\mu_0 m}{\epsilon'+m}+\mu'\right)\frac{1}{\epsilon'},[\boldsymbol{\nabla}(\mathbf{\Sigma}\cdot[\mathbf{E}\times\boldsymbol{\pi}])-\boldsymbol{\nabla}(\mathbf{\Sigma}\cdot[\boldsymbol{\pi}\times\mathbf{E}])+\Delta\mathbf{E}]\right\}_+$$
$$-\frac{\mu_0 m}{16}\left\{\frac{2\epsilon'^2+2\epsilon' m+m^2}{\epsilon'^4(\epsilon'+m)^2},(\boldsymbol{\pi}\cdot\boldsymbol{\nabla})\boldsymbol{\nabla}(\boldsymbol{\pi}\cdot\mathbf{E}+\mathbf{E}\cdot\boldsymbol{\pi})\right\}_+ +\frac{1}{2}\left\{\left(\frac{\mu_0 m}{\epsilon'}+\mu'\right),\boldsymbol{\nabla}(\mathbf{\Pi}\cdot\mathbf{H})\right\}_+$$
$$-\frac{\mu'}{4}\left\{\frac{1}{\epsilon'(\epsilon'+m)},[(\mathbf{\Pi}\cdot\boldsymbol{\pi})\boldsymbol{\nabla}(\boldsymbol{\pi}\cdot\mathbf{H})+(\boldsymbol{\nabla}(\mathbf{H}\cdot\boldsymbol{\pi}))(\mathbf{\Pi}\cdot\boldsymbol{\pi})+2\pi\boldsymbol{\nabla}(\boldsymbol{\pi}\cdot\mathbf{j}+\mathbf{j}\cdot\boldsymbol{\pi})]\right\}_+. \tag{35}$$

The equation of spin motion is defined by the formula

$$\frac{d\mathbf{\Pi}}{dt}=i[\mathcal{H}'',\mathbf{\Pi}].$$

For particles in a nonstationary electroweak field, it takes the form

$$\begin{aligned}\frac{d\mathbf{\Pi}}{dt}=&\left\{\left(\frac{\mu_0 m}{\epsilon'+m}+\mu'\right)\frac{1}{\epsilon'},[\mathbf{\Pi}\times[\mathbf{E}\times\boldsymbol{\pi}]]\right\}_+ +\left\{\left(\frac{\mu_0 m}{\epsilon'}+\mu'\right),[\mathbf{\Sigma}\times\mathbf{H}]\right\}_+\\ &-\frac{\mu'}{2}\left\{\frac{1}{\epsilon'(\epsilon'+m)},([\mathbf{\Sigma}\times\boldsymbol{\pi}](\boldsymbol{\pi}\cdot\mathbf{H})+(\mathbf{H}\cdot\boldsymbol{\pi})[\mathbf{\Sigma}\times\boldsymbol{\pi}])\right\}_+\\ &-\frac{G}{2\sqrt{2}}\left\{\frac{1}{\epsilon'},(C_1\{[\mathbf{\Sigma}\times\boldsymbol{\pi}],n(\mathbf{r})\}_+ +C_2[\mathbf{\Sigma}\times[\boldsymbol{\sigma}'\times\boldsymbol{\nabla}n(\mathbf{r})]])\right\}_+ .\end{aligned}\tag{36}$$

The corresponding equation for stationary electroweak fields was derived in Ref. 34.

The transition to the semiclassical description is also simple. For free particles, the lower spinor is equal to zero in the FW representation. For particles in external fields, the maximum ratio of the lower and upper spinors is of the first order of W_{int}/E, where W_{int} is the energy of the particle interaction with external fields. Thus, we obtain $(\chi^\dagger\chi)/(\phi^\dagger\phi)\sim(W_{\mathrm{int}}/E)^2$. Therefore, the contribution of the lower spinor is negligible and the transition to the semiclassical equations is performed by averaging the operators in the equations for the upper spinor. It is usually possible to neglect the commutators between the coordinate and kinetic momentum operators and between different components of the kinetic momentum operator (see Ref. 36). As a result, the operators $\boldsymbol{\sigma},\boldsymbol{\sigma}'$, and $\boldsymbol{\pi}$ should be substituted by the corresponding classical quantities: the average spin, $\boldsymbol{\xi}$ ($\boldsymbol{\xi}'$ for matter particles), and the kinetic momentum. For the latter quantity we retain the designation $\boldsymbol{\pi}$. The semiclassical equations of particle and spin motion are

$$\begin{aligned}\frac{d\boldsymbol{\pi}}{dt}=&e\mathbf{E}+\frac{e}{\epsilon'}[\boldsymbol{\pi}\times\mathbf{H}]-\frac{1}{2}\left(\frac{\mu_0 m}{\epsilon'+m}+\mu'\right)\frac{1}{\epsilon'}[2\boldsymbol{\nabla}(\boldsymbol{\xi}\cdot[\boldsymbol{\pi}\times\mathbf{E}])-\Delta\mathbf{E}]\\ &-\frac{\mu_0 m}{4}\cdot\frac{2\epsilon'^2+2\epsilon' m+m^2}{\epsilon'^4(\epsilon'+m)^2}(\boldsymbol{\pi}\cdot\boldsymbol{\nabla})\boldsymbol{\nabla}(\boldsymbol{\pi}\cdot\mathbf{E})+\left(\frac{\mu_0 m}{\epsilon'}+\mu'\right)\boldsymbol{\nabla}(\boldsymbol{\xi}\cdot\mathbf{H})\\ &-\frac{\mu'}{\epsilon'(\epsilon'+m)}[(\boldsymbol{\xi}\cdot\boldsymbol{\pi})\boldsymbol{\nabla}(\mathbf{H}\cdot\boldsymbol{\pi})+2\pi\boldsymbol{\nabla}(\mathbf{j}\cdot\boldsymbol{\pi})],\end{aligned}\tag{37}$$

$$\begin{aligned}\frac{d\boldsymbol{\xi}}{dt}=&2\left(\frac{\mu_0 m}{\epsilon'+m}+\mu'\right)\frac{1}{\epsilon'}[\boldsymbol{\xi}\times[\mathbf{E}\times\boldsymbol{\pi}]]+2\left(\frac{\mu_0 m}{\epsilon'}+\mu'\right)[\boldsymbol{\xi}\times\mathbf{H}]\\ &-\frac{2\mu'}{\epsilon'(\epsilon'+m)}(\mathbf{H}\cdot\boldsymbol{\pi})[\boldsymbol{\xi}\times\boldsymbol{\pi}]-\frac{G}{\sqrt{2}\epsilon'}(2C_1[\boldsymbol{\xi}\times\boldsymbol{\pi}]n(\mathbf{r})+C_2[\boldsymbol{\xi}\times[\boldsymbol{\xi}'\times\boldsymbol{\nabla}n(\mathbf{r})]]).\end{aligned}\tag{38}$$

Equation (37) shows that the particle motion depends on the spin orientation. The corresponding term determines the Stern–Gerlach force.

It is not as convenient to use the Dirac representation to derive quantum equations of particle and spin motion in a similar manner. In this case, it is necessary to extract the polarization operator, **O**, from the obtained equations. This problem is rather difficult because the operator **O** in the Dirac representation is defined by the cumbersome expression given in Ref. 17.

For particles in external fields, the FW transformation also changes the form of the kinetic momentum operator. In particular, the equation of spin motion in the Dirac representation depends on the operator $\boldsymbol{\pi}_{\mathrm{D}}=U^{-1}\boldsymbol{\pi}U$ just as the corresponding equation in the FW representation depends

on the operator $\boldsymbol{\pi}$. However, these two equations differ in their functional dependence on $\boldsymbol{\pi}$. The use of the FW representation protects from both an error in derived equations of particle and spin motion and an incorrect interpretation of these equations.

Another method of transition to the semiclassical description is based on the trajectory-coherent solution of the Dirac equation.[37]

VIII. DISCUSSION

As mentioned above, the proposed method permits obtaining a transformed Hamiltonian to within first-order terms in the field parameters after the first transformation. In this case, all the other canonical methods need several transformations.[1,5,6,10,12,20,21] Therefore, the method described above can be successfully used even for solving nonrelativistic problems. For this purpose, the transformation operator, U, can be expanded in a series of $1/m$. Of course, such an expansion is helpful only in the case of transformation of the operator $\mathcal{E}-i(\partial/\partial t)$. The transformation of other operators leads to the appearance of the term $\beta\epsilon$ in Eq. (31).

Consider the classical example of the FW transformation for a nonrelativistic Dirac particle in an electromagnetic field. We calculate the Hamiltonian to within terms of orders of $(p/m)^4$ and p^2W/m^3, where W means $e\Phi$, $e\mathbf{A}$ (see Refs. 1 and 20). In this approximation, the first double commutator in Eq. (29) is negligible and the second one is equal to

$$\frac{1}{4}\left[\frac{\beta\mathcal{O}}{\sqrt{2\epsilon(\epsilon+m)}},\left[\frac{\beta\mathcal{O}}{\sqrt{2\epsilon(\epsilon+m)}},\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\right]\right]=\frac{1}{2m^2}\left[\boldsymbol{\gamma}\cdot\boldsymbol{\pi},\left[\boldsymbol{\gamma}\cdot\boldsymbol{\pi},\left(\mathcal{E}-i\frac{\partial}{\partial t}\right)\right]\right]$$

$$=\frac{e}{2m^2}[\boldsymbol{\Sigma}\cdot(\mathbf{E}\times\boldsymbol{\pi})-\boldsymbol{\Sigma}\cdot(\boldsymbol{\pi}\times\mathbf{E})-\boldsymbol{\nabla}\cdot\mathbf{E}]. \quad (39)$$

As

$$\epsilon=\sqrt{m^2+(\boldsymbol{\alpha}\cdot\boldsymbol{\pi})^2}=\sqrt{m^2+\boldsymbol{\pi}^2-e\boldsymbol{\Sigma}\cdot\mathbf{H}}=m+\frac{\boldsymbol{\pi}^2}{2m}-\frac{\boldsymbol{\pi}^4}{8m^3}-\frac{e}{2m}\boldsymbol{\Sigma}\cdot\mathbf{H},$$

the transformed Hamiltonian is expressed by the well-known formula[1,20]

$$\mathcal{H}''=\beta\left(m+\frac{\boldsymbol{\pi}^2}{2m}-\frac{\boldsymbol{\pi}^4}{8m^3}\right)+e\Phi-\frac{e}{2m}\boldsymbol{\Pi}\cdot\mathbf{H}+\frac{e}{8m^2}[\boldsymbol{\Sigma}\cdot(\mathbf{E}\times\boldsymbol{\pi})-\boldsymbol{\Sigma}\cdot(\boldsymbol{\pi}\times\mathbf{E})-\boldsymbol{\nabla}\cdot\mathbf{E}]. \quad (40)$$

Thus, the proposed method permits obtaining this formula after the computation of only one double commutator. All the other canonical methods require cumbersome calculations.[1,5,12,20,21] For example, the classical method of Foldy and Wouthuysen require three successive transformations and a calculation of numerous commutators. The noncanonical methods (the Pauli's elimination method and others)[4,11,21–25] permit deriving Hamiltonian (40) in an easier way. Nevertheless, the proposed method is very simple even compared to them. Moreover, it gives an opportunity to find a transformed Hamiltonian with any accuracy even for relativistic particles in external fields.

IX. SUMMARY

In this work, a method of FW transformation for relativistic particles in external fields is proposed. This method is simple and reliable. It performs the exact FW transformation as in known particular cases,[5,7,8] as in others. This property distinguishes the proposed method from the other methods developed for relativistic particles.[9–11] The method is based on the well-known elaborations.[1,20] First, a transformation similar to the FW transformation for free particles is performed for particles in external fields. Second, a transformation similar to the FW transformation for nonrelativistic particles is carried out. In the general case, the FW transformation is

approximate. As an example, the Hamilton operator in the FW representation for relativistic particles with AMM interacting with nonstationary electroweak fields is found to within second derivatives of potentials.

Resolvent convergence in norm for Dirac operator with Aharonov–Bohm field

Hideo Tamura[a)]
Department of Mathematics, Okayama University, Okayama 700-8530, Japan

(Received 30 January 2003; accepted 10 April 2003)

We consider the Hamiltonian for relativistic particles moving in the Aharonov–Bohm magnetic field in two dimensions. The field has δ-like singularity at the origin, and the Hamiltonian is not necessarily essentially self-adjoint. The self-adjoint realization requires one parameter family of boundary conditions at the origin. We approximate the point-like field by smooth ones and study the problem of norm resolvent convergence to see which boundary condition is physically reasonable among admissible boundary conditions. We also study the effect of perturbations by scalar potentials. Roughly speaking, the obtained result is that the limit self-adjoint realization is different even for small perturbation of scalar potentials according to the values of magnetic fluxes. It changes at half-integer fluxes. The method is based on the resolvent analysis at low energy on magnetic Schrödinger operators with resonance at zero energy and the resonance plays an important role from a mathematical point of view. However it has been neglected in earlier physical works. The emphasis here is placed on this natural aspect. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1580200]

I. INTRODUCTION

The relativistic Hamiltonian of massless particle moving in the Aharonov–Bohm field is formally defined as the operator

$$H^D=\sigma_1\pi_1+\sigma_2\pi_2 \tag{1.1}$$

acting on the space $[L^2]^2=[L^2(\mathbf{R}^2)]^2$, where

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}$$

are the Pauli spin matrices and

$$\pi_j=-i\partial_j-a_{j\alpha},\quad A_{0\alpha}=(a_{1\alpha},a_{2\alpha})=\alpha(-x_2/|x|^2,x_1/|x|^2),\quad \partial_j=\partial/\partial x_j,$$

for $j=1,2$. For notational brevity, we here confine ourselves to the massless Hamiltonian H^D throughout the entire discussion. However, the obtained results easily extend to the Hamiltonian $\sigma_1\pi_1+\sigma_2\pi_2+m\beta$, $\beta=\sigma_3$, with mass $m>0$. Since the vector potential $A_{0\alpha}:\mathbf{R}^2\to\mathbf{R}^2$ is written as

$$A_{0\alpha}=\alpha(-\partial_2\log|x|,\partial_1\log|x|),$$

it has the point-like magnetic field

$$\nabla\times A_{0\alpha}=\partial_1 a_{2\alpha}-\partial_2 a_{1\alpha}=\alpha\Delta\log|x|=2\pi\alpha\delta(x)$$

a)Electronic mail: tamura@math.okayama-u.ac.jp

with flux α. Let $\theta=\theta(x)$ be the azimuth angle from the positive x_1 axis. Then $A_{0\alpha}$ takes the form $A_{0\alpha}=\alpha\nabla\theta$, and hence

$$H^D=e^{i\alpha\theta}(-i\sigma_1\partial_1-i\sigma_2\partial_2)e^{-i\alpha\theta}$$

in a formal way. When $\alpha\notin\mathbf{Z}$ is not an integer, $e^{i\alpha\theta}$ is a multivalued function, and the magnetic effect comes from the multivaluedness. We always assume that

$$0<\alpha<1. \tag{1.2}$$

If we replace $A_{0\alpha}(x)$ by $-A_{0\alpha}(x)$, it is easily seen that a similar argument applies to the case $-1<\alpha<0$ under a natural modification. However, if $|\alpha|>1$, then the norm resolvent convergence cannot be in general expected. We will later make a brief comment on the matter [Remarks 3.2 and 5.1 (3)]. According to Ref. 12 [see also (Refs. 7–9 and 19)], we know that H^D is not essentially self-adjoint in $[C_0^\infty(\mathbf{R}^2-\{0\})]^2$ and it has the deficiency indices (1,1). If $u\in[L^2]^2$ is in the domain of some self-adjoint extension, then it behaves like

$$u=\begin{pmatrix}(u_{-1}+o(1))r^{-\alpha}\\(u_{-2}+o(1))e^{i\theta}r^{-(1-\alpha)}\end{pmatrix}+o(1),\quad r=|x|\to 0, \tag{1.3}$$

for some pair (u_{-1},u_{-2}) in the polar coordinate system (r,θ) under assumption (1.2). The ratio $\kappa=iu_{-1}/u_{-2}$ can be shown to be a real number independent of u, and the self-adjoint extension H_κ has the domain

$$\mathcal{D}(H_\kappa)=\{u\in[L^2]^2:H^Du\in[L^2]^2,\quad u_{-1}+i\kappa u_{-2}=0\} \tag{1.4}$$

parametrized by κ, $-\infty<\kappa\leqslant\infty$, where

$$u_{-1}=\lim_{|x|\to 0}|x|^\alpha u_1(x),\quad u_{-2}=\lim_{|x|\to 0}|x|^{1-\alpha}e^{-i\theta}u_2(x)$$

for $u={}^t(u_1,u_2)\in[L^2]^2$, and H^Du is understood in the distribution sense. If $\kappa=\infty$, then $u_{-2}=0$ and the lower component has a weak singularity near the origin for $u\in\mathcal{D}(H_\infty)$, while the singularity of upper component is weak in the case $\kappa=0$. It is impossible to impose the boundary condition in which both components of wave functions remain bounded near the origin.

We approximate $2\pi\alpha\delta(x)$ by a smooth field with compact support. Let $b\in C_0^\infty(\mathbf{R}^2\to\mathbf{R})$ be given field with flux $\alpha=\int b(x)\,dx/2\pi$ and set

$$b_\varepsilon(x)=\varepsilon^{-2}b(x/\varepsilon)$$

for $\varepsilon>0$ small enough, where the integration without domain is taken over the whole space. Then b_ε preserves the flux $\int b_\varepsilon(x)\,dx=2\pi\alpha$ and it approximates $b_\varepsilon\to 2\pi\alpha\delta(x)$ as $\varepsilon\to 0$ in the distribution sense. We define the potential $A\in C^\infty(\mathbf{R}^2\to\mathbf{R}^2)$ associated with field b by

$$A(x)=(-\partial_2\varphi(x),\partial_1\varphi(x)) \tag{1.5}$$

and set $A_\varepsilon(x)=\varepsilon^{-1}A(x/\varepsilon)$, where

$$\varphi(x)=(2\pi)^{-1}\int \log|x-y|\,b(y)\,dy. \tag{1.6}$$

As is easily seen, A and A_ε satisfy $\nabla\times A=\Delta\varphi=b$ and $\nabla\times A_\varepsilon=b_\varepsilon$. We further define

$$H_\varepsilon^D=\sigma_1\nu_{1\varepsilon}+\sigma_2\nu_{2\varepsilon} \tag{1.7}$$

as the Hamiltonian approximating H^D, where $(\nu_{1\varepsilon},\nu_{2\varepsilon})=-i\nabla-A_\varepsilon$. This Hamiltonian admits a unique self-adjoint realization with domain $\mathcal{D}(H_\varepsilon^D)=[H^1(\mathbf{R}^2)]^2$, $H^s(\mathbf{R}^2)$ being the Sobolev space of order s. As the first main theorem (Theorem 3.1), we obtain that H_ε^D is convergent to H_∞ in the sense (norm resolvent sense) that

$$(H_\varepsilon^D+i)^{-1}\to(H_\infty+i)^{-1},\quad \varepsilon\to 0,$$

in norm. The attempt of approximation to point-like fields has been often done in physical literatures. For example, the approximation by the bounded potential

$$\tilde{A}(x)=\alpha(-x_2/|x|^2,x_1/|x|^2)\quad \text{on } \{|x|>1\},\quad \tilde{A}(x)=0\quad \text{on } \{|x|<1\}$$

has been studied in a series of works (Refs. 15, 16, and 18). A similar problem has been studied for the nonrelativistic particles. We write $L(p,q)=(-i\nabla-p)^2+q$ for the Schrödinger operator with vector and scalar potentials $p:\mathbf{R}^2\to\mathbf{R}^2$ and $q:\mathbf{R}^2\to\mathbf{R}$. Let $A_{0\alpha}$, A, and A_ε be as above. According to Refs. 1 and 11, $L(A_{0\alpha},0)$ is known to have the deficiency indices (2,2) as a symmetric operator over $C_0^\infty(\mathbf{R}^2-\{0\})$, and one of possible self-adjoint extensions has the domain

$$\mathcal{D}=\{u\in L^2: L(A_{0\alpha},0)u\in L^2,\quad \lim_{|x|\to 0}|u(x)|<\infty\}. \tag{1.8}$$

If $u\in\mathcal{D}$, then the wave function u remains bounded around the origin. This is not the case for the relativistic particles, as stated above. The self-adjoint operator with domain $\mathcal{D}$ is often called the Aharonov–Bohm Hamiltonian (Ref. 3) and we denote it by L_{AB}. We have proved in Ref. 22 that $L(A_\varepsilon,0)$ converges to L_{AB} in the norm resolvent sense. The difference between the nonrelativistic and relativistic cases can be explained as follows. Since the spin matrices satisfy the anticommutator relation $\sigma_j\sigma_k+\sigma_k\sigma_j=2\delta_{jk}$ and since $\sigma_1\sigma_2=i\sigma_3$ and

$$[\nu_{1\varepsilon},\nu_{2\varepsilon}]=\nu_{1\varepsilon}\nu_{2\varepsilon}-\nu_{2\varepsilon}\nu_{1\varepsilon}=ib_\varepsilon,$$

we take the square to obtain the Pauli operator

$$(H_\varepsilon^D)^2=\begin{pmatrix}\nu_{1\varepsilon}^2+\nu_{2\varepsilon}^2-b_\varepsilon & 0\\ 0 & \nu_{1\varepsilon}^2+\nu_{2\varepsilon}^2+b_\varepsilon\end{pmatrix}=\begin{pmatrix}L(A_\varepsilon,-b_\varepsilon) & 0\\ 0 & L(A_\varepsilon,b_\varepsilon)\end{pmatrix}.$$

Then $L(A_\varepsilon,\mp b_\varepsilon)$ have additional δ-like potentials $\mp b_\varepsilon\sim\mp 2\pi\alpha\delta(x)$ for $\varepsilon>0$ small enough. The repulsive potential b_ε makes the lower component vanish near the origin, but the attractive one $-b_\varepsilon$ makes the upper component singular.

We define the unitary operator $J_\varepsilon:L^2\to L^2$ or $[L^2]^2\to[L^2]^2$ by

$$(J_\varepsilon f)(x)=\varepsilon^{-1}f(x/\varepsilon). \tag{1.9}$$

Then we have $L(A_\varepsilon,\mp b_\varepsilon)=\varepsilon^{-2}J_\varepsilon L(A,\mp b)J_\varepsilon^*$ and

$$(L(A_\varepsilon,\mp b_\varepsilon)+1)^{-1}=\varepsilon^2 J_\varepsilon(L(A,\mp b)+\varepsilon^2)^{-1}J_\varepsilon^*.$$

Thus the proof of Theorem 3.1 is reduced to the analysis on the behavior of resolvent $(L(A,\mp b)+\varepsilon^2)^{-1}$ as $\varepsilon\to 0$. In particular, it is significant that $L(A,-b)$ has a resonance state at zero energy. We can represent $L(A,\pm b)$ as

$$L(A,\pm b)=\nu_\pm\nu_\mp=\nu_\mp^*\nu_\mp, \tag{1.10}$$

so that the operators are both non-negative, where $\nu_\pm=\nu_1\pm i\nu_2$ with $(\nu_1,\nu_2)=-i\nabla-A$. A simple calculation yields the relation

$$\nu_+=-ie^{-\varphi}(\partial_1+i\partial_2)e^{\varphi} \tag{1.11}$$

for φ defined by (1.6). Hence the equation $L(A,-b)u=0$ has a bounded solution behaving like

$$\tilde{\rho}=e^{-\varphi(x)}=|x|^{-\alpha}(1+O(|x|^{-1})), \quad |x|\to\infty.$$

Such a solution is called a resonance state. On the other hand, $L(A,b)$ can be shown to have no resonance state at zero energy. Thus the two operators $L(A,\pm b)$ have the different spectral property at zero energy. It seems that this essential aspect has not been recognized in earlier physical literatures.

We discuss the effect of perturbations by scalar potentials in the latter sections. The obtained result (Theorem 5.1) strongly depends on flux α, and the limit self-adjoint extension H_κ changes at $\alpha=1/2$. What is interesting is that it occurs even for small perturbation of scalar potentials. We set

$$V_\varepsilon(x)=\varepsilon^{-1}V(x/\varepsilon)$$

for $V\in C_0^\infty(\mathbf{R}^2\to\mathbf{R})$, and we define $H_\varepsilon(V_\varepsilon)$ by

$$H_\varepsilon(V_\varepsilon)=H_\varepsilon^D+V_\varepsilon=\sigma_1\nu_{1\varepsilon}+\sigma_2\nu_{2\varepsilon}+V_\varepsilon. \tag{1.12}$$

Roughly speaking, the operator $H+V=\sigma_1\nu_1+\sigma_2\nu_2+V$ is said to have a resonance state at zero energy, if the equation $(H+V)u=0$ admits a bounded but not square integrable solution. The precise definition is formulated in Sec. V (Definition 5.1). If $H+V$ do not have a resonance state at zero energy, then $H_\varepsilon(V_\varepsilon)$ is proved to converge to H_∞ for $0<\alpha<1/2$ and to H_0 for $1/2<\alpha<1$ in the norm resolvent sense. If $\alpha=1/2$, then $H_\varepsilon(V_\varepsilon)$ is convergent to H_κ for some κ determined from the above resonance state $\tilde{\rho}$ of $L(A,-b)$. If, on the other hand, $H+V$ has a resonance state at zero energy, then the situation is completely reversed. We obtain that $H_\varepsilon(V_\varepsilon)$ is convergent to H_0 for $0<\alpha\leqslant 1/2$ and to H_∞ for $1/2<\alpha<1$.

Our motivation of the study on the convergence to point-like fields comes from an application to the scattering of Dirac particles by magnetic fields (Refs. 2, 7, and 14). For example, the asymptotic behavior of the amplitude in the scattering by the small disk has been calculated under a certain impenetrable boundary condition in the book [Ref. 2 (Sec.7.10)]. The behavior changes discontinuously at half-integer fluxes. Another motivation is to study the scattering of Dirac particles by electromagnetic fields with small support in the interaction of cosmic string with matter (Ref. 7). The amplitude there has been also explicitly calculated for the electric potential of characteristic function of the small disk, and its asymptotic behavior has been shown to take a different form at half-integer fluxes as the support of electromagntic field shrinks. This phenomenon also seems to be closely related to the resonance at zero energy of magnetic Schrödinger operators. However, such a discontinuity at half-integer fluxes in the asymptotic form is completely hidden behind this explicit calculation using the Bessel functions. The argument developed here seems to account for this phenomenon partly. The present work is the first step toward analyzing this problem from a mathematical point of view.

The spectral problems for Dirac Hamiltonians with Aharonov–Bohm fields in two dimensions has been recently discussed from various aspects by several authors. For example, Sitenko (Ref. 21) has studied the vacuum polarization effects in the background of singular magnetic vortex for all self-adjoint extensions, and Falomir and Pisani (Ref. 13) have determined the spectrum in the presence of a uniform magnetic field.

II. KREIN THEORY ON SELF-ADJOINT EXTENSION

In this section we discuss the self-adjointness of the symmetric operator H^D defined by (1.1). This is defined as an operator acting on $[C_0^\infty(\mathbf{R}^2-\{0\})]^2$. We write

$$H^D=\begin{pmatrix} 0 & \pi_- \\ \pi_+ & 0 \end{pmatrix}, \quad \pi_\pm=\pi_1\pm i\,\pi_2,$$

and denote by $\overline{H^D}$ and $(H^D)^*$ the closure and adjoint of H^D in $[L^2]^2$. Let

$$\Sigma_\pm = \mathrm{Ker}\,((H^D)^* \mp i) = \{u \in [L^2]^2 : ((H^D)^* \mp i)u = 0\}.$$

The pair (n_+, n_-), $n_\pm = \dim \Sigma_\pm$, is called the deficiency indices of H^D. As is well known, H^D has self-adjoint extensions if and only if $n_+ = n_-$.

We shall show that $n_+ = n_- = 1$. Suppose that

$$((H^D)^* - i)u = 0, \quad u = {}^t(u_1, u_2) \in [L^2]^2. \tag{2.1}$$

Then u_2 satisfies

$$(\pi_+ \pi_- + 1)u_2 = (\pi_1^2 + \pi_2^2 + 1)u_2 = 0$$

in $\mathbf{R}^2 \setminus \{0\}$, and u_1 is given by $u_1 = -i\pi_- u_2$. The operator $\pi_\pm$ has the representation

$$\pi_+ = e^{i\theta}(-i\partial_r + r^{-1}(\partial_\theta - i\alpha)), \quad \pi_- = e^{-i\theta}(-i\partial_r - r^{-1}(\partial_\theta - i\alpha))$$

in terms of the polar coordinates (r, θ), and

$$\pi_1^2 + \pi_2^2 = (-i\nabla - A_{0\alpha})^2 = -\partial_r^2 - r^{-1}\partial_r + r^{-2}(-i\partial_\theta - \alpha)^2.$$

We write $H_\nu(z) = H_\nu^{(1)}(z)$ for the Hankel function of first kind. All Hankel functions are throughout understood to be of the first kind. Since

$$(z^\nu H_\nu(az))' = az^\nu H_{\nu-1}(az) \tag{2.2}$$

by formula, it follows that

$$(H_{1-\alpha}(ir)e^{i\theta}) = H'_{1-\alpha}(ir) - i(1-\alpha)r^{-1}H_{1-\alpha}(ir) = H_{-\alpha}(ir).$$

If we make use of this relation, then the solution $u \in [L^2]^2$ to (2.1) takes the form

$$u_2 = cH_{1-\alpha}(ir)e^{i\theta}, \quad u_1 = -icH_{-\alpha}(ir) = -ice^{i\alpha\pi}H_\alpha(ir)$$

with constant c. This is the solution corresponding to angular momentum $l = 0$. The solutions with momentum $l \geqslant 1$ are obtained by

$$u_2 = cH_{l+1-\alpha}(ir)e^{i(l+1)\theta}, \quad u_1 = -icH_{l-\alpha}(ir)e^{il\theta},$$

but these are not in $[L^2]^2$ because of the strong singularity near the origin. The same reasoning applies to solutions with momentum $l < 0$. Thus we see that $\Sigma_+ = \{u \in [L^2]^2 : u = c\psi_+\}$ is the one-dimensional space spanned by

$$\psi_+ = N_\alpha \begin{pmatrix} -i^{1+2\alpha}H_\alpha(ir) \\ H_{1-\alpha}(ir)e^{i\theta} \end{pmatrix}, \quad \|\psi_+\|_{L^2} = 1, \tag{2.3}$$

where

$$N_\alpha = (\sin \alpha\pi)^{1/2}/2. \tag{2.4}$$

The normalization constant N_α is calculated by use of the formula

$$2\pi \int_0^\infty r|H_\alpha(ir)|^2 \, \mathrm{d}r = 4\alpha/(\sin \alpha\pi).$$

Similarly $\Sigma_- = \{u \in [L^2]^2 : u = c\psi_-\}$ is spanned by

$$\psi_- = N_\alpha \begin{pmatrix} i^{1+2\alpha} H_\alpha(ir) \\ H_{1-\alpha}(ir) e^{i\theta} \end{pmatrix}, \quad \|\psi_-\|_{L^2} = 1, \tag{2.5}$$

with the same constant N_α.

The Krein theory determines a family of all possible self-adjoint extensions. According to Theorem X.2 and its Corollary of Ref. 20 there is a one-to-one correspondence between the unitary mapping $U:\Sigma_+ \to \Sigma_-$ and the self-adjoint extension H_U, which acts as

$$H_U u = \overline{H}^D v + i v_+ - i U v_+$$

on the domain $\mathcal{D}(H_U) = \{u \in [L^2]^2 : u = v + v_+ + U v_+, \ v \in \mathcal{D}(\overline{H}^D), \ v_+ \in \Sigma_+\}$.

Lemma 2.1: Let J be the isometry operator defined by

$$J = -(\overline{H}^D - i)(\overline{H}^D + i)^{-1} : \Sigma_+^\perp \to \Sigma_-^\perp$$

where $\Sigma_\pm^\perp = \mathrm{Ran}\,(\overline{H}^D \pm i)$ is the orthogonal complement of $\Sigma_\pm$. Then the resolvent $(H_U + i)^{-1}$ is represented as

$$(H_U + i)^{-1} = (1/2i)(1 + (U \oplus J)) : [L^2]^2 = \Sigma_+ \oplus \Sigma_+^\perp \to [L^2]^2 = \Sigma_- \oplus \Sigma_-^\perp .$$

Proof: Let $f \in [L^2]^2$ and set $u = (1/2i)(1 + (U \oplus J))f$. We decompose f into $f = h + g$, where $h \in \Sigma_+$ and $g \in \Sigma_+^\perp$. Then

$$u = (1/2i)((1 + J)g + (1 + U)h).$$

Since $g \in \Sigma_+^\perp = \mathrm{Ran}(\overline{H}^D + i)$, we can write $g = (\overline{H}^D + i)\tilde{g}$ for some $\tilde{g} \in \mathcal{D}(\overline{H}^D)$. Thus $(1 + J)g = 2i\tilde{g} \in \mathcal{D}(\overline{H}^D)$, and hence $u \in \mathcal{D}(H_U)$. We calculate

$$(H_U + i)u = (1/2i)((\overline{H}^D + i)(1 + J)g + (H_U + i)(1 + U)h).$$

Then we obtain $(H_U + i)u = g + h = f$, so that $u = (H_U + i)^{-1} f$. This proves the lemma. □

We examine what boundary condition H_U satisfies at the origin. When $\nu > 0$ is not an integer, $H_\nu(z)$ is represented as

$$H_\nu(z) = J_\nu(z) + i N_\nu(z) = (i/\sin \nu\pi)(e^{-i\nu\pi} J_\nu(z) - J_{-\nu}(z))$$

in terms of Bessel functions, and it obeys

$$H_\nu(z) = -(i/\sin \nu\pi)(1/\Gamma(1 - \nu))(z/2)^{-\nu}(1 + O(|z|^{2\nu}) + O(|z|^2)), \quad |z| \to 0.$$

We now use the abstract lemma in Ref. 20 (p.138). According to the notation there, we have

$$\mathcal{D}((H^D)^*) = \mathcal{D}(\overline{H}^D) \oplus_{\overline{H}^D} \Sigma_+ \oplus_{\overline{H}^D} \Sigma_- .$$

This implies that $v = {}^t(v_1, v_2) \in \mathcal{D}(\overline{H}^D)$ obeys

$$\int_0^{2\pi} v_1(r,\theta)\, \mathrm{d}\theta = o(r^{-\alpha}), \quad \int_0^{2\pi} v_2(r,\theta) e^{-i\theta}\, \mathrm{d}\theta = o(r^{-(1-\alpha)})$$

as $r = |x| \to 0$. The other Fourier coefficients vanish at the origin. Hence $u = {}^t(u_1, u_2) \in \mathcal{D}(H_U)$ satisfies

$$\int_0^{2\pi} u_1(r,\theta)\, \mathrm{d}\theta = 2\pi(u_{-1} + o(1)) r^{-\alpha}, \quad \int_0^{2\pi} u_2(r,\theta) e^{-i\theta}\, \mathrm{d}\theta = 2\pi(u_{-2} + o(1)) r^{-(1-\alpha)}$$

for some pair (u_{-1},u_{-2}) as in (1.3). The unitary mapping U acts as the multiplication $e^{i\zeta}\times$ for some ζ, $-\pi<\zeta\leqslant\pi$, between the one-dimensional spaces $\Sigma_{\pm}$. If we take account of the above behavior of Hankel functions, then the ratio $\kappa=iu_{-1}/u_{-2}$ is calculated as the real number

$$\kappa=(2^{2\alpha-1}\Gamma(\alpha)/\Gamma(1-\alpha))\tan(\zeta/2) \tag{2.6}$$

independent of $u\in\mathcal{D}(H_U)$. Thus we can obtain the family $\{H_\kappa\}$ of self-adjoint extensions with domain $\mathcal{D}(H_\kappa)$ parametrized as in (1.4). If $\zeta=\pi$ and hence $\kappa=\infty$, then

$$\mathcal{D}(H_\infty)=\{u={}^t(u_1,u_2)\in[L^2]^2:H^Du\in[L^2]^2,\quad \lim_{|x|\to 0}|x|^{1-\alpha}e^{-i\theta}u_2(x)=0\},$$

and if $\zeta=0$ and hence $\kappa=0$, then

$$\mathcal{D}(H_0)=\{u={}^t(u_1,u_2)\in[L^2]^2:H^Du\in[L^2]^2,\quad \lim_{|x|\to 0}|x|^{\alpha}u_1(x)=0\}.$$

Roughly speaking, only one component of Dirac wave functions has a weak singularity near the origin in the two special cases $\kappa=\infty$ and $\kappa=0$, while both the components have in general strong singularities in the other cases. Thus it is not allowed as a boundary condition that both the components remain bounded near the origin.

We denote by $(\ ,\ )_{L^2}$ the scalar product in L^2 or $[L^2]^2$. We write

$$f\otimes g=(\ \cdot\ ,g)_{L^2}f:L^2\to L^2$$

for the integral operator with kernel $f(x)\,\overline{g(y)}$, and use a similar notation for the operator $u\otimes v:[L^2]^2\to[L^2]^2$ defined by $(u\otimes v)w=(w,v)_{L^2}u$. This operator is represented in the matrix form

$$u\otimes v=(u_j\otimes v_k)_{1\leqslant j,k\leqslant 2},\quad u_j\otimes v_k:L^2\to L^2,$$

for $u={}^t(u_1,u_2)$ and $v={}^t(v_1,v_2)$ in $[L^2]^2$.

We end the section by deriving the relation between the two resolvents $(H_\kappa+i)^{-1}$ and $(H_\infty+i)^{-1}$. Since $U:\Sigma_+\to\Sigma_-$ takes the form $U=e^{i\zeta}(\psi_-\otimes\psi_+)$, it follows from Lemma 2.1 that

$$(H_\kappa+i)^{-1}-(H_{\kappa'}+i)^{-1}=(1/2i)(e^{i\zeta}-e^{i\zeta'})(\psi_-\otimes\psi_+),$$

where κ and κ' are related to ζ and ζ' through (2.6), respectively. If, in particular, $\zeta'=\pi$, then we obtain

$$(H_\kappa+i)^{-1}=(H_\infty+i)^{-1}+(1/2i)(e^{i\zeta}+1)(\psi_-\otimes\psi_+). \tag{2.7}$$

This relation plays a basic role in the future argument. This is a special case of the Krein formula between resolvents. We refer to Ref. 5 (Chap. VII) for the general Krein theory for self-adjoint extensions.

III. NORM RESOLVENT CONVERGENCE

We consider the problem as to which self-adjoint extension is realized as a norm resolvent limit of Hamiltonians with smooth magnetic fields having small support when the support is shrinking. Let H_ε^D be defined by (1.7). The aim here is to prove the following theorem.

Theorem 3.1: *Assume (1.2). Then H_ε^D is convergent to H_∞ in the norm resolvent sense as $\varepsilon\to 0$.*

Remark 3.1: The potential associated with given field $b\in C_0^\infty(\mathbf{R}^2\to\mathbf{R})$ is not uniquely determined. Let $\tilde{A}\in C^\infty(\mathbf{R}^2\to\mathbf{R}^2)$ be another potential having b as a field. Then it takes the form $\tilde{A}$

$=A+\nabla g$ with some $g\in C^\infty(\mathbf{R}^2\to\mathbf{R})$. If $g(x)\to 0$ at infinity, we can prove the norm resolvent convergence for $\tilde{A}_\varepsilon=\varepsilon^{-1}\tilde{A}(x/\varepsilon)$ also. This can be shown in the course of the proof of the theorem.

Before going into the proof, we fix the notation and introduce several auxiliary operators. We assume for brevity that the field $b\in C_0^\infty(\mathbf{R}^2\to\mathbf{R})$ has support in the unit disk. According to Ref. 22 (Lemma 2.1) [see (2.2) there], we can construct a potential $a\in C^\infty(\mathbf{R}^2\to\mathbf{R}^2)$ associated with field b such that

$$a(x)=(a_1(x),a_2(x))=A_{0\alpha}(x)=\alpha(-x_2/|x|^2,x_1/|x|^2) \tag{3.1}$$

for $|x|>2$. Then we define

$$p_j=-i\partial_j-a_j,\quad p_{j\varepsilon}=-i\partial_j-a_{j\varepsilon}$$

for $j=1,2$, and

$$K=\sigma_1 p_1+\sigma_2 p_2,\quad K_\varepsilon=\sigma_1 p_{1\varepsilon}+\sigma_2 p_{2\varepsilon},$$

where $a_\varepsilon(x)=\varepsilon^{-1}a(x/\varepsilon)=(a_{1\varepsilon}(x),a_{2\varepsilon}(x))$. Both K and K_ε are self-adjoint operators with domain $[H^1(\mathbf{R}^2)]^2$.

We again denote by $L(p,q)=(-i\nabla-p)^2+q$ the Schrödinger operator with vector potential p and scalar one q. According to this notation, we further define

$$L=L(a,0)=p_1^2+p_2^2,\quad L_\varepsilon=L(a_\varepsilon,0)=p_{1\varepsilon}^2+p_{2\varepsilon}^2 \tag{3.2}$$

and

$$L_\pm=L(a,\pm b)=p_1^2+p_2^2\pm b,\quad L_{\pm\varepsilon}=L(a_\varepsilon,\pm b_\varepsilon).$$

These are self-adjoint operators with domain $H^2(\mathbf{R}^2)$. If we set

$$p_\pm=p_1\pm ip_2,\quad p_{\pm\varepsilon}=p_{1\varepsilon}\pm ip_{2\varepsilon},$$

then $L_\pm=p_\pm p_\mp=p_\mp^* p_\mp$ and $L_{\pm\varepsilon}=p_{\pm\varepsilon}p_{\mp\varepsilon}$ as in (1.10). We can easily show

$$p_{+\varepsilon}(L_{-\varepsilon}+1)^{-1}=(L_{+\varepsilon}+1)^{-1}p_{+\varepsilon},\quad p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1}=(L_{-\varepsilon}+1)^{-1}p_{-\varepsilon} \tag{3.3}$$

and the resolvent $(K_\varepsilon+i)^{-1}$ is calculated as

$$(K_\varepsilon+i)^{-1}=\begin{pmatrix} -i(L_{-\varepsilon}+1)^{-1} & p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1} \\ (L_{+\varepsilon}+1)^{-1}p_{+\varepsilon} & -i(L_{+\varepsilon}+1)^{-1}\end{pmatrix}. \tag{3.4}$$

We now assert that

$$(K_\varepsilon+i)^{-1}\to(H_\infty+i)^{-1},\quad \varepsilon\to 0, \tag{3.5}$$

in norm. To prove the assertion, we analyze the behavior as $\varepsilon\to 0$ of $(L_{\pm\varepsilon}+1)^{-1}$. By (3.1), $a_\varepsilon(x)\to A_{0\alpha}(x)$ as $\varepsilon\to 0$ for $x\neq 0$, and hence we have

$$L_{\pm\varepsilon}\to L(A_{0\alpha},0)=(-i\nabla-A_{0\alpha})^2$$

on $C_0^\infty(\mathbf{R}^2-\{0\})$. As stated in Sec. I, the limit operator $L(A_{0\alpha},0)$ has the deficiency indices (2,2). The Krein theory yields a family $\{L_U\}$ of all possible self-adjoint extensions which is parametrized by 2×2 unitary mapping U from one deficiency subspace to the other one. The operator L_U is realized as a differential operator with some boundary conditions at the origin. If w belongs to $\mathcal{D}(L_U)$, then w behaves like

$$w=(w_{-0}r^{-\alpha}+w_{+0}r^{\alpha}+o(r^{\alpha}))+(w_{-1}r^{-(1-\alpha)}+w_{+1}r^{1-\alpha}+o(r^{1-\alpha}))e^{i\theta}+o(r)$$

near the origin for some coefficients $w_{\pm l}$, $l=0,1$, and there exist 2×2 matrices $B_{\pm}$ for which the boundary condition is described as the relation

$$B_{-}\begin{pmatrix} w_{-0} \\ w_{-1} \end{pmatrix}+B_{+}\begin{pmatrix} w_{+0} \\ w_{+1} \end{pmatrix}=0$$

between these four coefficients. For later references, we distinguish the two special operators among the family of self-adjoint extensions. One is the Aharonov–Bohm Hamiltonian L_{AB} with domain

$$\mathcal{D}(L_{AB})=\{w\in L^2: L(A_{0\alpha},0)w\in L^2, \quad w_{-0}=w_{-1}=0\}$$

and the other is L_Z with domain

$$\mathcal{D}(L_Z)=\{w\in L^2: L(A_{0\alpha},0)w\in L^2, \quad w_{+0}=w_{-1}=0\}.$$

Let $J_{\varepsilon}: L^2\to L^2$ be the unitary operator defined by (1.9). Then we have

$$(L_{\pm\varepsilon}+1)^{-1}=\varepsilon^2 J_{\varepsilon}(L_{\pm}+\varepsilon^2)^{-1}J_{\varepsilon}^{*},$$

so that the behavior as $\varepsilon\to 0$ of resolvents $(L_{\pm\varepsilon}+1)^{-1}$ strongly depends on the spectral structure of $L_{\pm}$ at low energy. We explain the resonance state at zero energy in some details. We have assumed in (1.2) that $0<\alpha<1$. Hence it follows from the Aharonov–Casher theorem (Ref. 4) that $L_{\pm}=p_{\mp}^{*}p_{\mp}$ has no bound states at zero energy. It should be noted that L_{-} has bound states in the case that $\alpha>1$, even if $L_{-}\geqslant 0$ is non-negative. The resonance space $E_{\pm}$ at zero energy of $L_{\pm}$ is defined by

$$E_{\pm}=\{u\in C^{\infty}(\mathbf{R}^2): L_{\pm}u=0, \quad u \text{ is bounded}\}.$$

We look at the structure of the resonance spaces. We consider E_{-} only. A similar reasoning applies to E_{+} also. We recall the facts obtained in Ref. 22 (Sec. V): (1) $\dim E_{-}\leqslant 2$. (2) If $\dim E_{-}=2$, then E_{-} is spanned by the linearly independent pair

$$e_l(x)=r^{-\nu}e^{il\theta}+g_l, \quad \nu=|l-\alpha|, \quad l=0,1,$$

where the remainder term $g_l\in L^2\cap C^{\infty}$ falls off like $\partial^{\beta}g_l=O(|x|^{-\nu-1-|\beta|})$. (3) If $\dim E_{-}=1$, then E_{-} is spanned by the linear combination

$$e(x)=c_l r^{-\alpha}+c_2 r^{-1+\alpha}e^{i\theta}+g, \quad |c_1|+|c_2|\neq 0,$$

where $g\in L^2\cap C^{\infty}$ obeys the bound as above at infinity. If $u\in E_{-}$, then

$$L_{-}u=p_{+}^{*}p_{+}u=p_1^2u+p_2^2u-bu=0, \quad b\in C_0^{\infty}(\mathbf{R}^2),$$

by definition, and we have by Lemma 4.3 in Ref. 22 (or by the argument used for its proof) that p_1u and p_2u are in L^2. This implies that $p_{\pm}u$ are also in L^2 and hence it follows by use of partial integration that $p_{+}u=0$ for $u\in E_{-}$. Let φ be defined by (1.6). The function φ behaves like $\varphi(x)=\alpha\log|x|+O(|x|^{-1})$ at infinity, so that $e^{\varphi(x)}=|x|^{\alpha}(1+O(|x|^{-1}))$. Recall that $a\in C^{\infty}(\mathbf{R}^2\to\mathbf{R}^2)$ has the property (3.1). The potential a takes the form

$$a=(-\partial_2\varphi(x),\partial_1\varphi(x))+\nabla h=A+\nabla h \tag{3.6}$$

for some $h\in C^{\infty}(\mathbf{R}^2\to\mathbf{R})$, where h obeys $h=O(|x|^{-1})$ at infinity. We can write

$$p_{+}=-ie^{ih}e^{-\varphi}(\partial_1+i\partial_2)e^{\varphi}e^{-ih} \tag{3.7}$$

as in (1.11) and similarly for $p_- = p_+^*$. Thus we see that $e^{\varphi} e^{-ih} u$ is an entire function for $u \in E_-$. This implies that $E_- = \{c\rho\}$ is the one-dimensional space spanned by $\rho = e^{ih} e^{-\varphi}$, and the resonance state ρ behaves like

$$\rho(x) = |x|^{-\alpha}(1 + O(|x|^{-1})), \quad |x| \to \infty. \tag{3.8}$$

On the other hand, we can show in a similar way that $\dim E_+ = 0$. If we take account of these facts, then Theorem 6.1 in Ref. 22 implies the following lemma.

Lemma 3.1: As $\varepsilon \to 0$, one has

$$(L_{+\varepsilon} + i)^{-1} \to (L_{AB} + i)^{-1}, \quad (L_{-\varepsilon} + i)^{-1} \to (L_Z + i)^{-1},$$

in norm.

Remark 3.2: If $\alpha > 1$, then it follows from the Aharonov–Casher theorem in Ref. 4 that L_- has the zero eigenvalue with multiplicity $[\alpha]$, $[\alpha]$ being the greatest integer not exceeding α. Hence $L_{-\varepsilon} = \varepsilon^{-2} J_\varepsilon L_- J_\varepsilon^*$ has also eigenstates at zero energy. But L_Z never has an eigenstate at zero energy. Thus $L_{-\varepsilon}$ is not convergent to L_Z in norm resolvent sense. It seems that $(L_{-\varepsilon} + i)^{-1}$ is strongly convergent to $(L_Z + i)^{-1}$, so that Theorem 3.1 remains true in the strong sense even for $\alpha > 1$. We do not go into the details here.

We calculate the resolvent $(H_\infty + i)^{-1}$. Consider the equation $(H_\infty + i)u = f$ for $f = {}^t(f_1, f_2) \in [C_0^\infty(\mathbf{R}^2 - \{0\})]^2$. Then $u = {}^t(u_1, u_2)$ satisfies

$$(L(A_{0\alpha}, 0) + 1)u_2 = \pi_+ f_1 - i f_2, \quad u_1 = i\pi_- u_2 - i f_1$$

for the Aharonov–Bohm potential $A_{0\alpha}(x)$. We see that $u \in \mathcal{D}(H_\infty)$ implies $u_2 \in \mathcal{D}(L_{AB})$. Thus $u_2 = (L_{AB} + 1)^{-1}(\pi_+ f_1 - i f_2)$ and

$$u_1 = -i(1 - \pi_-(L_{AB} + 1)^{-1}\pi_+) f_1 + \pi_-(L_{AB} + 1)^{-1} f_2,$$

so that we have

$$(H_\infty + i)^{-1} = \begin{pmatrix} i\pi_-(L_{AB} + 1)^{-1}\pi_+ - i & \pi_-(L_{AB} + 1)^{-1} \\ (L_{AB} + 1)^{-1}\pi_+ & -i(L_{AB} + 1)^{-1} \end{pmatrix}. \tag{3.9}$$

Lemma 3.2: One has the relation

$$1 - \pi_-(L_{AB} + 1)^{-1}\pi_+ = (L_Z + 1)^{-1}.$$

Proof: We note that the operator on the left-hand side of the relation is bounded. Let $f, g \in C_0^\infty(\mathbf{R}^2 - \{0\})$. By (3.1), there exists $\delta > 0$ such that $\pi_\pm f = p_{\pm\varepsilon} f$ and $\pi_\pm g = p_{\pm\varepsilon} g$ for $0 < \varepsilon < \delta$. Since

$$(\pi_-(L_{AB} + 1)^{-1}\pi_+ f, g)_{L^2} = \lim_{\varepsilon \to 0} ((L_{+\varepsilon} + 1)^{-1} p_{+\varepsilon} f, p_{+\varepsilon} g)_{L^2}$$

by Lemma 3.1, it follows from (3.3) that

$$((1 - \pi_-(L_{AB} + 1)^{-1}\pi_+) f, g)_{L^2} = \lim_{\varepsilon \to 0} ((L_{-\varepsilon} + 1)^{-1} f, g)_{L^2}.$$

This, together with Lemma 3.1 again, proves the lemma. □

We denote by $Op(\varepsilon^\nu)$ and $op(\varepsilon^\nu)$ the classes of bounded operators B_ε acting on L^2 or $[L^2]^2$ such that the operator norm of B_ε obeys the bound $\|B_\varepsilon\| = O(\varepsilon^\nu)$ and $\|B_\varepsilon\| = o(\varepsilon^\nu)$, respectively, as $\varepsilon \to 0$. We now prove Theorem 3.1, accepting the three lemmas below as proved. The proof of the lemmas is done in the next section.

Lemma 3.3: $\chi(L_+ + \varepsilon^2)^{-1}\chi = Op(\varepsilon^0)$ for $\chi \in C_0^\infty(\mathbf{R}^2 \to \mathbf{R})$.

Lemma 3.4: $p_{\pm\varepsilon}(L_{+\varepsilon}+1)^{-1}\to\pi_{\pm}(L_{AB}+1)^{-1}$ *in norm as* $\varepsilon\to 0$.

Lemma 3.5: $\chi(L_{-}+\varepsilon^2)^{-1}\chi=Op(\varepsilon^{-2\alpha})$ *for* $\chi\in C_0^{\infty}(\mathbf{R}^2\to\mathbf{R})$.

Proof of Theorem 3.1: We first prove (3.5). The two resolvents $(K_\varepsilon+i)^{-1}$ and $(H_\infty+i)^{-1}$ are represented by (3.4) and (3.9), respectively. If we use Lemma 3.2, then

$$(H_\infty+i)^{-1}=\begin{pmatrix} -i(L_Z+1)^{-1} & \pi_-(L_{AB}+1)^{-1} \\ (L_{AB}+1)^{-1}\pi_+ & -i(L_{AB}+1)^{-1}\end{pmatrix}.$$

By Lemma 3.4, we have $p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1}\to\pi_-(L_{AB}+1)^{-1}$ and

$$(L_{+\varepsilon}+1)^{-1}p_{+\varepsilon}=(p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1})^*\to(\pi_-(L_{AB}+1)^{-1})^*=(L_{AB}+1)^{-1}\pi_+ .$$

Hence Lemma 3.1 implies (3.5). Next we prove the norm resolvent convergence for the operator H_ε^D in question. Let $A\in C^\infty(\mathbf{R}^2\to\mathbf{R}^2)$ be defined by (1.5). Then $A=a-\nabla h$ by (3.6), and

$$(H_\varepsilon^D+i)^{-1}=\exp(-ih_\varepsilon)(K_\varepsilon+i)^{-1}\exp(ih_\varepsilon),$$

where $h_\varepsilon(x)=h(x/\varepsilon)$. By definition, $K=\varepsilon J_\varepsilon^* K_\varepsilon J_\varepsilon$ is independent of ε. We have

$$(K+i\varepsilon)^{-1}=\begin{pmatrix} -i\varepsilon(L_-+\varepsilon^2)^{-1} & p_-(L_++\varepsilon^2)^{-1} \\ (L_{+\varepsilon}+\varepsilon^2)^{-1}p_+ & -i\varepsilon(L_++\varepsilon^2)^{-1}\end{pmatrix} \tag{3.10}$$

and $(K_\varepsilon+i)^{-1}=\varepsilon J_\varepsilon(K+i\varepsilon)^{-1}J_\varepsilon^*$. For any $\delta>0$ small enough, we can take $M>0$ so large that $|h_\varepsilon(x)|<\delta$ for $|x|\geqslant\varepsilon M$, and hence $|\exp(\pm ih_\varepsilon)-1|<2\delta$ for x as above. On the other hand, we can prove that

$$\varepsilon\|\chi_M(K+i\varepsilon)^{-1}\chi_M\|=O(\varepsilon)+O(\varepsilon^{2(1-\alpha)})$$

for the characteristic function χ_M of $\{|x|<M\}$. In fact, Lemma 3.3 yields

$$\|\chi_M(L_++i\varepsilon^2)^{-1}p_+\chi_M\|+\|\chi_M p_-(L_++i\varepsilon^2)^{-1}\chi_M\|=O(1),\quad \varepsilon\to 0,$$

by elliptic estimate. Note that $\chi_{\varepsilon M}=J_\varepsilon\chi_M J_\varepsilon^*$ for $\chi_{\varepsilon M}(x)=\chi_M(x/\varepsilon)$. Hence

$$\begin{aligned}\|(K_\varepsilon+i)^{-1}\chi_{\varepsilon M}\|^2&=\|(K_\varepsilon+i)^{-1}J_\varepsilon\chi_M\|^2\\ &=\|\chi_M J_\varepsilon^*(K_\varepsilon-i)^{-1}(K_\varepsilon+i)^{-1}J_\varepsilon\chi_M\|\\ &=O(\varepsilon)\,\|\chi_M((K+i\varepsilon)^{-1}-(K-i\varepsilon)^{-1})\chi_M\|\to 0\end{aligned}$$

by Lemmas 3.3 and 3.5, and also $\|(H_\varepsilon^D+i)^{-1}\chi_{\varepsilon M}\|\to 0$ by gauge transformation. Thus we obtain

$$\|(H_\varepsilon^D+i)^{-1}-(K_\varepsilon+i)^{-1}\|\to 0.$$

This, together with (3.5), completes the proof. □

IV. RESOLVENT ANALYSIS AT LOW ENERGY ON SCHRÖDINGER OPERATORS I

We shall prove Lemmas 3.3, 3.4, and 3.5 which remain unproved. Throughout the section, we denote by $\chi\in C_0^\infty(\mathbf{R}^2\to\mathbf{R})$ a real function such that $\operatorname{supp}\chi\subset B_M$ and $\chi=1$ on $B_{M/2}$, where $B_M=\{|x|<M\}$ for $M\gg 1$ fixed arbitrarily. We further denote by $k\in\mathbf{C}$ a small complex number with $\operatorname{Im}k>0$.

Let $L=L(a,0)$ be as in (3.2). We first make a brief review on the spectral property of L from Ref. 22. Let $L_c^2=\{u\in L^2:\operatorname{supp}u\subset B_M\}$ be the space of L^2 functions with support in B_M. Then we know that there exists a limit

$$G_0 = \lim_{k\to 0} (L-k^2)^{-1}$$

and the limit operator $G_0: L^2_c \to L^2_{-1}$ is bounded into the weighted L^2 space $L^2_{-1} = L^2(\mathbf{R}^2; \langle x\rangle^{-2}\,dx)$, where $\langle x\rangle = (1+|x|^2)^{1/2}$. By (3.1), L coincides with

$$L = L(A_{0\alpha}, 0) = -\partial_r^2 - r^{-1}\partial_r + r^{-2}(-i\partial_\theta - \alpha)^2$$

on $\{|x|>2\}$, and hence $u_l(x) = r^\nu e^{il\theta}$, $\nu = |l-\alpha|$, satisfies $Lu_l = 0$ there. If we define ω_l by

$$\omega_l = c_l(1-\chi)u_l + c_l G_0[L,\chi]u_l, \quad c_l = (l+\nu)^{1/2}/2\nu, \tag{4.1}$$

for $l = 0,1$, then ω_l behaves like

$$\omega_l = c_l r^\nu e^{il\theta} + O(1) \tag{4.2}$$

as $r = |x| \to \infty$, and it solves $L\omega_l = 0$. Such a solution is shown to be unique [see Ref. 22 (Lemma 4.3)]. The argument here is based on the proposition below, which has been proved as Proposition 4.2 in Ref. 22.

Proposition 4.1: Let the notation be as above and let $\nu = |l-\alpha|$ again. Then

$$\chi(L-k^2)^{-1}\chi = \chi G_0 \chi + \sum_{l=0,1} \gamma_l(k) i^{-2\nu} k^{2\nu} (\chi\omega_l \otimes \chi\omega_l) + Op(|k|^2), \quad |k| \to 0,$$

for some coefficients $\gamma_l(k)$, and $\gamma_l(k)$ behaves like

$$\gamma_l(k) = \gamma_l + o(1) \tag{4.3}$$

as $|k| \to 0$, where

$$\gamma_l = -(2^{1-2\nu}\Gamma(1-\nu))/((l+\nu)\Gamma(\nu)). \tag{4.4}$$

The precise value of γ_l is not required to prove the lemmas, but it is important in studying the effect of perturbation by scalar potentials in the latter sections.

Next we consider the operator $L_+ = L(a,b) = L + b$. We shall show that $(L_+ - k^2)^{-1}$ admits an expansion similar to that in Proposition 4.1. We have the relation

$$(L_+ - k^2)^{-1} = (L-k^2)^{-1}(1 + b(L-k^2)^{-1})^{-1} \tag{4.5}$$

by the resolvent identity. Since L_+ has neither bound states nor resonance states at zero energy, $1 + bG_0: L^2_c \to L^2_c$ has the bounded inverse

$$T = (1 + bG_0)^{-1}: L^2_c \to L^2_c.$$

We see that there exists a limit

$$G_+ = \lim_{k\to 0} (L_+ - k^2)^{-1}$$

and the limit operator $G_+ = G_0 T: L^2_c \to L^2_{-1}$ is bounded. The inverse T is represented as

$$T = LG_+ = 1 - bG_+ : L^2_c \to L^2_c \tag{4.6}$$

and it follows that the adjoint operator $T^* = 1 - G_+ b: L^2_{\mathrm{loc}} \to L^2_{\mathrm{loc}}$ is well defined as an operator from the space L^2_{loc} of locally square integrable functions into itself. If we define

$$\omega_{+l} = T^*\omega_l = \omega_l - G_+ b\omega_l \tag{4.7}$$

for $l=0,1$, then ω_{+l} solves $L_+\omega_{+l}=0$ and obeys (4.2) at infinity.

Proposition 4.2: Let the notation be as above. Then

$$\chi(L_+-k^2)^{-1}\chi=\chi G_+\chi+\sum_{l=0,1}\gamma_{+l}(k)i^{-2\nu}k^{2\nu}(\chi\omega_{+l}\otimes\chi\omega_{+l})+Op(|k|^2)$$

for some coefficients $\gamma_{+l}(k)$ *obeying* $\gamma_{+l}(k)=\gamma_l+o(1)$ *as in Proposition 4.1.*

Proof: We start with the relation

$$\chi(L_+-k^2)^{-1}\chi=\chi(L-k^2)^{-1}(1+b(L-k^2)^{-1})^{-1}\chi$$

obtained from (4.5). Set

$$E(k)=\sum_{l=0,1}\gamma_l(k)i^{-2\nu}k^{2\nu}(\omega_l\otimes\omega_l):L^2_c\to L^2_{\mathrm{loc}}.$$

Then we have

$$(1+b(L-k^2)^{-1})^{-1}=(1+TbE(k))^{-1}T+Op(|k|^2)$$

by Proposition 4.1, and hence $(L_+-k^2)^{-1}$ is expanded as

$$\chi(L_+-k^2)^{-1}\chi=G_1+G_2(k)+Op(|k|^2),$$

where $G_1=\chi G_0T\chi=\chi G_+\chi$ and

$$G_2(k)=\chi E(k)(1+TbE(k))^{-1}T\chi+\chi G_0((1+TbE(k))^{-1}-1)T\chi.$$

We can calculate $G_2(k)$ as

$$G_2(k)=\chi(1-G_0Tb)E(k)(1+TbE(k))^{-1}T\chi=\chi T^*E(k)\left(\sum_{j=0}^{\infty}(-1)^j(TbE(k))^j\right)T\chi.$$

Hence it follows from (4.7) that

$$G_2(k)=\sum_{0\leqslant l,m\leqslant 1}\gamma_{lm}(k)(\chi\omega_{+l}\otimes\chi\omega_{+m})$$

for some 2×2 matrix $(\gamma_{lm}(k))_{0\leqslant l,m\leqslant 1}$. The components obey $\gamma_{lm}(k)=O(|k|^2)$ for $l\neq m$, and $\gamma_{ll}(k)=\gamma_l i^{-2\nu}k^{2\nu}(1+o(1))$. This completes the proof. □

Proof of Lemma 3.3: The lemma follows from Proposition 4.2. □

Proof of Lemma 3.4: We have

$$\chi((L_++i\varepsilon^2)^{-1}-(L_+-i\varepsilon^2)^{-1})\chi=Op(\varepsilon^{2\alpha})+Op(\varepsilon^{2(1-\alpha)})$$

by Proposition 4.2. Since $J_\varepsilon^*(L_{+\varepsilon}+i)^{-1}J_\varepsilon=\varepsilon^2(L_++i\varepsilon^2)^{-1}$, it follows that

$$\|\chi_\varepsilon(L_{+\varepsilon}+i)^{-1}\|^2=\|\chi J_\varepsilon^*(L_{+\varepsilon}+i)^{-1}(L_{+\varepsilon}-i)^{-1}J_\varepsilon\chi\|=O(\varepsilon^{2+2\alpha})+O(\varepsilon^{2+2(1-\alpha)}),$$

where $\chi_\varepsilon(x)=\chi(x/\varepsilon)$. Hence

$$\|\chi_\varepsilon(L_{+\varepsilon}+1)^{-1}\|=O(\varepsilon^{1+\alpha})+O(\varepsilon^{1+(1-\alpha)}).$$

If we set $u_\varepsilon=(L_{+\varepsilon}+1)^{-1}f$ for $f\in L^2$, then u_ε satisfies the equation

$$(L_{+\varepsilon}+1)u_\varepsilon=(p_{1\varepsilon}^2+p_{2\varepsilon}^2)u_\varepsilon+b_\varepsilon u_\varepsilon+u_\varepsilon=f$$

and obeys the bound

$$\|\chi_\varepsilon u_\varepsilon\|_{L^2}=(O(\varepsilon^{1+\alpha})+O(\varepsilon^{1+(1-\alpha)}))\|f\|_{L^2}. \tag{4.8}$$

Thus we have

$$\|\chi_\varepsilon p_{j\varepsilon} u_\varepsilon\|_{L^2}=(O(\varepsilon^{\alpha})+O(\varepsilon^{1-\alpha}))\|f\|_{L^2} \tag{4.9}$$

by elliptic estimate. A similar argument applies to $v=(L_{AB}+1)^{-1}f$. Note that

$$J_\varepsilon^*(L_{AB}+1)^{-1}J_\varepsilon=\varepsilon^2(L_{AB}+\varepsilon^2)^{-1}.$$

The Green kernel of $(L_{AB}-k^2)^{-1}$ is explicitly represented in terms of the Bessel functions after separation into the polar coordinates, and it admits an expansion similar to $(L_+-k^2)^{-1}$. Thus we obtain

$$\|\chi_\varepsilon v\|_{L^2}=(O(\varepsilon^{1+\alpha})+O(\varepsilon^{1+(1-\alpha)}))\|f\|_{L^2} \tag{4.10}$$

and

$$\|\chi_\varepsilon \pi_j v\|_{L^2}=(O(\varepsilon^{\alpha})+O(\varepsilon^{1-\alpha}))\|f\|_{L^2}. \tag{4.11}$$

By (3.1), $p_j=\pi_j$ on $\{|x|>2\}$, so that $(1-\chi_\varepsilon)(\pi_j-p_{j\varepsilon})=0$. Since $\chi_\varepsilon=1$ on $\operatorname{supp} b_\varepsilon$, $w_\varepsilon=u_\varepsilon-v$ satisfies

$$(1-\chi_\varepsilon)(p_{1\varepsilon}^2+p_{2\varepsilon}^2+1)w_\varepsilon=0$$

and it follows from (4.8) and (4.10) that

$$\|(1-\chi_\varepsilon)p_{j\varepsilon}w_\varepsilon\|_{L^2}=(O(\varepsilon^{\alpha})+O(\varepsilon^{1-\alpha}))\|f\|_{L^2}.$$

This, together with (4.9) and (4.11), yields

$$\|p_{j\varepsilon}(L_{+\varepsilon}+1)^{-1}-\pi_j(L_{AB}+1)^{-1}\|=O(\varepsilon^{\alpha})+O(\varepsilon^{1-\alpha})$$

and the proof is complete. □

We move to the proof of Lemma 3.5. We analyze the behavior as $|k|\to 0$ of $(L_--k^2)^{-1}$. Decompose b into the product $b=b^{1/2}|b|^{1/2}$, where $b^{1/2}=|b|^{1/2}\operatorname{sgn} b$ with $\operatorname{sgn} b=b/|b|$. Then we have

$$(L_--k^2)^{-1}=(L-k^2)^{-1}+(L-k^2)^{-1}|b|^{1/2}Z(k)^{-1}b^{1/2}(L-k^2)^{-1} \tag{4.12}$$

by repeated use of the resolvent identity, where

$$Z(k)=1-b^{1/2}(L-k^2)^{-1}|b|^{1/2}.$$

Since L_- has a resonance state at zero energy, $1-b^{1/2}G_0|b|^{1/2}:L^2\to L^2$ is not invertible. Let

$$X=\{v\in L^2: v=b^{1/2}G_0|b|^{1/2}v\}.$$

According to Ref. 22, $\dim X=1$, and $v\in X$, $v\neq 0$, satisfies $(v,|b|^{1/2}\omega_0)_{L^2}\neq 0$ and $(v,|b|^{1/2}\omega_1)_{L^2}=0$ for ω_l defined by (4.1). We normalize $\eta_0\in X$ as

$$(\eta_0,|b|^{1/2}\omega_0)_{L^2}=1,\quad (\eta_0,|b|^{1/2}\omega_1)_{L^2}=0 \tag{4.13}$$

and define

$$\rho_0=G_0|b|^{1/2}\eta_0. \tag{4.14}$$

Then ρ_0 solves $L_-\rho_0=0$ and behaves like

$$\rho_0(x)=(2\pi\alpha)^{-1/2}r^{-\alpha}+g, \quad r\to\infty, \tag{4.15}$$

with some $g\in L^2$ [see (5.8) and (5.9) in Ref. 22]. Thus ρ_0 spans the resonance space E_- of L_- at zero energy, because $\dim E_-=1$ as shown already in Sec. III.

Proposition 4.3: Let $\rho_0\in E_-$ be the resonance state defined above. Then

$$\chi(L_--k^2)^{-1}\chi=\gamma_-(k)i^{2\alpha}k^{-2\alpha}(\chi\rho_0\otimes\chi\rho_0)+Op(|k|^0), \quad |k|\to 0,$$

for some coefficient $\gamma_-(k)$ obeying $\gamma_-(k)=-1/\gamma_0+o(1)$, γ_0 being as in (4.4).

Proof: For brevity, we prove the lemma when $b(x)\geqslant 0$. If $b(x)$ is not non-negative, $b^{1/2}G_0|b|^{1/2}$ is not necessarily self-adjoint. The argument below undergoes a slight change, but it is not serious. We skip the detail. Let Q_0 and Q be the orthogonal projections defined by $Q_0=\eta_1\otimes\eta_1$ and $Q=1-Q_0$, where $\eta_1=\eta_0/\|\eta_0\|_{L^2}$. Since $1-b^{1/2}G_0b^{1/2}$:Ran $Q\to$Ran Q is invertible and since

$$Q_0((b^{1/2}\omega_1)\otimes(b^{1/2}\omega_1))=((b^{1/2}\omega_1)\otimes(b^{1/2}\omega_1))Q_0=0$$

by (4.13), it follows from Proposition 4.1 that the inverse $Z(k)^{-1}$ takes the form

$$Z(k)^{-1}=\gamma(k)i^{2\alpha}k^{-2\alpha}(\eta_0\otimes\eta_0)+Op(|k|^0)$$

for some coefficient $\gamma(k)$ having the property in the proposition. This yields the relation. □

Proof of Lemma 3.5: The lemma follows from Proposition 4.3. □

Remark 4.1: Proposition 4.1 remains true for $\chi\nabla(L-k^2)^{-1}\chi$. For example, we have

$$\chi\nabla(L-k^2)^{-1}\chi=\chi\nabla G_0\chi+\sum_{l=0,1}\gamma_l(k)i^{-2\nu}k^{2\nu}(\chi\nabla\omega_l\otimes\chi\omega_l)+Op(|k|^2).$$

This follows by elliptic estimate. A similar relation is true for $(L_+-k^2)^{-1}$ in Proposition 4.2.

We end the section by making a brief comment on the limit as $\varepsilon\to 0$ of the resolvent $(K\pm i\varepsilon)^{-1}$ calculated in (3.10). We formally write $(K\pm i0)^{-1}$ for the limit $\lim_{\varepsilon\to 0}(K\pm i\varepsilon)^{-1}$. If we combine (3.10) with Propositions 4.2, 4.3 and Remark 4.1, then we see that these limits have the different properties according as $0<\alpha<1/2$, $\alpha=1/2$ or $1/2<\alpha<1$:

$$\text{if} \quad 0<\alpha<1/2, \quad (K\pm i0)^{-1} \quad \text{exists and} \quad (K+i0)^{-1}=(K-i0)^{-1},$$

$$\text{if} \quad \alpha=1/2, \quad (K\pm i0)^{-1} \quad \text{exists but} \quad (K+i0)^{-1}\neq(K-i0)^{-1},$$

$$\text{if} \quad 1/2<\alpha<1, \quad (K\pm i0)^{-1} \quad \text{does not exist.}$$

It is obvious by gauge transformation that $H=\sigma_1\nu_1+\sigma_2\nu_2$ preserves the same property as above. This means that H has a property similar to the three dimensional Laplacian for the case $0<\alpha<1/2$ and to the one- or two-dimensional Laplacian for the case $1/2<\alpha<1$.

V. EFFECT OF SCALAR POTENTIALS AND RESONANCE STATE

The remaining three sections are devoted to the study on the effect of perturbation by scalar potentials. We assume that $V\in C_0^\infty(\mathbf{R}^2\to\mathbf{R})$ satisfies

$$\lambda_0=(V\rho_0,\rho_0)_{L^2}\neq 0 \tag{5.1}$$

for ρ_0 spanning the resonance space of L_- at zero energy. We set $V_\varepsilon(x)=\varepsilon^{-1}V(x/\varepsilon)$ and define $K_\varepsilon(V_\varepsilon)$ by

$$K_\varepsilon(V_\varepsilon)=K_\varepsilon+V_\varepsilon=\sigma_1 p_{1\varepsilon}+\sigma_2 p_{2\varepsilon}+V_\varepsilon,$$

which is self-adjoint with domain $\mathcal{D}(K_\varepsilon(V_\varepsilon))=[H^1(\mathbf{R}^2)]^2$. We study the norm resolvent convergence for this Hamiltonian. The obtained result is invariant under gauge transformations. In particular, it remains true for the Hamiltonian $H_\varepsilon^D+V_\varepsilon$.

We define the resonance state at zero energy of the operator

$$K+V=\sigma_1 p_1+\sigma_2 p_2+V=\sum_{j=1}^{2}\sigma_j(-i\partial_j-a_j)+V$$

before formulating the result. The definition is different according as $0<\alpha\leqslant 1/2$ or $1/2<\alpha<1$. By (3.7), we have $p_+=-2i\,e^{ih}e^{-\varphi}\overline{\partial}e^{\varphi}e^{-ih}$, where $\overline{\partial}=(1/2)(\partial_1+i\partial_2)$. The Cauchy–Riemann operator $\overline{\partial}$ has the fundamental solution $(1/\pi)(x_1+ix_2)^{-1}$. We denote by $\overline{\partial}^{-1}$ the convolution operator

$$\overline{\partial}^{-1}=(1/\pi)\,(x_1+ix_2)^{-1}*.$$

According to this notation, we define

$$p_+^{-1}=-(2i)^{-1}e^{ih}e^{-\varphi}\overline{\partial}^{-1}e^{\varphi}e^{-ih}$$

and $p_-^{-1}=(p_+^{-1})^*$. By definition, we have $p_\pm p_\pm^{-1}=1$.

Lemma 5.1: One has the relations

$$p_-G_+=p_+^{-1},\quad G_+p_+=p_-^{-1}$$

on bounded functions with compact support.

Proof: We prove only the first relation. The second one follows by taking the adjoint. We set $w_1=p_+^{-1}f$ for a function f as in the lemma. Then $w_1\in L^2$ and it solves $p_+w_1=f$. If, on the other hand, we set $w_2=p_-G_+f\in L^2_{-1}$, then w_2 satisfies

$$p_+w_2=p_+p_-G_+f=L_+G_+f=f$$

and $w_2\in L^2$. In fact, we have $\|p_-G_+f\|_{L^2}<\infty$ by a simple use of partial integration. Set $w=e^{\varphi}e^{-ih}(w_1-w_2)$. Then w is an entire function. Note that $e^{\varphi}=O(|x|^{\alpha})$ at infinity for $0<\alpha<1$. Since $w_1-w_2\in L^2$, we can easily show that $w=0$, and hence $w_1=w_2$. Thus the lemma is obtained. □

We now recall that $G_+:L^2_c\to L^2_{-1}$ is bounded. Hence

$$|V|^{1/2}p_+^{-1}|V|^{1/2}=|V|^{1/2}p_-G_+|V|^{1/2}:L^2\to L^2$$

is bounded by elliptic estimate, and also it follows by adjoint that

$$|V|^{1/2}p_-^{-1}|V|^{1/2}=|V|^{1/2}G_+p_+|V|^{1/2}:L^2\to L^2$$

is bounded.

We first consider the case $0<\alpha\leqslant 1/2$. We write $V^{1/2}=|V|^{1/2}/V$ and define $\Phi=\{u\in[L^2]^2:Z_0u=-u\}$, where

$$Z_0=V^{1/2}F_0|V|^{1/2},\quad F_0=\begin{pmatrix}0 & p_-G_+\\ G_+p_+ & 0\end{pmatrix}. \tag{5.2}$$

Since $Z_0:[L^2]^2\to[L^2]^2$ is a compact operator, it follows that $\dim\Phi<\infty$. As is easily seen from Lemma 5.1, $v=F_0|V|^{1/2}u$ with $u\in\Phi$ belongs to $L^2\times L^\infty$ and it solves $(K+V)v=0$. We further define $\Phi_0=\{u\in\Phi:(u,|V|^{1/2}\tilde{\rho}_0)_{L^2}=0\}$ with $\tilde{\rho}_0=(\rho_0,0)$. By definition, we have $\dim\Phi/\Phi_0\leqslant 1$.

Lemma 5.2: If $u\in\Phi_0$, then $v=F_0|V|^{1/2}u$ is in $[L^2]^2$ and hence v becomes a bound state associated with zero eigenvalue. If, conversely, v is a bound state, then $u=-V^{1/2}v$ belongs to Φ_0.

Proof: Let $u={}^t(u_1,u_2)\in\Phi_0$ and $v={}^t(v_1,v_2)=F_0|V|^{1/2}u$. Then $(u_1,|V|^{1/2}\rho_0)=0$ by assumption, and it is easy to see that $v_1\in L^2$. Since $\rho_0=ce^{-\varphi}e^{ih}$ for some $c\neq 0$, $v_2=p_-^{-1}|V|^{1/2}u_1$ behaves like

$$v_2(x)=c\,(u_1,|V|^{1/2}\rho_0)_{L^2}e^{\varphi}e^{-ih}(x_1-ix_2)^{-1}+O(|x|^{-2+\alpha}),\quad |x|\to\infty, \tag{5.3}$$

for another $c\neq 0$. Hence it follows that

$$(u_1,|V|^{1/2}\rho_0)_{L^2}=0\Leftrightarrow v\in[L^2]^2. \tag{5.4}$$

This proves the first statement. The second one is also easy to prove. If $v\in[L^2]^2$ satisfies $(K+V)v=0$, then $v=-F_0Vv$. Hence we have

$$u=-V^{1/2}v=V^{1/2}F_0Vv=Z_0V^{1/2}v=-Z_0u,$$

which, together with (5.4), implies that $u\in\Phi_0$. □

If $\dim\Phi/\Phi_0=1$, then the above lemma implies that $(K+V)v=0$ has a solution $v={}^t(v_1,v_2)\in L^2\times L^\infty$ with $(v,V\tilde{\rho}_0)_{L^2}\neq 0$, and hence it follows from (5.3) that v_2 behaves like

$$v_2(x)=cr^{-1+\alpha}e^{i\theta}(1+o(1)),\quad r=|x|\to\infty,$$

for $c\neq 0$. The converse is also true.

We move to the case $1/2<\alpha<1$. Recall that $\lambda_0\neq 0$ by assumption (5.1). This enables us to define the projection

$$P=\lambda_0^{-1}(V^{1/2}\tilde{\rho}_0\otimes|V|^{1/2}\tilde{\rho}_0):[L^2]^2\to[L^2]^2. \tag{5.5}$$

Let $Q=1-P$. We further define

$$\Psi=\{u\in[L^2]^2:QZ_0Qu=-u\},\quad \Psi_0=\{u\in\Psi:(u,Z_0^*|V|^{1/2}\tilde{\rho}_0)_{L^2}=0\}.$$

We again have $\dim\Psi/\Psi_0\leqslant 1$.

Lemma 5.3: If $u\in\Psi_0$, then $v=F_0|V|^{1/2}u$ becomes a bound state associated with zero eigenvalue. If, conversely, v is a bound state, then $u=-V^{1/2}v$ belongs to Ψ_0.

Proof: If $u\in\Psi_0$, then $PZ_0u=0$ and it follows that

$$u=-QZ_0Qu=-Z_0u=-V^{1/2}F_0|V|^{1/2}u=-V^{1/2}v.$$

This shows that $|V|^{1/2}u=-Vv$ and hence $(K+V)v=0$. If we write $v=F_0|V|^{1/2}u=-F_0|V|^{1/2}Z_0u$, then the first statement follows from (5.4). To prove the second one, we repeat the same computation as in the proof of Lemma 5.2 to obtain the relation $u=-Z_0u$. Since $v=-F_0Vv\in[L^2]^2$, it again follows from (5.4) that

$$(u,|V|^{1/2}\tilde{\rho}_0)_{L^2}=-(v,V\tilde{\rho}_0)_{L^2}=0.$$

This implies that $Pu=0$ and we obtain $u\in\Psi_0$. □

Lemma 5.4: If $\dim\Psi/\Psi_0=1$, then $(K+V)v=0$ has a solution such that $v={}^t(v_1,v_2)\in L^\infty\times L^2$ and

$$v_1(x)=cr^{-\alpha}(1+o(1)),\quad |x|\to\infty,$$

for $c\neq 0$. The converse is also true.

Proof: Let $u\in\Psi$ be a representative of Ψ/Ψ_0. We set $v=F_0|V|^{1/2}u-\mathrm{d}\tilde{\rho}_0$, where

$$\mathrm{d}=\lambda_0^{-1}(u,Z_0^*|V|^{1/2}\tilde{\rho}_0)_{L^2}\neq 0.$$

Then $(Vv,\tilde{\rho}_0)_{L^2}=0$, and $v_1(x)=-\mathrm{d}\rho_0(x)(1+o(1))$ at infinity. We show that $(K+V)v=0$. To see this, we calculate

$$V^{1/2}v=Z_0u-PZ_0u=QZ_0u=-u.$$

Since $K\tilde{\rho}_0=0$, we obtain $Kv=|V|^{1/2}u=-Vv$. We claim that $v_2\in L^2$. This follows from (5.4), because $(u,|V|^{1/2}\tilde{\rho}_0)_{L^2}=-(Vv,\tilde{\rho}_0)_{L^2}=0$. Thus the first statement is established. We shall prove the converse. Let $v\in L^\infty\times L^2$ be a solution to $(K+V)v=0$ with the properties in the lemma. We assert that v takes the form $v=-F_0Vv+c_0\tilde{\rho}_0$ for some $c_0\neq 0$. To see this, we set $w=v+F_0Vv$. Then $Kw=0$ and the first component w_1 behaves like $w_1=cr^{-\alpha}(1+o(1))$ for $c\neq 0$ in the lemma, because $v_1\notin L^2$ behaves in a similar way by assumption. Thus $w=c_0\tilde{\rho}_0$. The constant $c_0\neq 0$ is determined as

$$c_0=\lambda_0^{-1}(F_0Vv,V\tilde{\rho}_0)_{L^2}=\lambda_0^{-1}(V^{1/2}v,Z_0^*|V|^{1/2}\tilde{\rho}_0)_{L^2}$$

by use of (5.4). In fact, we have

$$(-F_0Vv+c_0\tilde{\rho}_0,V\tilde{\rho}_0)_{L^2}=(Vv,\tilde{\rho}_0)_{L^2}=(Vv_1,\rho_0)_{L^2}=0$$

because $v_2\in L^2$. If we set $u=-V^{1/2}v$, then $u\in[L^2]^2$ satisfies the relation $u=-Z_0u+PZ_0u=-QZ_0u$. Hence we have $u\in\Psi$, and also it follows that

$$(u,Z_0^*|V|^{1/2}\tilde{\rho}_0)_{L^2}=-(V^{1/2}v,Z_0^*|V|^{1/2}\tilde{\rho}_0)_{L^2}=-\lambda_0c_0\neq 0.$$

This implies the second statement, and the proof is complete. □

We combine Lemmas 5.2, 5.3, and 5.4 to formulate the precise definition of resonance state at zero energy.

Definition 5.1: The operator $K+V$ is said to admit a resonance state at zero energy, if the following condition is fulfilled.

(1) Assume that $0<\alpha\leqslant 1/2$. The equation $(K+V)v=0$ has a solution such that $v={}^t(v_1,v_2)\in L^2\times L^\infty$ and

$$v_2(x)=r^{-1+\alpha}e^{i\theta}(1+o(1)),\quad |x|\to\infty.$$

(2) Assume that $1/2<\alpha<1$ and that (5.1) is fulfilled. $(K+V)v=0$ has a solution such that $v={}^t(v_1,v_2)\in L^\infty\times L^2$ and

$$v_1(x)=r^{-\alpha}(1+o(1)),\quad |x|\to\infty.$$

We note that the definition is invariant under gauge transformations. We are now in a position to state the second main theorem.

Theorem 5.1: *Assume that the flux α satisfies (1.2) and that $K+V$ has no bound states at zero energy. Then one has the following three statements.*

(1) Let $0<\alpha<1/2$. If $K+V$ does not have a resonance state at zero energy, then $K_\varepsilon(V_\varepsilon)$ converges to H_∞ in the norm resolvent sense, and if $K+V$ has a resonance state, then $K_\varepsilon(V_\varepsilon)$ converges to H_0.

(2) Let $\alpha=1/2$. Assume that $K+V$ does not have a resonance state at zero energy, so that $(1+Z_0)^{-1}:[L^2]^2\to[L^2]^2$ exists as a bounded operator. Define the real number λ_2 by

$$\lambda_2=((1+Z_0)^{-1}V^{1/2}\tilde{\rho}_0,|V|^{1/2}\tilde{\rho}_0)_{L^2}$$

with $\tilde{\rho}_0 = {}^t(\rho_0, 0) \in [L^2]^2$. *Then* $K_\varepsilon(V_\varepsilon)$ *converges to* H_κ *with* $\kappa = \tan(\zeta/2)$ *determined through (2.6) with*

$$\zeta = \arg((i\lambda_2 - \gamma_0)/(i\lambda_2 + \gamma_0)),$$

where $\gamma_0 = -2$ *is as in Proposition 4.1. If* $K+V$ *has a resonance state, then* $K_\varepsilon(V_\varepsilon)$ *converges to* H_0.

(3) Let $1/2 < \alpha < 1$. *Assume that (5.1) is fulfilled. If* $K+V$ *does not have a resonance state at zero energy, then* $K_\varepsilon(V_\varepsilon)$ *converges to* H_0, *and if* $K+V$ *has a resonance state, then* $K_\varepsilon(V_\varepsilon)$ *converges to* H_∞.

The theorem is proved in the next section. We follow the argument used in the proof of Theorem 1.2.5 in Ref. 6 and of Theorem 3.3 in Ref. 10. The major part of the argument is again occupied by the resolvent analysis at low energy of magnetic Schrödinger operator with resonance state at zero energy. We end the section by making some brief comments on the theorem.

Remark 5.1: (1) If $V(x) \geqslant 0$ or $V(x) \leqslant 0$ and if it is sufficiently small but not identically zero, then $K+V$ has neither bound state nor resonance state at zero energy. The theorem asserts that the limit Hamiltonian changes at $\alpha = 1/2$ even for small perturbations of scalar potentials, and also it is interesting that the situation is completely reversed when $K+V$ has a resonance state. (2) The same reason as in Remark 3.2 applies to $K_\varepsilon(V_\varepsilon) = \varepsilon^{-1} J_\varepsilon (K+V) J_\varepsilon^*$. The norm convergence is not true without assuming that $K+V$ has no bound states at zero energy. (3) The restriction (1.2) is technical. The same results as in the theorem seem to remain true even for $\alpha > 1$ in the strong convergence sense, so that the limit Hamiltonian changes at half-integer fluxes. (4) The assumption (5.1) also seems to be technical. This is used for proving the third statement only, and a similar assumption has been used in Ref. 10 for the analysis on resolvents at low energy of Schrödinger operators in two dimensions. However the idea in the recent work (Ref. 17) may make it possible to remove the assumption.

VI. PROOF OF THEOREM 5.1

We prove Theorem 5.1 in this section. The proof requires several new lemmas on the behavior at low energy of resolvents of magnetic Schrödinger operators besides the propositions in Sec. IV. In formulating these lemmas, we use $\chi \in C_0^\infty(\mathbf{R}^2 \to \mathbf{R})$ with the same meaning as ascribed in Sec. IV and denote by $o_2(\varepsilon^\sigma)$ remainder terms with L^2 norm obeying the bound $o(\varepsilon^\sigma)$. We further define $\xi_l(x)$ by

$$\xi_l(x) = H_\nu(ir) e^{il\theta}, \quad \nu = |l - \alpha|, \tag{6.1}$$

for $l = 0,1$. According to this notation, we have

$$\psi_+ = N_\alpha \begin{pmatrix} -i^{1+2\alpha}\xi_0 \\ \xi_1 \end{pmatrix}, \quad \psi_- = N_\alpha \begin{pmatrix} i^{1+2\alpha}\xi_0 \\ \xi_1 \end{pmatrix}$$

by (2.3) and (2.5).

Lemma 6.1: Let ω_{+l} *be defined by (4.7). Then*

$$(L_{+\varepsilon} + 1)^{-1} J_\varepsilon \chi = \sum_{l=0,1} \beta_{+l}(\varepsilon) i^\nu \varepsilon^{1+\nu} (\xi_l \otimes \chi \omega_{+l}) + Op(\varepsilon^2)$$

for some coefficient $\beta_{+l}(\varepsilon)$, *and* $\beta_{+l}(\varepsilon)$ *behaves like* $\beta_{+l}(\varepsilon) = \beta_l + o(1)$ *as* $\varepsilon \to 0$, *where*

$$\beta_l = i(2\pi)^{-1/2} (2^{-\nu} \Gamma(1-\nu)/(l+\nu)^{1/2}) \sin \nu\pi. \tag{6.2}$$

Lemma 6.2: Let β_0 *be as above and let* γ_0 *be as in Proposition 4.1. Let* ρ_0 *be the resonance state defined by (4.14). Then*

$$(L_{-\varepsilon}+1)^{-1}J_\varepsilon\chi=-i^\alpha(\beta_0/\gamma_0)\varepsilon^{1-\alpha}((\xi_0+o_2(1))\otimes\chi\rho_0)+Op(\varepsilon).$$

Lemma 6.3: One has

$$p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1}J_\varepsilon\chi=Op(\varepsilon).$$

Lemma 6.4: One has

$$p_{+\varepsilon}(L_{-\varepsilon}+1)^{-1}J_\varepsilon\chi=i^{-\alpha}(\beta_0/\gamma_0)\varepsilon^{1-\alpha}((\xi_1+o_2(1))\otimes\chi\rho_0)+Op(\varepsilon).$$

We proceed to proving Theorem 5.1, accepting the above lemmas as proved. The proof of these lemmas is done in Sec. VII.

Proof of Theorem 5.1: For brevity, we assume throughout the proof that $V(x)\geqslant 0$, so that the operator Z_0 defined by (5.2) becomes self-adjoint. We write $R_\varepsilon=(K_\varepsilon(V_\varepsilon)+i)^{-1}$. Then we obtain

$$R_\varepsilon=(K_\varepsilon+i)^{-1}-(K_\varepsilon+i)^{-1}V_\varepsilon^{1/2}X_\varepsilon^{-1}V_\varepsilon^{1/2}(K_\varepsilon+i)^{-1}$$

from the resolvent identity, where $X_\varepsilon=1+V_\varepsilon^{1/2}(K_\varepsilon+i)^{-1}V_\varepsilon^{1/2}$. We define Y_ε by

$$Y_\varepsilon=J_\varepsilon^*X_\varepsilon J_\varepsilon=1+V^{1/2}(K+i\varepsilon)^{-1}V^{1/2}.$$

Then R_ε is rewritten as

$$R_\varepsilon=(K_\varepsilon+i)^{-1}-\varepsilon^{-1}((K_\varepsilon+i)^{-1}J_\varepsilon V^{1/2})Y_\varepsilon^{-1}((K_\varepsilon-i)^{-1}J_\varepsilon V^{1/2})^*.$$

We analyze the behavior as $\varepsilon\to 0$ of operators on the right-hand side. By Theorem 3.1, $(K_\varepsilon+i)^{-1}\to(H_\infty+i)^{-1}$. If we make use of relation (3.3), then we can obtain

$$(K_\varepsilon\pm i)^{-1}=\begin{pmatrix}\mp i(L_{-\varepsilon}+1)^{-1} & p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1}\\ p_{+\varepsilon}(L_{-\varepsilon}+1)^{-1} & \mp i(L_{+\varepsilon}+1)^{-1}\end{pmatrix}$$

from (3.4). By Lemmas 6.1–6.4, we have

$$(K_\varepsilon+i)^{-1}J_\varepsilon V^{1/2}=(\beta_0/\gamma_0)N_\alpha^{-1}i^{-\alpha}\varepsilon^{1-\alpha}((\psi_-+o_2(1))\otimes q_0)+Op(\varepsilon),\tag{6.3}$$

where $q_0={}^t(V^{1/2}\rho_0,0)$. Similarly $((K_\varepsilon-i)^{-1}J_\varepsilon V^{1/2})^*$ takes the form

$$((K_\varepsilon-i)^{-1}J_\varepsilon V^{1/2})^*=(\overline{\beta_0}/\gamma_0)N_\alpha^{-1}i^{\alpha}\varepsilon^{1-\alpha}(q_0\otimes(\psi_++o_2(1)))+Op(\varepsilon).\tag{6.4}$$

The operator $(K+i\varepsilon)^{-1}$ also has been calculated as

$$(K+i\varepsilon)^{-1}=\begin{pmatrix}-i\varepsilon(L_-+\varepsilon^2)^{-1} & p_-(L_++\varepsilon^2)^{-1}\\ (L_++\varepsilon^2)^{-1}p_+ & -i\varepsilon(L_++\varepsilon^2)^{-1}\end{pmatrix}$$

in (3.10). By (4.2) and (4.7), ω_{+0} obeys $\omega_{+0}=(1/2)\alpha^{-1/2}r^\alpha+g$ for some $g\in L^2_{-1}$, and it solves $L_+\omega_{+0}=0$ uniquely (see Lemma 4.3 of Ref. 22). Since $L_+=p_+p_-$ with

$$p_-=p_+^*=ie^{ih}e^{\varphi}(-\partial_1+i\partial_2)e^{-\varphi}e^{-ih},$$

we see that $p_-\omega_{+0}=0$. In fact, ω_{+0} is given by $\omega_{+0}=ce^{ih}e^{\varphi}$ for some constant $c\neq 0$. Thus we have

$$V^{1/2}p_-(L_++\varepsilon^2)^{-1}V^{1/2}=V^{1/2}(p_-G_++\varepsilon^{2(1-\alpha)}\gamma_{+1}(i\varepsilon)(p_-\omega_{+1}\otimes\omega_{+1}))V^{1/2}+Op(\varepsilon^2)$$

by Proposition 4.2 (see Remark 4.1) and similarly for $V^{1/2}(L_++\varepsilon^2)^{-1}p_+V^{1/2}$. Hence it follows from Proposition 4.3 that

$$Y_\varepsilon = 1 + Z_0 - i\gamma_-(i\varepsilon)\varepsilon^{1-2\alpha}(q_0 \otimes q_0) + \varepsilon^{2(1-\alpha)}Z_1(\varepsilon) + Op(\varepsilon),$$

where $\gamma_-(i\varepsilon) = -1/\gamma_0 + o(1)$ as $\varepsilon \to 0$ and

$$Z_1(\varepsilon) = \gamma_{+1}(i\varepsilon)V^{1/2}\begin{pmatrix} 0 & p_-\omega_{+1}\otimes\omega_{+1} \\ \omega_{+1}\otimes p_-\omega_{+1} & 0 \end{pmatrix}V^{1/2}. \tag{6.5}$$

Note that $p_- = \pi_-$ on $\{|x|>2\}$, and recall the form of operator π_- (see Sec. II). Then it follows from (4.7) that $p_-\omega_{+1} = cr^{-\alpha} + g$ for some $c \neq 0$. We see by Lemma 5.1 (or by the argument in the proof) that the remainder term g is in L^2. Since $p_-\omega_{+1}$ satisfies $p_+p_-\omega_{+1} = L_+\omega_{+1} = 0$, we have $p_-\omega_{+1} = c\rho_0$ for another $c \neq 0$, and hence

$$Z_1(\varepsilon) = c\gamma_{+1}(i\varepsilon)(q_0 \otimes q + q \otimes q_0) \tag{6.6}$$

with $q = {}^t(0, V^{1/2}\omega_{+1})$. The argument is different from now on according as $0<\alpha<1/2$, $\alpha = 1/2$ or $1/2<\alpha<1$.

(1) Assume that $0<\alpha<1/2$. If $K+V$ has neither bound nor resonance state at zero energy, then the bounded inverse $(1+Z_0)^{-1}:[L^2]^2 \to [L^2]^2$ exists, and hence Y_ε has an inverse bounded uniformly in ε. Thus it follows that $R_\varepsilon \to (H_\infty + i)^{-1}$ in norm. Next we consider the case when $K+V$ has a resonance state. Since $K+V$ has no bound states by assumption, $\dim \Phi = 1$ and $\dim \Phi_0 = 0$. Let Φ be spanned by $q_1 \in [L^2]^2$ with $\|q_1\|_{L^2} = 1$. Then $\lambda_1 = (q_1, q_0)_{L^2} \neq 0$ by definition. We denote by $\Pi_1 = q_1 \otimes q_1$ the projection on Φ and write $\Pi = 1 - \Pi_1$ for the projection on the orthogonal complement $\Phi^\perp$. Then $\Pi(1+Z_0)\Pi:\Phi^\perp \to \Phi^\perp$ has an bounded inverse and $\Pi_1(q_0 \otimes q_0)\Pi_1 = |\lambda_1|^2\Pi_1$. Thus Y_ε^{-1} takes the form

$$Y_\varepsilon^{-1} = -i(\gamma_0/|\lambda_1|^2)\varepsilon^{2\alpha-1}(q_1 \otimes q_1) + op(\varepsilon^{2\alpha-1}). \tag{6.7}$$

Since $\Gamma(1-\alpha)\Gamma(\alpha) = \pi/(\sin \alpha\pi)$ by formula, a direct calculation yields

$$|\beta_0|^2/\gamma_0 = -\sin \alpha\pi/4 = -N_\alpha^2 \tag{6.8}$$

by (2.4). We combine (6.3), (6.4), (6.7), and (6.8) to obtain that

$$R_\varepsilon = (H_\infty + i)^{-1} - i(\psi_- \otimes \psi_+) + op(\varepsilon^0).$$

This determines $\zeta = 0$ by (2.7) and hence $\kappa = 0$ by (2.6). Thus we obtain that $R_\varepsilon \to (H_0 + i)^{-1}$.

(2) If $\alpha = 1/2$, then Y_ε takes the form

$$Y_\varepsilon = 1 + Z_0 + (i/\gamma_0)(q_0 \otimes q_0) + op(\varepsilon^0)$$

and $\gamma_0 = -2$. Assume that zero is not a resonance energy. If we set $q_2 = (1+Z_0)^{-1}q_0$, then the real number λ_2 in the theorem is represented as $\lambda_2 = (q_2, q_0)_{L^2}$, and Y_ε^{-1} is calculated as

$$\begin{aligned} Y_\varepsilon^{-1} &= (1 + (i/\gamma_0)(q_2 \otimes q_0))^{-1}(1+Z_0)^{-1} + op(\varepsilon^0) \\ &= (1 - (i/(\gamma_0 + i\lambda_2))(q_2 \otimes q_0))(1+Z_0)^{-1} + op(\varepsilon^0). \end{aligned}$$

Thus we obtain

$$R_\varepsilon = (H_\infty + i)^{-1} + c_2(\psi_- \otimes \psi_+) + op(\varepsilon^0)$$

with $c_2 = \lambda_2/(\gamma_0 + i\lambda_2)$, and

$$e^{i\zeta} = 2ic_2 - 1 = (i\lambda_2 - \gamma_0)/(i\lambda_2 + \gamma_0).$$

This determines $\kappa = \tan(\zeta/2)$ through (2.6). If $K+V$ has a resonance state, the lemma below yields the desired relation

$$R_\varepsilon=(H_\infty+i)^{-1}-i(\psi_-\otimes\psi_+)+op(\varepsilon^0)=(H_0+i)^{-1}+op(\varepsilon^0).$$

Lemma 6.5: Under the above situation, one has

$$(q_0,Y_\varepsilon^{-1}q_0)_{L^2}=i\gamma_0+o(1),\quad \varepsilon\to 0.$$

Proof: If we again denote by Π_1 and $\Pi=1-\Pi_1$ the projections on Φ and $\Phi^\perp$, respectively, then

$$Y_{11}=\Pi_1(1+Z_0)\Pi_1=0,\quad Y_{01}=\Pi(1+Z_0)\Pi_1=0,\quad Y_{10}=\Pi_1(1+Z_0)\Pi=0,$$

and $Y_{00}=\Pi(1+Z_0)\Pi:\Phi^\perp\to\Phi^\perp$ is invertible. We write

$$q_0=\Pi q_0+\Pi_1 q_0=r_0+r_1.$$

We set $D=(i/\gamma_0)(q_0\otimes q_0)$ and decompose it into the sum

$$D=\sum_{0\leqslant j,k\leqslant 1}D_{jk},\quad D_{jk}=(i/\gamma_0)(r_j\otimes r_k).$$

We represent $Y_\varepsilon=1+Z_0+D+op(\varepsilon^0)$ in the matrix form

$$Y_\varepsilon=\begin{pmatrix}Y_{00}+D_{00} & D_{01}\\ D_{10} & D_{11}\end{pmatrix}+op(\varepsilon^0):\begin{pmatrix}\Phi^\perp\\ \Phi\end{pmatrix}\to\begin{pmatrix}\Phi^\perp\\ \Phi\end{pmatrix}.$$

By (5.4), $r_1\neq 0$, and hence $D_{11}:\Phi\to\Phi$ is invertible. We have

$$D_{11}^{-1}=-i\gamma_0\|r_1\|_{L^2}^{-4}(r_1\otimes r_1)$$

and $D_{00}-D_{01}D_{11}^{-1}D_{10}=0$. If we make use of this relation, then

$$Y_\varepsilon^{-1}=\begin{pmatrix}Y_{00}^{-1} & -Y_{00}^{-1}D_{01}D_{11}^{-1}\\ -D_{11}^{-1}D_{10}Y_{00}^{-1} & D_{11}^{-1}(1+D_{10}Y_{00}^{-1}D_{01}D_{11}^{-1})\end{pmatrix}+op(\varepsilon^0).$$

We compute

$$(r_0,Y_{00}^{-1}D_{01}D_{11}^{-1}r_1)_{L^2}=(r_0,Y_{00}^{-1}r_0)_{L^2},\quad (r_1,D_{11}^{-1}D_{10}Y_{00}^{-1}r_0)_{L^2}=(Y_{00}^{-1}r_0,r_0)_{L^2}$$

and

$$(r_1,D_{11}^{-1}(1+D_{10}Y_{00}^{-1}D_{01}D_{11}^{-1})r_1)_{L^2}=i\gamma_0+(Y_{00}^{-1}r_0,r_0)_{L^2}.$$

This completes the proof of the lemma. □

(3) The final case is $1/2<\alpha<1$. The projection $P=\lambda_0^{-1}(q_0\otimes q_0):[L^2]^2\to[L^2]^2$ is defined by (5.5). Set $Q=1-P$ again. Then

$$Y_\varepsilon=\tau(\varepsilon)P+Q+Z_0+\varepsilon^{2(1-\alpha)}Z_1(\varepsilon)+Op(\varepsilon),$$

where

$$\tau(\varepsilon)=1-i\lambda_0\gamma_-(i\varepsilon)\varepsilon^{1-2\alpha}=\varepsilon^{1-2\alpha}(i\lambda_0/\gamma_0+o(1)).$$

We can easily prove that

$$(\tau(\varepsilon)P+Q)^{-1}=\delta(\varepsilon)P+Q,\quad (1+QZ_0P)^{-1}=1-QZ_0P,$$

where $\delta(\varepsilon)=1/\tau(\varepsilon)=\varepsilon^{2\alpha-1}(-i\gamma_0/\lambda_0+o(1))$. The two relations yield

$$Y_\varepsilon=(\tau(\varepsilon)P+Q)(1+QZ_0P)T_\varepsilon$$

and hence we have

$$Y_\varepsilon^{-1}=T_\varepsilon^{-1}(\delta(\varepsilon)(P-QZ_0P)+Q), \tag{6.9}$$

where

$$T_\varepsilon=1+QZ_0Q+\delta(\varepsilon)(1-QZ_0)PZ_0+\varepsilon^{2(1-\alpha)}QZ_1(\varepsilon)+Op(\varepsilon).$$

By (6.6), we see that $QZ_1(\varepsilon)Q=0$. Let $\Sigma_0=\mathrm{Ran}\,P$ and $\Sigma=\mathrm{Ran}\,Q$. The second factor on the right-hand side of (6.9) has the matrix representation

$$\delta(\varepsilon)(P-QZ_0P)+Q=\begin{pmatrix}\delta(\varepsilon)P & 0\\ -\delta(\varepsilon)QZ_0P & Q\end{pmatrix}:\begin{pmatrix}\Sigma_0\\ \Sigma\end{pmatrix}\to\begin{pmatrix}\Sigma_0\\ \Sigma\end{pmatrix}, \tag{6.10}$$

while T_ε takes the form $T_\varepsilon=(T_{jk}(\varepsilon))_{0\leqslant j,k\leqslant 1}$, where

$$T_{00}=P(1+Op(\varepsilon^{2\alpha-1}))P,\quad T_{01}=P(\delta(\varepsilon)Z_0+Op(\varepsilon))Q,$$

$$T_{10}=Q(Op(\varepsilon^{2\alpha-1})+Op(\varepsilon^{2(1-\alpha)}))P,\quad T_{11}=Q(1+Z_0-\delta(\varepsilon)Z_0PZ_0+Op(\varepsilon))Q.$$

The inverse T_ε^{-1} can be calculated as $T_\varepsilon^{-1}=(S_{jk}(\varepsilon))_{0\leqslant j,k\leqslant 1}$, where

$$S_{00}=(T_{00}-T_{01}T_{11}^{-1}T_{10})^{-1},\quad S_{01}=-T_{00}^{-1}T_{01}(T_{11}-T_{10}T_{00}^{-1}T_{01})^{-1},$$

$$S_{10}=-T_{11}^{-1}T_{10}(T_{00}-T_{01}T_{11}^{-1}T_{10})^{-1},\quad S_{11}=(T_{11}-T_{10}T_{00}^{-1}T_{01})^{-1}.$$

We now analyze the behavior as $\varepsilon\to 0$ of inverse Y_ε^{-1}. We first deal with the resonance case. We claim that Y_ε^{-1} takes the form

$$Y_\varepsilon^{-1}=\begin{pmatrix}Pop(\varepsilon^{2\alpha-1})P & POp(\varepsilon^0)Q\\ QOp(\varepsilon^0)P & QOp(\varepsilon^{1-2\alpha})Q\end{pmatrix}. \tag{6.11}$$

Note that

$$(f\otimes q_0)Q=0,\quad Q(q_0\otimes f)=0$$

for $f\in[L^2]^2$. Hence we combine (6.11) with (6.3) and (6.4) to obtain that $R_\varepsilon\to(H_\infty+i)^{-1}$. When $K+V$ has a resonance state at zero energy,

$$\dim\Psi=\dim\mathrm{Ker}(Q+QZ_0Q)=1$$

and $\dim\Psi_0=0$. Let Ψ be spanned by $q_3\in[L^2]^2$ with $\|q_3\|_{L^2}=1$. We denote by $Q_3=q_3\otimes q_3$ the projection on Ψ and decompose $Q=Q_3+Q(1-Q_3)=Q_3+Q_4$. Since $\dim\Psi_0=0$, $\lambda_3=(Z_0q_3,q_0)_{L^2}\neq 0$. The operator T_{11} is represented in the form

$$T_{11}=Q_4(1+Z_0+Op(\varepsilon^{2\alpha-1}))Q_4-(\delta(\varepsilon)|\lambda_3|^2/\lambda_0)Q_3+Q_4Op(\varepsilon^{2\alpha-1})Q_3+Q_3Op(\varepsilon^{2\alpha-1})Q_4.$$

Hence

$$T_{11}^{-1}=-(\tau(\varepsilon)\lambda_0/|\lambda_3|^2)Q_3+QOp(\varepsilon^0)Q.$$

As is easily seen, $T_{00}^{-1}=P(1+op(\varepsilon^0))P$. Similarly we have

$$(T_{11}-T_{10}T_{00}^{-1}T_{01})^{-1}=-(\tau(\varepsilon)\lambda_0/|\lambda_3|^2)Q_3+QOp(\varepsilon^0)Q$$

and $(T_{00}-T_{01}T_{11}^{-1}T_{10})^{-1}=P(1+op(\varepsilon^0))P$. Thus we obtain

$$T_\varepsilon^{-1}=\begin{pmatrix} P(1+op(\varepsilon^0))P & (\lambda_0/|\lambda_3|^2)PZ_0Q_3+Pop(\varepsilon^0)Q \\ Q(Op(\varepsilon^0)+Op(\varepsilon^{3-4\alpha}))P & QOp(\varepsilon^{1-2\alpha})Q \end{pmatrix}.$$

This, together with (6.9) and (6.10), implies that

$$Y_\varepsilon^{-1}=\begin{pmatrix} \delta(\varepsilon)P(1-(\lambda_0/|\lambda_3|^2)Z_0Q_3Z_0+op(\varepsilon^0))P & POp(\varepsilon^0)Q \\ QOp(\varepsilon^0)P & QOp(\varepsilon^{1-2\alpha})Q \end{pmatrix}.$$

Since $PZ_0Q_3Z_0P=(|\lambda_3|^2/\lambda_0)P$, (6.11) follows at once. If $K+V$ does not have a resonance state, then $\dim\Psi=0$, and $T_{11}(\varepsilon):\Sigma\to\Sigma$ admits an inverse bounded uniformly in ε. We repeat the same argument as above to obtain that

$$Y_\varepsilon^{-1}=\begin{pmatrix} \delta(\varepsilon)P(1+op(\varepsilon^0))P & POp(\varepsilon^0)Q \\ QOp(\varepsilon^0)P & QOp(\varepsilon^{1-2\alpha})Q \end{pmatrix},$$

so that $Y_\varepsilon^{-1}\sim -i(\gamma_0/\lambda_0^2)\varepsilon^{2\alpha-1}(q_0\otimes q_0)$. Hence we have

$$R_\varepsilon=(H_\infty+i)^{-1}-i(\psi_-\otimes\psi_+)+op(\varepsilon^0)=(H_0+i)^{-1}+op(\varepsilon^0)$$

in the same way as in case (1). Thus the proof of the theorem is now complete. □

VII. RESOLVENT ANALYSIS AT LOW ENERGY ON SCHRÖDINGER OPERATORS II

The last section is devoted to proving Lemmas 6.1–6.4 which remain unproved. The argument here is based on the following proposition obtained as Proposition 7.1 in Ref. 22. The proposition has been proved for $(L_\varepsilon-i)^{-1}$, but the argument there applies to $(L_\varepsilon-\sigma^2)^{-1}$, $\mathrm{Im}\,\sigma>0$, without any serious modification.

Proposition 7.1: Let L_ε be defined by (3.2) and let $\sigma\in\mathbf{C}$ be as above. Then

$$(L_\varepsilon-\sigma^2)^{-1}J_\varepsilon\chi=\sum_{l=0,1}\beta_l(\varepsilon)\sigma^\nu\varepsilon^{1+\nu}(\mu_l\otimes\chi\omega_l)+Op(\varepsilon^2)$$

for some coefficients $\beta_l(\varepsilon)$, where $\mu_l(x)=H_\nu(\sigma r)e^{il\theta}$ and $\beta_l(\varepsilon)$ behaves in the same manner as in Lemma 6.1.

Proof of Lemma 6.1: We use the relations $J_\varepsilon^*(L_{+\varepsilon}+1)^{-1}J_\varepsilon=\varepsilon^2(L_++\varepsilon^2)^{-1}$ and $b_\varepsilon J_\varepsilon=\varepsilon^{-2}J_\varepsilon b$. Then we have

$$(L_{+\varepsilon}+1)^{-1}J_\varepsilon\chi=(L_\varepsilon+1)^{-1}J_\varepsilon\chi-(L_\varepsilon+1)^{-1}J_\varepsilon b(L_++\varepsilon^2)^{-1}\chi$$

by the resolvent identity. We apply Proposition 7.1 with $\sigma=i$ to $(L_\varepsilon+1)^{-1}J_\varepsilon b$ and Proposition 4.2 with $k=i\varepsilon$ to $\chi(L_++\varepsilon^2)^{-1}\chi$. Since $\omega_{+l}=\omega_l-G_+b\omega_l$ by (4.7) and since $\mu_l=\xi_l$ for $\sigma=i$, the desired relation is obtained. □

Proof of Lemma 6.2: We have

$$(L_{-\varepsilon}+1)^{-1}J_\varepsilon\chi=(L_\varepsilon+1)^{-1}J_\varepsilon\chi+(L_\varepsilon+1)^{-1}J_\varepsilon b(L_-+\varepsilon^2)^{-1}\chi$$

by the resolvent identity. The first operator on the right-hand side is of class $Op(\varepsilon)$ by Proposition 7.1. We apply Proposition 4.3 to $\chi(L_-+\varepsilon^2)^{-1}\chi$ in the second operator. Since

$$(b\rho_0,\omega_0)_{L^2}=(b^{1/2}G_0|b|^{1/2}\eta_0,|b|^{1/2}\omega_0)_{L^2}=(\eta_0,|b|^{1/2}\omega_0)_{L^2}=1$$

and since $(b\rho_0,\omega_1)_{L^2}=(\eta_0,|b|^{1/2}\omega_1)_{L^2}=0$ by (4.13), the desired relation again follows from Proposition 7.1 with $\sigma=i$. □

Proof of Lemma 6.3: Since $p_{-\varepsilon}^* p_{-\varepsilon}=p_{+\varepsilon}p_{-\varepsilon}=L_{+\varepsilon}$, we have

$$(p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1})^* p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1}=(L_{+\varepsilon}+1)^{-1}-(L_{+\varepsilon}+1)^{-2}$$

and hence

$$\|p_{-\varepsilon}(L_{+\varepsilon}+1)^{-1}J_\varepsilon\chi\|^2=\|\chi(\varepsilon^2(L_++\varepsilon^2)^{-1}-\varepsilon^4(L_++\varepsilon^2)^{-2})\chi\|.$$

By Proposition 4.2, $\|\chi(L_++\varepsilon^2)^{-1}\chi\|=O(1)$ as $\varepsilon\to 0$. This implies that

$$\|\chi(L_++\varepsilon^2)^{-1/2}\|=O(1).$$

Thus the bound in the lemma is obtained. □

Proof of Lemma 6.4: We prove the lemma only in the simple case that $b(x)\geqslant 0$. We assert that

$$p_{+\varepsilon}(L_{-\varepsilon}-i)^{-1}J_\varepsilon\chi=-i^{(3-\alpha)/2}(\beta_0/\gamma_0)\varepsilon^{1-\alpha}((\tau_1+o_2(1))\otimes\chi\rho_0)+Op(\varepsilon), \tag{7.1}$$

where $\tau_1(x)=H_{1-\alpha}(i^{1/2}r)e^{i\theta}$. This implies the lemma. In fact, we use (3.3) to obtain

$$p_{+\varepsilon}(L_{-\varepsilon}+1)^{-1}=(1-(1+i)(L_{+\varepsilon}+1)^{-1})p_{+\varepsilon}(L_{-\varepsilon}-i)^{-1}$$

and it follows from Lemma 3.1 that

$$(1-(1+i)(L_{+\varepsilon}+1)^{-1})\tau_1\to f_1=(1-(1+i)(L_{AB}+1)^{-1})\tau_1$$

strongly in L^2. The function $f_1\in L^2$ satisfies $(\pi_1^2+\pi_2^2+1)f_1=0$. Hence it takes the form $f_1(x)=g(r)e^{i\theta}$, where g solves

$$-g''-r^{-1}g'+((1-\alpha)^2r^{-2}+1)g=0.$$

Thus $f_1=cH_{1-\alpha}(ir)e^{i\theta}=c\xi_1$ for some coefficient c. Since $u\in\mathcal{D}(L_{AB})$ vanishes at the origin, $f_1-\tau_1$ also vanishes, so that c is determined as $c=i^{(1-\alpha)/2}$. Hence we see that (7.1) implies the relation of the lemma.

We shall show (7.1). We make use of the relation

$$(L_{-\varepsilon}-i)^{-1}J_\varepsilon\chi=(L_\varepsilon-i)^{-1}J_\varepsilon\chi+(L_\varepsilon-i)^{-1}J_\varepsilon b(L_--i\varepsilon^2)^{-1}\chi$$

to decompose

$$p_{+\varepsilon}(L_{-\varepsilon}-i)^{-1}J_\varepsilon\chi=I_1(\varepsilon)+I_2(\varepsilon),$$

where $I_1(\varepsilon)=p_{+\varepsilon}(L_\varepsilon-i)^{-1}J_\varepsilon\chi$ and

$$I_2(\varepsilon)=p_{+\varepsilon}(L_\varepsilon-i)^{-1}J_\varepsilon b(L_--i\varepsilon^2)^{-1}\chi.$$

Since $p_{-\varepsilon}p_{+\varepsilon}=L_{-\varepsilon}=L_\varepsilon-b_\varepsilon$, it follows from Proposition 4.1 that

$$\|I_1(\varepsilon)\|^2=\|\chi J_\varepsilon^*(L_\varepsilon+i)^{-1}(L_\varepsilon-b_\varepsilon)(L_\varepsilon-i)^{-1}J_\varepsilon\chi\|=O(\varepsilon^2).$$

To evaluate $I_2(\varepsilon)$, we use Proposition 4.3 with $k=i^{1/2}\varepsilon$ for $b(L_--i\varepsilon^2)^{-1}\chi$. Then

$$I_2(\varepsilon)=p_{+\varepsilon}(L_\varepsilon-i)^{-1}J_\varepsilon\chi(\gamma_-(k)i^\alpha\varepsilon^{-2\alpha}(b\rho_0\otimes\chi\rho_0)+Op(\varepsilon^0)),$$

where $\gamma_-(k)$ obeys $\gamma_-(k)=-1/\gamma_0+o(1)$. Since $p_{+\varepsilon}(L_\varepsilon-i)^{-1}J_\varepsilon\chi=Op(\varepsilon)$ as is seen from the proof of Lemma 6.3, (7.1) follows from the lemma below at once. □

Lemma 7.1: One has the relation

$$p_{+\varepsilon}(L_\varepsilon - i)^{-1} J_\varepsilon b\rho_0 = i^{3(1-\alpha)/2}\beta_0 \varepsilon^{1+\alpha}\tau_1 + o_2(\varepsilon^{1+\alpha}).$$

Proof: Since $b^{1/2}G_0 b^{1/2}\eta_0 = \eta_0$, it follows from (4.14) that $b\rho_0 = b^{1/2}\eta_0$. We write

$$g_\varepsilon = \varepsilon^{-(1+\alpha)} p_{+\varepsilon}(L_\varepsilon - i)^{-1} J_\varepsilon b\rho_0 = \varepsilon^{-(1+\alpha)}\Lambda(\varepsilon)\eta_0,$$

where $\Lambda(\varepsilon) = p_{+\varepsilon}(L_\varepsilon - i)^{-1} J_\varepsilon b^{1/2}$. To prove the lemma, it suffices to show that

$$g_\varepsilon \to g_0 = i^{3(1-\alpha)/2}\beta_0\tau_1$$

strongly in L^2. We first show that $\|g_\varepsilon\|_{L^2} \to \|g_0\|_{L^2}$. If we make use of the relation $p_{+\varepsilon}^* p_{+\varepsilon} = L_{-\varepsilon} = L_\varepsilon - b_\varepsilon$, then a simple calculation yields

$$\Lambda(\varepsilon)^*\Lambda(\varepsilon) = (\varepsilon^2/2)(\Pi(\varepsilon) + \Pi(\varepsilon)^*) - \varepsilon^2\Pi(\varepsilon)^*\Pi(\varepsilon),$$

where $\Pi(\varepsilon) = b^{1/2}(L - i\varepsilon^2)^{-1}b^{1/2}$. We apply Proposition 4.1 with $k = i^{1/2}\varepsilon$ to $\Pi(\varepsilon)$. Then

$$\Pi(\varepsilon) = b^{1/2}G_0 b^{1/2} + \sum_{l=0,1} \gamma_l(k) i^{-\nu}\varepsilon^{2\nu}(b^{1/2}\omega_l \otimes b^{1/2}\omega_l) + Op(\varepsilon^2).$$

Since $(\eta_0, b^{1/2}\omega_0)_{L^2} = 1$ and $(\eta_0, b^{1/2}\omega_1)_{L^2} = 0$ by (4.13), we have

$$\Pi(\varepsilon)\eta_0 = \eta_0 + \gamma_0(k) i^{-\alpha}\varepsilon^{2\alpha} b^{1/2}\omega_0 + o_2(\varepsilon^{1+\alpha})$$

and similarly for $\Pi(\varepsilon)^*\eta_0$ with coefficient $\gamma_0(k)i^{-\alpha}$ replaced by $\overline{\gamma_0(k)} i^{\alpha}$. Thus

$$\|g_\varepsilon\|_{L^2}^2 = \varepsilon^{-2(1+\alpha)}\|\Lambda(\varepsilon)\eta_0\|_{L^2}^2 = -\gamma_0 \cos(\alpha\pi/2) + o(1).$$

On the other hand, we use the formula

$$\|\tau_1\|_{L^2}^2 = 2\pi \int_0^\infty r|H_{1-\alpha}(i^{1/2}r)|^2 \, dr = 2/\sin(\alpha\pi/2)$$

to obtain that

$$\|g_0\|_{L^2}^2 = |\beta_0|^2\|\tau_1\|_{L^2}^2 = 2|\beta_0|^2/\sin(\alpha\pi/2).$$

Since $2|\beta_0|^2/\sin(\alpha\pi/2) = -\gamma_0\cos(\alpha\pi/2)$ by (6.8), it follows that $\|g_\varepsilon\|_{L^2} \to \|g_0\|_{L^2}$. Next we shall show that $g_\varepsilon \to g_0$ is weak. Let $f \in C_0^\infty(\mathbf{R}^2 - \{0\})$. Then $p_{-\varepsilon} f = \pi_- f$ for $\varepsilon > 0$ small enough, and

$$(g_\varepsilon, f)_{L^2} = \varepsilon^{-(1+\alpha)}((L_\varepsilon - i)^{-1} J_\varepsilon b^{1/2}\eta_0, \pi_- f)_{L^2}.$$

We have

$$(L_\varepsilon - i)^{-1} J_\varepsilon b^{1/2}\eta_0 = i^{\alpha/2}\beta_0 \varepsilon^{1+\alpha}\tau_0 + o_2(\varepsilon^{1+\alpha})$$

by Proposition 7.1 with $\sigma = i^{1/2}$, where $\tau_0 = H_\alpha(i^{1/2}r)$. Hence it follows that

$$(g_\varepsilon, f)_{L^2} \to i^{\alpha/2}\beta_0(\pi_+\tau_0, f)_{L^2}.$$

By (2.2), we can calculate

$$\pi_+\tau_0 = -i^{3/2}H_{\alpha-1}(i^{1/2}r)e^{i\theta} = -i^{3/2}e^{i(1-\alpha)\pi}\tau_1 = i^{3/2-2\alpha}\tau_1.$$

This shows that $g_\varepsilon \to g_0$ is weak, and the proof is complete. □

Regularity for Lorentz metrics under curvature bounds

Michael T. Anderson[a)]
Department of Mathematics, S.U.N.Y. at Stony Brook, Stony Brook, New York 11794-3651

(Received 27 January 2003; accepted 11 April 2003)

Let (**M**, **g**) be an $(n+1)$-dimensional space–time, with bounded curvature, with respect to a bounded framing. If (**M**, **g**) is vacuum, or satisfies a weak condition on the stress-energy tensor, then it is shown that (**M**, **g**) locally admits coordinate systems in which the Lorentz metric **g** is well-controlled in the (space–time) Sobolev space $L^{2,p}$, for any $p<\infty$. This result is essentially optimal. The result allows one to control the regularity of limits of sequences of space–times, with uniformly bounded curvature, and has applications to the structure of boundaries and extensions of space–times. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1580199]

I. INTRODUCTION

A well-known issue in the geometry of space–times is to understand the regularity of metrics with given bounds on the curvature tensor. This issue is closely connected to the diffeomorphism invariance of general relativity and the problem of choosing a good gauge, i.e., local coordinate system, in which the metric has optimal regularity. It is not at all clear if the most commonly used local coordinates, namely harmonic or wave coordinates, have such optimal regularity; in any case, this has not been addressed in the literature. The regularity issue also arises frequently in the analysis and discussions of the behavior at the boundary and definitions of singularities for space–times. For instance, if the curvature remains bounded on approach to a possible boundary or singularity of space–time, it is important to understand how smooth the metric remains. If the metric remains sufficiently smooth (in some local coordinates), it may then be possible to extend the space–time through the boundary or the singularity to a larger space–time, essentially then removing the purported boundary or singularity; see Refs. 1–4 for further discussion.

More specifically, it has been an open problem for some time, cf. Refs. 2 and 5–7 for instance, whether a space–time (**M**, **g**) which has curvature bounded in L^{∞} in a suitable sense has coordinate charts in which the metric components $\mathbf{g}_{\alpha\beta}$ are in $C^{1,\gamma}\cap L^{2,p}$, for any $\gamma<1$, $p<\infty$. Here $C^{k,\gamma}$ is the Hölder space of functions whose kth derivatives are Hölder continuous of order γ, while $L^{k,p}$ is the Sobolev space of functions with k weak derivatives in L^{p}. Previous work (see the references above) only gives bounds on the metric components in $C^{0,\gamma}$, so that one has a loss of one derivative.

The first purpose of this article is to provide an affirmative solution to this problem, at least for vacuum space–times or space–times satisfying a weak condition on the stress-energy tensor. Second, this result is applied to examine the regularity of limits of sequences of space–times, or that of space–times with curvature defined only distributionally in L^{∞}. Also included is a preliminary discussion of behavior at the boundary, and the related extension problem, for space–times in any dimension.

The solution of the corresponding regularity problem in Riemannian geometry has been known for some time, and it is useful to state the exact result in this context before considering the Lorentzian analog. Thus, let (M,g) be a Riemannian n-manifold, with say C^{∞} smooth metric g. Suppose there exists a point $p\in M$ such that

$$\mathrm{dist}_g(p,\partial M)\geqslant 1. \tag{1.1}$$

a)Electronic mail: anderson@math.sunsyb.edu

Let $R=R_{ijkl}$ denote the Riemann curvature tensor of (M,g), and let $B_p(r)$ denote the geodesic ball of radius r about p in (M,g). Suppose one has bounds

$$|R|_{L^\infty(B_p(1))}\leqslant C,\ \ \mathrm{vol}_g B_p(\tfrac{1}{2})\geqslant v_o\,, \tag{1.2}$$

for arbitrary constants $C<\infty$, $v_o>0$. Then there exists a constant $r_o>0$, depending only on C, v_o and n, such that the ball $B_p(r_o)$ admits a coordinate chart $U=\{u_k\}$, in which the metric g is $C^{1,\gamma}\cap L^{2,p}$, for any $\gamma<1$, $p<\infty$. Further, there exists a constant R_o, depending only on C, v_o, n and p, such that

$$\|g_{ij}\|_{L^{2,p}}\leqslant R_o\,, \tag{1.3}$$

where the norm is taken over the ball $B_p(r_o)$. A proof of this result may be found in Ref. 8, for instance. By Sobolev embedding $C^{1,\gamma}\subset L^{2,p}$, for $\gamma=1-n/p$, so that (1.3) also gives a bound on g_{ij} in $C^{1,\gamma}$.

This degree of regularity under the bound (1.2) is almost optimal. There are examples of metrics satifying (1.2) which are not $C^{1,1}$ in any coordinate system. Using somewhat more sophisticated analytic techniques, one can show that g_{ij} is in the Zygmund space C^2_*, cf. Ref. 9 (Prop. III.10.2).

The point here is that the estimate (1.3) applies to *all* metrics satisfying the bound (1.2). Thus, while (1.3) may be obvious for a given, possibly explicit, smooth metric, (1.3) applies to the space of all sufficiently smooth metrics, as well as their limits, provided (1.2) holds. In addition, one has an *a priori* bound on the size of the region where (1.3) holds.

A direct analog of this result for Lorentzian metrics is false, due to the existence of large families of nonflat space–times for which the curvature norm $|\mathbf{R}|^2=\mathbf{R}_{ijkl}\mathbf{R}^{ijkl}$ vanishes identically. Thus, consider, for instance, the class of vacuum plane-fronted gravitational waves on $\mathbb{R}^4$, with metric of the form

$$\mathbf{g}=-dudv-h(x,y,u)du^2+(dx^2+dy^2), \tag{1.4}$$

$$\Delta_{(x,y)}h=0. \tag{1.5}$$

For such metrics, the two possible scalar invariants in the curvature tensor, namely

$$|\mathbf{R}|^2=\langle\mathbf{R},\mathbf{R}\rangle=\mathbf{R}_{ijkl}\mathbf{R}^{ijkl}\quad\text{and}\quad\langle\mathbf{R},{*}\mathbf{R}\rangle=\mathbf{R}_{ijkl}({*}\mathbf{R})^{ijkl},$$

vanish identically. The vacuum Einstein equations impose only the condition (1.5), i.e., that h is harmonic as a function of (x,y). Thus, the function h may be an arbitrary function of u, and so is not controlled in any Hölder or Sobolev space. It is thus clear that there is no coordinate system in which a general metric $\mathbf{g}$ of the form (1.4) is controlled in $L^{2,p}$, or even C^0.

To deal with this situation, one imposes bounds on the components of $\mathbf{R}$ in a fixed coordinate system or framing. An efficient way to do this is to choose a future-directed unit timelike vector $T=e_0$ and extend it to an orthonormal frame e_α, $0\leqslant\alpha\leqslant n$, where the space–time dimension is $n+1$. Since the space $T^\perp$ orthogonal to T is spacelike and $O(n)$ is compact, the particular choice of framing for $T^\perp$ is unimportant. The norm of $\mathbf{R}$ w.r.t. T is then defined as

$$|\mathbf{R}|^2_T=\sum\ (R_{ijkl})^2, \tag{1.6}$$

where the components are w.r.t. the framing e_α.

Observe that if, at a point $p\in\mathbf{M}$, the vector $T=T_p$ is contained in a compact subset W of the future interior null cone $T^+_p\mathbf{M}$, then the norms (1.6) are all equivalent, with constant depending only on W. Hence, if K is a compact subset of the space–time $(\mathbf{M},\mathbf{g})$ and T is a continuous vector

field on K, then T (or more precisely, Im T, where T is viewed as a section of the tangent bundle), lies within a compact subset of $T^+\mathbf{M}$, where $T^+\mathbf{M}$ is the bundle of future interior null cones in the tangent bundle $T\mathbf{M}$.

To state the main result, we need the following definition, which is essentially just a normalization on the size of the region to be considered in ($\mathbf{M}$, $\mathbf{g}$), as is (1.1).

Definition 1: Let Ω be a domain in a smooth Lorentz manifold ($\mathbf{M}$, $\mathbf{g}$). Then Ω satisfies the size conditions if the following holds: The domain Ω admits a smooth time function t, with $c_o^{-1} \leqslant \|\nabla t\| \leqslant c_o$, for an arbitrary but fixed constant $c_o < \infty$. Further, one has

$$C_1 = B_p(1) \times [-1,1] \subset\subset \Omega, \tag{1.7}$$

i.e., the one-cylinder C_1 has compact closure strictly contained in Ω. Here $B_p(r)$ is the geodesic r-ball about a point p in S, where $S = S_0 = t^{-1}(0)$ and the metric g on S is that induced from $\mathbf{g}$. The product $B_p(1) \times [-1,1]$ is identified with a subset of Ω by the flow of ∇t, i.e., $(q,s) \to \gamma_q(s)$, where $\gamma_q(s)$ is the flow line of ∇t, starting at q and terminating on the s-level set $S_s = t^{-1}(s)$.

Let $T = \nabla t / \|\nabla t\|$ be the corresponding future-directed unit timelike vector field, and set

$$D = \text{Im}\, T|_{C_1} \subset\subset T^+\Omega. \tag{1.8}$$

The size conditions represent a Lorentzian analog of the condition (1.1). They can always be realized by choosing Ω to be a sufficiently small open set in ($\mathbf{M}$, $\mathbf{g}$) and rescaling the metric up sufficiently. Essentially, they just serve to normalize the data.

The main result of the article is then the following:

Theorem 2: *Let Ω be a domain in a vacuum $(n+1)$-dimensional space–time ($\mathbf{M}$, $\mathbf{g}$), $n \geqslant 2$, satisfying the size conditions. Suppose that there are constants $C < \infty$ and $v_o > 0$ such that*

$$|\mathbf{R}|_T \leqslant C, \quad \text{vol}_g B_p(\tfrac{1}{2}) \geqslant v_o. \tag{1.9}$$

Then there exists a constant $r_o > 0$, depending only on C, v_o, c_o, D, (and n), and a coordinate system (τ, x_i), $1 \leqslant i \leqslant n$, on the r_o-cylinder

$$C_{r_o} = D_p(r_o) \times [-r_o, r_o] \subset C_1, \tag{1.10}$$

such that the components of the metric $\mathbf{g}_{\alpha\beta}$ are in $C^{1,\gamma} \cap L^{2,p}$, for any $\gamma < 1$, $p < \infty$. Here $D_p(r)$ is the geodesic r-ball about p in the level set $\tau = 0$ and the product structure is that induced by the flow of $\nabla\tau$.

Further, there exists a constant $R_o < \infty$, depending only on C, v_o, c_o, D and the exponent p, such that, on C_{r_o},

$$\|\mathbf{g}_{\alpha\beta}\|_{L^{2,p}} \leqslant R_o. \tag{1.11}$$

More precisely, for any $k \leqslant 2$, and $0 \leqslant \alpha, \beta \leqslant n$,

$$\|\partial_\mu^k \mathbf{g}_{\alpha\beta}\|_{L_x^{2-k,p}} \leqslant R_o, \tag{1.12}$$

where ∂_μ^k denotes any k-fold space–time partial derivative and the spatial $L_x^{2-k,p}$ norm is taken over any spatial slice $\{\tau = \text{const}\}$ in C_{r_o}. The constant R_o is independent of τ in $[-r_o, r_o]$.

The coordinates in Theorem 2 are geometrically natural; the time coordinate τ is a Gaussian (equidistant) coordinate, while the spatial coordinates are chosen to be harmonic on the spatial slices $\{\tau = \text{const}\}$. It is not clear if there exist space–time harmonic (or wave) coordinates, in which $\mathbf{g}$ has this degree of regularity.

The condition that ($\mathbf{M}$, $\mathbf{g}$) is vacuum, i.e., $\mathbf{Ric}_\mathbf{g} = 0$, is used in only in minor way. It is used, via the Bianchi identity, only to obtain L^p bounds on the second time derivatives $\partial_\tau \partial_\tau \mathbf{g}_{0\alpha}$ of the

components $\mathbf{g}_{0\alpha}$. This is equivalent to bounds on the second time derivatives on the components of the shift vector of the coordinates, i.e., a bound on the acceleration of the shift. Such acceleration components do not appear in any component of the curvature tensor $\mathbf{R}$. All other estimates on $\partial_\gamma^k \mathbf{g}_{\alpha\beta}$ are independent of the Einstein equations.

The vacuum condition can be weakened to an assumption on the stress-energy tensor $\mathcal{T}$ in the Einstein equations, of the form

$$\|\nabla_T \mathcal{T}\|_{L_x^{-1,p}} \leqslant C. \tag{1.13}$$

Here $L_x^{-1,p}$ is the dual space of $L_o^{1,q}$, the space of $L_x^{1,q}$ functions of compact support on spatial slices $\{\tau = \text{const}\}$ within C_{r_o}, $p^{-1}+q^{-1}=1$.

The condition (1.13) will be satisfied automatically for many physically natural matter fields, cf. Remark 4.

Theorem 2 is formulated in such a way that it is easy to pass to limits. Thus, suppose $(\mathbf{M}_i, \mathbf{g}_i)$ is a sequence of smooth space–times satisfying the hypotheses of the theorem. There exist then domains $\Omega_i \subset (\mathbf{M}_i, \mathbf{g}_i)$, points $p_i \in \Omega_i$ such that the size conditions (1.7) and (1.8) hold, with D_i uniformly compact in $T^+\Omega_i$, (i.e., T does not become arbitrarily close to null cones). If (1.9) and (1.13) hold uniformly on Ω_i, then there is a subsequence which converges to a limit $C^{1,\gamma} \cap L^{2,p}$ space–time $(\mathbf{M}, \mathbf{g})$, defined at least on an r_o-cylinder C_{r_o}. Further, the convergence to the limit is $C^{1,\gamma}$ and weak $L^{2,p}$, and the bound (1.12) holds on the limit.

Define a Lorentz manifold $(\mathbf{M}, \mathbf{g})$ to be weakly regular if $\mathbf{g}$ is a continuous Lorentz metric, with $\mathbf{g} \in L^{1,2}_{loc}(\mathbf{M})$. It is well-known, cf. Refs. 1 and 10, for example, that such metrics have a well-defined curvature tensor $\mathbf{R}$ in the sense of distributions. This leads to the following corollary.

Corollary 3: Let $(\mathbf{M}, \mathbf{g})$ *be a weakly regular Lorentz manifold, and let* $\Omega \subset\subset \mathbf{M}$ *be a domain with compact closure in* $\mathbf{M}$. *Suppose the size conditions hold locally on* Ω, *in that the constant* $\frac{1}{2}$ *is replaced by a small constant* δ_o *so that* $B_p(\delta_o) \subset\subset \mathbf{M}$, *for any* $p \in \Omega$. *Suppose also the bounds (1.9) hold locally and uniformly on* δ_o *cylinders as in (1.7), centered at any* $p \in \Omega$.

Then Ω *may be covered by a finite atlas of charts in which the metric* $\mathbf{g} = \mathbf{g}_{\alpha\beta}$ *satisfies all the bounds in (1.12), except for the* L_x^p *bound on* $\partial_\tau \partial_\tau \mathbf{g}_{0\alpha}$. *The bounds in (1.12) depend, near* $\partial\Omega$, *on the distance of* $\partial\Omega$ *to* $\partial\mathbf{M}$.

If in addition the bound (1.13) holds distributionally on $\mathbf{M}$ *[e.g.,* $(\mathbf{M}, \mathbf{g})$ *is a weak solution of the vacuum equations], then all bounds in (1.12) hold locally on* $(\Omega, \mathbf{g})$.

We refer to the proof of Corollary 3 below for the precise meaning that (1.13) holds distributionally.

The proof of Theorem 2 and Corollary 3 follow in Sec. II, while Sec. III concludes the article with several remarks and extensions of these results, together with some open problems.

II. PROOFS OF THE RESULTS

In this section, we prove Theorem 2 and Corollary 3. For clarity, the proof of Theorem 2 is divided into several steps, each treating basically separate issues. In the following, as already above, space–time quantities are generally denoted in boldface while spatial quantities are not in boldface.

A. Step I (Initial choice of domain)

Let $B_p(r)$ be the intrinsic geodesic ball about p in S. Since S is achronal in the cylinder C_1 from (1.7), the extrinsic radius of $B_p(r)$ is bounded below for r small. Thus, if γ is any spacelike curve in $(\mathbf{M}, \mathbf{g})$ from p to $x \in \partial B_p(r_1) \subset S$, for r_1 small, then the length $L(\gamma)$ satisfies $L(\gamma) \geqslant l_o r_1$; the constants l_o and r_1 depend only on c_o and D in Definition 1.

Let $\mathcal{D}_{r_1}$ be the domain of dependence of $B_p(r_1)$ in the manifold $(\mathbf{M}, \mathbf{g})$. Thus, by choosing r_1 sufficiently small, again depending only on c_o, D, one has

$$\mathcal{D}_{r_1} \subset\subset \Omega, \tag{2.1}$$

i.e., $\mathcal{D}_{r_1}$ has compact closure in Ω.

The region $\mathcal{D}_{r_1}$ is globally hyperbolic and hence any pair of time-related points in $\mathcal{D}_{r_1}$ may be joined by a timelike maximizing geodesic in $\mathcal{D}_{r_1}$. Recall from Definition 1 that the curves γ_x are the flow lines of ∇t through x. For $r_2 > 0$ small (to be determined below), let

$$q = \gamma_p(-r_2), \tag{2.2}$$

so $q \ll p$, i.e., q is to the past of p. For x to the future of p, $x \gg p$, let

$$\tau(x) = \mathrm{dist}_{\mathbf{g}}(x,q) - \mathrm{dist}_{\mathbf{g}}(p,q), \tag{2.3}$$

so that $\tau(p) = 0$ and $\tau(x) > 0$, for $x \gg p$. The distance $\tau(x)$ is realized by a maximizing timelike geodesic $\sigma_v(\tau) = \exp_q(\tau + \tau_o)v$ from q to x; here $v \in T_q^+\mathbf{M}$, with $\mathbf{g}(v,v) = -1$, and $\tau_o = \mathrm{dist}_{\mathbf{g}}(p,q)$. This normalization gives $p = \sigma_{v_o}(0)$, for some $v_o \in T_q^+\mathbf{M}$. Let

$$N = \nabla \tau$$

be the corresponding unit timelike vector field, so that N is the tangent vector to geodesics σ issuing from q. Although N is well-defined and smooth along the individual geodesics $\sigma_v(\tau)$ [for any τ until one reaches the boundary of $(\mathbf{M}, \mathbf{g})$], at points where the exponential map $\exp_q$ has cut or conjugate points, N is not uniquely defined. Of course, past such cut or conjugate points, the geodesics $\sigma_v(\tau)$ are no longer maximal. Thus, in general, τ is merely Lipschitz and N, as a vector field, is defined only almost everywhere to the future of q. At the end of step I (via the work in step V), it will be seen that in fact τ and N are smooth, in suitable domains of a definite size. In the following, unless stated otherwise, all geodesics are assumed to be maximal, i.e., they are not continued past the conjugate or cut points of q.

Next, let $\Sigma = \Sigma_0 = \tau^{-1}(0)$ and similarly let Σ_τ be the τ-level set of τ in $\mathcal{D}_{r_1}$. Since the geodesics are maximal, $\sigma_v(\tau) \in \Sigma_\tau$, and $p \in \Sigma = \Sigma_0$. Again, in general, Σ_τ is only Lipschitz. For $r_2 \leqslant r_1$, consider the intrinsic geodesic ball $B_p(r_2) \subset S$ and let

$$\mathcal{C} = \{x \in \mathcal{D}_{r_1} : x = \sigma(\tau),\ \ \tau \leqslant r_2, \quad \text{and} \ \ \sigma(\tau) \cap B_p(r_2) \neq \varnothing\} \subset \mathcal{D}_{r_1}. \tag{2.4}$$

This is the "cone" of maximal geodesics σ starting at q, hitting S within $B_p(r_2)$, and terminating at time $\tau = r_2$.

Observe that the vector field N restricted to $\mathcal{C}$ stays within a compact subset of $T^+\mathbf{M}$. In fact, since N is parallel along its geodesic flow lines, this needs to be verified only at the base point q, where it holds by construction. It then follows from the curvature bound (1.9) and the remarks following (1.6) that

$$|\mathbf{R}|_N \leqslant C_1 = C_1(C,D). \tag{2.5}$$

Now the curvature bound (2.5) and the Rauch comparison theorem (cf. Ref. 11, for instance) imply that if r_2 is sufficiently small, depending (explicitly) only on C_1, then the exponential map $\exp_q$ restricted to the interior future null cone in T_q^+, has no conjugate points in $\mathcal{C}$. Thus, $\exp_q$ is of maximal rank, and so a local diffeomorphism on $\mathcal{C}$. In fact, for r_1 is sufficiently small, again depending only on C and c_o, no timelike or null geodesic within $\mathcal{D}_{r_1}$ has conjugate points, and so $\exp_x$ is of maximal rank on timelike geodesics in $\mathcal{D}_{r_1}$, $\forall x \in \mathcal{D}_{r_1}$.

Since $\mathcal{D}_{r_1}$ is globally hyperbolic and without timelike conjugate points, it follows then from Ref. 11 (Thm. 11.16, for instance) that any pair of points $x, y \in \mathcal{D}_{r_1}$ with $y \gg x$, may be joined by a *unique* maximizing timelike geodesic in $\mathcal{D}_{r_1}$, provided $\mathcal{D}_{r_1}$ is future one-connected (i.e., any pair of timelike curves joining x and y are homotopic through timelike curves).

In general, $\mathcal{D}_{r_1}$ need not be future one-connected. Consider, for example, the past null cone of two-dimensional Minkowski space in hyperbolic coordinates $t \in (-\infty, 0)$, $\phi \in (-\infty, \infty)$,

$$-dt^2+t^2d\phi^2.$$

If ϕ is identified periodically, with any period, then the resulting space–time is globally hyperbolic but not future one-connected. The future exponential map based at any point q has cut points; if the period of ϕ is sufficiently small, or if q is sufficiently close to $\{0\}$, then cut points occur arbitrarily close to q.

However, $\mathcal{D}_{r_1}$ is future one-connected if it has a simply connected Cauchy surface S, i.e., $S \equiv S_{r_1}=S\cap\mathcal{D}_{r_1}$, for S as in (1.7) ff. To see this, let γ_1, γ_2 be two timelike curves with common endpoints in $\mathcal{D}_{r_1}$. The flow of the timelike vector field ∇t gives a strong deformation retraction of $\gamma_1\cup\gamma_2$ onto a closed loop $\lambda_1\cup\lambda_2$ in S. If S is simply connected, then λ_1 may be deformed into λ_2 within S. These two homotopies, timelike along ∇t and spacelike along the Cauchy surfaces S_t, may be performed simultaneously, but with the latter at a larger speed than the former, to produce a timelike homotopy from γ_1 to γ_2.

We will prove later that S (or more precisely, a domain in S of a definite size) is simply connected. However, in order not to overburden the arguments that follow with such further issues, we assume in the following, through step IV, that the Cauchy surface $S\subset\mathcal{D}_{r_1}$ is simply connected. This hypothesis will be removed in step V, using the results obtained in the previous steps.

It follows then that the exponential map $\exp_q$ is a diffeomorphism onto $\mathcal{C}$, when restricted to a suitable domain in $T_q^+\mathbf{M}$. The time function τ is smooth in $\mathcal{C}\setminus\{q\}$, as are the level sets $\Sigma_\tau\cap\mathcal{C}$, and there is a unique maximizing geodesic from q to any point in $\mathcal{C}$.

From now on, we consider $\Sigma_\tau\subset\mathcal{C}$, and so let Σ_τ denote the prior Σ_τ intersected with $\mathcal{C}$. The level sets Σ_τ form a foliation of $\mathcal{C}$ by equidistant spacelike hypersurfaces, with unit normal N.

B. Step II (Initial curvature and volume estimates)

The geodesic congruence σ on $(\mathcal{C},\mathbf{g})$ satisfies the Riccati or transport equation

$$K'+K^2+\mathbf{R}_N=0. \tag{2.6}$$

Here $K=D^2\tau$ is the second fundamental form or extrinsic curvature of the leaves Σ_τ, $\mathbf{R}_N$ is the symmetric bilinear form given by $\mathbf{R}_N(X)=\langle\mathbf{R}(N,X)X,N\rangle$ and $'$ is the covariant derivative in the direction N. Hence, the bound (2.5) gives

$$|K'+K^2|\leq C_1.$$

This estimate holds on Σ_τ, for all $\tau\in[-r_2,r_2]$. It then follows by standard comparison theory for the Riccati ODE (2.6) that if r_2 is sufficiently small, depending only on c_o, D, and C_1, then

$$|K|_{L^\infty}\leq C_2, -|K'|_{L^\infty}\leq C_2, \tag{2.7}$$

on all Σ_τ, $\tau\in[-r_2/2,r_2]$. The constant C_2 depends only on r_2 and C_1. The Gauss equation relating the curvature $\mathbf{R}$ of the ambient manifold $(\mathbf{M},\mathbf{g})$ with that of the spatial slices Σ_τ reads

$$\mathbf{R}_{ijkl}=R_{ijkl}+K_{ik}K_{jl}-K_{il}K_{jk}, \tag{2.8}$$

for spatial components $(ijkl)$. This, together with the bounds (2.5) and (2.7), thus gives the bound

$$|R_g|_{L^\infty}\leq C_3, \tag{2.9}$$

on Σ_τ, $\tau\in[-r_2/2,r_2]$. Let dK be the exterior derivative (w.r.t. the connection induced by g) of K, when K is viewed as a one-form with values in $T\Sigma_\tau$, i.e., $dK(X,Y,Z)=(\nabla_XK)(Y,Z)-(\nabla_YK)(X,Z)$. The Gauss–Codazzi equations are

$$dK=\mathbf{R}^N,$$

where $\mathbf{R}^N(X,Y,Z)=\langle \mathbf{R}(N,X),Y,Z\rangle$. Hence, (2.5) also implies

$$|dK|_{L^\infty}\leqslant C_3. \tag{2.10}$$

We record also the well-known constraint equations:

$$\begin{aligned} \delta K &= -dH-\mathbf{Ric}(N),\\ R-|K|^2+H^2 &= 2\mathbf{Ric}(N,N)+\mathbf{R}, \end{aligned} \tag{2.11}$$

where $H=$ tr K is the mean curvature and the operators δ and d are taken on Σ_τ.

Next, we use the bounds above to obtain a lower volume bound on the spatial slices Σ_τ, $\tau\in[-r_2/2,r_2]$, from that on the slice $S=S_0$ in (1.9). To do this, let $\hat{S}=S\cap\mathcal{C}$. The domain $\hat{S}$ may be written as a graph over $\Sigma=\Sigma_0\subset\mathcal{C}$ via the time coordinate τ in the usual way. Thus, each geodesic $\sigma=\sigma_v$ intersects Σ and $\hat{S}$ in exactly two points $\sigma(\tau_1)$, $\sigma(\tau_2)$, with $|\tau_i|\leqslant r_2$. For $x=\sigma_v(\tau_1)\in\Sigma$, let $u(x)=\tau_2-\tau_1$, so that $\sigma_v(\tau_2)\in\hat{S}$. This gives a diffeomorphism $\phi:\Sigma\to\hat{S}$, and hence

$$\text{vol } \hat{S}=\int_{\hat{S}}dV_{\hat{S}}=\int_\Sigma \phi^*(dV_{\hat{S}})=\int_\Sigma J dV_\Sigma,$$

where $J=\det D\phi$ is the Jacobian of ϕ. Since both $\hat{S}$ and Σ are spacelike, the function u is a Lipschitz function (cf. Ref. 1) whose (weak) derivative is uniformly bounded, since both normal vectors N and T lie in compact subsets of interior null cones. In addition, the (uniform) time τ exponential map, mapping Σ to Σ_τ, has Jacobian uniformly bounded above and below on $[-r_2/2,r_2]$, by the bound (2.7). (Recall that $H=$tr K measures the infinitesimal volume expansion or contraction.) It follows that the Jacobian J is uniformly bounded below (depending only on C, D). Hence,

$$\text{vol } \Sigma\geqslant v_1\cdot\text{vol } \hat{S}. \tag{2.12}$$

Now the lower bound on vol $B_p(\frac{1}{2})\subset S$ in (1.9) does not immediately imply a lower bound on vol $\hat{S}$ (it could *a priori* happen that most all of the volume of $B_p(\frac{1}{2})$ occurs outside $\hat{S}$). However, in this case one can repeat all the estimates (2.6)–(2.9) when the construction of $\mathcal{C}$ is based at other center points q' in place of q. Thus, for $p'\in B_p(\frac{1}{2})\subset S$, define q' as in (2.2) and let $\mathcal{C}'$ be then as in (2.4). The same estimates as above then hold in $\mathcal{C}'$. The corresponding domains $\hat{S}'=S\cap\mathcal{C}'$ give a covering of $B_p(\frac{1}{2})\subset S$. Hence the volume bound in (1.9) and the estimates above now do give the existence of points $p_o\in B_p(\frac{1}{2})\subset S$ such that

$$\text{vol } \Sigma_{p_o}\geqslant v_2>0, \tag{2.13}$$

where Σ_{p_o} is the level set of τ (i.e., τ_o) containing p_o and $v_2=v_2(v_o,D,C_1)$. [The local estimate (2.12) does not in fact depend on the absence of future cut points of $\exp_q$, cf. the discussion concerning (2.59) below.]

Recall the standard volume comparison theorem in Riemannian geometry: if (N,g) is a Riemannian n-manifold, with $\text{Ric}_g\geqslant-(n-1)k$, then the ratio

$$\frac{\text{vol } D(r)}{\text{vol } D_k(r)},$$

is monotone nonincreasing in r. Here $D(r)$ denotes the volume of a geodesic r-ball at any fixed point, while $D_k(r)$ is the geodesic r-ball in the n-dimensional space form of constant curvature k. It then follows from the curvature bound (2.9), together with (2.13), that the geodesic balls $D_{p_o}(r)\subset(\Sigma_{p_o},g)$ satisfy

$$\text{vol } D_{p_o}(r)\geqslant v_3 r^n,$$

for all $r\leqslant r_2$, where v_3 depends only on v_2 and C_3.

Observe that a similar estimate also holds for geodesic balls on other spatial slices Σ_τ, with $\Sigma_0=\Sigma_{p_o}$, for $\tau\in[-r_2/2,r_2]$. Namely, the L^∞ bound on K in (2.7) bounds the infinitesimal distortion in the spatial metrics, and hence distances and volumes, under the flow of N. It follows that within the cylinder $\mathcal{C}_o$ centered at p_o, the volume estimate above holds for balls $D_{p_\tau}(r)\subset\Sigma_\tau$; thus, for $p_\tau=\sigma_{v_o}(\tau)$, where $p_o=\sigma_{v_o}(0)$, and for $r\leqslant r_2$, one has

$$\text{vol } D_{p_\tau}(r)\geqslant v_4 r^n, \tag{2.14}$$

$v_4=v_4(v_o,C,D)$. An upper bound on the volume of vol $D_{p_\tau}(r)$ of the form (2.14) follows immediately from the curvature bound (2.9).

In the construction above, we have shifted the original base point p to a new base point p_o. However, one may now use these estimates to obtain equivalent volume bounds for the slices Σ_τ within the original cylinder $\mathcal{C}$ centered at p. This may be done by constructing a suitable chain, of bounded cardinality, of overlapping cylinders $\mathcal{C}_i$ from $\mathcal{C}_o$ to $\mathcal{C}$. One then uses the arguments above on each $\mathcal{C}_i$, together with the fact that upper and lower volume bounds of spatial slices are equivalent to upper and lower volume bounds of each cylinder $\mathcal{C}_i$.

Thus, in the following, we work on the original cylinder $\mathcal{C}$ from (2.4) centered at p; the bound (2.14) holds with p in place of p_o.

C. Step III (Local coordinates)

In this step, we define the cylinder C_{r_o} and the local coordinate system on it, and obtain in addition some initial estimates on $\mathbf{g}_{\alpha\beta}$. The local coordinates are Gaussian in time and harmonic in space (Gaussian-harmonic coordinate system).

Thus, the function τ from (2.3) is chosen as the time coordinate on $\mathcal{C}$. To construct spatial harmonic coordinates, start with the slice $\Sigma=\Sigma_0$ within $\mathcal{C}$. By (2.9) and (2.14), one has the bounds

$$|R_g|\leqslant C_3, \text{vol}_g D_p(r_2)\geqslant v_4. \tag{2.15}$$

It then follows, for instance from the discussion in Sec. I, that there exists $r_o>0$, depending only on C_3 and v_4, such that the geodesic ball $D_p(r_o)\subset\Sigma$ admits a harmonic coordinate system $\{x_i\}$, $1\leqslant i\leqslant n$, in which the spatial metric $g=\mathbf{g}|_\Sigma$ is controlled in $L^{2,p}$, i.e.,

$$\|g_{ij}\|_{L^{2,p}}\leqslant R_o, \tag{2.16}$$

where the $L^{2,p}$ norm is taken on $D_p(r_o)$, and $R_o=R_o(C_3,v_4,p)$. The harmonic functions x_i are solutions to the Dirichlet problem

$$\Delta_g x_i=0,\ x_i|_{\partial D}=\phi_i, \tag{2.17}$$

where $D=D_p(r_o)$ and ϕ_i are suitably chosen boundary values (approximating linear-type functions, cf. Ref. 8).

Let $\phi_{i,\tau}=\phi_i\circ\psi_\tau$, where ψ_τ is the time τ flow from Σ_τ to Σ_0 along the integral curves of N. Thus, ψ_τ maps a domain $D_\tau\subset\Sigma_\tau$ diffeomorphically onto D and $\phi_{i,\tau}$ are functions defined on ∂D_τ. It follows that

$$N(\phi_{i,\tau})=1 \quad \text{at} \quad \partial D_\tau. \tag{2.18}$$

Define the functions x_i on D_τ to be solutions to the Dirichlet problem

$$\Delta_{g_\tau} x_i=0, \quad x_i|_{\partial D_\tau}=\phi_{i,\tau}. \tag{2.19}$$

By (2.9) and (2.14), the estimate (2.15) holds uniformly on D_τ, for $\tau\in[-r_2/2,r_2]$. Hence, as with Σ_0, $r_o>0$ may be chosen, depending only on C_3 and v_4, such that the functions $\{x_i\}$ form a harmonic coordinate system on $D_\tau\subset\Sigma_\tau$, on which one has the bounds

$$\|g_{ij}\|_{L^{2,p}}\leq R_o, \tag{2.20}$$

where the $L^{2,p}$ norm is taken on D_τ and $g=g_\tau$. The estimate (2.20) holds for all $|\tau|\leq r_o$.

This construction gives the local coordinate system (τ,x_i), $1\leq i\leq n$, on the r_o-cylinder

$$C_{r_o}=D_p(r_o)\times[-r_o,r_o] \tag{2.21}$$

about p, where the product structure is defined by the flow of $\nabla\tau$. For the remainder of the proof, Σ_τ is now redefined to be its intersection with C_{r_o}, i.e., $\Sigma_\tau\equiv D_\tau$.

The metric $\mathbf{g}$ in these coordinates has the form

$$\mathbf{g}=(-1+|\xi|^2)(d\tau)^2+g_{ij}(dx_i+\xi_i d\tau)(dx_j+\xi_j d\tau), \tag{2.22}$$

where $\xi=\{\xi_i\}$ is the shift vector. Thus,

$$\partial/\partial\tau=N+\xi,$$

with $N=\nabla\tau$. The lapse function α of this foliation satisfies $\alpha\equiv 1$.

On each slice $\Sigma_\tau\subset C_{r_o}$, one has good spatial control, namely for $g_{ij}=\mathbf{g}_{ij}=\mathbf{g}|_{\Sigma\tau}$, (2.20) holds. As usual, Latin indices i,j, denote spatial variables, i.e., $1\leq i,j\leq n$, while Greek indices α, β denote space–time variables, $0\leq\alpha,\beta\leq n$.

In the following, all Sobolev norms $L^{k,p}$ are understood to be spatial norms, i.e., the derivatives and norms are taken on spatial leaves Σ_τ. Thus, for emphasis or clarity, we sometimes write $L^{k,p}_x$ in place of $L^{k,p}$. All estimates will be independent of τ, for $\tau\leq r_o$.

D. Step IV ($L^{2,p}$ estimates of $g_{\alpha\beta}$)

In this next step, we extend the estimate (2.20) to include the remaining terms $\mathbf{g}_{0\alpha}$, $0\leq\alpha\leq n$, and also obtain estimates on the time derivatives of $\mathbf{g}_{\alpha\beta}$.

Before beginning, we first improve the estimate (2.7) on the second fundamental form. Recall the Simons (or Bochner-Weitzenbock) formula (cf. Ref. 12, Chap. 1I):

$$D^*DK=\delta dK+d\delta K-\mathcal{R}(K)$$

on (Σ_τ,g_τ), where the term $\mathcal{R}(K)$ is linear in the curvature and K; the exact form of $\mathcal{R}(K)$ plays no role in the argument, but for completeness is given by $\mathcal{R}(K)=Ric\circ K+K\circ Ric-2R\circ K$, where $R\circ K$ is the action of the curvature tensor R on symmetric bilinear forms. The elliptic operator $D^*D=-trD^2$ is the so-called rough Laplacian.

In the following, we frequently write $f\in L^{k,p}$ or $f\in L^{k,p}_x$ as shorthand for f is uniformly bounded in $L^{k,p}$ along the spatial slices Σ_τ, $|\tau|\leq r_o$.

By (2.10), $dK\in L^\infty$, and hence $\delta dK\in L^{-1,p}_x$, for all $p<\infty$; recall that these spaces are defined as following (1.13). Similarly, by (2.11), since $dd=0$,

$$d\delta K=d(\mathbf{Ric}N)\in L^{-1,p}_x; \tag{2.23}$$

here we recall that the operators δ and d are spatial. The term $\mathcal{R}(K)$ is also bounded in L^∞. Hence, one has

$$D^*DK = Q_1, \tag{2.24}$$

where Q_1 is uniformly bounded in $L_x^{-1,p}$, for any $p<\infty$, while K is uniformly bounded in L^∞. By (2.20), the coefficients of D^*D in the local coordinates $\{x_i\}$ are controlled in $L^{2,p}\subset C^{1,\gamma}$. It then follows from standard elliptic regularity theory, cf. Ref. 13, that

$$|K|_{L_x^{1,p}} \leqslant C_2, \tag{2.25}$$

where $C_2 = C_2(C, v_o, c_o, D, p)$, on all spatial slices Σ_τ, $|\tau| \leqslant r_o$.

E. Spatial estimates

Here, we prove that the components $\mathbf{g}_{0\alpha}$ also satisfy the $L^{2,p} = L_x^{2,p}$ estimate (2.20) uniformly on Σ_τ. One has $N = \mathbf{g}^{0\alpha}\partial_\alpha$, $\nabla x_i = \mathbf{g}^{i\alpha}\partial_\alpha$. Hence, $N(x_i) = \langle N, \nabla x_i\rangle = \mathbf{g}^{0\alpha}\mathbf{g}^{i\beta}\mathbf{g}_{\alpha\beta} = \mathbf{g}^{0i}$.

To obtain estimates on $N(x_i)$, differentiate the harmonic coordinate condition (2.17), in the normal (i.e., N) direction. Let $x_i' = N(x_i)$. Since $\Delta x_i = 0$, a standard computation [cf. Ref. 12, (1.184) for example] gives

$$\Delta x_i' = -\Delta' x_i = \langle D^2 x_i, K\rangle - \langle dx_i, \delta K + \tfrac{1}{2} dH\rangle. \tag{2.26}$$

Here, as above and in the following, all metric quantities in (2.26) are on spatial slices Σ_τ.

By (2.25), K is uniformly bounded in $L^{1,p}$. The term $D^2 x_i$ is also uniformly bounded in $L^{1,p}$, since by (2.20) the spatial metric is uniformly bounded in $L^{2,p}$ and hence the coordinate functions are uniformly bounded in $L^{3,p}$. Further, both δK and dH are uniformly bounded in L^p. Thus,

$$\Delta x_i' = Q_2,$$

where Q_2 is uniformly bounded in L^p, $|\tau| \leqslant r_o$. As before, the coefficients of Δ are controlled in $L^{2,p}$. Further, by construction, cf. (2.18), $x_i' = 1$ on $\partial\Sigma_\tau$. Hence, standard elliptic regularity again gives

$$\|x_i'\|_{L^{2,p}} = \|\mathbf{g}^{0i}\|_{L^{2,p}} \leqslant C_4, \tag{2.27}$$

where $C_4 = C_4(C, v_o, c_o, D, p)$. Observe also that

$$\mathbf{g}^{00} = -1 \tag{2.28}$$

(since the lapse function $\alpha \equiv 1$). Hence $\mathbf{g}^{0\alpha} \in L^{2,p}$, i.e., the $L^{2,p}$ norm of $\mathbf{g}^{0\alpha}$ is uniformly bounded, $0 \leqslant \alpha \leqslant n$.

From this and (2.20), it is then an elementary exercise in linear algebra to see that

$$\|\mathbf{g}_{\alpha\beta}\|_{L^{2,p}} \leqslant C_5. \tag{2.29}$$

Briefly, $\mathbf{g}^{0\gamma} = (\det \mathbf{g}_{\alpha\beta})^{-1} A_{0\gamma}$, where $A_{0\gamma}$ is the $(0,\gamma)$ cofactor in the matrix $\mathbf{g}_{\alpha\beta}$. The cofactor A_{00} involves only g_{ij}, and hence by (2.20), $A_{00} \in L^{2,p}$. Thus $\det \mathbf{g}_{\alpha\beta} \in L^{2,p}$. The same reasoning on $\mathbf{g}^{0\alpha}$ then gives $A_{0\alpha} \in L^{2,p}$, for all α. Each determinant A_{0k} may be expanded along the first column to obtain a linear form in the variables $\mathbf{g}_{0i}$, with coefficients $(n-1)\times(n-1)$ determinants. Thus, one has a linear system of n equations in n unknowns $\mathbf{g}_{0i}$. The matrix of this system is the $(n-1)$-compound G_{n-1} of the matrix $[g_{ij}]$, i.e., $(G_{n-1})_{kl} = \det A_{kl}$, where A_{kl} is the (k,l) cofactor of $[g_{ij}]$. Since $[g_{ij}]$ is nonsingular, and since $[g_{ij}]$ nonsingular implies that G_{n-1} is nonsingular (cf. Ref. 14, §1.4 for instance), it follows that this linear system is invertible.

The components $\mathbf{g}_{0i}$ are rational expressions in $\{g_{ij}\}$ and $\{A_{0k}\}$, each of which is now bounded in $L^{2,p}$. Hence $\mathbf{g}_{0i}$ is bounded in $L^{2,p}$. Finally, since $1=\mathbf{g}^{0\alpha}\mathbf{g}_{\alpha 0}=\mathbf{g}^{00}\mathbf{g}_{00}+\mathbf{g}^{0i}\mathbf{g}_{i0}$, it follows from (2.28) that $\mathbf{g}_{00}$ is also bounded in $L^{2,p}$. This establishes the bound (2.29).

Recall that $\partial_\tau = N+\xi$, while $\langle N,\partial_i\rangle = 0$, $i>0$, by construction. Since $\langle \partial_i,\partial_\tau\rangle = \mathbf{g}_{i0}$ is bounded in $L^{2,p}$, it follows that $\langle \xi,\partial_i\rangle$ is bounded in $L^{2,p}$. Hence the shift vector $\xi=\{\xi_i\}$ is bounded in $L^{2,p}$,

$$\|\xi\|_{L^{2,p}} \leqslant C_6. \tag{2.30}$$

This completes the $L^{2,p}$ estimates of $\mathbf{g}_{\alpha\beta}$ in spatial directions.

F. First time derivatives

Next we turn to estimates on the time derivatives of $\mathbf{g}_{\alpha\beta}$, i.e., $L^{1,p}$ estimates for $\partial_\tau \mathbf{g}_{\alpha\beta}$. To begin, using the Leibniz rule, and the fact that $[\partial_\alpha,\partial_\tau]=0$, it suffices to estimate

$$\langle \nabla_{\partial_\alpha}\partial_\tau,\partial_\beta\rangle = \langle \nabla_{\partial_\alpha}N,\partial_\beta\rangle + \langle \nabla_{\partial_\alpha}\xi,\partial_\beta\rangle. \tag{2.31}$$

Suppose first $\alpha>0$, $\beta>0$, so $(\alpha,\beta)=(i,j)$. The first term in (2.31) is then K_{ij}, which is bounded in $L^{1,p}$ by (2.25), while the second term is also bounded in $L^{1,p}$ by (2.30) [and the $L^{2,p}$ spatial bounds on $\mathbf{g}_{\alpha\beta}$ in (2.29)]. This gives uniform $L^{1,p}$ bounds on $\partial_\tau g_{ij}$, i.e.,

$$\|\partial_\tau g_{ij}\|_{L^{1,p}_x} \leqslant C_7. \tag{2.32}$$

It follows of course that also

$$\|\partial_{x_k}\partial_\tau g_{ij}\|_{L^p_x} \leqslant C_7.$$

The bounds on $\partial_\tau \mathbf{g}_{0\alpha}$ require more work. Writing $\partial_\tau = N+\xi$ as above, the $L^{2,p}$ spatial estimates above imply that $\xi(\mathbf{g}_{0\alpha})$ is bounded in $L^{1,p}$, so one needs to obtain $L^{1,p}$ bounds on $N(\mathbf{g}_{0\alpha})$.

Recall that $x_i' = N(x_i) = \mathbf{g}^{0i}$. Hence $N(\mathbf{g}^{0i}) = NN(x_i) = x_i''$. To obtain estimates on x_i'', differentiate the equation (2.17) in the N direction twice. This gives

$$\Delta x_i'' = -(2\Delta' x_i' + \Delta'' x_i). \tag{2.33}$$

Here, as before, all metric quantities are on the spatial slices Σ_τ. It has already been proved that $x_i' \in L^{2,p}$. From the form of Δ' in (2.26), one then easily sees that

$$\Delta' x_i' \in L^p.$$

Next, one has

$$\Delta'' x_i = N\langle D^2 x_i, K\rangle - N\langle dx_i, \delta K + \tfrac{1}{2} dH\rangle. \tag{2.34}$$

To estimate these terms, let e_α be a local orthonormal basis on Σ_τ, with $\nabla_{e_\alpha} e_\beta = 0$ at any fixed point in Σ_τ. Then the first term in (2.34) may be written

$$N\langle D^2 x_i, K\rangle = N(D^2 x_i(e_a,e_b))\cdot K(e_a,e_b) + D^2 x_i(e_a,e_b)\cdot N(K(e_a,e_b)).$$

By (2.25) and (2.7), $K_{ab} \in L^{1,p}$ and $NK_{ab} \in L^p$, while by (2.20), $D^2 x_i \in L^{1,p}$. Thus

$$D^2 x_i(e_a,e_b)\cdot N(K(e_a,e_b)) \in L^p. \tag{2.35}$$

Further $N(D^2 x_i(e_a,e_b)) = N\langle \nabla_{e_a} dx_i, e_b\rangle = \langle \nabla_N \nabla_{e_a} dx_i, e_b\rangle$, so that

$$N(D^2 x_i(e_a,e_b)) = \langle \nabla_{e_a}\nabla_N dx_i, e_b\rangle + \langle R(N,e_a)dx_i, e_b\rangle - \langle \nabla_{e_b} dx_i, \nabla_{e_a} N\rangle. \tag{2.36}$$

The curvature term in (2.36) is bounded in L^∞, while the last term equals $\langle D^2 x_i(e_b), K(e_a)\rangle$, which is bounded in L^∞. For the first term, one has

$$\langle \nabla_{e_a}\nabla_N dx_i, e_b\rangle = e_a\langle \nabla_N dx_i, e_b\rangle = e_a\langle \nabla_{e_b} dx_i, N\rangle = -e_a(K(dx_i, e_b)). \tag{2.37}$$

Since $K \in L^{1,p}$, this term is bounded in L^p. Combining these estimates, it follows that the first term in (2.34) is bounded in L^p.

For the next term in (2.34), $N\langle dx_i, dH\rangle = \langle \nabla_N dx_i, dH\rangle + \langle dx_i, \nabla_N dH\rangle = \langle \nabla_{dH} dx_i, N\rangle + \langle N, \nabla_{dx_i} dH\rangle$, so that

$$N\langle dx_i, dH\rangle = -2K(dH, dx_i), \tag{2.38}$$

which is bounded in L^p.

Finally, $-N\langle dx_i, \delta K\rangle = Ne_a K(dx_i, e_a) - NK(\nabla_{e_a} e_a, dx_i) - NK(e_a, \nabla_{e_a} dx_i)$. By (2.7), the latter two terms are in L^∞. For the first term, $Ne_a K(dx_i, e_a) = e_a NK(dx_i, e_a) - (\nabla_{e_a} N)(K(dx_i, e_b))$. The latter term here is $-[K(e_a)](K(dx_i, e_b))$, which is bounded in L^p by (2.25). For the first term, since $NK(dx_i, e_a)$ is bounded in L^∞, $e_a NK(dx_i, e_a) = \mathrm{div}(N(K(dx_i)))$ is bounded in $L^{-1,p}$, since the derivatives e_a are spatial. This shows that

$$N\langle dx_i, \delta K\rangle \in L^{-1,p}. \tag{2.39}$$

Thus, combining these estimates on (2.33) gives a uniform bound on $\Delta x_i''$ in $L^{-1,p}$. On the boundary $\partial\Sigma_\tau$, one has $x_i'' = 0$. It then follows from elliptic regularity as before [as in (2.24)] that

$$N(\mathbf{g}^{0i}) = x_i'' \in L^{1,p}.$$

Of course, by (2.28), $N(\mathbf{g}^{00}) = 0$. As above, $\mathbf{g}_{0i}$ is a rational expression in $\{g_{ij}\}$ and $\{A_{0k}\}$. The bound (2.32) implies that each of these has N-derivative in $L^{1,p}$ and hence, by the same arguments as before, $N(\mathbf{g}_{0\alpha}) \in L^{1,p}$. This gives uniform bounds

$$\|\partial_\tau \mathbf{g}_{\alpha\beta}\|_{L^{1,p}_x} \leqslant C_8. \tag{2.40}$$

This completes the estimates for the first time derivatives on spatial slices. In particular, all Christoffel symbols are bounded in $L^{1,p}_x$.

G. Second time derivatives

Finally, we obtain L^p estimates on the second time derivatives $\partial_\tau\partial_\tau \mathbf{g}_{\alpha\beta}$. To do this, take ∂_τ of the term $\langle \nabla_{\partial_\alpha}\partial_\tau, \partial_\beta\rangle$ in (2.31). One then obtains

$$\langle \nabla_{\partial_\alpha}\nabla_{\partial_\tau}\partial_\tau, \partial_\beta\rangle + \langle \mathbf{R}(\partial_\tau, \partial_\alpha)\partial_\tau, \partial_\beta\rangle.$$

The curvature term is bounded in L^p, in fact L^∞. (This uses the fact that ξ is controlled, so the framing is controlled.)

Write $\nabla_{\partial_\tau}\partial_\tau = \Gamma^\gamma_{00}\partial_\gamma$. Hence

$$\langle \nabla_{\partial_\alpha}\nabla_{\partial_\tau}\partial_\tau, \partial_\beta\rangle = \Gamma^\gamma_{00}\langle \nabla_{\partial_\alpha}\partial_\gamma, \partial_\beta\rangle + \partial_\alpha(\Gamma^\gamma_{00})\langle \partial_\gamma, \partial_\beta\rangle.$$

By the first derivative estimates above, the Christoffel symbols are bounded in $L^{1,p}_x$. The first term is a product of Christoffel symbols, and hence is bounded in $L^{1,p/2}_x \subset L^{np/(2n-p)}$, by Sobolev embedding. For $p > n$ (recall that p is arbitrarily large), $L^{np/(2n-p)} \subset L^p$. Thus the first term is bounded in L^p.

For the second term, if $\alpha > 0$, then $\partial_\alpha(\Gamma^\gamma_{00})$ is bounded in L^p by (2.40). Hence, this gives

$$\|\partial_\tau\partial_\tau g_{ij}\|_{L^p} \leqslant C_9, \tag{2.41}$$

uniformly in τ. It remains to estimate the second time derivatives of $\mathbf{g}_{0\alpha}$. These correspond to the second order time behavior of the shift vector ξ.

These estimates are the most involved, and are the only estimates dependent on the Einstein equations. To obtain these estimates, one needs to differentiate (2.17) three times in the normal N direction. Thus, from (2.17) again,

$$\Delta x_i''' = -3\Delta' x_i'' - 3\Delta'' x_i' - \Delta''' x_i . \tag{2.42}$$

Recall $x_i' = \mathbf{g}^{0i}$ is bounded in $L^{2,p}$, while $x_i'' = N(\mathbf{g}^{0i})$ is bounded in $L^{1,p}$. From previous work, it is then straightforward to bound the first two terms on the left in (2.42).

To see this, one has

$$\Delta' x_i'' = \langle D^2 x_i'', K\rangle - \langle dx_i'', \delta K + \tfrac{1}{2} dH\rangle,$$

which is bounded in $L_x^{-1,p}$, since $x_i'' \in L_x^{1,p}$. To estimate the term $\Delta'' x_i'$, one just replaces x_i in the estimates (2.34)–(2.39) by $N(x_i)$. Using the fact that $N(x_i) \in L^{2,p}$, one sees by checking term by term that this is bounded in $L^{-1,p}$.

It remains to analyze

$$\Delta''' x_i = NN\langle D^2 x_i, K\rangle - NN\langle dx_i, \delta K + \tfrac{1}{2} dH\rangle. \tag{2.43}$$

To begin,

$$NN\langle D^2 x_i, K\rangle = \langle \nabla_N \nabla_N D^2 x_i, K\rangle + 2\langle \nabla_N D^2 x_i, \nabla_N K\rangle + \langle D^2 x_i, \nabla_N \nabla_N K\rangle. \tag{2.44}$$

By the Riccati equation (2.6), $\nabla_N K$ is bounded in L^∞, while by the estimate on (2.36), $\nabla_N D^2 x_i$ is bounded in L^p. Hence, the middle term in (2.44) is bounded in L^p. For the last term, taking the N-derivative of the Riccati equation (2.6) gives

$$\langle D^2 x_i, \nabla_N \nabla_N K\rangle = -2\langle D^2 x_i, (\nabla_N K)K\rangle - \langle D^2 x_i, \nabla_N \mathbf{R}_N\rangle. \tag{2.45}$$

The first term in (2.45) is bounded in L^∞. The second (curvature) term in (2.45) will be analyzed below.

For the first term in (2.44), one needs to take N-derivatives of all terms following (2.35) to (2.37). The only one which is not bounded in $L^{-1,p}$ by previous estimates is the term

$$N\langle \mathbf{R}(N, e_a) dx_i, e_b\rangle = (\nabla_N \mathbf{R})(N, e_a, dx_i, e_b) + \text{lower order}. \tag{2.46}$$

We return again to this curvature term below, and proceed with the second term in (2.43).

Again, to estimate this, one takes N-derivatives of the estimates in (2.38) to (2.39). This gives first

$$NK(dH, dx_i) \in L^p,$$

since NK is bounded. For the δK term, modulo lower order terms, this is of the form

$$\begin{aligned} N\langle \nabla_N \nabla_{e_a} K(dx_i), e_a\rangle &= N\langle \nabla_{e_a} \nabla_N K(dx_i), e_a\rangle + N\langle \mathbf{R}(N, e_a) K(dx_i), e_a\rangle \\ &= \langle \nabla_N \nabla_{e_a} \nabla_N K(dx_i), e_a\rangle + (\nabla_N \mathbf{R})(N, e_a, K(dx_i), e_a) \\ &= \langle \nabla_{e_a} \nabla_N \nabla_N K(dx_i), e_a\rangle + (\nabla_N \mathbf{R})(N, e_a, K(dx_i), e_a) \\ &\quad + \langle \mathbf{R}(N, e_a) \nabla_N K(dx_i), e_a\rangle; \end{aligned}$$

the equalities here are understood to be modulo lower order terms. Modulo terms bounded in L^p, this may be rewritten as

$$\nabla_{e_a}(\nabla_N \mathbf{R})(N,K(dx_i),N,e_a)+(\nabla_N \mathbf{R})(N,e_a,K(dx_i),e_a). \tag{2.47}$$

Combining these estimates gives then uniform $L_x^{-1,p}$ bounds on all terms in (2.43), except for the four curvature terms of the form $(\nabla_N \mathbf{R})N$.

We obtain bounds on the curvature terms via the contracted second Bianchi identity on $(\mathbf{M}, \mathbf{g})$:

$$\boldsymbol{\delta}\mathbf{R} = -\mathbf{dRic},$$

or more precisely, cf. Ref. 12, (16.3),

$$\boldsymbol{\delta}\mathbf{R}(X,Y,Z) = -\mathbf{dRic}(Y,Z,X). \tag{2.48}$$

Write, on $\mathbf{M}$,

$$(\nabla_N \mathbf{R})N = -\boldsymbol{\delta}\mathbf{R}+\delta\mathbf{R} = \mathbf{dRic}+\delta\mathbf{R}, \tag{2.49}$$

where the divergences $\boldsymbol{\delta}$, δ are the space–time and spacelike divergences on Σ_τ, respectively.

Now the space–time curvature $\mathbf{R}$ is bounded in L^∞ (in bounded framings). Hence the spatial divergence $\delta\mathbf{R}$ is bounded in $L_x^{-1,p}$, for any $p<\infty$. Thus, the curvature term (2.46) may be rewritten, modulo $L_x^{-1,p}$, as

$$(\nabla_N \mathbf{R})(N,e_a,dx_i,e_b) = \mathbf{dRic}(dx_i,e_b,e_a) \in L_x^{-1,p},$$

where the last estimate follows since all derivatives of **Ric** are taken in spatial directions. Similarly, for the second curvature term in (2.47), one has, for the same reasons, modulo $L_x^{-1,p}$,

$$(\nabla_N \mathbf{R})(N,e_a,K(dx_i),e_a) = \mathbf{dRic}(K(dx_i),e_b,e_a) \in L_x^{-1,p}.$$

This leaves left the two curvature terms:

$$\langle D^2 x_i, \nabla_N \mathbf{R}_N\rangle \quad \text{and} \quad \nabla_{e_a}(\nabla_N \mathbf{R})(N,K(dx_i),N,e_a). \tag{2.50}$$

The second term is of form $\delta\mathbf{dRic}(N,K(dx_i))$ (to leading order), which cannot be controlled without the Einstein equation, since it involves differentiation in the N direction. Similarly,

$$\nabla_N \mathbf{R}_N = \mathbf{dRic}(N,\cdot,\cdot), \quad \text{modulo } L_x^{-1,p}, \tag{2.51}$$

is not controlled without the Einstein equations.

Dropping the usual constants, the Einstein equations on $(\mathbf{M}, \mathbf{g})$ are

$$\mathbf{Ric} - \frac{\mathbf{R}}{2} g = \mathcal{T}, \tag{2.52}$$

where $\mathcal{T}$ is the stress-energy tensor. Suppose $(\mathbf{M}, \mathbf{g})$ is vacuum, or more generally, suppose the stress-energy tensor $\mathcal{T}$ satisfies

$$d\mathcal{T}(N,e_a,e_b) \in L_x^{-1,p}, \tag{2.53}$$

where e_a, e_b are spatial. Since the Einstein equations and the bound (2.5) imply that $\nabla_{e_a}\mathcal{T}(N) \in L_x^{-1,p}$, (2.53) is equivalent to

$$\nabla_N \mathcal{T} \in L_x^{-1,p}, \text{ or } \mathcal{L}_N \mathcal{T} \in L_x^{-1,p}, \tag{2.54}$$

where $\mathcal{L}_N$ denotes the Lie derivative in the direction N.

Combining the bound (2.53) with the estimates obtained above on the terms in (2.42) then gives

$$\Delta x_i''' = \Delta NN(\mathbf{g}^{0i}) \in L_x^{-2,p}, \tag{2.55}$$

since $\delta\mathbf{dRic}(N,K(dx_i)) \in L_x^{-2,p}$, not $L_x^{-1,p}$. As before, since the coefficients of the Laplacian are well-controlled (i.e., bounded in $L^{2,p}$), and the functions x_i''' have 0 boundary values, elliptic regularity gives

$$NN(\mathbf{g}^{0i}) \in L^p.$$

(One sees this from duality in the standard way, using the fact that $\Delta: L_o^{2,p} \to L^p$ is an isomorphism, cf. also Ref. 15.)

Applying the linear algebra argument as before then gives the bound

$$\partial_\tau \partial_\tau \mathbf{g}_{0\alpha} \in L^p. \tag{2.56}$$

This completes all of the estimates on $\mathbf{g}_{\alpha\beta}$. We refer to Remark 4 below for further discussion on use of the Einstein equations. Finally, the assumptions (2.53) or (2.54) are equivalent to (1.13). To see this, both T and N lie within a compact subset of $T^+\Omega$. Since the covariant derivative w.r.t. T or N involves only the pointwise behavior of these vector fields, one may replace T by N in (1.13), which then corresponds to (2.54).

H. Step V (Issue of cut points)

In this final step, we show that by passing to a smaller cylinder if necessary, of definite size within C_{r_o}, the exponential map $\exp_{q'}$ at a suitable base point q' has no future cut points. By the work above, this will complete the proof.

To begin, return to the "cone" $\mathcal{C}$ in (2.4). Let V be the collection of timelike unit vectors in $T_q^+\mathcal{D}_{r_1}$ for which there is a maximal geodesic σ_v issuing from q and terminating in $\mathcal{C}$. Let

$$\tilde{\mathcal{C}} = \{sv : v \in V, s \leq r_1\} \subset T_q^+\mathcal{D}_{r_1}, \tag{2.57}$$

so that in particular $\exp_q \tilde{\mathcal{C}}$ contains $\mathcal{C}$. Here, as in step I, r_1 is chosen so that no geodesic $\sigma_v(s)$, for $v \in V$, has conjugate points with $s \leq r_1$. Of course the geodesics $\sigma_v(s)$ now are no longer necessarily maximal. Since $\exp_q$ is of maximal rank on $\tilde{\mathcal{C}}$, we work on the pullback $(\tilde{\mathcal{C}}, \tilde{\mathbf{g}})$, where

$$\tilde{\mathbf{g}} = (\exp_q)^* \mathbf{g}. \tag{2.58}$$

The domain $\tilde{\mathcal{C}}$ is a compact connected cone in $T_q\mathbf{M}$, w.r.t. the vector space structure. By the Gauss lemma, the straightline generators of this cone are geodesics in the $\tilde{\mathbf{g}}$ metric. Let $\tilde{\tau}$ denote the distance to the origin $\{0\}$ w.r.t. $\tilde{\mathbf{g}}$, within $\tilde{\mathcal{C}}$. This is now a smooth function on $\tilde{\mathcal{C}} \setminus \{0\}$, and serves as the parameter for the geodesics from $\{0\}$. Inside the cutlocus of $\exp_q$ on $\tilde{\mathcal{C}}$ (i.e., where $\exp_q$ is a diffeomorphism), $\tilde{\tau}$ is just the lift of the function τ from (2.3), up to an additive constant.

The level sets $\tilde{\Sigma}_{\tilde{\tau}} \subset \tilde{\mathcal{C}}$ of τ are smooth, and hence the images $\exp_q \tilde{\Sigma}_{\tilde{\tau}}$ are smoothly immersed submanifolds in $\mathcal{C}$. The original Lipschitz level surface Σ_τ is just the part of $\exp_q \tilde{\Sigma}_{\tilde{\tau}}$ contained in the domain $U^\tau = \{x : \tau(x) \geq \tau\} \cap \mathcal{C}$. Observe that the timelike exponential map $\exp_0$ of $(\tilde{\mathcal{C}}, \tilde{\mathbf{g}})$ based at 0 is a diffeomorphism onto $\tilde{\mathcal{C}}$; this map has no conjugate or cut points within $\tilde{\mathcal{C}}$.

Thus, we are now in exactly the same situation as at the end of step I, with $(\tilde{\mathcal{C}}, \tilde{\mathbf{g}})$ in place of $(\mathcal{C}, \mathbf{g})$. Set $\tilde{S} = (\exp_q)^{-1}(\mathcal{C}) \subset \tilde{\mathcal{C}}$, so that $\tilde{S}$ is an embedded hypersurface in $\tilde{\mathcal{C}}$. Since $\exp_q$ is a local isometry of $\tilde{S}$ onto $\hat{S}$, one has

$$\mathrm{vol}_{\tilde{g}} \tilde{S} \geq \mathrm{vol}_g \hat{S}. \tag{2.59}$$

Hence, by the same reasoning as in step II, the volume estimate (2.14) holds on the smooth hypersurfaces $\tilde{\Sigma}_{\tilde{\tau}}$.

We may thus apply the work in steps II–IV to conclude that there is an $r_o>0$, depending only on C, D, c_o, v_o, and an r_o-cylinder $\tilde{C}_{r_o}\subset\tilde{\mathcal{C}}$, centered on $\tilde{p}$, on which there are coordinates $(\tilde{\tau},\tilde{x}_i)$ in which the metric $\tilde{\mathbf{g}}$ is controlled in $L^{2,p}$ in the sense that (1.12) holds.

It remains to prove the existence of a suitable cylinder C' "downstairs," i.e., within $(\Omega,\mathbf{g})$, with these properties. Thus, let $\tilde{\Sigma}_{\tilde{\tau}}$ now denote the part of $\tilde{\Sigma}_{\tilde{\tau}}$ contained in $\tilde{C}_{r_o}$. Each $\tilde{\Sigma}_{\tilde{\tau}}$ is an n-ball, topologically. Recall, as in step II, that $\tilde{S}\cap\tilde{C}_{r_o}$ is a graph over $\tilde{\Sigma}_{\tilde{\tau}_o}$, for some $\tilde{\tau}_o$. Hence, $\tilde{S}\cap\tilde{C}_{r_o}$ is also an n-ball topologically. By construction, both $\tilde{\Sigma}_{\tilde{\tau}_o}$ and $\tilde{S}\cap\tilde{C}_{r_o}$ have a uniform lower bound on their volume and size, i.e., $\mathrm{dist}_{\tilde{g}}(\tilde{p},\partial(\tilde{S}\cap\tilde{C}_{r_o}))\geqslant r_3>0$ (and similarly for $\tilde{\Sigma}_{\tilde{\tau}_o}$). These bounds depend only on the initial bounds on C, v_o and D, c_o.

Let U be the interior of the cutlocus of $\exp_q|_{\tilde{\mathcal{C}}}$. The domain U is starshaped w.r.t. the origin $\{0\}$ in $T_q^+\mathcal{D}_{r_1}$. Further, again by construction, $\tilde{S}\cap\tilde{C}_{r_o}$ is contained in the closure $\overline{U}$ of U. If $(\tilde{S}\cap\tilde{C}_{r_o})\cap\partial U\neq\varnothing$, one may perturb it slightly, along the geodesic straight lines to $\{0\}$, to obtain an n-ball $\tilde{S}'\subset\tilde{C}_{r_o}$ with $\tilde{S}'\subset U$. As before, the ball $\tilde{S}'$ has a definite lower bound on its volume and its size.

The exponential map $\exp_q$ now gives a diffeomorphism, in fact an isometry, from $(\tilde{S}',\tilde{g})$ to (S',g), $S'=\exp_q\tilde{S}'$. Let $\mathcal{D}'$ be the domain of dependence of S' in $(\mathbf{M},\mathbf{g})$. This gives a globally hyperbolic region $\mathcal{D}'\subset(\mathbf{M},\mathbf{g})$, with a simply connected Cauchy surface of definite size and volume. The work of steps I–IV may now be applied to this situation within $(\mathbf{M},\mathbf{g})$ to produce a new cylinder C', centered at p, satisfying the bounds (1.12).

This completes the proof of Theorem 2. ■

It is an open question whether Theorem 2 holds without an assumption of the form (1.13), i.e., whether there exist coordinate systems in which (1.12) holds under only the bounds (1.9).

Remark 4: From the physical point of view, most stress-energy tensors $\mathcal{T}$ derive from matter fields satisfying a hyperbolic system of PDE, of first or second order. In such a situation, these equations can frequently be used to interchange a time derivative $\nabla_N\mathcal{T}$ on spatial slices, with a spatial derivative $\nabla_X\mathcal{T}$, modulo lower order terms, e.g., $(\nabla_N\mathcal{T})(X)\sim(\nabla_X\mathcal{T})(N)$, modulo lower order terms. This is exactly the process used via the second Bianchi identity above. For instance, this is easily seen to be the case for electromagnetic fields, via use of the Maxwell equation $\mathbf{dF}=0$.

When the matter equations allow for such time–space replacement, modulo lower order terms, the condition (1.13) is of course not necessary in Theorem 2.

Next we turn to the proof of Corollary 3.

Let $(\mathbf{M},\mathbf{g})$ be a weakly regular space–time, satisfying the size conditions, and satisfying the bound (1.9) distributionally. Thus, the components of $\mathbf{R}$, well-defined as distributions, are in fact bounded in L^∞.

Any such space–time $(\mathbf{M},\mathbf{g})$ is a limit of a sequence of (C^∞) smooth space–times $(\mathbf{M},\mathbf{g}_k)$, cf. Ref. 10 (Theorem 4), for instance. The metrics $\mathbf{g}_k$ are obtained in the usual way by taking the convolution of $\mathbf{g}$ with a sequence of smooth mollifiers. The local size conditions and local volume bound in (1.9), with δ_o in place of $\frac{1}{2}$, depend only on the C^0 behavior of the metric. Since the convergence to the limit is C^0, it follows that local size conditions and local volume bounds hold uniformly on the sequence $(\mathbf{M},\mathbf{g}_k)$. Similarly, the fact that $|\mathbf{R}|_T$ is bounded on $(\mathbf{M},\mathbf{g}_k)$ implies that the curvature $|\mathbf{R}_{\mathbf{g}_k}|_{T_k}$ of $(\mathbf{M},\mathbf{g}_k)$ is uniformly bounded, for unit timelike vector fields $T_k\to T$, as $k\to\infty$.

It then follows from Theorem 2 that for any $p\in\Omega$, there are r_o-cylinders $((C_{r_o})_k,p_k)\subset\subset(\mathbf{M},\mathbf{g}_k)$, with $p_k\to p$, and coordinates on $(C_{r_o})_k$ in which the metric $\mathbf{g}_k$ is controlled: this in the sense that the bounds (1.12) hold, with the exception of the bound on $\partial_0\partial_0\mathbf{g}_{0\alpha}$. Since the bounds on C, v_o and D, c_o, hold uniformly on $(\mathbf{M},\mathbf{g}_k)$, and p_k remains a bounded

distance away from $\partial\mathbf{M}$, it follows that there is a limit cylinder $(C_{r_o},p)\subset(\mathbf{M},\mathbf{g})$ on which (1.12) holds, again except for the bound on $\partial_0\partial_0\mathbf{g}_{0\alpha}$.

This proves the first part of Corollary 1.3. For the second part, one needs to make sense of the condition (1.13) on $(\mathbf{M}, \mathbf{g})$. It suffices to do this locally, i.e., on cylinders $C_{r_o}\subset(\mathbf{M},\mathbf{g})$. Of course $\nabla_N\mathbf{Ric}$, or equivalently $\nabla_N\mathcal{T}$, is well-defined in $L^{-1,p}(\Omega)$, (since $\mathbf{Ric}\in L^\infty$), but one needs to define it in $L^{-1,p}(\Sigma_\tau)$.

To do this, from the above, we know that $g_\tau=\mathbf{g}|_{\Sigma_\tau}$ is in $L^{2,p}_x(\Sigma_\tau)$, for any $\Sigma_\tau\subset C_{r_o}$. Let h be a symmetric bilinear form in $L^{1,q}(\Sigma_\tau)$, of compact support, for a given τ. Extend h into C_{r_o} by the flow of N, so that $\mathcal{L}_N h=0$. Hence, h is defined on all $\Sigma_\tau\subset C_{r_o}$. Formally, or alternately on the smooth approximations $(\mathbf{M},\mathbf{g}_k)$ of $(\mathbf{M}, \mathbf{g})$, one has

$$\int_{\Sigma_\tau}\langle h,\nabla_N\mathbf{Ric}\rangle dV=\int_{\Sigma_\tau}N\langle h,\mathbf{Ric}\rangle dV-\int_{\Sigma_\tau}\langle\nabla_N h,\mathbf{Ric}\rangle dV. \tag{2.60}$$

Observe that $\nabla_N h=\mathcal{L}_N h+h(\nabla_{\partial_a}N,\partial_b)+h(\partial_a,\nabla_{\partial_b}N)=h(K(\partial_a),\partial_b)+h(K(\partial_b),\partial_a)$. Since $K\in L^{1,p}(\Sigma_\tau)$ and p is large, it follows $\nabla_N h$ is well-defined in $L^q(\Sigma_\tau)$, for any τ. Hence, the second term in (2.60) is well-defined (since $\mathbf{Ric}$ is bounded in L^∞).

For the first term on the right in (2.60), one has

$$\int_{\Sigma_\tau}N\langle h,\mathbf{Ric}\rangle dV=\frac{d}{d\tau}\int_{\Sigma_\tau}\langle h,\mathbf{Ric}\rangle dV-\int_{\Sigma_\tau}\langle h,\mathbf{Ric}\rangle H dV. \tag{2.61}$$

The second term in (2.61) is well-defined, since again $H\in L^{1,p}\subset C^\alpha$. Thus, to define (1.13) on C_{r_o}, we require that the derivative

$$\frac{d}{d\tau}\int_{\Sigma_\tau}\langle h,\mathbf{Ric}\rangle dV, \text{ or equivalently, } \frac{d}{d\tau}\int_{\Sigma_\tau}\langle h,\mathcal{T}\rangle dV \tag{2.62}$$

exist for all $\tau\in[-r_o,r_o]$, for any h as above. Under this condition, the bound (1.13) on C_{r_o} is then equivalent to a uniform bound on (2.62), for all $\tau\in[-r_o,r_o]$.

Given this definition of the condition (1.13) on the limit C_{r_o}, it follows from the same proof as in Theorem 2 that $\partial_0\partial_0\mathbf{g}_{0\alpha}$ is uniformly bounded in $L^p(\Sigma_\tau)$, $|\tau|\leqslant r_o$. This completes the proof of Corollary 3. ■

III. DISCUSSION AND CONCLUDING REMARKS

We conclude the paper with several remarks extending the validity of Theorem 2, together with some open problems.

Theorem 2 gives the existence of cylinders C of a definite size in the interior of $\mathbf{M}$, and a definite distance away from any boundary $\partial\mathbf{M}$, on which there exist coordinates in which the metric is controlled in $L^{2,p}$. Of course, by rescaling up suitably to realize the size conditions, applying Theorem 2, and then rescaling back down, the cylinders C may be chosen to be arbitrarily close to $\partial\mathbf{M}$. (This is already implicit in Corollary 3.) However, the coordinates may change in the (smaller and smaller) cylinders as one approaches $\partial\mathbf{M}$.

The main reason it is necessary to stay a definite distance away from $\partial\mathbf{M}$ in the proof is that one needs to work in globally hyperbolic regions, as in (2.1), which are future one-connected. If $\mathbf{M}$ is globally hyperbolic and future one-connected to begin with, then it is no longer necessary to stay a given distance away from $\partial\mathbf{M}$. We describe an alternate version of Theorem 2 in this context.

Thus, suppose $(\mathbf{M}, \mathbf{g})$ is globally hyperbolic and future one-connected; [for instance, $(\mathbf{M}, \mathbf{g})$ has a simply connected Cauchy surface]. Choose any point $q\in\mathbf{M}$ and timelike unit vector $N_o\in T^+_q\mathbf{M}$. Let $V\subset T^+_q\mathbf{M}$ be the compact cone of unit vectors forming a fixed angle θ with N_o, and

let $\mathcal{C}=\exp_q \pi v$, $v \in V$, be the corresponding "cone" in $(\mathbf{M}, \mathbf{g})$. Also, let N be the corresponding vector field tangent to the geodesics $\sigma_v(\tau)=\exp_q(\pi v)$, and let Σ_τ be the level sets of τ in $\mathcal{C}$. We make the following assumptions: there exist constants $C<\infty$ and $v_o>0$ such that

$$|\mathbf{R}|_N \leqslant C, \quad \text{within } \mathcal{C}, \tag{3.1}$$

$$\text{vol } \Sigma_\tau \geqslant v_o \cdot (\text{diam } \Sigma_\tau)^n. \tag{3.2}$$

Although (3.2) is understood to hold for all $\tau \leqslant r_1$, for a fixed r_1, the methods used in step II show that it suffices to assume (3.2) holds for a fixed $\tau_o>0$, where the size τ_o depends only on C in (3.1). The bound (3.2) is of course scale-invariant.

We then have the following result, valid at least up to a point in $\partial\mathbf{M}$.

Corollary 5: Let $(\mathbf{M}, \mathbf{g})$ *be a globally hyperbolic, future one-connected space–time satisfying the assumptions (3.1) and (3.2). Suppose also* $(\mathbf{M}, \mathbf{g})$ *is vacuum, or more generally, satisfies (1.13). Then there exist small constants* $d_o>0$, *and* $r_o>0$, *depending only on* C, v_o, N_o *and* θ, *such that if*

$$\sigma_{N_o}(\tau) \in \mathbf{M}, \ \forall \tau < d_o,$$

then there exist coordinates (τ, x_i) *on the cylinder*

$$C_{r_o}(d_1)=D_p(r_o d_o)\times[d_1/2, d_1] \subset \mathbf{M}, \tag{3.3}$$

in which the metric satisfies the bounds (1.12). Here d_1 *is the largest value such that* $d_1 \leqslant d_o$ *and* $C_{r_o}(d_1)$ *is contained in* $\mathbf{M}$.

The proof of this result is exactly the same as that of Theorem 2. In fact, it is simpler, since the issues of global hyperbolicity and future one-connected are assumed, and one works with N in place of the vector field T from Definition 1. Thus, for d_o small as above, and for $C(V)$ the cone on V in $T_q\mathbf{M}$, the exponential map $\exp_q$ restricted to $(C(V)\backslash\{q\})\cap B_0(d_1)$ is a diffeomorphism onto $(\mathcal{C}\cap B_q(d_1))$, where $B_q(d_1)=\exp_q(B_0(d_1))$. The domain $\mathcal{C}\cap B_q(d_1)$ plays exactly the same role as $\mathcal{C}$ in step I. All the estimates of steps II–IV then proceed just as before and are uniform for $\tau \in [d_1/2, d_1]$. ■

Remark 6: One may also derive a version of Theorem 2, (or Corollary 3), without the lower volume bound in (1.9). Thus, one has a uniform spatial curvature bound (2.9), either on the slices $\Sigma_\tau \subset \mathcal{C}$ downstairs, or on the slices $\widetilde{\Sigma}_{\tilde{\tau}} \subset \widetilde{\mathcal{C}}$ upstairs in $T_q\mathbf{M}$. [The bound (2.9) does not require any *a priori* volume bound.] If the volume Σ_τ or $\widetilde{\Sigma}_{\tilde{\tau}}$ is very small, then the injectivity radius of g_τ is very small, i.e., the spatial metric g_τ is highly collapsed in the sense of Cheeger-Gromov. However (as before), the Rauch comparison theorem implies that the intrinsic exponential map on Σ_τ or $\widetilde{\Sigma}_{\tilde{\tau}}$ is still of maximal rank on geodesic balls of a definite size (depending only on the curvature bound). Suppose first one works in the situation of $\Sigma_\tau \subset \mathcal{C}$. Then just as before in timelike directions, one can lift the metric g_τ up to the tangent space by pulling back by its exponential map, i.e., consider the metric $\tilde{g}_\tau=(\exp_{p_\tau})^* g_\tau$ defined on balls in $T_{p_\tau}\Sigma_\tau$. The metric $\tilde{g}_\tau$ has a uniform lower bound on the volumes of small balls. All the arguments in steps II–IV can then be carried out as before on this "unwrapped" space–time and the corresponding unwrapped cylinder $\widetilde{C}_{r_o}$. This gives coordinates $(\tilde{\tau}, \tilde{x}_i)$ for $\widetilde{C}_{r_o}$ on which the metric $\tilde{\mathbf{g}}$ satisfies the bounds (1.12). The same procedure holds when working with $\widetilde{\Sigma}_{\tilde{\tau}}$. These coordinates upstairs within $T_q\mathbf{M}$ give then "multi-valued" coordinates downstairs in $(\mathbf{M}, \mathbf{g})$.

To conclude, we mention two open problems. First, for certain purposes, the L^∞ bound on the curvature in (1.11) may be viewed as too strong. It would be of interest to know if a version of Theorem 2 holds with suitable L^p bounds on $|\mathbf{R}|_T$, $p>n/2$, in place of L^∞ bounds.

Second, it would be very interesting if the Einstein equations could be used to remove the dependence of these results on bounds on the full curvature, i.e., if bounds on the full curvature could be replaced by bounds on the Ricci curvature, possibly introducing other hypotheses not related to curvature. This seems to be a challenging problem; cf. Ref. 16 for some further discussion.

(Received 22 August 2002; accepted 23 December 2002)

We discuss the Riemann–Lanczos problems in two, three, and four dimensions using the theory of exterior differential systems and Janet–Riquier theory. We show that the Riemann–Lanczos problem in two dimensions is always a system in involution. For each of the two possible signatures we give the general solution in both instances and show that the occurrence of characteristic coordinates need not affect the result. In three dimensions, the Riemann–Lanczos problem is not in involution as an identity occurs. This does not prevent the existence of singular solutions and we give an example for the *reduced* Gödel space–time. A prolongation of this problem, whereby an integrability condition is added, leads to a prolonged system in involution. The Riemann–Lanczos problem in four dimensions is not in involution and needs to be prolongated as Bampi and Caviglia suggested. But *singular* solutions of it can be found and we give examples for the Gödel, Kasner, and Debever–Hubaut space–times. © *2003 American Institute of Physics.*

I. INTRODUCTION

The problem of generating the space–time Weyl conformal curvature tensor C_{abcd} from a tensor potential is called the **Weyl–Lanczos problem** and the analogous problem for the Riemann curvature tensor the Riemann–Lanczos problem.

The Lanczos tensor potential admits the following index symmetries,

$$L_{[ab]c}=L_{abc}, \tag{1}$$

where $a,b,c,s=0,1,2,3$ for four dimensions and

$$L_{[abc]}=0. \tag{2}$$

Apart from these, we may impose two gauge conditions: the differential gauge condition

$$L_{ab}{}^{s}{}_{;s}=0, \tag{3}$$

where ";" indicates covariant differentiation and we often write $f_{ab}=L_{ab}{}^{s}{}_{;s}$, and the algebraic gauge or trace free condition

$$L_{a}{}^{s}{}_{s}=0. \tag{4}$$

[a)]Electronic mail: pdolan@inctech.com
[b)]Electronic mail: agerber03@yahoo.co.uk

Lanczos discovered the Weyl–Lanczos equations,[1] where he introduced a Lagrangian based on the double dual of the Riemann tensor R_{abcd}. The Lanczos tensor L_{abc} arose as a Lagrange multiplier for this Lagrangian. Lanczos found an expression for the Weyl tensor in terms of certain Lagrange multipliers L_{abc}, namely,

$$C_{abcd}=L_{abc;d}-L_{abd;c}+L_{cda;b}-L_{cdb;a}+g_{bc}L_{(ad)}+g_{ad}L_{(bc)}-g_{bd}L_{(ac)}-g_{ac}L_{(bd)} + \tfrac{2}{3}L^{ms}{}_{m;s}(g_{ac}g_{bd}-g_{ad}g_{bc}), \tag{5}$$

where $L_{ad}=L_a{}^s{}_{d;s}-L_a{}^s{}_{s;d}$. These are *the Weyl–Lanczos equations*. Further, if we impose (3) and (4) above, we can simplify (5) considerably to

$$C_{abcd}=L_{abc;d}-L_{abd;c}+L_{cda;b}-L_{cdb;a}-g_{bc}L^s{}_{ad;s}-g_{ad}L^s{}_{bc;s}+g_{bd}L^s{}_{ac;s}+g_{ac}L^s{}_{bd;s}. \tag{6}$$

Many solutions to (6) are known and solutions for vacuum space–times can be found in Ref. 2.

We can also attempt to express the Riemann curvature tensor in terms of a comparable tensor potential $\hat{L}_{abc}$ which leads to the **Riemann–Lanczos problem**. Udeschini Brinis[3] had wanted to describe the space–time Riemann tensor in terms of a Lanczos tensor $\hat{L}_{abc}$ and proposed the Riemann–Lanczos relations

$$R_{abcd}=\hat{L}_{abc;d}-\hat{L}_{abd;c}+\hat{L}_{cda;b}-\hat{L}_{cdb;a}. \tag{7}$$

But the difficulties with the relations (7) were pointed out in two papers by Bampi and Caviglia[4,5] where they proved existence of theorems for solutions of (5) and (7). Whereas the Weyl–Lanczos problem is always in involution, the Riemann–Lanczos problem is *not* and only singular solutions of it can occur if the problem is **not** modified. Bampi and Caviglia showed the following.

(i) The Weyl–Lanczos problem (5) or (6) has nonsingular solutions for $n=4, 5$, where n is the dimension of the space–time manifold M.
(ii) For $n=4$ the Riemann–Lanczos problem (7) has no nonsingular solutions but it does have "singular" solutions which means that the Cartan characters do not adopt their maximal values.
(iii) The differential gauge condition (3) has no effect on the existence or nonexistence of solutions of either (5) or (7).

Bampi and Caviglia[5] also suggested a prolongation of the Riemann–Lanczos equations to make them a system in involution.

In the Riemann–Lanczos problem, we meet Eq. (2) and possibly (3) but **not** (4), which leaves us with 20 independent components for the $\hat{L}_{abc}$ in four dimensions. *We always assume that the cyclic conditions* (2) *hold* but **not** *the trace-free conditions* (4). If Eqs. (4) were to hold, we would have

$$R=4\hat{L}^{nk}{}_{k;n}=-4\hat{L}^{nk}{}_{n;k}=0,$$

which would lead to inconsistencies. Because we are only going to talk about the Riemann–Lanczos problem in this article, we will change notation from $\hat{L}_{abc}$ to L_{abc} from now on. We will also write the Riemann–Lanczos equations in solved form as

$$f^{(R)}_{abcd}:=R_{abcd}-L_{abc;d}+L_{abd;c}-L_{cda;b}+L_{cdb;a}. \tag{8}$$

The paper by Massa and Pagani[6] concerning a modification of the Riemann–Lanczos problem used a different approach to the above work of Bampi and Caviglia. Accordingly, we do not consider Ref. 6 here. As Ref. 7 is based on Ref. 6 it is also not applicable here.

II. EXTERIOR DIFFERENTIAL SYSTEMS

First we introduce some theory of exterior differential systems (EDSs) which we are going to apply to the Riemann–Lanczos problems in two, three, and four dimensions. Good and detailed accounts of the theory of exterior differential systems can be found in Refs. 8–10.

A. Exterior differential systems and Pfaffian systems

We denote a formal N-dimensional manifold by $\mathcal{M}$ of which the space–time manifold M is an n-dimensional submanifold. Then, for a collection of differential forms we define an **exterior differential system** (EDS) as a collection of one-forms $\alpha^{(1)}_{i_1}$, two-forms $\alpha^{(2)}_{i_2}$ and so on up to p-forms $\alpha^{(p)}_{i_p}$ and possibly zero-forms on our formal N-dimensional manifold $\mathcal{M}$. A **Pfaffian system** $\mathcal{P}$ is a special EDS containing only one-forms θ^α and 0-forms.[11–13] We denote the **rank** of $\mathcal{P}$ by s which is given by the number s of independent one-forms in $\mathcal{P}$. Consider now the collection of all vector fields on $\mathcal{M}$ denoted by $\mathcal{X}(\mathcal{M})$. There is a subset of $\mathcal{X}(\mathcal{M})$ given by all those vector fields which annihilate the Pfaffians in $\mathcal{P}$,

$$\mathcal{D} := \{X \in \mathcal{X}(\mathcal{M}) \,|\, \theta^\alpha(X) = 0, \quad \alpha = 1,...,s\},$$

so that the number of independent vector fields in $\mathcal{D}$ is $N-s$. We call $\mathcal{D}$ the **dual system** to $\mathcal{P}$. For any Pfaffian system $\mathcal{P}$, we can also look at its **derived system** $\mathcal{P}'$ for which we can write[14]

$$\mathcal{P}' := \{\theta^\alpha \in \mathcal{P} | d\theta^\alpha(X,Y) = 0, \quad \forall X, Y \in \mathcal{D}, \quad \alpha = 1,...,s\},$$

where $\mathcal{P}' \subset \mathcal{P}$ always holds. Further, we denote by $\overline{\mathcal{D}}$

$$\overline{\mathcal{D}} := \{Y \in \mathcal{X}(\mathcal{M}) | d\theta^\alpha(X,Y) = 0, \quad \forall X \in \mathcal{D}, \quad \forall \alpha = 1,...,s\}.$$

Pfaffian systems are classified according to the ease with which they can be integrated. The most familiar Pfaffian systems are also the simplest, namely, **complete Pfaffian systems** to which the celebrated **Frobenius theorem** applies. We say that a Pfaffian system $\mathcal{P}$ is *complete* if and only if $\mathcal{P} = \mathcal{P}'$ holds, or, in other words $\mathcal{D} = \overline{\mathcal{D}}$. *In general, Pfaffian systems are not complete* but each Pfaffian system can be enlarged by adding further one-forms until it becomes complete or becomes inconsistent. The minimal enlarged Pfaffian system which is complete is known as the **associated system** $\mathcal{A}(\mathcal{P})$ of $\mathcal{P}$ and its dimension is called the **class** c of $\mathcal{P}$. Sometimes, $\mathcal{A}(\mathcal{P})$ is also called the **Cartan system** $C(\mathcal{P})$.[15] Further, the dual space of $C(\mathcal{P})$ usually denoted by $C(\mathcal{D}) = C(\mathcal{P})^\perp$ is the space containing all Cauchy characteristic vector fields.

A good account of Pfaffian systems characterized by Vessiot vector fields can be found in Refs. 14 and 16 and many examples are given in Ref. 17. A Vessiot vector field system $\mathcal{D} = \mathcal{P}^\perp$ is complete means then that $[\mathcal{D},\mathcal{D}] \subseteq \mathcal{D}$ for all $Y \in \mathcal{D}$ which is equivalent to $\overline{\mathcal{D}} = \mathcal{D}$.

When a vector field system $\mathcal{D}$ or Pfaffian system $\mathcal{P}$ fails to be complete, a slightly weaker condition may hold on some subsystem of $\mathcal{D}$. Such a possibility is that a vector field system is in **involution**, which is defined as follows:

Definition 1: Involutory subsystem of a vector field system. An involutory subsystem $\mathcal{T}$ of a vector field system $\mathcal{D}$ is a subsystem $\mathcal{T}$ of $\mathcal{D}$ such that $[\mathcal{T},\mathcal{T}] \subseteq \mathcal{D}$, which means that $\mathcal{T}$ is closed relative to $\mathcal{D}$ but not relative to $\mathcal{T}$ itself.

B. Integral elements and Cartan characters

All definitions in this section are based on Ref. 18 which relies on Cartan's original work whereas the work in Ref. 19 varies slightly from Ref. 9 in some definitions. When an EDS Σ or a Pfaffian system $\mathcal{P}$ is given, we try to find manifolds on which all the differential forms of Σ or $\mathcal{P}$ are annihilated. We will construct tangent spaces to such manifolds, where the dimension of each of them can be deduced from a sequence of non-negative integers called the Cartan characters. Such tangent spaces are called *integral elements* and are defined as follows.

Definition 2: Integral element. A p-dimensional subspace $(E^p)_x$ at a point x of the tangent space $T_x(\mathcal{M})$ of a N-dimensional manifold $\mathcal{M}$ is called an integral element of an EDS Σ if $\alpha^i_j(E^p)_x=0$ at x for all forms α^i_j in Σ, which means that all differential forms of Σ are annihilated on $(E^p)_x$ at $x\in\mathcal{M}$.

Once we have found such a p-dimensional integral element $(E^p)_x\subset T_x\mathcal{M}$ spanned by $V^1,\ldots,V^p$, we look for vectors $V_x^{p+1}\in T_x\mathcal{M}$ in such a way that the space generated by $(E^p)_x$ and V_x^{p+1} forms a $(p+1)$-dimensional integral element. The conditions on such a tangent vector V_x^{p+1} at the point $x\in\mathcal{M}$ are

$$\begin{aligned}
&\alpha^1_{i_1}(V_x^{p+1})=0, \quad 1\leqslant i_1\leqslant k_1,\\
&\alpha^2_{i_2}(V^{j_1},V_x^{p+1})=0, \quad 1\leqslant i_2\leqslant k_2, \quad 1\leqslant j_1\leqslant p,\\
&\vdots\\
&\alpha^{p+1}_{i_{p+1}}(V^1,V^2,\ldots,V^p,V_x^{p+1})=0, \quad 1\leqslant i_{p+1}\leqslant k_{p+1}.
\end{aligned} \tag{9}$$

The vectors V_x^{p+1} that satisfy the above system of linear equations generate the **polar space** $H((E^p)_x)^\perp$ of $(E^p)_x$, where $H((E^p)_x)$ is the polar system (9). Depending on the ranks of the polar systems generated, we can divide integral elements into three classes which are called **regular, ordinary**, and **singular**. We look at the subsystem $\alpha^1_1(V^1_x)=\cdots=\alpha^1_{k_1}(V^1_x)=0$ of (9), where $s_0(x)=r(H(E^0)_x)$ is its rank. From this, we obtain the integer

$$s_0:=\max_{\{x\in\mathcal{M}\}}(r(H((E^0)_x)))$$

called the **zeroth Cartan character**. We define a **regular point** $x\in\mathcal{M}$ to be a point where $s_0(x)=s_0$. Then, a one-dimensional integral element $(E^1)_x$ is an **ordinary** integral element if x is a regular point. Let the polar space of $(E^1)_x$ in $T_x\mathcal{M}$ have rank $r(H((E^1)_x))=s_1(x)+s_0(x)$. From this, we define

$$s_1:=\max_{\{x\in\mathcal{M},V^2\in T_x\mathcal{M}\}}r(H((E^1)_x))-s_0,$$

which is called the **first Cartan character**. If, for $x\in\mathcal{M}$, $s_1(x)=s_1$ holds, then the integral element $(E^1)_x$ is called **regular**. A two-dimensional integral element $(E^2)_x$ then is called **ordinary** if it contains at least one regular one-dimensional integral element. We define inductively as follows.

Definition 3: Cartan characters. The pth Cartan character is inductively defined as

$$s_p=\max_{\{x\in\mathcal{M},V^{p+1}\in T_x\mathcal{M}\}}r(H((E^p)_x))-\sum_{i=0}^{p-1}s_i.$$

Based on this we can state that a p-dimensional integral element $(E^p)_x$ is called **ordinary** if it contains at least one $(p-1)$-dimensional regular integral element. A p-dimensional integral element is called **regular** if its polar space $H((E^p)_x)$ has maximal rank $r(H((E)^p)_x)=s_p$. All other integral elements are called **singular**.

Note that a sequence of integral elements $(E^0)_x\subset(E^1)_x\subset\cdots\subset(E^p)_x$ at a point $x\in\mathcal{M}$ is called a **regular chain** of integral elements if all its $(E^k)_x$, $1\leqslant k\leqslant p-1$, are regular and $(E^p)_x$ is at least ordinary. The maximal dimension an ordinary integral element can adopt is called the **genus** g of Σ or $\mathcal{P}$. Integral elements are the tangent planes to manifolds which are solution manifolds for a given EDS Σ and Pfaffian systems $\mathcal{P}$ and defined as follows.

Definition 4: Integral manifolds. An integral manifold $\mathcal{N}$ of an EDS Σ on $\mathcal{M}$ is a p-dimensional submanifold $\mathcal{N}$ of $\mathcal{M}$ such that each k-dimensional vector subspace $(E^k)_x\subset T_x\mathcal{N}$ for $1\leqslant k\leqslant p$ annihilates all the k-forms in the EDS Σ.

C. Reduced characters and involution

If we wish to look for specific integral manifolds transversal to some given submanifold, we must introduce an **independence condition** $\Omega=\omega^1\wedge\cdots\wedge\omega^n\neq 0$, which is sometimes also called the *volume element*, where the ω^i are one-forms characterizing such a submanifold. If we select $x^1,\ldots,x^n$ as local independent coordinates, where we will use brackets to indicate powers of x^i such as in $(x^i)^n$, then Ω is given by $\Omega=dx^1\wedge\cdots\wedge dx^n$. All integral elements on which Ω *does not vanish* are called **admissible integral elements** according to Ref. 10 and we can define the following.

Definition 5: Involutive systems. An EDS with independence condition (Σ,Ω) *is in involution with respect to* Ω *at a point* $x\in\mathcal{M}$ *means that there exists an* **admissible ordinary** *integral element of dimension n of* (Σ,Ω) *at x.*

In order to determine the reduced characters, we need to introduce the **reduced polar systems** $H^{\mathrm{red}}((E^p)_x)$ which are defined as polar systems, where one suppresses all components involving $\omega^1,\ldots,\omega^n$ in each one-form of a given (9). We then define the reduced rank $s_0'(x)$ $:=r(H^{\mathrm{red}}((E^0)_x))$ and $s_0':=\max(_{\{x\in\mathcal{M}\}}s_0'(x))$ so that we can define the reduced characters inductively as follows.

Definition 6: Reduced Cartan characters. The reduced Cartan characters s_p' *are inductively defined as*

$$s_p':=\max(_{\{x\in\mathcal{M},V_x^{p+1}\in T_x\mathcal{M}\}}r(H^{\mathrm{red}}((E^p)_x)))-\sum_{i=0}^{p-1}s_i'\,.$$

For a Pfaffian system $(\mathcal{P},\Omega)$ the reduced Cartan characters can also be computed in the following way. Given a Pfaffian system $\mathcal{P}$ consisting of s one-forms θ^α with independence condition Ω $=\omega^1\wedge\cdots\wedge\omega^n\neq 0$, we denote by π^λ all the extra $N-s-n$ one-forms such that $(\theta^\alpha,\omega^i,\pi^\lambda)$, $1\leqslant\alpha\leqslant s$, form a coframe on our formal N-dimensional manifold $\mathcal{M}$. Once we have chosen such one-forms π^λ, we can write each $d\theta^\alpha$ as

$$d\theta^\alpha=A^\alpha_{\lambda i}\pi^\lambda\wedge\omega^i+\tfrac{1}{2}B^\alpha_{ij}\omega^i\wedge\omega^j+\tfrac{1}{2}C^\alpha_{\lambda\kappa}\pi^\lambda\wedge\pi^\kappa(\mathrm{mod}\mathcal{I}(\mathcal{P})),\tag{10}$$

where $\mathcal{I}(\mathcal{P})$ is the differential ideal generated by $\mathcal{P}$. In Eqs. (10), the terms $A^\alpha_{\lambda i}$ form the **tableau matrix** and we call the terms B^α_{ij} the **torsion terms**, where the notion of torsion here has nothing to do with affine connections. The Pfaffian system is called **quasi-linear** if all the $C^\alpha_{\lambda\kappa}=0$. We say that the torsion can be absorbed if a suitable transformation Φ

$$\Phi:\pi^\lambda\to\pi^\lambda+p_i^\lambda\omega^i$$

with

$$\tilde{B}^\alpha_{ij}=B^\alpha_{ij}+A^\alpha_{\lambda j}p_i^\lambda-A^\alpha_{\lambda i}p_j^\lambda\,,\tag{11}$$

can be found such that $\tilde{B}^\alpha_{ij}=0$. When $B^\alpha_{ij}\neq 0$ in every coframe $(\theta^\alpha,\omega^e,\pi^\lambda)$, the system possesses integrability conditions which will prevent it from being in involution. From the tableau matrix $A^\alpha_{\lambda i}$, we can determine the reduced Cartan characters directly[8,10] because $r(A^\alpha_{\lambda 1})=s_1'$ and the rank of

$$\begin{pmatrix}A^\alpha_{\lambda 1}\\A^\alpha_{\lambda 2}\end{pmatrix}$$

is equal to $s_1'+s_2'$ and so on. There are many versions of **Cartan's test for involution**,[9] some of which one can find in Refs. 8 and 10, and we state it as follows.

Theorem 1: *Cartan's test for involution. A Pfaffian system* $(\mathcal{P}, \Omega)$ *is in involution means that* $s_0 = s_0'$, $s_1 = s_1', \ldots, s_p = s_p'$ *and a coframe transformation can be found such that* **all** *its torsion terms* B_{ij}^{α} *vanish identically.*

An important question is whether and when ordinary integral manifolds exist and whether, given some initial data, they are unique. The **Cartan–Kähler theorems**[8,10] give some answers to these questions for real-analytic systems. They reduce to the **Cauchy–Kovalevskaya theorem** when the number of equations equals the number of unknowns given by m so that $n = m$.[20] The first Cartan–Kähler theorem specifies under which conditions a unique integral manifold of dimension p can be constructed from a $(p-1)$-dimensional one. The second theorem states that under certain conditions a chain of regular integral manifolds of increasing dimension exists.[8–10] If there is no general solution for a given EDS (Σ, Ω), then there could be identities or integrability conditions so that we must **prolong** the system by adding in these conditions and by enlarging the space of our formal jet coordinates to higher order, where in Refs. 8 and 10 a detailed account of this procedure can be found. The key result for prolongations in the real analytic case is given by the **Cartan–Kuranishi theorem** which states that an EDS (Σ, Ω) which is not in involution and not inconsistent becomes either involutive or inconsistent after a **finite** number of prolongations.[21]

Comment: We should point out that in Refs. 22–24 there is a quantity similar to the Cartan characters also introduced by Cartan[9] called the **degré d'arbitraire**. Einstein had introduced the **strength** of a system of equations in his last unified field theory of electromagnetism and gravity in order to measure how strongly such a system restricts the solution. A discussion between him and Cartan on this subject is presented in Ref. 25. Sué finally compared Cartan's degree of arbitrariness and Einstein's strength in Refs. 23 and 24 for linear systems of equations. Seiler derived a relation between this degree of arbitrariness and the Cartan characters for nonlinear, overdetermined higher-order systems of PDEs.[22]

Before we introduce Janet–Riquier theory, we illustrate the above theory with the example of a coordinate transformation to Euclidean coordinates in two dimensions. For the line element we therefore have

$$ds^2 = y^2 dx^2 + dy^2 = du^2 + dU^2,$$

where u, U are the Euclidean coordinates. For this to hold we must have

$$y^2 = p^2 + P^2, \quad 0 = pq + PQ, \quad 1 = q^2 + Q^2,$$

where we introduced the Monge notation

$$p := \frac{\partial u}{\partial x}, \quad q := \frac{\partial u}{\partial y}, \quad r := \frac{\partial^2 u}{\partial x^2}, \quad s := \frac{\partial^2 u}{\partial x \partial y}, \quad t := \frac{\partial^2 u}{\partial y^2},$$

$$P := \frac{\partial U}{\partial x}, \quad Q := \frac{\partial U}{\partial y}, \quad R := \frac{\partial^2 U}{\partial x^2}, \quad S := \frac{\partial^2 U}{\partial x \partial y}, \quad T := \frac{\partial^2 U}{\partial y^2}.$$

These are local coordinates on a jet bundle $\mathcal{J}^2(\mathbb{R}^2, \mathbb{R}^2)$ with $N = 2 + 2 + 4 + 6 = 14$ formal dimensions, where we have $n = 2$ independent and $m = 2$ dependent variables. After differentiating the above equations, we obtain a Pfaffian system $\mathcal{P}$ with $s = 12$ independent one-forms which can locally be expressed as

$$\theta^1 = du - p\,dx - q\,dy,$$

$$\theta^2 = dU - P\,dx - Q\,dy,$$

$$\theta^3 = dp - r\,dx - s\,dy,$$

$$\theta^4 = dP - R\,dx - S\,dy,$$

$$\begin{aligned}
\theta^5 &= dq - s\,dx - t\,dy,\\
\theta^6 &= dQ - S\,dx - T\,dy,\\
\theta^7 &= p\,dr + r\,dp + P\,dR + R\,dP,\\
\theta^8 &= q\,dr + r\,dq + Q\,dR + R\,dQ + dy,\\
\theta^9 &= p\,ds + s\,dp + P\,dS + S\,dP - dy,\\
\theta^{10} &= q\,ds + s\,dq + Q\,dS + S\,dQ,\\
\theta^{11} &= p\,dt + t\,dp + P\,dT + T\,dP,\\
\theta^{12} &= q\,dt + t\,dq + Q\,dT + T\,dQ.
\end{aligned} \tag{12}$$

As the rank of $\mathcal{D}$ is $N-s=14-12=2$, where $s=12$, the system (12) can dually be characterized by two Vessiot vector fields V^1, V^2 generating $\mathcal{D}$, where

$$\begin{aligned}
V^i = {} & V^i_x\frac{\partial}{\partial x} + V^i_y\frac{\partial}{\partial y} + (pV^i_x + qV^i_y)\frac{\partial}{\partial u} + (PV^i_x + QV^i_y)\frac{\partial}{\partial U} + (rV^i_x + sV^i_y)\frac{\partial}{\partial p} + (RV^i_x + SV^i_y)\frac{\partial}{\partial P}\\
& + (sV^i_x + tV^i_y)\frac{\partial}{\partial q} + (SV^i_x + TV^i_y)\frac{\partial}{\partial Q} + V^i_r\frac{\partial}{\partial r} + V^i_R\frac{\partial}{\partial R} + V^i_s\frac{\partial}{\partial s} + V^i_S\frac{\partial}{\partial S} + V^i_t\frac{\partial}{\partial t} + V^i_T\frac{\partial}{\partial T},
\end{aligned}$$

$$i=1,2, \tag{13}$$

and the coefficients V^i_r, V^i_R, V^i_s, V^i_S, V^i_t, V^i_T are determined through the condition that the six one-forms $\theta^7,\ldots,\theta^{12}$ are annihilated by V^1, V^2. Because here we have $d\theta^\alpha(V^1,V^2)\equiv 0$, we find that the system (12) is *complete*. It means that $C(\mathcal{P})=\mathcal{D}$ so that $c=2$ and, therefore, both V^1 and V^2 are Cauchy characteristics. They form an involution of maximal dimension $g=2$ and because $s=12$ and $s=s_0=s_0'$, then $s_0=s_0'=12$. We see that $t=\partial^2 u/\partial y^2=0$ and $T=\partial^2 U/\partial y^2=0$ so that the solution must be linear in y. The general solution is then given by

$$\begin{aligned}
u &= y\cos(x+\epsilon)+a, & U &= y\sin(x+\epsilon)+b,\\
p &= -y\sin(x+\epsilon), & P &= y\cos(x+\epsilon),\\
q &= \cos(x+\epsilon), & Q &= \sin(x+\epsilon),\\
r &= -y\cos(x+\epsilon), & R &= -y\sin(x+\epsilon),\\
s &= -\sin(x+\epsilon), & S &= \cos(x+\epsilon),\\
t &= 0, & T &= 0,
\end{aligned}$$

where $\{a,b,\epsilon\}$ are arbitrary constants corresponding to the translational and rotational degrees of freedom. This also gives a local parametrization of the two-dimensional integral manifold which corresponds to this solution.

III. JANET–RIQUIER THEORY

In the original Janet–Riquier theory of systems of partial differential equations (PDEs), there was an algorithm created to explain how a given system of PDEs could be brought into passive orthonomic form. Passivity is the *absence* of integrability conditions and orthonomicity is a form of *ordering* of the partial derivatives of a system. The passive orthonomic system of a system of PDEs was the predecessor of what is now called a formally integrable system or involutory system of PDEs. A theory created by Riquier[26] and developed by Janet[27,28] and later by Thomas [29] now called Janet–Riquier theory helps to decide such questions. A good account of this theory as in the

form as created in Refs. 26, 27 and 29 is given in Russian by S. P. Finikov.[30] In order to obtain intrinsic results Spencer[31] and then Goldschmidt[32] introduced a new coordinate independent approach based on homological algebra. An account of this theory can be found in Ref. 33.

There are many algorithms which have been implemented by algebraic computing. Some of them are concerned with the choice of particular rankings such as the REDUCE package DINV by Gerdt.[34] Reid[35] developed a computer package based on MAPLE which brings a system into *solved form*, which is a modification of an orthonomic system.[36] Seiler[22,37] uses the theory of the involutive symbol, which is a modernized version of the original Janet–Riquier theory, to determine whether systems are in involution. Janet–Riquier theory is well illustrated by the Janet example[28,33,37] and applications to general relativity have previously been made such as in Refs. 38–40.

For a system of partial differential equations (=system of PDEs) of order q, which we will denote by $\mathcal{R}_q$ from now on, we use $x^1,\ldots,x^n$ for the independent variables, where we will use brackets to indicate powers of any x^i such as in $(x^i)^n$, and u^α for the m dependent variables. Their derivatives on the jet bundle of order q, denoted by $\mathcal{J}^q(\mathbb{R}^n,\mathbb{R}^m)$, are denoted by $u^\alpha_{,J}$, where J is a multi-index. We associate a **monomial** $x^J=(x^1)^{j_1}\cdot\cdots\cdot(x^n)^{j_n}$ with each partial derivative $u^\alpha_{,J}$, where $J=(j_1,\ldots,j_n)$ is a **multi-index** and $\|J\|=j_1+\ldots+j_n$ is the order of the derivative. This means that to each set of partial derivatives of each dependent variable u^α corresponds a unique set of monomials.

Then, we **order the partial derivatives** of a system of PDEs in a systematic way. Very often we will use an inverse lexicographic ordering based on $x^n>\ldots>x^2>x^1$ on their partial derivatives so that $u_{,n}>\ldots>u_{,2}>u_{,1}$ and so on. A **ranking** amongst *all* partial derivatives is defined as follows.

Definition 7: Ranking of derivatives. A ranking of derivatives is a total ordering $\mathcal{R}_>$ of all the partial derivatives $u^\alpha_{,J}$ (for m, n fixed) satisfying the two following conditions (where J and K are multi-indices).

(i) *If $\|J\|>\|K\|$, then $u^\alpha_{,J}>u^\alpha_{,K}$.*
(ii) *If $u^\alpha_{,J^1}>u^\alpha_{,J^2}$, then $(u^\alpha_{,J^1})_{,K}>(u^\alpha_{,J^2})_{,K}$ for any multi-index K.*

A special subclass of these rankings are called **orderly rankings** which are rankings such that (*i*) holds for different indices α referring to different unknowns u^α (see Ref. 41 for more details). Then, the system can be brought into a more organized form called **orthonomic form**. This is achieved by determining the partial derivative highest in the ranking in each equation of $\mathcal{R}_q$ and calling it the **leading** derivative of the equation. Once this equation is solved for its leading derivative which then becomes the only term on its LHS, we call it a **principal** derivative. All other partial derivatives of that order which are not in the set of principal derivatives are called **parametric derivatives**. Based on this we can define an orthonomic system.

Definition 8: Orthonomic system. A system of partial differential equations $\mathcal{R}_q$ of order q is orthonomic with respect to a given ranking $\mathcal{R}_>$ if

(i) *all the PDEs are solved with respect to their leading derivatives*;
(ii) *no two leading derivatives are the same; and*
(iii) *no parametric derivative in any equation of $\mathcal{R}_q$ can be a principal derivative in another equation of $\mathcal{R}_q$ or even a partial derivative of any order of a principal derivative.*

Those independent variables by means of which we can differentiate the principal derivative of an equation without reintroducing a derivative already produced by means of differentiating another principal derivative are called **multiplicative variables** for the equation. This induces multiplicative variables for the monomials corresponding to the partial derivatives.[33] To avoid nonintrinsic results, one introduces special coordinates called **δ-regular coordinates** and uses the theory of the **involutive symbol** of a system $\mathcal{R}_q$ which we will introduce next.

A. Involutive symbol and formal integrability

In order to determine the **symbol** of a system of PDEs only the highest-order partial derivatives of each equation in $\mathcal{R}_q$ matter. We denote the quantities corresponding to each partial derivative $u^{\alpha}_{,J}$ by V^{α}_{J} and define the symbol $\mathcal{M}_q$ as follows.

Definition 9: Symbol of $\mathcal{R}_q$. A system of partial differential equations $\mathcal{R}_q$ of order q, locally described by p equations in solved form as $\Phi^{\tau}(x^i,u^{\alpha},u^{\alpha}_{,J})=0$ for $\tau=1,...,p$, has a solution space $\mathcal{M}_q$ for the unknowns V^{α}_{J} with $\alpha=1,...,m$, $\|J\|=q$:

$$\mathcal{M}_q:\sum_{\alpha,\|J\|=q}\left(\frac{\partial\Phi^{\tau}}{\partial u^{\alpha}_{,J}}\right)V^{\alpha}_{J}=0, \tag{14}$$

where we formally differentiate with respect to the $u^{\alpha}_{,J}$. $\mathcal{M}_q$ is called the **symbol of** $\mathcal{R}_q$.

For simplicity the matrix rather than the map is usually regarded as the symbol of $\mathcal{R}_q$. We associate with each symbol equation its multiplicative variables which are the same as the multiplicative variables which its corresponding equation in $\mathcal{R}_q$ adopts. Then, we determine the **class of an equation** in $\mathcal{M}_q$ by counting the number of multiplicative variables it adopts—a number denoted by k such that $0\leqslant k\leqslant n$—and define

$$\beta^{(k)}_{q}:=\text{number of equations of class } k \text{ in } \mathcal{M}_q(\text{or}\mathcal{R}_q).$$

The definition of the **Cartan characters** $\alpha^{(k)}_{q}$ is based on the $\beta^{(k)}_{q}$ and is given by

$$\alpha^{(k)}_{q}:=m\cdot\binom{n+q-k-1}{q-1}-\beta^{(k)}_{q}, \tag{15}$$

where $m\cdot\Sigma_{k=1}^{n}\binom{n+q-k-1}{q-1}$ is the total number of partial derivatives of order q that a system $\mathcal{R}_q$ will have. Earlier in this article, we denoted the $n+1$ Cartan characters of an EDS by s_k, $k=0,1,2,\ldots,n$ but here we write s_k, $k,=1,2,\ldots,n$ as $\alpha^{(k)}_{q}$ as Janet–Riquier theory does not give s_0. In δ-regular coordinates $\alpha^{(k)}_{q}$ equals the number of parametric derivatives of class k and order q. When no identities are present, the symbol is said to be involutive, which can be equivalently expressed as[33] follows.

Theorem 2: *Involutive symbol. In a δ-regular coordinate system the following conditions are equivalent*:

(i) *The symbol $\mathcal{M}_q$ is involutive.*
(ii) $\dim(\mathcal{M}_{q+1})=\Sigma^{n}_{k=1}k\cdot\alpha^{(k)}_{q}$.
(iii) *The rank r of $\mathcal{M}_{q+1}$ is* $r(\mathcal{M}_{q+1})=\Sigma^{n}_{k=1}k\cdot\beta^{(k)}_{q}$.
(iv) *Prolongation with respect to* **nonmultiplicative variables** *does not lead to any new equations.*

But a system of equations $\mathcal{R}_q$ which has an involutive symbol $\mathcal{M}_q$ can still admit integrability conditions. They can be revealed by means of projecting our prolonged system $\mathcal{R}_{q+1}$, which is obtained by differentiating $\mathcal{R}_q$ with respect to all its n independent variables, back onto $\mathcal{R}_q$. In general, we will denote first projections onto lower-order systems by $\mathcal{R}^{(1)}_{q+r}=\pi^{(q+r+1)}_{q+r}(\mathcal{R}_{q+r+1})$. If $\mathcal{R}^{(1)}_{q}$ is not identical to $\mathcal{R}_q$, then integrability conditions occur. If they are identical we can characterize a *formally integrable system* $\mathcal{R}_q$ as[33,37] a system of partial differential equations $\mathcal{R}_q$ for which $\mathcal{R}^{(1)}_{q+r}=\mathcal{R}_{q+r}$ for all $r\geqslant 0$. A special situation occurs when $\mathcal{M}_q$ is involutive *and* $\mathcal{R}_q$ is formally integrable.[37] Then, we obtain ideal systems of equations which are called involutive systems of equations.

Definition 10: Involutive systems of equations. A system of equations $\mathcal{R}_q$ is involutive if and only if its symbol $\mathcal{M}_q$ is involutive and $\mathcal{R}_q$ is formally integrable.

There exists an important criterion for involution that tells us that we only need to prolong once for an involutive system to prove this:

Theorem 3: *Criterion for involution. $\mathcal{R}_q$ is a system in involution means that its symbol $\mathcal{M}_q$ is involutive and $\mathcal{R}^{(1)}_{q}=\mathcal{R}_q$.*

We will now apply the above theory to the Riemann–Lanczos problem.

IV. THE RIEMANN–LANCZOS PROBLEM

In the Bampi–Caviglia papers[4,5] the Riemann–Lanczos problem in four dimensions was written as an EDS. Here we are going to introduce a Pfaffian system based on (8) which differs slightly from that in Ref. 4 because we incorporate the cyclic conditions (2) as well. Independently of the space–time dimension n, we can use the exterior differentials of Eqs. (8) in solved form together with the *contact conditions* K_{abc} to obtain the system

$$\begin{aligned} df^{(R)}_{abcd} &= (R_{abcd,e}+\alpha_{abcde})dx^e - dP_{abcd}+dP_{abdc}-dP_{cdab}+dP_{cdba}+\Gamma^n_{ad}(dL_{nbc}+dL_{ncb}) \\ &\quad -\Gamma^n_{ac}(dL_{nbd}+dL_{ndb})+\Gamma^n_{bc}(dL_{nad}+dL_{nda})-\Gamma^n_{bd}(dL_{nac}+dL_{nca}), \\ K_{abc} &= dL_{abc}-P_{abce}dx^e, \\ dK_{abc} &= dx^e\wedge dP_{abce}, \end{aligned} \tag{16}$$

where α_{abcde} is given by

$$\alpha_{abcde}=\Gamma^n_{ad,e}(L_{nbc}+L_{ncb})-\Gamma^n_{ac,e}(L_{nbd}+L_{ndb})+\Gamma^n_{bc,e}(L_{nad}+L_{nda})-\Gamma^n_{bd,e}(L_{nac}+L_{nca}). \tag{17}$$

The (x^a, L_{abc}, P_{abcd}) are local jet coordinates on $\mathcal{J}^1(\mathbb{R}^n,\mathbb{R}^m)$ with $P_{abcd}=\partial L_{abc}/\partial x^d$ when projected onto our space–time manifold and m is the number of independent Lanczos components L_{abc}. A Vessiot vector field $V\in\mathcal{D}$ is then locally given as

$$V=V^e\frac{\partial}{\partial x^e}+V^eP_{abce}\frac{\partial}{\partial L_{abc}}+V_{abcd}\frac{\partial}{\partial P_{abcd}}, \tag{18}$$

where m of the $n\cdot m$ components V_{abcd} are defined through the requirement that $df^{(R)}_{abcd}(V)=0$. This leads to the m independent equations

$$\begin{aligned} V_{\{abcd\}} &= V^e[R_{abcd,e}+\alpha_{abcde}+\Gamma^n_{ad}(P_{nbce}+P_{ncbe})-\Gamma^n_{ac}(P_{nbde}+P_{ndbe})+\Gamma^e_{bc}(P_{nade}+P_{ndae}) \\ &\quad -\Gamma^n_{bd}(P_{nace}+P_{ncae})], \end{aligned} \tag{19}$$

where $\{abcd\}$ denotes the Riemann-type symmetrization performed over the indices $abcd$. Before we comment on the Riemann–Lanczos problem in four dimensions, we look at the two- and three-dimensional cases.

A. The Riemann–Lanczos problem in two dimensions

First, we consider the Riemann–Lanczos problem in a two-dimensional space–time. In two space–time dimensions there is only one independent Riemann–Lanczos equation $f^{(R)}_{1212}$. We have two given independent variables x^1, x^2, two dependent variables L_{121}, L_{122} and four Monge derivatives P_{1211}, P_{1212}, P_{1221}, P_{1222} so that $(x^1,x^2,L_{121},L_{122},P_{1211},P_{1212},P_{1221},P_{1222})$ are local coordinates on the jet bundle $\mathcal{J}^1(\mathbb{R}^2,\mathbb{R}^2)$ with $N=2+2+4=8$. We leave the metric tensor components completely arbitrary so that $f^{(R)}_{1212}$ is given as

$$f^{(R)}_{1212}=R_{1212}-2P_{1212}+2P_{1221}+2L_{121}(\Gamma^1_{12}-\Gamma^2_{22})-2L_{122}(\Gamma^1_{11}+\Gamma^2_{12})=0. \tag{20}$$

We define α_{1212e} in the two-dimensional case to be

$$\alpha_{1212e}=R_{1212,e}-2L_{121}(\Gamma^1_{12,e}-\Gamma^2_{22,e})-2L_{122}(\Gamma^1_{11,e}+\Gamma^2_{12,e}), \tag{21}$$

where $e=1,2$. The Pfaffian system derived from (20) is locally given by

$$\theta^1=\alpha_{12121}dx^1+\alpha_{12122}dx^2-2dP_{1212}+2dP_{1221}+2(\Gamma^1_{12}-\Gamma^2_{22})dL_{121}-2(\Gamma^1_{11}+\Gamma^2_{12})dL_{122},$$

$$\theta^2=dL_{121}-P_{1211}dx^1-P_{1212}dx^2, \tag{22}$$

$$\theta^3=dL_{122}-P_{1221}dx^1-P_{1222}dx^2,$$

where θ^1 is the exterior derivative of $f^{(R)}_{abcd}$ and θ^2, θ^3 are the two contact conditions and $d\theta^2$, $d\theta^3$ their exterior derivatives. The zeroth character is $s_0=3$, since we only have to count the number of one-forms in (22). Omitting all the terms involving dx^1, dx^2 in the one-forms in (22), the same number is obtained so that $s_0'=3$, leading to our first result $s_0=s_0'=3$. Further characters were obtained to be $s_1=s_1'=2$ and $s_2=s_2'=1$. A detailed discussion of the polar systems and their Cartan characters for this case can be found in Ref. 42.

We can also compute the characters using the tableau, and by determining the torsion we then find out whether the system possesses integrability conditions. In order to form a complete coframe for our example (22), we have to add three one-forms π^Λ, where Λ now is a *collective index* with $\Lambda\in\{1211,1221,1222\}$, to the five one-forms θ^1, θ^2, θ^3, ω^1, ω^2 and so we choose

$$\pi_{1211}:=dP_{1211},\quad \pi_{1221}:=dP_{1221},\quad \pi_{1222}:=dP_{1222}.$$

The dP_{1212} can be expressed through θ^1 as

$$dP_{1212}=\pi_{1221}+((\tfrac{1}{2}\alpha_{12121}+(\Gamma^1_{12}-\Gamma^2_{22})(P_{1211}-(\Gamma^1_{11}+\Gamma^2_{12})P_{1221}))\omega^1$$
$$+((\tfrac{1}{2}\alpha_{12122}+(\Gamma^1_{12}-\Gamma^2_{22})(P_{1212}-(\Gamma^1_{11}+\Gamma^2_{12})P_{1222}))\omega^2(\mathrm{mod}\ \{\theta^\alpha\}). \tag{23}$$

Having accomplished this, we can then expand the exterior derivatives of the contact conditions as

$$d\theta^1\equiv 0,$$

$$d\theta^2\equiv-\pi_{1211}\wedge\omega^1-\pi_{1221}\wedge\omega^2+((\tfrac{1}{2}\alpha_{12121}+(\Gamma^1_{12}-\Gamma^2_{22})P_{1211}-(\Gamma^1_{11}+\Gamma^2_{12})P_{1221}))\omega^1\wedge\omega^2, \tag{24}$$

$$d\theta^3\equiv-\pi_{1221}\wedge\omega^1-\pi_{1222}\wedge\omega^2\quad(\mathrm{mod}\ \mathcal{I}(\mathcal{P})).$$

Therefore, we obtain for the tableau matrices

$$A^\alpha_{\Lambda 1}=\begin{pmatrix}0&0&0\\-1&0&0\\0&-1&0\end{pmatrix},\quad A^\alpha_{\Lambda 2}=\begin{pmatrix}0&0&0\\0&-1&0\\0&0&-1\end{pmatrix},$$

where $\alpha=1,2,3$ and Λ is one of the collective indices $\Lambda\in\{1211,1221,1222\}$. This leads to $s_1'=2$, $s_2'=1$, and the only nonvanishing torsion term is given by

$$B^2_{12}=-[\tfrac{1}{2}\alpha_{12121}-(\Gamma^1_{12}-\Gamma^2_{22})P_{1211}+(\Gamma^1_{11}+\Gamma^2_{12})P_{1221}]. \tag{25}$$

If we wish to absorb the torsion coefficients, we must find a transformation Φ with $\pi^\lambda\to\pi^\lambda+p^\lambda_i\omega^i$ and quantities p^λ_i such that

$$0=\tilde{B}^\alpha_{ij}=B^\alpha_{ij}+A^\alpha_{\lambda j}p^\lambda_i-A^\alpha_{\lambda i}p^\lambda_j.$$

In our case this leads to the system

$$0=A^1_{\Lambda 2}p^\Lambda_1-A^1_{\Lambda 1}p^\Lambda_2,$$

$$0 = B^2_{12} + A^2_{\Lambda 2} p^\Lambda_1 - A^2_{\Lambda 1} p^\Lambda_2 , \tag{26}$$

$$0 = A^3_{\Lambda 2} p^\Lambda_1 - A^3_{\Lambda 1} p^\Lambda_2 .$$

One solution *ansatz* to fulfill (26) is to choose $p^2_1 := B^2_{12}$ while all other p^Λ_i vanish: thus the torsion is absorbed and the system is therefore in involution.[9,10] Adding the exterior derivative of the differential gauge condition $L_{12}{}^s{}_{;s} = 0$ does not change the involutivity. Obviously then $s_0 = s'_0 = 4$ so that the set of Cartan characters (s_0, s_1, s_2) in this case is given by (4, 2, 0). Detailed calculations and a REDUCE code are given in Ref. 42.

Next, we use Janet–Riquier theory to reproduce these results. We have a system of equations $\mathcal{R}_1$ with $n = m = 2$, $q = 1$ and the symbol $\mathcal{M}_1$ consists only of a single equation

$$-2V_{1212} + 2V_{1221} = 0, \tag{27}$$

which is of class 2 whatever the choice of the orderly ranking. (Note that here and in subsequent sections, where Janet–Riquier theory is applied, the *symbol variables* V_{abcd}, V_{abcde} have no connection with Vessiot vector fields V.) This yields

$$\alpha^{(1)}_1 = 2, \quad \alpha^{(2)}_1 = 1.$$

Trivially, all variables are multiplicative variables and the symbol of one equation is always involutive. We have $\dim(\mathcal{R}_1) = 5$ and $\dim(\mathcal{M}_1) = 3$ and our prolonged system of equations $\mathcal{R}_2$ consists of $f^{(R)}_{1212}$, $f^{(R)}_{1212,1}$, $f^{(R)}_{1212,2}$. No integrability conditions can be created because

$$\dim(\mathcal{R}^{(1)}_1) = \dim(\mathcal{R}_2) - \dim(\mathcal{M}_2) = 9 - 4 = 5 = \dim(\mathcal{R}_1),$$

and the system is linear so that formal integrability is demonstrated and the system $\mathcal{R}_1$ is involutive.

If we incorporate the differential gauge condition $L_{ab}{}^s{}_{;s} = 0$, then $\mathcal{M}_1$ is formed by

$$\begin{aligned} -2V_{1212} + 2V_{1221} &= 0, \\ g^{11}V_{1211} + g^{12}V_{1221} + g^{12}V_{1212} + g^{22}V_{1222} &= 0, \end{aligned} \tag{28}$$

which again has all its equations of class 2 whatever the choice of the orderly ranking be and so we obtain $\alpha^{(1)}_1 = 2$, $\alpha^{(2)}_1 = 0$. The result is that $\mathcal{R}_1$ is formally integrable and involutive.[42] We conclude that *the Riemann–Lanczos problem in two dimensions is always in involution and the differential gauge condition does not affect the result*. The Cartan characters (s_0, s_1, s_2) are (3, 2, 1) when no differential gauge condition is imposed but (4, 2, 0) when it is imposed.

We can give the general solution for the two-dimensional Riemann–Lanczos problem explicitly. First, we look at the general two-dimensional space–time with Lorentzian signature and line element in characteristic coordinates x^1, x^2 written as

$$ds^2 = -e^{2\rho} dx^1 dx^2,$$

where ρ is an arbitrary function of x^1, x^2. We find that the general solution is of the form

$$\begin{aligned} L_{121} &= e^{2\rho} f_1(x^1) - \tfrac{1}{4} e^{2\rho} \rho_{,x^1}, \\ L_{122} &= e^{2\rho} f_2(x^2) + \tfrac{1}{4} e^{2\rho} \rho_{,x^2}, \end{aligned} \tag{29}$$

where $f_1(x^1)$, $f_2(x^2)$ are two arbitrary functions depending on one local coordinate each. This is in agreement with the result for the Cartan characters claiming that the general solution depends on two arbitrary functions of one variable each. The symbol derived from $f^{(R)}_{1212}$, $L_{12}{}^s{}_{;s}$ is

$$0 = -2V_{1212} + 2V_{1221},$$
$$0 = -V_{1212} - V_{1221}, \tag{30}$$

from which we obtain $\beta_1^{(1)} = \beta_1^{(2)} = 1$ based on the ranking stemming from $x^2 \succ x^1$. This leads to $\alpha_1^{(1)} = \alpha_1^{(2)} = 1$, which **cannot be** the intrinsic result as we already solved the two-dimensional problem in the previous section. We conclude that the above coordinate frame is not δ-regular and we need to perform a coordinate transformation of the form

$$d\tilde{x}^1 = a_{11}dx^1 + a_{12}dx^2, \quad d\tilde{x}^2 = a_{21}dx^1 + a_{22}dx^2$$

in order to obtain the correct values for $\alpha_1^{(1)}$, $\alpha_1^{(2)}$. After such a transformation, the new symbol in orthonomic form is

$$V_{1222} = -\frac{a_{21}}{a_{22}} V_{1221},$$
$$V_{1212} = -\frac{a_{11}}{a_{12}} V_{1211}. \tag{31}$$

Now, both equations are of class 2 so that $\beta_1^{(1)} = 0$, $\beta_1^{(2)} = 2$, which produces $\alpha_1^{(1)} = 2$, $\alpha_1^{(2)} = 0$ which is the known intrinsic result for the Cartan characters.

For spaces with Euclidean signature we can write their line element as

$$ds^2 = e^{2\rho}((dx^1)^2 + (dx^2)^2),$$

where ρ is again an arbitrary function of x^1, x^2. We obtain the solution

$$L_{121} = e^{2\rho}(f_1(x^1 + x^2) - \tfrac{1}{2}\rho_{,x^2}),$$
$$L_{122} = e^{2\rho}(f_2(x^1 - x^2) + \tfrac{1}{2}\rho_{,x^1}), \tag{32}$$

and the intrinsic values for the characters are $\alpha_1^{(1)} = 2$, $\alpha_1^{(2)} = 0$.

B. The Riemann–Lanczos problem in three dimensions

In three space–time dimensions with local coordinates x^1, x^2, x^3, we obtain eight independent components of the Lanczos tensor, namely, L_{121}, L_{122}, L_{131}, L_{133}, L_{232}, L_{233}, L_{123}, L_{132} when imposing the cyclic conditions (2). Each of them has three first-order partial derivatives so that we use the jet bundle $\mathcal{J}^1(\mathbb{R}^3, \mathbb{R}^8)$ with formal dimension $N = 3 + 8 + 8 \cdot 3 = 35$ to express the EDS. We obtain the six independent Riemann–Lanczos equations whose exterior derivatives are $df_{1212}^{(R)}$, $df_{1313}^{(R)}$, $df_{2323}^{(R)}$, $df_{1213}^{(R)}$, $df_{1223}^{(R)}$, $df_{1323}^{(R)}$. We find that the Riemann–Lanczos problem in three dimensions is not in involution and its reduced characters (s_0', s_1', s_2', s_3') are (14, 8, 7, 3), where detailed calculations can be found in Ref. 42. We can test this result with the REDUCE code given in Ref. 42 and immediately obtain (8, 7, 3) for the reduced characters (s_1', s_2', s_3') and that the system is not in involution. It is sufficient to use an *arbitrary diagonalized line element* which describes three-dimensional space–times completely as is shown in Ref. 43.

We can also use the tableau matrix to calculate this result. First, we must complete our set of 14 one-forms together with the three ω^e to a complete coframe consisting of $N = 35$ elements by introducing the 18 π^Λ such that $(df_{abcd}^{(R)}, K_{abc}, \omega^e, \pi^\Lambda)$ forms a cobasis on $\mathcal{M}$. We introduce the 18 π^Λ using collective indices Λ with $\Lambda = 1,...,18$ with the following correspondence between $\pi^\Lambda \leftrightarrow dP_{abcd}$:

$$\pi^1 \leftrightarrow dP_{1211}, \quad \pi^2 \leftrightarrow dP_{1221}, \quad \pi^3 \leftrightarrow dP_{1311},$$

$$\pi^4 \leftrightarrow dP_{1331}, \quad \pi^5 \leftrightarrow dP_{2321}, \quad \pi^6 \leftrightarrow dP_{2331},$$

$$\pi^7 \leftrightarrow dP_{1231}, \quad \pi^8 \leftrightarrow dP_{1321}, \quad \pi^9 \leftrightarrow dP_{1222},$$

$$\pi^{10} \leftrightarrow dP_{1312}, \quad \pi^{11} \leftrightarrow dP_{1332}, \quad \pi^{12} \leftrightarrow dP_{2322},$$

$$\pi^{13} \leftrightarrow dP_{2332}, \quad \pi^{14} \leftrightarrow dP_{1232}, \quad \pi^{15} \leftrightarrow dP_{1322},$$

$$\pi^{16} \leftrightarrow dP_{1333}, \quad \pi^{17} \leftrightarrow dP_{2333}, \quad \pi^{18} \leftrightarrow dP_{1233}.$$

When using the correspondence $\theta^\alpha \leftrightarrow K_{abc}$ the eight dK_{abc} can be recast as

$$\begin{aligned}
d\theta^1 &\equiv -\pi^1\wedge\omega^1 - \pi^2\wedge\omega^2 - \pi^7\wedge\omega^3 + \pi^{10}\wedge\omega^3 - \pi^8\wedge\omega^3 + \tfrac{1}{2}B^1_{i2}\omega^i\wedge\omega^2 + \tfrac{1}{2}B^1_{i3}\omega^i\wedge\omega^3,\\
d\theta^2 &\equiv -\pi^2\wedge\omega^1 - \pi^9\wedge\omega^2 - 2\pi^{14}\wedge\omega^3 - \pi^5\wedge\omega^3 + \tfrac{1}{2}B^2_{i3}\omega^i\wedge\omega^3,\\
d\theta^3 &\equiv -\pi^3\wedge\omega^1 - \pi^{10}\wedge\omega^2 - \pi^4\wedge\omega^3 + \tfrac{1}{2}B^3_{i3}\omega^i\wedge\omega^3,\\
d\theta^4 &\equiv -\pi^4\wedge\omega^1 - \pi^{11}\wedge\omega^2 - \pi^{16}\wedge\omega^3,\\
d\theta^5 &\equiv -\pi^5\wedge\omega^1 - \pi^{12}\wedge\omega^2 - \pi^{13}\wedge\omega^3 + \tfrac{1}{2}B^5_{i3}\omega^i\wedge\omega^3,\\
d\theta^6 &\equiv -\pi^6\wedge\omega^1 - \pi^{13}\wedge\omega^2 - \pi^{17}\wedge\omega^3,\\
d\theta^7 &\equiv -\pi^7\wedge\omega^1 - \pi^{14}\wedge\omega^2 - \pi^{18}\wedge\omega^3,\\
d\theta^8 &\equiv -\pi^8\wedge\omega^1 - \pi^{15}\wedge\omega^2 - \tfrac{1}{2}\pi^{11}\wedge\omega^3 - \tfrac{1}{2}\pi^8\wedge\omega^3 - \tfrac{1}{2}\pi^6\wedge\omega^3 + \tfrac{1}{2}B^8_{i3}\omega^i\wedge\omega^3 \pmod{\mathcal{I}(\mathcal{P})}.
\end{aligned} \tag{33}$$

Using the tableau matrices derived from (33) we obtain $s_1' = 8$, $s_2' = 7$ and $s_3' = 3$. We also find that all remaining torsion coefficients B^α_{ij} in (33) can be absorbed so that no integrability conditions occur at this stage. However, because we have the rank deficiency in the reduced polar matrix leading to $s_2 = s_2' + 1$, the system admits an identity and is **not in involution**. This makes prolongation necessary, but the process of prolongation often becomes simpler when Janet–Riquier theory is used in the way that we now show.

The symbol $\mathcal{M}_1$ for the unprolonged Riemann–Lanczos problem in three dimensions consists of the six linear equations derived from $f^{(R)}_{1212}$, $f^{(R)}_{1313}$, $f^{(R)}_{2323}$, $f^{(R)}_{1213}$, $f^{(R)}_{1223}$, $f^{(R)}_{1323}$ and is given in orthonomic form as (where nonmultiplicative variables are indicated by a $\cdot$)

$$\begin{aligned}
&V_{1212} = V_{1221} && x^1x^2\cdot\\
&V_{1313} = V_{1331} && x^1x^2x^3\\
&V_{2323} = V_{2332} && x^1x^2x^3\\
&V_{1213} = V_{1231} - V_{1312} + V_{1321} && x^1x^2x^3\\
&V_{1223} = 2V_{1232} - V_{1322} + V_{2321} && x^1x^2x^3\\
&V_{1323} = \frac{1}{2}(V_{1332} + V_{1233} + V_{2331}) && x^1x^2x^3.
\end{aligned}$$

We imposed the ranking $x^3 \succ x^2 \succ x^1$ which then induced the ranking $P_{abc3} \succ P_{abc2} \succ P_{abc1}$ and amongst each set P_{abce} the ranking $P_{233e} \succ P_{232e} \succ P_{132e} \succ P_{123e} \succ P_{133e} \succ P_{131e} \succ P_{122e} \succ P_{121e}$. From this we now obtain $\beta^{(1)}_1 = 0$, $\beta^{(2)}_1 = 1$, $\beta^{(3)}_1 = 5$ and $\alpha^{(1)}_1 = 8$, $\alpha^{(2)}_1 = 7$, $\alpha^{(3)}_1 = 3$. The above results are intrinsic because we used δ-regular coordinates.[42]

In order to see whether the symbol is involutive, we differentiate each equation with respect to x^1, x^2, x^3 from which we can produce $\mathcal{M}_2$, where its sparse coefficient matrix is given and explained in detail in Ref. 42. We obtain $r(\mathcal{M}_2)=18$ which does not coincide with the total number of multiplicative variables

$$\sum_{k=1}^{3} k\cdot\beta_1^{(k)}=17\neq r(\mathcal{M}_2)=18,$$

so that $\mathcal{M}_1$ is it not involutive. Therefore, we prolong $\mathcal{R}_1$ to $\mathcal{R}_2$ which consists of 24 equations, 18 of which are the partial derivatives S_{abcde} of the six $f^{(R)}_{abcd}$. We order the S_{abcde} such that $S_{abc33}\succ S_{abc23}\succ S_{abc22}\succ S_{abc13}\succ S_{abc12}\succ S_{abc11}$ and then amongst each set $S_{233ij}\succ S_{232ij}\succ S_{132ij}\succ S_{123ij}\succ S_{133ij}\succ S_{131ij}\succ S_{122ij}\succ S_{121ij}$. We find that the prolonged symbol $\mathcal{M}_2$ in orthonomic form is given by

$$\begin{array}{lll}
\boxed{1} & V_{12112}=V_{12211} & x^1\ \cdot\ \cdot\\
\boxed{2} & V_{12122}=V_{12212} & x^1\ x^2\ \cdot\\
\boxed{3} & V_{12123}=2V_{12312}-V_{13212}+V_{23211} & x^1\ x^2\ \cdot\\
\boxed{4} & V_{13113}=V_{13311} & x^1\ \cdot\ \cdot\\
\boxed{5} & V_{13123}=V_{13312} & x^1\ x^2\ \cdot\\
\boxed{6} & V_{13133}=V_{13313} & x^1\ x^2\ x^3\\
\boxed{7} & V_{23213}=V_{23312} & x^1\ \cdot\ \cdot\\
\boxed{8} & V_{23223}=V_{23322} & x^1\ x^2\ \cdot\\
\boxed{9} & V_{23233}=V_{23323} & x^1\ x^2\ x^3\\
\boxed{10} & V_{12113}=V_{12311}-V_{13112}+V_{13211} & x^1\ \cdot\ \cdot\\
\boxed{11} & V_{13122}=2V_{13212}-V_{12312}-V_{23211} & x^1\ x^2\ \cdot\\
\boxed{12} & V_{12133}=\frac{3}{2}V_{12313}-\frac{1}{2}V_{13312}+\frac{1}{2}V_{23311} & x^1\ x^2\ x^3\\
\boxed{13} & V_{12213}=2V_{12312}-V_{13212}+V_{23211} & x^1\ \cdot\ \cdot\\
\boxed{14} & V_{12223}=2V_{12322}-V_{13222}+V_{23212} & x^1\ x^2\ \cdot\\
\boxed{15} & V_{12233}=\frac{3}{2}V_{12323}+\frac{1}{2}V_{23312}-\frac{1}{2}V_{13322} & x^1\ x^2\ x^3\\
\boxed{16} & V_{13213}=\frac{1}{2}(V_{13312}+V_{12313}+V_{23311}) & x^1\ \cdot\ \cdot\\
\boxed{17} & V_{13223}=\frac{1}{2}(V_{13322}+V_{12323}+V_{23312}) & x^1\ x^2\ \cdot\\
\boxed{18} & V_{13233}=\frac{1}{2}(V_{13323}+V_{12333}+V_{23313}) & x^1\ x^2\ x^3,
\end{array}$$

where the groups of three equations each correspond to $f^{(R)}_{1212,i}$, $f^{(R)}_{1313,i}$, $f^{(R)}_{2323,i}$, $f^{(R)}_{1213,i}$, $f^{(R)}_{1223,i}$, $f^{(R)}_{1323,i}$ so that $\boxed{1}\leftrightarrow f^{(R)}_{1212,1}$ and so on. This system produces six equations of class 1, 7 of class 2 and 5 of class 3 leading to $\beta_2^{(1)}=6$, $\beta_2^{(2)}=7$, $\beta_2^{(3)}=5$. The total number of multiplicative variables equals 35 and, if $\mathcal{M}_2$ were involutive, we would have to obtain $r(\mathcal{M}_3)=35$. From differentiating $\mathcal{R}_2$ with respect to all three space–time coordinates, we obtain the symbol $\mathcal{M}_3$ and find that $r(\mathcal{M}_3)=35$, which means that $\mathcal{M}_2$ is involutive.[42] But we can show that the symbol equation ∂_3 [Eq. (3)], where $3\leftrightarrow\boxed{3}$ above, can also be created as a linear combination

$$\partial_3[\text{Eq. (3)}]=2\partial_2[\text{Eq. (16)}]+2\partial_3[\text{Eq. (11)}]-2\partial_3[\text{Eq. (13)}]-\partial_2[\text{Eq. (5)}]-\partial_1[\text{Eq. (7)}] \tag{34}$$

using formal differentiation so that $r(\mathcal{M}_3)=\Sigma_{k=1}^{3}\, k\cdot\beta_2^{(k)}=35$. However, it turns out that when (34) is rewritten in terms of the full equations from $\mathcal{R}_3$ as

$$I=f^{(R)}_{1212,33}+f^{(R)}_{1313,22}+f^{(R)}_{2323,11}-2\,f^{(R)}_{1323,12}-2\,f^{(R)}_{1213,23}+2\,f^{(R)}_{1223,13}, \tag{35}$$

it is not a trivial identity any longer and cannot be obtained by means of any linear combination of the $f^{(R)}_{abcd}$ and their derivatives $f^{(R)}_{abcd,e}$ so that $r(\mathcal{R}_3)=6+18+36=60$. We have

$$\dim(\mathcal{R}_1)=18,\quad \dim(\mathcal{M}_1)=18,$$

$$\dim(\mathcal{R}_2)=56,\quad \dim(\mathcal{M}_2)=30,$$

$$\dim(\mathcal{R}_3)=100,\quad \dim(\mathcal{M}_3)=45,$$

which leads us to the important consequence that

$$\dim(\mathcal{R}_2^{(1)})=\dim(\mathcal{R}_3)-\dim(\mathcal{M}_3)=100-45=55=\dim(\mathcal{R}_2)-1.$$

This means that **one integrability condition of the form (35) occurs**. Our new system of equations has to be given by

$$0=f^{(R)}_{abcd},$$

$$0=f^{(R)}_{abcd,e}, \tag{36}$$

$$0=I.$$

We find that the symbol of (36) is simply given by the previous $\mathcal{M}_2$ together with

$$V_{12323}=\frac{1}{(\Gamma^3_{12}-\Gamma^3_{13})}[V_{23312}(\Gamma^3_{13}-\Gamma^3_{12})+2\Gamma^3_{33}V_{12312}-V_{13322}(2\Gamma^1_{11}+\Gamma^3_{12}+\Gamma^3_{13})], \tag{37}$$

which adopts three multiplicative variables. Therefore, we obtain for (36)

$$\beta^{(1)}_{2,(1)}=6,\beta^{(2)}_{2,(1)}=7,\beta^{(3)}_{2,(1)}=6\ \text{ so that }\ \alpha^{(1)}_{2,(1)}=18,\alpha^{(2)}_{2,(1)}=9,\alpha^{(3)}_{2,(1)}=2.$$

We see that $r(\mathcal{M}_3^{(1)})=r(\mathcal{M}_3)+3=38$ because the three derivatives resulting from (37) are linearly independent and because $r(\mathcal{R}_3^{(1)})=r(\mathcal{R}_1)+r(\mathcal{R}_2^{(1)})+35+3=63$ which leads to

$$\dim(\mathcal{R}_2^{(2)})=\dim(\mathcal{R}_3^{(1)})-\dim(\mathcal{M}_3^{(1)})=97-42=55=\dim(\mathcal{R}_2^{(1)}).$$

Because $r(\mathcal{M}_3^{(1)})=\Sigma_{k=1}^{3}\, k\cdot\beta^{(k)}_{2,(1)}=6+14+18=38$, $\mathcal{M}_2^{(1)}$ is involutive and, because $\dim(\mathcal{R}_2^{(2)})=\dim(\mathcal{R}_2^{(1)})=55$, there are no integrability conditions that can occur and so the system $\mathcal{R}_2^{(1)}$ is in involution.

Even though the above prolongation of the Riemann–Lanczos problem mathematically leads to a prolonged system in involution, this prolonged system (36) does not respect general covariance. This is not satisfactory from a general relativity point of view and we are going to suggest a covariant version of the above prolongation. Instead of adding the partial derivatives to our equations, we look at the following new system of equations:

$$0=f^{(R)}_{abcd}, \tag{38}$$

$$0 = f^{(R)}_{abcd;e}\,.$$

The symbol of this modified system obviously coincides with that of the system formed by $f^{(R)}_{abcd}$, $f^{(R)}_{abcd,e}$ and, again, we obtain for the rank of $\mathcal{M}_3$ that $r(\mathcal{M}_3)=\Sigma^3_{k=1}\,k\cdot\beta^k_2=35$ so that $\mathcal{M}_2$ is involutive. We now have to see whether the linear combination (34) also holds for the full covariant system here. Calculations show that this is not the case and we obtain a covariant version of the above integrability condition in solved form given by

$$I_{\mathrm{Cov}}=f^{(R)}_{1212;33}+f^{(R)}_{1313;22}+f^{(R)}_{2323;11}-f^{(R)}_{1323;12}-f^{(R)}_{1323;21}-f^{(R)}_{1213;23}-f^{(R)}_{1213;32}+f^{(R)}_{1223;13}+f^{(R)}_{1223;31}\,. \tag{39}$$

This condition can be rewritten again in solved form as

$$I_{\mathrm{Cov}}=B_{12123;3}+B_{13132;2}+B_{23231;1}\,. \tag{40}$$

where $B_{abcde}:=f^{(R)}_{ab[cd;e]}$ which amounts to the covariant derivatives of the Bianchi identities for the R_{abcd} involved in (40). We can rewrite I_{Cov} (Ref. 44) in a more concise form using **bivectors**, where we introduce the bivector-indices $\underline{A}:=12$, $\underline{B}:=31$, $\underline{C}:=23$. The integrability condition I_{Cov} can then be expressed as

$$I_{\mathrm{Cov}}=f^{(R)}_{\underline{AA};(33)}+f^{(R)}_{\underline{BB};(22)}+f^{(R)}_{\underline{CC};(11)}+2(f^{(R)}_{\underline{AC};(13)}+f^{(R)}_{\underline{BC};(12)}+f^{(R)}_{\underline{AB};(23)})=\sum_{x,y=1}^{3}\sum_{X,Y=1}^{3}f^{(R)}_{XY;(xy)}\,. \tag{41}$$

Our new covariantly prolonged system is then given by

$$\begin{aligned} 0&=f^{(R)}_{abcd}\,,\\ 0&=f^{(R)}_{abcd;e}\,,\\ 0&=I_{\mathrm{Cov}}\,. \end{aligned} \tag{42}$$

It is $r(\mathcal{R}^{(1)}_2)=6+19=25$, $r(\mathcal{R}^{(1)}_3)=6+19+38=63$ as well as $r(\mathcal{M}^{(1)}_2)=19$, $r(\mathcal{M}^{(1)}_3)=38$ so that $\mathcal{M}^{(1)}_3$ coincides with the previous symbol for the prolongation involving partial derivatives. Once again it is $\dim(\mathcal{R}^{(2)}_2)=\dim(\mathcal{R}^{(1)}_2)=55$. We find that the system (42) also consists of a system in involution which respects general covariance. Therefore, we prefer (42) as a prolongation to a second-order system in involution for the Riemann–Lanczos problem in three dimensions and we conclude the following.

Theorem 4: *Proposition. The Riemann–Lanczos problem in three dimensions is not in involution. Its reduced characters* (s'_0,s'_1,s'_2,s'_3) *are (14, 8, 7, 3). They modify to (17, 8, 7, 0) when the differential gauge conditions are imposed. The Riemann–Lanczos problem becomes involutive after one prolongation which is obtained by adding either of the integrability conditions (35) or (40) and now its Cartan characters* $(\alpha^{(1)}_2,\alpha^{(2)}_2,\alpha^{(3)}_2)$ *for* $\mathcal{R}^{(1)}_2$ *are (18, 9, 2).*

C. The problem in four dimensions and singular solutions

In the Bampi–Caviglia papers[4,5] the Riemann–Lanczos problem was written as an EDS and found not to be in involution in four dimensions. In their second paper[5] they introduced a prolongation to create an involutive system. Our Pfaffian system for four dimensions is given by (16), where $n=4$ and the number of independent Lanczos components L_{abc} is $m=20$. We obtain (x^a,L_{abc},P_{abcd}) local jet coordinates on $\mathcal{J}^1(\mathbb{R}^4,\mathbb{R}^{20})$ with $N=4+20+80=104$ formal dimensions. For a Vessiot vector field V, 20 of the 80 components V_{abcd} are defined through the requirement that $df^{(R)}_{abcd}(V)=0$ given by (19). The 60 remaining components $V_{abcd}-V_{\{abcd\}}$ can be chosen arbitrarily for the first Vessiot vector field. As shown in Ref. 4 a rank deficiency between the s_i and the s'_i occurs due to six identities and the system (16) fails to be involutive.

The reduced Cartan characters can be computed using the REDUCE computer code in Ref. 42 based on the EDS package by Hartley.[45] For a number of space–times such as the conformally flat, Kasner, Gödel, some Debever types, and plane wave space–times we verified that the reduced Cartan characters $(s_0',s_1',s_2',s_3',s_4')$ were (40, 20, 19, 15, 6) when the differential gauge condition (3) was not included and (40, 20, 19, 15, 0) when it was included but *neither* differential system is *in involution*.[42]

Nevertheless, singular solutions exist and occur when some of the integral elements are *singular* so that the characters are not maximal. In the remaining sections of this article, we will give a examples of singular solutions for the Riemann–Lanczos problem mostly in four dimensions.

D. Debever-type space–times: Example

We expect singular solutions to occur for most of the Debever type space–times for which a line element is given by

$$ds^2=dt^2-f^2(t,y,z)dx^2-dy^2-dz^2 \tag{43}$$

with $f(t,y,z)$ being one of the functions given in Refs. 46 and 47. Specifically, for a Debever space–time with $f=y^2$ of Petrov type *D* we are interested in singular solutions such that

$$\pounds_\xi L_{abc}=0 \tag{44}$$

is possible using $\pounds_\xi R_{abcd}=0$ and the fact that $\nabla\pounds_\xi=\pounds_\xi\nabla$ for ξ any Killing vector field (=KV). There are three KVs corresponding to the ignorable coordinates *t, x*, and *z* and the components of the fourth KV are $\xi^4=(z,0,0,t)$.[48] The only nonvanishing independent Riemann–Lanczos equations are $f^{(R)}_{txty},f^{(R)}_{xyxy},f^{(R)}_{xzyz}$. A singular solution with vanishing Lie derivatives along Killing directions is then given by

$$L_{txt}=C_1y^4,\quad L_{tyz}=C_2y^{-2},\quad L_{xyx}=C_3y^2+y^3,$$

where C_1,C_2,C_3 are arbitrary constants. On a submanifold of (16) with $f^{(R)}_{abcd}=0$ for the above line element this solution corresponds to a singular integral manifold for which the (reduced) characters are $s_0=s_0'=3$ while all higher characters vanish. The Vessiot vector fields which span the tangent spaces of this singular solution manifold are locally given as

$$\begin{aligned}
V^1&=\frac{\partial}{\partial t},\\
V^2&=\frac{\partial}{\partial x},\\
V^3&=\frac{\partial}{\partial y}+4C_1y^3\frac{\partial}{\partial L_{txt}}-2C_2y^{-3}\frac{\partial}{\partial L_{tyz}}-4C_2y^{-3}\frac{\partial}{\partial L_{tzy}}+(2C_3y+3y^2)\frac{\partial}{\partial L_{xyx}}+4C_1y^3\frac{\partial}{\partial L_{xzz}}\\
&\quad+12y^2\frac{\partial}{\partial P_{txty}}+6C_2y^{-4}\frac{\partial}{\partial P_{tyzy}}+12C_2y^{-4}\frac{\partial}{\partial P_{tzyy}}+2(C_3+3y)\frac{\partial}{\partial P_{xyxy}}+12y^2\frac{\partial}{\partial P_{xzzy}},\\
V^4&=\frac{\partial}{\partial z},
\end{aligned} \tag{45}$$

where we substituted

$$V^3_{txty}=12y^2,\quad V^3_{tyzy}=6C_2y^{-4},\quad V^3_{xyxy}=2(C_3+3y),$$

and where $V^3_{txty}=V^3_{xzzy}$ and $V^3_{tzyy}=2V^3_{tyzy}$.

E. Singular solution for Gödel space–time

Gödel space–time is a perfect fluid space–time admitting closed timelike curves with line element

$$ds^2=a^2(dt^2-dx^2-dz^2+\tfrac{1}{2}e^{2x}dy^2+2e^x dtdy). \tag{46}$$

It is well known[49] that this space–time admits a G_5 as an isometry group of which three Killing vectors ξ^1,ξ^2,ξ^3 are based on the ignorable coordinates *t, y, z*. The other two are given by

$$\xi^4=\frac{\partial}{\partial x}-y\frac{\partial}{\partial y},\quad \xi^5=-2e^{-x}\frac{\partial}{\partial t}+y\frac{\partial}{\partial x}+\left(e^{-2x}-\frac{1}{2}y^2\right)\frac{\partial}{\partial y}.$$

But here, the Riemann–Lanczos problem does not admit singular solutions which inherit all the space–time symmetries. However, it is possible to find singular solutions with $\pounds_\xi L_{abc}=0$ imposed for the three Killing vectors based on ignorable coordinates and we find the solution[42]

$$L_{txy}=-\frac{a^2}{8}e^x,\quad L_{tyx}=\frac{a^2}{8}e^x,\quad L_{txt}=-\frac{a^2}{8},\quad L_{xyy}=\frac{3a^2}{16}e^{2x}.$$

This solution does not satisfy all the differential gauge conditions (3) however.[42] The tangent spaces of this singular integral manifold are spanned by four Vessiot vector fields which are locally given as

$$\begin{aligned}
V^1&=\frac{\partial}{\partial t},\\
V^2&=\frac{\partial}{\partial x}+\frac{a^2}{8}e^x\frac{\partial}{\partial L_{txy}}+\frac{a^2}{8}e^x\frac{\partial}{\partial L_{tyx}}+\frac{3a^2}{8}e^{2x}\frac{\partial}{\partial L_{xyy}}+\frac{1}{3}e^x\left(\frac{5a}{16}-\frac{1}{2}-e^{2x}\frac{3a}{16}\right)\frac{\partial}{\partial P_{txyx}}\\
&\quad-\frac{1}{3}e^x\left(\frac{5a}{16}-\frac{1}{2}-e^{2x}\frac{3a}{16}\right)\frac{\partial}{\partial P_{tyxx}}+\frac{3}{4a}e^{2x}\frac{\partial}{\partial P_{xyyx}},\\
V^3&=\frac{\partial}{\partial y},\\
V^4&=\frac{\partial}{\partial z},
\end{aligned} \tag{47}$$

where $V^2_{tyxx}=V^2_{txyx}$.

Note that the solution above is *also a singular solution* to the **reduced** Gödel space–time when we choose the line element

$$ds^2=a^2(dt^2-dx^2+\tfrac{1}{2}e^{2x}dy^2+2e^x dtdy) \tag{48}$$

to describe the reduced Gödel space–time.

F. Kasner space–time

For Kasner space–time we choose the line element

$$ds^2=dt^2-t^{2p_1}dx^2-t^{2p_2}dy^2-t^{2p_3}dz^2. \tag{49}$$

Kasner space–time admits a G_3 based on the three ignorable coordinates x, y, z. If we impose $\pounds_\xi L_{abc}=0$, the six nonvanishing components of the Riemann–Lanczos equations are $f^{(R)}_{txtx}, f^{(R)}_{tyty}, f^{(R)}_{tztz}, f^{(R)}_{xyxy}, f^{(R)}_{xzxz}, f^{(R)}_{yzyz}$. The last three equations can be solved for $L_{txx}, L_{tyy}, L_{tzz}$. But, inserting this solution into the first three equations leads to the inconsistent solution

$$L_{txx}=-\tfrac{1}{4}p_1t^{2p_1-1}, \quad P_{txxt}=(\tfrac{1}{2}-\tfrac{3}{4}p_1)p_1t^{2p_1-2},$$

$$L_{tyy}=-\tfrac{1}{4}p_2t^{2p_2-1}, \quad P_{tyyt}=(\tfrac{1}{2}-\tfrac{3}{4}p_2)p_2t^{2p_2-2},$$

$$L_{tzz}=-\tfrac{1}{4}p_3t^{2p_3-1}, \quad P_{tzzt}=(\tfrac{1}{2}-\tfrac{3}{4}p_3)p_3t^{2p_3-2},$$

because $P_{abcd}\neq\partial L_{abc}/\partial x^d$. However, there are singular solutions for which some of the components L_{abc} are linear in either x, y or z with no Lie symmetries along Killing directions. We find that

$$L_{txt}=C_1t^{2p_1-2}x, \quad L_{txx}=C_4t^{2p_1-1},$$

$$L_{tyt}=C_2t^{2p_2-2}y, \quad L_{tyy}=C_5t^{2p_2-1},$$

$$L_{tzt}=C_3t^{2p_3-2}z, \quad L_{tzz}=C_6t^{2p_3-1},$$

$$L_{xyx}=C_7t^{-2p_3}y, \quad L_{xyy}=C_{10}t^{-2p_3}x,$$

$$L_{xzx}=C_8t^{-2p_2}z, \quad L_{xzz}=C_{11}t^{-2p_2}x,$$

$$L_{yzy}=C_9t^{-2p_1}z, \quad L_{yzz}=C_{12}t^{-2p_1}y$$

is a singular solution for Kasner space–time for the following constants:

$$C_4=\frac{C_1}{(p_1-1)}-\frac{p_1}{2}, \quad C_5=\frac{C_2}{(p_2-1)}-\frac{p_2}{2},$$

$$C_6=\frac{C_3}{(p_3-1)}-\frac{p_3}{2}, \quad C_7=\frac{p_1C_2}{2-p_1},$$

$$C_8=\frac{p_1C_3}{2-p_1}, \quad C_9=\frac{p_2C_3}{2-p_2},$$

$$C_{10}=\frac{-p_2C_1}{2-p_2}, \quad C_{11}=\frac{-p_3C_1}{2-p_3},$$

$$C_{12}=\frac{-p_3C_2}{2-p_3}.$$

A computer code, which determines the rather longish expressions for C_1, C_2, C_3 in terms of p_1, p_2, p_3, can be found in Ref. 42.

V. CONCLUSION

In two dimensions, the Riemann–Lanczos problem is very simple and we showed that it is always in involution. The general solution was given for both possible choices of signature, Lorentzian and Euclidean.

In three dimensions, a prolongation becomes necessary to make it a system in involution. An integrability condition based on the derivatives of the Bianchi identities occurs when we use

Janet–Riquier theory and introduce the second-order partial derivatives S_{abcde} as new jet coordinates. A singular solution for the unprolonged problem for the reduced Gödel space–time is given.

The Riemann–Lanczos problem in four dimensions is not in involution as already shown in Ref. 4. But singular solutions for the Riemann–Lanczos problem do exist and we found some for Kasner, Gödel, and a Debever-type spacetime.

(Received 22 August 2002; accepted 23 December 2002)

The Weyl–Lanczos equations in four dimensions form a system in involution. We compute its Cartan characters explicitly and use Janet–Riquier theory to confirm the results in the case of all space–times with a diagonal metric tensor and for the plane wave limit of space–times. We write the Lanczos wave equation as an exterior differential system and, with assistance from Janet–Riquier theory, we compute its Cartan characters and find that it forms a system in involution. We compare these Cartan characters with those of the Weyl-Lanczos equations. All results hold for the real analytic case. © *2003 American Institute of Physics.*

I. INTRODUCTION

A. The Weyl–Lanczos equations and the Lanczos tensor wave equation in four dimensions

Lanczos[1] generated the space–time Weyl conformal tensor C_{abcd} from a tensor potential L_{abc} by covariant differentiation such that C_{abcd} is given by

$$C_{abcd}=L_{abc;d}-L_{abd;c}+L_{cda;b}-L_{cdb;a}+g_{bc}L_{(ad)}+g_{ad}L_{(bc)}-g_{bd}L_{(ac)}-g_{ac}L_{(bd)} + \tfrac{2}{3}L^{ms}{}_{m;s}(g_{ac}g_{bd}-g_{ad}g_{bc}), \tag{1}$$

where $L_{ad}=L_a{}^s{}_{d;s}-L_a{}^s{}_{s;d}$ and ";" denotes covariant differentiation. We call (1) the Weyl–Lanczos equations. The index symmetries of the Lanczos tensor L_{abc} have to match the symmetries of (1) and so it is usual to impose

$$L_{abc}=L_{[ab]c} \tag{2}$$

and

$$L_{[abc]}=0. \tag{3}$$

and the trace-free (gauge) condition

$$L_a{}^s{}_s=0. \tag{4}$$

The algebraic Eqs. (2)–(4) leave us with only 16 independent components for the L_{abc}. If we then introduce the differential gauge conditions

a)Electronic mail: pdolan@inctech.com
b)Electronic mail: agerber03@yahoo.co.uk

$$L_{ab}{}^{s}{}_{;s}=0, \tag{5}$$

which we often denote by $f_{ab}:=L_{ab}{}^{s}{}_{;s}$, we can simplify (1) considerably to get

$$C_{abcd}=L_{abc;d}-L_{abd;c}+L_{cda;b}-L_{cdb;a}-g_{bc}L^{s}{}_{ad;s}-g_{ad}L^{s}{}_{bc;s}+g_{bd}L^{s}{}_{ac;s}+g_{ac}L^{s}{}_{bd;s}. \tag{6}$$

We will denote the Weyl–Lanczos equations in solved form as

$$f_{abcd}=C_{abcd}-L_{abc;d}+L_{abd;c}-L_{cda;b}+L_{cdb;a}+g_{bc}L^{s}{}_{ad;s}+g_{ad}L^{s}{}_{bc;s}-g_{bd}L^{s}{}_{ac;s}-g_{ac}L^{s}{}_{bd;s}. \tag{7}$$

We note that Eqs. (5) and (6) constitute a system of 16 linear first-order partial differential equations in four dimensions. It was already shown in Ref. 2 for the real analytic case that the above four-dimensional Weyl–Lanczos equations consist of an exterior differential system (EDS) in involution with respect to the space–time variables.

From the Weyl–Lanczos problem it is possible to generate a Lanczos tensor wave equation and from this the Penrose wave equation for the Weyl tensor C_{abcd} can be derived.[3] It is given by

$$\Box L_{abc}+2R^{s}_{c}L_{abs}-R^{s}_{a}L_{bcs}-R^{s}_{b}L_{cas}-g_{ac}R^{ls}L_{lbs}+g_{bc}R^{ls}L_{las}-\tfrac{1}{2}RL_{abc}=J_{abc}, \tag{8}$$

where

$$J_{abc}=\tfrac{1}{2}R_{c[a;b]}-\tfrac{1}{6}g_{c[a}R_{;b]}, \quad \Box L_{abc}=g^{sm}L_{abc;s;m}.$$

Penrose's nonlinear wave equation for the space–time Weyl tensor[4]

$$\Box C_{abcd}-C_{ab}{}^{sm}C_{smcd}+4C_{asm[c}C^{m}{}_{d]}{}^{s}{}_{b}+\frac{R}{4}C_{abcd}=J_{[ab][c;d]}+J_{[cd][a;b]}-{}^{*}J^{*}_{[ab][c;d]}-{}^{*}J^{*}_{[cd][a;b]} \tag{9}$$

was derived in Ref. 3 from (8) and can be found for all dimensions $n\geqslant 4$. It was not derived from the wave equations for the Lanczos tensor candidate, which was given for $n=5$ by Edgar and Höglund.[5] We postpone to a later paper the discussion of the five-dimensional Weyl–Lanczos problem and the related tensor wave equation for the Lanczos potential. It is not clear from the published tensor wave equation of Edgar and Höglund[5] in five dimensions that there is still an *independent* derivation of the Penrose wave equation from it as in four dimensions.

In this article, we are going to compute the Cartan characters for the Weyl–Lanczos equations in four dimensions explicitly using both EDS theory and Janet–Riquier theory[6,7] and we will derive corresponding results for the four-dimensional wave equation.

II. WEYL–LANCZOS EQUATIONS IN FOUR DIMENSIONS

The theory of exterior differential systems (EDSs) can be found in many places such as in Refs. 8–11. In Ref. 2 it was shown that the Weyl–Lanczos relations in four dimensions are a system in involution with respect to the space–time variables. They constitute a system in involution as compared to the Riemann–Lanczos equations, which do not, even in vacuum space–times when $C_{abcd}=R_{abcd}$, because each problem is based on different partial differential equations. (Of course, this is carrying formality about vacuum space–times to excessive lengths. Why choose a system of PDEs which is not in involution in preference to one which is in involution?)

A. The Weyl–Lanczos equations as an EDS

We introduce the local coordinates (x^{e},L_{abc},P_{abcd}) on the jet bundle $\mathcal{J}^{1}(\mathbb{R}^{4},\mathbb{R}^{16})$ which form our formal manifold $\mathcal{M}$ of formal dimension $N=4+16+64=84$. The exterior derivatives of the f_{abcd} and of $f_{ab}=L_{ab}{}^{s}{}_{;s}$ constitute our first 16 one-forms. We also have to add 16 **contact condi-**

tions K_{abc} in order to make sure that the P_{abcd} can be considered as partial derivatives of the L_{abc} when projected onto the space–time manifold. We obtain the Pfaffian system $\mathcal{P}$ as given in Ref. 2,

$$\begin{aligned} df_{abcd}=&[C_{abcd,e}+\alpha_{abcde}+\gamma_{abcde}]dx^e-dP_{abcd}+dP_{abdc}-dP_{cdab}+dP_{cdba}+g_{bc}g^{ns}dP_{nads}\\ &+g_{ad}g^{ns}dP_{nbcs}-g_{bd}g^{ns}dP_{nacs}-g_{ac}g^{ns}dP_{nbds}+\Gamma^n_{ad}(dL_{nbc}+dL_{ncb})-\Gamma^n_{ac}(dL_{nbd}\\ &+dL_{ndb})+\Gamma^n_{bc}(dL_{nad}+dL_{nda})-\Gamma^n_{bd}(dL_{nac}+dL_{nca})-g_{bc}g^{ns}(\Gamma^m_{ns}dL_{mad}+\Gamma^m_{as}dL_{nmd}\\ &+\Gamma^m_{ds}dL_{nam})-g_{ad}g^{ns}(\Gamma^m_{ns}dL_{mbc}+\Gamma^m_{bs}dL_{nmc}+\Gamma^m_{cs}dL_{nbm})+g_{bd}g^{ns}(\Gamma^m_{ns}dL_{mac}\\ &+\Gamma^m_{as}dL_{nmc}+\Gamma^m_{cs}dL_{nam})+g_{ac}g^{ns}(\Gamma^m_{ns}dL_{mbd}+\Gamma^m_{bs}dL_{nmd}+\Gamma^m_{ds}dL_{nbm}),\end{aligned}$$

$$\begin{aligned} df_{ab}=&(P_{abns}g^{ns}_{,e}-L_{mbn}\Gamma^m_{as,e}-L_{amn}\Gamma^m_{bs,e}-L_{abm}\Gamma^m_{ns,e})dx^e+g^{ns}(dP_{abns}-\Gamma^m_{as}dL_{mbn}-\Gamma^m_{bs}dL_{amn}\\ &-\Gamma^m_{ns}dL_{abm}),\end{aligned}$$

$$K_{abc}=dL_{abc}-P_{abce}dx^e, \tag{10}$$

where α_{abcde} and γ_{abcde} are given in Appendix A. The system (10) consists of a system in involution in the real analytic case and does not possess any Cauchy characteristics. The Cartan characters (s_0,s_1,s_2,s_3,s_4) were computed to be (32,16,16,16,0) or (16,16,16,16,0) due to df_{abcd} and df_{ab} vanishing identically when pulled back onto the submanifold with $f_{abcd}=0$, $f_{ab}=0$ for a number of space–times in a computation based on REDUCE computer codes.[12]

We can also compute the reduced Cartan characters for (10) using the tableau matrix. First, we must complete $(df_{abcd},df_{ab},\omega^e)$ so that it turns into a complete coframe on $\mathcal{M}$, say $(df_{abcd},df_{ab},K_{abc},\omega^e,\pi^\Lambda)$ by adding $N-s-n=48$ new one-forms π^Λ. Accordingly, we add the 48 new cobasis elements chosen as

$$\pi^\Lambda\leftrightarrow dP_{abc1},\quad \Lambda=1,...,16,$$

$$\pi^\Lambda\leftrightarrow dP_{abc2},\quad \Lambda=17,...,32,$$

$$\pi^\Lambda\leftrightarrow dP_{abc3},\quad \Lambda=33,...,48,$$

where the ordering of the P_{abcd} based on the indices *abc* is given in Appendix A and where Λ is a collective index subject to Einstein's summation convention and corresponding to the set of indices *abc*. Here, the independence condition Ω is given by $\Omega=\omega^1\wedge\omega^2\wedge\omega^3\wedge\omega^4$,where $\omega^1=dx^1$, $\omega^2=dx^2$, $\omega^3=dx^3$, $\omega^4=dx^4$. We can now express the 16 dK_{abc}, where the α below are arranged in the same way as the L_{abc} in Appendix A, as

$$d\theta^\alpha=A^\alpha_{\Lambda1}\pi^\Lambda\wedge\omega^1+A^\alpha_{\Lambda2}\pi^\Lambda\wedge\omega^2+A^\alpha_{\Lambda3}\pi^\Lambda\wedge\omega^3-dP_{abc4}\wedge\omega^4. \tag{11}$$

Further calculations are based on the assumption that we can express each of the 16 dP_{abc4} in (11) as a distinct linear combination of the df_{abcd}, K_{abc}, $dL_{ab}{}^{s}{}_{;s}$ and the ω^e.[12] We obtain the only nonvanishing components of the tableau matrices $A^\alpha_{\Lambda1}$, $A^\alpha_{\Lambda2}$ and $A^\alpha_{\Lambda3}$ to be $A^\alpha_{\Lambda1}=A^\alpha_{\Lambda2}=A^\alpha_{\Lambda3}=-1$ if α and Λ refer to the same group of indices *abc*. This leads to

$$\begin{pmatrix} A^\alpha_{\Lambda1}\\ A^\alpha_{\Lambda2}\\ A^\alpha_{\Lambda3}\\ A^\alpha_{\Lambda4}\end{pmatrix}=\begin{pmatrix} A & 0 & 0\\ 0 & A & 0\\ 0 & 0 & A\\ X_1 & X_2 & X_3\end{pmatrix},$$

which is a 64×48 matrix, and where X_1, X_2, X_3 stand for $A^\alpha_{\Lambda4}$ and each A is given by the 16×16 matrix $A:=-\mathbb{I}_{16}$. From this we can immediately deduce that the reduced characters are

$s_1'=s_2'=s_3'=16$ and $s_4'=0$. However, this method does not supply s_0' but here clearly $s_0=s_0'=s=32$ which is simply the number of independent one-forms in (10) so that $(s_0',s_1',s_2',s_3',s_4')$ is given by (32, 16, 16, 16, 0). When (10) is pulled back onto the submanifold, where $f_{abcd}=0$ and $f_{ab}=0$, we get (16, 16, 16, 16, 0). One can show that the torsion terms B_{ij}^{α} can be made to vanish through applying a corresponding coframe transformation. This rather cumbersome calculation can be carried out using a REDUCE code in Ref. 12 based on the package EDS.[13]

B. The Weyl–Lanczos equations as a system of PDEs

The theory in this section and for the Lanczos wave equation below is based on a modernized version of Janet–Riquier theory[14–16] which can be found in Refs. 17 and 7. A review together with some results on the Riemann–Lanczos problems in two and three dimensions is given in Ref. 12.

Here, we use (6) and (5) as our first-order system of PDEs denoted by $\mathcal{R}_1$. Using a computer code in Ref. 12, we derived the symbol $\mathcal{M}_1$ for any space–time with diagonal metric

$$ds^2=a_1(dx^1)^2-a_2(dx^2)^2-a_3(dx^3)^2-a_4(dx^4)^2, \tag{12}$$

where a_1, a_2, a_3, a_4 depend on all space–time variables. We replace the four components L_{121}, L_{131}, L_{141}, L_{122} and their partial derivatives by solving (4) for them and we choose an ordering $\succ$ for the P_{abce} in such a way that $P_{abc4}\succ P_{abc3}\succ P_{abc2}\succ P_{abc1}$ and then the sets of P_{abce} ordered according to $\mathcal{R}_{\succ}^{(W,4)}$ for each $e=1, 2, 3, 4$, where $\mathcal{R}_{\succ}^{(W,4)}$ is given in Appendix A. This produces an orderly ranking and induces such a ranking amongst the *symbol variables* V_{abcd}.[7,17] Then, $\mathcal{M}_1$ is given in orthonomic form by

$$\begin{aligned}
&(f_{1212})\quad V_{3434}=\frac{a_4}{a_1}V_{1331}+\frac{a_3}{a_1}V_{1441}-\frac{a_4}{a_2}V_{2332}-\frac{a_3}{a_2}V_{2442}+V_{3443},\\
&(f_{1213})\quad V_{2434}=\frac{a_4}{a_1}V_{1321}-\frac{a_4}{a_2}V_{2322}+V_{2443}+V_{3442},\\
&(f_{1313})\quad V_{2424}=\frac{a_4}{a_3}V_{2323}+V_{2442}-\frac{a_2a_4}{a_1a_3}V_{1331}-\frac{a_2}{a_3}V_{3443},\\
&(f_{1214})\quad V_{2334}=V_{2343}+\frac{a_3}{a_2}V_{2422}+V_{3432}-\frac{a_3}{a_1}V_{1421},\\
&(f_{1314})\quad V_{2324}=\frac{a_2}{a_1}V_{1431}+V_{2342}-V_{2423}-\frac{a_2}{a_3}V_{3433},\\
&(f_{1323})\quad V_{1424}=\frac{a_4}{a_3}V_{1323}-\frac{a_4}{a_3}V_{1233}+V_{1442}-\frac{a_4}{a_3}V_{2331},\\
&(f_{1223})\quad V_{1434}=\frac{a_4}{a_2}V_{1232}-\frac{a_4}{a_2}V_{1322}+V_{1443}+\frac{a_4}{a_2}V_{2321},\\
&(f_{1224})\quad V_{1334}=V_{1343}+\frac{a_3}{a_2}V_{1422}-\frac{a_3}{a_2}V_{2421}-\frac{a_3}{a_2}V_{1242},\\
&(f_{1234})\quad V_{1234}=V_{1243}+V_{1342}-V_{1432}-V_{2341}+V_{2431},\\
&(f_{1324})\quad V_{1324}=V_{1243}+V_{1342}-V_{1423}+V_{2431},
\end{aligned} \tag{13}$$

$$(L_{12}{}^{s}{}_{;s}) \quad V_{1244}=-\frac{a_4}{a_3}V_{2331}-V_{2441}+\frac{a_4}{a_3}V_{1332}+V_{1442}-\frac{a_4}{a_3}V_{1233},$$

$$(L_{13}{}^{s}{}_{;s}) \quad V_{1344}=-\frac{a_4}{a_2}V_{1322}-\frac{a_4}{a_3}V_{1333}+\frac{a_4}{a_2}V_{2321}-V_{3441},$$

$$(L_{14}{}^{s}{}_{;s}) \quad V_{1444}=-\frac{a_4}{a_2}V_{1422}-\frac{a_4}{a_3}V_{1433}+\frac{a_4}{a_2}V_{2421}+\frac{a_4}{a_3}V_{3431},$$

$$(L_{23}{}^{s}{}_{;s}) \quad V_{2344}=-\frac{a_4}{a_1}V_{1231}+\frac{a_4}{a_1}V_{1321}-\frac{a_4}{a_2}V_{2322}-\frac{a_4}{a_3}V_{2333},$$

$$(L_{24}{}^{s}{}_{;s}) \quad V_{2444}=-\frac{a_4}{a_1}V_{1241}+\frac{a_4}{a_1}V_{1421}-\frac{a_4}{a_2}V_{2422}-\frac{a_4}{a_3}V_{2433},$$

$$(L_{34}{}^{s}{}_{;s}) \quad V_{3444}=-\frac{a_4}{a_1}V_{1341}+\frac{a_4}{a_1}V_{1431}+\frac{a_4}{a_2}V_{2342}-\frac{a_4}{a_2}V_{2432}-\frac{a_4}{a_3}V_{2432}.$$

All 16 equations in (13) are of class 4 because all variables x^1, x^2, x^3, x^4 are multiplicative variables for each equation so that we obtain $\beta_1^{(1)}=0$, $\beta_1^{(2)}=0$, $\beta_1^{(3)}=0$, $\beta_1^{(4)}=16$. For the sum $\Sigma_{k=1}^{4}\beta_1^{(k)}=16$, and because we only have 16 equations, this means that we are already using coordinates which are δ-regular.[12] Then, the Cartan characters are $\alpha_1^{(1)}=16$, $\alpha_1^{(2)}=16$, $\alpha_1^{(3)}=16$, $\alpha_1^{(4)}=0$ according to the formula[7,12,17]

$$\alpha_q^{(k)}=m\binom{n+q-k-1}{q-1}-\beta_q^{(k)}. \tag{14}$$

Now, we must verify that our symbol is involutive and we prolong f_{abcd}, f_{ab} by differentiating each equation in $\mathcal{R}_1$ with respect to x^1, x^2, x^3, x^4 to obtain $\mathcal{R}_2$. We find that we can rewrite the prolonged symbol $\mathcal{M}_2$ of $\mathcal{R}_2$ in such a way that each equation contains a distinct component V_{abcde} so that $r(\mathcal{M}_2)=64$.[12] But we also have $\Sigma_{k=1}^{4}k\cdot\beta_1^{(k)}=64$ which means that $\mathcal{M}_1$ is involutive. In order to show that the system is formally integrable, we have to verify that the canonical projection of $\mathcal{R}_2$ from second to first order $\pi_1^2(\mathcal{R}_2)$ coincides with $\mathcal{R}_1$ itself. Our system is a linear system of PDEs and therefore involution follows.[12]

For a general space–time, the calculations are more cumbersome and in Ref. 12 we looked at the plane-wave limit which all space–times possess. A good account of the plane-wave limit of space–times is given in Ref. 18. All space–times can locally be expressed using a line element

$$ds^2=2dx^1dx^2+a(dx^3)^2+2b_3dx^2dx^3+2b_4dx^2dx^4-c_{33}(dx^3)^2-2c_{34}dx^3dx^4-c_{44}(dx^4)^2, \tag{15}$$

where a, b_3, b_4, c_{33}, c_{34}, c_{44} are functions of all four coordinates. When a plane-wave limit is taken, the metric (15) becomes[18]

$$ds^2=2dx^1dx^2-C_{33}(dx^3)^2-2C_{34}dx^3dx^4-C_{44}(dx^4)^2, \tag{16}$$

where C_{33}, C_{34}, and C_{44} are arbitrary functions of x^1 only. We can determine the symbol for the metric (16) but we see that for whatever ranking we choose, the coordinates are not δ-regular.[12] We perform a linear coordinate transformation[17] which we choose to be

$$\begin{aligned} d\tilde{x}^1&=a_{11}dx^1+a_{12}dx^2,\\ d\tilde{x}^2&=a_{21}dx^1+a_{22}dx^2, \end{aligned} \tag{17}$$

$$d\tilde{x}^3 = dx^3,$$

$$d\tilde{x}^4 = dx^4,$$

where $a_{11}=a_{12}=a_{21}=1/\sqrt{2}$, $a_{22}=-1/\sqrt{2}$. This produces a new, only slightly different metric line element for (16) which is

$$ds^2=(d\tilde{x}^1)^2-(d\tilde{x}^2)^2-C_{33}(d\tilde{x}^3)^2-2C_{34}d\tilde{x}^3d\tilde{x}^4-C_{44}(d\tilde{x}^4)^2. \tag{18}$$

Even though this seems a minor transformation, the change from **characteristic** to **noncharacteristic coordinates**, which are now δ-regular, is necessary in order to obtain the Cartan characters. Then, we evaluate $f_{abcd}=0$, $f_{ab}=0$ for the new line element (16) and order the P_{abcd} such that $P_{abc1}>P_{abc2}>P_{abc3}>P_{abc4}$ instead, whereas we leave the ordering in each set P_{abce} unchanged as in $\mathcal{R}_{>}^{(W,4)}$ which leads to an orderly ranking. In this way we obtain an orthonomic system, where each symbol equation is of the form[12]

$$V_{abc1}=f(g_{a'b'},V_{c'd'e'f'}). \tag{19}$$

This system is composed of 16 equations all of class 4 which leads to $\beta_1^{(1)}=\beta_1^{(2)}=\beta_1^{(3)}=0$, $\beta_1^{(4)}=16$ and therefore to the Cartan characters $\alpha_1^{(1)}=\alpha_1^{(2)}=\alpha_1^{(3)}=16$ and $\alpha_1^{(4)}=0$. We obtained the further result that $r(\mathcal{M}_2)=\Sigma_{k=1}^4 k\cdot\beta_1^{(k)}=64$ and that no integrability conditions occur[12] so that the Weyl–Lanczos equations consist of a system in involution for all plane-wave limits of space–times with Cartan characters (16, 16, 16, 0).

III. LANCZOS WAVE EQUATION IN FOUR DIMENSIONS

In this section, we look at the Lanczos wave equation at first as an EDS and then as a system of PDEs. We again determine the Cartan characters and show that it consists of a system in involution in the real analytic case using each theory, a result which can be derived from the scalar wave equation directly.

A. The Lanczos wave equation as an EDS

We describe the Lanczos tensor wave equation in terms of an EDS on a jet bundle $\mathcal{J}^2(\mathbb{R}^4,\mathbb{R}^{16})$ with formal dimension $N=4+16+64+160=244$ and the local coordinates $(x^e,L_{abc},P_{abcd},S_{abcde})$ composed by 4 space–time coordinates x^e, 16 L_{abc}, 64 P_{abcd}, and 160 S_{abcde}. The S_{abcde} are the variables corresponding to the second-order partial derivatives of the L_{abc} when projected onto our space–time manifold. We denote the components of the wave equation in solved form by $\mathcal{W}_{abc}$.

In addition to the exterior derivations of $\mathcal{W}_{abc}$, we need to add two sets of contact conditions, K_{abc} and K_{abcd}, when we write the Lanczos wave equation as an EDS. Altogether, we obtain the Pfaffian system

$$d\mathcal{W}_{abc}=d\mathcal{W}_{abc},$$

$$K_{abc}=dL_{abc}-P_{abce}dx^e, \tag{20}$$

$$K_{abcd}=dP_{abcd}-S_{abcde}dx^e.$$

There $d\mathcal{W}_{abc}$ are the exterior derivatives of the components of the wave equation in solved form which are locally given by

$$\begin{aligned}d\mathcal{W}_{abc}=&[\Box L_{abc}+2R^s_cL_{abs}-R^s_aL_{bcs}-R^s_bL_{cas}-g_{ac}R^{ls}L_{lbs}+g_{bc}R^{ls}L_{las}-\tfrac{1}{2}RL_{abc}-J_{abc}]_{,e}dx^e\\&+g^{sm}[dS_{abcms}-\Gamma^n_{am,s}dL_{nbc}-\Gamma^n_{ms,s}dL_{anc}-\Gamma^n_{cm,s}dL_{abn}-\Gamma^n_{as}dP_{nbcm}+\Gamma^n_{as}\Gamma^k_{nm}dL_{kbc}\\&+\Gamma^n_{as}\Gamma^k_{bm}dL_{nkc}+\Gamma^n_{as}\Gamma^k_{cm}dL_{nbk}-\Gamma^n_{bs}dP_{ancm}+\Gamma^n_{bs}\Gamma^k_{am}dL_{knc}+\Gamma^n_{bs}\Gamma^k_{nm}dL_{akc}\end{aligned}$$

$$+\Gamma^n_{bs}\Gamma^k_{cm}dL_{ank}-\Gamma^n_{cs}dP_{abnm}+\Gamma^n_{cs}\Gamma^k_{am}dL_{kbn}+\Gamma^n_{cs}\Gamma^k_{bm}dL_{akn}+\Gamma^n_{cs}\Gamma^k_{nm}dL_{abk}$$
$$-\Gamma^n_{ms}dP_{abcn}+\Gamma^n_{ms}\Gamma^k_{an}dL_{kbc}+\Gamma^n_{ms}\Gamma^k_{bn}dL_{akc}+\Gamma^n_{ms}\Gamma^k_{cn}dL_{abk}]+2R^s_c dL_{abs}-R^s_a dL_{bcs}$$
$$-R^s_b dL_{cas}-g_{ac}R^{ls}dL_{lbs}+g_{bc}R^{ls}dL_{las}-\tfrac{1}{2}RdL_{abc}. \tag{21}$$

For a number of space–times, we could show that the Cartan characters (s_0,s_1,s_2,s_3,s_4) are given by (96, 64, 48, 32, 0) and that the system is in involution.[12]

Again, we can determine the reduced Cartan characters using the tableau matrices $A^\alpha_{\Lambda i}$. First, we complete $(dW_{abc},K_{abc},K_{abcd},\omega^e)$ to a coframe on our formally 244-dimensional jet-bundle. In (20) we have 96 one-forms to which we add the 4 one-forms $\omega^1=dx^1$, $\omega^2=dx^2$, $\omega^3=dx^3$, $\omega^4=dx^4$ so that we need to add a further 144 forms π^Λ in order to obtain a complete coframe of $N=244$ one-forms. Again, Λ is a collective index subject to Einstein's summation convention, this time replacing complete sets of indices *abcd* in dS_{abcde}. In order to obtain intrinsic values, we choose to replace all components dS_{abcde}, where either *d* or *e* are $=4$, first, and so on based on x^4 being our first coordinate, then x^3, then x^2, and x^1 last. The correspondence of $\pi^\Lambda\leftrightarrow dS_{abcde}$ is given in detail in Appendix B. We solve each $d\mathcal{W}_{abc}$ for a distinct dS_{abc11}. Because $dK_{abc}=0$ (mod $(\mathcal{P})$), we only need to consider dK_{abcd} when computing the tableau matrices and the reduced Cartan characters. We can now write the 64 dK_{abcd} as

$$d\theta^\alpha\equiv A^\alpha_{\Lambda 2}\pi^\Lambda\wedge\omega^2+A^\alpha_{\Lambda 3}\pi^\Lambda\wedge\omega^3+A^\alpha_{\Lambda 4}\pi^\Lambda\wedge\omega^4-dS_{abc11}\wedge\omega^1+B^\alpha_{ij}\omega^i\wedge\omega^j. \tag{22}$$

From this we find that the only nonvanishing tableau matrix components $A^\alpha_{\Lambda i}$ for $i\neq 1$ are given by $A^\alpha_{\Lambda i}=-1$ when the indices α and Λ correspond to the same set of indices *abcd* as given in Appendix B and $A^\alpha_{\Lambda i}=0$ otherwise. This leads to

$$\begin{pmatrix} A^\alpha_{\Lambda 4}\\ A^\alpha_{\Lambda 3}\\ A^\alpha_{\Lambda 2}\\ A^\alpha_{\Lambda 1}\end{pmatrix}=\begin{pmatrix} 0 & 0 & A\\ 0 & B & 0\\ C & 0 & 0\\ X_1 & X_2 & X_3\end{pmatrix},$$

which is a 160×144 matrix and where X_1, X_2, X_3 stand for $A^\alpha_{\Lambda 1}$ and A is a 64×64 matrix with $A=-\mathbb{I}_{64}$, B is a 48×48 matrix with $B=-\mathbb{I}_{48}$ and C is a 32×32 matrix with $C=-\mathbb{I}_{32}$ so that the total rank $r=144$ is obtained. We obtain $s'_1=64$, $s'_2=48$, $s'_3=32$, and $s'_4=0$, meaning that the set of reduced Cartan characters $(s'_0,s'_1,s'_2,s'_3,s'_4)$ is (96, 64, 48, 32, 0). Computer codes show that we can find a coframe transformation such that the torsion terms B^α_{ij} can be absorbed and the system is in involution with Cartan characters (96, 64, 48, 32, 0) for a number of space–times.[12]

B. The Lanczos wave equation as a system of PDEs

We denote the system (8) formed by the 16 components of the wave equation by $\mathcal{R}_{2,\text{wave}}$, where the index "2" refers to the order of the system. Due to the definition of the symbol $\mathcal{M}_q$ of a system of PDEs $\mathcal{R}$, only the highest-order derivatives lead to terms in the symbol so that the only terms contributing to the symbol $\mathcal{M}_{2,\text{wave}}$ are parts of the $\Box L_{abc}$-terms. The 16 equations for the symbol for an arbitrary space–time each look like

$$V_{abc44}=\frac{1}{g^{44}}(g^{11}V_{abc11}+g^{22}V_{abc22}+g^{33}V_{abc33}+2g^{12}V_{abc12}+2g^{13}V_{abc13}+2g^{14}V_{abc14}$$
$$+2g^{23}V_{abc23}+2g^{24}V_{abc24}+2g^{34}V_{abc34}). \tag{23}$$

We can easily see that by ordering the S_{abcde} in such a way that $S_{abc44}>S_{abc34}>S_{abc33}>S_{abc24}>S_{abc23}>S_{abc22}>S_{abc14}>S_{abc13}>S_{abc12}>S_{abc11}$ based on $x^4>x^3>x^2>x^1$ and by choosing for each set of S_{abcij} the ordering $\mathcal{R}^{(\text{wave},4)}_>$ given in Appendix B, an orderly ranking is achieved.

Because all equations of form (23) are of class 4, it means that $\beta_2^{(4)}=16$ is the maximal value for $\beta_2^{(4)}$ and $\beta_2^{(1)}=\beta_2^{(2)}=\beta_2^{(3)}=0$ so that the Cartan characters are $\alpha_2^{(1)}=64$, $\alpha_2^{(2)}=48$, $\alpha_2^{(3)}=32$, $\alpha_2^{(4)}=0$. Further calculations show that $\mathcal{M}_{2,\text{wave}}$ is involutive and *no integrability conditions occur* because the system is linear so that the Lanczos wave equation in four dimensions consists of a system in involution with Cartan characters (64, 48, 32, 0).[12]

We can also derive this result directly from the *scalar wave equation*

$$\Box\Psi=0, \tag{24}$$

where Ψ is our scalar component depending on x^1, x^2, x^3, x^4. We use a formal manifold $\mathcal{M}$ with $N=19$ formal dimensions of which a local basis is given by the four x^e, one dependent variable Ψ, four P_e and ten S_{ef} on our jet bundle $\mathcal{J}^2(\mathbb{R}^4,\mathbb{R})$. We obtain $\beta_2^{(1)}=\beta_2^{(2)}=\beta_2^{(3)}=0$ and $\beta_2^{(4)}=1$ and the characters are $\alpha_2^{(1)}=4$, $\alpha_2^{(2)}=3$, $\alpha_2^{(3)}=2$, $\alpha_2^{(4)}=0$. The symbol of a single equation is always involutive and we further find that $r(\mathcal{M}_3)=4$ and therefore $\dim(\mathcal{M}_3)=16$ whereas $r(\mathcal{R}_3)=5$ and $\dim(\mathcal{R}_3)=30$. We also find that $\dim(\mathcal{R}_2)=14$ and

$$\dim(\mathcal{R}_2^{(1)})=\dim(\mathcal{R}_3)-\dim(\mathcal{M}_3)=30-16=14,$$

so that we conclude that $\dim(\mathcal{R}_2)=\dim(\mathcal{R}_2^{(1)})=14$. Because the system is linear, no integrability conditions can occur and the scalar wave equation (24) consists of a system in involution with characters (4, 3, 2, 0). Note that in the case of the Lanczos wave equation, we are dealing with 16 equations because we have 16 independent components L_{abc} and find the correspondence between the two sets of characters is here given by

$$16\cdot(4,3,2,0)=(64,48,32,0).$$

If we compare the characters of the Weyl–Lanczos equations with those of the Lanczos wave equation, we need to prolongate the Weyl–Lanczos equations once to second order. But for an involutive system the characters of the symbol $\mathcal{M}_{q+r}$ of the prolonged system together with the $\beta_{q+r}^{(k)}$ are directly determined by[7,17]

$$\alpha_{q+r}^k=\sum_{i=k}^{n}\binom{r+i-k-1}{r-1}\alpha_q^{(i)},\quad \beta_{q+r}^k=\sum_{i=k}^{n}\binom{r+i-k-1}{r-1}\beta_q^{(i)},$$

where in our case $n=4$, $m=16$, $q=1$, and $r=1$, which leads to the result (48, 32, 16, 0) for $(\alpha_2^{(1)},\alpha_2^{(2)},\alpha_2^{(3)},\alpha_2^{(4)})$ for the prolonged Weyl–Lanczos equations. This shows that, based on the $\alpha_2^{(k)}$ for both systems, the Weyl–Lanczos equations are more restrictive than the Lanczos wave equation with characters (64,48,32,0). The general solution of the Weyl–Lanczos equations only depends on 16 arbitrary functions of three variables whereas the general solution for the Lanczos wave equations contains 32 arbitrary functions of three variables.

IV. CONCLUSION

We obtained the Cartan characters (s_0,s_1,s_2,s_3,s_4) for the Weyl–Lanczos equations given as a Pfaffian system in involution which are (32, 16, 16, 16, 0) and (16, 16, 16, 16, 0) when pulled back onto the submanifold where the Weyl–Lanczos equations themselves vanish identically. These results were obtained assisted by REDUCE codes based on the EDS package. Using Janet–Riquier theory the Cartan characters were obtained to be (16, 16, 16, 0) for a diagonalized space–time and for the plane wave limit taken of any space–time and these systems were in involution.

We showed that the Lanczos wave equation also consists of a Pfaffian system in involution and that its Cartan characters are given by (96, 64, 48, 32, 0). We also found that the Lanczos wave equation was less restrictive than the Weyl–Lanczos equations allowing for 32 arbitrary

functions of three variables as opposed to only 16 which can also be derived from the scalar wave equation. In practice many of the arbitrary functions involved may amount to gauge contributions though. All results hold for the real analytic case.

APPENDIX A: THE WEYL–LANCZOS EQUATIONS

Here, we give the expressions for the α_{abcde} and the γ_{abcde} occurring in the EDS for the Weyl–Lanczos equations given by (10):

$$\alpha_{abcde}=\Gamma^n_{ad,e}(L_{nbc}+L_{ncb})+\Gamma^n_{bc,e}(L_{nad}+L_{nda})-\Gamma^n_{ac,e}(L_{nbd}+L_{ndb})-\Gamma^n_{bd,e}(L_{nac}+L_{nca}). \tag{A1}$$

The quantity γ_{abcde} is given by

$$\begin{aligned}\gamma_{abcde}=&g_{bc}[P_{nads}g^{ns}_{,e}-L_{mad}(\Gamma^m_{ns}g^{ns})_{,e}-L_{nmd}(\Gamma^m_{as}g^{ns})_{,e}-L_{nam}(\Gamma^m_{ds}g^{ns})_{,e}]+g_{ad}[P_{nbcs}g^{ns}_{,e}\\&-L_{mbc}(\Gamma^m_{ns}g^{ns})_{,e}-L_{nmc}(\Gamma^m_{bs}g^{ns})_{,e}-L_{nbm}(\Gamma^m_{cs}g^{ns})_{,e}]-g_{bd}[P_{nacs}g^{ns}_{,e}-L_{mac}(\Gamma^m_{ns}g^{ns})_{,e}\\&-L_{nmc}(\Gamma^m_{as}g^{ns})_{,e}-L_{nam}(\Gamma^m_{cs}g^{ns})_{,e}]-g_{ac}[P_{nbds}g^{ns}_{,e}-L_{mbd}(\Gamma^m_{ns}g^{ns})_{,e}-L_{nmd}(\Gamma^m_{bs}g^{ns})_{,e}\\&-L_{nbm}(\Gamma^m_{ds}g^{ns})_{,e}]+g_{bc,e}[P_{nads}g^{ns}-L_{mad}(\Gamma^m_{ns}g^{ns})-L_{nmd}(\Gamma^m_{as}g^{ns})-L_{nam}(\Gamma^m_{ds}g^{ns})]\\&+g_{ad,e}[P_{nbcs}g^{ns}-L_{mbc}(\Gamma^m_{ns}g^{ns})-L_{nmc}(\Gamma^m_{bs}g^{ns})-L_{nbm}(\Gamma^m_{cs}g^{ns})]-g_{bd,e}[P_{nacs}g^{ns}\\&-L_{mac}(\Gamma^m_{ns}g^{ns})-L_{nmc}(\Gamma^m_{as}g^{ns})-L_{nam}(\Gamma^m_{cs}g^{ns})]-g_{ac,e}[P_{nbds}g^{ns}-L_{mbd}(\Gamma^m_{ns}g^{ns})\\&-L_{nmd}(\Gamma^m_{bs}g^{ns})-L_{nbm}(\Gamma^m_{ds}g^{ns})].\end{aligned} \tag{A2}$$

When introducing the collective index Λ for the additional coframe elements π^Λ, we ordered the L_{abc} according to

$$\begin{aligned}&L_{133}<L_{144}<L_{123}<L_{132}<L_{124}<L_{142}<L_{134}<L_{143}<L_{232}<L_{233}<L_{242}<L_{244}\\&\quad<L_{234}<L_{243}<L_{343}<L_{344}\end{aligned}$$

from which we deduce the ordering for the $\pi^\Lambda \leftrightarrow dP_{abce}$ in such a way that the dP_{abce} are arranged like the L_{abc} above. The π^Λ are then labeled:

$$\pi^1 \leftrightarrow dP_{1331},\ldots,\quad \pi^{16}\leftrightarrow dP_{3441},$$

$$\pi^{17} \leftrightarrow dP_{1332},\ldots,\quad \pi^{32}\leftrightarrow dP_{3442},$$

$$\pi^{33} \leftrightarrow dP_{1333},\ldots,\quad \pi^{48}\leftrightarrow dP_{3443}.$$

When expressing the Weyl–Lanczos equations as a system of PDEs, we used the standard orderly ranking (if not stated otherwise explicitly) which is based on the ordering $P_{abc4}>P_{abc3}>P_{abc2}>P_{abc1}$. Then, amongst each set of the P_{abci} we order them according to

$$\begin{aligned}&P_{344i}>P_{343i}>P_{243i}>P_{234i}>P_{244i}>P_{242i}>P_{233i}>P_{232i}>P_{143i}>P_{134i}>P_{142i}>P_{124i}>P_{132i}\\&\quad>P_{123i}>P_{144i}>P_{133i}.\end{aligned}$$

This leads to an orderly ranking for the P_{abcd} for the Weyl–Lanczos equations denoted by $\mathcal{R}^{(W,4)}_>$.

APPENDIX B: THE LANCZOS WAVE EQUATION

Here, we specify the correspondence between the π^{Λ} and the dS_{abcde} for the Lanczos wave equation. For both i,j fixed we assume that the dS_{abcij} are ordered according to the ordering of the L_{abc} in Appendix A. For the first 64 π^{Λ}, where we have used the fact that $x^4>x^3>x^2>x^1$ for our independent variables in order to obtain intrinsic results, we obtain the labeling (for the pairs of indices $ij=44$, 34, 24, 14)

$$\pi^{1}\leftrightarrow dS_{13344},\ldots,\quad \pi^{16}\leftrightarrow dS_{34444},$$

$$\pi^{7}\leftrightarrow dS_{13334},\ldots,\quad \pi^{32}\leftrightarrow dS_{34434},$$

$$\pi^{33}\leftrightarrow dS_{13324},\ldots,\quad \pi^{48}\leftrightarrow dS_{34424},$$

$$\pi^{49}\leftrightarrow dS_{13314},\ldots,\quad \pi^{64}\leftrightarrow dS_{34414}.$$

Then, the next 48 π^{Λ} are given by (for $ij=33$, 23, 13)

$$\pi^{65}\leftrightarrow dS_{13333},\ldots,\quad \pi^{80}\leftrightarrow dS_{34433},$$

$$\pi^{81}\leftrightarrow dS_{13323},\ldots,\quad \pi^{96}\leftrightarrow dS_{34423},$$

$$\pi^{97}\leftrightarrow dS_{13313},\ldots,\quad \pi^{112}\leftrightarrow dS_{34413}.$$

The last 32 π^{Λ} are denoted as follows (for $ij=22$, 12)

$$\pi^{113}\leftrightarrow dS_{13322},\ldots,\quad \pi^{128}\leftrightarrow dS_{34422},$$

$$\pi^{129}\leftrightarrow dS_{13312},\ldots,\quad \pi^{144}\leftrightarrow dS_{34412}.$$

We assumed that all the dS_{abc11} can be solved for by the 16 exterior derivatives of the wave equation $d\mathcal{W}_{abc}$ and expressed the dS_{abc11} in this way.

Using Janet–Riquier theory, an orderly ranking $\mathcal{R}_{>}^{(\text{wave},4)}$ for the 160 second-order partial derivatives S_{abcde} for the Lanczos wave equation is based on

$$S_{abc44}>S_{abc34}>S_{abc33}>S_{abc24}>S_{abc23}>S_{abc22}>S_{abc14}>S_{abc13}>S_{abc12}>S_{abc11}$$

and then amongst each set S_{abcij} for i,j fixed in the same way as for the P_{abci} in Appendix A, namely,

$$S_{344ij}>S_{343ij}>S_{243ij}>S_{234ij}>S_{244ij}>S_{242ij}>S_{233ij}>S_{232ij}>S_{143ij}>S_{134ij}>S_{142ij}>S_{124ij}>S_{132ij}$$
$$>S_{123ij}>S_{144ij}>S_{133ij}.$$

A space–time in toroidal coordinates

J. P. Krisch and E. N. Glass[a)]
Department of Physics, University of Michigan, Ann Arbor, Michgan 48109

(Received 18 July 2002; accepted 26 March 2003)

We present an exact solution of Einstein's field equations in toroidal coordinates. The solution has three regions: an interior with a string equation of state; an Israel boundary layer; and an exterior with constant isotropic pressure and constant density, locally isometric to anti–de Sitter space–time. The exterior can be a cosmological vacuum with negative cosmological constant. The size and mass of the toroidal loop depend on the size of Λ. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1580999]

I. INTRODUCTION

There has been increasing interest in space–times with nonspherical topology and negative cosmological constant. Much of the discussion has focused on structures with horizons in anti–de Sitter (AdS) space–times.[1–5] Vanzo[6] pointed out that, in AdS space, there are black hole solutions with genus g horizons. Aminneborg *et al.* (ABHP)[1] discussed space–times locally isometric to AdS with horizons of arbitrary genus. While many current models of the universe seem to indicate that Λ is positive, there are some models with $\Lambda<0$.[7] Aside from their physical relevance to the actual structure of the Universe, solutions in AdS are very interesting as a comparison case to asymptotically flat solutions. For example, Hawking and Page[8] have discussed the relevance of a negative Λ to black hole thermal stability. The $2+1$ Bañados–Teitelboim–Zanelli[9] black hole solution and its $3+1$ black string[10] lift have generated a large literature.[11]

In this work we discuss a toroidal fluid solution embedded in a locally AdS exterior. There is an overall metric scale factor which depends on the size of Λ. The solution has three regions:

(i) an interior solution with an equation of state, $\rho+p_{\varphi}=0$;
(ii) an Israel[12] boundary layer with surface stress energy S_{ij} and stringlike content $S_{00}+S_{\varphi\varphi}=0$; and
(iii) an exterior with constant isotropic pressure, constant density, and a negative cosmological constant. Just as in the ABHP study, the exterior metric is locally isometric to AdS. The solution models an extended loop with interior structure. The size of the loop and its mass depend on the cosmological constant. The solution can be used to model both micro loops or very large loop structures, depending on the size of Λ.

There have been other discussions of circular string structures. Frolov, Israel and Unruh[13] started with an axially symmetric space–time and discussed the relation between internal string structure and angular deficit, then transformed the metric to toroidal coordinates to discuss the mass structure of circular cosmic strings. Using toroidal coordinates, Hughes *et al.*[14] studied weak field loops. Sen and Banerjee[15] have discussed a solution for a circular cosmic string loop in cylindrical coordinates. Because often a particular choice of surfaces can simplify the solution of the field equations, we begin with toroidal coordinates.

Cartesian toroids are discussed in the next section. In Sec. III we write the field equations for the space–time and develop the interior and exterior solutions. Matching conditions are presented in the fourth section. The Israel boundary layer is described in the fifth section. In Sec. VI we

[a)]Permanent address: Physics Department, University of Windsor, Ontario N9B 3P4, Canada. Electronic mail: englass@umich.edu

discuss the mass, and the final section concludes with a general discussion.

II. CARTESIAN TOROIDS

The relation between Cartesian coordinates (x,y,z) and toroidal coordinates (η,ϑ,φ) on $\mathcal{R}^3$ is[16]

$$x=a\frac{\sinh(\eta)\cos(\varphi)}{\cosh(\eta)-\cos(\vartheta)}, \tag{1a}$$

$$y=a\frac{\sinh(\eta)\sin(\varphi)}{\cosh(\eta)-\cos(\vartheta)}, \tag{1b}$$

$$z=a\frac{\sin(\vartheta)}{\cosh(\eta)-\cos(\vartheta)}, \tag{1c}$$

with $0\leqslant\eta<\infty$, $0\leqslant\vartheta\leqslant 2\pi$, $0\leqslant\varphi\leqslant 2\pi$. Here "$a$" is a constant scale factor.

In toroidal coordinates, the Euclidean metric $dx^2+dy^2+dz^2$ becomes

$$dL^2=\frac{a^2}{[\cosh(\eta)-\cos(\vartheta)]^2}[d\eta^2+d\vartheta^2+\sinh^2(\eta)d\varphi^2]. \tag{2}$$

The torus $\eta=\eta_0$ described by dL^2 has a circular cross section with circumference $2\pi a\,\mathrm{csch}(\eta_0)$, and the center of the toroid circular cross section is a distance $a\coth(\eta_0)$ from the origin. The equation of the $\varphi=0$, $y=0$ circles, Eq. (1b), is[17]

$$[x-a\coth(\eta_0)]^2+z^2=a^2\,\mathrm{csch}^2(\eta_0).$$

As η_0 increases, the radius of the loop decreases and the torus approaches the flat torus, a distance "a" from the origin. Looking down the z-axis (about which φ has range $0\leqslant\varphi\leqslant 2\pi$) at the torus, one sees two concentric circles. The $\vartheta=$constant surfaces, $0\leqslant\vartheta\leqslant 2\pi$, are spheres centered on the z-axis. From Eq. (1) these spheres have equation

$$(x^2+y^2+z^2-a^2)/2az=\cot(\vartheta),$$

which defines the relation of ϑ to the torus.

III. SPACE–TIME

For the curved space torus, one must construct two different metrics, an exterior for $0\leqslant\eta\leqslant\eta_0$ and an interior for $\eta_0\leqslant\eta\leqslant\infty$. The metric that we use to describe the space–time is a simple generalization of the flat space metric:

$$ds^2=\frac{a^2}{[\cosh(\eta)-\cos(\vartheta)]^2}[-h^2(\eta)dt^2+e^{2\mu(\eta)}d\eta^2+d\vartheta^2+h^2(\eta)d\varphi^2]. \tag{3}$$

Note that metric (3) cannot reduce to the Minkowski metric.

A. Field equations

We write Einstein's field equations using the conventions of Misner, Thorne, and Wheeler[18] and Wald.[19] The field equations are ($G=c=1$)

$$G_{\alpha\beta}=8\pi T_{\alpha\beta}. \tag{4}$$

Using flow vector $\hat{u}^\alpha\hat{u}_\alpha=-1$, the energy-momentum tensor for a fluid is given in terms of principal pressures as

$$T_{\alpha\beta}=\rho\hat{u}_\alpha\hat{u}_\beta+p_1\hat{x}_\alpha\hat{x}_\beta+p_2\hat{y}_\alpha\hat{y}_\beta+p_3\hat{z}_\alpha\hat{z}_\beta. \tag{5}$$

In the following development, we write the field equations allowing for fluid anisotropy. We do not include Λ explicitly in the stress-energy tensor but will interpret the stress-energy associated with a metric solution in terms of Λ if appropriate. Using metric (3) above with $\Psi=\cosh(\eta)-\cos(\vartheta)$ and $u^\alpha\partial_\alpha=(\Psi/ah)\partial_t$, the field equations are

$$\begin{aligned}8\pi\rho a^2e^{2\mu}&=-8\pi p_\varphi a^2e^{2\mu}\\&=-\cosh^2(\eta)-2\cosh(\eta)\cos(\vartheta)+3+2\sinh(\eta)\Psi(h'/h)-\Psi^2(h''/h)+\Psi^2\mu'(h'/h)\\&\quad-2\Psi\mu'\sinh(\eta)+e^{2\mu}[-3+\cos^2(\vartheta)+2\cosh(\eta)\cos(\vartheta)],\end{aligned} \tag{6a}$$

$$\begin{aligned}8\pi p_\eta a^2e^{2\mu}&=3\cosh^2(\eta)-3-4\Psi\sinh(\eta)(h'/h)+\Psi^2(h'/h)^2\\&\quad+e^{2\mu}[3-2\cosh(\eta)\cos(\vartheta)-\cos^2(\vartheta)],\end{aligned} \tag{6b}$$

$$\begin{aligned}8\pi p_\vartheta a^2e^{2\mu}&=\cosh^2(\eta)-3+2\cosh(\eta)\cos(\vartheta)-2\Psi\sinh(\eta)[2(h'/h)-\mu']\\&\quad+\Psi^2[2(h''/h)-2\mu'(h'/h)+(h'/h)^2]+3e^{2\mu}\sin^2(\vartheta),\end{aligned} \tag{6c}$$

where $\partial h/\partial\eta$ and $\partial\mu/\partial\eta$ are abbreviated by h' and μ'.

B. Interior solution

Let $h^2=[d_0\sinh(\eta)-b_0]^2$, $e^{2\mu}=1$. The interior metric is

$$g^{\text{in}}_{\alpha\beta}dx^\alpha dx^\beta=(a/\Psi)^2[-h^2dt^2+d\eta^2+d\vartheta^2+h^2d\varphi^2]. \tag{7}$$

The energy-momentum components for g^{in} are

$$8\pi a^2\rho=-8\pi a^2p_\varphi=(b_0/h)[\cosh^2(\eta)-\cos^2(\vartheta)], \tag{8a}$$

$$8\pi a^2p_\eta=(\Psi/h^2)\{(d_0^2+b_0^2)\Psi-2b_0h[\cosh(\eta)+\cos(\vartheta)]\}, \tag{8b}$$

$$8\pi a^2p_\vartheta=(\Psi/h^2)[(d_0^2+b_0^2)\Psi-4b_0h\cos(\vartheta)]. \tag{8c}$$

The equation of state is

$$\rho+p_\varphi=0. \tag{9}$$

The interior metric has quadratic Weyl invariant

$$C_{\alpha\beta\mu\nu}C^{\alpha\beta\mu\nu}=\frac{4}{3}d_0^2\frac{\Psi^4}{a^4h^4}[b_0\sinh(\eta)+d_0]^2, \tag{10}$$

and Ricci scalar

$$R_{\alpha\beta}g^{\alpha\beta}_{\text{in}}=-\frac{2\Psi}{a^2h^2}\{(d_0^2+b_0^2)\Psi-2b_0h[\cosh(\eta)+2\cos(\vartheta)]\}. \tag{11}$$

C. Exterior solution

The solution to be used in the toroid exterior is

$$g^{\text{ex}}_{\alpha\beta}dx^\alpha dx^\beta=\frac{a^2}{[\cosh(\eta)-\cos(\vartheta)]^2}[-h^2(\eta)dt^2+e^{2\mu(\eta)}d\eta^2+d\vartheta^2+h^2(\eta)d\varphi^2]. \tag{12}$$

In order to describe a cosmological vacuum, p_η will have to be constant. The cosine terms should vanish. From the general field equations we write p_η, grouping the terms:

$$\begin{aligned}8\pi p_\eta a^2 e^{2\mu} &= 3\cosh^2(\eta) - 3 - 4\sinh(\eta)\cosh(\eta)(h'/h) + 3e^{2\mu} + \cosh^2(\eta)(h'/h)^2 \\ &+ \cos(\vartheta)[-2\cosh(\eta)e^{2\mu} + 4\sinh(\eta)(h'/h) - 2\cosh(\eta)(h'/h)^2] \\ &+ \cos^2(\vartheta)[-e^{2\mu} + (h'/h)^2].\end{aligned}$$

To eliminate the $\cos^2$ term, take $(h'/h)^2 = e^{2\mu}$. The cosine term then becomes

$$4\cos(\vartheta)e^{\mu}[-\cosh(\eta)e^{\mu} + \sinh(\eta)].$$

Requiring this term to vanish provides one nontrivial solution

$$e^{\mu} = \sinh(\eta)/\cosh(\eta), \quad h = \cosh(\eta). \tag{13}$$

Substituting (13), the energy-momentum components of g^{ex} are

$$8\pi\rho = -3/a^2, \tag{14a}$$

$$8\pi p_\eta = 8\pi p_\vartheta = 8\pi p_\varphi = 3/a^2. \tag{14b}$$

This can be a space–time with negative cosmological constant $\Lambda = -3/a^2$. The metric is conformally flat and has constant negative Ricci scalar $R = -12/a^2$. $g^{\alpha\beta}_{\text{ex}}$ is locally isometric to the AdS metric.

IV. MATCHING INTERIOR TO EXTERIOR

The two metrics to be joined are

$$\begin{aligned}g^{\text{in}}_{\alpha\beta}dx^\alpha dx^\beta &= \frac{a^2}{\Psi^2}\{-[d_0\sinh(\eta) - b_0]^2 dt^2 + d\eta^2 + d\vartheta^2 + [d_0\sinh(\eta) - b_0]^2 d\varphi^2\}, \\ g^{\text{ex}}_{\alpha\beta}dx^\alpha dx^\beta &= \frac{a^2}{\Psi^2}\left[-\cosh^2(\eta)dt^2 + \frac{\sinh^2(\eta)}{\cosh^2(\eta)}d\eta^2 + d\vartheta^2 + \cosh^2(\eta)d\varphi^2\right].\end{aligned} \tag{15}$$

Matching the metrics one obtains

$$\cosh(\eta_0) = d_0\sinh(\eta_0) - b_0.$$

Matching the extrinsic curvature yields

$$d_0\cosh(\eta_0) = \sinh(\eta_0).$$

The bounding surface is thus defined by

$$\cosh(\eta_0) = \frac{b_0}{d_0^2 - 1}, \tag{16a}$$

$$\sinh(\eta_0) = \frac{d_0 b_0}{d_0^2 - 1}, \tag{16b}$$

with

$$b_0^2+d_0^2=1. \tag{17}$$

This implies that both b_0 and d_0 are less than 1. On the boundary the stresses are

$$8\pi a^2\rho=-8\pi a^2 p_\varphi=[b_0^2\cos^2(\vartheta)-1], \tag{18a}$$

$$8\pi a^2 p_\eta=\Psi b_0[-3+b_0\cos(\vartheta)], \tag{18b}$$

$$8\pi a^2 p_\vartheta=\Psi b_0[-1+3b_0\cos(\vartheta)]. \tag{18c}$$

A problem with the matching is that p_η does not smoothly join to the exterior stress. This mismatch would lead to a dynamic boundary. Therefore, an Israel boundary layer will be developed.

V. THE BOUNDARY LAYER

A. Position of the layer

If the interior and exterior solutions do not match derivatives but join over an Israel surface layer,[12] then the position of the boundary will be set by matching only h at $\eta=\eta_0$. For the exterior we have

$$h=\cosh(\eta), \quad e^\mu=\sinh(\eta)/\cosh(\eta).$$

For the interior

$$h=d_0\sinh(\eta)-b_0, \quad e^{2\mu}=1.$$

Matching the interior and exterior at $\eta=\eta_0$ provides

$$\cosh(\eta_0)=d_0\sinh(\eta_0)-b_0.$$

Note that the $e^{2\mu}$ term need not match, since it is the coefficient of $d\eta^2$ and the match is for η constant surfaces. Rearranging, we have the bounding surface

$$\cosh(\eta_0)=\frac{b_0+\mathbb{k}d_0(b_0^2+d_0^2-1)^{1/2}}{d_0^2-1}, \quad \mathbb{k}=(\pm 1), \tag{19a}$$

$$\sinh(\eta_0)=\frac{d_0b_0+\mathbb{k}(b_0^2+d_0^2-1)^{1/2}}{d_0^2-1}. \tag{19b}$$

B. Parameter constraints

Constraints can be set on d_0 and b_0 by requiring

$$\sinh(\eta_0)>0, \quad \cosh(\eta_0)>0, \quad \rho_{\text{interior}}>0.$$

Both of the hyperbolic functions in Eq. (19) have a sign choice which is the same for both functions. There are eight possible parameter $(\mathbb{k},d_0,b_0)$ combinations for both $d_0^2>1$ and $d_0^2<1$ for a total of 16 cases. The hyperbolic conditions eliminate eight and the density constraint five more. The three remaining allowed parameter combinations with their constraints are

$$(1)\ \ d_0^2>1:[\mathbb{k}=+1,\ d_0>0,\ b_0>0],\ \text{no constraints},$$

$$(2)\ \ d_0^2>1:[\mathbb{k}=-1,\ d_0>0,\ b_0>0],\ \ \sqrt{b_0^2+d_0^2-1}<\left|\frac{b_0}{d_0}\right|,\ \ \sqrt{b_0^2+d_0^2-1}<|d_0 b_0|, \tag{20}$$

$$(3)\ \ d_0^2<1:[\mathbb{k}=-1,\ d_0>0,\ b_0>0],\ \ \sqrt{b_0^2+d_0^2-1}>\left|\frac{b_0}{d_0}\right|,\ \ \sqrt{b_0^2+d_0^2-1}>|d_0 b_0|.$$

The algebraic details are in the Appendix.

C. Extrinsic curvature

We are interested in a space–time that could describe a loop of matter with an energy density equal to the loop tension over a bounding Israel surface layer at $\eta=\eta_0$. The stress-energy content of the surface layer S_{ij} (Ref. 12) is given by

$$8\pi S_{ij}=\gamma_{ij}-\gamma h_{ij}^{(b)} \tag{21}$$

with $h_{ij}^{(b)}$ the metric of the bounding torus. γ_{ij} is the difference between the extrinsic curvatures of the exterior and interior metrics on the boundary

$$\gamma_{ij}=K_{ij}^{\mathrm{ex}}-K_{ij}^{\mathrm{in}}=\langle K_{ij}\rangle.$$

Calculating the general extrinsic curvature on the bounding torus $\eta=\eta_0$ with unit normal n_α we have

$$K_{ij}=-n_{\alpha;\beta}h_i^\alpha h_j^\beta,$$

$$K_{ij}=n_\alpha\Gamma_{ij}^\alpha=-(n_\alpha/2)g^{\alpha\beta}g_{ij,\beta}.$$

With $\Psi=\cosh(\eta)-\cos(\vartheta)$ and $\eta^\alpha\partial_\alpha=\partial/\partial\eta$, we have for the extrinsic curvatures on the boundary

$$K_{00}=(n_\alpha\eta^\alpha)\frac{\Psi^2}{2e^{2\mu}}\frac{\partial}{\partial\eta}(h^2/\Psi^2), \tag{22a}$$

$$K_{\varphi\varphi}=-K_{00}, \tag{22b}$$

$$K_{\vartheta\vartheta}=(n_\alpha\eta^\alpha)\frac{\Psi^2}{2e^{2\mu}}\frac{\partial}{\partial\eta}(1/\Psi^2). \tag{22c}$$

$K_{\vartheta\vartheta}$ will match across the boundary with the metrics we have found. Using Eq. (22a) and forming K_{00} we have

$$K_{00}=\frac{h}{\Psi}[\Psi h'-h\sinh(\eta)]. \tag{23}$$

Establishing the difference between inner and outer spaces and matching h on the boundary, the discontinuity in the extrinsic curvature is

$$\langle K_{00}\rangle=h[\sinh(\eta_0)-d_0\cosh(\eta_0)].$$

Therefore the boundary layer has a stress energy content

$$8\pi S_{00}=\cosh(\eta_0)[d_0\cosh(\eta_0)-\sinh(\eta_0)]=-8\pi S_{\varphi\varphi}. \tag{24}$$

Requiring $S_{00}>0$ and substituting for $\cosh(\eta_0)$ and $\sinh(\eta_0)$ from Eq. (19) implies $\mathbb{k}=1$. Thus one parameter set remains:

$$d_0^2 > 1 : [\mathbb{k} = +1,\ d_0 > 0,\ b_0 > 0]. \tag{25}$$

The stress energy content of the boundary layer represents a toroidal loop with a stringlike equation of state.

VI. MASS

When the generator of time translations is Killing vector ξ^ν, then the Einstein four-momentum $p^\mu = \sqrt{-g} T^\mu_\nu \xi^\nu$ is conserved and a mass can be associated with three-volume dV_μ,

$$M = \int_{3vol} \sqrt{-g} T^\mu{}_\nu \xi^\nu dV_\mu,$$

where $dV_\mu = t,_\mu d\eta d\vartheta d\varphi$. Substituting we have the mass inside the torus:

$$M = \frac{2\pi b_0 a^2}{8\pi} \int_{\eta_0}^{\infty} \int_0^{2\pi} \frac{h}{\Psi^3} [\cosh(\eta) + \cos(\vartheta)] d\vartheta d\eta$$

$$= \frac{\pi b_0 a^2}{8 \sinh^4(\eta_0)} \{4 d_0 \sinh(\eta_0) \cosh^2(\eta_0) - b_0 [2 \sinh^2(\eta_0) + 3]\}. \tag{26}$$

A similar calculation can be repeated for the mass associated with the surface layer. In the Israel formalism the surface stress energy is defined in geodesic coordinates as the thickness ε of the layer approaches zero:

$$S_{\mu\nu} = \lim_{\varepsilon \to 0} \int_0^\varepsilon T_{\mu\nu} dx. \tag{27}$$

Start with the definition of the mass in a three-volume and take the limit as the distance between tori goes to zero:

$$M' = \int_{3vol} \sqrt{-g} T^\mu{}_\nu \xi^\nu dV_\mu = \int_{3vol} \sqrt{-g} T^0{}_\nu \xi^\nu d\eta d\vartheta d\varphi.$$

In the limit of zero layer thickness

$$M' = \lim_{\varepsilon \to 0} \int \int \int_{\eta_0 - \varepsilon}^{\eta_0} \sqrt{-g_{tt} g_{\vartheta\vartheta} g_{\varphi\varphi} g_{\eta\eta}}\ T^0{}_\nu \xi^\nu d\eta d\vartheta d\varphi. \tag{28}$$

Assume that the limit can be taken inside the integral and that over the range of the $\eta-$ integral that $\sqrt{-g_{tt} g_{\vartheta\vartheta} g_{\varphi\varphi}}$ is approximately constant and takes its value on η_0:

$$M' = \int \int \sqrt{-g_{tt}(\eta_0, \vartheta) g_{\vartheta\vartheta}(\eta_0, \vartheta) g_{\varphi\varphi}(\eta_0, \vartheta)}\ d\vartheta d\varphi \lim_{\varepsilon \to 0} \int_{\eta_0 - \varepsilon}^{\eta_0} (T^0{}_\nu \xi^\nu \sqrt{g_{\eta\eta}} d\eta),$$

$$M' = \int \int \sqrt{-g_{tt} g_{\vartheta\vartheta} g_{\varphi\varphi}}\ S^0{}_\nu \xi^\nu d\vartheta d\varphi.$$

Integration results in

$$M' = \frac{a h^2}{4} [d_0 - \tanh(\eta_0)] \frac{2\pi}{\sinh(\eta_0)}. \tag{29}$$

VII. DISCUSSION

In summary, we have obtained a fluid solution to the field equations that describes a positive density torus with a boundary layer, embedded in a locally AdS exterior. The solution has two parameters, d_0 and b_0 with a restricted range. The fluid and boundary layers both have a stringlike equation of state. The solution can describe a variety of structures, depending on the parameter value chosen. First consider the size of the loop, $R_\vartheta = a\,\mathrm{csch}(\eta_0)$. For the allowed parameter set we have, in the limit $b_0^2 \gg |d_0^2 - 1|$,

$$\frac{R_\vartheta[\mathbb{k}=+1,\, d_0^2>1]}{a} \sim \frac{d_0-1}{b_0}.$$

R_ϑ/a can become very small and the torus will approach the flat torus a distance "a" from the center of the torus loop. The size of the loop depends on the scale parameter, "a." The size of the scale factor is determined by the cosmological constant. From the field equations we have

$$\frac{8\pi G}{c^2}\rho_{\text{exterior}} = -\frac{3}{a^2}, \quad |\Lambda| = \frac{3}{a^2}. \tag{30}$$

For example, if this density is roughly the same order as the critical density, we would have $|\rho| \sim 10^{-27}$ kg/m^3 and one finds that $a \sim 10^{28}$ m. If the solution is used to describe a primordial universe with a large negative Λ, the scale factor could be much smaller and micro loops could be possible.

The mass description is also dependent on the size of the scale factor. We have from Eq. (26) for the fluid interior

$$M = \frac{\pi b_0 a^2}{8}\left[\frac{4d_0}{\sinh(\eta_0)} + \frac{4d_0}{\sinh^3(\eta_0)} - \frac{2b_0}{\sinh^2(\eta_0)} - \frac{3b_0}{\sinh^4(\eta_0)}\right].$$

For the surface layer we have Eq. (29),

$$M' = \frac{\pi}{2} a h^2 [d_0 - \tanh(\eta_0)] \frac{1}{\sinh(\eta_0)}.$$

One thing that is immediately obvious is the different dependence on the scale parameter. In the large b_0 limit taken above we have

$$M' \sim \frac{\pi}{2} a b_0,$$

$$M \sim \frac{\pi}{4} a^2 (d_0^2 - 1).$$

The fluid inside the torus does not depend on b_0 in this limit. In the current universe, if $a \gg 1$ and if $b_0 \ll a$, the fluid inside the torus can dominate the mass because of the scale factor. If $b_0 \sim a$ and $d_0 \to 1$, the mass in the surface layer could dominate the loop structure. While the size of the thin-loop torus depends on "a," the "fat" torus can extend much closer in to the origin. As above, if, in the primordial universe, the cosmological constant was negative and much larger, the scale factor, "a," could be quite small. The solution could then describe micro loops with the surface layer the dominant mass contribution.

Several extensions of this solution might be possible. Adding time dependence to generate an oscillating loop for a Casimir calculation would be quite interesting. Time dependence could also

be used to check the evolution and stability over time of a primordial loop. This solution could also be regarded as a step toward generating multi segment Brevik–Nielson[20] loops with metric dependent tensions.

APPENDIX: MATCHING CONSTRAINTS

The hyperbolic functions are, with $S(b_0,d_0):=(b_0^2+d_0^2-1)^{1/2}$,

$$\cosh(\eta_0)=\frac{b_0+\mathbb{k}d_0S}{d_0^2-1},\quad \mathbb{k}=(\pm 1), \tag{A1a}$$

$$\sinh(\eta_0)=\frac{d_0b_0+\mathbb{k}S}{d_0^2-1}. \tag{A1b}$$

The conditions to be satisfied are

$$\sinh(\eta_0)>0,$$

$$\cosh(\eta_0)>0.$$

The cosh function is always positive and $\sinh(\eta_0)$ is positive because the range for the interior metric is $\eta_0<\eta<\infty$. The parameters must always satisfy the condition

$$b_0^2+d_0^2>1.$$

The equal sign with $S=0$ is not a possibility since that would imply an exact match of interior and exterior.

1. $\sinh(\eta_0)>0$

$$\frac{d_0b_0+\mathbb{k}S}{d_0^2-1}>0$$

A: $d_0^2>1$, $\mathbb{k}=+1$, $0<d_0b_0+S$
- (1) ($d_0>0$, $b_0>0$) condition satisfied
- (2) ($d_0<0$, $b_0<0$) condition satisfied
- (3) ($d_0>0$, $b_0<0$) condition satisfied if $|d_0b_0|<S$
- (4) ($d_0<0$, $b_0>0$) condition satisfied if $|d_0b_0|<S$

B: $d_0^2>1$, $\mathbb{k}=-1$, $0<d_0b_0-S$
- (5) ($d_0>0$, $b_0>0$) condition satisfied if $S<|d_0b_0|$
- (6) ($d_0<0$, $b_0<0$) condition satisfied if $S<|d_0b_0|$
- (7) ($d_0>0$, $b_0<0$) condition excluded
- (8) ($d_0<0$, $b_0>0$) condition excluded

C: $d_0^2<1$, $\mathbb{k}=+1$, $0<-d_0b_0-S$
- (9) ($d_0>0$, $b_0>0$) condition excluded
- (10) ($d_0<0$, $b_0<0$) condition excluded
- (11) ($d_0>0$, $b_0<0$) condition satisfied if $S<|d_0b_0|$
- (12) ($d_0<0$, $b_0>0$) condition satisfied if $S<|d_0b_0|$

D: $d_0^2<1$, $\mathbb{k}=-1$, $0<-d_0b_0+S$
- (13) ($d_0>0$, $b_0>0$) condition satisfied if $|d_0b_0|<S$
- (14) ($d_0<0$, $b_0<0$) condition satisfied if $|d_0b_0|<S$
- (15) ($d_0>0$, $b_0<0$) condition satisfied
- (16) ($d_0<0$, $b_0>0$) condition satisfied

Summary of Condition 1

$d_0^2>1$, $\mathbb{k}=-1$, $(d_0>0, b_0<0)$ and $(d_0<0, b_0>0)$ are excluded
$d_0^2<1$, $\mathbb{k}=+1$, $(d_0>0, b_0>0)$ and $(d_0<0, b_0<0)$ are excluded

2. $\cosh(\eta_0)>0$

$$\frac{b_0+d_0\mathbb{k}S}{d_0^2-1}>0$$

A: $d_0^2>1$, $\mathbb{k}=+1$, $0<b_0+d_0S$
(1) $(d_0>0, b_0>0)$ condition satisfied
(2) $(d_0<0, b_0<0)$ condition excluded
(3) $(d_0>0, b_0<0)$ condition satisfied if $|b_0|<d_0S$
(4) $(d_0<0, b_0>0)$ condition satisfied if $|b_0|>|d_0|S$
B: $d_0^2>1$, $\mathbb{k}=-1$, $0<b_0-d_0S$
(5) $(d_0>0, b_0>0)$ condition satisfied if $d_0S<b_0$
(6) $(d_0<0, b_0<0)$ condition satisfied if $|d_0|S>|b_0|$
(7) $(d_0<0, b_0>0)$ condition satisfied
(8) $(d_0>0, b_0<0)$ condition excluded
C: $d_0^2<1$, $\mathbb{k}=+1$, $0<-b_0-d_0S$
(9) $(d_0>0, b_0>0)$ condition excluded
(10) $(d_0<0, b_0<0)$ condition satisfied
(11) $(d_0>0, b_0<0)$ condition satisfied if $|b_0|>d_0S$
(12) $(d_0<0, b_0>0)$ condition satisfied if $b_0<|d_0|S$
D: $d_0^2<1$, $\mathbb{k}=-1$, $0<-b_0+d_0S$
(13) $(d_0>0, b_0>0)$ condition satisfied if $|b_0|<d_0S$
(14) $(d_0<0, b_0<0)$ condition satisfied if $|b_0|>|d_0|S$
(15) $(d_0<0, b_0>0)$ condition excluded
(16) $(d_0>0, b_0<0)$ condition satisfied
Summary of Condition 2
$d_0^2>1$, $\mathbb{k}=+1$, $(d_0<0, b_0<0)$ is excluded
$d_0^2>1$, $\mathbb{k}=-1$, $(d_0>0, b_0<0)$ is excluded
$d_0^2<1$, $\mathbb{k}=+1$, $(d_0>0, b_0>0)$ is excluded
$d_0^2<1$, $\mathbb{k}=-1$, $(d_0<0, b_0>0)$ is excluded
When the constraints for the two conditions are put together, the cases
$k=+1$, $d_0<0$, $b_0>0$, are eliminated for both $d_0^2>1$ and $d_0^2<1$.
Summary of existing cases after hyperbolic conditions are imposed

$$d_0^2>1:\mathbb{k}=+1 \tag{A2}$$

$$(d_0>0,\ b_0>0)$$

$$(d_0>0,\ b_0<0):\ |d_0b_0|<S,\ \left|\frac{b_0}{d_0}\right|<S$$

$$d_0^2>1:\mathbb{k}=-1 \tag{A3}$$

$$(d_0>0,\ b_0>0):S<|d_0b_0|,\ S<\left|\frac{b_0}{d_0}\right|$$

$$(d_0<0,\ b_0<0):\ S<|d_0b_0|,\ S>\left|\frac{b_0}{d_0}\right|$$

$$d_0^2<1:\mathbb{k}=+1 \tag{A4}$$

$$(d_0>0,\ b_0<0): S<|d_0 b_0|,\ S<\left|\frac{b_0}{d_0}\right|$$

$$d_0^2<1: \mathbb{k}=-1 \tag{A5}$$

$$(d_0>0,\ b_0>0):\ S>|d_0 b_0|,\ S>\left|\frac{b_0}{d_0}\right|$$

$$(d_0<0,\ b_0<0):\ S>|d_0 b_0|,\ S<\left|\frac{b_0}{d_0}\right|$$

$$(d_0>0,\ b_0<0).$$

Now we require the fluid density inside the torus to be positive:

$$8\pi a^2\rho=(b_0/h)[\cosh^2(\eta_0)-\cos^2(\vartheta)]>0.$$

$\cosh(\eta_0)$ will always be greater than 1 since it equals 1 at $\eta=0$, which is outside of the torus interior. In the interior $\eta_0\leqslant\eta\leqslant\infty$. We have

$$\frac{b_0}{d_0\sinh(\eta_0)-b_0}>0,$$

$$\frac{1}{\frac{d_0}{b_0}\sinh(\eta_0)-1}>0,$$

$$\frac{d_0}{b_0}\,\frac{b_0 d_0+\mathbb{k}S}{d_0^2-1}>1.$$

3. $d_0^2>1$

$$d_0^2+\mathbb{k}\frac{d_0}{b_0}S>d_0^2-1$$

$$-\mathbb{k}\frac{d_0}{b_0}S<1$$

$\mathbb{k}=+1$, $(b_0>0,\ d_0>0)$ and $(b_0<0,\ d_0<0)$. No constraints

$\mathbb{k}=-1$, $(b_0>0,\ d_0>0)$ and $(b_0<0,\ d_0<0)$ with constraint $\left|\frac{d_0}{b_0}\right|S<1$

4. $d_0^2<1$

$$-d_0^2-\mathbb{k}\frac{d_0}{b_0}S>1-d_0^2$$

$$-\mathbb{k}\frac{d_0}{b_0}S>1$$

$$\mathbb{k}=+1,\ (b_0<0,\ d_0>0)\ \text{with constraint}\ S>\left|\frac{b_0}{d_0}\right| \tag{A6}$$

$$\mathbb{k}=-1,\ (b_0>0,\ d_0>0)\ \text{and}\ (b_0<0,\ d_0<0)\ \text{with constraint}\ S>\left|\frac{b_0}{d_0}\right|$$

Summarizing all constraints provides

$$d_0^2>1:\mathbb{k}=+1 \tag{A7}$$

$$(d_0>0,\ b_0>0)$$

$$(d_0>0,\ b_0<0):\ |d_0b_0|<S,\ \left|\frac{b_0}{d_0}\right|<S,\ S<\left|\frac{b_0}{d_0}\right|\ \text{is excluded}$$

$$d_0^2>1:\mathbb{k}=-1 \tag{A8}$$

$$(d_0>0,\ b_0>0):S<|d_0b_0|,\ S<\left|\frac{b_0}{d_0}\right|$$

$$(d_0<0,\ b_0<0):\ S<|d_0b_0|,\ S>\left|\frac{b_0}{d_0}\right|,\ S<\left|\frac{b_0}{d_0}\right|\ \text{is excluded}$$

$$d_0^2<1:\mathbb{k}=+1 \tag{A9}$$

$$(d_0>0,\ b_0<0):S<|d_0b_0|,\ S<\left|\frac{b_0}{d_0}\right|,\ S>\left|\frac{b_0}{d_0}\right|\ \text{is excluded}$$

$$d_0^2<1:\mathbb{k}=-1 \tag{A10}$$

$$(d_0>0,\ b_0>0):\ S>|d_0b_0|,\ S>\left|\frac{b_0}{d_0}\right|$$

$$(d_0<0,\ b_0<0):\ S>|d_0b_0|,\ S<\left|\frac{b_0}{d_0}\right|,\ S>\left|\frac{b_0}{d_0}\right|\ \text{is excluded}$$

$$(d_0>0,b_0<0)\ \text{is excluded}$$

The three allowed parameter combinations are

$$d_0^2>1:\mathbb{k}=+1\ \ (d_0>0,\ b_0>0)$$

$$d_0^2>1:\mathbb{k}=-1\ \ (d_0>0,\ b_0>0):S<|d_0b_0|,\ S<\left|\frac{b_0}{d_0}\right|$$

$$d_0^2<1:\mathbb{k}=-1\ \ (d_0>0,\ b_0>0):\ S>|d_0b_0|,\ S>\left|\frac{b_0}{d_0}\right|$$

Prolongation methods and Cartan characters for the three-dimensional Riemann–Lanczos problem

A. Gerber[a)]
Laboratoire de Mathématiques et Physique Théorique, Université de Tours, Parc de Grandmont, 37200 Tours, France

(Received 21 February 2003; accepted 26 March 2003)

The Riemann–Lanczos problem in two dimensions is in involution and its general solution is known. The three-dimensional Riemann–Lanczos problem is not in involution and needs to be prolongated. We write the three-dimensional Riemann–Lanczos problem as an exterior differential system and prolong it to second order. Using algebraic computing we find that we have to add an integrability condition to make it a system in involution. We also suggest a prolongation of the three-dimensional Riemann–Lanczos problem in the same way as Bampi and Caviglia did for four dimensions. After supplementing this three-dimensional system with an integrability condition, it becomes involutive with Cartan characters (17,8,2) or (20,10,3) if no cyclic conditions are imposed. We present the relevant sections of REDUCE computer codes by means of which these results were obtained. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1578181]

I. INTRODUCTION

Apart from the Weyl conformal tensor, which can be expressed by means of a third-order tensor potential, an expression which was first found by Lanczos,[1] we can also express the Riemann tensor using a third-order tensor potential. This third-order tensor potential is usually called the **Lanczos tensor** and its components are denoted by L_{abc}. For the Weyl–Lanczos problem as well as for the Riemann–Lanczos problem the Lanczos tensor components L_{abc} are subject to the following symmetry condition,

$$L_{abc}=L_{[ab]c}, \tag{1}$$

and, sometimes, we also impose the cyclic conditions

$$L_{[abc]}=0. \tag{2}$$

In this paper we confine ourselves to the discussion of the **Riemann-Lanczos equations** which were first published in Ref. 2 as

$$R_{abcd}=L_{abc;d}-L_{abd;c}+L_{cda;b}-L_{cdb;a}. \tag{3}$$

For practical reasons we will often write Eqs. (3) in solved form as

$$f^{(R)}_{abcd}=R_{abcd}-L_{abc;d}+L_{abd;c}-L_{cda;b}+L_{cdb;a} \tag{4}$$

denoted by $f^{(R)}_{abcd}$. If we impose (1) together with (2), we obtain two independent components L_{abc} in two dimensions, eight independent components in three dimensions and 20 independent components L_{abc} in four dimensions. We also have one independent Riemann–Lanczos equation in

a)Electronic mail: agerber@gargan.math.univ-tours.fr, agerber03@yahoo.co.uk

two dimensions, six independent in three dimensions and 20 independent Riemann–Lanczos equations in four dimensions. Unless stated otherwise we will not impose the differential gauge conditions

$$L_{ab}{}^{s}{}_{;s}=0\,. \tag{5}$$

We *never* assume the trace-free gauge conditions

$$L_{a}{}^{s}{}_{s}=0 \tag{6}$$

to hold for the Riemann–Lanczos problem because then we would automatically obtain $R=0$ for the Ricci scalar which leads to inconsistencies.

As explained in Refs. 3 and 4, Eqs. (3) do not form a system in involution in four dimensions and a prolongation is presented there. The work in this article is based on Refs. 3–6 for the Riemann–Lanczos problem as an exterior differential system. First, we are going to present a few results already known for the Riemann–Lanczos problems in two and three dimensions. Then we are going to use the theory of **exterior differential systems (EDS)** and algebraic computing to present two different prolongations for the three-dimensional Riemann–Lanczos problem to make it involutive, and, we compute its **Cartan characters**. Algebraic computing supports the calculations as some can be very cumbersome such as the computation of the Cartan characters. There are programs developed by Wahlquist and Estabrook based on MATEMATICA which compute Cartan characters, and, applications of these programs can be found in Ref. 7. Here, we are going to use the REDUCE package EDS by Hartley[8] and present the relevant sections of computer codes we used in Appendices A, B and C.

II. THE RIEMANN–LANCZOS PROBLEM AS AN EDS

Exterior differential systems (EDS) in general and Cartan characters in particular are discussed in Refs. 9–13. We can express the Riemann–Lanczos problem as an exterior differential system (EDS) as it was done in Ref. 3. We use a first-order jet bundle $\mathcal{J}^1(\mathbb{R}^n,\mathbb{R}^m)$, where n denotes the number of local space–time coordinates and m is the number of independent Lanczos components L_{abc}. Local coordinates are then given by (x^e,L_{abc},P_{abcd}) characterizing a formal manifold $\mathcal{M}$ of dimension $N=n+m+n\cdot m$. The EDS itself is formed by

$$\begin{aligned} df^{(R)}_{abcd}&=d(R_{abcd}-L_{abc;d}+L_{abd;c}-L_{cda;b}+L_{cdb;a}),\\ K_{abc}&=dL_{abc}-P_{abce}dx^e\ , \end{aligned} \tag{7}$$

where sometimes $f^{(R)}_{abcd}=0$ is also assumed, which in subsequent cases does not change any of the results obtained except that it reduces the values of the zeroth Cartan characters s_0 and their reduced counterparts s_0'. The K_{abc} are the **first-order contact conditions** and the P_{abcd} coincide with $P_{abcd}=\partial L_{abc}/\partial x^d$ when projected onto the space–time manifold. Next, we briefly recast the results already known for the Riemann–Lanczos problems in two and in three dimensions. Some of these results were obtained using Janet–Riquier theory[14–16] of which modernized versions can be found in Refs. 17–19.

A. The Riemann–Lanczos problem in two dimensions

The Riemann–Lanczos problem in two dimensions was discussed in Refs. 5 and 6. We choose $(x^1,x^2,L_{121},L_{122},P_{1211},P_{1212},P_{1221},P_{1222})$ as local coordinates on $\mathcal{J}^1(\mathbb{R}^2,\mathbb{R}^2)$ so that the corresponding formal manifold $\mathcal{M}$ is eight-dimensional. We leave the metric tensor components completely arbitrary and obtain the only independent Riemann–Lanczos equation in solved form,

$$f^{(R)}_{1212}=R_{1212}-2P_{1212}+2P_{1221}+2L_{121}(\Gamma^1_{12}-\Gamma^2_{22})-2L_{122}(\Gamma^1_{11}+\Gamma^2_{12})\ , \tag{8}$$

where Γ^a_{bc} are the Christoffel symbols. We can write the Pfaffian system derived from (8) as

$$\theta^1=\alpha_{12121}dx^1+\alpha_{12122}dx^2-2dP_{1212}+2dP_{1221}+2(\Gamma^1_{12}-\Gamma^2_{22})dL_{121}-2(\Gamma^1_{11}+\Gamma^2_{12})dL_{122},$$

$$\theta^2=dL_{121}-P_{1211}dx^1-P_{1212}dx^2\ , \tag{9}$$

$$\theta^3=dL_{122}-P_{1221}dx^1-P_{1222}dx^2\ ,$$

where θ^1 is the exterior derivative of $f^{(R)}_{abcd}$ and the one-forms θ^2,θ^3 are the two contact conditions. The quantity α_{1212e} is given by

$$\alpha_{1212e}=R_{1212,e}-2L_{121}(\Gamma^1_{12,e}-\Gamma^2_{22,e})-2L_{122}(\Gamma^1_{11,e}+\Gamma^2_{12,e}) \tag{10}$$

for $e=1,2$. We obtained the result that the Riemann–Lanczos problem in two dimensions is in involution with Cartan characters $(s_0,s_1,s_2)=(3,2,1)$.[5,6] If the exterior derivative of (5) given by $dL_{12}{}^s_{;s}=0$ is included in (9), the problem remains in involution with Cartan characters $(s_0,s_1,s_2)=(4,2,0)$. These results are confirmed using Janet–Riquier theory.[6]

The general solution to the Riemann–Lanczos problem in two dimensions is known.[5] For a space–time with Lorentzian signature given by

$$ds^2=-e^{2\rho}dx^1dx^2\ ,$$

where ρ is an arbitrary function of x^1 and x^2, the general solution is

$$L_{121}=e^{2\rho}(f_1(x^1)-\tfrac{1}{4}\rho_{,1})\ ,\quad L_{122}=e^{2\rho}(f_2(x^2)+\tfrac{1}{4}\rho_{,2})\ ,$$

where $f_1(x^1),f_2(x^2)$ are two arbitrary functions depending on one local coordinate each. For spaces with Euclidean signature given by

$$ds^2=e^{2\rho}((dx^1)^2+(dx^2)^2)\ ,$$

where ρ is again an arbitrary function of x^1 and x^2, the general solution is

$$L_{121}=e^{2\rho}(f_1(x^1+x^2)-\tfrac{1}{2}\rho_{,2})\ ,\quad L_{122}=e^{2\rho}(f_2(x^1-x^2)+\tfrac{1}{2}\rho_{,1})\ .$$

Both solutions depend on two arbitrary functions of one variable each, a fact which reflects the intrinsic meaning of the highest nonvanishing Cartan character which is in the two above cases $s_1=2$. (Here we also imposed the differential gauge condition $L_{12}{}^s_{;s}=0$. For more details see Ref. 5.)

B. The Riemann–Lanczos problem in three dimensions

In three space–time dimensions with local coordinates x^1, x^2, x^3, we obtain eight independent components of the Lanczos tensor, namely, L_{121}, L_{122}, L_{131}, L_{133}, L_{232}, L_{233}, L_{123}, L_{132} when imposing the cyclic conditions (2). Each of the components has three first-order partial derivatives so that we use the jet bundle $\mathcal{J}^1(\mathbb{R}^3,\mathbb{R}^8)$ with formal dimension $N=3+8+24=35$ to express the EDS. There are six independent Riemann–Lanczos equations whose exterior derivatives are $df^{(R)}_{1212}$, $df^{(R)}_{1313}$, $df^{(R)}_{2323}$, $df^{(R)}_{1213}$, $df^{(R)}_{1223}$, $df^{(R)}_{1323}$ and eight contact conditions K_{abc}. In this way, we obtain for the zeroth Cartan character and its reduced counterpart $s_0=s_0'=6+8=14$. Using the above local coordinates the EDS is then again of the form (7). It is sufficient to consider line elements with diagonalized metric tensor because of Ref. 20.

As discussed in detail in Ref. 6 an identity occurs so that for the second Cartan character $s_2=s_2'+1$ leading to $s_2'=7$ and to $s_2=8$. This means that the necessary condition for a system to be in involution requiring that each Cartan character coincides with its reduced counterpart[9,10,13] is not fulfilled and the three-dimensional Riemann–Lanczos problem is not in involution and its reduced characters (s_0',s_1',s_2',s_3') are (14,8,7,3). This result was confirmed with the REDUCE code given in Appendix A.

We also used Janet–Riquier theory to examine the three-dimensional Riemann–Lanczos problem further. After a prolongation to second order we found that the *integrability condition I*, given in solved form as

$$I = f^{(R)}_{1212,33} + f^{(R)}_{1313,22} + f^{(R)}_{2323,11} - 2\, f^{(R)}_{1323,12} - 2\, f^{(R)}_{1213,23} + 2\, f^{(R)}_{1223,13}, \tag{11}$$

had to be added so that the new prolonged system is given by

$$0 = f^{(R)}_{abcd}, \quad 0 = f^{(R)}_{abcd,e}, \quad 0 = I\ . \tag{12}$$

In Ref. 5 it is shown in detail that the system (12) consists of a system in involution with Cartan characters (18,9,2) when (2) is also imposed. There, the integrability condition (11) is also expressed in a better form respecting general covariance, namely, as I_{Cov}:

$$\begin{aligned} I_{Cov} &= 2(f^{(R)}_{1212;(33)} + f^{(R)}_{1313;(22)} + f^{(R)}_{2323;(11)} - f^{(R)}_{1323;(12)} - f^{(R)}_{1213;(23)} + f^{(R)}_{1223;(13)}) \\ &= B_{12123;3} + B_{13132;2} + B_{23231;1} = 0\ , \end{aligned} \tag{13}$$

where the B_{abcde} are $B_{abcde} = f^{(R)}_{ab[cd;e]}$, which reduce to the Bianchi identities for the R_{abcd} involved. The covariantly prolonged system, where we add the covariant derivatives instead of the partial derivatives, is then given by

$$0 = f^{(R)}_{abcd}, \quad 0 = f^{(R)}_{abcd;e}, \quad 0 = I_{Cov}\ . \tag{14}$$

This also forms a system in involution again with Cartan characters (18,9,2),[5] and we prefer it to (12) because it is based on covariant differentiation rather than partial differentiation. Next, we are going to present two different prolongation methods based on the theory of exterior differential systems (EDS) which will lead to the same result.

III. A PROLONGATION USING EDS AND JET BUNDLES

In this section we show that we can use computer algebra to express the systems (12) and (14) as EDS and obtain results in agreement with those for the three-dimensional Riemann–Lanczos problem based on Janet–Riquier theory. We introduce S_{abcde} as second-order jet coordinates so that our local coordinates are now given by $(x^e, L_{abc}, P_{abcd}, S_{abcde})$ on a jet bundle $\mathcal{J}^2(\mathbb{R}^3, \mathbb{R}^8)$ with formal dimension $N = 3 + 8 + 24 + 48 = 83$. Again, we obtain $P_{abcd} = \partial L_{abc}/\partial x^d$ and $S_{abcde} = \partial^2 L_{abc}/\partial x^d \partial x^e$ if P_{abcd} and S_{abcde} are projected onto the space–time manifold. The prolonged system is then given by

$$\begin{aligned} f^{(R)}_{abcd} &= R_{abcd} - L_{abc;d} + L_{abd;c} - L_{cda;b} + L_{cdb;a}\ , \\ K_{abc} &= dL_{abc} - P_{abce} dx^e, \quad K_{abcd} = dP_{abcd} - S_{abcde} dx^e\ , \end{aligned} \tag{15}$$

where K_{abcd} are the **second-order contact conditions**. When applying a computer code of which extracts are given in Appendix B, combined with the one in Appendix A to this system, we find that (15) is clearly *not in involution* with reduced Cartan characters (s'_1, s'_2, s'_3) given by (18,9,3) with (2) imposed and given by (21,11,4) otherwise. However, if we add either of the conditions I_{Cov} or I, respectively, and augment (15) to the system

$$\begin{aligned} I_{Cov} &= B_{12123;3} + B_{13132;2} + B_{23231;1} \qquad (\text{or } I), \\ f^{(R)}_{abcd} &= R_{abcd} - L_{abc;d} + L_{abd;c} - L_{cda;b} + L_{cdb;a}\ , \\ f^{(R)}_{abcd;e} &= R_{abcd;e} - L_{abc;de} + L_{abd;ce} - L_{cda;be} + L_{cdb;ae} \quad (\text{or } f^{(R)}_{abcd,e}), \\ K_{abc} &= dL_{abc} - P_{abce} dx^e, \end{aligned} \tag{16}$$

$$K_{abcd}=dP_{abcd}-S_{abcde}dx^e\ ,$$

the system (16) turns out to be in involution with its set of Cartan characters (s_1,s_2,s_3) being (17,8,2) if (2) is imposed or (20,10,3) if no cyclic conditions are imposed. These results were obtained using computer codes of which details are given in the Appendixes A and B. We could derive the results for all metrics of the form

$$ds^2=(dx^1)^2-b\cdot(dx^2)^2-c\cdot(dx^3)^2\ , \tag{17}$$

where the functions b and c depend on one local coordinate each, or where either or both were precisely given in terms of local coordinates. Further, the results were also obtained for some space–times typically given with nondiagonal line element such as the reduced Gödel space–time. The restrictions of the results are due to limited memory available for computing. We believe that when the use of memory is economized further, we will be able to generalize these results to all three-dimensional spacetimes.

There is a reason why we do not obtain the Cartan characters (18,9,2), as we did when using Janet–Riquier theory, when we apply the theory of exterior differential systems. If we look at the system (15), we obtain its reduced characters to be (18,9,3) and that the system is not in involution. Using the integrability condition I_{Cov} (or I), we can express one of the S_{abcde} in terms of the other such second-order jet variables plus lower-order terms. We then build our integral elements for the system (16) which are our tangent spaces of an integral manifold representing a solution to our system of equations (for details see Refs. 9–13). When we construct the first **integral element** $(E^1)_x$ at a point $x\in\mathcal{M}$, we express one of the dS_{abcde} through the others which causes the value of the first reduced Cartan character s_1' to drop by one from 18 to $s_1'=17$. The same procedure applies at the second stage for a two-dimensional integral element $(E^2)_x$ so that $s_2'=8$, and, at the third stage for a three-dimensional integral element $(E^3)_x$ we have $s_3'=2$. Because the system (16) is involutive, which we could show for all spacetimes of type (17) using algebraic computing, these are equally the values for the Cartan characters themselves. Therefore, we obtain for the Cartan characters (17,8,2) with (2) imposed or (20,10,3) otherwise when we use the theory of EDS. This does not contradict the values obtained in Ref. 5 based on Janet–Riquier theory. The above results for the Cartan characters and for involutivity were computed using computer codes based on extracts of a code given in Appendix B added to a modified version of that in Appendix A for metric line elements as explained above based on (17). Next, we will examine whether the same kind of prolongation as suggested in Ref. 4 for four dimensions does lead to an involutive system in three dimensions.

IV. A PROLONGATION BASED ON TENSOR DECOMPOSITIONS

It is instructive to look at a prolongation for the Riemann–Lanczos problem in three dimensions constructed in the same way as Bampi and Caviglia did in Ref. 4 for four dimensions and to see whether this leads to an involutive system in three dimensions. We are going to use the local coordinates (x^a,L_{abc},P_{abcd}) again but not the S_{abcde} in this approach. In order to obtain a complete coframe with $N=3+8+24=35$ elements [or $N=3+9+27=39$ if we do not impose the cyclic conditions (2)] and from that to obtain further coordinates, we introduce the 18 new one-forms [or 21 if (2) is not imposed]

$$\omega_{abcd}=dP_{abcd}-dP_{\{abcd\}}=(\overline{\omega}_{abcde}+\hat{\omega}_{abcde})dx^e\ , \tag{18}$$

where the brackets $\{abcd\}$ indicate a Riemann-type symmetry imposed on the indices $abcd$.[3] The quantities $\overline{\omega}_{abcde}$ and $\hat{\omega}_{abcde}$ have the same symmetry conditions as in Ref. 4 only here for three dimensions, namely,

$$\begin{aligned}\overline{\omega}_{abcde}&=\overline{\omega}_{[ab][cd]e}=-\overline{\omega}_{cdabe}\,,\\ \hat{\omega}_{abcde}&=\hat{\omega}_{[ab](cd)e}\,.\end{aligned} \tag{19}$$

Even though we are not going to use the S_{abcde}, which correspond to the second-order partial derivatives $S_{abcde}=\partial^2 L_{abc}/\partial x^d \partial x^e$ when projected onto the spacetime manifold, it has to hold

$$S_{abc[de]}=\overline{\omega}_{abc[de]}+\hat{\omega}_{abc[de]}+A_{abc[de]}=0\,,$$

where the quantity $A_{abcde}=A_{\{abcd\}e}$ is given by

$$A_{abcde}=\frac{1}{4}\left(\frac{\partial f^{(R)}_{abcd}}{\partial x^e}-S_{abcde}+S_{abdce}-S_{cdabe}+S_{cdbae}\right)\,, \tag{20}$$

and does no longer contain any terms involving S_{abcde}. Now, we add the $\overline{\omega}_{abcde}$ and $\hat{\omega}_{abcde}$ as new coordinates of a formal manifold $\mathcal{M}$ with local coordinates $(x^e, L_{abc}, P_{abcd}, \overline{\omega}_{abcde}, \hat{\omega}_{abcde})$ of formal dimension $N=3+9+27+63=102$ without the cyclic conditions and $N=3+8+24+54=89$ when taking the cyclic conditions (2) into account. Our prolonged EDS in three dimensions using this prolongation method is then given by

$$\begin{aligned}
f^{(R)}_{abcd}&=R_{abcd}-L_{abc;d}+L_{abd;c}-L_{cda;b}+L_{cdb;a}\,,\\
\mathcal{W}_{abcde}&=\overline{\omega}_{abc[de]}+\hat{\omega}_{abc[de]}+A_{abc[de]}\,,\\
K_{abc}&=dL_{abc}-P_{abce}dx^e,\\
K_{abcd}&=dP_{abcd}-(\overline{\omega}_{abcde}+\hat{\omega}_{abcde}+A_{abcde})dx^e,\\
d\mathcal{W}_{abcde}&=d\overline{\omega}_{abc[de]}+d\hat{\omega}_{abc[de]}+B_{abc[de]f}dx^f\,,
\end{aligned} \tag{21}$$

where $dA_{abcde}=B_{abc[de]f}dx^f$ and $B_{abcdef}=B_{abcd(ef)}=B_{\{abcd\}ef}$ for the same reasons as discussed in Ref. 4, and K_{abcd} are the one-forms corresponding to the second-order contact conditions expressed in terms of the variables $\overline{\omega}_{abcde}$ and $\hat{\omega}_{abcde}$. Using a computer code producing the system (21) of which details are given in Appendix C below, we see that the system (21) is clearly *not in involution* with reduced characters (18,9,3) if (2) is imposed or (21,11,4) if (2) is not imposed. Using the commands *torsion* and *prolong* from the EDS package,[8] which suggests prolongations wherever possible, we see that an integrability condition has to be added to (21) in order to make it an involutive system. After some calculations and further algebraic computations, we find that we have to add *precisely* I_{Cov} given in (13) [or I given in (11) also possible] again, which is *the same integrability condition* as for the EDS before and also the one obtained by Janet–Riquier theory. The new augmented system is now given by

$$\begin{aligned}
I_{Cov}&=B_{12123;3}+B_{13132;2}+B_{23231;1}\qquad(\text{or } I),\\
f^{(R)}_{abcd}&=R_{abcd}-L_{abc;d}+L_{abd;c}-L_{cda;b}+L_{cdb;a}\,,\\
\mathcal{W}_{abcde}&=\overline{\omega}_{abc[de]}+\hat{\omega}_{abc[de]}+A_{abc[de]}\,,\\
K_{abc}&=dL_{abc}-P_{abce}dx^e,\\
K_{abcd}&=dP_{abcd}-(\overline{\omega}_{abcde}+\hat{\omega}_{abcde}+A_{abcde})dx^e,\\
d\mathcal{W}_{abcde}&=d\overline{\omega}_{abc[de]}+d\hat{\omega}_{abc[de]}+B_{abc[de]f}dx^f\,.
\end{aligned} \tag{22}$$

We find that the system (22) is involutive with Cartan characters (17,8,2) if we impose the cyclic conditions (2) and with Cartan characters (20,10,3) otherwise. Again, these results were obtained for metrics of the form (17) and the results were computed using computer codes based on those

given in Appendixes A and C. We conclude that in three dimensions it is not sufficient to simply prolong the Riemann–Lanczos problem to a second-order system but we must also add the integrability condition $ICov$ (or I) to make it a system in involution.

V. CONCLUSION

As opposed to two dimensions, in three dimensions the Riemann–Lanczos problem is not in involution and we showed that when we prolongate it to second order using the theory of exterior differential systems and add the integrability condition $ICov$ (or I), it turns into an involutive system with Cartan characters (17,8,2) with cyclic conditions imposed or with characters (20,10,3) when no cyclic conditions are imposed. This confirms a result given in Ref. 5, where Janet–Riquier theory was used.

When we use the prolongation method by Bampi and Caviglia[4] applied to three dimensions, we find that this prolonged system is clearly not in involution in three dimensions. However, after supplementing it with the *same integrability condition* $ICov$ (or I), it becomes involutive and its Cartan characters are again (17,8,2) with (2) imposed or (20,10,3) otherwise. The above results were obtained for space–times which admit metric line elements of type (17) using algebraic computing based on the REDUCE package EDS. It is of interest to improve the efficiency of the computer codes further so that we can obtain the above results for all three-dimensional space–times using algebraic computing.

APPENDIX A: EDS AND COMPUTER ALGEBRA

The REDUCE package EDS by D. Hartley[8] is a very reliable algebraic computing package when one wants to calculate properties of EDS. In Ref. 8 important commands such as **eds**, **contact**, **pde2eds**, **pullback**, **lift**, **restrict**, **characters**, **involution**, **torsion**, and **prolong** are explained in detail. They and further available commands perform all important calculations for exterior differential systems efficiently.

The computer code, which creates the unprolonged Riemann–Lanczos equations in three dimensions, is given next, where a version for four dimensions can be found in Ref. 6. We use the package EXCALC here first to create the differential forms for the exterior differential system used later on because some of the jet variables below do contain nontensorial indices. The package EDS uses the contravariant components of quantities in all expressions whereas EXCALC uses covariant components (see Ref. 21 for details on REDUCE packages). After that we use the package EDS to calculate properties of our exterior differential system so created. First, we introduce the notation used in the computer codes below, where all indices run over the three space–time dimensions denoted by t, x, y here.

This produces the result that the Riemann–Lanczos problem in three dimensions is not in involution with reduced characters (18,9,3) if the cyclic conditions are imposed or (21,11,4) if they are not imposed.

APPENDIX B: THE PROLONGED RIEMANN–LANCZOS PROBLEM USING JET BUNDLES

Here, we give the important sections of a computer code producing the prolonged EDS including the integrability condition $ICov$ (or I) as discussed in Sec. III. This part has to be combined with the code given in Appendix A omitting part (*) and part (**). Here, we use the further notation:

f4(-a,-b,-c,-d,-e), f7(-a,-b,-c,-d,-e,-f)	1st and 2nd-order partial derivatives of Riemann-Lanczos equations,
m1(-a,-b,-c,-d,-e), m2(-a,-b,-c,-d,-e,-f)	1st and 2nd-order covariant derivatives of Riemann-Lanczos equations,
w5(-a,-b,-c,-d),w6(-a,-b,-c,-d,-e)	2nd and 3rd-order contact conditions.

```
%Impose cyclic conditions for S(-x,-y,-t,-a,-b) and
%V(-x,-y,-t,-a,-b,-c) if they were imposed before.
```

```
%In dLtoP, dPtoS, dStoV below, replacements are made for all
%components L, P, S listed separately, which is abbreviated here:

The algebraic entropy of classical mechanics[a)]

Robert I. McLachlan and Brett Ryland[b)]
Institute of Fundamental Sciences, Massey University, Palmerston North, New Zealand

(Received 14 October 2002; accepted 3 March 2003)

We describe the ''Lie algebra of classical mechanics,'' modelled on the Lie algebra generated by kinetic and potential energy of a simple mechanical system with respect to the canonical Poisson bracket. It is a polynomially graded Lie algebra, a class we introduce. We describe these Lie algebras, give an algorithm to calculate the dimensions c_n of the homogeneous subspaces of the Lie algebra of classical mechanics, and determine the value of its entropy $\lim_{n\to\infty} c_n^{1/n}$. It is $1.825\,423\,774\,201\,08\ldots$, a fundamental constant associated with classical mechanics. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1576904]

I. INTRODUCTION. CLASSES OF LIE ALGEBRAS

The class of 'simple mechanical systems' is defined by pairs (Q,V), where the configuration space Q is a real Riemannian manifold and the potential energy V is a smooth real function on Q. The phase space T^*Q has a canonical Poisson bracket and a kinetic energy $T:T^*Q\to\mathbb{R}$ associated with the metric on Q. In general, the smooth functions on a Poisson manifold form a Lie algebra under the Poisson bracket. In the case of a simple mechanical system, we are given two distinguished functions, namely the kinetic and potential energies, and one can ask what Lie algebra they generate under the Poisson bracket.

In this paper we study, not the Lie algebra generated by a *particular* V and T, but the Lie algebra defined by the whole *class* of simple mechanical systems. That is, one should think of the dimension of Q as being arbitrarily large, and the metric and potential energies also being arbitrary.

This question arose out of very practical considerations of the calculations required to derive high-order symplectic integrators by splitting and composition, used in applications including molecular, celestial, and accelerator dynamics.[17,10] The vector field X which is to be integrated is split as $X=A+B$, where A and B have the same properties (e.g., Hamiltonian) as X, but can be integrated exactly. We write $\exp(tX)$ for the time-t flow of X. The most common such integrator is the leap-frog method

$$\varphi(\tau):=\exp(\tfrac{1}{2}\tau A)\exp(\tau B)\exp(\tfrac{1}{2}\tau A),$$

where the small parameter τ is the time step.

From the Baker–Campbell–Hausdorff formula,[7] the map $\varphi(\tau)$ can be represented (up to any power in τ) as a flow $\exp(\tau\tilde{X})$, where

$$\tilde{X}=A+B+\tau^2(\tfrac{1}{12}[B,[B,A]]-\tfrac{1}{24}[A,[A,B]])+\mathcal{O}(\tau^4). \tag{1}$$

Because it is the flow of a vector field $\mathcal{O}(\tau^2)$-close to the original one, the integrator is second order. The function $\tilde{X}$ is called the *modified vector field* in the numerical integration literature.[10]

For simple mechanical systems, we split the Hamiltonian as $H=T+V$. The flow of (the Hamiltonian vector field of) V can of course always be calculated easily, but calculating the flow

[a)]Dedicated to Gerhard Wanner on the occasion of his 60th birthday. Of trees and the counting of trees, may there be no end!

[b)]Electronic mail: r.mclachlan@massey.ac.nz

of the kinetic energy T requires that Q have integrable (and even fairly simple) geodesics. Because the Lie algebras of Hamiltonian vector fields and of Hamiltonian functions are isomorphic under $[X_T, X_V] = X_{\{V,T\}}$, there is a series formally identical to Eq. (1) involving the Hamiltonians T and V with respect to the Poisson bracket.

In the series of Eq. (1) we see the Lie algebra generated by A and B entering. Such series, for example in the proof of the BCH formula, are usually considered in the context of the free Lie algebra $L(A,B)$ with two generators A and B. One can in fact consider the more general composition

$$\prod_{i=1}^{s} \exp(a_i \tau A) \exp(b_i \tau B) = \exp(Z), \tag{2}$$

where $Z \in L(A,B)$. Requiring $Z = \tau(A+B) + O(\tau^{p+1})$ for some integer $p > 1$ gives a system of equations in the a_i and b_i which must be satisfied for the method to have order p.[17,24] In the case of general A and B, then, at each order $n = 1, \ldots, p$ there are $\dim L_n(A,B)$ such *order conditions*. Here $L_n(A,B)$ is the subspace of $L(A,B)$ consisting of homogeneous elements of order n. Witt's formula[7] states that

$$\dim L_n(A,B) = \frac{1}{n} \sum_{d|n} \mu(d) 2^{n/d}, \tag{3}$$

where $\mu(d)$ is the Möbius function defined by $\mu(1) = 1$, $\mu(d) = (-1)^k$ if d is the product of k distinct primes, and $\mu(d) = 0$ otherwise. Notice that in this case

$$\dim L_n(A,B) \sim \frac{2^n}{n};$$

the dimensions grow exponentially with n. The base (2 in this case) of the exponent is called the *entropy* of $L(A,B)$. In general, the entropy of a graded vector space $\bigoplus L_n$ is

$$\limsup_{n \to \infty} (\dim L_n)^{1/n},$$

if this limit exists.[21] [We shall use generalizations of Witt's formula[12,19] to calculate the dimensions and entropies of other free Lie algebras, see Eqs. (15), (17) below.]

In this approach it is assumed that there are no Lie identities satisfied by the vector fields A and B. This is reasonable if one wants the method to work for all A and B. However, in the case of simple mechanical systems, the Lie algebra is *never* free, regardless of T, V, or the dimension of the system. There are always identities satisfied by kinetic and potential energy. The simplest of these is

$$\{V, \{V, \{V, T\}\}\} \equiv 0. \tag{4}$$

For, working in local coordinates (q,p) with $T = \frac{1}{2} p^T M(q) p$, and recalling the canonical Poisson bracket

$$\{A,B\} := \sum_i \frac{\partial A}{\partial q_i} \frac{\partial B}{\partial p_i} - \frac{\partial A}{\partial p_i} \frac{\partial B}{\partial q_i},$$

we have that

$$\{V,T\} = \sum_{i,j} \frac{\partial V}{\partial q_i} M_{ij}(q) p_j$$

is of degree 1 in p, and that

$$\{V,\{V,T\}\}=\sum_{i,j}\frac{\partial V}{\partial q_i}M_{ij}\frac{\partial V}{\partial q_j} \tag{5}$$

is a function of q only. So V and $\{V,\{V,T\}\}$ commute.

Thus, it was realized early on[16] that in deriving high-order integrators as in Eq. (2) for simple mechanical systems, the order conditions corresponding to $\{V,\{V,\{V,T\}\}\}$ and to all its higher Lie brackets can be dropped. This means that more efficient integrators can be designed for this class of systems. Much work has been done on this special case, both because of its intrinsic theoretical and practical importance, and because it allows such big improvements over the general case. For example, one can design special (corrector or processor) methods of the form $\varphi\psi\varphi^{-1}$,[3] special methods for nearly integrable systems such as the solar system,[4,23] special methods involving exact evaluation of the forces associated with the modified potential [Eq. (5)],[5] and so on—see Ref. 17 for a survey. All of these studies rely on the structure of the Lie algebra generated by kinetic and potential energy. Bases for this Lie algebra have been constructed, more or less by hand, for small orders.[5,6,20] In particular, Murua[20] associates a unique tree of a certain type to each independent order condition of symplectic Runge–Kutta–Nyström methods (very closely related to the problem considered here), and enumerates these up to order 6. (Iserles *et al.*[11] extend this approach to some other classes of polynomial vector fields.) However, a systematic description of the entire Lie algebra is clearly preferred.[18]

Not many classes of Lie algebras have been completely described. Here are two examples from the literature. First, Duchamp and Krob[9] completely describe all partially-commutative Lie algebras

$$L(A_1,\ldots,A_n;[A_i,A_j]=0,(i,j)\in C),$$

where C specifies the pairs of commuting variables. Second, Kirillov, Kontsevich, and Molev[13] studied the Lie algebra L generated by two vector fields on $\mathbb{R}$ in general position, conjectured that

$$\sum_{\sigma\in S_4}(-1)^{\mathrm{sgn}(\sigma)}[x_{\sigma(1)},x_{\sigma(2)},x_{\sigma(3)},x_{\sigma(4)},y]=0 \quad \forall x_1,x_2,x_3,x_4,y\in L \tag{6}$$

generates all identities, and calculated the dimensions of its homogeneous subspaces and the asymptotic growth of their dimension. If their conjecture is true, L is a *PI-algebra*,[2,8] one which the identities which hold in the Lie algebra [such as Eq. (6)] are satisfied by *all* elements of the Lie algebra.

Returning to the case of simple mechanical systems, it is clear that every Lie bracket of T and V is a homogeneous polynomial in p. Furthermore, the degrees of these polynomials combine in a natural way. We therefore introduce the following class $\mathfrak{P}$ of Lie algebras.

We use the notation $[XY]:=[X,Y]$, $[XYZ]:=[X,[Y,Z]]$, and for sets $\mathfrak{X}$, $\mathcal{Y}$, $[\mathfrak{X}\mathcal{Y}]:=[\mathfrak{X},\mathcal{Y}]$ $:=\{[X,Y]:X\in\mathfrak{X},Y\in\mathcal{Y}\}$.

Definition 1: A Lie algebra L is of class $\mathfrak{P}$ (polynomially graded) if it is graded, i.e., $L=\bigoplus_{n\geqslant 0}L_n$, and its homogeneous subspaces L_n satisfy

$$[L_n,L_m]\subseteq L_{n+m-1} \text{ if } n>0 \text{ or } m>0,$$
$$[L_0,L_0]=0. \tag{7}$$

Note that this implies $[(L_0)^{n+1}L_n]=0$ for all n. We call the grading of L its grading by degree.

For example, the Lie algebra generated by kinetic and potential energy is of class $\mathfrak{P}$, where the grading is by total degree in p. The Lie algebra of all polynomial vector fields on a linear space is of class $\mathfrak{P}$, where the grading is by total degree. We will give more examples later.

Such a grading is quite different from the natural grading of a free Lie algebra. Two important differences are that (i) It is not Abelian. For, $[L_2,[L_0,L_0]]=0$ while $[L_0,[L_0,L_2]]\subseteq L_0$. (ii) It is not finite, in the sense that elements of L_n are Lie brackets of unboundedly many other elements of L. For example, the bracket of any number of elements of degree 1 is still of degree 1.

We also need the concept of a Lie algebra which is free in a certain class.

Definition 2 (Ref. 8): Let F be a Lie algebra of class $\mathfrak{P}$ generated by a set $\mathfrak{X}$. Then F is called a free Lie algebra in the class $\mathfrak{P}$, freely generated by the set $\mathfrak{X}$, if for any Lie algebra R of class $\mathfrak{P}$, every mapping $\mathfrak{X}\to R$ can be extended to a unique homomorphism $F\to R$. We write $F=L_{\mathfrak{P}}(\mathfrak{X})$.

In addition to the grading by degree, $L_{\mathfrak{P}}(\mathfrak{X})$ also carries the standard grading which we call the grading by *order*, generated by $\mathrm{order}(X)=1$ for all generators $X\in\mathfrak{X}$ and $\mathrm{order}([Y,Z])=\mathrm{order}(Y)+\mathrm{order}(Z)$. [The term *order* is chosen here because it corresponds to order in the sense of numerical integrators, as in Eq. (1).]

Because of the importance of the grading by degree for Lie algebras generated by kinetic and potential energy, we make the following definition.

Definition 3: The Lie algebra $L_{\mathfrak{P}}(A,B)$, free in the class $\mathfrak{P}$, where A has degree 2 and B has degree 0, is called the Lie algebra of classical mechanics.

Two Lie algebras of class $\mathfrak{P}$ are easy to describe. First, the Lie algebra with k generators of degree $\geqslant 1$ which is free in the class $\mathfrak{P}$ is just the standard free Lie algebra on k generators—the degrees can never decrease if the Lie algebra has no elements of degree 0. Second, the Lie algebra with generators $\mathfrak{X}=\{X_1,\ldots,X_k\}$ of degree 0 and generators $\mathcal{Y}=\{Y_1,\ldots,Y_l\}$ of degree 1, free in the class $\mathfrak{P}$, is $\mathcal{Y}\oplus\bigoplus_{n\geqslant 0}[\mathcal{Y}^n\mathfrak{X}]$, and only contains elements of degree 0 and 1. (In both of these cases, the grading by degree is in fact Abelian.)

However, we want to describe the Lie algebra of classical mechanics, $L_{\mathfrak{P}}(A,B)$. This is the simplest nontrivial case as it includes the essential feature of $\mathfrak{P}$ that degrees can both increase and decrease under Lie brackets.

The paper is organized as follows. In Sec. II, we give a construction which describes $L_{\mathfrak{P}}(A,B)$ as the direct sum of an Abelian and a free Lie algebra, both with an infinite number of generators. In Sec. III, we enumerate the dimensions of the homogeneous (by order) components of $L_{\mathfrak{P}}(A,B)$ and hence in Sec. IV numerically compute its entropy. Section V considers special cases (e.g., of mechanical systems with Euclidean metric; these turn out not to be free in the class $\mathfrak{P}$) and other examples of polynomially graded Lie algebras.

II. STRUCTURE OF THE LIE ALGEBRA OF CLASSICAL MECHANICS

Let $\psi: L(A,B)\to L_{\mathfrak{P}}(A,B)$ be the unique homomorphism from the free Lie algebra to the free Lie algebra of class $\mathfrak{P}$. The kernel $\ker\psi$ can be thought of as the set of identities of $L_{\mathfrak{P}}(A,B)$. For example, we showed above [Eq. (4)] that $[BBBA]\in\ker\psi$. This implies that $[CBBBA]\in\ker\psi$ for all $C\in L(A,B)$. However, we will see below that $[BBBA]$ is not the only generator of the ideal $\ker\psi$.

Our description of $L_{\mathfrak{P}}(A,B)$ is based on the following two observations. First, suppose one wants to describe the Lie algebra with three generators A,B,C which is free in the class of Lie algebras with $C=0$. Since C generates all identities in this class, this Lie algebra is just $L(A,B)$: one merely has to drop the generator C. To generalize this idea, suppose the free Lie algebra $L(A,B)$ can be factored as $\bigoplus_i L(\mathfrak{X}_i)$ for certain generating sets $\mathfrak{X}_i$ with elements in $L(A,B)$, such that some subset $\mathcal{Y}$ of $\cup_i\mathfrak{X}_i$ generates all the identities in $\mathfrak{P}$. Then, we have

$$L_{\mathfrak{P}}(A,B)\cong\bigoplus_i L(\mathfrak{X}_i\backslash(\mathcal{Y}\cap\mathfrak{X}_i)), \tag{8}$$

again we merely drop these generators.

If $\mathcal{Y}$ only generates *some* of the identities of $\mathfrak{P}$, then dropping these generators gives a sum of free Lie algebras which is surjectively homomorphic to $L_{\mathfrak{P}}(A,B)$. This can be used to get upper bounds for the dimensions of the homogeneous subspaces of $L_{\mathfrak{P}}(A,B)$.

Second, given a description of $L_{\mathfrak{P}}(A,B)$ as such a sum [Eq. (8)] of free Lie algebras, we can apply standard techniques to describe it in detail, for example, to construct bases, to compute its dimensions with respect to degree and/or order, and to compute the asymptotic growth of these dimensions.

We begin by stating the crucial tool we shall use, the Lazard factorization of free Lie algebras.

Theorem 1: (Refs. 14, 7, 15) *Let $\mathfrak{X}$ and $\mathcal{Y}$ be sets of generators. Then*

$$L(\mathfrak{X}\cup\mathcal{Y})\cong L(\mathcal{Y})\oplus L(\cup_{n\geqslant 0}[\mathcal{Y}^n\mathfrak{X}]).$$

Applying the Lazard factorization to $L(A,B)$ with $\mathfrak{X}=\{A\}$, $\mathcal{Y}=\{B\}$, gives

$$L(A,B)\cong B\oplus L(A,[BA],[BBA],[BBBA],\dots)$$

where the elements $[B^nA]$ for $n\geqslant 3$ are all identities in $\mathfrak{P}$. Thus, $L_{\mathfrak{P}}(A,B)$ is surjectively homomorphic to $B\oplus L(A,[BA],[BBA])$. The three generators have degrees 2 (A), 1 ($[BA]$), and 0 ($[BBA]$). The idea now is to eliminate this new element of degree 0. (Formally, the generators $[B^nA]$, $n\geqslant 3$, do remain in the generating set; but they and all succeeding Lie brackets of them will be dropped at the final stage when we pass to $L_{\mathfrak{P}}(A,B)$, so we do not need to keep track of them and just indicate them by $*$.) This gives

$$\begin{aligned}L(A,B)&\cong B\oplus L(A,[BA],[BBA],*)\\&\cong B\oplus[BBA]\oplus L(A,[BA],[BBA,A],[BBA,BA],[BBA,BBA,A]),*),\end{aligned}$$

where the generators now have degrees 2, 1, 1, 0, and 0, respectively. Continuing in this way we get the following.

Theorem 2: *Let the degree of A be 2 and the degree of B be 0 with respect to the polynomial grading [Eq. (7)]. Then for all $k\geqslant 0$ we have the following isomorphism*:

$$L(A,B)\cong\mathcal{Z}_k\oplus L(A,\mathfrak{X}_k,\mathcal{Y}_k,*),$$

where

$$\begin{gathered}\mathfrak{X}_0=\varnothing,\quad \mathfrak{X}_{k+1}=\mathfrak{X}_k\cup[\mathcal{Y}_k,A],\\ \mathcal{Y}_0=\{B\},\quad \mathcal{Y}_{k+1}=[\mathcal{Y}_k,\mathfrak{X}_k]\cup[\mathcal{Y}_k,\mathcal{Y}_k,A]=[\mathcal{Y}_k,\mathfrak{X}_{k+1}],\\ \mathcal{Z}_0=\varnothing,\quad \mathcal{Z}_{k+1}=\mathcal{Z}_k\cup\mathcal{Y}_k,\end{gathered}\tag{9}$$

and $*$ represents generators which are zero in $\mathfrak{P}$, i.e., elements of the kernel of the homomorphism $L(A,B)\to L_{\mathfrak{P}}(A,B)$. The generating sets have the following properties.

(1) All elements of $\mathcal{Y}_k$ and $\mathcal{Z}_k$ have degree 0, and all elements of $\mathfrak{X}_k$ have degree 1.
(2) The Lie algebra spanned by $\mathcal{Z}_k$ is Abelian.
(3) $\mathfrak{X}_k=[\mathcal{Z}_k,A]$.
(4) All elements of $\mathcal{Y}_k$ and $\mathcal{Z}_k$ have odd order, and all elements of $\mathfrak{X}_k$ have even order.
(5) The element of smallest order in $\mathcal{Y}_k$ is $(-1)^k[[BA]^kB]$, with order $2k+1$.
(6) The element of largest order in $\mathcal{Y}_k$ is B_k, defined recursively by $B_0=B$, $B_{k+1}=[B_k,[B_k,A]]$. It has order $2^{k+1}-1$.
(7) The finite sets $\mathfrak{X}_k$ and $\mathcal{Z}_k$ converge to infinite sets $\mathcal{Z}$ and $\mathfrak{X}=[\mathcal{Z},A]$ in the sense that the sets

$$\{X{:}X\in\mathfrak{X}_k,\text{order}(X)\leqslant n\}$$

are all equal for $k\geqslant n/2$. We have

$$L(A,B)\cong\mathcal{Z}\oplus L(A,\mathfrak{X},*)$$

and

$$L_{\mathfrak{P}}(A,B)\cong\mathcal{Z}\oplus L(A,\mathfrak{X}).\tag{10}$$

TABLE I. Elements of degree 0 and order $\leqslant 11$ (i.e., functions of q only or modified potentials of simple mechanical systems) appearing at iteration k of Eq. (9). The new elements are numbered consecutively $Z_1, Z_2, \ldots$ The degree 1 elements $X_n := [Z_n, A]$ also appear.

k	$\mathcal{Y}_k$	Order
1	$Z_1 = B$	1
2	$Z_2 = [Z_1, X_1]$ $(= [BBA])$	3
3	$Z_3 = [Z_2, X_1]$ $(= [BBA, BA])$	5
	$Z_4 = [Z_2, X_2]$ $(= [BBA, [BBA, A]])$	7
4	$Z_5 = [Z_3, X_1]$ $(= [[BBA, BA], BA])$	7
	$Z_6 = [Z_3, X_2]$ $(= [[BBA, BA], [BBA, A]])$	9
	$Z_7 = [Z_3, X_3]$	11
	$Z_8 = [Z_4, X_1]$	9
	$Z_9 = [Z_4, X_2]$	11
5	$Z_{10} = [Z_5, X_1]$	9
	$Z_{11} = [Z_5, X_2]$	11
	$Z_{12} = [Z_6, X_1]$	11
	$Z_{13} = [Z_8, X_1]$	11
6	$Z_{14} = [Z_{10}, X_1]$	11

(8) The sizes of the sets $\mathfrak{X}_k$ and $\mathcal{Y}_k$ obey the iteration

$$\begin{aligned} |\mathfrak{X}_{k+1}| &= |\mathfrak{X}_k| + |\mathcal{Y}_k|, \\ |\mathcal{Y}_{k+1}| &= |\mathcal{Y}_k|\,|\mathfrak{X}_{k+1}| \end{aligned} \tag{11}$$

with initial conditions $|\mathfrak{X}_0| = 0$, $|\mathcal{Y}_0| = 1$. This iteration generates the sequence of $|\mathfrak{X}_k|$ values

$$0,1,2,4,12,108,10\,476,108\,625\,644,\ldots; \tag{12}$$

there is a constant $\gamma \approx 1.1555$ such that for sufficiently large k, $|\mathfrak{X}_k| = [\gamma^{2^k}]$.

Proof: The iteration results from successive elimination of elements of degree 0, each iteration introducing only a finite number of new elements nonzero in $\mathfrak{P}$, which have degrees 0 and 1. The other points then follow easily. The final description of $L_{\mathfrak{P}}(A,B)$, Eq. (10), follows because the generators of $L(A,\mathfrak{X},*)$ have degree 2 (A), 1 $(\mathfrak{X})$, or are identically zero $(*)$. Therefore $L(A,\mathfrak{X},*)$ contains no elements of degree 0, so $L_{\mathfrak{P}}(A,\mathfrak{X}) = L(A,\mathfrak{X})$. The sequence of Eq. (12) is Sloane's sequence A001696,[22] which comes from the same iteration [Eq. (11)]; the reference there to Ref. 1 shows how to establish its doubly-exponential growth. ●

The rapid growth of the sets $\mathfrak{X}_k$ and $\mathcal{Y}_k$ means that it is impossible to carry out the iteration exactly very far. In practice the generating set $\mathcal{Z}$ can be found up to any order n by dropping any terms of order $>n$ as soon they appear in $\mathcal{Y}_k$ (i.e., by quotienting all Lie algebras by the ideal consisting of all elements of order $>n$). We then have $\mathcal{Y}_{[(n+1)/2]} = 0$ and the iteration terminates.

The results of the six iterations required when $n = 12$ are shown in Table I. We name the elements of $\mathcal{Z}$ $Z_1, Z_2, \ldots$ as they are successively generated by the algorithm. This gives a short description of the elements of $(L_{\mathfrak{P}})_n(A,B)$ of order $\leqslant 12$ in terms of 14 elements of degree 0, 14 elements of degree 1, and 1 element of degree 2, which generate a total of 283 elements of order $\leqslant 12$ (see Tables II and III).

III. DIMENSIONS OF THE HOMOGENEOUS COMPONENTS

We now turn to the enumeration of $\mathfrak{X}_k$ and $\mathcal{Y}_k$ by order. We introduce the generating functions

$$x_k(t) = \sum_{n=1}^{\infty} |\{X \in \mathfrak{X}_k : \mathrm{order}(X) = n\}|\, t^n,$$

TABLE II. Dimensions of Lie algebras graded by order. Column 2: Of the free Lie algebra with two generators. Column 3: Of the Lie algebra of classical mechanics, $L_{\mathfrak{P}}(A,B)$ where A (kinetic energy) has degree 2 in p and B (potential energy) has degree 0 in p, i.e., is a function of q only. Column 4: Number of modified potentials of order n in $L_{\mathfrak{P}}(A,B)$. Column 5: Upper bound for maximum number of linearly independent Poisson brackets of order n when $M=\mathbb{R}^n$ with the Euclidean metric, i.e., $A=p^{\mathrm{T}}p$. Column 6: As column 5, but $V(q)$ is a cubic polynomial.

$$\tilde{y}_k(t)=\sum_{n=1}^{\infty}\left|\{Y\in\mathcal{Y}_k:\mathrm{order}(Y)=n\}\right|t^n,\quad \tilde{z}_k(t)=\sum_{n=1}^{\infty}\left|\{Z\in\mathcal{Z}_k:\mathrm{order}(Z)=n\}\right|t^n$$

which from Eq. (9) obey

$$x_0=0,\quad \tilde{y}_0=0,\quad \tilde{z}_0=t,$$

$$x_{k+1}=x_k+t\tilde{y}_k,\quad \tilde{y}_{k+1}=\tilde{y}_k x_{k+1},\quad \tilde{z}_{k+1}=\tilde{z}_k+\tilde{y}_k.$$

We can eliminate the t-dependence of this map by introducing $y_k=t\tilde{y}_k$ and $z_k=t\tilde{z}_k$. Then $z_k\equiv x_k$ for all k and the rest of the system is

TABLE III. Dimensions of $L_{\mathfrak{P}}(A,B)$, graded by degree m and by order n.

$$x_0=0, \quad y_0=t^2,$$
$$x_{k+1}=x_k+y_k, \quad y_{k+1}=y_k x_{k+1}. \tag{13}$$

The polynomials $x_k(t)$ converge to a formal power series $x(t)$. The polynomials $y_k(t)$ converge, again in the sense of formal power series, to 0. The power series $x(t)$ completely determines the dimensions of the homogeneous components of $(L_{\mathfrak{P}})_n(A,B)$ [including its abelian part $\mathcal{Z}$, because $z_k(t)=x_k(t)/t$]. We find

$$x(t)=t^2+t^4+t^6+2t^8+3t^{10}+6t^{12}+12t^{14}+24t^{16}+50t^{18}+107t^{20}+232t^{22}+508t^{24}+1124t^{26}$$
$$+2513t^{28}+5665t^{30}+12858t^{32}+29356t^{34}+67371t^{36}+\cdots. \tag{14}$$

(For example, the $1+1+1+2+3+6=14$ generators of weight $\leqslant 12$ are given in Table I.) Amazingly, this power series has appeared before (apparently as a curiosity) from the same iteration [Eq. (13), and it appears as Sloane's sequence A045761[22]].

The classical formula of Witt [Eq. (3)] can be extended to free Lie algebras with more general generating sets.[12,19] For any set $\mathcal{A}$ with generating function $a(t)=\Sigma_{n>0}|\{A\in\mathcal{A}:\text{order}(A)=n\}|t^n$, the dimensions $c_n=\dim L_n(\mathcal{A})$ of the homogeneous components of the graded Lie algebra $L(\mathcal{A})=\bigoplus_{n>0}L_n(\mathcal{A})$ are given by

$$c_n=\sum_{d|n}\frac{1}{d}\mu(d)b_{n/d}, \tag{15}$$

where

$$-\log(1-a(t))=\sum_{n>0}b_n t^n.$$

In Maple, one can compute the dimensions easily by `c=EULERi(INVERT(a))` (these functions are available in Ref. 22), where a and c are the sequences of coefficients of $a(t)$ and $c(t)$, respectively.

We apply Eq. (15) to $L_{\mathfrak{P}}(A,B)\cong\mathcal{Z}\oplus L(A,\mathfrak{X})$. The generating function for the grading by order of $\{A\}\cup\mathfrak{X}$ is $t+x(t)$. This gives the dimensions listed in Table II for $1\leqslant n\leqslant 40$. A dramatic reduction in the dimensions compared to those of the free Lie algebra of rank 2 is evident.

More generally still, Kang and Kim[12] consider the grading of a free Lie algebra by an abelian semigroup S which satisfies the finiteness condition that any $s \in S$ is a sum of other elements of S in only finitely many ways. Then we have

$$\dim L_s(\mathcal{A}) = \sum_{d|s} \frac{1}{d} \mu(d) b_{s/d} \tag{16}$$

where

$$-\log(1-a(t)) = \sum_{s \in S} b_s t^s$$

and $d|s$ means that there exists $\tau \in S$ such that $d\tau = s$, in which case we write $s/d = \tau$.

We can use this to calculate the dimensions of $L_{\mathfrak{P}}(A,B)$ with respect to the bigrading by order and degree. We first simplify the grading by degree [Eq. (7)] by introducing $\text{degree}'(x) := \text{degree}(x) - 1$. Then (as long as no elements of degree 0 enter, which now holds), the semigroup of the grading by degree′ is isomorphic to the non-negative integers under addition. Including the grading by order gives $S = \mathbb{Z}^{>0} \times \mathbb{Z}^{\geqslant 0}$. Note that the finiteness condition holds for S since it holds for $\mathbb{Z}^{>0}$. Since $\text{order}(A) = 2$, $\text{degree}'(A) = 1$, and $\text{degree}'(X) = 0$ for all $X \in \mathcal{X}$, the generating function of $\{A\} \cup \mathcal{X}$ is $ut + x(t)$ and we apply Eq. (16) with

$$b_{t,u} = -[t^n u^m] \log(1 - ut - x(t)).$$

This gives the dimensions for $n, m \leqslant 16$ as shown in Table III.

IV. ASYMPTOTICS OF THE DIMENSIONS AND CALCULATION OF THE ENTROPY

From Eq. (15), the asymptotic growth of the dimensions c_n is determined by the analytic structure—the location and type of the singularities—of $-\log(1-a(t))$. These correspond to zeros and singularities of $1-a(t)$. In particular, if $1-a(t)$ has a simple zero at $t = \alpha$ and no other zero with $|t| \leqslant \alpha$, then

$$c_n \sim \frac{1}{n} \left(\frac{1}{\alpha} \right)^n \tag{17}$$

and the Lie algebra has entropy $1/\alpha$.

The generating function of $\{A\} \cup \mathcal{X}$ is $t + x(t)$. We therefore need to study the analytic structure of the function $1 - (t + x(t))$. We therefore study the map of Eq. (13) considered as a map

$$\varphi : \mathbb{C}^2 \to \mathbb{C}^2, \quad (x,y) \mapsto (x+y, y(x+y))$$

with initial conditions $x = 0$, $y = t^2$. If the iterates of the map converge to $(x^*,0)$ say, then $x(t) = x^*$. Curiously, the map preserves the area $(1/y)\, dx \wedge dy$, although this plays no role in the analysis.

The map φ has a line of degenerate fixed points $(x,0)$ with eigenvalues x and 1. The fixed points with $|x| > 1$ are unstable and one can show that the fixed points with $|x| < 1$ are stable. The map remembers its initial condition, and the function $x(t)$ is the x-coordinate of the fixed point reached from initial condition $(0,t^2)$.

We can see immediately that (i) for t real and positive, $x(t)$ is strictly increasing; and (ii) if the map converges then $|x(t)| \leqslant 1$. For t real and positive, the sequence $\{y_k\}$ is increasing, and if there is a k such that $y_k > 1$, then $x_k \to \infty$. Therefore we define

$$\beta = \inf\{t \in \mathbb{R}^+ : x_k(t) \to \infty\}.$$

Because

$$|x_{k+1}|\leqslant|x_k|+|z_k|,\quad |z_{k+1}|=|z_k||x_{k+1}|,$$

the map converges in the disk $\{t:|t|<\beta\}$.

We can get a crude bound on β immediately, but more detailed knowledge requires a numerical study of the map φ. Let t be real, let $I(x,y)=y+x-1+\sqrt{2y}$, and suppose $x>0$, $y>0$, and $I(x,y)<0$. Then

$$\begin{aligned} I\circ\varphi-I&=y(x+y)+x+y-1+\sqrt{2y(x+y)}-(y+x-1+\sqrt{2y})\\ &=y(x+y)+\sqrt{2y}(\sqrt{x+y}-1)\leqslant y(1-\sqrt{2y})+\sqrt{2y}\sqrt{1-\sqrt{2y}}-1)\\ &\leqslant y(1-\sqrt{2y})+\sqrt{2y}(1-\tfrac{1}{2}\sqrt{2y})-1)=-\sqrt{2}y^{3/2}<0. \end{aligned}$$

Therefore, the orbit must stay in the bounded region $x>0$, $y>0$, $I(x,y)<0$, with x_k increasing and y_k decreasing. Therefore the orbit converges to some fixed point $(x,0)$. [Here the curve $x=1-\sqrt{2y}-y$ was chosen because it is a good approximation of the stable manifold of (1,0).] Since $I(0,t^2)<0$ for $0<t^2<2-\sqrt{3}$, we have $\beta>\sqrt{2-\sqrt{3}}>0.51$. Better approximations of β can be obtained as the roots of $I\circ\varphi^k(0,\beta^2)=0$ (i.e., by requiring the kth iterate to land in the trapping region), but these must be calculated numerically. On the other hand, $x_2=t^2+t^4>1$ if $t>0.79$, so we have the bounds $0.51<\beta<0.79$.

We have that $dx(t)/dt>0$ on $[0,\beta)$, with $x(0)=0$ and $x(\beta)=1$; and $1-t$ is decreasing. Therefore $1-t-x(t)$ has exactly one zero in $[0,\beta)$, and it is simple. The zero is α, the reciprocal of the required entropy of $L_{\mathfrak{P}}(A,B)$. The numerical value of α can be determined by solving $1-t-x(t)=0$ numerically. [In MATLAB, by `function x=f(t); x=0; y=t^2; while y>1e-16, x=x+y; y=y*x; end; x=1-t-x;` and `alpha=fsolve('f',0.5).`] This gives the value of the entropy of $L_{\mathfrak{P}}(A,B)$ as

$$1/\alpha=1.825\,423\,774\,201\,08\cdots. \tag{18}$$

Are there any other solutions to $1-t-x(t)=0$? Because the coefficients of $x(t)$ are all non-negative, there can be none in the disk $|t|\leqslant\alpha$. To say more we have to proceed numerically. First, if $|x_k|$ and $|y_k|$ get too large then the orbit blows up. Let

$$D=\{(x,y)\in\mathbb{C}^2:|y|>2|x|>2\}.$$

Suppose $(x_k,y_k)\in D$. Then

$$|x_{k+1}|\geqslant||y_k|-|x_k||>|x_k|>1$$

and

$$|y_{k+1}|=|x_{k+1}||y_k|>2|x_{k+1}|,$$

i.e., we have $(x_{k+1},y_{k+1})\in D$. The orbit then stays in D and cannot converge—in fact, it must blow up doubly exponentially. The first iterate $(x_1,y_1)=(t^2,t^4)$ is in D if $|t|>\sqrt{2}$, and the second iterate $(x_2,y_2)=(t^2+t^4,t^4(t^2+t^4))$ is in D if $|t|>1.272\,02$. In practice, if an iterate enters this region one can immediately stop the calculation and report that the map diverges.

Using this criterion we computed the function $x(t)$ numerically. See Figs. 1 and 2.

We have made the following numerical observations.

(1) The singularity of $x(t)$ closest to the origin is at
$$t=\beta=1/1.582\,079\,127\,34\cdots. \tag{19}$$
(2) There are no zeros of $1-t-x(t)$ in the disk $|t|<\beta$.
(3) The map converges only in a connected, simply connected region with a fractal boundary.

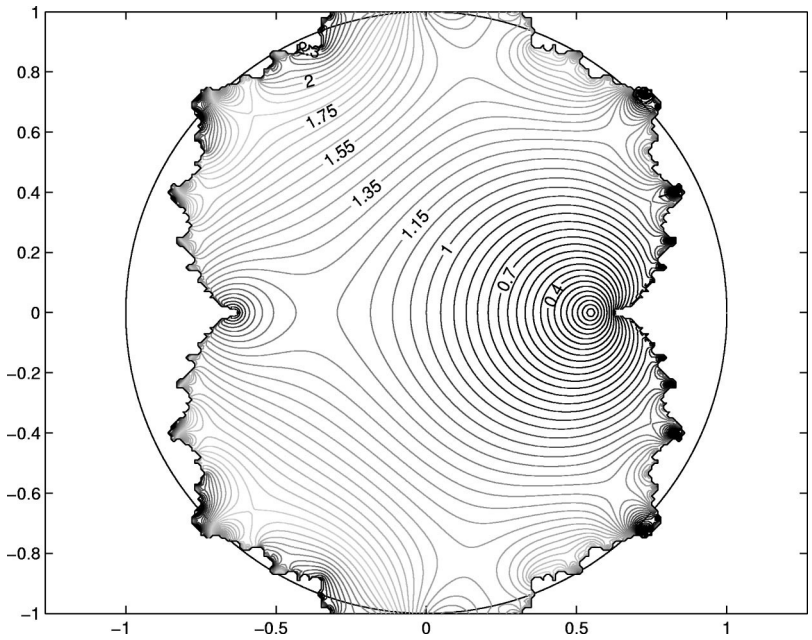

FIG. 1. Contour plot of $|1-t-x(t)|$, showing its main zero at $t=\alpha=1/1.8254\cdots$ and other zeros (two sequences approaching $t=\beta$). The unit circle is also shown.

(4) The function $x(t)$ is analytic everywhere inside this region but has a square root singularity everywhere on its boundary.
(5) For each point z on the boundary, $x(t)\sim 1-a(t-z)^{1/2}$ for some constant a depending on z, as $t\to z$.

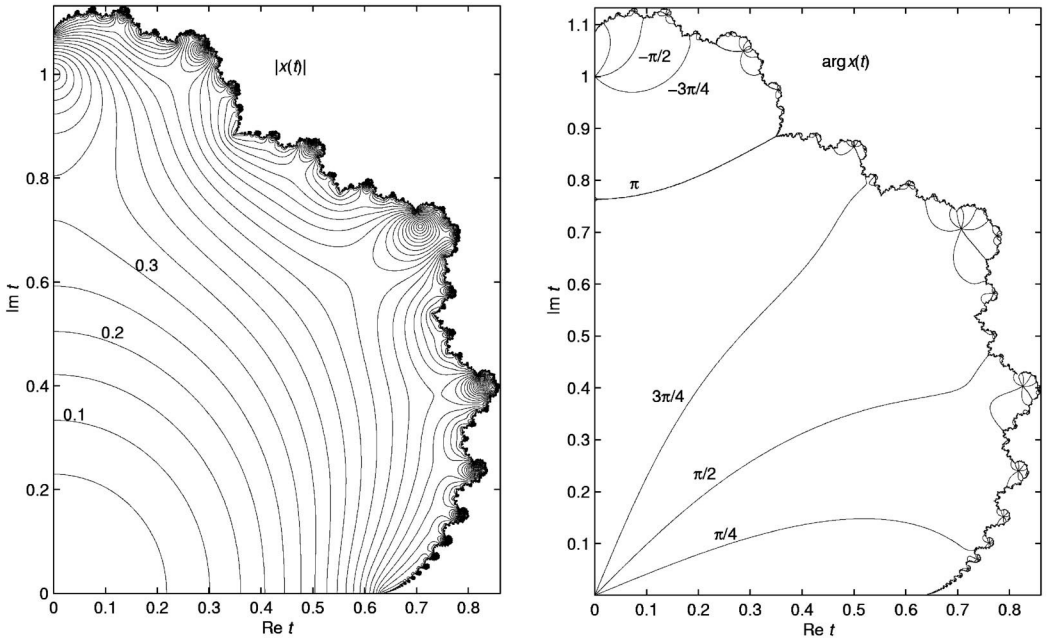

FIG. 2. Contour plots of $|x(t)|$ (left, contour interval 0.05) and arg $x(t)$ (right).

(6) There is only one zero of $1-t-x(t)$ in $|t|\leqslant\beta$.
(7) The other zeros of $1-t-x(t)$ form two infinite sequences α_n, $\overline{\alpha_n}$, with $\mathrm{Re}(\alpha_n)>\beta$ for all n and $\lim_{n\to\infty}\alpha_n=\beta$.

Because of the fractal nature of the boundary, we are unlikely to be able to solve the map φ or find α in closed form. Observation (4) would imply that this boundary forms a natural boundary for the function $x(t)$. Observation (5) would imply that the number of modified potentials of order n, $[t^{n+1}]x(t)$, is $\mathcal{O}(n^{-3/2}\beta^{-n})$. Observation (6) would imply that the next term in the asymptotic growth of $c_n=\dim(L_{\mathfrak{P}})_n(A,B)$ comes from the square root singularity at $t=\beta$. Indeed, by computing c_n numerically for $n<80$ we find that

$$c_n\sim n^{-1}\alpha^{-n}-\begin{cases}1.51n^{-1/2}\beta^{-n} & n \text{ odd}\\ 1.61n^{-3/2}\beta^{-n} & n \text{ even}\end{cases}$$

and

$$[t^{n+1}]x(t)\sim 0.9628n^{-3/2}\beta^{-n}$$

for n even. These are all consistent with the observed singularity structure of $1-t-x(t)$.

V. DISCUSSION

A. Physical interpretation of the generators

There is a particularly nice interpretation of $L_{\mathfrak{P}}(A,B)\cong\mathcal{Z}\oplus L(A,\mathfrak{X})$ in the specific case of simple mechanical systems. In local coordinates, let $A=T(p)=\frac{1}{2}p^TM(q)p$ be the kinetic energy, where $M(q)$ is the inverse of the metric (or mass matrix), and let $B=V(q)$ be the potential energy. The set $\mathcal{Z}$ consists of functions of q only, and we think of them as modified potentials. Elements of the span of $\mathcal{Z}$,

$$\sum_{Z\in\mathcal{Z}}a_Z\tau^{\mathrm{degree}(Z)}Z=a_1\tau V+a_2\tau^3M(V',V')+\cdots,$$

and their flows, can be evaluated explicitly and used to construct high-order integrators of the full system $T+V$ [see Eq. (23) for more terms]. Now consider the generator $X=[Z,A]\in\mathfrak{X}$. It is the cotangent lift of the gradient flow of the modified potential Z; we have $X=M(q)(Z(q),p)$ and Hamilton's equations are

$$\dot q=M(q)Z'(q)=\mathrm{div}_{M^{-1}(q)}Z=:f(q),\quad \dot p=-f'(q)^{\mathrm{T}}p.$$

So in a sense the modified potentials and the kinetic energy together contain a complete description of the Lie algebra.

B. Euclidean mechanical systems

Recall that on each manifold M, each simple mechanical system (say with kinetic energy T and potential energy V) generates a Lie algebra of class $\mathfrak{P}$. Therefore there is a homomorphism $\psi(M,T,V)$ from $L_{\mathfrak{P}}(A,B)$ onto this Lie algebra. One can ask whether the system (M,T,V) is in general position, i.e., if the two Lie algebras are actually isomorphic and $\ker\psi(M,T,V)=0$. This is unlikely, because of the existence of identities such as Eq. (6) in Lie algebras of vector fields. One can therefore consider larger *classes* of systems and ask whether they are in general position. That is, does the class satisfy any identities other than those corresponding to the grading by degree [Eq. (7)]? We conjecture that for the class of all simple mechanical systems, it does not.

Conjecture 1: The only identities satisfied by all simple mechanical systems are those due to the grading by degree. That is,

$$\bigcap_{M,T,V} \ker \psi(M,T,V) = 0.$$

This is best discussed by introducing a smaller class which we shall see is *not* in general position. Namely, let $M=\mathbb{R}^n$ with the Euclidean metric. Then in coordinates the kinetic energy is $T(p)=\frac{1}{2}\Sigma_{i=1}^{n} p_i^2$. The first few modified potentials are then

$$Z_1 = V,$$

$$Z_2 = [BBA] = V'(V'),$$

$$Z_3 = [BBA,BA] = 2V''(V',V'),$$

$$Z_4 = [BBA,[BBA,A]] = 4V''(V''(V'),V'),$$

$$Z_5 = [[BBA,BA],BA] = 2V'''(V',V',V') + 4V''(V''(V'),V'),$$

where we regard the kth derivative of V as a real-valued symmetric linear function on k vectors. Each modified potential of order $2n-1$ is a linear combination of the scalar elementary differentials of order n of V. Each such differential can be associated to a free tree with n nodes. (See, for example, Ref. 10 for a discussion of elementary differentials and trees.) The number of such trees for $n \geqslant 1$ is (Sloane's A000055[22]) 1, 1, 1, 2, 3, 6, 11, 23, 47, 106, 235, ... This should be compared with the number of modified potentials in Eq. (14), namely 1, 1, 1, 2, 3, 6, 12, 24, 50, 107, 232, ... There are three interesting consequences.

(i) For $n \leqslant 6$, the sequences are the same. In fact, one can check that in the modified potentials of orders $2n-1 \leqslant 11$, all trees appear, in invertible linear combinations, so these modified potentials are in general independent.

(ii) For $n=7,8,9$, there are more modified potentials than free trees. In particular, only 11 of the 12 modified potentials of order 13 can be linearly independent. This proves that the class of *Euclidean* mechanical systems is not in general position.

(iii) For $n \geqslant 10$, there are fewer modified potentials than free trees. In fact, the former have entropy $1/\beta = 1.582\cdots$ while the latter (since the free trees have entropy given by Otter's constant, $2.955\cdots$) have entropy $\sqrt{2.955\cdots} = 1.719\cdots$. Thus, for large n, only certain combinations of the trees appear in $\mathcal{Z}$.

So far we have only considered the modified potentials $\mathcal{Z}$ themselves. If these are independent, then $\mathcal{X}=[\mathcal{Z},A]$ is independent too. However, there is still a possibility for extra identities to hold in the Lie algebra generated by A and $\mathcal{X}$. A term of order n and degree m is a sum of elementary differentials of V and p, corresponding to trees with $(n+m+1)/2$ nodes, of which m leaves are labeled p and the remaining nodes are labeled V. In this case we find that for $(n+m+1)/2 \leqslant 7$ there are always sufficient labeled free trees to prevent forced dependencies among the Lie brackets. For example, of the 11 free trees with 7 nodes, there are 12, 20, 24, 18, 9, 3, and 1 trees in which $m=0$, 1, 2, 3, 4, 5, and 6 leaves are colored p, respectively. The dimensions of the corresponding homogeneous subspaces of $L_{\mathfrak{P}}(A,B)$ with $(n+m+1)/2=7$ are (from Table III) 12, 18, 20, 14, 8, 3, and 1, respectively. Thus, only in the case $m=0$, corresponding to the modified potentials themselves, is a dependency forced in this way.

The algorithm for $L_{\mathfrak{P}}(A,B)$ [Eqs. (9) and (13)] can be modified to take into account the dependencies amongst the Lie brackets in the Euclidean case. To get an upper bound on the dimensions and entropy of the Lie algebra in this case, we assume that the dependency appears only when forced. Let c_n be the number of free trees with n nodes. At iteration k, we already have $z_{k,2n} := [t^{2n}]\tilde{z}_k$ elements of order $2n-1$ in $\mathcal{Z}_k$, and $y_{k,2n} := [t^{2n}]\tilde{y}_k$ elements of order $2n-1$ have just been created in $\mathcal{Y}_k$. If $z_{k,2n}+y_{k,2n} > c_n$, we replace $\mathcal{Y}_k$ by a smaller set, of $c_n - z_{k,2n} - y_{k,2n}$ elements, which together with the order $2n-1$ elements of $\mathcal{Z}_k$, forms a basis of the c_n elementary differentials. In terms of the generating functions, we add the final step to the iteration of Eq. (13):

$$y_{k+1} \leftarrow \sum_{n \geqslant 1} \min(y_{k+1,2n}, c_n - z_{k+1,2n}) t^{2n}. \tag{20}$$

Let the resulting limiting formal series be $x_E(t)$, $y_E(t)$, and $z_E(t)$. The generating function for $x_E(t)$ is then computed to be

$$x_E(t) = t^2 + t^4 + t^6 + 2t^8 + 3t^{10} + 6t^{12} + 11t^{14} + 23t^{16} + 47t^{18} + 102t^{20} + 221t^{22} + 484t^{24} + 1069t^{26} + 2386t^{28} + 5364t^{30} + 12143^{32} + 27645t^{34} + 63259t^{36} + \cdots \tag{21}$$

which should be compared with Eq. (14). At order 14, 16, and 18 the dimensions are limited by the number of elementary differentials, but for $n>9$, $[t^{2n}]x_E(t) < [t^{2n}]x(t) < c_n$. Because the new map on generating functions, Eq. (20), is not analytic, it is harder to determine the location of its smallest singularity. We found the smallest root of successive polynomial truncations of $1 - t - x_E(t)$ and extrapolated these results to obtain

$$1/\alpha_E = 1.825\,0339\cdots, \quad 1/\beta_E = 1.574\cdots. \tag{22}$$

These are upper bounds for the entropy of the class of Euclidean mechanical systems and their modified potentials, respectively.

(Murua[20] has also considered this case, in the context of order conditions for Hamiltonians of the form $\frac{1}{2}\Sigma p_i^2 + V(q)$. He finds a unique independent tree of a certain type for each order condition, and enumerates these up to order 6. It would be interesting to compare the two approaches at higher order.)

The situation is quite different for non-Euclidean, i.e., general, mechanical systems. Repeating the above calculation for a general kinetic energy $T(p) = \frac{1}{2} p^T M(q) p$, we get the following modified potentials. The associated trees will be explained below.

$$Z_1 = V = \bullet$$

$$Z_2 = [BBA] = M(V',V') =$$

$$Z_3 = [BBA,BA] = 2M(V',V''(M(V'))) + M'(V',V',M(V')) = 2$$

$$Z_4 = [BBA,[BBA,A]]$$
$$= 4V'(M(V''(M(V''(M(V')))))) + 3V'(M(V''(M(M'(V',V'))))) + M(M'(V',V'),M'(V',V')) \tag{23}$$
$$= 4 \quad + 3$$

$$Z_5 = [[BBA,BA],BA] = 4V'(M(V''(M(V''(M(V')))))) + 2V'''(M(V'),M(V'),M(V')) + 6M'(V',M(V'),V''(M(V'))) + M'(V',V',M(V''(M(V')))) + M'(V',M(V'),M'(V',V')) + M''(M(V'),M(V'),V',V')$$
$$= 4 \quad + 2 \quad + 6 \quad + \quad + \quad + \quad .$$

In this case each modified potential of order $2n-1$ is a scalar elementary differential of *V and M*. These correspond to bicolored free trees with $2n-1$ nodes, of which n nodes are labeled V (shown as solid circles above) and $n-1$ nodes are labeled M (shown as open circles above); the

latter must have at least two branches since a derivative of M has at least two indices. Of the 1, 1, 3, 11, 47, and 235 free trees of order 1, 3, 5, 7, 9, and 11 respectively, exactly 1, 1, 2, 8, 34, and 175 of them can be colored (labeled) in this way. The calculation above shows that of these colorable trees, precisely one coloring of 1, 1, 2, and 7 of these colorable trees occur in the modified potentials of orders $\leqslant 7$. (The other colorings of these trees do not occur, because of the way in which the trees at each order are built from the trees of lower order. The colorable 7-node tree  also does not occur.) It is clear that there is enormously much more freedom in this case than in the (Euclidean, $T(p)=\frac{1}{2}\Sigma p_i^2$) case considered previously. Therefore, we believe that all the modified potentials are independent in this case. This supports Conjecture 1.

C. Other polynomially graded Lie algebras

We close with a list of some other Lie algebras of class $\mathfrak{P}$. In each case one can consider the case of two generators A and B of degrees 2 and 0 and the induced homomorphism from $L_{\mathfrak{P}}(A,B)$.

(1) The case of classical mechanics. The objects are real functions on a cotangent bundle, homogeneous polynomial in p. This can be specialized to the following cases.
   (a) Q any Riemannian manifold, any potential energy, degree(X) is the total degree of X in p. Entropy is $\leqslant 1.8254\cdots$ [Eq. (18)] with Conjecture 1 implying equality.
   (b) $Q=\mathbb{R}^n$ with the Euclidean metric. Entropy is $\leqslant 1.8250\cdots$ [Eq. (22)]. It is remarkable that these two Lie algebras, not previously distinguished from each other in the literature, differ starting at order 13, and have slightly different entropy.
   (c) $Q=\mathbb{R}^n$, functions polynomial in p *and* q. We can then introduce a bigrading by degree in p and by degree in q. To get a new Lie algebra, one of the generators has to be degree 0 in each grading, which forces Q Euclidean, $A=\frac{1}{2}\Sigma p_i^2$, $B=V(q)$ polynomial. For example, we have computed the dimensions of the Lie algebra generated by cubic potentials for small n in Table II—they are remarkably small. See Ref. 11 for an analysis of this case in terms of special types of trees.

(2) Homogeneous polynomial vector fields on $\mathbb{R}^m$ graded by total degree in $x_1,\ldots,x_k$ for some $1\leqslant k\leqslant m$. In the case $k=m$, the vector fields in $\mathfrak{X}$ associated with $L(A,B)$ [degree(A)$=2$, degree(B)$=0$] are associated with free trees in which each node has degree at most 2 (since only the first two derivatives of A are nonzero). Their numbers are 1, 1, 1, 2, 3, 6, 11, 23 (so far the same as for the free trees), then 46, 98, 207, 451, ... (Sloane's A001190[22]), which gives an upper bound for the number of independent elements of $\mathcal{Z}$ of each odd order. These grow more slowly than the free trees, and even more slowly than $\mathcal{Z}$, with entropy 1.5758, compared to 1.5821 [Eq. (19)] for $\mathcal{Z}$. Perhaps in this case the trees $\mathfrak{T}$ generate the Lie algebra as $\mathfrak{T}\oplus L(A,[\mathfrak{T},A])$?

(3) As the previous item, but multigrading by total degree in different subsets of the variables.

(4) Homogeneous polynomial vector fields with the variables partitioned (x,y) with $x\in\mathbb{R}^k$, $y\in\mathbb{R}^m$, and the vector fields of the form $p(\partial/\partial x)+q(\partial/\partial y)$ with either $\text{degree}_y(q)\leqslant\text{degree}_y(p)+1$, or $p\equiv 0$ and $\text{degree}_y(q)=0$. Simple mechanical systems form examples of this class. So do high-order ODEs of the form $y^{(n)}=f(y,\ldots,y^{(n-2)})$ when rewritten as first-order systems

$$\dot{x}_i=x_{i+1},\quad i=0,\ldots,n-2,$$
$$\dot{x}_{n-1}=f(x_1,\ldots,x_{n-2}),$$

with $x_i=y^{(i)}$, $k=n-1$, and $m=1$.

(5) Consider the Schrödinger equation

$$i\dot{\psi} = \nabla^2 \psi + V(x)\psi,$$

where ∇^2 is the Euclidean Laplacian. The two operators ∇^2 and $V(x)$ generate a Lie algebra of class $\mathfrak{P}$, where the grading is by degree of the differential operators. For example,

$$[\nabla^2, V]\psi = \nabla \cdot (V\psi) + V\nabla \cdot \psi$$

is of degree 1,

$$[V, V, \nabla^2]\psi = (\nabla \cdot (V^2))\psi$$

is of degree 0, and

$$[V, V, V, \nabla^2]\psi \equiv 0.$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 7 JULY 2003

Towards the complete classification of homogeneous two-component integrable equations

Mikhail V. Foursov[a)]
ENSSAT, 6 rue de Kérampont, 22305 Lannion Cedex, France

(Received 4 December 2001; accepted 7 February 2003)

In this article we suggest an improved method for classifying general two-component integrable evolution equations, homogeneous in a given weighting scheme. This method relies on linear changes of variables and on an appropriate splitting of the solution space. To illustrate the method, we implement the classification of coupled KdV-type equations. We show that there are five nontriangular systems possessing higher order generalized symmetries. One of these systems is previously unknown. This seems to be the first classification of coupled integrable equations homogeneous in a given weighting scheme, without any restrictions on the form of the main matrix. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1580998]

I. INTRODUCTION

Among many different approaches to the problem of classification of integrable evolution equations, the most successful ones are based on the existence of infinitely many conservation laws or generalized symmetries. These two methods were extensively used by many authors (cf. Mikhailov, Shabat, and Sokolov[25] or Mikhailov, Shabat, and Yamilov[26]) and they led to the discovery of many new systems, both *S*-integrable and *C*-integrable in Calogero's terminology.[4]

In the present article we consider two-component systems of evolution equations homogeneous in a given weighting scheme. More precisely, we are interested in the general case, i.e., in the systems whose main matrices are not of any special form.

We suggest a method for completely classifying such equations possessing higher order generalized symmetries. It is based on techniques widely used in the field of classification of integrable equations. We think that our method offers an improvement with respect to other versions, since it consists of a simultaneous reduction of the equation and the symmetry to a canonical form, while in general one only searches for the canonical forms of the equation.

To illustrate the method, we present the case of coupled KdV-type equations and apply the techniques similar to the ones used in our previous articles[9–11] about the systematic classification of integrable symmetrically-coupled KdV-type,[9] Burgers-type[10] and mKdV/pKdV-type equations.[11]

Coupled integrable systems come up in many physical applications. From the mathematical point of view, the interest in them has recently been rekindled as a consequence of the key result of Sanders and Wang[31] who showed that the list of known integrable homogeneous, autonomous polynomial scalar evolution equations with linear leading terms is exhaustive, whereas more general classes of equations, such as scalar complex evolution equations involving the complex conjugate, were not yet treated in complete generality. (We recall that scalar complex equations can be equivalently written as two-component systems of real equations for the real and imaginary parts.)

Two-component integrable systems have often been considered in the literature. Unfortunately, to implement classifications of such systems is usually an intractable problem. The only attempt to investigate very general two-component systems was done by Mikhailov, Shabat, and

[a)]Present address: IRISA/Université de Rennes-I, Campus de Beaulieu, 35042 Rennes Cedex, France. Electronic mail: foursov@irisa.fr

Sokolov[25] and Svinolupov,[33] who worked with Burgers- and Schrödinger-type vector equations.

It thus became necessary to consider narrower classes of equations in order to do a complete classification. It was noticed that many important integrable equations are homogeneous as differential polynomials in a certain weighting scheme. Several classes of homogeneous equations were thus dealt with by many authors. We will mention here the works of Gerdt and Zharkov,[14] Sanders and Wang,[31] Olver and Sokolov,[29,30] Meshkov[20,24] and Foursov.[8–11]

Coupled KdV-type equations were first considered by Hirota and Satsuma,[17,32] who showed that the system

$$\begin{cases} u_t = u_{xxx} + uu_x + vv_x, \\ v_t = -2v_{xxx} - uv_x \end{cases} \tag{1}$$

possesses multi-soliton solutions and infinitely many conservation laws. Another similar integrable equation was found by Ito,[18]

$$\begin{cases} u_t = u_{xxx} + 3uu_x + 3vv_x, \\ v_t = vu_x + uv_x, \end{cases} \tag{2}$$

who showed that it possesses a recursion operator and an infinite number of nontrivial conservation laws. Yet another integrable equation of this type was found by Drinfeld and Sokolov[6] in the study of the Kac–Moody algebras

$$\begin{cases} u_t = 3vv_x, \\ v_t = 2v_{xxx} + vu_x + 2uv_x. \end{cases} \tag{3}$$

Its recursion operator was recently found by Wang.[35]

Other two-component KdV-type equations were considered by Fuchssteiner,[13] Nutku and Oğus,[27] Gerdt and Zharkov,[14] Zharkov,[39] and Foursov.[8,9] Several new integrable equations were found, all reducible to a triangular form.

More generally, one can consider multi-component KdV-type equations. This is the path taken by Antonowicz and Fordy,[1] Ma,[21] and Ma and Pavlov,[22] among others. They have considered multi-dimensional coupled KdV-type systems and were able to find several generalizations of the scalar Hamiltonian operators that provide us with a bi-Hamiltonian structure for these systems. Along the same vein, Gürses and Atalay Karasu[15,16] attempted to classify multi-dimensional KdV equations of the type

$$u_t^i = b_j^i u_{xxx}^j + s_{jk}^i u^j u_x^k \tag{4}$$

that possess a recursion operator of degree 4. They found the conditions on b's and s's that insure integrability in the recursion operator sense, but they were unable to find the general solution. Another drawback of this approach is that *a priori* one does not know the degree of the recursion operator. For example, the Drinfeld–Sokolov equation is of type (4), but its recursion operator is of degree 6.

Yet another path to the classification problem was followed by Ayşe Karasu[19] who has investigated the two-component KdV-type equations that pass the Painlevé PDE test.[37] She presented 15 classes of such equations. Her classification has a big disadvantage: the equations were considered in the most general form and many of the systems are far too complicated to be worked with. Using scaling in all variables and linear changes of dependent variables, these 15 classes could have been reduced to a much simpler form.

II. STATEMENT OF THE PROBLEM

Definition 1: Let us consider a system of two equations

$$\begin{cases} u_t = F[u,v], \\ v_t = G[u,v]. \end{cases} \tag{5}$$

Here $F[u,v]=F(u,v,u_x,v_x,u_{xx},\dots)$ denotes a differential polynomial function of u and v, i.e., a function of u, v and their x-derivatives. This equation can be interpreted as a scalar complex equation in the variable $z=u+iv$ involving its complex conjugate $\overline{z}=u-iv$.

Definition 2: A system (5) is called *decoupled* or *triangular* if it involves either an equation depending only on u or an equation depending only on v.

For a decoupled system, we can first solve the equation depending on only one variable and then, using it, reduce the other equation to an x,t-dependent one-component equation. As a consequence, one function has no effect on the other and thus these equations are less interesting for applications. In our classifications we will only consider equations that cannot be decoupled by a change of variables.

Remark: There are in fact two more reasons not to consider decouplable equations. First, Fokas' conjecture is certainly false for them. Second, the number of decouplable equations is extremely large even in the simplest cases, rendering any thorough investigation of them impossible.

Definition 3: A second system of t-independent evolution equations,

$$\begin{cases} u_t = Q_1[u,v], \\ v_t = Q_2[u,v], \end{cases} \tag{6}$$

is said to be a *generalized symmetry* of (5) if their flows formally commute:

$$\mathbf{D_K}(\mathbf{Q}) - \mathbf{D_Q}(\mathbf{K}) = \mathbf{0}. \tag{7}$$

Here $\mathbf{Q}=(Q_1,Q_2)$, $\mathbf{K}[u,v]=(F[u,v],G[u,v])$ and $\mathbf{D_K}$ denotes the Fréchet derivative of $\mathbf{K}$ defined by $\mathbf{D_K}(\mathbf{Q})=(d/d\varepsilon)\,\mathbf{K}[\mathbf{u}+\varepsilon\mathbf{Q}[\mathbf{u}]]|_{\varepsilon=0}$. For a more detailed explanation of generalized symmetries, see Ref. 28.

Definition 4: Let us call the system (5) *integrable* if it possesses infinitely many generalized symmetries.

We remark that in all the known cases it is sufficient to produce only a certain fixed number of generalized symmetries to guarantee integrability. The property of possessing a fixed number of generalized symmetries has the advantage of being easy to verify. But for every class of equations we have to choose carefully the necessary number of symmetries. One symmetry would be the most convenient case, but it is well-known that one symmetry is not enough to insure the existence of an infinite number thereof. The first counter-example is due to Bakirov[2] (see Ref. 3 for a proof).

Fokas[7] has thus conjectured that for an n-component system it suffices to produce n higher symmetries. Quite recently, van der Kamp and Sanders[34] have found an example of a two-component system possessing exactly two higher-order symmetries. We note, however, that there is no pattern for the orders of the two symmetries in this ''anomalous'' example, the system being of order 7 and the two symmetries of orders 11 and 29. Moreover, the Bakirov and van der Kamp–Sanders systems are trivially decoupled, while in this work we consider only ''truly'' coupled equations. And for all the known cases of integrable non-decouplable equations Fokas' conjecture is still valid (as a matter of fact, only one higher symmetry seems to be enough in all these cases). Since all the known symmetry ''pathologies'' occur only for decoupled systems, it is reasonable to continue to rely on Fokas' conjecture for integrability of nondecoupled systems.

The classification problem: to find all nontriangularizable equations of a given class that possess a higher order generalized symmetry of a certain specified class. Implementing this clas-

sification for several different classes of symmetries will provide us the equations possessing several higher-order symmetries. Using Fokas' conjecture, we can thus conclude that these equations are integrable.

III. CLASSIFICATION OF HOMOGENEOUS EQUATIONS

For a given PDE, it is relatively easy to check the existence of higher-order generalized symmetries. However, if one is interested in finding all equations from a certain class possessing this property, the problem becomes significantly harder. At first, several attempts were made to classify general classes of scalar and coupled integrable equations. It was soon realized that is in an intractable problem in practically all cases of interest. The only classification that was successfully (and satisfactorily) completed is the case of general second-order evolution equations $u_t = F(t,x,u,u_x,u_{xx})$ (see Ref. 25).

As a consequence, it became necessary to consider narrower classes in order to be able to investigate them completely. It was noticed that many integrable evolution equations are homogeneous as differential polynomials in a certain weighting scheme (i.e., they possess a scaling Lie symmetry). Moreover, the right-hand sides of symmetries of such equations can be split into homogeneous components, each of which is a symmetry itself. Therefore, without loss of generality, we can restrict our attention to homogeneous symmetries.

Definition 5: Let us introduce the following *weighting scheme* on the space of differential functions. It will assign weight n to the dependent variables u,v and weight 1 to the x-differentiation. The weight of a monomial is the sum of the weights of its factors and the weight of a PDE $u_t = P[u]$ is $\deg P - n$.

When $n=2$, we will call this weighting the *KdV weighting*. The Hirota–Satsuma, Ito, and Drinfeld–Sokolov equations, as well as the trivially coupled KdV equation, are homogeneous in this weighting.

In the case when both the equation and the symmetry are homogeneous in a certain weighting scheme, the classification problem reduces to solving (large) systems of polynomial equations, called the *obstruction equations*. For scalar equations, this system can be easily resolved by Gröbner basis techniques. However, for general classes of coupled homogeneous equations the resulting system is highly nonlinear and it seems to be impossible to solve it in any case of interest. The method we suggest in the next section uses linear transformations of variables to reduce this general problem to 17 subcases, thereby reducing the dimension of the solution space by two or three. In each of the 17 cases, we can then successfully solve the corresponding system of polynomial equations, at least for coupled KdV-type equations.

To compute the symmetries, we use a MAPLE package written by the author. This package uses the same algorithm as the MATHEMATICA package created by Olver.[29] The latter package was successfully used to implement several classifications of integrable equations (e.g., Olver and Sokolov[29,30] and Foursov[8–11]).

Even though it is quite simple to directly compute the symmetry condition (7), the obtained system of polynomial equations is often too big to be dealt with as a whole. To overcome this difficulty, Olver[29] suggested splitting the commutator (7) into homogeneous parts as algebraic polynomials. This way, one first computes the coefficients of linear monomials, then of quadratic ones, of cubic ones, etc. On every step we can either completely resolve the corresponding system or reduce it to the Gröbner basis form (and then consider each branch separately, if necessary). This method allows one to significantly simplify the problem in the majority of cases. A more detailed explanation and examples of the algorithm can be found in Ref. 29 or 8.

IV. ALGORITHM

Definition 6: Consider a nondegenerate system of two evolution equations

$$\begin{cases} u_t = \alpha u_k + \beta v_k + \text{lower order terms}, \\ v_t = \gamma u_k + \delta v_k + \text{lower order terms}, \end{cases} \tag{8}$$

where u_k and v_k are kth order derivatives with respect to x. By a *nondegenerate* system I mean a system that does involve the kth order derivatives (i.e., not all of α, β, γ, δ vanish). We call the matrix $A=\left(\begin{smallmatrix}\alpha & \beta\\ \gamma & \delta\end{smallmatrix}\right)$ the *main matrix* of the system (8). In vector notation we will write the system as

$$\mathbf{u}_t = A\mathbf{u}_k + \text{lower order terms}, \tag{9}$$

where $\mathbf{u}=(u,v)$.

Proposition 7: If the system of the form $\mathbf{u}_t=B\mathbf{u}_k+\cdots$ is a generalized symmetry of $\mathbf{u}_t=A\mathbf{u}_k+\cdots$, then the two main matrices commute, i.e., $[A,B]=0$.

Proposition 8: Under a general linear invertible change of dependent variables

$$\mathbf{w}=K\mathbf{u} \tag{10}$$

(where K is an invertible matrix) the system (9) is mapped to the system $\mathbf{w}_t=A'\mathbf{w}_k+\cdots$ with the main matrix $A'=KAK^{-1}$.

Corollary 9: By a linear invertible change of dependent variables (10) a system of type (9) can be reduced to a system with the main matrix in Jordan canonical form.

Definition 10: We say that the equation $\mathbf{u}_t=A\mathbf{u}_k+\cdots$ is in *canonical form* if the main matrix A is of one of the following forms:

$$\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},\quad \begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix},\quad \begin{pmatrix}1 & 0\\ 0 & a\end{pmatrix},\quad \begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix},\quad \begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}, \tag{11}$$

where a is a constant satisfying $|a|\geqslant 1$, $a\neq 1$.

Remark: The subcases $a=1$ and $a=0$ are written separately for three reasons. First, in the known cases, the solution set for either of these two values is different from the solution set for a generic value of a. Thus this branching seems to be always necessary. Moreover, in case $a=1$, the main matrix commutes with all the other matrices and thus any linear transformation (10) preserves this canonical form. Last, but not least, the conditions $a\neq 1$ and $a\neq 0$ are crucial for successful solving of the obstruction equations.

Corollary 11: Any nondegenerate system (9) can be reduced to canonical form by a linear transformation of type (10). Moreover, the canonical form of the main matrix is unique and well-defined.

The proof is a straightforward application of the fact that a nonzero coefficient of the main matrix can be rescaled to 1 by an appropriate scaling in t. We remark that in general there seems to be no canonical form for the lower order terms. In all the five cases, we can still rescale u and v. And in the case of unit main matrix, any transformation of type (10) is allowed. As a consequence, if one wants to know whether the given system is integrable, he has to reduce it first to canonical form and then compare it to the known integrable equations of this type modulo transformations of type (10) preserving this particular canonical form.

To simplify the symmetry in a way similar to the way we treated the equation, we use the following proposition from linear algebra.

Proposition 12: Two commuting 2×2 matrices can be simultaneously reduced to (a multiple of) their Jordan canonical forms by a transformation $A\rightarrow KAK^{-1}$ for some nondegenerate matrix K.

Remark: This proposition is false for matrices of higher dimension. Thus our method will have to be slightly modified for these cases.

Proposition 13: If the system of the form $\mathbf{u}_t=B\mathbf{u}_k+\cdots$ is a generalized symmetry of $\mathbf{u}_t=A\mathbf{u}_k+\cdots$ with A in canonical form (11), then B can be reduced to Jordan canonical form by a transformation of type (10).

The proof relies on the trivial fact that if $\mathbf{u}_t=\mathbf{Q}$ is a symmetry, so is $\mathbf{u}_t=k\mathbf{Q}$ for any constant k.

Definition 14: We say that the symmetry $\mathbf{u}_t = B\mathbf{u}_m + \cdots$ is in *canonical form* if its main matrix B is of one of the following forms:

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & b \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 \\ 0 & a \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \tag{12}$$

where $a \neq 1$ and $b \neq 0$ are constants.

This list is somewhat different from (11), since we can only apply the changes of variables (10) that preserve all canonical forms of the equation (9).

We have thus put together all the building blocks to prove the following key result.

Theorem 15: By a linear change of variables of type (10), every nondegenerate equation of the type (9) can be reduced to canonical form, simultaneously with its nondegenerate symmetries of type $\mathbf{u}_t = B\mathbf{u}_m + \cdots$.

This simple trick is crucial for implementing successful classifications of integrable equations. Indeed, as a rule, the greater is the number of arbitrary parameters in the main matrices, the harder are the required computations. Writing the equations and the symmetries in canonical form allows one to reduce the number of parameters to at most 1 for each canonical matrix, thereby paving the road for complete classification of many classes of integrable equations.

We remark that not all the canonical main matrices for the equation and for the symmetry are pairwise commuting. There are eight noncommuting pairs. As a consequence, in order to completely classify the equations of a certain type possessing generalized symmetries of a certain (different) type, both of type (9), it is sufficient to consider equations and symmetries with the pairs of main matrices belonging to the list of 17 commuting pairs of canonical matrices.

V. CLASSIFICATION OF COUPLED KdV-TYPE INTEGRABLE EQUATIONS

To illustrate our method, we will show how it helps to resolve the problem of classification of coupled KdV-like equations. We choose this class because we think it is the simplest class of coupled homogeneous equations to deal with, and at the same time a very interesting one. Moreover, it is the class most often considered in the literature. We would like to note that in spite of all the efforts, only particular subclasses were completely investigated. The algorithm we suggest allowed us to finally solve this problem and to find one new integrable equation.

Let us thus consider evolution equations of weight 3 in the KdV weighting, i.e., the equations of the form

$$\begin{cases} u_t = \alpha u_{xxx} + \beta v_{xxx} + \lambda_1 u u_x + \lambda_2 v u_x + \lambda_3 u v_x + \lambda_4 v v_x, \\ v_t = \gamma u_{xxx} + \delta v_{xxx} + \mu_1 u u_x + \mu_2 v u_x + \mu_3 u v_x + \mu_4 v v_x. \end{cases} \tag{13}$$

As shown in Sec. III, we can reduce any equation of this type to an equation having its main matrix in canonical form. We implemented six classifications of equations of this type. To be precise, we searched for equations possessing symmetries of orders 4, 5, 6, 7, 8 and 9. The polynomial equations that appear during the classification can be solved using Gröbner basis techniques in the majority of subcases. When the main matrix of the equation is $\mathrm{diag}(1,a)$, the MAPLE's ''grobner'' package is not efficient for solving the corresponding systems. However, we can do some additional splitting of the solution space and successfully treat each branch separately. In this way, we were able to prove the following three theorems.

Theorem 16: A two-component system of evolution equations (13) that possesses a symmetry of weight 4, 6 or 8 in the KdV weighting is reducible to triangular form by some linear change of dependent variables (10).

Theorem 17: A two-component system of evolution equations (13) possesses a symmetry of weight 5 in the KdV weighting, if and only if it is reducible [by a linear change of dependent variables (10) and/or a rescaling] either to triangular form or to one of the following four equations:

$$\begin{cases} u_t = u_{xxx} + uu_x + vv_x, \\ v_t = -2v_{xxx} - uv_x, \end{cases} \tag{14}$$

$$\begin{cases} u_t = u_{xxx} + 3uu_x + 3vv_x, \\ v_t = vu_x + uv_x, \end{cases} \tag{15}$$

$$\begin{cases} u_t = u_{xxx} + v_{xxx} + 2vu_x + 2uv_x, \\ v_t = v_{xxx} - 9uu_x + 6vu_x + 3uv_x + 2vv_x, \end{cases} \tag{16}$$

$$\begin{cases} u_t = u_{xxx} + 2vu_x + uv_x, \\ v_t = uu_x. \end{cases} \tag{17}$$

We remark that (14) is the Hirota–Satsuma system, (15) is the Ito system, while (17) is the rescaled Drinfeld–Sokolov equation in our canonical form. The system (16) seems to be new. Our computations show that it possesses generalized symmetries of orders 5, 7, 9, 11, 13, 15 and 17, as well as conserved densities of weights 2, 4, 6, 8, 10, 12 and 14. We have thus a very good reason to conjecture that it is integrable, i.e., that it possesses infinitely many generalized symmetries.

Theorem 18: A two-component system of evolution equations (13) possesses a symmetry of weights 7 or 9 in the KdV weighting, if and only if it is reducible [by a linear change of dependent variables (10) and/or a rescaling] either to triangular form, to one of (14)–(17), or else to the following system:

$$\begin{cases} u_t = 4u_{xxx} + 3v_{xxx} + 4uu_x + vu_x + 2uv_x, \\ v_t = 3u_{xxx} + v_{xxx} - 4vu_x - 2uv_x - 2vv_x. \end{cases} \tag{18}$$

Remark: The system (18) is not presented here in canonical form. We prefer this form, since all its coefficients are integer-valued. In canonical form, the main matrix is $\mathrm{diag}(1, -(7+3\sqrt{5})/2)$ and the coefficients depend on $\sqrt{5}$.

The system (18) possesses generalized symmetries of orders 7, 9, 11, 13 and 17, as well as conserved densities of weights 2, 4, 8, 10, 12 and 14. Therefore it is also very likely to be integrable. We remark that its symmetry pattern is rather unusual. It is also characteristic of the Ramani equation,[5] as well as of several equations found by Drinfeld and Sokolov[6] in the study of Kac–Moody algebras.

The explicit form of the system (18) seems to be new. (It was also found by Meshkov,[23] independently of us.) We did an extensive search in the literature, but were unable to find any explicit equation equivalent to (18). It appears, however, albeit implicitly, in a paper of Wilson[38] in the study of equations related to the Kac–Moody algebra $C_2^{(1)}$.

To end up, we would like to remark that *a priori* we do not know the order of the first higher-order symmetry. In this article we have limited our attention to the symmetries of order at most 9. Similar computations can of course be made in order to search for symmetries of yet higher order. These computations become rapidly very time-consuming as the order increases. We do not implement them here, since we think that it is highly unlikely any new integrable equations can be found in this way.

VI. CONCLUSIONS

In this article we have presented an improved method allowing one to implement complete classifications of two-component homogeneous integrable evolution equations. Applying these techniques to KdV-type equations, we were able to find a new integrable equation. (Another application, to Sawada–Kotera and Kaup–Kupershmidt-type equations, can be found in Ref. 12.)

An interesting open problem is to produce recursion operators for this new system (16), as well as for the system (18), whose recursion operator seems to be unknown. Jing Ping Wang[36] demonstrated that the system (18) does not possess symmetries of orders $10n+5$. We thus conjecture that if this recursion operator exists, its degree should be 10.

Another interesting direction is to generalize this method to consider more general classes of systems. For example, coupled equations homogeneous in *some* weighting scheme is a particularly interesting class. This would require finding equivalence classes under *general transformations of variables* preserving the evolutionary form of the equation. This problem is resolved by Cartan's equivalence method. Unfortunately, this seems to be impossible at the current stage of development of computer algebra tools, as there is no package allowing one to tackle the problem of classification of equivalence classes for systems of PDEs. However, such packages are currently under development. Their successful realization would allow one to find the complete list of integrable coupled homogeneous evolution equations.

ACKNOWLEDGMENTS

I would like to thank Gérard Jacob, Peter Olver, Michel Petitot, and Luis Valero Elizondo for helpful discussions, Jing Ping Wang for investigating the new integrable equations, Marc Moreno Maza for checking my solutions and the Computer Science department at the INSA of Rennes for its hospitality.

Isospectrality of spherical MHD dynamo operators: Pseudo-hermiticity and a no-go theorem

Uwe Günther[a] and Frank Stefani[b]
Research Center Rossendorf, P.O. Box 510119, D-01314 Dresden, Germany

(Received 8 August 2002; accepted 13 March 2003)

The isospectrality problem is studied for the operator of the spherical hydromagnetic α^2-dynamo. It is shown that this operator is formally pseudo-Hermitian (J-symmetric) and lives in a Krein space. Based on the J-symmetry, an operator intertwining Ansatz with first-order differential intertwining operators is tested for its compatibility with the structure of the α^2-dynamo operator matrix. An intrinsic structural inconsistency is obtained in the set of associated matrix Riccati equations. This inconsistency is interpreted as a no-go theorem which forbids the construction of isospectral α^2-dynamo operator classes with the help of first-order differential intertwining operators. © *2003 American Institute of Physics.*

I. INTRODUCTION

The magnetic fields of stars and planets are generated by the homogeneous dynamo effect in moving electrically conducting fluids.[1] This effect is explained within the framework of magnetohydrodynamics (MHD), but its experimental demonstration was missing until recently. In 1999, the first successful dynamo experiments in Riga and Karlsruhe[2] opened up a new way for the laboratory investigation of homogeneous dynamos. In connection with the data analysis for the existing experiments and the design of new dynamo experiments there is a growing interest in the spectral properties of dynamos. Of particular interest is the question of whether isospectral dynamos can exist. The first numerical results on this topic were published in Refs. 3, 4, but rigorous results are still missing.

As a step towards clarification of this issue, we study in the present paper the question of whether operator intertwining techniques from quantum mechanics (QM) can be adopted to MHD dynamo models. In case of an affirmative answer we would obtain an efficient tool for constructing isospectral classes of MHD dynamo operators. Otherwise we would get a no-go theorem which would forbid a straight analogy with quantum mechanical models.

Let us start by recalling some essentials of operator intertwining transformations in QM.[5] Two operators H_0 and H_1 are said to be intertwined if there exist operators A_+ and A_- so that

$$H_1 A_+ = A_+ H_0, \quad A_- H_1 = H_0 A_- . \tag{1}$$

For the corresponding eigenfunctions ϕ_0 and ϕ_1 holds, up to normalization,

$$\phi_1 = A_+ \phi_0, \quad A_- \phi_1 = \phi_0,$$

and the operators H_0 and H_1 are isospectral, except for those states that are annihilated by A_+ or A_-. In the case of one-dimensional Schrödinger operators $H_0 = p^2 + V_0(x)$ and $H_1 = p^2 + V_1(x)$ with the momentum operator given as $p = -i\partial_x$, the intertwining operators can be chosen as first-order differential operators,

[a]Electronic mail: u.guenther@fz-rossendorf.de
[b]Electronic mail: f.stefani@fz-rossendorf.de

$$A_+ = A := ip + f, \quad A_- = A^\dagger = -ip + f. \tag{2}$$

Structural compatibility of H_0 and H_1 with the intertwining relations (1) requires that the function $f(x)$ and the potentials $V_0(x)$, $V_1(x)$ are connected by the consistency conditions

$$V_1 = V_0 + 2f',$$

$$-f' + f^2 = V_0 - E, \tag{3}$$

$$f' + f^2 = V_1 - E, \tag{4}$$

where the prime denotes differentiation with respect to x; and E is a constant of integration. Linearization of the Riccati differential equations (3), (4) shows that this constant can be interpreted as eigenvalue of the Schrödinger operators H_0 and H_1,

$$H_0\chi_0 = E\chi_0, \quad \text{for} \quad f = -\frac{\chi_0'}{\chi_0}, \tag{5}$$

$$H_1\chi_1 = E\chi_1, \quad \text{for} \quad f = \frac{\chi_1'}{\chi_1}, \tag{6}$$

where χ_0 and χ_1 are formal, and not necessarily normalized eigenfunctions of H_0 and H_1, respectively. They are connected by the product relation

$$\chi_0\chi_1 = c, \tag{7}$$

with c a nonvanishing constant. It is straightforward to verify that the shifted Schrödinger operators are factorizable in terms of the intertwining operators,

$$H_0 - E = A^\dagger A, \quad H_1 - E = AA^\dagger.$$

First-order differential intertwining transformations of type (2) are known as Darboux transformations[6] and are widely used to generate isospectral operator classes from given operators with known spectra.[5,7,8] In particular, intertwining constructions are a basic ingredient of supersymmetric quantum mechanical models[5,9] and their generalizations to pseudo-supersymmetric systems.[10,11] As it was demonstrated in Ref. 12, a double-intertwining (double commutation) method can provide a tool for inserting additional eigenvalues in spectral gaps of given background Schrödinger and Jacobi operators.

Motivated by the large number of exact results on isospectral classes obtained by operator intertwining constructions, it is natural to investigate whether MHD dynamo operators are also suitable for this technique. For this purpose we study in the present paper the simplest mean-field MHD dynamo configuration—the spherical α^2-dynamo.[1] In terms of the radial momentum operator $p = -i(\partial_r + 1/r)$ the 2×2 operator matrix of the α^2-dynamo is given as

$$\hat{H}_l[\alpha] \equiv \begin{pmatrix} -p^2 - \dfrac{l(l+1)}{r^2} & \alpha(r) \\ p\alpha(r)p + \alpha(r)\dfrac{l(l+1)}{r^2} & -p^2 - \dfrac{l(l+1)}{r^2} \end{pmatrix}, \tag{8}$$

and lives on the domain

$$\mathcal{D}(\hat{H}_l[\alpha]) := \left\{ \psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} : \ \psi \in \tilde{\mathcal{H}} \equiv \mathcal{H} \oplus \mathcal{H}, \ \mathcal{H} = L_2(\Omega, r^2 dr), \right.$$

$$\Omega=[0,1],\ \ \psi(1)=0,\ \ r\psi(r)|_{r\to 0}\to 0\},$$

in the Hilbert space $\tilde{\mathcal{H}}$. (A brief outline of the derivation of the α^2-dynamo operator matrix from the MHD mean-field induction equation can be found in the Appendix.) It describes the coupled l-modes of the poloidal and toroidal magnetic field components in a mean-field dynamo model with helical turbulence function $\alpha(r)$. The function $\alpha(r)$ does not depend on l and we assume that it is real-valued, positive definite, bounded, and sufficiently smooth on Ω: $\mathrm{Im}\,\alpha=0$, $0<\alpha\leqslant c_1<\infty$, $\alpha\in C^4(\Omega)$. The idealized boundary condition $\psi(r=1)=0$ corresponds to a superconducting spherical boundary shell and is chosen here to ensure simplicity of the subsequent considerations.[13] For more realistic models with a close relation to stellar dynamos, the spherical fluid configurations confined to $r<1$ can be assumed as embedded in empty space. The boundary condition should then be replaced by $\hat{B}_l\psi|_{r=1}=0$ with $\hat{B}_l=\mathrm{diag}[\partial_r+(l+1)/r,1]$ (see, e.g., Ref. 1) what will require a more general approach than that presented in the present paper.

Exploring the fundamental symmetry of the α^2-dynamo operator matrix we find in Sec. II that $\hat{H}_l[\alpha]$ acts as a symmetric operator on the Hilbert space $\tilde{\mathcal{H}}$ when this is endowed with an indefinite metric J. That means the α^2-dynamo operator matrix is a J-symmetric (formally J-self-adjoint) operator,

$$\hat{H}_l[\alpha]=\hat{H}_l^\sharp[\alpha]:=J\hat{H}_l^\dagger[\alpha]J,$$

living in a Krein space $\tilde{\mathcal{K}}=\tilde{\mathcal{H}}_J$.[14] J-self-adjointness is a natural property of operators from different fields of physics. Examples are, e.g., the super-symmetric Dirac operator,[15] PT-symmetric non-Hermitian Hamiltonians in QM[10,16] as well as the Wheeler–DeWitt operator for a cosmological Friedman–Robertson–Walker model coupled to a real massive scalar field.[10] Since the recent paper series[10,11,17] of Mostafazadeh on non-Hermitian operators with real spectra, J-self-adjoint operators are also known as pseudo-Hermitian operators.

In analogy with the simple quantum mechanical model described above, we base our isospectrality analysis on an intertwining Ansatz for two α^2-dynamo operators with helical turbulence functions $\alpha_0(r)$, $\alpha_1(r)$,

$$\hat{H}_{l_0}[\alpha_0]-EI=-\hat{A}\hat{A}^\sharp,\quad \hat{H}_{l_1}[\alpha_1]-EI=-\hat{A}^\sharp\hat{A},$$

and intertwining operator matrices $\hat{A}$, $\hat{A}^\sharp$ that are first-order differential operators,

$$\hat{A}:=iR(r)p+Q(r),\quad \hat{A}^\sharp:=-ipR^\sharp(r)+Q^\sharp(r).$$

This Ansatz leads to a set of six consistency conditions on the matrices $R(r)$ and $Q(r)$ which are studied in Sec. III. It is shown that one pair of conditions fixes the structure of $R(r)$ in terms of the helical turbulence functions $\alpha_0(r)$ and $\alpha_1(r)$. A second pair is equivalent to the symmetry relations $B=B^\sharp$, $U=U^\sharp$ on the matrix functions

$$B:=R^\sharp Q,$$

$$U:=R[Q^\sharp-(R^\sharp)']=RBR^{-1}-R(R^\sharp)',$$

and can be regarded as an implicit consequence of the J-pseudo-Hermiticity of the operator matrices $\hat{H}_{l_0}[\alpha_0]$ and $\hat{H}_{l_1}[\alpha_1]$. (The prime denotes the derivative with respect to r.) The remaining two conditions can be transformed into a pair of coupled matrix Riccati differential equations (MREs) on B and U.

The consistency of the six conditions is analyzed in Sec. IV with the help of a step-by-step reduction of their complexity. First, we conclude from the limiting behavior of the MREs for $r\to 0$ that the angular mode numbers l_0 and l_1 in the two dynamo operator matrices should be connected by the incremental relation $l_1=l_0+1$. Then we use the J-symmetry of B to derive from

the coupled MREs a system of coupled nonlinear ordinary differential equations (ODEs) involving the helical turbulence functions $\alpha_0(r)$ and $\alpha_1(r)$. Analyzing these ODEs, we are able to show the existence of an inherent contradiction between them. As an implication, we arrive at a no-go theorem which states that the six consistency conditions cannot be fulfilled simultaneously and that, hence, the structure of the α^2-dynamo operator matrices is not suitable for an operator intertwining technique based on an Ansatz with first-order differential intertwining operators.

In the concluding section (V) we briefly discuss some other methods which could be useful for studying isospectrality issues of the dynamo operator matrix and which possibly could provide a technique to construct classes of isospectral spherical α^2-dynamo operators.

II. *J*-SYMMETRY OF THE DYNAMO OPERATOR MATRIX

In this section, we study the fundamental symmetry J of the α^2-dynamo operator matrix (8) which allows us to choose an appropriate Ansatz for the intertwining operators A_+ and A_-.

We start our consideration by introducing the auxiliary operator

$$Q[\alpha] := p\alpha p + \alpha \frac{l(l+1)}{r^2},$$

defined on the domain

$$\mathcal{D}(Q) = \{\phi:\ \ \phi \in \mathcal{H} = L_2(\Omega, r^2 dr), \phi(1) = 0,\ \ r\phi(r)|_{r\to 0} \to 0\},$$

in the Hilbert space $\mathcal{H}$. The operator $Q[\alpha]$ is a formally self-adjoint singular differential operator $Q = Q^\dagger$ which acts as symmetric operator on $\mathcal{H}$. [In the subsequent compatibility analysis of the operator intertwining construction we restrict our attention to symmetric (formally self-adjoint) operators. For simplicity, we leave questions of self-adjoint extensions and corresponding generalized boundary conditions[18,19] for the bi-component functions ψ aside.] In terms of $Q[\alpha]$ the dynamo operator matrix and its formal adjoint read as

$$\hat{H}_l[\alpha] = \begin{pmatrix} -Q[1] & \alpha \\ Q[\alpha] & -Q[1] \end{pmatrix}, \quad \hat{H}_l^\dagger[\alpha] = \begin{pmatrix} -Q[1] & Q[\alpha] \\ \alpha & -Q[1] \end{pmatrix},$$

so that the fundamental (canonical) symmetry can be obtained as

$$\hat{H}_l[\alpha] = \hat{H}_l^\sharp[\alpha] := J\hat{H}_l^\dagger[\alpha]J, \quad J = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{9}$$

Diagonalizing the matrix J,

$$J \to \eta = S^T J S, \quad S = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \quad \eta = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

we see that $\hat{H}_l[\alpha]$ is equivalent to the operator matrix,

$$\breve{H}_l[\alpha] = S^T \hat{H}_l[\alpha] S = \frac{1}{2} \begin{pmatrix} Q[\alpha-2] + \alpha & -Q[\alpha] + \alpha \\ Q[\alpha] - \alpha & Q[-\alpha-2] - \alpha \end{pmatrix},$$

with the property $\breve{H}_l[\alpha] = \eta \breve{H}_l[\alpha]^\dagger \eta$. The fundamental η-symmetry of the operator matrix $\breve{H}_l[\alpha]$ implies that $\mathcal{D}(\breve{H}_l)$ could be endowed with the indefinite metric η so that $\breve{H}_l[\alpha]$ becomes a symmetric operator on $\mathcal{D}(\breve{H}_l)$. Due to the invariance of the signature under the transformation S the domain $\mathcal{D}(\hat{H}_l)$ can also be endowed with a natural indefinite inner product $[\cdot,\cdot]_J$ defined by the metric J,

$$[x,y]_J := (x,Jy), \quad x,y \in \tilde{\mathcal{H}} = \mathcal{H} \oplus \mathcal{H},$$

where $(\cdot,\cdot)$ denotes the usual inner (scalar) product in the Hilbert space $\tilde{\mathcal{H}}$. This means that $\hat{H}_l[\alpha]$ is a J-symmetric operator which acts as symmetric operator in a Krein space $\tilde{\mathcal{K}} = \tilde{\mathcal{H}}_J$,

$$[\hat{H}_l x,y]_J = [x,\hat{H}_l^\sharp y]_J .$$

[For surveys on operators in Krein spaces (Hilbert spaces with additional indefinite inner product structures) we refer to the mathematical literature.[14,20]] From its operator-matrix representation (9) we see that J is self-adjoint, involutory and unitary,

$$J^\dagger = J, \quad J^2 = I, \quad J^{-1} = J^\dagger,$$

so that $\hat{H}_l[\alpha]$ is a J-pseudo-Hermitian operator in the sense of Refs. 10, 11, 17.

The eigenvalues of J-pseudo-Hermitian operators are known[10,14,20] to be either real or to come in complex-conjugate pairs. Here we illustrate this property by passing from the eigenvalue problem for the linear operator pencil,

$$\hat{L}_l[\alpha,\lambda]\psi := (\hat{H}_l[\alpha] - \lambda)\psi = 0,$$

to the eigenvalue problem $L_l[\alpha,\lambda]\psi_1 = 0$ for the associated quadratic operator pencil $L_l[\alpha,\lambda]$. This pencil can be derived explicitly from the Ansatz

$$\psi = \begin{pmatrix} \psi_1 \\ \dfrac{1}{\alpha}[Q[1]+\lambda]\psi_1 \end{pmatrix},$$

with $\alpha(r) \neq 0$. As result we obtain

$$L_l[\alpha,\lambda]\psi_1 \equiv \left\{ [Q[1]+\lambda]\frac{1}{\alpha}[Q[1]+\lambda] - Q[\alpha] \right\} \psi_1 = 0$$

$$= (A_2\lambda^2 + A_1\lambda + A_0)\psi_1 = 0.$$

The operators

$$A_0 := Q[1]\frac{1}{\alpha}Q[1] - Q[\alpha], \quad A_1 := Q[1]\frac{1}{\alpha} + \frac{1}{\alpha}Q[1], \quad A_2 := \frac{1}{\alpha},$$

are formally self-adjoint on $\mathcal{D}(Q)$ so that the functionals $a_j := (A_j\psi_1,\psi_1)$, $j = 1,2,3$ are real-valued: $\mathrm{Im}\, a_j = 0$.

From the quadratic equation

$$(L_l[\alpha,\lambda]\psi_1,\psi_1) = a_2\lambda^2 + a_1\lambda + a_0 = 0,$$

we conclude that the eigenvalues of the J-pseudo-Hermitian dynamo operator matrix $\hat{H}_l$ and its associated pencil L_l occur as eigenvalue pairs,[21]

$$\lambda_\pm = \frac{1}{2a_2}(-a_1 \pm \sqrt{a_1^2 - 4a_0a_2}).$$

Obviously, the sign of the discriminant $\Delta := a_1^2 - 4a_0a_2$ defines whether $\lambda_\pm$ are both real or pairwise complex conjugate. The transition from real eigenvalues $\lambda_\pm$ to complex ones occurs at $\Delta = 0$ where the eigenvalue becomes two-fold degenerate $\lambda_+ = \lambda_- = \lambda_0 = -a_1/2a_2$. This general

behavior of $\lambda_\pm$ confirms the results of numerical simulations,[4] which showed that a scaling of the helical turbulence function α leads to a pairwise intersection of real eigenvalue branches of $\hat{H}_l$ and a transition at the intersection points to a pair of complex conjugate eigenvalues.

We note that at the two-fold degenerate points λ_0 of the spectrum with $\Delta=0$ a Jordan–Keldysh chain[22] exists for the linear operator pencil,

$$\hat{L}_l(\lambda_0)\psi=0, \quad \hat{L}_l(\lambda_0)\chi=\psi,$$

as well as for the quadratic operator pencil,

$$L_l(\lambda_0)\psi_1=0, \quad L_l(\lambda_0)\chi_1+\partial_\lambda L_l(\lambda_0)\psi_1=0.$$

Both are built up from eigenvectors ψ, ψ_1 and associated vectors χ, χ_1, respectively.

III. CONSISTENCY CONDITIONS AND MATRIX RICCATI EQUATIONS

The fundamental J-symmetry (J-pseudo-Hermiticity) of the α^2-dynamo operator matrix provides a natural Ansatz for an intertwining construction which respects this symmetry:

$$\hat{H}_{l_0}[\alpha_0]-EI=-\hat{A}\hat{A}^\sharp, \quad \hat{H}_{l_1}[\alpha_1]-EI=-\hat{A}^\sharp\hat{A}. \tag{10}$$

In general, the operator matrix $\hat{A}$ could be an nth-order differential operator of the form

$$\hat{A}=\sum_{k=1}^{n} R_k(r)(ip)^k+Q(r),$$

with 2×2 matrices $R_k(r)$ and $Q(r)$ as coefficients. For simplicity, we restrict our attention in the present paper to the first-order differential operator,

$$\hat{A}=iR(r)p+Q(r), \tag{11}$$

with J-adjoint $\hat{A}^\sharp=-ipR^\sharp(r)+Q^\sharp(r)$. Here we define the $\sharp$-operation for a given 2×2 matrix C as

$$C^\sharp=JC^\dagger J=JC^{*T}J.$$

An asterisk and superscript ''^{T}'' denote complex conjugation and transposition, respectively.

Let us introduce the abbreviations

$$K_{0,1}:=I-\alpha_{0,1}\sigma_-,$$

$$M_{0,1}:=K_{0,1}\frac{l_{0,1}(l_{0,1}+1)}{r^2}+EI-\alpha_{0,1}\sigma_+,$$

with the nilpotent matrices $\sigma_\pm$ defined as

$$\sigma_+:=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix}, \quad \sigma_-:=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}.$$

The shifted α^2-dynamo operator matrices in (10) take then the short form

$$\hat{H}_{l_{0,1}}[\alpha_{0,1}]-EI=-pK_{0,1}p-M_{0,1}. \tag{12}$$

Substituting (11) and (12) into the intertwining Ansatz (10), making use of commutation relations like $[p,R(r)]=-iR'(r)$ and equating the coefficient matrices of the p^2, p, I terms we obtain the following six consistency conditions:

$$\hat{H}_{l_0}: \quad p^2: \ RR^\sharp = K_0, \tag{13}$$

$$p: \ RQ^\sharp - QR^\sharp - R(R^\sharp)' + R'R^\sharp = 0, \tag{14}$$

$$I: \ QQ^\sharp - R(R^\sharp)'' + R(Q^\sharp)' - Q(R^\sharp)' = M_0; \tag{15}$$

$$\hat{H}_{l_1}: \quad p^2: \ R^\sharp R = K_1, \tag{16}$$

$$p: \ -R^\sharp Q + Q^\sharp R = 0, \tag{17}$$

$$I: \quad Q^\sharp Q - (R^\sharp Q)' = M_1. \tag{18}$$

For a successful intertwining construction these matrix equations should be fulfilled simultaneously. So, the main task consists in finding explicit solution sets for (13)–(18). Alternatively, we should obtain intrinsic contradictions within this equation system which could be interpreted as a no-go theorem forbidding this construction for α^2-dynamo operator matrices.

We start our analysis with Eqs. (13) and (16). From the tautologies $RR^\sharp R = RR^\sharp R$ and $R^\sharp RR^\sharp = R^\sharp RR^\sharp$ follows:

$$RK_1 = K_0 R, \quad K_1 R^\sharp = R^\sharp K_0,$$

what with

$$R = \begin{pmatrix} r_{11} & r_{12} \\ r_{21} & r_{22} \end{pmatrix}, \quad R^\sharp = \begin{pmatrix} r_{22}^* & r_{12}^* \\ r_{21}^* & r_{11}^* \end{pmatrix}$$

yields

$$r_{12} = 0, \quad \frac{\alpha_1}{\alpha_0} = \frac{r_{11}}{r_{22}} = \frac{r_{11}^*}{r_{22}^*}. \tag{19}$$

Hence, we can set

$$r_{11} = |r_{11}| e^{i\gamma}, \quad r_{22} = |r_{22}| e^{i\gamma}, \quad r_{21} = |r_{21}| e^{i(\gamma+\varepsilon)}.$$

Using this and (19) in

$$RR^\sharp = K_0 = \begin{pmatrix} 1 & 0 \\ -\alpha_0 & 1 \end{pmatrix}, \quad R^\sharp R = K_1 = \begin{pmatrix} 1 & 0 \\ -\alpha_1 & 1 \end{pmatrix},$$

we find

$$R = e^{i\gamma} \begin{pmatrix} \sqrt{\dfrac{\alpha_1}{\alpha_0}} & 0 \\ -\dfrac{1}{2}\sqrt{\alpha_0 \alpha_1}(1 + i \tan \varepsilon) & \sqrt{\dfrac{\alpha_0}{\alpha_1}} \end{pmatrix}, \tag{20}$$

where the phases γ and ε are still undefined.

As a next step we analyze Eqs. (14) and (17). It is easily seen that defining the matrices

$$U:=R[Q^\sharp-(R^\sharp)'],\quad B:=R^\sharp Q, \tag{21}$$

these equations are equivalent to the J-symmetry relations

$$U=U^\sharp,\quad B=B^\sharp.$$

Due to the different symmetry content of B and Q it is natural to consider B as the primary structural element of the intertwining construction, and Q as a secondary one. So, we perform our subsequent investigation in terms of B and R. Explicitly, the J-symmetry is realized by the matrix structure

$$B=\begin{pmatrix} b_1+ib_4 & b_2 \\ b_3 & b_1-ib_4 \end{pmatrix},\quad \operatorname{Im} b_k=0,\quad k=1,\ldots,4. \tag{22}$$

Furthermore, we exclude Q from (21) to obtain

$$U=RBR^{-1}-R(R^\sharp)'. \tag{23}$$

Introducing the notation $N:=R^{-1}R'$ and substituting (23) into the symmetry relation $U=U^\sharp$ yields the additional constraint

$$[B,K_1^{-1}]=N^\sharp-N. \tag{24}$$

From Eq. (20) we find

$$N=i\gamma' I+\begin{pmatrix} -q & 0 \\ f & q \end{pmatrix},$$

$$q=\frac{1}{2}\left(\frac{\alpha_0'}{\alpha_0}-\frac{\alpha_1'}{\alpha_1}\right), \tag{25}$$

$$f=-\frac{\alpha_1}{2}\left[\frac{\alpha_0'}{\alpha_0}(1+i\tan\varepsilon)+i\frac{\varepsilon'}{\cos^2\varepsilon}\right], \tag{26}$$

so that (24) transforms to

$$\alpha_1\begin{pmatrix} b_2 & 0 \\ -2ib_4 & -b_2 \end{pmatrix}=-2i\gamma' I+\begin{pmatrix} 2q & 0 \\ f^*-f & -2q \end{pmatrix}.$$

Finally, we arrive at the following restrictions on the phase γ and the components b_2 and b_4 of the matrix B:

$$\gamma'=0,\quad b_2=\frac{2q}{\alpha_1},\quad b_4=\frac{\operatorname{Im} f}{\alpha_1}=-\frac{1}{2}\left(\frac{\alpha_0'}{\alpha_0}\tan\varepsilon+\frac{\varepsilon'}{\cos^2\varepsilon}\right). \tag{27}$$

Summarizing the implications of the first four consistency conditions, we see that they are free of intrinsic contradictions. From the initially eight arbitrary complex-valued functions contained in the matrices R and Q, only the three real-valued functions (b_1,b_3,ε) are still undefined. Together with the helical turbulence functions (α_0,α_1) and the constants $(\gamma,E,l_0,l_1)\in\mathbb{R}^2\times\mathbb{Z}_+^2$, we expect them to be highly fine-tuned by the remaining two consistency conditions (15) and (18).

Let us study these conditions now. Making use of the definitions of U and B in (21), their implications

$$Q^\sharp-(R^\sharp)'=R^{-1}U, \tag{28}$$

$$(Q^\sharp)'-(R^\sharp)''=-R^{-1}R'R^{-1}U+R^{-1}U',$$

$$Q=(R^\sharp)^{-1}B, \tag{29}$$

and setting at the end $RR^\sharp=K_0$, $R^\sharp R=K_1$ according to Eqs. (13), (16), we find that (15) and (18) transform to the matrix Riccati equations (MREs)

$$U'=M_0-UK_0^{-1}U, \tag{30}$$

$$B'=-M_1+BK_1^{-1}B. \tag{31}$$

Similar to the linearization of the scalar Riccati equations mentioned in (3)–(6) of the Introduction, the MREs (30), (31) can be linearized by an Ansatz,[23,24]

$$U=VW^{-1},\quad V,W\in\mathbb{C}^{2\times 2},\quad \det(W)\neq 0, \tag{32}$$

$$B=XY^{-1},\quad X,Y\in\mathbb{C}^{2\times 2},\quad \det(Y)\neq 0. \tag{33}$$

As result we arrive at the equation systems

$$\begin{pmatrix}V'\\W'\end{pmatrix}=\begin{pmatrix}0 & M_0\\ K_0^{-1} & 0\end{pmatrix}\begin{pmatrix}V\\W\end{pmatrix},\quad \begin{pmatrix}X'\\Y'\end{pmatrix}=-\begin{pmatrix}0 & M_1\\ K_1^{-1} & 0\end{pmatrix}\begin{pmatrix}X\\Y\end{pmatrix}. \tag{34}$$

The 4×2 matrices

$$\begin{pmatrix}V\\W\end{pmatrix},\begin{pmatrix}X\\Y\end{pmatrix}\in\mathbb{C}^{4\times 2}$$

are defined up to $GL(2,\mathbb{C})\times GL(2,\mathbb{C})$-transformations

$$\begin{pmatrix}\tilde V\\ \tilde W\end{pmatrix}=\begin{pmatrix}VG_0\\ WG_0\end{pmatrix},\quad \begin{pmatrix}\tilde X\\ \tilde Y\end{pmatrix}=\begin{pmatrix}XG_1\\ YG_1\end{pmatrix},\quad G_0,G_1\in GL(2,\mathbb{C}),$$

and can be interpreted as homogeneous coordinates of two points on a complex Grassmann manifold $G_2(\mathbb{C}^4)$ which consists of 2-dimensional complex subspaces in $\mathbb{C}^4$ (see, e.g., Refs. 23, 24). The matrices $U=VW^{-1}$ and $B=XY^{-1}$ are the corresponding affine coordinates of these points.

Differentiating (34) and substituting $V=K_0W'$, $X=-K_1Y'$, it is easily seen that the equation systems (34) are equivalent to the second-order matrix differential equations,

$$\begin{aligned}(\partial_r K_0\partial_r-M_0)W&=0,\\ (\partial_r K_1\partial_r-M_1)Y&=0.\end{aligned} \tag{35}$$

This implies that the matrices $\tilde W=r^{-1}W$, $\tilde Y=r^{-1}Y$ should be formal (non-normalized) solutions of the eigenvalue equations for the dynamo operator matrices $\hat H_{l_0}[\alpha_0]$, $\hat H_{l_1}[\alpha_1]$, respectively,

$$\hat H_{l_0}[\alpha_0]\tilde W=E\tilde W,\quad \hat H_{l_1}[\alpha_1]\tilde Y=E\tilde Y.$$

A comparison with the simple QM model from the Introduction shows that the intertwining operator matrix $\hat A$ should be expressible in terms of W or Y, and that W and Y should be connected by a product invariant like (7). With the help of (28), (29) and (34) we find

$$\hat A=R(ip-Y'Y^{-1})=(ip+K_0W'W^{-1}K_0^{-1})R.$$

In order to obtain the product invariant which connects W and Y, we use a slightly modified version of (23),

$$U=RB^{\sharp}R^{-1}-R(R^{\sharp})',$$

and substitute from (32)–(34),

$$U=RR^{\sharp}W'W^{-1}, \quad B^{\sharp}=-(Y^{\sharp})^{-1}(Y^{\sharp})'R^{\sharp}R,$$

so that

$$W'W^{-1}=-(R^{\sharp})^{-1}(Y^{\sharp})^{-1}(Y^{\sharp})'R^{\sharp}-(R^{\sharp})^{-1}(R^{\sharp})'. \tag{36}$$

This equation is of the type $g=g_1n$, $(\partial_r g)g^{-1}=(\partial_r g_1)g_1^{-1}+g_1(\partial_r n)n^{-1}g_1^{-1}$. Hence, integration of (36) yields the product invariant,

$$Y^{\sharp}R^{\sharp}W=C, \quad \det(C)\neq 0,$$

with C a constant nonsingular matrix.

So far, we have obtained a 1:1 generalization of the intertwining technique from the simple QM example described in the Introduction to our J-symmetric dynamo operator model. It remains to test whether the MREs of this model are consistent. This will be the subject of the next section.

IV. NO-GO THEOREM

In order to test the pair of MREs (30), (31) for consistency, we make use of (23), (24) as well as the relation

$$N+K_1^{-1}N^{\sharp}K_1=K_1^{-1}K_1'=K_1',$$

and transform the MRE for U [Eq. (30)] into an equivalent MRE for B. As result, we arrive at the following pair of MREs:

$$B'=R^{-1}M_0R-K_1^{-1}BB+BK_1'+[NN^{\sharp}+(N^{\sharp})']K_1, \tag{37}$$

$$B'=-M_1+BK_1^{-1}B, \tag{38}$$

which should be satisfied simultaneously. The corresponding consistency test will be performed in two steps:

(1) From the limiting behavior at $r\to 0$ we will derive a relation between l_0 and l_1.

(2) We will extract from Eqs. (37), (38) a system of nonlinear ODEs for the helical turbulence functions α_0,α_1 and for the components $b_1,\ldots,b_4$ of the matrix B. By mutual substitutions of these ODEs we will find an inconsistency which can be interpreted as a no-go theorem.

A. Limiting behavior at $r\to 0$

From the assumed nonsingular behavior of the helical turbulence functions at $r\to 0$ follows that they can be approximated as

$$\alpha_{0,1}(r\to 0)\approx c_{0,1}+a_{0,1}r+\mathcal{O}(r^2) \quad , \quad c_{0,1}\neq 0.$$

Substituting this approximation in a slightly rewritten version of the defining equation (35) for the matrix Y,

$$\left[I\partial_r^2-\alpha_1'\sigma_-\partial_r-\frac{l_1(l_1+1)}{r^2}I-\begin{pmatrix} E & -\alpha_1 \\ \alpha_1 & E-\alpha_1^2 \end{pmatrix}\right]Y=0, \tag{39}$$

we obtain the estimate

$$Y(r\to 0)\approx r^{-l_1}\left(I+\frac{a_1}{2}\sigma_- r+\mathcal{O}(r^2)\right)(r^{2l_1+1}C_+ + C_-),$$

where C_+, C_- are arbitrary nonsingular constant matrices $\det(C_\pm)\neq 0$. Correspondingly, it holds

$$Z:=Y'Y^{-1}\approx -l_1 r^{-1}I+\frac{a_1}{2}\sigma_- +\mathcal{O}(r), \tag{40}$$

$$B=-K_1 Y'Y^{-1}\approx l_1 r^{-1}I-[c_1 l_1 r^{-1}+(l_1+1/2)a_1]\sigma_- +\mathcal{O}(r). \tag{41}$$

A comparison of (41) with (22) shows that the components b_2 and b_4 of the matrix B vanish at least as

$$b_2, b_4\approx\mathcal{O}(r), \quad \text{for } r\to 0.$$

Furthermore, we find with the help of Eqs. (25), (26) and (27) that $q\approx\mathcal{O}(r)$ and, hence, $a_0/c_0 = a_1/c_1$, as well as $q', f, f'\approx\mathcal{O}(1)$ which implies $N, N^\sharp, (N^\sharp)'\approx\mathcal{O}(1)$.

We are now well prepared to perform a partial consistency test of (37) and (38) by comparing the singular terms of these equations in the vicinity of the origin $r=0$. From the MREs (37) and (38) we find

$$-K_1^{-1}K_1' Z - Z' = \frac{l_0(l_0+1)}{r^2}I - K_1^{-1}ZK_1 Z - ZK_1' +\mathcal{O}(1), \tag{42}$$

$$-K_1^{-1}K_1' Z - Z' = -\frac{l_1(l_1+1)}{r^2}I + ZZ +\mathcal{O}(1), \tag{43}$$

respectively. Substituting Z from (40) and equating the coefficients of the r^{-2}, r^{-1}-terms we obtain from Eq. (42),

$$l_1 = l_0+1, \quad a_1 = 0,$$

and, hence, also $a_0=0$. Equation (43) is automatically satisfied, because Y is defined by the corresponding linearized equation (39). The incremental relation $l_1=l_0+1$ is well known from ladder operator constructions for spherically symmetric Hamiltonians in QM.[5] This is not surprising, because this ladder operator construction can be recovered from the intertwining construction (10) for the α^2-dynamo operator matrices by the two-step transition: 1. $\alpha_0=\alpha_1=\alpha$, 2. $\alpha\to 0$.

B. Systems of coupled nonlinear ODEs and their inconsistency

The system of eight coupled nonlinear ODEs for the components $b_1,\ldots,b_4$ of the matrix B is easily obtained from the MREs (37), (38), e.g., with the help of the matrix multiplication package of MATHEMATICA©. For our analysis it is sufficient to consider only the simplest four equations of this system, i.e., the σ_+ and I projections of (37) and (38):

$$b_2' = 2b_1 b_2 + \alpha_1(1+b_2^2), \tag{44}$$

$$= -2b_1 b_2 - \frac{\alpha_0^2}{\alpha_1}, \tag{45}$$

$$b_1' = b_1^2 + b_2 b_3 - b_4^2 - E - \frac{l_1(l_1+1)}{r^2} + \alpha_1 b_1 b_2, \tag{46}$$

$$= -b_1^2 - b_2 b_3 + b_4^2 + E + \frac{l_0(l_0+1)}{r^2} - \alpha_1' b_2 + \frac{\alpha_0^2}{2} + q' - q^2. \tag{47}$$

Equating the right-hand-sides of (44), (45) and using $b_2 = 2q/\alpha_1$ from (27) we are able to express b_1 as

$$b_1 = -\frac{4q^2 + \alpha_0^2 + \alpha_1^2}{8q}. \tag{48}$$

Taking into account that $q = \partial_r \ln(\alpha_0/\alpha_1)/2$ according to (25) and that the helical turbulence functions α_0 and α_1 do not depend on l_0 or l_1 we conclude from Eq. (48) that b_1 should not depend on l_0 or l_1 too. On the other hand, the addition of (46) and (47) together with the relation $l_0 = l_1 - 1$ gives

$$2b_1' = -\frac{2l_1}{r^2} + 2q\left(b_1 - \frac{\alpha_1'}{\alpha_1}\right) + \frac{\alpha_0^2}{2} + q' - q^2,$$

which by integration leads to a function b_1 which depends on l_1. That means, the term depending on l_1 cannot be compensated by a combination of l_1-independent terms. This is an obvious contradiction to (48) and we have to conclude that the consistency conditions (13)–(18) cannot be fulfilled simultaneously. This means that we are lead to the

No-go theorem: The structure of the MHD α^2-dynamo operator matrix is incompatible with an operator intertwining technique which is based on first-order differential intertwining operators.

A similar situation occurs also for three-dimensional spherically symmetric models in QM.[5] There the l-dependent centrifugal term sets so strong restrictions on the form of the allowed potential that an intertwining construction built on first-order differential intertwining operators is only possible for the following three cases: the constant potential $V(r) = \text{const}$, the Coulomb potential $V(r) \propto 1/r$, and the potential of the three-dimensional isotropic harmonic oscillator with $V(r) \propto r^2$. Richer classes of allowed potentials are only found for models in their s states, when $l = 0$. Such states are *a priori* excluded for the α^2-dynamo operator matrix due to its construction [see Eq. (A5)].

V. CONCLUDING REMARKS

In the present paper, we have tested the MHD α^2-dynamo operator matrix for its compatibility with the simplest variant of an intertwining construction based on *first-order* differential intertwining operators. The operators have been chosen in accordance with the fundamental J-symmetry (pseudo-Hermiticity) of the operator matrix and lead to a set of six matrix equations as consistency conditions. With the help of a step-by-step reduction of the complexity we have extracted their basic structural elements and have shown that they contain an intrinsic inconsistency. So, we have to conclude that the structure of the α^2-dynamo operator matrix is not compatible with the considered first-order differential intertwining Ansatz. This fact is the subject of the formulated no-go theorem.

It remains to test whether intertwining constructions can be built from second-order or higher-order differential intertwining operators. Energy shift operators based on second-order differential expressions are known for harmonic oscillators with time-dependent frequencies and additional $1/r^2$-term[25] as well as for the spherically symmetric oscillator and the Coulomb potential.[5] A generalization of the technique to the MHD α^2-dynamo operator matrix seems realistic.

Another approach for a clarification of the considered isospectrality problem could consist in a generalization of the Gelfand–Levitan technique for vector-valued Sturm–Liouville problems.[26]

Concerning its general structure, the α^2-dynamo operator matrix $\hat{H}_l[\alpha]$ is a singular non-self-adjoint matrix Sturm–Liouville operator which by a unitary transformation can be recast into the standard form

$$-\partial_r P_2(r)\partial_r + P_0(r).$$

In 1998, Jodeit and Levitan[26] analyzed the isospectrality problem for matrix Sturm–Liouville operators with $P_2(r)=I$ and $P_0(r)$ a symmetric matrix. They showed that if two vector-valued Sturm–Liouville problems are isospectral then the eigenfunctions of one problem can be constructed from the eigenfunctions of the other problem with the help of a matrix Gelfand–Levitan transformation. So, a generalization of this technique to Sturm-Liouville problems with nonsymmetric $P_0(r)$ and $P_2(r)\neq I_2$ would naturally cover the isospectrality problem for the MHD α^2-dynamo operator matrix.

APPENDIX A: DERIVATION OF THE α^2-DYNAMO OPERATOR MATRIX FROM THE MEAN-FIELD INDUCTION EQUATION

For completeness we sketch here the main steps of the derivation of the 2×2 operator matrix $\hat{H}_l[\alpha]$ for a model with helical turbulence function $\alpha(r)$. The outline follows the technique for models with $\alpha=\text{const}$ as presented in Ref. 1.

The spherical MHD mean-field α^2-dynamo in its kinematic regime is described by the induction equation for the magnetic field,

$$\partial_t \mathbf{B} = \boldsymbol{\nabla}\times(\alpha\mathbf{B}) + \nu_m \Delta \mathbf{B}, \tag{A1}$$

supplemented by the condition $\boldsymbol{\nabla}\cdot\mathbf{B}=0$. The magnetic diffusivity ν_m is assumed to be constant and the helical turbulence function α to depend only on the distance from the origin $\alpha=\alpha(r)$. Decomposition into toroidal and poloidal components $\mathbf{B}=\mathbf{B_t}+\mathbf{B_p}$ and setting $\mathbf{B_p}=\boldsymbol{\nabla}\times\mathbf{A_t}$ allows for a decomposition of the induction equation (A1):

$$\partial_t \mathbf{B_t} = \boldsymbol{\nabla}\times(\alpha\boldsymbol{\nabla}\times\mathbf{A_t}) - \nu_m \boldsymbol{\nabla}\times\boldsymbol{\nabla}\times\mathbf{B_t}, \tag{A2}$$

$$\partial_t \mathbf{A_t} = \alpha\mathbf{B_t} - \nu_m \boldsymbol{\nabla}\times\boldsymbol{\nabla}\times\mathbf{A_t}. \tag{A3}$$

Furthermore, the fields $\mathbf{B_t}$ and $\mathbf{A_t}$ can be represented as

$$\mathbf{A_t} = -\mathbf{r}\times\boldsymbol{\nabla}F_1, \quad \mathbf{B_t} = -\mathbf{r}\times\boldsymbol{\nabla}F_2,$$

where F_1 and F_2 are single-valued scalar functions which are normalized on the unit sphere S^2 by the condition

$$\int_{S^2} F_{1,2}\ d\omega = 0. \tag{A4}$$

With the help of the relations

$$\Delta(\mathbf{r}\times\boldsymbol{\nabla}F_1) = \mathbf{r}\times\boldsymbol{\nabla}\Delta F_1,$$

$$\boldsymbol{\nabla}\times[\alpha\boldsymbol{\nabla}\times(-\mathbf{r}\times\boldsymbol{\nabla}F_1)] = \mathbf{r}\times\boldsymbol{\nabla}\left[\frac{1}{r}(\partial_r\alpha)(\partial_r r F_1) + \alpha\Delta F_1\right],$$

$$\alpha \mathbf{r}\times\nabla F_2 = \mathbf{r}\times\nabla(\alpha F_2),$$

Eqs. (A2) and (A3) can be rewritten as

$$\mathbf{r}\times\nabla[\,\nu_m \Delta F_1 + \alpha F_2 - \partial_t F_1] = 0,$$

$$\mathbf{r}\times\nabla\left[\,\nu_m \Delta F_2 - \frac{1}{r}(\partial_r \alpha)(\partial_r r F_1) - \alpha \Delta F_1 - \partial_t F_2\right] = 0.$$

It follows that the expressions in the square brackets are functions of r and t alone which must vanish due to the normalization condition (A4) and its implication $\int_{S^2} \Delta F_{1,2}\, d\omega = 0$. By re-scaling of r and t one sets the magnetic diffusivity to unity $\nu_m = 1$ and the boundary conditions at $r = 1$.

With the help of a series expansion in spherical harmonics,

$$F_{1,2} = \sum_{l,m,n} e^{\lambda_{l,n} t} F_{1,2}^{(l,m,n)}(r) Y_l^m(\theta,\phi) \in L^2(\Omega, r^2 dr) \otimes L^2(S^2, d\omega), \quad \Omega = [0,1],$$

one obtains the eigenvalue problem

$$\Delta_l F_1^{(l,m,n)} + \alpha F_2^{(l,m,n)} = \lambda_{l,n} F_1^{(l,m,n)},$$

$$\Delta_l F_2^{(l,m,n)} - \frac{1}{r}(\partial_r \alpha)(\partial_r r F_1^{(l,m,n)}) - \alpha \Delta_l F_1^{(l,m,n)} = \lambda_{l,n} F_2^{(l,m,n)}.$$

Here we used the notation $\Delta_l = (1/r^2)\,\partial_r r^2 \partial_r - l(l+1)/r^2$ and the fact that due to the symmetry of the dynamo configuration[1] the eigenvalues $\lambda_{l,n}$ depend only on l and n. We note that the normalization condition (A4) implies

$$F_{1,2}^{(l=0,m,n)} = 0. \tag{A5}$$

Finally, the substitutions $p = -i(\partial_r + 1/r)$, $\psi_{1,2} = F_{1,2}^{(l,m,n)} \in L^2(\Omega, r^2 dr)$ lead to the eigenvalue problem for the α^2-dynamo operator matrix $\hat{H}_l[\alpha]$ as it is given in Eq. (8) of the Introduction.

Special solution of the inhomogeneous Bloch equation

M. Kobayashi[a)]
Department of Physics, Gifu University, Yanagido, Gifu 501-1193, Japan

(Received 20 June 2002; accepted 3 April 2003)

A solution of the inhomogeneous Bloch equation is given for a class of three-dimensional time-varying magnetic fields by finding the fundamental system in terms of a set of the three independent solutions of the homogeneous Bloch equation. This class is distinguished by requiring a nonlinear relation between one of the magnetic field components and the other two components and their derivatives. A brief discussion of the magnetic field class characteristics and an illustrative example are given. © *2003 American Institute of Physics.*

I. INTRODUCTION

Since the Bloch equation[1] was proposed in 1946, various workers have tried to solve it analytically. As yet few exact solutions are known.[2] Very recently, an interesting solution was found to the homogeneous Bloch equation.[3] This was done by solving the Riccati equation to which the homogeneous Bloch equation reduces.[4] The reason why we persist in solving the homogeneous Bloch equation analytically is due to the fact that the inhomogeneous Bloch equation is uniquely solved by finding a fundamental system in terms of a set of three independent solutions of the homogeneous Bloch equation. By linearizing the Riccati equation, a set of three solutions of the homogeneous Bloch equation are found.[5] The fundamental matrix in terms of these solutions becomes singular. This means two of them serve as independent solutions. We have clarified the utility and limitation of this approach to solve the homogeneous Bloch equation.

The purpose of this paper is to find a fundamental system of solutions using the standard method of solving the Riccati equation.[6] We thus discover a solution of the inhomogeneous Bloch equation for a class of time-varying magnetic fields.

In Sec. II we solve the Riccati equation and find a set of three independent solutions of the homogeneous Bloch equation. Then in Sec. III we give a solution of the inhomogeneous Bloch equation using the fundamental system of solutions. A brief discussion of the magnetic field class characteristics and an illustrative example are given in Sec. IV. The final section is devoted to our conclusions.

II. THE RICCATI EQUATION

The Bloch equation for magnetization with infinite relaxation times is a homogeneous system of three first-order linear differential equations, and given by

$$\dot{\mathbf{M}} = -\gamma(\mathbf{B}\times\mathbf{M}), \tag{1}$$

where an overdot means differentiation with respect to time. Here **M** and **B** are the magnetization vector and the applied magnetic field, respectively, and γ is the gyromagnetic ratio.

It immediately follows from Eq. (1) that the magnitude of the magnetization vector is preserved. Thus we can define **m** by

a)Electronic mail: masanori@cc.gifu-u.ac.jp

$$\mathbf{m}=\frac{\mathbf{M}}{|\mathbf{M}|}, \tag{2}$$

which obeys the Bloch equation, i.e.,

$$\dot{\mathbf{m}}=-\gamma(\mathbf{B}\times\mathbf{m}), \tag{3}$$

with

$$\mathbf{m}\cdot\mathbf{m}=1. \tag{4}$$

Let us introduce the two variables, ξ and η, defined by

$$m_1+i\,m_2=\xi(1-m_3), \tag{5}$$

and

$$m_1-i\,m_2=\frac{1}{\eta}(m_3-1); \tag{6}$$

then we find

$$\xi=\frac{m_1+i\,m_2}{1-m_3}=\frac{1+m_3}{m_1-i\,m_2}, \tag{7}$$

and

$$\eta=-\frac{1-m_3}{m_1-i\,m_2}=-\frac{m_1+i\,m_2}{1+m_3}, \tag{8}$$

and the relationships between ξ and η such that

$$\xi\eta^*=\xi^*\eta=-1, \tag{9}$$

$$\xi\xi^*=\frac{1+m_3}{1-m_3}, \tag{10}$$

and

$$\eta=-\frac{1-m_3}{1+m_3}\xi. \tag{11}$$

Differentiating Eq. (7) with respect to time and substituting Eq. (3) into it, we find the Riccati equation,

$$\dot{\xi}=\tfrac{1}{2}\gamma(B_2+i\,B_1)\,\xi^2-i\,\gamma B_3\,\xi+\tfrac{1}{2}\gamma(B_2-i\,B_1). \tag{12}$$

Similarly, we also find the same Riccati equation for η. Here use has been made of the relationship

$$B_1\,m_2-B_2\,m_1=-\tfrac{1}{2}(B_2+i\,B_1)(m_1+i\,m_2)-\tfrac{1}{2}(B_2-i\,B_1)(m_1-i\,m_2). \tag{13}$$

Let z be defined by

$$z=\left(\frac{B_2-i\,B_1}{B_2+i\,B_1}\right)^{1/2}; \tag{14}$$

then we find

$$z = \pm i\, e^{i\psi}, \tag{15}$$

where

$$B_2 \pm i\, B_1 = \pm i\, B_0\, e^{\mp i\psi}, \tag{16}$$

with

$$B_0 = \sqrt{B_1^2 + B_2^2}, \tag{17}$$

and

$$\psi = \cos^{-1}\left(\frac{B_1}{B_0}\right) = \sin^{-1}\left(\frac{B_2}{B_0}\right) = \tan^{-1}\left(\frac{B_2}{B_1}\right). \tag{18}$$

Having assigned the two phases of z to ξ and η, we define

$$\xi = -i\, e^{i\psi} u, \tag{19}$$

and

$$\eta = i\, e^{i\psi} v. \tag{20}$$

Thus we find the relationships from Eqs. (9), (10), and (11):

$$u v^* = u^* v = 1, \tag{21}$$

$$u u^* = \frac{1+m_3}{1-m_3}, \tag{22}$$

and

$$v = \frac{1-m_3}{1+m_3} u. \tag{23}$$

Since u is defined by Eq. (19),

$$\xi = z u, \tag{24}$$

with

$$z = -i\, e^{i\psi}, \tag{25}$$

then the Riccati equation (12) turns out to be

$$z \dot{u} = \tfrac{1}{2}\gamma(B_2 - i B_1)(u^2+1) - (\dot{z} + i\,\gamma B_3 z)\, u. \tag{26}$$

Notice that the Riccati equation (26) can be solved by requiring the coefficient of u to be proportional to the coefficient of u^2+1;

$$\dot{z} + i\,\gamma B_3 z = i\, C\, \tfrac{1}{2}\gamma(B_2 - i B_1), \tag{27}$$

where C is an arbitrary real constant. This produces a separation of the variables, u and z, and leads to an expression for z consistent with the previous definition after solving the resulting first-order linear differential equation.[6]

Using Eqs. (16) and (25), we rewrite Eq. (27) in the form

$$\dot{z} = i(-\gamma B_3 + \tfrac{1}{2} C\, \gamma B_0) z\,. \tag{28}$$

The solution of Eq. (28) is easily found and given by

$$z = -i\, e^{i\psi}, \tag{29}$$

where

$$\psi = \int_{t_0}^{t} \left[-\gamma B_3(\tau) + \frac{1}{2} C\, \gamma B_0(\tau) \right] d\tau\,. \tag{30}$$

Substituting Eq. (27) into Eq. (26), we find

$$\dot{u} = \tfrac{1}{2} \gamma B_0 (u^2 - i\, C\, u + 1)\,, \tag{31}$$

where we have used Eqs. (16) and (25).

Solving Eq. (31), we find two solutions:

$$u_1 = i\, \alpha + \beta \tan(\beta \chi)\,, \tag{32}$$

and

$$u_2 = i\, \alpha - \beta \cot(\beta \chi)\,, \tag{33}$$

where α and β are given by

$$\alpha = \tfrac{1}{2} C\,, \tag{34}$$

and

$$\beta = \sqrt{1 + \alpha^2}\,, \tag{35}$$

and

$$\chi = \frac{1}{2} \gamma \int_{t_0}^{t} B_0(\tau)\, d\tau\,. \tag{36}$$

Similarly we find the solutions for η as

$$\eta = i\, e^{i\psi} v\,, \tag{37}$$

with

$$v = \frac{1}{(u\, u^*)} u\,, \tag{38}$$

where v is the solution of the differential equation;

$$\dot{v} = -\tfrac{1}{2} \gamma B_0 (v^2 + i\, C\, v + 1)\,. \tag{39}$$

We thus find the solutions of Eq. (39),

$$v_1 = -[i\,\alpha + \beta \tan(\beta\,\chi)]\,, \tag{40}$$

and

$$v_2 = -[i\,\alpha - \beta \cot(\beta\,\chi)]\,. \tag{41}$$

The solutions of the Riccati equation for ξ and η have the same forms.

We have found two solutions of the Riccati equation (12):

$$\xi_1 = -i\,e^{i\psi} u_1 = e^{i\psi}[\alpha - i\,\beta \tan(\beta\,\chi)]\,, \tag{42}$$

and

$$\xi_2 = -i\,e^{i\psi} u_2 = e^{i\psi}[\alpha + i\,\beta \cot(\beta\,\chi)]\,. \tag{43}$$

The Riccati equation (12) can be cast in the more convenient form

$$\dot{\xi} = i\,\dot{\chi}\,e^{-i\psi}\,\xi^2 - i\,\dot{\chi}_3\,\xi - i\,\dot{\chi}\,e^{i\psi}\,, \tag{44}$$

where

$$\chi_3 = \gamma \int_{t_0}^{t} B_3(\tau)\,d\tau\,. \tag{45}$$

Here we have used Eqs. (16), (17), and (36).

By using the solutions (42) and (43), we can find a third solution of the Riccati equation (44). Since $\xi_i\,,(i=1,2)$ are the solutions of Eq. (44), we have

$$\dot{\xi} - \dot{\xi}_i = i\,\dot{\chi}\,e^{-i\psi}(\xi^2 - \xi_i^2) - i\,\dot{\chi}_3(\xi - \xi_i) \quad (i=1,2)\,, \tag{46}$$

namely,

$$\frac{\dot{\xi} - \dot{\xi}_i}{\xi - \xi_i} = i\,\dot{\chi}\,e^{-i\psi}(\xi + \xi_i) - i\,\dot{\chi}_3 \quad (i=1,2)\,. \tag{47}$$

Thus we find

$$\frac{\dot{\xi} - \dot{\xi}_1}{\xi - \xi_1} - \frac{\dot{\xi} - \dot{\xi}_2}{\xi - \xi_2} = i\,\dot{\chi}\,e^{-i\psi}(\xi_1 - \xi_2)\,. \tag{48}$$

The solution of the differential equation (48) is

$$\frac{\xi - \xi_1}{\xi - \xi_2} = C_1 \exp\left\{ i \int_{t_0}^{t} \dot{\chi}(\tau) e^{-i\psi(\tau)}[\xi_1(\tau) - \xi_2(\tau)]\,d\tau \right\}, \tag{49}$$

where C_1 is a constant of integration. The third solution is obtained by substituting Eqs. (42) and (43) into Eq. (49). The result turns out to be

$$\frac{\xi_3 - \xi_1}{\xi_3 - \xi_2} = \tan(\beta\,\chi)\,, \tag{50}$$

where we have chosen C_1 as

$$C_1 = \tan[\beta\,\chi(t_0)]\,. \tag{51}$$

Thus we find

$$\xi_3 = e^{i\psi}\left[\alpha - i\,\beta\frac{1+\tan(\beta\chi)}{1-\tan(\beta\chi)}\right] = e^{i\psi}\left[\alpha + i\,\beta\frac{1+\cot(\beta\chi)}{1-\cot(\beta\chi)}\right]. \tag{52}$$

III. THE FUNDAMENTAL SYSTEM

A set of three solutions of the homogeneous Bloch equation is obtained from the Riccati equation (12) corresponding to equations Eqs. (42), (43), and (52).

Let $\mathbf{m}^{(i)}$ $(i=1,2,3)$, be

$$m_1^{(i)} = \frac{\xi_i + \xi_i^*}{1+\xi_i\,\xi_i^*}, \tag{53}$$

$$m_2^{(i)} = -\,i\,\frac{\xi_i - \xi_i^*}{1+\xi_i\,\xi_i^*}, \tag{54}$$

and

$$m_3^{(i)} = -\,\frac{1-\xi_i\,\xi_i^*}{1+\xi_i\,\xi_i^*}; \tag{55}$$

then the fundamental matrix K is defined by

$$(K)_{ij} = K_{ij} = m_i^{(j)} \quad (i,j=1,2,3)\,. \tag{56}$$

Here use has been made of the definitions of ξ and η, Eqs. (5) and (6), respectively, together with Eq. (9).

Substituting Eqs. (42), (43), and (52) into Eqs. (53), (54), and (55), we write out the elements of the fundamental matrix here:

$$K_{11} = m_1^{(1)} = \frac{1}{\beta^2}\{\alpha[1+\cos(2\beta\chi)]\cos\psi + \beta\sin(2\beta\chi)\sin\psi\}, \tag{57}$$

$$K_{21} = m_2^{(1)} = \frac{1}{\beta^2}\{\alpha[1+\cos(2\beta\chi)]\sin\psi - \beta\sin(2\beta\chi)\cos\psi\}, \tag{58}$$

$$K_{31} = m_3^{(1)} = -\left(\frac{1-\alpha^2}{\beta^2}\right)\frac{1}{2}[1+\cos(2\beta\chi)] + \frac{1}{2}[1-\cos(2\beta\chi)], \tag{59}$$

$$K_{12} = m_1^{(2)} = \frac{1}{\beta^2}\{\alpha[1-\cos(2\beta\chi)]\cos\psi - \beta\sin(2\beta\chi)\sin\psi\}, \tag{60}$$

$$K_{22} = m_2^{(2)} = \frac{1}{\beta^2}\{\alpha[1-\cos(2\beta\chi)]\sin\psi + \beta\sin(2\beta\chi)\cos\psi\}, \tag{61}$$

$$K_{32} = m_3^{(2)} = -\left(\frac{1-\alpha^2}{\beta^2}\right)\frac{1}{2}[1-\cos(2\beta\chi)] + \frac{1}{2}[1+\cos(2\beta\chi)], \tag{62}$$

$$K_{13} = m_1^{(3)} = \frac{1}{\beta^2}\{\alpha[1-\sin(2\beta\chi)]\cos\psi + \beta\cos(2\beta\chi)\sin\psi\}, \tag{63}$$

$$K_{23}=m_2^{(3)}=\frac{1}{\beta^2}\{\alpha[1-\sin(2\beta\chi)]\sin\psi-\beta\cos(2\beta\chi)\cos\psi\}, \tag{64}$$

and

$$K_{33}=m_3^{(3)}=-\left(\frac{1-\alpha^2}{\beta^2}\right)\frac{1}{2}[1-\sin(2\beta\chi)]+\frac{1}{2}[1+\sin(2\beta\chi)]. \tag{65}$$

First of all we have to calculate the determinant of the fundamental matrix. The result turns out to be

$$\det K=\frac{2\alpha}{\beta^3}=C\left(\frac{2}{\sqrt{4+C^2}}\right)^3. \tag{66}$$

This means that the fundamental matrix is nonsingular and the three solutions of the homogeneous Bloch equation are linearly independent.

The homogeneous Bloch equation (3) is written in the form

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{m}=A\,\mathbf{m}, \tag{67}$$

where the normalized magnetization vector $\mathbf{m}$ is a column vector and A is 3×3 matrix and given by

$$A=\begin{pmatrix} 0 & \gamma B_3 & -\gamma B_2 \\ -\gamma B_3 & 0 & \gamma B_1 \\ \gamma B_2 & -\gamma B_1 & 0 \end{pmatrix}. \tag{68}$$

The homogeneous Bloch equation turns out to be

$$\dot{K}_{ij}=\dot{m}_i^{(j)}=A_{ik}\,m_k^{(j)}=A_{ik}\,K_{kj}\quad(i,j=1,2,3), \tag{69}$$

where we assume summation over repeated indices and

$$(A)_{ij}=A_{ij}. \tag{70}$$

Thus we find

$$\dot{K}=A\,K. \tag{71}$$

Similarly, we find

$$\det\dot{K}=\dot{K}_{ij}\,K_{ij}^C=A_{ik}\,K_{kj}\,K_{ij}^C=A_{ik}\,\delta_{ki}\det K=\mathrm{tr}\,A\det K, \tag{72}$$

where K_{ij}^C is the cofactor of K_{ij} and

$$K_{ik}\,K_{jk}^C=\delta_{ij}\det K. \tag{73}$$

The solution of the differential equation (72) is

$$\det K=\det K(t_0)\exp\left[\int_{t_0}^{t}\mathrm{tr}\,A(\tau)\,d\tau\right], \tag{74}$$

with

$$\operatorname{tr} A = 0 . \tag{75}$$

Thus we find that Eq. (66) is exactly the solution we want.

The inhomogeneous Bloch equation has the form

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{m} = A\,\mathbf{m} + \mathbf{b} , \tag{76}$$

where the column vector **b** is given by

$$b_i = -\frac{m_i}{T_i} \quad (i = 1, 2, 3) . \tag{77}$$

Here $T_i \quad (i = 1, 2, 3)$ are relaxation times.

The fundamental system of solutions of the homogeneous system is a set of three linearly independent magnetization vector, $\mathbf{m}^{(i)} \quad (i = 1, 2, 3)$. Using the fundamental matrix K defined by Eq. (56), the unique solution to the inhomogeneous system (76) is

$$\mathbf{m} = K K^{-1}(t_0)\,\mathbf{m}(t_0) + K \int_{t_0}^{t} K^{-1}(\tau)\,\mathbf{b}(\tau)\,d\tau , \tag{78}$$

where the inverse matrix of K is defined by

$$K^{-1} = \frac{\operatorname{adj} K}{\det K} , \tag{79}$$

with

$$(\operatorname{adj} K)_{ij} = K^{C}_{ji} . \tag{80}$$

The cofactors of $K_{ij} \quad (i, j = 1, 2, 3)$, are listed in the Appendix.

IV. CHARACTERISTICS OF THE MAGNETIC FIELD CLASS AND ILLUSTRATIVE EXAMPLE

In this section we give a brief discussion of the import of the restriction imposed on the magnetic field through the relation (81) below and an illustrative example of precession.

Differentiating Eq. (30) with respect to time, we find

$$\gamma B_3 = \frac{\dot{B}_1 B_2 - B_1 \dot{B}_2}{B_1^2 + B_2^2} + \frac{1}{2} C\,\gamma \sqrt{B_1^2 + B_2^2} , \tag{81}$$

where we have used Eq. (18). The third component of the magnetic field is expressed by the other two independent time-varying magnetic field components. The effect of the assumption (27) is to restrict the acceptable domain of the magnetic field variation to the region of $(\mathbf{B}, \dot{\mathbf{B}})$-space where the relationship (81) holds.

To discuss the characteristics of the magnetic field class we give some insight to the meaning of the restriction (81) which must be satisfied by the applied magnetic field in order to obtain the solution which is developed in the article.

The simplest practical discussion would center on the behavior of the third component when the first two components are harmonically varying;

$$\mathbf{B}(t) = (B_0(t)\cos(\omega t), B_0(t)\sin(\omega t), B_3(t)) , \tag{82}$$

with ω being a constant angular velocity (harmonic frequency). The restriction (81) leads to the relation

$$B_3(t) = -\frac{\omega}{\gamma} + \frac{1}{2} C B_0(t) . \tag{83}$$

This immediately suggests the effect of the variation of the constant C as a controlling influence on the third component of the applied magnetic field; the effects of variation of harmonic frequency, gyromagnetic ratio and the magnitude of the harmonic field thus being easily interpreted.

If the magnitude of the harmonic field, B_0, is time-independent, we then find the well-known solution of classical precession.

V. CONCLUSIONS

We have found a solution of the inhomogeneous Bloch equation for a class of time-varying magnetic fields. This has been done by finding the fundamental system in terms of a set of the three independent solutions of the homogeneous Bloch equation.

Notice that we can find a solution of the homogeneous Bloch equation in another form:

$$\mathbf{m}^{(1)} + \mathbf{m}^{(2)} = \frac{2\alpha}{\beta} \mathbf{m}^{(4)} , \tag{84}$$

where

$$\mathbf{m}^{(4)} = \left(\frac{1}{\beta} \cos\psi, \frac{1}{\beta} \sin\psi, \frac{\alpha}{\beta} \right)^{\mathrm{T}} . \tag{85}$$

Here we have used Eqs. (57) to (62). This is a generalized solution of the classical precession which can be decomposed into the two independent solutions, $\mathbf{m}^{(1)}$ and $\mathbf{m}^{(2)}$.

In general, the Riccati equation (44) can be rewritten in the form

$$\dot{u} = \dot{\chi} u^2 - i(\dot{\psi} + \dot{\chi}_3) u + \dot{\chi} , \tag{86}$$

where

$$\xi = -iue^{i\psi} . \tag{87}$$

It seems to be difficult to find a general solution of Eq. (86), because $\dot{\chi}_3$ is contained in the coefficient of u. The simplest soluble case is to be imposed the restriction as

$$\dot{\psi} + \dot{\chi}_3 = C\dot{\chi} . \tag{88}$$

This is exactly the same as Eq. (81).

Also note that the solutions obtained by using the linearized Riccati equation[5] were restricted to the case of

$$C = \pm 2 \quad \text{or} \quad \alpha = \pm 1 , \tag{89}$$

in which some simplifications of the solutions (57)–(65) occur.

ACKNOWLEDGMENTS

I am indebted to Y. Takahashi for the discussions at earlier stages of this work. I thank M. Kawasaki for continual discussions about solutions of the Bloch equation.

APPENDIX: THE COFACTORS OF K_{ij} $(i, j=1, 2, 3)$

We list here the cofactors of the element of the fundamental matrix K:

$$K_{11}^{C}=\frac{1}{2}\left(\frac{1-\alpha^2}{\beta^3}\right)[1-\cos(2\beta\chi)-\sin(2\beta\chi)]\cos\psi - \frac{1}{\beta^2}\left\{\alpha[\cos(2\beta\chi)-\sin(2\beta\chi)]\sin\psi-\frac{1}{2}\beta[1+\cos(2\beta\chi)+\sin(2\beta\chi)]\cos\psi\right\}, \tag{A1}$$

$$K_{21}^{C}=\frac{1}{2}\left(\frac{1-\alpha^2}{\beta^3}\right)[1-\cos(2\beta\chi)-\sin(2\beta\chi)]\sin\psi + \frac{1}{\beta^2}\left\{\alpha[\cos(2\beta\chi)-\sin(2\beta\chi)]\cos\psi+\frac{1}{2}\beta[1+\cos(2\beta\chi)+\sin(2\beta\chi)]\sin\psi\right\}, \tag{A2}$$

$$K_{31}^{C}=\frac{\alpha}{\beta^3}[1-\cos(2\beta\chi)-\sin(2\beta\chi)], \tag{A3}$$

$$K_{12}^{C}=\frac{1}{2}\left(\frac{1-\alpha^2}{\beta^3}\right)[1+\cos(2\beta\chi)-\sin(2\beta\chi)]\cos\psi - \frac{1}{\beta^2}\left\{\alpha[\cos(2\beta\chi)+\sin(2\beta\chi)]\sin\psi-\frac{1}{2}\beta[1-\cos(2\beta\chi)+\sin(2\beta\chi)]\cos\psi\right\}, \tag{A4}$$

$$K_{22}^{C}=\frac{1}{2}\left(\frac{1-\alpha^2}{\beta^3}\right)[1+\cos(2\beta\chi)-\sin(2\beta\chi)]\sin\psi + \frac{1}{\beta^2}\left\{\alpha[\cos(2\beta\chi)+\sin(2\beta\chi)]\cos\psi+\frac{1}{2}\beta[1-\cos(2\beta\chi)+\sin(2\beta\chi)]\sin\psi\right\}, \tag{A5}$$

$$K_{32}^{C}=\frac{\alpha}{\beta^3}[1+\cos(2\beta\chi)-\sin(2\beta\chi)], \tag{A6}$$

$$K_{13}^{C}=-\frac{1}{\beta}\left(1-\frac{1-\alpha^2}{\beta^2}\right)\sin(2\beta\chi)\cos\psi+\frac{2\alpha}{\beta^2}\cos(2\beta\chi)\sin\psi, \tag{A7}$$

$$K_{23}^{C}=-\frac{1}{\beta}\left(1-\frac{1-\alpha^2}{\beta^2}\right)\sin(2\beta\chi)\sin\psi-\frac{2\alpha}{\beta^2}\cos(2\beta\chi)\cos\psi, \tag{A8}$$

and

$$K_{33}^{C}=\frac{2\alpha}{\beta^3}\sin(2\beta\chi). \tag{A9}$$

The determinant of the fundamental matrix is found by using Eqs. (A1) to (A9):

$$\det K = K_{i1} K^C_{i1} = K_{i2} K^C_{i2} = K_{i3} K^C_{i3} = \frac{2\alpha}{\beta^3}. \tag{A10}$$

Quaternionic roots of SO(8), SO(9), F_4 and the related Weyl groups

Mehmet Koca,[a] Ramazan Koç,[b] and Muataz Al-Barwani[c]
Department of Physics, College of Science, Sultan Qaboos University, P.O. Box 36, Al-Khod 123, Muscat, Sultanate of Oman

(Received 1 January 2003; accepted 31 March 2003)

The root systems of SO(8), SO(9) and F_4 are constructed by quaternions. Triality manifests itself as permutations of pure quaternion units e_1, e_2 and e_3. It is shown that the automorphism groups of the associated root systems are the finite subgroups of O(4) generated by left-right actions of unit quaternions on the root systems. The relevant finite groups of quaternions, the binary tetrahedral and binary octahedral groups, play essential roles in the construction of the Weyl groups and their conjugacy classes. The relations between the Dynkin indices, standard orthogonal vector and the quaternionic weights are obtained. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1578177]

I. INTRODUCTION

The Lie groups SO(8), SO(9), F_4 and their Lie algebras have generated more interest[1] regarding their use in building massless supersymmetry and supergravity multiplets of the superstring theories and M-theory,[2] respectively. The SO(8) is the light-cone little group of the superstring theories in $9+1$ dimensions, which are certain limits of a bigger theory, called M-theory existing in $10+1$ dimensions. The massless degrees of freedom of M-theory require certain irreducible representations of SO(9). If algebraic structures play any role in ultimate unification of the fundamental forces, the F_4 seems to be a natural symmetry in which SO(9) can be embedded with a triply symmetric way.

In what follows we construct the root systems of SO(8), SO(9) and F_4 in terms of quaternions[3] and their Weyl group elements as pairs of unit quaternions acting on the quaternion weights from left and right. We show that the quaternion elements of the binary tetrahedral group and the binary octahedral group are relevant structures both for the root systems as well as the Weyl group elements of SO(8) and F_4, respectively. The SO(9) plays a transition stage between SO(8) and F_4.

For the root systems of these Lie algebras and their weights form lattices in four-dimensional Euclidean space, it is expected that their automorphism groups are the finite subgroups of O(4). The defining representation of O(4) can be constructed by the actions of a pair of unit quaternions (p,r) on an arbitrary quaternion q as $q\rightarrow pqr$ and $q\rightarrow p\bar{q}r$ with $\bar{q}$ being quaternion conjugate of q. The finite subgroups of O(4) can be classified with the use of finite subgroups of quaternions.[4]

We have organized the article as follows: The O(4) group of quaternions are introduced in Sec. II along with the binary tetrahedral group and the binary octahedral group of quaternions with their relevant subgroups, coset structures and the conjugacy classes. In Sec. III, we introduce the quaternionic simple roots of SO(8), construct its root system and its Weyl group with quaternions. The conjugacy classes of the Weyl group with its subgroup structures and extension of the Weyl group by the Dynkin diagram symmetry of SO(8) have been explicitly constructed.

The SO(9) root system and its Weyl group have been studied in Sec. IV. A similar analysis for

the F_4 algebra has been done in Sec. V. Embeddings of SO(9) in F_4, extension of $W(F_4)$ by the Dynkin diagram symmetry, relations between the Dynkin indices and the quaternionic weights and a number of interesting aspects of the Weyl groups have been worked out in relevant sections. Finally, in Sec. VI we discuss our results along with their possible use in four-dimensional crystallography as well as the superstring theories and M-theory.

II. THE O(4) SYMMETRY OF QUATERNIONS

A quaternion $q=\Sigma_{a=0}^{3} q_a e_a$ with q_a real numbers and $e_a(e_0=1,e_1,e_2,e_3)$ quaternion units is a vector in four-dimensional Euclidean space where pure quaternions satisfy the relations

$$e_i e_j = -\delta_{ij} + \epsilon_{ijk} e_k, \quad i,j,k=1,2,3. \tag{1}$$

Here δ_{ij} and ϵ_{ijk} are the usual Kronecker and Levi-Civita symbols, respectively. The quaternions of unit norm $q\overline{q}=\overline{q}q=1$ with quaternion conjugate $\overline{q}=q_0-\Sigma_{i=1}^{3} q_i e_i$ form a group isomorphic to SU(2). The finite subgroups of quaternions relevant to our discussions are the quaternion group $Q=\langle 2,2,2\rangle$ of order 8, the binary octahedral group $T=\langle 3,3,2\rangle=2A_4$ of order 24 and the binary octahedral group $O=\langle 4,3,2\rangle=2S_4$ of order 48. [There are a number of notations in the literature for the finite subgroups of quaternions. (The notation for the finite subgroups of quaternions $\langle p,q,r\rangle$ which is introduced by Coxeter and Moser[5] means the group generators A,B,C satisfy the relations $A^p=B^q=C^r=Z, Z^2=1$.) We will interchangeably use all; however, we will mainly follow the notations of the Atlas of Finite Groups.[6] The group $G=AB$ denotes any group having a normal subgroup structure A, for which the corresponding quotient group has structure B. The finite groups of quaternions are of this type, e.g., $2A_4$, $2S_4$ and $2A_5$ are the double covers of the tetrahedral, octahedral and icosahedral groups where 2 stands for the center of the group. The group $G=A\times B$ (or $G=A:B$ in the notation of Ref. 6) is the semi-direct product of two groups A and B where A is the invariant subgroup and B is the quotient group. An important difference from the previous case is that a copy of B lies within the group G. The direct product of two groups is denoted by $G=A\times B$.] The conjugacy classes of $2A_4$ and $2S_4$ will be used when we construct the Weyl groups $W(D_4)$, $W(B_4)$ and $W(F_4)$ of the Lie algebras SO(8), SO(9) and F_4, respectively, and they are given in Tables I and II. The positive and negative subscripts are self-explanatory and are chosen such that these discrete quaternions will also stand for positive and negative roots of the Lie algebras of interest.

For completeness, here we introduce the important properties of the O(4) symmetry of quaternions. A pair of unit quaternions (p,r), with $p\overline{p}=r\overline{r}=1$, multiplying an arbitrary quaternion q from left and right,

$$(p,r): q \to pqr = e^{\alpha P} q e^{\beta R}, \tag{2}$$

leaves the quaternion norm $q\overline{q}=\overline{q}q$ invariant. Here $P=-\overline{P}$ and $R=-\overline{R}$ are pure quaternions. It can be shown that the determinant of the 4×4 matrix corresponding to the transformation (2) is

TABLE II. The conjugacy classes of $2S_4$.

4	$6_+\oplus 6_-;6_+=\left\{\frac{1}{\sqrt{2}}(e_1\pm e_2),\frac{1}{\sqrt{2}}(e_2\pm e_3),\frac{1}{\sqrt{2}}(e_3\pm e_1)\right\}, 6_-=-6_+$
8	$6'_+:\left\{\frac{1}{\sqrt{2}}(1\pm e_1),\frac{1}{\sqrt{2}}(1\pm e_2),\frac{1}{\sqrt{2}}(1\pm e_3)\right\}$
8	$6'_-=-6'_+:\left\{\frac{1}{\sqrt{2}}(-1\pm e_1),\frac{1}{\sqrt{2}}(-1\pm e_2),\frac{1}{\sqrt{2}}(-1\pm e_3)\right\}$

$+1$, thereby indicating that it is an element of the SO(4) subgroup. The left and right rotations in (2) are actually representing a double rotation through the angles $\alpha+\beta$, $\alpha-\beta$ about planes generated by vectors $(O,P-R,1+RP)$ and $(O,P+R,1-RP)$, respectively.[7] The two planes are orthogonal to each other. In addition to the transformation in (2) one can define a transformation

$$(p,r)^*:q\rightarrow p\overline{q}r, \tag{3}$$

which also leaves $q\overline{q}=\overline{q}q$ invariant. Since (3) leaves $p+r$ invariant and changes sign of $p-r$ for general unit quaternions p and r, it follows that $(p,r)^*$ is a rotary reflection having determinant -1. Therefore (p,r) and $(p,r)^*$ generate the group O(4). Below we give some properties of the group elements:

$$\begin{gathered}(a,b)(c,d)=(ac,db),\quad (a,b)^{-1}=(a^{-1},b^{-1})=(\overline{a},\overline{b}),\\ (a,b)^*(c,d)^*=(a\overline{d},\overline{c}b),\quad (a,b)^{*-1}=(b,a)^*,\\ (a,b)(c,d)^*=(ac,db)^*,\\ (a,b)^*(c,d)=(a\overline{d},\overline{c}b)^*.\end{gathered} \tag{4}$$

The element $(1,1)^*$ acts as a conjugation $(1,1)^*:q\rightarrow\overline{q}$, which leaves the SO(4) invariant:

$$(1,1)^*(a,b)(1,1)^{*-1}=(\overline{b},\overline{a})^*(1,1)^{\times}=(\overline{b},\overline{a})\in \mathrm{SO}(4). \tag{5}$$

This shows that SO(4) is an invariant subgroup of O(4) dividing O(4) into two cosets generated by the elements (a,b) and $(a,b)(1,1)^*=(a,b)^*\neq(1,1)^*(a,b)=(\overline{b},\overline{a})^*$ for a general element (a,b). The quotient group $\mathrm{O}(4)/\mathrm{SO}(4)=2=Z_2$ is represented by $(1,1)^*$ and $(1,1)$, a copy of which is within the group O(4). Therefore we have the semi-direct product structure $\mathrm{O}(4)=\mathrm{SO}(4)\rtimes 2$. The SO(3) subgroup of SO(4) is generated by the elements $(a,\overline{a})$, which can be extended to O(3) by $(1,1)^*$. But we note that $(1,1)^*$ and the SO(3) elements are commutative as we have

$$(a,\overline{a})(1,1)^*=(1,1)^*(a,\overline{a})=(a,\overline{a})^*. \tag{6}$$

This relation proves that O(3) has a direct product structure $\mathrm{O}(3)=2\times\mathrm{SO}(3)$.

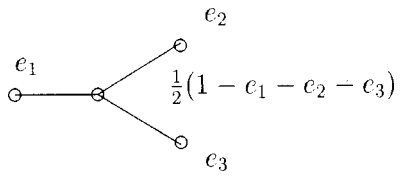

FIG. 1. Dynkin diagram of SO(8) with unit quaternions.

Quaternions can be represented by 2×2 unitary matrices where the quaternion units have the correspondence $1\rightarrow I, e_i\rightarrow -i\sigma_i$ where I is the 2×2 unit matrix while σ_i are the Pauli matrices. The transformations (2) and (3) can be written in terms of 2×2 unitary matrices in the forms

$$e^{-i\alpha\vec{n}\cdot\vec{\sigma}}\begin{pmatrix} q_0+iq_3 & iq_1+q_2 \\ iq_1-q_2 & q_0-iq_3 \end{pmatrix} e^{-i\beta\vec{m}\cdot\vec{\sigma}}$$

and

$$e^{-i\alpha\vec{n}\cdot\vec{\sigma}}\begin{pmatrix} q_0-iq_3 & -iq_1-q_2 \\ -iq_1+q_2 & q_0+iq_3 \end{pmatrix} e^{-i\beta\vec{m}\cdot\vec{\sigma}},$$

respectively. Determinants of the matrices q and $q^\dagger$ are left invariant corresponding to the norms of the vectors q and $\overline{q}$, respectively.

The finite subgroups of O(4) can be obtained from the finite subgroups of quaternions by the rules given in (4). We will analyze some of them when we deal with the Weyl groups $W(D_4)$, $W(B_4)$ and $W(F_4)$ as well as the full automorphism groups of the root systems. In an earlier publication[8] we have introduced a general method to construct the conjugacy classes of the Coxeter group H_4. A similar method also applies here in the construction of conjugacy classes of the Weyl groups of interest.

III. THE ROOT SYSTEM OF SO(8) AND ITS WEYL GROUP $W(D_4)$

In this section we will construct the root system of SO(8) and its automorphism group with quaternions. In one publication[3] one of us (MK) has given the root systems of SO(8), SO(9) and F_4 in terms of quaternions. However, no one has since then constructed the automorphism groups of their root systems as finite subgroups of O(4) using quaternions.

The scalar product of two quaternions q_1 and q_2 can be defined by $(q_1,q_2)=\frac{1}{2}(q_1\overline{q_2}+q_2\overline{q_1})$. In the four-dimensional Euclidean space the quaternion units $e_a(a=0,1,2,3)$ with this scalar product form an orthonormal basis. The familiar orthogonal vector system l_i $(i=1,2,\ldots,r)$ used for the construction of root systems of Lie algebras[9] is given for $r=4$ in terms of the quaternion units as

$$l_1=\frac{1}{\sqrt{2}}(1+e_1),\quad l_2=\frac{1}{\sqrt{2}}(1-e_1),\quad l_3=\frac{1}{\sqrt{2}}(e_2+e_3),\quad l_4=\frac{1}{\sqrt{2}}(e_2-e_3). \tag{7}$$

The Dynkin diagram of SO(8) with quaternion simple roots scaled by $\sqrt{2}$ is depicted in Fig. 1. [Root systems of SO(8), SO(9) and F_4 will be represented by quaternions scaled by $\sqrt{2}$.]

The positive roots of SO(8) with the simple roots in Fig. 1 are

$$r_+=\{1,e_1,e_2,e_3,\tfrac{1}{2}(1\pm e_1\pm e_2\pm e_3)\}=\{1,3_+,4_+,\overline{4}_+\}. \tag{8}$$

The nonzero roots including their negatives form the set $T=V_0\oplus V_1\oplus V_2$, where

$$V_0=\{\pm e_a\quad (a=0,1,2,3)\}=\{\pm 1,3_+,3_-\}, \tag{9a}$$

TABLE III. The conjugacy classes of $W(D_4)$ with quaternions.

Class	Order	Type	No. of elements
1	1	(1,1)	1
2	2	$(-1,1)$	1
3	4	$(3_+,\pm 1)\oplus(\pm 1,3_+)$	12
4	3	$(4_+,4_+)\oplus(\overline{4}_+,\overline{4}_+)$	32
5	6	$-[(4_+,4_+)\oplus(\overline{4}_+,\overline{4}_+)]$	32←Coxeter element
6	2	$\pm(e_1,e_1),\pm(e_2,e_3),\pm(e_3,e_2)$	6
7	2	$\pm(e_2,e_2),\pm(e_3,e_1),\pm(e_1,e_3)$	6
8	2	$\pm(e_3,e_3),\pm(e_2,e_1),\pm(e_1,e_2)$	6
9	2	$(p,p)^*=(r_+,r_+)^*$[a]	12
10	2	$-(r_+,r_+)^*$	12
11	4	$\pm(e_1r_+,r_+)^*$	24
12	4	$\pm(e_2r_+,r_+)^*$	24
13	4	$\pm(e_3r_+,r_+)^*$	24

[a]r_+ represent the positive quaternionic roots in (8).

$$V_1=\{4_+\oplus 4_-\}, \tag{9b}$$

$$V_2=\{\overline{4}_+\oplus\overline{4}_-\}=\overline{V}_1 \tag{9c}$$

form the binary tetrahedral group $2A_4$ of order 24. The set V_0 is the quaternion group Q of order 8 and represents the vertices of a hyperoctahedron in four dimensions.[4] Similarly the sets of quaternions V_1 and V_2 each represent a hyperoctahedron, however any two sets, say V_1 and V_2, form a hypercube in four dimensions. The symmetry of the root system of SO(8) is the symmetry of three congruent hyperoctahedrons. The quaternion group V_0 is an invariant subgroup of $2A_4$ where V_1 and $\overline{V}_1$ are the cosets obtained by multiplying V_0 on the left by

$$t=\tfrac{1}{2}(1+e_1+e_2+e_3),\quad t^2=-\overline{t},\ \text{i.e.,}\quad V_1=t\ V_0\ \text{ and }\ \overline{V}_1=\overline{t}V_0=V_2. \tag{10}$$

In fact $(t,\overline{t})$ is an SO(3) group element permuting the pure quaternion units e_i $i=1,2,3$ in the cyclic order

$$t\ e_i\overline{t}=e_{i+1}\ \text{ mod }\ 3,\quad i=1,2,3. \tag{11}$$

The binary tetrahedral group can be written as $T=V_0{:}3$ where 3 is the cyclic group of order 3.

The Weyl group of $W(D_4)$ of SO(8) is generated by reflections with respect to the hyperplanes orthogonal to the simple roots. An arbitrary quaternion q is reflected by the quaternionic root $\alpha'=\sqrt{2}\alpha$ where α is unit quaternion

$$q\to q-\frac{2(q,\alpha')}{(\alpha',\alpha')}\alpha'=-\alpha\overline{q}\alpha=-(\alpha,\alpha)^*. \tag{12}$$

The generators of $W(D_4)$ in terms of the unit quaternion simple roots can be written as

$$-(e_1,e_1)^*,\ -(e_2,e_2)^*,\ -(e_3,e_3)^*,\ -(\overline{t,t})^*. \tag{13}$$

A computer calculation leading to the 192 elements of $W(D_4)$ with 13 conjugacy classes is given in Table III.

There is, however, a simpler way to obtain the group elements of $W(D_4)$ by hand. We start with the quaternion group V_0, elements of which are the roots of $SU(2)^4$ subalgebra of SO(8). The automorphism group of the set V_0 is just the set of elements

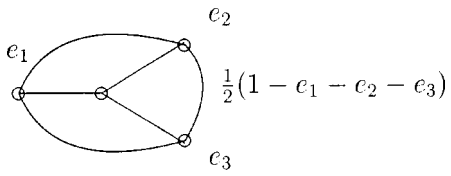

FIG. 2. The cyclic Dynkin diagram symmetry.

$$(V_0,V_0) \text{ and } (V_0,V_0)^* \tag{14}$$

forming a group of order $32\times 2=64$. Before proceeding further we note the following products of sets $V_a(a=0,1,2)$ satisfying the relations

$$V_a\ V_b=V_{a+b} \text{ mod } 3; \quad a,b=0,1,2. \tag{15}$$

The group elements of $W(D_4)$ can be generated by multiplying (14) by the element $a=(t,t)$ with $a^3=(1,1)$ on the left or on the right. Since $a=(t,t)$ is one of the elements of the set (V_1,V_1) we have a great number of choices for the coset representatives. Instead of choosing a particular element we use the whole set of elements (V_1,V_1) to generate the rest of elements $W(D_4)$. Multiplying (14) by (V_1,V_1) and $(V_1,V_1)^2=(V_2,V_2)$ and using (15) we obtain the sets of elements

$$W(D_4): \begin{matrix}(V_0,V_0),\ (V_1,V_1),\ (V_2,V_2)\\ (V_0,V_0)^*,\ (V_1,V_1)^*,\ (V_2,V_2)^*\end{matrix}. \tag{16}$$

Using (4) and (15) we can show that the elements in (16) form a group of order $32\times 6=192$, the conjugacy classes of which are the elements given in Table III. Obviously, the elements of $W(D_4)$ in (16) leave the root system Φ_{D_4} of SO(8),

$$\Phi_{D_4}=V_0\oplus V_1\oplus V_2, \tag{17}$$

invariant. However, the full automorphism group of Φ_{D_4} is not the Weyl group $W(D_4)$. The Dynkin diagram symmetry resulting in the simple roots $t\ e_i\overline{t}=e_{i+1}$ with $(e_4=e_1)$ shown in (11) can be represented by an element of SO(4), $b=(t,\overline{t})$ with $b^3=(1,1)$. The cyclic symmetry of the simple roots is shown in Fig. 2. All Dynkin diagram symmetries leave the associated Weyl groups invariant. In the present example that means

$$bW(D_4)\ b^{-1}=W(D_4). \tag{18}$$

Adjoining the generator b to $W(D_4)$ one generates a larger group which we denote by $\text{Aut}'\ \Phi_{D_4}=W(D_4)\rtimes Z_3$. The $\text{Aut}'\ \Phi_{D_4}$ is not the full automorphism of Φ_{D_4}. One can, by exchanging any pair of e_i and leaving the third term intact, extend the $\text{Aut}'\ \Phi_{D_4}$ to $\text{Aut}\ \Phi_{D_4}$ which we will discuss later. With the action of $b=(t,\overline{t})\in(V_1,V_2)$ on the elements of $W(D_4)$ in (16) on the left or right one generates the elements of the $\text{Aut}'\ \Phi_{D_4}$:

$$\text{Aut}'\ \Phi_{D_4}=\{(V_a,V_b)\oplus(V_a,V_b)^*\} \text{ with } a,b=0,1,2. \tag{19}$$

Here we have altogether 18 sets of 32 sets of quaternions which form a group of order 576. Interestingly enough, it exploits the whole set of elements of the binary tetrahedral group $T=\Phi_{D_4}$ with all possible combinations. Therefore we can concisely write (19) as

$$\text{Aut}'\ \Phi_{D_4}=\{(T,T)\oplus(T,T)^*\}. \tag{20}$$

TABLE IV. The conjugacy classes of Aut′ Φ_{D_4} of order 576.

Class	Order	Type	No. of elements
1	1	(1,1)	1
2	2	$(-1,1)$	1
3	6	$(4_+,1)\oplus(1,\overline{4}_+)$	8
4	6	$(\overline{4}_+,1)\oplus(1,4_+)$	8
5	3	$-[(4_+,1)\oplus(1,\overline{4}_+)]$	8
6	3	$-[(\overline{4}_+,1)\oplus(1,4_+)]$	8
7	4	$(3_+,\pm 1)\oplus(\pm 1,3_+)$	12
8	3	$(4_+,\overline{4}_+)$	16
9	3	$(4_+,4_+)\oplus(\overline{4}_+,\overline{4}_+)$	32
10	6	$-[(4_+,4_+)\oplus(\overline{4}_+,\overline{4}_+)]$	32
11	6	$-(4_+,\overline{4}_+)$	16
12	3	$(\overline{4}_+,4_+)$	16
13	6	$-(\overline{4}_+,4_+)$	16
14	12	$(4_+,6)\oplus(6,\overline{4}_+)$	48
15	12	$(\overline{4}_+,6)\oplus(6,4_+)$	48
16	2	$(3_+,3_+)\oplus(-3_+,3_+)$	18
17	2	$(12_+,12_+)^*$	12
18	2	$-(12_+,12_+)^*$	12
19	4	$(3_+r_+,r_+)^*\oplus(-3_+r_+,r_+)^*$	72
20	6	$(4_+r_+,r_+)^*$	48
21	6	$(\overline{4}_+r_+,r_+)^*$	48
22	6	$-(4_+r_+,r_+)^*$	48
23	6	$-(\overline{4}_+r_+,r_+)^*$	48

The elements (T,T) form a finite subgroup of SO(4) of order 288. The conjugacy classes of Aut′ Φ_{D_4} are given in Table IV.

The full automorphism group of Φ_4 is obtained by extending the Aut′ Φ_4 by a generator $c=-((1/\sqrt{2})(e_2-e_3),(1/\sqrt{2})(e_2-e_3))^*$ which leads to the transformations $1\to 1$, $e_1\to e_1$, $e_2\leftrightarrow e_3$. The Dynkin diagram symmetry of this transformation is shown in Fig. 3.

The Aut′ Φ_4 is invariant under conjugation by the generator c

$$c\ \ \mathrm{Aut}'\ \ \Phi_4\ \ c^{-1}=\mathrm{Aut}'\ \ \Phi_4, \tag{21}$$

so that the full automorphism group Aut $\Phi_4=$ Aut′ $\Phi_4:Z_2$. It is also true that

$$c\ W(D_4)\ c^{-1}=W(D_4). \tag{22}$$

Therefore the generators b and c generate a group $D_3\approx S_3$ satisfying the generation relations

$$c\ \ b\ \ c^{-1}=b^{-1}. \tag{23}$$

Therefore now the Aut Φ_4 can be written as

$$\mathrm{Aut}\ \ \Phi_4=W(D_4)\rtimes S_3. \tag{24}$$

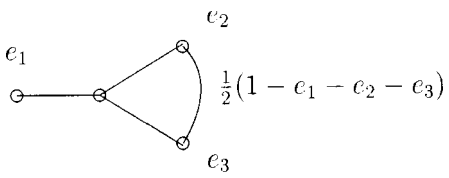

FIG. 3. The Dynkin diagram symmetry of SO(8) exchanging two simple roots leaving the other root intact.

This is the group of order 1152 which is also isomorphic to the Weyl group of F_4. Had we extended $W(D_4)$ by c we would have obtained the Weyl group of SO(9),

$$W(B_4)=W(D_4)\rtimes Z_2 \tag{25}$$

of order 384. The details of these works will be dealt with in the following sections.

We now turn back to further aspects of the root system of SO(8) and its Weyl group $W(D_4)$. The weight vector of any irreducible representation of SO(8) is represented by a quaternion $q=q_0+q_1e_1+q_2e_2+q_3e_3$. The relations between the quaternion components of a weight vector and the Dynkin indices $\wedge=(a_1,a_2,a_3,a_4)$ and the Weyl vector δ are given by

$$q_0=\frac{1}{\sqrt{2}}(a_1+2a_2+a_3+a_4),\quad q_1=\frac{1}{\sqrt{2}}a_1,\quad q_2=\frac{1}{\sqrt{2}}a_4,\quad q_3=\frac{1}{\sqrt{2}}a_3, \tag{26a}$$

$$\delta=\frac{1}{\sqrt{2}}(5+e_1+e_2+e_3). \tag{26b}$$

The Dynkin diagram symmetry on the indices (a_1,a_4,a_3) is now transformed to an S_3 symmetry on the pure quaternion units e_1, e_2 and e_3. This symmetry is even more apparent in the dimension formula which we do not want to illustrate for it is lengthy. However, similar triality symmetries can be shown on the Weyl group $W(D_4)$. The highest weights of some low dimensional irreducible representations of SO(8) are given in the quaternion weights versus Dynkin indices in Table V. When we examine the character table of $W(D_4)$ we note that the elements $\pm(e_1,e_1)$, $\pm(e_2,e_3)$ and $\pm(e_3,e_2)$ are in the same conjugacy classes which together with the elements $(-1,1)$ and $(1,1)$ form an elementary Abelian subgroup of $W(D_4)$ denoted by $2^3=Z_2^3$. Obviously this is an invariant subgroup where the quotient group $S_4=W(D_4)/Z_2^3$ is generated by the set of elements

$$(e_3,e_3)^*,\quad (t,t)^*. \tag{27}$$

The generators $(e_3,e_3)=(e_3,e_3)^*(1,1)^*$ and $(t,t)=(t,t)^*(1,1)^*$ generate the tetrahedral subgroup A_4 of S_4 of order 12. The A_4 involves the generators (e_3,e_3), (e_2,e_1), (e_1,e_2) and $(1,1)$ which form the elementary Abelian group 2^2 (Klein's fier-gruppe); under the cyclic group generator $a=(t,t)$ of order 3, the Klein's four-group is left invariant. This analysis reveals the whole skeleton of the Weyl group $W(D_4)$,

$$W(D_4)=2^3\rtimes S_4=2^3\rtimes A_4\rtimes 2=2^3\rtimes 2^2\rtimes 3\rtimes 2. \tag{28}$$

We could have chosen the generators of S_4 as

$$(e_2,e_2)^*\ \text{ and }\ (t,t)^*, \tag{29}$$

which leave the same elementary Abelian group 2^3 invariant. A closer inspection of Table III (class numbers 6, 7, 8) shows that we have three alternative choices for the elementary Abelian group 2^3 and two choices for S_4 generators for each elementary abelian group of order 8. This is another explicit indication that the $W(D_4)$ is invariant under an outer automorphism of S_3.

IV. THE ROOT SYSTEM OF SO(9) AND ITS WEYL GROUP $W(B_4)$

The standard simple roots of SO(9) with the orthogonal vectors l_i $(i=1,2,3,4)$[7] and its positive roots are

$$l_1-l_2,\quad l_2-l_3,\quad l_3-l_4,\quad l_4, \tag{30a}$$

TABLE V. The highest weights of some low dimensional irreducible representations of SO(8) with quaternions versus Dynkin indices.

Dimension	Dynkin indices	Quaternion weight
8_v	(1000)	$\frac{1}{\sqrt{2}}(1+e_1)$
8_s	(0001)	$\frac{1}{\sqrt{2}}(1+e_2)$
8_c	(0010)	$\frac{1}{\sqrt{2}}(1+e_3)$
28	(0100)	$\sqrt{2}$
35_v	(2000)	$\sqrt{2}(1+e_1)$
35_s	(0002)	$\sqrt{2}(1+e_2)$
35_c	(0020)	$\sqrt{2}(1+e_3)$
56_v	(0011)	$\sqrt{2}+\frac{1}{\sqrt{2}}(e_2+e_3)$
56_s	(1010)	$\sqrt{2}+\frac{1}{\sqrt{2}}(e_3+e_1)$
56_c	(1001)	$\sqrt{2}+\frac{1}{\sqrt{2}}(e_1+e_2)$
112_v	(3000)	$\frac{3}{\sqrt{2}}(1+e_1)$
112_s	(0003)	$\frac{3}{\sqrt{2}}(1+e_2)$
112_c	(0030)	$\frac{3}{\sqrt{2}}(1+e_3)$

$$l_i \pm l_j, \quad 1 \leqslant i \leqslant j \leqslant 4, \qquad l_i, \quad 1 \leqslant i \leqslant 4. \tag{30b}$$

Its Dynkin diagram with quaternion simple roots scaled by $\sqrt{2}$ is shown in Fig. 4.

The scaled quaternion roots of SO(9) will be given by the sets of quaternions

$$\Phi_{B_4}: V_0, \quad V_1, \quad V_2 \quad \text{and} \quad V_x' = \left\{ \begin{array}{l} \frac{1}{2}(\pm 1 \pm e_1) \\ \frac{1}{2}(\pm e_2 \pm e_3) \end{array} \right\}. \tag{31}$$

The set in V_x' is the scaled short roots. The actual short roots of unit norm are denoted by the set $V_x = \sqrt{2} V_x'$. The first three simple roots in Fig. 4 are the simple roots of SO(8). The reflection by the simple root $\alpha_4 = \sqrt{2}\alpha_4' = (1/\sqrt{2})(e_2 - e_3)$ can be computed by

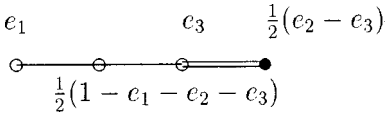

FIG. 4. Dynkin diagram of SO(9) with scaled quaternion simple roots.

TABLE VI. The conjugacy classes of $W(B_4)$ with quaternions.

Class	Order	Type of elements	No. of elements
1	1	(1,1)	1
2	2	$(-1,1)$	1
3	4	$(\pm e_i,\pm 1), i=1,2,3$	12
4	2	$\{\pm(e_d,e_d),\pm(e_d,e_1),\pm(e_1,e_d), d=2,3\}$	12
5	2	$\pm\{(e_1,e_1),(e_2,e_3),(e_3,e_2)\}$	6
6	2	$\pm\{(a_{12},a_{31}),(a_{31},a_{12}),(a_{23},a_{23})\}$[a]	24
7	8	$\pm\{(a_{01},a_{23}),(a_{23},a_{01}),(a_{02},a_{12}),\ (a_{12},a_{02}),(a_{03},a_{31}),(a_{31},a_{03})\}$	48
8	3	$\{(4_+,4_+),(\overline{4}_+,\overline{4}_+)\}$	32
9	6	$-\{(4_+,4_+),(\overline{4}_+,\overline{4}_+)\}$	32
10	4	$\{(a_{01},a_{01}),(a_{02},a_{03}),(a_{03},a_{02})\}$	12
11	4	negatives of elements of class (10)	12
12	2	$\{(e_a.e_a)^*,(4_+,4_+)^*,(\overline{4}_+,\overline{4}_+)^*, a=0,1,2,3\}$	12
13	2	negatives of elements in class (12)	12
14	4	$\pm\{(e_de_a,e_a)^*,(e_d4_+,4_+)^*,(e_d\overline{4}_+,\overline{4}_+)^*, d=1,2\ \&\ a=0,1,2,3\}$	48
15	4	$\pm\{(e_1e_a,e_a)^*,(e_2\overline{4}_+,\overline{4}_+),(e_34_+,4_+), a=0,1,2,3\}$	24
16	6	$\{(\overline{4}_+a_{02},a_{02})^*,(\overline{4}_+a_{12},a_{12})^*,(\overline{4}_+a_{03},a_{03})^*,(\overline{4}_+a_{31},a_{31})^*\}$	32
17	6	negatives of elements in class (16)	32
18	4	$\pm\{(e_ia_{23},a_{23})^*,(e_ia_{01},a_{01})^*, i=1,2,3\}$	24
19	2	$\{(a_{01},a_{01})^*,(a_{23},a_{23})^*\}$	4
20	2	negatives of elements in class (19)	4

[a] $a_{ab}=(1/\sqrt{2})(e_a\pm e_b)$.

$$q\to q'=q-\frac{2(q,\alpha_4)}{(\alpha_4,\alpha_4)}\alpha_4 \quad \text{with} \quad (\alpha_4,\alpha_4)=1,$$
$$q'=-\alpha_4\overline{q}\alpha_4. \tag{32}$$

The group elements of $W(B_4)$ then can be generated by the reflection generators

$$-(e_1,e_1)^*,\ -(\overline{t,t})^*,\ -(e_3,e_3)^*,c=-\left(\frac{1}{\sqrt{2}}(e_2-e_3),\frac{1}{\sqrt{2}}(e_2-e_3)\right)^*. \tag{33}$$

The elements of the Weyl group $W(B_4)$ are given in Table VI with their conjugacy classes. The elements of $W(B_4)$ not only involve the set (V_x,V_x) but also (V_y,V_z), (V_z,V_y) and their star elements. Here the sets of V_y and V_z are obtained from V_x by cyclic permutation of e_1, e_2, and e_3,

$$V_y=\left\{\begin{array}{l}\frac{1}{\sqrt{2}}(\pm 1\pm e_2)\\ \\ \frac{1}{\sqrt{2}}(\pm e_3\pm e_1)\end{array}\right\},\quad V_z=\left\{\begin{array}{l}\frac{1}{\sqrt{2}}(\pm 1\pm e_3)\\ \\ \frac{1}{\sqrt{2}}(\pm e_1\pm e_2)\end{array}\right\}. \tag{34}$$

Since $W(D_4)$ is invariant under the action of the element c as shown in (22) the elements of $W(B_4)$ can also be obtained from the elements of $W(D_4)$ in (16) by multiplication of c with those in (16) on the left. This can be achieved in a simpler way by using the multiplication table of the sets V_0, V_1, V_2, V_x, V_y and V_z given in Table VII.

By multiplying the elements of $W(D_4)$ in (16) by (V_x,V_x) on the left we obtain the elements of $W(B_4)$ in pairs of sets

TABLE VII. The multiplication table of the sets $V_0, V_1, V_2, V_x, V_y, V_z$. (It is the same multiplication table of the group S_3.)

	V_0	V_1	V_2	V_x	V_y	V_z
V_0	V_0	V_1	V_2	V_x	V_y	V_z
V_1	V_1	V_2	V_0	V_z	V_x	V_y
V_2	V_2	V_0	V_1	V_y	V_z	V_x
V_x	V_x	V_y	V_z	V_0	V_1	V_2
V_y	V_y	V_z	V_x	V_2	V_0	V_1
V_z	V_z	V_x	V_y	V_1	V_2	V_0

$$\begin{gathered}(V_0,V_0),(V_1,V_1),(V_2,V_2),\\ (V_0,V_0)^*,(V_1,V_1)^*,(V_2,V_2)^*,\\ (V_x,V_x),(V_y,V_z),(V_z,V_y),\\ (V_x,V_x)^*,(V_y,V_z)^*,(V_z,V_y)^*.\end{gathered} \tag{35}$$

This is a group of order $12\times 32=384$ elements generated by the generators of $W(B_4)$ in (33) leaving the root system of SO(9) in (31) invariant. The invariance of the elements of $W(D_4)$ can also be shown concisely in the following relations

$$\begin{gathered}(V_x,V_x)^*(V_a,V_a)(V_x,V_x)^{*-1}=(V_b,V_b),\\ a,b=0,1,2\\ (V_x,V_x)^*(V_a,V_a)^*(V_x,V_x)^{*-1}=(V_b,V_b)^*,\end{gathered} \tag{36}$$

which implies that $W(B_4)=W(D_4):Z_2$. We also note that the generator $c=-((1/\sqrt{2})(e_2-e_3),(1/\sqrt{2})(e_2-e_3))^*$ together with the elements of the elementary Abelian group of order 8, $\pm(e_1,e_1),\pm(e_2,e_3),\pm(e_3,e_2),\pm(1,1)$ given before, form an elementary Abelian group 2^4 of order 16. The same elements of S_4 generated by the generators in (27) leave the group 2^4 invariant, which implies that the Weyl group has the form $W(B_4)=2^4\rtimes S_4=2^4\rtimes 2^2\rtimes 3\rtimes 2$.

A few other facts about SO(9) are in order. The positive roots in terms of the scaled quaternions read as follows:

$$1,e_1,e_2,e_3,\quad \tfrac{1}{2}(1\pm e_1\pm e_2\pm e_3),\quad \tfrac{1}{2}(1\pm e_1),\quad \tfrac{1}{2}(e_2\pm e_3). \tag{37}$$

The transformation between the weight vector in the Dynkin basis and the quaternion basis as well as the Weyl vector in terms of quaternions are given as follows:

$$q_0=\frac{1}{\sqrt{2}}(a_1+2(a_2+a_3)+a_4),\ \ q_1=\frac{1}{\sqrt{2}}a_1,\ \ q_2=\frac{1}{\sqrt{2}}(a_3+a_4),\ \ q_3=\frac{1}{\sqrt{2}}a_3, \tag{38a}$$

$$\delta=\frac{1}{\sqrt{2}}(6+e_1+2e_2+e_3). \tag{38b}$$

The highest weights of some of the low dimensional irreducible representations of SO(9) are given in Table VIII. Embedding of SO(9) in F_4 will be discussed in the next section. The Coxeter elements are all in the same conjugacy classes. One can choose the products of the generators in an arbitrary order. Without loss of generality we can construct the Coxeter element as the products

TABLE VIII. Some of the low dimensional irreducible representations of SO(9) in quaternion basis versus Dynkin indices.

Dimension	Dynkin indices	Quaternion weights
9	(1000)	$\frac{1}{\sqrt{2}}(1+e_1)$
16	(0001)	$\frac{1}{\sqrt{2}}(1+e_2)$
36	(0100)	$\sqrt{2}$
44	(2000)	$\sqrt{2}(1+e_1)$
84	(0010)	$\sqrt{2}+\frac{1}{\sqrt{2}}(e_2+e_3)$
126	(0002)	$\sqrt{2}(1+e_2)$
128	(1001)	$\sqrt{2}+\frac{1}{\sqrt{2}}(e_1+e_2)$

$$M=\left(\frac{1}{\sqrt{2}}(e_2-e_3),\frac{1}{\sqrt{2}}(e_2-e_3)\right)^*(e_3,e_3)^*\left(\frac{1}{2}(1-e_1-e_2-e_3),\frac{1}{2}(1-e_1-e_2-e_3)\right)^*(e_1,e_1)^*. \tag{39}$$

A simple calculation leads to the element

$$M=\left(\frac{1}{\sqrt{2}}(1+e_3),\frac{1}{\sqrt{2}}(e_1-e_3)\right) \tag{40}$$

with the right property $M^8=(1,1)$. When we convert M to the 4×4 matrix in the quaternion basis and calculate the eigenvalues we obtain the complex exponents with the correct Coxeter exponents of SO(9).

V. THE AUTOMORPHISM GROUP OF F_4 ROOT SYSTEM

The simple roots of F_4 in the standard orthogonal basis are given in the respective order:

$$l_2-l_3,\quad l_3-l_4,\quad l_4,\quad \tfrac{1}{2}(l_1-l_2-l_3-l_4). \tag{41}$$

The Dynkin diagram and the scaled quaternionic simple roots of F_4 are shown in Fig. 5. The positive scaled roots and the Weyl vector in terms of quaternions are

$$1,e_1,e_2,e_3,\quad \tfrac{1}{2}(1\pm e_1\pm e_2\pm e_3),$$

$$\tfrac{1}{2}(1\pm e_1),\quad \tfrac{1}{2}(1\pm e_2),\quad \tfrac{1}{2}(1\pm e_3), \tag{42a}$$

$$\tfrac{1}{2}(e_2\pm e_3),\quad \tfrac{1}{2}(e_1\pm e_3),\quad \tfrac{1}{2}(e_1\pm e_2),$$

$$\delta=\frac{1}{\sqrt{2}}(8+3e_1+2e_2+e_3). \tag{42b}$$

The relations between the quaternion weights and the Dynkin indices are determined as

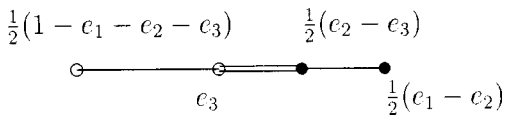

FIG. 5. The Dynkin diagram of F_4 with the scaled roots of quaternions.

$$q_0=\frac{1}{\sqrt{2}}(2a_1+3a_2+2a_3+a_4),\quad q_1=\frac{1}{\sqrt{2}}(a_2+a_3+a_4),$$
$$q_2=\frac{1}{\sqrt{2}}(a_2+a_3),\quad q_3=\frac{1}{\sqrt{2}}a_2. \tag{43}$$

Some low dimensional representations using quaternions are given in Table IX. The complete root system of F_4 consists of the sets of elements

$$V_0,\ V_1,\ V_2,\ V_x',\ V_y',\ \text{and}\ V_z', \tag{44}$$

where

$$V_y'=\left\{\begin{array}{c}\frac{1}{2}(\pm 1\pm e_2)\\ \frac{1}{2}(\pm e_3\pm e_1)\end{array}\right\},\quad V_z'=\left\{\begin{array}{c}\frac{1}{2}(\pm 1\pm e_3)\\ \frac{1}{2}(\pm e_1\pm e_2)\end{array}\right\}. \tag{45}$$

The roots of F_4 in (45) represent the weights of the spinor representation $\underline{16}$ of SO(9). A cyclic symmetry on e_1,e_2 and e_3 leaves (44) invariant, however it replaces $(\overline{45})$ by the pairs V_z',V_x' and V_x',V_y', which indicate that the spinor representation $\underline{16}$ and thereby the roots of SO(9) can be embedded in F_4 three symmetric ways. The three alternative ways of SO(9) roots in F_4 are

$$V_0,\quad V_1,\quad V_2,\quad V_i\quad (i=x,y,z), \tag{46}$$

TABLE IX. Some of the low dimensional irreducible representations of F_4 with the quaternion highest weights.

Dimension	Dynkin indices	Quaternion weights
26	(0001)	$\frac{1}{\sqrt{2}}(1+e_1)$
52	(1000)	$\sqrt{2}$
273	(0010)	$\sqrt{2}+\frac{1}{\sqrt{2}}(e_1+e_2)$
324	(0002)	$\sqrt{2}(1+e_1)$
1053	(1001)	$\sqrt{2}+\frac{1}{\sqrt{2}}(1+e_1)$
1053′	(2000)	$2\sqrt{2}$
1274	(0100)	$\sqrt{2}+\frac{1}{\sqrt{2}}(1+e_1+e_2+e_3)$
2652	(0003)	$\frac{3}{\sqrt{2}}(1+e_1)$

one i at a time. The Weyl group $W(F_4)$ can be generated from the reflection generators of simple roots in Fig. 5. We have already obtained it from $W(D_4)$ as an extension by the Dynkin diagram symmetry of SO(8). Now we can determine the elements more explicitly as sets of elements of the binary octahedral group.

The Weyl group $W(B_4)$ is not an invariant subgroup of $W(F_4)$. But by the transformation

$$b\ W(B_4)\ b^{-1}=W'(B_4) \tag{47}$$

with $b=(t,\overline{t})$ and $b^3=(1,1)$, we generate new sets of elements representing $W(B_4)$ in $W(F_4)$. Indeed a left and right application of b,b^2 and b^3 on the set of elements $W(B_4)$ in (35) generate the whole set of elements of $W(F_4)$:

$$(V_a,V_b),(V_a,V_b)^*,\quad a=0,1,2, \tag{48a}$$

$$(V_i,V_j),(V_i,V_j)^*,\quad i,j=x,y,z. \tag{48b}$$

We have $9\times 4=36$ pair of sets each involving 32 elements which yield the order $36\times 32=1152$ of $W(F_4)$. The elements in (48a) constitute the group of order 576, an extension of $W(D_4)$ by b. The set of elements

$$(V_a,V_b),(V_i,V_j),\quad a=0,1,2,\quad i,j=x,y,z, \tag{49}$$

also form a different group of order 576, a finite subgroup of SO(4). Several other interesting subgroups can be determined. The embedding of the Weyl group $W(B_4)$ in $W(F_4)$ in three different ways and selection of those elements from (48a) is straightforward.

We have noted in (24) that the Aut $\Phi_{D_4}=W(D_4):S_3$. Indeed Aut $\Phi_{D_4}\approx W(F_4)$ and, using the cosets of $W(D_4)$, we can prove that

$$W(F_4)=W(D_4):S_3. \tag{50}$$

We recall from (16) that the elements of $W(D_4)$ are of the form

$$(V_a,V_a),\ (V_a,V_a)^*,\quad a=0,1,2. \tag{51}$$

We can readily show that the elements of $W(F_4)$ in (48a) can be generated by applying the generators $A=(V_1,V_2)$ and $B=(V_x,V_x)$ with $A^3=B^2=(V_0,V_0)$ on the left of the elements of $W(D_4)$ in (51) since the $W(D_4)$ is an invariant subgroup of $W(F_4)$:

$$\begin{aligned} A\ W(D_4)\ A^{-1}&=W(D_4),\\ B\ \ W(D_4)\ \ B^{-1}&=W(D_4). \end{aligned} \tag{52}$$

Now we can show that the coset representatives A and B generate the group $D_3=S_3$. We recall that the generation relations of a dihedral group D_n is given by[5] $b\ a\ b^{-1}=a^{n-1}$, $a^n=b^2=1$. Here A and B satisfy the relation

$$B\ A\ B^{-1}=A^2=A^{-1}. \tag{53}$$

Therefore $W(F_4)$ is the semi-direct product of $W(D_4)$ with S_3:

$$W(F_4)=W(D_4)\rtimes S_3. \tag{54}$$

The conjugacy classes of $W(F_4)$ are given in Table X.

The automorphism group Aut Φ_{F_4} of the root system of F_4 can be obtained by adding another generator determined from the Dynkin diagram symmetry of F_4 diagram to the Weyl group

TABLE X. The conjugacy classes of $W(F_4)$ with quaternions.

generators of F_4. The Dynkin diagram symmetry of F_4 is obtained by exchanging the short and long roots which is shown in Fig. 6. In an explicit form, exchanges of long and short roots

$$\frac{1}{2}(1-e_1-e_2-e_3)\leftrightarrow\frac{1}{\sqrt{2}}(e_1-e_2),\quad e_3\leftrightarrow\frac{1}{\sqrt{2}}(e_2-e_3), \tag{55}$$

will result in the transformation

$$1\rightarrow\frac{1}{\sqrt{2}}(1+e_1),\ e_1\rightarrow\frac{1}{\sqrt{2}}(1-e_1),\quad e_2\rightarrow\frac{1}{\sqrt{2}}(e_2+e_3),\ e_3\rightarrow\frac{1}{\sqrt{2}}(e_2-e_3). \tag{56}$$

This transformation is a rotation in four-dimensional space which exchanges the following sets of roots of F_4,

$$V_0\leftrightarrow V_x,\quad V_1\leftrightarrow V_y,\quad V_2\leftrightarrow V_z, \tag{57}$$

and can be represented by the generator

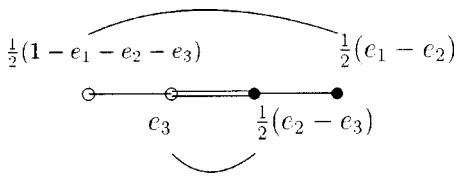

FIG. 6. The Dynkin diagram symmetry of F_4.

$$d=\left(\frac{1}{\sqrt{2}}(e_2+e_3),-e_2\right)\in(V_x,V_0). \tag{58}$$

When it is put in the form of Eq. (2) it turns out that it is a rotation by π in the plane determined by the quaternions $q_1=0$, $q_2=(1/\sqrt{2})(e_2+e_3)-e_2$ and $q_3=1-(1/\sqrt{2})(1+e_1)$. It is clear from (56) that while $q_1=0$ remains fixed q_2 and q_3 are transformed to their negatives $q_2\rightarrow -q_2$ and $q_3\rightarrow -q_3$.

Since the Dynkin diagram symmetry exchanges the simple roots leading to the interchange of the generators of $W(F_4)$ pairwise, the Weyl group of F_4 is left invariant:

$$d\ \ W(F_4)\ \ d^{-1}=W(F_4). \tag{59}$$

It can be extended to the Aut Φ_{F_4} by a left multiplication of d on the elements of $W(F_4)$ in (46). This can also be achieved by the left multiplication of (V_x,V_0) on $W(F_4)$ leading to the result

$$(V_a,V_b),\quad (V_i,V_j),\quad (V_a,V_i),\quad (V_i,V_a),\quad a,b=0,1,2, \tag{60a}$$

$$(V_a,V_b)^*,\quad (V_i,V_j)^*,\quad (V_a,V_i)^*,\quad (V_i,V_a)^*,\quad i,j=x,y,z. \tag{60b}$$

The Aut Φ_{F_4} is a group of order 2304 whose SO(4) subgroup is of order 1152. Interestingly enough the Aut Φ_{F_4} is the group fully generated by the elements of the binary octahedral group O. That means the elements in (60) can be written as

$$(O,O)\oplus(O,O)^*. \tag{61}$$

In summary, we have the following isomorphisms:

$$\begin{aligned}&\text{Aut}\ \ \Phi_{F_4}=\{(O,O)\oplus(O,O)^*\},\\ &\text{Aut}\ \ \Phi_{D_4}=W(F_4),\\ &\text{Aut}\ \ \Phi'_{D_4}=\{T,T)\oplus(T,T)^*\},\end{aligned} \tag{62}$$

with the subgroup sequence

$$\text{Aut}\ \ \Phi'_{D_4}\subset\text{Aut}\ \ \Phi_{D_4}\subset\text{Aut}\ \ \Phi_{F_4}. \tag{63}$$

The conjugacy classes of Aut Φ_{F_4} are given in Table XI.

One of the interesting subgroups of $W(F_4)$ is of order 384 isomorphic to $W(B_4)$, however it does not leave the root system of SO(9) in any form given by (46) invariant. The group elements are given as follows:

$$\begin{aligned}&(V_0,V_0),\quad (V_1,V_2),\quad (V_2,V_1),\\ &(V_0,V_0)^*,\quad (V_1,V_2)^*,\quad (V_2,V_1)^*,\end{aligned} \tag{64a}$$

$$\begin{aligned}&(V_x,V_x),\quad (V_y,V_y),\quad (V_z,V_z),\\ &(V_x,V_x)^*,\quad (V_y,V_y)^*,\quad (V_z,V_z)^*.\end{aligned} \tag{64b}$$

The set of elements in (64a) form a group of order 192 with 16 conjugacy classes and leaves the roots system of SO(8) invariant, however this group is not the Weyl group generated by the reflections on simple roots.

TABLE XI. Conjugacy classes of the group Aut Φ_{F_4} of order 2304.

Class	Order	Type	No. of elements

VI. CONCLUSIONS

We are motivated by the work of P. Ramond and his collaborators[1] to construct the elements of the Weyl groups $W(D_4)$, $W(B_4)$ and $W(F_4)$ with pairs of quaternions. We have observed that the group Aut Φ_{F_4} is isomorphic to the finite subgroup of O(4) of order 2304 represented by the quaternion elements of the binary octahedral group O in the form $(O,O)\oplus(O,O)^*$. Several subgroups of this group have potential interest, in particular, those corresponding to the Weyl groups $W(D_4)$, $W(B_4)$ and $W(F_4)$. The group $(T,T)\oplus(T,T)^*$, where T stands for the quaternion elements of the binary tetrahedral group, is the extension of the Weyl group $W(D_4)$ by the cyclic symmetry of the Dynkin diagram of SO(8).

The triality of SO(8) and the embedding of $W(B_4)$ in the $W(F_4)$ by a cyclic symmetry involves the permutation symmetry of pure quaternion units e_1, e_2, e_3. The weights of irreducible representations of any of these Lie algebras have been constructed with quaternions and the relations between the Dynkin indices and the standard orthogonal vectors in four dimensions have been established. The symmetry between the vector, spinor and conjugate spinor representations of SO(8) is a manifestation of the S_3 symmetry imposed on the quaternion units e_i. The conjugacy classes of the Weyl groups and the automorphism groups have been constructed. It has been also noted that without a need of computer calculation one can construct the conjugacy classes by hand using the conjugacy classes of the binary tetrahedral and binary octahedral groups.

The groups we have dealt with have the potential importance in four-dimensional crystallography. They involve a great number of crystallographic point groups in three dimensions as subgroups which we have pointed out the general structure without referring to any particular example.

The most important aspect of our work perhaps is that the root systems of the Lie algebras of SO(8) and F_4 have a multiplication structure which led to a straightforward method for the construction of their automorphism groups. We are optimistic that the quaternionic representations of the root systems and the automorphism groups of SO(8), SO(9) and F_4 may pave a new road for further insights toward the symmetries of supersrings in ten dimensions and M-theory in 11 dimensions.

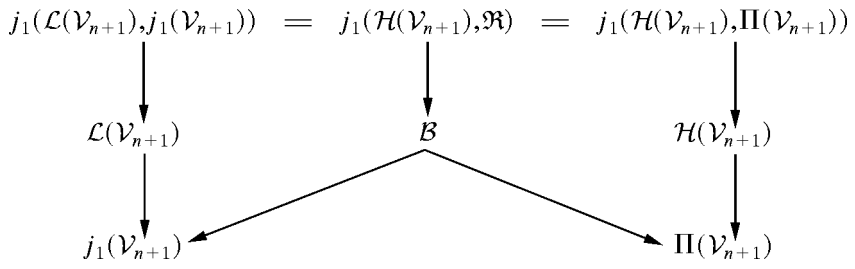
I. INTRODUCTION

In a recent paper,[1] a new geometrical framework for a unified formulation of Lagrangian and Hamiltonian dynamics has been proposed. The analysis provides a gauge-invariant extension to nonautonomous systems of classical results due to Tulczyjew.

The core of the procedure developed in Ref. 1 may be summarized into the following diagram:



(1.1)

in which:

$\mathcal{V}_{n+1}$, $j_1(\mathcal{V}_{n+1})$ and $\Pi(\mathcal{V}_{n+1})$ denote, respectively, the configuration space–time, the velocity space–time and the phase space of a holonomic system with n degrees of freedom. All spaces are fibered over the real line $\mathfrak{R}$ through the absolute time function t.

$\mathcal{L}(\mathcal{V}_{n+1})\to j_1(\mathcal{V}_{n+1})$ and $\mathcal{H}(\mathcal{V}_{n+1})\to\Pi(\mathcal{V}_{n+1})$ denote principal fiber bundles with structural group $(\mathfrak{R},+)$, called, respectively, the *Lagrangian* and the *Hamiltonian bundles*. The latter have been introduced in Ref. 2 (see also Ref. 1 and references therein) to give a geometric arrangement to the gauge structure of classical mechanics.

$j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$, $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$ and $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ are the first-jet bundles, respectively, associated with the fibrations $\mathcal{L}(\mathcal{V}_{n+1})\to j_1(\mathcal{V}_{n+1})$, $\mathcal{H}(\mathcal{V}_{n+1})\to\Pi(\mathcal{V}_{n+1})$ and $\mathcal{H}(\mathcal{V}_{n+1})\to\mathfrak{R}$. All bundles are mutually diffeomorphic, and represent the generalization of the so-called *Tulczyjew triple* $T^*(T(M))\leftrightarrow T(T^*(M))\leftrightarrow T^*(T^*(M))$ (see, for example, Refs. 3 and 4). Moreover, all spaces are principal fiber bundles over a base manifold $\mathcal{B}$, endowed with a canonical symplectic structure.

In the resulting geometrical setting, a central role is played by the space $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$. In fact, the assignment of Lagrangian or Hamiltonian dynamics—expressed geometrically through sections $l:j_1(\mathcal{V}_{n+1})\to\mathcal{L}(\mathcal{V}_{n+1})$ or $h:\Pi(\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$—gives rise in a natural way to corresponding surfaces in $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$. By the very definition of $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$, these latter have

a)Electronic mail: vignolo@dima.unige.it

the nature of first-order differential equations yielding the evolution of the system. Switching from the Lagrangian to the Hamiltonian description of dynamics is then merely switching between two different representations of the same surface in $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$, related to each other by what is usually referred to as the Legendre transformation.

II. THE ROUTH'S PROCEDURE

Given a mechanical system as above, assume that the configuration space–time $\mathcal{V}_{n+1}$ is fibered over a $r+1$-dimensional manifold $\mathcal{V}_{r+1}$, in turn fibered over $\mathfrak{R}$ through absolute time t.

Typically, this is the situation occurring in the study of systems with geometrical symmetries, summarized into a Lie group G acting freely and properly on $\mathcal{V}_{n+1}$, the base space $\mathcal{V}_{r+1}$ being then identified with the quotient space $\mathcal{V}_{r+1}:=\mathcal{V}_{n+1}/G$.

In what follows, we shall refer the manifolds $\mathcal{V}_{r+1}$ and $\mathcal{V}_{n+1}$ to local fibered coordinates t,q^α and t,q^α,q^a, respectively ($\alpha=1,\ldots,r$, $a=r+1,\ldots,n$), subject to the transformation laws

$$\overline{t}=t+c, \quad \overline{q}^\beta=\overline{q}^\beta(t,q^\alpha), \quad \overline{q}^b=\overline{q}^b(t,q^\alpha,q^a).$$

Now, let $j_1(\mathcal{V}_{r+1})$ denote the first-jet bundle of $t:\mathcal{V}_{r+1}\to\mathfrak{R}$ and $\mathcal{N}:=j_1(\mathcal{V}_{r+1})\times_{\mathcal{V}_{r+1}}\mathcal{V}_{n+1}$ be the fiber product over $\mathcal{V}_{r+1}$ between $j_1(\mathcal{V}_{r+1})$ and $\mathcal{V}_{n+1}$.

We shall put on $j_1(\mathcal{V}_{r+1})$, $j_1(\mathcal{V}_{n+1})$ and $\mathcal{L}(\mathcal{V}_{n+1})$, respectively, jet and fibered coordinates expressed by (the significant part of) $t,q^\alpha,q^a,\dot{q}^\alpha,\dot{q}^a,\dot{u}$. The latter undergo the transformation laws[1,2]

$$\overline{\dot{q}}^\beta=\frac{\partial\overline{q}^\beta}{\partial q^\alpha}\dot{q}^\alpha+\frac{\partial\overline{q}^\beta}{\partial t}, \quad \overline{\dot{q}}^b=\frac{\partial\overline{q}^b}{\partial q^a}\dot{q}^a+\frac{\partial\overline{q}^b}{\partial q^\alpha}\dot{q}^\alpha+\frac{\partial\overline{q}^b}{\partial t}, \quad \overline{\dot{u}}=\dot{u}+\frac{\partial f}{\partial q^a}\dot{q}^a+\frac{\partial f}{\partial q^\alpha}\dot{q}^\alpha+\frac{\partial f}{\partial t}$$

with $f(t,q^\alpha,q^a)\in\mathcal{F}(\mathcal{V}_{n+1})$.

In view of these, it is a straightforward matter to verify the affine nature of the fibration $j_1(\mathcal{V}_{n+1})\to\mathcal{N}$.

Therefore, all the arguments stated in Ref. 1 apply equally well to the *affine principal fibration* $\mathcal{L}(\mathcal{V}_{n+1})\to j_1(\mathcal{V}_{n+1})\to\mathcal{N}$. In particular, referring systematically the reader to Ref. 1 for proofs, comments, and notations, one has the following.

Given any point $z\in\mathcal{N}$, let us denote by $\mathcal{L}(\mathcal{V}_{n+1})^*_z$ the space of affine sections $\sigma_z:j_1(\mathcal{V}_{n+1})_z\to\mathcal{L}(\mathcal{V}_{n+1})_z$, $j_1(\mathcal{V}_{n+1})_z$ and $\mathcal{L}(\mathcal{V}_{n+1})_z$ being the fibers over z of $j_1(\mathcal{V}_{n+1})$ and $\mathcal{L}(\mathcal{V}_{n+1})$, respectively. In coordinates, every $\sigma_z\in\mathcal{L}(\mathcal{V}_{n+1})^*_z$ admits a representation of the form

$$\dot{u}=\xi_0+\xi_a\dot{q}^a.$$

There exists a one-parameter group of translations acting on $\mathcal{L}(\mathcal{V}_{n+1})^*_z$; the quotient of $\mathcal{L}(\mathcal{V}_{n+1})^*_z$ under this action will be denoted by $j_1(\mathcal{V}_{n+1})^*_z$.

Introducing the spaces $\mathcal{L}(\mathcal{V}_{n+1})^*:=\cup_{z\in\mathcal{N}}\mathcal{L}(\mathcal{V}_{n+1})^*_z$ and $j_1(\mathcal{V}_{n+1})^*:=\cup_{z\in\mathcal{N}}j_1(\mathcal{V}_{n+1})^*_z$, we obtain an affine principal fibration $\mathcal{L}(\mathcal{V}_{n+1})^*\to j_1(\mathcal{V}_{n+1})^*\to\mathcal{N}$, *dual* of $\mathcal{L}(\mathcal{V}_{n+1})\to j_1(\mathcal{V}_{n+1})\to\mathcal{N}$ in the sense described in Ref. 1. We refer $\mathcal{L}(\mathcal{V}_{n+1})^*$ to local coordinates $t,q^\alpha,q^a,\dot{q}^\alpha,\xi_a,\xi_0$, subject to transformation laws

$$\overline{\xi}_b=\left(\xi_a+\frac{\partial f}{\partial q^a}\right)\frac{\partial q^a}{\partial\overline{q}^b}, \quad \overline{\xi}_0=\xi_0+\xi_a\left(\frac{\partial\overline{q}^a}{\partial q^\alpha}\dot{q}^\alpha+\frac{\partial q^a}{\partial\overline{t}}\right)+\frac{\partial f}{\partial\overline{q}^\alpha}\overline{\dot{q}}^\alpha+\frac{\partial f}{\partial\overline{t}}$$

with $f(t,q)\in\mathcal{F}(\mathcal{V}_{n+1})$. In particular, $j_1(\mathcal{V}_{n+1})^*$ coincides with the quotient space $\mathcal{L}(\mathcal{V}_{n+1})^*/(\partial/\partial\xi_0)$ generated by the action induced by the fundamental vector field $\partial/\partial\xi_0$.

Denoting by $j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$ and $j_1(\mathcal{L}(\mathcal{V}_{n+1})^*,j_1(\mathcal{V}_{n+1})^*)$ the first-jet bundles, respectively, associated with the principal bundles $\mathcal{L}(\mathcal{V}_{n+1})\to j_1(\mathcal{V}_{n+1})$ and $\mathcal{L}(\mathcal{V}_{n+1})^*\to j_1(\mathcal{V}_{n+1})^*$, there exists a canonical diffeomorphism $\psi:j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))\to j_1(\mathcal{L}(\mathcal{V}_{n+1})^*,j_1(\mathcal{V}_{n+1})^*)$. Referring $j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$ ($\simeq j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$) to local co-

ordinates t, q^α, q^a, p_0, p_α, p_a, q^α, $\dot{q}^a$, $\dot{p}_0$, $\dot{p}_\alpha$, $\dot{p}_a$ and $j_1(\mathcal{L}(\mathcal{V}_{n+1})^*, j_1(\mathcal{V}_{n+1})^*)$ to local jet-coordinates t, q^α, q^a, $\dot{q}^\alpha$, ξ_a, ξ_0, ξ_{0_t}, $\xi_{0_{q^\alpha}}$, $\xi_{0_{q^a}}$, $\xi_{0_{\dot{q}^\alpha}}$, $\xi_{0_{\xi_a}}$, the diffeomorphism ψ is described by the relations

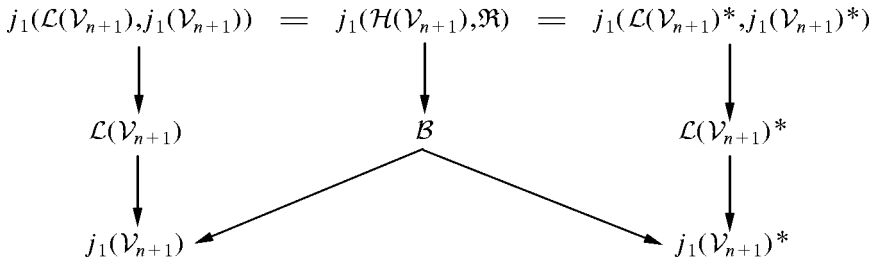
$$t=t, \quad q^\alpha=q^\alpha, \quad q^a=q^a, \quad \dot{q}^\alpha=\dot{q}^\alpha, \quad \xi_a=p_a, \quad \xi_0=p_0+p_\alpha\dot{q}^\alpha,$$

$$\xi_{0_t}=\dot{p}_0, \quad \xi_{0_{q^\alpha}}=\dot{p}_\alpha, \quad \xi_{0_{q^a}}=\dot{p}_a, \quad \xi_{0_{\dot{q}^\alpha}}=p_\alpha, \quad \xi_{0_{\xi_a}}=-\dot{q}^a.$$

Following Ref. 1, we shall identify systematically both $j_1(\mathcal{L}(\mathcal{V}_{n+1}), j_1(\mathcal{V}_{n+1}))$ and $j_1(\mathcal{L}(\mathcal{V}_{n+1})^*, j_1(\mathcal{V}_{n+1})^*)$ with $j_1(\mathcal{H}(\mathcal{V}_{n+1}), \mathfrak{R})$, referred to local coordinates t, q^α, q^a, p_0, p_α, p_a, $\dot{q}^\alpha$, $\dot{q}^a$, $\dot{p}_0$, $\dot{p}_\alpha$, $\dot{p}_a$, and we shall regard the relation

$$\xi_0=p_0+p_\alpha\dot{q}^\alpha=\dot{u}-p_a\dot{q}^a \tag{2.1}$$

as a coordinate transformation on $j_1(\mathcal{H}(\mathcal{V}_{n+1}), \mathfrak{R})$. Equation (2.1) represents changes of trivialization of the principal bundle $j_1(\mathcal{H}(\mathcal{V}_{n+1}), \mathfrak{R}) \to \mathcal{B}$. Once again, the previous discussion may be summarized into the commutative diagram



(2.2)

analogous of (1.1).

Now, let $l: j_1(\mathcal{V}_{n+1}) \to \mathcal{L}(\mathcal{V}_{n+1})$ be a Lagrangian section, locally expressed as (see Refs. 1 and 2)

$$\dot{u}=L(t,q,\dot{q}). \tag{2.3}$$

As pointed out in Ref. 1, the surface $\mathcal{E} := j_1(l)(j_1(\mathcal{V}_{n+1}))$, image of $j_1(\mathcal{V}_{n+1})$ under the first-jet extension $j_1(l)$ of l, carries complete information on dynamics. Indeed, the surface $\mathcal{E}$ is described by the equations

$$p_0=-\frac{\partial L}{\partial \dot{q}^\alpha}\dot{q}^\alpha-\frac{\partial L}{\partial \dot{q}^a}\dot{q}^a+L, \quad \dot{p}_0=\frac{\partial L}{\partial t}, \quad p_\alpha=\frac{\partial L}{\partial \dot{q}^\alpha}, \tag{2.4a}$$

$$\dot{p}_\alpha=\frac{\partial L}{\partial q^\alpha}, \quad p_a=\frac{\partial L}{\partial \dot{q}^a}, \quad \dot{p}_a=\frac{\partial L}{\partial q^a} \tag{2.4b}$$

providing, as pointed out in the Introduction, a set of ordinary differential equations for the determination of the evolution of the system.

Making use of the right vertical arrows of the diagram (2.2), we may project $\mathcal{E}$ into $\mathcal{L}(\mathcal{V}_{n+1})^*$ and $j_1(\mathcal{V}_{n+1})^*$, so generating two maps $\Lambda_l: j_1(\mathcal{V}_{n+1}) \to \mathcal{L}(\mathcal{V}_{n+1})^*$ and $\lambda_l: j_1(\mathcal{V}_{n+1}) \to j_1(\mathcal{V}_{n+1})^*$ locally expressed as

$$\Lambda_l, \quad p_a=\frac{\partial L}{\partial \dot{q}^a}, \quad \xi_0=L-\frac{\partial L}{\partial \dot{q}^a}\dot{q}^a; \tag{2.5a}$$

$$\lambda_l, \quad p_a = \frac{\partial L}{\partial \dot{q}^a}. \tag{2.5b}$$

Under the regularity assumption $\| \partial^2 L / \partial \dot{q}^a \partial \dot{q}^b \| \neq 0$, the map λ_l may be (locally) inverted so that the composite map $\Lambda_l \circ \lambda_l^{-1}$ defines a section $r: j_1(\mathcal{V}_{n+1})^* \to \mathcal{L}(\mathcal{V}_{n+1})^*$. The explicit representation of r may be achieved by solving Eqs. (2.5b) with respect to the variables $\dot{q}^a$ and substituting the result into the second equation (2.5a). In this way we get the final expression

$$\xi_0 = -R(t,q^\alpha,q^a,\dot{q}^\alpha,p_a) := L(t,q^\alpha,q^a,\dot{q}^\alpha,p_a) - p_a \dot{q}^a(t,q^\alpha,q^a,\dot{q}^\alpha,p_a). \tag{2.6}$$

The function R involved in Eq. (2.6) is commonly known as the *Routhian function*.[5] Accordingly, the maps (2.5) and the section (2.6) are, respectively, the *Routh Maps* and the *Routhian section* associated with l.

At this point, it is a straightforward matter to verify that the image space $j_1(r)(j_1(\mathcal{V}_{n+1})^*) \subset j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ [$j_1(r)$ denoting the first-jet extension of r] coincides with the surface $\mathcal{E}$ generated by the given Lagrangian section l. In other words, through the Routhian section r, we obtain a representation of the surface $\mathcal{E}$ in terms of the variables t, q^α, $\dot{q}^\alpha$, p_a, ξ_0, given by the equations

$$\xi_0 = -R(t,q^\alpha,q^a,\dot{q}^\alpha,p_a), \quad \dot{p}_0 = -\frac{\partial R}{\partial t}, \quad \dot{q}^a = \frac{\partial R}{\partial p_a}, \tag{2.7a}$$

$$\dot{p}_a = -\frac{\partial R}{\partial q^a}, \quad \dot{p}_\alpha = -\frac{\partial R}{\partial q^\alpha}, \quad p_\alpha = -\frac{\partial R}{\partial \dot{q}^\alpha}. \tag{2.7b}$$

Once again, Eqs. (2.7) fix the evolution of the system. In particular, writing the equations of motion in the form (2.7) is especially worthwhile whenever the variables q^a $(a = r+1,\ldots,n)$ are cyclic[6] in the Lagrangian function $L(t,q,\dot{q}) \in \mathcal{F}(j_1(\mathcal{V}_{n+1}))$ involved in Eq. (2.3). Indeed, under the stated circumstance, the Routhian function $R(t,q^\alpha,\dot{q}^\alpha,p_a)$ is independent of the variables q^a too. Therefore, the first set of Eqs. (2.7b) imply the evolution equations $p_a = c_a$ const. Due to this fact, by Eqs. (2.7) themselves we derive the decoupled differential equations

$$\frac{d}{dt}\left(\frac{\partial R}{\partial \dot{q}^\alpha}\right) - \frac{\partial R}{\partial q^\alpha} = 0, \quad \dot{q}^a = \frac{\partial R}{\partial p_a} \tag{2.8}$$

with $R(t,q^\alpha,\dot{q}^\alpha,c_a)$, and with the constants c_a fixed by the initial data. Equations (2.8) are the well-known Routh's equations[5] yielding a reduction of the problem of motion.

(Received 5 April 2003; accepted 9 April 2003)

Many integrable equations are known to be reductions of the self-dual Yang–Mills equations. This article discusses some of the well known reductions including the standard soliton equations, the classical Painlevé equations and integrable generalizations of the Darboux–Halphen system and Chazy equations. The Chazy equation, first derived in 1909, is shown to correspond to the equations studied independently by Ramanujan in 1916. © *2003 American Institute of Physics.*

I. INTRODUCTION

The self-dual Yang–Mills (SDYM) equations (a system of equations for Lie algebra-valued functions of $\mathbb{C}^4$) play a central role in the field of integrable systems and also play a fundamental role in several other areas of mathematics and physics.

From the perspective of integrable systems, the study of the SDYM equations became particularly intriguing when, in 1985, R. S. Ward[59] conjectured that

> *... many (and perhaps all?) of the ordinary and partial differential equations that are regarded as being integrable or solvable may be obtained from the self-dual gauge field equations (or its generalizations) by reduction.*

That the SDYM equations are a rich source of integrable systems is suggested by the fact that they are the compatibility condition of an associated linear problem which admits enormous freedom if one allows the associated Lie algebra (the so-called gauge algebra) to be arbitrary. In light of this and other results, the SDYM equations are often referred to as the master integrable system. The SDYM equations provide us with a means of generating and classifying many integrable systems and they also give a unified geometrical framework in which to analyze them. Moreover, in the context of the inverse scattering transform, an integrable equation admits well-behaved solutions obtained via the related linear problems.

The SDYM equations are of great importance in their own right and have found a remarkable number of applications in both physics and mathematics. These equations arise in the context of gauge theory,[49] in classical general relativity,[63,39] and can be used as a powerful tool in the analysis of four-manifolds.[29]

For finite-dimensional gauge groups the integrability of the SDYM equations can be understood from both the inverse scattering transform and geometric points of view.[58,13,26] An excellent reference related to the geometric aspects is Mason and Woodhouse.[41] Our point of view deals

with the algebraic and analytic aspects and novel reductions via infinite-dimensional gauge algebras.

The use of certain infinite-dimensional gauge algebras in the self-dual Yang–Mills equations is an important development in the theory. Using these Lie algebras, reductions of the SDYM equations to many important equations including the Kadomtsev–Petviashvili, Davey–Stewartson, $2+1$-dimensional n-wave, and Chazy equations have been found. Recently a generalized Darboux–Halphen system has been obtained as a reduction of the SDYM equations with an infinite-dimensional gauge algebra.[7] These equations are solvable via an associated linear problem, yet their solutions do not possess the Painlevé property—the characteristic singularity structure often thought to be the hallmark of integrability. A special case of the Darboux–Halphen system is equivalent to the generalized Chazy equation. Much work remains to be done in order to identify the class of infinite-dimensional gauge algebras for which the SDYM equations are integrable. These investigations force us to take a much closer look at the idea of integrability itself.

Throughout we will present geometrical interpretations and reasoning whenever we believe that they provide a deeper insight into the reduction process and the properties of the resulting equations. However, this article has been written with the nongeometer in mind. We hope that our survey will be accessible to a wide variety of researchers from many different branches of mathematics and physics.

In Sec. II we introduce the self-dual Yang–Mills equations and their underlying linear problem. In Sec. III we discuss reductions of the SDYM equations to integrable PDEs. Many of the reductions in this section can be found in Ablowitz and Clarkson.[1] In this section we also consider reductions to PDEs when the underlying Lie algebra is infinite dimensional. Such reductions include the Kadomtsev–Petviashvili and Davey–Stewartson equations. In Sec. IV we describe reductions of the SDYM equations with finite-dimensional Lie algebras to ODEs. In particular, the integrable cases of the equations of motion of a spinning top are recovered, together with some generalizations. We also describe the reductions of SDYM to the Painlevé equations due to Mason and Woodhouse.[41] Finally, Sec. V considers the reduction of the SDYM with an infinite-dimensional Lie algebra to a generalized Darboux–Halphen system whose general solution is densely branched about movable singularities and can contain movable natural barriers. This equation in turn has reductions to the Chazy equation and integrable generalizations of the Chazy equation.

II. THE SDYM EQUATIONS

In this section we motivate the SDYM equations from the points of view of both integrable systems and gauge theory.

A. Linear problems and integrable systems

Recall that many $1+1$-dimensional integrable systems are solved via related linear problems of the form

$$\mathbf{\Psi}_x = X\mathbf{\Psi}, \tag{1}$$

$$\mathbf{\Psi}_t = T\mathbf{\Psi}, \tag{2}$$

where X and T are square matrices of the same dimension which are functions of x, t, and the spectral parameter ζ. The compatibility of these equations (i.e., $\mathbf{\Psi}_{xt}=\mathbf{\Psi}_{tx}$) is equivalent to

$$X_t - T_x + [X,T] = 0. \tag{3}$$

In 1973, Ablowitz *et al.*[10,11] solved the inverse scattering problem in the case

$$X = \begin{pmatrix} -i\zeta & q(x,t) \\ r(x,t) & i\zeta \end{pmatrix}, \quad T = \begin{pmatrix} A & B \\ C & -A \end{pmatrix}, \tag{4}$$

where A,B,C are (Laurent) polynomials in ζ.

Below we list several choices of T that yield a number of integrable equations which will be discussed in later sections.

(i) The Korteweg–de Vries equation:

$$q_t+6qq_x+q_{xxx}=0,$$

$$T=\begin{pmatrix} -4i\zeta^3+2iq\zeta-q_x & 4q\zeta^2+2iq_x\zeta-(2q^2+q_{xx}) \\ -4\zeta^2+2q & 4i\zeta^3-2iq\zeta+q_x \end{pmatrix}$$

$$(r=-1).$$

(ii) The nonlinear Schrödinger equation:

$$iq_t=q_{xx}\pm 2q^2q^*,$$

$$T=\begin{pmatrix} 2i\zeta^2+iqr & -2q\zeta-iq_x \\ 2r\zeta+ir_x & -2i\zeta^2-iqr \end{pmatrix}$$

$$(r=\mp q^*).$$

(iii) The sine-Gordon equation:

$$u_{xt}=\sin u$$

$$T=\zeta^{-1}\begin{pmatrix} \frac{1}{4}i\cos u & \frac{1}{4}i\sin u \\ \frac{1}{4}i\sin u & -\frac{1}{4}i\cos u \end{pmatrix} \tag{5}$$

$$(q=-r=-\tfrac{1}{2}u_x).$$

It should be noted that the dependence on the spectral parameter and the restriction to 2×2 systems given by (4) is not the only choice for which the inverse scattering problem can be solved for Eq. (3) (see, for example, Refs. 3 and 57).

A simple, natural, and highly symmetric generalization of the linear problem (1) and (2) to four variables; x_1, x_2, t_1, t_2 is given by

$$\left(\frac{\partial}{\partial x_1}+\zeta\frac{\partial}{\partial x_2}\right)\Psi=(X_1+\zeta X_2)\Psi, \tag{6}$$

$$\left(\frac{\partial}{\partial t_1}+\zeta\frac{\partial}{\partial t_2}\right)\Psi=(T_1+\zeta T_2)\Psi, \tag{7}$$

where X_1, X_2; T_1, T_2 are functions from $\mathbb{C}^4$ to $\mathfrak{sl}(n;\mathbb{C})$—the Lie algebra of $n\times n$ trace-free matrices with complex-valued entries. The compatibility of this system is equivalent to the self-dual Yang–Mills equations with gauge algebra $\mathfrak{sl}(n;\mathbb{C})$ (see Sec. II C below). From the general form of this linear problem it is clear that many integrable equations are reductions of the self-dual Yang–Mills equations because their associated linear problems arise as reductions of the linear problem for the SDYM equations. Notice, however, that the right sides of Eqs. (6) and (7) are linear in ζ whereas in the AKNS scheme, the right side of Eq. (2) can be a Laurent polynomial in ζ. However, it turns out that reductions of (6) and (7) can have much more general dependence on the spectral parameter.

B. The Yang–Mills equations

Non-Abelian gauge theories first appeared in the seminal work of Yang and Mills[65] as a non-Abelian generalization of Maxwell's equations. Let G be a Lie group (referred to as the gauge group) with Lie algebra LG and let $\{x^\mu\}_{\mu=0,\ldots,3}$ be coordinates on a four-dimensional manifold M which can be $\mathbb{R}^4$, $\mathbb{R}^{1,3}$ or $\mathbb{R}^{2,2}$. Given $A_\mu(\mathbf{x}) \in \mathrm{LG}$, we introduce the covariant derivatives

$$D_\mu = \partial_\mu - A_\mu, \tag{8}$$

and their commutators

$$F_{\mu\nu} = -[D_\mu, D_\nu] = \partial_\mu A_\nu - \partial_\nu A_\mu - [A_\mu, A_\nu]. \tag{9}$$

The fact that the Yang–Mills equations have a natural geometric interpretation was recognized early on in the history of gauge theory. The covariant derivatives (8) can be used to obtain a local representation of a connection on a principal fiber bundle over M. The one-form $A := A_\mu dx^\mu$ is called the *connection one-form* and $F := \frac{1}{2} F_{\mu\nu} dx^\mu dx^\nu$ the *curvature two-form* of the connection. F can also be expressed as the exterior covariant derivative of A given by

$$F = DA := dA - A \wedge A.$$

Recall that the Hodge dual operator on the four-dimensional manifold M takes any two-form $T = \frac{1}{2} T_{\mu\nu} dx^\mu \wedge dx^\nu$ to the dual two-form $*T = \frac{1}{2} \varepsilon_{\mu\nu}{}^{\gamma\delta} T_{\gamma\delta} dx^\mu \wedge dx^\nu$ where $\varepsilon_{\mu\nu\gamma\delta}$ is totally antisymmetric with $\varepsilon_{0123} = 1$ and the standard metric on M is used to raise and lower indices. The Yang–Mills equations then have the simple form

$$D*F = 0$$

together with the Bianchi identity

$$DF = 0,$$

which follows from the definitions of exterior covariant derivative D and F. Note that under the gauge transformation

$$A_\mu \mapsto g^{-1} A_\mu g + g^{-1} \partial_\mu g, \quad g \in \mathrm{G}, \tag{10}$$

the components of the curvature two-form transform as

$$F_{\mu\nu} \mapsto g^{-1} F_{\mu\nu} g, \tag{11}$$

which corresponds to the transformation of the fibers by the right action of the structure group G on the principal bundle.

C. The self-dual Yang–Mills equations

The Yang–Mills equations are a set of coupled, second-order PDEs in four dimensions for the LG-valued gauge potential functions A_μ's, and are extremely difficult to solve in general. It is, however, possible to obtain a special class of first-order reductions of the full Yang–Mills equations by noting that any F that satisfies

$$*F = \lambda F \tag{12}$$

for some constant λ, also satisfies the Yang–Mills equations by virtue of the Bianchi identity: $DF = 0$. From (12) we must have

$$**F = \lambda * F = \lambda^2 F. \tag{13}$$

However, $**F = gF$ where $g = \det[g_{\mu\nu}]$ is the determinant of the metric on M. Hence

$$\lambda = \begin{cases} \pm 1 & \text{on } \mathbb{R}^4,\ \mathbb{R}^{2,2}; \\ \pm i & \text{on } \mathbb{R}^{3,1}. \end{cases}$$

All real solutions of the equations $*F = \pm iF$ are trivial. On $\mathbb{R}^4$ and $\mathbb{R}^{2,2}$, the equations $*F = (-)F$ are called the (anti-)self-dual Yang–Mills equations. We will work in $\mathbb{R}^4$ with the standard metric

$$ds^2 = (dx^0)^2 + (dx^1)^2 + (dx^2)^2 + (dx^3)^2.$$

The SDYM equations now take the form

$$F_{01} = F_{23}, \quad F_{02} = F_{31}, \quad F_{03} = F_{12}. \tag{14}$$

We introduce the null coordinates

$$\sigma = \frac{1}{\sqrt{2}}(x^1 + ix^2), \quad \tau = \frac{1}{\sqrt{2}}(x^0 - ix^3),$$

$$\tilde{\sigma} = \frac{1}{\sqrt{2}}(x^1 - ix^2), \quad \tilde{\tau} = \frac{1}{\sqrt{2}}(x^0 + ix^3).$$

It then follows from $A = A_\mu dx^\mu = A_\sigma d\sigma + A_{\tilde{\sigma}} d\tilde{\sigma} + A_\tau d\tau + A_{\tilde{\tau}} d\tilde{\tau}$ that

$$A_0 = \frac{1}{\sqrt{2}}(A_\tau + A_{\tilde{\tau}}), \quad A_1 = \frac{1}{\sqrt{2}}(A_\sigma + A_{\tilde{\sigma}}),$$

$$A_2 = \frac{i}{\sqrt{2}}(A_\sigma - A_{\tilde{\sigma}}), \quad A_3 = -\frac{i}{\sqrt{2}}(A_\tau - A_{\tilde{\tau}}),$$

and the SDYM equations become

$$F_{\sigma\tau} = 0, \quad F_{\tilde{\sigma}\tilde{\tau}} = 0, \quad F_{\sigma\tilde{\sigma}} + F_{\tau\tilde{\tau}} = 0. \tag{15}$$

Equations (15) are the compatibility condition of the isospectral linear problem

$$(\partial_\sigma + \zeta\partial_{\tilde{\tau}})\boldsymbol{\Psi} = (A_\sigma + \zeta A_{\tilde{\tau}})\boldsymbol{\Psi}, \tag{16}$$

$$(\partial_\tau - \zeta\partial_{\tilde{\sigma}})\boldsymbol{\Psi} = (A_\tau - \zeta A_{\tilde{\sigma}})\boldsymbol{\Psi}, \tag{17}$$

where ζ is the spectral parameter and $\boldsymbol{\Psi}$ is a local section of the Yang–Mills fiber bundle. The compatibility condition is simply $(\partial_\tau - \zeta\partial_{\tilde{\sigma}})(\partial_\sigma + \zeta\partial_{\tilde{\tau}})\boldsymbol{\Psi} = (\partial_\sigma + \zeta\partial_{\tilde{\tau}})(\partial_\tau - \zeta\partial_{\tilde{\sigma}})\boldsymbol{\Psi}$. On using Eqs. (16) and (17), this gives

$$[F_{\sigma\tau} - \zeta(F_{\sigma\tilde{\sigma}} + F_{\tau\tilde{\tau}}) + \zeta^2 F_{\tilde{\sigma}\tilde{\tau}}]\boldsymbol{\Psi} = 0.$$

The gauge transformation (10) can be understood by setting $\boldsymbol{\Psi} = g\tilde{\boldsymbol{\Psi}}$ in (16) and (17) and demanding that the A_μ's transform so as to preserve the form of these equations.

A very compact way of writing the SDYM equations was introduced by Pohlmeyer.[48] Following Yang,[64] and working with the Lie algebra su(2), Pohlmeyer noted that the vanishing of $F_{\sigma\tau}$ and $F_{\tilde{\sigma}\tilde{\tau}}$ allows us to write (locally)

$$A_\sigma=(\partial_\sigma C)C^{-1},\quad A_\tau=(\partial_\tau C)C^{-1},$$

$$A_{\tilde{\sigma}}=(\partial_{\tilde{\sigma}}D)D^{-1},\quad A_{\tilde{\tau}}=(\partial_{\tilde{\tau}}D)D^{-1},$$

for some C and D in the Lie group G. Letting $J=C^{-1}D\in\mathrm{G}$ we see that the last equation in (15) becomes

$$\partial_{\tilde{\sigma}}(J^{-1}\partial_\sigma J)+\partial_{\tilde{\tau}}(J^{-1}\partial_\tau J)=0. \tag{18}$$

III. EXAMPLES OF REDUCTIONS

Perhaps the simplest reductions of the SDYM equations are those in which the A_μ's are taken to be independent of certain coordinates. With the exception of the reduction to the Ernst equation, all reductions in this section will be with respect to translational symmetries. That is, the A_μ's will be taken to depend only on two linear combinations of the variables x^0, x^1, x^2, and x^3 (or equivalently σ, $\tilde{\sigma}$, τ, and $\tilde{\tau}$).

A. The nonlinear Schrödinger equation

Following Mason and Sparling,[40] let us consider the case in which the Lie algebra is $\mathfrak{sl}(2;\mathbb{C})$ (trace-free 2×2 matrices over the field of complex numbers) and the A_μ's are functions of $x=\sigma+\tilde{\sigma}$ and $t=\tilde{\tau}$ only. We use the gauge freedom and take $A_\sigma=0$. (Note that this involves solving a linear equation for g.)

In terms of the matrix-valued functions $P:=A_\tau$, $Q:=A_{\tilde{\sigma}}$ and $R:=A_{\tilde{\tau}}$, the self-dual Yang–Mills equations (15) are

$$P_x=0, \tag{19}$$

$$Q_x-P_t-[P,R]=0, \tag{20}$$

$$R_x-Q_t-[Q,R]=0. \tag{21}$$

Note that Eqs. (19)–(21) are invariant if P, Q, and R all undergo the same constant similarity transformation. Hence if P is independent of t it can be put into canonical form. In particular, if it is diagonalizable we can, without loss of generality, assume it has the form

$$P=\begin{pmatrix}k & 0\\ 0 & -k\end{pmatrix},$$

for some constant k. From Eq. (20) we see that Q_x must have zero diagonal part. Hence we can take

$$Q=\begin{pmatrix}0 & q\\ -r & 0\end{pmatrix}.$$

Equation (20) gives the parametrization of the off-diagonal elements of R in terms of q and r. So up to a constant (which can be gauged away), Eq. (21) gives

$$R=\frac{1}{2k}\begin{pmatrix}qr & q_x\\ r_x & -qr\end{pmatrix},$$

together with the equations

$$2kq_t=q_{xx}+2q^2r,$$

$$2kr_t=-r_{xx}-2qr^2.$$

Choosing $k=i/2$, $r=\pm q^*$, gives the nonlinear Schrödinger equation

$$iq_t=q_{xx}\pm 2|q|^2q.$$

B. The Korteweg–de Vries equation

Mason and Sparling[40] also considered the above reduction for the case in which P is not diagonalizable. Let P take the canonical form

$$P=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}.$$

We then find that

$$Q=\begin{pmatrix}v & 1\\ w & -v\end{pmatrix},$$

where $w=v_x-v^2$ (up to an arbitrary function of t),

$$R=\frac{1}{8}\begin{pmatrix}4(v_x-v^2)_x & -8v_x\\ v_{xxx}-4vv_{xx}-2v_x^2+4v^2v_x & -4(v_x-v^2)_x\end{pmatrix}$$

and $u=-v_x$ satisfies the Korteweg–de Vries equation

$$u_t=\tfrac{1}{4}u_{xxx}+3uu_x.$$

C. The sine-Gordon equation

Suppose that the A_μ's depend on $x=\sigma$ and $t=\tilde{\sigma}$ only. If we use a gauge in which $A_{\tilde{\sigma}}=0$, then the linear problem (16) and (17) for the SDYM equations becomes

$$\partial_x\Psi=(A_\sigma+\zeta A_{\tilde{\tau}})\Psi,\quad \partial_t\Psi=-\frac{1}{\zeta}A_\tau\Psi.$$

Here we choose the Lie algebra to be $\mathfrak{su}(2)$ so that the A_μ's are skew-Hermitian. We introduce the parametrization

$$A_\sigma=-\frac{i}{2}\begin{pmatrix}c & 0\\ 0 & -c\end{pmatrix},\quad A_\tau=-\frac{i}{2}\begin{pmatrix}0 & a-ib\\ a+ib & 0\end{pmatrix},\quad A_{\tilde{\tau}}=-\frac{i}{2}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}$$

(Ref. 14), where a,b,c are real functions of x and t. The SDYM equations are equivalent to

$$\frac{\partial a}{\partial x}=-bc,\quad \frac{\partial b}{\partial x}=ac,\quad \frac{\partial c}{\partial t}=-b. \tag{22}$$

It follows from the first two equations of (22) that a^2+b^2 is independent of x. We choose $a^2+b^2=1$ and introduce the parametrization $a=\cos u$, $b=\sin u$. This gives $c=\partial u/\partial x$. The third equation in (22) then becomes the sine-Gordon equation

$$u_{xt}=-\sin u.$$

D. The *N*-wave equations

Following Chakravarty and Ablowitz,[14] we consider the case in which the A_μ's are functions of σ and τ only and the Lie algebra is $\mathfrak{su}(n;\mathbb{R})$. In this case, from the self-duality equation $F_{\tilde{\sigma}\tilde{\tau}}=0$, it follows that $[A_{\tilde{\sigma}},A_{\tilde{\tau}}]=0$. We take

$$A_{\tilde{\sigma}}=\mathrm{diag}(a_1,a_2,\ldots,a_n), \quad A_{\tilde{\tau}}=\mathrm{diag}(b_1,b_2,\ldots,b_n),$$

where the a_j's and b_j's are constants (we can use a gauge transformation to make them constant). Using the parametrization $A_\sigma=[A_{ij}]$ and $A_\tau=[B_{ij}]$, the vanishing of $F_{\sigma\tilde{\sigma}}+F_{\tau\tilde{\tau}}$ implies that $[A_\sigma,A_{\tilde{\sigma}}]+[A_\tau,A_{\tilde{\tau}}]=0$, which gives

$$A_{ij}=\lambda_{ij}B_{ij},$$

where

$$\lambda_{ij}=-\frac{b_i-b_j}{a_i-a_j}, \quad i\neq j,$$

and we have assumed that the a_j's are distinct. Finally, the vanishing of $F_{\sigma\tau}$ gives the N-wave interaction equations,

$$\frac{\partial B_{ij}}{\partial\sigma}-\lambda_{ij}\frac{\partial B_{ij}}{\partial\tau}=\sum_{k=1}^{n}(\lambda_{ik}-\lambda_{kj})B_{ik}B_{kj}. \tag{23}$$

In the case $N=3$ and in which B is skew-Hermitian, Eq. (23) becomes the three-wave interaction equation.[66] The equation (23) for arbitrary N was studied by Ablowitz and Haberman.[3]

E. The chiral field equations

A number of important reductions of the SDYM equations come directly from Eq. (18). If J depends only on $x=\sigma+\tilde{\sigma}$ and $t=\tau+\tilde{\tau}$, then Eq. (18) becomes the chiral field equation

$$(J^{-1}J_x)_x+(J^{-1}J_t)_t=0. \tag{24}$$

Using $\sigma=(1/\sqrt{2})(x^1+ix^2)$, $\tilde{\sigma}=(1/\sqrt{2})(x^1-ix^2)$, Ward[61,60] obtained a $2+1$-dimensional generalization of Eq. (24) by considering a reduction of Eq. (18) in which J depends on $t=\tau+\tilde{\tau}$ and σ and $\tilde{\sigma}$. This gives

$$(J^{-1}J_t)_t+(J^{-1}J_\sigma)_{\tilde{\sigma}}=0, \tag{25}$$

which has been studied by Manakov and Zakharov[38] and Villarroel.[56] More generally, Ward obtains the equation

$$\begin{aligned}-(J^{-1}J_t)_t+(J^{-1}J_x)_x+(J^{-1}J_y)_y+a[(J^{-1}J_y)_x-(J^{-1}J_x)_y]+b[(J^{-1}J_t)_y-(J^{-1}J_y)_t]\\ +c[(J^{-1}J_x)_t-(J^{-1}J_t)_x]=0,\end{aligned} \tag{26}$$

where (a,b,c) is spacelike $(-a^2+b^2+c^2=1)$ or timelike $(-a^2+b^2+c^2=-1)$. If (a,b,c) is timelike, then Eq. (26) can be transformed to (25).

F. The Ernst equation

Following L. Witten,[62] we let J in Eq. (18) be a function of $\rho=\sqrt{(x^1)^2+(x^2)^2}$ and $z=x^3$ only. That is, $\rho^2=2\sigma\tilde{\sigma}$ and $z=(i/\sqrt{2})(\tau-\tilde{\tau})$. Equation (18) becomes

$$\rho^{-1}(\rho J^{-1}J_\rho)_\rho+(J^{-1}J_z)_z=0. \tag{27}$$

When J is a real symmetric matrix in $\mathrm{SL}(2;\mathbb{R})$, we can parametrize J as

$$J=\frac{1}{f}\begin{pmatrix}1 & g\\ g & f^2+g^2\end{pmatrix}.$$

In terms of this parametrization, Eq. (27) becomes

$$f\Delta f=\nabla f\cdot\nabla f-\nabla g\cdot\nabla g,$$

$$f\Delta g=2(\nabla f)\cdot(\nabla g),$$

where $\nabla:=(\partial_\rho,\partial_z)$ and $\Delta:=\partial_\rho^2+\rho^{-1}\partial_\rho+\partial_z^2$ are the axisymmetric forms of the gradient and Laplacian on $\mathbb{R}^3$, respectively, in cylindrical-polar coordinates. Introducing the variable $\mathcal{E}:=f+ig$, this system can be written compactly as

$$\Re(\mathcal{E})\Delta\mathcal{E}=\nabla\mathcal{E}\cdot\nabla\mathcal{E}. \tag{28}$$

Equation (28) is called the Ernst equation and describes stationary axisymmetric space–times in general relativity.[30] The function $\mathcal{E}$ is known as the Ernst potential.

G. Toda molecule

In this reduction we choose the Lie algebra to be simple and of rank N [e.g., $\mathfrak{sl}(N+1;\mathbb{C})$]. We use the basis $\{H_j,E_j^+,E_j^-\}_{j=1}^N$, which satisfies

$$\begin{gathered}[H_i,H_j]=0,\quad [E_i^+,E_j^-]=\delta_{ij}H_j,\\ [H_i,E_j^+]=K_N^{ji}E_j^+,\quad [H_i,E_j^-]=-K_N^{ji}E_j^-,\end{gathered} \tag{29}$$

where $K_N=[K_N^{ij}]$ is a Cartan matrix. Recall that an $N\times N$-matrix K is called a Cartan matrix if it satisfies the following properties:

(1) $K^{ii}=2$.
(2) K^{ij} is a nonpositive integer if $i\neq j$.
(3) $K^{ij}=0$ if and only if $K^{ji}=0$.
(4) K is positive definite with rank N.

We choose the A_μ's to be functions of σ and $\tilde{\sigma}$ only and of the form

$$A_\sigma=\sum_{k=1}^N u_k(\sigma,\tilde{\sigma})H_k,\quad A_{\tilde{\sigma}}=\sum_{k=1}^N v_k(\sigma,\tilde{\sigma})H_k,$$

$$A_\tau=\sum_{k=1}^N w_k(\sigma,\tilde{\sigma})E_k^+,\quad A_{\tilde{\tau}}=\sum_{k=1}^N w_k(\sigma,\tilde{\sigma})E_k^-.$$

Substituting the above A_μ's into the self-duality equations and using the commutation relations (29), a straightforward calculation shows that the functions u_k and v_k, $k=1,2,\ldots,N$ can be eliminated from the resulting equations, which then yield

$$\Delta\phi_i=-\sum_{j=1}^N K_N^{ij}\exp(\phi_j),\quad i=1,2,\ldots,N, \tag{30}$$

where $w_i=\exp(\phi_i/2)$ and $\Delta\phi=\phi_{\sigma\tilde{\sigma}}$. Equations (30) are known as the Toda molecule equations.[46] The case $N=1$ corresponds to the Liouville equation $\Delta\phi_1=-2\exp(\phi_1)$.

The above analysis can be repeated for the case in which a basis $\{H_j, E_j^+, E_j^-\}_{j=0}^N$ satisfies the relations (29) in which $\tilde{K}_N$ is now taken to be an extended Cartan matrix. An $(N+1)\times(N+1)$ matrix is said to be an extended Cartan matrix if and only if it is of rank N and satisfies properties 1–3 above. Note that, in particular, an extended Cartan matrix possesses a zero eigenvalue because it is not of maximal rank. This gives the Toda lattice equation

$$\Delta\phi_i = -\sum_{j=1}^{N} \tilde{K}_N^{ij} \exp(\phi_j), \quad i=0,1,\ldots,N. \tag{31}$$

In particular, if we take

$$\tilde{K}_N = \begin{pmatrix} 2 & -1 & 0 & \cdots & 0 & -1 \\ -1 & 2 & -1 & & 0 & 0 \\ 0 & \ddots & \ddots & \ddots & \vdots & \\ \vdots & & \ddots & \ddots & \ddots & 0 \\ 0 & & & -1 & 2 & -1 \\ -1 & 0 & \cdots & 0 & -1 & 2 \end{pmatrix},$$

then Eq. (31) becomes the two-dimensional Darboux–Toda equation

$$\Delta\phi_i = \exp(\phi_{i-1}) - 2\exp(\phi_i) + \exp(\phi_{i+1}), \tag{32}$$

where $\phi_i = \phi_{i+N+1}$. The system (32) was known to Darboux[28] in the nineteenth century.

H. Infinite-dimensional algebras and 2+1 equations

In Ref. 9, Ablowitz, Chakravarty, and Takhtajan considered reductions of the SDYM equations in which the Lie algebra is the infinite-dimensional Lie algebra of formal matrix differential operators in an auxiliary variable y. They then considered reductions in which the A_μ's depend only on two space–time variables. The resulting equations then depends on three variables.

1. The 2+1-dimensional N-wave equation

First consider a reduction in which the A_μ's are functions of $x=\sigma$ and $t=\tau$ only. Then the resulting SDYM linear system is given by

$$\partial_x\Psi = (A_\sigma + \zeta A_{\tilde{\tau}})\Psi,$$

$$\partial_t\Psi = (A_\tau - \zeta A_{\tilde{\sigma}})\Psi,$$

where Ψ is a function of x,t,y and ζ. Choose a gauge in which $A_{\tilde{\tau}}=B$ and $A_{\tilde{\sigma}}=C$, where B and C are constant, commuting $n\times n$ matrices. We take the remaining gauge potentials of the form $A_\sigma = U + B\partial_y$ and $A_\tau = V + C\partial_y$, where $U(x,y,t), V(x,y,t) \in \mathfrak{sl}(n,\mathbb{C})$. By taking $\Psi = Ge^{-\zeta y}$, we obtain a simpler, reduced linear system from above,

$$\partial_x G = (U + B\partial_y)G, \tag{33}$$

$$\partial_t G = (V + C\partial_y)G, \tag{34}$$

in terms of the function $G(x,y,t)$. The system (33) and (34) is the standard linear system related to the $2+1$-dimensional N-wave equations. The compatibility of (33) and (34) is

$$\partial_t U - \partial_x V + [U,V] - C\partial_y U + B\partial_y V = 0, \quad [B,V] = [C,U],$$

which gives

$$[B,\partial_t Q]-[C,\partial_x Q]-C[B,\partial_y Q]+B[C,\partial_y Q]+[[B,Q],[C,Q]]=0,$$

where $U=[B,Q]$ and $V=[C,Q]$. In the case when B and C are diagonal and Q is off-diagonal, these equations can be transformed to the $2+1$ N-wave equations

$$\frac{\partial Q_{ij}}{\partial t}=a_{ij}\frac{\partial Q_{ij}}{\partial x}+b_{ij}\frac{\partial Q_{ij}}{\partial y}+\sum_{k=1}^{n}(a_{ik}-a_{kj})Q_{ik}Q_{kj},$$

where a_{ij}, b_{ij} are suitable constants depending on the matrix elements of B and C.

2. KP, mKP, and DS equations

Chakravarty, Kent, and Newman[21] also obtained the Kadomtsev–Petviashvili, modified Kadomtsev–Petviashvili, and Davey–Stewartson equations directly as reductions of the SDYM equations with an infinite-dimensional Lie algebra of formal matrix differential operators. If the A_μ's are assumed to depend on $x=\sigma+\tilde{\sigma}$ and $t=\tau$ only, then the linear problem (16) and (17) becomes

$$\partial_x\mathbf{\Psi}=(A_\sigma+\zeta A_{\tilde{\tau}})\mathbf{\Psi}, \tag{35}$$

$$\partial_t\mathbf{\Psi}=(A_\tau+\zeta[A_\sigma+A_{\tilde{\sigma}}]+\zeta^2 A_{\tilde{\tau}})\mathbf{\Psi}. \tag{36}$$

The connection components are taken to be of the form

$$A_\sigma=U_0+U_1\partial_y,\quad A_{\tilde{\sigma}}=-(B_0+B_1\partial_y),\quad A_\tau=V_0+V_1\partial_y+V_2\partial_y^2,\quad A_{\tilde{\tau}}=A,$$

where the coefficients are 2×2 matrix-valued functions of x and t. In order to simplify the integrability conditions of (35) and (36), we demand (as in the $2+1$ N-wave case) that the spectral parameter ζ be eliminated from this system after a change of variable of the form $\mathbf{\Psi}=G\mathrm{e}^{-\zeta y}$. It can be shown that this requirement implies that $U_1=V_2=B_1+A$ and $V_1=U_0+B_0$. Subsequently, the system (35) and (36) becomes

$$\partial_x G=(U_0+A\partial_y)G, \tag{37}$$

$$\partial_t G=(V_0+[U_0+B_0]\partial_y+A\partial_y^2)G. \tag{38}$$

Appropriate choices of the matrices A, B, U, and V give the linear problem for the KP, mKP, and DS equations (see Ref. 21).

Another notable reduction with an infinite-dimensional gauge algebra was considered in Ref. 39 by Mason and Newman. They showed that the SDYM equations with the Lie algebra of the Lie group of volume preserving diffeomorphisms on a four-manifold, in which the A_μ's are independent of the space-time coordinates σ, $\tilde{\sigma}$, τ, and $\tilde{\tau}$, are equivalent to the self-dual Einstein equations. In particular, the reduction to the Plebanski heavenly equation is given in Ref. 22. This equation in turn has a reduction to the Monge–Ampere equation.

I. The SDYM hierarchy

In Ref. 9, the authors studied an infinite hierarchy of equations whose first member was the SDYM system. Each member of the hierarchy has the same underlying spectral problem, and the higher flows are derived from an infinite sequence of nonlocal conservation laws associated with the SDYM equations. Furthermore, many well known integrable hierarchies in $1+1$- and $2+1$-dimensions are derived from the symmetry reductions of the self-dual hierarchy.

In an appropriate gauge, the kth member of the SDYM hierarchy is given by

$$\partial_{\tau_k}A_\sigma-\partial_\sigma\Phi_{k-1}+[A_\sigma,\Phi_{k-1}]=0, \tag{39}$$

where Φ_n is given recursively by

$$(\partial_{\tilde{\tau}} - \mathrm{ad}\, A_{\tilde{\tau}})\Phi_{n+1} = -(\partial_\sigma - \mathrm{ad}\, A_\sigma)\Phi_n - \partial_{\tilde{\sigma}} A_\sigma \delta_{n0}, \quad n = 0,1,\ldots,$$

and $\Phi_0 = -A_{\tilde{\sigma}}$. Equation (39) is the compatibility condition for the system

$$D_1\Psi = \mathcal{A}_1\Psi, \quad D_2\Psi = \mathcal{A}_2\Psi, \tag{40}$$

where, for $k = 2,3,\ldots$,

$$D_1 = \partial_\sigma + \zeta\partial_{\tilde{\tau}}, \quad \mathcal{A}_1 = A_\sigma + \zeta A_{\tilde{\tau}},$$

$$D_k = \partial_{\tau_k} - \zeta^{k-1}\partial_{\tilde{\sigma}}, \quad \mathcal{A}_k = (\zeta^{k-1}\Phi)_+, \quad \Phi = \sum_{n=0}^{\infty} \Phi_n \zeta^{-n},$$

and $(F)_+$ denotes the power series part of the Laurent expansion of F about $\zeta = 0$. Note that if $k = 2$, then $D_2 = \partial_\tau - \zeta\partial_{\tilde{\sigma}}$ and $\mathcal{A}_2 = A_\tau - \zeta A_{\tilde{\sigma}}$, where $\tau = \tau_2$ and we have identified A_τ with Φ_1. In this case the linear problem (40) becomes the standard linear problem for the SDYM equations.

As mentioned above, the reduction of the SDYM equations to the $1+1$- and $2+1$-dimensional integrable equations can be extended to a reduction of the SDYM hierarchy to the corresponding hierarchies. In this way, we can obtain, for example, both the $1+1$- and $2+1$-dimensional N-wave hierarchies. In particular, the Davey–Stewartson equation (DS) can be obtained as the second member of the $2+1$-dimensional N-wave hierarchy. See Ref. 9 for details.

IV. ODE REDUCTIONS

A. Integrable tops

The equations of motion for a spinning top have played a fundamental role in the early development of the theory of integrable systems.

1. The Euler–Arnold–Manakov top

In this reduction, following Chakravarty, Ablowitz, and Clarkson,[18,19] we take the Lie algebra to be $\mathfrak{sl}(n;\mathbb{C})$ and we assume that the A_μ's are functions of $t = \sigma$ only. The vanishing of $F_{\tilde{\sigma}\tilde{\tau}}$ demands that $A_{\tilde{\sigma}}$ and $A_{\tilde{\tau}}$ commute. We take these matrices to be diagonal and of the form

$$A_{\tilde{\sigma}} = \mathrm{diag}(a_1, a_2, \ldots, a_n), \quad A_{\tilde{\tau}} = \mathrm{diag}(b_1, b_2, \ldots, b_n),$$

where the a_j's and b_j's are constants. The equation $F_{\sigma\tilde{\sigma}} + F_{\tau\tilde{\tau}} = 0$ is now the algebraic equation $[A_\sigma, A_{\tilde{\sigma}}] + [A_\tau, A_{\tilde{\tau}}] = 0$, which gives the elements of $A_\sigma = [A_{ij}]$ in terms of the elements of $A_\tau = [B_{ij}]$ as

$$A_{ij} = -\frac{b_j - b_i}{a_j - a_i} B_{ij}, \quad i \neq j,$$

provided $a_i \neq a_j$, $b_i \neq b_j$ for $i \neq j$.

Choosing $a_i = b_i^2$, $i = 1,\ldots,n$, and A_σ and A_τ to be skew-symmetric, we have $A_{ij} = -(b_i + b_j)^{-1} B_{ij}$ and the vanishing of $F_{\sigma\tau}$ gives

$$\frac{dB_{ij}}{dt} = \sum_{k=1}^{n} \left(\frac{1}{b_j + b_k} - \frac{1}{b_k + b_i} \right) B_{ik} B_{kj}. \tag{41}$$

Equations (41) were first considered by Manakov[37] and Arnold[12] and are the equations of motion for a free n-dimensional rigid body about a fixed point. In the case $n = 3$, we obtain Euler's equations for a free spinning body about a fixed point,

$$\frac{dL_1}{dt}=\gamma_1 L_2 L_3, \quad \frac{dL_2}{dt}=\gamma_2 L_3 L_1, \quad \frac{dL_3}{dt}=\gamma_3 L_1 L_2, \tag{42}$$

where

$$L_1=B_{23}, \quad L_2=B_{31}, \quad L_3=B_{12}, \quad I_1=-(b_2+b_3), \quad I_2=-(b_3+b_1), \quad I_3=-(b_1+b_2),$$

and

$$\gamma_1=\frac{I_2-I_3}{I_2 I_3}, \quad \gamma_2=\frac{I_3-I_1}{I_3 I_1}, \quad \gamma_3=\frac{I_1-I_2}{I_1 I_2}.$$

In Eq. (42), (L_1,L_2,L_3) is the angular momentum in the body frame and the I_k's are the principal moments of inertia. Reductions to other integrable tops, including the Kowalevsaya top, are described in Refs. 18 and 19.

B. The Painlevé equations

With the exception of the reduction to the Ernst equation, all of the above reductions have been with respect to translational symmetries. In other words, the reductions have all resulted from considering A_μ's that depend only on one or more linear combination of the variables σ, $\tilde{\sigma}$, τ, and $\tilde{\tau}$. In this section we follow Mason and Woodhouse[41,42] and obtain reductions to the Painlevé equations by considering reductions by conformal symmetries.

The Painlevé equations are the following six classically known ODEs:

$$P_I \quad u''=6u^2+t,$$

$$P_{II} \quad u''=2u^3+tu+\alpha,$$

$$P_{III} \quad u''=\frac{1}{u}u'^2-\frac{1}{t}u'+\frac{1}{t}(\alpha u^2+\beta)+\gamma u^3+\frac{\delta}{u},$$

$$P_{IV} \quad u''=\frac{1}{2u}u'^2+\frac{3}{2}u^3+4tu^2+2(t^2-\alpha)u+\frac{\beta}{u},$$

$$P_V \quad u''=\left\{\frac{1}{2u}+\frac{1}{u-1}\right\}u'^2-\frac{1}{t}u'+\frac{(u-1)^2}{t^2}\left(\alpha+\frac{\beta}{u}\right)+\frac{\gamma u}{t}+\frac{\delta u(u+1)}{u-1},$$

$$P_{VI} \quad u''=\frac{1}{2}\left\{\frac{1}{u}+\frac{1}{u-1}+\frac{1}{u-t}\right\}u'^2-\left\{\frac{1}{t}+\frac{1}{u-1}+\frac{1}{u-t}\right\}u'$$
$$+\frac{u(u-1)(u-t)}{t^2(t-1)^2}\left\{\alpha+\frac{\beta t}{u^2}+\frac{\gamma(t-1)}{(u-1)^2}+\frac{\delta t(t-1)}{(u-t)^2}\right\}.$$

These equations have played a very important role in integrable systems. Indeed they arise from similarity reductions of classical soliton equations and as monodromy preserving deformation equations associated with linear systems of ODEs with rational coefficients.

The SDYM equations are invariant under the group of conformal transformations (transformations that preserve the metric up to an over all factor). The metric on $\mathbf{R}^4$ in null coordinates, $d\sigma\, d\tilde{\sigma}+d\tau\, d\tilde{\tau}$, is proportional to $\varepsilon_{\alpha\beta\gamma\delta}dx^{\alpha\beta}dx^{\gamma\delta}$, where $[x^{\alpha\beta}]$ is the skew-symmetric singular matrix

$$[x^{\alpha\beta}]=\begin{pmatrix} 0 & \lambda & \sigma & \tilde{\tau} \\ -\lambda & 0 & -\tau & \tilde{\sigma} \\ -\sigma & \tau & 0 & 1 \\ -\tilde{\tau} & -\tilde{\sigma} & -1 & 0 \end{pmatrix}, \tag{43}$$

where $\lambda=\sigma\tilde{\sigma}+\tau\tilde{\tau}$.

Consider a mapping of the form $x\mapsto y=gxg^T$, where $g\in \mathrm{GL}(4;\mathbb{C})$. Then the mapping $x\mapsto y/y^{23}$ generates a conformal transformation of $\mathbb{C}^4$ as it maps the space of matrices of the form (43) into itself. In fact, every proper conformal transformation arises in this way. The generators of the conformal transformations are called conformal Killing vectors. In order to calculate the associated conformal Killing vectors we consider a one-parameter family of transformations given by $g=\exp(\epsilon K)=I+\epsilon K+O(\epsilon^2)$, where $K\in \mathfrak{gl}(4;\mathbb{C})$. Hence $y=x+\epsilon(Kx+xK^T)+O(\epsilon^2)$. Consider the case in which the matrix K has a 1 in the $\mu\nu$ component and zeros elsewhere. In components we have

$$y^{\alpha\beta}=x^{\alpha\beta}+\epsilon(x^{\alpha\nu}\delta^{\beta\mu}-x^{\beta\nu}\delta^{\alpha\mu})+O(\epsilon^2).$$

So

$$x^{\alpha\beta}\mapsto\tilde{x}^{\alpha\beta}=y^{\alpha\beta}/y^{23}=x^{\alpha\beta}+\epsilon(x^{\alpha\nu}\delta^{\beta\mu}-x^{\beta\nu}\delta^{\alpha\mu}+x^{\alpha\beta}q^{\mu\nu})+O(\epsilon^2),$$

where $q^{\mu\nu}=x^{3\nu}\delta^{2\mu}-x^{2\nu}\delta^{3\mu}$. By considering the appropriate components of $[x^{\alpha\beta}]$ we find

$$\sigma\mapsto\sigma+\epsilon(x^{0\nu}\delta^{2\mu}-x^{2\nu}\delta^{0\mu}+\sigma q^{\mu\nu})+O(\epsilon^2),$$

$$\tilde{\sigma}\mapsto\tilde{\sigma}+\epsilon(x^{1\nu}\delta^{3\mu}-x^{3\nu}\delta^{1\mu}+\tilde{\sigma}q^{\mu\nu})+O(\epsilon^2),$$

$$\tau\mapsto\tau+\epsilon(x^{2\nu}\delta^{1\mu}-x^{1\nu}\delta^{2\mu}+\tau q^{\mu\nu})+O(\epsilon^2),$$

$$\tilde{\tau}\mapsto\tilde{\tau}+\epsilon(x^{0\nu}\delta^{3\mu}-x^{3\nu}\delta^{0\mu}+\tilde{\tau}q^{\mu\nu})+O(\epsilon^2).$$

It follows that the conformal Killing vector $X_{\mu\nu}$ associated with the matrix K which is one in the $\mu\nu$-entry and zero elsewhere, is

$$X_{00}=\sigma\partial_\sigma+\tilde{\tau}\partial_{\tilde{\tau}},\quad X_{20}=-\sigma\tilde{\tau}\partial_\sigma-\tilde{\sigma}\tilde{\tau}\partial_{\tilde{\sigma}}+\sigma\tilde{\sigma}\partial_\tau-\tilde{\tau}^2\partial_{\tilde{\tau}},$$

$$X_{01}=\tilde{\sigma}\partial_{\tilde{\tau}}-\tau\partial_\sigma,\quad X_{21}=\tau\tilde{\tau}\partial_\sigma-\tilde{\sigma}^2\partial_{\tilde{\sigma}}-\tau\tilde{\sigma}\partial_\tau-\tilde{\sigma}\tilde{\tau}\partial_{\tilde{\tau}},$$

$$X_{10}=\tilde{\tau}\partial_{\tilde{\sigma}}-\sigma\partial_\tau,\quad X_{30}=\sigma^2\partial_\sigma-\tau\tilde{\tau}\partial_{\tilde{\sigma}}+\sigma\tau\partial_\tau+\sigma\tilde{\tau}\partial_{\tilde{\tau}},$$

$$X_{11}=\tilde{\sigma}\partial_{\tilde{\sigma}}+\tau\partial_\tau,\quad X_{31}=-\sigma\tau\partial_\sigma-\tilde{\sigma}\tau\partial_{\tilde{\sigma}}-\tau^2\partial_\tau+\sigma\tilde{\sigma}\partial_{\tilde{\tau}},$$

$$X_{02}=\partial_{\tilde{\tau}},\quad X_{22}=-\tilde{\sigma}\partial_{\tilde{\sigma}}-\tilde{\tau}\partial_{\tilde{\tau}},$$

$$X_{03}=-\partial_\sigma,\quad X_{23}=\tilde{\tau}\partial_\sigma-\tilde{\sigma}\partial_\tau,$$

$$X_{12}=\partial_{\tilde{\sigma}},\quad X_{32}=-\tau\partial_{\tilde{\sigma}}+\sigma\partial_{\tilde{\tau}},$$

$$X_{13}=\partial_\tau,\quad X_{33}=-\sigma\partial_\sigma-\tau\partial_\tau.$$

Note that there are 15 independent conformal Killing vectors since $X_{00}+X_{11}+X_{22}+X_{33}=0$. This corresponds to the fact that we could have taken $g\in \mathrm{SL}(4;\mathbb{C})$, which would mean that the trace of K is zero.

The Painlevé equations correspond to reductions of the SDYM equations when the Lie algebra is $\mathfrak{sl}(2;\mathbb{C})$. The conformal Killing vectors of these reductions correspond to the following four-parameter subgroups of GL(4;$\mathbb{C}$). Mason and Woodhouse[42] call these the Painlevé groups:

$$P_I,\ P_{II}\ \begin{pmatrix} a_4 & a_3 & a_2 & a_1 \\ 0 & a_4 & a_3 & a_2 \\ 0 & 0 & a_4 & a_3 \\ 0 & 0 & 0 & a_4 \end{pmatrix},$$

$$P_{III}\ \begin{pmatrix} a_4 & a_2 & 0 & 0 \\ 0 & a_4 & 0 & 0 \\ 0 & 0 & a_3 & a_1 \\ 0 & 0 & 0 & a_3 \end{pmatrix},$$

$$P_{IV}\ \begin{pmatrix} a_3 & a_2 & a_1 & 0 \\ 0 & a_3 & a_2 & 0 \\ 0 & 0 & a_3 & 0 \\ 0 & 0 & 0 & a_4 \end{pmatrix},$$

$$P_V\ \begin{pmatrix} a_2 & a_1 & 0 & 0 \\ 0 & a_2 & 0 & 0 \\ 0 & 0 & a_3 & 0 \\ 0 & 0 & 0 & a_4 \end{pmatrix},$$

$$P_{VI}\ \begin{pmatrix} a_4 & 0 & 0 & 0 \\ 0 & a_3 & 0 & 0 \\ 0 & 0 & a_2 & 0 \\ 0 & 0 & 0 & a_1 \end{pmatrix}.$$

The conformal Killing vectors associated with the Painlevé equations are discussed below.

P_I, P_{II}: The conformal Killing vectors associated with the Painlevé subgroup given above are of the form

$$a_1X_{03}+a_2(X_{02}+X_{13})+a_3(X_{01}+X_{12}+X_{23})+a_4(X_{00}+X_{11}+X_{22}+X_{33}).$$

In this case the vector multiplying a_4 is zero. More generally for the reductions described for other Painlevé equations below, the conformal Killing vector associated with a_4 is a linear combination of the conformal Killing vectors associated with a_1, a_2, and a_3.

The vectors multiplying a_1, a_2, and a_3 are, respectively,

$$\tilde{X}_1=-\partial_\sigma,$$

$$\tilde{X}_2=\partial_\tau+\partial_{\tilde{\tau}},$$

$$\tilde{X}_3=(\tilde{\tau}-\tau)\partial_\sigma+\partial_{\tilde{\sigma}}-\tilde{\sigma}\partial_\tau+\tilde{\sigma}\partial_{\tilde{\tau}}.$$

We now choose new variables w^1, w^2, w^3, and t, such that

$$\tilde{X}_i(w^j)=\delta_i^j,\quad \tilde{X}_i(t)=0,\quad i,j=1,2,3. \tag{44}$$

A particular choice is

$$w^1=-\sigma+\tilde{\sigma}(\tilde{\tau}-\tau)-\tfrac{2}{3}\tilde{\sigma}^3,\quad w^2=\tilde{\tau}-\tfrac{1}{2}\tilde{\sigma}^2,\quad w^3=\tilde{\sigma},\quad t=\tilde{\tau}-\tau-\tilde{\sigma}^2.$$

Using the gauge freedom, we let the one-form A have the form

$$A=W_j dw^j,$$

where the W_j's are functions of t only. That is, the gauge freedom has been used to choose the coefficient of dt to be zero. Hence,

$$A=-W_1 d\sigma+([\tilde{\tau}-\tau-2\tilde{\sigma}^2]W_1-\tilde{\sigma}W_2+W_3)d\tilde{\sigma}-\tilde{\sigma}W_1 d\tau+(\tilde{\sigma}W_1+W_2)d\tilde{\tau},$$

from which we can read the values of A_σ, $A_{\tilde{\sigma}}$, A_τ, and $A_{\tilde{\tau}}$. The SDYM equations are

$$W_1'=0,\quad W_2'=[W_1,W_3],\quad W_3'=[W_2,tW_1+W_3].$$

From these equations it follows that three conserved quantities are $l=\mathrm{Tr}(W_1W_2)$, $m=\mathrm{Tr}(W_3W_1+\frac{1}{2}W_2^2)$, and $n=\mathrm{Tr}(W_2W_3)$.

Using the residual gauge freedom, W_1 can be put into one of the canonical forms,

$$\begin{pmatrix} k & 0 \\ 0 & -k \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},$$

where k is a constant. The first case leads to P_{II} while the second leads to P_I. If we choose y to be one of the roots of the gauge-invariant equation

$$\det([W_1,yW_2-W_3])=0\,,$$

we find that (up to simple rescalings) y solves the appropriate Painlevé equation.

For the other Painlevé equations, we list the conformal Killing vectors, the choices for the w^j's and t, and the reduced SDYM equations.

P_{III}

$$\tilde{X}_1=\tilde{\tau}\partial_\sigma-\tilde{\sigma}\partial_\tau,$$

$$\tilde{X}_2=-\tau\partial_\sigma+\tilde{\sigma}\partial_{\tilde{\tau}},$$

$$\tilde{X}_3=-\sigma\partial_\sigma-\tilde{\sigma}\partial_{\tilde{\sigma}}-\tau\partial_\tau-\tilde{\tau}\partial_{\tilde{\tau}}.$$

$$w^1=-\tau/\tilde{\sigma},\quad w^2=\tilde{\tau}/\tilde{\sigma},\quad w^3=-\log\tilde{\sigma},\quad t=\tilde{\sigma}^{-1}\sqrt{\sigma\tilde{\sigma}+\tau\tilde{\tau}}.$$

$$W_1'=0,\quad tW_2'=2[W_3,W_2],\quad W_3'=2t[W_1,W_2].$$

P_{IV}

$$\tilde{X}_1=\partial_{\tilde{\tau}},$$

$$\tilde{X}_2=-\tau\partial_\sigma+\partial_{\tilde{\sigma}}+\tilde{\sigma}\partial_{\tilde{\tau}},$$

$$\tilde{X}_3=\sigma\partial_\sigma+\tau\partial_\tau.$$

$$w^1=\tilde{\tau}-\tfrac{1}{2}\tilde{\sigma}^2,\quad w^2=-\sigma/\tau,\quad w^3=\log\tau,\quad t=\tilde{\sigma}+\sigma/\tau.$$

$$W_1'=0,\quad W_2'=[tW_2+W_3,W_1],\quad W_3'=[W_3,W_2]. \tag{45}$$

P_V

$$\tilde{X}_1=-\tau\partial_\sigma+\tilde{\sigma}\partial_{\tilde{\tau}},$$

$$\tilde{X}_2=\sigma\partial_\sigma+\tilde{\sigma}\partial_{\tilde{\sigma}}+\tau\partial_\tau+\tilde{\tau}\partial_{\tilde{\tau}},$$

$$\tilde{X}_3=-\tilde{\sigma}\partial_{\tilde{\sigma}}-\tilde{\tau}\partial_{\tilde{\tau}}.$$

$$w^1=\tilde{\tau}/\tilde{\sigma},\quad w^2=\log([\sigma\tilde{\sigma}+\tau\tilde{\tau}]/\tilde{\sigma}),\quad w^3=\log(\tau/\tilde{\sigma}),\quad t=\sigma/\tau+\tilde{\tau}/\tilde{\sigma}.$$

$$W_1'=0,\quad W_2'=[W_3,W_1],\quad tW_3'=[tW_1+W_2,W_3].$$

P_{VI}

$$\tilde{X}_1=-\sigma\partial_\sigma-\tau\partial_\tau,$$

$$\tilde{X}_2=-\tilde{\sigma}\partial_{\tilde{\sigma}}-\tilde{\tau}\partial_{\tilde{\tau}}$$

$$\tilde{X}_3=\tilde{\sigma}\partial_{\tilde{\sigma}}+\tau\partial_\tau.$$

$$w^1=-\log\sigma,\quad w^2=-\log\tilde{\tau},\quad w^3=\log(\tilde{\sigma}/\tilde{\tau}),\quad t=-(\tau\tilde{\tau})/(\sigma\tilde{\sigma}).$$

$$W_1'=0,\quad tW_2'=[W_2,W_3],\quad t(1-t)W_3'=[W_3,tW_1+W_2].$$

1. Reduction of the linear problem

Note that each of the symmetry reductions of the SDYM equations to one of the Painlevé equations extends to a reduction of the linear problem (16) and (17). However, in finding a reduction of the linear problem, the spectral parameter ζ must also be transformed. The symmetries of the field equations are lifted to symmetries of the linear problem. For P_{VI} we extend the reduction above to the linear problem (16) and (17) by restricting $\mathbf{\Psi}$ to have the form $\mathbf{\Psi}(\sigma,\tau,\tilde{\sigma},\tilde{\tau};\zeta)=\psi(t;\lambda)$, where $\lambda=\tilde{\tau}/(\sigma\zeta)$. Note that then

$$\tau\partial_\tau\mathbf{\Psi}=-\tilde{\sigma}\partial_{\tilde{\sigma}}\mathbf{\Psi}=t\partial_t\psi,\quad \text{and}\quad \tilde{\tau}\partial_{\tilde{\tau}}\mathbf{\Psi}=-\sigma\partial_\sigma\mathbf{\Psi}=t\partial_t\psi+\lambda\partial_\lambda\psi.$$

The linear problem (16) and (17) then becomes

$$\partial_\lambda\psi=-\left[\frac{W_2}{\lambda-1}-\frac{W_1+W_2+W_3}{\lambda-1}+\frac{W_3}{\lambda-t}\right]\psi,\quad \partial_t\psi=\frac{W_3}{\lambda-t}\psi. \tag{46}$$

The system of equations (46) is the isomonodromy problem for P_{VI}. The compatibility of (46) gives Eqs. (45), which are equivalent to P_{VI}. Isomonodromy problems for the above reductions

to P_I–P_V can be obtained in the same way. Indeed, it is often easier to identify a reduction to one of the Painlevé equations from the form of the isomonodromy problem. By comparing the isomonodromy problem to those in the literature, we can identify the component that will satisfy the appropriate Painlevé equation.

V. THE DARBOUX–HALPHEN SYSTEM

In this section we consider a reduction of the SDYM equations to an integrable generalization of the classical Darboux–Halphen system. Its general solution is densely branched and contains a movable natural barrier.

Consider the reduction of the SDYM equations in which the A_μ's are functions of $t:=-x^0$ only. This gives the well known Nahm equations[43]

$$\dot{A}_1=[A_2,A_3], \quad \dot{A}_2=[A_3,A_1], \quad \dot{A}_3=[A_1,A_2], \tag{47}$$

where we have chosen a gauge in which $A_0\equiv 0$.

Using $\mathfrak{diff}(S^3)$, the infinite-dimensional Lie algebra of vector fields on S^3, we choose the components of the connection to be of the form

$$A_i(t)=\sum_{j,k=1}^{3} O_{ij}M_{jk}(t)X_k\,. \tag{48}$$

The X_k's are divergence-free vector fields on S^3 and satisfy the $\mathfrak{su}(2)$ commutation relations

$$[X_i,X_j]=\sum_{k=1}^{3} \varepsilon_{ijk}X_k\,, \tag{49}$$

where ε_{ijk} is totally antisymmetric and $\varepsilon_{123}=1$. The SO(3) matrix $[O_{ij}]$ is used to represent the points of S^3 (see, e.g., Ref. 55) and the action of the vector fields X_i on O_{jk} is given by[6]

$$X_iO_{jk}=\sum_{l=1}^{3} \varepsilon_{ikl}O_{jl}\,. \tag{50}$$

Substituting Eq. (48) into Eq. (47) and using (49) and (50) together with the identities

$$\sum_{i,j,k=1}^{3} \varepsilon_{ijk}O_{ip}O_{jq}O_{kr}=\varepsilon_{pqr}\,, \quad \sum_{i=1}^{3} \varepsilon_{ijk}\varepsilon_{imn}=\delta_{jm}\delta_{kn}-\delta_{jn}\delta_{km},$$

yields

$$\dot{M}=(\mathrm{Adj}\,M)^T+M^TM-(\mathrm{Tr}\,M)M, \tag{51}$$

where $(\mathrm{Adj}\,M):=(\det M)M^{-1}$ is the adjoint of M and the dot denotes differentiation with respect to t. Equation (51) was first derived in Ref. 20. Equation (51) was also derived in Ref. 34 where it was shown to represent an SU(2) invariant hypercomplex four-manifold. Since the Weyl curvature of a hypercomplex four-manifold is self-dual, Eq. (51) describes a class of self-dual Weyl Bianchi IX space–times with Euclidean signature.[15]

In order to solve Eq. (51) we first introduce a simple factorization. If the eigenvalues of the symmetric part, M_s, of M are distinct, then M_s can be diagonalized using a (complex) orthogonal matrix P. In this case we may write

$$M=M_s+M_a=P(d+a)P^{-1},$$

where $d:=\mathrm{diag}\,(\omega_1,\omega_2,\omega_3)$, $\omega_i\neq\omega_j$, $i\neq j$, and the nonzero elements of the skew-symmetric matrix a are denoted as $a_{12}=-a_{21}=\tau_3$, $a_{23}=-a_{32}=\tau_1$ and $a_{31}=-a_{13}=\tau_2$. Using the above factorization of M, Eq. (51) can be transformed into

$$\begin{aligned}\dot\omega_1&=\omega_2\omega_3-\omega_1(\omega_2+\omega_3)+\tau^2,\\ \dot\omega_2&=\omega_3\omega_1-\omega_2(\omega_3+\omega_1)+\tau^2,\\ \dot\omega_3&=\omega_1\omega_2-\omega_3(\omega_1+\omega_2)+\tau^2,\end{aligned}\tag{52}$$

where $\tau^2:=\tau_1^2+\tau_2^2+\tau_3^2$ and

$$\dot\tau_1=-\tau_1(\omega_2+\omega_3),\quad \dot\tau_2=-\tau_2(\omega_3+\omega_1),\quad \dot\tau_3=-\tau_3(\omega_1+\omega_2),\tag{53}$$

together with the linear equation

$$\dot P+Pa=0,\tag{54}$$

for the matrix P. The system (52) with $\tau^2=0$ is the classical Darboux–Halphen system which appeared in Darboux's analysis of triply orthogonal surfaces[27] and was later solved by Halphen.[32] Halphen also studied and solved Eqs. (52)–(56),[31] which are linearizable in terms of Fuchsian differential equations with three regular singular points.

Taking the differences between the various equations in (52) results in

$$\omega_1=-\frac{1}{2}\frac{d}{dt}\ln(\omega_2-\omega_3),\quad \omega_2=-\frac{1}{2}\frac{d}{dt}\ln(\omega_3-\omega_1),\quad \omega_3=-\frac{1}{2}\frac{d}{dt}\ln(\omega_1-\omega_2).$$

Together with Eqs. (53), these equations show that

$$\begin{aligned}\alpha^2&:=\frac{\tau_1^2}{(\omega_1-\omega_2)(\omega_3-\omega_1)},\\ \beta^2&:=\frac{\tau_2^2}{(\omega_2-\omega_3)(\omega_1-\omega_2)},\\ \gamma^2&:=\frac{\tau_3^2}{(\omega_3-\omega_1)(\omega_2-\omega_3)}\end{aligned}\tag{55}$$

are constants. Without loss of generality we choose α, β, and γ to have nonnegative real parts. Hence, provided the symmetric part of M has distinct eigenvalues, Eq. (51) reduces to the third-order system (52), where

$$\tau^2=\alpha^2(\omega_1-\omega_2)(\omega_3-\omega_1)+\beta^2(\omega_2-\omega_3)(\omega_1-\omega_2)+\gamma^2(\omega_3-\omega_1)(\omega_2-\omega_3),\tag{56}$$

together with the linear equation (54) for P. In Refs. 47 and 33, solutions of equations (52)–(56) for special choices of α, β, and γ were determined in terms of automorphic forms.

Note that the system (52) with τ^2 as in (56) is invariant under the transformation

$$t\mapsto\mu(t):=\frac{at+b}{ct+d},\quad \omega_j(t)\mapsto\frac{\omega_j(\mu(t))}{(ct+d)^2}+\frac{c}{ct+d},\quad ad-bc=1.$$

We introduce the μ-invariant function

$$s := \frac{\omega_1 - \omega_3}{\omega_2 - \omega_3}. \tag{57}$$

Differentiating Eq. (57) and using the system (52) yields $\dot{s} = 2s(\omega_1 - \omega_2)$. Repeating this process gives $\ddot{s} = 2(\dot{s} - 2\omega_3 s)(\omega_1 - \omega_2)$. Solving these two equations together with (57) for the ω's gives

$$\begin{aligned} \omega_1 &= -\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{s}}{s(s-1)}, \\ \omega_2 &= -\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{s}}{s-1}, \\ \omega_3 &= -\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{s}}{s}. \end{aligned} \tag{58}$$

Substituting the parametrization (58) into any of the equations in (52) shows that $s(t)$ must satisfy

$$\{s,t\} + \frac{\dot{s}^2}{2}V(s) = 0, \tag{59}$$

where

$$\{s,t\} := \frac{d}{dt}\left(\frac{\ddot{s}}{\dot{s}}\right) - \frac{1}{2}\left(\frac{\ddot{s}}{\dot{s}}\right)^2$$

is the Schwarzian derivative and V is given by

$$V(s) = \frac{1-\beta^2}{s^2} + \frac{1-\gamma^2}{(s-1)^2} + \frac{\beta^2+\gamma^2-\alpha^2-1}{s(s-1)}. \tag{60}$$

The general solution of Eq. (59) is given implicitly by

$$t(s) = \frac{u_1(s)}{u_2(s)}, \tag{61}$$

where $u_1(s)$ and $u_2(s)$ are two independent solutions of the Fuchsian differential equation

$$\frac{d^2u}{ds^2} + \frac{1}{4}V(s)u = 0 \tag{62}$$

with regular singular points at 0, 1, and ∞. The transformation

$$u(s) = s^{c/2}(1-s)^{(a+b-c+1)/2}\chi(s) \tag{63}$$

maps Eq. (62) to the Gauss hypergeometric equation

$$s(1-s)\frac{d^2\chi}{ds^2} + [c-(a+b+1)s]\frac{d\chi}{ds} - ab\chi = 0, \tag{64}$$

where $a = (1+\alpha-\beta-\gamma)/2$, $b = (1-\alpha-\beta-\gamma)/2$, and $c = 1-\beta$ (see, e.g., Refs. 45 and 2). Note that from the general solution $s(t)$ of Eq. (59) we can reconstruct the ω_j's from Eqs. (58) and the τ_j's then follow from (55).

From Eq. (61), if α, β, and γ are non-negative real numbers such that $\alpha+\beta+\gamma<1$, then the upper- (or lower-) half s-plane is mapped to a triangular region in the t-plane whose sides are the

arcs of circles and whose vertices subtend angles of $\alpha\pi$, $\beta\pi$, and $\gamma\pi$. Moreover, if α, β, and γ are either 0 or reciprocals of integers, then s is an analytic function of t on the interior of a circle on the complex sphere $\mathbb{C}\cup\infty$ but cannot be analytically extended across any point of the circle. That is, the circle is a natural barrier for the function $s(t)$.

The solution procedure just outlined allows us to obtain explicit expressions for the conserved quantities for the generalized Darboux–Halphen system (52) and (56). In Ref. 36, it was shown that the classical Darboux–Halphen system admits no meromorphic first integrals. In Ref. 17, the first integrals for the full system (52) and (56) were found and shown to be branched and transcendental involving hypergeometric functions. The existence of these integrals is consistent with Ref. 36 because even in the classical case they are branched despite the fact that the general solution is single-valued.

Fix two linearly independent solutions u_1 and u_2 of Eq. (62) with Wronskian

$$W(u_1,u_2)=u_1u_2'-u_2u_1'=1, \tag{65}$$

where prime denotes differentiation with respect to s. Then the general solution of Eq. (59) is given implicitly by

$$t(s)=\frac{J_2u_1(s)-J_1u_2(s)}{I_2u_1(s)-I_1u_2(s)}, \tag{66}$$

where I_α and J_α, $\alpha=1,2$, are constants satisfying $I_1J_2-I_2J_1=1$. Differentiating Eq. (66) twice and using (65) gives

$$I_2u_1-I_1u_2=\dot{s}^{1/2}, \quad I_2u_1'-I_1u_2'=\tfrac{1}{2}\dot{s}^{-3/2}\ddot{s}. \tag{67}$$

Solving the linear equations (67) for I_1 and I_2 gives

$$I_\alpha=\frac{d\phi_\alpha}{dt}, \quad \phi_\alpha=\dot{s}^{-1/2}u_\alpha(s), \quad \alpha=1,2. \tag{68}$$

The constants J_1 and J_2 are then obtained from Eqs. (66) and (68) together with the normalization $I_1J_2-I_2J_1=1$. They are given by

$$J_\alpha=tI_\alpha-\phi_\alpha, \quad \alpha=1,2\,.$$

So, the I_α and J_α, taken to be functions of $t,s,\dot{s}$ and $\ddot{s}$ are first integrals for the Schwarzian equation. In terms of the Darboux–Halphen variables, these quantities are

$$\phi_\alpha=\sqrt{2r(\omega_i)}\,u_\alpha(s(\omega_i))\,, \quad I_\alpha=\sqrt{\frac{2}{r(\omega_i)}}\,u_\alpha'(s(\omega_i))-(\omega_1-\omega_2-\omega_3)\sqrt{\frac{r(\omega_i)}{2}}\,u_\alpha(s(\omega_i))\,,$$

where $r(\omega_i)=\sqrt{(\omega_2-\omega_3)/(\omega_1-\omega_2)(\omega_1-\omega_3)}$ and $s(\omega_i)$ is given by Eq. (57).

In terms of these variables, the Darboux–Halphen system (52) and (56) can be written as the Hamiltonian system

$$\dot{\phi}_\alpha=\frac{\partial H}{\partial I_\alpha}=I_\alpha\,, \quad \dot{I}_\alpha=-\frac{\partial H}{\partial\phi_\alpha}=0\,, \quad H=\frac{I_1^2+I_2^2}{2}, \quad \alpha=1,2, \tag{69}$$

subject to the algebraic constraint

$$\phi_1I_2-\phi_2I_1=W(u_1,u_2)=1. \tag{70}$$

The canonical coordinates $\{I_\alpha,\phi_\alpha\}$ are analogs of the action-angle variables for the Darboux–Halphen system. The phase space dynamics of the system is restricted to the constraint subspace

given by Eq. (70). This represents a three-dimensional complex quadric. Poisson–Nambu structures for the generalized Darboux–Halphen system (52) and (56) are presented in Ref. 17 which are similar to those for rigid body dynamics in three dimensions.[44,54] The system is also written as a gradient flow in Ref. 16.

A. The Chazy equation

Let ω_1, ω_2, ω_3 be a solution of (52) with $\tau=0$ and define $y:=-2(\omega_1+\omega_2+\omega_3)$. Then y is a solution of the equation[17,18]

$$\frac{d^3y}{dt^3}=2y\frac{d^2y}{dt^2}-3\left(\frac{dy}{dt}\right)^2, \tag{71}$$

which was studied by Chazy.[23–25] Furthermore, given a solution y of the Chazy equation (71), let ω_1, ω_2, and ω_3 be the three roots of the cubic equation

$$\omega^3+\frac{1}{2}y\omega^2+\frac{1}{2}\frac{dy}{dz}\omega+\frac{1}{12}\frac{d^2y}{dt^2}=0.$$

If the ω_j's are distinct, then they solve the classical Darboux–Halphen system [i.e., the system (52) with $\tau=0$].

The general solution of the Chazy equation is given by

$$y(t(s))=6\frac{d}{dt}\ln\chi_1(s),\quad t(s)=\chi_2(s)/\chi_1(s), \tag{72}$$

where χ_1 and χ_2 are two independent solutions of the special hypergeometric equation

$$s(1-s)\frac{d^2\chi}{ds^2}+\left(\frac{1}{2}-\frac{7}{6}s\right)\frac{d\chi}{ds}-\frac{1}{144}\chi=0.$$

On replacing χ_1 and χ_2 with the independent linear combinations $a\chi_1+b\chi_2$ and $c\chi_1+d\chi_2$, $ad-bc=1$, it can be seen from Eq. (72) that the Chazy equation admits the symmetry

$$y(t)\mapsto\tilde{y}(t)=(ct+d)^{-2}y\left(\frac{at+b}{ct+d}\right)-\frac{6c}{ct+d},\quad ad-bc=1. \tag{73}$$

As well as having a general solution in terms of special hypergeometric functions as described above, the Chazy equation (71) is related to the theory of modular functions.[8,53] Indeed, a particular solution of (71) is given by

$$y(t):=i\pi E_2(t), \tag{74}$$

where

$$E_2(t):=1+\frac{6}{\pi^2}\sum_{m=1}^{\infty}\sum_{n=-\infty}^{\infty}\frac{1}{(mt+n)^2} \tag{75}$$

is the second Eisenstein series. [Note that the series (75) is not absolutely convergent, so the order of the sum is important.] The second Eisenstein series can also be written as the Fourier series

$$E_2(t)=1-24\sum_{n=1}^{\infty}\sigma_1(n)q^n,\quad q=\mathrm{e}^{2\pi it},$$

where $\sigma_1(n)$ is the sum of the divisors of n.

Furthermore, the solution (74) can be written in terms of a special logarithmic potential,

$$y(t)=\frac{1}{2}\frac{d}{dt}\ln\Delta(t), \tag{76}$$

where Δ is the discriminant cusp form of weight 12, which satisfies

$$\Delta(\mu(t))=(ct+d)^{12}\Delta(t), \quad \mu\in \mathrm{PSL}(2;\mathbf{Z}). \tag{77}$$

This shows that there is a deep connection between the Chazy equation and the theory of modular forms.

The discriminant modular form has the well known representation

$$(2\pi)^{-12}\Delta(t)=q\prod_{n=1}^{\infty}(1-q^n)^{24}=\sum_{n=1}^{\infty}\tau(n)q^n,$$

where $q=\mathrm{e}^{2\pi it}$ and the coefficient function $\tau(n)$ is called the Ramanujan τ-function (see, e.g., Ref. 52). From Eqs. (76) and (74) it can be shown that Δ satisfies the homogeneous ODE of degree 4;

$$\Delta^3\frac{d^4\Delta}{dt^4}-5\Delta^2\frac{d\Delta}{dt}\frac{d^3\Delta}{dt^3}-\frac{3}{2}\Delta^2\left(\frac{d^2\Delta}{dt^2}\right)^2+12\Delta\left(\frac{d\Delta}{dt}\right)^2\frac{d^2\Delta}{dt^2}-\frac{13}{2}\left(\frac{d\Delta}{dt}\right)^4=0.$$

Rankin[51] first showed that the discriminant cusp form satisfies this equation. Since Δ has no zeros or poles and satisfies a homogeneous equation it is the natural analog of the τ function that appears in Hirota's method (see, e.g., Sec. 3.3 of Ref. 4).

Note that the characterization of the Ramanujan coefficients $\tau(n)$ is a major problem in number theory. These famous numbers arise naturally as the Fourier coefficients of $\Delta(t)$ when we write the Chazy equation in the above homogeneous form.

Furthermore, there is another important correspondence between the Chazy equation and Ramanujan's work. In 1916 Ramanujan[50] proved that the functions

$$P(q)=1-24\sum_{n=1}^{\infty}\sigma_1(n)q^n,$$

$$Q(q)=1+240\sum_{n=1}^{\infty}\sigma_3(n)q^n,$$

$$R(q)=1-504\sum_{n=1}^{\infty}\sigma_5(n)q^n,$$

where $\sigma_k(n)=\Sigma_{d|n}d^k$, $k=1,3,5$ (sum of the divisors of n to the kth power), satisfy

$$q\frac{dP}{dq}=\frac{1}{12}(P^2-Q),$$

$$q\frac{dQ}{dq}=\frac{1}{3}(PQ-R), \tag{78}$$

$$q\frac{dR}{dq}=\frac{1}{2}(PR-Q^2).$$

Using $q=e^{2\pi it}$, $\tau=\pi t$, the equations (78) take the form

$$\frac{dP}{d\tau}=\frac{i}{6}(P^2-Q),$$

$$\frac{dQ}{d\tau}=\frac{2i}{3}(PQ-R), \tag{79}$$

$$\frac{dR}{d\tau}=i(PR-Q^2).$$

Using the first of the above equations to find Q: $Q=P^2+6i\,dP/d\tau$, the second equation implies $R=-9(d^2P/d\tau^2)+9iP\,(dP/d\tau)+P^3$. Then the last of the above equations yields

$$\frac{d^3\tilde{y}}{d\tau^3}=2y\frac{d^2\tilde{y}}{d\tau^2}-3\left(\frac{d\tilde{y}}{d\tau}\right)^2,$$

where $P(q)=-i\tilde{y}(\tau)$. Finally, in terms of $\tilde{y}(\tau)=\pi^{-1}y(t)$, y satisfies the Chazy equation (71). Thus the special solution (74) yields $y(t)=i\pi E_2(t)=i\pi P(q)$. Knowing $P(q)$, from (78) we can obtain the other functions $Q(q)$ and $R(q)$ directly. Moreover, since we know the general solution of the Chazy equation, we know the general solution of the equations of Ramanujan. Note that Q and R are also called the normalized Eisenstein series E_4 and E_6 (see, e.g., Ref. 35).

As an historical postscript we note that Chazy and Ramanujan both worked on the same equation at nearly the same time, but apparently they did not know this!

B. The generalized Chazy equation

Let $(\omega_1,\omega_2,\omega_3)$ be a solution of (52)–(56). Ablowitz, Chakravarty, and Halburd[5,7] showed that

$$y:=-2(\omega_1+\omega_2+\omega_3)=-2\operatorname{Tr}M \tag{80}$$

solves

$$\frac{d^3y}{dt^3}-2y\frac{d^2y}{dt^2}+3\left(\frac{dy}{dt}\right)^2=\frac{4}{36-n^2}\left(6\frac{dy}{dt}-y^2\right)^2, \tag{81}$$

if and only if either $\alpha=\beta=\gamma=:2/n$ or exactly one of the parameters α, β, γ is $2/n$ and the other two are $\frac{1}{3}$. Equation (81) was also studied by Chazy[23–25] and is usually referred to as the *generalized Chazy equation* [to contrast it with the classical Chazy equation (71), which is the special case $n=\infty$].

It follows from Eqs. (58) and (80) that the general solution of (81) is given by

$$y(t)=\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{s}^6}{s^4(s-1)^4}. \tag{82}$$

In Chazy's analysis of Eq. (81) he showed that its solution is given by

$$y(t)=\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{J}^6}{J^4(J-1)^3}, \tag{83}$$

where the Schwarz function J solves Eq. (59) with (60) and $\alpha=1/n$, $\beta=\frac{1}{3}$, $\gamma=\frac{1}{2}$. The function J, and hence y, is single-valued if n is an integer greater than 1. The choice $n=\infty$ again corresponds to the classical Chazy equation (71).

Equations (82) and (83) suggest that there is a relationship between J and the special Schwarzian triangle functions s described above. In the case when s corresponds to the choice $\alpha=\beta=\gamma=2/n$, it can be shown that

$$J=\frac{4}{27}\frac{(s^2-s+1)^3}{s^2(s-1)^2},$$

and, similarly, when $\alpha=2/n$, $\beta=\gamma=\frac{1}{3}$, we have

$$J=-4s(s-1)$$

(see Ref. 5).

VI. SUMMARY AND DISCUSSION

The SDYM equations are a rich source of integrable systems. The classical soliton equations in $1+1$ dimensions and the well known Painlevé quations P_I-P_{VI} are reductions of the SDYM equations with finite-dimensional Lie algebras. Reductions of the SDYM equations using infinite-dimensional algebras are of particular interest. They yield the classical $2+1$-dimensional soliton equations, the Chazy equations and a ninth-order generalization of the Darboux–Halphen system.

(Received 26 March 2003; accepted 9 April 2003)

The set of real finite-gap sine-Gordon solutions corresponding to a fixed spectral curve consists of several connected components. A simple explicit description of these components obtained by the authors recently is used to study the consequences of this property. In particular this description allows to calculate the topological charge of solutions (the averaging of the x-derivative of the potential) and to show that the averaging of other standard conservation laws is the same for all components. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1588742]

I. INTRODUCTION. ALGEBRO-GEOMETRICAL SOLUTIONS AND THE REALITY REDUCTIONS. THE TOPOLOGICAL CHARGE

The algebro-geometrical (or finite-gap) solutions play a very important role in the modern theory of soliton equations with periodic and quasiperiodic boundary conditions. The main property characterizing these solutions is the following: the wave function of the auxiliary linear operator is meromorphic in the spectral parameter on the finite part of an algebraic Riemann surface. This allows one to apply the powerful tools of classical algebraic geometry, and to write explicit representations for solutions and wave functions in terms of Riemann Θ-functions of several variables. Usually the algebro-geometrical solutions are dense in the space of the periodic ones, and if the nonlinearity tends to zero, they degenerate to finite Fourier sums. Therefore their role in the soliton theory is rather similar to the role of finite Fourier series for the linear PDEs.

The algebro-geometrical solutions of solition equations were first introduced in Ref. 1 in 1974 dedicated to the integration of the Korteveg–de Vries (KdV) equation with periodic boundary conditions. Real nonsingular periodic algebro-geometrical KdV solutions can be characterized by the following property: the number of gaps (forbidden bands or zones) in the spectrum of the auxiliary Schrödinger operator acting in the Hilbert space $L_2(R)$ is finite. This characterization is not valid for other systems [for example, the spectrum of non-self-adjoint auxiliary operator for the self-focusing nonlinear Schrödinger equation (NLS) has no gaps for any regular potential], but nevertheless the algebro-geometrical solutions are called finite-gap.

The complete theory of algebro-geometrical KdV solutions involving the spectral theory of periodic (quasiperiodic) finite-gap Schrödinger operators on the line and its unification with algebraic geometry and analysis on the Riemann surfaces, time dynamics and algebro-geometric hamiltonian aspects was constructed in Refs. 2–7 (see in the survey article, Ref. 8) and in Refs. 9 and 10. Complex finite-gap solutions of the NLS and sine-Gordon (SG) equations were constructed in Refs. 11 and 12. Finite-gap solutions of the $2+1$ Kadomtsev–Petviashvili (KP) eqation were constructed in Ref. 13 on a basis of a purely algebraic formulation of the finite-gap approach developed in this article. The algebro-geometric spectral theory of the stationary periodic 2D

[a)]Electronic mail: pgg@landau.ac.ru
[b)]Electronic mail: novikov@ipst.umd.edu

Schrödinger operator was developed in Refs. 14 and 15. In these papers it was shown that the proper analog of the finite-gap constraint in the two-dimensional case is the following: the restriction of the Bloch variety to one energy level is algebraic, and the spectral data is ''collected'' at this energy level only. Such potentials can be treated as ''integrable'' at one energy. It means that the wave functions for this energy and arbitrary complex quaismomenta can be written explicitly in terms of Riemann Θ-functions, but the information about the spectral properties at other energies is very restricted.

The algebro-geometrical approach allows us to obtain explicit compact formulas for solutions. But the Θ-functions of several variables are very complicated from the analytic point of view; therefore the existence of such formulas does not lead sometimes to the simple solution of the problem of selecting physically or geometrically meaningful solutions among generic complex ones. For example, it is very easy to describe reality conditions for the KdV, defocusing NLS or sinh-Gordon equation

$$\frac{\partial^2 u}{\partial \xi \partial \eta} = 4 \sinh u(\xi, \eta)$$

(in all these cases the auxiliary linear operators are self-adjoint). However, the reality reductions for the self-focusing NLS or the sine-Gordon equation found in Ref. 16 are rather nontrivial. It was shown in Ref. 15 that analogous reductions are responsible for the absence of magnetic field in the theory of the 2D Schrödinger operator. A good review of reality reductions can be found in Ref. 17.

The sine-Gordon equation

$$u_{tt} - u_{xx} + \sin u(x,t) = 0 \tag{1}$$

derived in the 19th century geometry in the light-cone representation

$$u_{\xi\eta} = 4 \sin u, \quad u = u(\xi, \eta), \tag{2}$$

where

$$x = 2(\xi + \eta), \quad t = 2(\xi - \eta), \quad \partial_\xi = 2\partial_x + 2\partial_t, \quad \partial_\eta = 2\partial_x - 2\partial_t \tag{3}$$

is one of the most important systems of the soliton theory. One of its distinguished properties is the folowing. Usually if we fix the spectral curve (or equivalently all local conservation laws), then the level set is a connected Jacobi torus. It is true for KdV, defocusing and self-focusing NLS and for both real reductions of the KP equation. But in the sine-Gordon case the level set is a union of 2^m real Jacobi tori, where m denotes the number of pairs of negative branch points. As a corollary, the result of averaging a generic functional depends not only on the spectral curve, but also on the component. This property is also essential if we calculate the action-angle variables (this problem was studied in Refs. 18 and 19).

The averaged densities of conservation laws arose naturally as Hamiltonians of the Whitham equations. These equations describe the evolution of parameters of the asymptotic solutions in the form of a slowly varying N-phase wavetrains. The Whitham equations for the sine-Gordon were derived in Ref. 20, but the connectivity components of the level sets were not discussed. Let us point out that the Whitham equations are hyperbolic only in the ''stable'' case, when all branch point are negative and the number of components is always greater than 1.

It is possible to extract from the calculations of Ref. 20 that for all classical local conservation laws except the topological charge the result of averaging is the same for all components, but this property was never pointed out explicitly. In Sec. IV we give a simple explanation of it.

Remark: The number of real tori was calculated in Ref. 16, and their characterization in terms of the complex Jacobi torus was obtained in Ref. 21, see also Ref. 22. An elementary description of these tori was obtained by the authors in Refs. 23 and 24 (see Sec. II below).

Another interesting property of the sine-Gordon equation is the following. In the theory of constant negative curvature surfaces $u(\xi,\eta)$ denotes the angle between asymptotic lines. In the theory of Josephson junctions u has the meaning of a phase. In both situations it is defined up to an additive constant $c=2\pi n$. Therefore, it is natural to call a solution $u(x,t)$ space-periodic with the period T if $\exp\{iu(x+T)\}=\exp\{iu(x)\}$. The integer n such that $u(x+T)=u(x)+2\pi n$ is called **topological charge**: the real number $\overline{n}=n/T$ denotes the **density of topological charge**. These quantities are the ''most stable'' conservation laws surviving all real periodic nonintegrable perturbations. The density of topological charge can be naturally extended to all nonsingular quasi-periodic solutions using the formula

$$\overline{n}=\lim_{T\to\infty}[u(x+T)-u(x)]/2\pi T.$$

One of the most natural problems is the following: *how to calculate the topological charge of real periodic SG solutions in terms of the spectral data: the Riemann surface and the divisor*. It turned out that nobody succeeded to extract the answer from the explicit description of the real components described in terms of the Jacobi torus and Θ-functional formulas, found in Refs. 21 and 22. An attempt was made almost 20 years ago in Ref. 18 to solve this problem. For this purpose the so-called ''Algebro-Topological'' approach was developed in Ref. 18, and an interesting formula was proposed. However, as it was pointed out in Ref. 19, the idea of the proof presented in Ref. 18 works only if the spectral curve is sufficiently close to a degenerate one. A complete solution using a new development of the main idea of Ref. 18 was obtained only recently by the authors in Refs. 23 (for the so-called stable curves) and 24 for generic ones. Our proof is based on a new effective description of the real components in terms of divisors. We present a summary of these results in Sec. III.

Remark: Formally we can define topological charge for any nonsingular complex solution. But if the solution has poles, this quantity became ill-defined, and no natural nonsingularity condition in terms of the spectral data for complex potentials is known. It explains why only real solutions are discussed.

II. FINITE-GAP SINE-GORDON SOLUTIONS

The ''soliton-type'' solutions of sine-Gordon were found already in the 19th century using substitution discovered by Bianchi and S. Lie. Now this method is called ''Backlund transformation.''

In the early 1970s G. Lamb found out (see Ref. 25) that the sine-Gordon equation is analogous to KdV in the following sense: the so-called ''inverse scattering method'' can be applied to it. The modern approach was started in Ref. 26. The critical point of this approach is the following zero-curvature representation for SG,

$$\Psi_x=\tfrac{1}{4}(U+V)\Psi,\quad \Psi_t=\tfrac{1}{4}(U-V)\Psi, \tag{4}$$

where

$$U=U(\lambda,x,t)=\begin{bmatrix} i(u_x+u_t) & 1 \\ -\lambda & -i(u_x+u_t)\end{bmatrix}, \tag{5}$$

$$V=V(\lambda,x,t)=\begin{bmatrix} 0 & -\dfrac{1}{\lambda}e^{iu} \\ e^{-iu} & 0.\end{bmatrix}. \tag{6}$$

To construct generic complex finite-gap SG solutions, assume that we have the following spectral data:

(1) A nonsingular hyperelliptic Riemann surface Γ $[\mu^2=R(\lambda)]$, where $R(\lambda)=\Pi_{k=0}^{2g}(\lambda-E_k)$, such that $E_0=0$ and $E_i\neq E_j, i,j=0,1,\ldots,2g$. It has exactly $2g+2$ branch points $E_0=0$, $E_1,\ldots,E_{2g},\infty$; the genus of Γ is equal to g. A point $\gamma\in\Gamma$ is by definition a pair of complex numbers $\gamma=(\lambda,\mu)$ such that $\mu^2=R(\lambda)$.
(2) A divisor D of degree g, i.e., set (or formal sum) of g points $D=\gamma_1+\cdots+\gamma_g$.

For generic data Γ,D there exists an unique two-component "Baker–Akhiezer" vector-function $\Psi(\gamma,x,t)$ such that the following hold.

(1) For fixed (x,t) the function $\Psi(\gamma,x,t)$ is meromorphic in the variable $\gamma\in\Gamma$ outside the points $0,\infty$ and has at most first order poles at the divisor points γ_k, $k=1,\ldots,g$.
(2) $\Psi(\gamma,x,t)$ has essential singularities at the points $0,\infty$ with the following asymptotics:

$$\Psi(\gamma,x,t)=\begin{pmatrix}1+o(1)\\ i\sqrt{\lambda}+O(1)\end{pmatrix}e^{i\sqrt{\lambda}(x+t)/4}\quad\text{as}\quad\lambda\to\infty, \tag{7}$$

$$\Psi(\gamma,x,t)=\begin{pmatrix}\phi_1(x,t)+o(1)\\ i\sqrt{\lambda}\phi_2(x,t)+O(\lambda)\end{pmatrix}e^{-(i/\sqrt{\lambda})[(x-t)/4]}\quad\text{as}\quad\lambda\to 0, \tag{8}$$

where $\phi_1(x,t)$, $\phi_2(x,t)$ are some functions of the variables x,t.

Denote the divisor of zeros of the first component ψ_1 by $D(x,t)=\Sigma_j\gamma_j(x,t)$. The vector-function $\Psi(\gamma,x,t)$ satisfies to the zero-curvature equations (4) with potential given by the formula

$$u(x,t)=i\ln\frac{\phi_2(x,t)}{\phi_1(x,t)}, \tag{9}$$

and the function $u(x,t)$ solves the SG equation (2). In terms of the divisor of zeros $D(x,t)$ the potenital $u(x,t)$ can be easily written explicitly:

$$e^{iu(x,t)}=\frac{\Pi_{j=1}^{g}(-\lambda_j(x,t))}{\sqrt{\Pi_{j=1}^{2g}E_j}}. \tag{10}$$

The x and t dynamics of the divisor $D(x,t)$ can be described in terms of Dubrovin equations (see Ref. 24). From (10) it follows that the potential $u(x,t)$ is singular at the point (x_0,t_0) if and only if one of the points $\gamma_k(x_0,t_0)$ coincides with 0 or ∞. Collisions of two or more divisor points result in singularities in the solutions of Dubrovin equations, but all symmetric combinations of the divisor points including the potential $u(x,t)$ remain nonsingular.

Remark: The first component ψ_1 of the Baker–Akhiezer vector-function Ψ is a partial case of the general scalar two-point Baker–Akhiezer functions satisfying to the second order linear Schrödinger equation $L_1\psi_1=0$ invented in Ref. 14. Here we have

$$L_1=\frac{\partial^2}{\partial\xi\partial\eta}+A(\xi,\eta)\frac{\partial}{\partial\eta}+W(\xi,\eta),$$

$-A=\partial_\xi\log\phi_1$. In this special case our surface Γ is hyperelliptic, the selected points coincide with $0,\infty$ and corresponding local parameters are chosen as $\sqrt{\lambda},1/\sqrt{\lambda}$. The second function ψ_2 satisfies to similar equation $L_2\psi_2=0$ where the operator L_2 is obtained from L_1 by the so-called Laplace transformations and vice versa. It is known that cyclic Laplace chains of length 2 lead to the SG equation in the general complex case (see Ref. 27).

Lemma 1: Assume that the spectral data (Γ,D), $D=\gamma_1+\cdots,\gamma_g$ *satisfy the following reality constraints*:

(1) The set of branch points of the Riemann surface Γ *contains real points or complex conjugate pairs of points only, and all real branch points are nonpositive. Without loss of generality we*

may assume that the first $2m+1$ *of them,* $E_0=0$, E_1, E_2, $\ldots$, E_{2m}, *are real and* $0>E_1>E_2>\cdots>E_{2m}$, *and for* $k>m$ *we have* $E_{2k}=\overline{E}_{2k-1}$, $\operatorname{Im} E_{2k}\neq 0$. *Then the spectral curve* Γ *is real and admits a* $\mathbb{Z}_2\times\mathbb{Z}_2$*-group of involutions generated by the standard holomorphic involution*

$$\sigma:\Gamma\to\Gamma: \quad \sigma(\lambda,\mu)=(\lambda,-\mu), \tag{11}$$

transposing the sheets, and by the antiholomorphic involution

$$\tau:\Gamma\to\Gamma: \quad \tau(\lambda,\mu)=(\overline{\lambda},\overline{\mu}) \tag{12}$$

(*complex conjugation*).

(2) *There exists a meromophic differential* Ω *with two simple poles at the points* $0,\infty$ *such that the zeros of* Ω *are located at the points* $D+\tau D$. *We shall call such divisors* **admissible**. *Without loss of generality we can normalize* Ω *to be real*: $\tau\Omega=\overline{\Omega}$.

Then the potential $u(x,t)$ *is real and nonsingular*.

Remark: The constraints on the spectral curve were found in Ref. 12. The characterization of admissible divisors and the proof of nonsingularity were obtained in Ref. 16.

It is easy to check (see, for example, Ref. 24)

Lemma 2: If D *is an admissible divisor, then the divisor of zeros* $D(x,t)=\gamma_1(x,t)+\cdots+\gamma_g(x,t)$ *is admissible for all* x,t

Assume that we have a real meromorphic differential Ω with exactly two simple poles at the points $0,\infty$. We can associate an admissible divisor D to it if and only if $2g$ zeros of Ω can be presented as a union of two subsets D and D_1 such that $D_1=\tau D$. It is possible if and only if all real roots of Ω have even multiplicity.

Definition 1: Assume that the spectral curve Γ *satisfies the reality conditions formulated above. A real meromorphic differential* Ω *on* Γ *with exactly two simple poles at the points* $0,\infty$ *is called* **admissible** *if the multiplicity of all real roots is even.*

Without loss of generality we may assume that the residues of Ω at the points 0 and ∞ are equal to $+1$ and -1, respectively. Then we have

$$\Omega=\left(1-\frac{\lambda P_{g-1}(\lambda)}{R(\lambda)^{1/2}}\right)\frac{d\lambda}{2\lambda}, \tag{13}$$

where $P_{g-1}(\lambda)$ is a polynomial of degree at most $g-1$ with real coefficients. Let us call the polynomial $P_{g-1}(\lambda)$ **admissible** if Ω is an admissible differential.

Denote the map associating an admissible polynomial with an admissible divisor by $\Pi:D\to P_{g-l}(\lambda)$. The inverse map Π^{-1} is multivalued. If $P_{g-1}(\lambda)$ is an admissible polynomial, then the equation

$$\begin{aligned}\mu&=\lambda P_{g-1}(\lambda),\\ R(\lambda)&=\mu^2\end{aligned} \tag{14}$$

has $2g+1$ roots. One of them is the point (0,0), the other $2g$ roots form g pairs. To define an admissible divisor we have to choose one point from each pair: therefore we have at most 2^g possibilities depending on the number of real points. In the generic case we have no real roots, so the number is equal to 2^g in this case.

The description of connected components suggested by the authors in Refs. 23 and 24 is based on the following simple observation:

Consider a pair of functions of the real variable λ:

$$f_{\pm}(\lambda)=\pm\frac{\sqrt{R(\lambda)}}{\lambda}. \tag{15}$$

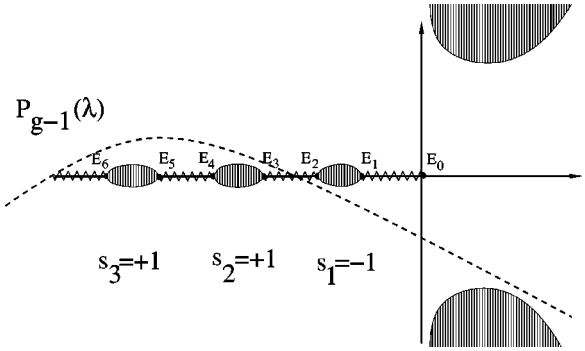

FIG. 1. The graph of $P_{g-1}(\lambda)$ and the forbidden domains.

We assume that the functions $f_{\pm}(\lambda)$ are defined only for such $\lambda \neq 0$ that $R(\lambda) \geqslant 0$, i.e., these functions are real-valued. Let us draw the graphs of these functions $y=f_{+}(\lambda)$, $y=f_{-}(\lambda)$, and fill in the following domains (see Fig. 1):

$$\lambda<0, y^2<\frac{R(\lambda)}{\lambda^2}, \qquad \lambda>0, y^2>\frac{R(\lambda)}{\lambda^2}. \tag{16}$$

Lemma 3: The polynomial $P_{g-1}(\lambda)$ is admissible if and only if the graph of $P_{g-1}(\lambda)$ does not cross the black open domains (but it can touch their boundaries).

Now we can associate with each admissible polynomial a **topological type**, i.e., a collection of m numbers $s_k=\pm 1$, $k=1,\ldots,m$, defined by the following rule:

$$s_k=1 \text{ if } P_{g-1}(\lambda) \geqslant f_{+}(\lambda) \text{ as } E_{2k} \leqslant \lambda \leqslant E_{2k-1},$$

$$s_k=-1 \text{ if } P_{g-1}(\lambda) \leqslant f_{-}(\lambda) \text{ as } E_{2k} \leqslant \lambda \leqslant E_{2k-1}.$$

Using simple algebraic estimates (see Ref. 24) it is easy to check:

Lemma 4: Each topological type is presented by the convex subset in the space of polynomials P_{g-1}. Each of these 2^m connected components is nonempty and depends continuously on the branch points $E_1,\ldots,E_{2g}$.

The x and t dynamics of admissible divisors may be rather nontrivial (a number of numeric experiments are discussed in Ref. 22). In contrast with the self-adjoint case (KdV, defocusing NLS, sinh-Gordon) the admissible position of a given divisor point depends on the position of other ones (the admissibility constraints are nonlocal). The trajectory of a single divisor point may be not well-defined because divisor points may collide and a small variation of parameters near the collision point results in a bifurcation of trajectories. If the potential $u(x,t)$ is periodic with the period T, the corresponding divisor is generically periodic only modulo permutations. But the following properties can be easily proved using the characterization formulated above.

Lemma 5: Projections of the points of admissible divisors to the λ-plane could not lie in the segments $[E_1,E_0]$, $[E_3,E_2]$, $\ldots,(-\infty,E_{2m}]$. Moreover, it is possible to choose an open neighborhood of these segments such that the projections of these points could not lie in it.

Lemma 6: Assume that the projection of a point $\gamma_s=(\lambda_s,\mu_s)$ of an admissible divisor to the λ-plane lie in the segments $[E_{2k},E_{2k-1}]$; then $\mu_s<0$ if $s_k=1$ and $\mu_s>0$ if $s_k=-1$.

III. THE TOPOLOGICAL CHARGE OF REAL SOLUTIONS

It is well-known (see, for example, Refs. 21 and 22) that after the Abel transform the x-dynamics of sine-Gordon corresponds to the motion along the straight line

$$\vec{X}=\vec{X}_0+\vec{U}x, \tag{17}$$

in the Jacobi torus, where $\vec{U}$ denotes the noramalized vector of b-periods of the quasimomentum differential dp:

$$U^k=-\frac{1}{2\pi}\oint_{b_k} dp. \tag{18}$$

Let us recall that by definition dp is a meromorphic differential with zero a-periods and two second order poles at 0, ∞ such that

$$dp=\begin{cases}\left(\dfrac{1}{8\sqrt{\lambda}}+o\left(\dfrac{1}{\lambda}\right)\right)d\lambda \quad \text{as} \quad \lambda\to\infty,\\ \left(\dfrac{1}{8\lambda\sqrt{\lambda}}+o\left(\dfrac{1}{\lambda}\right)\right)d\lambda \quad \text{as} \quad \lambda\to 0.\end{cases} \tag{19}$$

The real part of the Jacobi torus is isomorphic to the factor $\mathbb{R}^n/\mathbb{Z}^n$, therefore we can apply the following simple analytic lemma:

Lemma 7: Let $u(\vec{X}), X\in\mathbb{R}^n$ *be a smooth function in* $\mathbb{R}^n$ *such that* $\exp(iu(\vec{X}))$ *is single-valued on the torus* $\mathbb{R}^n/\mathbb{Z}^n$, *i.e.*, $\exp(iu(\vec{X}+\vec{N}))=\exp(iu(\vec{X}))$ *for any integer vector* $\vec{N}$. *Denote by* $u(x)$ *restriction of* $u(\vec{X})$ *to the straight line* $\vec{X}=\vec{X}_0+x\cdot\vec{U}$. *Then the density of topological charge* $\overline{n}=\lim_{T\to\infty}[u(x+T)-u(x)]/2\pi T$ *is well-defined; it does not depend on the point* $\vec{X}_0$ *and can be expressed by the following formula:*

$$\overline{n}=\sum_{k=1}^{n} n_k U^k, \tag{20}$$

where $\vec{U}=(U^1,U^2,\ldots,U^n)$, *and* n_k *are topological charges along the basic cycles* $\mathcal{A}_k, k=1,\ldots,n$:

$$u(X^1,X^2,\ldots,X^k+1,\ldots,X^n)-u(X^1,X^2,\ldots,X^k,\ldots,X^n)=2\pi n_k. \tag{21}$$

The main step is the calculation of the charges along the basic cycles $\mathcal{A}_k$. To obtain a convenient answer the choice of canonical basis is very important. For **stable** surfaces (surfaces without complex branch points) the proper system of a-cycles was constructed in Ref. 18.

We work with the following system of cuts $[E_1,E_0],[E_3,E_2],\ldots,(-\infty,E_{2g}]$. Let us denote the sheet containing the line $\lambda\in\mathbb{R},\lambda>0$ $\mu>0$ by G_+ and the second sheet by G_- (see Fig. 2).

For the generic real curves with $2m$ negative branch points $E_1,\ldots,E_{2m}$ and $g-m$ complex adjoint pairs $E_{2j-1},E_{2j}=\overline{E}_{2j-1}$, $j=m+1,\ldots,g$, we choose first m a-cycles exactly as in the stable case. The last $g-m$ a-cycles should be chosen as coverings on Γ over the path on the λ-plane connecting the points E_{2j-1} and E_{2j} for $j>m$. All these paths should not meet each other. All of them should cross positive part of the line $\lambda>0$ in one point κ_j (i.e., in two points of Riemann surface) such that $\kappa_{m+1}<\kappa_{m+2}<\cdots<\kappa_g$. This basis depends on the order of the complex conjugate pairs only (see Fig. 3).

We assume also that the cycles $b_1,b_2,\ldots,b_m$ are the ovals lying over the segments $[E_2,E_1]$, $[E_4,E_3]$, $[E_{2m},E_{2m-1}]$, respectively.

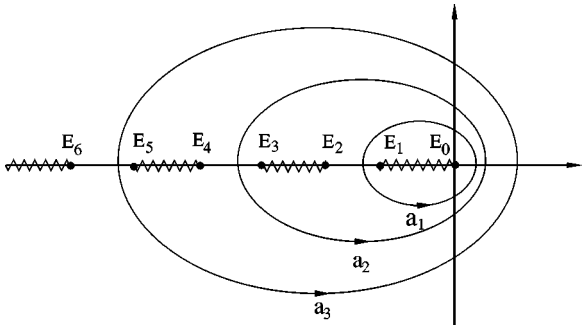

FIG. 2. The basic *a*-cycles: the stable case.

For the complex conjugate pairs of branch points $E_{2j},E_{2j-1},j>m$, we make the cuts connecting each of these points with $i\infty$ or $-i\infty$ such that the cuts do not intersect the real line. As before we denote the sheet containing the line $\lambda\in\mathbb{R},\lambda>0$ $\mu>0$ by G_+ and the second sheet by G_-. The orientation of the cycles $b_l,l=1,\ldots,m$, coincides with the standard orientation of the negative semi-line $\mathbb{R}_-$ at the sheet G_+; they are opposite at the sheet G_-.

Consider a basic cycle $\mathcal{A}_k$ on the real component of Jacobi torus, represented by the closed curve B_k on this torus. The image of this cycle in the surface Γ (i.e., image of it under the inverse Abel map) is a closed oriented curve C_k (may be consisting from several connected components) homological to the cycle $a_k\in H_1(\Gamma,\mathbb{Z})$. From Lemma 5 it follows that this curve does not touch the closed segments on the real line $[-\infty,E_{2m}],\ldots,[E_3,E_2],[E_1,0]$, and if it crosses the negative semi-line at the inteval $[E_{2l},E_{2l-1}]$, then it happens in the sheet G_+ if $(-1)^{l-1}s_l>0$ and in the sheet G_- if $(-1)^{l-1}s_l<0$. From formula (10) it follows that the topological charge along the cycle $\mathcal{A}_k$ is given by

$$n_k=\tilde{C}_k\circ\mathbb{R}_-, \tag{22}$$

where $\tilde{C}_k$ is the projection of C_k to the λ-plane, and $\circ$ denotes the intersection index of curves on the λ-plane. Taking into account that any intersection with the negative semi-line is the intersection with one of the *b*-cycles we obtain the following.

Lemma 8: The topological charge along the cycle $\mathcal{A}_k$ on the real torus in the Jacobian variety is equal to the intersection index of the corresponding curve C_k with the **counting cycle of the real component** *on the Riemann surface* Γ,

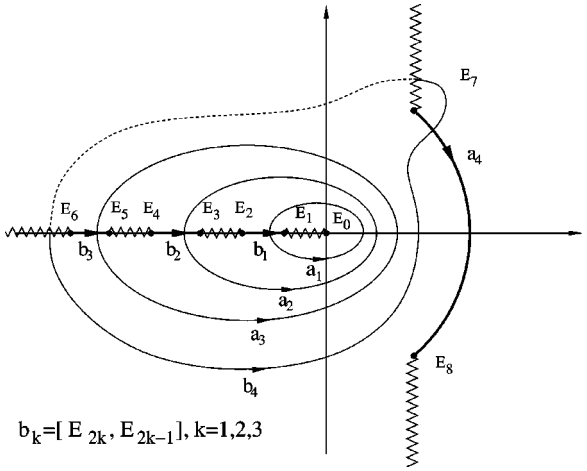

FIG. 3. The basic cycles: the generic case.

$$n_k = C_k \circ \left(\sum_{l=1}^{m} (-1)^{l-1} s_l b_l \right). \tag{23}$$

Let us mention that the cycle C_k is homotopic to a_k on Γ. Therefore $C_k \circ b_l = \delta_{kl}$ and

$$\begin{gathered} n_k = (-1)^{k-1} s_k \quad \text{for } k \leqslant m, \\ n_k = 0 \quad \text{for } k > m. \end{gathered} \tag{24}$$

Combining (20) with (24), we obtain our main result:

Theorem 1: *For any real solution the density of topological charge along the variable x is given by the formula*

$$\overline{n} = \frac{1}{2} \sum_{k=1}^{m} (-1)^{k-1} s_k U^k, \tag{25}$$

where the components U^k of the vector $\vec{U}$ are defined by (18).

IV. AVERAGING OF THE LOCAL CONSERVATION LAWS AND TOPOLOGICAL TYPES

For a generic functional

$$F[u] = \int f(e^{iu}, e^{-iu}, u_x, u_{xx}, \ldots, u_t, u_{tx}, u_{txx}, \ldots) dx \tag{26}$$

the result of averaging over a real componet of the Jacobi torus depends on the topolgical type. For example, by averaging of u_x we get the topological charge. But if we average the sine-Gordon Hamiltonian

$$H[u] = \int \left[\frac{u_t^2}{2} + \frac{u_x^2}{2} + (1 - \cos(u)) \right] dx, \tag{27}$$

the result is the same for all components. Therefore it is natural to formulate the following:

Problem: How to characterize the functionals such that the averaging does not depend on the topological type.

A complete classification seems to be a complicated problem. But it is rather easy to formulate a natural sufficient condition.

If $f(e^{iu}, e^{-iu}, u_x, u_{xx}, \ldots, u_t, u_{tx}, u_{txx}, \ldots)$ is a polynomial of its arguments, then it can be written as a symmetric rational function of the divisor coordinates $f = \tilde{f}(\lambda_1(x,t), \ldots, \lambda_g(x,t), \mu_1(x,t), \ldots, \mu_g(x,t))$.

Lemma 9: Consider the following form on the $\underbrace{\Gamma \times \Gamma \times \cdots \times \Gamma}_{g \text{ times}}$

$$W_f = \tilde{f}(\lambda_1, \ldots \lambda_g, \mu_1, \ldots, \mu_g) \prod_{k<l} (\lambda_k - \lambda_l) \prod_{k=1}^{g} \frac{d\lambda_k}{\mu_k}. \tag{28}$$

If we fix all divisor points except γ_1, we obtain a meromorphic differential on Γ with poles only at 0 and ∞. Assume that the residues of this differential are equal to 0 identically in $\gamma_2, \ldots, \gamma_g$. Then for a given spectral curve the averaging does not depend on the topological type.

Proof: Following Ref. 20 we can calculate the averaging of $F[u]$ using the formula

$$\overline{F[u]} = C \oint_{a_1} \cdots \oint_{a_g} W_f, \tag{29}$$

where C is the normalization constant, and **all cycles a_k have the proper topological type**. The last condition was not discussed in Ref. 20. The deformations of the integration cycles do not affect the integral if we do not cross 0. If the condition of Lemma 9 is fulfilled, then we can move the integration path through 0 and ''reach'' any topological type without changing the integral.

As a corollary we immediately get the following statement:

Theorem 2: *Assume that the functional $F[u]$ is invariant with respect to the following symmetries*: $\sigma_k:(\lambda_k,\mu_k)\to(\lambda_k,-\mu_k)$, $\sigma_k:(\lambda_l,\mu_l)\to(\lambda_l,\mu_l)$ *for* $l\neq k$. *Then the result of averaging does not depend on the topological type.*

Important example: Consider the densities of ''higher SG Hamiltonians'' defined as odd expansion coefficients of the function

$$\frac{\Psi_x(\lambda,x,t)}{\Psi(\lambda,x,t)} \tag{30}$$

at the points 0 and ∞. Direct calculation shows that

$$\frac{\Psi_x}{\Psi} = \frac{1}{4}\left[\frac{\Psi_\xi}{\Psi} + \frac{\Psi_\eta}{\Psi}\right], \tag{31}$$

where

$$\frac{\Psi_\xi}{\Psi} = i\frac{\mu + Q^\xi(\lambda)}{(\lambda-\lambda_1(x,t))\cdots(\lambda-\lambda_g(x,t))}, \tag{32}$$

$$\frac{\Psi_\eta}{\Psi} = i\frac{[\mu+\lambda Q^\eta(\lambda)][-\lambda_1(x,t),\ldots,(-\lambda_g(x,t))]}{\lambda(\lambda-\lambda_1(x,t))\cdots(\lambda-\lambda_g(x,t))\sqrt{E_1\cdots E_{2g}}}, \tag{33}$$

and $Q^\xi(\lambda)$, $Q^\eta(\lambda)$ are polynomials of degree $g-1$ determined by the following conditions:

$$Q^\xi(\lambda_k(x,t)) = \mu_k(x,t), \quad Q^\eta(\lambda_k(x,t)) = \frac{\mu_k(x,t)}{\lambda_k(x,t)}. \tag{34}$$

We see that the odd part of $\Psi_x\Psi^1$ depends on $\lambda_k(x,t)$ but not $\mu_k(x,t)$. Therefore the averaging of the ''higher SG Hamiltonians'' does not depend on the topological type.

(Received 15 December 2002; accepted 9 April 2003)

This article is about the focusing nonlinear Schrödinger equation on the half-line. The initial function vanishes at infinity while boundary data are local perturbations of periodic or quasi-periodic (finite-gap) functions. We study the corresponding scattering problem for the Zakharov–Shabat compatible differential equations, the representation of the solution of the nonlinear Schrödinger equation in the quarter of the (x,t)-plane through functions, which satisfy Marchenko integral equations. We use this formalism to investigate the asymptotic behavior of the solution for large time. We prove that under certain conditions a periodic (quasi-periodic) behavior at infinity of boundary data generates an unbounded train of asymptotic solitons running away from the boundary. The asymptotics of the solution shows that boundary data with periodic behavior as time tends to infinity generates a train of such asymptotic solitons even in the case when the initial function is identically zero. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1588465]

I. INTRODUCTION

The nonlinear Schrödinger equation is one of the most important completely integrable nonlinear equations. It has various applications in nonlinear optics, hydrodynamics, quantum field theory, etc. After the Korteweg–de Vries equation, the nonlinear Schrödinger equation was the second for which an inverse scattering transform was discovered by V. E. Zakharov and A. B. Shabat.[41,42] During the next three decades the nonlinear Schrödinger equation was studied by a large number of researchers of different orientation ranging from pure mathematics to applied physics. We mention only some results related to the Cauchy problem for the nonlinear Schrödinger equation on the whole line with initial functions vanishing at infinity.[16] The solvability of the Cauchy problem was proved and a representation for the solution was obtained via the Gelfand–Levitan–Marchenko equation or, alternatively, via the solution of a Riemann–Hilbert problem for an analytic matrix-valued function. It was also proved that the nonlinear Schrödinger equation with vanishing initial data is a completely integrable infinite-dimensional Hamiltonian system.

In the last decade there has been an increase activity in the investigation of initial boundary value problems on the half line. Among publications,[2–14,17–25,29–40] devoted to this problem, the more interesting and significant results were obtained by A. S. Fokas[18] and A. S. Fokas and A. R. Its.[22] Below we will use a modification of this approach. In the framework of the Fokas–Its approach we recently found characteristic properties of the scattering data for the compatible Zakharov–Shabat eigenvalue problem associated with focusing and defocusing nonlinear Schrödinger equations on the half-axis with initial and boundary functions of Schwartz type.[9]

In this article we consider a more complicated problem where boundary data have a periodic or quasi-periodic behavior as t tends to infinity. Our main goal is to study the asymptotic behavior

a)Electronic mail: aboutet@math.jussieu.fr

of a solution. To the best of our knowledge such a problem was not considered elsewhere. So, we consider the Dirichlet and/or the Neumann initial-boundary value problem for the focusing nonlinear Schrödinger equation:

$$iq_t+q_{xx}+2|q|^2q=0, \quad \text{with} \quad x,t\in\mathbb{R}_+, \tag{1.1}$$

$$q(x,0)=u(x), \quad \text{with} \quad x\in\mathbb{R}_+, \tag{1.2}$$

$$q(0,t)=v(t) \quad \text{or} \quad q_x(0,t)=v_1(t) \quad \text{with} \quad t\in\mathbb{R}_+, \tag{1.3}$$

$$u(0)=v(0) \qquad \text{or} \quad u_x(0)=v_1(0), \tag{1.4}$$

where $u(x)$ vanishes as $x\to\infty$, and the boundary values are perturbations

$$v(t)=\alpha(t)+\hat{v}(t), \quad \hat{v}(t)\to 0, \quad t\to+\infty, \tag{1.5}$$

$$v_1(t)=\beta(t)+\hat{v}_1(t), \quad \hat{v}_1(t)\to 0, \quad t\to+\infty \tag{1.6}$$

of "finite-gap" functions $\alpha(t)$ and $\beta(t)$, which are periodic or quasi-periodic. The functions $\hat{v}(t)$ and $\hat{v}_1(t)$ vanish at $+\infty$. The definition of "finite-gap" functions $\alpha(t)$ and $\beta(t)$ will be given later.

We assume that the solution $q(x,t)$ of the NLS equation for $x,t\in\mathbb{R}_+$ is infinitely differentiable, continuous with all its derivatives up to the boundary $\{x=0\}\cup\{t=0\}$ of the quarter xt-plane and $q(x,t)\in\mathcal{S}(\mathbb{R}_+)$ in x for any fixed $t\in\mathbb{R}_+$, where $\mathcal{S}(\mathbb{R}_+)$ is the space of infinitely differentiable functions on $\mathbb{R}_+$ such that derivatives of any order $n\geqslant 0$ vanish at infinity faster than any negative power of x:

$$\mathcal{S}(\mathbb{R}_+)=\{u(x)\in C^\infty(\mathbb{R}_+)\,|\,x^m u^{(n)}(x)\in L^\infty(\mathbb{R}_+) \quad \text{for any} \quad m,n\geqslant 0\}.$$

They will be referred as "Schwartz functions." So the initial function $u(x)$ and $\hat{v}(t)$, $\hat{v}_1(t)$ are of Schwartz type. Standard notations will be used throughout the article:

$$\sigma_0=\begin{pmatrix}1&0\\0&1\end{pmatrix}, \quad \sigma_2=\begin{pmatrix}0&-i\\i&0\end{pmatrix}, \quad \sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

Our study of the solution $q(x,t)$ is based on simultaneous spectral analysis of two eigenvalue problems, one for the linear x-equation

$$\begin{gathered} w_x+ik\sigma_3 w=Q(x,t)w,\\ Q(x,t)=\begin{pmatrix}0&q(x,t)\\-\overline{q}(x,t)&0\end{pmatrix}, \end{gathered} \tag{1.7}$$

the other for the linear t-equation

$$\begin{gathered} w_t+2ik^2\sigma_3 w=\hat{Q}(x,t,k)w,\\ \hat{Q}(x,t,k)=2kQ(x,t)-i(Q^2(x,t)+Q_x(x,t))\sigma_3. \end{gathered} \tag{1.8}$$

Equations (1.7) and (1.8) are the well-known Zakharov–Shabat,[41] or Ablowitz–Kaup–Newel–Segur,[1] system of linear equations associated to q. Both equations are compatible if and only if $q(x,t)$ satisfies the nonlinear Schrödinger equation (1.1).

The main goal of this article is to study the scattering problem for compatible differential equations (1.7) and (1.8), the representation of the solution $q(x,t)$ through functions satisfying Marchenko integral equations, and the asymptotic behavior of $q(x,t)$ as $t\to+\infty$. We prove that

the principal (nonvanishing) part of the asymptotics is a series of asymptotic solitons. The asymptotics of the solution shows that boundary functions $v(t)$ or $v_1(t)$ with periodic behavior at infinity generate a train of such solitons even in the case when the initial data $u(x)$ vanish identically.

Now let us introduce the so-called *finite-gap functions* $\alpha(t)$ and $\beta(t)$. We refer to the Appendix for more details.

Let $\mathcal{X}$ be the hyperelliptic Riemann surface of genus g given by the equation

$$z^2=\prod_{j=0}^{g}(k-E_j)(k-\overline{E_j}),$$

with $E_j\in\mathbb{C}$, $\operatorname{Im}E_j>0$, $E_i\neq E_j$ for $i\neq j$, and $\operatorname{Re}E_0\leqslant\operatorname{Re}E_1\leqslant\cdots\leqslant\operatorname{Re}E_g$. $\mathcal{X}$ is a double covering of the complex k-plane $\overline{\mathbb{C}}=\mathbb{C}\cup\{\infty\}$ obtained by gluing two copies of $\overline{\mathbb{C}}$ along cuts γ_j whose endpoints are the $2g+2$ branch points E_j, $\overline{E_j}$. Let

$$\pi:\mathcal{X}\to\overline{\mathbb{C}}$$

be the canonical projection on the k-plane. Each point in the k-plane has two preimages on $\mathcal{X}$, except for the $2g+2$ branch points. Denote the preimage of $k=\infty$ on the upper (lower) sheet of $\mathcal{X}$ by $\mathcal{P}=\infty^+$ (respectively $\mathcal{P}=\infty^-$). We fix the branch of the square root by relation

$$\sqrt{\prod_{j=0}^{g}(k-E_j)(k-\overline{E_j})}=\pm k^{g+1}[1+\mathrm{O}(k^{-1})],\quad k\to\infty^{\pm}\in\mathcal{X}_{\pm}. \tag{1.9}$$

Let $D=\mathcal{P}_1+\cdots+\mathcal{P}_g$ be a nonspecial integral divisor on $\mathcal{X}\setminus\{\infty^+,\infty^-\}$ and let $\phi(t,\mathcal{P})$ be the Baker–Akhiezer vector function on $\mathcal{X}$ whose divisor of poles is D. That means

(i) $\phi(t,\mathcal{P})$ is meromorphic on $\mathcal{X}\setminus\{\infty^+,\infty^-\}$ with divisor of poles D; and
(ii) the product $\phi(t,\mathcal{P})\exp\{2\,\mathrm{i}k^2(\mathcal{P})t\}$ is analytic in the neighborhoods of $\infty^{\pm}$.

The Baker–Akhiezer vector-function satisfies the following equation:[28]

$$\phi_t+2\mathrm{i}k^2\sigma_3\phi=\hat{Q}_g(t,k)\phi, \tag{1.10}$$

where $k=\pi(\mathcal{P})$ is the canonical projection of $\mathcal{P}\in\mathcal{X}$ on the complex k-plane and

$$\hat{Q}_g(t,k)=2kQ_g(t)-\mathrm{i}(Q_g^2(t)+Q_{1g}(t))\sigma_3,$$

$$Q_g(t)=\begin{pmatrix}0 & \alpha(t)\\ -\overline{\alpha}(t) & 0\end{pmatrix},\quad Q_{1g}(t)=\begin{pmatrix}0 & \beta(t)\\ -\overline{\beta}(t) & 0\end{pmatrix}.$$

Definition: $\alpha(t)$ and $\beta(t)$ are called *finite-gap* if (1.10) has a solution which is a Baker–Akhiezer vector-function on some hyperelliptic Riemann surface $\mathcal{X}$ of finite genus.

The explicit representation of $\phi(t,\mathcal{P})$ given in the Appendix yields corresponding representations for $\alpha(t)$ and $\beta(t)$ through theta functions which leads to their periodicity or quasiperiodicity in $t\in\mathbb{R}$.

A. First case: Re $E_0<0$

So, $E_0=\mathrm{i}a-b$ with $a>0$ and $b>0$. Assume the solution $q(x,t)$ of the Dirichlet or Neumann problem (1.1)–(1.6) exists and satisfies the smoothness assumptions mentioned above. Then we prove that

$$q(x,t)=2\overline{K}_2(x,x,t), \tag{1.11}$$

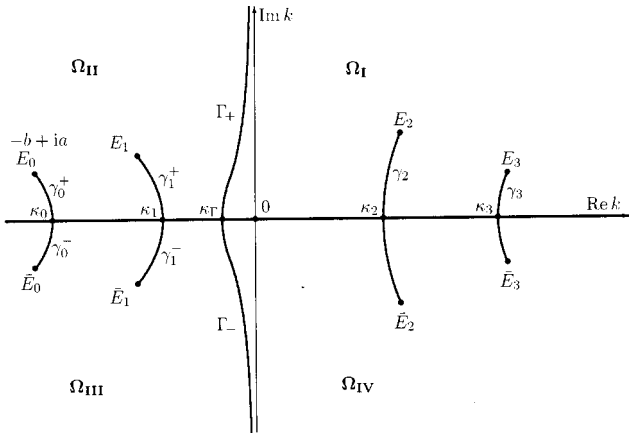

FIG. 1. Spectrum Σ of (1.10).

where $\overline{K}_2(x,y,t)$ together with some $K_1(x,y,t)$ satisfy the linear integral Marchenko equations:

$$K_1(x,y,t)-\int_x^\infty \overline{K}_2(x,z,t)H(z+y,t)\mathrm{d}z=0 \quad \text{for} \quad 0\leqslant x<y<\infty, \tag{1.12}$$

$$\overline{K}_2(x,y,t)+\overline{H}(x+y,t)+\int_x^\infty K_1(x,z,t)\overline{H}(z+y,t)\mathrm{d}z=0 \tag{1.13}$$

with kernel

$$H(x,t)=\sum_{k_j\in\Omega_I} m_j^1 \mathrm{e}^{\mathrm{i}k_j x+4\mathrm{i}k_j^2 t}+\sum_{z_j\in\Omega_{II}} m_j^2 \mathrm{e}^{\mathrm{i}z_j x+4\mathrm{i}z_j^2 t}+\frac{1}{2\pi}\int_{\partial\Omega_{II}} c(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2 t}\mathrm{d}k$$
$$+\frac{1}{2\pi}\int_{-\infty}^{\infty} r(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2 t}\mathrm{d}k. \tag{1.14}$$

(i) Ω_I, $\Omega_{II}\subset\mathbb{C}$ are some domains defined by the spectrum of the t-equation (1.10) with finite-gap coefficients $\alpha(t)$ and $\beta(t)$. See Fig. 1 above.

(ii) The function $r(k)$, eigenvalues $k_j\in\Omega_I$ and numbers m_j^1 $(j=1,\ldots,l)$ are uniquely defined only by initial data $u(x)$.

(iii) The remaining scattering data $c(k)$, eigenvalues $z_j\in\Omega_{II}$ and numbers m_j^2 $(j=1,\ldots,m)$ depend on both initial and boundary data.

Note that $H(x,t)$ is only defined for $x\geqslant 0$ because for $x<0$ the integral over the infinite contour $\partial\Omega_{II}$ does not converge.

Theorem 1: *Let $q(x,t)$ be the solution of the nonlinear problem (1.1)–(1.6) given by (1.11)–(1.14). Let $E_0=-b+\mathrm{i}a$. We assume $b<0$ and $\min_{1\leqslant j\leqslant m}\mathrm{Re}\, z_j>-b$. Let $N\in\mathbb{N}$ and*

$$G_N(t)=\left\{x\in\mathbb{R}_+ \;\middle|\; x>4bt-\frac{1}{2b}\log t^{N+1}\right\}.$$

Then, $q(x,t)$ has in $G_N(t)$ the following asymptotics, for $t\to\infty$:

$$|q(x,t)|^2=\sum_{j=1}^{[(N+1)/2]}\frac{4a^2}{\cosh^2[2a(x-4bt-x_j)+\log t^{2j-1/2}]}+o(1),$$

where

$$x_j = x_j^{(0)} + \frac{1}{2\pi}\int_{-\infty}^{-b} \frac{\log[1+|\rho(\lambda)|^2]}{(\lambda+b)^2+a^2}\,d\lambda,$$

$$\rho(\lambda) = r(\lambda) + c(\lambda),$$

and the numbers $x_j^{(0)}$ *depend on* γ_0^+ *and* $c(k)$.

Remark: If there exist eigenvalues z_j with $\mathrm{Re}\, z_j < -b$, then the asymptotics of the function $|q(x,t)|^2$ will contain additionally a finite number of ordinary solitons

$$\sum_{\mathrm{Re}\, z_j < -b} \frac{4\,\mathrm{Im}^2 z_j}{\cosh^2[2\,\mathrm{Im}\, z_j(x+4\,\mathrm{Re}\, z_j t - y_j)]}$$

which move faster than asymptotic solitons away from the boundary in the domain $x > 4bt$ and correspond to those eigenvalues $z_j \in \Omega_{\mathrm{II}}$ for which $\mathrm{Re}\, z_j < -b$.

It is easy to see that asymptotic solitons given by Theorem 1 are similar to ordinary solitons but their velocities depend on t. In contrast with ordinary solitons they are not exact solutions of the nonlinear equation, however they satisfy it with increasing accuracy when $t \to \infty$. For this reason such objects are called asymptotic solitons. The number of these asymptotic solitons increases to infinity when $t \to \infty$ if the observation domain in the neighborhood of the solution front is extended correspondingly.

B. Second case: Re $E_0 > 0$

Now let us consider the case when the finite-gap function $\alpha(t)$ or $\beta(t)$ are such that all branch points E_j have a positive real part. In contrast with the first case, such boundary functions do not generate asymptotic solitons.

Theorem 2: *Let the boundary functions be such that* $\mathrm{Re}\, E_0 > 0$. *Then, the solution* $q(x,t)$ *has in the domain*

$$x > z_0 t,$$

$$z_0 = \min_{1 \le j \le m} |\mathrm{Re}\, z_j| - \varepsilon, \quad \varepsilon > 0,$$

the following asymptotics, for $t \to \infty$*:*

$$|q(x,t)|^2 = \sum_{j=1}^{m} \frac{4\,\mathrm{Im}^2 z_j}{\cosh^2[2\,\mathrm{Im} z_j(x+4\,\mathrm{Re}\, z_j t - y_j)]} + o(1).$$

If in addition $\{z_j \in \Omega_{\mathrm{II}}\} = \varnothing$, *then, in the same domain for* $t \to \infty$,

$$|q(x,t)|^2 = \frac{1}{4\pi t}\log\left[1 + \left|\rho\left(-\frac{x}{4t}\right)\right|^2\right] + o(t^{-1}),$$

with

$$\rho(k) = r(k) + c(k), \quad z_0 > 0 \ \textit{arbitrary}.$$

Qualitatively these results do not depend on whether the initial function $u(x)$ is identically zero or not. In the case $u(x) \equiv 0$ the scattering function $r(k)$ is also identically zero, and $\rho(k)$ depends on the boundary data only. Thus we have the following

Summary: (1) Boundary data $v(t)$ *or* $v_1(t)$ *with periodic or quasi-periodic behavior such that* $\mathrm{Re}\, E_0 < 0$ *generate an unbounded train of asymptotic solitons which run away from the boundary.*

(2) For boundary data $v(t)$ or $v_1(t)$ with periodic or quasi-periodic behavior such that $\mathrm{Re}\, E_0>0$, *only a finite number of ordinary solitons may exist.*

(2′) If in addition the set of eigenvalues $\{z_j \in \Omega_{\mathrm{II}}\}$ is empty, then the solution $q(x,t)$ does not contain any soliton.

Generated by eigenvalues $k_j \in \Omega_{\mathrm{I}}$ [in this case $u(x) \not\equiv 0$] ordinary solitons run to the boundary $x=0$ and they are absorbed by the boundary in finite time.

II. BASIC SOLUTIONS

Let us write the x- and t-equations in the form

$$W_x = U(x,t,k)W, \tag{2.1}$$

$$W_t = V(x,t,k)W, \tag{2.2}$$

where $U(x,t,k)$ and $V(x,t,k)$ are 2×2 matrices given by

$$U(x,t,k) = Q(x,t) - \mathrm{i}k\sigma_3,$$

$$V(x,t,k) = 2kQ(x,t) - \mathrm{i}(Q^2(x,t) + Q_x'(x,t))\sigma_3 - 2\mathrm{i}k^2\sigma_3.$$

Lemma 1: Let the system (2.1) and (2.2) be compatible for all k. Let $W(x,t,k)$ satisfy the x-equation (2.1) for all t, and let $W(x_0,t,k)$ satisfy the t-equation (2.2) for some $x=x_0$ (including the case $x_0=\infty$).

Then $W(x,t,k)$ satisfies the t-equation for all x.

Proof: See, e.g., Ref. 9. □

Notations: The over-bar denotes the complex conjugation; $\mathbb{C}_{\pm}$ denotes the upper (lower) complex half plane; I, II, III, IV are the first, second, third and fourth quadrants of the complex plane. If A is a 2×2 matrix, we denote A^- the first column of A, and A^+ the second column of A:

$$A = (A^- \quad A^+) = \begin{pmatrix} a_1^- & a_1^+ \\ a_2^- & a_2^+ \end{pmatrix}.$$

We denote $[A,B]=AB-BA$ the commutator of two matrices A and B.

In this section we shall introduce three solutions of both x- and t-equations. They are called ''basic'' solutions.

C. First basic solution

First of all, since $q(x,t)\to 0$ as $x\to\infty$, then we can choose the 2×2 matrix-valued *Jost solution* of the x-equation (1.7) as the first basic solution. It has the integral representation (see, e.g., Ref. 16)

$$\Psi(x,t,k) = \left(\mathrm{e}^{-\mathrm{i}kx\sigma_3} + \int_x^{\infty} K(x,y,t)\mathrm{e}^{-\mathrm{i}ky\sigma_3}\mathrm{d}y \right) \mathrm{e}^{-2\mathrm{i}k^2t\sigma_3}, \tag{2.3}$$

where

$$K(x,y,t) = \begin{pmatrix} K_1(x,y,t) & -\overline{K_2}(x,y,t) \\ K_2(x,y,t) & \overline{K_1}(x,y,t) \end{pmatrix}$$

with $K_1, K_2 \in C^{\infty}(\mathbb{R}_+\times\mathbb{R}_+\times\mathbb{R}_+)$ and of Schwartz type in $x+y$ for any $t\in\mathbb{R}_+$. Moreover, $K(x,x,t)$ and $Q(x,t)$ are connected by

$$[\sigma_3, K(x,x,t)] = Q(x,t)\sigma_3. \tag{2.4}$$

This last equality leads to the important formula

$$q(x,t)=2\overline{K_2}(x,x,t) \tag{1.11}$$

for the solution $q(x,t)$ of the nonlinear Schrödinger equation (1.10). $\Psi(x,t,k)$ satisfies the x-equation (1.7). It also satisfies the t-equation (1.8) with $x=\infty$, because $e^{-ik(x+2kt)\sigma_3}$ satisfies both Eqs. (1.7) and (1.8) for $Q(x,t)\equiv 0$. Then, Lemma 1 implies that $\Psi(x,t,k)$ satisfies the t-equation for any $x\in\mathbb{R}_+$, both equations being assumed compatible.

The integral representation (2.3) and Lemma 1 imply the following properties of the matrix-valued Jost solution $\Psi(x,t,k)$ (cf. Ref. 16).

Proposition: The first basic solution $\Psi(x,t,k)$ has the following properties:

(1) $\Psi(x,t,k)$ satisfies both x-and t-equations (1.7) and (1.8).
(2) $\Psi(x,t,k)=\sigma_2\overline{\Psi}(x,t,k)\sigma_2$ for $k\in\mathbb{R}$.
(3) $\det\Psi(x,t,k)\equiv 1$ for $k\in\mathbb{R}$.
(4) $\Psi(x,t,k)$ is C^∞ in $(x,t,k)\in\mathbb{R}_+\times\mathbb{R}_+\times\mathbb{R}$.
(5) $\Psi^+(x,t,k)$ is analytic in $k\in\mathbb{C}_+$, and $\Psi^-(x,t,k)$ is analytic in $k\in\mathbb{C}_-$.
(6) $\sigma_2\overline{\Psi}^-(x,t,k)=i\Psi^+(x,t,\overline{k})$ for any $k\in\mathbb{C}_-$.
(7) For $k\to\infty$,

$$e^{ikx+2ik^2t}\Psi^-(x,t,k)=\begin{pmatrix}1\\0\end{pmatrix}+O(k^{-1}) \quad \text{if} \quad \operatorname{Im}k\leqslant 0,$$

$$e^{-ikx-2ik^2t}\Psi^+(x,t,k)=\begin{pmatrix}0\\1\end{pmatrix}+O(k^{-1}) \quad \text{if} \quad \operatorname{Im}k\geqslant 0.$$

D. Second basic solution

Now let us introduce the second basic solution $\Phi(x,t,k)$ of the x- and t-equations which satisfies the initial condition

$$\Phi(0,0,k)=\sigma_0. \tag{2.5}$$

It can be represented as a product of two 2×2 matrices:

$$\Phi(x,t,k)=\varphi(x,t,k)\hat{\varphi}(t,k), \tag{2.6}$$

where $\varphi(x,t,k)$ satisfies the x-equation under the condition $\varphi(0,t,k)=\sigma_0$, and $\hat{\varphi}(t,k)$ satisfies the t-equation with $x=0$ under the initial condition $\hat{\varphi}(0,k)=\sigma_0$. Lemma 1 implies that $\Phi(x,t,k)$ satisfies both equations (1.7) and (1.8). The existence of the solution $\varphi(x,t,k)$ and its integral representation

$$\varphi(x,t,k)=e^{-ikx\sigma_3}+\int_{-x}^{x}A(x,y,t)e^{-iky\sigma_3}dy \tag{2.7}$$

with some integral kernel $A(x,y,t)$ is proved in Ref. 9. $\hat{\varphi}(t,k)$ can be found as solution of the Volterra integral equation:

$$\hat{\varphi}(t,k)=e^{-2ik^2t\sigma_3}+\int_0^t e^{2ik^2(\tau-t)}\hat{Q}(0,\tau,k)\hat{\varphi}(\tau,k)d\tau, \tag{2.8}$$

where

$$\hat{Q}(0,t,k)=2k\begin{pmatrix}0 & v(t)\\ -\overline{v}(t) & 0\end{pmatrix}+i|v(t)|^2\sigma_3+i\begin{pmatrix}0 & v_1(t)\\ \overline{v_1}(t) & 0\end{pmatrix}.$$

For $\hat{\varphi}(t,k)$ the following integral representation,

$$\hat{\varphi}(t,k)=\mathrm{e}^{-2\mathrm{i}k^2t\sigma_3}+\int_{-t}^{t}B(t,s)\mathrm{e}^{-2\mathrm{i}k^2s\sigma_3}\mathrm{d}s+k\int_{-t}^{t}C(t,s)\mathrm{e}^{-2\mathrm{i}k^2s\sigma_3}\mathrm{d}s, \tag{2.9}$$

can be found in Ref. 9. In the present case $A(x,y,t)$, $B(t,s)$ and $C(t,s)$ are C^∞ and bounded.

The integral representations (2.6)–(2.9) yield the following properties of $\Phi(x,t,k)$.

Proposition: The second basic solution $\Phi(x,t,k)$ has the following properties:

(1) $\Phi(x,t,k)$ *satisfies both x- and t-equations.*
(2) $\overline{\Phi(x,t,\overline{k})}=\sigma_2\Phi(x,t,k)\sigma_2$ *for any* $k\in\mathbb{C}$.
(3) $\det\Phi(x,t,k)\equiv 1$ *for* $k\in\mathbb{C}$.
(4) $\Phi(x,t,k)\in C^\infty(\mathbb{R}_+\times\mathbb{R}_+\times\mathbb{C})$.
(5) $\Phi(x,t,k)$ *is an entire function in* $k\in\mathbb{C}$.
(6) For $k\in\mathbb{C}$, $k\to\infty$,

$$\Phi(x,t,k)=\left[I+\mathrm{O}(k^{-1})+\mathrm{O}\left(\frac{\mathrm{e}^{2\mathrm{i}kx\sigma_3}}{k}\right)+\mathrm{O}\left(\frac{\mathrm{e}^{4\mathrm{i}k^2t\sigma_3}}{k}\right)\right]\mathrm{e}^{-\mathrm{i}k(x+2kt)\sigma_3}.$$

(7) For $k\in\Omega_1$, $k\to\infty$,

$$\mathrm{e}^{\mathrm{i}kx+2\mathrm{i}k^2t}\Phi^-(x,t,k)=\begin{pmatrix}1\\0\end{pmatrix}+\mathrm{O}(k^{-1}).$$

The last asymptotic relation can be easily proved using large k asymptotics for $\varphi^{\mp}(x,t,k)$ and $\hat{\varphi}^-(t,k)$.

E. Third basic solution

The third basic solution involves a *Floquet–Bloch solution* of the equation (1.10). We have supposed that the functions $\alpha(t)$ and $\beta(t)$ are finite-gap. This means that there exists a hyperelliptic Riemann surface $\mathcal{X}$ and a Baker–Akhiezer vector-function $\phi(t,\mathcal{P})$, $\mathcal{P}\in\mathcal{X}$, which satisfies (in t) the equation (1.10). Using theta function theory (Appendix or Ref. 15) one can write

$$\phi(t,\mathcal{P})=\chi(t,\mathcal{P})\exp\left(-\mathrm{i}t\int_{\underline{E}_g}^{\mathcal{P}}\Omega(\mathcal{Q})\right).$$

Let $D=\mathcal{P}_1+\cdots+\mathcal{P}_g$ be the divisor of poles of $\phi(t,\mathcal{P})$. For all $t\in\mathbb{R}$ the function $\chi(t,\mathcal{P})$ is defined on $\mathcal{X}\backslash\{\mathcal{P}_1,\ldots,\mathcal{P}_g\}$. Moreover, $\Omega(\mathcal{P})$ is an Abelian differential on $\mathcal{X}$ characterized by the following properties:

(1) It is holomorphic on $\mathcal{X}\backslash\{\infty^{\pm}\}$.
(2) It has the following behavior for $\mathcal{P}\to\infty^{\pm}$:

$$\Omega(\mathcal{P})=\pm\mathrm{d}(2k^2)+\mathrm{O}\left(\frac{\mathrm{d}k}{k^2}\right),$$

where $k=k(\mathcal{P})$.
(3) It satisfies the normalization conditions:

$$\int_{a_j}\Omega(\mathcal{P})=0,\quad j=1,\ldots,g,$$

where $a_1,\ldots,a_g$ are suitable one-cycles on $\mathcal{X}$.

More details about $\phi(t,\mathcal{P})$ are given in the Appendix.

Let $e(t,k)$ be the projection of $\phi(t,\mathcal{P})$ on the upper sheet $\mathcal{X}_+$, namely $e(t,k)=\phi(t,\mathcal{P})$, where $\mathcal{P}\in\mathcal{X}_+$ and $\pi(\mathcal{P})=k$. This function $e(t,k)$ satisfies (1.10) in $t\in\mathbb{R}$, and it is meromorphic away from $\Sigma\cup\{\infty\}$ where

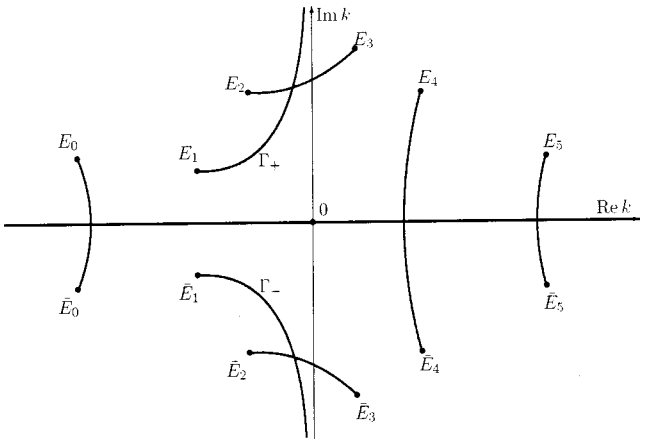

FIG. 2. The second type of Σ.

$$\Sigma := \left\{ k \in \mathbb{C} \,\middle|\, \operatorname{Im} \mu(k) = \operatorname{Im} \int_{\overline{E}_g}^{\mathcal{P}} \Omega(\mathcal{P}') = 0 \right\}.$$

It is known[15] that the function $\mu(k)$ can be written in the form

$$\mu(k) = \int_{\overline{E}_g}^{k} \frac{s^{g+2} + \mu_1 s^{g+1} + \cdots + \mu_{g+2}}{X(s)} \mathrm{d}s,$$
$$X(s) = \sqrt{\prod_{j=0}^{g} (s - E_j)(s - \overline{E_j})}. \tag{2.10}$$

This integral representation shows that

$$\Sigma = \mathbb{R} \cup \Gamma \cup \gamma_0 \cup \cdots \cup \gamma_g,$$

where $\mathbb{R}$ is the real axis in the complex k-plane, Γ is an infinite contour on $\mathbb{C}$, asymptotic to the imaginary axis $\mathrm{i}\mathbb{R}$ and invariant by complex conjugation, and the γ_j's are finite arcs whose endpoints are the branch points E_j and $\overline{E_j}$. We denote

$$\Sigma_E = \{E_0, \overline{E_0}, \ldots, E_g, \overline{E_g}\},$$
$$\Sigma_\kappa = \{\kappa_j \,|\, \kappa_j \quad \text{self-intersection of} \quad \Sigma\}. \tag{2.11}$$

There exist two types of Σ:

(1) For the first type the complex plane $\mathbb{C}$ is divided into two nonintersecting left and right "half-planes" by Γ (Fig. 1).
(2) The second type of Σ is that when Γ does not divide the plane $\mathbb{C}$. It consists of two connected parts $\Gamma_\pm \subset \mathbb{C}_\pm$ with endpoints $E_+ = E_{j_0}$ and $E_- = \overline{E}_{j_0}$ for some $0 \leqslant j_0 \leqslant g$ (Fig. 2).

Away from endpoints, γ_j and Γ are analytic curves. In what follows we will consider only cases where Σ is of the first type. Let us denote

$$\Omega_{\mathrm{I}} = \{k \in \mathbb{C} \,|\, \operatorname{Im} k > 0, \operatorname{Im} \mu(k) > 0\},$$
$$\Omega_{\mathrm{II}} = \{k \in \mathbb{C} \,|\, \operatorname{Im} k > 0, \operatorname{Im} \mu(k) < 0\},$$

$$\Omega_{\mathrm{III}}=\{k\in\mathbb{C}|\operatorname{Im}k<0,\operatorname{Im}\mu(k)>0\},$$

$$\Omega_{\mathrm{IV}}=\{k\in\mathbb{C}|\operatorname{Im}k<0,\operatorname{Im}\mu(k)<0\}. \tag{2.12}$$

So, we obtain a partition of the complex k-plane:

$$\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{III}}\cup\Omega_{\mathrm{IV}}\cup\Sigma=\mathbb{C},$$

where

$$\Sigma=\{k\in\mathbb{C}|\operatorname{Im}\mu(k)=0\}=\mathbb{R}\cup\Gamma\cup\gamma_0\cup\cdots\cup\gamma_g,$$

$$\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{III}}=\{k\in\mathbb{C}|\operatorname{Im}\mu(k)>0\},$$

$$\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{IV}}=\{k\in\mathbb{C}|\operatorname{Im}\mu(k)<0\}.$$

Now we input the matrix-valued Floquet–Bloch solution

$$\mathcal{E}(t,k)=\begin{pmatrix} e_1(t,k) & -\overline{e_2}(t,\overline{k}) \\ e_2(t,k) & \overline{e_1}(t,\overline{k}) \end{pmatrix}$$

of (1.10), which is bounded in $t\in\mathbb{R}$ for $k\in\Sigma$. We remind that $e(t,k)$ is C^∞ in $t\in\mathbb{R}$ and $k\in\Sigma\setminus(\Sigma_\kappa\cup\Sigma_E)$. It is meromorphic away from $\Sigma\cup\{\infty\}$.

For $k\in\mathbb{C}\setminus\Sigma$ the matrix-valued function $\mathcal{E}(t,k)$ is unbounded in $t\in\mathbb{R}$. However, its first column $\mathcal{E}^-(t,k)$ has exponential decay in the domain $\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{IV}}$ as $t\to\infty$ and the second column $\mathcal{E}^+(t,k)$ has exponential decay in the domain $\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{III}}$:

$$\mathcal{E}^{\mp}(t,k)=\mathrm{O}(\mathrm{e}^{\pm 2\operatorname{Im}\mu(k)t}),\quad t\to\infty.$$

But, they grow exponentially when $k\in\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{III}}$ and $k\in\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{IV}}$, respectively. The determinant

$$\det\mathcal{E}(t,k)=\Delta(k)=1+e_2(0,k)\overline{e_2}(0,\overline{k}) \tag{2.13}$$

does not vanish at any $k\neq E_j,\overline{E_j}$.

Examples: The simplest examples of finite-gap boundary data are as follows. If $g=0$, there exist only two branch points E_0 and $\overline{E_0}$. Let us put $E_0=\mathrm{i}a-b$, $a>0$, $b>0$.

Then the function $\mu(k)$ has the form

$$\mu(k)=2(k-b)\sqrt{(k+b)^2+a^2},$$

$$X(k)=\sqrt{(k+b)^2+a^2},$$

and the function $e(t,k)$ can be written as

$$e(t,k)=\begin{pmatrix} 1 \\ \dfrac{\mathrm{i}\mathrm{e}^{-\mathrm{i}\omega t}}{a}(k+b-X(k)) \end{pmatrix}\mathrm{e}^{-\mathrm{i}\mu(k)t}.$$

Using Eq. (1.10) one finds

$$\alpha(t)=a\mathrm{e}^{2\mathrm{i}\omega t},$$

$$\beta(t)=2\mathrm{i}ab\mathrm{e}^{2\mathrm{i}\omega t},$$

where $\omega=a^2-2b^2$. This case of simplest periodic behavior of boundary data was studied in Ref. 10. The genus $g=1$ produces elliptic functions $\alpha(t)$ and $\beta(t)$ which are periodic in $t\in\mathbb{R}$. For $g\geqslant 2$ the functions $\alpha(t)$ and $\beta(t)$ can also be periodic. In general, these functions are quasi-periodic in $t\in\mathbb{R}$ with finite number of frequencies.

We introduce the third basic solution as follows. Let $\hat{\Psi}(t,k)$ be a solution of the Volterra integral equation

$$\hat{\Psi}(t,k)=\mathcal{E}(t,k)-\int_t^\infty \mathcal{E}(t,k)\mathcal{E}^{-1}(\tau,k)[\hat{Q}(0,\tau,k)-\hat{Q}_0(\tau,k)]\hat{\Psi}(\tau,k)\mathrm{d}\tau, \tag{2.14}$$

where $\hat{Q}(0,t,k)$ is as in (2.8), and

$$\hat{Q}_0(t,k)=\begin{pmatrix} \mathrm{i}|\alpha(t)|^2 & 2k\alpha(t)+\mathrm{i}\beta(t) \\ -2k\overline{\alpha}(t)+\mathrm{i}\beta(t) & -\mathrm{i}|\alpha(t)|^2 \end{pmatrix},$$

which means the matrix $\hat{\Psi}(t,k)$ satisfies the t-equation with $x=0$ under the asymptotic condition $\hat{\Psi}(t,k)=\mathcal{E}(t,k)+o(1)$ as $t\to\infty$. We input the matrix

$$Y(x,t,k)=\varphi(x,t,k)\hat{\Psi}(t,k), \quad k\in\Sigma, \tag{2.15}$$

where $\varphi(x,t,k)$ is as in (2.7). Lemma 1 implies that $Y(x,t,k)$ is a solution of the x- and t-equations with

$$\det Y(x,t,k)=\det\mathcal{E}(t,k)=\Delta(k), \quad k\in\Sigma.$$

For k outside of Σ the function $\hat{\Psi}(t,k)$, hence also $Y(x,t,k)$, is unbounded in $t\in\mathbb{R}_+$. The matrix-valued function $Y(x,t,k)$ has the same analytic properties in $k\in\mathbb{C}$ as $\mathcal{E}(t,k)$, since the Green matrix $\mathcal{E}(t,k)\mathcal{E}^{-1}(\tau,k)$ is an entire function in $k\in\mathbb{C}$, and the integral equation (2.14) is of Volterra type with $\tau\in(t,\infty)$. Therefore, $Y^-(x,t,k)$ is meromorphic in the domain $\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{IV}}$, and $Y^+(x,t,k)$ is meromorphic in $\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{III}}$.

The properties of the solution $Y(x,t,k)$ follow from the integral representation (2.7) and from the integral Volterra equation (2.14):

Proposition: The third basic solution $Y(x,t,k)$ has the following properties:

(1) $Y(x,t,k)$ *is a solution of both x- and t-equations.*
(2) $Y(x,t,k)=\sigma_2\overline{Y}(x,t,\overline{k})\sigma_2$ *for* $k\in\Sigma$.
(3) $\det Y(x,t,k)=\Delta(k)$ *for* $k\in\Sigma$.
(4) $Y(x,t,k)\in C^\infty(\mathbb{R}_+\times\mathbb{R}_+\times\Sigma')$ *where* $\Sigma'=\Sigma\backslash(\Sigma_\kappa\cup\Sigma_E)$.
(5) $Y^+(x,t,k)$ *is meromorphic in* $k\in\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{III}}$.
(6) $Y^-(x,t,k)$ *is meromorphic in* $k\in\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{IV}}$.
(7) $\sigma_2\overline{Y^-}(x,t,k)=\mathrm{i}Y^+(x,t,\overline{k})$ *for* $k\in\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{IV}}$.
(6) For $k\in\Omega_{\mathrm{II}}$, $k\to\infty$,

$$\mathrm{e}^{\mathrm{i}kx+2\mathrm{i}k^2t}Y^-(x,t,k)=\begin{pmatrix}1\\0\end{pmatrix}+\mathrm{O}(k^{-1}).$$

III. "SCATTERING" (TRANSITION) MATRICES

Definition (scattering matrices): The basic solutions we have introduced are clearly linearly dependent:

$$\Phi(x,t,k)=\Psi(x,t,k)S(k),$$

$$Y(x,t,k)=\Phi(x,t,k)P(k), \tag{3.1}$$

$$Y(x,t,k)=\Psi(x,t,k)R(k).$$

The matrices $S(k)$, $P(k)$ and $R(k)$ depend neither on x nor on t because by virtue of the x-equation they do not depend on x, and by virtue of the t-equation they do not depend on t. Hence for $k\in\mathbb{R}$ and for $k\in\Sigma$ we have

$$S(k)=\Psi^{-1}(0,0,k), \quad k\in\mathbb{R};$$

$$P(k)=Y(0,0,k), \quad k\in\Sigma; \tag{3.2}$$

$$R(k)=S(k)P(k), \quad k\in\mathbb{R}.$$

Let us study the properties of these "scattering" (transition) matrices. Properties of $S(k)$ follow from the scattering problem for the x-equation with $t=0$. Indeed, consider the problem on the whole x-axis by putting

$$q(x,0)=\hat{u}(x)=\begin{cases}0 & \text{for} \quad x\in(-\infty,0],\\ u(x) & \text{for} \quad x\in[0,\infty).\end{cases}$$

For simplicity, and to make considerations more transparent, we also suppose that

$$\frac{\mathrm{d}^n}{\mathrm{d}x^n}u(x)\bigg|_{x=0}=\frac{\mathrm{d}^n}{\mathrm{d}t^n}v(t)\bigg|_{t=0}=\frac{\mathrm{d}^n}{\mathrm{d}t^n}v_1(t)\bigg|_{t=0}=0 \tag{3.3}$$

for any $n\geqslant 0$. Let $\tilde{\Psi}(x,k)$ be the Jost solution[16] normalized by

$$\tilde{\Psi}(x,k)=\mathrm{e}^{-\mathrm{i}kx\sigma_3} \quad \text{for} \quad x<0,$$

and let $\tilde{T}(k)$ be the transition matrix for that case, i.e.,

$$\tilde{\Psi}(x,k)=\Psi(x,0,k)\tilde{T}(k).$$

Putting $x=0$ we find $S(k)\equiv\tilde{T}(k)$. Hence the "scattering" matrix $S(k)$ has all properties of the transition matrix $\tilde{T}(k)$.[16]

Properties of $S(k)$: The scattering matrix $S(k)$ satisfies

(i) $S(k)=\sigma_2\overline{S(k)}\sigma_2$ *for* $k\in\mathbb{R}$;
(ii) $\det S(k)\equiv 1$ *for* $k\in\mathbb{R}$;
(iii) $S(k)\in C^\infty(\mathbb{R})$.

For the half-axis case there are additional properties:

(iv) $S(k)=\begin{pmatrix} s_2^+(k) & -s_1^+(k)\\ -s_2^-(k) & s_1^-(k)\end{pmatrix}$ *where* $s_j^+(k)=\Psi_j^+(0,0,k)$.
(v) *The first line* $(s_2^+(k) \quad -s_1^+(k))$ *is analytic in* $k\in\mathbb{C}_+$.
(vi) *The second line* $(-s_2^-(k) \quad s_1^-(k))$ *is analytic in* $k\in\mathbb{C}_-$. [For an arbitrary function $\hat{u}(x)$, $x\in\mathbb{R}$, these analytic properties do not hold; $s_2^+(k)$ and $s_1^-(k)$ are only analytic functions in $k\in\mathbb{C}_+$ and $k\in\mathbb{C}_-$, respectively. In our case $\hat{u}(x)\equiv 0$ for $x<0$, therefore $s_1^+(k)$ and $s_2^-(k)$ are also analytic functions in $k\in\mathbb{C}_\pm$.]

(vii) *If* $k\in\mathbb{C}_+$ *and* $k\to\infty$,

$$s_2^+(k)=1+\mathrm{O}(k^{-1}),$$
$$s_1^+(k)=\mathrm{O}(k^{-1}).$$

(viii) *Under condition* (3.3) $s_1^+(k)\in\mathcal{S}(\mathbb{R})$ *and* $s_2^+(k)-1$ *is the Fourier transform of a complex-valued function* $f(y)\in\mathcal{S}(\mathbb{R}_+)$.

Proof: To prove the last item we use limit formulas

$$s_1^+(k)=\lim_{x\to-\infty}\mathrm{e}^{-\mathrm{i}kx}\Psi_1^+(x,0,k),$$

$$s_2^+(k)=\lim_{x\to-\infty}\mathrm{e}^{-\mathrm{i}kx}\Psi_2^+(x,0,k),$$

which follow from the definition of the matrix $S(k)$. If one puts

$$\chi_j(x,k)=\mathrm{e}^{-\mathrm{i}kx}\Psi_j^+(x,0,k),$$

the x-equation yields

$$\chi_1'+2\mathrm{i}k\chi_1=\hat{u}(x)\chi_2,\quad \chi_1(x,k)\to0\quad\text{as}\quad x\to+\infty,$$

$$\chi_2'=-\overline{\hat{u}(x)}\chi_1,\quad \chi_2(x,k)\to1\quad\text{as}\quad x\to+\infty.$$

Integrating these equations we find

$$\chi_1(x,k)=-\int_x^\infty \mathrm{e}^{2\mathrm{i}k(y-x)}\hat{u}(y)\chi_2(y,k)\mathrm{d}y,$$

$$\chi_2(x,k)=1+\int_x^\infty\overline{\hat{u}(y)}\chi_1(y,k)\mathrm{d}y,$$

and therefore

$$s_1^+(k)=-\int_{-\infty}^\infty\hat{u}(x)\mathrm{e}^{2\mathrm{i}kx}\chi_2(x,k)\mathrm{d}x=-\int_{-\infty}^\infty\hat{u}(x)\mathrm{e}^{2\mathrm{i}kx}\mathrm{d}x-\int_{-\infty}^\infty\hat{u}(x)\mathrm{e}^{2\mathrm{i}kx}\mathrm{d}x\int_0^\infty\overline{K}_1(x,x+y)\mathrm{e}^{\mathrm{i}ky}\mathrm{d}y,$$

$$s_2^+(k)=1+\int_{-\infty}^\infty\overline{\hat{u}(x)}\chi_1(x,k)\mathrm{d}x=1-\int_0^\infty\mathrm{e}^{\mathrm{i}kx}\mathrm{d}x\int_{-\infty}^\infty\overline{\hat{u}(y)}\overline{K}_2(y,y+x)\mathrm{d}y,$$

where $\overline{K}_1(x,y)$ and $\overline{K}_2(x,y)$ are entries of the kernel of triangular integral transformation (2.3). Taking into account that both functions $\overline{K}_1(x,y)$ and $\overline{K}_2(x,y)$ are of Schwartz type and that $\hat{u}(x)$ is of Schwartz type on the whole axis, which follows from (3.3), we arrive to the statement of the last item. □

The matrix $S(k)=\Psi^{-1}(0,0,k)$ is determined by the function $u(x)\in\mathcal{S}(\mathbb{R}_+)$. The entries of this matrix are not independent and can be recovered from one known function. Let $s(k)\equiv s_1^+(k)/s_2^+(k)$ be given and let

$$\Sigma_{\mathrm{d}}^{\mathrm{ic}}=\{k_1,\ldots,k_n\}=\{k_j\in\mathbb{C}_+|s_2^+(k_j)=0\}$$

be the set of zeros of the analytic function $s_2^+(k)$. Since $\det S(k)\equiv1$, then $|s_2^+(k)|^2+|s_1^+(k)|^2\equiv1$ for any $k\in\mathbb{R}$. This identity yields the well-known formula:

$$s_2^+(k)=\prod_{k_j\in\mathbb{C}_+}\frac{k-k_j}{k-\overline{k_j}}\exp\left\{\frac{\mathrm{i}}{2\pi}\int_{-\infty}^{\infty}\frac{\log[1+|s(\lambda)|^2]\mathrm{d}\lambda}{\lambda-k}\right\}. \tag{3.4}$$

The remaining entries of $S(k)$ are also recovered:

$$s_1^+(k)=s(k)s_2^+(k),\quad s_2^-(k)=-\overline{s_1^+}(\overline{k}),\quad s_1^-(k)=\overline{s_2^+}(\overline{k}).$$

So, the function $s_2^+(k)$ may vanish at some points $k_j\in\mathbb{C}_+$ and the set $\Sigma_{\mathrm{d}}^{\mathrm{ic}}$ is not empty. Moreover, these zeros can be multiple and there can exist limit points on the real axis $\mathbb{R}$.[16] To avoid these difficulties we shall consider a subset $\mathcal{S}_0(\mathbb{R}_+)$ of functions $u(x)\in\mathcal{S}(\mathbb{R}_+)$ for which $s_2^+(k)$ has a finite number of simple zeros in $\mathbb{C}_+$ and $s_2^+(k)\neq 0$ for $k\in\mathbb{R}$.

Let us briefly discuss the discrete spectrum of the x-problem. The main relation of the x-scattering problem is

$$\frac{1}{s_2^+(k)}\Phi^-(x,t,k)=\Psi^-(x,t,k)+r(k)\Psi^+(x,t,k)\quad\text{for}\quad k\in\mathbb{R}, \tag{3.5}$$

where

$$r(k)=-\frac{s_2^-(k)}{s_2^+(k)}. \tag{3.6}$$

The function $F(x,t,k)=\Phi^-(x,t,k)/s_2^+(k)$ is analytic in $k\in\mathbb{C}_+$ with the exception of a discrete set

$$\Sigma_{\mathrm{d}}^{\mathrm{ic}}=\{k_j\in\mathbb{C}_+|s_2^+(k_j)=0,\quad j=1,2,\ldots,n\},$$

where it has poles. If

$$s_2^+(k_j)=\det(\Phi^-(x,t,k_j)\quad\Psi^+(x,t,k_j))=0,$$

then $\Phi^-(x,t,k_j)=\gamma_j^1\Psi^+(x,t,k_j)$. Hence,

$$\mathrm{res}_{k_j}F(x,t,k)=c_j^1\Psi^+(x,t,k_j)$$

with

$$c_j^1=\frac{\gamma_j^1}{\dot{s}_2^+(k_j)},\quad j=1,2,\ldots,n,$$

$$\gamma_j^1=\frac{1}{s_1^+(k_j)}.$$

The dot denotes differentiation w.r.t. k. Note that $s_1^+(k_j)\neq 0$ because otherwise we come to a contradiction: $\Psi_+(x,t,k_j)\equiv 0$ since $\Psi_1^+(0,0,k_j)=s_1^+(k_j)=0$ and $\Psi_2^+(0,0,k_j)=s_2^+(k_j)=0$. The set of zeros $\Sigma_{\mathrm{d}}^{\mathrm{ic}}$ is finite because $s_2^+(k)\to 1$ as $k\to\infty$ and we have supposed that $s_2^+(k)\neq 0$ for any $k\in\mathbb{R}$. We also assume that zeros are simple, i.e., $\dot{s}_2^+(k_j)\neq 0$.

Using asymptotics of the function $\Phi^-(x,t,k)$ at $k=\infty$, for $\mathrm{Im}\,k\geqslant 0$, we find

$$F(x,t,k)=\left[\begin{pmatrix}1\\0\end{pmatrix}+\mathrm{O}(|k|^{-1})\right]\mathrm{e}^{-\mathrm{i}kx-2\mathrm{i}k^2t}\quad\text{for}\quad|k|\to\infty,\ k\in\Omega_1, \tag{3.7}$$

which will be used below. So, we come to the following:

Properties of $r(k)$: The reflection coefficient $r(k)$ satisfies the following.

(i) $r(k)\in\mathcal{S}(\mathbb{R})$. [For arbitrary functions $u(x)$ which do not satisfy (3.3) the reflection coefficient $r(k)$ does not belong to the Schwartz space $\mathcal{S}(\mathbb{R})$ since, for example, $\lim_{k\to\infty}2ikr(k)=u(0)\neq 0$.]

(ii) $r(k)$ *is the ratio of two functions* $-s_2^-(k)$ *and* $s_2^+(k)$ *which are analytic in* $k\in\mathbb{C}_-$ and $k\in\mathbb{C}_+$, respectively.

Properties of $t(k)$*: The transmission coefficient is given by* $t(k)=[s_2^+(k)]^{-1}$ *with*

$$s_2^+(k)=\prod_{k_j\in\mathbb{C}_+}\frac{k-k_j}{k-\overline{k_j}}\exp\left\{\frac{i}{2\pi}\int_{-\infty}^{\infty}\frac{\log[1+|s(\lambda)|^2]d\lambda}{\lambda-k}\right\}, \tag{3.4}$$

$\mathrm{Im}\,k_j>0$, $j=1,\ldots,n$, *and* $k_i\neq k_j$ *for* $i\neq j$. *Moreover,* $|s(k)|=|r(k)|$.

These properties follow from the x-scattering problem on the whole axis and can be found in Ref. 16. We also take into account that for the half-axis case $s_2^-(k)=-\overline{s_1^+}(\overline{k})$ is analytic in $k\in\mathbb{C}_-$ and the constants γ_j^1 are not independent parameters (that takes place for whole axis), and they are given in terms of the value of $s_1^+(k)$ at k_j:

$$\gamma_j^1=\frac{1}{s_1^+(k_j)}.$$

Analytic properties of the "scattering" matrix $P(k)$ are derived from the defining relation, i.e., from (3.2), (2.15), and (2.14):

$$P(k)=\mathcal{E}(0,k)+\int_0^{\infty}\mathcal{E}(0,k)\mathcal{E}^{-1}(t,k)[\hat{Q}(0,t,k)-\hat{Q}_0(t,k)]\hat{\Psi}(t,k)dt.$$

We stress only the main properties of $P(k)=\begin{pmatrix}p_1^-(k) & p_1^+(k)\\ p_2^-(k) & p_2^+(k)\end{pmatrix}$.

Properties of $P(k)$*: The scattering matrix* $P(k)$ *satisfies the following.*

(i) $P(k)=\sigma_2\overline{P(\overline{k})}\sigma_2$ *for* $k\in\Sigma$.
(ii) $\det P(k)\equiv\Delta(k)$ *for* $k\in\Sigma$.
(iii) $P(k)$ *is* C^{∞} *for* $k\in\Sigma'$.
(iv $P^+(k)$ *is meromorphic in* $k\in\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{III}}$.
(v) $P^-(k)$ *is meromorphic in* $k\in\Omega_{\mathrm{II}}\cup\Omega_{\mathrm{IV}}$.
(vi) $P(k)=\sigma_0+O(k^{-1})$, $k\in\Sigma$, $k\to\infty$.

Below we need to study properties of the "scattering" matrix $R(k)$ introduced by Eqs. (3.1) and (3.2). If we denote

$$R(k)=\begin{pmatrix}R_{\mathrm{II}}(k) & R_{\mathrm{I}}(k)\\ R_{\mathrm{IV}}(k) & R_{\mathrm{III}}(k)\end{pmatrix},$$

then

$$R_{\mathrm{I}}(k)=-\overline{R}_{\mathrm{IV}}(\overline{k}),\quad R_{\mathrm{III}}(k)=\overline{R}_{\mathrm{II}}(\overline{k})\quad\text{for } k\in\Sigma.$$

Moreover,

$$R_{\mathrm{II}}(k)=p_1^-(k)s_2^+(k)-p_2^-(k)s_1^+(k) \tag{3.8}$$

is meromorphic in $k\in\Omega_{\mathrm{II}}$ [hence $R_{\mathrm{III}}(k)$ is meromorphic in $k\in\Omega_{\mathrm{III}}$] and

$$R_{\mathrm{IV}}(k)=p_2^-(k)s_1^-(k)-p_1^-(k)s_2^-(k) \tag{3.9}$$

is meromorphic in $k \in \Omega_{IV}$ [hence $R_I(k)$ is meromorphic in $k \in \Omega_I$]. We remind that the branch of the square root (1.9) is fixed throughout the article and we deal with a single-valued analytic branch of the function $\mu(k)$ defined in (2.10).

From (3.1) we derive

$$Y^+(x,t,k) = R_I(k)\Psi^-(x,t,k) + R_{III}(k)\Psi^+(x,t,k).$$

Hence,

$$R_I(k) = \det(Y^+(x,t,k) \quad \Psi^+(x,t,k)),$$

$$R_{III}(k) = \det(\Psi^-(x,t,k) \quad Y^+(x,t,k)).$$

Let us put $x=0$, and $k = k_1 + ik_2 \in \Omega_I$. Using (2.3), (2.15), and (2.14) for large enough t we obtain

$$|R_I(k)| \leqslant C_1(k)\exp[8(k_1^0 k_2^0 - k_1 k_2)t],$$

where $C_1(k)$ is independent of t, and

$$k_1^0 k_2^0 = \max_{1 \leqslant j \leqslant n} [\mathrm{Re}\, k_j \mathrm{Im}\, k_j],$$

where $k_j \in \Omega_I$ is an eigenvalue of the x-scattering problem. Taking into account the analyticity of $R_I(k)$ in $k \in \Omega_I \backslash D$, choosing k large enough and putting $t \to \infty$ we find $R_I(k) \equiv 0$ for any $k \in \Omega_I$, hence also $R_{IV}(k) \equiv 0$ for any $k \in \Omega_{IV}$. So, we come to the main property of the compatible scattering problem for x- and t-equations.

Properties of $R(k)$: Let $\Gamma \cap \mathbb{R} = \{\kappa_\Gamma\}$. Then, for $k \in [\kappa_\Gamma, \infty)$, the "scattering" matrix $R(k)$ is diagonal:

$$R(k) = \begin{pmatrix} \rho_-(k) & 0 \\ 0 & \rho_+(k) \end{pmatrix}$$

with

$$\rho_+(k) = \frac{p_2^+(k)}{s_2^+(k)} = \frac{p_1^+(k)}{s_1^+(k)},$$

$$\rho_-(k) = \frac{p_1^-(k)}{s_1^-(k)} = \frac{p_2^-(k)}{s_2^-(k)}, \tag{3.10}$$

and the important relation

$$\frac{p_1^+(k)}{p_2^+(k)} \equiv \frac{s_1^+(k)}{s_2^+(k)}. \tag{3.11}$$

This relation means that $s(k) = s_1^+(k)/s_2^+(k)$, which is meromorphic on $\mathbb{C}_+$, is a meromorphic continuation of $p(k) = p_1^+(k)/p_2^+(k)$, which is meromorphic on Ω_I.

The asymptotic behavior of $S(k)$ and $P(k)$ yields the following asymptotic expansions, for $k \to \pm\infty$:

$$R_{\mathrm{II}}(k)=1+\frac{\rho_1}{k}+\cdots,$$

$$R_{\mathrm{IV}}(k)=\frac{\omega_1}{k}+\frac{\omega_2}{k^2}+\cdots.$$

Since $R_{\mathrm{IV}}(k)\equiv 0$ for $k\in[\kappa_\Gamma,\infty)$, then its asymptotic behavior is

$$R_{\mathrm{IV}}(k)=\mathrm{O}(k^{-\infty}) \quad \text{for} \quad k\to-\infty.$$

Hence,

$$R_{\mathrm{IV}}(k),\ \ R_{\mathrm{I}}(k)\in C^\infty(\mathbb{R}\backslash(\Sigma\kappa\cap\mathbb{R})),$$

$$R_{\mathrm{IV}}(k)\equiv 0 \quad \text{for} \quad k\in[\kappa_\Gamma,\infty), \tag{3.12}$$

$$R_{\mathrm{I}}(k)\equiv 0 \quad \text{for} \quad k\in[\kappa_\Gamma,\infty).$$

Therefore $R_{\mathrm{IV}}(k)$, $R_{\mathrm{I}}(k)$ and all their derivatives vanish at $k=\kappa_\Gamma$.

Since $\det R(k)\equiv\Delta(k)$, then

$$\rho_-(k)\rho_+(k)=|\rho_+(k)|^2\equiv\Delta(k).$$

Hence, $\rho_\pm(k)$ can be written

$$\rho_\pm(k)=\sqrt{\Delta(k)}\,\mathrm{e}^{\pm\mathrm{i}\nu(k)}, \quad k\in[\kappa_\Gamma,\infty) \tag{3.13}$$

for some real function $\nu(k)$ defined for $k\in[\kappa_\Gamma,\infty)$. This function has an analytic continuation also denoted $\nu(k)$ on $\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{IV}}$. This continuation satisfies $\nu(k)=\overline{\nu(\overline{k})}$ and tends to zero when $k\to\infty$ in view of the asymptotics of $s_2^+(k)$ and $p_2^+(k)$. It has logarithmic singularities at the points of the divisor D and different boundary values on cuts γ_j.

Indeed, in view of (3.10),

$$p_j^+(k)=\rho_+(k)\,s_j^+(k) \quad \text{for} \quad j=1,2. \tag{3.14}$$

$\rho_+(k)$ must have poles at the points of the divisor D and at the points where $s_1^+(k)$ and $s_2^+(k)$ vanish. On the other hand, $s_1^+(k)$ and $s_2^+(k)$ must simultaneously vanish at poles in view of the analyticity of the functions $p_j^+(k)$ in the domain $\Omega_{\mathrm{I}}\backslash D$. Hence $\Psi^+(x,t,k)$ is identically zero when k is a pole, which is impossible. So $\rho_+(k)$ is analytic in $k\in\Omega_{\mathrm{I}}$ with the exception of the points of the divisor D where it has simple poles. Hence the functions $p_j^+(k)$ and $s_j^+(k)$ have a common set of zeros, possibly empty, in Ω_{I}.

Other statements about $\nu(k)$ are very easy. So, for $R_{\mathrm{II}}(k)$ which is meromorphic in $k\in\Omega_{\mathrm{II}}$ we obtain

$$R_{\mathrm{II}}(k)=\frac{s_2^+(k)}{p_2^+(k)}\Delta(k)=\sqrt{\Delta(k)}\,\mathrm{e}^{-\mathrm{i}\nu(k)} \quad \text{for} \quad k\in\Gamma_+. \tag{3.15}$$

The last formula follows from relations

$$R_{\mathrm{II}}(k)=p_1^-(k)s_2^+(k)-p_2^-(k)s_1^+(k),$$

$$p_1^+(k)s_2^+(k)-p_2^+(k)s_1^+(k)=0.$$

Hence, $R_{\mathrm{II}}(k)$ has a meromorphic continuation to Ω_{I}, where it coincides with the function $\Delta(k)/\rho_+(k)$. Therefore $R_{\mathrm{II}}(k)$ does not vanish for $k\in[\kappa_\Gamma,\infty)\cup\Gamma_+$, and its only zeros are among the $z_j\in\Omega_{\mathrm{II}}$. Let $\Sigma_{\mathrm{d}}^{\mathrm{bc}}$ be the set of zeros of $R_{\mathrm{II}}(k)$:

$$\Sigma_{\mathrm{d}}^{\mathrm{bc}}=\{z_1,\ldots,z_m\}=\{z_j\in\Omega_{\mathrm{II}}|R_{\mathrm{II}}(z_j)=0\}.$$

Let

$$\rho(k):=\frac{R_{\mathrm{IV}}(k)}{R_{\mathrm{II}}(k)}.$$

As above we also assume the number of zeros of $R_{\mathrm{II}}(k)$ is finite and they are simple, i.e., $\dot{R}_{\mathrm{II}}(z_j)\neq 0$.

Properties of $\rho(k)$ and $R_{\mathrm{II}}(k)$: $\rho(k)$ and $R_{\mathrm{II}}(k)$ have the following properties:

(1) They satisfy the determinant relation

$$1+|\rho(k)|^2=\frac{\Delta(k)}{|R_{\mathrm{II}}(k)|^2},\quad k\in\mathbb{R}. \tag{3.16}$$

(2) $\rho(k),R_{\mathrm{II}}(k)\in C^\infty(\mathbb{R}\backslash(\Sigma_\kappa\cap\mathbb{R}))$ *and* $\rho(k)\equiv 0$ *for* $k\in[\kappa_\Gamma,\infty)$.

(3) $R_{\mathrm{II}}(k)=\sqrt{\Delta(k)}\,\mathrm{e}^{-\mathrm{i}\nu(k)}$ *for* $k\in[\kappa_\Gamma,\infty)$, *where* $\nu(k)$ *is real-valued and has an analytic continuation to* $\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{IV}}$.

(4) $\rho(k)$ *and all its derivatives have jumps at the real points* $\kappa_j<\kappa_\Gamma$*:*

$$\rho^{(l)}(\kappa_j-0)-\rho^{(l)}(\kappa_j+0)=f^{(l)}(\kappa_j),\quad l=0,1,\ldots, \tag{3.17}$$

where $f(k)$ *is defined for* $k\in\gamma_j^+=\gamma_j\cap\overline{\Omega}_{\mathrm{II}}$ by

$$f(k)=2\mathrm{i}\,\frac{\sqrt{\Pi_{i=0}^{g}(k-E_i)(k-\overline{E_i})}}{R_{\mathrm{II}}(k-0)R_{\mathrm{II}}(k+0)}\prod_{l=1}^{g}\frac{1}{k-\lambda_l},$$
$$\lambda_l=\pi(\mathcal{P}_l),\quad D=\mathcal{P}_1+\cdots+\mathcal{P}_g. \tag{3.18}$$

(5) The function

$$\rho(k)-r(k)=\frac{p_2^-(k)}{R_{\mathrm{II}}(k)s_2^+(k)}$$

has a meromorphic continuation to Ω_{II}.

Proof: The fourth item will be proved in the next section. The last item follows from Eqs. (3.8) and (3.9) which yield

$$p_1^-(k)=R_{\mathrm{IV}}(k)s_1^+(k)+R_{\mathrm{II}}(k)s_1^-(k)=R_{\mathrm{II}}(k)[1/s_2^+(k)+s_1^+(k)(\rho(k)-r(k))],$$

$$p_2^-(k)=R_{\mathrm{IV}}(k)s_2^+(k)+R_{\mathrm{II}}(k)s_2^-(k)=R_{\mathrm{II}}(k)s_2^+(k)[\rho(k)-r(k)]\quad\text{for}\quad k\in\mathbb{R}_-,$$

and the difference $\rho(k)-r(k)$ has a meromorphic continuation to the domain Ω_{II} because the l.h.s. is meromorphic in $k\in\Omega_{\mathrm{II}}$. Hence, the r.h.s. must have a meromorphic continuation to the domain Ω_{II}.

Besides we remind that $p_1^+(k)/p_2^+(k)=s_1^+(k)/s_2^+(k)$ has a meromorphic continuation to the domain $\mathbb{C}_+$, i.e., this ratio has no jump over the arcs γ_j^+.

The second main relation of the compatible scattering problem is

$$G(x,t,k)=\frac{1}{R_{\mathrm{II}}(k)}Y^-(x,t,k)=\Psi^-(x,t,k)+\rho(k)\Psi^+(x,t,k)\quad\text{for}\quad k\in\mathbb{R}. \tag{3.19}$$

The function $G(x,t,k)$ is analytic in $k\in\Omega_{\mathrm{II}}$, $k\neq z_j$ with poles at z_j's. Singularities at the points $\lambda_j=\pi(\mathcal{P}_j)$, $\mathcal{P}_j\in D$, are reduced since the divisor D does not depend on x and t, and $Y^-(x,t,k)$ and $R_{\mathrm{II}}(k)$ have simple poles at λ_j simultaneously. If $R_{\mathrm{II}}(z_j)=0$, $j=1,\ldots,m$, then $Y^-(x,t,z_j)$ and $\Psi^+(x,t,z_j)$ are linearly dependent:

$$Y^-(x,t,z_j)=\gamma_j^2\Psi^+(x,t,z_j),$$

hence

$$\mathrm{res}_{z_j}G(x,t,k)=c_j^2\Psi^+(x,t,z_j),$$

$$c_j^2=\frac{\gamma_j^2}{\dot{R}_{\mathrm{II}}(z_j)}$$

(the dot denotes differentiation with respect to k) with

$$\gamma_j^2=\frac{p_1^-(z_j)}{s_1^+(z_j)}=\frac{p_2^-(z_j)}{s_2^+(z_j)}.$$

Using asymptotics of the function $Y^-(x,t,k)$ at $k=\infty$ with $k\in\Omega_{\mathrm{II}}$, we find

$$G(x,t,k)=\left[\begin{pmatrix}1\\0\end{pmatrix}+\mathrm{O}(|k|^{-1})\right]\mathrm{e}^{-\mathrm{i}kx-2\mathrm{i}k^2t} \tag{3.20}$$

for $|k|\to\infty$, $k\in\Omega_{\mathrm{II}}$.

This asymptotic formula will be used in the next section. □

IV. THE MAIN INTEGRAL EQUATIONS

The main relations of the compatible scattering problem follow from (3.1), (3.2) and (3.5), (3.19):

$$F(x,t,k)=\Psi^-(x,t,k)+r(k)\Psi^+(x,t,k) \quad \text{for} \quad k\in\mathbb{R}, \tag{4.1}$$

$$G(x,t,k)=\Psi^-(x,t,k)+\rho(k)\Psi^+(x,t,k) \quad \text{for} \quad k\in\mathbb{R}. \tag{4.2}$$

These relations give

$$G(x,t,k)-F(x,t,k)=c(k)\Psi^+(x,t,k), \tag{4.3}$$

where $c(k)$ can be written as follows

$$c(k)=\rho(k)-r(k)=\begin{cases}-r(k) & \text{for} \quad k\in[\kappa_\Gamma,\infty),\\ \dfrac{p_2^-(k)}{s_2^+(k)\,R_{\mathrm{II}}(k)} & \text{for} \quad k\in(-\infty,\kappa_\Gamma].\end{cases} \tag{4.4}$$

Hence, $c(k)$ has a meromorphic continuation from the interval $(-\infty,\kappa_\Gamma]$ to the domain Ω_{II}, because $p_2^-(k)$, $s_2^+(k)$ and $R_{\mathrm{II}}(k)$ are meromorphic in $k\in\Omega_{\mathrm{II}}$. Hence, (4.3) is also true for $k\in\overline{\Omega}_{\mathrm{II}}$. The function $c(k)$ has poles at the z_j's, where $s_2^+(z_j)=R_{\mathrm{II}}(z_j)=0$. Since the number of zeros of $s_2^+(k)$ and $R_{\mathrm{II}}(k)$ is finite and they are simple, all poles of $c(k)$ are simple and their number is finite. Indeed, we only have to check the case $s_2^+(z_0)=R_{\mathrm{II}}(z_0)=0$. Due to (3.8) we also find $p_2^-(z_0)=0$. Poles which are related to the divisor D are reduced.

In view of the continuation of $c(k)$ to Ω_{II} we have the following relation on Γ_+:

$$\frac{Y^-(x,t,k-0)}{R_{\rm II}(k-0)}-\frac{\Phi^-(x,t,k+0)}{s_2^+(k+0)}=c(k)\Psi^+(x,t,k)\quad\text{for}\quad k\in\Gamma_+. \tag{4.5}$$

To deduce the integral equations of the inverse scattering problem let us put

$$h^-(x,t,k)=G(x,t,k)-\begin{pmatrix}1\\0\end{pmatrix}e^{-ikx-2ik^2t}\quad\text{for}\quad k\in(-\infty,\kappa_\Gamma],$$

$$h^+(x,t,k)=F(x,t,k)-\begin{pmatrix}1\\0\end{pmatrix}e^{-ikx-2ik^2t}\quad\text{for}\quad k\in[k_\Gamma,\infty\rangle.$$

$h^-(x,t,k)$ has different left and right boundary values at each $k\in\gamma_j^+=\gamma_j\cap\overline{\Omega}_{\rm II}$:

$$\begin{aligned}h^-(x,t,k-0)-h^-(x,t,k+0)&=G(x,t,k-0)-G(x,t,k+0)\\&=\frac{Y^-(x,t,k-0)R_{\rm II}(k+0)-Y^-(x,t,k+0)R_{\rm II}(k-0)}{R_{\rm II}(k+0)R_{\rm II}(k-0)}.\end{aligned}$$

Since $R_{\rm II}(k)=\det(Y^-(x,t,k)\ \ \Psi^+(x,t,k))$ one can find

$$\begin{aligned}&Y^-(x,t,k-0)R_{\rm II}(k+0)-Y^-(x,t,k+0)R_{\rm II}(k-0)\\&\quad=Y^-(x,t,k-0)\det(Y^-(x,t,k+0)\quad\Psi^+(x,t,k))\\&\qquad-Y^-(x,t,k+0)\det(Y^-(x,t,k-0)\quad\Psi^+(x,t,k))\\&\quad=\det(Y^-(x,t,k+0)\quad Y^-(x,t,k-0))\Psi^+(x,t,k)\\&\quad=\det(e(0,k+0)\quad e(0,k-0))\Psi^+(x,t,k).\end{aligned}$$

Comparing analytic properties of

$$\det(e(0,k+0)\quad e(0,k-0))\ \text{ and }\ \frac{2i\sqrt{X(k)}}{(k-\lambda_1)\cdots(k-\lambda_g)},\quad \lambda_l=\pi(\mathcal{P}_l),\quad D=\sum_{l=1}^g\mathcal{P}_l$$

as functions on the Riemann surface $\mathcal{X}$ we infer that they coincide. Therefore

$$h^-(x,t,k-0)-h^-(x,t,k+0)=f(k)\Psi^+(x,t,k),\quad k\in\gamma_j^+=\gamma_j\cap\overline{\Omega}_{\rm II}, \tag{4.6}$$

where

$$f(k)=2i\frac{\sqrt{\Pi_{j=0}^g(k-E_j)(k-\overline{E_j})}}{R_{\rm II}(k-0)R_{\rm II}(k+0)}\prod_{l=1}^g\frac{1}{k-\lambda_l}.$$

Taking into account analytic continuation of the relation (4.3) to $\Omega_{\rm II}$ we find that for $k\in\gamma_j^+$

$$[c(k-0)-c(k+0)]\Psi^+(x,t,k)=G(x,t,k-0)-G(x,t,k+0),$$

and as above

$$c(k-0)-c(k+0)=f(k),\quad k\in\gamma_j^+, \tag{4.7}$$

where $c(k\mp0)$ are the left and right boundary values of $c(k)$ on γ_j^+.

Let us consider the integral

$$J(x,y,t)=\frac{1}{2\pi}\int_{-\infty}^{\kappa_\Gamma}h^-(x,t,k)\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}\mathrm{d}k+\frac{1}{2\pi}\int_{\kappa_\Gamma}^{\infty}h^+(x,t,k)\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}\mathrm{d}k.$$

Using Eqs. (4.1)–(4.3) and (2.3) we find

$$J(x,y,t)=\begin{pmatrix}K_1\\K_2\end{pmatrix}(x,y,t)+\begin{pmatrix}0\\1\end{pmatrix}F_s(x+y,t)+\int_x^\infty\begin{pmatrix}-\overline{K}_2\\\overline{K}_1\end{pmatrix}(x,z,t)F_s(z+y,t)\mathrm{d}z,$$

where

$$\begin{aligned}F_s(x,t)&=\frac{1}{2\pi}\int_{-\infty}^{\kappa_\Gamma}\rho(k)\mathrm{e}^{\mathrm{i}k(x+y)+4\mathrm{i}k^2t}\mathrm{d}k+\frac{1}{2\pi}\int_{\kappa_\Gamma}^{\infty}r(k)\mathrm{e}^{\mathrm{i}k(x+y)+4\mathrm{i}k^2t}\mathrm{d}k\\&=\frac{1}{2\pi}\int_{-\infty}^{\kappa_\Gamma}c(k)\mathrm{e}^{\mathrm{i}k(x+y)+4\mathrm{i}k^2t}\mathrm{d}k+\frac{1}{2\pi}\int_{-\infty}^{\infty}r(k)\mathrm{e}^{\mathrm{i}k(x+y)+4\mathrm{i}k^2t}\mathrm{d}k.\end{aligned}$$

On the other hand, using estimates (3.7) and (3.20) of $F(x,t,z)$ and $G(x,t,z)$ for large k, taking into account (4.3), (4.5) and (4.6), and applying the Jordan lemma, we find

$$\begin{aligned}J(x,y,t)=&\mathrm{i}\sum_{\substack{k_j\in\Omega_\mathrm{I}\\ s_2^+(k_j)=0}}\mathrm{res}_{k_j}[h^+(x,t,k)\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}]+\mathrm{i}\sum_{\substack{z_j\in\Omega_\mathrm{II}\\ R_\mathrm{II}(z_j)=0}}\mathrm{res}_{z_j}[h^-(x,t,k)\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}]\\&-\frac{1}{2\pi}\int_{\Gamma_+}[h^-(x,t,k)-h^+(x,t,k)]\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}\mathrm{d}k-\frac{1}{2\pi}\sum_{\gamma_j^+\in\overline{\Omega}_\mathrm{II}}\int_{\gamma_j^+}[h^-(x,t,k-0)\\&-h^-(x,t,k+0)]\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}\mathrm{d}k\\=&-\sum_{k_j\in\Omega_\mathrm{I}}m_j^1\mathrm{e}^{\mathrm{i}k_jy+2\mathrm{i}k_j^2t}\Psi^+(x,t,k_j)-\sum_{z_j\in\Omega_\mathrm{II}}m_j^2\mathrm{e}^{\mathrm{i}z_jy+2\mathrm{i}z_j^2t}\Psi^+(x,t,z_j)\\&-\frac{1}{2\pi}\int_{\Gamma_+}c(k)\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}\Psi^+(x,t,k)\mathrm{d}k-\frac{1}{2\pi}\sum_{\gamma_j^+\in\overline{\Omega}_\mathrm{II}}\int_{\gamma_j^+}f(k)\mathrm{e}^{\mathrm{i}ky+2\mathrm{i}k^2t}\Psi^+(x,t,k)\mathrm{d}k.\end{aligned}$$

Finally, we have the following integral equations of the inverse scattering:

$$K_1(x,y,t)-\int_x^\infty\overline{K}_2(x,z,t)H(z+y,t)\mathrm{d}z=0\quad\text{for}\quad 0\leqslant x<y<\infty,\tag{4.8}$$

$$\overline{K}_2(x,y,t)+\overline{H}(x+y,t)+\int_x^\infty K_1(x,z,t)\overline{H}(z+y,t)\mathrm{d}z=0,\tag{4.9}$$

with the kernel

$$\begin{aligned}H(x,t)=&\sum_{k_j\in\Omega_\mathrm{I}}m_j^1\mathrm{e}^{\mathrm{i}k_jx+4\mathrm{i}k_j^2t}+\sum_{z_j\in\Omega_\mathrm{II}}m_j^2\mathrm{e}^{\mathrm{i}z_jx+4\mathrm{i}z_j^2t}+\frac{1}{2\pi}\sum_{\gamma_j^+\in\overline{\Omega}_\mathrm{II}}\int_{\gamma_j^+}f(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2t}\mathrm{d}k\\&+\frac{1}{2\pi}\left(\int_{-\infty}^{\kappa_\Gamma}+\int_{\Gamma_+}\right)c(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2t}\mathrm{d}k+\frac{1}{2\pi}\int_{-\infty}^{\infty}r(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2t}\mathrm{d}k.\end{aligned}\tag{4.10}$$

The coefficients m_j^1 and m_j^2 are given by

$$m_j^1=[\mathrm{i}s_1^+(k_j)\dot{s}_2^+(k_j)]^{-1},$$
$$m_j^2=p_1^-(z_j)[\mathrm{i}s_1^+(z_j)\dot{R}_{\mathrm{II}}(z_j)]^{-1}=p_2^-(z_j)[\mathrm{i}s_2^+(z_j)\dot{R}_{\mathrm{II}}(z_j)]^{-1}=-\mathrm{i}\ \mathrm{res}_{z_j}c(k). \tag{4.11}$$

Taking into account the jump relations (4.7) for $c(k)$ on γ_j^+ the kernel $H(x,t)$ can be written in the form (1.14). For further analysis of the kernel properties we rewrite this kernel (4.10) as follows:

$$H(x,t)=\sum_{k_j\in\Omega_{\mathrm{I}}} m_j^1\mathrm{e}^{\mathrm{i}k_jx+4\mathrm{i}k_j^2t}+\sum_{z_j\in\Omega_{\mathrm{II}}} m_j^2\mathrm{e}^{\mathrm{i}z_jx+4\mathrm{i}z_j^2t}+\frac{1}{2\pi}\sum_{\gamma_j^+\in\Omega_{\mathrm{II}}^-}\int_{\gamma_j^+} f(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2t}\mathrm{d}k$$
$$+\frac{1}{2\pi}\int_{-\infty}^{\kappa_\Gamma}\rho(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2t}\mathrm{d}k+\int_{\Gamma_+} c(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2t}\mathrm{d}k+\frac{1}{2\pi}\int_{\kappa_\Gamma}^{\infty} r(k)\mathrm{e}^{\mathrm{i}kx+4\mathrm{i}k^2t}\mathrm{d}k, \tag{4.12}$$

using the relation

$$c(k)+r(k)=\rho(k). \tag{4.13}$$

For any fixed $t\in\mathbb{R}_+$ the function $H(x,t)$ will be rapidly decreasing for $x\to\infty$, if (3.17) and (4.13) are fulfilled. Indeed, using the method of steepest descent and integration by parts we see that $H(x,t)=\mathrm{O}(x^{-\infty})$ because $c(k)$, $r(k)$, $\rho(k)$ are C^∞ away from self-intersection points κ_j and, according to their asymptotic behavior, they vanish at infinity as well as their derivatives of any order. The integrated terms vanish at the points $k=\kappa_j\mp 0$ because of relations (3.17) on jumps of $\rho(k)$ and their derivatives and

$$\frac{\mathrm{d}^m}{\mathrm{d}k^m}(\rho(k)-c(k)-r(k))\bigg|_{k=\kappa_\Gamma}=0,\quad m=0,1,2,\ldots, \tag{4.14}$$

which follows from (4.13). The contribution of the stationary point $[k_{\mathrm{st}}=-(x+y)/(8t)\in\mathbb{R}_-]$ is given by the Schwartz type function $\rho(k)$. Hence $H(x,t)$ is rapidly decreasing for $x\to\infty$ for any fixed t.

On the other hand, using (4.9) for $y=x$ one can prove that $H(x,t)\in C^\infty(\mathbb{R}_+\times\mathbb{R}_+)$ and is of Schwartz type, $H(x,t)=\mathrm{O}(x^{-\infty})$, as $x\to\infty$, since $K_1(x,y,t)$ and $K_2(x,y,t)$ belong to $C^\infty(\mathbb{R}_+\times\mathbb{R}_+\times\mathbb{R}_+)$ and are of Schwartz type also as $x+y\to\infty$, and Eq. (4.9) is a Volterra integral equation with respect to the kernel $H(x,t)$. Using the method of steepest descent and integrating by parts as above, taking into account the discontinuity of $\rho(k)$ at the points $\kappa_j<\kappa_\Gamma$ and its vanishing with all derivatives at the point κ_Γ we find that relations (3.17) must be fulfilled because $H(x,t)=\mathrm{O}(x^{-\infty})$.

Remark: For $t=0$ the kernel $H(x,t)|_{t=0}$ coincides with the kernel

$$H_0(x)=\sum_{k_j\in\mathbb{C}_+} m_j^1\mathrm{e}^{\mathrm{i}k_jx}+\frac{1}{2\pi}\int_{-\infty}^{\infty} r(k)\,\mathrm{e}^{\mathrm{i}kx}\mathrm{d}k,$$

because in this case ($t=0$) the integrals over the boundary of Ω_{II} can be evaluated by using jump relations (4.7) and the residues of the function $c(k)$. After integration we find that $H(x,0)=H_0(x)$. Then Marchenko integral equations with kernel $H_0(x)$ yield that $q(x,0)=u(x)$.

Definition (scattering data): Now it is natural to introduce the set

$$\mathcal{R}=\{k_1,\ldots,k_n\in\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{II}};\ z_1,\ldots,z_m\in\Omega_{\mathrm{II}};\ \ r(k),\rho(k),R_{\mathrm{II}}(k)\} \tag{4.15}$$

and to call $\mathcal{R}$ the *scattering data* for the compatible system of differential equations (1.7) and (1.8) with $q(x,t)$ satisfying (1.1)–(1.6).

The kernel $H(x,t)$ of the Marchenko equations is completely defined by the scattering data $\mathcal{R}$ because the missing coefficients m_j^1, m_j^2 of (4.11) and the functions $f(k)$, $c(k)$ can be determined from scattering data values.

We remind that both finite-gap functions $\alpha(t)$, $\beta(t)$ and the corresponding Riemann surface $\mathcal{X}$ are given. Therefore, the function

$$\Delta(k)=\det \mathcal{E}(t,k)$$

is also known. It immediately follows from properties proved above that scattering data $\mathcal{R}$ satisfy the following conditions.

Condition A:

(1) $r(k)\in\mathcal{S}(\mathbb{R})$.
(2) $r(k)=b(k)/a(k)$, where $b(k):=-s_2^-(k)$ is analytic in $k\in\mathbb{C}_-$, and $a(k):=s_2^+(k)$ is analytic for $k\in\mathbb{C}_+$ and has the form

$$a(k)=\prod_{j=1}^{n}\frac{k-k_j}{k-\overline{k_j}}\exp\left[\frac{\mathrm{i}}{2\pi}\int_{-\infty}^{\infty}\frac{\log(1+|r(s)|^2)\mathrm{d}s}{s-k}\right],\quad k\in\mathbb{C}_+.$$

Condition B:

(1) $\rho(k),R_{\mathrm{II}}(k)\in C^\infty(\mathbb{R}\backslash(\Sigma_\kappa\cap\mathbb{R}))$ and $\rho(k)\equiv 0$ for $k\in[\kappa_\Gamma,\infty)$.
(2) $R_{\mathrm{II}}(k)$ is analytic in $k\in\Omega_{\mathrm{II}}$, where it has a finite number of zeros $z_1,\ldots,z_m$, each of multiplicity 1.
(3) $\rho(k)$ and $R_{\mathrm{II}}(k)$ are connected by

$$1+|\rho(k)|^2=\frac{\Delta(k)}{|R_{\mathrm{II}}(k)|^2},\quad k\in\mathbb{R}.$$

(4) $R_{\mathrm{II}}(k)=\sqrt{\Delta(k)}\,\mathrm{e}^{-\mathrm{i}\nu(k)}$ for $k\in[\kappa_\Gamma,\infty)$, where $\nu(k)$ is a real-valued function with analytic continuation to $\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{IV}}$.
(5) $\rho(k)$ and all its derivatives have jumps at the real points $\kappa_j<\kappa_\Gamma$:

$$\rho^{(l)}(\kappa_j-0)-\rho^{(l)}(\kappa_j+0)=f^{(l)}(\kappa_j),\quad l=0,1,\ldots,$$

where $f(k)$ is defined for $k\in\gamma_j^+=\gamma_j\cap\overline{\Omega}_{\mathrm{II}}$ by

$$f(k)=2\mathrm{i}\frac{\sqrt{\Pi_{j=0}^{g}(k-E_j)(k-\overline{E_j})}}{R_{\mathrm{II}}(k-0)R_{\mathrm{II}}(k+0)}\prod_{l=1}^{g}\frac{1}{k-\lambda_l},\quad \lambda_l=\pi(\mathcal{P}_l).$$

Condition C:

(1) The function $c(k)=\rho(k)-r(k)$ extends analytically to Ω_{II}, where it has a finite number of poles $z_1,\ldots,z_m$, all simple, and satisfies the jump relations:

$$c(k-0)-c(k+0)=f(k),\quad k\in\gamma_j^+.$$

One can think that properties A–C are characteristic, i.e., that they are also sufficient for numbers $k_1,\ldots,k_n$, $z_1,\ldots,z_m$ and functions $r(k)$, $\rho(k)$, $R_{\mathrm{II}}(k)$ to be the scattering data of a compatible system of x- and t-equations (1.7) and (1.8) with $q(x,t)$ satisfying (1.1)–(1.6).

Anyway, formula (1.11) and Marchenko integral equations (4.8) and (4.9) represent a solution of the focusing nonlinear Schrödinger equation if the kernel (4.10) is sufficiently smooth and rapidly decreasing as $x\to\infty$. It follows from statements of the next section.

V. GENERATION OF ASYMPTOTIC SOLITONS BY BOUNDARY DATA

Let $\mathcal{R}=\{k_1,\ldots,k_n\in\Omega_{\mathrm{I}}\cup\Omega_{\mathrm{II}};\ z_1,\ldots,z_m\in\Omega_{\mathrm{II}};r(k),\rho(k),R_{\mathrm{II}}(k)\}$ be data satisfying conditions A–C. Then the following statements are true.

Statements: (1) The xt-integral equation

$$K(x,y,t)+\mathcal{H}(x+y,t)+\int_x^\infty K(x,z,t)\mathcal{H}(z+y,t)\mathrm{d}z=0,$$
$$0\leqslant x<y<\infty,\quad 0\leqslant t<\infty, \tag{5.1}$$

with the 2×2 matrix kernel

$$\mathcal{H}(x,t)=\begin{pmatrix} 0 & H(x,t)\\ -\overline{H}(x,t) & 0\end{pmatrix},$$

where $H(x,t)$ is given by (4.10), is uniquely solvable in the space $L^1(x,\infty)$ for any $x\geqslant 0$ and $t\geqslant 0$.

(2) The solution $K(x,y,t)$ belongs to $C^\infty(\mathbb{R}_+\times\mathbb{R}_+\times\mathbb{R}_+)$, it and all its derivatives decrease faster than any negative power of $x+y$, for $x+y\to\infty$, and t fixed.

(3) The matrix

$$\Psi(x,t,k)=\left[\mathrm{e}^{-\mathrm{i}kx\sigma_3}+\int_x^\infty K(x,y,t)\mathrm{e}^{-\mathrm{i}ky\sigma_3}\mathrm{d}y\right]\mathrm{e}^{-2\mathrm{i}k^2t\sigma_3}$$

satisfies the symmetry condition

$$\Psi(x,t,k)=\sigma_2\overline{\Psi}(x,t,k)\sigma_2\quad\text{for}\quad k\in\mathbb{R}$$

and is a solution of the x-equation (1.7) with $Q(x,t)$ given by

$$Q(x,t)=\sigma_3K(x,x,t)\sigma_3-K(x,x,t). \tag{5.2}$$

(4) $\Psi(x,t,k)$ is a solution of the x- and t-equations constructed from the matrix $Q(x,t)$ and its derivative $Q_x(x,t)$, using Eqs. (5.2), (1.7), (1.8) and (2.4).

Statement 1 follows from the following lemma about the solvability of the xt-integral equation.

Lemma 2: Let $\mathcal{R}$ be data satisfying conditions A–C. *Then, the xt-integral equation (5.1) is uniquely solvable in the space $L^1(x,\infty)$.*

Proof: Under conditions A–C the integral operator of the xt-integral equation is compact in the space $L^1(x,\infty)$. Then, by Fredholm theory the xt-integral equation has a unique solution if the homogeneous equation has no nonzero solution. If a nonzero solution does exist in $L^1(x,\infty)$, in view of the homogeneity of the integral equation, it is bounded, hence it belongs to $L^2(x,\infty)$. The integral operator is clearly skew-Hermitian in $L^2(x,\infty)$, so we obtain a contradiction, because the only solution in this case is zero. □

We omit proofs of the remaining statements because they are almost the same as in Ref. 16. Now let us sketch the proof of the main result.

Sketch of proof of Theorem 1: For study of the asymptotic behavior of the solution $q(x,t)$ we use the integral equation (5.1), which is uniquely solvable in the space $L^1(x,\infty)$ and, due to the statements above, represents a C^∞ and fast decreasing function $q(x,t)$. We carry out the asymptotic analysis of the integral equation by reducing the problem to degenerated integral equations, obtaining a determinant formula for the solution and its asymptotics as $t\to\infty$.

Taking into account properties A–C and using the method of steepest descent and integration by parts we come to the following decomposition of the scalar kernel $H(x,t)$ as $t\to\infty$:

$$H(x,t)=H_N(x,t)+H_1(x,t)+R_0(x,t)+R_1(x,t), \tag{5.3}$$

where $H_N(x,t)$ is a degenerate one:

$$H_N(x+y,t)=\mathrm{e}^{-(a+\mathrm{i}b)(\xi+\eta)}\sum_{m=0}^{N-1}\frac{d_m(t)}{m!t^{m+3/2}}(\xi+\eta)^m,$$

$$\xi=x-4bt,\quad \eta=y-4bt.$$

$R_0(x+y,t)$ is given in terms of $\rho(k)$ by

$$R_0(x+y,t)=\frac{1}{\sqrt{16\pi t}}\rho\left(-\frac{x+y}{8t}\right)\exp\left[\frac{\mathrm{i}\pi}{4}-4\mathrm{i}t\left(\frac{x+y}{8t}\right)^2\right].$$

$H_1(x+y,t)$ and $R_1(x+y,t)$ admit the estimates

$$|H_1(x+y,t)|\leqslant C_1|\xi+\eta|^N\ t^{-N-3/2}\mathrm{e}^{-a(\xi+\eta)},$$

$$|R_1(x+y,t)|\leqslant C_2t^{-3/2}\left|\rho''\left(-\frac{x+y}{8t}\right)\right|.$$

Let $\hat{H}$ be the integral operator which acts in $L^2(x,\infty)$ by

$$(\hat{H}f)(y)=\int_x^\infty\begin{pmatrix}0 & H(y+z,t)\\ -\overline{H}(y+z,t) & 0\end{pmatrix}\begin{pmatrix}f_1(y)\\ f_2(y)\end{pmatrix}\mathrm{d}z.$$

Then the Marchenko integral equations take the form

$$\begin{gathered}(I+\hat{H})K=G,\\ K=(K_1\ \ K_2),\quad G=(0\ \ \overline{H}).\end{gathered}\tag{5.4}$$

Under conditions A–C, (5.4) has a unique solution $\hat{H}$ in $L^2(x,\infty)$ and

$$\|(I+\hat{H})^{-1}\|\leqslant 1.$$

Let $\hat{H}_N$, $\hat{R}_0$, $\hat{H}_1$, $\hat{R}_1$ be the corresponding integral operators in $L^2(x,\infty)$ given by the kernels H_N, R_0, H_1, R_1. We look for a solution of (5.4) in the form

$$K=\tilde{K}+\psi,$$

where $\tilde{K}$ satisfies

$$\begin{gathered}(I+\hat{H}_N+\hat{R}_0)\tilde{K}=G_N+G_0,\\ G_N=(0\ \ \overline{H}_N),\quad G_0=(0\ \ \overline{R}_0).\end{gathered}\tag{5.5}$$

Then, $\psi=K-\tilde{K}$ satisfies

$$(I+\hat{H})\psi=G_1-\hat{H}_1\tilde{K}-\hat{R}_1\tilde{K},$$

$$G_1=(0\ \ \overline{H}_1+\overline{R}_1).$$

The last equation yields the estimate

$$\|\psi\|=\|K-\tilde{K}\|\leqslant C(N)t^{-1/2+\epsilon}$$

in the domain $\Omega_N(t)$ with $0<\epsilon<\frac{1}{2}$. This estimate allows us to consider below the integral equation (5.5) instead of (5.4).

The next step is as follows. Let $L=(L_1(x,y,t)\quad L_2(x,y,t))$ be a solution of

$$(I+\hat{R}_0)L=G_R,$$
$$G_R=(0\quad \overline{R}_0). \tag{5.6}$$

Then, the solution $\tilde{K}$ of (5.5) can be written in the form

$$\tilde{K}=L+(I+\hat{Q})M, \tag{5.7}$$

where $I+\hat{Q}=(I+\hat{R}_0)^{-1}$, and $\hat{Q}$ is an integral operator. The kernel $Q(y,z)$ of this operator has an explicit representation via the vector-function $L(y,z)$. The substitution of (5.7) into (5.5) yields a degenerate integral equation

$$M+\hat{H}_N(I+\hat{Q})M=G_N-\hat{H}_N L. \tag{5.8}$$

The next decisive step is that (5.6) can be explicitly solved in the limit $t\to\infty$. Namely, it is possible to show[26] that for $t\to\infty$

$$\|L_1(x,y,t)-L_1^{(\infty)}(x,y,t)\|_{C([X,\infty))}=o(1),$$
$$\|L_2(x,y,t)-L_2^{(\infty)}(x,y,t)\|_{L^2(X,\infty)}=o(1),\quad t\to\infty,$$

where

$$L_1^{(\infty)}(x,y,t)=-\frac{2}{\sqrt{\pi}}e^{\pi i/4}\int_X^\infty N(X,Z)\rho(-Z-Y)\exp(4it[X^2-Y^2+2(X-Y)Z])dZ,$$

$$L_2^{(\infty)}(x,y,t)=\frac{1}{\sqrt{t}}N(X,Y)\exp[4it(X+Y)^2],\quad X=\frac{x}{t},\quad Y=\frac{y}{t},$$

with

$$N(X,Y)=\frac{1}{4\sqrt{\pi}}e^{\pi i/4}\rho(-X-Y)\exp\left(\frac{i}{2\pi}\int_X^\infty\frac{\ln[1+|\rho(-X-S)|^2]}{S-Y-i0}dS\right).$$

This explicit formula and the degenerate integral equation (5.8) allow us to complete the proof of Theorem 1 in the same way as in Ref. 26. □

Sketch of proof of Theorem 2: In the case of Theorem 2, when $\min_{0\leqslant j\leqslant g}\mathrm{Re}\,E_j>0$, the kernel $H(x,t)$ has the form

$$H(x,t)=\sum_{k_j\in\Omega_{\mathrm{I}}}m_j^1e^{ik_jx+4ik_j^2t}+\sum_{z_j\in\Omega_{\mathrm{II}}}m_j^2e^{iz_jx+4iz_j^2t}+\frac{1}{2\pi}\left(\int_{-\infty}^{\kappa_\Gamma}+\int_{\Gamma_+}\right)c(k)e^{ikx+4ik^2t}dk$$
$$+\frac{1}{2\pi}\int_{-\infty}^{\infty}r(k)e^{ikx+4ik^2t}dk.$$

Therefore the corresponding decomposition as $t\to\infty$ will be similar to (5.3), but now the degenerate kernel has an ordinary solitonic form:

$$H_N(x,t)=\sum_{k_j\in\Omega_{\mathrm{I}}} m_j^1 \mathrm{e}^{\mathrm{i}k_j x+4\mathrm{i}k_j^2 t}+\sum_{z_j\in\Omega_{\mathrm{II}}} m_j^2 \mathrm{e}^{\mathrm{i}z_j x+4\mathrm{i}z_j^2 t}.$$

It is easy to see that such a kernel generates

(i) solitons which move to the right, i.e., away from the boundary (they correspond to the eigenvalues $k_j\in\Omega_{\mathrm{I}}$ and $z_j\in\Omega_{\mathrm{II}}$ with negative real part),
(ii) and other solitons which move to the left (they correspond to the eigenvalues $k_j\in\Omega_{\mathrm{I}}$ with positive real part) and which are absorbed by the boundary $x=0$ in finite time.

The proof of Theorem 2 we carry out by the same approach as above, using Ref. 27. □

APPENDIX: FINITE-GAP FUNCTIONS

Let $\mathcal{X}$ be the hyperelliptic Riemann surface of genus g given by the equation

$$z^2=\prod_{j=0}^{g}(k-E_j)(k-\overline{E}_j),$$

where $\mathrm{Im}\,E_j>0$, $E_i\neq E_j$ for $i\neq j$. This Riemann surface is a double covering of the complex k-plane $\overline{\mathbb{C}}=\mathbb{C}\cup\{\infty\}$ obtained by gluing two copies of $\overline{\mathbb{C}}$ along cuts γ_j whose endpoints are the $2g+2$ branch points E_j, $\overline{E}_j$. Let

$$\pi:\mathcal{X}\to\overline{\mathbb{C}}$$

be the canonical projection on the k-plane, and let $k=k(\mathcal{P})=\pi(\mathcal{P})$ be the image of a point $\mathcal{P}\in\mathcal{X}$. Each point $k\in\overline{\mathbb{C}}$ has two preimages on $\mathcal{X}$, except for the $2g+2$ branch points. Denote the preimage of $k=\infty$ on the upper (lower) sheet $\mathcal{X}^+$ ($\mathcal{X}^-$) of $\mathcal{X}$ by $\mathcal{P}=\infty^+$ ($\mathcal{P}=\infty^-$). We fix the branch of the square root by the asymptotic behavior

$$\sqrt{\prod_{j=0}^{g}(k-E_j)(k-\overline{E}_j)}=\pm k^{g+1}[1+\mathrm{O}(k^{-1})],\qquad k\to\infty^{\pm}\in\mathcal{X}_{\pm}. \tag{A1}$$

Let $D=\mathcal{P}_1+\cdots+\mathcal{P}_g$ be a nonspecial integral divisor on $\mathcal{X}\backslash\{\infty^+,\infty^-\}$ and let $\phi(t,\mathcal{P})$ be the Baker–Akhiezer vector function on $\mathcal{X}$ whose divisor of poles is D:

(i) $\phi(t,\mathcal{P})$ is meromorphic on $\mathcal{X}\backslash\{\infty^+,\infty^-\}$ with divisor of poles D;
(ii) the product $\phi(t,\mathcal{P})\exp\{2\,\mathrm{i}k^2(\mathcal{P})t\}$ is analytic at $\infty^{\pm}$.

The Baker–Akhiezer function satisfies the following equation:[28]

$$\phi_t+2\mathrm{i}k^2\sigma_3\phi=\hat{Q}_g(t,k)\phi, \tag{A2}$$

where $k=k(\mathcal{P})$, $\mathcal{P}\in\mathcal{X}$, and

$$\hat{Q}_g(t,k)=2kQ_g(t)-\mathrm{i}(Q_g^2(t)+Q_{1g}(t))\sigma_3$$

$$Q_g(t)=\begin{pmatrix}0 & \alpha(t)\\ -\overline{\alpha}(t) & 0\end{pmatrix},\quad Q_{1g}(t)=\begin{pmatrix}0 & \beta(t)\\ -\overline{\beta}(t) & 0\end{pmatrix}.$$

Definition: The functions $\alpha(t)$ and $\beta(t)$ are called *finite-gap* if there exists a Baker–Akhiezer vector-function on a hyperelliptic Riemann surface $\mathcal{X}$ of finite genus which is a solution of (A2).

The function $\phi(t,\mathcal{P})$ can be written[28] through Riemann theta functions. To establish this representation we need to define several notions.

The first is a homology basis on the hyperelliptic Riemann surface $\mathcal{X}$. It is a system of equivalent classes of closed, noncontractible, oriented contours on $\mathcal{X}$. Two contours are considered equivalent if their difference (the union with the orientation of one contour reversed) forms the oriented boundary of a surface in $\mathcal{X}$. The equivalence classes will be referred to by representatives. Two contour representatives of the same class are called homologous cycles. The integral of any meromorphic differential without residues gives the same value over any two homologous cycles. The system of homology classes is a linear space with integer coefficients $H_1(\mathcal{X},\mathbb{Z})$. The zero element is the equivalence class of contractible oriented loops on $\mathcal{X}$. It is a topological result that this space has dimension $2g$. Let c_1 and c_2 be two oriented closed contours on $\mathcal{X}$. The intersection number $c_1\cdot c_2$ is defined as the number of times c_2 crosses c_1 from the right of c_1, minus the number of times c_2 crosses c_1 from the left. The intersection number is a skew-symmetric bilinear form on $H_1(\mathcal{X},\mathbb{Z})$. A *canonical homology basis* is a symplectic basis, i.e., a basis $\{a_1,\ldots,a_g;b_1,\ldots,b_g\}$ of $H_1(\mathcal{X},\mathbb{Z})$ such that

$$a_j\cdot a_k=b_j\cdot b_k=0,\quad a_j\cdot b_l=\delta_{jl}.$$

This does not make the basis unique, even up to homology equivalence of class representatives. Any linear transformation with integer coefficients of the basis elements will preserve the intersection number but modify the particular basis. One can select a particular homology basis in order to simplify the formulas that we will write down, but the results themselves, by uniqueness, are independent of this choice. Once the homology cycles a_j are fixed, the dual cycles b_j are determined by the intersection relation up to transformation of the form:

$$b_j\to b_j+\sum_{l=1}^{g} s_{jl}a_l,$$

where the s_{jl}'s are integers and $s_{lj}=s_{jl}$.

The next ingredient we need are the *normalized holomorphic differentials, Riemann theta functions, Abel map and Jacobian variety*. The space of *holomorphic differentials* on $\mathcal{X}$ has dimension g, with basis $\{\omega_1(\mathcal{P}),\ldots,\omega_g(\mathcal{P})\}$ that can be written

$$\omega_j(\mathcal{P})=\frac{\Sigma_{i=0}^{g}c_{ji}k^i(\mathcal{P})}{X_{\mathcal{X}}(\mathcal{P})}\,\mathrm{d}k(\mathcal{P}),$$

where $X_{\mathcal{X}}(\mathcal{P})$ is a lifting of the function $X(k)$ from the cut plane to the Riemann surface $\mathcal{X}$: if $\mathcal{P}$ is on the first sheet of $\mathcal{X}$, then $X_{\mathcal{X}}(\mathcal{P})=X(k(\mathcal{P}))$, and if $\mathcal{P}$ is on the second sheet of $\mathcal{X}$, then $X_{\mathcal{X}}(\mathcal{P})=-X(k(\mathcal{P}))$. The coefficients c_{jl} are uniquely determined by the normalization relations:

$$\int_{a_l}\omega_j(\mathcal{P})=\delta_{jl}.$$

These *normalized holomorphic differentials* define the b-period matrix B by

$$B_{jl}=\int_{b_l}\omega_j(\mathcal{P}).$$

This matrix is symmetric with imaginary part positive definite.

Associated with B there is a *Riemann theta function* Θ defined by the Fourier series

$$\Theta(u_1,\ldots,u_g)=\sum_{\mathbf{n}\in\mathbb{Z}^g}\exp\{\pi\mathrm{i}(B\mathbf{n},\mathbf{n})+2\pi\mathrm{i}(\mathbf{n},\mathbf{u})\}.$$

where $\mathbf{u}\in\mathbb{C}^g$ and $(\mathbf{n},\mathbf{u})=n_1u_1+\cdots+n_gu_g$.

Let $\{\mathbf{e}_j|j=1,\ldots,g\}$ be the standard basis of $\mathbb{C}^g$ and let $B\mathbf{e}_j$ be the jth column of the matrix B. Let $\Lambda\subset\mathbb{C}^g$ be the lattice generated by the vectors $\mathbf{e}_j$ and $B\mathbf{e}_j$ for $j=1,\ldots,g$. Then, by definition, the *Jacobian variety* of $\mathcal{X}$ is the complex torus $\mathrm{Jac}\mathcal{X}=\mathbb{C}^g/\Lambda$. The *Abel map* $\mathbf{A}:\mathcal{X}\to\mathrm{Jac}\mathcal{X}$ is defined by

$$A_j(\mathcal{P},\mathcal{P}_0)=\int_{\mathcal{P}_0}^{\mathcal{P}}\omega_j(\mathcal{Q}),\quad j=1,\ldots,g,$$

where $\mathcal{P}_0\in\mathcal{X}$ is arbitrarily fixed, and $\mathcal{Q}$ is the integration variable. The *Abel map* is extended by linearity to integral divisors. If D is a divisor of degree 0, then $\mathbf{A}(D,\mathcal{P}_0)$ do not depend on the choice of $\mathcal{P}_0$. Abel's theorem states that if $D=D^+-D^-$ is the divisor of a meromorphic function on $\mathcal{X}$ with D^+, D^- the divisors of zeros and poles, then $\mathbf{A}(D,\mathcal{P}_0)=0$ in $\mathrm{Jac}\mathcal{X}$. Besides, for any nonspecial integral divisor $D=\mathcal{P}_1+\cdots+\mathcal{P}_g$ of degree g there exists a vector $\mathbf{w}(D)$ such that the Riemann theta function $\Theta[\mathbf{A}(\mathcal{P},\mathcal{P}_0)+\mathbf{w}(D)]$ defined on $\mathcal{X}$ cut along of the cycles a_j and b_j has precisely g zeros which are the points $\mathcal{P}_j$. The vector $\mathbf{w}(D)$ is defined by

$$\mathbf{w}(D)=-\mathbf{A}(D,\mathcal{P}_0)-\mathbf{K},$$

where the Riemann constant $\mathbf{K}=(K_1,\ldots,K_g)\in\mathbb{C}^g/\Lambda$ is defined by

$$K_j=\frac{1}{2}-\frac{B_{jj}}{2}+\sum_{\substack{l=1\\ l\neq j}}^{g}\int_{a_l}\left(\int_{\mathcal{P}_0}^{\mathcal{Q}}\omega_j\right)\omega_l.$$

Next, we consider on $\mathcal{X}$ a meromorphic Abel differential Ω which is holomorphic except at ∞^+ and ∞^-, where it has the behavior

$$\Omega(\mathcal{P})=\pm\mathrm{d}(2k^2(\mathcal{P}))+\mathrm{O}\left(\frac{\mathrm{d}k(\mathcal{P})}{k^2(\mathcal{P})}\right),\quad \mathcal{P}\to\infty^{\pm},$$

and which is normalized by the conditions

$$\int_{a_j}\Omega(\mathcal{Q})=0,\quad j=1,2,\ldots,g.$$

Note that $\Omega(\mathcal{P})$ has no residues. Let $\mathbf{V}=(V_1,\ldots,V_g)\in\mathbb{C}^g$ defined by

$$V_j=\frac{1}{2\pi\mathrm{i}}\int_{b_j}\Omega.$$

Finally we consider the *Abel integral* $L(\mathcal{P})$ *of logarithmic kind*, which is characterized by the following asymptotics:

$$\mathrm{d}L(\mathcal{P})=\pm\mathrm{d}\log k(\mathcal{P})+\mathrm{O}\left(\frac{\mathrm{d}k(\mathcal{P})}{k^2(\mathcal{P})}\right),\quad \mathcal{P}\to\infty^{\pm},$$

and by the normalization conditions:

$$\int_{a_j}\mathrm{d}L(\mathcal{Q})=0,\quad j=1,\ldots,g.$$

Then, the *Baker–Akhiezer vector function* $\phi(t,\mathcal{P})$ has the form

$$\phi(t,\mathcal{P})=\chi(t,\mathcal{P})\exp\left(-\mathrm{i}t\int_{E_g}^{\mathcal{P}}\Omega(\mathcal{Q})\right),$$

where $\chi(t,\mathcal{P})=(\chi_1(t,\mathcal{P})\ \ \chi_2(t,\mathcal{P}))$ with

$$\chi_1(t,\mathcal{P})=\frac{\Theta[\mathbf{A}(\mathcal{P},\mathcal{P}_0)+\mathbf{w}(D)+t\mathbf{V}]}{\Theta[\mathbf{A}(\infty^+,\mathcal{P}_0)+\mathbf{w}(D)+t\mathbf{V}]}\times\frac{\Theta[\mathbf{A}(\infty^+,\mathcal{P}_0)+\mathbf{w}(D)]}{\Theta[\mathbf{A}(\mathcal{P},\mathcal{P}_0)+\mathbf{w}(D)]}\mathrm{e}^{\mathrm{i}\Omega_0 t},$$

$$\chi_2(t,\mathcal{P})=2\mathrm{i}\frac{\Theta[\mathbf{A}(\mathcal{P},\mathcal{P}_0)+\mathbf{w}(D)+t\mathbf{V}-2\mathbf{A}(\infty^-,\mathcal{P}_0)]}{\Theta[\mathbf{w}(D)+t\mathbf{V}-\mathbf{A}(\infty^-,\mathcal{P}_0)]}\times\frac{\Theta[\mathbf{A}(\infty^-,\mathcal{P}_0)+\mathbf{w}(D)]}{\Theta[\mathbf{A}(\mathcal{P},\mathcal{P}_0)+\mathbf{w}(D)]}\mathrm{e}^{L(\mathcal{P})}\mathrm{e}^{-\mathrm{i}\Omega_0 t}.$$

The constant Ω_0 is defined by the relations

$$\int_{\mathcal{P}_0}^{\mathcal{P}}\Omega(\mathcal{Q})\mp\Omega_0=\pm 2k^2(\mathcal{P})+\mathrm{O}\left(\frac{1}{k(\mathcal{P})}\right),\quad \mathcal{P}\to\infty^{\pm}.$$

For any $t\in\mathbb{R}$ the vector function $\chi(t,\mathcal{P})$ is bounded on $\mathcal{X}$ except at the points of the divisor $D=\mathcal{P}_1+\cdots+\mathcal{P}_g$. Therefore, $\phi(t,\mathcal{P})$ is the Floquet–Bloch solution of the equation (A2). This representation for Baker–Akhiezer vector-function was first derived by A. R. Its in 1975. The asymptotic expansions of the Baker–Akhiezer function at $\infty^{\pm}$ and Eq. (A2) give representations for the finite-gap functions $\alpha(t)$ and $\beta(t)$ through theta functions from which their periodicity in $t\in\mathbb{R}$, or, in general, their quasi-periodicity if $g\geqslant 2$ is derived.

Lax equations scattering and KdV

P. C. Sabatier[a)]
Laboratoire de Physique Mathmatique et Thorique, Universit des Sciences et Techniques du Languedoc, Place Eugne Bataillon, 34095—Montpellier, France

(Received 5 April 2003; accepted 9 April 2003)

The study of the Korteveg–de Vries (KdV) equation is considered as a special chapter of potential scattering where the dynamic scattering equation is a set of coupled ''Lax'' equations. With this approach, all points of view and all tools of potential scattering have their counterpart in the standard inverse scattering transform, which appears as a straightforward consequence. If the approach is transposed to the quarterplane problem, it shows a generalization to KdV of the solutions obtained by Fokas in the linearized KdV problem, but unfortunately the last step is iterative and complicated. The method can also be used to study NLS. [DOI: 10.1063/1.1589179]

I. SCATTERING BY LAX EQUATIONS

We consider a special chapter of potential scattering where the ''dynamic equation'' is a set of coupled (Lax) equations. We already wrote down basic properties, transformation properties, consistency relations, and explicit expansions of solutions.[1–4] Here we recall the approach and we show how it can be applied to boundary value problems.

The nonlinear KdV equation

$$\frac{\partial V}{\partial t}+\frac{1}{4}V'''-\frac{3}{2}VV'=0, \tag{1.1}$$

where ''prime'' denotes x-derivative, is the condition for the existence of continuous second derivatives of two-vector solutions F of two linear (Lax) equations

$$\frac{\partial F}{\partial x}=\mathbf{M}F, \quad \frac{\partial F}{\partial t}=\mathbf{N}F, \tag{1.2}$$

where the matrices $\mathbf{M}$ and $\mathbf{N}$ depend on k, x, t, as follows:

$$\mathbf{M}=\mathbf{M}_0+\mathbf{V}(x,t)=:\begin{pmatrix} 0 & 1 \\ -k^2 & 0 \end{pmatrix}+\begin{pmatrix} 0 & 0 \\ V(x,t) & 0 \end{pmatrix}, \tag{1.3}$$

$$\mathbf{N}=k^2\mathbf{M}_0+\begin{pmatrix} V_1 & V_0 \\ k^2V_0+V_2 & -V_1 \end{pmatrix}=:k^2\mathbf{M}_0+\mathbf{W}, \tag{1.4}$$

$$V_0=\tfrac{1}{2}V(x,t), \quad V_1=-\tfrac{1}{4}V', \quad V_2=\tfrac{1}{2}V^2-\tfrac{1}{4}V''. \tag{1.5}$$

It is clear from (1.2) that if F exists, it has the form

$$F=\begin{pmatrix} f \\ f' \end{pmatrix}. \tag{1.6}$$

a)Electronic mail: sabatier@lpm.univ-montp2.fr

We note that since **M** and **N** have zero-trace, the matrix determinant $\det(F,G)$ of two solutions of (1.2) does not depend on x or t. For a given function $V(x,t)$, which is solution of (1.1), the space $\mathcal{F}$ of solutions F of (1.2) is two-dimensional. Assuming now on demand that $V(x,t)$ goes to zero "rapidly enough" as $x\to\pm\infty$ with fixed t or $t\to\pm\infty$ with fixed x, we can define "scattering problems" if we can construct "Jost solutions" F with given asymptotic properties, which are written here in terms of the function

$$E(k,x,t)=\begin{pmatrix}1\\ ik\end{pmatrix}\exp[i(kx+k^3t)]=\begin{pmatrix}e\\ e'\end{pmatrix}:$$

$$\overleftarrow{F}(k,x,t)-E(k,x,t)=o(|x|^{-1}) \quad \text{fixed } t,\ x\to\infty, \tag{1.7}$$

$$\hat{F}(k,x,t)-E(-k,x,t)=o(|x|^{-1}) \quad \text{fixed } t,\ x\to-\infty, \tag{1.8}$$

$$\vec{F}(k,x,t)-E(k,x,t)=o(|t|^{-1}) \quad \text{fixed } x,\ t\to\infty, \tag{1.9}$$

$$\check{F}(k,x,t)-E(-k,x,t)=o(|t|^{-1}) \quad \text{fixed } x,\ t\to-\infty. \tag{1.10}$$

For $k\neq 0$, $F(k,)$ and $F(-k,)$ are a basis in the space $\mathcal{F}$, so that

$$\hat{F}(k,)=\hat{\eta}(k)\overleftarrow{F}(-k,)+\hat{\eta}(k)\overleftarrow{F}(k,), \tag{1.11}$$

$$\overleftarrow{F}(k,)=\eta(k)\vec{F}(k,)+\xi(k)\vec{F}(-k,), \tag{1.12}$$

$$\check{F}(k,)=\check{\eta}(k)\vec{F}(-k,)+\check{\xi}(k)\vec{F}(k,). \tag{1.13}$$

Each of these relations is associated to an inverse one, for example, (1.12) to

$$\vec{F}(k,)=\eta(-k)\overleftarrow{F}(k,)-\xi(k)\overleftarrow{F}(-k,). \tag{1.14}$$

Inserting the reverse relation in the direct relation yields the unitarity relation, here

$$\eta(k)\,\eta(-k)-\xi(k)\,\xi(-k)=1. \tag{1.15}$$

Similar relations exist for the other coefficients.

For real V, which is the case here, the Jost solutions take conjugate values as $k\to-k$ in $\mathbb{R}$ and the coefficients written above behave accordingly. It is clear that these "global scattering" coefficients depend only on k, hence they are invariants in the x, t, plane.

Beside the global scattering problem defined above, we can now define scattering problems by $V(x,t)$, fixed x or fixed t. Scattering coefficients can be related to the global ones by retracing from the functions F the usual Jost solutions of this scattering problem. As an example, on a fixed t axis, assuming $|V(x,t)|\in L^1_1(\mathbb{R})$, the Schrödinger scattering problem on the axis has coefficients $R_+(k,t)$, $T(k,t)$. From their asymptotic behavior, we see that the Jost solutions $\binom{f^+}{f'^+}$ and $\binom{f^-}{f'^-}$ are equal to $\overleftarrow{F}$, respectively, $\hat{F}$, times trivial phase factors so that

$$\hat{\eta}(k)=[T(k)]^{-1}, \tag{1.16}$$

$$\hat{\xi}(k)=[T(k)]^{-1}R^+(k,t)\exp[2ik^3t]. \tag{1.17}$$

One recognizes in Eq. (1.16) the usual KdV invariant. As for Eq. (1.7), it gives trivially the "standard IST" (inverse scattering transform) where $V(x,t)$ is constructed from $T(k)$ (bound states) and $R^+(k,t)$, so that the boundary value problem with data $V(x,t_0)$ in L^1_1 is solved for any finite t. A similar analysis can be done on a fixed x axis.[3,4] If a spectral measure is identified in global scattering from the scattering by $V(x,t)$ on a full x-axis, the corresponding Jost solutions or

transformation kernels are solutions[3,4] of integral equations whose kernel involves this measure multiplied by $(k+k')^{-1}$, and going to a t-axis is formally done if we replace this factor by $(k^3+k'^3)^{-1}(k^2-kk'+k'^2)$. This symmetry is particularly obvious in the multisolitonic case, but does exist in all others. The IST on axes are nothing but a trivial consequence of translation invariance in the global scattering problem.

The situations become quite different if two half-axes are involved, as an elbow: if we try solving an inverse problem from informations on each axis, we define "*de facto*" a scanning of $V(x,t)$, which must be possible and consistent! What still makes our global scattering approach interesting is that all the conditions for solving the problem can be reproduced on a linear companion problem in such a way that if a solution of the linear problem does exist, we can transpose it. Fokas[5] gave a general approach to linear problems of this kind, by using Fourier representations of solutions. Now let us recall two properties of the Fourier representations.

(a) If a function f is known only on $\mathbb{R}^+$, it has an infinity of Fourier representations, corresponding to different continuations on $\mathbb{R}^-$.
(b) In many cases, a given Fourier integral may be written in terms of various measures, with different supports in the complex plane.

Fokas[6] was able to extend his ideas to nonlinear cases, but we do not follow the same lines. As a tool for transposing to the nonlinear case, we notice that if a function $V(x)$ is derived from a transformation kernel $K(x,y)$ represented[7] by an expansion over products of solutions, allowances seen for Fourier transforms are transposed: (a) the transformation kernels corresponding to different continuations of V outside the interval where it is considered on an axis give the same functions on the interval and (b) the support of a measure giving the transformation kernel can be displaced in the complex plane. In what follows we use these remarks, together with the global scattering approach.

II. CONSISTENCY CONDITIONS

The condition that $V(x,t)$ solves KdV can also be expressed in terms of global Jost solutions: it follows from the zero trace property and the differentiability that

$$\frac{\partial}{\partial t}\det[\mathbf{V}E,F]=\frac{\partial}{\partial x}\det[\mathbf{W}E,F], \tag{2.1}$$

where E can be evaluated for $\pm k$, F can be any solution of (1.2), and they can be chosen independently, so that for a given sort of F there exists two independent relations (2.1), one with $E(k,)$ and $F(k,)$, the other one with $E(-k,)$ and $F(k,)$.

In the following we are interested in functions $V(x,t)$ that go to zero, together with their two first derivatives, as $x\to+\infty$, fixed $t\geqslant 0$. Two independent consistency conditions can be written. Satisfying both conditions is necessary and sufficient for V to satisfy KdV, and it appears that their most convenient formulation is

$$\frac{\partial}{\partial t}\int_0^\infty dy\,\det[F(-k,y,t),\mathbf{V}(y,t)E(\pm k,y,t)]=-\det[F(-k,0,t),\mathbf{W}(k^2,0,t)E(\pm k,0,t)], \tag{2.2}$$

and, explicitly,

$$\begin{aligned}\dot{I}_1&=\frac{\partial}{\partial t}\int_0^\infty dy f(-k,y,t)e(-k,y,t)V(y,t)\\&=f'(-k,0,t)e(-k,0,t)[V_1(0,t)-ikV_0(0,t)]\\&\quad-f(-k,0,t)e(-k,0,t)[V_2(0,t)+ikV_1(0,t)+k^2V_0(0,t)],\end{aligned} \tag{2.3}$$

$$\dot{I}_2=\frac{\partial}{\partial t}\int_0^\infty dy f(-k,y,t)e(k,y,t)V(y,t)$$
$$=f'(-k,0,t)e(k,0,t)[V_1(0,t)+ikV_0(0,t)]$$
$$-f(-k,0,t)e(k,0,t)[V_2(0,t)-ikV_1(0,t)+k^2V_0(0,t)], \tag{2.4}$$

where we used the value $\exp[i(kx+k^3t)]$ of the first component e of E.

III. COMPANION LINEAR PROBLEM

We study solutions F_L of the pair of equations

$$\frac{\partial F_L}{\partial x}=\mathbf{M}_0F_L+\mathbf{V}E, \quad \frac{\partial F_L}{\partial t}=\mathbf{N}_0F_L+\mathbf{W}_LE, \tag{3.1}$$

where $\mathbf{W}_L$ is defined as $\mathbf{W}$ but with $V_2=-1/4V''$. It is readily shown that F_L is twice continuously diffrentiable if and only if V satisfies LKdV:

$$\frac{\partial V}{\partial t}+\frac{1}{4}V'''=0. \tag{3.2}$$

The consistency conditions are derived as in Sec. II and the one corresponding to (2.3) will be written concisely as

$$\frac{\partial}{\partial t}\int_0^\infty dy\ \det[E^\pm,VE^-]_y=-\det[E^\pm,W_LE^-]_{x=0}, \tag{3.3}$$

and, explicitly,

$$\frac{\partial}{\partial t}\int_0^\infty dy V(y,t)=-V_2(0,t), \tag{3.4}$$

$$\frac{\partial}{\partial t}\int_0^\infty e^{-2i(ky+k^3t)}V(y,t)dy=-e^{-2ik^3t}[2k^2V_0(0,t)+2ikV_1(0,t)+V_2(0,t)]. \tag{3.5}$$

IV. THE LINEAR QUARTERPLANE PROBLEM

We wish to construct $V(x,t)$ which is a solution of Eq. (3.2) and has prescribed values $V(x,0)$, $x\geqslant 0$, $V(0,t)$, $0\leqslant t$ (satisfying convenient general constraints). This can be done by identifying completely a representation of $V(x,t)$. Now, it is obvious that $V(x,t)$ has plenty of possible representations (e.g., Laplace in time) in terms of separable solutions of Eq. (3.2). But **it is not before the tricky idea of Fokas**[5] that a special one enables us to manage the $V(0,t)$ condition. I recall the representations of Fokas with my view and my notations ($k\to -k$ compared to Fokas). We set

$$V(x,t)=-2\frac{\partial}{\partial x}\int_{\mathbb{R}}\exp[2i(k'x+k'^3t)]\xi(k')dk'-2\frac{\partial}{\partial x}\int_\Lambda\exp[2i(k'x+k'^3t)]\tau(k')dk', \tag{4.1}$$

where Λ consists of the ray $k=|k|e^{i\pi/3}$, oriented from ∞ to 0, and the ray $k=|k|e^{2i\pi/3}$, oriented from 0 to ∞. This choice of contour is a **joker** because for $t=0$, the integral over Λ vanishes for any $x>0$ if the function $\tau(k)$ is holomorphic in $\bar{\Lambda}$, which we take as a working assumption. Hence the Fourier transform determines $\xi(k)$ from the data $V(x,0)$. To determine $\tau(k)$, we recall that Eqs. (3.4) and (3.5) are necessary and sufficient for V to satisfy Eq. (3.2), but (3.4) can be

forgotten since it is a special value of (3.5), the value $k=0$, provided that $V\in L_1^1(\mathbb{R}^+)$ and $V(x,t)$ is continuous at (0,0), which we assume. Thus it remains to enforce Eq. (3.5), which we do after substituting into it Eq. (4.1) and subtracting the calculated part due to $\xi(k)$: on the right hand side, the V_i's are replaced by, say, δV_i, and we get

$$2\frac{\partial}{\partial t}\int_\Lambda dk'\frac{k'\tau(k')}{k'-k}e^{2i(k'^3-k^3)t}=-e^{-2ik^3t}[2k^2\delta V_0(0,t)+2ik\delta V_1(0,t)+\delta V_2(0,t)]. \quad (4.2)$$

Identifying the powers of k, we see that τ is bijectively related by Fourier transforms to any of the δV_1's. We can derive it from δV_0 and then calculate δV_1 and δV_2:

$$2i\int_\Lambda dk'k'\tau(k')e^{2ik'^3t}=-\delta V_0(0,t), \quad (4.3)$$

$$\tau(k')=-\frac{3k'}{2\pi i}\int_0^\infty e^{-2ik'^3t}\delta V_0(0,t), \quad (4.4)$$

and we see that τ indeed satisfies the working assumption.

V. THE NONLINEAR QUARTERPLANE PROBLEM

We gave transformation operators adapted to studies on x-axes and others adapted to studies on t-axes. Both give representations of $V(x,t)$ but we did not emphasize the fact that like in the linear case and like in ordinary potential scattering, there are many more or less equivalent representations and we wish to use this freedom as trickily as Fokas did it in the linear case. As a matter of fact, assume $V(x,0)\in L_1^1(0,\infty)$ and look for $V(x,t)$, fixed $t\geqslant 0$, in $L_1^1(0,\infty)$. We know that there exists a kernel $\kappa(x,y,t)$ such that

$$\overleftarrow{f}(k,x,t)=e^{i(kx+k^3t)}+\int_x^\infty \kappa(x,y,t)e^{i(ky+k^3t)}dy, \quad (5.1)$$

$$V(x,t)=-2\frac{\partial}{\partial x}\kappa(x,x,t). \quad (5.2)$$

We know that κ can be expanded into products $(ef)(k,x,t)$ and that this can be done in several equivalent ways, for instance by "continuing" $V(x,t)$, fixed t, for $x<0$, keeping V in $L_1^1(\mathbb{R})$. Discrete spectrum values and continuous ones may be selected, but they are not independent, and we can also move in the complex plane the part corresponding to the spectrums. Hence, we decide to seek $\kappa(x,y,t)$ as

$$\kappa(x,y,t)=\kappa^s(x,y,t)+\kappa^\tau(x,y,t), \quad (5.3)$$

$$\kappa^\tau(x,y,t)=\int_\Lambda e^{i(k'y+k'^3t)}f(k',x,t)\tau(k')dk'. \quad (5.4)$$

For $t=0$, with our assumption on $V(x,0)$, f is holomorphic in $\mathrm{Im}\,k'\geqslant 0$, and it follows that κ^τ vanishes at any $x\geqslant 0$, $t=0$, if $\tau(k')$ is holomorphic in Λ. We take it as a working assumption on τ. Then $\kappa^s(x,y,0)=\kappa(x,y,0)$ can be constructed as a transformation operator on the $t=0$ line. It is defined directly from $\overleftarrow{f}(k,x,0)$ after $\overleftarrow{f}$ has been constructed from $V(x,0)$ by solving the Volterra integral equation:

$$\overleftarrow{F}(k,x,0)=\begin{pmatrix}1\\ ik\end{pmatrix}e^{ikx}-\int_x^\infty dy\begin{pmatrix}\cos k(y-x) & -\dfrac{\sin k(y-x)}{k}\\ k\sin k(y-x) & \cos k(y-x)\end{pmatrix}\mathbf{V}(y,0)\overleftarrow{F}(k,y,0), \tag{5.5}$$

$$\kappa^s(x,y,0)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}e^{-iky}[\overleftarrow{f}(k,x,0)-e^{ikx}]dk. \tag{5.6}$$

It can also be derived by the Faddeev–Marchenko methods as an expansion over products $e(k,x,t)\ f(k,x,t)$, since it is the kernel associated to scattering coefficients readily written at $x=0$ in terms of $f(\pm k,0,0)$. They correspond to a "potential" $V(x,0)$ continued by 0 for negative x. The expansion involves an integral over $k\in\mathbb{R}$ and a finite sum over the eigenvalues $i\kappa_\ell$, $\ell=1,2,...,N$. Introducing the auxiliary notations

$$g(k,x,t)=e(k,x,t)f(k,x,t), \tag{5.7}$$

$$\tilde{g}(k,x,t)=e(-k,x,t)f(k,x,t), \tag{5.8}$$

it is clear that the expansions of $\kappa(x,y,t)$ yield

$$V(x,t)=\int d\omega(k')g'(k',x,t), \tag{5.9}$$

where g' is the x derivative of g, and the measure $d\omega(k')$ consists of three parts, with separate supports: $\mathbb{R}$ (continuous spectrum), $i\kappa_\ell$ (discrete spectrum), and Λ (ternary support, as we shall call it). Let us insert now Eq. (5.9) in Eqs. (2.2) and (2.3). We are able to calculate explicitly all the integrals over y thanks to a number of formulas that follow from Eqs. (1.2)–(1.5), and are reproduced below, with dots indicating time derivatives and notations condensed for convenience:

$$g''=2ikg'+Vg, \tag{5.10}$$

$$\dot{g}=(k^2+\tfrac{1}{2}V)g'-\tfrac{1}{4}(V'+2ikV)g, \tag{5.11}$$

$$\dot{g}'=(2ik^3+\tfrac{1}{2}ikV+\tfrac{1}{4}V')g+(k^2V-\tfrac{1}{2}ikV'+\tfrac{1}{2}V^2-\tfrac{1}{4}V'')g, \tag{5.12}$$

$$g(-k)g'(k')-g(k')g'(-k)=-\frac{k'+k}{k'-k}\frac{\partial}{\partial x}[g(-k)g(k')]-\frac{i}{k'-k}\frac{\partial}{\partial x}[g(-k)g'(k')-g(k')g'(-k)], \tag{5.13}$$

$$\tilde{g}''=-2ik\tilde{g}'+V\tilde{g}, \tag{5.14}$$

$$\tilde{g}=(k^2+\tfrac{1}{2}V)\tilde{g}'-\tfrac{1}{4}(V'-2ikV)\tilde{g}, \tag{5.15}$$

$$\tilde{g}'=(-2ik^3-\tfrac{1}{2}ikV+\tfrac{1}{4}V')\tilde{g}'+\left(k^2V+\tfrac{1}{2}ikV'+\frac{V^2}{2}-\tfrac{1}{4}V''\right)\tilde{g}, \tag{5.16}$$

$$\tilde{g}(-k)g'(k')-g(k')\tilde{g}'(-k)=-\frac{k'-k}{k'+k}\frac{\partial}{\partial x}[\tilde{g}(-k)g(k')]-\frac{i}{k'+k}\frac{\partial}{\partial x}[\tilde{g}(-k)g'(k')-g(k')\tilde{g}'(-k)]. \tag{5.17}$$

All calculations are elementary but lengthy. The results are

$$\dot{I}_1 = -e^{-ik^3t}\{f'(-k,0,t)[\alpha(t)+ikC(t)]-f(-k,0,t)[ik\alpha(t)+\beta(t)-\gamma(t)-k^2C(t)]\}$$
$$= e^{-ik^3t}\{f'(-k,0,t)[V_1(0,t)-ikV_0(0,t)]-f(-k,0,t)[V_2(0,t)+ikV_1(0,t)+k^2V_0(0,t)]\}, \tag{5.18}$$

$$\dot{I}_2 = -e^{ik^3t}\{f'(-k,0,t)[\alpha(t)-ikC(t)]-f(-k,0,t)[-ik\alpha(t)+\beta(t)-\gamma(t)-k^2C(t)]\}$$
$$= e^{ik^3t}\{f'(-k,0,t)[V_1(0,t)+ikV_0(0,t)]-f(-k,0,t)[V_2(0,t)-ikV_1(0,t)+k^2V_0(0,t)]\}, \tag{5.19}$$

where

$$\alpha = \frac{1}{2}\int d\omega(k')\left\{\frac{1}{2}V(0,t)g(k',0,t)+ik'g'(k',0,t)\right\}, \tag{5.20}$$

$$\beta = \frac{1}{2}\int d\omega(k')\left\{\frac{1}{2}V'(0,t)g(k',0,t)+iV(0,t)k'g(k',0,t)\right\}, \tag{5.21}$$

$$\gamma = \frac{1}{2}\int d\omega(k')\left\{\frac{1}{2}V(0,t)g'(k',0,t)+2k'^2g'(k',0,t)\right\}, \tag{5.22}$$

$$C = \frac{1}{2}\int d\omega(k')g'(k',0,t). \tag{5.23}$$

Equating the two values that appear on the right hand side of $\dot{I}_1$ (respectively, $\dot{I}_2$), we obtain a linear system for f and f'. The cancelling of coefficients ensures the consistency and the equality of k powers; more precisely, setting

$$P = \alpha + V_1 + ik(V_0 - C) \tag{5.24}$$

we get

$$f'(-k,0,t)P(k,t)-f(-k,0,t)[-ikP(k,t)+V_2(0,t)-\gamma(t)+\beta(t)]=0,$$
$$f'(-k,0,t)P(-k,t)-f(-k,0,t)[ikP(-k,t)+V_2(0,t)-\gamma(t)+\beta(t)]=0. \tag{5.25}$$

Hence

$$V_0(0,t) = C(t), \tag{5.26}$$

$$V_1(0,t) = -\alpha(t), \tag{5.27}$$

$$V_2(0,t) = \beta(t) - \gamma(t). \tag{5.28}$$

The transformation kernel that produces Eq. (5.9) is

$$\kappa(x,y,t) = -\frac{1}{2}\int d\omega(k')f(k',x,t)e^{i(k'x+k'^3t)}. \tag{5.29}$$

As it is inserted into (5.1), it produces for $g(k,x,t)$ and $g'(k,x,t)$ linear integral equations that enable us to construct functions from $d\omega$ (they are the Cauchy form of the Gelfand–Levitan–Marchenko equations):

$$g(k,x,t) = e^2(k,x,t)\left[1-\frac{i}{2}\int \frac{d\omega(k')}{k+k'+i\epsilon}g(k',x,t)\right], \tag{5.30}$$

$$g'(k,x,t)=e^2(k,x,t)\left\{2ik-\frac{i}{2}\int\frac{d\omega(k')}{k+k'+i\epsilon}[g'(k',x,t)+2ikg(k',x,t)]\right\}. \tag{5.31}$$

The $\epsilon(\to 0^+)$ which appears comes from a regularizing of the infinite integral on y which is necessary only when $\mathbb{R}$ is the support of the concerned part of $d\omega$. From (5.31) we see that the right hand side of (5.23) contains only one independent piece of information, which is $d\omega(k')$. If we succeed to get it from $V_0(0,t)$ by solving Eq. (5.26), not only do we obtain $d\omega(k)$ and $g(k,0,t)$, but (readily) $V_1(0,t)$ and $V_2(0,t)$ from (5.27) and (5.28) and [by solving (5.30) and (5.31) for $x\neq 0$], $V(x,t)$ and all this in a consistent way with KdV requirements. The problem is therefore solved as in the linear case, provided this set of three equations has a solution $d\omega(k')$ with the desired supports:

$$g(k,t)=e^{2ik^3t}\left[1-\frac{i}{2}\int\frac{d\omega(k')}{k+k'+i\epsilon}g(k',t)\right], \tag{5.32}$$

$$g'(k,t)=e^{2ik^3t}\left\{2ik-\frac{i}{2}\int\frac{d\omega(k')}{k+k'+i\epsilon}[g'(k',t)+2ikg(k',t)]\right\}, \tag{5.33}$$

$$V(0,t)=\int d\omega(k')g'(k',t), \tag{5.34}$$

where we used the condensed notation $g(k',t)$ for $g(k',0,t)$. As for the support conditions, we know the value of $d\omega(k)$ on $\mathbb{R}$ [continuous spectrum of $V(x,0)$] and on the imaginary half axis [discrete spectrum of $V(x,0)$] and we must make sure that the value $d\tau(k)$ on Λ enables the Fokas joker. So as to make the iterations easy to follow, we leave $d\omega$ everywhere it is possible. First we display Eq. (5.34) in favor of $\tau(k)dk$, the measure completing it to $d\omega$ being collectively called $d\sigma$:

$$\int_\Lambda dk'\,\tau(k')2ik'e^{2ik'^3t}=V(0,t)-\int d\sigma(k')2ik'e^{2ik'^3t}+\frac{i}{2}\int d\omega(k)e^{2ik^3t}\int\frac{d\omega(k')}{k'+k+i\epsilon}[g'(k',t)+2ikg(k',t)]. \tag{5.35}$$

Both sides are limited to $t>0$ and inverting yields $\tau(k)$:

$$\tau(k'')=\tau_0(k'')+\frac{3k''}{2\pi}\int_0^\infty e^{-2ik''^3t}dt\left\{\int d\omega(k)e^{2ik^3t}\int\frac{d\omega(k')}{k'+k+i\epsilon}[g'(k',t)+2ikg(k',t)]\right\}, \tag{5.36}$$

$$\tau(k)=\tau_0(k)+N(g,g',\tau). \tag{5.37}$$

This equation should be combined with (5.32) and (5.33) which read in concise notations as

$$g=g_0+L(g,\tau), \tag{5.38}$$

$$g'=g_0'+M(g,g',\tau). \tag{5.39}$$

The set of equations is studied more easily in the case without discrete spectrum, where $d\sigma=\rho(k)dk$ [known from $V(x,0)$]. In any case we have to prove the convergence of the algorithm

$$\tau_{n+1}(k)=\tau_0(k)+N(g_n,g_n',\tau_n), \tag{5.40}$$

$$g_{n+1}=g_0+L(g_n,\tau_n), \tag{5.41}$$

$$g'_{n+1}=g'_0+M(g_n,g'_n,\tau_n). \tag{5.42}$$

It is possible to do it if conveniently defined norms $\|\rho\|$ **and** $\|\tau_0\|$ are small enough and the result can be extended if there is a discrete spectrum. This, of course, is a poor result compared to the standard IST! We sketch the proof only in the oversimplified case where $V(x,0)$ is set equal to zero $(x>0)$. Thus we meet only k integrals over Λ, where $e^{\pm 2ik^3t}$ is a number of modulus one and where we can use the bound, for any function f:

$$\left|\int_\Lambda f(k)dk\right| \leqslant \int_0^\infty \{|f(|k|e^{i\pi/3})|+|f(|k|e^{2i\pi/3})|\}d|k|. \tag{5.43}$$

In the following, this integral will be denoted for convenience as $\int_{|\Lambda|}|f(k)|dk$.

Now, from the formula

$$\tau_0(k)=\frac{3k}{2\pi}\int_0^\infty e^{-2ik^3t}V(0,t)dt \tag{5.44}$$

we can show that if $V\in L^2(0,\infty)\cap L^1(0,\infty)$, which is a cheap assumption, for $k\in\Lambda$, there exists T and $\overline{\tau}$ with

$$|\tau_0(k)|\leqslant\frac{|k|}{1+|k|}T_0(|k|)\leqslant\overline{\tau_0}, \tag{5.45}$$

where $T_0(|k|)$ is in $L^2(\mathbb{R})$, and its norm is smaller than the number, say, $\overline{\tau_0}$. Suppose now the inequality (5.44) holds for $\tau(k)$, with $\overline{T}$, $\overline{\tau}$. Then one easily shows from (5.38) and (5.39) that $|g|$ and $|k|^{-1}|g'|$ are bounded. Using now the sup norm for $|g|$ and $|k|^{-1}|g|$, the L^2 norm of $(1+|k|)|k|^{-1}|\tau(k)|$ for τ, we show that the operator (L,M,N) acting on (g,g',τ) is contracting if $\|\tau_0\|$ is small enough and that the working assumptions are satisfied.

VI. ALTERNATIVE KERNEL, FINAL REMARKS AND POSSIBLE EXTENSIONS

(a) What makes the method work is that $\kappa(x,y,t)$ [or $\kappa(x,x,t)$] and therefore $V(x,t)$, is "separated" into two parts, a part I that reduces at $t=0$ to the kernel of the global scattering problem defined at $t=0$ from $V(x,0)$ $(x>0)$ and zero $(x<0)$, and a part II that does not contribute to $V(x,0)$ at $x\geqslant 0$. One can try to obtain this separation property in another way, by combining a similar part I to a part II that reduces at $t=0$ to the kernel of the global scattering problem defined at $t=0$ from an unknown $V(x,0)$ $(x<0)$, and zero $(x\geqslant 0)$. The kernel constructed from I and II has therefore the separation property. It has an expansion over products of solutions but involving both $\check{f}$ and $\hat{f}$. This last fact, however, does not alter very much the developments of Sec. V and one gets to three equations similar to (5.32)–(5.34). Working on this alternative method is now our current interest because the separation on the axis $t=0$ is natural: as a matter of fact, all the developments can be written "exactly" in the purely multisolitonic case.

(b) In previous papers[3] we showed that transformation kernels related to t-axes are easily constructed: it is often sufficient to replace $(k+k')^{-1}$ inside equations like (5.38) by $(k^3+k'^3)^{-1}(k^2-kk'+k'^2)$ and rewrite it by means of integrals over t. Hence there are approaches on t-axes similar to those on x-axes. It is not impossible that combining an x-approach and a t-approach eventually brings a linearization of the quarterplane problem.

(c) We have shown a global scattering by a set of two linear equations whose C^2 consistency is expressed by KdV and is such that another set of equations, whose C^2 consistency is expressed by LKdV, shows the linear limit of solutions. A quite similar situation exists for at least another set of two linear equations:

$$\frac{\partial H}{\partial x}=\mathbf{m}H, \quad \frac{\partial H}{\partial t}=\mathbf{n}H, \tag{6.1}$$

where

$$\mathbf{m}=\begin{pmatrix} -ik & v \\ u & ik \end{pmatrix}, \tag{6.2}$$

$$\mathbf{n}=\begin{pmatrix} 2ik^2+iuv & -i\dfrac{\partial v}{\partial x}-2kv \\ i\dfrac{\partial u}{\partial x}-2ku & -2ik^2-iuv \end{pmatrix}. \tag{6.3}$$

They are C^2-consistent if the fields u and v satisfy the nonlinear system,

$$\begin{aligned} &\frac{\partial v}{\partial t}+i\frac{\partial^2 v}{\partial x^2}-2iuv^2=0, \\ &\frac{\partial u}{\partial t}-i\frac{\partial^2 u}{\partial x^2}+2iu^2v=0, \end{aligned} \tag{6.4}$$

which for $v=-cu^*$, real c, reduces to NLS:

$$i\frac{\partial u}{\partial t}+\frac{\partial^2 u}{\partial x^2}+2c|u|^2u=0. \tag{6.5}$$

Potential scattering, both on x- and t-axes, can be managed as in the KdV case.

The Davey–Stewartson I equation on the quarter plane with homogeneous Dirichlet boundary conditions

A. S. Fokas[a)]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Cambridge, CB3 0WA, United Kingdom

(Received 5 May 2003; accepted 5 May 2003)

Dromions are exponentially localized coherent structures supported by nonlinear integrable evolution equations in two spatial dimensions. In the study of *initial-value* problems on the plane, such solutions occur only if one imposes nontrivial boundary conditions at infinity, a situation of dubious physical significance. However, it is established here that dromions appear naturally in the study of *boundary-value* problems. In particular, it is shown that the long time asymptotics of the solution of the Davey–Stewartson I equation in the quarter plane with arbitrary initial conditions and with zero Dirichlet boundary conditions is dominated by dromions. The case of nonzero Dirichlet boundary conditions is also discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1588744]

I. INTRODUCTION

We consider the Davey–Stewartson (DS) I equation:[1]

$$iq_t+\tfrac{1}{2}(q_{xx}+q_{yy})-(\varphi_x+|q|^2)q=0, \tag{1.1a}$$

$$\varphi_{xx}-\varphi_{yy}+2|q|^2x=0. \tag{1.1b}$$

In the context of water waves this equation is the shallow water limit of the Benney–Roskes[2] equation in the case of dominant surface tension. In this case $q(x,y,t)$ is the amplitude of a surface wave packet and φ is the velocity potential of the associated mean flow. In general the DSI equation provides a two-dimensional generalization of the nonlinear Schrödinger equation and can be derived from general asymptotic considerations.[3]

We introduce characteristic coordinates and we also replace the second order equation (1.1b) by two first order equations: Let ξ,η, $U_1(\xi,\eta,t)$, $U_2(\xi,\eta,t)$, be defined by

$$\xi=x+y, \quad \eta=x-y, \quad U_1=-\varphi_\eta-\tfrac{1}{2}|q|^2, \quad U_2=-\varphi_\xi-\tfrac{1}{2}|q|^2. \tag{1.2}$$

Then the DSI equation becomes

$$iq_t+q_{\xi\xi}+q_{\eta\eta}+(U_1+U_2)q=0, \tag{1.3a}$$

$$U_{1_\xi}=\tfrac{1}{2}|q|^2_\eta, \tag{1.3b}$$

$$U_{2_\eta}=\tfrac{1}{2}|q|^2_\xi. \tag{1.3c}$$

a)Electronic mail: t.fokas@damtp.cam.ac.uk

Indeed, writing Eq. (1.1a) in characteristic coordinates and using the definitions of U_1, U_2, we find Eq. (1.3a). Also the definition of U_1 implies $U_{1_\xi} = -\varphi_{\eta\xi} - |q|^2_\xi/2$; writing Eq. (1.1b) in characteristic coordinates and using this equation to replace $\varphi_{\eta\xi}$, we find Eq. (1.3b), and similarly for Eq. (1.3c).

A. Formulation of the problem

Let the complex-valued function $q(\xi,\eta,t)$ and the real-valued functions $U_1(\xi,\eta,t)$, $U_2(\xi,\eta,t)$, satisfy Eqs. (1.3) in the domain

$$0<\xi<\infty, \quad 0<\eta<\infty, \quad t>0, \tag{1.4}$$

with the following initial and boundary conditions:

$$\begin{gathered} q(\xi,\eta,0)=q_0(\xi,\eta), \quad 0<\xi<\infty, \quad 0<\eta<\infty, \\ q(0,\eta,t)=0, \quad U_1(0,\eta,t)=u_1(\eta,t), \quad 0<\eta<\infty, \quad t>0, \\ q(\xi,0,t)=0, \quad U_2(\xi,0,t)=u_2(\xi,t), \quad 0<\xi<\infty, \quad t>0, \end{gathered} \tag{1.5}$$

where the functions $q_0(\xi,\eta)$, $u_1(\eta,t)$, $u_2(\xi,t)$ have sufficient smoothness and they also decay as $\xi\to\infty$ and $\eta\to\infty$.

Notations:

(i) Bar denotes complex conjugation.
(ii) $M_{11}, M_{12}, M_{21}, M_{22}$ denote the (11), (12), (21), (22) entries of the 2×2 matrix M.
(iii) M_D, M_0 denote the diagonal and the off-diagonal parts of the 2×2 matrix M.

Theorem 1.1: Given $q_0(\xi,\eta)$, define the vector $(M_1(\xi,\eta,k), M_2(\xi,\eta,k))^T$ by

$$\begin{gathered} M_{1_\xi} - ikM_1 = -\tfrac{1}{2}q_0 M_2, \quad M_{2_\eta} = \tfrac{1}{2}\overline{q_0}M_1, \quad 0<\xi<\infty, \quad 0<\eta<\infty, \quad \operatorname{Im} k\leqslant 0, \\ \lim_{\xi\to\infty} M_1 = 0, \quad M_2(\xi,0,k)=1. \end{gathered} \tag{1.6}$$

Given q_0 and M_2, define $S_0(k,l)$ by

$$S_0(k,l)=\frac{1}{4\pi}\int_0^\infty\int_0^\infty d\xi\, d\eta\, q_0(\xi,\eta)M_2(\xi,\eta,k)e^{-ik\xi-il\eta}, \quad \operatorname{Im} k\leqslant 0, \quad \operatorname{Im} l\leqslant 0. \tag{1.7}$$

Given S_0, u_1, u_2, define $\hat{S}(\xi,\eta,t)$ by

$$i\hat{S}_t+\hat{S}_{\xi\xi}+\hat{S}_{\eta\eta}+(u_1(\eta,t)+u_2(\xi,t))\hat{S}=0, \quad 0<\xi<\infty, \quad 0<\eta<\infty, \quad t>0, \tag{1.8a}$$

$$\hat{S}(\xi,\eta,0)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} dk\,dl\, e^{ik\xi+il\eta}S_0(k,l), \quad 0<\xi<\infty, \quad 0<\eta<\infty, \tag{1.8b}$$

$$\hat{S}(\xi,0,t)=0, \quad 0<\xi<\infty, \quad t>0, \tag{1.8c}$$

$$\hat{S}(0,\eta,t)=0, \quad 0<\eta<\infty, \quad t>0. \tag{1.8d}$$

Given $\hat{S}$, define the 2×2 matrices $M^+(\xi,\eta,t,k)$ and $M^-(\xi,\eta,t,k)$ as the solution of the following nonlocal Riemann-Hilbert problem:

(i) M^+ and M^- are analytic for $\operatorname{Im} k>0$ and $\operatorname{Im} k<0$, respectively.

(ii) $M^{\pm}=I+O(1/k),\ k\to\infty,\ \mathrm{Im}\,k\neq 0.$

(iii) For real k, M^{+} and M^{-} satisfy the following jump condition,

$$\begin{aligned}\begin{pmatrix}M_{11}^{+}\\ M_{21}^{+}\end{pmatrix}(\xi,\eta,t,k)-\begin{pmatrix}M_{11}^{-}\\ M_{21}^{-}\end{pmatrix}(\xi,\eta,t,k)&=-\int_{-\infty}^{\infty}dl\overline{S(l,k,t)}e^{-il\xi-ik\eta}\begin{pmatrix}M_{12}^{+}\\ M_{22}^{+}\end{pmatrix}(\xi,\eta,t,l),\\ \begin{pmatrix}M_{12}^{+}\\ M_{22}^{+}\end{pmatrix}(\xi,\eta,t,k)-\begin{pmatrix}M_{12}^{-}\\ M_{22}^{-}\end{pmatrix}(\xi,\eta,t,k)&=-\int_{-\infty}^{\infty}dlS(k,l,t)e^{il\eta+ik\xi}\begin{pmatrix}M_{11}^{-}\\ M_{21}^{-}\end{pmatrix}(\xi,\eta,t,l),\end{aligned}\tag{1.9}$$

where

$$S(k,l,t)=\frac{1}{4\pi^2}\int_0^{\infty}\int_0^{\infty}d\xi d\eta\hat{S}(\xi,\eta,t)e^{-ik\xi-il\eta}.\tag{1.10}$$

This Riemann–Hilbert problem has a unique global solution.

Define $q(\xi,\eta,t)$ by

$$q=2i\lim_{k\to\infty}(kM_{12}).\tag{1.11}$$

Then q satisfies (1.3) and (1.5).

Remark 1.1: Although the evolution of the scattering data $S(k,l,t)$ is in principle determined by Eqs. (1.8), the relevant time dependence is complicated. In turn, this makes it difficult to determine the long time behavior of the solution M of the RH problem (1.9). This difficulty can be bypassed by formulating an *inverse problem* for $S(k,l,t)$. Since Eq. (1.8a) is precisely the one studied in Ref. 4, the relevant analysis is identical with the one presented in Ref. 4: (a) If u_1 and u_2 are time-independent, then the analysis of (1.8) is intimately related with the analysis of the time-independent Schrödinger equation

$$\psi_{xx}+(u(x)+k^2)\psi=0,$$

where u is either u_1 or u_2. After a long time the solution of (1.8) is dominated by the *discrete* spectrum of u_1 and of u_2. If u_1 and u_2 have N_1 and N_2 discrete eigenvalues, respectively, then the long time asymptotics of q is given by an (N_1,N_2)-*breather* solution. (b) If u_1 and u_2 are time-dependent, then the analysis of (1.8) is related with the analysis of the time-dependent Schrödinger equation. Assuming a certain completeness relation for the eigenfunctions of the time-dependent Schrödinger equation, the long time asymptotics of the solution q is dominated again by the associated discrete spectrum; in this case the solution is dominated by an (N_1,N_2)-*dromion* solution.

Remark 1.2: The explicit form of the (N_1,N_2)-dromion solution can be found in Ref. 4, see also Refs. 5 and 6. Dromion solutions are exponentially decaying in both ξ and η. However, in contrast to the one-dimensional solitons, these solutions do *not* preserve their form upon interaction and therefore can exchange energy. These coherent strucures can be driven everywhere in the quarter-plane $\xi\geqslant 0,\eta\geqslant 0$, by choosing a suitable motion for $u_1(\eta,t),u_2(\xi,t)$.

Remark 1.3: A characteristic feature of boundary-value problems for integrable evolution partial differential equations (PDEs) in one spatial dimension is that the (spectral) functions defining the associated Riemann–Hilbert problems *cannot* in general be expressed explicitly in terms of the given boundary conditions.[7] Explicit formulas can be obtained only for a particular class of boundary conditions which are referred to in Ref. 7 as *linearizable*. The situation is similar for boundary-value problems in two spatial dimensions. We emphasize that Eqs. (1.8) are explicitly defined in terms of the given initial conditions, thus the homogeneous Dirichlet problem (1.3)–(1.5) belongs to the class of linearizable conditions. It is shown below that for nonhomogeneous Dirichlet boundary conditions, the equations defining $\hat{S}$, in addition to the *given* Dirichlet boundary conditions, also involve the *unknown* Neumann boundary values.

Proposition 1.1: Let the complex-valued function $q(\xi,\eta,t)$ satisfy a nonhomogeneous Dirichlet boundary-value problem in the quarter plane, namely, Eqs. (1.3)–(1.5), where $q(0,\eta,t)=0$ and $q(\xi,0,t)=0$ are replaced by

$$q(0,\eta,t)=g_0(\eta,t), \quad q(\xi,0,t)=f_0(\xi,t), \tag{1.12}$$

and the functions g_0, f_0 have sufficient smoothness and they also decay as $\eta\to\infty, \xi\to\infty$. *Assume* that there exists a global solution.

This solution can be expressed by Eq. (1.11) through the solution of the Riemann–Hilbert problem defined in Theorem 1.1. This problem is uniquely defined in terms of the function $\hat{S}(\xi,\eta,t)$ which satisfy the following:

(i) $\hat{S}$ solves the linear evolution PDE

$$i\hat{S}_t+\hat{S}_{\xi\xi}+\hat{S}_{\eta\eta}+(u_1+u_2)\hat{S}+\int_0^{\xi} d\tilde{\xi}F_1(\xi,\tilde{\xi},t)\hat{S}(\tilde{\xi},\eta,t)+\int_0^{\eta} d\tilde{\eta}F_2(\eta,\tilde{\eta},t)\hat{S}(\xi,\tilde{\eta},t)=0, \tag{1.13}$$

where

$$F_1(\xi,\tilde{\xi},t)=\frac{1}{4}[\overline{f_1}(\tilde{\xi},t)f_0(\xi,t)-\overline{f_0}(\tilde{\xi},t)f_1(\xi,t)]-\frac{1}{16}f(\xi,t)\overline{f}(\tilde{\xi},t)\int_{\tilde{\xi}}^{\xi} d\xi'|f(\xi',t)|^2,$$

$$F_2(\eta,\tilde{\eta},t)=\frac{1}{4}[\overline{g_1}(\tilde{\eta},t)g_0(\eta,t)-\overline{g_0}(\tilde{\eta},t)g_1(\eta,t)]-\frac{1}{16}g(\eta,t)\overline{g}(\tilde{\eta},t)\int_{\tilde{\eta}}^{\eta} d\eta'|g(\eta',t)|^2,$$

and $g_1(\eta,t), f_1(\xi,t)$ denote the Neumann boundary values $q_\xi(0,\eta,t), q_\eta(\xi,0,t)$.

(ii) $\hat{S}$ satisfies the initial and boundary conditions

$$\hat{S}(\xi,\eta,0)=\hat{S}_0(\xi,\eta), \quad \hat{S}(\xi,0,t)=\pi f_0(\xi,t), \quad \hat{S}(0,\eta,t)=\pi g_0(\eta,t), \tag{1.14}$$

where $\hat{S}_0(\xi,\eta)$ is defined in terms of $q_0(\xi,\eta)$ by the rhs of Eq. (1.7).

Remark 1.4: In the case of boundary-value problems for evolution PDEs in one spatial dimension, the unknown boundary values can be characterized in terms of the given boundary conditions through the analysis of certain *global relations*.[7,8] Such global relations exist in two spatial dimensions and can also be used for the characterization of the unknown boundary values. This analysis, which is rather complicated, will be presented elsewhere.

B. Organization of the article

The DSI equation admits a Lax pair formulation. The t-independent part of the Lax pair [see Eqs. (4.2)] is analyzed in Sec. II. The specific form of the t-part of the Lax pair [see Eqs. (3.4)] depends on the specific form of the boundary conditions. The t-part of the Lax pair for the homogeneous and nonhomogeneous Dirichlet cases is discussed in Secs. III and V, respectively. The proof of Theorem 1.1 is presented in Sec. IV. Section VI contains further discussion.

II. THE t-INDEPENDENT PART OF THE LAX PAIR

Throughout this section we *suppress the t-dependence*. The t-independent part of the Lax pair is given by Eq. (4.2). Analyzing this equation in characteristic coordinates we find the following:

Proposition 2.1: Let the vectors

$$\begin{pmatrix} M_{11}^+ \\ M_{21}^+ \end{pmatrix}, \begin{pmatrix} M_{12}^+ \\ M_{22}^+ \end{pmatrix}, \begin{pmatrix} M_{11}^- \\ M_{21}^- \end{pmatrix}, \begin{pmatrix} M_{12}^- \\ M_{22}^- \end{pmatrix}, \tag{2.1}$$

which are functions of ξ,η,k, be defined by

$$M_{11}^{+}=1-\frac{1}{2}\int_0^{\xi}d\xi' qM_{21}^{+},\quad M_{12}^{+}=-\frac{1}{2}\int_0^{\xi}d\xi' e^{ik(\xi-\xi')}qM_{22}^{+},$$

$$M_{21}^{+}=-\frac{1}{2}\int_{\eta}^{\infty}d\eta' e^{ik(\eta'-\eta)}\overline{q}M_{11}^{+},\quad M_{22}^{+}=1+\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}M_{12}^{+},$$

$$M_{11}^{-}=1-\frac{1}{2}\int_0^{\xi}d\xi' qM_{21}^{-},\quad M_{12}^{-}=\frac{1}{2}\int_{\xi}^{\infty}d\xi' e^{ik(\xi-\xi')}qM_{22}^{-},\tag{2.2}$$

$$M_{21}^{-}=\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}e^{ik(\eta'-\eta)}M_{11}^{-},\quad M_{22}^{-}=1+\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}M_{12}^{-},$$

where $q(\xi,\eta)$ has sufficient smoothness and decay. Then we have the following.

(1) The first two vectors in (2.1) are analytic in k for $\operatorname{Im}k>0$, while the last two vectors in (2.1) are analytic for $\operatorname{Im}k<0$.

(2) For real k, the vectors (2.1) satisfy the relationships

$$\begin{pmatrix}M_{11}^{+}\\M_{21}^{+}\end{pmatrix}(\xi,\eta,k)-\begin{pmatrix}M_{11}^{-}\\M_{21}^{-}\end{pmatrix}(\xi,\eta,k)=-\int_{-\infty}^{\infty}dl\overline{S(l,k)}e^{-il\xi-ik\eta}\begin{pmatrix}M_{12}^{+}\\M_{22}^{+}\end{pmatrix}(\xi,\eta,l),\tag{2.3a}$$

$$\begin{pmatrix}M_{12}^{+}\\M_{22}^{+}\end{pmatrix}(\xi,\eta,k)-\begin{pmatrix}M_{12}^{-}\\M_{22}^{-}\end{pmatrix}(\xi,\eta,k)=-\int_{-\infty}^{\infty}dlS(k,l)e^{il\eta+ik\xi}\begin{pmatrix}M_{11}^{-}\\M_{21}^{-}\end{pmatrix}(\xi,\eta,l),\tag{2.3b}$$

where $S(k,l)$ is defined by

$$S(k,l)=\frac{1}{4\pi}\int_0^{\infty}\int_0^{\infty}d\xi d\eta q(\xi,\eta)M_{22}^{-}(\xi,\eta,k)e^{-ik\xi-il\eta},\quad \operatorname{Im}k\leqslant 0,\quad \operatorname{Im}l\leqslant 0.\tag{2.4}$$

(3) The vectors (2.1) have the following behavior for large k:

$$M_{11}^{\pm}=1+O\left(\frac{1}{k}\right),\quad M_{22}^{\pm}=1+O\left(\frac{1}{k}\right),\quad M_{12}^{\pm}=O\left(\frac{1}{k}\right),\quad M_{21}^{\pm}=O\left(\frac{1}{k}\right),\quad k\to\infty,\quad \operatorname{Im}k\neq 0.\tag{2.5}$$

Proof:

(1) The vector $(M_{11}^{+},M_{21}^{+})^{T}$ satisfies a system of linear Volterra integral equations with kernel analytic in k for $\operatorname{Im}k>0$ (since $\eta'\geqslant\eta$). Thus this vector is analytic for $\operatorname{Im}k>0$ and similarly for the other vectors.

(2) Let the matrices $\Psi^{+}(\xi,\eta,k)$ and $\Psi^{-}(\xi,\eta,k)$ be defined by

$$\Psi^{\pm}=\begin{pmatrix}M_{11}^{\pm}e^{ik\eta} & M_{12}^{\pm}e^{-ik\xi}\\ M_{21}^{\pm}e^{ik\eta} & M_{22}^{\pm}e^{-ik\xi}\end{pmatrix}.\tag{2.6}$$

Then

$$\Psi_{11}^{+}=e^{ik\eta}-\frac{1}{2}\int_0^{\xi}d\xi' q\Psi_{21}^{+},\quad \Psi_{12}^{+}=-\frac{1}{2}\int_0^{\xi}d\xi' q\Psi_{22}^{+},$$

$$\Psi_{21}^{+}=\frac{1}{2}\int_{\eta}^{\infty}d\eta'\overline{q}\Psi_{11}^{+},\quad \Psi_{22}^{+}=e^{-ik\xi}+\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}\Psi_{12}^{+},$$

$$\Psi_{11}^{-}=e^{ik\eta}-\frac{1}{2}\int_0^{\xi}d\xi' q\Psi_{21}^{-},\quad \Psi_{12}^{-}=\frac{1}{2}\int_{\xi}^{\infty}d\xi' q\Psi_{22}^{-},\tag{2.7}$$

$$\Psi_{21}^{-}=\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}\Psi_{11}^{-},\quad \Psi_{22}^{-}=e^{-ik\xi}+\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}\Psi_{12}^{-}.$$

Subtracting the equations defining the vectors $(\Psi_{12}^{+},\Psi_{22}^{+})^T$ and $(\Psi_{12}^{-},\Psi_{22}^{-})^T$ we find

$$\Psi_{12}^{+}-\Psi_{12}^{-}=-\frac{1}{2}\int_0^{\infty}d\xi' q\Psi_{22}^{-}-\frac{1}{2}\int_0^{\xi}d\xi' q(\Psi_{22}^{+}-\Psi_{22}^{-}),\tag{2.8a}$$

$$\Psi_{22}^{+}-\Psi_{22}^{-}=\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}(\Psi_{12}^{+}-\Psi_{12}^{-}).\tag{2.8b}$$

Using the definition of $S(k,l)$, it follows that the first term of the rhs of Eq. (2.8a) equals

$$-\int_{-\infty}^{\infty}dlS(k,l)e^{il\eta}.$$

Comparing Eqs. (2.8) with the equation satisfied by $(\Psi_{11}^{-},\Psi_{21}^{-})^T$ we find Eq. (2.3b) written in terms of the functions $\Psi^{\pm}$ instead of the functions $M^{\pm}$.

Similarly subtracting the equations defining the vectors $(\Psi_{11}^{+},\Psi_{21}^{+})^T$ and $(\Psi_{11}^{-},\Psi_{21}^{-})^T$ we find Eq. (2.3a), where instead of $-\overline{S(l,k)}$ we have the function

$$T(k,l)=-\frac{1}{4\pi}\int_0^{\infty}\int_0^{\infty}d\xi d\eta\overline{q}(\xi,\eta)M_{11}^{+}(\xi,\eta,k)e^{ik\eta+il\xi}.\tag{2.9}$$

We will now show that

$$T(k,l)=-\overline{S(l,k)}.\tag{2.10}$$

Indeed, the vectors $(\Psi_{11}^{+},\Psi_{21}^{+})^T$ and $(\Psi_{12}^{-},\Psi_{22}^{-})^T$ satisfy the equations

$$\Psi_{11_{\xi}}^{+}=-\tfrac{1}{2}q\Psi_{21}^{+},\quad \overline{\Psi_{12_{\xi}}^{-}}=-\tfrac{1}{2}\overline{q}\,\overline{\Psi_{22}^{-}},$$

$$\Psi_{21_{\xi}}^{+}=\tfrac{1}{2}\overline{q}\Psi_{11}^{+},\quad \overline{\Psi_{22_{\eta}}^{-}}=\tfrac{1}{2}q\,\overline{\Psi_{12}^{-}}.$$

Hence

$$(\Psi_{11}^{+}(k)\overline{\Psi_{12}^{-}(l)})_{\xi}=-(\Psi_{21}^{+}(k)\overline{\Psi_{22}^{-}(l)})_{\eta},$$

where for convenience of notation we have suppressed the (ξ,η) dependence. Integrating this equation we find

$$\int_0^\infty d\eta[\Psi_{11}^+(k)\overline{\Psi_{12}^-(l)}|_{\xi=\infty}-\Psi_{11}^+(k)\overline{\Psi_{12}^-(l)}|_{\xi=0}]=-\int_0^\infty d\xi[\Psi_{21}^+(k)\overline{\Psi_{22}^-(l)}|_{\eta=0}$$
$$-\Psi_{21}^+(k)\overline{\Psi_{22}^-(l)}|_{\eta=0}].$$

Using Eq. (2.7) to compute the boundary values appearing above, for example,

$$\Psi_{12}^-|_{\xi=\infty}=\Psi_{21}^+|_{\eta=\infty}=0,\quad \Psi_{11}^+(k)|_{\xi=0}=e^{ik\eta},\quad \Psi_{22}^-(l)|_{\eta=0}=e^{-il\xi},$$

we find

$$\int_0^\infty d\eta e^{ik\eta}\int_0^\infty d\xi'\,\overline{q}\overline{\Psi_{22}^-(l)}=\int_0^\infty d\xi e^{il\xi}\int_0^\infty d\eta'\,\overline{q}\Psi_{11}^+(k).$$

The lhs of this equation is the complex conjugate of $S(l,k)$, while the rhs equals $-T(k,l)$.

(3) Equations (2.2) and integration by parts imply Eqs. (2.5). Q.E.D.

III. THE *t*-PART OF THE LAX PAIR FOR THE HOMOGENOUS DIRICHLET CASE

In what follows we first derive the t-part of the Lax pair for the vector $(\Psi_{12}^-,\Psi_{22}^-)^T$.

Proposition 3.1: Assume that there exists a function $q(\xi,\eta,t)$ with sufficient smoothness and decay which satisfies Eqs. (1.3)–(1.5). Let the vector $\Psi=(\Psi_1,\Psi_2)^T$ satisfy

$$\Psi_1(\xi,\eta,t,k)=\frac{1}{2}\int_\xi^\infty d\xi' q(\xi',\eta,t)\Psi_2(\xi',\eta,t,k), \tag{3.1a}$$

$$\Psi_2(\xi,\eta,t,k)=e^{-ik\xi}+\frac{1}{2}\int_0^\eta d\eta'\,\overline{q}(\xi,\eta',t)\Psi_1(\xi,\eta',t,k),\quad \mathrm{Im}\,k\leqslant 0. \tag{3.1b}$$

Then the function $\psi_1(\eta,t,k)$ defined by

$$\psi_1(\eta,t,k)=\Psi_1(0,\eta,t,k)$$

solves

$$i\psi_{1_t}+\psi_{1_{\eta\eta}}+u_1(\eta,t)\psi_1-\left(k^2\psi_1+\frac{1}{2}q_\xi(0,\eta,t)\right)-i\int_{-\infty}^\infty dl\,\gamma(k-l,t)\psi_1(\eta,t,l)=0, \tag{3.2}$$

where

$$\gamma(k,t)=\frac{i}{2\pi}\int_0^\infty d\xi u_2(\xi,t)e^{-ik\xi}. \tag{3.3}$$

Proof: We will first show that if $(\Psi_1,\Psi_2)^T$ satisfies Eqs. (3.1) and $q(\xi,\eta,t)$ satisfies Eqs. (1.3)–(1.5), then

$$\Psi_{1_t}=i(\partial_\xi-\partial_\eta)^2\Psi_1+iq(\partial_\xi-\partial_\eta)\Psi_2+iU_1\Psi_1-iq_\eta\Psi_2+v_1, \tag{3.4a}$$

$$\Psi_{2_t}=-i(\partial_\xi-\partial_\eta)^2\Psi_2-i\overline{q}(\partial_\xi-\partial_\eta)\Psi_1-iU_2\Psi_2-i\overline{q}_\xi\Psi_1+v_2, \tag{3.4b}$$

where the vector $v=(v_1,v_2)^T$ is given by

$$v(\xi,\eta,t,k)=-ik^2\Psi(\xi,\eta,t,k)+\int_{-\infty}^{\infty}dl\,\gamma(k-l,t)\Psi(\xi,\eta,t,l). \tag{3.5}$$

Indeed, the vector $\Psi=(\Psi_1,\Psi_2)^T$ satisfies

$$\Psi_{1_\xi}=-\tfrac{1}{2}q\Psi_2,\quad \Psi_{2_\eta}=\tfrac{1}{2}\overline{q}\Psi_1. \tag{3.6}$$

Suppose that Ψ satisfies equations similar with (3.4) but with $v=0$. It is straightforward to verify that the compatibility condition of Eq. (3.4) with $v=0$, and of Eqs. (3.6) yields Eqs. (1.3). Actually, if Eqs. (1.3) are valid, then Eqs. (3.4) and (3.6) are compatible for any vector v given by

$$v(\xi,\eta,t,k)=\int_{-\infty}^{\infty}dl\Gamma(k,l,t)\Psi(\xi,\eta,t,l).$$

The precise form of Γ depends on the boundary conditions that Ψ and q satisfy. Indeed, Ψ_1 can be written in the form

$$\Psi_1=-\int_{\xi}^{\infty}d\xi'\Psi_{1_{\xi'}}\quad\text{or}\quad \Psi_{1_t}=-\int_{\xi}^{\infty}d\xi'(\Psi_{1_t})_{\xi'}.$$

By replacing in the above equation Ψ_{1_t} by $A+v_1$, where A is defined in the rhs of Eq. (3.4a), we find

$$v_1=-\lim_{\xi\to\infty}[i(\partial_\xi-\partial_\eta)^2\Psi_1+iq(\partial_\xi-\partial\eta)\Psi_2+iU_1\Psi_1-iq_\eta\Psi_2]-\int_{\xi}^{\infty}d\xi'v_{1_{\xi'}}.$$

Using

$$\lim_{\xi\to\infty}q=\lim_{\xi\to\infty}\Psi_1=0,$$

the term in the bracket vanishes. Also

$$v_{1_\xi}=\int_{-\infty}^{\infty}dl\Gamma\Psi_{1_\xi}=\int_{-\infty}^{\infty}dl\Gamma\left(-\frac{q_1}{2}\Psi_2\right)=-\frac{q_1}{2}v_1.$$

Hence

$$v_1=\frac{1}{2}\int_{\xi}^{\infty}d\xi'q_1v_2. \tag{3.7a}$$

Similarly starting with

$$\Psi_2=\int_0^{\eta}d\eta'\Psi_{2_{\eta'}}+e^{-ik\xi}\quad\text{or}\quad \Psi_{2_t}=\int_0^{\eta}d\eta'(\Psi_{2_t})_{\eta'},$$

we find

$$v_2=[i(\partial_\xi-\partial_\eta)^2\Psi_2+i\overline{q}(\partial_\xi-\partial_\eta)\Psi_1+iU_2\Psi_2+i\overline{q}_\xi\Psi_1]_{\eta=0}+\frac{1}{2}\int_0^{\eta}d\eta'\overline{q}v_1.$$

Using

$$\Psi_1|_{\eta=0}=q|_{\eta=0}=0,\quad(\partial_\xi-\partial_\eta)^2\Psi_2|_{\eta=0}=-k^2e^{-ik\xi},$$

it follows that

$$v_2 = -ik^2 e^{-ik\xi} + iu_2(\xi,t)e^{-ik\xi} + \frac{1}{2}\int_0^\eta d\eta' \overline{q} v_1. \tag{3.7b}$$

Equations (3.7) imply that the term $-ik^2 \exp[-ik\xi]$ gives rise to $-ik^2\Psi$, while the term

$$iu_2(\xi,t)e^{-ik\xi} = \int_{-\infty}^{\infty} dl\, \gamma(k-l,t)e^{-il\xi} \tag{3.8}$$

gives rise to the term $\int_{-\infty}^{\infty} dl\, \gamma(k-l,t)\Psi(l)$. Also Eq. (3.8) implies that $\gamma(k,t)$ is given by Eq. (3.3).

Equation (3.2) follows from the evaluation of Eq. (3.4a) at $\xi=0$. In this respect we note

$$\Psi_{1_{\xi\eta}}|_{\xi=0} = -\tfrac{1}{2}[q_\eta \Psi_2 + q\Psi_{2\eta}]_{\xi=0} = 0,$$

since $q(0,\eta,t) = q_\eta(0,\eta,t) = 0$. Also

$$\Psi_{1_{\xi\xi}}|_{\xi=0} = -\tfrac{1}{2}[q_\xi \Psi_2 + q\Psi_{2\xi}]_{\xi=0} = -\tfrac{1}{2} q_\xi(0,\eta,t),$$

since $\Psi_2(0,\eta,t,k) = 1$. Q.E.D.

Using Eq. (3.2), it is now straightforward to obtain the time evolution of $S(k,l,t)$:

Proposition 3.2: Let $S(k,l,t)$ be defined by Eq. (2.4), where $M_{22}^-(\xi,\eta,t,k) = \Psi_2 \exp[-ik\xi]$, Ψ_2 is defined in terms of $q(\xi,\eta,t)$ in Eqs. (3.1), and q evolves in time according to Eqs. (1.3)–(1.5). Let

$$\hat{S}(\xi,\eta,t) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} dk dl e^{ik\xi + il\eta} S(k,l,t). \tag{3.9}$$

Then $\hat{S}$ satisfies Eqs. (1.8).

Proof: Using $(M_{12}^-, M_{22}^-)^T = e^{-ik\xi}(\Psi_1,\Psi_2)^T$, it follows that the vector $\Psi = (\Psi_1,\Psi_2)^T$ satisfies Eqs. (3.1). Also

$$S(k,l,t) = \frac{1}{4\pi}\int_0^\infty\int_0^\infty d\xi d\eta q(\xi,\eta)e^{-il\eta}\Psi_2(\xi,\eta,k) = \frac{1}{2\pi}\int_0^\infty d\eta e^{-il\eta}\Psi_1(0,\eta,t,k), \tag{3.10}$$

where the first equality uses the definition of S [see Eq. (2.4)] and the second equality uses Eq. (3.1a). Hence using $\Psi_1(0,\eta,t,k) = \psi_1(\eta,t,k)$ and replacing in Eq. (3.9) S by the rhs of Eq. (3.10) we find

$$\hat{S}(\xi,\eta,t) = \int_{-\infty}^{\infty} dk e^{ik\xi}\psi_1(\eta,t,k). \tag{3.11}$$

In order to find the time evolution of $\hat{S}$ we need to take the k-Fourier transform of Eq. (3.2). In this respect we note that if $q(0,\eta,t) = 0$, Eqs. (3.1) imply

$$\psi_1 = -\frac{1}{2}\frac{q_\xi(0,\eta,t)}{k^2} + O\left(\frac{1}{k^3}\right), \quad k\to\infty. \tag{3.12}$$

Using this estimate, Eq. (3.2) implies Eq. (1.8a). In this respect we note that the k-Fourier transform of $k^2\psi_1 + \frac{1}{2}q_\xi(0,\eta,t)$ equals $\hat{S}_{\xi\xi}$. Indeed, if $s(x)$ denotes the Fourier transform of ψ,

$$s(x)=\int_{-\infty}^{\infty}e^{ikx}\psi(k)dk,\quad x>0, \tag{3.13}$$

and if $\psi(k)$ for large k is given by

$$\psi(k)=\frac{\alpha}{k^2}+O\left(\frac{1}{k^3}\right),\quad k\to\infty, \tag{3.14}$$

then

$$\frac{d^2s}{dx^2}=\int_{-\infty}^{\infty}e^{ikx}[\alpha-k^2\psi(k)]dk. \tag{3.15}$$

In order to derive this result we note that the definition of $s(x)$ can be rewritten as

$$s(x)=\int_{-\infty}^{\infty}e^{ikx}\left[\psi(k)+\frac{\alpha}{1+k^2}\right]dk+\alpha\int_{-\infty}^{\infty}\frac{e^{ikx}}{1+k^2}dk;$$

the second integral above can be computed explicitly and equals πe^{-x}. Thus

$$\frac{d^2s}{dx^2}=\int_{-\infty}^{\infty}e^{-ikx}\left[\frac{\alpha k^2}{1+k^2}-\psi(k)\right]dk+\alpha\pi e^{-x};$$

simplifying the rhs of this equation we find (3.15).

Since $\psi_1(0,t,k)=\Psi_1(0,0,t,k)=0$, Eq. (3.11) implies $\hat{S}(\xi,0,t)=0$. Also

$$\hat{S}(0,\eta,t)=\int_{-\infty}^{\infty}dk\,\psi_1(\eta,t,k)=0,$$

since ψ_1 is analytic for $\mathrm{Im}\,k<0$ and is of $O(1/k^2)$ as $k\to\infty$ [see Eq. (3.12)]. Q.E.D.

IV. PROOF OF THEOREM 1.1

In both Secs. II and III it was *assumed* that $q(\xi,\eta,t)$ exists, it is smooth, and it has sufficient decay. Then, under this assumption, it was shown in Sec. II that q can be obtained through the solution of a RH problem uniquely defined in terms of $S(k,l,t)$. Furthermore, it was shown in Sec. III that S satisfies Eqs. (1.8). We will now prove that $q(\xi,\eta,t)$ can be constructed through the solution of the RH problem (1.9) *without* the *a priori* assumption of existence. Furthermore, this result is valid *without* the need for the norms of $q_0(\xi,t),u_1(\eta,t),u_2(\xi,t)$ to be small.

The function $S_0(k,l)$ is defined through the solution $(M_1(\xi,\eta),M_2(\xi,\eta))^T$ of the linear integral equations (1.6). These equations are of Volterra type, and thus, if $q_0\in L_1$, are always solvable.

The Fourier transform $\hat{S}(\xi,\eta,t)$ of the function $S(k,l,t)$ satisfies the linear PDE (1.8a) with the initial condition $\hat{S}_0(\xi,\eta)$ and with homogeneous Dirichlet boundary conditions. Thus if $u_1(\eta,t),u_2(\xi,t)$ have sufficient smoothness and decay, $S(k,l,t)$ is well defined.

If the functions $S,S_k,S_l\in L_2$ for fixed t, the RH problem (1.9) has a global solution provided that its homogeneous version has only the *trivial* solution. This is indeed the case:[4] Let μ satisfy Eqs. (1.9) but with $\mu=O(1/k)$ as $k\to\infty$. The jump conditions imply

$$\mu_{11}^{+}(k)-\mu_{11}^{-}(k)=-\int_{-\infty}^{\infty}dl\overline{S(l,k)}e^{-il\xi-ik\eta}\mu_{12}^{+}(l), \tag{4.1a}$$

$$\mu_{12}^{+}(k)-\mu_{12}^{-}(k)=-\int_{-\infty}^{\infty}dlS(k,l)e^{il\eta+ik\xi}\mu_{11}^{-}(l), \tag{4.1b}$$

where for convenience of notation we have suppressed the ξ,η,t dependence of μ,S. Multiplying Eq. (4.1a) by $\overline{\mu_{11}^{-}(\overline{k})}$, Eq. (4.1b) by $\overline{\mu_{22}^{+}(\overline{k})}$, integrating over k, and adding the resulting equations we find an equation whose lhs equals

$$\int_{-\infty}^{\infty}dk(|\mu_{11}^{-}(k)|^2+|\mu_{12}^{+}(k)|^2),$$

while the rhs is imaginary [in this derivation we have used that the integrals of $\overline{\mu_{11}^{-}(\overline{k})}\mu_{11}^{+}(k)$ and of $\overline{\mu_{22}^{+}(\overline{k})}\mu_{12}^{-}(k)$ vanish since these products are analytic for $\mathrm{Im}\,k>0$ and $\mathrm{Im}\,k<0$, respectively, and are of $O(1/k^2)$ as $k\to\infty$]. Hence, $\mu_{11}^{-}=\mu_{12}^{+}=0$.

For the proof of the fact that $q(\xi,\eta,0)=q_0(\xi,\eta)$ we note that $q(\xi,\eta,0)$ is defined through the RH problem (1.9) but with $S_0(k,l)$ instead of $S(k,l,0)$. By repeating the analysis of Sec. II where $q(\xi,\eta,t)$ is now replaced by the given function $q_0(\xi,\eta)$, it follows that $q_0(\xi,\eta)$ is characterized by precisely the same RH problem as the problem characterizing $q(\xi,\eta,0)$. [We note that $(M_1,M_2)^T=(M_{12}^{-},M_{22}^{-})^T$.] Hence the unique solution of this RH problem implies $q(\xi,\eta,0)=q_0(\xi,\eta)$.

We now show that if $q(\xi,\eta,t)$ is defined through the solution of the RH problem (1.9), then q satisfies the DSI equation. This proof is based on the extended version of the dressing method presented in Ref. 9. The dressing method can be used to show that if M solves an appropriate RH problem, then M also solves both parts of the associated Lax pair. Hence, using the compatibility condition of this pair, q solves the relevant nonlinear PDE.

We first show that M solves the t-independent part of the Lax pair

$$M_x+\sigma_3M_y-ik[\sigma_3,M]+QM=0, \tag{4.2}$$

where

$$\xi=x+y,\quad \eta=x-y,\quad \sigma_3=\mathrm{diag}(1,-1),\quad Q=\begin{pmatrix}0 & q\\ -\overline{q} & 0\end{pmatrix}, \tag{4.3}$$

and $[,]$ denotes the usual matrix commutator. Indeed, the jump condition of the RH problem can be written in the form

$$M^{+}(x,y,t,k)-M^{-}(x,y,t,k)=\int_{-\infty}^{\infty}dl\tilde{M}(x,y,t,l)F(x,y,t,k,l), \tag{4.4}$$

where $\tilde{M}$ denotes the matrix with first and second column vectors $(M_{11}^{-},M_{21}^{-})^T$ and $(M_{12}^{+},M_{22}^{+})^T$, respectively, and F denotes the off-diagonal matrix with

$$F_{12}(x,y,t,k,l)=-S(k,l,t)e^{ik(x+y)+il(x-y)}, \tag{4.5a}$$

$$F_{21}(x,y,t,k,l)=\overline{F_{12}(x,y,t,l,k)}. \tag{4.5b}$$

Using

$$F_{12x}=i(k+l)F_{12},\quad F_{21x}=-i(k+l)F_{21},$$

$$F_{12y}=i(k-l)F_{12},\quad F_{21y}=i(k-l)F_{21},$$

and writing these equations in a matrix form, we find

$$F_x = il\sigma_3 F - ikF\sigma_3, \quad F_y = i(k-l)F. \tag{4.6}$$

Let the operators D_x, D_y be defined by

$$D_x M = M_x + ikM\sigma_3, \quad D_y M = M_y - ikM. \tag{4.7}$$

These definitions and Eqs. (4.6) imply that

$$D_x \int_{-\infty}^{\infty} dl \tilde{M}(l) F(k,l) = \int_{-\infty}^{\infty} dl (D_x \tilde{M}(l)) F(k,l),$$

$$D_y \int_{-\infty}^{\infty} dl \tilde{M}(l) F(k,l) = \int_{-\infty}^{\infty} dl (D_y \tilde{M}(l)) F(k,l),$$

where for simplicity of notation we have suppressed the x,y,t dependence. Hence, both $D_x M$ and $D_y M$ satisfy the same jump condition as M. Using the fact that QM also satisfies the same jump condition, it follows that the expression

$$D_x M + \sigma_3 D_y M + QM \tag{4.8}$$

satisfies the same jump condition as M. Using

$$M = I + \frac{M^{(1)}(x,y,t)}{k} + \frac{M^{(2)}(x,y,t)}{k^2} + O\left(\frac{1}{k^3}\right), \tag{4.9}$$

it follows that the large k behavior of the expression (4.8) is given by

$$(Q - i[\sigma_3, M^{(1)}]) + O\left(\frac{1}{k}\right).$$

Hence if we define Q by

$$Q(x,y,t) = i[\sigma_3, M^{(1)}], \tag{4.10}$$

the expression (4.8) satisfies the homogeneous version of the RH problem, therefore it vanishes and M satisfies equation (4.2). We note that Q is off diagonal; furthermore Eq. (4.5b) implies certain symmetry relations for M, which in turn implies that $(Q)_{21} = -\overline{(Q)}_{12}$. In summary, if M satisfies the RH problem (1.9) and if q is defined through M by Eq. (1.11), then M satisfies the t-independent part of the Lax pair.

We now show that M also satisfies the t-part of the Lax pair. For this purpose, rather than assuming that S satisfies Eq. (1.8a) we first assume that $S(k,l,t)$ satisfies the equation

$$iS_t - (k^2 + l^2)S + \int_{-\infty}^{\infty} d\nu (-i)\gamma_1(\nu - l, t) S(k, \nu, t) + i\gamma_2(\nu, t) S(k - \nu, l, t), \tag{4.11}$$

where the functions γ_1, γ_2 are defined by

$$\gamma_1(\nu,t) = \frac{i}{2\pi} \int_{-\infty}^{\infty} d\eta u_1(\eta, t) e^{i\nu\eta}, \quad \gamma_2(\nu,t) = -\frac{i}{2\pi} \int_{-\infty}^{\infty} d\xi u_2(\xi, t) e^{-i\nu\xi}. \tag{4.12}$$

These equations imply that F satisfies the evolution equation

$$F_t = ik^2 F\sigma_3 - il^2 \sigma_3 F + \int_{-\infty}^{\infty} d\nu (\Gamma(x,y,t,\nu - l) F(x,y,t,k,\nu) - F(x,y,t,k-\nu,l)\Gamma(x,y,t,\nu)), \tag{4.13}$$

where Γ is defined by

$$\Gamma(x,y,t,\nu)=e^{i\nu y}\,\mathrm{diag}(e^{-i\nu x}\gamma_1(\nu),e^{i\nu x}\gamma_2(\nu)). \tag{4.14}$$

Indeed, using

$$F_{12}(x,y,t,k,l)=-S(k,l,t)e^{ik\xi+il\eta},\quad \Gamma_{11}(x,y,t,\nu)=e^{-i\nu\eta}\gamma_1(\nu,t),$$
$$\Gamma_{22}(x,y,t,\nu)=e^{i\nu\xi}\gamma_2(\nu,t),$$

the (12) component of Eq. (4.13) yields Eq. (4.11).

The time dependence of F suggests the introduction of the operator D_t defined by

$$D_tM=M_t-ik^2M\sigma_3+\int_{-\infty}^{\infty}d\nu M(x,y,t,k-\nu)\Gamma(x,y,t,\nu). \tag{4.15}$$

Indeed it can be shown that

$$D_t\int_{-\infty}^{\infty}dl\tilde{M}(l)F(k,l)=\int_{-\infty}^{\infty}dl(D_t\tilde{M}(l))F(k,l).$$

This equation is a direct consequence of the definition of D_t and of Eq. (4.13) provided that

$$\int_{-\infty}^{\infty}dl\int_{-\infty}^{\infty}d\nu\tilde{M}(l)\Gamma(\nu-l)F(k,\nu)=\int_{-\infty}^{\infty}dl\int_{-\infty}^{\infty}d\nu\tilde{M}(l-\nu)\Gamma(\nu)F(k,l);$$

this equality is established by replacing on the rhs $l-\nu$ by ν and then exchanging l and ν in the resulting equation.

Since D_tM satisfies the same jump condition as M, following the same logic as in the derivation of Eq. (4.2) it follows that

$$-D_tM+i\sigma_3D_y^2M+BD_yM+AM=0, \tag{4.16}$$

where the matrices $A(x,y,t)$ and $B(x,y,t)$ will be chosen by the requirement that the lhs of Eq. (4.16) is of $O(1/k)$ as $k\to\infty$. In this respect we first introduce the following notations for the $O(1/k)$ term of M [see Eq. (4.9)]:

$$M^{(1)}(x,y,t)=\begin{pmatrix}a & b\\ c & d\end{pmatrix}. \tag{4.17}$$

Equation (4.10) yields

$$b=\frac{q}{2i},\quad c=\frac{\overline{q}}{2i}. \tag{4.18}$$

The $O(1/k)$ term of Eq. (4.2) implies

$$M_x^{(1)}+\sigma_3M_y^{(1)}-i[\sigma_3,M^{(2)}]+QM^{(1)}=0. \tag{4.19}$$

The diagonal and off-diagonal parts of this equation yield

$$\partial_xM_D^{(1)}+\sigma_3\partial_yM_D^{(1)}+QM_O^{(1)}=0, \tag{4.20}$$

$$\partial_xM_O^{(1)}+\sigma_3\partial_yM_O^{(1)}-i[\sigma_3,M_O^{(2)}]+QM_D^{(1)}=0. \tag{4.21}$$

Equation (4.20) implies

$$a_\xi = -\frac{|q|^2}{4i}, \quad d_\eta = \frac{|q|^2}{4i}. \tag{4.22}$$

Using the definitions of D_t and D_y, Eq. (4.16) becomes

$$M_t = -ik^2[\sigma_3, M] - ikBM + 2k\sigma_3 M_y + AM + BM_y + i\sigma_3 M_{yy} - \int_{-\infty}^{\infty} d\nu M(x,y,t,k-\nu)\Gamma(x,y,t,\nu). \tag{4.23}$$

The $O(k)$ term of this equation yields

$$B = -[\sigma_3, M^{(1)}],$$

thus [comparing with Eq. (4.10)]

$$B = iQ. \tag{4.24}$$

The $O(1)$ term of Eq. (4.23) yields

$$-i[\sigma_3, M^{(2)}] - iBM^{(1)} + 2\sigma_3 M_y^{(1)} + A - \int_{-\infty}^{\infty} d\nu \Gamma(x,y,t,\nu) = 0. \tag{4.25}$$

Using Eq. (4.19) to replace the first two terms of this equation we find

$$-M_x^{(1)} + \sigma_3 M_y^{(1)} + A - \int_{-\infty}^{\infty} d\nu \Gamma(x,y,t,\nu) = 0.$$

Solving this equation for A and using the definition of Γ [Eqs. (4.14) and (4.12)] we find

$$A_{11} = 2a_\eta + iu_1, \quad A_{12} = 2b_\eta, \quad A_{21} = 2c_\xi, \quad A_{22} = 2d_\xi - iu_2. \tag{4.26}$$

In summary, if the time evolution of $S(k,l,t)$ is given by Eq. (4.11), where γ_1 and γ_2 are defined by Eq. (4.12), then the time evolution of M is given by (4.23) where $B = iQ$ and the components of the matrix A are given by Eqs. (4.26).

Letting

$$M = \Psi \operatorname{diag}(e^{-ik\eta}, e^{ik\xi}), \tag{4.27}$$

and using that the y-derivative of the above diagonal matrix equals ik times this matrix, it follows that the time evolution of Ψ is given by

$$\Psi_t = i\sigma_3\partial_y^2\Psi + iQ\partial_y\Psi + A\Psi + ik^2\Psi\sigma_3 - \int_{-\infty}^{\infty} d\nu \Psi(x,y,t,k-\nu)\operatorname{diag}(\gamma_1(\nu,t), \gamma_2(\nu,t)). \tag{4.28}$$

With a particular choice of the constants of integration, Eqs. (4.22) yield

$$a = \frac{i}{4}\int_0^\xi d\xi' |q|^2, \quad d = -\frac{i}{4}\int_0^\eta d\eta' |q|^2. \tag{4.29}$$

Then the first and the fourth of equations (4.26) become

$$A_{11} = i\left(\frac{1}{2}\int_0^\xi d\xi' |q|_\eta^2 + u_1(\eta,t)\right), \quad A_{22} = -i\left(\frac{1}{2}\int_0^\eta d\eta' |q|_\xi^2 + u_2(\xi,t)\right).$$

Using these expressions as well as Eqs. (4.18), Eqs. (4.26) become

$$A_{11}=iU_1, \quad A_{12}=-iq_\eta, \quad A_{21}=-i\overline{q}_\xi, \quad A_{22}=-iU_2. \tag{4.30}$$

Denoting by $(\Psi_1,\Psi_2)^T$ the second column vector of Ψ, replacing A in Eq. (4.28) by Eqs. (4.30), and noting that $\gamma_2=-\gamma$, where γ is defined by Eq. (3.3), Eq. (4.28) implies that Ψ_1,Ψ_2 satisfy precisely Eqs. (3.4) where the vector v is defined by Eq. (3.5).

The vector $(\Psi_1,\Psi_2)^T$ also satisfies

$$\Psi_{1\xi}=-\tfrac{1}{2}q\Psi_2, \quad \Psi_{2\eta}=\tfrac{1}{2}\overline{q}\Psi_1. \tag{4.31}$$

It can be verified that the compatibility of Eqs. (3.4) and (4.31) yields Eqs. (1.3).

It remains to (a) show that the Fourier transform of Eq. (4.11) yields Eq. (1.8a); (b) justify the choice of the constants of integration of Eqs. (4.22); and (c) establish that $q(0,\eta,t)=q(\xi,0,t)=0$. These interelated facts can be proved by ''reversing'' the relevant arguments used in Sec. III.

Q.E.D.

V. THE *t*-PART OF THE LAX PAIR FOR THE NONHOMOGENEOUS CASE

For simplicity of notation throughout this section we suppress the t-dependence.

Proposition 5.1: Let the vector Ψ satisfy Eqs. (3.1) where q satisfies Eqs. (1.3) on the quarter plane. Then the function $\psi_1(\eta,k)=\Psi_1(0,\eta,k)$ satisfies the following equation:

$$i\psi_{1_t}+\psi_{1_{\eta\eta}}-\left[k^2\psi_1+\frac{ikq}{2}+\frac{q_\xi}{2}+\frac{q}{8}\int_0^\eta d\eta'|q|^2\right]+u_1\psi_1-i\int_{-\infty}^{\infty}dl[\gamma(k-l)+\delta(k-l,k)+\varepsilon(k-l,k)]\psi_1(\eta,l)-\frac{q_\xi}{4}\int_0^\eta d\eta'\overline{q}\psi_1+\frac{q}{4}\int_0^\eta d\eta'\overline{q}_\xi\psi_1-\frac{1}{16}\int_0^\eta d\eta'|q|^2\int_0^{\eta'}d\hat{\eta}\overline{q}\psi_1=0, \tag{5.1}$$

where q,q_ξ in the first bracket are evaluated at $(0,\eta)$; $|q|,\overline{q}\psi_1,\overline{q}_\xi\psi_1$ in the integrals with respect to $d\eta'$ are evaluated at $(0,\eta')$; $\overline{q}\psi_1$ in the integral with respect to $d\hat{\eta}$ is evaluated at $(0,\hat{\eta})$; γ is defined by Eq. (3.3); and δ,ε are defined by

$$\delta(l,k)=\frac{i}{8\pi}\int_0^\infty\int_0^\infty d\xi d\hat{\xi}[\overline{q}_\eta(\xi,0)q(\hat{\xi}+\xi,0)-\overline{q}(\xi,0)q_\eta(\hat{\xi}+\xi,0)]e^{-ik\hat{\xi}-il\xi}, \tag{5.2}$$

$$\varepsilon(l,k)=-\frac{i}{32\pi}\int_0^\infty\int_0^\infty\int_0^\infty d\xi d\hat{\xi}d\xi'\overline{q}(\xi,0)|q(\hat{\xi}+\xi,0|^2q(\xi+\hat{\xi}+\xi',0)e^{-ik\hat{\xi}-ik\xi'-il\xi}. \tag{5.3}$$

Proof: We first show that Ψ satisfies Eqs. (3.4) where v is defined by Eq. (3.5) with the additional term

$$\int_{-\infty}^{\infty}dl(\delta(k-l,k)+\varepsilon(k-l,k))\Psi(\xi,\eta,l).$$

Indeed, proceeding as in the proof of Proposition 3.1 we find that the forcing of the equation satisfied by v_2 involves the following additional terms:

$$\frac{i}{4}\left[\overline{q}_\eta(\xi,0)\int_\xi^\infty d\xi' q(\xi',0)e^{-ik\xi'}-\overline{q}(\xi,0)\int_\xi^\infty d\xi' q_\eta(\xi',0)e^{-ik\xi'}\right]$$
$$-\frac{i}{16}\overline{q}(\xi,0)\int_\xi^\infty d\xi'|q(\xi',0)|^2\int_{\xi'}^\infty d\xi'' q(\xi'',0)e^{-ik\xi''}. \tag{5.4}$$

For the computation of these additional terms we have used the following expressions, where for convenience of notation we have suppressed the k-dependence:

$$\psi_1(\xi,0)=\frac{1}{2}\int_\xi^\infty d\xi' q(\xi',0)e^{-ik\xi'}, \quad \psi_2(\xi,0)=e^{-ik\xi},$$

$$\psi_{1_\xi}(\xi,0)=-\tfrac{1}{2}q(\xi,0)e^{-ik\xi},$$

$$\psi_{1_\eta}(\xi,0)=\frac{1}{2}\int_\xi^\infty d\xi' q_\eta(\xi',0)e^{-ik\xi'}+\frac{1}{4}\int_\xi^\infty d\xi'|q(\xi',0)|^2\psi_1(\xi',0), \tag{5.5}$$

$$\psi_{2_{\xi\xi}}(\xi,0)=-k^2e^{-ik\xi},$$

$$\psi_{2_{\eta\xi}}(\xi,0)=\tfrac{1}{2}\overline{q}_\xi(0,\eta)\psi_1(\xi,0)-\tfrac{1}{4}|q|^2(\xi,0)e^{-ik\xi},$$

$$\psi_{2_{\eta\eta}}(\xi,0)=\tfrac{1}{2}\overline{q}_\eta(\xi,0)\psi_1(\xi,0)+\tfrac{1}{2}\overline{q}(\xi,0)\psi_{1_\eta}(\xi,0).$$

Denoting the first bracket in (5.4) by

$$\int_\xi^\infty d\xi' A(\xi,\xi')e^{-ik\xi'}=\int_{-\infty}^\infty dl\,\delta(k-l,k)e^{-il\xi},$$

replacing $k-l$ by l and $\xi'-\xi$ by $\hat{\xi}$, we find

$$\int_0^\infty d\hat{\xi}A(\xi,\hat{\xi}+\xi)e^{-ik\hat{\xi}}=\int_{-\infty}^\infty dl\,\delta(l,k)e^{il\xi},$$

which yields (5.2). Similarly denoting the second term in (5.4) by

$$\int_\xi^\infty d\xi' A(\xi,\xi')\int_{\xi'}^\infty d\xi'' B(\xi'')e^{-ik\xi''}=\int_{-\infty}^\infty dl\,\varepsilon(k-l,k)e^{-il\xi},$$

replacing $k-l$ by l, $\xi''-\xi'$ by $\hat{\hat{\xi}}$, and $\xi'-\xi$ by $\hat{\xi}$, we find

$$\int_0^\infty d\hat{\xi}A(\xi,\hat{\xi}+\xi)\int_0^\infty d\hat{\hat{\xi}}B(\hat{\hat{\xi}}+\hat{\xi}+\xi)e^{-ik(\hat{\xi}+\hat{\hat{\xi}})}=\int_{-\infty}^\infty dl\,\varepsilon(l,k)e^{il\xi},$$

which yields (5.3).

Equation (5.1) follows by evaluating Eq. (3.4a) at $\xi=0$. For this computation we use the following equations, where again for convenience of notation we have suppressed the k-dependence:

$$\psi_2(0,\eta)=1+\frac{1}{2}\int_0^\eta d\eta'\,\overline{q}(0,\eta')\psi_1(0,\eta'),\quad \psi_{2_\eta}(0,\eta)=\tfrac{1}{2}\overline{q}(0,\eta)\psi_1(0,\eta),$$

$$\psi_{2_\xi}(0,\eta)=-ik+\frac{1}{2}\int_0^\eta d\eta'\,\overline{q}_\xi(0,\eta')\psi_1(0,\eta')-\frac{1}{4}\int_0^\eta d\eta'\,|\overline{q}(0,\eta')|^2\psi_2(0,\eta'),$$

$$\psi_{1_{\xi\xi}}(0,\eta)=-\tfrac{1}{2}q_\xi(0,\eta)\psi_2(0,\eta)-\tfrac{1}{2}q(0,\eta)\psi_{2_\xi}(0,\eta),\tag{5.6}$$

$$\psi_{1_{\xi\eta}}(0,\eta)=-\tfrac{1}{2}q_\eta(0,\eta)\psi_2(0,\eta)-\tfrac{1}{4}|q(0,\eta)|^2\psi_1(0,\eta).$$

Q.E.D.

Proposition 5.2: Let $S(k,l,t)$ be defined by Eq. (2.4), where $M_{22}^-=\Psi_2\exp[-ik\xi]$, Ψ is defined in terms of q in Eqs. (3.1) and q evolves in time according to Eq. (1.3). Let $\hat{S}$ be defined in terms of S by Eq. (3.9). Then $\hat{S}$ satisfies the equation

$$i\hat{S}_t+\hat{S}_{\xi\xi}+\hat{S}_{\eta\eta}+(u_1+u_2)\hat{S}+\int_0^\xi d\tilde{\xi}F_1(\xi,\tilde{\xi},t)\hat{S}(\tilde{\xi},\eta,t)+\int_0^\eta d\tilde{\eta}F_2(\eta,\tilde{\eta},t)\hat{S}(\xi,\tilde{\eta},t)=0,\tag{5.7}$$

where

$$F_1(\xi,\tilde{\xi},t)=\frac{1}{4}[\overline{q}_\eta(\tilde{\xi},0)q(\xi,0)-\overline{q}(\tilde{\xi},0)q_\eta(\xi,0)]-\frac{1}{16}q(\xi,0)\overline{q}(\tilde{\xi},0)\int_{\tilde{\xi}}^\xi d\xi'\,|q(\xi',0)|^2,$$

$$F_2(\eta,\tilde{\eta},t)=\frac{1}{4}[\overline{q}_\xi(0,\tilde{\eta})q(0,\eta)-\overline{q}(0,\tilde{\eta})q_\xi(0,\eta)]-\frac{1}{16}q(0,\eta)\overline{q}(0,\tilde{\eta})\int_{\tilde{\eta}}^\eta d\eta'\,|q(0,\eta')|^2.\tag{5.8}$$

Furthermore, $\hat{S}$ satisfies the boundary conditions

$$\hat{S}(\xi,0,t)=\pi q(\xi,0),\quad \hat{S}(0,\eta,t)=\pi q(0,\eta).\tag{5.9}$$

Proof: The analog of Eq. (3.12) is now

$$\psi_1=\frac{-iq(0,\eta)/2}{k}-\frac{q_\xi/2+(q/8)\int_0^\eta d\eta'|q(0,\eta')|^2}{k^2}+O\left(\frac{1}{k^3}\right),\quad k\to\infty.\tag{5.10}$$

Equation (3.11) yields

$$\hat{S}(\xi,0,t)=\int_{-\infty}^\infty dke^{ik\xi}\Psi_1(0,0,t,k)=\frac{1}{2}\int_{-\infty}^\infty dke^{ik\xi}\int_0^\infty d\xi'\,q(\xi',0)e^{-ik\xi'}=\pi q(\xi,0).$$

Furthermore,

$$\hat{S}(0,\eta,t)=\int_{-\infty}^\infty dk\Psi_1(0,\eta,t,k)=\int_{-\infty}^\infty dk\left[\Psi_1(0,\eta,t,k)+\frac{i}{2}\frac{q(0,\eta)}{k}\right]-\frac{i}{2}\int_{-\infty}^\infty\frac{dk}{k}q(0,\eta),$$

$$=\pi q(0,\eta),$$

since $\Psi_1(0,\eta,t,k)$ is analytic for $\mathrm{Im}\,k<0$.

Taking the Fourier transform of Eq. (5.1) and using the estimate (5.10) we find Eq. (5.7). In this respect we note that if we denote the bracket on the rhs of Eq. (5.2) by $A(\xi,\hat{\xi})$, then the contribution of the term involving γ is given by

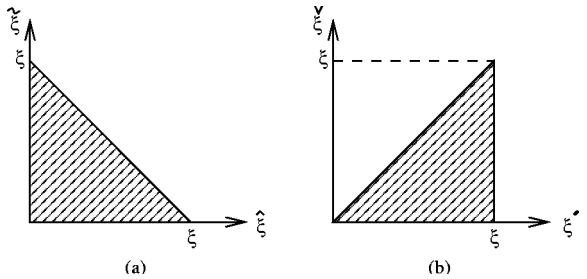

FIG. 1. The change of variables from $(\tilde{\xi},\ \hat{\xi})$ to $(\check{\xi},\ \xi')$.

$$
\begin{aligned}
&-i\int_{-\infty}^{\infty}dl\int_{-\infty}^{\infty}dk\,\gamma(k-l,t)\psi_1(l)e^{ik\xi}\\
&\quad=\frac{1}{8\pi}\int_{-\infty}^{\infty}dl\int_{-\infty}^{\infty}dk\int_0^{\infty}d\xi'\int_0^{\infty}d\hat{\xi}A(\xi',\hat{\xi})e^{-ik\hat{\xi}-i(k-l)\xi'+ik\xi}\psi_1(l)\\
&\quad=\frac{1}{4}\int_0^{\infty}d\xi'\int_0^{\infty}d\hat{\xi}A(\xi',\hat{\xi})\,\delta(\hat{\xi}-(\xi-\xi'))\hat{S}(\xi',\eta,t)\\
&\quad=\frac{1}{4}\int_0^{\infty}d\xi'\,\theta(\xi-\xi')A(\xi',\xi-\xi')\hat{S}(\xi',\eta,t),
\end{aligned}
$$

where $\psi_1(l)=\psi_1(\eta,l)$. Similarly the contribution of the term involving δ is given by

$$
\begin{aligned}
&-\frac{1}{32}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dkdl\int_0^{\infty}\int_0^{\infty}\int_0^{\infty}d\tilde{\xi}d\hat{\xi}d\xi'\overline{q}(\tilde{\xi},0)|q(\hat{\xi}+\tilde{\xi},0|^2q(\tilde{\xi}+\hat{\xi}\\
&\quad+\xi',0)e^{-ik\hat{\xi}-ik\xi'-i(k-l)\tilde{\xi}+ik\xi}\psi_1(l)\\
&\quad=-\frac{q(\xi,0)}{16}\int_0^{\infty}d\tilde{\xi}\int_0^{\infty}d\hat{\xi}\,\theta(\xi-\tilde{\xi}-\hat{\xi})\overline{q}(\tilde{\xi},0)|q(\hat{\xi}+\tilde{\xi},0)|^2\hat{S}(\tilde{\xi},\eta)\\
&\quad=-\frac{q(\xi,0)}{16}\int_0^{\xi}d\tilde{\xi}\int_0^{\xi-\tilde{\xi}}d\hat{\xi}\overline{q}(\tilde{\xi},0)|q(\hat{\xi}+\tilde{\xi},0)|^2\hat{S}(\tilde{\xi},\eta).
\end{aligned}
$$

The area of integration is depicted in Fig. 1(a). Making the change of variables $\xi'=\hat{\xi}+\tilde{\xi}$, $\check{\xi}=\tilde{\xi}$, the area of integration is mapped to the area depicted in Fig. 1(b). Thus the relevant integral becomes

$$
\frac{-q(\xi,0)}{16}\int_0^{\xi}d\check{\xi}\left(\int_{\check{\xi}}^{\xi}d\xi'|q(\xi',0)|^2\right)\overline{q}(\check{\xi},0)\hat{S}(\check{\xi},\eta).
$$

Also regarding the last term of Eq. (5.1) we note that taking its Fourier transform we find

$$
\frac{-q(0,\eta)}{16}\int_0^{\eta}d\eta'|q(0,\eta')|^2\int_0^{\eta'}d\hat{\eta}\overline{q}(0,\hat{\eta})\hat{S}(\xi,\hat{\eta},t).
$$

Changing the order of the integration we find that the relevant contribution involves the last term of F_2, see Eq. (5.8). Q.E.D.

VI. DISCUSSION

In the last decade considerable progress has been made in the understanding of boundary-value problems for integrable nonlinear evolution PDEs in *one* spatial dimension. For example, two of the articles in this special issue are concerned with this development.[10,11] Here, to our knowledge for the first time, a boundary-value problem is solved in *two* spatial dimensions.

It has been emphasized by the author that an important difference between initial- and boundary-value problems is the following: For initial-value problems one needs to perform the spectral analysis of the t-independent part of the Lax pair only, while for boundary-value problems the spectral analysis of *both* parts of the Lax pair is needed. In this respect we recall the following developments:

(i) It is interesting that the spectral analysis of the t-part of the Lax pair (in addition to that of the t-independent part) was first considered not for an equation in one spatial dimension but for an equation in two spatial dimensions, namely the DSI equation: In Ref. 4 Eqs. (1.3) were solved on the plane, but with nontrivial boundary conditions at infinity,

$$U_1(\xi,\eta,t)\to u_1(\eta,t), \quad \xi\to\infty; \quad U_2(\xi,\eta,t)\to u_2(\xi,t), \quad \eta\to\infty.$$

The authors of Ref. 4, rather than performing the explicit spectral analysis of the relevant t-dependent eigenvalue equation, made use of a certain completeness relation (of course the derivation of this relation is based on the spectral analysis of the Schrödinger eigenvalue equation).

(ii) In Ref. 12 the *independent* spectral analysis of the two parts of the Lax pair of the nonlinear Schrödinger equation led to the formulation of the solution in terms of *two* Riemann–Hilbert (RH) problems, which had to be solved in sequence.

(iii) In Ref. 13 the above two RH problems were combined and the solution q was expressed in terms of a *single* RH problem. This RH problem has the distinctive and very useful feature of involving jump matrices with *explicit* exponential (x,t) dependence.

(iv) It was shown in Ref. 14 that the above RH problem can be derived in a straightforward manner by performing the *simultaneous* spectral analysis of the Lax pair. The rigorous proof that the solution of this RH problem yields the unique solution of the given initial-boundary value problem was presented in Refs. 7 and 8.

In the present article we have implemented for Eqs. (1.3)–(1.5) the construction of (i) above. The main reason for using (i) instead of (iv) is the fact that for the case of homogeneous Dirichlet boundary conditions the analysis of the t-part of the Lax pair is very similar to the analysis presented in Ref. 4.

The implementation of (iv) for the initial-boundary value problem formulated in Proposition 1.1 remains open. Furthermore, the analysis of the associated global relation, which characterizes g_1 and f_1 in terms of g_0, f_0 and q_0, also remains open.

(Received 26 March 2003; accepted 9 April 2003)

It is the aim of the present article to give all formulations of the *n*-component KP hierarchy and clarify connections between them. The generalization to the *n*-component KP hierarchy is important because it contains many of the most popular systems of soliton equations, like the Davey–Stewartson system (for $n=2$), the two-dimensional Toda lattice (for $n=2$), the *n*-wave system (for $n\geqslant 3$) and the Darboux–Egoroff system. It also allows us to construct natural generalizations to the Davey–Stewartson and Toda lattice systems. Of course, the inclusion of all these systems in the *n*-component KP hierarchy allows us to construct their solutions by making use of vertex operators. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1590055]

I. INTRODUCTION

The remarkable link between the soliton theory and the group GL_∞ was discovered in the early 1980s by Sato[40] and developed, making use of the spinor formalism, by Date, Jimbo, Kashiwara, and Miwa.[7–9,24] The basic object that they considered is the KP hierarchy of partial differential equations, which they studied through a sequence of equivalent formulations that we describe below. The first formulation is a deformation (or Lax) equation of a formal pseudo-differential operator $L=\partial+u_1\partial^{-1}+u_2\partial^{-2}+\cdots$, introduced in Refs. 40 and 52:

$$\frac{\partial L}{\partial x_n}=[B_n,L], \quad n=1,2,\ldots. \tag{1}$$

Here u_i are unknown functions in the indeterminates x_1, $x_2,\ldots$, and $B_n=(L^n)_+$ stands for the differential part of L^n. The second formulation is given by the following zero curvature (or Zakharov–Shabat) equations:

$$\frac{\partial B_m}{\partial x_n}-\frac{\partial B_n}{\partial x_m}=[B_n,B_m], \quad m,n=1,2,\ldots. \tag{2}$$

These equations are compatibility conditions for the following linear system

$$Lw(x,z)=zw(x,z), \quad \frac{\partial}{\partial x_n}w(x,z)=B_nw(x,z), \quad n=1,2,..., \tag{3}$$

on the wave function

$$w(x,z)=(1+w_1(x)z^{-1}+w_2(x)z^{-2}+\cdots)e^{x_1z+x_2z^2+\cdots}. \tag{4}$$

[a)]Electronic mail: kac@math.mit.edu
[b)]Electronic mail: dleur@math.uu.nl

Provided that (2) holds, the system (3) has a unique solution of the form (4) up to multiplication by an element from $1+z^{-1}\mathbb{C}[\![z^{-1}]\!]$. Introduce the wave operator

$$P=1+w_1(x)\partial^{-1}+w_2(x)\partial^{-2}+\cdots, \tag{5}$$

so that $w(x,z)=Pe^{x_1z+x_2z^2+\cdots}$. Then the existence of a solution of (3) is equivalent to the existence of a solution of the form (5) of the following Sato equation, which is the third formulation of the KP hierarchy:[41,52]

$$\frac{\partial P}{\partial x_k}=-(P\circ\partial\circ P^{-1})_-\circ P, \quad k=1,2,..., \tag{6}$$

where the formal pseudo-differential operators P and L are related by

$$L=P\circ\partial\circ P^{-1}. \tag{7}$$

Let $P^*=1+(-\partial)^{-1}\circ w_1+(-\partial)^{-2}\circ w_2+\cdots$ be the formal adjoint of P and let

$$w^*(x,z)=(P^*)^{-1}e^{-x_1z-x_2z^2-\cdots}$$

be the adjoint wave function. Then the fourth formulation of the KP hierarchy is the following bilinear identity:

$$\mathrm{Res}_{z=0}w(x,z)w^*(x',z)dz=0 \quad \text{for any } x \text{ and } x'. \tag{8}$$

Next, this bilinear identity can be rewritten in terms of Hirota bilinear operators defined for an arbitrary polynomial Q as follows:

$$Q(D)f(x)\cdot g(x)\overset{\text{def}}{=}Q\left(\frac{\partial}{\partial y}\right)(f(x+y)g(x-y))\big|_{y=0}. \tag{9}$$

Towards this end, introduce the famous τ-function $\tau(x)$ by the formulas

$$w(x,z)=\Gamma^+(z)\tau/\tau, \quad w^*(x,z)=\Gamma^-(z)\tau/\tau. \tag{10}$$

Here $\Gamma^{\pm}(z)$ are the vertex operators defined by

$$\Gamma^{\pm}(z)=e^{\pm(x_1z+x_2z^2+\cdots)}e^{\mp(z^{-1}\tilde{\partial}/\partial x_1+z^{-2}\tilde{\partial}/\partial x_2+\cdots)}, \tag{11}$$

where $\tilde{\partial}/\partial x_j$ stands for $(1/j)(\partial/\partial x_j)$. The τ-function exists and is uniquely determined by the wave function up to a constant factor. Substituting the τ-function in the bilinear identity (8) we obtain the fifth formulation of the KP hierarchy as the following system of Hirota bilinear equations:

$$\sum_{j=0}^{\infty}S_j(-2y)S_{j+1}(\tilde{D})e^{\sum_{r=1}^{\infty}y_rD_r}\tau\cdot\tau=0. \tag{12}$$

Here $y=(y_1,y_2,\ldots)$ are arbitrary parameters and the elementary Schur polynomials S_j are defined by the generating series

$$\sum_{j\in\mathbb{Z}}S_j(x)z^j=\exp\sum_{k=1}^{\infty}x_kz^k. \tag{13}$$

The τ-function formulation of the KP hierarchy allows one to construct easily its N-soliton solutions. For that introduce the vertex operator:[8,9]

$$\Gamma(z_1,z_2)=:\Gamma^+(z_1)\Gamma^-(z_2):\tag{14}$$

(where the sign of normal ordering $::$ means that partial derivatives are always moved to the right), and show using the bilinear identity (8) that if τ is a solution of (12), then $(1+a\Gamma(z_1,z_2))\tau$, where $a, z_1, z_2\in\mathbb{C}^\times$, is a solution as well. Since $\tau=1$ is a solution, the function

$$f_N\equiv(1+a_1\Gamma(z_1^{(1)},z_2^{(1)}))\cdots(1+a_N\Gamma(z_1^{(N)},z_2^{(N)}))\cdot 1\tag{15}$$

is a solution of (12), too. This is the τ-function of the N-soliton solution.

The first application of the KP hierarchy, as well as its name, comes from the fact that the simplest nontrivial Zakharov–Shabat equation, namely (2) with $m=2$ and $n=3$, is equivalent to the Kadomtsev–Petviashvili equation if we let $x_1=x$, $x_2=y$, $x_3=t$, $u=2u_1$:

$$\frac{3}{4}\frac{\partial^2 u}{\partial y^2}=\frac{\partial}{\partial x}\left(\frac{\partial u}{\partial t}-\frac{3}{2}u\frac{\partial u}{\partial x}-\frac{1}{4}\frac{\partial^3 u}{\partial x^3}\right).\tag{16}$$

Recall also that the celebrated KdV and Boussinesq equations are simple reductions of (16). Since the functions u and τ are related by

$$u=2\frac{\partial^2}{\partial x^2}\log\tau,\tag{17}$$

the functions $2(\partial^2/\partial x^2)\log f_N$ are solutions of (16), called the N-soliton solutions.

The connection of the KP hierarchy to the representation theory of the group GL_∞ is achieved via the spinor formalism. Consider the Clifford algebra $C\ell$ on generators ψ_j^+ and ψ_j^- ($j\in 1/2+\mathbb{Z}$) and the following defining relations (i.e., $\psi_i^\pm$ are free charged fermions):

$$\psi_i^+\psi_j^-+\psi_j^-\psi_i^+=\delta_{i,-j},\quad \psi_i^\pm\psi_j^\pm+\psi_j^\pm\psi_i^\pm=0.\tag{18}$$

The algebra $C\ell$ has a unique irreducible representation in a vector space F (resp. F^*) which is a left (resp. right) module admitting a nonzero vector $|0\rangle$ (resp. $\langle 0|$) satisfying

$$\psi_j^\pm|0\rangle=0\ \ (\text{resp. } \langle 0|\psi_{-j}^\pm=0)\quad \text{for } j>0.\tag{19}$$

These representations are dual to each other with respect to the pairing

$$\langle\langle 0|a,b|0\rangle\rangle=\langle 0|ab|0\rangle$$

normalized by the condition $\langle 0|1|0\rangle=1$.

The Lie algebra gl_∞ embeds in $C\ell$ by letting

$$r(E_{ij})=\psi_{-i}^+\psi_j^-.\tag{20}$$

Exponentiating gives a representation R of the group GL_∞ on F and F^*. Let, for $n\in\mathbb{Z}$,

$$\alpha_n=\sum_{j\in 1/2+\mathbb{Z}}\psi_{-j}^+\psi_{j+n}^-\quad\text{for } n\neq 0,\quad \alpha_0=\sum_{j>0}\psi_{-j}^+\psi_j^--\sum_{j<0}\psi_j^-\psi_{-j}^+.\tag{21}$$

and consider the following operator on F:

$$H(x)=\sum_{n=1}^{\infty}x_n\alpha_n.\tag{22}$$

For a positive integer m let

$$\langle \pm m| = \langle 0|\psi^{\pm}_{1/2}\cdots\psi^{\pm}_{m-1/2} \in F^* \quad \text{and} \quad |\pm m\rangle = \psi^{\pm}_{-m+1/2}\cdots\psi^{\pm}_{-1/2}|0\rangle \in F.$$

Then the Fock space is realized on the vector space of polynomials $B=\mathbb{C}[x_1,x_2,\ldots;Q,Q^{-1}]$ via the isomorphism $\sigma: F \tilde{\to} B$ defined by

$$\sigma(a|0\rangle) = \sum_{m\in\mathbb{Z}} \langle m|e^{H(x)}a|0\rangle Q^m. \tag{23}$$

This remarkable isomorphism is called the boson-fermion correspondence and goes back to the work of Skyrme[44] and many other physicists; this beautiful form of it is an important part of the work of Date, Jimbo, Kashiwara, and Miwa.[8,9,24]

Using that

$$[\alpha_m,\alpha_n] = m\delta_{m,-n} \tag{24}$$

(i.e., that the α_n are free bosons), it is not difficult to show that the isomorphism σ is characterized by the following two properties:[27]

$$\sigma(|m\rangle) = Q^m, \quad \sigma\alpha_n\sigma^{-1} = \frac{\partial}{\partial x_n} \quad \text{and} \quad \sigma\alpha_{-n}\sigma^{-1} = nx_n \quad \text{if } n>0. \tag{25}$$

Using (25), it is easy to recover the following well-known properties of the boson-fermion correspondence.[8,9,27] Introduce the fermionic fields

$$\psi^{\pm}(z) = \sum_{j\in 1/2+\mathbb{Z}} \psi^{\pm}_j z^{-j-1/2}.$$

Then one has

$$\sigma\psi^{\pm}(z)\sigma^{-1} = Q^{\pm 1}z^{\pm\alpha_0}\Gamma^{\pm}(z), \tag{26}$$

$$\sigma\left(\sum_{i,j\in 1/2+\mathbb{Z}} r(E_{ij})z_1^{i-1/2}z_2^{-j-1/2}\right)\sigma^{-1} = \frac{1}{z_1-z_2}\Gamma(z_1,z_2). \tag{27}$$

Hence $\Gamma(z_1,z_2)$ lies in a "completion" of the Lie algebra gl_∞ acting on B via the boson-fermion correspondence. Therefore, the group GL_∞ and its "completion" act on B and Date, Jimbo, Kashiwara, and Miwa show that all elements of the orbit $\mathcal{O}=\mathrm{GL}_\infty\cdot 1$ and its completions satisfy the bilinear identity (12). Since $\Gamma(z_1,z_2)^2=0$ and $\Gamma(z_1,z_2)$ lies in a completion of gl_∞, we see that $\exp a\Gamma(z_1,z_2)=1+a\Gamma(z_1,z_2)$ leaves a completion of the orbit $\mathcal{O}$ invariant, which explains why (15) are solutions of the KP hierarchy.

Since the orbit $\mathrm{GL}_\infty|0\rangle$ (which is the image of $\mathcal{O}$ in the fermionic picture) can be naturally identified with the cone over a Grassmannian, we arrive at the remarkable discovery of Sato that solutions of the KP hierarchy are parametrized by an infinite-dimensional Grassmannian.[41]

It was subsequently pointed out in Refs. 27 and 30 that the bilinear Eq. (8) (in the bosonic picture) corresponds to the following remarkably simple equation on the τ-function in the fermionic picture:

$$\sum_{k\in 1/2+\mathbb{Z}} \psi^+_k\tau\otimes\psi^-_{-k}\tau = 0. \tag{28}$$

This is the fermionic formulation of the KP hierarchy. Since (1) is equivalent to

$$\mathrm{Res}_{z=0}\psi^+(z)\tau\otimes\psi^-(z)\tau = 0, \tag{29}$$

it is clear from (10) and (11) that Eqs. (8) and (29) are equivalent. Since $\tau=|0\rangle$ obviously satisfies (1) and $R\otimes R(\mathrm{GL}_\infty)$ commutes with the operator $\Sigma_k \psi_k^+\otimes\psi_{-k}^-$, we see why any element of $R(\mathrm{GL}_\infty)|0\rangle$ satisfies (28). Thus, the most natural approach to the KP hierarchy is to start with the fermonic formulation (28), go over to the bilinear identity (8) and then to all other formulations (see Refs. 27, 30, and 25). This approach was generalized in Ref. 33.

Our basic idea is to start once again with the fermonic formulation of KP, but then use the *n*-component boson-fermion correspondence, also considered by Date, Jimbo, Kashiwara, and Miwa.[7,24] This leads to a bilinear equation on a matrix wave function, which in turn leads to a deformation equation for a matrix formal pseudo-differential operator, to matrix Sato equations and to matrix Zakharov–Shabat-type equations.

The corresponding linear problem has been already formulated in Sato's paper[41] and Date, Jimbo, Kashiwara, and Miwa[7] have written the corresponding bilinear equation for the wave function, but the connection between these formulations remained somewhat obscure.

It is the aim of the present article to give all formulations of the *n*-component KP hierarchy and clarify connections between them. The generalization to the *n*-component KP is important because it contains many of the most popular systems of soliton equations, like the Davey–Stewartson system (for $n=2$), the two-dimensional Toda lattice (for $n=2$), and the *n*-wave system (for $n\geqslant 3$). It also allows us to construct natural generalizations of the Davey–Stewartson and Toda lattice systems. Of course, the inclusion of all these systems in the *n*-component KP hierarchy allows us to construct their solutions by making use of vertex operators.

Hirota's direct method[23] requires some guesswork to introduce a new function (the τ-function) for which the equations in question take a bilinear form. The inclusion of the equations in the *n*-component KP hierarchy provides a systematic way of construction of the τ-functions, the corresponding bilinear equations and a large family of their solutions.

The difficulty of the τ-function approach lies in the fact that the hierarchy contains too many Hirota bilinear equations. To deal with this difficulty we introduce the notion of an energy of a Hirota bilinear equation. We observe that the most interesting equations are those of lowest energy. For example, in the $n=1$ case the lowest energy $(=4)$ nontrivial equation is the classical KP equation in the Hirota bilinear form, in the $n=2$ case the lowest energy $(=2)$ equations form the two-dimensional Toda chain and the energy 2 and 3 equations form the Davey–Stewartson system in the bilinear form, and in the $n\geqslant 3$ case the lowest energy $(=2)$ bilinear equations form the *n*-wave system in the bilinear form.

The Hirota bilinear equations of the *n*-component KP hierarchy also play a role in the theory of theta functions of Riemann surfaces. To be more specific, Maffei[35] shows that the theta function of a Riemann surfaces gives a τ function for the *n*-component KP hierarchy. He then uses the results of Sec. III D, formula (80), to show that such a theta function satisfies the Fay trisecant formula. He also shows that more complicated relations in the hierarchy give some theta relations obtained by Gunning in Ref. 20.

There is a new phenomenon in the *n*-component case, which does not occur in the one-component case: the τ-function and the wave function are a collection of functions $\{\tau_\alpha\}$ and $\{W_\alpha\}$ parametrized by the elements of the root lattice M of type A_{n-1}. The set $\mathrm{supp}\ \tau=\{\alpha\in M|\tau_\alpha\neq 0\}$ is called the support of the τ-function τ. We show that $\mathrm{supp}\ \tau$ is a convex polyhedron whose edges are parallel to roots; in particular, $\mathrm{supp}\ \tau$ is connected, which allows us to relate the behavior of the *n*-component KP hierarchy at different points of the lattice M. It is interesting to note that the ''matching conditions'' which relate the functions W_α and W_β, $\alpha,\beta\in M$, involve elements from the subgroup of translations of the Weyl group (Ref. 25, Chap. 6) of the loop group $\mathrm{GL}(\mathbb{C}[z,z^{-1}])$ and are intimately related to the Bruhat decomposition of this loop group (see Ref. 40). We are planning to study this in a future publication.

The behavior of solutions obtained via vertex operators in the *n*-component case is much more complicated than for the ordinary KP hierarchy. In particular, they are not necessarily multisoliton solutions (i.e., a collection of waves that preserve their form after interaction). For that reason we call them the multisolitary solutions. Some of the multisolitary solutions turn out to be the so called dromion solutions, which have become very popular recently.[6,19,22,21] These solutions decay

exponentially in all directions (and they are not soliton solutions; in particular, they exist only for $n>1$). It is a very interesting problem for which values of parameters the multisolitary solutions are soliton or dromion solutions.

Note also that the Krichever method for construction of the quasiperiodic solutions of the KP hierarchy as developed in Refs. 42 and 43 applies to the n-component KP (see, e.g., Ref. 35).

As shown in Refs. 41 and 8, the mth reduction of the KP hierarchy, i.e., the requirement that L^m is a differential operator, leads to the classical formulation of the celebrated KdV hierarchy for $m=2$, Boussinesq for $m=3$ and all the Gelfand–Dickey hierarchies for $m>3$. The totality of τ-functions for the mth reduced KP hierarchy turns out to be the orbit of the vacuum under the loop group of SL_m.

We define in a similar way the $[m_1,m_2,\dots,m_n]$-reduction of the n-component KP and show that the totality of τ-functions is the orbit of the vacuum vector under the loop group of $\mathrm{SL}_{m_1+\cdots+m_n}$ (see also Ref. 5). Even the case that all $m_j=1$ turns out to be extremely interesting (it is trivial if $n=1$), as it gives the $1+1$ n-wave system for $n\geqslant 3$, the Darboux-Egoroff system from topological field theory (see also Ref. 50) and the decoupled nonlinear Schrödinger (or AKNS) system for $n=2$. We note that the $[1,1,\dots,1]$-reduced n-component KP, which we call the n-component NLS hierarchy, admits a natural generalization to the case of an arbitrary simple Lie group G (the n-component NLS corresponding to GL_n). These hierarchies, which might be called the GNLS hierarchies, contain the systems studied by many authors (Refs. 10, 52, 53, and 33, among others).

The article is set out as follows. In Sec. II we explain the construction of the semi-infinite wedge representation F of the group GL_∞ and write down the equation of the GL_∞-orbit $\mathcal{O}$ of the vacuum $|0\rangle$ (Proposition 2.1). This equation is called the KP hierarchy in the fermionic picture. As usual, the Plücker map makes $\mathcal{O}$ a $\mathbb{C}^\times$-bundle over an infinite-dimensional Grassmannian. We describe the ''support'' of $\tau\in\mathcal{O}$ (Proposition 2.2).

In Sec. III we introduce the n-component bosonization and write down the fermionic fields in terms of bosonic ones via vertex operators (Theorem 3.1). This allows us to transport the KP hierarchy from the fermionic picture to the bosonic one (66) and write down the n-component KP hierarchy as a system of Hirota bilinear Eqs. (70). We describe the support of a τ-function in the bosonic picture (Proposition 3.1). At the end of the section we list all Hirota bilinear equations of lowest energy (73)–(79).

We start Sec. IV with an exposition of the theory of matrix formal pseudo-differential operators, and prove the crucial Lemma 4.1. This allows us to reformulate the n-component KP hierarchy (66) in terms of formal pseudo-differential operators [see (95) and (103)]. Using the crucial lemma we show that the bilinear Eq. (66) is equivalent to the Sato Eq. (113) and matching conditions (107) on the wave operators $P^+(\alpha)$. We show that Sato equation is the compatibility condition of Sato's linear problem (121) on the wave function (Proposition 4.3), and that compatibility of Sato equation implies the equivalent Lax and Zakharov–Shabat equations (Lemma 4.3). We prove that compatibility conditions completely determine the wave operators $P^+(\alpha)$ once one of them is given (Proposition 4.1). At the end of the section we write down explicitly the first Sato and Lax equations and relations between them.

In Sec. V we show that many well-known $2+1$ soliton equations are the simplest equations of the n-component KP hierarchy, and deduce from Sec. IV expressions for their τ-functions and the corresponding Hirota bilinear equations.

Using vertex operators we write down in Sec. VI the N-solitary solutions (219) of the n-component KP and hence of all its relatives. We discuss briefly the relation of this general solution to the known solutions to the relatives.

In Sec. VII we discuss the $[m_1,m_2,\dots,m_n]$-reductions of the n-component KP hierarchy. They reduce the $2+1$ soliton equations to $1+1$ soliton equations. We show that at the group theoretic level it corresponds to a reduction from GL_∞ (or rather a completion of it) to the subgroup $\mathrm{SL}_{m_1+\cdots+m_n}(\mathbb{C}[t,t^{-1}])$ (Proposition 7.1). We discuss in more detail the $[1,1,\dots,1]$-reduced n-component KP, which is a generalization of the NLS system and which admits further generalization to any simple Lie group.

In Sec. VIII we introduce the Lie algebra $W_{1+\infty}(\mathrm{gl}_n)$ and describe the Orlov–Schulman–Adler–Shiota–van Moerbeke formula for the n-component KP hierarchy. This formula gives a connection between the action of $W_{1+\infty}(\mathrm{gl}_n)$ on a tau function and the Orlov-Schulman symmetries of the wave function.

II. THE SEMI-INFINITE WEDGE REPRESENTATION OF THE GROUP GL_∞ AND THE KP HIERARCHY IN THE FERMIONIC PICTURE

Consider the infinite complex matrix group

$$\mathrm{GL}_\infty=\{A=(a_{ij})_{i,j\in\mathbb{Z}+1/2}|A \text{ is invertible and all but a finite number of } a_{ij}-\delta_{ij} \text{ are } 0\}$$

and its Lie algebra

$$\mathrm{gl}_\infty=\{a=(a_{ij})_{i,j\in\mathbb{Z}+1/2}| \text{ all but a finite number of } a_{ij} \text{ are } 0\}$$

with bracket $[a,b]=ab-ba$. The Lie algebra gl_∞ has a basis consisting of matrices E_{ij}, $i,j\in\mathbb{Z}+1/2$, where E_{ij} is the matrix with a 1 on the (i,j)th entry and zeros elsewhere.

Let $\mathbb{C}^\infty=\oplus_{j\in\mathbb{Z}+1/2}\mathbb{C}v_j$ be an infinite-dimensional complex vector space with fixed basis $\{v_j\}_{j\in\mathbb{Z}+1/2}$. Both the group GL_∞ and its Lie algebra gl_∞ act linearly on $\mathbb{C}^\infty$ via the usual formula:

$$E_{ij}(v_k)=\delta_{jk}v_i.$$

The well-known semi-infinite wedge representation is constructed as follows.[27] The semi-infinite wedge space $F=\Lambda^{1/2\infty}\mathbb{C}^\infty$ is the vector space with a basis consisting of all semi-infinite monomials of the form $v_{i_1}\wedge v_{i_2}\wedge v_{i_3}\wedge\cdots$, where $i_1>i_2>i_3>\cdots$ and $i_{\ell+1}=i_\ell-1$ for $\ell\gg 0$. We can now define representations R of GL_∞ and r of gl_∞ on F by

$$R(A)(v_{i_1}\wedge v_{i_2}\wedge v_{i_3}\wedge\cdots)=Av_{i_1}\wedge Av_{i_2}\wedge Av_{i_3}\wedge\cdots, \tag{30}$$

$$r(a)(v_{i_1}\wedge v_{i_2}\wedge v_{i_3}\wedge\cdots)=\sum_k v_{i_1}\wedge v_{i_2}\wedge\cdots\wedge v_{i_{k-1}}\wedge av_{i_k}\wedge v_{i_{k+1}}\wedge\cdots. \tag{31}$$

These equations are related by the usual formula:

$$\exp(r(a))=R(\exp a) \quad \text{for } a\in\mathrm{gl}_\infty.$$

The representation r of gl_∞ can be described in terms of a Clifford algebra. Define the wedging and contracting operators ψ_j^+ and ψ_j^- $(j\in\mathbb{Z}+1/2)$ on F by

$$\psi_j^+(v_{i_1}\wedge v_{i_2}\wedge\cdots)=\begin{cases}0 & \text{if } j=i_s \text{ for some } s,\\ (-1)^s v_{i_1}\wedge v_{i_2}\cdots\wedge v_{i_s}\wedge v_{-j}\wedge v_{i_{s+1}}\wedge\cdots & \text{if } i_s>-j>i_{s+1};\end{cases}$$

$$\psi_j^-(v_{i_1}\wedge v_{i_2}\wedge\cdots)=\begin{cases}0 & \text{if } j\neq i_s \text{ for all } s,\\ (-1)^{s+1} v_{i_1}\wedge v_{i_2}\wedge\cdots\wedge v_{i_{s-1}}\wedge v_{i_{s+1}}\wedge\cdots & \text{if } j=i_s.\end{cases}$$

These operators satisfy the following relations $(i,j\in\mathbb{Z}+1/2,\lambda,\mu=+,-)$:

$$\psi_i^\lambda\psi_j^\mu+\psi_j^\mu\psi_i^\lambda=\delta_{\lambda,-\mu}\delta_{i,-j}, \tag{32}$$

hence they generate a Clifford algebra, which we denote by $\mathcal{C}\ell$.

Introduce the following elements of F $(m\in\mathbb{Z})$:

$$|m\rangle=v_{m-1/2}\wedge v_{m-3/2}\wedge v_{m-5/2}\wedge\cdots.$$

It is clear that F is an irreducible $\mathcal{C}\ell$-module such that

$$\psi_j^{\pm}|0\rangle = 0 \quad \text{for } j > 0. \tag{33}$$

It is straightforward that the representation r is given by the following formula:

$$r(E_{ij}) = \psi_{-i}^{+}\psi_j^{-}. \tag{34}$$

Define the *charge decomposition*

$$F = \bigoplus_{m \in \mathbb{Z}} F^{(m)} \tag{35}$$

by letting

$$\text{charge}(v_{i_1} \wedge v_{i_2} \wedge \cdots) = m \quad \text{if } i_k + k = \frac{1}{2} + m \quad \text{for } k \gg 0. \tag{36}$$

Note that

$$\text{charge}(|m\rangle) = m \quad \text{and} \quad \text{charge}(\psi_j^{\pm}) = \pm 1. \tag{37}$$

It is clear that the charge decomposition is invariant with respect to $r(\mathrm{gl}_\infty)$ [and hence with respect to $R(\mathrm{GL}_\infty)$]. Moreover, it is easy to see that each $F^{(m)}$ is irreducible with respect to gl_∞ (and GL_∞). Note that $|m\rangle$ is its highest weight vector, i.e.,

$$r(E_{ij})|m\rangle = 0 \quad \text{for } i < j,$$

$$r(E_{ii})|m\rangle = 0 \ \ (\text{resp.} = |m\rangle) \quad \text{if } i > m \ \ (\text{resp. if } i < m).$$

The main object of our study is the GL_∞-orbit

$$\mathcal{O} = R(\mathrm{GL}_\infty)|0\rangle \subset F^{(0)}$$

of the vacuum vector $|0\rangle$.

Proposition 2.1:[27] *A nonzero element τ of $F^{(0)}$ lies in $\mathcal{O}$ if and only if the following equation holds in $F \otimes F$:*

$$\sum_{k \in \mathbb{Z}+1/2} \psi_k^{+} r \otimes \psi_{-k}^{-} \tau = 0. \tag{38}$$

Proof: It is clear that $\Sigma_k \psi_k^{+}|0\rangle \otimes \psi_{-k}^{-}|0\rangle = 0$ and it is easy to see that the operator $\Sigma_k \psi_k^{+} \otimes \psi_{-k}^{-} \in \mathrm{End}(F \otimes F)$ commutes with $R(g) \otimes R(g)$ for any $g \in \mathrm{GL}_\infty$. It follows that $R(g)|0\rangle$ satisfies (38). For the proof of the converse statement (which is not important for our purposes) see Ref. 27 or 30. □

Equation (38) is called the *KP hierarchy in the fermionic picture*.

Note that any nonzero element τ from the orbit $\mathcal{O}$ is of the form

$$\tau = u_{-1/2} \wedge u_{-3/2} \wedge u_{-5/2} \wedge \cdots, \quad \text{where } u_j \in \mathbb{C}^\infty \quad \text{and } u_{-k} = v_{-k} \quad \text{for } k \gg 0. \tag{39}$$

This allows us to construct a canonical map φ: $\mathcal{O} \to \mathrm{Gr}$ by $\varphi(\tau) = \Sigma_i \mathbb{C} u_{-i} \subset \mathbb{C}^\infty$, where Gr consists of the subspaces of $\mathbb{C}^\infty$ containing $\Sigma_{j=k}^{\infty} \mathbb{C} v_{-j-1/2}$ for $k \gg 0$ as a subspace of codimension k. It is clear that the map φ is surjective with fibers $\mathbb{C}^\times$.

A more general approach using the spin group of the above Clifford algebra is given in Ref. 32. As in the KP case there is a connection to Matrix models, see, e.g., Refs. 4 and 51.

Consider the free $\mathbb{Z}$-module $\widetilde{L}$ with the basis $\{\delta_j\}_{j \in 1/2+\mathbb{Z}}$, let $\widetilde{\Delta}\,(\text{resp. } \widetilde{\Delta}_0) = \{\delta_i - \delta_j | i, j \in 1/2 + \mathbb{Z}\,(\text{resp. } i, -j \in 1/2 + \mathbb{Z}_+), i \neq j\}$, and let $\widetilde{M} \subset \widetilde{L}$ (resp. $\widetilde{M}_0 \subset \widetilde{L}$) be the $\mathbb{Z}$-span of $\widetilde{\Delta}\,(\text{resp. } \widetilde{\Delta}_0)$. We define the weight of a semi-infinite monomial by

$$\text{weight}(\psi_{i_1}^{+}\cdots\psi_{i_s}^{+}\psi_{j_1}^{-}\cdots\psi_{j_t}^{-}|0\rangle)=\delta_{-i_1}+\cdots+\delta_{-i_s}-\delta_{j_1}-\cdots-\delta_{j_t}. \tag{40}$$

Note that weights of semi-infinite monomials from $F^{(0)}$ lie in $\widetilde{M}_0$. Given $\tau\in F$ we denote by $f\,\text{supp}\,\tau$, and call it the *fermionic support of* τ, the set of weights of semi-infinite monomials that occur in τ with a nonzero coefficient.

Proposition 2.2: If $\tau\in\mathcal{O}$, *then f supp* τ *is the intersection of* $\widetilde{M}_0$ *with a convex polyhedron with vertices in* $\widetilde{M}_0$ *and edges in* $\widetilde{\Delta}_0$.

Proof: According to the general result (Ref. 40, Lemma 4), the edges of the convex hull of $f\,\text{supp}\,\tau$ must be parallel to the elements of $\widetilde{\Delta}_0$. But if the difference of weights of two semi-infinite monomials is a multiple of $\delta_i-\delta_j$, then it is clearly equal to $\pm(\delta_i-\delta_j)$. Hence edges of the convex hull of $f\,\text{supp}\,\tau$ are elements of $\widetilde{\Delta}_0$, and the proposition follows. □

III. THE *n*-COMPONENT BOSONIZATION AND THE KP HIERARCHY IN THE BOSONIC PICTURE

Using a bosonization one can rewrite (38) as a system of partial differential equations. There are, however, many different bosonizations. In this article we focus on the *n*-component bosonizations, where $n=1,2,\ldots$.

For that purpose we relabel the basis vectors v_i and with them the corresponding fermionic operators (the wedging and contracting operators). This relabeling can be done in many different ways, see, e.g., Ref. 46. The simplest one is the following.

Fix $n\in\mathbb{N}$ and define for $j\in\mathbb{Z}$, $1\leqslant j\leqslant n$, $k\in\mathbb{Z}+1/2$:

$$v_k^{(j)}=v_{nk-(1/2)(n-2j+1)},$$

and correspondingly:

$$\psi_k^{\pm(j)}=\psi_{nk\pm(1/2)(n-2j+1)}^{\pm}.$$

Notice that with this relabeling we have

$$\psi_k^{\pm(j)}|0\rangle=0 \quad \text{for } k>0.$$

The charge decomposition (36) can be further decomposed into a sum of *partial charges* which are denoted by charge_j, $j=1,\ldots,n$, defined for a semi-infinite monomial $v\equiv v_{i_1}\wedge v_{i_2}\wedge\cdots$ of weight $\Sigma_i a_i\delta_i$ by

$$\text{charge}_j(v)=\sum_{k\in\mathbb{Z}}a_{kn+j-1/2}, \tag{41}$$

which is equivalent to

$$\text{charge}_j\ \ \psi_k^{\pm(i)}=\pm\delta_{ij}, \quad \text{charge}_j|0\rangle=0.$$

Another important decomposition is the *energy decomposition* defined by

$$\text{energy}|0\rangle=0, \quad \text{energy}\ \ \psi_k^{\pm(j)}=-k. \tag{42}$$

Note that energy is a non-negative number which can be calculated by

$$\text{energy}(v)=\sum_{k\in 1/2+\mathbb{Z}}a_k\left(\left[\frac{k}{n}\right]+\frac{1}{2}\right). \tag{43}$$

Introduce the fermionic fields ($z\in\mathbb{C}^{\times}$):

$$\psi^{\pm(j)}(z)\overset{\text{def}}{=}\sum_{k\in\mathbb{Z}+1/2}\psi_k^{\pm(j)}z^{-k-1/2}. \tag{44}$$

Next we introduce bosonic fields ($1\leqslant i,j\leqslant n$):

$$\alpha^{(ij)}(z)\equiv\sum_{k\in\mathbb{Z}}\alpha_k^{(ij)}z^{-k-1}\overset{\text{def}}{=}:\psi^{+(i)}(z)\psi^{-(j)}(z):, \tag{45}$$

where $::$ stands for the *normal ordered product* defined in the usual way (λ, $\mu=+$ or $-$):

$$:\psi_k^{\lambda(i)}\psi_\ell^{\mu(j)}:=\begin{cases}\psi_k^{\lambda(i)}\psi_\ell^{\mu(j)} & \text{if } \ell>0,\\ -\psi_\ell^{\mu(j)}\psi_k^{\lambda(i)} & \text{if } \ell<0.\end{cases} \tag{46}$$

One checks (using, e.g., the Wick formula) that the operators $\alpha_k^{(ij)}$ satisfy the commutation relations of the affine algebra $\mathrm{gl}_n(\mathbb{C})\hat{}$ with central charge 1, i.e.,

$$[\alpha_p^{(ij)},\alpha_q^{(k\ell)}]=\delta_{jk}\alpha_{p+q}^{(i\ell)}-\delta_{i\ell}\alpha_{p+q}^{(kj)}+p\,\delta_{i\ell}\delta_{jk}\delta_{p,-q}, \tag{47}$$

and that

$$\alpha_k^{(ij)}|m\rangle=0 \quad \text{if } k>0 \quad \text{or } k=0 \quad \text{and } i<j. \tag{48}$$

The operators $\alpha_k^{(i)}\equiv\alpha_k^{(ii)}$ satisfy the canonical commutation relation of the associative oscillator algebra, which we denote by $\mathfrak{a}$:

$$[\alpha_k^{(i)},\alpha_\ell^{(j)}]=k\,\delta_{ij}\delta_{k,-\ell}, \tag{49}$$

and one has

$$\alpha_k^{(i)}|m\rangle=0 \quad \text{for } k>0. \tag{50}$$

It is easy to see that restricted to $\mathrm{gl}_n(\mathbb{C})\hat{}$, $F^{(0)}$ is its basic highest weight representation (see Ref. 25, Chap. 12). The $\mathrm{gl}_n(\mathbb{C})\hat{}$-weight of a semi-infinite monomial v is as follows:

$$\Lambda_0+\sum_{j=1}^{n}\text{charge}_j(v)\,\delta_j-\text{energy}(v)\,\tilde{\delta}. \tag{37}$$

Here Λ_0 is the highest weight of the basic representation, $\{\delta_j\}$ is the standard basis of the weight lattice of $\mathrm{gl}_n(\mathbb{C})$ and $\tilde{\delta}$ is the primitive imaginary root (Ref. 25, Chap. 7).

In order to express the fermionic fields $\psi^{\pm(i)}(z)$ in terms of the bosonic fields $\alpha^{(ii)}(z)$, we need some additional operators Q_i, $i=1,\ldots,n$, on F. These operators are uniquely defined by the following conditions:

$$Q_i|0\rangle=\psi_{-1/2}^{+(i)}|0\rangle, \quad Q_i\psi_k^{\pm(j)}=(-1)^{\delta_{ij}+1}\psi_{k\mp\delta_{ij}}^{\pm(j)}Q_i. \tag{52}$$

They satisfy the following commutation relations:

$$Q_iQ_j=-Q_jQ_i \quad \text{if } i\neq j, \quad [\alpha_k^{(i)},Q_j]=\delta_{ij}\delta_{k0}Q_j. \tag{53}$$

Theorem 3.1:[7,24]

$$\psi^{\pm(i)}(z)=Q_i^{\pm1}z^{\pm\alpha_0^{(i)}}\exp\left(\mp\sum_{k<0}\frac{1}{k}\alpha_k^{(i)}z^{-k}\right)\exp\left(\mp\sum_{k>0}\frac{1}{k}\alpha_k^{(i)}z^{-k}\right). \tag{54}$$

Proof: See Ref. 46.

The operators on the right-hand side of (54) are called vertex operators. They made their first appearance in string theory (cf. Ref. 16).

We shall use below the following notation:

$$|k_1,\ldots,k_n\rangle = Q_1^{k_1}\cdots Q_n^{k_n}|0\rangle. \tag{55}$$

Remark 3.1: One easily checks the following relations:

$$[\alpha_k^{(i)},\psi_m^{\pm(j)}] = \pm\delta_{ij}\psi_{k+m}^{\pm(j)}.$$

They imply formula (54) for $\psi^{\pm(i)}(z)$ except for the first two factors, which require some additional analysis.

We can describe now the n-component boson-fermion correspondence. Let $\mathbb{C}[x]$ be the space of polynomials in indeterminates $x=\{x_k^{(i)}\}$, $k=1,2,\ldots$, $i=1,2,\ldots,n$. Let L be a lattice with a basis $\delta_1,\ldots,\delta_n$ over $\mathbb{Z}$ and the symmetric bilinear form $(\delta_i|\delta_j)=\delta_{ij}$, where δ_{ij} is the Kronecker symbol. Let

$$\epsilon_{ij} = \begin{cases} -1 & \text{if } i>j, \\ 1 & \text{if } i\leqslant j. \end{cases} \tag{56}$$

Define a bimultiplicative function $\epsilon: L\times L\to\{\pm 1\}$ by letting

$$\epsilon(\delta_i,\delta_j) = \epsilon_{ij}. \tag{57}$$

Let $\delta=\delta_1+\cdots+\delta_n$, $M=\{\gamma\in L|(\delta|\gamma)=0\}$, $\Delta=\{\alpha_{ij}:=\delta_i-\delta_j|i,j=1,\ldots,n,i\neq j\}$. Of course M is the root lattice of $\mathrm{sl}_n(\mathbb{C})$, the set Δ being the root system.

Consider the vector space $\mathbb{C}[L]$ with basis e^γ, $\gamma\in L$, and the following twisted group algebra product:

$$e^\alpha e^\beta = \epsilon(\alpha,\beta)e^{\alpha+\beta}. \tag{58}$$

Let $B=\mathbb{C}[x]\otimes_{\mathbb{C}}\mathbb{C}[L]$ be the tensor product of algebras. Then the n-component boson-fermion correspondence is the vector space isomorphism

$$\sigma: F\xrightarrow{\sim} B, \tag{59}$$

given by

$$\sigma(\alpha_{-m_1}^{(i_1)}\cdots\alpha_{-m_s}^{(i_s)}|k_1,\ldots,k_n\rangle) = m_1\cdots m_s x_{m_1}^{(i_1)}\cdots x_{m_s}^{(i_s)}\otimes e^{k_1\delta_1+\cdots+k_n\delta_n}. \tag{60}$$

The transported charge and energy then will be as follows:

$$\mathrm{charge}(p(x)\otimes e^\gamma) = (\delta|\gamma), \quad \mathrm{charge}_j(p(x)\otimes e^\gamma) = (\delta_j|\gamma), \tag{61}$$

$$\mathrm{energy}(x_{m_1}^{(i_1)}\cdots x_{m_s}^{(i_s)}\otimes e^\gamma) = m_1+\cdots+m_s+\tfrac{1}{2}(\gamma|\gamma). \tag{62}$$

We denote the transported charge decomposition by

$$B = \bigoplus_{m\in\mathbb{Z}} B^{(m)}.$$

The transported action of the operators $\alpha_m^{(i)}$ and Q_j looks as follows:

$$\sigma\alpha_{-m}^{(j)}\sigma^{-1}(p(x)\otimes e^\gamma) = mx_m^{(j)}p(x)\otimes e^\gamma, \quad \text{if } m>0,$$

$$\sigma\alpha_m^{(j)}\sigma^{-1}(p(x)\otimes e^{\gamma})=\frac{\partial p(x)}{\partial x_m}\otimes e^{\gamma},\quad \text{if } m>0,$$
$$\sigma\alpha_0^{(j)}\sigma^{-1}(p(x)\otimes e^{\gamma})=(\delta_j|\gamma)p(x)\otimes e^{\gamma}, \tag{63}$$
$$\sigma Q_j\sigma^{-1}(p(x)\otimes e^{\gamma})=\epsilon(\delta_j,\gamma)p(x)\otimes e^{\gamma+\delta_j}.$$

Using the isomorphism σ we can reformulate the KP hierarchy (38) in the bosonic picture as a hierarchy of Hirota bilinear equations.

We start by observing that (38) can be rewritten as follows:

$$\mathrm{Res}_{z=0}dz\left(\sum_{j=1}^{n}\psi^{+(j)}(z)\tau\otimes\psi^{-(j)}(z)\tau\right)=0,\quad \tau\in F^{(0)}. \tag{64}$$

Here and further $\mathrm{Res}_{z=0}dz\Sigma_j f_j z^j$ (where f_j are independent of z) stands for f_{-1}. Notice that for $\tau\in F^{(0)}$, $\sigma(\tau)=\Sigma_{\gamma\in M}\tau_\gamma(x)e^{\gamma}$. Here and further we write $\tau_\gamma(x)e^{\gamma}$ for $\tau_\gamma\otimes e^{\gamma}$. Using Theorem 3.1, Eq. (64) turns under $\sigma\otimes\sigma: F\otimes F\xrightarrow{\sim}\mathbb{C}[x',x'']\otimes(\mathbb{C}[L']\otimes\mathbb{C}[L''])$ into the following equation:

$$\mathrm{Res}_{z=0}dz\left(\sum_{j=1}^{n}\sum_{\alpha,\beta\in M}\epsilon(\delta_j,\alpha-\beta)z^{(\delta_j|\alpha-\beta)}\exp\left(\sum_{k=1}^{\infty}(x_k^{(j)'}-x_k^{(j)''})z^k\right)\right.$$
$$\left.\times\exp\left(-\sum_{k=1}^{\infty}\left(\frac{\partial}{\partial x_k^{(j)'}}-\frac{\partial}{\partial x_k^{(j)''}}\right)\frac{z^{-k}}{k}\right)\tau_\alpha(x')(e^{\alpha+\delta_j})'\tau_\beta(x'')(e^{\beta-\delta_j})''\right)=0. \tag{65}$$

Hence for all $\alpha,\beta\in L$ such that $(\alpha|\delta)=-(\beta|\delta)=1$ we have

$$\mathrm{Res}_{z=0}\left(dz\sum_{j=1}^{n}\epsilon(\delta_j,\alpha-\beta)z^{(\delta_j|\alpha-\beta-2\delta_j)}\exp\left(\sum_{k=1}^{\infty}(x_k^{(j)'}-x_k^{(j)''})z^k\right)\right.$$
$$\left.\times\exp\left(-\sum_{k=1}^{\infty}\left(\frac{\partial}{\partial x_k^{(j)'}}-\frac{\partial}{\partial x_k^{(j)''}}\right)\frac{z^{-k}}{k}\right)\tau_{\alpha-\delta_j}(x')\tau_{\beta+\delta_j}(x'')\right)=0. \tag{66}$$

Now making the change of variables

$$x_k^{(j)}=\tfrac{1}{2}(x_k^{(j)'}+x_k^{(j)''}),\quad y_k^{(j)}=\tfrac{1}{2}(x_k^{(j)'}-x_n^{(j)''}),$$

(66) becomes

$$\mathrm{Res}_{z=0}\left(dz\sum_{j=1}^{n}\epsilon(\delta_j,\alpha-\beta)z^{(\delta_j|\alpha-\beta-2\delta_j)}\exp\left(\sum_{k=1}^{\infty}2y_k^{(j)}z^k\right)\exp\left(-\sum_{k=1}^{\infty}\frac{\partial'}{\partial y_k^{(j)}}\frac{z^{-k}}{k}\right)\right.$$
$$\left.\times\tau_{\alpha-\delta_j}(x+y)\tau_{\beta+\delta_j}(x-y)\right)=0. \tag{67}$$

We can rewrite (67) using the elementary Schur polynomials defined by (13):

$$\sum_{j=1}^{n}\epsilon(\delta_j,\alpha-\beta)\sum_{k=0}^{\infty}S_k(2y^{(j)})S_{k-1+(\delta_j|\alpha-\beta)}\left(-\frac{\tilde{\partial}}{\partial y^{(j)}}\right)\tau_{\alpha-\delta_j}(x+y)\tau_{\beta+\delta_j}(x-y)=0. \tag{68}$$

Here and further we use the notation

$$\frac{\tilde{\partial}}{\partial y}=\left(\frac{\partial}{\partial y_1},\frac{1}{2}\frac{\partial}{\partial y_2},\frac{1}{3}\frac{\partial}{\partial y_3},\ldots\right).$$

Using Taylor's formula we can rewrite (68) once more:

$$\sum_{j=1}^{n}\epsilon(\delta_j,\alpha-\beta)\sum_{k=0}^{\infty}S_k(2y^{(j)})S_{k-1+(\delta_j|\alpha-\beta)}\left(-\frac{\tilde{\partial}}{\partial u^{(j)}}\right)$$
$$\times e^{\Sigma_{j=1}^{n}\Sigma_{r=1}^{\infty}y_r^{(j)}\partial/\partial u_r^{(j)}}\tau_{\alpha-\delta_j}(x+u)\tau_{\beta+\delta_j}(x-u)|_{u=0}=0. \tag{69}$$

This last equation can be written as the following generating series of Hirota bilinear equations:

$$\sum_{j=1}^{n}\epsilon(\delta_j,\alpha-\beta)\sum_{k=0}^{\infty}S_k(2y^{(j)})S_{k-1+(\delta_j|\alpha-\beta)}(-\widetilde{D^{(j)}})e^{\Sigma_{j=1}^{n}\Sigma_{r=1}^{\infty}y_r^{(j)}D_r^{(j)}}\tau_{\alpha-\delta_j}\cdot\tau_{\beta+\delta_j}=0 \tag{70}$$

for all $\alpha,\beta\in L$ such that $(\alpha|\delta)=-(\beta|\delta)=1$. Hirota's dot notation used here and further is explained in the Introduction [see (9)].

Equation (70) is known (see Refs. 7, 8, and 24) as the *n*-component KP hierarchy of Hirota bilinear equations. This equation still describes the group orbit: $\sigma(\mathcal{O})=\sigma R\sigma^{-1}(\mathrm{GL}_\infty)\cdot 1$.

Remark 3.2: Equation (70) is invariant under the transformations $\alpha\mapsto\alpha+\gamma$, $\beta\mapsto\beta+\gamma$, where $\gamma\in M$. Transformations of this type are called Schlesinger transformations.

Let $\tau=\Sigma_{\gamma\in L}\tau_\gamma(x)e^\gamma\in B$; the set $\mathrm{supp}\ \tau=_{\mathrm{def}}\{\gamma\in L|\tau_\gamma\neq 0\}$ is called the *support* of τ.

Proposition 3.1: Let $\tau\in\mathbb{C}[[x]]\otimes\mathbb{C}[M]$ be a solution to the KP hierarchy (67). Then supp τ is the intersection of M with a convex polyhedron with vertices in M and edges parallel to elements of Δ.

Proof: Consider the linear map $\overline{\sigma}:\tilde{L}\to L$ defined by $\overline{\sigma}(\delta_j)=\delta_{(j+1/2)\bmod n}$, where $a\bmod n$ stands for the element of the set $\{1,\ldots,n\}$ congruent to $a\bmod n$. Then it is easy to see that for $\tau\in F$ we have

$$\mathrm{supp}\ \ \sigma(\tau)=\overline{\sigma}(f\ \ \mathrm{supp}\ \ \tau).$$

Now Proposition 3.1 follows from Proposition 2.2. □

The indeterminates $y_k^{(j)}$ in (70) are free parameters, hence the coefficient of a monomial $y_{k_1}^{(j_1)}\cdots y_{k_s}^{(j_s)}$ $(k_i\in\mathbb{N},k_1\leqslant k_2\leqslant\cdots,j_i\in\{1,\ldots,n\})$ in Eq. (70) gives us a Hirota bilinear equation of the form

$$\sum_{i=1}^{n}\sum_{\alpha,\beta}Q_{k;\alpha,\beta}^{(j)}(D)\tau_{\alpha-\delta_i}\cdot\tau_{\beta+\delta_i}=0, \tag{71}$$

where $Q_{k,\alpha,\beta}^{(j)}$ are polynomials in the $D_r^{(i)}$, $k=(k_1,\ldots,k_s)$, $j=(j_1,\ldots,j_s)$ and $\alpha,\beta\in L$ are such that $(\alpha|\delta)=-(\beta|\delta)=1$. Each of these equations is a partial differential equation (PDE) in the indeterminates $x_k^{(j)}$ on functions τ_γ, $\gamma\in M$.

Recall that an expression $Q(D)\tau_\alpha\cdot\tau_\beta$ is identically zero if and only if $\alpha=\beta$ and $Q(D)=-Q(-D)$. The corresponding Hirota bilinear equation is then called *trivial* and can be disregarded.

Let us point out now that the energy decomposition (62) induces the following energy decomposition on the space of Hirota bilinear equations:

$$\mathrm{energy}(Q_{k;\alpha,\beta}^{(j)}(D)\tau_{\alpha-\delta_i}\cdot\tau_{\beta+\delta_i})=k_1+\cdots+k_s+\tfrac{1}{2}((\alpha|\alpha)+(\beta|\beta)). \tag{72}$$

It is clear that the energy of a nontrivial Hirota bilinear equation is at least 2.

Below we list the Hirota bilinear equations of lowest energy for each *n*.

$n=1$. In this case we may drop the superscript in $D_k^{(1)}$ and the subscript in τ_α (which is 0). Each monomial $y_{k_1}\cdots y_{k_s}$ gives a Hirota bilinear equation of the form

$$Q_k(D)\tau\cdot\tau=0$$

of energy $k_1+\cdots+k_s+1$. An easy calculation shows that the lowest energy of a nontrivial equation is 4, and that there is a unique nontrivial equation of energy 4, the classical KP equation in the Hirota bilinear form:

$$(D_1^4-4D_1D_3+3D_2^2)\tau\cdot\tau=0. \tag{73}$$

$n\geqslant 2$. There is an equation of energy 2 for each unordered pair of distinct indices i and k (recall that $\alpha_{ik}=\delta_i-\delta_k$ are roots):

$$D_1^{(i)}D_1^{(k)}\tau_0\cdot\tau_0=2\tau_{\alpha_{ik}}\tau_{\alpha_{ki}}. \tag{74}$$

Furthermore, for each ordered pair of distinct indices i and j there are three equations of energy 3:

$$(D_2^{(i)}+D_1^{(i)2})\tau_0\cdot\tau_{\alpha_{ij}}=0, \tag{75}$$

$$(D_2^{(j)}+D_1^{(j)2})\tau_{\alpha_{ij}}\cdot\tau_0=0, \tag{76}$$

$$D_1^{(i)}D_2^{(j)}\tau_0\cdot\tau_0+2D_1^{(j)}\tau_{\alpha_{ij}}\cdot\tau_{\alpha_{ji}}=0. \tag{77}$$

$n\geqslant 3$. There is an equation of energy 2 and an equation of energy 3 for each ordered triple of distinct indices i, j, k:

$$D_1^{(k)}\tau_0\cdot\tau_{\alpha_{ij}}=\epsilon_{ik}\epsilon_{kj}\epsilon_{ij}\tau_{\alpha_{ik}}\tau_{\alpha_{kj}}, \tag{78}$$

$$D_2^{(k)}\tau_0\cdot\tau_{\alpha_{ij}}=\epsilon_{ij}\epsilon_{kj}\epsilon_{ik}D_1^{(k)}\tau_{\alpha_{ik}}\cdot\tau_{\alpha_{kj}}. \tag{79}$$

[Note that (76) is a special case of (79) where $k=j$.]

$n\geqslant 4$. There is an algebraic equation of energy 2 for each ordered quadruple of distinct indices i, j, k, ℓ:

$$\epsilon_{ij}\epsilon_{k\ell}\tau_0\tau_{\alpha_{ik}+\alpha_{j\ell}}+\epsilon_{i\ell}\epsilon_{jk}\tau_{\alpha_{ik}}\tau_{\alpha_{j\ell}}+\epsilon_{ik}\epsilon_{j\ell}\tau_{\alpha_{i\ell}}\tau_{\alpha_{jk}}=0. \tag{80}$$

Equations (74)–(80), together with an algebraic equation of energy 3 for each ordered sextuple of distinct indices similar to (80), form a complete list of nontrivial Hirota bilinear equations of energy $\leqslant 3$ of the n-component KP hierarchy.

IV. THE ALGEBRA OF FORMAL PSEUDO-DIFFERENTIAL OPERATORS AND THE n-COMPONENT KP HIERARCHY AS A DYNAMICAL SYSTEM

The KP hierarchy and its n-component generalizations admit several formulations. The one given in the previous section obtained by the field theoretical approach is the τ-function formulation given by Date, Jimbo, Kashiwara, and Miwa.[7] Another well-known formulation, introduced by Sato,[41] is given in the language of formal pseudo-differential operators. We will show that this formulation follows from the τ-function formulation given by Eq. (66).

We shall work over the algebra $\mathcal{A}$ of formal power series over $\mathbb{C}$ in indeterminates ξ and $x=(x_k^{(j)})$, where $k=1,2,...$ and $j=1,...,n$. The indeterminate ξ will be viewed as a variable and the $x_k^{(j)}$ as parameters. Let

$$\partial = \frac{\partial}{\partial \xi}.$$

A *formal $n\times n$ matrix pseudo-differential operator* is an expression of the form

$$P(\xi,x,\partial) = \sum_{j\leqslant N} P_j(\xi,x)\partial^j, \tag{81}$$

where P_j are $n\times n$ matrices over $\mathcal{A}$. The largest N such that $P_N \neq 0$ is called the *order* of $P(\xi,x,\partial)$ [write $\operatorname{ord} P(\xi,x,\partial) = N$]. The coefficient P_{-1} is called the *residue* of P (write $\operatorname{Res}_\partial P = P_{-1}$). Let Ψ denote the vector space over $\mathbb{C}$ of all expressions (81). We have a linear isomorphism $s:\Psi \to \operatorname{Mat}_n(\mathcal{A}((z)))$ given by $s(P(\xi,x,\partial)) = P(\xi,x,z)$. The matrix series $P(\xi,x,z)$ in indeterminates ξ, x and z is called the *symbol* of $P(\xi,x,\partial)$.

Now we may define a product $\circ$ on Ψ making it an associative algebra:

$$s(P\circ Q) = \sum_{n=0}^{\infty} \frac{1}{n!} \frac{\partial^n s(P)}{\partial z^n} \partial^n s(Q).$$

We shall often drop the multiplication sign $\circ$ when no ambiguity may arise. Letting $\Psi(m) = \{P \in \Psi \,|\, \operatorname{ord}\Psi \leqslant m\}$, we get a $\mathbb{Z}$-filtration of the algebra Ψ:

$$\cdots \Psi(m+1) \supset \Psi(m) \supset \Psi(m-1) \supset \cdots. \tag{82}$$

One defines the differential part of $P(\xi,x,\partial)$ by $P_+(\xi,x,\partial) = \Sigma_{j=0}^N P_j(\xi,x)\partial^j$, and let $P_- = P - P_+$. We have the corresponding vector space decomposition:

$$\Psi = \Psi_- \oplus \Psi_+. \tag{83}$$

One defines a linear map $*:\Psi\to\Psi$ by the following formula:

$$\left(\sum_j P_j \partial^j\right)^* = \sum_j (-\partial)^j \circ {}^t P_j. \tag{84}$$

Here and further ${}^tP$ stands for the transpose of the matrix P. Note that $*$ is an anti-involution of the algebra Ψ. In terms of symbols the anti-involution $*$ can be written in the following closed form:

$$P^*(\xi,x,z) = \left(\exp \partial \frac{\partial}{\partial z}\right) {}^t P(\xi,x,-z). \tag{85}$$

It is clear that the anti-involution $*$ preserves the filtration (82) and the decomposition (83).

Introduce the following notation:

$$z\cdot x^{(j)} = z\xi + \sum_{k=1}^{\infty} z^k x_k^{(j)}, \quad e^{z\cdot x} = \operatorname{diag}(e^{z\cdot x^{(1)}},\ldots,e^{z\cdot x^{(n)}}).$$

The algebra Ψ acts on the space U_+ (resp. U_-) of formal oscillating matrix functions of the form

$$\sum_{j\leqslant N} P_j z^j e^{z\cdot x}\left(\text{resp. } \sum_{j\leqslant N} P_j z^j e^{-z\cdot x}\right), \quad \text{where } P_j \in \operatorname{Mat}_n(\mathcal{A}),$$

in the obvious way:

$$P(\xi,x)\partial^j e^{\pm z\cdot x} = P(\xi,x)(\pm z)^j e^{\pm z\cdot x}.$$

We can now prove the following fundamental lemma.

Lemma 4.1: For $P,Q\in\Psi$ one has

$$\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})({}^tQ(\xi-\eta,x',-z)e^{z(\eta-\xi)})dz=\mathrm{Res}_{\partial}P(\xi,x,\partial)\circ Q^*(\xi,x',\partial)\circ e^{\eta\partial}. \quad (86)$$

Proof: We first prove Eq. (86) for $\eta=0$, i.e.,

$$\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})({}^tQ(\xi,x',-z)e^{-z\xi})dz=\mathrm{Res}_{\partial}P(\xi,x,\partial)\circ Q^*(\xi,x',\partial). \quad (87)$$

For this purpose we let $P(\xi,x,\partial)=\Sigma_i P_i\partial^i$ and ${}^tQ(\xi,x',\partial)=\Sigma_j Q_j(-\partial)^j$. Then the left-hand side of (87) is

$$\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})({}^tQ(\xi,x',-z)e^{-z\xi})dz=\sum_{i+j=-1}P_i\ {}^tQ_j. \quad (88)$$

The right-hand side of (87) is equal to $\mathrm{Res}_{\partial}\Sigma_{i,j}P_i\partial^{i+j}\,{}^tQ_j$. Since $\binom{k-1}{k}=0$ for $k>0$ we deduce that this is equal to

$$\begin{aligned}\mathrm{Res}_{\partial}\sum_{i,j}P_i\partial^{i+j}\ {}^tQ_j&=\mathrm{Res}_{\partial}\sum_{i,j}\sum_{k=0}^{\infty}\binom{i+j}{k}\frac{\partial^k\ {}^tQ}{\partial\xi^k}\partial^{i+j-k}\\&=\sum_{i+j+1=k\geqslant 0}\binom{i+j}{k}\frac{\partial^k\ {}^tQ}{\partial\xi^k}\partial^{i+j-k}\\&=\sum_{i+j=-1}P_i\ {}^tQ_j,\end{aligned}$$

which is equal to (88). This proves (87). Next, we use Taylor's formula and rewrite the left-hand side of (86):

$$\begin{aligned}&\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})({}^tQ(\xi-\eta,x',-z)e^{z(\eta-\xi)})dz\\&=\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})\sum_{k=0}^{\infty}\frac{(-\eta)^k}{k!}\frac{\partial^k}{\partial\xi^k}({}^tQ(\xi,x',-z)e^{-z\xi})dz\\&=\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})\sum_{k=0}^{\infty}\frac{(-\eta)^k}{k!}\sum_{\ell=0}^{k}\binom{k}{\ell}\frac{\partial^{\ell}\ {}^tQ(\xi,x',-z)}{\partial\xi^{\ell}}(-z)^{k-\ell}e^{-z\xi}dz\\&=\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})\sum_{k=0}^{\infty}\frac{(\eta)^k}{k!}{}^t((-\partial)^kQ(\xi,x',\partial))e^{-z\xi}dz. \quad (89)\end{aligned}$$

Using (87) we find that the last line of (89) is equal to

$$\mathrm{Res}_{\partial}\sum_{k=0}^{\infty}\frac{(\eta)^k}{k!}P(\xi,x,\partial)\circ Q^*(\xi,x',\partial)\circ\partial^k,$$

which is equal to the right-hand side of (86). □

As a consequence of this lemma one finds the following corollary.

Corollary 4.1: The equality

$$\mathrm{Res}_{z=0}(P(\xi,x,z)e^{z\xi})({}^tQ(\xi',x',-z)e^{-z\xi'})dz=0 \quad (90)$$

is equivalent to

$$(P(\xi,x,\partial)\circ Q^*(\xi,x',\partial))_- = 0. \tag{91}$$

Proof: Substitute $\xi' = \xi - \eta$ in (90). Now use Lemma 4.1 and one obtains that

$$\mathrm{Res}_\partial P(\xi,x,\partial)\circ Q^*(\xi,x',\partial)\circ e^{\eta\partial} = 0.$$

Next write $e^{\eta\partial} = \Sigma_{j=0}^{\infty}(\partial^j/j!)\,\eta^j$ and (91) follows immediately. The converse is proved in a similar way. □

In this article we will sometimes use infinite order pseudo-differential operators. Following Mulase[37] we define a valuation

$$\mathrm{val}_x : \mathcal{A}\backslash\{0\} \to \{0,1,2,3,\ldots\}$$

by

$$\mathrm{val}_x x_k^{(j)} = \mathrm{energy}(x_k^{(j)}) = k$$

and take a completion of Ψ defined as follows:

$$\hat{\Psi} = \left\{ P = \sum_{j\in\mathbb{Z}} P_j\partial^j \,\middle|\, P_j \in \mathcal{A} \quad \text{and there is a positive real number } C_P \right.$$
$$\left. \text{and positive integers } M_P \text{ and } N_P \text{ such that } \mathrm{val}_x P_j > C_P j - N_P \quad \text{for all } j > M_P \right\}.$$

The completion $\hat{\Psi}$ has a natural associative algebra structure. We refer for more information to Refs. 36 and 37. It is straightforward to check the following:

Remark 4.1: Lemma 4.1 and Corollary 4.1 also hold for $P,Q \in \hat{\Psi}$.

We proceed now to rewrite the formulation (66) of the *n*-component KP hierarchy in terms of formal pseudo-differential operators.

Let $1 \leqslant a,\ b \leqslant n$ and recall formula (66) where α is replaced by $\alpha + \delta_a$, β by $\beta - \delta_b$ and all $x_1^{(j)}$ for $1 \leqslant j \leqslant n$ by $x_1^{(j)} + \xi$:

$$\mathrm{Res}_{z=0}\left(dz \sum_{j=1}^{n} \epsilon(\delta_j, \alpha + \delta_a - \beta + \delta_b) z^{(\delta_j|\alpha+\delta_a-\beta+\delta_b-2\delta_j)} \exp\left(\sum_{k=1}^{\infty} (x_k^{(j)\prime} - x_k^{(j)\prime\prime}) z^k \right) \right.$$
$$\left. \times \exp\left(-\sum_{k=1}^{\infty} \left(\frac{\partial}{\partial x_k^{(j)\prime}} - \frac{\partial}{\partial x_k^{(j)\prime\prime}} \right) \frac{z^{-k}}{k} \right) \tau_{\alpha+\alpha_{a_j}}(\xi',x')\,\tau_{\beta-\alpha_{b_j}}(\xi'',x'') \right) e^{z(\xi'-\xi'')} = 0$$
$$(\alpha,\beta \in M). \tag{92}$$

For each $\alpha \in \mathrm{supp}\ \tau$ we define the (matrix valued) functions

$$V^{\pm}(\alpha,\xi,x,z) = (V_{ij}^{\pm}(\alpha,\xi,x,z))_{i,j=1}^{n} \tag{93}$$

as follows:

$$V_{ij}^{\pm}(\alpha,\xi,x,z) \overset{\text{def}}{=} \epsilon(\delta_j, \alpha + \delta_i) z^{(\delta_j|\pm\alpha+\alpha_{ij})} \exp\left(\pm \sum_{k=1}^{\infty} x_k^{(j)} z^k \right)$$
$$\times \exp\left(\mp \sum_{k=1}^{\infty} \frac{\partial}{\partial x_k^{(j)}} \frac{z^{-k}}{k} \right) \tau_{\alpha\pm\alpha_{ij}}(\xi,x)/\tau_\alpha(\xi,x) e^{\pm z\xi}. \tag{94}$$

It is easy to see that Eq. (92) is equivalent to the following bilinear identity:

$$\mathrm{Res}_{z=0} V^+(\alpha,\xi,x,z)\ {}^tV^-(\beta,\xi',x',z)dz=0 \quad \text{for all} \quad \alpha,\beta\in M. \tag{95}$$

Define $n\times n$ matrices $W^{\pm(m)}(\alpha,\xi,x)$ by the following generating series [cf. (94)]:

$$\sum_{m=0}^{\infty} W_{ij}^{\pm(m)}(\alpha,\xi,x)(\pm z)^{-m}=\epsilon_{ji}z^{\delta_{ij}-1}\left(\exp\mp\sum_{k=1}^{\infty}\frac{\partial}{\partial x_k^{(j)}}\frac{z^{-k}}{k}\right)\tau_{\alpha\pm\alpha_{ij}}(\xi,x))/\tau_\alpha(\xi,x). \tag{96}$$

Note that

$$W^{\pm(0)}(\alpha,\xi,x)=I_n, \tag{97}$$

$$W_{ij}^{\pm(1)}(\alpha,\xi,x)=\begin{cases}\pm\epsilon_{ji}\tau_{\alpha\pm\alpha_{ij}}/\tau_\alpha & \text{if } i\neq j,\\ -\tau_\alpha^{-1}\dfrac{\partial\tau_\alpha}{\partial x_1^{(i)}} & \text{if } i=j,\end{cases} \tag{98}$$

$$W_{ij}^{\pm(2)}(\alpha,\xi,x)=\begin{cases}\mp\epsilon_{ji}\dfrac{\partial\tau_{\alpha\pm\alpha_{ij}}}{\partial x_1^{(j)}}\Big/\tau_\alpha & \text{if } i\neq j,\\ \left(\mp\dfrac{1}{2}\dfrac{\partial\tau_\alpha}{\partial x_2^{(i)}}+\dfrac{1}{2}\dfrac{\partial^2\tau_\alpha}{\partial x_1^{(i)2}}\right)\Big/\tau_\alpha & \text{if } i=j.\end{cases} \tag{99}$$

We see from (94) that $V^\pm(\alpha,\xi,x,z)$ can be written in the following form:

$$\begin{aligned}V^\pm(\alpha,\xi,x,z)&=\left(\sum_{m=0}^{\infty}W^{\pm(m)}(\alpha,\xi,x)R^\pm(\alpha,\pm z)(\pm z)^{-m}\right)e^{\pm z\cdot x}\\&=\sum_{m=0}^{\infty}W^{\pm(m)}(\alpha,\xi,x)(\pm z)^{-m}R^\pm(\alpha,\pm z)S^\pm(x,\pm z)e^{z\xi},\end{aligned} \tag{100}$$

where

$$\begin{aligned}R^\pm(\alpha,z)&=\sum_{i=1}^{n}\epsilon(\delta_i,\alpha)E_{ii}(\pm z)^{\pm(\delta_i|\alpha)},\\ S^\pm(x,z)&=\sum_{i=1}^{n}e^{\pm\sum_{j=1}^{\infty}x_j^{(i)}(\pm z)^j}E_{ii}.\end{aligned} \tag{101}$$

Here and further E_{ij} stands for the $n\times n$ matrix whose (i,j) entry is 1 and all other entries are zero. Now it is clear that $V^\pm(\alpha,\xi,x,z)$ can be written in terms of formal pseudo-differential operators

$$\begin{aligned}P^\pm(\alpha)\equiv P^\pm(\alpha,\xi,x,\partial)&=I_n+\sum_{m=1}^{\infty}W^{\pm(m)}(\alpha,\xi,x)\partial^{-m}.\\ R^\pm(\alpha)=R^\pm(\alpha,\xi,\partial)\quad&\text{and}\quad S^\pm=S^\pm(x,\partial)\end{aligned} \tag{102}$$

as follows:

$$V^\pm(\alpha,\xi,x,z)=P^\pm(\alpha)R^\pm(\alpha)e^{\pm z\cdot x}=P^\pm(\alpha)R^\pm(\alpha)S^\pm e^{\pm zx}. \tag{103}$$

Since obviously

$$R^-(\alpha,\partial)^{-1}=R^+(\alpha,\partial)^* \quad \text{and} \quad S^-(x,\partial)^{-1}=S^+(x,\partial)^*, \tag{104}$$

using Corollary 4.1 and Remark 4.1 we deduce from the bilinear identity (95)

$$(P^+(\alpha,\xi,x,\partial)R^+(\alpha-\beta,\partial)S^+(x-x',\partial)P^-(\beta,\xi,x'\partial)^*)_-=0 \tag{105}$$

for any $\alpha,\ \beta\in\text{supp}\ \tau$.

Furthermore, put $x=x'$. Then one deduces from (105) with $\alpha=\beta$ that

$$P^-(\alpha)=(P^+(\alpha)^*)^{-1}, \tag{106}$$

since $R^\pm(0)=I_n$ and $P^\pm(\alpha)\in I_n+\Psi_-$. Equations (105) and (106) imply

$$(P^+(\alpha)R^+(\alpha-\beta)P^+(\beta)^{-1})_-=0 \quad \text{for all} \quad \alpha,\beta\in\text{supp}\ \tau. \tag{107}$$

In the rest of this article we sometimes write $P(\alpha)$, $W(\alpha)^{(k)}$ instead of $P^+(\alpha)$ and $W(\alpha)^{+(k)}$.

Proposition 4.1: Given $\beta\in supp\ \tau$, all the pseudo-differential operators $P(\alpha)$, $\alpha\in supp\ \tau$, are completely determined by $P(\beta)$ from Eqs. (107). Moreover, if $\alpha=\beta+\alpha_{ij}$, then

$$P(\alpha)=\left(\left(\epsilon_{ij}\partial+\frac{\partial\log W_{ij}^{(1)}(\beta)}{\partial x_1^{(i)}}\right)E_{ii}-\frac{\epsilon_{ij}}{W_{ij}^{(1)}(\beta)}E_{ji}+\sum_{\substack{k=1\\k\neq i,j}}^{n}\epsilon_{ik}\epsilon_{jk}\left(E_{kk}-\frac{W_{kj}^{(1)}(\beta)}{W_{ij}^{(1)}(\beta)}E_{ik}\right)\right)P(\beta). \tag{108}$$

Proof: For $P=I_n+\Sigma_{j=1}^{\infty}W^{(j)}\partial^{-j}$ we have

$$P^{-1}=I_n-W^{(1)}\partial^{-1}+(W^{(1)2}-W^{(2)})\partial^{-2}+\cdots. \tag{109}$$

We have for $i\neq j$:$R(\alpha_{ij})=A\partial+B+C\partial^{-1}$, where

$$A=\epsilon_{ij}E_{ii}, \quad B=\sum_{\substack{k=1\\k\neq i,j}}^{n}\epsilon_{ik}\epsilon_{jk}E_{kk}, \quad C=\epsilon_{ji}E_{jj}. \tag{110}$$

Let $\alpha,\beta\in M$ be such that $\alpha-\beta=\alpha_{ij}$. It follows from (109) and (107) that $P(\alpha)R(\alpha-\beta)P(\beta)^{-1}=(P(\alpha)R(\alpha-\beta)P(\beta)^{-1})_+=A\partial+B+W^{(1)}(\alpha)A-AW^{(1)}(\beta)$, or equivalently

$$P(\alpha)(A\partial+B+C\partial^{-1})=(A\partial+B+W^{(1)}(\alpha)A-AW^{(1)}(\beta))P(\beta).$$

Using (110),

$$\begin{aligned}W_{ii}^{(1)}(\alpha)-W_{ii}^{(1)}(\beta)&=W_{ii}^{(1)}(\beta+\alpha_{ij})-W_{ii}^{(1)}(\beta)\\&=-\tau_{\beta+\alpha_{ij}}^{-1}\frac{\partial\tau_{\beta+\alpha_{ij}}}{\partial x_i^{(1)}}+\tau_\beta^{-1}\frac{\partial\tau_\beta}{\partial x_i^{(1)}}\\&=\epsilon_{ij}\frac{\partial\log(\epsilon_{ji}\tau_{\beta+\alpha_{ij}}/\tau_\beta)}{\partial x_i^{(1)}}=\epsilon_{ij}\frac{\partial\log W_{ij}^{(1)}(\beta)}{\partial x_i^{(1)}},\end{aligned}$$

and for $k\neq i$

$$W_{ki}^{(1)}(\alpha)=W_{ki}^{(1)}(\beta+\alpha_{ij})=\epsilon_{ik}\frac{\tau_{\beta+\alpha_{ij}+\alpha_{ki}}}{\tau_{\beta+\alpha_{ij}}}=\epsilon_{ik}\frac{\tau_{\beta+\alpha_{kj}}}{\tau_\beta}\frac{\tau_\beta}{\tau_{\beta+\alpha_{ij}}}=\epsilon_{ji}\epsilon_{ik}\epsilon_{jk}\frac{W_{kj}^{(1)}(\beta)}{W_{ij}^{(1)}(\beta)},$$

we obtain (108).

Due to Proposition 3.2 for any $\alpha,\beta \in \operatorname{supp} \tau$ there exist a sequence $\gamma_1,\dots,\gamma_k$ such that $\alpha=\gamma_1$, $\beta=\gamma_k$ and $\gamma_i-\gamma_{i+1}\in\Delta$ for all $i=1,...,k-1$. The proposition now follows. □

We call operators of the form (108) which produce new wave functions Schlesinger–Bäcklund differential operators (see Ref. 49).

Remark 4.2: The functions $P^+(\alpha,\xi,x,z)$ $(\alpha\in M)$ determine the τ-function $\Sigma_\alpha \tau_\alpha(\xi,x)e^\alpha$ up to a constant factor. Namely, we may recover $\tau_\alpha(\xi,x)$ from functions $P^+_{jj}(\alpha,x,z)$ as follows. We have from (96)

$$\log P^+_{jj}(\alpha,\xi,x,z)=\log \tau_\alpha\left(x^{(p)}_\ell+\delta_{\ell,1}\xi-\frac{\delta_{jp}}{\ell z^\ell}\right)-\log \tau_\alpha(x^{(p)}_\ell+\delta_{\ell,1}\xi).$$

Putting $\xi=0$ and applying to both sides the operator $\partial/\partial z-\Sigma_{k\geqslant 1}z^{-k-1}\partial/\partial x^{(j)}_k$ (that kills the first summand on the right), we obtain

$$\left(\frac{\partial}{\partial z}-\sum_{k\geqslant 1} z^{-k-1}\frac{\partial}{\partial x^{(j)}_k}\right)\log P^+_{jj}(\alpha,x,z)=\sum_{k\geqslant 1} z^{-k-1}\frac{\partial}{\partial x^{(j)}_k}\log \tau_\alpha(x).$$

Hence

$$\frac{\partial}{\partial x^{(j)}_m}\log \tau_\alpha(x)=\operatorname{Res}_{z=0}dz\ \ z^m\left(\frac{\partial}{\partial z}-\sum_{k\geqslant 1} z^{-k-1}\frac{\partial}{\partial x^{(j)}_k}\right)\log P^+_{jj}(\alpha,x,z). \tag{111}$$

This determines $\tau_\alpha(x)$ and hence $\tau_\alpha(\xi,x)$ up to a constant factor. It follows from (98) and Proposition 3.2 that these constant factors are the same for all α.

Introduce the following formal pseudo-differential operators $L(\alpha)$, $C^{(j)}(\alpha)$, $L^{(j)}(\alpha)$ and differential operators $B_m(\alpha)$ and $B^{(j)}_m(\alpha)$:

$$\begin{aligned}
&L(\alpha)\equiv L(\alpha,\xi,x,\partial)=P^+(\alpha)\circ\partial\circ P^+(\alpha)^{-1},\\
&C^{(j)}(\alpha)\equiv C^{(j)}(\alpha,\xi,x,\partial)=P^+(\alpha)E_{jj}P^+(\alpha)^{-1},\\
&L^{(j)}(\alpha)\equiv C^{(j)}(\alpha)L(\alpha)=P^+(\alpha)E_{jj}\circ\partial\circ P^+(\alpha)^{-1},\\
&B_m(\alpha)\equiv(L(\alpha)^m)_+=(P^+(\alpha)\circ\partial^m\circ P^+(\alpha)^{-1})_+,\\
&B^{(j)}_m(\alpha)\equiv(L^{(j)}(\alpha)^m)_+=(P^+(\alpha)E_{jj}\circ\partial^m\circ P^+(\alpha)^{-1})_+.
\end{aligned} \tag{112}$$

Using Corollary 4.1 we can now derive the Sato equations from Eq. (95):

Lemma 4.2: Each formal pseudo-differential operator $P=P^+(\alpha)$ satisfies the Sato equations:

$$\frac{\partial P}{\partial x^{(j)}_k}=-(PE_{jj}\circ\partial^k\circ P^{-1})_-\circ P=B^{(j)}_k P-PE_{jj}\circ\partial^k. \tag{113}$$

Proof: Notice first that

$$\begin{aligned}
&\left(\frac{\partial}{\partial x_k^{(j)}}-B_k^{(j)}(\alpha)\right)V^+(\alpha,x,z)\\
&\quad=\left(\frac{\partial}{\partial x_k^{(j)}}-B_k^{(j)}(\alpha)\right)P^+(\alpha)R^+(\alpha)e^{z\cdot x}\\
&\quad=\left(\frac{\partial P^+(\alpha)}{\partial x_k^{(j)}}R^+(\alpha)+P^+(\alpha)R^+(\alpha)E_{jj}\partial^k-B_k^{(j)}(\alpha)P^+(\alpha)R^+(\alpha)\right)e^{z\cdot x}\\
&\quad=\left(\frac{\partial P^+(\alpha)}{\partial x_k^{(j)}}+P^+(\alpha)E_{jj}\partial^k-B_k^{(j)}(\alpha)P^+(\alpha)\right)R^+(\alpha)e^{z\cdot x}\\
&\quad=\left(\frac{\partial P^+(\alpha)}{\partial x_k^{(j)}}+L^{(j)}(\alpha)^kP^+(\alpha)-B_k^{(j)}(\alpha)P^+(\alpha)\right)R^+(\alpha)e^{z\cdot x}\\
&\quad=\left(\frac{\partial P^+(\alpha)}{\partial x_k^{(j)}}+(L^{(j)}(\alpha)^k)_-P^+(\alpha)\right)R^+(\alpha)e^{z\cdot x}.
\end{aligned}$$

Next apply $\partial/\partial x_k^{(j)}-B_k^{(j)}(\alpha)$ to the Eq. (95) for $\alpha=\beta$ to obtain

$$\mathrm{Res}_{z=0}dz\left(\frac{\partial P^+(\alpha)}{\partial x_k^{(j)}}+(L^{(j)}(\alpha)^k)_-\right)(P^+(\alpha)R^+(\alpha)e^{z\cdot x})^t(P^-(\alpha)R^-(\alpha)e^{-z\cdot x'})=0.$$

Now apply Corollary 4.1 and (106) to obtain

$$\left(\left(\frac{\partial P^+(\alpha)}{\partial x_k^{(j)}}+(L^{(j)}(\alpha)^k)_-P^+(\alpha)\right)P^+(\alpha)^{-1}\right)_-=0,$$

which proves the lemma. □

Proposition 4.2: Consider the formal oscillating functions $V^+(\alpha,xi,x,z)$ *and* $V^-(\alpha,\xi,x,z)$, $\alpha\in M$, *of the form (103), where* $R^\pm(\alpha,z)$ *are given by (101) and* $P^\pm(\alpha,xi,x,\partial)\in I_n+\Psi_-$. *Then the bilinear identity (95) for all* $\alpha,\beta\in supp\ \tau$ *is equivalent to the Sato Eq. (113) for each* $P=P^+(\alpha)$ *and the matching condition (105) for all* $\alpha,\beta\in supp\ \tau$.

Proof: We have proved already that the bilinear identity (95) implies (113) and (105). To prove the converse, denote by $A(\alpha,\beta,\xi,xi',x,x')$ the left-hand side of (95). The same argument as in the proof of Lemma 4.2 shows that

$$\left(\frac{\partial}{\partial x_k^{(j)}}-B_k^{(j)}(\alpha)\right)A(\alpha,\beta,\xi,\xi',x,x')=0, \tag{114}$$

$$A(\alpha,\beta,\xi,\xi',x,x')=0,\quad \text{if } x_k^{(i)}=x_k'^{(i)}\quad \text{for } k\geqslant 1, \tag{115}$$

where $B_k^{(j)}(\alpha)$ is defined by (112).

Denote by $A_1(\alpha,\beta)$ the expression for $A(\alpha,\beta,\xi,\xi',x,x')$ in which we set $x_k^{(j)}=x_k'^{(j)}=0$ for all k. Expanding $A(\alpha,\beta,\xi,\xi',x,x')$ in a power series in $x_k^{(i)}-x_k'^{(i)}$ for $k\geqslant 1$, we see from (114) and (115) that it remains to prove

$$A_1(\alpha,\beta)=0. \tag{116}$$

But the same argument as in the proof of Lemma 4.1 shows that

$$A_1(\alpha,\beta)=\mathrm{Res}_\partial W^+(\alpha,\xi,\partial)R^+(\alpha-\beta,\partial)W^-(\beta,\xi,\partial)*e^{y\partial}dz,$$

where $y=\xi-\xi'$. Hence, (116) follows from (105). □

Fix $\alpha\in M$; we have introduced above a collection of formal pseudo-differential operators $L\equiv L(\alpha)$, $C^{(i)}\equiv C^{(i)}(\alpha)$ of the form

$$\begin{gathered} L=I_n\partial+\sum_{j=1}^{\infty}U^{(j)}(\xi,x)\partial^{-j}, \\ C^{(i)}=E_{ii}+\sum_{j=1}^{\infty}C^{(i,j)}(\xi,x)\partial^{-j},\quad i=1,2,...,n, \end{gathered} \tag{117}$$

subject to the conditions

$$\sum_{i=1}^{n}C^{(i)}=I_n,\quad C^{(i)}L=LC^{(i)},\quad C^{(i)}C^{(j)}=\delta_{ij}C^{(i)}. \tag{118}$$

They satisfy the following set of equations for some $P\in I_n+\Psi_-$:

$$\begin{gathered} LP=P\partial, \\ C^{(i)}P=PE_{ii}, \\ \frac{\partial P}{\partial x_k^{(i)}}=-(L^{(i)k})_-P,\quad \text{where } L^{(i)}=C^{(i)}L. \end{gathered} \tag{119}$$

Notice that the first and last equations of (119) imply that

$$\frac{\partial P}{\partial\xi}=\sum_{i=1}^{n}\frac{\partial P}{\partial x_1^{(i)}},$$

since $L=I_n\partial+\Sigma_i(L^{(i)})_-$.

Proposition 4.3: The system of Eqs. (119) has a solution $P\in I_n+\Psi_-$ if and only if we can find a formal oscillating function of the form

$$W(\xi,x,z)=\left(I_n+\sum_{j=1}^{\infty}W^{(j)}(\xi,x)z^{-j}\right)e^{z\cdot x} \tag{120}$$

that satisfies the linear equations

$$LW=zW,\quad C^{(i)}W=WE_{ii},\quad \frac{\partial W}{\partial x_k^{(i)}}=B_k^{(i)}W. \tag{121}$$

Proof (119)⇒(121): Put $W=Pe^{z\cdot x}$. Then we have

$$LW = LPe^{z\cdot x} = P\partial e^{z\cdot x} = zPe^{z\cdot x} = zW;$$

$$C^{(i)}W = C^{(i)}Pe^{z\cdot x} = PE_{ii}e^{z\cdot x} = Pe^{z\cdot x}E_{ii} = WE_{ii};$$

$$\frac{\partial W}{\partial x_k^{(i)}} = \frac{\partial P}{\partial x_k^{(i)}} + P\frac{\partial e^{z\cdot x}}{\partial x_k^{(i)}} = -(L^{(i)k})_- Pe^{z\cdot x} + z^k PE_{ii}e^{z\cdot x} = -(L^{(i)k})_- W + PE_{ii}\partial^k e^{z\cdot x}$$

$$= -(L^{(i)k})_- W + C^{(i)}P\partial^k e^{z\cdot x} = -(L^{(i)k})_- W + C^{(i)}L^k Pe^{z\cdot x} = -(L^{(i)k})_- W + L^{(i)k}W = B_k^{(i)}W.$$

(121)⇒(119): Define $P\in\Psi$ by $W=Pe^{z\cdot x}$. If $LW=zW$, then $LPe^{z\cdot x}=zPe^{z\cdot x}=P\partial e^{z\cdot x}$, hence $LP=P\partial$.

If $C^{(i)}W=WE_{ii}$, then $C^{(i)}Pe^{z\cdot x}=Pe^{z\cdot x}E_{ii}=PE_{ii}e^{z\cdot x}$, hence $C^{(i)}P=PE_{ii}$.

Finally, the last equation of (121) gives $(\partial/\partial x_k^{(i)})(Pe^{z\cdot x}) = -(L^{(i)k})_- Pe^{z\cdot x} + L^{(i)k}Pe^{z\cdot x}$. Since we have already proved the first two equations of (119), we derive (as above) $L^{(i)k}Pe^{z\cdot x} = z^k Pe^{z\cdot x} = P\partial e^{z\cdot x}/\partial x_k^{(i)}$. Hence $(\partial P/\partial x_k^{(i)})e^{x\cdot z} = -(L^{(i)k})_- Pe^{x\cdot z}$, which proves that P satisfies the Sato equations. □

Remarks 4.3: (a) It is easy to see that the collection of formal pseudo-differential operators $\{L, C^{(1)},\ldots,C^{(n)}\}$ of the form (117) and satisfying (118) can be simultaneously conjugated to the trivial collection $\{\partial, E_{11},\ldots,E_{nn}\}$ by some $P\in I_n+\Psi_-$. It follows that the solution of the form (120) to the linear problem (121) is unique up to multiplication on the right by a diagonal matrix of the form

$$D(z) = \exp -\sum_{j=1}^{\infty} a_j z^{-j}/j, \tag{122}$$

where the a_j are diagonal matrices over $\mathbb{C}$ (indeed, this is the case for the trivial collection). The space of all solutions of (121) in formal oscillating functions is obtained from one of the form (120) by multiplying on the right by a diagonal matrix over $\mathbb{C}((z))$. For that reason the (matrix valued) functions

$$W^+(\alpha,\xi,x,z) = P^+(\alpha)e^{x\cdot z}, \quad \alpha\in \text{supp}\ \tau, \tag{123}$$

are called the *wave functions* for τ. The formal pseudo-differential operator $P^+(\alpha)$ is called the wave operator. The functions $W^-(\alpha,\xi,x,z)=P^-(\alpha)e^{-x\cdot z}$ are called the adjoint wave functions and the operators $P^-(\alpha)$ [which are expressed via $P^+(\alpha)$ by (106)] are called the adjoint wave operators. Note that $V^+(\alpha,\xi,x,z)$ are solutions of (121) as well since they are obtained by multiplying $W^+(\alpha,xi,x,z)$ on the right by $R^+(\alpha,z)$.

(b) Multiplying the wave function $W^+(\alpha,\xi,x,z)$ on the right by $D(z)$ given by (122) corresponds to multiplying the corresponding τ-function by $\exp tr\Sigma_{k=1}^{\infty}a_k x_k$, where $x_k = \text{diag}(x_k^{(1)},\ldots,x_k^{(n)})$.

(c) The collection $\{L, C^{(1)},\ldots,C^{(n)}\}$ determines uniquely $P\in I_n+\Psi_-$ up to the multiplication of P on the right by a formal pseudo-differential operator with constant coefficients from $I_n+\Psi_-$.

We shall now rewrite the compatibility conditions of the system (119) [or equivalent compatibility conditions of the system (121)] in the form of Lax equations and Zakharov–Shabat equations.

Lemma 4.3: If for every $\alpha\in M$ the formal pseudo-differential operators $L\equiv L(\alpha)$ and $C^{(j)}\equiv C^{(j)}(\alpha)$ of the form (117) satisfy conditions (118) and if the Eqs. (119) have a solution $P\equiv P(\alpha)\in I_n+\Psi_-$, then the differential operators $B_k^{(j)}\equiv B_k^{(j)}(\alpha)=(L^{(j)}(\alpha)^k)_+$ satisfy one of the following equivalent conditions:

$$\frac{\partial L}{\partial x_k^{(j)}} = [B_k^{(j)}, L],$$

$$\frac{\partial C^{(i)}}{\partial x_k^{(j)}} = [B_k^{(j)}, C^{(i)}], \tag{124}$$

$$\frac{\partial L^{(i)}}{\partial x_k^{(j)}} = [B_k^{(j)}, L^{(i)}], \tag{125}$$

$$\frac{\partial B_\ell^{(i)}}{\partial x_k^{(j)}} - \frac{\partial B_k^{(j)}}{\partial x_\ell^{(i)}} = [B_k^{(j)}, B_\ell^{(i)}]. \tag{126}$$

Proof (cf. Ref. 43): To derive the first equation of (124) we differentiate the equation $LP = P\partial$ by $x_k^{(j)}$:

$$\frac{\partial L}{\partial x_k^{(j)}} P + L \frac{\partial P}{\partial x_k^{(j)}} = \frac{\partial P}{\partial x_k^{(j)}} \partial,$$

and substitute Sato's equation [see (119)]. Then one obtains

$$\frac{\partial L}{\partial x_k^{(j)}} P = (B_k^{(j)} L - L B_k^{(j)}) P,$$

from which we derive the desired result. The second equation of (124) is proven analogously: differentiate $C^{(i)}P = PE_{ii}$, substitute Sato's equation and use the fact that $[L^{(j)k}, C^{(i)}] = 0$.

Next we prove the equivalence of (124), (125), and (126). The implication (124)⇒(125) is trivial. To prove the implication (125)⇒(124) note that $L = \Sigma_{j=1}^n L^{(j)}$ implies that the first equation of (124) follows immediately. As for the second one, we have

$$\frac{\partial C^{(i)}}{\partial x_k^{(j)}} = \left(\frac{\partial L^{(i)}}{\partial x_k^{(j)}} - C^{(i)} \frac{\partial L}{\partial x_k^{(j)}} \right) L^{-1} = ([B_k^{(j)}, L^{(i)}] - C^{(i)}[B_k^{(j)}, L]) L^{-1}$$

$$= ([B_k^{(j)}, C^{(i)}] L) L^{-1} = [B_k^{(j)}, C^{(i)}].$$

Next, we prove the implication (125)⇒(126). Since both $\partial/\partial x_k^{(j)}$ and $ad\, B_k^{(j)}$ are derivations, (125) implies

$$\frac{\partial L^{(i)\ell}}{\partial x_k^{(j)}} = [B_k^{(j)}, L^{(i)\ell}].$$

Hence:

$$\left(\frac{\partial B_\ell^{(i)}}{\partial x_k^{(j)}} - \frac{\partial B_k^{(j)}}{\partial x_\ell^{(i)}} - [B_k^{(j)}, B_\ell^{(i)}] \right) + \left(\frac{\partial (L^{(i)\ell})_-}{\partial x_k^{(j)}} - \frac{\partial (L^{(j)k})_-}{\partial x_\ell^{(i)}} + [(L^{(j)k})_-, (L^{(i)\ell})_-] \right)$$

$$= [B_k^{(j)}, L^{(i)\ell}] - [B_\ell^{(i)}, L^{(j)k}] - [B_k^{(j)}, B_\ell^{(i)}] + [(L^{(j)k})_-, (L^{(i)\ell})_-] = [L^{(j)k}, L^{(i)\ell}] = 0.$$

Since $\Psi_- \cap \Psi_+ = \{0\}$, both terms on the left-hand side are zero, proving (126).

Finally, we prove the implication (126)⇒(125). We rewrite (126):

$$\frac{\partial L^{(i)\ell}}{\partial x_k^{(j)}}-[B_k^j,L^{(i)\ell}]=\frac{\partial (L^{(i)\ell})_-}{\partial x_k^{(j)}}+\frac{\partial B_k^{(j)}}{\partial x_\ell^{(i)}}-[B_k^{(j)},(L^{(i)\ell})_-].$$

This right-hand side has order $k-1$, hence

$$\frac{\partial L^{(i)\ell}}{\partial x_k^{(j)}}-[B_k^{(j)},L^{(i)\ell}]\in\Psi(k-1)\quad\text{for every}\quad \ell>0. \tag{127}$$

Now suppose that $\partial L^{(i)}/\partial x_k^{(j)}-[B_k^{(j)},L^{(i)}]\neq 0$. Then

$$\lim_{\ell\to\infty}\operatorname{ord}\left(\frac{\partial L^{(i)\ell}}{\partial x_k^{(i)}}-[B_k^{(j)},L^{(i)\ell}]\right)=\infty,$$

which contradicts (127). □

Equations (124) and (125) are called *Lax type* equations. Equations (126) are called the *Zakharov–Shabat-type* equations. The latter are the compatibility conditions for the linear problem (121). Indeed, since $(\partial/\partial x_k^{(j)})(\partial/\partial x_\ell^{(i)})W=(\partial/\partial x_\ell^{(i)})(\partial/\partial x_k^{(j)})W$, one finds

$$0=\frac{\partial}{\partial x_k^{(j)}}(B_\ell^{(i)}W)-\frac{\partial}{\partial x_\ell^{(i)}}(B_k^{(j)}W)=\left(\frac{\partial B_\ell^{(i)}}{\partial x_k^{(j)}}-\frac{\partial B_k^{(j)}}{\partial x_\ell^{(i)}}-[B_k^{(j)},B_\ell^{(i)}]\right)W.$$

Notice that as a by-product of the proof of Proposition 4.4, we obtain complementary Zakharov–Shabat equations:

$$\frac{\partial (L^{(i)\ell})_-}{\partial x_k^{(j)}}-\frac{\partial (L^{(j)k})_-}{\partial x_\ell^{(i)}}=[(L^{(i)\ell})_-,(L^{(j)k})_-]. \tag{128}$$

Proposition 4.4: Sato Eq. (113) on $P\in I_n+\Psi_-$ *imply Eqs. (126) on differential operators* $B_k^{(i)}=(L^{(i)k})_+$.

Proof is the same as that of the corresponding part of Lemma 4.3. □

Remark 4.4: The above results may be summarized as follows. The *n*-component KP hierarchy (70) of Hirota bilinear equations on the τ-function is equivalent to the bilinear Eq. (95) on the wave function, which is related to the τ-function by formula (94) and Remark 4.2. The bilinear Eq. (95) for each $\alpha=\beta$ implies the Sato Eq. (113) on the formal pseudo-differential operator $P\equiv P(\alpha)$. Moreover, Eq. (113) on $P(\alpha)$ for each α together with the matching conditions (105) are equivalent to the bilinear identity (95). Also, the Sato equation [or rather (119)] is a compatibility condition for the linear problem (121) for the wave function. The Sato equation in turn implies the system of Lax-type Eq. (125) [or equivalent systems (124) or (126), which is the most familiar form of the compatibility condition] on formal pseudo-differential operators $L^{(i)}$ [resp. L and $C^{(i)}$ satisfying constraints (118)]. The latter formal pseudo-differential operators are expressed via the wave function by formulas (112) and (100)–(103).

We next write down explicitly some of the Sato Eq. (113) on the matrix elements $W_{ij}^{(s)}$ of the coefficients $W^{(s)}(\xi,x)$ of the pseudo-differential operator

$$P=I_n+\sum_{m=1}^{\infty}W^{(m)}(\xi,x)\partial^{-m}.$$

We shall write W_{ij} for $W_{ij}^{(1)}$ to simplify notation. We have for $i\neq k$

$$\frac{\partial W_{ij}}{\partial x_1^{(k)}}=W_{ik}W_{kj}-\delta_{jk}W_{ij}^{(2)}, \tag{129}$$

$$\frac{\partial W_{ij}^{(2)}}{\partial x_1^{(k)}} = W_{ik}W_{kj}^{(2)} - \delta_{jk}W_{ij}^{(3)}. \tag{130}$$

Next, calculating $\partial W_{ij}/\partial x_2^{(k)}$ from (113) and substituting (129) and (130) in these equations, we obtain

$$\frac{\partial W_{ij}}{\partial x_2^{(k)}} = W_{ik}\frac{\partial W_{kj}}{\partial x_1^{(k)}} - \frac{\partial W_{ik}}{\partial x_1^{(k)}}W_{kj} \quad \text{if } k \neq i \quad \text{and } k \neq j, \tag{131}$$

$$\frac{\partial W_{ij}}{\partial x_2^{(j)}} = 2\frac{\partial W_{jj}}{\partial x_1^{(j)}}W_{ij} - \frac{\partial^2 W_{ij}}{\partial x_1^{(j)2}} \quad \text{if } i \neq j, \tag{132}$$

$$\frac{\partial W_{ij}}{\partial x_2^{(i)}} = -2\frac{\partial W_{ii}}{\partial x_1^{(i)}}W_{ij} + \frac{\partial^2 W_{ij}}{\partial x_1^{(i)2}} \quad \text{if } i \neq j, \tag{133}$$

$$\frac{\partial W_{ii}}{\partial x_2^{(i)}} = \frac{\partial^2 W_{ii}}{\partial x_1^{(i)2}} + 2\sum_{p\neq i} W_{ip}\frac{\partial W_{pi}}{\partial x_1^{(i)}} - 2W_{ii}\partial W_{ii} + 2\partial W_{ii}^{(2)}. \tag{134}$$

Remark 4.5: Substituting expressions for the $W_{ij} = W_{ij}^{(1)}(\alpha = 0, x)$ given by (98), the above equations turn into the Hirota bilinear equations found in Sec. III D as follows:

(129) for $i = j \Rightarrow$(74)
(129) for $i \neq j \Rightarrow$(78)
(133)$\Rightarrow$(75)
(132)$\Rightarrow$(76)
(131) for $i = j \Rightarrow$(77) (with j replaced by k),
(131) for $i \neq j \Rightarrow$(79).

We now write down explicitly some of the Lax Eqs. (124) of the n-component KP hierarchy and auxiliary conditions (118) for the formal pseudo-differential operators

$$L = I_n\partial + \sum_{j=1}^{\infty} U^{(j)}(\xi, x)\partial^{-j} \quad \text{and} \quad C^{(i)} = E_{ii} + \sum_{j=1}^{\infty} C^{(i,j)}(\xi, x)\partial^{-j} \ (i = 1, \ldots, n). \tag{135}$$

For the convenience of the reader, recall that x stands for all indeterminates $x_i^{(k)}$, where $i = 1,2,\ldots$ and $k = 1,\ldots,n$, that the auxiliary conditions are

$$\sum_{i=1}^{n} C^{(i)} = I_n, \quad C^{(i)}C^{(j)} = \delta_{ij}C^{(i)}, \quad C^{(i)}L = LC^{(i)}, \tag{136}$$

and that the Lax equations of the n-component KP hierarchy are

$$\frac{\partial L}{\partial x_i^{(k)}} = [B_i^{(k)}, L], \tag{137a}$$

$$\frac{\partial C^{(\ell)}}{\partial x_i^{(k)}} = [B_i^{(k)}, C^{(\ell)}], \tag{137b}$$

where $B_i^{(k)} = (C^{(k)}L^i)_+$. For example, we have

$$B_1^{(k)} = E_{kk}\partial + C^{(k,1)}, \quad B_2^{(k)} = E_{kk}\partial^2 + C^{(k,1)}\partial + 2E_{kk}U^{(1)} + C^{(k,2)}. \tag{138}$$

Denote by $C_{ij}^{(k,\ell)}$ and $U_{ij}^{(k)}$ the (i,j)th entries of the $n\times n$ matrices $C^{(k,\ell)}$ and $U^{(k)}$, respectively. Then the ∂^{-1} term of the second Eq. (136) gives

$$C_{ij}^{(k,1)}=0 \quad \text{if } i\neq k \quad \text{and } j\neq k, \quad \text{or } i=j=k, \tag{139}$$

$$C_{kj}^{(k,1)}=-C_{kj}^{(j,1)}. \tag{140}$$

Hence the matrices $C^{(j,1)}$ are expressed in terms of the functions

$$A_{ij}:=C_{ij}^{(j,1)} \quad (\text{note that } A_{ii}=0).$$

The ∂^{-2} term of the second Eq. (136) allows one to express most of the $C_{ij}^{(k,2)}$ in terms of the A_{ij}:

$$C_{ij}^{(k,2)}=-A_{ik}A_{kj} \quad \text{if } i\neq k \quad \text{and } j\neq k, \tag{141}$$

$$C_{k,k}^{(k,2)}=\sum_{p=1}^{n} A_{kp}A_{pk}. \tag{142}$$

Furthermore, the ∂^{-1} term of the Lax Eq. $(137b)_1$ gives

$$\frac{\partial A_{ij}}{\partial x_1^{(k)}}=A_{ik}A_{kj} \quad \text{for distinct } i,j,k, \tag{143}$$

$$C_{ij}^{(j,2)}=-\frac{\partial A_{ij}}{\partial x_1^{(j)}} \quad \text{for } i\neq j, \tag{144}$$

$$C_{ij}^{(i,2)}=\sum_{\substack{p=1\\ p\neq i}}^{n}\frac{\partial A_{ij}}{\partial x_1^{(p)}} \quad \text{for } i\neq j. \tag{145}$$

The ∂^{-2} term of that equation gives for $i\neq j$ (recall that $\partial=\partial/\partial x_1^{(1)}+\cdots+\partial/\partial x_1^{(n)}$):

$$C_{ij}^{(i,3)}=-\frac{\partial C_{ij}^{(i,2)}}{\partial x_1^{(j)}}+A_{ij}C_{jj}^{(i,2)}-\sum_{p=1}^{n}(A_{ip}\partial A_{pj}+C_{ip}^{(i,2)}A_{pj}), \tag{146}$$

$$C_{ij}^{(j,3)}=-\sum_{\substack{p=1\\ p\neq i}}^{n}\frac{\partial C_{ij}^{(j,2)}}{\partial x_1^{(p)}}-A_{ij}C_{ii}^{(j,2)}+\sum_{p=1}^{n}A_{ip}C_{pj}^{(j,2)}. \tag{147}$$

Substituting (141), (142), and (145) [resp. (141), (142), and (144)] in (146) [resp. in (147)] we obtain for $i\neq j$

$$C_{ij}^{(i,3)}=-\left(\partial-\frac{\partial}{\partial x_1^{(i)}}\right)^2 A_{ij}-2\sum_{\substack{p=1\\ p\neq i}}^{n}A_{ip}A_{pi}A_{ij}, \tag{148}$$

$$C_{ij}^{(j,3)}=\frac{\partial^2 A_{ij}}{\partial x_1^{(j)2}}+2\sum_{\substack{p=1\\ p\neq j}}^{n}A_{ij}A_{jp}A_{pj}. \tag{149}$$

Furthermore, the ∂^0 and ∂^{-1} terms of the Lax Eq. $(137a)_1$ give respectively for $i\neq j$

$$U_{ij}^{(1)}=-\partial A_{ij}, \tag{150}$$

$$\frac{\partial U_{ii}^{(1)}}{\partial x_1^{(j)}} = -\partial(A_{ij}A_{ji}). \tag{151}$$

Finally, the ∂^{-1} term of the Lax Eq. $(137b)_2$ gives

$$\frac{\partial A_{ij}}{\partial x_2^{(j)}} = -2A_{ij}U_{jj}^{(1)} - C_{ij}^{(j,3)} \quad \text{for } i \neq j, \tag{152}$$

$$\frac{\partial A_{ij}}{\partial x_2^{(i)}} = \partial^2 A_{ij} - 2\partial C_{ij}^{(i,2)} - C_{ij}^{(i,3)} + 2U_{ii}^{(1)}A_{ij} \quad \text{for } i \neq j, \tag{153}$$

$$\frac{\partial A_{ij}}{\partial x_2^{(k)}} = A_{ik}\frac{\partial A_{kj}}{\partial x_1^{(k)}} - A_{kj}\frac{\partial A_{ik}}{\partial x_1^{(k)}} \quad \text{for } i \neq k \quad \text{and } j \neq k. \tag{154}$$

Finally, we write down explicitly expressions for $U^{(1)}$ and $C^{(i,1)}$ in terms of τ-functions. Recall that

$$P = I_n + \sum_{j=1}^{\infty} W^{(j)}\partial^{-j},$$

$$L = P\partial P^{-1} = I_n\partial + \sum_{j=1}^{\infty} U^{(j)}\partial^{-j},$$

$$C^{(i)} = PE_{ii}P^{-1} = E_{ii} + \sum_{j=1}^{\infty} C^{(i,j)}\partial^{-j}.$$

Using (152) we have

$$U^{(1)} = -\partial W^{(1)}, \tag{155}$$

$$U^{(2)} = W^{(1)}\partial W^{(1)} - \partial W^{(2)}, \tag{156}$$

$$C^{(i,1)} = [W^{(1)}, E_{ii}], \tag{157}$$

$$C^{(i,2)} = [W^{(2)}, E_{ii}] + [E_{ii}, W^{(1)}]W^{(1)}. \tag{158}$$

Using (98) we obtain from (155) and (157), respectively

$$U_{ij}^{(1)} = \begin{cases} -\epsilon_{ji}\partial(\tau_{\alpha+\alpha_{ij}}/\tau_\alpha) & \text{if } i \neq j, \\ \partial\left(\dfrac{\partial\tau_\alpha}{\partial x_1^{(i)}} \Big/ \tau_\alpha\right) & \text{if } i = j, \end{cases} \tag{159}$$

$$A_{ij} \equiv C_{ij}^{(j,1)} = \epsilon_{ji}\tau_{\alpha+\alpha_{ij}}/\tau_\alpha. \tag{160}$$

[Recall that by (139) and (140) all the matrices $C^{(k,1)}$ can be expressed via the functions A_{ij}.] Using (98) and (99) and (156) and (158) one also may write down the matrices $U^{(2)}$ and $C^{(i,2)}$ in terms of τ-functions, but they are somewhat more complicated and we will not need them anyway.

V. THE DARBOUX-EGOROFF SYSTEM, THE *n*-WAVE INTERACTION EQUATIONS, THE GENERALIZED TODA CHAIN AND THE GENERALIZED DAVEY–STEWARTSON EQUATIONS AS SUBSYSTEMS OF THE *n*-COMPONENT KP

In this section we show that some well-known soliton equations, as well as their natural generalizations, are the simplest equations of the various formulations of the *n*-component KP hierarchy. To simplify notation, let

$$t_i = x_2^{(i)}, \quad x_i = x_1^{(i)}. \tag{161}$$

Let $n \geqslant 3$. Then the *n*-component KP in the form of Sato equation contains the system (129) of $n(n-1)(n-2)$ equations on n^2-n functions $W_{ij}\,(i \neq j)$ in the indeterminates x_i (all other indeterminates being parameters):

$$\frac{\partial W_{ij}}{\partial x_k} = W_{ik} W_{kj} \quad \text{for distinct } i,j,k. \tag{162}$$

This is sometimes called the *n*-wave equation. The τ-function is given by the formula (98) for a fixed $\alpha \in M$:

$$W_{ij} = \epsilon_{ji} \tau_{\alpha+\alpha_{ij}} / \tau_\alpha. \tag{163}$$

Substituting this in (162) gives the Hirota bilinear Eq. (78):

$$D_1^{(k)} \tau_\alpha \cdot \tau_{\alpha+\alpha_{ij}} = \epsilon_{ik}\epsilon_{kj}\epsilon_{ij} \tau_{\alpha+\alpha_{ik}} \tau_{\alpha+\alpha_{kj}}. \tag{164}$$

Note that due to (157), $W_{ij} = A_{ij}$ if $i \neq j$, hence (162) is satisfied by the A_{ij} as well.

One usually adds to (162) the following equations, whose group theoretical meaning we shall explain in Sec. VII:

$$\partial W_{ij} = 0, \quad i \neq j. \tag{165}$$

Using (119), this is equaivalent to

$$\sum_{k=1}^{n} \frac{\partial W_{ij}}{\partial x_k} = 0.$$

If one adds the symmetry $W_{ij} = W_{ji}$ one obtains the Darboux–Egoroff system:

$$\frac{\partial W_{ij}}{\partial x_k} = W_{ik} W_{kj} \quad \text{for distinct } i,j,k,$$

$$\sum_{k=1}^{n} \frac{\partial W_{ij}}{\partial x_k} = 0, \tag{166}$$

$$W_{ij} = W_{ji}.$$

These equations describe certain flat diagonal metrics and classifiy (locally) massive topological field theories see Refs. 12–15. For a group theoretical interpretation of this system as a subsystem of the *n*-component KP we refer to Ref. 50.

Let now $a = \mathrm{diag}(a_1,...,a_n)$, $b = \mathrm{diag}(b_1,...,b_n)$ be arbitrary diagonal matrices over $\mathbb{C}$. We reduce the system (162) to the plane:[11]

$$x_k = a_k x + b_k t.$$

A direct calculation shows that (162) reduces then to the following equation on the matrix $W=(W_{ij})$ (note that its diagonal entries do not occur):

$$\left[a,\frac{\partial W}{\partial t}\right]-\left[b,\frac{\partial W}{\partial x}\right]=[\![a,W],[b,W]\!]+b\partial Wa-a\partial Wb. \tag{167}$$

Hence, imposing the constraint (165), we obtain the famous $1+1$ n-wave system (cf. Refs. 11 and 38):

$$\left[a,\frac{\partial W}{\partial t}\right]-\left[b,\frac{\partial W}{\partial x}\right]=[\![a,W],[b,W]\!]. \tag{168}$$

Let now

$$x_k=a_kx+b_kt-y. \tag{169}$$

Then Eq. (167) gives

$$\left[a,\frac{\partial W}{\partial t}\right]-\left[b,\frac{\partial W}{\partial x}\right]-a\frac{\partial W}{\partial y}b+b\frac{\partial W}{\partial y}a=[\![a,W],[b,W]\!]. \tag{170}$$

If we let

$$Q_{ij}=-(a_i-a_j)W_{ij},$$

Eq. (170) turns into the following system, which is called in Ref. 1, (5.4.30a,c), the $2+1$ n-wave interaction equations ($i\neq j$):

$$\frac{\partial Q_{ij}}{\partial t}=a_{ij}\frac{\partial Q_{ij}}{\partial x}+b_{ij}\frac{\partial Q_{ij}}{\partial y}+\sum_k\ (a_{ik}-a_{kj})Q_{ik}Q_{kj}, \tag{171}$$

where

$$a_{ij}=(b_i-b_j)/(a_i-a_j),\quad b_{ij}=b_i-a_ia_{ij}. \tag{172}$$

On the other hand, letting (we assume that $a_1>\cdots>a_n$)

$$w_{ij}=W_{ij}/(a_i-a_j)^{1/2}, \tag{173}$$

the Eq. (177) gives for $i\neq j$

$$\frac{\partial w_{ij}}{\partial t}-a_{ij}\frac{\partial w_{ij}}{\partial x}-b_{ij}\frac{\partial w_{ij}}{\partial y}=\sum_k\ \epsilon_{ijk}w_{ik}w_{kj}, \tag{174}$$

where

$$\epsilon_{ijk}=\frac{a_ib_k+a_kb_j+a_jb_i-a_kb_i-a_jb_k-a_ib_j}{((a_i-a_k)(a_k-a_j)(a_i-a_j))^{1/2}}. \tag{175}$$

Imposing the constraint $\overline{w_{ij}}=-w_{ji}$, we obtain from (174) the following Hamiltonian system (considered in Ref. 38, pp. 175, 242, for $n=3$ and called there the $2+1$ three-wave system) ($i<j$):

$$\frac{\partial w_{ij}}{\partial t}-a_{ij}\frac{\partial w_{ij}}{\partial x}-b_{ij}\frac{\partial w_{ij}}{\partial y}=\frac{\partial H}{\partial\overline{w_{ij}}}, \tag{176}$$

where

$$H=\sum_{\substack{i,k,j\\ i<k<j}} \epsilon_{ijk}(w_{ik}w_{kj}\overline{w}_{ij}+\overline{w}_{ik}\overline{w}_{kj}w_{ij}). \tag{177}$$

Finally, let $n=3$ and let $u_1=iw_{13}$, $u_2=i\overline{w}_{13}$, $u_3=iw_{12}$, $a_1=-a_{23}$, $b_1=-b_{23}$, $a_2=-\overline{a}_{13}$, $b_2=-\overline{b}_{13}$, $a_3=-a_{12}$, $b_3=-b_{13}$. Then, after imposing the constraint $\epsilon_{132}=1$, Eqs. (176) turn into the well-known 2+1 three-wave interaction equations [see Ref. 1, (5.4.27)]:

$$\frac{\partial u_j}{\partial t}+a_j\frac{\partial u_j}{\partial x}+b_j\frac{\partial u_j}{\partial y}=i\overline{u}_k\overline{u}_\ell, \tag{178}$$

where (j,k,ℓ) is an arbitrary cyclic permutation of 1, 2, 3.

Let $n\geqslant 2$. Then the n-component KP in the form of Sato equations contains the following subsystem of the system of Eq. (129) for arbitrary $\alpha\in M$ on the functions $W_{ij}(\alpha)$ in the indeterminates x_i (all other indeterminates being parameters):

$$\frac{\partial W_{ii}(\alpha)}{\partial x_j}=W_{ij}(\alpha)W_{ji}(\alpha)\quad \text{if } i\neq j. \tag{179}$$

The τ-function is given by (98) ($\alpha\in M$)

$$W_{ij}(\alpha)=\begin{cases}\epsilon_{ji}\tau_{\alpha+\alpha_{ij}}/\tau_\alpha & \text{if } i\neq j,\\ -\dfrac{\partial}{\partial x_i}\log\tau_\alpha & \text{if } i=j.\end{cases} \tag{180}$$

Substituting this in (179) gives the Hirota bilinear Eq. (74):

$$D_iD_j\tau_\alpha\cdot\tau_\alpha=2\tau_{\alpha+\alpha_{ij}}\tau_{\alpha-\alpha_{ij}}. \tag{181}$$

In order to rewrite (179) in a more familiar form, let for $i\neq j$

$$U_{ij}(\alpha)=\log\epsilon_{ji}W_{ij}(\alpha)=\log(\tau_{\alpha+\alpha_{ij}}/\tau_\alpha). \tag{182}$$

Note that $\log(\tau_{\alpha+\alpha_{ij}}/\tau_\alpha)=-\log(\tau_{(\alpha+\alpha_{ij})-\alpha_{ij}}/\tau_{\alpha+\alpha_{ij}}$. Hence from (180) we obtain

$$U_{ij}(\alpha)=-U_{ji}(\alpha+\alpha_{ij})\quad \text{if } i\neq j. \tag{183}$$

Furthermore, we have

$$\begin{aligned}\frac{\partial^2}{\partial x_i\partial x_j}U_{ij}(\alpha)&=\frac{\partial^2}{\partial x_i\partial x_j}\log\tau_{\alpha+\alpha_{ij}}-\frac{\partial^2}{\partial x_i\partial x_j}\log\tau_\alpha\\ &=\frac{\partial W_{ii}(\alpha)}{\partial x_j}-\frac{\partial W_{ii}(\alpha+\alpha_{ij})}{\partial x_j}\\ &=W_{ij}(\alpha)W_{ji}(\alpha)-W_{ij}(\alpha+\alpha_{ij})W_{ji}(\alpha+\alpha_{ij})\\ &=-\frac{\tau_{\alpha+\alpha_{ij}}}{\tau_\alpha}\frac{\tau_{\alpha-\alpha_{ij}}}{\tau_\alpha}+\frac{\tau_{\alpha+2\alpha_{ij}}}{\tau_{\alpha+\alpha_{ij}}}\frac{\tau_\alpha}{\tau_{\alpha+\alpha_{ij}}}\\ &=e^{U_{ij}(\alpha+\alpha_{ij})-U_{ij}(\alpha)}-e^{U_{ij}(\alpha)-U_{ij}(\alpha-\alpha_{ij})}.\end{aligned}$$

Thus the functions $U_{ij}(\alpha)\,(i\neq j)$ satisfy the following generalized Toda chain [with constraint (183)]:

$$\frac{\partial^2 U_{ij}(\alpha)}{\partial x_i \partial x_j} = e^{U_{ij}(\alpha+\alpha_{ij})-U_{ij}(\alpha)} - e^{U_{ij}(\alpha)-U_{ij}(\alpha-\alpha_{ij})}. \tag{184}$$

Note also that (162) for distinct i, j and k becomes

$$\frac{\partial U_{ij}(\alpha)}{\partial x_k} = \epsilon_{ik}\epsilon_{kj}\epsilon_{ji} e^{U_{ij}(\alpha)+U_{ik}(\alpha)+U_{kj}(\alpha)}. \tag{185}$$

One should be careful about the boundary conditions. Let $S=\operatorname{supp}\tau$; recall that by Proposition 2.4, S is a convex polyhedron with vertices in M and edges parallel to roots. It follows that (184) should be understood as follows:

(i) If $\alpha\notin S$, then $U_{ij}(\alpha)=0$ and (184) is trivial.
(ii) If $\alpha\in S$, but $\alpha+\alpha_{ij}\notin S$, then (184) is trivial.
(iii) If $\alpha\in S$, but $\alpha-\alpha_{ij}\notin S$, then the second term on the right-hand side of (184) is removed.
(iv) If $\alpha\in S$, $\alpha+\alpha_{ij}\in S$, but $\alpha+2\alpha_{ij}\notin S$, then the first term on the right-hand side of (184) is removed.

Let now $n=2$, and let $u_n=U_{12}(n\alpha_{12})$. Then we get the usual Toda chain:

$$\frac{\partial^2 u_n}{\partial x_1 \partial x_2} = e^{u_{n+1}-u_n} - e^{u_n-u_{n-1}}, \quad n\in\mathbb{Z}. \tag{186}$$

It is a part of the Toda lattice hierarchy discussed in Ref. 47.

Let $n\geqslant 2$. Then the n-component KP in the form of Sato equations contains the system of Eqs. (132), (133), (131) and (129) for $j\neq k$ on n^2 functions W_{ij} in the indeterminates x_k and $t_k\,(k=1,\ldots,n)$ (all other indeterminates being parameters):

$$\frac{\partial W_{ij}}{\partial t_j} = -\frac{\partial^2 W_{ij}}{\partial x_j^2} + 2\frac{\partial W_{jj}}{\partial x_j} W_{ij} \quad \text{if } i\neq j, \tag{187}$$

$$\frac{\partial W_{ij}}{\partial t_i} = \frac{\partial^2 W_{ij}}{\partial x_i^2} - 2\frac{\partial W_{ii}}{\partial x_i} W_{ij} \quad \text{if } i\neq j, \tag{188}$$

$$\frac{\partial W_{ij}}{\partial t_k} = W_{ik}\frac{\partial W_{kj}}{\partial x_k} - \frac{\partial W_{ik}}{\partial x_k} W_{kj} \quad \text{if } i\neq k \quad \text{and } j\neq k, \tag{189}$$

$$\frac{\partial W_{ij}}{\partial x_k} = W_{ik}W_{kj} \quad \text{if } i\neq k \quad \text{and } j\neq k. \tag{190}$$

This is a system of n^3-n evolution Eqs. (187)–(189) and $n(n-1)^2$ constraints (190) which we call the generalized Davey–Stewartson system.

Note that the τ-functions of this system are given by (98), where we may take $\alpha=0$. The corresponding to (187)–(190) Hirota bilinear equations are (76), (75), (77) if $i=j$ and (79) if $i\neq j$; (74) if $i=j$ and (78) if $i\neq j$, respectively.

Now, note that letting

$$\varphi_{ij} = \frac{1}{2}\left(\frac{\partial W_{ii}}{\partial x_i} + \frac{\partial W_{jj}}{\partial x_j} + \frac{\partial W_{ii}}{\partial x_j} + \frac{\partial W_{jj}}{\partial x_i}\right) (=\varphi_{ji})$$

and subtracting (188) from (187) we obtain using (190)

$$\frac{\partial W_{ij}}{\partial t_j}-\frac{\partial W_{ij}}{\partial t_i}=-\left(\frac{\partial^2}{\partial x_i^2}+\frac{\partial^2}{\partial x_j^2}\right)W_{ij}+2W_{ij}(\varphi_{ij}-W_{ij}W_{ji}). \tag{191}$$

Also, from (190) we obtain

$$\frac{\partial^2\varphi_{ij}}{\partial x_i\partial x_j}=\frac{1}{2}\left(\frac{\partial}{\partial x_i}+\frac{\partial}{\partial x_j}\right)^2(W_{ij}W_{ji}). \tag{192}$$

Let now $n=2$; to simplify notation, let

$$q=W_{12},\quad r=W_{21},\quad \varphi=\varphi_{12}=\varphi_{21}.$$

Then, making the change of indeterminates

$$s=-2i(t_1+t_2),\quad t=-2i(t_1-t_2),\quad x=x_1+x_2,\quad y=x_1-x_2, \tag{193}$$

Eqs. (191) and (192) turn into the decoupled Davey–Stewartson system:

$$\begin{aligned} i\frac{\partial q}{\partial t}&=-\frac{1}{2}\left(\frac{\partial^2 q}{\partial x^2}+\frac{\partial^2 q}{\partial y^2}\right)+q(\varphi-qr),\\ i\frac{\partial r}{\partial t}&=\frac{1}{2}\left(\frac{\partial^2 r}{\partial x^2}+\frac{\partial^2 r}{\partial y^2}\right)-r(\varphi-qr),\\ \frac{\partial^2\varphi}{\partial x^2}-\frac{\partial^2\varphi}{\partial y^2}&=2\frac{\partial^2(qr)}{\partial x^2}. \end{aligned} \tag{194}$$

Due to (98), the corresponding τ-functions are given by the following formulas, where we let $\tau_n=\tau_{n\alpha_{12}}$:

$$q=-\tau_1/\tau_0,\quad r=\tau_{-1}/\tau_0,\quad \varphi=-\frac{\partial^2}{\partial x^2}\log\tau_0, \tag{195}$$

the Hirota bilinear equations being (cf. Ref. 22)

$$\begin{aligned} (iD_t+\tfrac{1}{2}D_x^2+\tfrac{1}{2}D_y^2)\tau_1\cdot\tau_0&=0,\\ (-iD_t+\tfrac{1}{2}D_x^2+\tfrac{1}{2}D_y^2)\tau_{-1}\cdot\tau_0&=0,\\ (D_x^2-D_y^2)\tau_0\cdot\tau_0&=2\tau_1\tau_{-1}. \end{aligned} \tag{196}$$

Finally, imposing the constraint

$$r=\kappa\overline{q},\quad \text{where}\ \ \kappa=\pm 1, \tag{197}$$

we obtain the classical Davey–Stewartson system

$$\begin{aligned} i\frac{\partial q}{\partial t}+\frac{1}{2}\left(\frac{\partial^2 q}{\partial x^2}+\frac{\partial^2 q}{\partial y^2}\right)&=(\varphi-\kappa|q|^2)q,\\ \frac{\partial^2\varphi}{\partial x^2}-\frac{\partial^2\varphi}{\partial y^2}&=2\kappa\frac{\partial^2|q|^2}{\partial x^2}. \end{aligned} \tag{198}$$

Remark 5.1: It is interesting to compare the above results with that obtained via the Lax equations. To simplify notation, let $U_i=U_{ii}^{(1)}$. Substituting (149) [resp. (148)] in (152) [resp. (153)], we obtain for $i\neq j$

$$\frac{\partial A_{ij}}{\partial t_j}=-\frac{\partial^2 A_{ij}}{\partial x_j^2}-2A_{ij}U_j-2\sum_{k\neq j}A_{ij}A_{jk}A_{kj}, \tag{199}$$

$$\frac{\partial A_{ij}}{\partial t_i}=\frac{\partial^2 A_{ij}}{\partial x_i^2}+2A_{ij}U_i+2\sum_{k\neq i}A_{ij}A_{ik}A_{ki}. \tag{200}$$

These equation together with (143), (151), and (154) give a slightly different version of the generalized DS system (recall that $A_{ij}=W_{ij}$ if $i\neq j$ and $U_i=-\partial W_{ii}$). For $n=2$ we get again the classical DS system after the change of indeterminates (193) if we let $\varphi=-\frac{1}{2}(U_1+U_2)$.

Finally, we explain what happens in the well-known case $n=1$. In this case $C^{(1)}=1$ and auxiliary conditions (136) are trivial. Lax Eq. (137b) is trivial as well, and Lax Eq. (137a) becomes

$$\frac{\partial L}{\partial x_i}=[B_i,L],\quad i=1,2,..., \tag{201}$$

where $L=\partial+\Sigma_{j=1}^{\infty}u_j(x)\partial^{-j}$, $\partial=\partial/\partial x_1$ and $B_i=(L^i)_+$. Thus, the KP hierarchy is a system of partial differential Eqs. (201) on unknown functions u_1, u_2,... in indeterminates x_1, x_2,.... By Lemma 3.6, (201) is equivalent to the following system of Zakharov–Shabat equations:

$$\frac{\partial B_\ell}{\partial x_k}-\frac{\partial B_k}{\partial x_\ell}=[B_k,B_\ell]. \tag{202}$$

By (138) we have

$$B_1=\partial,\quad B_2=\partial^2+2u_1. \tag{203}$$

Furthermore, we have

$$B_3=\partial^3+3u_1\partial+3u_2+3\frac{\partial u_1}{\partial x_1}. \tag{204}$$

Thus we see that Eqs. $(202)_{k,1}$ are all trivial, the first nontrivial equation of (202) being

$$\frac{\partial B_2}{\partial x_3}-\frac{\partial B_3}{\partial x_2}=[B_3,B_2].$$

Substituting in it (203) and (204), the coefficients of ∂^0 and ∂^1 give, respectively,

$$2\frac{\partial u_1}{\partial x_3}-2\frac{\partial^2 u_1}{\partial x_1\partial x_2}-6u_1\frac{\partial u_1}{\partial x_1}=3\frac{\partial u_2}{\partial x_2}-3\frac{\partial^2 u_2}{\partial x_1^2}, \tag{205}$$

$$6\frac{\partial u_2}{\partial x_1}=3\frac{\partial u_1}{\partial x_2}-\frac{\partial^2 u_1}{\partial x_1^2}. \tag{206}$$

Differentiating (205) by x_1 and substituting $\partial u_2/\partial x_1$ from (206) gives a PDE on $u=2u_1$, where we let $x_1=x$, $x_2=y$, $x_3=t$:

$$\frac{3}{4}\frac{\partial^2 u}{\partial y^2}=\frac{\partial}{\partial x}\left(\frac{\partial u}{\partial t}-\frac{3}{2}u\frac{\partial u}{\partial x}-\frac{1}{4}\frac{\partial^3 u}{\partial x^3}\right). \tag{207}$$

This is the classical KP equation. Due to (159), the connection between u and the τ-function is given by the famous formula

$$u=2\frac{\partial^2}{\partial x^2}\log\tau. \tag{208}$$

Substituting u in (207) gives the Hirota bilinear Eq. (73).

VI. SOLITON AND DROMION SOLUTIONS

We turn now to the construction of solutions of the n-component KP hierarchy. As in Ref. 9 we make use of the vertex operators (54). When transported via the n-component boson-fermion correspondence σ from F to $B=\mathbb{C}[x]\otimes\mathbb{C}[L]$, they take the following form:

$$\psi^{\pm(i)}(z)=Q_i^{\pm 1}z^{\pm\alpha_0^{(i)}}\left(\exp\pm\sum_{k=1}^{\infty}z^k x_k^{(i)}\right)\left(\exp\mp\sum_{k=1}^{\infty}\frac{z^{-k}}{k}\frac{\partial}{\partial x_k^{(i)}}\right). \tag{209}$$

Note that for $z,w\in\mathbb{C}^\times$ such that $|w|<|z|$ we have (λ, $\mu=+$ or $-$)

$$\psi^{\lambda(i)}(z)\psi^{\mu(j)}(w)=(z-w)^{\delta_{ij}\lambda\mu}Q_i^{\lambda 1}Q_j^{\mu 1}z^{\lambda\alpha_0^{(i)}}w^{\mu\alpha_0^{(j)}}\exp\sum_{k=1}^{\infty}(\lambda z^k x_k^{(i)}+\mu w^k x_k^{(j)})$$
$$\times\exp-\sum_{k=1}^{\infty}\left(\lambda\frac{z^{-k}}{k}\frac{\partial}{\partial x_k^{(i)}}+\mu\frac{w^{-k}}{k}\frac{\partial}{\partial x_k^{(j)}}\right). \tag{210}$$

We let for $0<|w|<|z|$

$$\Gamma_{ij}(z,w)\overset{\text{def}}{=}\psi^{+(i)}(z)\psi^{-(j)}(w)=(z-w)^{-\delta_{ij}}Q_iQ_j^{-1}z^{\alpha_0^{(i)}}w^{-\alpha_0^{(j)}}\exp\sum_{k=1}^{\infty}(z^k x_k^{(i)}-w^k x_k^{(j)})$$
$$\times\exp-\sum_{k=1}^{\infty}\left(\frac{z^{-k}}{k}\frac{\partial}{\partial x_k^{(i)}}-\frac{w^{-k}}{k}\frac{\partial}{\partial x_k^{(j)}}\right). \tag{211}$$

Using (210), we obtain for $|z_1|>|z_2|>\cdots>|z_{2N-1}|>|z_{2N}|>0$

$$\Gamma_{i_1i_2}(z_1,z_2)\cdots\Gamma_{i_{2N-1}i_{2N}}(z_{2N-1},z_{2N})$$
$$=\prod_{1\le k\le\ell\le 2N}(z_k-z_\ell)^{(-1)^{k+\ell}\delta_{i_ki_\ell}}Q_{i_1}Q_{i_2}^{-1}\cdots Q_{i_{2N-1}}Q_{i_{2N}}^{-1}\prod_{m=1}^{2N}z_m^{(-1)^{m-1}\alpha_0^{(i_m)}}$$
$$\times\exp\left(-\sum_{m=1}^{2N}\sum_{k=1}^{\infty}(-1)^m z_m^k x_k^{(m)}\right)\exp\left(\sum_{m=1}^{2N}\sum_{k=1}^{\infty}(-1)^m\frac{z_m^{-k}}{k}\frac{\partial}{\partial x_k^{(m)}}\right). \tag{212}$$

We may analytically extend the right-hand side of (212) to the domain $\{z_i \neq 0,\ z_i \neq z_j \text{ if } i \neq j,\ i,j = 1,...,2N\}$. Then we deduce from (212) for $N=2$ that in this domain we have

$$\Gamma_{i,i_2}(z_1,z_2)\Gamma_{i_3,i_4}(z_3,z_4) = \Gamma_{i_3,i_4}(z_3,z_4)\Gamma_{i,i_2}(z_1,z_2), \tag{213}$$

$$\Gamma_{ij}(z_1,z_2)^2 \equiv \lim_{\substack{z_3 \to z_1 \\ z_4 \to z_2}} \Gamma_{ij}(z_1,z_2)\Gamma_{ij}(z_3,z_4) = 0. \tag{214}$$

Remark 6.1: Let $A=(a_{ij})$ be a $n \times n$ matrix over $\mathbb{C}$ and let $z_i,\ w_i\ (i=1,...,n)$ be nonzero complex numbers such that $z_i \neq w_j$. Due to (34) the sum

$$\Gamma_A(z,w) = \sum_{i,j=1}^{n} a_{ij}\Gamma_{ij}(z_i,w_j) \tag{215}$$

lies in a completion of $r(\mathrm{gl}_\infty)$.

By (213) and (214) we obtain

$$\exp \Gamma_A(z,w) = \prod_{i,j=1}^{n} (1 + a_{ij}\Gamma_{ij}(z_i,w_j)). \tag{216}$$

Lemma 6.1: (a) If τ is a solution of the n-component KP hierarchy (70) of Hirota bilinear equations, then $(\exp \Gamma_A(z,w))\tau$ is a solution as well for any complex $n \times n$ matrix A and any $z = (z_1,...z_n),\ w=(w_1,...,w_n) \in \mathbb{C}^{\times n}$ such that $z_i \neq w_j$.

(b) For any collection of complex $n \times n$-matrices $A_1,...,A_N$ and any collection $z^{(1)},...,z^{(N)}$, $w^{(1)},...,w^{(N)} \in \mathbb{C}^{\times n}$ with all coordinates distinct, the function

$$\exp \Gamma_{A_1}(z^{(1)},w^{(1)}) \cdots \exp \Gamma_{A_N}(z^{(N)},w^{(N)}) \cdot 1 \tag{217}$$

is a solution of the n-component KP hierarchy (70).

Proof: (a) follows from Proposition 2.1 and Remark 6.1. (b) follows from (a) since the function $1 = \sigma|0\rangle$ satisfies (38). □

We call (217) the *N-solitary τ-function* (of the *n*-component KP hierarchy).

In order to write down (217) in a more explicit form, introduce the lexicographic ordering on the set S of all triples $s=(p,i,j)$, where $p \in \{1,...,N\},\ i,j \in \{1,...,n\}$ (i.e., $s_1 < s_2$ if $p_1 < p_2$, or $p_1 = p_2$ and $i_1 < i_2$ or $p_1 = p_2$, $i_1 = i_2$ and $j_1 < j_2$). Given N $n \times n$ complex matrices $A_p = (a_{ij}^{(p)})$, we let $a_s = a_{ij}^{(p)}$ for $s=(p,i,j) \in S$; given in addition two sets of nonzero complex numbers z_s and w_s, all distinct, parametrized by $s \in S$, introduce the following constants:

$$c(s_1,...,s_r) = \prod_{k=1}^{r} a_{s_k} \prod_{\ell=k+1}^{r} \epsilon_{i_k i_\ell}\epsilon_{i_k j_\ell}\epsilon_{j_k i_\ell}\epsilon_{j_k j_\ell} \prod_{1 \leq k < \ell \leq r} \frac{(z_{s_k} - z_{s_\ell})^{\delta_{i_k i_\ell}}(w_{s_k} - w_{s_\ell})^{\delta_{j_k j_\ell}}}{(z_{s_k} - w_{s_\ell})^{\delta_{i_k j_\ell}}(w_{s_k} - z_{s_\ell})^{\delta_{j_k i_\ell}}}. \tag{218}$$

Then the *N*-solitary solution (217) can be written as follows:

$$1 + \sum_{r=1}^{Nn^2} \sum_{(1,1,1) \leq s_1 < \cdots < s_r \leq (N,n,n)} c(s_1,...,s_r) \left(\exp \sum_{k=1}^{r} \sum_{m=1}^{\infty} (z_{s_k}^m x_m^{(i_k)} - w_{s_k}^m x_m^{(j_k)}) \right) e^{\sum_{k=1}^{r} \alpha_{i_k j_k}}. \tag{219}$$

Let $n=1$. Then the index set S is naturally identified with the set $\{1,...,N\}$, the two sets of complex numbers we denote by z_{2j-1} and z_{2j}, $j=1,...,N$, and we let $A_p = (z_{2p-1} - z_{2p})^{-1} a_p$, where a_p are some constants. Then (219) becomes the well-known formula (see Ref. 9) for the τ-function of the *N*-soliton solution:

$$\tau^{(N)}=1+\sum_{r=1}^{N}\sum_{1\leqslant j_1<\cdots<j_r\leqslant N}\prod_{k=1}^{r}a_{j_k}\prod_{1\leqslant k<\ell\leqslant 2r}(z_{j_k}-z_{j_\ell})^{(-1)^{k+\ell}}\exp\sum_{k=1}^{r}\sum_{m=1}^{\infty}(z_{j_{2k-1}}^m-z_{j_{2k}}^m)x_m. \tag{220}$$

Letting $x_1=x$, $x_2=y$, $x_3=t$ and all other indeterminates constants $x_4=c_4,\ldots$, we obtain, due to (208), the soliton solution of the classical KP Eq. (207):

$$u(t,x,y)=2\frac{\partial^2}{\partial x^2}\log\tau^{(N)}(x,y,t,c_4,c_5,\ldots). \tag{221}$$

In particular, the τ-function of the one-soliton solution is

$$\tau^{(1)}(x,y,t)=1+\frac{a}{z_1-z_2}\exp((z_1-z_2)x+(z_1^2-z_2^2)y+(z_1^3-z_2^3)t+\text{const}), \tag{222}$$

and we get the corresponding one-soliton solution of the classical KP Eq. (207):

$$u(x,y,t)=\frac{(z_1-z_2)^2}{2}\cosh^{-2}\left(\frac{1}{2}((z_1-z_2)x+(z_1^2-z_2^2)y+(z_1^3-z_2^3)t)+\text{const}\right). \tag{223}$$

Let $n=2$. Then any $\tau\in\mathbb{C}[x]\otimes\mathbb{C}[M]$ can be written in the form

$$\tau=\sum_{\ell\in\mathbb{Z}}\tau_\ell e^{\ell\alpha_{12}},\quad \text{where}\quad \tau_\ell\equiv\tau_{\ell\alpha_{12}}.$$

For a N-solitary solution $\tau^{(N)}$ given by (219) we then have

$$\tau_\ell^{(N)}=\delta_{\ell.0}+\sum_{r=1}^{4N}\sum_{(s_1,\ldots,s_r)}c(s_1,\ldots,s_r)\exp\sum_{k=1}^{r}\sum_{m=1}^{\infty}(z_{s_k}^m x_m^{(i_k)}-w_{s_k}^m x_m^{(j_k)}), \tag{224}$$

where $(s_1,\ldots,s_r)$ run over the subset $(225)_2$ of S^r, where

$$\begin{cases}(1,1,1)\leqslant s_1<s_2\cdots<s_r\leqslant(N,n,n)\\ \#\{(i_k,j_k)|i_k>j_k\}-\#\{(i_k,j_k)|i_k<j_k\}=\ell.\end{cases} \tag{225}$$

Letting [cf. (195)]

$$q=-\frac{\tau_1(x,y,t,c,c_3^{(1)},\ldots)}{\tau_0(x,y,t,c,c_3^{(1)},\ldots)},\quad r=\frac{\tau_{-1}(x,y,t,c,c_3^{(1)},\ldots)}{\tau_0(x,y,t,c,c_3^{(1)},\ldots)},$$
$$\varphi=-\frac{\partial^2}{\partial x^2}(\log\tau_0(x,y,t,c,c_3^{(1)},\ldots)), \tag{226}$$

where $x=x_1^{(1)}+x_2^{(1)}$, $y=x_1^{(1)}-x_2^{(1)}$, $t=-2i(x_2^{(1)}-x_2^{(2)})$, $c=-2i(x_2^{(1)}+x_2^{(2)})$ and all other indeterminates $x_k^{(j)}$ are arbitrary constants $c_k^{(j)}$, we obtain an N-solitary solution of the decoupled Davey–Stewartson system (194).

We turn now to the classical Davey–Stewartson system (198) for $\kappa=-1$. The constraint (197) gives

$$\tau_1/\tau_0=\overline{\tau_{-1}/\tau_0}.$$

One way of satisfying this constraint is to let

$$a_{ij}^{(p)}=(-1)^{i+j}\overline{a}_{ji}^{(p)},\quad z_{(p,i,j)}=-\overline{w}_{(p,j,i)},$$
$$c_2=0,\quad c_k^{(j)}\in i^{k+1}\mathbb{R}. \tag{227}$$

We shall concentrate now on the case $N=1$. It will be convenient to use the following notation:

$$x_1=x_1^{(1)},\quad x_2=x_1^{(2)},$$

$$z_{ij}=z_{(1,i,j)},\quad a_i=a_{(1,i,i)}\in\mathbb{R}_+(1\leqslant i,j\leqslant 2),\quad a_3=a_{(1,1,2)}\in\mathbb{C},$$

$$C(z,w)=\frac{z-w}{z+\overline{w}},\quad D(z,w)=\frac{|a_3|^2}{(z+\overline{z})(w+\overline{w})},$$

$$A_j(z)=(z+\overline{z})\left(x_j-(-1)^j it\frac{z-\overline{z}}{4}\right)+\sum_{k=3}^{\infty}(z^k-(-\overline{z})^k)c_k^{(j)}\quad (j=1,2),$$

$$A_3(z,w)=zx_1+\overline{w}z_2+it\left(\frac{z^2}{4}+\frac{\overline{w}^2}{4}\right)+\sum_{k=3}^{\infty}(z^kc_k^{(1)}-(-\overline{w})^kc_k^{(2)}).$$

Then $q=-\tau_1/\tau_0$ and $\varphi=-\frac{1}{2}(\partial/\partial x_1+\partial/\partial x_2)^2\log\tau_0$ is a solution of (198), where

$$\tau_1=a_3e^{A_3(z_{12},z_{21})}(1+a_1C(z_{12},z_{11})e^{A_1(z_{11})})(1+a_2C(\overline{z}_{21},\overline{z}_{22})e^{A_2(z_{22})}), \tag{228a}$$

$$\tau_0=(1+a_1e^{A_1(z_{11})})(1+a_2e^{A_2(z_{22})})+D(z_{12},z_{21})e^{A_3(z_{12},z_{21})+\overline{A_3(z_{12},z_{21})}}(1+a_1|C(z_{12},z_{21})|^2e^{A_1(z_{11})})$$
$$\times(1+a_2|C(z_{21},z_{22})|^2e^{A_2(z_{22})}). \tag{228b}$$

Consider now two special cases of (228a) and (228b):

$$(D)\quad z_1\equiv z_{11}=z_{12}\quad\text{and}\quad z_2\equiv z_{22}=z_{21},$$

$$(S)\quad a_i=0\quad (i=1,2),$$

and let $T=D$ or S. Then (228a) and (228b) reduce to

$$\tau_1=a_3e^{A_3(z_1,z_2)}\ \text{ in both cases,} \tag{229a}$$

$$\tau_0^{(T)}=(1+\delta_{TD}a_1e^{A_1(z_1)})(1+\delta_{TD}a_2e^{A_2(z_2)})+D(z_1,z_2)e^{A_1(z_1)+A_2(z_2)}, \tag{229b}$$

so that $q^{(T)}=-\tau_1/\tau_0^{(T)}$, $\varphi^{(T)}=-\frac{1}{2}(\partial/\partial x_1+\partial/\partial x_2)^2\log\tau_0^{(T)}$ is a solution of (198).

In order to rewrite $q^{(T)}$ in a more familiar form, let ($j=1$, 2 and $a_j(z_j+\overline{z_j})>0$)

$$p_j^{(T)}=(a_j(z_j+\overline{z_j}))^{-1/2}\quad\text{if } T=D\quad\text{and }=1\quad\text{if } T=S,$$

$$\mu_1=\mu_{1R}+i\mu_{1I}=\tfrac{1}{2}\overline{z}_1,\quad \mu_2=\mu_{2R}+i\mu_{2I}=\tfrac{1}{2}z_2,$$

$$m_j^{(T)}=2\sqrt{2}\mu_{jR}p_j^{(T)}e^{-\sum_{k=3}^{\infty}(-1)^j((-1)^j2\mu_j)^kc_k^{(j)}},$$

$$\xi_j=2x_j+2\mu_{jI}t,\quad \tilde{\xi}_j=\frac{1}{\mu_{jR}}\log\frac{|m_j^{(T)}|}{\sqrt{2\mu_{jR}}},$$

$$\rho^{(T)}=-a_3p_1^{(T)}p_2^{(T)}.$$

Then we obtain the following expression for $q^{(T)}$:

$$\frac{4\rho^{(T)}(\mu_{1R}\mu_{2R})^{1/2}\exp\{-(\mu_{1R}(\xi_1-\tilde{\xi}_1)+\mu_{2R}(\xi_2-\tilde{\xi}_2))+i(-(\mu_{1I}\xi_1+\mu_{2I}\xi_2)+(|\mu_1|^2+|\mu_2|^2)t+\arg m_1 m_2)\}}{((\delta_{TD}+\exp(-2\mu_{1R}(\xi_1-\tilde{\xi}_1))(\delta_{TD}+\exp(-2\mu_{2R}(\xi_2-\tilde{\xi}_2))+|\rho^{(T)}|^2)}.$$

The function $q^{(D)}$ is precisely the (1,1)-dromion solution of the Davey–Stewartson Eqs. (198) with $\kappa=-1$ found in Ref. 19 (provided that $\mu_{jR}\in\mathbb{R}_+$). On the other hand, if we let $\mu_{1I}=\mu_{2I}=0$, then $q^{(T)}$ reduces to the two-dimensional breather solution found in Ref. 6. Finally, $q^{(S)}$ is a one-solution solution.

Recall that the dromion solutions of the DS equation were originally discovered in Refs. 6, 18, and 19 (see also Ref. 22). The dromion solutions of the DS equation were first studied from the point of view of the spinor formalism in Ref. 21.

Similarly, we obtain the following solutions of the two-dimensional Toda chain (186):

$$u_\ell=\begin{cases}\log(\tau_{\ell+1}^{(N)}/\tau_\ell^{(N)}) & \text{if } -N\leqslant\ell\leqslant N-1,\\ 0 \quad \text{otherwise,}\end{cases} \tag{230}$$

where the τ-functions $\tau_\ell^{(N)}$ are obtained from (224) by letting all indeterminates $x_m^{(j)}$ with $m>1$ be arbitrary constants:

$$\tau_\ell^{(N)}=\delta_{\ell,0}+\sum_{r=1}^{4N}\sum_{(s_1,\dots,s_r)}c(s_1,\dots,s_r)c_{s_1}\cdots c_{s_r}\exp\sum_{k=1}^{r}(x_{i_k}z_{s_k}-x_{j_k}w_{s_k}), \tag{231}$$

where $(s_1,\dots,s_r)$ runs over $(225)_2$ and $c_s\,(s\in S)$ are arbitrary constants.

Let now $n\geqslant 3$. Then we obtain solutions of the $2+1$ n-wave system (170) as follows. For $1\leqslant i,\ j\leqslant n$ let

$$\tau_{ij}^{(N)}=\delta_{ij}+\sum_{r=1}^{Nn^2}\sum_{(s_1,\dots,s_r)}c_{s_1}\cdots c_{s_r}\exp\sum_{k=1}^{r}(a_{i_k}x+b_{i_k}t-y)z_{s_k}-(a_{j_k}x+b_{j_k}t-y)w_{s_k}, \tag{232}$$

where $(s_1,\dots,s_r)$ runs over $(225)_n$ and $c_s\,(s\in S)$ are arbitrary constants. Then $W_{ij}=\epsilon_{ji}\tau_{ij}/\tau_0\,(i\neq j)$ is a solution of (170), and $Q_{ij}=\epsilon_{ij}(a_i-a_j)\tau_{ij}/\tau_0\,(i\neq j)$ is a solution of (171).

VII. $[m_1,m_2,\dots,m_n]$-REDUCTIONS OF THE n-COMPONENT KP HIERARCHY

Fix a positive integer $m\geqslant n$ and let $m_1+m_2+\cdots+m_n$ be a partition of m into n parts. Let $\omega_j=\exp 2\pi i/m_j$ for $j=1,2,\dots,n$. Introduce the following m^2 fields ($1\leqslant i,j\leqslant n,\ 1\leqslant k\leqslant m_i,\ 1\leqslant\ell\leqslant m_j$):[46]

$$\alpha^{(ijk\ell)}(z)\equiv\sum_{p\in\mathbb{Z}}\alpha_p^{(ijk\ell)}z^{-p-1}=:\psi^{+(i)}(\omega_i^k z)\psi^{-(j)}(\omega_j^\ell z):, \tag{233}$$

where the normal ordering is defined by (46). Note that

$$\alpha^{(ijm_im_j)}(z)=\alpha^{(ij)}(z), \tag{234}$$

where $\alpha^{(ij)}(z)$ are the bosonic fields, defined by (45), which generate the affine algebra $\mathrm{gl}_n(\mathbb{C})\hat{}$ with central charge 1 [see (47)]. It is easy to check that for arbitrary m, the fields $\alpha^{(ijk\ell)}(z)$ generate the affine algebra $\mathrm{gl}_m(\mathbb{C})\hat{}$ with central charge 1. In other words, all the operators $\alpha_p^{(ijk\ell)}$ ($1\leqslant i,j\leqslant n,\ 1\leqslant k\leqslant m_i,\ 1\leqslant\ell\leqslant m_j,\ p\in\mathbb{Z}$) together with 1 span $\mathrm{gl}_m(\mathbb{C})\hat{}$ in its representation in F with central charge 1, the charge decomposition being the decomposition into irreducibles. Hence, using (54), (60) and (63), we obtain the vertex operator realization of this representation of $\mathrm{gl}_m(\mathbb{C})\hat{}$ in the vector space B (see Ref. 46 for details).

Now, restricted to the subalgebra $\mathrm{sl}_m(\mathbb{C})\hat{}$, the representation in $F^{(0)}$ is not irreducible any more, since $\mathrm{sl}_m(\mathbb{C})\hat{}$ commutes with all the operators

$$\beta^{(s)}_{km_n}=\sqrt{\frac{m_n}{m}}\sum_{i=1}^{n}\alpha^{(i)}_{km_i},\quad k\in\mathbb{Z}. \tag{235}$$

In order to describe the irreducible part of the representation of $\mathrm{sl}_m(\mathbb{C})\hat{}$ in $B^{(0)}$ containing the vacuum 1, we choose the complementary generators of the oscillator algebra $\mathfrak{a}$ contained in $\mathrm{sl}_m(\mathbb{C})\hat{}$ $(k\in\mathbb{Z})$:

$$\beta^{(j)}_k=\begin{cases}\alpha^{(j)}_k & \text{if } k\notin m_j\mathbb{Z},\\ \dfrac{M_{j+1}\alpha^{(j+1)}_{\ell m_{j+1}}-m_{j+1}(\alpha^{(1)}_{\ell m_1}+\alpha^{(2)}_{\ell m_2}+\cdots+\alpha^{(j)}_{\ell m_j})}{\sqrt{M_{j+1}(M_{j+1}-m_{j+1})}} & \text{if } k=\ell m_j \text{ and } 1\leqslant j<n,\end{cases} \tag{236}$$

where $M_j=m_1+m_2+\cdots+m_{j-1}$ and $M_1=0$. So the operators (235) and (236) also satisfy relations (49). Hence, introducing the new indeterminates

$$y^{(j)}_k=\begin{cases}x^{(j)}_k & \text{if } k\notin m_j\mathbb{N},\\ \dfrac{M_{j+1}x^{(j+1)}_{\ell m_{j+1}}-(m_1x^{(1)}_{\ell m_1}+m_2x^{(2)}_{\ell m_2}+\cdots+m_jx^{(j)}_{\ell m_j})}{\sqrt{M_{j+1}(M_{j+1}-m_{j+1})}} & \text{if } k=\ell m_j \text{ and } 1\leqslant j<n,\\ \dfrac{m_1x^{(1)}_{\ell m_1}+m_2x^{(2)}_{\ell m_2}+\cdots+m_nx^{(n)}_{\ell m_n}}{\sqrt{mm_n}} & \text{if } k=\ell m_n \text{ and } j=n,\end{cases} \tag{237}$$

we have $\mathbb{C}[x]=\mathbb{C}[y]$ and

$$\sigma(\beta^{(j)}_k)=\frac{\partial}{\partial y^{(j)}_k}\quad\text{and}\quad\sigma(\beta^{(j)}_{-k})=ky^{(j)}_k\quad\text{if } k>0. \tag{238}$$

Now it is clear that the irreducible with respect to $\mathrm{sl}_m(\mathbb{C})\hat{}$ subspace of $B^{(0)}$ containing the vacuum 1 is the vector space

$$B^{(0)}_{[m_1,m_2,\ldots,m_n]}=\mathbb{C}[y^{(j)}_k|1\leqslant j<n,\quad k\in\mathbb{N},\quad\text{or } j=n,\quad k\in\mathbb{N}\backslash m_n\mathbb{Z}]\otimes\mathbb{C}[Q]. \tag{239}$$

The vertex operator realization of $\mathrm{sl}_m(\mathbb{C})\hat{}$ in the vector space $B^{(0)}_{[m_1,m_2,\ldots m_n]}$ is then obtained by expressing the fields (233) in terms of vertex operators (54), which are expressed via the operators (236), the operators $Q_iQ_j^{-1}$ and $\alpha^{(i)}_0-\alpha^{(j)}_0$ $(1\leqslant i<j\leqslant n)$ (see Ref. 46 for details).

The n-component KP hierarchy of Hirota bilinear equations on $\tau\in B^{(0)}=\mathbb{C}[y]\otimes\mathbb{C}[M]$ when restricted to $\tau\in B^{(0)}_{[m_1,m_2,\ldots,m_n]}$ is called the $[m_1,m_2,\ldots,m_n]$-th *reduced* KP *hierarchy*. It is obtained from the n-component KP hierarchy by making the change of variables (237) and putting zero all terms containing partial derivates by $y^{(n)}_{m_n}$, $y^{(n)}_{2m_n}$, $y^{(n)}_{3m_n},\ldots$.

It is clear from the definitions and results of Sec. IV that the condition on the n-component KP hierarchy to be $[m_1,m_2,\ldots,m_n]$th reduced, i.e.,

$$\sum_{j=1}^{n}\frac{\partial\tau}{\partial x^{(j)}_{km_j}}=0,\quad\text{for all } k\in\mathbb{N},$$

implies the following equivalent conditions (cf. Ref. 9):

$$\left(\sum_{j=1}^{n} L(\alpha)^{km_j} C^{(j)}\right)_- = 0, \tag{240}$$

$$\sum_{j=1}^{n} \frac{\partial W(\alpha)}{\partial x_{km_j}^{(j)}} = W(\alpha) \sum_{j=1}^{n} z^{km_j} E_{jj}, \tag{241}$$

$$\sum_{j=1}^{n} \frac{\partial \tau}{\partial x_{m_j}^{(j)}} = \lambda \tau, \quad \text{for some } \lambda \in \mathbb{C}. \tag{242}$$

It follows from (240) that these conditions automatically imply that all of them hold if all m_j are replaced by any, but the same, multiple of m_j.

The totality of solutions of the $[m_1,m_2,\ldots,m_n]$th reduced KP hierarchy is given by the following.

Proposition 7.1: Let $\mathcal{O}_{[m_1,m_2,\ldots,m_n]}$ *be the orbit of 1 under the (projective) representation of the loop group* $\mathrm{SL}_m(\mathbb{C}[t,t^{-1}])$ *corresponding to the representation of* $\hat{\mathrm{sl}}_m$ *in* $B^{(0)}_{[m_1,m_2,\ldots,m_n]}$. *Then*

$$\mathcal{O}_{[m_1,m_2,\ldots,m_n]} = \sigma(\mathcal{O}) \cap B^{(0)}_{[m_1,m_2,\ldots,m_n]}.$$

In other words, the τ-functions of the $[m_1,m_2,\ldots,m_n]$*th reduced KP hierarchy are precisely the τ-functions of the KP hierarchy in the variables* $y_k^{(j)}$, *which are independent of the variables* $y_{\ell m_n}^{(n)}$, $\ell \in \mathbb{N}$.

Proof is the same as of a similar statement in Ref. 27. □

Remark 7.1: The above representation of $\mathrm{sl}_m(\mathbb{C})\hat{}$ in $B^{(0)}_{[m_1,m_2,\ldots,m_n]}$ is a vertex operator construction of the basic representation corresponding to the element of the Weyl group S_m of $\mathrm{sl}_m(\mathbb{C})$ consisting of n cycles of length m_1, $m_2,\ldots,m_n$ (see Refs. 26 and 46). In particular, for $n=1$ this is the principal realization,[34] and for $m=1$ this is the homogeneous realization. $[m]$th reduced one-component KP was studied in a great detail in Ref. 8 (see also Ref. 27).

Let $n=1$. Then the $[2]$-reduced KP hierarchy becomes the celebrated KdV hierarchy on the differential operator $S \equiv (L^2)_+ = \partial^2 + u$, where $u = 2u_1$:

$$\frac{\partial}{\partial x_{2n+1}} S^{1/2} = [(S^{n+1/2})_+, S^{1/2}], \quad n = 1,2,..., \tag{243}$$

the first equation of the hierarchy being the classical Korteweg–deVries equation

$$4\frac{\partial u}{\partial t} = \frac{\partial^3 u}{\partial x^3} + 6u\frac{\partial u}{\partial x}. \tag{244}$$

Of course, the $[3]$-reduced KP is the Boussinesq hierarchy, and the general $[m]$-reduced KPs are the Gelfand–Dickey hierarchies.

Let $n=2$. The equations of the $[1,1]$-reduced two-component KP are independent of x, hence Eq. (194) becomes independent of x and φ becomes 0 [see (195)]. Thus, Eq. (94) turns into the decoupled nonlinear Schrödinger system (called also the AKNS system):

$$\begin{aligned} i\frac{\partial q}{\partial t} &= -\frac{1}{2}\frac{\partial^2 q}{\partial y^2} - q^2 r, \\ i\frac{\partial r}{\partial t} &= \frac{1}{2}\frac{\partial^2 r}{\partial y^2} + q r^2. \end{aligned} \tag{245}$$

Thus (245) is a part of the [1,1]-reduced two-component KP. For that reason the one-reduced two-component KP is sometimes called the nonlinear Schrödinger hierarchy. Of course, under the constraint (197), we get the nonlinear Schrödinger equation

$$i\frac{\partial q}{\partial t}=-\frac{1}{2}\frac{\partial^2 q}{\partial y^2}-\kappa|q|^2 q. \tag{246}$$

Similarly, under the same reduction the two-dimensional Toda chain (186) turns into the one-dimensional Toda chain

$$\frac{\partial^2 u_n}{\partial x^2}=e^{u_n-u_{n-1}}-e^{u_{n+1}-u_n}(\text{here } x=2y_1^{(1)}). \tag{247}$$

Thus, the one-dimensional Toda chain is a part of the nonlinear Schrödinger hierarchy. It was studied from the representation theoretical point of view in Ref. 45.

Let $n\geqslant 3$. Since the constraint (165) is contained among the constraints of the [1,1,...,1]-reduced n-component KP hierarchy, we see that the $1+1$ n-wave system (168) is a part of the [1,1,...,1]-reduced n-component KP hierarchy. Note also that the [1,1,...,1]-reduction of the n-component KP reduces the $2+1$ n-wave interaction system (171) into the $1+1$ system (168).

Since the nonlinear Schrödinger system (245) is a part of the [1,1]-reduced two-component KP hierarchy, the [1,1,...,1]-reduced n-component KP hierarchy will be called the n-component NLS. Let us give here its formulation since it is especially simple.

Given a $n\times n$ matrix $C(z)=\Sigma_j C_j z^j$, we let

$$C(z)_-=\sum_{j<0} C_j z^j, \quad C(z)_+=\sum_{j\geqslant 0} C_j z^j.$$

Also, given a diagonal complex matrix $a=\mathrm{diag}(a_1,...,a_n)$ we let

$$x_k^a=\sum_{j=1}^n a_k x_k^{(j)}, \quad \frac{\partial}{\partial x_k^a}=\sum_{j=1}^n a_k\frac{\partial}{\partial x_k^{(j)}}.$$

Let $\mathfrak{h}$ denote the set of all traceless diagonal matrices over $\mathbb{C}$.

The n-component NLS hierarchy is the following system on matrix valued functions,

$$P(\alpha)\equiv P(\alpha,x,z)=1+\sum_{j>0} W^{(j)}(\alpha,x)z^{-j}, \quad \alpha\in M,$$

where $x=\{x_k^{(a)}|a\in\mathfrak{h},k=1,2,...\}$:

$$\frac{\partial P(\alpha)}{\partial x_k^{(\alpha)}}=-(P(\alpha)\alpha P(\alpha)^{-1}z^k)_- P(\alpha) \tag{248}$$

with additional matching conditions

$$(P(\alpha)R(\alpha-\beta,z)P(\beta)^{-1})_-=0, \quad \alpha,\beta\in M, \tag{249}$$

where $R(\gamma,z)\equiv R^+(\gamma,z)$ is defined by (101).

This formulation implies the Lax form formulation if we consider $C^{(a)}(x,z)=P(\alpha)aP(\alpha)^{-1}$ for each $a\in\mathfrak{h}$ and fixed α. Consider a family of commuting matrix valued functions of the form

$$C^{(a)} \equiv C^{(a)}(x,z) = a + \sum_{j>0} C_j^{(a)}(x) z^{-j},$$

depending linearly on $a \in \mathfrak{h}$, and let $B_k^{(a)} = (C^{(a)} z^k)_+$. Then the Lax form of the n-component NLS is

$$\frac{\partial C^{(a)}}{\partial x_k^{(b)}} = [B_k^{(b)}, C^{(a)}], \quad a,b \in \mathfrak{h}, \quad k = 1,2,\ldots. \tag{250}$$

The equivalent zero curvature form of the n-component NLS is

$$\frac{\partial B_\ell^{(a)}}{\partial x_k^{(b)}} - \frac{\partial B_k^{(b)}}{\partial x_\ell^{(a)}} = [B_k^{(b)}, B_\ell^{(a)}], \quad a,b \in \mathfrak{h}, \quad k,\ell = 1,2,\ldots. \tag{251}$$

Since for the $[1,1,\ldots,1]$-reduced n-component KP one has $L = \partial$, i.e., all $U^{(j)} = 0$, we see from Remark 5.1 that the n-component NLS in the form (250) contains the following system of equations on functions $A_{ij} \equiv (C_1^{E_{jj}})_{ij}$ $(i \neq j)$:

$$\frac{\partial A_{ij}}{\partial t_j} = -\frac{\partial^2 A_{ij}}{\partial x_j^2} - 2\sum_{k \neq j} A_{ij} A_{jk} A_{kj},$$

$$\frac{\partial A_{ij}}{\partial t_i} = \frac{\partial^2 A_{ij}}{\partial x_i^2} + 2\sum_{k \neq i} A_{ij} A_{ik} A_{ki},$$

$$\frac{\partial A_{ij}}{\partial t_k} = A_{ik}\frac{\partial A_{kj}}{\partial x_k} - A_{kj}\frac{\partial A_{ik}}{\partial x_k}, \quad \text{if } i \neq k, \quad j \neq k, \tag{252}$$

$$\frac{\partial A_{ij}}{\partial x_k} = A_{ik} A_{kj}, \quad \text{if } i \neq k, \quad j \neq k,$$

$$\sum_k \frac{\partial A_{ij}}{\partial x_k} = \sum_k \frac{\partial A_{ij}}{\partial t_k} = 0.$$

This reduces to (215) if $n = 2$.

Remark 7.2: Equations (248), (250), and (251) still make sense if we consider an arbitrary algebraic group G and a reductive commutative subalgebra $\mathfrak{h}$ of its Lie algebra $\mathfrak{g}$. The functions $P(\alpha)$ take values in $G(\mathcal{A}((z)))$ and the functions $C^{(a)}$ take values in $\mathfrak{g}(\mathcal{A}((z)))$. If G is a simply laced simple Lie group, the element $R(\gamma,z) \in G(\mathbb{C}[z,z^{-1}])$ in matching conditions (249) can be generalized as follows. Let $\mathfrak{h}$ be a Cartan subalgebra of $\mathfrak{g}$, normalize the Killing form on $\mathfrak{g}$ by the condition that $(\alpha|\alpha) = 2$ for any root α, and identify $\mathfrak{h}$ with $\mathfrak{h}^*$ using this form. Let $M(\text{resp. } L) \subset \mathfrak{h}^* = \mathfrak{h}$ be the root (resp. weight) lattice and let $\epsilon(\alpha,\beta)$: $M \times M \to \{\pm 1\}$ be a bimultiplicative function such that $\epsilon(\alpha,\alpha) = (-1)^{(1/2)(\alpha|\alpha)}$, $\alpha \in M$. Define $R(\alpha,z) \in H(\mathbb{C}[z,z^{-1}])$ for each α as follows:

$$R(\alpha,z) = c_\alpha z^\alpha, \tag{253}$$

where in any finite-dimensional representation V of G, $c_\alpha \in H$ and $z^\alpha \in H$ for $z \in \mathbb{C}^\times$ are defined by

$$c_\alpha(v) = \epsilon(\beta,\alpha) v, \quad z^\alpha(v) = z^{(\alpha|\beta)} v \quad \text{if } v \in V_\beta. \tag{254}$$

Note that this GNLS hierarchy is closely related to the Bruhat decomposition in the loop group $G(\mathbb{C}((z)))$.

It is clear that we get the τ-function of the $[\ell,\ell,...,\ell]$th reduced n-component KP hierarchy if we let in (217)

$$w_s = \omega_s z_s, \quad s \in S, \tag{255}$$

where ω_s are arbitrary ℓth roots of 1. The totality of τ-functions is (a completion of) the orbit of $1 \in B^{(0)}$ under the group $\mathrm{SL}_m(\mathbb{C}[t,t^{-1}])$.

VIII. $W_{1+\infty}(\mathrm{gl}_n)$ AND THE ORLOV–SCHULMAN–ADLER–SHIOTA–VAN MOERBEKE FORMULA

In recent years Adler, Shiota, and van Moerbeke[2,3] proved a formula, conjectured by Orlov and Schulman,[39] which connects the action of $W_{1+\infty}$ on the tau-function of the one-component KP hierarchy to the so-called ''additional symmetries'' of the wave function. These Orlov–Schulman symmetries were also independently found by Fokas and Santini in Ref. 18. In this section we shall give a generalization of this formula, obtained by one of the authors in Ref. 48, for the n-component KP case.

In the spirit of Refs. 28, 29, and 41, we introduce the bosonic fields

$$J^{(ab,\ell)}(z) = \sum_{k\in\mathbb{Z}} J_k^{(ab,\ell)} z^{-k-\ell-1} = :\frac{\partial^\ell \psi^{+(a)}(z)}{\partial z^\ell} \psi^{-(b)}(z):, \tag{256}$$

and their generating series

$$J^{(ab)}(y,w) =: :\psi^{+(a)}(y)\psi^{-(b)}(w): = \sum_{\ell=0}^{\infty} \frac{(y-w)^\ell}{\ell!} J^{(ab,\ell)}(w) = \sum_{\ell=0}^{\infty} \frac{(y-w)^\ell}{\ell!} \sum_{k\in\mathbb{Z}} J_k^{(ab,\ell)} w^{-k-\ell-1}. \tag{257}$$

It is straightforward, but tedious, to check that these operators satisfy the following commutation relations:

$$[J_k^{(ab,\ell)}, J_p^{(cd,q)}] = \delta_{bc} \sum_{m=0}^{q} \binom{q}{m} [k+l]_m J_{k+\ell+p+q-m}^{(ad,\ell+q-m)} - \delta_{ad} \sum_{m=0}^{\ell} \binom{\ell}{m} [p+q]_m J_{k+\ell+p+q-m}^{(cb,\ell+q-m)}$$
$$+ \delta_{ad}\delta_{bc}\delta_{k,-p}(-)^\ell \ell! q! \binom{k+\ell}{\ell+q+1},$$

where $[x]_m = x(x-1)(x-2)\cdots(x-m+1)$. Hence these operators $J_k^{(ab,\ell)}$ together with 1 satisfy the commutation relations of the Lie algebra $W_{1+\infty}(\mathrm{gl}_n)$, the central extension of the Lie algebra of differential operators on $(\mathbb{C}[t,t^{-1}])^n$, where the central element acts as 1. If one substitutes (54) into (257) and using (63), one obtains the following vertex operator expression for the generating series of the fields $J^{(ab,\ell)}(w)$:

$$J^{(ab)}(y,w) = \frac{1}{(y-w)^{\delta_{ab}}}(X^{(ab)}(y,w) - \delta_{ab}), \quad \text{where}$$

$$X^{(ab)}(y,w) = \epsilon(\delta_a,\delta_b) e^{\delta_a - \delta_b} y^{\delta_a} w^{-\delta_b} \widetilde{X}^{(ab)}(y,w), \quad \text{and} \tag{258}$$

$$\widetilde{X}^{(ab)}(y,w) = \exp\left(\sum_{k=1}^{\infty} (x_k^{(a)} y^k - x_k^{(b)} w^k)\right) \exp\left(-\sum_{k=1}^{\infty} \left(\frac{\partial}{\partial x_k^{(a)}} \frac{y^{-k}}{k} - \frac{\partial}{\partial x_k^{(b)}} \frac{w^{-k}}{k}\right)\right).$$

In order to give the Orlov–Schulman–Adler–Shiota–van Moerbeke (OSASM) formula, we have to introduce some infinite order pseudo-differential operators for $\alpha \in \operatorname{supp} \tau$:

$$\Gamma = \xi I_n + \sum_{a=1}^{n} \sum_{k=1}^{\infty} k x_k^{(a)} \partial^{k-1} E_{aa},$$

$$M(\alpha) = P^+(\alpha) R^+(\alpha) S^+(\alpha) \xi S^+(\alpha)^{-1} R^+(\alpha)^{-1} P^+(\alpha)^{-1} = P^+(\alpha) R^+(\alpha) \Gamma R^+(\alpha)^{-1} P^+(\alpha)^{-1}, \tag{259}$$

$$C^{(ij)}(\alpha) = P^+(\alpha) R^+(\alpha) S^+(\alpha) E_{ab} S^+(\alpha)^{-1} R^+(\alpha)^{-1} P^+(\alpha)^{-1}.$$

Notice that Γ, $M(\alpha)$, $C^{(ij)}(\alpha) \in \hat{\Psi}$. One has the following linear problem for the wave function $V^+(\alpha, \xi, x, z)$:

$$\begin{aligned} L(\alpha) V^+(\alpha, \xi, x, z) &= z V^+(\alpha, \xi, x, z), \\ M(\alpha) V^+(\alpha, \xi, x, z) &= \frac{\partial V^+(\alpha, \xi, x, z)}{\partial z}, \\ C^{(ij)}(\alpha) V^+(\alpha, \xi, x, z) &= V^+(\alpha, \xi, x, z) E_{ij} \\ B_k^{(j)}(\alpha) V^+(\alpha, \xi, x, z) &= \frac{\partial V^+(\alpha, \xi, x, z)}{\partial x_k^{(j)}}. \end{aligned} \tag{260}$$

In the spirit of Sec. VIII. We introduce

$$Y_k^{(ab,\ell)}(\alpha) = M(\alpha)^\ell L(\alpha)^{k+\ell} C^{(ab)}(\alpha), \tag{261}$$

and define

$$\begin{aligned} Y^{(ab)}(\alpha, y, w) &= \sum_{\ell=0}^{\infty} \frac{(y-w)^\ell}{\ell!} \sum_{k \in \mathbb{Z}} w^{-k-\ell-1} Y_k^{(ab,\ell)}(\alpha) \\ &= \sum_{\ell=0}^{\infty} \frac{(y-w)^\ell}{\ell!} \sum_{k \in \mathbb{Z}} w^{-k-\ell-1} M(\alpha)^\ell L(\alpha)^{k+\ell} C^{(ab)}(\alpha). \end{aligned} \tag{262}$$

Let $\delta(w-z) = \Sigma_{n \in \mathbb{Z}} w^{-n} z^{n-1}$. Using (259) we calculate

$$\begin{aligned} Y^{(ab)}(\alpha, y, w) V^+(\alpha, \xi, x, z) &= \sum_{\ell=0}^{\infty} \frac{(y-w)^\ell}{\ell!} \sum_{k \in \mathbb{Z}} w^{-k-\ell-1} M(\alpha)^\ell L(\alpha)^{k+\ell} C^{(ab)}(\alpha) V^+(\alpha, \xi, x, z) \\ &= \sum_{\ell=0}^{\infty} \frac{(y-w)^\ell}{\ell!} \sum_{k \in \mathbb{Z}} w^{-k-\ell-1} z^{k+\ell} \frac{\partial^\ell V^+(\alpha, \xi, x, z)}{\partial z^\ell} E_{ab} \\ &= \delta(w-z) \sum_{\ell=0}^{\infty} \frac{(y-w)^\ell}{\ell!} \frac{\partial^\ell V^+(\alpha, \xi, x, z)}{\partial z^\ell} E_{ab} \\ &= \delta(w-z) V^+(\alpha, \xi, x, y) E_{ab}. \end{aligned} \tag{263}$$

The deduction of the OSASM formula is based on two things; (1) the bilinear identity (64) in a slightly modified form (with all $x_1^{(i)}$'s replaced by $x_1^{(i)} + \xi$), viz.,

$$\mathrm{Res}_{z=0}dz\sum_{j=1}^{n}\psi^{+(j)}(z)e^{z\xi}\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)e^{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}\otimes\psi^{-(j)'}(z)$$
$$\times e^{-z\xi'}\tau_{\beta+\delta_j-\delta_k}(\xi'x')(e^{\beta+\delta_j-\delta_k})'=0, \tag{264}$$

and (2) the commutation relations (32), which we rewrite as follows:

$$\psi^{\lambda(i)}(w)\psi^{\mu(j)}(z)+\psi^{\mu(j)}(z)\psi^{\lambda(i)}(w)=\delta_{\lambda_j-\mu}\delta_{ij}\delta(w-z). \tag{265}$$

Now, let $\psi^{+(a)}(y)e^{y\xi}\psi^{-(b)}(w)e^{w\xi}\otimes 1$ act on the bilinear identity (264). We obtain, using (265),

$$\mathrm{Res}_{z=0}dz\sum_{j=1}^{n}\{\psi^{+(j)}(z)\psi^{+(a)}(y)\psi^{-(b)}(w)e^{(z+y-w)\xi}-\delta_{jb}\psi^{+(a)}(y)e^{y\xi}\delta(w-z)\}$$
$$\times\tau_{\alpha+\delta_i+\delta_b-\delta j-\delta_a}(\xi,x)e^{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}\otimes\psi^{-(j)'}(z)e^{-z\xi'}\tau_{\beta+\delta_j-\delta_k}(\xi'x')(e^{\beta+\delta_j-\delta_k})'=0. \tag{266}$$

Since $\psi^{+(a)}(y)\psi^{-(b)}(w)=J^{(ab)}(y,w)-\delta_{ab}/(y-w)$ and since we can subtract a multiple of (264), we can replace $\psi^{+(a)}(y)\psi^{-(b)}(w)$ by $J^{(ab)}(y,w)$. Now remove the tensor product and the factors $e^{\alpha+\delta_i}$ and $(e^{\beta+\delta_k})'$ and divide by $\tau_\alpha(\xi,x)\tau_\beta(\xi',x')$. Notice that by doing this, the action of $J^{(ab)}(y,w)$ is no longer well-defined. For that reason we introduce $\mathbb{J}^{(ab)}(y,w)$ as follows:

$$(y-w)^{\delta_{ab}}\mathbb{J}^{(ab)}(y,w)\tau_\gamma(\xi,x)=\{\epsilon(\delta_a,\delta_b)\epsilon(\delta_a-\delta_b,\gamma)y^{(\delta_a|\gamma)}w^{-(\delta_b|\gamma)}e^{y\cdot x^{(a)}-w\cdot x^{(b)}}$$
$$\times e^{-\eta^{(a)}(x,y)+\eta^{(b)}(x,w)}-\delta_{ab}\}e^{(y-w)\xi}\tau_\gamma(x,t),$$

where $\eta^{(a)}(x,z)=\Sigma_{k=1}^{\infty}(\partial/\partial x_k^{(a)})(z^{-k}/k)$. So (266) turns into

$$\mathrm{Res}_{z=0}dz\left\{\delta(w,z)V_{ia}^{+}(\alpha,\xi,x,y)V_{kb}^{-}(\beta,\xi',x',z)+\sum_{j=1}^{n}e^{-\eta^{(j)}(x,z)}\right.$$
$$\left.\times\left(\frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)}{\tau_{\alpha+\delta_i-\delta_j}(\xi,x)}\right)V_{ij}^{+}(\alpha,\xi,x,z)V_{kj}^{-}(\beta,\xi',x'z)\right\}=0.$$

Using (263) one obtains

$$\mathrm{Res}_{z=0}dz\left\{E_{ii}\left(Y^{(ab)}(\alpha,y,w)V^{+}(\alpha,\xi,x,z)+\sum_{j=1}^{n}e^{-\eta^{(j)}(x,z)}\right.\right.$$
$$\left.\left.\times\left(\frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)}{\tau_{\alpha+\delta_i-\delta_j}(\xi,x)}\right)\right)V^{+}(\alpha,\xi,x,z)E_{jj}\right\}^{t}V^{-}(\beta,\xi',x',z)=0.$$

Now notice that

$$e^{-\eta^{(j)}(x,z)}\left(\frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)}{\tau_{\alpha+\delta_i-\delta_j}(\xi,x)}\right)V^{+}(\alpha,\xi,x,z)E_{jj}$$
$$=\sum_{k=0}^{\infty}c_{jk}L(\alpha)^{-k}C^{(j)}(\alpha)V^{+}(\alpha,\xi,x,z)$$
$$=\left\{\left(\sum_{k=1}^{\infty}c_{jk}L(\alpha)^{-k}C^{(j)}(\alpha)\right)_{-}+\frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)}{\tau_{\alpha+\delta_i-\delta_j}(\xi,x)}E_{jj}\right\}V^{+}(\alpha,\xi,x,z),$$

hence

$$\mathrm{Res}_{z=0} dz E_{ii} \left(Y^{(ab)}(\alpha,y,w) + \sum_{j=1}^{n} \sum_{k=0}^{\infty} c_{jk} L(\alpha)^{-k} C^{(j)}(\alpha) \right) V^{+}(\alpha,\xi,x,z) \ {}^{t}V^{-}(\beta,\xi',x',z) = 0.$$

Now take $\beta=\alpha$ and use Corollary 4.1 and Remark 4.1; one obtains

$$E_{ii} \left(Y^{(ab)}(\alpha,y,w)_{-} + \sum_{j=1}^{n} \left(\sum_{k=0}^{\infty} c_{jk} L(\alpha)^{-k} C^{(j)}(\alpha) \right)_{-} \right) = 0.$$

Hence

$$\begin{aligned} &-E_{ii} Y^{(ab)}(\alpha,y,w)_{-} V^{+}(\alpha,\xi,x,z) \\ &\quad = E_{ii} \sum_{j=1}^{n} e^{-\eta^{(j)}(x,z)} \left(\frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)}{\tau_{\alpha+\delta_i-\delta_j}(\xi,x)} \right) V^{+}(\alpha,\xi,x,z) E_{jj} \\ &\qquad - \frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_b-\delta_a}(\xi,x)}{\tau_{\alpha}(\xi,x)} E_{ii} V^{+}(\alpha,\xi,x,z). \end{aligned}$$

So we obtain the following generalization of the Orlov–Schulman–Adler–Shiota–van Moerbeke formula.

Theorem 8.1:

$$\begin{aligned} &-(Y^{(ab)}(\alpha,y,w)_{-} V^{+}(\alpha,\xi,x,z))_{ij} \\ &\quad = \left\{ e^{-\eta^{(j)}(x,z)} \left(\frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)}{\tau_{\alpha+\delta_i-\delta_j}(\xi,x)} \right) - \frac{\mathbb{J}^{(ab)}(y,w)\tau_{\alpha+\delta_b-\delta_a}(\xi,x)}{\tau_{\alpha}(\xi,x)} \right\} V^{+}_{ij}(\alpha,\xi,x,z). \end{aligned} \tag{267}$$

Introducing the modes of

$$\mathbb{J}^{(ab)}(y,w) = \sum_{\ell=0}^{\infty} \frac{(y-w)^{\ell}}{\ell!} \sum_{k\in\mathbb{Z}} \mathbb{J}^{(ab,\ell)}_{k} w^{-k-\ell-1}, \tag{268}$$

one has the following.

Corollary 8.1:

$$\begin{aligned} &-((M(\alpha)^{\ell} L(\alpha)^{k+\ell} C^{(ab)}(\alpha))_{-} V^{+}(\alpha,\xi,x,z))_{ij} \\ &\quad = \left\{ e^{-\eta^{(j)}(x,z)} \left(\frac{\mathbb{J}^{(ab,\ell)}_{k}\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(\xi,x)}{\tau_{\alpha+\delta_i-\delta_j}(\xi,x)} \right) - \frac{\mathbb{J}^{(ab,\ell)}_{k}\tau_{\alpha+\delta_b-\delta_a}(\xi,x)}{\tau_{\alpha}(\xi,x)} \right\} V^{+}_{ij}(\alpha,\xi,x,z). \end{aligned}$$

Proof: Compare in (267) the expansions for the vertex operators $Y^{(ab)}(\alpha,y,w)$ as in (262) and $\mathbb{J}^{(ab)}(y,w)$ as in (268). □

Additional symmetries and solutions of the dispersionless KP hierarchy

Luis Martínez Alonso[a] and Manuel Mañas[b]
Departamento de Física Teórica II, Universidad Complutense, E28040 Madrid, Spain

(Received 15 January 2003; accepted 9 April 2003)

The dispersionless KP hierarchy is considered from the point of view of the twistor formalism. A set of explicit additional symmetries is characterized and its action on the solutions of the twistor equations is studied. A method for dealing with the twistor equations by taking advantage of hodograph type equations is proposed. This method is applied for determining the orbits of solutions satisfying reduction constraints of Gelfand–Dikii type under the action of additional symmetries. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1587873]

I. INTRODUCTION

The so-called dispersionless hierarchies[1–9] provide an interesting type of nonlinear integrable model which cannot be studied by the standard schemes of the KP theory and require an entirely new approach. From the point of view of the Lax formalism, dispersionless hierarchies arise as the quasiclassical limits of Lax pair equations performed by replacing operators by phase space functions and commutators by Poisson brackets. In this way, when dealing with dispersionless hierarchies, instead of the associated auxiliary linear system of the standard formalism of integrable systems the underlying equations to be solved are of Hamilton–Jacobi type.

Several methods of solution of dispersionless hierarchies have been formulated. In Refs. 3 and 4 (see also Refs. 11 and 12) Kodama and Gibbons gave a direct method based on the use of reductions in which the dependent variables depend on a finite number of unknown functions. The corresponding reduced hierarchy becomes an infinite set of compatible hydrodynamic systems solvable by hodographic techniques. A $\overline{\partial}$ scheme has been proposed by Konopelchenko *et al.* in Refs. 13–15, which introduces an associated $\overline{\partial}$ equation of Hamilton–Jacobi type. In this article we deal with the twistorial method of Takasaki and Takebe,[9,10] Two important advantages of this method are the following.

(1) It provides a convenient scheme for describing the symmetries.
(2) All local solutions can be determined by means of the twistor method.

The main aim of this article is to present a technique for deriving explicit examples of both additional symmetries and solutions of dispersionless hierarchies within the framework of the twistor formalism. It requires a new formulation of the twistor equations which involves a certain type of generating function for canonical transformations of twistor data as well as the use of hodograph equations. To show our strategy, we concentrate on the dispersionless KP (dKP) hierarchy, which is the prototype of this kind of integrable hierarchy. Its Lax pair formulation involves a phase space with a canonical pair of coordinates (p,x) and an associated Poisson bracket

$$\{F,G\}=\frac{\partial F}{\partial p}\frac{\partial G}{\partial x}-\frac{\partial F}{\partial x}\frac{\partial G}{\partial p}.$$

[a]Electronic mail: luism@fis.ucm.es
[b]Electronic mail: manuel@darboux.fis.ucm.es

It is useful to introduce an enlarged Lax formalism with a pair of canonically conjugate variables $\mathcal{L}=\mathcal{L}(p,\mathbf{t})$ and $\mathcal{M}=\mathcal{M}(p,\mathbf{t})$ (i.e. $\{\mathcal{L},\mathcal{M}\}=1$) depending on p and an infinite set of time parameters

$$\mathbf{t}:=(t_1=x,t_2,\ldots,t_n,\ldots),$$

which are assumed to admit expansions of the form

$$\mathcal{L}=p+\sum_{n\geqslant 1}\frac{u_n(\mathbf{t})}{p^n},\quad \mathcal{M}=\sum_{n\geqslant 2}nt_n\mathcal{L}^{n-1}+x+\sum_{n\geqslant 1}\frac{v_n(\mathbf{t})}{\mathcal{L}^{n+1}},\tag{1}$$

as $p\to\infty$ and $\mathcal{L}\to\infty$, respectively. The Lax equations of the dKP hierarchy are

$$\frac{\partial\mathcal{L}}{\partial t_n}=\{\mathcal{B}_n,\mathcal{L}\},\quad \frac{\partial\mathcal{M}}{\partial t_n}=\{\mathcal{B}_n,\mathcal{M}\},\quad n\geqslant 2,\tag{2}$$

where

$$\mathcal{B}_n:=(\mathcal{L}^n)_{\geqslant 0}.$$

Here $(\mathcal{F})_{\geqslant 0}$ denotes the projection of a Laurent series $\mathcal{F}$ in the variable p on the subspace generated by the non-negative powers of p [we will also use the notation $(\mathcal{F})_{\leqslant -1}:=\mathcal{F}-(\mathcal{F})_{\geqslant 0}$]. The system of compatibility equations

$$\frac{\partial\mathcal{B}_m}{\partial t_n}-\frac{\partial\mathcal{B}_n}{\partial t_m}+\{\mathcal{B}_m,\mathcal{B}_n\}=0,\quad m\neq n,\tag{3}$$

yields an infinite set of nonlinear equations for the coefficients u_n of the expansion (1) of $\mathcal{L}$. In particular for $(n,m)=(2,3)$ one gets the dKP equation (Zabolotskaya–Khokhlov equation)

$$(u_t-3uu_x)_x=\tfrac{3}{4}u_{yy},\quad u:=u_1,t:=t_3,y:=t_2.\tag{4}$$

This is an interesting nonlinear model with applications, in the study of quasi-plane sound beams,[17] quasi-transonic flows past thin wings[18] or Einstein-Weyl spaces.[19]

In the next section we first describe in brief the twistor approach to the solutions and symmetries of the dKP hierarchy. Then we present a class of additional symmetries depending on arbitrary functions of one variable, the action of which can be explicitly determined. As a particular case they include the symmetries of the dKP equation found by Dunajski, Mason and Tod in Ref. 19. The first part of Sec. III is devoted to a new formulation of twistor equations which is appropriate for dealing with the transformation laws of solutions under the action of symmetries. In the second part of Sec. III we show how solutions of the dKP hierarchy satisfying reduction constraints of Gelfand–Dikii type transform under the class of additional symmetries introduced in Sec. II. Finally, some explicit examples are worked out.

II. SYMMETRIES IN THE TWISTOR FORMALISM

A. Twistorial structure of the dKP hierarchy

The twistor formalism of the dKP hierarchy is based on the degenerate symplectic form[9]

$$\omega:=\mathrm{d}p\wedge\mathrm{d}x+\sum_{n\geqslant 2}\mathrm{d}\mathcal{B}_n\wedge\mathrm{d}t_n,\tag{5}$$

which plays the role of the Gindikin bundle[16] of curved twistor theory. The form ω encodes both the Lax equations and their compatibility conditions into the simple system

$$\omega = \mathrm{d}\mathcal{L} \wedge \mathrm{d}\mathcal{M}, \qquad \omega \wedge \omega = 0. \tag{6}$$

From the first equation we have that

$$\mathrm{d}\left(\mathcal{M}\mathrm{d}\mathcal{L} + p\,\mathrm{d}x + \sum_{n\geqslant 2} \mathcal{B}_n \mathrm{d}t_n \right) = 0,$$

so that there exists a generating function $S = S(\mathcal{L}, \mathbf{t})$ for the canonical transformation $(p,x) \mapsto (\mathcal{L}, \mathcal{M})$ satisfying

$$\mathrm{d}S = \mathcal{M}\mathrm{d}\mathcal{L} + p\,\mathrm{d}x + \sum_{n\geqslant 2} \mathcal{B}_n \mathrm{d}t_n,$$

or equivalently

$$\mathcal{M} = \frac{\partial S}{\partial \mathcal{L}}, \quad p = \frac{\partial S}{\partial x}, \quad \mathcal{B}_n = \frac{\partial S}{\partial t_n}, \quad n \geqslant 2. \tag{7}$$

Notice that from (1) and the first equation of (7) it follows that S can be defined as

$$S(\mathcal{L}, \mathbf{t}) = \sum_{n\geqslant 1} t_n \mathcal{L}^n - \sum_{n\geqslant 1} \frac{v_n(\mathbf{t})}{n} \mathcal{L}^{-n}.$$

The twistor scheme for solving the dKP hierarchy is based on the following result.[9]

Theorem 1: *Let (P(p,x),X(p,x)) be a pair of canonically conjugate variables (i.e. $\{P,X\}=1$). Then we have the following:*

(1) Given two functions $(\mathcal{L}(p,\mathbf{t}), \mathcal{M}(p,\mathbf{t}))$ of the form (1) such that the composite functions $(P(\mathcal{L},\mathcal{B}), X(\mathcal{L},\mathcal{B}))$ have Laurent series expansions in p satisfying the twistor equations

$$(P(\mathcal{L},\mathcal{M}))_{\leqslant -1} = 0, \quad (X(\mathcal{L},\mathcal{M}))_{\leqslant -1} = 0, \tag{8}$$

then $(\mathcal{L},\mathcal{M})$ gives a solution of the dKP hierarchy (2). The pair

$$(P(p,x), X(p,x))$$

is called the twistor data *of the solution $(\mathcal{L},\mathcal{M})$.*

(2) Each solution of the dKP hierarchy admits a set $(P(p,x), X(p,x))$ of twistor data.

In general, we cannot assume the existence of appropriate solutions $(\mathcal{L},\mathcal{M})$ of (8). For example, the canonical variables

$$P := p^2 x, \quad X := \frac{1}{p}, \tag{9}$$

determine the twistor equations

$$(\mathcal{L}^2 \mathcal{M})_{\leqslant -1} = 0, \quad \left(\frac{1}{\mathcal{L}} \right)_{\leqslant -1} = 0,$$

which obviously have no solutions satisfying (1).

B. Symmetry transformations

One of the main features of the twistor equations is that the symmetry properties of the dKP hierarchy can be formulated in a convenient way.[9] Indeed, the natural group acting on the set of twistor data $(P(p,x),X(p,x))$ is the group of canonical transformations generated by one-parameter groups of the form

$$\begin{aligned} &\exp(s\{F,\cdot\}):(P,X)\mapsto(P(s),X(s)), \quad F=F(p,x),\\ &P(s):=P(\exp(s\{F,\cdot\})p,\exp(s\{F,\cdot\})x),\\ &X(s):=X(\exp(s\{F,\cdot\})p,\exp(s\{F,\cdot\})x), \end{aligned} \tag{10}$$

where

$$\exp(s\{F,\cdot\})G:=G+s\{F,G\}+\frac{s^2}{2}\{F,\{F,G\}\}+\cdots.$$

The following theorem can be proved.[9]

Theorem 2: *A one-parameter group of canonical transformations (10) induces an action* $(\mathcal{L},\mathcal{M})\mapsto(\mathcal{L}(s),\mathcal{M}(s))$ *on the set of solutions of the dKP hierarchy determined by the flow*

$$\frac{\partial\mathcal{L}}{\partial s}=\{\mathcal{L},F(\mathcal{L},\mathcal{M})_{\leqslant -1}\}, \quad \frac{\partial\mathcal{M}}{\partial s}=\{\mathcal{M},F(\mathcal{L},\mathcal{M})_{\leqslant -1}\}. \tag{11}$$

Let us consider symmetries of the dKP hierarchy generated by double series of the form

$$F(\mathcal{L},\mathcal{M})=\sum_{i=-\infty}^{\infty}\sum_{j=-\infty}^{\infty}c_{ij}\mathcal{L}^i\mathcal{M}^j. \tag{12}$$

We will concentrate on the $(r+1)$th *truncated dKP hierarchies* defined as the sets of the first $r+1$ flows of the dKP hierarchy $(r\geqslant 2)$. Thus in order to analyze their symmetries we may set $t_n=0,\forall n\geqslant r+1$, and so we may write

$$\mathcal{M}=(r+1)t_{r+1}\mathcal{L}^r+rt_r\mathcal{L}^{r-1}+\cdots+x+\mathcal{O}\left(\frac{1}{\mathcal{L}^2}\right). \tag{13}$$

By substituting this expansion in (12), a series expansion of F in powers of $\mathcal{L}$ is obtained. Let us now investigate those symmetries of the $(r+1)$th truncated dKP hierarchy which do not involve the action of higher dKP flows. To this end, we have to avoid terms of the form $\{(\mathcal{L}^n)_{\geqslant 0},\mathcal{L}\}$ with $n>(r+1)$ on the right-hand side of the first equation in (11). Hence we impose $c_{ij}=0$ for $(i+jr)>(r+1)$, so that F can be expressed in the form

$$F(\mathcal{L},\mathcal{M})=\sum_{n\leqslant r+1}\alpha_n\left(\frac{\mathcal{M}}{(r+1)\mathcal{L}^r}\right)\mathcal{L}^n, \tag{14}$$

with $\alpha_n(t)$ being arbitrary smooth functions. Furthermore, Eq. (11) for $\mathcal{L}$ can be written as

$$\frac{\partial\mathcal{L}}{\partial s}=\frac{\partial F}{\partial\mathcal{M}}+\{F(\mathcal{L},\mathcal{M})_{\geqslant 0},\mathcal{L}\}, \tag{15}$$

and it is easy to see that only those terms in (14) with $n\geqslant 1$ contribute to $\partial u/\partial s$.

Therefore, we conclude that the symmetries of the $(r+1)$th truncated dKP hierarchy which do not involve higher dKP flows and define a nontrivial action on the coefficient u are of the form

$$F(\mathcal{L},\mathcal{M})=\sum_{n=1}^{r+1}\alpha_n\left(\frac{\mathcal{M}}{(r+1)\mathcal{L}^r}\right)\mathcal{L}^n. \tag{16}$$

This means that, under these conditions, there are essentially $r+1$ types of symmetry generators of the $(r+1)$th truncated dKP hierarchy given by

$$F_i(\mathcal{L},\mathcal{M}):=\alpha\left(\frac{\mathcal{M}}{(r+1)\mathcal{L}^r}\right)\mathcal{L}^i,\quad i=1,\ldots,r+1, \tag{17}$$

with $\alpha=\alpha(t)$ being an arbitrary function.

The action of the one-parameter groups generated by F_i on the coefficient u can be explicitly found. Indeed, by identifying the coefficients of $1/p$ in both members of (15) one gets a first-order *linear* partial differential equation for

$$u(s,\mathbf{t}):=\exp(s\{F_i,\cdot\})u(\mathbf{t}),$$

the integration of which provides the symmetry transformation

$$u=u(\mathbf{t})\mapsto\tilde{u}=u(s,\mathbf{t}).$$

Let us illustrate these facts by considering the case $r=2$. We observe that (13) implies that near points t in the region of analyticity of α

$$\alpha\left(\frac{\mathcal{M}}{3\mathcal{L}^2}\right)=\alpha(t)+\frac{2}{3}y\alpha'(t)\frac{1}{\mathcal{L}}+\left(\frac{1}{3}x\alpha'(t)+\frac{2}{9}y^2\alpha''(t)\right)\frac{1}{\mathcal{L}^2}+\mathcal{O}\left(\frac{1}{\mathcal{L}^3}\right). \tag{18}$$

One finds the following results for the corresponding three generators (17):

(1) F_1

From (15) we have

$$\frac{\partial\mathcal{L}}{\partial s}=\alpha'\left(\frac{\mathcal{M}}{3\mathcal{L}^2}\right)\frac{1}{3\mathcal{L}}+\alpha(t)\frac{\partial\mathcal{L}}{\partial x},$$

so that

$$\frac{\partial u}{\partial s}=\alpha(t)\frac{\partial u}{\partial x}+\frac{1}{3}\alpha'(t). \tag{19}$$

The solution of this equation is

$$u=U(x+s\alpha(t),y,t)+\tfrac{1}{3}s\alpha'(t),$$

where U is an arbitrary function. It leads to the symmetry

$$\tilde{u}=u(x+s\alpha(t),y,t)+\tfrac{1}{3}s\alpha'(t). \tag{20}$$

(2) F_2

In this case (15) becomes

$$\frac{\partial\mathcal{L}}{\partial s}=\frac{1}{3}\alpha'\left(\frac{\mathcal{M}}{3\mathcal{L}^2}\right)+\frac{2}{3}y\alpha'(t)\frac{\partial\mathcal{L}}{\partial x}+\alpha(t)\frac{\partial\mathcal{L}}{\partial y},$$

and the equation for u is

$$\frac{\partial u}{\partial s}=\frac{2}{3}y\alpha'(t)\frac{\partial u}{\partial x}+\alpha(t)\frac{\partial u}{\partial y}+\frac{2}{9}y\alpha''(t), \tag{21}$$

which has the solution

$$u=U(x+\tfrac{2}{3}sy\alpha'(t)+\tfrac{1}{3}s^2\alpha(t)\alpha'(t),y+s\alpha(t),t)+\tfrac{2}{9}sy\alpha''(t)+\tfrac{1}{9}s^2\alpha(t)\alpha''(t),$$

where U is an arbitrary function. The corresponding symmetry transformation of the dKP equation is

$$\tilde{u}=u(x+\tfrac{2}{3}sy\alpha'(t)+\tfrac{1}{3}s^2\alpha(t)\alpha'(t),y+s\alpha(t),t)+\tfrac{2}{9}sy\alpha''(t)+\tfrac{1}{9}s^2\alpha(t)\alpha''(t). \tag{22}$$

(3) F_3

Now Eq. (15) takes the form

$$\frac{\partial\mathcal{L}}{\partial s}=\frac{1}{3}\alpha'\left(\frac{\mathcal{M}}{3\mathcal{L}^2}\right)\mathcal{L}+\left(\frac{1}{3}x\alpha'(t)+\frac{2}{9}y^2\alpha''(t)\right)\frac{\partial\mathcal{L}}{\partial x}+\frac{2}{3}y\alpha'(t)\frac{\partial\mathcal{L}}{\partial y}+\alpha(t)\frac{\partial\mathcal{L}}{\partial t},$$

which implies

$$\frac{\partial u}{\partial s}=\left(\frac{1}{3}x\alpha'(t)+\frac{2}{9}y^2\alpha''(t)\right)\frac{\partial u}{\partial x}+\frac{2}{3}y\alpha'(t)\frac{\partial u}{\partial y}+\alpha(t)\frac{\partial u}{\partial t}+\frac{1}{3}\alpha'(t)u+\frac{1}{9}x\alpha''(t)+\frac{2}{27}y^2\alpha'''(t). \tag{23}$$

The solution of this equation is

$$u=(c'(t))^{2/3}U\left(x(c'(t))^{1/3}+\frac{2}{9}y^2\frac{c''(t)}{(c'(t))^{2/3}},y(c'(t))^{2/3},s+c(t)\right)$$
$$+\frac{1}{9}x\frac{c''(t)}{c'(t)}+\frac{2}{27}y^2\left(\frac{c'''(t)}{c'(t)}-\frac{4}{3}\left(\frac{c''(t)}{c'(t)}\right)^2\right),$$

where U is an arbitrary function and $c(t)$ is such that $c'(t)=1/\alpha(t)$. Hence, by defining $T:=T(s,t)$ through the implicit relation

$$c(T)=s+c(t),$$

and by taking into account that

$$T':=\frac{\partial T}{\partial t}=\frac{c'(t)}{c'(T)},$$

one finds that the symmetry transformation determined by (23) is

$$\tilde{u}=(T')^{2/3}u\left(x(T')^{1/3}+\frac{2}{9}y^2\frac{T''}{(T')^{2/3}},y(T')^{2/3},T\right)+\frac{1}{9}x\frac{T''}{T'}+\frac{2}{27}y^2\left(\frac{T'''}{T'}-\frac{4}{3}\left(\frac{T''}{T'}\right)^2\right). \tag{24}$$

The three symmetries (20), (22), and (24) coincide with the symmetries of the dKP equation found by Dunajski, Mason, and Tod.[19] by analyzing equivalence transformations of Einstein–Weyl spaces.

1. Transformation law of twistor data

According to (10) the dKP symmetry generated by (17) corresponds to a canonical transformation law of the twistor data determined by the Hamiltonian system

$$\frac{\mathrm{d}p}{\mathrm{d}s}=\{\alpha(\rho)p^i,p\},\quad \frac{\mathrm{d}x}{\mathrm{d}s}=\{\alpha(\rho)p^i,x\},\tag{25}$$

where we are denoting

$$\rho:=\frac{x}{(r+1)p^r}.$$

In terms of (p,ρ) this system becomes

$$\frac{\mathrm{d}p}{\mathrm{d}s}=-\frac{\alpha'(\rho)}{r+1}p^{i-r},\quad \frac{\mathrm{d}\rho}{\mathrm{d}s}=i\frac{\alpha(\rho)}{r+1}p^{i-r-1},\tag{26}$$

and by taking into account that the Hamiltonian function

$$h:=\alpha(\rho)p^i$$

is a constant of the motion it follows that the solution of (25) can be written as

$$p(s)=\frac{p}{(j_\rho)^{1/(r+1)}},\quad x(s)=(r+1)j\,p(s)^r.\tag{27}$$

Here $j=j(s,\rho,h)$ is the evolution law of the variable ρ. That is to say, it is the solution of the initial value problem

$$\frac{\partial j}{\partial s}=\beta(\rho,h),\quad j(0,\rho,h)=\rho,\tag{28}$$

where

$$\beta(\rho,h):=\frac{i}{r+1}\left(\frac{\alpha(\rho)}{h}\right)^{(r+1)/i}h.$$

The expressions (27) define the action of the additional symmetries (17) on the twistor data. It is important to observe that the solution of (28) satisfies

$$s=\int_\rho^{j(s,\rho,h)}\frac{\mathrm{d}\rho}{\beta(\rho,h)},$$

and, as a consequence, one deduces that the first-order derivatives of j with respect to ρ and h are

$$\begin{aligned} j_\rho&=\left(\frac{\alpha(j)}{\alpha(\rho)}\right)^{(r+1)/i},\\ j_h&=s\left(\frac{i}{r+1}-1\right)\left(\frac{\alpha(j)}{h}\right)^{(r+1)/i}=\left(\frac{i}{r+1}-1\right)\frac{s}{p(s)^{r+1}}. \end{aligned}\tag{29}$$

As we will see below, these relations will be useful for determining the action of the additional symmetries on the solutions of the twistor equations.

III. SOLUTIONS OF THE dKP HIERARCHY

A. Generating functions and hodograph equations

We are going to present a scheme for solving twistor equations which is particularly suitable to investigate the action of the additional symmetries introduced in the above section. An ingre-

dient of our analysis is the use of a type of generating functions for canonical transformations of twistor data,[20] which allows us to introduce hodograph type equations to formulate part of the constraints imposed by the twistor equations.

Let $(P(p,x),X(p,x))$ be a pair of canonically conjugate variables. Then for each positive integer r we have

$$\mathrm{d}P\wedge\mathrm{d}X=\mathrm{d}p\wedge\mathrm{d}x=\mathrm{d}(p^{r+1})\wedge\mathrm{d}\rho,\quad \rho:=\frac{x}{(r+1)p^r}.$$

Hence there exists an associated generating function $J_r:=J_r(P,\rho)$ of the canonical transformation $(p,x)\mapsto(P,X)$ such that

$$\mathrm{d}J_r=p^{r+1}\mathrm{d}\rho+X\mathrm{d}P,$$

or equivalently

$$p^{r+1}=\frac{\partial J_r(P,\rho)}{\partial\rho},\quad X=\frac{\partial J_r(P,\rho)}{\partial P}. \tag{30}$$

In this way by denoting

$$\mathcal{M}_r:=\frac{\mathcal{M}}{(r+1)\mathcal{L}^r},$$

we deduce

$$\frac{\partial}{\partial p}J_r(P(\mathcal{L},\mathcal{M}),\mathcal{M}_r)=\frac{\partial J_r}{\partial P}(P(\mathcal{L},\mathcal{M}),\mathcal{M}_r)\frac{\partial P(\mathcal{L},\mathcal{M})}{\partial p}+\frac{\partial J_r}{\partial\rho}(P(\mathcal{L},\mathcal{M}),\mathcal{M}_r)\frac{\partial\mathcal{M}_r}{\partial p}$$

$$=X(\mathcal{L},\mathcal{M})\frac{\partial P(\mathcal{L},\mathcal{M})}{\partial p}+\mathcal{L}^{r+1}\frac{\partial\mathcal{M}_r}{\partial p},$$

and by taking into account that

$$\mathcal{L}^{r+1}\frac{\partial\mathcal{M}_r}{\partial p}=\frac{1}{r+1}\frac{\partial(\mathcal{L}\mathcal{M})}{\partial p}-\frac{\partial S}{\partial p},$$

where S is the function introduced in (7), we deduce that

$$X(\mathcal{L},\mathcal{M})=\frac{(\partial/\partial p)\,(S+J_r(P(\mathcal{L},\mathcal{M}),\mathcal{M}_r)-[1/(r+1)]\mathcal{L}\mathcal{M})}{(\partial/\partial p)\,P(\mathcal{L},\mathcal{M})}. \tag{31}$$

This formula enables us to state the following:

Theorem 3: *In terms of the function*

$$\mathcal{S}_r:=S+J_r(P(\mathcal{L},\mathcal{M}),\mathcal{M}_r)-\frac{1}{r+1}\mathcal{L}\mathcal{M}, \tag{32}$$

the second twistor equation $(X(\mathcal{L},\mathcal{M}))_{\leqslant -1}=0$ *is equivalent to the following two conditions*

(1) The expansion of $\mathcal{S}_r$ *in powers of* p *satisfies*

$$(\mathcal{S}_r)_{\leqslant -1}=0. \tag{33}$$

(2) At each zero p_i *of* $\partial P(\mathcal{L},\mathcal{M})/\partial p$ *it is verified that*

$$\frac{\partial \mathcal{S}_r}{\partial p}(p_i,\mathbf{t})=0. \tag{34}$$

Henceforth we will refer to (34) as the *hodograph equations*.

A natural problem is to determine generating functions $J_r(P,\rho)$ leading to solvable twistor equations. In this sense, an important class arises when $P=P(p,x)$ is independent of x and has a finite-order expansion as $p\to\infty$:

$$P(p)=\sum_{n=-\infty}^{N} a_n p^n.$$

The corresponding generating function J_0 is of the form

$$J_0(P,x)=f(P)+g(P)x,$$

where $g(P)$ is the inverse function of $P=P(p)$. As a consequence

$$J_0(P(\mathcal{L},\mathcal{M}),\mathcal{M})=f(P(\mathcal{L}))+\mathcal{L}\mathcal{M},$$

$$\mathcal{S}_0=S+f(P(\mathcal{L})).$$

It can be shown that, provided $f(P(p))$ admits a Laurent expansion as $p\to\infty$, the twistor equations determined by J_0 have a solution. Moreover, it turns out that solving the hodograph equations for $\mathcal{S}_0$ is enough for computing $\mathcal{L}$. Let us illustrate these facts with the following important example

Gelfand–Dikii reductions: If we set

$$J_0(P,x)=f(P^{1/m})+P^{1/m}x, \quad f(P^{1/m}):=\sum_{n=-\infty}^{\infty} c_n P^{n/m}, \tag{35}$$

for a given integer $m>1$, the associated twistor data are

$$P=p^m, \quad X=\frac{1}{mp^{m-1}}(f'(p)+x). \tag{36}$$

Then, the first twistor equation is

$$\mathcal{L}^m=(\mathcal{L})_{\geqslant 0},$$

so that

$$\mathcal{L}^m=p^m+q_{m-2}(\mathbf{u})p^{m-2}+\cdots+q_1(\mathbf{u})p+q_0(\mathbf{u}), \tag{37}$$

where the functions $q_i(\mathbf{u})$ depend on the $(m-1)$ first coefficients $\mathbf{u}:=(u_1,\ldots,u_{m-1})$ of the expansion (1) of $\mathcal{L}$. This constraint defines the mth Gelfand–Dikii reduction of the dKP hierarchy.

For example the first few reductions are

$$m=2, \quad \mathcal{L}^2=p^2+2u_1,$$

$$m=3, \quad \mathcal{L}^3=p^3+3u_1p+3u_2,$$

$$m=4, \quad \mathcal{L}^4=p^4+4u_1p^2+4u_2p+6u_1^2+4u_3.$$

To determine $\mathcal{L}$ we must find the $(m-1)$ unknowns u_i as functions of $\mathbf{t}$ through the second twistor equation. Thus, according to Theorem 2, we impose

$$\mathcal{S}_0 = S + f(\mathcal{L}) = (S + f(\mathcal{L}))_{\geqslant 0} = \sum_{n\geqslant 1} (t_n + c_n)(\mathcal{L}^n)_{n\geqslant 0} + c_0 .$$

Hence, by using (37) we can express $\mathcal{S}_0$ as a function of $(p,\mathbf{t},\mathbf{u})$. If we now impose the hodograph equations (34), we get $(m-1)$ implicit equations

$$\left(\sum_{n\geqslant 1} (t_n + c_n) \frac{\partial}{\partial p} (\mathcal{L}^n)_{n\geqslant 0} \right) \Bigg|_{p=p_i(\mathbf{u})} = 0, \quad i = 1,\ldots,m-1, \tag{38}$$

which determine the functions $u_i(\mathbf{t})$ and, consequently, $\mathcal{L}$. Furthermore, by eliminating p in (37) we can express p as a function $p = p(\mathcal{L},\mathbf{t})$, which under substitution into

$$S = \sum_{n\geqslant 1} t_n \mathcal{L}^n - \left(\sum_{n\geqslant 1} t_n \mathcal{L}^n - f(\mathcal{L}) \right)_{\leqslant -1},$$

leads to $\mathcal{M} = \partial S/\partial \mathcal{L}$. Thus, it is easy to see that the functions $\mathcal{L}$ and $\mathcal{M}$ are solutions of the twistor equations which satisfy (1) and, therefore, they solve the dKP hierarchy Henceforth these solutions will be called *Gelfand–Dikii solutions* of the dKP hierarchy.

For instance, if $m = 2$ (dKdV reduction),

$$\mathcal{L}^2 = p^2 + 2u, \quad u := u_1,$$

and we set $t_n = 0$, $\forall n > 3$, one gets the hodograph relation

$$3ut + x = F(u), \tag{39}$$

which solves the dKdV equation $u_t = 3uu_x$. Here

$$F(u) := - = \frac{\partial}{\partial p} \sum_{n\geqslant 1} c_n \cdot (\mathcal{L}^n)_{n\geqslant 0}\big|_{p=0}$$

can be assumed to be an arbitrary smooth function of u. Some elementary solutions provided by (39) are

$$F(u) = cu, \quad u = -\frac{x}{3t-c},$$

$$F(u) = cu^2, \ \ u = \frac{1}{2c}(3t + \sqrt{9t^2 + 4cx}), \tag{40}$$

$$F(u) = cu^3, \ \ u = \frac{f}{2c} + \frac{2t}{f}, \ \ f := \left(4x + 4c^2 \sqrt{x^2 - \frac{4t^3}{c}} \right)^{1/3}.$$

B. The action of additional symmetries on Gelfand–Dikii solutions

Our aim now is to characterize solutions of the dKP hierarchy by applying the symmetry transformations (17) to Gelfand–Dikii solutions. Obviously we may start from solutions of the hodograph equations (38) and then perform the corresponding symmetry transformation. However, in order to do it we need to know how the coefficients u_i of the expansion (1) of $\mathcal{L}$ transform under the symmetries (17), which requires us to solve a system of first-order linear partial differential equations. We are trying instead an alternative way consisting in determining the generating

functions $J_r(P,\rho)$ for the transformed twistor data and then solving the corresponding twistor equations according to the scheme of Theorem 3. In this alternative procedure the problem reduces to solving a system of implicit algebraic equations.

The dKP symmetry generated by (17) acts on twistor data according to the canonical transformation (27). In particular, the twistor data (36) for the Gelfand–Dikii reductions transform as

$$P(s)=\left(\frac{p}{(j_\rho)^{1/(r+1)}}\right)^m,$$
$$X(s)=\frac{P^{(m-1)/m}}{m}(f'(P^{1/m})+(r+1)j\,P^{r/m}). \tag{41}$$

Hence, by taking into account that j is a function of (s,ρ,h), it follows that

$$p^{r+1}=j_\rho P^{(r+1)/m}=\frac{\partial}{\partial\rho}(jP^{(r+1)/m})-\hat{h}_\rho j_h P^{(r+1)/m},$$

$$X=\frac{\partial}{\partial P}(f(P)^{1/m}+jP^{(r+1)/m})-\hat{h}_P j_h P^{(r+1)/m},$$

where

$$\hat{h}=\hat{h}(P,\rho):=h(p(P,\rho),\rho)=\alpha(\rho)p(P,\rho)^i.$$

By using now (29) we deduce

$$p^{r+1}=\frac{\partial J_r^{(i)}(P,\rho)}{\partial\rho},\quad X=\frac{\partial J_r^{(i)}(P,\rho)}{\partial P}, \tag{42}$$

where

$$J_r^{(i)}(s,P,\rho):=f(P^{1/m})+j(s,\rho,\hat{h})P^{(r+1)/m}+s\left(1-\frac{i}{r+1}\right)\hat{h}(P,\rho). \tag{43}$$

Wide families of solutions of the $(r+1)$th truncated dKP can be found by solving the twistor equations associated with the generating functions (43). The calculations are simple but long and require computer aid. To illustrate the strategy for computing these solutions let us consider the family of generating functions $J_r^{(i)}$ with

$$i=r+1\geqslant m. \tag{44}$$

The choice $i=r+1$ means that we are dealing with the orbits of Gelfand–Dikii solutions under the action of the symmetry generator

$$F_{r+1}(\mathcal{L},\mathcal{M}):=\alpha\left(\frac{\mathcal{M}}{(r+1)\mathcal{L}^r}\right)\mathcal{L}^{r+1}. \tag{45}$$

Thus, according to (29) the function j in (43) is determined from α through the solution of the initial value problem

$$\frac{\partial j}{\partial s}=\alpha(\rho),\quad j(0,\rho)=\rho. \tag{46}$$

Hence j is independent of h and by setting s to be a constant, we may take j as a function of ρ only. Therefore, the generating functions $J_r^{(i)}$ that we are considering are

$$J_r(P,\rho)=f\left(P^{1/m}\right)+j(\rho)\,P^{(r+1)/m}. \tag{47}$$

Notice that

$$P=\frac{p^m}{(j_\rho)^{m/(r+1)}}, \tag{48}$$

so that the first twistor equation reads

$$\mathbb{L}^m=(\mathbb{L}^m)_{\geqslant 0}, \tag{49}$$

where

$$\mathbb{L}:=\frac{\mathcal{L}}{j_\rho(\mathcal{M}_r)}, \quad \mathcal{M}_r:=\frac{\mathcal{M}}{(r+1)\mathcal{L}^r}. \tag{50}$$

From (1) one deduces at once that the integer powers of $\mathcal{L}$ have expansions of the form

$$\begin{aligned}\mathcal{L}^N&=p^N+\cdots+a_n(u_1,\ldots,u_{N-n-1})p^n+\cdots+b_n(u_1,\ldots,u_{N+n-1})\frac{1}{p^n}+\cdots,\\ \frac{1}{\mathcal{L}^N}&=\frac{1}{p^N}+\cdots+c_n(u_1,\ldots,u_{n-N-1})\frac{1}{p^n}+\cdots.\end{aligned} \tag{51}$$

Furthermore, (1) implies that for any smooth function $g=g(t)$ the composite function $g(\mathcal{M}_r)$ can be expanded in the form

$$\begin{aligned}g(\mathcal{M}_r)&=g\left(t_{r+1}+\frac{rt_r}{r+1}\frac{1}{\mathcal{L}}+\cdots+\frac{v_n(\mathbf{t})}{r+1}\frac{1}{\mathcal{L}^n}+\cdots\right)\\ &=g(t_{r+1})+\frac{rt_r}{r+1}g'(t_{r+1})\frac{1}{p}+\cdots+d_n(\mathbf{t},u_1,\ldots,u_{n-2},v_1,\ldots,v_{n-r-1})\frac{1}{p^n}+\cdots.\end{aligned} \tag{52}$$

Thus, from (51) and (52) and by taking into account (44), we deduce that $\mathbb{L}$ is of the form

$$\mathbb{L}=(q_m(\mathbf{t},\mathbf{u})p^m+\cdots+q_1(\mathbf{t},\mathbf{u})p+q_0(\mathbf{t},\mathbf{u}))^{1/m}, \tag{53}$$

where $\mathbf{u}:=(u_1,\ldots,u_{m-1})$.

Two different cases arise.

(1) $\mathbf{r}=\mathbf{m}-1,\mathbf{m}$. This is the simplest situation since from (51)–(53) it follows at once that

$$\mathcal{S}_r=\left(\sum_{s=1}^{r}\frac{r-s+1}{r+1}t_s\mathcal{L}^s+\gamma\mathbb{L}^{m+n}+j(\mathcal{M}_r)\mathbb{L}^{r+1}\right)_{\geqslant 0}$$

is a function depending of $(p,\mathbf{t})$ and $\mathbf{u}=(u_1,\ldots,u_{m-1})$. Therefore, the $(m-1)$ hodograph equations

$$\frac{\partial\mathcal{S}_r}{\partial p}(p_i,\mathbf{t})=0, \tag{54}$$

where $p_i=p_i(\mathbf{t},\mathbf{u})$ are the zeros of $\partial\mathbb{L}^m/\partial p$, are enough for determining $\mathbf{u}$.

(2) $\mathbf{r}\geqslant\mathbf{m}+\mathbf{1}$. The function $\mathcal{S}_r=(\mathcal{S}_r)_{\geqslant 0}$ depends on $(p,\mathbf{t})$ and $\tilde{\mathbf{u}}=(u_1,\ldots,u_{r-1})$, so that in addition to the $(m-1)$ hodograph equations (54) a set of $(r-m)$ new equations involving $\mathbf{t}$ and $\tilde{\mathbf{u}}$ are required. These additional equations are supplied by vanishing the coefficients of the negative powers $1/p^n$ $(n=1,\ldots,r-m)$ in

$$(\mathbb{L}^m)_{\leqslant -1}=0.$$

C. Examples

In the following examples we exhibit solutions u of the dKP equation (4) depending on an arbitrary function $j=j(\rho)$. They are orbits of Gelfand–Dikii solutions u_0 under the action of the symmetry generated by (45). Notice that according to (45)–(46) we can obtain u_0 by setting $j=\rho$ in the expression of u.

(1) For

$$r=m=2, \quad f(P^{1/2}):=\gamma P^{7/2},$$

the generating function (47) becomes

$$J_2(P,\rho)=\gamma P^{7/2}+j(\rho)P^{3/2}, \quad \rho:=\frac{x}{3p^2}, \tag{55}$$

and $\mathbb{L}^2$ takes the form

$$\begin{aligned}\mathbb{L}^2&=(\mathbb{L}^2)_{\geqslant 0}\\ &=\frac{p^2}{(j'(t))^{2/3}}-\frac{4}{9}\frac{yj''(t)}{(j'(t))^{5/3}}p+\frac{2u_1}{(j'(t))^{2/3}}-\frac{2}{9}\frac{xj''(t)}{(j'(t))^{5/3}}-\frac{4}{27}\frac{y^2j'''(t)}{(j'(t))^{5/3}}+\frac{20}{81}\frac{y^2(j''(t))^2}{(j'(t))^{8/3}}.\end{aligned} \tag{56}$$

Hence $\partial\mathbb{L}^2/\partial p$ has a unique zero given by

$$p_1=\frac{2}{9}y\frac{j''(t)}{j'(t)}.$$

Moreover, the expression of

$$\mathcal{S}_2=(\tfrac{1}{3}y\mathcal{L}^2+\tfrac{2}{3}x\mathcal{L}+\gamma\mathbb{L}^7+j(\mathcal{M}_2)\mathbb{L}^3)_{\geqslant 0}$$

as a function of p can be computed by using (57) and the expansion

$$\begin{aligned}j(\mathcal{M}_2)=j(t)+\frac{2}{3}yj'(t)\frac{1}{p}+\left(\frac{x}{3}j'(t)+\frac{2}{9}y^2j''(t)\right)\frac{1}{p^2}\\ +\left(-\frac{2}{3}yj'(t)u_1+\frac{4}{81}y^3j'''(t)+\frac{2}{9}xyj''(t)\right)\frac{1}{p^3}+\mathcal{O}\left(\frac{1}{p^4}\right).\end{aligned}$$

In this way the hodograph equation $(\partial\mathcal{S}_2/\partial p)|_{p=p_1}=0$ turns out to be an equation for $u=u_1$, which yields the following solution of the dKP equation

$$u=\frac{F}{105\gamma}-\frac{6j(t)j'(t)^{4/3}}{F}+\frac{9j'(t)j''(t)x+6j'(t)j'''(t)y^2-8j''(t)^2y^2}{81(j'(t))^2}, \tag{57}$$

where

$$F:=\gamma^{2/3}(-7350j'(t)^{4/3}j''(t)y^2-33075j'(t)^{7/3}x+105\sqrt{35\,G})^{1/3},$$

$$G:=\frac{1}{\gamma}(648j(t)^3j'(t)^4+140\gamma j'(t)^{8/3}j''(t)^2y^4+1260\gamma j'(t)^{11/3}j''(t)xy^2+2835\gamma j'(t)^{14/3}x^2).$$

(2) By setting

$$r=m=3,\quad f(P^{1/3}):=\gamma P^{7/3},$$

in (47) one finds that the first two coefficients of the expansion (1) of $\mathcal{L}$ are given by

$$u=u_1=-\frac{1}{1024\,j_1^2}(90\,j_2^2t^2-72\,j_1j_3t^2-128\,j_1j_2y+Z^2), \tag{58}$$

$$u_2=\frac{-21\,\gamma j_1^8j_2t\,Z^4+F\,Z^2+8388608\,j_1^{59/4}y+2359296\,j_1^{55/4}j_2t^2}{114688\,\gamma j_1^{11}Z}, \tag{59}$$

where

$$j_i:=\frac{\partial^i j}{\partial\rho^i}(t_4),\quad i\geqslant 0,$$

$$F:=-16384\,j_0j_1^{47/4}+7168\,\gamma j_1^{10}j_2x-13440\,\gamma j_1^9j_2^2ty+5670\,\gamma j_1^8j_2^3t^3$$
$$+2016\,\gamma j_1^{10}j_4t^3-7560\,\gamma j_1^9j_2j_3t^3+10752\,\gamma j_1^{10}j_3ty,$$

and $Z=Z(x,y,t,t_4)$ is a root of the equation

$$49\,j_1^{30}\gamma^2Z^{10}+(5\,637\,144\,576\,\gamma j_1^{151/4}x+2\,113\,929\,216\,\gamma j_1^{147/4}j_2\,ty-1\,610\,612\,736\,j_0^2j_1^{75/2}$$
$$+396\,361\,728\,\gamma j_1^{147/4}j_3t^3-297\,271\,296\,\gamma\,j_1^{143/4}j_2^2t^3)Z^4+422\,212\,465\,065\,984\,j_1^{87/2}y^2$$
$$+33\,397\,665\,693\,696\,j_1^{83/2}j_2^2t^4+237\,494\,511\,599\,616\,j_1^{85/2}j_2t^2y=0.$$

(Received 10 January 2003; accepted 9 April 2003)

We present in detail an extended resolvent approach for investigating linear problems associated to $2+1$ dimensional integrable equations. Our presentation is based as an example on the nonstationary Schrödinger equation with potential being a perturbation of the one-soliton potential by means of a decaying two-dimensional function. Modification of the inverse scattering theory as well as properties of the Jost solutions and spectral data as follows from the resolvent approach are given. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1587874]

I. INTRODUCTION

The extended resolvent approach to the study of the spectral theory of differential operators was developed in Refs. 1–8 as a method that from one side unifies all known approaches of the inverse scattering theory, such as dressing transformation, nonlocal Riemann–Hilbert problem, d-bar method and, from the other side, enables considering operators of more generic type, say, with nontrivial asymptotic behavior at space infinity. Our presentation is based on the study of the well known differential operator

$$\mathcal{L}(x,\partial_x)=i\partial_{x_2}+\partial_{x_1}^2-u(x),\quad x=(x_1,x_2), \tag{1.1}$$

i.e., the nonstationary Schrödinger equation $\mathcal{L}(x,\partial_x)\Phi(x,k)=0$ which is the linear problem associated to the Kadomtsev–Petviashvili I equation (KPI):[9]

$$(u_t-6uu_{x_1}+u_{x_1x_1x_1})_{x_1}=3u_{x_2x_2}. \tag{1.2}$$

This equation has been known to be integrable for about three decades.[10,11] The Cauchy problem for this equation with rapidly decaying initial data was studied by using the inverse scattering method in Refs. 12–15. At the same time, it is well known that (1.2) is a $(2+1)$-dimensional generalization of the famous Korteweg–de Vries (KdV) equation. Indeed, if $u_1(t,x_1)$ obeys KdV, then

$$u(t,x_1,x_2)=u_1(t,x_1+\mu x_2+3\mu^2 t) \tag{1.3}$$

solves (1.2) for an arbitrary constant $\mu\in\mathbb{R}$. Thus, it is natural to consider solutions of (1.2) that are not decaying in all directions at space infinity but have one-dimensional rays with behavior of

[a]Electronic mail: boiti@le.infn.it
[b]Electronic mail: pempi@le.infn.it
[c]Electronic mail: pogreb@mi.ras.ru
[d]Electronic mail: prinari@le.infn.it

the type (1.3). The scattering theory for the simplest example of such potentials in (1.1) was developed in Ref. 16. There, the Cauchy problem for the KPI equation was considered with initial data

$$u(x)=u_1(x_1)+u_2(x), \tag{1.4}$$

where $u_1(x_1)$ is the zero time value of the one-soliton solution of the KdV equation and $u_2(x)$ is a smooth real function that decays rapidly enough on the (x_1,x_2)-plane. We consider here a simplified case of (1.3) in which $\mu=0$. The generic case is reconstructed by means of the Galileo invariance of (1.2), that is, if $u(t,x)$ is a solution of KPI, then

$$\tilde{u}(t,x_1,x_2)=u(t,x_1+\mu x_2+3\mu^2 t,x_2+6\mu t) \tag{1.5}$$

also obeys this equation.

In Ref. 1 it was mentioned that the standard approach to the spectral theory of the operator (1.1) based on the integral equation for the Jost solution fails for potentials of the above type. In Ref. 16 the direct problem was studied by using a modified integral equation for the Jost solution, i.e., an equation that involves as background solution the Jost solution of the one-soliton potential and corresponding Green's function. An appropriate Jost solution was introduced and it was shown that, in addition to a standard jump across the real k-axis, where k is the spectral parameter, it also has a jump across a segment of the imaginary axis of the complex k-plane. In the modified formulation of the direct and inverse problems given in Ref. 16 some essential properties of the Jost solutions and relations between spectral data were stated without proof. The reason for this was that a technique based on the Jost solutions themselves is not enough for the study of these properties and especially for investigating relations among spectral data. This gap can be filled effectively in the framework of the extended resolvent approach that we present in detail in this article. The outline of the article is as follows. In Sec. II we give the basic notions of the resolvent approach. In particular, we demonstrate that in this framework the known results for a decaying potential in (1.1) follow readily. In Sec. III we consider the theory of the two-dimensional operator (1.1) with the pure one-dimensional $[u_2(x)\equiv 0$ in (1.4)] one-soliton potential $u_1(x_1)$. In Sec. IV we apply the resolvent approach to the operator (1.1) with a potential $u(x)$ that is a perturbation of this one-dimensional potential. We introduce and study the properties of the corresponding resolvent and Green's functions, Jost and auxiliary Jost solutions and advanced/retarded solutions. In Sec. IV E we investigate the properties of the spectral data and derive their characterization equations. In Sec. V we summarize the main aspects of the spectral theory developed in the framework of the extended resolvent approach.

II. BASIC OBJECTS OF THE RESOLVENT APPROACH

A. Extension of differential operators and resolvent

Let $\mathcal{A}=\mathcal{A}(x,\partial_x)$ denote a differential operator with kernel

$$A(x,x')=\mathcal{A}(x,\partial_x)\delta(x-x'), \quad x=(x_1,x_2), \tag{2.1}$$

$\delta(x)=\delta(x_1)\delta(x_2)$ being the two-dimensional δ-function. Here we consider the two-dimensional situation, but the whole procedure can be applied in any dimension. In what follows we consider differential operators whose kernels $A(x,x')$ belong to the space $\mathcal{S}'$ of tempered distributions of the four real variables x and x'. Differential operators are polynomials with respect to the derivatives. In order to exploit this property we introduce the **extension** of differential operators, i.e., to any differential operator $\mathcal{A}$ we associate the differential operator $A(s)$ with kernel

$$A(x,x';s)\equiv e^{-s(x-x')}A(x,x')=\mathcal{A}(x,\partial_x+s)\delta(x-x'), \tag{2.2}$$

where all variables x, x', $s\in\mathbb{R}^2$. Under the above condition kernels of the extended operators form a subclass in the space $\mathcal{S}'$ of tempered distributions $A(x,x';s)$ of six real variables. We

consider generic elements $A(x,x';s)$, $B(x,x';s)$, etc., of this space $\mathcal{S}'$ as operators (not necessarily differentiable) $A(s)$, $B(s)$, etc., with the standard composition rule

$$(AB)(x,x';s)=\int dx''\,A(x,x'';s)\,B(x'',x';s). \tag{2.3}$$

Since the kernels are distributions this composition is neither necessarily defined for all pairs of operators nor necessarily associative. On the space of these distributions we define the operation of Hermitian conjugation $A^\dagger$ as

$$A^\dagger(x,x';s)=\overline{A(x',x;-s)}, \tag{2.4}$$

where bar denotes complex conjugation and in the case of matrix operators the matrix on the r.h.s. must be transposed.

The kernels of the extended differential operators depend polynomially on the variables $s=(s_1,s_2)$ so that the analytic continuation of the kernels with respect to these variables is admissible. In what follows we denote such kernels as $A(x,x';\mathbf{s})$ using boldface font for the complex variable $\mathbf{s}$ which has s as real part. So, for the variable $\mathbf{s}$ we write

$$\mathbf{s}=\mathbf{s}_\Re+i\mathbf{s}_\Im=(\mathbf{s}_1,\mathbf{s}_2)\in\mathbb{C}^2,\quad \mathbf{s}_\Re\equiv s\in\mathbb{R}^2. \tag{2.5}$$

In the following we will use the same notation $\mathbf{k}=\mathbf{k}_\Re+i\mathbf{k}_\Im\equiv k+i\mathbf{k}_\Im$ for the other complex spectral parameter $\mathbf{k}\in\mathbb{C}$ we introduce.

Thanks to (2.2) continuation (2.5) (analytic for the differential operators) is given by

$$A(x,x';\mathbf{s})=e^{-i\mathbf{s}_\Im(x-x')}A(x,x';\mathbf{s}_\Re). \tag{2.6}$$

Since this formula is well defined in the space $\mathcal{S}'$ for any operator $A(s)$, it can be used as the definition of the continuation (in general not analytic) of a generic $A(s)$ in the complex domain, $\mathbf{s}\in\mathbb{C}^2$.

An operator A can have an inverse in the sense of the composition law (2.3), say $AA^{-1}=I$ or $A^{-1}A=I$ (in general left and right inverse can be different), where I is the unity operator in $\mathcal{S}'$,

$$I(x,x';s)=\delta(x-x'). \tag{2.7}$$

Thanks to (2.6) continuation to the complex domain of the operator inverse to (extended) differential operator $A(s)$ equals to the inverse of continued differential operator $A(\mathbf{s})$. Therefore, we can impose to the inverse the additional condition that the product

$$A(\mathbf{s}+\mathbf{s}')^{-1}A(\mathbf{s})^{-1},\quad \mathbf{s},\mathbf{s}'\in\mathbb{C}, \tag{2.8}$$

is a bounded function of $\mathbf{s}'$ in a neighborhood of $\mathbf{s}'=0$. Then, if the inversion $A^{-1}(s)$ exists, it is unique and, therefore, in the following in order to guarantee the uniqueness of the inverse we will always require that this condition is fulfilled.

In order to clarify the meaning of the introduced extension of differential operators it is convenient to consider the ''shifted'' Fourier transform

$$A(p;\mathbf{s})=\frac{1}{(2\pi)^2}\int dx\int dx'\,e^{i(p-\mathbf{s}_\Im)x+i\mathbf{s}_\Im x'}A(x,x';\mathbf{s}_\Re), \tag{2.9}$$

where $p\in\mathbb{R}^2$, $px=p_1x_1+p_2x_2$, and $\mathbf{s}\in\mathbb{C}^2$ and to consider it as the kernel of the operator $A(s)$ in the transformed p space. In this space the extension of a differential operator $\mathcal{A}$ with constant coefficients is particularly simple. Indeed, we have $A(p;\mathbf{s})=a(\mathbf{s})\delta(p)$, where $a(\mathbf{s})$ is a polynomial in $\mathbf{s}$. For the kernel of the inverse operator we get trivially $A^{-1}(p;\mathbf{s})=\delta(p)/a(\mathbf{s})$ and condition (2.8) means that possible terms proportional to $\delta(a(\mathbf{s}))$ must be omitted.

Let D_j denote the extension of the differential operator ∂_{x_j} $(j=1,2)$, i.e., according to (2.2) let

$$D_j(x,x';s)=(\partial_{x_j}+s_j)\,\delta(x-x'),\quad j=1,2. \tag{2.10}$$

In terms of the Fourier transform (2.9) $D_j(p;\mathbf{s})=\mathbf{s}_j\delta(p)$ and then $D_j^{-1}(p;\mathbf{s})=\mathbf{s}_j^{-1}\delta(p)$, so that inverting (2.9) we get

$$D_j^{-1}(x,x';s)=e^{-s(x-x')}[\,\theta(x_j-x_j')-\theta(-s_j)\,]\,\delta(x_{j+1}-x_{j+1}'), \tag{2.11}$$

where $j+1\equiv(j+1)\mathrm{mod}2$. These operators are just the standard resolvents of the operators ∂_{x_j}. This observation motivates the name extended resolvent for the mathematical object we introduced. In fact, we added a complex (spectral) parameter not to the operator itself but to the operators ∂_{x_j}. Below we discuss the relevance of this modification and compare our approach to the standard spectral theory of differential operators.

By (2.10) we have that $D_j(x,x';\mathbf{s})=(\partial_{x_j}+\mathbf{s}_j)\,\delta(x-x')$ that is, of course, an analytic (polynomial) function of $\mathbf{s}$. But for the continuation of the inverse operator we get by (2.11) and (2.6)

$$D_j^{-1}(x,x';\mathbf{s})=e^{-\mathbf{s}(x-x')}[\,\theta(x_j-x_j')-\theta(-\mathbf{s}_{j\Re})\,]\,\delta(x_{j+1}-x_{j+1}'), \tag{2.12}$$

that is not analytic with respect to $\mathbf{s}_j$. Moreover, let us perform the operation inverse to imbedding (2.2), i.e., to any operator $A(s)$ with kernel $A(x,x';s)$ we associate its "hat-kernel"

$$\hat{A}(x,x';s)=e^{s(x-x')}A(x,x';s). \tag{2.13}$$

It is clear that these objects (in the generic case) do not belong to the space $\mathcal{S}'(\mathbb{R}^6)$ of distributions, while we still can use their composition relation

$$\widehat{(AB)}(x,x';s)=\int dx''\,\hat{A}(x,x'';s)\,\hat{B}(x'',x';s) \tag{2.14}$$

derived from (2.3). Let now $A(s)$ be the extension of a differential operator $\mathcal{A}$. Then of course $\hat{A}(x,x';s)=A(x,x')$, i.e., the kernel of the original differential operator. In particular this means that $\hat{A}(x,x';s)$ is independent of the variables s. At the same time, as demonstrated by example (2.11), for an operator inverse to a differential operator, the dependence on s of the kernel $\widehat{A^{-1}}(x,x';s)$ is in general nontrivial, for instance,

$$\widehat{D_j^{-1}}(x,x';s)=[\,\theta(x_j-x_j')-\theta(-s_j)\,]\,\delta(x_{j+1}-x_{j+1}'). \tag{2.15}$$

Using the "hat-operation," for any differential operator $\mathcal{A}(x,\partial_x)$, equalities $AA^{-1}=A^{-1}A=I$ take the form

$$\mathcal{A}(x,\partial_x)\widehat{A^{-1}}(x,x';s)=\mathcal{A}^{\mathrm{d}}(x',\partial_{x'})\widehat{A^{-1}}(x,x';s)=\delta(x-x'), \tag{2.16}$$

where $\mathcal{A}^{\mathrm{d}}$ is the operator dual to $\mathcal{A}$. Thus the hat-kernel (2.13) of the operator inverse to an extended differential operator gives a two-parametric ($s\in\mathbb{R}^2$) family of Green's functions of the operator $\mathcal{A}$. In what follows for equalities of the type (2.16) we use the following special notation,

$$\vec{\mathcal{A}}\,\widehat{A^{-1}}(s)=\widehat{A^{-1}}(s)\tilde{\mathcal{A}}=I, \tag{2.17}$$

where $\vec{\mathcal{A}}$ denotes the operator $\mathcal{A}$ applied to the x-variable of the function $\widehat{A^{-1}}(x,x';s)$ and $\tilde{\mathcal{A}}$ denotes the operator dual to $\mathcal{A}$ applied to the x'-variable of the same kernel. We also see that any discontinuity of the kernel $\widehat{A^{-1}}(x,x';s)$ with respect to the s-variables belongs to the null space of

the operator $\mathcal{A}$ and its dual. The same is valid for the derivatives of such kernels with respect to the s-variables. Let us mention that for kernels continued by means of (2.6) we have by (2.13) the relation

$$A(x,x';\mathbf{s})=e^{-\mathbf{s}(x-x')}\hat{A}(x,x';\mathbf{s}_{\mathfrak{R}}), \tag{2.18}$$

and for the inversion $A^{-1}(\mathbf{s})$ of a differential operator $A(\mathbf{s})$

$$A(\mathbf{s})\frac{\partial A^{-1}(\mathbf{s})}{\partial\overline{\mathbf{s}}_j}=\frac{\partial A^{-1}(\mathbf{s})}{\partial\overline{\mathbf{s}}_j}A(\mathbf{s})=0. \tag{2.19}$$

Thus the d-bar derivatives of the inverse operator also annulate the differential operator and its dual, while by (2.13)

$$\left(\frac{\partial A^{-1}(\mathbf{s})}{\partial\overline{\mathbf{s}}_j}\right)\widehat{\ }\Big|_{\mathbf{s}_{\mathfrak{I}}=0}=\frac{1}{2}\frac{\partial\widehat{A^{-1}}(s)}{\partial s_j},\quad s=\mathbf{s}_{\mathfrak{R}}, \tag{2.20}$$

where both derivatives are considered in the sense of distributions.

B. Resolvent approach in the case of rapidly decaying potential

1. Definition of the resolvent

The extension of operator $\mathcal{L}(x,\partial_x)$ in (1.1) is given by

$$L(s)=L_0(s)-U, \tag{2.21}$$

where

$$L_0=iD_2+D_1^2 \tag{2.22}$$

has kernel

$$L_0(x,x';s)=[i(\partial_{x_2}+s_2)+(\partial_{x_1}+s_1)^2]\delta(x-x'), \tag{2.23}$$

and U, which is called the potential operator, has kernel

$$U(x,x';s)=u(x)\,\delta(x-x'), \tag{2.24}$$

which is independent of s. Below we always suppose that $u(x)$ is real, which by (2.4) is equivalent to

$$L^{\dagger}=L. \tag{2.25}$$

The main object of our approach is the (extended) resolvent $M(s)$ of the operator $L(s)$, which is defined as the inverse of the operator L, that is, M satisfies

$$LM=ML=I, \tag{2.26}$$

and obeys condition (2.8). The main advantage of using the extended resolvent is that its derivatives with respect to s are given in terms of its reduced values that are just the Jost solutions (and their generalizations) of the linear problem under consideration. In their turn discontinuities and derivatives of these solutions lead us to the spectral data, again given as ''further'' reductions of the resolvent. Let us consider first the resolvent M_0 of the bare operator L_0. In terms of the Fourier transformation (2.9) and thanks to condition (2.8) we get for the kernel of this operator $M_0(p;\mathbf{s})=\delta(p)(i\mathbf{s}_2+\mathbf{s}_1^2)^{-1}$. Inverting transformation (2.9) we get for the hat-kernel

$$\hat{M}_0(x,x';s)=\frac{1}{2\pi i}\int_{\mathbf{k}_\Im=s_1} d\mathbf{k}_\Re[\theta(x_2-x_2')-\theta(2\mathbf{k}_\Re\mathbf{k}_\Im-s_2)]\,\Phi_0(x,\mathbf{k})\Psi_0(x',\mathbf{k}), \tag{2.27}$$

where we introduced the functions

$$\Phi_0(x,\mathbf{k})=e^{-i\mathbf{k}x_1-i\mathbf{k}^2x_2},\quad \Psi_0(x,\mathbf{k})=e^{i\mathbf{k}x_1+i\mathbf{k}^2x_2}, \tag{2.28}$$

where $\mathbf{k}=\mathbf{k}_\Re+i\mathbf{k}_\Im\in\mathbb{C}$ is a complex (one-dimensional) spectral parameter for which we again use boldface font and also, in order to simplify notation, standard font for its real part, i.e., $\mathbf{k}_\Re\equiv k$. The functions $\Phi_0(x,\mathbf{k})$ and $\Psi_0(x,\mathbf{k})$ which naturally appeared in (2.27) obey the differential equations

$$\mathcal{L}_0(x,\partial_x)\Phi_0(x,\mathbf{k})\equiv(i\partial_{x_2}+\partial_{x_1}^2)\Phi_0(x,\mathbf{k})=0, \tag{2.29}$$

$$\mathcal{L}_0^{\mathrm{d}}(x,\partial_x)\Psi_0(x,\mathbf{k})\equiv(-i\partial_{x_2}+\partial_{x_1}^2)\Psi_0(x,\mathbf{k})=0, \tag{2.30}$$

i.e., solve the nonstationary Schrödinger equation and its dual in the case of zero potential. Thus they can be considered as the Jost solutions for this trivial case. Notice also that they obey the conjugation property

$$\overline{\Phi_0(x,\mathbf{k})}=\Psi_0(x,\overline{\mathbf{k}}). \tag{2.31}$$

By using notation (2.17) we can write

$$\vec{\mathcal{L}}_0\hat{M}_0(s)=\hat{M}_0(s)\tilde{\mathcal{L}}_0=I, \tag{2.32}$$

showing that the hat version of the extended resolvent $\hat{M}_0(s)$ is a two-parametric set of Green's functions of operator (1.1) and its dual. In analogy with these notations we write

$$\vec{\mathcal{L}}_0\Phi_0(\mathbf{k})=0,\quad \Psi_0(\mathbf{k})\tilde{\mathcal{L}}_0=0, \tag{2.33}$$

considering $\Phi_0(\mathbf{k})$ and $\Psi_0(\mathbf{k})$ as "vector" and "covector" with "components" labeled by the variable x.

The resolvent M_0 given in (2.27) obeys the following properties. It is a continuous function of s when $s\neq 0$, it is bounded but discontinuous at $s=0$, it is self-adjoint [cf. (2.25)], that is $M_0^\dagger=M_0$, and from (2.27) we have

$$\frac{\partial\hat{M}_0(s)}{\partial s_1}=\frac{i}{\pi}\int_{\mathbf{k}_\Im=s_1} d\mathbf{k}_\Re\,\overline{\mathbf{k}}\,\delta(2\mathbf{k}_\Re\mathbf{k}_\Im-s_2)\,\Phi_0(\mathbf{k})\otimes\Psi_0(\mathbf{k}), \tag{2.34}$$

$$\frac{\partial\hat{M}_0(s)}{\partial s_2}=\frac{1}{2\pi i}\int_{\mathbf{k}_\Im=s_1} d\mathbf{k}_\Re\,\delta(2\mathbf{k}_\Re\mathbf{k}_\Im-s_2)\,\Phi_0(\mathbf{k})\otimes\Psi_0(\mathbf{k}), \tag{2.35}$$

where, in correspondence with the "vector" interpretation of the Jost solutions, the direct product in (2.34), (2.35) is defined in the standard way as an operator with kernel

$$(\Phi_0(\mathbf{k})\otimes\Psi_0(\mathbf{k}))(x,x')=\Phi_0(x,\mathbf{k})\Psi_0(x',\mathbf{k}). \tag{2.36}$$

Derivatives in (2.34) and (2.35) can be considered in the standard sense when $s_1\neq 0$, while in vicinity of $s_1=0$ they must be understood in the distributional sense. It is easy to see that the integral in (2.27) is exponentially divergent when, say, $s_2\to\infty$. Thus, indeed, $\hat{M}_0(x,x';s)\notin\mathcal{S}'(\mathbb{R}^6)$.

2. The resolvent and Hilbert identity

The resolvent of the operator L can also be defined as the solution of the integral equations

$$M=M_0+M_0UM, \quad M=M_0+MUM_0. \tag{2.37}$$

Under a small norm assumption on the potential we expect that the solution M exists and is unique (the same for both integral equations) if the condition (2.8) is required. Taking into account the properties of M_0 given above, we get that thanks to the reality of the potential $u(x)$ the resolvent is self-adjoint,

$$M^\dagger=M, \tag{2.38}$$

$M(s)$ is a continuous function of s when $s\neq 0$ and discontinuous at $s=0$, and by (2.26) has the asymptotic expansion

$$M(s_1,s_2+\mathbf{s}_2')=\frac{I}{i\mathbf{s}_2'}+\frac{L(s)}{\mathbf{s}_2'^2}+\cdots, \quad \mathbf{s}_2'\in\mathbb{C}, \quad \mathbf{s}_2'\to\infty. \tag{2.39}$$

As we mentioned above essential information on the spectrum of the operator $\mathcal{L}$ can be derived from the d-bar derivatives of the resolvent $M(\mathbf{s})$ continued in the complex domain. In order to study these derivatives we use the following analog of the well known Hilbert identity,

$$M'-M=-M'(L'-L)M, \tag{2.40}$$

where L' is another operator of the type (1.1) and M' is its resolvent. Let us choose $U'=U$ and let $L=L(\mathbf{s})$ and $L'=L(\mathbf{s}')$ and the same for their resolvents. Then (2.40) can be written in the form

$$M(\mathbf{s}')-M(\mathbf{s})=-M(\mathbf{s}')(L_0(\mathbf{s}')-L_0(\mathbf{s}))M(\mathbf{s}), \tag{2.41}$$

or by (2.26) as

$$M(\mathbf{s}')-M(\mathbf{s})=M(\mathbf{s}')L_0(\mathbf{s}')(M_0(\mathbf{s}')-M_0(\mathbf{s}))L_0(\mathbf{s})M(\mathbf{s}), \tag{2.42}$$

that gives

$$\frac{\partial M(\mathbf{s})}{\partial\overline{\mathbf{s}}_j}=M(\mathbf{s})L_0(\mathbf{s})\frac{\partial M_0(\mathbf{s})}{\partial\overline{\mathbf{s}}_j}L_0(\mathbf{s})M(\mathbf{s}). \tag{2.43}$$

In terms of hat-kernels as defined in (2.13), thanks to (2.20), we get

$$\frac{\partial\hat{M}(s)}{\partial s_j}=\hat{M}(s)\tilde{\mathcal{L}}_0\frac{\partial\hat{M}_0(s)}{\partial s_j}\vec{\mathcal{L}}_0\hat{M}(s), \quad j=1,2, \tag{2.44}$$

and then by (2.34) and (2.35) for $s_1\neq 0$

$$\frac{\partial\hat{M}(s)}{\partial s_1}=\frac{i}{\pi}\int_{\mathbf{k}_\mathfrak{I}=s_1}d\mathbf{k}_\mathfrak{R}\,\overline{\mathbf{k}}\,\delta(2\mathbf{k}_\mathfrak{R}\mathbf{k}_\mathfrak{I}-s_2)\,\Phi(\mathbf{k})\otimes\Psi(\mathbf{k}), \tag{2.45}$$

$$\frac{\partial\hat{M}(s)}{\partial s_2}=\frac{1}{2\pi i}\int_{\mathbf{k}_\mathfrak{I}=s_1}d\mathbf{k}_\mathfrak{R}\,\delta(2\mathbf{k}_\mathfrak{R}\mathbf{k}_\mathfrak{I}-s_2)\,\Phi(\mathbf{k})\otimes\Psi(\mathbf{k}), \tag{2.46}$$

where we introduced the functions

$$\Phi(x,\mathbf{k})=\int dx'\,(\mathcal{L}_0^{\mathrm{d}}(x',\partial_{x'})G(x,x',\mathbf{k}))\Phi_0(x',\mathbf{k}), \tag{2.47}$$

$$\Psi(x',\mathbf{k})=\int dx\,\Psi_0(x,\mathbf{k})\,\mathcal{L}_0(x,\partial_x)\,G(x,x',\mathbf{k}), \tag{2.48}$$

with $G(x,x',\mathbf{k})$ defined as a specific value of the resolvent itself

$$G(x,x',\mathbf{k})=\hat{M}(x,x';\mathbf{k}_{\mathfrak{I}},2\mathbf{k}_{\mathfrak{R}}\mathbf{k}_{\mathfrak{I}}). \tag{2.49}$$

In what follows we consider the function $G(x,x',\mathbf{k})$ as the kernel of the operator $G(\mathbf{k})$ and the functions $\Phi(x,\mathbf{k})$ and $\Psi(x',\mathbf{k})$ as vector $\Phi(\mathbf{k})$ and covector $\Psi(\mathbf{k})$. For shortness we write equations of the type (2.47)–(2.49) as

$$\Phi(\mathbf{k})=G(\mathbf{k})\vec{\mathcal{L}}_0\Phi_0(\mathbf{k}),\quad \Psi(\mathbf{k})=\Psi_0(\mathbf{k})\vec{\mathcal{L}}_0G(\mathbf{k}), \tag{2.50}$$

$$G(\mathbf{k})=\hat{M}(s)|_{s=(\mathbf{k}_{\mathfrak{I}},2\mathbf{k}_{\mathfrak{R}}\mathbf{k}_{\mathfrak{I}})}. \tag{2.51}$$

Relation (2.49) shows that the function $G(x,x',\mathbf{k})$ is in one-to-one correspondence with the resolvent $\hat{M}(x,x';s)$ iff $\mathbf{k}_{\mathfrak{I}}\neq 0$, that is, iff the points along the above mentioned discontinuity of the resolvent at $s=0$ are excluded. In order to study this discontinuity we introduce the following notation for the specific limits of the resolvent at this point of discontinuity,

$$G_{\pm}(x,x')=\lim_{s_2\to\pm 0}\lim_{s_1\to 0}\hat{M}(x,x';s), \tag{2.52}$$

where the limit $s_1\to 0$ is independent of the sign. Now we choose in (2.42) both s and s' real, $s_1'=s_1=0$ and consider the limits $s_2'\to\pm 0$, $s_2\to\mp 0$. We get

$$G_+-G_-=G_{\pm}\vec{\mathcal{L}}_0(G_{0,+}-G_{0,-})\vec{\mathcal{L}}_0G_{\mp}, \tag{2.53}$$

where $G_{0,\pm}$ is defined in terms of the bare resolvent $\hat{M}_0$ like in (2.52), so that by (2.27) we have

$$G_{0,\pm}(x,x')=\frac{\pm\theta(\pm(x_2-x_2'))}{2\pi i}\int dk\,\Phi_0(x,k)\Psi_0(x',k), \tag{2.54}$$

and

$$G_{0,+}-G_{0,-}=\frac{1}{2\pi i}\int dk\,\Phi_0(k)\otimes\Psi_0(k). \tag{2.55}$$

Inserting this relation in the r.h.s. of (2.53) we derive the equality

$$G_+-G_-=\frac{1}{2\pi i}\int dk\,\Phi_{\pm}(k)\otimes\Psi_{\mp}(k), \tag{2.56}$$

where we introduced the functions $\Phi_{\pm}(x,k)$ and $\Psi_{\pm}(x,k)$, which, in analogy with (2.50) and using the same notation, are defined by

$$\Phi_{\pm}(k)=G_{\pm}\vec{\mathcal{L}}_0\Phi_0(k),\quad \Psi_{\pm}(k)=\Psi_0(k)\vec{\mathcal{L}}_0G_{\pm}. \tag{2.57}$$

Next we consider in detail the properties of all the objects introduced so far, $G(\mathbf{k})$, $\Phi(\mathbf{k})$, $\Psi(\mathbf{k})$, $G_{\pm}(\mathbf{k})$, $\Phi_{\pm}(k)$, and $\Psi_{\pm}(k)$.

3. Properties of the Green's function

Thanks to (2.17) it is clear that $G(\mathbf{k})$ defined in (2.49) is a Green's function of the operator $\mathcal{L}$ depending on the complex parameter $\mathbf{k}$,

$$\vec{\mathcal{L}}G(\mathbf{k})=G(\mathbf{k})\vec{\mathcal{L}}=I. \tag{2.58}$$

Properties of this Green's function follow from the properties of $M(s)$. In particular, thanks to the definition (2.4) and to (2.38) (i.e., reality of the potential u) we get

$$\overline{G(x,x',\mathbf{k})}=G(x',x,\overline{\mathbf{k}}). \tag{2.59}$$

Applying the reduction (2.49) to equalities (2.37) we get that this function obeys the integral equations

$$G(\mathbf{k})=G_0(\mathbf{k})+G_0(\mathbf{k})UG(\mathbf{k}),\quad G(\mathbf{k})=G_0(\mathbf{k})+G(\mathbf{k})UG_0(\mathbf{k}), \tag{2.60}$$

where the Green's function $G_0(\mathbf{k})$ of the operator $\mathcal{L}_0$ is defined by the general formula (2.51) in terms of M_0 and thanks to (2.27) it equals

$$G_0(x,x',\mathbf{k})=\frac{1}{2\pi i}\int dk'\,[\,\theta(x_2-x_2')-\theta(\mathbf{k}_\Im k')\,]\,\Phi_0(x,\mathbf{k}'+k)\Psi_0(x',\mathbf{k}+k'). \tag{2.61}$$

By (2.60) it is easy to check that the function

$$g(x,x',\mathbf{k})=e^{i\mathbf{k}(x_1-x_1')+i\mathbf{k}^2(x_2-x_2')}G(x,x',\mathbf{k}) \tag{2.62}$$

is a bounded function of its arguments and that

$$\lim_{\mathbf{k}\to\infty} g(x,x',\mathbf{k})=0 \tag{2.63}$$

if the potential $u(x)$ decays rapidly enough. The function $G(x,x',\mathbf{k})$ is a continuously differentiable function of $\mathbf{k}$ in the whole complex plane $\mathbb{C}$ with exception of the real axis $\mathbf{k}_\Im=0$, as follows from (2.49). By (2.45) and (2.46) for $\mathbf{k}_\Im\neq 0$ we have

$$\frac{\partial G(\mathbf{k})}{\partial \mathbf{k}_\Re}=\frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi i}\Phi(\mathbf{k})\otimes\Psi(\mathbf{k}),\quad \frac{\partial G(\mathbf{k})}{\partial \mathbf{k}_\Im}=\frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi}\Phi(\mathbf{k})\otimes\Psi(\mathbf{k}), \tag{2.64}$$

so that in the complex domain this Green's function is analytic,

$$\frac{\partial G(\mathbf{k})}{\partial \overline{\mathbf{k}}}=0,\quad \mathbf{k}_\Im\neq 0, \tag{2.65}$$

and discontinuous at the real axis.

The Hilbert identity (2.41) allows us also to find relations among the Green's function at different values of the parameter $\mathbf{k}$. For this sake we choose $\mathbf{s}_1'=\mathbf{s}_1=s_1\in\mathbb{R}$ and let $\mathbf{s}_2',\mathbf{s}_2\in\mathbb{C}$. By (2.23) $\mathcal{L}(s_1,\mathbf{s}_2')-\mathcal{L}(s_1,\mathbf{s}_2)=i(\mathbf{s}_2'-\mathbf{s}_2)I$. Inserting this equality in (2.41) we can divide both parts by $\mathbf{s}_2'-\mathbf{s}_2$ and thanks to condition (2.8) we get

$$M(s_1,\mathbf{s}_2')M(s_1,\mathbf{s}_2)=i\frac{M(s_1,\mathbf{s}_2')-M(s_1,\mathbf{s}_2)}{\mathbf{s}_2'-\mathbf{s}_2}. \tag{2.66}$$

In terms of the hat-kernel of the resolvent by (2.18) we then have

$$\int dx'\, e^{(\mathbf{s}_2'-\mathbf{s}_2)x_2'}\hat{M}(x,x';s_1,\mathbf{s}_{2\mathfrak{R}}')\hat{M}(x',x'';s_1,\mathbf{s}_{2\mathfrak{R}})$$

$$= i\frac{e^{(\mathbf{s}_2'-\mathbf{s}_2)x_2''}\hat{M}(x,x'';s_1,\mathbf{s}_{2\mathfrak{R}}')-e^{(\mathbf{s}_2'-\mathbf{s}_2)x_2}\hat{M}(x,x'';s_1,\mathbf{s}_{2\mathfrak{R}})}{\mathbf{s}_2'-\mathbf{s}_2}.$$

Next we perform the Fourier transform with respect to the difference $\mathbf{s}_{2\mathfrak{I}}'-\mathbf{s}_{2\mathfrak{I}}$ and denote $\mathbf{s}_{2\mathfrak{R}}'=s_2'$, $\mathbf{s}_{2\mathfrak{R}}=s_2$. We get for $s_1'=s_1$

$$\int dx_1'\,\hat{M}(x,x';s')\hat{M}(x',x'';s)=i\hat{M}(x,x'';s')[\theta(x_2''-x_2')-\theta(s_2-s_2')]$$

$$-i\hat{M}(x,x'';s)[\theta(x_2-x_2')-\theta(s_2-s_2')].$$

Finally, we introduce $\mathbf{k}_{\mathfrak{I}}=s_1'=s_1$, $\mathbf{k}_{\mathfrak{R}}=s_2/(2s_1)$, $k'=(s_2'-s_2)/(2s_1)$. Then $s'=(\mathbf{k}_{\mathfrak{I}},2(\mathbf{k}_{\mathfrak{R}}+k')\mathbf{k}_{\mathfrak{I}})$ and $s=(\mathbf{k}_{\mathfrak{I}},2\mathbf{k}_{\mathfrak{R}}\mathbf{k}_{\mathfrak{I}})$ and using definition (2.49) we can rewrite the above equality in terms of the Green's function as

$$\int dx_1'\,G(x,x',\mathbf{k}+k')G(x',x'',\mathbf{k})$$

$$= iG(x,x'',\mathbf{k}+k')[\theta(x_2''-x_2')-\theta(-\mathbf{k}_{\mathfrak{I}}k')]-iG(x,x'',\mathbf{k})[\theta(x_2-x_2')-\theta(-\mathbf{k}_{\mathfrak{I}}k')],$$

$$\mathbf{k}\in\mathbb{C},\quad k'\in\mathbb{R}. \tag{2.67}$$

Properties of the functions $G_{\pm}(x,x')$ as well follow from the properties of the resolvent. Both of them are also Green's functions of the operator (1.1) and its dual,

$$\vec{\mathcal{L}}G_{\pm}=G_{\pm}\tilde{\mathcal{L}}=I, \tag{2.68}$$

obey the conjugation property

$$\overline{G_{\pm}(x,x')}=G_{\mp}(x',x), \tag{2.69}$$

and the integral equations

$$G_{\pm}=G_{0,\pm}+G_{0,\pm}UG_{\pm},\quad G_{\pm}=G_{0,\pm}+G_{\pm}UG_{0,\pm}, \tag{2.70}$$

where $G_{0,\pm}$ is given in (2.54).

The limiting values of the Green's function $G(\mathbf{k})$ on the real axis in a sense must be close to the Green's functions $G_{\pm}$. Indeed, introducing notations

$$G^{\pm}(x,x',k)=G(x,x',k\pm i0),\quad k\in\mathbb{R}, \tag{2.71}$$

we see by (2.49) that they are given by the following limits of the resolvent

$$G^{\pm}(x,x',k)=\lim_{\varepsilon\to+0}\hat{M}(x,x';\pm\varepsilon,\pm 2k\varepsilon), \tag{2.72}$$

so like in (2.52) they correspond to $\hat{M}(s)$ at $s=0$. But the resolvent is discontinuous at this point, so in the generic situation these limits are different. In order to find relations between them we again start from (2.42) choosing both s' and s to be real. Performing for s' the limiting procedure (2.72) and for s the one in (2.52) we get

$$G^{\sigma}(k)-G_{\pm}=(G_{\pm}\tilde{\mathcal{L}}_0)(G_0^{\sigma}(k)-G_{0,\pm})(\vec{\mathcal{L}}_0G^{\sigma}(k)), \tag{2.73}$$

where $k\in\mathbb{R}$ and $\sigma=+,-$. Then, thanks to (2.54) and definitions (2.57) we get from (2.73)

$$G^{\sigma}(k)-G_{\pm}=\frac{\mp 1}{2\pi i}\int dk'\ \theta(\mp\sigma(k-k'))\Phi_{\pm}(k')\otimes(\Psi_0(k')\vec{\mathcal{L}}_0G^{\sigma}(k)), \tag{2.74}$$

where for the "covector" $\Psi_0(k')\vec{\mathcal{L}}_0G^{\sigma}(k)$ we used a shorthand notation analogous to that in (2.50). Finally, let us mention that the relation between G_+ and G_- was given in (2.56).

4. Jost and advanced/retarded solutions. Bilinear representation for the resolvent

We have shown that the derivatives of the resolvent and its discontinuities are given in terms of the functions $\Phi(\mathbf{k})$, $\Psi(\mathbf{k})$, $\Phi_{\pm}(k)$, and $\Psi_{\pm}(k)$ which in their turn are obtained as special reductions of the resolvent. Here we describe the properties of these functions. Thanks to (2.33) and (2.58) it follows directly from definitions (2.50) that the functions $\Phi(x,\mathbf{k})$ and $\Psi(x,\mathbf{k})$ obey the nonstationary Schrödinger equation with potential $u(x)$ and its dual, that is,

$$\vec{\mathcal{L}}\Phi(\mathbf{k})=0,\quad \Psi(\mathbf{k})\tilde{\mathcal{L}}=0, \tag{2.75}$$

where we use the same notation as in (2.33). Thanks to (2.59) we get the conjugation property

$$\overline{\Phi(x,\mathbf{k})}=\Psi(x,\overline{\mathbf{k}}) \tag{2.76}$$

and the integral equations for these functions,

$$\Phi(\mathbf{k})=\Phi_0(\mathbf{k})+G_0(\mathbf{k})U\Phi(\mathbf{k}),\quad \Psi(\mathbf{k})=\Psi_0(\mathbf{k})+\Psi(\mathbf{k})UG_0(\mathbf{k}), \tag{2.77}$$

follow if we apply $\tilde{\mathcal{L}}_0\Phi_0$ from the right to the first equation in (2.60) and $\Psi_0\vec{\mathcal{L}}_0$ from the left to the second one. Thanks to (2.61) they are just the standard[12] equations for the Jost solution of the nonstationary Schrödinger equation and its dual. Thus, in what follows we refer to $\Phi(x,\mathbf{k})$ and $\Psi(x,\mathbf{k})$ as Jost solutions and to $G(x,x',\mathbf{k})$ as to the Green's function of the Jost solutions. By (2.65) these solutions are analytic functions of the spectral parameter $\mathbf{k}$ for $\mathbf{k}_\jmath\neq 0$ and are discontinuous at the real axis. Inserting (2.51) into (2.50) we get by (2.18) and (2.28) the standard representation

$$\Phi(x,\mathbf{k})=e^{-i\mathbf{k}x_1-i\mathbf{k}^2x_2}\chi(x,\mathbf{k}),\quad \Psi(x,\mathbf{k})=e^{i\mathbf{k}x_1+i\mathbf{k}^2x_2}\xi(x,\mathbf{k}), \tag{2.78}$$

where

$$\chi(x,\mathbf{k})=\int dx'\ (ML_0)(x,x';\mathbf{s}),\quad \xi(x',\mathbf{k})=\int dx\ (L_0M)(x,x';\mathbf{s}), \tag{2.79}$$

for $\mathbf{s}=(-i\mathbf{k},-i\mathbf{k}^2)$. From (2.77) we get that χ and ξ are normalized at infinity,

$$\lim_{\mathbf{k}\to\infty}\chi(x,\mathbf{k})=\lim_{\mathbf{k}\to\infty}\xi(x,\mathbf{k})=1, \tag{2.80}$$

while the potential $u(x)$ is reconstructed by their means as

$$u(x)=-2i\lim_{\mathbf{k}\to\infty}\mathbf{k}\partial_{x_1}\chi(x,\mathbf{k})=2i\lim_{\mathbf{k}\to\infty}\mathbf{k}\partial_{x_1}\xi(x,\mathbf{k}). \tag{2.81}$$

Solutions $\Phi(x,\mathbf{k})$ and $\Psi(x,\mathbf{k})$ obey orthonormality relation, i.e., their "scalar product" equals

$$\frac{1}{2\pi}\int dx_1\ \Psi(x,\mathbf{k}+k')\Phi(x,\mathbf{k})=\delta(k'),\quad \mathbf{k}\in\mathbb{C},\quad k'\in\mathbb{R}. \tag{2.82}$$

In order to prove it we apply $\tilde{\mathcal{L}}_0\Phi_0(\mathbf{k})$ to (2.67) from the right. Thanks to (2.28) and (2.62) the integrand in the first term on the r.h.s. of (2.67) is rapidly decaying when $x_2''\to\infty$ and we can integrate by parts, that gives zero due to (2.33). Thus by recalling (2.50) we obtain

$$\int dx_1' G(x,x',\mathbf{k}+k')\Phi(x',\mathbf{k}) = -i[\theta(x_2-x_2') - \theta(-\mathbf{k}_\Im k')]\Phi(x,\mathbf{k}) \tag{2.83}$$

and by taking the complex conjugate and using the conjugation properties (2.59) and (2.76)

$$\int dx_1'\Psi(x',\mathbf{k}+k')G(x',x,\mathbf{k}) = i[\theta(x_2-x_2') - \theta(-\mathbf{k}_\Im k')]\Psi(x,\mathbf{k}+k'). \tag{2.84}$$

Next we apply $\Psi_0(\mathbf{k}+k')\vec{\mathcal{L}}_0$ to (2.83) from the left and recalling (2.50) and (2.28) we have

$$\int dx_1' \Psi(x',\mathbf{k}+k')\Phi(x',\mathbf{k}) = \int dx\, \Psi_0(x,\mathbf{k}+k')\,\delta(x_2-x_2')\Phi(x,\mathbf{k}) - i\int dx\, \Psi_0(x,\mathbf{k}+k') \times[\theta(x_2-x_2') - \theta(-\mathbf{k}_\Im k')]u(x)\Phi(x,\mathbf{k}). \tag{2.85}$$

Now (2.82) follows if we consider (2.84) for G_0 and Ψ_0, insert it in the second term on the r.h.s. of (2.85) and use the first equation in (2.77).

The properties of the functions $\Phi_\pm(x,k)$ and $\Psi_\pm(x,k)$ are derived analogously from their definition (2.57). By (2.68) they obey

$$\vec{\mathcal{L}}\Phi_\pm(k) = 0, \quad \Psi_\pm(k)\tilde{\mathcal{L}} = 0. \tag{2.86}$$

Their conjugation property

$$\overline{\Phi_\pm(x,k)} = \Psi_\mp(x,k) \tag{2.87}$$

and the integral equations

$$\Phi_\pm(k) = \Phi_0(k) + G_{0,\pm}U\Phi_\pm(k), \quad \Psi_\pm(k) = \Psi_0(k) + \Psi_\pm(k)UG_{0,\pm}, \tag{2.88}$$

follow from their definition and Eqs. (2.70), where the Green's function $G_{0,\pm}$ is defined in (2.54). Thus $\Phi_\pm(x,k)$ and $\Psi_\pm(x,k)$ are just the standard[12] advanced/retarded solutions of the nonstationary Schrödinger equation and its dual. Correspondingly, in what follows we refer to $G_\pm(x,x')$ as to the Green's function of the advanced/retarded solutions. In analogy with derivation of (2.82) we can get the orthonormality relation

$$\frac{1}{2\pi}\int dx_1\, \Psi_\pm(x,k+k')\Phi_\mp(x,k) = \delta(k'), \quad k,k'\in\mathbb{R}. \tag{2.89}$$

The properties of the Jost solutions enable us to reconstruct $M(s)$ from (2.45) in the form

$$\hat{M}(x,x';s) = \frac{1}{2\pi i}\int_{\mathbf{k}_\Im=s_1} d\mathbf{k}_\Re\,[\theta(x_2-x_2') - \theta(2\mathbf{k}_\Re\mathbf{k}_\Im - s_2)]\,\Phi(x,\mathbf{k})\Psi(x',\mathbf{k}) \tag{2.90}$$

that generalizes (2.27) to the case of nonzero potentials. Indeed, thanks to (2.78) and to the boundedness of χ and ξ the integral, on the interval fixed by the θ-functions, is convergent, the kernel $M(x,x';s) = e^{-s(x-x')}\hat{M}(x,x';s)$ has zero limit for $s_2\to\infty$ in accordance with (2.39), and expression (2.45) for the derivative of $M(s)$ with respect to s_1 follows from (2.90) at $s_1\neq 0$ thanks to the analyticity of the Jost solutions at $\mathbf{k}_\Im\neq 0$. At the same time we know that the resolvent must be continuous at $s_1=0$ when $s_2\neq 0$. In order to formulate this property, we introduce in analogy with (2.71) a specific notation for the limiting values of the Jost solutions at the real axis, i.e.,

$$\Phi^{\pm}(x,k)=\Phi(x,k\pm i0), \quad \Psi^{\pm}(x,k)=\Psi(x,k\pm i0). \tag{2.91}$$

Then the above mentioned condition of continuity reads as

$$\int dk\,\Phi^{+}(k)\otimes\Psi^{+}(k)=\int dk\,\Phi^{-}(k)\otimes\Psi^{-}(k). \tag{2.92}$$

Representation (2.90) plays a crucial role in the resolvent approach since it enables us to express all objects of the spectral theory in terms of the Jost solutions. In particular, thanks to (2.51), for the Green's function of the Jost solutions we get

$$G(x,x',\mathbf{k})=\frac{1}{2\pi i}\int dk'\,[\,\theta(x_2-x_2')-\theta(\mathbf{k}_\Im k')\,]\,\Phi(x,\mathbf{k}+k')\Psi(x',\mathbf{k}+k'), \tag{2.93}$$

that in its turn generalizes (2.61). Moreover, from (2.90) one can get an expression of the advanced/retarded Green's functions in terms of the limiting values of the Jost solutions. Applying the limiting procedure (2.52) to (2.90) we get

$$G_{\pm}(x,x')=\frac{\pm\,\theta(\pm(x_2-x_2'))}{2\pi i}\int dk\,\Phi^{\sigma}(x,k)\Psi^{\sigma}(x',k), \tag{2.94}$$

where $\sigma=+,-$ and we used notation (2.91) for the limiting values of the Jost solutions at the real axis. Condition (2.92) guarantees that the $G_{\pm}$'s are independent of the sign σ as it must be.

From the behavior at large s_2 of the bilinear representation (2.90), comparing with (2.39) we obtain also the following important property of the Jost solutions:

$$\frac{1}{2\pi}\int_{x_2'=x_2} d\mathbf{k}_{\Re}\,\Psi(x',\mathbf{k})\Phi(x,\mathbf{k})=\delta(x_1-x_1'), \tag{2.95}$$

which can be considered a completeness relation.

5. Relations among Jost and advanced/retarded solutions. Spectral data

In the previous section, in the framework of the extended resolvent approach, we obtained in (2.93) a bilinear representation in terms of the Jost solutions of the Green's function for the Jost solutions and in (2.94) of the Green's function for the advanced/retarded solutions. We derived also Eq. (2.74) relating these Green's functions. We can now exploit these results for deriving relations among the advanced/retarded and Jost solutions on the real axis and use them to introduce the spectral data. In fact, applying $\tilde{\mathcal{L}}_0\Phi_0(k)$ to (2.74) from the right, recalling definitions (2.50) and (2.57), we get (notice that $k\in\mathbb{R}$)

$$\Phi^{\sigma}(k)=\int dk'\,\Phi_{\pm}(k')r_{\pm}^{\sigma}(k',k), \quad \sigma=+,-, \tag{2.96}$$

while the relations among $\Psi^{\sigma}(k)$ and $\Psi_{\pm}(k)$ can be derived analogously or follow by conjugation properties (2.76) and (2.87). Here we introduced the spectral data

$$r_{\pm}^{\sigma}(k',k)=\delta(k'-k)\mp\theta(\pm\sigma(k'-k))r^{\sigma}(k',k), \quad k',k\in\mathbb{R}, \tag{2.97}$$

$$r^{\sigma}(k',k)=\frac{\Psi_0(k')\vec{\mathcal{L}}_0G^{\sigma}(k)\tilde{\mathcal{L}}_0\Phi_0(k)}{2\pi i}\equiv\frac{\Psi_0(k')\vec{\mathcal{L}}_0\Phi^{\sigma}(k)}{2\pi i}. \tag{2.98}$$

Recalling ''vector'' and ''covector'' notations [cf. (2.47), (2.48), and (2.50)], the ''expectation values'' at the numerator have the following explicit expressions:

$$\Psi_0(k')\vec{\mathcal{L}}_0 G^\sigma(k)\tilde{\mathcal{L}}_0\Phi_0(k)=\int dx\int dx'\,\Psi_0(x,k')(\mathcal{L}_0(x,\partial_x)\mathcal{L}_0^{\mathrm{d}}(x',\partial_{x'})G^\sigma(x,x',k))\Phi_0(x',k), \tag{2.99}$$

$$\Psi_0(k')\vec{\mathcal{L}}_0\Phi^\sigma(k)=\int dx\,\Psi_0(x,k')\mathcal{L}_0(x,\partial_x)\Phi^\sigma(x,k), \tag{2.100}$$

showing that they are functions of k' and k only.

In order to get the advanced/retarded solutions in terms of the boundary values of the Jost ones we use (2.94) and the limiting values (2.71) of (2.93) on the real axis. Then

$$G^\sigma(k)-G_\pm=\frac{\mp 1}{2\pi i}\int dk'\;\theta(\pm\sigma(k'-k))\Phi^\sigma(k')\otimes\Psi^\sigma(k'),\quad \sigma=+,-, \tag{2.101}$$

and in the same way as above we readily derive

$$\Phi_\pm(k)=\int dk'\,\Phi^\sigma(k')\overline{r_\pm^{-\sigma}(k,k')}. \tag{2.102}$$

Now inserting these expressions into (2.96) and taking into account the orthonormality properties (2.82) and (2.89) of the Jost and advanced/retarded solutions we derive that the spectral data obey characterization equations,[17] which we discuss below in Sec. IV E 2 in a more general situation.

The alternative spectral data defined as

$$F^\sigma(k,k')=\int dk''\,\overline{r_\pm^{-\sigma}(k'',k)}r_\pm^{-\sigma}(k'',k'), \tag{2.103}$$

where the r.h.s. is independent of the choice of $\pm$ thanks to the above mentioned characterization equations, allow expressing the discontinuity of the Jost solutions across the real axis as

$$\Phi^\sigma(k)=\int dk'\,\Phi^{-\sigma}(k')F^{-\sigma}(k',k). \tag{2.104}$$

The inverse problem can be formulated in the standard way by using the fact that the Jost solution $\Phi(x,\mathbf{k})$ is an analytic function of $\mathbf{k}$ for $\mathbf{k}_\mathfrak{I}\neq 0$, has the discontinuity (2.104) at the real axis and obeys the normalization condition given by (2.78) and (2.80). In Ref. 5 we also demonstrated that the inverse problem can be formulated in terms of the resolvent itself. Here we skip this for brevity, as well as many other results that follow from the extended resolvent approach, like the introduction and properties of the dressing operators,[5] derivation of the time evolution of the spectral data corresponding to the KPI equation and algorithmic construction of time evolutions compatible with the given linear problem.[4]

III. CASE OF ONE-DIMENSIONAL POTENTIAL

A. Main definitions

In this section we consider the spectral theory of the differential operator (1.1) when the perturbation $u_2(x)$ in (1.4) is identically zero, i.e., we consider the extended differential operator

$$L_1(s)=L_0(s)-U_1,\quad U_1(x,x';s)=u_1(x_1)\delta(x-x'), \tag{3.1}$$

where $L_0(s)$ is defined in (2.22). Here and in the following we use the subscript 1 for all objects related to the case of a one-dimensional potential. In addition we choose u_1 to be the one-soliton solution of the KdV equation at the initial time $t=0$, that is,

$$u_1(x_1)=\frac{-2\kappa^2}{\cosh^2\kappa(x_1-x_0)}, \tag{3.2}$$

where x_0 and $\kappa>0$ are arbitrary constants. This choice is sufficient for showing the main peculiar aspects of the imbedding of a one-dimensional potential into two dimensions and is particularly convenient, since all objects relevant to the extended resolvent approach to inverse scattering can be explicitly given.

The Jost and dual Jost solutions [cf. (2.78)] are given by

$$\Phi_1(x,\mathbf{k})=e^{-i\mathbf{k}x_1-i\mathbf{k}^2x_2}\chi_1(x,\mathbf{k}),\quad \Psi_1(x,\mathbf{k})=e^{i\mathbf{k}x_1+i\mathbf{k}^2x_2}\xi_1(x,\mathbf{k}), \tag{3.3}$$

where as always we use boldface font for the complex spectral parameter $\mathbf{k}$, and

$$\chi_1(x_1,\mathbf{k})=\frac{\mathbf{k}-i\kappa\tanh\kappa(x_1-x_0)}{\mathbf{k}-i\kappa},\quad \xi_1(x_1,\mathbf{k})=\frac{\mathbf{k}+i\kappa\tanh\kappa(x_1-x_0)}{\mathbf{k}+i\kappa}. \tag{3.4}$$

They satisfy the differential equations

$$\vec{\mathcal{L}}_1\Phi_1(\mathbf{k})=0,\quad \Psi_1(\mathbf{k})\tilde{\mathcal{L}}_1=0, \tag{3.5}$$

and are analytic in the complex $\mathbf{k}$-plane with the exception of a pole at $\mathbf{k}=i\kappa$ and at $\mathbf{k}=-i\kappa$, correspondingly. Strictly speaking, in order to deal with Jost solutions defined in the standard way one would have to consider, for instance, $\Phi_1(x,\mathbf{k})$ multiplied by $(\mathbf{k}-i\kappa)/(\mathbf{k}+i\kappa\,\mathrm{sgn}\,\mathbf{k}_\Im)$, but this would introduce unnecessary complications. So, these Jost solutions have no discontinuity at the real axis and when we are considering their value at the real axis we can omit the superscript $\pm$. They obey, however, the conjugation property (2.76).

It is convenient to introduce the residua of functions $\Phi_1(x,\mathbf{k})$ and $\Psi_1(x,\mathbf{k})$ at the poles and their values at the conjugate points. We write

$$\operatorname*{res}_{\mathbf{k}=i\kappa}\Phi_1(x,\mathbf{k})=i\sqrt{\frac{\kappa}{\pi}}e^{\kappa x_0}\varphi_1(x),\quad \Phi_1(x,-i\kappa)=\frac{e^{-\kappa x_0}}{2\sqrt{\kappa\pi}}\varphi_1(x), \tag{3.6}$$

$$\operatorname*{res}_{\mathbf{k}=-i\kappa}\Psi_1(x,\mathbf{k})=-i\sqrt{\frac{\kappa}{\pi}}e^{\kappa x_0}\psi_1(x),\quad \Psi_1(x,i\kappa)=\frac{e^{-\kappa x_0}}{2\sqrt{\kappa\pi}}\psi_1(x), \tag{3.7}$$

where

$$\varphi_1(x)=\frac{\sqrt{\kappa\pi}\,e^{i\kappa^2x_2}}{\cosh\kappa(x_1-x_0)},\quad \psi_1(x)=\overline{\varphi_1(x)}. \tag{3.8}$$

Functions φ_1 and ψ_1 satisfy the differential equations

$$\vec{\mathcal{L}}_1\varphi_1=0,\quad \psi_1\tilde{\mathcal{L}}_1=0. \tag{3.9}$$

The equation

$$\operatorname*{res}_{\mathbf{k}=i\kappa}\Phi_1(x,\mathbf{k})=2i\kappa e^{2\kappa x_0}\Phi_1(x,-i\kappa), \tag{3.10}$$

or an analogous equation for Ψ_1, closes the formulation of the inverse problem for this Jost solution.

The orthonormality relation for the Jost solutions is not modified with respect to (2.82),

$$\frac{1}{2\pi}\int dx_1\,\Psi_1(x,\mathbf{k}+k')\Phi_1(x,\mathbf{k})=\delta(k'),\quad k'\in\mathbb{R},\quad \mathbf{k}\in\mathbb{C}, \tag{3.11}$$

but now it is accompanied by the scalar products

$$\int dx_1\,\psi_1(x)\Phi_1(x,\mathbf{k})=\int dx_1\,\Psi_1(x,\mathbf{k})\varphi_1(x)=0,\quad |\mathbf{k}_\Im|<\kappa, \tag{3.12}$$

$$\frac{1}{2\pi}\int dx_1\psi_1(x)\varphi_1(x)\equiv\frac{1}{2\pi}\int dx_1|\psi_1(x)|^2\equiv\frac{1}{2\pi}\int dx_1|\varphi_1(x)|^2=1, \tag{3.13}$$

where condition $|\mathbf{k}_\Im|<\kappa$ in (3.12) is necessary for the convergence of the integral. On the other side, the completeness relation is essentially modified with respect to the case of decaying potential (2.95) considered above, since we have

$$\int_{x_2'=x_2} d\mathbf{k}_\Re\,\Phi_1(x,\mathbf{k})\Psi_1(x',\mathbf{k})+\theta(\kappa-|\mathbf{k}_\Im|)\varphi_1(x)\psi_1(x')\Big|_{x_2'=x_2}=2\pi\delta(x_1-x_1'). \tag{3.14}$$

B. Resolvent

The resolvent $M_1(s)$ according to our general definition is the inverse, in the sense of (2.26), of the extended operator (3.1) and its hat-kernel obeys the equations

$$\vec{\mathcal{L}}_1\hat{M}_1(s)=\hat{M}_1(s)\tilde{\mathcal{L}}_1=I. \tag{3.15}$$

Taking into account that the completeness relation (3.14) is modified with respect to (2.95) and that this relation is the first order term of the asymptotic expansion of the resolvent as $s_2\to\infty$, it is natural to expect that the bilinear representation (2.90) is also modified by an additional term proportional to the product $\varphi_1(x)\psi_1(x')$. In fact we get

$$\hat{M}_1(x,x';s)=\frac{1}{2\pi i}\Bigg(\int_{\mathbf{k}_\Im=s_1} d\mathbf{k}_\Re[\,\theta(x_2-x_2')-\theta(2\mathbf{k}_\Re\mathbf{k}_\Im-s_2)\,]\,\Phi_1(x,\mathbf{k})\Psi_1(x',\mathbf{k})$$
$$+\theta(\kappa-|s_1|)\,[\,\theta(x_2-x_2')-\theta(-s_2)\,]\varphi_1(x)\psi_1(x')\Bigg). \tag{3.16}$$

Performing the transformation (2.13) and taking into account the properties of the Jost solutions and of the functions $\varphi_1(x)$ and $\psi_1(x')$ one can check that $M_1(x,x';s)\in\mathcal{S}'$ and obeys integral equations of the kind (2.37) with $U=U_1$. The second term in (3.16) is different from zero in the interval $|s_1|<\kappa$, it compensates the discontinuities of the first term at $s_1=\pm\kappa$, which are consequence of the pole singularities of $\Phi_1(x,\mathbf{k})$ and $\Psi_1(x,\mathbf{k})$. On the other side, this term introduces a discontinuity in $M_1(s)$ at $s_2=0$ for all $|s_1|<\kappa$ and not only at $s_1=0$ as it was for the resolvent of the decaying case. By direct calculations one can prove the regularity with respect to s-variables of

$$\hat{M}_{1,\mathrm{reg}}(s)=\hat{M}_1(s)-\Gamma(s)\,\varphi_1(x)\psi_1(x'), \tag{3.17}$$

where

$$\Gamma(s)=\frac{\operatorname{sgn}s_1}{(2\pi)^2}\log\frac{s_2+2is_1(s_1-\kappa)}{s_2+2is_1(s_1+\kappa)}, \tag{3.18}$$

the logarithm being the principal part with the cut along the negative real axis. Thus, we see that the extended resolvent in the case of one-dimensional potentials gets logarithmic singularities at the points $s=(\pm\kappa,0)$. The singular part of the resolvent has the structure of a direct product.

C. Properties of the resolvent and Green's functions

For the discontinuity of the resolvent at $s_2=0$ we get from (3.16)

$$\lim_{s_2\to+0}\hat{M}_1(s)-\lim_{s_2\to-0}\hat{M}_1(s)=\frac{\theta(\kappa-|s_1|)}{2\pi i}\varphi_1\otimes\psi_1, \tag{3.19}$$

which also follows from (3.17). For all other values of s the resolvent (3.16) has derivatives with respect to s of the form of (2.34), (2.35):

$$\frac{\partial\hat{M}_1(s)}{\partial s_1}=\frac{i}{\pi}\int_{\mathbf{k}_\Im=s_1}d\mathbf{k}_\Re\,\overline{\mathbf{k}}\,\delta(2\mathbf{k}_\Re\mathbf{k}_\Im-s_2)\,\Phi_1(\mathbf{k})\otimes\Psi_1(\mathbf{k}), \tag{3.20}$$

$$\frac{\partial\hat{M}_1(s)}{\partial s_2}=\frac{1}{2\pi i}\int_{\mathbf{k}_\Im=s_1}d\mathbf{k}_\Re\,\delta(2\mathbf{k}_\Re\mathbf{k}_\Im-s_2)\,\Phi_1(\mathbf{k})\otimes\Psi_1(\mathbf{k}), \tag{3.21}$$

which at the vicinity of the point $s_1=0$ have to be considered in the distributional sense. Thus, we can introduce the Green's function $G_1(x,x',\mathbf{k})$ of the Jost solutions by using the same definition as in (2.51). Then, from (3.16) we get the bilinear representation

$$\begin{aligned}G_1(x,x',\mathbf{k})=&\frac{1}{2\pi i}\int dk'\,[\,\theta(x_2-x_2')-\theta(\mathbf{k}_\Im k')\,]\,\Phi_1(x,k'+\mathbf{k})\Psi_1(x',k'+\mathbf{k})\\&+\frac{\theta(\kappa-|\mathbf{k}_\Im|)}{2\pi i}[\,\theta(x_2-x_2')-\theta(-\mathbf{k}_\Re\mathbf{k}_\Im)\,]\varphi_1(x)\psi_1(x'),\end{aligned} \tag{3.22}$$

which was already derived in Ref. 16, but starting from another point of view. It is easy to check that this Green's function obeys the conjugation property (2.59) and that the function $g_1(x,x',\mathbf{k})$ defined like in (2.62) has property (2.63). Taking into account that the resolvent obeys (2.37) with $U=U_1$ we get that the Green's function obeys integral equations of the type (2.60),

$$G_1(\mathbf{k})=G_0(\mathbf{k})+G_0(\mathbf{k})U_1G_1(\mathbf{k}),\quad G_1(\mathbf{k})=G_0(\mathbf{k})+G_1(\mathbf{k})U_1G_0(\mathbf{k}), \tag{3.23}$$

it is analytic when $\mathbf{k}_\Re\mathbf{k}_\Im\neq0$, continuous up to the borders of these quadrants, and in this region in analogy with (2.64) we obtain

$$\frac{\partial G_1(\mathbf{k})}{\partial\mathbf{k}_\Im}=\frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi}\Phi_1(\mathbf{k})\otimes\Psi_1(\mathbf{k}). \tag{3.24}$$

In addition to the standard discontinuity at the real axis, the Green's function has also a discontinuity

$$G_1(+0+i\mathbf{k}_\Im)-G_1(-0+i\mathbf{k}_\Im)=\frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi i}\,\theta(\kappa-|\mathbf{k}_\Im|)\,\varphi_1\otimes\psi_1 \tag{3.25}$$

at the imaginary axis when $|\mathbf{k}_\Im|<\kappa$. Using (3.17) one can prove that the function $G_1(\mathbf{k})-\gamma(\mathbf{k})\,\varphi_1\otimes\psi_1$, where

$$\gamma(\mathbf{k})=\Gamma(s)|_{s=(\mathbf{k}_\Im,2\mathbf{k}_\Re\mathbf{k}_\Im)}\equiv\frac{\operatorname{sgn}\mathbf{k}_\Im}{(2\pi)^2}\log\frac{\mathbf{k}-i\kappa}{\mathbf{k}+i\kappa}, \tag{3.26}$$

is a bounded continuous function of $\mathbf{k}$ in vicinity of the cut $\mathbf{k}_{\Re}=0$, $|\mathbf{k}_{\Im}|<\kappa$ with exception of the point $\mathbf{k}=0$. As a consequence the regularized function

$$G_{1,\mathrm{reg}}(\mathbf{k})=G_1(\mathbf{k})+2\pi i\,\gamma(\mathbf{k})(\mathbf{k}\,\mathrm{sgn}\,\mathbf{k}_{\Im}-i\kappa)\Phi_1(\mathbf{k})\otimes\Psi_1(\mathbf{k}) \tag{3.27}$$

has finite limits at the points $\mathbf{k}=\pm i\kappa$, while it is discontinuous at $\mathbf{k}_{\Re}=0$ and $\mathbf{k}_{\Im}=0$. In (3.27) the multiplier $(\mathbf{k}\,\mathrm{sgn}\,\mathbf{k}_{\Im}-i\kappa)$ compensates the poles of $\Phi_1(\mathbf{k})$ and $\Psi_1(\mathbf{k})$. Note that the regularized function $g_{1,\mathrm{reg}}(\mathbf{k})$ constructed from $G_{1,\mathrm{reg}}(x,x',\mathbf{k})$ like in (2.62) is bounded with respect to x and has finite limits when $x\to\infty$.

Let us mention that in the case of the Jost solutions Φ_1 and Ψ_1 the integrals in definitions (2.47) and (2.48) are divergent and they must be conveniently regularized in the following way:

$$\Phi_1(x,\mathbf{k})=\lim_{\varepsilon\to+0}\int dx'\,(G_1(\mathbf{k})\tilde{\mathcal{L}}_0)(x,x')\Phi_0(x',\mathbf{k})e^{i\varepsilon\mathbf{k}_{\Im}x'_2}, \tag{3.28}$$

$$\Psi_1(x,\mathbf{k})=\lim_{\varepsilon\to+0}\int dx'\,e^{-i\varepsilon\mathbf{k}_{\Im}x'_2}\Psi_0(x',\mathbf{k})(\vec{\mathcal{L}}_0G_1(\mathbf{k}))(x',x), \tag{3.29}$$

where $\mathbf{k}_{\Im}\neq0$. As the result of this regularization we get (see Refs. 2 and 4) a modification of the integral equations for the Jost solutions with respect to the standard ones[10,12–15] that are not applicable in the case of one-dimensional potentials. In particular, in spite of the cut that $G_1(x,x',\mathbf{k})$ has on the imaginary axis, we have

$$\Phi_1(+0+i\mathbf{k}_{\Im})-\Phi_1(-0+i\mathbf{k}_{\Im})=2i\sqrt{\kappa\pi}e^{\kappa x_0}\delta(\mathbf{k}_{\Im}-\kappa)\varphi_1 \tag{3.30}$$

in agreement with (3.6).

When $s_1=0$ the kernel $\hat{M}_1(s)$ is discontinuous at $s_2=0$. This means that we have to introduce the advanced/retarded Green's functions like in (2.52). By (3.16) we get the following bilinear representation for these Green's functions in terms of the Jost solutions on the real axis:

$$G_{1,\pm}(x,x')=\frac{\pm\theta(\pm(x_2-x'_2))}{2\pi i}\left(\int dk\,\Phi_1(x,k)\Psi_1(x',k)+\varphi_1(x)\psi_1(x')\right). \tag{3.31}$$

The singular part of these Green's functions is equal to zero, as follows from (3.18). These Green's functions obey the conjugation property (2.69).
